Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

Dedications

To our neuroradiology friends and colleagues all over the world: Thanks for your longstanding interest, support, and generosity in sharing cases and concepts. This newest edition is for you.

AO

To the loves of my life: Craig, Sophia, Aubrey, and Ian. Thank you for your endless patience, love, and support.

KLS

To Palmi and Aanya: Thanks for all your support and patience.
To Michael and Beverly: Thanks for everything.

MJ

Contributing Authors

A. James Barkovich, MD
Professor of Radiology and Biomedical Imaging, Neurology, Pediatrics, and Neurological Surgery
UCSF-Benioff Children's Hospital
University of California, San Francisco
San Francisco, California

H. Ric Harnsberger, MD
R.C. Willey Chair in Neuroradiology
Professor of Radiology and Otolaryngology
University of Utah School of Medicine
Salt Lake City, Utah

Luke N. Ledbetter, MD
Assistant Professor of Radiology
Division of Neuroradiology
University of Kansas Medical Center
Kansas City, Kansas

Nicholas A. Koontz, MD
Assistant Professor of Clinical Radiology
Department of Radiology and Imaging Sciences
Indiana University School of Medicine
Indianapolis, Indiana

Kevin R. Moore, MD
Pediatric Neuroradiologist
Primary Children's Hospital
Salt Lake City, Utah

Charles Raybaud, MD, FRCPC
Derek Harwood-Nash Chair in Medical Imaging
Division Head of Neuroradiology
The Hospital for Sick Children
Professor of Radiology
University of Toronto
Toronto, Ontario, Canada

Anna Illner, MD
Pediatric Neuroradiologist
Texas Children's Hospital
Assistant Professor of Radiology
Baylor College of Medicine
Houston, Texas

Sheri L. Harder, MD, FRCPC
Assistant Professor of Radiology
Division of Neuroradiology
Loma Linda University Medical Center
Loma Linda, California

Gregory L. Katzman, MD, MBA
Professor of Neuroradiology
Vice Chair of Radiology Operations
Chief Quality Officer
Chief Business Development Officer
Department of Radiology
University of Chicago School of Medicine
Chicago, Illinois

Bronwyn E. Hamilton, MD
Professor of Radiology
Oregon Health & Science University
Portland, Oregon

Lubdha M. Shah, MD
Associate Professor of Radiology
Division of Neuroradiology
University of Utah School of Medicine
Salt Lake City, Utah

Perry P. Ng, MBBS (Hons), FRANZCR
Adjunct Associate Professor
Department of Radiology
University of Utah School of Medicine
Salt Lake City, Utah
Interventional Neuroradiologist
Centura Health Physician Group
Denver, Colorado

Gary M. Nesbit, MD
Professor of Radiology, Neurology, Neurological Surgery
Dotter Interventional Institute
Oregon Health & Science University
Portland, Oregon

Ulrich Rassner, MD
Associate Professor of Radiology
Division of Neuroradiology
University of Utah School of Medicine
Salt Lake City, Utah

https://CafePezeshki.IR

Laurie A. Loevner, MD
Chief, Division of Neuroradiology
Director, Head and Neck Radiology
Professor of Radiology, Otorhinolaryngology: Head and Neck Surgery, and Neurosurgery
University of Pennsylvania Health System Perelman School of Medicine at the University of Pennsylvania
Philadelphia, Pennsylvania

Jeffrey S. Anderson, MD, PhD
Associate Professor of Radiology and Bioengineering
University of Utah School of Medicine
Salt Lake City, Utah

Chang Yueh Ho, MD
Assistant Professor of Radiology
Director of Pediatric Neuroradiology
Program Director of Pediatric Neuroradiology Fellowship
Riley Hospital for Children
Indiana University School of Medicine
Indianapolis, Indiana

Edward P. Quigley, III, MD, PhD
Associate Professor of Radiology
Division of Neuroradiology
University of Utah School of Medicine
Salt Lake City, Utah

John H. Rees, MD
Chief of Neuroradiology: Partners Imaging
Sarasota, Florida
Assistant Professor of Radiology
Georgetown University
Previously: Visiting Scientist
Armed Forces Institute of Pathology
Washington, DC

Majda M. Thurnher, MD
Associate Professor of Radiology
Medical University Vienna
Department of Biomedical Imaging and Image-Guided Therapy
Vienna, Austria

Gary L. Hedlund, DO
Adjunct Professor of Radiology
University of Utah School of Medicine
Pediatric Neuroradiologist
Department of Medical Imaging
Primary Children's Hospital
Salt Lake City, Utah

James M. Provenzale, MD
Professor of Radiology
Duke University Medical Center
Durham, North Carolina

Yoshimi Anzai, MD, MPH
Professor of Radiology
Associate Chief Medical Quality Officer
University of Utah
Salt Lake City, Utah

Susan I. Blaser, MD, FRCPC
Staff Neuroradiologist
The Hospital for Sick Children
Professor of Neuroradiology
University of Toronto
Toronto, Ontario, Canada

P. Ellen Grant, MD
Associate Professor in Radiology, Harvard Medical School
Founding Director, Center for Fetal-Neonatal Neuroimaging & Developmental Science
Director of Fetal and Neonatal Neuroimaging Research
Children's Hospital Boston Endowed Chair in Neonatology
Children's Hospital Boston
Boston, Massachusetts

Gilbert Vézina, MD
Director, Program in Neuroradiology
Children's National Medical Center
Professor of Radiology and Pediatrics
The George Washington University School of Medicine and Health Sciences
Washington, DC

Blaise V. Jones, MD
Associate Director of Radiology
Neuroradiology Section Chief
Cincinnati Children's Hospital Medical Center
Professor of Clinical Radiology and Pediatrics
University of Cincinnati College of Medicine
Cincinnati, Ohio

Preface

Welcome to one of the first volumes in the third series of the brand new *Diagnostic Imaging* books. You'll note that our newest book bears the imprint of both Amirsys and Elsevier. The fresh new look and layout reflects our best creative efforts. Yet, we've kept the synoptic, highly efficient bulleted text that you've come to expect from us as well as the beloved key facts summary boxes at the beginning of each diagnosis.

A lot has happened since we published the second edition of *Diagnostic Imaging: Brain* back in 2010. We've added new diagnoses, including important topics such as tumor pseudoprogression and pseudoresponse. New entities such as CLIPPERS and the hot subject of IgG4-related disease are included. There are literally thousands of new images in the diagnosis galleries together with references that have been updated with the latest findings. You told us you loved the section introductions that were a new feature of the second edition, so we've included new and updated introductions to reflect the current thinking on these general topics.

The second edition covered the fourth (2007) edition of the World Health Organization (WHO) classification and grading of brain tumors. These have been published every seven years. If you "do the math," you know the fifth edition would normally have been published in 2014. It wasn't. So before you ask, I'll tell you it isn't coming out in 2015 either. The field of tumor diagnosis is changing so rapidly with the advent of genomic analysis that it's almost impossible to keep up with it. Our neuropathology colleagues expect to publish an online update in 2016 (maybe). So, what we've done here is update the neoplasms section with the latest literature to give you the current best understanding of classification and grading. It's changing rapidly so stay tuned.

We've loved hearing from you. We appreciate (and pay close attention to) your ideas and input on what new diagnoses or information you'd like to see included. Many of you have shared cool cases with us, and we've selected images from some that are used in this new edition with our grateful acknowledgement. After all, YOU are the reason we keep doing these books. So thanks for your interest and input. Enjoy our newest "baby"!

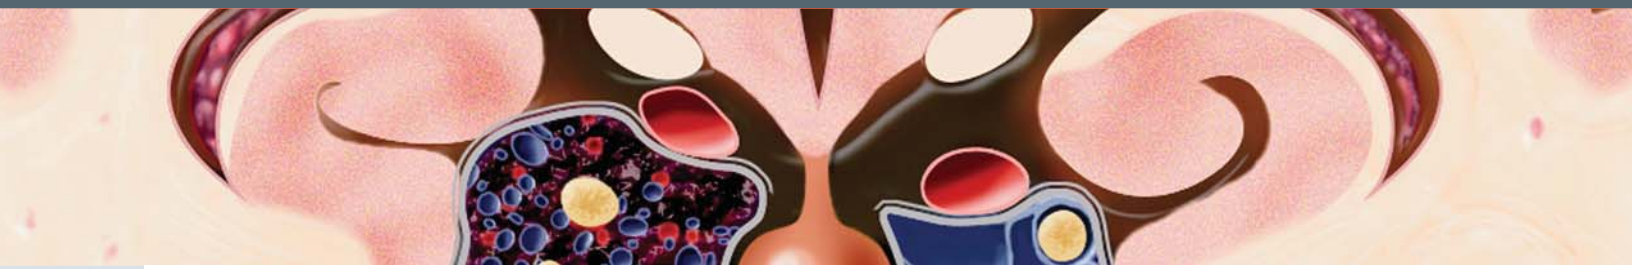
TABLE OF CONTENTS



Part I: Pathology-Based Diagnoses

SECTION 1: CONGENITAL MALFORMATIONS

4 **Congenital Malformations Overview**
A. James Barkovich, MD

HINDBRAIN HERNIATIONS, MISCELLANEOUS MALFORMATIONS

8 **Chiari 1**
Susan I. Blaser, MD, FRCPC and Anne G. Osborn, MD, FACR
12 **Chiari 2**
Susan I. Blaser, MD, FRCPC and Kevin R. Moore, MD
16 **Chiari 3**
Susan I. Blaser, MD, FRCPC and Kevin R. Moore, MD
18 **Callosal Dysgenesis**
Charles Raybaud, MD, FRCPC and Anne G. Osborn, MD, FACR
22 **Lipoma**
A. James Barkovich, MD

HINDBRAIN MALFORMATIONS

26 **Dandy-Walker Continuum**
Susan I. Blaser, MD, FRCPC
30 **Rhombencephalosynapsis**
Blaise V. Jones, MD and Anne G. Osborn, MD, FACR
34 **Unclassified Cerebellar Dysplasias**
Blaise V. Jones, MD
36 **Molar Tooth Malformations (Joubert)**
Charles Raybaud, MD, FRCPC and Anne G. Osborn, MD, FACR

DISORDERS OF DIVERTICULATION/CLEAVAGE

40 **Holoprosencephaly**
Charles Raybaud, MD, FRCPC and Anne G. Osborn, MD, FACR
44 **Holoprosencephaly Variants**
Anna Illner, MD
48 **Syntelencephaly (Middle Interhemispheric Variant)**
Charles Raybaud, MD, FRCPC
52 **Septooptic Dysplasia**
A. James Barkovich, MD

MALFORMATIONS OF CORTICAL DEVELOPMENT

56 **Microcephaly**
Gary L. Hedlund, DO
60 **Congenital Muscular Dystrophy**
Charles Raybaud, MD, FRCPC
64 **Heterotopic Gray Matter**
Charles Raybaud, MD, FRCPC
68 **Polymicrogyria**
A. James Barkovich, MD
72 **Lissencephaly**
Blaise V. Jones, MD
76 **Schizencephaly**
Blaise V. Jones, MD
80 **Hemimegalencephaly**
Anne G. Osborn, MD, FACR and Blaise V. Jones, MD

FAMILIAL TUMOR/NEUROCUTANEOUS SYNDROMES

84 **Neurofibromatosis Type 1**
Gilbert Vézina, MD and Anne G. Osborn, MD, FACR
88 **Neurofibromatosis Type 2**
Gilbert Vézina, MD
92 **von Hippel-Lindau Syndrome**
Anne G. Osborn, MD, FACR and Gilbert Vézina, MD
96 **Tuberous Sclerosis Complex**
Gilbert Vézina, MD and Anne G. Osborn, MD, FACR
100 **Sturge-Weber Syndrome**
Gilbert Vézina, MD and Anne G. Osborn, MD, FACR
104 **Meningioangiomatosis**
Anne G. Osborn, MD, FACR
106 **Basal Cell Nevus Syndrome**
Gilbert Vézina, MD
110 **Hereditary Hemorrhagic Telangiectasia**
Anne G. Osborn, MD, FACR and Charles Raybaud, MD, FRCPC
114 **Encephalocraniocutaneous Lipomatosis**
Gilbert Vézina, MD
118 **Lhermitte-Duclos Disease**
Anne G. Osborn, MD, FACR and P. Ellen Grant, MD
122 **Neurocutaneous Melanosis**
Gilbert Vézina, MD
126 **Aicardi Syndrome**
P. Ellen Grant, MD
128 **Li-Fraumeni Syndrome**
Gilbert Vézina, MD
130 **Schwannomatosis**
Nicholas A. Koontz, MD

https://CafePezeshki.IR

TABLE OF CONTENTS

SECTION 2: TRAUMA

134 **Introduction to CNS Imaging, Trauma**
Anne G. Osborn, MD, FACR

PRIMARY EFFECTS OF CNS TRAUMA

140 **Scalp and Skull Injuries**
Anne G. Osborn, MD, FACR
144 **Missile and Penetrating Injury**
Anne G. Osborn, MD, FACR and Sheri L. Harder, MD, FRCPC
148 **Epidural Hematoma, Classic**
Anne G. Osborn, MD, FACR and Gregory L. Katzman, MD, MBA
152 **Epidural Hematoma, Variant**
Anne G. Osborn, MD, FACR
156 **Acute Subdural Hematoma**
Anne G. Osborn, MD, FACR and Bronwyn E. Hamilton, MD
160 **Subacute Subdural Hematoma**
Anne G. Osborn, MD, FACR and Bronwyn E. Hamilton, MD
164 **Chronic Subdural Hematoma**
Anne G. Osborn, MD, FACR
168 **Traumatic Subarachnoid Hemorrhage**
Anne G. Osborn, MD, FACR and Gregory L. Katzman, MD, MBA
172 **Cerebral Contusion**
Anne G. Osborn, MD, FACR
176 **Diffuse Axonal Injury**
Anne G. Osborn, MD, FACR
180 **Subcortical Injury**
Anne G. Osborn, MD, FACR and Gregory L. Katzman, MD, MBA
184 **Pneumocephalus**
Anne G. Osborn, MD, FACR and Gregory L. Katzman, MD, MBA
188 **Abusive Head Trauma**
Gary L. Hedlund, DO

SECONDARY EFFECTS OF CNS TRAUMA

192 **Intracranial Herniation Syndromes**
Anne G. Osborn, MD, FACR
196 **Post-Traumatic Brain Swelling**
Anne G. Osborn, MD, FACR
200 **Traumatic Cerebral Ischemia/Infarction**
Anne G. Osborn, MD, FACR and Gregory L. Katzman, MD, MBA
204 **Brain Death**
Anne G. Osborn, MD, FACR
206 **Second Impact Syndrome**
Anne G. Osborn, MD, FACR
208 **Traumatic Intracranial Arterial Dissection**
Anne G. Osborn, MD, FACR
212 **Traumatic Carotid Cavernous Fistula**
Anne G. Osborn, MD, FACR and Perry P. Ng, MBBS (Hons), FRANZCR
214 **Chronic Traumatic Encephalopathy**
Anne G. Osborn, MD, FACR

SECTION 3: SUBARACHNOID HEMORRHAGE AND ANEURYSMS

218 **Subarachnoid Hemorrhage & Aneurysms Overview**
Anne G. Osborn, MD, FACR

SUBARACHNOID HEMORRHAGE

220 **Aneurysmal Subarachnoid Hemorrhage**
Anne G. Osborn, MD, FACR
224 **Perimesencephalic Nonaneurysmal SAH**
Anne G. Osborn, MD, FACR
226 **Convexal Subarachnoid Hemorrhage**
Anne G. Osborn, MD, FACR
228 **Superficial Siderosis**
Anne G. Osborn, MD, FACR and H. Ric Harnsberger, MD

ANEURYSMS

232 **Saccular Aneurysm**
Anne G. Osborn, MD, FACR and Perry P. Ng, MBBS (Hons), FRANZCR
236 **Pseudoaneurysm**
Anne G. Osborn, MD, FACR
238 **Vertebrobasilar Dolichoectasia**
Anne G. Osborn, MD, FACR
240 **ASVD Fusiform Aneurysm**
Anne G. Osborn, MD, FACR
242 **Non-ASVD Fusiform Aneurysm**
Anne G. Osborn, MD, FACR
244 **Blood Blister-Like Aneurysm**
Anne G. Osborn, MD, FACR

SECTION 4: STROKE

248 **Stroke Overview**
Karen L. Salzman, MD

NONTRAUMATIC INTRACRANIAL HEMORRHAGE

254 **Evolution of Intracranial Hemorrhage**
Karen L. Salzman, MD and Ulrich Rassner, MD
258 **Spontaneous Nontraumatic Intracranial Hemorrhage**
Karen L. Salzman, MD and Laurie A. Loevner, MD
262 **Hypertensive Intracranial Hemorrhage**
Karen L. Salzman, MD and Laurie A. Loevner, MD
266 **Remote Cerebellar Hemorrhage**
Karen L. Salzman, MD and Bronwyn E. Hamilton, MD
268 **Germinal Matrix Hemorrhage**
Karen L. Salzman, MD and P. Ellen Grant, MD

ATHEROSCLEROSIS AND CAROTID STENOSIS

272 **Intracranial Atherosclerosis**
Anne G. Osborn, MD, FACR
276 **Extracranial Atherosclerosis**
Karen L. Salzman, MD and Bronwyn E. Hamilton, MD
280 **Arteriolosclerosis**
Karen L. Salzman, MD

https://CafePezeshki.IR

TABLE OF CONTENTS

NONATHEROMATOUS VASCULOPATHY

284 **Aberrant Internal Carotid Artery**
Karen L. Salzman, MD and H. Ric Harnsberger, MD
288 **Persistent Carotid Basilar Anastomoses**
Karen L. Salzman, MD and Charles Raybaud, MD, FRCPC
290 **Sickle Cell Disease, Brain**
Anna Illner, MD
294 **Moyamoya**
Anne G. Osborn, MD, FACR and Anna Illner, MD
298 **Primary Arteritis of the CNS**
Anne G. Osborn, MD, FACR
302 **Miscellaneous Vasculitis**
Anne G. Osborn, MD, FACR
306 **Reversible Cerebral Vasoconstriction Syndrome**
Karen L. Salzman, MD and Perry P. Ng, MBBS (Hons), FRANZCR
308 **Vasospasm**
Karen L. Salzman, MD and Perry P. Ng, MBBS (Hons), FRANZCR
312 **Systemic Lupus Erythematosus**
Karen L. Salzman, MD and Gary M. Nesbit, MD
316 **Cerebral Amyloid Disease**
Karen L. Salzman, MD and Bronwyn E. Hamilton, MD
320 **CADASIL**
Karen L. Salzman, MD and Ulrich Rassner, MD
324 **Behçet Disease**
Karen L. Salzman, MD
326 **Susac Syndrome**
Karen L. Salzman, MD and Jeffrey S. Anderson, MD, PhD
328 **Fibromuscular Dysplasia**
Karen L. Salzman, MD and Perry P. Ng, MBBS (Hons), FRANZCR

CEREBRAL ISCHEMIA AND INFARCTION

330 **Hydranencephaly**
Anne G. Osborn, MD, FACR
332 **White Matter Injury of Prematurity**
P. Ellen Grant, MD
336 **Term Hypoxic Ischemic Injury**
P. Ellen Grant, MD
340 **Adult Hypoxic Ischemic Injury**
Karen L. Salzman, MD and Lubdha M. Shah, MD
344 **Hypotensive Cerebral Infarction**
Anne G. Osborn, MD, FACR and Bronwyn E. Hamilton, MD
348 **Childhood Stroke**
Anne G. Osborn, MD, FACR and Blaise V. Jones, MD
352 **Cerebral Hemiatrophy**
Karen L. Salzman, MD
354 **Acute Cerebral Ischemia-Infarction**
Anne G. Osborn, MD, FACR and Edward P. Quigley, III, MD, PhD
358 **Subacute Cerebral Infarction**
Karen L. Salzman, MD and Sheri L. Harder, MD, FRCPC
362 **Chronic Cerebral Infarction**
Sheri L. Harder, MD, FRCPC and Anne G. Osborn, MD, FACR
366 **Multiple Embolic Cerebral Infarctions**
Karen L. Salzman, MD
367 **Fat Emboli Cerebral Infarction**
Karen L. Salzman, MD
368 **Lacunar Infarction**
Karen L. Salzman, MD and Ulrich Rassner, MD
372 **Cerebral Hyperperfusion Syndrome**
Anne G. Osborn, MD, FACR
376 **Dural Sinus Thrombosis**
Anne G. Osborn, MD, FACR
380 **Cortical Venous Thrombosis**
Anne G. Osborn, MD, FACR and Bronwyn E. Hamilton, MD
384 **Deep Cerebral Venous Thrombosis**
Anne G. Osborn, MD, FACR and Bronwyn E. Hamilton, MD
388 **Dural Sinus and Aberrant Arachnoid Granulations**
H. Ric Harnsberger, MD

SECTION 5: VASCULAR MALFORMATIONS

394 **Vascular Malformations Overview**
Anne G. Osborn, MD, FACR

CVMS WITH AV SHUNTING

396 **Arteriovenous Malformation**
Anne G. Osborn, MD, FACR and Perry P. Ng, MBBS (Hons), FRANZCR
400 **Dural AV Fistula**
Anne G. Osborn, MD, FACR and Perry P. Ng, MBBS (Hons), FRANZCR
404 **Pial AV Fistula**
Anne G. Osborn, MD, FACR
406 **Vein of Galen Aneurysmal Malformation**
Anne G. Osborn, MD, FACR and Anna Illner, MD

CVMS WITHOUT AV SHUNTING

410 **Developmental Venous Anomaly**
Anne G. Osborn, MD, FACR
416 **Sinus Pericranii**
Anne G. Osborn, MD, FACR and Anna Illner, MD
420 **Cavernous Malformation**
Anne G. Osborn, MD, FACR
424 **Capillary Telangiectasia**
Anne G. Osborn, MD, FACR

SECTION 6: NEOPLASMS

430 **Neoplasms Overview**
Anne G. Osborn, MD, FACR

ASTROCYTIC TUMORS, INFILTRATING

434 **Low-Grade Diffuse Astrocytoma**
Karen L. Salzman, MD
438 **Anaplastic Astrocytoma**
Karen L. Salzman, MD
442 **Glioblastoma**
Karen L. Salzman, MD
446 **Gliosarcoma**
Karen L. Salzman, MD
448 **Gliomatosis Cerebri**
Karen L. Salzman, MD

https://CafePezeshki.IR

TABLE OF CONTENTS

ASTROCYTIC TUMORS, LOCALIZED

452 **Pilocytic Astrocytoma**
Karen L. Salzman, MD and Chang Yueh Ho, MD
456 **Pilomyxoid Astrocytoma**
Anne G. Osborn, MD, FACR
460 **Pleomorphic Xanthoastrocytoma**
Karen L. Salzman, MD
464 **Subependymal Giant Cell Astrocytoma**
Anne G. Osborn, MD, FACR and John H. Rees, MD

OLIGODENDROGLIAL AND MISCELLANEOUS TUMORS

468 **Oligodendroglioma**
Karen L. Salzman, MD
472 **Anaplastic Oligodendroglioma**
Karen L. Salzman, MD
476 **Astroblastoma**
Karen L. Salzman, MD
478 **Chordoid Glioma of the Third Ventricle**
Karen L. Salzman, MD and John H. Rees, MD
480 **Angiocentric Glioma**
Karen L. Salzman, MD and Majda M. Thurnher, MD

EPENDYMAL TUMORS

482 **Infratentorial Ependymoma**
Anne G. Osborn, MD, FACR and Majda M. Thurnher, MD
486 **Supratentorial Ependymoma**
Majda M. Thurnher, MD
490 **Subependymoma**
Karen L. Salzman, MD

CHOROID PLEXUS TUMORS

494 **Typical Choroid Plexus Papilloma**
Anne G. Osborn, MD, FACR and Chang Yueh Ho, MD
498 **Choroid Plexus Carcinoma**
Anne G. Osborn, MD, FACR and Chang Yueh Ho, MD

NEURONAL AND MIXED NEURONAL-GLIAL TUMORS

502 **Ganglioglioma**
Karen L. Salzman, MD
506 **Desmoplastic Infantile Astrocytoma and Ganglioglioma**
Chang Yueh Ho, MD
510 **DNET**
Karen L. Salzman, MD and Laurie A. Loevner, MD
514 **Central Neurocytoma**
Karen L. Salzman, MD
518 **Extraventricular Neurocytoma**
Karen L. Salzman, MD
520 **Cerebellar Liponeurocytoma**
Karen L. Salzman, MD and John H. Rees, MD
521 **Papillary Glioneuronal Tumor**
Karen L. Salzman, MD and John H. Rees, MD
522 **Rosette-Forming Glioneuronal Tumor**
Karen L. Salzman, MD and Majda M. Thurnher, MD

PINEAL PARENCHYMAL TUMORS

524 **Pineocytoma**
Karen L. Salzman, MD and Laurie A. Loevner, MD
528 **Pineal Parenchymal Tumor of Intermediate Differentiation**
Karen L. Salzman, MD and Anne G. Osborn, MD, FACR
530 **Pineoblastoma**
Anne G. Osborn, MD, FACR and Laurie A. Loevner, MD
534 **Papillary Tumor of the Pineal Region**
Karen L. Salzman, MD and John H. Rees, MD

EMBRYONAL AND NEUROBLASTIC TUMORS

536 **Medulloblastoma**
Anne G. Osborn, MD, FACR and Majda M. Thurnher, MD
540 **Supratentorial PNET**

General Imaging Approach to Brain Malformations

Whenever an infant or child is referred for imaging because of either seizures or delayed development, a brain malformation is a possible cause. If the child appears dysmorphic in any way (low-set ears, abnormal facies, hypotelorism), the likelihood of an underlying brain malformation is even higher. In all such cases, imaging should be geared toward showing a structural abnormality. The imaging sequences should maximize contrast between gray matter and white matter, have high spatial resolution, and should be acquired as volumetric data whenever possible so that images can be reformatted in any plane or as a surface rendering. The high resolution and ability to reformat will aid in the diagnosis of subtle abnormalities. High-resolution T1-weighted volumetric images are essential for this purpose. If possible, volumetric T2-weighted images can be acquired, but the images must have excellent spatial resolution and sharp contrast between gray matter and white matter, which is not currently easy to achieve with volumetric T2-weighted sequences. If contrast between gray and white matter is poor with volumetric acquisition, acquire two dimensional sequences (2D) in at least two planes and with relatively thin (3-4 mm) section size. FLAIR images are not particularly useful in looking for malformations, as the contrast between gray matter and white matter is often poor. Diffusion-weighted images are not currently of diagnostic utility, although the use of diffusion tensor imaging (DTI) to acquire color fractional anisotropy (FA) maps and perform tractography is useful to better understand the connectivity of the malformed brain and may become clinically useful in the near future.

After acquisition of appropriate images, image analysis must take place in an orderly manner. The midline structures (including cerebral commissures, septum pellucidum, nose and rhinencephalon, pituitary gland, and hypothalamus), the cerebral cortex (cortical thickness, gyral pattern, and cortical-white matter junction), cerebral white matter (myelination, presence of nodules or clefts), the basal ganglia, the ventricular system (are all ventricles completely present and normally shaped), the interhemispheric fissure, and the midbrain hindbrain structures (brainstem and cerebellum) should all be scrutinized in every patient.

Evaluate the midline structures first, as many disease processes of children take place in the midline, including anomalies of the cerebral commissures (corpus callosum, anterior commissure, and hippocampal commissure), midline tumors (suprasellar, pineal, brainstem, and fourth ventricle), anomalies of the cerebellar vermis, and anomalies of the craniocervical junction. Anomalies of the cerebral commissures are the most common of brain malformations; more than 130 syndromes involving them have been described. Many of these are associated with anomalies of the hypothalamus, so remember to always look at the hypothalamus and pituitary gland to ensure that the posterior pituitary gland is in the sella turcica and not in the median eminence of the hypothalamus. The midline leptomeninges are important in commisural development, so make sure to look for other anomalies associated with abnormal midline leptomeninges, such as interhemispheric lipomas and interhemispheric cysts when the commissures are absent or dysmorphic. Remember that large cerebrospinal fluid (CSF) spaces in the posterior fossa (mega cisterna magna) are often associated with anomalies of the cerebellum. The reason for this has only recently been discovered. Several cerebellar growth factors derive from the overlying leptomeninges. Therefore, abnormalities of the cerebellar leptomeninges may result in anomalies of the cerebellum itself, as well as abnormalities of the surrounding CSF spaces. This is the basis of development of the Dandy-Walker malformation: It requires abnormal development of the cerebellum itself and of the overlying leptomeninges. Looking at the midline image also gives an idea of the relative head size by assessing the craniofacial ratio. In the normal neonate, the ratio of the cranial vault to the face on midline images is 5:1 or 6:1. By the age of 2 years, it should be 2.5:1, and by age 10 years, it should be about 1.5:1.

After looking at the midline, evaluate the brain from outside to inside. Start with the cerebral cortex. Is the thickness normal (2-3 mm)? If it is too thick, think of pachygyria or polymicrogyria. Is the cortical-white matter junction smooth or irregular? If it is irregular, think of polymicrogyria or the cobblestone cortex seen associated with congenital muscular dystrophies such as muscle-eye-brain disease. The location of these abnormalities is important as well. Pachygyria more severe in the parietal and occipital lobes suggests a mutation of *TUBA1A*, whereas pachygyria worst in the frontal lobes suggests a mutation of *DCX*. Similarly, there are many different polymicrogyria syndromes that depend upon the location of the polymicrogyria: Bilateral frontal polymicrogyria is a different entity than bilateral perisylvian polymicrogyria or bilateral parasagittal parietooccipital polymicrogyria; it is important to be specific in reporting the location of the abnormality. If the cortex is abnormally thin, one should think of a prenatal injury (infectious or ischemic), particularly if the thinning is focal or multifocal.

After the cortex, look at the cerebral white matter. Make sure myelination is appropriate for age (there are many sources of normal myelination charts, including journal articles and textbooks). Then, look for areas of abnormal myelination within the deep white matter. Diffuse layers of hypomyelination or amyelination associated with overlying polymicrogyria should raise suspicion for congenital cytomegalovirus infection. More localized foci of delayed or absent myelination are often seen in deep white matter of patients with congenital muscular dystrophy and in the subcortical white matter of those with focal cortical dysplasias (FCDs). With FCDs, the absent myelination may be localized to a gyrus or may extend centrally as a curvilinear cone-shaped abnormality coursing from the cortex to the superolateral margin of a lateral ventricle (this is known as the "transmantle" sign). Also, look for nodules of heterotopic gray matter in the periventricular or deep white matter. Subcortical heterotopia typically extend from the cortex all the way to the lateral ventricular wall, while periventricular nodular heterotopia are more localized to the immediate subependymal/periventricular region. Heterotopia might be difficult to differentiate from unmyelinated or injured white matter on T1-weighted images, so be sure to look at T2-weighted images or FLAIR images to ensure that the lesion is isointense to gray matter on all sequences.

The basal ganglia are sometimes abnormal in disorders of neuronal migration, as they are formed from neurons generated in the medial and lateral ganglionic eminences, the same germinal zones that produce GABAergic neurons that migrate to the cerebral cortex. In particular, the basal ganglia tend to be dysmorphic in appearance in patients with

https://CafePezeshki.IR

Brain Anomaly Imaging Checklist

Anomaly	Findings
Anomalies of the Cerebral Cortex	
Agyria/pachygyria	Thick cortex, smooth inner margin, few shallow sulci
Polymicrogyria	Thin undulating cortex, irregular inner margin
Cobblestone cortex	Thick cortex, irregular inner margin, abnormal myelin
Focal cortical dysplasia	Blurred gray-white junction, ± abnormal myelination
White Matter Abnormalities With Cortical Malformation	
Polymicrogyria	Enlarged perivascular spaces
Cobblestone cortex	Delayed myelination, patchy hypomyelination
Congenital cytomegalovirus	Deep layers of hypomyelination/gliosis
Focal cortical dysplasia	Focal subcortical hypomyelination
Malformations Associated With Absent Septi Pellucidi	
Septooptic dysplasia	
Holoprosencephaly	
Bilateral schizencephaly	
Bilateral polymicrogyria	
Rhombencephalosynapsis	
Malformations with prolonged severe hydrocephalus	

subcortical heterotopia. In addition, the hippocampi are often abnormal in malformations of cortical development. In patients with lissencephaly, in particular, the hippocampi are incompletely folded. Sometimes, the only structural abnormalities in children with developmental delay are hippocampal; always look to make sure that they are fully folded and not too round.

Always look at the entire interhemispheric fissure (IHF); if the cerebral hemispheres are continuous across the midline, holoprosencephaly should be diagnosed. In severe holoprosencephalies, the interhemispheric fissure is completely absent, whereas in milder forms of holoprosencephaly certain areas of the interhemispheric fissure will be absent (anterior IHF in semilobar holoprosencephaly, central IHF in syntelencephaly). Look at the septum pellucidum; absence of the septum is seen in corpus callosum dysgenesis/agenesis, septo-optic dysplasia, and in some cases of schizencephaly or bilateral polymicrogyria. While checking the septum, look at the lateral ventricles to ensure that they are normal in size and shape. Abnormally enlarged trigones and temporal horns are often associated with callosal anomalies and pachygyria. Enlarged frontal horns are often seen in bilateral frontal polymicrogyria.

Don't forget to look carefully at the posterior fossa; anomalies of the brainstem and cerebellum are commonly overlooked. Make sure that the 4th ventricle and cerebellar vermis are normally sized. In newborns, the vermis should extend from the inferior colliculi to the obex, while infants and older children should have a vermis that extends from the intercollicular sulcus to the obex. Also, make sure you see normal vermian fissures. If the fissuration of the vermis looks abnormal, look at an axial or coronal image to make sure the vermis is present; if the cerebellar hemispheres are continuous without a vermis between them, make a diagnosis of rhombencephalosynapsis. If the 4th ventricle has an abnormal rectangular shape (with a horizontal superior margin) with a narrow isthmus and small vermis, think about a molar tooth malformation. To confirm this diagnosis, look for the molar tooth sign of the lower midbrain, consisting of large, horizontal superior cerebellar peduncles extending posteriorly toward the cerebellum, and a longitudinal cleft in the superior vermis. Make sure that the components of the brainstem are of normal size; in a child, the height of the pons should be double that of the midbrain on the midline sagittal image. An important clue can be provided by looking at the size of the pons compared to that of the cerebellar vermis. Since much of the anterior pons is composed of the decussation of the middle cerebellar peduncles, development hypoplasia of the cerebellum is nearly always associated with hypoplasia of the ventral pons. If the pons is normal in the setting of a small cerebellum, it is most likely that the cerebellum lost volume near the end of gestation or after birth. Remember that a small posterior fossa, intracranial **hypo**tension, **or** intracranial **hyper**tension can result in descent of the cerebellum below the foramen magnum. Look for causes of a small posterior fossa (clival anomaly, anomaly of the craniovertebral junction), intracranial hypertension (space-occupying mass, hydrocephalus), or evidence of intracranial hypotension (large dural venous sinuses, large pituitary gland, "slumping" brainstem) before making a diagnosis of Chiari 1 malformation. Finally, remember to look at the size of the CSF spaces in the posterior fossa, enlargement of which may be a sign of abnormal leptomeningeal development.

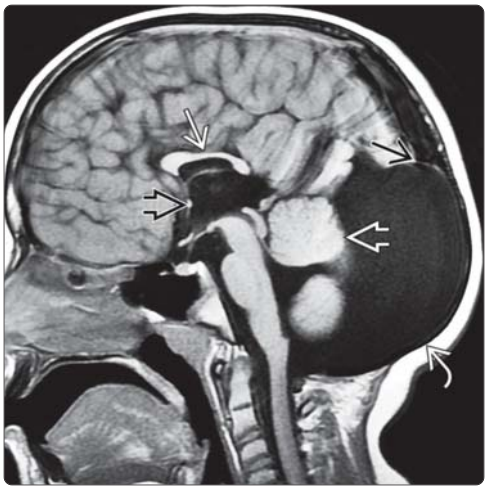
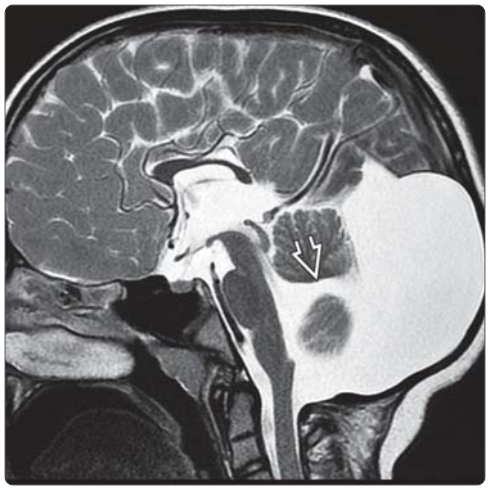
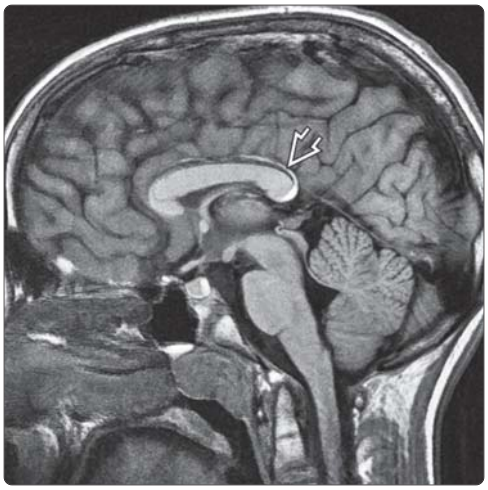
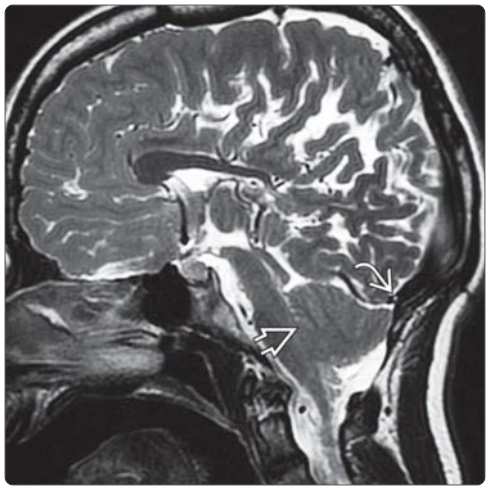
(Left) *Midline analysis using sagittal T1WI MR shows classic findings of Dandy Walker spectrum with a large posterior fossa cyst, high torcular and a small, upwardly rotated vermis. There is also a significant commissural anomaly with only a small corpus callosum remnant present. The rostrum and splenium are absent. The anterior commissure is present and appears normal.* **(Right)** *T2WI in the same case shows the 4th ventricle is open dorsally, contiguous with the huge posterior fossa cyst.*



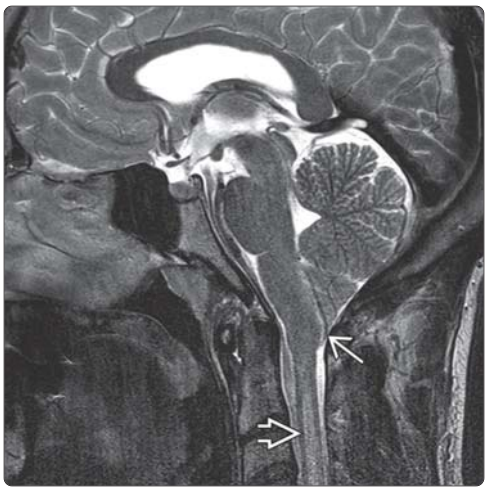


(Left) *Sagittal T1WI shows a hypoplastic callosum rostrum and splenium, plus a small interhemispheric lipoma.* **(Right)** *Sagittal T2WI shows a very small posterior fossa with a low-lying torcular and an elongated 4th ventricle that lacks a fastigium. This patient has a classic Chiari 2 malformation.*

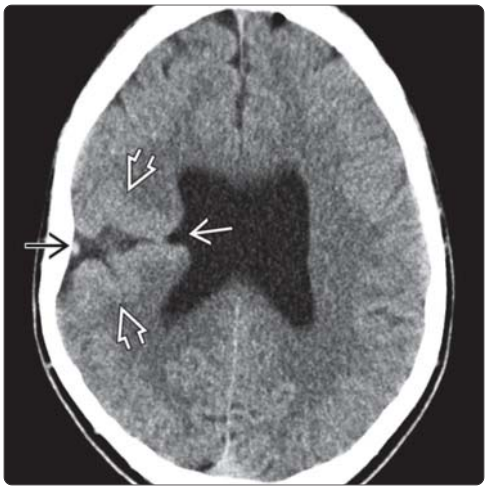




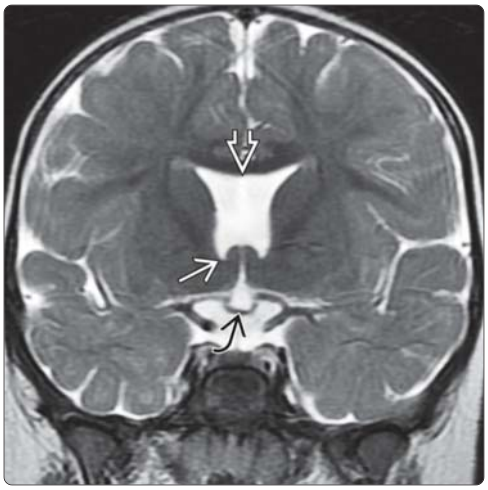
(Left) *Midline analysis of a sagittal T2WI shows a normal-sized posterior fossa. The cerebellar tonsils are pointed and displaced inferiorly 1 cm below the foramen magnum. Note cord hyperintensity, suggesting a "pre-syrinx" state in this case of Chiari 1 malformation.* **(Right)** *Axial T2WI in the same case shows the mass-like thickening of the right medial parietal gray matter and distorted sulcal-gyral pattern of cortical dysplasia.*



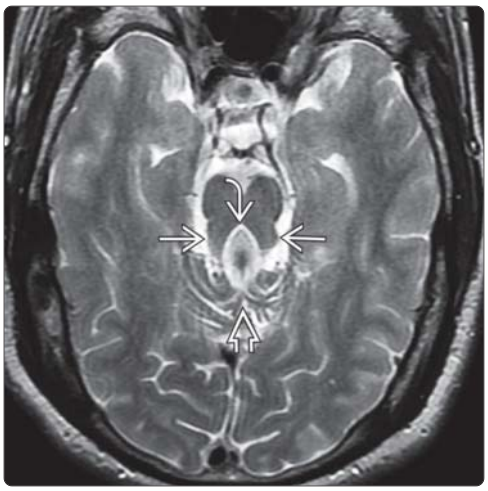
https://CafePezeshki.IR



(Left) *Axial NECT scan in an 18-year-old male with seizures shows a unilateral schizencephalic cleft extending from the pial surface of the brain ⇨ to the ventricle. Note the characteristic CSF "nipple" ➡ at the ventricular margin. The cleft is lined by thickened, dysplastic gray matter ➡.* **(Right)** *Axial T2WI shows bilateral schizencephalic clefts ➡ lined by dysplastic gray matter ➡. Note the abnormal cortical veins ⇨ associated with the clefts.*



(Left) *Axial T2WI MR allows analysis of midline and shows absent interhemispheric fissure in frontal lobes (white matter continuous across midline ➡). This finding, plus the absence of frontal horns, gives the diagnosis of holoprosencephaly.* **(Right)** *Analysis of coronal images shows a squared-off appearance to the lateral ventricles with inferiorly pointed frontal horns ➡, absent septum pellucidum ➡, and hypoplastic optic chiasm ⇨ characteristic of septooptic dysplasia.*



(Left) *Midline analysis of posterior fossa structures shows an upwardly convex superior 4th ventricle and a dysplastic-appearing vermis.* **(Right)** *Axial T2WI in the same case shows the elongated 4th ventricle ➡, cleft vermis ➡, and thickened, horizontally oriented superior cerebellar peduncles ➡ forming the classic molar tooth sign of Joubert syndrome.*

KEY FACTS

TERMINOLOGY

- Chiari 1 malformation (CM1)
  - CM1: Constellation of findings (not a disease, not simply a measurement)
- No clear consensus definition of what constitutes CM1
  - Traditional: Elongated, peg-shaped cerebellar tonsils extend below foramen magnum into upper cervical spinal canal
  - The "5 mm" criterion for tonsillar displacement below basion-opisthion line is flawed criterion
    - Tonsillar position is a morphometric distribution and also changes with time
    - Tonsillar position **plus** shape/configuration (elongated, pointed)
    - Tonsillar position also risk factor for syrinx (the lower the tonsils, the higher the risk)
  - "Crowding" of posterior fossa with compression of CSF spaces
  - Evaluate skull base, upper cervical spine
    - PF may be undersized, shallow (especially children)
    - Short clivus, CVJ assimilation anomalies common

TOP DIFFERENTIAL DIAGNOSES

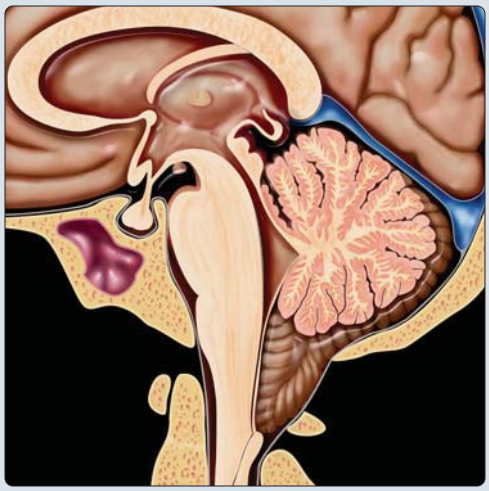
- Normal anatomic variant (normal-shaped tonsils below FM)
- Intracranial hypotension
  - Critical not to mistake this for CM1
- Acquired tonsillar herniation (don't call "acquired Chiari 1")
- "Complex Chiari malformation" ("Chiari 1.5" is neurosurgical term)
  - Tonsillar herniation complicated by other abnormalities (caudal descent of brainstem with low-lying obex, bony anomalies, such as "retroflexed" odontoid)

CLINICAL ISSUES

- Up to 50% of CM1 is asymptomatic

DIAGNOSTIC CHECKLIST

- Look for findings of intracranial hypotension before making diagnosis of CM1



(Left) *Sagittal graphic demonstrates pointed peg-like tonsils extending below foramen magnum, elongating the normally positioned 4th ventricle.* **(Right)** *Sagittal T2WI in a 23-year-old male with classic Chiari 1 malformation shows low-lying pointed tonsils ➡ and hyperintensity in the upper cervical cord ➡ that may represent "presyrinx" state.*

(Left) *Sagittal T1WI MR shows normal 4th ventricle position and appearance. The fastigium ➡ is in normal position, helping to distinguish from Chiari 2 malformation. There is inferior displacement of the ectopic cerebellar tonsils ➡ through the foramen magnum with odontoid process retroflexion and clivus foreshortening.* **(Right)** *Axial T2WI MR confirms inferior displacement of ectopic cerebellar tonsils ➡ through the foramen magnum, producing foramen magnum crowding.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Chiari 1 malformation (CM1)

Synonyms

- Chiari type I

Definitions

- No clear consensus definition of what constitutes CM1
  - Traditional: Elongated, peg-shaped cerebellar tonsils extend below foramen magnum into upper cervical spinal canal
    - The "5 mm" criterion for tonsillar displacement below basion-opisthion line is flawed criterion
      - Tonsillar position is a morphometric distribution and also changes with time
  - CM1: Constellation of findings (not a disease, not simply a measurement)
    - Tonsillar position **plus** shape/configuration (elongated, pointed)
      - Tonsillar position also risk factor for syrinx (the lower the tonsils, the higher the risk)
    - "Crowding" of posterior fossa with compression of CSF spaces
    - Evaluate skull base, upper cervical spine
      - Short clivus, craniovertebral junctioni (CVJ) assimilation anomalies common

IMAGING

General Features

- Best diagnostic clue
  - Combination of inferiorly displaced "pointed" tonsils with "crowded" posterior fossa, effaced retrocerebellar CSF spaces at foramen magnum/upper cervical level
- Morphology
  - Low-lying, pointed peg-like tonsils with oblique vertical sulci, elongated but normally located 4th ventricle (normal dorsally-pointed fastigium)

CT Findings

- Bone CT
  - Often normal; abnormal cases → short clivus, CVJ segmentation/fusion anomalies

MR Findings

- T1WI
  - Pointed (not rounded) tonsils ≥ 5 mm below foramen magnum
  - "Tight" foramen magnum with small/absent cisterns
  - ± 4th ventricle elongation, hindbrain anomalies
- T2WI
  - Oblique tonsillar folia (sergeant's stripes like)
  - ± short clivus → apparent descent of 4th ventricle, medulla
  - ± syringohydromyelia (14-75%)
- MR cine
  - Disorganized CSF pulsation, ↑ brainstem/cerebellar tonsil motion → ↑ peak systolic velocity, ↓ flow through foramen magnum
    - Tonsillar pulsatility may be better predictor than CSF flow

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR ± sagittal cine MR

DIFFERENTIAL DIAGNOSIS

Normal Tonsillar Displacement Below Foramen Magnum

- Tonsils may normally lie below foramen magnum
- Unless also pointed, with "crowded" appearance around FM, probably not CM1 and is normal anatomic variant

Intracranial Hypotension

- "Pull from below" (LP shunt, CSF leak) secondary to intracranial hypotension
  - "Sagging" brainstem, tonsillar herniation, smooth dural enhancement, dilated epidural plexus, retrospinal C1/C2 fluid collection, spinal hygroma
- Don't mistake this for Chiari 1
  - FM/C1 decompression can exacerbate CSF leak with disastrous consequences

Acquired Tonsil Herniation (Acquired Chiari 1)

- Acquired basilar invagination → small posterior fossa
  - Osteogenesis imperfecta
  - Paget disease
  - Craniosynostosis
  - Rickets
  - Achondroplasia
  - Acromegaly
- "Push from above"
  - Chronic VP shunt; thick skull, premature sutural fusion, arachnoidal adhesions
  - ↑ intracranial pressure (ICP), intracranial mass

Complex Chiari Malformation

- Sometimes called "Chiari 1.5" by neurosurgeons
  - Tonsillar herniation with caudal descent of brainstem (low-lying obex, nucleus gracilis)
  - Bony anomalies (such as retroflexed odontoid, C0-C1 assimilation, short clivus, etc.)
  - More severe clinical phenotype than CM1, may require anterior, as well as posterior, decompression

PATHOLOGY

General Features

- Etiology
  - Hydrodynamic theory
    - Systolic piston-like descent of impacted tonsils/medulla → plugging of CSF pathway at foramen magnum
    - During diastole, rapid recoil of brainstem/tonsils disimpacts foramen magnum, permits normal CSF diastolic pulsation
  - Posterior fossa underdevelopment theory
    - Underdeveloped occipital somites of paraxial mesoderm → small posterior fossa → secondary tonsillar herniation
    - But: Not all CM1 patients have small posterior fossae
- Genetics

https://CafePezeshki.IR

- Autosomal dominant inheritance with reduced penetrance or autosomal recessive inheritance
- Syndromic/familial associations
  - Velocardiofacial/microdeletion chromosome 22, Williams syndrome, craniosynostosis, achondroplasia, Hajdu-Cheney syndrome, and Klippel-Feil syndrome
- Associated abnormalities
  - 4th occipital sclerotome syndromes (50%): Short clivus, CVJ segmentation/fusion anomalies
  - Osseous skull base/skeletal anomalies (25-50%)
    - Scoliosis ± kyphosis (42%); left thoracic curve
    - Retroflexed odontoid process (26%)
    - Platybasia, basilar invagination (25-50%)
    - Klippel-Feil syndrome (5-10%)
    - Incomplete C1 ring ossification (5%)
    - Atlantooccipital assimilation (1-5%)
  - Syringomyelia (30-60%); 60-90% in symptomatic CM1 patients
    - Most common C4-C6; holocord hydrosyringomyelia, cervical/upper thoracic syrinx, syringobulbia uncommon
  - Hydrocephalus (11%)
- FM arachnoid adhesions, obstruction → decreased communication between cranial, spinal CSF compartments

Staging, Grading, & Classification

- Diagnostic criteria: Herniation of at least 1 cerebellar tonsil > 5 mm or herniation of both tonsils ≥ 3-5 mm below line connecting basion with opisthion
  - Herniation of both tonsils ≥ 3-5 mm below foramen magnum + syrinx, cervicomedullary kink, 4th ventricular elongation, or pointed tonsils → congenital CM1
  - Tonsil herniation ≤ 5 mm does not exclude CM1

Gross Pathologic & Surgical Features

- Herniated, sclerotic tonsils grooved by opisthion
- Arachnoidal scarring and adhesions at foramen magnum

Microscopic Features

- Tonsillar softening or sclerosis with Purkinje/granular cell loss

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Up to 50% asymptomatic (especially if ≤ 5 mm caudal displacement)
  - Most common symptoms at presentation are headache, neck pain
  - Symptomatic patients present with constellation of findings
    - Sudden death (rare)
    - Suboccipital headache, cranial nerve palsy, ocular disturbances, otoneurologic dysfunction
    - Cord motor or sensory abnormalities, gait disturbance, neuropathic joint
    - Tonsillar herniation > 12 mm nearly always symptomatic; ~ 30% with tonsils 5-10 mm below foramen magnum asymptomatic
    - CM1 patients with syrinx nearly always present with symptoms referable to syrinx; if syrinx extends into medulla, bulbar symptoms predominate
  - Trauma is common precipitating event for symptom onset (24%)
- Clinical profile
  - Clinical CM1 syndrome: Headache, pseudotumor-like episodes, Ménière disease-like syndrome, lower cranial nerve and spinal cord signs

Demographics

- Age
  - 10 months to 65 years; syrinx, congenital CVJ anomalies hasten presentation
- Gender
  - F > M (3:2)
- Epidemiology
  - Incidence: 0.01-0.6% all age groups, 0.9% pediatric patient groups
  - Asymptomatic CM1 discovered incidentally on imaging relatively common; perhaps best described as cerebellar tonsillar ectopia)

Natural History & Prognosis

- Natural history not clearly understood
  - Many patients asymptomatic, CM1 discovered incidentally
  - Increasing ectopia → ↑ risk of syrinx
- Children respond better to treatment than adults

DIAGNOSTIC CHECKLIST

Consider

- Degree of tonsillar correlates with clinical severity
- Unless tonsils > 5 mm and pointed ± "crowded posterior fossa" probably not clinically significant

Image Interpretation Pearls

- Don't use 5 mm cut-off point alone to diagnosis CM1 (with pathological and clinical implications)

KEY FACTS

TERMINOLOGY

- Complex hindbrain malformation
- Virtually 100% associated with neural tube closure defect (NTD), usually lumbar myelomeningocele (MMC)

IMAGING

- Crowded posterior fossa, widened tentorial incisura, tectal beaking, inferior vermian displacement
- Cascade or waterfall of cerebellum/brainstem downward
  - Uvula/nodulus/pyramid of vermis → sclerotic peg
  - Cervicomedullary kink (70%)
  - Towering cerebellum → compresses midbrain, associated beaked tectum
  - 4th ventricle elongated with no posterior point (fastigium)
- Lacunar skull: Focal calvarial thinning with scooped-out appearance

TOP DIFFERENTIAL DIAGNOSES

- Chiari 1 malformation
- Chiari 3 malformation
- Intracranial CSF hypotension
- Severe, chronic shunted hydrocephalus (congenital)

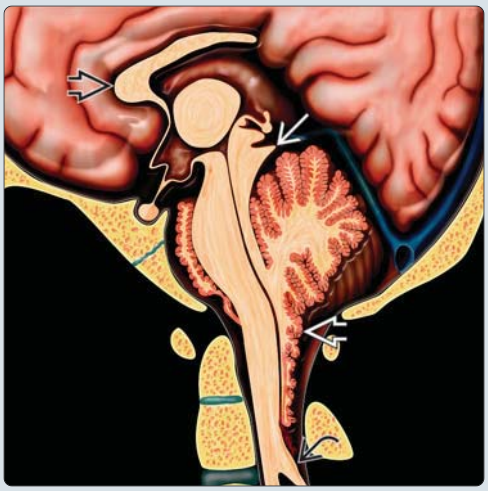
PATHOLOGY

- Secondary to sequelae of CSF leakage through open spinal dysraphism during gestation (4th fetal week)
- Methylenetetrahydrofolate reductase (*MTHFR*) mutations → abnormal folate metabolism
- Spine- and brain/skull-associated anomalies common

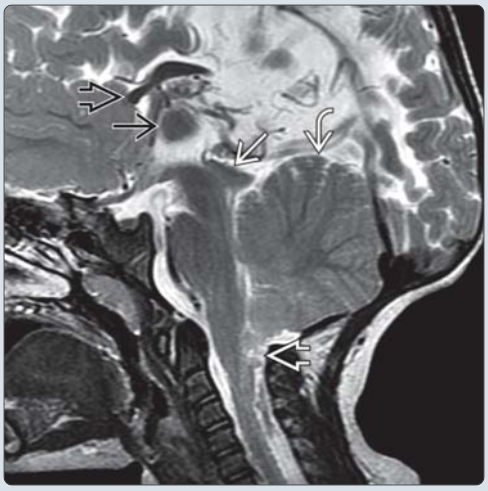
DIAGNOSTIC CHECKLIST

- Towering cerebellum, downward vermian displacement, ± brainstem compression diagnostic for Chiari 2 especially if MMC present

(Left) *Sagittal graphic of the posterior fossa and upper cervical spine demonstrates characteristic findings of Chiari 2 malformation, including callosal dysgenesis ⇨, tectal beaking ➡, small posterior fossa, vermian ectopia ➡, and medullary kinking ⇨.* **(Right)** *Sagittal T1WI MR reveals characteristic Chiari 2 malformation findings. Note the tectal beaking ➡, vermian displacement ➡ through the foramen magnum, large massa intermedia ➡, and dysplastic corpus callosum ⇨.*



(Left) *Sagittal T2WI MR confirms characteristic findings of Chiari 2 malformation, including tectal beaking ➡, vermian displacement through the foramen magnum ➡, "towering" cerebellum ➡, large massa intermedia ⇨, and dysplastic corpus callosum ⇨.* **(Right)** *Axial T2WI MR shows characteristic posterior fossa crowding at the foramen magnum, reflecting small dimensions of the posterior fossa combined with cerebellar ectopia and vermian displacement through the foramen magnum.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Chiari 2 malformation (CM2)

Synonyms

- Chiari type II

Definitions

- Complex hindbrain malformation
  - Virtually 100% associated with neural tube closure defect (NTD), usually lumbar myelomeningocele (MMC)
    - Rare reports in closed spinal dysraphism (probably misinterpreted Chiari 1)

IMAGING

General Features

- Best diagnostic clue
  - Downward herniation of cerebellar vermis plus myelomeningocele
- Location
  - Posterior fossa (PF), upper cervical spine; syrinx may involve entire cord
- Size
  - Posterior fossa smaller than normal
- Morphology
  - Cerebellum "wraps" around medulla and "towers" through incisura, with "beaked" tectum and heart-shaped midbrain

CT Findings

- NECT
  - Crowded posterior fossa, widened tentorial incisura, tectal beaking, and inferior vermian displacement
- Bone CT
  - Small PF
    - Low-lying tentorium/torcular inserts near foramen magnum
    - Large, funnel-shaped foramen magnum with "notched" opisthion
    - "Scalloped" posterior petrous pyramids, clivus
  - Posterior C1 arch anomalies (66%), enlarged cervical canal
  - Lacunar skull: Focal calvarial thinning with scooped-out appearance
    - Mostly resolved by 6 months, but some scalloping of inner table often persists into adulthood

MR Findings

- T1WI
  - Cascade or waterfall of cerebellum/brainstem downward
    - Uvula/nodulus/pyramid of vermis → sclerotic peg
    - Cervicomedullary kink (70%)
    - Towering cerebellum → compresses midbrain, associated beaked tectum
    - 4th ventricle elongated with no posterior point (fastigium)
  - Open spinal dysraphism, MMC ~ 100% (lumbar > > cervical)
  - Hydrosyringomyelia (20-90%)
- T2WI
  - Similar to T1WI + hyperintense, gliotic cerebellar tissue
  - ± 4th ventricular lesions (rare)
    - Roof of 4th ventricle adjacent/within choroid plexus
    - Glial or arachnoidal cysts, glial or choroidal nodules, subependymoma
- MR cine
  - Phase contrast cine MR → restricted CSF flow through foramen magnum
- Diffusion tensor imaging (DTI)
  - Fractional anisotropy (FA) map and quantitative analysis defines callosal dysgenesis, confirms abnormal white matter architecture

Ultrasonographic Findings

- Grayscale ultrasound
  - Fetal obstetrical ultrasound (US) pivotal for early diagnosis
    - MMC may be identified as early as 10 weeks
    - Characteristic brain findings (lemon and banana signs) seen as early as 12 weeks

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR for initial brain, spine evaluation
  - Follow-up brain CT or MR to assess hydrocephalus
  - Cervical spine MR for progressive brainstem or spinal symptoms

DIFFERENTIAL DIAGNOSIS

Chiari 1

- No association with myelomeningocele
- Tonsillar herniation (not vermis)

Chiari 3

- Brainstem, cerebellum herniating through C1-C2 spinal dysraphism

Intracranial Hypotension

- Symptomatic expression of low CSF pressure; distinguishable by clinical onset and symptoms
- Slumping posterior fossa with pons compressed against clivus, dural thickening/enhancement

Severe, Chronic Shunted Hydrocephalus (Congenital)

- May cause collapsed brain, upwardly herniated cerebellum

PATHOLOGY

General Features

- Etiology
  - Secondary to sequelae of CSF leakage through open spinal dysraphism during gestation (4th fetal week)
    - Abnormal neurulation → CSF escapes through NTD → failure to maintain 4th ventricular distention → hypoplastic PF chondrocranium → displaced/distorted PF contents
    - Exceedingly rare cases of closed spinal dysraphism with Chiari 2 malformation may contradict this theory
  - Alternative theory proposes association between Chiari 2 malformation and myelomeningocele is due to rostral and caudal neural tube dysgenesis

https://CafePezeshki.IR

- Genetics
  - Methylenetetrahydrofolate reductase (*MTHFR*) mutations associated with abnormal folate metabolism
    - *MTHFR* mutations **plus** folate deficiency → ↑ risk NTD → Chiari 2
    - 4-8% risk of 2nd affected child
- Associated abnormalities
  - Spine
    - Open dysraphism (MMC) ~ 100% (lumbar > > cervical)
    - Posterior arch C1 anomalies (66%)
    - Syringohydromyelia (20-90%)
    - Diastematomyelia (5%)
    - Klippel-Feil syndrome
    - Cervical myelocystocele
  - Brain/skull
    - Corpus callosum (CC) dysgenesis (90%), aqueductal stenosis, rhombencephalosynapsis, gray matter malformations, absent septum pellucidum, fused forniceal columns
    - Lacunar skull (Lückenschädel)
- Hydrocephalus and severity of brain malformation relate to size of PF, degree of caudal hindbrain descent

Gross Pathologic & Surgical Features

- Small PF → contents shift down into cervical spinal canal
  - Cerebellar hemispheres/tonsils "wrap" around medulla
  - Pons/cranial nerve roots often elongated
  - Compressed/elongated/low 4th ventricle → pouch in cervical canal
  - Medullary kink
  - ± syringohydromyelia

Microscopic Features

- Purkinje cell loss, sclerosis within herniated tissues

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Neonate: MMC, enlarging head circumference ± hydrocephalus symptoms
  - Older child/adult: Clinical hydrocephalus, symptoms referable to tethered cord (MMC repair)
  - All age groups: Varying degrees of lower extremity paralysis/sphincter dysfunction/bulbar signs
- Clinical profile
  - Usually presents within context of known MMC
    - Infants: Enlarging head circumference
    - Child/adult: Known Chiari 2 malformation, signs of hydrocephalus/shunt failure ± bulbar symptoms
- Laboratory
  - Fetal screening: ↑ alpha-fetoprotein

Demographics

- Age
  - Usually presents at birth with MMC ± hydrocephalus
- Gender
  - M = F
- Epidemiology
  - Incidence: 0.44 per 1,000 births, ↓ with folate replacement therapy

Natural History & Prognosis

- Most common cause of death in MMC
  - Brainstem compression/hydrocephalus, intrinsic brainstem "wiring" defects
- Progression of spinal neurological deficits is rare; suspect hydrocephalus, associated undiagnosed spinal deformity (diastematomyelia), tethered cord
- Cerebellar tonsil/vermian ectopia may "improve" (ascend) following postnatal repair

Treatment

- Folate supplement for pregnant mothers (preconception → 6 weeks post conception) significantly decreases MMC risk
- Surgical management
  - Chiari decompression with resection of posterior foramen magnum, C1 ring
  - CSF diversion/shunting
  - Fetal MMC repair in selected patients may ameliorate Chiari 2 severity

DIAGNOSTIC CHECKLIST

Consider

- Brain/spinal axis MR to detect presence of Chiari 2, assess severity, look for complications

Image Interpretation Pearls

- Low torcular herophili indicates small posterior fossa
- CT or MR showing towering cerebellum, downward vermian displacement, ± brainstem compression diagnostic of Chiari 2

KEY FACTS

TERMINOLOGY

- Chiari 3 malformation (CM3)
- Synonyms: Chiari III, rhombencephalocele

IMAGING

- Low occipital or high cervical meningoencephalocele containing cerebellum ± brainstem, meninges, vessels, CSF
- Midline bone defect within supraoccipital bone, opisthion

TOP DIFFERENTIAL DIAGNOSES

- Isolated occipital encephalocele
- Other occipital encephaloceles
  - Iniencephaly
  - Syndromic occipital encephalocele

PATHOLOGY

- Severity classified by sac contents
- Cephalocele contents: Meninges, cerebellum, brainstem ± cervical cord, occipital poles, vasculature
  - Disorganized (neuronal migration anomalies, cortical dysplasias) and gliotic brain tissue
  - Lining of sac may show gray matter heterotopias
- Associated abnormalities: Corpus callosum anomalies, gray matter heterotopia, syringohydromyelia, tethered cord

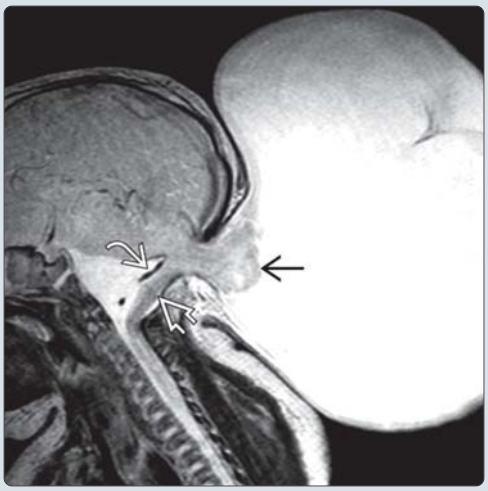
CLINICAL ISSUES

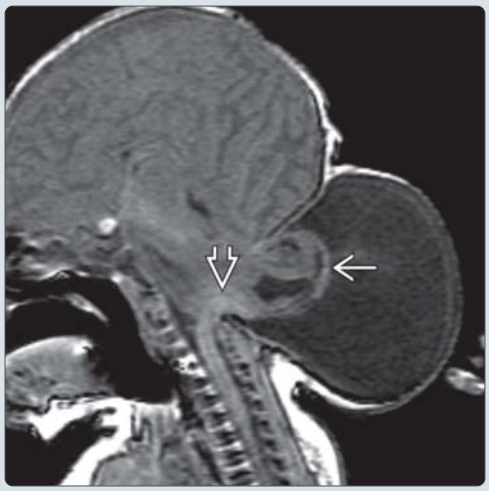
- Microcephaly, severe developmental delay, spasticity, hypotonia, seizures
- Mechanical brainstem traction, respiratory deterioration, lower cranial nerve dysfunction

DIAGNOSTIC CHECKLIST

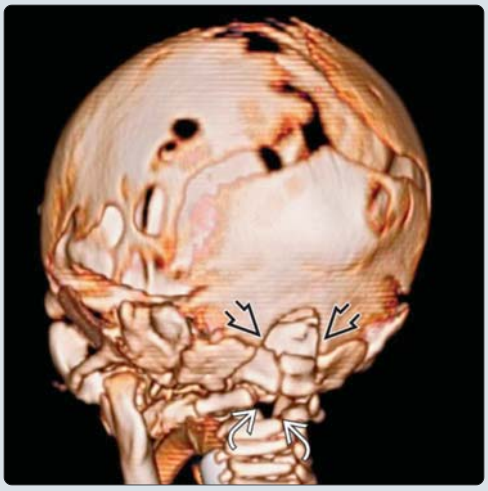
- Occipitocervical cephalocele containing cerebellum ± brainstem in conjunction with C1-C2 spina bifida = Chiari 3 malformation

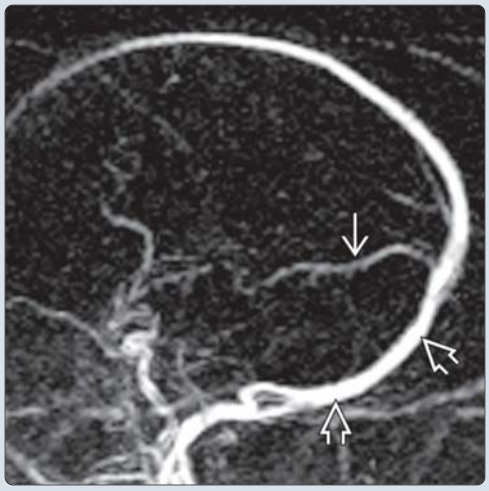
(Left) *Sagittal T2WI MR reveals a large defect in the ventral chondral portion of the supraoccipital bone and opisthion of foramen magnum. Gliotic cerebellar tissue ⇨ protrudes into a large sac. Note the displacement of the brainstem ⇨ and basilar artery ⇨.* **(Right)** *Sagittal T1WI MR shows a large meningoencephalocele composed of meninges, CSF, cerebellum ⇨, brainstem ⇨, and upper cervical spinal cord herniated through a bone defect in the lower occiput and upper cervical spine.*





(Left) *Bone CT 3D shaded surface rendering of the posterior calvaria/upper cervical spine in a Chiari 3 malformation (CM3) patient shows a large defect ⇨ of the ventral chondral and squamous supraoccipital bones in conjunction with upper cervical spina bifida ⇨.* **(Right)** *Sagittal MRV demonstrates typical venous abnormalities of Chiari 3. The straight sinus ⇨ and vein of Galen is severely hypoplastic. Large occipital sinuses ⇨ rather than transverse sinuses are present.*





https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Chiari III, rhombencephalocele

Definitions

- Combined cephalocele with myelocele herniating through high cervical ± low occipital dysraphic defect

IMAGING

General Features

- Best diagnostic clue
  - Skin-covered upper cervical meningoencephalocele containing cerebellum

CT Findings

- NECT
  - Midline posterior cephalocele containing cerebellum
  - Small posterior cranial fossa ± scalloped clivus, lacunar skull
- Bone CT
  - Opisthion, upper cervical osseous dysraphic bone defect
- CTA
  - Basilar artery "pulled" into defect along with brainstem into cephalocele sac
  - ± veins/dural sinuses within cephalocele sac
  - Anomalous &/or ptotic veins, dural sinuses

MR Findings

- T1WI
  - High cervical cephalocele sac containing meninges and cerebellum ± brainstem, upper cervical cord
  - Cisterns, 4th ventricle, dural sinuses may extend into cephalocele (50%)
- T2WI
  - Tissues in cephalocele sac may be bright (gliosis), strand-like (necrotic), or hypointense (hemorrhagic)

Imaging Recommendations

- Best imaging tool
  - Multiplanar brain MR with MRV to characterize occipitocervical encephalocele, vessels
  - Multiplanar bone CT to evaluate osseous defects

DIFFERENTIAL DIAGNOSIS

Isolated Occipital Encephalocele

- Spares foramen magnum, lacks intracranial Chiari 2 findings

Other Occipital Encephaloceles

- Iniencephaly
- Syndromic occipital encephalocele
  - Meckel-Gruber, Goldenhar-Gorlin, MURCS (müllerian, renal, cervical-spine), Walker-Warburg, amniotic band

PATHOLOGY

General Features

- Genetics
  - 677C → T mutation on methylenetetrahydrofolate reductase (*MTHFR*) gene (≤ 50%)
- Associated abnormalities
  - Corpus callosum anomalies, gray matter heterotopia, syringohydromyelia, tethered cord
  - Previously described in combination with intracranial CM2 manifestations
    - Now thought that tectum, lower brainstem findings actually reflect distortion related to cerebellar displacement into sac

Gross Pathologic & Surgical Features

- Cephalocele contents: Meninges, cerebellum, brainstem ± cervical cord, ± occipital poles, ± vasculature

Microscopic Features

- Disorganized (neuronal migration anomalies, cortical dysplasias, gliotic) brain tissue within sac

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Occipital/upper cervical cephalocele, microcephaly
  - Discovered by fetal ultrasound/MR or surprise at birth
- Other signs/symptoms
  - Mechanical brainstem traction, respiratory deterioration, lower cranial nerve dysfunction
- Clinical profile
  - Severe developmental delay, spasticity, hypotonia, seizures

Demographics

- Age
  - Newborn
- Gender
  - F > M (as in all NTDs) in most series
- Epidemiology
  - Rare; 1-4.5% of all Chiari malformations

Natural History & Prognosis

- Dependent on amount, type of herniated tissue
- Prognosis usually dismal, with severe disability and early death

Treatment

- Surgical resection, encephalocele repair
  - Resect or repair sac (most structures in sac are nonfunctioning)
  - If amount CNS tissue in sac > intracranial → not surgical candidate
- Cerebrospinal fluid diversion for hydrocephalus

DIAGNOSTIC CHECKLIST

Consider

- Chiari 3 in newborn presenting with low occipital encephalocele

KEY FACTS

TERMINOLOGY

- Partial or complete absence of corpus callosum (CC), hippocampal commissure (HC), or anterior commissure (AC); can be isolated or associated with additional cerebral malformations
- Spectrum of congenital CC structural abnormalities
  - Total agenesis (absence from birth of all anatomically defined regions of CC)
  - Partial agenesis (absence from birth of at least 1, but not all, regions of CC)
  - Hypoplasia (thinner CC with normal anteroposterior extent)
  - Hyperplasia (thick CC resulting from decreased postnatal axonal pruning)
  - Dysgenesis (CC present but malformed in some way, including partial ACC and hypoplasia of CC)

IMAGING

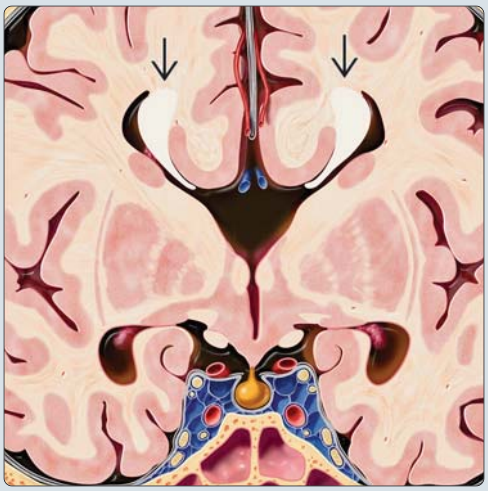
- Absent corpus callosum on sagittal, coronal views
- Atrium/occipital horns often dilated ("colpocephaly")
- DTI: Callosal fiber tracts form Probst bundles instead of crossing, where corpus callosum is absent
- Vertical/posterior course of anterior cerebral artery

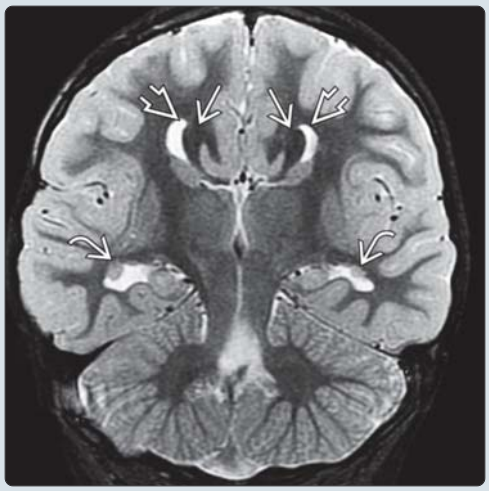
CLINICAL ISSUES

- Any age; classically identified in early childhood, most common malformation found in fetuses
- Seizures, developmental delay, cranial deformity/hypertelorism
- Sporadic/isolated agenesis/dysgenesis corpus callosum: Normal/near normal at 3 years (75%), but subtle cognitive defects apparent with increasing complexity of school tasks
- Agenesis/dysgenesis corpus callosum with associated/syndromic anomalies = worst

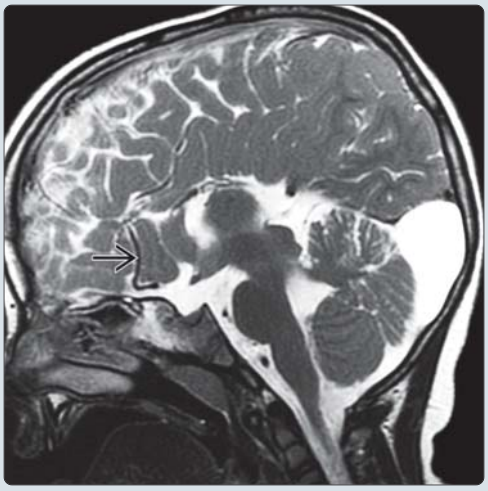
DIAGNOSTIC CHECKLIST

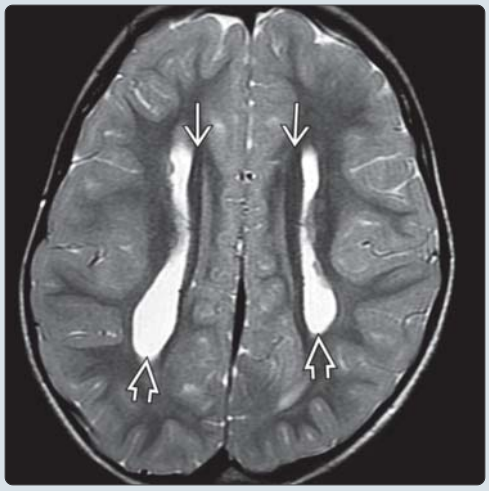
- Look for absent/incomplete corpus callosum rather than indirect signs
- Fully assess for associated lesions





(Left) *Coronal graphic shows a lack of transverse corpus callosum and separate lateral ventricles. The interhemispheric fissure extends to the 3rd ventricle. The bundles of Probst ⇨ contain the parasagittally rerouted callosal fibers.* **(Right)** *Coronal T2WI with callosal dysgenesis shows Viking helmet or moose head appearance of widely separated lateral ventricles ⇨. The very hypointense white matter tracts medial to the lateral ventricles are the Probst bundles ⇨. Note the heterotopic GM ⇨.*





(Left) *Sagittal T2WI in the same patient shows absence of the corpus callosum, radially-oriented gyri converging on a high-riding 3rd ventricle. Note the azygous anterior cerebral artery (ACA) ⇨. The anterior commissure is also absent.* **(Right)** *Axial T2WI in the same case shows the characteristic parallel, nonconverging lateral ventricles ⇨ seen in corpus callosum agenesis. Heavily myelinated Probst bundles ⇨ are seen just medial to the lateral ventricles.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Agenesis/dysgenesis corpus callosum (ACC)

Synonyms

- Callosal agenesis/dysgenesis, commissural agenesis/dysgenesis

Definitions

- Partial or complete absence of corpus callosum (CC), hippocampal commissure (HC), or anterior commissure (AC); can be isolated or associated with additional cerebral malformations
- Spectrum of congenital CC structural abnormalities
  - Total agenesis (absence from birth of all anatomically defined regions of CC)
  - Partial agenesis (absence from birth of at least 1, but not all, regions of CC)
  - Hypoplasia (thinner CC with normal anteroposterior extent)
  - Hyperplasia (thick CC resulting from decreased postnatal axonal pruning)
  - Dysgenesis (CC present but malformed in some way, including partial ACC and hypoplasia of CC)

IMAGING

General Features

- Best diagnostic clue
  - Partially or completely absent CC on midline sagittal and coronal planes
  - Lateral ventricles separate and parallel (axial), bull's head, trident, Viking helmet, or moose head appearances (coronal)
- Size
  - When present, CC remnants vary in size, extent, shape
    - Prior to myelin maturation, may be difficult to define (T2WI is better)
- Morphology
  - Commissural plate, clockwise
    - AC
    - Lamina rostralis and rostrum
    - Genu, body and isthmus, splenium
    - HC below CC, largest posterior to septum pellucidum

CT Findings

- NECT
  - On axial CT, lateral ventricles key to diagnosis
    - Parallel and separate
    - Atrium/occipital horns dilated ("colpocephaly")
- CTA
  - Anterior cerebral arteries (ACAs) course directly upward in interhemispheric fissure

MR Findings

- T1WI
  - Sagittal
    - Absent or incomplete commissures, expanded 3rd ventricular roof
    - Abnormal cingulate gyrus: Radiating sulcal pattern
    - AC may be absent, small, or normal
  - Coronal
    - Interhemispheric fissure extends down to 3rd ventricular roof
    - Probst bundles: Medial parasagittal white matter tracts, brighter than other myelin on T1WI, indent lateral ventricles ("bull's head," etc.)
    - Bifid temporal horns and rounded hippocampi
  - Axial
    - Parallel separate lateral ventricles, colpocephaly
- T2WI
  - Same morphology as on T1WI
    - Probst bundles darker than rest of white matter
  - Variants and associated malformations
    - High-riding 3rd ventricle
    - Partial agenesis usually affects posterior CC and HC
    - Multiple interhemispheric cysts (meningeal dysplasia)
    - Lipomas: Nodular, curvilinear
    - Malformations of cortical development (MCD): Polymicrogyria-like cortical malformation (often along midline cysts), subcortical or periventricular nodular heterotopia
    - Malformation of eyes, hindbrain (Dandy-Walker), hypothalamus-pituitary, cord, heart
- DWI
  - DTI: Callosal fiber tracts form Probst bundles instead of crossing, where CC is absent
  - Callosal remnants may contain axons from any part of cerebrum
- MRA
  - Vertical/posterior course of ACA (no genu to sweep around), ± azygous ACA
- MRV
  - Occasional midline venous anomalies, persistent falcine sinus

Ultrasonographic Findings

- Grayscale ultrasound
  - Coronal
    - Absent CC, bull's head lateral ventricles, separated lateral ventricles, colpocephaly
  - Sagittal
    - Radially arranged gyri "point to" 3rd ventricle
- Color Doppler
  - Abnormal posterior ACA course

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Multiplanar MR (look for associated malformations)
  - If MR unavailable, multiplanar CT will diagnose ACC
  - In fetuses, use ultrafast single-shot T2WI in 3 planes

DIFFERENTIAL DIAGNOSIS

Destruction of Corpus Callosum

- Surgery (callosotomy), trauma
- Hypoxic-ischemic encephalopathy, infarcts, hemorrhages
- Metabolic (Marchiafava-Bignami) with necrosis, longitudinal splitting of CC

https://CafePezeshki.IR

Stretched Corpus Callosum

- Thinned CC (e.g., hydrocephalus), but all parts present

Hypoplastic Corpus Callosum

- CC thin, but all parts present

Immature Corpus Callosum

- Premyelinated CC may be difficult to confirm; look for cingulate gyrus

Thick Corpus Callosum ("Mega-Corpus Callosum")

- Excessively thick CC can be isolated or occur with brain malformations, congenital metabolic diseases
  - Probably due to delayed retraction of transitory collateral axons

PATHOLOGY

General Features

- Etiology
  - Axons fail to form
    - Rare: CRASH syndrome/*L1CAM* gene defect, "cobblestone" lissencephaly
  - Axons not guided to midline (mutations in adhesion molecules)
  - Axons reach midline but fail to cross (absence or malfunction of midsagittal guiding substrate)
    - Turn and form large, aberrant, parasagittal Probst bundles
  - Miscellaneous
    - Toxic: Fetal alcohol exposure may affect *L1CAM*
    - Infection: In utero cytomegalovirus (CMV)
    - Inborn errors of metabolism: Nonketotic hyperglycinemia, pyruvate dehydrogenase deficiency, maternal phenylketonuria (PKU), Zellweger
- Genetics
  - Genetics of associated/syndromic CC anomalies
    - Most common abnormality seen as part of CNS malformations: > 130 syndromes
    - Chiari 2, frontonasal dysplasia, syndromic craniosynostoses, MCD, tubulin mutations, etc.
    - Aicardi syndrome: X-linked ACC, polymicrogyria and heterotopia, infantile spasms, retinal lacunae, developmental delay
- Associated abnormalities
  - MCD: Heterotopia, lissencephaly, polymicrogyria, etc.
  - Ocular/hypothalamic-pituitary/cord/facial anomalies
  - Heart, limbs
  - ACC may be malformation in itself or feature of many malformative syndromes

Staging, Grading, & Classification

- May be isolated or part of syndrome; complete or partial
- May have interhemispheric dysplasia: Meningeal cysts, lipomas
- May be part of syndrome (> 130)

Gross Pathologic & Surgical Features

- Leaves of septum pellucidum laterally displaced, contain Probst bundles
- Probst bundles contain parasagittal callosal bundle
  - Only form if callosal neurons present
  - Variable-sized bundles smaller than normal CC
- Associated dysgenetic brain lesions

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizures, developmental delay, cranial deformity-hypertelorism
  - Hypopituitarism-hypothalamic malfunction
  - Autism spectrum disorders
- Clinical profile
  - None specific

Demographics

- Age
  - Any age, classically identified in early childhood, most common malformation found in fetuses
- Gender
  - M > F, if isolated finding
- Epidemiology
  - 0.5-70 per 10,000 live births
  - 4% of CNS malformations
  - Can be isolated (often males) or part of other CNS malformations

Natural History & Prognosis

- Sporadic/isolated ACC: Normal/near normal at 3 years (75%), but subtle cognitive defects apparent with increasing complexity of school tasks
- ACC with associated/syndromic anomalies = worst

DIAGNOSTIC CHECKLIST

Consider

- Syndromic associations common

Image Interpretation Pearls

- Look for absent/incomplete CC rather than indirect signs
- Fully assess for associated lesions

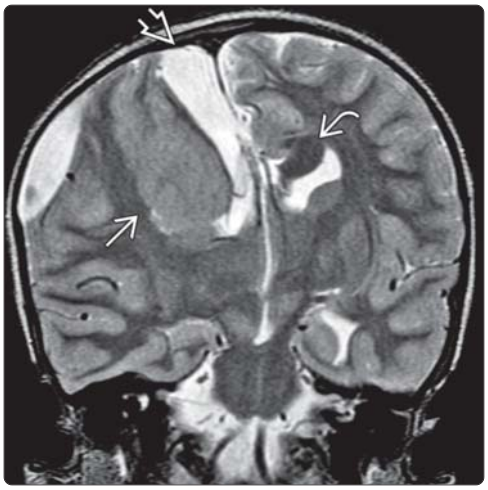
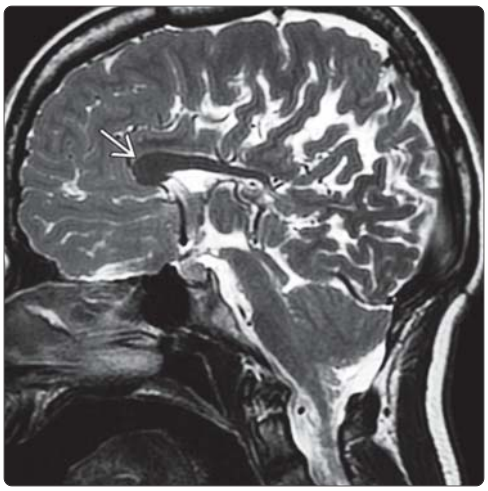
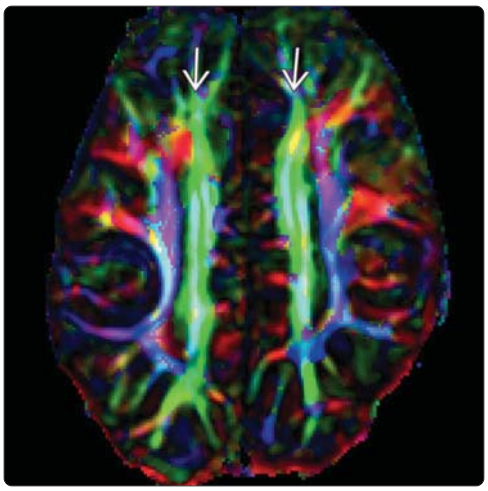
https://CafePezeshki.IR



(Left) *Sagittal T1WI MR shows pure partial agenesis/dysgenesis corpus callosum (ACC). The posterior portion of the corpus callosum is missing ⇨, but the junction with the fornix ⇨ seems preserved. Posterior coronals would show Probst bundles, whereas anterior images would appear normal.* **(Right)** *Coronal T2WI MR shows ACC with (shunted) interhemispheric meningeal cysts ⇨. Note the massive nodular heterotopia on the patient's right ⇨. A Probst bundle has formed on the left ⇨ but not on the right.*

(Left) *Axial NECT with widened windows shows ACC with colpocephaly, calcified ⇨ midline lipoma that extends through choroid fissures into lateral ventricles ⇨.* **(Right)** *Axial T1WI MR in ACC shows parallel ventricles, colpocephaly, and a midline lipoma ⇨. Note that the lipoma protrudes through the choroid fissure into the lateral ventricles ⇨.*





(Left) *Sagittal T1WI MR in a 19-year-old female with Chiari 2 is shown. ACC in Chiari 2 is always partial ⇨; Probst bundles are never seen. Note the multiple supra- and infratentorial Chiari 2 features.* **(Right)** *Axial DTI of a child with complete callosal agenesis shows Probst bundles as green uncrossed callosal fibers ⇨ coursing front to back.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Intracranial lipoma (ICL)
- Mass of mature nonneoplastic adipose tissue
- CNS lipomas are congenital malformations, not true neoplasms

IMAGING

- Well-delineated lobulated extraaxial mass with fat attenuation/intensity
- 80% supratentorial
  - 40-50% interhemispheric fissure (over corpus callosum; may extend into lateral ventricles, choroid plexus)
  - 15-20% suprasellar (attached to infundibulum, hypothalamus)
  - 10-15% tectal region (usually inferior colliculus/superior vermis)
- 20% infratentorial
- Cerebellopontine angle (may extend into internal auditory canal, vestibule)
- Lobulated pial-based fatty mass that may encase vessels and cranial nerves
- CT: -50 to -100 Hounsfield units (HU) (fat density)
- Ca++ varies from none to extensive
- Standard SE MR: Hyperintense on T1WI
- Becomes hypointense with fat suppression

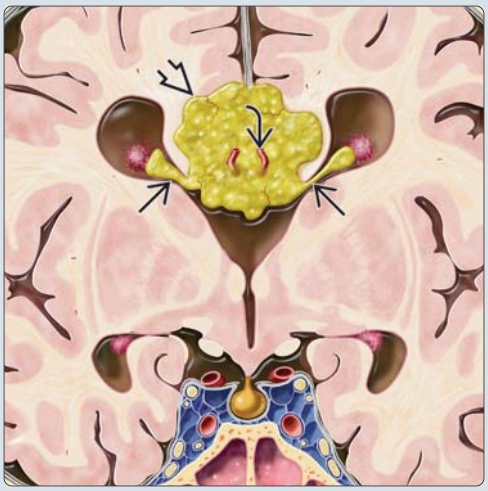
TOP DIFFERENTIAL DIAGNOSES

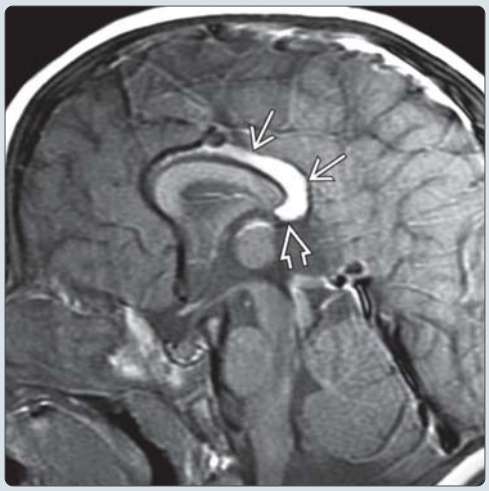
- Teratoma
  - Locations similar to lipoma
  - Tissue from all 3 embryonic germ layers

DIAGNOSTIC CHECKLIST

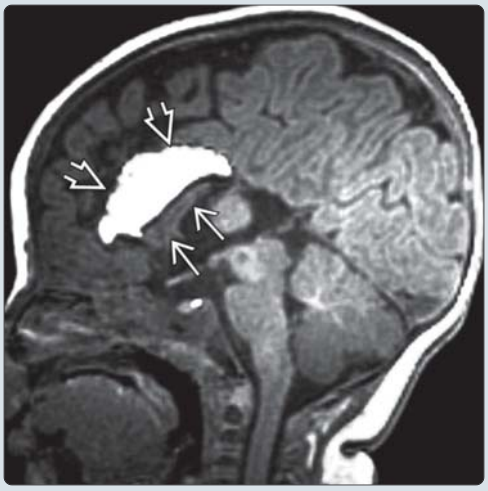
- When in doubt, use fat-saturation sequence
- Could high signal on T1WI be due to other substances with short T1 (e.g., subacute hemorrhage)
- Beware: Lipoma can mimic intracranial air on NECT (use bone windows to distinguish)

(Left) *Coronal graphic shows callosal agenesis with a bulky tubulonodular interhemispheric lipoma* ⇨ *that encases the arteries* ⇨ *and extends into the lateral ventricles* ⇨. **(Right)** *Sagittal T1WI MR shows a rather thin curvilinear interhemispheric lipoma in a 9 month old. Note that the hyperintense lipoma* ⇨ *is thicker posteriorly than anteriorly. It wraps around the back of the corpus callosum and extends beneath the corpus* ⇨ *into the velum interpositum.*





(Left) *Sagittal T1WI MR in a neonate shows a large, tubulonodular, interhemispheric lipoma* ⇨ *dorsal to a wedge-shaped callosal remnant* ⇨. *The brain is otherwise normal.* **(Right)** *Axial T2WI FS MR in the same patient shows the lipoma* ⇨ *as hypointense and lying between the 2 cerebral hemispheres. The lipoma extends through the choroidal fissures into the lateral ventricles* ⇨ *where it is in the stroma of the choroid plexuses.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Intracranial lipoma (ICL)

Synonyms

- Lipomatous hamartoma

Definitions

- Mass of mature nonneoplastic adipose tissue
  - CNS lipomas are congenital malformations, not true neoplasms
  - Lipoma variants in CNS include angiolipoma, hibernoma, osteolipoma

IMAGING

General Features

- Best diagnostic clue
  - Well-delineated lobulated extraaxial mass with fat attenuation/intensity
- Location
  - Midline location common
  - 80% supratentorial
    - 40-50% interhemispheric fissure (over corpus callosum [CC]; may extend into lateral ventricles, choroid plexus)
    - 15-20% suprasellar (attached to infundibulum, hypothalamus)
    - 10-15% tectal region (usually inferior colliculus/superior vermis)
    - Uncommon: Meckel cave, lateral cerebral fissures, middle cranial fossa
  - 20% infratentorial
    - Cerebellopontine angle (may extend into internal auditory canal, vestibule)
    - Uncommon: Jugular foramen, foramen magnum
- Size
  - Varies from tiny to very large
- Morphology
  - Lobulated pial-based fatty mass that may encase vessels and cranial nerves
  - 2 kinds of interhemispheric lipoma
    - Curvilinear type (thin ICL curves around callosal body, splenium)
    - Tubulonodular type (bulky mass; frequent Ca++, usually associated with callosal agenesis)

Radiographic Findings

- Radiography
  - Usually normal
  - Very large interhemispheric lipomas may show low density
  - Tubulonodular lipomas may show rim Ca++

CT Findings

- NECT
  - -50 to -100 Hounsfield units (HU); fat density
  - Ca++ varies from none to extensive
    - Present in 65% of bulky tubulonodular CC lipomas
    - Rare in posterior fossa, parasellar lesions
- CECT
  - Does not enhance
- CTA
  - May demonstrate aberrant pericallosal artery course in interhemispheric lipoma associated with callosal dysgenesis

MR Findings

- T1WI
  - Hyperintense mass
  - Becomes hypointense with fat suppression
  - Chemical shift artifact in frequency-encoding direction
- T2WI
  - Hypointense on conventional spin-echo (SE) with striking chemical shift artifact
    - Round/linear "filling defects" present where vessels and cranial nerves pass through lipoma
    - May show low signal intensity foci (Ca++)
  - FSE: Iso- to hyperintense (J-coupling)
- PD/intermediate
  - Iso- to hyperintense (depending on repetition and echo times)
    - Striking chemical shift artifact
- STIR
  - Hypointense
- FLAIR
  - Hyperintense
- T2* GRE
  - Hypointense
- DWI
  - Diffusion tensor imaging visualizes altered fiber connections if associated callosal dysgenesis present
- T1WI C+
  - Does not enhance

Ultrasonographic Findings

- Grayscale ultrasound
  - Fetal/neonatal mass, generally hyperechoic
  - May show other fetal anomalies (CC agenesis, etc.)

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Add fat-suppression sequence for confirmation

DIFFERENTIAL DIAGNOSIS

Dural Dysplasia

- Fat often in falx, cavernous sinuses
- Metaplastic ossified dura may contain fat

Dermoid

- Density usually 20-40 HU
- Signal intensity usually more heterogeneous
- Rupture with cisternal fat droplets common
- Usually no associated malformations (common with lipoma)
- Dermoids often calcify; lipomas in locations other than interhemispheric do not

Teratoma

- Locations similar to lipoma
- Tissue from all 3 embryonic germ layers

https://CafePezeshki.IR

- Imaging appearance usually more heterogeneous
  - May show foci of contrast enhancement

Lipomatous Differentiation of Neoplasm

- May occur occasionally in PNETs, ependymoma, gliomas
- Cerebellar liponeurocytoma
  - Primarily hypointense on T1WI, mixed with hyperintense foci
  - Patchy, irregular enhancement
- Meningiomas, schwannomas, metastases rarely have lipomatous transformation

Subacute Hemorrhage

- T1 shortening can be confused with lipoma
- Use T2* (hemorrhage blooms), fat saturation (hemorrhage does not suppress)

Encephalocraniocutaneous Lipomatosis

- Eye anomalies, skin lesions, intracranial lipomas, cortical dysgenesis

PATHOLOGY

General Features

- Etiology
  - Persistent maldevelopment of embryonic meninx primitiva
    - Normally differentiates into leptomeninges, cisterns
    - Maldifferentiates into fat instead
  - Developing pia-arachnoid invaginates through embryonic choroid fissure
    - Explains frequent intraventricular extension of interhemispheric lipomas
- Genetics
  - No known defects in sporadic ICL
- Associated abnormalities
  - Most common: Interhemispheric lipoma with corpus callosum anomalies
  - Other congenital malformations: Cephaloceles, closed spinal dysraphism
  - Encephalocraniocutaneous lipomatosis → Fishman syndrome
  - Pai syndrome → facial clefts, skin lipomas; occasional ICLs, usually interhemispheric

Gross Pathologic & Surgical Features

- Yellow lobulated fatty mass attached to leptomeninges, sometimes adherent to brain
- Cranial nerves, arteries/veins pass through lipoma

Microscopic Features

- Identical to adipose tissue elsewhere
- Cells vary in shape/size, measure up to 200 μm
- Occasional nuclear hyperchromasia; mitoses rare/absent
- Liposarcoma: Extremely rare malignant intracranial adipose tumor

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually found incidentally at imaging, autopsy
  - Rare: Cranial neuropathy (vestibulocochlear dysfunction, facial pain), seizures (associated with other congenital anomalies)
  - Seizures associated with lipomas over (dysmorphic) cortex

Demographics

- Age
  - Any age
- Gender
  - M = F
- Ethnicity
  - None known
- Epidemiology
  - < 0.5% of all intracranial masses (not true neoplasm)

Natural History & Prognosis

- Benign, usually stable
- May expand with corticosteroids
  - High-dose, long-term administration may result in neural compressive symptoms

Treatment

- Generally not surgical lesion
  - Surgery has high morbidity/mortality
- Reduce/eliminate steroids

DIAGNOSTIC CHECKLIST

Consider

- Could high signal on T1WI be due to other substances with short T1 (e.g., subacute hemorrhage)

Image Interpretation Pearls

- When in doubt, use fat-saturation sequence
- Beware: Lipoma can mimic intracranial air on NECT (use bone windows to distinguish)

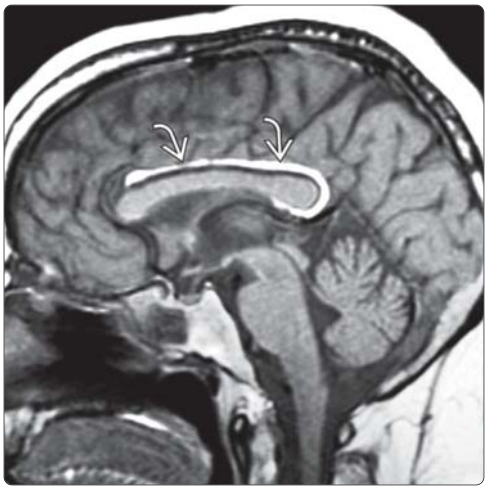
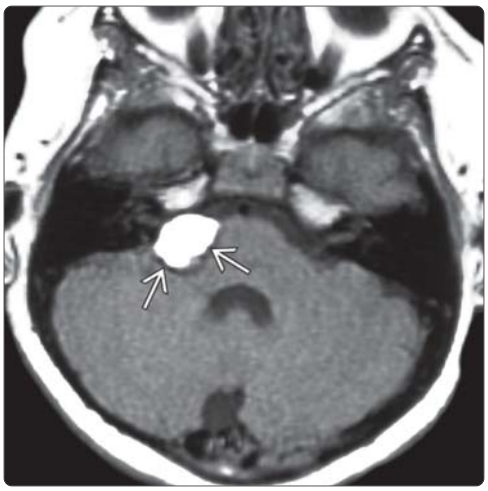
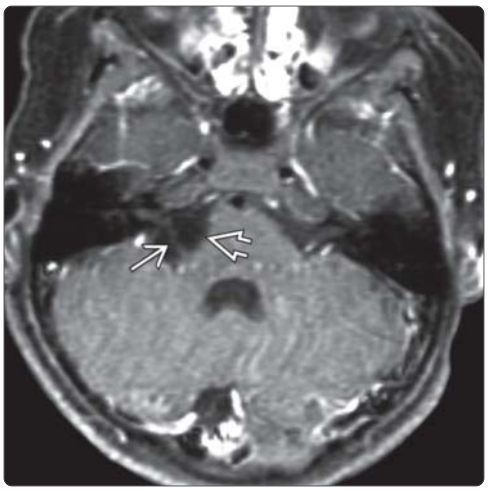
https://CafePezeshki.IR



(Left) *Axial NECT in a young woman studied for an unrelated headache shows a hypodense linear structure ➡ in the midline.* **(Right)** *Sagittal T1WI MR in the same patient shows that the linear structure ➡ is a curvilinear interhemispheric lipoma that wraps around the posterior aspect of a hypogenetic corpus callosum and courses into the posterior part of the velum interpositum. The callosal genu and splenium are incompletely formed.*

(Left) *Sagittal T1WI MR in a 25-year-old man with unrelated symptoms shows a hypothalamic lipoma ➡, which is located in the tuber cinereum of the hypothalamus (between the infundibulum and the mammillary bodies).* **(Right)** *Sagittal T1WI MR shows a tectal lipoma ➡ situated immediately posterior to the inferior tectum and between the inferior colliculus and the superior surface of the cerebellar vermis. This is a very common location for lipomas.*





(Left) *Axial T1WI MR shows a round lipoma ➡ in the right cerebellopontine angle cistern, adjacent to the internal auditory canal (IAC). Lipomas do not cause hearing loss and should not be resected.* **(Right)** *Axial T1WI C+ FS MR shows that the mass ➡ becomes very hypointense after the fat-suppression pulse is applied. With fat signal suppressed, the 8th cranial nerve ➡ can be seen coursing through the lipoma in the cerebellopontine angle cistern to the internal auditory canal.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- DWS represents broad spectrum of cystic posterior fossa (PF) malformations
  - Dandy-Walker spectrum (DWS)/complex (DWC)
  - "Classic" DW malformation (DWM)
  - Hypoplastic vermis with rotation (HVR)
  - Persistent Blake pouch cyst (BPC)
  - Mega cisterna magna (MCM)

IMAGING

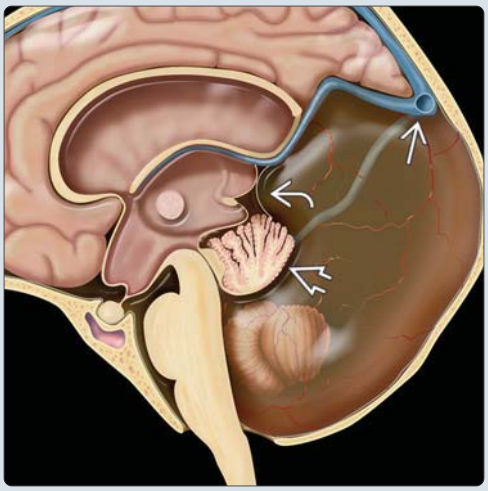
- "Classic" DWM
  - Cystic dilatation of 4th ventricle → enlarged PF
  - Vermis hypoplastic, rotated superiorly
- HVR
  - Variable vermian hypoplasia
  - PF/brainstem normal-sized
  - No or small cyst, "keyhole" vallecula
- BPC
  - "Open" 4th ventricle communicates with cyst
  - Fastigial recess, primary fissure, PF/brainstem normal
- MCM
  - Enlarged pericerebellar cisterns communicate with basal subarachnoid spaces
- Occipital bone may appear scalloped/remodeled with **all** DWS types (including MCM)
- Routine MR imaging (thin sagittal views crucial)

PATHOLOGY

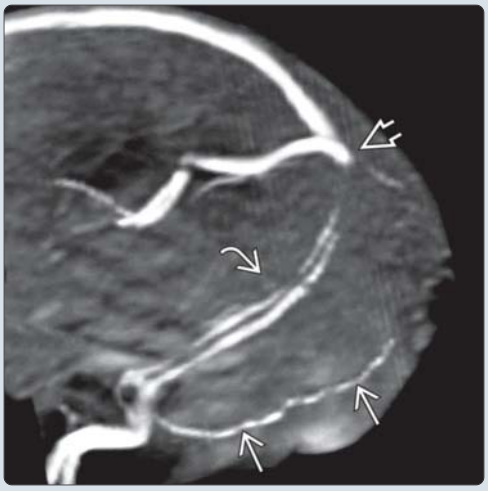
- Most severe to mildest: DWM with 4th ventriculocele → classic DWM → HVR → BPC → MCM
- Numerous syndromes associated with DWS

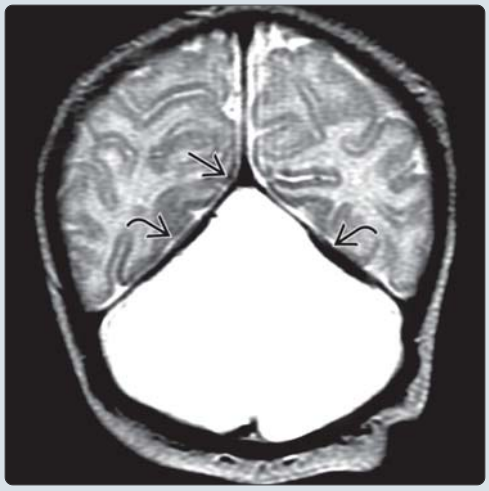
CLINICAL ISSUES

- Marked heterogeneity in genetic, clinical findings
- DWM: 80% diagnosed by 1 year



(Left) *Sagittal graphic of classic Dandy-Walker malformation shows an enlarged posterior fossa, elevated torcular herophili, superior rotation of hypoplastic cerebellar vermis, an overexpanded 4th ventricle with a thin wall, and a dilated ventricle (hydrocephalus).* **(Right)** *Sagittal T2WI MR DWS shows a hypoplastic, rotated vermis, lack of fastigial crease, and incomplete vermian lobulation of the posterior lobules beyond the primary fissure. The cyst wall is faintly seen.*





(Left) *Sagittal MRV demonstrates torcular-lambdoid inversion. The transverse sinuses angle upward toward the torcular as the cyst has prevented normal fetal torcular descent. Note the persistent fetal occipital sinus.* **(Right)** *Coronal T2WI MR demonstrates a huge, fluid-filled posterior fossa. Again, notice that the transverse sinuses are angled upward toward the torcular herophili.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Dandy-Walker (DW) spectrum (DWS), DW complex (DWC), "classic" DW malformation (DWM)
- Hypoplastic vermis with rotation (HVR), formerly DW variant (DWV)
- Persistent Blake pouch cyst (BPC), mega cisterna magna (MCM)

Definitions

- DWS represents heterogeneous spectrum of cystic posterior fossa (PF) malformations

IMAGING

General Features

- Best diagnostic clue
  - DWM: Large PF with small, counterclockwise (CCW) rotated vermis
  - HVR, BPC: Failure of "closure" of 4th ventricle
- Location
  - Posterior fossa
- Size
  - Variable
- Morphology
  - DWS (from most to least severe)
    - 4th ventriculocele (10-15% of cases)
      - DWM with large 4th ventricle erodes occipital bone → "encephalocele"
    - "Classic" DWM
      - Cystic dilatation of 4th ventricle → enlarged PF, superiorly rotated hypoplastic vermis
      - Torcular-lambdoid inversion: Cyst mechanically hinders normal fetal caudal migration of torcular
    - HVR (formerly DW variant)
      - Variable vermian hypoplasia, no or small cyst, normal sized PF/brainstem, "keyhole" vallecula
    - BPC
      - "Open" 4th ventricle communicates with infravermian cyst, normal fastigial recess, and primary fissure
    - MCM
      - Enlarged retrocerebellar cistern communicates with foramen magnum and basal subarachnoid spaces
      - Cistern crossed by falx cerebelli, tiny veins
      - Normal vermis/4th ventricle

Radiographic Findings

- Radiography
  - Enlarged calvaria, particularly posterior fossa
  - DWM: Lambdoid-torcular inversion (transverse sinus grooves elevated above lambda)
    - Sinuses are originally above lambda in fetus; cyst mechanically hinders descent

CT Findings

- NECT
  - DWM: Large posterior fossa
    - Variable-sized cyst communicates with 4th ventricle
    - Torcular-lambdoid inversion (torcular above lambdoid suture)
  - Occipital bone may appear scalloped, remodeled with all DWS types, including MCM

MR Findings

- T1WI
  - Sagittal DWM
    - Floor of 4th ventricle present
    - 4th ventricle opens dorsally to variable-sized CSF cyst
    - Cyst wall difficult to discern
    - Vermian remnant (± fastigium, fissures) rotated CCW, over cyst
    - ± remnant fused to tentorium
    - Elevated torcular with high/steeply sloping tentorium (classic)
  - Sagittal HVR
    - Smaller PF ± cyst
    - 4th ventricle "open" with partial CCW rotation vermis, presence of fastigium, fissures variable
  - Sagittal BPC
    - Rotated but normal-appearing vermis
    - Free communication of 4th ventricle with prominent inferior CSF space
    - Basal cisterns compressed posteriorly or effaced
  - Sagittal MCM
    - Normal vermis (not rotated/hypoplastic)
    - 4th ventricle is "closed"
- T2WI
  - Associated anomalies
    - Cortical dysplasia, heterotopias, myelination delays (syndromic DWS)
- FLAIR
  - ± very slight signal difference between cyst, CSF
  - ± compressed basal cisterns
- DWI
  - Very slight restriction may be seen if reduced fluid motion
- MRV
  - Elevated torcular herophili (DWM)

Ultrasonographic Findings

- Identical to MR; can diagnose in fetus

Nonvascular Interventions

- Cisternography delineates cyst wall

Imaging Recommendations

- Best imaging tool
  - MR best characterizes severity, associated anomalies
- Protocol advice
  - Routine MR imaging (thin sagittal views crucial)

DIFFERENTIAL DIAGNOSIS

Dandy-Walker Spectrum

- "In-between" cases common

Posterior Fossa Arachnoid Cyst (AC)

- Location: Retrocerebellar, supravermian, or in cerebellopontine angle
- Included in DW spectrum by some authors

https://CafePezeshki.IR

- Normal 4th ventricle compressed or displaced
- AC not traversed by falx cerebelli, tiny veins
- ACs lined by arachnoid cells/collagen

Molar Tooth Deformity (Joubert)

- Prototype = Joubert anomaly
- Episodic hyperpnea, oculomotor apraxia, retinal dystrophy, ± renal cysts, hepatic fibrosis
- Split vermis, bat wing 4th ventricle, mesencephalon is shaped like molar tooth

Isolated 4th Ventricle

- Inferior 4th ventricle "closed" vs. "open" in DWM/DWV on sagittal view

PATHOLOGY

General Features

- Etiology
  - Rhombencephalic roof divides into cephalic (anterior membranous area [AMA]) and caudal (posterior membranous area [PMA])
    - AMA invaded by neural cells → becomes cerebellum
    - PMA expands then disappears to form outlet foramina of 4th ventricle
  - Hindbrain development arrested
    - Defective AMA and PMA → DWM and HVR
    - Defective PMA only → BPC and MCM
- Genetics
  - Majority sporadic, x-linked DWM reported
    - Some have interstitial deletions of 3q2, which encompass *ZIC1* and *ZIC4* genes
  - Many, many syndromes with DWS
    - Chromosomal or midline anomalies; PHACES (facial hemangiomas, coarctation, DWS in 81%)
    - Neurocutaneous melanosis
- Associated abnormalities
  - 2/3 have associated CNS/extracranial anomalies
    - Craniofacial, cardiac/urinary tract anomalies, polydactyly, orthopedic ± respiratory problems
- Embryology
  - Common association DWM/HVR with facial, cardiovascular anomalies suggests onset between formation, migration of neural crest cells (3rd-4th postovulatory week)

Staging, Grading, & Classification

- Spectrum: DWM with 4th ventriculocele (most severe) → classic DWM → HVR → BPC → MCM (mildest)

Gross Pathologic & Surgical Features

- DWM: Large PF with big CSF-containing cyst
  - Inferior margin vermian remnant continuous with cyst wall
  - 4th ventricle choroid plexus absent or displaced into lateral recesses

Microscopic Features

- DWM: Outer cyst wall layer continuous with leptomeninges
  - Intermediate stretched neuroglial layer is continuous with vermis
  - Inner layer of glial tissue lined with ependyma/ependymal nests
  - ± anomalies of inferior olivary nuclei/corticospinal tract crossings

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - DWM: Macrocephaly, bulging fontanel, etc.
  - MCM: Incidental finding
- Clinical profile
  - Marked heterogeneity in genetic, clinical findings

Demographics

- Age
  - DWM: 80% diagnosed by 1 year
- Gender
  - M ≤ F
- Epidemiology
  - 1:25,000-100,000 births
  - Accounts for 1-4% of all hydrocephalus cases

Natural History & Prognosis

- Classic DWM: Very variable
- Cognitive outcome dependent upon associated syndromes or supratentorial anomalies/hydrocephalus and completeness of residual vermis
  - Intelligence normal in 35-50% of patients with classic DWM
    - Small remnant without fissures or fastigium
      - Seizures
      - Cognitive delay
      - Poor motor skills/balance
    - Large remnant, normal lobulation and fastigium, normal supratentorial brain
      - Better cognition
      - Better skills/balance

Treatment

- CSF diversion **if** hydrocephalus: VP shunt ± cyst shunt/marsupialization

DIAGNOSTIC CHECKLIST

Consider

- Many associated syndromes, mimics

Image Interpretation Pearls

- Presence of fastigium/vermian lobulation predicts cognitive outcome
- Thin sagittal views crucial for delineation, diagnosis

Reporting Tips

- Is fastigium/vermian lobulation normal?

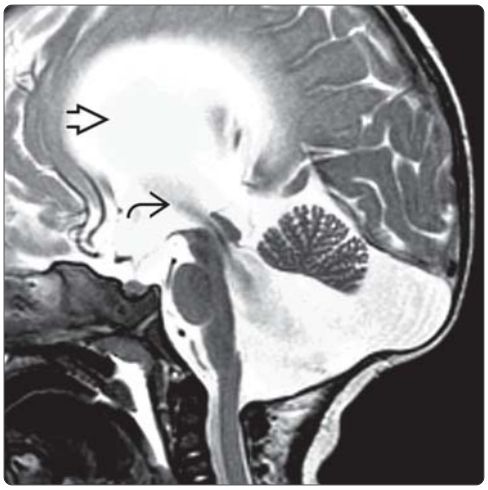
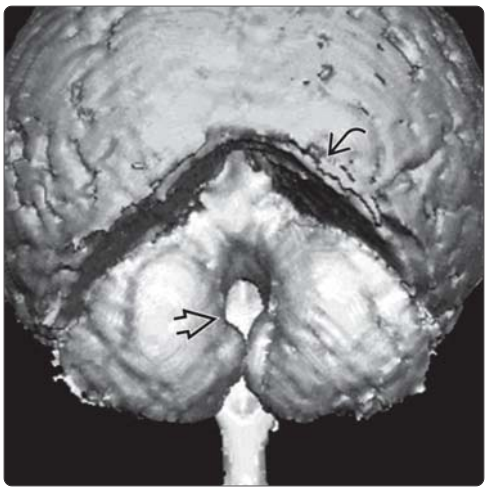
https://CafePezeshki.IR



(Left) *Sagittal T2WI MR in a patient with DWM demonstrates hydrocephalus, a large posterior fossa, cephalad rotation of a small, incompletely lobulated vermis with a very shallow fastigial crease ⇨, and a very thin cyst wall ⇨.* **(Right)** *Sagittal T2WI MR in HVR shows ventriculomegaly ⇨, patent aqueduct with prominent flow void ⇨, and a large posterior fossa. There is no torcular-lambdoid inversion.*

(Left) *Sagittal bSSFP demonstrates ventriculomegaly ⇨ in a patient with open inferior 4th ventricle. There is cyst wall visualization inferiorly ⇨. The posteriorly displaced choroid plexus ⇨ suggests Blake pouch cyst. Fastigial recess, primary fissure, and vermian lobulation are intact.* **(Right)** *Sagittal bSSFP shows a closed inferior 4th ventricle with acquired Chiari 1 ⇨. The primary fissure ⇨ and the vermis are compressed by the wall of the retrocerebellar cyst.*



(Left) *Axial T2WI MR in a patient with DWM reveals relative hypoplasia of the cerebellar hemispheres and nonvisualization of the vermis at its usual location. There is a focal calvarial ⇨ defect at the site of a prior occipital encephalocele.* **(Right)** *Coronal 3D surface reconstruction of the brain (viewed from the inferoposterior aspect) from T1 gradient-echo sequence shows the typical elevation of the tentorium ⇨ and separation of the cerebellar hemispheres ⇨ without intervening vermis.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Rhombencephalosynapsis (RES): Congenital continuity (lack of division) of cerebellar hemispheres
  - Complete or partial absence of vermis
  - Varying degrees of midline fusion of cerebellar hemispheres, dentate nuclei
  - May be partial; any portions of hemispheres may be affected

IMAGING

- Small, single hemisphere cerebellum
  - Continuous white matter (WM) tracts crossing midline
  - Absent primary fissure
  - Fused dentate nuclei
  - Small diamond- or keyhole-shaped 4th ventricle
  - ± aqueductal stenosis → hydrocephalus
  - ± corpus callosum dysgenesis (especially posterior)

TOP DIFFERENTIAL DIAGNOSES

- Molar tooth malformations
- Lhermitte-Duclos syndrome
- Vermian hypoplasia
- Diffuse cerebellar cortical dysplasia

PATHOLOGY

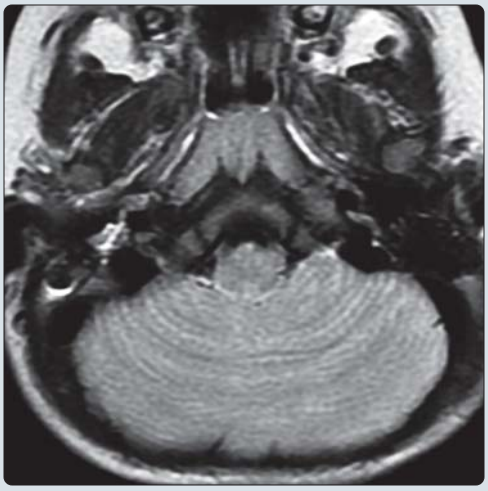
- Failure of vermian differentiation
  - Differentiation of vermis required to separate cerebellar hemispheres

DIAGNOSTIC CHECKLIST

- Remember to define associated supratentorial anomalies
- Can be mimicked by mechanically induced cerebellar deformation in chronically shunted patients

(Left) *Coronal graphic of rhombencephalosynapsis shows that no vermis is present in the midline of the cerebellum. Instead, the folia, interfoliate sulci, and cerebellar white matter* ⇨ *are continuous across the cerebellar midline.* **(Right)** *Sagittal T1WI in this child with rhombencephalosynapsis shows absence of the normal vermian lobules and fissures. The cerebellum appears abnormally rounded.*

(Left) *Axial T2WI in the same patient shows continuity of the cerebellar folia of both hemispheres across the midline.* **(Right)** *Coronal T2WI shows the absence of a vermis, with continuity of the cerebellar WM and cortex across the midline* ⇨.



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Rhombencephalosynapsis (RES)

Definitions

- Congenital continuity (lack of division) of cerebellar hemispheres
  - Complete or partial absence of vermis
  - Varying degrees of midline fusion of cerebellar hemispheres, dentate nuclei
    - Hemispheres usually continuous across midline
    - May be partial, affect any part(s) of hemispheres
  - Best classified as abnormal induction of dorsal cerebellar midline

IMAGING

General Features

- Best diagnostic clue
  - Single (often small) hemisphere cerebellum with continuous white matter (WM) tracts crossing midline
    - Small diamond- or keyhole-shaped 4th ventricle
    - Fused dentate nuclei
- Location
  - Midline posterior fossa
- Size
  - Posterior fossa typically smaller than usual
- Morphology
  - Round or oval solitary cerebellar hemisphere

CT Findings

- NECT
  - Cerebellar hemispheric fusion
  - Diamond- or keyhole-shaped 4th ventricle
  - Narrowed transverse diameter of cerebellum
  - Often hydrocephalus with absent septum

MR Findings

- T1WI
  - Sagittal
    - Absent primary fissure
    - ± upwardly rounded fastigial recess of 4th ventricle
      - Nodulus preserved if fastigial recess present
    - ± aqueductal stenosis → hydrocephalus
    - ± corpus callosum dysgenesis (especially posterior)
  - Axial
    - ± collicular fusion
    - ± supratentorial cortical dysplasias
- T2WI
  - Coronal
    - Fused cerebellar hemispheres → total or partial
      - Continuous WM tracts across midline
      - Midline superior "tenting" of WM
    - Absent or severely hypoplastic vermis
    - Transverse folia
    - ± absent septum pellucidum
    - ± fused thalami and fornices
  - Fetal
    - Can be identified on fetal MR
      - Typically performed to investigate hydrocephalus seen on US
    - Abnormal shape of 4th ventricle and absence of vermis most reliable signs

Ultrasonographic Findings

- Grayscale ultrasound
  - Occasionally identified on fetal sonography

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - High-resolution FSE T2WI in multiple imaging planes
    - T2WI more clearly defines posterior fossa structures in neonate and infant

DIFFERENTIAL DIAGNOSIS

Molar Tooth Malformations

- Joubert syndrome
  - Vermian dysplasia with prominent superior cerebellar peduncles
  - 4th ventricle has bat wing shape

Lhermitte-Duclos Disease

- Dysplastic cerebellar gangliocytoma
- Striated cerebellar hemisphere
- Associated with Cowden syndrome

Vermian Hypoplasia

- Small vermis without hemispheric fusion
- Vermis develops enough to separate hemispheres, then arrests

Single Hemisphere Cerebellar Hypoplasia

- Often secondary to in utero insult

Diffuse Cerebellar Cortical Dysplasia

- May be associated with congenital muscular dystrophies
- Type 2 lissencephaly

PATHOLOGY

General Features

- Etiology
  - Unknown; 2 major theories
    - Failure of vermian differentiation
      - Based on evidence that hemispheres develop as unpaired structure from cerebellar primordium
      - Differentiation of vermis required to separate cerebellar hemispheres
      - Better explains cases of partial rhombencephalosynapsis
    - Vermian agenesis allowing hemisphere continuity
      - Based on theory that hemispheres form separately from rhombic lips
      - Absence of vermian development allows hemispheres to become apposed and then fuse in midline
- Genetics
  - *FGF8* and *LMX1A* genes may influence expression of isthmic organizer

https://CafePezeshki.IR

- Isthmic organizer
  - Controls/influences patterning of midbrain and anterior hindbrain
  - Located within neuroepithelium of isthmic constriction at midbrain-hindbrain boundary
- No genetic mutations have been found in rhombencephalosynapsis
- Associated abnormalities
  - Frequently occurs with other midline anomalies
    - Absent septum pellucidum, holoprosencephalies
    - Callosal and anterior commissure dysgenesis
    - Thalamic fusion with 3rd ventricle atresia (diencephalosynapsis)
    - Collicular fusion ± aqueductal stenosis/atresia, hydrocephalus
  - Prosencephalic and midline facial anomalies
  - Occasional associated extracranial anomalies
    - Segmentation and fusion anomalies in spine
    - Cardiovascular (conotruncal) anomalies reported
    - Variable respiratory, GU anomalies reported
    - Musculoskeletal anomalies common: Phalangeal and radial ray

Staging, Grading, & Classification

- Partial fusion
  - Fusion may be in any part of cerebellum
- Presence or absence of supratentorial anomalies

Gross Pathologic & Surgical Features

- Typical
  - Fused cerebellar hemispheres
  - Fused cerebellar white matter → large corpus medullare
  - Absent posterior cerebellar incisura, vallecula
  - Horseshoe-shaped dentate nuclei
  - Agenesis or hypogenesis of anterior vermis, velum medullare anterior, and nuclei fastigii
  - Hypoplastic posterior vermis
    - Nodulus may form
- Rare
  - Aventriculy (also called synencephalyor telencephalosynapsis)
  - Encysted 4th ventricle

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Variable neurological signs
    - Ataxia, gait abnormalities, seizures
    - Developmental delay
    - RES discovered in near-normal patients at autopsy
  - Most common associated congenital syndrome = Gomez-Lopez-Hernandez syndrome
    - Cerebello-trigeminal-dermal dysplasia
      - RES with scalp alopecia, abnormal head shape
      - Trigeminal anesthesia
      - Craniofacial dysmorphisms, short stature common

Demographics

- Age
  - Usually found during early infancy or childhood
  - Rarely an incidental finding
- Epidemiology
  - Rare but increasingly recognized on MR

Natural History & Prognosis

- Developmental delay
- Psychiatric disorders (self injurious, bipolar, hyperactive)
- Additional midline supratentorial anomalies and hydrocephalus → worse prognosis

Treatment

- Treat related hydrocephalus, monitor hypothalamic-pituitary axis

DIAGNOSTIC CHECKLIST

Consider

- Rhombencephalosynapsis in severe congenital hydrocephalus
- Isolated rhombencephalosynapsis is less common than with supratentorial anomalies

Image Interpretation Pearls

- Can be mimicked by mechanically induced cerebellar deformation in chronically shunted patients

Reporting Tips

- Remember to define associated supratentorial anomalies

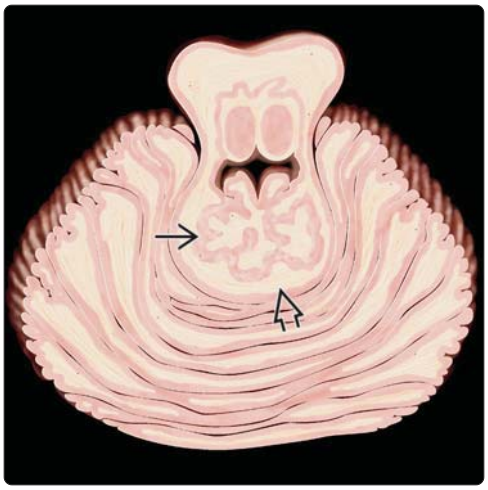
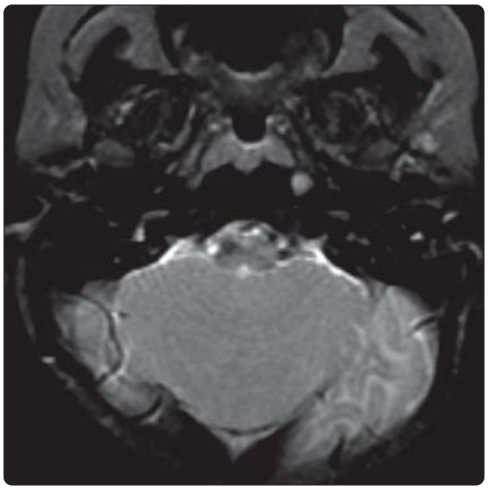
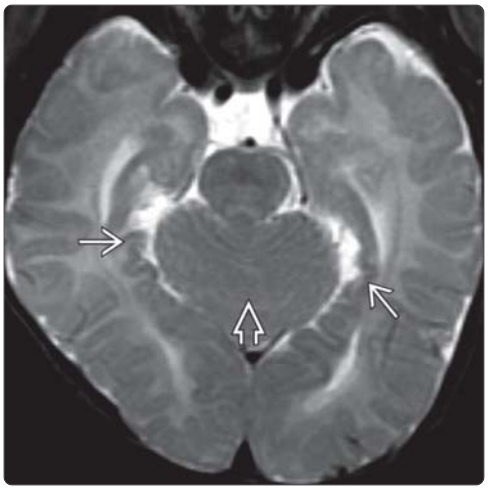
https://CafePezeshki.IR



(Left) *Axial graphic of rhombencephalosynapsis shows the absence of vermis. There is fusion of folia, interfoliate sulci, dentate nuclei ⇨, and cerebellar white matter ⇨ across the midline.* **(Right)** *Axial NECT in a child with rhombencephalosynapsis shows the cerebellum appears continuous across the midline, without a discernible vermis.*





(Left) *Axial T2WI in a case of classic rhombencephalosynapsis shows the vermis is absent and the cerebellar hemispheres appear fused across the midline.* **(Right)** *More cephalad axial T2WI in the same patient shows the cerebellum appears fused across the midline ⇨. Note the abnormal gray matter in the adjacent medial temporal lobes ⇨.*

(Left) *Midline sagittal T2WI in an 11-year-old male with mild mental retardation appears almost normal.* **(Right)** *Coronal T2WI in the same case shows the cerebellar white matter ⇨ is fused across the midline.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Focal or diffuse dysplasias of cerebellar hemispheres or vermis not associated with other known malformations or syndromes

IMAGING

- Asymmetry or focal disruption of cerebellar folial and sulcal morphology
  - Sometimes frank cleft is present
- Bumpy gray-white matter interface in cerebellum
- Lack of normal arborization of white matter
- Abnormal hyperintense signal in subcortical white matter → cyst-like foci
- Cerebellar gray matter heterotopia
- Enlarged and vertically oriented fissures
- Disordered foliation

PATHOLOGY

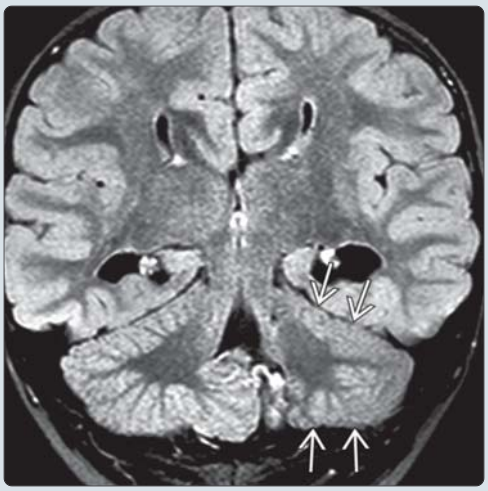
- Cerebellar cortex does not assume adult-like histology prior to age 1
- In 1 study of 147 normal infants, minor cerebellar dysplasias were identified in close to 85%
  - Some minor dysplasias involute after 9 months of age

CLINICAL ISSUES

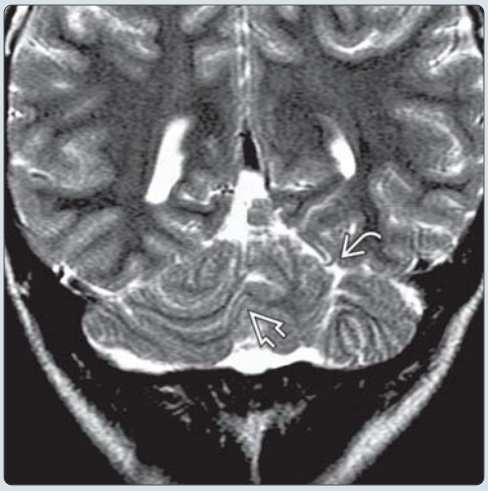
- Hypotonia, microcephaly, speech delay

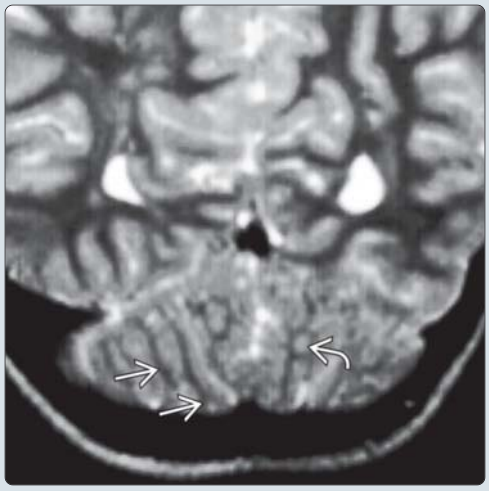
DIAGNOSTIC CHECKLIST

- Assess for "cobblestone" lissencephaly and congenital muscular dystrophy when considering diagnosis of isolated cerebellar dysplasia
- Look for and document associated posterior fossa and supratentorial lesions
- Small cerebellar hemisphere in fetus may reflect dysplasia



(Left) *Coronal FLAIR MR in a 5 year old with developmental delay and right hemiparesis shows agenesis of the corpus callosum with focal dysplasia of the left cerebellar hemisphere. Note the abnormal foliation in the small affected hemisphere compared to the normal right side.* **(Right)** *Axial T2WI MR in the same patient shows the distorted and disorganized pattern of white matter in the dysplastic left hemisphere in comparison with the normal right cerebellum (folia should be parallel to calvaria in axial plane).*





(Left) *Coronal T2WI MR in a child with vermian hypoplasia shows disordered foliation in the right hemisphere and a prominent vertical fissure on the left. These disorders are thought to most likely be disruptions due to prenatal injury.* **(Right)** *Coronal T2WI MR in a 4-year-old boy with global developmental delay shows a very abnormal cerebellum with vertically oriented folia and fissures along with nodular areas of gray matter, likely cerebellar heterotopia.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Diffuse cerebellar dysplasia
- Cerebellar cortical dysplasia

Definitions

- Focal or diffuse dysplasias of cerebellar hemispheres or vermis not associated with other known malformations or syndromes
  - Excludes Dandy-Walker spectrum, Lhermitte-Duclos disease, rhombencephalosynapsis, molar tooth malformations, congenital muscular dystrophies, syndromic (e.g., PHACES)
  - Excludes infectious (e.g., cytomegalovirus), metabolic etiologies (including inherited, e.g., congenital disorders of glycosylation-1a)

IMAGING

General Features

- Best diagnostic clue
  - Asymmetry or focal disruption of cerebellar folia and sulcal morphology
- Location
  - Variable
    - Can involve both hemispheres and vermis or mainly vermis
    - Can be uni- or bilateral
- Size
  - Variable
- Morphology
  - Variable

CT Findings

- Irregular morphology of 4th ventricle or cisterna magna

MR Findings

- T1WI
  - Bumpy gray-white matter interface in cerebellum
  - Lack of normal arborization of white matter
- T2WI
  - Cyst-like foci in subcortical white matter
  - Gray matter heterotopias, disordered foliation
  - Enlarged and vertically oriented fissures

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Use thin-slice profile T2WI in axial and coronal planes to define cerebellar morphology

DIFFERENTIAL DIAGNOSIS

Rhombencephalosynapsis

- Fused cerebellar hemispheres with vermian hypo-/aplasia

Molar Tooth Malformations (Joubert)

- Bat wing 4th ventricle

Cerebellar Dysplasia Associated With Lissencephalies

- Congenital muscular dystrophies

PATHOLOGY

General Features

- Cerebellar cortex does not assume adult-like histology prior to age 1
- In 1 study of 147 normal infants, minor cerebellar dysplasias were identified in close to 85%
  - Some minor dysplasias involute after 9 months of age

Gross Pathologic & Surgical Features

- Dysmorphic foliation, hemispheres often small
- Primitive foliation
- Mega cisternal magna

Microscopic Features

- Fusing of apposed molecular layers
- Small cavities with meningeal vessels
- Nodules of Purkinje cells
- Deficient/absent granular layer

Associated Findings

- Cerebral cortical dysplasia
- Agenesis/dysgenesis of corpus callosum
- Macro-/microscopic heterotopia
  - Most often posterior (occipital/temporal horns)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Hypotonia, microcephaly, speech delay
- Other signs/symptoms
  - Ataxia, facial malformations, abnormal eye movements, motor delay

DIAGNOSTIC CHECKLIST

Consider

- Assess for "cobblestone" lissencephaly and congenital muscular dystrophy when considering diagnosis of isolated cerebellar dysplasia

Reporting Tips

- Look for and document-associated posterior fossa and supratentorial lesions

KEY FACTS

TERMINOLOGY

- Joubert syndrome and related disorders (JSRD)
  - Hindbrain anomaly characterized by dysmorphic vermis, lack of decussation of superior cerebellar peduncle, central pontine tracts, corticospinal tracts
  - JSRD considered as a ciliopathy
- Also sometimes called molar tooth malformation (MTM)

IMAGING

- Molar tooth appearance of midbrain on axial images
- Midline vermian clefting
- Thick, horizontal (perpendicular to brainstem), superior cerebellar peduncles
- Midline depression of 4th ventricular floor at isthmus (thin isthmus on midline)
- High-definition T2 (CISS/FIESTA) provides exquisite structural analysis
- HASTE allows clear identification of molar tooth sign in fetuses
- DTI is useful complementary technique

TOP DIFFERENTIAL DIAGNOSES

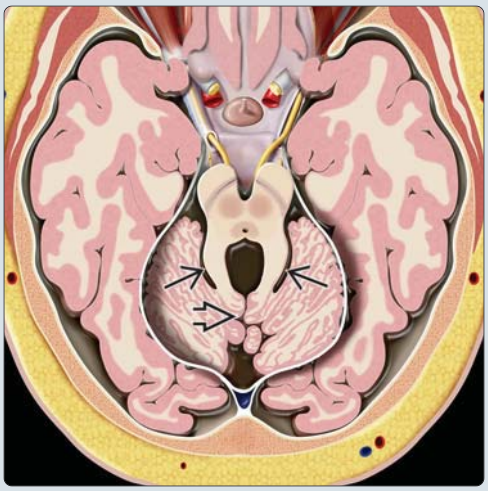
- Dandy-Walker continuum
- Vermian and pontocerebellar hypoplasia
- Cerebellar vermian hypoplasia
- Cerebellar vermian atrophy

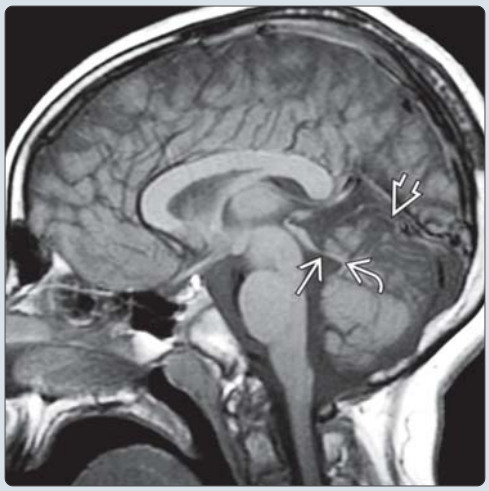
PATHOLOGY

- > 20 causative genes have been discovered so far
  - All encode for proteins expressed in primary cilium/its apparatus
- Absence of decussation of superior cerebellar peduncles
- Near total absence of pyramidal decussation

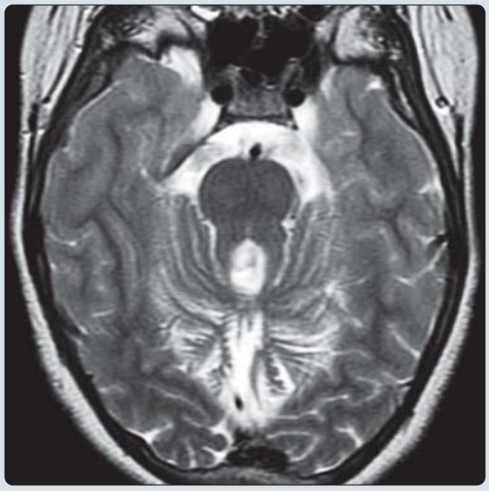
CLINICAL ISSUES

- Ataxia, developmental delay, oculomotor and respiratory abnormalities





(Left) *Axial graphic depicts Joubert malformation. Thickened superior cerebellar peduncles around the elongated 4th ventricle form the classic molar tooth seen in this anomaly. Note the cleft cerebellar vermis.* **(Right)** *Sagittal T1WI in a patient with classic Joubert syndrome shows a small, grossly malformed cerebellar vermis with upwardly convex superior 4th ventricle and a rounded fastigial point.*



(Left) *Axial T1 MP-RAGE image in the same patient shows a classic molar tooth sign with a foreshortened midbrain and a narrow isthmus. Thick, elongated superior cerebellar peduncles surround an elongated 4th ventricle. Note the vermis clefting.* **(Right)** *Axial T2WI in the same case shows the molar tooth sign even more clearly.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Molar tooth malformation (MTM)
- Joubert syndrome and related disorders (JSRD)
  - Include Joubert, Dekaban-Arima, COACH, Senior-Loken, Varadi-Papp, Joubert-polymicrogyria syndromes
  - New genes/syndromes with MTM continue to be described
  - JSRD considered as ciliopathy

Definitions

- Hindbrain anomaly characterized by dysmorphic vermis, thick horizontal superior cerebellar peduncles (SCPs)
  - Sagittal clefting of cerebellar vermis
  - Abnormal brainstem nuclei
  - SCPs, central pontine tracts, corticospinal tracts do not decussate

IMAGING

General Features

- Best diagnostic clue
  - Molar tooth appearance of midbrain on axial images
  - Small vermis with midline clefting
- Location
  - Brainstem isthmus (pontomesencephalic)
  - Vermis and superior (efferent) cerebellar peduncle
- Morphology
  - Hard to identify vermis with midline sagittal cleft
    - Dorsal 4th ventricle has dysmorphic, irregular fastigium
  - Thick, horizontal (perpendicular to brainstem), superior cerebellar peduncles
  - Midline depression of 4th ventricular floor at isthmus (thin isthmus on midline)

CT Findings

- NECT
  - Vermis clefting
  - 4th ventricle has bat wing configuration

MR Findings

- T1WI
  - Sagittal
    - Normal midline appearance of vermis lost
    - Dysmorphic roof of 4th ventricle with fastigial point lost
    - Large CSF spaces, but tentorium in normal location
  - Coronal
    - Vermian clefting above apposed hemispheres (cleft lined with cortex)
  - Axial: Vermian clefting, molar tooth appearance
    - Anteriorly pointed ventricular floor at pons-midbrain junction (thin isthmus)
    - Prominent, in-plane, parallel superior cerebellar peduncles (molar roots)
- T2WI
  - Same findings as T1WI
    - Better contrast than T1WI
    - Prominent CSF spaces common
    - Abnormal myelination sometimes
  - High-definition T2 (CISS/FIESTA) provides exquisite structural analysis
  - HASTE allows clear identification of molar tooth sign in fetuses
- Diffusion tensor imaging (DTI)
  - Superior cerebellar peduncles fail to decussate in mesencephalon
  - ± thinning of middle cerebral peduncle, ventral pontocerebellar tracts

Ultrasonographic Findings

- Prenatal ultrasound shows small vermis, large cisterna magna
  - May show supernumerary digits, heart disease, kidney disease, etc.

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Use high definition; posterior fossa structures are small
  - DTI is useful complementary technique

DIFFERENTIAL DIAGNOSIS

Dandy-Walker Continuum

- Hypo/agenetic vermis (not clefting)
- Cerebellar hemispheres often small
- Elevated tentorium

Vermian and Pontocerebellar Hypoplasia

- Vermis is small, no clefting
- Variable abnormalities of pons, medulla, midbrain

Rhombencephalosynapsis

- Cerebellar hemispheres/dentates are fused without differentiated midline vermis

Cerebellar Vermian Atrophy

- Midbrain, cerebellar peduncles normal; normal vermian foliation with enlarged fissures
- Causal context (prematurity, metabolic, etc.)

PATHOLOGY

General Features

- Etiology
  - Thought to result from mutations of ciliary/centrosomal proteins that can affect cell migration, axonal pathway, other still unknown mechanisms
    - Referred to as ciliopathy
    - Seen in many syndromes (Meckel-Gruber, orofacial-digital syndrome type VI (OFD VI), Bardet-Biedl, Senior-Loken, others)
- Genetics
  - Predominately autosomal recessive
  - > 20 causative genes discovered so far
    - All encoding proteins expressed in primary cilia and its apparatus
    - Associated CNS findings include ocular anomalies, polymicrogyria, cephaloceles, hamartomas
    - Mutations in CSPP1 → classical Joubert syndrome

https://CafePezeshki.IR

- Malformation complexes probably result from disruption of several of the many different processes involving cilia
- Associated abnormalities
  - Polymicrogyria; renal, retinal, hepatic abnormalities
    - Prominent CSF spaces and ventriculomegaly
    - Rarely: Meningoencephaloceles, microcephaly, lissencephaly, agenesis of corpus callosum
    - Hypothalamic hamartomas
  - Juvenile nephronophthisis or multicystic dysplastic kidney
  - Ocular anomalies (retinal dysplasias and colobomata)
  - Hepatic fibrosis and cysts, heart disease, polydactyly

Gross Pathologic & Surgical Features

- Midbrain-hindbrain malformation characterized by
  - Dysmorphic vermis with midline cleft
  - Thick horizontal SCPs
  - Ocular colobomas, polymicrogyria can be found

Microscopic Features

- Absence of decussation of superior cerebellar peduncles
- Near total absence of pyramidal decussation
- Dysplasias and heterotopia of cerebellar nuclei
- Structural anomalies in multiple locations
  - Inferior olivary nuclei, descending trigeminal tract, solitary fascicle, dorsal column nuclei

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Core features: Hypotonia, ataxia, intellectual disability
  - Other: Variable involvement of retina, kidneys, liver
- Other signs/symptoms
  - Neonate: Nystagmus, alternating apnea, hyperpnea (Joubert syndrome), seizures
  - Characteristic facial features
    - Large head
    - Prominent forehead
    - High, rounded eyebrows
    - Epicanthal folds
    - Upturned nose with evident nostrils
    - Tongue protrusion and rhythmic tongue motions
    - In OFD VI, teratomas of tongue
  - Retinal anomalies
    - Congenital retinal dystrophy
    - Pigmentary retinopathy
    - Chorioretinal colobomata
    - Fundus flavus

Demographics

- Age
  - Infancy and childhood; isolated oculomotor apraxia may present later
- Gender
  - M = F

Natural History & Prognosis

- Early death in affected infants
- Older children → problems with temperament, hyperactivity, aggressiveness, and dependency
  - Most affected children are severely impaired

Treatment

- Genetic counseling, physical therapy, occupational therapy

DIAGNOSTIC CHECKLIST

Consider

- MTM whenever scanning infants/children with severe hypotonia and ocular anomalies

Image Interpretation Pearls

- If vermis not recognized or looks small and dysmorphic on sagittal image
- Sometimes vermis looks nearly normal
  - Look for vermian cleft and molar tooth sign on axials

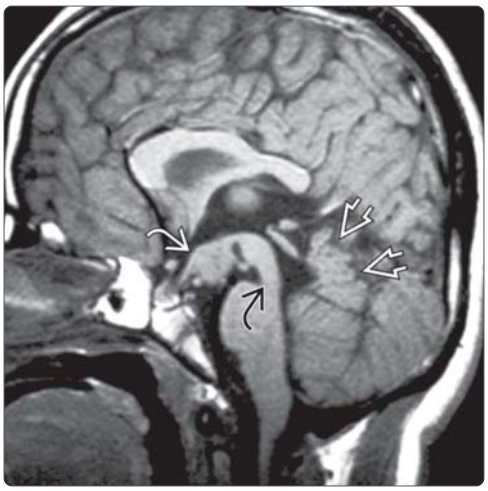
(Left) *Sagittal T2WI MR (HASTE) of a 27-week fetus shows a dysmorphic 4th ventricle ➡ with a hardly recognizable vermis ➡ (abnormal shape, no normal fissures identified). The posterior fossa cisterns are markedly enlarged. Supratentorial structures are normal.* **(Right)** *Axial T2WI MR (HASTE) in the same patient demonstrates an anteriorly pointed 4th ventricle ➡ and thick superior cerebellar peduncles ➡, giving an appearance like a molar tooth.*

(Left) *Sagittal T1WI MR shows classic molar tooth malformation (MTM). Midbrain is elongated and narrow at isthmus ➡. Vermis ➡ is small and dysplastic (abnormal foliation). Fourth ventricle is high, at pons-midbrain junction.* **(Right)** *Axial T1WI MR shows molar tooth sign. Midbrain is narrow in midline due to absent decussation of superior cerebellar peduncles (SCPs). SCPs ➡ are large and horizontal, forming the "roots" of the molar tooth.*



(Left) *Sagittal T1WI MR shows typical features of Joubert with narrow midbrain isthmus ➡, small dysplastic vermis ➡, and a hypothalamic hamartoma ➡ that is characteristic of the Varadi-Papp syndrome.* **(Right)** *Sagittal T1WI MR shows subtle MTM with slightly high 4th ventricle and small vermis. The cerebellar hemisphere ➡ is seen to come into the midline below the abnormal vermis.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

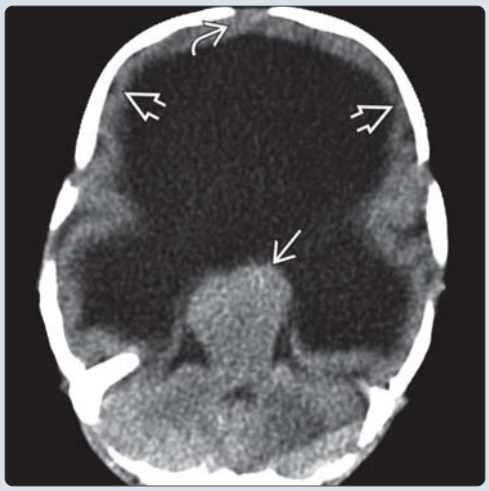
- Incomplete separation of cerebral hemispheres

IMAGING

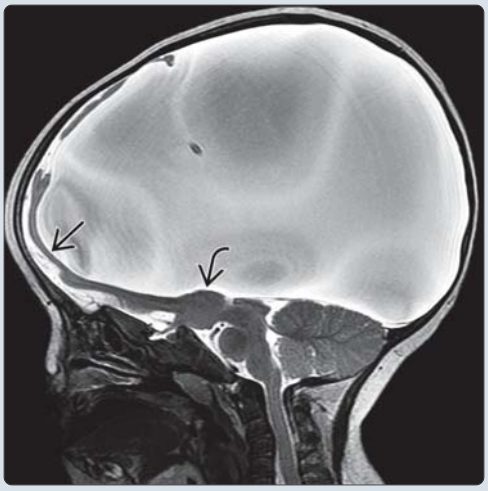
- Anomaly and severity defined by degree of forebrain cleavage
  - Spectrum; no clear division between types
- Alobar holoprosencephaly (HPE)
  - Single "ball," "cup," or "pancake" brain around primitive monoventricle
  - ± dorsal cyst, dysmorphic facies
- Semilobar HPE
  - Frontal lobes > 50% fused
  - Thalami, hypothalamus "fused"
  - Posterior interhemispheric fissure, falx may be present
  - ± dorsal cyst, mild/absent facial malformations
- Lobar HPE
  - Interhemispheric fissure present along most of midline
  - Only most inferior frontal lobes fused
  - Thalami almost/completely separated
  - Septum pellucidum always absent
  - Rudimentary frontal horns, ± 3rd ventricle, corpus callosum normal or incomplete

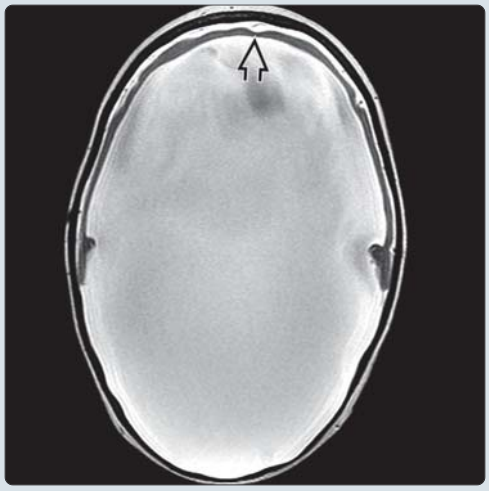
TOP DIFFERENTIAL DIAGNOSES

- Maximal obstructive hydrocephalus
  - Some cortex, falx present; basal ganglia separated
- Hydranencephaly
  - Minimal/no cortex, basal ganglia separated, falx present
- Syntelencephaly or middle interhemispheric variant (MIH) of HPE
  - Anterior, posterior hemispheres separated by falx
  - Midsections fused across midline
- Septooptic dysplasia
  - Frontal horns well formed; fornices fused but present
- Schizencephaly
  - Hemispheric clefts lined with heterotopic gray matter, fornices present



(Left) *3D reconstruction of the facial bones in a newborn infant with a cleft lip and palate shows severe hypotelorism ⇨ and a moderately large midline defect of the maxilla extending into the hard palate and nasal septum ⇨. The 2 central incisors are absent.* **(Right)** *Axial NECT scan in the same patient shows a horseshoe-shaped central monoventricle with a thin rim of surrounding cortex ⇨ that is fused across the midline ⇨. The basal ganglia ⇨ are also fused, characteristic of alobar holoprosencephaly.*





(Left) *Sagittal T2WI in the same patient at 17 months shows the posterior fossa and brainstem appear relatively normal. The supratentorial compartment is almost completely filled with the CSF-containing monoventricle. The hypothalamus and basal ganglia ⇨ are fused and there is a thin rim of agyric cortex ⇨ around the anterior aspect of the monoventricle.* **(Right)** *T2WI in the same patient shows the thin cortex is fused across the midline anteriorly ⇨. No interhemispheric fissure was present and the falx is absent.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Holoprosencephaly (HPE)

Synonyms

- Formerly called arrhinencephaly

Definitions

- Incomplete separation of cerebral hemispheres

IMAGING

General Features

- Best diagnostic clue
  - Single ventricle
  - Absent or partial hemispheric and basal cleavage with absent/incomplete interhemispheric fissure/falx
  - Azygous anterior cerebral artery (ACA)
  - ± associated facial defects
- Location
  - Forebrain ± midface
- Morphology
  - Anomaly and severity defined by degree of forebrain cleavage
    - Spectrum; no clear division between types
  - Alobar HPE
    - Single "ball," "cup," or "pancake" brain around primitive monoventricle
      - ± dorsal cyst, dysmorphic facies
  - Semilobar HPE
    - Frontal lobes > 50% fused
    - Posterior interhemispheric fissure, falx may be present
    - Thalami, hypothalamus "fused"
    - ± dorsal cyst, mild/absent facial malformations
  - Lobar HPE
    - Interhemispheric fissure present along most of midline
    - Only most inferior frontal lobes fused
    - Thalami almost/completely separated
    - Septum pellucidum always absent
    - Rudimentary frontal horns, ± 3rd ventricle, corpus callosum normal or incomplete

CT Findings

- NECT
  - Single ventricle without septum pellucidum
  - Uncleaved basal nuclei
  - Variable extent of posterior interhemispheric fissure
  - Variable degree of aplasia of midface, nasal cavity, and paranasal sinuses (all derived from neural crest)

MR Findings

- T1WI
  - Evaluates severity: Alobar, semilobar, or lobar HPE
    - Degree of differentiation of single ventricular cavity, presence of dorsal cyst
      - 3rd ventricle identified when thalami are separated
    - Hemispheric cleavage (extent of interhemispheric fissure [IHF], falx) defines anatomic severity
      - Alobar: No fissure
      - Semilobar: Divided temporal lobes around midbrain
      - Lobar: Fissure extends anteriorly to frontal lobes, posterior callosum present
      - All intermediate degrees can be encountered
    - Gyration variably developed, from agyria to well convoluted
    - Variable extent of basal cleavage: Thalami, striatum, hypothalamus
  - Sylvian angle (SA) reflects frontal development, hence severity of HPE as well
    - Superiorly tilted sylvian fissures (↑ SA) = less developed frontal lobes, more severe HPE
- T2WI
  - Same as T1WI
  - In addition, evaluates myelin maturation, optic nerves/globes, olfactory nerves, pituitary
- DWI
  - DTI helps in identifying white matter (WM) tracts
- MRA
  - ACA
    - May present with early fan-like array of branching arteries over surface of single frontal lobe
- MRV
  - Absent venous sinuses correlate falx/tentorium malformations

Ultrasonographic Findings

- Grayscale ultrasound
  - HPE diagnosable on fetal ultrasound and MR

Angiographic Findings

- Azygous ACA

Imaging Recommendations

- Best imaging tool
  - MR (3-planar, high definition), special attention to midline

DIFFERENTIAL DIAGNOSIS

Severe Obstructive Hydrocephalus

- Severe obstructive hydrocephalus may have massively enlarged ventricles, thin rim of cortex
- Falx present; basal ganglia separated

Hydranencephaly

- Water bag brain appearance; little or no cortex; falx present

Syntelencephaly or Middle Interhemispheric Variant (MIH) of HPE

- Single ventricular cavity: No septum pellucidum, no fornix, no 3rd ventricular roof
- Azygous ACA
- Noncleavage of anterior-inferior basal ganglia (BG)
- Interhemispheric cortical continuity usually in posterior frontal-parietal area
- Anterior &/or posterior corpus callosum found

Absent Septum Pellucidum

- False single ventricular cavity and paired ACA
- Septooptic dysplasia (fornices fused but present)
- Schizencephaly (hemispheric clefts, fornices present)

https://CafePezeshki.IR

Torn Septum Pellucidum

- Severe, usually congenital hydrocephalus
- Typically macrocephalic (HPE usually microcephalic), fornices present

PATHOLOGY

General Features

- Etiology
  - Primary defect of ventral induction, patterning
    - Results in total or partial failure of separation of prosencephalon into 2 separate hemispheres
  - Multifactorial; at least 13 HPE-associated genes but no strict genotype-phenotype correlation
    - Chromosomal abnormality (classically trisomy 13) in 25-50%
      - *SHH* gene 1 of the most important in ventralizing signals during forebrain development
      - *SHH* also controls neural crest (midface), oligodendrocytic (myelination) development
    - Other: Environmental/maternal factors: Diabetes (1% HPE in diabetic mothers), alcohol, retinoid acid, plant alkaloids (*Veratrum californicum*)
- Associated abnormalities
  - HPE mostly sporadic, sometimes familial, 25% syndromic
  - 80% of facial anomalies; correlate with severity of HPE
    - Cyclopia, proboscis; single nare; single nasal bone/absent internasal suture
    - Midline cleft lip or palate; premaxillary agenesis
    - Single maxillary central incisor; absent superior lingual frenulum

Staging, Grading, & Classification

- Class 1 HPE spectrum: All ranges of decreasing severity may be found in same pedigree
  - Includes alobar, semilobar, lobar
  - Midfacial abnormalities without overt brain malformation
    - Flat face, maxillary hypoplasia, midline cleft lip/palate, hypotelorism
  - Isolated single maxillary central incisor (SMCI)
    - Often associated with, but not always an indicator of, HPE
- Class 2 syntelencephaly, or MIH variant of HPE
  - Posterior frontal-parietal cortical continuity across midline; both callosal genu and splenium often present

Gross Pathologic & Surgical Features

- Variable hypoplasia of cortex, variable gyral development
- Variable degree of separation of diencephalon and BG with incorporation into upper brainstem
- Dorsal cyst represents posteriorly located tela choroidea of single ventricle

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Facial malformation with hypotelorism
  - Seizures (50%) and developmental delays
  - Hypothalamic/pituitary malfunction (75%, mostly diabetes insipidus), poor body temperature regulation
  - Dystonia and hypotonia: Severity correlates with degree of BG nonseparation
- Clinical profile
  - Mentally retarded microcephalic infant with hypotelorism

Demographics

- Age
  - Presentation in infancy or early childhood
    - Can be diagnosed with fetal US or MR
- Gender
  - M:F = 1.4:1
- Epidemiology
  - Most common malformation of brain and face in humans
  - 1.3/10,000 live births, but 1 in 250 conceptuses

Natural History & Prognosis

- Over represented in fetal demise, stillbirths
- Clinical severity and life expectancy relate to degree of hemispheric and deep gray nuclei nonseparation (alobar HPE = worst)

Treatment

- Treat seizures and endocrine dysfunction

DIAGNOSTIC CHECKLIST

Consider

- Whenever HPE in doubt, look at basal forebrain for cleavage failure

Image Interpretation Pearls

- Not all cases of missing septum pellucidum are single ventricles

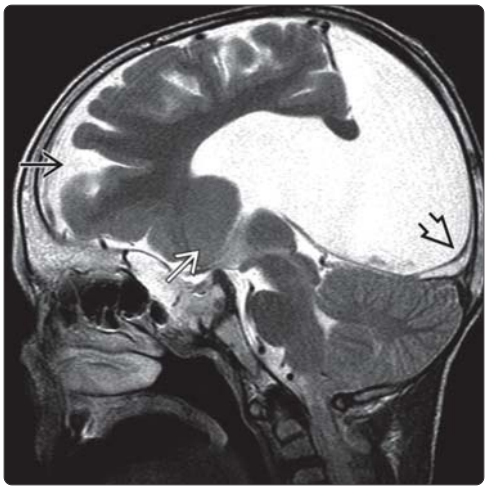
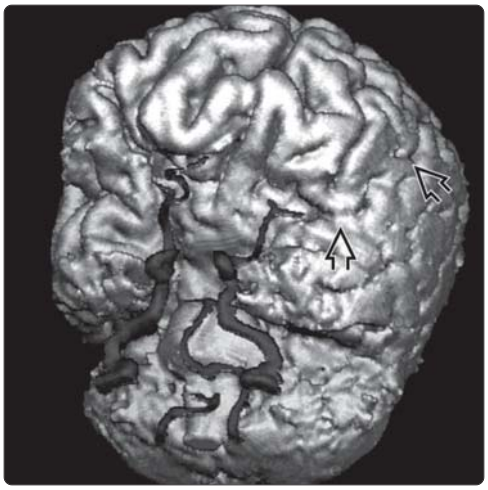
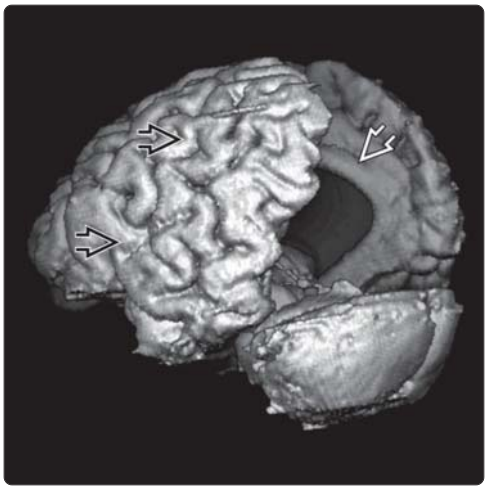
https://CafePezeshki.IR

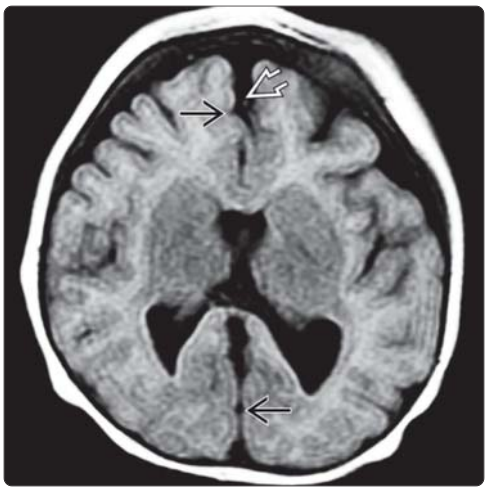


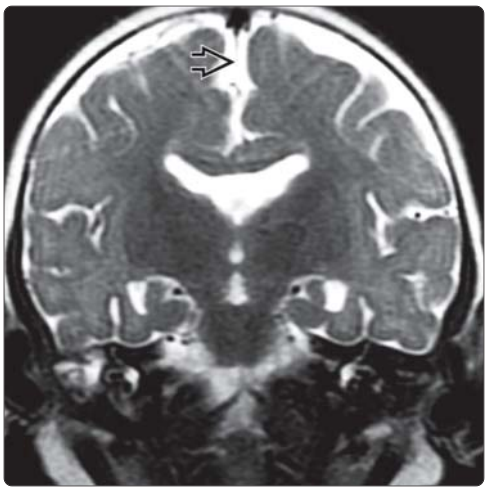
(Left) *Sagittal T2WI MR shows small, single frontal lobe ⇨ with single undivided anterobasal striatum ➡ and the widely expanded tela choroidea forming the prosencephalic dorsal cyst ⇨.* **(Right)** *Axial T1WI MR in the same patient shows lack of hemispheric division. The Sylvian fissures ➡ are anteromedial due to frontal hypoplasia. The anterobasal striatum ⇨ and medial thalamus ➡ are not divided, and the ventricular atria open posteriorly into the dorsal cyst.*





(Left) *Oblique 3D reconstruction was obtained in the same child with semilobar holoprosencephaly (HPE). The major finding is absence of anterior interhemispheric fissure. The gyral pattern is almost normal, but the sylvian fissure ⇨ is shallow and vertical (due to frontal lobe hypoplasia).* **(Right)** *Oblique posterior view of surface rendering 3D T1 gradient-echo sequence shows the large dorsal cyst ➡. Note that the temporal ⇨ cortex shows no normal recognizable gyral pattern. The cerebellum appears normal.*





(Left) *Axial T1WI in a 7 month old with central incisor shows mostly separated frontal lobes with a moderately well-developed interhemispheric fissure ⇨ and falx ➡. The septum pellucidum is absent and the frontal horns appear rudimentary.* **(Right)** *Coronal T2WI in the same patient shows the falx cerebri ⇨ in a well-developed interhemispheric fissure. The basal ganglia are separated. The temporal horns are relatively well-formed but vertically oriented. The findings are consistent with lobar holoprosencephaly.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Solitary median maxillary central incisor (SMMCI)
- Middle interhemispheric variant of holoprosencephaly (MIH) (syntelencephaly)
- SMMCI: 1 of several microforms of autosomal dominant holoprosencephaly (HPE)

IMAGING

- MIH: Interhemispheric fusion of posterior frontal/parietal lobes with normal separation of frontal/occipital poles
- SMMCI: Findings range from isolated dental abnormality to alobar HPE
  - Up to 90% have congenital nasal atresia/stenosis

TOP DIFFERENTIAL DIAGNOSES

- Hypodontia: Congenital absence of teeth
- Mesiodens: Supernumerary tooth
- Classic holoprosencephaly

PATHOLOGY

- MIH: Linked to *ZIC2* mutation at 13q32
- *SHH* and *TGIF* mutations identified in SMMCI

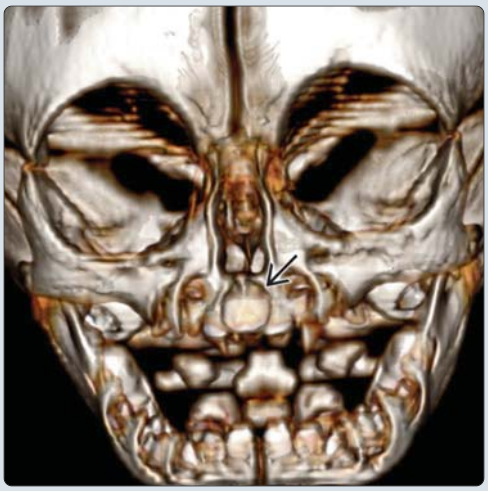
CLINICAL ISSUES

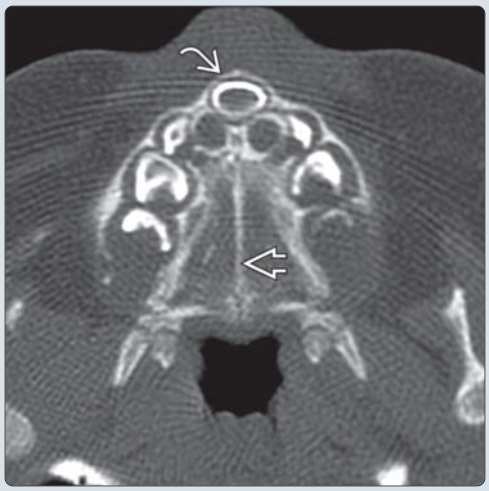
- SMMCI: 1:50,000; MIH: Rare
- SMMCI prognosis: Determined by CNS involvement; isolated SMMCI or other microforms, good to excellent
- Clinical profile MIH most similar to lobar HPE

DIAGNOSTIC CHECKLIST

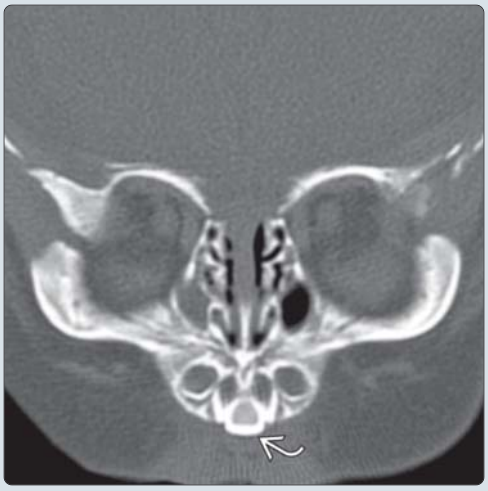
- SMMCI: Inspect nose for nasal stenosis
- SMMCI can be microform HPE, and further MR evaluation of brain should be performed

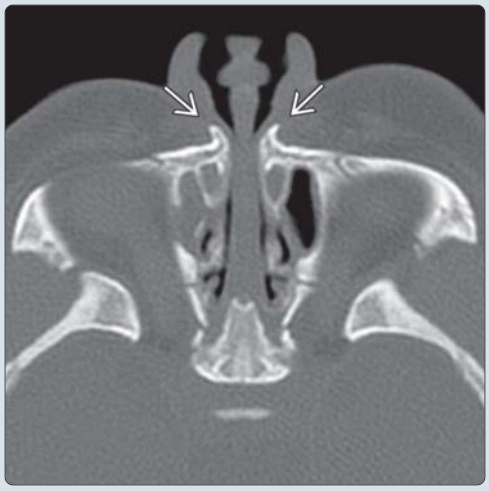
(Left) *Axial NECT 3D reconstruction shows hypotelorism and an unerupted solitary median maxillary central incisor (SMMCI)* ⇨. **(Right)** *Axial NECT in the same patient shows the precise midline location of the SMMCI* ⇨. *In addition to the prominent midpalatal ridge* ⇨, *the hard palate appears transversely narrow and V-shaped. Although some cases of SMMCI are isolated, many are microforms of holoprosencephaly, and further evaluation with brain MR should be performed.*





(Left) *Coronal NECT performed in a newborn for nasal obstruction shows the SMMCI* ⇨. *The brain was normal.* **(Right)** *Axial NECT in the same patient shows pyriform aperture stenosis* ⇨ *causing nasal obstruction. Up to 90% of patients with SMMCI have nasal obstruction 2° to choanal atresia, mid-nasal stenosis, or pyriform aperture stenosis and are thus identified in the newborn period. Approximately 60% of patients with pyriform aperture stenosis have SMMCI.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Solitary median maxillary central incisor (SMMCI)
- Middle interhemispheric variant of holoprosencephaly (MIH)

Synonyms

- Syntelencephaly

Definitions

- SMMCI: 1 of several microforms of autosomal dominant holoprosencephaly (HPE)
- MIH: HPE variant characterized by dorsal telencephalic fusion

IMAGING

General Features

- Best diagnostic clue
  - SMMCI: Single, midline central maxillary incisor
  - MIH: Midline continuity of posterior frontal/parietal lobes with normal separation of frontal/occipital poles
- Location
  - SMMCI: Midline, superior alveolar ridge
  - MIH: Posterior frontal and parietal lobes
- Size
  - SMMCI: Equivalent to normal central incisor
- Morphology
  - SMMCI: Symmetric crown
- MIH
  - Features distinguishing MIH from classic HPE
    - Continuity of posterior frontal and parietal lobes across midline
    - Normal separation of frontal poles with present anterior interhemispheric fissure (IHF)/falx
    - Callosal (CC) dysgenesis characterized by presence of genu and splenium with absent body
    - Normal separation of hypothalamus, basal ganglia
  - Frequent features of MIH
    - Continuity of sylvian fissures across midline
    - Incomplete thalamic separation (33%)
    - Cortical dysplasia/heterotopia
  - Occasional features of MIH
    - Cerebellar abnormalities (20%): Cerebellar hypoplasia, Chiari 1 and 2, cephalocele
  - Features in common with classic HPE
    - Absent septum pellucidum
    - Azygous anterior cerebral artery

CT Findings

- NECT
  - SMMCI
    - Single, midline central maxillary incisor
    - Midpalatal vomerine ridge
    - V-shaped palate
    - Up to 90% have choanal atresia, midnasal stenosis, or pyriform aperture stenosis
  - MIH
    - Interhemispheric isodense band of brain ± sylvian fissure (SF)
- CTA
  - MIH
    - Azygous anterior cerebral artery
    - Middle cerebral artery branches identified in abnormal SF

MR Findings

- T1WI
  - SMMCI
    - Findings range from isolated dental abnormality to alobar HPE
    - Frequent microcephaly, hypotelorism
    - Occasional pituitary/stalk hypoplasia
  - MIH
    - Fused posterior frontal, parietal lobes isointense to brain on all pulse sequences; ± SF fusion
    - Frequent heterotopia/cortical dysplasia along fusion
    - Normal myelin maturation (in contrast to classic HPE)
    - Dysgenetic CC (genu > splenium present, absent body)
- T2WI
  - MIH: 25% hyperintense dorsal cyst
    - Occurs with thalamic noncleavage → obstructs 3rd ventricle
- MRA
  - MIH
    - Azygous anterior cerebral artery
    - Middle cerebral artery branches identified in abnormal SF

Prenatal US/MR

- MIH can be identified in 2nd trimester
- SMMCI can be identified on prenatal MR

Imaging Recommendations

- Best imaging tool
  - SMMCI: Maxillofacial CT
  - MIH: MR with multiplanar 3D T1 gradient-echo sequence
- Protocol advice: Follow-up brain MR for SMMCI

DIFFERENTIAL DIAGNOSIS

Hypodontia

- Congenital absence of teeth
- 2nd premolars, 3rd molars, and maxillary lateral incisors most commonly affected

Mesiodens

- Supernumerary permanent tooth between central maxillary incisors
- Conical, slightly off midline

Classic Holoprosencephaly

- Failure of basal forebrain structures to cleave
- Severity of malformation related to degree of anterior brain development
  - Alobar (least differentiated): Absent IHF, falx, and CC with pancake-like mass of brain
  - Semilobar: IHF/falx formed posteriorly; splenium CC present; fused caudate heads
  - Lobar (most differentiated): IHF/falx extend anteriorly; genu CC aplastic/hypoplastic; minimal frontal lobe fusion

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Theory for SMMCI: Lack of midline cell division and lateral growth of dental lamina by day 35-38 gestation → fusion of left and right dental lamina into single midline incisor
  - MIH: Impaired expression of roof plate properties by week 3-4 gestation alters mitosis/apoptosis → faulty IHF formation and fusion of cerebral hemispheres
- Genetics
  - SMMCI: Microform of autosomal dominant HPE (ADHPE); fewer reported sporadic cases
    - Most common genetic mutations ADHPE: *SHH* 7q36, *ZIC2* 13g32, *SIX3* 2p21, *TGIF* 18p11.3
    - *SHH* and *TGIF* mutations identified in SMMCI
    - Variable expression of ADHPE accounts for wide range of phenotypes (alobar HPE → microforms)
    - 70% penetrance of ADHPE → risk of SMMCI or other microform in offspring obligate carrier = 13-14%
    - Risk of severe (semilobar/alobar) HPE in offspring obligate carrier ADHPE = 16-21%
  - Mutations of SMMCI not associated with HPE: 22q11 deletion, ring chr 18, 47XXX
  - MIH: Linked to *ZIC2* mutation at 13q32
    - In mice, *ZIC2* plays role in differentiation of embryonic roof plate; mutations cause neural tube defects, HPE
    - In contrast to other genes linked to classic HPE, *ZIC2* is not involved in ventral patterning of neuraxis → accounts for lack of severe midline facial dysmorphisms in MIH
- Associated abnormalities
  - SMMCI: VACTERL, CHARGE, velocardiofacial syndrome, ectodermal dysplasia, Duane syndrome, cardiac anomalies (25%), vertebral anomalies
  - MIH: Report of 5 patients with *ZIC2* mutations with limb, renal, and genital anomalies

Gross Pathologic & Surgical Features

- MIH: IHF present in frontal, occipital poles; hemispheric fusion of posterior frontal and parietal lobes; fused SF
- MIH: Foci of undifferentiated cortex, subependymal gray matter heterotopia

Microscopic Features

- MIH: Callosal fibers identified anteriorly, posteriorly

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - SMMCI
    - Neonatal nasal obstruction (choanal atresia, midnasal stenosis, or pyriform aperture stenosis)
    - Eruption deciduous SMMCI at 7-8 months; absent upper labial frenulum
  - MIH
    - Spasticity, hypotonia, seizures, developmental delay
- Other signs/symptoms
  - SMMCI
    - Short stature (50%), hypotelorism, microcephaly
      - 33% short stature 2° to ↓ growth hormone
    - Other microforms of ADHPE: Cleft lip, midface hypoplasia, microcephaly, coloboma, choanal atresia, midnasal stenosis, pyriform aperture stenosis, developmental delay, learning difficulties
    - SMMCI with severe HPE (alobar) uncommon
  - MIH
    - Mild facial dysmorphisms frequent: Hypertelorism, cleft lip/palate, SMMCI
    - Severe facial dysmorphisms (as with classic HPE) do not occur
    - Endocrine disorders uncommon
- Clinical profile
  - SMMCI
    - Infant with SMMCI, short stature, hypotelorism
    - Isolated SMMCI in mother and offspring with classic HPE
  - MIH
    - Infant/young child with spasticity

Demographics

- Age
  - SMMCI: Eruption of deciduous incisor at 7-8 months
- Gender
  - Isolated SMMCI more common in females
- Epidemiology
  - SMMCI: 1:50,000
  - MIH: Rare

Natural History & Prognosis

- Prognosis
  - SMMCI: Determined by CNS involvement; isolated SMMCI or other microforms, good to excellent
  - MIH: Mild/moderate psychomotor delay, seizures
    - Clinical profile of MIH most similar to lobar HPE

Treatment

- SMMCI: No treatment for isolated dental abnormality
  - Hormone replacement, corrective surgery for other microforms of ADHPE
- MIH: Antiepileptics

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- SMMCI: Inspect nose for nasal stenosis

Reporting Tips

- SMMCI can be microform HPE and further MR evaluation of brain should be performed

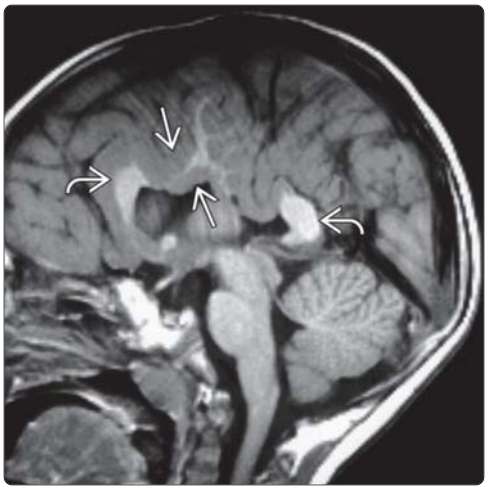
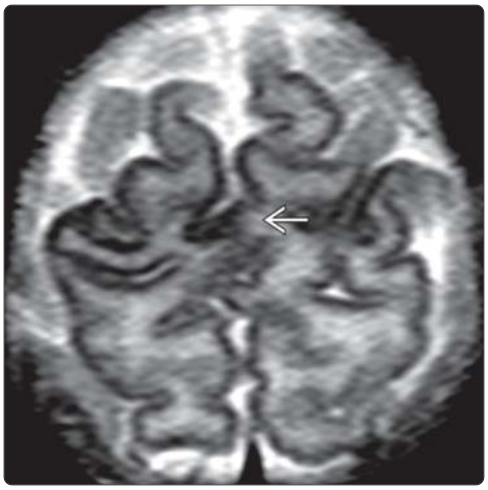
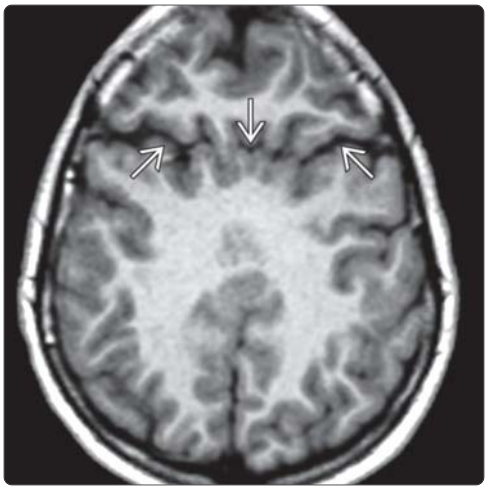
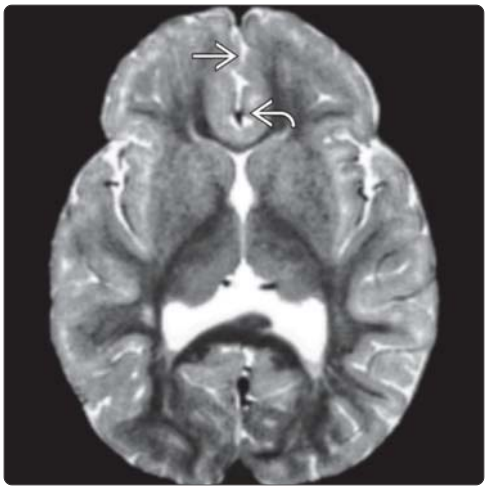
https://CafePezeshki.IR



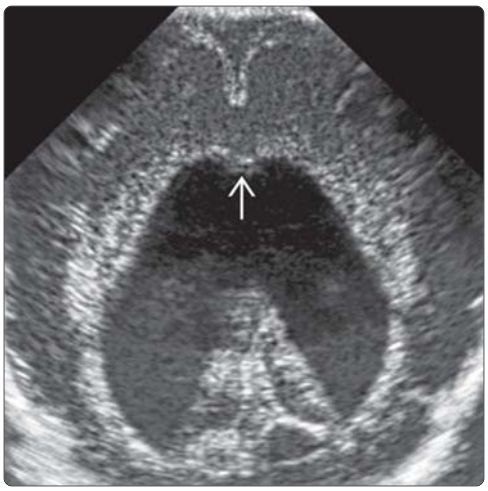


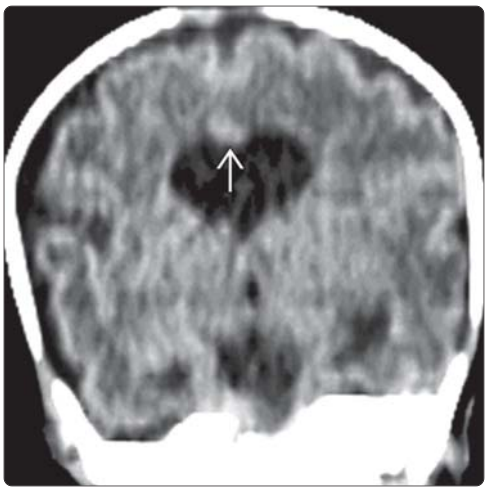
(Left) *Sagittal T1WI MR shows middle interhemispheric variant (MIH) of holoprosencephaly (HPE). GM & WM are continuous across midline at the posterior frontal/parietal lobe levels. Heterotopia/cortical dysplasia cross the midline ➡. In contrast to classic HPE, the callosal body is absent with present genu & splenium ➡. The pituitary/hypothalamus are usually normal in MIH.* **(Right)** *Axial T2WI MR in a patient with MIH shows posterior frontal/parietal continuity across the midline ➡.*





(Left) *Axial T1WI MR shows continuity of frontal white matter & sylvian fissures ➡ across the midline. Sylvian fissure continuity is an inconstant finding but fairly specific for MIH when present.* **(Right)** *Axial T2WI FS MR shows absent septum pellucidum and an azygous anterior cerebral artery ➡ as seen in classic HPE. In contrast to classic HPE, the anterior interhemispheric fissure ➡ & falx are formed and the basal ganglia are separated. Incomplete thalamic separation occurs in 33% of patients.*





(Left) *Cranial ultrasound in a premature newborn with MIH nicely demonstrates abnormal continuity of the cerebral hemispheres across midline at the mid cranial level. Note the gray matter nodule ➡ in the midline.* **(Right)** *Coronal reconstruction from axial NECT in the same patient confirms MIH. In the location of the posterior frontal and parietal lobes, there is continuity of gray and white matter across the midline. Characteristic of MIH is the gray matter nodule in the midline ➡.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Syntelencephaly; middle interhemispheric (MIH) variant of holoprosencephaly (HPE)

IMAGING

- Single ventricular cavity (100%)
- Fused dorsal mid- or posterior hemispheric cortex (100%) (by definition)
- Azygous anterior cerebral artery (ACA) (100%)
- Abnormal sylvian fissure (SF) spans both hemispheres (86%)
- Heterotopia, cortical malformations (86%)
- Dysgenetic corpus callosum (CC)
- Hypertelorism (most HPEs have hypotelorism)

TOP DIFFERENTIAL DIAGNOSES

- Classic HPE
- Septooptic dysplasia
- Bilateral schizencephaly
- Bilateral perisylvian polymicrogyria (PMG)

PATHOLOGY

- High occurrence of syntelencephaly (as well as other forms of HPE) has been observed in babies born from diabetic mothers
- *ZIC2* mutation at 13q32 is observed in 5-6% of patients

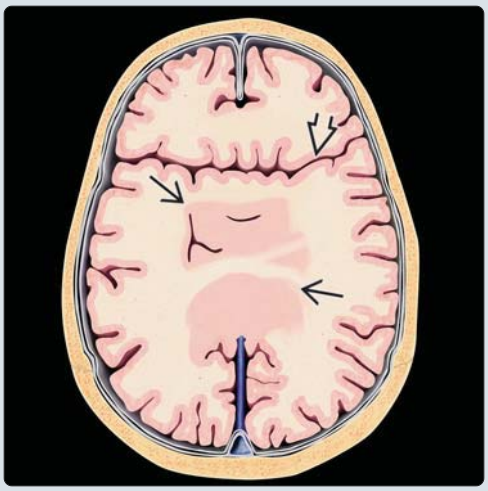
CLINICAL ISSUES

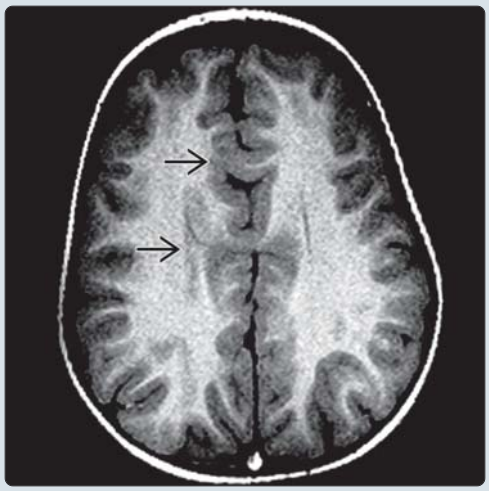
- Spasticity (86%), hypotonia (57%), dystonia (50%), seizures (40%), developmental delay (common)
- Mild facial dysmorphisms frequent: Hypertelorism, cleft lip/palate

DIAGNOSTIC CHECKLIST

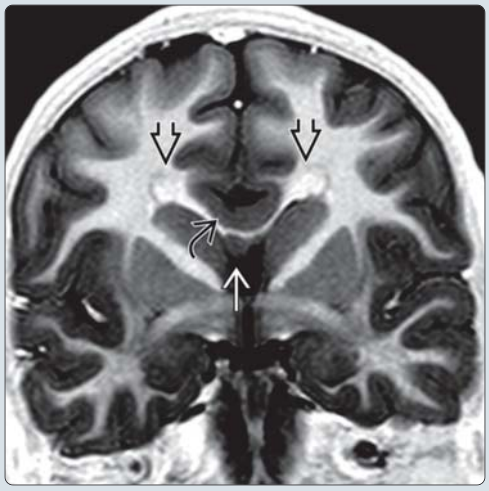
- Always look for IHF, septum pellucidum
- Look at bridging cortex lining upper surface of pseudo-corpus callosum
- Distortion of the anterior interhemispheric fissure on prenatal imaging: Look for cerebral midline anomalies

(Left) *Axial graphic depicts classic findings of syntelencephaly, with an anomalous coronal fissure ⇨ and both gray matter (GM) and white matter (WM) bridges ⇨ crossing the interhemispheric fissure in several locations. The gray matter in the cortical bridges appears thickened and dysplastic.* **(Right)** *Axial T1WI MR shows white and gray matter crossing the interhemispheric fissure in the midline ⇨, creating several interhemispheric cortical bridges.*





(Left) *Sagittal T1WI MR shows posterior frontal interhemispheric fusion. Note the well-developed callosal splenium ⇨/posterior body, azygous ACA ⇨, & heterotopic GM bulging into the ventricle under the interhemispheric fusion ⇨.* **(Right)** *Coronal T1WI MR (same patient) shows a thick layer of cortex ⇨ crossing the interhemispheric fissure; some GM ⇨ protrudes into the ventricular lumen. Note the parasagittal bright T1 signal bundle of WM ⇨ on each side, which may represent misdirected callosal fibers.*



https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Syntelencephaly
- Middle interhemispheric variant (MIH) of holoprosencephaly (HPE)

Definitions

- Variant of HPE characterized by lack of separation of midportion of hemispheres

IMAGING

General Features

- Best diagnostic clue
  - Midline continuity of posterior frontal/parietal cortex with normal separation of frontal pole
  - Single ventricular cavity
- Location
  - Midline
- Size
  - Typically normocephalic
- Morphology
  - Noncleavage of dorsal aspect of cerebral hemispheres, usually posterior frontal lobes
  - Single ventricular cavity
  - Single (azygous) anterior cerebral artery (ACA)
  - Mostly normal ventral hemispheres, basal ganglia, and hypothalamus

CT Findings

- Axial view: Absent septum pellucidum
- Sagittal reformats: Segmented corpus callosum (typically, only genu and splenium present)
- Coronal reformats: Cortical bridge between midportion of hemispheres, convex upper border of lateral ventricles
- Bone algorithms of facial bones: Cleft lip, cleft palate, hypertelorism
  - Never hypotelorism (unlike true HPE)

MR Findings

- T1WI
  - Hemispheres
    - Unseparated ("fused") dorsal mid-hemispheric cortex (100%) (by definition)
    - Single ventricular cavity (100%)
    - Single abnormal sylvian fissure (SF) spans both hemispheres dorsally (86%)
    - Heterotopia, cortical malformations (86%)
      - Thick cortex lining anterior interhemispheric fissure
      - Heterotopic gray matter nodules often situated on top of lateral ventricle bodies
    - Dysgenetic corpus callosum (CC)
      - Genu and splenium only (61%)
      - Genu or splenium (22%)
      - Genu, splenium, and some of body (20%)
    - Olfactory sulci normal (57%), olfactory bulbs (64%)
    - Hippocampi poorly developed
  - Deep gray matter
    - Lentiform nuclei normal, anterobasal caudate fused (11%)
    - Hypothalamus usually normal
    - Thalami fused (33%)
  - Midbrain
    - Incomplete segmentation diencephalon-mesencephalon (18%)
  - Posterior fossa
    - Chiari malformation, cerebellar hypoplasia possible
  - Meninges
    - Dorsal cyst (25%), may require CSF diversion
    - Rarely, cephaloceles overlying unseparated portion of hemispheres
  - Others
    - No endocrinopathy (unlike HPE)
    - Normal thermoregulation (unlike HPE)
- T2WI
  - Brain morphology
    - Similar to T1WI
  - Brain maturation
    - Myelination is normal, in keeping with patient age (unlike in classic HPE)
- MRA
  - ACA (100%)

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Multisequence triplanar
  - T1-weighted IR, MP-RAGE/SPGR provide exquisite gray/white contrast
  - DTI may help in understanding white matter organization

Ultrasonographic Findings

- Grayscale ultrasound
  - Absent septum pellucidum
  - Absence of middle portion of interhemispheric fissure
- Color Doppler
  - Azygous anterior cerebral artery

DIFFERENTIAL DIAGNOSIS

Classic Holoprosencephaly

- Single hemisphere and ventricle
- Failure of cleavage
  - Hypothalamus
  - Basal ganglia
  - Prefrontal cerebrum

Septooptic Dysplasia

- Absent/incomplete septum pellucidum
- Well-separated cerebral hemispheres
- Well-separated basal ganglia and thalami
- Normal corpus callosum
- Bilateral ACA

Bilateral Schizencephaly

- Clefts communicate with ventricles
- Well-separated cerebral hemispheres
- Bilateral ACA

Bilateral Perisylvian Polymicrogyria (PMG)

- Well-divided hemispheres and ventricles

https://CafePezeshki.IR

- Bilateral ACA

PATHOLOGY

General Features

- Etiology
  - Mitosis/apoptosis of embryonic roof plate form interhemispheric fissure (IHF) after neural tube closure (fetal weeks 3-4)
    - Impaired expression of roof plate properties alters mitosis and apoptosis → faulty dorsal IHF formation, poor cleavage of cerebral hemispheres
  - High occurrence of syntelencephaly (as well as other forms of HPE) has been observed in babies born from diabetic mothers
- Genetics
  - Presumably linked to dorsal induction genes
    - Genes linked to classic HPE (e.g., sonic hedgehog [*SHH*]) mostly affect ventral induction
      - May explain importance of facial defects in classic HPE
    - By contrast, dorsal induction disorder is predominant in syntelencephaly
      - May explain lack of severe midline facial dysmorphisms
      - Presumably induction of neural crest that forms midfacial skeleton proceeds normally
    - *ZIC2* mutation at 13q32 is observed in 5-6% of patients
      - Involved in differentiation of embryonic roof plate
- Associated abnormalities
  - Hypertelorism
  - Cleft lips, palate

Staging, Grading, & Classification

- Classic spectrum of HPEs from alobar to lobar
- Syntelencephaly considered milder end of spectrum
  - Clinically severe, although less than complete HPE

Gross Pathologic & Surgical Features

- IHF present at frontal, occipital poles
  - Hemispheric fusion posterior frontal and parietal lobes
- Lentiform nuclei normal, caudate fused
- Thalami fused in 1/3
- Hypothalamus not fused

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Developmental disorders
    - Spasticity (86%)
    - Hypotonia (57%)
    - Dystonia (50%)
    - Seizures (40%)
    - Developmental delay (speech, etc.) (100%)
    - Absence of choreoathetosis (common in classic HPE)
- Other signs/symptoms
  - Mild facial dysmorphisms frequent
    - Hypertelorism
    - Cleft lip/palate
- Clinical profile
  - Developmental delay
  - Spasticity
  - Seizures

Demographics

- Age
  - Presents in infancy

Natural History & Prognosis

- Static course

Treatment

- Rehabilitation

DIAGNOSTIC CHECKLIST

Consider

- Always look for normal IHF, septum pellucidum in fetuses, developmentally delayed children

Image Interpretation Pearls

- Distortion of the anterior interhemispheric fissure on prenatal imaging: Look for cerebral midline anomalies
- Look at ventricle
- Look at bridging cortex lining upper surface of pseudo-corpus callosum

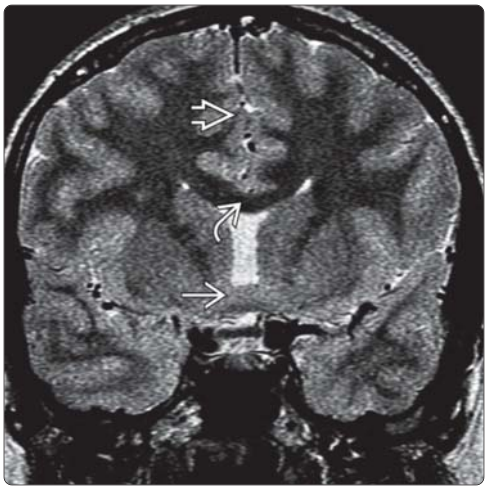
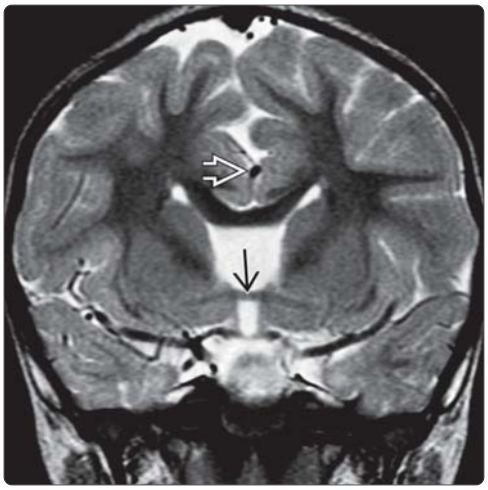
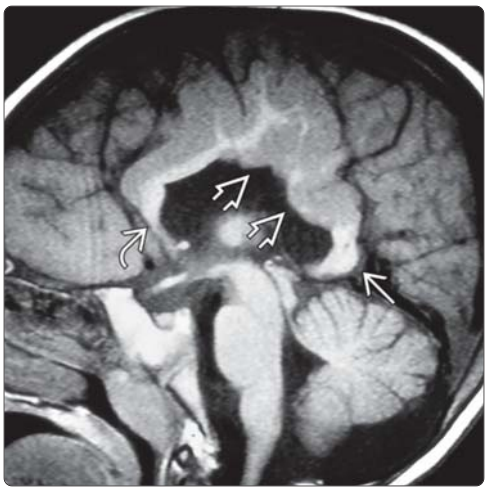
https://CafePezeshki.IR

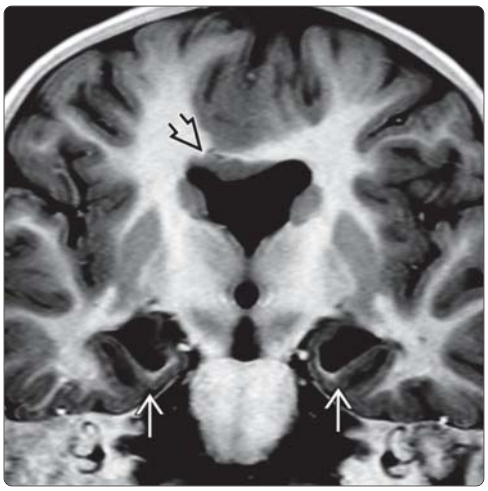


(Left) *Sagittal T1WI MR shows a patient with frontal interhemispheric fusion. The posterior CC is well developed, but the anterior portion is attenuated.* **(Right)** *Coronal thin section T2WI MR shows a continuous bridge of cortex anteriorly between the frontal lobes, with an interhemispheric fissure present dorsally. A single ventricular cavity is present, without a septum pellucidum or forniceal columns. Note the fusion of the anterobasal caudate (nucleus accumbens).*



(Left) *Sagittal T1WI MR shows a patient with a more posterior hemispheric fusion. No frank callosal splenium can be seen, although some white matter fibers appear to be crossing the midline just above the lateral ventricles. The genu is present, although hypoplastic.* **(Right)** *Coronal T2WI MR shows clearly separate frontal lobes with azygous ACA. No septum pellucidum can be identified. The anterior commissure appears normal. The hypothalamus is well divided above the chiasm.*





(Left) *Sagittal T1WI MR shows middle hemispheric fusion. The splenium and rostrum are well delineated. In the area of interhemispheric continuity, gray matter encroaches on the ventricular lumen. Interhemispheric fissure was normal in the anterior frontal and the parietooccipital areas.* **(Right)** *Coronal T1WI MR shows a single ventricular cavity and interhemispheric cortical continuity. Note the heterotopic gray matter on the ventricular roof and the poorly developed hippocampi.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Septooptic dysplasia (SOD)
- De Morsier syndrome

IMAGING

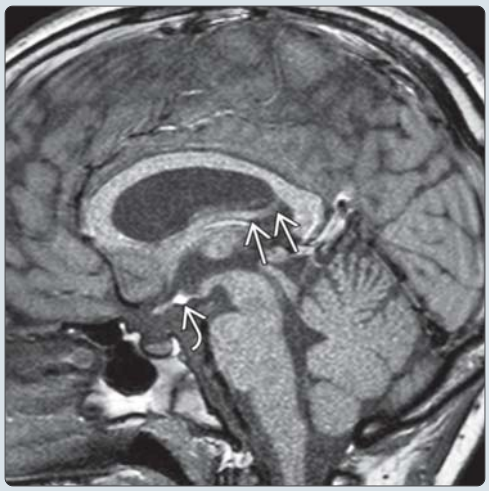
- Absent septum pellucidum, small optic chiasm
- Optic nerves, pituitary gland, septum pellucidum
- Coronal imaging shows
  - Flat-roofed ventricles
  - Downward pointing anterior horns
- 3 orthogonal planes crucial to identify all findings
  - Absent septum pellucidum, flat roof of frontal horns, small optic chiasm

CLINICAL ISSUES

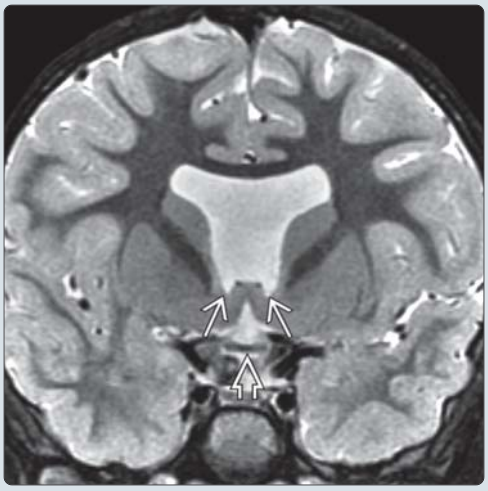
- Newborns: Hypoglycemic seizures, apnea, cyanosis, hypotonia, prolonged conjugated jaundice, and (in boys) microphallus
- Abnormal endocrine function (60%): Look for multiple pituitary deficiencies
- Normal endocrine function (40%): Often have schizencephaly, seizures
- Child with short stature, endocrine dysfunction
- Normal or color blindness, visual loss, nystagmus, strabismus
- ± mental retardation, spasticity, microcephaly, anosmia
- 75-90% have brain abnormalities; 45% have pituitary insufficiency
- Bilateral optic nerve hypoplasia (70%)

DIAGNOSTIC CHECKLIST

- SOD in small stature pediatric patient with absent septum pellucidum
- Small optic nerves, with ectopic posterior pituitary lobe, with absent septum pellucidum



(Left) *Coronal graphic depicts flat-roofed anterior horns and the absence of a midline septum pellucidum. The anterior horns are draped inferiorly around the fornices ⇨, and the optic chiasm ➡ is small.* **(Right)** *Sagittal T1WI MR shows absent septum pellucidum (note the low-lying fornices ➡) and the ectopic posterior lobe of the pituitary gland ➡ at the median eminence. Note that the pituitary gland is small for an adolescent, and the infundibulum is not seen.*



(Left) *Coronal T2WI FSE MR shows the absence of septum pellucidum and pointing ➡ of the inferior margins of the frontal horns, draped over fornices. Note that the optic chiasm ⇨ is normal in size, as is often the case in septooptic dysplasia (SOD).* **(Right)** *Coronal T2WI FSE MR in the same patient at the level of the intraorbital optic nerves shows unilateral optic nerve hypoplasia. The right optic nerve ⇨ is tiny, running through a small optic nerve sheath. The left optic nerve ⇨ is normal.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Septooptic dysplasia (SOD)

Synonyms

- De Morsier syndrome
- Kaplan-Grumbach-Hoyt syndrome
- Suprasellar dysgenesis
- Septooptic-pituitary dysgenesis

Definitions

- Heterogeneous association characterized by optic nerve hypoplasia (ONH), absent septum pellucidum, hypothalamic-pituitary dysfunction
  - De Morsier (1956): Described 7 patients with SOD
  - Hoyt (1978): Described association of SOD with hypopituitarism
- Some authors consider SOD and lobar holoprosencephaly to overlap
- SOD plus: Abnormal optic nerves/chiasm, septum pellucidum, pituitary gland, plus cortical dysplasias

IMAGING

General Features

- Best diagnostic clue
  - Absent septum pellucidum, small optic chiasm
- Location
  - Optic nerves, pituitary gland, septum pellucidum
- Size
  - Small optic nerves
  - Small pituitary gland with ectopic posterior lobe
  - Absent septum pellucidum
- Morphology
  - Coronal imaging shows
    - Flat-roofed ventricles
    - Downward-pointing anterior horns

CT Findings

- NECT
  - Absent septum pellucidum
  - Large lateral ventricles
  - Small bony optic foramina on axial and coronal imaging

MR Findings

- T1WI
  - 3 orthogonal planes crucial to identify all findings
    - Absent septum pellucidum (remnants may be present)
    - Flat roof of frontal horns, pointed inferior aspect of frontal horns
    - Small optic chiasm/nerves (fat saturation aides visualization of optic nerves)
    - ± thin pituitary stalk, small anterior lobe of pituitary
    - ± posterior pituitary ectopia
    - Callosal-forniceal continuation or fused midline fornices
    - Thin corpus callosum
    - Vertical hippocampi
    - ± hypoplastic/absent olfactory nerves
    - ± schizencephaly
    - ± heterotopia, polymicrogyria
    - Midbrain-hindbrain abnormalities (short midbrain, small pons, thick quadrigeminal plate, vermian dysplasia) significant but underrecognized component of SOD spectrum
- T2WI
  - Deficient falx (especially anteriorly) ± hypomyelination
- T1WI C+
  - ± ectopic posterior pituitary lobe
  - Delayed enhancement of anterior pituitary lobe on dynamic MR

Angiographic Findings

- Conventional

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Coronal, sagittal thin sections through sella/orbits
  - Use fat saturation or CISS/FIESTA/SPACE to better see optic nerves

DIFFERENTIAL DIAGNOSIS

Syndromes Overlapping With Septooptic Dysplasia

- Optic-infundibular dysplasia, normal septum
- Schizencephaly with absent septum

Kallmann Syndrome

- Absent olfactory nerves
- ± visual, septal, pituitary abnormalities

Holoprosencephaly

- Similar to SOD
  - Many consider it same disorder as SOD

Isolated Ectopic Posterior Pituitary Lobe

- Normal chiasm/nerves, septum pellucidum

PATHOLOGY

General Features

- Etiology
  - Theories
    - Midline heritable defect (mild holoprosencephaly variant)
    - Or secondary degeneration of optic nerve fibers due to cerebral lesion
    - Or vascular disruption (field defect) during brain development
    - Damage to cerebral and optic nerve around 6th week gestation
    - Teratogens: Cytomegalovirus, antiepileptic drugs, alcohol, maternal diabetes
- Genetics
  - Most are sporadic
  - Some are autosomal dominant or recessive
  - Some cases have mutations in *HESX1* gene
    - Homozygous mutations = full syndrome
    - Heterozygous mutations = milder pituitary phenotypes

https://CafePezeshki.IR

- Inactivation of *HESX1* (3p21.2-3p21.2) by Arg53Cys substitution leads to deficient anterior pituitary lobe (does not occur in sporadic SOD)
- Mutations of *FGFR1*, *PROKR2* also described
- Associated abnormalities
  - Frequently associated with other cerebral anomalies
    - Most common = schizencephaly
    - Perisylvian polymicrogyria
    - Midline malformations (callosal dysgenesis, etc.)
    - Ocular anomalies (coloboma, anophthalmia, microphthalmia)
    - Olfactory tract/bulb hypoplasia
    - Incomplete hippocampal rotation
  - Overlapping syndromes with optic, septal, frontal lobe, midline, olfactory deficiencies

Staging, Grading, & Classification

- Isolated ONH: Visual defect only; intelligence and growth normal
- ONH and septal deficiency: Same as isolated
- ONH and septal and pituitary deficiency: May have developmental delay
- Complete septal agenesis: Worse developmental prognosis
- Intrauterine or perinatal insult (especially meningitis) as cause of optic nerve, chiasmatic, and hypothalamic deficiency

Gross Pathologic & Surgical Features

- Small optic chiasm/nerves
- Small or absent geniculate nucleus
- Deficient/absent septum pellucidum
- Forniceal columns (± fused) → run along roof of 3rd ventricle
- Common: Hypoplasia pituitary, olfactory lobes

Microscopic Features

- Optic nerves, chiasm have sparse or absent myelinated fibers
- Geniculate nucleus (if found): Disorganized layering of small neurons

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Newborns: Hypoglycemic seizures, apnea, cyanosis, hypotonia, prolonged conjugated jaundice, and (in boys) microphallus
  - Abnormal endocrine function (60%): Look for multiple pituitary deficiencies
  - Normal endocrine function (40%): Often have schizencephaly, seizures
- Clinical profile
  - Child with short stature, endocrine dysfunction
  - Normal or color blindness, visual loss, nystagmus, strabismus
  - ± mental retardation, spasticity, microcephaly, anosmia

Demographics

- Age
  - Generally detected in infants
  - More common among younger mothers and 1st born child
- Gender
  - M = F
- Epidemiology
  - 1 in 50,000 worldwide
  - Optic nerve hypoplasia
    - 60% have brain abnormalities (not just schizencephaly); 62-88% have pituitary insufficiency
      - 30% have both
    - 25-50% have absent septum pellucidum
  - Septooptic dysplasia
    - 75-90% have brain abnormalities; 45% have pituitary insufficiency
    - Bilateral optic nerve hypoplasia (70%)

Natural History & Prognosis

- Hypothalamic and pituitary crises; sudden death (hypocortisolism)
- Depends upon severity of associated brain and pituitary malformations

Treatment

- Hormonal replacement therapy

DIAGNOSTIC CHECKLIST

Consider

- SOD in small stature pediatric patient with absent septum pellucidum

Image Interpretation Pearls

- Small optic nerves, + ectopic posterior pituitary lobe, plus absent septum pellucidum

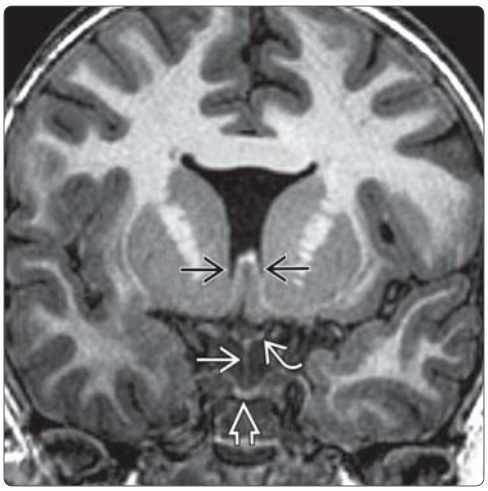
(Left) *Axial steady state acquisition (FIESTA) MR with 1 mm sections shows that the right intraorbital section of the optic nerve is extremely thin. Steady state magnetization sequences are excellent for assessing the optic nerve, both in the intraorbital and intracranial segments.* **(Right)** *Axial steady-state acquisition (FIESTA) MR with 1 mm sections in the same patient shows the small intracranial right optic nerve. Compare this with the normal left optic nerve.*

(Left) *Sagittal T1WI MR in a young boy shows stretched corpus callosum and low-lying fornix to suggest absent septum. The optic chiasm is tiny, and the pituitary infundibulum is very attenuated.* **(Right)** *Axial T1WI MR in the same patient confirms absent septum pellucidum and brain anomalies, such as left posterior sylvian polymicrogyria, and transmantle column of heterotopic gray matter extending from the tip of the right occipital horn to the medial occipital cortex.*



(Left) *Sagittal T1WI MR shows anomalous corpus callosum with discontinuous genu and an abnormally thick, flat, callosal body. The optic chiasm is unusually thin, the pituitary infundibulum is not seen, and the anterior lobe of the pituitary gland is too small.* **(Right)** *Coronal T1WI MR in the same patient shows tiny optic tracts, infundibulum, and anterior lobe of the pituitary gland. The inferior aspects of frontal horns are pointed, curving around the fornices.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Primary (genetic) microcephaly, secondary (nongenetic) microcephaly
- Proportionate vs. disproportionate volume loss of structures

IMAGING

- Imaging findings dictated by cause of microcephaly
  - Dysmorphic vs. destructive
  - Brain anomalies give clues to causative gene
- Consider supplemental use of NECT to detect Ca++
- MR brain: SWI or GRE T2* (blood and Ca++), 3D T1 gradient-echo (brain topography), FLAIR for detecting subdurals
- Ca++ in TORCH and pseudo-TORCH syndromes

TOP DIFFERENTIAL DIAGNOSES

- Antenatal: Preeclampsia, maternal infection (TORCH), maternal diabetes, fetal alcohol syndrome
- Perinatal: Hypoxic-ischemic encephalopathy (HIE), infection
- Postnatal: Prolonged status epilepticus, HIE, hypoglycemia, meningeo-encephalitis, neurodegenerative, abusive head injury

PATHOLOGY

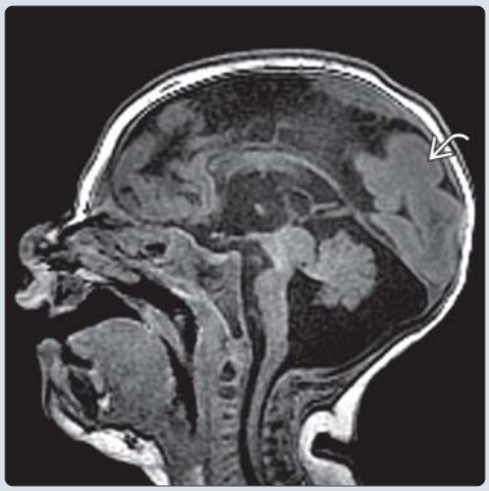
- From any cause, there is reduced growth of brain, ↓ proliferation of glia and neurons
- Simple gyral pattern (oligogyria) vs. dysmorphic growth

CLINICAL ISSUES

- Criteria for diagnosis of microcephaly: Head circumference > 3 standard deviations (SDs) below mean for age and sex

DIAGNOSTIC CHECKLIST

- If midline anomalies accompany microcephaly, consider fetal alcohol syndrome



(Left) *Sagittal T1WI MR in an 11-month-old infant shows severe microcephaly with normal posterior fossa structures. Notice the very low craniofacial ratio, which is < 1. The cerebellum and brainstem are disproportionately large.* **(Right)** *Sagittal T1WI MR in a microcephalic newborn (craniofacial ratio slightly ~ 1.5) shows a very small corpus callosum. The pons and cerebellum are disproportionately small compared with the cerebrum. The occipital gyral pattern is simplified.*

(Left) *Coronal T2WI MR of a neonate with MSG group 5 and a head circumference > 3 standard deviations below the mean shows the brain surface is smooth, with reduced white matter volume and an indistinct appearance of the cortical-white matter junction.* **(Right)** *Axial T2WI MR of a microcephalic infant with classical lissencephaly (type 1, LIS1) shows a thick inner band of cortex, cell sparse zone, thin outer cortex, shallow sylvian fissures, and an "hourglass" configuration of the brain.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Microcephaly (MCPH)

Synonyms

- Microcephaly with simplified gyral pattern (MSG)

Definitions

- Primary (genetic): Mendelian inheritance **or** associated with genetic syndrome
  - MSG: Head circumference > 3 standard deviations (SDs) below mean, simplified gyri, shallow sulci
  - Microlissencephaly: Head circumference > 3 SDs below mean, pachy- or agyria
- Secondary (nongenetic): Noxious agent affecting fetal, neonatal, or infant brain growth

IMAGING

General Features

- Best diagnostic clue
  - ↓ craniofacial proportions, suture overlap, simplified gyri, shallow sulci
  - Imaging findings dictated by the cause of MCPH
  - More severe MCPH is associated with simplification of gyral pattern
  - Classify by gene mutation if known; also by
    - Relative size of supratentorial/infratentorial structures
    - Supratentorial anomalies (polymicrogyria, heterotopia, callosal anomalies)
    - Association with extra-CNS anomalies
      - Musculoskeletal, cardiac, gastrointestinal, etc.
- Imaging: Dictated by cause of MCPH
  - Primary (genetic) MCPH: Prenatal vs. postnatal, often associated with developmental delay (DD)
    - Prenatal MCPH: Associated with severe MCPH (< 3 standard deviations from mean) at birth
    - Postnatal MCPH: Low normal head size at birth, dropping percentiles (10% to < 1%) during infancy
  - Secondary (nongenetic) MCPH
    - Hypoxic-ischemic encephalopathy (HIE): ± cortical, white matter, or basal ganglia volume loss
    - TORCH infection: Ca++, abnormal white matter, neuronal migration anomalies, germinolytic cysts
    - Abusive head injury: Encephalomalacia, chronic subdurals, ± parenchymal lacerations
- Lateral radiograph, CT scout, or sagittal MR: ↓ craniofacial proportions
  - Normal craniofacial ratios: Preterm (5:1), term (4:1), 2 years (3:1), 3 years (2.5:1), 12 years (2:1), adult (1.5:1)

Radiographic Findings

- Radiography
  - ↓ craniofacial ratio, slanted forehead, closely apposed or overlapping calvarial sutures

CT Findings

- NECT
  - Small cranial vault: Sutures closely apposed, overlapping ± secondary craniosynostosis
  - Ca++ in TORCH and pseudo-TORCH syndromes
  - Cortical surface: Normal ↔ simplified ↔ migrational abnormalities ↔ microlissencephaly

MR Findings

- T1WI
  - Primary (genetic) MCPH, MSG
    - Small yet normal brain ↔ simplified gyral pattern (oligogyria) ↔ microlissencephaly
    - Normal myelination ↔ hypomyelination ↔ demyelination
    - ± various telencephalic anomalies: Callosal absence or dysgenesis, holoprosencephaly, polymicrogyria (PMG), cobblestone cortex, agyria/pachygyria
      - Brainstem/cerebellum may proportional, disproportionately large, or disproportionately small compared with cerebrum
  - Secondary (nongenetic) MCPH
    - Destructive changes: Encephalomalacia, ± Ca++ TORCH infections, ± subdural collections
- T2WI
  - Primary (genetic) MCPH, MSG, or microlissencephaly
    - Sulci (1/4-1/2 normal depth), simplified cortex ↔ pachygyria ↔ heterotopia ↔ PMG ↔ microlissencephaly
    - ↓ commisural fiber tracts, normal basal ganglia volume, ± cerebellar hypoplasia
    - White matter maturation: Normal ↔ hypomyelinated ↔ demyelinated
    - Possible midline anomalies: Absent corpus callosum, holoprosencephaly
  - Secondary (nongenetic) MCPH
    - White matter: Gliosis, cavitation, demyelination, diminished volume, ± hypointensity (Ca++)
    - Cortex: Normal ↔ simplified ↔ polymicrogyria (TORCH)
    - May see thick calvaria, subdurals from shrinking brain
- PD/intermediate
  - Gliosis (↑ signal) and Ca++ (↓ signal) more common in secondary MCPH (infection)
- FLAIR
  - Periventricular: Cavitation (↓ signal), gliosis (↑ signal), ± hyperintense chronic subdural collections
- T2* GRE
  - Sequelae to nonaccidental trauma: Hypointensities from hemorrhagic parenchymal shear injury
- DWI
  - T2 shine through associated with gliosis or demyelination
- MRS
  - ↓ NAA; myoinositol and choline may be ↑ in states of ongoing demyelination and neurodegeneration

Ultrasonographic Findings

- Grayscale ultrasound
  - ± basal ganglia or thalamic Ca++ (TORCH or HIE), ± germinolytic cysts (TORCH)

Imaging Recommendations

- Best imaging tool
  - NECT detects: Ca++ (TORCH, pseudo-TORCH, HIE), encephalomalacia, and subdural collections in abusive head injury

https://CafePezeshki.IR

- MR depicts: Gyral pattern, cortical organization/migration, myelination, midline anomalies, relative size of cerebrum to posterior fossa structures, gliosis, hemorrhage
- Protocol advice
  - Consider supplemental use of NECT to detect Ca++
  - MR brain: SWI or GRE T2* (blood and Ca++), 3D T1 gradient-echo (brain topography), FLAIR for detecting subdurals

DIFFERENTIAL DIAGNOSIS

Secondary (Nongenetic) Microcephaly

- Antenatal
  - Preeclampsia, maternal infection (TORCH), maternal diabetes, fetal alcohol syndrome (FAS)
- Perinatal
  - Hypoxic-ischemic encephalopathy, infection
- Postnatal
  - Prolonged status epilepticus, HIE, hypoglycemia, meningoencephalitis, neurodegenerative, abusive head injury
- Noxious insult

PATHOLOGY

General Features

- Etiology
  - From any cause, there is reduced growth of brain, ↓ proliferation of glia and neurons
- Genetics
  - Primary (genetic) MCPH is typically autosomal recessive (e.g., familial form → 1/40,000 births)
  - Syndrome associations
    - MCPH genetic heterogeneity: Mutations in 1q31 most prevalent
    - Down (21-trisomy), Edward (18-trisomy), Cri-du-chat (5p-), Cornelia de Lange, Rubinstein-Taybi

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Severe mental retardation, ± seizures, developmental delay
- Criteria for diagnosis of MCPH: Head circumference > 3 SDs below mean for age and sex

Demographics

- Age
  - Primary (genetic) MCPH often detected in utero or shortly after birth
  - Secondary (nongenetic) MCPH usually results from insults within first 2 years of life
- Gender
  - Variable based on type: Primary (autosomal recessive inheritance) vs. secondary (nongenetic)
- Ethnicity
  - Common genetic forms ~ panethnic; certain syndromic causes of MCPH may show ethnic preference
- Epidemiology
  - Incidence of MCPH in general population: 0.06-0.16%
  - Incidence of genetically determined MCPH: Familial 1/40,000, Down syndrome 1/800

Natural History & Prognosis

- Dictated by cause of MCPH, variable seizures, mental retardation, and motor handicap

Treatment

- Supportive; genetic testing available for some microcephalic disorders

DIAGNOSTIC CHECKLIST

Consider

- Presence of cerebellar hypoplasia more common in primary MCPH
- If midline anomalies accompany microcephaly, consider FAS

Image Interpretation Pearls

- MR provides most sensitive tool for investigating simplified cortex in MCPH

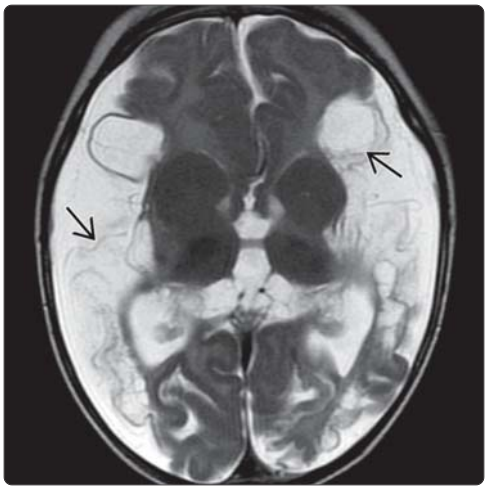
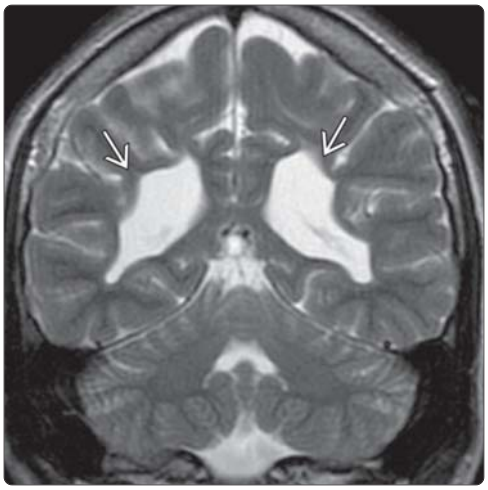
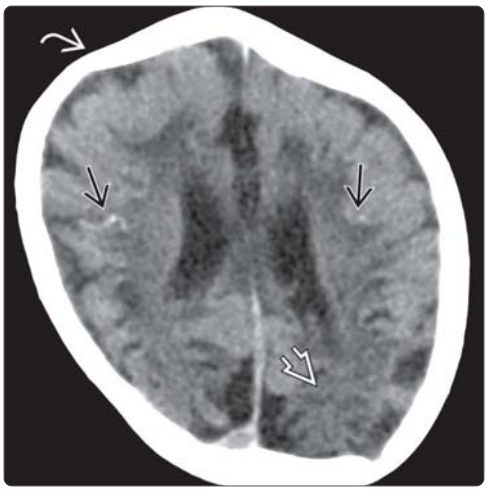
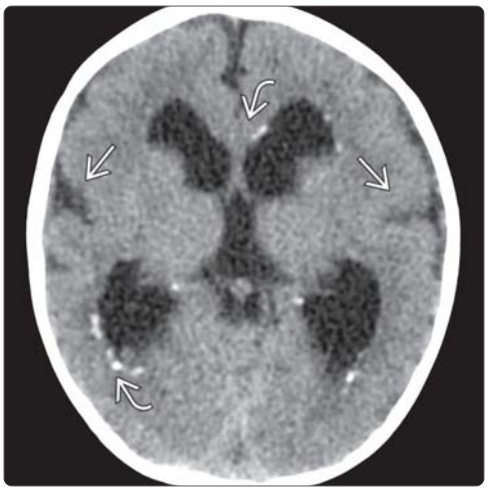
(Left) *Axial T2WI MR of a microcephalic neonate with alobar holoprosencephaly shows fused anterior cerebral tissue ➡. The monoventricle is uncovered posteriorly (dorsal cyst) ⇨. The coronal suture overlap ➡ reflects micrencephaly.* **(Right)** *Axial T2WI MR in a profoundly microcephalic newborn with hydranencephaly shows that the obliteration of tissue is in the carotid arterial distributions. Note the small residual islands of cerebral tissue ⇨ from the frontal and temporal lobes.*





(Left) *Axial T2WI MR in an infant with microcephaly resulting from in utero middle cerebral artery territory infarctions shows extensive hemispheric cystic encephalomalacia ⇨.* **(Right)** *Coronal T2WI MR in a premature microcephalic infant with a maternal history of chorioamnionitis demonstrates marked reduction of periventricular and deep white matter ➡. Axial FLAIR (not shown) revealed findings of periventricular gliosis. These findings reflect a remote perinatal brain injury.*





(Left) *Axial NECT in a microcephalic infant, who was the product of a precipitous birth following placental abruption, shows scattered focal subcortical calcifications ⇨, cerebral cortical atrophy ➡, and overlapping of the right coronal suture ⇗, reflecting micrencephaly.* **(Right)** *Axial NECT in a microcephalic infant with a congenital CMV infection shows scattered periventricular calcifications ⇗. Note the shallow sylvian fissures ➡ and associated simplified gyri (polymicrogyria seen on MR).*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Congenital muscular dystrophies (CMD): Heterogeneous group of autosomal recessive myopathies presenting at birth with hypotonia

IMAGING

- Cobblestone brain with myelination defects and Z-shaped brainstem in hypotonic infant
  - Look for enlarged tectum
- Polymicrogyria, abnormal myelin, cerebellar cysts

PATHOLOGY

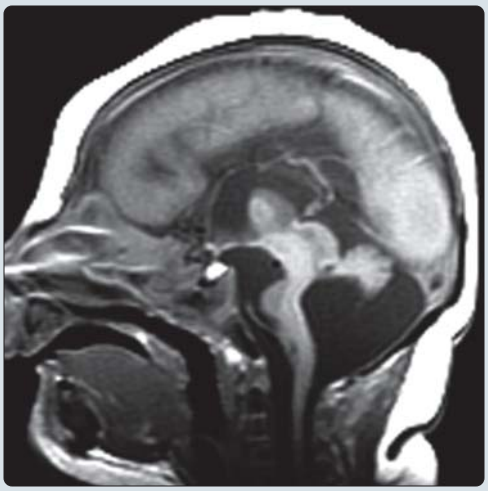
- Mutations in molecules (merosin: Laminin-α2) with roles in cell migration and connection
- Skeletal muscle extracellular matrix protein that binds dystrophin-associated glycoprotein complex utilized in migration of oligodendrocyte precursors
- Autosomal recessive
- CMDs with brain anomalies have hypoglycosylation of α-dystroglycan → neurons overmigrate through gaps in external lamina; "pebbled" brain surface
- Marked phenotypic overlap amongst Fukuyama CMD, Walker-Warburg, and muscle-eye-brain (MEB)
- Muscle biopsy: Mild to moderate dystrophic changes, ± inflammatory infiltrate, ± absent staining laminin-α2

CLINICAL ISSUES

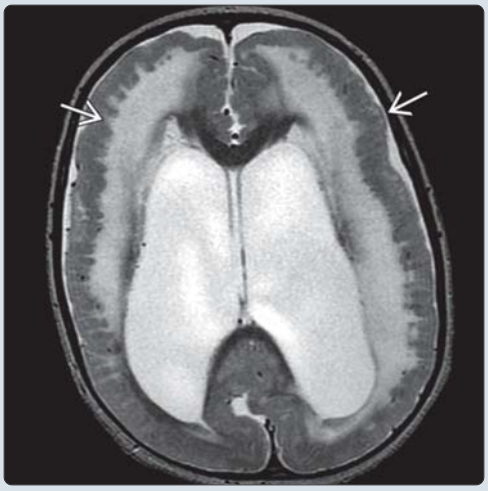
- Hypotonia, developmental delay, poor vision, seizures
- "Floppy" newborn

DIAGNOSTIC CHECKLIST

- Not all Z-shaped brainstems are CMD
- Not all CMD have Z-shaped brainstems (e.g., merosin [-] CMD)



(Left) *Sagittal T1WI MR shows facial dysmorphism, smooth brain, and absent commissures (anterior, callosal, hippocampal). Note the kinked "Z-shaped" brainstem, with small, rotated vermis giving a pseudo-Dandy-Walker appearance. Tentorium is not elevated, however.* **(Right)** *Sagittal T1WI shows a small, flattened pons ⇨, large tectum ⇨, and lack of normal gyration/sulcation in the parietaloccipital region with a cortex that appears thick but somewhat irregular ⇨. The vermis ⇨ is severely hypoplastic.*



(Left) *Axial T2WI in the same patient shows the classic "pebbly" look of cobblestone gyri ⇨. Severe ventriculomegaly and hypomyelination of the white matter are also present.* **(Right)** *Coronal T2WI in the same case shows the cobblestone cortex with multiple cysts ⇨. "Cobblestone" lissencephaly (LIS2) and congenital muscular dystrophy (CMD) with severe CNS malformations (Walker-Warburg).*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Congenital muscular dystrophy (CMD)

Synonyms

- Dystroglycanopathies
- CMD 1: Merosin (+) or merosin (-) CMD
- CMD 2-4: "Cobblestone" lissencephaly (LIS2); CMD with severe CNS malformations

Definitions

- CMDs: Heterogeneous group of autosomal recessive myopathies presenting at birth with hypotonia
- CMDs without major brain malformations are either merosin (+) or merosin (-)
  - CMD 1 merosin (+) normal laminin-α2 expression: Normal/very mild imaging findings (cerebellar hypoplasia, nonspecific white matter [WM] changes, focal PMG)
  - CMD 1 merosin (-) deficient laminin-α2 expression: Significant dys-/hypomyelination of WM
- CMD 2-4 with major brain abnormalities (50%) variably associated ("cobblestone" brain, abnormal WM signal, ocular and cerebellar anomalies)
  - CMD 2: Fukuyama CMD (FCMD) least severe
  - CMD 3: Santavuori muscle-eye-brain (MEB) (Finnish type)
  - CMD 4: Walker-Warburg syndrome (WWS) most severe
- Mixed patterns may occur: Merosin (-) CMD with brain malformations
- All result from disturbed late migration of neurons

IMAGING

General Features

- Best diagnostic clue
  - "Cobblestone" brain and Z-shaped brainstem in hypotonic infant
- Morphology
  - CMDs with major brain malformations (WWS most severe)
    - "Cobblestone" brain ± ventriculomegaly ± posterior cephalocele
      - Often nodules of gray matter below cobblestone cortex
    - Agenesis/hypogenesis of corpus callosum
    - Flat or Z-shaped brainstem or notched pons, hypoplastic vermis
  - Less severe cases have polymicrogyria-like malformation with dysmorphic cerebellum, disturbed myelination

CT Findings

- NECT
  - All imaging findings most severe in WWS
    - Huge ventriculomegaly, shallow or absent sulci
    - ↓ attenuation WM
    - Vermian hypoplasia (Dandy-Walker-like) ± posterior cephalocele

MR Findings

- T1WI
  - Thin, dysplastic, polymicrogyric (PMG) or "pebbled" hemispheric cortex, ± ventriculomegaly
  - ± callosal, septal, or vermian hypogenesis
  - Flat, deeply clefted, notched, Z-shaped brainstem with large tectum
- T2WI
  - PMG or "pebbled" cortex, abnormal myelin, cysts cerebellum
    - CMD merosin (-): Dysmyelination centrum semiovale ≤ subcortical WM
    - FCMD, MEB: WM abnormalities in 50%
    - WWS: Severe WM hypomyelination

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Multiplanar, multisequence for white matter, brainstem, and cerebellar changes

DIFFERENTIAL DIAGNOSIS

Multiple Disorders With Brainstem Clefting

- Joubert (mesencephalon and vermian hypoplasia); midline clefting syndromes

Horizontal Gaze Palsy Associated With Progressive Scoliosis (HGPS): Chr 11q23

- Also: Brainstem hypoplasia/clefting, mild cerebellar atrophy

CEDNIK Syndrome

- Mutation of *SNAP29* on 22q11.2

True Polymicrogyria

- Myelination, posterior fossa normal

Peroxisomal Biogenesis Disorders

- Polymicrogyria, hypomyelination, germinolytic cysts

PATHOLOGY

General Features

- Etiology
  - Mutations in molecules (laminin-α2, α-dystroglycan, *ADGRG1*, others) with roles in attachment of radial glial cells to pial limiting membrane (PLM)
    - Disturbed attachment results in gaps in PLM, overmigration of neurons into subarachnoid space
    - Laminin mutations impair oligodendrocyte migration
- Genetics
  - Autosomal recessive
  - CMD 1 merosin (+): Genetic defect(s) unknown
  - CMD 1 merosin (-): Mutation in gene for laminin-α2 on Chr 6
  - CMDs with brain anomalies have hypoglycosylation of α-dystroglycan → neurons overmigrate through gaps in external lamina; "pebbled" brain surface
    - FCMD: Mutation in gene encoding fukutin (*FKTN* at 9q31)
    - MEB: O-Mannoside N-acetyl-glucosaminyl-transversae (*POMGNT1* at 1p32-p34)
    - WWS: O-Mannosyltransferase gene (*POMT1*)

https://CafePezeshki.IR

- Mutations in *FKRP* (fukutin-related protein gene) may cause congenital or late-onset phenotypes
- Other CMD variants with known defects
  - CMD with mutation integrin-α7 gene on Chr 12
  - CMD with familial junctional epidermolysis bullosa (plectin gene on Chr 8)
  - CMD with spine rigidity (linked to Chr 1 in some)
- Mixed patterns and intermediate forms occur
  - CMD merosin (-) with brain anomalies, cerebellar cysts, vermis hypoplasia, mental retardation
- Associated abnormalities
  - Some associated features in CMD variants with "not yet found" mutations: Occipitotemporal PMG, occipital agyria, calf-hypertrophy, arthrogryposis, ptosis, adducted thumbs

Staging, Grading, & Classification

- CMD 1: Abnormal WM varies from mild (CMD 1 merosin [+]) to more severe (CMD 1 merosin [-])
- CMD 2: FCMD: Moderate dysplasia of cerebral neocortex and cerebellum, abnormal WM
  - Frontal PMG, occipital cobblestone cortex, "peripheral 1st" myelination pattern
- CMD 3: Finnish-type MEB, less severe than CMD 4
  - Ventriculomegaly, vermian hypogenesis, dysplastic cortex, patchy abnormal WM, ± callosal dysgenesis
- CMD 4: Walker-Warburg, most severe
  - "Cobblestone" brain, massive ventriculomegaly with absent/abnormal callosum, no myelin, kinked pons-midbrain, vermian hypoplasia ± cephalocele

Gross Pathologic & Surgical Features

- CMDs with brain malformations
  - Supratentorial: Coarse gyri, agyric regions, ± ventriculomegaly and focal interhemispheric fusion
  - Brainstem: Variable degrees of pontine hypoplasia and fused colliculi; flat, cleft, or Z-shaped brainstem
  - Cerebellum: Cerebellar hypoplasia, PMG, and cysts ± encephalocele
  - Ocular: Retinal/optic nerve dysplasias, microphthalmia, buphthalmos, glaucoma, anterior chamber dysplasias, cataracts
- Marked phenotypic overlap amongst FCMD, Walker-Warburg, and MEB

Microscopic Features

- Cortical disorganization, cerebral and cerebellar PMG
- Fibroglial proliferation of leptomeninges (→ "pebbled" surface and trapped CSF "cysts")
- Hypoplasia of white matter
- Muscle biopsy: Mild to moderate dystrophic changes, ± inflammatory infiltrate, ± absent staining laminin-α2

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Hypotonia, developmental delay, poor vision, seizures

Demographics

- Age
  - CMD with brain malformations can be diagnosed in utero via US and MR, otherwise in early infancy
  - FCMD: High percentage of spontaneous abortions
- Gender
  - M = F usually (some M > F or M < F variants)
- Ethnicity
  - FCMD most common in Japan (carrier state 1:88)
  - MEB more prevalent in Finland
  - WWS has worldwide distribution
- Epidemiology
  - 7-12 per 100,000 children in Japan; incidence elsewhere uncertain

Natural History & Prognosis

- CMD 1 (merosin [+]): Mild or nonprogressive; most can sit, some can walk; intellect usually normal
- CMD 1 (merosin [-]): More severe; intellect usually normal; some have seizures
- FCMD: Early contractures, rarely learn to walk, death < 20 years
- MEB: May survive to 20 years but spasticity and contractures
- WWS: Lethal in infancy

Treatment

- No treatment other than supportive

DIAGNOSTIC CHECKLIST

Consider

- Typical brainstem and cerebellar findings should prompt diagnosis even if eyes and supratentorial cortex radiographically normal
- PMG-like cortex with myelination defects: Look for brainstem, cerebellar, and ocular findings

Image Interpretation Pearls

- Not all Z-shaped brainstems are CMD
- Not all CMD have Z-shaped brainstems (e.g., merosin [-] CMD)
- Look for large tectum

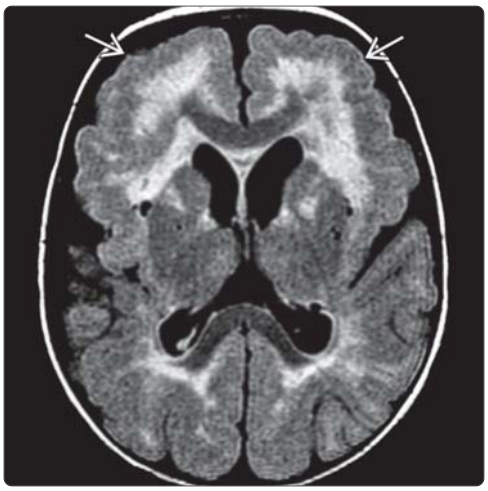
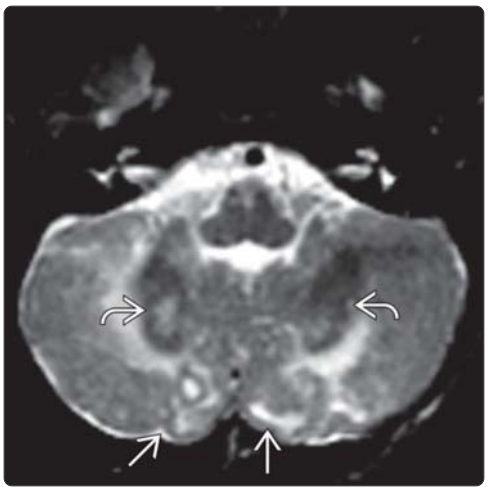
https://CafePezeshki.IR

(Left) *Sagittal T2WI (ultrafast single shot) MR in a 20-week-old fetus shows kinked brainstem, dilated 4th ventricle, and hypoplastic vermis. At GA 20 weeks, the abnormal hindbrain is the most significant diagnostic feature of WWS (confirmed postnatally).* **(Right)** *Axial T2WI (ultrafast single shot) MR shows an agyric brain; sylvian fissure at this GA should be apparent. No corpus callosum as well as ventriculomegaly without hydrocephalus are consistent with poor development of WM.*

(Left) *Axial FLAIR MR in a 9-month-old girl, whose brother has MEB, shows prominent CSF spaces and irregular sulcation. Myelination is extensively abnormal ➡ in subcortical, deep, and periventricular WM, with more normal posterior limb of the internal capsule and callosum.* **(Right)** *Sagittal T1WI MR in MEB shows grossly normal forebrain and commissural morphology. Cerebellar vermis is small with microcysts. Note the large tectum ➡ and small pons (flat ventrally ➡ and excavated dorsally ➡).*





(Left) *Axial FLAIR MR in a 1-year-old girl with FCMD shows large pericerebral spaces, mild ventriculomegaly, and abnormal myelination sparing the corpus callosum. Bilateral frontal polymicrogyria ➡ is a relatively specific finding.* **(Right)** *Axial T2WI MR in FCMD shows a cerebellar cortex that appears blurred due to polymicrogyria. Note the poor myelination of arbor vitae with prominence of dentate nuclei ➡. Multiple high T2 signal cortical microcysts ➡ are typical of FCMD.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Heterotopia (HTP)
- Arrested/disrupted migration of groups of neurons from periventricular germinal zone (GZ) to cortex

IMAGING

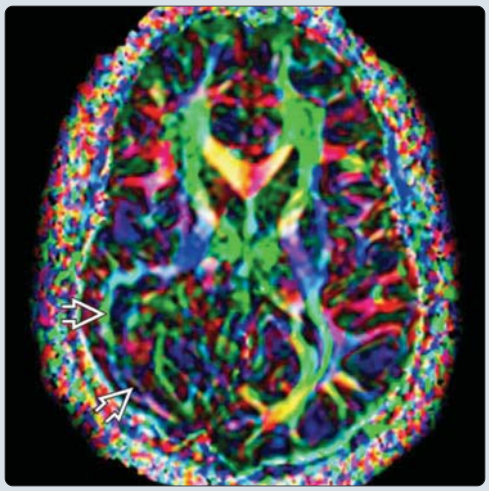
- Ectopic nodule or ribbon, isointense with gray matter (GM) on every MR sequence
- Periventricular, subcortical/transcerebral, molecular layer
- Periventricular HTP located next to periventricular white matter (WM) (GZ of cerebral mantle) but not in corpus callosum (fiber tract) or next to basal ganglia (GZ of ganglionic eminence)
- Variable: From tiny to huge, isolated to diffuse
- Thin-slice, high-definition 3D acquisition, heavily weighted T1 provides optimal contrast and definition
- Large nodular HTP: Often thinned, polymicrogyric-looking overlying cortex

TOP DIFFERENTIAL DIAGNOSES

- Tuberous sclerosis
- "Closed-lip" schizencephaly
- Tumors

PATHOLOGY

- Periventricular nodular HTP often genetic when diffuse
  - *FLNA* gene commonly involved (required for cell migration to cortex) on Xq28
- Band HTP: Mild form of type 1 (classic) lissencephaly (agyria/pachygyria/double cortex)
  - Predominantly posterior lissencephaly/band HTP: Deletion *LIS1* located on 17p13.3
  - Predominantly anterior lissencephaly/band HTP: Deletion *DCX* = double cortin on Xq22.3-q23



(Left) *Axial T2WI MR in a 6-year-old girl with refractory epilepsy shows massive right posterior subcortical heterotopia (HTP) containing cortex-like GM, white matter (WM), and CSF spaces ⇨, and blood vessels ⇨. The mass may suggest a tumor, but the hemisphere is small. Note the thin overlying cortex.* **(Right)** *Axial DTI color FA map (same patient) depicts the complete disorganization of white matter (WM) in and around nodular subcortical HTP ⇨. Red=R-L, green=A-P, blue=S-I fiber orientation. Other hues imply intermediate directions.*

(Left) *Axial 3D T2WI MR shows subcortical band heterotopia in a 12-year-old boy. The symmetric HTP lies below an intermediate layer of WM. It is thicker posteriorly, in keeping with LIS1 mutation (autosomal recessive). The overlying cortex looks essentially normal.* **(Right)** *Axial T1WI MR in the same patient coregistered with magnetoencephalography (MEG) shows that the MEG spikes (triangles) originate from HTP, yet both the HTP and overlying cortex participate in the epileptogenic loop.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Heterotopia (HTP); malformations of cortical development (MCD)

Synonyms

- Gray matter heterotopia; double cortex = band HTP

Definitions

- Heterotopias: Group of MCD characterized by presence of excessive neurons (either isolated or clustered) in subcortical white matter (WM)
  - Reflects arrested/disrupted migration of groups of neurons anywhere from periventricular germinal zone (GZ) to cortex

IMAGING

General Features

- Best diagnostic clue
  - Nodule, clump of nodules or ribbon of tissue isointense with gray matter (GM) on every MR sequence but in wrong location
- Location
  - 3 groups according to location/distribution of heterotopic neurons
    - Neuronal heterotopia (characterized by individual misplaced neurons in WM)
    - Nodular heterotopia (nodules of GM within WM)
    - Band (laminar) heterotopia (double cortex)
  - GM heterotopia can be diffuse or localized; occur anywhere from ependyma to pia
    - Diffuse: Subcortical laminar (band) heterotopia, extensive bilateral periventricular nodular heterotopia
    - Localized: Subependymal (uni- or bilateral), subcortical (nodular, laminar), or unilateral transmantle extension from subependymal region to cortex
- Size
  - Variable: From tiny to huge, isolated to diffuse
- Morphology
  - Periventricular nodular heterotopia (most common)
    - Focal/multifocal asymmetric GM indentation of ventricle
    - Diffuse vs. anterior vs. posterior
  - Band heterotopia = laminar HTP, double cortex
    - Thick symmetric subcortical GM band with thin cortex
  - Subcortical nodular heterotopia
    - Focal HTP nodules, often single
      - Large nodular HTP: Often thinned, polymicrogyria-like overlying cortex
    - Multinodular, swirling GM mass continuous both with cortex and ventricular surface; contain GM, WM, sometimes pia, vessels, and CSF
  - Associated subcortical and periventricular HTP

CT Findings

- NECT
  - Isodense with GM (extremely rare dysplastic Ca++)
- CECT
  - No enhancement

MR Findings

- T1WI
  - Imaging characteristics match GM
  - Well demarcated
- T2WI
  - Imaging characteristics match GM
  - If subcortical, look for continuity with cortex and ventricular surface
    - If large → small ipsilateral hemisphere, large ipsilateral ventricle common (poor WM development)
- FLAIR
  - GM signal
- DWI
  - DTI shows connectivity patterns

Ultrasonographic Findings

- Grayscale ultrasound
  - Fetal US and MR have documented periventricular heterotopia

Nuclear Medicine Findings

- PET
  - Band HTP: Glucose uptake ≥ normal cortex
- SPECT (HMPAO-SPECT)
  - Perfusion similar to normal cortex; HTP included in brain circuitry

Imaging Recommendations

- Best imaging tool
  - MR imaging
- Protocol advice
  - Thin-slice and high-definition 3D acquisition, heavily weighted T1 provides optimal contrast and definition

DIFFERENTIAL DIAGNOSIS

Tuberous Sclerosis

- Subependymal nodules of tuberous sclerosis bulge into ventricular lumen, along thalamocaudate groove, or over caudate
  - Often calcify; may enhance; associated with tubers, subependymal giant cell astrocytoma

"Closed-Lip" Schizencephaly

- Gray matter extending from cortex to ventricle lines cleft (look for "kissing" ventricle)
  - Transcerebral HTP may be associated with, even contralateral to, schizencephalic cleft

Tumors

- Ependymal seeding

Cytomegalovirus

- Periventricular calcifications

PATHOLOGY

General Features

- Etiology
  - Genetic: Mutations alter molecular interactions at multiple migration points → migration arrest → HTP
    - Mutation impairs neuroblast from migrating along radial glial cell to cortex

https://CafePezeshki.IR

- Acquired (rare): Toxins/infections → reactive gliosis/macrophage infiltration → disturbed neuronal migration/cortical positioning
- Genetics
  - Periventricular nodular HTP often genetic
    - *FLNA* gene commonly involved (required for cell migration to cortex) on Xq28
    - Other periventricular HTP localizing to 5p15.1, 5p15.33, 7q11.23
    - Microcephaly and nodular periventricular HTP: *ARFGEF2*
  - Band HTP is mild form of classic lissencephaly (agyria/pachygyria/double cortex)
    - Predominantly posterior lissencephaly/band HTP: Deletion *LIS1* located on 17p13.3
    - Predominantly anterior lissencephaly/band HTP: Deletion *DCX* = double cortin on Xq22.3-q23
    - Mutations of Tubulin genes and microtubule associated protein genes also cause band HTP
- Associated abnormalities
  - Associated malformations vary with location of periventricular HTP
    - Hypoplasia of corpus callosum with diffuse or anterior periventricular HTP
    - Agenesis of corpus callosum with interhemispheric cysts (e.g., Aicardi syndrome): Nodular subcortical HTP nearly always present
    - Corpus callosum dysgenesis, cerebellar and hippocampal malformations associated with trigonal and temporal periventricular HTP
- Embryology
  - Cellular migration: Cell-cycle control, cell-cell adhesion, growth factor, neurotransmitter release, interaction with matrix proteins
    - Pyramidal cell progenitors produced in subventricular GZ (mantle) migrate toward surface, guided by radial glia
    - Stop-signal from Cajal-Retzius cells in molecular layer (future cortical layer 1)
    - Inside-out process: Younger neurons more superficial
    - Migration essentially finished by week 20
  - Abnormal migration
    - → GZ (periventricular HTP), → mantle but below cortex (subcortical HTP), → molecular layer, beyond pia → meninges (leptomeningeal HTP = "cobblestone" brain)

Staging, Grading, & Classification

- Classification by location, type, and size; phenotype may predict genotype
  - Periventricular nodular HTP
    - Isolated, multiple, diffuse/anterior/posterior, uni-/bilateral
  - Band HTP (laminar HTP, double cortex) part of lissencephaly type 1
    - Lesser form of agyria, agyria/pachygyria spectrum
  - Leptomeningeal HTP
    - Seen in "cobblestone" brain (often with congenital muscular dystrophies)

Gross Pathologic & Surgical Features

- Variable gray matter masses

Microscopic Features

- Multiple cell types, immature/dysplastic cells
  - Excitatory exceeds inhibitory

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Cognitive function, seizure onset/severity depend on location/degree of abnormalities
- Clinical profile
  - Young child with developmental delay, seizures

Demographics

- Age
  - Severe cases present in infancy with seizure and severe motor and cognitive dysfunction
  - In milder cases, epilepsy may appear in 2nd decade and tends to become severe
- Gender
  - Males with X-linked disorders have significantly worse brain malformation and outcome
- Epidemiology
  - 17% of neonatal CNS anomalies at autopsy
  - Found in up to 40% of patients with intractable epilepsy

Natural History & Prognosis

- Variable life span dependent on extent of malformation and severity of epilepsy
- Can be incidental on imaging/autopsy

Treatment

- Palliative surgery reserved for intractable seizures

DIAGNOSTIC CHECKLIST

Consider

- Gray matter HTP common and commonly associated with other anomalies

Image Interpretation Pearls

- Gray matter HTP does not enhance or calcify
  - Extremely rare dystrophic Ca++

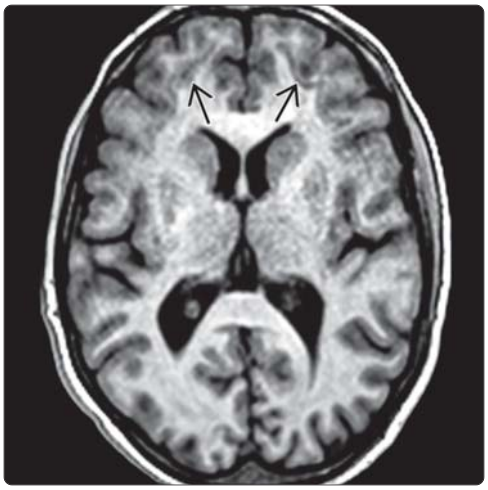
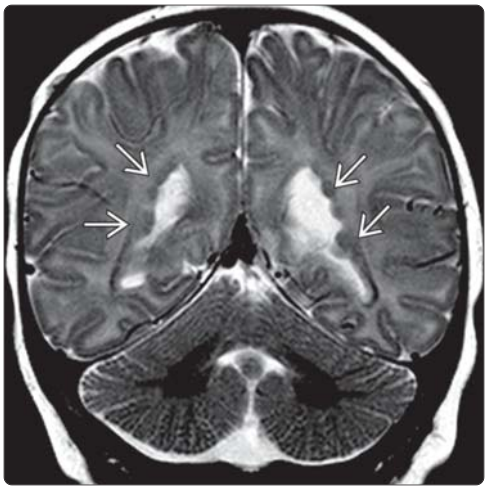
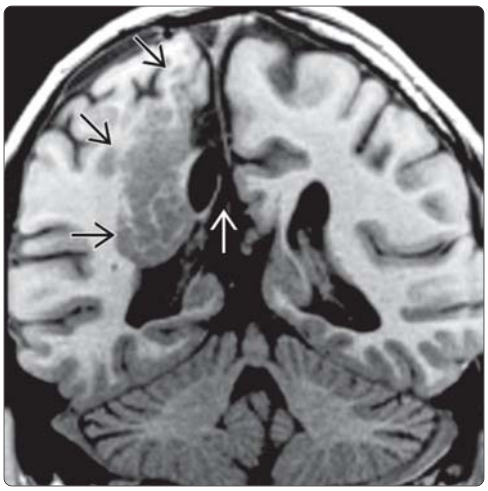
https://CafePezeshki.IR

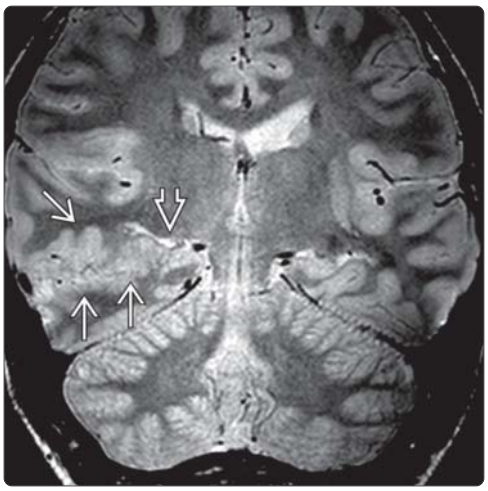


(Left) *Axial T1WI MR in a 15-year-old girl with severe epilepsy shows small, bilateral, frontal band HTP ⇨ seen under a normal-looking cortex. The anterior location of the HTP suggests a DCX gene defect.* **(Right)** *Axial T2WI MR shows a 2-year-old girl with optic atrophy disclose bilateral perisylvian polymicrogyria, absent septum pellucidum, and a single nodular periventricular HTP ➡, isointense to cortex. Heterotopia are rarely seen beneath polymicrogyria.*



(Left) *Coronal T2WI MR in a 5-month-old boy shows mild ventriculomegaly with multiple nodular periventricular HTP ➡ lining the ventricular atria. A mega cisterna magna was also present.* **(Right)** *Axial T1WI MR of a 9-year-old girl with headaches (no seizures) reveals extensive bilateral periventricular nodules, isointense to gray matter ⇨ that continuously line the lateral ventricles. Bilateral diffuse nodular periventricular HTP is often related to a FLNA mutation (Xq28).*





(Left) *Coronal T1WI MR in a 15-year-old boy with epilepsy shows ACC with interhemispheric meningeal cysts and a massive nodular subcortical HTP ⇨, located on the medial aspect of the hemisphere, adjacent to previously drained cysts ➡.* **(Right)** *Coronal T2WI MR shows surface coil in a 14-year-old boy with intractable mesial temporal epilepsy. A large nodular subcortical HTP ➡ extends to where the hippocampus should have been ➡. A normal right hippocampus cannot be identified.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Malformation due to abnormality in late neuronal migration and cortical organization
  - Neurons reach cortex but distribute abnormally, forming multiple small undulating gyri
  - Result is cortex containing multiple small sulci that often appear fused on gross pathology and imaging

IMAGING

- Excessively small and prominent convolutions
- Predilection for perisylvian regions; when bilateral, often syndromic
- Small irregular gyri, but cortex appears normal or thick on MR
- May appear as deep infolding of thick cortex
- MR comprehensively assesses malformation; NECT for suspected Ca++ (TORCH)
- Best sequence: Volume 3D SPGR (T1 weighted) in mature brain; thin-section T2WI if unmyelinated

TOP DIFFERENTIAL DIAGNOSES

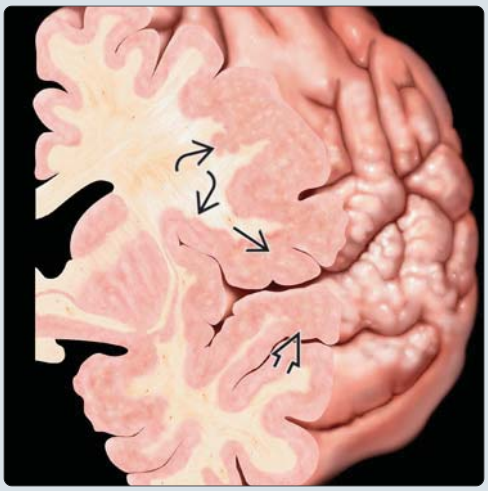
- Microcephaly with simplified gyral pattern
- Hemimegalencephaly
- Congenital cytomegalovirus
- Pachygyria
- "Cobblestone" malformations

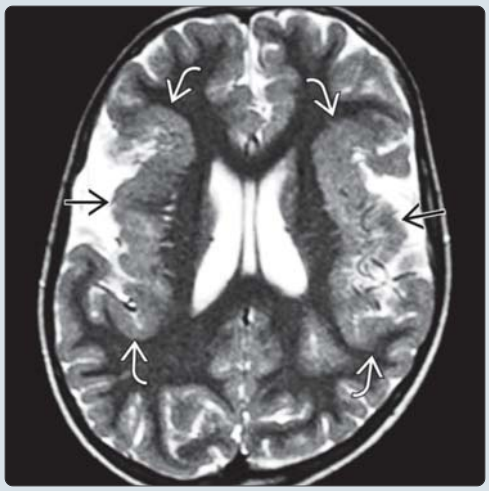
CLINICAL ISSUES

- Polymicrogyria most commonly → developmental delay, seizure
- Onset and severity of seizures, neurological deficits relate to extent of malformation, presence of associated anomalies

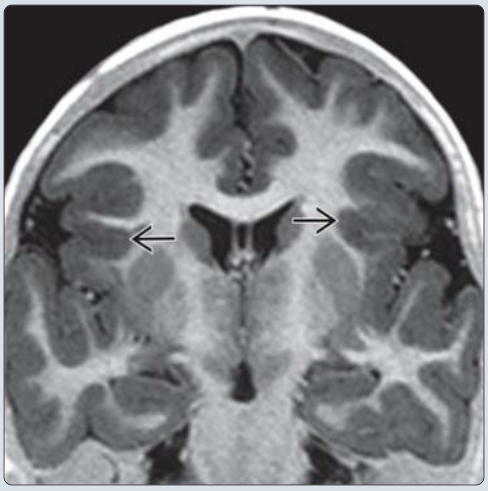
DIAGNOSTIC CHECKLIST

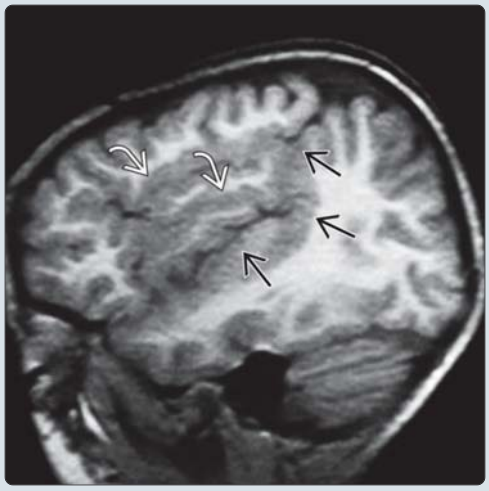
- Remember that polymicrogyria can result from injury, infection, metabolic or destructive causes
- If visual or auditory symptoms, rule out congenital infection





(Left) *Coronal oblique graphic shows the thickened pebbly gyri of polymicrogyria involving the frontal and temporal opercula. Note the abnormal sulcation and the irregular cortical-white matter junction in the affected regions.* **(Right)** *Axial T2WI MR of a patient with bilateral perisylvian polymicrogyria shows a thickened, irregular cortex in the insulae, as well as frontal and parietal opercula. Incidental cavum septi pellucidi is also seen.*





(Left) *Coronal T1WI MR of the same patient shows thickened, deeply undulating insulae and opercula around the abnormal sylvian fissures. PMG is often more poorly characterized in the coronal plane. The microgyri are not as well seen.* **(Right)** *Sagittal T1WI MR shows the characteristic continuation of the perisylvian PMG posteriorly into the superior parietal lobule, which establishes the diagnosis. Other abnormal horizontal sulci with thick, irregular cortex are present.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Polymicrogyria (PMG)

Definitions

- PMG: Heterogeneous disorder with "too many/too small" cortical gyri
  - Pathologically, clinically, radiologically, etiologically heterogeneous
- Malformation due to abnormality in both early (impaired proliferation, migration of neuroblasts) and late (disordered postmigrational cortical maturation) neuronal migration and cortical organization
  - Neurons reach cortex, but distribute abnormally, forming multiple small undulating gyri
  - Result is cortex containing multiple small sulci with fusion of molecular layer (layer 1) of cortex
    - May give false impression of several large, thick gyri

IMAGING

General Features

- Best diagnostic clue
  - Excessively small gyri and prominent convolutions
- Location
  - Can be unilateral, bilateral, multifocal
  - Predilection for perisylvian regions
  - When bilateral, often symmetric
- Size
  - Ranges from single gyrus to entire cerebrum
- Morphology
  - Small irregular gyri, but cortex looks normal or thick
  - May appear as deep infolding of thick cortex

CT Findings

- NECT
  - Look for altered sulcation pattern; suggests PMG
  - Excessive small convolutions difficult to detect on CT due to poor contrast resolution
  - Will detect periventricular Ca++ if secondary to cytomegalovirus (CMV)

MR Findings

- T1WI
  - Irregular cortical surface, often seen best on parasagittal images
  - May appear as arc of thick (5-7 mm) cortex with irregular cortex-white matter junction, without normal sulci
  - May appear as deep infolding of irregular, thick cortex
- T2WI
  - Polymicrogyria (2 imaging patterns)
    - < 12 months: Small, fine undulating cortex with normal thickness (3-4 mm)
    - > 18 months: Thick, bumpy cortex (6-8 mm), ± large perivascular spaces, ± cortical infolding
- STIR
  - Less useful due to poor spatial resolution
- FLAIR
  - May be difficult to see microgyri because of poor contrast between cortex and white matter
  - Allows differentiation between dilated perivascular spaces (common in PMG) and abnormal myelination (suggests dystroglycanopathy/"cobblestone" malformation or prenatal infection, such as CMV)
- T2* GRE
  - Hypointense foci of periventricular Ca++ → CMV
- T1WI C+
  - Amplifies dysplastic leptomeningeal veins (when present) overlying regions of polymicrogyria
- MRV
  - Demonstrates large leptomeningeal veins overlying abnormal cortex
- MRS
  - ↓ NAA at seizure-precipitating, atrophic, &/or hypomyelinated sites

Angiographic Findings

- May see large veins in clefts of PMG

Nuclear Medicine Findings

- PET
  - Increased metabolism during ictus
  - Hypometabolic interictally

Other Modality Findings

- Fetal MR and US: Agyric cortex normal up to 26 weeks
  - Premature appearance of sulci suggests early PMG
- Prenatal MR can detect PMG and other anomalies of cortical development as early as 22 weeks

Imaging Recommendations

- Best imaging tool
  - MR comprehensively assesses malformation; NECT for suspected Ca++ (TORCH)
- Protocol advice
  - Volume 3D SPGR (T1 weighted) in mature brain; thin-section T2WI if unmyelinated

DIFFERENTIAL DIAGNOSIS

Malformations Secondary to Inborn Errors of Metabolism

- Mitochondrial and pyruvate metabolism disorders
- Zellweger syndrome: Deficiency of peroxisomes, severe hypomyelination, cortical malformations

Microcephaly With Simplified Gyral Pattern

- Disorder of stem cell proliferation, head circumference < 3 standard deviations (SDs) below mean
- Normal cortical thickness, smooth inner cortical margin, normal primary and secondary sulci

Hemimegalencephaly (HME)

- Disorder of neuronal proliferation, migration, and differentiation
- In HME, affected hemisphere is large; in unilateral PMG, affected hemisphere is small

Congenital Cytomegalovirus

- Association with neuronal migration anomalies including PMG
- If infant with brain malformations, Ca++, ventricular dilatation, cerebellar hypoplasia, evaluate for CMV

https://CafePezeshki.IR

Pachygyria

- Thicker cortex (8-10 mm), smooth gray-white matter junction

"Cobblestone" Malformations

- Associated with hypomyelination, cerebellar dysgenesis, pontine hypoplasia
- Often associated with congenital muscular dystrophy

PATHOLOGY

General Features

- Etiology
  - Causes: Intrauterine infection, ischemia, toxins, or gene mutations
    - Timing: 2nd 1/2 of 2nd trimester
- Genetics
  - Many gene mutations associated with PMG but in none is PMG sole or specific abnormality
  - Mutations of Xq28, Xq21.33-q23 (*SRPX2*),16q12.2-21, 1p36, and 22q11.2, and genetic loci on chromosomes 1p36.3, 2p16.1-p23, 4q21.21-q22.1, 6q26-q27, and 21q21.3-22.1 have been identified
  - Associated with many loci but few genes
    - Most consistent genetic defect associated with PMG: del 22q11.2
    - Bilateral frontoparietal PMG is autosomal recessive, distinct clinicoradiologic profile
- Associated abnormalities
  - Congenital bilateral perisylvian syndrome (Foix-Chavany-Marie)
  - Aicardi, Zellweger, Delleman, DiGeorge, Warburg micro syndromes

Staging, Grading, & Classification

- Polymicrogyria → unlayered or 4-layered cytoarchitecture

Gross Pathologic & Surgical Features

- Multiple small gyri that lie in haphazard orientation
- Fusion of molecular layer (cortical layer 1)
- Multiple appearances and locations
  - Unilateral: Focal, perisylvian, or hemispheric
  - Bilateral symmetrical: Perisylvian, frontal, frontoparietal, lateral parietal, medial parasagittal parietooccipital
  - Bilateral asymmetrical

Microscopic Features

- Range of histology reflecting derangement of 6-layered lamination of cortex
  - Cortical layers 4 and 5 most involved
  - Leptomeningeal embryonic vasculature overlies malformation
  - Myelination within subcortical or intracortical fibers changes cortical appearance on T2-weighted images
  - Areas of 6-layered, 4-layered, and 2-layered cortex may be found

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Polymicrogyria most commonly → developmental delay, seizure
    - Bilateral perisylvian PMG may cause faciopharyngoglossomasticatory diplegia
    - Unilateral PMG often → hemiparesis/seizures
  - When PMG is 2° to CMV infection, presentation may be congenital deafness
- Clinical profile
  - Onset and severity of seizures, neurological deficits relates to location and extent of malformation

Demographics

- Age
  - Varies with extent/location of malformation
- Gender
  - No gender preference
- Ethnicity
  - Found in all populations
- Epidemiology
  - Malformations of cortical development found in ~ 40% of children with intractable epilepsy

Natural History & Prognosis

- Variable based on severity of genetic mutation, resultant malformation, associated anomalies
- Many patients are self-sufficient, integrated into society

Treatment

- Options, risks, complications
  - Focal PMG may be resected in refractory epilepsy
  - Corpus callosotomy if bilateral or diffuse unresectable lesions

DIAGNOSTIC CHECKLIST

Consider

- Polymicrogyria always seen with schizencephaly
- Look for PMG in congenital hemiplegia with epilepsy
- When associated with macrocephaly, think of macrocephaly, PMG, polydactyly, hydrocephalus (MPPH)

Image Interpretation Pearls

- Sylvian region most common location for PMG
- Open sylvian fissures with thick cortex → polymicrogyria

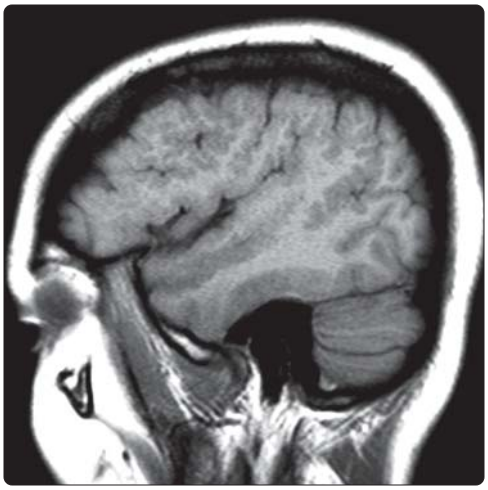
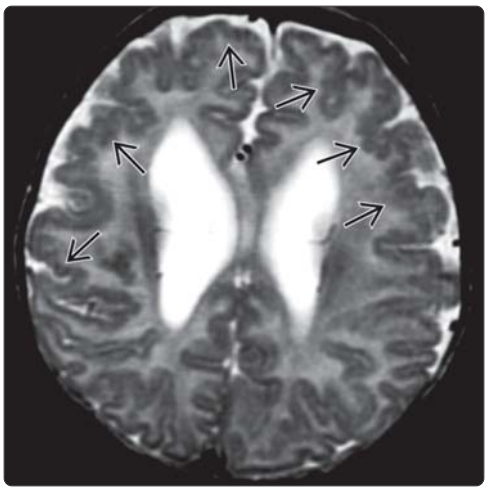
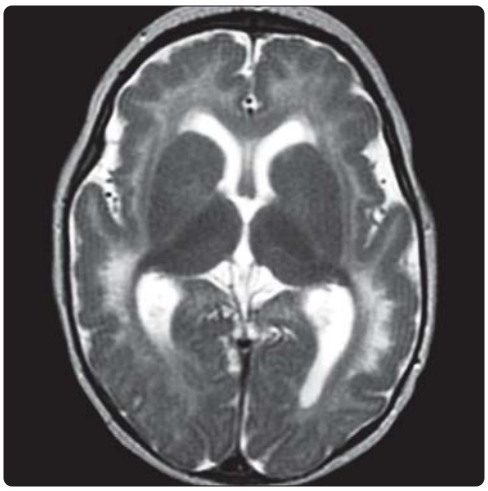
(Left) *Axial T1WI MR shows a large infolding of thickened cortex ⇨ with irregularity of the cortical-white matter junction in the posterior right frontal lobe. This is a characteristic appearance of focal polymicrogyria (PMG).* **(Right)** *Axial T2WI FSE MR shows diffuse PMG. Distinct microgyri can be seen in the individual gyri, but this particular case is also characterized by abnormally thin gyri separated by abnormally deep sulci.*



(Left) *Axial proton density MR in an asymptomatic adult shows multiple, small delicate gyri ⇨ in the posterior left frontal and parietal lobes. Compare with the coarse appearance of the prior image. PMG can have a spectrum of appearances on MR.* **(Right)** *Sagittal T1WI MR in the same patient shows the extent of the PMG involving most of the frontal and parietal lobes, as well as the superior temporal lobe. Most hemispheric PMG is centered in the sylvian fissure region.*





(Left) *Axial T2WI MR of a patient with bilateral frontal PMG shows multiple tiny irregularities ⇨ at the junction of the cortex and white matter throughout the frontal lobes. Volume of frontal white matter is diminished, and the frontal horns are large.* **(Right)** *Axial T2WI MR shows a patient with congenital CMV infection. PMG is present throughout much of the lateral frontal and temporal lobes with abnormally hyperintense underlying white matter.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Disorders of cortical formation caused by arrested neuronal migration, resulting in thick 4-layer cortex and smooth brain surface

IMAGING

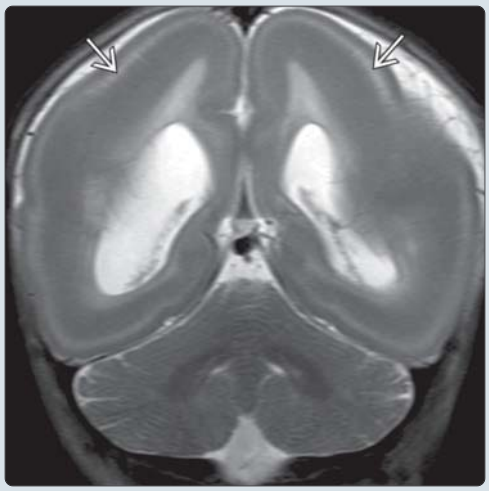
- Hourglass or figure 8 shape of cerebral hemispheres
- Truncated arborization of white matter
- 3 layers may be distinguished on T2WI in neonate
  - Outer cellular layer → may be relatively thin, smooth
  - Intervening cell-sparse layer
  - Deeper, thick layer of arrested neurons mimicking band heterotopia
- Posterior > anterior brain involvement in *LIS1*

TOP DIFFERENTIAL DIAGNOSES

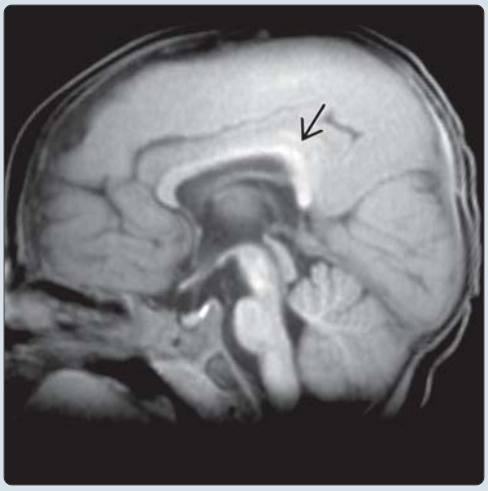
- Band heterotopia (BH)
  - Significant overlap (considered mildest end of lissencephaly spectrum)
  - Overwhelmingly female, associated with *DCX* gene mutations
  - Outer cortical layer in BH has relatively normal sulcation and thickness
- Microcephaly with simplified gyral pattern
- "Cobblestone" lissencephalies (type 2 lissencephaly)
  - Congenital muscular dystrophies
- Immature brain

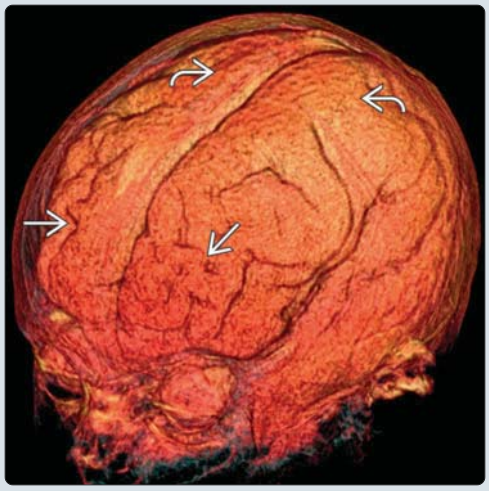
PATHOLOGY

- Caused by variety of gene alterations, resulting in spectrum of phenotypes
- *LIS1* gene → 17p13.3
  - Miller-Dieker syndrome
- *DCX* gene → Xq22.3-q23
- *RELN* gene → 7q22
  - Norman-Roberts syndrome
- *ARX* gene → Xp21.1
- *TUBA1A* gene → 12q12-q14.3



(Left) *Axial NECT scan in a child with type 1 lissencephaly shows shallow sylvian fissures ⇨ with thick, smooth cortex ⇨ showing virtually complete absence of sulci. Note the relative paucity of white matter.* **(Right)** *Coronal T2WI MR in another case of lissencephaly shows complete absence of cerebral sulcation, but the cerebellum is unaffected. A hyperintense cell-sparse zone ⇨ separates the thin cortical ribbon from the thicker band of disorganized neurons, which is in turn separated from the ventricles by white matter.*





(Left) *Midline sagittal T1WI MR clearly shows relatively normal sulcation at frontal and occipital poles, with fewer sulci in between. Note the characteristic 90° angle ⇨ between the callosal body and splenium.* **(Right)** *Anterosuperior perspective of a volume-rendered surface-shaded reconstruction in the same infant shows the relative preservation of sulcation anteriorly ⇨ with many fewer cortical sulci over the vertex further posteriorly ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Lissencephaly (LIS)

Synonyms

- Classical LIS, type 1 LIS, pachygyria-agyria complex, X-linked LIS

Definitions

- Disorders of cortical formation caused by arrested neuronal migration, resulting in thick 4-layer cortex and smooth brain surface
- Significant overlap with band heterotopia (BH)
  - BH → overwhelmingly female, associated with *DCX* gene mutations
    - Considered mildest end of lissencephaly spectrum
  - Outer cortical layer in BH has relatively normal sulcation and thickness

IMAGING

General Features

- Best diagnostic clue
  - Absence or diminished number of cortical sulci throughout cerebral hemispheres with thick cortex
  - Hourglass or figure 8 shape of cerebral hemispheres
- Location
  - Cerebral hemispheres
- Size
  - Normocephalic to microcephalic

CT Findings

- NECT
  - Thick band of disorganized neurons often appears better defined than gray matter in normal infants
  - May see small midline calcifications in Miller-Dieker syndrome
  - May see periventricular calcifications in CMV-associated lissencephaly
- CECT
  - Large vessels in sylvian fissures

MR Findings

- T1WI
  - Small number of shallow sulci with broad intervening gyri
    - Smooth cortical surface
  - Mildly to moderately enlarged ventricles
  - Truncated arborization of white matter
  - Thick deep band of gray matter may resemble myelinated white matter
  - Small cerebellum and corpus callosum, absence of anterior limb of internal capsule in LIS associated with tubulin mutations
- T2WI
  - Best sequence for distinction of cortical layers in neonate
    - 3 layers may be distinguished
      - Outer cellular layer may be relatively thin, smooth
      - Intervening cell-sparse layer
      - Deeper thick layer of arrested neurons mimicking band heterotopia
  - Prominent vessels in shallow sylvian fissures
- T2* GRE
  - Midline calcification in Miller-Dieker
  - Periventricular and subcortical white matter calcifications in CMV-related lissencephaly
- MRS
  - ↓ N-acetylaspartate (NAA) in affected cortex

Ultrasonographic Findings

- Grayscale ultrasound
  - Late intrauterine documentation possible

Nuclear Medicine Findings

- PET
  - Inner cellular layer has higher glucose utilization than outer layer (fetal pattern)

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Utilize T2WI for best distinction of cortical layers in neonate
  - Multiplanar reconstructed volume T1WI ideal in child with completed myelination
  - Surface-shaded volume rendering may provide unique perspective on undersulcation for clinicians

DIFFERENTIAL DIAGNOSIS

Band Heterotopia

- Double cortex
  - Band of smooth gray matter separated from cortex by layer of normal-appearing white matter (WM)
    - Overlying cortex has shallow sulci
- Complete or partial
- Overwhelmingly female

Microcephaly With Simplified Gyral Pattern

- Head circumference ≤ 3 standard deviations below normal
- Too few gyri and abnormally shallow sulci
- No tertiary sulci

"Cobblestone" Lissencephalies (Formerly Type 2 Lissencephaly, LIS2)

- Congenital muscular dystrophies
  - Fukuyama congenital muscular dystrophy, Walker-Warburg syndrome, muscle-eye-brain disease
- "Pebbly" surface of brain, cerebellar and ocular abnormalities, congenital muscular dystrophy

Immature Brain

- Sulci do not fully develop until ~ 40 weeks gestation

PATHOLOGY

General Features

- Etiology
  - Genetic or acquired
    - Mutations of genes encoding for proteins required for normal neuronal migration
    - CMV-infected cells can fail to migrate or arrest
- Genetics

https://CafePezeshki.IR

- Caused by variety of gene alterations, resulting in spectrum of phenotypes
  - *LIS1* gene → 17p13.3
    - Regulates microtubule motor protein cytoplasmic dynein
    - Defects lead to parietooccipital agyria, classical lissencephaly
  - *DCX* gene → Xq22.3-q23
    - Encodes for doublecortin (microtubule-binding) and stabilizing protein
    - Mutation in males leads to frontal agyria
    - Mutation in females leads to band heterotopia
  - *RELN* gene → 7q22
    - Encodes for reelin, extracellular matrix protein that regulates neuronal migration and synaptic plasticity
    - Mutations lead to Norman-Roberts syndrome → small cerebellum, hypoplastic brainstem, mild decrease of cortical sulci gyri
  - *ARX* gene → Xp21.1
    - Homeobox-containing gene
    - Mutations lead to frontal pachygyria, parietooccipital agyria, agenesis of corpus callosum, and ambiguous genitalia
  - *TUBA1A* gene → 12q12-q14.3
    - Encodes for microtubule constituent proteins
    - Mutations lead to perisylvian pachygyria, posterior pachygyria, dysgenetic internal capsule, cerebellar hypoplasia
- Associated abnormalities
  - Miller-Dieker syndrome
    - Cardiac, GI, and renal anomalies
    - Characteristic facial features → prominent forehead, upturned nares, thickened upper lip, hypertelorism, low ears, small jaw
  - Norman-Roberts syndrome
    - Low sloping forehead, prominent nasal bridge

Microscopic Features

- 4-layer cortex (*LIS1* and *DCX*)
  - Superficial molecular or marginal layer
  - Thin outer cortical layer of neurons (large, abnormal position)
  - "Cell-sparse" WM zone
  - Thick deep cortical layer of neurons (lack orderly arrangement)
- Hypoplastic corticospinal tracts

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Developmental delay and seizures
- Clinical profile
  - Global developmental delay and seizures
    - Severe and diffuse involvement → diagnosis in infancy
    - Limited involvement, diagnosed in later childhood
  - Females with BH may be minimally symptomatic, mild seizures only
  - Microcephaly in *ARX*, *RELN*, and *TUBA1A* associated with LIS

Demographics

- Age
  - Usually diagnosed early in life
  - Mild/partial cases may have delayed presentation
  - BH may be asymptomatic
- Gender
  - *DCX* gene mutations
    - Mothers → band heterotopia
      - BH > 90% female
    - Sons → lissencephaly
- Epidemiology
  - 1-4:100,000 live births

Natural History & Prognosis

- Significant mental retardation, motor deficits, seizures, early demise
- Exception, with focal subcortical BH, patients often lead normal life

Treatment

- Supportive

DIAGNOSTIC CHECKLIST

Consider

- Patterns of gyral abnormalities may provide insight into genetic defect

Image Interpretation Pearls

- When suspecting lissencephaly in neonate, verify gestational age
  - Especially important in assessing fetal MR or US
    - Agyric (smooth) cortex is normal up to 26 weeks
  - Look for specific signs on fetal studies
    - Presence or absence of parietooccipital fissure; poor development of sylvian fissure

Reporting Tips

- Be very hesitant to use term "band heterotopia" in males
- Describe regions of involvement to help in clinical management, classification
- "Pachygyria" is useful as descriptive term, not as diagnostic label
- Associated findings (corpus callosum, cerebellum, internal capsule) aid in finding genetic syndrome

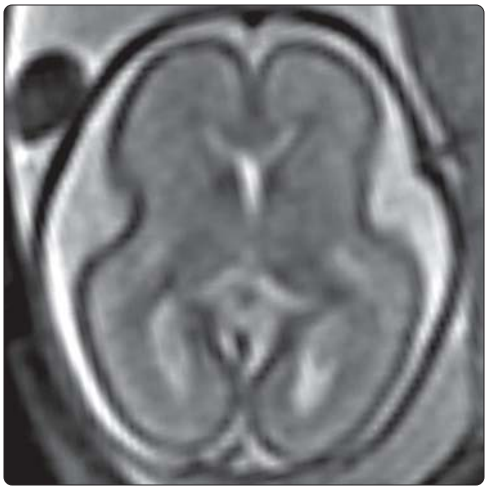
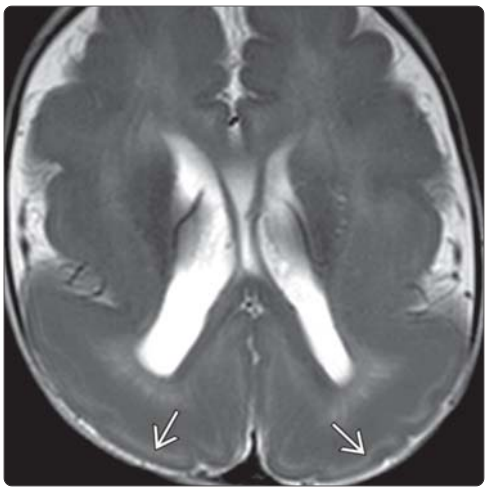
https://CafePezeshki.IR

(Left) *Sagittal T1WI MR shows a smooth and featureless cortex in the supratentorial brain with a normal cerebellum and brainstem in this infant with the Miller-Dieker syndrome caused by larger deletions of the LIS1 gene.* **(Right)** *Axial NECT in another child with classic lissencephaly shows the lack of arborization of the otherwise clearly delineated white matter. Note the subtle low attenuation of the cell-sparse zone ➔ in the right occipital pole.*



(Left) *Axial T2WI from a fetal MR exam at 22 weeks gestation shows an hourglass configuration of the cerebrum reminiscent of type 1 lissencephaly. However, this is normal at 22 weeks gestational age.* **(Right)** *Axial T1WI MR in another neonate with lissencephaly shows narrower but equally shallow sylvian fissures compared to the fetal MR. The slightly hyperintense signal deep to the cortex ➔ represents the deep zone of disorganized neurons.*



(Left) *Sagittal T2WI MR clearly shows the frontal predominance of pachygyria in this child with lissencephaly. The frontal pattern is characteristically seen in cases caused by mutations of the DCX gene.* **(Right)** *Axial T2WI MR in another child shows parietooccipital predominance of pachygyria, a pattern seen with TUBA1A and LIS1 gene mutations. Bright signal can be seen in the cell-sparse zone ➔ between the thick subcortical band of disorganized neurons and thin superficial cortex.*

https://CafePezeshki.IR

KEY FACTS

IMAGING

- Transmantle gray matter (GM) lining clefts
  - Look for dimple in wall of ventricle if cleft is narrow/closed
- Up to 1/2 of schizencephalies are bilateral
  - When bilateral, 60% are open-lipped on both sides
- Gray matter lining clefts may appear hyperdense
- Ca++ when associated with CMV or *COL4A1* mutations
- Prior to myelination T2WI more clearly defines lesion

TOP DIFFERENTIAL DIAGNOSES

- Encephaloclastic porencephaly
  - Lined by gliotic white matter (WM), not dysplastic GM
- Hydranencephaly
  - Residual tissue is supplied by posterior circulation
- Semilobar holoprosencephaly
  - Can mimic bilateral open-lip schizencephaly

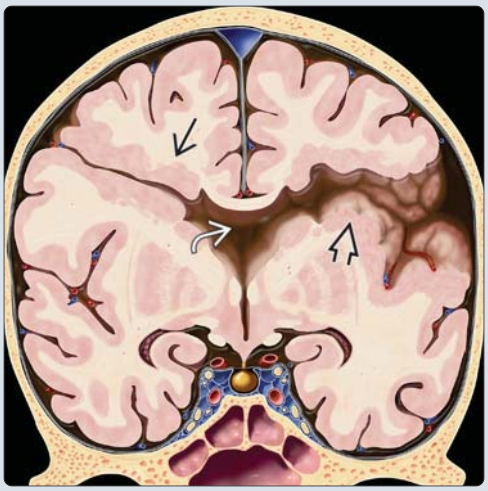
PATHOLOGY

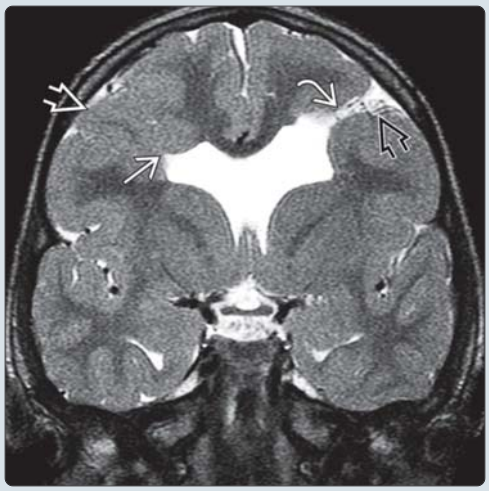
- Can be result of acquired in utero insult affecting neuronal migration
- 1/3 of children with schizencephaly have non-CNS abnormalities
- Infection (CMV), vascular insult, maternal trauma, toxin

CLINICAL ISSUES

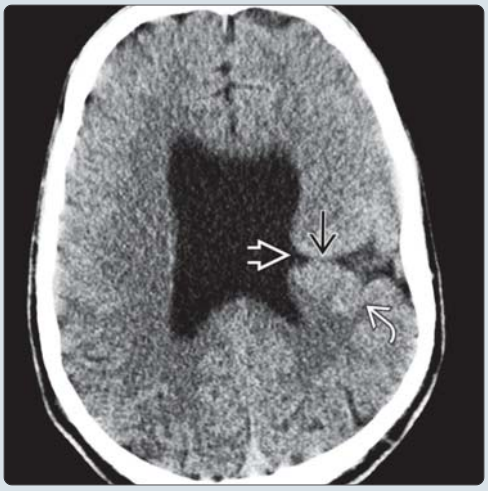
- Unilateral: Seizures or mild motor deficit
- Bilateral: Developmental delay, paresis, microcephaly, spasticity
- Seizure more common with unilateral clefts
- Size of clefts and presence of associated malformative lesions govern severity of impairment

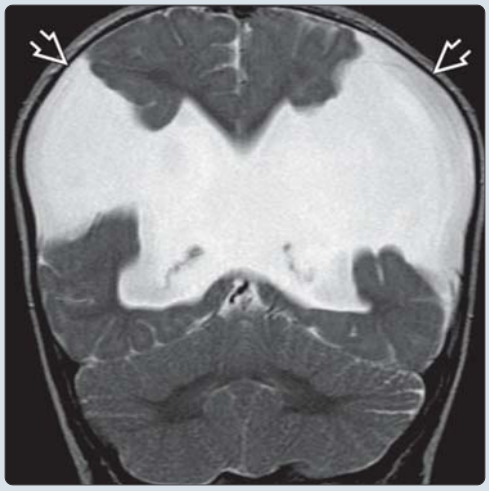
(Left) *Coronal graphic shows right closed-lip ⇨ and left open-lip ⇨ schizencephaly, both lined by gray matter. Note absence of septum pellucidum ⇨.* **(Right)** *Coronal T2FS MR shows bilateral schizencephaly. A closed-lip defect is seen on the right ⇨, extending from the pial surface to the ventricular outpouching ⇨, while a mildly open lip defect lined with dysplastic gray matter is present on the left ⇨. Note the abnormal vessels in the left-sided schizencephalic cleft ⇨.*





(Left) *Axial NECT in a 19-year-old male in the ER for trauma shows a "nipple" or outpouching of the left lateral ventricle ⇨ that extends into a full-thickness CSF cleft ⇨. The cleft is lined with heterotopic gray matter ⇨. This is a classic unilateral schizencephaly.* **(Right)** *Coronal T2WI shows large bilateral open-lip schizencephalic clefts ⇨.*





https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Agenetic porencephaly

Definitions

- Clefts in brain parenchyma that extend from cortical surface to ventricle (pia to ependyma), lined by dysplastic gray matter (GM)

IMAGING

General Features

- Best diagnostic clue
  - Transmantle gray matter lining clefts
    - Look for dimple in wall of ventricle if cleft is narrow/closed
- Location
  - Frontal and parietal lobes near central sulcus
- Size
  - Closed-lip (small defect) or open-lip (large defect)
- Morphology
  - Up to 1/2 of schizencephalies are bilateral
    - When bilateral, 60% are open-lipped on both sides

CT Findings

- NECT
  - Cleft of CSF density (in open-lip schizencephaly)
  - GM lining clefts may appear hyperdense
  - Dimple on lateral wall of lateral ventricle indicating ependymal margin of cleft
  - Ca++ when associated with cytomegalovirus (CMV)
  - Thinning and expansion of calvaria can be seen with large open-lipped clefts
- CECT
  - Large, primitive-appearing veins near cleft

MR Findings

- T1WI
  - Distinction of GM lining cleft can be difficult prior to myelination
  - Closed-lip → irregular tract of GM extending from cortical surface to ventricle
    - Lining GM can appear dysplastic → lumpy/bumpy on margin of cleft or at gray-white interface
  - Open lip → can be wide and wedge-shaped or with nearly parallel walls
    - GM lining cleft may be harder to discern than in closed-lip
- T2WI
  - Infolding of gray matter along transmantle clefts
    - Prior to myelination T2WI more clearly defines lesion
- FLAIR
  - Gliotic foci present in later insults
- T2* GRE
  - May show Ca++ when associated with CMV
- MRV
  - Developmental venous anomalies (DVAs) overlying cleft
- 3D surface rendered MR
  - Clearly shows relationship of adjacent gyri/sulci to cleft in cerebral mantle
- fMR: Functional reorganization of undamaged hemisphere reported

Ultrasonographic Findings

- Grayscale ultrasound
  - Diagnosable by fetal ultrasound and fetal MR; progressive changes have been reported

Nuclear Medicine Findings

- PET
  - Normal or ↑ glucose metabolism and perfusion of wall of cleft (normal gray matter activity)

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - < 9 months → rely on T2WI
  - > 9 months → rely on T1WI
  - Volumetric acquisitions that allow multiplanar reformatting and surface rendering

DIFFERENTIAL DIAGNOSIS

Encephaloclastic Porencephaly

- Cleft in brain due to insult after migration complete
- Lined by gliotic white matter (WM), not dysplastic GM

Hydranencephaly

- Destruction of tissue in middle and anterior cerebral artery territory
  - Residual tissue is supplied by posterior circulation → posterior fossa, occipital poles, medial temporal lobes
- Severe schizencephaly with hydrocephalus can strongly mimic; may be a continuum

Semilobar Holoprosencephaly

- Can mimic bilateral open-lip schizencephaly

PATHOLOGY

General Features

- Etiology
  - Can be result of acquired in utero insult affecting germinal zone prior to neuronal migration
    - Infection (CMV), vascular insult, maternal trauma, toxin
    - Reported with alloimmune thrombocytopenia
    - Experimental schizencephaly induced by mumps virus
- Genetics
  - Mutations of *COL4A1*, *COL4A2* have been associated with schizencephaly
    - Expressed in the basement membrane of blood vessels in many organs
    - Mutations are associated with small vessel disease affecting multiple organs
    - Weakness in vessel walls 2° to mutation may result in prenatal, perinatal, or postnatal hemorrhages
- Associated abnormalities
  - Septooptic dysplasia (SOD), de Morsier syndrome
    - Heterogeneous disorder characterized by hypoplasia of optic nerves and absent septum pellucidum
      - 45% have pituitary insufficiency

https://CafePezeshki.IR

- Schizencephaly seen in up to 35%, usually bilateral
- Septum pellucidum is absent in large percentage of schizencephaly cases, especially bilateral schizencephaly
- Frontal lobe dysplasia
- Hippocampal and callosal anomalies
- Contralateral polymicrogyria is common
- Periventricular heterotopia often seen adjacent to cleft

Staging, Grading, & Classification

- Type 1 (closed-lip)
  - 15-20%
- Type 2 (open-lip)
  - 80-85%

Gross Pathologic & Surgical Features

- Transmantle clefts with separated or apposed gray matter lining
- Thalami, corticospinal tracts may be atrophied or not formed

Microscopic Features

- Little if any glial scarring
- Loss of normal laminar architecture
- Pachygyria, polymicrogyria, or heterotopic gray matter

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Unilateral: Seizures or mild motor deficit ("congenital" hemiparesis)
  - Bilateral: Developmental delay, paresis, microcephaly, spasticity
    - Seizure more common with unilateral clefts
    - Faciopharyngoglossomasticatory diplegia
      - Automatic motility preserved, voluntary impaired
- Other signs/symptoms
  - Psychiatric disorders
  - Perisylvian syndrome
    - Pseudobulbar palsy

Demographics

- Epidemiology
  - 1.54/100,000; common with young parents, absent prenatal care
  - 1/3 of children with schizencephaly have non-CNS abnormalities
    - > 50% likely due to vascular disruption
      - Gastroschisis, bowel atresias, and amniotic band disruption sequence

Natural History & Prognosis

- Malformation is stable; development of epilepsy common
- Size of clefts and presence of associated malformative lesions govern severity of impairment

Treatment

- Treat seizures and hydrocephalus
  - Lesionectomy, hemispherectomy

DIAGNOSTIC CHECKLIST

Consider

- Image to confirm etiology of congenital hemiparesis or epilepsy
  - Perinatal stroke vs. unilateral schizencephaly

Image Interpretation Pearls

- Multiplanar imaging to avoid in-plane oversight of closed-lip clefts
  - If plane of imaging is same as plane of cleft, abnormality may be overlooked
- Contours of lateral walls of lateral ventricles should be smooth
  - Dimples may indicate subtle closed-lip schizencephaly
- Absence of septum pellucidum should prompt thorough investigation for schizencephaly &/or polymicrogyria
- Consider large bilateral open-lip schizencephaly when diagnosis is semilobar holoprosencephaly or hydranencephaly
- Clefts may by asymmetrical in size
  - Always look closely for small contralateral cleft

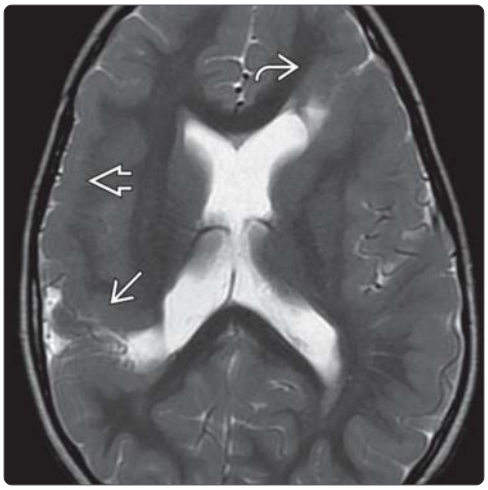
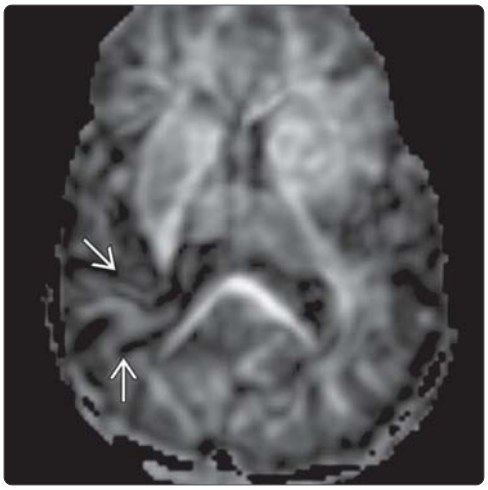
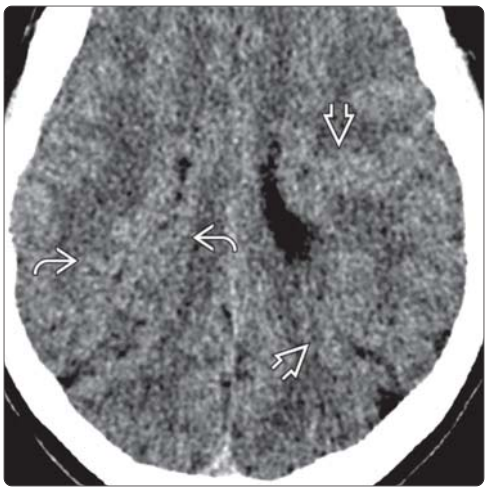
https://CafePezeshki.IR

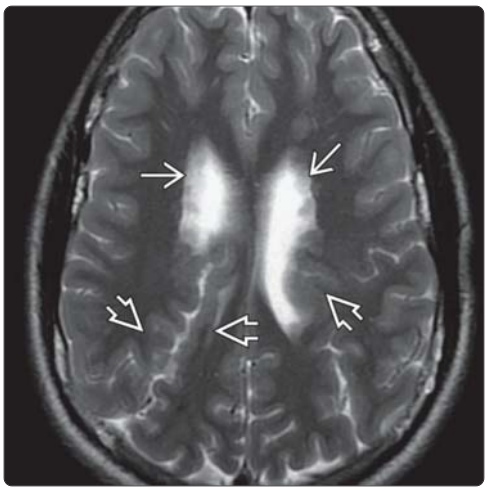




(Left) *Axial T2WI MR in a 2 year old with seizures and developmental delay shows 2 closed-lip schizencephalic clefts, 1 in the right parietal lobe ➡ and 1 in the left frontal lobe ⇨. Note the additional cortical dysplasia ➡ extending anteriorly along the frontal lobe from the right-sided cleft.* **(Right)** *Axial fractional anisotropy map from DTI in the same child shows disruption of white matter (WM) tracts at the site of the right parietal cleft ➡. This image is inferior to the WM distortion on the left.*

(Left) *Axial NECT shows a bat-wing configuration of the lateral ventricles due to bilateral large open-lipped schizencephaly. Note the dystrophic calcification bordering the right lateral ventricle wall ⇨, suggesting a history of intrauterine CMV infection as the source of this child's migrational abnormality.* **(Right)** *Axial T1WI MR in the same child shows the abnormally thick and featureless cortex lining the schizencephalic clefts ➡, as well as absence of the septum pellucidum.*





(Left) *Axial NECT in a 9 year old with seizures shows abnormal gray matter extending from the hemispheric surface to the lateral ventricle at the right frontoparietal junction ⇨. Additional regions of abnormal gray matter ➡ can be seen on the left.* **(Right)** *Axial T2WI MR in the same child shows more clearly that the thickened, irregular gray matter lines schizencephalic clefts in each hemisphere ➡. Additional foci of heterotopic gray matter ➡ can be seen in each lateral ventricle.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Hemimegalencephaly (HMEG): Hamartomatous overgrowth of hemisphere
  - Probably misnomer as < 1 whole hemisphere often involved

IMAGING

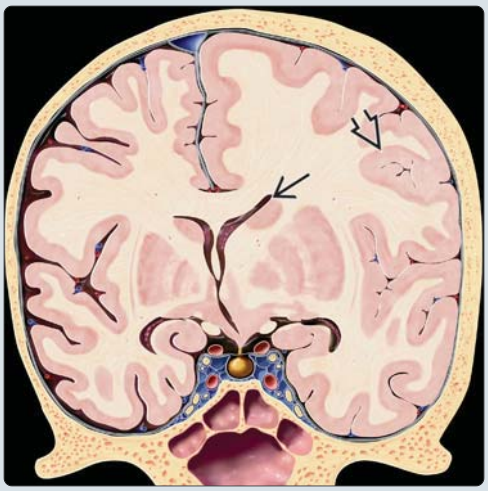
- Large cerebral hemisphere, hemicranium
  - Posterior falx and occipital pole "swing" to contralateral side
  - Lateral ventricle usually large, misshapen ("pointed" frontal horn)
- Hypertrophied WM often hyperintense on T2/FLAIR (accelerated myelination)

PATHOLOGY

- Etiology: HMEG is prototype infantile tauopathy
  - Upregulation of phosphorylated tau
  - Postzygotic somatic mosaicism (only some cells have mutations; some/many parts of brain spared)
  - Activation of mTOR signaling pathway causes overgrowth of normal/abnormal cells
  - HMEG, focal cortical dysplasia (FCD2b) may be same disorder with different timing of somatic mutation
- Gross pathology
  - Enlarged hemisphere with abnormal, thick gyri
  - GM-WM junction indistinct ("blurred")
- Microscopic features of HMEG identical to FCD2b, TSC
  - Dysmorphic and megalocytic neurons, balloon cells
  - White matter hypertrophy, hypermyelination and gliosis

CLINICAL ISSUES

- Anticonvulsants usually ineffective (mTOR inhibitors may help)
- Anatomic or functional hemispherectomy



(Left) *Coronal graphic shows overgrowth of the left cerebral hemisphere. Note the shift of midline structures, excess of white matter (WM), thick flattened/dysmorphic gyri, and abnormal ipsilateral anterior horn.* **(Right)** *Axial NECT in a 4-year-old female with intractable seizures shows enlarged right hemisphere, hemicranium, with enlarged white matter in the corona radiata, and ipsilateral corpus callosum, as well as the fornix. The falx is displaced across the midline.*

(Left) *Axial T2WI in the same patient shows the enlarged hemisphere with hyperintense WM, enlarged deformed right ventricle, and thickened dysplastic cortex.* **(Right)** *Coronal T2WI shows the right hemisphere is enlarged, with the falx displaced across the midline. The ipsilateral frontal horn is deformed and pointed. The findings are those of classic HMEG.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hemimegalencephaly (HMEG)

Synonyms

- HMEG probably misnomer as < 1 whole hemisphere often involved (so-called hemi-hemimegalencephaly)
- Dysplastic megalencephaly (generic for all forms of segmental brain overgrowth with cortical dysplasia)

Definitions

- Hamartomatous overgrowth of part/all of hemisphere
- Defect of cellular organization, neuronal migration

IMAGING

General Features

- Best diagnostic clue
  - Mild, moderate, or markedly enlarged dysplastic hemisphere or portion of hemisphere
    - Dysplastic cortex (commonly with diffuse or perisylvian polymicrogyria)
    - Abnormal white matter
  - Displaced posterior falx
  - Large lateral ventricle with abnormally shaped (pointed) frontal horn
- Location
  - Any lobe may be involved (frontal most common)
    - Infrequently involves ipsilateral cerebellum
- Size
  - Usually grossly enlarged, can be subtle
- Morphology
  - Variable, from lissencephaly to polymicrogyria

CT Findings

- NECT
  - Large cerebral hemisphere, hemicranium
  - Posterior falx and occipital pole "swing" to contralateral side
  - Lateral ventricle is large with abnormally shaped frontal horn
  - Dystrophic Ca++ of white matter (WM) or of thickened cortex
- CECT
  - Large vessels common

MR Findings

- T1WI
  - Thickened cortex
  - Frequently increased WM signal
    - "Accelerated myelination" → mineralization; disorganized heterotopic neurons cause T1 shortening
  - Neuronal heterotopias: Subpial, subcortical, or periventricular
  - Lateral ventricle is usually large and frontal horn is pointed
  - Uncommonly cerebellar tonsils herniate (bulky supratentorial brain tissue displaces tonsils)
- T2WI
  - Pachygyria, polymicrogyria
  - Size and signal intensity of affected hemisphere change over time
    - May atrophy and become hypointense with constant seizure activity
  - Margins between gray-white matter often blurred
    - Dysplastic neurons scattered throughout white matter
  - ± cerebellar hemiovergrowth, heterotopias
- FLAIR
  - Gliosis-like bright signal in white matter
- T2* GRE
  - Dystrophic calcifications
- DWI
  - Can show abnormal fiber tracts connecting hemispheres
    - Helpful for assessing residual connections after functional hemispherectomy
- T1WI C+
  - May have bizarre enhancement
  - Enhancement of primitive cortical veins, developmental venous anomalies
- MRS
  - With seizures, progressive ↓ NAA and ↑ creatine, choline, and myoinositol
- Magnetoencephalography (MEG)
  - Somatosensory maps predict severity of cortical lamination defects

Ultrasonographic Findings

- Grayscale ultrasound
  - Diagnosis can be made in fetus and neonate

Nuclear Medicine Findings

- PET
  - Glucose hypometabolism in 50%
- SPECT
  - Increased (during seizure) or decreased tracer uptake in affected side

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR
- Protocol advice
  - Serial imaging may be required to document full extent of abnormality
    - Abnormal regions become more apparent with myelination of normal areas
  - Abnormal signal in WM may be best indicator of extent of abnormality
  - Status of contralateral hemisphere key for clinical decision-making

DIFFERENTIAL DIAGNOSIS

Focal Cortical Dysplasia Type 2

- Small or large areas with blurring of gray-white junction
- Hyperintensity in underlying white matter; often more extensive than seen on MR

Rasmussen Encephalitis

- Unilateral encephalitis with progressive atrophy
- Almost always unilateral

https://CafePezeshki.IR

Tuberous Sclerosis (TSC)

- HME of lobe or hemisphere = occasional manifestation
- Heavy burden of tubers can mimic HME
  - Bilaterally distributed

Gliomatosis Cerebri

- Diffusely infiltrating glioma
- Rare in children
  - Multicentric glioma more common

PATHOLOGY

General Features

- Etiology
  - Abnormal proliferation, migration, and differentiation of neurons
  - Embryology
    - Impaired "stop" sign during proliferation of neurons, glia in germinal matrices
    - Results in proliferation of too many cells of all types
      - Variable patterns of overgrowth reflect somatic mosaicism in presence of mutations
- Genetics
  - HMEG is prototype infantile tauopathy
    - Neuropathologic tetrad
      - Dysmorphic and megalocytic neurons
      - Activation of mTOR signaling pathway (causes overgrowth of normal/abnormal cells)
      - Postzygotic somatic mosaicism (only some cells have mutations; some/many parts of brain spared)
      - Upregulation of phosphorylated tau
  - HMEG and focal cortical dysplasia (FCD2b) may be same disorder with different timing of somatic mutation in mitotic cycles of neuroepithelium
    - Difference is size, extent of resulting cerebral lesions
    - FCD2b is anatomically "transmantle dysplasia," usually isolated
    - HMEG involves entire hemisphere or quadrant or major portion of telencephalon
      - Ipsilateral olfactory bulb, basal ganglia, diencephalic structures, as well as associated meninges, blood vessels, cranial nerves commonly affected
      - Ipsilateral brainstem enlargement, cerebellar enlargement/dysplasia
- Associated abnormalities
  - HMEG can be isolated or associated with neurocutaneous syndromes
    - Most common: Epidermal nevus syndromes (including Proteus)

Gross Pathologic & Surgical Features

- Large hemisphere, shallow sulci, fused and disorganized gyri
- Regional polymicrogyria, pachygyria, and heterotopias

Microscopic Features

- Microscopic features of HMEG are identical to those of TSC, FCD2a

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizures, developmental delay
  - Macrocrania
- Other signs/symptoms
  - Hemiparesis, hemihypertrophy
- Clinical profile
  - Most common = neonate/infant with severe epilepsy
  - Severe developmental delay and contralateral hemiparesis common

Demographics

- Age
  - Usually diagnosed during 1st year of life
- Epidemiology
  - ~ 3% of cortical dysplasias that are diagnosed by imaging

Natural History & Prognosis

- Intractable seizures with progressive hemiparesis
- Poor outcome → intractable seizures and developmental delay

Treatment

- Anticonvulsants usually ineffective
- mTOR inhibitor everolimus potential treatment
- Anatomic or functional hemispherectomy
  - Confirm normal contralateral hemisphere first
  - Anatomic hemispherectomy may require shunting of surgical cavity
    - Significant risk of shunt malfunctions

DIAGNOSTIC CHECKLIST

Consider

- Involved hemisphere may atrophy (from chronic seizures)

Image Interpretation Pearls

- Serial imaging shows remarkable signal transformation with myelin maturation
- Hemimegalencephaly is only condition in which increase in parenchymal volume is associated with increase in ipsilateral ventricle volume

Reporting Tips

- Goals of imaging → identify/quantify lesion, identify contralateral abnormalities

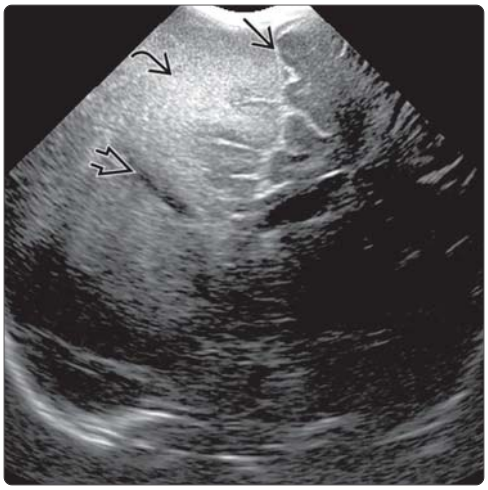
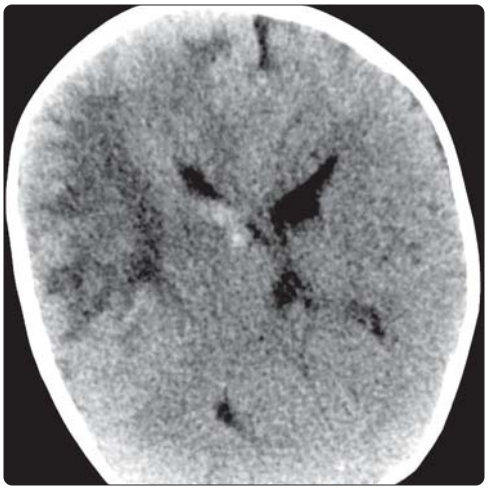
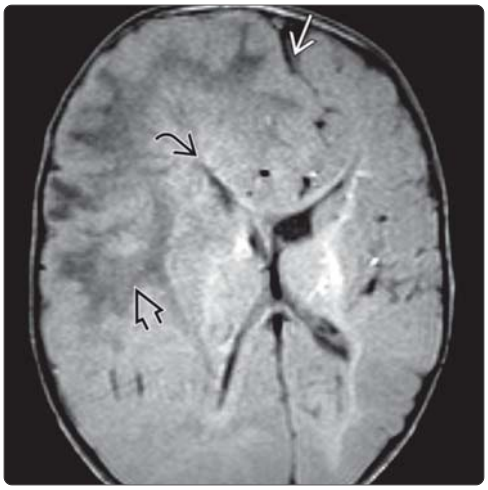
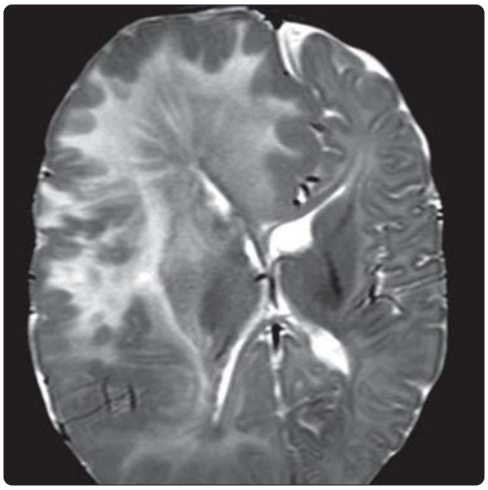
https://CafePezeshki.IR



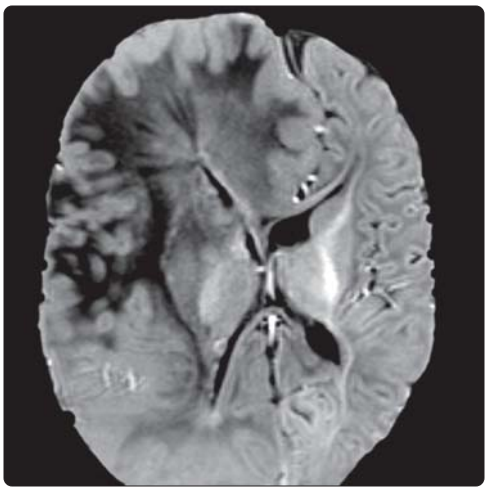


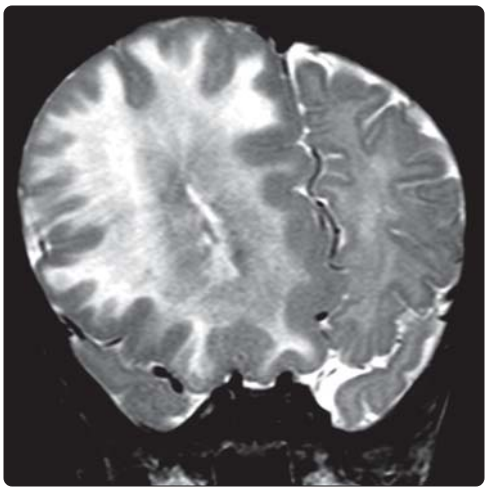
(Left) *Coronal ultrasound in a newborn with seizures shows an enlarged right hemisphere with hyperechoic WM ⇨ and an abnormally pointed right frontal horn ⇨. The interhemispheric fissure ⇨ is displaced across the midline.* **(Right)** *Axial NECT in the same patient shows the grossly enlarged right hemicranium with abnormally hypodense WM in the frontal and anterior parietal lobes.*





(Left) *Axial T1WI in the same patient shows the enlarged right hemisphere with marked displacement of the falx and interhemispheric fissure to the left ➡. The ipsilateral frontal horn is pointed ⇨ and the WM ⇨ is hypointense.* **(Right)** *T2WI in the same patient shows the WM is expanded and hyperintense compared to the normal left side. The overlying cortex appears dysplastic and the gray-white matter junction is indistinct.*





(Left) *Axial inversion recovery (IR) MR shows the cortex of the entire hemisphere is abnormal. The frontal and temporal cortex is polymicrogyric, while the parietal and occipital cortex is thickened and flattened.* **(Right)** *Coronal T2WI in the same patient emphasizes the size difference between the right and left hemispheres in this case of classic hemimegalencephaly. (Courtesy P. Rodriguez, MD.)*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Neurofibromatosis type 1 (NF1), von Recklinghausen disease, peripheral neurofibromatosis

IMAGING

- FASI on T2WI in 70-90% of preteen children
  - White matter (WM) lesions are hyperintense and typically poorly defined; no mass effect
  - WM lesions may also involve cerebellar white matter, globus pallidus, thalamus, brainstem
- Neoplasms
  - Plexiform neurofibromas
    - Sphenoid wing and occipital bone dysplasia found in association with plexiform tumors
  - Optic pathway gliomas
  - Parenchymal gliomas
- Vascular dysplasias → stenosis, moyamoya, aneurysm

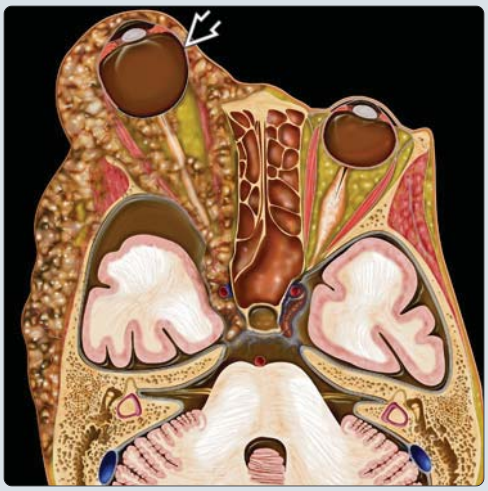
PATHOLOGY

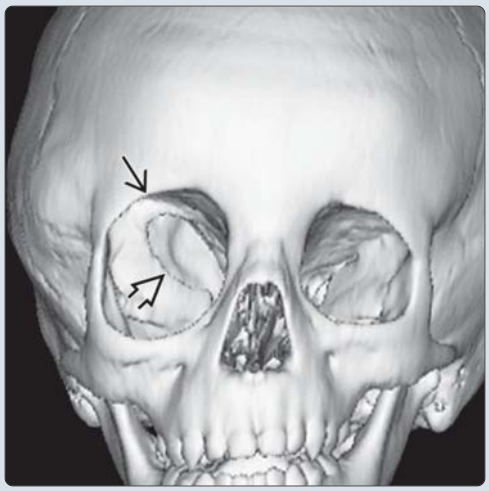
- Autosomal dominant; gene locus is chromosome 17q12
- Gene product is neurofibromin (negative regulator of RAS protooncogene)
  - Neurofibromin also regulates neuroglial progenitor function
  - Required for normal glial and neuronal development
  - Inactivated in NF-1 → tissue proliferation, tumor development
- FASIs related to (transient) intramyelinic edema

CLINICAL ISSUES

- ~ 50% have macrocephaly; in part 2° to ↑ WM volume
- OPG can cause progressive vision loss
- Café au lait spots are earliest finding
- Most common neurocutaneous and inherited tumor syndrome

(Left) *Axial graphic shows enlarged right middle cranial fossa, dysplastic sphenoid wing, and a large orbital/periorbital plexiform neurofibroma. Note the exophthalmos and buphthalmos of the involved globe.* **(Right)** *3D shaded surface display of a patient with neurofibromatosis type 1 (NF1) shows enlarged right orbit with sphenoid wing hypoplasia, markedly enlarged superior orbital fissure.*





(Left) *Axial T2FS MR in an 18-month-old child shows an extensive plexiform neurofibroma infiltrating the scalp, orbit, and extending into the cavernous sinus through the SOF. Note the bag of worms appearance.* **(Right)** *T1 C+ FS scan in the same patient shows the plexiform neurofibroma enhances strongly, mildly heterogeneously.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neurofibromatosis type 1 (NF1)

Synonyms

- von Recklinghausen disease, peripheral neurofibromatosis

Definitions

- Neurocutaneous disorder (phakomatosis) characterized by
  - Waxing/waning white matter (WM) lesions
    - Sometimes called focal areas of signal intensity (FASI), nonspecific bright foci, unidentified bright objects (UBOs)
  - Optic nerve glioma (ONG)
  - Optic pathway glioma (OPG): Chiasm/tract ± nerve
  - Other gliomas: Brainstem, cerebral hemisphere, basal ganglia
  - Neurofibromas/plexiform neurofibromas (PNF)
  - Vascular dysplasias
  - Hyperpigmented macules (café au lait spots)
  - Dysplastic skeletal lesions

IMAGING

General Features

- Best diagnostic clue
  - FASIs on T2WI in 70-90% of preteen children
  - Plexiform neurofibromas
  - Optic pathway gliomas
- Location
  - WM lesions may also involve cerebellar white matter, globus pallidus, thalamus, brainstem
  - Plexiform lesions often apparent on brain imaging
    - Scalp lesions over occiput
    - Skull base lesions extending into retropharynx
    - Orbital lesions extending from cavernous sinus through orbit into periorbital soft tissues
  - OPG in 15% → intraorbital optic nerves (ON), chiasm/hypothalamus, optic tracts; rarely into radiations
- Size
  - WM lesions: 2-20 mm
  - Chiasmatic glioma: 3-50 mm
  - Brainstem can show moderate to marked enlargement ("hamartoma")
    - Probably result of vacuolation
    - Less T1 hypointense and T2 hyperintense than brainstem glioma
    - Resolves in teen years/young adulthood
  - Plexiform lesions can be massive
- Morphology
  - WM lesions: Spherical/ovoid, often amorphous
  - ONG: Conform to and enlarge ON and chiasm; can be spherical in chiasm and hypothalamus

Radiographic Findings

- Radiography
  - Sphenoid wing and occipital bone dysplasia found in association with plexiform tumors

CT Findings

- NECT: Sphenoid dysplasia with associated enlargement of middle cranial fossa, ipsilateral proptosis
  - Enlarged optic nerve/chiasm
- CTA: Vascular dysplasias → stenosis, moyamoya, aneurysm

MR Findings

- T1WI
  - WM lesions usually isointense to surrounding tissue
    - Irregular hyperintensity may reflect myelin clumping or microcalcification
- T2WI
  - WM lesions are hyperintense and typically poorly defined; no mass effect, disappear by early 20s
    - T2WI may be more sensitive than FLAIR for WM lesions in cerebellum
  - ONG iso-/hyperintense to normal parenchyma
  - ↑ T2 signal and mild-moderate enlargement of hippocampi (uni- or bilateral)
- STIR
  - Excellent definition of plexiform/paraspinal neurofibromas
- DWI
  - ↑ ADC values in FASI compared to normal-appearing white matter (NAWM)
  - ↑ ADC values in NF NAWM compared to controls
    - Reflects accumulation of fluid within myelin sheath
  - ↓ FA in adult NF1 brains compared to healthy brains
- T1WI C+
  - WM lesions/FASI do not enhance
    - Enhancement raises concern for neoplasm
  - Plexiform lesions have variable enhancement
    - Less well defined than on STIR images
  - Visual pathway gliomas have variable enhancement
    - Significance of ↓ enhancement in response to treatment uncertain
- T1WI C+ FS
  - Best sequence for evaluation of ONG
- MRA
  - Useful in evaluation of vascular lesions
- MRS
  - Benefit in evaluation of WM lesions to distinguish from visual pathway glioma
    - WM lesions have relative preservation of NAA
    - Glioma have ↓ NAA with elevated choline

Angiographic Findings

- Most vascular lesions non-CNS, caused by vascular intimal proliferation
  - Aneurysms/AVMs, renal artery stenosis, aortic stenosis/coarctation; moyamoya

Imaging Recommendations

- Best imaging tool
  - MR
    - Benefit of routine surveillance imaging controversial
    - Coronal STIR sequences essential when imaging spine or head and neck
- Protocol advice
  - Include fat-saturated post-contrast imaging of orbits
  - Consider MRA if moyamoya suspected

https://CafePezeshki.IR

DIFFERENTIAL DIAGNOSIS

Demyelinating Disease

- Lesions of acute disseminated encephalomyelitis or multiple sclerosis mimic WM lesions of NF1

Viral Encephalitis

- Ebstein-Barr (EBV), cytomegalovirus (CMV)

Gliomatosis Cerebri

- If FASI are extensive; FASI lack mass effect

Mitochondrial Encephalopathies

- Pantothenate kinase-associated neurodegeneration (PKAN, Hallervorden-Spatz), Leigh syndrome, glutaric acidurias, Kearns-Sayre syndrome
- Often have lesions in basal ganglia or thalami that resemble WM lesions of NF1

Krabbe Disease (Globoid Cell Leukodystrophy)

- Can cause optic nerve enlargement mimicking ONG

PATHOLOGY

General Features

- Etiology
  - *G*ene product is neurofibromin (negative regulator of RAS protooncogene)
    - Inactivated in NF1 → tissue proliferation, tumor development
  - Neurofibromin also regulates neuroglial progenitor function
    - Required for normal glial and neuronal development
  - Oligodendrocyte myelin glycoprotein also embedded in *NF1* gene
- Genetics
  - AD; gene locus on chromosome 17q12
    - Penetrance = 100%
  - ~ 50% new mutations

Staging, Grading, & Classification

- 2 or more of the following fulfills diagnostic criteria for NF1
  - ≥ 6 café au lait spots measuring ≥ 15 mm in adults or 5 mm in children
  - ≥ 2 neurofibromas or 1 plexiform neurofibroma
  - Axillary/inguinal freckling
  - Visual pathway glioma
  - ≥ 2 iris hamartomas ("Lisch nodules")
  - Distinctive bony lesion (sphenoid wing dysplasia, thinning of long bone ± pseudoarthrosis)
  - 1st-degree relative with NF1

Gross Pathologic & Surgical Features

- Gliomas usually pilocytic astrocytomas
  - Frankly malignant in < 20%
- Slight ↑ incidence of medulloblastoma/ependymoma
- Rare subependymal glial nodules
  - Can result in CSF obstruction

Microscopic Features

- WM lesions (FASI)
  - Probably related to (transient) intramyelinic edema
  - No demyelination, axonal degeneration, or inflammation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Café au lait spots are earliest finding
  - ~ 50% have macrocephaly; in part 2° to ↑ WM volume
  - OPG can cause progressive vision loss

Demographics

- Epidemiology
  - Incidence is 1:3,000-5,000
  - Most common neurocutaneous syndrome
  - Most common inherited tumor syndrome

Natural History & Prognosis

- Morbidity related to specific manifestations
  - OPG → vision loss/blindness, hypothalamic dysfunction
  - Plexiform NF → risk of sarcomatous degeneration
  - Paraspinal NF → kyphoscoliosis
  - Vascular stenoses → hypertension (renal artery), stroke
- FASI increase in number/size in 1st decade of life, regress afterwards; rarely seen in adults
- NF1-related learning disability in 40-60%
- Visual pathway gliomas in NF1 often have more indolent clinical course than sporadic optic glioma

Treatment

- Clinical observation
- Chemotherapy and radiation for OPG

DIAGNOSTIC CHECKLIST

Consider

- Absence of visible stigmata does not exclude NF1
- Be aware of potential for vascular lesions

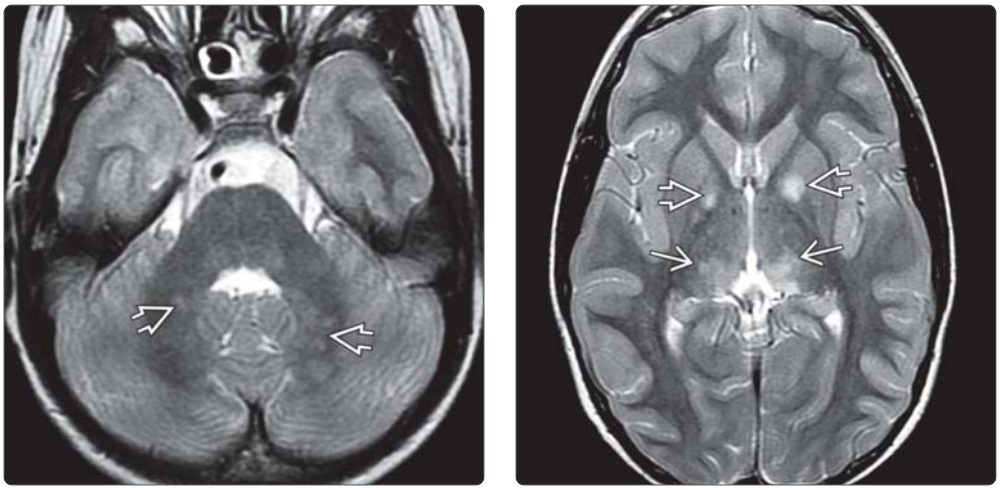
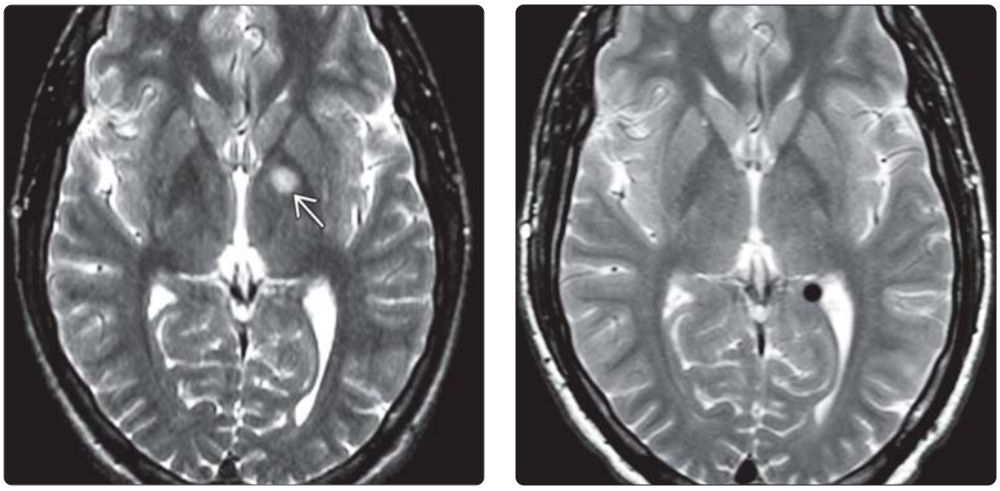
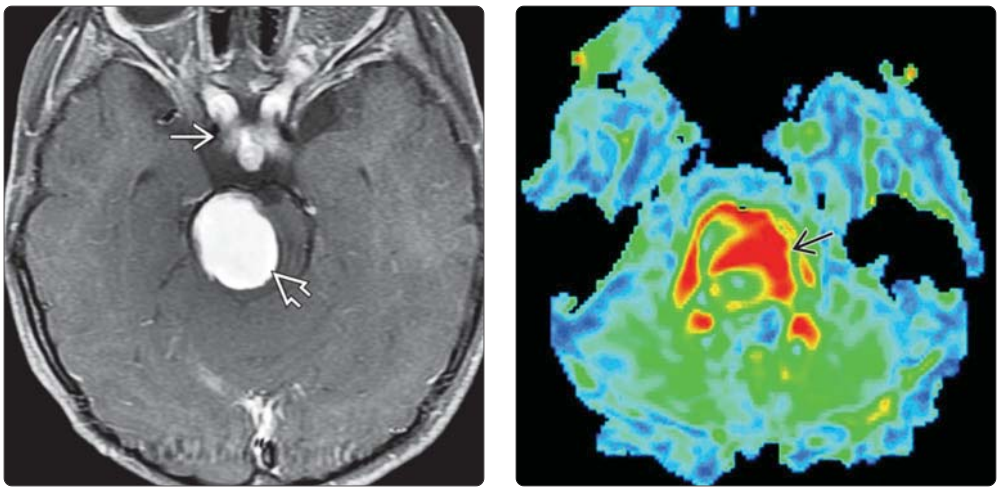
https://CafePezeshki.IR



(Left) *Axial T2WI in a 7-year-old boy with NF1 snows multiple ill-defined hyperintense foci in both cerebral peduncles* ⇨. **(Right)** *More cephalad T2WI in the same patient shows hyperintense foci in both globi pallidi* ⇨ *as well as patchy hyperintensities in both thalami* ⇨. *Six years later, all the FASIs had completely disappeared.*



(Left) *T2WI in a 13-year-old boy with NF1 shows a single hyperintense focus* ⇨ *in the left globus pallidus.* **(Right)** *In the same patient 6 years later, T2WI is normal. The focus of abnormal signal intensity (FASI) has completely disappeared.*



(Left) *Axial T1 C+ FS in a patient with NF1 shows an enhancing lesion in the pons* ⇨ *as well as enlarged, enhancing optic nerves/chiasm* ⇨. **(Right)** *Axial MR perfusion shows increased rCBV in the pons* ⇨. *The optic nerves and chiasm showed no increased rCBV. Biopsy of the pontine lesion showed pilocytic astrocytoma, WHO grade I, with no evidence for malignant degeneration. PAs are very vascular neoplasms and often exhibit a malignant-like spectrum on MRS, so don't be fooled.*

https://CafePezeshki.IR

Neurofibromatosis Type 2

KEY FACTS

TERMINOLOGY

- Familial cancer syndrome
  - Multiple cranial nerve (CN) schwannomas, meningiomas, and spinal tumors

IMAGING

- Best diagnostic clue: Bilateral vestibular schwannomas (VSs)
- Multiple extraaxial tumors
  - Schwannomas of CNs and spinal nerve roots
  - Meningiomas on dural surfaces (up to 50%)
- Intraaxial tumors
  - Ependymomas in spinal cord and brainstem (6%)
- Recommendation: Use high-resolution T1 C+ FS MR through basal cisterns to evaluate cranial nerves

TOP DIFFERENTIAL DIAGNOSES

- Schwannomatosis
- Multiple meningiomas
- Metastases

PATHOLOGY

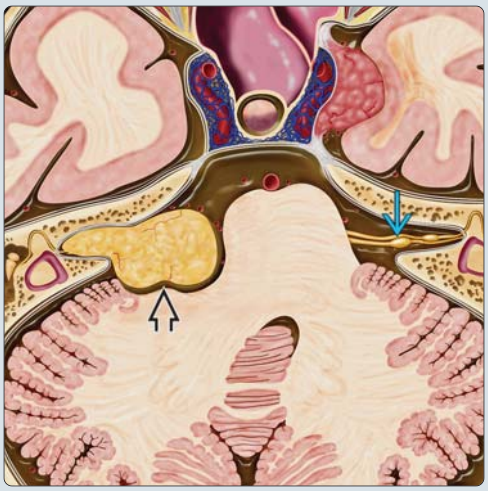
- All neurofibromatosis type 2 (NF2) families have chromosome 22q12 abnormalities
- *NF2* gene encodes for merlin protein

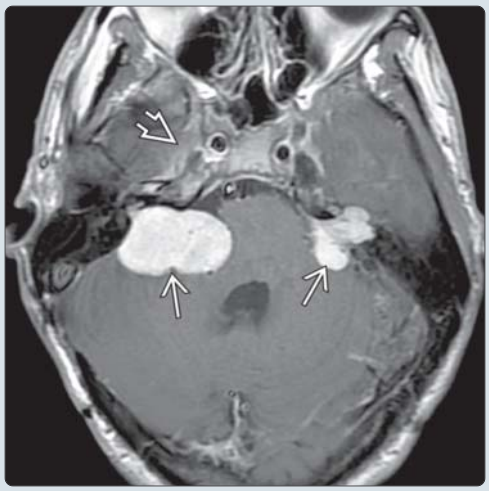
CLINICAL ISSUES

- Usually presents between 2nd and 4th decades with hearing loss, ± vertigo
- Incidence: 1:25,000-30,000
- Life span substantially shortened by presence of meningiomas and by complications related to lower cranial neuropathies (i.e., aspiration)

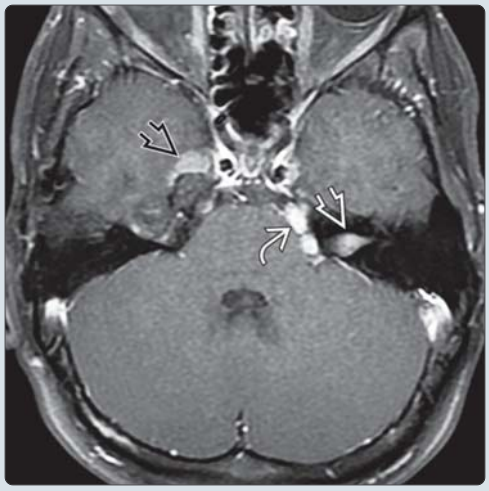
DIAGNOSTIC CHECKLIST

- Carefully evaluate other cranial nerves in any new diagnosis of schwannoma or meningioma in child/adolescent/young adult





(Left) *Axial graphic shows bilateral cerebellopontine angle (CPA) schwannomas pathognomonic of neurofibromatosis type 2 (NF2). The tumor on the right is large and several small schwannomas are seen on the left vestibulocochlear nerves.* **(Right)** *Axial T1 C+ MR in a patient with typical NF2 shows bilateral vestibular schwannomas and a right cavernous sinus meningioma.*



(Left) *Axial T2WI in a 14-year-old male with left sensorineural hearing loss shows a mass in the left internal auditory canal and another lesion in the right cavernous sinus. Note the small nodules along the right vestibular nerve.* **(Right)** *T1 C+ FS in the same patient shows the left IAC mass enhances, as does the right cavernous sinus lesion. In addition, 2 enhancing nodules are seen along the cisternal left trigeminal nerve. The patient was subsequently diagnosed with NF2.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neurofibromatosis type 2 (NF2)
- Vestibular schwannoma (VS)

Synonyms

- Acoustic neurofibromatosis, central neurofibromatosis
- Multiple intracranial schwannomas, meningiomas, and ependymomas (MISME)

Definitions

- Familial cancer syndrome causing multiple cranial nerve (CN) schwannomas, meningiomas, and spinal tumors

IMAGING

General Features

- Best diagnostic clue
  - Bilateral vestibular schwannomas
- Location
  - Multiple extraaxial tumors
    - Schwannomas of CNs and spinal nerve roots
    - Meningiomas on dural surfaces (up to 50%)
  - Intraaxial tumors
    - Ependymomas in spinal cord and brainstem (6%)
- Size
  - Cranial nerve tumors typically symptomatic while still small but can achieve great size
- Morphology
  - Tumors grow spherically but accommodate to bony canals (e.g., internal auditory canal [IAC])
- Multiplicity of lesions
  - Schwannomas of other cranial nerves in 50%
    - CN5 most common; also CN3, CN12 common
  - Schwannoma of spinal nerves (up to 90%)
  - Meningiomas (often multiple)
  - Intramedullary ependymomas (spinal cord)
  - Cerebral calcifications
  - Posterior lens opacities (juveniles, in 60-80%)
  - Meningioangiomatosis
  - Glial microhamartomas

CT Findings

- NECT
  - Vestibular schwannoma
    - Cerebellopontine angle (CPA) mass ± widened IAC
    - Isodense to hyperdense
    - Rarely cystic/necrotic
  - Meningioma
    - High-density, dural-based mass(es)
  - Nonneoplastic cerebral Ca++ (uncommon)
    - Extensive choroid plexus Ca++
    - Cortical surface
    - Ventricular lining
- CECT
  - Cranial nerve tumor enhancement
  - Meningioma enhancement

MR Findings

- T1WI
  - Schwannomas
    - Hypointense to isointense
    - Rare cystic change
  - Meningiomas
    - Isointense to hypointense
    - Occasional hyperintense foci from Ca++
- T2WI
  - Schwannomas
    - Small intracanalicular lesions can be shown on high-resolution T2WI
  - Meningiomas
    - May incite significant adjacent edema
- T2* GRE
  - Shows nonneoplastic Ca++ to best advantage
- DWI
  - Some meningiomas have restricted diffusion
    - Characteristic of atypical or malignant meningioma
- T1WI C+
  - Schwannomas
    - Diffuse enhancement
    - Usually homogeneous
    - T1 C+ with fat saturation and thin-slice profile essential for identification of small CN tumors
    - Vestibular schwannomas typically "bulge" into CPA cistern from IAC
  - Meningiomas
    - Diffuse enhancement of tumor, may be plaque like
- MRS
  - Meningioma
    - Absent NAA peak, ↑ alanine, ± lactate
  - Schwannoma
    - Absent NAA peak, ↑ myoinositol, usually no lactate

Nonvascular Interventions

- Myelography
  - Will demonstrate multiple spinal tumorlets
    - Replaced by contrast-enhanced MR

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR
- Protocol advice
  - Use high-resolution T1 C+ FS MR through basal cisterns to evaluate cranial nerves
  - Evaluation for spinal disease is critical

DIFFERENTIAL DIAGNOSIS

Schwannomatosis

- Multiple schwannomas without vestibular tumors
- No cutaneous stigmata or meningiomas

Cerebellopontine Angle (CPA) Masses

- Arachnoid cyst
  - Follows CSF on all sequences
- Epidermoid
  - DWI easily distinguishes from arachnoid cyst
- Aneurysm
  - PICA/AICA/VA aneurysms may project into CPA
  - Pulsation artifact in phase-encoding direction
- Ependymoma

https://CafePezeshki.IR

- Extends into CPA from 4th ventricle

Multiple Meningiomas

- Recurrent or metastatic
- Secondary to radiation therapy

Metastases

- CNS primary
  - Glioblastoma, PNET-MB, germinoma, ependymoma
- Non-CNS primary

Inflammatory Disease

- Granulomatous disease: Sarcoidosis, tuberculosis
- Neuritis: Bell palsy, Lyme disease

PATHOLOGY

General Features

- Etiology
  - 50% of patients have known family history of NF2; 50% new mutations
  - Mutations cause truncated, inactivated merlin protein (**m**eosin-**e**rzin-**r**axidin-**l**ike protein)
  - Tumor cells are usually hemizygous or homozygous for *NF2* mutations
- Genetics
  - Autosomal dominant
  - All NF2 families have chromosome 22q12 abnormalities
  - Germline, somatic *NF2* gene mutations
    - *NF2* gene encodes for merlin protein
    - *NF2* gene functions: Links cytoskeleton and cell membranes; also tumor suppressor gene
    - Molecular pathway mTORC1 is affected; inhibitors may inhibit tumor growth
- Multiple schwannomas, meningiomas, ependymomas

Staging, Grading, & Classification

- NF2-associated schwannomas are WHO grade I
- Diagnostic criteria
  - Bilateral vestibular schwannomas or
  - 1st-degree relative with NF2 and 1 vestibular schwannoma or
  - 1st-degree relative with NF2 and 2 of the following
    - Neurofibroma
    - Meningioma
    - Glioma
    - Schwannoma
    - Posterior subcapsular lenticular opacity

Gross Pathologic & Surgical Features

- Schwannomas are round-ovoid encapsulated masses
- Meningiomas are unencapsulated but sharply circumscribed

Microscopic Features

- NF2-related schwannomas have higher proliferative activity than sporadic tumors but not necessarily more aggressive course

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually presents between 2nd and 4th decades with hearing loss, ± vertigo
    - Caution: 25% of patients over 50 years and 50% over 70 years who have bilateral VSs at initial presentation do not have NF2 mutations (and is therefore chance occurrence)
  - 1/3 of children with NF2 present with hearing loss, 1/3 present with other cranial nerve symptoms
  - May present with meningioma before vestibular schwannomas develop
    - Children presenting with meningioma should have testing for NF2
- Other signs/symptoms
  - Scoliosis, paraplegia, or neck pain from spinal lesions
- Clinical profile
  - Wishart type: Early onset, rapid progression before adulthood, more severe presentation
  - Gardner type: Later onset, less severe manifestations

Demographics

- Epidemiology
  - 1:25,000-30,000

Natural History & Prognosis

- Life span substantially shortened by presence of meningiomas and by complications related to lower cranial neuropathies (i.e., aspiration)
- VS progression in NF2 patients not undergoing active treatment
  - 31% at 1 year; 64% at 2 years, 79% at 3 years

Treatment

- Complete resection of CN8 schwannoma if feasible
  - Can be difficult as NF2 tumors tend to splay/envelop CNs instead of displacing them
  - Stereotaxic radiosurgery option increasing
- Subtotal microsurgical resection with functional cochlear nerve preservation in last hearing ear

DIAGNOSTIC CHECKLIST

Consider

- Carefully evaluate other cranial nerves in any new diagnosis of vestibular schwannoma or meningioma in child/adolescent
- Study entire neuraxis in suspected cases (multiple small, asymptomatic schwannomas on cauda equina common)

Image Interpretation Pearls

- Coronal thin-slice T1WI C+ FS MR to assess cranial nerves

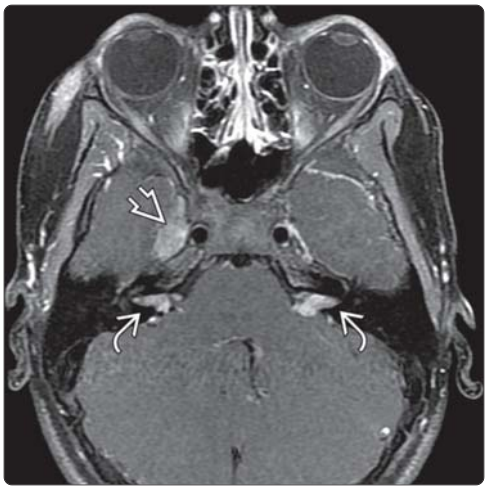
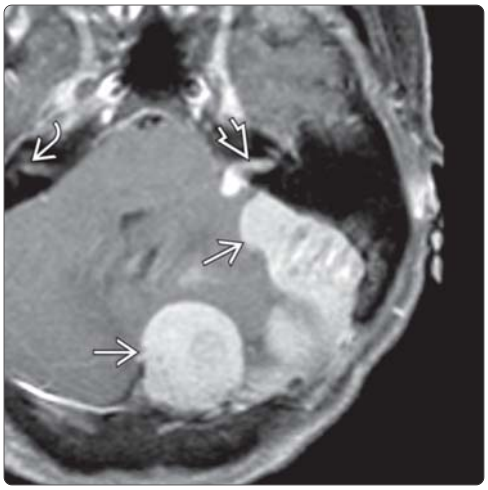
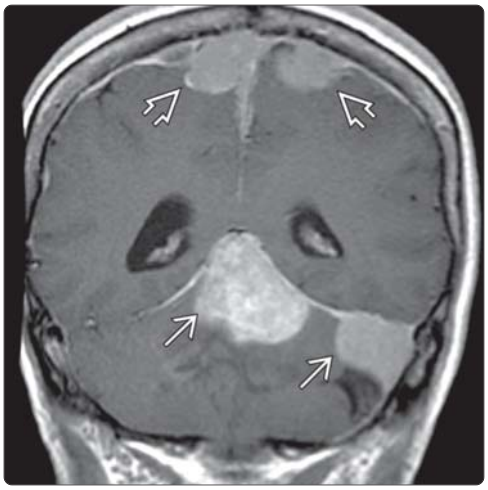
https://CafePezeshki.IR

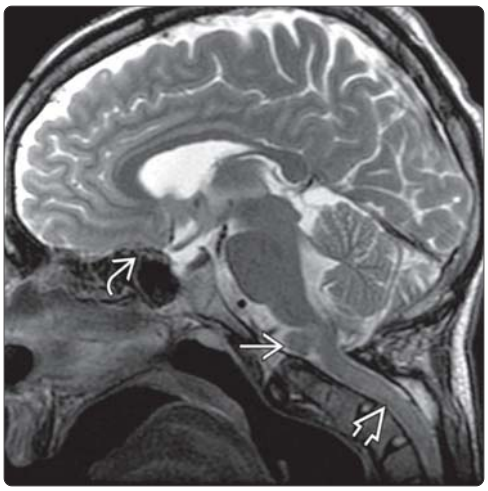


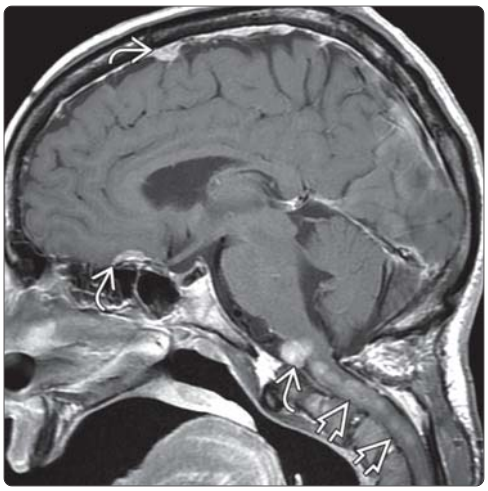
(Left) *Axial T1WI C+ FS MR of a 9 year old reveals small, enhancing vestibular schwannomas in the IAC-CPA bilaterally. An enhancing mass is also demonstrated in the right trigeminal cistern and found to be a trigeminal schwannoma.* **(Right)** *Axial T2WI FS MR in the same patient shows expansion and T2-hypointense signal in the right trigeminal cistern. The IAC/CPA masses are not well appreciated. This child was asymptomatic for these lesions.*





(Left) *Axial T1WI C+ MR of a 70-year-old woman with NF2 shows extensive meningiomatosis with dural-based masses in the posterior fossa. There is a small enhancing mass in the left IAC-CPA and a tiny, almost imperceptible one at the fundus of the right internal auditory canal.* **(Right)** *Coronal T1WI C+ MR shows the dural-based meningiomas in the posterior fossa and along the falx and convexities. In this patient, the meningiomatosis predominates over the schwannomas.*





(Left) *Sagittal T2WI FS MR of the brain and the upper cervical spine shows "blistering" of the planum sphenoidale, an extraaxial mass in front of the medulla at the foramen magnum, and an enlarged, hyperintense cervical spinal cord.* **(Right)** *Sagittal T1WI C+ MR in the same patient shows multiple enhancing meningiomas and enhancing ependymoma of the upper cervical cord. A "swan neck" deformity is noted in the upper neck from prior multilevel laminectomies.*

https://CafePezeshki.IR

von Hippel-Lindau Syndrome

KEY FACTS

TERMINOLOGY

- Autosomal dominant familial syndrome with hemangioblastomas (HGBLs), clear cell renal carcinoma, cystadenomas, pheochromocytomas

IMAGING

- 2 or more CNS HGBLs or 1 HGBL plus visceral lesion or retinal hemorrhage
- HGBLs vary from tiny mass to very large with even larger associated cysts

TOP DIFFERENTIAL DIAGNOSES

- Vascular metastasis
- Solitary hemangioblastoma
- Pilocytic astrocytoma
- Hemispheric medulloblastoma in teenager or young adult
- Multiple AVMs in vascular neurocutaneous syndrome

PATHOLOGY

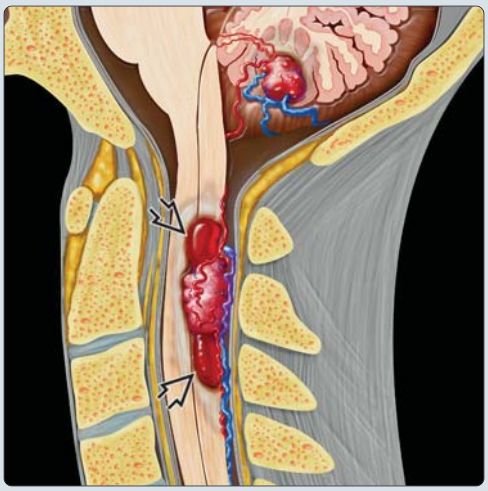
- von Hippel-Lindau (VHL) phenotypes, subtypes based on absence or presence of pheochromocytoma
  - Type 1: Low risk of pheochromocytoma
  - Type 2: High risk of pheochromocytoma
    - Type 2A (low risk of renal cell carcinoma)
    - Type 2B high risk of renal cell carcinoma)
    - Type 2C (familial pheochromocytoma without either HGBL or RCC)

CLINICAL ISSUES

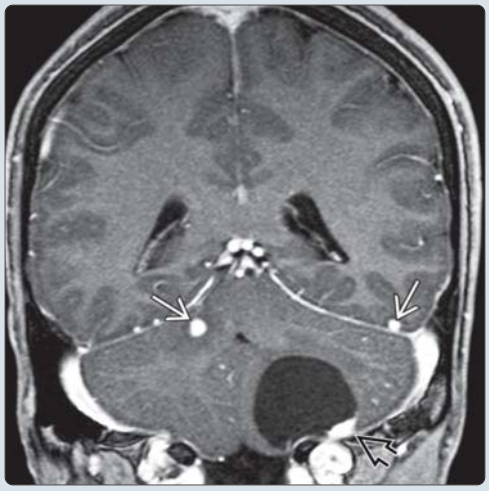
- Earliest symptom in VHL often visual
  - Retinal HGBL, peak in teenage
- HGBLs → multiple periods of tumor growth (usually associated with increasing cyst size) separated by periods of arrested growth

DIAGNOSTIC CHECKLIST

- Follow NIH screening rules



(Left) *Sagittal graphic shows 2 hemangioblastomas (HGBLs) in von Hippel-Lindau (VHL). In this patient, the spinal cord tumor has an associated cyst ⇨ and would cause myelopathy. The small cerebellar HGBL would be asymptomatic.* **(Right)** *Abdominal VHL lesions include bilateral renal cysts ⇨, carcinomas ⇨, pancreatic cysts ⇨, and adrenal pheochromocytoma ⇨.*



(Left) *Sagittal T1C+FS MR in a patient with VHL shows multiple cerebellar ⇨, spinal hemangioblastomas ⇨.* **(Right)** *Coronal T1C+FS in an asymptomatic 26-year-old male with pancreatic cysts and a family history of VHL shows 2 solid ⇨ and 1 cystic hemangioblastoma with a mural nodule ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- von Hippel-Lindau (VHL) syndrome

Definitions

- Autosomal dominant familial syndrome with hemangioblastomas (HGBLs), clear cell renal carcinoma, cystadenomas, pheochromocytomas
  - Affects 6 different organ systems, including eye, ear, and central nervous system (CNS)
  - Involved tissues often have multiple lesions
  - Lesions → benign cysts, vascular tumors, carcinomas

IMAGING

General Features

- Best diagnostic clue
  - 2 or more CNS HGBLs; or 1 HGBL plus visceral lesion or retinal hemorrhage
- Location
  - HGBLs in VHL in 60-80% of patients
    - Typically multiple
    - 40-50% in spinal cord (posterior 1/2)
    - 44-72% cerebellum (posterior > anterior 1/2)
    - 10-25% brainstem (posterior medulla)
    - HGBLs arise from pia; if lesion is in deep white matter or in center of cord, it is not HGBL
  - Ocular angiomas
    - Found in 25-60% of *VHL* gene carriers
    - Cause retinal detachment, hemorrhage
  - Endolymphatic sac tumors (ELST)
    - Large T-bone mass; located posterior to internal auditory canal near vestibular aqueduct
- Size
  - HGBLs vary from tiny mass to very large with even larger associated cysts
- Morphology
  - HGBL may be solid, solid with central necrosis, or cystic with enhancing mural nodule

CT Findings

- NECT
  - HGBL: 2/3 → well-delineated cerebellar cyst with nodule
    - Nodule typically abuts pial surface
    - 1/3 solid, without cyst
  - ELST → permeative, destructive changes in petrous bone
- CECT
  - Intense enhancement of tumor nodule

MR Findings

- T1WI
  - HGBL: Mixed iso- to hypointense nodule, ± "flow voids"
  - Associated cyst iso- to slightly hyperintense to cerebrospinal fluid (CSF)
  - Cystadenoma of ELS: Heterogeneous hyper-/hypointense
- T2WI
  - HGBL: Hyperintense nodule, cyst
  - Cystadenoma of ELS: Hyperintense mass
- FLAIR
  - HGBL: Hyperintense cyst with variable edema
  - Cystadenoma of ELS: Hyperintense mass
- T2* GRE
  - HGBL: "Blooms" if hemorrhage present
- T1WI C+
  - HGBL: Tumor nodule enhances strongly; cyst wall does not enhance
  - Tiny asymptomatic enhancing nodules commonly found
  - Cystadenoma of ELS: Heterogeneous enhancement

Angiographic Findings

- Conventional
  - HGBL: DSA shows intensely vascular mass, prolonged stain
  - A-V shunting (early draining vein) common

Imaging Recommendations

- Best imaging tool
  - Brain: MR ± contrast
- Protocol advice
  - Scan entire brain and spine
- NIH recommendations
  - Contrast-enhanced MR of brain/spinal cord every 2 years from age 11 years
  - US of abdomen from 11 years, yearly
  - Abdominal CT from 20 years, yearly/every other year
  - MR of temporal bone if hearing loss/tinnitus/vertigo

DIFFERENTIAL DIAGNOSIS

Vascular Metastasis

- Usually solid, not cyst with nodule
- Some tumors (e.g., renal clear cell carcinoma) can resemble HGBL histopathologically

Solitary Hemangioblastoma

- 25-40% of HGBLs occur in VHL
- No *VHL* mutations, family history, other tumors or cysts

Pilocytic Astrocytoma

- Usually younger than VHL patients
- Tumor nodule lacks vascular flow voids (more characteristic of HGBL)
- Tumor nodule often does not abut pial or ependymal surface

Hemispheric Medulloblastoma in Teenager or Young Adult

- Rare; occur in peripheral cerebellar hemisphere
- May appear extraparenchymal
- Solid, gray matter intensity on T2WI

Multiple AVMs in Vascular Neurocutaneous Syndrome

- Osler-Weber-Rendu, Wyburn-Mason, etc.
- Small AVMs may resemble HGBL at angiography

PATHOLOGY

General Features

- Genetics
  - Autosomal dominant inheritance with high penetrance, variable expression

https://CafePezeshki.IR

  - 20% of cases due to new mutation
- Germline mutations of *VHL* tumor suppressor gene
  - Chromosome 3p25-26
  - Gene product: pVHL; inactivation of pVHL results in overexpression of hypoxia-inducible mRNAs, including vascular endothelial growth factor (VEGF)
  - Involved in cell cycle regulation, angiogenesis
  - Disease features vary depending on specific *VHL* mutations
  - Posterior distribution of HGBLs = result of tumor development during embryogenesis
    - Tumors are derived from embryonic multipotent cells

Staging, Grading, & Classification

- Capillary hemangioblastoma: WHO grade I

Gross Pathologic & Surgical Features

- HGBL seen as well-circumscribed, very vascular, reddish nodule
  - 75% at least partially cystic; fluid is amber colored

Microscopic Features

- 2 components in HGBL
  - Rich capillary network
  - Large, vacuolated stromal cells with clear cytoplasm

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - VHL is clinically very heterogeneous; phenotypic penetrance: 97% at 65 years
    - Rate of new tumor development not constant, varies with age (peak at 30-34 years)
  - Retinal angiomas
    - Earliest symptom in VHL often visual; peak in teenage years
    - Retinal detachment, vitreous hemorrhages
  - Cerebellar HGBLs
    - Headache (obstructive hydrocephalus)
    - Peak 4th decade
    - Nearly 75% of symptom-producing tumors have associated cyst, peritumoral edema
  - Spinal cord HGBLs
    - Progressive myelopathy
    - 95% associated syrinx
  - ELSTs
    - Prevalence in VHL patients is 3.6%
    - Can be 1st presentation of VHL so need molecular testing
- Clinical profile
  - Diagnosis of VHL: Capillary hemangioblastoma in CNS/retina and 1 of typical VHL-associated tumors or previous family history
  - VHL phenotypes, subtypes based on absence or presence of pheochromocytoma
    - Type 1: Low risk of pheochromocytoma
    - Type 2: High risk of pheochromocytoma
      - Type 2A (low risk of renal cell carcinoma)
      - Type 2B high risk of renal cell carcinoma)
      - Type 2C (familial pheochromocytoma without either HGBL or RCC)

Demographics

- Age
  - VHL presents in young adults: Mean age of presentation
    - Retinal angioma: 25 years
    - Cerebellar HGBL, pheochromocytoma: 30 years
    - Endolymphatic sac tumor: 31 years
    - Renal carcinoma: 33 years
- Epidemiology
  - 1:35,000-50,000

Natural History & Prognosis

- Renal carcinoma proximal cause of death in 15-50%
- HGBLs → multiple periods of tumor growth (usually associated with increasing cyst size) separated by periods of arrested growth
- On average, new lesion develops every 2 years in VHL

Treatment

- Ophthalmoscopy yearly from infancy
- Physical/neurological examination yearly
- Surgical resection of symptomatic cerebellar/spinal hemangioblastoma
- Stereotactic radiosurgery provides tumor control in 70-90%
- Laser treatment of retinal angiomas

DIAGNOSTIC CHECKLIST

Consider

- Follow NIH screening rules
- Look for ELS tumors in VHL patients with dysequilibrium, hearing loss, or aural fullness

Image Interpretation Pearls

- Solitary HGBL in young patient may indicate VHL

KEY FACTS

TERMINOLOGY

- Tuberous sclerosis complex (TSC)
- Multisystem genetic disorder with epilepsy, multiorgan tumors, and hamartomas
  - Spectrum of central nervous system (CNS) hamartomas; all contain dysplastic neurons and giant (balloon) cells
  - Caused by mutation in *TSC1* or *TSC2* gene
  - Now considered an infantile (developmental) tauopathy
    - Tau abnormally expressed in many of dysmorphic neurons and glial cells of TSC
    - Similar to focal cortical dysplasia 2

IMAGING

- Calcified subependymal nodules (SEN) (hamartomas)
- Subependymal giant cell astrocytoma (SEGA) (15%); most located at foramen of Monro
- Cortical/subcortical tubers (95%)
- White matter (WM) radial migration lines
- Cyst-like WM lesions (cystoid brain degeneration)
- Cortical/subcortical tubers: Early T1 ↑ but variable after myelin maturation
- SEN enhancement more visible on MR than on CT

TOP DIFFERENTIAL DIAGNOSES

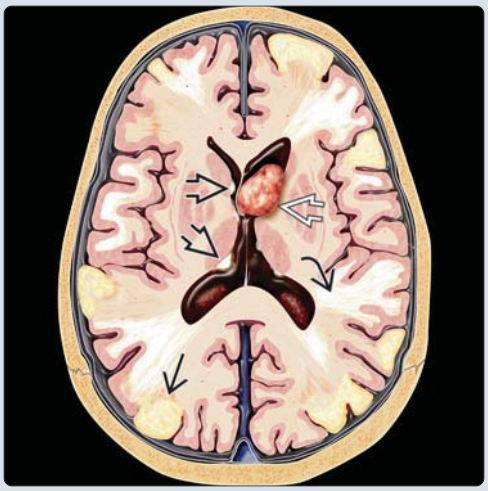
- X-linked subependymal heterotopia
- TORCH syndromes
  - CMV with periventricular Ca++, typical WM lesions, polymicrogyria
- Taylor-type cortical dysplasia (FCD type 2)

PATHOLOGY

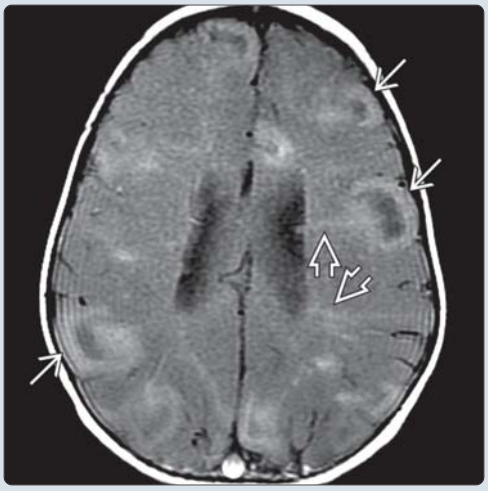
- Abnormal differentiation/proliferation of germinal matrix cells
- Mutations in TSC tumor suppressor genes cause abnormal cellular differentiation, proliferation

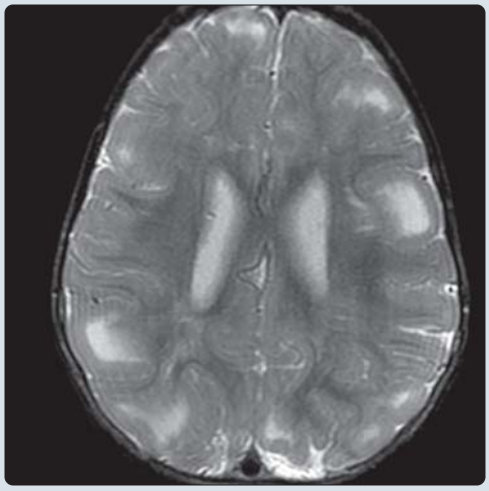
DIAGNOSTIC CHECKLIST

- FLAIR and T1 MT most sensitive sequences for diagnosis
- SEN (< 1.3 cm) vs. SEGA (> 1.3 cm, enlarging)



(Left) *Axial graphic of typical brain involvement in tuberous sclerosis complex shows a giant cell astrocytoma ➡ in the left foramen of Monro, subependymal nodules ➡, radial migration lines ➡, and cortical/subcortical tubers ➡.* **(Right)** *Axial FLAIR surveillance scan in a 14-year-old boy with known TSC shows a well-demarcated lobulated mass in the left frontal horn ➡, a subependymal giant cell astrocytoma. Note multiple expanded gyri with poor gray-white differentiation (tubers ➡), subcortical WM hyperintensities.*





(Left) *Axial T1WI MR with magnetization transfer (MT) in a 13 month old shows classic findings of TS: Multiple cortical/subcortical tubers ➡ and white matter (WM) radial migration lines ➡. These lesions are well demonstrated as the signal from normal WM is suppressed by the MT pulse.* **(Right)** *Axial T2WI MR demonstrates tubers as T2-hyperintense lesions beneath expanded ("clubbed") gyri. The white matter radial migration lines are not well appreciated.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Tuberous sclerosis complex (TSC)

Synonyms

- Bourneville-Pringle syndrome

Definitions

- Multisystem genetic disorder with epilepsy, multiorgan tumors, and hamartomas
  - Spectrum of central nervous system (CNS) hamartomas; all contain dysplastic neurons and giant (balloon) cells
  - Caused by mutation in *TSC1* or *TSC2* gene
  - Now considered infantile (developmental) tauopathy
    - Tau abnormally expressed in many of dysmorphic neurons and glial cells of TSC

IMAGING

General Features

- Best diagnostic clue
  - Calcified subependymal nodules (hamartomas)
    - 98% have subependymal nodules (SENs)
- Location
  - Subependymal giant cell astrocytomas (SEGA) arise in 15%; most located at foramen of Monro
  - Cortical/subcortical tubers (95%)
    - Frontal > parietal > occipital > temporal > cerebellum
    - ↑ number of tubers → ↑ neurologic symptoms
  - White matter radial migration lines (WMRMLs)
    - Represent heterotopic glia with neurons along path of cortical migration from ventricle to cortex
  - Cyst-like white matter (WM) lesions (cystoid brain degeneration)
- Size
  - Thickened cortex, enlarged gyri associated with cortical/subcortical tubers
  - SEN that grows over time and measures > 1.3 cm = SEGA
- Morphology
  - Gyral expansion, sometime pyramidal shape
  - 20% have "potato eye" central depression

CT Findings

- NECT
  - SENs
    - Along caudothalamic groove > atrial > > temporal
    - 50% Ca++ (progressive after 1 year)
  - Tubers
    - Early: Low-density/Ca++ cortical/subcortical mass
    - Later: Isodense/Ca++ (50% by 10 years)
  - Ventriculomegaly common even without SEGA
- CECT
  - Enhancing/enlarging SEN suspicious for SEGA

MR Findings

- T1WI
  - Cortical/subcortical tubers: Early T1 ↑ but variable after myelin maturation
  - Focal lacune-like cysts (vascular etiology)
  - WMRMLs, tubers: Bright signal with magnetization transfer (MT) imaging
    - Use of MT increases sensitivity to small tuber detection
- T2WI
  - Variable signal (relative to myelin maturation)
- FLAIR
  - WMRMLs: Streaky linear or wedge shaped ↑ signal
  - FLAIR becomes more positive with age
- T2* GRE
  - Ca++ SEN more readily discerned; ↑ susceptibility on T2* SWI with age
- DWI
  - ↑ ADC values in epileptogenic tubers
  - ↑ ADC, ↓ FA in normal-appearing WM on DTI
- T1WI C+
  - SEN enhancement more visible on MR than on CT
    - 30-80% enhance (enlarging SEN at foramen of Monro: SEGA)
    - Other enhancing lesions followed (unless growing or obstructing CSF)
  - 3-4% of tubers enhance
- MRA
  - Rare aneurysms and dysplasias/moyamoya
- MRS
  - ↓ NAA/Cr, ↑ mI/Cr in subcortical tubers, SENs

Ultrasonographic Findings

- Grayscale ultrasound
  - Fetal documentation of rhabdomyoma: TSC confirmed in 96%
    - Identified as early as 20 weeks gestation

Imaging Recommendations

- Best imaging tool
  - MR with contrast
- Protocol advice
  - MR with contrast, ± NECT (document Ca++ SENs)
  - Yearly surveillance imaging if incompletely calcified SEGA or enhancing SEGA
    - Look for rapid growth, ± ventricular obstruction

DIFFERENTIAL DIAGNOSIS

X-Linked Subependymal Heterotopia

- Isointense to gray matter (GM) T1/T2+

(S)TORCH

- Cytomegalovirus (CMV): Periventricular Ca++, typical WM lesions, polymicrogyria

Taylor-Type Cortical Dysplasia (FCD Type 2)

- Also due to mTOR pathway mutation

PATHOLOGY

General Features

- Etiology
  - Abnormal differentiation/proliferation of germinal matrix cells
  - Migrational arrest of dysgenetic neurons
- Genetics
  - ~ 50% of TSC cases inherited
    - Autosomal dominant, high but variable penetrance

https://CafePezeshki.IR

  - De novo: Spontaneous mutation/germline mosaicism (60-85%)
  - Mutations in TSC tumor suppressor genes cause activation of mTOR protein → ↑ protein synthesis + cell proliferation
    - 2 distinct loci: *TSC1* (9q34) encodes "hamartin"; *TSC2* (16p13.3) encodes "tuberin"
- Associated abnormalities
  - Renal: Angiomyolipoma and cysts (40-80%)
  - Cardiac: Rhabdomyomas (50-65%); majority involute over time
  - Lung: Cystic lymphangiomyomatosis/fibrosis
  - Solid organs: Adenomas, leiomyomas
  - Skin: Ash leaf spots (majority), including scalp/hair; facial angiofibromas; shagreen patches
  - Extremities: Subungual fibromas (15-20%), cystic bone lesions, undulating periosteal new bone formation
  - Ocular: "Giant drusen" (50%), retinal astrocytomas (which may regress)
  - Dental pitting of permanent teeth in most adults

Staging, Grading, & Classification

- SEGA: WHO grade I

Gross Pathologic & Surgical Features

- Firm cortical masses ("tubers") with dimpling ("potato eye")

Microscopic Features

- Cortical dysplasia with balloon cells, dysmorphic neurons
- Myelin loss, vacuolation, and gliosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Neurologic manifestations most frequent (85%), major cause of morbidity/mortality
  - Classic clinical triad
    - Facial angiofibromas (90%), mental retardation (50-80%), seizures (Sz) (80-90%)
      - All 3 ("epiloia"): 30%
- Clinical profile
  - Sz (infantile spasms in very young), facial angiofibroma, hypopigmented skin lesions, mental retardation
  - Infant/toddler: Infantile spasms (20-30%), autism → bad prognosis
    - Infantile spasms occur before development of facial lesions, shagreen patches
  - Diagnostic criteria: 2 major or 1 major plus 2 minor
    - Major: Facial angiofibroma/forehead plaque, sub-/periungual fibroma, ≥ 3 hypomelanotic macules, shagreen patch, multiple retinal nodular hamartomas, cortical tuber, SEN, SEGA, cardiac rhabdomyoma, lymphangioleiomyomatosis, renal angiomyolipoma
    - Minor: Dental enamel pits, hamartomatous rectal polyps, bone cysts, cerebral WM radial migration lines (> 3 = major sign), gingival fibromas, nonrenal hamartoma, retinal achromic patch, confetti skin lesions, multiple renal cysts

Demographics

- Age
  - Diagnosed at any age
    - 1st year of life if infantile spasms or surveillance for positive family history
    - Child: Autistic-like behavior, mental retardation, seizures, or skin lesions
    - Adult diagnoses reported with demonstration of symptomatic SEGA on brain imaging
- Epidemiology
  - 1:6,000 live births

Treatment

- Surveillance MR every 1-3 years during childhood/adolescence
- Treat seizures: Infantile spasms respond to vigabatrin
- Resect isolated tubers if seizure focus or if able to identify seizure focus among many tubers
- SEGAs resected if obstructing foramen of Monro
- Oral rapamycin (inhibitor of mTOR protein signaling pathway) reported to cause regression of SEGA

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- FLAIR and T1 MT most sensitive sequences for diagnosis
- T1WI readily documents early WM abnormalities (premyelin maturation)
- SEN differs from SEGA based on size
  - SEN < 1.3 cm
  - SEGA > 1.3 cm

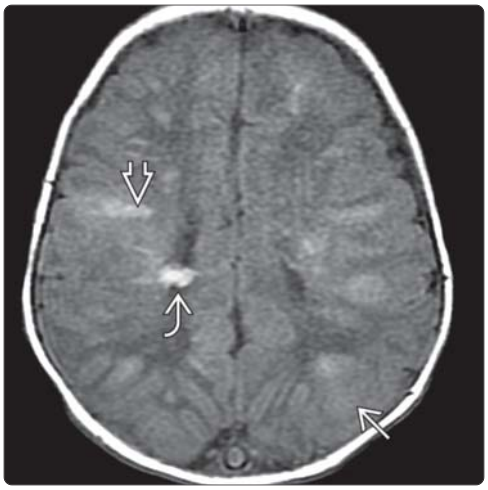
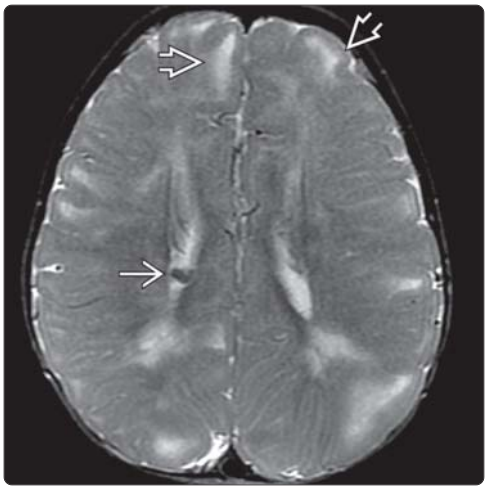
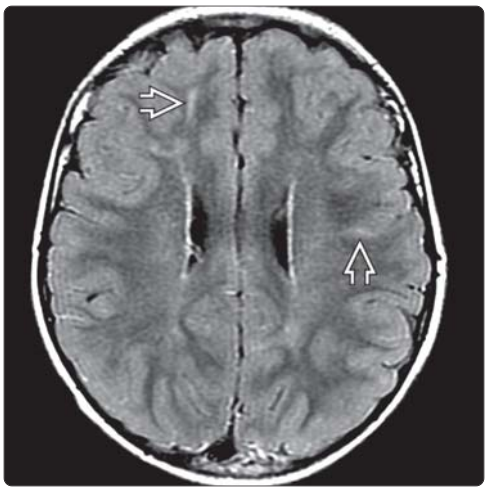
https://CafePezeshki.IR

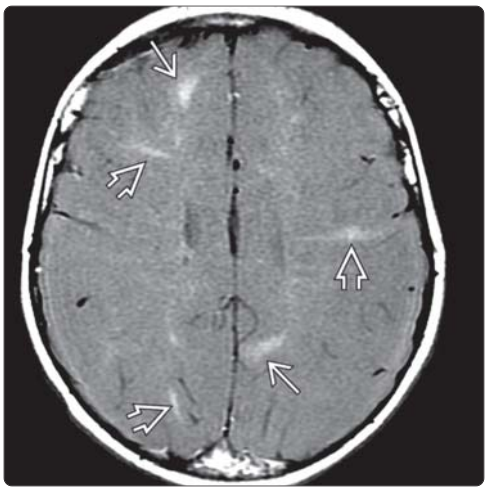




(Left) *Axial T1WI MR in a 13 day old nicely demonstrates multiple T1-bright subcortical tubers ⇨, WM radial migration lines ⇨, and a hyperintense subependymal nodule (SEN) ⇨. The unaffected, unmyelinated WM is hypointense.* **(Right)** *Axial T2WI MR in the same patient at 1 year of age shows T2-hypointense SEN ⇨ and multiple T2-bright tubers. Some abnormalities evident on the prior scan are not appreciated; some tubers not previously evident ⇨ are now seen.*

(Left) *Axial T2WI MR in a 1 month old shows multiple T2-hypointense SENs ⇨ originating from the walls of the lateral ventricles. The cortex of the right frontal lobe ⇨ is thickened and probably diffusely dysplastic.* **(Right)** *Axial NECT of a different patient demonstrates a calcified SEN ⇨ along the anterior margin of the atrium of the left lateral ventricle. A hypodense, probably cystic tuber ⇨ is appreciated in the inferior left frontal lobe.*





(Left) *Axial FLAIR MR shows multiple ill-defined, hyperintense bands ⇨ extending radially from the cortex to the lateral ventricle in this 6-year-old child.* **(Right)** *Axial T1WI MR with magnetization transfer (MT) in the same patient demonstrates multiple T1-bright lesions pathognomonic for subcortical tubers ⇨ and radial migration lines ⇨. The diagnosis of TS is much more easily and confidently made with the T1 with MT images than with the FLAIR images.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Synonyms: Sturge-Weber-Dimitri, encephalotrigeminal angiomatosis

IMAGING

- Imaging features are pial angioma with sequelae of chronic venous ischemia
  - Pial angiomatosis unilateral (80%), bilateral (20%)
  - Cortical Ca++, atrophy, and enlarged ipsilateral choroid plexus
  - "Tram-track" calcification in cortex (not angioma)
- Early: Transient hyperperfusion → "accelerated" myelin maturation
- Late: Increased signal in region of gliosis and decreased cortical signal in regions of calcification
- Early: Serpentine leptomeningeal enhancement, pial angiomatosis of subarachnoid space
- SWI delineates enlarged, tortuous medullary white matter (WM) veins

PATHOLOGY

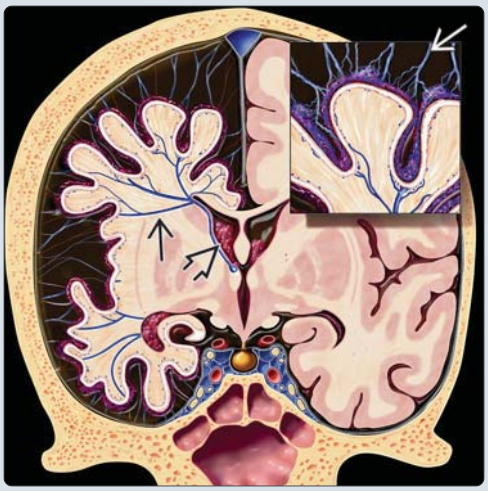
- Somatic mutation of *GNAQ* causes Sturge-Weber Syndrom (SWS) and nonsyndromic "port-wine" stains

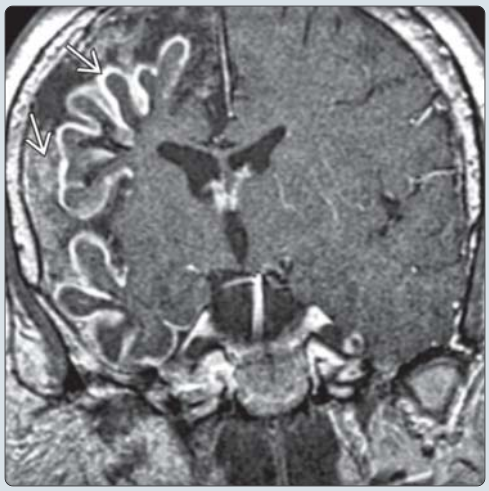
CLINICAL ISSUES

- "Port-wine" stain, seizures, hemiparesis
- Rare: 1:20,000-50,000
- ↑ extent of lobar involvement and atrophy leading to increased likelihood of seizures
- Seizures cause further brain injury

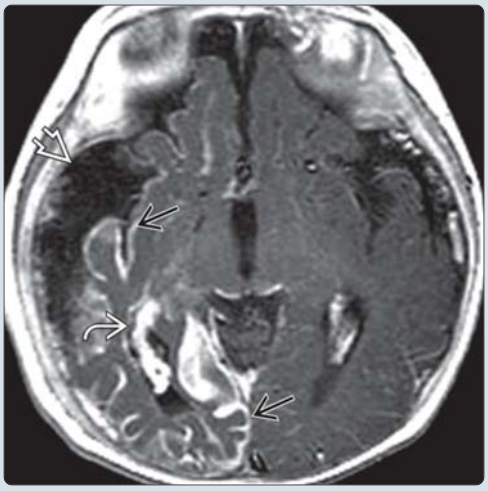
DIAGNOSTIC CHECKLIST

- FLAIR C+ most sensitive sequence to detect pial angioma (especially in infancy)
- T2 hypointensity of white matter underlying angioma is clue to early diagnosis
- Identification of retinal angioma critical in subtle/early cases





(Left) *Coronal graphic shows extensive pial angiomatosis surrounding affected gyri, prominent deep medullary collaterals shunt venous blood to deep system, enlarged ipsilateral choroid plexus, and atrophy of the right cerebral hemisphere.* **(Right)** *Coronal T1WI C+ MR shows extensive serpentine enhancement of thickened pia (pial angiomatosis) and enlarged subarachnoid space over the right cerebral hemisphere. Severe right-sided hemiatrophy is evident.*



(Left) *Axial T1 C+ MR shows classic Sturge-Weber syndrome (SWS) with atrophy of the right hemisphere, enlargement of the ipsilateral choroid plexus, and an extensive pial angioma covering almost the entire surface of the hemisphere.* **(Right)** *More cephalad T1 C+ scan in the same patient shows similar findings. On this image, a cluster of dilated vessels in the subarachnoid space is also visible.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Sturge-Weber syndrome (SWS)

Synonyms

- Sturge-Weber-Dimitri, encephalotrigeminal angiomatosis

Definitions

- Usually sporadic congenital (but not inherited) malformation in which fetal cortical veins fail to develop normally
  - Imaging features are sequelae of progressive venous occlusion and chronic venous ischemia

IMAGING

General Features

- Best diagnostic clue
  - Cortical Ca++, atrophy, and enlarged ipsilateral choroid plexus
- Location
  - Pial angiomatosis unilateral (80%) or bilateral (20%)
  - Occipital > parietal > frontal/temporal lobes > diencephalon/midbrain > cerebellum

Radiographic Findings

- Radiography
  - "Tram-track" calcification

CT Findings

- NECT
  - Gyral/subcortical white matter (WM) Ca++
    - Ca++ not in leptomeningeal angioma
    - Progressive, generally posterior to anterior
  - Late
    - Cerebral atrophy
    - Hyperpneumatization of paranasal sinuses
    - Thick diploe
- CECT
  - Serpentine leptomeningeal enhancement
  - Ipsilateral choroid plexus enlargement usual
    - Choroidal fissure if frontal involvement
    - Trigonal glomus if posterior involvement

MR Findings

- T1WI
  - Early: ↑ WM volume subjacent to pial angiomatosis
  - Late: Atrophy of WM and gray matter
- T2WI
  - Early: Transient hyperperfusion → "accelerated" myelin maturation
  - Late: Increased T2 signal in region of gliosis and decreased cortical signal in regions of calcification
- FLAIR
  - Late: Gliosis in involved lobes
- T2* GRE
  - "Tram-track" gyral calcifications
  - SWI delineates enlarged, tortuous medullary WM veins
- DWI
  - Restricted diffusion in acute ischemia
- T1WI C+
  - Early: Serpentine leptomeningeal enhancement, pial angiomatosis of subarachnoid space
    - Amount of CE increases if MR performed during ictal period; mimics disease progression
  - Late: "Burnt out" → decreased pial enhancement, increased cortical/subcortical Ca++; atrophy
  - Engorged, enhancing choroid plexus
  - Susceptibility weighted imaging (SWI) superior to T1 C+ for identification of enlarged transmantle and periventricular veins
- MRA
  - Rare high-flow arteriovenous malformations
- MRV
  - Progressive sinovenous occlusion
    - Lack of superficial cortical veins
    - ↑ prominence deep collateral (medullary/subependymal) veins
- MRS
  - ↑ choline, ↓ NAA in affected areas
- Fat saturation: Orbital enhancement > 50%, best seen with T1 C+ fat saturation
  - Choroidal angioma, periorbital soft tissues, bony orbit, and frontal bone
- Susceptibility-weighted imaging: Useful for detection of cortical Ca++

Ultrasonographic Findings

- Pulsed Doppler
  - ↓ middle cerebral artery velocity

Angiographic Findings

- Conventional
  - Pial blush, rare arteriovenous malformation
  - Findings mostly venous: Paucity of normal cortical veins, extensive medullary and deep collaterals

Nuclear Medicine Findings

- PET
  - Progressive hypoperfusion, progressive glucose hypometabolism
- SPECT: Transient hyperperfusion (early), hypoperfusion (late)
  - Pattern inconsistent; may be smaller or larger than abnormality detected on CT/MR

Imaging Recommendations

- Best imaging tool
  - Enhanced MR
- Protocol advice
  - NECT to evaluate for calcification (may be more extensive than recognized on MR)
  - MR with contrast (assess extent, uni-/bilaterality, orbital involvement)
    - Contrast-enhanced FLAIR improves conspicuity of leptomeningeal angiomatosis
    - Perfusion may predict progression

DIFFERENTIAL DIAGNOSIS

Other Vascular Phakomatoses (Neurocutaneous Syndromes)

- Blue rubber bleb nevus syndrome

https://CafePezeshki.IR

- Multiple small, cutaneous venous malformations plus intracranial developmental venous anomalies
- Wyburn-Mason syndrome
  - Facial vascular nevus; visual pathway &/or brain arteriovenous malformation (AVM)
- Klippel-Trenaunay-Weber syndrome
  - Osseous/soft tissue hypertrophy, extremity vascular malformations
  - May be combined with some features of SWS
- PHACES
  - **P**osterior fossa malformations, **h**emangiomas, **a**rterial anomalies, **c**oarctation of aorta, **c**ardiac, **e**ye, and **s**ternal anomalies
- Meningioangiomatosis
  - Ca++ common; variable leptomeningeal enhancement; atrophy usually absent
  - May invade brain through Virchow-Robin perivascular spaces

Leptomeningeal Enhancement

- Meningitis, leptomeningeal metastases, and leukemia; encephalocraniocutaneous lipomatosis

PATHOLOGY

General Features

- Etiology
  - Somatic mutation of *GNAQ* causes SWS and nonsyndromic "port-wine" stains
  - Persistent fetal vasculature → deep venous occlusion/stasis → anoxic cortex
- Genetics
  - Usually sporadic: Probable somatic mutation or cutaneous mosaicism
    - Fibronectin (found in SWS "port-wine"-derived fibroblasts and SWS surgical brain samples) regulates angiogenesis and vasculogenesis
  - Very rarely familial but occasionally with other vascular phakomatosis
- Associated abnormalities
  - 50% have extracranial "port-wine" stains (torso or extremities), so evaluate for other vascular phakomatoses
- Upper facial nevus flammeus ± visceral angiomatosis
- Embryology
  - 4-8 weeks: Embryonic cortical veins fail to coalesce and develop → persistent primordial vessels
  - Visual cortex adjacent to optic vesicle and upper fetal face

Staging, Grading, & Classification

- Roach scale
  - Type 1: Facial, choroid + leptomeningeal
  - Type 2: Facial only, ± glaucoma
  - Type 3: Leptomeningeal angioma only (5% of all)

Microscopic Features

- Pial angioma = multiple, thin-walled vessels in enlarged sulci
- Cortical atrophy, Ca++
- Occasional underlying cortical dysplasia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Upper facial nevus flammeus ("port-wine" stain) (98%), ± V2, V3
  - Eye findings especially with upper and lower lid nevus flammeus
    - Choroidal angioma (70%) → increased intraocular pressure/congenital glaucoma → buphthalmos
    - Retinal telangiectatic vessels, scleral angioma, iris heterochromia
  - Ipsilateral gingival hemangioma frequently affects maxilla or mandible
  - Seizures (75-90%), hemiparesis (30-66%)
  - Stroke-like episodes, neurological deficit, migraines
- Clinical profile
  - "Port-wine" stain, seizures, hemiparesis

Demographics

- Age
  - Facial lesion visible at birth
    - Pial angiomatosis may be occult if no facial lesion and no seizures to prompt imaging
  - Seizures develop in 1st year of life
    - Infantile spasms → tonic/clonic, myoclonic
- Epidemiology
  - Rare: 1:20,000-50,000

Natural History & Prognosis

- ↑ extent of lobar involvement and atrophy leading to increased likelihood of seizures
- Seizures cause further brain injury
- Progressive hemiparesis (30%), homonymous hemianopsia (2%)

Treatment

- Aggressive seizure management, ± resect affected lobes (hemisphere)
- Low-dose aspirin may decrease frequency of stroke-like episodes

DIAGNOSTIC CHECKLIST

Consider

- Child with facial nevus flammeus who reaches 2 years of age with normal neurological and MR exams probably does not have brain involvement

Image Interpretation Pearls

- FLAIR C+ most sensitive sequence to detect leptomeningeal angioma, especially in infancy

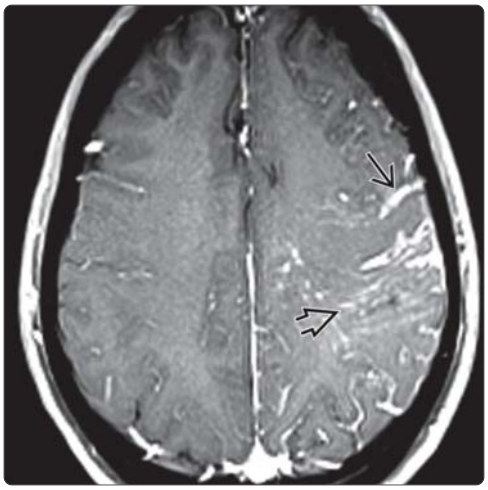
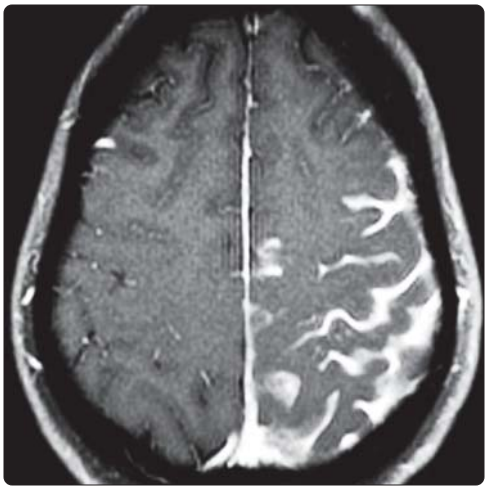
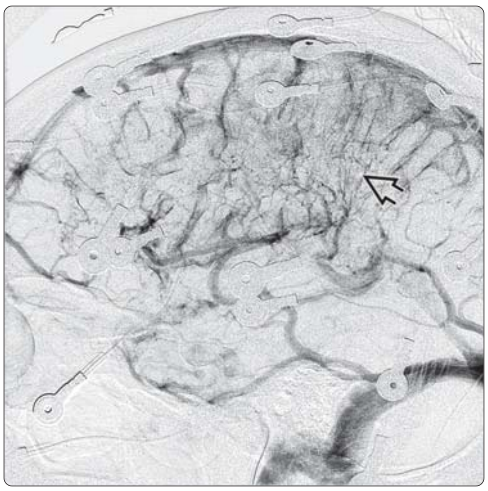
(Left) *Axial FLAIR in a 25-year-old female with a left-sided "port-wine" stain shows hyperintensity in the left parietooccipital sulci ("ivy" sign).* **(Right)** *Axial T1 C+ FS scan in the same patient shows an extensive pial angioma. Note the enlargement of the ipsilateral choroid plexus.*





(Left) *More cephalad T1 C+ FS in the same patient shows the enhancing pial angioma filling the enlarged sulci. Also note the enlarged collateral medullary white matter veins that are draining the affected brain.* **(Right)** *T1 C+ FS scan in the same patient shows the enlarged convexity sulci are entirely filled with the intensely enhancing pial angioma.*



(Left) *Axial T2* SWI MIP in the same patient shows the enlarged, tortuous medullary white matter veins that drain centrally into enlarged subependymal veins.* **(Right)** *Lateral DSA, venous phase, of the left internal carotid angiogram performed as part of a Wada test for language localization shows a paucity of normal cortical veins with a prolonged vascular "blush" caused by contrast stasis in multiple enlarged medullary veins.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Benign hamartomatous cortical, subcortical white matter (WM) lesion with leptomeningeal vascular malformation

IMAGING

- Cortical/subcortical WM mass characterized by calcification, enhancing meningovascular proliferation
  - 50% involve cortex (frontal, temporal lobes most common)
  - ~ 90% involve subcortical WM
  - NECT: Linear, gyriform, or nodular Ca++
- MR
  - T1WI: Cortex iso-, WM hypointense
  - T2/FLAIR: Cortex hypointense, WM hyperintense
  - T1C+: Slight gyriform enhancement

TOP DIFFERENTIAL DIAGNOSES

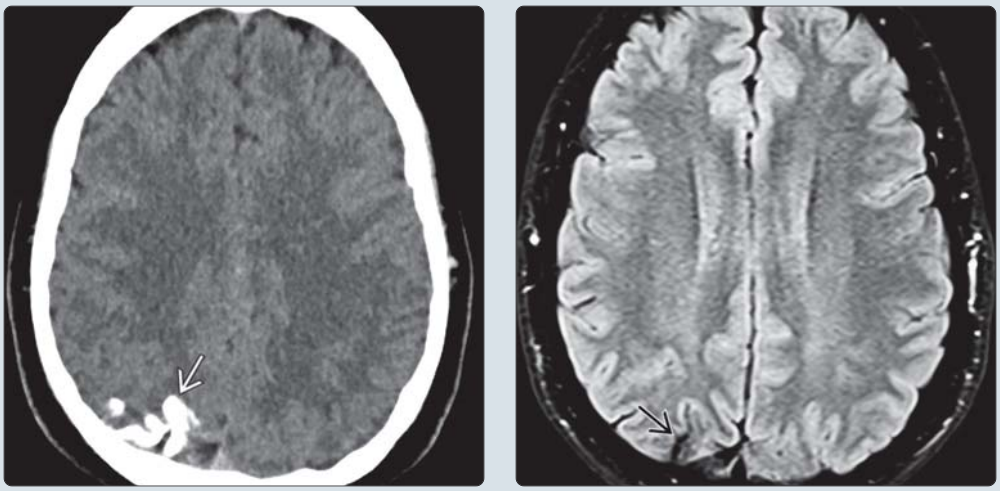
- Meningioma
- Oligodendroglioma
- Sturge-Weber disease
- Other: DNET, granuloma, parasites, ganglioglioma

PATHOLOGY

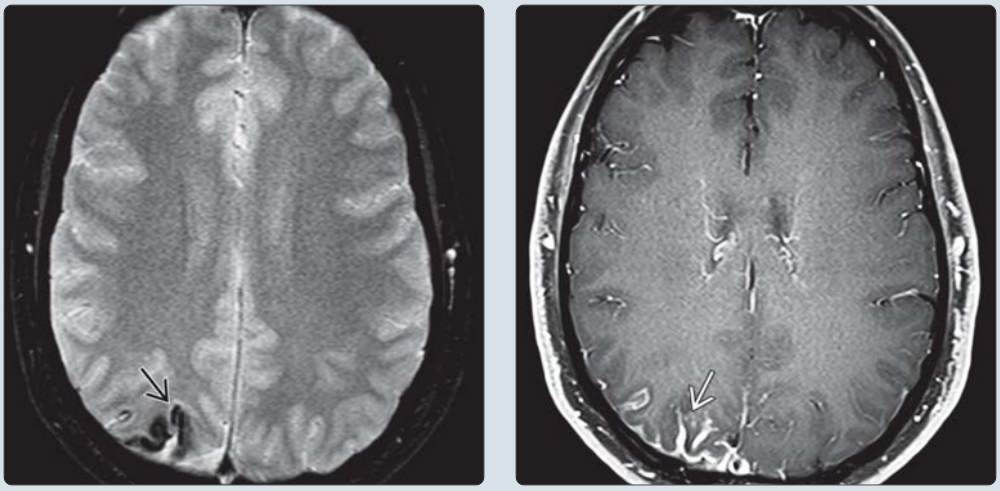
- Uncertain etiology
  - Hamartoma, meningioma invading brain, or vascular malformation
  - Neurofibromatosis (particularly NF2) in 50%
- Gross appearance
  - Vascular-appearing gyriform mass in cortex, subcortical WM
- Microscopic
  - Proliferation of meningothelial cells, irregularly branched blood in both cortex, subcortical WM
  - No malignant degeneration

CLINICAL ISSUES

- Gross total resection for treatment of seizure disorder; excellent prognosis with excision



(Left) *Axial NECT scan in a 33-year-old male with longstanding seizures shows a calcified, gyriform mass in the high right posterior parietal lobe* ➡. **(Right)** *Axial FLAIR in the same patient shows the cortical mass is hypointense* ➡.



(Left) *T2* GRE shows blooming* ➡ *of the gyriform calcification and cortex.* **(Right)** *Axial T1 C+ FS MR shows serpentine gyriform enhancement of the mass* ➡. *There were no other lesions seen and no cutaneous abnormalities. This is a case of presumed (not surgically-proven) meningioangiomatosis.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Benign hamartomatous cortical, subcortical white matter (WM) lesion with leptomeningeal vascular proliferation

IMAGING

General Features

- Best diagnostic clue
  - Cortical/subcortical WM mass characterized by calcification, enhancing meningovascular proliferation
- Location
  - ~ 90% involve subcortical WM
  - 50% involve cortex (frontal, temporal lobes most common)
- Size
  - 1-4 cm (mean: ~ 2.5 cm)

CT Findings

- NECT
  - Solitary hyperdense, often calcified mass
    - Ca++ linear, gyriform, or nodular
  - Occasional: Hemorrhage and cysts
  - Little or no observable mass effect
- CECT
  - Little or no enhancement

MR Findings

- T1WI
  - Cortical component isointense to gray matter (GM)
    - WM component hypointense
- T2WI
  - Cortex hypointense, WM hyperintense
    - May demonstrate areas of signal void (Ca++)
    - ± hyperintense cysts
- FLAIR
  - Cortex hypointense, WM hyperintense
- T2* GRE
  - Hypointense ("blooms")
- T1WI C+
  - Cortex: Slight enhancement (gyriform)
  - WM: No enhancement

Imaging Recommendations

- Protocol advice
  - NECT to look for calcium; MR for signal intensity, enhancement characteristics

DIFFERENTIAL DIAGNOSIS

Lesions With Calcification and Cysts

- Meningioma
- Oligodendroglioma
- Granulomatous meningitis
  - Sarcoid, tuberculosis
- Parasitic diseases (cysticercosis)
- Ganglioglioma
- Sturge-Weber disease
- Dysembryoplastic neuroepithelial tumor

PATHOLOGY

General Features

- Etiology
  - Uncertain
    - Hamartoma, meningioma invading brain, or vascular malformation
- Associated abnormalities
  - Neurofibromatosis (NF) found in 1/2 of patients (particularly neurofibromatosis type 2 [NF2])
  - Meningioma (25%)

Gross Pathologic & Surgical Features

- Vascular-appearing cortical/subcortical mass
  - Serpentine pial vessels overlying lesion
- Psammomatous or serpentine Ca++

Microscopic Features

- Proliferation of meningothelial cells, irregularly branched blood in both cortex, subcortical WM
- Does not undergo malignant degeneration

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Intractable seizures, headaches
  - Often asymptomatic, found incidentally (especially with NF)
- Clinical profile
  - Children, young adults ± seizure disorder

Treatment

- Generally solitary, slow-growing
- Gross total resection for treatment of seizure disorder; excellent prognosis with excision

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Calcified cortical/subcortical WM mass ± gyriform enhancement

KEY FACTS

TERMINOLOGY

- Basal cell nevus syndrome (BCNS), nevoid basal cell carcinoma syndrome (NBCCS), Gorlin syndrome, Gorlin-Goltz syndrome
- BCNS: Hereditary tumor syndrome characterized by multiple basal cell epitheliomas (BCE)/basal cell carcinomas (BCC), odontogenic keratocysts, palmoplantar pits, dural Ca++, ± medulloblastoma

IMAGING

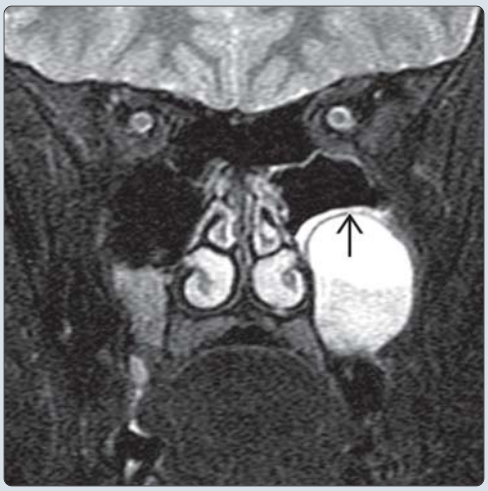
- Multiple jaw cysts, prominent dural Ca++, macrocephaly
- Keratocystic odontogenic tumors (KOT) in 80-90%
  - Most patients with BCNS have KOT; 5% of patients with KOT have BCNS
- Large, uni-/multilocular sharply marginated cysts containing unerupted teeth
- Early Ca++ of falx cerebri, tentorium, periclinoid ligaments (dural bridging), dura, pia, choroid plexus, and basal ganglia

TOP DIFFERENTIAL DIAGNOSES

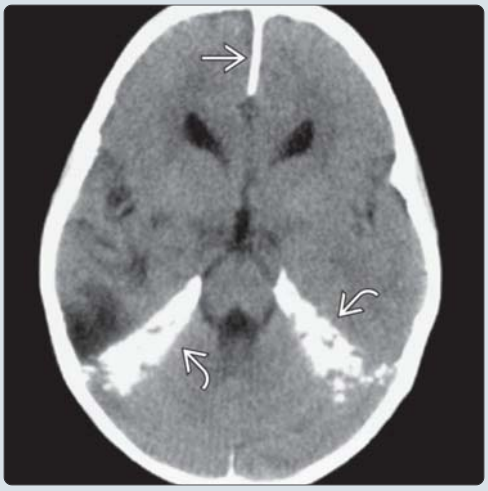
- Prominent dural calcifications (physiologic, metabolic)
- Maxillary/mandibular cyst(s)
  - Ameloblastoma
  - Dentigerous or aneurysmal bone cyst
  - Cherubism
  - Giant reparative granuloma
  - Odontogenic myxoma
  - Maxillary sinus mucocele

PATHOLOGY

- Desmoplastic medulloblastoma seen in 4-20% (1-2% of patients with medulloblastomas have BCNS)
- Mutation of inactivated tumor suppressor genes *PTCH1*
  - < 2% risk of medulloblastoma
- *SUFU* mutations common in patients without *PTCH1* mutation
  - Risk of medulloblastoma 20x higher than *PTCH1*



(Left) *Coronal T2WI MR of a classic BCNS shows a large, unilocular, T2-hyperintense cyst arising from the left maxillary alveolar ridge. The cyst bulges into the maxillary sinus, displacing the floor of the sinus and secretions superiorly. Distinguishing a sinus mucous retention cyst from an alveolar ridge/dental cyst is best done on coronal images.* **(Right)** *Coronal T1WI MR shows a T1-hypointense cystic mass. The floor of the sinus is less well characterized than on the coronal T2 image.*



(Left) *Axial NECT of a 16 year old with BCNS reveals extensive lamellar calcifications of the falx cerebri and the tentorium cerebelli. A defect is evident in the right temporal lobe secondary to the resection of a convexity meningioma.* **(Right)** *Axial bone CT demonstrates a well-defined, expansile lesion in the angle of the mandible on the left. At surgery, pathologic exam showed the lesion to be an odontogenic keratocyst.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Basal cell nevus syndrome (BCNS)

Synonyms

- Nevoid basal cell carcinoma syndrome (NBCCS), Gorlin syndrome, Gorlin-Goltz syndrome

Definitions

- Hereditary tumor syndrome characterized by multiple basal cell epitheliomas (BCE)/basal cell carcinomas (BCC), keratocystic odontogenic tumors (KOT), palmoplantar pits, dural Ca++, ± medulloblastoma

IMAGING

General Features

- Best diagnostic clue
  - Multiple jaw cysts, prominent dural Ca++, macrocephaly
  - Other skeletal features: Hyperaerated paranasal sinuses, splayed/fused/bifid ribs, kyphoscoliosis, platybasia, Sprengel deformity of scapulae
- Location
  - Cysts: Mandible, maxilla
  - Ca++: Intracranial dura
- Size
  - Variable enlargement of mandible, maxilla

CT Findings

- NECT
  - Keratocystic odontogenic tumors (KOT) in 80-90%
    - Large, uni-/multilocular, sharply marginated cysts containing unerupted teeth
    - Mandible > maxilla
  - Early Ca++ of falx cerebri, tentorium, periclinoid ligaments (dural bridging), dura, pia, choroid plexus, and basal ganglia
  - ± ventriculomegaly
  - ± callosal dysgenesis
  - Cysts of all kinds common
- CECT
  - Look for
    - Desmoplastic medulloblastoma
    - Meningioma
    - Colloid cyst

MR Findings

- T1WI
  - KOT are hypointense to isointense, contain hypointensity representing unerupted tooth
  - Dural Ca++ difficult to observe on MR
  - Look for perineural spread as loss of perineural fat
- T2WI
  - KOT are hyperintense, contain hypointensity representing unerupted tooth
- T1WI C+
  - Cysts may show thin peripheral enhancing rim
  - Look for perineural spread of head and neck BCC using fat-saturated images

Nuclear Medicine Findings

- Bone scan
  - May show ↑ uptake

Imaging Recommendations

- Best imaging tool
  - MR to screen for medulloblastoma (especially if SUFU[+]), cystic jaw lesions
  - CT of face for oral surgery planning
- Protocol advice
  - Low mA 2-3 mm axial CT of face, including mandible, coronal reformats
  - Fat-saturated T2 and T1 C+ to diagnose jaw KOTs, perineural BCC spread

DIFFERENTIAL DIAGNOSIS

Prominent Dural Calcifications

- Physiologic (usually less striking than BCNS)
- Metabolic (hyperparathyroidism, long-term hemodialysis)

Keratocystic Odontogenic Tumors (Maxillary/Mandibular Cysts)

- Ameloblastoma
  - Bubbly appearing, solitary lesion may contain unerupted tooth
  - When large, associated enhancing soft tissue mass nearly always present
  - May have enhancing solid mural nodule
- Dentigerous cyst
  - Unilocular cyst surrounding tooth crown
  - No enhancing soft tissue
- Cherubism
  - Symmetrical cystic fibrous dysplasia of mandible
- Aneurysmal bone cyst
  - Multilocular, multiseptated mass in mandible
  - Enhancing soft tissues inside and outside of bony rim
- Giant reparative granuloma
  - Solitary mass, generally solid, does not contain unerupted tooth
- Odontogenic myxoma
  - Radiolucent areas with bony trabeculations
  - Well- or poorly defined margins, aggressive growth; benign histology
- Miscellaneous maxillary masses
  - Maxillary sinus mucocele: Contains no cysts or septa; smooth expansion of sinus walls
  - Incisor canal cyst: Small; found in midline anterior maxilla, posterior to incisors; water density/intensity
  - Globulomaxillary cyst: Small; located between lateral incisor and canine

PATHOLOGY

General Features

- Etiology
  - PATCHED (*PTCH1*) gene encodes sonic hedgehog (SHH) receptor and tumor suppressor protein defective in BCNS
- Genetics
  - Autosomal dominant: Complete penetrance, variable expression

https://CafePezeshki.IR

- de novo mutations (40%)
  - New mutations ↑ with advanced paternal age
- Mutation of inactivated tumor suppressor genes *PTCH1*
  - < 2% risk of medulloblastoma
- *SUFU* mutations common in patients without *PTCH1* mutation
  - Risk of medulloblastoma 20x higher than *PTCH1*
- Associated abnormalities
  - Neoplasms (mutation inactivated tumor suppressor genes)
    - Rare ameloblastoma and squamous cell cancer
    - Desmoplastic medulloblastoma: Seen in 4-20% (1-2% of patients with medulloblastomas have BCNS)
    - Cardiac, abdominal, and pelvic mesenchymal tumors
- 3x more common in mandible than in maxilla
  - Mainly in premolar and retromolar triangle area
- Usually multiple, small or large, unilocular or multilocular
- May cross midline

Staging, Grading, & Classification

- Need either 2 major or 1 major/2 minor criteria for diagnosis
- Major criteria: > 2 (or 1 < 30 years) basal cell carcinomas; > 10 basal cell nevi; KOT or polyostotic bone cyst; ≥ 3 palmar/plantar pits; lamellar or (< 20 years) falx Ca++; family history
- Minor criteria: Rib or vertebral anomalies, macrocrania/frontal bossing; cardiac or ovarian fibromas; mesenteric cysts; facial clefting (5-13%), hand (long fingers, short 4th metacarpal, polydactyly) or ocular anomalies; bridging of sella turcica, medulloblastoma

Gross Pathologic & Surgical Features

- KOT: Expansile mandible &/or maxillary cysts with unerupted tooth
  - Satellite cyst formation is common; may involve coronoid process
  - Maxillary canine/premolar area > retromolar

Microscopic Features

- KOT: Parakeratinized lining and ↑ epithelial growth factor receptor

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Jaw and maxilla deformity with pain
- Desmoplastic medulloblastoma in boys 2 years and younger (before syndrome apparent)
  - Beware: Irradiation induced ↑ number BCC
- BCE (75%) onset at puberty, resemble nevi or skin tags; BCC by 40 years
- Skin (other): Epidermal (kerato) cysts (55%), milia, fibromas, lipomas
- Palmar and plantar pits (> 85%): Usually noticed after childhood
- Multiple KOT that may fracture or become infected
- Dysmorphic facies, large head/brow, everted mandibular angle, hypertelorism, lip clefts common, macrosomia, tall stature
- Cognition normal if no malformations/tumors and no prior irradiation (mental retardation in 5%)

Demographics

- Age
  - Usually diagnosed during 1st decade of life
    - KOT usually forms before 7 years of age
- Gender
  - No predilection
- Ethnicity
  - No predilection
- Epidemiology
  - 1 in 57,000 (1 in 200 with BCC have syndrome, 1 in 5 if < 19 years old)
  - Most patients with BCNS have KOT; 5% of patients with KOT have BCNS

Natural History & Prognosis

- Develop enormous numbers of basal cell carcinomas
  - Especially fair skin, sun exposure, irradiation
  - Darkly pigmented skin protective, has smaller numbers of BCC

Treatment

- Surgery for KOT; surgery/chemotherapy, avoid radiotherapy for medulloblastoma

DIAGNOSTIC CHECKLIST

Consider

- When precocious dural Ca++ and KOT are detected

Image Interpretation Pearls

- Multiple mandibular cysts containing teeth or parts of teeth

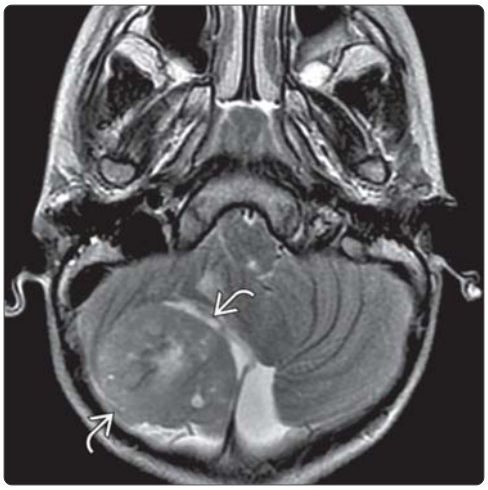
https://CafePezeshki.IR



(Left) *Axial T2WI MR in a 3-year-old boy shows a well-defined T2-hypointense mass ➡ in the posterior right cerebellar hemisphere. Only slight edema surrounds the mass, which was proven to be a medulloblastoma at pathology.* **(Right)** *Axial NECT in the same patient, obtained preoperatively, reveals 2 small dural-based calcifications ➡. Such calcifications are not normal in a child of this age and should prompt a work-up for basal cell nevus syndrome (BCNS). BCNS was confirmed with a molecular genetic test.*

(Left) *Axial T1WI C+ FS MR in a 6-year-old child with known BCNS shows a small cystic mass in the anterior left maxillary ridge, consistent with an keratocystic odontogenic tumor. The cyst has a thin, faintly enhancing rim ➡ and an unerupted tooth medially. The MR was performed as a screening test for medulloblastoma.* **(Right)** *Axial T2WI FS MR in the same patient shows moderate hyperintensity of the lesion contents and a hypointense unerupted tooth ➡ medial to the lesion.*

(Left) *Coronal T2WI FS MR reveals a T2-hypointense mass filling the left nasal cavity and extending into ethmoid air cells ➡. This 19 year old with BCNS was radiated for medulloblastoma and developed a radiation-induced rhabdomyosarcoma.* **(Right)** *Coronal T1WI C+ FS MR shows moderate enhancement of the nasal mass, which infiltrates the dura above the roof of the ethmoid air cells ➡. A falx meningioma is also evident ➡.*

KEY FACTS

TERMINOLOGY

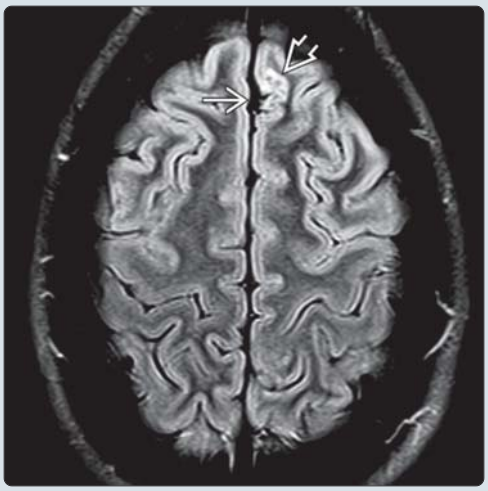
- Hereditary hemorrhagic telangiectasia (HHT)
  - Rendu-Osler-Weber, Osler-Weber-Rendu syndrome
- Autosomal dominant disorder with widely distributed, multisystem angiodysplastic lesions
  - Mucocutaneous telangiectasias with AVMs in visceral organs (primarily lungs, brain, liver)

IMAGING

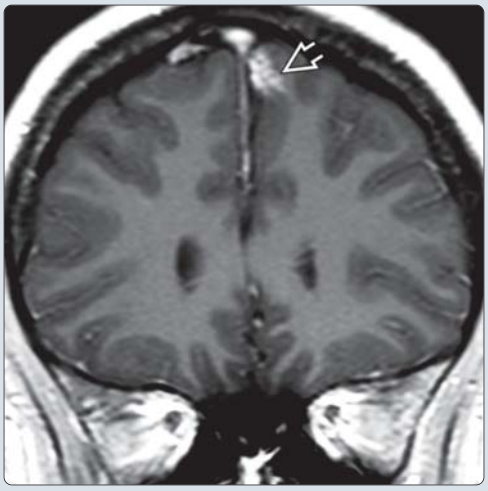
- Best diagnostic clue
  - Multiple pulmonary (pAVM) or cerebral arteriovenous malformations (cAVM) in patient with recurrent epistaxis
- MR
  - "Blooming" of capillary telangiectasias (SWI > GRE)
    - "Fluffy" enhancement on T1 C+
  - cAVM: Nest ("tangle") of flow voids, gliosis
- Useful: Multislice CT/CTA of lungs and liver

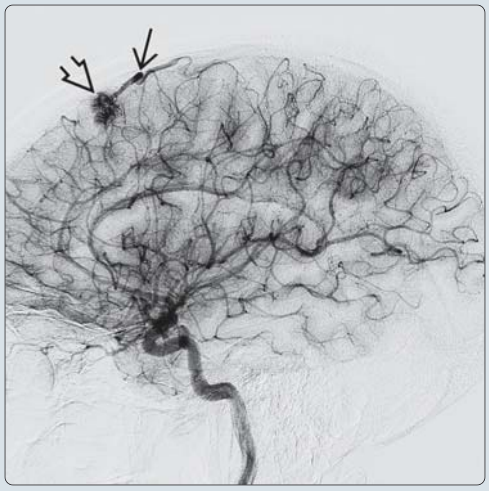
PATHOLOGY

- Genetically heterogeneous disorder caused by mutations in TGF-β/BMP signaling pathway
  - Endoglin (*ENG*) mutations cause HHT1
  - Activin A receptor type II-like 1 (*ACVRL1/ALK1*) mutations cause HHT2
  - *SMAD4* mutations cause the combined Juvenile Polyposis/HHT syndrome
- 3 types of vascular malformations in HHT
  - Most common: Capillary vascular malformation (61%)
    - Tangle of abnormal vessels
    - No shunt, no dilated feeding artery or draining vein
  - Nidus-type AVM: 43%
    - Dilated network of abnormal vessels
    - AV shunting (early draining vein)
  - Direct high-flow AVF: 12%
    - Shunt with absence of intervening nidus between feeding artery, draining vein



(Left) *Axial FLAIR MR in an 18-year-old male with family history of hereditary hemorrhagic telangiectasia (HHT) was obtained as part of routine screening. A small left medial frontal hyperintensity ⇨ with associated flow voids ⇨ is present.* **(Right)** *Axial T1 C+ MR in the same patient shows the lesion ⇨ enhances intensely.*





(Left) *Coronal T1 C+ scan in the same patient shows the lesion ⇨ has a somewhat "speckled" appearance.* **(Right)** *Lateral view of the left internal carotid DSA obtained in the same patient shows a small AVM nidus ⇨ with an early draining vein ⇨. Genetic profiling showed ENG mutation.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hereditary hemorrhagic telangiectasia (HHT)

Synonyms

- Rendu-Osler, Rendu-Osler-Weber, Osler-Weber-Rendu syndrome

Definitions

- Autosomal dominant disorder with widely distributed, multisystem angiodysplastic lesions
  - Mucocutaneous telangiectasias and arteriovenous malformations (AVMs) in visceral organs (primarily lungs, brain, liver)

IMAGING

General Features

- Best diagnostic clue
  - Multiple pulmonary (pAVM) or cerebral arteriovenous malformation (cAVM) in patient with recurrent epistaxis
- Location
  - Capillary telangiectasias: Scalp, nasopharynx, orbit
  - Intracranial vascular malformations most often superficially located
- Size
  - Vascular malformations in HHT usually small ("micro-AVMs" or "capillary vascular malformations"), often incidental
- Morphology
  - Dilated tangle of vessels, "blooming" artifacts
- Number
  - Multiple vascular malformations: 44%

CT Findings

- NECT
  - Brain
    - AVM: Isodense serpentine vessels
    - Abscess: Low-density mass, iso-/hyperdense rim
- CECT
  - Brain
    - Strong, uniform, vascular nidus enhancement
    - Ring enhancement of abscesses (late cerebritis, early capsule stage)
    - DVA not rare (4%)
- CTA
  - Demonstrates feeders and draining veins of AVMs, AVFs
  - Visceral evaluation also needed

MR Findings

- T1WI
  - Nidus-type AVM: Flow voids common, ± hemorrhage
  - Capillary vascular malformations, DVA not visualized
- T2WI
  - cAVM: Flow voids ± hemorrhage, gliosis
- FLAIR
  - cAVM: Nest ("tangle") of flow voids, gliosis
- T2* GRE
  - "Blooming" of capillary malformations (SWI > GRE)
- T1WI C+
  - Capillary vascular malformation
    - Subcentimeter "fluffy" blush of enhancement without abnormal vascular dilation
    - Usually supratentorial, superficial
  - Delineates cAVM nidus, feeding arteries, and draining veins
- MRA
  - Demonstrates intermediate to large cAVMs
  - Capillary vascular malformations usually not visualized
- MRV
  - May demonstrate DVA

Angiographic Findings

- Vascular malformations shown in brain and nasal mucosa
  - Only 10-20% > 10 mm

Imaging Recommendations

- Best imaging tool
  - Brain: MR C+, T2* (SWI > GRE)
- Protocol advice
  - Brain: MR C+, T2* (SWI > GRE), MRA
    - Lungs, liver: Multislice CT/CTA useful

DIFFERENTIAL DIAGNOSIS

Nasal Mucosal "Blush"

- Prominent but normal nasal mucosal "blush" can mimic capillary telangiectasia

Multiple Intracranial AVMs Without HHT

- 50% associated with other vascular neurocutaneous syndrome (Wyburn-Mason, etc.)

Multiple Intracranial DVAs

- Less common than in blue rubber bleb nevus syndrome (BRBN)

Multiple Capillary Telangiectasias

- Can be found incidentally without HHT
- Capillary telangiectasias in HHT more common outside brain (e.g., mucosa)

Multiple Cavernous Malformations

- Familial cavernous malformation syndrome

PATHOLOGY

General Features

- Etiology
  - Genetically heterogeneous disorder caused by mutations in TGF-β/BMP signaling pathway
    - TGF-β regulates cell proliferation, differentiation, apoptosis, migration
    - Abnormal TGF-β signal transduction affects
      - Vasculogenesis
      - Angiogenesis
      - Endothelial cell properties
- Genetics
  - Endoglin (*ENG*) mutations cause HHT1
  - Activin A receptor type II-like 1 (*ACVRL1/ALK1*) mutations cause HHT2
    - *ENG, ACVRL1* mutations detected in 85% of HHT cases (roughly = percentages)

https://CafePezeshki.IR

- *SMAD4* mutations cause the combined Juvenile Polyposis/HHT syndrome
- 15% of patients with HHT have no mutation in *ENG, ACVRL1,* or *SMAD4*
  - 1% have missense mutations in bone morphogenetic 9 (*GDF2*) gene

Staging, Grading, & Classification

- Most cAVMs in HHT are low grade (Spetzler-Martin 1 or 2)

Gross Pathologic & Surgical Features

- Multiple telangiectasias of mucosa, dermis, viscera
- 3 types of vascular malformations in HHT
  - Most common: Capillary vascular malformations (61%)
    - Tangle of abnormal vessels but no shunt, no dilated feeding artery or draining vein
  - Nidus-type AVM: 43%
    - Dilated network of abnormal vessels
    - AV shunting (early draining vein)
  - Direct high-flow AVF: 12%
    - Shunt with absence of intervening nidus between feeding artery and draining vein
- Other associated vascular anomalies
  - DVA: 4.3%
  - Aneurysms: 2.4%
  - Cavernous malformation: 1%

Microscopic Features

- Smallest telangiectasias = focal dilatations of postcapillary venules that enlarge and extend through capillaries toward arterioles → AVF/AVM

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Recurrent epistaxis from nasal mucosal telangiectasias
    - 50% have nosebleeds by 10 years, 80-90% by 21 years; 95% lifetime
    - Wide variation in severity
- Other signs/symptoms
  - Telangiectasia locations
    - Lips
    - Mouth
    - Tongue
    - Around nails
- Clinical profile
  - HHT diagnosis based on combination of findings (Shovlin criteria)
    - Mucocutaneous telangiectasias
    - Spontaneous/recurrent episodes of epistaxis
    - Visceral involvement
    - Family history
  - Significant phenotypic variability
    - 70% of patients with pAVMs have HHT
      - Pulmonary, brain AVMs more common in HHT1
      - 5-15% of HHT patients have pAVMs
    - > 50% of patients with multiple cAVMs have HHT
      - 5-13% of HHT patients have cAVMs (usually late in life)
    - 2-17% of HHT patients have hepatic AVMs (depends on kindred)
      - Hepatic AVMs more common in HHT2
- Neurologic symptoms common
  - Intracranial bleed from AVM/AVF
  - TIA, stroke, abscess secondary to pAVMs

Demographics

- Age
  - Epistaxis typically begins by age 10
  - Most HHT patients are symptomatic by age 21
  - Skin lesions appear later (most by age 40)
- Epidemiology
  - Rare: 1-2:10,000

Natural History & Prognosis

- Epistaxis
  - Increases in frequency and severity
- HHT cAVMs have lower bleeding risk than sporadic AVMs
  - Rare cases may regress spontaneously
  - Significant lifetime risk of brain abscess or stroke if pAVM present
- GI bleeding limits lifespan when < 50 years old
  - Many require multiple transfusions and endoscopies
  - Heart failure with hepatic AVM: Poor prognosis

Treatment

- pAVMs: Excellent results with embolization
- cAVMs: Embolization vs. radiosurgery depending on size and location
- Mucosal telangiectasias (nose, GI tract): Laser coagulation
- Prophylactic antibiotics prior to all dental work if pAVM present
- IV iron useful if oral iron fails to maintain satisfactory level

DIAGNOSTIC CHECKLIST

Consider

- Screening brain MR in family members of HHT patients

Image Interpretation Pearls

- Most common cerebral vascular malformation in HHT patients = AVM (not telangiectasia)
- Brain abscess and ischemia uncommon but serious complication in HHT patients with pAVMs

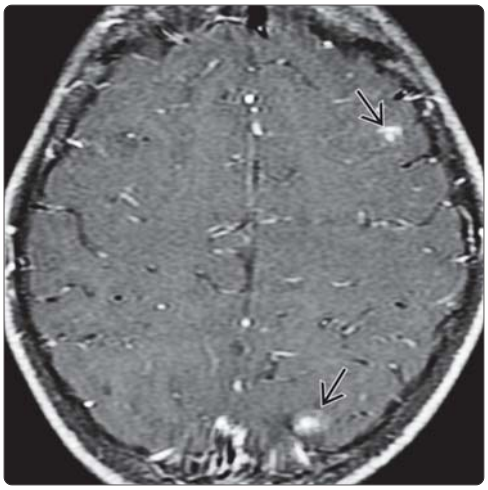
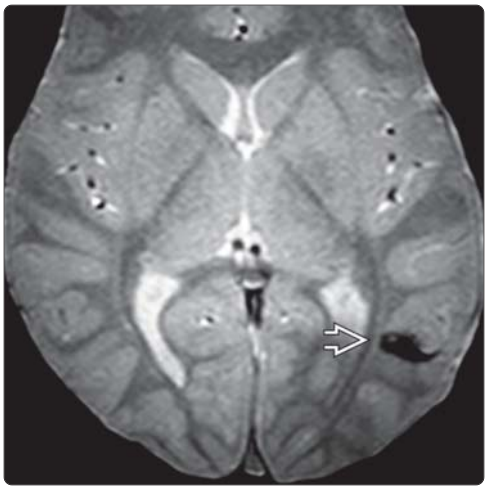
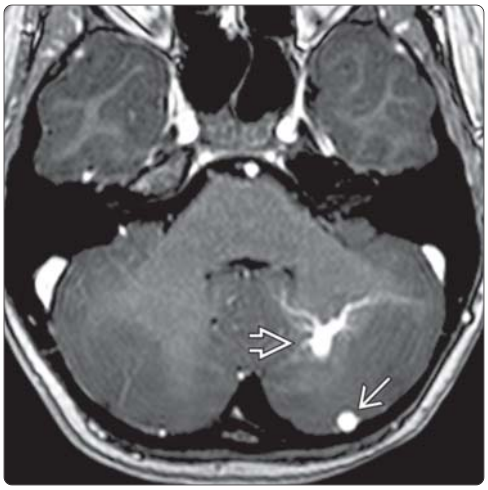
https://CafePezeshki.IR

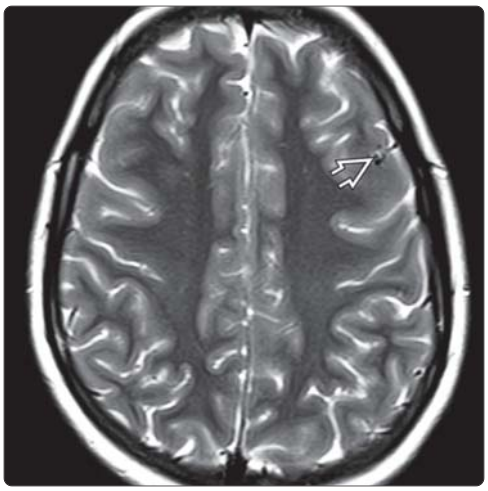


(Left) *A screening T1 C+ FS 3T MR scan was obtained in this 11-year-old female with a family history of HHT shows 2 tiny "fluffy" foci of enhancement consistent with capillary vascular malformations (sometimes called "micro-AVMS").* **(Right)** *More cephalad T1 C+ FS scan in the same patient shows 2 additional micro-AVMS. Sporadic multiple AVMs are uncommon. At least 50% of such cases are eventually proven to have HHT (usually HHT1).*





(Left) *Axial T2* GRE MR of a child with diagnosed HHT shows hypointensity in the left parietooccipital region due to susceptibility effects of a pial telangiectasia. Similar lesions were seen in the right cerebellum and left middle temporal sulci (not shown).* **(Right)** *Axial T1WI C+ SPGR MR in a child with diagnosed HHT shows a left cerebellar DVA draining into a posterior pial vein. Although not specific, DVAs are more common in HHT than in the general population.*



(Left) *Axial T2WI in a 16-year-old female with HHT1 who had a negative screening MR at age 9 shows a small round and linear "flow void" in the left frontal lobe.* **(Right)** *Axial CTA was obtained in the same patient. This shows a well-delineated tubular structure suggesting a vascular malformation. A pial arteriovenous fistula was found and resected at surgery. AVFs are the least common of the three major types of cerebral vascular malformations associated with HHT1.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Rare congenital neurocutaneous syndrome characterized by ipsilateral scalp, eye, and brain abnormalities

IMAGING

- Unilateral cerebral hemispheric atrophy ipsilateral to scalp lipoma
- Intracranial (IC) lipomas in ~ 2 out of 3 patients
- Spinal lipomas/lipomatosis frequent; cervicothoracic > lumbar
- Polymicrogyria of temporal, parietal, &/or occipital lobes
- ± diffuse, ipsilateral leptomeningeal enhancement
- Scalp/intracranial lipomas

TOP DIFFERENTIAL DIAGNOSES

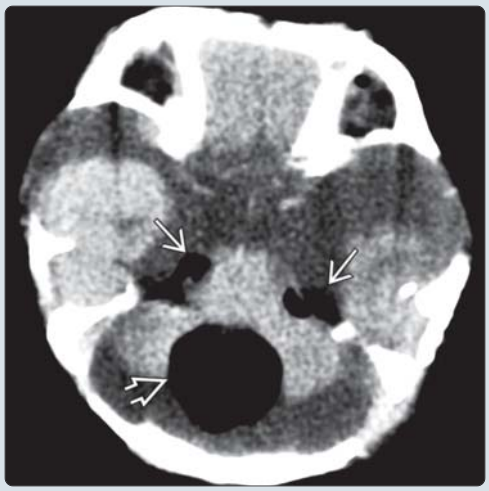
- Sturge-Weber syndrome
- Oculocerebrocutaneous syndrome
- Epidermal nevus syndrome
  - Ipsilateral epidermal nevus, hemimegalencephaly, facial lipoma, and hemihypertrophy
- Proteus syndrome
  - Progressive asymmetric, bilateral trunk/limb hypertrophy

PATHOLOGY

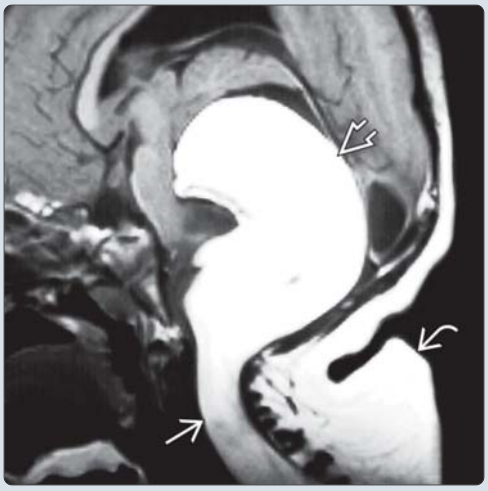
- Defect in development of mesenchymal tissues

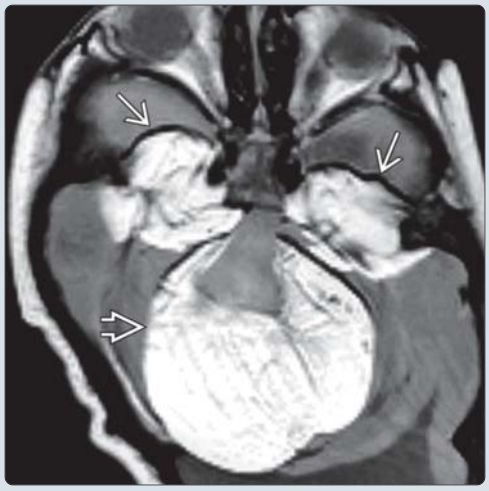
CLINICAL ISSUES

- Nevus psiloliparus: Sharply demarcated focus of scalp alopecia overlying scalp lipoma
- Hallmark of encephalocraniocutaneous lipomatosis (ECCL)
- Newborn with nevus psiloliparus, scleral mass, and periocular papules
- Rare; ~ 54 reported cases (likely underreported)



(Left) *Clinical photograph of a scalp shows the typical appearance of "nevus psiloliparus," a well-circumscribed area of scalp alopecia. The nevus overlies a lipoma and is the hallmark of encephalocraniocutaneous lipomatosis.* **(Right)** *Axial NECT scan in a 2 year old with encephalocraniocutaneous lipomatosis (ECCL) shows focal lipomas in both cerebellopontine angle (CPA) cisterns ➡ and the cisterna magna ➡.*





(Left) *Sagittal T1WI in the same patient obtained 3 years later shows a very large suboccipital lipoma ➡. The foramen magnum lipoma has massively increased in size and now occupies most of the posterior fossa ➡. The foramen magnum lipoma now extends inferiorly into the upper cervical spine ➡.* **(Right)** *Axial T1WI in the same patient shows how much the posterior fossa lipoma ➡ has increased in size compared to the baseline NECT. The CPA lipomas extend into Meckel caves ➡.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Encephalocraniocutaneous lipomatosis (ECCL)

Synonyms

- Haberland syndrome, Fishman syndrome

Definitions

- Rare congenital neurocutaneous syndrome characterized by ipsilateral scalp, eye, and brain abnormalities
- 1st described in 1970 by Catherine Haberland

IMAGING

General Features

- Best diagnostic clue
  - Unilateral cerebral hemispheric atrophy ipsilateral to scalp lipoma
  - Other frequent ipsilateral CNS abnormalities
    - Middle cranial fossa arachnoid cyst
    - Cortical dysplasia
    - Cortical Ca++
  - Intracranial (IC) lipomas in ~ 2 out of 3 patients
  - Spinal lipomas/lipomatosis frequent; cervicothoracic > lumbar
  - Rarely, CNS abnormalities limited to IC lipoma
- Location
  - Intracranial lipomas
    - CP angle, Meckel cave, foramen magnum
    - Usually ipsilateral to scalp lipoma; occasionally contra- or bilateral
  - All other CNS anomalies ipsilateral to scalp lipoma
- Morphology
  - Focal occipital lobe atrophy and occipital horn enlargement characteristic

CT Findings

- NECT
  - Hemispheric atrophy, ventriculomegaly
    - Ventriculomegaly primarily due to volume loss although hydrocephalus occasionally present
  - Low-density scalp lipoma (may be difficult to identify, particularly if at vertex)
  - ± cortical Ca++
    - Identified as early as 1st month of life, progressive
  - ± focal calvarial enlargement
    - Usually underlies scalp lipoma
- CECT
  - ± diffuse, ipsilateral leptomeningeal (LM) enhancement
- CTA
  - Arterial ectasias, pouches, and aneurysms described in older patients

MR Findings

- T1WI
  - Scalp/intracranial lipomas
  - Polymicrogyria of temporal, parietal, &/or occipital lobes
  - Scleral choristoma occasionally visible; heterogeneous with focal areas of hyperintensity
- T2WI
  - Cortical Ca++ hypointense
  - Lipomas hyperintense on T2 FSE
  - Arachnoid cysts isointense to CSF
- FLAIR
  - Nulling of signal from arachnoid cyst
- T2* GRE
  - "Blooming" of cortical Ca++
- DWI
  - Arachnoid cyst isointense to CSF
- T1WI C+
  - ± diffuse, ipsilateral leptomeningeal enhancement
- MRA
  - Arterial ectasias, pouches, and aneurysms described in older patients

Ultrasonographic Findings

- Ventriculomegaly reported on 3rd trimester US

Angiographic Findings

- Conventional
  - Arterial ectasias, pouches, and aneurysms described in older patients

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR
- Protocol advice
  - Multiplanar MR with fat saturation to identify scalp lipoma (may be missed on CT)
  - MRA may disclose vascular abnormalities

DIFFERENTIAL DIAGNOSIS

Sturge-Weber Syndrome (SWS)

- Unilateral hemispheric cerebral atrophy and cortical Ca++, LM enhancement ipsilateral to forehead port-wine nevus
  - CNS findings frequently posterior

Oculocerebrocutaneous Syndrome (OCCS)

- Characterized by unique cutaneous striated muscle hamartoma, cystic microphthalmia, and giant tectum absent vermis malformation
- Cortical dysplasia, agenesis of corpus callosum, and Dandy-Walker malformation frequently present
- Cutaneous, eye, and CNS anomalies usually ipsilateral but less consistently than ECCL

Epidermal Nevus Syndrome (ENS)

- Ipsilateral epidermal nevus, hemimegalencephaly, facial lipoma, and hemihypertrophy
- Occasional scleral choristoma

Proteus Syndrome

- Progressive asymmetric, bilateral trunk/limb hypertrophy
- Osteomas, lipomas, and pigmented nevi common
- CNS anomalies uncommon; hemimegalencephaly most common

PATHOLOGY

General Features

- Etiology
  - Defect in development of mesenchymal tissues

https://CafePezeshki.IR

  - Affects mostly neural crest cells surrounding brain and forming vessels
- Genetics
  - Sporadic
  - May survive autosomal lethal gene by somatic mosaicism
- ECCL considered distinct entity; however, some clinical/imaging overlap with SWS, OCCS, ENS, and proteus syndrome
- Embryology-anatomy
  - 3rd week gestation: Embryonic disc consists of ectoderm, mesoderm, entoderm
  - Neural tube develops from ectoderm during 3rd week gestation
  - 4th and 5th week gestation: Mesoderm forms mesenchymal sheath over brain and spinal cord → precursor blood vessels, bone, cartilage, and fat

Gross Pathologic & Surgical Features

- Brain: Cortical atrophy, white matter hypoplasia, ventriculomegaly, polymicrogyria, wallerian degeneration brainstem
  - Arterial ectasias, pouches, aneurysms described in older patients
- Leptomeninges: Thick, gray, gelatinous with excess underlying arteries, veins, and varicose capillaries
- Skull: Macrocranium with focal hyperostosis
- Scalp: Focal lipomatous thickening with overlying circumscribed alopecia
- Face: Multiple, tiny, white/purple/yellow periocular > perinasal papules

Microscopic Features

- Brain: Abnormal 4-layered cytoarchitecture, mineral concretions outer cortical lamina, scattered glial nodules
- Leptomeninges: Lipoangiomatosis
- Skull: Diploic replacement with mature fat cells
- Scalp: Benign lipoma > fibrolipoma expanding into dermis; absent hair follicles with preserved erector pili muscles
- Skin: Subcutaneous angiofibroma, fibrolipoma, or lipoma
- Eye: Corneal limbus/scleral choristoma
  - Other ocular abnormalities: Persistent hyaloid vasculature, coloboma, cloudy cornea, lens dislocation, ectopic pupils

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Nevus psiloliparus: Sharply demarcated focus of scalp alopecia overlying scalp lipoma
    - Hallmark of ECCL
- Other signs/symptoms
  - Ipsilateral ocular choristomas and periocular > perinasal papules; epibulbar dermoid
  - Macrocranium (unrelated to hydrocephalus)
  - Seizures, psychomotor delay, spastic hemiparesis
  - Infrequent scoliosis, foot deformities, sensorimotor deficits (2° to spinal lipoma)
- Clinical profile
  - Newborn/infant with nevus psiloliparus, scleral mass, and periocular papules; seizures in infants

Demographics

- Age
  - Newborn > infant presentation
  - Rare presentation in teen/adult patients with cutaneous, ocular lesions
- Gender
  - M = F
- Ethnicity
  - No racial or geographic predilection
- Epidemiology
  - Rare; ~ 54 reported cases (likely underreported)

Natural History & Prognosis

- Reported growth lipomas and ocular choristomas; remaining congenital abnormalities static
- Abnormal vasculature, aneurysms later in life
- Majority with variable degrees of psychomotor impairment and dependency
- Few reports of neurologically normal patients with nevus psiloliparus; nonsyndromic nevus psiloliparus vs. ECCL with minimal CNS involvement

Treatment

- Antiepileptics
- Shunt placement for hydrocephalus

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Considerable imaging overlap with SWS → search for scalp lipoma
- Low-density IC lipoma may be difficult to distinguish from CSF on CT

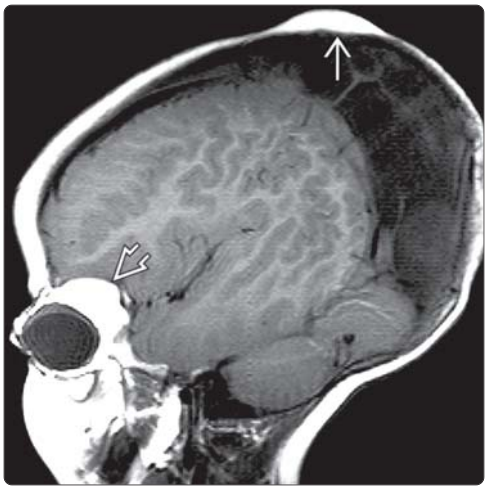
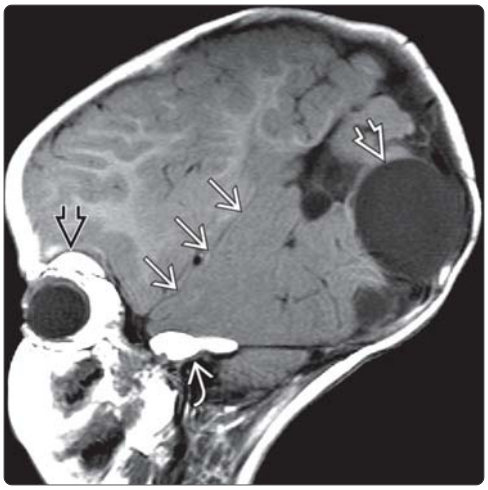
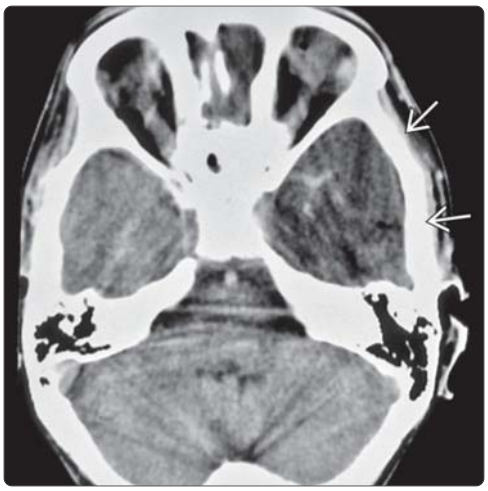
https://CafePezeshki.IR



(Left) *Sagittal T1WI MR shows an ipsilateral scalp ⇨ and orbital ⇨ lipoma. The globe is buphthalmic with a scleral lipodermoid.* **(Right)** *Axial T2WI MR shows marked left ventriculomegaly with herniation of the ventricle through the choroidal fissure and hemispheric volume loss. The herniated ventricle is displacing the posterior aspect of the cerebral hemisphere ⇨ anteriorly, thereby compressing and distorting the hemispheric parenchyma.*



(Left) *Sagittal T1WI MR shows ipsilateral orbital ⇨ and middle cranial fossa ⇨ lipomas. The cerebral cortex ⇨ is distorted by the enlarged lateral ventricle. Note the intracranial cyst ⇨.* **(Right)** *Axial T1WI MR shows an intracranial lipoma in the interhemispheric fissure ⇨ and an extracranial lipoma ⇨ in subcutaneous fat. There is no hemispheric atrophy or ventriculomegaly. The patient is clinically normal. The findings may represent a forme fruste of ECCL.*



(Left) *Axial NECT shows a middle cranial fossa arachnoid cyst in a patient with ECCL. Note the expansion of the left middle cranial fossa ⇨ by the cyst. The cyst is ipsilateral to hemispheric atrophy and a scalp lipoma. Scalp lipoma is sometimes poorly seen by imaging.* **(Right)** *Sagittal T1WI MR shows large, subcutaneous lipomas ⇨ in the upper neck and the occipital area of the scalp. Note the small lipoma ⇨ immediately behind the cerebellar vermis.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Lhermitte-Duclos disease (LDD)
  - Benign cerebellar lesion; unclear if neoplastic, malformative, or hamartomatous
- Multiple hamartoma syndrome (MHAM) → autosomal dominant, mutation in *PTEN* gene, associated with increased incidence of malignancy
  - MHAM = Cowden syndrome (CS); Cowden plus Lhermitte-Duclos (COLD) = MHAM with LDD
    - CS is most common phenotype of PTEN hamartoma tumor syndrome
  - LDD now considered manifestation of MHAM and a neurocutaneous syndrome

IMAGING

- Relatively well-defined cerebellar mass with striated/corduroy/tigroid/gyriform pattern
- LDD always in cerebellum and may be large → mass effect, tonsillar herniation, hydrocephalus

TOP DIFFERENTIAL DIAGNOSES

- Subacute cerebellar infarction
- Cerebellitis
- Unclassified cerebellar dysplasias
- Ganglioglioma
- Medulloblastoma

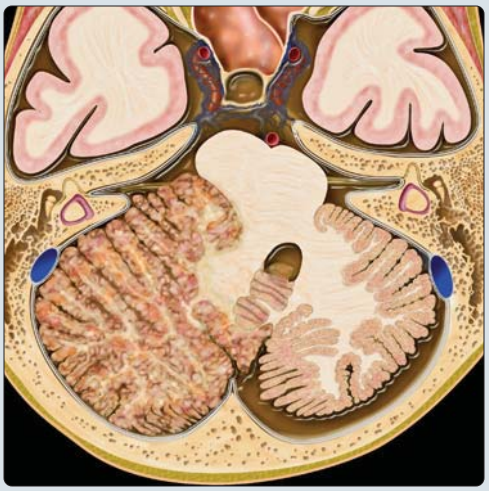
CLINICAL ISSUES

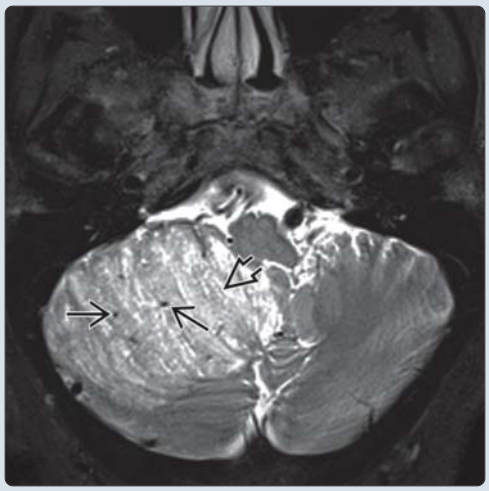
- Most common presentation: Headache, nausea and vomiting, ataxia, blurred vision
  - Can present in coma
- Shunting or surgical debulking for symptomatic patients with hydrocephalus

DIAGNOSTIC CHECKLIST

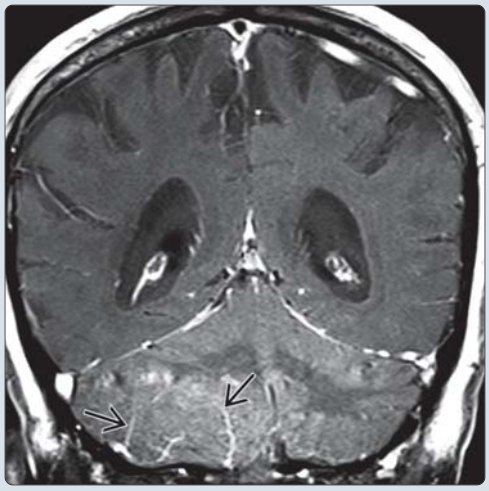
- If LDD, screen for MHAM; if MHAM, screen for LDD
- Long-term cancer screening needed, especially thyroid and breast (↑ malignancy in MHAM)

(Left) *Axial graphic shows thickened and irregular cerebellar folia in the right cerebellar hemisphere. This results in the enlargement of the hemisphere & mass effect upon the brainstem that are typical of Lhermitte-Duclos disease (LDD).* **(Right)** *Axial T2WI in a 76-year-old man with nonspecific headaches shows a hyperintense right cerebellar hemispheric mass. The widened "gyriform" folia ⇨ give the mass a distinctive striated appearance. Several dot-like flow voids ⇨ are present in-between the enlarged folia.*





(Left) *Axial T1 C+ FS in the same patient shows the thickened folia do not enhance but the prominent flow voids seen on the T2WI show strong, uniform enhancement ⇨ suggesting they are vascular structures.* **(Right)** *Coronal T1 C+ scan in the same case shows the enhancing vessels ⇨ nicely. The findings were pathognomonic of LDD so the mass was not biopsied.*



https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Lhermitte-Duclos disease (LDD)
  - Dysplastic cerebellar gangliocytoma, gangliocytoma dysplasticum, hamartoma of cerebellum
  - Hamartoblastoma, cerebelloparenchymal disorder 6, granule cell hypertrophy, granular cell hypertrophy, granulomolecular hypertrophy
  - Diffuse ganglioneuroma of cerebellar cortex, diffuse cerebellar hypertrophy, neurocytic blastoma, myelinated neurocytoma, purkingeoma
- Multiple hamartoma syndrome (MHAM)
  - Multiple hamartoma-neoplasia syndrome, Cowden disease, Cowden syndrome (CS), Cowden-Lhermitte-Duclos syndrome (COLD)

Definitions

- Lhermitte-Duclos disease → neurological manifestation of MHAM
  - Benign cerebellar lesion but unclear if neoplastic, malformative, or hamartomatous
  - Association between LDD and MHAM probably represents new neurocutaneous syndrome
- Multiple hamartoma syndrome
  - Autosomal dominant, variable expression, typically mutation in *PTEN* gene
  - Hamartomatous neoplasms of skin (90-100%), mucosa, GI tract, bones, CNS, eyes, and GU tract
  - Associated with increased incidence of malignancy

IMAGING

General Features

- Best diagnostic clue
  - Grossly thickened cerebellar folia with striated (tigroid) gyriform pattern
- Location
  - Always in cerebellum, usually unilateral
  - Often involves vermis, rarely brainstem
- Size
  - Size variable, may be large → mass effect, tonsillar herniation, hydrocephalus
- Morphology
  - Infiltrative but well demarcated

CT Findings

- NECT
  - Normal to high attenuation with striations
    - Occasionally cystic areas &/or calcifications
  - May compress 4th ventricle, cause obstructive hydrocephalus
- CECT
  - ± enhancement

MR Findings

- T1WI
  - Iso- to hypointense with striations
- T2WI
  - ↑ signal with characteristic iso- to hypointense striations
  - May have bizarre gyriform appearance
- FLAIR
  - ↑ signal with striations
  - May have hypointense cysts
- T2* GRE
  - Veins between folia
- DWI
  - ↑ signal on DWI usually due to ↑ T2 signal
    - Sometimes due to hypercellularity, ↑ axonal density
  - Low to ↑ ADC; ↑ ADC in white matter, cysts
  - May have ↑ fractional anisotropy (FA) in white matter
- PWI
  - May show areas of ↑ rCBV and rCBF
- T1WI C+
  - ± enhancement (increased vascularity in molecular layer and leptomeninges, predominantly venous)
- MRS
  - ↓ NAA, ↓ choline, ↓ myoinositol
  - Variable lactate, may show prominent peak

Nuclear Medicine Findings

- PET
  - ↑ uptake FDG PET and 11C-methionine PET
  - Report of ↑ CBF, ↓ OEF, and similar $CMRO_2$ compared to normal cerebral hemisphere

Imaging Recommendations

- Best imaging tool
  - MR with DWI, MRS, and contrast
- Protocol advice
  - Coronal T2 may be helpful
  - If LDD, initiate work-up for MHAM and screen for malignancies
  - If it enhances, consider differential diagnosis carefully

DIFFERENTIAL DIAGNOSIS

Subacute Cerebellar Infarction

- Mass effect, ↑ signal on DWI but vascular territory

Cerebellitis/Vasculitis

- Acute onset of symptoms

Unclassified Cerebellar Dysplasias

- Do not progress, hydrocephalus rare

Ganglioglioma

- May have bizarre appearance simulating LDD

Tuberous Sclerosis Complex

- Rarely mass-like cerebellar dysplastic lesions but other features of tuberous sclerosis complex

Medulloblastoma

- Lateral desmoplastic type may have somewhat striated appearance
- ↑ signal on DWI but most have marked ↑ Cho/NAA

Meningeal Metastases

- Nodular leptomeningeal enhancement

Meningeal Granulomatous Disease

- Nodular leptomeningeal enhancement

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Unclear whether hamartomatous, neoplastic, or congenital malformative origin
    - Nonproliferation/absence of malignant transformation favors hamartomatous nature
- Genetics
  - Many have mutations of *PTEN* gene at 10q23.31 (tumor suppressor gene)
  - Activation of PTEN/AKT/mTOR pathway suggests role for mTOR in pathogenesis
- Associated abnormalities
  - Most patients with LDD likely have MHAM

Staging, Grading, & Classification

- WHO grade I

Gross Pathologic & Surgical Features

- Markedly enlarged cerebellar hemisphere/vermis
  - Wide, thick cerebellar folia have grossly gyriform appearance

Microscopic Features

- Widening of molecular cell layer → occupied by abnormal ganglion cells
- Absence of Purkinje cell layer
- Hypertrophy of granule cell layer
- ↓ volume of white matter
- Histologically may be confused with ganglion cell tumor

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, nausea and vomiting, papilledema, unsteady gait, upper limb ataxia and dysmetria, blurred vision, lower cranial nerve palsies
- Other signs/symptoms
  - Sensory motor deficits, vertigo, neuropsychological deficits
- Clinical profile
  - If LDD, screen for MHAM; if MHAM, screen for LDD

Demographics

- Age
  - Any; most common between 20-40 years
- Gender
  - M ≈ F
- Ethnicity
  - No known predilection
- Epidemiology
  - ↑ degree of penetrance in family members

Natural History & Prognosis

- Many do not grow or grow only slowly
- If mass effect is not relieved prognosis is poor
- Post-surgery recurrences are rare but do occur

Treatment

- Options, risks, complications
  - Borders of lesion blend into normal surrounding cerebellum → total resection difficult
  - Shunting or surgical debulking for symptomatic patients with hydrocephalus

DIAGNOSTIC CHECKLIST

Consider

- Search for other features of MHAM when LDD is diagnosed and vice versa
- Long-term cancer screening needed (especially breast in women, thyroid in men and women)

Image Interpretation Pearls

- Relatively well-defined cerebellar mass with striated tigroid or gyriform pattern

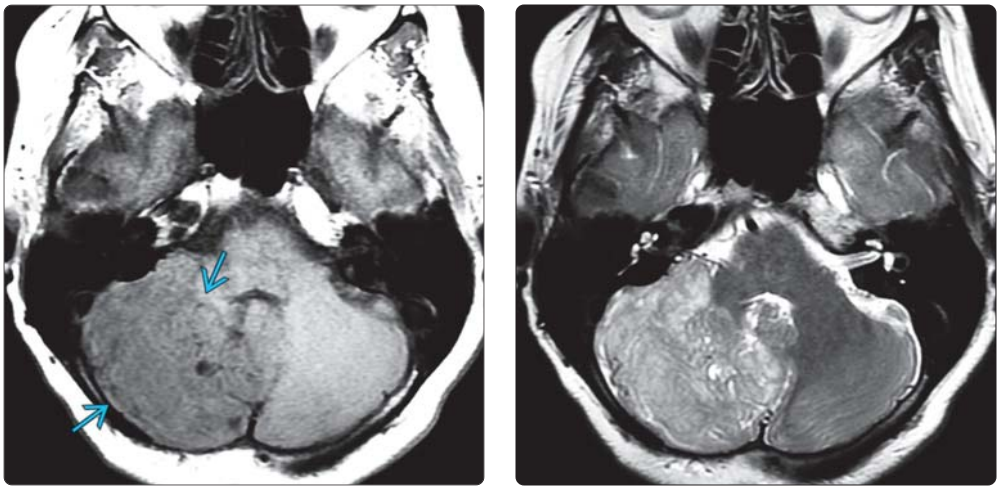
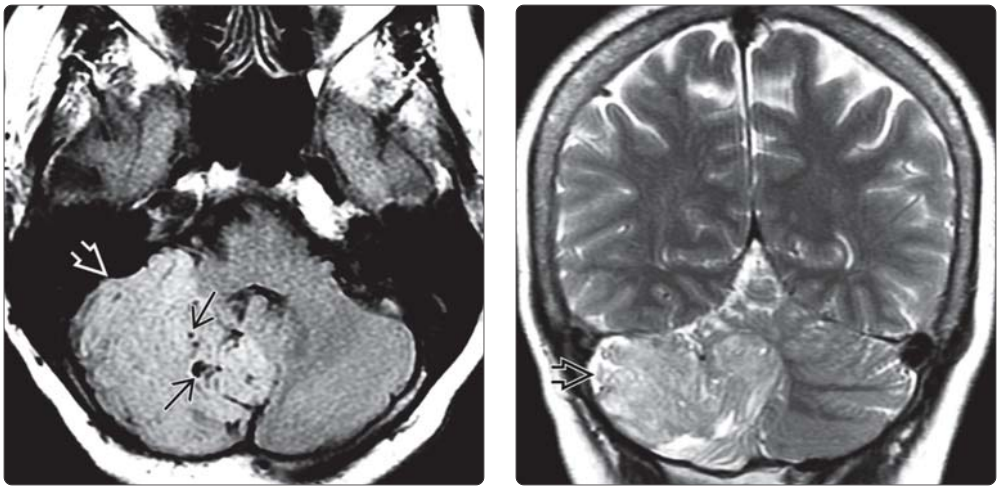
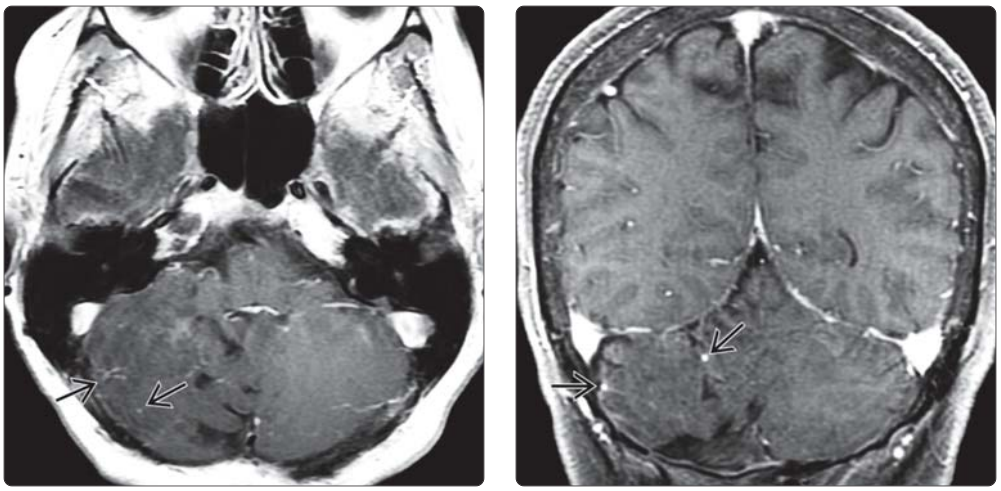
https://CafePezeshki.IR



(Left) *Axial T1WI in a 57-year-old woman with headaches shows a mildly hypointense mass in the right cerebellar hemisphere ⇨ and vermis.* **(Right)** *T2WI in the same patient shows the mass is hyperintense and has a striated gyriform appearance.*



(Left) *Axial FLAIR scan in the same patient shows the mass ⇨ is hyperintense compared to the normal left cerebellar hemisphere. Several fluid-filled cysts within the mass suppress completely ⇨.* **(Right)** *Coronal T2WI shows the mass has a striped or tigroid pattern. The cerebellar folia are expanded ⇨ compared to the normal left cerebellum.*



(Left) *T1 C+ MR in the same patient shows no enhancement of the mass, but punctate and linear enhancing foci ⇨ representing prominent vessels are seen.* **(Right)** *Corontal T1 C+ FS shows the enhancing vessels ⇨ but no enhancement of the mass itself. The preoperative diagnosis was cerebellar neoplasm. This is a biopsy-proven case of dysplastic cerebellar gangliocytoma (LDD). Further evaluation revealed Cowden disease and the need for active cancer surveillance was identified.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Congenital phakomatosis characterized by giant &/or multiple melanocytic nevi (GCMN) of the skin in association with melanotic lesions of CNS
- CNS disease
  - Primary leptomeningeal melanocytic neoplasms (LMNs)
    - Can be circumscribed (usually adults) or diffuse (more often children)
    - Benign or malignant
  - Leptomeningeal melanocytosis (LMs): Excess of benign melanotic cells in leptomeninges (most frequently in children with neurocutaneous melanosis [NCM])
  - Leptomeningeal melanoma (LMm) or melanomatosis: Malignant melanoma of leptomeninges
- Genetic studies show NCM is a RASopathy

IMAGING

- GCMN + foci of T1 hyperintensity in amygdala, cerebellum, or cerebral cortex
- GCMN + diffuse leptomeningeal (LM) enhancement

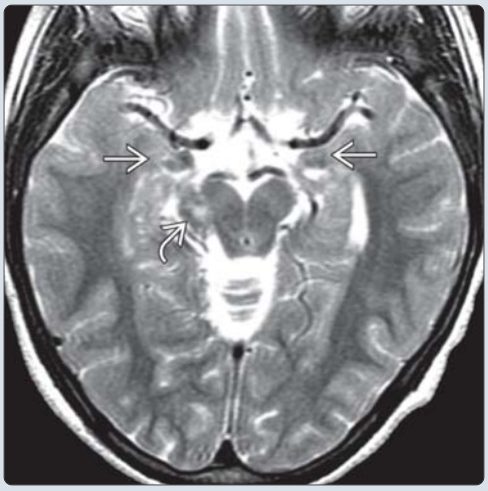
CLINICAL ISSUES

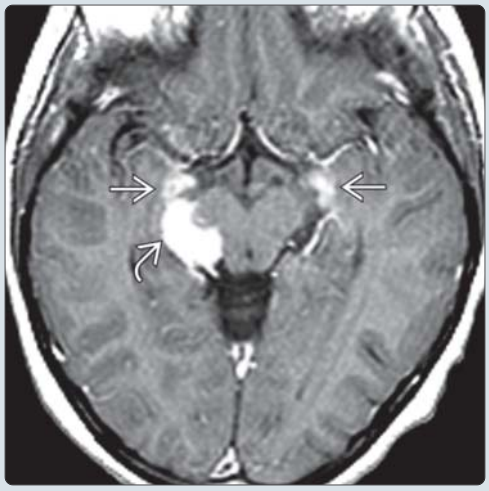
- Criteria for diagnosis
  - Giant or multiple (≥ 3) cutaneous melanocytic nevi
  - Child: 6 cm body, 9 cm head maximal diameter
  - Cutaneous melanoma only in patients with benign meningeal lesions
  - Leptomeningeal melanoma only in patients with benign cutaneous lesions
- Sx NCM manifests by 2-3 years of age
- Asx NCM: Parenchymal melanosis often stable
- GCMN (isolated or NCM): 5-15% lifetime risk of malignant degeneration (melanoma)

DIAGNOSTIC CHECKLIST

- Normal MR does not exclude diagnosis NCM
- LMs cannot be distinguished from LMm by imaging

(Left) *Graphic shows localized dark (melanotic) pigmentation of the leptomeninges. Inset demonstrates extension of melanosis into the brain substance along the Virchow-Robin spaces* ⇨. **(Right)** *Axial T1WI MR of a 6 year old with benign parenchymal and leptomeningeal melanosis shows multiple foci of T1 shortening (hyperintense signal) in the amygdala* ⇨ *(indicates parenchymal involvement), and in the right ambient cistern* ⇨ *(indicates leptomeningeal disease).*





(Left) *Axial T2WI MR in the same patient reveals T2 shortening (hypointense signal) of the mass lesions in the amygdala* ⇨ *and the ambient cistern* ⇨. *Note that the abnormal signal is more difficult to see on T2-weighted images.* **(Right)** *Axial T1 C+ MR in the same patient demonstrates enhancement of the leptomeningeal lesion* ⇨. *The parenchymal lesions* ⇨ *do not enhance, and are actually slightly less conspicuous, as is often the case following contrast injection.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neurocutaneous melanosis (NCM)

Definitions

- Congenital phakomatosis characterized by giant &/or multiple melanocytic nevi (GCMN) of the skin in association with melanotic lesions of CNS
  - CNS disease: Parenchymal
    - Melanosis or melanocytosis: Focal collection of benign melanotic cells
    - Malignant melanoma or melanomatosis (MM)
  - CNS disease: Leptomeningeal (LM)
    - Primary leptomeningeal melanocytic neoplasms (LMNs)
      - Can be circumscribed (usually adults) or diffuse (more often children)
      - Benign or malignant
      - Leptomeningeal melanocytosis (LMs): Excess of benign melanotic cells in leptomeninges (most frequently in children with NCM)
      - Leptomeningeal melanoma (LMm) or melanomatosis: Malignant melanoma of leptomeninges
  - Genetic studies show NCM is a RASopathy

IMAGING

General Features

- Best diagnostic clue
  - GCMN + foci of T1 hyperintensity in amygdala, cerebellum, or cerebral cortex
  - GCMN + diffuse LM enhancement
- Location
  - Parenchymal melanosis: Amygdala, cerebellum, basis pontis, thalami, base of frontal lobes
  - LMs or LMm: Diffuse LM involvement; rarely focal
  - MM: Temporal lobe most common
- Size
  - Parenchymal melanosis: < 1 cm
  - MM: Typically several cm
- Morphology
  - Parenchymal melanosis: Round or oval lesions, sometimes curvilinear in cortex
  - LMs/LMm: Linear or nodular (bulky)
  - MM: Large, round mass
- 64% symptomatic (Sx), patients with NCM (MM, LMm, ± LMs) have hydrocephalus
  - Communicating > noncommunicating
- Arachnoid cysts occasionally identified
- Spinal involvement (LM enhancement, intra- or extramedullary cyst, syrinx, arachnoiditis) in 20%
- Stable free radicals in melanin responsible for MR appearance

CT Findings

- NECT
  - Parenchymal melanosis: Normal or hyperdense
  - MM: Hyperdense mass with edema, mass effect; frequent necrosis/hemorrhage
- CECT
  - Parenchymal melanosis: No enhancement
  - LMs: Normal or diffuse LM enhancement
  - LMm: Diffuse LM enhancement
  - MM: Avid enhancement, often heterogeneous

MR Findings

- T1WI
  - Parenchymal melanosis: Hyperintense
  - LMs/LMm: Sulci/cisterns normal, iso- or hyperintense
  - MM: Mixed signal intensity; frequently hyperintense
- T2WI
  - Parenchymal melanosis: Mixed signal intensity, frequently hypointense; no edema, mass effect
  - LMs/LMm: Sulci/cisterns normal, iso- or hypointense
  - MM: Mixed signal intensity with edema, mass effect; frequent necrosis, hemorrhage
- FLAIR
  - LMm/LMs: Variable leptomeningeal hyperintensity
- T2* GRE
  - "Blooming" of hemorrhage and melanin
- T1WI C+
  - Parenchymal melanosis: No enhancement
  - LMs: Normal or diffuse LM enhancement
  - LMm: Diffuse LM enhancement
  - MM: Avid enhancement, often heterogeneous

Imaging Recommendations

- Best imaging tool
  - MR C+ brain and spine
- Protocol advice
  - MR screen for asymptomatic (Asx) infants with GCMN

DIFFERENTIAL DIAGNOSIS

T1-Hyperintense Mass

- Lipoma: Chemical shift artifact, extraaxial (subarachnoid) location
- Dermoid: Chemical shift artifact, extraaxial location, sharply demarcated, exerts mass effect
- Acute/subacute hemorrhage: Marked T2 hypointensity, mass effect/edema, neurological deficit
- Hemorrhagic, nonmelanotic neoplasms: Areas of marked T2 hypointensity, mass effect/edema

Diffuse Leptomeningeal Enhancement

- Carcinomatous meningitis/CSF seeding: History of 1° malignancy, linear/nodular LM enhancement
- Infectious meningitis (routine bacterial, TB, coccidioidomycosis): Basal cisterns, linear enhancement, signs/symptoms of meningitis; positive CSF cultures
- Noninfectious inflammation (sarcoidosis, Wegener granulomatosis): Linear/nodular enhancement

PATHOLOGY

General Features

- Genetics
  - NCM caused by postzygotic somatic mutations in codon 61 of *NRAS*
    - Both diffuse, circumscribed LMNs
    - BRAF mutations may play role in some NCM patients

https://CafePezeshki.IR

- Associated abnormalities
  - Association with cerebellar hypoplasia (< 10%)
    - Abnormal meningeal cells causally related to hindbrain malformation
    - Cerebellar melanosis always present with cerebellar hypoplasia
    - Dandy-Walker malformation occasionally seen
- Embryology
  - Neural crest-derived primordial cells migrate, differentiate into melanocytes in pia mater and basal layer of epidermis
  - Melanocytes in epidermis at 8-10 weeks gestation
  - Melanocytes in pia mater at 23 weeks gestation
- Anatomy
  - Melanocytes normally present in pia mater over convexities, base of brain, ventral brainstem, upper cervical cord, and lumbosacral spinal cord
  - Melanocytes normally surround blood vessels but do not extend into Virchow-Robin (VR) spaces

Staging, Grading, & Classification

- Criteria for diagnosis
  - Giant or multiple (≥ 3) cutaneous melanocytic nevi
    - Child: 6 cm body, 9 cm head maximal diameter
    - Adult: 20 cm maximal diameter
  - Cutaneous melanoma only in patients with benign meningeal lesions
  - Leptomeningeal melanoma only in patients with benign cutaneous lesions

Gross Pathologic & Surgical Features

- Parenchymal melanosis: Focal, abnormal pigmentation within brain
- LMs/LMm: Darkly pigmented, thickened pia mater
- MM: Pigmented mass, ± necrosis, hemorrhage
- GCMN: Giant or multiple pigmented, hairy nevi
  - Giant nevi comprise 66% (in NCM)
    - Lumbosacral > occipital, upper back
    - Involvement of head and neck occurs in 94%
    - Patients with nevi ≥ 50 cm at highest risk NCM
  - Multiple nevi comprise 34%

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - ↑ intracranial pressure (seizures, vomiting, headache, macrocranium, CN6 palsy, lethargy)
  - Other signs/symptoms
    - Focal neurological deficit, psychiatric disturbance in rare older child/young adult presentation
- Clinical profile
  - Asymptomatic infant with GCMN (parenchymal melanosis)
    - Parenchymal melanosis may causes seizures
  - Infant/child with GCMN + signs/symptoms ↑ intracranial pressure (LMm, ± LMs, MM)
    - Histologically benign disease (LMs) may be symptomatic
- CSF (Sx NCM): ↑ protein, ↓ glucose, ± benign/malignant melanotic cells

Demographics

- Age
  - Sx NCM manifests by 2-3 years of age
- Epidemiology
  - NCM: Rare; 100+ reported cases
  - GCMN: 1:20,000 live births
    - Sx NCM: < 3% patients with GCMN
    - ~ 30% of patients with GCMN have parenchymal melanosis (Asx NCM)

Natural History & Prognosis

- Natural history
  - Asx NCM: Parenchymal melanosis often stable
    - Few reports of regression, and degeneration into MM
  - GCMN (isolated or NCM): 5-15% lifetime risk of malignant degeneration (melanoma)
- Prognosis
  - Asx NCM: Unknown; at risk developing Sx NCM
  - Sx NCM: Dismal; median survival 6.5 months after symptom onset
    - Prognosis equally poor for histologically benign (LMs) or malignant (LMm, MM) Sx NCM

Treatment

- Asx NCM: Screening with MR beginning 6 months of age
- Sx NCM: Shunt hydrocephalus (filter prevents peritoneal seeding)
  - Surgery, XRT, systemic/intrathecal chemotherapy
    - Palliative; no significant alteration course of NCM

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Normal MR does not exclude diagnosis of NCM
- LMs cannot be distinguished from LMm by imaging
  - Clinically irrelevant since Sx LMs and LMm have equally poor prognosis

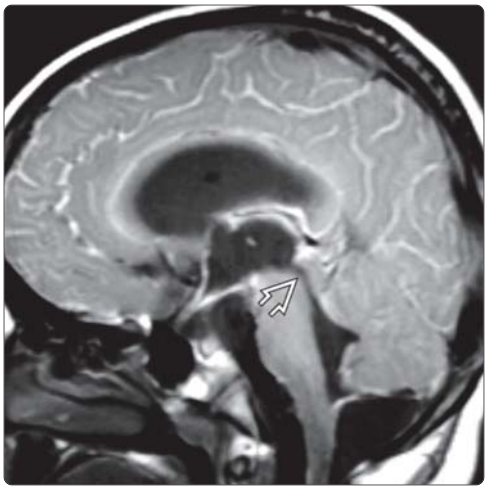
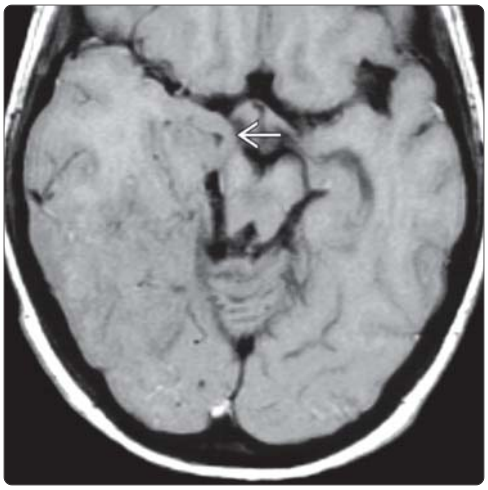
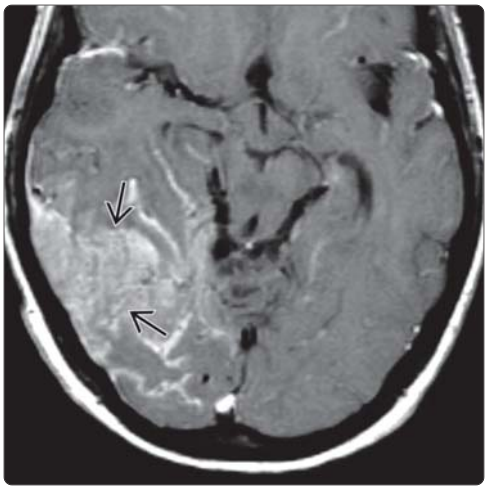
(Left) *Axial T1WI MR of a 4-year-old child with neurocutaneous melanosis (NCM) reveals 2 small deposits ➡ of T1-hyperintense melanin on the surface of the right cerebellar hemisphere.* **(Right)** *Axial T1WI MR shows foci of intrinsic high signal intensity ➡ in 2 regions of the cerebral cortex, representing cortical melanosis in the setting of NCM. These lesions are stable over the short term and do not appreciably change after administration of paramagnetic contrast.*



(Left) *Axial T1 C+ MR shows diffuse neurocutaneous melanosis in a 6-year-old child. The pial melanosis involves virtually the entire surface of the brain and enhances strongly and uniformly. Moderate to severe lateral ventriculomegaly is evident.* **(Right)** *Sagittal T1WI MR in the same patient reveals patent aqueduct of Sylvius ➡ and enlarged basilar cisterns. Thus, the hydrocephalus is of the extraventricular obstructive type. Diffusely abnormal leptomeningeal enhancement is evident.*





(Left) *Axial T1WI MR shows significant mass effect in the right posterior temporal and occipital lobes with effacement of the surface sulci. The uncus is herniated ➡. Only minimal hyperintensity is evident. Surgery disclosed extensive melanosis that had invaded the brain via the perivascular spaces.* **(Right)** *Axial T1WI C+ MR in the same patient shows a strongly enhancing superficial mass ⇨ that fills the adjacent sulci and extends deeply into the underlying brain parenchyma.*

KEY FACTS

TERMINOLOGY

- Classic triad of callosal dysgenesis, infantile spasms, and chorioretinal lacunae but more complex with other major features

IMAGING

- Callosal agenesis: Complete (70%), partial (30%)
- Polymicrogyria: Frontal or perisylvian (~ 100%)
- Heterotopia: Periventricular (100%), subcortical (30%)
- Intracranial cysts: Midline > intraventricular; other extraaxial sites; choroid plexus; intraparenchymal
- Ocular coloboma
- Choroid plexus papillomas
- Hemispheric asymmetry
- Hypoplastic/dysplastic cerebellar hemispheres or vermis

TOP DIFFERENTIAL DIAGNOSES

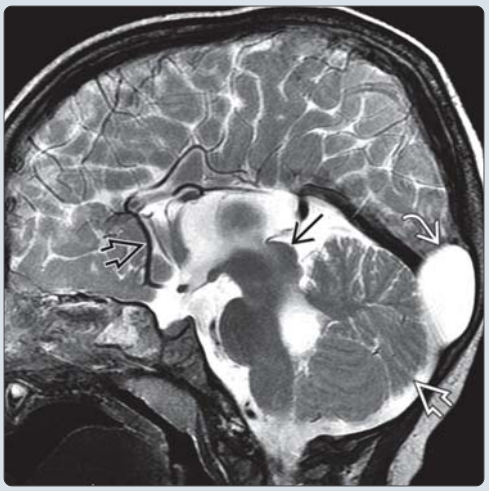
- Congenital toxoplasmosis
- Congenital CMV

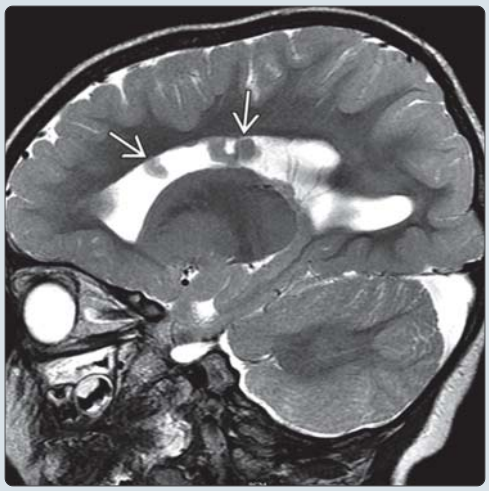
PATHOLOGY

- Females; males with chromosome 47 XXY
  - Probably de novo mutation on X chromosome
  - Dominant inheritance; hemizygous lethality in males

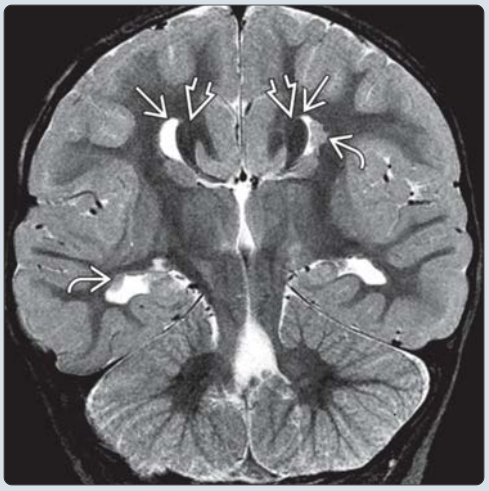
CLINICAL ISSUES

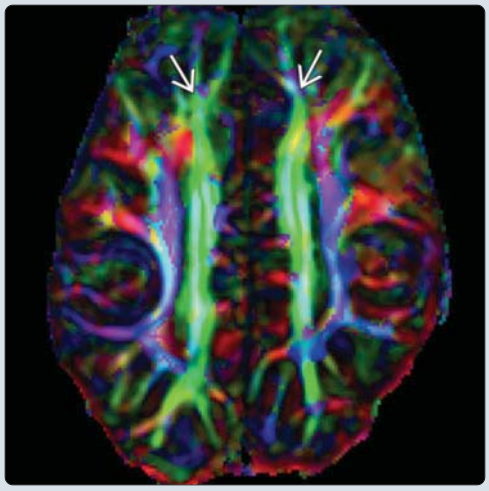
- Infantile spasms or other early-onset epilepsy, typically poorly controlled
- Chorioretinal lacunae: Only true pathognomonic feature (may be unilateral)
- 91% function at < 1-year level, 21% able to walk, 4% able to communicate
- Many need surgery for scoliosis





(Left) *Sagittal T2FS MR scan in a 4-year-old female with known Aicardi syndrome and coloboma with chorioretinal lacunae shows near complete agenesis of the corpus callosum with an azygous ACA ⇨. A retrocerebellar cyst ⇨ with elevation of the torcular is present. The vermis ⇨ and tectum ⇨ appear dysplastic.* **(Right)** *More lateral T2FS MR in the same patient shows multiple nodules of heterotopic gray matter ⇨ protruding into the lateral ventricle.*





(Left) *Coronal T2FS scan in the same patient shows the characteristic "Viking helmet" ⇨ of corpus callosum dysgenesis. Prominent heavily myelinated Probst bundles ⇨ are present, as are multiple nodules of periventricular heterotopic gray matter ⇨.* **(Right)** *Axial color DTI in the same patient shows the prominent, parallel, and nonconverging Probst bundles in green ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Aicardi (AIC) syndrome

Definitions

- Classic triad of callosal dysgenesis, infantile spasms, and chorioretinal lacunae

IMAGING

General Features

- Best diagnostic clue
  - Major features
    - Callosal agenesis: Complete (70%), partial (30%)
    - Polymicrogyria: Frontal or perisylvian (~ 100%)
    - Heterotopia: Periventricular (100%), subcortical (30%)
    - Intracranial cysts: Midline > intraventricular; other extraaxial sites; choroid plexus; intraparenchymal
    - Ocular coloboma
    - Choroid plexus papillomas
  - Supporting features
    - Vertebral or rib abnormalities
    - Microphthalmia
    - Hemispheric asymmetry
  - Other reported CNS imaging findings
    - Hypoplastic/dysplastic cerebellar hemispheres or vermis
    - Enlarged cisterna magna
    - Increased tectal size
    - Optic nerve hypoplasia
    - Delayed myelination

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Volumetric T1 in myelinated brains
  - High resolution T2 in infants
  - Contrast to diagnose choroid plexus papillomas

CT Findings

- NECT
  - No calcifications

DIFFERENTIAL DIAGNOSIS

Congenital Toxoplasmosis

- Calcifications, no polymicrogyria or heterotopia

Congenital Cytomegalovirus

- Calcifications, no heterotopia

Other Genetic Syndromes

- Microphthalmia with linear skin defects (MLS) shares some features, but eye lesions are not lacunae

PATHOLOGY

General Features

- Etiology
  - Unknown
- Genetics
  - Females; males with chromosome 47 XXY
    - Probably de novo mutation on X chromosome
    - Dominant inheritance; hemizygous lethality in males
- Associated abnormalities
  - Scoliosis secondary to costovertebral anomalies, often requiring surgery
  - ± distinct facial phenotype, ~ 25% microphthalmia
  - ± cleft lip and palate
  - Probable increased incidence of benign and malignant extra-CNS tumors
  - Probable increased incidence of vascular malformations/tumors

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Infantile spasms or other early onset epilepsy, typically poorly controlled
  - Chorioretinal lacunae: Only true pathognomonic feature (may be unilateral)
  - Majority have severe psychomotor retardation

Demographics

- Age
  - Most present in infancy; range is 3 days to 12 years
- Gender
  - Female almost exclusively, rare male 47 XXY
- Epidemiology
  - Early lethality in males → spontaneous abortion
  - Almost exclusively female after 2nd trimester

Natural History & Prognosis

- Median age of survival 18.5 ± 4 years

Treatment

- Symptomatic only

KEY FACTS

TERMINOLOGY

- Li-Fraumeni syndrome (LFS)
- Autosomal dominant familial cancer syndrome
  - 75% of LFS have loss of function mutations in *TP53* tumor suppressor gene
  - Lifelong ↑ risk of osteosarcoma, soft tissue sarcoma, leukemia, breast cancer, brain tumors, melanoma, adrenal cortical tumors

IMAGING

- Astrocytoma: Cerebrum > cerebellum > spine
- Choroid plexus carcinoma: Lateral ventricle > > 4th ventricle

TOP DIFFERENTIAL DIAGNOSES

- Hereditary syndromes causing familial cancers, including brain tumors
- Tuberous sclerosis
- von Hippel-Lindau
- Medulloblastoma
- Basal cell nevus syndrome
- Turcot
- Neurofibromatosis type 1
- Carney complex
- Melanoma-astrocytoma syndrome

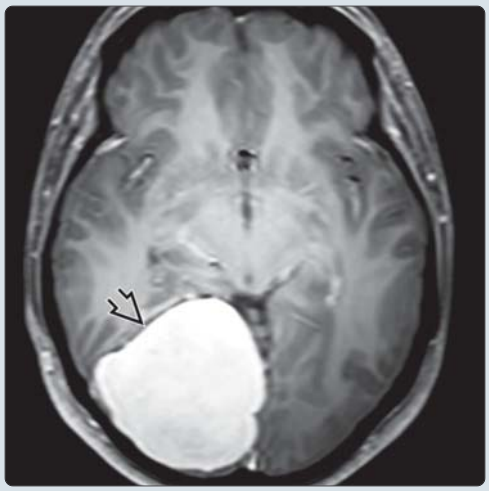
PATHOLOGY

- p53: Transcription factor important in apoptosis, cell cycle control; frequently mutated in tumors
- Breast cancer (24-30%), soft tissue sarcoma (12-18%), brain tumors (12-14%), bone sarcoma (12-13%), adrenocortical carcinoma (6%)

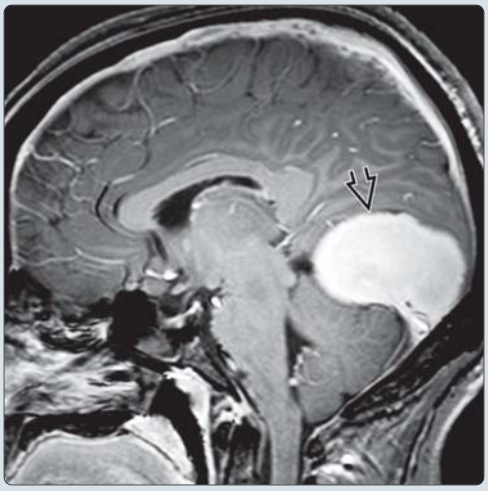
CLINICAL ISSUES

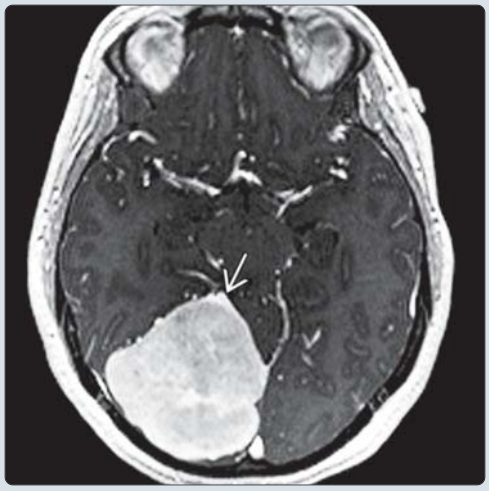
- Propensity to develop additional primary neoplasms
- BTs: High prevalence below 10 years of age

(Left) *A 38-year-old female with a history of breast cancer presented to the ER with several months of increasingly severe headache and visual difficulties. NECT scan shows a large hyperdense mass ⇨ in the right occipital region.* **(Right)** *Axial T1 C+ FS in the same patient shows a large, intensely enhancing right occipital mass ⇨.*



(Left) *Sagittal T1 C+ FS MR shows the well-demarcated, intensely enhancing mass ⇨ abuts the dura.* **(Right)** *Axial presurgical contrast-enhanced SPGR shows a subtle dural "tail" along the tentorium cerebelli ⇨. Preoperative diagnosis of meningioma was confirmed at surgery. Further evaluation disclosed TP53 germline mutation and Li-Fraumeni syndrome (LFS) was diagnosed.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Li-Fraumeni syndrome (LFS)
- Li-Fraumeni-like (LFL) syndromes

Synonyms

- Sarcoma, breast, leukemia, and adrenal syndrome

Definitions

- Autosomal dominant familial cancer syndrome
  - Lifelong ↑ risk of osteosarcoma, soft tissue sarcoma, leukemia, breast cancer, brain tumors, melanoma, adrenal cortical tumors
  - 75% of LFS have loss of function mutations in *TP53* tumor suppressor gene

IMAGING

General Features

- Best diagnostic clue
  - CNS tumor in child with 2 1st- and 2nd-degree relatives with cancer
- Location
  - Astrocytoma: Cerebrum > cerebellum > spine
  - Choroid plexus carcinoma (CPC): Lateral ventricle > > 4th ventricle

Imaging Recommendations

- Best imaging tool
  - MR with contrast

DIFFERENTIAL DIAGNOSIS

Hereditary Syndromes Causing Familial Cancers, Including Brain Tumors

- Neurofibromatosis type 1
  - Neurofibroma, optic glioma, astrocytoma
  - Rhabdomyosarcoma, parathyroid adenoma, pheochromocytoma, others
- Tuberous sclerosis
  - Ependymoma, giant cell astrocytoma
  - Renal angiomyolipoma/carcinoma
- von Hippel-Lindau
  - Hemangioblastoma (cerebellum, spinal cord)
  - Hemangioblastoma (pancreas, kidney); renal cell carcinoma, pheochromocytoma, papillary cystadenoma (epididymis)
- Basal cell nevus syndrome
  - Medulloblastoma
  - Basal cell nevi/carcinoma, ovarian carcinoma
- Carney complex
  - Melanotic schwannoma
  - Myxoma (eyelid, atrium), Sertoli cell tumor, pheochromocytoma, pituitary adenoma
- Melanoma-astrocytoma syndrome
  - Cerebral astrocytoma, other CNS tumors
  - Cutaneous malignant melanoma
- Turcot
  - Medulloblastoma, glioblastoma multiforme, astrocytoma, ependymoma
  - Colon cancer, basal cell carcinoma, gastric cancer

PATHOLOGY

General Features

- Etiology
  - Mutation in *TP53* suppressor gene (17p13); AD

Staging, Grading, & Classification

- LFS diagnostic clinical criteria
  - Proband with sarcoma diagnosed < 45 years **and** 1st- or 2nd-degree relative with any cancer diagnosed < 45 years or any sarcoma at any age
  - Or: Proband with multiple tumors (except multiple breast), 2 of which are in LFS spectrum, and 1st occurred ≤ 46 years
  - Or: Childhood adrenocortical carcinoma (50-100% have underlying *TP53* germline mutation); other suggestive tumors include choroid plexus carcinoma, rhabdomyosarcoma, or multiple childhood cancers
- LFL: 3 different schemes; most predictive is Chompet
  - Proband with sarcoma, brain tumor, breast cancer, or adrenocortical carcinoma (ACC) < 36 years
  - **And** 1 1st- or 2nd-degree relative with cancer < 46 years
  - **Or** proband with multiple primary tumors, 2 of which are sarcoma, brain tumor, breast cancer, or ACC

Gross Pathologic & Surgical Features

- Breast cancer (24-30%), soft tissue sarcoma (12-18%), BT (12-14%), bone sarcoma (12-13%), ACC (6%)
- Less frequent tumors: Lung, hematopoietic system, stomach, colorectum, skin, ovary

Microscopic Features

- Astrocytoma (50%), CPC (15%)
- Medulloblastoma, PNET less common

CLINICAL ISSUES

Demographics

- Age
  - BTs: High prevalence below 10 years of age
- Epidemiology
  - LFS 50% chance of cancer by age 40, 90% by age 60
  - Females 93% lifetime cancer risk, males 75%

Natural History & Prognosis

- Propensity to develop additional primary neoplasms

Treatment

- Total resection of tumors ± chemotherapy
- Avoid radiation: Risk of radiation-induced tumors

DIAGNOSTIC CHECKLIST

Consider

- Nearly all CPC have p53 germline mutations

SELECTED REFERENCES

KEY FACTS

IMAGING

- Multiple circumscribed, encapsulated masses following course of cranial or peripheral nerves **without** involvement of CN8
- MR C+ is mainstay of schwannomatosis imaging

TOP DIFFERENTIAL DIAGNOSES

- Neurofibromatosis type 2
- Sporadic schwannoma
- Neurofibromatosis type 1
- Sporadic neurofibroma

PATHOLOGY

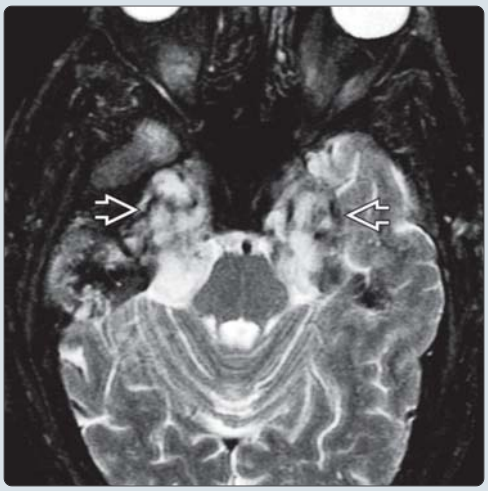
- Germline mutation of *SMARCB1* gene
  - *SMARCB1* mutation is **not** found in sporadic (nonsyndromic schwannomas)
  - *SMARCB1* mutation is **not** found in NF2

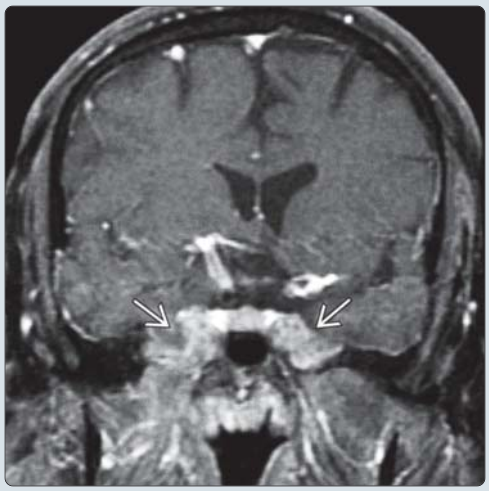
CLINICAL ISSUES

- Incidence thought to be similar to NF2 (~ 1/40,000)
- Typically presents with pain, which may be disabling
  - In contradistinction to NF2, which more frequently presents with neurologic deficits
- Peak incidence between ages 30-60
  - Contrast with NF1 (typically diagnosed in 1st decade)
  - Contrast with NF2 (typically diagnosed in 2nd decade)
- **Normal** life expectancy
  - Contrast with NF2 (↓ life expectancy)

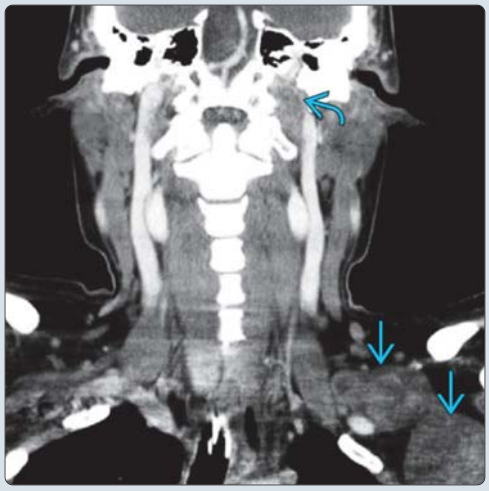
DIAGNOSTIC CHECKLIST

- In patient > 30 years of age
  - With **multiple nonvestibular schwannomas**
    - Consider diagnosis of schwannomatosis
    - **And** recommend high-resolution MR imaging of temporal bones/internal auditory canals to screen for NF2





(Left) *Axial T2WI MR of a 47-year-old man with schwannomatosis reveals bulky, fusiform enlargement of the bilateral trigeminal nerves ⇨, which demonstrate heterogeneous increased T2 signal and exert mass effect on the pons without associated signal abnormality.* **(Right)** *Coronal T1WI C+ FS MR of the same patient reveals enhancing, globular masses ⇨ involving the bilateral trigeminal ganglia, which extend into the infrazygomatic masticator spaces via widened foramina ovale. IACs (not shown) were normal.*



(Left) *Axial CECT of the neck in a 31-year-old woman with schwannomatosis shows a circumscribed, encapsulated, heterogeneously enhancing, submucosal mass ⇨ in the supraglottic larynx, which nearly completely effaces the laryngeal airway.* **(Right)** *Coronal reconstruction reveals additional heterogeneous density masses involving the left brachial plexus ⇨ and jugular foramen ⇨, compatible with numerous schwannomas in this patient with schwannomatosis.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Schwannomatosis: Multiple schwannomas of peripheral nervous system **without** involvement of vestibular nerves

IMAGING

General Features

- Best diagnostic clue
  - Multiple circumscribed, encapsulated masses following course of cranial or peripheral nerves **without** involvement of CN8

CT Findings

- NECT
  - Iso- to slightly hyperdense compared to brain
  - Look for effect on adjacent bone, foramina
    - Smooth enlargement
    - Thin, sclerotic,"surgical"-appearing margins
- CECT
  - Variable, often heterogenous enhancement

MR Findings

- Variable signal intensity on all sequences due to varying amounts of Antoni A and Antoni B regions
- Hyperintense on T2WI, PD, FLAIR, and STIR
- Intense, typically heterogeneous enhancement on T1WI C+

Imaging Recommendations

- Best imaging tool
  - MR C+ is mainstay of schwannomatosis imaging

PATHOLOGY

General Features

- Genetics
  - Complex, incompletely understood genetics involving germline involvement of *SMARCB1* gene, which is **NOT** found in sporadic, nonsyndromic schwannomas
    - Tumor supressor gene found on chromosome 22
    - Likely involves multi-hit mutation phenomenon involving *SMARCB1* and *NF2* genes in affected tissues

Staging, Grading, & Classification

- **Baseline criteria** (all 4 must be met)
  - Patients must not fulfill any existing sets of diagnostic criteria for NF2
  - No evidence of vestibular schwannoma on MR
  - No 1st-degree relative with NF2
  - No known constitutional *NF2* gene mutation
- **Definite** diagnosis
  - Age > 30 **AND** 2 or more nonintradermal schwannomas (1 histologically proven); **OR** 1 pathologically confirmed schwannoma **AND** 1st-degree relative meeting diagnostic criteria
- **Possible** diagnosis
  - Age < 30 **AND** 2 or more nonintradermal schwannomas (1 histologically proven); **OR** age > 45 **AND** 2 or more nonintradermal schwannomas (1 histologically proven); **OR** radiologic evidence of schwannoma **AND** 1st-degree relative meeting criteria for definite diagnosis
- **Segmental** schwannomatosis
  - Meets criteria for definite or possible schwannomatosis, but confined to 1 limb or 5 or fewer contiguous spinal elements

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain, typically neuropathic in quality; may be disabling
    - In contradistinction to NF2, which more frequently presents with neurologic deficits
  - Symptom onset typically in 2nd or 3rd decade of life
    - Compared to NF1 (1st decade) and NF2 (2nd decade)

Demographics

- Epidemiology
  - Reported incidence ranges from 1/40,000 to 1/1.7 million, probably closer to 1/40,000 (similar to NF2)

Natural History & Prognosis

- **NORMAL** life expectancy, unlike NF2 patients who have reduced life expectancy

Treatment

- Symptom control with pain management
- Surgical intervention only if spinal cord compression or symptoms clearly due to schwannoma
- No role for radiation therapy; evolving role of chemotherapy

DIAGNOSTIC CHECKLIST

Consider

- Patient may have schwannomatosis if
  - Age > 30
  - > 1 schwannoma
  - No vestibular schwannoma

Image Interpretation Pearls

- **DO NOT** favor diagnosis of schwannomatosis in patient younger than age 30 as vestibular schwannomas may not yet have developed
  - As patient age at time of diagnosis ↑, likelihood of schwannomatosis ↑ & likelihood of NF2 ↓

Reporting Tips

- In patient > 30 years of age, presence of multiple nonvestibular schwannomas should prompt radiologist to suggest diagnosis of schwannomatosis, as well as recommend high-resolution MR imaging of temporal bones/IACs to screen for NF2

Approach to Head Trauma

General Considerations

Epidemiology: Trauma is the most common worldwide cause of death and disability in children and young adults. In these patients, neurotrauma is responsible for the vast majority of cases. In the USA and Canada, emergency departments (ED) treat more than 8 million patients with head injuries annually, representing 6-7% of all ED visits.

The vast majority of patients with head trauma are classified as having minimal or minor injury. Minimal head injury is defined as no neurologic alteration or loss of consciousness (LOC). Minor head injury or concussion is epitomized by a walking, talking patient with a Glasgow Coma Score (GCS) of 13-15 who has experienced LOC, amnesia, or disorientation.

Of all head-injured patients, ~ 10% sustain fatal brain injury whereas another 5-10% of neurotrauma survivors have permanent serious neurologic deficits. A number have more subtle deficits ("minimal brain trauma"), whereas 20-40% of patients have moderate disability.

Etiology and Mechanisms of Injury

The etiology of traumatic brain injury (TBI) varies according to patient age. Falls are the leading cause of TBI in children younger than 4 years and in elderly patients older than 75 years. Gunshot wounds are most common in adolescent and young adult males but relatively rare in other groups. Motor vehicle and auto-pedestrian collisions occur at all ages without gender predilection.

TBI can be a missile or nonmissile injury. Missile injury results from penetration of the skull, meninges, &/or brain by an external object (such as a bullet).

Nonmissile closed head injury (CHI) can be caused by direct blows or penetrating injuries. However, nonmissile CHI is a more common cause of neurotrauma. High-speed accidents exert significant acceleration/deceleration forces, causing the brain to move suddenly within the skull. Forcible impaction of the brain against the unyielding calvaria and hard, knife-like dura results in gyral contusion. Rotation and abrupt changes in angular momentum may deform, stretch, and damage long vulnerable axons, resulting in axonal injury.

Classification of Head Trauma

The most widely used **clinical** classification of brain trauma, the GCS, depends on the assessment of 3 features: Best eye, verbal, and motor responses. Using the GCS, TBI can be designated as mild (13-15), moderate (9-12), or severe (≤ 8).

TBI can also be divided pathoetiologically into primary and secondary injuries. Primary injuries occur at the time of initial trauma. Skull fractures, epi- and subdural hematomas, contusion, and axonal injuries are examples of primary traumatic injuries.

Secondary injuries occur later and include cerebral edema, perfusions, and brain herniations. Large arteries, such as the internal carotid, vertebral, and middle meningeal arteries, can be injured either directly at the time of initial trauma or indirectly as a complication of brain herniations.

How to Image Acute Head Trauma

Imaging is absolutely critical to the diagnosis and management of the patient with acute TBI. The goal of emergent imaging is 2-fold: (1) identify treatable injuries and (2) detect and delineate the presence of secondary injuries, such as herniation syndromes.

MDCT: Multidetector row CT (MDCT) is the "workhorse" of brain trauma imaging and is also used as a screening procedure in a wide variety of clinical settings. Whenever possible, helically acquired, thin-section, nonenhanced CT scans from the foramen magnum to the vertex with both soft tissue and bone algorithm should be obtained. Coronal and sagittal images reformatted from the axial source data are extremely helpful, especially in detecting thin peritentorial subdural hematomas. "Subdural" windowing (e.g., window width of 150-200 HU) of the soft tissue images on PACS (or film, if PACS is not available) is also highly recommended. The scout view should always be displayed and evaluated as part of the study.

Whole-body, CT-based studies for patients with multiple traumas are becoming increasingly more common. Soft tissue and bone algorithm reconstructions with multiplanar (usually coronal and sagittal) reformatted images of the spine are often included as part of the initial trauma evaluation.

CTA: CT angiography (CTA) is an appropriate modality in the setting of penetrating neck injury, cervical fracture/subluxation, skull base fractures that traverse the carotid canal or a dural venous sinus, and suspected vascular dissections.

MR: MR is generally a secondary modality most often used in the late acute or subacute stages of brain injury. It is helpful in detecting focal/regional/global perfusion alterations, assessing the extent of hemorrhagic and nonhemorrhagic injuries, and assisting in long-term prognosis. MR should also be considered if nonaccidental trauma is suspected either clinically or on the basis of initial CT scan findings.

Who and When to Image?

Many clinical studies have attempted to determine whom to image and when. Three major and widely used appropriateness criteria for imaging acute head trauma have been published: The American College of Radiology (ACR) Appropriateness Criteria, the New Orleans Criteria (NOC), and the Canadian Head CT Rule (CHCR).

The American College of Radiology has delineated and published updated appropriateness criteria for imaging head trauma. Emergent NECT in mild/minor CHI with the presence of a focal neurologic deficit &/or other risk factors is deemed very appropriate, as is imaging all traumatized children under 2 years of age.

Between 6-7% of patients with minor head injury have positive findings on head CT scans; most also have headache, vomiting, drug or alcohol intoxication, seizure, short-term memory deficits, or physical evidence of trauma above the clavicles. CT should be used liberally in these cases as well as in patients over 60 years of age and in children under the age of 2.

Repeat CT of patients with head injury should be obtained if there is sudden clinical deterioration, regardless of initial imaging findings. Delayed development or enlargement of both extra- and intraaxial hemorrhages typically occurs within 36 hours following the initial traumatic event.

Approach to Skull Base and Facial Trauma

Fractures involving the base of the skull (BOS) range from a solitary linear fracture to complex injuries involving the craniofacial bones. BOS fractures are often associated with intracranial injuries, such as cerebral contusion, intra- and

https://CafePezeshki.IR

extraaxial hemorrhages, and vascular or cranial nerve injuries. The objective of imaging patients with BOS &/or facial trauma is to depict the location and extent of the fractures and identify associated injuries to vital structures. Accurate imaging interpretation also aids in surgical planning and in the prevention of complications, such as CSF leak.

Skull Base Trauma

Anterior skull base (ASB) fractures: ASB trauma is frequently associated with sinonasal cavity &/or orbital injuries. The majority of these patients have facial fractures. Imaging should determine if the fractures cross the cribriform plate, traverse the frontal sinuses, and involve the orbital apex or optic canals.

Central skull base (CSB) fractures: Imaging patients with CSB trauma may involve the sphenoid bone, clivus, cavernous sinuses, and carotid canal. Injury to the internal carotid artery and CN 3, 4, 6 &/or the trigeminal nerve divisions can be present.

Temporal bone (T-bone) fractures: T-bone fractures can be oriented parallel (longitudinal) or perpendicular (transverse) to the petrous ridge. Longitudinal fractures are more common and traverse the mastoid and middle ear cavity, often disrupting the ossicles and extending into the squamous portion of the T-bone. Transverse fractures often cross the inner ear and extend into the occipital bone.

Imaging evaluation should include the determination of ossicular chain integrity, inner ear &/or facial nerve canal involvement, and whether the T-bone tegmen (roof) is transgressed.

Posterior skull base (PSB) fractures: Fractures of the occipital bones may be isolated or associated with transverse petrous T-bone fractures. PSB fractures may extend into the transverse or sigmoid sinuses, jugular foramen, or hypoglossal canal. Craniocervical junction injuries are also common in patients with trauma to the PSB.

Facial Trauma

Orbit fractures: There are 2 types of orbit fractures: (1) those that involve the orbital walls/rim and (2) so-called blowout fractures. Blowout fractures may involve the orbital floor (inferior blowout) or ethmoid (medial blowout), but the rim is intact. Imaging should determine if (1) there are other orbital or facial fractures and (2) whether there is entrapment of the inferior ± medial rectus muscles and fat.

Facial bone (Le Fort) fractures: There are 3 types of Le Fort fractures. Le Fort I is a horizontal fracture through the maxilla that involves the piriform aperture. Le Fort II is a pyramidal fracture that involves the nasofrontal junction, infraorbital rims, medial orbital walls, orbital floors, and the zygomaticomaxillary suture lines.

Le Fort III, a.k.a. craniofacial separation, consists of nasofrontal junction fractures that extend laterally through the orbital walls and zygomatic arches.

All 3 Le Fort fractures involve the pterygoid plates and often exhibit elements of more than 1 type of facial bone fracture.

Zygomaticomaxillary fractures: The prominent position of the zygomatic arch renders it susceptible to trauma. A zygomaticomaxillary complex (ZMC) fracture, formerly referred to as a "tripod fracture," has 4 involved articulations and 5 distinct fractures.

Imaging in ZMC fractures should determine how displaced/comminuted the fracture is, whether there is involvement of the orbital floor/apex &/or lamina papyracea, and how the lateral orbital wall is displaced.

Complex midfacial fracture: Complex midfacial fracture, or "facial smash injury," consists of multiple facial fractures that cannot be classified as 1 of the named patterns. It is important to determine the posterior displacement of the midface, as this is a highly cosmetically deforming injury. Associated injuries to the orbit &/or skull face must be delineated in detail.

Nasoorbitoethmoid (NOE) fracture: NOE fractures may disrupt the medial canthal tendon and extend into the lacrimal apparatus. Displacement or comminution of the bony fragments posteriorly into the ethmoid or superiorly into the anterior fossa should be identified.

Mandible fracture: Mandibular fractures can occur within or posterior to the teeth. The mandible essentially functions as a "ring of bone" and multiple, often bilateral, fractures are common. The fractures should be located, the degree/direction of fragment displacement identified, and the condyles evaluated for subluxation or dislocation. Involvement of the inferior alveolar canal and teeth should be determined.

Approach to Spine and Cord Trauma

Imaging Acute Spine Injuries

While radiographs are still used for evaluating the spine, MDCT has become the procedure of choice in rapidly assessing patients with possible spine injuries. In patients with moderate to severe injuries, obtaining large datasets that are subsequently parsed into C-, T-, and L-spine studies together with chest, abdomen, and pelvis is increasingly common.

Thin section axial images are easily reformatted into sagittal and coronal views. Both bone algorithm and soft tissue reconstructions are typically performed. CTA is a helpful adjunct if vascular injury is a risk (BOS fractures that cross carotid canal or dural venous sinus, cervical spine fractures that traverse foramen transversarium, posterior element subluxation, etc.). Emergent MR imaging is especially helpful in patients with suspected ligamentous complex damage, traumatic disc herniation, or cord injury.

Spine Fracture Classification

Craniovertebral junction: Initial evaluation in patients with suspected craniovertebral junction (CVJ) injury should begin with a focus on identification of craniocervical malalignment followed by delineation of specific fractures. These are classified by level and type of injury as well as potential for instability. Although an exhaustive description is beyond the scope of this text, a few selected fractures are briefly delineated here.

C1 fractures often involve the posterior arch. A Jefferson fracture is a vertical compression fracture in which both the anterior and posterior rings are disrupted and displaced radially. A combined lateral mass displacement (relative to C2 lateral masses) of ~ 7 mm indicates disruption of the transverse ligament and potential instability.

Odontoid fractures are classified anatomically into 3 types: Type I = avulsed tip, type II = transverse dens fracture above the C2 body, and type III fractures involve the superior portion

https://CafePezeshki.IR

New Orleans Criteria in Minor Head Injury

CT Indicated if GCS = 15 Plus Any of the Following
Headache
Vomiting
Patient > 60 years
Intoxication (drugs, alcohol)
Short-term memory deficits (anterograde amnesia)
Visible trauma above clavicles
Seizure

Thoracolumbar Injury Severity Score

	Description	Qualifier	Points
Injury Mechanism			
	Compression		
		Simple	1
		Lateral angulation > 15°	1
		Burst	1
	Translation/rotational		3
	Distraction		4
Posterior Ligamentous Complex			
	Intact		0
	Suspected/indeterminate for disruption		2
	Injured		3
Neuro Status			
	Nerve root involvement		2
	Cord, conus involvement (incomplete)		3
	Cord, conus involvement (complete)		2
	Cauda equina involvement		3

Score is a total of 3 components. Score ≤ 3 suggests nonoperative treatment, whereas score of 4 is indeterminate. Score ≥ 5 suggests operative treatment. For injury mechanism, the worst level is used and the injury is additive. An example is a distraction injury with burst without angulation is 1 (simple compression) + 1 (burst) + 4 (distraction) = 6 points. Modified from Vaccaro AR et al: Reliability of a novel classification system for thoracolumbar injuries: the Thoracolumbar Injury Severity Score. Spine (Phila Pa 1976). 31(11 Suppl):S62-9; discussion S104, 2006.

of the C2 body. Odontoid fractures are especially common in elderly osteoporotic patients who experience falls.

Cervical spine fracture classification: Cervical spine fractures are classified functionally, according to presumed mechanism of injury. Cervical hyperflexion injuries range from simple compression fractures and "clay shoveler fracture" (C7-T1 spinous process avulsion) to unstable injuries, such as posterior ligament disruption with anterior subluxation, bilateral interfacetal dislocation, and flexion teardrop fracture.

In cervical hyperflexion and rotation injury, unilateral facet dislocation (± fracture) is common. Forward displacement of a vertebra < 50% of the AP diameter of the body is typical. The articular pillars are fractured in hyperextension with rotation injury.

Cervical vertical compression injury can cause a Jefferson fracture. In cervical "burst" fractures, there is middle column involvement with bony retropulsion.

Thoracolumbar fracture classification: Multiple systems for classifying thoracolumbar fractures have been developed. In the increasingly popular thoracolumbar injury classification and severity score (TLICS), injury mechanism, integrity of the posterior ligamentous complex, and neurologic status are each scored. The total number of TLICS points is then used to guide treatment.

KEY FACTS

IMAGING

- **Cephalohematoma**
  - Subperiosteal hematoma
  - Between outer table of calvaria, periosteum
  - Does not cross sutures
  - Usually unilateral, small, and resolves spontaneously
- **Subgaleal hematoma**
  - Forms under aponeurosis (galea) of occipitofrontalis muscle
  - Not limited by sutures
  - May become very large
  - Can extend around entire circumference of skull
- **Fractures**
  - Calvarial fractures rarely, if ever, occur without overlying scalp hematoma
  - Base of skull fractures (temporal bone, clivus, sinuses, etc.): Look for extension into arterial or venous channel

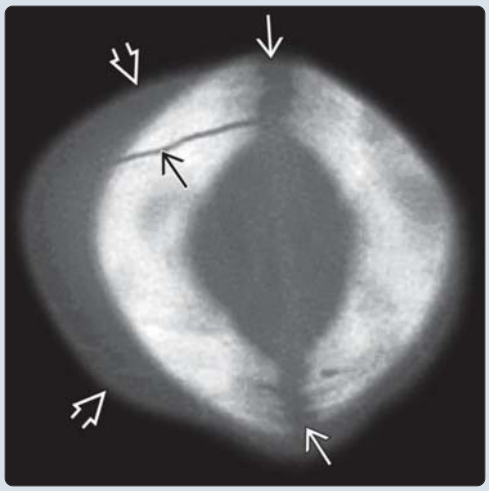
TOP DIFFERENTIAL DIAGNOSES

- Vascular grooves
- Sutures
- Venous lakes
- Arachnoid granulations
- Wormian bones

CLINICAL ISSUES

- **Cephalohematoma**
  - Occurs in 1% of newborns
  - Usually caused by instrumented delivery
  - Diagnosed clinically; infrequently imaged
- **Subgaleal hematoma**
  - Common in head trauma
  - Occurs in all ages
  - Large expanding hematoma in infant can be life threatening

(Left) *Graphic shows the skull of a newborn, including the anterior fontanelle, coronal, metopic, and sagittal sutures. Cephalohematoma ⇨ is subperiosteal, focal, and limited by sutures. Subgaleal hematoma ➡ is under the scalp aponeurosis, much more extensive, and not bounded by sutures.* **(Right)** *Bone CT in a newborn with a traumatic delivery shows a linear skull fracture ⇨ and cephalohematoma ➡ overlying the parietal bone. Note that the cephalohematoma does not cross the sagittal suture ➡.*



(Left) *Bone CT shows a diastatic fracture of the sagittal suture ⇨. A very large subgaleal hematoma ➡ extends around the entire circumference of the skull. The superior sagittal sinus is torn and the intracranial blood seen on soft tissue windows was a vertex venous epidural hematoma.* **(Right)** *T2WI MR scan in an abused infant shows a very large mixed acute/subacute subgaleal hematoma ➡ crossing the sutures and extending over the face/orbits.*

TERMINOLOGY

Synonyms

- Scalp swelling, soft tissue swelling, scalp hematoma

Definitions

- Scalp injuries: Lacerations, hematomas
  - Laceration: Focal discontinuity in scalp
    - Variable extent and thickness
    - Foreign bodies, subcutaneous air common
  - Hematoma: Hemorrhage in or between scalp layers
- Skull injuries: Fractures

IMAGING

General Features

- Best diagnostic clue
  - Skull fracture vs. normal structure (e.g., suture or vascular groove): Rarely, if ever, occurs without overlying scalp "lumps and bumps"
  - Important to distinguish between 2 types of scalp hematoma
    - Cephalohematoma
    - Subgaleal hematoma
- Location
  - **Cephalohematoma**
    - Subperiosteal hematoma
      - Between outer table of calvaria, periosteum
      - Elevates periosteum
      - Does not cross sutures
      - Extracranial equivalent of intracranial epidural hematoma
      - Usually unilateral
  - **Subgaleal hematoma**
    - Hematoma under aponeurosis (galea) of occipitofrontalis muscle
    - External to periosteum
    - Not limited by sutures
  - **Fractures**
    - Calvarial
      - Rarely, if ever, occurs without overlying scalp hematoma
    - Base of skull (BOS) (including mastoids, sinuses)
      - Temporal bone, sphenoid bone, clivus, etc.
      - Look for extension into arterial or venous channel
- Size
  - **Cephalohematoma**
    - Rarely large (contained by periosteum)
  - **Subgaleal hematoma**
    - Can be extensive, even life threatening
    - Not limited by sutures
    - Often bilateral, often spreads diffusely around entire calvaria
  - **Fractures**
    - Size varies
    - Can be simple or comminuted
    - Can be closed or open
- Morphology
  - **Cephalohematoma**
    - Rounded
    - Half dome shape
  - **Subgaleal hematoma**
    - Diffuse, poorly demarcated
    - Usually circumferential, nonfocal
  - **Fractures**
    - Linear: Sharply marginated
      - Middle cranial fossa is most common site
    - Depressed: Inwardly depressed fragments
    - Elevated: Fragments lifted, usually rotated
    - Diastatic: Widens suture or synchondrosis
      - Usually in combination with linear skull fracture that extends into adjacent suture
      - Traumatic suture diastasis usually in children with severe BOS fractures
    - "Growing": Post-traumatic leptomeningeal cyst
      - Arachnoid, contused brain herniate through dural tear
      - Causes craniocerebral erosion
      - Growing skull fractures slowly widen with time
      - Can present months or years after trauma

Radiographic Findings

- No role in modern imaging of head trauma

CT Findings

- **Scalp injuries**
  - Cephalohematoma
    - Unilateral scalp mass limited by sutures
    - Chronic cephalohematomas may calcify
  - Subgaleal hematoma
    - Extensive soft tissue mass
    - May extend around entire circumference of skull
- **Skull fractures**
  - Linear skull fracture
    - Sharply marginated lucent line(s)
  - Depressed skull fracture
    - Comminuted fragments imploded inwardly
  - Elevated skull fracture
    - Elevated, rotated skull segment
  - Diastatic skull fracture
    - Widened suture or synchondrosis
    - Usually accompanied by linear skull fracture
  - "Growing" skull fracture
    - Difficult to detect in acute stage
    - Progressively widening, unhealing fracture
    - Lucent lesion with rounded, scalloped margins
    - Cerebrospinal fluid and soft tissue trapped within expanding fracture
    - Brain is usually encephalomalacic

MR Findings

- Used to evaluate complications, not acute manifestations

Angiographic Findings

- Consider CTA/MRA if
  - Fracture crosses carotid canal or dural venous sinus
  - Clivus fracture is present
    - High association with neurovascular injury
  - High-risk cervical injury
    - Cervical spine fracture &/or dislocation
    - Distraction injury

https://CafePezeshki.IR

- Penetrating neck trauma

Imaging Recommendations

- Best imaging tool
  - NECT
    - Obtain both soft tissue and bone algorithm reconstructions
    - Thin section multiplanar reconstructions for complex BOS fractures
    - 3D shaded surface display (SSD) CT
      - Especially useful for depressed, diastatic fractures
      - Helpful if complex facial fractures are present
  - CTA (high-risk injuries)
- Protocol advice
  - MR
    - Use T2* (GRE/SWI) for hemorrhage
    - DWI for ischemic complications

DIFFERENTIAL DIAGNOSIS

Normal Structures

- Vascular grooves
  - Well-corticated margins
  - Not as sharp or lucent as linear skull fractures
  - No adjacent scalp hematoma
- Sutures
  - In predictable locations (coronal, sagittal, mastoid, etc.)
  - ≤ 2 mm and no adjacent linear skull fracture
  - Densely corticated
  - Less distinct than fractures
- Venous lakes, arachnoid granulations
  - In predictable locations
    - Parasagittal
    - Adjacent to/within dural venous sinus
  - Often connect with vascular channel
  - Round/ovoid shape
  - Smooth, well corticated

Normal Variants

- Wormian bones
  - Common (≥ 1 in 50% of children)
  - Rare: Osteogenesis imperfecta
  - Typical locations (e.g., lambdoid suture)
  - No overlying soft tissue injury

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Scalp swelling
  - Soft ("boggy") scalp hematoma is associated with intracranial injury in head-injured children
- Other signs/symptoms
  - Vary with type and extent of brain injury

Etiology and Epidemiology

- **Cephalohematoma**
  - Occurs in 1% of newborns
  - Usually related to birth trauma
    - Instrumented delivery
    - Sometimes vacuum-assisted delivery
- **Subgaleal hematoma**
  - Common in head trauma
  - Occurs in all ages
- **Fractures**
  - Linear
    - Low-impact injury
    - Delivered over relatively wide surface area
  - Depressed
    - High-impact, high-energy direct blow
      - Often with blunt object
    - Force radiates centrifugally
    - Delivered over small surface

Natural History and Prognosis

- **Cephalohematoma**
  - Diagnosed clinically; infrequently imaged
  - Usually resolves spontaneously without treatment
  - Occasionally calcifies, causing firm palpable mass
  - Complications are rare
- **Subgaleal hematoma**
  - Large expanding hematoma in infant can be life threatening
- **Fractures**
  - Usually heal spontaneously
  - Complications
    - Vascular injury
    - Dura/arachnoid laceration ± cerebrospinal fluid leak
    - Cranial nerve injury
    - Leptomeningeal cyst (rare)

DIAGNOSTIC CHECKLIST

Consider

- CTA/MRA if high risk for vascular injury
  - Fracture crosses vascular channel, dural venous sinus

Image Interpretation Pearls

- Linear fracture vs. normal (e.g., suture or vascular groove): If no overlying soft tissue swelling is present, it is rarely, if ever, a skull fracture

KEY FACTS

TERMINOLOGY

- Impalement injury

IMAGING

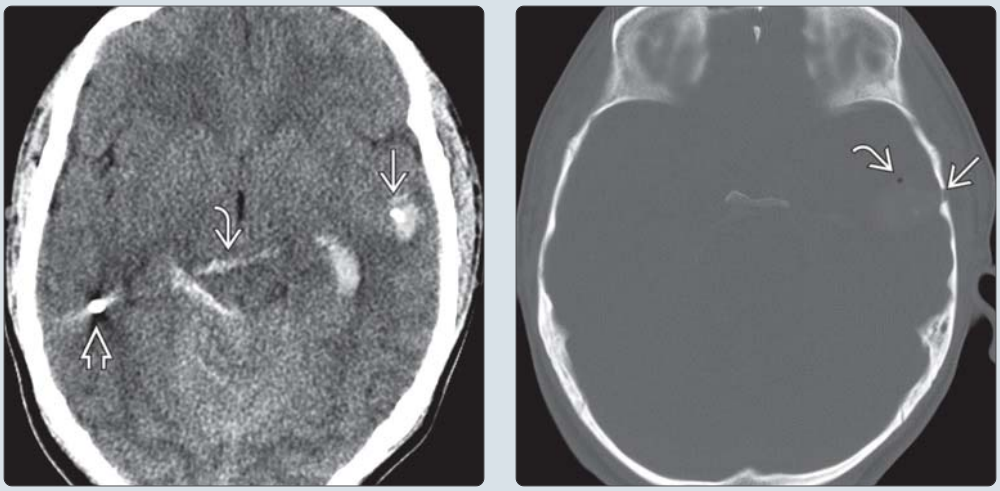
- Single or multiple intracranial foreign bodies, missile tract, pneumocephalus, entry ± exit wound
- Extent of injury extremely variable depending on
  - Size, shape, and number of projectiles
  - Projectile velocities
  - Entry/exit site(s) and course through brain
- Entry site → embedded bullet and bone fragments
- Epidural, subdural, subarachnoid hemorrhage
- Hemorrhagic tract through brain
- Intracerebral, intraventricular hemorrhage
- Ischemia and infarction
- Brain herniation
- Nuclear medicine brain death scanning with cerebral perfusion agents can be confirmatory test
- Best imaging tool → NECT ± CTA
- Vascular injury

CLINICAL ISSUES

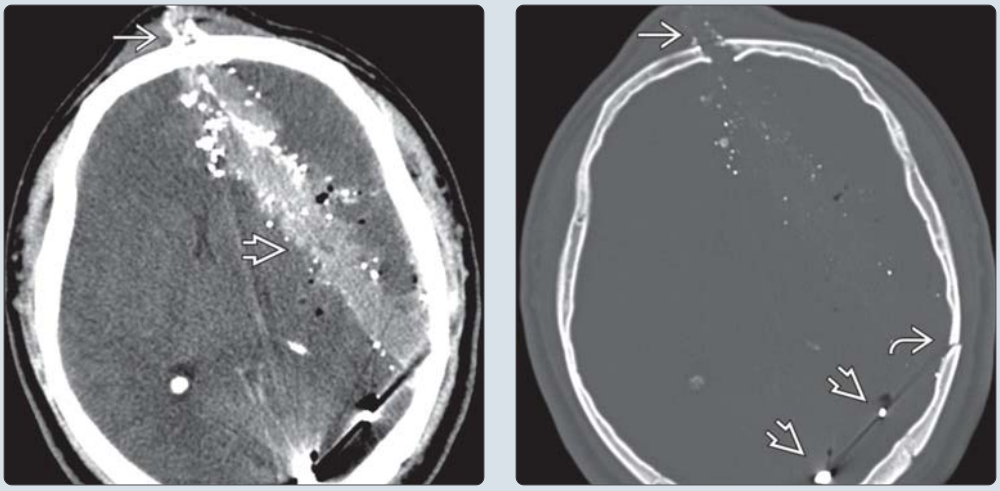
- Prognosis ranges from brain death to full recovery
- High morbidity and mortality

DIAGNOSTIC CHECKLIST

- Injury is most severe when
  - Missile is large and traveling at high velocities
  - If it fragments through tissue early in its path
- Reporting tips
  - Determine entry site
  - Assess missile path
  - Evaluate for exit site and secondary ricochet paths
  - Consider vascular injury



(Left) *Axial NECT shows a small-caliber, low-velocity injury. A bullet fragment is present in the left temporal lobe ➡ with minimal adjacent hemorrhage. A narrow hemorrhagic tract extends through the midbrain ➡ with a 2nd fragment imbedded in the right temporal lobe ➡. Regional subarachnoid and intraventricular blood are also seen.* **(Right)** *Axial bone CT demonstrates the tiny entry site in the squamous temporal bone ➡, with a focus of underlying intracranial air ➡.*



(Left) *Axial NECT shows a large-caliber, high-velocity injury with a frontal entry site ➡ and a wide oblique hemorrhagic tract ➡ that extends to the left temporoparietal region. There is sulcal effacement and midline shift to the right.* **(Right)** *Axial bone CT shows the frontal entry site ➡ and left parietal fracture ➡. Multiple bone and bullet fragments and foci of air are noted along the tract. Ricocheted metallic fragments ➡ are seen posteriorly, away from the primary trajectory.*

TERMINOLOGY

Synonyms

- Impalement injury
- Stabbing injury

Definitions

- Cranial trauma from high-velocity projectile (typically gunshot wound [GSW]) or impalement with sharp object

IMAGING

General Features

- Best diagnostic clue
  - Single or multiple intracranial foreign bodies, missile tract, pneumocephalus, entry ± exit wound
- Location
  - Supra- or infratentorial, affecting cerebral/cerebellar hemispheres or brainstem
- Size
  - Small linear tract if small caliber and low velocity
  - Large linear tract if large caliber and high velocity
- Morphology
  - Extremely variable depending on
    - Size, shape, number of projectiles
    - Projectile velocities
    - Entry/exit site(s), course through brain
  - Skull fracture(s)
    - Entry site → embedded bullet and bone fragments
    - Exit site → if high enough velocity
    - Pneumocephalus
  - Intracranial hemorrhage
    - Epidural, subdural, subarachnoid hemorrhage
    - Hemorrhagic tract through brain
    - Intracerebral, intraventricular hemorrhage
  - Vascular injury
    - Pseudoaneurysm, dissection, arteriovenous fistula (AVF), spasm
  - CSF leak
  - Secondary effects
    - Ischemia and infarction
    - Brain herniation

CT Findings

- NECT
  - Best assessment of extent of soft tissue injury
  - Identify entrance and exit wounds
- Bone CT
  - Osseous entry and exit sites and pneumocephalus shown to better advantage
  - Metallic fragments easier to evaluate
- CTA
  - Evaluate for pseudoaneurysm, dissection, or traumatic AVF

MR Findings

- T1WI
  - Variable signal (hemorrhage, foreign bodies, air)
- T2WI
  - Edema from pressure wave
  - Variable signal (hemorrhage, foreign bodies, air)
- T2* GRE
  - "Blooming" from hemorrhage, as well as susceptibility artifact from foreign bodies, air
- DWI
  - Secondary infarction
- MRA
  - Evaluate for pseudoaneurysm, dissection, or traumatic AVF
- MRV
  - Venous injury or thrombosis if missile tract crosses or tears interdural veins or lacerates sinus
  - Dural sinus thrombosis: Reported incidence < 5% with penetrating trauma

Angiographic Findings

- Conventional
  - Traumatic intracranial aneurysms in atypical locations
    - Proximal to or beyond circle of Willis and major arterial bifurcations
  - Extracranial pseudoaneurysms vary in size, configuration
    - Small saccular lesions
    - Fusiform dilatations
    - Large paravascular collections with huge cavitating hematomas
  - Other possible injuries
    - Traumatic direct carotid cavernous fistulas, dural AVFs involving meningeal vessels
    - Extracranial AVFs
    - Arterial dissection
  - Vascular spasm from projectile velocity or subarachnoid hemorrhage

Nuclear Medicine Findings

- Nuclear medicine brain death scanning with cerebral perfusion agents can be confirmatory test

Imaging Recommendations

- Best imaging tool
  - NECT
- Protocol advice
  - NECT ± CTA
  - Consider MR/MRA/MRV
  - Conventional cerebral angiography depending on type of trauma and degree of injury

DIFFERENTIAL DIAGNOSIS

Nonprojectile Intracranial Injury

- Contusion
- Axonal injury

PATHOLOGY

General Features

- Etiology
  - Pressure wave in front of missile crushes/stretches/disintegrates tissue, creates temporary cavitation
- General pathology comments
  - Appearance and degree of injury highly variable
  - Traumatic aneurysms account for < 1% of all intracranial aneurysms

https://CafePezeshki.IR

Gross Pathologic & Surgical Features

- Highly variable depending on severity of trauma

Microscopic Features

- Highly variable
  - Ranges from axonal transection to axonal edema
  - Vascular transection to luminal injury

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Highly variable depending on type and degree of traumatic injury
    - Motor deficits
    - Cranial nerve palsies
    - Visual field defects
- Other signs/symptoms
  - Post-traumatic seizures

Demographics

- Age
  - Any age can be affected, but younger patients involved more often
- Gender
  - M > F
- Ethnicity
  - Some studies document higher frequency of intentional assault injury among certain minority groups
- Epidemiology
  - Highly variable; incidence higher in inner cities and combat situations
    - May be influenced by regional legislation and social attitudes toward gun control
  - Accidental
  - Intentional
    - Self-inflicted/suicidal
      - Percent increase with age
    - Assault/homicidal intent

Natural History & Prognosis

- Prognosis ranges from brain death to full recovery
  - High morbidity and mortality
    - Most fatalities occur within 1st day
- Poor outcomes associated with
  - Transventricular or bihemispheric central type of trajectory → predictive of high morbidity/mortality
  - Low Glasgow coma scale (GCS) value at presentation
  - High head abbreviated injury score (AIS)
  - Pupil irregularity
  - Low blood pressure
  - Older patient
- Good outcomes associated with tangential gunshot wounds
  - Bullet fragments do not penetrate inner table of skull
    - Skull fracture and intracranial hemorrhage can still be present

Treatment

- Options, risks, complications
  - Dependent upon type and degree of injury
- Debridement
  - Penetrating objects may be left in place
- Decompressive craniectomy
- CSF diversion to control hydrocephalus
  - Especially in setting of infratentorial injury
- Intracranial pressure control

DIAGNOSTIC CHECKLIST

Consider

- Could there be associated vascular injury and aneurysm formation
- Post-traumatic pseudoaneurysm may be overlooked on CT (often obscured by hemorrhagic contusion)

Image Interpretation Pearls

- Injury is most severe when missile is large and traveling at high velocity and if it fragments through tissue early in its path

Reporting Tips

- Determine entry site
- Assess missile path
  - Determine extent of wound, including bone fragmentation and ricochet paths
- Evaluate for exit site and secondary ricochet paths
- Consider vascular injury

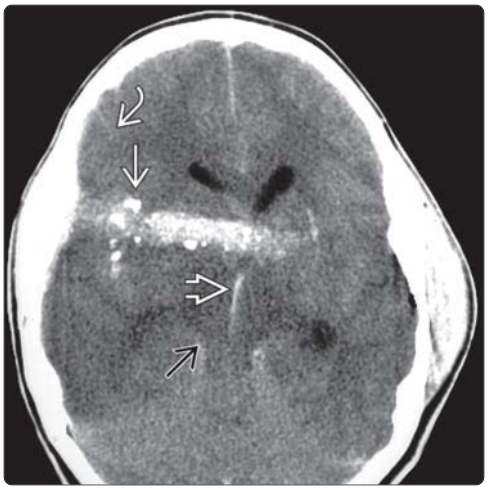
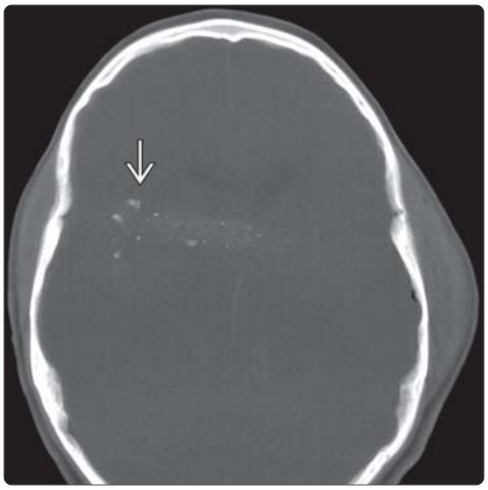
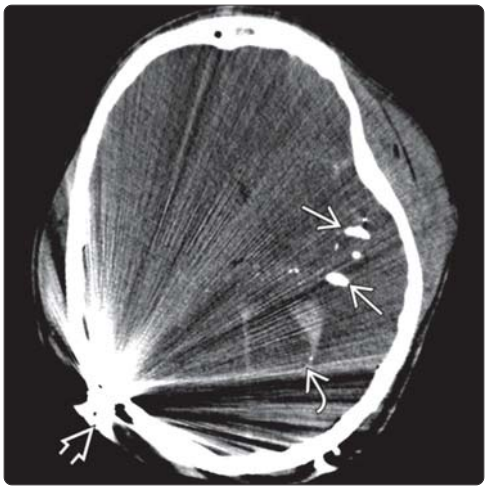
https://CafePezeshki.IR

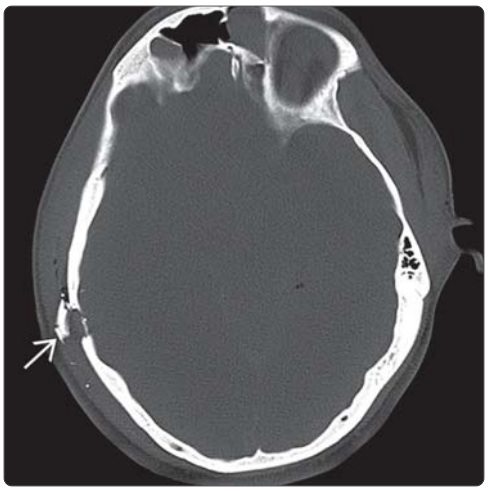




(Left) *Axial NECT shows extensive hemorrhage along the small-caliber missile trajectory from right to left ➡, crossing both basal ganglia. Scattered subarachnoid blood ➡ and minimal intraventricular blood ➡ are seen, along with diffuse sulcal effacement and early transtentorial herniation ⇨. (Right) Axial bone CT in the same patient confirms the presence of intracranial bullet and bone fragments on the right ➡ near the entry site.*



(Left) *Axial NECT scan in a 15-year-old male with a high-caliber gunshot wound shows diffuse brain swelling, hemorrhage in the left occipital horn ➡. Multiple small metallic fragments are present under the entrance wound in the left temporal lobe ➡. The deformed bullet lies under the right parietal galea ➡ where it ultimately lodged after losing velocity.* **(Right)** *More cephalad scan shows large left temporal subgaleal hematoma with extracranial ➡ and intracranial ⇨ bullet fragments.*



(Left) *Bone CT scans show the blown-out right posterior temporal skull fracture ➡ marking the site of the exit wound.* **(Right)** *More cephalad scan shows the multiple extra- and intracranial bullet fragments. The patient had a Glasgow coma scale (GCS) of 3 at the scene and expired shortly after admission. Further investigation disclosed the patient had been shot in an argument over a drug deal. As 90% of people are right-handed, left-sided GSWs are not often self-inflicted.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Blood collection between skull and dura

IMAGING

- NECT
  - Hyperdense, biconvex, extraaxial collection
  - > 95% unilateral, supratentorial
  - Does not cross sutures unless venous or sutural diastasis/fracture is present
  - Compresses/displaces underlying brain, subarachnoid space
  - Low-density "swirl" sign: Active/rapid bleeding with unretracted clot
  - 1/3-1/2 have other significant lesions
- Bone CT
  - Skull fracture in 90-95%

TOP DIFFERENTIAL DIAGNOSES

- Subdural hematoma
- Neoplasm
- Infection/inflammation
- Extramedullary hematopoiesis

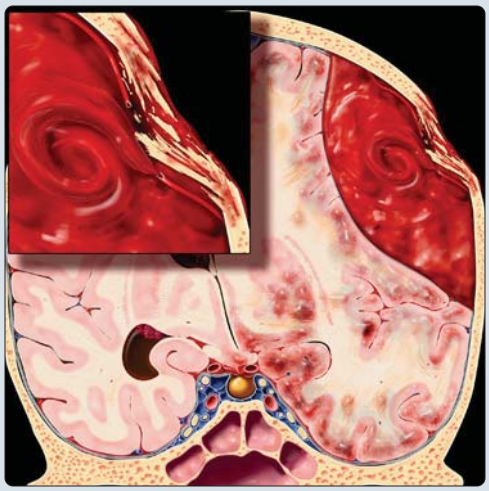
PATHOLOGY

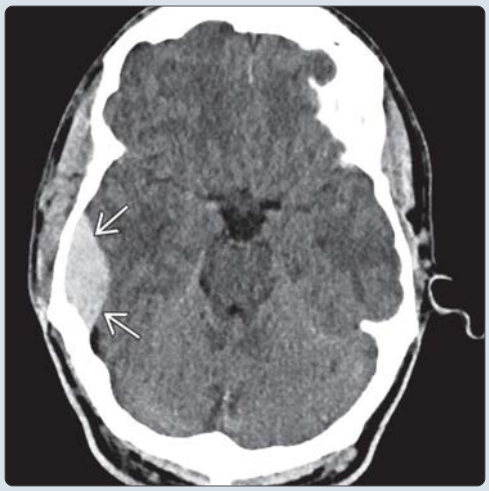
- Arterial (90-95%)
  - Arterial epidural hematoma (EDH) is most often near middle meningeal artery groove fracture
- Venous EDH (5-10%)
  - Fracture is adjacent to dural sinus
  - Common sites: Vertex, anterior middle cranial fossa

CLINICAL ISSUES

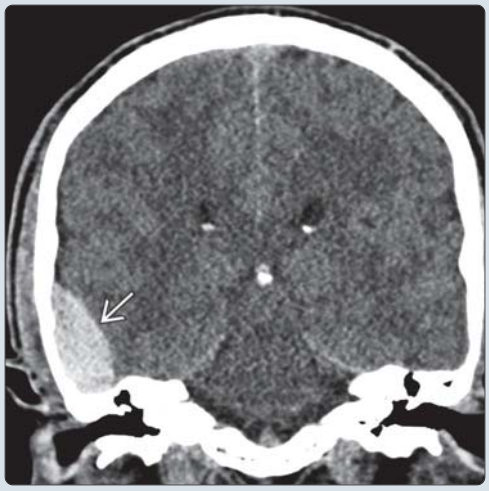
- Classic "lucid interval"
  - ~ 50% of cases
- Good outcome if promptly recognized and treated
- Some EDHs < 1 cm may be managed nonoperatively
  - Anterior middle fossa epidural hematoma is usually venous, benign

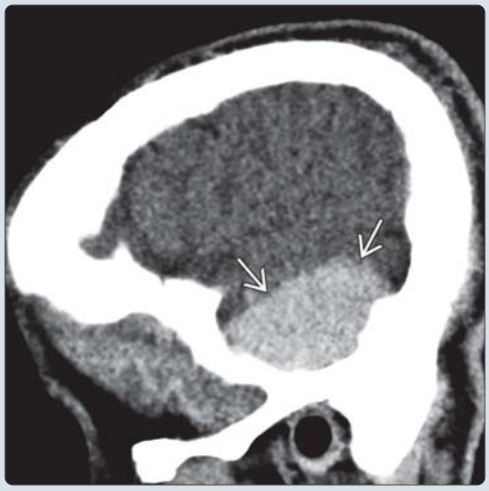
(Left) *Coronal graphic illustrates swirling acute hemorrhage from a laceration of the middle meningeal artery by an overlying skull fracture. The epidural hematoma displaces the dura inward as it expands.* **(Right)** *Axial NECT scan in a 47-year-old man with head trauma shows a classic biconvex (lentiform) uniformly hyperdense epidural hematoma (EDH) ➡ in the right middle fossa. Bone CT (not shown) disclosed a nondisplaced skull fracture underlying the hematoma.*





(Left) *Coronal scan reformatted from the axial date nicely demonstrates the classic middle cranial fossa acute EDH ➡.* **(Right)** *Sagittal NECT scan reformatted from the axial source date in the same patient shows the classic biconvex configuration of the acute middle fossa EDH ➡ is present in all 3 major imaging planes.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Epidural hematoma (EDH)

Definitions

- Blood collection between inner table of skull and outer (periosteal) layer of dura

IMAGING

General Features

- Best diagnostic clue
  - Hyperdense, biconvex, extraaxial collection on NECT
- Location
  - Epidural space (between skull and dura)
  - Nearly all EDHs occur at impact (coup) site
    - 90-95% arterial
    - 90-95% adjacent to skull fracture
    - 90-95% unilateral (bilateral rare)
  - Supratentorial (90-95%)
    - 65% temporoparietal, 35% frontal/parietooccipital
  - 5-10% in posterior fossa
  - Venous EDH (5%)
- Size
  - Variable; rapid expansion is typical
    - Attains maximum size within 36 hours
  - Slower accumulation of blood in venous EDH
- Morphology
  - Biconvex or lentiform extraaxial collection
  - Arterial EDHs usually do not cross sutures
    - Exception: If sutural diastasis/fracture is present
    - Compresses/displaces underlying brain, subarachnoid space
  - Venous EDH
    - Adjacent to venous sinus crossed by fracture
      - Skull base, vertex
      - Anterior middle fossa
    - May "straddle" sutures, dural attachments
      - Can cross falx, tentorium
    - Dural sinus displaced, usually not occluded
  - 1/3-1/2 have other significant lesions
    - Mass effect, secondary herniations common
    - Contrecoup subdural hematoma
    - Cerebral contusions

CT Findings

- NECT
  - Acute: 2/3 hyperdense, 1/3 mixed density
    - Acute EDH with retracted clot = 60-90 HU
    - Low-density "swirl" sign: Active/rapid bleeding with unretracted clot
    - Medial hyperdense margin: Displaced dura
  - Air in EDH (20%) suggests sinus or mastoid fracture
  - Vertex EDH is easily overlooked
  - Chronic EDH → hypo-/mixed density
  - CT "comma" sign
    - EDH plus subdural hematoma
    - Often temporoparietal or temporoparietooccipital
    - Important to identify → treated as 2 separate surgical entities
- CECT
  - Acute: May show contrast extravasation (rare)
  - Chronic: Peripheral dural enhancement from neovascularization, granulation
- Bone CT
  - Skull fracture in 95%

MR Findings

- T1WI
  - Acute: Isointense with brain
  - Subacute/early chronic: Hyperintense
  - Black line between EDH and brain: Displaced dura
- T2WI
  - Acute: Variable hyper- to hypointense
  - Early subacute: Hypointense
  - Late subacute/early chronic: Hyperintense
  - Black line between EDH and brain: Displaced dura
- T1WI C+
  - Venous EDH: Look for displaced dural sinus by hematoma
  - Spontaneous (nontraumatic) EDH: Enhancement of hemorrhagic epidural mass
- MRV
  - Assess venous sinus integrity
  - Hematoma may displace venous sinus, impede flow

Angiographic Findings

- Diagnostic
  - Avascular mass effect; displaced cortical arteries
  - If middle meningeal artery (MMA) laceration present
    - May form arteriovenous fistula → "tram-track" sign
      - Simultaneous opacification of MMA, both middle meningeal veins
  - Venous EDH: Look for displaced dural sinus

Imaging Recommendations

- Best imaging tool
  - NECT with bone CT for traumatic cases
  - MR + MRV if venous EDH suspected
- Protocol advice
  - Consider MR if EDH straddles dural compartments or sinuses on NECT

DIFFERENTIAL DIAGNOSIS

Acute Subdural Hematoma (aSDH)

- EDH and SDH may coexist
- Acute SDH is usually crescentic (occasionally biconvex)
- Crosses sutures but limited by dural attachments

Neoplasm

- Meningioma
- Soft tissue component (subperiosteal) of osseous mass
  - Metastasis, lymphoma, primary sarcoma
- Dural-based mass
  - Metastases, lymphoma, mesenchymal tumor

Infection/Inflammation

- Subperiosteal extension of osseous inflammatory lesion
- Epidural empyema secondary to osteomyelitis
- Soft tissue from granulomatous osseous lesion
  - Tuberculosis

https://CafePezeshki.IR

Extramedullary Hematopoiesis

- History of blood dyscrasia

PATHOLOGY

General Features

- Etiology
  - Trauma most common
    - Fracture lacerates vessel
      - Arterial (90-95%), venous (5-10%)
    - Arterial EDH is most often near MMA groove fracture
    - Venous EDH is usually near fracture that crosses dural sinus
  - Nontraumatic
    - Coagulopathy, thrombolysis, vascular malformation, neoplasm, epidural anesthesia, Paget disease of skull
    - "Spontaneous" EDH is rare; may arise from skull metastases
- Associated abnormalities
  - Skull fracture in 95%, may cross MMA groove
  - Subdural/subarachnoid hemorrhage, contusion

Gross Pathologic & Surgical Features

- EDH is a subperiosteal hematoma
  - Outer dural layer function as periosteum of inner calvaria
- Hematoma collects between calvaria and outer dura
  - Rarely crosses sutures
    - Exception: Venous EDH, large hematoma with diastatic fracture
- "Vertex" EDH (rare)
  - Usually venous: Linear or diastatic fracture crosses superior sagittal sinus
- 20% have blood in both epidural and subdural spaces at surgery or autopsy

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Classic "lucid interval": ~ 50% of cases
    - Initial brief loss of consciousness (LOC)
    - Subsequent asymptomatic time between LOC and symptom/coma onset
  - Headache, nausea, vomiting, seizures, focal neurological deficits (e.g., field cuts, aphasia, weakness)
  - Mass effect/herniation common
    - Pupil-involving CN3 palsy, somnolence, ↓ consciousness, coma
- Clinical profile
  - Alcohol and other intoxications are associated with ↑ incidence of EDH

Demographics

- Age
  - More common < 20 years; extremely rare in elderly
  - Uncommon in infants
- Gender
  - M:F = 4:1
- Epidemiology
  - 1-4% of imaged head trauma patients
  - 5-15% of patients with fatal head injuries

Natural History & Prognosis

- Factors affecting rate of growth
  - Arterial vs. venous, rate of extravasation
  - Occasionally decompresses through fracture into scalp
  - Tamponade
- Delayed development or enlargement common
  - 10-25% of cases within first 36 hours
- Good outcome if promptly recognized and treated
  - Overall mortality is ~ 5%
  - Bilateral EDHs have higher mortality and morbidity
    - 15-20% mortality rate
- Increased mortality in posterior fossa EDH (26%)
  - Can have delayed symptom onset secondary to slower expansion from lower venous pressure

Treatment

- Prompt recognition and appropriate treatment are essential
  - Poor outcome often related to delayed referral, diagnosis, or operation
- Most EDHs are surgically evacuated
  - Options: Endovascular/endoscopic if poor surgical candidate
  - Mixed-density acute EDHs require earlier, more aggressive treatment
- Some EDHs < 1 cm with no cerebral edema are managed nonoperatively
  - Repeat CT in first 36 hours to monitor for change
    - 23% enlarge within 36 hours
    - Mean enlargement: 7 mm
  - Anterior middle fossa EDHs are venous and usually do not require surgery
- Complications: Mass effect, edema, herniations

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- NECT is highly sensitive
  - Coronal CT reconstructions to evaluate vertex EDH
- Use bone CT to look for fracture
- Consider CTV if fracture is near venous sinus

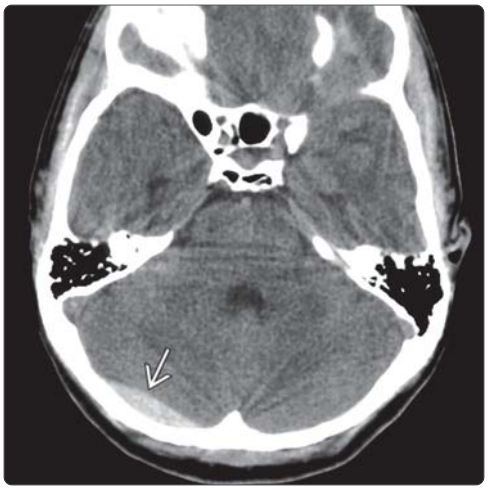
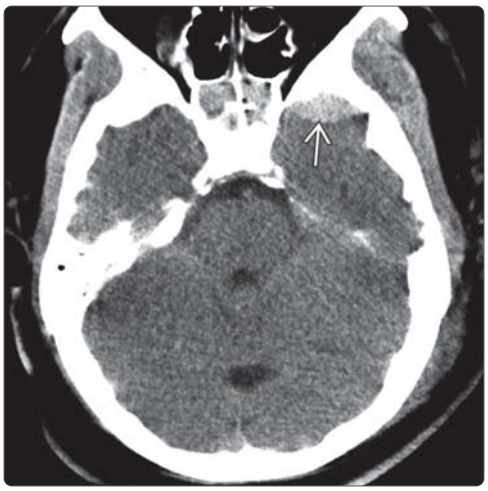
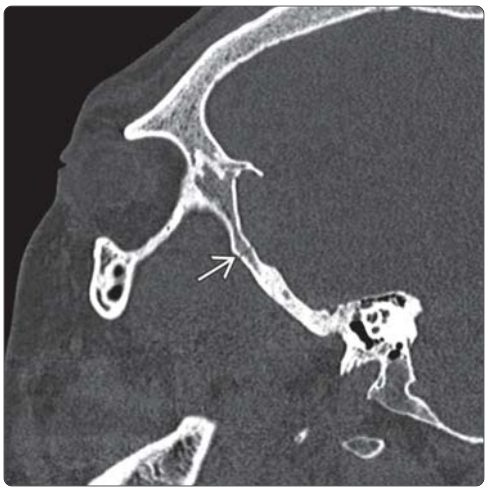
(Left) *Axial bone CT demonstrates a portion of a comminuted fracture about the pterion* ➡. **(Right)** *Axial NECT in the same case reveals a small yet classic biconvex epidural hematoma* ➡ *underlying the skull fracture. There is also a posterior falcine subdural hematoma tracking along the tentorium* ➡ *and superior sagittal sinus* ⇨.



(Left) *Axial NECT demonstrates a biconvex venous epidural hematoma that extends both below* ➡ *the tentorium as well as above it.* **(Right)** *Axial NECT in the same patient demonstrates a biconvex venous epidural hematoma that extends both above* ➡ *and below the tentorium.*





(Left) *Axial NECT shows an anterior middle fossa epidural hematoma* ➡. **(Right)** *Sagittal bone CT shows a nondisplaced linear fracture* ➡ *that crosses the greater sphenoid wing. Such epidural hematomas cross the sphenoparietal sinus, are usually venous, and typically do not require surgery.*

https://CafePezeshki.IR

KEY FACTS

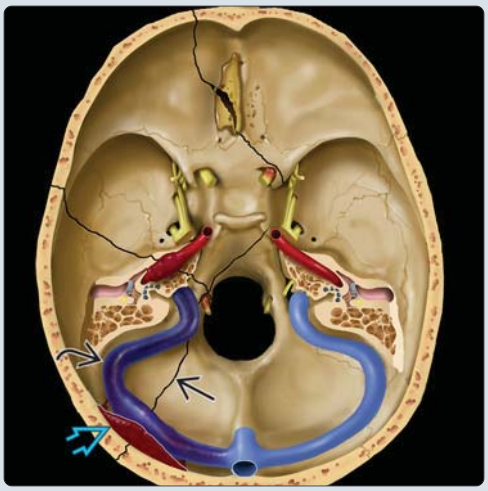
TERMINOLOGY

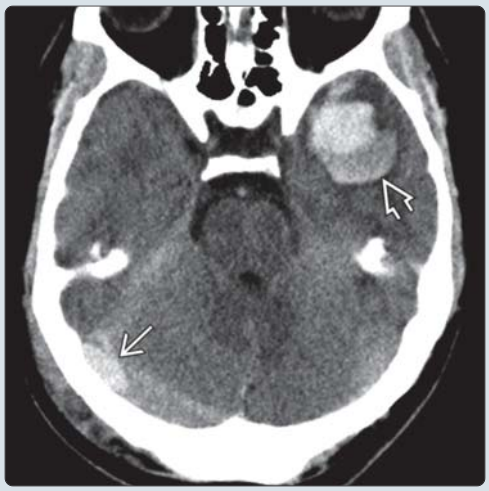
- "Typical" epidural hematoma (EDH)
  - Arterial laceration
  - 90-95% supratentorial (temporoparietal most common)
  - Biconvex, unilateral
- Atypical EDH
  - Unusual etiology
  - Unusual location
  - Unusual shape or density

IMAGING

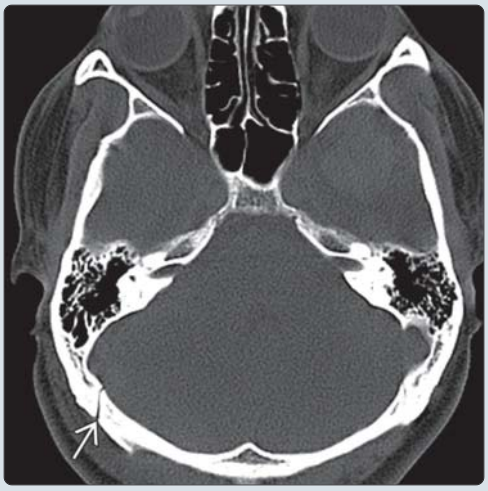
- Venous EDH (10% of EDHs)
  - Fracture (linear, diastatic) crosses dural venous sinus
  - Skull base, vertex
  - Easily overlooked
  - Coronal, sagittal reformats key to diagnosis
- Anterior Temporal EDH (10% of EDHs)
  - Middle cranial fossa
    - In front of--not lateral to--temporal lobe
  - Fracture crosses sphenoparietal sinus
  - Generally asymptomatic (1-2 cm, stable size)
  - No reported cases requiring surgery
- Vertex EDH (1-2% of EDHs)
  - Fracture crosses, lacerates superior sagittal sinus
  - Accumulates slowly
  - Symptoms often delayed
  - Easily overlooked, size underestimated on axial CT
  - Coronal, sagittal reformatted images key
- Clival EDH (< 1% of EDHs)
  - Lacerates clival venous plexus
  - Self-limited; dura tightly attached, so rarely large
  - Asymptomatic unless associated vascular, cranial nerve injury
  - Biconvex hyperdensity immediately posterior to clivus
  - Sagittal reformatted images key to diagnosis

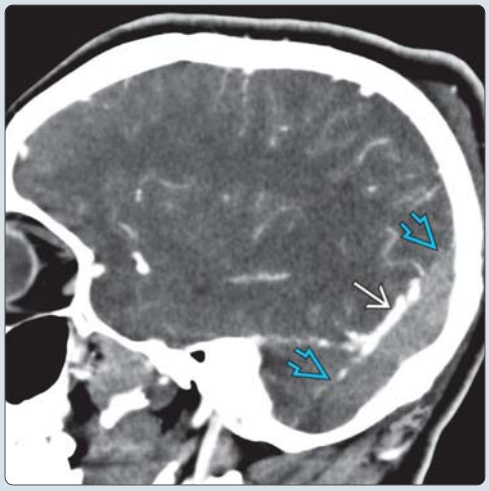
(Left) *Axial graphic depicts different basilar skull fractures that cross, and may injure, important vascular structures. Note the linear skull fracture crossing the right transverse sinus. The lacerated sinus causes a venous EDH to accumulate. The injured sinus often thromboses, as is depicted here.* **(Right)** *Axial NECT scan in a 26-year-old man who fell 10 meters onto his head shows a large left temporal lobe contusion. A small biconvex hyperdense fluid collection is seen adjacent to the right transverse sinus.*





(Left) *Bone CT in the same patient shows a diastatic fracture through the right lambdoid suture.* **(Right)** *Sagittal CT venogram shows that the transverse sinus is elevated and displaced anteriorly by a hyperdense venous EDH. Note that the venous EDH lies both above and below the site of dural attachment. Venous EDHs commonly cross dural attachments, whereas classic arterial EDHs rarely do.*





https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Typical EDH
  - Arterial laceration
  - 90-95% supratentorial (temporoparietal most common)
  - Lateral temporoparietal location
  - Biconvex, unilateral
- Atypical EDH
  - Unusual etiology
    - Venous, not arterial
  - Unusual location
    - Anterior middle cranial fossa EDH
    - Vertex EDH
    - Clival EDH
  - Unusual shape or density
    - Venous EDH may decompress into dural sinus
    - Initially hyperdense but may become mostly hypodense

IMAGING

Venous EDH

- 10% of all EDHs
- Fracture (linear, diastatic) crosses dural venous sinus
- Most common sites
  - Skull base, vertex
  - Can cross dural attachments
  - Often crosses sutures
- Imaging
  - Easily overlooked
  - Coronal, sagittal reformats key to diagnosis
  - CTA/CTV helpful

Anterior Temporal EDH

- Not uncommon (10% of all EDHs)
- Etiology
  - Fracture crosses sphenoparietal sinus
  - Anterior middle cranial fossa
    - In front of (not lateral to) temporal lobe
  - Anatomically limited
    - Laterally by sphenoparietal suture
    - Medially by orbital fissure
- Clinical
  - Generally asymptomatic
  - No reported cases requiring surgery
- Imaging
  - Virtually all have associated skull fractures (use thin sections, bone algorithm)
    - 57% greater sphenoid wing
    - 43% zygomaticomaxillary
  - Size
    - Stable; do not enlarge with time
    - 1-2 cm maximum diameter

Vertex EDH

- Uncommon (1-2% of EDHs)
  - Usually venous
- Linear &/or diastatic fracture
  - Crosses superior sagittal sinus
  - Usually crosses midline
- Clinical
  - Accumulates slowly
  - Symptoms often delayed
- Imaging
  - Easily overlooked; size is underestimated on axial CT
  - Coronal, sagittal reformatted images key
  - CTV/MR with MRV helpful

Clival EDH

- Very rare (< 1% of EDHs)
- Linear skull fracture crosses basisphenoid
  - Lacerates clival venous plexus
  - Self-limited; dura tightly attached, so rarely large
- Clinical
  - Asymptomatic unless associated vascular or cranial nerve injury
- Imaging
  - Biconvex hyperdensity posterior to clivus
  - Sagittal reformatted images key to diagnosis

DIFFERENTIAL DIAGNOSIS

Subdural Hematoma

- Usually crescentic (not biconvex)
- Confined by dural attachments of falx or tentorium
- Can coexist with EDH

Hyperdense Neoplasm

- Trauma history absent
- Hyperdense neoplasms include
  - Meningioma
  - Lymphoma
  - Metastasis

Dural Pseudotumors

- IgG4-related disease
- Histiocytoses
- Infection (tuberculosis)

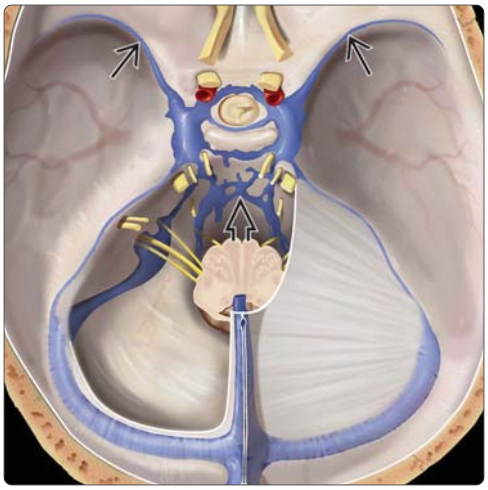
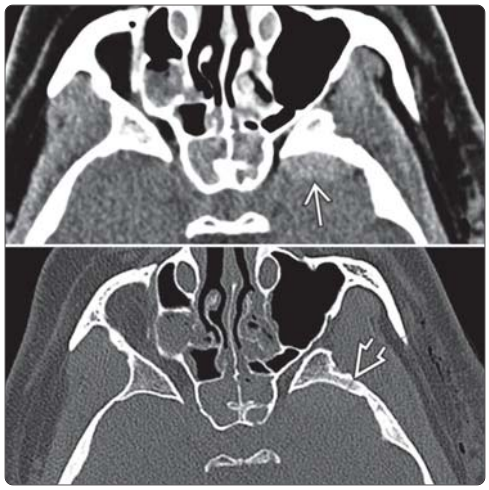
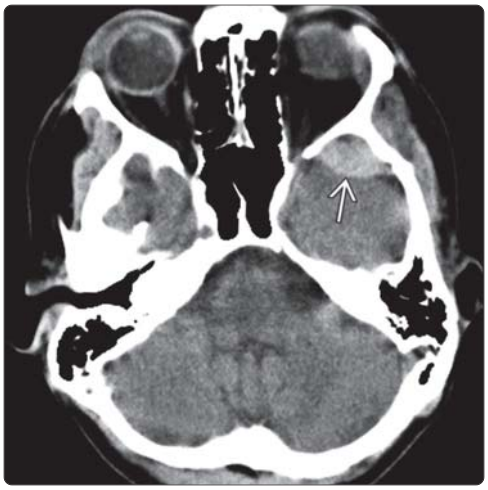
https://CafePezeshki.IR

(Left) *Axial graphic depicts the dural venous sinuses at the skull base. The sphenoparietal sinuses ⇨ curve around the greater sphenoid wing, then drain into the cavernous sinus. The clival venous plexus ⇨ is usually septated, so venous EDHs in this location are typically limited.* **(Right)** *Axial NECT scan (top) shows a small biconvex EDH ➡ anterior to the left temporal lobe. Bone CT (below) shows a nondisplaced linear fracture ➡ through the greater sphenoid wing.*

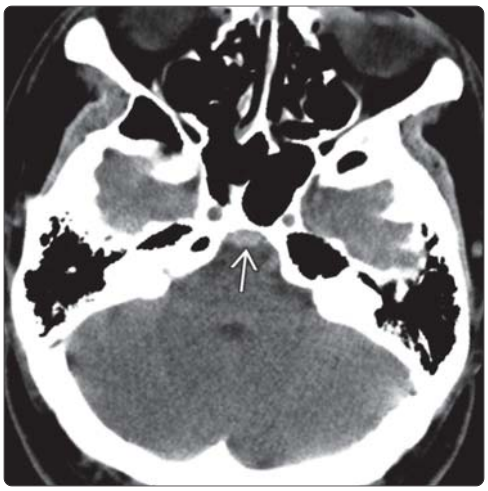


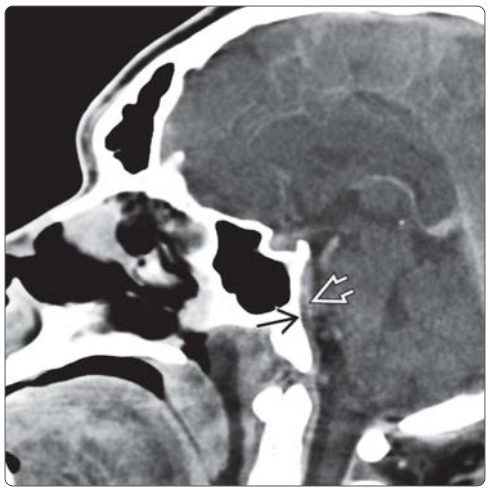


(Left) *Axial NECT scan shows a typical anterior temporal epidural hematoma ➡.* **(Right)** *Follow-up NECT scan in the same patient 24 hours later shows that the anterior temporal EDH ➡ is unchanged in size but now appears mostly hypodense. This is not caused by rapid bleeding; it is most likely caused by decompression of the EDH into the lacerated sphenoparietal sinus.*



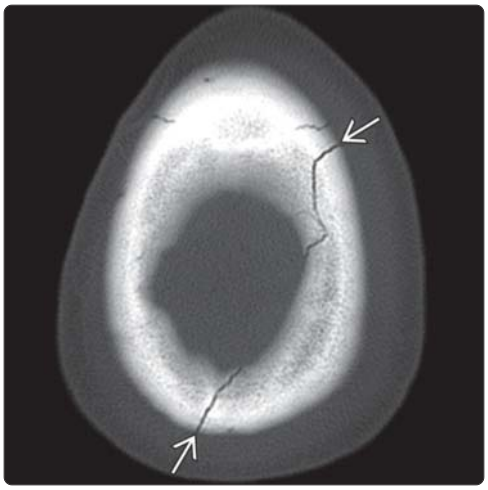
(Left) *Axial NECT scan in a 19-year-old man with basilar skull fractures shows a small biconvex EDH ➡ posterior to the clivus.* **(Right)** *Sagittal CT venogram in the same patient demonstrates the small clival EDH ⇨ under the enhancing clival venous plexus ➡.*





https://CafePezeshki.IR

(Left) *Axial NECT scan in a 57-year-old man shows a biconvex EDH ➡ over the left frontal convexity of the brain.* **(Right)** *Coronal NECT scan reformatted from the axial data in the same patient shows the vertex EDH ➡.*



(Left) *Axial bone CT in the same patient shows a linear fracture ➡ that crosses the midline.* **(Right)** *Two hours later, the patient deteriorated. Axial CT venogram shows the vertex EDH has enlarged, narrowing the superior sagittal sinus (SSS) ➡ which also appears somewhat irregular in configuration. The EDH now contains hypodense foci ➡, suggesting ongoing acute hemorrhage into the epidural space.*

(Left) *Coronal reformatted CTV shows the vertex EDH ➡ is much larger and now crosses the midline. The SSS ➡, is displaced inferiorly from the calvaria and appears severely compressed. An "empty delta" sign is present, suggesting the SSS is at least partially thrombosed.* **(Right)** *Sagittal CTV nicely shows the expanding vertex EDH, which now appears to have 2 adjacent compartments ➡. Venous EDH was evacuated at surgery and the torn, partially thrombosed SSS repaired.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Acute blood in/between inner border cell layer of dura, arachnoid

IMAGING

- NECT as initial screening study
  - Use both bone, soft tissue algorithms
  - Use both standard brain, wide windows (150HU)
  - Coronal, sagittal reformatted scans best for detecting small subdural hematomas (SDHs)
- Findings
  - Crescentic hyperdense extraaxial collection
    - Spreads diffusely over cerebral convexity
    - Often extends along falx, tentorium
  - Inward displacement of cortical veins, sulci
  - May cross sutures, not dural attachments

TOP DIFFERENTIAL DIAGNOSES

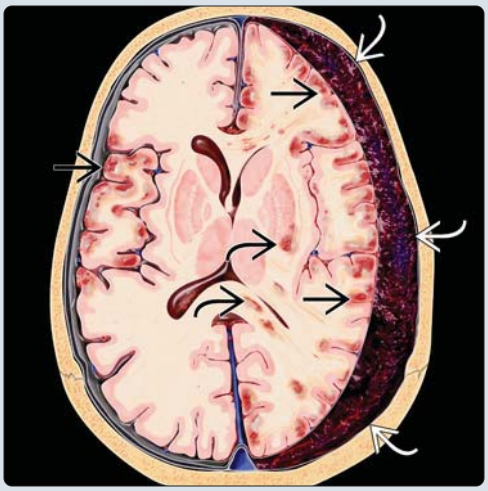
- Other subdural fluid collections
  - Mixed SDH (acute on chronic/subacute SDH)
    - Hyperdense foci in pockets of iso-, hypodense fluid
  - Subdural hygroma
    - Clear CSF, no encapsulating membranes
  - Subdural effusion
    - Near CSF density
  - Subdural empyema
    - Peripheral enhancement, hyperintensity on FLAIR; restricted diffusion on DWI
- Acute epidural hematoma (typically crescentic)

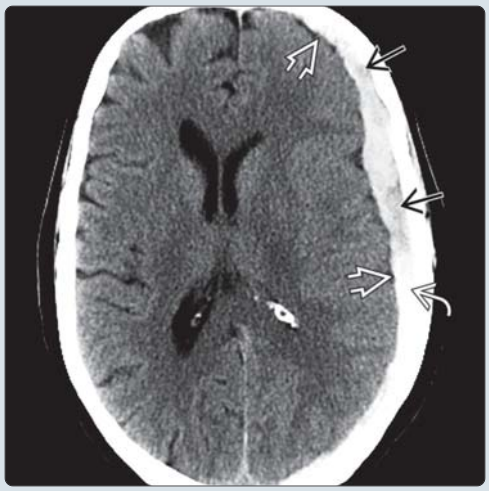
PATHOLOGY

- Trauma most common cause
- Nontrauma (spontaneous) more common in elderly

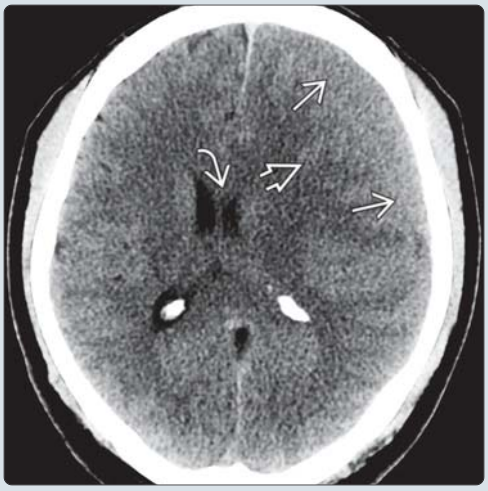
DIAGNOSTIC CHECKLIST

- Inform responsible clinician if unsuspected finding
- Multiplanar reconstructions, wide windows best for subtle acute SDHs





(Left) *Graphic shows acute subdural hematoma (aSDH) compressing the left hemisphere and lateral ventricle, resulting in midline shift. Coexisting cortical contusions and axonal injuries are common in aSDHs.* **(Right)** *Axial NECT in a 58-year-old woman with head trauma shows a classic aSDH extending over the left convexity and compressing the underlying subarachnoid space. The subtle hypodense foci within the hyperdense aSDH represent unclotted blood and risk for rapid hematoma expansion.*



(Left) *Occasionally, acute SDHs are isodense to the underlying brain. Note the aSDH with mass effect, inward displacement of the underlying gray-white interface, and left-to-right subfalcine herniation of the lateral ventricles.* **(Right)** *More cephalad NECT scan in the same patient again shows the isodense aSDH. The underlying sulci are completely effaced. Compare this appearance of "absent sulci" with the normal-appearing CSF-filled sulci over the right hemisphere.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Acute subdural hematoma (aSDH)

Definitions

- Acute blood in or between inner border cell layer of dura and arachnoid

IMAGING

General Features

- Best diagnostic clue
  - CT: Crescentic, hyperdense, extraaxial collection spread diffusely over affected hemisphere
- Location
  - Between arachnoid and inner border cell layer of dura
  - Supratentorial convexity > interhemispheric, peritentorial
- Morphology
  - Crescent-shaped extraaxial fluid collection
  - May cross sutures, not dural attachments
  - May extend along falx, tentorium, and anterior and middle fossa floors

CT Findings

- NECT
  - Hyperacute SDH (≤ 6 hours) may have heterogeneous density or hypodensity
  - aSDH (6 hours to 3 days)
    - aSDH: 60% homogeneously hyperdense
    - 40% mixed hyper-, hypodense with active bleeding (swirl sign), torn arachnoid with CSF accumulation, clot retraction
    - Rare: Isodense aSDH (coagulopathy, anemia with Hgb < 8-10 g/dL)
    - If no new hemorrhage, density decreases ± 1.5 HU/day
- CECT
  - Inward displacement of cortical veins, gray-white interface
  - Dura and membranes enhance when subacute

MR Findings

- T1WI
  - Hyperacute (< 12 hours): Iso- to mildly hyperintense
  - Acute (12 hours to 2 days): Mildly hypointense
- T2WI
  - Hyperacute: Mildly hyperintense
  - Acute: Hypointense
- FLAIR
  - Typically hyperintense to CSF
  - Signal intensity varies depending on relative T1 and T2 effects
    - Acute hematomas can be isointense to CSF due to T2 shortening effects of intracellular methemoglobin
  - Often most conspicuous sequence
- T2* GRE
  - Hypointense unless hyperacute
- DWI
  - Heterogeneous signal (nonspecific)
  - May differentiate extraaxial empyema (marked central hyperintensity) from hemorrhage
- T1WI C+
  - Enhancement of displaced cortical veins
  - Hematoma doesn't enhance (delayed scans sometimes show minimal)
- MR signal of SDH is quite variable
  - Often evolves in similar fashion to intraparenchymal hemorrhage
  - Recurrent hemorrhage common; results in acute and chronic blood products even at initial exam
  - SDH signal is variable due to recurrent hemorrhage; difficult to age accurately
  - Pia-arachnoid membrane tears can lead to CSF leakage into SDH collections and may alter signal intensity by CSF dilution

Angiographic Findings

- CTA
  - Mass effect from extraaxial collection; veins displaced from inner table of skull
  - DSA only if underlying vascular lesion suspected on CTA

Imaging Recommendations

- Best imaging tool
  - NECT as initial screening study
    - Use both bone, soft tissue algorithms
    - Use both standard brain, wide windows (150HU)
    - Coronal, sagittal reformatted scans best for detecting small SDHs
  - MR is more sensitive but rarely used
    - Better depicts extent, age(s) of SDH
    - ± additional findings of traumatic brain injury

DIFFERENTIAL DIAGNOSIS

Other Subdural Collections

- Subdural hygroma
  - Clear CSF, no encapsulating membranes
- Subdural effusion
  - Xanthochromic fluid secondary to extravasation of plasma from membrane or meningitis
  - Near CSF density
- Empyema: Peripheral enhancement, hyperintensity on FLAIR; restricted diffusion on DWI

Epidural Hematoma

- Biconvex extraaxial collection
- Often associated with fracture
- May cross dural attachments, limited by sutures

Pachymeningopathies (Thickened Dura)

- Chronic meningitis (may be indistinguishable)
- Neurosarcoid: Often lumpy-bumpy appearance
- Postsurgical (e.g., shunt)
- Intracranial hypotension
  - "Slumping" midbrain, tonsillar herniation

Tumor

- Dural-based enhancing masses
  - Meningioma, lymphoma, leukemia, metastases
  - Mass like, not crescentic

https://CafePezeshki.IR

- ± skull and extracranial soft tissue involvement

Chemical Shift Artifact (MR)

- Marrow or subcutaneous fat may "shift," appear intracranial, and mimic T1 hyperintense SDH
  - Seen with ↑ field of view or ↓ bandwidth
  - Worse with higher field strength MR

PATHOLOGY

General Features

- Etiology
  - Trauma most common cause
    - Tearing of bridging cortical veins as they cross subdural space to drain into dural sinus
    - Nonimpact (falls) as well as direct injury
    - Trauma may be minor, particularly in elderly
      - Often recurrent with initial subclinical episodes
  - Nontraumatic (spontaneous) acute subdural hematoma (aSDH) is less common in nonelderly
    - Dissection of intraparenchymal hematoma into subarachnoid, then subdural space
    - Aneurysm rupture
    - Vascular malformations: Dural arteriovenous fistula, arteriovenous malformation (AVM), cavernoma
      - Typically other hemorrhages present (parenchymal &/or subarachnoid)
    - Moyamoya (greater propensity for hemorrhage in adults, ischemia in children)
    - Dural invasion by tumor with secondary hemorrhage (prostate cancer)
    - Spontaneous hemorrhage with severe coagulopathy
  - Predisposing factors
    - Atrophy
    - Ventricular shunting (→ increased traction on superior cortical veins)
    - Anticoagulation, intrinsic or extrinsic coagulopathy (e.g., alcohol abuse)
- Associated abnormalities
  - > 70% have other significant associated traumatic lesions
  - If mass effect, shift > aSDH thickness, suspect underlying edema/excitotoxic injury

Gross Pathologic & Surgical Features

- "Currant jelly" crescent-shaped hematoma
- Membranes/granulation tissue develop later

Microscopic Features

- Outer membrane of proliferating fibroblasts and capillaries
  - Fragile capillaries may become source of recurrent hemorrhage
- Inner membrane (made up of dural fibroblasts or border cells) forms fibrocollagenous sheet

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Most commonly following trauma
  - Varies from asymptomatic to loss of consciousness
    - "Lucid" interval in aSDH: Initially awake, alert patient loses consciousness a few hours after trauma
    - Patients with early symptomatic presentation (< 4 hours) and advanced age have poor prognosis
  - Other symptoms (focal deficit, seizure) from mass effect, diffuse brain injury, secondary ischemia
  - Coagulopathy or anticoagulation increase risk and extent of hemorrhage

Demographics

- Any age, more common in elderly
- No gender predilection
- Epidemiology
  - Found in 30% of autopsy cases following craniocerebral trauma

Natural History & Prognosis

- Can grow slowly with increased mass effect if untreated
- Compresses and displaces underlying brain
- Recurrent hemorrhage common; in children, raises suspicion of nonaccidental trauma

Treatment

- Poor prognosis (35-90% mortality)
  - Emergency preoperative high-dose mannitol may improve outcome
- Surgically relevant features (especially in elderly)
  - Maximum hematoma thickness (≥ 10 mm), midline shift
- Lethal if hematoma volume > 8-10% of intracranial volume

DIAGNOSTIC CHECKLIST

Consider

- NECT initial screen
- MR if degree of mass effect &/or symptoms are greater than expected for size of SDH
  - Helps identify extent of traumatic brain injury
  - MR to evaluate nontraumatic causes
- In child with recurrent or mixed-age hemorrhage, suspect nonaccidental trauma

Image Interpretation Pearls

- Wide window settings for CT increases conspicuity of subtle SDH
- FLAIR, T2* usually most sensitive sequences for SDH
- CT density and MR intensity vary with age and degree of recurrent hemorrhage and contribution of CSF (arachnoid tears)

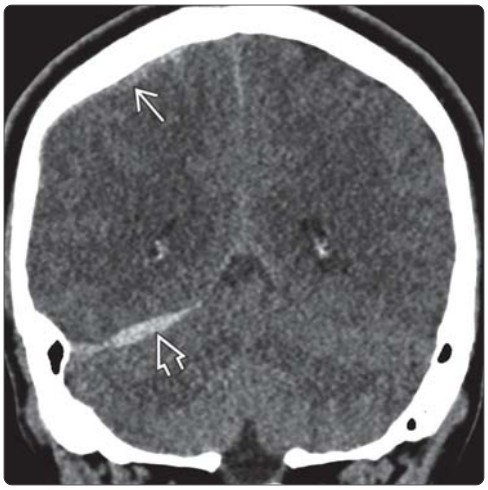
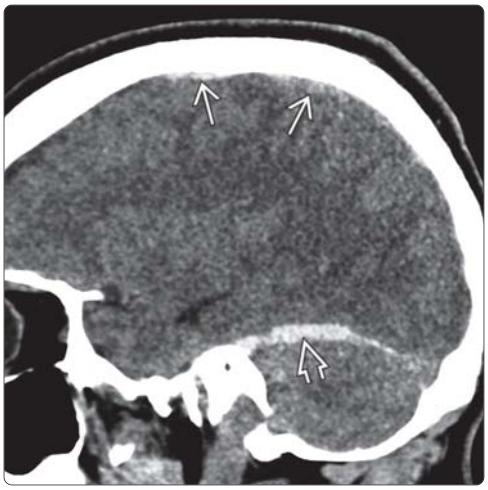
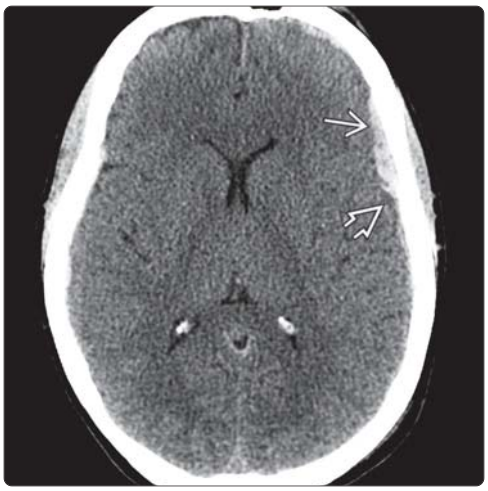
(Left) *Coronal graphic depicts thin aSDH layering along the falx and tentorium. Such aSDHs may be difficult to identify on axial images alone. Multiplanar reconstructions are very helpful in identifying small thin aSDHs.* **(Right)** *Axial NECT scan in a 31-year-old man with minor trauma shows subtle hyperdensity along the tentorium and inferior falx near the confluence of the venous sinuses.*





(Left) *Coronal reformatted scan from the axial data in the same patient shows the small acute peritentorial SDH. A small subtle convexity aSDH is seen here and was not visible on the axial scan.* **(Right)** *Sagittal reformatted image in the same patient shows the peritentorial aSDH and the subtle convexity aSDH that was invisible on the axial study.*



(Left) *Axial NECT scan in a 30-year-old man with head trauma shows a small mixed density aSDH over the left frontal and parietal lobes. Subtle hypodensity within the aSDH was concerning for rapid accumulation of unclotted blood.* **(Right)** *The patient (same case) deteriorated 5 hours later. The aSDH has expanded significantly, and there are multiple foci of hypodensity within the hematoma indicating rapid bleeding. Note the subfalcine herniation of the lateral ventricles.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Subacute (~ 3 days to 3 weeks) collection
  - In subdural space (between arachnoid and dura or within inner border cell layer)
  - Partially liquified clot, resorbing blood products
  - Surrounded by granulation tissue ("membrane")

IMAGING

- Crescent-shaped, iso- to hypodense extraaxial collection
  - Spreads diffusely over hemisphere
  - May be of same density as underlying cortex
  - Look for inwardly displaced "dots" of cerebrospinal fluid (CSF)
- May cross sutures, not dural attachments
- T1 iso- to hyperintense
- T2 hyperintense
- Does not suppress on FLAIR
- DWI may show "double layer" appearance
- General imaging recommendations
  - NECT initial screen
  - Consider CECT for membranes/loculations
  - MR is more sensitive for SDH, detecting additional traumatic brain injuries

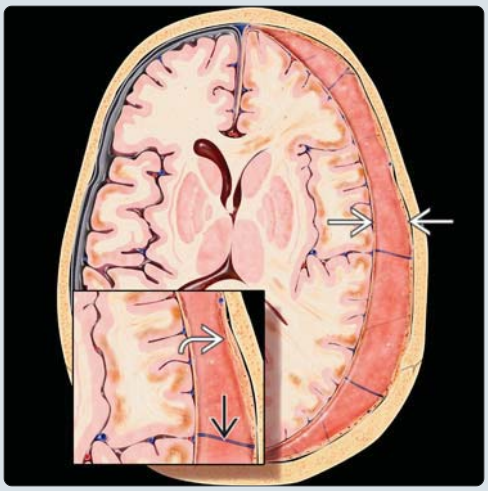
TOP DIFFERENTIAL DIAGNOSES

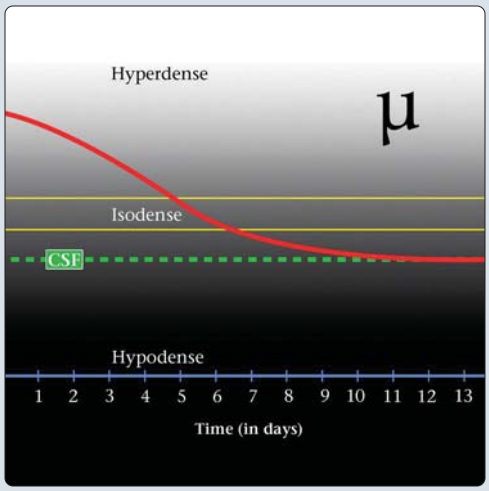
- Other subdural collections
  - Effusion
  - Hygroma
  - Empyema
- Pachymeningopathies (thickened dura)
  - Look for other signs of intracranial hypotension
- Chronic dural sinus thrombosis
- Tumor

PATHOLOGY

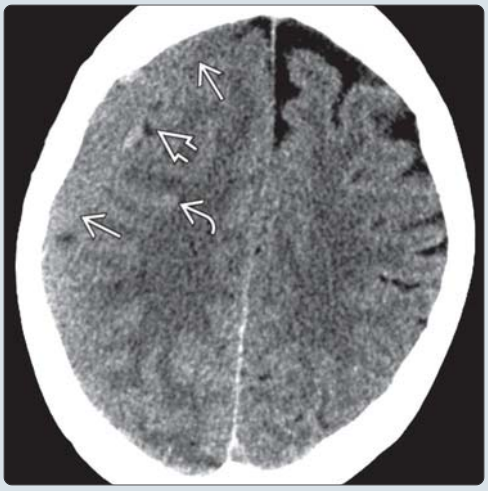
- Traumatic stretching/tearing of bridging cortical veins as they cross subdural space
- Trauma may be minor (particularly in elderly)

(Left) *Axial graphic shows a typical subacute subdural hematoma (sSDH) ➡. Inset shows the traversing "bridging" vein ⇨ and developing membranes ➡. These are often related to relatively minor trauma in the elderly.* **(Right)** *SDHs decrease by ~ 1.5 HU/day. By 7-10 days, blood in the hematoma becomes isodense with cortex. By about 10-14 days, it is hypodense compared to adjacent brain.*





(Left) *Axial NECT scan shows a right sSDH ➡ that is isodense with the underlying cortex. Note the inward displacement of "dots" of CSF ⇨ in compressed, underlying sulci. The gray-white matter (GM-WM) interface ➡ is "buckled" inwards (compared with normal-appearing left side).* **(Right)** *Bilateral "balanced" isodense sSDHs ➡ are present in the case. Note that both GM-WM interfaces are inwardly displaced & the underlying sulci are compressed. A displaced "dot" of CSF ⇨ is seen under the left sSDH.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Subacute subdural hematoma (sSDH)

Definitions

- Subacute (~ 3 days to 3 weeks) collection of partially liquified clot, resorbing blood products surrounded by granulation tissue ("membrane")

IMAGING

General Features

- Best diagnostic clue
  - Crescent-shaped, iso- to hypodense on CT, extraaxial collection that spreads diffusely over hemisphere
- Location
  - Between arachnoid and dura or within inner border cell layer of dura
- Morphology
  - Crescent-shaped extraaxial fluid collection
  - May cross sutures, not dural attachments
  - May extend along falx and tentorium
  - Compresses and displaces underlying brain surface, cortical vessels, and subarachnoid space fluid
    - Sulci are often effaced
  - Recurrent, mixed-age hemorrhage is common and raises suspicion of nonaccidental trauma in children
  - CT density and MR signal intensity vary with age and organization of hemorrhage

CT Findings

- NECT
  - Iso- to hypodense; may be same density as underlying cortex
  - Gray-white matter (GM-WM) junction is displaced medially
  - Surface sulci do not reach inner calvarial table
  - May see line of displaced/compressed sulci as "dots" of cerebrospinal fluid (CSF)
  - Density varies depending on stage of evolution
    - Progression from hyperdense (acute SDH) to isodense (sSDH) to hypodense (chronic SDH) over ~ 3 weeks
    - Recurrent hemorrhage can result in mixed density hematomas
- CECT
  - Dura and membranes enhance
  - Inward displacement of enhancing cortical vessels

MR Findings

- T1WI
  - Typically iso- (early sSDH) to hyperintense (late sSDH)
- T2WI
  - Varies; becomes more hyperintense with time (extracellular methemoglobin)
  - May see linear hypointensity due to membranes that predispose to repeated hemorrhage
- PD/intermediate
  - Variable signal: Iso- to hyperintense, depending on protein content or rebleed into collection and relative T1 and T2 contributions
- FLAIR
  - Signal varies depending on relative contribution of T1 and T2 effects
  - Typically does not suppress
    - Prominent T1 shortening often results in bright FLAIR signal
    - May be hypointense (early sSDH) due to T2 shortening effects
    - Early subacute hematomas, if small, can be nearly "invisible" on FLAIR
      - Look carefully for mass effect, sulcal effacement, &/or vessel displacement
- T2* GRE
  - Susceptibility artifact ("blooming") common
- DWI
  - Signal intensity varies with hematoma age
    - Crescentic high intensity with low intensity rim next to brain
      - "Double layer" appearance
      - Hyperintense band indicates relatively fresh bleeding from outer membrane
    - Hyperintense foci suggest solid clots
- T1WI C+
  - Enhancing and thickened dura is common
  - Enhancing membranes may be seen
    - Suggest unstable SDH prone to rehemorrhage
    - Delayed scans may show contrast diffusion into SDH
- Signal on MR often parallels that of intracerebral hematoma
  - Exceptions reported for early subacute hematomas
  - T2/FLAIR may be hyperintense in early sSDH
- Early MR is favored as most concurrent injuries are more conspicuous in early subacute phase

Imaging Recommendations

- Best imaging tool
  - NECT as initial screen
  - Consider CECT for membranes/loculations
  - MR is more sensitive for SDH
    - Can show additional findings of traumatic brain injury
- Protocol advice
  - Add FLAIR, DWI, and GRE to MR protocol for hemorrhage/trauma indications

DIFFERENTIAL DIAGNOSIS

Other Subdural Collections

- Effusion
  - MR: Typically follows CSF signal
  - Often related to meningitis, postop, or intracranial hypotension
- Empyema
  - MR: Peripheral enhancement; DWI+
  - Often related to sinus infection or penetrating injury
- Hygroma
  - MR: Follows CSF signal; no membranes
  - Results from tear in arachnoid; without hemorrhage

Pachymeningopathies (Thickened Dura)

- Chronic meningitis (may be indistinguishable)
- Postsurgical (shunt, etc.)
- Intracranial hypotension

https://CafePezeshki.IR

- "Slumping" midbrain; tonsillar herniation
- Sarcoid (often nodular, more lumpy-bumpy appearance)

Chronic Dural Sinus Thrombosis

- Diffuse dural thickening and enhancement

Tumor

- Meningioma, lymphoma, leukemia, metastases
- Dural-based enhancing mass ± skull involvement

Chemical Shift Artifact

- Marrow or subcutaneous fat may "shift" → can appear intracranial and mimic T1 hyperintense SDH

PATHOLOGY

General Features

- Etiology
  - Traumatic stretching and tearing of bridging cortical veins as they cross subdural space
  - Trauma may be minor, particularly in elderly
  - Mechanisms of enlargement
    - Rehemorrhage
    - Serum protein exudation

Gross Pathologic & Surgical Features

- Membranes: Granulation tissue with resorbing blood products
- Outer membrane related to hematoma enlargement with repetitive hemorrhages
- Inner membrane related to liquefaction of subdural hematoma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Range from asymptomatic to loss of consciousness
- Other signs/symptoms
  - Headaches, seizures, focal neurological deficit

Demographics

- Age
  - Young and elderly
- Gender
  - M > F
- Epidemiology
  - SDH is found in 10-20% of patients imaged and 30% of autopsy cases following craniocerebral trauma

Natural History & Prognosis

- Can spontaneously resolve or enlarge
- Older age and brain atrophy are contributory factors in conversion of traumatic SDH into subacute and chronic SDH
- Higher recurrence rate for skull base location SDH compared with convexity SDH

Treatment

- Surgical drainage indicated if growing/symptomatic
- Resection of membranes, if present
- "Separated" morphology has highest rehemorrhage rates

DIAGNOSTIC CHECKLIST

Consider

- Contrast enhancement if suspected isodense SDH to look for membrane formation/loculations
- MR with DWI to assess for presence of membranes

Image Interpretation Pearls

- Remember: MR signal of SDH is quite variable
  - Generally (but not always) evolves in pattern similar to intracerebral hemorrhage
- Enhancement is helpful to differentiate sSDH and chronic SDH from pachymeningopathies
- If sSDHs present without trauma history, evaluate coagulation status and look for signs of intracranial hypotension

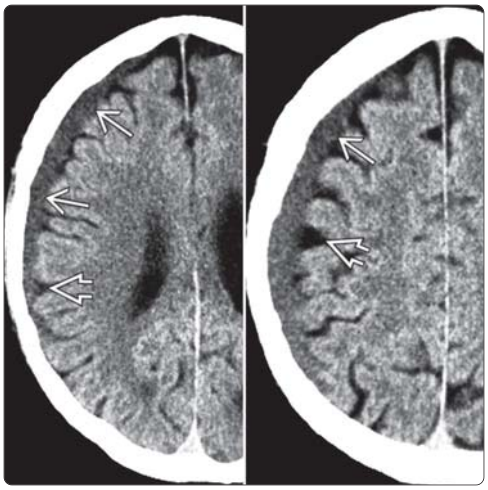
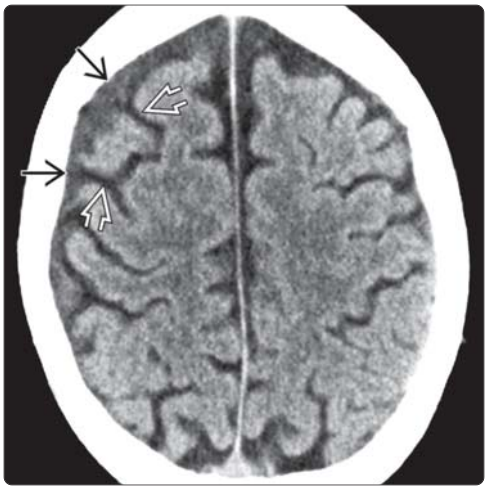
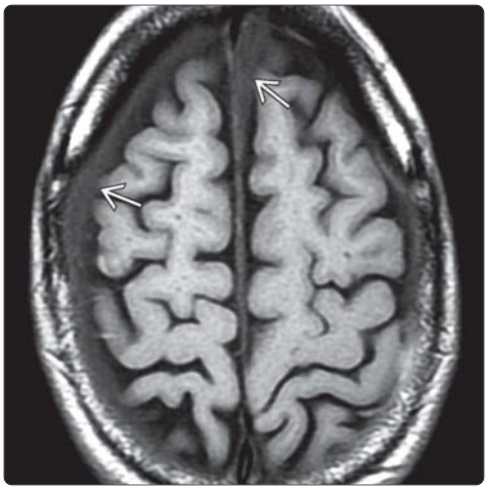
https://CafePezeshki.IR

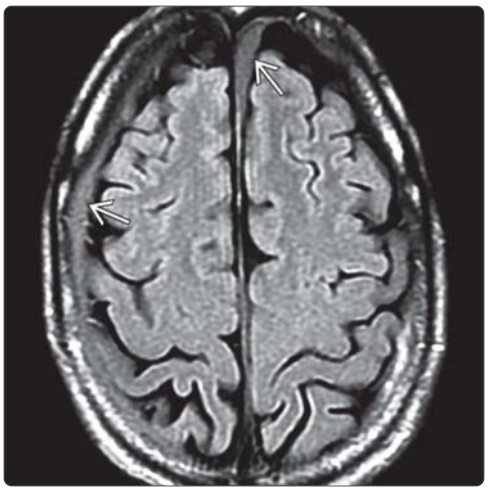


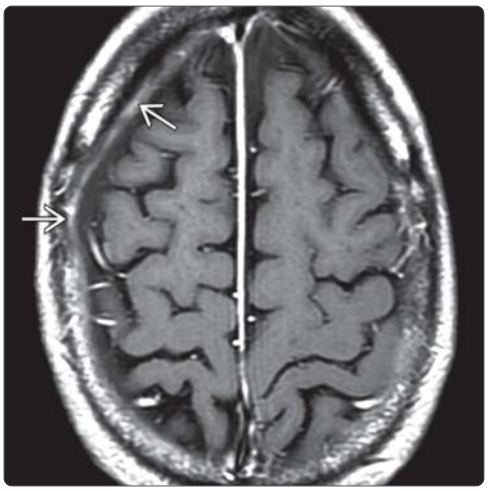
(Left) *NECT scan in an elderly patient with a late sSDH and moderate cortical atrophy shows the difference between the nearly isodense SDH* ⇨ *and the hypodense CSF in the underlying compressed subarachnoid spaces* ⇨. **(Right)** *SDHs of different ages are common in elderly anticoagulated patients. The right SDH is subacute (isodense with underlying brain), and the left-sided collection is more chronic-appearing. Note the severe compression of the underlying brain and sulci. The falx is partially calcified.*





(Left) *Axial NECT scan in a 59-year-old man with seizures and no definite history of head trauma shows a right frontal extraaxial fluid collection* ⇨ *that is slightly hyperdense relative to CSF in the underlying sulci* ⇨. **(Right)** *T1WI MR in the same patient shows there are bilateral subdural collections* ⇨ *that appear slightly hyperintense compared with CSF. This is a typical MR finding in subacute SDHs.*





(Left) *FLAIR scan in the same patient shows that the subacute fluid collections* ⇨ *do not suppress, illustrating their difference compared with normal CSF.* **(Right)** *T1 C+ scan in the same patient shows that the outer membrane of the sSDH enhances* ⇨. *Findings are consistent with late subacute subdural hematomas.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Chronic subdural hematoma (cSDH)
- Chronic (> 3 weeks to months) subdural blood products
  - Mixed chronic and acute hemorrhage is common

IMAGING

- Crescent-shaped extraaxial collection
  - Spreads diffusely over affected hemisphere
  - Surrounded by enhancing membranes
  - Often septated, loculated, with fluid-fluid levels
  - Recurrent, mixed-age hemorrhage is common and raises suspicion of nonaccidental trauma in children
- Imaging recommendations
  - NECT is good initial screen
  - Use wide window settings (150-200 HU)
  - MR better demonstrates cSDH

TOP DIFFERENTIAL DIAGNOSES

- Subdural hygroma
- Subdural effusion
- Subdural empyema

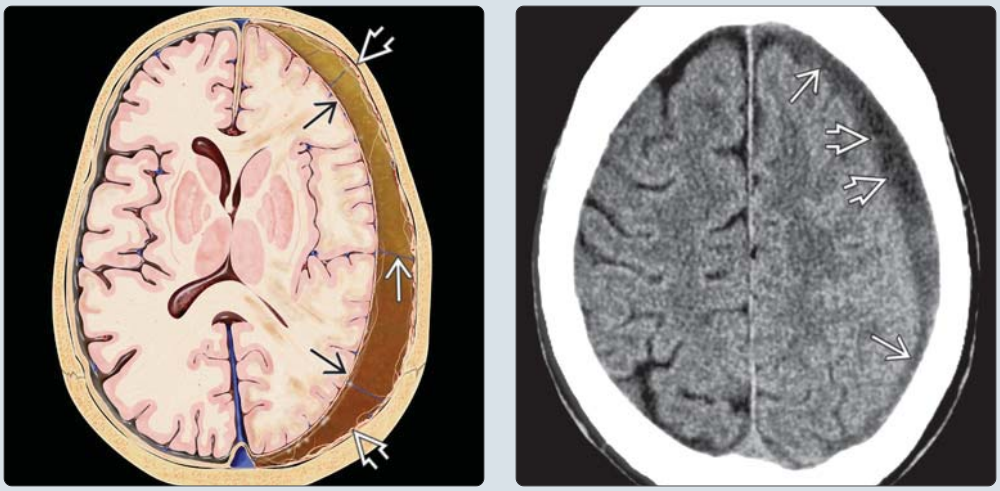
PATHOLOGY

- Serosanguineous fluid
- Encapsulated by granulation tissue: "Neomembranes" with fragile capillaries
- 5% multiloculated with fluid-blood density levels

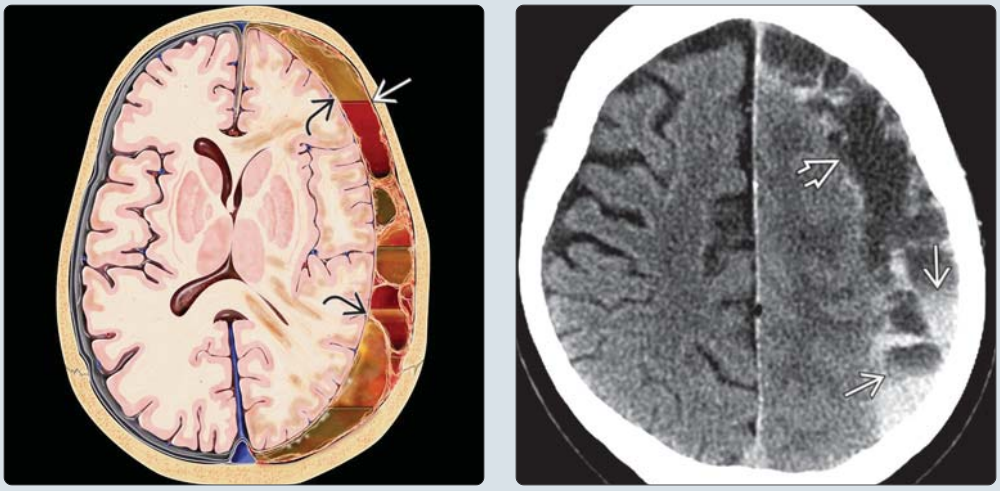
CLINICAL ISSUES

- Treatment
  - Surgical drainage with resection of membranes
- Older age, brain atrophy are contributory factors in conversion of traumatic SDH into cSDH
- Recurrence risk varies with type
  - Separated SDH has highest risk
  - Large > small preoperative collections
  - Residual postoperative volume > 80 mL

(Left) *Axial graphic depicts pathology of classic chronic subdural hematoma (SDH) with the formation of thin internal ⇨, thicker external ⇨ membranes. Note the stretched bridging veins ⇨ crossing the SDH, top-to-bottom gradation of fluid from serosanguinous to more proteinaceous contents.* **(Right)** *Axial NECT depicts chronic SDH (cSDH) as crescentic hypodense extraaxial fluid collection ⇨ over the left hemisphere. Stretched cortical veins ⇨ are faintly visible as they cross the SDH.*



(Left) *Axial graphic depicts "mixed" subdural hematoma. Numerous loculations ⇨ that contain hemorrhages of multiple ages are present. Note the fluid-fluid levels with mixed acute, subacute blood ⇨. Rehemorrhage into preexisting subacute &/or chronic SDH is common.* **(Right)** *Axial NECT shows classic left-sided "mixed" SDH ⇨. Note the multiple loculations and fluid-fluid levels ⇨ formed by acute rehemorrhage into preexisting loculated chronic SDH.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Chronic subdural hematoma (cSDH)

Definitions

- Chronic (> 3 weeks to months) collection of blood products in subdural space
  - May have foci of more acute hemorrhage ("mixed" SDH)

IMAGING

General Features

- Best diagnostic clue
  - Crescent-shaped, multiseptated, extraaxial collection with enhancing surrounding membranes that spreads diffusely over affected hemisphere
- Location
  - Potential space between inner layer of dura mater and arachnoid
  - Supratentorial convexity is most common
- Morphology
  - Crescent-shaped extraaxial fluid collection
  - May cross sutures, not dural attachments
  - May extend along falx and tentorium
  - Compresses and displaces underlying brain surface, cortical vessels, and subarachnoid space fluid
  - Often septated, with internal membranes
  - Calcification in 1-2%
  - Enhancement of encapsulating membranes
  - Recurrent, mixed-age hemorrhage is common and raises suspicion of nonaccidental trauma in children
  - CT density and MR signal intensity vary with age and organization of hemorrhage

CT Findings

- NECT
  - Density varies, depending on stage of evolution
    - Typically follows cerebrospinal fluid (CSF) density
    - Progression from hyperdense (acute SDH) to isodense (subacute SDH) to hypodense (cSDH) over ~ 3 weeks
    - Progressive increase in density &/or size of cSDH from 3 weeks to 3 months; likely from rebleed of fragile neocapillaries in outer membrane
    - Eventual resorption in most cSDHs > 3 months (outer membrane stabilizes and is thus not prone to rebleed)
  - Calcification can be seen along periphery of chronic collections, typically those present for many years
- CECT
  - Inward displacement of enhancing cortical vessels
  - Enhancement of dura and membranes

MR Findings

- T1WI
  - Variable, depending on stage of evolution
    - Isointense to CSF if stable/chronic
    - Hyperintense with rebleed or ↑ protein
- T2WI
  - Variable, depending on stage of evolution
    - Isointense to CSF if stable/chronic
    - Hypointense with rebleed
  - T2-hypointense signal is seen in majority of cSDHs (73%) and is related to repeat hemorrhage
  - Membranes usually hypointense
- PD/intermediate
  - Iso- to hyperintense, depending on protein content or rebleed into collection
- FLAIR
  - Hyperintense to CSF in most cases
    - Depends on inherent T1 and T2 signal characteristics &/or presence of protein
  - Usually most sensitive sequence for detection of SDH
- T2* GRE
  - Hypointense signal from subacute-chronic blood products
  - May be hyperintense from T2 effects
- DWI
  - Variable signal
  - Hyperintense outer membranes suggest predisposition to repeated hemorrhage
- T1WI C+
  - Peripheral &/or dural enhancement
  - Delayed scans show contrast diffusion into SDH
- Signal of SDH is quite variable on MR
  - Generally evolves in pattern similar to intracerebral hemorrhage

Imaging Recommendations

- Best imaging tool
  - NECT is good initial screen
  - MR better demonstrates cSDH
    - cSDH is frequently hyperintense (due to methemoglobin) on T1, T2, PD, FLAIR
  - MR is uniquely suited to evaluate nonaccidental trauma cases, since differing ages of blood products are better characterized
    - Membranes and clot are better demonstrated on MR
      - Thickened or extensive neomembranes or clot with mass effect are indications for cSDH evacuation and membranectomy
- Protocol advice
  - Use wide window settings (150-200 HU) to identify small SDH

DIFFERENTIAL DIAGNOSIS

Subdural Hygroma

- Clear CSF (surgery/trauma tears arachnoid)
- No blood; no encapsulating membranes
- No enhancement

Subdural Effusion

- Usually occurs as complication of meningitis
- Plasma exudate, not CSF

Subdural Empyema

- Pus accumulated in subdural space
- Peripheral enhancement
- Restricted diffusion (hyperintense) centrally

Pachymeningopathies (Thickened Dura)

- Chronic meningitis (may be indistinguishable)
- Postsurgical (shunt, etc.)

https://CafePezeshki.IR

- Intracranial hypotension ("slumping" midbrain, tonsillar herniation)
- Sarcoid (nodular, "lumpy-bumpy")

Tumors

- Meningioma, lymphoma, leukemia, metastases
- Metastatic lesions may also result in SDH, particularly breast and prostate cancers and melanoma metastases
- Dural-based enhancing mass
- ± skull involvement

Chemical Shift Artifacts

- Marrow or subcutaneous fat may "shift"; can appear intracranial and mimic T1-hyperintense SDH
- Seen with ↑ field of view or ↓ bandwidth

PATHOLOGY

General Features

- Etiology
  - SDH most commonly results from traumatic stretching and tearing of bridging cortical veins as they cross subdural space to drain into dural sinus
  - Chronic SDH
    - Develops over 2-3 weeks
    - May continue to enlarge
    - May resolve spontaneously if membrane stabilizes
    - DWI may show hyperintense band that suggests fresh hemorrhage and propensity for enlargement
  - Mechanisms for SDH enlargement
    - Rehemorrhage
    - Serum protein exudation
- Associated abnormalities
  - Trauma is most common cause

Staging, Grading, & Classification

- Blood in subdural space incites tissue reaction resulting in organization and resorption of hematoma
- Chronic SDH may be classified by internal architecture
  - Homogeneous/laminar
    - Homogeneous content; may be laminar with thin layer of fresh blood along inner membrane
  - Separated
    - Hematocrit level
    - Sometimes content gradually changes ("gradated")
  - Trabecular
    - Heterogeneous with internal septa
    - Thickened or calcified capsule

Gross Pathologic & Surgical Features

- Serosanguineous fluid
- Encapsulated by granulation tissue: "Neomembranes" with fragile capillaries
- 5% multiloculated with fluid-blood density levels
- Cycle of recurrent bleeding → coagulation → fibrinolysis

Microscopic Features

- Outer membrane formed by proliferating fibroblasts and capillaries; fragile capillaries are hypothesized as source of recurrent hemorrhage in cSDH
- Inner membrane formed by dural fibroblasts or border cells; forms fibrocollagenous sheet

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Varies from asymptomatic to loss of consciousness
    - Lucid interval in acute SDH: Initially awake and alert patient who loses consciousness a few hours after trauma
  - Other symptoms from mass effect, diffuse brain injury, secondary ischemia

Demographics

- Age
  - Any age but elderly most at risk
  - Chronic SDH is most common type of intracranial hemorrhage in elderly
- Epidemiology
  - SDH is found in 10-20% of patients who are imaged and 30% of autopsy cases following head trauma

Natural History & Prognosis

- Extent of primary brain injury is most important factor affecting outcome
- Older age, brain atrophy are contributory factors in conversion of traumatic SDH into cSDH
- ~ 15% of cSDHs recur
  - Recurrence rate
    - Higher for skull base location SDH compared with convexity SDH
    - Higher with bilateral SDHs
    - High for separated SDH, low for trabeculated SDH
    - Low if preoperative volume < 115 mL, residual postoperative volume < 80 mL

Treatment

- Surgical drainage with resection of membranes
- Recurrence risk of cSDH varies with type
  - Separated SDH has highest risk; thickened or calcified membrane almost never rehemorrhages

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Enhancement may help differentiate chronic SDH from pachymeningopathies
- If no history of trauma, consider underlying vascular lesion or dural metastases

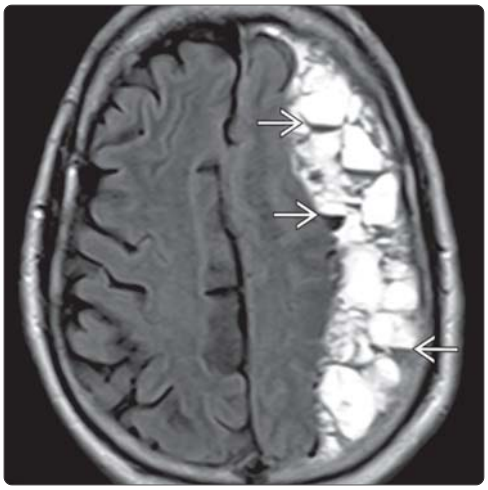
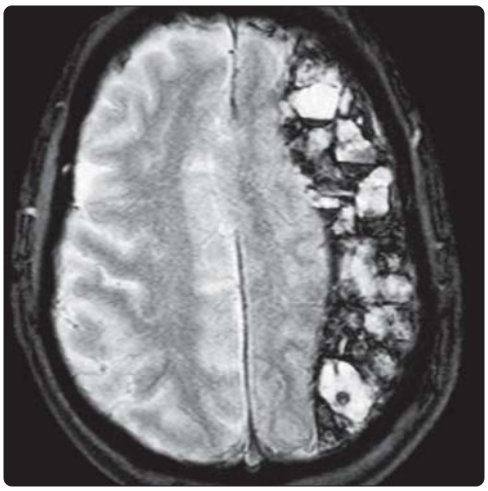
(Left) *NECT in an elderly patient with multiple falls shows a "bubbly" fluid collection with loculations and multiple blood-fluid levels* ➡. **(Right)** *CTA in the same patient shows the "bubbly" crescentic fluid collection. Note the inward displacement of brain with compressed sulci and displaced cortical veins* ➡.



(Left) *Coronal T1WI MR in the same patient shows that the loculated pouches of fluid* ➡ *are mostly hyperintense. A few hypointense pockets of more acute hemorrhage* ⇨ *are present within the loculations.* **(Right)** *Axial FLAIR is dramatic, showing that the hyperintense loculations contain numerous hypointensities* ➡ *layering in the dependent portions of the pockets. The appearance suggests acute on chronic ("mixed") subdural hematoma.*



(Left) *T2* GRE MR scan shows multiple hypointense "blooming" foci, consistent with hemorrhage into a chronic loculated subdural hematoma.* **(Right)** *T1WI C+ FS MR shows some enhancement around the margins of the cSDH* ➡, *consistent with a membrane of organizing granulation tissue.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Blood within subarachnoid spaces
  - Contained between pia and arachnoid membranes

IMAGING

- High density on CT, hyperintensity on FLAIR

TOP DIFFERENTIAL DIAGNOSES

- Nontraumatic SAH
- Meningitis: Cellular and proteinaceous debris
- Carcinomatosis meningitis
- Pseudosubarachnoid hemorrhage
- Gadolinium administration
- High-inspired oxygen

PATHOLOGY

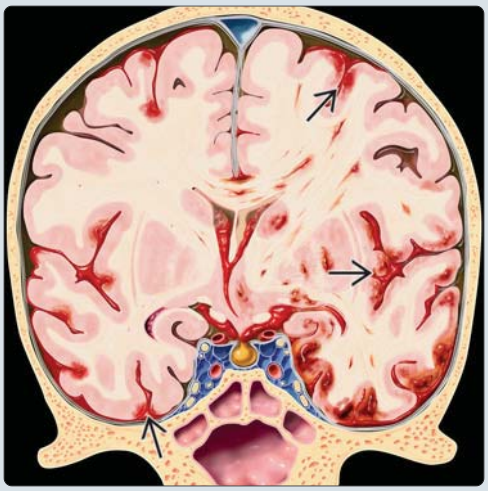
- Associated with contusions, subdural or epidural hematoma, diffuse axonal injury

CLINICAL ISSUES

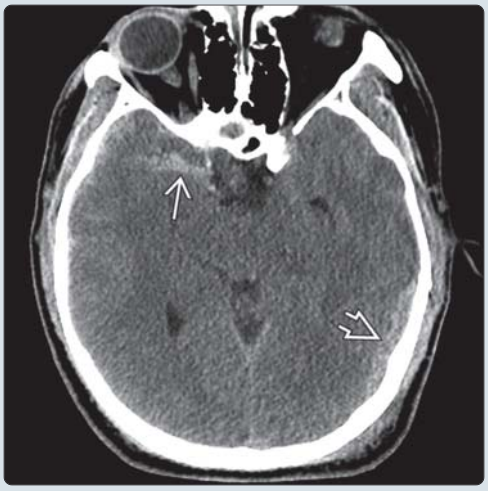
- Headache, emesis, decreased consciousness
- Trauma is most common cause of SAH
- Outcome is related in logistic regression analysis to
  - Admission Glasgow Coma Scale score
  - Amount of subarachnoid blood
- Isolated tSAH, no other injuries usually benign
- Poor prognosis if associated with other intracranial injuries
- Vasospasm develops earlier than with aneurysmal SAH
- Associated with ↓ neuropsychologic profiles, worse vocational outcomes in 1 year follow-up

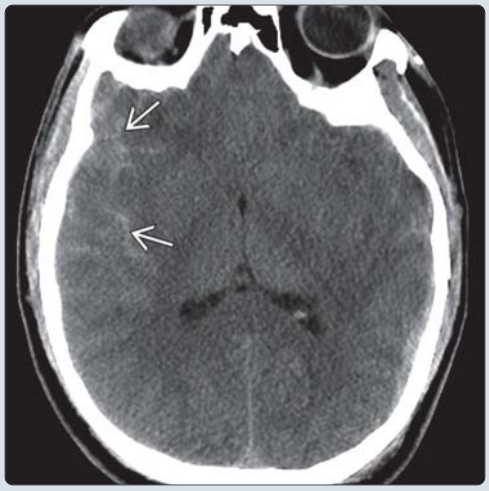
DIAGNOSTIC CHECKLIST

- Isolated supratentorial sulcal blood common
- Hyperdense blood in interpeduncular cistern may be only manifestation of subtle SAH



(Left) *Coronal graphic depicts findings in a severe traumatic brain injury. Closed head trauma has resulted in multiple gyral contusions and subarachnoid hemorrhage. Most tSAHs occur adjacent to parenchymal brain injuries and are found centered around the sylvian fissures, inferior frontotemporal, and convexity sulci.* **(Right)** *Axial NECT in a patient with head trauma and tSAH demonstrates focal hyperdense collections in a few left posterior frontal sulci bordering the interhemispheric fissure.*





(Left) *Axial NECT scan in a 28-year-old man with closed head injury shows tSAH in the right sylvian fissure. Note the absence of blood in the adjacent suprasellar cistern, a more common site for aneurysmal SAH. A left parietal epidural hematoma is also present. Traumatic SAH often occurs in combination with other injuries.* **(Right)** *Axial NECT scan in the same patient shows the typical curvilinear configuration of tSAH in the sulci of the right temporal lobe.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Traumatic subarachnoid hemorrhage (tSAH)

Definitions

- Blood within subarachnoid spaces
  - Contained between pia and arachnoid membranes

IMAGING

General Features

- Best diagnostic clue
  - High density on NECT
  - Sulcal-cisternal FLAIR hyperintensity (in trauma patient)
- Location
  - Can be focal or diffuse
    - Focal SAH adjacent to contusion, subdural/epidural hematoma, fracture, laceration
      - Sylvian fissure, inferior frontal subarachnoid spaces most common
      - Isolated convexity sulci (adjacent to contusion)
    - Diffusely in subarachnoid space &/or basal cisterns
    - Layering on tentorium

CT Findings

- NECT
  - High density in subarachnoid space(s)/cisterns
  - Hyperdense blood in interpeduncular cistern may be only manifestation of subtle SAH
  - Identical to aneurysmal SAH except for location
    - Adjacent to contusions, subdural hematoma
    - Convexity sulci > basal cisterns

MR Findings

- T1WI
  - Hyperintense to ventricular CSF ("dirty" CSF)
- T2WI
  - Isointense to CSF (not detected)
- FLAIR
  - Hyperintense sulci/cisterns; more sensitive, less specific than CT
- T2* GRE
  - Occasionally hypointense
- DWI
  - Evaluation of tSAH-induced spasm
    - Restricted diffusion in areas of ischemia

Angiographic Findings

- Conventional DSA
  - Exclusion of aneurysm, evaluation of tSAH-induced spasm: CTA replaces DSA
  - Beaded appearance of spasm-involved vessels
    - From 2-3 days to 2 weeks after trauma

Imaging Recommendations

- Best imaging tool
  - NECT; FLAIR for subtle SAH

DIFFERENTIAL DIAGNOSIS

Nontraumatic SAH (ntSAH)

- Ruptured aneurysm
  - Causes 80-90% of all ntSAH
  - Aneurysm identified on DSA, CTA, MRA in > 90%
- Ruptured dissecting aneurysm
- Arteriovenous malformation (AVM)
  - Account for 15% of ntSAH
  - Identified on DSA, CTA, MRA
- Perimesencephalic venous hemorrhage
  - Limited to basal cisterns: Clot around basilar artery
  - Normal DSA, CTA, MRA
- Cerebral infarction with reperfusion hemorrhage
  - Presence of known infarct
- Anticoagulation therapy
  - Long-term warfarin (Coumadin) therapy; usually unrecognized mild head trauma
  - Alcohol abuse as cause of abnormal coagulation
- Blood dyscrasia
  - Usually known preexisting entity
- Eclampsia (pregnancy-induced hypertension)
  - Reported complication, eclampsia symptomatology
- Spinal vascular malformation
  - Spontaneous
  - Negative initial and repeat cerebral DSA
  - MR: Spinal SAH, cord edema
  - MRA and DSA to establish diagnosis

Meningitis: Cellular and Proteinaceous Debris

- Dirty CSF on CT
- Hyperintensity on FLAIR due to T1 shortening and failure of signal nulling

Carcinomatosis Meningitis

- Cellular CSF prevents FLAIR CSF nulling

Pseudosubarachnoid Hemorrhage

- Severe cerebral edema → diffusely hypodense brain
- Dura, circulating blood in arteries/venous sinuses look relatively hyperdense compared to adjacent brain

Gadolinium Administration

- IV contrast for routine-enhanced MR may cause FLAIR hyperintensity
  - Stroke, high-grade gliomas, or meningiomas (neoplasm surfaces contact subarachnoid spaces/ventricles)
  - CSF changes more evident close to pathology &/or hemisphere involved

High-Inspired Oxygen

- 100% O_2 during general anesthesia
  - May cause incomplete nulling of subarachnoid CSF
  - Hyperintense sulcal CSF on FLAIR
  - Ventricular CSF not affected

PATHOLOGY

General Features

- Etiology
  - Tearing of vessels in subarachnoid space
  - Traumatic dissecting aneurysm → basal cisternal SAH

https://CafePezeshki.IR

  - Most often from vertebral artery dissection
  - Suspect with basilar skull fracture
  - Mimics aneurysmal SAH
- Genetics
  - *APOE* ε4 allele predisposes to poor outcome after traumatic brain injury (TBI), SAH, and hemorrhagic stroke
- Associated abnormalities
  - Contusions, subdural or epidural hematoma, diffuse axonal injury

Staging, Grading, & Classification

- Grade 1: Thin tSAH ≤ 5 mm
- Grade 2: Thick tSAH > 5 mm
- Grade 3: Thin tSAH with mass lesion(s)
- Grade 4: Thick tSAH with mass lesion(s)

Gross Pathologic & Surgical Features

- Acute blood in sulci/cisterns
- Autopsy studies show
  - Bleeding from cortical arteries/veins
  - Leakage from surface contusions

Microscopic Features

- Evolutionary hemoglobin changes are different than described for intracerebral hematoma
  - Much slower progression, delayed degradation
  - Most likely secondary to high ambient oxygen tension of subarachnoid CSF

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, emesis, decreased consciousness
- Other signs/symptoms
  - May ↑ risk of corrected Q-T prolongation on ECG, ventricular tachycardia, sudden death
- Clinical profile
  - Trauma, not ruptured aneurysm, is most common cause of SAH

Demographics

- Age
  - Median = 43 years (standard deviation = 21.1 years)
- Gender
  - M:F = 2:1 for sustaining traumatic brain injury
- Epidemiology
  - tSAH found in 33% with moderate TBI, 60% with severe TBI
  - Found in almost all cases at autopsy
  - tSAH-associated vasospasm in 2-10% of cases
- Risk factors for TBI
  - Young age, low income, chronic alcohol/substance abuse
  - Prior episodes of TBI

Natural History & Prognosis

- Outcome related in logistic regression analysis to
  - Admission Glasgow Coma Scale score
  - Amount of subarachnoid blood
- Isolated tSAH in setting of mild TBI
  - Course typically benign
  - If no other significant trauma, can be managed without follow-up imaging/ICU admission
- Poor prognosis if associated with other intracranial injuries
  - Amount of tSAH on initial CT correlates with delayed ischemia, poor outcome
  - 46-78% of moderate to severe TBI associated with tSAH result in
    - Increased morbidity, leading to severe disability and persistent vegetative state
    - Increased mortality as high as 2x
- Acute hydrocephalus
  - Rare; usually obstruction of aqueduct or 4th ventricular outlet by clotted SAH
  - Obstructive, noncommunicating hydrocephalus
    - Asymmetric ventricular dilatation
- Delayed hydrocephalus
  - Defective CSF resorption
  - Obstructive communicating hydrocephalus
    - Symmetric ventricular dilatation
  - Observed in 11.96% of TBI patients after 3-month follow-up interval
  - No correlation between location of tSAH and development of hydrocephalus
- Vasospasm
  - Develops earlier with tSAH than with aneurysmal SAH
  - Peaks 7-10 days after injury
  - Threat remains up to 2 weeks
  - Uncommon cause of post-traumatic infarct
- Associated with ↓ neuropsychologic profiles, worse vocational outcomes in 1-year follow-up

Treatment

- Supportive therapy is primary treatment
  - Intubation, supplemental oxygen, IV fluids, therapy of altered vital signs
  - Sedatives; medications for pain, nausea, and vomiting
  - Anticonvulsants for seizures
- Nimodipine (calcium channel blocker) may prevent vasospasm and its complications

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- tSAH is often accompanied by additional injuries
- Isolated supratentorial sulcal blood is common
- Hyperdense blood in interpeduncular cistern may be only manifestation of subtle SAH

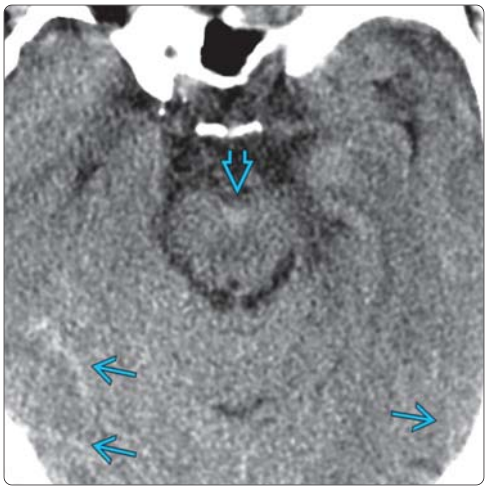
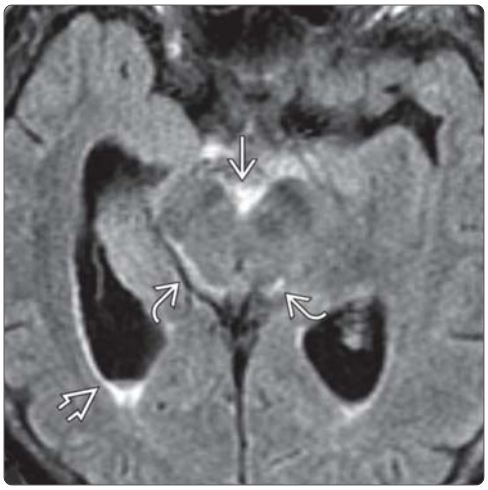
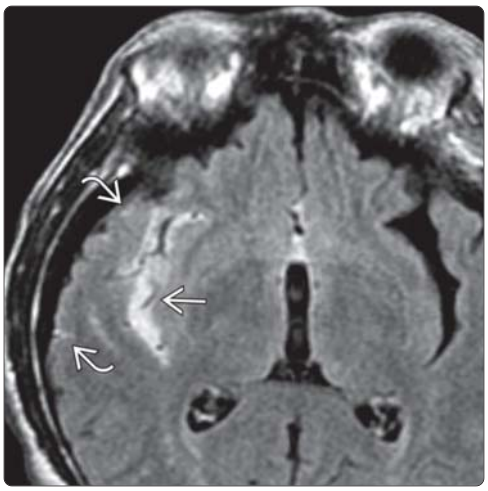
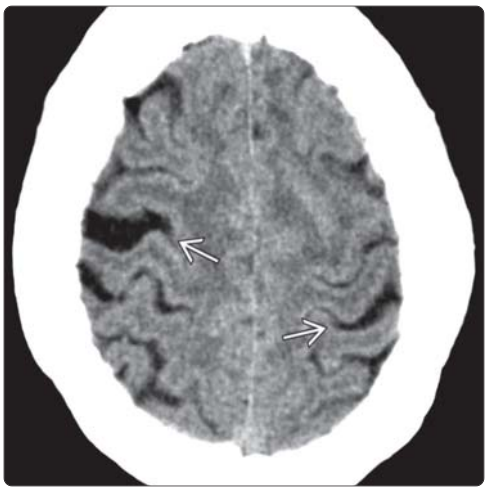
(Left) *Axial NECT shows hyperdense traumatic subarachnoid hemorrhage within the sulci, left sylvian fissure, ambient cisterns, and interhemispheric fissure.* **(Right)** *Axial NECT reveals a small collection of hyperdensity along a left frontal medial sulcus, representing traumatic subarachnoid hemorrhage.*





(Left) *Axial NECT demonstrates collections of hyperdensity within a few sulci and the interpeduncular cistern from tSAH.* **(Right)** *Axial FLAIR MR shows abnormal CSF hyperintensity within the interpeduncular cistern and ambient/quadrigeminal cisterns. It also reveals a small amount of layering-dependent hemorrhage within the right occipital horn.*





(Left) *Axial FLAIR MR demonstrates tSAH as an abnormal CSF hyperintensity within the right sylvian fissure, as well as within a few right sulci.* **(Right)** *Axial NECT shows widening of bilateral sulci, right more than left, by a CSF-isodense process due to subacute to chronic SAH.*

https://CafePezeshki.IR

Cerebral Contusion

KEY FACTS

TERMINOLOGY

- Brain surface injuries involving gray matter and contiguous subcortical white matter

IMAGING

- Best diagnostic clue: Patchy hemorrhages within edematous background
- Characteristic locations: Adjacent to irregular bony protuberance or dural fold
- Anterior inferior frontal lobes and anterior inferior temporal lobes most common
- FLAIR: Best for hyperintense cortical edema and subarachnoid hemorrhage
- GRE: Hypointense hemorrhagic foci "bloom"
- Best imaging tool
  - CT to detect acute hemorrhagic contusions, other intracranial lesions, and herniations
  - MR to detect presence and delineate extent of lesions
- Coup: Direct injury to brain beneath impact site
- Contrecoup: Injury opposite impact site; usually more severe than coup

TOP DIFFERENTIAL DIAGNOSES

- Infarct
- Venous sinus thrombosis
- Cerebritis
- Low-grade neoplasm
- Transient postictal changes

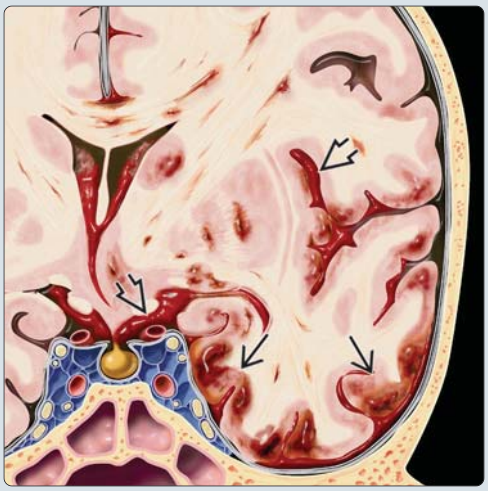
PATHOLOGY

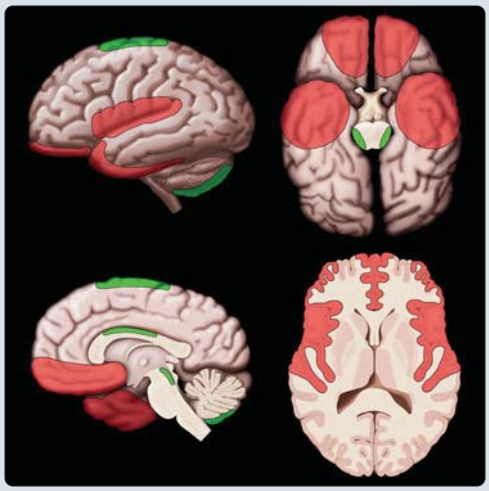
- Inflammation → worsening/enlarging lesions

CLINICAL ISSUES

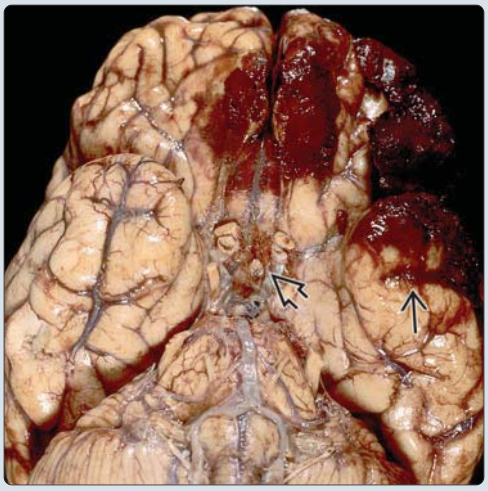
- Initial symptom: Confusion → obtundation
- Central goal: Prevent and treat secondary injury
- Mass effect and herniation may require evacuation

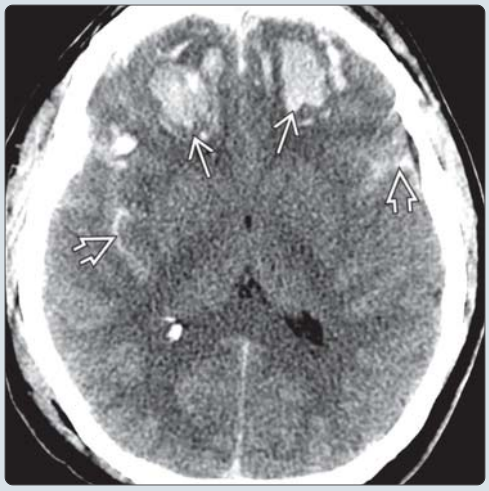
(Left) *Coronal graphic illustrates the pathology of closed head injury. Note the hemorrhagic foci involving gray matter of several contused gyri ⇨, axonal and deep gray injuries, and traumatic subarachnoid hemorrhage ⇨ in the basal cisterns and sylvian fissure.* **(Right)** *Graphics depict the most common sites of cerebral contusions in red. Less common sites are shown in green. The most common locations of all are the anteroinferior frontal and temporal lobes.*





(Left) *Gross pathology of the brain from a patient who died from a severe closed head injury shows bifrontal, temporal hemorrhagic contusions ⇨, as well as traumatic subarachnoid hemorrhage in the suprasellar cistern ⇨. (Courtesy R. Hewlett, MD.)* **(Right)** *NECT scan shows extensive frontotemporal contusions ⇨ and traumatic subarachnoid hemorrhage ⇨ in a patient with severe brain injury.*





https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Brain surface injuries involving gray matter and contiguous subcortical white matter

IMAGING

General Features

- Best diagnostic clue
  - Patchy hemorrhages within edematous background
- Location
  - Characteristic locations: Adjacent to irregular bony protuberance or dural fold
    - Anterior inferior frontal lobes and anterior inferior temporal lobes most common
    - 25% parasagittal ("gliding" contusions)
  - Less common locations
    - Parietal/occipital lobes, posterior fossa
  - Coup: Direct injury to brain beneath impact site
  - Contrecoup: Injury opposite impact site; usually more severe than coup
- Morphology
  - Early: Patchy, ill-defined, superficial foci of punctate or linear hemorrhage along gyral crests
  - 24-48 hours: Existing lesions enlarge and become more hemorrhagic; new lesions may appear
  - Chronic: Encephalomalacia with volume loss
  - Multiple, bilateral lesions in 90% of cases

CT Findings

- NECT
  - Early: Patchy, ill-defined, low-density edema with small foci of hyperdense hemorrhage
  - 24-48 hours
    - Edema, hemorrhage, and mass effect often increase
    - New foci of edema and hemorrhage may appear
    - Petechial hemorrhage may coalesce
  - Chronic
    - Become isodense, then hypodense
    - Encephalomalacia with volume loss
  - Secondary lesions
    - Herniations/mass effect with secondary infarction
    - Hydrocephalus due to hemorrhage
- Perfusion CT
  - More sensitive than NECT in detection of cerebral contusions (87.5% vs. 39.6%, respectively)

MR Findings

- T1WI
  - Acute: Inhomogeneous isointensity and mass effect
  - Chronic: Focal or diffuse atrophy
- FLAIR
  - Acute: Best for hyperintense cortical edema and subarachnoid hemorrhage (SAH)
  - Chronic
    - Hyperintense demyelination and microglial scarring
    - Hypointense hemosiderin staining
    - Hypointense cavitation (cystic encephalomalacia)
- T2* GRE
  - Acute: Hypointense hemorrhagic foci "bloom"
  - Chronic: Hypointense hemosiderin deposits
- DWI
  - Hyperintense in areas of cell death
  - Decreased apparent diffusion coefficient (ADC) correlates with poor outcome
  - Diffusion tensor imaging sometimes shows white matter damage when CT, routine MR appear normal
- MRS
  - ↓ NAA, ↑ choline

Nuclear Medicine Findings

- SPECT Tc-99m HMPAO imaging
  - Depicts focal changes in 53% with mild injury
  - Negative in 1st month predicts good outcome
    - Positive can predict poor clinical outcome

Imaging Recommendations

- Best imaging tool
  - CT to detect acute hemorrhagic contusions, other intracranial lesions, and herniations
  - MR to detect presence and delineate extent of lesions
- Protocol advice
  - FLAIR for edema and SAH; GRE for hemorrhagic foci

DIFFERENTIAL DIAGNOSIS

Infarct

- No trauma history
- Characteristic acute onset focal neurologic deficit
- Vascular distribution: Spares frontal and temporal poles

Venous Sinus Thrombosis

- Edema and hemorrhage adjacent to occluded sinus

Cerebritis

- No trauma history
- Herpes typically involves medial temporal lobe

Low-Grade Neoplasm

- No trauma history
- Solitary nonhemorrhagic lesion
- No predilection for anterior frontal or temporal lobes

Transient Postictal Changes

- No trauma history
- Preceding or ongoing seizure activity
- May be hyperintense on DWI; can enhance acutely

PATHOLOGY

General Features

- Etiology
  - Stationary head struck by object
    - Direct injury beneath impact site
    - Contusion is rare without fracture
  - Moving head: Motor vehicle crash, falls
    - Differential accel-/deceleration and rotational forces on portions of brain with different densities
    - Gliding injury: Cortex anchored to dura by arachnoid granulations; subcortical tissue glides more than cortex
  - Traffic injuries are main cause in young adults (20–40 years)

https://CafePezeshki.IR

- Falls are main cause in infants (0–4 years) and elderly (≥ 70 years)
- Associated abnormalities
  - Soft tissue injuries in 70% of patients
  - Subdural hematoma (SDH), traumatic SAH, intraventricular hemorrhage
  - Skull fracture at coup site

Gross Pathologic & Surgical Features

- Contusions
  - Edema along gyral crests
  - Petechial hemorrhages (most evident in 24-48 hours)
  - Small hemorrhages may coalesce into hematoma
  - Delayed hematomas may develop 24-48 hours later
- Lacerations
  - Intracerebral hematoma with "burst" lobe
  - SDH communicates with hematoma via lacerated brain, torn pia-arachnoid
- Liquefaction and encephalomalacia in chronic phase

Microscopic Features

- Capillary disruption → blood extravasation: RBCs cause visible hemorrhage, plasma leads to edema
- Perivascular hemorrhage, ↑ pinocytic activity of endothelial cells, and cytotoxic edema of astroglial cells
- Higher levels of serum protein S100B and IL-6 correlate with ultrastructural changes of endothelial cells

Cellular Features

- Chemokine, nitric oxide activation occurs early
  - Inflammatory response → neutrophil oxidative burst → proteolytic and neurotoxic enzyme release
  - Neuroinflammation mediated by cyto-/chemokines, complement
    - Contributes to secondary ischemic damage, contusion enlargement
  - CNS cells synthesize distinct chemokines
    - Chemokine CCL2 is highly expressed early in pericontusional area
    - Chemokine CXCL8 (a.k.a. IL-8) is highly expressed as late inflammatory mediator
  - Inflammatory processes contribute to pericontusional cytotoxic injury via astrocytic activation with capillary vessel compression and leukocyte accumulation → microvascular occlusion
- Blood-brain barrier failure aided by proinflammatory factor activation and matrix metalloproteinases
- Injured cortex upregulates peroxisome proliferator-activated receptor α (PPAR-α) binding activity and protein expression
  - Peaks 24–72 hours post-injury; PPAR-α agonists protect against excessive oxidative stress and inflammation in traumatic brain injury (TBI) and stroke

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Varies with severity; from mild confusion to obtundation
    - ± Cerebral dysfunction, seizures

Demographics

- Age
  - Children:adults = 2:1; highest risk between 15-24 years
- Gender
  - M:F = 3:1
- Epidemiology
  - Annual cerebral contusion incidence is 200 per 100,000 brain trauma-related hospitalizations
  - Contusion is 2nd most common primary traumatic neuronal injury (44%); diffuse axonal injury (DAI) is most common
  - 1.4 million suffer TBI each year in USA; 50,000 die and 80,000 experience long-term disability
  - TBI causes 6.5% of deaths in USA (32 per 100,000)

Natural History & Prognosis

- Varies with extent of primary injury
- Outcome is critically dependent on extent of brain damage that evolves after initial insult
  - Secondary lesions: Hypoxia, hypotension, ischemia, brain edema, and ↑ intracranial pressure
- Highest mortality rate: Elderly population
  - Linear increase of 40-50% in odds of poor outcome for every 10 years of age
- 90% of patients survive injury
  - ~ 25% have significant residual complaints
- Temporal and especially brainstem contusions are independent risk factors for poor outcome
- In severe TBI, 63% have good clinical outcome, 32% have excellent clinical outcome

Treatment

- Central goal: Prevent or rapidly treat secondary injury
- Mitigate secondary effects of ↑ intracranial pressure, perfusion disturbances

DIAGNOSTIC CHECKLIST

Consider

- Repeat exam recommended if initial exam negative but symptoms persist for 24-48 hours

Image Interpretation Pearls

- Inferior anterior frontal lobes most often injured
- Mixed-density contusions can be mistaken for common artifacts caused by orbital roof

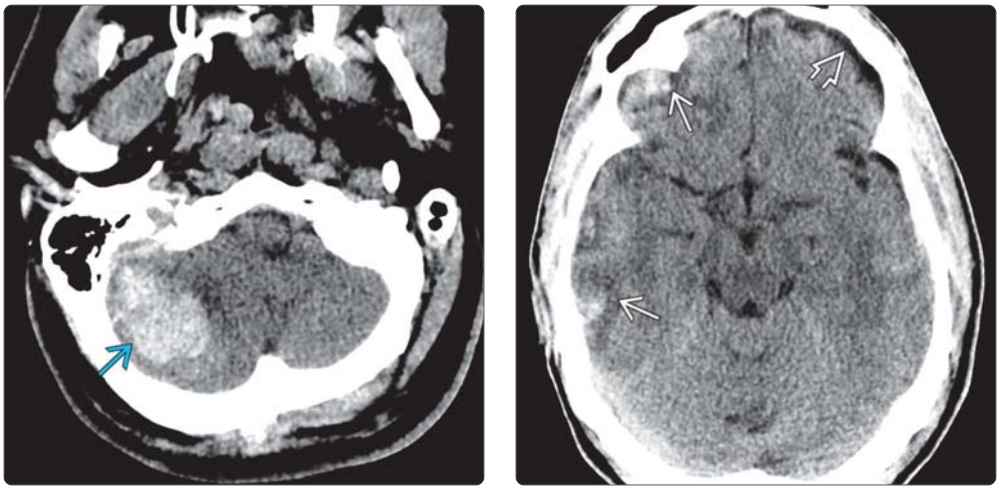
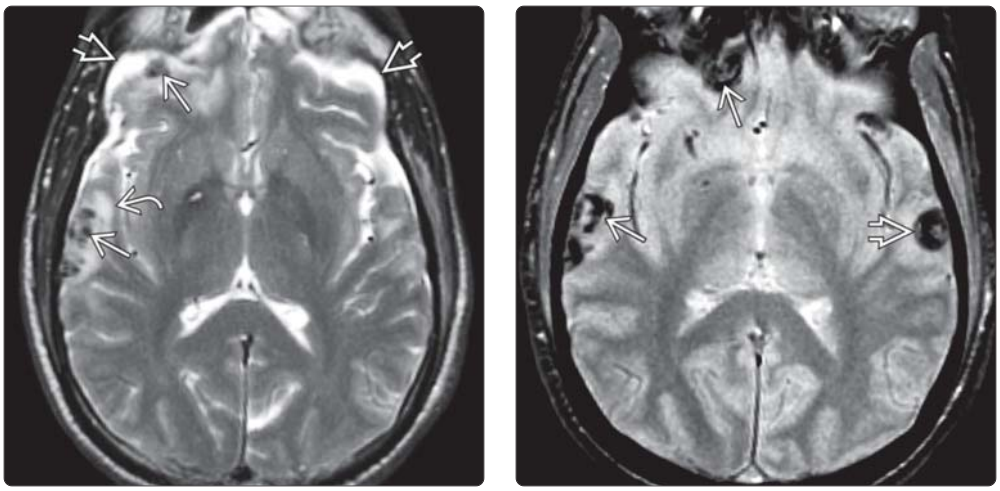
(Left) *Initial axial NECT scan in a 24-year-old man with severe closed head injury and GCS of 8 on admission shows only a focal contusion in the left inferior frontal lobe* ⇨ *and a small amount of subarachnoid hemorrhage (SAH) in the inferior interhemispheric fissure* ⇨. **(Right)** *Repeat NECT scan 6 hours later shows interval appearance of cortical contusions along the surface of the right temporal lobe* ⇨. *Cortical contusions commonly "bloom" (i.e., become more conspicuous) on follow-up imaging studies.*



(Left) *Axial NECT reveals a coup hemorrhagic contusion of the right cerebellar hemisphere. The contusion has coalesced into a focal hematoma* ⇨. **(Right)** *NECT scan 24 hours after head trauma shows frontotemporal contusions* ⇨ *and left inferior frontal subdural hygroma* ⇨.



(Left) *T2WI in the same patient obtained immediately after the CT scan shows contusions* ⇨ *with perilesional edema* ⇨ *and small bilateral subdural hygromas* ⇨. **(Right)** *T2* GRE in the same patient shows "blooming" of right frontotemporal contusions* ⇨. *A left temporal contusion* ⇨ *is apparent that was not evident on the T2WI.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Traumatic axonal stretch injury

IMAGING

- General features
  - Can be hemorrhagic or nonhemorrhagic
    - Microbleeds important imaging marker for diffuse axonal injury (DAI)
    - Intraventricular hemorrhage correlates with DAI
  - Location
    - Subcortical/deep WM, corpus callosum
    - Deeper brain involvement = ↑ severity, poor prognosis
- NECT often normal (50-80%)
- MR
  - FLAIR: Hyperintense foci
  - T2*GRE: Hypointense "blooming" foci (hemorrhage)
  - SWI: Depicts significantly more DAI foci than GRE
  - DWI: May show restricted diffusion

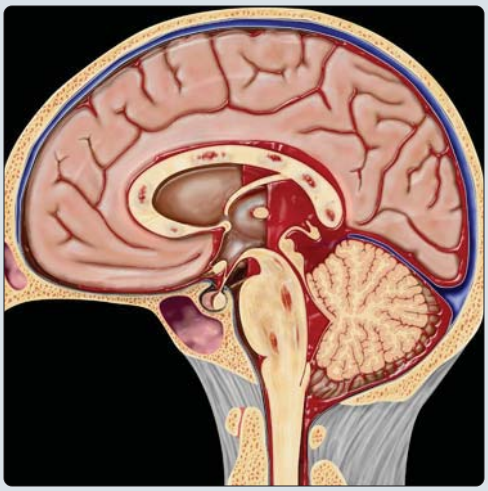
PATHOLOGY

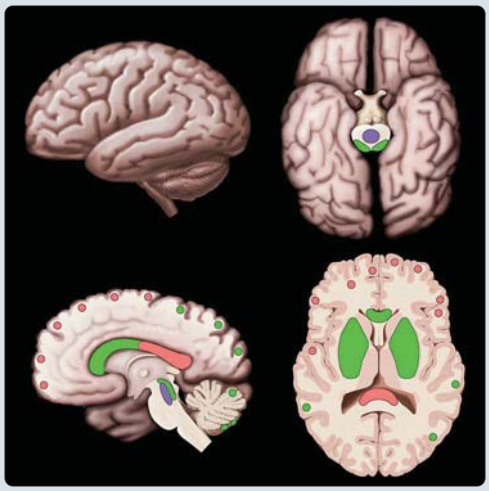
- Closed head injury (CHI)
  - Sudden deceleration, abrupt changes in angular momentum
- Cortex, WM have different densities, rotate at different speeds in CHI
  - Axons stretched (rarely disconnected or "sheared")
  - Occurs at interfaces between tissues of differing density
- 80% of lesions are microscopic, nonhemorrhagic

DIAGNOSTIC CHECKLIST

- Consider DAI if
  - Low GCS, minimal findings on NECT
- Remember
  - The deeper the abnormalities, the more severe the brain injury
  - Remember: Visible lesions are "tip of iceberg"

(Left) *Sagittal graphic illustrates multiple diffuse axonal injury hemorrhagic foci within the corpus callosum and brainstem.* **(Right)** *Graphics depict the most common sites of axonal injury in red. Frequent but relatively less common locations are shown in green. Injury to the midbrain/upper pons (purple) is uncommon but often lethal. In general, the deeper the abnormalities, the more severe the injury.*





(Left) *Axial NECT scan in a 25-year-old man involved in a high-impact MVA shows multiple hemorrhagic foci in the subcortical WM ⇨, external ⇨ and internal ⇨ capsules, basal ganglia ⇨, and thalami ⇨. Blood is also present in the 3rd and lateral ventricles.* **(Right)** *More cephalad NECT scan in the same patient shows punctate peripheral hemorrhages in the subcortical WM ⇨. Traumatic subarachnoid hemorrhage is also present.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Diffuse axonal injury (DAI)

Definitions

- Traumatic axonal stretch injury

IMAGING

General Features

- Best diagnostic clue
  - Microbleeds (important imaging marker for DAI)
  - Punctate lesions at corticomedullary junction, corpus callosum, deep gray matter, brainstem
- Location
  - Gray-white matter (GM-WM) interface (67%), especially frontotemporal lobes
  - Corpus callosum (20%); 3/4 involve splenium, posterior body
  - Brainstem, especially dorsolateral midbrain and upper pons (poor prognosis)
  - Less common
    - Deep GM, internal/external capsule, tegmentum, fornix, corona radiata, cerebellar peduncles
- Size
  - Punctate to 15 mm
- Morphology
  - Punctate, round, ovoid foci; often hemorrhagic
  - Nearly always multiple bilateral lesions

CT Findings

- NECT
  - Often normal (50-80%)
    - > 30% with negative CT have positive MR
  - Nonhemorrhagic: Small, hypodense foci
  - Hemorrhagic: Small, hyperdense foci (20-50%)
    - 10-20% evolve to focal mass lesion
    - Repeat scans often reveal "new" lesions

MR Findings

- T1WI
  - Usually normal
- T2WI
  - Nonhemorrhagic: Hyperintense foci
  - Hemorrhagic: Hypointense foci
- FLAIR
  - Nonhemorrhagic DAI: Hyperintense foci
  - Hemorrhagic DAI: Hypointense foci
- T2* GRE
  - Most sensitive "routine" sequence
    - Microbleeds may be visible only on GRE
    - Hypointense foci (susceptibility from blood products)
  - SWI
    - Depicts significantly more DAI foci than GRE
- DWI
  - May show foci of restricted diffusion
  - Diffusion tensor imaging (DTI)
    - Fractional anisotropy (FA) maps document integrity and direction of white matter tracts
    - Damage to WM may be visible on FA maps
    - DTI "tractograms" allow delineation of WM tract disruption pattern
      - Detect abnormalities when routine imaging, including GRE, is normal
- MRS
  - Normal-appearing brain
    - ↓ N-acetyl aspartate in WM 2° to neuronal injury
    - ↑ choline in GM suggestive of inflammation
  - Abnormal NAA/Cr and Cho/Cr accurately predicts outcomes in
    - Normal-appearing brain (85%)
    - Visibly injured brain (67%)

Nuclear Medicine Findings

- PET
  - Hypometabolism in cingulate gyrus, lingual gyrus, and cuneus
    - Dysfunction of above regions plays key role in neuropsychologic deficits
- SPECT
  - May show focal perfusion abnormalities

Imaging Recommendations

- Best imaging tool
  - MR for detection
- Protocol advice
  - Nonhemorrhagic: FLAIR + DWI ± DTI tractography
  - Hemorrhagic: SWI best (use T2* GRE if not available)

DIFFERENTIAL DIAGNOSIS

Multifocal Nonhemorrhagic Lesions

- Aging: No trauma history; leukoaraiosis and lacunes
- Demyelinating disease: Ovoid, may enhance

Multifocal Hemorrhagic Lesions

- Cerebral amyloid angiopathy: Elderly, normotensive
- Chronic hypertension: Older, hypertensive
- Cavernous malformations: Mixed-age hemorrhages
- Hemorrhagic tumors: Enhancing masses

PATHOLOGY

General Features

- Etiology
  - Overlying cortex moves at different speed in relation to underlying deep brain structures
    - Results in axonal stretching, particularly where brain tissues of different density intersect
  - Trauma-induced forces of inertia
    - Differential acceleration/deceleration and rotational/angular forces
    - Head impact not required
  - Axons stretched, rarely disconnected or "sheared" (only in most severe injury)
  - Effect on nondisruptively injured axons
    - Traumatic depolarization, ion fluxes, spreading depression, and excitatory amino acid release
    - Metabolic alterations with accelerated glycolysis and lactate accumulation
    - Cellular swelling, cytotoxic edema, and apoptosis
  - Corpus callosum injury

https://CafePezeshki.IR

  - Believed due to rotational shear/strain forces
  - Posterior falx prevents tissue displacement, allowing greater tensile stresses locally

Staging, Grading, & Classification

- Adams and Gennarelli staging
  - Stage 1: Frontal and temporal lobe GM/WM interface lesions (mild traumatic brain injury [TBI])
  - Stage 2: Lesions in lobar WM and corpus callosum (moderate TBI)
  - Stage 3: Lesions of dorsolateral midbrain and upper pons (severe TBI)
- Increasing severity of traumatic force correlates with deeper brain involvement

Gross Pathologic & Surgical Features

- Multiple, small, round, ovoid, linear lesions

Microscopic Features

- 80% of lesions are microscopic, nonhemorrhagic
  - Visible lesions are "tip of iceberg"
- Impaired axoplasmic transport, axonal swelling
- Axonal swelling 2° to "axotomy" and "retraction" balls
- Microglial clusters
- Macro-, microbleeds (torn penetrating vessels = diffuse vascular injury)
- Wallerian degeneration

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Transient LOC, retrograde amnesia in mild TBI
  - LOC at moment of impact: Moderate to severe TBI
  - Immediate coma typical
    - Persistent vegetative state in severe cases
    - Slow recovery in many cases
  - Greater impairment than with cerebral contusions, intracerebral hematoma, extraaxial hematomas
- Clinical profile
  - Suggestive in patient with clinical symptoms disproportionate to imaging findings
  - Most common primary traumatic neuronal injury (48%)
    - Usually in setting of high-velocity MVA
    - Admission GCS may not correlate with outcome

Demographics

- Age
  - Any, but most common in 15-24 year olds
  - May occur in utero if pregnant woman subjected to sufficient force
- Gender
  - Men 2x as likely to sustain traumatic brain injury; peaks at 20–24 years
- Epidemiology
  - 2,000,000 traumatic brain injuries annually in USA
  - Leading cause of death/disability in children and young adults
  - ~ 50% of all primary intraaxial traumatic brain lesions in moderate and severe TBI
  - 80-100% autopsy prevalence in fatal injuries
  - Survivors incur annual cost of > $40,000,000,000 (~ 0.5% of GNP)

Natural History & Prognosis

- Spectrum of severity: Mild to severe
  - Mild TBI most common: Clinical abnormalities may persist for months or longer
    - Headache, memory and mild cognitive impairment, personality change (post-concussion syndrome)
- Severe DAI rarely causes death
  - > 90% remain in persistent vegetative state (brainstem spared)
  - Prognosis worsens as number of lesions increases
- 10% of patients who return to normal function do so within 1 year
  - May experience prolonged symptoms
- Brainstem damage (pontomedullary rent) associated with immediate or early death
- Neurocognitive deficits thought to persist in 100% of severe, 67% of moderate, and 10% of mild TBI
  - Figures may significantly underestimate sequelae of mild and moderate TBI

Treatment

- No real treatment; supportive therapy
- Treatment of comorbidities: Herniation, hemorrhage(s), hydrocephalus, seizures

DIAGNOSTIC CHECKLIST

Consider

- Consider DAI if symptoms are disproportionate to imaging findings

Image Interpretation Pearls

- Best detected by FLAIR (nonhemorrhagic) or SWI (hemorrhagic)

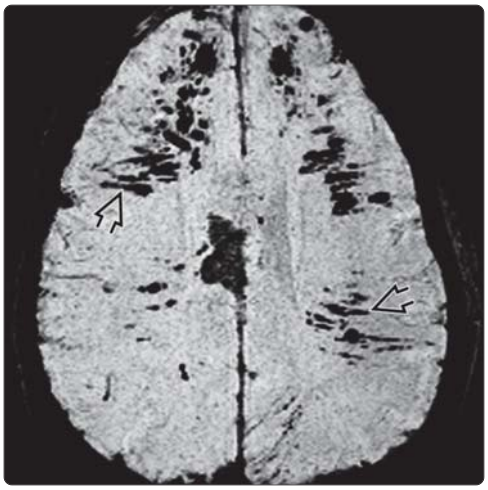
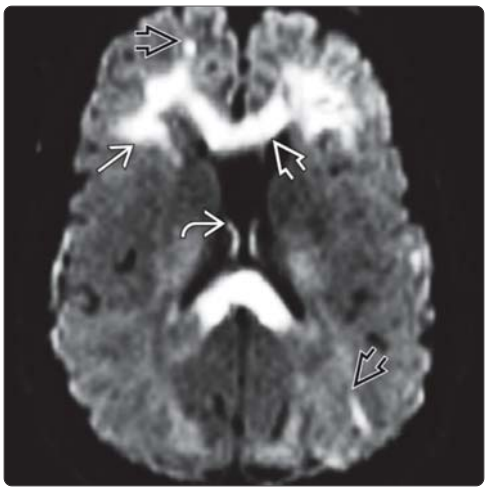
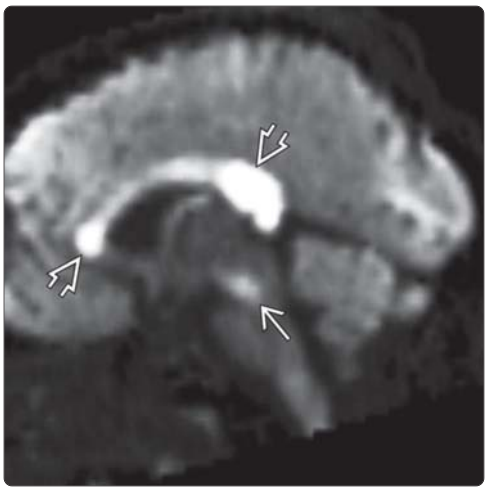
(Left) *Axial NECT scan in a 26-year-old woman involved in a high-impact MVA shows only a small linear hemorrhage in the corpus callosum ➡. GCS was 6 at the accident scene.* **(Right)** *Because of the discrepancy between the lack of findings on NECT and the low GCS, MR was obtained. FLAIR scan shows hyperintensity in the corpus callosum ➡ and subcortical WM ➡.*



(Left) *T2* GRE scan in the same patient shows multiple punctate and linear "blooming" hypointense foci in the subcortical and deep white matter ➡ and corpus callosum ➡.* **(Right)** *Axial SWI with MIP shows innumerable punctate and linear hypointense foci ➡ that follow the course of the axons within the corona radiata.*





(Left) *Axial DWI in the same patient shows intense restriction in the frontal white matter ➡ as well as throughout the corpus callosum ➡, both fornices ➡, and subcortical WM ➡.* **(Right)** *Midline sagittal DWI in the same patient shows the intense restricted diffusion throughout the corpus callosum ➡. A smaller focus of restricted diffusion is present in the midbrain ➡.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Subcortical injury (SCI): Deep DAI lesions of brainstem, basal ganglia, thalamus, and regions around 3rd ventricle
- IVH: Hemorrhage within ventricular system
- CH: Hemorrhage localized to choroidal plexus

IMAGING

- SCI: FLAIR most sensitive → hyperintense foci
- IVH: Hyperdense intraventricular blood; fluid-heme level common
- CH: Localized hyperdense choroidal hemorrhage

TOP DIFFERENTIAL DIAGNOSES

- SCI: Cavernous malformation, lacunar infarcts, small vessel ischemia
- IVH: None
- CH: Normal calcification may mask small hemorrhages

PATHOLOGY

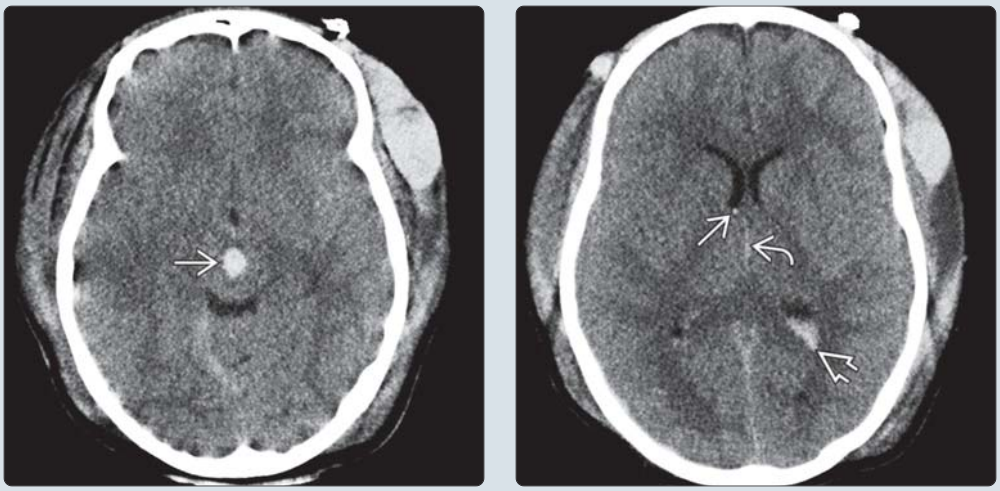
- SCI: Most commonly induced by shear-strain forces that disrupt penetrating &/or choroidal vessels
- IVH: Disruption of subependymal veins
- CH: Traumatic shear forces damage to choroid tissue

CLINICAL ISSUES

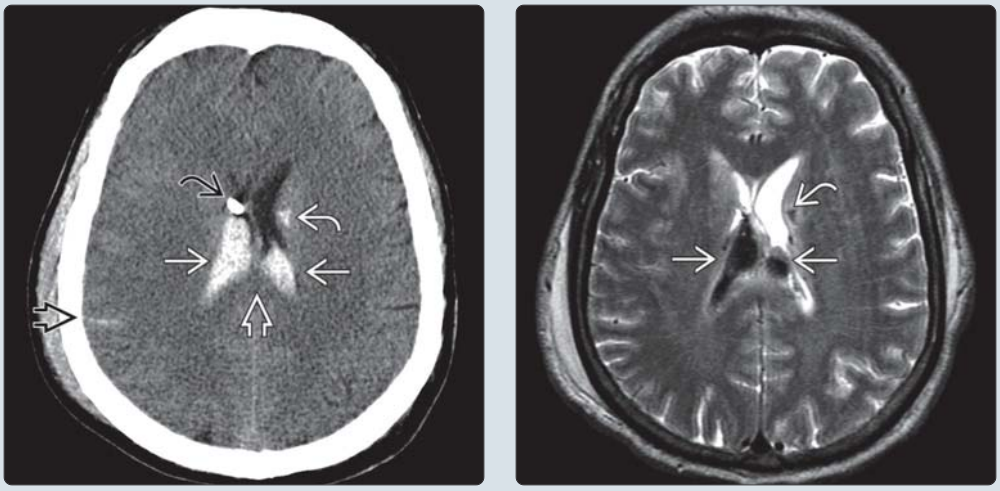
- SCI: Profound neurologic deficits
- IVH: Obtundation, seizures
- CH: Can lead to IVH

DIAGNOSTIC CHECKLIST

- Delayed development of deep lesions common
  - Initial scan may show only diffuse brain swelling
  - Focal lesions often appear 24-48 hours later
- Remember: The deeper the lesion, the more severe the injury



(Left) *Initial axial NECT in a 17-year-old girl involved in a high-speed MVA demonstrated only diffuse brain swelling (not shown). Because of persisting low GCS, repeat scan was obtained 24 hours later, showing a focal midbrain hemorrhage.* **(Right)** *More cephalad scan shows a punctate hemorrhage in the right fornix and in the 3rd and lateral ventricles. The patient expired 1 week later. The presence of deep lesions and intraventricular hemorrhage (IVH) indicate severe subcortical injury.*



(Left) *Axial NECT in a patient with subcortical injury shows a hyperdense choroidal hemorrhage within choroid plexus substance of both ventricles. Note the subarachnoid hemorrhage, corpus callosum DAI, left caudate hemorrhagic DAI, and a ventriculostomy tube tip.* **(Right)** *Axial T2WI MR in the same patient shows hypointense hemorrhages distending the choroid plexi. A left caudate hemorrhagic DAI is again seen.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Subcortical injury (SCI)

Definitions

- Traumatic lesions of brainstem (BS), basal ganglia (BG), thalamus, and ventricles, composed of
  - Deep diffuse axonal injury (DAI)-type SCI lesions
  - Intraventricular hemorrhage (IVH)
  - Choroid hemorrhage (CH)

IMAGING

General Features

- Best diagnostic clue
  - SCI: Punctate hemorrhages
  - IVH: Hyperdense intraventricular CSF on NECT, fluid-heme level common
  - CH: Hyperdense, enlarged choroid on NECT
- Location
  - SCI: BS, BG, thalamus, and regions around 3rd ventricle
    - Most within thalamus and putamen
  - IVH: Intraventricular spaces
  - CH: Localized within choroid tissue
- Size
  - SCI: Limited to size of structure involved
  - IVH: Can fill/expand ventricles
  - CH: Limited to size of choroid involved
- Morphology
  - SCI: Petechial, linear, globular
  - IVH: Can cast ventricle
  - CH: Shape of choroid involved

CT Findings

- NECT
  - SCI: Often normal; petechial hyperdense foci
    - Deep nuclei, dorsolateral BS, periaqueductal
    - Rarely overt hemorrhage
  - IVH
    - Hyperdense intraventricular blood
    - May fill, even expand, ventricle
    - Fluid-heme level common
  - CH: Localized hyperdense choroidal hemorrhage

MR Findings

- T1WI
  - SCI: Acutely isointense
  - IVH: Fluid-heme level common
- T2WI
  - SCI: Acutely hyperintense
  - IVH: Fluid-heme
- FLAIR
  - SCI: Most sensitive sequence → hyperintense foci
  - IVH: Detection comparable to CT in acute stage
- T2* GRE
  - SCI: Susceptibility of petechial hemorrhage
- DWI
  - SCI: Foci of restricted diffusion
    - ↓ apparent diffusion coefficient (ADC)
    - Damage to white matter reduces anisotropy: Visible on FA maps
    - DTI "tractograms" allow delineation of pattern of white matter tract disruption
    - Detects abnormalities when routine imaging, including GRE, are normal
- SWI
  - Depicts significantly more DAI foci than GRE

Imaging Recommendations

- Best imaging tool
  - SCI: MR > > > CT
    - Protocol analogous to DAI
  - ICH/CH: NECT > MR
    - Protocol analogous to subarachnoid hemorrhage (SAH)
- Protocol advice
  - SCI: FLAIR and GRE
  - ICH/CH
    - CT = NECT
    - MR = FLAIR and GRE

DIFFERENTIAL DIAGNOSIS

Subcortical Injury

- Cavernous malformation: Symptoms without trauma
- Lacunar infarcts: Located in central tegmentum of pons/BS
- Small vessel ischemia

Intraventricular Hemorrhage

- ± choroid plexus hemorrhage

Choroid Hemorrhage

- Normal calcification may mask small hemorrhages

PATHOLOGY

General Features

- Etiology
  - SCI: Most commonly induced by shear-strain forces that disrupt penetrating &/or choroidal vessels
    - Usually very small, typically nonhemorrhagic
  - SCI: Less commonly
    - Dorsolateral BS impacts tentorial incisura with violent brain motion
    - Anterorostral BS damaged with sudden craniocaudal brain displacement
  - IVH
    - Disruption of subependymal veins (most common)
    - Bleeding from choroid plexus
    - Shearing injuries
    - Basal ganglia/intracerebral hemorrhage with rupture into ventricles
    - Isolated IVH in absence of parenchymal hematoma is unusual
  - CH: Traumatic shear forces damage to choroid tissue
- Associated abnormalities
  - SCI: All stages of DAI present (without exception), cerebral contusion, intracranial hemorrhages
  - IVH: DAI, deep GM/BS/intracerebral hemorrhage, SAH, cerebral contusion, hydrocephalus
  - CH: DAI, SAH, cerebral contusion

https://CafePezeshki.IR

Staging, Grading, & Classification

- SCI: BS injury (BSI)
  - Primary injury: Direct result of trauma
    - DAI; most common primary BSI
    - Direct laceration/contusion; rare
    - Multiple primary petechial hemorrhages; not associated with more superficial DAI
    - Pontomedullary rent or separation; may occur without widespread brain injury
  - Secondary injury: Indirect result of trauma, most common cause of BSI; usually herniation
- SCI: When BSI → BS hemorrhage
  - Group 1: Midline rostral anterior BS, posterior to interpeduncular cistern (69%)
    - Associated with anterior impact; 71% survival
  - Group 2: Misc foci of acute BS hemorrhage (18%)
    - Associated with transtentorial herniation and BS compression; 88% survival
  - Group 3: Any BS hemorrhage
    - Associated with transtentorial herniation and BS compression; 100% mortality

Gross Pathologic & Surgical Features

- SCI
  - Usually nonhemorrhagic, yet more often hemorrhagic than other primary intraaxial injuries
  - 2° to rich network of perforating vessels in basal ganglia and thalamus
- IVH
  - Gross blood collected within ventricular system
  - Blood-CSF level common
    - Layering, rather than clot formation, likely relates to intrinsic antithrombotic CSF properties due to high concentrations of fibrinolytic activators
  - May cast/expand involved ventricle
- CH: Hemorrhagic choroid tissue

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - SCI: Profound neurologic deficits
    - Low initial Glasgow coma scale scores; coma
  - IVH: Obtundation, seizures

Demographics

- Age
  - Any, but most common in 15–24 year olds
- Gender
  - Men 2x as likely to sustain traumatic brain injury (TBI); peaks at 20–24 years
- Epidemiology
  - SCI: In 5-10% TBI, 3rd most common primary traumatic neuronal injury
  - IVH: Present in 60% of patients with corpus callosal DAI, 12% in patients without

Natural History & Prognosis

- SCI: Severely injured patients
  - Poor prognosis, often die soon after trauma
  - Regain consciousness very slowly and retain permanent neurological impairment/disability
- SCI: May proceed to BS hemorrhage
  - Associated with high mortality
- IVH
  - Gradually clears as resorbed, although patients > 20 cc of blood do poorly
  - Hydrocephalus rare manifestation
    - Early: CSF outlet obstruction
      - Obstructive, noncommunicating
      - Asymmetric ventricular dilatation
    - Late: Arachnoid dysfunction of CSF resorption
      - Obstructive, communicating hydrocephalus
      - Symmetric ventricular dilatation
  - Hemorrhagic dilation of 4th ventricle: Ominous predictor with 100% reported mortality
  - At baseline, predicts 2x increase in mortality
    - Does not predict functional outcome
- CH: Can lead to IVH

Treatment

- SCI
  - Supportive therapy
  - Treatment considerations of indirect/associated abnormalities: Herniation, hematoma, hydrocephalus, seizures, etc.
- IVH
  - Ventriculostomy
  - Excellent results following r-TPA thrombolytic therapy
    - Effective and safe, despite preexisting multiple hemorrhagic intracranial injuries
  - Repeat NECT to evaluate for hydrocephalus, treatment complications

DIAGNOSTIC CHECKLIST

Consider

- PSCI results from severe trauma: Often highly complex cases with a multitude of abnormal findings
  - When you think you have finished reviewing the case, look at everything 1 more time

Image Interpretation Pearls

- Delayed development of visible lesions common

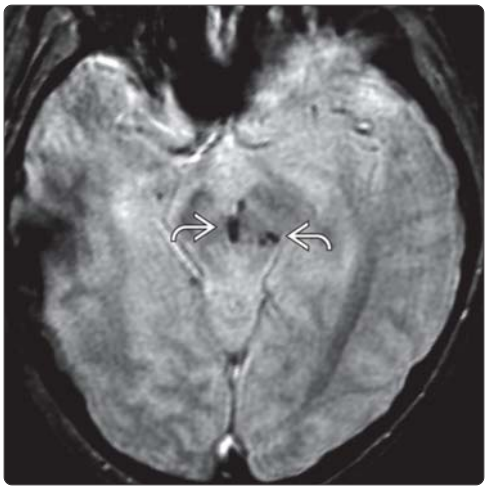
(Left) *Axial FLAIR MR demonstrates subcortical injury diffuse axonal injury (DAI) lesions in the midbrain. There are also subdural hematomas. Not shown are DAI of bilateral cerebral peduncles, as well as the left caudate, internal capsule, and anterior lentiform nuclei. Also not seen are bifrontal and bitemporal hemorrhagic cortical contusions.* **(Right)** *Axial DWI MR in the same patient shows diffusion abnormality of the midbrain Subcortical injury (SCI) DAI lesions. Note the subdural hematomas.*



(Left) *Axial T2* GRE MR shows susceptibility of SCI DAI hemorrhage involving the midbrain and left cerebral peduncle. The patient had corresponding hemiplegia.* **(Right)** *Axial FLAIR MR in the same patient reveals more SCI DAI lesions involving the right lentiform nuclei, left thalamus, and corpus callosum.*

(Left) *Axial NECT shows a hyperdense hemorrhagic subcortical diffuse axonal injury lesion of the right middle cerebellar peduncle/cerebellar hemisphere.* **(Right)** *Axial FLAIR MR in this case also reveals hyperintense subcortical injury of the tectum (on this slice, inferior colliculi) and adjacent vermis. There is also a right temporal lobe hemorrhagic contusion, as well as subarachnoid hemorrhage within many of the sulci and the interpeduncular fossa.*

https://CafePezeshki.IR

Pneumocephalus

KEY FACTS

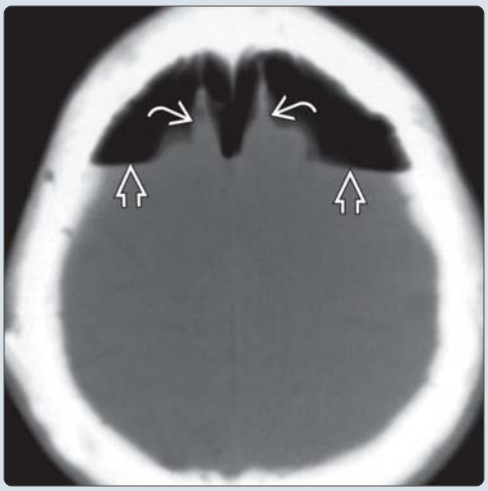
TERMINOLOGY
- Presence of air or gas within skull

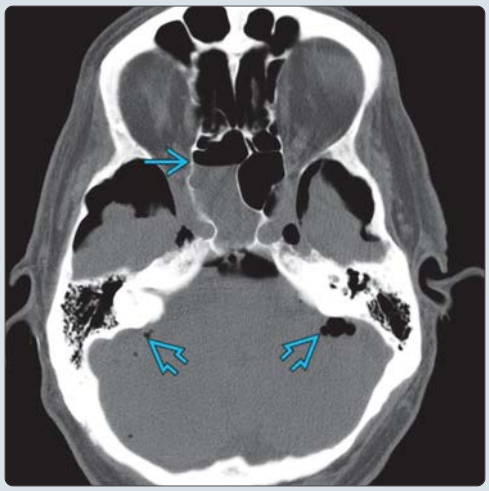
IMAGING
- Can occur in any compartment
  - Epidural
  - Subdural
  - Subarachnoid
  - Parenchyma (pneumatocele), ventricles, intravascular
- CT: Very low density (-1,000 HU)
- MR: Foci of absent signal on all sequences, "blooms" on T2*
- Best imaging tool: NECT

PATHOLOGY
- Mechanism: Dural tear allows abnormal communication and air introduction
- Most common etiology: Trauma (74%)
  - Present in 3% of all skull fractures, 8% of paranasal sinus fractures
- Other common causes: Postsurgical
- Rare: Infection, tumor

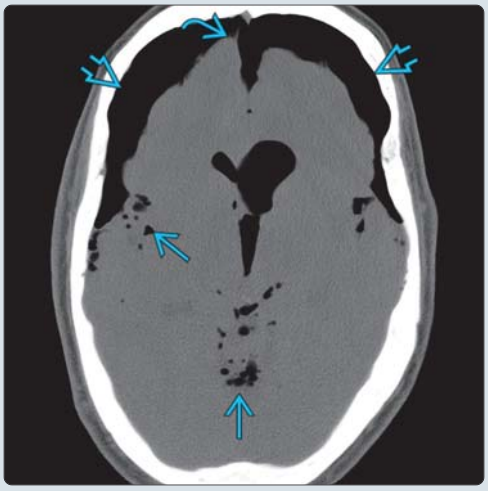
CLINICAL ISSUES
- Most common symptom: Headache
- Mortality (15%)
- Most common complication: CSF leak (50%)
- Infection (25%): Meningitis, epidural abscess, cerebritis, brain abscess
- Most often resolves on its own after removal of primary etiology

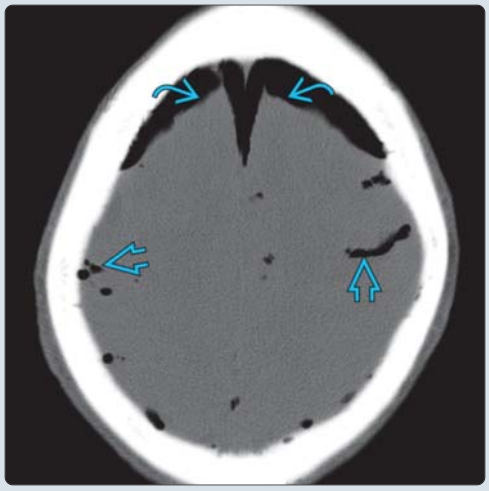
DIAGNOSTIC CHECKLIST
- Pneumocephalus usually not problem: Find out what's causing it
- Intravenous air usually of no clinical significance





(Left) *Axial NECT shows subdural air with air-fluid levels. "Pointing" of the frontal lobes, with compression and separation of the frontal lobes by subdural air, is sometimes called the "Mount Fuji" sign. This finding indicates tension pneumocephalus and can be a surgical emergency.* **(Right)** *Axial NECT in a 71-year-old man with skull base fractures (not shown) demonstrates an air-fluid level in the sphenoid sinus, multiple "spots and dots" of subarachnoid air, and bilateral middle fossa subdural air.*





(Left) *More cephalad scan in the same patient shows large, bifrontal, subdural air collections with a right "Mount Fuji" sign. Air is also present in the 3rd ventricle and frontal horns of the lateral ventricles. "Spots and dots" of air are in the subarachnoid spaces.* **(Right)** *Axial NECT through the vertex in the same patient shows the "pointed" frontal lobes and widened interhemispheric fissure. The curvilinear foci and dots of air are in the convexity sulci.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Pneumatocele (when focal)

Definitions

- Presence of air or gas within skull (always abnormal)

IMAGING

General Features

- Best diagnostic clue
  - Air anywhere within cranium
- Location
  - Can occur in any compartment
    - Extracerebral: Epidural, subdural, subarachnoid
    - Intracerebral: Brain parenchyma, cerebral ventricles
    - Intravascular: Arteries, veins, venous sinuses
- Size
  - Variable: Tiny to huge collection(s)
- Morphology
  - Focal to diffuse

CT Findings

- NECT
  - Very low density (-1,000 HU)
  - Epidural pneumocephalus
    - Remains localized
    - Does not move with changes of head position
  - Subdural pneumocephalus
    - Confluent, often forms air-fluid level(s)
    - Moves with changes of head position
    - May see cortical veins stretched within subdural air
  - Tension pneumocephalus
    - "Mount Fuji" sign
      - Subdural air separates/compresses frontal lobes, creates widened interhemispheric space between frontal lobe tips, mimicking silhouette of Mount Fuji
    - ± mass effect (frontal horns of lateral ventricles displaced posteriorly)
  - Subarachnoid pneumocephalus
    - Multifocal, nonconfluent
    - Droplet-shaped, often within sulci
  - Intraventricular pneumocephalus
    - Rarely in isolation
  - Intravascular air most often venous; arterial rare, usually fatal

MR Findings

- T2WI
  - Sinusitis, mastoiditis
- T1WI C+
  - Any causative enhancing mass
    - Neoplasm eroding through skull typically causes dural thickening; may cause pneumocephalus if air-containing structure is breached
- MR: Foci of absent signal on all sequences, "blooms" on T2*
  - Any compartment
  - Iatrogenic
    - Ventriculostomy procedure: Also increased FLAIR signal along tract
    - ICP monitor placement
    - Invasive subdural electrodes

Imaging Recommendations

- Best imaging tool
  - NECT
- Protocol advice
  - Evaluate variable windows at PACS workstation

DIFFERENTIAL DIAGNOSIS

Traumatic

- Associated with other findings of trauma
- May also be found within any compartment

Iatrogenic

- Most often after surgical procedure
- Expected pneumocephalus seen in affected compartments and nondependent subarachnoid space
- May see intravascular, cavernous sinus following vascular access procedure; asymptomatic
- Susceptibility from hardware

Infectious

- Rare sequela of gas-producing infection

PATHOLOGY

General Features

- Etiology
  - Mechanism: Dural tear allows abnormal communication and air introduction via 2 possible events
    - Ball-valve mechanism from straining, coughing, sneezing, Valsalva
    - Vacuum phenomenon caused by CSF loss
  - Most common etiology = trauma
    - Blunt trauma produces skull &/or paranasal sinus fractures
    - Air cell involvement: Frontal > ethmoid > sphenoid > mastoid
    - Penetrating: GSW, knife, penetrable foreign bodies
  - Surgery (2nd most common)
    - Prevalence varies; almost universal with supratentorial surgery
    - Hypophysectomy
    - Paranasal sinus surgery
      - Functional endoscopic sinus surgery (FESS) → cribriform plate
  - Neoplasm invading into/from sinus
    - Osteoma: Frontal > ethmoid
    - Pituitary adenoma
    - Mucocele: Most often frontal
    - Epidermoid
    - Meningioma
  - Infection from gas-forming organism
    - Extension from mastoiditis, sinusitis
    - Aerobic, anaerobic, or mixed infectious organisms
  - Iatrogenic
    - Shunt placement/manipulation
    - ICP monitor placement

https://CafePezeshki.IR

  - Invasive subdural electrodes for localization of seizure foci and functional mapping
  - Tension pneumocephalus
    - Most commonly after neurosurgical evacuation of subdural hematoma
    - Lumbar drain placement, skull base surgery, paranasal sinus and posterior fossa surgery in sitting position
    - Use of nitrous oxide during anesthesia
  - Rarely, open neural tube defect
- Associated abnormalities
  - CSF leak secondary to
    - Fracture: Cribriform plate, sphenoid sinus, mastoid air cells

Gross Pathologic & Surgical Features

- Air within skull
- Concomitant dural tear
- Direct communication outside ↔ inside established
  - Air is transmitted, forming pneumocephalus

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache
  - Acute: Most patients present within 4-5 days of inciting event
  - Chronic: Delay of several years reported
  - Tension: Headaches, ↓ level of consciousness, lateralizing deficits

Demographics

- Age
  - None; specific causes may have age prevalence
- Gender
  - None; specific causes may have gender prevalence
- Ethnicity
  - None; specific causes may have ethnic prevalence
- Epidemiology
  - Pneumocephalus present in 3% of all skull fractures, 8% of paranasal sinus fractures
  - 100% of patients undergoing supratentorial surgery have pneumocephalus in first 48 hours
  - Tension pneumocephalus: 2.5-16% prevalence following chronic subdural hematoma evacuation

Natural History & Prognosis

- Mortality (15%)
- Intravascular pneumocephalus
  - If trauma induced, associated with mortal injury
  - If no history of trauma or intracranial/intrathecal procedure
    - Usually venous, 2° to intravenous catheterization
    - Often seen within cavernous sinus
    - Patient will be asymptomatic
    - **Frequent** cause of consternation for on-call radiologists/residents
    - **Of no clinical concern**
- Tension pneumocephalus
  - Intracranial pressure rises as volume of air increases
  - Requires treatment
- Complications
  - Most common: CSF leak (50%)
  - Infection (25%): Meningitis, epidural abscess, cerebritis, brain abscess

Treatment

- Becomes an issue for air transport of trauma patients
  - Under normal flying conditions with ↓ cabin pressure, intracranial air volume will ↑ by ~ 30% at normal maximum cabin altitude of 8,000 feet
  - ↑ in ICP dependent upon both initial air volume and rate of change in cabin altitude
  - Intracranial air volume of 30 cc = estimated worst case ↑ of ICP from sea level to max altitude = 10 mm Hg → 31.8 mm Hg
  - Sea-level pressure should be maintained during air transport of patients with suspected intracranial air
- Pneumocephalus most often resolves on its own after removal of etiology
- Administration of normobaric supplemental O_2 significantly ↑ rate at which pneumocephalus resolves after craniotomy
  - At room air (21% FiO_2)
    - Resolves 31% per 24 hours
  - With nonrebreather mask delivering 68% FiO_2
    - Resolves 65% per 24 hours
- Tension pneumocephalus
  - Burr holes, craniotomy, needle aspirations, ventriculostomy, administration of 100% oxygen, and closure of dural defects
  - Mixed success rates

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Pneumocephalus usually not problem: Find out what's causing it
- Intravascular/cavernous sinus air without trauma or intracranial/intrathecal procedure generally of no clinical significance

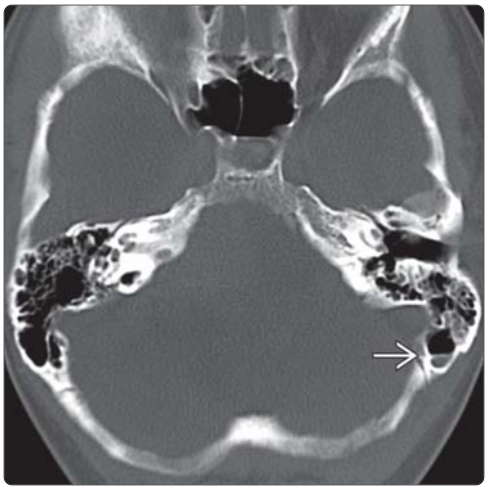
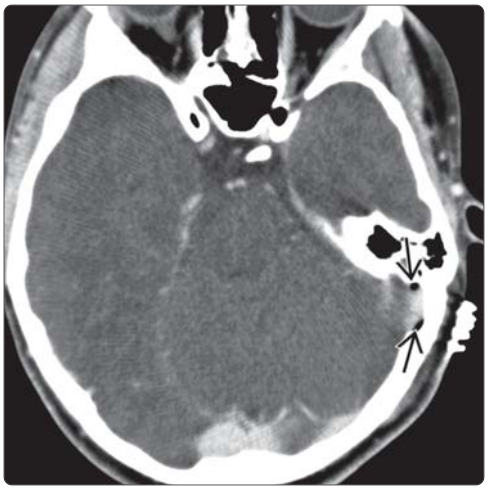
(Left) *Axial bone CT demonstrates a fracture of the right frontal bone* ⇨ *with an associated underlying focal air collection* ⇨*, as well as intraventricular air in the left frontal horn* ⇨*. Pneumocephalus may be described as "pneumatocele" when focal.* **(Right)** *Axial bone CT in a child with multiple fractures* ⇨ *shows air in the arteries that comprise the circle of Willis* ⇨*. Intraarterial air generally portends a grave prognosis.*





(Left) *Bone reconstruction of head CT in a patient with head trauma and skull base fractures shows a mastoid air-fluid level in the left temporal bone* ⇨*.* **(Right)** *Source image from a CTA in the same patient shows epidural air* ⇨ *around the left transverse sinus. The dural venous sinuses are intact without evidence for associated epidural hematoma.*

(Left) *Axial NECT following cardiac ablation and severe air embolism shows multiple foci of intraparenchymal gas* ⇨*, probably within cortical arteries and penetrating branches.* **(Right)** *Axial NECT in the same patient obtained 12 hours later shows that most of the air has resorbed and diffuse cerebral edema has ensued.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Intentionally inflicted injury
- Abusive head trauma (AHT), inflicted head injury, nonaccidental head injury

IMAGING

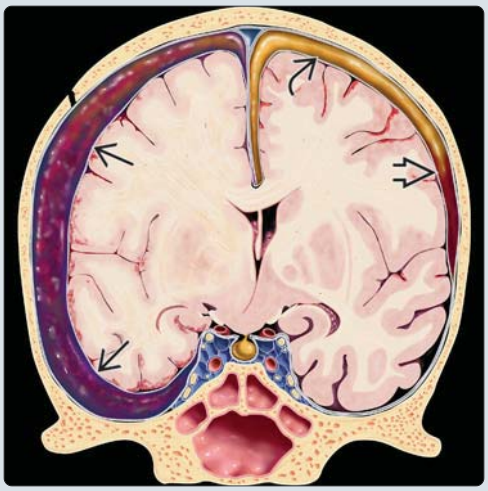
- Plays key role in early diagnosis
  - Disparate brain injuries relative to proffered history
- Skeletal survey, NECT as initial primary imaging tools
  - Detection/characterization of intracranial hemorrhage
  - Detection/characterization of fractures
- MR
  - Delayed (24-72 hours) for detection of parenchymal injuries, demonstration of unexplained, different-aged subdural hemorrhages (SDHs)
    - Use T1WI, T2WI, T2*/SWI (best sequence varies with SDH age)
    - DWI key for identification of parenchymal insult
    - Use T1W1 C+ to detect subdural membranes of cSDH
    - Sagittal/coronal best for small peritentorial SDHs

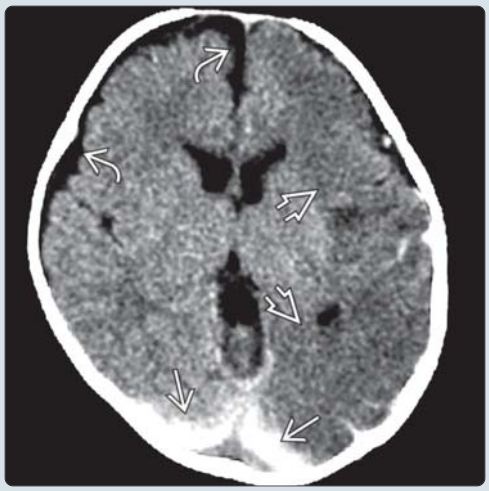
PATHOLOGY

- Direct impact injury
  - Skull fractures
  - Underlying brain injury
- Violent "to and fro" shaking
  - Diffusely distributed subdural hematomas
  - Cortical contusions, axonal injury, parenchymal lacerations
- Ischemic injury
  - Global hypoxic brain injury
  - Territorial infarcts
  - Excitotoxic edema

CLINICAL ISSUES

- 17-25:100,000 annual incidence
  - Most common cause of traumatic death in infancy





(Left) *Coronal graphic of AHT shows an acute SDH over the right hemisphere and a smaller left subdural hemorrhage (SDH) with "hematocrit" effect producing layering of blood products. Other injuries (traumatic subarachnoid hemorrhage [SAH], cortical contusions) are illustrated and are common in AHT.* **(Right)** *Axial NECT in suspected AHT shows varied attenuation SDHs with low attenuation right, bilateral high attenuation SDHs. Note the diffuse edema involving almost the entire left hemisphere.*

(Left) *Axial T1WI MR in an infant with AHT shows subacute right SDH extending into the interhemispheric fissure and a more chronic-appearing left subdural collection (cSDH vs. hygroma).* **(Right)** *Axial T2WI MR in the same patient shows hypointensity in the dependent portion of the right SDH with "hematocrit effect", suggesting a more acute component to the hematoma (hematohygroma). Hematohygromas may also arise from a single traumatic event.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Abusive head trauma (AHT)
  - Reflects various potential injury mechanisms

Synonyms

- Inflicted head injury; nonaccidental head injury

Definitions

- Intentionally inflicted brain injury

IMAGING

General Features

- Best diagnostic clue
  - Multiple brain injuries disproportionately severe relative to proffered history
    - Spectrum of findings, including scalp injuries, skull fractures, intracranial hemorrhages, cerebral contusions, shear injuries, ischemic brain injury, retinal hemorrhages

CT Findings

- NECT
  - Primary imaging tool in initial evaluation of suspected AHT
  - Sensitive in detection and characterization of fractures
    - Helical technique with multiplanar reformatting and 3D surface modeling is essential in order to detect fractures in axial plane
  - Highly sensitive in detection and characterization of intracranial hemorrhage
    - Subdural hemorrhage (SDH): > 50% of cases
      - Dominant feature of AHT
      - Over cerebral convexities, in interhemispheric fissure, overlying tentorium
    - Subarachnoid hemorrhage (SAH): ≤ 50% of cases
      - Commonly associated with SDH
      - More common in sulci over convexities; differs from SAH associated with aneurysms, which is more common in basal cisterns
    - Intraventricular hemorrhage (IVH)
    - Epidural hemorrhage (EDH) uncommon in child abuse
    - Shear injuries
      - Typical locations include corticomedullary junction, brainstem, corpus callosum
      - May not be hemorrhagic
    - Cortical contusions
      - Surface of frontal and temporal lobes
      - Hyperattenuating; develop "halo" of edema over 1st few days
      - Focal atrophy chronically
    - Parenchymal brain laceration (PBL)
      - Subcortical cleft ± hematocrit level
      - Parietal, temporal, convexity
      - Strongly suggestive of AHT
  - Ischemic injury
    - Varies from global hypoxic brain injury to individual vascular territory infarction
    - Actual etiology uncertain
    - Reversal sign: White matter appears more dense than gray matter
      - Indicates severe (irreversible) injury
  - Subdural hygromas can develop 12-36 hours after injury
    - CSF-attenuation subdural collections of CSF that leak from subarachnoid space
    - Most resolve without direct treatment
    - Should be considered imaging proxy for AHT in children < 2y
- CTA
  - Helpful in detection of arterial injuries complicating abuse
    - Vascular injuries may manifest in delayed fashion

MR Findings

- T1WI
  - Variable signal of blood products
    - SDH most often bright
    - Sagittal/coronal plane best for detecting small SDH along tentorium, over convexities
  - May see hyperintensity of cortical ribbon → petechial hemorrhage vs. laminar necrosis
- T2WI
  - Ischemic insult (hypoxic ischemic injury, HII) in neonates and infants manifest as loss of cortical ribbon
    - SDH dark → bright
- PD/intermediate
  - Very sensitive in detection of small SDHs, PBLs
  - Often identifies periventricular injury better than FLAIR or T2WI in neonates and infants
- DWI
  - Key sequence for identification of acute brain insult, including PBLs and DAI
- T1WI C+
  - May demonstrate enhancing membranes
- MRA
  - May identify/characterize arterial injury
- MRS
  - ↓ NAA, ↑ Cho/Cr ratio, ↓ Cr, ↑ lactate/lipid peaks are poor prognostic indicators
    - May be normal in first 24 hours
- SWI/T2*
  - Highly sensitive for presence of blood products (± for chronic SDH)
    - May help detect sites of prior injury, including PBLs
  - Beware: Chronic blood products in subdural compartments may show NO blooming or dephasing
- May be difficult to obtain MR in acute setting
  - More difficult to monitor unstable patient
  - Requires sedation/anesthesia
- Delayed (24-72 hours) MR may be most sensitive for detection of parenchymal injuries
- Post-traumatic hygroma follows CSF signal intensity

Imaging Recommendations

- Best imaging tool
  - NECT with multiplanar reformats for acute assessment
    - Avoid strong dating language
    - Use serial imaging (CT/MR)
- Protocol advice

https://CafePezeshki.IR

- Multiplanar reformats to assess for fractures, SDH, EDH, parenchymal injuries
- MR at 24-72 hours
  - Sagittal/coronal T1WI, T2WI, T2*/SWI for subtle peritentorial SDH (depends on age of SDH)
  - T2* (SWI) for hemorrhagic injuries
    - Note: cSDH may lack susceptibility ("blooming")
  - DWI to assess parenchymal injuries (DAI, PBL, HII)
  - Use IV contrast to characteristic cSDH
  - MRA/MRV to assess vascular injury
- Consider adding cervical spine MR, especially in children < 1-2y

DIFFERENTIAL DIAGNOSIS

Accidental Trauma

- Appropriate history for degree of injury
  - Brain parenchymal injury less common than with AHT

Mitochondrial Encephalopathies

- Glutaric acidurias (types 1 and 2), Menkes syndrome

Overshunting

- "Passive" subdurals secondary to collapse of ventricular system

Meningitis

- Subdural empyemas or sympathetic effusions

Coagulopathies

- Intracranial hemorrhage from normal activities

Neuroblastoma

- May present with "raccoon eyes," mimicking skull base fracture
- Epidural metastatic disease can mimic SDH

Leukemia

- Highly cellular hyperdense leptomeningeal metastases can mimic hemorrhage

PATHOLOGY

General Features

- Etiology
  - Varied mechanisms
    - Direct impact injury: Direct blow to cranium or impact of skull on object
      - Skull fractures and injury to immediately underlying brain
      - Note: Lack of impact is common in AHT
  - Shaking injury: Violent "to and fro" shaking of head
    - Diffusely distributed subdural hematomas, SAH
  - Intracranial venous thrombosis not associated with SDH in neonates, infants, children

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Discordance between stated history and degree of injury
    - "Killer couch": Injuries commonly attributed to infant rolling off couch onto floor
  - Retinal hemorrhage in up to 96%
- Other signs/symptoms
  - Presentation with "apnea" (33-45%), unexplained seizures, "unable to rouse"

Demographics

- Age
  - Median: 2.2-4.6 months
- Epidemiology
  - 17-25:100,000 annual incidence
  - Most common cause of traumatic death in infancy: 1,200 deaths per year in USA
  - Risk factors
    - < 1 year, prematurity, twin, male, physical handicap, stepchild
    - Young parents, ↓ socioeconomic status
      - 1/3 of perpetrators under influence of alcohol or drugs

Natural History & Prognosis

- Mortality: 15-38% (60% if coma at presentation)
- Neurologic deficits include acquired microcephaly (93%), early post-traumatic seizures (79%), late post-traumatic epilepsy (> 20%), poor visual outcome (20-65%)

Treatment

- Notification to local Child Protection Agency mandated in USA/Canada/Australia/some European countries
  - Multidisciplinary child abuse team intervention

DIAGNOSTIC CHECKLIST

Consider

- Inborn error of metabolism or bleeding dyscrasia may simulate nonaccidental injury
  - Appropriately investigating these possibilities both improves patient care and clarifies criminal investigation

Image Interpretation Pearls

- Avoid imprecise/strong dating language on initial NECT
- Look for combination of hemispheric brain edema and bilateral or interhemispheric SDH
- Serial imaging helps establish SCH age (CT/MR)
- In children <2y, subdural hygroma is a proxy for trauma
- Presence of PBLs specific for AHT

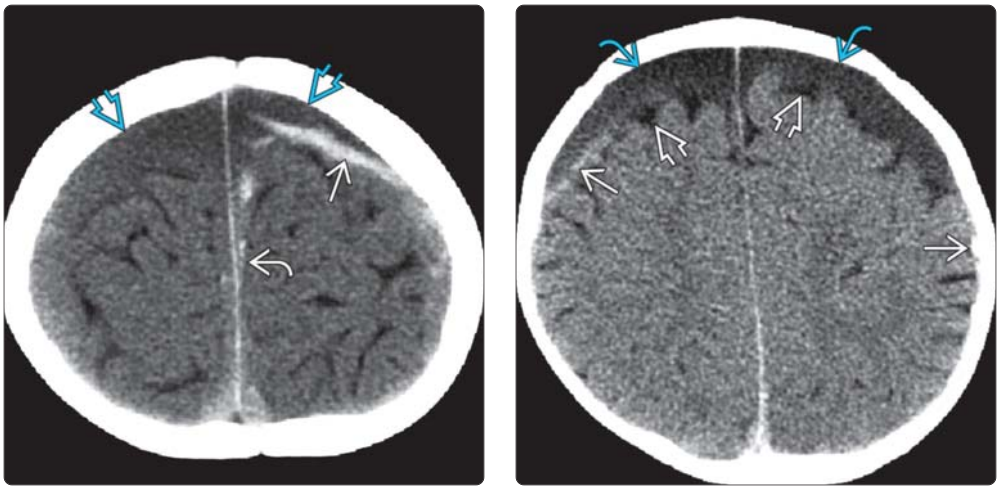
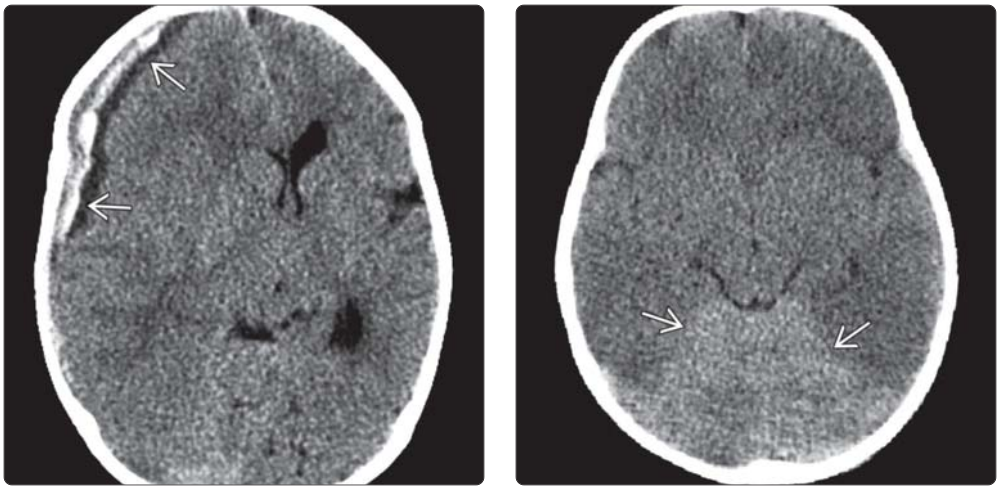
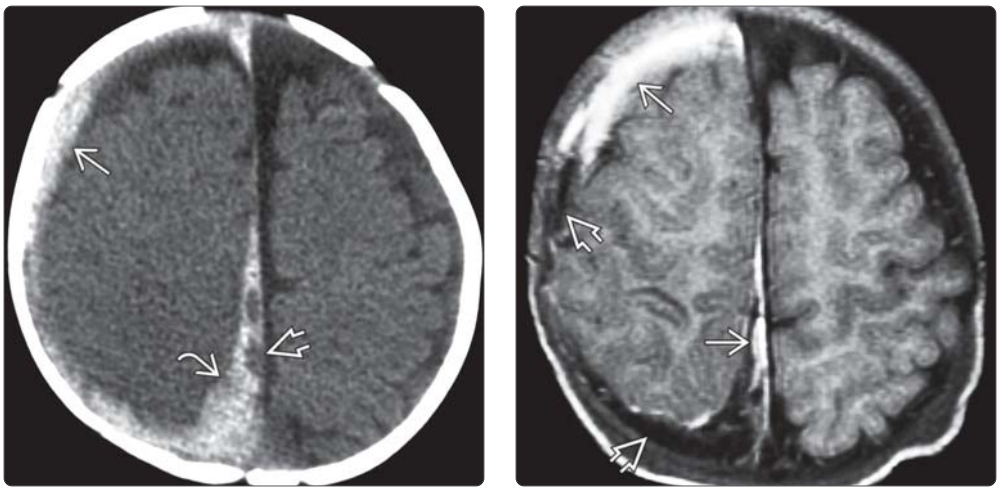
https://CafePezeshki.IR



(Left) *Axial NECT shows mixed low ➡ and high attenuation ⇨ SDHs in an infant with inflicted injury. Extension into the interhemispheric fissure ➡ is a common finding in such cases.* **(Right)** *Findings of mixed-attenuation SDHs in child abuse can be subtle. Axial NECT shows large, bifrontal, low attenuating SDHs ⇨ with hyperattenuating components ➡. Note the hypoattenuating "dots" of CSF ➡ in compressed, displaced sulci underlying the chronic SDHs.*



(Left) *Axial NECT in an abused infant shows mixed attenuation right frontotemporal SDHs ➡. Note that the mass effect underlying the SDHs is much greater than the thickness of the SDHs, indicating right hemispheric swelling. Excitotoxic brain injury can occur with repeated concussions ("2nd impact syndrome"). While this is more common in athletes, it also occurs in AHT.* **(Right)** *Bilateral diffuse brain swelling in AHT makes the normally perfused cerebellum ➡ appear white ("reversal" sign).*



(Left) *Axial NECT scan in an infant with suspected AHT shows an extensive right-sided mixed attenuation SDH ➡ that extends into the interhemispheric fissure ➡. Some loculated hypoattenuating pockets ➡ suggest different-aged hematomas may be present.* **(Right)** *T1WI (same case) shows 2 different-aged subdural hematomas. Late subacute hematoma is hyperintense ➡; more acute blood is hypointense ➡. "Differing age" SDHs are suggestive of AHT.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Brain displaced from 1 compartment into another

IMAGING

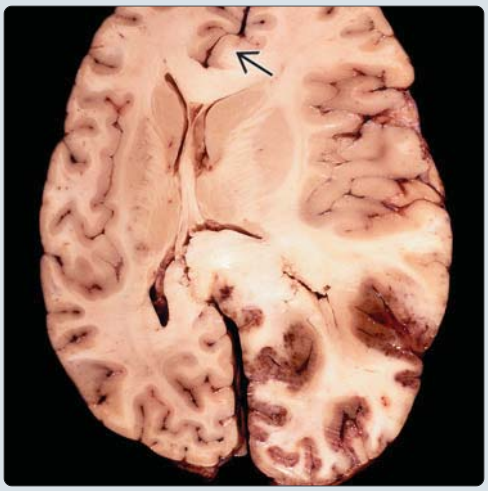
- Subfalcine herniation
  - Cingulate gyrus displaced under falx
  - Ipsilateral ventricle compressed and displaced across midline
  - Contralateral ventricle dilated
- Unilateral descending transtentorial herniation (DTH)
  - Temporal lobe displaced medially into incisura
  - Encroaches on, then effaces suprasellar cistern
- Bilateral DTH ("central herniation")
  - Both temporal lobes herniated into tentorial hiatus
  - Diencephalon crushed against skull base
  - Suprasellar cistern, CSF spaces obliterated
  - Midbrain/pons displaced inferiorly
- Ascending transtentorial herniation
  - Cerebellum displaced up through incisura
  - Quadrigeminal cistern, tectum flattened
- Tonsillar herniation
  - Tonsils impacted into foramen magnum
  - Cisterna magna obliterated
- Transalar herniation
  - Ascending (middle fossa mass) or descending (frontal mass)
  - Brain, middle cranial artery (MCA) herniated across sphenoid wing
- Transdural/transcranial herniation
  - Brain extruded through dural/skull defect

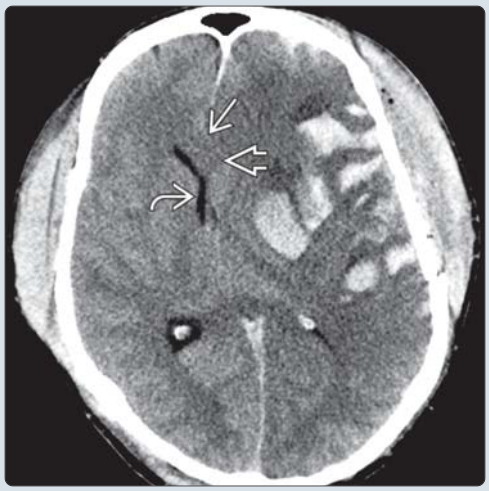
TOP DIFFERENTIAL DIAGNOSES

- Intracranial hypotension

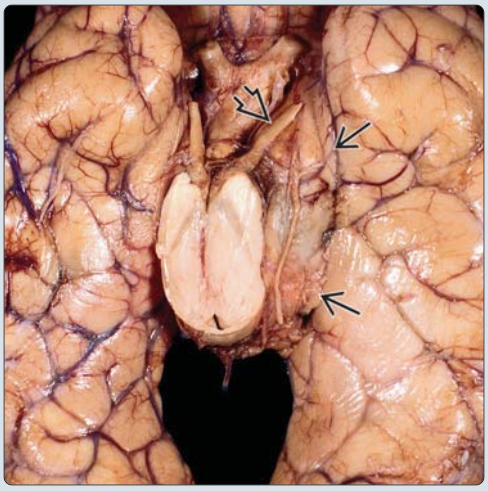
DIAGNOSTIC CHECKLIST

- DWI, T2* for ischemic, hemorrhagic complications





(Left) *Axial gross pathology section through the ventricles in a patient who died of multiple traumatic injuries shows findings of severe subfalcine herniation. Ventricles are displaced across the midline, and the cingulate gyrus ⇨ is herniated under the falx. Left PCA infarct occurred secondary to descending transtentorial herniation. (Courtesy R. Hewlett, MD.)* **(Right)** *Axial NECT in severe trauma shows subfalcine herniation ➡ with severely compressed left ➡ and slightly dilated right lateral ventricle ➡.*



(Left) *Submentovertex gross pathology shows findings of unilateral descending transtentorial herniation. Undersurface of herniated temporal lobe shows "grooving" ⇨ from impaction against the tentorium. Note the 3rd nerve compression ⇨ and midbrain displacement. (Courtesy R. Hewlett, MD.)* **(Right)** *Axial NECT in a patient with CHI injury shows changes of left descending transtentorial herniation, with uncus ➡ and hippocampus ➡ herniated into the suprasellar cistern. The right side of the cistern is preserved.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Subfalcine herniation (SFH)
- Descending transtentorial herniation (DTH)

Definitions

- Herniation of brain from 1 compartment (normally separated by calvarial &/or dural boundaries) to another

IMAGING

General Features

- Best diagnostic clue
  - Several herniation types (findings vary)
    - SFH: Lateral, 3rd ventricles displaced across midline
    - DTH: Temporal lobe displaced over and into tentorial incisura
- Subfalcine herniation
  - Most common herniation
  - Cingulate gyrus displaced under falx
  - Ipsilateral ventricle compressed and displaced across midline
  - Complications
    - Early: Contralateral ventricle enlarged secondary to obstruction at foramen of Monro
    - Late: Anterior cerebral arteries (ACAs) displaced → compressed against free edge of falx → occlusion → secondary infarct
- Unilateral DTH
  - 2nd most common herniation
  - Medial temporal lobe displaced medially into incisura
    - Early/mild DTH: Uncus effaces ipsilateral suprasellar cistern
    - Moderate DTH: Hippocampus effaces ipsilateral quadrigeminal cistern
      - Displaces, mildly compresses midbrain
    - Severe DTH: Medial temporal lobe, temporal horn displaced inferiorly into upper CPA cistern
      - Suprasellar cistern obliterated
  - Complications
    - Contralateral midbrain compressed against tentorium, may cause Kernohan notch
      - Ipsilateral hemiplegia ("false localizing" sign)
      - Supratentorial mass causes compression of **contralateral** peduncle against tentorial edge
    - Midbrain (Duret) hemorrhages
    - Posterior cerebral artery (PCA) displaced inferiorly over free edge of tentorium
      - PCA kinking/occlusion leads to secondary occipital infarct
- Bilateral DTH ("central herniation")
  - Less common; seen with severe supratentorial mass effect(s)
  - Both temporal lobes herniated into tentorial hiatus
  - Optic chiasm/diencephalon crushed against skull base
  - Midbrain displaced inferiorly
    - Anterior inferior 3rd ventricle displaced posteriorly behind dorsum sella
    - Angle between midbrain and pons becomes more acute
  - Complications
    - Penetrating basal arteries occlusion → basal infarcts
- Ascending transtentorial herniation
  - Less common than descending herniation
  - Cerebellum displaced up through incisura
  - Quadrigeminal cistern compressed, tectum flattened
  - Complications
    - Aqueduct obstruction → hydrocephalus
- Tonsillar herniation
  - Most common herniation seen with posterior fossa mass
  - Tonsils pushed inferiorly, impacted into foramen magnum
    - Displacement > 5 mm
    - Tonsil folia become vertically oriented
  - Cisterna magna obliterated
  - Complications
    - 4th ventricle obstruction → hydrocephalus
- Transalar herniation
  - Rare
  - Brain, middle cranial artery (MCA) herniated across sphenoid wing
  - Ascending or descending
    - Ascending: Middle cranial fossa/temporal lobe mass displaces sylvian fissure, MCA, up/over sphenoid wing
    - Descending: Anterior fossa/frontal lobe mass forces gyrus rectus posteroinferiorly over sphenoid wing, displaces sylvian fissure/MCA backward
  - Complication
    - MCA compressed against sphenoid → infarct
- Transdural/transcranial herniation
  - Rare
    - Sometimes called "brain fungus"
    - Can be life threatening
  - Brain, vessels herniated through dural &/or skull defect
  - Trauma (skull fracture lacerates dura), craniotomy
  - ↑ intracranial pressure (ICP) forces brain through dura ± subgaleal extension

CT Findings

- NECT
  - Ventricles displaced; sulci/cisterns obliterated

MR Findings

- T1WI
  - Best anatomic definition
- T2WI
  - Best for complications (e.g., edema, infarcts, hydrocephalus)
- T2* GRE
  - Best for hemorrhagic foci (e.g., Duret hemorrhages)
- DWI
  - Secondary ischemia/infarcts
- DTI
  - ± corticospinal tract disruption
  - Kernohan notch → loss of FA

Imaging Recommendations

- Best imaging tool
  - NECT is best rapid screen
  - Multiplanar MR for complications
- Protocol advice

https://CafePezeshki.IR

- Add DWI, T2* (GRE), SWI for ischemic, hemorrhagic complications

DIFFERENTIAL DIAGNOSIS

Intracranial Hypotension (IH)

- Brain "pulled," not "pushed" down
- Pituitary gland often engorged
- Dural thickening, enhancement often present

Chiari 1

- Congenital anomaly with low-lying tonsils
- Brain otherwise normal

PATHOLOGY

General Features

- Etiology
  - Trauma most common clinical setting
  - Mass lesions, large infarcts, and inflammatory lesions
  - Hemorrhage, extracellular fluid, or added tissue accumulate within closed space
  - CSF spaces (cisterns, ventricles) initially compressed
  - Intracranial volume cannot be accommodated
    - Gross mechanical displacement of brain, vessels → herniation
  - Secondary effects exacerbate severity of primary injuries
  - Herniations, ↑ ICP, altered cerebral hemodynamics → ischemia and infarction
    - PCA occlusion → occipital infarct most common
    - ACA occlusion → distal (cingulate gyrus) infarcts
    - Perforating vessels → basal ganglia, capsule infarcts
    - Midbrain Duret hemorrhage can occur from stretching/tearing of pontine perforators
- Associated abnormalities
  - Secondary obstructive hydrocephalus
  - Ischemia, hemorrhage, necrosis

Gross Pathologic & Surgical Features

- Grossly swollen, edematous brain
- Gyri compressed and flattened against calvaria
- Sulci effaced

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Focal neurologic deficit
    - Contralateral hemiparesis
    - Ipsilateral pupil-involving CN3 palsy
    - Ipsilateral hemiplegia
      - Kernohan notch → compression of opposite cerebral peduncle against tentorium
      - "False localizing" signs
  - Decreased mental status or obtundation

Natural History & Prognosis

- Brain death if ICP continues to rise, mass effect progresses unabated

Treatment

- Mitigate secondary effects
- Removal of mass or decompressive craniectomy
- Prolonged post-traumatic brain hypersensitivity
  - May offer potential "therapeutic window"
  - Possible use of neuroprotective agents

DIAGNOSTIC CHECKLIST

Consider

- IH syndrome
  - Can mimic some features of herniations caused by supratentorial mass
    - Common features
      - "Slumping" midbrain
      - "Closed" midbrain-pontine angle
      - Tonsillar herniation
      - ± subdural hematomas
    - Distinguishing features in IH
      - Brain appears "pulled" down, not "pushed" down
      - Dural thickening, enhancement
      - Pituitary engorgement

Image Interpretation Pearls

- Use DWI, T2* sequences in brain trauma, suspected herniation

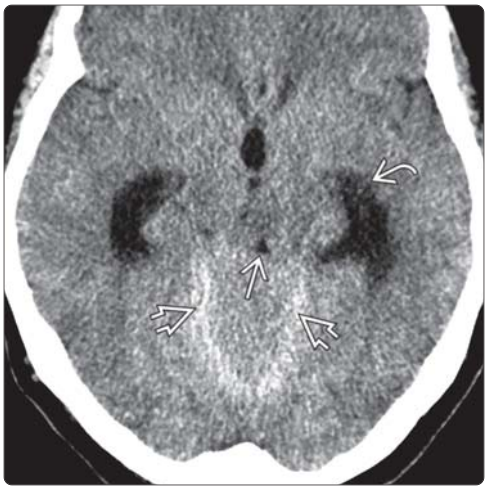
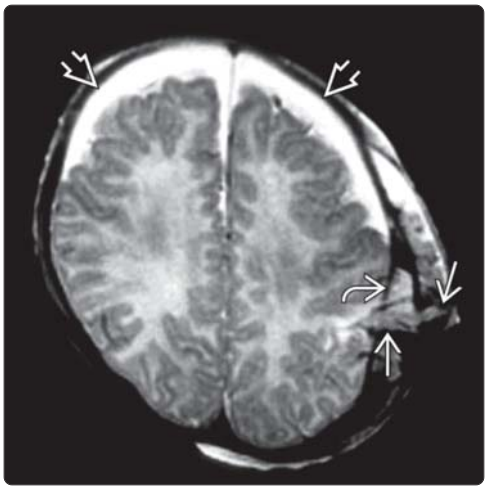
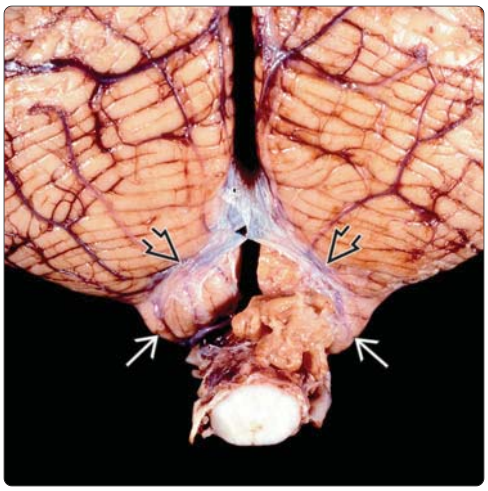
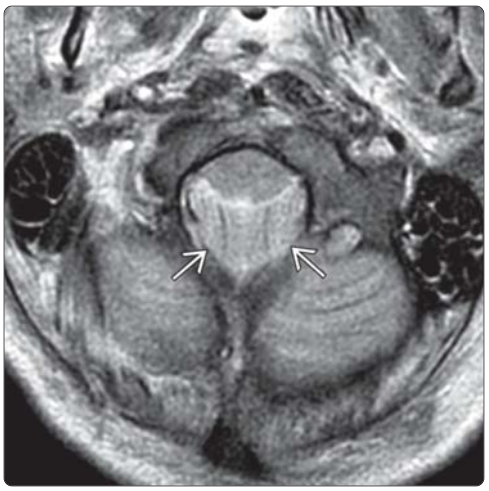
(Left) *Sagittal autopsy demonstrates findings of complete bilateral descending transtentorial herniation with the optic chiasm and 3rd ventricle ⇨ draped over the sella. The midbrain is displaced inferiorly and the angle with pons is decreased ⇨. (Courtesy R. Hewlett, MD.)* **(Right)** *Sagittal MP RAGE T1WI obtained just prior to death in a patient with complete central herniation shows inferior displacement of midbrain, pons, and cerebellar tonsils. (Courtesy R. Hewlett, MD.)*





(Left) *Axial NECT shows findings of ascending transtentorial herniation. The vermis is displaced superiorly through the tentorial incisura ⇨, flattening and compressing the tectal plate ⇨. The aqueduct is obstructed, causing acute hydrocephalus with transependymal CSF flow ⇨.* **(Right)** *Axial T2WI MR in an infant with a left parietal skull fracture shows transcalvarial herniation of the brain and accompanying vessels ⇨ through torn dura ⇨. Bilateral chronic SDHs are present ⇨.*





(Left) *Gross pathology of an autopsied brain seen posteriorly shows bilateral tonsillar herniation. Note the grooving of tonsils ⇨ from impaction against the foramen magnum as the tonsils ⇨ are forced inferiorly into the upper cervical spine. (Courtesy R. Hewlett, MD.)* **(Right)** *Axial T2WI MR shows severe tonsillar herniation with both tonsils ⇨ displaced inferiorly, filling the cisterna magna and displacing the upper cervical spinal cord anteriorly.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Vasogenic edema (VE), cytotoxic edema (CTE), cerebral edema (CE), diffuse brain swelling (DBS)
- 2 basic forms of brain edema in trauma: VE and CTE (often coexist)
  - VE: Extracellular edema, follows blood-brain barrier (BBB) breakdown
  - CTE: Intracellular (closed barrier) edema

IMAGING

- Compressed ventricles, effaced sulci
- Vasogenic more prominent in WM, cytotoxic more prominent in GM
- Secondary effects of CE
  - Brain herniation(s)
  - Vascular compression → infarction
- DWI together with ADC differentiates VE from CTE
  - CTE: Cellular swelling (↑ signal on DWI, ↓ ADC)
  - VE: Increased extracellular brain water (↑ ADC)
- Brain edema accompanied by ↑ ICP, ↑ pulsatility index, ↓ blood flow velocity within 24 hours → poor prognosis
- Disturbed cerebral autoregulation during 1st 48 hours correlates with poor outcome

TOP DIFFERENTIAL DIAGNOSES

- Anoxic encephalopathy
- Metabolic encephalopathy
- Pressure-related edema

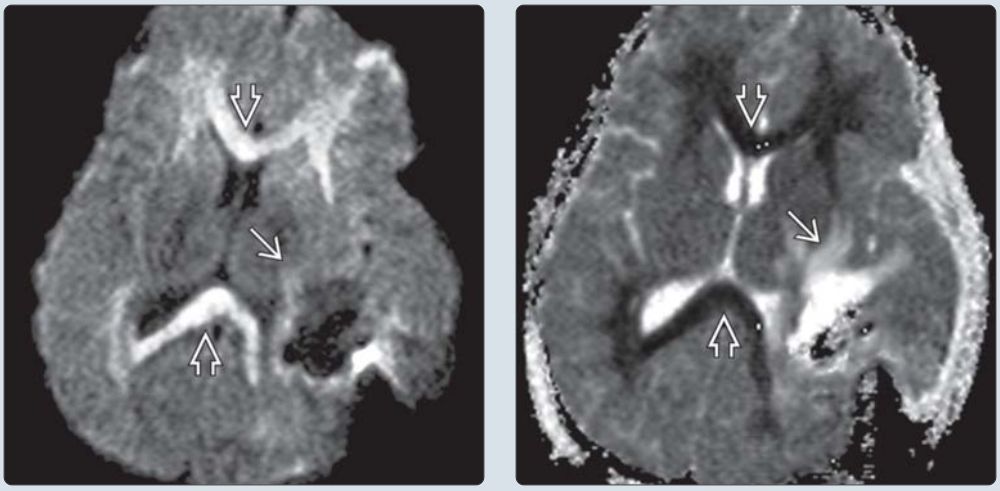
CLINICAL ISSUES

- Goal = maintain cerebral perfusion pressure (CPP) without inducing hydrostatic vasogenic edema
- DBS more common in children than adults

DIAGNOSTIC CHECKLIST

- Consider hypoxia as contributing factor

(Left) *Axial NECT demonstrates acute left periatrial hemorrhage ⇨ with minimal surrounding vasogenic edema. Note diffuse sulcal effacement, midline shift to the right, and early trapping of the right lateral ventricle ⇨.* **(Right)** *Axial T2WI MR in the same patient demonstrates left periatrial hemorrhage with increased surrounding edema. Interval left craniectomy is noted with extracalvarial herniation of brain parenchyma ⇨. Edema related to the splenium of the corpus callosum ⇨ is also noted.*



(Left) *Axial DWI MR demonstrates increased signal in the corpus callosum and cerebral white matter ⇨, consistent with edema. Edema is also noted around the left periatrial hematoma ⇨.* **(Right)** *Axial ADC in the same patient demonstrates corresponding hypointensity in the corpus callosum and cerebral white matter ⇨, confirming cytotoxic edema. Bright signal on ADC surrounding the left periatrial hemorrhage reflects increased diffusivity, characteristic of vasogenic (not cytotoxic) edema ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Vasogenic edema (VE), cytotoxic edema (CTE), cerebral edema (CE), diffuse brain swelling (DBS)

Definitions

- Brain, CSF, and blood coexist in closed intracranial compartment
  - To maintain normal ICP, ↑ pressure in 1 compartment must be balanced by ↓ in others (Monro-Kellie doctrine)
- CE (secondary effect of trauma, ischemia) is dynamic process involving glutamate-mediated excitotoxicity, cell damage
- 2 basic forms of brain edema in trauma: VE and CTE often coexist
  - VE: Extracellular edema, follows blood-brain barrier (BBB) breakdown
  - CTE: Intracellular (closed barrier) edema

IMAGING

General Features

- Best diagnostic clue
  - Compressed ventricles, effaced sulci due to focal or diffuse increase in brain water
- Location
  - Vasogenic more prominent in white matter (WM); cytotoxic more prominent in gray matter (GM)
    - Often coexist
- Morphology
  - Compressed ventricles, effaced sulci
  - Secondary effects of CE
    - Brain herniation(s)
    - Vascular compression → infarction

Radiographic Findings

- Radiography
  - ± fractures, split sutures

CT Findings

- NECT
  - Compressed ventricles, effaced sulci
  - Low-attenuation brain parenchyma: WM > GM
    - Subcortical WM less resistant to fluid accumulation than GM
    - Loss of GM-WM interfaces
  - Vasogenic edema more prominent in WM
  - Cytotoxic edema more prominent in GM
  - ↓ supratentorial perfusion with preservation of infratentorial perfusion → "white cerebellum" sign
  - Multifocal hemorrhages often present
- CECT
  - Usually no enhancement unless BBB disrupted
- Xenon CT
  - Edema is major contributor to brain swelling
  - Cerebral blood volume actually decreases in proportion to cerebral blood flow

MR Findings

- T1WI
  - Hypointense edema
- T2WI
  - Hyperintense edema
- FLAIR
  - Hyperintense edema
  - Less useful in newborn due to normally ↑ water content of neonatal brain
- T2* GRE
  - ± blood products
- DWI
  - DWI together with ADC differentiates VE from CTE
    - CTE: Cellular swelling (↓ ADC)
    - VE: Increased extracellular brain water (↑ ADC)
  - Diffusion tensor imaging (DTI): ↓ diffusion anisotropy early, when MR/DWI still normal
  - DTI identifies traumatic penumbra, potentially salvageable brain
- T1WI C+
  - Patchy enhancement if BBB breakdown
- MRA
  - ± decreased flow ("thinned" arteries)
  - Vascular obstruction (compression or dissection during herniation) → post-traumatic infarction
- MRV
  - Sinus compression with severe edema
- MRS
  - ↓ NAA, elevated Cho (membrane breakdown), presence of lactate predicts poor prognosis
- Perfusion: ↓ brain perfusion with progressive ↑ ICP

Ultrasonographic Findings

- Pulsed Doppler
  - Brain edema accompanied by ↑ ICP, ↑ pulsatility index, ↓ blood flow velocity within 24 hours → poor prognosis
  - Moving correlation index between mean arterial BP and ICP = PRx (measures cerebral vasomotor reactivity)
    - PRx < 0.3 = intact reactivity; PRx > 0.3 = impaired reactivity
    - Disturbed cerebral autoregulation during first 48 hours correlates with poor outcome

Angiographic Findings

- Conventional
  - Slow arteriovenous transit if ↑ ICP

Nuclear Medicine Findings

- PET
  - PET/SPECT: ↓ rCBV, hypometabolism (dependent upon timing)

Imaging Recommendations

- NECT performed due to accessibility in critically ill trauma patients
- DWI with ADC maps (or DTI) important to differentiate VE, CTE
- Multiplanar MR allows characterization of acquired cerebral herniations
  - Subfalcine (cingulate), tonsillar, uncal, transtentorial (central ascending, central descending, lateral), transalar, external

https://CafePezeshki.IR

DIFFERENTIAL DIAGNOSIS

Anoxic Encephalopathy

- Hypoxic-ischemic encephalopathy, drowning, cardiopulmonary arrest

Metabolic Encephalopathy

- Uremia, mitochondrial disorders

Pressure-Related Edema

- Posterior reversible encephalopathy syndrome
  - Hypertensive encephalopathy, cyclosporine/FK506 encephalopathy, L-asparaginase, eclampsia
  - Predominantly VE in subcortical WM parietooccipital regions
- Venous obstruction with ↑ venous pressure

Meningitis/Encephalitis

- Diffuse sulcal effacement, leptomeningeal ± parenchymal enhancement

PATHOLOGY

General Features

- Etiology
  - Vasogenic edema
    - ↑ BBB permeability
    - Endothelial tight junctions disrupted → leakage of proteins/Na++/water → fluid shift into extracellular spaces
    - Primarily WM, myelin (major association bundles, relative sparing of commissural/projection fibers)
  - Cytotoxic edema
    - Intracellular (closed barrier) edema
    - Energy failure → loss of Na++/K homeostasis
    - Intracellular water uptake causes cell swelling, compression of extracellular space
  - Other brain water disturbances
    - Hydrocephalic (interstitial)
    - Hydrostatic (congestive)
    - Hypo-osmotic

Gross Pathologic & Surgical Features

- ↑ brain water, obliteration of cisterns/ventricles/sulci

Microscopic Features

- Extracellular fluid of cortex neuropil → swelling and shrinkage of pre-/postsynaptic structures, synaptic disassembly
- Effects of hypoxia and cell death

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Altered consciousness
  - Coma
- Clinical profile
  - < 2 years old: Inflicted injury in 80%
  - Teens and adults: Motor vehicle crash, assaults
    - Car crashes, especially auto without seat belts, motorcyclists/bicyclists without helmets
  - > 65 years old: Accidental falls

Demographics

- Age
  - DBS more common in children than adults
- Gender
  - M:F = 1.6-2:1
- Ethnicity
  - African American, Native Americans overrepresented
- Epidemiology
  - 1.5 million traumatic brain injuries per year (USA)
    - Highest incidence in children < 5 years old

Natural History & Prognosis

- Slowly expanding lesions can be accommodated without elevated ICP
- Rapid expansion (trauma, rapid tumor growth, abscess) → rapid rise of ICP
  - Followed by "cascade" of sequelae (e.g., excitotoxin release) → cell death
- Post-traumatic edema generally resolves within 2 weeks, atrophy (due to cellular death) ensues

Treatment

- Goal = maintain cerebral perfusion pressure (CPP) without inducing hydrostatic vasogenic edema
  - ↑ CPP in selected patients with intact cerebral vasomotor reactivity
- Decompressive surgery
- Osmotherapy, neuroprotective agents, steroids, all controversial

DIAGNOSTIC CHECKLIST

Consider

- Hypoxia as contributing factor

Image Interpretation Pearls

- Image timing crucial: VE (1st hours) replaced by CTE

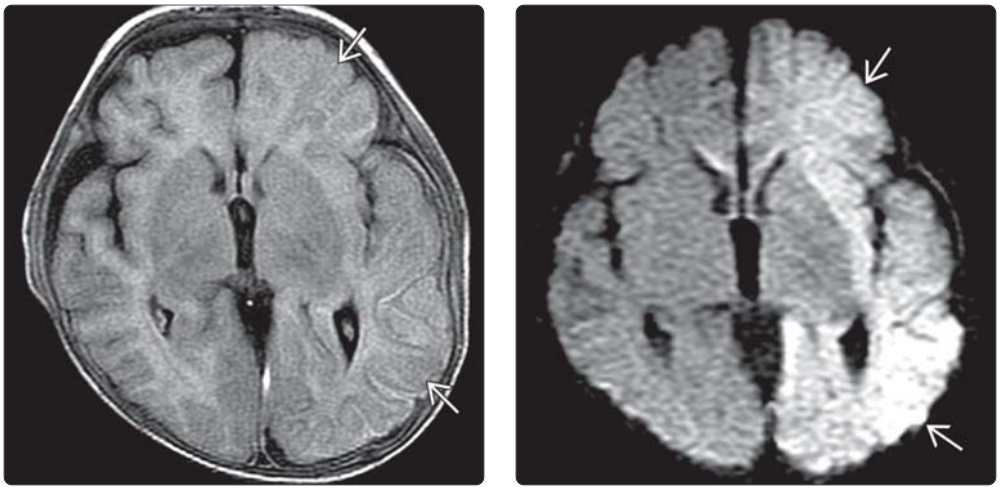
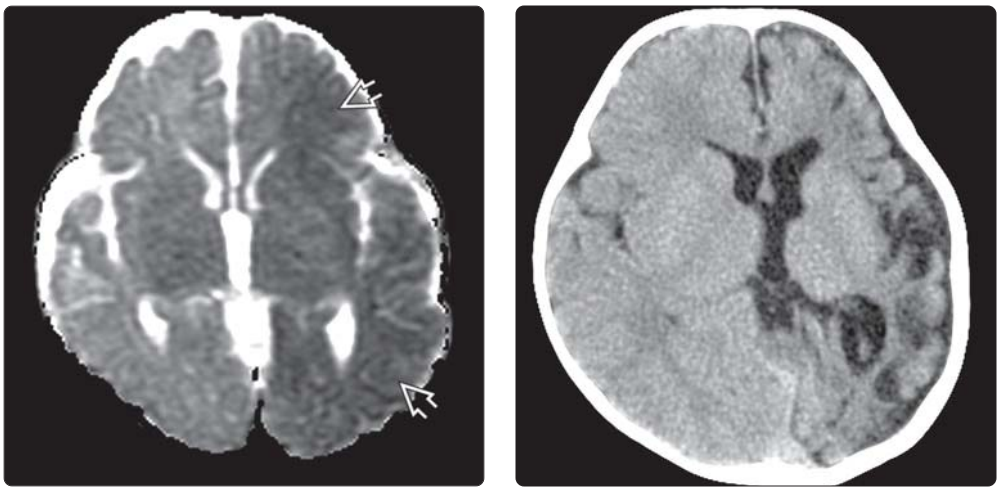
(Left) *Axial NECT in a 3-year-old boy who was not belted into a child car seat and was ejected during a high-impact MVA shows that the cerebral hemispheres are diffusely hypodense without gray-white differentiation. Some subarachnoid and peritentorial subdural blood is present.* **(Right)** *More cephalad scan in the same patient shows complete lack of gray-white differentiation. The lateral ventricles are compressed and almost inapparent. There is severe post-traumatic brain swelling.*



(Left) *Axial T1WI shows left hemispheric brain swelling in a child with nonaccidental head trauma. Note the sulcal effacement and diffuse signal loss ➡ of the left hemispheric cortical gray matter.* **(Right)** *Axial DWI MR in the same patient shows left hemispheric edema ➡ involving the cortex, subcortical, and periventricular white matter in a nonvascular distribution.*



(Left) *Axial ADC map shows extensive left hemispheric decreased ADC ➡ in the same toddler, confirming cytotoxic edema.* **(Right)** *Axial NECT at follow-up shows volume loss of the left hemicranium with compensatory enlargement of the ventricular system secondary to atrophy of the cortex and underlying white matter, particularly posteriorly. Infants with repeated inflicted brain injury are especially prone to excitotoxic injury in the brain underlying SDHs.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Post-traumatic cerebral ischemia (PTCI)
- Hemodynamic alterations induced by traumatic brain injury (TBI)
  - Can be local, regional, generalized perfusion alteration(s)

IMAGING

- Best diagnostic clue: Restricted diffusion
- Most commonly occurs in PCA vascular distribution
  - MCA, ACA, vertebrobasilar relatively common
  - Less common: Perforating, cerebellar arteries
- Best imaging tool: MR + DWI/ADC
  - Diffusion most sensitive sequence
  - Midsagittal imaging to evaluate for herniation

TOP DIFFERENTIAL DIAGNOSES

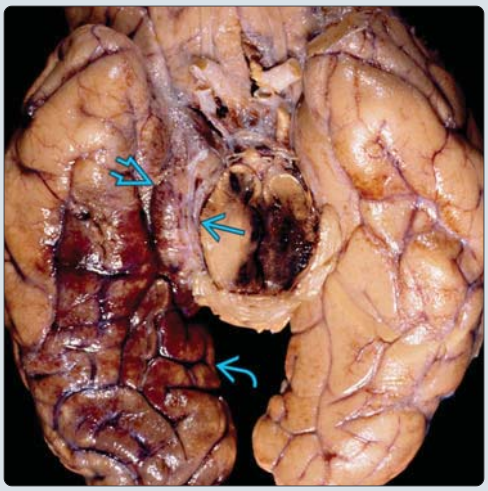
- Nontraumatic ischemia/infarction
- Vascular (multi-infarct) dementia
- Atherosclerotic occlusion
- Subarachnoid-induced vasospasm

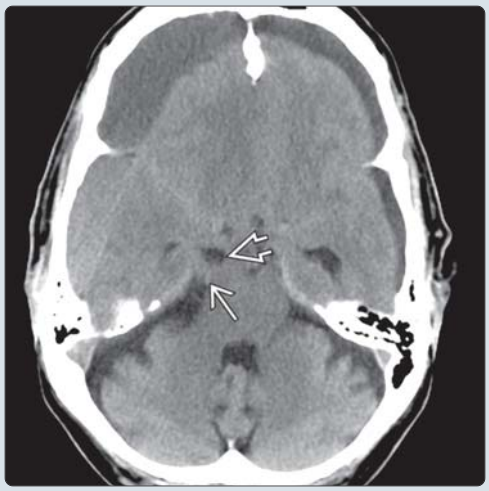
PATHOLOGY

- Primary TBI = direct damage at time of trauma
- Secondary brain injury occurs after initial trauma
  - Due to systemic responses to initial injuries
  - PTCI may be most common cause of secondary brain injury in setting of severe TBI
  - 2° injuries often more devastating than 1° TBI
  - 2° injury can occur after negative initial imaging
- Mechanical shift of brain with herniation across falx &/or tentorium → 80-90% of PTCI

CLINICAL ISSUES

- Most common sign: GCS ≤ 8
- Symptoms often delayed 12-24 hours to several weeks
- PTCI occurs in 1.9-10.4% of craniocerebral trauma
- Ischemic damage present in 90% of fatal TBI deaths





(Left) *Submentovertex view of autopsied brain in a patient with uncal herniation ⇨ and occlusion of the adjacent posterior cerebral artery ⇨ against the tentorium shows a secondary hemorrhagic infarct in the ipsilateral occipital lobe ⇨. (Courtesy R. Hewlett, MD.)* **(Right)** *Axial NECT in a patient with a large mixed-age SDH shows herniation of the right uncus ⇨ and compression of the ipsilateral PCA ⇨.*

(Left) *Lateral DSA shows an inferiorly displaced PCA ⇨ secondary to descending transtentorial herniation of the adjacent temporal lobe. Note the points at which the herniated PCA passes over the edge of the tentorium ⇨. The distal PCA is severely kinked and narrowed ⇨. Worsening herniation will occlude the PCA and result in secondary infarction.* **(Right)** *Axial NECT scan in a patient with severe bifrontal traumatic contusions shows a right PCA infarct ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Post-traumatic cerebral ischemia (PTCI)

Definitions

- Hemodynamic alterations induced by traumatic brain injury (TBI)
  - Can be local, regional, generalized perfusion alteration(s)

IMAGING

General Features

- Best diagnostic clue
  - Restricted diffusion
- Location
  - Most commonly occurs in PCA vascular distribution
    - MCA, ACA, vertebrobasilar relatively common
    - Less common: Perforating arteries, cortical/subcortical, cerebellar

CT Findings

- NECT
  - Initial primary lesions of TBI
    - Hyperdense traumatic subarachnoid hemorrhage, subdural hematoma, &/or epidural hematoma
    - Hypodense contusion, ± dense hemorrhagic foci
    - Diffuse axonal injury
    - Calvarial fractures
  - Subsequent secondary hypodense ischemia
    - Downward transtentorial herniation → PCA occlusion
    - Subfalcine → ACA occlusion
    - Central → basal perforating vessel occlusions
- CT perfusion
  - May reveal changes in CBF, CBV, time to peak, &/or mean transit time

MR Findings

- T1WI
  - Acute ischemia: Hypointense
  - Sagittal best to evaluate for herniation(s)
- T2WI
  - Acute ischemia: Hyperintense
- FLAIR
  - Acute ischemia: Hyperintense
- T2* GRE
  - Best for imaging any hemorrhagic foci
- DWI
  - Restricted diffusion
  - Often multiple; may separate DWI negative moderate TBI from DWI positive severe TBI
- MRA
  - Vessel occlusion, regional hypoperfusion
- MRS
  - TBI: ↓ NAA/Cr & ↑ lactate; persistent abnormalities prognostic
- MR perfusion
  - T2* sensitive echo-planar MR with 1st-pass gadolinium bolus
    - May reveal hypoperfusion changes in relative CBF, CBV, time to peak, &/or mean transit time

Angiographic Findings

- DSA
  - May show vessel displacement, occlusion from herniations
  - ± vasospasm 2º to traumatic SAH

Nuclear Medicine Findings

- SPECT: Tc-99m HMPAO
  - Very sensitive for cortical ischemia
  - Demonstrates high sensitivity and specificity within initial 48 hours for infarction

Imaging Recommendations

- Best imaging tool
  - MR + DWI/ADC
- Protocol advice
  - Diffusion most sensitive sequence
  - Midsagittal imaging to evaluate for herniation

DIFFERENTIAL DIAGNOSIS

Nontraumatic Ischemia/Infarction

- Appears identical; no trauma history

Vascular (Multi-Infarct) Dementia

- Elderly; no trauma history

Atherosclerotic Occlusion

- Elderly; typical location in proximal ICA

SAH-Induced Vasospasm

- Usually in setting of ruptured aneurysm

PATHOLOGY

General Features

- Etiology
  - Motor vehicle accidents most common cause of PTCI
  - Variety of mechanisms account for PTCI
    - Direct vascular compression by mass effects
    - Systemic hypoperfusion
    - Vascular injury, embolization
    - Cerebral vasospasm from traumatic SAH
    - Venous congestion at craniectomy site
  - 2 most common mechanisms
    - Mechanical shift of brain with herniation across falx &/or tentorium → 80-90% of PTCI
    - Result of intracranial space-occupying lesion
  - PTCI relationship with inciting brain injury
    - Primary TBI = direct damage at time of trauma
    - Secondary brain injury occurs after initial trauma
      - Due to systemic responses to initial injuries
      - Most 2° injuries result from ↑ ICP, cerebral herniations
      - 2° injuries often more devastating than those sustained from primary injuries
      - PTCI may be most common cause of secondary brain injury in setting of severe TBI
- Associated abnormalities
  - Intracranial hemorrhages, calvarial fractures, contusions, diffuse axonal injury

https://CafePezeshki.IR

Gross Pathologic & Surgical Features

- Profound global or regional cerebral hypoperfusion occurs in most patients with Glasgow Coma Scores (GCS) ≤ 8
- Specific infarctions (in order of prevalence)
  - PCA: Compression of PCA against rigid tentorial edge from medial temporal lobe herniation
  - ACA: Subfalcine herniation of cingulate gyrus compresses 1 or both ACAs &/or their branches
  - MCA: Gross herniation or severe cerebral edema
  - Lenticulostriate, thalamoperforating arteries
    - Compression of perforating arteries against skull base
    - Gross mass effects also stretching/attenuation of these small perforating vessels
  - Cortical/subcortical: Direct compression from overlying masses; 2 mechanisms
    - Direct pressure effects limit arterial flow
    - Local venous drainage compression occurs
    - Both often result in hemorrhagic infarcts
  - Superior cerebellar artery
    - Ascending or descending transtentorial herniation compresses artery against tentorium
  - PICA: Compression of artery from tonsillar herniation

Microscopic Features

- Blood-brain barrier disruption with vasogenic edema
- Excitatory amino acids induce cellular swelling → cytotoxic edema
- Overproduction of free radicals and apoptosis
- Neurotransmitter release, metabolic perturbation, and membrane depolarization → ion dysfunction
  - PTCI impedes return of ion homeostasis, contributing to development of ↑ ICP
- Inflammatory processes → massive astrocytic activation with leukocyte accumulation and capillary vessel compression → microvascular occlusion

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Most common sign: GCS ≤ 8
  - No reliable clinical findings indicate presence of traumatic cerebral ischemia
  - Neurological signs from brain injury obscure focal findings that may be from secondary ischemia
- Clinical profile
  - Symptoms often delayed 12-24 hours to several weeks
  - Varies greatly with type of injury

Demographics

- Age
  - Children:adults = 2:1 (aged 15-24 at highest risk)
- Gender
  - M:F = 2:1
- Epidemiology
  - TBI: Leading cause of death and disability in children and adults
  - 2 million traumatic brain injuries annually in USA
  - Survivors incur annual cost of > $40 billion (~ 0.5% of GNP)
  - TBI causes ~ 50,000 deaths and 235,000 hospitalizations annually in USA
  - PTCI occurs in 1.9-10.4% of craniocerebral trauma
  - Ischemic damage present in 90% of fatal TBI deaths

Natural History & Prognosis

- Poor prognosis: Presence of subdural hematoma, brain swelling/edema, traumatic SAH
- Good prognosis: Patients with none or only 1 poor prognostic factor
- Presence of blunt cerebral vascular injury and treatment with factor VIIa are risk factors for developing PTCI
- Outcome: 50% die or are left in persistent vegetative state

Treatment

- Treatment of comorbidities: Herniation, hemorrhage(s), hydrocephalus, seizures
- Cerebral perfusion **must** be monitored to detect secondary cerebral ischemia following TBI
- Herniation &/or diffuse swelling may require craniectomy

DIAGNOSTIC CHECKLIST

Consider

- Cause of ischemia

Image Interpretation Pearls

- Secondary brain injury can occur after negative primary radiologic evaluation
- May occur hours to days or even weeks after admission

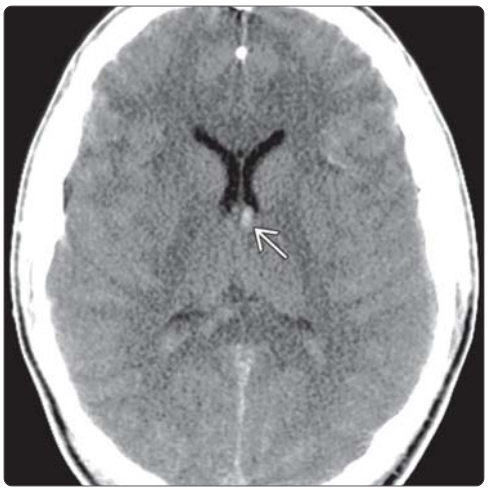
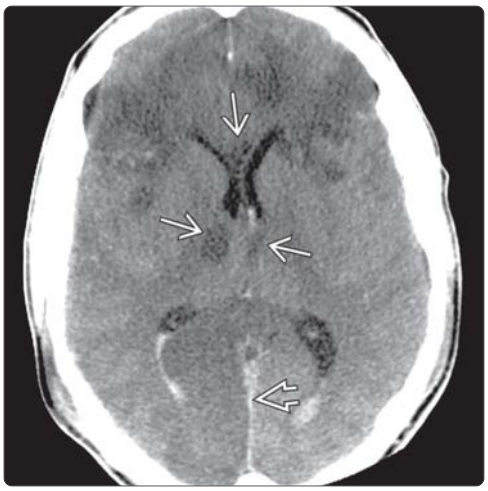
(Left) *Axial autopsy shows severe herniation of the medial cerebral hemisphere under the falx cerebri ⇨. This herniation can cause secondary ACA occlusion.* **(Right)** *Axial autopsy of severe subfalcine herniation shows cingulate gyrus herniation ⇨. The accompanying ACA can be compressed against the inferior falx ⇨, causing a secondary distal ACA infarct.*

(Left) *Axial NECT shows severe subfalcine herniation caused by a malignant left MCA infarction ⇨. Note hypodensity in the cingulate gyrus ⇨.* **(Right)** *More cephalad axial NECT in the same case again shows the left MCA infarct ⇨. The distal cingulate gyrus infarction ⇨ is caused by the severe subfalcine herniation.*





(Left) *Axial NECT in a patient involved in a high-speed MVA shows hemorrhage in the left fornix ⇨ and diffuse brain swelling with sulcal obliteration.* **(Right)** *Follow-up scan in the same case 1 week later shows a right PCA infarct ⇨ and multiple hypodensities ⇨ in the basal ganglia and corpus callosum genu caused by central herniation, compression of multiple perforating arteries against the skull base.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Brain death (BD); death by neurological criteria (DNC)
- Complete, irreversible cessation of brain function

IMAGING

- No flow in intracranial arteries or venous sinuses
  - No intravascular enhancement on CT or MR
  - "Light bulb" sign on radionuclide study
- Diffuse cerebral edema
  - Gyri swollen, ventricles/cisterns compressed
  - Gray-white matter borders effaced

TOP DIFFERENTIAL DIAGNOSES

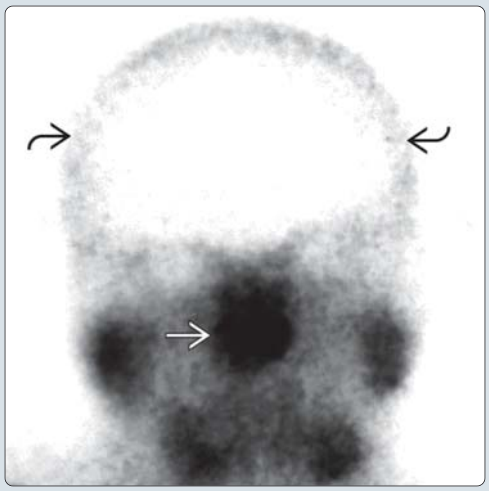
- Reversible diffuse cerebral edema
  - Drug overdose
  - Status epilepticus (clinically can mimic BD)
  - Acute metabolic dysfunction (e.g., fulminant hepatic failure)
- Technical difficulty
  - Missed bolus (nuclear study, CTA)
  - Dissection (catheter angiography)
  - Vasospasm (catheter angiography)
- Massive cerebral infarction/edema

PATHOLOGY

- Severe cell swelling, ↑ intracranial pressure (ICP)

CLINICAL ISSUES

- Complex assessment, often misunderstood by nonspecialists and families
  - DNC highly reliable with
    - Experienced examiners
    - Using established criteria
- Imaging may confirm but does not substitute for clinical criteria
- Reversible causes of coma must be excluded
- Remember: BD is primarily clinical diagnosis, legal criteria vary



(Left) *Axial NECT shows complete loss of gray-white matter differentiation and diffuse sulcal and gyral effacement in this patient with diffuse cerebral edema and clinical brain death. The lateral ventricles are also effaced posteriorly* ➡. **(Right)** *Anteroposterior Tc-99m HMPAO scan shows the classic "light bulb"* ⇨ *and "hot nose" signs* ➡ *related to lack of intracerebral blood flow in brain death. No radionuclide is seen in the intracranial arteries or veins. (Courtesy B. Vomocil, MD.)*

(Left) *Antemortem axial T2WI in a 50-year-old woman with CBD obtained just before death shows small ventricles and swollen gyri with near-complete obliteration of the surface sulci.* **(Right)** *Submentovertex MIP of MRA in the same patient shows flow only in extracranial branches of the external carotid arteries* ➡. *No flow is present in the intracranial vasculature.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Brain death (BD); death by neurological criteria (DNC)

Definitions

- Complete, irreversible cessation of brain function

IMAGING

General Features

- Best diagnostic clue
  - No flow in intracranial arteries or venous sinuses on Tc-99m ECD (Neurolite)
- Imaging may confirm but does not substitute for clinical criteria

CT Findings

- NECT
  - Diffuse cerebral edema (GM-WM borders effaced)
    - White cerebellum sign (sometimes called cerebellar "reversal" sign with density of cerebellum >> hemispheres)
    - Pseudosubarachnoid appearance due to venous congestion in effaced sulci
  - Swollen gyri; compressed ventricles/cisterns
- CTA
  - Useful confirmatory or add-on test for BD
  - Does not replace neurological testing
  - No intravascular enhancement

MR Findings

- T1WI
  - Hypointense, swollen cortex ± gray-white matter differentiation lost
  - Sulci, cisterns obliterated
- T2WI
  - Cortex hyperintense, gyri swollen
- T2* GRE
  - Cortical, medullary veins hypointense
    - Stagnant flow with deoxyhemoglobin
- DWI
  - Hemispheric high signal, severe ADC drop

Angiographic Findings

- Conventional
  - No intracranial flow
  - Contrast stasis (ECA fills, supraclinoid ICA does not)

Nuclear Medicine Findings

- Tc-99m-labeled exametazime scintigraphy
  - Absent intracranial uptake ("light bulb" sign)
  - Increased extracranial activity ("hot nose" sign)

Imaging Recommendations

- Best imaging tool
  - EEG plus bedside scintigraphy (Neurolite)

DIFFERENTIAL DIAGNOSIS

Reversible Diffuse Cerebral Edema

- Drug overdose
- Status epilepticus (clinically can mimic BD)
- Acute metabolic dysfunction (e.g., fulminant hepatic failure)

Technical Difficulty

- Missed bolus (Nuclear study, CTA)
- Dissection (catheter angiography)
- Vasospasm (catheter angiography)

Massive Cerebral Infarction/Edema

- "Malignant" MCA infarct can mimic BD

PATHOLOGY

General Features

- Etiology
  - Severe cell swelling, ↑ intracranial pressure (ICP)
  - Markedly elevated ICP, ↓ cerebral blood flow
    - If ICP > end-diastolic pressure in cerebral arteries, diastolic reversal occurs
    - If ICP > systolic pressure, blood flow ceases

Gross Pathologic & Surgical Features

- Markedly swollen brain with severely compressed sulci
- Bilateral descending transtentorial herniation
  - Downward displacement of diencephalon
  - "Grooving" of temporal lobes by tentorial incisura

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Profound coma (GCS = 3) with "known cause"
  - Reversible causes of coma must be excluded
- Clinical profile
  - Complex assessment, often misunderstood by nonspecialists and families
    - DNC highly reliable with experienced examiners using established criteria
  - Brain death is primarily a clinical diagnosis; legal criteria vary
  - Ancillary studies help confirm clinical diagnosis

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Dysautoregulation/second impact syndrome
- Repeated head trauma within "window of vulnerability" before brain recovers from initial concussive injury
- Can result in catastrophic brain swelling with permanent disability or death

IMAGING

- Thin, acute subdural hematoma (aSDH)
  - Disproportionate mass effect
    - Degree of midline (subfalcine) shift more than accounted for by thickness of aSDH
- Swollen, hypodense cerebral hemisphere under aSDH
  - Underlying sulci compressed, then obliterated
- Best imaging tools
  - NECT as initial screening
  - MR with T2*, DWI

TOP DIFFERENTIAL DIAGNOSES

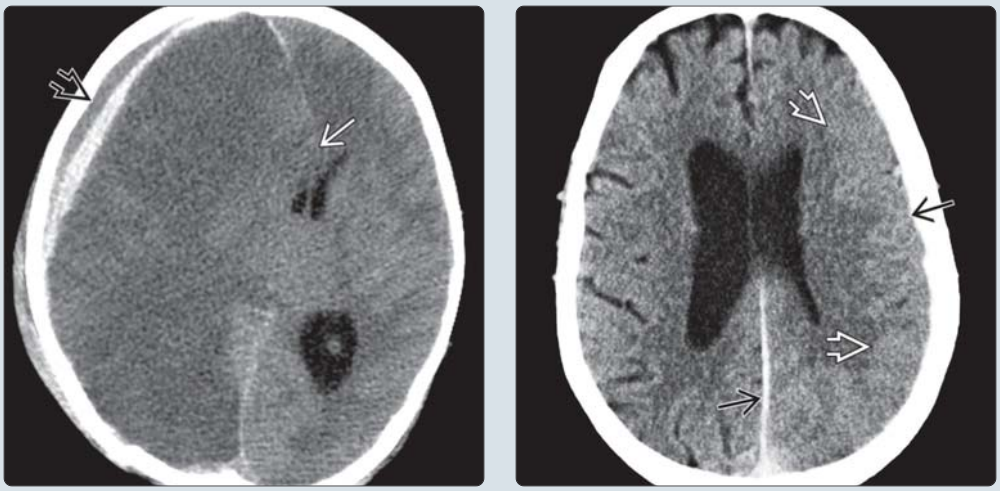
- Acute subdural hematoma (without underlying dysautoregulation)
- Nonaccidental trauma (child abuse)

PATHOLOGY

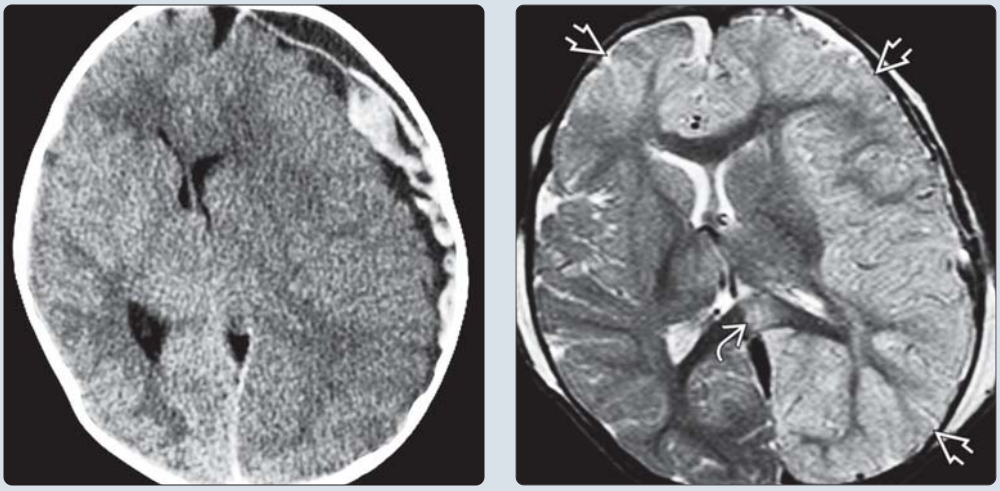
- Thin subdural hematoma
- Underlying brain swollen, hyperemic
  - ± secondary infarcts
  - ± uncal, central, tonsillar herniations

CLINICAL ISSUES

- Severe headache
- Vomiting
- May have dramatic, sudden collapse, coma
- Most common in
  - Adolescent males involved in high-impact sports
  - Abused infants
  - Elderly patients with repeated falls, head impacts



(Left) *Axial NECT in an abused infant with repeated inflicted head trauma shows a mixed-density right SDH. The underlying right hemisphere is diffusely swollen and hypodense. Note disproportionate mass effect, subfalcine herniation compared to relatively thin SDH.* **(Right)** *Axial NECT in an elderly patient with repeated falls and head trauma shows a thin aSDH. Underlying cortex is swollen with disproportionate mass effect on left lateral ventricle.*



(Left) *Axial NECT in an abused infant shows mixed acute, subacute/chronic SDH overlying a swollen, hypodense hemisphere.* **(Right)** *Axial fat-suppressed T2WI in the same case two days later, after evacuation of the SDH, shows swollen hyperintense cortex underlying bilateral SDHs. Note hyperintensity in the corpus callosum splenium. Findings are consistent with excitotoxic injury.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Second impact syndrome (SIS)

Synonyms

- Dysautoregulation

Definitions

- Repeated head trauma within "window of vulnerability" before brain recovers from initial concussive injury
- Can result in catastrophic brain swelling with permanent disability or death

IMAGING

General Features

- Best diagnostic clue
  - Thin, acute subdural hematoma (aSDH)
  - Disproportionate mass effect
    - More midline shift than can be attributed to aSDH
    - Swelling of ipsilateral cerebral hemisphere
  - Brain swelling may be sudden, catastrophic

CT Findings

- NECT
  - Small, thin aSDH (usually ≤ 0.5 cm)
    - Crescent-shaped, hyper- or mixed-density aSDH
      - May have hypodense foci if actively bleeding
  - Mass effect disproportionate to size of aSDH
    - Degree of midline (subfalcine) shift more than accounted for by thickness of aSDH
  - Swollen, hypodense cerebral hemisphere under aSDH
    - Underlying sulci compressed, then obliterated
    - Gray-white matter initially preserved
    - Unilateral (uncal) descending transtentorial herniation
  - Progressive brain swelling → basal cisterns effaced
    - Complete central herniation
    - Midbrain distorted, compressed inferiorly

MR Findings

- T1WI
  - aSDH iso-/mixed intensity
  - Underlying cortex swollen, hypointense
- T2WI
  - Gyri swollen, hyperintense
  - Underlying sulci compressed
- FLAIR
  - Cortex hyperintense
- T2* GRE
  - Usually negative for intraparenchymal hemorrhage
- DWI
  - Gyri show restricted diffusion
- MRS
  - Decreased NAA

Imaging Recommendations

- Best imaging tool
  - NECT as initial screening
- Protocol advice
  - MR with T2*, DWI

DIFFERENTIAL DIAGNOSIS

Acute Subdural Hematoma (Without Underlying Dysautoregulation)

- Mass effect, midline shift proportionate to width of aSDH
- Usually no history of repetitive head injury

Nonaccidental Trauma (Child Abuse)

- Repeated injuries with mixed acute, subacute SDHs
- If underlying brain swelling is disproportionate to SDH size
  - Swelling of subjacent brain may be sudden, catastrophic
  - May represent a type of SIS with dysautoregulation

PATHOLOGY

General Features

- Etiology
  - Previous head injury opens "window of vulnerability"
    - If second injury (impact) before brain heals completely, SIS may result
  - Loss of autoregulation of CBF → vascular engorgement → ↑ ICP → brain herniation
    - May represent excitotoxic brain injury with increased release, leakage, or decreased reuptake of glutamate

Gross Pathologic & Surgical Features

- Thin subdural hematoma
- Underlying brain swollen, hyperemic
  - ± secondary infarcts
  - ± uncal, central, tonsillar herniations

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Severe headache
  - Vomiting
  - Variable consciousness
  - May have dramatic, sudden collapse, coma

Demographics

- Most common: Adolescent males involved in high-impact sports
- Other
  - Abused infants
  - Elderly patients with repeated falls, head impacts

Natural History & Prognosis

- Generally poor

KEY FACTS

TERMINOLOGY

- Dissection
  - Intramural hematoma extends along vessel wall
- Dissecting aneurysm
  - Dissection + aneurysmal dilation contained by adventitia
- Pseudoaneurysm
  - Lumen contained by thrombus outside vessel wall

IMAGING

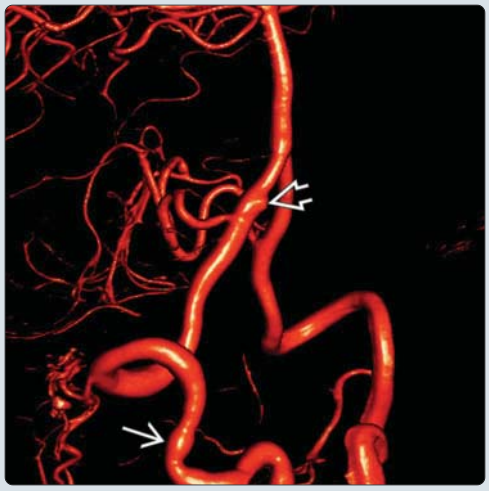
- Location
  - Often adjacent to falx, skull, tentorium, or region of significant motion
  - Posterior circulation most common
    - Vertebral arteries most common site (72%)
    - Extension into basilar artery rare
  - Anterior circulation uncommon
    - Supraclinoid internal carotid artery
    - Distal, more peripheral (A2, M2, P2, and beyond) where vessel contacts dura or skull
- NECT: Basal subarachnoid hemorrhage
  - Looks like aneurysmal SAH
  - In unusual locations, more extensive than tSAH
- MR: Hyperintense hematoma + central "flow void"
  - "Target" or "crescent" sign
- CTA/MRA/DSA
  - Enlarged vessel due to dissecting aneurysm or mural thrombus
  - Long segment narrowing or tapered occlusion
  - Intraluminal flap (± on DSA/MRA; best seen on DSA)
  - ± dissecting aneurysm (irregular, wide-neck; at side wall, usually not at vessel bifurcations)

TOP DIFFERENTIAL DIAGNOSES

- Atherosclerosis
- Vasospasm
- Vasculitis
- Fibromuscular dysplasia (FMD)

(Left) *Axial NECT scan in a 29-year-old female involved in a high-speed MVA shows SAH ⇨ surrounding the lower medulla.* **(Right)** *More cephalad NECT scan in the same patient shows extensive SAH filling the basal cisterns, outlining the midbrain. Note the enlargement of the temporal horns ⇨ indicating early extraventricular obstructive hydrocephalus.*

(Left) *Slightly oblique lateral DSA in the same patient shows focal fusiform enlargement of the left vertebral artery ⇨ suggesting a dissecting pseudoaneurysm may be the etiology for the subarachnoid hemorrhage.* **(Right)** *Oblique 3D color shaded surface display in the same patient shows the focal right dissecting aneurysm ⇨ as well as a 2nd dissecting aneurysm along the distal right vertebral artery ⇨. The patient had a cardiac arrest after the DSA and expired.*



https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Traumatic dissection and pseudoaneurysm

Definitions

- Dissection: Intramural hematoma extends along vessel wall
- Intimal extension
  - Intimal flap
  - True and false lumen
- Arterial transection
  - Extension through adventitia
- Dissecting aneurysm: Aneurysmal dilation of vessel due to dissection, contained only by adventitia
  - Hematoma between media/adventitia common
- Pseudoaneurysm: Lumen contained only by thrombus outside vessel wall

IMAGING

General Features

- Best diagnostic clue
  - NECT: Basal extensive subarachnoid hemorrhage (SAH) mimics aneurysmal SAH, but often more extensive than traumatic SAH or in unusual locations
  - MR: Hyperintense crescent in vessel wall with central or eccentric flow void on axial T1WI and T2WI ("target" or "crescent" sign)
    - Subarachnoid hyperintensity on FLAIR due to hemorrhage
    - Enlarged vessel due to dissecting aneurysm or mural thrombus
  - MRA, CTA, DSA
    - Long segment narrowing or tapered occlusion
    - Intraluminal flap on MRA/CTA source images
    - ± irregular, eccentric side wall dissecting aneurysm
      - Usually not at bifurcation
- Location
  - Often occurs at contact points with falx, skull, tentorium, or at region of significant motion
  - Posterior circulation most common
    - Vertebral arteries most common (72%)
    - Posterior inferior cerebellar artery (PICA) occurs, but less common
    - Extension into basilar artery rare
  - Anterior circulation uncommon
    - Supraclinoid internal carotid artery
    - Otherwise, more peripheral (A2, M2, P2, and beyond)
      - Usually where vessel contacts dura or skull
- Morphology
  - Tapered stenosis with occlusion
  - Irregular vessel narrowing
  - Fusiform irregular dilatation or focal dissecting aneurysm
  - Intimal flap and double (true and false) lumen
  - Intramural hematoma

CT Findings

- NECT
  - Basal SAH mimics aneurysmal SAH but is more extensive than typical traumatic SAH
    - Atypical SAH located in upper interhemispheric fissure, along tentorium
  - Acute embolic infarct
    - Hypodensity in vascular distribution
    - Hemorrhagic conversion, gyral hyperdensity
  - Basal skull fracture in some cases
- CTA
  - Tapered narrowing &/or occlusion
  - False lumen and flap visible in minority of cases
  - CTA source images show intraluminal flap and vessel wall thickening
  - Irregular dissecting aneurysm: Fusiform or wide-neck

MR Findings

- T1WI
  - Acute thrombus within vessel may be hypointense on T1WI
  - Subacute = hyperintense crescentic intramural hematoma
  - Absent or decreased flow void
- T2WI
  - "Target" or "crescent" sign: Central or eccentric intraluminal flow void surrounded by hyperintense dot in vessel wall
  - Acute infarct hyperintense
    - ± hemorrhagic conversion (hypointense on T2WI, T2*)
- FLAIR
  - Hyperintense CSF: SAH
  - Hyperintense acute infarct
- DWI
  - Hyperintensity in acute infarct
- MRA
  - Amorphous mild hyperintensity in wall of vessel (intramural hematoma) partially surrounds more marked flow-related hyperintensity but may obscure detail
    - PC MRA may better characterize lumen
  - Decreased flow may be manifested by decreased caliber and intensity of lumen of vessels distal to dissection, especially on 3D TOF

Angiographic Findings

- Conventional
  - Tapered narrowing or occlusion
  - Irregular lumen or intimal flap
  - Focal aneurysmal dilatation is usually wide-neck, irregular, triangular in shape, occurring in unusual locations
  - Embolic occlusion of distal branches

Imaging Recommendations

- Best imaging tool: MR and MRA
- Protocol advice
  - Initial NECT important to assess for SAH
  - MR/MRA → CTA if MRA equivocal
  - Conventional angiography indicated when clinical suspicion is high, but MR/MRA is negative, &/or for therapeutic intervention

https://CafePezeshki.IR

DIFFERENTIAL DIAGNOSIS

Atherosclerosis

- Luminal irregularity and stenosis most marked in cavernous carotid artery, vertebral and basilar arteries
  - No aneurysmal dilatation
- Focal and eccentric when involves pial branches
- Mural calcification on NECT, CTA, or MRA source images

Vasospasm

- Smooth narrowing usually centered at vessel bifurcation
- Most severe where SAH is greatest
- No aneurysmal dilatations

Vasculitis

- Short or long segment smooth narrowing not centered on vessel bifurcations
- Regions of narrowing alternate with normal vessel lumen or mild aneurysmal dilatation
- Isolated aneurysmal dilatation less common

Fibromuscular Dysplasia (FMD)

- Rarely intracranial, virtually always in association with extracranial involvement
  - Internal carotid artery opposite C2 in 2/3 of cases
- Alternating zones of focal narrowing and aneurysmal dilatation
  - Corrugated pipe appearance
- Long segment stenosis or aneurysmal dilatation
- May be cause of spontaneous dissection
  - Visualization of vessel wall on MR needed to differentiate between FMD and dissection ± FMD
  - FMD produces focal vessel wall thickening without hemorrhage or calcification

Spontaneous (Nontraumatic) Basal SAH

- Ruptured aneurysm
- Benign perimesencephalic SAH

PATHOLOGY

General Features

- Etiology
  - Skull base fracture
  - Direct injury to intracranial vessel from contact with falx, tentorium, skull
  - Vulnerability of intracranial vertebral artery to longitudinal extension
    - Stretching from hyperextension or rotational neck movement
  - Shearing type injury at motion segments: Supraclinoid ICA, MCAs
  - Minor injury often overlooked in history
- Associated abnormalities
  - Fibromuscular dysplasia, arterial fenestrations
  - Collagen disorders, rheumatoid arthritis
  - Metabolic/genetic disorders: Angiolipomatosis, Marfan, α-1-antitrypsin deficiency

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, obtundation, CN3 palsy

Demographics

- Epidemiology
  - 1.5-10% of SAH

Natural History & Prognosis

- If vessel patent, may resolve spontaneously
- Acute emboli is common complication in acute phase
- Rupture is very common with dissecting aneurysm or pseudoaneurysm

Treatment

- Anticoagulation to prevent progressive thrombosis and embolization with distal infarction
- Angioplasty and stent treatment for severely stenotic lesion
- Endovascular occlusion usually of parent vessel or stent/coils or stent graft without adequate collaterals
- Surgical occlusion, wrapping, or bypass

DIAGNOSTIC CHECKLIST

Consider

- Dissection when young patient presents with acute "spontaneous" infarction
  - Inquire about mild trauma or falls in 24 hours prior to onset of symptoms
- Dissecting aneurysm at unusual locations: Pericallosal, distal MCA, distal PCA, not at branch points

Image Interpretation Pearls

- Look for "target" sign in internal carotid or vertebral artery on images at or just below skull base

KEY FACTS

TERMINOLOGY

- Direct carotid cavernous fistula (CCF), high-flow CCF
- Single-hole tear/transection of cavernous internal carotid artery (ICA) with arteriovenous shunt into cavernous sinus (CS)

IMAGING

- General features
  - Proptosis, dilated superior ophthalmic vein (SOV) and CS, extraocular muscle (EOM) enlargement
  - Skull base fracture involving sphenoid bone/carotid canal ↑ likelihood of ICA injury
- MRA: ↑ flow-related signal in CS and SOV
- CT/CTA may be suggestive; should proceed to DSA to confirm and treat
- DSA is definitive
  - Early filling of CS + outflow pathways including retrograde filling of SOV, angular + facial veins
  - Reduced or absent antegrade flow in ICA beyond fistula, depending on size of ICA tear

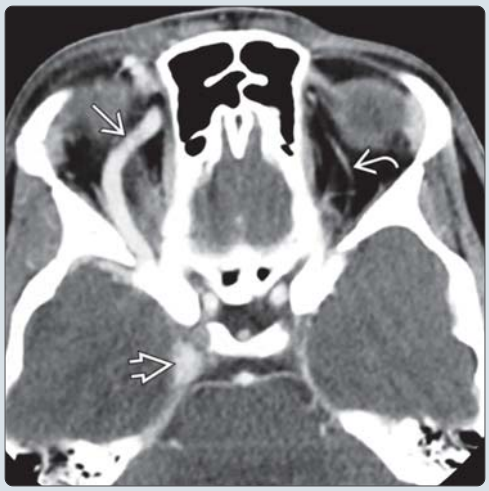
TOP DIFFERENTIAL DIAGNOSES

- Indirect CCF
  - Low-flow CCF, CS dural arteriovenous fistula (dAVF)

CLINICAL ISSUES

- Bruit, pulsating exophthalmos, orbital edema/erythema, ↓ vision, glaucoma, headache
- Hemispheric ischemia if ↓ flow in ICA beyond CCF
- Focal deficits → cranial nerves 3-6
- Endovascular treatment options include
  - Transarterial-transfistula balloon embolization
  - Transvenous embolization
  - Pipeline/covered stent placement
  - ICA sacrifice

(Left) *Coronal graphic depicts a carotid cavernous fistula (CCF). The right cavernous sinus ⇨ is enlarged by numerous dilated arterial and venous channels.* **(Right)** *CECT scan shows classic findings of CCF. The right cavernous sinus ⇨ is enlarged and the ipsilateral superior ophthalmic vein ⇨ is more than 4x the size of the left superior ophthalmic vein ⇨.*



(Left) *T2WI shows typical MR findings of CCF with an enlarged right cavernous sinus ⇨ containing numerous abnormal "flow voids" ⇨.* **(Right)** *Lateral DSA in CCF shows opacification of the cavernous sinus in the arterial phase. Also outlined are many of the venous outflow pathways of the cavernous sinus, including the superior ophthalmic veins ⇨, superior and inferior petrosal sinuses ⇨, and pterygoid and pharyngeal venous plexi ⇨.*

TERMINOLOGY

Abbreviations

- Carotid cavernous fistula (CCF)

Synonyms

- Direct CCF, high-flow CCF

Definitions

- Single-hole tear/transection of cavernous internal carotid artery (ICA) with arteriovenous shunt into cavernous sinus (CS)

IMAGING

General Features

- Best diagnostic clue
  - Proptosis, dilated superior ophthalmic vein (SOV) and CS, extraocular muscle (EOM) enlargement

CT Findings

- NECT
  - Skull base fracture involving sphenoid bone/carotid canal ↑ likelihood of ICA injury
  - Proptosis, enlarged SOV, CS, and EOMs
    - "Dirty" orbital fat secondary to edema
  - Subarachnoid hemorrhage (SAH) from associated trauma or arterialized flow into cortical veins
- CECT
  - Dilated SOV and CS
  - ↑ enhancement of EOMs, patchy enhancement of intraorbital fat

MR Findings

- T1WI C+
  - Same as CECT
- MRA
  - ↑ flow-related signal in CS and SOV
  - Signal loss in ICA secondary to turbulent flow

Ultrasonographic Findings

- Doppler: Reversal of flow in dilated SOV (intra- to extracranial)

Angiographic Findings

- Conventional
  - Early filling of CS + outflow pathways including
    - Retrograde filling of SOV, angular + facial veins
    - Contralateral CS
    - Petrosal sinuses → internal jugular vein(s)
  - Reduced or absent antegrade flow in ICA beyond fistula depending on size of ICA tear

Imaging Recommendations

- Best imaging tool
  - DSA is definitive
  - CT/CTA may be suggestive: Should proceed to DSA to confirm and treat
- Protocol advice
  - DSA: Magnification, high frame rate to visualize exact site of shunt
  - CTA: Thin-section scans with reformations

DIFFERENTIAL DIAGNOSIS

Indirect CCF

- a.k.a. low-flow CCF, CS dural arteriovenous fistula (dAVF)

EOM Enlargement

- Graves ophthalmopathy
- Inflammatory pseudotumor, neoplasm

PATHOLOGY

General Features

- Etiology
  - Skull base fracture with bony fragment injuring ICA
  - Stretch injury of vessel wall between fixed points at foramen lacerum and anterior clinoid process
- Associated abnormalities
  - Arterialized flow in CS with retrograde venous reflux
    - Superior/inferior ophthalmic veins → proptosis, chemosis, ↑ intraocular pressure → ↓ retinal perfusion pressure → blindness
    - Cortical veins → increased SAH risk
  - Reduced antegrade flow in ICA beyond fistula → hemispheric ischemia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - May present days to weeks post trauma
  - Bruit, pulsating exophthalmos, orbital edema/erythema, ↓ vision, glaucoma, headache
  - Hemispheric ischemia if ↓ flow in ICA beyond CCF
  - Severe/rapid vision loss, SAH → emergency
  - Focal deficits → cranial nerves 3-6

Natural History & Prognosis

- Endovascular options include
  - Transarterial-transfistula detachable balloon embolization
  - Transvenous embolization
  - Pipeline stent across ICA tear
  - ICA sacrifice with coils or detachable balloons (if patient tolerates lack of antegrade flow beyond fistula or passes balloon test occlusion)

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Enlarged SOV and CS, proptosis, intraorbital edema

Reporting Tips

- CT/MR may be suggestive, but DSA is required for definitive diagnosis and treatment

KEY FACTS

TERMINOLOGY

- Definition
  - Neurodegenerative disease 2º to repetitive concussive/subconcussive head injuries
- Abbreviations
  - Chronic traumatic encephalopathy (CTE)
- Synonyms
  - Dementia pugilistica ("punch-drunk")
  - Postconcussion syndrome

IMAGING

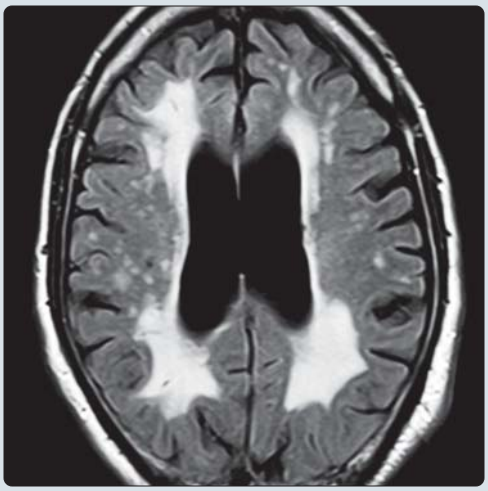
- MR
  - Age-inappropriate volume loss
    - Voxel-based morphometry shows disproportionate involvement of medial temporal lobes
  - Nonspecific T2/FLAIR punctate, confluent hyperintensities in deep, periventricular WM
  - DTI shows reduced FA, increased MD with loss of WM integrity
    - Uncinate and superior/inferior longitudinal fasciculi
  - T2* shows microbleeds in ~ 10%
- PET
  - Temporoparietal hypometabolism on FDG-PET
  - PET imaging ligands for phosphorylated tau may be in vivo biomarker

PATHOLOGY

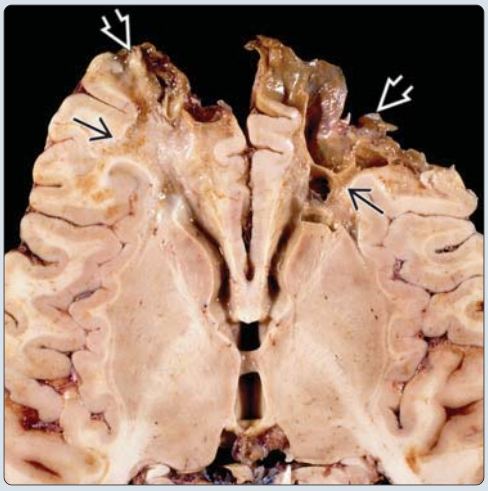
- Etiology
  - Repetitive head trauma
  - Contact sports (football, soccer, hockey, boxing, wrestling, mixed martial arts, etc.)
  - Battlefield exposure to blast waves generated by IEDs
- Gross: Likened to octogenarian Alzheimer patient
- Microscopic: Neurofibrillary tangles, Aβ plaques

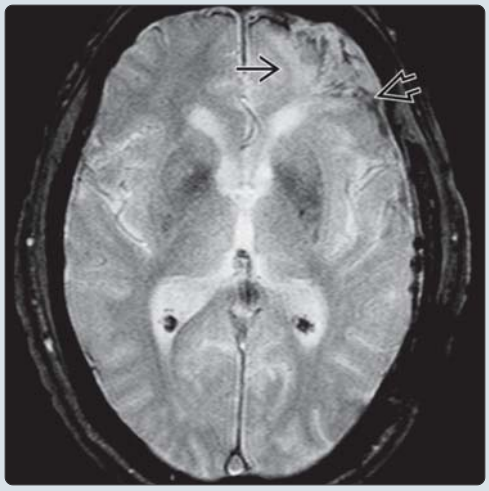
CLINICAL ISSUES

- Cognitive dysfunction, memory loss
- Variable mood, personality, behavior disorders



(Left) *Axial FLAIR scan in a middle-aged former professional athlete with early-onset dementia shows diffuse bihemispheric volume loss with extensive confluent and punctate hyperintensities in the subcortical and deep cerebral white matter (WM).* **(Right)** *Axial T2* SWI scan in the same patient shows numerous punctate "blooming" foci in the subcortical and deep WM ⇨, consistent with microbleeds in this case of clinically diagnosed chronic traumatic encephalopathy (CTE).*





(Left) *Autopsy in a patient who survived a single episode of severe head injury shows remote effects of head trauma. Note the bifrontal encephalomalacia ⇨ and extensive gliosis in the subcortical WM ⇨. Note absence of microbleeds.* **(Right)** *Axial T2* GRE in an elderly patient with a single episode of moderate head trauma shows left frontal encephalomalacia and gliosis ⇨ with superficial siderosis of the adjacent cortex ⇨. Note the absence of microbleeds in this case.*

TERMINOLOGY

Abbreviations

- Chronic traumatic encephalopathy (CTE)

Synonyms

- Dementia pugilistica
  - Old term originally applied to boxer's dementia
- "Punch-drunk" syndrome
- Postconcussion syndrome

Definitions

- Neurodegenerative disease induced by repetitive concussive and subconcussive head injuries

IMAGING

General Features

- Best diagnostic clue
  - Variable age-inappropriate volume loss
    - Ventricular volume ↑
    - Progressive, continues beyond initial injury
  - Findings resemble Alzheimer dementia
- Location
  - Generalized atrophy but especially medial temporal lobes (hippocampus, amygdala, uncus)

CT Findings

- Volume loss with increased ventricle to brain ratio

MR Findings

- T1WI
  - Age-inappropriate volume loss
    - Generalized increase in ventricles, sulci
  - Voxel-based morphometry shows disproportionate involvement of medial temporal lobes
- T2WI
  - Nonspecific punctate, confluent hyperintensities in deep, periventricular WM
- FLAIR
  - Nonspecific punctate, confluent hyperintensities in deep, periventricular WM
- T2* GRE
  - Microbleeds in ~ 10% of CTE cases
  - SWI shows susceptibility foci in subcortical, deep WM
- DWI
  - Reduced FA, increased MD with loss of WM integrity
    - Uncinate and superior/inferior longitudinal fasciculi
    - Fornix
    - Cingulum
    - Hippocampus

Nuclear Medicine Findings

- Temporoparietal hypometabolism in PET
- May show signs of persistent chronic neuroinflammation
- PET imaging ligands for phosphorylated tau may be in vivo biomarker

Imaging Recommendations

- Best imaging tool
  - 3T MR with SWI, voxel-based morphometry

DIFFERENTIAL DIAGNOSIS

Normal Aging Brain

- Mild increase in ventricle to brain ratio
- Generalized volume loss (not disproportionate medial temporal lobes)
- Few to no "blooming black dots" on T2* (GRE or SWI)

Alzheimer Disease

- Both AD, CTE show accumulation of tau aggregates
  - CTE more superficial cortical layers, around deep sulci
- May be indistinguishable from CTE on standard imaging studies

PATHOLOGY

General Features

- Etiology
  - Repetitive head trauma
    - Contact sports (football, soccer, hockey, boxing, wrestling, mixed martial arts, etc.)
    - Battlefield exposure to blast waves generated by IEDs
  - Tauopathy
    - Coexisting Aβ pathology common
  - Long-term sequelae
    - Excitotoxicity
    - Apoptosis
    - Inflammation
    - Demyelination and WM pathology

Gross Pathologic & Surgical Features

- Likened to octogenarian Alzheimer patient
- Frontotemporal volume loss
  - Associational neocortex involvement common
- Cavum septi pellucidi often torn or septated

Microscopic Features

- Neurofibrillary tangles
- Aβ plaques
- Diffuse neuronal loss

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Cognitive dysfunction, memory loss
  - Impaired executive function
  - Variable mood, personality, behavior disorders
  - Paranoia, panic attacks

Subarachnoid Hemorrhage

Overview: The subarachnoid spaces (SASs) are CSF-filled spaces between the arachnoid (on the outside) and the pia (on the inside). Focal expansions of the SASs at the base of the brain and around the brainstem, tentorial incisura, and foramen magnum form the brain cisterns.

The SASs are anatomically unique as they surround the entire brain, spinal cord, and spinal nerve roots and contain all the major brain arteries and cortical veins.

Acute extravasation of blood into the CSF spaces between the arachnoid membrane and pia can be caused by arterial leaks or torn veins. Blood can also extend into the SASs from parenchymal hemorrhage that ruptures through the cortex and pia, spilling into the adjacent SAS.

Trauma, "burst" aneurysm, vascular malformations, and amyloid angiopathy are potential causes of subarachnoid hemorrhage (SAH). The most common cause of SAH is trauma. Traumatic subarachnoid hemorrhage (tSAH) occurs when hemorrhage from contused brain or lacerated cortical vessels extends into sulci adjacent to the injury.

Aneurysmal subarachnoid hemorrhage (aSAH): nontraumatic "spontaneous" SAH represents about 5% of all acute "strokes." The most common cause of nontraumatic SAH is a ruptured intracranial saccular ("berry") aneurysm (aSAH). Because most saccular aneurysms are located either on the circle of Willis or at the middle cerebral artery bifurcation, the most common locations for aSAH are the suprasellar cistern and sylvian fissures.

Aneurysmal SAH can be focal or diffuse. Attempts to determine the precise anatomic location of a suspected intracranial aneurysm based on the distribution of SAH are necessarily imprecise. Anterior interhemispheric aSAH is typically associated with rupture of a superiorly directed ACoA aneurysm. aSAH seen primarily in the posterior fossa cisterns &/or 4th ventricle suggests a PICA aneurysm. MCA bi- or trifurcation aneurysm may cause focal hemorrhage in the adjacent sylvian fissure.

Perimesencephalic nonaneurysmal subarachnoid hemorrhage (pnSAH): An uncommon but important cause of SAH, pnSAH is a clinically benign variant that is probably venous in origin. pnSAH is confined to the cisterns around the midbrain and anterior to the pons.

Convexal subarachnoid hemorrhage (cSAH): An uncommon subset of nontraumatic SAH occurs over the dorsolateral surface ("convexity") of the cerebral hemispheres. The basal and perimesencephalic cisterns are typically spared. cSAH typically affects just one sulcus or a grouping of adjacent sulci. Common etiologies in older adults are amyloid angiopathy or vasculitis while vasculitis and reversible cerebral vasoconstriction syndrome are common causes in patients < 60 years old. Cortical vein occlusion with cSAH occurs at all ages.

Superficial siderosis (SS): Chronic, recurrent SAH results in hemosiderin deposition on the pia and cranial nerves. The brain, brainstem, cerebellum, and spinal cord can all be affected, although the posterior fossa is most commonly involved.

The classic clinical presentation of SS is in an adult with a history of trauma or surgery, who presents with ataxia and bilateral sensorineural hearing loss. A history of aSAH is uncommon. SS is best identified on T2* (GRE or SWI).

Aneurysms and Arterial Ectasias

Terminology and overview: The word "aneurysm" comes from the combination of 2 Greek words meaning "across" and "broad." Hence, brain arterial aneurysms are widenings or dilatations of intracranial arteries.

Intracranial aneurysms are generally classified by their phenotypic appearance. Saccular or "berry" aneurysms are the most common type. Fusiform aneurysms are focal dilatations that involve the entire circumference of a vessel and extend for relatively short distances. Ectasias refer to generalized arterial enlargement without focal dilatation and are not true aneurysms.

Saccular aneurysm: As the name implies, saccular aneurysms (SAs) are focal sac- or berry-like arterial dilatations. The vast majority are acquired lesions, the result of an underlying genetically based susceptibility plus superimposed mechanical stresses on vessel walls. SAs lack the 2 strongest layers of blood vessel walls, the internal elastic lamina and the muscular layer. The aneurysm sac itself consists of only intima and adventitia.

Most SAs arise at major blood vessel bifurcations, where hemodynamic stresses are highest. The vast majority of intracranial aneurysms are located on the circle of Willis plus the middle cerebral artery bi- or trifurcation. 90% are "anterior circulation" aneurysms, i.e., on the internal carotid artery and its branches. The posterior communicating artery is considered part of the anterior circulation; the vertebrobasilar artery and branches constitute the "posterior circulation."

Pseudoaneurysm: Pseudoaneurysms (PAs) are focal arterial dilatations not contained by layers of the normal arterial wall. They are often irregularly shaped and generally arise on vessels distal to the circle of Willis.

A pseudoaneurysm develops when a completely disrupted blood vessel hemorrhages. A paravascular hematoma forms and then cavitates, establishing a communication with the parent vessel wall. The wall of a PA thus consists only of organized clot. Pseudoaneurysms are much less common than either SAs or fusiform aneurysms. PAs are acquired lesions caused by trauma, infection or inflammation ("mycotic" aneurysm), drug abuse, and neoplasm ("oncotic" aneurysm).

Blood blister-like aneurysm: Blood blister-like aneurysms (BBAs) are eccentric hemispherical outpouchings that can develop at any location. Most commonly found on the greater curvature of the supraclinoid internal carotid artery, they are lined only by a thin layer of adventitia. They are difficult to detect, difficult to treat, and prone to rupture at smaller size and younger age than typical saccular aneurysms.

Fusiform aneurysms: Fusiform aneurysms can be atherosclerotic (common) or nonatherosclerotic (rare). They involve long, nonbranching vessel segments and are seen as more focal circumferential outpouchings from an ectatic vessel. Fusiform aneurysms are more common in the vertebrobasilar (posterior) circulation.

Vertebrobasilar dolichoectasia: Fusiform enlargement or ectasia, also called arteriectasis, is commonly seen in patients with advanced atherosclerotic disease. Less commonly, fusiform ectasias occur with collagen-vascular disorders and non-ASVD arteriopathies.

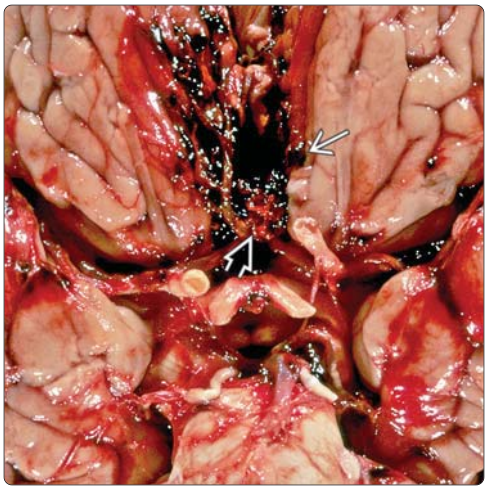
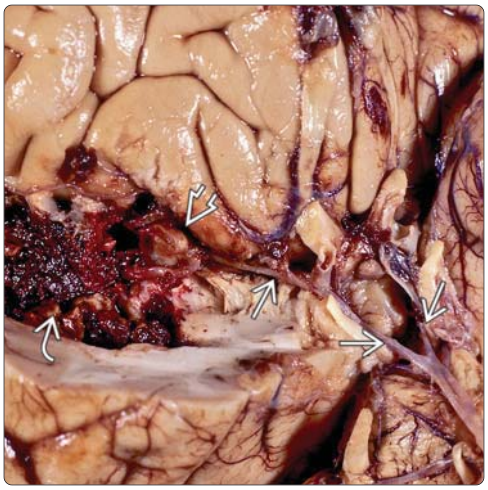
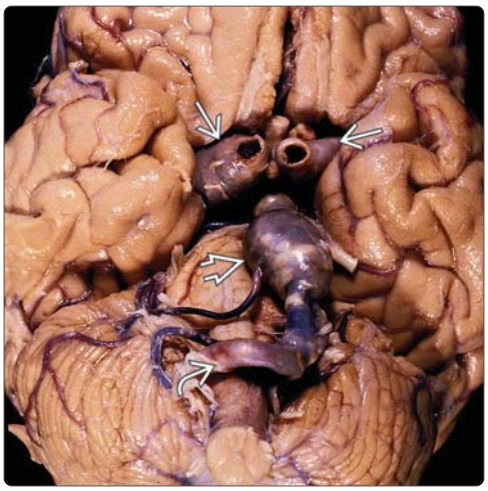
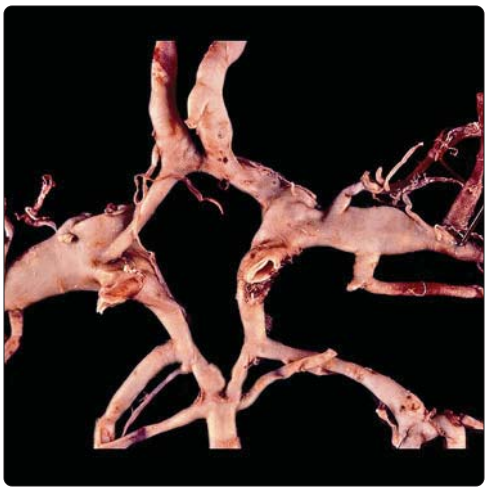
(Left) *Diagram depicts the circle of Willis with relative prevalence of intracranial saccular aneurysms. Most are "anterior circulation" with 1/3 occurring on the ACoA ⇨ and 1/3 at the internal carotid/PCoA junction ⇨. 15-20% are found at the MCA bi- or trifurcation ⇨. Only 10% occur on the "posterior circulation."* **(Right)** *Circle of Willis dissected from an autopsied brain shows a classic unruptured IC-PCoA saccular aneurysm ⇨. (Courtesy B. Horten, MD.)*





(Left) *Autopsied brain shows a small ruptured ACoA aneurysm ⇨ with extensive focal clot in the interhemispheric fissure ⇨. Diffuse SAH is also present. (Courtesy B. Horten, MD.)* **(Right)** *This patient died of cerebral ischemia several days after rupture of a saccular MCA aneurysm ⇨, which is surrounded by clot in the sylvian fissure ⇨. Note the extreme narrowing of the M1 MCA segment and both posterior cerebral arteries, indicative of severe vasospasm ⇨. (Courtesy R. Hewlett, MD.)*





(Left) *Gross pathology shows atherosclerotic fusiform ectasias of the vertebrobasilar system ⇨, as well as both internal carotid arteries and M1 MCA segments ⇨. Focal enlargement of the basilar artery represents a fusiform aneurysm ⇨ caused by ASVD. (Courtesy R. Hewlett, MD.)* **(Right)** *Nonatherosclerotic fusiform ectasias of the M1, A1, A2, and PCoAs are seen in a patient with HIV-associated vasculopathy. (Courtesy L. Rourke, MD.)*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- SAH caused by ruptured aneurysm (aSAH)
  - Saccular (SA) > > dissecting aneurysm (DA)

IMAGING

- CT/CTA
  - Hyperdense sulci on NECT
  - Distribution varies with aneurysm location
  - Suprasellar cistern (IC-PCoA, ACoA aneurysms)
  - Sylvian fissure (middle cerebral artery [MCA] bifurcation)
  - Prepontine, CPA cisterns (posterior inferior cerebellar artery [PICA], BA bifurcation SA or vertebral DA)
  - CTA 90-95% positive if aneurysm ≥ 2 mm
- MR/MRA
  - FLAIR hyperintense sulci, cisterns (nonspecific)
  - "Blooms" on T2* GRE
  - TOF MRA 85-95% sensitive for aneurysms ≥ 3 mm
- DSA
  - Used if CTA negative
  - If endovascular treatment is option

TOP DIFFERENTIAL DIAGNOSES

- Nonaneurysmal SAH
- "Pseudo-SAH"
- Reversible cerebral vasoconstriction syndrome (RCVS)

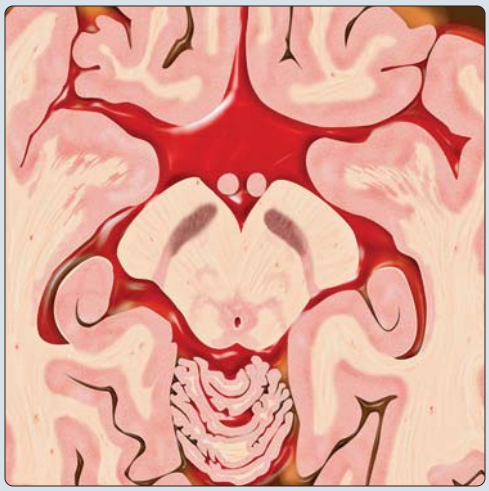
CLINICAL ISSUES

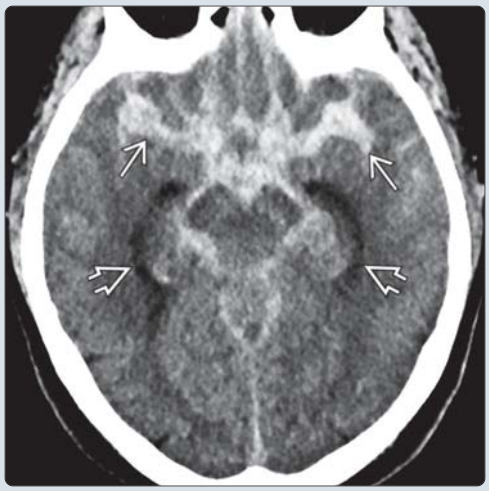
- Sudden onset severe headache
  - "Thunderclap/worst headache of life"
- 50% mortality
  - Vasospasm 1-3 weeks post aSAH
- 20% rebleed within 1st 2 weeks
- Treatment
  - Coil embolization ("coiling") generally > clipping

DIAGNOSTIC CHECKLIST

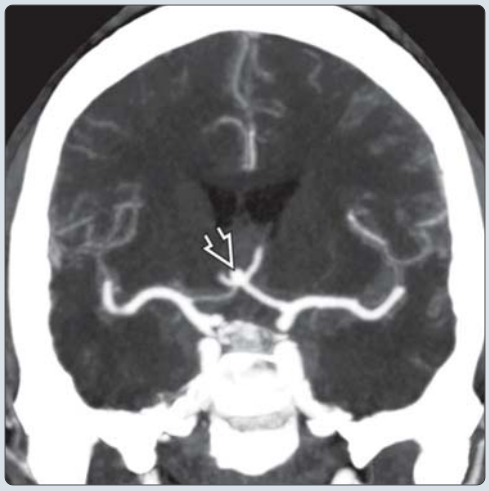
- Diffuse low-density brain makes normal arteries look hyperdense, can mimic aSAH

(Left) *Axial graphic through the midbrain depicts SAH in red throughout the basal cisterns. Given the diffuse distribution of SAH without focal hematoma, statistically the most likely location of the ruptured aneurysm is the ACoA.* **(Right)** *Axial NECT scan in a 63-year-old man found down in a parking lot shows diffuse SAH ➡ throughout the basal cisterns. Note the enlargement of both temporal horns of the lateral ventricles ➡ consistent with early extraventricular obstructive hydrocephalus.*





(Left) *Coronal MIP image of the CTA obtained in the same patient shows a saccular aneurysm ➡ projecting superiorly from the anterior communicating artery.* **(Right)** *Coronal shaded surface display of the DSA obtained in the same patient nicely demonstrates the "culprit" aneurysm ➡. The lesion was successfully coiled after this diagnostic DSA was performed.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Aneurysmal subarachnoid hemorrhage (aSAH)

Definitions

- Extravasation of blood into subarachnoid space
  - Usually from ruptured saccular aneurysm
  - Less common: Intracranial dissection, dissecting aneurysm

IMAGING

General Features

- Best diagnostic clue
  - Hyperdense basal cisterns, sulci on NECT
- Location
  - Suprasellar, basal, sylvian, interhemispheric cisterns
    - ± intraventricular hemorrhage (IVH)
  - aSAH distribution depends on location of saccular aneurysm (SA)
    - aSAH highest near site of rupture
      - Anterior communicating artery (ACoA) aneurysm → anterior interhemispheric fissure
      - Middle cerebral artery (MCA) aneurysm → sylvian fissure
      - Basilar tip, superior cerebellar artery (SCA), posterior inferior cerebellar artery (PICA) SA, or vertebral artery (VA) dissecting aneurysm (DA) → prepontine cistern, foramen magnum, 4th ventricle
    - "Culprit" aneurysm sometimes seen as filling defect within hyperdense aSAH
  - SAs typically located at bifurcation points along intradural ICA, circle of Willis (COW), MCA
    - 90% located on anterior circulation: ACoA, posterior communicating artery (PCoA), MCA, carotid terminus, carotid-ophthalmic, superior hypophyseal
    - 10% on posterior circulation: Basilar tip, PICA, anterior inferior cerebellar artery (AICA), SCA
  - DAs: Intradural V4 VA segment most common
  - Blood blister aneurysm (BBA)
    - Dorsal supraclinoid ICA
    - Rarely MCA, basilar artery

CT Findings

- NECT
  - 95% positive in first 24 hours, < 50% by 1 week
  - "Effaced" sylvian fissure if subacute, filled with isodense SAH
  - Hydrocephalus common, may occur early
  - ± intraparenchymal hemorrhage at site of ruptured aneurysm
- CTA
  - 90-95% positive if aneurysm ≥ 2 mm

MR Findings

- T1WI
  - Acute aSAH is isointense to CSF
  - CSF may appear mildly hyperintense ("dirty")
- T2WI
  - Difficult to see on T2WI (hyperintense)
- FLAIR
  - Hyperintense
    - More sensitive than CT but less specific
- T2* GRE
  - Striking sulcal "blooming"
- DWI
  - May see foci of restricted diffusion if vasospasm
- MRA
  - TOF MRA 85-95% sensitive for aneurysms ≥ 3 mm

Angiographic Findings

- CTA has high sensitivity, specificity for detecting ruptured aneurysm(s)
  - Best in initial diagnosis of SAH, patient triage
- Conventional 4-vessel angiogram still gold standard
  - Must image
    - Both ICA circulations
    - Both VAs or dominant VA + reflux to contralateral PICA
  - SA
    - Saccular outpouching at arterial branch point
    - Look for Murphy teat = site of rupture
    - Look for additional aneurysms (20% multiple)
      - If > 1 aneurysm, then biggest, most irregular ± adjacent vasospasm is likely source of bleed
  - DA
    - Irregular ± dilated or stenotic V4 segment of VA
  - BBA
    - Smooth/irregular bleb/dome-shaped outpouching
    - Not associated with major vessel branch point
    - Most common along supraclinoid ICA
  - DSA negative in 15% of aSAH; repeat positive < 5%
    - Evaluate ECAs (to exclude dural AV fistula [dAVF])
    - SA may not be seen on initial DSA if optimal projection not obtained, spontaneous partial or complete aneurysm thrombosis, &/or presence of vasospasm
    - Consider repeating DSA in 5-7 days

Imaging Recommendations

- Best imaging tool
  - NECT + multiplanar CTA
- Protocol advice
  - Proceed to DSA if NECT consistent with aSAH but CTA negative
  - Consider MR if DSA + CTA negative
  - Likelihood of aneurysm in patient who is CT negative, LP positive, CTA negative is low

DIFFERENTIAL DIAGNOSIS

Nonaneurysmal SAH

- Perimesencephalic SAH
  - Small SAH, localized to interpeduncular cistern
  - Presumed venous etiology with low recurrence rate
- Traumatic subarachnoid hemorrhage
  - Adjacent to contusions, subdural hematomas
  - Rarely from intracranial dissection or rupture of traumatic pseudoaneurysm
- Subarachnoid hemorrhage, NOS
  - Vascular malformation: Arteriovenous malformation (AVM), cavernous hemangioma

https://CafePezeshki.IR

Reversible Cerebral Vasoconstriction Syndrome (RCVS)

- Clinical: "Thunderclap" headache
- SAH typically in cortical sulci vs. basal cisterns with aSAH

"Pseudo-SAH"

- Hypodense brain: Severe cerebral edema
- Hyperdense CSF: Intrathecal contrast; meningitis

PATHOLOGY

General Features

- Etiology
  - Saccular aneurysms
    - Berry aneurysms: Congenital deficiency of internal elastic lamina and tunica media at arterial branch points → focal vessel wall weakness
      - ↑ risk: Familial intracranial aneurysms (5% of cases), adult polycystic kidney disease, aortic coarctation
    - May be related to high-flow arteriopathy along feeding vessel of AVM or, less commonly, dAVF
    - ↑ aneurysm rupture risk if female, smoker, HTN
  - Fusiform aneurysms
    - Dissection from trauma, hypertension, ASVD
    - Underlying arteriopathy including fibromuscular dysplasia (FMD), Marfan, Ehlers-Danlos, infection
    - Mycotic
  - Blood-blister aneurysm: All layers absent (contained in fibrous cap)
- Associated abnormalities
  - Vasospasm
    - Caused by blood breakdown products, apolipoprotein-E genotype, endothelin-1 release from CSF leukocytes
    - 70% develop angiographic evidence of vasospasm
    - 30% have clinically apparent vasospasm
    - Starts ~ day 3-4 post SAH; peaks ~ 7-9 days, lasts ~ 12-16 days
  - Cerebral salt-wasting syndrome
    - Excessive renal Na+ excretion → hyponatremia, hypovolemia
  - Terson syndrome
    - Intraocular (retinal, vitreous) hemorrhage associated with SAH secondary to rapid ↑ intracranial pressure

Staging, Grading, & Classification

- Clinical grading: Hunt and Hess (H&H) grade 0-5
  - 0: No SAH (unruptured aneurysm)
  - 1: No symptoms, minimal headache, slight nuchal rigidity
  - 2: Moderate to severe headache, nuchal rigidity
    - No neurologic deficit except CN palsy
  - 3: Drowsy, minimal neurologic deficit
  - 4: Stuporous, moderate/severe hemiparesis
  - 5: Coma, decerebrate rigidity, moribund appearance
- Fisher CT grading
  - 1: No SAH visible
  - 2: Diffuse, thin layer (< 1 mm)
  - 3: Localized clot or thick layer (> 1 mm)
  - 4: Intraventricular blood

Gross Pathologic & Surgical Features

- Blood in basal cisterns, sulci, and ventricles

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Sudden "thunderclap/worst headache of life"
  - 10% preceded by "sentinel hemorrhage" = self-limiting SAH + headache in preceding days/weeks

Demographics

- Age
  - Peak = 40-60 years
- Gender
  - M:F = 1:2
- Epidemiology
  - Aneurysms cause 85% of spontaneous SAHs
  - Incidence ~ 9.9 per 100,000 population

Natural History & Prognosis

- 50% mortality; 20% rebleed within first 2 weeks
- Clinical outcome inversely proportional to initial H&H or WFNS grade
- Vasospasm + ischemia → delayed morbidity, mortality
  - Severity correlates with amount of SAH (Fisher CT grade); inverse correlation with patient age
- 90% hydrocephalus at presentation
  - ~ 10% require permanent CSF diversion

Treatment

- Ruptured aneurysm
  - Coil embolization ("coiling"), if anatomy favorable
    - Lower rates of acute adverse events; long-term, all cause morbidity
  - Microneurosurgical clipping
    - Proven effective over decades but invasive, higher morbidity/mortality compared with coiling
    - 1 study: Death or dependence at 1 year = 23.7% with coiling vs. 30.7% with clipping
- Vasospasm
  - Ca++ antagonists, "triple-H" therapy (hypervolemia, hemodilution, hypertension)
  - Endovascular: Intraarterial Ca++ antagonist ("chemical angioplasty"), balloon angioplasty
- Hydrocephalus
  - Temporary or permanent CSF diversion

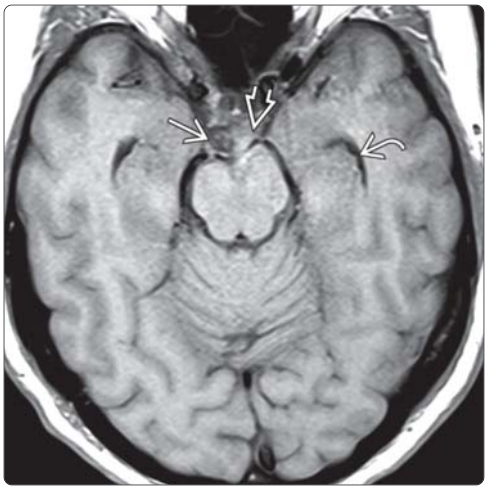
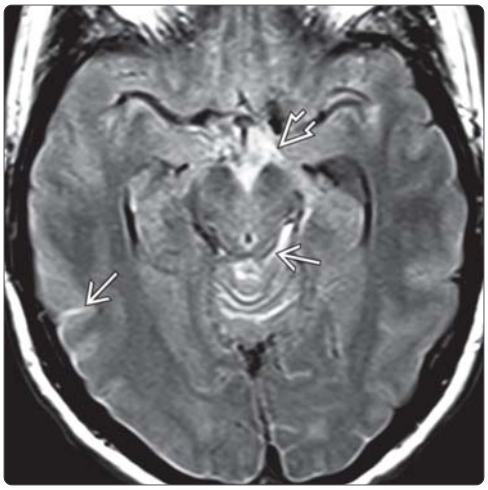
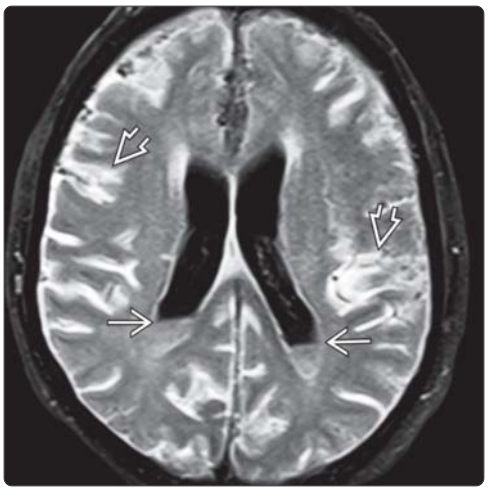
https://CafePezeshki.IR

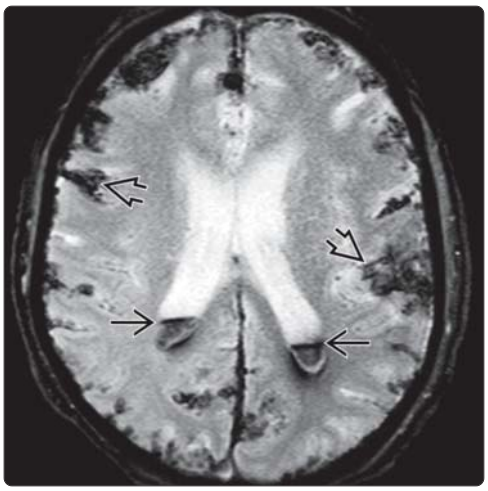


(Left) *Sagittal T1WI illustrates typical findings of acute aneurysmal SAH. Note "dirty" CSF ➡ that appears isointense with adjacent brain. The normal basilar artery "flow void" ➡ is surrounded by the SAH.* **(Right)** *Axial T1WI in the same patient shows a nice contrast between the isointense (with brain) "dirty" CSF ➡ and the more normal-appearing hypointense ("dark") CSF in the cistern ➡ and temporal horns ➡.*



(Left) *Normal CSF suppresses on FLAIR. FLAIR scan in the same patient shows CSF in the suprasellar cistern ➡ is abnormally hyperintense. Sulcal-cisternal hyperintensity is also seen in the left perimesencephalic and superior cerebellar cisterns as well as the parietooccipital subarachnoid spaces ➡.* **(Right)** *Axial NECT in an 83-year-old man found down shows diffuse SAH, seen here as hyperdense fluid ➡ in virtually all the visualized sulci. CSF-blood level ➡ is also present in the lateral ventricles.*





(Left) *FLAIR scan obtained 2 days later in the same patient shows diffuse sulcal hyperintensity ➡ and normally suppressed CSF in the lateral ventricles with blood-fluid level ➡.* **(Right)** *Axial GRE scan in the same patient shows blood in the sulci as "blooming" hypointensities ⇨. The blood-CSF level ⇨ in the lateral ventricles is also clearly seen.*

https://CafePezeshki.IR

Perimesencephalic Nonaneurysmal SAH

KEY FACTS

TERMINOLOGY

- SAH centered immediately anterior to midbrain ± pons
- No source demonstrated at CTA/DSA/MRA

IMAGING

- NECT: Hyperdense prepontine, perimesencephalic CSF
  - Often involves interpeduncular, ambient, quadrigeminal cisterns
  - ± thin extension into posterior suprasellar, proximal sylvian/interhemispheric fissures
  - Does not extend into distal sylvian, interhemispheric fissures
- CTA used to exclude basilar tip aneurysm
- MR
  - T1: Iso- to hyperintense
  - T2 variable (iso- to hyper-) intensity compared to CSF
  - FLAIR: Hyperintense prepontine, perimesencephalic CSF

TOP DIFFERENTIAL DIAGNOSES

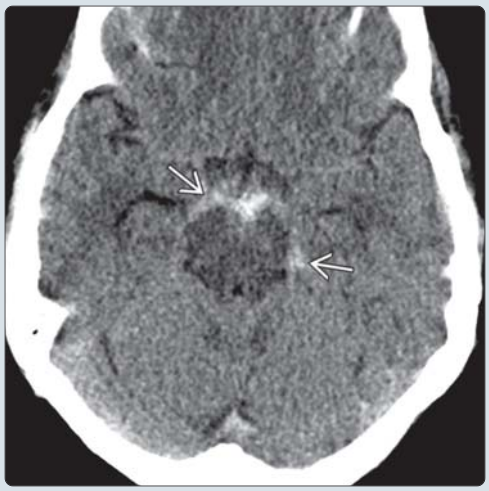
- Aneurysmal SAH
- Traumatic SAH
- Artifact: FLAIR

PATHOLOGY

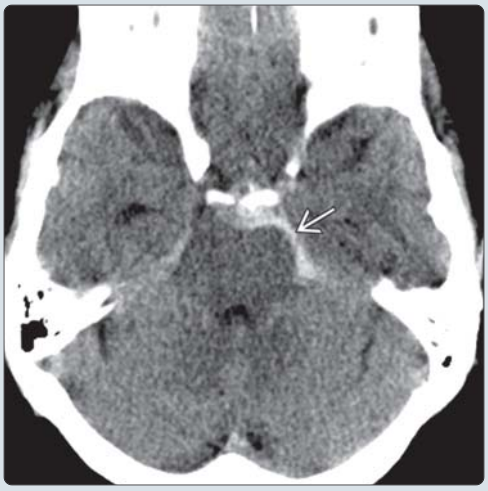
- Most likely from ruptured perimesencephalic/prepontine vein
  - More common if basal vein of Rosenthal small, drains into veins other than Galen
- 5% of pnSAHs have other etiologies
  - Basilar bifurcation aneurysm, dissection most common
  - Other: Trauma, dAVF, spinal cord vascular malformation, vascular neoplasm

CLINICAL ISSUES

- Benign course: Rebleed rare (< 1%); no vasospasm



(Left) *Axial graphic shows a classic pnSAH. Hemorrhage is confined to the interpeduncular fossa and ambient (perimesencephalic) cisterns ➡. The source is usually venous in pnSAHs, unlike in aneurysmal SAHs.* **(Right)** *Axial NECT of a 49-year-old woman in the ER with a "thunderclap" headache shows SAH around the midbrain in the perimesencephalic cisterns ➡. Note the absence of blood in the sylvian fissures and anterior suprasellar subarachnoid space.*



(Left) *Axial NECT in the same patient shows the subarachnoid blood ➡ extends inferiorly in front of the pons.* **(Right)** *Coronal CTA in the same patient with reconstructed view through the basilar artery bifurcation shows no evidence for aneurysm. The high density in the vessels is easily discernible even with the presence of significant SAH. DSA (not shown) confirmed the absence of aneurysm. This case illustrates classic findings in pnSAH.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Perimesencephalic nonaneurysmal subarachnoid hemorrhage (pnSAH)

Synonyms

- Benign perimesencephalic SAH

Definitions

- SAH centered immediately anterior to midbrain ± pons
- No source demonstrated at angiography

IMAGING

General Features

- Best diagnostic clue
  - Hyperdense prepontine, perimesencephalic CSF
- Location
  - Subarachnoid cisterns around midbrain and anterior to pons
  - Often involves interpeduncular, ambient, quadrigeminal cisterns
  - Some thin extension into posterior suprasellar, proximal sylvian/interhemispheric fissures
  - Does not extend into distal sylvian, interhemispheric fissures
  - May have small amount of blood in occipital horns but no frank IVH

CT Findings

- NECT
  - High attenuation anterior to pons and around midbrain

MR Findings

- T1WI
  - Iso- to hyperintense CSF around midbrain
- T2WI
  - Variable; iso- to hypointense blood in CSF
- FLAIR
  - Hyperintense
    - May be mimicked by CSF pulsation artifact
- T2* GRE
  - Hypointense, "blooming"

Angiographic Findings

- CTA/MRA/DSA
  - No source of hemorrhage identified on CTA
  - DSA generally not required to confirm diagnosis

Imaging Recommendations

- Best imaging tool
  - NECT best screening for pnSAH
  - CTA to exclude basilar tip aneurysm
  - DSA optional
  - MR/MRA may confirm SAH or cause; may negate need for repeat DSA
- Protocol advice
  - NECT with CTA
  - MR/MRA may help confirm diagnosis
  - Consider cervical MR to exclude rare spinal vascular source

DIFFERENTIAL DIAGNOSIS

Aneurysmal SAH

- More extensive hemorrhage
- Basilar bifurcation aneurysm may have pnSAH pattern

Traumatic SAH

- Perisylvian, convexity more common than perimesencephalic pattern

Artifact: FLAIR

- Incomplete CSF suppression
  - > 50% O_2 concentration
- Pulsation artifact

PATHOLOGY

General Features

- Etiology
  - Most likely from ruptured perimesencephalic/prepontine vein
    - More common if basal vein of Rosenthal small, drains into veins other than Galen
  - 5% of pnSAHs have other etiologies
    - Basilar bifurcation aneurysm, dissection most common
    - Other: Trauma, dAVF, spinal cord vascular malformation, vascular neoplasm

Gross Pathologic & Surgical Features

- Clotted blood in perimesencephalic cisterns

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache (usually Hunt/Hess grade 1 or 2)

Demographics

- Age: 40-60 years
- Gender: M = F
- Epidemiology
  - Majority of angiogram-negative SAH

Natural History & Prognosis

- Benign course: Rebleed rare (< 1%); no vasospasm
- More extensive pnSAH may develop hydrocephalus

Convexal Subarachnoid Hemorrhage

KEY FACTS

TERMINOLOGY

- Unique type of SAH
  - Localized to sulci over top ("convexity") of brain

IMAGING

- NECT: Hyperdensity in 1 or several adjacent dorsolateral convexity sulci
  - Spares basal, perimesencephalic cisterns
- MR
  - Sulcal CSF replaced by isointense fluid in convexity sulcus ("dirty CSF")
  - Hyperintense sulcus on FLAIR
  - GRE, SWI show "blooming" in affected sulci

TOP DIFFERENTIAL DIAGNOSES

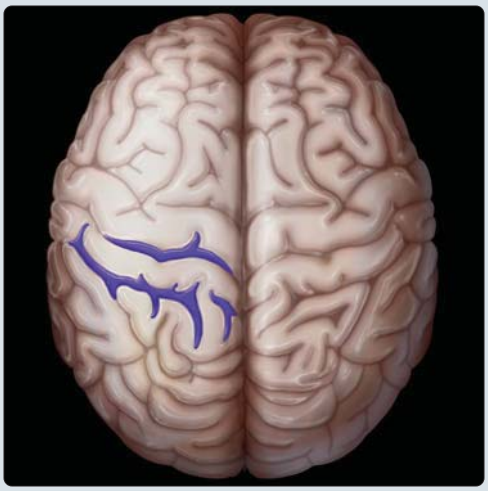
- Aneurysmal subarachnoid hemorrhage (aSAH)
- Perimesencephalic nonaneurysmal subarachnoid hemorrhage (pnSAH)
- Traumatic subarachnoid hemorrhage (tSAH)

PATHOLOGY

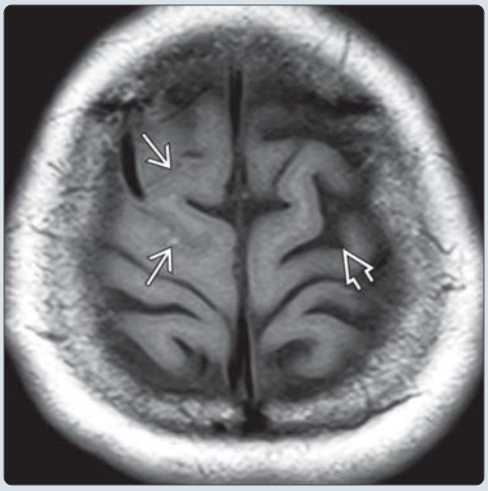
- Most common etiology varies with age
  - Elderly patients: Amyloid angiopathy, venous thrombosis, vasculitis
  - Middle aged: Reversible cerebral vasoconstriction syndrome (RCVS), vasculitis, vein thrombosis
  - Young adults, children: Drugs, vasculitis, vein/dural sinus thrombosis

CLINICAL ISSUES

- 7% of all spontaneous (nontraumatic) SAH
- Most common: Middle-aged female
- Presentation varies with age
  - < 60 years of age: Sudden "thunderclap" headache (e.g., RCVS)
  - > 60 years of age: Transient sensory, motor symptoms, less intense headache (CAA)



(Left) *Graphic of brain seen from above shows convexal subarachnoid hemorrhage (SAH) in blue affecting adjacent sulci but sparing the basal cisterns.* **(Right)** *Axial NECT in a 28-year-old woman with severe headache following delivery shows focal subarachnoid hemorrhage ➔ over the right cerebral convexity.*



(Left) *Axial T1WI MR in the same patient shows "dirty" fluid filling, effacing the normal sulcal CSF in the right convexity sulci ➔ (compare to normal hypointense signal intensity in the contralateral sulci ➔).* **(Right)** *Axial FLAIR MR in the same patient shows hyperintense right convexity sulci ➔ (contrast with the normal suppressed hypointense CSF over the left convexity). Postpartum vasculopathy was diagnosed at DSA (not shown).*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Subarachnoid hemorrhage (SAH)
- Convexal subarachnoid hemorrhage (cSAH)

Definitions

- Unique type of SAH
  - SAH localized to sulci over top ("convexity") of brain

IMAGING

General Features

- Best diagnostic clue
  - Hyperdensity in 1 or several dorsolateral convexity sulci on NECT
  - Hyperintense sulcus on FLAIR MR
- Location
  - Top, upper sides of brain
  - Unilateral > bilateral

CT Findings

- Often faint hyperdensity in 1 or more adjacent convexity sulci
- Spares basal, perimesencephalic cisterns

MR Findings

- T1WI
  - Sulcal CSF replaced by isointense fluid in convexity sulcus ("dirty CSF")
- T2WI
  - Hyperintensity of acute blood difficult to perceive
- FLAIR
  - Focal sulcal hyperintensity
- T2* GRE
  - GRE, SWI show "blooming" in affected sulci
  - Look for other findings
    - Occluded cortical vein, dural sinus
    - Microbleeds, superficial siderosis (amyloid angiopathy)

Angiographic Findings

- May show findings of vasculitis, dural sinus/cortical vein occlusion
- Sequential studies may show reversible cerebral vasoconstrictions (RCVS)

Imaging Recommendations

- Best imaging tool
  - NECT as screening
  - MR with T2* (GRE, SWI)

DIFFERENTIAL DIAGNOSIS

Aneurysmal Subarachnoid Hemorrhage (aSAH)

- aSAH typically centered in suprasellar/central basal cisterns
- More diffuse, spreads peripherally

Perimesencephalic Nonaneurysmal Subarachnoid Hemorrhage (pnSAH)

- pnSAH around midbrain, in front of pons
- May spread into posterior suprasellar cistern, proximal sylvian fissures
- Does not extend into distal sylvian, interhemispheric fissures

Traumatic Subarachnoid Hemorrhage (tSAH)

- Cortical contusions common with tSAH
- Anterior inferior temporal, frontal lobes most common sites
  - Hemorrhage is in sulci adjacent to contusions
  - Sylvian fissure blood common

PATHOLOGY

General Features

- Etiology
  - Most common etiology varies with age
    - Elderly patients: Amyloid angiopathy, venous thrombosis, vasculitis
    - Middle aged: Reversible cerebral vasoconstriction syndrome (RCVS), vasculitis, vein thrombosis
    - Young adults, children: Drugs, vasculitis, vein/dural sinus thrombosis
  - Less common causes of cSAH
    - PRES
    - Coagulopathy
    - Ruptured superficial vascular malformation
    - Hemorrhagic neoplasm
  - Rare causes of cSAH
    - Neoplasm
    - Septi emboli

CLINICAL ISSUES

Presentation

- 2 main clinical presentations by patient age
  - < 60 years of age: RCVS with sudden "thunderclap" headache
    - May have "trigger" (vasoactive, sympathomimetic agents, stimulants, etc.)
  - > 60 years of age: CAA with transient sensory, motor symptoms, less intense headache

Demographics

- 7% of all spontaneous (nontraumatic) SAH
- Most common: Middle-aged female

Natural History & Prognosis

- Varies with etiology

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Look for subtle effacement or "fuzzing" of convexity sulci
- Look for etiology of cSAH (i.e., hyperdense clot in cortical vein or dural sinus)

SELECTED REFERENCES

1. Mangla R et al: Cerebral convexity subarachnoid hemorrhage: various causes and role of diagnostic imaging. Emerg Radiol. ePub, 2014
2. Marder CP et al: Subarachnoid hemorrhage: beyond aneurysms. AJR Am J Roentgenol. 202(1):25-37, 2014

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Chronic, recurrent SAH
  - Causes hemosiderin deposition on surfaces of brain, brainstem, cranial nerves (CNs), spinal cord

IMAGING

- Nonenhanced CT findings
  - Slightly hyperdense rim over brain surface
  - High-density line most evident along brainstem
  - **Caveat**: Do not mistake high-density rim on brain surfaces (not cisterns) as acute SAH
- MR findings
  - T2* (GRE, SWI) most sensitive to hemosiderin deposition
  - Contours of brain and cranial nerves "outlined by black" (hypointense rim) on T2 or T2* GRE MR images
  - CN8 often appears darker, thicker than normal
- If diagnosis of superficial siderosis (SS) is made, must search for cause of recurrent SAH
  - Image entire neuraxis to look for potential bleeding sources
    - Whole brain MR with contrast and MRA
    - Total spine MR if brain negative for underlying lesion

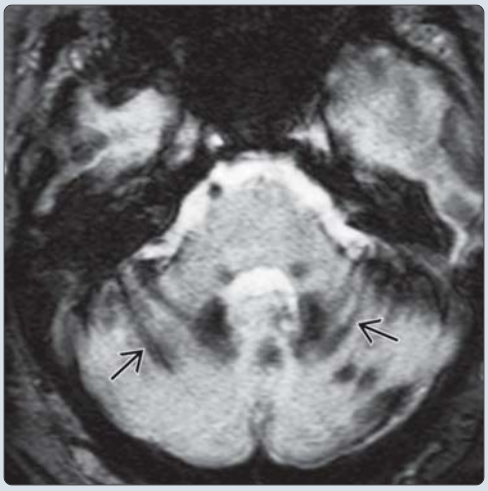
TOP DIFFERENTIAL DIAGNOSES

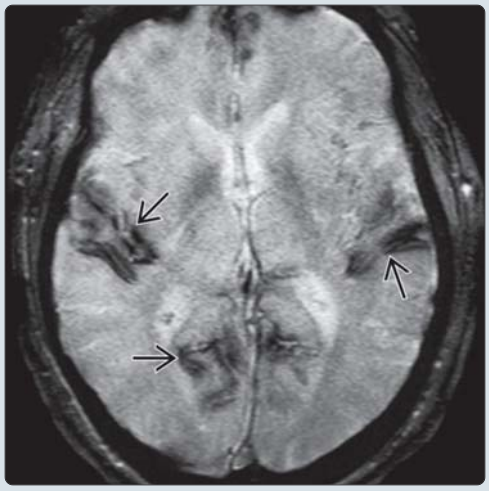
- "Bounce point" artifact
- Brain surface vessels
  - Usually surface veins, enhance (SS doesn't)
- Neurocutaneous melanosis (usually cutaneous nevi)

PATHOLOGY

- Causes of recurrent SAH with SS
  - Cerebral amyloid angiopathy
  - Bleeding CNS neoplasm
  - Vascular malformations, aneurysms
  - Surgery, trauma
  - CSF hypovolemia syndromes

(Left) *Axial graphic shows darker brown hemosiderin staining on all surfaces of the brain, meninges, and cranial nerves. Notice that cranial nerves 7 and 8 in the cerebellopontine angle-internal auditory canal ⇨ are particularly affected.* **(Right)** *Axial T2WI in a 64-year-old female with bilateral sensorineural hearing loss for 3 years shows a thin "black" line coating the surface of the cerebellum, especially notable over the flocculi ⇨.*





(Left) *Axial T2* GRE scan in the same patient shows the extensive hemosiderin deposition over the cerebellar folia as curvilinear thick "black lines" ⇨.* **(Right)** *More cephalad scan in the same patient shows prominent superficial siderosis ⇨ along the sylvian fissures, medial occipital lobes.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Superficial siderosis (SS), subarachnoid hemorrhage (SAH)

Synonyms

- Siderosis, central nervous system siderosis

Definitions

- Chronic, recurrent SAH → hemosiderin deposition on pial surfaces of brain, brainstem, cranial nerves (CNs), spinal cord

IMAGING

General Features

- Best diagnostic clue
  - Surface of brain, CNs outlined by hypointense rim on T2 or T2* GRE MR images
- Location
  - Cerebral hemispheres, cerebellum, brainstem, cranial nerves, spinal cord may all be variably affected
- Size
  - Curvilinear low signal along CNS surfaces varies in thickness but usually ≤ 2 mm
- Morphology
  - Curvilinear dark lines on CNS surfaces

CT Findings

- NECT
  - Cerebral and cerebellar atrophy
    - Especially marked in posterior fossa
      - Cerebellar sulci often disproportionately large
  - CN8 may be hyperdense
  - Slightly hyperdense rim over brain surface
    - Brainstem changes most evident
    - CT relatively insensitive to SS compared to MR
    - **Caveat**: Do not mistake high-density rim on brain surfaces (not cisterns) as acute SAH
- CECT
  - No enhancement typical

MR Findings

- T1WI
  - Hyperintense signal may be seen on CNS surfaces
- T2WI
  - High-resolution, thin-section T2 MR of CPA-IAC
    - CN8 appears darker, thicker than normal
    - Adjacent cerebellar structures, brainstem show low signal surfaces
    - Less easily seen than on T2* GRE images
  - In diffuse disease, ventricles and choroid plexus, brain, brainstem, cerebellum, and cervical spinal cord surfaces all have hypointense hemosiderin rim
  - Vermian and cerebellar atrophy most prominent
- FLAIR
  - Dark border on local surface of brain, brainstem, cerebellum, and cranial nerves
- T2* GRE
  - More sensitive to hemosiderin than standard T2 sequence
  - "Blooming" dark signal along pia, subpial brain
    - Deposition thicker, more conspicuous on GRE, SWI than T2WI
    - May show ventricular ependyma, choroid plexus deposition
  - Look for "blooming" black dots in parenchyma (may indicate cerebral amyloid angiopathy)
- T1WI C+
  - Does not enhance

Imaging Recommendations

- Best imaging tool
  - Brain MR
    - Once diagnosis of SS is made, look for cause of recurrent SAH
    - Whole brain MR without and with contrast +MRA
    - Then total spine MR if brain negative for underlying lesion (e.g., spinal ependymomas may cause recurrent SAH, superficial siderosis)
    - Note: MR findings do not correlate with clinical severity of disease
- Protocol advice
  - Brain MR
    - Unenhanced MR with FLAIR
    - If SS suspected, add T2* (GRE, SWI) sequences to confirm
  - Image entire neuraxis to look for potential bleeding sources

DIFFERENTIAL DIAGNOSIS

"Bounce Point" Artifact

- Mismatch between repetition time (TR) and inversion time (TI) on inversion recovery T1 and FLAIR sequences
  - Imaging clue: Not present on all sequences

Brain Surface Vessels

- Usually surface veins
- Linear, focal area of low signal on brain surface
- Enhance on T1C+ (SS doesn't)

Neurocutaneous Melanosis

- Congenital syndrome
- Large or multiple cutaneous melanocytic nevi
- Benign or malignant pigment cell tumors of leptomeninges may be low signal on surface of brain
- T1 high signal diffusely in pia-arachnoid
- T2 low signal diffusely in pia-arachnoid
- Typically enhances on T1C+

Meningioangiomatosis

- Hamartomatous proliferation of meningeal cells that may extend into underlying cerebral cortex
- Leptomeninges are thick, infiltrated with fibrous tissue
- Usually calcified
- Enhances on T1C+

PATHOLOGY

General Features

- Etiology
  - Repeated SAH deposits hemosiderin on meningeal lining of CNS

https://CafePezeshki.IR

- Affects brain, brainstem, cerebellum, cranial nerves, spinal cord
  - Hemosiderin is cytotoxic to neurons
    - "Free" iron with excess production of hydroxyl radicals is best current hypothesis explaining cytotoxicity
  - CN8 is extensively lined with CNS myelin, which is supported by hemosiderin-sensitive microglia
    - Increased exposure in CPA cistern
- Associated abnormalities
  - Look carefully for causes of recurrent SAH
    - Aneurysm
    - Arteriovenous or cavernous malformation
    - Cerebral amyloid angiopathy
    - Bleeding CNS neoplasm
    - Trauma, surgery
    - CSF hypovolemia syndromes

Gross Pathologic & Surgical Features

- Dark brown discoloration of pia, ependyma, subpial tissue
- Causes of recurrent SAH found in ~ 70%
  - Dural pathology (70%)
    - Traumatic cervical nerve root avulsion
    - CSF cavity lesion (surgical cavity) with "fragile" neovascularity most common
  - Bleeding neoplasms (20%)
    - Ependymoma, oligodendroglioma, astrocytoma, etc.
  - Vascular abnormalities (10%)
    - Arteriovenous malformation (AVM) or aneurysm
    - Multiple cavernous malformations near brain surface
  - Cerebra; amyloid angiopathy

Microscopic Features

- Hemosiderin staining of meninges and subpial tissues to 3 mm depth
- Thickened leptomeninges
- Cerebellar folia: Loss of Purkinje cells and Bergmann gliosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Bilateral sensorineural hearing loss (SNHL) in 95%
  - Mimics cerebellar degenerative disorder
    - Progressive cerebellar ataxia
    - Pyramidal signs
- Clinical profile
  - Past history of trauma or intradural surgery common
    - Past history of SAH rare
  - Classic presentation is adult patient with bilateral SNHL, ataxia
  - Seen less commonly as late complication of treated childhood cerebellar tumor
- Laboratory
  - CSF from lumbar puncture
    - High protein (100%)
    - Xanthochromic (75%)
- Other symptoms
  - Ataxia (88%)
  - Bilateral hemiparesis
  - Hyperreflexia, bladder disturbance, anosmia, dementia, and headache
  - Presymptomatic phase averages 15 years

Demographics

- Age
  - Broad range: 14-77 years
- Gender
  - M:F = 3:1
- Epidemiology
  - Rare chronic progressive disorder
  - 0.15% of patients undergoing MR

Natural History & Prognosis

- Bilateral worsening SNHL and ataxia within 15 years of onset
- Deafness almost certain if unrecognized
- 25% bedridden in years after 1st symptom
  - Result of cerebellar ataxia, myelopathic syndrome, or both

Treatment

- Treat source of bleeding
  - Surgically remove source of bleeding (surgical cavity, tumor)
  - Endovascular therapy for AVM and aneurysm
- Cochlear implantation for SNHL

DIAGNOSTIC CHECKLIST

Consider

- Remember that SS is effect, not a cause
- Look for source of recurrent SAH in spine or brain
- MR findings do not correlate with severity of patient's symptoms
  - MR diagnosis may be made in absence of symptoms

Image Interpretation Pearls

- CNS surfaces, including cranial nerves, appear "outlined in black" on T2 MR

Reporting Tips

- Describe individual findings of SS
- Describe any possible sites of chronic SAH
- If no site of SAH visible, recommend full spine MR in search of SAH site
  - Treatment of SAH site may arrest progression of associated symptoms

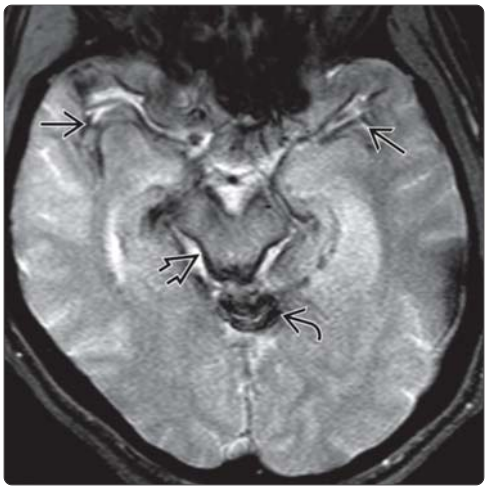
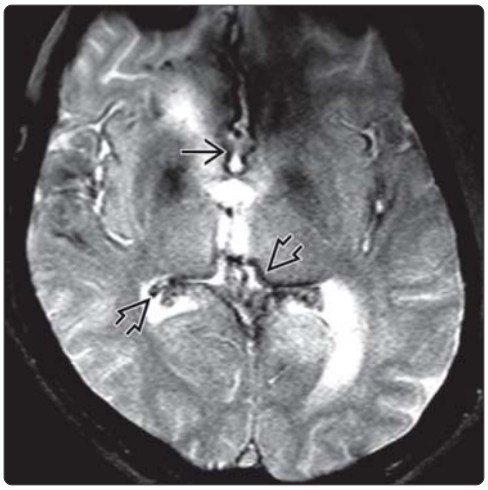
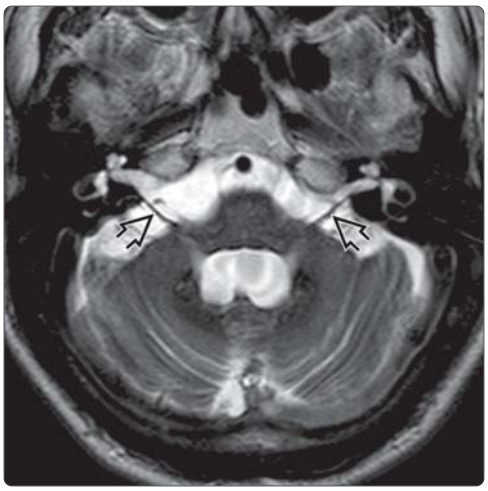
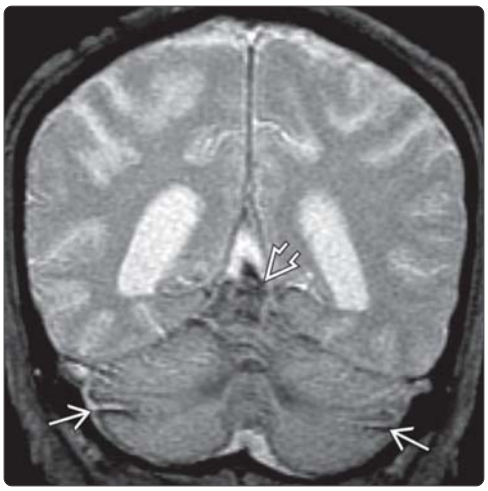
(Left) *Axial T2* GRE scan in a 51-year-old male with bilateral sensorineural hearing loss and remote history of resection of a left frontal oligodendroglioma shows hypointensity coating the medulla ⇨ cerebellar flocculi ⇨, CNs 9-11 ⇨, and staining the 4th ventricle choroid plexus ⇨.* **(Right)** *More cephalad scan in the same patient shows superficial siderosis (SS) of the 7th and 8th CNs ⇨ as well as the ependyma of the 4th ventricle ⇨.*





(Left) *More cephalad T2*GRE scan in the same patient shows diffuse SS along both sylvian fissures ⇨ and coating the midbrain ⇨, top of the vermis ⇨.* **(Right)** *More cephalad T2* GRE scan shows coating along the surfaces of both sylvian fissures as well as the interhemispheric fissure ⇨. Note the hemosiderin staining the ependyma, choroid plexi of the lateral ventricles ⇨.*





(Left) *Axial T2WI in a 60-year-old male with progressive ataxia, bilateral sensorineural hearing loss exhibits SS seen here as "thicker, blacker" CN8s ⇨. Note the cerebellar atrophy with large 4th ventricle, prominent folia.* **(Right)** *Sometimes SS is limited to the posterior fossa. Coronal T2* GRE demonstrates extensive superficial siderosis in the posterior fossa. "Blooming" of the hemosiderin on the surfaces is seen as a hypointense outline. The superior vermis ⇨ as well as the cerebellar folia ⇨ are involved.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Intracranial saccular aneurysm (SA)
- Outpouching affecting only part of arterial circumference
  - Lacks internal elastic lamina ± tunica media

IMAGING

- Round/lobulated arterial outpouching
  - Usually arises from bifurcations of circle of Willis (COW), supraclinoid ICA, MCA, cerebellar arteries
  - 90% occur in anterior circulation
  - 10% posterior circulation: Basilar tip, cerebellar arteries (PICA most common)
  - Rare (< 1%): Trigeminal artery, vertebrobasilar junction fenestration
- Ruptured SAs result in SAH
- May have mural Ca++
- Sensitivity of multislice CTA > 95% for SA > 2 mm
- 3D TOF: > 90% sensitive for aneurysms ≥ 3 mm

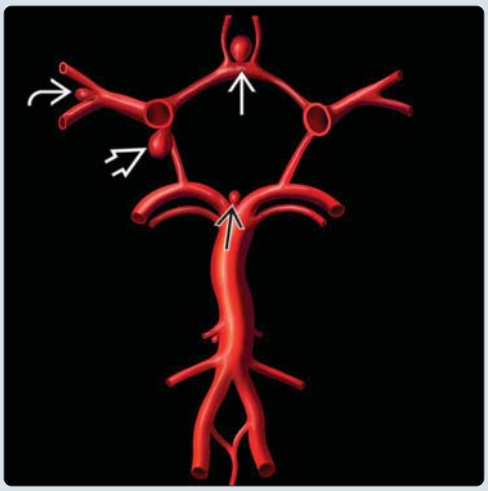
TOP DIFFERENTIAL DIAGNOSES

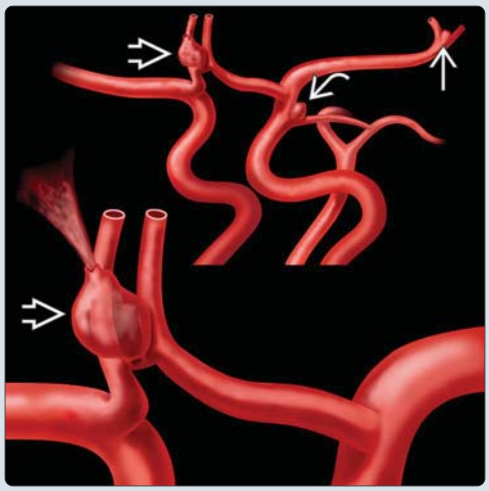
- Vessel loop
- Vessel infundibulum
- Fusiform aneurysm
- Flow void MR mimic (e.g., aerated anterior clinoid)

CLINICAL ISSUES

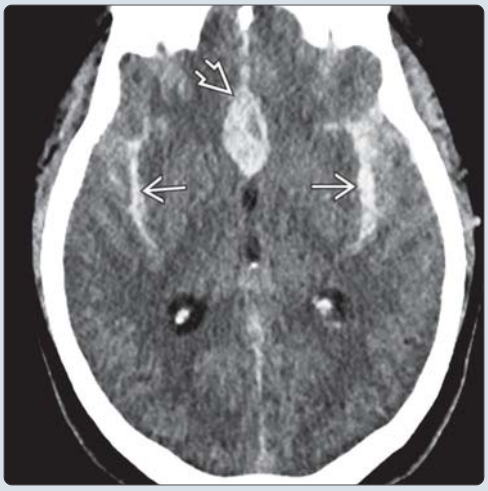
- Vast majority of unruptured SAs are asymptomatic
  - 2-6% incidental finding at autopsy, imaging
- 80-90% of nontraumatic SAH caused by ruptured SA
- Treatment
  - Endovascular coiling vs. surgical clipping
  - 22.6% relative, 6.9% absolute risk ↓ for coiling vs. surgery for ruptured aneurysms
  - ↓ morbidity, mortality, and hospital costs; quicker recovery for unruptured aneurysms

(Left) *Most common sites for SAs are ACoA ➡ and IC-PC junction ➡. MCA bifurcation ➡ and basilar tip ➡ are other frequent sites.* **(Right)** *Graphic illustrates rupture of an ACoA aneurysm ➡ with active extravasation from a superiorly directed bleb (Murphy teat). An additional posterior communicating artery SA ➡ and tiny bleb at the left MCA bifurcation ➡ are seen. Patients with SAs have a 20% chance of having > 1 aneurysm.*





(Left) *A 63-year-old man was found down in a parking lot and brought to the ER. Axial NECT scan showed diffuse subarachnoid hemorrhage ➡ with a focal hematoma ➡ in the anteroinferior aspect of the interhemispheric fissure.* **(Right)** *Coronal MIP of the CTA in the same patient shows a 4 mm saccular aneurysm ➡ projecting upwards from the anterior communicating artery.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Intracranial saccular aneurysm (SA)

Synonyms

- Berry aneurysm, true aneurysm

Definitions

- Arterial outpouching affecting only part of arterial circumference
  - Lacks internal elastic lamina ± tunica media

IMAGING

General Features

- Best diagnostic clue
  - Round/lobulated arterial outpouching
    - Usually arises from bifurcations of circle of Willis (COW), supraclinoid ICA, MCA, cerebellar arteries
- Location
  - 90% occur in anterior circulation
    - ACoA, PCoA, MCA bifurcation, carotid terminus most common sites
    - Other: Paraclinoid ICA, superior hypophyseal, anterior choroidal artery (AChA)
  - 10% posterior circulation: Basilar tip, cerebellar arteries (PICA most common)
  - Rare (< 1%): Trigeminal artery, vertebrobasilar junction fenestration
  - Vessel bifurcation > side wall aneurysm (e.g., blood blister-like aneurysm)
- Size
  - Small (< 3 mm) to giant (> 2.5 cm)
- Morphology
  - Round, ovoid daughter lobe(s)
  - Narrow or wide necked
  - Branch vessel may be incorporated into aneurysm neck (can preclude coil embolization)

CT Findings

- NECT
  - Ruptured SAs result in subarachnoid hemorrhage (SAH)
    - Pattern of SAH may help localize SA location
  - If SA contains thrombus → hyperdense to brain
  - May have mural Ca++
- CECT
  - Lumen of patent SA enhances uniformly
  - Completely thrombosed SA may have rim enhancement
- CTA
  - Sensitivity of multislice CTA > 95% for SA > 2 mm
  - Look for > 1 aneurysm, as SA is multiple in 20% of patients
  - Look for associated SAH vasospasm if ruptured SA
  - Alternative to DSA as 1st imaging technique in SAH

MR Findings

- T1WI
  - Patent aneurysm (signal varies)
    - 50% have flow void
    - 50% iso-/heterogeneous signal (slow/turbulent flow, saturation effects, phase dispersion)
  - Partially/completely thrombosed aneurysm
    - Signal depends on age of thrombus
    - Common: Mixed signal, laminated thrombus
    - Hypointense + "blooming" on susceptibility sequences (GRE, SWI)
- T2WI
  - Typically hypointense (flow void)
  - May be laminated with very hypointense rim
- FLAIR
  - Acute SAH: High signal in sulci, cisterns
- DWI
  - May see restricted diffusion secondary to ischemia from SAH vasospasm
  - Thromboembolic events from intraaneurysmal thrombus (rare)
- T1WI C+
  - Slow flow in patent lumen may enhance
  - Increased phase artifact in patent SAs
- MRA
  - 3D TOF: > 90% sensitive for aneurysms ≥ 3 mm
  - Short T1 substances, such as subacute hemorrhage, may simulate flow on TOF MRA

Angiographic Findings

- Conventional DSA
  - Technique
    - Bilateral carotid + dominant vertebral artery injections with reflux to contralateral PICA or "4 vessel" cerebral DSA required
    - Cross-compression of contralateral carotid may be needed for evaluation of ACoA
    - Rotational DSA with 3D surface-shaded display (SSD) reconstructions may be helpful, but prone to artifact depending on window settings
  - Rare: Contrast extravasation with active SAH
  - Look for Murphy teat (bleb at site of recent rupture) vs. daughter lobe (smaller outpouching from aneurysm fundus, likely indicating focal wall weakness, ↑ future rupture risk)

Imaging Recommendations

- Best imaging tool
  - NECT + CTA for work-up of SAH
  - CTA or MRA for screening of high-risk groups
- Protocol advice
  - Dual energy direct bone removal CT angiography for evaluation of skull base/paraclinoid SA
  - 3D SSD reconstructions helpful to visualize ACoA and MCA bifurcation

DIFFERENTIAL DIAGNOSIS

Vessel Loop

- Use multiple projections

Vessel Infundibulum

- < 3 mm, conical, vessel arises directly from apex
- Commonly at posterior communicating artery (PCoA) and anterior choroidal artery (AChA) origins

https://CafePezeshki.IR

Fusiform Aneurysm

- Sausage-shaped morphology with separate inflow, outflow pathways
- Long segment, usually located distal to COW
- Can be secondary to ASVD
- Often pseudoaneurysm etiology
  - Trauma, mycotic, vasculitic, connective tissue disease

Flow Void (MR Mimic)

- Aerated anterior clinoid or supraorbital cell

PATHOLOGY

General Features

- Etiology
  - SA development and rupture risk reflect complex combination of inherited susceptibility + acquired mechanically mediated vessel wall stresses
  - Abnormal vascular hemodynamics → ↑ wall stress
    - Flow-related "bioengineering fatigue" in vessel wall more likely with asymmetric COW → ↑ development of SA at site of anomaly
      - Aplastic A1 segment, persistent trigeminal artery
      - No definite relationship with arterial fenestrations
- Genetics
  - Familial intracranial aneurysms (FIAs)
    - No known heritable connective tissue disorder
    - Occur in "clusters" (1st-order relatives)
    - Younger patients, no female predominance compared to sporadic SAs
    - Consider screening with CTA or MRA
- Associated abnormalities
  - ↑ SA incidence in patients with
    - Fibromuscular dysplasia (FMD): Autosomal dominant, sporadic
  - Bicuspid aortic valve
  - Autosomal dominant polycystic kidney disease (10% have SA)
  - Intracranial AVM: Feeding pedicle ("flow related") aneurysms in 30%
    - May regress after treatment of AVM

Gross Pathologic & Surgical Features

- Round/lobulated sac, thin or thick wall, ± SAH

Microscopic Features

- Disrupted/absent internal elastic lamina
- Muscle layer absent
- May have "teat" of fragile adventitia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Vast majority of unruptured SA are asymptomatic
    - Cranial neuropathy uncommon (e.g., pupil-involving CN3 palsy from PCoA aneurysm)
    - TIA/stroke from thromboembolic events secondary to intraaneurysmal thrombus (rare)
  - 80-90% of nontraumatic SAH caused by ruptured SA
    - Headache (typical = "thunderclap")
- Clinical profile
  - 2 common scenarios
    - Middle-aged patient with "worst headache of life" from ruptured SA → SAH
    - Incidental finding on imaging performed for unrelated symptoms in patient of any age

Demographics

- Age
  - ↑ incidence of SA with age; rare in children
- Gender
  - M < F (especially with multiple aneurysms)
- Epidemiology
  - 2-6% incidental finding of unruptured SA at autopsy
  - Annual risk of de novo aneurysm formation = 0.8% in patients with previous SA

Natural History & Prognosis

- Rupture risk
  - Size: Low risk of SA rupture if < 7 mm
  - Growth, rupture risk for unruptured aneurysms
    - Growth rate = 3.9% per year
    - 1.8% per year rupture risk
  - ~ 20% of ruptured unsecured SA rebleed within 2 weeks, 50% in 6 months
  - Shape: Daughter lobe likely ↑ risk of future SAH; Murphy teat = site of recent rupture and possible rebleed if untreated
  - ↑ in females with history of HTN, smoking

Treatment

- Endovascular coiling
  - Ruptured SA: 22.6% relative, 6.9% absolute risk ↓ for coiling vs. surgery (1 study)
  - Unruptured SA: Coiling vs. clipping
    - ↓ morbidity, mortality, and hospital costs; shorter hospital stay; quicker recovery
- Surgical clipping
  - Lower SA recurrence risk compared with coiling, although rebleeding risk is low with either Rx
  - May have advantage in MCA and other SA where branch vessel arising from SA must be preserved

DIAGNOSTIC CHECKLIST

Consider

- Blood blister-like aneurysm if negative CTA in patient with SAH → perform DSA
- Perimesencephalic bleed in patient with blood localized to interpeduncular cistern

Image Interpretation Pearls

- Diffuse SAH without focal hematoma → ACoA is most likely site of ruptured SA
- Absence of sylvian fissures may be clue to subacute (isodense) SAH

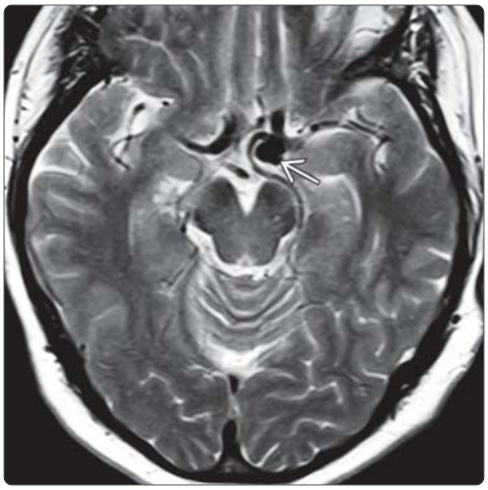
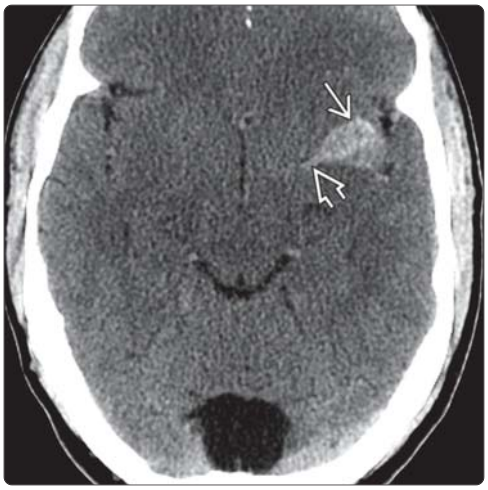
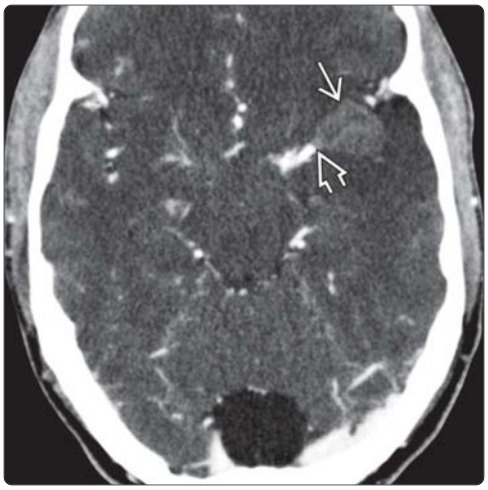
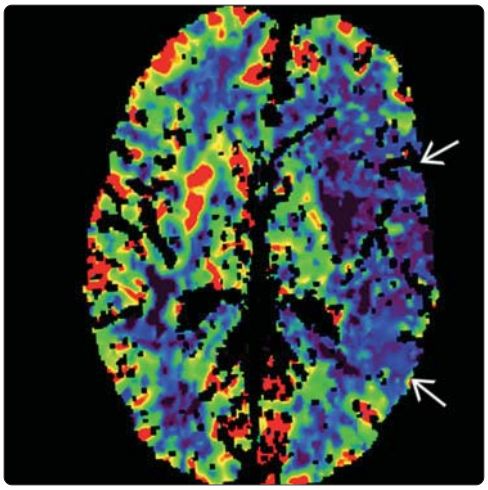
https://CafePezeshki.IR



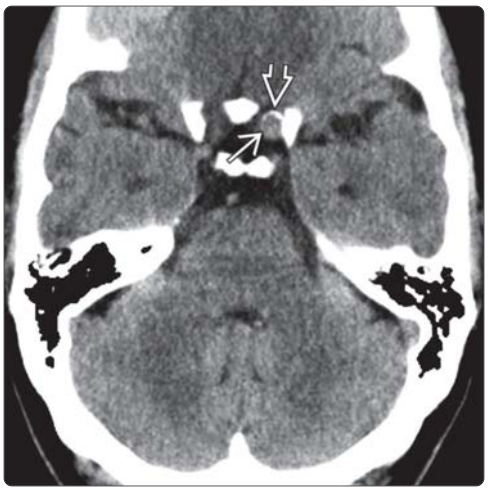


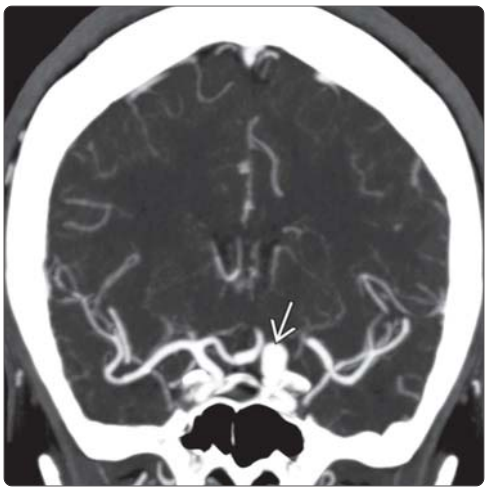
(Left) *Patent saccular aneurysms are seen as rounded hypointense "flow voids" on MR. This saccular aneurysm at the distal ICA bifurcation ➡ was found incidentally on the T2WI of this elderly patient.* **(Right)** *Thrombosed SAs can appear very hyperdense. This patient presented in the ER with sudden onset of right hemiparesis. NECT scan, obtained as the initial study in the standard stroke protocol, shows an ovoid hyperdensity ➡ with what appears to be thrombus in the left proximal MCA ➡.*





(Left) *Source image from the CTA in the same patient shows abrupt "cut-off" of the left MCA ➡ and nonfilling of a large, completely thrombosed saccular aneurysm ➡.* **(Right)** *CT perfusion study in the same patient shows markedly decreased cerebral blood flow in the left MCA distribution ➡. The basal ganglia (supplied by lenticulostriate branches from the unoccluded proximal MCA) are spared. Cerebral infarction can be caused by distal migration of clot from a thrombosed SA.*





(Left) *Some aneurysms exhibit mural calcification. NECT scan shows an incidentally discovered SA, seen here as a well-demarcated rounded hyperdensity ➡ with a peripheral rim of calcification ➡.* **(Right)** *CTA was subsequently performed in the same patient. Coronal MIP shows a patent saccular aneurysm ➡ at the terminal bifurcation of the left ICA.*

https://CafePezeshki.IR

Pseudoaneurysm

KEY FACTS

TERMINOLOGY

- Focal arterial dilatation not contained by layer(s) of normal arterial wall

IMAGING

- General features
  - Irregular, lobulated or fusiform arterial outpouching
    - At atypical site for true (saccular) aneurysm
- NECT
  - Focal hematoma adjacent to vessel
- CTA
  - Focal, often irregular dilatation of vessel
- T1WI: Hematoma signal varies with clot age
- GRE: Hypointense

TOP DIFFERENTIAL DIAGNOSES

- Saccular aneurysm
- Dissecting aneurysm

PATHOLOGY

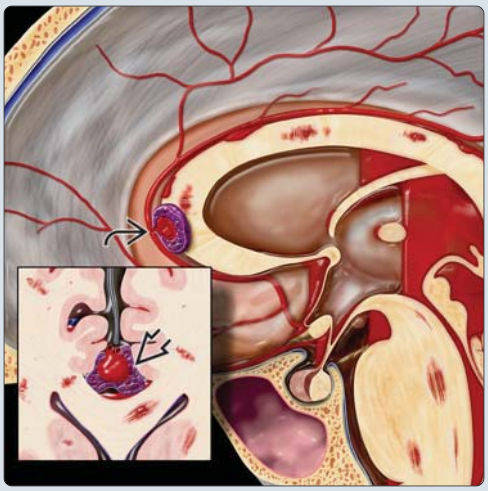
- Etiology
  - Trauma (penetrating or blunt)
  - Infection, inflammation ("mycotic" aneurysm)
  - Drug abuse, neoplasm ("oncotic" aneurysm)
  - Spontaneous dissection, underlying vasculopathy
  - XRT, surgery for H&N cancer ("carotid blow-out")

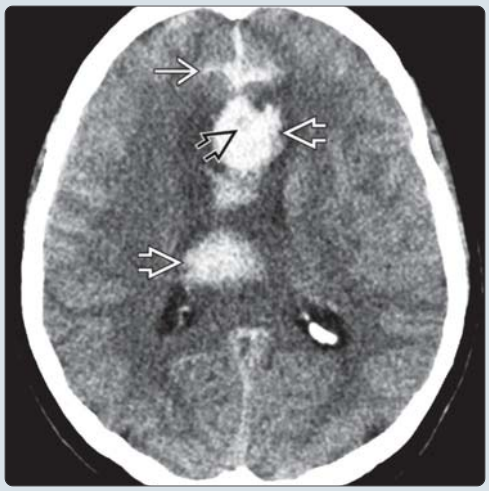
CLINICAL ISSUES

- Interval between initial injury, Sx varies from few days to several months
- PA rupture → sudden headache with SAH, parenchymal hematoma
- Other: Delayed stroke/SAH/parenchymal bleed following CHI

DIAGNOSTIC CHECKLIST

- Enhancing focus within hematoma may represent pseudoaneurysm





(Left) *Sagittal graphic shows sequelae of closed head injury. A pseudoaneurysm of distal ACA is seen. Note lesion is contained by cavitated clot ⇨ that communicates with the ACA ⇨.* **(Right)** *Axial NECT in a 52-year-old woman with sudden onset of severe headache 2 weeks following closed head injury shows subarachnoid hemorrhage ⇨ and focal hematomas within the corpus callosum ⇨. A subtle focus of relative hypodensity ⇨ is present within the genu clot.*

(Left) *Emergent CTA in the same patient was obtained and disclosed an irregular, contrast-filled lobulated outpouching of the anterior cerebral artery ⇨.* **(Right)** *Sagittal CTA reformatted from the axial source data in the same patient nicely depicts the source of the callosal hematoma ⇨. A bleeding traumatic pseudoaneurysm ⇨ was found at surgery.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Focal arterial dilatation not contained by layer(s) of normal arterial wall
  - Complete disruption of arterial wall

IMAGING

General Features

- Best diagnostic clue
  - Irregular, often fusiform arterial outpouching at atypical site for SA
- Location
  - Intracranial
    - Distal MCA, ACA, PCA, distal to circle of Willis
    - Petrous/cavernous ICA , vertebral artery (VA)
- Morphology
  - Often irregular ± fusiform shape

CT Findings

- NECT
  - Focal hematoma adjacent to vessel
  - Base of skull fx ± other CT signs of trauma (e.g., contusion, DAI, extraaxial hemorrhage)
- CTA
  - Focal often irregular vessel dilatation
    - Confined by adjacent hematoma

MR Findings

- T1WI
  - Hematoma signal varies with clot age
  - ± associated flow void within hematoma
- T2* GRE
  - Hypointense
- T1WI C+
  - Pseudoaneurysm enhances strongly
- MRA
  - Contrast-enhanced MRA recommended
    - Subacute hematoma may obscure pseudoaneurysm with TOF MRA

Angiographic Findings

- DSA
  - Lobulated or fusiform arterial outpouching
  - Pseudoaneurysm, distal parent vessel may fill/empty slowly → decreased perfusion

Imaging Recommendations

- Best imaging tool
  - CTA with multiplanar recons ± shaded surface display (SSD)
  - DSA for definitive diagnosis ± endovascular Rx

DIFFERENTIAL DIAGNOSIS

Saccular Aneurysm

- Circle of Willis > VA or distal ICA branches

Dissecting Aneurysm

- VA > ICA
- Contained by vessel wall (media, adventitia)

Active Extravasation (Other Causes)

- CTA shows focal enhancement within hematoma but often not contiguous with adjacent vessels

PATHOLOGY

General Features

- Etiology
  - Inciting event weakens arterial wall, which subsequently ruptures
    - Paravascular hematoma forms
    - Hematoma cavitates, communicates with residual lumen
    - PA wall consists of cavitated clot, fibrous tissue
  - Causes
    - Trauma (penetrating or blunt)
    - Infection, inflammation ("mycotic" aneurysm)
    - Drug abuse, neoplasm ("oncotic" aneurysm)
    - Spontaneous dissection, underlying vasculopathy
    - XRT, surgery for H&N cancer ("carotid blow-out")

Gross Pathologic & Surgical Features

- Purplish mass of organized hematoma

Microscopic Features

- Wall disruption, necrosis
- ± inflammatory or neoplastic cells

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - PA rupture → sudden headache with SAH, parenchymal hematoma
    - Interval between initial injury, Sx varies from few days to several months
    - Delayed ischemia, infarction common
- Clinical profile
  - Patient with delayed stroke/SAH/parenchymal bleed following closed head injury (CHI)

DIAGNOSTIC CHECKLIST

Consider

- Pseudoaneurysm in patient who develops delayed hematoma following CHI

Image Interpretation Pearls

- Enhancing focus within hematoma may represent pseudoaneurysm

KEY FACTS

TERMINOLOGY

- Extensive ectatic, elongated vertebrobasilar artery (VBA)
- Usually associated with decreased blood flow velocity

IMAGING

- General findings
  - Irregular, elongated, tortuous VBA
  - Usually 6-12 mm, can be giant (> 2.5 cm)
  - Focal arterial dilatation = fusiform aneurysm
- CT
  - Hyperdense tortuous enlarged vessel, Ca++ common
  - Enlarged lumen enhances, intramural thrombus does not
- MR
  - Signal varies with flow, presence/age of thrombus
  - Dynamic CE MRA best
  - 3D TOF inadequate (slow flow saturation effects)

TOP DIFFERENTIAL DIAGNOSES

- Fusiform aneurysm, ASVD
- Giant serpentine aneurysm
- Nonatherosclerotic fusiform vasculopathy
- Dissecting aneurysm

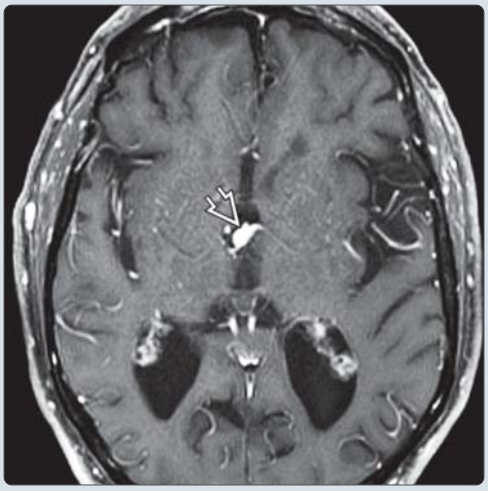
CLINICAL ISSUES

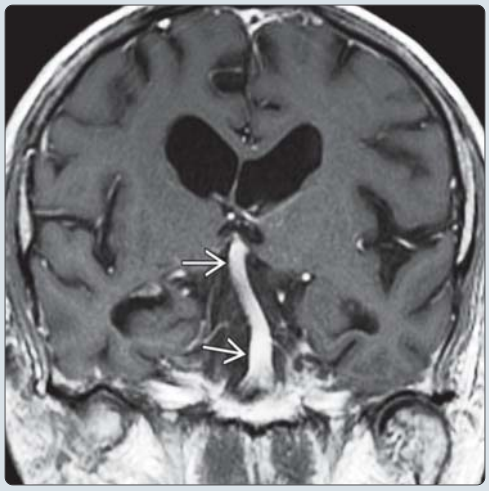
- Peak age = 7th, 8th decades
- Often asymptomatic
  - Vertebrobasilar TIAs
  - Progressive cranial nerve compression less common
  - Rare: Hemorrhage, hydrocephalus

DIAGNOSTIC CHECKLIST

- Slow complex flow → heterogeneous signal, TOF artifact
- Dynamic contrast-enhanced CTA/MRA or DSA necessary to delineate true lumen

(Left) *Autopsied brain seen from below shows ectatic, very tortuous basilar artery ⇨ with extensive yellow plaques of atherosclerosis. No focal areas of dilatation are seen, so this is vertebrobasilar dolichoectasia, a relatively common finding in elderly patients. (Courtesy R. Hewlett, MD.)* **(Right)** *Sagittal T1WI MR in a 76-year-old man with headaches shows a very elongated, unusually ectatic basilar artery ⇨. The basilar tip elevates and indents the 3rd ventricle ⇨.*





(Left) *Axial T1 C+ FS MR shows the strongly enhancing basilar bifurcation ⇨ as it indents the inferior 3rd ventricle.* **(Right)** *Coronal T1 C+ MR shows the extremely ectatic, elongated basilar artery ⇨ characteristic of typical vertebrobasilar dolichoectasia.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Vertebrobasilar dolichoectasia (VBD)

Synonyms

- Fusiform vertebrobasilar ectasia

Definitions

- Extensive ectatic, elongated vertebrobasilar artery (VBA)
  - Usually associated with decreased blood flow velocity

IMAGING

General Features

- Best diagnostic clue
  - Irregular, tortuous VBA ± long segment nonfocal fusiform arterial enlargement
- Location
  - Basilar > dominant vertebral or both vertebral arteries
    - Other arteries (e.g., PICA, often involved)
- Size
  - Usually moderate (6-12 mm)
    - May be giant (> 2.5 cm diameter)
- Morphology
  - Diffuse or multifocal ectatic vessel
    - If focal dilatation = atherosclerotic fusiform aneurysm

CT Findings

- NECT
  - Hyperdense tortuous enlarged vessel
    - Thickened walls, Ca++ common
    - Thrombus common
- CECT
  - Enlarged lumen enhances
    - Intramural thrombus/plaque does not
- CTA
  - Enlarged tubular ± focal fusiform vertebrobasilar arteries with tortuosity

MR Findings

- T1WI
  - Signal varies with flow, presence/age of thrombus
- T2WI
  - Lumen, thrombus hypointense
- FLAIR
  - Slow flow may cause intraluminal hyperintensity
- T1WI C+
  - Lumen enhances intensely
    - Pulsation artifact common
- MRA
  - Dynamic CE MRA best
  - 3D TOF inadequate (slow-flow saturation effects)

Imaging Recommendations

- Best imaging tool
  - Dynamic contrast-enhanced CTA/MRA
- Protocol advice
  - CTA/MRA (2D TOF &/or contrast-enhanced) for vessel delineation
  - T2/FLAIR for brainstem delineation

DIFFERENTIAL DIAGNOSIS

Fusiform Aneurysm

- Focal elongated aneurysmal outpouching
- Often superimposed on VBD

Giant Serpentine Aneurysm

- Round/oval mass
- Tortuous lumen, variable thrombus
- Delineation of outer wall morphology on T1, T2, or CT is crucial

Nonatherosclerotic Fusiform Vasculopathy

- Younger patient with inherited vasculopathy, inflammatory disease
- Anterior > posterior circulation

Dissecting Aneurysm

- Vertebral > basilar artery
- Lacks changes of ASVD, Ca++
- Usually more focal or with narrowing

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Often asymptomatic
    - Vertebrobasilar TIAs
    - Progressive cranial nerve compression less common
    - Rare: Hemorrhage, hydrocephalus

Demographics

- Incidence estimate 1.3%
- Peak age = 7th, 8th decades

Natural History & Prognosis

- Slow progressive increasing ectasia
  - May become symptomatic or develop symptoms of other ASVD
- Subarachnoid hemorrhage uncommon
  - Usually with associated focal fusiform aneurysm

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Slow complex flow may have heterogeneous signal, saturation artifacts
- Dynamic contrast-enhanced CTA/MRA or DSA necessary to delineate true lumen

KEY FACTS

TERMINOLOGY

- Atherosclerotic fusiform aneurysm (ASVD FA)
- ASVD → abnormal dilation, tortuosity of intracranial arteries
- Aneurysms with separate inflow, outflow ostia

IMAGING

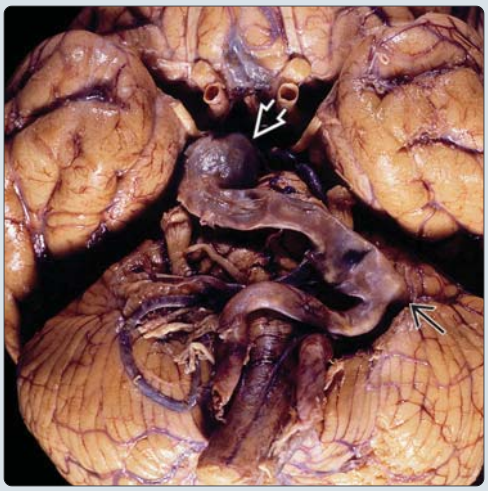
- Exaggerated arterial ectasia(s) + focal fusiform/saccular enlargement
  - Long segment irregular fusiform or ovoid arterial dilatation
  - Usually large (> 2.5 cm), may be giant
  - Vertebrobasilar > carotid circulation
- CT: Hyperdense, Ca++ common
- MR: Signal varies flow, presence/age of hematoma
  - Lumen, intramural clot often heterogeneous
  - Residual lumen enhances, intramural clot does not
  - Prominent phase artifact common
- Noncontrast 3D TOF inadequate due to flow saturation, phase dispersion
- Dynamic contrast-enhanced MRA for aneurysm delineation, T2 for brainstem delineation

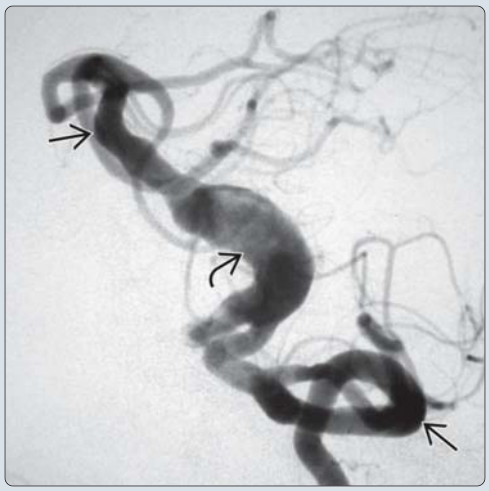
CLINICAL ISSUES

- Peak age: 7th to 8th decades
- Presentation
  - Ischemic stroke > compressive symptoms (cranial neuropathy)
    - Ranges from TIA to catastrophic pontine ischemia, "locked-in" syndrome
- Unlike saccular aneurysms, rupture with subarachnoid hemorrhage (SAH) and headache rare

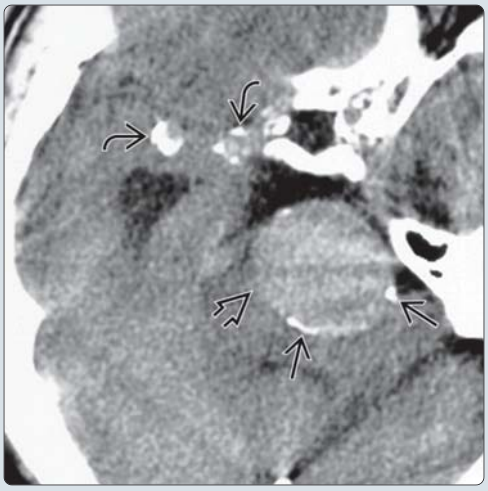
DIAGNOSTIC CHECKLIST

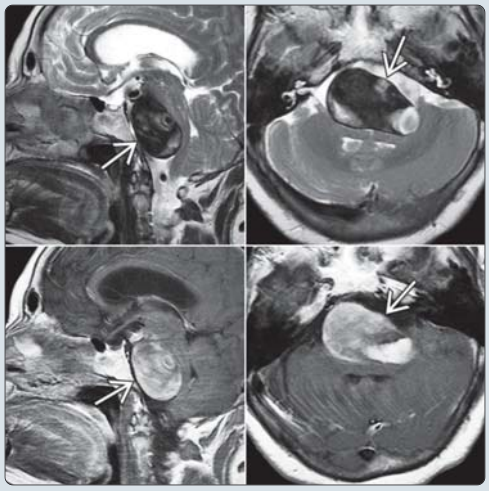
- DSA or contrast-enhanced CTA/MRA necessary to delineate patent lumen
- Slow/complex flow in residual lumen → heterogeneous signal
- Consider dissecting aneurysm, non-ASVD etiology if younger patient





(Left) *Autopsy shows a very tortuous vertebrobasilar artery with an atherosclerotic fusiform aneurysm that extends from the vertebral artery junction ⇨ to the distal basilar bifurcation ⇨. (Courtesy R. Hewlett, M.D.)* **(Right)** *Oblique DSA in the same patient 2 years later shows dolichoectasia of the proximal distal vertebral arteries ⇨. A fusiform ASVD aneurysm lies between the arterial ectasias. The residual lumen is indicated ⇨. The aneurysm had enlarged but also partially thrombosed, leading to mild TIAs.*





(Left) *NECT scan shows typical hyperdense atherosclerotic fusiform aneurysm ⇨ with mural calcifications ⇨. Note extensive calcification of the internal carotid, right middle cerebral arteries ⇨.* **(Right)** *Series of MR images shows the bizarre appearance of classic atherosclerotic fusiform vertebrobasilar aneurysm ⇨. (Courtesy M. Hartel, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Atherosclerotic fusiform aneurysm (ASVD FA)

Synonyms

- Giant fusiform aneurysm, megacolichobasilar artery

Definitions

- ASVD → abnormal dilation, tortuosity of intracranial arteries
  - Aneurysms with separate inflow, outflow ostia

IMAGING

General Features

- Best diagnostic clue
  - Long segment fusiform/ovoid arterial dilatation
- Location
  - Vertebrobasilar > carotid circulation
- Size
  - Usually large (> 2.5 cm), may be giant
- Morphology
  - Solitary/multifocal generalized dolichoectasia
  - Focal fusiform aneurysmal dilatation

CT Findings

- NECT
  - Hyperdense thrombus, isodense residual lumen
    - Ca++ common
- CECT
  - Residual lumen enhances; intramural clot does not
- CTA
  - Exaggerated arterial ectasia(s) + focal fusiform enlargement

MR Findings

- T1WI
  - Signal varies with degree of flow, presence/age of hematoma
- T2WI
  - Lumen, intramural clot often hypointense but heterogeneous
- T1WI C+
  - Residual lumen enhances intensely
    - Prominent phase artifact common
- MRA
  - Noncontrast 3D TOF inadequate due to slow flow, saturation, phase dispersion effects

Imaging Recommendations

- Best imaging tool
  - Dynamic contrast-enhanced MRA or CTA
- Protocol advice
  - Dynamic contrast-enhanced MRA
  - T2, DWI (brainstem compression/edema, infarcts)

DIFFERENTIAL DIAGNOSIS

Atherosclerotic Dolichoectasia

- No focal fusiform/saccular dilatation

Giant Serpentine Aneurysm (GSA)

- Large, partially thrombosed mass with layered clot, no definable neck
- More common in MCA or PCA

Nonatherosclerotic Fusiform Vasculopathy

- Younger patient (inherited vasculopathy, immune disorder)

Dissecting Aneurysm

- Vertebral > basilar artery
- Lacks changes of ASVD in other vessels

PATHOLOGY

General Features

- Etiology
  - ASVD usual cause of basilar FA in older adults

Gross Pathologic & Surgical Features

- Generalized ASVD with focally dilated fusiform arterial ectasia(s)
- Thickened intima, intramural/intraluminal thrombus

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Ischemic stroke > compressive symptoms (cranial neuropathy)
    - Ranges from TIA to catastrophic pontine ischemia, "locked-in" syndrome
  - Unlike saccular aneurysms, rupture with subarachnoid hemorrhage (SAH) and headache rare

Demographics

- Peak age: 7th to 8th decades

Natural History & Prognosis

- After formation, ASVD FAs have aggressive growth course
  - Progressive enlargement, thrombosis → ↑ TIAs, stroke
  - Steady worsening of presenting signs, symptoms

Treatment

- Endovascular: Coils, flow-diverting stents (e.g., pipeline)

DIAGNOSTIC CHECKLIST

Consider

- Dissecting aneurysm, non-ASVD etiology if younger patient

Image Interpretation Pearls

- Slow/complex flow → heterogeneous signal
- DSA or contrast-enhanced CTA/MRA to delineate patent lumen

KEY FACTS

TERMINOLOGY

- Fusiform elongations occurring in absence of generalized intracranial ASVD
  - Usually caused by inherited/acquired vasculopathy

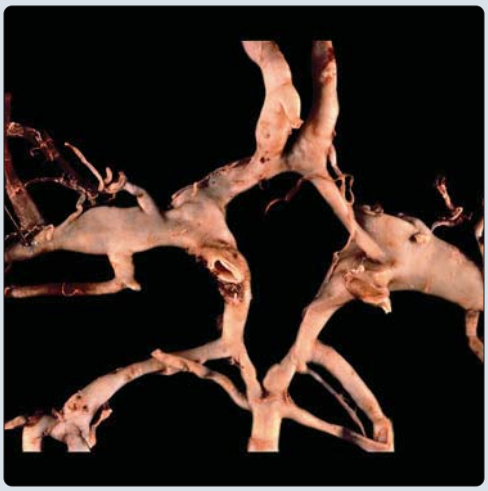
IMAGING

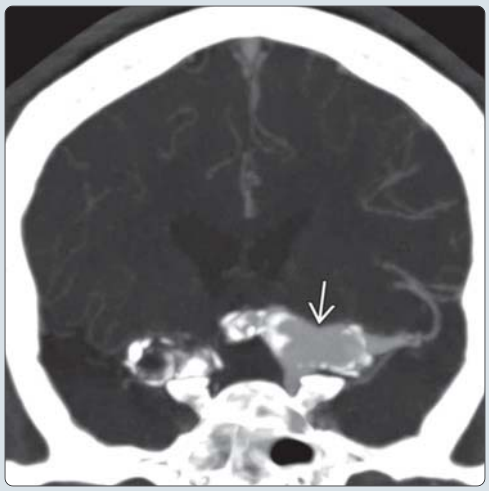
- General features
  - Long segment of tubular, fusiform, or ovoid arterial dilatation
  - Can be solitary or multifocal
  - Carotid, vertebrobasilar equally affected
  - Multiple lesions common
- CT
  - Hyperdense; Ca++ common
  - Strong, uniform enhancement (unless significant thrombus)
- MR
  - Mixed signal intensity (varies with flow, presence/age of hematoma)
  - May require dynamic contrast-enhanced MRA for accurate delineation
  - T2WI delineates outer wall of aneurysm and intraluminal or mural thrombus
  - DWI may show restriction from distal embolic complications
- CTA, DSA, MRA
  - Elongated, ectatic vessel ± more focal aneurysmal outpouching
  - Long, nonbranching vessel segments

PATHOLOGY

- Etiology
  - Collagen vascular disorders (i.e., SLE)
  - Viral, other infectious agents (e.g., varicella, HIV)
  - Inherited (e.g., Marfan, Ehlers-Danlos, neurofibromatosis type 1)
  - Drug abuse, neoplasm (e.g., atrial myxoma)

(Left) *Dissected circle of Willis in a hemophiliac child with HIV shows nonatherosclerotic fusiform vasculopathy involving multiple vessels, most striking in the MCAs. (Courtesy L. Rourke, MD.)* **(Right)** *Coronal MIP view of a CTA in a 25-year-old HIV positive man with a history of multiple strokes shows calcific vasculopathy with a fusiform aneurysm of the left distal ICA, proximal ACA, and MCA ➡.*





(Left) *Axial T2WI MR in the same patient shows the "flow void" of the left MCA fusiform aneurysm ➡. The right MCA is also enlarged but completely thrombosed ➡. TERMINOLOGY

Abbreviations

- Non-ASVD fusiform aneurysm/vasculopathy (FA)

Definitions

- Fusiform elongations occurring in the absence of generalized intracranial ASVD
  - Usually caused by inherited/acquired vasculopathy

IMAGING

General Features

- Best diagnostic clue
  - Long segment tubular, fusiform, or ovoid arterial dilatation(s)
- Location
  - Long, nonbranching vessel segments
    - Carotid, vertebrobasilar equally affected
    - Multiple lesions common

CT Findings

- NECT
  - Hyperdense; Ca++ common
- CECT
  - Lumen enhances strongly, clot does not

MR Findings

- T1WI
  - Elongated, tortuous flow void
  - Mixed signal intensity common, varies with
    - Flow velocity, direction, turbulence
    - ± clot (laminated layers of organized thrombus)
- T2WI
  - Mixed signal intensity (varies with flow, presence/age of hematoma)
- FLAIR
  - Slow flow can be hyperintense
- DWI
  - May show restriction from distal embolic complications
- T1WI C+
  - Residual lumen enhances strongly
- MRA
  - May require dynamic contrast-enhanced MRA for accurate lumen delineation

Angiographic Findings

- DSA
  - Solitary/multifocal ectasias, ± focal aneurysmal outpouchings

Imaging Recommendations

- Best imaging tool
  - CTA or MR + contrast-enhanced MRA

DIFFERENTIAL DIAGNOSIS

Vertebrobasilar Dolichoectasia

- Older patient with ASVD in other cranial vessels

Giant Serpentine Aneurysm

- Large, partially thrombosed mass

Atypical Saccular Aneurysm

- Looks identical to fusiform aneurysm

Pseudoaneurysm

- May look identical to fusiform aneurysm

PATHOLOGY

General Features

- Etiology
  - Collagen vascular disorders (i.e., SLE)
  - Viral, other infectious agents (e.g., varicella, HIV)
  - Drug abuse, neoplasm (e.g., atrial myxoma)
  - Inherited (e.g., Marfan, Ehlers-Danlos, neurofibromatosis type 1)

Staging, Grading, & Classification

- Type 1: Typical dissecting aneurysm
- Type 2: Segmental ectasias due to viral, neurocutaneous syndrome, radiation
- Type 3: Dolichoectatic dissecting aneurysms
- Type 4: Atypically located saccular aneurysm (i.e., lateral wall, unrelated to branching zones)

Gross Pathologic & Surgical Features

- Focally dilated fusiform arterial ectasia(s)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain, SAH > TIA, cranial neuropathy in dissection from collagen disorder etiology
  - Commonly asymptomatic or TIA/stroke in viral and neurocutaneous etiology

Natural History & Prognosis

- Type 1: Rebleed common
- Type 2: Benign clinical course
- Type 3: Slow but progressive enlargement
- Type 4: Rerupture risk high

Treatment

- Dependent upon underlying cause, expected natural history, location, and anatomy
- Often combined surgical, endovascular measures

DIAGNOSTIC CHECKLIST

Consider

- Non-ASVD fusiform aneurysm in young patient with dilated intracranial vessels

KEY FACTS

TERMINOLOGY

- Blood blister-like aneurysm (BBA)
  - Broad-based bulge at nonbranch point

IMAGING

- Half-dome or blood blister-like shape
- Supraclinoid internal carotid artery (ICA) most common site
  - Rarely MCA, ACA, ACoA, basilar artery
  - Usually small (< 6 mm; mean: 3 mm)
- NECT: Subarachnoid hemorrhage (SAH)
- CTA: Frequently subtle so CTA often called negative
- Best imaging tool: High-resolution DSA
  - Obtain multiple obliques ± 3D DSA

TOP DIFFERENTIAL DIAGNOSES

- Saccular aneurysm (SA)
- Vasospasm
- Atherosclerotic vascular disease (ASVD)
- Vessel infundibulum

PATHOLOGY

- Focal arterial wall defect covered with fibrous tissue
  - ± thin layer of adventitia (pseudoaneurysm)

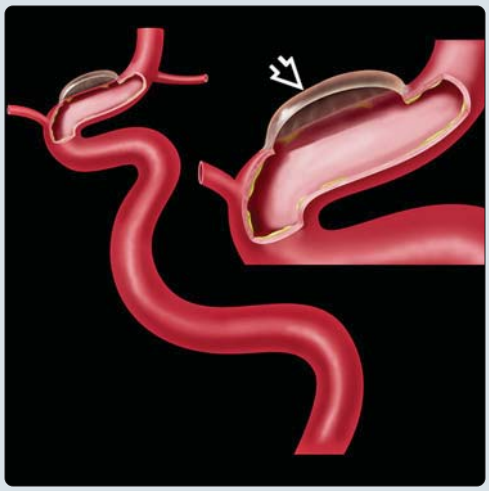
CLINICAL ISSUES

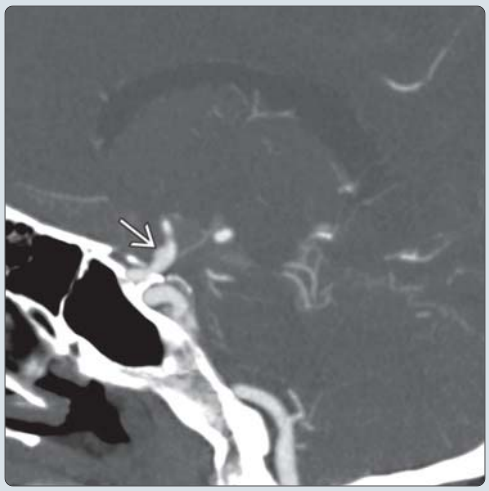
- Middle-aged patient often with angiogram negative SAH
- Fragile, difficult to treat
  - BBAs tend to rupture earlier, at smaller size than SA
  - Higher rebleed rate compared to SA
  - High risk of BBA rupture, ICA laceration during surgery
  - Small size, wide-neck make coiling difficult
  - Flow-diverter stents often preferred

DIAGNOSTIC CHECKLIST

- Angiogram negative SAH may be caused by BBA
- Look for subtle dome or bulging of supraclinoid ICA when SA is not seen in patient with SAH

(Left) *Sagittal graphic shows a blood blister-like aneurysm (BBA) arising from the dorsal (superolateral) wall of a supraclinoid internal carotid artery (ICA). The BBA is covered only by a thin fibrous wall.* **(Right)** *Reformatted lateral view of the CTA in a patient with subarachnoid hemorrhage (SAH) on NECT scan shows a small broad-based contrast-filled hemispheric bulge along the greater curvature of the ICA. (Courtesy C. D. Phillips, MD.)*





(Left) *Lateral DSA in the same patient shows the classic appearance of a blood blister-like aneurysm and confirms the CTA finding of a focal broad-based hemispheric bulge.* **(Right)** *Lateral right ICA DSA shows a small hemispherical bulge along the ventral paraclinoid ICA in a patient with SAH. Adjacent irregularity of the ICA lumen more distally likely reflects associated dissection or ASVD. There is vasospasm involving the ACA and a PCoA infundibulum.*

TERMINOLOGY

Abbreviations

- Blood blister-like aneurysm (BBA)

Definitions

- Broad-based bulge at nonbranch point
  - Supraclinoid internal carotid artery (ICA) > > MCA, ACA, basilar artery

IMAGING

General Features

- Best diagnostic clue
  - Small, broad-based, hemispherical bulge on anterosuperior (dorsal) wall of supraclinoid ICA
  - Rapid change in size/morphology on follow-up angiograms
- Location
  - Nonbranching sites on supraclinoid ICA most common (dorsal wall > ventral)
  - MCA (M1), ACA (A1), anterior communicating artery, basilar artery (rare)
- Size
  - Usually small (< 6 mm; mean: 3 mm)
- Morphology
  - Half-dome or blood blister-like shape

CT Findings

- NECT
  - Aneurysmal subarachnoid hemorrhage (aSAH)
- CTA
  - ± asymmetric bulging of supraclinoid ICA
  - Frequently subtle so CTA often called negative

MR Findings

- FLAIR
  - Hyperintense CSF if SAH present
- MRA
  - ± visualized on high-resolution MRA

Angiographic Findings

- Conventional DSA
  - BBAs often small, subtle
  - Slight irregularity/small focal hemispherical bulge of arterial wall at characteristic location
  - Multiple projections ± 3D DSA helpful

Imaging Recommendations

- Best imaging tool
  - High-resolution DSA
    - Obtain multiple obliques ± 3D DSA

DIFFERENTIAL DIAGNOSIS

Saccular Aneurysm (SA)

- True aneurysm, typically at arterial bifurcation

Vasospasm

- Usually symmetrical, concentric narrowing of vessel

Atherosclerotic Vascular Disease (ASVD)

- Common in patients with BBA, difficult to distinguish

Vessel Infundibulum

- Funnel-shaped vessel origin; < 3 mm
- Common at posterior communicating artery (PCoA), anterior choroidal artery (AChA) origins

PATHOLOGY

General Features

- Etiology
  - ASVD with ulceration, hematoma formation
  - ICA dissection, arteriosclerosis, hypertension

Gross Pathologic & Surgical Features

- Focal arterial wall defect covered with fibrous tissue
  - ± thin layer of adventitia (pseudoaneurysm)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - "Thunderclap" headache 2° to SAH
- Clinical profile
  - Middle-aged patient with angiogram negative SAH

Demographics

- Gender
  - M:F = 1:2
- Epidemiology
  - 1-6% of all intracranial aneurysms resulting in SAH

Natural History & Prognosis

- More aggressive behavior, more intraoperative complications than SA
  - Tends to rupture earlier, at smaller size than SA
  - Higher rebleed rate compared with SA

Treatment

- Fragile, difficult to treat
  - Clipping, wrapping carry high rupture risk
    - BBA avulsion, ICA laceration
    - High risk of BBA rupture during dissection (45%)
- Endovascular
  - Small size, wide-neck make coiling difficult
  - Flow-diverter stents feasible alternative

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Angiogram negative SAH may be caused by BBA
  - Consider early repeat DSA as rebleed risk higher than with typical saccular aneurysm
  - Look for subtle dome or bulging of supraclinoid ICA when SA is not seen in patient with SAH

Introduction

Stroke is a generic term that describes the clinical event of a sudden onset of neurologic deficit secondary to cerebrovascular disease. Stroke has 4 main etiologies, including cerebral infarction (80%), intraparenchymal hemorrhage (15%), nontraumatic subarachnoid hemorrhage (5%), and venous infarction (approximately 1%). Clinically, ischemic infarction is the most common etiology and will be the main topic of this introduction. The principal cause of cerebral infarction is atherosclerosis and its sequelae.

Ischemic Infarction

There are 3 major clinical ischemic stroke subtypes based upon the classification from a multicenter clinical trial (trial of drug ORG 10172 in acute stoke treatment [TOAST]). These 3 subtypes include large artery/atherosclerotic infarctions, cardioembolic infarctions, and small vessel occlusion (lacunar) infarctions.

Large artery/atherosclerotic strokes represent approximately 40% of strokes and can arise from thrombosis at the site of a plaque or from emboli produced at the plaque that lodge downstream. The most common site of atherosclerotic plaque is at the carotid bifurcation with involvement of the distal common carotid artery and the 1st 2 cm of the internal carotid artery. The most frequently occluded intracranial vessel is the middle cerebral artery (MCA). Other common locations for atherosclerotic plaque include the carotid siphon and proximal anterior and middle cerebral arteries. The vertebral and basilar arteries are also commonly involved by atherosclerosis.

Cardioembolic disease accounts for 15-25% of ischemic strokes. Risk factors include myocardial infarction, ventricular aneurysm, atrial fibrillation or flutter, cardiomyopathy, and valvular heart disease.

Lacunar infarcts are small in size (< 15 mm), typically in the basal ganglia and thalamus, and account for 15-30% of all strokes. They are often multiple and are due to embolic, atheromatous, or thrombotic lesions in the single penetrating end arterioles that supply the deep gray nuclei, including the lenticulostriate and thalamoperforating arteries. Other common locations for lacunar infarcts include the internal capsule, pons, and corona radiata.

Intraparenchymal Hemorrhage

Intraparenchymal hemorrhage represents ~ 15% of all strokes and includes multiple etiologies. Hypertensive hemorrhage is the most common etiology, representing ~ 40-60% of all primarily intracranial hemorrhages. Other etiologies include amyloid angiopathy in elderly patients, as well as vascular malformations, vasculitis, drugs, and bleeding diathesis.

Risk factors for hemorrhagic stroke include increasing age, hypertension, smoking, excessive alcohol consumption, prior ischemic stroke, abnormal cholesterol, and anticoagulant medications.

Although the MR physics related to hemorrhage are complex, the stages are generally accepted as hyperacute, acute, early subacute, late subacute, and chronic.

Nontraumatic Subarachnoid Hemorrhage

Nontraumatic subarachnoid hemorrhage is typically related to an aneurysm (75%) or a vascular malformation, such as an arteriovenous malformation or cavernous angioma. Nonaneurysmal "perimesencephalic" subarachnoid hemorrhage is uncommon.

Venous Infarction

Dural sinus or cerebral vein occlusion is rare, representing less than 1% of strokes. Venous thrombosis risk factors include pregnancy, trauma, dehydration, infection, oral contraceptives, coagulopathies, malignancies, collagen vascular diseases, and protein C and S deficiencies. Venous infarcts occur in only ~ 50% of venous thrombosis cases, and can be differentiated from arterial infarcts by the location of the ischemia. Superior sagittal sinus thrombosis typically results in T2/FLAIR hyperintense parasagittal lesions, while thrombosis of the transverse sinus often results in T2/FLAIR hyperintensities in the posterior temporal lobe. Additionally, venous infarcts more commonly present with associated hemorrhage. Contrast-enhanced CT is useful to identify the "empty-δ" sign representing thrombus within a major dural sinus, typically the superior sagittal or transverse sinus.

Approach to Stroke Imaging

Cerebral ischemia results from significantly decreased blood flow to selected areas or the entire brain. Stroke progresses in stages from ischemia to actual infarction. In the most common situation, MCA occlusion, there is a densely ischemic central core and a less densely ischemic "penumbra." The central core is usually irreversibly damaged unless reperfusion is quickly established, whereas the cells within the penumbra may remain viable but at risk for several hours. Current stroke therapies attempt to rescue the "at-risk" cells.

Currently, acute stroke protocols vary among different institutions. The exact protocol is often based on the availability of CT vs. MR, technology/software, time of stroke, physician expertise, and the possibility of neurointervention. Typically, stroke neurologists work with neuroradiologists to devise a plan that best serves the patient's needs.

Most stroke protocols begin with a noncontrast head CT to evaluate for hemorrhage or mass, which directly affects treatment decisions. Additionally, > 1/3 MCA territory hypodensity at presentation is considered by most to be a contraindication to thrombolysis, as it is associated with a greater risk of fatal hemorrhage. CTA is useful to evaluate for large vessel occlusion. When available, CT perfusion is an excellent way to evaluate for large vessel ischemia.

MR with diffusion-weighted imaging (DWI) is particularly useful for acute ischemia when CT perfusion is negative and the clinical suspicion for stroke remains. MR is also the primary imaging tool when the clinical question includes a posterior fossa or brainstem lesion. MR with perfusion imaging (PWI) has been found extremely helpful in guiding therapy when available.

Most stroke protocols use 3-hour and 6-hour windows for treatment of nonhemorrhagic ischemic stroke. If the patient presents within 6 hours after the initial onset of symptoms, an unenhanced CT is typically the initial study of choice to exclude a mass or hemorrhage. If there is a hemorrhage or mass, no thrombolytic therapy is initiated. If there is no hemorrhage or mass and the patient is within 3 hours after onset of symptoms, the patient is eligible for intravenous (IV) thrombolysis. If the patient is between 3 and 6 hours of onset, either a CTA with CT perfusion or an MR with DWI and PWI is performed to determine if they are eligible for treatment. If the patient has an intracranial thrombus with a penumbra,

https://CafePezeshki.IR

Five Stages of Intraparenchymal Hemorrhage

Stage	Time (Range)	Blood Products	T1	T2
Hyperacute	< 24 hours	Oxyhemoglobin	Isointense	Bright
Acute	1-3 days (hours to days)	Deoxyhemoglobin	Isointense	Dark
Early subacute	> 3 days (days to 1 week)	Intracellular methemoglobin	Bright	Dark
Late subacute	> 7 days (1 week to months)	Extracellular methemoglobin	Bright	Bright
Chronic	> 14 days (≥ months)	Hemosiderin	Dark	Dark

intraarterial (IA) thrombolysis or IA thrombectomy is recommended. If there is no penumbra, IA therapy may not benefit the patient, so each case is evaluated individually.

The effective therapeutic window for the posterior circulation is thought to be longer than the 3-6-hour window, but the exact time is variable and depends on collateral circulation. Therefore, patients with vertebrobasilar thrombosis are evaluated individually for risk vs. benefit of IA thrombolysis or thrombectomy.

Ischemic Penumbra

Ischemic stroke results in a core of tissue that has undergone irreversible injury. The ischemic penumbra is the area of brain that may be salvageable with appropriate therapy. The penumbra typically surrounds the ischemic core and is supported by collateral circulation.

The ischemic penumbra can be identified by a combination of MR diffusion (DWI) and perfusion imaging (PWI). DWI is the most reliable estimate of the ischemic core and generally correlates with irreversible injury. However, with early reperfusion following thrombolysis, some reversal of DWI can be observed. PWI evaluates the presence of a penumbra. With MR, the mismatch between the DWI and PWI defines the penumbra. This model provides a practical means to estimate the ischemic penumbra. In general, if there is no diffusion/perfusion mismatch, therapy may be ineffective.

With the newer CT perfusion techniques, an ischemic penumbra may also be measured with CT.

With the urgency of acute stroke, MR may be impractical. However, with new faster MR protocols and the superiority of MR to CT in detecting small vessel ischemia and brainstem ischemia, MR may be a preferred technique.

CT Perfusion (pCT)

Cerebral perfusion refers to the tissue-level blood flow in the brain. This flow is evaluated by 3 main parameters at pCT: Cerebral blood flow (CBF), cerebral blood volume (CBV), and mean transit time (MTT).

CBF is defined as the volume of blood moving through a given unit volume of brain per unit time. CBF uses units of milliliters of blood per 100 g of brain tissue per minute. Studies suggest that CBF is a reasonable marker for the ischemic penumbra.

CBV is defined as the total volume of blood in a given unit volume of brain. This includes blood in the tissues as well as blood in the large-capacitance vessels, such as arteries, arterioles, capillaries, venules, and veins. CBV uses units of milliliters of blood per 100 g of brain tissue. Some studies suggest that CT perfusion-acquired CBV is a reasonably reliable marker of the ischemic core.

MTT is defined as the average of the transit time of blood through a given brain region. The transit time of blood through the brain parenchyma varies depending on the distance traveled between arterial inflow and venous outflow. MTT equals CBV/CBF.

CBF/CBV mismatch correlates with stroke enlargement in untreated or unsuccessfully treated patients. Those patients with a CBF/CBV match or those with early complete recanalization do not exhibit progression of the ischemic stroke.

The general treatment guidelines for pCT are as follows. If there is a CBF/CBV mismatch, with a larger CBF suggesting an ischemic penumbra, the patient is likely a good candidate for therapy. Many treatment guidelines suggest that a ≥ 20% CBF/CBV mismatch should be present to consider thrombolysis. Some authors propose that if there is no mismatch between CBV and CBF, treatment is unlikely to benefit the patient.

CT Perfusion Interpretation Pearls

The MTT is the most sensitive parameter for perfusion deficits. Although it is generally elevated due to a thromboembolic process, it may be elevated in a patient with significant arterial atherosclerotic narrowing. In early ischemia, MTT is elevated and CBF is decreased. However, the CBV can be preserved or even elevated due to capillary bed dilatation in very early ischemia. Once a CBF threshold is reached, CBV starts to decline. This results in the ischemic core, which has a matched decrease in CBF and CBV, whereas a mismatch between CBF and CBV suggests a penumbra.

Differential Diagnosis

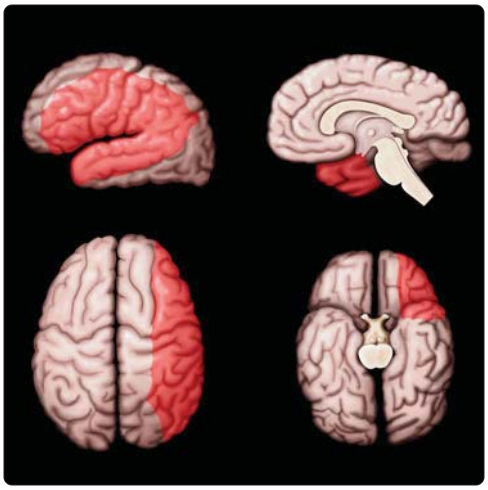
When considering **stroke** in a **child** or **young adult**, several possible etiologies should be addressed, including arterial dissection, vascular malformation with hemorrhage, drug abuse, or clotting disorder. In **young children**, other possibilities include congenital heart disease with emboli and idiopathic progressive arteriopathy of childhood (moyamoya disease).

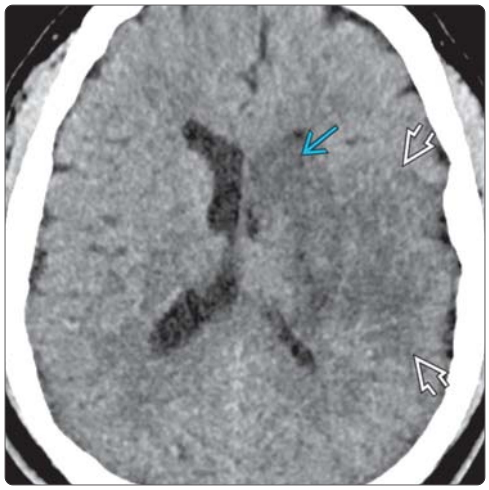
In a middle-aged or older **adult**, the typical stroke etiologies include arterial thromboembolism, hypertensive hemorrhage, and cerebral amyloid angiopathy.

When evaluating a **hemorrhagic stroke**, etiologies in **children** include vascular lesions, hematologic disorder, vasculopathy, and venous infarct. In a **young adult**, considerations include vascular malformations, drug abuse, and less commonly venous occlusions or vasculitis. In **older adults**, common considerations for intracranial hemorrhage include hypertensive hemorrhage, neoplasm, cerebral amyloid angiopathy, and, less commonly, dural sinus/cerebral venous occlusion and coagulopathy.

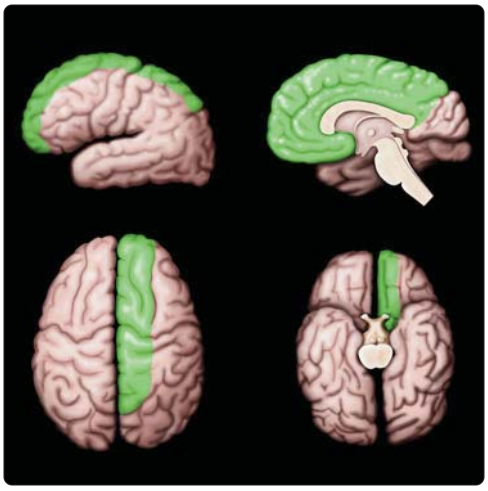
https://CafePezeshki.IR

(Left) *Graphic shows the cortical MCA distribution in red. MCA distribution typically involves the majority of the lateral surface of the hemisphere, including the frontal, temporal, and parietal lobes. In addition, the majority of the lenticulostriate arteries arise from the M1 segment and supplies the basal ganglia.* **(Right)** *Axial CT shows a large left MCA distribution infarct ➡ with involvement of the basal ganglia ⇨, indicating involvement of the lenticulostriate perforating arteries, which typically arise from the M1 segment.*

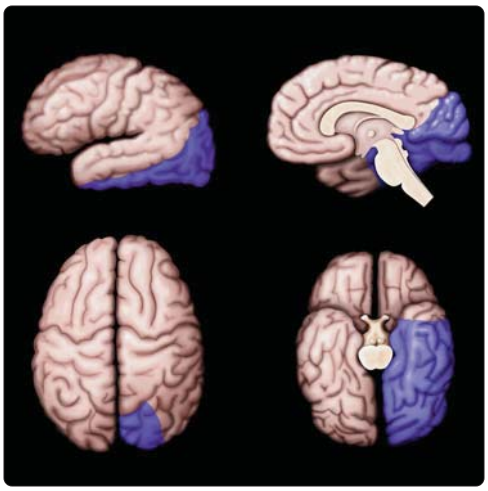


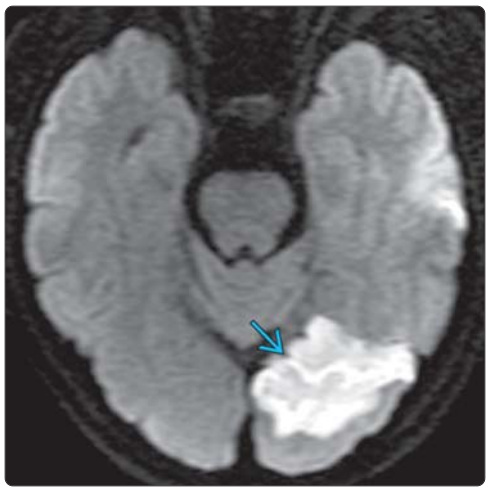


(Left) *Graphic shows the ACA cortical vascular territories in green. The ACA supplies the medial anteroinferior frontal lobe, the anterior 2/3 of the medial hemisphere surface, and a variable amount of territory over the cerebral convexity. The corpus callosum is also typically supplied primarily by the ACA branches: Callosal perforating, pericallosal, and posterior splenial branches.* **(Right)** *Axial DWI MR shows diffusion restriction in the left ACA distribution ➡ within the medial parafalcine frontal lobe.*

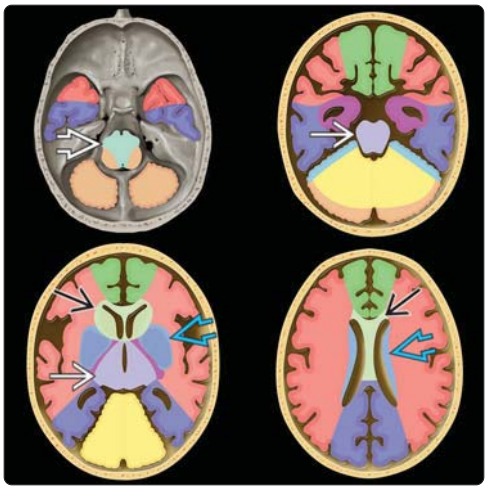


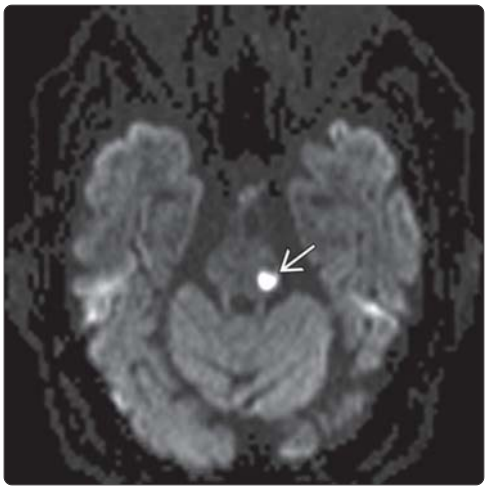
(Left) *Graphic shows the typical PCA vascular territory, including the occipital lobes, inferior temporal lobes, and medial posterior 1/3 of the interhemispheric brain. Patients with PCA ischemia most commonly present with visual complaints. Large vessel/atherosclerotic strokes represent ~ 40% of strokes. The carotid bifurcation is the most common site of atherosclerotic plaque.* **(Right)** *Axial DWI MR shows diffusion restriction ⇨ in the occipital lobe related to PCA ischemia. DWI is the most sensitive MR sequence for acute ischemia.*



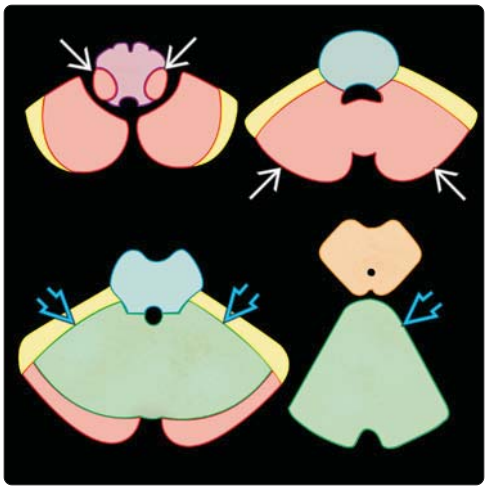


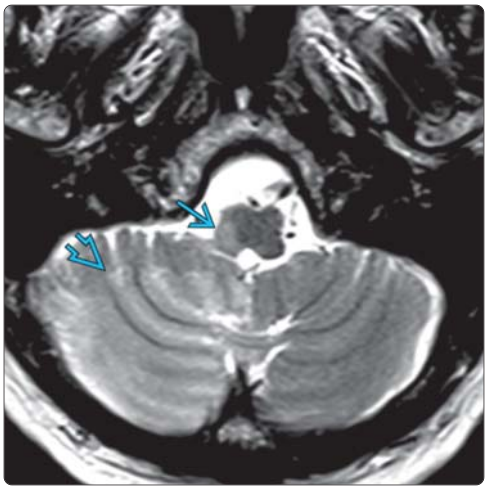
https://CafePezeshki.IR



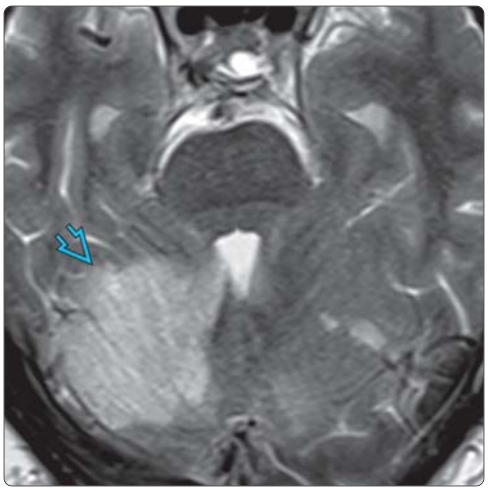


(Left) *Axial graphic shows the major penetrating artery distributions. The pontine and thalamic perforating arteries ➡, as well as the medullary perforators ➡, arise from the vertebrobasilar system. The medial ➡ and lateral ➡ lenticulostriate arteries arise from the anterior circulation and supply the basal ganglia. The choroidal arteries are shown in magenta.* **(Right)** *Axial DWI MR shows diffusion restriction related to acute ischemia ➡ in a pontine-perforating artery distribution.*





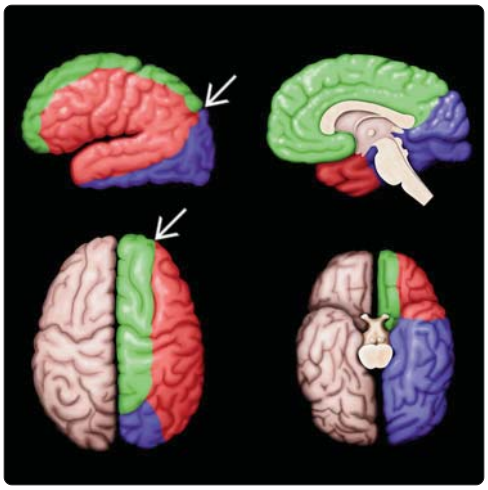
(Left) *Axial graphic shows the cerebellar artery distributions. The superior cerebellar artery (SCA) ➡ (green) supplies the superior cerebellum. The posterior inferior cerebellar artery (PICA) (peach) ➡ supplies the majority of the inferior cerebellum and lateral medulla. The anterior inferior cerebellar artery (AICA) (yellow) supplies the petrosal surface of the cerebellum.* **(Right)** *Axial T2WI MR shows hyperintensity in the right inferior cerebellum ➡ and lateral medulla ➡ related to a PICA infarct from a vertebral artery embolus.*

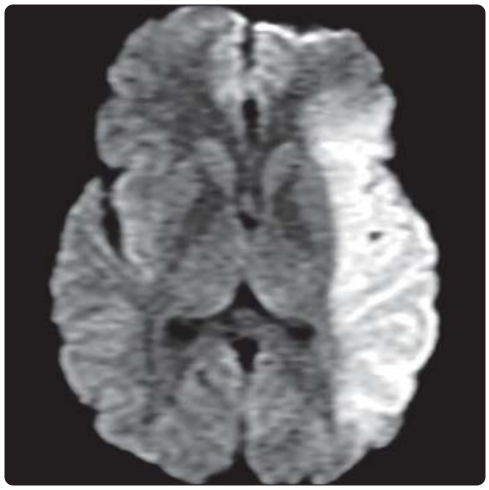


(Left) *Axial T2WI MR shows hyperintensity and local mass effect in the right superior cerebellum ➡ related to an acute SCA infarct. SCA infarcts may involve the superior cerebellum and the upper lateral pons.* **(Right)** *Axial DWI MR image shows acute diffusion restriction ➡ in the anterior, inferior cerebellum laterally in an AICA distribution. AICA primarily supplies the ventral pons and petrosal surface of the cerebellar hemispheres, the brachium pontis, flocculus, and inner ear as well as CN7 and CN8.*

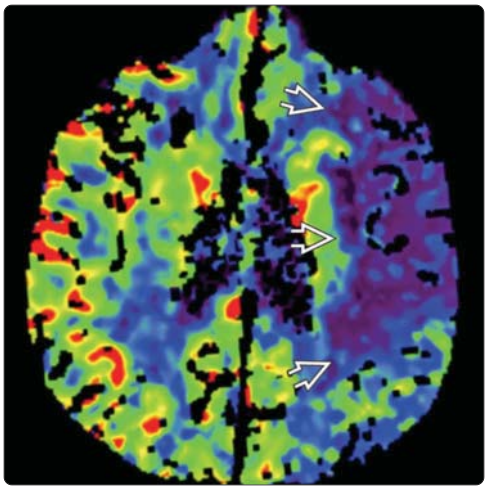
https://CafePezeshki.IR

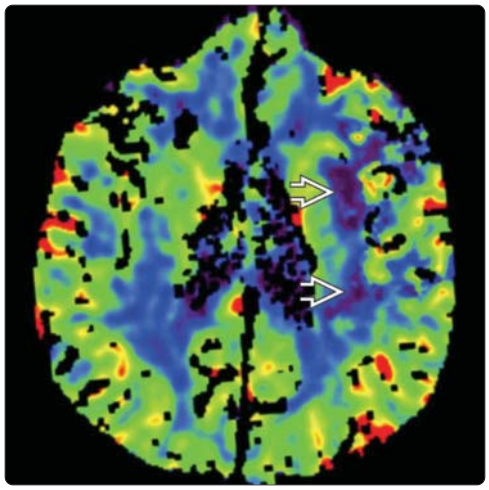
(Left) *Whole brain graphics show the major arterial supply to the hemispheres. The MCA (red) supplies the lateral aspects of the frontal and temporal lobes. The ACA (green) supplies the medial hemispheres. The PCA (purple) supplies the occipital lobes and inferior temporal lobes. The watershed zone ⇨ is the border between the major vascular territories.* **(Right)** *Axial DWI MR shows restriction in left MCA territory with preservation of the basal ganglia. The MCA territory is the most common location for ischemic stroke.*



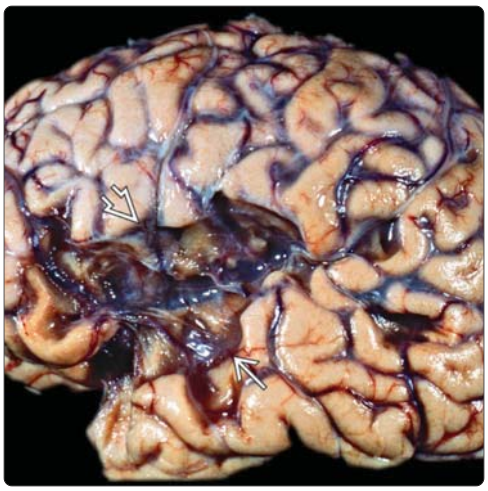


(Left) *Axial CT perfusion CBF color map shows a large area of decreased blood flow ⇨ in the left hemisphere related to hyperacute MCA ischemia.* **(Right)** *Axial CT perfusion CBV color map in the same patient shows a much smaller area of decreased blood volume ⇨. The CBV is a marker for the ischemic core. This CBF/CBV mismatch correlates with the presence of a large ischemic penumbra, which suggests the patient would benefit from intraarterial thrombolytic therapy or clot retrieval.*

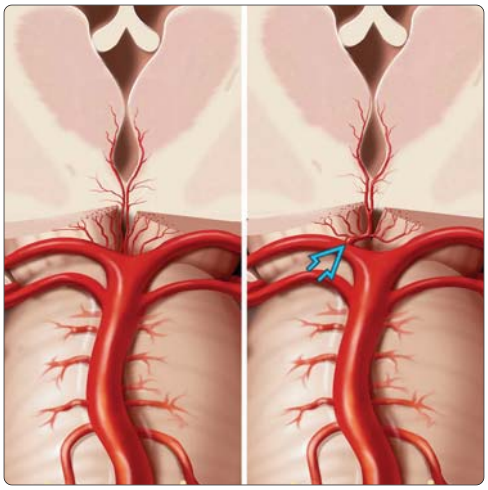


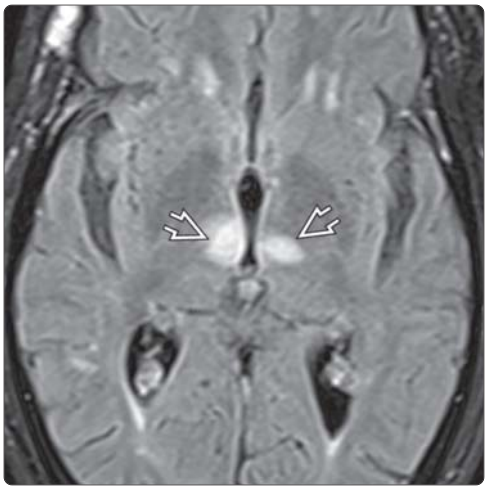


(Left) *Lateral gross pathology shows a chronic MCA infarct with hemorrhage and encephalomalacia in the frontal operculum ⇨ and temporal lobe ⇨.* **(Right)** *Axial FLAIR MR shows multiple hyperintense foci ⇨ in the watershed zones between the major cerebral artery territories (MCA, PCA, and ACA) related to acute ischemia from hypoperfusion. The posterior confluence where all 3 vascular distributions meet together at the vertex ⇨ is especially vulnerable to cerebral hypoperfusion.*

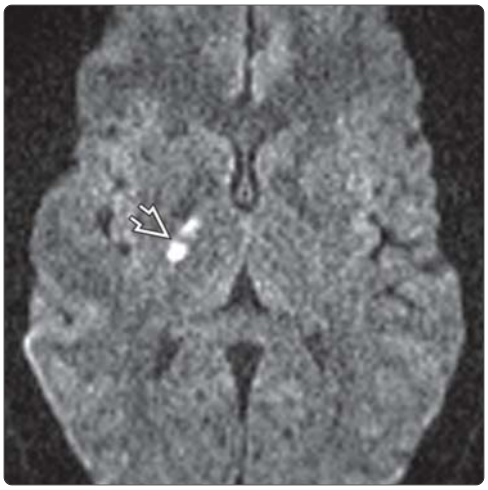


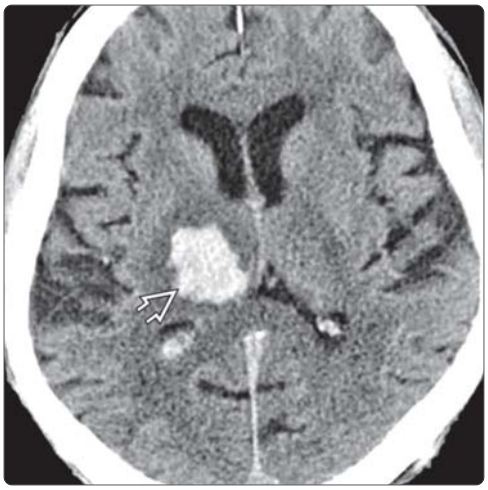
https://CafePezeshki.IR



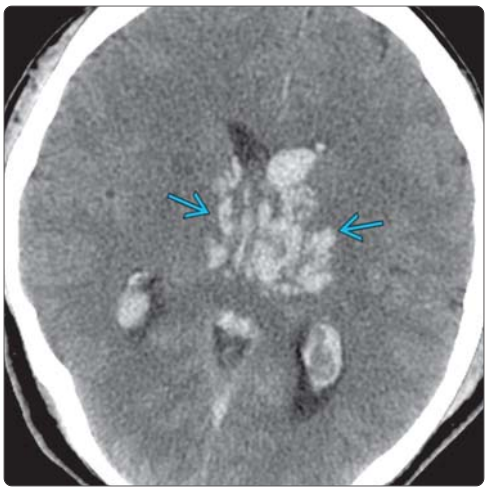


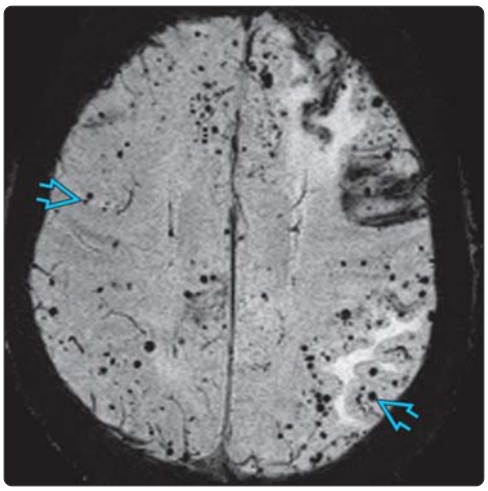
(Left) *Coronal oblique graphic of the rostral basilar artery shows (left panel) the typical arterial supply to the medial thalami by multiple PCA and basilar tip perforators. Right panel shows the anatomic variant, artery of Percheron ⇨, in which a single large perforating artery from P1 supplies bilateral thalami and the medial midbrain.* **(Right)** *Axial FLAIR MR shows hyperintensity in the bilateral medial thalami ⇨ related to an acute artery of Percheron infarct. Extension to the medial midbrain is often present.*





(Left) *Axial DWI MR shows hyperintensity related to acute ischemia in the posterior limb of the internal capsule ⇨ in an anterior choroidal artery distribution. The anterior choroidal artery typically supplies the lateral midbrain, uncus, thalamus, posterior limb of internal capsule, and the optic tract. The posterior choroidal artery typically supplies the pulvinar, thalamus, medial temporal lobe, splenium, and choroid plexus.* **(Right)** *Axial CT shows a classic thalamic hypertensive hemorrhage ⇨, the 2nd most common cause of stroke.*





(Left) *Axial CT shows bilateral thalamic hemorrhage ⇨ related to deep venous thrombosis. Venous thrombosis risk factors include pregnancy, trauma, dehydration, infection, oral contraceptives, coagulopathies, malignancies, collagen vascular diseases, and protein C and S deficiencies.* **(Right)** *Axial SWI MR image in an elderly patient shows extensive susceptibility artifact related microhemorrhages ⇨ in the bilateral hemispheres. Pattern is typical of cerebral amyloid angiopathy.*

https://CafePezeshki.IR

KEY FACTS

IMAGING

- Hyperdense (50-70 HU) mass on CT; peripheral edema develops over 1st days
- Hematoma matures more slowly in center (core) than in periphery
- MR: Intracranial hemorrhage staging based on T1 and T2 signal characteristics
  - MR as sensitive as CT in hyperacute phase and more sensitive in subacute and chronic phase
  - MR signal change proceeds peripherally to centrally

PATHOLOGY

- Very common: Hypertension (HTN), cerebral amyloid angiopathy, trauma, hemorrhagic vascular malformations
- Common: Infarct with reperfusion, coagulopathy, blood dyscrasia, drug abuse, tumor (glioma, metastases)

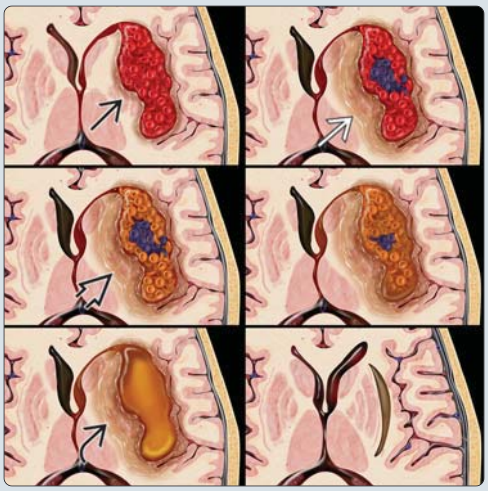
CLINICAL ISSUES

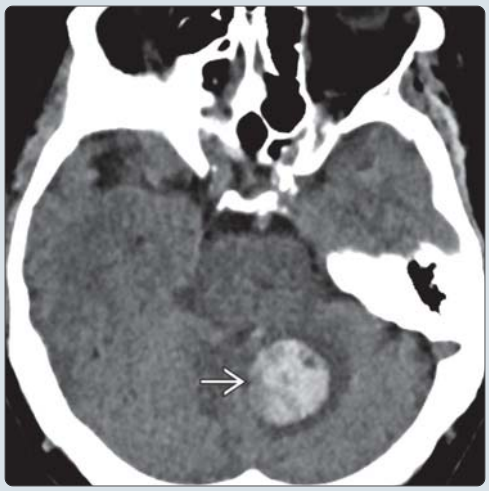
- Incidence: ~ 30-40 per 100,000
- HTN, ↑ age most important risk factors
- Prognosis depends on size, initial level of consciousness, and location
  - 35-52% dead at 1 month (50% of whom died in first 2 days); 59% dead at 1 year
- Intracerebral hematoma (ICH) with warfarin use correlates with higher mortality (2x as high at 3 months)
- Rate of anticoagulant-related ICH has increased over last decades (up to 20%)
- HTN (90%), vomiting (50%), ↓ consciousness (50%), headache (40%), seizures (10%)

DIAGNOSTIC CHECKLIST

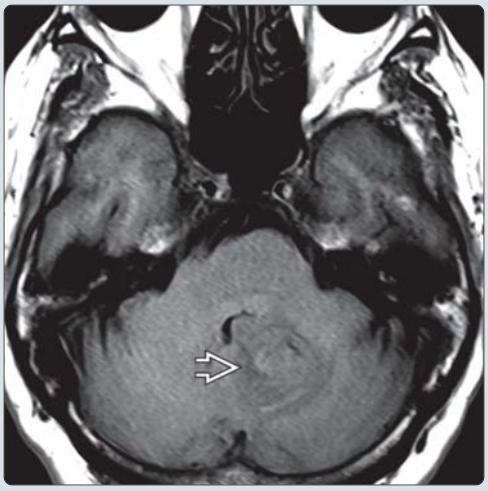
- Marked heterogeneity of acute hematoma on CT predicts hematoma growth and ↑ mortality
- Swirl sign, contrast extravasation, and enhancement indicate hematoma growth and ↑ mortality
- Fluid-fluid levels → question of underlying coagulopathy

(Left) *Axial graphic shows the evolution of parenchymal hemorrhage from hyperacute ⇨ (intracellular oxy-Hgb) to acute ➡ (intracellular deoxy-Hgb with surrounding edema) . Early ⇨ and late subacute (intra- and extracellular met-Hgb respectively) are followed by a chronic cystic cavity ⇨ with a hemosiderin stain.* **(Right)** *Axial NECT shows a hyperdense mass related to an acute left cerebellar hemorrhage ➡ with minimal surrounding edema in a patient with hypertension.*





(Left) *Axial T1WI MR in the same patient shows the cerebellar hemorrhage ➡ is predominantly isointense and mildly hypointense to the surrounding brain parenchyma, indicating hyperacute blood products.* **(Right)** *Axial T2WI MR in the same patient shows the hyperacute hemorrhage to be hyperintense to the surrounding brain parenchyma with a peripheral hypointense rim ⇨. Intraparenchymal hemorrhage evolves from peripheral to central with the central core maturing more slowly.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Intracerebral hematoma (ICH)

Synonyms

- Intraparenchymal hemorrhage

IMAGING

General Features

- Best diagnostic clue
  - Hyperdense (50-70 HU) mass on CT; peripheral edema develops over 1st few days
  - Hematoma matures more slowly in center (core) than in periphery
  - MR: ICH staging based on T1 and T2 signal
  - MR as sensitive as CT in hyperacute phase and more sensitive in subacute and chronic phases
- Location
  - Supratentorial > infratentorial brain
- Size
  - Near microscopic to very large; solitary >> multiple
- Morphology
  - Ovoid; larger hematomas have more irregular shape and heterogeneous attenuation

CT Findings

- NECT
  - Hyperacute and acute: Hyperdense mass (0-3 days)
    - Immediate: Heterogeneous with 40-60 HU
    - CT density increases to 60-80 HU over first few hours secondary to clot formation and retraction
    - Clot maturation can increase density to 80-100 HU in hematoma core
    - Isodense if Hgb < 8-10 (hemophilia, renal failure)
    - Fluid-fluid levels seen in larger hematomas, mostly with coagulopathies or anticoagulation
    - Edema and mass effect initially mild (< 3 hours)
    - Swirl sign: Extraaxial collection with hyperdense clot and smaller hypodense area in swirled configuration (implies active bleeding)
  - Subacute: 3-10 days
    - Progressive attenuation loss (↓ 1.5 HU/day)
    - Edema peaks at ~ 5 days
    - Isodense in 1-4 weeks, dependent on original size
  - Chronic: > 10 days
    - Residua: ↓ attenuation foci (37%), no visible residua (27%), slit-like lesions (25%), Ca++ (10%)
- CECT
  - Active bleeding: Contrast pooling; CTA "spot" sign
  - Subacute-chronic: Rim enhancement (3 days to 1 month)
  - Chronic: Enhancement disappears (2-6 months)

MR Findings

- T1WI
  - Hyperacute (< 24 hours): Isointense to mildly hypointense
  - Acute (~ 1-3 days): Isointense to mildly hypointense
  - Early subacute (~ 3-7 days): ↑ signal periphery, isointense center
  - Late subacute/early chronic (~ 1-2 weeks/4 weeks): Diffuse ↑ signal
  - Late chronic (> 1 month): Iso- to hypointense
- T2WI
  - Hyperacute: Hyperintense, may have subtle hypointense rim, hyperintense peripheral edema
  - Acute: Markedly hypointense, increased edema
  - Early subacute: ↓ hypointensity, ↑ edema
  - Late subacute/early chronic: Progressive central signal increase, peripheral hypointensity
  - Late chronic: Hypointense rim or cleft, no edema
- FLAIR
  - Same as on T2WI
    - May show subarachnoid extension of hemorrhage
- T2* GRE
  - Hyperacute: Typically hypointense margin; differentiates hemorrhage from other masses
  - Acute: Marked diffuse hypointensity
  - Early subacute: Hypointensity (> T2WI and FLAIR)
  - Late subacute/early chronic: Increasing low signal rim
  - Late chronic: Persistent marked hypointense nodule or cleft due to glial hemosiderin staining
- DWI
  - Signal on DWI strongly affected by underlying T2 signal (T2 shine through and T2 "black out")
  - ADC shows diffusion restriction in core during hyperacute, acute, and early subacute phase
- T1WI C+
  - Peripheral enhancement can develop within a few days and persist for months
- SWI (susceptibility weighted imaging)
  - ↑ sensitivity for microscopic hemorrhage than GRE

Imaging Recommendations

- Best imaging tool
  - Initial diagnosis: NECT or MR
  - Staging/work-up: MR, MRA/MRV, or CTA/CTV
  - Angiography if no clear cause

DIFFERENTIAL DIAGNOSIS

Fat-Containing Lesions

- Lipoma, dermoid
- Mimics subacute ICH (↑ T1WI, ↑ T2WI)
- Chemical shift artifact, lack of edema, loss of intensity on fat-saturated images confirm diagnosis

Calcified Lesions

- Dural plaque, thrombosed aneurysm, meningioma
- Hypointense on T2WI and GRE, variable on T1WI

Proteinaceous Fluid Collections

- Colloid cyst, Rathke cleft cyst, craniopharyngioma
- Mildly hyperintense on T1WI, hypointense on T2WI

PATHOLOGY

General Features

- Etiology
  - Very common: HTN, cerebral amyloid angiopathy (CAA), trauma, hemorrhagic vascular malformations

https://CafePezeshki.IR

- Common: Infarct with reperfusion, coagulopathy, blood dyscrasia, drug abuse, tumor
- Less common: Dural sinus thrombosis, eclampsia, endocarditis with septic emboli, fungal infection (aspergillosis, mucormycosis), encephalitis
- Genetics
  - ICH can occur sporadically or with familial syndromes (familial CAA, familial cavernous malformations)
- Associated abnormalities
  - Vasogenic edema forms rapidly, peaks at ~ 5 days
  - May decompress into ventricles/subarachnoid space

Staging, Grading, & Classification

- No consistent definition of hematoma stages for MR
  - Hyperacute: < 24 hours; acute: ~ 1-3 days; early subacute: ~ 3-7 days; late subacute: ~ 1-2 weeks; chronic ~ > 1 month

Gross Pathologic & Surgical Features

- Acute to early subacute: Blood-filled cavity surrounded by vasogenic edema, inflammation
- Early subacute to early chronic: Organizing clot, vascularized wall
- Late chronic: Hemosiderin scar with gliosis

Microscopic Features

- Immediate
  - Water-rich liquid hematoma; 95-98% oxy-Hgb
- Hyperacute
  - RBCs contain diamagnetic oxy-Hgb
  - High water content (↑ T2 and ↓ T1)
  - Peripheral vasogenic edema begins
- Acute
  - Deoxy-Hgb in intact RBCs
    - Paramagnetic deoxy-Hgb with 4 unpaired electrons in intact RBC causes field gradient across cell membrane → ↓ T2WI and GRE
    - Paramagnetic center of Hgb inaccessible to water molecules → no T1 shortening
  - Severe edema
- Early subacute
  - Deoxy-Hgb in intact RBCs oxidized to paramagnetic met-Hgb with 5 unpaired electrons
    - Susceptibility induced gradient across cell membrane → T2WI and GRE hypointensity
  - Met-Hgb formation begins at hematoma periphery → T1 hyperintensity initially seen at margin
- Late subacute-early chronic
  - RBC lysis → release met-Hgb into extracellular space → loss of gradient across RBC membrane
    - Loss of magnetic heterogeneity and increased water content → ↑ T2WI and FLAIR intensity
  - Persistent dipole-diploe interaction → T1 shortening
  - Edema and mass effect decrease
- Chronic
  - Lysed RBCs and clot taken up by macrophages
  - Met-Hgb converted into ferritin and hemosiderin
  - Residual cysts, clefts with hemosiderin scar, persist indefinitely in areas with intact blood-brain barrier
  - Edema, inflammation resolve

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - HTN (90%), vomiting (50%), ↓ consciousness (50%), headache (40%), seizures (10%)
- Clinical profile
  - HTN, ↑ age most important risk factors
  - Increasing incidence of anticoagulation-related ICH

Demographics

- Incidence
  - ~ 30/100,000 (USA); 37/100,000 (Europe)
- Age
  - Risk increases with age (mean 63 [USA], 70 [Europe])
- Gender
  - Men < 65 years have 3.4x higher risk; > 65 years: No significant gender difference
- Ethnicity
  - Higher risk of ICH for African Americans (3.8x higher risk) and Hispanics (2.6x higher risk) compared with Caucasians

Natural History & Prognosis

- 1 or more rebleeds occur in 1/4 of cases
  - Rebleed: Increased mortality
    - 70% died with 2nd or 3rd ICH
- Prognosis depends on size, initial level of consciousness, and location
  - Higher mortality with posterior fossa and lobar hemorrhage than with deep hemorrhage
  - Ventricular extension: Higher mortality for lobar hemorrhage, but lower mortality for thalamic bleeds
  - ICH with warfarin use correlates with higher mortality (2x as high at 3 months)
- 20% independent at 6 months

Treatment

- Surgical evacuation as needed

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- MR more sensitive, more accurate staging of ICH
- Large area of surrounding vasogenic edema more commonly seen with underlying neoplasm
- Marked heterogeneity of acute hematoma on CT predicts hematoma growth and mortality
- Swirl sign, contrast extravasation, and enhancement indicate hematoma growth and ↑ mortality
- Fluid-fluid levels: Question of underlying coagulopathy

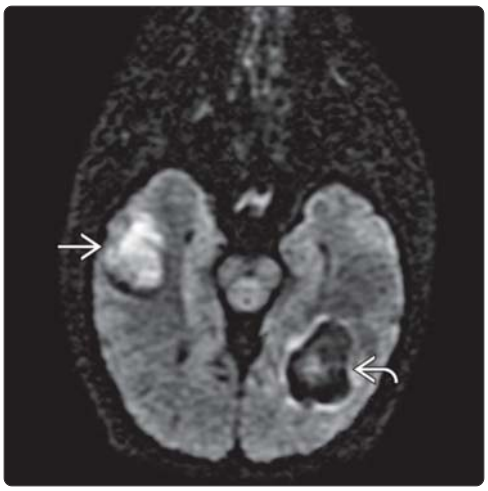
(Left) *Axial T2WI MR shows a large hypertensive hemorrhage in the left basal ganglia, which shows early subacute blood products that are predominantly hypointense* ⇨ *with surrounding edema* ⇨*. The anterior aspect of the hemorrhage shows hyperintense signal suggesting more acute blood products* ⇨*.* **(Right)** *Axial SWI shows the hypointense hemorrhage* ⇨ *and multiple other foci of susceptibility (from hemosiderin) related to remote microhemorrhages* ⇨ *from chronic hypertension.*

(Left) *Axial T1WI MR shows hemorrhages in an amyloid angiopathy patient. There is a hyperacute* ⇨ *(isointense) and an acute/early subacute* ⇨ *(hyperintense) left posterior hemorrhage as well as a late subacute (hyperintense) right temporal hemorrhage* ⇨*.* **(Right)** *Axial T2WI MR shows heterogeneous bright signal in the hyperacute* ⇨ *portion and low signal in the acute/early subacute* ⇨ *portion of the posterior hemorrhage. The late subacute* ⇨ *hemorrhage has bright T1 and T2 signal intensity.*



(Left) *Axial DWI MR 21 hours after initial imaging shows that the signal on DWI is mostly determined by underlying T2 effects with T2 shine through* ⇨ *in the right subacute hemorrhage and T2 blackout* ⇨ *in the acute/early subacute hemorrhage.* **(Right)** *Axial ADC shows that signal on DWI is mostly determined by underlying T2 effects. Only the acute/early subacute hemorrhage shows low signal on ADC* ⇨*, while increased diffusivity is seen in the late subacute right temporal hemorrhage* ⇨*.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Primary intraparenchymal hemorrhage (pICH)
- Acute nontraumatic intracranial hemorrhage (ICH)

IMAGING

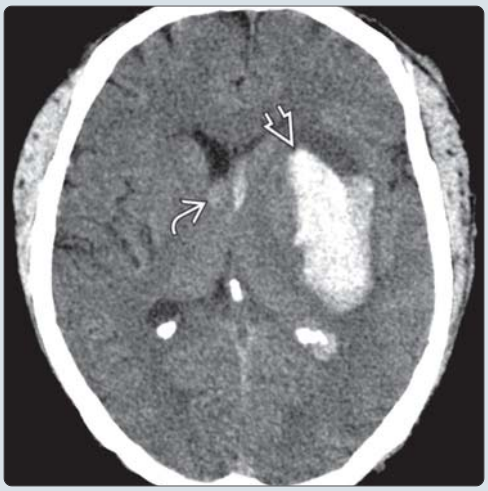
- Acute round or oval intracerebral hematoma
- Subcentimeter "microbleeds" to massive ICH
- Hematoma location for common causes of pICH
  - HTN: Basal ganglia > thalamus > pons > cerebellum
  - Amyloid angiopathy: Lobar
  - Arteriovenous malformation (AVM): Any location
  - Cavernous malformation: Any location
  - Venous sinus thrombosis: Subcortical white matter
  - Neoplasm: Any location
- Recommended imaging protocol
  - If HTN with striatocapsular hematoma → stop
  - If atypical hematoma → CTA or MR/MRA
  - Atypical hematoma or unclear history: MR (T2*, DWI, C+)
  - If standard study suggests vascular etiology → CTA/MRA
  - If concern for venous infarct → CTV/MRV

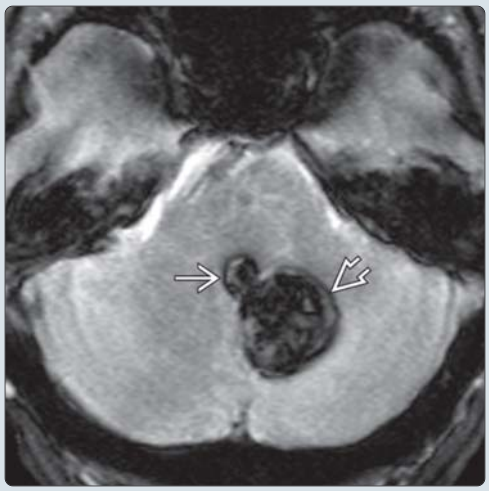
PATHOLOGY

- Pediatric patients, < 18 years old: Vascular malformation (~ 50%) > hematologic disorders, vasculopathy, venous infarct, neoplasm
- Young adults, < 45 years old: Vascular malformation, drug abuse, venous thrombosis, PRES, vasculitis, neoplasm
- Adults > 45 years old: HTN, amyloid > neoplasm (primary or metastatic), venous infarct, coagulopathy

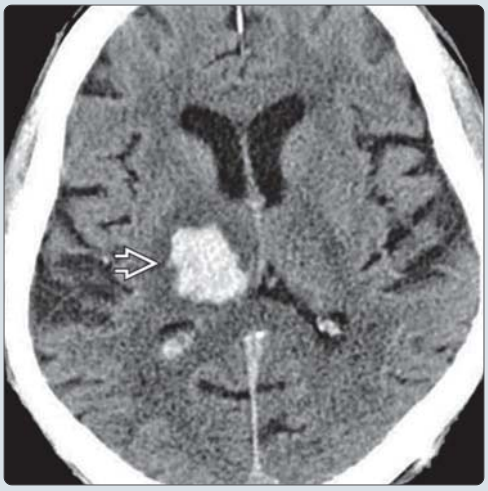
CLINICAL ISSUES

- ICH causes ~ 15% of acute strokes
- Treatment: Control of ICP, hydrocephalus
- Surgical evacuation when clinically indicated
- If positive spot sign indicates active bleeding, predicts hematoma expansion and poor outcome
- 1-year mortality approaches 60%





(Left) *Axial CT shows a hyperdense hematoma centered in the left external capsule and putamen ⇨ with associated edema and mass effect, as well as intraventricular extension of hemorrhage ⇨. This is the most common location for a hypertensive hemorrhage.* **(Right)** *Axial GRE MR in a 71-year-old male shows an acute hypertensive hemorrhage in the left cerebellar hemisphere ⇨ with extension to the 4th ventricle ⇨. The posterior fossa accounts for ~ 10% of all hypertensive hemorrhages.*



(Left) *Axial CT in a 58-year-old hypertensive female shows a hyperdense hemorrhage ⇨ in the right thalamus with surrounding edema. No additional imaging is required in this patient.* **(Right)** *Axial CT in this 5 year old shows a large frontal lobe hemorrhage ⇨ with surrounding edema and mass effect. Additional imaging revealed an underlying cavernous malformation. In children, vascular lesions represent ~ 50% of all intracranial hemorrhages.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Primary intraparenchymal hemorrhage (pICH), hemorrhagic stroke

Definitions

- Acute nontraumatic intracranial hemorrhage (ICH)
  - Etiology often initially unknown

IMAGING

General Features

- Best diagnostic clue
  - Acute nontraumatic intracerebral hematoma
- Location
  - Varies with etiology
    - Hypertension (HTN): Deep gray matter (basal ganglia, thalamus), pons, cerebellar hemisphere
    - Amyloid angiopathy: Lobar
    - Arteriovenous malformation (AVM): Any location
    - Cavernous malformation: Any location, common in brainstem
    - Venous sinus thrombosis: Subcortical white matter (WM) adjacent to occluded sinus
    - Neoplasm: Any location, posterior fossa common
- Size
  - Subcentimeter "microbleeds" to massive hemorrhage
- Morphology
  - Typically round or oval; often irregular when large
  - Patterns with HTN and amyloid angiopathy
    - Acute parenchymal hematoma
    - Multiple subacute/chronic "microbleeds" in deep gray matter (HTN > amyloid) &/or subcortical white matter (amyloid > HTN)
    - Microbleeds often seen only on GRE or SWI MR

CT Findings

- NECT
  - Acute hyperdense round/elliptical mass
  - May be mixed iso-/hyperdense
  - May have fluid-fluid level
    - Coagulopathy
    - Brisk bleeding
    - Bleed into cystic mass
  - Peripheral low density (edema)
  - Deep (ganglionic) ICH may rupture into ventricles
- CTA
  - Often nonrevealing
  - ± underlying vascular malformation (AVM, aneurysm)
  - Look for dural sinus venous thrombosis

MR Findings

- T1WI
  - Hyperacute (< 24 hours)
    - Isointense center (oxygenated Hgb)
    - Isointense periphery (deoxygenated Hgb, clot-tissue interface)
    - Hypointense rim (vasogenic edema)
- T2WI
  - Hyperacute (< 24 hours)
    - Hyperintense, heterogeneous center
    - May have subtle hypointense periphery
    - Hyperintense rim of edema
- T2* GRE
  - Hypointense
  - Multifocal hypointense lesions ("black dots")
    - Basal ganglia (BG) and thalami suggests HTN
    - Subcortical WM suggests amyloid angiopathy
- DWI
  - T2 shine through common; may see "DWI restriction" in core
- T1WI C+
  - May enhance if underlying neoplasm, vascular malformation
- MRA
  - Often normal, look for vascular lesion
- MRV
  - Look for dural sinus thrombosis

Angiographic Findings

- DSA, often negative
  - Look for dural sinus occlusion, "stagnating vessels" (thrombosed AVM)

Imaging Recommendations

- Best imaging tool
  - Screening: NECT
    - If patient with HTN and BG hematoma → stop
    - Consider CTA to exclude underlying vascular lesion
  - Standard MR (include T2*, SWI, DWI)
    - If no clear cause of hemorrhage, or atypical appearance on CT
    - If T2* shows multifocal "black dots" → stop
    - T1WI C+ to assess for underlying tumor
    - If standard study suggests vascular etiology → MRA/CTA
  - Follow-up: Repeat MR if etiology unclear ± DSA if initial MRA/CTA negative
- Protocol advice
  - Atypical hematoma or unclear history: MR (with T2*, SWI, DWI, T1WI C+)
  - Add MRV if concern for venous infarct

DIFFERENTIAL DIAGNOSIS

Hypertensive Intracranial Hemorrhage

- Patients usually older
- BG hematoma most common location

Vascular Malformation

- AVM, cavernous malformation most common
- ICH rate in AVMs of BG or thalamus (9.8% per year) much higher than AVMs in other locations

Cerebral Amyloid Angiopathy

- Older patients (70 years old, normotensive)
- Usually lobar hemorrhage
- Microbleeds ("black dots") on T2* peripheral location

Underlying Neoplasm

- Causes 2-15% of nontraumatic ICHs
- Primary (glioblastoma) or metastasis

https://CafePezeshki.IR

- Typically shows enhancement

Venous Thrombosis

- May result in hemorrhagic venous infarct
- Risk factors: Dehydration, pregnancy, oral contraceptives

Anticoagulation

- "Growing" hematoma, fluid-fluid levels common
- Check history

Drug Abuse

- May have hypertensive striatocapsular hemorrhage
- Uncommon = pseudoaneurysm rupture into cerebrum

Vasculitis

- Often results in subarachnoid hemorrhage (SAH) rather than ICH
- Patients usually younger

Dural AVF (With Cortical Venous Drainage)

- Dilated venous "flow voids"

Ruptured Pseudoaneurysm

- Mycotic (endocarditis)
- Traumatic
- Vasculopathy

PATHOLOGY

General Features

- Etiology
  - Pediatric patients, < 18 years old: Vascular malformation (~ 50%) > hematologic disorders, vasculopathy, venous infarct, neoplasm
  - Young adults, < 45 years old: Vascular malformation, drug abuse, venous thrombosis, PRES, vasculitis, neoplasm
  - Adults > 45 years old: HTN, amyloid > neoplasm (primary or metastatic), venous infarct, coagulopathy
- Genetics
  - MMP-9, cytokine gene expression ↑ after acute spontaneous ICH
  - Apolipoprotein E (*APOE*) gene and its ε2 and ε4 alleles are strongly associated with ICH

Staging, Grading, & Classification

- Clinical "ICH score" correlates with 30-day mortality
  - Admission GCS
  - > 80 years old, ICH volume
  - Infratentorial
  - Presence of intraventricular hemorrhage

Gross Pathologic & Surgical Features

- Findings range from petechial "microbleeds" to gross parenchymal hematoma

Microscopic Features

- Coexisting microangiopathy common in amyloid, HTN

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 90% of patients with recurrent pICH are hypertensive
  - Large ICHs present with sensorimotor deficits, impaired consciousness

Demographics

- Age
  - Any age
- Epidemiology
  - Parenchymal hemorrhage causes ~ 15% of acute strokes

Natural History & Prognosis

- Prognosis related to location, size of ICH
- Hematoma enlargement common in first 24-48 hours
  - Risk factors: EtOH, low fibrinogen, coagulopathy, irregularly shaped hematoma
- 20-30% of patients die within 48 hours despite intervention
- Edema associated with poor outcome
- Mortality: 30-55% in 1st month
- 1-year mortality approaches 60%
- 30% rebleed within 1 year
- Most survivors have significant deficits
- Incidence ~ 25 per 100,000 per year worldwide
- If positive spot sign indicates active bleeding, predicts hematoma expansion and poor outcome

Treatment

- Control of ICP, hydrocephalus
- Surgical evacuation when clinically indicated

DIAGNOSTIC CHECKLIST

Consider

- Consider underlying etiology for hemorrhage (AVM, amyloid, neoplasm, drug use, etc.)

Image Interpretation Pearls

- Unexplained ICH → search for microbleeds on T2* MR
- Fluid-fluid level, iso-/mildly hyperdense clot may indicate coagulopathy

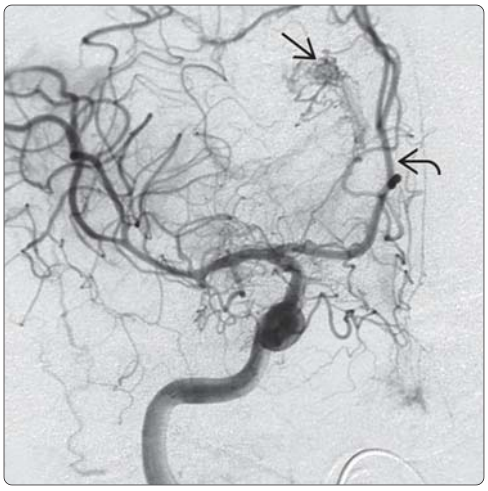
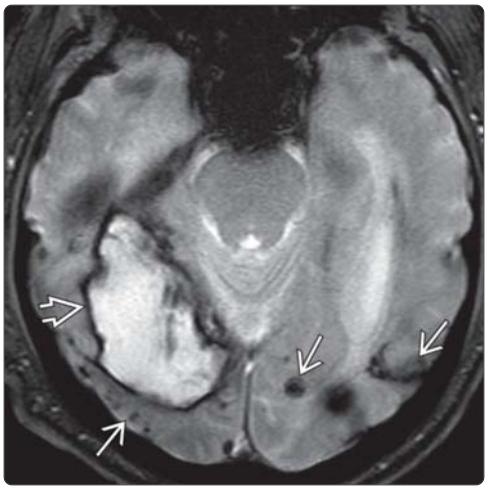
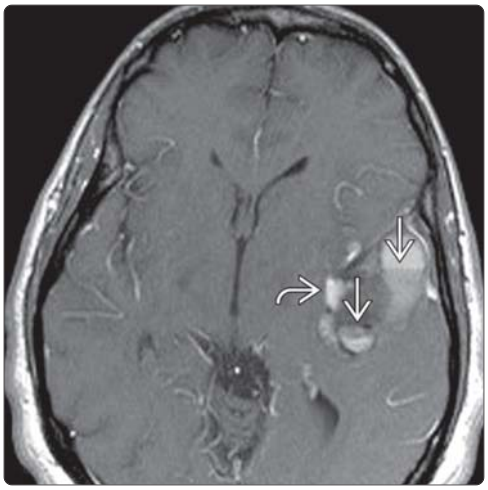
(Left) *Axial CT image in a 73-year-old male shows an acute frontal and parietal lobe hemorrhage. MR showed underlying enhancement and biopsy disclosed metastatic disease related to melanoma.* **(Right)** *Axial gross pathology, sectioned through the middle of the cerebellum, shows an acute spontaneous intraparenchymal hemorrhage. Note the atherosclerosis in the basilar artery. No underlying lesion was identified in this patient with chronic hypertension. (Courtesy R. Hewlett, MD.)*



(Left) *Axial NECT shows what appears to be a classic hypertensive striatocapsular hemorrhage with intraventricular extension. However, in this young patient, underlying etiologies must be considered, including drug abuse & vascular lesions.* **(Right)** *Anteroposterior DSA from a right internal carotid artery injection shows an avascular mass in the basal ganglia (hematoma) with midline shift of the anterior cerebral artery. There is a cluster of abnormal arteries (AVM) fed by a large anterior choroidal artery.*





(Left) *Axial GRE image shows a large occipital lobe hemorrhage and multiple other foci of susceptibility artifact or "blooming," related to hemosiderin deposition in this elderly patient with cerebral amyloid disease. The MR was done to exclude an underlying mass.* **(Right)** *Axial T1WI C+ MR shows lobular cerebral hematoma in the left temporal lobe. Note fluid-fluid levels in the hematoma from brisk bleeding. The more avidly enhancing region in sulcus represented pseudoaneurysm.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Hypertensive intracranial hemorrhage (hICH)
- Acute nontraumatic intracerebral hemorrhage (ICH) 2° to systemic hypertension
- 2nd most common cause of stroke

IMAGING

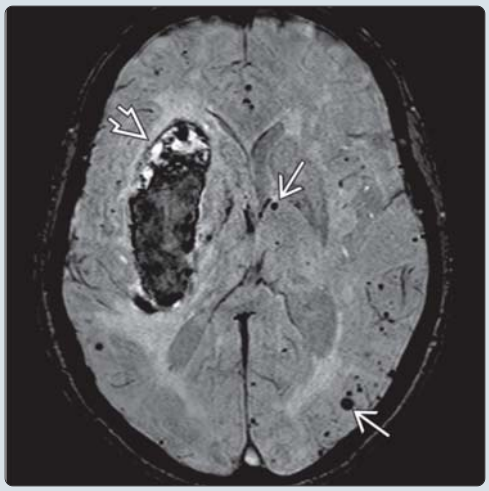
- Initial screen = NECT in patients with HTN
- CT: Acute round or oval hyperdense mass
  - Striatocapsular: Putamen/external capsule (60-65%)
  - Thalamus (15-25%)
  - Pons, cerebellum (10%)
- Multifocal "microbleeds" (1-5%)
- Heterogeneous density (coagulopathy, active bleed)
- Other findings: Intraventricular extension, mass effect, hydrocephalus, herniation
- MR signal intensity (varies with age of clot)
  - Hyperacute (< 24 hours): T1WI iso-hypo/T2WI hyper
  - Acute (~ 1-3 days): T1WI iso-hypo/T2WI hypo
  - Subacute (days): T1WI hyper/T2WI hypo-hyper
  - Chronic (weeks-months): T1WI hyper/T2WI hypo

TOP DIFFERENTIAL DIAGNOSES

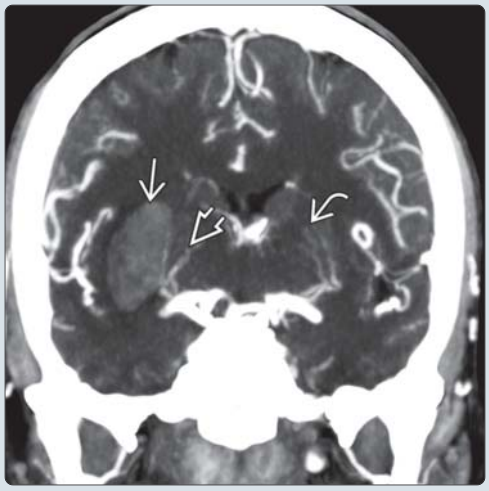
- Cerebral amyloid angiopathy
- Hemorrhagic neoplasm
- Coagulopathy
- Deep cerebral venous thrombosis
- Drug abuse (especially in young patient)
- Vascular malformation (rare in elderly)

CLINICAL ISSUES

- HTN single most important risk factor for **all** types of stroke
- 10-15% of stroke patients have hICH
- 40-50% of nontraumatic ICHs caused by hICH
- HTN most common cause of spontaneous ICH in patients 45-70 years old
- 10-15% of hypertensive patients with spontaneous ICH have underlying aneurysm or AVM



(Left) *Axial CT in a 61-year-old female with a history of hypertension shows the classic appearance of a left basal ganglia hemorrhage involving the putamen and external capsule (striatocapsular). Note the additional areas of periventricular hypodensity ⇨ likely related to chronic small vessel ischemia.* **(Right)** *Axial SWI image shows a large hypertensive basal ganglia hemorrhage ⇨, as well as multiple foci of susceptibility artifact ⇨ from hemosiderin deposition related to microhemorrhages from chronic hypertension.*



(Left) *Axial graphic shows a classic acute hypertensive basal ganglia/external capsule hemorrhage with dissection into the lateral ventricle. Hemorrhage extends through the foramen of Monro to the 3rd ventricle.* **(Right)** *A coronal CTA in a young patient with a right basal ganglia hemorrhage ⇨ shows displacement of the lenticulostriate arteries ⇨ medially, compared to the normal left side ⇨ by the hematoma. There is no spot sign that would indicate active bleeding. No underlying vascular lesion is present.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hypertensive intracranial hemorrhage (hICH)

Synonyms

- Stroke, hypertensive hemorrhage

Definitions

- Acute nontraumatic intracerebral hemorrhage (ICH) secondary to systemic hypertension (HTN)

IMAGING

General Features

- Best diagnostic clue
  - Round or oval hyperdense mass in basal ganglia (BG) or thalamus in patients with hypertension
- Location
  - Striatocapsular: Putamen/external capsule (60-65%)
  - Thalamus (15-25%)
  - Pons, cerebellum (10%)
  - Lobar (5-10%)
- Size
  - Subcentimeter ("microbleeds") to several centimeters
- Morphology
  - Typically rounded or oval
  - 2 distinct patterns seen with hICH
    - Acute focal hematoma
    - Multiple subacute/chronic "microbleeds" (1-5%)

CT Findings

- NECT
  - Round or oval hyperdense parenchymal mass
  - Heterogeneous density if coagulopathy or active bleeding
  - Intraventricular extension of hemorrhage common
  - Mass effect, hydrocephalus, herniation common
- CECT
  - No enhancement in acute hICH
- CTA
  - Avascular mass effect in acute hICH
  - No underlying vascular lesion

MR Findings

- T1WI
  - Varies with age of clot
    - Hyperacute hematoma (< 24 hours)
      - Oxyhemoglobin (Hgb) (iso-/hypointense)
    - Acute hematoma (~ 1 to 3 days)
      - DeoxyHgb (iso-/hypointense)
    - Early subacute hematoma (~ 3 to 7 days)
      - Intracellular metHgb (hyperintense)
    - Late subacute hematoma (week to months)
      - Extracellular metHgb (hyperintense)
    - Chronic hematoma
      - Hypointense (± hyperintense center)
- T2WI
  - Appearance of hematoma varies with stage
    - Hyperacute hematoma (< 24 hours)
      - OxyHgb (hyperintense)
    - Acute hematoma (~ 1 to 3 days)
      - DeoxyHgb (hypointense)
    - Subacute hematoma (3-7 days)
      - Intracellular metHgb (hypointense)
    - Late subacute hematoma (week to months)
      - Extracellular metHgb (hyperintense)
    - Chronic hematoma (months)
      - Hemosiderin (hypointense)
    - Remote hematoma (months to years)
      - Hypointense hemosiderin scar ± central hyperintense cavity
  - "White matter (WM) hyperintensities" are hICH risk markers
- T2* GRE
  - Multifocal hypointense lesions ("black dots") in deep grey nuclei and peripheral WM
    - Common with longstanding HTN
    - Also seen with amyloid angiopathy (more peripheral)
- DWI
  - Hypo- or mixed hypo-/hyperintense (early hematoma)
- T1WI C+
  - Typically no enhancement with acute hematoma
  - Contrast extravasation = active hemorrhage
- MRA
  - Negative

Angiographic Findings

- Conventional
  - DSA usually normal if history of HTN with deep ganglionic hemorrhage
    - May show avascular mass effect
    - Rare: "Bleeding globe" microaneurysm on lenticulostriate artery (LSA)
  - Coexisting vascular abnormalities
    - Increased prevalence of unruptured intracranial aneurysms

Imaging Recommendations

- Best imaging tool
  - Initial screen = NECT in patients with HTN
  - If atypical age or history, consider MR with T2* or CTA
  - If hyperacute ischemic "stroke" suspected, MR with T2* and DWI
  - If MR shows classic hematoma with coexisting multifocal "black dots," most likely amyloid angiopathy or chronic HTN
  - If MR shows atypical hematoma, MRA or CTA
  - If MRA or CTA inconclusive, consider DSA

DIFFERENTIAL DIAGNOSIS

Cerebral Amyloid Angiopathy

- Lobar > > basal ganglionic hemorrhage
- Usually elderly, often normotensive
- Only 5-10% of hICHs are lobar, but HTN is so common that it is always consideration

Hemorrhagic Neoplasm

- Metastases and primary (e.g., GBM)
- Typically older adult or elderly

https://CafePezeshki.IR

Venous Thrombosis

- May have history of dehydration, flu, pregnancy, birth control pills
- May present as lobar hematoma
- Look for hyperdense dural sinus (not always present)

Deep Cerebral Venous Thrombosis

- Less common than dural sinus or cortical vein thrombosis
- Look for hyperdense internal cerebral veins, intraventricular hemorrhage
- Look for hypodense bilateral thalami

Coagulopathy

- Elderly patients on anticoagulant therapy

Drug Abuse

- Cocaine and other drugs may cause sudden ↑ HTN
- Be suspicious if unexplained BG bleed in young patient

Vascular Malformation

- Patients usually normotensive, younger
- Most common is cavernous malformation
  - Look for "black dots" (multiple lesions) on T2* (GRE, SWI) scans
- Less common = thrombosed hemorrhagic AVM or dAVF or MCA aneurysm

PATHOLOGY

General Features

- Etiology
  - Chronic HTN with atherosclerosis, lipohyalinosis, fibrinoid necrosis, abrupt wall rupture ± pseudoaneurysm formation
  - "Bleeding globe" (penetrating lenticulostriate pseudoaneurysm)
  - Diffuse "microbleeds" common

Gross Pathologic & Surgical Features

- Large ganglionic hematoma ± IVH
- Subfalcine herniation, hydrocephalus (common)
- Coexisting small chronic hemorrhages, ischemic lesions (common)

Microscopic Features

- Severe arteriosclerosis with lipohyalinosis
- May see may see small fibrosed pseudoaneurysm or fibrous balls (fibrosed miliary aneurysm)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 10-15% of stroke patients have hICH
  - Large ICHs present with sensorimotor deficits, impaired consciousness
- Clinical profile
  - HTN single most important risk factor for **all** types of stroke
  - Major risk factor = HTN (increases risk of ICH 4x)

Demographics

- Age
  - Adults, most common elderly
- Gender
  - Males > females
- Ethnicity
  - Higher incidence in African Americans
- Epidemiology
  - 40-50% of primary nontraumatic ICHs caused by hypertensive hemorrhage
  - HTN most common cause of spontaneous ICH in patients 45-70 years
  - 10-15% of all stroke cases; associated with highest mortality rate
  - 10-15% of hypertensive patients with spontaneous ICH have underlying aneurysm or AVM

Natural History & Prognosis

- Presence of microbleeds on MR is strong predictor of future hICH
- Bleeding can persist for up to 6 hours following ictus
- Neurologic deterioration common within 48 hours
  - Increasing hematoma, edema
  - Hydrocephalus
  - Herniation syndromes
- Recurrent hICH in 5-10% of cases, usually different location
- Prognosis related to location, size of hICH
- 80% mortality in massive hICH with IVH
- 1/3 of survivors are severely disabled

Treatment

- Control of ICP and hydrocephalus

DIAGNOSTIC CHECKLIST

Consider

- Does patient have history of poorly controlled systemic HTN
- Could there be underlying coagulopathy, hemorrhagic neoplasm, or vascular malformation
- Consider substance abuse in young patients with unexplained hICH

Image Interpretation Pearls

- Underlying cause of lobar ICH is often difficult to determine
- Subarachnoid extension of hematoma on CT is usually indicative of nonhypertensive etiology; consider lobar ICH caused by vascular abnormality

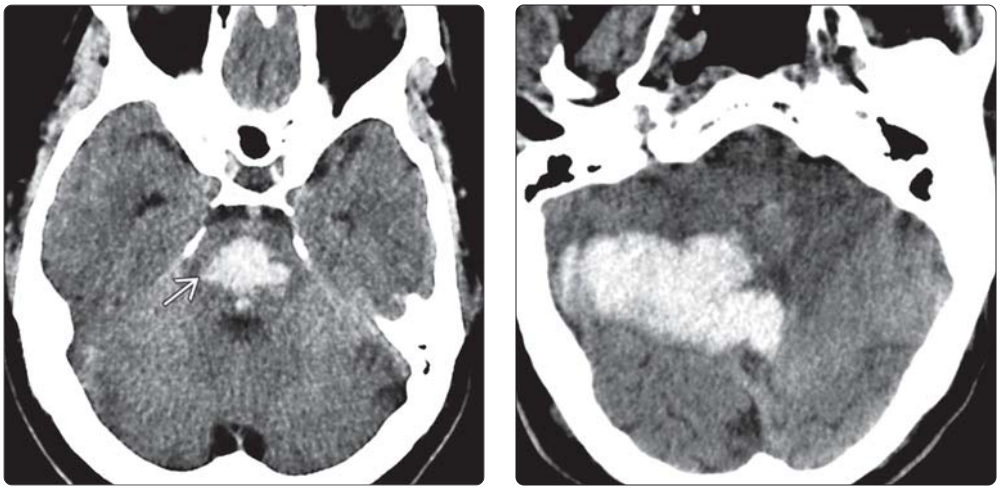
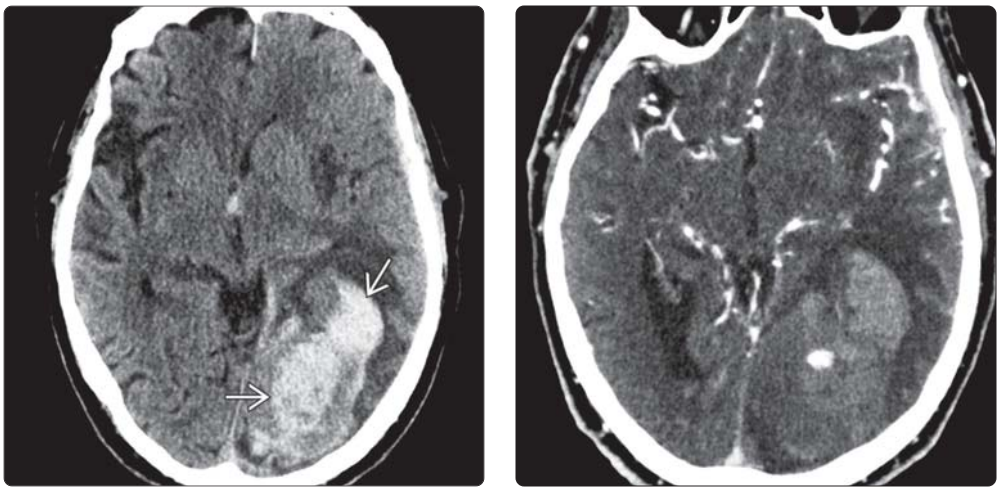
https://CafePezeshki.IR

(Left) *Axial CT in a 55-year-old male who presented to the ER with an acute stroke shows a hemorrhage in the right temporal lobe and external capsule with surrounding edema and mass effect.* **(Right)** *Coronal CTA in the same patient shows a large MCA aneurysm ➡ as the etiology for this patient's acute hemorrhage. CTA is often key in evaluation of an acute hemorrhage in a patient with an atypical history or an unusual hemorrhage location.*



(Left) *NECT scan in a 52-year-old hypertensive man with sudden onset of multiple cranial neuropathies shows a pontine hemorrhage ➡.* **(Right)** *NECT scan in an elderly hypertensive man shows a right cerebellar hemorrhage. The posterior fossa (pons, cerebellum) is a relatively uncommon location for hypertensive hemorrhages, yet it is the 3rd most common overall site (after the basal ganglia and thalami).*



(Left) *NECT scan in an 80-year-old man in the ER with a "brain attack" shows a heterogeneous acute left occipital hematoma ➡. Lobar hemorrhages account for just 5-10% of hypertensive bleeds.* **(Right)** *Because of the unusual appearance and location of the hematoma, emergent CTA was performed in the same patient. Contrast extravasation into the hematoma ("spot" sign) indicates active bleeding. Surgery disclosed an actively bleeding hemorrhagic metastasis (adenocarcinoma).*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Remote cerebellar hemorrhage (RCH)
  - Typically after supratentorial craniotomy
  - Less often after spinal surgery
  - Remote to primary surgical site
  - No underlying pathologic lesion

IMAGING

- General features
  - "Zebra" sign (blood layered over cerebellar folia)
  - Location varies (in/over hemisphere, vermis)
  - Subarachnoid &/or superficial parenchymal bleed
  - Contralateral to side of surgery (29%)
  - Ipsilateral (22%), bilateral (33%), vermis only (9%)
- Imaging recommendations
  - NECT initial screen, ± CTA to exclude other etiology
  - MR ± contrast, ± MRA
  - Include T2* (GRE ± SWI)

TOP DIFFERENTIAL DIAGNOSES

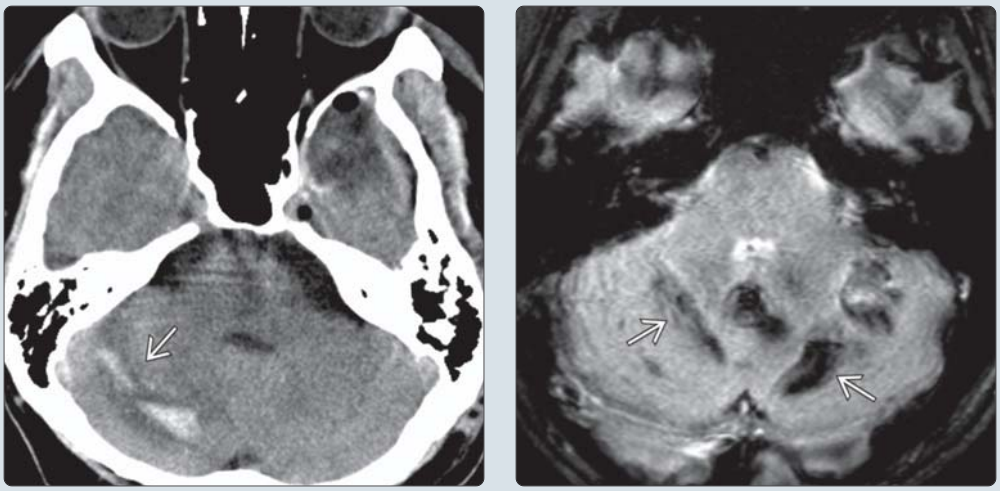
- Hypertensive hemorrhage
- Coagulopathy-related spontaneous hemorrhage
- Neoplasm with hemorrhage

PATHOLOGY

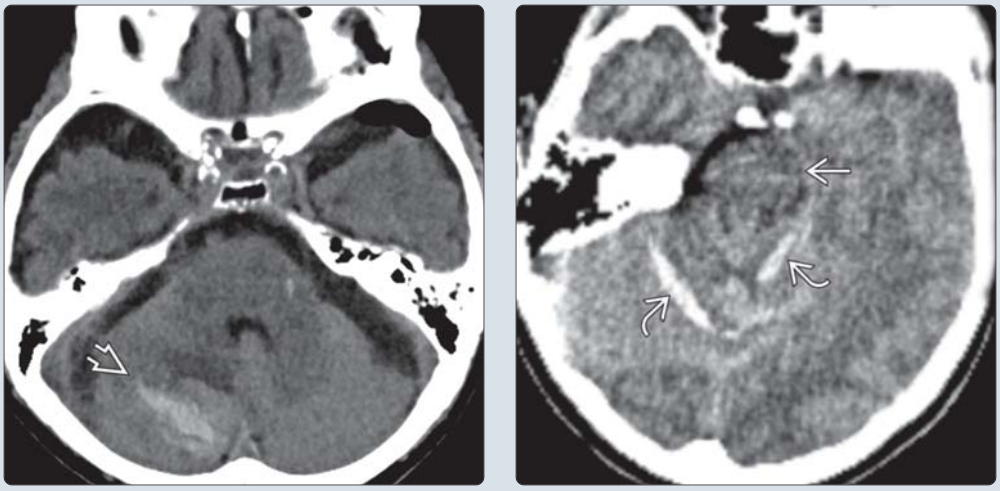
- CSF hypovolemia → inferior cerebellar displacement "sagging" → vein stretching, bleeding
- RCH usually seen in immediate postoperative period
- Most occur within hours to 1 day postoperatively

CLINICAL ISSUES

- True incidence unknown (~ at 0.1-0.6% of supratentorial craniotomies)
  - Most often after aneurysm surgery, temporal lobectomy for epilepsy or mass resection
- Occasionally asymptomatic, occult (not imaged)
- Death/disability in ~ 50% of cases
- RCH is typically self-limited



(Left) *Axial CT shows acute hemorrhage ➡ in the right cerebellum related to remote cerebellar hemorrhage (RCH) in a young patient who had a left temporal lobectomy. The etiology is thought to be related to CSF hypovolemia resulting in inferior displacement of the cerebellum and secondary venous injury.* **(Right)** *Axial GRE MR image in RCH shows the typical susceptibility artifact or "blooming" ➡ related to recent hemorrhage. The hemorrhage may be unilateral, bilateral, or isolated to the vermis.*



(Left) *Axial CT shows right RCH ➡ in this 86 year old who underwent left sided burr holes and catheter placement for drainage of a left subdural hygroma. This hemorrhage was found incidentally. Most patients need no intervention for RCH.* **(Right)** *Axial CT in a patient doing poorly immediately after surgery for meningioma resection shows linear cerebellar hemorrhages bilaterally ➡ along the folia, known as the "zebra" sign. This is a common pattern seen in RCH. Cisternal effacement is also present ➡.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Remote cerebellar hemorrhage (RCH)

Definitions

- Cerebellar hemorrhage following CNS surgery, typically supratentorial
  - Remote to primary surgical site
  - No underlying pathologic lesion
  - CSF drainage → cerebellar "sagging" → vein stretching, bleeding
- Less commonly may occur after spinal surgery

IMAGING

General Features

- Best diagnostic clue
  - "Zebra" sign (blood layered over cerebellar folia)
    - Following supratentorial craniotomy or spinal surgery
- Location
  - Sublocation in cerebellum varies
  - Subarachnoid &/or superficial parenchymal bleed
- Morphology
  - Superior cerebellar folia most common pattern

CT Findings

- NECT
  - Hyperdense

MR Findings

- T1WI
  - Varies with age/stage of hematoma
- T2WI
  - Usually mixed hypo-/hyperintense
- T2* GRE
  - Useful to confirm hemorrhage ("blooms")
    - T2* most sensitive for parenchymal blood
    - SWI more sensitive than GRE
- T1WI C+
  - No enhancement
- MRA
  - Negative

Angiographic Findings

- DSA negative for underlying vascular etiology
- No cortical venous/dural sinus occlusion

Imaging Recommendations

- Best imaging tool
  - NECT initial screen, ± CTA
  - MR with and without contrast, MRA
    - Include GRE and SWI
- Protocol advice
  - MRI with T2*, gadolinium, plus vascular imaging (MRA &/or DSA)

DIFFERENTIAL DIAGNOSIS

Hypertensive Hemorrhage

- Basal ganglia > thalamus > pons/cerebellum > lobar
- Lobar > superficial/foliar pattern
- T2* may reveal microbleeds elsewhere

Coagulopathy-Related Spontaneous Hemorrhage

- Iatrogenic: Warfarin, heparin, aspirin
- Disseminated intravascular coagulation

Neoplasm With Hemorrhage

- Metastases > primary neoplasm
- Vasogenic edema, nodular enhancement

Vascular Malformation

- Cavernous malformation
- AVM, dAVF

Cerebral Amyloid Angiopathy

- Lobar hemorrhage is typical
- Rarely involves cerebellum

PATHOLOGY

General Features

- Etiology
  - CSF (cerebrospinal fluid) hypovolemia is likely cause
    - May lead to "brain sagging," occlusion/tearing of bridging veins
    - Result = hemorrhagic venous infarct

Gross Pathologic & Surgical Features

- Hemorrhagic necrosis without underlying vascular malformation or tumor

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - ↓ consciousness, seizures in postoperative period
  - Cerebellar signs
    - From primary bleed or herniation (less common)
  - Can be asymptomatic
    - Discovered incidentally on postoperative imaging

Treatment

- Intervention for RCH rarely indicated

DIAGNOSTIC CHECKLIST

Consider

- MR initial evaluation after screening NECT ± CTA

Image Interpretation Pearls

- Cerebellar bleed in a patient with history of craniotomy or spinal surgery is likely RCH

https://CafePezeshki.IR

KEY FACTS

IMAGING

- Cerebral: Blood products in subependymal region, usually involving caudothalamic notch
- Cerebellar: Blood products on cerebellar surface, usually caudal
- US is standard of care: Sensitive but not specific and user dependent
- MR most sensitive and specific; important, though, to weigh risks of transport

TOP DIFFERENTIAL DIAGNOSES

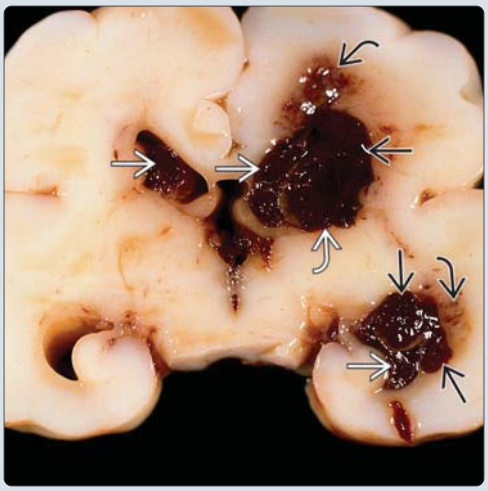
- Deep venous thrombosis with hemorrhage
- Arterial ischemic infarction
- Isolated choroid plexus hemorrhage
- Isolated intraventricular hemorrhage

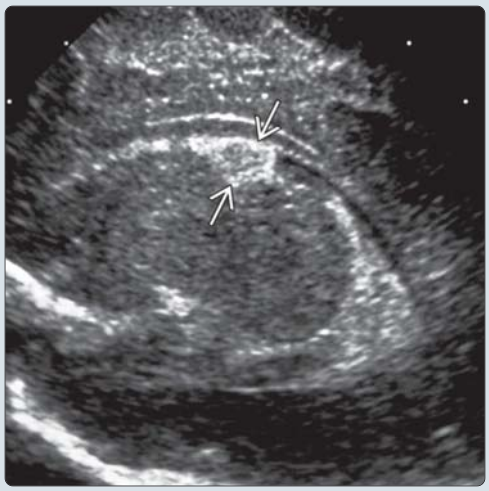
PATHOLOGY

- Germinal matrix hemorrhage (GMH): Rupture of gray matter capillaries
- PHI: Venous hemorrhagic infarction likely due to GMH ± IVH compressing vein in ventricular wall
- Hydrocephalus
- Periventricular leukomalacia (high association with GMH + IVH)
- Selective neuronal necrosis (pontine > thalamus, basal ganglia, hippocampus)
- Grade 1: GMH (typically caudothalamic notch)
- Grade 2: GMH + IVH
- Grade 3: GMH + IVH + ventriculomegaly
- Grade 4 (PHI): Hemorrhagic periventricular venous infarction

CLINICAL ISSUES

- Most common < 32 weeks gestation age, < 1,500 g
- Rare > 34 weeks gestation age
- ~ 90% of GM bleeds occur in ≤ 3 days
- Maximal extent reached ≤ 5 days
- Hydrocephalus is most important consequence





(Left) *Coronal gross pathology section shows a left germinal matrix hemorrhage (GMH) with intraventricular extension and associated PHI in both the left frontal and temporal lobes. Note the clotted blood extending outward from the left lateral ventricle into the medullary veins.* **(Right)** *Sagittal transfontanelle ultrasound in a premature infant shows a focus of increased echogenicity in the caudothalamic notch without intraventricular extension, consistent with a grade 1 GMH.*

(Left) *Axial T2 MR image shows a small focus of hemorrhage in the left germinal matrix and along the right lateral ventricle in this premature infant with a history of oligohydramnios and a grade 2 GMH.* **(Right)** *Axial SWI MR in the same premature infant shows hypointensity or "blooming" related to hemorrhage in the left germinal matrix and within the lateral ventricles. GMH typically occurs in premature infants less than 32 weeks gestational age.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Germinal matrix hemorrhage (GMH)

Synonyms

- Grade 4 GMH = periventricular hemorrhagic infarction (PHI)
- Cerebellar GMH = external granular layer hemorrhage
- Germinal matrix = ventricular + subventricular zone (SVZ)

Definitions

- Germinal matrix
  - Highly vascular, neural tube-derived structure
    - Dynamic; varies both temporally, spatially
  - Contains multiple cell types
    - Neural stem cells
    - Restricted neural progenitor cells
    - Ependymal cells
    - Premigratory/migrating neurons, glia

IMAGING

General Features

- Best diagnostic clue
  - Cerebral: Blood products in subependymal region, usually involving caudothalamic notch
    - ± intraventricular hemorrhage
    - ± choroid plexus bleed (often associated with GMH + intraventricular hemorrhage [IVH])
    - ± ventriculomegaly
    - ± PHI
  - Cerebellar: Blood products on cerebellar surface
- Location
  - Cerebral GMH: Hemorrhage into GM along lateral ventricular wall, most commonly caudothalamic notch
  - Cerebellar GMH: Hemorrhage into cerebellar GM over cerebellar hemisphere + vermian surface
  - PHI: Hemorrhage in periventricular white matter adjacent to GM in caudothalamic notch in venous distribution
- Size
  - Variable

CT Findings

- NECT
  - High attenuation due to blood products

MR Findings

- T1WI
  - Blood products initially isointense but become hyperintense after ~ 3 days
- T2WI
  - Blood products hypointense (hyperacute blood that is hyperintense on T2 not currently reported due to typical delay in MR > 12 hours)
  - Become centrally hyperintense with hypointense rim as they evolve
- T2* GRE
  - Blood products "bloom"
- DWI
  - Signal variable (low T2 drives signal down, low ADC drives signal up)
  - ADC low due to clotted blood

Ultrasonographic Findings

- Grayscale ultrasound
  - Subependymal mass with ↑ echogenicity
    - Typically caudothalamic notch
    - ± intraventricular echogenicity, ventriculomegaly
- Color Doppler
  - Helps differentiate echogenic choroid plexus from avascular echogenic hemorrhage

Imaging Recommendations

- Best imaging tool
  - US is standard of care: Sensitive but not specific and user dependent
  - MR most sensitive and specific; important, though, to weigh risks of transport
- Protocol advice
  - US: High-frequency probe, multiple focal points

DIFFERENTIAL DIAGNOSIS

Deep Venous Thrombosis With Hemorrhage

- Typically > 34 weeks gestation age (GA)
- Hemorrhage can occur in caudothalamic notch at site where terminal vein joins choroid vein to form internal cerebral vein

Arterial Ischemic Infarction

- No blood products on MR, arterial vascular distribution

Isolated Choroid Plexus Hemorrhage

- No blood products in ventricular wall

Isolated Intraventricular Hemorrhage

- Typically > 34 weeks GA; no blood products in ventricular wall

White Matter Injury of Prematurity

- Involves periventricular and deep white matter; no "blooming" on gradient-echo imaging

Ventriculitis

- No blood products on MR

PATHOLOGY

General Features

- Etiology
  - GMH: Rupture of GM capillaries may occur in relation to many factors
    - Altered cerebral blood flow (CBF) caused by
      - Rapid volume expansion
      - Hypercarbia
      - ↑ hemoglobin or blood glucose
      - Hypoxic-ischemic events
    - Increase in cerebral venous pressure (delivery, heart failure, positive pressure ventilation, etc.)
    - Coagulopathy
    - Capillary fragility
    - Deficient vascular support
    - Increased fibrinolytic activity
    - Hypoxic-ischemic injury

https://CafePezeshki.IR

- PHI: Venous hemorrhagic infarction likely due to GMH ± IVH compressing terminal vein
- Associated abnormalities
  - Hydrocephalus
  - Periventricular leukomalacia (high association with GMH + IVH)
  - Selective neuronal necrosis (pontine > thalamus, basal ganglia, hippocampus)

Staging, Grading, & Classification

- Papile (based on head ultrasound)
  - Grade 1: GMH (typically caudothalamic notch)
  - Grade 2: GMH + IVH
  - Grade 3: GMH + IVH + ventriculomegaly
  - Grade 4: GMH + IVH + ventriculomegaly + parenchymal extension
- Volpe (based on head ultrasound)
  - Grade 1: GMH + IVH < 10% ventricular area on parasagittal view
  - Grade 2: GMH + IVH 10-50% ventricular area on parasagittal view
  - Grade 3: GMH + IVH > 50% ventricular area on parasagittal view
  - Periventricular echodensity (probable PHI)

Gross Pathologic & Surgical Features

- GMH originates in subependymal GM
- PHI = venous hemorrhagic infarction

Microscopic Features

- Normally 2.54 ± 0.56 mm thick at 23-24 weeks GA, decreasing to 1.73 ± 0.71 mm at 29-30 weeks GA, and only 0.50 ± 0.26 mm at 35-36 weeks GA
- Subependymal hemorrhage in GM, typically caudothalamic notch if > 28 weeks GA
- Hemorrhage occurs in prominent endothelial-lined vessels similar to capillary venule or small venule
- ± obliterative arachnoiditis secondary to IVH and spread into subarachnoid space

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Silent > stuttering decline > catastrophic decline
    - Stuttering over hours to days
      - Altered consciousness, hypotonia, abnormal eye movements, abnormal respiration
    - Catastrophic over minutes to hours
      - Coma, flaccid &/or fixed pupils, apnea, seizures, decerebrate posturing
  - Most common presentation of GMH + IVH
    - Premature infant with respiratory distress syndrome on mechanical ventilation
- Other signs/symptoms
  - Drop in hematocrit

Demographics

- Age
  - Most common < 32 weeks GA, < 1,500 g
  - Rare > 34 weeks GA
  - Can occur in utero

Natural History & Prognosis

- > 20 weeks GM gives rise to oligodendrocytes and astrocytes
- Blood products have adverse effect on maturing SVZ cells on oligodendrocyte precursors
- ~ 90% of GM bleeds occur in ≤ 3 days
- Maximal extent reached ≤ 5 days
- Short-term prognosis
  - Grades 1 and 2: Mortality and incidence of posthemorrhagic ventriculomegaly < 15% if > 750 g
  - Grade 3: Mortality < 35% and incidence of posthemorrhagic ventriculomegaly > 75%
  - PHI: Mortality up to 45%, and incidence of posthemorrhagic ventriculomegaly > 80%
- Incidence of long-term neurological sequelae
  - Grade 1: 15%
  - Grade 2: 25%
  - Grade 3: 50%
  - PHI: 75%

Treatment

- Supportive, rarely shunting of secondary hydrocephalus
- Current emphasis on prevention

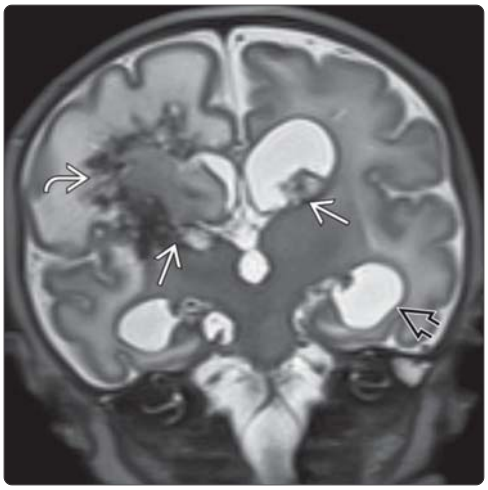
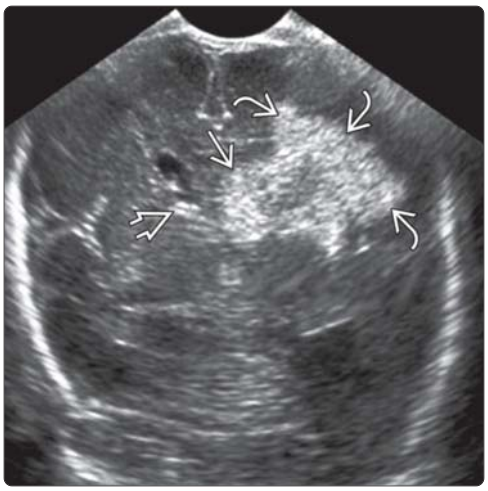
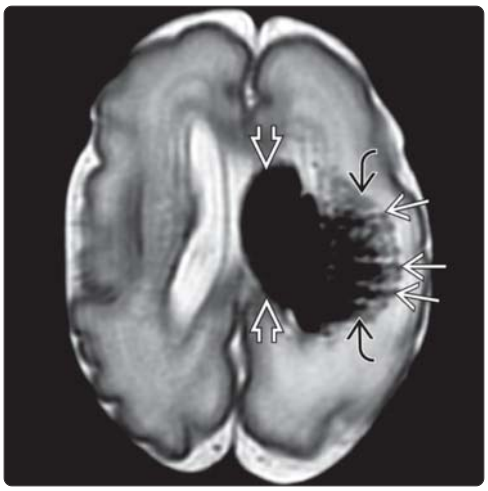
(Left) *Coronal ultrasound in a premature infant shows increased echogenicity in the bilateral caudothalamic notch due to GMH, intraventricular extension of blood, and enlargement of the lateral ventricles, including the temporal horns, diagnostic of a grade 3 germinal matrix hemorrhage (GMH).* **(Right)** *Axial T1WI MR in a premature infant with a grade 3 hemorrhage shows large bilateral GMHs and an extensive mixed intensity intraventricular clot with persistent right lateral ventricle enlargement.*



(Left) *Coronal T2 HASTE MR in a fetus of 23 weeks gestational age shows decreased signal along the inferomedial surface of the left cerebellar hemisphere, consistent with a cerebellar GMH.* **(Right)** *Coronal T2 HASTE MR in a 33-week premature infant shows bilateral germinal matrix hemorrhages and associated ventriculomegaly. The right germinal matrix hemorrhage has extended into the right frontal lobe with surrounding edema in this patient with a grade 4 GMH.*





(Left) *Coronal transfontanelle ultrasound in a premature infant shows a small increased echogenicity due to GMH in the right caudothalamic notch. The GMH on the left is obscured by the intraventricular extension and very echogenic associated PHI.* **(Right)** *Axial T2WI MR in the same infant shows hypointense hemorrhage in the ventricle and the associated PHI. Note the radiating pattern of the medullary venous thrombosis in the PHI.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Intracranial atherosclerotic vascular disease (ASVD)
- Intracranial atherosclerotic stenosis (ICAS)

IMAGING

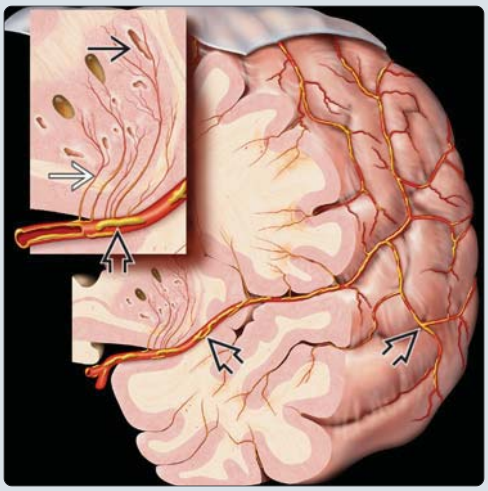
- Gold standard is now high-resolution MR (HRMR) with direct vessel wall imaging
  - HRMR vessel wall imaging >> depicting lumen (DSA, CTA, MRA)
- Imaging findings (HRMR)
  - Crescent shaped or eccentric thickening
  - May show asymmetric hyperintensity of intraplaque hemorrhage on T1WI
  - Noncircumferential, short segment, irregular enhancement
- CTA/MRA/DSA
  - Visualizes lumen, not wall
  - Warfarin-aspirin symptomatic intracranial disease (WASID) method for calculating ICAS
    - % stenosis = [1- (diameter stenosis/diameter normal)] x 100
  - Focal stenosis, luminal irregularities in cortical vessels can mimic vasculitis
    - Most common cause of vasculitic-like appearance at angiography in middle-aged/older patient is intracranial ASVD

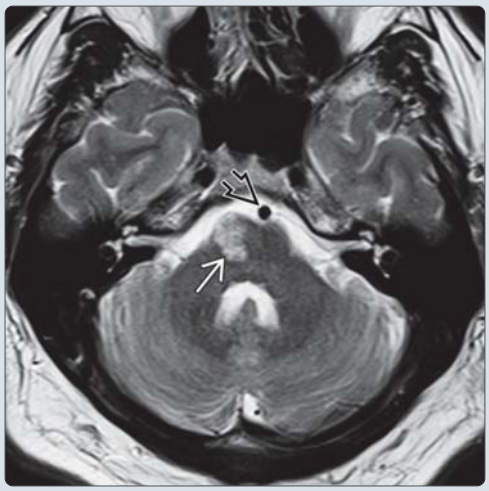
TOP DIFFERENTIAL DIAGNOSES

- Vasculitis/arteritis
- Vasospasm
- Dissection
- Nonocclusive thrombus or embolus

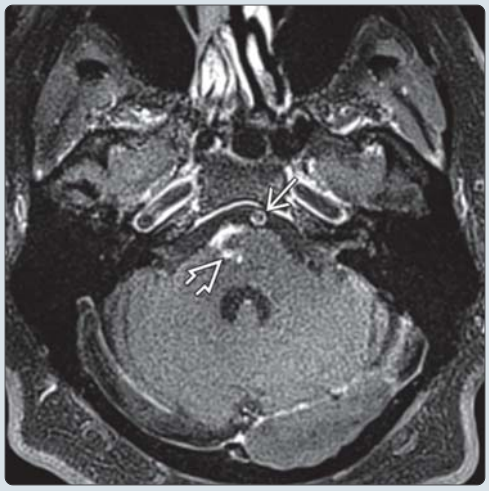
CLINICAL ISSUES

- Disease burden of intracranial ASVD greatly underestimated
- Most common cause of intracranial vascular stenosis in adults
- Independent correlation with T2/FLAIR hyperintensities





(Left) *Coronal graphic shows atherosclerotic plaques (ASVD) involving the major intracranial arteries and their branches. Inset shows penetrating (lenticulostriate) arteries and lacunar infarcts. ASVD plaques are typically short segment, irregular, noncircumferential, and may enhance.* **(Right)** *Axial T2WI shows a typical pontine perforating artery infarct. The basilar artery "flow void" appears normal.*



(Left) *Axial thin-section 3T T1FS MR in the same patient shows a crescent of hyperintensity in the wall of the basilar artery suggesting intraplaque hemorrhage.* **(Right)** *Thin-section 3T T1C+FS MR in the same patient shows enhancement of the subacute infarct. A partial rim of crescentic enhancement crescentic in the basilar artery wall is also present, consistent with chronic inflammation within an ASVD plaque.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Intracranial atherosclerotic vascular disease (ASVD)
- Intracranial atherosclerotic stenosis (ICAS)

Definitions

- Narrowing or ectasia of intracranial arteries secondary to ASVD

IMAGING

General Features

- Best diagnostic clue
  - ASVD plaque in vessel wall directly visualized with high-resolution MR (HRMR)
    - HRMR vessel wall imaging >> depicting lumen (DSA, CTA, MRA)
    - Crescent shaped or eccentric thickening
    - ± intraplaque hemorrhage, enhancement
  - Stenotic intracranial artery on CTA/MRA/DSA
    - Visualizes lumen, not wall
  - Less common: Dolichoectasia
    - Enlargement/tortuosity without stenosis
- Location
  - Distal basilar artery (BA), cavernous/supraclinoid ICA most common
  - Less common sites
    - Circle of Willis (COW)
    - MCA rare (2% of cases) **but** high stroke risk
- Morphology
  - Usually eccentric, irregular thickening ± ulceration, hemorrhage

CT Findings

- NECT
  - Mural Ca++
- CTA
  - MDR CTA has high sensitivity/specificity
    - In patients with > 50% stenosis or occlusion of large arteries
    - Caveat: Mural Ca++ may ↓ specificity

MR Findings

- T1WI
  - Decreased/absent flow void
  - Also seen in slow flow
    - Proximal (extracranial) stenosis, dissection
  - HRMR may show crescentic, asymmetric hyperintensity of intraplaque hemorrhage
- T2WI
  - Decreased/absent flow void
- FLAIR
  - Slow flow or occlusion may appear hyperintense
    - "Dot" sign (slow flow in distal branches)
  - Intracranial ASVD independently associated with progressively greater white matter hyperintensity (WMH) burden
- T1WI C+ FS
  - HRMR may demonstrate noncircumferential, short segment, irregular enhancement
  - May demonstrate contrast filling mural ulcerations
- MRA
  - 3D time of flight (TOF) contrast-enhanced MRA
  - Focal stenosis, ectasia, or irregularity
    - 3D TOF may overestimate stenosis
      - Secondary to spin saturation
      - Poor evaluation for slow, in-plane flow
    - Enhanced MRA less affected by spin saturation (also faster)
    - Combined with CTA, sensitivity/specificity ~ DSA
  - CTA > MRA for evaluation of in-stent restenosis
  - Dolichoectasia may also cause reduced flow

Angiographic Findings

- DSA may show
  - Focal stenosis, luminal irregularities
  - Thrombosis, occlusion
  - Ectasia/elongation
  - "Giant" serpentine/fusiform aneurysms (less common)
- Measuring ICAS
  - Warfarin-aspirin symptomatic intracranial disease (WASID) method
    - % stenosis = [1- (diameter stenosis/diameter normal)] x 100
    - For MC, intracranial vertebral and basilar arteries use most severe degree of stenosis vs. diameter of proximal artery at its widest, nontortuous normal segment

Imaging Recommendations

- Best imaging tool
  - Gold standard is now HRMR with direct vessel wall imaging
  - DSA/CTA/MRA depict lumen, not wall
- Protocol advice
  - High-resolution thin-section 3T pre- and post-contrast-enhanced T1 FS
  - CTA or MRA for proximal intracranial stenoses

DIFFERENTIAL DIAGNOSIS

Vasculitis/Arteritis

- Usually involves smaller (tertiary) branches
- More likely associated with hemorrhage
- Can be primary or secondary
- Often associated with systemic disease
- Elevated ESR, autoimmune parameters

Vasospasm

- Subarachnoid hemorrhage related, maximal 7 days post bleed
- Drug-related (sympathomimetics)

Moyamoya

- Usually involves distal ICA and proximal COW with relative sparing of basilar artery
- Frequently bilateral

Dissection

- Smooth tapering
- T1 hyperintense crescent = thrombus, best seen with fat-sat sequences

https://CafePezeshki.IR

- Younger patients
- Can have minimal or no history of trauma

Nonocclusive Thrombus or Embolus

- Appearance of rounded, central nonopacification with peripheral enhancing rim on contrast study

PATHOLOGY

General Features

- Etiology
  - Probably multiple etiologies
    - Lipid hypothesis
      - High plasma LDL leads to LDL-cholesterol deposition in intima
    - Response to injury hypothesis
      - Focal endothelial change or intimal injury leads to platelet aggregation and plaque formation
    - Unifying hypothesis
      - Endothelial injury leads to increased permeability of LDL; plaques grow by thrombus formation on plaque surface and transendothelial leakage of plasma lipids
  - Smoking associated with intracranial atherosclerosis
  - Atherosclerosis is systemic, multifactorial disease
  - Intracranial atherosclerosis associated with atherosclerosis of carotids, coronaries, aorta, renal arteries, iliofemoral system

Gross Pathologic & Surgical Features

- Earliest macroscopic finding: Intimal fatty streaks
- Fibrous atheromatous plaques contain
  - Smooth muscle cells, monocytes, other leukocytes
  - Connective tissue: Collagen, elastic fibers, proteoglycans
  - Intra- and extracellular lipid deposits
  - Angiogenesis produces new capillaries at plaque periphery
    - Leads to intraplaque hemorrhage and ulceration
    - Hemorrhage leads to dystrophic ferrocalcinosis (seen as calcification on CT, as iron on MR)
- Arterial narrowing due to plaque
  - Flow limiting beyond 50% ICAS
  - Ischemic symptoms depend on collaterals
    - Slow occlusion leads to more collaterals, fewer symptoms
    - Rapid occlusion (from thrombosis or emboli) does not permit time for collaterals to develop, infarct likely
- Arterial irregularity from disrupted endothelium may form thrombogenic surface leading to thrombosis or emboli

Microscopic Features

- Intracranial plaque components
  - Lipid, fibrous tissue, calcium
  - Chronic inflammatory markers (e.g., IL-6)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Transient ischemic attack, due to emboli, severe stenosis, progressive occlusion
  - Plaque rupture usually leads to stroke
  - Vascular stenosis leads to stuttering ischemia from intermittent thrombosis

Demographics

- Age
  - Older age
- Gender
  - M = F
- Epidemiology
  - Disease burden of intracranial ASVD underestimated
    - 3rd most common cause of thromboembolic stroke, after carotid and cardiac sources
    - Basis for cerebral thromboembolism in over 90%
  - Most common cause of intracranial vascular stenosis in adults
  - ↑ prevalence in black, Asian, Hispanic, Indian populations
    - 15-30% of strokes in blacks, 30-50% in Asians

Natural History & Prognosis

- Poor; progressive disease unless treated aggressively
  - High risk of recurrent stroke

Treatment

- Low saturated fat and cholesterol diet and exercise
- Cholesterol lowering drugs ("statins") if lifestyle interventions are insufficient
- Plaque stabilization ("statins") may decrease stroke
- Angioplasty &/or stenting in some cases

DIAGNOSTIC CHECKLIST

Consider

- CTA &/or MRA as excellent screening tool
- High-resolution vessel wall imaging

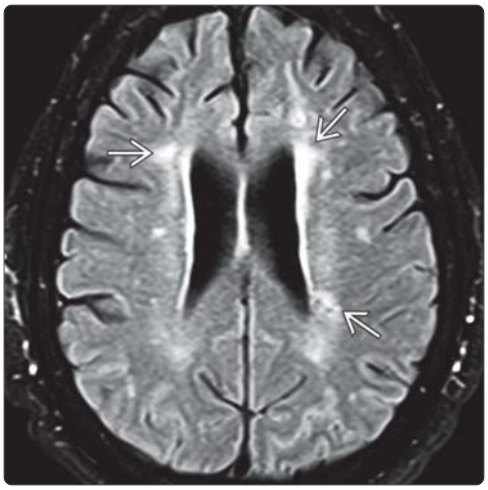
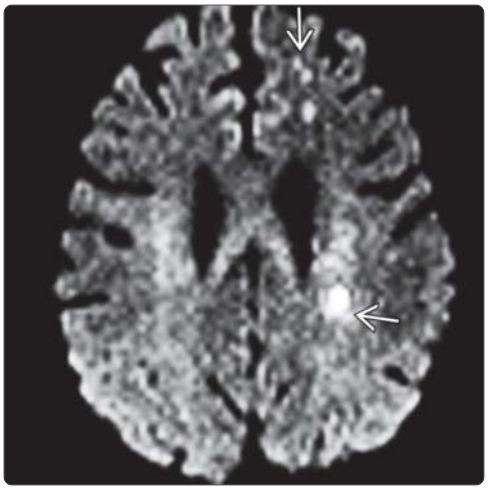
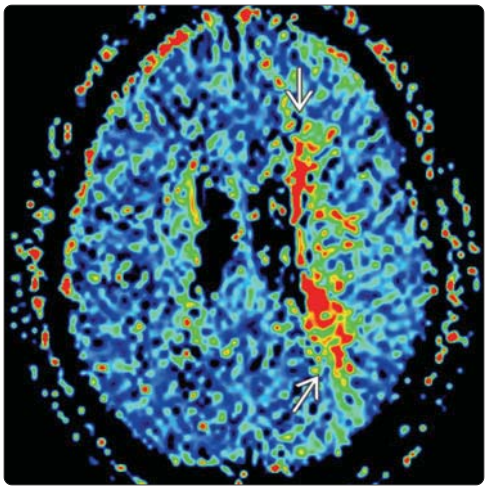
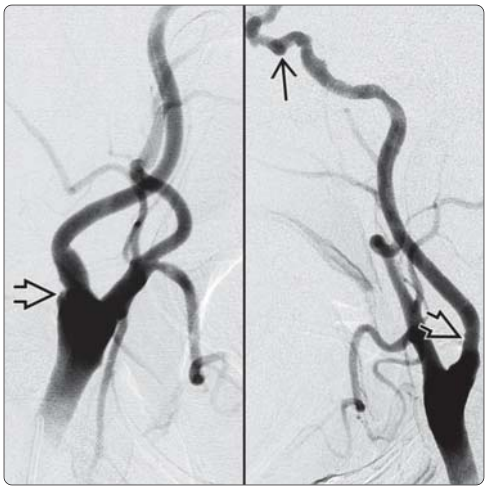
https://CafePezeshki.IR



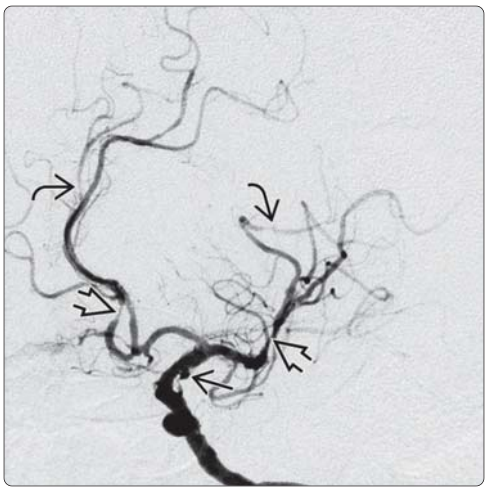


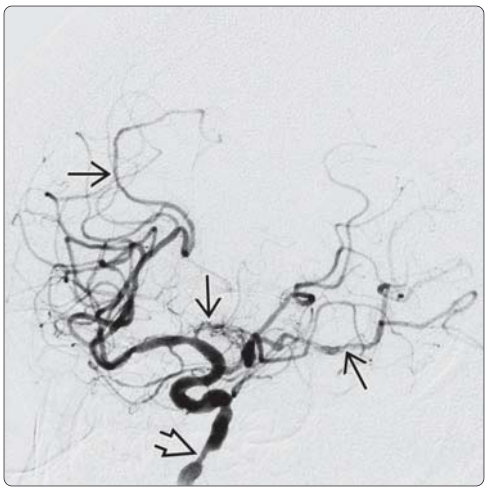
(Left) *A 68-year-old male in the ER with acute stroke symptoms had a negative NECT (not shown). MR shows extensive focal and confluent hyperintensities ➡ in the coronal radiata and deep periventricular white matter (WM) of both hemispheres.* **(Right)** *Axial DWI in the same patient shows several foci of restricted diffusion ➡ that "line up" along the periventricular deep WM of the left hemisphere.*





(Left) *MR perfusion in the same patient shows no evidence for a major territorial infarct. However, there is prolonged mean transit time (MTT) ➡ in the internal watershed zone of the left hemisphere deep cerebral WM.* **(Right)** *Because the MR perfusion scan suggested deep watershed zone ischemia, a DSA was performed. While there are some minor irregularities of both proximal internal carotid arteries ⇨, no flow-limiting stenoses were identified. The most severe disease affects the left cavernous ICA ⇨.*





(Left) *Oblique view of the intracranial left ICA shows irregularities in the cavernous/supraclinoid segments ⇨. High-grade stenosis of the M2 and A2 segments are present ⇨. Note the irregularities of more peripheral branches ⇨.* **(Right)** *Oblique view of the right intracranial ICA shows a high-grade stenosis of the cavernous segment ⇨, as well as multifocal areas of irregularity and narrowing of more distal vessels ⇨. The findings in this case are those of severe intracranial ASVD.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Degenerative process resulting from plasma lipid deposition in arterial walls

IMAGING

- Smooth/irregular narrowing of proximal ICA
- Ca++ in arterial walls
- ICA, vertebrobasilar arteries most common sites
- Single diameter thresholds for CTA: 2.2mm (50% stenosis), 1.3mm (70% stenosis)
- Protocol advice
  - Color Doppler US as initial screen
  - CTA/MRA or contrast MRA
  - Consider DSA prior to carotid endarterectomy, in equivocal cases or if CTA/MRA shows "occlusion"

PATHOLOGY

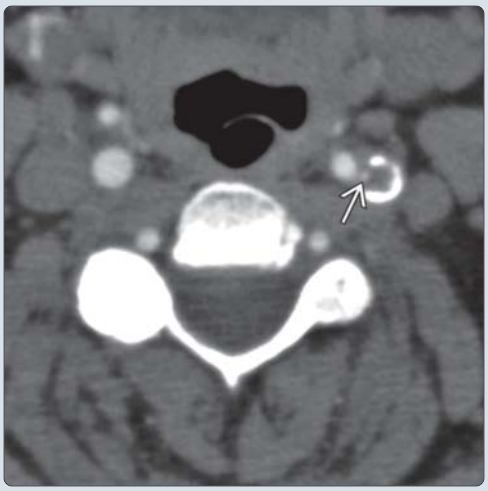
- NASCET method: % stenosis = (normal lumen - minimal residual lumen)/normal lumen, x 100
- Mild (< 50%), moderate (50-70%), severe (70-99%)
- Intraplaque hemorrhage is independent stroke risk factor

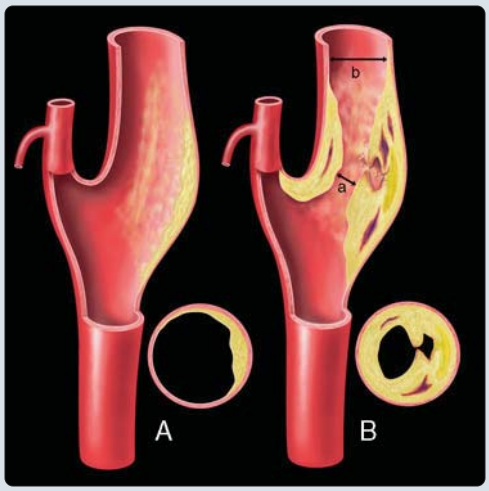
CLINICAL ISSUES

- CEA if symptomatic carotid stenosis ≥ 70% (NASCET)
- Symptomatic moderate stenosis (50-69%) also benefits from CEA (NASCET)
- Asymptomatic patients benefit even with stenosis of 60% (ACAS)
- Carotid stenting depends on preop risk factors
- Signs/symptoms (can be asymptomatic)
  - Carotid bruit, TIA, stroke (may be silent)

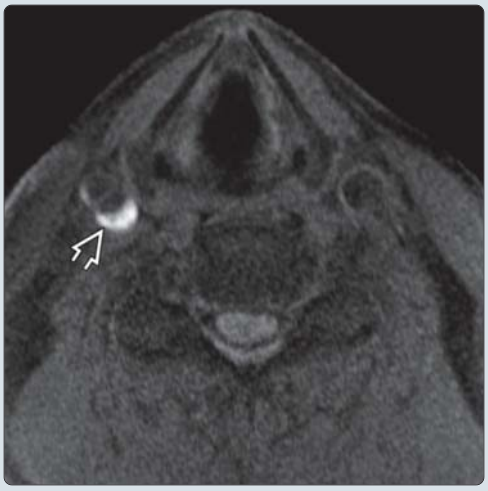
DIAGNOSTIC CHECKLIST

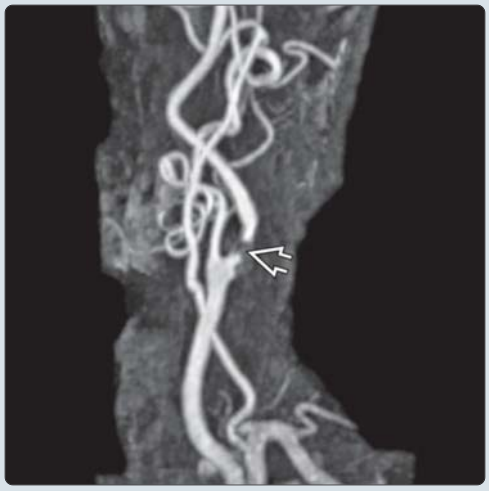
- DSA remains gold standard but acceptable noninvasive preoperative imaging includes any 2
  - US, CTA, TOF or enhanced MRA
- Late-phase DSA important to rule out pseudoocclusion
  - High-grade stenosis with "string" sign





(Left) *Axial CTA shows a severe stenosis of the proximal left ICA with a small residual lumen ➡. Note the typical peripheral mural calcification and the lower density lipid-rich core of the more central soft plaque in the left ICA.* **(Right)** *Graphic shows the mild form of ASVD (A) with "fatty streaks" & slight intimal thickening. The severe form (B) is characterized by intraplaque hemorrhage, ulceration, & platelet thrombi. NASCET calculation for % of stenosis = (b-a)/b x 100 where b = normal ICA lumen & a = minimal residual ICA lumen.*





(Left) *Axial MP-RAGE sequence shows intraplaque hemorrhage ➡ in the right ICA as a hyperintense crescent. Intraplaque hemorrhage is an independent stroke risk factor, regardless of ICA percent stenosis. (Courtesy JS McNally, MD, PhD.)* **(Right)** *Coronal oblique MRA shows signal loss as a "flow gap" in the left internal carotid artery ➡ indicating severely restricted flow, typically > 95% stenosis. The patient underwent an emergency left carotid endarterectomy.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Atherosclerotic vascular disease (ASVD)

Definitions

- Degenerative process resulting from plasma lipid deposition in arterial walls

IMAGING

General Features

- Best diagnostic clue
  - Smooth or irregular narrowing of proximal ICA
  - Ca++ deposition in arterial walls
- Location
  - ICA, vertebrobasilar arteries most common sites
    - Proximal ICA, common carotid bifurcations
  - Affects large/medium/small arteries, arterioles
- Size
  - Ranges from microscopic lipid deposition to fatty streaks to gross plaque
    - Generally 0.3-1.5 cm in diameter
- Morphology
  - Begins initially as smooth, slight eccentric thickening of vessel intima
  - Progresses to more focal and prominent eccentric thickening (subintimal macrocyte and smooth muscle cell deposition)
  - Subintimal hemorrhage from "new vessels" further narrows lumen
  - Ulceration with rupture of fibrous cap and intima occurs, resulting in "ulcerated plaque"

CT Findings

- NECT
  - Ca++ in vessel walls
  - Large plaques may show low-density foci (soft plaque)
  - Ectasia, tortuosity, fusiform vessel dilatation
- CTA
  - CTA as accurate as DSA for ICA stenosis
  - Visualizes degree of stenosis vs. occlusion
  - CTA can characterize plaque composition
    - Shows hemorrhage, ulceration, fibrous cap
    - Use MPR and MIP reconstructions
    - Detection of ulceration: Up to 94% sensitivity, 99% specificity

MR Findings

- T1WI
  - Wall thickening, luminal narrowing
  - Absence of "flow void"
    - May occur if vessel occluded or severely stenotic
  - Hyperintense in plaque hemorrhage
- T1WI C+ FS
  - High-resolution ICA imaging with dedicated surface coils can characterizes plaque composition
  - Hemorrhage/plaques with a higher percentage of lipid-rich/necrotic core
    - Independently associated with a thin or ruptured fibrous cap ("at risk" plaque)
- MRA
  - 2D TOF or contrast enhanced
  - Degree of stenosis visualized
  - Signal loss may occur if high-grade (> 95%) stenosis
    - Severe narrowing causes "flow gap"

Ultrasonographic Findings

- Grayscale imaging allows visualization of noncalcified (hypoechoic) or calcified (hyperechoic) plaque in vessel wall
- Hypoechoic plaques are independent risk factors for stroke; strong correlation with ↑ lipoprotein(s)
- Doppler measures flow velocity; peak systolic velocity is best single parameter for quantifying stenosis
- Spectral analysis allows evaluation of waveform; morphologic changes in waveform occur with ↑ stenosis
- Color Doppler may detect high-grade occlusions more reliably than conventional Doppler

Angiographic Findings

- Identifies degree of stenosis, morphology of plaque, tandem stenoses, potential collateral pathways as coexisting pathology (i.e., aneurysm)
- Plaque surface irregularity associated with increased risk of stroke at all degrees of stenosis
- Tandem lesions (distal stenoses) present in ~ 2% of patients with significant cervical ICA lesions
- Hemodynamic effect of tandem stenoses additive: If both lesions are severe enough to ↓ flow separately
  - If only 1 tandem lesion is critical, flow is governed by more severe lesion
- Late phase DSA important in high-grade stenosis or suspected occlusion to rule out "pseudoocclusion"

Imaging Recommendations

- Best imaging tool
  - DSA remains gold standard → acceptable noninvasive preoperative imaging includes any 2 of following: US, CTA, TOF, or contrast MRA
    - Exception: Late-phase DSA remains important in suspected high-grade stenosis or occlusion to rule out pseudoocclusion
- Protocol advice
  - Color Doppler US as initial screen
  - CTA/MRA or contrast MRA
  - Consider T1WI FS or MPRAGE for intraplaque hemorrhage
  - Consider DSA prior to carotid endarterectomy in equivocal cases or if CTA/MRA shows "occlusion"

DIFFERENTIAL DIAGNOSIS

Dissection

- Typically spares carotid bulb; no calcification
- Seen in young or middle-aged groups
- Smoother, longer narrowing without intracranial involvement

Fibromuscular Dysplasia

- "String of beads" > > long-segment stenosis

Vasospasm

- Usually iatrogenic (catheter-induced), transient

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - 3 main hypotheses
    - Lipid hypothesis: Relates ASVD to high-plasma LDL levels causing LDL-cholesterol deposits in arterial intima
    - Response to injury hypothesis: ASVD is initiated by focal endothelial damage that initiates platelet aggregation and plaque formation
    - Unifying theory: Suggests that endothelial injury is accompanied by increased permeability to macromolecules, such as LDL
  - Other factors include, diet, genes, mechanical stress (e.g., wall shear, anatomic variations), inflammation, hyperhomocysteinemia
  - Complex, multifactorial process; pathogenesis remains controversial
    - Likely a combination of lipid retention, inflammation, neoangiogenesis
  - Intraplaque hemorrhage is independent stroke risk factor
  - ASVD likely interaction of genetic and environmental factors, likely no single cause
  - Irregular plaques correlate with higher stroke risk
  - Good collaterals correlates with lower stroke risk
  - Significant ICA narrowing seen in 20-30% of ICA territory strokes vs. 5-10% of general population
- Genetics
  - Probably multigenic
  - Plaques develop faster in those with genetic predisposition and acquired risk factors (HTN, smoking, type 2 diabetes, obesity)

Staging, Grading, & Classification

- Methods for calculating degree of stenosis vary: NASCET, ACAS, ECST, and VACSG
- NASCET method: % stenosis = (normal lumen - minimal residual lumen)/normal lumen, x 100
  - Mild (< 50%), moderate (50-69%), severe (70-99%)
- Single diameter thresholds for CTA: 2.2mm (50% stenosis), 1.3mm (70% stenosis)

Gross Pathologic & Surgical Features

- 2 well-accepted lesions described: Atheromatous plaque and fatty streak
  - Atheromatous plaque: Most important, principal cause of arterial narrowing in adults
  - Fatty streak: Precursor of atheromatous plaque; present universally in children, even in 1st year
- Intimal fatty streaks are earliest macroscopically visible lesions
- Plaques are whitish-yellow, protrude intraluminally, vary in size

Microscopic Features

- Fibroatheromatous plaques, develop after lipid deposition
- Plaques contain cells (monocytes/macrophages, leukocytes, smooth muscle), connective tissue, intra-/extracellular lipid deposits
- Necrotic core of lipid, cholesterol, cellular debris, lipid-laden foam cells, and fibrin form within plaque
- Neovascularization may lead to vessel rupture, intraplaque hemorrhage, and ulceration
- Atheromatous plaque may rupture (fibrous cap weakens and fractures); may lead to distal embolization

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Variable: Asymptomatic, carotid bruit, TIA, stroke (may be silent)
- Clinical profile
  - Stroke risk factors: Smoking, hypertension, diabetes, obesity, hypercholesterolemia, advanced age

Demographics

- Age
  - Usually middle-aged to elderly
- Gender
  - M > F
- Ethnicity
  - African Americans at highest risk for ASVD
- Epidemiology
  - Leading cause of morbidity, mortality in USA
  - ASVD is largest risk factor for stroke
  - Ischemic stroke → up to 40% of deaths in elderly
  - Stroke occurs in > 70% of patients with ICA occlusion
  - 90% of large, recent infarcts are caused by thromboemboli
  - Epidemiological, experimental evidence that increased dietary lipid (cholesterol, saturated fat) and smoking correlate with atherosclerosis

Treatment

- Carotid endarterectomy (CEA) if symptomatic carotid stenosis ≥ 70% (NASCET)
- Symptomatic moderate stenosis (50-69%) also benefits from CEA (NASCET)
- ICA stenting depends on preoperative risk factors

DIAGNOSTIC CHECKLIST

Consider

- For patients undergoing CEA, adequacy of collateral circulation is critical; consider MRA or DSA
- To calculate degree of stenosis on DSA, ≥ 2 projections are required to profile plaque adequately

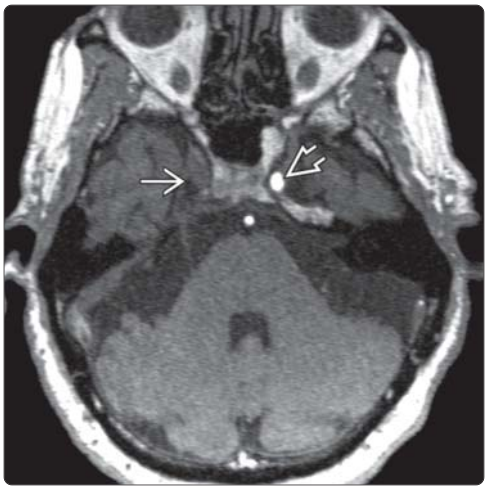
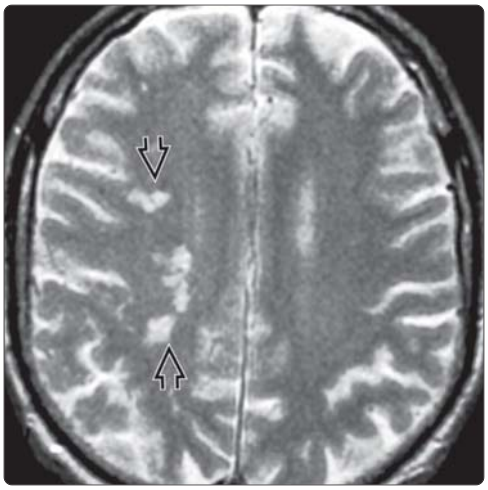
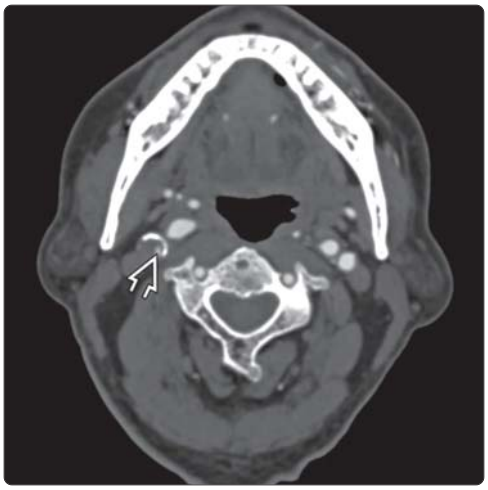
https://CafePezeshki.IR

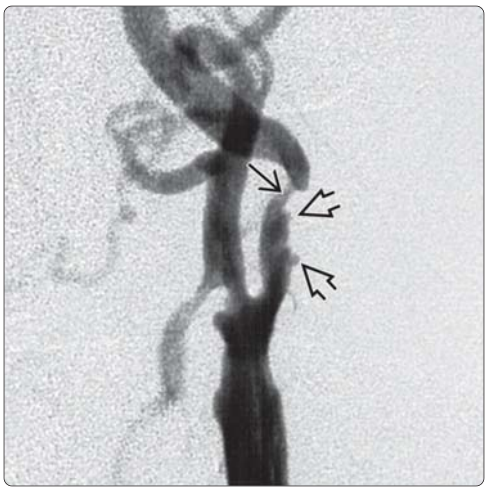


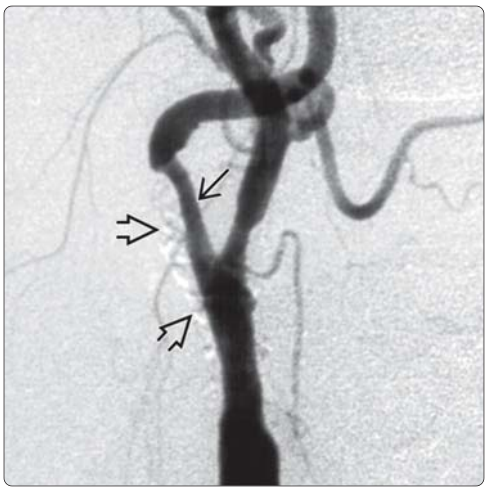


(Left) *Axial MRA shows a lack of flow in the right cavernous ICA ⇨. Note the normal flow related enhancement of the left cavernous ICA ⇨.* **(Right)** *Axial T2 MR image in the same patient shows a vertical line of white matter hyperintensities ⇨. These lesions form a rosary-like pattern and are along the deep white matter watershed zone where the cortical penetrating arteries meet the deep perforating arteries from the circle of Willis. They should alert the radiologist to the possibility of a flow-limiting lesion, often related to carotid ASVD.*



(Left) *Axial CTA shows a severe right common carotid artery stenosis with a very small residual lumen ⇨. Although DSA is considered the gold standard for evaluation of carotid stenosis, there is a linear relationship between CTA and DSA measurements of percent stenosis by NASCET criteria.* **(Right)** *Lateral DSA shows severe, short segment stenosis ⇨ of the right ICA. This patient would be amenable to an endovascular carotid stent or carotid endarterectomy.*





(Left) *Lateral angiography in a patient with left hemisphere TIAs shows a high-grade stenosis ⇨ distal to the left ICA bulb. Multiple irregularities in the atherosclerotic plaque are seen here as outpouchings of contrast ⇨. Irregularity is an independent risk factor for thromboembolic stroke, making this an "at risk" plaque.* **(Right)** *Lateral angiography in the same patient shows long-segment stenosis of the right ICA origin ⇨. Note the subtraction artifact from dense wall calcification ⇨.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Sclerosis of small-sized arteries (arterioles)
  - Common with chronic hypertension (HTN) &/or diabetes
  - May lead to vascular dementia (VaD)

IMAGING

- Multifocal white matter (WM) hypodensity on CT
- Patchy/confluent ↑ T2/FLAIR hyperintensities
  - Broad or confluent base with ventricles
  - Periventricular > deep > juxtacortical involvement
- Findings nonspecific
  - Large number of causes other than arteriopathy
  - Demyelination, infection, inflammatory, drug related, metabolic, age-related
- Caused by several types of arteriopathy
  - Arteriolosclerosis
  - Chronic hypertension (more basal ganglia, periventricular white matter involvement)
  - Diabetes mellitus (more peripheral involvement)

TOP DIFFERENTIAL DIAGNOSES

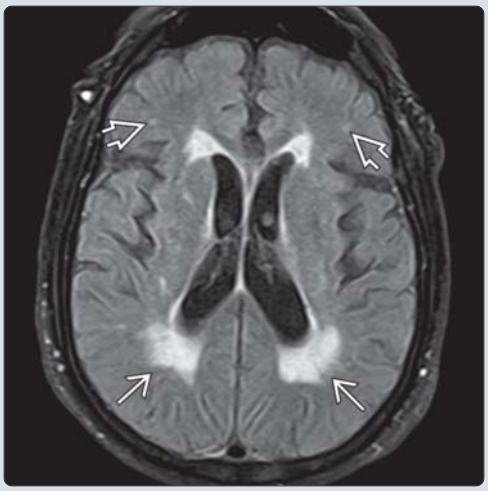
- Age-related white matter changes
- Perivascular (Virchow-Robin) spaces (PVSs)
- Demyelinating disease
- VaD
- Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL)
- Cerebral amyloid angiopathy (CAA)

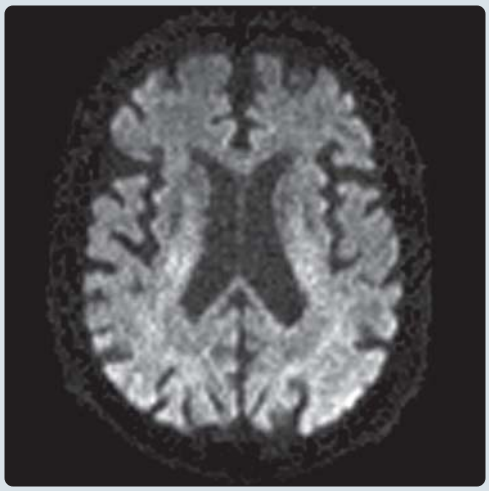
CLINICAL ISSUES

- Clinical and radiographic picture overlaps
  - Multi-infarct (vascular) dementia: Caused by arteriolosclerosis &/or multiple infarcts
  - Subcortical arteriosclerotic encephalopathy (SAE; Binswanger disease)

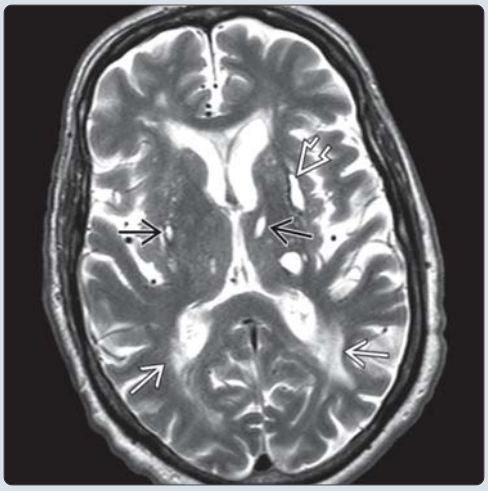
DIAGNOSTIC CHECKLIST

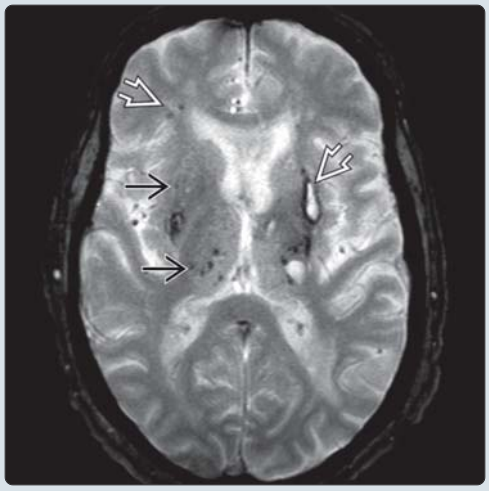
- Use FLAIR, T2* (GRE, SWI) sequences in all elderly patients
  - Look for microbleeds (HTN, CAA)





(Left) *Axial FLAIR MR image shows mild atrophy and confluent periventricular ⇨ and punctate subcortical ⇨ white matter hyperintensity typical for arteriolosclerosis (chronic small vessel disease) in this elderly patient with mild cognitive impairment.* **(Right)** *Axial DTI trace image shows no areas of diffusion restriction to suggest acute ischemia in this elderly patient. Arteriolosclerosis may mask an acute ischemic event, so DWI or DTI sequences are helpful to exclude acute ischemia in this patient population.*





(Left) *Axial T2 MR image in a patient with chronic hypertension shows confluent regions of periventricular hyperintensity ⇨ related to arteriolosclerosis. There are chronic lacunar infarcts ⇨ and a chronic hypertensive basal ganglia hemorrhage ⇨.* **(Right)** *Axial GRE MR image shows hypointensity related to hemosiderin along the chronic hypertensive hemorrhage. Multiple foci of susceptibility artifact or "blooming" are seen in the deep gray nuclei ⇨ and white matter ⇨ related to microhemorrhages from chronic hypertension.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Small vessel disease, microvascular disease, microangiopathy
- Imaging correlate = leukoaraiosis or periventricular leukoencephalopathy

Definitions

- Sclerosis of small-sized arteries (arterioles)
  - Commonly from chronic HTN, hypercholesterolemia &/or diabetes mellitus (DM)
  - May lead to vascular dementia

IMAGING

General Features

- Best diagnostic clue
  - White matter (WM) hypodensity (rarefaction) on CT
  - Patchy/confluent hyperintensity on T2WI/FLAIR
- Location
  - Periventricular white matter (PVWM) and deep WM
    - Broad or confluent base with ventricle
    - Periventricular (particularly along atria of lateral ventricles) > deep > subcortical involvement
  - Basal ganglia (BG)
    - More BG involvement with chronic HTN
    - More peripheral WM involvement
      - Diabetes mellitus, cerebral amyloid angiopathy
- Size
  - Varies, progresses with age
  - Range: Punctate to large confluent
- Morphology
  - Bilateral patchy or confluent

CT Findings

- NECT
  - Multifocal/confluent ill-defined hypodense areas that spare cortex
  - Broad or confluent base with ventricles
    - Periventricular > deep > juxtacortical involvement
- CECT
  - No enhancement

MR Findings

- T1WI
  - Patchy or confluent hypointense foci
- T2WI
  - Ill-defined hyperintensities, typically ≥ 5 mm
- PD/intermediate
  - Patchy or confluent hyperintense foci
- FLAIR
  - Most conspicuous sequence for hyperintensities
  - Significance of PVWM hyperintensities is controversial
    - Findings are nonspecific and occur with normal aging
    - Likely due to several types of arteriopathy, many of which are combined
      - Arteriolosclerosis
      - Chronic hypertension &/or diabetes mellitus
      - Cerebral amyloid angiopathy
      - Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL)
- T2* GRE
  - Multifocal "black dots" or susceptibility artifact, more commonly seen with chronic hypertension, amyloid angiopathy
- DWI
  - No associated restriction, unless acute lesion
- T1WI C+
  - Nonenhancing
- MRS
  - Reduced N-acetyl aspartate (NAA), NAA/Cr
- ± generalized atrophy (large ventricles, sulci)
- Extensive/confluent lesions found in 2-6% of normal elderly

Angiographic Findings

- Small and larger vessel arterial stenoses

Nuclear Medicine Findings

- PET/SPECT: In absence of atrophy, rCBF/rMRGlu usually normal

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - MR with FLAIR, DWI, T2* (GRE or SWI)

DIFFERENTIAL DIAGNOSIS

Age-Related White Matter Changes

- Significant overlap with normal, mild cognitive impairment (MCI) and demented elderly
- Other risk factors (HTN, DM) common

Perivascular (Virchow-Robin) Spaces (PVSs)

- Variable size, well delineated
- Most common around anterior commissure, deep white matter
- Signal, attenuation like CSF
- Peripheral high signal on FLAIR can be seen with both PVSs (in up to 25%) and with lacunar infarcts

Demyelinating Disease

- MS > ADEM
- Usually ovoid, periventricular
- Callososeptal interface involved (rare with ASVD)
- Younger patient population

Vascular Dementia (VaD) Overlaps With Arteriolosclerotic Disease

- Cognitive impairment
  - Multi-infarct dementia (MID)
  - Subcortical arteriosclerotic encephalopathy (Binswanger-type vascular dementia)
    - Longstanding hypertension, progressive decline in mental function, gait disturbances, ± minor strokes
    - Clinical diagnosis, not an imaging diagnosis
- Large and small infarcts

CADASIL

- Younger patient (≤ 40) with PVWM hyperintensities

https://CafePezeshki.IR

- Stronger predilection for anterior temporal and frontal lobe involvement

Cerebral Amyloid Angiopathy (CAA)

- Amyloid deposition in walls of small to medium-sized arteries and arterioles
- Lobar hemorrhages and microhemorrhages characteristic
- T2* GRE and SWI sequences key to diagnosis

PATHOLOGY

General Features

- Etiology
  - Hypertensive occlusive disease of small penetrating arteries
    - Results in white matter lesions and lacunar infarcts
- Genetics
  - General risk factors for peripheral/cerebral vascular diseases
    - *APOE*E4* alleles
    - Angiotensinogen gene promoter
  - CADASIL
    - *NOTCH3* mutations
- Associated abnormalities
  - Microangiopathy-related cerebral damage = PVWM hyperintensities, lacunar infarcts
  - PVWM hyperintensities on imaging does not always have pathologic correlate

Staging, Grading, & Classification

- European Task Force on Age-Related White Matter Changes (ARWMC) rating scale for MR and CT (for ill-defined lesions ≥ 5 mm)
  - White matter lesions
    - 0 = no lesions (including symmetrical caps, bands)
    - 1 = focal lesions
    - 2 = beginning confluence of lesions
    - 3 = diffuse involvement, ± U-fibers
  - Basal ganglia lesions
    - 0 = no lesions
    - 1 = 1 focal lesion (≥ 5 mm)
    - 2 = > 1 focal lesion
    - 3 = confluent lesions

Gross Pathologic & Surgical Features

- Generalized volume loss with prominent sulci and ventricles
- Periventricular and deep WM spongiosis
- Multifocal lacunar infarcts often present

Microscopic Features

- Normal age-related changes
- Imaging PVWM hyperintensities have spectrum of histopathologic correlates
  - Degenerated myelin (myelin "pallor")
  - Axonal loss with increased extracellular fluid
  - Gliosis, spongiosis
  - Lipofibrohyalinolysis with small vessel occlusions
  - Dilated perivascular spaces

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Broad range
    - May be normal, have mild cognitive impairment or dementia
- Clinical profile
  - Older patient with cerebrovascular risk factors (hypertension, hypercholesterolemia, diabetes, etc.)

Demographics

- Age
  - PVWM hyperintensities almost universal after 65 years
  - Lacunar infarcts in 1/3 of asymptomatic healthy patients > 65 years
- Gender
  - M = F
- Epidemiology
  - Vascular dementia (VaD): 3rd most common cause of dementia (after Alzheimer disease, Lewy body disease), accounts for 15% of cases
  - VaD is caused by arteriolosclerosis &/or multiple cortical/subcortical infarcts

Treatment

- Modification of known cerebrovascular risk factors

DIAGNOSTIC CHECKLIST

Consider

- Use FLAIR, T2* (GRE, SWI) sequences in elderly patients
- GRE/SWI hypointensities suggest chronic hypertension or amyloid
- More peripheral location suggests amyloid
- Anterior temporal lobe involvement in middle-aged patient suggests CADASIL

Image Interpretation Pearls

- Many causes of PVWMs other than arteriopathy (demyelination, infection, inflammatory, toxic, metabolic)
- Clinical and imaging findings overlap with multi-infarct (vascular) dementia, subcortical arteriosclerotic encephalopathy (Binswanger disease)

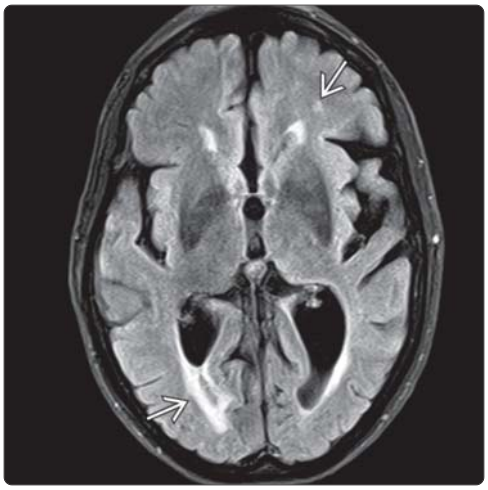
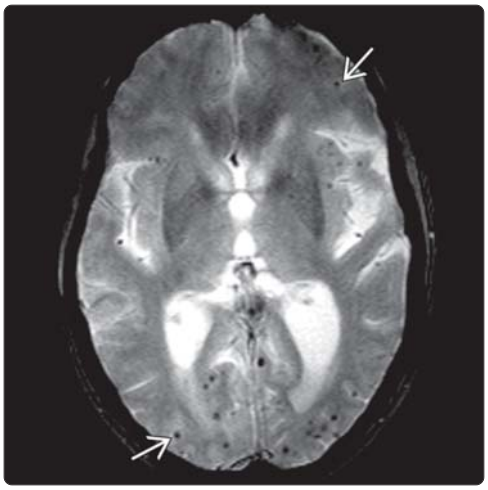
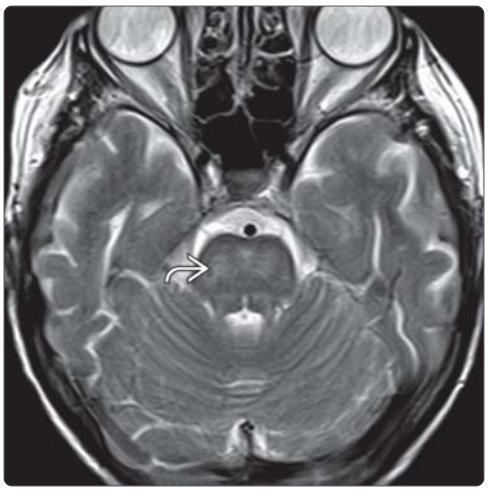
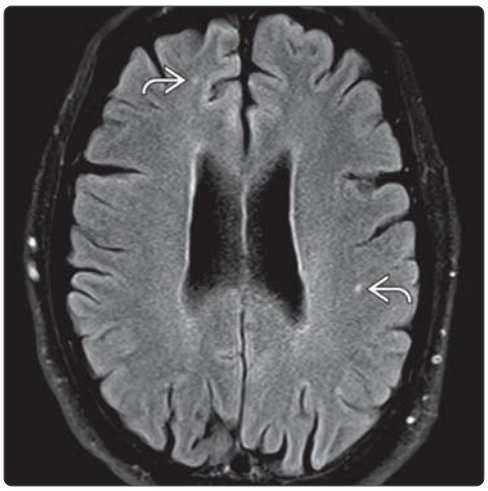
(Left) *Axial noncontrast CT shows diffuse atrophy and extensive confluent periventricular and subcortical hypodensity ➡ typical for severe arteriolosclerosis in this elderly patient with dementia.* **(Right)** *Axial CT at the level of the corona radiata shows extensive involvement of the white matter ➡ by arteriolosclerosis (chronic small-vessel ischemia) in this patient with longstanding hypertension and a clinical diagnosis of vascular dementia (Binswanger-type).*





(Left) *Axial FLAIR MR image shows mild periventricular and subcortical white matter hyperintensity ➡ related to arteriolosclerosis in a 51-year-old woman with cerebral amyloid angiopathy.* **(Right)** *Axial GRE image shows the typical peripheral distribution of hypointensity or "blooming" related to susceptibility artifact from blood products in the cortex and subcortical white matter ➡ of this patient with amyloid angiopathy. Note the relative sparing of the deep gray nuclei.*





(Left) *Axial T2 MR image shows the typical patchy central hyperintensity in the pons related to arteriolosclerosis in ➡ in this patient with a history of hypertension.* **(Right)** *Axial FLAIR MR image in a 65-year-old normotensive man shows a few punctate foci of hyperintensity ➡ in the subcortical white matter. Note the mild diffuse volume loss, a typical finding in normal aging.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Aberrant internal carotid artery (AbICA): Congenital vascular anomaly resulting from failure of formation of extracranial ICA with arterial collateral pathway

IMAGING

- Appearance of AbICA on thin section (< 1 mm) temporal bone CT is diagnostic
- AbICA appears as tubular lesion crossing middle ear from posterior to anterior
- Enlarged inferior tympanic canaliculus important observation
- Caution: Do not mistake AbICA for glomus tympanicum paraganglioma

TOP DIFFERENTIAL DIAGNOSES

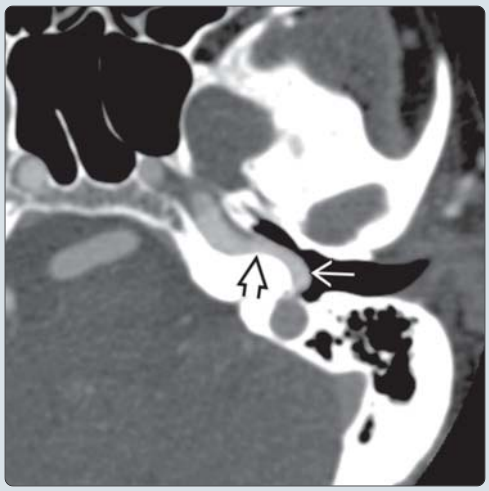
- Vascular middle ear lesion
  - Glomus tympanicum paraganglioma
  - Dehiscent jugular bulb
  - Lateralized internal carotid artery

PATHOLOGY

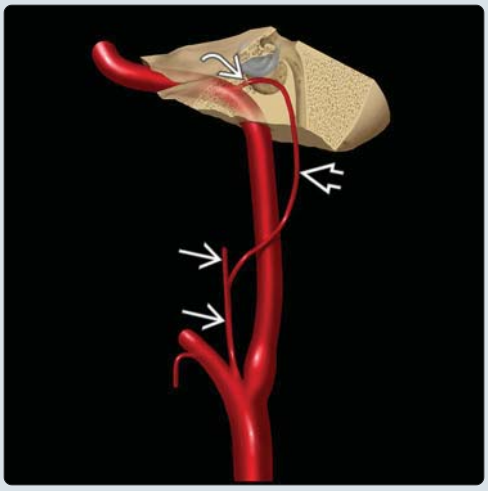
- Best explanation: "Alternative blood flow" theory
  - Persistence of pharyngeal artery system means C1 portion of ICA is absent
  - Mature arterial collateral system compensates for absent C1 and vertical petrous ICA segments
  - Ascending pharyngeal artery → inferior tympanic artery → caroticotympanic artery → posterolateral aspect of horizontal petrous ICA
- 30% of AbICA have persistent stapedial artery

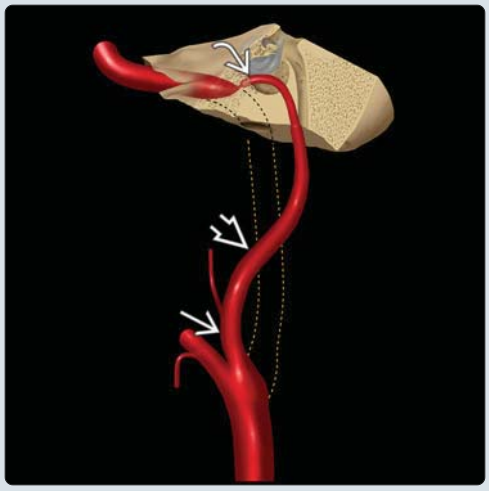
CLINICAL ISSUES

- Typically asymptomatic and discovered at time of routine physical exam, during middle ear surgery, or as incidental imaging finding
- Associated symptoms: Pulsatile tinnitus and conductive hearing loss
- No treatment is best treatment



(Left) *Axial graphic of the left temporal bone illustrates a classic AbICA ➡ rising along the posterior cochlear promontory and crossing along the medial middle ear wall to rejoin the horizontal petrous ICA ⇨. At the point of reconnection to the horizontal petrous ICA, stenosis ➡ is often present.* **(Right)** *Axial CTA image through the middle ear shows the looping aberrant internal carotid ➡ on the low cochlear promontory. Note the caliber change ⇨ as the AbICA rejoins the normal horizontal segment of the ICA.*





(Left) *Lateral graphic of a normal adult cervical and petrous ICA reveals the inferior tympanic artery ➡ branching off the ascending pharyngeal artery ➡, passing into the T-bone to anastomose with the very small caroticotympanic artery ➡ on the cochlear promontory.* **(Right)** *Lateral graphic depicts failure of the cervical ICA to develop (dotted lines), with the ascending pharyngeal ➡, inferior tympanic ➡, and caroticotympanic ➡ arteries providing an alternative collateral arterial channel resulting in an AbICA.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Aberrant internal carotid artery (AbICA)

Synonyms

- Aberrant carotid artery

Definitions

- Congenital vascular anomaly resulting from failure of formation of extracranial ICA with arterial collateral pathway

IMAGING

General Features

- Best diagnostic clue
  - Tubular structure running horizontally through middle ear cavity from posterior to anterior
- Location
  - Enters posterior middle ear through enlarged inferior tympanic canaliculus
    - Posterior and lateral to expected site of petrous carotid canal
  - Courses anteriorly across cochlear promontory to join horizontal petrous ICA through dehiscent carotid plate
  - Most commonly unilateral
- Size
  - Smaller than horizontal petrous ICA
- Morphology
  - Tubular morphology is key observation

CT Findings

- CECT
  - Enhancement equivalent to other arteries
    - **Caution**: Glomus tympanicum paraganglioma also enhances: Use morphology to differentiate tubular AbICA from ovoid paraganglioma
- Bone CT
  - Appearance of AbICA on thin section (< 1 mm) temporal bone CT is diagnostic
  - Axial bone CT
    - AbICA appears as tubular lesion crossing middle ear from posterior to anterior
    - **Enlarged inferior tympanic canaliculus** is important observation
      - Anteromedial to stylomastoid foramen and mastoid segment of facial nerve
    - Smaller AbICA often stenotic at point of reconnection with horizontal petrous ICA
    - Carotid foramen and vertical segment of petrous ICA are absent
  - Coronal bone CT
    - AbICA appears as round, soft tissue lesion on cochlear promontory
      - Single slice looks disturbingly like glomus tympanicum paraganglioma
      - **Caution**: Do not mistake AbICA for glomus tympanicum paraganglioma
      - Tubular nature of AbICA is key observation
    - Inferior tympanic canaliculus is vertical tube posterolateral to normal location of vertical segment of petrous ICA
      - Rises at coronal level of round window niche
  - If **persistent stapedial artery** associated
    - Absent foramen spinosum
    - Enlarged anterior tympanic segment of CN7 canal
- CTA
  - Diagnostic for AbICA
  - Usually not necessary, as CT alone is diagnostic

MR Findings

- Conventional MR does not reliably identify AbICA
- MRA source images and reformatted images show aberrant nature of vessel
  - AbICA enters skull base posterior and lateral, compared to normal contralateral side
  - Frontal reformat: Petrous segment of ICA extends laterally instead of medially
    - In left ear, AbICA looks like 7
    - In right ear, AbICA looks like reverse 7

Angiographic Findings

- Frontal view: Petrous segment of ICA extends laterally instead of medially
- Lateral view: Absent extracranial course of suprabifurcation ICA (C1 segment)
  - Smaller caliber vessels arise from bifurcation posteriorly, looping back to horizontal segment of petrous ICA
    - Stenosis may be present at site of reconnection between AbICA and horizontal petrous ICA
- Conventional angiography no longer necessary to confirm imaging diagnosis
  - CTA or MRA sufficient if uncertainty arises from bone CT images

Imaging Recommendations

- Best imaging tool
  - T-bone CT: Tubular morphology and posterolateral position diagnostic
    - Contrast CT or CTA not necessary
- Protocol advice
  - Bone CT: < 1 mm axial and coronal images
  - If MR is used, MRA is critical component

DIFFERENTIAL DIAGNOSIS

Glomus Tympanicum Paraganglioma

- Otoscopy: Pink/red, pulsatile, retrotympanic mass
- Bone CT: Focal ovoid mass on cochlear promontory
- MR: T1WI C+ enhancing mass

Lateralized Internal Carotid Artery

- Otoscopy: Vague, vascular hue deep behind tympanic membrane
- Bone CT: Dehiscent lateral wall of petrous ICA genu

Petrous Internal Carotid Artery Aneurysm

- Otoscopy: Negative unless large
- Bone CT: Focal, smooth, petrous ICA canal expansion
  - ICA has normal course but focal ovoid, expansile portion
- CTA or MRA is diagnostic of nonthrombosed aneurysm

https://CafePezeshki.IR

Dehiscent Jugular Bulb

- Otoscopy: Gray-blue retrotympanic mass in posteroinferior quadrant
- Bone CT: Focal absence of sigmoid plate
  - "Bud" from superolateral jugular bulb enters middle ear as a "mass"

Cholesterol Granuloma in Middle Ear

- Otoscopy: Blue-black retrotympanic mass
- Bone CT: Appears identical to acquired cholesteatoma
- MR: High signal on T1 and T2 without contrast suggests diagnosis

Congenital Cholesteatoma in Middle Ear

- Otoscopy: White-tan retrotympanic mass
- Bone CT: Multilobular soft tissue middle ear mass medial to ossicles
- MR: Low T1, high T2 signal mass; DWI restricted diffusion

PATHOLOGY

General Features

- Etiology
  - Etiology of AbICA is controversial
  - Best explanation: "Alternative blood flow" theory
    - Persistence of pharyngeal artery system means C1 portion of ICA is absent
    - Mature arterial collateral system compensates for absent C1 and vertical petrous ICA segments
      - Ascending pharyngeal artery → inferior tympanic artery → caroticotympanic artery → posterolateral aspect of horizontal petrous ICA
  - Results of absent extracranial ICA C1 segment
    - Ascending pharyngeal, inferior tympanic, and caroticotympanic arteries enlarge
    - Inferior tympanic canaliculus enlarges to accommodate enlarged inferior tympanic artery
    - Bony margin of posterolateral horizontal petrous ICA canal is penetrated at site of caroticotympanic artery origin
- Associated abnormalities
  - 30% of AbICAs have **persistent stapedial artery**
    - Enlarged anterior tympanic segment of CN7 canal
    - Absent ipsilateral foramen spinosum

Gross Pathologic & Surgical Features

- Pulsatile aberrant artery is found in middle ear cavity

Microscopic Features

- Histologically normal artery

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Most commonly asymptomatic
    - Discovered at time of routine physical exam, during middle ear surgery, or as incidental imaging finding
  - Associated symptoms
    - Pulsatile tinnitus (PT) (pulse-synchronous sound)
      - May be subjective (only patient hears) or objective (patient and clinician hear)
      - Subjective PT: Pulsatile sound may transmit directly through cochlear promontory to basal turn of cochlea
      - Objective PT: When stenosis present at junction of AbICA and normal horizontal petrous ICA
    - Conductive hearing loss
    - Vertigo, otalgia rare
  - Otoscopy: Retrotympanic pink-red mass
    - Inferior aspect of tympanic membrane
    - May mimic paraganglioma

Demographics

- Age
  - Average at presentation: 38 years
- Gender
  - M < F in single study (N = 16)
- Epidemiology
  - Very rare disorder

Natural History & Prognosis

- No long-term sequelae reported with AbICA
- Poor prognosis results only if misdiagnosis → biopsy
  - Pseudoaneurysm may require endovascular repair
- If tinnitus is loud, AbICA can be debilitating

Treatment

- **No treatment** is best treatment
- Greatest risk is misdiagnosis leading to biopsy
- Most patients have minor symptoms that do not require treatment
- Persistent stapedial artery does not need to be treated

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Radiologist must remain firm on imaging diagnosis despite clinical impression of paraganglioma
  - Biopsy or attempted resection of misdiagnosed AbICA can be disastrous
    - Hemorrhage, stroke, or death may result from vessel injury

Reporting Tips

- Report diagnosis; offer no differential diagnosis
- Equivocal report such as "cannot exclude paraganglioma" may lead to surgical intervention

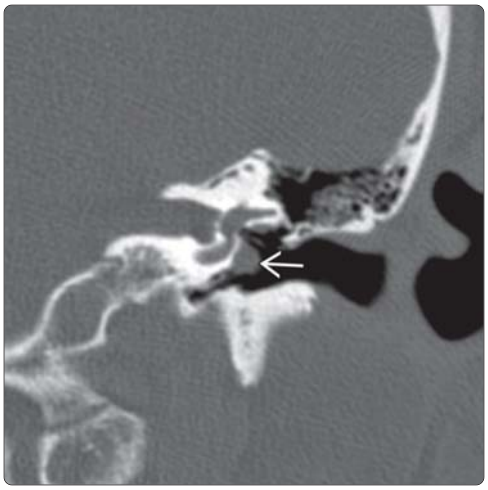
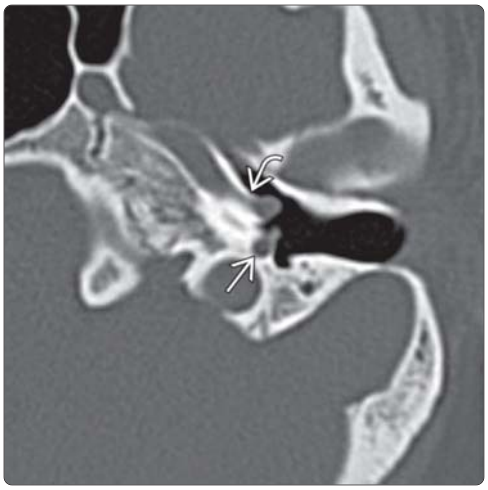
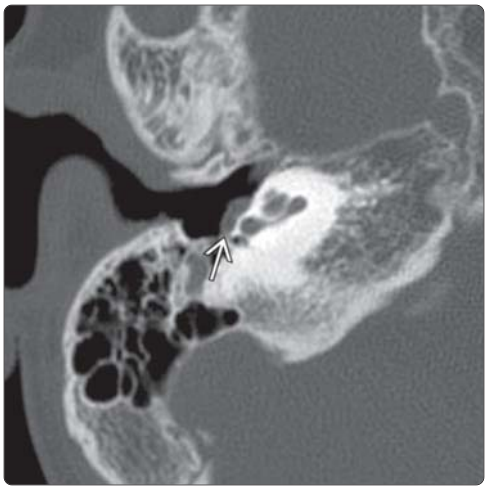
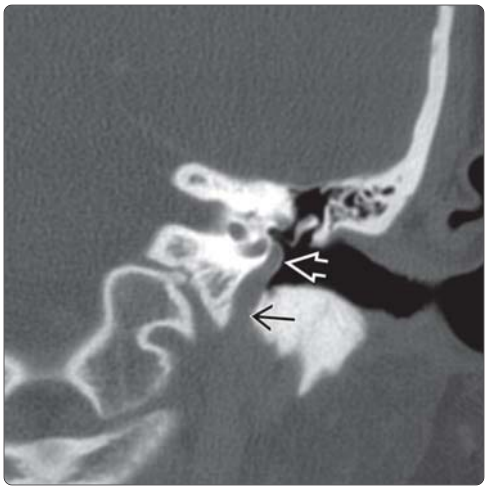
https://CafePezeshki.IR



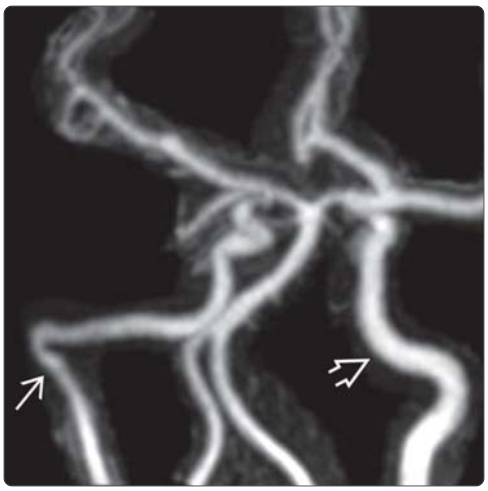


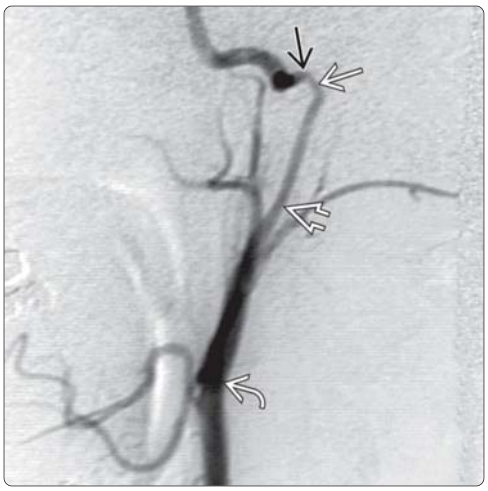
(Left) *Coronal left T-bone CT at the level of the oval window shows the AbICA as a "mass" located on the cochlear promontory resembling a glomus tympanicum paraganglioma. Accidental biopsy of AbICA may have devastating consequences.* **(Right)** *Axial bone CT reveals a smaller caliber aberrant internal carotid artery (AbICA) entering the middle ear cavity through an enlarged inferior tympanic canaliculus, coursing across the middle ear on cochlear promontory, and reentering the horizontal petrous ICA.*





(Left) *Axial bone CT of the right ear shows the AbICA entering the posteromedial middle ear cavity and looping across the low cochlear promontory in this young adult with a vascular retrotympanic mass. Its tubular shape can help prevent a misdiagnosis.* **(Right)** *Coronal bone CT of the left ear shows the posterior aspect of an AbICA with its enlarged inferior tympanic canaliculus and looping course up onto the cochlear promontory. The tubular configuration of the vessel is diagnostic.*





(Left) *Frontal oblique MRA image shows a right AbICA with a characteristic reverse 7 shape. Note the typical configuration of the contralateral normal ICA.* **(Right)** *Lateral internal carotid angiography of an AbICA reveals that the normal extracranial ICA is replaced by an enlarged collateral circuit, which includes the ascending pharyngeal, inferior tympanic, and caroticotympanic arteries. Note the caliber change from the AbICA to the horizontal petrous ICA.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Persistent carotid basilar anastomoses (PCBA)
- Persistence of normally transient embryonic-type arterial supply from carotid to basilar system
- 4 types, named according to anatomic relationship to cranial or spinal nerves

IMAGING

- Prominent unusual vessel between internal carotid artery (ICA) and basilar artery (BA)
  - Levels distributed from tentorial hiatus to below foramen magnum, at specific nerve levels (CN5, CN8, CN12; C1-C3)
- Persistent trigeminal artery (PTA); from intracavernous ICA and BA
  - Most common (0.1-0.2%)
- Persistent otic artery (POA); from petrous ICA to BA through internal auditory canal (IAC)
  - Very rare
- Persistent hypoglossal artery (PHA); from cervical ICA (C1-C2 level) to BA
  - Rare (0.03-0.09%)
- Proatlantal intersegmental artery (PIA); from cervical ICA (C2-C3 level), or rarely external carotid artery (ECA) to vertebral artery between C1 and occiput
  - 3rd most common

TOP DIFFERENTIAL DIAGNOSES

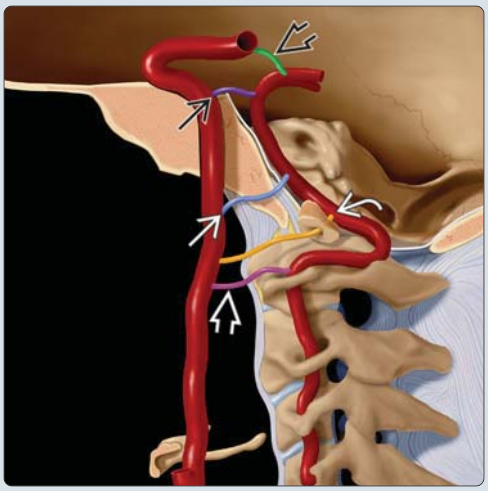
- ICA origin of posterior cerebral artery (PCA)
- Secondary anastomoses

PATHOLOGY

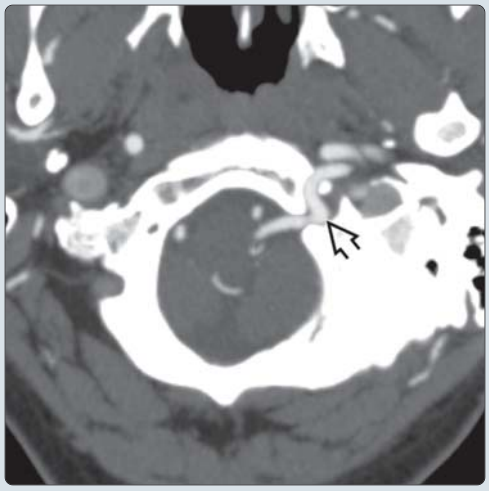
- Named according to parallel CN

CLINICAL ISSUES

- Asymptomatic; no treatment (unless aneurysms)



(Left) *Sagittal graphic shows anastomoses between the ICA and VA. A normal PCoA ⇨ connects PCA with the supraclinoid ICA. The PTA ⇨ connects the cavernous ICA and BA. The POA ⇨ connects the petrous ICA to the BA through the IAC. The PHA ⇨ connects the cervical ICA and the VA through the hypoglossal canal. The proatlantal artery ⇨ connects the cervical ICA and the VA at the C1 through C3 level.* **(Right)** *Sagittal MRA shows a PTA ⇨ connecting the proximal ICA siphon ⇨ with the mid-BA ⇨.*



(Left) *Axial CTA shows the classic appearance of a PTA ⇨ connecting the left internal carotid artery ⇨ to the basilar artery ⇨. A PTA is the most common type of persistent carotid basilar anastomoses occurring in 0.1-0.2% of cases. These are typically incidental findings, unless they are associated with other vascular lesions.* **(Right)** *Axial CTA shows a PHA ⇨ extending through the left hypoglossal canal and paralleling the CN12. The PHA connects the cervical ICA to the BA.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Persistent carotid basilar anastomoses (PCBA)

Synonyms

- Vestigial carotid-basilar anastomoses

Definitions

- Persistence of normally transient embryonic-type arterial supply from carotid to basilar system

IMAGING

General Features

- Best diagnostic clue
  - Abnormal internal carotid artery (ICA)-basilar artery (BA) connection below level of posterior communicating artery (PCoA)
- Location
  - From sellar to occipitovertebral level
- Morphology
  - Persistent trigeminal artery (PTA), from intracavernous ICA to BA, most common (0.1-0.2%)
    - Saltzman type 1: PTA supplies distal BA, PCoAs usually absent; proximal BA usually hypoplastic
    - Saltzman type 2: PTA fills superior cerebellar arteries, PCAs supplied via patent PCoAs
  - Persistent otic artery (POA), from petrous ICA to BA through internal auditory canal (IAC); rare
    - Vertebral arteries (VAs) absent or hypoplastic
  - Persistent hypoglossal artery (PHA), from cervical ICA (C1-C2 level) to BA; rare (0.03-0.09%)
    - Parallels CN12 in hypoglossal canal
  - Proatlantal intersegmental artery (PIA); from cervical ICA (C2-C3 level), or rarely external carotid artery (ECA) to VA between C1 and occiput (3rd most common)
    - Most caudal of PCBAs; VAs absent or hypoplastic

CT Findings

- CECT
  - Large caliber vessel between BA and ICA
- CTA
  - Delineates presence and course of vascular anomaly, associated abnormalities (e.g., saccular aneurysm)

MR Findings

- T2WI
  - Prominent unusual vessel between ICA and BA
    - Levels distributed from tentorial hiatus to below foramen magnum, presumably at specific nerve levels (CN5, 8, 12; C1-C3)
- MRA
  - Depicts unusual vessel, its origin, course, and vertebrobasilar connection
  - Associated arterial anomalies (e.g., aneurysm)

Angiographic Findings

- Performed for other reasons (e.g., subarachnoid hemorrhage); shows vestigial artery and arterial flow

Imaging Recommendations

- Best imaging tool: MR and MRA or CTA

DIFFERENTIAL DIAGNOSIS

ICA Origin of Posterior Cerebral Artery (PCA)

- a.k.a. "fetal" origin of PCA (10-30% of cases)
- Common: Above sella, PCoA prominent, P1 segment of PCA hypoplastic/absent

Secondary Anastomoses

- To feed AV fistula
- To compensate for arterial occlusion/agenesis

PATHOLOGY

General Features

- Etiology
  - Failure of regression of primitive or embryonic arterial connections
- Associated abnormalities
  - 25% prevalence of other vascular anomalies
    - Controversial: Aneurysm (15%)
    - Rare: Carotid-cavernous fistula, arteriovenous malformation, arterial fenestration, moyamoya, neurofibromatosis type 1
    - Very rare: Absent CC/ICA, proximal subclavian artery, BA; aorta coarctation
- Embryology
  - Early transient segmental connections from ICA supply BA before intersegmental VAs develop
  - Named by cranial/spinal nerve they parallel
- Anatomy
  - Anatomic change in arterial supply associated with reorganized arterial pattern (hypoplastic/missing arterial segments)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Incidental finding at imaging or subarachnoid hemorrhage (SAH)
    - Rarely trigeminal neuralgia or pituitary dysfunction

Natural History & Prognosis

- Asymptomatic; no treatment (unless aneurysms)

KEY FACTS

TERMINOLOGY

- Abnormality in hemoglobin (Hgb) → change in shape ("sickling") → ↑ "stickiness" of erythrocytes (RBCs) → capillary occlusions, ischemia, infarctions, premature RBC destruction (hemolytic anemia)

IMAGING

- Best diagnostic clue
  - Cerebral infarct(s) in African American child
  - Moyamoya (MM, secondary)

TOP DIFFERENTIAL DIAGNOSES

- Vasculitis
- Other causes of MM (inherited and secondary)

PATHOLOGY

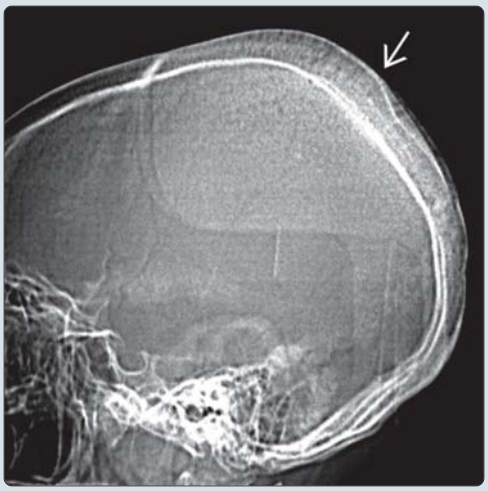
- Point mutation hemoglobin β gene, Chr 11p15.5: Glutamate → valine substitution
- Sickled RBCs adhere to endothelium → fragmentation of internal elastic lamina, degeneration of muscularis → large vessel vasculopathy ± aneurysm formation

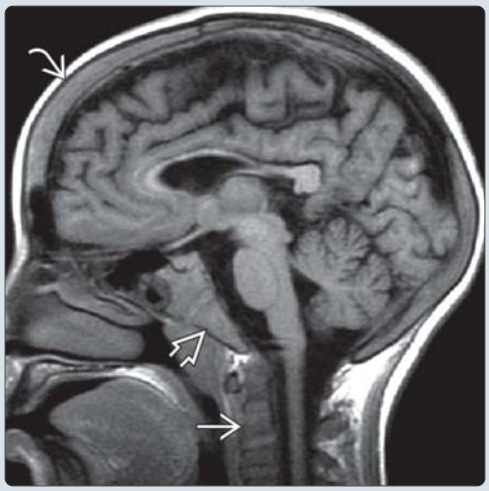
CLINICAL ISSUES

- Stroke
  - 17-26% of all patients with sickle cell disease (SCD)
  - 18x ↑ risk if transcranial Doppler velocities ICA/MCA > 200 cm/s
  - Peak incidence 1st decade of life
- 20% of children have white matter (WM) infarcts on MR without overt neurologic deficits = "silent infarcts"
  - 14x ↑ risk of stroke
- Regular blood transfusions keep Hgb S < 30%
  - ↓ stroke by up to 75%

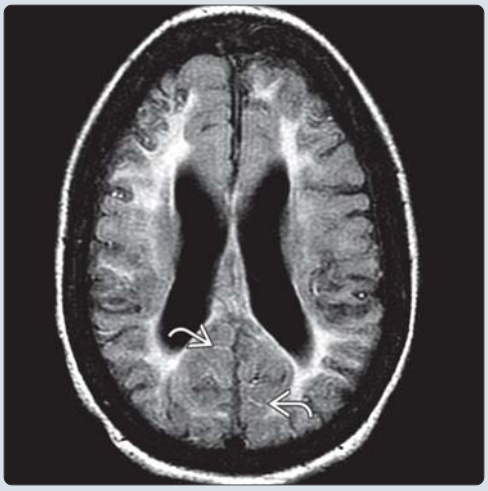
DIAGNOSTIC CHECKLIST

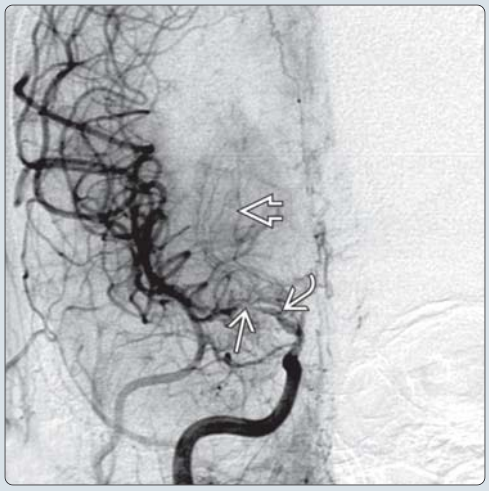
- Always consider SCD in African American child with cerebral infarction





(Left) *Lateral scout image from a CT examination shows marked diploic thickening due to red marrow hyperplasia, causing a hair on end appearance.* **(Right)** *Sagittal T1WI MR shows calvarial thickening and ↓ marrow signal intensity secondary to red marrow hyperplasia caused by chronic anemia. Loss of normal T1-hyperintense fatty marrow is also seen in the clivus and cervical spine. Iron deposition from repeat transfusions can also contribute to marrow signal abnormality.*





(Left) *Axial FLAIR MR shows considerable brain atrophy and signal hyperintensity due to chronic ischemic brain injury. Note the presence of "ivy" sign, branching abnormal hyperintensity in the cerebral sulci. The "ivy" sign is thought to occur secondary to slow collateral flow in engorged pial vessels.* **(Right)** *DSA AP view from a right ICA injection shows secondary moyamoya with enlarged lenticulostriate arteries resulting in a "puff of smoke" in this SCD patient with severe MCA and distal ICA stenosis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Sickle cell disease (SCD)

Definitions

- Abnormality in hemoglobin (Hgb) → change in shape ("sickling") → increased "stickiness" of erythrocytes (RBCs) → capillary occlusions, ischemia, infarctions, premature RBC destruction (hemolytic anemia)

IMAGING

General Features

- Best diagnostic clue
  - Cerebral infarct(s) in African American child
  - Secondary moyamoya (MM)
    - Narrowing of distal internal carotid arteries (ICA) or proximal anterior cerebral arteries (ACA), middle cerebral arteries (MCA)
    - Lenticulostriate collaterals in basal ganglia (BG)
- Location: ICAs, deep white matter (WM), cortex, bone marrow
- Cognitive impairment does not correlate with imaging findings
- Decreased gray matter volume in SCD children

Radiographic Findings

- Radiography
  - Thick skull with expanded diploic space
  - Opacified paranasal sinuses

CT Findings

- NECT
  - Hypodense gray or WM infarct(s) → diffuse atrophy
  - Rare: Subarachnoid (SAH) or intraventricular hemorrhage (IVH) from SCD-related aneurysm or MM
- CECT: Punctate enhancement BG from MM collaterals
- CTA: Stenosis of distal ICA, proximal circle of Willis (COW)

MR Findings

- T1WI
  - Hemorrhagic infarcts may be seen
  - Punctate flow voids in BG correspond to MM collaterals
  - Decreased signal, expanded marrow (↑ red marrow)
- T2WI
  - Cortical, deep WM infarcts
    - Often in ACA/MCA watershed distribution
    - Associated with reduced subcortical volumes
- FLAIR
  - Multifocal hyperintensities ± "ivy" sign of MM
- DWI: Diffusion restriction in acute infarcts
- PWI
  - ↑ cerebral blood flow (CBF) early: Adaptive response to anemia
  - ↓ CBF, ↑ mean transit time (MTT), ↑ time to peak (TTP) with arterial sludging, progressive COW narrowing
  - Arterial spin labeling (ASL) may be useful; assess CBF without use of contrast material
- T1WI C+: Vascular stasis and leptomeningeal collaterals in MCA territory with proximal MCA stenosis
- MRA
  - Enlarged, tortuous arteries early
    - Theory: Adaptive response to anemia and ↑ cerebral perfusion
  - Frequent eventual development of MM
  - Aneurysms in atypical locations
- MRS: ↑ lactate, ↓ NAA, ↓ Cho, ↓ Cr in areas of infarction (lactate seen only in acute infarctions)

Ultrasonographic Findings

- Transcranial Doppler (TCD): Hyperdynamic flow distal ICA/MCA secondary to proximal stenosis
  - Time-averaged mean velocities > 200 cm/s → high risk of ischemic stroke
  - Velocities between 170-200 cm/s, conditional

Angiographic Findings

- MM: Stenosis of distal ICA, proximal COW with BG and ECA → ICA collaterals
  - Association between MM with persistent primitive carotid-basilar arterial communications
- Fusiform aneurysms
- Periprocedural risk of stroke higher than other populations: Hydrate, transfuse before catheter study

Nuclear Medicine Findings

- PET, SPECT: Focal areas of ↓ brain perfusion described

Imaging Recommendations

- Best imaging tool
  - MR/MRA ± DSA
- Protocol advice
  - DWI differentiates acute infarcts from chronic
  - Turbulent dephasing due to anemia, rapid flow can mimic stenosis on "bright blood" MRA: Use lowest possible TE for "bright blood" MRA or "black blood" MRA if stenosis suspected

DIFFERENTIAL DIAGNOSIS

Vasculitis

- Idiopathic, infectious, autoimmune, substance abuse
- Classic imaging findings: Cortical and deep WM infarcts and parenchymal hemorrhage

Moyamoya (MM)

- Primary MM
  - Idiopathic, inherited
- Other causes of secondary MM
  - NF1, Down syndrome, radiation therapy, connective tissue disease, prothrombotic states

Thick Skull With Expanded Diploe

- Other chronic anemias (thalassemia)

PATHOLOGY

General Features

- Etiology
  - Abnormal hemoglobin (Hgb S) becomes "stiff" when deoxygenated → RBCs become sickle-shaped
  - Sickled RBCs lose pliability to traverse capillaries → vascular occlusion ("crisis"), cell destruction (hemolysis)

https://CafePezeshki.IR

- Sickled RBCs adhere to endothelium → fragments internal elastic lamina, degenerates muscularis → large vessel vasculopathy ± aneurysm formation
- Genetics
  - Point mutation of hemoglobin β gene, Chr 11p15.5: Glutamate → valine substitution
  - SCD: Autosomal recessive, both β-globin affected
  - Sickle cell trait: 1 β-globin affected → mild disease
    - Carrier
    - ↑ resistance to malaria (hence prevalence)
- Associated abnormalities
  - Anemia, reticulocytosis, granulocytosis
  - Susceptibility to pneumococcal infection (due to malfunctioning spleen)
  - Occasionally causes pseudotumor cerebri

Gross Pathologic & Surgical Features

- Bone, brain, renal, and splenic infarcts; hepatomegaly

Microscopic Features

- Severe anemia with sickled cells on smear
- Vascular occlusions due to masses of sickled RBCs

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Focal neurologic deficit
- Other signs/symptoms
  - Children: Learning difficulties, headache, psychiatric symptoms
- Clinical profile
  - African American child with stroke
- Stroke
  - 17-26% of all patients with SCD
  - 11% by age 20, 24% by age 45
  - 75% ischemic, 25% hemorrhagic
  - 20% of children have WM infarcts on MR but no overt neurologic deficit = "silent infarcts"
    - TCD usually normal
    - Associated with mild cognitive impairment
    - 14x ↑ risk of stroke consistent with patients with normal MR
  - 18x ↑ risk of stroke if TCD velocity of ICA or MCA > 200 cm/s
- Bone infarcts, avascular necrosis during crisis
- Osteomyelitis, especially *Salmonella*
- Gross hematuria from renal papillary necrosis and ulceration
- Splenic infarction from exposure to high altitude (e.g., flying)
- Infections common, especially *Pneumococcus* after splenic infarction

Demographics

- Age
  - Children = adults
  - Stroke risk highest from 2-5 years of age
- Gender: No predilection
- Ethnicity: Found primarily in African Americans and their decendents
- Epidemiology
  - Birth prevalence in African Americans: 1/375
  - Birth prevalence of sickle cell trait: 1/12
  - Primary cause of stroke in African American children
  - Incidence of cerebral lesions (MR) in patients with sickle cell trait: 10-19%

Natural History & Prognosis

- Unrelenting, severe hemolytic anemia beginning at few months of age after Hgb S replaces Hgb F (fetal)
- Cognitive dysfunction occurs even in absence of cerebral infarctions
- Repeated ischemic events → strokes with worsening motor and intellectual deficits
- Patients usually live to adulthood albeit with complications
- Prognosis poor for SCD without transfusions

Treatment

- Screening TCD
  - Detection ↑ velocity (> 200 cm/s)prompts brain MR and treatment with regular blood transfusions
  - Regular blood transfusions keep Hgb S < 30%
    - ↓ incidence of stroke by up to 75%
    - ↓ intimal hyperplasia COW vessels
- Hydroxyurea: ↓ incidence of painful crises and acute chest syndrome; may improve TCD velocities
  - Induces Hgb F, which ↓ vaso-occlusion and hemolysis
- Penicillin prophylaxis; pneumococcal vaccine
- Bone marrow transplantation is only curative therapy
  - Available only to few who have HLA-matched donor
- On horizon: Stem cell-based therapies

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Always consider SCD in African American child with cerebral infarction

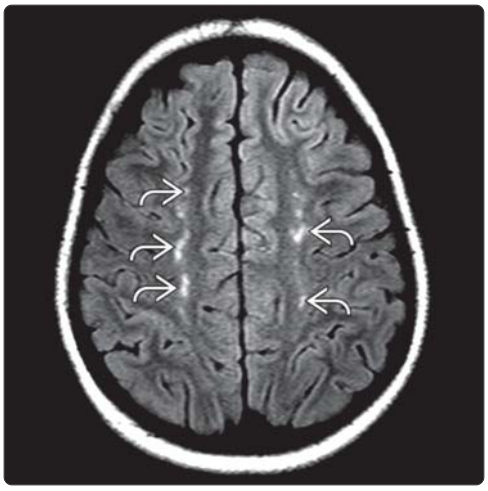
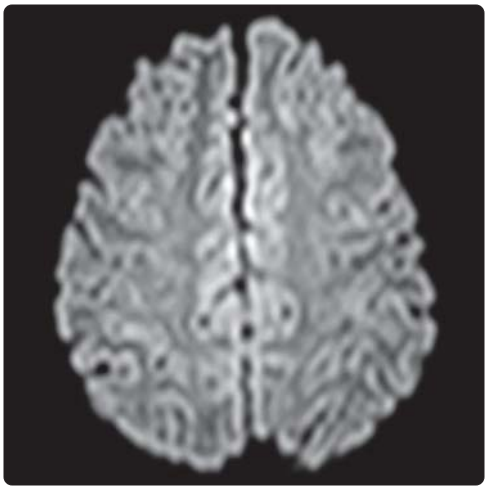
https://CafePezeshki.IR

(Left) *Axial FLAIR MR shows a characteristic appearance of the brain in sickle cell disease (SCD) with bilateral deep white matter and cortical (on right) infarcts with foci of cystic encephalomalacia. The infarcts are linearly arranged in the AP plane, a pattern consistent with watershed infarction.* **(Right)** *Axial T2WI MR in the same patient shows asymmetry of the internal carotid arteries (ICA) with ↓ caliber on the right, the side with greater brain injury. Vessel narrowing is a result of sickle cell vasculopathy.*





(Left) *Axial FLAIR MR in an asymptomatic teenager with SCD shows multiple, small foci of increased signal in the deep white matter watershed.* **(Right)** *Axial DWI MR in the same patient shows no reduced diffusion to suggest acute infarction; the infarcts are "silent." There is MR evidence of infarct without overt neurologic abnormality and usually normal ICA/MCA velocities on transcranial Doppler. Such patients often have mild cognitive impairment and are at increased risk of stroke.*

(Left) *MRA collapsed view does not demonstrate narrowing of the distal ICAs, proximal ACAs, or proximal MCAs. The vessels are mildly enlarged and tortuous, thought to occur as a pathophysiologic response to anemia and ↑ cerebral perfusion. This progressive vasculopathy eventually results in large and small vessel injury.* **(Right)** *MRA in the same patient shows a proximal basilar artery aneurysm. Patients with SCD are at ↑ risk of aneurysm, often in atypical locations.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Progressive narrowing of distal ICA/proximal circle of Willis (COW) vessels with secondary collateralization
  - Collateral vessels → cloud-like "puff of smoke" (moyamoya) at angiography
- Moyamoya disease (MMD) = primary (idiopathic) moyamoya
  - Marked East-West gradient (more common in Japan, Korea)
- Moyamoya pattern of collaterals = secondary to many etiologies

IMAGING

- Best diagnostic clue: Attenuated COW with multiple tiny basal ganglia "flow voids" on MR
- Best imaging tool: T1MRC+/MRA; DSA for delineating vascular details

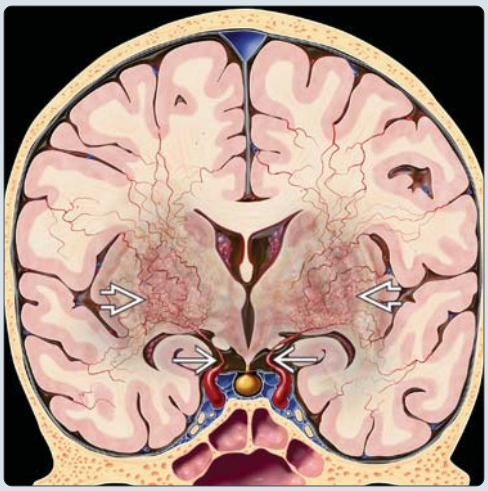
PATHOLOGY

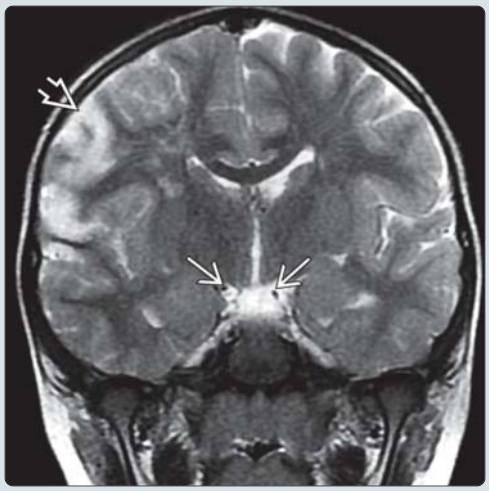
- Moyamoya disease
  - RNF213 polymorphism in 95% of familial East Asian population, 79% of sporadic
    - Correlated with early onset, severe form of MMD
- Secondary moyamoya (many causes)
  - Syndromic (e.g., NF1), inflammatory states, prothrombotic states, premature aging, congenital mesenchymal defects, suprasellar irradiation in childhood

CLINICAL ISSUES

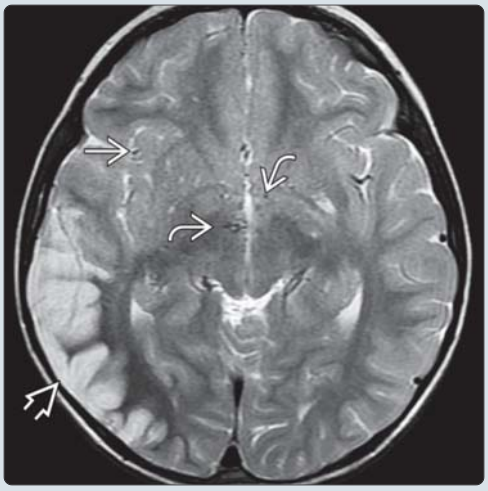
- Bimodal age peaks (5-10 years and 2nd peak during 4th decade)
- Most frequent cause of stroke in Asian children
- Presentation
  - Children: Recurrent TIAs; hemorrhage rare
  - Adults: TIAs, infarcts, hemorrhage (20%), migraines

(Left) *Coronal graphic shows severe tapering of both distal internal carotid arteries* ⇨ *and strikingly enlarged lenticulostriate arteries* ⇨ *coursing through basal ganglia. This is the puff of smoke (moyamoya) pattern.* **(Right)** *Coronal T2WI in a 3-year-old female with MMD shows severely attenuated supraclinoid internal carotid arteries* ⇨*. An acute cortical infarct is present in the right MCA distribution* ⇨*.*





(Left) *Axial T2WI in the same patient shows tiny, almost inapparent "flow voids" of the right MCA branches in the sylvian fissure* ⇨*. The acute cortical infarct has produced marked gyral edema, swelling* ⇨*. Note the tiny "squiggly" flow voids* ⇨ *from the basal collateral vessels.* **(Right)** *Coronal MIP of the time-of-flight MRA in the same patient shows the severely attenuated supraclinoid internal carotid arteries* ⇨ *and the puff of smoke appearance of the basal collateral vessels* ⇨*.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Moyamoya disease (MMD)

Synonyms

- Idiopathic progressive arteriopathy of childhood, spontaneous occlusion of circle of Willis (COW)

Definitions

- Progressive bilateral stenosis or occlusion of terminal internal carotid artery (ICA)/proximal COW with abnormal vascular network at base of brain
  - Compensatory development of collateral vascular network = "puff of smoke"
- Primary (idiopathic) moyamoya = moyamoya disease
  - More common Japan, Korea
- Secondary (acquired) moyamoya
  - Cranial radiation
  - Atherosclerosis
  - Neurofibromatosis

IMAGING

General Features

- Best diagnostic clue: Attenuated COW with multiple tiny basal ganglia "flow voids" on MR
- Location: Supraclinoid ICA/COW; anterior > > posterior circulation
- Size: Large vessel occlusion
- Morphology: "Puff of smoke" (moyamoya in Japanese)
  - Cloud-like lenticulostriate and thalamostriate collaterals on angiography

CT Findings

- NECT
  - Children: 50-60% show anterior > posterior atrophy
  - Adults can present with intracranial hemorrhage
- CECT: Enhancing dots (large lenticulostriates) in BG and abnormal net-like vessels at base of brain
- CTA: Abnormal COW and net-like collaterals
- Xe-133 CT: ↓ cerebral reserve with acetazolamide challenge

MR Findings

- T1WI: Multiple dot-like flow voids in BG
- T2WI
  - ↑ signal in small vessel cortical and white matter infarcts
  - Collateral vessels = net-like cisternal filling defects
- FLAIR
  - Bright sulci = leptomeningeal "ivy" sign
    - Slow-flowing engorged pial vessels, thickened arachnoid membranes
    - Correlates with decreased cerebral vascular reserve
- T2* GRE
  - Hemosiderin if prior hemorrhage
  - Asymptomatic microbleeds occasionally seen in adults
- DWI: Very useful for "acute on chronic" disease
- T1WI C+
  - Lenticulostriate collaterals → enhancing "dots" in BG and net-like thin vessels in cisterns
  - Leptomeningeal enhancement (contrast-enhanced "ivy" sign) ↓ after effective bypass surgery
- MRA: Narrowed distal ICA and proximal COW vessels, ± synangiosis
- MRV: Some vasculopathies may also involve veins
- MRS: Lactate in acutely infarcted tissue
  - NAA/Cr and Cho/Cr ratios frontal white matter improve/increase after revascularization
- PWI: ↓ perfusion in deep hemispheric white matter, relative ↑ perfusion in posterior circulation

Ultrasonographic Findings

- Grayscale: Reduction of ICA lumen size
- Pulsed Doppler
  - Doppler spectral waveforms in ICA show no flow (occluded) or high resistance (stenotic) flow pattern
  - ↑ end-diastolic flow velocity, ↓ vascular resistance in external CA (ECA) collaterals
- Color Doppler: Aliasing suggests stenoses
- Power Doppler: Contrast injection improves visualization of slow-flow stenotic vessels and collaterals

Angiographic Findings

- Conventional
  - Predominantly (not exclusively) anterior circulation
    - Narrow proximal COW and ICA (earliest)
    - Lenticulostriate and thalamoperforator collaterals (intermediate)
    - Transdural and transosseous EC-IC collaterals (late)
  - Dilatation and branch extension of anterior choroidal artery predicts adult hemorrhagic events

Nuclear Medicine Findings

- PET: ↓ hemodynamic reserve capacity
- SPECT I-123-iomazenil: Neuronal density preserved if asymptomatic, ↓ if symptomatic

Imaging Recommendations

- Best imaging tool: MR C+/MRA
- DSA for mapping collaterals, grading
- Protocol advice
  - Contrast improves detection: Synangiosis, collaterals
  - Catheter angiography defines anatomy of occlusions prior to bypass
- Diagnostic criteria: MR/MRA or catheter angiography
  - Stenosis/occlusion of terminal ICA or proximal ACA and MCA
  - Abnormal vascular network/flow voids in BG
  - Bilateral; unilateral findings presumptive

DIFFERENTIAL DIAGNOSIS

"Ivy" Sign

- Leptomeningeal metastases, subarachnoid hemorrhage, meningitis, increased inspired oxygen

Punctate Foci in Basal Ganglia

- Cribriform lacunar state: No enhancement

Severely Attenuated Circle of Willis

- Subarachnoid hemorrhage, meningitis, tumor encasement

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Moyamoya disease
    - RNF213 polymorphism in 95% of familial East Asian population, 79% of sporadic
      - Correlated with early onset, severe form of MMD
  - Secondary moyamoya
    - Down syndrome, tuberous sclerosis, sickle cell disease, connective tissue disease, progeria, NF1
      - NF1 with suprasellar tumor and radiation is disastrous
    - Morning glory syndrome; syndromes with aneurysms, cardiac and ocular defects
    - Inflammatory: CNS angiitis (of childhood), basal meningitis, atherosclerosis, H&N infections
    - Vasculopathies and prothrombotic states: XRT, Kawasaki, anticardiolipin antibody, factor V Leiden, polyarteritis nodosa, Behçet, SLE
- Epidemiology: Moyamoya disease
  - Incidence in Japan: 1:100,000
  - Incidence in North America, Europe: 0.1:100,000
  - 10-15% familial

Staging, Grading, & Classification

- Staging criteria (after Suzuki)
  - Stage 1: Narrowing of ICA bifurcation
  - Stage 2: ACA, MCA, PCA dilated
  - Stage 3: Maximal basal collaterals; small ACA/MCA
  - Stage 4: Fewer collaterals (vessels); small PCA
  - Stage 5: Further ↓ collaterals; absent ACA/MCA/PCA
  - Stage 6: Extensive ECA-pial collaterals

Gross Pathologic & Surgical Features

- Increased perforating (early) and ECA-ICA (late) collaterals in atrophic brain
- Hemorrhage (subarachnoid, intraventricular > parenchymal) adults
- Increased saccular aneurysms (especially basilar in adults)

Microscopic Features

- Intimal hyperplasia, medial layer thinness
- Excessive infolding, "waving" of internal elastic lamina
- Periventricular pseudoaneurysms (cause of hemorrhage)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Children: Transient ischemic attacks (TIAs), alternating hemiplegia (exacerbated by crying), headache
  - Adults: TIAs, cerebral infarct, or hemorrhage
    - Hemorrhagic presentation more common in Asian adults
- Other signs/symptoms
  - Children: Developmental delay, poor feeding, chorea
- Clinical profile
  - Children more likely to have TIAs and to progress; adults more likely to infarct (but slower progression)
  - Children more likely to have ipsilateral anterior plus posterior circulation involvement

Demographics

- Age
  - Bimodal age peaks (5-10 years and 2nd peak during 4th decade)
- Gender
  - M:F = 1:1.8; in familial cases, M:F = 1:5
- Most frequent cause of stroke in Asian children

Natural History & Prognosis

- Progressive narrowing, collateralization, and ischemia
- Prognosis depends on etiology, ability to form collaterals, age/stage at diagnosis
- Pediatric cases usually advance to stage 5 within 10 years of onset
  - Infantile moyamoya progresses faster
  - Pediatric cases present with stroke
- Hemorrhagic moyamoya more common in older patients with large collateral vessels
  - Has poorer outcome

Treatment

- Moyamoya disease
  - Indirect bypass: Encephalo-duro-arterio-synangiosis (EDAS) more effective in children
    - 5-year risk of ipsilateral stroke post EDAS = 15%
  - Direct bypass: Superficial temporal artery-middle cerebral artery (STA-MCA) more common in adults
- Anticoagulation; correct/control prothrombotic states and inflammatory etiologies
- Hypertransfusion for sickle cell-related moyamoya
- Perivascular sympathectomy or superior cervical ganglionectomy (adults)

DIAGNOSTIC CHECKLIST

Consider

- Seek secondary causes of moyamoya

Image Interpretation Pearls

- Enhanced asymmetric atrophy found on childhood CT, look for abnormal vascular pattern
- Adult moyamoya can present with IC hemorrhage

Reporting Tips

- Successful revascularization = ↓ basal collaterals, ↑ flow in MCA branches, ↑ caliber of STA (direct bypass)

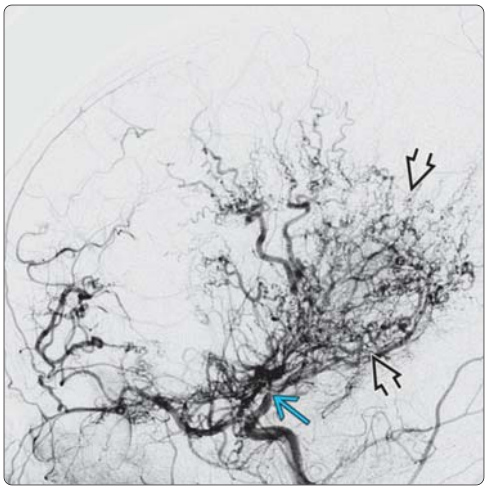
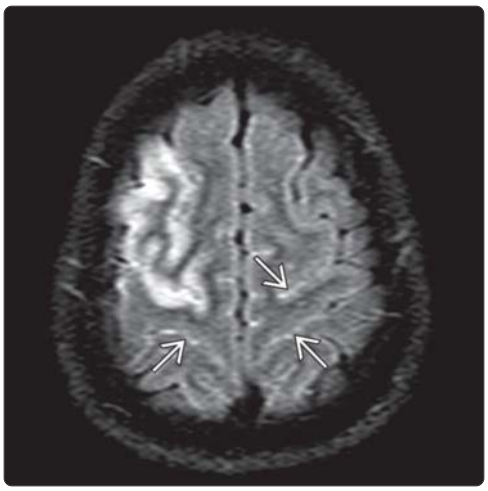
https://CafePezeshki.IR



(Left) *Axial MIP of time-of-flight MRA shows normal petrous, cavernous ICAs. There are almost no visible MCA branches of the right supraclinoid ICA, which is severely narrowed. Only a few distal vessels of the left MCA are seen, and there is a "flow gap" between the left supraclinoid ICA and proximal MCA.* **(Right)** *Lateral DSA of the right ICA injection in the same patient shows abrupt termination of its supraclinoid segment. The innumerable tiny, tortuous collateral vessels are the "puff of smoke" (moyamoya).*

(Left) *AP view of the left vertebral injection in the same patient shows it supplies additional tiny, tortuous collaterals at the base of the brain.* **(Right)** *Lateral DSA in the same patient shows the collaterals (moyamoya vessels) are supplied primarily by thalamoperforating and medial choroidal branches.*



(Left) *Axial FLAIR MR in a 12 year old with sudden left hemiplegia shows an acute right MCA territory infarct. Hyperintense signal in the cerebral sulci represents the "ivy" sign, caused by slow flow in engorged pial collaterals.* **(Right)** *Anteroposterior DSA of right ICA injection in the same patient shows severe focal narrowing of proximal MCA and occluded ACA. Lenticulostriates and thalamoperforator arteries are enlarged. Collateral flow from the posterior choroidal artery is also present.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Primary arteritis of CNS (PACNS)
  - No evidence of secondary (systemic) vasculitis
  - May involve intracranial arteries of any size
- 2 features essential for histopathologic diagnosis
  - Inflammation and necrosis of blood vessel wall

IMAGING

- CT
  - Look for secondary signs of vasculitis (ischemia, infarction)
  - Hypodensities on CT
  - Especially basal ganglia, subcortical white matter
- MR (high resolution)
  - Multifocal punctate, linear hyperintensities on T2/FLAIR
  - Vessel wall imaging with thin-section, high-resolution (3T) T1 C+
    - Circumferential, smooth, long segment
  - ± patchy parenchymal enhancement, restricted diffusion
  - DWI variable (may restrict)
- DSA
  - Once considered imaging gold standard
  - "Beaded" arteries (irregular stenoses, dilatations) on DSA
    - Peripheral branches > COW
  - Less common: Long-segment stenoses, pseudoaneurysms, occlusions

PATHOLOGY

- Brain biopsy may be required to confirm diagnosis
  - 75-80% sensitive
  - Negative biopsy does not exclude primary arteritis of CNS

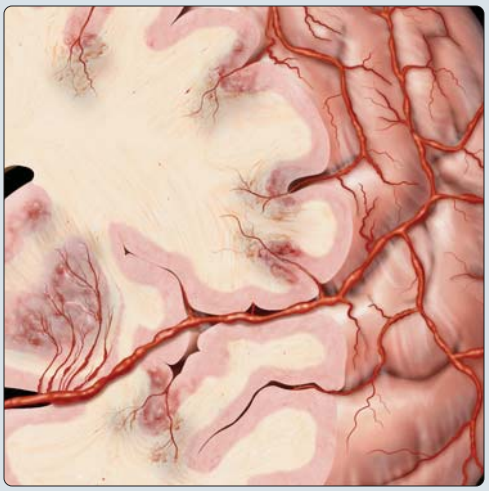
CLINICAL ISSUES

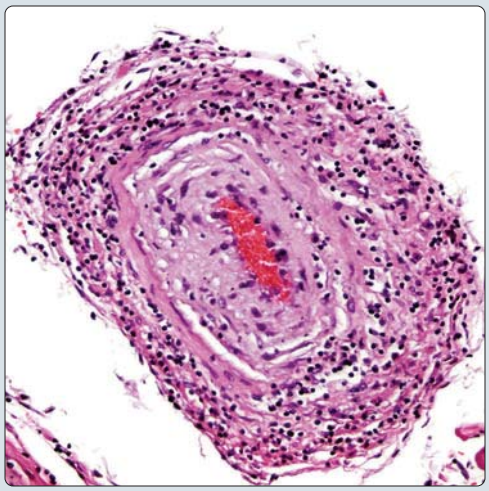
- Wide age range (mean: ~ 42 years)

DIAGNOSTIC CHECKLIST

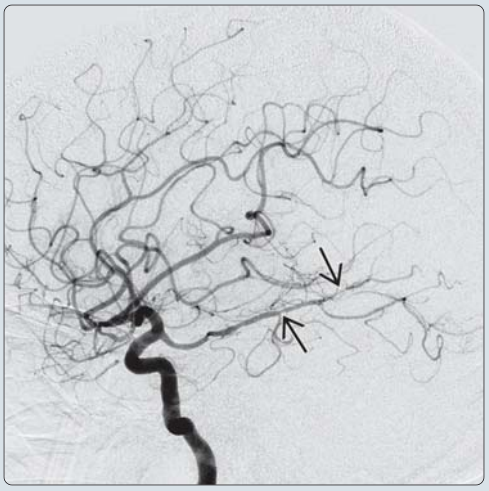
- Atherosclerosis is by far most common cause of vasculitis-like DSA pattern in older adults, not PACNS

(Left) *Coronal oblique graphic illustrates alternating segmental areas of narrowing and dilatation of the opercular and superficial MCA branches, as well as patchy multifocal ischemia within the underlying brain from primary arteritis of the CNS.* **(Right)** *Micropathology, low-power H and E section from the autopsy of a 71-year-old woman with multifocal T2 and FLAIR brain hyperintensities (not illustrated) shows intimal and adventitial necrosis and inflammatory changes, characteristic for CNS vasculitis.*





(Left) *Lateral DSA in a 34-year-old woman with multiple strokes shows markedly irregular posterior cerebral artery ⇨ with alternating areas of stenosis and dilatation.* **(Right)** *Thin-section T1 C+ FS in the same patient shows enhancement in the wall of the left PCA ⇨. Wall enhancement can occur in both vasculitis and atherosclerosis with chronic inflammation. Although this patient was a smoker and had cardiovascular risk factors, the young age and clinical features were most consistent with vasculitis.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Primary arteritis of CNS (PACNS)

Synonyms

- Vasculitis, vasculopathy

Definitions

- 2 cardinal features required for histopathologic diagnosis of vasculitis
  - Inflammation and necrosis of blood vessel wall
- PACNS: Arteritis confined to intracranial CNS without evidence for systemic vasculitis

IMAGING

General Features

- Best diagnostic clue
  - Circumferential, smooth, long-segment vessel wall enhancement
  - "Beaded" arteries (irregular stenoses, dilatations) on DSA
    - Nonspecific (intracranial atherosclerotic vascular disease (ASVD) > vasculitis)
  - Note: Imaging work-up can be normal; requires clinical/laboratory correlation
- Location
  - Pathologically leptomeningeal arteries and veins are affected, but involves intracranial vessels of any size
  - Brain is primary site, but spinal cord can also be involved
- Size
  - Degree of vessel narrowing may range from normal or minimally stenotic to completely occluded
- Morphology
  - Areas of smooth or slightly irregularly shaped stenoses alternating with dilated segments
  - Nonspecific (appearance similar to other vasculitides)

CT Findings

- NECT
  - Relatively insensitive; often normal
  - May see secondary signs, such as ischemia or infarction
    - Multifocal low-density areas especially in basal ganglia, subcortical white matter
  - May see hemorrhage (less typical)
- CECT
  - May see patchy areas of enhancement

MR Findings

- T1WI
  - Multifocal deep gray and subcortical hypointensities
- FLAIR
  - Multifocal deep gray and subcortical hyperintensities
- T2* GRE
  - May show petechial hemorrhage
- DWI
  - Restricted diffusion in acute stages
- T1WI C+
  - High-resolution MR can show vessel wall enhancement
  - May see patchy areas of parenchymal enhancement
    - Smooth, linear, circumferential
- MRA
  - Relatively insensitive, most often normal
  - May see some classic angiographic signs if larger vessels involved

Angiographic Findings

- DSA
  - Typical: Alternating stenosis with dilatation primarily involving 2nd-, 3rd-order branches
  - Less common: Long-segment stenoses, pseudoaneurysms, occlusions
  - Consider: Imaging renal arteries to evaluate for systemic vasculitis

Imaging Recommendations

- Best imaging tool
  - Vessel wall imaging with thin-section, high-resolution (3T) T1 C+
  - DSA once considered gold standard for imaging
    - Nonspecific (ASVD much more common than vasculitis)
- Protocol advice
  - 3T thin-section pre-, post-contrast T1WI to visualize vessel wall
  - DSA if lab studies positive, MR/MRA negative, and high clinical suspicion
  - CTA/MRA is useful for screening; spatial resolution insufficient for subtle disease

DIFFERENTIAL DIAGNOSIS

Intracranial Atherosclerotic Vascular Disease (ASVD)

- Advanced patient age
- Typical distribution (carotid siphon, proximal intracranial vessels)

Systemic CNS Vasculitis

- Secondary CNS involvement of systemic vasculitis, polyarteritis, SLE are most common
- DSA appearance indistinguishable from PACNS

Reversible Cerebral Vasoconstriction Syndrome

- Reversible; posterior circulation, watershed
- Can appear identical on DSA

Vasospasm

- Temporal relationship to subarachnoid hemorrhage
- Proximal trunks (COW) > peripheral branches

Intravascular Lymphoma

- Lacks vessel wall enhancement
- Hemorrhage more common

PATHOLOGY

General Features

- Etiology
  - Unknown
- Brain biopsy may be required to confirm diagnosis
  - Definite diagnosis made from mononuclear inflammation of vessel wall
  - 75-80% sensitive; negative biopsy does not necessarily exclude PACNS

https://CafePezeshki.IR

- Diagnosis can be established on clinical grounds, typical findings on DSA, and other investigatory grounds excluding other diseases
- Must be distinguished from other causes of CNS inflammation and noninflammatory vascular disease

Staging, Grading, & Classification

- PACNS: Highly heterogeneous group of vasculitides limited to CNS
  - Spectrum from granulomatous angiitis of CNS (GACNS) to benign angiopathy of central nervous system (BACNS) to reversible vasoconstrictive syndrome (RCVS)
  - BACNS, RCVS have more favorable outcome; all have indistinguishable angiographic appearance
- Clinical manifestations of CNS vasculitides may be identical
  - Acute onset, headache, normal to mildly abnormal CSF findings; female predominance in BACNS, RCVS
  - Focal weakness, seizures, hemorrhage, confusion, memory disorders, altered consciousness can be seen in each
  - Despite "benign" designation in BACNS and RCVS, some patients sustain significant neurological damage
  - Histories of heavy nicotine or caffeine use, OTC cold remedy use, and oral contraceptive or estrogen replacement
  - Precise relationship (if any) of these exposures remains unclear

Gross Pathologic & Surgical Features

- Characterized by ischemic lesions and small petechial hemorrhages
- Vessels of any size can be involved
- May see venulitis with parenchymal hemorrhages

Microscopic Features

- Mononuclear inflammation with necrosis of blood vessel walls is PACNS hallmark
- Variable degree of granulomatous and nongranulomatous angiitis of small vessels
- Typically involves media and adventitia of small leptomeningeal arteries and veins

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Stroke from vascular involvement (stenoses, occlusion, aneurysm)
  - Headache is also common
- Clinical profile
  - Clinical presentation is highly variable: Focal to diffuse manifestations and acute to chronic evolution
  - Subacute presentation over weeks or months is typical (mean = 5 months to diagnosis)
  - Headache and mental status change with focal deficits
  - No evidence of secondary vasculitis or other diseases mentioned in differential diagnosis should arouse suspicion

Demographics

- Age
  - Childhood to adulthood
  - Mean age ~ 42 years; range from age 3 to elderly
  - BACNS, RCVS patients tend to be young women
- Gender
  - Distribution of PACNS is nearly equal between sexes, with perhaps slight male predominance
- Epidemiology
  - Rare

Natural History & Prognosis

- Prognosis greatly improved with early recognition and therapy
- Delay in diagnosis may lead to additional morbidity
- PACNS: More likely to develop symptoms subacutely and remain undiagnosed for months
- BACNS: More likely to have relatively acute presentations and be diagnosed within weeks of onset
- Untreated PACNS: Risk of permanent cognitive dysfunction
- Often diagnosed posthumously; high index of suspicion is necessary to make correct diagnosis in timely basis

Treatment

- Few controlled studies on treatment of vasculitis, with considerable variation among centers on current therapeutic regimens
- Therapy typically comprises aggressive immunosuppressive approach
- High-dose steroid therapy with prolonged course and gradual taper controls disease in most cases
- Close monitoring of patients mandatory
- Without treatment, patients with PACNS tend to have progressively downhill courses often leading to death
- BACNS, RCVS patients may respond to less aggressive corticosteroid and Ca++ channel blocker therapy

DIAGNOSTIC CHECKLIST

Consider

- DSA when clinical suspicion of PACNS is strong, regardless of findings on MR

Image Interpretation Pearls

- Atherosclerosis is by far most common cause of vasculitis-like DSA pattern in older adults, not PACNS

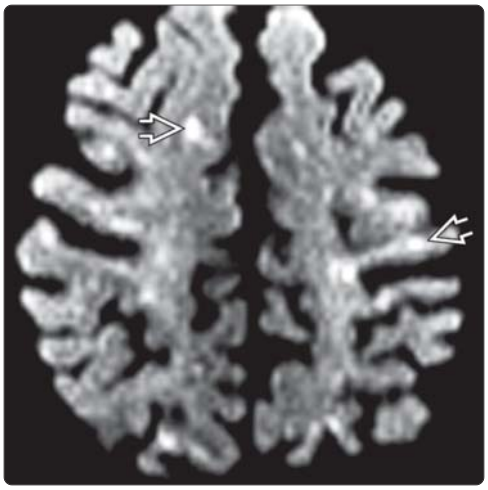
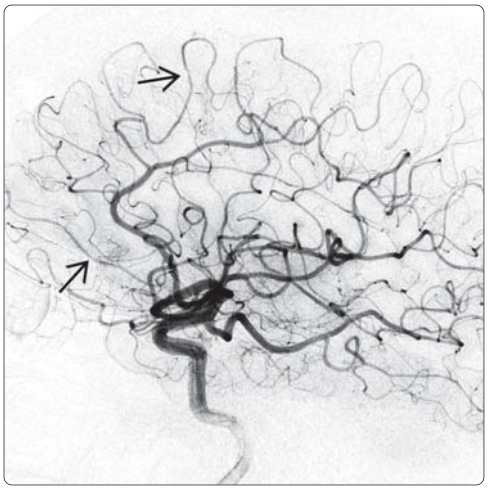
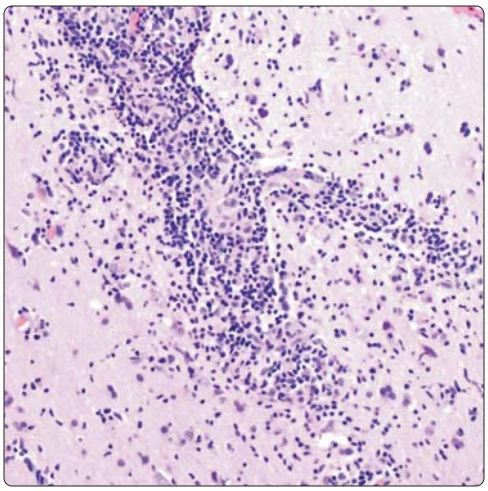
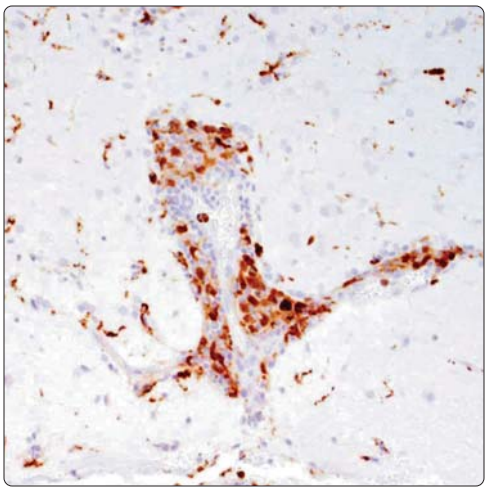
(Left) *Axial T1 C+ FS scan in a patient with progressive ataxia and slowly worsening diplopia for 6 years shows multifocal punctate and linear enhancing foci ⇨ in the medulla and cerebellar hemispheres.* **(Right)** *More cephalad T1 C+ FS scan in the same patient shows innumerable linear and dot-like areas of enhancement ⇨ in the subcortical and deep white matter of both hemispheres.*





(Left) *DWI in the same patient shows multiple small rounded and linear foci of restricted diffusion ⇨.* **(Right)** *Lateral DSA of the internal carotid angiogram subsequently obtained shows subtle areas of irregular narrowing ⇨ in distal cortical arteries suggestive of vasculitis.*





(Left) *Micrograph with H&E stain of the biopsy obtained in the same patient shows necrosis and inflammatory infiltrate thickening the wall of this penetrating cortical artery.* **(Right)** *Immunohistochemistry in the same patient is positive for CD68 T-cell lymphocytes. The final histopathologic diagnosis was PACNS.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Heterogeneous group of CNS disorders
  - Characterized by nonatheromatous inflammation and necrosis of blood vessel walls
  - Both arteries, veins may be affected

IMAGING

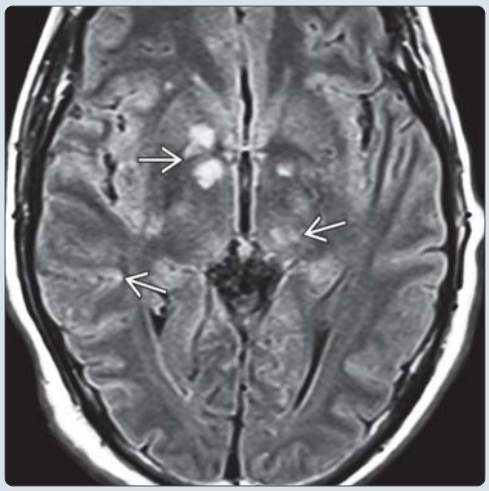
- CTA/MRA useful screening; spatial resolution usually insufficient for subtle disease
- MR
  - Basal ganglia, cortex, subcortical WM
    - Multifocal hypodensities/T2 hyperintensities
    - Look for secondary signs (ischemia/infarction)
  - High-resolution (3T, thin-section) T1C+ may demonstrate wall enhancement
    - Smooth, concentric
    - Long segment
    - Distal involvement (e.g., M2, M3, M4 branches > intracranial ICA or BA)
    - Multiple vessels usually affected
- DSA
  - Findings nonspecific (visualizes lumen, not vessel wall)
    - Multifocal areas of smooth or slightly irregular-shaped stenoses alternating with dilated segments
    - May occur in intracranial vessels of any size
    - Major differential diagnosis = intracranial atherosclerosis

TOP DIFFERENTIAL DIAGNOSES

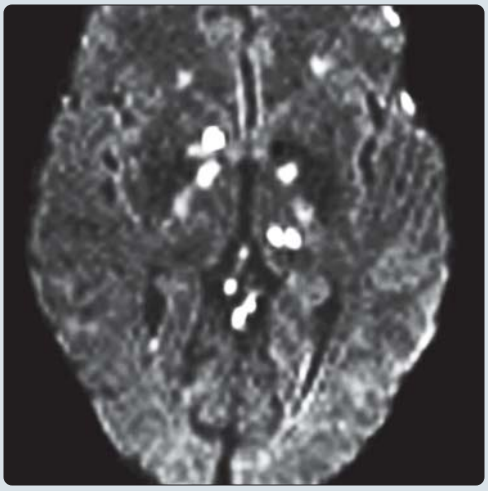
- Intracranial atherosclerotic vascular disease
- Arterial vasospasm
- Reversible cerebral vasoconstriction syndrome

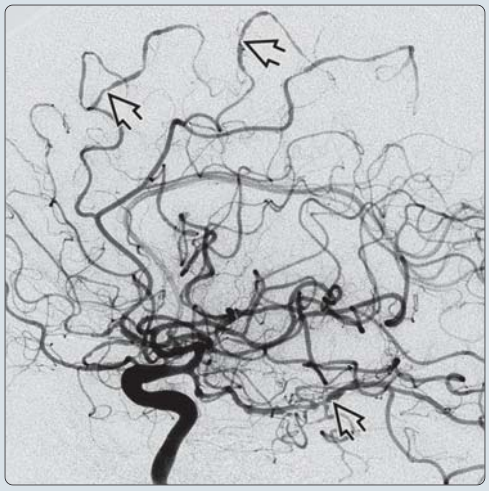
PATHOLOGY

- Vessel wall inflammation, necrosis common to all vasculitides



(Left) *Coronal oblique graphic shows vasculitis with medium vessel changes ⇨ and parenchymal changes seen as multifocal areas of edema, infarction, and scattered hemorrhages within the basal ganglia and at the gray-white junction.* **(Right)** *Axial FLAIR scan in a case of secondary CNS vasculitis shows multiple hyperintense foci in the basal ganglia, thalami, and cortex ⇨.*





(Left) *Axial DWI MR in the same case shows multiple small foci of restricted diffusion in the basal ganglia, thalami, and cortex.* **(Right)** *Lateral view of the internal carotid angiogram obtained in the same case shows multiple cortical vessels ⇨ with alternating areas of stenosis and dilatation ("beading"). The findings are consistent with multiple infarcts secondary to infectious (streptococcal) vasculitis.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Inflammatory vasculopathy (more general term indicating any vascular pathology with inflammation)
- Arteritis (specifies arterial inflammation)
- Angiitis (inflammation of either arteries or veins)

Definitions

- Heterogeneous group of CNS disorders characterized by nonatheromatous inflammation and necrosis of blood vessel walls
- Involves either arteries or veins

IMAGING

General Features

- Best diagnostic clue
  - Irregularities, stenoses, and vascular occlusions in pattern atypical for atherosclerotic disease
  - Imaging work-up can be normal; need clinical/laboratory correlation
- Location
  - Arteries and veins affected; occurs in intracranial vessels of any size
- Size
  - Degree of vessel narrowing may range from normal/minimally stenotic to occluded
- Morphology
  - Classic appearance: Multifocal areas of smooth or slightly irregular-shaped stenosis alternating with dilated segments
  - Variety of angiographic appearances depending on etiology, including vascular irregularities, stenoses, aneurysms, and occlusions

MR Findings

- T1WI
  - Can be normal early; ± multifocal cortical/subcortical hypointensities
- T2WI
  - Multifocal hyperintensities
- FLAIR
  - Subcortical, basal ganglia hyperintensities
- T2* GRE
  - May show hemorrhage
- DWI
  - Can see restricted diffusion in acute stage
- T1WI C+
  - May see patchy areas of parenchymal enhancement
  - High-resolution (3T, thin-section) T1C+ may demonstrate wall enhancement
    - Smooth, concentric
    - Long segment
    - Distal involvement (e.g., M2, M3, M4 branches > intracranial ICA or BA)
    - Multiple vessels usually affected
- MRA
  - May see some classic angiographic signs if larger vessels involved/vascular occlusion; may be normal

Angiographic Findings

- Conventional
  - Alternating stenosis and dilatation primarily involving 2nd, 3rd order branches
  - Less common: Long segment stenoses, pseudoaneurysms

Imaging Recommendations

- Best imaging tool
  - High-resolution contrast-enhanced MR with vessel wall imaging
  - DSA if MR/MRA negative
- Protocol advice
  - DSA if lab studies positive, MR/MRA negative
  - CTA/MRA useful screening; spatial resolution may be insufficient for subtle disease

DIFFERENTIAL DIAGNOSIS

Intracranial Atherosclerotic Vascular Disease

- Advanced patient age
- Typical distribution (carotid siphon, proximal intracranial vessels); extracranial manifestations of disease

Arterial Vasospasm

- Temporal relationship to subarachnoid hemorrhage (SAH)
- Involves proximal vasculature

Reversible Cerebral Vasoconstriction Syndrome

- Thunderclap headache ± subarachnoid hemorrhage
- Can mimic vasculitis on angiography
- Resolves with verapamil infusion

PATHOLOGY

General Features

- Etiology
  - Pattern of vessel wall inflammation, necrosis common to all vasculitides
  - Can be primary or secondary, caused by broad spectrum of infectious/inflammatory agents, drugs, etc.
  - Bacterial meningitis
    - Infarction due to vascular involvement seen in 25%
    - *Haemophilus influenzae* most common organism; common in children
  - Tuberculous meningitis
    - Vessels at skull base most commonly involved (i.e., supraclinoid ICA and M1-producing occlusions and stenoses)
  - Mycotic arteritis (*Aspergillus*, cocci, etc.)
    - Actinomyces may invade vessel walls leading to hemorrhage
    - Narrowing of basal cerebral or cortical vessels on angiography
  - Viral arteritis
    - Herpes simplex most common in North America
    - HIV-associated vasculitis increasing, especially in children
  - Syphilis arteritis
    - 2 forms: Syphilitic meningitis and gummatous vasculitis
    - Diffuse vasculitis involves cortical arteries and veins

https://CafePezeshki.IR

  - Gummatous vasculitis usually affects proximal MCA branches
- Polyarteritis nodosa
  - Most common systemic vasculitis to involve CNS (though late)
  - Microaneurysms due to necrosis of internal elastic lamina in 75%
- Cell-mediated arteritides
  - Giant cell arteritis (granulomatous infiltration of arterial walls)
  - Takayasu (primarily involves aorta, great vessels, branches)
  - Temporal arteritis (systemic; involves temporal, other extracranial arteries)
- ANCA associated (formerly Wegener)
  - May cause intracerebral and meningeal granulomas or vasculitis
  - CNS involved in 15-30% due to direct invasion from nose/sinuses
  - Chronic systemic arteritis involving lungs, kidneys, and sinuses
- Sarcoid (CNS involvement in 3-5% of cases)
  - Can extend along perivascular spaces, involve penetrating arteries
  - Meningitis, vasculitis involving vessels at base of brain
- Granulomatous angiitis (PACNS)
  - Primary angiitis isolated to CNS (idiopathic)
  - Manifest as multiple intracranial stenoses
- Collagen vascular disease (SLE, rheumatoid, scleroderma)
  - SLE: Most likely to involve CNS
  - Vasculitis relatively uncommon (variable findings; range from small vessel irregularities/stenoses/occlusions to fusiform aneurysms)
  - CVA seen in 50% due to cardiac disease or coagulopathy
- Drug abuse vasculitis
  - Drug can injure vessels directly or secondarily (usually hypersensitivity to contaminants)
  - Associated with both legitimate and illegal "street" drugs, including amphetamines, cocaine, heroin, and phenylpropanolamine and ergots
- Radiation
  - Acute arteritis produces transient white matter edema
  - Chronic changes more severe with vessel obliteration and brain necrosis, leukomalacia, mineralizing microangiopathy, and atrophy
  - Effects compounded with concomitant chemotherapy
- Moyamoya disease
  - Sometimes referred to as "idiopathic progressive arteriopathy of childhood"
  - Moyamoya is angiographic pattern, not specific disease; may be acquired or inherited
  - Any slowly progressive occlusion of supraclinoid ICAs may develop moyamoya pattern
  - Pattern has been reported with NF, atherosclerosis, radiation therapy
  - Prognosis depends upon rapidity and extent of vascular occlusions, as well as development of effective collaterals

Gross Pathologic & Surgical Features

- Characterized by ischemic lesions and small petechial hemorrhages
- Vessels of any size can be involved
- May see venulitis with parenchymal hemorrhages

Microscopic Features

- Inflammation and necrosis of blood vessel walls

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Stroke related to manifestations of vascular involvement (stenosis, occlusion, aneurysm)
  - Patients presenting with symptoms suggestive of vasculitis require brain neuroimaging, lumbar puncture, and angiography, but only biopsy allows definite diagnosis

Demographics

- Epidemiology
  - Atherosclerosis is by far most common cause of vasculitis-like angiographic pattern in adults
  - CNS vasculitis occurs in variety of clinical settings, some of which exhibit distinct age preference, others tissue tropism

Natural History & Prognosis

- Varies depending upon etiology; typically progressive if untreated

Treatment

- Most patients with CNS vasculitis are treated aggressively with combination of steroids, immunosuppressive medications

DIAGNOSTIC CHECKLIST

Consider

- Diagnosis is frequently made on basis of clinical presentation, brain MR, and cerebral angiography without pathologic confirmation

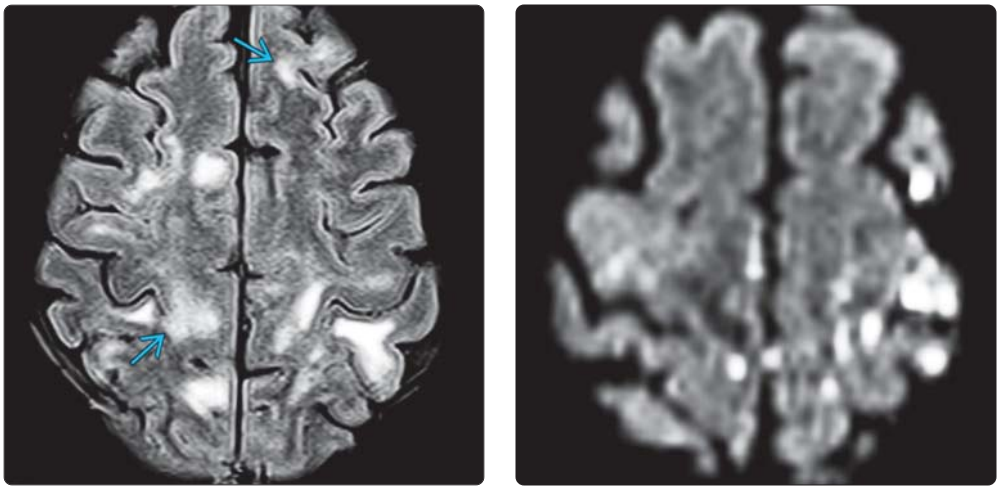
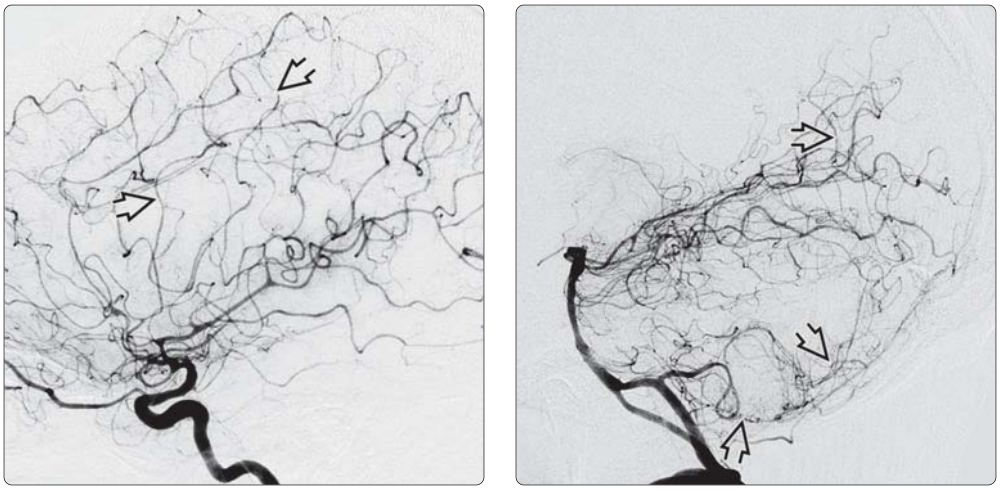
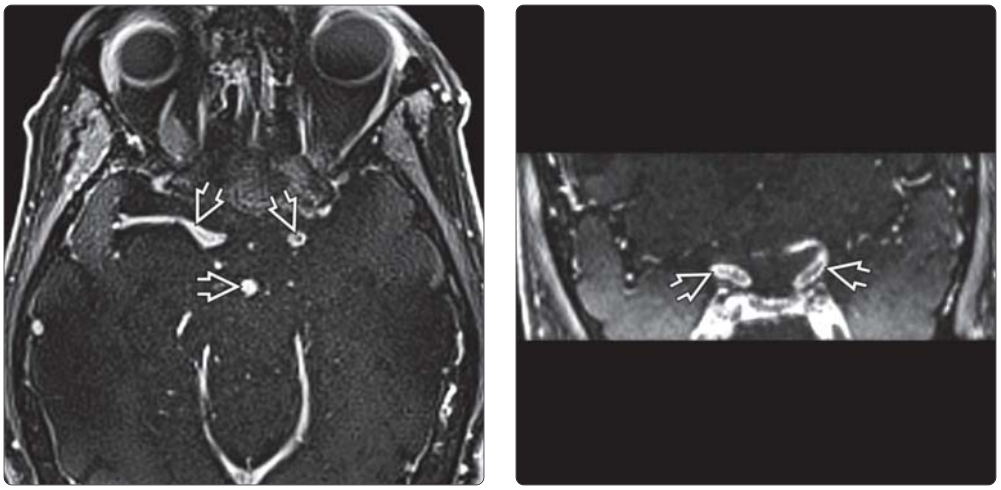
https://CafePezeshki.IR



(Left) *Axial FLAIR scan in a patient with polyarteritis nodosa, confusion, and then obtundation shows multifocal cortical and subcortical hyperintensities ⇨ in both hemispheres.* **(Right)** *DWI in the same case shows multiple small foci of restricted diffusion in the cortex and subcortical white matter.*



(Left) *Lateral DSA in the same case shows multifocal areas of vessel irregularity and constriction ⇨ in the distal left middle and anterior cerebral arteries giving the cortical vessels a "beaded" appearance.* **(Right)** *Lateral DSA of the left vertebral artery angiogram shows similar "beaded" appearance with multiple small areas of irregular stenosis ⇨. Findings are consistent with intracranial arteritis.*



(Left) *Axial T1 C+ FS MR in a patient with ANCA-positive vasculitis shows marked circumferential and linear enhancement of the left internal carotid, M1 middle cerebral, and distal basilar arteries ⇨.* **(Right)** *Coronal T1 C+ FS scan in the same patient shows striking enhancement of the supraclinoid internal carotid arteries ⇨. Vessel wall enhancement can occur in ASVD but is typically not this smooth, concentric, and linear.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Reversible cerebral vasoconstriction syndrome (RCVS), a.k.a. Call-Fleming syndrome
- Group of disorders characterized by
  - Reversible, multifocal cerebral artery vasoconstrictions
  - Severe headaches ± focal neurological deficits

IMAGING

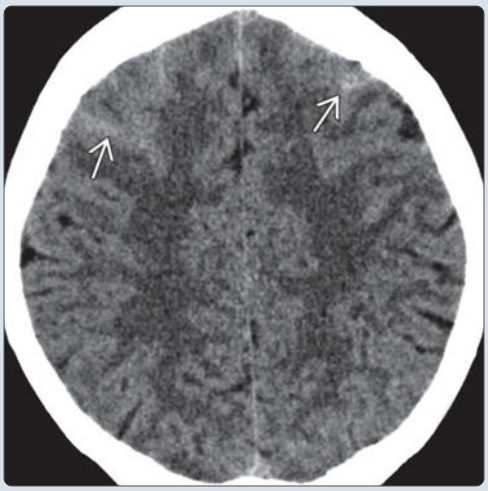
- Acute/recurrent headaches with vasculitic pattern (DSA)
- DSA = crucial for diagnosis (100% sensitive)
  - Involves large, medium-sized arteries
  - Diffuse, multifocal, segmental narrowing
  - Sometimes "string of beads" or "sausage strings"
- NECT often negative
  - Small cortical subarachnoid hemorrhage (SAHs) (20%) ± parenchymal hemorrhage
- CTA/MRA: May be normal if subtle changes (10%)
  - Diffuse segmental arterial constriction in 90%
- TCD: ↑ arterial velocities in MCA, ICA, ACA

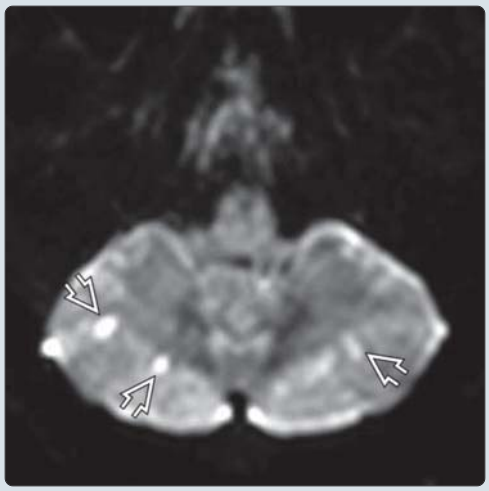
PATHOLOGY

- Thought to represent transient disturbance in control of cerebral vascular tone → vasoconstriction → ischemia, stroke, death
- Spontaneous (1/3 of cases) or precipitated by
  - Postpartum state
  - Exposure to vasoactive substances
- Can be associated with posterior reversible encephalopathy syndrome (PRES)

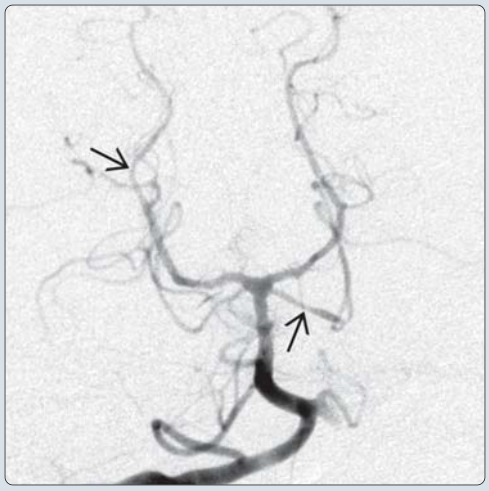
CLINICAL ISSUES

- Symptoms: Severe, acute "thunderclap" headache
  - Often recurrent (95%)
  - Ischemia/stroke (visual disturbance, aphasia, hemiparesis)
- Treatment
  - Discontinuation of vasoactive medications
  - Vasodilators (e.g., Ca++ antagonists)





(Left) *Axial NECT in a female patient with acute onset of severe headache shows limited cortical subarachnoid hemorrhage (SAH) in the sulci of the frontal lobes ⇨. DSA was performed to exclude a vascular lesion and showed multifocal arterial narrowings (not shown) related to RCVS.* **(Right)** *Axial DWI trace image shows multiple foci of hyperintensity ⇨ related to acute ischemia in this patient with RCVS who presented with an acute onset of a "thunderclap" headache. Ischemia is a common complication of RCVS.*



(Left) *Anteroposterior right vertebral artery DSA shows diffuse luminal irregularity and focal stenoses involving the basilar artery and posterior cerebral and superior cerebellar arteries ⇨. Similar changes were seen in the anterior circulation (not shown). The patient was treated with IA verapamil over the next 10 days.* **(Right)** *DSA repeated 2 weeks later shows significant interval resolution of the posterior circulation vasospasm. There are a few foci ⇨ of mild residual stenoses still evident.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Reversible cerebral vasoconstriction syndrome (RCVS)

Definitions

- Group of disorders characterized by
  - Reversible, multifocal cerebral artery vasoconstriction
  - Severe headaches (HA) ± focal neurological deficits

IMAGING

General Features

- Best diagnostic clue
  - Acute onset, usually recurrent HA with vasculitic pattern on DSA

CT Findings

- NECT
  - May see small cortical subarachnoid hemorrhage (SAH) in 20% of parenchymal hemorrhages
  - Cortical ± subcortical hypodensity secondary to ischemia/stroke
- CTA
  - May be normal or can see undulations of large/medium-sized arteries

MR Findings

- FLAIR
  - May see uni- or bilateral cortical SAH
  - Focal regions of ↑ signal secondary to stroke
- DWI
  - Most sensitive for regions of ischemia/stroke
- MRA
  - May be normal if subtle changes (10%); require DSA for diagnosis
  - Diffuse segmental arterial constriction in 90%

Ultrasonographic Findings

- Transcranial Doppler (TCD): ↑ arterial velocities consistent with vasospasm + ↓ luminal diameter of MCA, ICA, ACA in 70%

Angiographic Findings

- Crucial for diagnosis (100% sensitive)
- Diffuse, multifocal, segmental narrowing of large/medium-sized arteries
- Occasional dilated segments may appear like string of beads or sausage strings

DIFFERENTIAL DIAGNOSIS

Cerebral Vasculitis

- Similar angiographic appearance; clinical onset more insidious, CSF abnormalities
- e.g., primary angiitis of central nervous system (PACNS), systemic lupus, infection, sarcoidosis

SAH

- Aneurysm, dural fistula, trauma, arteriovenous malformation

PATHOLOGY

General Features

- Etiology
  - Thought to represent transient disturbance in control of cerebral vascular tone → vasoconstriction → ischemia, stroke, death
- Associated abnormalities
  - Occurs spontaneously (1/3 of cases) or may be precipitated by
    - Postpartum state
    - Exposure to vasoactive substances
      - Cannabis, cocaine, ecstasy, amphetamine derivatives, LSD
      - Selective serotonin reuptake inhibitors (SSRIs)
      - Nasal decongestants, pseudoephedrine
      - Ergotamine tartrate, bromocriptine, sumatriptan
    - Pheochromocytoma, bronchial carcinoid tumor

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Severe, acute onset ("thunderclap") headache
    - Often recurrent (95%)
    - Mimics SAH secondary to ruptured aneurysm
- Other signs/symptoms
  - Ischemia/stroke may result in visual disturbance, aphasia, hemiparesis
  - Seizures

Natural History & Prognosis

- Stroke occurs in 7-54%
- M:F = 1:2
- Up to 10% permanent disability
- Can be associated with posterior reversible encephalopathy syndrome (PRES)
- Vascular abnormalities resolve within several months

Treatment

- Discontinuation of vasoactive medications
- Vasodilators (e.g., Ca++ antagonists) PO/IV/IA infusion

DIAGNOSTIC CHECKLIST

Consider

- RCVS in patient with history of thunderclap headache but no SAH or limited cortical SAH

Image Interpretation Pearls

- Interval DSA may show improvement with vasodilator Rx

KEY FACTS

TERMINOLOGY

- Reversible stenosis of intracranial arteries
- Caused by exposure to blood breakdown products
  - Contraction of vascular smooth muscle
  - Histological changes in vessel wall

IMAGING

- General features (CTA/MRA/DSA)
  - Typically occurs 4-14 days after subarachnoid hemorrhage (SAH)
  - Smooth, relatively long segmental stenoses
  - Seen as arterial luminal irregularity/undulations
  - Multiple arteries, usually > 1 vascular territory
- CT perfusion
  - ↑ time to peak (TTP), ↑ mean transit time (MTT)
  - ↓ cerebral blood flow (CBF) in areas of hypoperfusion
- Transcranial Doppler (TCD)
  - ↑ mean flow velocity
  - Due to ↓ arterial cross-sectional area

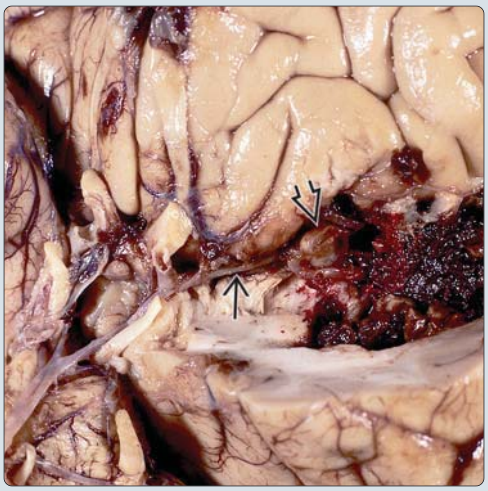
TOP DIFFERENTIAL DIAGNOSES

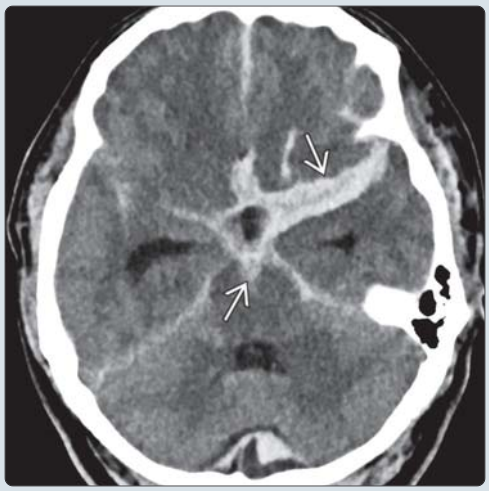
- Non-SAH causes of vasospasm
  - Meningitis
  - Acute hypertensive encephalopathy (PRES)
  - Reversible cerebral vasoconstriction syndrome (RCVS)
  - Migraine headache
- Vasculitis
- Atherosclerosis

CLINICAL ISSUES

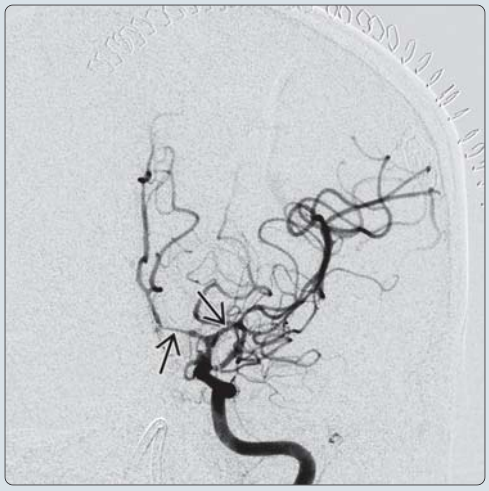
- Delayed ischemic neurological deficit (DIND)
  - ~ 1 week after SAH is typical
- Management
  - "Triple H" therapy
  - Endovascular (chemical or balloon angioplasty)

(Left) *Autopsied case of ruptured MCA aneurysm* ⇨ *with subarachnoid hemorrhage (SAH) in a patient who survived several days shows severe vasospasm of the parent MCA* ⇨. **(Right)** *Axial NECT in a 43-year-old male in the ER with "worst headache of life" shows diffuse subarachnoid hemorrhage* ⇨ *in the basal cisterns, especially in the left sylvian fissure.*





(Left) *CT angiogram in the same patient shows a lobulated aneurysm* ⇨ *at the left distal ICA bifurcation.* **(Right)** *Four days after emergency clipping of the aneurysm, the patient became drowsy and developed right-sided weakness. AP DSA of the left internal carotid artery shows mass effect, vasospasm* ⇨, *seen here as narrowing of the proximal ACA and MCA. The patient responded well to intraarterial infusion of verapamil.*



https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Subarachnoid hemorrhage (SAH) vasospasm

Definitions

- Exposure to blood breakdown products → reversible stenosis of intracranial arteries
  - Contraction of vascular smooth muscle
  - Histological changes in vessel wall

IMAGING

General Features

- Best diagnostic clue
  - Segmental stenoses (CTA/MRA/DSA)
    - Typically 4-14 days after SAH
- Location
  - Affects any intradural (subarachnoid) artery
  - Worst vasospasm typically adjacent to site of ruptured aneurysm (highest concentration of SAH)

Imaging Recommendations

- Best imaging tool
  - Gold standard is DSA (100% sensitive but nonspecific)
    - May follow with intraarterial (IA) therapy
  - TCD useful as bedside monitoring/screening tool
- Protocol advice
  - Multi-territorial vascular involvement is typical
  - Visualize both carotids, dominant vertebral artery

CT Findings

- NECT
  - May see residual SAH
  - Otherwise normal (unless ischemia/stroke)
  - Hypodensity in involved vascular territory may herald ischemia/infarction
  - Differentiate from retraction edema
    - Adjacent to surgical clip
    - Not confined to vascular territory
- CTA
  - Screening tool for involvement of large vessels
    - Circle of Willis, M1 segment, basilar artery
  - Attenuation/stenosis of arteries
    - Typically multi-territorial but asymmetric
  - Insensitive for smaller vessels (e.g., M2, distal segments)
- CT perfusion (pCT)
  - Hypoperfusion
    - ↑ time to peak (TTP), ↑ mean transit time (MTT)
    - ↓ cerebral blood flow (CBF)
    - Preservation of cerebral blood volume (CBV) may indicate adequacy of collateral flow
  - May miss distal vasospasm if pCT limited to 2 slices
    - Whole brain pCT recommended

MR Findings

- DWI
  - Most sensitive for vasospasm sequelae
    - If ischemia proceeds to infarction
- MRA
  - Not usually utilized for screening
  - CT more easily performed in patients in ICU S/P SAH
  - Vessel stenosis → signal void on TOF imaging
    - Depends on vasospasm severity

Ultrasonographic Findings

- Transcranial Doppler (TCD)
  - Poiseuille law: ↑ mean flow velocity occurs due to ↓ arterial cross-sectional area from vasospasm/stenosis
  - Low frequency transducer used to evaluate larger arteries at base of brain
  - Transtemporal window absent in 10% patients
  - > 80% accuracy for vasospasm detection if
    - Mean velocity in MCA > 120 cm/s, basilar artery > 70 cm/s
    - Lindegaard ratio (mean MCA velocity to extracranial ICA velocity) > 3
  - Sensitivity ~ 60% (operator dependent)
  - Specificity > 95% (in patients with known SAH)
  - Upward trends in mean velocities may be more indicative of vasospasm than absolute values

Angiographic Findings

- Arterial luminal irregularity/undulations
- Smooth, relatively long-segment stenoses
  - Multiple arteries, > 1 vascular territory typical

DIFFERENTIAL DIAGNOSIS

Meningitis

- Sulcal/cisternal enhancement

Acute Hypertensive Encephalopathy (PRES)

- Posterior > anterior circulation

Reversible Cerebral Vasoconstriction Syndrome (RCVS), Migraine Headaches

- Transient, may look identical

Vasculitis

- Can look identical to vasospasm, RCVS; typically shorter segmental stenoses/"beading" in vasculitis
- Absence of SAH on NECT is typical (SAH secondary to vasculitis is rare)
  - Subacute SAH may be iso-/hypodense on NECT; CSF analysis may help to detect blood breakdown products
- Inflammatory markers in serum, CSF often elevated

Atherosclerosis (ASVD)

- Usually older patients
- Short > long-segment stenoses
- Cavernous/extracranial ICA, vertebral artery often affected

PATHOLOGY

General Features

- Etiology
  - SAH vasospasm most commonly seen after aneurysm rupture
    - Other causes of SAH (e.g., trauma, AVM rupture) may also cause vasospasm
    - Diffuse nonaneurysmal SAH has potential for vasospasm similar to aSAH but < pnSAH
  - Exact pathophysiology is unknown

https://CafePezeshki.IR

- Causation is likely multifactorial
- Coating of vessel walls with blood breakdown products (e.g., oxyHgb) → release of free radicals from vessel wall
- Release of factors, including serotonin, angiotensin, prostaglandins, thromboxane, protein kinase C, phospholipase C and A2
- Possible role of ↓ nitric oxide activity from endothelium, ↑ endothelin-1 activity

Staging, Grading, & Classification

- Fisher CT score corresponds to risk of vasospasm development
  - 1: No SAH
  - 2: Small SAH, < 1 mm vertical layers
  - 3: Extensive SAH, > 1 mm vertical layers
  - 4: Intraventricular hemorrhage (IVH)

Microscopic Features

- Prolonged exposure of vessel wall to blood components → thickening of tunica media, intimal edema, subintimal cellular proliferation with muscle cells and fibroblasts

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Majority of patients with vasospasm are asymptomatic
  - Vasospasm is significant source of morbidity and mortality in patients with SAH
  - Delayed ischemic neurological deficit (DIND) ~ 1 week after SAH is typical
  - Focal neurological deficit(s): Motor, language, vision
- Other signs/symptoms
  - Altered mental status, ↓ level of consciousness

Demographics

- Age
  - Any age; more common in younger patients
- Epidemiology
  - 30,000 people per year have SAH in USA
  - 70% of patients after aneurysmal SAH develop some degree of vasospasm detectable by DSA; only 30% symptomatic

Natural History & Prognosis

- ~ time course of vasospasm following SAH
  - D3-4: Vasospasm begins
  - D7-10: Vasospasm peaks
  - D14-21: Vasospasm subsides
- Hyperacute vasospasm occurs in 10% of patients (onset < 48 hours from SAH)
- Aggressive treatment/prophylaxis in SAH patients can prevent stroke, death from ischemic sequela

Treatment

- Medical management
  - "Triple H" therapy = hypertension, hemodilution, hypervolemia
  - Oral or IV Ca++ antagonists (e.g., nimodipine)
  - Magnesium
- Endovascular
  - Chemical angioplasty: IA infusion of Ca++ antagonist has superseded papaverine
    - Less technically demanding than balloon angioplasty; can treat smaller distal vessels
    - Duration of effect may be up to 24 hours; additional IA treatments may be needed
    - Relatively low-risk: Side effect = hypotension, which could exacerbate hypoperfusion
  - Balloon angioplasty
    - Progressive dilatation of larger basal arteries: Intradural ICA and vertebral arteries, basilar artery, MCA (M1 ± M2 segments), ACA (A1 segment), PCA (P1 segment)
    - 1% risk of fatal vessel rupture, thromboembolic stroke, vessel dissection
  - Intracisternal thrombolytic therapy
    - Several clinical trials have shown moderate success; not widely accepted Rx
    - Recombinant tPA infused via ventriculostomy to lyse blood in subarachnoid spaces → ↓ breakdown to oxyHgb → prevent vasospasm

DIAGNOSTIC CHECKLIST

Consider

- Vasospasm as etiology of clinical deterioration, ischemic changes on NECT 4-14 days after aneurysmal SAH

Image Interpretation Pearls

- TCD is insensitive to changes in vessels beyond intradural ICA, M1, A1, and basilar arteries
  - Should proceed to DSA if involvement of more distal vessels suspected (e.g., pericallosal aneurysm rupture, nonaneurysmal SAH)

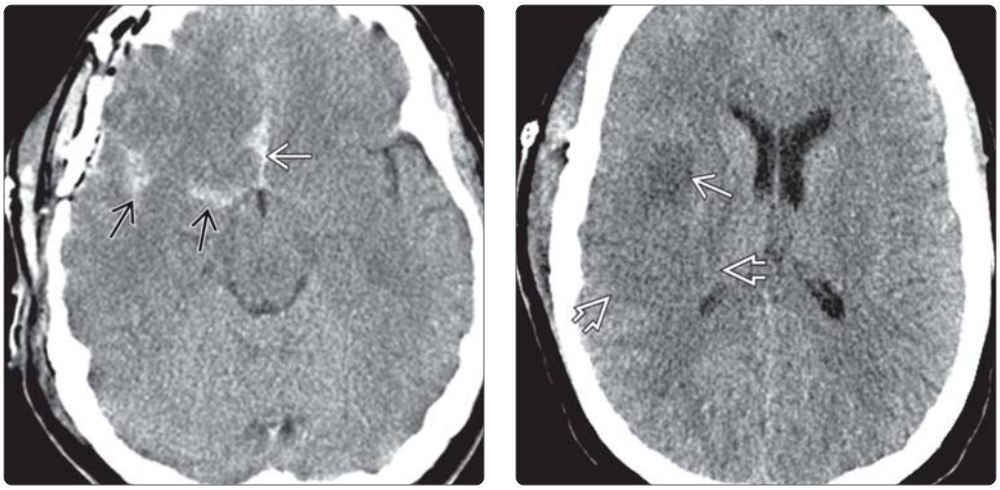
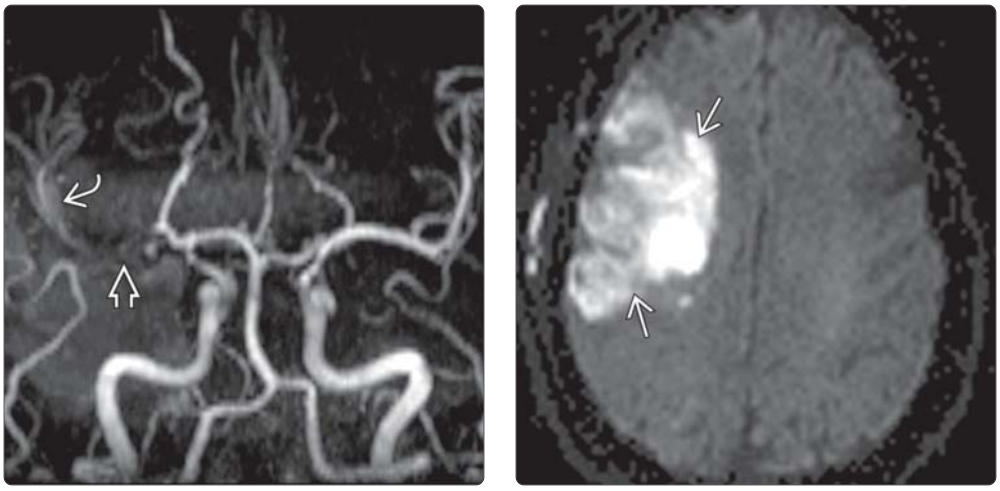
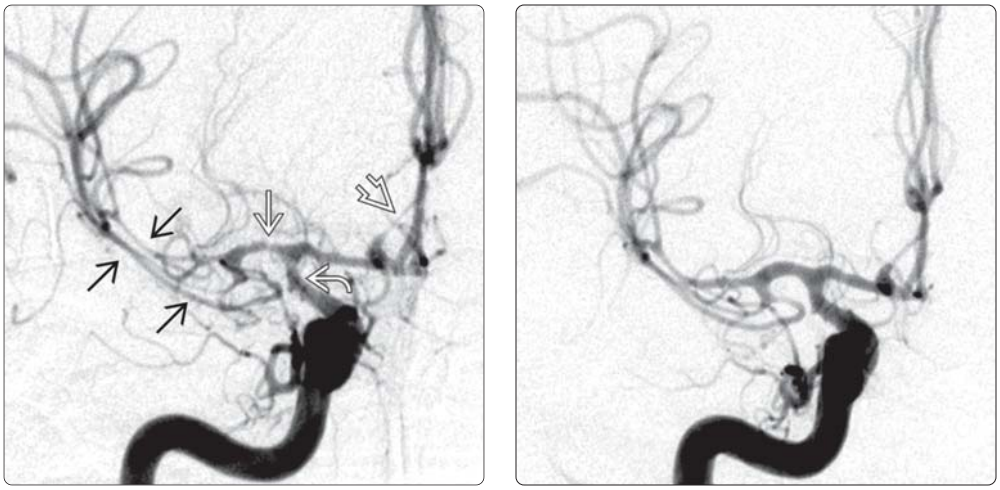
https://CafePezeshki.IR



(Left) *Axial NECT in a patient S/P resection of a sphenoidal ridge meningioma complicated by significant intraoperative hemorrhage shows SAH in the right sylvian fissure ⇨ and anterior interhemispheric fissure ➡. (Right) Axial NECT obtained 10 days later when the patient developed hemiparesis shows a focal area of low attenuation in the right frontal lobe ➡, consistent with infarction. There is blurring of both the superficial and deep gray-white interface ➡ adjacent to the infarct.*



(Left) *Anteroposterior 3D TOF MRA MIP image in the same patient shows no signal from flow-related enhancement along the right M1 segment ➡. The M2 vessels ➡ are attenuated compared with the left side, suggestive of reduced flow.* **(Right)** *Axial DTI MR shows a large area of ischemia/infarction in the right frontal lobe ➡. The constellation of imaging findings along with the delayed clinical deterioration 10 days after documented SAH made vasospasm the most likely etiology.*



(Left) *AP right ICA DSA confirms the presence of severe vasospasm involving the right M1 ➡ and M2 ⇨ segments, as well as the right A2 segment ➡ and carotid terminus ➡.* **(Right)** *DSA after infusion of 25 mg verapamil into the right ICA shows significant increase in caliber of all vasospastic segments. The patient underwent additional IA verapamil treatments in the ensuing days. Recurrence of vasospasm after chemical angioplasty is to be expected whereas balloon angioplasty is more durable.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Systemic lupus erythematosus (SLE), neuropsychiatric (NPSLE), CNS lupus
- Multisystem autoimmune disorder that affects respiratory, cardiovascular, GI, GU, musculoskeletal systems and CNS
  - CNS involved in up to 75%

IMAGING

- 4 general patterns
  - New infarcts (associated with ↑ anticardiolipin, ↑ lupus anticoagulant antibodies)
  - Focal areas of hyperintensity, primarily in gray matter (GM)
  - Multiple T2WI hyperintensities (microinfarctions)
  - Extensive, reversible white matter (WM) changes (cerebral edema)
- Multifocal WM microinfarcts, cerebral atrophy common
- Mild SLE: PET/SPECT more sensitive than MR
- Restricted diffusion (cytotoxic edema) in ischemia/infarct
- Increased diffusion (vasogenic edema) in vasculopathy
- Acute/active CNS lesions may enhance

TOP DIFFERENTIAL DIAGNOSES

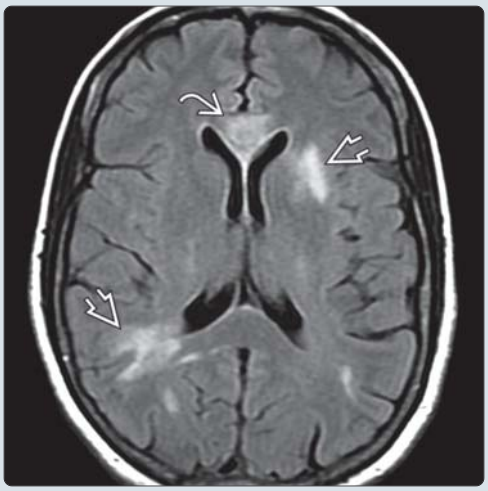
- Multiple sclerosis (MS), Susac syndrome
- Lyme encephalopathy
- Arteriolosclerosis (microvascular disease)
- Other vasculitides (e.g., PACNS)

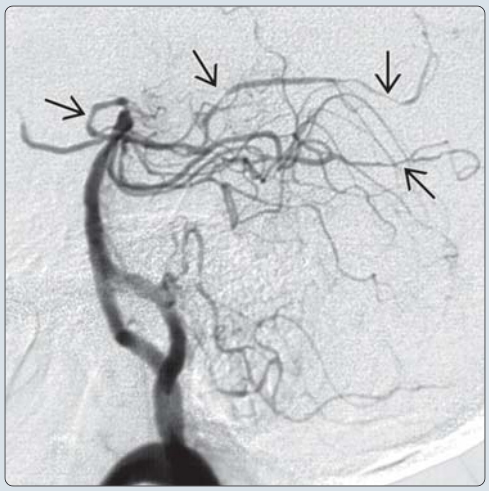
CLINICAL ISSUES

- Cerebral involvement may precede full-blown SLE picture or may develop during course of disease
- SLE associated with antiphospholipid syndrome (APS), posterior reversible encephalopathy syndrome (PRES), Lupus-related myelitis, Libman-Sacks endocarditis, emboli

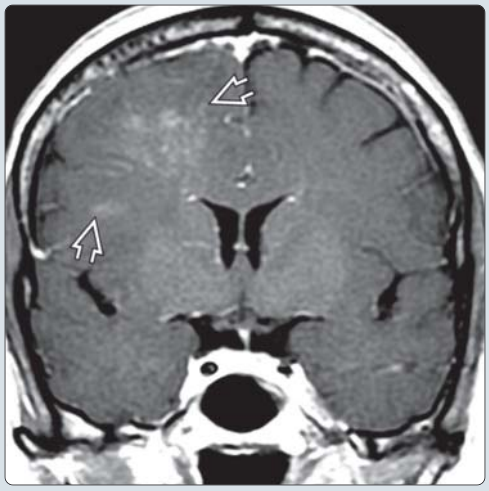
DIAGNOSTIC CHECKLIST

- Negative brain MR does not exclude cerebral lupus
- Role of imaging in SLE: Assess acute neurologic deficits





(Left) *Axial FLAIR MR image in an SLE patient with new neurologic symptoms. Note the multiple foci of FLAIR hyperintensity in the white matter ⇨ and the corpus callosum ⇨. This patient also had antiphospholipid syndrome, which is common in SLE patients.* **(Right)** *Lateral vertebrobasilar DSA shows multifocal stenoses ⇨ typical of a nonspecific vasculitis. This is uncommonly seen with lupus, which is more of a small-vessel vasculitis than other inflammatory vasculitides. DSA is often normal in SLE patients.*



(Left) *Axial FLAIR MR in a 52-year-old female with neuropsychiatric symptoms shows a large hyperintense frontal lobe lesion ⇨.* **(Right)** *Coronal T1 C+ MR image in the same patient shows linear enhancement throughout the frontal lobe ⇨. Biopsy disclosed CNS lupus vasculitis. While imaging of SLE is nonspecific, there are often multiple white matter hyperintensities as well as multifocal infarcts. Migratory edematous regions are also often seen.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Systemic lupus erythematosus (SLE), "lupus"
- Neuropsychiatric SLE (NPSLE), CNS SLE

Definitions

- Multisystem autoimmune disorder
  - CNS involved in up to 75% (CNS lupus or NPSLE)

IMAGING

General Features

- Best diagnostic clue
  - Most common finding = small multifocal white matter (WM) lesions
  - Focal infarcts of various sizes
  - Symptomatic "migratory" edematous areas
- Location
  - WM, gray matter (GM)
    - Frontal, parietal subcortical WM most common
- Morphology
  - Rounded or patchy lesions

CT Findings

- NECT
  - May be normal
  - Scattered patchy cortical/subcortical hypodensities common
  - Diffuse atrophy common
  - May see focal infarcts, cerebral calcification
  - May see cerebral edema (lupus cerebritis)
    - Can be life-threatening

MR Findings

- T2WI
  - 4 patterns of involvement
    - Focal infarcts (↑ anticardiolipin, ↑ lupus anticoagulant antibodies)
    - Multiple T2WI hyperintensities (microinfarctions)
    - Focal areas of hyperintensity, primarily in GM
    - Diffuse steroid-responsive subcortical lesions (associated ↑ antineurofilament antibodies)
  - Acute lesions on T2WI suggesting active NPSLE
    - New infarct, discrete GM lesions, diffuse GM hyperintensities, cerebral edema
- FLAIR
  - Multifocal WM hyperintensities
- DWI
  - Restricted diffusion (cytotoxic edema) in ischemia/infarct
  - Increased diffusion (vasogenic edema) in vasculopathy
- T1WI C+
  - Acute/active CNS lesions may enhance
- MRV
  - May show dural venous sinus thrombosis
    - Especially in antiphospholipid syndrome
- MRS
  - ^{1}H-MRS in NPSLE patients
  - ↓ N-acetyl aspartate in lesions, as well as normal-appearing WM/GM
  - ↑ choline related to disease activity, stroke, inflammation, chronic WM disease
  - No ↑ in lactate → anaerobic metabolism is not fundamental characteristic of NPSLE

Angiographic Findings

- CTA/MRA/DSA rarely detects cerebral lupus vasculitis

Nuclear Medicine Findings

- PET
  - Parietooccipital hypometabolism = most conspicuous finding in MR-negative NPSLE
- Tc-99m ethyl cysteinate dimer brain SPECT
  - Sensitive tool for early detection of brain abnormalities in SLE (more sensitive than MR)
  - Relatively nonspecific regional cerebral cortical hypoperfusion
    - Most hypoperfused areas: Parietal, frontal, and temporal lobes (MCA territory)
  - Positive findings also seen in patients without neuropsychiatric signs/symptoms

Imaging Recommendations

- Protocol advice
  - MR with T2, FLAIR, DWI
  - Consider PET in NPSLE if standard MR normal

DIFFERENTIAL DIAGNOSIS

Arteriolosclerosis

- Caused by diabetes, HTN, hypercholesterolemia
- T2WI hyperintense lesions within deep GM (basal ganglia, thalamus), centrum semiovale
- Diffuse, confluent regions of periventricular hyperintense WM involvement (leukoaraiosis)

Multiple Sclerosis (MS)

- Hyperintense T2 WM lesions on T2WI
- Periventricular WM (callososeptal interface)
- SLE lesions not confined to periventricular WM, favor gray-white junction or involve cortex/deep nuclei

Antiphospholipid Antibody Syndrome (Non-SLE)

- Spontaneous fetal loss, thrombocytopenia
- Early stroke, recurrent arterial + venous thromboses
- Infarcts of various sizes and T2 hyperintense WM foci

Lyme Encephalopathy

- Hyperintense periventricular WM lesions on T2WI
- May enhance, resemble MS or ADEM

Susac Syndrome

- Microangiopathy of unknown etiology
- Triad of HA/encephalopathy, branch retinal artery occlusions, hearing loss
- Deep WM, corpus callosum multifocal hyperintense lesions on T2WI, FLAIR
  - Central CC > callososeptal interface
  - May enhance (acute)
  - Central callosal "holes" in subacute/chronic

https://CafePezeshki.IR

Other Vasculitides

- Primary angiitis of CNS, polyarteritis nodosa (PAN), Wegener granulomatosis, Behçet disease, syphilis, Sjögren syndrome

PATHOLOGY

General Features

- Etiology
  - Pathogenesis of NPSLE is likely multifactorial
  - Diffuse neuropsychiatric symptoms
    - Neuronal dysfunction mediated by antibodies: Anti-neuronal, anti-ribosomal P-protein, and anti-cytokines
  - Focal neurologic symptoms
    - Circulating immune complexes → vascular injury
    - Endothelial cell activation by cytokines and complement activation → occlusive vasculopathy
    - Antiphospholipid antibodies (APL-Ab) → macro- and microvascular thrombosis
  - Late stage SLE: Accelerated atherosclerosis
    - ↑ intravascular complement turnover and APL-Ab
- Genetics
  - Genetic predisposition to SLE
    - HLA-DR2, HLA-DR3, null complement alleles
    - Congenital deficiencies of complement (C4, C2)
- Associated abnormalities
  - Lupus-related myelitis (transverse myelitis)
  - Libman-Sacks endocarditis, emboli
  - APS
  - Posterior reversible encephalopathy syndrome (PRES)

Gross Pathologic & Surgical Features

- Cortical atrophy, infarcts, hemorrhage
- Vasculitis → CNS ischemia or hemorrhage (intraparenchymal/subarachnoid)
- Edema → reversible leukoencephalopathy
- WM degeneration, myelin vacuolation of spinal cord

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - CNS involvement in up to 75% of cases
    - Migraine, seizures, stroke, chorea
    - Transverse myelopathy, cranial neuropathies, aseptic meningitis
    - Psychosis, mood disorders, acute confusional state, cognitive dysfunction
  - Subclinical CNS disease in SLE: Transient event
- Clinical profile
  - Multisystem autoimmune disorder that affects respiratory, cardiovascular, GI, GU, musculoskeletal systems and CNS
  - Cerebral involvement may precede full-blown SLE picture or may develop during course of disease
    - Most frequently within first 3 years
  - Diffuse psychiatric or focal neurologic symptoms
  - Movement disorders (chorea, parkinsonism)
  - Significant overlap with antiphospholipid antibody syndrome (APS)
    - 25-40% of SLE patients have APS

Demographics

- Age
  - All age groups affected; peak incidence in young adulthood (20-45)
- Gender
  - Strong female predominance (as high as 5:1 during childbearing years)
- Ethnicity
  - High prevalence in African American women
- Epidemiology
  - Incidence of SLE (USA): 14.6-50.8 in 100,000 people
  - CNS lupus affects 30-40% of SLE patients

Natural History & Prognosis

- Neurologic complications worsen prognosis of SLE
  - Transient neurologic deficits, chronic brain injury
- SLE patients with APL-Ab have additional risk for neuropsychiatric events
- Mortality rate in NPSLE: 7-40%

Treatment

- Immunosuppressive agents (steroids, cyclophosphamide) for suspected vasculitis
- Lifelong anticoagulation for APL-Ab-mediated thromboembolic events
- Intrathecal methotrexate plus dexamethasone in severe cases
- Primary prevention of accelerated ASVD and narrowing of blood vessels: Prophylactic aspirin, lipid-lowering drugs

DIAGNOSTIC CHECKLIST

Consider

- Difficult to differentiate active from old NPSLE lesions
- Obtain MR with DWI within 24 hours of neurologic event onset

Image Interpretation Pearls

- Most important role of imaging in NPSLE: Assessment of acute focal (stroke-like) neurologic deficits
  - Lupus-related CNS vasculitis
  - Thromboembolic events due to vasculopathy or endocarditis (Libman-Sacks)
  - APL-Ab-mediated thrombosis
  - Microangiopathy (including thrombotic thrombocytopenic purpura)
  - Accelerated ASVD
- Negative brain MR does not exclude cerebral lupus

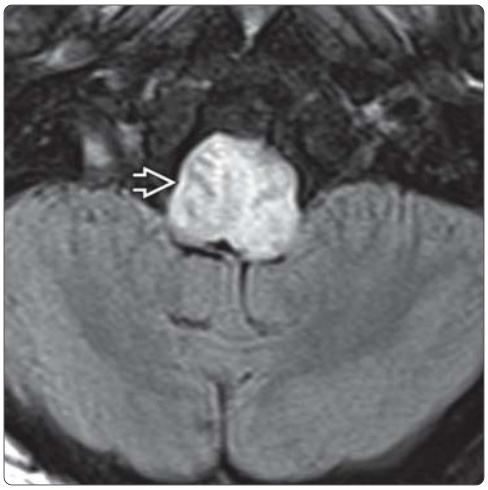
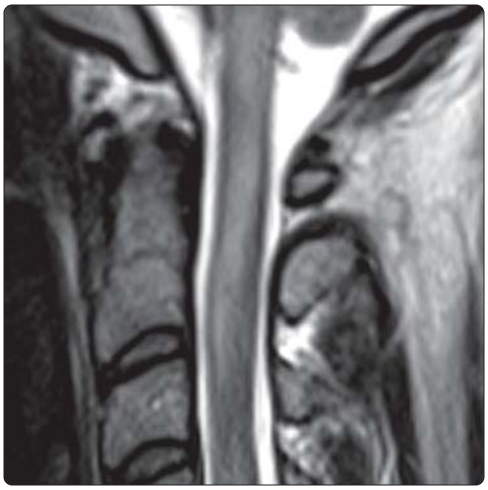
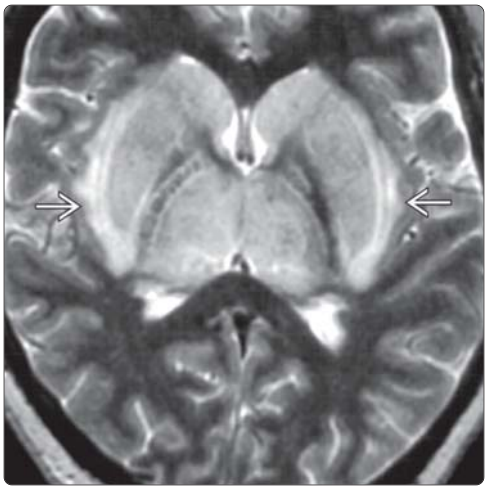
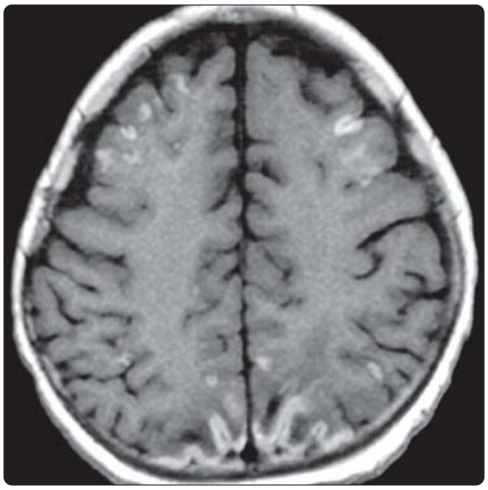
https://CafePezeshki.IR



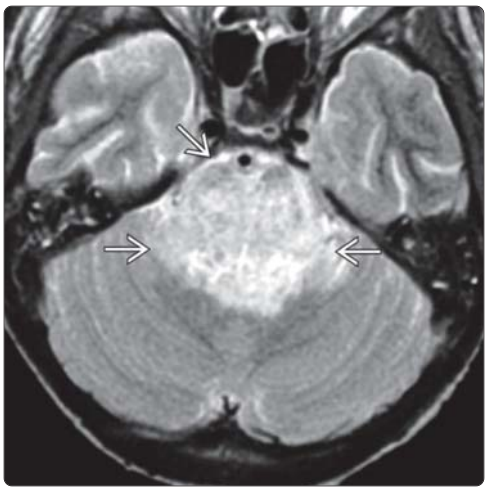


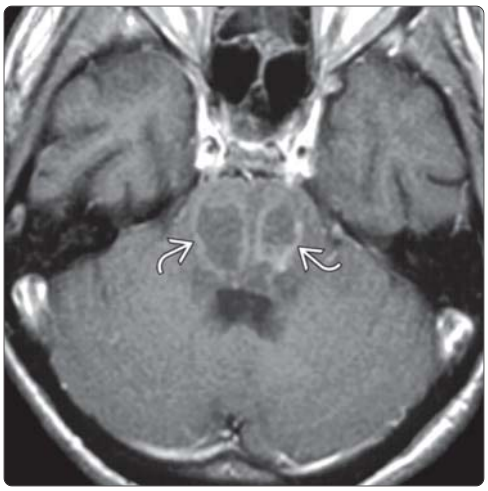
(Left) *Axial FLAIR image in a 32-year-old female with CNS lupus shows marked enlargement and hyperintensity of the medulla ⇨. Following treatment, her symptoms and imaging findings completely resolved.* **(Right)** *Sagittal T2 MR image shows hyperintensity in the cervical spinal cord related to systemic lupus erythematosus (SLE) myelitis, a type of transverse myelitis.*





(Left) *Axial T2 MR shows extensive hyperintensity in the basal ganglia, which appear edematous. Note the hyperintensity in the external and extreme capsules ⇨ due to 1 form of NPSLE, probably a neurotoxic response related to antineuronal antibodies.* **(Right)** *Axial T1WI MR shows multifocal areas of gyriform hyperintensity in the occipital cortex, as well as the frontal gray matter near the anterior watershed zone due to PRES, a secondary complication of systemic renal involvement from lupus.*





(Left) *Axial T2WI MR shows hyperintensity in the enlarged pons and middle cerebellar peduncles ⇨ in this unusual variant of lupus vasculitis. Although small-vessel vasculitis commonly involves the posterior fossa, it is usually a multifocal peripheral pattern.* **(Right)** *Axial T1WI C+ MR in the same patient shows 2 regions of ring enhancement ⇨ in the central pons due to areas of ischemic necrosis. Lupus vasculitis, which this patient has, is uncommon. Necrotic infarcts in lupus are even less common.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Cerebral amyloid deposition occurs in 3 morphologic varieties
  - Common: Cerebral amyloid angiopathy (CAA)
  - Uncommon: Mass-like lesion ("amyloidoma")
  - Rare: Inflammatory; diffuse (encephalopathic) white matter (WM) involvement

IMAGING

- General findings
  - Normotensive demented patient
  - Lobar hemorrhage(s) of different ages
  - Multifocal "black dots" on T2* or SWI MR
- Protocol advice
  - NECT = best initial screening (for acute hemorrhage)
  - MR with T2* &/or SWI

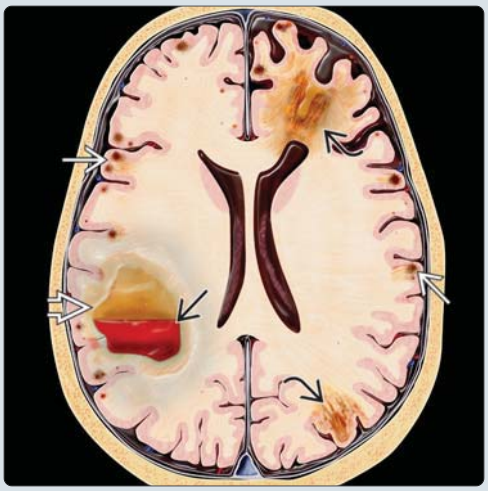
TOP DIFFERENTIAL DIAGNOSES

- Multifocal "black dots" on T2/T2* MR
  - Hypertensive microhemorrhages
  - Multiple cavernous malformations (type 4)
  - Ischemic stroke with microhemorrhage
  - Diffuse axonal injury
  - Hemorrhagic metastases
  - Posterior reversible encephalopathy syndrome (PRES)

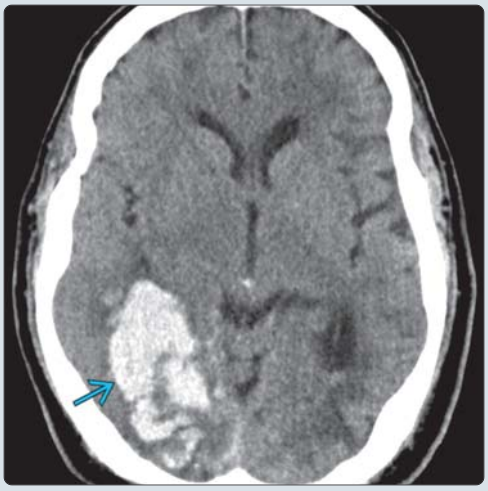
CLINICAL ISSUES

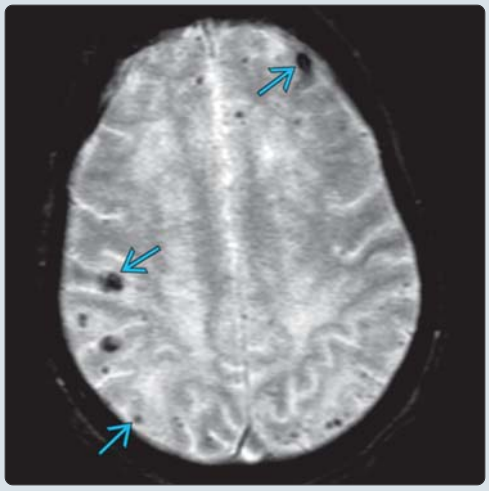
- CAA: Common cause of "spontaneous" lobar hemorrhage in elderly
  - Causes up to 15-20% of primary intracranial hemorrhage (ICH) in patients > 60 years old
  - Stroke-like clinical presentation with "spontaneous" lobar ICH
  - Chronic: Can cause vascular dementia
- CAA common in elderly patients with dementia
  - 2/3 normotensive, 1/3 hypertensive
  - 40% with subacute dementia/overt Alzheimer (overlap common)

(Left) *Axial graphic shows an acute hematoma with a blood-fluid level. Multiple microbleeds and old lobar hemorrhages are also typical findings in cerebral amyloid disease.* **(Right)** *Axial SWI MR in a 70-year-old man with cognitive impairment and acute visual changes shows multiple lobar hemorrhages and microhemorrhages related to cerebral amyloid angiopathy (CAA). SWI and T2* sequences are the most sensitive sequences for identifying microhemorrhages characteristic of CAA.*



(Left) *Axial CT image in a 72-year-old woman with no history of hypertension shows an acute right occipital lobe hemorrhage.* **(Right)** *Axial GRE MR in the same patient shows multiple foci of susceptibility artifact "blooming" related to microhemorrhages in a typical location for CAA. CAA patients most often present with acute focal neurologic deficits related to the lobar hemorrhage. Patients also present with cognitive impairment related to the microhemorrhages.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Cerebral amyloid angiopathy (CAA)

Synonyms

- "Congophilic angiopathy," cerebral amyloidosis

Definitions

- CAA is common cause of "spontaneous" lobar hemorrhage in elderly
- Cerebral amyloid deposition occurs in 3 morphologic varieties
  - CAA (common)
  - Amyloidoma (uncommon)
  - Inflammatory CAA: Amyloid β-related angiitis (ABRA) with diffuse white matter (WM) inflammatory involvement (rare)

IMAGING

General Features

- Best diagnostic clue
  - Normotensive demented patient with
    - Lobar hemorrhage(s) of different ages
    - Multifocal cortical/subcortical microhemorrhages "black dots" on T2*
- Location
  - Cortical/subcortical WM (gray-white junction)
  - Parietal + occipital lobes most common at autopsy; also frontal + temporal on imaging
  - Less common in brainstem, deep gray nuclei, cerebellum, hippocampus
- Size
  - Acute lobar hemorrhage tends to be large
  - Hypointense foci on dark T2*/susceptibility sequences ("blooming") seen with chronic microbleeds, but not specific for CAA
    - Microbleeds and macrobleeds may represent distinct entities in CAA
- Morphology
  - Acute hematomas are large, often irregular, with dependent blood sedimentation

CT Findings

- NECT
  - Patchy or confluent cortical/subcortical hematoma with irregular borders, surrounding edema
  - Hemorrhage may extend to subarachnoid space or into ventricles
  - May present with convexal subarachnoid hemorrhage
  - Rare: Gyriform Ca++
  - Generalized atrophy common

MR Findings

- T1WI
  - Lobar hematoma (signal varies with age of clot)
- T2WI
  - Acute hematoma iso-/hypointense
    - 1/3 have old hemorrhages (lobar, petechial) seen as multifocal punctate "black dots"
  - Focal or patchy/confluent WM disease associated in nearly 70%
  - Rare form: Nonhemorrhagic diffuse inflammatory with confluent WM hyperintensities
    - Acute white matter vasogenic edema may be seen in acute inflammatory forms
      - Can mimic posterior reversible encephalopathy syndrome (PRES) on imaging
    - Asymmetric pattern and multiple microbleeds are suggestive
    - Lack typical PRES predisposing factors (e.g., hypertensive crisis, immunosuppressive drugs)
    - Acute inflammatory CAA = steroid responsive
- T2* GRE
  - Multifocal "black dots"
- T1WI C+
  - CAA, lobar hemorrhages usually do not enhance
  - Amyloidoma (focal, nonhemorrhagic mass[es])
    - Mass effect generally minimal/mild
    - May show moderate/striking enhancement, mimic neoplasm
    - Often extends medially to lateral ventricular wall with fine radial enhancing margins
    - Rare: Patchy, infiltrating
  - Inflammatory (ABRA)
    - May see sulcal/cisternal enhancement
- Susceptibility weighted imaging (SWI)
  - Multifocal hypointensities (microbleeds) similar to T2* GRE, but more sensitive

Nuclear Medicine Findings

- 99m Tc-ECD SPECT: Decreased cerebral perfusion
- PET amyloid imaging agents (carbon 11-labeled Pittsburgh Compound B [11C PiB])
  - Demonstrate Aβ accumulation

Imaging Recommendations

- Best imaging tool
  - NECT = best initial screening study (for acute hemorrhage)
  - MR with T2* or SWI for nonacute evaluation (dementia)

DIFFERENTIAL DIAGNOSIS

Hypertensive Microhemorrhages

- Deep structures (basal ganglia, thalami, cerebellum) > cortex, subcortical WM
- Often coexists with CAA
- Younger patients than CAA (< 65 years old)

Multiple Cavernous Malformations

- Look for "locules" of blood with fluid-fluid levels or multiple ages of hemorrhage
- Often dense on CT due to calcification

Ischemic Stroke With Microhemorrhage

- Multifocal hemosiderin deposits
  - Found in 10-15% of patients with acute ischemic strokes
- Hemorrhagic lacunar infarcts

Other Causes of Multifocal "Black Dots"

- Traumatic diffuse axonal injury
  - History of trauma

https://CafePezeshki.IR

- Location in corpus callosum, subcortical/deep white matter, brainstem
- Hemorrhagic metastases
  - Location similar to CAA (gray-white junction)
  - Variable enhancement, edema
- Metallic microemboli from artificial heart valves
- PRES
  - Associated with acute hypertensive crisis or immunosuppressive therapy in most
  - Symmetric lesions more typical
- CADASIL
  - Usually nonhemorrhagic
  - Most common site = cortical-subcortical (up to 27% in thalami/brainstem)

PATHOLOGY

General Features

- Etiology
  - CAA caused by accumulation of aggregated Aβ in small vessels
  - Amyloidosis = rare systemic disease caused by extracellular deposition of β-amyloid
  - 10-20% of cases are localized form, including CNS
  - Can be primary/idiopathic
  - Can be secondary (associated with dialysis, medullary thyroid cancer, type 2 diabetes)
- Genetics
  - Sporadic (amyloid β-protein type)
    - Most common
    - APOE*E4 allele associated with CAA-related hemorrhage
    - Older patients, ± Alzheimer disease
  - Hereditary cerebral hemorrhage with amyloidosis
    - Autosomal dominant inheritance
    - Amyloid precursor protein encoded by *APP* gene on chromosome 21
    - Types include Dutch, British, Flemish, Italian, etc.
    - More severe and earlier onset than sporadic form

Staging, Grading, & Classification

- WHO classification of amyloidoses
  - Primary systemic amyloidosis
  - Secondary amyloidosis
  - Hereditary systemic amyloidosis
  - Hemodialysis-related systemic amyloidosis
  - Medullary thyroid carcinoma
  - Type 2 diabetes

Gross Pathologic & Surgical Features

- Lobar hemorrhage(s)
- Multiple small cortical hemorrhages

Microscopic Features

- Interstitial, vascular/perivascular deposits of amorphous protein
  - Shows apple-green birefringence when stained with Congo red, viewed under polarized light
  - 3 components
    - Fibrillar protein component (varies/defines amyloidosis type)
    - Serum amyloid P
    - Charged glycosaminoglycans (ubiquitous)
- Microaneurysms, fibrinoid necrosis, hyaline thickening
- 15% have CAA-related perivascular inflammation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute: Stroke-like clinical presentation with "spontaneous" lobar intracranial hemorrhage
  - Chronic: Dementia (CAA)
- Clinical profile
  - CAA common in demented elderly patients
    - 2/3 normotensive, 1/3 hypertensive
    - 40% with subacute dementia/overt Alzheimer (overlap common)

Demographics

- Age
  - Usually older when sporadic (> 60 years old)
  - Inflammatory CAA younger
    - May mimic PRES with acute edema, but steroid responsive
- Gender
  - No gender predilection
- Epidemiology
  - 1% of all strokes
  - Causes up to 15-20% of primary ICH in patients > 60 years old
  - Frequency of CAA in elderly
    - ~ 20-40% of normal elderly (autopsy)
    - ~ 90% in patients with Alzheimer disease
    - Common in Down syndrome

Natural History & Prognosis

- Multiple, recurrent hemorrhages
- Progressive cognitive decline

Treatment

- Evacuate focal hematoma if patient < 75 years old, no intraventricular hemorrhage, not parietal
- Consider immunosuppressive therapy in inflammatory CAA
- Adverse prognostic factors: Low Glasgow coma scale scores, APOE4 allele

DIAGNOSTIC CHECKLIST

Consider

- GRE (T2*) &/or SWI in all elderly

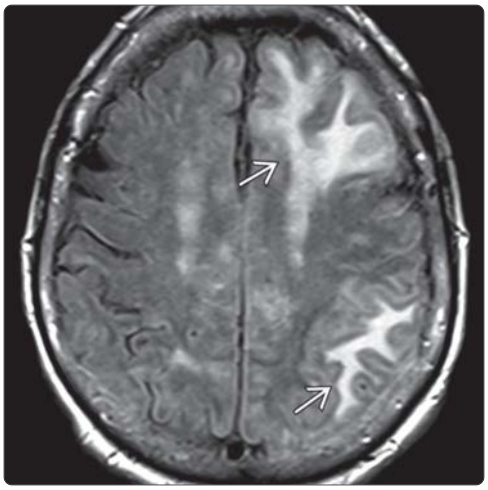
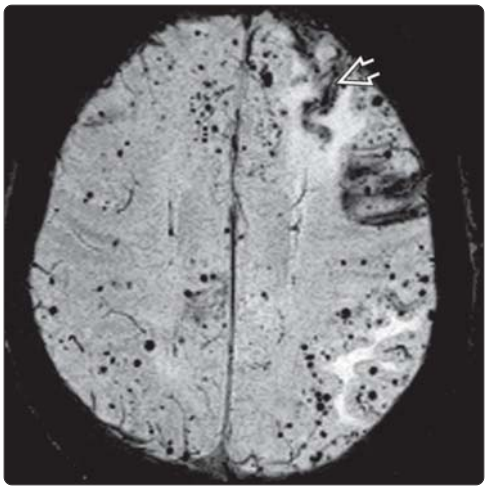
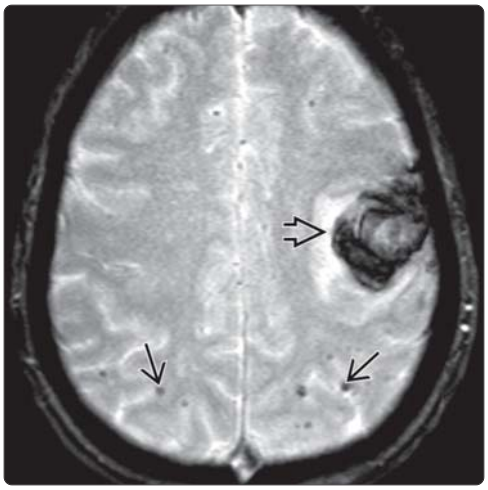
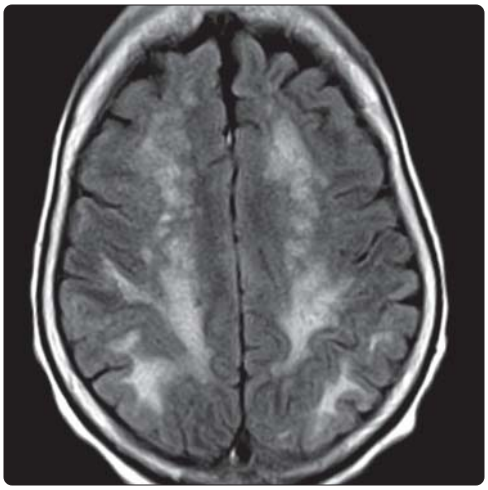
https://CafePezeshki.IR



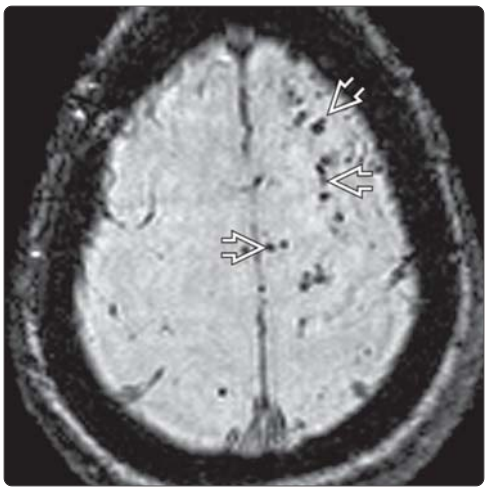


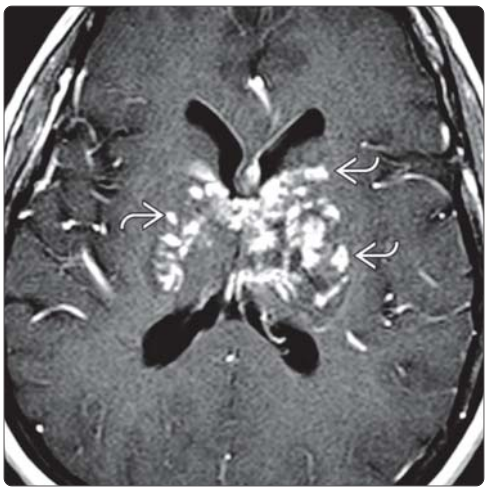
(Left) *Axial FLAIR MR image in an 82-year-old woman with acute onset of neurologic deficits shows hyperintensity in the left frontal and parietal lobes ⇨, not seen on prior imaging.* **(Right)** *Axial SWI image in the same patient shows extensive foci of susceptibility artifact, "blooming" related to microhemorrhages throughout the brain parenchyma typical of CAA. Linear hypointensity ⇨ is related to superficial siderosis. Inflammatory amyloid was diagnosed at biopsy. She responded well to corticosteroid treatment.*





(Left) *Axial T2* GRE shows a left hemispheric lobar hematoma ⇨. Note the multifocal "black dots" ⇨, whose peripheral location is highly suggestive of amyloid angiopathy.* **(Right)** *Axial FLAIR MR image in a 73 year old with CAA shows the typical confluent white matter lesions seen in cerebral amyloid angiopathy and arteriolosclerosis (chronic microvascular ischemia). SWI (not shown) confirmed the multiple microhemorrhages typical of CAA.*





(Left) *Axial SWI shows hypointensities in the cortex and along the pial surfaces ⇨ in this patient with CAA.* **(Right)** *Axial T1 C+ MR shows innumerable small foci of enhancement ⇨ with mild mass effect in the basal ganglia bilaterally and periventricular white matter, following a perivascular distribution. A minority of amyloidosis cases present in this fashion, with "amyloidomas" that mimic neoplastic or possibly atypical infectious/inflammatory etiologies.*

https://CafePezeshki.IR

CADASIL

KEY FACTS

TERMINOLOGY

- Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL)
- Hereditary small-vessel disease due to mutations in *NOTCH3* gene on chromosome 19, which causes stroke in young to middle-aged adults

IMAGING

- Diffuse white matter (WM) hyperintensities = leukoaraiosis, early finding
- Multiple lacunar infarcts
- Anterior temporal pole, external capsule and paramedian superior frontal lobe highly sensitive and specific locations
- Diffusion restriction in acute lacunar infarcts
- Protocol Advice: MR with T2, FLAIR, and DWI

TOP DIFFERENTIAL DIAGNOSES

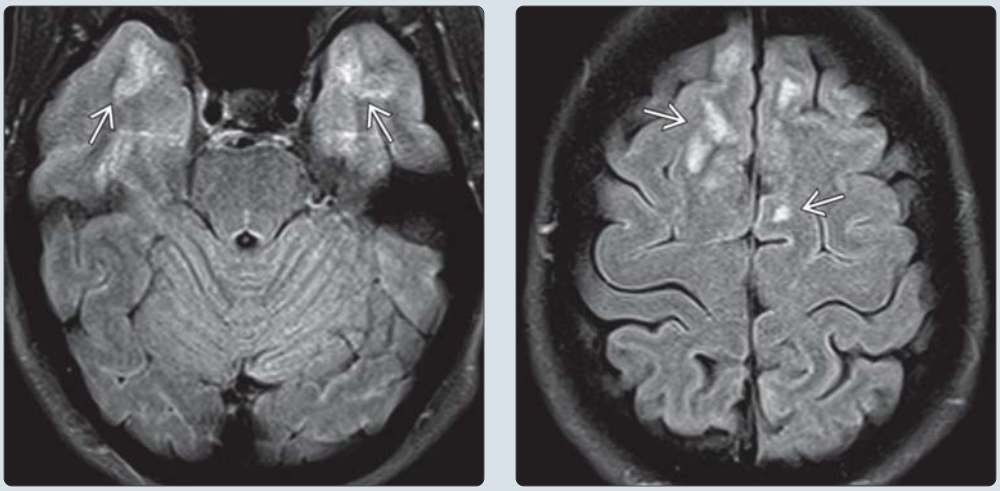
- Arteriolosclerosis, MELAS, subcortical arteriosclerotic encephalopathy (SAE), primary angiitis of CNS

PATHOLOGY

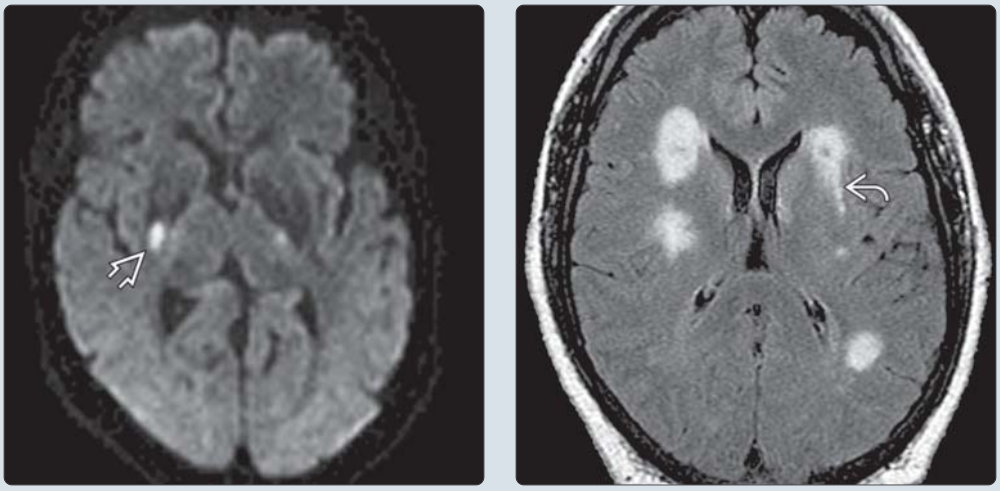
- Autosomal dominant disease with mutation in *NOTCH3* results in arteriopathy affecting penetrating cerebral and leptomeningeal arteries

CLINICAL ISSUES

- Most frequent hereditary small-vessel disease of the brain
- TIA/stroke or migraine with aura often initial presentation
- TIA or stroke most common manifestation of disease (60-85% of all patients)
  - Often absence of traditional risk factors
- Migraines, if present, often precede other findings
- Average onset of stroke slightly earlier for men, but not significantly different (M = 50.7, F = 52.5)
- Clinical differential diagnosis includes multiple sclerosis, dementia, and CNS vasculitis
- No specific therapy, supportive therapy to reduce stroke and myocardial infarct risk



(Left) *Axial FLAIR MR of a young patient with migraines shows focal hyperintensity ➡ in the anterior temporal lobes highly suggestive of CADASIL. NOTCH3 mutation confirmed CADASIL.* **(Right)** *Axial FLAIR MR in the same patient shows additional subcortical hyperintense foci in the paramedian superior frontal lobes ➡, which is a highly sensitive and specific location for lesions in patients with CADASIL, in addition to the anterior temporal lobes and external capsule.*



(Left) *Axial DWI trace image in a young adult female with no vascular risk factors shows an acute lacunar ➡ infarct in the right basal ganglia. CADASIL was diagnosed by the presence of a NOTCH3 mutation.* **(Right)** *Axial FLAIR MR shows multiple hyperintense white matter lesions with involvement of the external capsule ➡. External capsule disease location is characteristic for CADASIL and rarely seen with the more common arteriolosclerosis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL)

Definitions

- Hereditary small-vessel disease due to mutations in *NOTCH3* gene on chromosome 19, which causes stroke in young to middle-aged adults

IMAGING

General Features

- Best diagnostic clue
  - Characteristic subcortical lacunar infarcts and leukoencephalopathy in young/middle-aged adults
- Location
  - Anterior temporal lobe, external capsule, paramedian superior frontal lobe highly sensitive and specific
  - Lacunar infarcts in basal ganglia (BG) and subcortical location
    - BG > frontal > parietal > anterior temporal lobes
  - Most common involvement in order of frequency
    - Younger patients: Frontal lobe, parietal lobe, external capsule, anterior temporal lobe
    - Older patients: Additionally posterior temporal and occipital lobes often involved
  - Cerebral cortex is generally spared
- Size
  - Multiple infarcts of various sizes, typically lacunar

CT Findings

- NECT
  - Subcortical and BG hypodense lesions

MR Findings

- T1WI
  - 2 types of lesions
    - Large, coalescent, isointense WM lesions
    - Small, well-delineated, hypointense lesions that spare cortex
  - Loss of contrast between grey matter and white matter in early stages of CADASIL
- T2WI
  - Diffuse white matter hyperintensities (WMHs) = leukoaraiosis, early finding
  - Discrete hyperintense lacunar infarctions
  - Anterior temporal pole and paramedian superior frontal lobe highly sensitive and specific
- FLAIR
  - Discrete hyperintense lacunar infarcts and WMHs
- T2* GRE
  - Microhemorrhages in 25-50% of patients, ↑ with age
- DWI
  - Diffusion restriction in acute lacunar infarcts
- PWI
  - Reduced CBF and CBV in areas of WM signal abnormality without significant MTT changes
    - ↓ CBF may precede WM signal abnormality
  - Decreased hemodynamic reserve after acetazolamide challenge in areas of WM signal abnormality

Angiographic Findings

- Digital subtraction angiogram is normal in CADASIL

Nuclear Medicine Findings

- PET
  - 18F-FDG PET: ↓ cortical and subcortical glucose metabolism

Imaging Recommendations

- Protocol advice
  - MR with T2, FLAIR, and DWI

DIFFERENTIAL DIAGNOSIS

Arteriolosclerosis

- Older patients, typically > 50 years
- Periventricular and deep WM T2/FLAIR hyperintensities
- Cerebrovascular risk factors: Hypertension, hypercholesterolemia, diabetes

MELAS

- **M**itochondrial **e**ncephalomyopathy with **l**actic **a**cidosis and **s**troke-like episodes
- Younger age, mean age onset 15 years
- Bilateral, multifocal, cortical, and subcortical FLAIR hyperintense lesions
- Normal to increased ADC values within 48 hours of neurological deficit of abrupt onset should raise possibility of MELAS, especially if conventional MR images show infarct-like lesions
- Lesions disappear with clinical improvement, and ADC returns to normal (tissue recovery)

Subcortical Arteriosclerotic Encephalopathy (SAE)

- Type of vascular dementia, associated with hypertension
- Multiple lacunar infarcts in lenticular nuclei, pons, thalamus, internal capsule, and caudate nuclei
- Diffuse, confluent periventricular WM involvement

Primary Angiitis of CNS

- Lumen irregularities in distal cerebral arteries on digital subtraction angiogram

Hypercoagulable States

- Antiphospholipid antibodies, protein S deficiency
  - Stroke in young and middle-aged adults, with high rate of recurrence
- "Antiphospholipid syndrome": Early stroke, recurrent arterial and venous thromboses, spontaneous fetal loss, thrombocytopenia
- Cortical and lacunar infarcts of various sizes
- T2 WMHs, dural sinus thrombosis
- Abnormal angiogram: Vasculitis-like findings and stenoses at origin of great vessels

PATHOLOGY

General Features

- Etiology
  - Autosomal dominant disease with mutation in *NOTCH3* results in arteriopathy affecting penetrating cerebral and leptomeningeal arteries

https://CafePezeshki.IR

- Narrowed lumen of affected vessels results in ↓ CBF and metabolism
  - In CADASIL patients with minor WMHs, cerebral vasodilatory capacity preserved but ↓ total CBF
- Genetics
  - Point mutations in *NOTCH3* gene on chromosome 19p13 with autosomal dominant transmission
    - *NOTCH3* codes for large transmembrane receptor physiologically expressed in vascular smooth muscle cell
    - Extracellular domain has 34 epidermal growth factor repeats (EGFR) with 6 cysteine residues
    - More than 150 CADASIL mutations are described
      - Mutations result in odd number of cysteine residues on affected EGFR
  - De novo mutations have been reported
- Associated abnormalities
  - Small vessels of other organs (skin, muscle, liver, spleen) affected, but clinical manifestations are predominantly cerebral

Gross Pathologic & Surgical Features

- Features characteristic of chronic small artery disease
  - Diffuse myelin pallor; periventricular and centrum semiovale WM rarefaction
  - WM and BG lacunar infarcts
  - Dilated perivascular spaces
  - Macroscopic appearance of cortex shows atrophy

Microscopic Features

- Specific arteriopathy of small penetrating cerebral and leptomeningeal arteries characterized by
  - Arterial wall thickening (→ luminal stenosis) with normal endothelium
  - Nonamyloid extracellular granular osmiophilic deposits in media extending into adventitia
  - Morphologically altered smooth muscle cells, which can disappear from vessel wall
- Widespread cortical apoptosis, especially of layer 3 and 5

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - TIA/stroke or migraine with aura often initial presentation
  - TIA or stroke most common manifestation of disease (60-85% of all patients)
    - Average age of onset: 41-49 years, range: 20-58 years
    - Often absence of traditional risk factors
    - Most have recurrent strokes
    - Often recurrent lacunar strokes
  - Migraine with aura (often atypical) (20-40%)
    - When present often 1st manifestation at younger age than TIA/stroke
    - Average age 25-30 years, with earlier onset in women (1-10 years earlier than men)
  - Cognitive deficits common, increase with age
    - Almost 90% have executive dysfunction, often associated with changes in memory and attention
  - Behavioral disturbances common (75%)
    - Depression (46%), disturbed sleep (45%), irritability/lability (43%), apathy (41%)
  - Seizures (5-10%); may be related to stroke rather than primary manifestation of CADASIL
- Clinical profile
  - Large variations in clinical presentation
  - Young or middle-aged patient often 1st presenting with migraines with aura or TIA/stroke

Demographics

- Age
  - Onset of ischemic symptoms in mid-adulthood
    - MR changes appear at average age of 30 years and precede stroke/TIA by 10-15 years
    - Migraines, if present, often precede other findings
- Gender
  - No gender preference, but prognosis/life expectancy different for females and males
- Epidemiology
  - Prevalence is unknown
    - Over 500 families described worldwide
    - Small study in Scotland found minimum prevalence of 1.98/100,000
      - Predicted prevalence of about 4/100,000
      - Likely underestimates true prevalence due to variety of factors
  - Most frequent hereditary brain small-vessel disease

Natural History & Prognosis

- Average age of stroke onset slightly earlier for men but not significantly different (M = 50.7, F = 52.5 years)
- Disease progression typically more rapid in men with earlier death

Treatment

- No specific therapy for CADASIL, supportive care

DIAGNOSTIC CHECKLIST

Consider

- Awareness of clinical and radiological features of CADASIL in young and middle-aged adults allows early diagnosis
- Consider CADASIL in acute unexplained encephalopathy

Image Interpretation Pearls

- Imaging hallmark: Subcortical WMHs and lacunar infarcts
- Characteristic WMHs seen on MR often before onset of symptoms
- Temporal WM involvement suggests CADASIL in a young adult

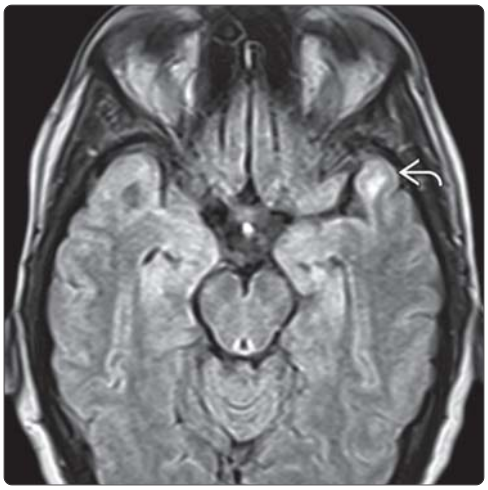
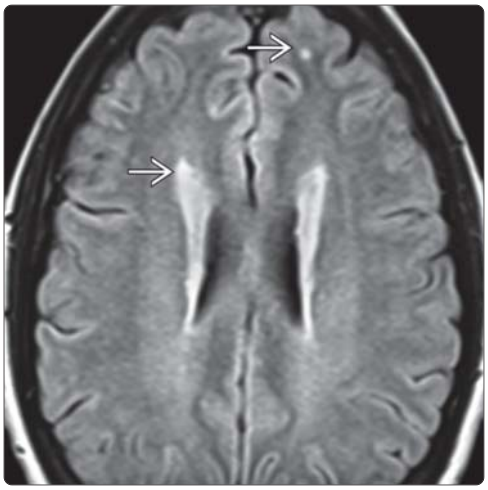
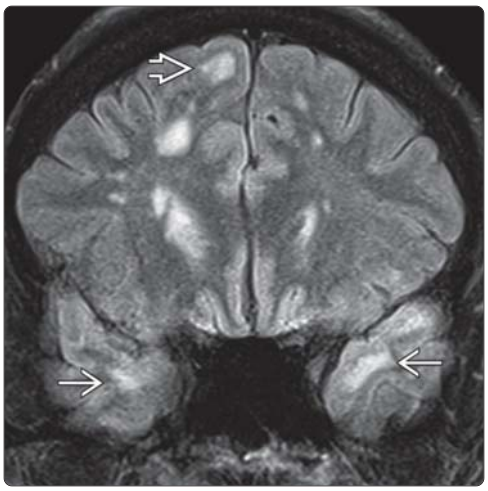
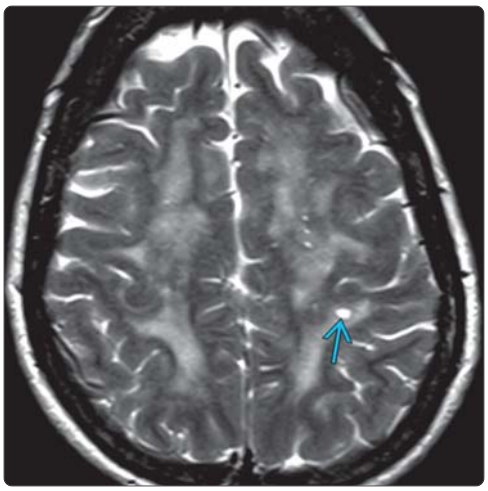
(Left) *Axial FLAIR MR in a 40-year-old female with CADASIL shows extensive white matter hyperintensities with involvement of the external capsules* ➡ *as well as a chronic left basal ganglia lacunar infarct* ⇨. **(Right)** *Axial FLAIR MR in the same patient shows diffuse white matter disease. Diffuse white matter disease with associated lacunar infarcts should raise suspicion for CADASIL in a young patient.*





(Left) *Axial FLAIR MR through the temporal lobes shows focal subcortical white matter hyperintensities* ➡, *very early changes in a 31-year-old patient with genetically proven CADASIL and migraines with visual auras as the only symptom.* **(Right)** *Axial FLAIR MR in the same patient shows nonspecific hyperintensities* ➡ *in the frontal and periventricular white matter. These white matter lesions are often seen before the onset of symptoms.*





(Left) *Coronal FLAIR image shows multiple hyperintense white matter lesions in the anterior temporal lobes* ➡, *frontal lobes* ⇨ *and periventricular location in this 38-year-old male with CADASIL. This disease affects the smooth muscle cells in penetrating cerebral and leptomeningeal arteries.* **(Right)** *Axial T2 MR in a patient with CADASIL shows extensive confluent white matter disease as well as a chronic lacunar infarct* ⇨. *CADASIL is the most common hereditary small vessel disease of the brain.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Chronic, idiopathic relapsing-remitting multisystem vascular-inflammatory disease characterized by recurrent orogenital ulcerations and uveitis
  - CNS involved in up to 20-25% of patients

IMAGING

- Best diagnostic clue: T2 hyperintense brainstem lesion in patient with oral and genital ulcers
  - Midbrain > pons > basal ganglia (BG) > thalami > white matter
  - Focal or multifocal lesions
  - May see expansion of involved structures acutely
- T2WI: Hyperintense lesions
- T1WI C+: Patchy enhancement typical
- ↓ NAA in acute lesions
  - NAA may normalize when lesions resolve
- May see atrophy of involved structures chronically

TOP DIFFERENTIAL DIAGNOSES

- Gliomatosis cerebri
- ADEM
- Primary CNS lymphoma
- Vasculitis
- Multiple sclerosis

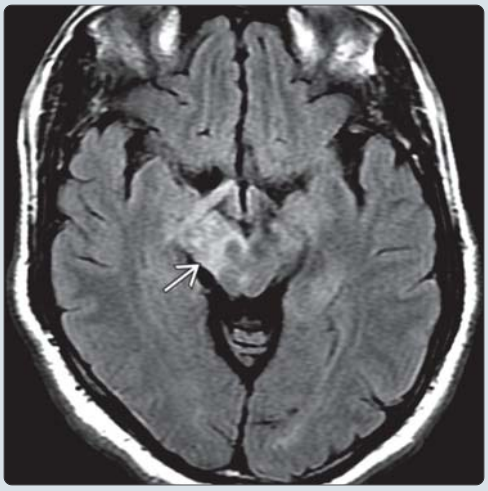
CLINICAL ISSUES

- Neurologic deficit (hemiparesis), headache, seizure common presenting features
- Young adults, median age: 40 years

DIAGNOSTIC CHECKLIST

- Consider Behçet disease in young adult with brainstem or deep gray nucleus lesion
- Enhancement pattern may help differentiate Behçet disease from other etiologies

(Left) *Axial FLAIR MR image shows abnormal hyperintensity and mild expansion of the left ventral midbrain ➡ and patchy hyperintensity in the right midbrain ➡ in this 35-year-old man with neuro-Behçet disease. This chronic, relapsing idiopathic multisystem vascular-inflammatory disease is also characterized by oral and genital ulcers.* **(Right)** *Axial T1 C+ MR image in the same patient shows enhancement of the large midbrain lesion ⇨. Imaging typically mimics neoplasm, vasculitis, and demyelination.*



(Left) *Axial FLAIR MR image in the same patient 2 years later shows resolution of the left midbrain lesion and development of a large right midbrain lesion ➡ involving the cerebral peduncle. A relapsing-remitting clinical course is typical.* **(Right)** *Axial T2WI MR shows hyperintensity in the pons with mild expansion ➡ in a young man with oral ulcers and a clinical diagnosis of Behçet disease. Other lesions were present in the midbrain and basal ganglia. Thalamic and white matter involvement is less common in this disease.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Neuro-Behçet disease

Definitions

- Chronic, idiopathic relapsing-remitting multisystem vascular-inflammatory disease characterized by recurrent orogenital ulcerations and uveitis
  - CNS involved in up to 20-25% of patients

IMAGING

General Features

- Best diagnostic clue
  - T2-hyperintense brainstem lesion in young adult with oral and genital ulcers
- Location
  - Brainstem is most common location
    - Ventral midbrain (cerebral peduncles) and pons typically involved
  - Basal ganglia (BG) commonly involved
  - May involve thalami and white matter (WM)
  - Rarely affects spinal cord, mesial temporal lobes
  - Additional nonparenchymal form with vessel involvement: Sinus thrombosis > > arterial occlusion, aneurysm
- Size
  - Variable
- Morphology
  - May enlarge involved structures acutely
  - Focal or multifocal lesions

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR

CT Findings

- NECT: Often normal
  - May see subtle hypointense lesions

MR Findings

- T1WI: Isointense or hypointense lesions
- T2WI: Hyperintense lesions
  - May see expansion of involved structures
- FLAIR: Hyperintense lesions
- DWI: Variable; acute lesion may show restriction
- T1 C+: Patchy enhancement common
- MRS: ↓ NAA in acute lesions

DIFFERENTIAL DIAGNOSIS

Gliomatosis Cerebri

- T2 hyperintense mass with enlargement of involved structures
- Typically no enhancement

ADEM

- T2 hyperintense lesions in subcortical WM and deep gray nuclei after viral prodrome or vaccination
- Brainstem involvement uncommon

Primary CNS Lymphoma

- Enhancing lesions typically abut ependymal surfaces
- Often T2 hypointense, DWI positive

Vasculitis

- T2 hyperintense lesions, often supratentorial
- Diffusion restriction acutely
- Variable enhancement

Multiple Sclerosis

- Callososeptal interface lesions most common
- Ventral brainstem lesions less common

PATHOLOGY

General Features

- Etiology
  - Multisystem, vascular-inflammatory disease of unknown origin
- Associated abnormalities
  - Patients with CNS disease typically have orogenital ulcerations and uveitis

Microscopic Features

- Perivascular infiltration with inflammatory cells ± signs of necrosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Neurologic deficit (hemiparesis), headache, seizure
  - Neurologic involvement typically months to years after systemic disease (Initial presentation in 5%)
- Clinical profile
  - CSF studies: Pleocytosis and ↑ protein levels

Demographics

- Age
  - Young adults typically, 20-40 years; also reported in children
- Gender
  - M > F in neuro-Behçet
- Epidemiology
  - 5-25% of patients have CNS involvement

Treatment

- Corticosteroids and immunosuppressive therapy

DIAGNOSTIC CHECKLIST

Consider

- Behçet disease in young adult with brainstem or deep gray nucleus lesion

SELECTED REFERENCES

KEY FACTS

TERMINOLOGY

- Microangiopathy of brain, retina, and cochlea

IMAGING

- T2 hyperintense corpus callosum (CC) lesions in patient with clinical triad
  - Encephalopathy, bilateral hearing loss, and branch retinal artery occlusions
- Multifocal T2 hyperintensities similar to MS
  - More often round, mid-callosal rather than callososeptal location
- May involve brainstem, basal ganglia, thalamus, subcortical white matter, centrum semiovale
- Lesions may show acute diffusion restriction
- Variable enhancement of lesions and leptomeninges

TOP DIFFERENTIAL DIAGNOSES

- Multiple sclerosis
- ADEM
- Systemic lupus erythematosus
- Vasculitis

PATHOLOGY

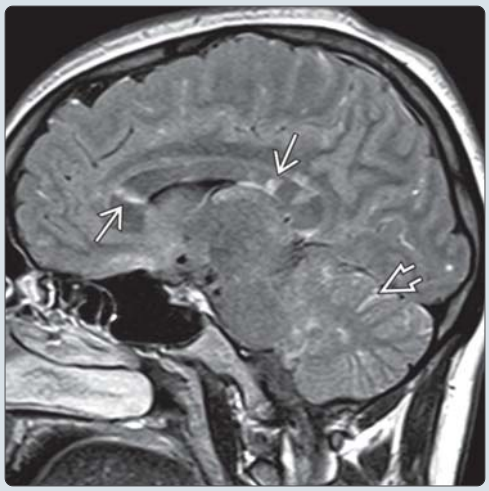
- Microinfarctions in cerebral cortex that are generally not seen on imaging
- No demyelination seen on pathology

CLINICAL ISSUES

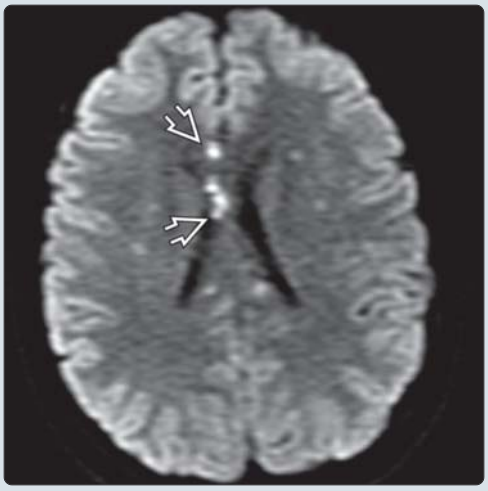
- 20-40 years old
- Usually self-limited (2-4 years) but may lead to permanent deafness or blindness

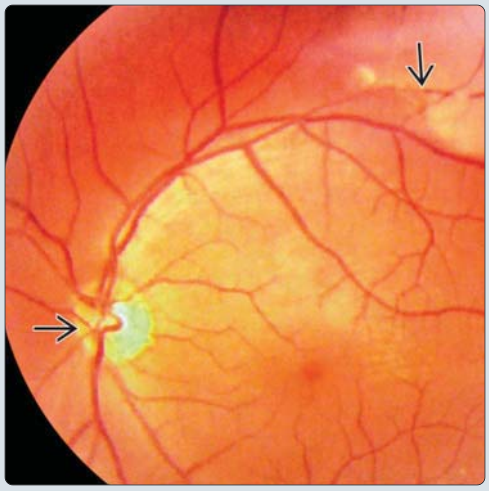
DIAGNOSTIC CHECKLIST

- Most patients do not exhibit entire triad (up to 97% at time of presentation)
- Complete triad seen after 2 weeks or after 2 years
- Consider Susac syndrome in patients with corpus callosum lesions and clinical triad



(Left) *Axial FLAIR MR image shows multiple hyperintensities ⇨ in corpus callosum of this 27-year-old female patient with Susac syndrome who presented with headache and confusion. The classic clinical triad includes encephalopathy, bilateral hearing loss, & branch retinal artery occlusions.* **(Right)** *Sagittal FLAIR C+ MR image (same patient) shows classic involvement ⇨ of corpus callosum body with hyperintense lesions. Note leptomeningeal enhancement ⇨, which may be seen in up to 50% of patients.*





(Left) *Axial DWI trace image shows multiple hyperintense lesions ⇨, many of which had corresponding low ADC values representing true diffusion restriction. Acute lesions may mimic vasculitis.* **(Right)** *Funduscopic examination shows multiple retinal artery branch occlusions and irregularities ⇨, classic for Susac syndrome. Susac syndrome is often mistaken for multiple sclerosis on imaging studies. Its etiology is uncertain but most likely represents an autoimmune microangiopathy, not a demyelinating disorder.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Retinocochleocerebral vasculopathy, formerly known as small infarctions of cochlear, retinal, and encephalic tissue (SICRET syndrome)

Definitions

- Microangiopathy of brain, retina, and cochlea

IMAGING

General Features

- Best diagnostic clue
  - T2 hyperintense corpus callosum (CC) lesions in patient with clinical triad
  - Encephalopathy, bilateral hearing loss, and branch retinal artery occlusions
- Location
  - Body and splenium of CC, middle layers, classically
  - May involve brainstem, basal ganglia (BG), thalamus, subcortical white matter (WM), centrum semiovale

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR

CT Findings

- NECT
  - Often normal
  - May exclude other causes of hearing loss, encephalopathy

MR Findings

- T2WI
  - Multifocal T2 hyperintensities similar to those seen in multiple sclerosis (MS)
    - More often round, mid-callosal rather than located at callososeptal interface
  - May see lesions in brainstem, BG, thalamus, subcortical WM, centrum semiovale
- FLAIR
  - Round, punched-out, hyperintense callosal lesions
- DWI
  - Callosal lesions may show diffusion restriction acutely (microinfarcts)
- T1WI C+
  - Variable enhancement of WM lesions
  - Variable leptomeningeal enhancement
- DTI: Decreased fractional anisotropy (FA) in WM tracts, particularly CC

DIFFERENTIAL DIAGNOSIS

Multiple Sclerosis

- Most common misdiagnosis, with similar appearance of callosal WM lesions
- Typically periventricular and callososeptal interface location

ADEM

- Viral prodrome or post vaccination, monophasic
- T2 hyperintense lesions in BG and WM

Systemic Lupus Erythematosus

- Multifocal WM T2 hyperintensities, vasculitic features

Vasculitis

- DWI +, FLAIR hyperintense lesions
- Does not involve the corpus callosum

PATHOLOGY

Microscopic Features

- No demyelination seen on pathology
- Normal axon density, reactive glial changes
- Microinfarctions in cerebral cortex, generally not seen on imaging

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Bilateral hearing loss (cochlear)
    - May be unilateral or asymmetric
    - May be associated with tinnitus, vertigo, unsteady gait, nausea, vomiting, and nystagmus
  - Encephalopathy (headaches most common, often severe or migrainous)
  - Branch retinal artery occlusions
- Other signs/symptoms
  - Memory impairment, confusion, behavioral disturbances, ataxia, dysarthria, paranoid psychosis, occasional mutism
  - CSF: High protein and lymphocytic pleocytosis
- Clinical differential diagnosis: Migraine headaches, Ménière disease (bilateral sensorineural hearing loss)

Demographics

- Age: 20-40 years old
- Gender: F >>> M

Natural History & Prognosis

- Usually self-limited (2-4 years) but may lead to permanent deafness or blindness

Treatment

- Immunosuppressants and antithrombotics

DIAGNOSTIC CHECKLIST

Consider

- Most patients do not exhibit entire triad (up to 97% at time of presentation)
- Complete triad may be seen after 2 weeks or after 2 years

Image Interpretation Pearls

- Consider Susac syndrome in patients with corpus callosum lesions and clinical triad

KEY FACTS

TERMINOLOGY

- Fibromuscular dysplasia (FMD)
  - Arterial disease of unknown etiology
  - Overgrowth of smooth muscle, fibrous tissue
  - Affects medium/large arteries

IMAGING

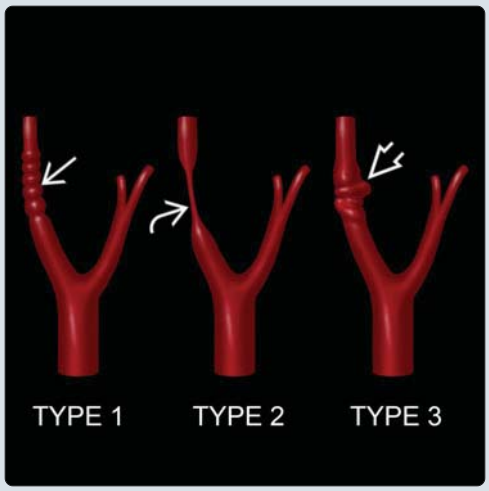
- Renal artery is most common overall site (~ 75%)
- Cervicocranial FMD (~ 70%)
  - ICA (30-50%) > ECA > vertebral arteries (10-20%)
  - Carotid bifurcation is typically spared
  - > 50% of cases are bilateral
  - Intracranial rare (supraclinoid ICA, MCA)
- CTA
  - Arterial luminal irregularity or "beading" ± stenosis or aneurysm (rare)
- DWI-MR
  - Most sensitive for ischemic sequela of FMD
- DSA
  - Type 1 (85%): Classic "string of beads" = medial fibroplasia
  - Type 2 (10%): Long, tubular stenosis = intimal fibroplasia
  - Type 3 (5%): Asymmetric outpouching from 1 side of artery = periadventitial fibroplasia

TOP DIFFERENTIAL DIAGNOSES

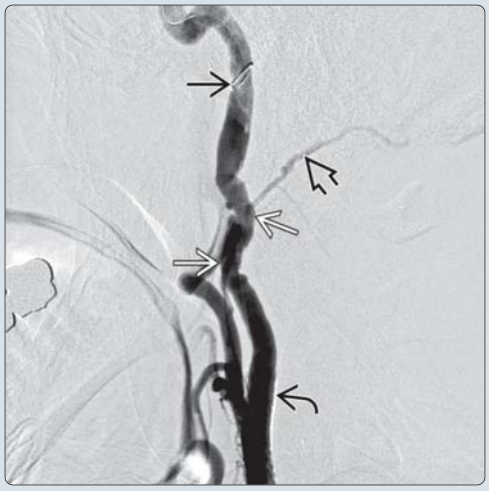
- Atherosclerosis
- Standing waves
- Nonatherosclerotic vasculopathies

CLINICAL ISSUES

- Symptoms: HTN, stroke, dissection
- Treatment
  - Antiplatelet ± anticoagulant Rx to reduce risk of thromboembolic sequela (stroke)
  - Balloon angioplasty
  - Covered stent, arterial reconstruction for aneurysm



(Left) *Sagittal CTA shows a classic appearance of FMD in a 40-year-old female following trauma. There is type I FMD in the cervical carotid artery with alternating areas of constriction and dilatation. C1-C2 is the most common location. Note the typical sparing of the carotid bulb.* **(Right)** *Carotid bifurcation graphic shows the principal subtypes of FMD. Type 1 appears as alternating areas of constriction and dilatation, type 2 as tubular stenosis, and type 3 as focal corrugations ± a diverticulum.*



(Left) *Oblique DSA of the left carotid artery shows ASVD stenosis of the carotid bulb. Note the mural calcification seen as faint subtraction artifact. Superiorly, the ICA shows luminal irregularity and beading, consistent with FMD. Additional FMD involvement of an ECA branch is evident.* **(Right)** *Lateral DSA after carotid stenting across the ASVD stenosis shows a distal protection device in situ. Note the irregularity of the ICA and occipital artery due to FMD.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Fibromuscular dysplasia (FMD)

Definitions

- Arterial disease of unknown etiology
  - Overgrowth of smooth muscle, fibrous tissue
  - Affects medium/large arteries

IMAGING

General Features

- Best diagnostic clue
  - Luminal irregularity ("beaded") arteries in young/middle-aged patient
- Location
  - Renal artery = most common site overall (~ 75%)
  - Craniocervical arteries (~ 70%)
    - ICA (30-50%) > ECA > vertebral arteries (10-20%)
    - > 50% of cases have bilateral involvement
    - Spare the carotid bifurcation
  - Intracranial rare (supraclinoid ICA, MCA)
- Morphology
  - Arterial luminal corrugations, classic "string of beads" appearance
    - ± arterial stenosis, aneurysm

CT Findings

- CTA
  - Arterial luminal irregularity or "beading"
    - ± stenosis or aneurysm (uncommon)
    - Mural Ca++ absent

MR Findings

- DWI
  - Most sensitive for ischemic sequela of FMD
- MRA
  - May see "string of beads" appearance

Ultrasonographic Findings

- Color Doppler
  - Visible ridges or thickening of carotid wall ± stenosis

Angiographic Findings

- 3 subtypes with distinctive appearances on DSA
  - Type 1 (85%): Classic "string of beads" = medial fibroplasia
  - Type 2 (10%): Long, tubular stenosis = intimal fibroplasia
  - Type 3 (5%): Asymmetric outpouching from 1 side of artery = periadventitial fibroplasia

DIFFERENTIAL DIAGNOSIS

Atherosclerosis

- Usually older patients
- Typically short segment stenosis (not "string of beads"), associated with mural Ca++

Arterial "Standing Waves"

- Oscillations from normal retrograde flow during cardiac cycle, unknown etiology
- Appears as transient "string of beads"
  - Very regular periodicity, smoothness differentiate from FMD

Nonatherosclerotic Vasculopathies

- Takayasu, giant cell arteritis

PATHOLOGY

General Features

- Etiology
  - Unknown; thought to be dysplastic rather than degenerative or inflammatory
- Associated abnormalities
  - Intracranial saccular aneurysms in ~ 10%
  - Spontaneous dissection (20% in ICA)
  - Thromboembolic sequela due to disturbed flow → thrombus formation
    - TIA or stroke in 15-20%

Microscopic Features

- Overgrowth of smooth muscle cells and fibrous tissue in arterial wall

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Hypertension due to renal involvement (stenosis)
- Other signs/symptoms
  - Craniocervical FMD
    - Stenosis → TIA/stroke
    - Dissection ± stroke
    - Aneurysm → mass effect on adjacent structures, rupture (rare)

Demographics

- Age
  - Onset of symptoms: 25-50 years old
- Gender
  - M:F = 1:9 (most common subtype)

Natural History & Prognosis

- Slow progression of arterial irregularities ± stenoses

Treatment

- Antiplatelet ± anticoagulant Rx to reduce risk of thromboembolic sequela (stroke)
- Balloon angioplasty of stenoses
- Covered stent, arterial reconstruction for aneurysm

DIAGNOSTIC CHECKLIST

Consider

- FMD in younger patients with HTN, stroke, dissection
- Head CTA/MRA in FMD patients to exclude associated intracranial aneurysm(s)

KEY FACTS

TERMINOLOGY

- Absence of cerebral hemispheres with intact thalamus, brainstem, cerebellum, skull/meninges
  - Associated space filled with CSF ("water bag brain")
  - Probably caused by in utero vascular occlusion, infection, or trauma after 1st trimester

IMAGING

- Absent cerebrum with fluid-filled cranial vault
- Thalamus, cerebellum, brainstem, falx intact
- Temporal, occipital lobe remnants common
- Macrocephaly

TOP DIFFERENTIAL DIAGNOSES

- Severe hydrocephalus
- Alobar holoprosencephaly (HPE)
- Severe bilateral open-lip schizencephaly
- Cystic encephalomalacia

PATHOLOGY

- In utero compromise of anterior cerebral circulation
- Implicated: Anoxia, infection, thrombophilic states, maternal toxin exposure, radiation, genetic factors, twin-twin transfusion

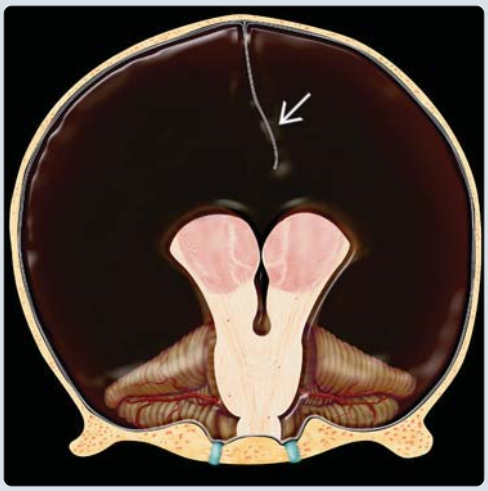
CLINICAL ISSUES

- Newborn with macrocephaly, developmental failure, calvarial transillumination
  - Hyperirritability, hyperreflexia, seizures
- Neurological function limited to brainstem
- Prognosis: Death in infancy; prolonged survival rare
- Ventricular shunt treats macrocephaly

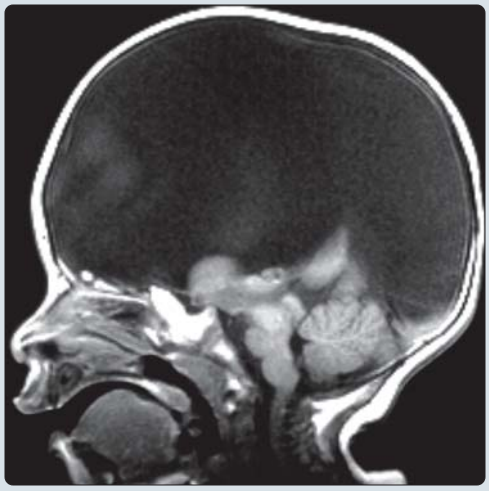
DIAGNOSTIC CHECKLIST

- Intact falx distinguishes hydranencephaly from alobar HPE
- Thin cortical mantle along inner table distinguishes severe hydrocephalus from hydranencephaly

(Left) *Coronal graphic shows classic features of hydranencephaly. The cerebral hemispheres are nearly absent, but the thalami, brainstem, and cerebellum are intact. The falx cerebri ⇨ appears to "float" in a CSF-filled rostral cranial vault.* **(Right)** *Axial NECT shows cerebral hemispheres replaced by CSF with no cortical mantle appreciated except in the medial temporal lobes ⇨. The posterior fossa and diencephalic structures supplied by the posterior cerebral circulation are intact.*



(Left) *Sagittal T1WI in a newborn with macrocephaly shows hydranencephaly. No cortical mantle is visible. CSF fills virtually all of the expanded supratentorial spaces. The brainstem and cerebellum appear normal.* **(Right)** *Coronal T1 MR in the same patient shows the expanded, CSF-filled spaces with only tiny amounts of residual brain present ⇨. Note that the CSF appears somewhat heterogeneous due to pulsation. (Courtesy A. Illner, MD.)*



https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Absence of cerebral hemispheres with intact thalamus, brainstem, cerebellum, skull/meninges
  - Associated space filled with CSF
  - Probably caused by in utero vascular occlusion, infection, or trauma after 1st trimester
- Hemihydranencephaly: Rare unilateral form

IMAGING

General Features

- Best diagnostic clue
  - Absent cerebrum with fluid-filled cranial vault
  - Falx cerebri and posterior fossa structures intact
- Location
  - Cerebral hemispheres
- Morphology
  - "Water bag" brain
- Thalamus, cerebellum, brainstem, falx intact
- Medial temporal, occipital lobe remnants common

CT Findings

- Fluid-filled cranial vault
- Macrocephaly

MR Findings

- Absent cerebral mantle
- Falx cerebri partially/completely intact
- No gliosis in remaining brain structures

Ultrasonographic Findings

- Anechoic cranial vault

Other Modality Findings

- CTA, MRA: Atretic, stenotic, occluded, malformed or normal supraclinoid carotids and branch vessels
- Prenatal US/MR: Severe hemorrhage may precede hydranencephaly

Imaging Recommendations

- Best imaging tool
  - Prenatal US allows therapeutic intervention
  - Postnatal MR best delineates extent of destruction

DIFFERENTIAL DIAGNOSIS

Severe Hydrocephalus

- Thin cortical mantle compressed against inner table

Alobar Holoprosencephaly (HPE)

- Fused midline structures; absent falx

Severe Bilateral Open-Lip Schizencephaly

- Perisylvian transmantle cleft lined by abnormal gray matter

Cystic Encephalomalacia

- Scattered cerebral cavities, gliosis

PATHOLOGY

General Features

- Etiology
  - In utero compromise of anterior cerebral circulation
  - Brain injury results in liquefactive necrosis by 20-27 weeks gestation
  - Implicated: Anoxia, infection, thrombophilic states, maternal toxin exposure, radiation, genetic factors, twin-twin transfusion
  - *COL4A1* mutations with large prenatal hemorrhages
- Genetics
  - Sporadic
  - Rare autosomal recessive syndromes
    - Fowler: Hydranencephaly, fetal akinesia, CNS vasculopathy
    - Microhydranencephaly: Hydranencephaly, microcephaly, small body (Chr 16p13.3-12.1)
- Associated abnormalities
  - Few reports: Vascular malformations, renal dysplasia

Gross Pathologic & Surgical Features

- Leptomeningeal-lined, fluid-filled "sacs" in lieu of cerebral hemispheres

Microscopic Features

- Hemosiderin-laden macrophages over remnant brain

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Macrocephaly (intact choroid plexus secretes CSF)
- Other signs/symptoms
  - Hyperirritability, hyperreflexia, seizures
- Clinical profile
  - Newborn with macrocephaly, developmental failure, calvarial transillumination

Demographics

- Age: Diagnosis usually made in 1st few weeks of life
- Epidemiology: < 1:10,000 births; 10x ↑ teenage moms

Natural History & Prognosis

- Neurological function limited to brainstem
- Progressive hydrocephalus requiring CSF diversion

Treatment

- Ventriculoperitoneal shunt treats macrocephaly
- Endoscopic coagulation of choroid plexus

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Intact falx distinguishes hydranencephaly from alobar HPE
- Thin cortical mantle along inner table distinguishes severe hydrocephalus from hydranencephaly

KEY FACTS

TERMINOLOGY

- White matter injury of prematurity (WMIP) is not the same as germinal matrix hemorrhage (GMH)
  - In WMIP, primary injury is to white matter; in GMH, primary injury is to vessels in germinal matrix
- Periventricular leukomalacia (PVL) = WMIP, but term WMIP is used to emphasize that not all white matter injury is periventricular
- Encephalopathy of prematurity = WMIP and associated neuronal/axonal abnormalities

IMAGING

- Best early ultrasound (US) clue: Hyperechoic "flare" with loss of normal tissue echo texture
- Best early MR clue: T1 hyperintensity and decreased diffusion (bright DWI, low ADC) in affected areas
  - Acute DWI abnormality > T1 and T2 abnormality, also acute DWI > chronic injury visible on MR
- Best late MR clue: White matter volume loss, sometimes gliosis or ventriculomegaly
- White matter cavitation has become rare in modern neonatal ICUs

TOP DIFFERENTIAL DIAGNOSES

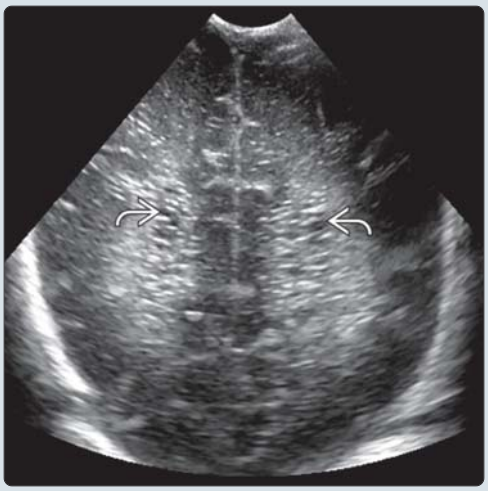
- Normal periventricular halo
- Infection
- Inborn errors of metabolism

PATHOLOGY

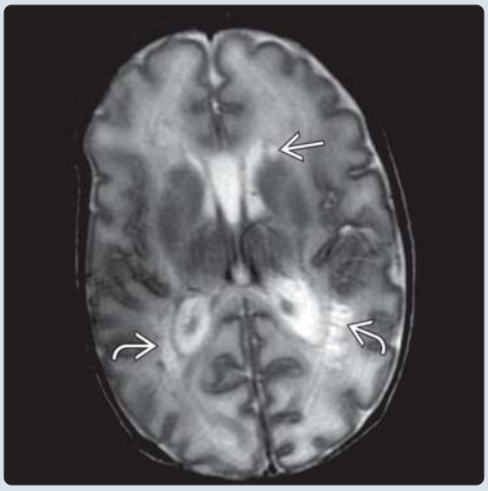
- Primarily initiating factors: Inflammation (due to maternal infection/postnatal sepsis) and ischemia

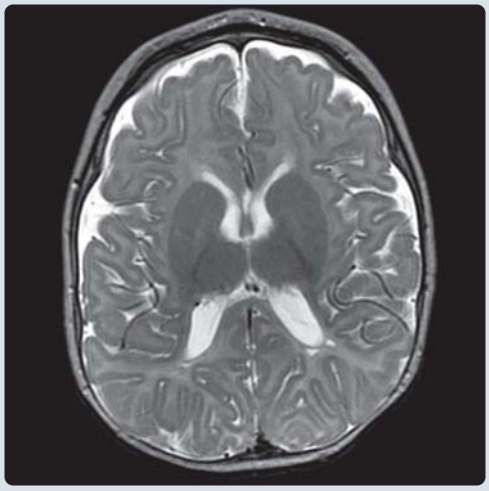
CLINICAL ISSUES

- Typically silent
- Severity and extent of brain abnormalities = destructive processes and developmental disturbances



(Left) *Oblique transfontanelle cranial ultrasound in a 34 week gestational age (GA) infant at 17 days old shows diffusely increased echogenicity throughout the white matter with subtle regions of cavitation, usually called cystic change.* **(Right)** *Axial T2WI MR in the same 34-week GA infant 1 day later better illustrates the severity and extent of the white matter injury. More extensive white matter cavitation (cystic regions) are clearly identified.*





(Left) *Axial T1WI MR in the same 34-week GA infant at 18 days old shows cavitary white matter injury in the peritrigonal regions and, to a lesser degree, adjacent to the left frontal horn.* **(Right)** *Axial T2WI MR in the same infant at 3 months old shows almost complete collapse of the cavities, resulting in ex vacuo ventricular enlargement and white matter volume loss. On follow-up at 2 years old, this child has mild spastic diplegia and mild language delay.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- White matter injury of prematurity (WMIP), hypoxic-ischemic encephalopathy (HIE), hypoxic-ischemic injury (HII), periventricular leukomalacia (PVL), very low birth weight (VLBW)

Definitions

- WMIP is not the same as germinal matrix hemorrhage (GMH)
  - In WMIP, primary injury is to white matter; in GMH, primary injury is to vessels in germinal matrix
- PVL = WMIP, but term WMIP is used here to emphasize that not all white matter injury is periventricular
- VLBW = infant ≤ 1,500 g (1-5% of all births)
- Encephalopathy of prematurity = WMIP and associated neuronal/axonal abnormalities

IMAGING

General Features

- Best diagnostic clue
  - Best early ultrasound (US) clue: Hyperechoic "flare" with loss of normal tissue echo texture
  - Best early MR clue: T1 hyperintensity and decreased diffusivity (bright DWI, low ADC) in affected areas
  - Best late MR clue: WM volume loss, sometimes with gliosis/ventriculomegaly
  - WM cavitation has become rare in modern neonatal ICUs
- Location
  - Focal (most common peritrigonal) or diffuse WM
  - Thalami (may be secondary to WM injury)
  - Often associated with inferomedial cerebellar hemorrhage
- Size
  - Most WM lesions are 3 mm or less
- Morphology
  - Chronic: WM volume loss
    - ↓ WM volume (especially corpus callosum [CC])
    - Undulating ventricular borders
    - Secondary ventriculomegaly (variable severity)
    - ± cortical and deep gray volume loss
    - ± pontine and cerebellar volume loss

CT Findings

- NECT
  - Insensitive to nonhemorrhagic WMIP

MR Findings

- T1WI
  - Early
    - May be normal, often underestimates extent of injury
    - WM ↓ T1 signal: Diffuse (edema or ischemia) or focal (cavitation)
    - Focal WM ↑ T1 signal (myelin breakdown products, hemorrhage, or microglial activation) ± cavitation
  - Late: Morphological changes as above
- T2WI
  - Early
    - May be normal, often underestimates extent of injury
    - WM ↑ T2 signal: Diffuse (edema or ischemia) or focal (cavitation)
    - Focal WM ↓ T2 signal (myelin breakdown products, hemorrhage, or microglial activation)
  - Late: Morphological changes as above, gliosis (if injury occurred > 24-26 weeks gestational age)
- FLAIR
  - Early: Insensitive to injury
  - Late: Same as T2 but ↑ sensitivity to periventricular gliosis
- T2* GRE
  - Blooming at sites of hemorrhage
- DWI
  - Most sensitive in acute stage
  - ↑ signal and ↓ ADC in areas of recent injury, but time course for DWI and ADC evolution and normalization not known
  - Acute DWI abnormality larger in size than acute or chronic T1 and T2 abnormalities
- MRS
  - ↑ lactate
  - ↓ NAA (normal in premature infants)
  - ↑ excitatory neurotransmitters
  - **Caveat**: Small amounts of lactate are often seen in WM and CSF of uninjured premature neonates

Ultrasonographic Findings

- Grayscale ultrasound
  - Early: Focal or diffuse increased echogenicity, most prominent adjacent to frontal horns and trigone
  - Subacute: ± cavitation (may take ~ 7-10 days to appear)
  - Late: Cavities often collapse; WM volume loss, secondary ventriculomegaly

Imaging Recommendations

- Best imaging tool
  - MR with DWI
    - Most sensitive and specific imaging modality
    - Benefits must be balanced with risk of transport to MR
    - ↑ sensitivity and ↑ specificity to type of injury (ischemia, hemorrhage vs. edema) compared to US
  - Head US
    - Still screening tool of choice: Inexpensive and can be performed bedside, but ↓ sensitivity and specificity compared to MR
- Protocol advice
  - Current practice parameter recommendations
    - Screening head US in all infants GA < 30 weeks at 7-14 days old and at 36-40 corrected GA
  - MR
    - When US is abnormal: MR ASAP to clarify scope of injury and aid in prognosticating, include DWI
    - At discharge for at-risk VLBW neonates with normal screening cranial sonograms

DIFFERENTIAL DIAGNOSIS

Normal Periventricular Halo

- Normal hyperechoic "blush" posterosuperior to ventricular trigones, seen on parasagittal sonography

https://CafePezeshki.IR

- Suspect WMIP if echogenicity is asymmetric, coarse, globular, or more hyperechoic than glomi of choroid plexus

Infection

- Congenital CMV infection: Microcephaly, calcifications, WM edema, ± polymicrogyria, DWI negative
- *Citrobacter*, frontal lobes
- Enteroviruses (especially echovirus, parechovirus)

Inborn Errors of Metabolism

- Urea cycle disorders, mitochondrial disorders

PATHOLOGY

General Features

- Etiology
  - Primarily initiating factors: Inflammation (due to maternal infection/postnatal sepsis) and ischemia
  - Unique risk factors of premature brain
    - Intrinsic vulnerability of immature oligodendroglia and subplate neurons to free radicals, excitotoxicity, and cytokines
    - Abundant microglia
    - Impaired cerebrovascular autoregulation → pressure-passive cerebral circulation
    - Periventricular vascular anatomical and physiological factors (arterial end zones)
  - Primary injury to WM ± subplate neurons
  - Currently unclear if more widespread neuronal/axonal abnormalities primary or secondary to resulting growth disturbances/WM injury
- Associated abnormalities
  - Intraventricular hemorrhage

Staging, Grading, & Classification

- Focal: Localized necrosis in deep WM with loss of all cellular components
  - Macroscopic: Cysts ≥ 1-2 mm (< 5% of VLBW infants, also called cystic PVL)
  - Microscopic: Cysts not resolved by current imaging, evolve to glial scar
- Diffuse: Marked astrogliosis and microgliosis, abnormal promyelinating oligodendrocyte maturation (results in hypomyelination, volume loss)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute: Typically silent, ± perirolandic sharp waves on EEG; need to consider risk and screen
- Clinical profile
  - Mother: Poor antepartum care, preterm premature rupture of membranes, chorioamnionitis, preeclampsia, group B strep
  - Preterm neonate: VLBW, intraventricular hemorrhage, respiratory distress syndrome type 1, hypocarbia, hypotension, sepsis, anemia, apnea

Demographics

- Age
  - Incidence of WMIP in VLBW infants is < 20% (down from 50% in 2001)
  - Worldwide ~ 5% of preterm infants have WMIP
- Gender
  - M > F
- Epidemiology
  - VLBW → < 20% incidence (higher if associated with intraventricular hemorrhage)
  - Gestational age < 33 weeks → higher incidence
  - > 50% of patients with cystic WMIP or grade 3 intraventricular hemorrhage develop cerebral palsy

Natural History & Prognosis

- Severity and extent of brain abnormalities = destructive processes + developmental disturbances
- Spastic diplegia/quadriplegia, seizures, microcephaly, blindness, deafness in severe cases
- Poor outcome if intraventricular hemorrhage with WMIP, WMIP with volume loss, widespread infarction, or seizures
- Spastic diplegia (associated with cystic WMIP)
- Cognitive deficits in absence of motor deficits (associated with noncystic WMIP and cerebellar injury)
  - Many have impaired working memory and attention deficits
  - Basis of cognitive deficits may be due to thalamic, cerebellum, as well as cerebral cortical involvement

Treatment

- Prenatal care significantly reduces preterm birth (35% down to 8%)
- Supportive

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Cranial ultrasound underestimates WMIP
- As with HII of term, injuries evolve over time

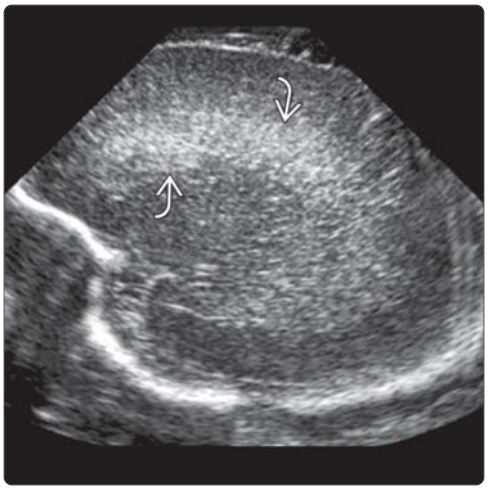
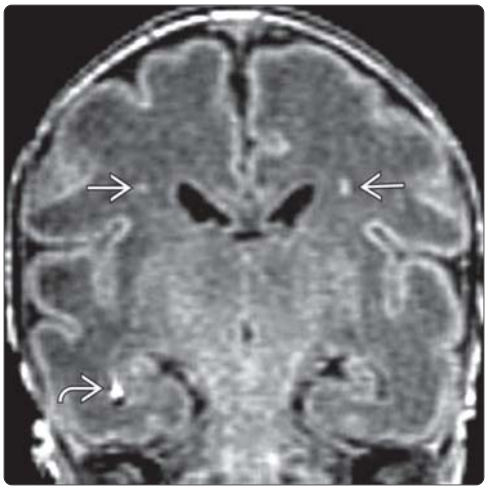
https://CafePezeshki.IR



(Left) *Sagittal oblique transfontanelle cranial ultrasound in a 3-day-old premature infant shows hazy increased echogenicity or hyperechoic "flare" throughout the hemispheric white matter.* **(Right)** *Sagittal oblique cranial ultrasound in the same infant a few days later shows the development of small cavitations within the hyperechoic white matter. The lesions progressed to large areas of cavitation in the injured white matter during the next week (not shown).*



(Left) *Coronal T1WI MR shows bilateral foci of white matter injury in the deep white matter. This type of white matter injury of prematurity (WMIP) is far more common than the cavitary type, which has become uncommon with modern perinatal care in the neonatal ICU. Note the incidental germinal matrix hemorrhage in the right temporal lobe.* **(Right)** *Sagittal T1WI MR shows multiple foci of WMIP in the deep white matter in this child born at 27 weeks. The sulcation pattern is very immature.*

(Left) *Coronal T1WI MR shows bilateral WMIP. This is the most common location (deep white matter), which is why the term periventricular leukomalacia has been replaced. Note the small cerebellum (normal), which grows more in later gestation and postnatally.* **(Right)** *Axial T1WI MR shows very little sulcation in this 26-week prematurely born baby. The deep peritrigonal WMIP is a common location; the left-sided one is large. The foci around the frontal horns are germinal zones.*

KEY FACTS

TERMINOLOGY

- Hypoxic-ischemic injury (HII): Imaging pattern of injury due to acquired global arterial hypoperfusion (though many factors can increase vulnerability and potential injury)
- Hypoxic-ischemic encephalopathy (HIE): Clinical syndrome defined in term or near-term neonates

IMAGING

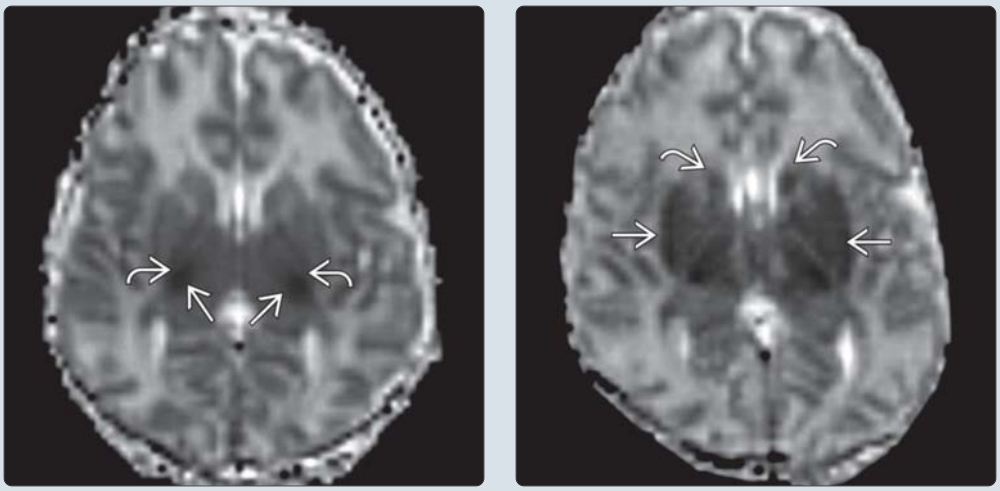
- Profound HII: Low ADC in ventrolateral (VL) thalamus ± corticospinal tract (CST) in posterior limb internal capsule (PLIC)
- Partial HII: VL thalamus and CST in PLIC spared, cortical injury maximal at depths of sulci
- Bright DWI and ↓ ADC occur early, even when T1WI/T2WI normal
- Injuries evolve over time: DWI and ADC abnormality can ↑ in size and severity over 1st few days due to delayed cell death; DWI and ADC normalize or ↑ around 7-10 days
- US and CT insensitive, particularly after therapeutic hypothermia

TOP DIFFERENTIAL DIAGNOSES

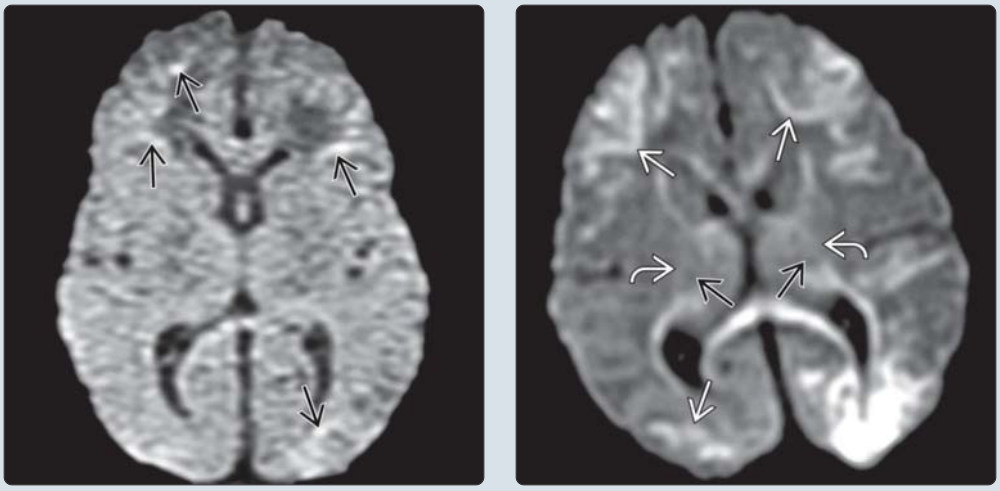
- Venous injury
  - Edema, hemorrhage, or ischemia in venous distribution
- Hypoglycemia
  - Predominantly posterior distribution, check glucose
- Mitochondrial disorders
- Urea cycle disorders
- Other inborn errors in metabolism
  - Especially isolated sulfite oxide deficiency, molybdenum cofactor deficiency
- Kernicterus (accentuated by sepsis, hypoxia)

CLINICAL ISSUES

- Treatment: Hypothermia to 33.5°C for 72 hours



(Left) *Axial ADC map in a 1-day-old neonate with an Apgar score of 0 at 5 minutes shows marked ADC decrease involving the ventrolateral thalami and CST in posterior limb internal capsule (PLIC) bilaterally. This case was proven to be profound hypoxic-ischemic injury (HII).* **(Right)** *Axial ADC in the same neonate at 4 days old shows the ADC decrease to now involve the bilateral caudate and lentiform nuclei. The delayed appearance of ADC abnormalities suggests that delayed necrosis has occurred in the interval.*



(Left) *Axial DWI MR of a 1-day-old neonate presenting with seizures shows scattered small foci of increased signal intensity, primarily at the depths of sulci. This infant was diagnosed with partial HII.* **(Right)** *Axial DWI MR in the same neonate at age 3 days shows marked progression of the extent and severity of the DWI abnormality suggesting delayed necrosis. Note the involvement of the depths of sulci, as well as the sparing of ventrolateral thalamus and corticospinal tract in PLIC.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hypoxic-ischemic injury (HII), hypoxic-ischemic encephalopathy (HIE)

Synonyms

- Hypoxic-ischemic insult, perinatal or birth asphyxia, asphyxia neonatorum

Definitions

- HII: Imaging pattern of injury due to acquired global arterial hypoperfusion (though many factors can increase vulnerability and potential injury)
  - Not all with HII meet clinical criteria for HIE
- HIE: Clinical syndrome defined in term or near-term neonates
  - Not all with HIE have HII on imaging
- Profound HII: Complete or nearly complete cessation of blood flow to brain
- Partial HII: Less severe reduction of cerebral blood flow

IMAGING

General Features

- Best diagnostic clue
  - Profound HII: Low ADC in ventrolateral thalamus (VLT) ± corticospinal tract (CST) in posterior limb internal capsule (PLIC)
  - Partial HII: VLT and CST in PLIC spared, cortical injury maximal at depths of sulci
- Location
  - Profound HII
    - VLT and CST in PLIC
    - ± perirolandic cortex, other cortical regions (in cortex depths of sulci more involved than apices of gyri), white matter, hippocampi, midbrain, dorsal brainstem, superior vermis
    - Subacute: Entire thalamus and basal ganglia may become involved
  - Partial HII
    - VLT + CST in PLIC spared
    - Bilateral symmetric or asymmetric involvement of cortex and subcortical white matter usually maximal at sulcal depths

CT Findings

- NECT
  - Insensitive
  - Profound HII: Deep gray nuclei may be indistinct due to ↓ attenuation
  - Partial HII: Loss of gray-white distinction

MR Findings

- T1WI
  - Profound HII
    - Subacute (beginning ~ 3 days): ↑ signal in VLT, ± posterolateral putamen, ± perirolandic cortex at depths of sulci, loss of normal ↑ signal of CST in PLIC
  - Partial HII
    - Subacute: ↑ signal depths of sulci starting ~ 3 days
- T2WI
  - Profound HII
    - Acute: Blurring of deep gray nuclei ± cortical margins
    - Subacute: ↓ signal in VLT ± posterolateral putamen starting ~ 6 days, ↑ signal in white matter
    - Chronic: ↑ signal ± volume loss in VLT, ± posterolateral putamen, ± other areas of gliosis and volume loss
  - Partial HII
    - Acute: Blurring of cortical margins
    - Subacute: ↑ signal in white matter
    - Chronic: Variable volume loss and gliosis
- T2* GRE
  - Rarely blooming to suggest hemorrhage directly related to HII
- DWI
  - Bright DWI and ↓ ADC occur early, even when T1WI/T2WI normal
  - Injuries evolve over time: DWI and ADC abnormality can ↑ in size and severity over 1st few days due to delayed cell death; DWI normalizes and ADC normalizes or ↑ around 7-10 days
  - Less sensitive after therapeutic hypothermia
- MRA
  - Typically normal or loss of signal due to turbulent flow in small neonatal arteries
- MRV
  - Typically normal, often focal narrowing in superior sagittal sinus due to moulding
- MRS
  - ↓ NAA correlates with worse prognosis
  - ↑ α-glutamate/glutamine peaks in basal ganglia (BG) correlate with ↑ severity of injury
  - ↑ lactate correlates with worse prognosis

Ultrasonographic Findings

- Grayscale ultrasound
  - Insensitive, may see ↑ echogenicity in injured areas
- Color Doppler
  - ↓ resistive indices in severe profound HII
  - Good to rule out clot in circle of Willis

Imaging Recommendations

- Best imaging tool
  - Combined DWI and MRS: Extremely sensitive for early ischemic necrosis
    - Be aware that therapeutic hypothermia may reduce early sensitivity to injury
- Protocol advice
  - In milder injuries, DWI may take 24 hours to become abnormal
    - To ↑ sensitivity to subtle injury, look at ADC as well as DWI and consider ↑ b values

DIFFERENTIAL DIAGNOSIS

Venous Injury

- Edema, hemorrhage, or ischemia in venous distribution
- Not global arterial hypoperfusion = technically not HII

Hypoglycemia

- Predominantly posterior distribution, check glucose
- Exacerbates hypoxic-ischemic injury

https://CafePezeshki.IR

Mitochondrial Disorders

- Consider if history benign
- Pattern can be identical to HII

Urea Cycle Disorders

- Pattern of BG and thalamus involvement different

Other Inborn Errors in Metabolism

- Many have BG abnormalities; thalamus uncommon

Kernicterus

- Accentuated by sepsis, hypoxia
- Mimics profound injury, acute on T1WI; has confirmed hyperbilirubinemia
- Globus pallidus (not putamen or thalamus)

PATHOLOGY

General Features

- Etiology
  - Profound HII
    - Sentinel event: Equivalent to cardiorespiratory arrest
    - Severe lack of blood flow and O_2 for minutes to ~ 1 hour
    - Injury maximal to areas with high metabolic demand
  - Partial HII
    - No sentinel event, therefore less well understood
    - Moderate lack of blood flow and oxygen for hours to days; persistent or intermittent
    - Redistribution of blood flow to areas of high metabolic demand → sparing of these regions
  - Asphyxia triggers cascade of cellular biochemical events → abnormal function, edema, or death of cell
    - Extracellular glutamate accumulates, activates postsynaptic excitatory amino acid receptors
    - Postsynaptic receptor distribution changes with development → different damage patterns at different gestational ages
  - Many chances for cell loss
    - Primary neuronal (death at time of insult)
    - Reactive cell death (reperfusion injury hours or days later)
    - Seizure-related cell injury
- Genetics
  - Seek inborn errors of metabolism if apparent HII with normal Apgar or if > 1 HII child in family
    - Isolated sulfite oxidase deficiency, molybdenum cofactor deficiency present early, imaging findings similar to HII
    - Differentiate by clinical course
- Associated abnormalities
  - Maternal: Infection, preeclampsia, diabetes, cocaine
  - Infant: ↓ gestational age, ↓ Hgb, growth retardation, ↓ Ca++/glucose, sepsis, hyperthermia, seizures, congenital heart disease; ↑ urine S100B protein
  - Ischemia often multiorgan (e.g., cardiac, renal)

Staging, Grading, & Classification

- Sarnat stage (based on clinical and EEG findings)

Gross Pathologic & Surgical Features

- Profound HII: Hippocampal, BG, thalamic, perirolandic atrophy
- Partial HII: Ulegyria, gliosis, and atrophy with sparing perirolandic region

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Sarnat I (mild): Hyperalert/irritable, mydriasis, ↑ HR, EEG normal
  - Sarnat II (mod): Lethargy, hypotonia, miosis, ↓ HR, seizure (SZ)
  - Sarnat III (severe): Stupor, flaccid, reflexes absent, SZ

Demographics

- Age
  - Near or full term in immediate prenatal, intrapartum, and postnatal period
- Epidemiology
  - HIE: Up to 2/1,000 (0.2%) live births

Natural History & Prognosis

- Varies from normal outcome (Sarnat I) to spastic quadriparesis, developmental delay, microcephaly, and SZ (Sarnat III)
- Profound HII (VL thalamus injury): Extrapyramidal cerebral palsy, high mortality, high morbidity
- Partial HII: Spastic quadriparesis

Treatment

- Resuscitation, correct fluid, and electrolyte imbalance
- Treat seizures
- Therapeutic hypothermia: Cool to 33.5°C for 72 hours

DIAGNOSTIC CHECKLIST

Consider

- Prenatal HII with in utero injury and recovery or inborn errors of metabolism if atypical clinical presentation

Image Interpretation Pearls

- DWI critical, but evolves over time: Can be normal < 1 day, ↑ in severity over days, then normalize ~ 1 week

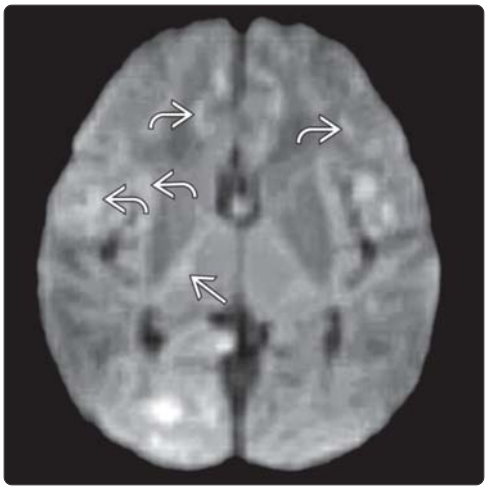
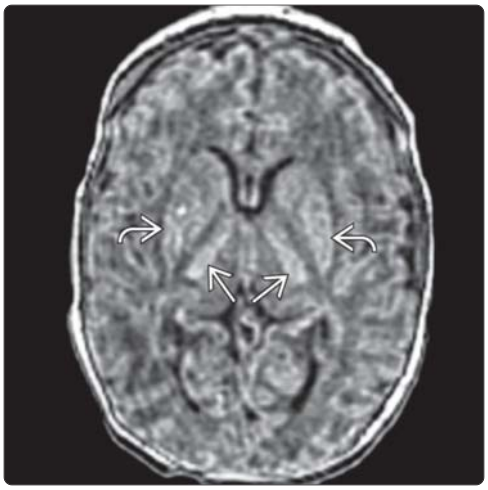
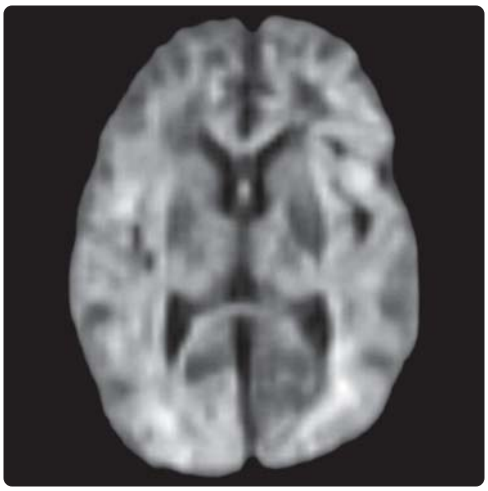
https://CafePezeshki.IR

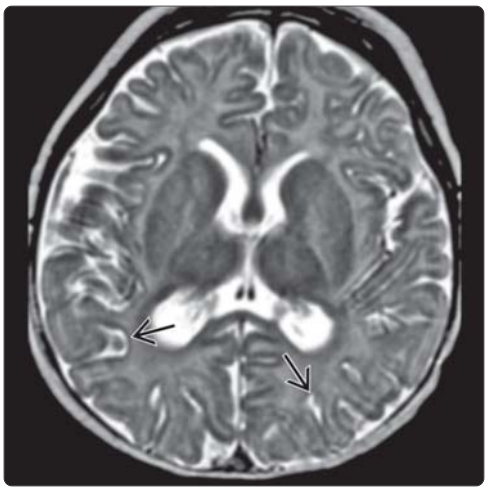


(Left) *Axial DWI MR in a neonate with profound HII shows ↑ signal in the right VL thalamus (VLT)/corticospinal tract (CST) region ➡ with multiple other foci of cortical/subcortical increased signal. Note the depths of sulci ➡ are often preferentially involved in profound HII.* **(Right)** *Axial ADC map in the same neonate better demonstrates the low ADC in the VLT ➡ and CST ➡ with multiple other regions of cortical/subcortical white matter involved. ADC shows neonatal injury better than DWI.*



(Left) *Axial T1WI MR of a 9-day-old neonate who suffered birth injury and has profound HII shows increased signal intensity bilaterally in the VLT ➡ and putamina ➡.* **(Right)** *Axial T2WI MR in the same infant 6 months later is shown. The diffuse cystic encephalomalacia seen here goes beyond the visualized DWI/ADC abnormalities seen on the neonatal MR, suggesting processes of delayed cell death continued after the neonatal period.*





(Left) *Axial DWI MR in an infant with partial HII shows diffuse cortical white matter and deep gray increased signal with sparing of the VLT and CST.* **(Right)** *Axial T2WI MR in the same infant at 6 months shows diffuse volume loss with scattered subtle areas of cortical thinning at the depths of sulci ⇨, indicating that regions of marked decreased diffusion as seen on the previous image do not always progress to frank cystic encephalomalacia.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Hypoxic ischemic injury (HII) includes global hypoxic ischemic injury, global anoxic injury, cerebral hypoperfusion injury
  - Etiologies: Cardiac arrest, cerebrovascular disease, drowning, asphyxiation

IMAGING

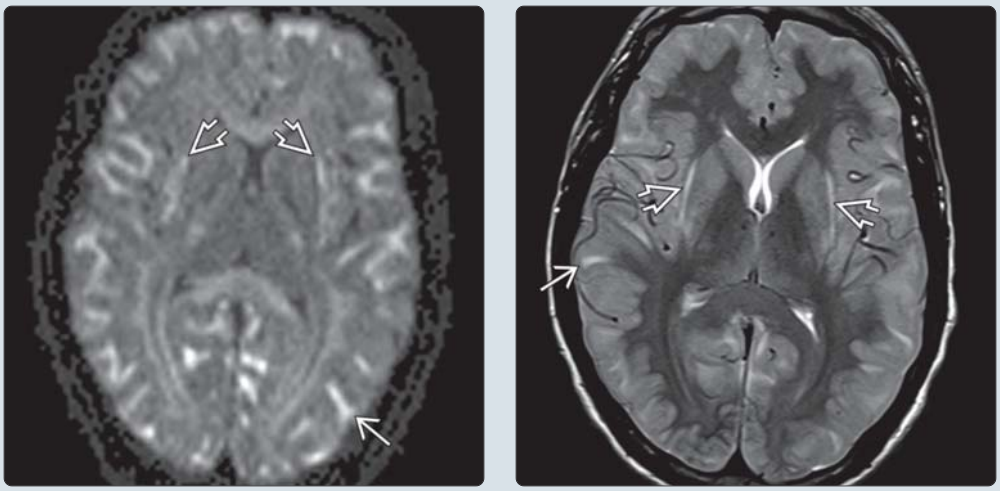
- Injury patterns highly variable depending on brain maturity, severity and length of insult
  - Mild to moderate: Watershed zone infarcts
  - Severe: Gray matter structures (basal ganglia, thalami, cortex, cerebellum, hippocampi)
- MR best to assess overall extent of injury within hours after HII event
  - DWI: 1st modality to be positive (within hours)
  - DWI: Restriction in deep nuclei ± cortex
  - T2/FLAIR: ↑ signal in cerebellum, basal ganglia, cortex
  - Acute changes not reliably identified with T2
- MRS: More sensitive and indicative of severity of injury in first 24 hours after HII
  - ↑ lactate, ↑ glutamine-glutamate

TOP DIFFERENTIAL DIAGNOSES

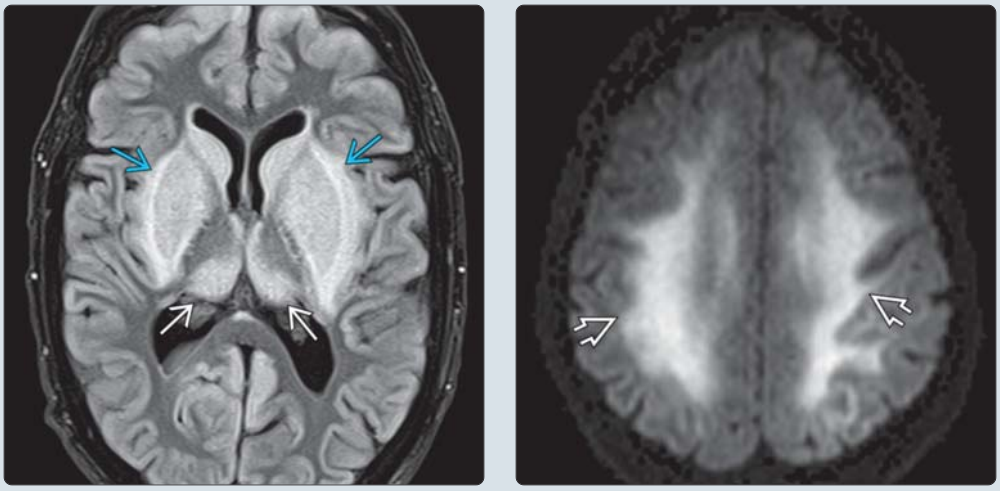
- Ischemic territorial infarction
- Traumatic cerebral edema
- Toxic/metabolic disorder
- Acute hypertensive encephalopathy, PRES
- Creutzfeldt-Jakob disease
- MELAS

PATHOLOGY

- Common underlying process regardless of cause
  - ↓ CBF and ↓ blood oxygenation
  - Switch from oxidative phosphorylation to anaerobic metabolism
  - Glutamate-related cytotoxic processes



(Left) *Axial DTI trace image in a 21-year-old unresponsive man shows extensive hyperintensity related to cytotoxic edema throughout the cortex and subcortical white matter (WM) ➡ as well as the external capsules ➡ in this patient with severe HII.* **(Right)** *Axial T2 MR in the same patient shows hyperintensity throughout the cortex, subcortical WM ➡, and the external capsules ➡. Complete effacement of the sulci is related to gyral swelling. Involvement of the visual and sensorimotor cortex is common in severe HII.*



(Left) *Axial FLAIR MR shows symmetric hyperintensity of the basal ganglia ➡ and thalami ➡ in this patient status post cardiac arrest. T2 and FLAIR images typically become positive in the early subacute period (> 24 hours to 2 weeks) with increased signal and swelling of the injured GM structures.* **(Right)** *Axial DTI trace image shows extensive WM hyperintensity ➡ related to cytotoxic edema in this 43-year-old woman with mild to moderate HII. DWI signal abnormalities may pseudonormalize by the end of the 1st week.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Hypoxic ischemic injury (HII), hypoxic ischemic encephalopathy (HIE)

Definitions

- Includes various etiologies of injury: Global hypoxic ischemic injury, global anoxic injury, cerebral hypoperfusion injury

IMAGING

General Features

- Best diagnostic clue
  - Symmetric T2/FLAIR hyperintensity in deep gray nuclei ± cortex
- Location
  - Mild to moderate: Watershed zone infarcts
  - Severe: Gray matter (GM) structures (basal ganglia [BG], thalami, cerebral cortex [sensorimotor and visual], cerebellum, hippocampi)
    - Cerebellar injury tends to be more common in older patients; Purkinje cells are sensitive to ischemia
  - Injury patterns are highly variable depending on brain maturity, severity and length of insult

CT Findings

- NECT
  - Diffuse cerebral edema with effacement of CSF-containing spaces
  - Decreased cortical gray matter attenuation with loss of normal gray-white differentiation
  - Decreased bilateral BG attenuation
  - Reversal or white cerebellum sign indicates severe injury with poor prognosis

MR Findings

- T1WI
  - Normal to very subtle abnormalities
  - BG may show T1 hyperintensity
  - Gray matter signal abnormalities may persist into end of 2nd week
  - Chronic stages show cortical pseudolaminar necrosis
- T2WI
  - Normal to very subtle abnormalities in first 24 hours
  - BG typically show T2 hyperintensity
  - Gray matter signal abnormalities may persist into end of 2nd week
  - Chronic stages show residual BG hyperintensity
- FLAIR
  - Symmetric hyperintensity in deep gray nuclei ± cortex
- DWI
  - 1st imaging modality to become positive, within hours after HII event
    - ↑ signal in cerebellar hemispheres, BG, cerebral cortex
  - DWI abnormalities pseudonormalize by end of 1st week
  - ADC is reduced in hyperacute phase following HII event due to influx of water from extra- to intracellular space
    - ADC values are reduced in severe white matter (WM) and in some severe BG and thalamic injury
    - ADC values may pseudonormalize or even be high initially in some less severe but clinically significant injuries
    - Abnormal ADC values pseudonormalize during 2nd week, whereas fractional anisotropy (FA) values continue to decrease
  - DTI: FA may be abnormal
    - Low FA may reflect breakdown in WM organization
    - Moderate BG/thalamic injury may result in atrophy but not overt infarct due to delayed apoptosis (may account for normal early ADC values)
      - Accompanying low FA within some severe and all moderate gray matter lesions → associated with significant later impairment
- PWI
  - In rat models, luxury perfusion immediately follows resuscitation from HII several hours of cortical and striatal mild hypoperfusion followed by hyperemia
- MRS
  - More sensitive and more indicative of injury severity in first 24 hours after HII
    - ↑ lactate at 1.3 ppm, ↑ glutamine-glutamate peak at 2.3 ppm
    - ↑ lactate after 24 hours portends poor neurologic outcome
    - NAA is usually normal in acute setting and declines 48 hours after acute injury

Imaging Recommendations

- Best imaging tool
  - MR, particularly DWI/DTI, is most sensitive modality to show abnormalities after ictus
- Protocol advice
  - DTI/DWI are most sensitive
  - Acute ischemic cerebral changes cannot be reliably identified with T2/FLAIR sequences
  - T2*GRE/SWI helpful to detect petechial or subarachnoid hemorrhage

DIFFERENTIAL DIAGNOSIS

Acute Cerebral Ischemia-Infarction

- Wedge-shaped T2 hyperintensity in vascular distribution
- DWI positive acutely

Traumatic Cerebral Edema/Ischemia

- Compressed ventricles and effaced sulci due to combination of vasogenic edema in WM and cytotoxic edema in GM → herniation of brain
- Vascular compression can lead to infarction

Toxic/Metabolic Disorder

- Selective vulnerability of GM to energy depletion
  - Carbon monoxide: T2 hyperintense GP ± subcortical WM
  - Methanol: Hyperintense putamen ± hemorrhagic necrosis
  - Mitochondrial encephalopathy: Symmetric BG abnormality
  - Drugs (heroin; methylenedioxymethamphetamine [MDMA], a.k.a. ecstasy): T2 hyperintense GP

https://CafePezeshki.IR

Acute Hypertensive Encephalopathy, PRES

- Predominantly vasogenic edema in subcortical WM of bilateral parietooccipital regions
- May involve deep gray nuclei

Creutzfeldt-Jakob Disease (CJD)

- Progressive T2 hyperintensity in BG, thalamus, and cerebral cortex
- FLAIR hyperintensity in cortex in sporadic CJD
- DWI: Restriction in deep gray nuclei and cortex; may resolve late in disease

MELAS

- **M**itochondrial myopathy, **e**ncephalopathy with **l**actic **a**cidosis, and **s**troke-like episodes
- Uncommon cause of childhood stroke
- Swollen T2 hyperintense gyri; crosses vascular distributions
- Spares subcortical and deep white matter

PATHOLOGY

Staging, Grading, & Classification

- Common underlying process regardless of cause of injury
  - Diminished cerebral blood flow and reduced blood oxygenation
  - Brain ischemia due to cardiac arrest or cerebrovascular disease and 2° to hypoxia due to ↓ blood flow
    - Switch from oxidative phosphorylation to anaerobic metabolism: ↓ ATP, ↑ lactate
    - Release of presynaptic glutamate → activation of NMDA receptors → triggers cytotoxic processes
      - Severe energy depletion → cell necrosis; lesser energy depletion → apoptosis
- Sites of brain injury determined by maturity of brain, severity of hypoxic-ischemic insult, and duration
- Selective vulnerability: Patterns of injury reflect dysfunction of selected excitatory neuronal circuits depleted most rapidly
  - Areas with highest concentrations of glutamate or excitatory amino acid receptors (GM) are more susceptible to injury
  - Areas with greatest energy demands become energy deficient
  - Cell death may not be evident until days after initial insult
- Delayed white matter injury: Postanoxic leukoencephalopathy
  - 2-3 weeks after HII in 2-3% of patients
  - Clinical stability followed by acute neurologic decline, most (75%) recover
- Brain-damaging effects of hypoxic-ischemia are age-dependent but do not increase linearly with advancing age and development
  - Immature brain is less resistant to HII than its adult counterpart
  - Intermediate age groups are more tolerant to HII than either very young or more mature ages
- Mechanism behind reduced diffusion during ischemia is thought to be caused by cytotoxic edema, which results from breakdown of cellular membrane Na/K pump system
  - As cytotoxic edema develops → shift of water from extracellular to intracellular space
  - Cell membrane remains intact, no overall ↑ in tissue water; **initially**: ↑ FA, ↓ ADC, normal T2
- Shorter intervals of HII primarily damage cerebral cortex and hippocampus, while longer periods result in more extensive damage and can be associated with cavitary lesions of cerebral hemispheres
  - Cavitary lesions, vertical band-like distribution of noncavitary lesions, mineralization more common in immature brain
- Patterns associated with poor clinical outcome: Diffuse cortical and deep gray matter pattern, medial occipital with perirolandic involvement, precentral gyrus involvement, diffuse white matter involvement, brainstem, cerebellar &/or hippocampal involvement

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Etiologies: Cardiac arrest, cerebrovascular disease, drowning, asphyxiation
  - Hypoxia in cases of near drowning involves putamen and caudate nucleus

Natural History & Prognosis

- Death or profound long-term neurologic disability
  - Neurological sequela, such as cerebral palsy and epilepsy

Treatment

- Supportive care; however, this does not prevent ongoing injury following causative insult
- Hypothermia
- Excitatory amino acid antagonists

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- If MR is negative in first 24 hours, repeat exam at 2-4 days to exclude delayed injury

Reporting Tips

- Important to describe extent of cortical and deep gray matter involvement

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

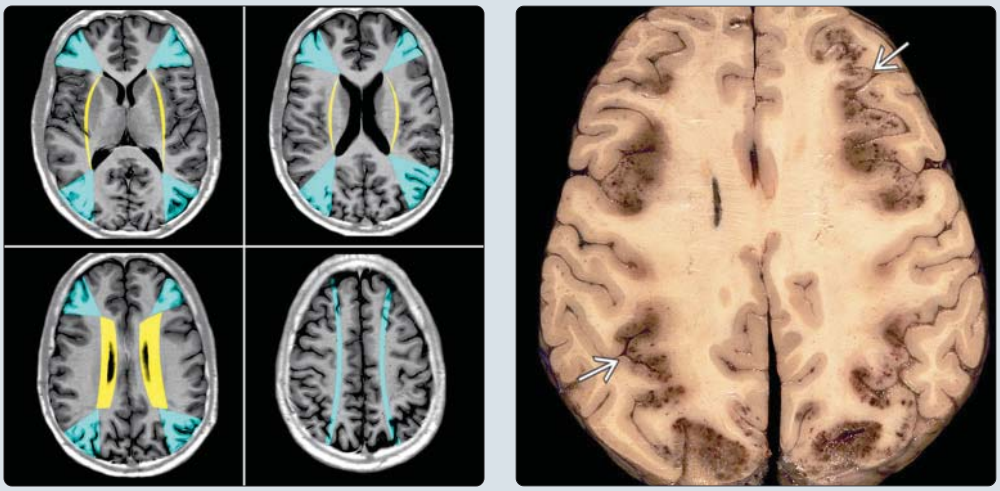
- Hypotensive cerebral infarction (HCI)
  - Infarction resulting from insufficient cerebral blood flow to meet metabolic demands (low-flow state)
  - 2 types of border zone or watershed infarcts
    - Border zone between major arterial territories
      - Typically at cortex, gray-white matter junctions
    - Border zone between perforating arteries
      - Typically in deep white matter (WM)

IMAGING

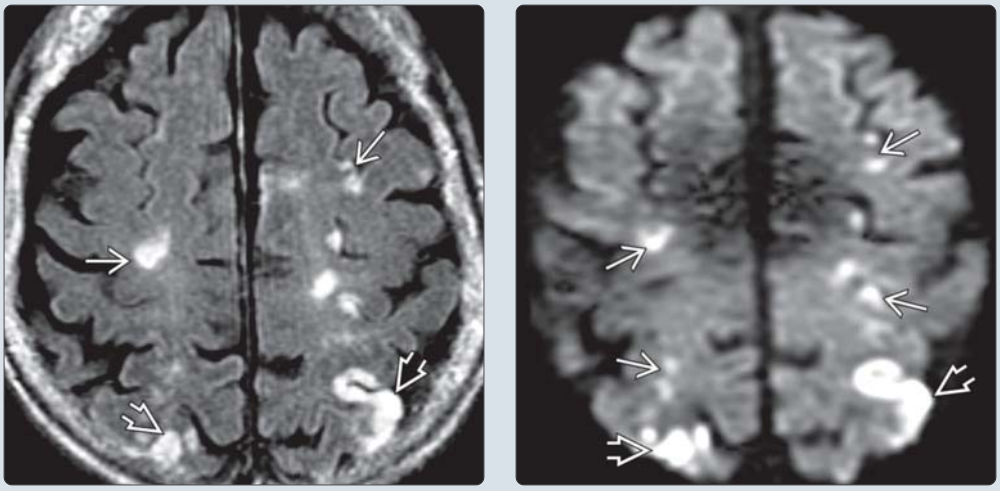
- Best imaging tool
  - MR with DWI/ADC ± pMR
- Cortical border zone
  - Between major arterial territories
  - Typically at gray-white matter junctions
  - Hypodensity between vascular territories
- White matter border zone
  - Between perforating arteries
  - Typically in deep WM (centrum semiovale)
  - ≥ 3 lesions
  - Linear AP orientation → string of pearls appearance
  - If unilateral, look for stenosis of major vessel
- Imaging recommendations
  - MR + GRE, DWI, MRA (both cervical, intracranial)
  - ± pMR (may show ↓ CBF to affected areas)
  - NECT, pCT, CTA if MR not available
  - CTA/DSA > MRA for determining total vs. near-occlusion of ICA

TOP DIFFERENTIAL DIAGNOSES

- Acute embolic cerebral infarction(s)
- Arteriosclerosis ("small vessel disease")
- Posterior reversible encephalopathy (PRES)
- Vasculitis
- Pseudolaminar necrosis (other causes [e.g., Reye, lupus, etc.])



(Left) *T1WI show 2 watershed (WS) zones. External WS zones are depicted in turquoise. Yellow lines indicate internal (deep white matter [WM]) watershed zones between perforating arteries and major territorial vessels.* **(Right)** *Axial gross pathology shows classic external (cortical) watershed infarcts ➡ from cerebral hypoperfusion. The patient survived several days, allowing for petechial hemorrhagic transformation to occur.*



(Left) *Axial FLAIR MR in a patient with transient global hypoperfusion secondary to a hypotensive episode shows multifocal hyperintensities along the cortical watershed zone ➡. Changes are most severe at the confluence of the ACA, PCA, and MCA cortical vascular territories ➡.* **(Right)** *DWI in the same patient shows corresponding areas of restricted diffusion in the cortical watershed zones bilaterally ➡, most severe at the trivascular confluence ➡. The diagnosis was hypotensive watershed cerebral infarctions.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hypotensive cerebral infarction (HCI)

Synonyms

- Border zone or watershed infarction

Definitions

- Infarction resulting from insufficient cerebral blood flow (CBF) to meet metabolic demands (low-flow state)

IMAGING

General Features

- Best diagnostic clue
  - Restricted diffusion on DWI/ADC
- Location
  - 2 types
    - Border zone between major arterial territories
      - Typically at gray-white matter junctions
    - Border zone between perforating arteries
      - Typically in deep white matter
  - Supratentorial structures in severe perinatal asphyxia
  - Bilateral abnormalities in global hypoxic-ischemic (HIE) events (with underlying vascular stenoses + relative hypoperfusion) can lead to unilateral presentations
- Morphology
  - Cortically based, wedge-shaped abnormality at border zone between vascular territories
  - Deep white matter (WM) watershed with rosary or string of pearls/beads appearance
    - Multiple round foci in linear orientation within centrum semiovale
  - Pseudolaminar necrosis = curvilinear, gyriform, cortical T1 shortening
  - Diffuse supratentorial abnormality (global HIE)

CT Findings

- NECT
  - Major arterial border zone infarcts
    - Hypodensity at gray-white matter junction between vascular territories
    - Severe (i.e., global HIE)
      - Usually significant hemodynamic compromise (i.e., hypotension)
      - Most all supratentorial gray-white matter junctions effaced
      - Basal ganglia (BG), thalami affected
      - Occasionally isolated to BG ± hippocampus
    - "White" cerebellum (sometimes called cerebellar reversal sign)
      - Cerebellum appears relatively hyperdense compared to supratentorial hypodensity
  - Deep WM watershed infarcts
    - ≥ 3 deep WM lesions within centrum semiovale
    - String of pearls appearance
      - Linear orientation in AP (front to back) direction
      - Parallel to lateral ventricle
      - Can resemble multiple emboli
    - Can be unilateral
      - Look for major vessel stenosis on side of infarcts
    - Bilateral if bilateral vessel stenoses ± significant hemodynamic event
- CECT
  - Enhancement in subacute HCI
- CTA
  - Use to determine complete vs. near-complete ICA occlusion
- CT perfusion
  - CBF ↓ in affected areas

MR Findings

- T1WI
  - Acute: Hypointense, swollen gyri ± BG
  - Subacute: Gyriform cortical hyperintensity = pseudolaminar necrosis
    - Usually with global HIE
- T2WI
  - Hyperintensity in involved areas
  - CSF cisterns/sulci compressed if severe
- FLAIR
  - Thrombosed vessels often hyperintense
  - More sensitive to early infarction
- DWI
  - Restricted diffusion (hyperintense on DWI, hypointense ADC)
    - Distinguishes cytotoxic from vasogenic edema
    - Helpful for evaluation following intraoperative anoxia
  - Global HIE may be diffusely hyperintense
    - Creates nearly "pseudonormal" appearance
- T1WI C+
  - Subacute infarcts enhance
    - Gyriform pattern common
    - ± basal ganglia
- MRA
  - Major vessel stenoses predispose to watershed infarction following hypotensive event
- MRS
  - ↑ lactate, ↓ NAA ± lactate doublet (intermediate TE)

Angiographic Findings

- DSA may delineate predisposing conditions for watershed infarct
  - Significant extracranial, major intracranial vessel stenosis

Imaging Recommendations

- Best imaging tool
  - MR + GRE, MRA, DWI
- Protocol advice
  - MR + DWI, MRA (both cervical, intracranial), ± pMR
  - NECT, pCT, CTA if MR unavailable

DIFFERENTIAL DIAGNOSIS

Cerebral Infarction (Acute, Multiple Embolic)

- Often bilateral, multiterritorial
- May also occur at border zones

Arteriosclerosis ("Small Vessel Disease")

- Scattered, multifocal lesions
- No specific predilection for watershed
- Confluent lesions around lateral ventricle atria
  - Common in chronic hypertension

https://CafePezeshki.IR

Posterior Reversible Encephalopathy (PRES)

- Usually does not restrict (vasogenic edema)
- Usually cortical/subcortical PCA distribution
- Less commonly can involve watershed zones, BG

Vasculitis

- Often subcortical
- Patchy enhancement in cortex, subcortical WM, BG

Pseudolaminar Necrosis (Other Causes)

- Associations with numerous other entities
  - Reye, lupus, central pontine myelinolysis, immunosuppressive therapy
- Petechial hemorrhage ("hemorrhagic transformation") in subacute thrombolic infarct

PATHOLOGY

General Features

- Etiology
  - Global brain injury due to disruption of perfusion or oxygenation
  - Causes include severe prolonged hypotension, cardiac arrest with resuscitation, profound asphyxia, and carbon monoxide inhalation
  - Major vessel stenoses predispose patient to infarcts at "border zone" between vascular territories during times of hemodynamic compromise
    - Deep WM infarcts (rosary pattern) correlate well with clinical hemodynamic compromise
    - Associated with proximal ICA stenosis/occlusion
  - Embolic infarcts also occur at border zones and thus complicate clinical and radiographic picture
    - Cortical border zone infarcts occur in 3.2% in patients with cardiac embolic sources
      - Compared to 3.6% in those with severe ICA obstruction
    - Directed embolization may account for many embolic-type, border zone infarcts (directional flow at bifurcations occurs from vessel size imbalances in circle of Willis)
- Border zone infarction → encephalomalacic brain ± "ulegyria"

Staging, Grading, & Classification

- Pattern classifications
  - Cortical border zone infarcts (bi- or unilateral)
  - Deep WM infarcts (penetrating artery watershed zone)
  - Cortical pseudolaminar necrosis
  - Predominately deep gray nuclei

Gross Pathologic & Surgical Features

- Pale, swollen brain; gray-white matter boundaries "smudged"
- Encephalomalacia (chronic)

Microscopic Features

- After 4 hours: Eosinophilic neurons with pyknotic nuclei
- 15-24 hours: Neutrophils invade, necrotic nuclei look like eosinophilic "ghosts"
- 2-3 days: Blood-derived phagocytes
- 1 week: Reactive astrocytosis, ↑ capillary density
- End result: Fluid-filled cavity lined by astrocytes
- Pseudolaminar necrosis affects 3rd, 5th, and 6th cortical layers

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Altered mental status, coma
- Clinical profile
  - Patient with high-grade ICA stenosis, transient hypotension leading to acute cerebral infarction
  - Resuscitated patient with profound asphyxia or prolonged systemic hypotension

Demographics

- Age
  - Any age
- Gender
  - No gender predilection
- Epidemiology
  - Hypotensive infarcts account for 0.7-3.2% of infarcts

Natural History & Prognosis

- Experimental literature suggests isolated hypoxic injury tolerated better than hypoxia complicated by hypotension
- Clinical outcome usually poor; depends on degree of injury
- Diffusion abnormalities restricted to deep nuclei without involvement of cerebral cortex suggest milder injury, and significant neurological recovery can occur

Treatment

- Treatment of underlying conditions
  - Correction of hypotension as rapidly as possible
  - Revascularization of major vessel stenoses

DIAGNOSTIC CHECKLIST

Consider

- MRA, CTA of cervical, intracranial vessels as proximal large vessel disease often present in setting of hypotensive infarction

Image Interpretation Pearls

- "Rosary" or "string of beads" appearance in centrum semiovale highly specific for hemodynamic compromise

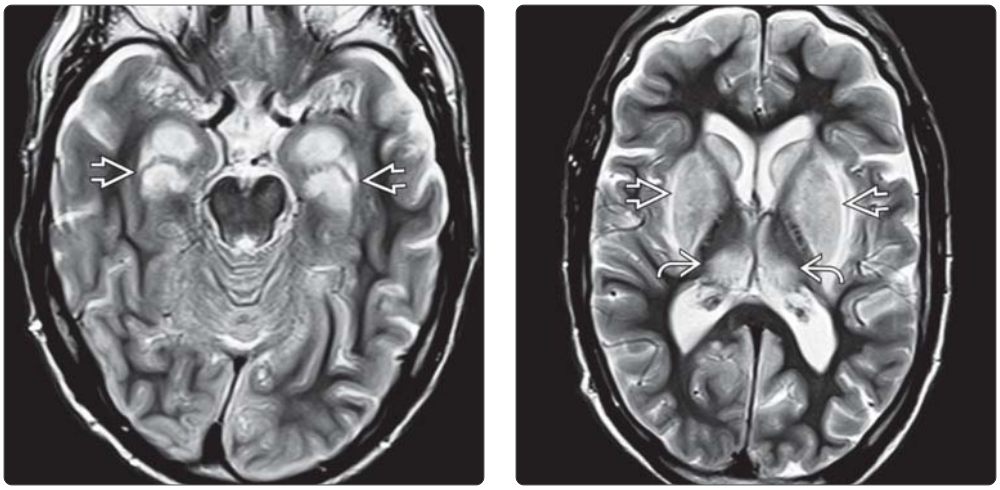
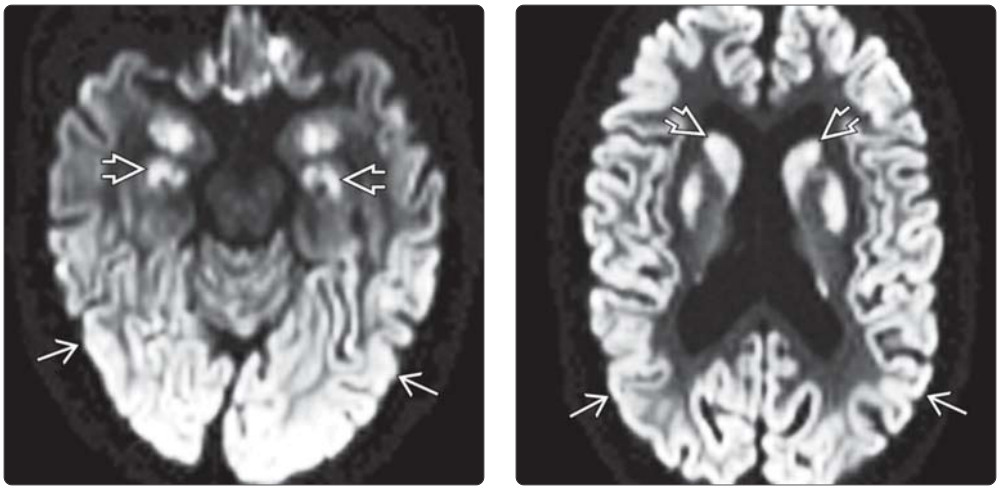
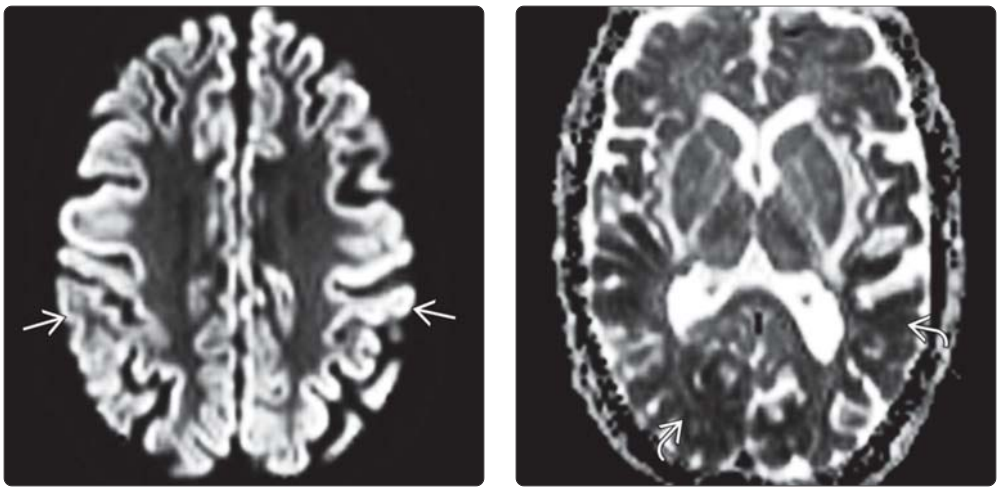
https://CafePezeshki.IR



(Left) *Axial T2WI in a 53-year-old man who suffered a cardiac arrest with prolonged resuscitation shows symmetric hyperintensity in both hippocampi ⇨. While not as noticeable, the cortical gray matter is also diffusely hyperintense.* **(Right)** *More cephalad T2WI in the same patient shows symmetric hyperintensity in the basal ganglia ⇨ and both thalami ⇨.*



(Left) *DWI in the same patient shows symmetric diffusion restriction in the hippocampi ⇨ and cortex ⇨.* **(Right)** *More cephalad DWI shows restricted diffusion in the basal ganglia ⇨. The symmetric diffusion restriction in the cortex ⇨ greatly accentuates the gray-white interface.*



(Left) *More cephalad image through the corona radiata shows the "super bright" cortex ⇨. The restricted diffusion is so severe and symmetric that it can be overlooked.* **(Right)** *ADC in the same patient through the basal ganglia shows that the restricted diffusion probably also involves the subcortical and deep white matter ⇨ in addition to the cortex and basal ganglia.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Acute alteration of neurologic function due to loss of vascular integrity

IMAGING

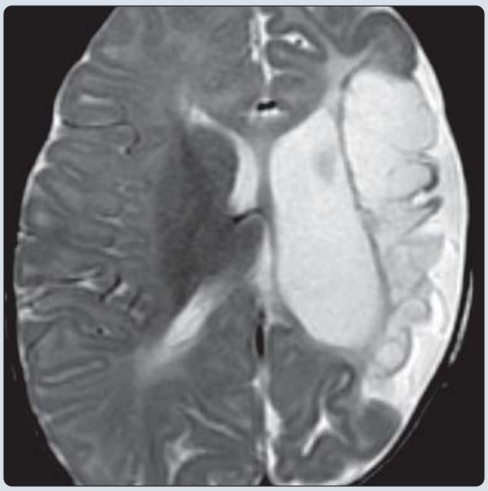
- Best imaging
  - MR with diffusion, perfusion, MRA
  - MRV if MRA negative and DWI positive
  - Can do emergent "limited" MR (FLAIR, DWI, SWI)
- Imaging findings
  - CT
    - "Insular ribbon" sign = loss of distinction of insular cortex
    - Hyperdense MCA sign (HMCAS) = increased density of thrombosed MCA
    - Look for calcified emboli (suggests heart disease)
    - ± CTA
  - MR
    - DWI is most sensitive imaging sequence for ischemic injury
    - Perfusion studies can identify ischemic penumbra
    - FLAIR may show intravascular signal
    - Arterial wall imaging may identify vasculopathy

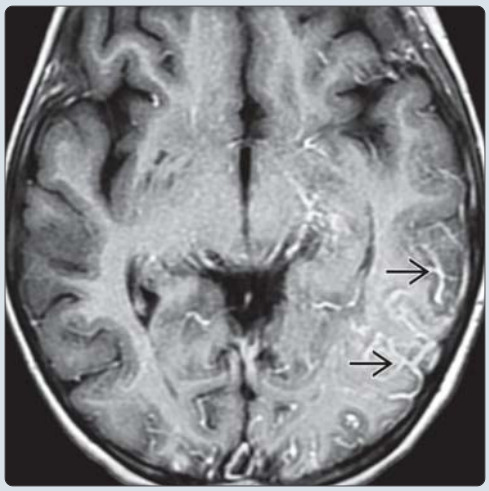
PATHOLOGY

- Etiology
  - Most common: Cardiac disease (25-50%)
  - Other: Sickle cell (200-400x increased risk), trauma
  - No underlying cause discovered in > 33% of cases

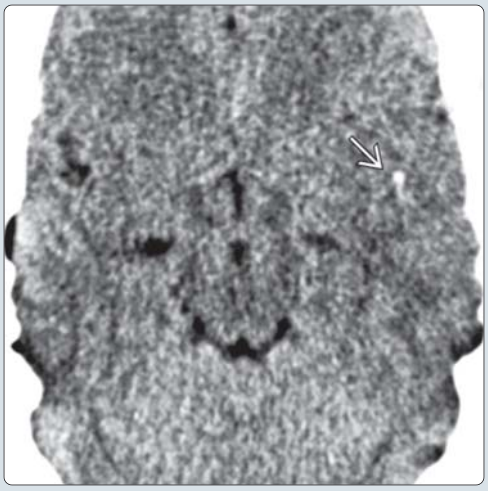
CLINICAL ISSUES

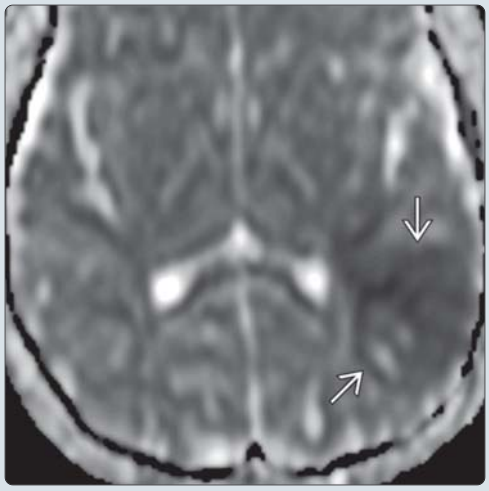
- Under-recognized as significant source of morbidity in pediatric population
  - Can be mistaken for seizure (postictal), migraine
  - Children with stroke often have delayed presentation
  - High risk of recurrence (20-40%), especially with calcified emboli





(Left) *Axial T2WI MR shows mature encephalomalacia in the vascular territory of the left MCA in this 4 month old with left hand preference. Handedness should not be apparent before 12-18 months.* **(Right)** *Axial T1WI C+ MR shows the characteristic "climbing ivy" sign of enhancing sulcal arteries ⇨ in a child with moyamoya vasculopathy secondary to sickle cell disease. Slow flow in MCA branches distal to the stenosis allows T1 shortening from contrast to overcome flow void effects.*





(Left) *Axial NECT in 15 year old with difficulty speaking and right hand weakness shows a hyperdense MCA ⇨. The patient presented 12 hours after symptom onset and was treated with aspirin only.* **(Right)** *Axial ADC in the same teenager shows reduced diffusion ⇨ in the distal left MCA territory. Encephalomalacia developed, but the patient had a normal neurologic exam 6 months later. Children often have a much greater capacity for neurologic recovery than adults, even with similar imaging findings.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Cerebral infarct, cerebral ischemia

Definitions

- Acute alteration of neurologic function due to loss of vascular integrity
  - Can be arterial or venous
  - Can be hemorrhagic or nonhemorrhagic

IMAGING

General Features

- Best diagnostic clue
  - Edema, restricted diffusion in affected territory
- Location
  - Proximal and distal middle cerebral artery (MCA) territory is most commonly affected
- Morphology
  - Stroke caused by arterial occlusion often conforms to arterial territory
  - Venous territories typically less well recognized

CT Findings

- NECT
  - Decreased attenuation of affected gray matter (GM)
    - "Insular ribbon" sign
      - Loss of distinction of insular cortex
  - Hyperdense MCA sign (HMCAS)
    - Increased density of thrombosed MCA
  - Hemorrhagic conversion of stroke
    - Cortical hemorrhage often petechial
    - White matter (WM) or deep nuclear hemorrhage often mass-like
      - Hematoma within infarcted tissue
  - Hyperdense dural sinus in venous thrombosis
    - "Delta" sign
- CECT
  - Enhancement of infarcted territory typically occurs after 5-7 days
  - Enhancement of sagittal sinus wall around nonenhancing clot
    - "Empty delta" sign
- CTA
  - Invaluable for demonstrating focal vascular abnormalities in acute setting
  - Can clearly show arterial occlusion/stenosis
  - Can be used to assess effect of treatment on vessel
    - Restoration of vascular integrity may not correlate with return of neurologic function

MR Findings

- T1WI
  - Gyral swelling and hypointensity in affected territory
  - Loss of normal vascular flow void
    - Entry slice artifact can cause false-positive
    - Irregular signal can be seen in normal veins due to slow flow
- T1WI FS
  - Use of fat saturation allows confident identification of crescent of mural hematoma in dissected vessel
    - Use in combination with MRA
- T2WI
  - Edema evident in affected territory after 12-24 hours of arterial occlusion
- FLAIR
  - More sensitive than T2WI for ischemia-induced cytotoxic edema
    - Hyperintense after 6-12 hours
  - Also shows loss of normal arterial flow voids
    - "Climbing ivy" sign = bright vessels in sulci distal to arterial occlusion (slow flow)
      - Same effect is seen with T1WI C+
      - Classically seen in moyamoya disease
- T2* GRE
  - Sensitive for detection of blood products, especially hemosiderin
    - May impact clinical decision making for acute therapy
- DWI
  - Most sensitive imaging sequence for ischemic injury
  - Diffusion restriction seen within 45 minutes of arterial occlusion
  - Apparent diffusion coefficient (ADC) mapping essential to avoid false-positive from T2 shine through
- PWI
  - Can provide valuable information regarding region at risk in setting of acute stroke
  - Ischemic penumbra = region with diminished perfusion not yet infarcted (perfusion-diffusion mismatch)
  - May define brain salvageable with acute stroke therapy
  - Arterial spin-labeling techniques hold promise for standardized perfusion imaging without contrast administration
- T1WI C+
  - Can provide earliest sign of proximal arterial occlusion = enhancement of arteries in territory distal to occlusion
    - Collateral flow to distal vascular bed is slower
    - Normal flow void caused by rapid arterial flow is outweighed by T1 shortening effect of contrast
  - Arterial wall imaging (3D acquisition, 1 mm spin-echo with contrast) may identify vasculopathy
- MRA
  - Sensitive in detection of arterial occlusion and stenosis in large and medium-sized cerebral vessels
- MRV
  - Can demonstrate focal occlusion, stenosis, or response to treatment
- MRS
  - ↑ lactate is hallmark of ischemia/infarct

Ultrasonographic Findings

- Grayscale ultrasound
  - Affected territory hyperechoic in acute/subacute stage
- Color Doppler
  - Direct Doppler evaluation ideal for surveillance of vascular occlusion in neonate with open sutures
  - Transcranial Doppler evaluation of circle of Willis through temporal squamosa
    - Increased velocities can predict stenoses detectable by MRA

https://CafePezeshki.IR

- Used as screening tool in children with sickle cell anemia

Angiographic Findings

- Catheter angiography rarely necessary in acute evaluation of childhood stroke
  - Only justified if contemplating endovascular therapy
- Best modality for detailed evaluation of primary arteriopathies

Imaging Recommendations

- Best imaging tool
  - MR with diffusion, perfusion, MRA
    - MRV if MRA negative and DWI positive
  - Can do emergent "limited" MR (FLAIR, DWI, SWI)

DIFFERENTIAL DIAGNOSIS

Mitochondrial Encephalopathies

- Mitochondrial myopathy, encephalopathy, lactic acidosis, and strokelike episodes syndrome (MELAS), myoclonic epilepsy with ragged red fibers (MERRF)

Encephalitis

- Viral encephalitides, ADEM, cerebritis

Toxins

- Carbon monoxide poisoning, ethylene glycol

PATHOLOGY

General Features

- Etiology
  - No underlying cause discovered in > 33% of cases
- Associated abnormalities
  - Cardiac disease (25-50%), sickle cell (200-400x increased risk), trauma
  - Chemotherapy, sepsis

Gross Pathologic & Surgical Features

- Pathologic findings similar to adults
- Anterior circulation > posterior; left > right

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Focal deficit often masked by lethargy, coma, irritability
  - Seizure = deficit often attributed to postictal state
- Other signs/symptoms
  - Speech difficulties, gait abnormality
  - Preceding transient events occur in 25%
- Under-recognized as significant source of morbidity in pediatric population
  - Children with stroke typically present in delayed fashion (> 24 hours)
    - Poor recognition/understanding of symptoms by child, caregiver, physician

Demographics

- Age
  - Incidence/mortality greatest in infants < 1 year old
- Gender
  - Boys > girls
- Epidemiology
  - 2-3/100,000 per year in USA
  - Mortality: 0.6/100,000
  - "Stroke belt"
    - Higher incidence in southeastern United States
  - Recent head/neck injury or infection increases odds ratio for stroke
  - Recognize syndromes with vasculopathy (NF1, PHACE, sickle cell disease)

Natural History & Prognosis

- Recurrence (20-40%)
- Capacity for recovery much greater than in adults
  - Fewer concomitant risk factors
  - Better quality of collateral vessels

Treatment

- Clinical window of opportunity/benefit much narrower than in adults
- Aspirin is mainstay of chronic therapy for fixed vascular lesions and vasculopathies
- Transfusion therapy for at-risk children with sickle cell disease
- Thrombolytic therapy has been used in a small number of cases
  - Higher than acceptable risk of hemorrhage
  - Use is mitigated by good outcome with less aggressive therapy in many cases

DIAGNOSTIC CHECKLIST

Consider

- Always consider stroke when evaluating a child with new onset seizure

Reporting Tips

- Be sure to investigate for hemorrhagic complications

Cerebral Hemiatrophy

KEY FACTS

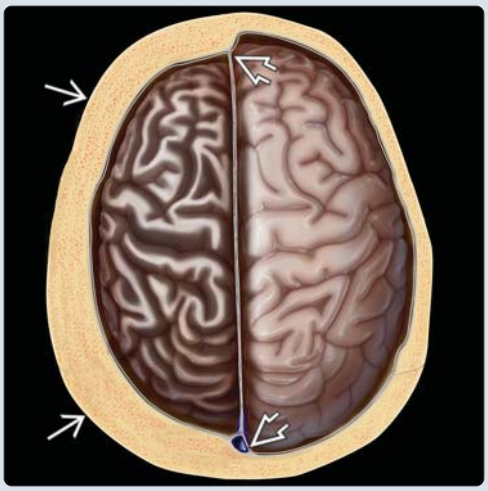
TERMINOLOGY
- Cerebral hemiatrophy (CH)
- Dyke-Davidoff-Masson syndrome (DDMS)

IMAGING
- General findings
  - Unilateral cerebral atrophy
  - Ipsilateral paranasal sinuses, mastoid hyperpneumatized
  - Ipsilateral calvarial thickening
- Associated findings
  - Ipsilateral cerebral peduncle, thalamus atrophic (wallerian degeneration)
  - ± crossed cerebellar atrophy/diaschisis
- MR may be helpful for etiology of hemiatrophy
  - Vascular/infectious insult
  - Encephalomalacia/gliosis
  - Corresponding T2/FLAIR hyperintensity

TOP DIFFERENTIAL DIAGNOSES
- Sturge-Weber syndrome
- Rasmussen encephalitis
- Hemimegalencephaly
- Large MCA infarction

PATHOLOGY
- In utero/early childhood (< 3 years) hemispheric insult
  - Unilateral
  - Usually vascular, traumatic, less commonly infectious
  - Lack of ipsilateral brain growth
  - Calvarial diploic spaces, sinuses expand inward

CLINICAL ISSUES
- Contralateral hemiplegia/hemiparesis
- Facial asymmetry, mental retardation
- Hemispherectomy for intractable seizures
  - 85% success rate if performed early



(Left) *Graphic depicts Dyke-Davidoff-Masson syndrome. The right hemisphere is shrunken and atrophic with a thickened overlying calvaria. If the insult occurs early in development, the falx will be inserted off midline.* **(Right)** *Coronal T1WI C+ FS MR shows an atrophic right hemisphere. The falx inserts off midline, and the left temporal bone is expanded and the mastoid ridge is elevated. The calvaria is thickened compared to the normal left side. (Courtesy M. Edwards-Brown, MD.)*

(Left) *Axial T2 MR image in a 16 year old with seizures and hemiparesis shows the classic features of Dyke-Davidoff-Masson syndrome with left hemisphere volume loss, thickened calvaria, and a markedly enlarged frontal sinus.* **(Right)** *Axial FLAIR MR in the same patient shows cortical atrophy and white matter gliosis. Note the enlarged lateral ventricle and the thickened calvaria. Lack of ipsilateral brain growth causes calvarial thickening and enlargement and hyperpneumatization of the paranasal sinuses.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Cerebral hemiatrophy (CH)

Synonyms

- Dyke-Davidoff-Masson syndrome (DDMS)

Definitions

- Syndrome of hemiplegia, seizures, facial asymmetry, and mental retardation

IMAGING

General Features

- Best diagnostic clue
  - Unilateral cerebral atrophy plus
    - Ipsilateral calvarial thickening
    - Ipsilateral paranasal sinuses, mastoid hyperpneumatized
- Location
  - 70% left hemisphere predominance
  - Right hemisphere ↑ perfusion may be protective in first 3 years of life

Imaging Recommendations

- Best imaging tool
  - NECT + bone CT

Radiographic Findings

- Radiography
  - Unilateral calvarial thickening
  - Ipsilateral expansion of paranasal sinuses, mastoid air cells
  - Elevation of ipsilateral greater sphenoid wing, petrous ridge

CT Findings

- NECT
  - Cerebral hemiatrophy
    - Enlarged sulci, CSF spaces
    - Ipsilateral enlarged ventricles
  - Ipsilateral hyperpneumatization
    - Paranasal sinuses
    - Mastoid air cells
  - ± contralateral mild compensatory hemispheric hypertrophy
- Bone CT
  - Ipsilateral calvaria may be thickened

MR Findings

- MR may be helpful for etiology of hemiatrophy
  - Hyperintensity on T2/FLAIR
  - Encephalomalacia, gliosis (vascular or infectious insult)
- Wallerian degeneration
  - Ipsilateral cerebral peduncle, thalamic atrophy

DIFFERENTIAL DIAGNOSIS

Sturge-Weber Syndrome

- Facial port wine stain + ipsilateral atrophy
- Pial angioma + dystrophic cortical Ca++
- Ipsilateral choroid plexus enlarged
- Skull, sinuses, mastoid may resemble DDMS

Rasmussen Encephalitis

- Rare cause of focal intractable seizures
- Hemiatrophy centered in medial temporal lobe, around sylvian fissure
- No calvarial features of DDMS

Hemimegalencephaly

- Hamartomatous overgrowth of cerebral hemisphere
- Smaller side is normal

Large MCA Infarction

- Atrophy limited to MCA distribution
- Insult after significant calvarial growth has occurred
- Lacks DDMS calvarial changes

PATHOLOGY

General Features

- Etiology
  - In utero/early childhood, unilateral hemispheric insult
    - Usually vascular, traumatic, or less commonly infectious
  - Lack of ipsilateral brain growth
    - Calvarial diploic spaces, sinuses expand inward
- Associated abnormalities
  - Crossed cerebellar atrophy/diaschisis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Contralateral hemiplegia/hemiparesis
  - Seizures, mental retardation

Demographics

- Age
  - Any age
  - Insult typically in utero or early childhood (< 3 years old)
- Gender
  - Males (70%), females (30%)
  - Males may be functionally more "hemispherically asymmetric"

Treatment

- Hemispherectomy for intractable seizures
  - 85% success rate if performed early

KEY FACTS

TERMINOLOGY

- Interrupted blood flow to brain resulting in cerebral ischemia/infarction with variable neurologic deficit

IMAGING

- Major artery (territorial) infarct
  - Generally wedge-shaped; both gray matter (GM), white matter (WM) involved
- Embolic infarcts
  - Often focal/small, at GM-WM interface
- NECT
  - Hyperdense vessel = clot ("dense MCA" sign)
  - Loss of GM-WM distinction in first 3 hours (50-70%)
    - "Insular ribbon" sign: GM-WM interface lost
    - "Disappearing basal ganglia" sign
  - Calcified embolus
    - Don't miss this (high risk of recurrent stroke)
- CTA: Excellent for major vessel occlusions
- pCT: CBF/CBV "mismatch" estimates penumbra
- MR
  - Parenchymal ± intraarterial FLAIR hyperintensity
  - ↑ intensity on DWI with corresponding ↓ on ADC
  - ↓ CBF, CBV on perfusion MR

TOP DIFFERENTIAL DIAGNOSES

- Hyperdense vessel mimics
- Parenchymal hypodensity (nonvascular causes)

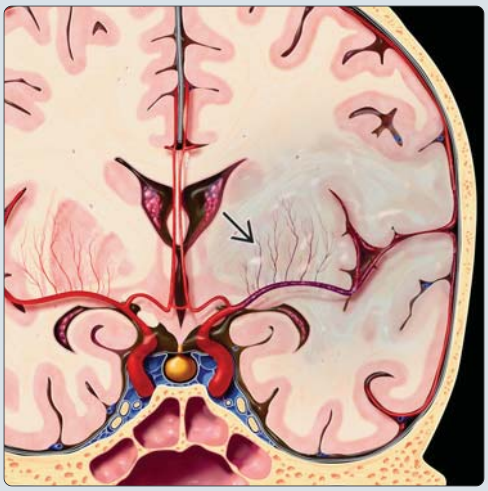
PATHOLOGY

- Severely ischemic core
  - CBF < (6-8 cm^3)/(100 g/min)
- Peripheral penumbra
  - CBF between (10-20 cm^3)/(100 g/min)

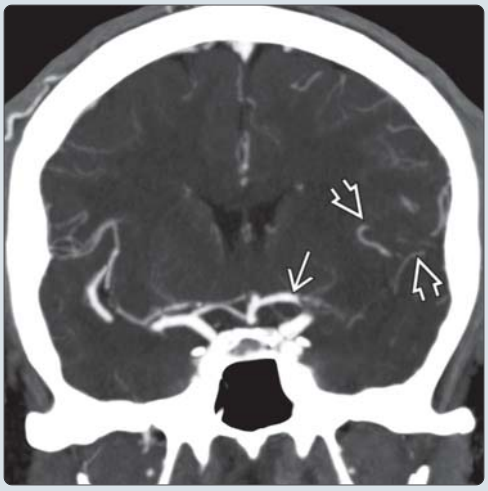
CLINICAL ISSUES

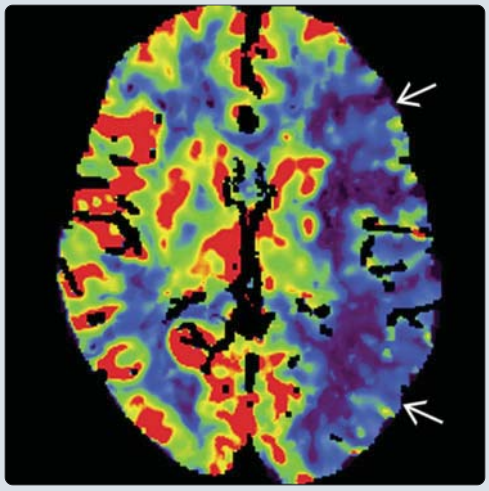
- 2nd most common cause of death worldwide
- #1 cause of morbidity in USA
- IV thrombolysis (< 3 hours of symptom onset)

(Left) *Coronal graphic illustrates left M1 occlusion. Proximal occlusion affects the entire MCA territory, including the basal ganglia (perfused by lenticulostriate arteries ⇨). Acute ischemia is often identified by subtle loss of the gray-white interfaces with blurring of the basal ganglia and an "insular ribbon" sign on the initial CT.* **(Right)** *NECT scan in a 46-year-old man shows a very "dense" left MCA ⇨ compared to the normal minimally hyperdense right MCA ⇨.*



(Left) *Coronal MIP view of the CTA in the same patient shows a proximal left MCA occlusion ⇨. Minimal filling of the distal MCA branches ⇨ is occurring via collaterals from the ACA and PCA.* **(Right)** *Axial CT perfusion shows decreased cerebral blood flow in the left MCA distribution ⇨.*





https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Stroke, cerebrovascular accident (CVA), brain attack

Definitions

- Interrupted blood flow to brain resulting in cerebral ischemia/infarction with variable neurologic deficit

IMAGING

General Features

- Best diagnostic clue
  - High signal on DWI with corresponding low signal on ADC (reduced diffusivity)
  - Decreased cerebral blood flow (CBF) and cerebral blood volume (CBV) on CT or MR perfusion
- Location
  - ≥ 1 vascular territories or at border-zones ("watershed")
- Size
  - Dependent on degree of compromise and collateral circulation
- Morphology
  - Territorial infarct
    - Conforms to arterial territory
    - Generally wedge-shaped, both gray matter (GM) and white matter (WM) involved
  - Embolic infarcts (often focal, at GM/WM interface)

CT Findings

- NECT
  - Hyperdense vessel (high specificity, low sensitivity)
    - Represents acute thrombus in cerebral vessel(s)
    - Hyperdense M1 MCA in 35-50%
    - "Dot" sign: Occluded MCA branches in sylvian fissure (16-17%)
  - Loss of GM-WM distinction in 1st 3 hours (50-70%)
    - Obscuration of deep gray nuclei
    - Loss of cortical "ribbon"
  - Parenchymal hypodensity
    - If > 1/3 MCA territory initially, larger lesion usually develops later
    - Temporary transition to isodensity (up to 54%) at 2-3 weeks post ictus (CT "fogging")
  - Gyral swelling, sulcal effacement appears between12-24 hours
  - "Hemorrhagic transformation" in 15-45%
    - Delayed onset (24-48 hours) most typical
    - Can be gross (parenchymal) or petechial
  - Calcified embolus
    - Round/ovoid hyperdensity in vessel lumen or sulcus
    - Source: Heart (calcific valvular disease) > cervical ASVD
    - High risk for recurrent strokes
- CECT
  - Enhancing cortical vessels: Slow flow or collateralization acutely
  - Absent vessels: Occlusion
  - Perfusion CT (pCT): Assess ischemic core vs. penumbra; identify patients who benefit most from revascularization
    - pCT calculates CBF, CBV, time to peak (TTP); deconvolution can give mean transit time (MTT)
  - Cortical/gyral enhancement after 48-72 hours
- CTA: Identify occlusions, dissections, stenoses, status of collaterals

MR Findings

- T1WI
  - Early cortical swelling and hypointensity, loss of GM-WM borders
- T2WI
  - Cortical swelling, hyperintensity develops by 12-24 hours
  - May normalize 2-3 weeks post ictus (MR "fogging")
- FLAIR
  - Parenchymal hyperintensity appears (6 hours post ictus) while other sequences normal
  - Intraarterial FLAIR hyperintensity is early sign of major vessel occlusion or slow flow
- T2* GRE
  - Detection of acute blood products
  - Arterial "blooming" (thrombosed vessel) from clot susceptibility
  - May see susceptibility from Ca++ embolus
- DWI
  - Hyperintense (cytotoxic edema)
    - Improves hyperacute stroke detection to 95%
    - Usually correlates to "infarct core" (final infarct size); some diffusion abnormalities reversible (TIA, migraine)
    - May have reduced sensitivity in brainstem and medulla in first 24 hours
    - Restriction typically lasts 7-10 days
      - High signal can persist up to 2 months post ictus
      - After 10 days, T2 effect may predominate over low ADC: T2 "shine-through"
  - Corresponding low signal on ADC maps
    - May normalize after tissue reperfusion
    - Hyper- or isointensity on ADC map (T2 "shine-through") may mimic diffusion restriction
  - Distinguish cytotoxic from vasogenic edema in complicated cases
    - May be helpful to evaluate new deficits after tumor resection
- PWI
  - Dynamic contrast bolus or arterial spin labeled techniques
    - Maximum slope gives relative CBF, CBV
    - Deconvolution gives absolute values
  - Bolus-tracking T2* gadolinium perfusion imaging (PWI) with CBV map
    - ↓ perfusion; 75% larger than DWI abnormality
    - DWI/PWI "mismatch": Penumbra or "at-risk" tissue
- T1WI C+
  - Variable enhancement patterns evolve over time
    - Hyperacute: Intravascular enhancement (stasis from slow antegrade or retrograde collateral flow)
    - Acute: Meningeal enhancement (pial collateral flow appears in 24-48 hours, resolves over 3-4 days)
    - Subacute: Parenchymal enhancement (appears after 24-48 hours, can persist for weeks/months)
- MRA: Major vessel occlusions, stenoses, status of collaterals
- MRS: Elevated lactate, decreased NAA

https://CafePezeshki.IR

- Conventional MR sequences positive in 70-80%
  - Restricted diffusion improves accuracy to 95%
- Diffusion tensor imaging (DTI)
  - Multidirectional diffusion-weighted images; at least 6 directions can be used to calculate DTI trace and ADC maps
    - Higher spatial resolution
  - May be more sensitive for small ischemic foci, emboli, cortical strokes

Angiographic Findings

- Conventional: Vessel occlusion (cut-off, tapered, "tram track")
  - Slow antegrade flow, retrograde collateral flow
- Neurointerventional: IA fibrinolytic therapy for treatment of selected acute nonhemorrhagic stroke within 6-hour window
  - IA mechanical clot removal with retriever device

Imaging Recommendations

- Best imaging tool
  - MR + DWI, T2* GRE
- Protocol advice
  - NECT as initial study to exclude hemorrhage/mass
    - CT perfusion and CTA if available
  - MR with DWI, FLAIR, GRE ± MRA, PWI
  - DSA with thrombolysis in selected patients

DIFFERENTIAL DIAGNOSIS

Hyperdense Vessel Mimics

- High hematocrit (polycythemia)
- Microcalcification in vessel wall
- Diffuse cerebral edema makes vessels appear relatively hyperdense
- Normal circulating blood always slightly hyperdense to normal brain

Parenchymal Hypodensity (Nonvascular Causes)

- Infiltrating neoplasm (e.g., astrocytoma)
- Cerebral contusion
- Inflammation (cerebritis, encephalitis)
- Evolving encephalomalacia
- Dural venous thrombosis with parenchymal venous congestion and edema
- Seizure

PATHOLOGY

General Features

- Etiology
  - Many causes (thrombotic vs. embolic, dissection, vasculitis, hypoperfusion)
  - Early: Critical disturbance in CBF
    - Severely ischemic core has CBF < (6-8 cm^3)/(100 g/min) (normal ~ [60 cm^3]/[100 g/min])
    - Oxygen depletion, energy failure, terminal depolarization, ion homeostasis failure
    - Bulk of final infarct → cytotoxic edema, cell death
  - Later: Evolution from ischemia to infarction depends on many factors (e.g., hyperglycemia influences "destiny" of ischemic brain tissue)
  - Ischemic penumbra CBF between (10-20 cm^3)/(100 g/min)
    - Theoretically salvageable tissue
    - Target of thrombolysis, neuroprotective agents
- Associated abnormalities
  - Cardiac disease, prothrombotic states
  - Additional stroke risk factors: C-reactive protein, homocysteine

Gross Pathologic & Surgical Features

- Acute thrombosis of major vessel
- Pale, swollen brain; GM-WM boundaries blurred

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Focal acute neurologic deficit
  - Paresis, aphasia, decreased mental status

Demographics

- Age
  - Usually older adults
  - Consider underlying disease (sickle cell, moyamoya, NF1, cardiac, drugs) in children, young adults
- Epidemiology
  - 2nd most common cause of death worldwide
  - #1 cause of morbidity in USA

Natural History & Prognosis

- Clinical diagnosis inaccurate in 15-20% of strokes
- Malignant MCA infarct (coma, death)
  - Up to 10% of all stroke patients
  - Fatal brain swelling with increased ICP

Treatment

- "Time is brain": IV rTPA window < 3 hours
  - IA window < 6 hours
- Patient selection most important factor in outcome
  - Symptom onset < 6 hours
  - No parenchymal hematoma on CT
  - < 1/3 MCA territory hypodensity

DIAGNOSTIC CHECKLIST

Consider

- DWI positive for acute stroke only if ADC correlates
- Rarely, ischemia or seizure may mimic tumor or encephalitis

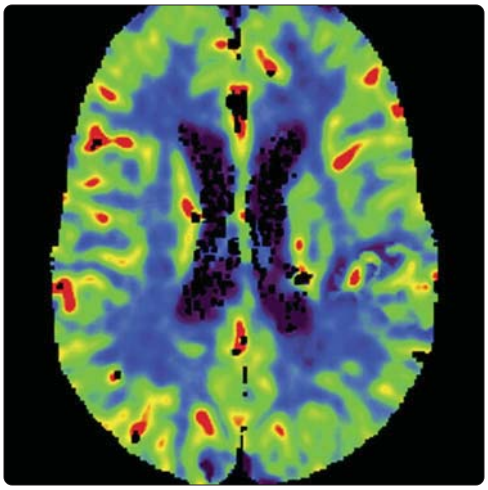
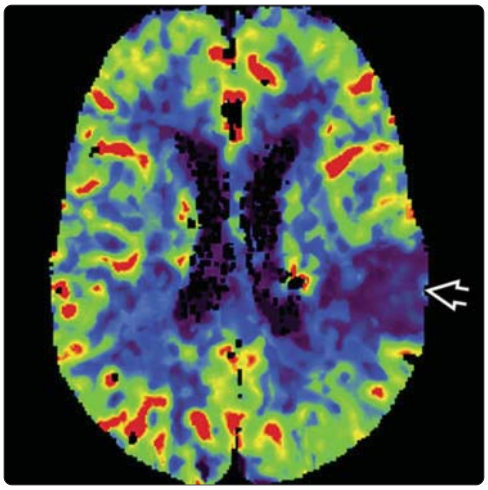
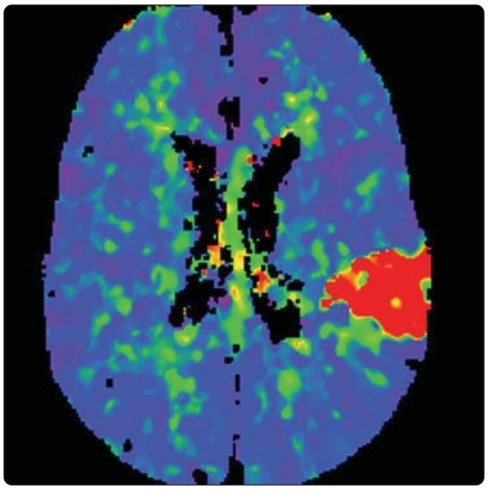
(Left) *Axial NECT in an 89-year-old male who had several visits to the ER for several falls ("rule out subdural hematoma") shows a calcified cerebral embolus ➡ in a right hemisphere sulcus.* **(Right)** *Sagittal reformatted NECT scan in the same patient shows the location in the right superior temporal sulcus ➡. The patient was subsequently shown to have calcific mitral valve disease. Calcified cerebral emboli carry a high risk of repeated stroke.*



(Left) *Axial NECT scan for a "brain attack" patient in the ER with sudden onset aphasia is normal.* **(Right)** *Axial CT perfusion was obtained immediately following the NECT scan. The cerebral blood volume appears grossly normal.*





(Left) *Axial CBF map in the same patient shows markedly reduced perfusion in the posterior division of the left middle cerebral artery ➡.* **(Right)** *Time to drain in the same patient shows severely reduced TTD, consistent with acute ischemia without infarction. IV TPA was administered and the symptoms resolved.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Subacute infarction ~ 2-14 days following initial ischemic event

IMAGING

- Best diagnostic clue: Gyral edema and enhancement within basal ganglia and cortex
- Typically wedge-shaped abnormality involving gray and white matter within vascular distribution
- Hemorrhagic transformation of initially ischemic infarction occurs in 20-25% of MCA occlusions, usually by 48-72 hours
- "2-2-2" rule = enhancement begins at 2 days, peaks at 2 weeks, disappears by 2 months
- MRS: ↑ lactate, ↓ NAA within infarcted tissue
- DWI: ↑ diffusion restriction, ↓ ADC initially, reversing as it proceeds into/through subacute stage
- "Fogging" effect = normal T2WI with striking enhancement on T1WI C+ 1-2 weeks following ictus

TOP DIFFERENTIAL DIAGNOSES

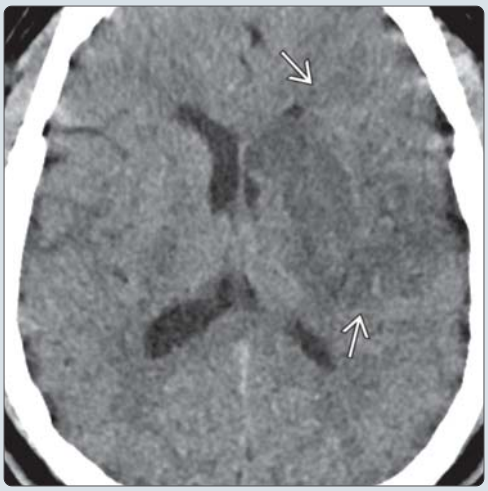
- Neoplasm
- Venous infarction
- Encephalitis/cerebritis

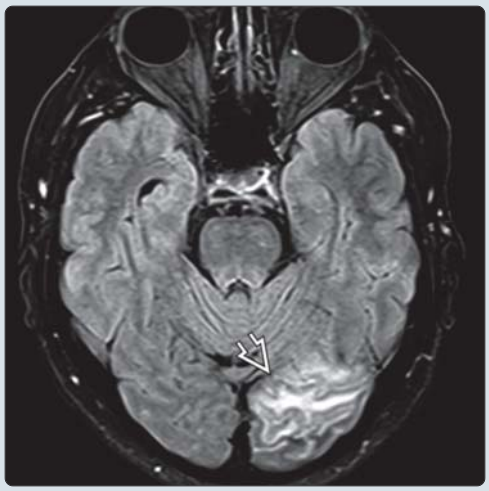
CLINICAL ISSUES

- Acute onset focal neurologic deficit
- Elderly patient with typical risk factors: Hypertension, diabetes, smoking history, obesity, hypercholesterolemia
- 1st month after infarction, mortality predominantly from neurologic complications; 1:4 die of recurrent stroke event
- Acute anticoagulation after 1st infarction reduces mortality

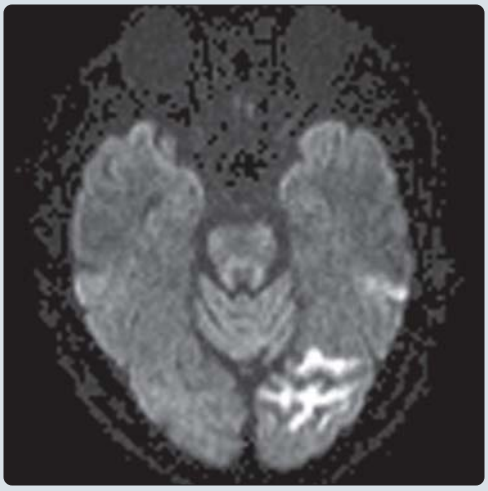
DIAGNOSTIC CHECKLIST

- Enhancement is key to defining subacute stage of cerebral infarction
- Subacute ischemia often mimics neoplasm
  - Recommend short-term follow-up to ensure expected course of evolution





(Left) *Axial CT obtained 48 hours after initial onset of weakness and speech difficulties shows the classic appearance of an early subacute cerebral infarct. Note the wedge-shaped, low-density area ➡ involving both the gray and white matter in the left MCA distribution.* **(Right)** *Axial FLAIR MR in a 58-year-old man 1 week after onset of visual changes shows classic imaging of a subacute infarct with hyperintensity in the cortex and subcortical white matter of the occipital lobe ➡ in a PCA distribution.*



(Left) *Axial DWI image in the same patient shows hyperintensity within the left PCA distribution. The hyperintensity represents a combination of true diffusion restriction and T2 shine through.* **(Right)** *Axial T1 C+ MR in the same patient shows gyriform enhancement along the cortex of the occipital lobe ➡. This enhancement may be seen as early as 2 days and may last up to 2 months after the patient's initial ischemic event. Without clinical history, imaging may mimic a tumor, venous infarct, or cerebritis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Subacute stroke, subacute cerebrovascular accident (CVA)

Definitions

- Focal brain necrosis following obstruction of blood flow to localized area of brain
- Subacute infarct ~ 2-14 days following initial ischemic event
- May occur ± hemorrhagic transformation (HT)

IMAGING

General Features

- Best diagnostic clue
  - Gyral edema, enhancement in basal ganglia/cortex
  - Look for hemorrhagic transformation
    - Typically occurs in 20-25% of cases 2-7 days after acute event
- Location
  - Cerebral hemispheres, brainstem, cerebellum in territorial vascular distribution
- Size
  - Extremely variable
  - Ranges from focal ("lacunes") to global (hemispheric)
- Morphology
  - Variable depending on location, size, etiology
  - Typically wedge shaped; involves both gray and white matter
    - Recognizable vascular distribution

CT Findings

- NECT
  - Wedge-shaped area of ↓ attenuation involving gray and white matter
  - Mass effect initially ↑, then ↓ by 7-10 days; often less than expected given lesion size as acuity resolves
  - Hemorrhagic transformation of ischemic infarct occurs in 20-25% of MCA occlusions, usually by 48-72 hours
    - Common locations are basal ganglia and cortex
    - Hemorrhagic foci detected in majority of medium/large subacute infarcts
- CECT
  - Enhancement typically patchy or gyral
  - May appear as early as 2-3 days after ictus; persists up to 8-10 weeks
  - "2-2-2" rule = enhancement begins at 2 days, peaks at 2 weeks, disappears by 2 months
- CTA
  - Evidence of subacute occlusion correlates strongly, independently with poor clinical outcome
    - Significantly worse discharge National Institutes of Health Stroke Scale (NIHSS) score
- CT perfusion
  - More useful in acute > subacute stroke
    - Helpful in predicting tissue outcome
  - Significant difference between infarct and peri-infarct tissue for both rCBF, rCBV

MR Findings

- T1WI
  - Hypointense edema with mass effect
  - HT: Signal changes of hemorrhage
  - May see gyriform ↑ signal (pseudolaminar necrosis)
- T2WI
  - Hyperintense edema with mass effect
  - "Fogging" effect = normal T2WI with striking enhancement on T1WI C+ 1-2 weeks following ictus
  - HT: Signal changes of evolving hemorrhage
  - Early wallerian degeneration can occur
    - Look for well-defined hyperintense band in corticospinal tract
- FLAIR
  - Hyperintense edema with mass effect
  - Hyperintensity ("dot" sign) in slow-flowing/occluded vessels
  - By 1 week, final infarct volume corresponds to FLAIR-defined abnormality
- T2* GRE
  - May see blooming if HT has occurred
- DWI
  - ↑ diffusion restriction, ↓ ADC initially, reversing as it proceeds into/through subacute stage
  - DWI, T1WI C+ complement each other in detecting subacute infarcts
    - Early subacute can be ↑ DWI and ↓ T1 C+
- T1WI C+
  - Intravascular enhancement in initial 48 hours; disappears at 3-4 days as vessels recanalize
  - Parenchymal enhancement (typically patchy or gyral)
    - May appear as early as 2-3 days after ictus
    - Can persist up to 8-10 weeks
- MRA
  - Vessel occlusion (large vessel)
- MRS
  - ↑ lactate, ↓ NAA within infarcted tissue
  - In subacute and chronic infarction, lactate/choline and NAA/choline ratios correlate with outcome
- MR T2* perfusion
  - ↓ rCBV of acute infarct increases in subacute stage, reflecting reperfusion hyperemia
  - Decreases again in chronic stage

Angiographic Findings

- Conventional
  - May see intraluminal thrombus &/or vessel occlusion
  - Slow antegrade flow with delayed arterial emptying
  - Slow retrograde filling through collateral vessels
  - "Bare" areas = regions of nonperfused or slowly perfused brain tissue

Nuclear Medicine Findings

- Diminished/absence of perfusion with SPECT or PET
- HMPAO SPECT may show reflow hyperemia after reperfusion in acute and subacute stages

Imaging Recommendations

- Best imaging tool
  - MR with DWI, T2*, T1WI C+
  - Consider CT or MR perfusion (more helpful in acute stroke)
- Protocol advice
  - CT and MR: C+ for assessing subacute age

https://CafePezeshki.IR

DIFFERENTIAL DIAGNOSIS

Neoplasm

- DWI: Vasogenic ("tumoral") edema instead of cytotoxic edema
- Enhancing mass instead of patchy, gyral enhancement
- Will not regress on follow-up imaging

Venous Infarction

- Nonarterial distribution
- Venous instead of arterial occlusion, typically major dural sinus
- More commonly hemorrhagic, primarily affecting white matter instead of cortex
- Different clinical presentation/setting (trauma, hypercoagulable states, pregnancy, dehydration)

Encephalitis/Cerebritis

- DWI: Strong restriction
- Nonvascular distribution
- Gyriform, ring-enhancing patterns (late cerebritis)
- Different clinical presentation

PATHOLOGY

General Features

- Etiology
  - Prolonged cerebral ischemia
  - Duration and severity of ischemic insult determines cellular viability
  - Less commonly, may be result of infectious etiologies
    - Sequelae of meningitis (bacterial, mycobacterial, etc.)
  - May also be result of inflammatory diseases, such as vasculopathy, angiitis, etc.
  - Uncontrolled, unilateral, supratentorial expanding lesions can cause descending tentorial herniation → ischemic infarction of occipital lobe
  - Ischemia/infarction involves typical vascular territories or watershed (border zone) distributions depending on etiology
  - Other factors: Adequacy of collateral blood supply, degree, duration, and distribution of flow reduction
- Genetics
  - Hypercholesterolemia, diabetes, hypertension, and homocysteine increase stroke risk

Gross Pathologic & Surgical Features

- Blurring of gray-white matter demarcation
- Mass effect with narrowing of sulci, displacement of adjacent structures
- Softening of ischemic tissues from water retention

Microscopic Features

- Fragmentation of axons and early disintegration of myelin sheaths; loss of oligodendrocytes, astrocytes
- 48 hours: Neutrophils begin to pass through vessel walls into brain tissue
- 72-96 hours: Macrophages aggregate around vessels
- 2 weeks: Macrophages are the predominate reactive cells

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute onset focal neurologic deficit
  - ~ 50% of patients with infarction → permanent neurologic deficits have preceding TIAs
- Clinical profile
  - Elderly patient with typical risk factors: Hypertension, diabetes, smoking history, obesity, hypercholesterolemia, etc.

Demographics

- Age
  - Usually > 55 years
  - Women often slightly older than men at presentation
- Gender
  - Females often more disabled after age adjustment
  - Fatality rates similar
- Epidemiology
  - Highest cause of USA adult morbidity
  - 3rd cause of USA adult mortality

Natural History & Prognosis

- 1st month after infarction, mortality predominantly from neurologic complications
  - 1:4 die of recurrent stroke event
- Later mortality from respiratory, cardiovascular causes

Treatment

- To improve long-term survival, aggressive management of pulmonary and cardiac disease is critical
- Acute anticoagulation after 1st infarction reduces mortality
- Current research: Therapeutic hypothermia and gene therapy (antiapoptotic protein BCL-2) during acute stroke event

DIAGNOSTIC CHECKLIST

Consider

- Is affected area another space-occupying pathology (i.e., tumor)
- Recommend short-term follow-up to ensure expected course of evolution

Image Interpretation Pearls

- Enhancement is key to defining subacute stage of cerebral infarction
- Appearance on DWI/ADC often helpful

KEY FACTS

IMAGING

- Volume loss with gliosis along affected margins
- Classic: Wedge-shaped area of encephalomalacia
- Territorial infarction
  - Involves brain supplied by major cerebral artery
- Watershed infarction
  - Involves brain **between** main vascular territories
- Lacunar infarction(s)
  - Most common in basal ganglia/thalami, deep white matter (WM)

TOP DIFFERENTIAL DIAGNOSES

- Porencephalic cyst
- Arachnoid cyst
- Postsurgical/post-traumatic encephalomalacia
- Low-attenuating tumors

PATHOLOGY

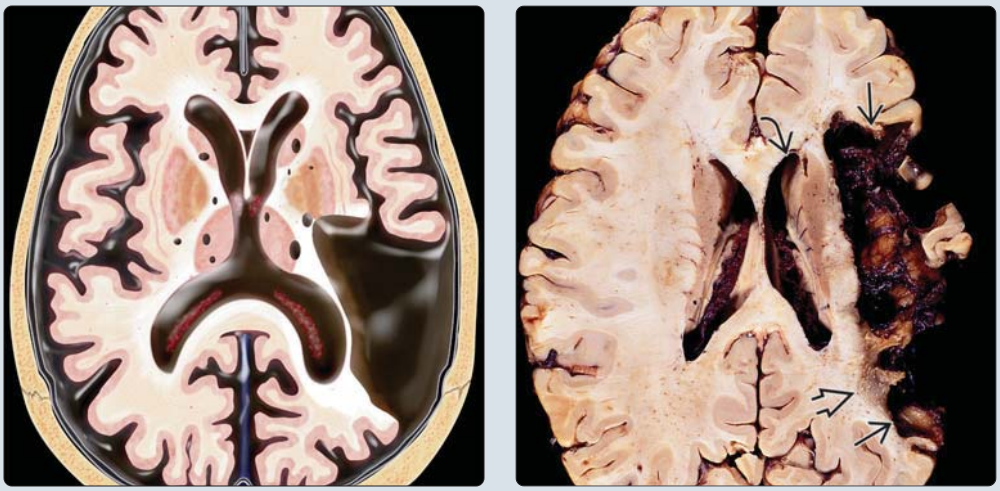
- Volume loss, gliosis are pathological hallmarks

CLINICAL ISSUES

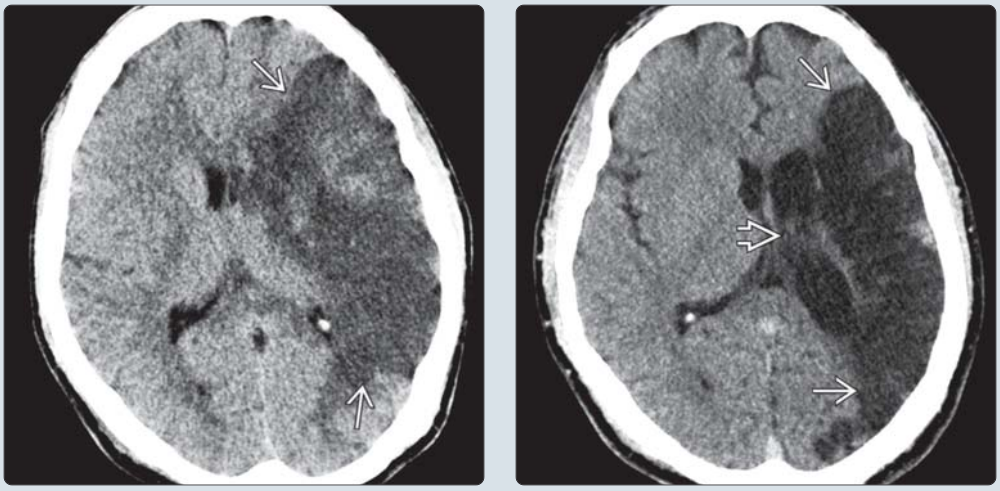
- Elderly patient with typical risk factors
- Focal neurologic deficit
  - Varies depending on size, location of cerebral infarction (CI)
- Stroke severity most consistent predictor of 30 day mortality after stroke
- Lacunar stroke most common stroke subtype associated with vascular dementia

DIAGNOSTIC CHECKLIST

- Evaluate for associated acute infarcts in same or different vascular territory
- Evaluate for underlying cause
  - CTA/MRA of extra-/intracranial vasculature
  - If negative, consider cardiac source
- Evaluate for risk factors



(Left) *Axial graphic shows chronic infarct involving the posterior left MCA territory. Infarct is lined with gliotic (WM). Small lacunar infarctions and atrophy also depicted.* **(Right)** *Axial gross pathology, sectioned through the midventricular level, shows a chronic left middle cerebral artery infarct with encephalomalacia in the classic MCA vascular distribution. Note the adjacent WM gliosis and the mild compensatory enlargement of the left lateral ventricle. (Courtesy R. Hewlett, MD.)*



(Left) *Axial NECT scan 2 days after large territorial infarction in the left MCA territory shows wedge-shaped hypodensity involving both cortex, white matter, and basal ganglia. Moderate mass effect is present, with subfalcine herniation of the lateral ventricles.* **(Right)** *Follow-up scan 2 months later shows findings of chronic infarct. The mass effect has resolved completely and there is frank encephalomalacia in the left MCA territory. The left lateral ventricle shows compensatory enlargement.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Cerebral infarction (CI)

Synonyms

- Old ischemic stroke
- Postinfarction encephalomalacia

Definitions

- End result of prolonged cerebral ischemia

IMAGING

General Features

- Best diagnostic clue
  - Volume loss with gliosis along affected margins
- Location
  - Cerebral hemispheres, brainstem, cerebellum
  - Territorial infarction involves brain tissue supplied by major cerebral artery
    - Common sites
      - Supratentorial: MCA, ACA, PCA distribution
      - Infratentorial: BA, PICA distribution
  - Watershed (border zone) infarction involves brain tissue **between** main vascular territories
  - Lacunar infarctions are small infarcts in deep penetrating artery distributions
    - Typically located in basal ganglia/thalami, white matter (WM)
- Size
  - Extremely variable
    - Ranging from focal ("lacunes") to lobar or global (hemispheric)
- Morphology
  - Extremely variable depending on location, size, etiology of vascular insult
  - Classic: Wedge-shaped area of encephalomalacia

CT Findings

- NECT
  - Focal, well-delineated, low-attenuation areas in affected vascular distribution
  - Adjacent sulci become prominent; ipsilateral ventricle enlarges
  - Wallerian degeneration may be present
  - Dystrophic Ca++ may very rarely occur in infarcted brain
- CECT
  - No enhancement
- CTA
  - May see lack of flow in affected vessel

MR Findings

- T1WI
  - Isointense to CSF in affected areas
  - Adjacent sulci become prominent; ipsilateral ventricle enlarges
  - Wallerian degeneration may be present
- T2WI
  - Isointense to CSF in affected areas
  - Borders of infarction may show ↑ signal secondary to gliosis/spongiosis
  - Differentiation of subacute from chronic infarction on standard SE/FSE sequences may be difficult due to prolonged relaxation times in both
- FLAIR
  - Low signal in encephalomalacic area
  - Hyperintense gliotic white matter at margins
- T2* GRE
  - May see hemosiderin staining in gliotic areas or along borders of infarction
- DWI
  - No restriction; increased diffusivity (↑ signal on ADC)
- T1WI C+
  - No enhancement
- MRA
  - May see lack of flow in affected vessel
- MRS
  - Shows loss of NAA peak in affected area

Angiographic Findings

- Conventional
  - May see lack of flow in affected vessel and its vascular territory

Imaging Recommendations

- Best imaging tool
  - CT or MR
- Protocol advice
  - No contrast necessary if imaging typical (i.e., lack of mass effect or volume loss)

DIFFERENTIAL DIAGNOSIS

Porencephalic Cyst

- Congenital cyst typically seen in younger age groups
- Also lined by gliotic white matter

Arachnoid Cyst

- No gliotic margins
- Usually in locations atypical for vascular territory
- Intact gray matter lining brain, displaced by cyst

Postoperative/Post-Traumatic Encephalomalacia

- History and associated findings help to distinguish
- May see leptomeningeal cyst in post-traumatic setting

Low-Attenuation Tumors

- Typically shows mass effect
- Usually slightly hyperdense/intense compared to CSF

PATHOLOGY

General Features

- Etiology
  - Prolonged cerebral ischemia
  - Duration and severity of ischemic insult determines cellular viability
    - Results of CI vary with sensitivity of individual cell types to ischemia
    - Other factors include adequacy of collateral blood supply, degree, duration, and distribution of flow reduction
  - Most CI caused by territorial, watershed, lacunar infarcts

https://CafePezeshki.IR

- Less commonly result of infectious/inflammatory etiologies
  - Sequelae of meningitis (bacterial, mycobacterial, etc.)
  - Vasculopathy, angiitis, etc.
- Rare
  - Unilateral descending tentorial herniation
  - May cause secondary ischemic infarction of occipital lobe
- Genetics
  - Hypercholesterolemia, diabetes, hypertension, homocysteine ↑ stroke risk

Gross Pathologic & Surgical Features

- Volume loss and gliosis pathological hallmarks
- Liquefaction resulting in cyst formation
- Cystic areas traversed by trabeculations of blood vessels, surrounded by firm glial tissue
- Typically in main vascular territories or watershed (border zone) distribution depending on etiology

Microscopic Features

- Fibrillary gliosis along margin of infarction
- Macrophages may persist in interstices of infarcts; some may contain hemosiderin

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Focal neurologic deficit with history of acute onset
- Clinical profile
  - Elderly patient with typical risk factors
    - Hypertension, diabetes, smoking history, obesity, hypercholesterolemia, etc.

Demographics

- Age
  - Usually > 55
- Gender
  - Women typically older than men
  - Females often more disabled after age adjustment
  - Fatality rates similar
- Epidemiology
  - 2nd or 3rd leading cause of death in Western world (after noncerebral cardiovascular disease and cancer)
  - Major cause of long-term disability
  - 1 in 5 with 1st stroke will survive to 10 years
  - Estimates in USA range from 760,000-780,000 annually; contributes to ~ 150,000 deaths/year
  - Estimated 5,800,000 stroke survivors in USA

Natural History & Prognosis

- Varies greatly depending on size of CI and degree of neurologic deficit
- Stroke severity most consistent predictor of 30 day mortality after stroke
- Mortality rates in USA declined dramatically in 1970s and 1980s, but plateaued by 1990s
- Stroke mortality in USA predicted to ↑ 3x as fast as general population over next 30 years
- Lacunar stroke most common stroke subtype associated with vascular dementia

Treatment

- Acute anticoagulation after 1st infarction associated with reduced mortality
- To improve long-term survival after CI, aggressive management of pulmonary and cardiac disease critical

DIAGNOSTIC CHECKLIST

Consider

- Could lesion be arachnoid cyst or porencephalic cyst

Image Interpretation Pearls

- Look for signs of volume loss in vascular territory
- Evaluate for associated acute infarcts in same or different vascular territory

Reporting Tips

- Evaluate for underlying cause
  - Multiple infarcts in different vascular territories
    - Suggests cardioembolic source or vasculitis
  - Bilateral watershed infarcts
    - Hypoperfusion event
  - Unilateral watershed infarct
    - Hypoperfusion event and ipsilateral carotid stenosis
  - Infarct in setting of trauma
    - Evaluate for dissection

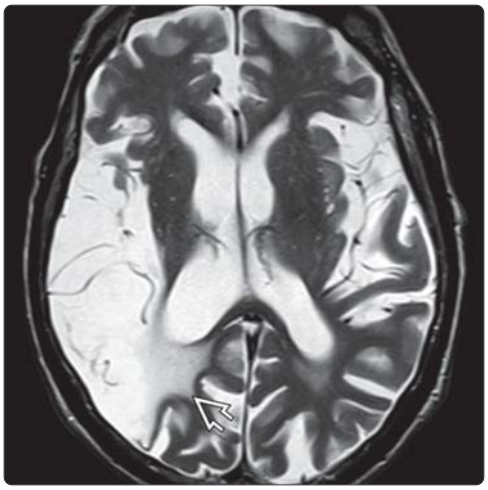
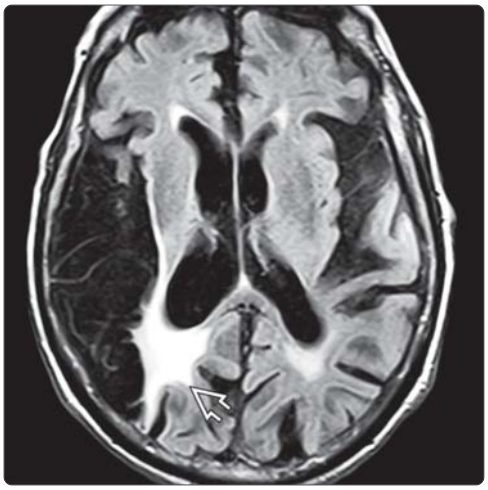
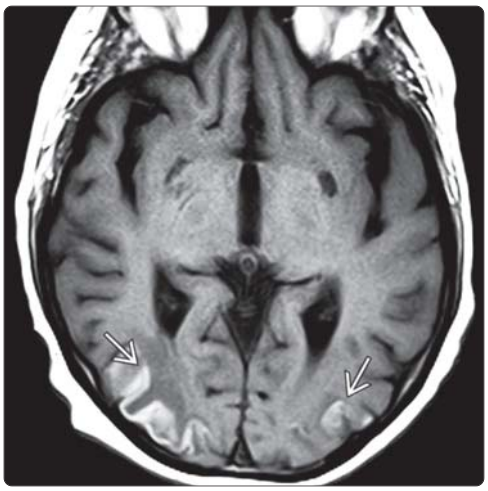
(Left) *Axial NECT scan shows classic chronic right MCA infarct ⇨. The encephalomalacic brain is low density and the ipsilateral right ventricle is enlarged.* **(Right)** *T1WI in the same patient shows the area of encephalomalacic brain ⇨ is the same signal intensity as CSF in the adjacent ventricle. Gliotic WM ⇨ bordering the infarct is hypointense to normal WM.*





(Left) *Axial T2WI in the same patient shows the chronic infarct is isointense with CSF but the gliotic brain ⇨ adjacent to the stroke is slightly less hyperintense.* **(Right)** *FLAIR MR in the same patient shows the cystic encephalomalacia caused by the stroke suppresses completely while the adjacent gliotic WM ⇨ remains hyperintense.*



(Left) *Axial NECT scan in a patient with visual difficulties, remote history of stroke shows bioccipital hypodensities ⇨.* **(Right)** *Axial T1WI in the same patient shows hypointense occipital WM with gyriform T1 shortening ⇨. This represents residua of hemorrhagic transformation in the chronic bioccipital infarct.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Infarcts in multiple arterial distributions from embolic source, often cardiac origin

IMAGING

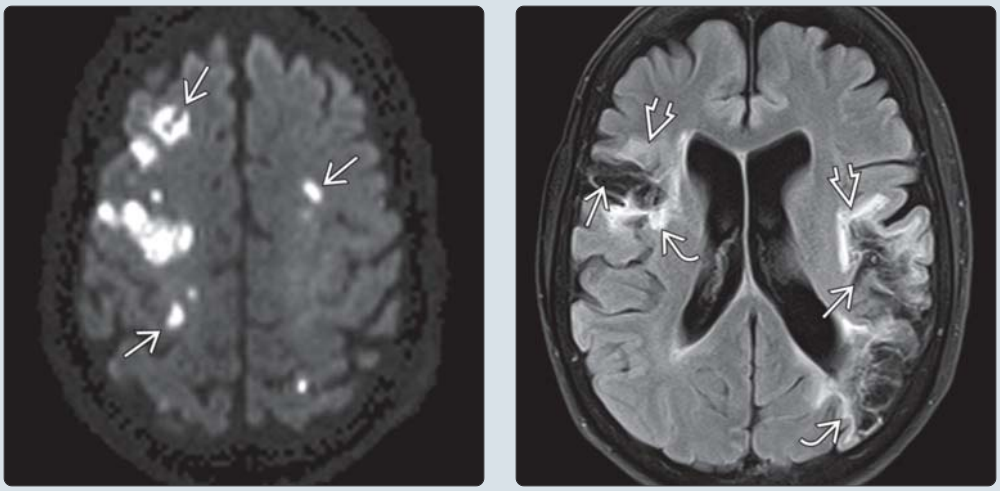
- Best imaging clue: DWI restriction in multiple vascular distributions
- NECT: Multiple regions of low attenuation, loss of gray-white differentiation
- T2/FLAIR: Multiple supratentorial and infratentorial regions of hyperintensity, often in a vascular distribution
  - May be of different ages
- Embolic infarcts tend to involve terminal cortical branches, producing wedge-shaped infarcts
- Cardiac echocardiography may show valve vegetations, intracardiac filling defect, or atrial or ventricular septal defect
- Best imaging tool: MR with DWI, FLAIR, T1WI C+

TOP DIFFERENTIAL DIAGNOSES

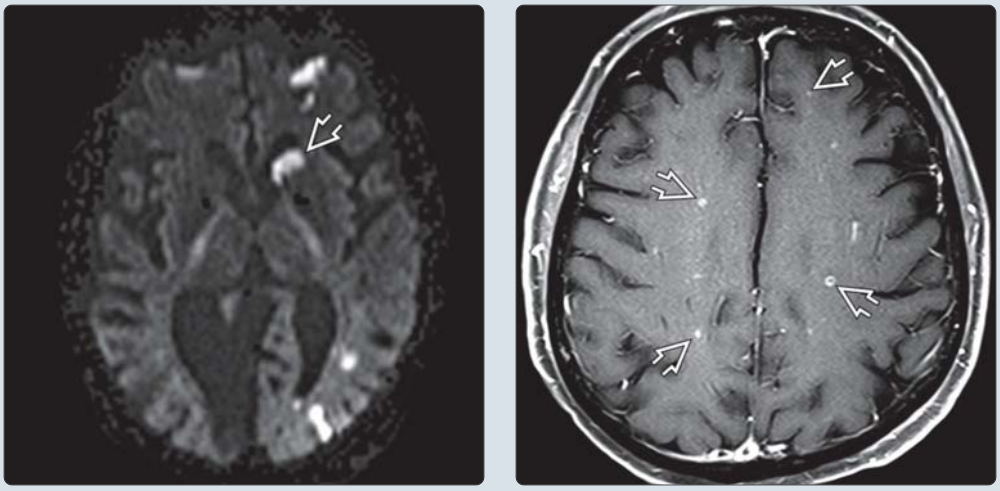
- Hypotensive cerebral infarction
- Multiple sclerosis
- Parenchymal metastases
- Vasculitis

CLINICAL ISSUES

- Multiple focal neurologic complaints not conforming to singular vascular distribution
- Peripheral signs of emboli, such as splinter hemorrhages or paradoxical emboli
- Cardiac source most common etiology of multiple embolic infarcts
  - May be septic or benign
- Carotid artery disease may cause multiple embolic infarct, if associated with variant PCA origin
- Cardiac and vascular evaluation → treat underlying disease



(Left) *Axial DTI trace image shows multiple regions of diffusion hyperintensity related to acute MCA distribution ischemia in bilateral hemispheres in a patient with embolic disease from a cardiac source.* **(Right)** *Axial FLAIR MR image shows bilateral chronic MCA distribution ischemia related to untreated atrial fibrillation. Note the areas of encephalomalacia with surrounding gliosis, typical of chronic ischemia.*



(Left) *Axial DTI trace shows acute ischemia in the left hemisphere in multiple vascular distributions. Note the involvement of the recurrent artery of Heubner from the ACA distribution (head of caudate), as well as the MCA and PCA territories, in this patient with severe internal carotid artery atherosclerotic disease and a fetal origin PCA.* **(Right)** *Axial T1 C+ FS MR shows multiple foci of enhancement in bilateral hemispheres related to septic emboli in a patient with cardiac valve vegetations.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Acute stroke related to fat emboli

IMAGING

- Acute ischemia with appropriate clinical history
  - Long bone or pelvic fractures, cardiac surgery, joint replacement surgery
- Often mimics thromboembolic stroke
- Commonly affects both gray and white matter (WM)
  - May affect deep and periventricular WM
  - May affect deep gray nuclei
- May involve typical vascular territory
- May mimic "watershed" infarct
- NECT: Typically negative acutely
  - "Hypodense MCA" sign related to fat within MCA
- T2WI: Multiple small, scattered hyperintense foci
- DWI: Acute diffusion restriction

TOP DIFFERENTIAL DIAGNOSES

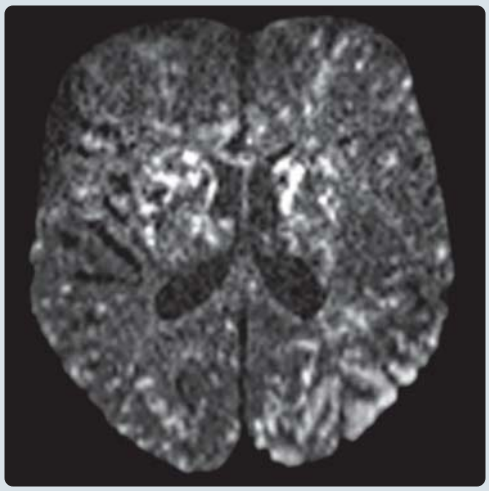
- Acute cerebral ischemia-infarction
- Acute hypertensive encephalopathy, PRES
- Vasculitis

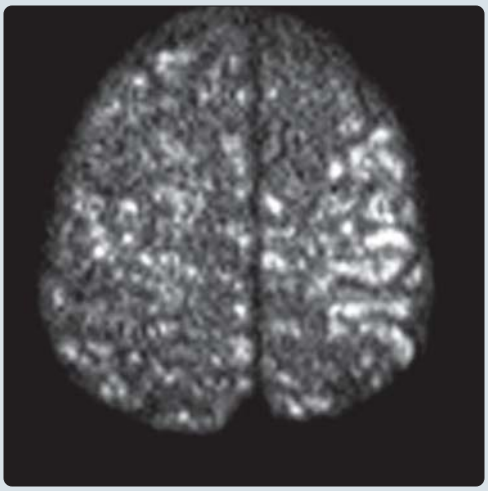
PATHOLOGY

- Fat emboli can pass through pulmonary capillaries without shunting lesions and result in systemic embolization (brain, kidneys most commonly)

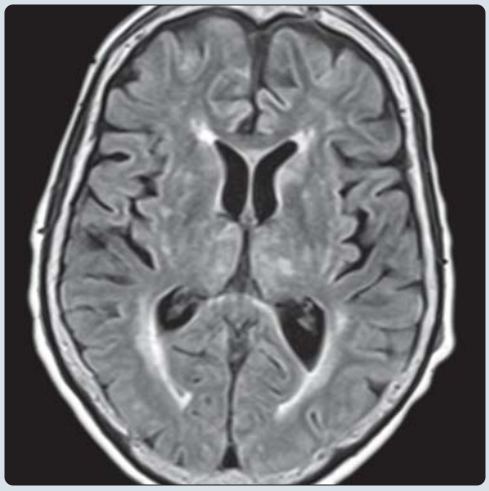
CLINICAL ISSUES

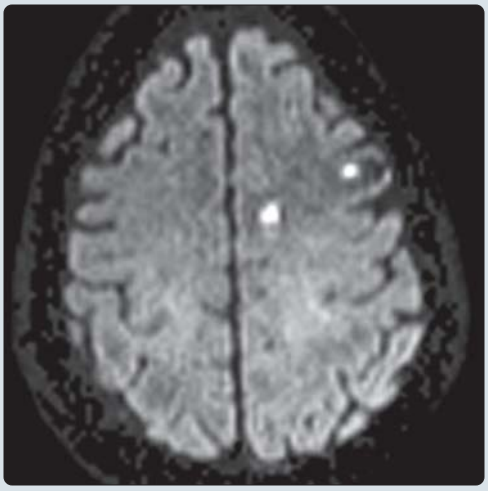
- Fat embolism syndrome: Pulmonary, CNS, and cutaneous manifestations
  - Hypoxia, deteriorating mental status, petechiae
- Neurological dysfunction varies from confusion to encephalopathy with coma and seizures
- Uncommon but potentially life-threatening
- Fat embolism syndrome after fractures: Up to 2.2%





(Left) *Axial DWI MR shows innumerable punctate foci of restriction throughout the white matter and gray matter of this 68 year old with mental status changes status post hip surgery. Note the extensive involvement of the basal ganglia and thalami.* **(Right)** *Axial DWI in the same patient shows the extensive foci of restriction related to acute ischemia from the patient's fat emboli. Note the more focal involvement of the left MCA territory with frontal and temporal lobe involvement.*





(Left) *Axial FLAIR MR in the same patient shows minimal abnormal hyperintensities in the deep gray nuclei and periventricular white matter. Diffusion imaging is the most sensitive sequence for acute stroke imaging.* **(Right)** *Axial DTI trace image shows 2 punctate foci of restriction related to fat emboli in this 39-year-old trauma patient with bilateral acetabular fractures. DTI may be more sensitive than DWI in acute ischemia. Imaging of fat emboli often mimics a typical thromboembolic stroke.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Small, deep cerebral infarcts located in basal ganglia and thalamus, pons, or cerebral white matter (WM), ≤ 15 mm

IMAGING

- Commonly deep gray nuclei, especially putamen, thalamus, caudate nuclei; internal capsule, pons
  - Other locations include deep and periventricular WM
- Range in size from microscopic to 15 mm
- Because of small size, most acute lacunar infarcts are not seen on CT scans
- Acute: T2/FLAIR increased signal
- Chronic: FLAIR central low signal with increased peripheral signal (gliosis)
- DWI: Restricted diffusion (hyperintense) if acute/subacute
  - May show small lesions otherwise undetectable
- Prominent perivascular spaces are main imaging differential diagnosis

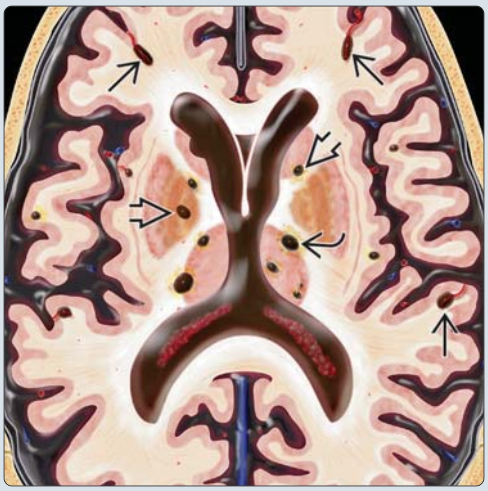
PATHOLOGY

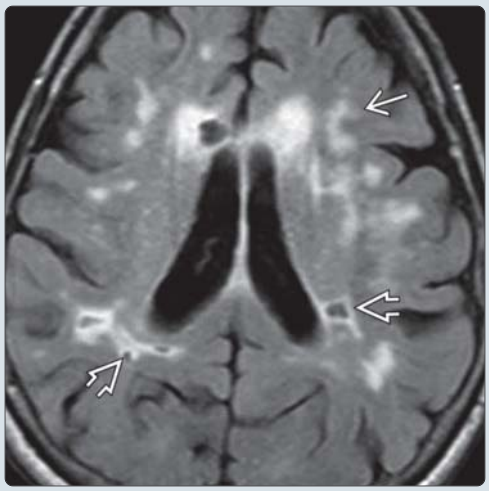
- Embolic, atheromatous, or thrombotic lesions in long, single penetrating end arterioles supplying deep cerebral gray matter
- Size of lacunar infarct depends on level of occlusion and anatomy of affected vessel

CLINICAL ISSUES

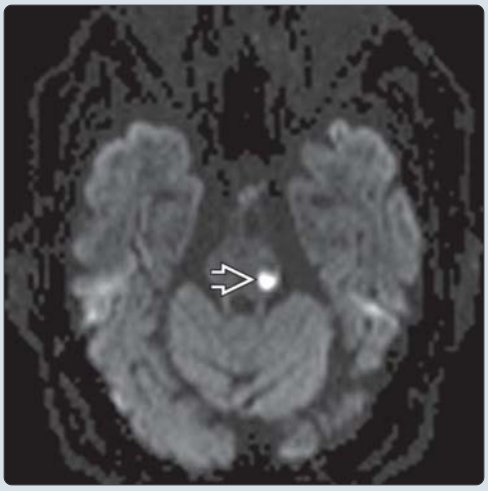
- Many different presentations, depending on size, location, number
- Most lacunar infarctions are clinically "silent," often subtle neurological deficits that may go unnoticed by patient and physician
- Typical risk factors for cerebrovascular disease: Hypertension, diabetes, smoking history, obesity, hypercholesterolemia, etc.
- Lacunar infarcts account for up to 25% of all strokes
- Lacunar stroke is most common stroke subtype associated with vascular dementia

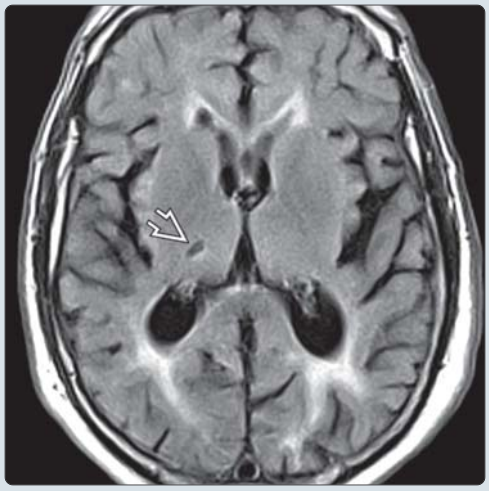
(Left) *Axial graphic illustrates numerous bilateral lacunar infarcts within the thalami and basal ganglia, the most common locations. Also shown are prominent perivascular (Virchow-Robin) spaces, a common normal variant.* **(Right)** *Axial FLAIR MR shows multiple chronic lacunar infarcts in the periventricular white matter with central hypointense encephalomalacia and mild peripheral hyperintense gliosis in a patient with chronic hypertension. Note the hyperintensity related to chronic small vessel ischemia.*





(Left) *Axial DWI MR image shows focal diffusion hyperintensity related to an acute lacunar infarct in the pons, a common location for lacunar infarcts. Risk factors for lacunar infarcts include hypertension, diabetes, smoking history, obesity, and hypercholesterolemia.* **(Right)** *Axial FLAIR MR shows a chronic lacunar infarct in the right thalamus with central encephalomalacia and mild peripheral gliosis. The surrounding gliosis and typical location can help differentiate a chronic lacunar infarct from a perivascular space.*





https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Lacunar infarction (LI), lacunar stroke
- "Lacunes"

Definitions

- Small, deep cerebral infarcts typically located in basal ganglia (BG) and thalamus, pons, or cerebral white matter (WM), ≤ 15 mm in size
- From Latin word "lacuna," meaning hole
  - Used to describe small focus of encephalomalacia
- "L'état lacunaire" or "lacunar state" = multifocal BG lacunar infarcts with surrounding gliosis

IMAGING

General Features

- Best diagnostic clue
  - Small, well-circumscribed areas of parenchymal abnormality (encephalomalacia) in BG, thalamus, WM
- Location
  - Commonly deep gray nuclei, especially putamen, thalamus, caudate nuclei; internal capsule, pons
  - Can be in other locations
    - Cerebral WM in patients > 65 years
    - Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) characteristically has subcortical lacunar infarcts
- Size
  - Commonly 3 mm to 15 mm
  - Majority < 8 mm
- Morphology
  - Typically round or ovoid

CT Findings

- NECT
  - When small, may not be seen on CT scans
  - Small, well-circumscribed areas of low (CSF) attenuation
  - Usually seen in setting of more extensive WM disease; typically multiple
- CECT
  - May enhance if late acute/early subacute

MR Findings

- T1WI
  - Small, well-circumscribed, hypointense foci
- T2WI
  - Small, well-circumscribed, hyperintense foci
- FLAIR
  - Acute: Increased signal
  - Chronic: Central cystic portion suppresses (low signal) with increased peripheral signal (gliosis)
- DWI
  - Restricted diffusion (hyperintense) if acute/subacute
  - May show lesions not seen on standard sequences
- PWI
  - Abnormal PWI seen in 2/3 of cases
- T1WI C+
  - May enhance if late acute/early subacute
- MRA
  - Normal

Imaging Recommendations

- Best imaging tool
  - NECT for chronic lacunes; MR with DWI for acutely symptomatic patient
  - MR better to distinguish lacunar infarcts from perivascular spaces
- Protocol advice
  - MR with DWI if acute

DIFFERENTIAL DIAGNOSIS

Prominent Perivascular Spaces

- Normal variant resulting from accumulation of interstitial fluid within enlarged Virchow-Robin spaces
- Found in all areas, but tend to cluster around anterior commissure and in cerebral WM
- Similar to CSF signal on all pulse sequences
- Found in patients of all ages
- Increase in size and frequency with advancing age
- Up to 25% have slight halo of ↑ signal on FLAIR or T2WI
- Can expand, occur in clusters (mimic neoplasm)

État Criblé

- Multiple enlarged Virchow-Robin spaces most commonly in basal ganglia
- Blood vessels in état criblé are thickened, ectatic, with sclerotic walls
- Perivascular tissues may show reactive astrocytosis and isomorphic gliosis with glial fibers extending along degenerated axons

Neurocysticercosis

- May mimic benign intraparenchymal cysts
- Imaging findings vary with developmental stage of cyst, as well as host response
- Solitary in 20-50%; when multiple, usually small number of cysts
- Inflammatory response around cyst may seal sulcus, making lesions appear intraaxial

PATHOLOGY

General Features

- Etiology
  - Embolic, atheromatous, or thrombotic lesions in long, single penetrating end arterioles supplying deep cerebral gray matter and WM
    - Size of LI depends on level of occlusion and anatomy of affected vessel
  - Some studies suggest chronic endothelial dysfunction in cerebral small vessel disease and LI
    - Subtle WM blood-brain barrier dysfunction in patients with LI, but not with cortical ischemic strokes
  - Endothelial prothrombotic changes may be important in mediating ischemic leukoaraiosis phenotype
- Genetics
  - Usually sporadic
  - May occur secondary to genetic disorder CADASIL
- Associated abnormalities

https://CafePezeshki.IR

- Most lacunar infarctions are clinically "silent," often subtle neurological deficits that may go unnoticed by patient and physician
- Small vessel cerebrovascular disease is important vascular cause of cognitive impairment

Gross Pathologic & Surgical Features

- Similar to other types of cerebral infarction
- Earliest visible change is slight discoloration and softening of affected area
- Within 48-72 hours necrosis is well established, and there is softening, disintegration of ischemic area with circumlesional swelling
- As resolution proceeds, liquefaction results in cyst formation; more apparent in lesions of larger size
- Cysts may be traversed by trabeculations of blood vessels and are surrounded by firm glial tissue

Microscopic Features

- Gliosis along margin of infarction
- Hypertensive hyalinization of supplying arterioles
- Pigmented macrophages can be found in some lacunes, suggesting possible hemorrhagic component

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Many different presentations, depending on size, location, number
  - Variable symptoms, ranging from clinically "silent" to focal neurologic deficit to cognitive impairment to dementia
    - In a study of patients ≥ 65 years 23% had isolated lacunar infarcts
      - 66% of these were single, 89% clinically silent
  - Significant correlation between pure motor strokes and presence of LI in internal capsule
  - About 1/4 of patients with classic lacunar syndrome have nonlacunar infarcts on MR
  - Responsible LI seen in ~ 60% of cases in lacunar syndromes
- Clinical profile
  - Elderly, hypertensive patient
  - Typical risk factors for cerebrovascular disease: Hypertension (HTN), diabetes (DM), smoking history, obesity, hypercholesterolemia, etc.

Demographics

- Age
  - Usually > 55 years, prevalence increases with age
  - Patients with coronary artery or peripheral vascular disease are at risk for infarcts at younger age
  - Patients with CADASIL present slightly earlier, with TIA/stroke-like symptoms, beginning at ~ 45 years; cognitive decline can start as early as age 35 years
- Gender
  - Not gender specific
- Epidemiology
  - Lacunar infarcts account for up to 25% of all strokes
  - Strong association with systemic hypertension
  - Lacunar stroke is most common stroke subtype associated with vascular dementia
  - Statistically significant incidence of isolated ipsilateral carotid stenosis in patients with LI located in carotid territory

Natural History & Prognosis

- Clinically "silent" to focal neurological deficit
- HTN and DM are significant risk factors for recurrent lacunar infarction
- Many patients with LI have good functional outcomes after 5 years
  - Increased risk of mortality, stroke recurrence, physical and cognitive decline with initial severe strokes and additional vascular risk factors
- **Early** mortality and stroke recurrence less common than nonlacunar infarcts; no difference after 1 month
- Silent infarcts more than double risk of subsequent strokes and dementia
- Presence of multiple LIs may be important prognostic indicator both for functional recovery, as well as higher rate of recurrence

Treatment

- Typical treatment is targeted toward underlying etiology of vasculopathy
- More studies on mechanisms, prevention, and treatment are needed to provide specific guidance on long-term management of LI patients
  - Risk-factor modification is likely to play large part in therapeutic interventions targeted at this stroke subtype

DIAGNOSTIC CHECKLIST

Consider

- Are "lacunes" really Virchow-Robin spaces
- Is there a treatable embolic source

Image Interpretation Pearls

- To be classified as LI, location must be end-artery territory and lesion must be smaller than 15 mm

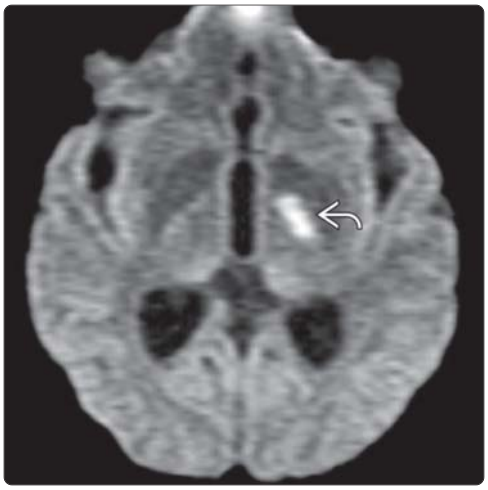
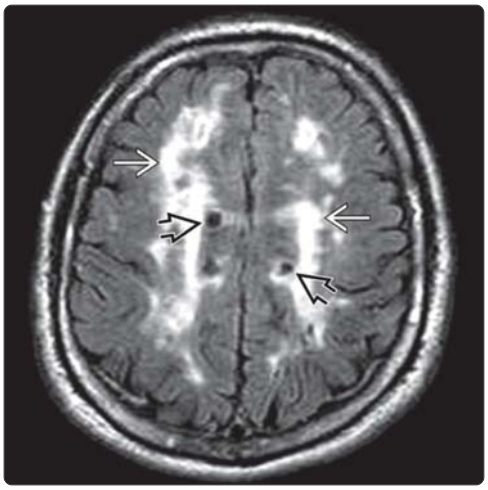
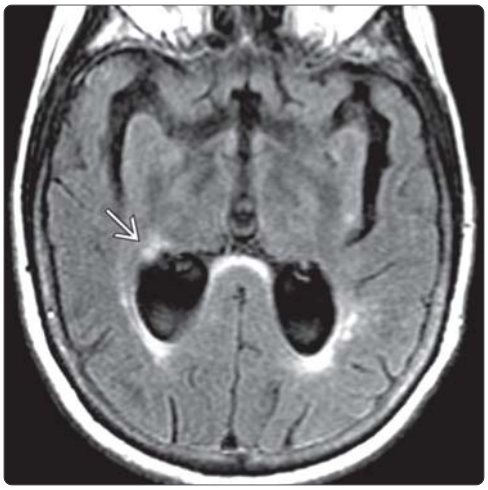
https://CafePezeshki.IR

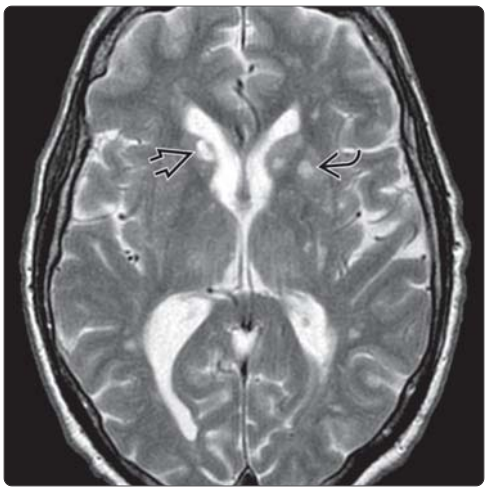


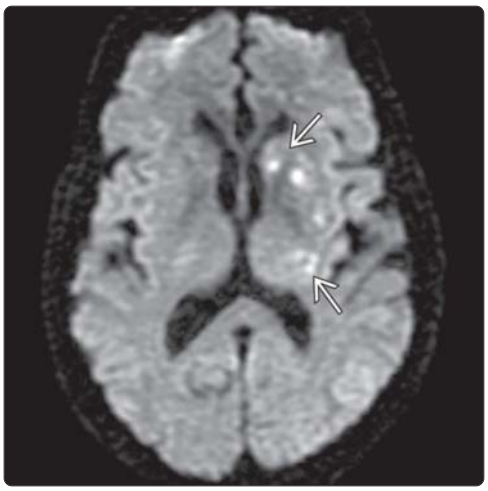


(Left) *Axial DWI MR shows hyperintensity related to an acute lacunar infarct involving the corticospinal tracts in the posterior limb of the internal capsule. Lacunar infarcts in this location have a high association with motor deficits, though the majority are clinically silent.* **(Right)** *Axial FLAIR MR shows extensive confluent white matter signal abnormality related to chronic small vessel ischemia (arteriolosclerosis). There are also multiple chronic lacunar infarcts in this young adult with CADASIL.*



(Left) *Axial FLAIR MR shows bilateral periventricular hyperintensity, as well as a focal hyperintensity, along the lateral thalamus related to an acute lacunar infarction. Lacunar infarcts are highly associated with vascular dementia.* **(Right)** *Axial DWI MR in the same patient shows hyperintensity related to acute ischemia. Without diffusion weighted imaging, it would be impossible to distinguish this acute lacune from an area of chronic small vessel disease, which commonly coexist.*





(Left) *Axial T2 MR image shows a classic appearance of multiple chronic lacunar infarcts in the basal ganglia, the most common location for this type of infarct. Note the bilateral involvement of the caudate heads and the left putamen.* **(Right)** *Axial DWI MR shows multiple foci of diffusion restriction related to multiple acute lacunar infarcts in this young adult with a drug abuse history. Drug abuse and arterial dissections are common risk factors for acute strokes in young patients.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Rare (1-3%) disorder most commonly occurring as complication of cerebral revascularization
  - Other etiologies less common
    - Status epilepticus
    - MELAS
- Major increase in ipsilateral cerebral blood flow (CBF) well above normal metabolic demands

IMAGING

- Ipsilateral gyral swelling, sulcal effacement in post-CEA patient
- ↑ CBF, CBV on perfusion MR (pMR), perfusion CT (pCT)

TOP DIFFERENTIAL DIAGNOSES

- Acute cerebral ischemia-infarction
- Status epilepticus
- MELAS
- Acute hypertensive encephalopathy, PRES
- Hypercapnia

PATHOLOGY

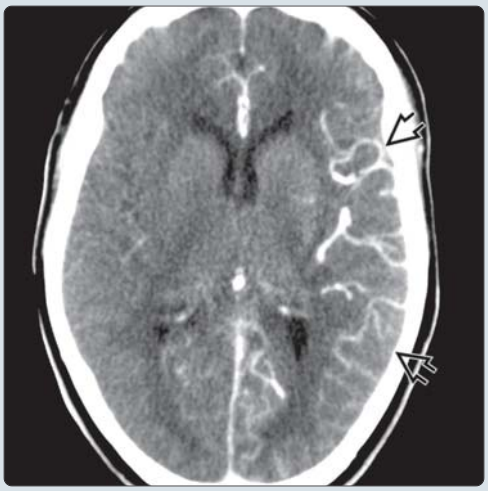
- Cerebral hyperperfusion syndrome (CHS) probably caused by maladaptive autoregulatory mechanisms, altered cerebral hemodynamics
  - "Normal perfusion pressure breakthrough"
  - Rapid restoration of normal perfusion following revascularization → hyperperfusion in previously underperfused brain

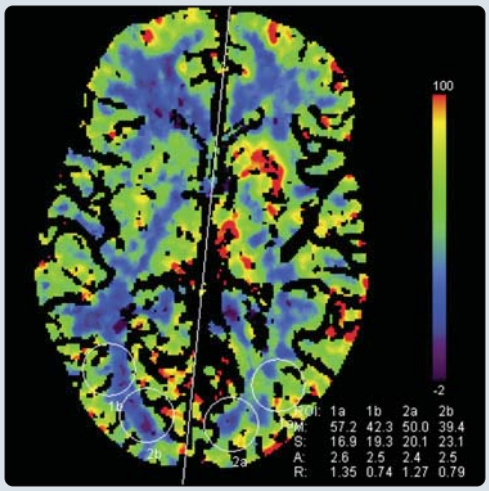
CLINICAL ISSUES

- ~ 3% of post-CEA patients develop CHS
- Classic: Triad of unilateral headache, neurologic deficit and seizures
  - Variable cognitive impairment
  - Ipsilateral face, eye pain

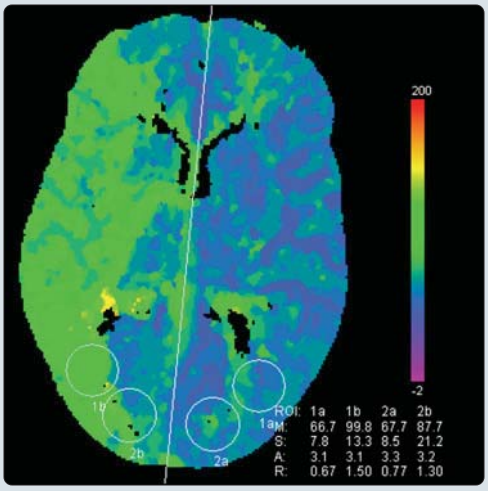
DIAGNOSTIC CHECKLIST

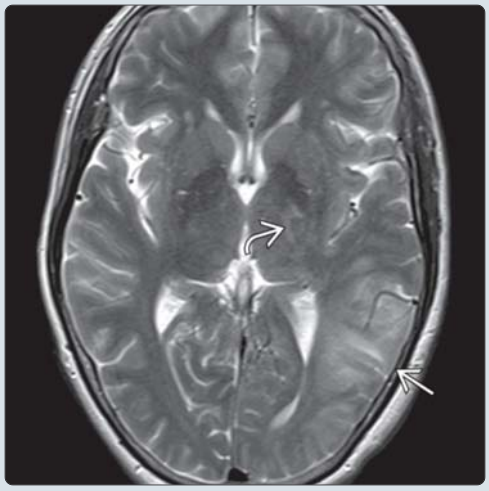
- Need to distinguish stroke/TIA from CHS





(Left) *A 56-year-old male with > 70% stenosis of his proximal left cervical ICA underwent carotid endarterectomy. A few hours after surgery, he became acutely confused and developed right-sided weakness. Perfusion source image shows markedly increased vasculature in the left hemisphere* ⇨. **(Right)** *CT perfusion obtained in the same patient appears relatively normal but CBF on the left (2a, 2b ROIs) is increased compared to the right side.*





(Left) *TTP in the same patient is even more striking. The abnormal side is not the right MCA distribution (green), but is the left side (blue) where the TTP is markedly shortened.* **(Right)** *Axial T2WI in the same patient shows gyral swelling, sulcal effacement, and hyperintensity in the left temporal and parietooccipital cortex/subcortical white matter* ⇨, *basal ganglia* ⇨. *DWI (not shown) was normal. This is a classic example of postcarotid endarterectomy hyperperfusion syndrome.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Cerebral hyperperfusion syndrome (CHS)

Synonyms

- Postcarotid endarterectomy hyperperfusion
- Luxury perfusion

Definitions

- Rare (1-3%) disorder most commonly occurring as complication of cerebral revascularization
  - Mildly ↑ CBF common after carotid endarterectomy (CEA), typically asymptomatic
  - CHS defined as ≥ 100% increase in rCBF compared to preoperative values
- Major increase in ipsilateral CBF well above normal metabolic demands
  - Usually following carotid revascularization procedure
  - May occur in other settings (e.g., status epilepticus, MELAS)

IMAGING

General Features

- Best diagnostic clue
  - Ipsilateral gyral swelling, sulcal effacement in post-CEA patient
  - ↑ CBF, CBV on perfusion MR (pMR), perfusion CT (pCT)
- Size
  - Variable
- Morphology
  - Follows vascular distribution

Imaging Recommendations

- Best imaging tool
  - MR with DWI, PWI
  - SPECT
- Protocol advice
  - Add T2* (GRE or SWI) to look for hemorrhage

CT Findings

- NECT
  - Gyral swelling
  - Cortical effacement
  - ± hypodensity (may occur without attenuation alterations)
  - Frank hemorrhage in < 1%
- CECT
  - Prominent vessels with ↑ intravascular enhancement
  - May demonstrate contrast extravasation in severe cases (rare)

MR Findings

- T1WI
  - Cortical swelling
  - ± mild hypointensity
  - Sulci effaced
- T2WI
  - Gyral swelling, hyperintensity
- FLAIR
  - Hyperintense cortex
  - Hyperintensity in subarachnoid spaces on post-contrast FLAIR reported 2° to BBB disruption
- T2* GRE
  - Frank hemorrhage in < 1%
  - "Blooming" on GRE or SWI
- DWI
  - Usually normal as edema is vasogenic, not cytotoxic
  - ~ 25% show small foci of restricted diffusion compared to preoperative DWI
- PWI
  - Elevated CBV, CBF
  - Prolonged MTT
    - Side-to-side difference of 3 seconds predictive of CHS
- T1WI C+
  - May be normal
  - May show slightly increased prominence of cerebral vessels
  - Parenchymal enhancement in severe cases
- MRA
  - Preoperative ↓ signal intensity in MCA may identify patients at risk for CHS

Other Modality Findings

- SPECT
  - N-isopropyl-p-I-123-iodoamphetamine or I-123-iomazenil SPECT
    - Shows hyperperfusion in ipsilateral cerebral hemisphere after surgery
    - Can be detected even in asymptomatic patients
    - May be correlated with long-term neuronal damage that CT, MR do not detect
    - May be associated with crossed cerebellar diaschisis

DIFFERENTIAL DIAGNOSIS

Acute Cerebral Ischemia-Infarction

- Time-to-peak/mean transit time prolonged (not decreased)
- Typically shows restriction on DWI (CHS often negative)

Status Epilepticus

- Metabolic hyperperfusion in affected brain
- History of seizure helpful but may not be available

Acute Hypertensive Encephalopathy, PRES

- Failed autoregulation → hyperperfusion → endothelial injury/vasogenic edema
- Predilection for posterior circulation
- Markedly elevated blood pressure (many etiologies)
  - Eclampsia, preeclampsia
  - Chemotherapy
  - Renal failure
  - Hemolytic uremic syndrome/thrombotic thrombocytopenic purpura
  - Drug abuse (especially cocaine)

MELAS

- Acute oxidative phosphorylation defect
- Stroke-like episodes related to vasogenic edema, hyperperfusion, neuronal damage
- Cortical hyperintensity, enhancement
- Perform MRS in unaffected region, look for lactate

https://CafePezeshki.IR

Hypercapnia

- Carbon dioxide is potent stimulator of CBF
- Vasodilatory effect on cerebral vasculature

PATHOLOGY

General Features

- Etiology
  - Cognitive impairment after CEA/stenting may result from
    - Cerebral embolization during dissection, stenting
    - Global cerebral hypoperfusion during carotid cross-clamping
    - Cerebral hyperperfusion syndrome
  - CHS probably caused by maladaptive autoregulatory mechanisms, altered cerebral hemodynamics
    - "Normal perfusion pressure breakthrough"
      - Chronic ischemia → impaired autoregulation
      - Loss of normal vasoconstriction
      - "Resistance" vessels become chronically dilated
      - Rapid restoration of normal perfusion following revascularization → hyperperfusion in previously underperfused brain

CLINICAL ISSUES

Presentation

- Classic: Triad of unilateral headache, neurologic deficit and seizures
- Other signs/symptoms
  - Variable cognitive impairment
  - Face, eye pain

Demographics

- Age
  - For postendarterectomy CHS, generally older patients
  - For other etiologies (e.g., seizure, MELAS), any age
- Epidemiology
  - ~ 3% of post-CEA patients develop mild CHS
  - Covariate clinical risk factors
    - Age
    - Hypertension (especially postoperative)
    - Diabetes
    - Bilateral lesions
    - Extent of ICA stenosis
      - High grade > low grade
    - Presence of contralateral carotid occlusion or high-grade stenosis
    - Duration of cross-clamping
    - Diminished carotid reserve
    - Poor collateral blood flow
    - Decreased cerebrovascular reactivity to acetazolamide challenge

Natural History & Prognosis

- Neurological emergency
  - If not treated promptly/adequately, can cause death or severe disability
- If no intracranial hemorrhage
  - Usually reversible
  - No major tissue destruction
  - May result in persistent mild cognitive impairment
- 1% of CHS with intracranial hemorrhage
  - Poor prognosis

Treatment

- Prevention
  - Minimize intraoperative cerebral ischemia
  - Consider continuing postoperative anesthesia/continuous sedation
  - Strict postoperative blood pressure control

DIAGNOSTIC CHECKLIST

Consider

- Post-CEA/carotid artery stenting patient with neurologic deficit
  - Need to distinguish stroke/transient ischemic attack from CHS

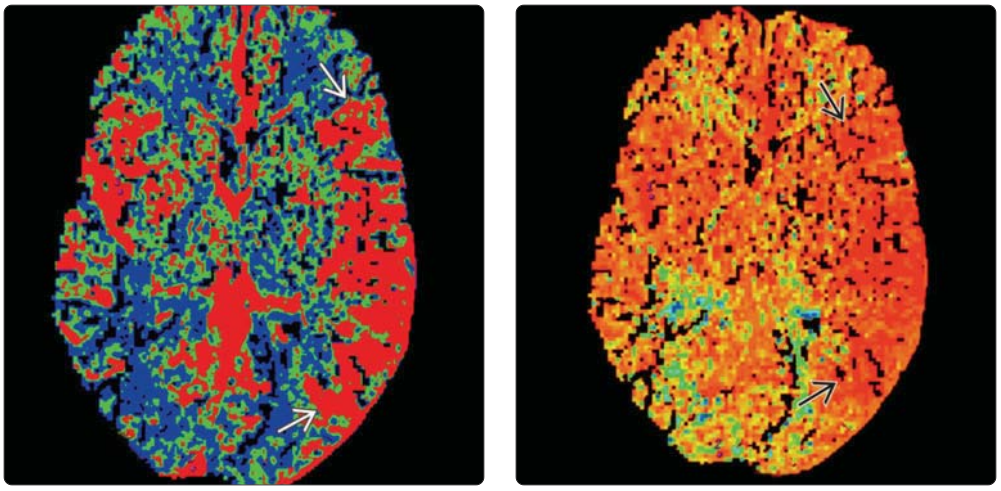
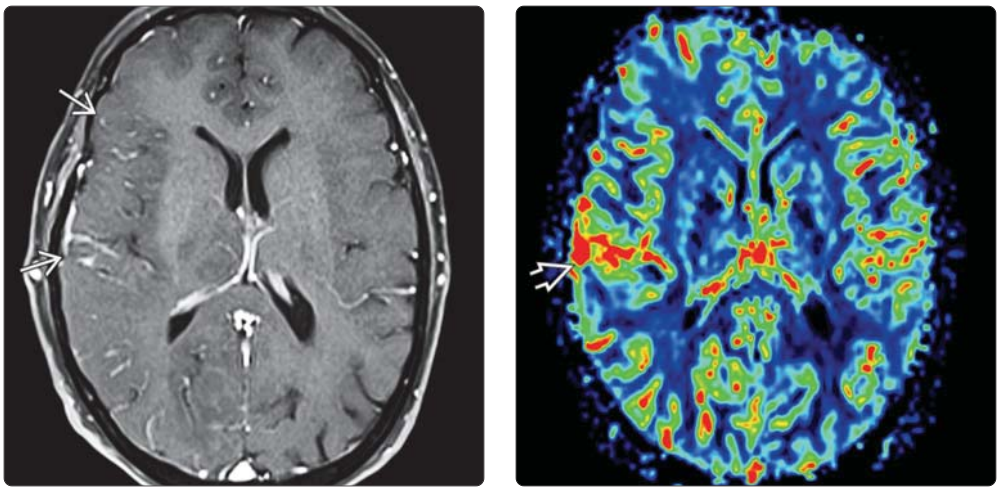
(Left) *Anteroposterior view of DSA shows abrupt occlusion of the left middle cerebral artery just distal to its origin ⇨ in a patient with a sudden onset of right-sided weakness and stroke-like symptoms. Little collateral filling of the distal MCA is seen.* **(Right)** *After superselective catheterization of the left MCA and infusion of tissue plasminogen activator for 2 hours, normal circulation was restored, as shown on this anteroposterior DSA.*



(Left) *Following restoration of normal blood flow in the previously occluded left MCA, the patient experienced worsening right-sided weakness and throbbing headache. This axial MR perfusion study shows elevated (red area ➡), not decreased, CBF in the left temporal and parietal lobes.* **(Right)** *Axial MR perfusion in the same patient shows elevated cerebral blood volume ⇨.*



(Left) *Cerebral hyperperfusion in status epilepticus is illustrated by this T1C+FS scan in a 52-year-old female with left-sided weakness following prolonged seizure. Note the increased intravascular, sulcal enhancement in the right temporal lobe compared to the left hemisphere ➡.* **(Right)** *pMR in the same patient shows increased CBF in the right temporal lobe ➡, corresponding to the increased intravascular enhancement noted on the T1C+FS MR.*

https://CafePezeshki.IR

KEY FACTS

IMAGING

- General features
  - "Empty delta" sign on CECT, T1WI C+ MR
- CT
  - Hyperdense sinus on NECT (usually > 70 HU)
  - ± hyperdense cortical veins ("cord" sign)
  - CTV: Filling defect (thrombus) in dural sinus
- MR
  - Hypointense thrombus "blooms" on T2* GRE
  - Absence of flow in occluded sinus on 2D TOF MRV
- Protocol recommendations
  - NECT, CECT scans ± CTV as initial screening
  - If CTs negative, MR + MRV (T2*, DWI, T1WI C+)
  - If MRV equivocal, DSA is gold standard

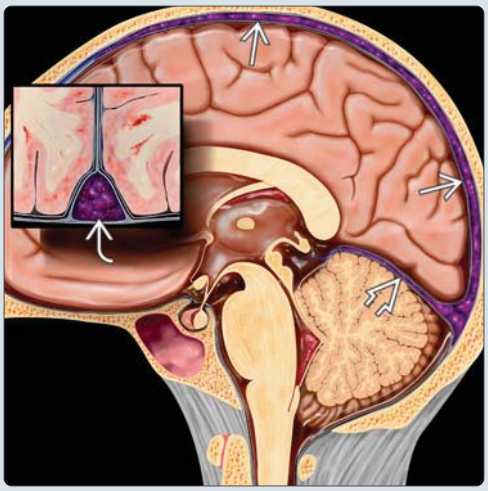
TOP DIFFERENTIAL DIAGNOSES

- Normal (arteries, veins normally slightly hyperdense)
- High hematocrit (newborns, polycythemia)
- Dural sinus hypoplasia/aplasia
  - No "blooming"; collaterals/venous infarcts absent
- "Giant" arachnoid granulations
  - Round/ovoid, not elongated like thrombus
- Acute subdural hematoma
  - Blood layered on tentorium can mimic transverse sinus (TS) thrombosis

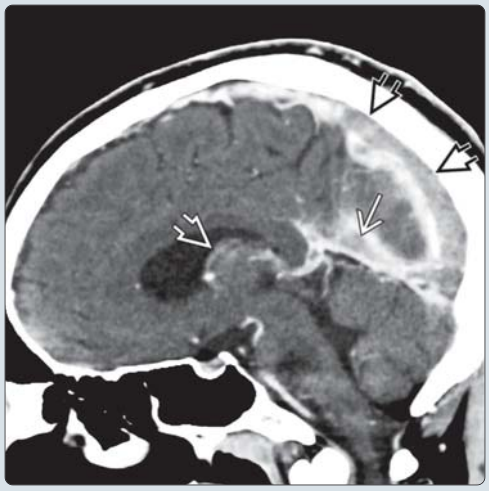
DIAGNOSTIC CHECKLIST

- Review MRV source images
  - Exclude pseudoocclusions (e.g., hypoplastic TS)
- Review T1 images to exclude false-negative MRV
- Review NECT to exclude dense thrombus as false-negative CECT or CTV
- Brain looks normal
  - Does not exclude CVT
- DSA helpful if noninvasive imaging inconclusive
- Chronic thrombosis may enhance
  - Recanalization or granulation tissue enhances

(Left) *Sagittal graphic shows thrombosis of the superior sagittal sinus ➡ and straight sinus ➡. Inset in the upper left reveals a thrombus in the superior sagittal sinus in cross section ("empty delta" sign) ➡ seen on contrast-enhanced imaging.* **(Right)** *NECT scan in a 25-year-old male with progressively increasing headaches shows hyperdensity in the right transverse ➡ and straight sinuses ➡. Both internal cerebral veins are hyperdense ➡ and the right thalamus ➡ is hypodense and edematous.*



(Left) *Axial source image from a CTV in the same patient shows the dura around the superior axial sinus enhances ➡, but its clot-filled lumen ➡ does not ("empty delta" sign).* **(Right)** *Sagittal reformatted view of the CTV in the same patient shows extensive nonenhancing thrombus in the superior sagittal ➡ and straight ➡ sinuses. The internal cerebral veins ➡ are occluded and do not enhance. Findings indicate extensive dural sinus, deep vein thrombosis.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Dural sinus thrombosis (DST)
  - Chronic dural sinus thrombosis (cDST)
- Cerebral vein thrombosis (CVT)

Definitions

- Thrombotic occlusion of intracranial dural sinuses

IMAGING

General Features

- Best diagnostic clue
  - Hyperdense (65-70 HU) on NECT
  - **"Empty delta" sign** on CECT, T1WI C+ MR
- Location
  - Thrombus in dural sinus ± adjacent cortical vein(s)

CT Findings

- NECT
  - Early imaging findings often subtle
  - Hyperdense sinus (compare to carotid arteries)
    - Usually > 65 HU (74 ± 9 HU vs. 53 ± 7 in normal)
    - Distinguish thrombus vs. hyperdense sinus from high hematocrit (HCT)
      - HU:HCT ratio in thrombus 1.9 ± 0.32 vs. 1.33 ± 0.12 nonthrombus
  - ± hyperdense cortical veins (**"cord" sign**)
  - ± venous infarct (50%)
    - Cortical/subcortical petechial hemorrhages, edema
    - Straight sinus (SS) ± internal cerebral veins (ICV) occlusion
      - Thalami/basal ganglia hypodense, swollen
- CECT
  - **"Empty delta" sign** (25-30%)
    - Enhancing dura surrounds nonenhancing thrombus
  - "Shaggy," enlarged/irregular veins (collateral channels)
- CTA/CTV
  - Filling defect (thrombus) in dural sinus
    - Caution: Acute clot can be hyperdense, obscured on CECT/CTV
      - Always include NECT for comparison

MR Findings

- T1WI
  - Acute thrombus: Isointense with brain
  - Subacute thrombus: Hyperintense
  - Chronic thrombus: Isointense
  - Normal variations in dural sinus flow may mimic thrombosis; vascular exam (CTV or MRV) more reliable to confirm suspected DST
- T2WI
  - Acute thrombus: Hypointense
    - Caution: Hypointense thrombus can mimic normal sinus "flow void"
  - Subacute thrombus: Hyperintense
  - Chronic thrombus: Hyperintense
    - Longstanding thrombosed sinus eventually appears isointense
  - Venous infarct: Mass effect with mixed hypo-/hyperintense signal in adjacent parenchyma
- PD/intermediate
  - Loss of normal flow voids
  - More sensitive than T2WI
- FLAIR
  - Clot signal varies
  - Venous ischemia/infarcts hyperintense
- T2* GRE
  - Hypointense thrombus usually **"blooms"**
  - ± hypointense petechial hemorrhages
- DWI
  - 40% have hyperintense clot in occluded vessel (usually T2 "shinethrough" effect)
  - DWI/ADC findings in parenchyma variable, heterogeneous
    - Mixture of vasogenic, cytotoxic edema
      - Cytotoxic edema may precede vasogenic edema
      - Parenchymal abnormalities may be reversible
- T1WI C+
  - Acute, subacute DST: Dura enhances, clot doesn't ("empty delta" sign)
  - cDST: longstanding clot can enhance
    - Organized fibrous tissue ± recanalization
      - Potential source of false-negative interpretation
    - Look for "squiggly" vessels
- MRV
  - 2D TOF or contrast MRV
  - Absence of flow in occluded sinus on 2D TOF MRV
    - Frayed or shaggy appearance of venous sinus
    - Abnormal collateral channels (e.g., enlarged medullary veins)
  - T1 hyperintense (subacute) clot can masquerade as flow on MRV; evaluate standard sequences, source images to exclude artifacts
    - Potential cause of false-negative MRV
  - Flow gaps on MIPs must be reviewed on source images to exclude hypoplastic sinus variants, particularly for transverse and sigmoid sinus
    - Potential source of false-positive interpretation on MIPs
  - Contrast-enhanced MRV (CE-MRV) shows thrombus, small vein detail, collaterals much better than 2D TOF
  - Phase contrast MRV not limited by T1 hyperintense thrombus
- SWI shows "blooming" clot
  - Caution: Cortical and deep veins are normally hypointense (deoxyhemoglobin)
  - Look for prominent medullary veins (slow collateral flow in some cases of DST)

Angiographic Findings

- Occlusion of involved sinus
- Slow flow in adjacent patent cortical veins
- Collateral venous drainage develops

Imaging Recommendations

- Best imaging tool
  - NECT, CECT scans ± CTV as initial screening
  - MR, MRV (include T2*, DWI, T1WI C+)
- Protocol advice

https://CafePezeshki.IR

- If CT/CECT/CTV negative, MR with MRV
- If MRV equivocal, cerebral angiography

DIFFERENTIAL DIAGNOSIS

Normal

- Arteries, veins normally slightly hyperdense on NECT

High Hematocrit

- Common in newborns (low density brain, physiologic polycythemia)
- Polycythemia vera (both arteries, veins equally hyperdense)

Dural Sinus Hypoplasia-Aplasia

- Congenital hypoplastic/aplastic transverse sinus
  - Transverse sinus flow gaps (31%); nondominant sinus
  - Right transverse sinus dominant (59%), left dominant (25%), codominant (16%)
- "High-splitting" tentorium

"Giant" Arachnoid Granulations

- Round/ovoid filling defect (clot typically long, linear)
- Cerebrospinal fluid (CSF) density/signal intensity
- Normal in 24% of CECT, 13% of MR
  - Transverse sinus most common location by imaging, left > right
  - Superior sagittal sinus most common location for arachnoid granulations on histopathology (lateral lacunae, not well seen by imaging)

Acute Subdural Hematoma

- Layered blood on tentorium cerebelli may mimic transverse sinus thrombosis

PATHOLOGY

General Features

- Etiology
  - Wide spectrum of predisposing causes
    - Trauma, infection, inflammation
    - Pregnancy, oral contraceptives
    - Metabolic (dehydration, thyrotoxicosis, cirrhosis)
    - Hematological (coagulopathy)
    - Collagen-vascular disorders (APLA syndrome)
    - Vasculitis (Behçet)
  - Most common pattern
    - Thrombus forms in dural sinus
    - Clot propagates into cortical veins
    - Venous drainage obstructed, venous pressure elevated
    - Blood-brain barrier breakdown with vasogenic edema, hemorrhage
    - Venous infarct with cytotoxic edema
- Genetics
  - Resistance to activated protein C (typically due to factor 5 Leiden mutation): Most common cause of sporadic CVT
  - Protein S deficiency
  - Prothrombin (factor II) gene mutation
- Associated abnormalities
  - Dural AV fistula; venous occlusive disease may be underlying etiologic factor

Staging, Grading, & Classification

- **Venous ischemia grading**
  - Type 1: No abnormality
  - Type 2: Hyperintense on T2/FLAIR; no enhancement
  - Type 3: Hyperintense on T2/FLAIR; enhancement
  - Type 4: Hemorrhage or venous infarction

Gross Pathologic & Surgical Features

- Sinus occluded, distended by acute clot
- Thrombus in adjacent cortical veins
- Edematous adjacent cortex; petechial hemorrhage

Microscopic Features

- Thrombosis of veins, proliferative fibrous tissue in chronic thromboses

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Clinical diagnosis often elusive
    - Most common = headache
    - Other = nausea, vomiting ± neurologic deficit

Demographics

- Age
  - Any age can be affected
- Gender
  - F > M
- Epidemiology
  - Venous accounts for 1% of acute strokes

Natural History & Prognosis

- Extremely variable: Asymptomatic to coma, death
  - Up to 50% of cases progress to venous infarction
  - Can be fatal if severe brain swelling, herniation

Treatment

- In-patient heparin followed by out-patient warfarin (Coumadin)
- In more severe cases, endovascular mechanical thrombectomy ± local heparin infusion

DIAGNOSTIC CHECKLIST

Consider

- Angiography for patients with suspected chronic DST
- Venous filling defect from arachnoid granulation

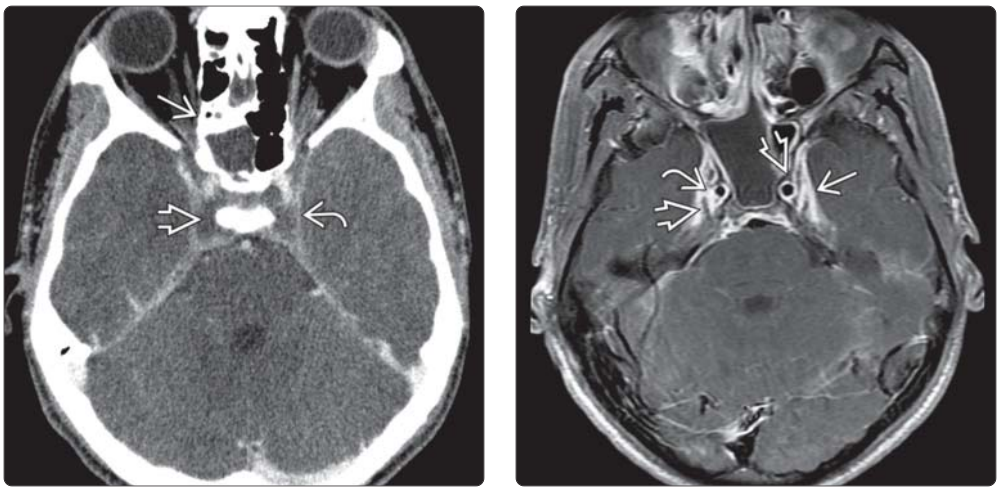
(Left) *NECT scan in a 68-year-old male with a 2-day history of headache and confusion shows no definite abnormality. The superior sagittal sinus ⇨ measured 60 HU.* **(Right)** *Axial CT venogram in the same patient shows nonenhancing thrombus ⇨ filling the entire SSS. The dural walls of the SSS enhance ⇨.*

(Left) *T2WI in the same patient shows hypointensity in the SSS ⇨ and cortical veins ⇨ mimicking normal "flow voids."* **(Right)** *T2* GRE in the same patient shows "blooming" thrombus in the SSS ⇨ and cortical veins ⇨. Acute thrombus can mimic normal "flow voids" on T2WI, but susceptibility-weighted scans (GRE or SWI) easily depict the intraluminal clots.*



(Left) *Cavernous sinus thrombosis can be difficult to diagnose. Most cases occur as complications from severe sphenoid sinusitis ⇨ and are seen as nonenhancing clot ⇨ contained by the enhancing dural walls ⇨.* **(Right)** *Axial T1C+FS MR in the same patient shows the nonenhancing clot ⇨ in the enhancing dural walls ⇨ and internal septae ⇨ of the CS. Patients with CS thrombophlebitis almost always have headache, cranial nerve palsies, and sphenoid sinusitis.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Cortical/cerebral venous thrombosis (CVT)
- Dural sinus thrombosis (DST)
- CVT with DST > isolated CVT without DST

IMAGING

- NECT
  - "Cord" sign (hyperdense vein)
  - Involved veins usually enlarged (distended with clot), irregular
  - ± petechial parenchymal hemorrhage, edema
- CECT
  - If DST, "empty delta" sign (25-30% of cases)
  - CTV: Thrombi may be seen as filling defects
- MR
  - Acute thrombus isointense on T1WI
  - Hypointense on T2WI (can mimic flow void)
  - T2* GRE best (clot usually blooms)
- 2D time of flight (TOF) MRV
  - Thrombus seen as sinus discontinuity, loss of vascular flow signal
  - Subacute thrombus T1 hyperintense (mimics patent flow on MIP)
- Imaging recommendations
  - NECT, CECT scans ± CTV
  - If CT negative → MR/MRV with T1WI C+, GRE
  - If MR is equivocal → DSA (gold standard)

TOP DIFFERENTIAL DIAGNOSES

- Normal (circulating blood slightly hyperdense)
- Anatomic variant (hypoplastic segment can mimic DST)

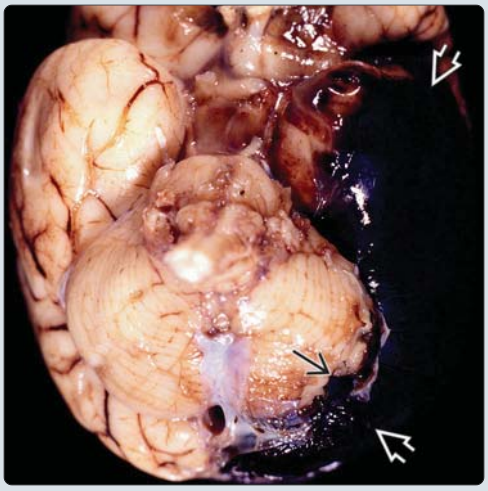
CLINICAL ISSUES

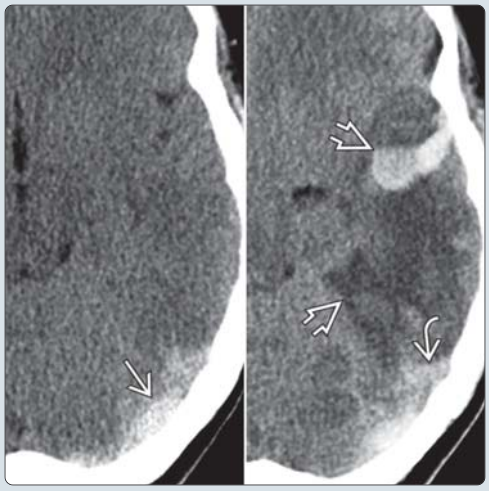
- Most common symptom is headache

DIAGNOSTIC CHECKLIST

- If "convexal" subarachnoid hemorrhage is seen, consider CVT

(Left) *Autopsy case shows thrombus in several cortical veins ⇨, the pathologic basis for the "cord" sign. (Courtesy E.T. Hedley-Whyte, MD.)* **(Right)** *Axial NECT scan in a patient with thrombosis of the superior sagittal sinus shows dense clot ⇨ filling and expanding the SSS. Thrombus is seen in a vein ⇨ over the cerebral convexity. Most (but not all) cortical vein thrombi occur as extension from clot in an adjacent dural venous sinus.*





(Left) *Autopsy case of transverse sinus thrombosis ⇨ that occluded the vein of Labbé shows extensive hemorrhagic venous infarction of the temporal, parietal, and occipital lobes ⇨. (Courtesy R. Hewlett, MD.)* **(Right)** *This 23-year-old woman presented in the ER with "migraine headache." Initial NECT scan (left) was called normal. Note the hyperdense thrombus in left TS ⇨. CT 1 day later (right) shows vein of Labbé thrombosis ⇨ and a large left temporal lobe hemorrhagic venous infarct ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Cortical/cerebral venous thrombosis (CVT)
- Dural sinus thrombosis (DST)

Definitions

- Superficial cerebral venous thrombosis
  - Usually with DST but isolated CVT without DST can occur

IMAGING

General Features

- Best diagnostic clue
  - "Cord" sign on NECT, T2* GRE
- Location
  - Cortical veins (unnamed)
    - Anastomotic vein of Labbé
    - Anastomotic vein of Trolard
  - Can be solitary, multiple
- Morphology
  - Veins usually enlarged (distended with clot), irregular
  - Linear, cigar-shaped thrombus

CT Findings

- NECT
  - Hyperdense cortical vein ("cord" sign) ± DST
  - Parenchymal abnormalities common
    - Petechial hemorrhage, edema
    - Hypodensity in affected vascular distribution
  - Need NECT to exclude false-negative CTV
    - Thrombus dense, can mimic enhancement
- CECT
  - If DST present
    - "Empty delta" sign (25-30% of cases)
  - "Shaggy," irregular enhancing veins (collateral channels)
- CTV
  - Thrombus seen as filling defect in cortical veins
  - Abnormal collateral channels (e.g., enlarged medullary veins)
  - Negative CTV does not exclude CVT
    - Limited value for chronic CVT
      - Organizing thrombosis also enhances
    - Limited value for nonocclusive thrombus
    - Optimize technique using thin slice (0.6 mm) MDCT with venous phase enhancement and dedicated sagittal and coronal MPR (1-2 mm)
    - Thick slice (3-5 mm) sliding or overlapping MIPs in sagittal and coronal planes
    - Concurrent NECT important to exclude false-negative CTV due to intrinsically dense thrombus
    - Subacute and chronic thromboses can enhance: Potential false-negative

MR Findings

- T1WI
  - Thrombus is isointense early, hyperintense later
  - ± venous infarct
    - Gyral swelling, edema hypointense
    - Iso- to slightly hyperintense foci if hemorrhagic
- T2WI
  - Thrombus hypointense acutely, hyperintense much later
    - Acute clot can mimic flow void
  - Venous infarct
    - Gyral swelling, edema hyperintense
    - Hypointense foci if hemorrhagic
- FLAIR
  - Thrombus usually hyperintense
  - Parenchymal edema hyperintense
- T2* GRE
  - GRE most sensitive sequence for thrombus
    - Hypointense ("black"), cord-like
  - SWI not as helpful due to intrinsic hypointensity of normal veins
- DWI
  - DWI/ADC varies with ischemia, type of edema, hemorrhage
    - Distinguishes cytotoxic from vasogenic edema
- T1WI C+
  - Thin (1 mm) 3D volume acquisition
  - Acute/early subacute clot: Peripheral enhancement outlines clot
  - Late clot: Thrombus, fibrous tissue often enhances
  - Venous infarct: Patchy enhancement
- MRV
  - 2D time of flight (TOF) MRV depicts thrombus as sinus discontinuity, loss of vascular flow signal
    - May see abnormal collateral channels (e.g., enlarged medullary veins)
    - Occluded veins at time of diagnosis may predict low rate of vessel recanalization 2 or 3 months later
  - Contrast-enhanced MRV (CE-MRV)
    - Faster; better depicts nonenhancing thrombus and small veins than TOF
  - TOF limitations
    - T1 hyperintense thrombus (subacute) may mimic patent flow on MIP (false-negative MRV)
    - Must evaluate source images and conventional MR sequences to exclude potential false-negatives
  - Phase contrast MRV: T1 hyperintense thrombus not misrepresented as flow

Ultrasonographic Findings

- Transcranial Doppler (TCD) ultrasound
  - Monitor venous flow velocities at ICU bedside
  - Follow therapy as decreasing velocities
  - Caveat: Normal venous velocities in serial measurements do not exclude diagnosis of CVT

Angiographic Findings

- Conventional DSA, venous phase
  - More accurate than MR, particularly for isolated cortical vein thrombosis
  - Considered gold standard
  - Chronic thromboses challenging due to enhancement from recanalization/organizing thrombus
- Interventional: Treatment with thrombolytics &/or mechanical declotting

Imaging Recommendations

- Best imaging tool
  - NECT, CECT ± CTV

https://CafePezeshki.IR

- MR with T1WI C+, GRE if CTV negative but high suspicion
- DSA is gold standard
- Protocol advice
  - If CT negative → MR with T1WI C+, GRE, MRV
  - If MR, MRV equivocal → DSA

DIFFERENTIAL DIAGNOSIS

Normal

- Circulating blood normally mildly hyperdense on NECT

Anatomic Variant

- Congenital hypoplasia can mimic DST
- Vein of Trolard, Labbé, superficial middle cerebral vein (SMCV) have reciprocal size relationship
  - If 2 are prominent, 3rd usually hypoplastic

"Giant" Arachnoid Granulation

- Can mimic DST
- Round/ovoid filling defect (clot is long, linear)
- CSF density, signal intensity

Cerebral Hemorrhage

- Mimics venous infarct
- Amyloid
- Cerebral contusion
- Hypertensive

PATHOLOGY

General Features

- Etiology
  - No cause identified in 20-25% of cases
  - Wide spectrum of predisposing causes (> 100 identified)
    - Trauma, infection, inflammation, malignancy
    - Pregnancy, oral contraceptives
    - Metabolic (dehydration, thyrotoxicosis, cirrhosis, hyperhomocysteinemia, etc.)
    - Hematological (coagulopathy)
    - Collagen-vascular disorders (e.g., APLA syndrome)
    - Vasculitis (e.g., Behçet)
    - Drugs (androgens, MDMA "ecstasy")
  - Most common pattern
    - Thrombus initially forms in dural sinus
    - Clot propagates into cortical veins
    - Venous drainage obstructed → ↑ venous pressure
    - Blood-brain barrier breakdown with vasogenic edema, hemorrhage
    - Venous infarct with cytotoxic edema ensues
  - Isolated CVT without DST occurs but is uncommon

Gross Pathologic & Surgical Features

- Sinus occluded, distended by acute clot
- Thrombus in adjacent cortical veins
- Adjacent cortex edematous, usually with petechial hemorrhage

Microscopic Features

- Thrombus in cortical vein(s) and sinus(es)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Clinical diagnosis often difficult, elusive
    - Headache (95%)
    - Seizure (47%), paresis (43%), papilledema (41%)
    - Altered consciousness (39%), comatose (15%)
    - Isolated intracranial hypertension (20%)
  - Focal neurologic deficits variable (depends on location)

Demographics

- Age
  - Any
- Gender
  - M < F
- Epidemiology
  - 1% of acute strokes

Natural History & Prognosis

- Extremely variable outcome; asymptomatic to death
  - Good outcome associated with isolated intracranial hypertension presentation, "delta" sign on CT (leading to earlier diagnosis)
  - Poor outcome associated with papilledema, altered consciousness, coma, age > 33 years, diagnostic delay > 10 days, intracerebral hemorrhage, involvement of straight sinus
- Up to 50% of cases progress to venous infarction
  - Overall mortality = 10%; recurrence as high as 12%

DIAGNOSTIC CHECKLIST

Consider

- If "convexal" subarachnoid hemorrhage is seen, consider CVT

Image Interpretation Pearls

- Include T2* GRE sequence on MR/MRV

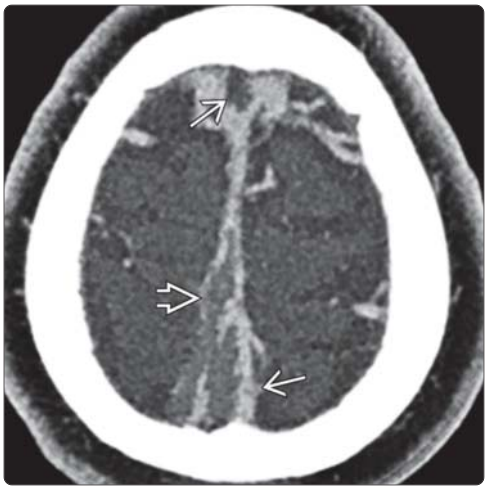
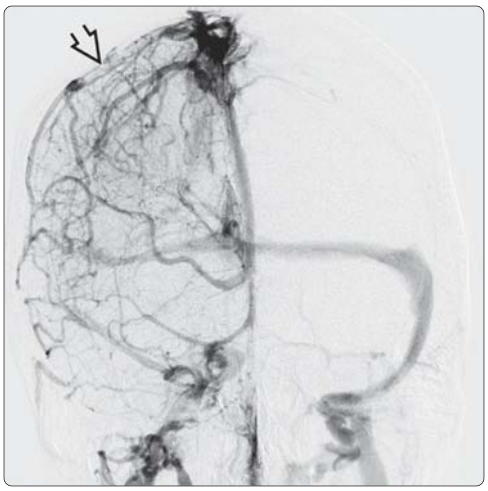
(Left) *FLAIR scan in a patient in the ER with headaches and convexal SAH on NECT (not shown) discloses hyperintense signal in the left central sulcus* ⇨. **(Right)** *T2* scan in the same patient shows the source of the convexal subarachnoid hemorrhage (SAH)* ⇨ *is a thrombosed a cortical vein* ⇨. *Note that the superior sagittal sinus* ⇨ *demonstrates no corresponding "blooming," suggesting that the thrombosed vein occurred in isolation, without involvement of other venous structures.*



(Left) *NECT scan in a 62-year-old female with headache and left-sided weakness shows a hyperdense superior sagittal sinus (measured 72 HU)* ⇨. *A hyperdense cortical vein is also present ("cord sign")* ⇨. **(Right)** *CTV in the same patient shows nonenhancing thrombus in the SSS ("empty delta sign")* ⇨ *as well as the cortical vein* ⇨.



(Left) *Sagittal CTV shows nonenhancing thrombus* ⇨ *in the partially occluded SSS as well as in the adjacent cortical vein* ⇨. **(Right)** *Right internal carotid DSA, venous phase, AP view, confirms nonenhancing thrombus* ⇨ *in a prominent vein of Trolard.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Thrombotic occlusion of deep cerebral veins
  - Usually affects both ICVs ± vein of Galen (VOG), straight sinus (SS)
  - Often occurs with more widespread deep sinus thrombosis

IMAGING

- NECT
  - Hyperdense ICV ± VOG, SS
  - Hypodense thalami/basal ganglia (BG), loss of gray-white matter interfaces
    - Variable loss of deep gray-white interfaces
    - Thalami seem to "disappear" into background WM hypodensity
  - ± petechial hemorrhages
- CECT
  - Loss of ICV enhancement, presence of enlarged collateral channels
  - "Shaggy," irregular veins (collateral channels) in deep WM, around tentorium
- MR
  - Acute clots hypointense on T2WI, "bloom" on T2*
  - Deep (medullary) WM veins prominent, tortuous on SWI
- Protocol advice
  - If CT/CECT/CTV scans negative → MR with MRV
  - If MRV equivocal → DSA

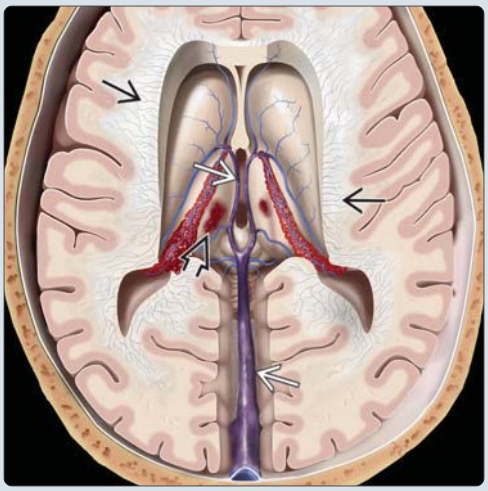
TOP DIFFERENTIAL DIAGNOSES

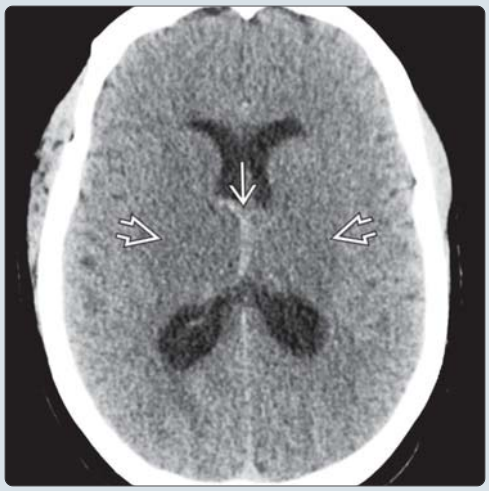
- Other bithalamic/basal ganglia lesions
  - Neoplasm (e.g., bithalamic astrocytoma)
  - Nonvenous ischemia (e.g., artery of Percheron infarct)
  - Toxic/metabolic disorders (e.g., carbon monoxide poisoning)

CLINICAL ISSUES

- Venous thrombosis = 1-2% of strokes
- ICV thrombosis = 10% of venous "strokes"

(Left) *Axial graphic depicts thrombosis of both ICVs and SS ⇨ with secondary hemorrhage in the choroid plexus and thalami ⇨. Edema in the thalami, basal ganglia, and deep cerebral white matter are common findings. Linear WM medullary veins ⇨ may become engorged and enhance.* **(Right)** *NECT in a 32-year-old female with severe headache shows hyperdense internal cerebral veins (ICVs) ⇨. Both thalami are edematous, symmetrically isodense ⇨ (normally hyperdense) compared to the surrounding white matter.*





(Left) *More inferior NECT in the same patient shows the vein of Galen ⇨ and straight sinus ⇨ are also thrombosed and hyperdense (measured 70 HU).* **(Right)** *Lateral DSA, venous phase, in the same patient shows normal opacification of the superior sagittal sinus and transverse sinus. The ICVs, vein of Galen, and straight sinus are thrombosed and do not fill with contrast. Deep (Galenic system) venous occlusion.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Deep cerebral venous thrombosis (DCVT)
- Internal cerebral vein (ICV) thrombosis

Definitions

- Thrombotic occlusion of deep cerebral veins
  - Usually affects both ICVs ± vein of Galen (VOG), straight sinus (SS)
  - Often with widespread dural sinus thrombosis (DST)

IMAGING

General Features

- Best diagnostic clue
  - Hyperdense ICV ± VOG, SS ± bithalamic hypodensity
    - Loss of deep gray-white matter interfaces
    - Thalami seem to "disappear" into background WH hypodensity
- Location
  - ICV ± VOG, SS, basal veins of Rosenthal
  - Bilateral ICV thrombosis > > unilateral
  - Edema (venous congestion)
    - Deep gray nuclei, internal capsule, medullary white matter (WM)
    - Variable involvement of midbrain, upper cerebellum

CT Findings

- NECT
  - Hyperdense ICVs ± SS, DST
  - Variable parenchymal abnormalities
    - Hypodense thalami/basal ganglia (BG), loss of gray-white matter interfaces
    - ± petechial hemorrhages
- CECT
  - "Empty delta" sign (if DST)
  - "Shaggy," irregular veins (collateral channels) in deep WM, around tentorium
- CTV
  - Loss of ICV enhancement, presence of enlarged collateral channels
  - Limited value in chronic cases as organizing thrombosis also enhances

MR Findings

- T1WI
  - Clot: Early T1 isointense, later hyperintense
  - Venous hypertension: Hypointense swelling of thalami, basal ganglia
  - Venous infarct: Hypointense edema, may be hemorrhagic
- T2WI
  - Acute thrombus hypointense, mimics flow voids
  - Hyperintense swelling of thalami, basal ganglia common
    - Corresponds to vasogenic ± cytotoxic edema
  - Venous infarct: Parenchymal swelling, hyperintense edema, may be hemorrhagic
- FLAIR
  - High signal in occluded veins
  - Best demonstrates hyperintense BG edema
- T2* GRE
  - Thrombus is hypointense, "blooms"
  - SWI shows engorged, prominent deep WM (medullary) veins
  - Variable petechial hemorrhages
- DWI
  - Variable findings
  - BG/thalami may restrict early, normalize later
  - Thrombus, hemorrhages may restrict
- T1WI C+
  - Acute/early subacute clot: Peripheral enhancement outlines clot
  - Late clot: Thrombus, fibrous tissue often enhances
  - Venous stasis in deep WM (medullary) veins seen as linear enhancing foci radiating outward from ventricles
  - Venous edema/hypertension: No enhancement
  - Parenchymal venous infarct: Patchy enhancement
- MRV
  - 2D time of flight (TOF) MRV shows "missing" ICVs, variably absent signal in VOG, SS
    - May see abnormal collateral channels
  - Contrast-enhanced MRV (CE-MRV)
    - Faster; better depicts nonenhancing thrombus and small veins than TOF
  - TOF limitations
    - T1 hyperintense thrombus falsely appears as patent flow on MIP
    - Always evaluate source images and conventional MR sequences
  - Phase contrast MRV: T1 hyperintense thrombus not misrepresented as flow

Angiographic Findings

- Conventional
  - DSA more accurate than MR
  - Normal deep cerebral veins are always present on angiography
    - In DCVT, occluded ICVs do not opacify ("absent")
    - Collateral venous channels (e.g.,medullary veins) enlarge
- Interventional: Treatment with thrombolytics &/or mechanical declotting

Imaging Recommendations

- Best imaging tool
  - NECT, CECT ± CTV venogram
  - Conventional DSA if intervention planned
- Protocol advice
  - If CT/CECT/CTV scans negative → MR with MRV
  - If MRV equivocal → DSA

DIFFERENTIAL DIAGNOSIS

Nonvenous Ischemic Injury

- Arterial occlusion
  - Artery of Percheron cerebral ischemia
  - Top of basilar cerebral infarction
- Global hypoxia

Primary CNS Lymphoma

- T2 hyperintense, enhancing mass(es)
- Along ependymal surfaces (thalami > basal ganglia)

https://CafePezeshki.IR

- Normal venous system

Bithalamic Astrocytoma

- T2 hyperintense mass in deep gray nuclei
- Normal venous system
- Elevated choline, decreased NAA
- Vasogenic not cytotoxic edema

Carbon Monoxide Poisoning

- T2 hyperintense deep gray nuclei, often globus pallidus
- Normal venous system
- Positive carboxyhemoglobin
- Classic cherry red skin is rare

PATHOLOGY

General Features

- Etiology
  - No cause identified in 20-25% of cases
  - Wide spectrum of causes (> 100 identified)
    - Trauma, infection, inflammation
    - Pregnancy, peripartum period
    - Metabolic (dehydration, thyrotoxicosis, cirrhosis, etc.)
    - Hematological (coagulopathy)
    - Collagen-vascular disorders (e.g., APLA syndrome)
    - Vasculitis (e.g., Behçet)
    - Drugs (oral contraceptives, androgens, ecstasy)
    - Ulcerative colitis
  - Most common sequence
    - Thrombus initially forms in dural sinus
    - Clot propagates into cortical veins
    - Venous drainage obstructed, venous pressure elevated
    - Blood-brain barrier breakdown with vasogenic edema, hemorrhage
    - Venous infarct with cytotoxic edema ensues
- Genetics
  - Factor 5 Leiden mutation is most common cause of sporadic CVT

Staging, Grading, & Classification

- Venous ischemia
  - Type 1: No abnormality
  - Type 2: High signal on T2WI/FLAIR; no enhancement
  - Type 3: High signal on T2WI/FLAIR; enhancement present
  - Type 4: Hemorrhage or venous infarction

Gross Pathologic & Surgical Features

- ICVs occluded, distended by acute clot
- Venous hypertension ensues
- Adjacent thalami edematous with variable hemorrhage

Microscopic Features

- Thrombus in occluded vessels

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, nausea, vomiting
    - ± neurologic deficit, seizure

Demographics

- Age
  - Any age
    - Especially elderly, debilitated patients
    - Pregnant, peripartum women, women on BCPs
- Gender
  - F > M
- Epidemiology
  - Venous thrombosis causes 1-2% of strokes
  - ICV thrombosis = 10% of venous "strokes"

Natural History & Prognosis

- Clinical diagnosis of CVT often elusive
- Outcome of CVT extremely variable, from asymptomatic to death
  - Majority have no residual deficits at 16 months
  - Subgroup (13%) have poor outcome
  - Predictors of death/dependence
    - Hemorrhage on admission CT
    - DWI demonstration of cytotoxic edema (infarction)

Treatment

- Heparin ± rTPA
- Endovascular thrombolysis

DIAGNOSTIC CHECKLIST

Consider

- DSA in equivocal cases and for intervention

Image Interpretation Pearls

- Early imaging findings subtle, often overlooked
- Obtain NECT concurrently with CTV
- "Flow voids" on T2 do not rule out DCVT
- 2D TOF MRV should not be interpreted without benefit of standard imaging sequences
- Nonvisualization of deep venous system on CTA/MRA/DSA always abnormal

KEY FACTS

TERMINOLOGY

- Arachnoid granulation (AG)
  - Defined as enlarged arachnoid villi projecting into major dural venous sinus lumen
- Aberrant arachnoid granulation (AbAG)
  - Defined as AG that penetrates dura, but fails to reach venous sinus, typically in sphenoid or temporal bone

IMAGING

- Intrasinus AG: Well-circumscribed, discrete, filling defect in venous sinus ± inner calvarial table erosion
  - CECT: Nonenhancing; density like CSF
  - MR: T1/T2 intensity follows CSF; FLAIR often hyperintense
- AbAG: Multiple focal outpouches in sphenoid bone or temporal bone
  - Sphenoid bone location: Greater wing
  - Temporal bone location: Posterior wall or tegmen
  - CT: Multiple smooth pits in sphenoid or T-bone
  - MR: T1 and T2 intensity follows CSF

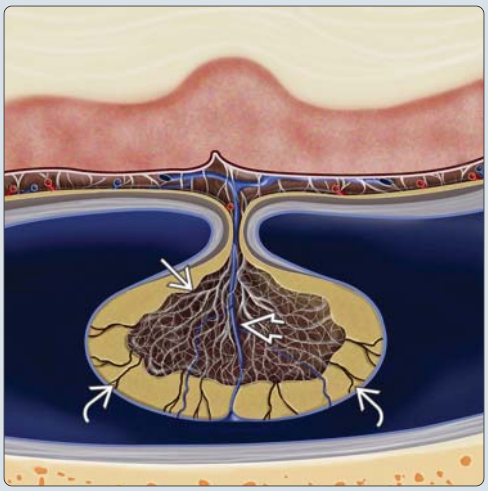
TOP DIFFERENTIAL DIAGNOSES

- Dural sinus hypoplasia-aplasia
- Transverse-sigmoid sinus pseudolesion
- Dural sinus thrombosis
- Dural arteriovenous fistula

CLINICAL ISSUES

- Intrasinus AG: Asymptomatic with rare exception
- Aberrant AG: Mostly asymptomatic
  - If large with rupture, **CSF leak** ± meningitis possible
  - Sphenoid bone: CSF leak → sphenoid fluid → rhinorrhea
  - T-bone: CSF leak → middle ear-mastoid fluid → otorrhea
  - Large AG may have associated **cephalocele** (± seizure)
  - **Meningitis** may complicate CSF leak
- Treatment
  - Intrasinus AG: No treatment required
  - Aberrant AG: No treatment unless CSF leak present

(Left) *Graphic shows a giant arachnoid granulation (AG) projecting from subarachnoid space into transverse sinus. CSF core ➡ extends into the AG and is separated by arachnoid cap cells from the venous sinus endothelium ➡. Giant AGs often contain prominent venous channels ➡ and septations.* **(Right)** *Axial CECT shows a giant arachnoid granulation cluster at the transverse-sigmoid venous sinus junction ➡. The 1st imaging interpretation of this finding mistakenly suggested venous sinus thrombosis.*



(Left) *Axial T1WI MR in the same patient reveals the multiple giant arachnoid granulations ➡ as low signal within the transverse and proximal sigmoid sinuses. The medial low signal line ➡ is the dura.* **(Right)** *Lateral internal carotid artery angiogram in same patient clearly depicts multiple giant arachnoid granulations in the transverse ➡ and proximal sigmoid ➡ venous sinuses. No intrasinus pressure gradient was present across the lesion.*

TERMINOLOGY

Abbreviations

- Arachnoid granulation (AG)
- Aberrant arachnoid granulation (AbAG)

Synonyms

- Pacchionian depressions, granulations, or bodies
- When large → "giant" arachnoid granulation
- When in sphenoid bone and T-bone → AbAG

Definitions

- Arachnoid villi: Termed used to describe smaller AG
- AG: Enlarged arachnoid villi projecting into major dural venous sinus lumen
- AbAG: AG that penetrated dura, but fails to reach venous sinus, typically in sphenoid or temporal bone
  - Also referred to as arachnoid pits or osteodural defects

IMAGING

General Features

- Best diagnostic clue
  - Intrasinus AG: Discrete filling defect in venous sinus ± inner calvarial table erosion
    - CECT: Nonenhancing; similar density to CSF
    - MR: T1/T2 intensity follows CSF; often hyperintense on FLAIR
  - AbAG: Multiple focal outpouches in sphenoid bone, often greater wing
    - Bone CT: Multiple smooth pits in sphenoid bone
    - MR: T1 and T2 intensity follows CSF
- Location
  - Most common location: Transverse sinus
  - Other locations: Sigmoid, sagittal, or straight sinus
  - AbAG location: Sphenoid bone, often greater wing, or lateral sinus wall
    - T bone: Posterior wall or tegmen tympani
- Size
  - 5-15 mm size range
  - If > 15 mm, called "giant AG"
- Morphology
  - Single or multiple ovoid lesions
  - Focal osseous pits in inner table of calvaria

CT Findings

- NECT
  - Intrasinus AG isodense with CSF
  - CSF pulsations may result in erosion or scalloping of inner table
  - AbAG: Focal osseous erosions in sphenoid bone
    - If large, may appear multilocular; mimic cystic bone lesion
- CECT
  - Nonenhancing, ovoid focal filling defect within venous sinus
  - Isodense to CSF
  - AbAG: CSF density with subtle rim (dural) enhancement
- CT venogram
  - Focal filling defect within venous sinus

MR Findings

- T1WI
  - Venous sinus defect isointense to CSF
- T2WI
  - Hyperintense (like CSF)
  - Surrounded by normal flow void of major venous sinus
  - AbAG: High signal outpouching into sphenoid bone
    - If large, may see arachnoid pouch bulging into sphenoid sinus lumen
      - Arachnoid strands seen as low signal lines within pouch
    - Larger lesions may have **CSF leak** into sphenoid sinus
      - Fluid levels seen in sphenoid sinus if leak present
    - Larger lesions may have **cephalocele** associated
- T1WI C+
  - Intrasinus AG: Ovoid without enhancement surrounded by enhancing blood in dural sinus
    - Veins, septae may enhance
  - AbAG: Nonenhancing foci in sphenoid bone
- MRV
  - Intrasinus AG
    - Source images show focal signal loss in location of AG
    - MRV reformation shows focal defect in affected sinus

Imaging Recommendations

- Best imaging tool
  - Intrasinus AG: Enhanced MR with MRV
  - AbAG: Bone CT of skull base
    - Enhanced MR focused to sphenoid bone area

DIFFERENTIAL DIAGNOSIS

Dural Sinus Hypoplasia-Aplasia

- Congenital hypoplastic-aplastic transverse sinus
- "High-splitting" tentorium

Transverse-Sigmoid Sinus Pseudolesion

- Asymmetric complex flow phenomenon in sinus mimics lesions
- Not present on all sequences; MRV sorts out

Dural Sinus Thrombosis

- Long-segment region of ↓ venous sinus flow
- NECT: Hyperdense
- CECT: Nonenhancing clot in venous sinus lumen
- MR: Hyperintense on T1 or lack of flow void on T2
  - T1 C+: Nonenhancing clot in venous sinus lumen

Dural AV Fistula

- MR: Recanalized, irregular transverse-sigmoid sinuses
  - MRA: Enlarged, feeding external carotid artery branches; early venous drainage
- Angio: Enlarged, feeding external carotid artery branches

PATHOLOGY

General Features

- Etiology
  - Intrasinus AG: Normal variant enlarged arachnoid villi
    - Penetrates dura overlying venous sinus
    - Arachnoid cap cells in margin of AG responsible for CSF resorption

https://CafePezeshki.IR

- Aberrant AG: AG that penetrates dura, but fails to reach venous sinus in sphenoid or temporal bone
  - CSF pulsations enlarge AbAG causing arachnoid pouch bulging
  - Bulging arachnoid pouch penetrates subjacent structures (dura, then underlying bone)
  - If pouch stretches to point of rupture, CSF enters air cells if involved
    - Sphenoid bone-sphenoid sinus: CSF leak → sphenoid fluid → rhinorrhea
    - Temporal bone-air cells: CSF leak → middle ear-mastoid fluid → otorrhea
    - Cephalocele possible in larger AbAG

Gross Pathologic & Surgical Features

- AG: Smooth arachnoid granulation projecting into venous sinus or subarachnoid space
- Aberrant AG: Osteodural defects in lateral sphenoid sinus wall or greater wing of sphenoid

Microscopic Features

- Enlarged arachnoid villi
- Central core of loose connective tissue with CSF
- Peripheral zone of dense connective tissue
- Projects through dura of venous sinus wall

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Intrasinus AG: Asymptomatic with rare exception
    - If suspect giant AG in venous sinus causing venous hypertension with headache, angiography with pressure measurements needed
    - In most cases, no pressure gradient across giant AG in dural venous sinus found
  - Aberrant AG: Mostly asymptomatic
    - If CSF pulsations enlarge AbAG in sphenoid sinus or temporal bone wall, CSF leak ± meningitis possible
      - Sphenoid sinus wall rupture: Rhinorrhea
      - Temporal bone air cell rupture: Otorrhea
    - If significant cephalocele occurs, seizure possible
- Other signs/symptoms
  - Benign intracranial hypertension in obese middle-aged females with rhinorrhea
    - Look for aberrant AG in the sphenoid bone adjacent to sphenoid sinus

Demographics

- Age
  - ↑ in frequency with ↑ age; ≥ 40 years
- Epidemiology
  - Intrasinus AG: 25% CECT or T2WI MR
  - Aberrant AG: Rare to see with imaging
    - Sphenoid bone: < 2%
    - Temporal bone: < 1%

Natural History & Prognosis

- Intrasinus AG: Remains asymptomatic
- Aberrant AG: May remain small
  - If enlarge in response to CSF pulsations may penetrate dura, bone and air cells
    - CSF leak, cephalocele, or meningitis may result

Treatment

- Intrasinus AG: No treatment required
- Aberrant AG: No treatment needed unless enlarged with resulting CSF leak
  - Can follow large, asymptomatic AbAG
  - If CSF leak present into sphenoid sinus or temporal bone, surgical dural repair necessary
    - Surgical repair prevents meningitis possibility

DIAGNOSTIC CHECKLIST

Consider

- If **intrasinus giant AG** with history of headache, consider angiogram to look for intrasinus pressure gradient
- If **aberrant AG** presents in lateral wall **sphenoid bone**, look for fluid in sphenoid sinus as evidence for CSF leak
  - Also use MR to evaluate for possible associated cephalocele
- If **aberrant AG** found in posterior wall of **temporal bone**, look for fluid in mastoid air cells as evidence for CSF leak

Image Interpretation Pearls

- Intrasinus AG
  - Confirm AG remains CSF density (as seen with CECT or CT angiogram) and intensity (as seen with T1 and T2 MR sequences)
  - Make sure proximal and distal venous sinus is normal from imaging perspective
- Aberrant AG in lateral sphenoid sinus wall or posterior wall temporal bone
  - If large or multiple, look for evidence of CSF leak

Sinus Pericranii 416
Cavernous Malformation 420
Capillary Telangiectasia 424

https://CafePezeshki.IR

General Considerations

Cerebrovascular malformations (CVMs) of the brain are a heterogeneous group of disorders that represent morphogenetic errors affecting arteries, capillaries, veins, or various combinations of vessels.

The presentation, natural history, and management approaches to CVMs depend on their type, location, size, and hemodynamic characteristics. Some CVMs such as venous or capillary malformations are almost always clinically silent and therefore usually identified at imaging or autopsy. Others, such as arteriovenous and cavernous malformations, may hemorrhage unexpectedly and without warning.

Terminology

Without a uniform consensus, there is much confusion regarding the nomenclature of brain CVMs. They have variously been called angiomas, hemangiomas, developmental anomalies, malformations, and hamartomas. For example, venous vascular malformations have been termed venous angiomas, venous anomalies, venous malformations, and developmental venous anomalies (DVAs). Cavernous malformations have been called cavernous angiomas, cavernous hemangiomas, and "cavernomas" in the literature.

Using accurate terminology when discussing brain vascular malformations is important. Two major groups of vascular anomalies are recognized: Vascular malformations and hemangiomas. All cerebrovascular malformations ("angiomas") are malformative lesions. In contrast, "hemangiomas" are true proliferating, vasoformative neoplasms and, in the most recent WHO classification "blue book," are included with the mesenchymal, nonmeningothelial tumors.

Hemangiomas are benign vascular neoplasms, not malformations, and can be capillary or cavernous. Most intracranial hemangiomas are found in the skull, meninges, and dural venous sinuses while most vascular malformations occur in the brain parenchyma. Therefore, the term hemangioma should be reserved for vasoproliferative neoplasms and not used to describe vascular malformations. In this text, CVMs are included in this section; hemangiomas are considered as neoplasms and included elsewhere.

Epidemiology

The overall prevalence of brain CVMs is difficult to estimate as accurate epidemiologic data are scarce. Cushing and Bailey found vascular anomalies constituted about 1% of all intracranial tumors. Using ICD-9 codes, hospital admission rates for CVMs have been calculated as approximately 1.5-1.8 cases per 100,000 person-years. CVMs are estimated to cause about 5% of all nontraumatic intracranial hemorrhages.

With modern imaging, and especially with contrast-enhanced MR, CVMs are found in up to 8-10% of imaged patients. Most (venous and capillary malformations) are asymptomatic and found incidentally.

Embryology

Development of the human fetal vascular system occurs via 2 related processes: Vasculogenesis and angiogenesis. Vasculogenesis begins with de novo differentiation of endothelial cells from mesoderm-derived precursors called hemangioblasts. Islands of hemangioblasts form an outer rim of endothelial cell precursors ("angioblasts") and an inner core of hematopoietic stem cells.

Angioblasts form capillary-like tubules that constitute the primitive vascular plexus. This embryonic vascular network is then remodeled by a process of sprouting, progressive anastomosis, and retrogressive differentiation. Endothelial cells differentiate into arterial and venous types preceded, and guided by, migrating activated pericytes during definitive organization of the growing vessel wall.

Angiogenesis is regulated by a number of intercell signaling and growth factors. Some of these include Ang-1, Ang-2, Tie2, VEGF, PDGF, and TGF-β1, among others. Mutations in components of the angiogenetic system have been associated with the development of various CVMs.

Classification

In general, CVMs have been traditionally classified by histopathology and, more recently, by embryology and molecular genetics. With the advent of neurovascular interventional procedures, CVMs have also been classified by a practical, more functional approach.

Histopathologic Classification

Most neuropathology texts classify CVMs into 4 major types: (1) Arteriovenous malformation, (2) venous angioma, (3) capillary telangiectasia, and (4) cavernous malformation. The histopathologic classification is used in this book.

Embryologic Classification

Lasjaunias et al have proposed an embryonic, "metameric" approach to classifying vascular malformations that accounts for the known relationship between some brain and cutaneous vascular malformations. They termed these "cerebral arterial metameric syndromes" or "CAMS." For example, a CAMS1 syndrome links AVMs in the prosencephalon with those of the nose and orbit. Hence a CAMS1 patient may have a neurocutaneous AVM in the nose or retina and a brain parenchymal AVM.

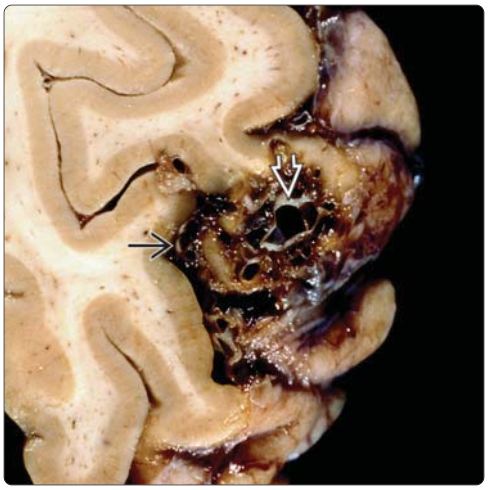
Molecular Classification

The identification of underlying causal genes in familial forms of CVMs has allowed the definition of an ever-increasing number of these disorders at the molecular level. Specific mutations in some genes (e.g., *CCM1/KRIT1*, *CCM2/MGC4607*, *CCM3/PDCD10*) cause autosomal dominantly inherited cavernous malformation syndromes (CCM1, CCM2, and CCM3). Some patients with brain AVMs also have cutaneous capillary malformations attributable to *RASA1* gene mutations. Hereditary hemorrhagic telangiectasias (HHT) result from several mutations, among them the endoglin gene (*ENG*) in HHT1. Whether cavernous and venous malformations are "molecularly distinct" or only "phenotypically distinct" lesions that result from the same *CCM* gene mutations is controversial.

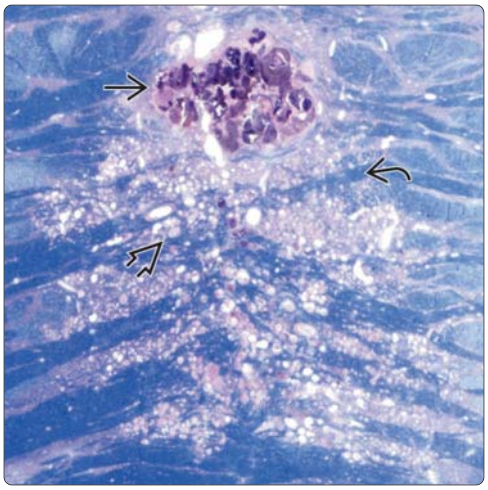
Functional Classification

Endovascular radiologists have proposed a functional, highly practical system that divides all CVMs into 2 basic categories: (1) CVMs that display arteriovenous shunting and (2) CVMs without AV shunting. The former category includes arteriovenous malformations and fistulae; the latter is basically everything else (venous, capillary, cavernous malformations). The former are amenable to intervention; the latter are either left alone or treated surgically.

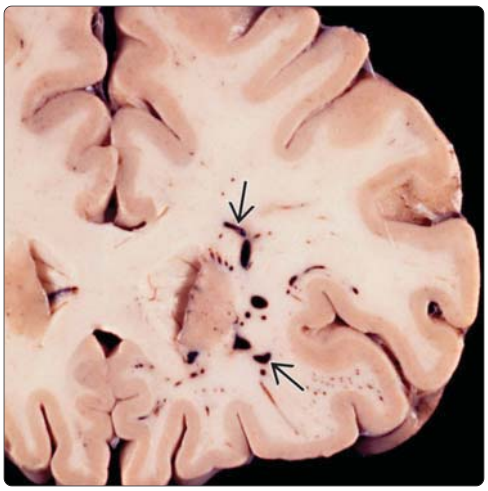
https://CafePezeshki.IR



(Left) *Autopsied brain depicts an unruptured arteriovenous malformation (AVM). Multiple thin-walled vessels form the AVM nidus. A larger vessel may represent an intranidal aneurysm. (Courtesy R. Hewlett, MD).* **(Right)** *Autopsy of a thrombosed carotid-cavernous fistula, another type of CVM that displays AV shunting, shows multiple enlarged, arterialized venous channels. (Courtesy B. Horten, MD.)*



(Left) *Autopsied case cut in the axial plane shows a large pontine capillary telangiectasia. Note the transverse pontine fibers crossing through the telangiectasia without interruption or distortion. (Courtesy B. Horten, MD.)* **(Right)** *Low-power micropathology demonstrates a mixed pontine cavernous-capillary malformation. Normal white matter is interspersed with a cavernous malformation and multiple tiny thin-walled vessels. (Courtesy AFIP.)*



(Left) *Coronal autopsied brain shows an incidental DVA in the frontal lobe adjacent to the lateral ventricle. Note enlarged venous channels with normal white matter in-between. (Courtesy M. Castillo, MD.)* **(Right)** *Clinical photograph of a patient with hereditary hemorrhagic telangiectasis and multiple episodes of severe epistaxis shows innumerable small capillary telangiectasias of the skin and scalp, nasal, and oral mucosa.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Pial vascular malformation of brain
  - Artery → vein shunting, no intervening capillary bed

IMAGING

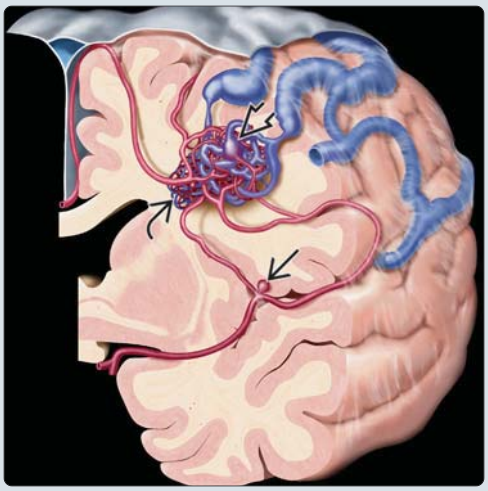
- General features
  - Supratentorial (85%), posterior fossa (15%)
- CT/CTA
  - Iso-/hyperdense serpentine vessels ± Ca++
  - Arterial feeders, nidus, draining veins enhance
- MR
  - "Bag of worms"/tangle of serpiginous "honeycomb" flow voids
  - No intervening normal brain in AVM nidus
  - Minimal/no mass effect
  - ± high signal (gliosis) on FLAIR
  - T2* GRE "blooming" if hemorrhage present
- DSA: Best delineates internal angioarchitecture, 3 components of AVM
  - Enlarged feeding arteries
  - Nidus of tightly packed vascular channels
  - Dilated draining veins
- Intranidal "aneurysm" > 50%
- Flow-related aneurysm on feeding artery (10-15%)

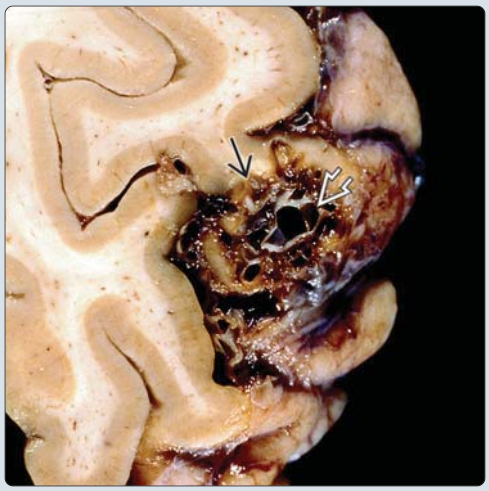
TOP DIFFERENTIAL DIAGNOSES

- Glioblastoma with AV shunting
- Dural AV fistula

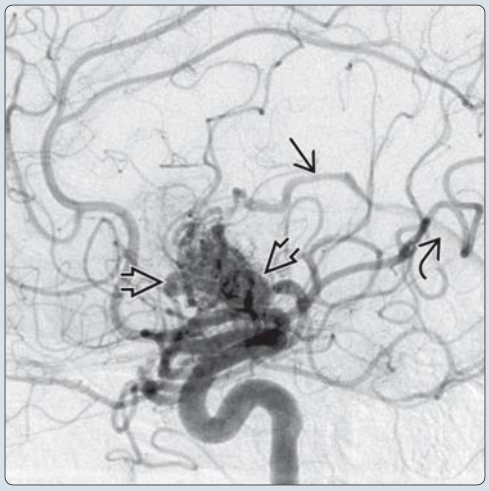
CLINICAL ISSUES

- Annual hemorrhage risk varies widely
  - Overall annual hemorrhage risk 2-4% (cumulative)
  - But ≤ 1% for unruptured, superficially-located nidi with superficial venous drainage
  - ≥ 30% for ruptured, deep-seated nidi with extensive deep venous drainage





(Left) *Coronal graphic shows a classic cerebral arteriovenous malformation (AVM). Note the nidus ⇨ with intranidal aneurysm ⇨ and enlarged feeding arteries with a "pedicle" aneurysm ⇨.* **(Right)** *Autopsy case demonstrates a classic AVM. The nidus ⇨ contains no normal brain in between the tightly paced vessels. A thin-walled intranidal aneurysm ⇨ is present. (Courtesy R. Hewlett, MD.)*



(Left) *Axial NECT (left) shows classic serpentine hyperdensities ⇨ of an unruptured AVM. CECT (right) shows strong uniform enhancement ⇨. Wedge-shaped configuration is typical.* **(Right)** *Lateral DSA of a classic AVM shows a nidus composed of tightly packed vessels ⇨. No intranidal or feeding pedicle aneurysms are present. Note the early deep venous drainage into the internal cerebral vein ⇨ and straight sinus ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Arteriovenous malformation (AVM)

Definitions

- Pial vascular malformation with direct artery → vein (AV) shunting, no intervening capillary bed

IMAGING

General Features

- Best diagnostic clue
  - "Bag of worms" (flow voids) on MR with minimal/no mass effect
- Location
  - May occur anywhere in brain
    - Supratentorial (85%), posterior fossa (15%)
  - 98% solitary, sporadic
    - Multiple AVMs rare, usually syndromic
- Size
  - Varies from microscopic to giant
  - Most symptomatic AVMs are 3-6 cm
- Morphology
  - 3 components
    - Enlarged feeding arteries
    - Nidus of tightly packed, enlarged vascular channels
    - Dilated draining veins
  - No normal brain in between

CT Findings

- NECT
  - May be normal (if AVM very small)
  - Iso-/hyperdense serpentine vessels
  - Ca++ in 25-30%
  - AVM bleed → parenchymal, intraventricular hemorrhage > > subarachnoid hemorrhage
  - Status postembolization: Liquid embolics appear hyperdense within nidus
- CECT
  - Strong enhancement of arterial feeders, nidus, draining veins
- CTA
  - Depicts enlarged arteries, draining veins

MR Findings

- T1WI
  - Signal varies with flow rate, direction, presence/age of hemorrhage
  - Tightly packed mass: "Honeycomb" of flow voids
- T2WI
  - Tangle of serpiginous, "honeycomb" flow voids
  - Variable hemorrhage
  - Little/no brain inside nidus
    - Some gliotic, high signal tissue may be present
- FLAIR
  - Flow voids ± surrounding high signal (gliosis)
- T2* GRE
  - "Blooming" if hemorrhage present
- T1WI C+
  - Strong enhancement of nidus, draining veins
  - Rapid flow may not enhance ("flow void")
- MRA
  - Helpful for gross depiction of flow, post embo/XRT
  - Does not depict detailed angioarchitecture

Angiographic Findings

- DSA best delineates internal angioarchitecture
- Use high frame rate, ↑ volume + rate of contrast injection per acquisition
- Depicts 3 components of AVMs
  - Enlarged arteries ± flow-related aneurysm(s)
  - Nidus of tightly packed vessels ± intranidal aneurysm(s)
  - Early draining veins ± venous stenoses due to high-flow venopathy (may ↑ intracranial hemorrhage [ICH] risk)
- 27-32% have "dual" arterial supply (pial, dural)

Imaging Recommendations

- Best imaging tool
  - DSA with high frame rate acquisitions ± superselective catheterization
- Protocol advice
  - Standard MR (include Gd-MRA, GRE sequences)

DIFFERENTIAL DIAGNOSIS

Glioblastoma With AV Shunting

- GBM enhances (tumor blush on DSA), has mass effect
- Some parenchyma between vessels

Thrombosed ("Cryptic") AVM

- Cavernous angioma
- Calcified neoplasm
- Oligodendroglioma
- Low-grade astrocytoma

Dural AV Fistula (dAVF)

- AV shunts within wall of patent ± partially thrombosed dural venous sinus, parallel venous channel, or adjacent cortical vein
- Most common location = transverse/sigmoid sinuses
- Differentiate from pial AVM by
  - Location: Nidus intimately related to dural venous sinus
  - Predominant blood supply is from dural (meningeal) arteries > > pial artery
    - e.g., middle and posterior meningeal arteries, artery of falx cerebelli, tentorial branches of cavernous ICA, occipital artery, artery of Davidoff and Schechter
  - Some parasitization of pial supply possible with larger dAVFs
  - Flow-related aneurysm are rare

PATHOLOGY

General Features

- Etiology
  - Dysregulated angiogenesis
    - Vascular endothelial growth factors (VEGFs), receptors mediate endothelial proliferation, migration
    - Cytokine receptors mediate vascular maturation, remodeling
- Genetics
  - Sporadic AVMs have multiple up-/down-regulated genes

https://CafePezeshki.IR

- Homeobox genes, such as *HOXD3* and *HOXB3*, involved in angiogenesis may malfunction
- Single nucleotide polymorphisms on p21 locus of chromosome 9 may predict clinical, angiographic AVM features
- Syndromic AVMs (2% of cases)
  - Multiple AVMs in *HHT1* (endoglin gene mutation)
  - Cerebrofacial arteriovenous metameric syndromes (CAMS) have orbit/maxillofacial + intracranial AVMs
- Associated abnormalities
  - Flow-related aneurysm on feeding artery (10-15%)
  - Intranidal "aneurysm" > 50%
  - Vascular "steal" may cause ischemia in adjacent brain
    - PET studies may show hemodynamic impairment

Staging, Grading, & Classification

- Spetzler-Martin (SM) scale
  - Sum of following estimates surgical risk from 1-5
    - Size
      - Small (< 3 cm) = 1
      - Medium (3-6 cm) = 2
      - Large (> 6 cm) = 3
    - Location
      - In "noneloquent" area = 0
      - Involves "eloquent" brain = 1
      - "Eloquent" = sensorimotor cortex, visual cortex, hypothalamus, thalamus, internal capsule, brainstem, cerebellar peduncles, deep nuclei
    - Venous drainage
      - Superficial only = 0
      - Deep = 1
- Lawton modified SM scale based on microsurgical outcomes
  - Grade III heterogeneous, divided into subtypes
    - Small AVM with both eloquent, deep venous drainage (Grade III-)
    - Medium-sized AVM with deep venous (Grade III) or eloquent (Grade III+)
    - Large AVM (grade III*)

Gross Pathologic & Surgical Features

- Wedge-shaped, compact mass of tangled vessels

Microscopic Features

- Wide phenotypic spectrum
  - Feeding arteries usually enlarged, but mature (may have some wall thickening)
  - Enlarged draining veins (may have associated varix, stenosis)
  - Nidus
    - Conglomeration of numerous tiny AV shunts
    - Thin-walled dysplastic vessels (no capillary bed)
    - Disorganized collagen, variable muscularization
    - No intervening normal brain (may have some gliosis)
  - Perinidal capillary network (PNCN)
    - Nidus surrounded by dilated capillaries in brain tissue 1-7 mm outside nidus border
    - Vessels in PNCN 10-25x larger than normal capillaries

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache with hemorrhage (50-60%)
  - Seizure (15-25%)
  - Focal neurologic deficit (10-25%)
- Clinical profile
  - Young adult with spontaneous (nontraumatic) ICH

Demographics

- Age
  - Peak presentation: 20-40 years (25% by age 15)
- Gender
  - M = F
- Epidemiology
  - Most common symptomatic cerebral vascular malformation (CVM)
  - Prevalence of sporadic AVMs: 0.04-0.52%

Natural History & Prognosis

- Brain AVMs have wide range of morphologies, angioarchitecture
  - Annual hemorrhage risk varies widely
    - Overall annual hemorrhage risk 2-4% (cumulative)
    - But ≤ 1% for unruptured, superficially-located nidi with superficial venous drainage
    - ≥ 30% for ruptured, deep-seated nidi with extensive deep venous drainage

Treatment

- Embolization
- Microneurosurgical resection
- Stereotactic radiosurgery

DIAGNOSTIC CHECKLIST

Consider

- MR of vascular-appearing lesion that has brain parenchyma in between flow voids may be vascular neoplasm, not AVM

Image Interpretation Pearls

- Look carefully for pedicle, intranidal aneurysms
- Look for subtle early draining veins; may be only clue to diagnosis of largely thrombosed AVMs

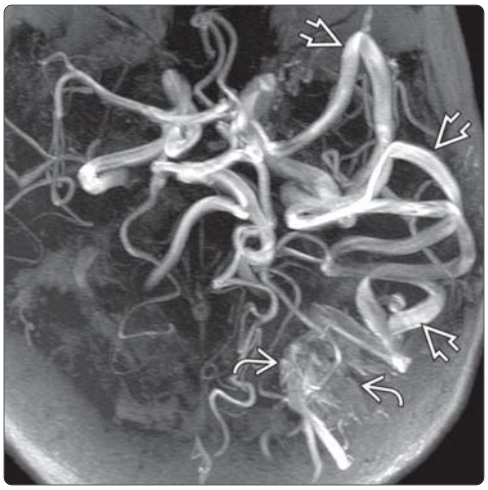
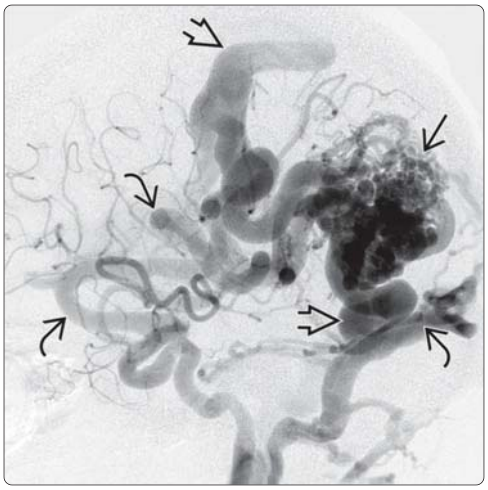
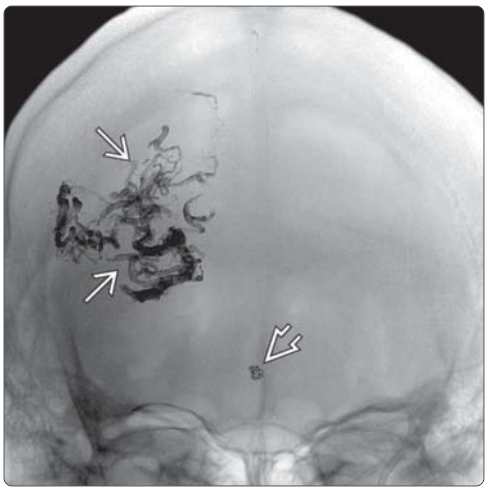
https://CafePezeshki.IR



(Left) *Axial TOF MRA MIP in a 38-year-old patient with a worsening headache and visual disturbance shows a left parietooccipital AVM ⇨ with massively dilated MCA feeding arteries ⇨.* **(Right)** *Axial T1WI C+ MR in the same patient shows avid enhancement of the nidus ⇨ and enlarged superficial draining veins ⇨. Note that a portion of the nidus ⇨ and feeding arteries ⇨ appear as flow voids due to the high flow within the vessels. Phase artifact ⇨ propagation across the image is striking.*



(Left) *Axial FLAIR MR shows "honeycomb" flow voids representing the AVM nidus ⇨. Large serpentine flow voids anterior to the nidus are MCA feeding arteries ± draining veins ⇨. Note only mild mass effect on the trigone of the left lateral ventricle relative to the size of the lesion. Some high signal adjacent to the nidus ⇨ likely represents gliosis.* **(Right)** *Lateral ICA DSA in the same patient shows enlarged MCA feeders ⇨, dilated/tortuous superficial draining veins ⇨, and AVM nidus ⇨.*



(Left) *Oblique left ICA 3D DSA shows enlarged anterior cerebral artery ⇨ supplying a frontal AVM ⇨. Note flow-related aneurysm of the anterior communicating artery ⇨, a potential cause of future ICH.* **(Right)** *Posteroanterior unsubtracted image, after 3 sessions of staged embolization of multiple ACA and MCA feeders, shows an onyx cast within the nidus and adjacent feeding arteries ⇨. The ACoA flow-related aneurysm was coiled ⇨ prior to embolization of the ACA feeders.*

https://CafePezeshki.IR

KEY FACTS

IMAGING

- Location: Dural sinus wall
  - Posterior fossa >> supratentorial
  - Can involve any dural sinus (TS/SS most common)
- NECT
  - Usually normal
  - ICH if outlet vein thrombosed or flow-related aneurysm, venous pouch ruptures
- Bone CT
  - Dilated transosseous calvarial vascular channels
  - ± enlarged foramen spinosum
- MR
  - Isointense thrombosed sinus ± flow voids on T1/T2WI
  - Thrombosed dural sinus blooms on T2*
  - May show parenchymal hemorrhage in dAVF with cortical venous drainage
  - FLAIR: Isointense thrombosed sinus ± adjacent edema if venous congestion or ischemia present
- MR/CTA: Network of tiny (crack-like) vessels in wall of thrombosed dural venous sinus

TOP DIFFERENTIAL DIAGNOSES

- Hypoplastic transverse-sigmoid sinus
- Sigmoid sinus-jugular foramen pseudolesion
- Thrombosed dural sinus
- Dural sinus stenosis

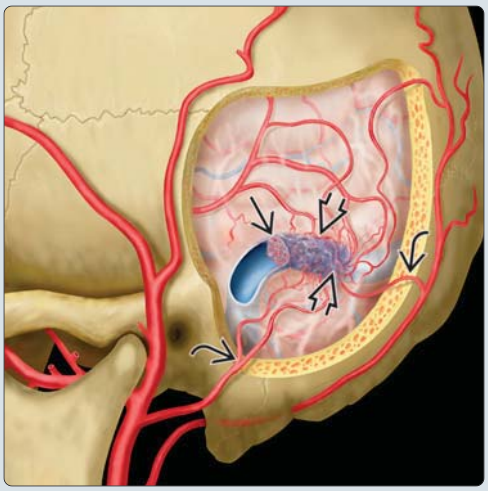
PATHOLOGY

- Adult dAVFs are usually acquired, not congenital
- Can occur in response to trauma, venous sinus thrombosis
- Pathological activation of neoangiogenesis

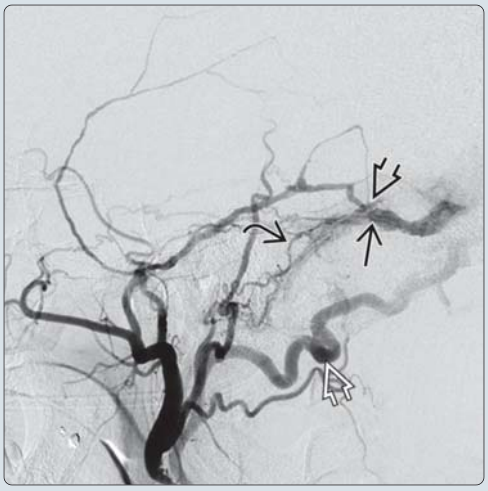
CLINICAL ISSUES

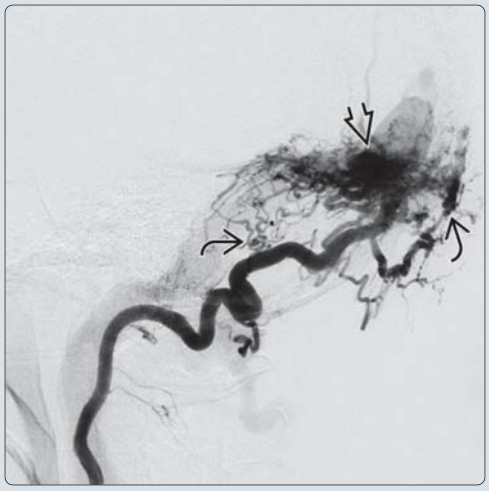
- 10-15% of all cerebrovascular malformations with AV shunting
- Adult >> child
- Prognosis depends on location, venous drainage pattern
- Treatment options: Endovascular, surgery, stereotaxic XRT

(Left) *Graphic depicts dAVF with thrombosed transverse sinus. Multiple transosseous branches from the external carotid artery supplying innumerable tiny arteriovenous fistulae in the dural wall.* **(Right)** *Mass-like surgical specimen from a resected dAVF in the transverse sinus wall shows innumerable crack-like vessels. (Courtesy R. Hewlett, MD.)*



(Left) *Lateral view of an external carotid DSA depicts typical angiographic findings of dAVF. The ipsilateral transverse sinus is occluded and there are multiple prominent branches from the posterior auricular artery supplying a dAVF in the TS wall. The occipital artery is markedly enlarged.* **(Right)** *Selective injection of the OA in the same patient nicely demonstrates the mass-like dAVF in the occluded TS. Note innumerable enlarged transosseous branches that pass intracranially to supply the dAVF.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Dural arteriovenous fistula (dAVF)

Synonyms

- Dural arteriovenous shunt (dAVS)

Definitions

- Heterogeneous group of lesions with common angioarchitecture (AV shunts in dural venous sinus wall)

IMAGING

General Features

- Best diagnostic clue
  - MR/CTA: Network of tiny (crack-like) vessels in wall of thrombosed dural venous sinus
  - DSA: Predominant arterial supply from meningeal arteries
  - Bone CT: Dilated transosseous calvarial vascular channels, enlarged foramen spinosum
- Location
  - Posterior fossa >> supratentorial
  - Can involve any dural venous sinus
    - Most common (35-40%) = transverse sinus (TS) + sigmoid sinus (SS)
    - Other common sites = cavernous sinus (CS), superior sagittal sinus (SSS), superior petrosal sinus (SPS)

CT Findings

- NECT
  - May see dilated vascular channels in skull from transosseous feeding arteries
  - Ipsilateral enlargement of foramen spinosum
    - Contains middle meningeal artery that commonly supplies dAVFs
  - Look for complications: Subarachnoid hemorrhage, cerebral edema (venous hypertension)
- CECT
  - May see tortuous feeding arteries ± flow-related aneurysms (uncommon), draining veins
  - Involved dural venous sinus completely/partially thrombosed or stenotic
- CTA
  - Standard 3D CTA may be useful in depicting gross angioarchitecture
  - 320-row detector dynamic 4D-CTA allows volumetric imaging, detailed spatial/temporal resolution

MR Findings

- T1WI
  - Isointense thrombosed dural sinus ± flow voids
- T2WI
  - Isointense thrombosed sinus ± flow voids
  - Focal hyperintensity in adjacent brain
    - Look for retrograde leptomeningeal venous drainage
    - Look for venous perfusion abnormalities
- FLAIR
  - Isointense thrombosed sinus ± adjacent edema (if venous ischemia/congestion)
- T2* GRE
  - Thrombosed dural sinus "blooms"
  - Rare: Parenchymal hemorrhage
    - Usually if cortical venous drainage present
    - Look for thrombosed draining veins
- DWI
  - Normal unless venous infarct or ischemia present
- T1WI C+
  - Chronically thrombosed sinus usually enhances
- MRA
  - Useful for gross depiction of angioarchitecture, dynamics
  - TOF MRA may be negative with small or slow-flow shunts
- MRV
  - Depicts occluded parent sinus, collateral flow
  - 3D phase contrast MRA with low VENC can identify fistula, feeding arteries, flow reversal in draining veins

Angiographic Findings

- Conventional
  - Multiple arterial feeders are typical
    - Dural/transosseous branches from ECA most common
    - Tentorial/dural branches from ICA, VA
    - Parasitization of pial arteries with larger dAVFs
  - Arterial inflow into parallel venous channel ("recipient pouch") common
  - Involved dural sinus often thrombosed or stenotic
  - Flow reversal in dural sinus/cortical veins correlates with progressive symptoms, risk of hemorrhage
  - Tortuous engorged pial veins ("pseudophlebitic" pattern) with venous congestion/hypertension (clinically aggressive)
  - High-flow venopathy → progressive stenosis, outlet occlusion, hemorrhage

Imaging Recommendations

- Best imaging tool
  - DSA ± superselective catheterization of dural, transosseous feeders
- Protocol advice
  - Screening MR, contrast-enhanced MRA
  - DSA to delineate vascular supply, venous drainage

DIFFERENTIAL DIAGNOSIS

Pial AVM

- Congenital vascular lesion with intraaxial nidus and no intervening normal brain parenchyma
- Predominant pial arterial supply, parasitization of dural supply possible (opposite to dAVF)

Sigmoid Sinus-Jugular Foramen Pseudolesion

- Slow or asymmetric flow creates variable signal on MR sequences
- Use MRV with multiple encoding gradients to clarify

Thrombosed Dural Sinus

- Collateral/congested venous drainage can mimic dAVF
- Can be spontaneous, traumatic, infectious (thrombophlebitis)

Dural Sinus Stenosis

- May have prominent collateral draining veins

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Adult dAVFs are usually acquired, not congenital
    - Often idiopathic
    - Can occur in response to trauma, venous sinus thrombosis
  - Infant dAVFs are congenital and usually associated with enlargement of dural venous sinuses
  - Pathological activation of neoangiogenesis
    - Proliferating capillaries within granulation tissue in dural sinus obliterated by organized thrombi
    - Budding/proliferation of microvascular network in inner dura connects to plexus of thin-walled venous channels, creating microfistulae
    - High bFGF, VEGF expression in dAVFs
- Associated abnormalities
  - Cortical venous drainage associated with edema, encephalopathy
  - Venous hypertension may lead to developmental delay in children
  - Arterialized flow in cortical veins/dural sinuses → high-flow venopathy, ↑ risk of ICH, encephalopathy

Staging, Grading, & Classification

- Cognard classification of intracranial dAVFs correlates venous drainage pattern with risk of ICH
  - Grade 1: In sinus wall, normal antegrade venous drainage (low risk; benign clinical course)
  - Grade 2A: In wall, reflux into sinus (but not cortical veins)
  - Grade 2B: Retrograde drainage into cortical veins (10-20% hemorrhage)
  - Grade 3: Direct cortical venous drainage, no venous ectasia (40% hemorrhage)
  - Grade 4: Direct cortical venous drainage, venous ectasia (65% hemorrhage)
  - Grade 5: Spinal perimedullary venous drainage (progressive myelopathy)

Gross Pathologic & Surgical Features

- Multiple enlarged dural arteries converge on wall of thrombosed dural sinus
- Cortical draining veins enlarged (± with stenoses, dilatation, tortuosity)

Microscopic Features

- Arterialized veins with irregular intimal thickening, variable loss of internal elastic lamina

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Clinical manifestations related to location, presence/absence of venous hypertension
    - TS-SS = pulsatile tinnitus
    - Cavernous sinus = pulsatile exophthalmos, CNs 3, 4, 6 neuropathy
    - Infant dAVF: Developmental delay, ↑ head circumference
  - Uncommon: Encephalopathic symptoms (venous hypertension, ischemia/thrombosis)
    - Progressive dementia
- Clinical profile
  - Middle-aged patient with pulse-synchronous tinnitus

Demographics

- Age
  - Adult >> child
    - Usually presents in middle-aged patients
    - Pediatric dAVFs rare, high mortality
- Epidemiology
  - 10-15% of all cerebrovascular malformations with AV shunting

Natural History & Prognosis

- Depends on location, venous drainage pattern
  - 98% of dAVFs without retrograde venous drainage have benign course
  - dAVFs with retrograde venous drainage have aggressive clinical course

Treatment

- Conservative: Observation ± carotid compression technique
- Treatment options if (1) hemorrhage risk exists or (2) for types 1 and 2A with debilitating pulsatile tinnitus
  - Embolization of arterial feeders with particulate or liquid agents, coil embolization of recipient venous pouch/sinus
  - Surgical skeletonization of involved dural venous sinus

DIAGNOSTIC CHECKLIST

Consider

- DSA for definitive exclusion of dAVF in patient with objective pulsatile tinnitus

Image Interpretation Pearls

- MR + MRA may be normal in small dAVF
- **Always** examine bilateral ICAs, ECAs, and vertebral arteries when performing DSA to exclude dAVF

https://CafePezeshki.IR

Pial AV Fistula

KEY FACTS

TERMINOLOGY

- Pial vascular malformation with direct arteriovenous (AV) shunting
  - One or more pial (cortical) arteries connects to single venous channel
  - No intervening capillary bed or nidus
  - May occur anywhere in brain, spinal cord
  - Can lie on surface/within brain or at ependyma
- Rare (1-2% of all brain vascular malformations)

IMAGING

- CT: Iso-/hyperdense serpentine vessels ± Ca++
  - Arterial feeder(s), draining veins enhance
- DSA
  - Dilated feeding artery drains directly into enlarged vein
  - ± confluence of arteries just before fistulous connection
  - No intervening nidus

TOP DIFFERENTIAL DIAGNOSES

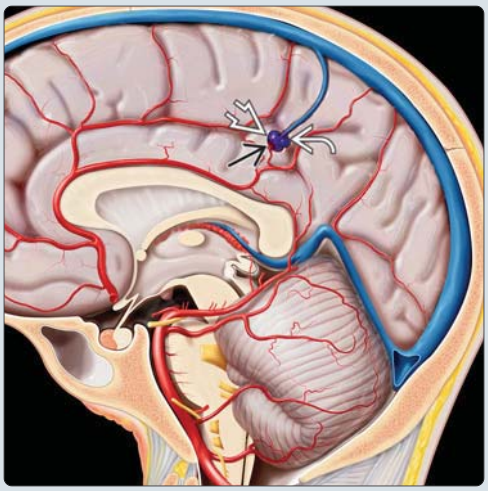
- Arteriovenous malformation (AVM)
- Dural AV fistula
- Vein of Galen aneurysmal malformation

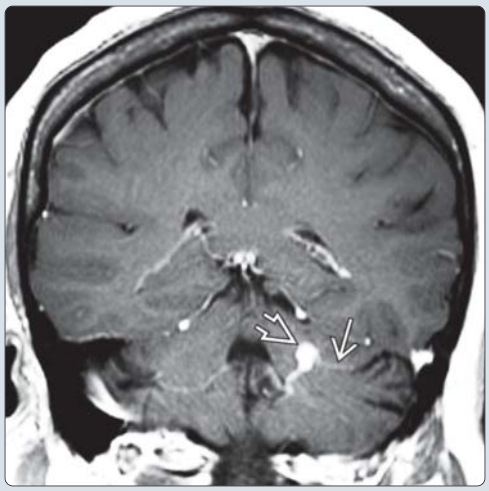
PATHOLOGY

- Enlarged mature arteries, variceal draining veins
- Draining veins are "arterialized" with thickened walls
  - May have variceal "aneurysms" ± high-flow venopathy, stenosis

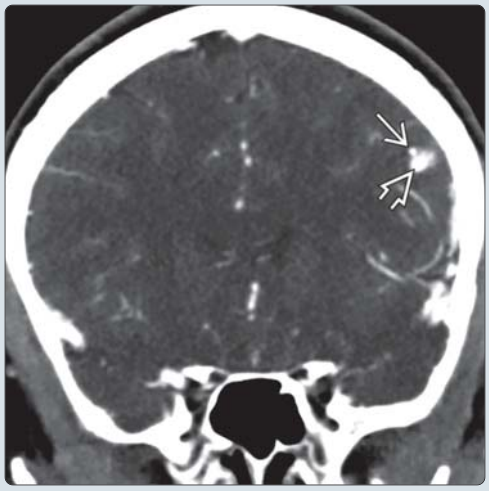
CLINICAL ISSUES

- Much higher hemorrhage risk than AVM
- Spontaneous obliteration may be more common, especially in infants
- Embolization curative if draining vein occluded at fistulous site





(Left) *Graphic depicts direct pial arteriovenous fistula seen here as abrupt change in vessel caliber from feeding arteries to a dilated, somewhat variceal-appearing draining vein. No intervening nidus is present, contrasting pial AVF from AVM.* **(Right)** *Coronal T1C+ MR shows a cerebellar pAVF with single arterial feeder draining into a venous varix.*



(Left) *Axial CT angiogram in a patient with HHT shows an enlarged vessel lying in a sulcus along the brain surface.* **(Right)** *Coronal CTA in the same case shows a small cluster of tiny arteries draining into a dilated vein. Pial AVF was found at surgery.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pial arteriovenous fistula (pAVF)

Definitions

- Pial vascular malformation with direct arteriovenous (AV) shunting
  - One or more pial (cortical) arteries connects to single venous channel
  - No intervening capillary bed or nidus
- Rare (1-2% of all brain vascular malformations)

IMAGING

General Features

- Best diagnostic clue
  - Dilated cortical artery, draining vein without focal nidus
- Location
  - On cortical surface, within brain parenchyma
  - May occur anywhere in brain, spinal cord
    - Rare in posterior fossa

CT Findings

- NECT
  - Iso-/hyperdense serpentine vessels
- CTA
  - Shows arterial feeder(s), draining vein/varix

MR Findings

- T2WI
  - Dilated serpiginous flow voids
  - Variable hemorrhage
- T2* GRE
  - ± "blooming" hypointense blood products

Angiographic Findings

- Delineates angioarchitecture
  - Fistula at site of abrupt change in vessel caliber
- Dilated feeding artery
  - Single > multiple
    - ± confluence of arteries just before fistulous connection
  - Drains directly into enlarged vein
- No intervening nidus
- Single draining vein (± varix)

Imaging Recommendations

- Best imaging tool
  - DSA best delineates angioarchitecture
- Protocol advice
  - CTA/CE MRA best noninvasive method

DIFFERENTIAL DIAGNOSIS

Arteriovenous Malformation (AVM)

- Has definite nidus composed of microscopic AV shunts
  - Nidus: A few millimeters to several centimeters in size
  - May have large fistulous connections within nidus
  - Angiomatous matrix of small vascular channels on DSA
- Much more common than pAVF

Dural AV Fistula (dAVF)

- AV shunts within wall of patent/partially thrombosed dural venous sinus (DVS)
- Drainage to dural sinus
- Differentiate from pial AVF by
  - Fistulas intimately related to DVS, within DVS wall
  - Predominant blood supply is from dural (meningeal) arteries > > pial artery
    - e.g., anterior, middle, and posterior meningeal arteries, tentorial branches of cavernous ICA, PCA, occipital artery, ascending pharyngeal artery

Vein of Galen Aneurysmal Malformation

- Mural type is pAVF of vein of Galen
- Merely a difference in location
  - Supply from medial posterior choroidal branches to prosencephalic vein
  - Drainage via straight sinus or persistent falcine sinus

PATHOLOGY

General Features

- Etiology
  - Factors of pAVMs: Dysregulated angiogenesis
  - Trauma
- Genetics
  - Sporadic pAVFs, like pAVMs, may have multiple up-/down-regulated genes
  - Syndromic pAVFs associated with *HHT1* (endoglin gene) mutation

Gross Pathologic & Surgical Features

- Draining veins are "arterialized"
  - Thickened walls ± stenosis of high-flow venopathy
  - May have variceal "aneurysms"

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache
  - Cranial bruit

Natural History & Prognosis

- ↑ ↑ hemorrhage risk compared to AVM
  - Mortality of > 60% if managed conservatively

Treatment

- Embolization
  - Curative if draining vein occluded at fistulous site
- Microsurgical disconnection

KEY FACTS

TERMINOLOGY

- Vein of Galen malformation (VGAM)
- Arteriovenous fistula between deep choroidal arteries, embryonic median prosencephalic vein
- High flow through MPV prevents formation of vein of Galen → VGAM is misnomer

IMAGING

- Best diagnostic clue: Large midline varix (MPV) in neonate/infant
- Embryonic falcine sinus drains MPV in 50%

TOP DIFFERENTIAL DIAGNOSES

- Vein of Galen aneurysmal dilatation (VGAD)
- Childhood dural arteriovenous fistula
- Complex developmental venous anomaly (DVA)
- Giant aneurysm

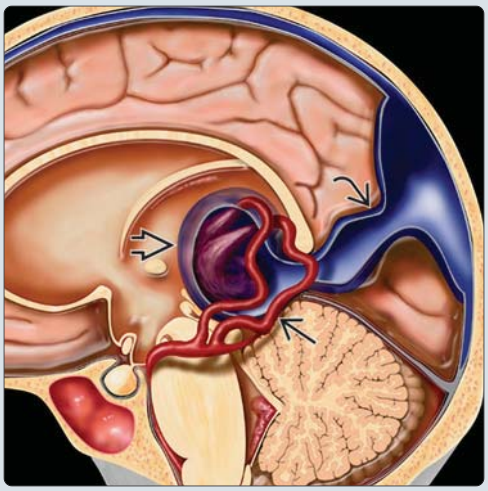
PATHOLOGY

- Most common extracardiac cause of high-output cardiac failure in newborn
- Associated abnormalities
  - Hydrocephalus
  - Cerebral ischemia/atrophy

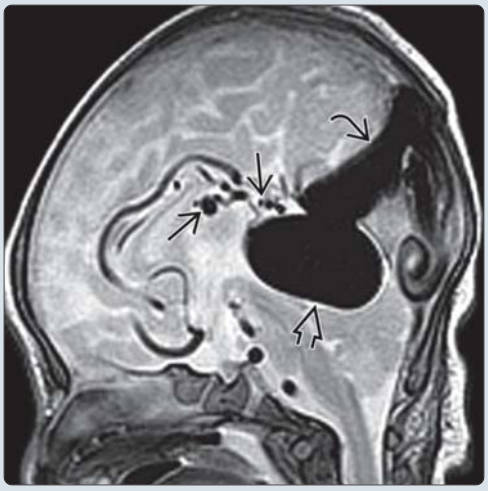
CLINICAL ISSUES

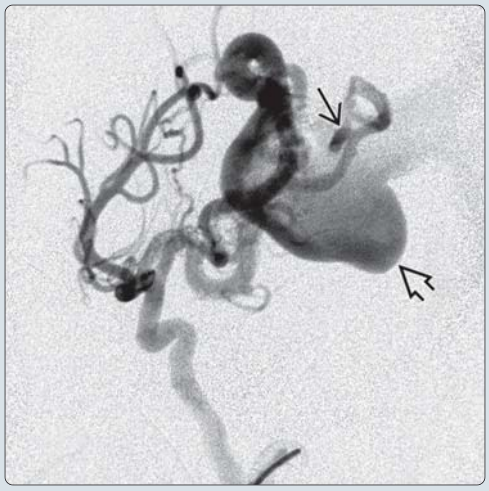
- Age: Neonatal presentation most common
- Prognosis related to volume of shunt, timing/success treatment
  - Single or staged transarterial embolization (TAE) at 4-5 months
- Brain damage or multisystem organ failure at presentation are contraindications to treatment

(Left) *Graphic depicts vein of Galen malformation. Enlarged posterior choroidal arteries ⇨ drain into a dilated median prosencephalic vein (MPV) of Markowski ⇨. The MPV drains into the superior sagittal sinus via an embryonic falcine sinus ⇨; the straight sinus is absent.* **(Right)** *CECT scan in a newborn with high-output congestive heart failure shows a massive VGAM ⇨ draining into an enlarged falcine sinus ⇨, causing obstructive hydrocephalus.*



(Left) *Sagittal T2WI shows prominent arteries ⇨ supplying an enlarged median prosencephalic vein ⇨. Note enlarged falcine sinus ⇨, absence of straight sinus.* **(Right)** *DSA in the same patient shows that the VGAM ⇨ is supplied by multiple direct arterial fistulas ⇨.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Vein of Galen (VofG), vein of Galen aneurysmal malformation (VGAM), median prosencephalic vein (MPV) of Markowski

Synonyms

- Vein of Galen "aneurysm," galenic varix

Definitions

- Arteriovenous fistula (AVF) between pericallosal/deep choroidal arteries and embryonic MPV (precursor of VofG)
- High flow through MPV prevents formation of vein of Galen; VGAM is misnomer

IMAGING

General Features

- Best diagnostic clue: Large midline varix (MPV) in neonate/infant
- Location: Quadrigeminal plate cistern
- Size: Few to several cm
- Morphology: Tubular or spherical varix

Radiographic Findings

- Chest radiograph: Congestive heart failure (CHF)
  - Cardiomegaly, pulmonary edema

CT Findings

- NECT
  - MPV mildly hyperdense to brain
  - Hydrocephalus
  - Subcortical white matter (WM) hypodensity and Ca++ → chronic venous ischemia
  - Intracranial (IC) hemorrhage (rare)
- CECT
  - Vascular enhancement feeding arteries, MPV
- CTA
  - Delineates feeding arteries, venous drainage

MR Findings

- T1WI
  - MPV: Flow void or heterogeneous due to fast or turbulent flow
    - Hyperintense foci: Thrombus
    - Phase artifact from fast, turbulent flow
  - Hyperintense foci within brain: Ca++, ischemia
  - Sag: Tectal compression, tonsillar herniation
- T2WI
  - MPV: Flow void or heterogeneous due to fast or turbulent flow
  - Flow voids from feeding arteries around MPV
  - Ischemic foci poorly seen in unmyelinated infant brain
- DWI: Restriction in acute ischemia/infarction
- MRA: Delineates arterial feeders
- MRA C+: Shows arterial and venous anatomy together
- MRV: Delineates MPV and venous anatomy
- Fetal MR: Can identify brain and other end-organ injury
- Significant injury seen on antenatal or postnatal imaging is contraindication to aggressive therapy

Ultrasonographic Findings

- Grayscale ultrasound
  - Mildly echogenic midline mass
- Color Doppler
  - Arterialized flow within MPV
- Antenatal US: VGAM identified in 3rd trimester
  - ↑ resistance middle cerebral artery → vascular steal
  - Cardiac dilatation, hydrops fetalis = poor prognosis

Angiographic Findings

- Common arterial feeders
  - Medial and lateral posterior choroidal arteries
  - Pericallosal arteries
- Venous anatomy
  - Embryonic falcine sinus drains MPV in 50%
    - Associated with absent straight sinus
  - Variable absence, stenoses of other sinuses
  - Reflux into pial venous system ↑ risk IC hemorrhage
    - Requires urgent treatment
  - Venous drainage from central brain structures typically not through MPV but superior petrosal and cavernous sinuses

Imaging Recommendations

- Best imaging tool
  - MR with MRA/MRV
  - Catheter angiogram ideally performed with 1st embolization (4-5 months of age)
- Protocol advice
  - MRA C+ may obviate need for MRV

DIFFERENTIAL DIAGNOSIS

Vein of Galen Aneurysmal Dilatation (VGAD)

- Arteriovenous malformation (AVM) with venous drainage into true vein of Galen
- Less common than VGAM
- Typically does not present before 3 years of age

Childhood Dural Arteriovenous Fistula

- High-flow fistulas: Neonatal presentation similar to VGAM
- Frequent giant aneurysms, venous varices
- External carotid artery → torcular, transverse, or superior sagittal sinus
- Spontaneous thrombosis may occur after delivery

Complex Developmental Venous Anomaly

- Dilatation of veins draining normal brain parenchyma
- No nidus or AV shunting
- Associated with blue rubber bleb nevus syndrome

Giant Aneurysm

- Not associated with venous abnormalities
- "Onion skin" layers in wall

PATHOLOGY

General Features

- Embryology
  - Normal
    - Choroid arterial tributaries drain to single temporary midline vein (MPV)

https://CafePezeshki.IR

  - MPV normally regresses during 11th week of gestation
  - By 12 weeks joins internal cerebral/basal veins to form VofG
  - Abnormal
    - MPV fails to degenerate
    - Primitive arteriovenous fistulous connects persist, forming VGAM
  - Week 5: Arterial supply to choroid plexus established from meninx primitiva
  - Week 10: Internal cerebral veins (ICVs) annex drainage of choroid plexus → regression MPV
  - Caudal MPV persists, joins ICVs to form vein of Galen
- Etiology
  - AVF of choroidal arteries and MPV
  - ↑ flow through fistula prevents normal regression MPV
- Genetics: Sporadic
  - Rare reports of hereditary vascular dysplasia syndromes
- Epidemiology
  - Rare: < 1% of cerebral vascular malformations
  - Up to 30% of pediatric vascular malformations
  - Most common extracardiac cause of high-output cardiac failure in newborns
- Associated abnormalities
  - Venous occlusion, stenosis
    - Primary atresia vs. occlusion 2° to increased pressure, flow
    - Provides right heart protection
  - Cerebral ischemia/atrophy
    - Arterial steal
    - Chronic venous hypertension
  - Hydrocephalus
    - ↓ CSF resorption 2° to ↑ venous pressure
    - ± cerebral aqueduct obstruction
  - Atrial septal defects; aortic coarctation

Staging, Grading, & Classification

- Lasjaunias system
  - Type I: Choroidal type (multiple choroidal arteries enter anterior MPV via tributary veins)
  - Type II: Mural type (single/multiple fistulas at inferolateral wall of MPV)
- Mortazavi system (0-1 no urgency, treat in 1 stage endovascular; 2 = urgent endovascular, treat in stages; 3 = consider endovascular treatment or palliation, treat in stages)
  - Arterial feeders
    - Any feeders other than P1-2, thalamoperforators, choroidal basilar = 0
    - Any of the following: P1-2, thalamoperforators, choroidal, basilar = 1
  - Clinical symptoms
    - No heart failure = 0
    - Heart failure = 1
  - Age
    - ≥ 5 months = 0
    - < 5 months = 1

Gross Pathologic & Surgical Features

- Malformations of structures adjacent to MPV
  - Pineal gland, tela choroidea of 3rd ventricle

Microscopic Features

- Thickened wall of MPV, ± Ca++

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Neonate: High-output CHF, cranial bruit
  - Infant: Macrocranium (hydrocephalus)
  - Older child, adult (rare): Headache, IC hemorrhage
- Other signs/symptoms
  - Developmental delay, failure to thrive, seizure, end-organ failure

Demographics

- Age: Neonatal presentation most common
  - Rarely diagnosed after age 3
- Gender: M:F = 2:1

Natural History & Prognosis

- Without treatment, death from intractable heart and multisystem failure occurs in neonates
- Prognosis related to volume of shunt, timing/success treatment
- High venous pressures in utero may result in significant injury to brain

Treatment

- Brain damage or multisystem organ failure at presentation is contraindication to treatment
- Medical therapy for CHF until 4-5 months of age
  - Failure therapy warrants earlier neurointervention
- Single or staged transarterial embolization (TAE) at 4-5 months
- Treatment for hydrocephalus controversial

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Imaging appearance diagnostic in appropriate clinical setting

Reporting Tips

- Report progressive brain injury on MRs

KEY FACTS

TERMINOLOGY

- Congenital cerebral vascular malformation with mature venous elements
- May represent anatomic variant of otherwise normal venous drainage

IMAGING

- General features
  - Umbrella-like collection of enlarged medullary (white matter) veins ("Medusa head")
  - At angle of ventricle
  - Numerous linear or dot-like enhancing foci
  - Converge on single enlarged "collector" vein
  - "Collector" vein drains into dural sinus/deep ependymal vein
  - Usually solitary, variable size (< 2-3 cm)
  - Hemorrhage may occur if mixed malformation or draining vein thromboses
- CT often normal; enlarged "collector" vein may appear hyperdense
- MR
  - Variable signal depending on size, flow
  - Hypointense on SWI (BOLD effect in draining veins)
  - Strong enhancement

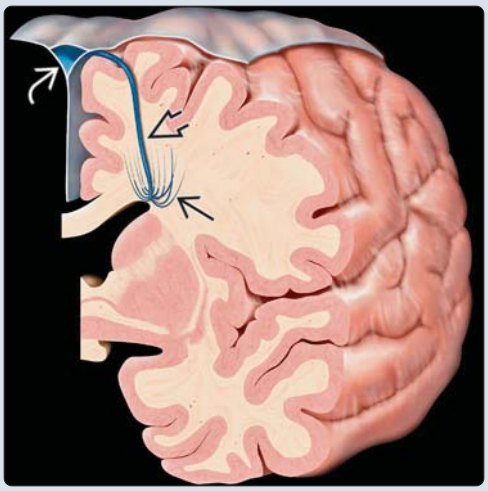
TOP DIFFERENTIAL DIAGNOSES

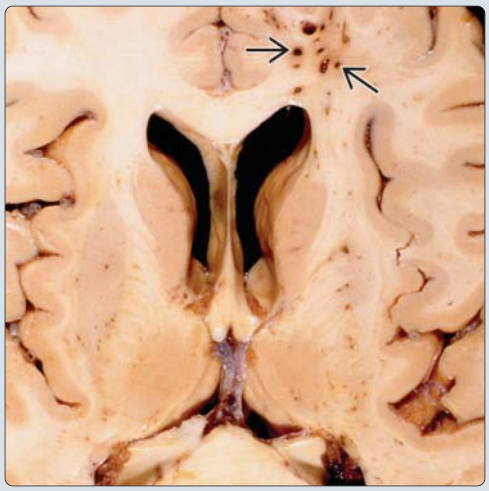
- Mixed vascular malformation (usually cavernoma)
- Vascular neoplasm
- Dural sinus thrombosis (chronic)

PATHOLOGY

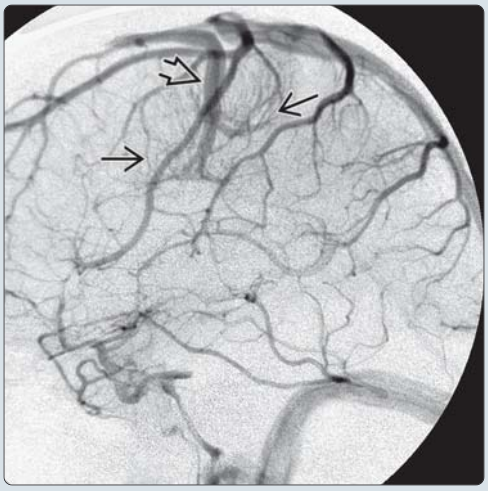
- 15-20% coexisting cavernous &/or capillary malformations
- Blue rubber bleb nevus syndrome (BRBNS)
- Sulcation-gyration disorders (may cause epilepsy)
- Cervicofacial venous or lymphatic malformation (CAMS-3)

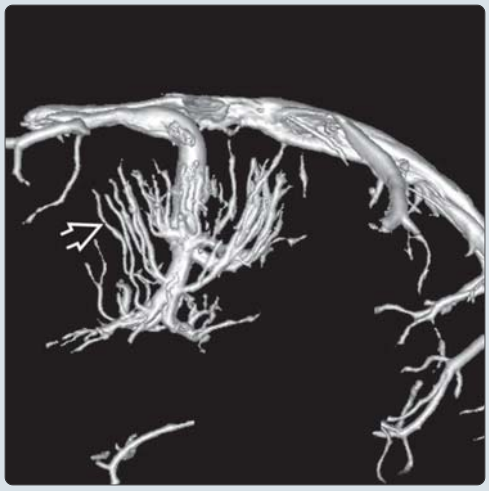
(Left) *Coronal oblique graphic depicts classic DVA with umbrella-like "Medusa head" of enlarged medullary (deep white matter) veins ⇨ converging on a dilated transcortical "collector" vein ⇨, which drains into the superior sagittal sinus ⇨.* **(Right)** *Gross pathology shows an incidental finding of DVA, seen here as scattered enlarged venous channels ⇨ near the frontal horn of the lateral ventricle. Normal white matter is seen between the venous tributaries. Note the absence of hemorrhage. (Courtesy R. Hewlett, MD.)*





(Left) *Lateral DSA, venous phase, shows classic "Medusa head" of DVA with numerous enlarged medullary veins ⇨ converging on an enlarged transcortical "collector" vein ⇨.* **(Right)** *3D shaded surface rendering in the same patient elegantly depicts the classic "Medusa head" of a DVA ⇨. (Courtesy P. Lasjaunias, MD.)*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Developmental venous anomaly (DVA)

Synonyms

- Venous angioma

Definitions

- Congenital cerebral vascular malformation with mature venous elements
- May represent anatomic variant of otherwise normal venous drainage

IMAGING

General Features

- Best diagnostic clue
  - "Medusa head" (dilated medullary white matter veins)
- Location
  - At angle of ventricle
    - Most common site: Near frontal horn
    - Other: Adjacent to 4th ventricle
- Size
  - Varies (may be extensive), but usually < 3 cm
- Morphology
  - Umbrella-like collection of enlarged medullary (white matter) veins
  - Large "collector" vein drains into dural sinus or deep ependymal vein
  - Usually solitary
    - Can be multiple in blue rubber bleb nevus syndrome

CT Findings

- NECT
  - Usual: Enlarged "collector" vein may appear hyperdense; this is not pathological
  - Occasional: Ca++ if mixed cavernous malformation (CM)
  - Rare: Acute parenchymal hemorrhage (if draining vein spontaneously thromboses)
- CECT
  - Numerous linear or dot-like enhancing foci
    - Well-circumscribed, round/ovoid, enhancing areas on sequential sections
    - Converge on single enlarged tubular draining vein
    - Occasionally seen as linear structure in single slice

MR Findings

- T1WI
  - Can be normal if DVA is small
  - Variable signal depending on size, flow
    - Flow void
  - Hemorrhage may occur if mixed malformation or draining vein thromboses
- T2WI
  - ± flow void
  - ± blood products
- FLAIR
  - Usually normal; may show hyperintense region if venous ischemia or hemorrhage present
- T2* GRE
  - May be hypointense ("blooms") on GRE if large or if coexisting CM with hemorrhage
  - Hypointense on SWI (BOLD effect in draining veins)
    - If high flow, deoxyhemoglobin reduced; may be isointense
- DWI
  - Usually normal or slightly increased diffusivity in drainage area
  - Rare: Acute venous infarct seen as hyperintense area of reduced diffusion
- PWI
  - Nearly 80% demonstrate perfusion abnormalities
    - Increased cerebral blood flow (CBF)
    - Increased cerebral blood volume (CBV)
    - Increased mean transit time (MTT)
- T1WI C+
  - Strong enhancement
    - Stellate, tubular vessels converge on "collector" vein
    - "Collector" vein drains into dural sinus/ependymal vein
- MRA
  - Arterial phase usually normal
  - Contrast-enhanced MRA may demonstrate slow-flow DVA
- MRV
  - Delineates "Medusa head" and drainage pattern
- MRS
  - Normal

Angiographic Findings

- DSA
  - Arterial phase normal in > 95% of cases
  - Capillary phase usually normal (rare: Prominent "blush" ± AV shunt)
  - Venous phase: "Medusa head"
  - < 5% atypical (transitional form of venous-arteriovenous malformation with enlarged feeders, AV shunting)

Nuclear Medicine Findings

- 75% of cases show hypometabolism in adjacent brain parenchyma

Imaging Recommendations

- Best imaging tool
  - T1 C+ MR plus SWI, MRV
- Protocol advice
  - Include T2* sequence (GRE, SWI)

DIFFERENTIAL DIAGNOSIS

Mixed Vascular Malformation (Usually Cavernoma)

- Hemorrhage often associated

Vascular Neoplasm

- Enlarged medullary veins
- Mass effect, usually enhances

Dural Sinus Thrombosis (Chronic)

- Chronic thrombosis → venous stasis
- Medullary veins enlarge as collateral drainage

Sturge-Weber Syndrome

- May develop strikingly enlarged medullary, subependymal, choroid plexus veins

https://CafePezeshki.IR

- Coexisting facial angioma

Venous Varix (Isolated)

- Occurs, but is rare without associated DVA

Demyelinating Disease

- Rare: Active, aggressive demyelination may have prominent medullary veins

PATHOLOGY

General Features

- Etiology
  - Does not express growth factors
  - Expresses structural proteins of mature angiogenesis
- Genetics
  - Approximately 50% inherited as autosomal dominant
  - Mutations in chromosome 9p
    - Segregates pedigrees with skin, oral and GI mucosa, brain venous malformations
- Associated abnormalities
  - 15-20% of those with DVAs have coexisting cavernous &/or capillary malformations
  - Blue rubber bleb nevus syndrome (BRBNS)
  - Sinus pericranii (cutaneous sign of underlying venous anomaly)
  - Sulcation-gyration disorders (may cause epilepsy)
  - Cervicofacial venous or lymphatic malformation (CAMS-3)
    - Embryology
      - Arrested medullary vein development at time when normal arterial development nearly complete
      - Developmental arrest results in persistence of large primitive embryonic deep white matter veins

Gross Pathologic & Surgical Features

- Radially oriented dilated medullary veins
- Venous radicals are separated by normal brain
- Enlarged transcortical or subependymal draining vein

Microscopic Features

- Dilated thin-walled vessels diffusely distributed in normal white matter (no gliosis)
- Occasional: Thickened, hyalinized vessel walls
- 20% have mixed histology (CM most common), may hemorrhage
- Variant: "Angiographically occult" DVA with malformed, compactly arranged vessels with partly degenerated walls

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually asymptomatic
  - Uncommon
    - Headache
    - Seizure (if associated with cortical dysplasia)
    - Hemorrhage with focal neurologic deficit (if associated with cavernous malformation or thrombosis)
- Clinical profile
  - Asymptomatic patient with DVA found incidentally on MR

Demographics

- Age
  - All ages
- Gender
  - M = F
- Ethnicity
  - No known predilection
- Epidemiology
  - Most common cerebral vascular malformation at autopsy
  - 60% of cerebral vascular malformations
  - 2.5-9% prevalence on contrast-enhanced MR scans

Natural History & Prognosis

- Hemorrhage risk: 0.15% per lesion per year
  - Stenosis or thrombosis of draining vein increases hemorrhage risk
  - Coexisting cavernous malformation increases hemorrhage risk

Treatment

- Solitary venous anomaly: None (attempt at removal may cause venous infarction)
- Histologically mixed venous anomaly: Determined by coexisting lesion

DIAGNOSTIC CHECKLIST

Consider

- DVAs contain (and provide main venous drainage for) intervening normal brain

Image Interpretation Pearls

- If you are not seeing 1 or 2 DVAs per month in usual outpatient setting, you are probably overlooking them
- If you are not doing much contrast-enhanced MR, you are probably missing incidental DVAs

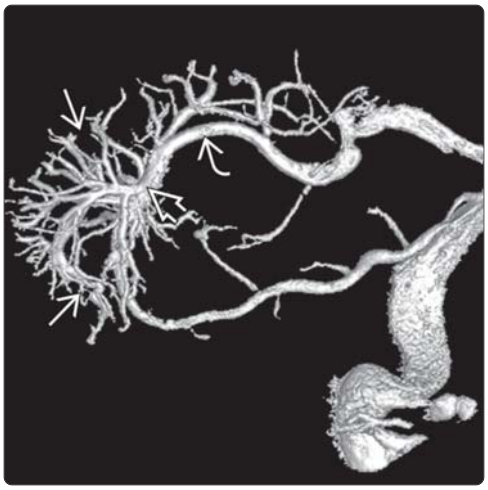
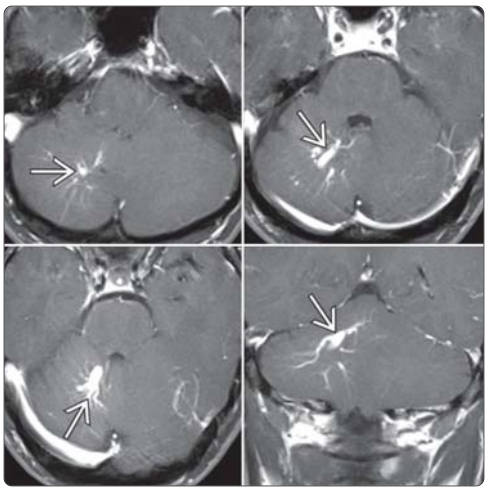
(Left) *Axial NECT shows a well-delineated hyperdensity in the left cerebellar hemisphere* ➡. **(Right)** *CTA with axial, sagittal, and coronal views and a 3D reconstruction in the same patient elegantly demonstrates the DVA* ⇨.



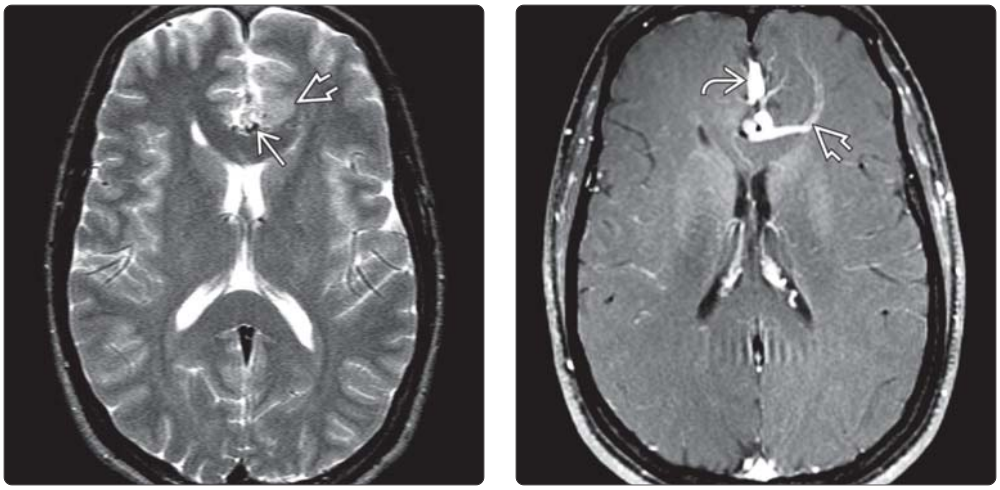
(Left) *Lateral 3D DSA rendered from the late venous phase of an internal carotid angiogram shows a large frontal DVA* ➡ *that drains into a septal tributary* ➡ *of the internal cerebral vein* ➡. *(Courtesy P. Lasjaunias, MD.)* **(Right)** *Anteroposterior 3D DSA shows a large right cerebellar DVA* ➡ *draining into an enlarged precentral cerebellar vein* ➡. *(Courtesy P. Lasjaunias, MD.)*



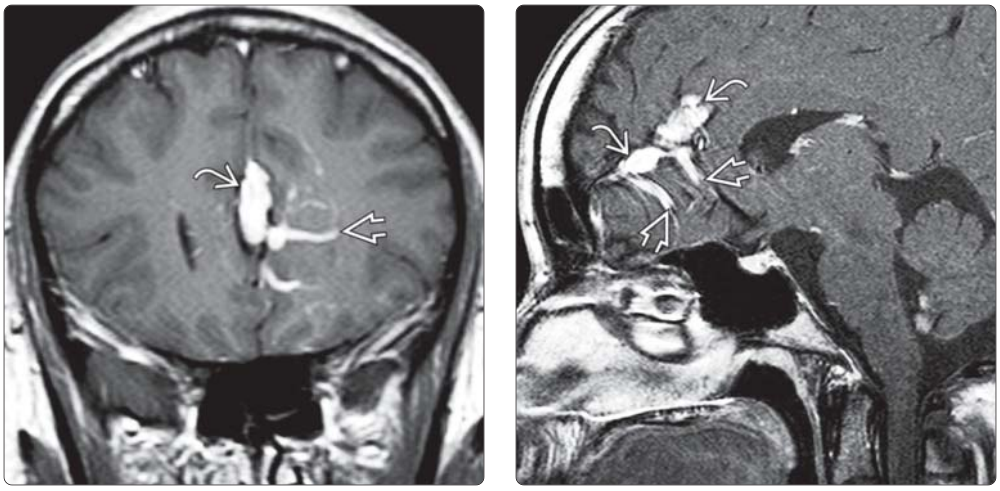
(Left) *Series of axial and coronal T1 C+ scans shows a large cerebellar DVA* ➡, *an incidental finding in this asymptomatic patient.* **(Right)** *AP DSA venous phase in the same patient shows the DVA with the "Medusa head"* ⇨ *of dilated veins and the large collector vein* ⇨.

https://CafePezeshki.IR

(Left) *DVAs can be associated with cortical dysplasia. Axial T2WI in a 32-year-old female with headaches shows left frontal cortical dysplasia adjacent to some prominent "flow voids".* **(Right)** *Axial T1 C+ FS in the same patient shows a giant left frontal venous angioma. The large tubular structure in the interhemispheric fissure is a large varix.*

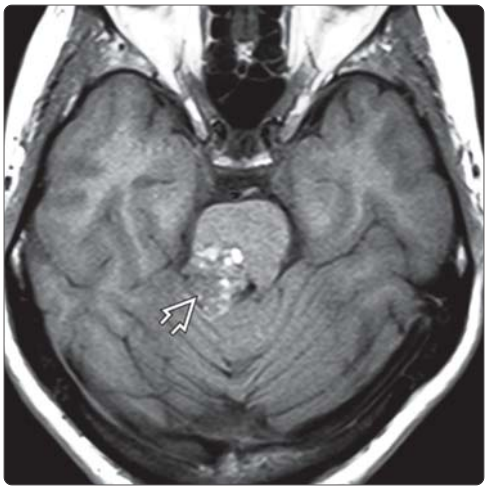


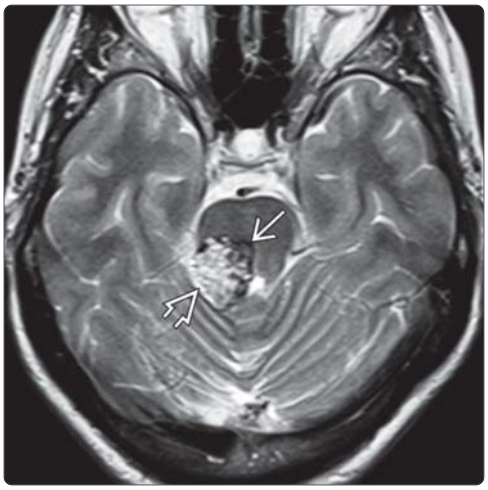
(Left) *Coronal T1 C+ MR in the same patient shows the large DVA draining into the interhemispheric varix.* **(Right)** *Sagittal T1 C+ MR in the same patient shows there are at least 2 large DVA "collector veins" draining into a large interhemispheric venous varix.*



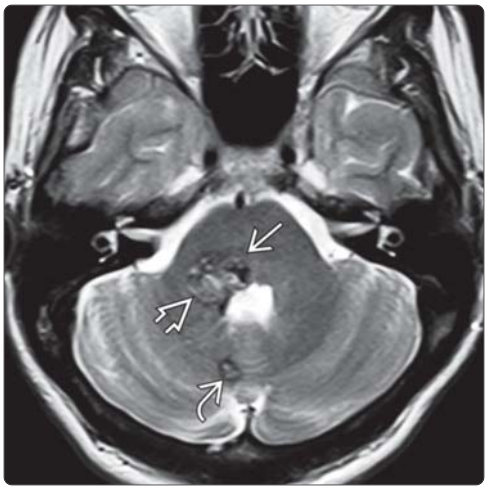
(Left) *Lateral DSA, early venous phase, in the same patient shows the enlarged medullary veins ("Medusa head") of the DVA. The large collector veins are beginning to fill with contrast.* **(Right)** *Late venous phase shows the giant varix draining the DVA empties into a markedly enlarged inferior sagittal sinus. The entire anterior third of the superior sagittal sinus is hypoplastic or absent, with the SSS originating near the coronal suture at the confluence of a prominent cortical vein.*

https://CafePezeshki.IR

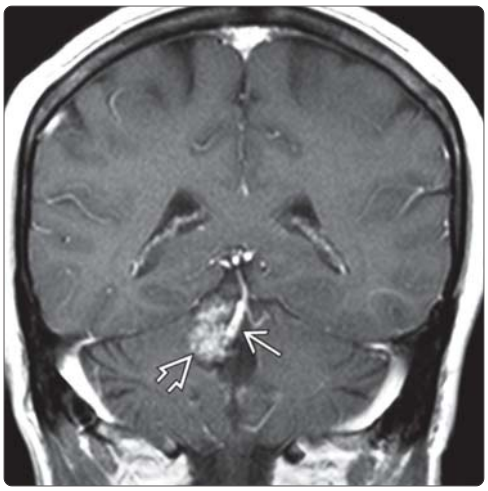




(Left) *Cerebral DVAs are frequently mixed with cavernous malformations. Axial T1WI shows a mixed signal intensity ("popcorn lesion") dorsally exophytic mass in the right midbrain* ➡. **(Right)** *T2WI in the same patient shows heterogeneous signal in the lesion* ➡, *which is surrounded by a very hypointense hemosiderin rim* ➡ *suggesting this is most likely a cavernous malformation.*



(Left) *More inferior T2WI in the same patient shows a second "popcorn ball" lesion* ➡ *posterior to the midbrain lesion, which extends inferiorly into the central pons and right cerebellar peduncle* ➡. *Faint linear hyperintensities* ➡ *can be seen lying in between the two lesions.* **(Right)** *T2* SWI shows both lesions* ⇨ *are profoundly hypointense. The linear intensities seen on the T2WI are also hypointense. The lesions represent hemorrhage, but the linear hypointensities* ⇨ *are deoxygenated blood in a DVA.*



(Left) *T1 C+ FS scan shows strong foci of linear and tubular enhancement* ➡ *typical for a DVA.* **(Right)** *Coronal T1 C+ MR shows the cavernous malformation* ➡ *and the DVA* ➡. *A mixed cavernous-venous malformation is common. Surgeons need to be cognizant of the presence of a DVA to avoid ligating the collector vein and causing a venous infarct.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Anomalous communication between intracranial dural venous sinus, extracranial venous circulation

IMAGING

- CTV, MRV delineates all vascular components of SP
  - Bone defect visualized on CT
  - 95% midline or parasagittal
    - Superior sagittal sinus most commonly involved

TOP DIFFERENTIAL DIAGNOSES

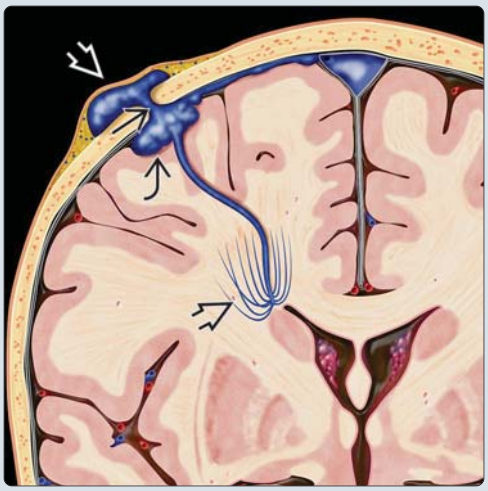
- Atretic cephalocele
  - Main DDx for SP is atretic cephalocele with herniated dural venous sinus (DVS)
- Dermoid cyst
- Hemangioma

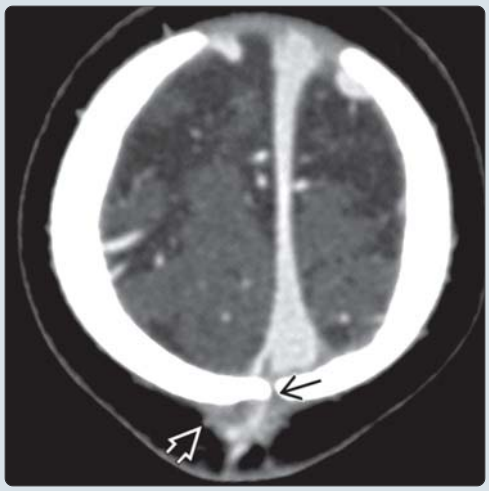
CLINICAL ISSUES

- Child with long history of painless, reducible scalp mass
- Excellent prognosis following surgical removal
- Surgery contraindicated if sinus pericranii serves as major intracranial venous outflow or drains developmental venous anomaly (DVA)

DIAGNOSTIC CHECKLIST

- Describe contribution of sinus pericranii (SP) to IC venous drainage
- Assess for associated DVA, other congenital venous variants
- Entire DVS network must be evaluated prior to sinus pericranii removal (CTV/MRV)
- DSA may be required to delineate intracranial venous outflow, differentiate SP from atretic cephalocele with herniated DVS
  - 25% dominant (drain majority of intracranial venous outflow)
  - 75% accessory (drain only minority of outflow)





(Left) *Coronal graphic shows parasagittal sinus pericranii (SP). SP is composed of an intracranial varix ⇨, transosseous vein ⇨, and DVA ⇨, plus a scalp varix ➡. SPs are typically midline/paramedian scalp varices that communicate with the SSS via a transosseous vein &/or cortical vein.* **(Right)** *Axial CTV demonstrates a small SP, seen here as a calvarial defect ⇨ through which a scalp venous varix ➡ drains into the SSS. No associated intracranial anomalies are present.*

(Left) *Sagittal reformatted CTV from the same patient nicely shows the scalp varix ➡ communicating through a calvarial defect ⇨ with the underlying SSS.* **(Right)** *Late venous phase DSA in another patient shows a small DP with a venous varix ⇨ communicating with the SSS via a tiny transosseous vein ⇨. This is an accessory type SP.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Sinus pericranii (SP)

Definitions

- Anomalous communication between intracranial dural venous sinus (DVS), extracranial venous circulation

IMAGING

General Features

- Best diagnostic clue
  - Vascular scalp lesion communicating with underlying DVS
- Location
  - 95% midline/parasagittal
    - Frontal (40%), parietal (34%), occipital (23%), temporal (4%)
  - Superior sagittal sinus (SSS) most commonly involved
    - Transverse sinus, torcular Herophili uncommon
- Size
  - Scalp lesion: 1-13 cm; most 2-6 cm
  - Bone defect: 1-4 mm (large defect rare)
- Morphology
  - Extracranial component
    - Most common = variably sized venous varix
    - Single or multiple enlarged vein(s)
    - True scalp venous malformation (VM) or AVM rare
  - Intracranial component
    - Midline SP: Direct transosseous communication with SSS
    - Parasagittal SP: Prominent cortical/scalp vein(s) connects with DVS
    - ± associated developmental venous anomaly (DVA)

CT Findings

- NECT
  - Homogeneous soft tissue density scalp mass
    - Septations, cysts, phleboliths rare (usually with VM)
  - Bone algorithm
    - Single/multiple, well-defined bone defect(s)
    - Pressure erosion from overlying varix/VM
- CECT
  - Intense, well-delineated enhancement
    - Heterogeneous if thrombus present or VM
- CTV: Best for delineating vascular components

MR Findings

- T1WI
  - Most iso-, hypo-, or mixed iso-/hypointense
    - Hyperintense if subacute thrombus present
    - "Flow voids" if rapidly flowing varix/VM
- T2WI
  - Most hyperintense
    - Mixed signal in large varix/VM secondary to turbulent flow
    - Flow voids in rapidly flowing varix/VM
- T1WI C+
  - Intense, sharply demarcated enhancement
    - Heterogeneous if thrombus present
    - Peripheral/solid enhancement if VM
- MRV
  - Delineates all vascular components of SP

Ultrasonographic Findings

- Grayscale ultrasound
  - Hypoechoic scalp mass and transosseous feeder(s)
  - Shadowing from skull limits IC evaluation
- Color Doppler
  - Demonstrates direction of flow

Angiographic Findings

- Late venous phase delineates connection between DVS, extracranial veins

Other Modality Findings

- Percutaneous venography (PV)
  - Visualization of scalp veins
  - Visualization of transosseous vein, DVS inconstant

Imaging Recommendations

- Best imaging tool
  - CTV, T1C+ MR/MRV
    - Both suitable for delineation of SP, associated intracranial anomalies
    - Bone defect best visualized on CT
- Protocol advice
  - DSA may be required to assess intracranial venous drainage preoperatively

DIFFERENTIAL DIAGNOSIS

Atretic Encephalocele

- Small herniation of IC contents through skull defect
- No enhancement unless vessels/DVS also herniate
- May be difficult to distinguish from SP on MR alone

Dermoid Cyst

- Well-defined fluid or fat density lesion
- Anterior fontanelle/bregma location classic

Hemangioma

- Intensely enhancing mass with flow voids
- Characteristic evolution

Rhabdomyosarcoma, Langerhans Cell Histiocytosis, Neuroblastoma Metastases

- Enhancing, destructive mass
- Invasion of DVS appears as filling defect

PATHOLOGY

General Features

- Etiology
  - Majority congenital
    - Probable anomalous venous development during late embryogenesis
    - Incomplete sutural fusion over prominent/abundant diploic or emissary veins
    - In utero DVS thrombosis
  - Traumatic
    - Disruption of emissary veins at outer table
    - Laceration or DVS thrombosis

https://CafePezeshki.IR

- Spontaneous
  - Secondary to remote, "forgotten" trauma
  - Subclinical, postnatal DVS thrombosis
- Associated abnormalities
  - DVA
  - Systemic venous malformations
  - Blue rubber bleb nevus syndrome
  - Multisutural craniosynostosis
    - SP forms secondary to DVS/internal jugular vein hypoplasia/atresia or IC hypertension
  - Isolated reports of cutis aplasia congenita

Staging, Grading, & Classification

- Based on intracranial venous outflow
  - 25% dominant (drain majority of intracranial venous outflow)
  - 75% accessory (drain only minority of outflow)

Gross Pathologic & Surgical Features

- Scalp varix/VM: Bluish, blood-filled sac or network of sacs beneath > above calvarial periosteum

Microscopic Features

- Scalp varix/VM: Nonmuscular venous channel(s)
  - Endothelial lining = congenital origin
  - Fibrous lining/capsule = traumatic origin
  - ± hemosiderin-laden macrophages, thrombus

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Painless nonpulsatile forehead/scalp mass (10% bluish discoloration)
    - Reduces in upright position
    - Distends when prone, with Valsalva, or crying
  - Rare: Pain, headache, nausea, dizziness
- Clinical profile
  - Child with long history of painless, reducible scalp mass

Demographics

- Age
  - Range: 0-70 years
    - Usually discovered in children, young adults
- Gender
  - Slight female predominance
- Epidemiology
  - Rare
    - 11% of patients presenting for treatment of craniofacial VMs

Natural History & Prognosis

- Not clearly understood
  - Usually stable, benign; rare spontaneous regression
  - Potential lifetime risk of hemorrhage, air embolus if SP injured is unknown
- Prognosis excellent following surgical removal

Treatment

- Evaluate entire DVS network to ensure feasibility of SP removal
  - Surgery contraindicated if SP is dominant type
- Surgery
  - Ligation of transosseous emissary vein(s), removal of scalp lesion, closure of bone hole(s) with bone wax
- Endovascular therapy
  - Suitable for accessory SP
  - Transvenous or direct percutaneous embolization (coils, glue)

DIAGNOSTIC CHECKLIST

Consider

- Blue rubber bleb nevus syndrome if SP associated with multiple intracranial DVAs

Image Interpretation Pearls

- Assess for associated intracranial venous anomalies (DVA), congenital venous variants
- Entire DVS network must be evaluated prior to sinus pericranii removal
- Diagnostic imaging appearance characteristic
  - Unless thrombosed, main DDx is cephalocele with herniated DVS

Reporting Tips

- Describe contribution of SP to IC venous drainage

KEY FACTS

TERMINOLOGY

- Cavernous malformation (CM)
- Benign vascular hamartoma
  - Contains masses of closely apposed immature blood vessels ("caverns"), no neural tissue
  - Intralesional hemorrhages of different ages

IMAGING

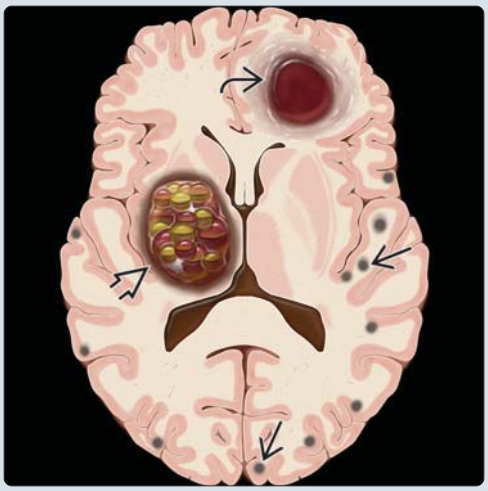
- General: Locules of variable size with blood at different stages of evolution
  - Variable appearance depending on hemorrhage/stage
  - CMs vary from microscopic to giant (> 6 cm)
- Classic MR: "Popcorn ball" appearance with complete hypointense hemosiderin rim on T2WI MR
- DSA: Usually normal ("angiographically occult vascular malformation") unless mixed with DVA
- Zabramski classification of CMs
  - Type 1 = subacute hemorrhage (may obscure underlying CM)
  - Type 2 = mixed signal intensity on T1, T2WI (classic "popcorn ball" lesion)
  - Type 3 = chronic hemorrhage (hypo- to isointense on T1, T2WI)
  - Type 4 = punctate microhemorrhages (blooming "black spots" on T2*)

TOP DIFFERENTIAL DIAGNOSES

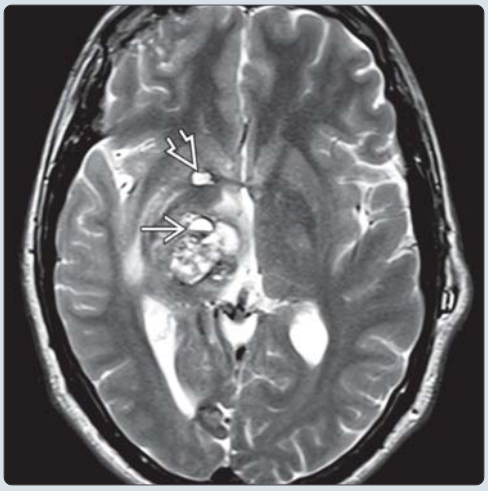
- Arteriovenous malformation
- Hemorrhagic neoplasm
- Calcified neoplasm
- Hypertensive microbleeds
- Amyloid angiopathy

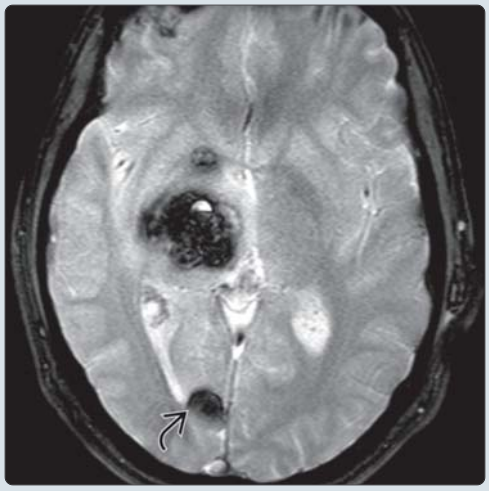
CLINICAL ISSUES

- Variable behavior (enlarge, regress, form de novo)
- All ages (peak = 40-60 years)



(Left) *Axial graphic depicts various stages of cavernous malformations with subacute hemorrhage ⇨ and classic "popcorn ball" ⇨ lesion with multiple blood-filled locules, surrounding hemosiderin rim. Multifocal "blooming black dots" ⇨ are also depicted.* **(Right)** *Axial NECT scan shows a mixed density right thalamic mass with edema. Note fluid-fluid level ➡ within the mass.*





(Left) *Axial T2WI in the same case shows the classic "popcorn ball" appearance of a CM with multiple fluid-filled locules ➡. A second, separate lesion is also present ➡.* **(Right)** *T2* GRE scan in the same case shows striking "blooming" in and around the two lesions. A third lesion ⇨ in the right occipital lobe is present but was difficult to see on the standard FSE T2-weighted sequence.*

TERMINOLOGY

Abbreviations

- Cavernous malformation (CM)

Synonyms

- Cavernoma

Definitions

- Benign vascular hamartoma with intralesional hemorrhages, no neural tissue
  - Contains masses of closely apposed immature blood vessels ("caverns")
  - Intralesional hemorrhages of different ages
- CMs exhibit range of dynamic behaviors (enlargement, regression, de novo formation)

IMAGING

General Features

- Best diagnostic clue
  - "Popcorn ball" appearance with complete hypointense hemosiderin rim on T2WI MR
- Location
  - Cavernous malformations can occur anywhere in body
  - Brain most common site
    - Hemispheres > brainstem, cerebellum
  - Spinal cord is rare (more common in patients with multiple CM syndrome)
- Size
  - CMs vary from microscopic to giant (> 6 cm)
  - Majority are 0.5-4 cm
- Morphology
  - Discrete, lobulated mass of interwoven vessels
  - Locules of variable size contain blood products at different stages of evolution

CT Findings

- NECT
  - Negative in 30-50%
  - Well-delineated round/ovoid hyperdense lesion, usually < 3 cm
    - 40-60% Ca++
    - No mass effect unless recent hemorrhage
  - Surrounding brain usually appears normal
- CECT
  - Little/no enhancement unless mixed with other lesion (e.g., developmental venous anomaly [DVA])
- CTA
  - Usually negative

MR Findings

- T1WI
  - Variable, depending on hemorrhage/stage
    - Common: "Popcorn ball" appearance of mixed hyper-, hypointense blood-containing locules
    - Less common: Acute hemorrhage (nonspecific)
  - T1 perilesional hyperintensity common
    - Helps differentiate CM from other hemorrhagic masses
- T2WI
  - Reticulated popcorn-like lesion is most typical
    - Mixed signal core, complete hypointense hemosiderin rim
    - Locules of blood with fluid-fluid levels
  - Less common: Hypointense
- FLAIR
  - May show surrounding edema in acute lesions
- T2* GRE
  - Prominent susceptibility effect (hypointense "blooming")
  - Multiple CMs: Numerous punctate hypointense foci ("black dots") on GRE scans are most common finding
    - SWI much more sensitive than GRE
- DWI
  - Susceptibility effects seen; surrounding brain is usually normal
- T1WI C+
  - Minimal or no enhancement (may show associated venous malformation)
- MRA
  - Normal (unless mixed malformation present)
  - Large acute hemorrhage may obscure more typical features of CM

Angiographic Findings

- Conventional
  - DSA
    - Usually normal ("angiographically occult vascular malformation")
    - Slow intralesional flow without AV shunting
    - Avascular mass effect if large or acute hemorrhage
    - ± other associated malformation (e.g., DVA)
    - Rare: Venous pooling, contrast "blush"

Imaging Recommendations

- Best imaging tool
  - MR
    - Standard T1, T2WI may be negative in small type 4 lesions
    - Use T2* sequence (SWI > GRE)
- Protocol advice
  - Use T2* GRE sequence with long TE (35 msec)
  - Include T1 C+ to look for associated anomalies (e.g., DVA)

DIFFERENTIAL DIAGNOSIS

"Popcorn Ball" Lesion

- Arteriovenous malformation
- Hemorrhagic neoplasm
- Calcified neoplasm

Multiple "Black Dots"

- Old trauma (diffuse axonal injury [DAI], contusions)
- Hypertensive microbleeds
- Amyloid angiopathy
- Capillary telangiectasias
- Rare: Fat emboli, thrombotic microangiopathy, pneumocephalus

PATHOLOGY

General Features

- Etiology

https://CafePezeshki.IR

- CMs are angiogenically immature lesions with endothelial proliferation, increased neoangiogenesis
- VEGF, β-FGF, TGF-α expressed

- Genetics
  - Sporadic CM
    - No *KRIT1* mutation
    - *PTEN* promoter methylation mutation common (also in familial CM syndrome)
  - Multiple (familial) CM syndrome is autosomal dominant, variable penetrance
    - 3 separate loci implicated: *KRIT1/CCM1*, *MGC4607/CCM2*, *PDCD10/CCM3* genes
      - KRIT1/CCM1 65-70%
      - MGC4607/CCM2 18%
      - PDCD10/CCM3 10-15%
- Associated abnormalities
  - Developmental venous anomaly (most common mixed vascular malformation)
  - Superficial siderosis
  - More T2/FLAIR WM hyperintensities in familial CMs

Staging, Grading, & Classification

- Zabramski classification of CMs
  - Type 1 = subacute hemorrhage (hyperintense on T1WI; hyper- or hypointense on T2WI)
  - Type 2 = mixed signal intensity on T1WI, T2WI with degrading hemorrhage of various ages (classic "popcorn ball" lesion)
  - Type 3 = chronic hemorrhage (hypo- to isointense on T1WI, T2WI)
  - Type 4 = punctate microhemorrhages ("black dots"), poorly seen except on GRE sequences

Gross Pathologic & Surgical Features

- Discrete, lobulated, bluish-purple (mulberry-like) nodule

Microscopic Features

- Angioarchitecture
  - "Bland" regions within thin-walled caverns
  - "Honeycombed" regions with notable capillary proliferation
- Thin-walled epithelial-lined spaces
  - Hemorrhage in different stages of evolution
  - Does not contain normal brain tissue

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizure (50%)
  - Neurologic deficit (25%) (may be progressive)
  - Asymptomatic (20%)

Demographics

- Age
  - Peak presentation: 40-60 years
    - May present in childhood
  - Familial CMs tend to present earlier than sporadic lesions
- Ethnicity
  - Multiple (familial) CM syndrome in Hispanic Americans of Mexican descent
    - Founder mutation in *KRIT1* (Q445X)
    - Positive family history = 90% chance of mutation resulting in CM
  - CMs may occur in any ethnic population
- Epidemiology
  - Most common angiographically "occult" vascular malformation
  - Approximate prevalence: 0.5%
    - 2/3 occur as solitary, sporadic lesion
    - 1/3 are multiple, familial

Natural History & Prognosis

- Broad range of dynamic behavior (may progress, enlarge, regress)
  - "Black spot" lesions mean bleeding rate 0.7% per lesion-year
- De novo lesions may develop
  - Therapeutic radiation may be "accelerator" of lesion formation
- Propensity for growth via repeated intralesional hemorrhages
  - Sporadic = 0.25-0.7% per year
  - Risk factor for future hemorrhage = previous hemorrhage
  - Rehemorrhage rate is initially high but decreases after 2-3 years
- Familial CMs at especially high risk for hemorrhage, forming new lesions
  - Estimated 1% per lesion per year

DIAGNOSTIC CHECKLIST

Consider

- Perform T2* scan to look for additional lesions in patients with spontaneous intracranial hemorrhage

KEY FACTS

TERMINOLOGY

- Brain capillary telangiectasia (BCT)
- Cluster of enlarged, dilated capillaries interspersed with normal brain parenchyma

IMAGING

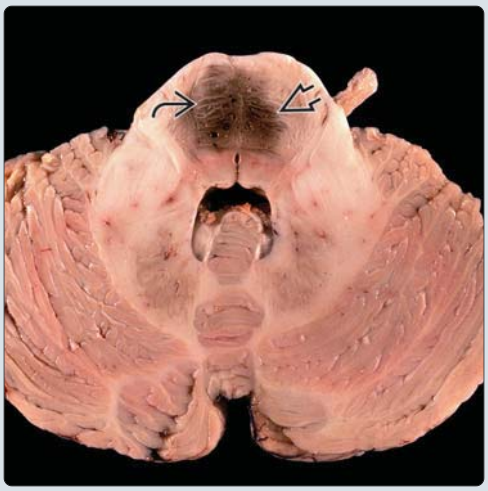
- General features
  - Common sites: Pons, cerebellum, spinal cord
  - Usually < 1 cm
- CT
  - Usually normal
- MR
  - T1WI usually normal
  - T2WI
    - 50% normal on T2WI
    - 50% show faint stippled foci of hyperintensity
  - Large BCTs may show ill-defined FLAIR hyperintensity
  - Moderately hypointense on GRE; profoundly hypointense on SWI
  - T1 C+ shows faint stippled or speckled brush-like enhancement
  - Large BCTs typically contain prominent linear draining vein(s)

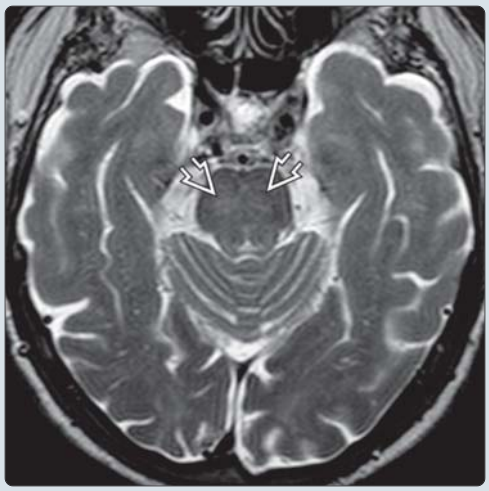
TOP DIFFERENTIAL DIAGNOSES

- Developmental venous anomaly
- Metastasis
- Cavernous malformation
- Capillary hemangioma

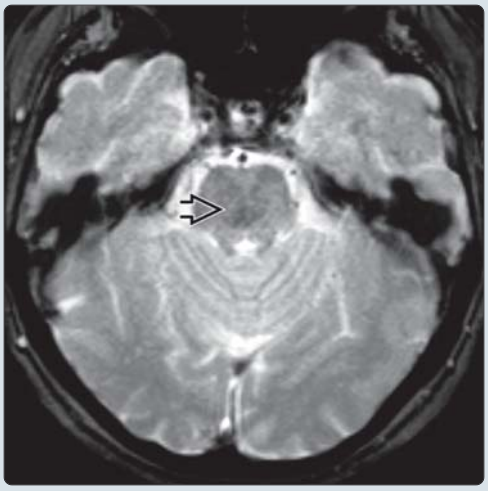
CLINICAL ISSUES

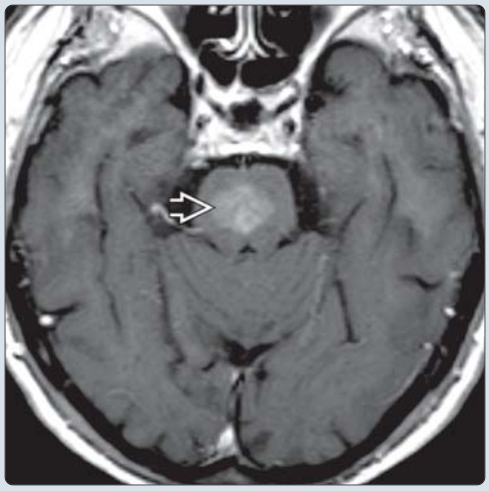
- BCTs represent 15-20% of all intracranial vascular malformations
- Usually found incidentally at autopsy or imaging
- Rare: Headache, vertigo, tinnitus
- Clinically benign, quiescent
  - Unless histologically mixed (usually with CM)





(Left) *Axial gross pathology shows a large capillary telangiectasia of the pons. The dusky color is caused by deoxygenated blood, not frank hemorrhage. Note undisturbed transverse pontine tracts crossing the telangiectasia.* **(Right)** *Axial T2WI in a neurologically normal patient with headaches shows very faint "stippled" hyperintensities in the central pons.*





(Left) *Axial T2* GRE in the same patient shows faint hypointensity in the central pons.* **(Right)** *Axial T1 C+ MR in the same patient shows faint brush-like enhancement in the central pons, characteristic of a large capillary telangiectasia. (Courtesy P. Rodriguez, MD.)*

TERMINOLOGY

Abbreviations

- Brain capillary telangiectasia (BCT)
- Cerebrovascular malformation (CVM)

Synonyms

- Capillary malformation
- **Not** capillary "hemangioma"
  - Hemangiomas are true benign vasoformative neoplasms
  - Usually in face, scalp, back, chest, orbit
  - Less common: Dura, venous sinuses
  - Exceptionally rare in brain parenchyma

Definitions

- Cluster of enlarged, thin-walled capillaries surrounded and separated by normal brain (usually WM)

IMAGING

General Features

- Best diagnostic clue
  - Hypointense lesion on T2* with faint brush-like enhancement
- Location
  - Can be found anywhere
  - Most common sites
    - Pons
    - Cerebellum
    - Medulla
    - Spinal cord
  - Up to 1/3 in cerebral hemispheres
    - White matter
    - Cortex
- Size
  - Usually < 1 cm
  - Occasionally "giant" (> 1 cm)
  - Solitary > > multiple
- Morphology
  - Small, poorly marginated
  - No mass effect
  - No edema

CT Findings

- NECT
  - Usually normal
  - Occasionally may show Ca++
    - Usually only if mixed histology (most commonly cavernous malformation)
- CECT
  - Usually normal

MR Findings

- T1WI
  - Usually normal
  - May be hyperintense or hypo-/hyperintense ("popcorn" appearance) if mixed with CM
- T2WI
  - 50% normal
  - 50% show faint stippled foci of hyperintensity
- FLAIR
  - Usually normal
  - If large, may show ill-defined hyperintensity
  - No mass effect, edema
- T2* GRE
  - GRE
    - Lesion moderately hypointense
      - **Not** hemorrhage (unless mixed with CM)
      - Sluggish blood flow allows oxy- → deoxyhemoglobin
    - Occasionally multifocal BCTs seen as black or gray "dots," if mixed with CMs
  - SWI
    - SWI even more sensitive than standard T2*GRE
    - Lesion may be profoundly hypointense
- DWI
  - Usually normal
- PWI
  - Shows profound drop in signal intensity with relatively rapid recovery to baseline
- T1WI C+
  - Faint stippled or mild speckled brush-like enhancement
    - May have enlarged central draining vein with prominent linear enhancement
  - Large BCTs
    - Usually contain punctate, linear/branching vessel(s)
      - Represent radicles of draining veins
      - Larger "collector" vein often present
    - Mixed BCT, developmental venous anomaly (DVA) common
- DTI
  - BCTs are interspersed with normal WM tracts
  - No alteration of FA
  - No disturbance/displacement of WM tracts

Angiographic Findings

- Conventional
  - Usually normal
  - Faint vascular "stain" ± draining vein
  - Look for associated DVA

Imaging Recommendations

- Best imaging tool
  - MR with T2*, T1 C+ sequences
- Protocol advice
  - Include SWI

DIFFERENTIAL DIAGNOSIS

Developmental Venous Anomaly (DVA)

- Often mixed with BCT

Metastasis

- Strong > > faint enhancement
- Pons/cerebellum rare locations

Cavernous Malformation

- Blood locules with fluid-fluid levels
- Complete hemosiderin rim
- Can be mixed with BCTs, cause hemorrhage

Capillary Hemangioma

- Vasoformative neoplasms, not congenital CVMs

https://CafePezeshki.IR

- Dura, venous sinuses > > brain parenchyma

PATHOLOGY

General Features

- Etiology
  - Precise etiology of sporadic BCTs unknown
  - May develop as complication of radiation
    - 20% of children after whole brain irradiation
- Genetics
  - May be related to mutated *SLPI*
    - ↑ perfusion → upregulated VEGF → ↑ capillary dysplasia
  - Capillary density increases with nonischemic venous hypertension
    - Hypoxia-inducible factor-1-α (HIF-1-α), downstream target VEGF upregulated
- Associated abnormalities
  - Often mixed with other vascular malformations (cavernous, venous)
  - Hereditary hemorrhagic telangiectasia
    - a.k.a. Osler-Weber-Rendu disease
    - Autosomal dominant disorder
    - Often complicated by vascular malformations in brain, lung, GI tract, liver
      - Brain capillary vasculary malformations most common phenotype in HHT
      - CTs also common in nasal mucosa (epistaxis, hemoptysis may be life threatening)
      - No correlation between HHT gene mutation, lesion type, or number
    - HHT-associated strokes usually secondary to pulmonary AVM/AV, brain AVM with bleed, SAH with saccular aneurysm
  - Macrocephaly capillary malformation (MCM) syndromes
    - a.k.a. macrocephaly-cutis marmorata telangiectatica congenita (M-CMTC)
      - Facial nevus flammeus, cutis marmorata
    - Rapid brain growth during infancy
      - Megalencephaly, polymicrogyria
      - Tonsillar herniation
      - Ventriculomegaly, dilated dural venous sinuses
      - Prominent perivascular spaces (PVSs)
      - Skin > > brain capillary malformations

Gross Pathologic & Surgical Features

- Most BCTs found incidentally
  - Large BCTs may appear pinkish or slightly dusky
  - No hemorrhage unless other vascular malformation (e.g., CM) present

Microscopic Features

- Cluster of dilated, but histologically normal capillaries
  - Thin-walled, endothelial-lined vascular channels
  - Largest channels may represent draining veins
- Normal brain interspersed between dilated capillaries
- Uncomplicated BCTs have no surrounding gliosis, hemorrhage, Ca++

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually found incidentally at autopsy or imaging
  - Rare: Headache, vertigo, tinnitus
- Clinical profile
  - Asymptomatic, middle-aged patient with poorly delineated, enhancing brainstem lesion

Demographics

- Age
  - Any; 30-40 years most common
  - Rarely identified in children, but does occur
- Epidemiology
  - 15-20% of all intracranial vascular malformations
  - Most common vascular malformation in HHT

Natural History & Prognosis

- Clinically benign, quiescent unless histologically mixed
- Rare reports of aggressive course

Treatment

- None

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Faintly enhancing pontine lesion that becomes moderately hypointense on T2* is usually BCT

Introduction

The most widely accepted classification of brain neoplasms is sponsored by the World Health Organization (WHO). A working group of world-renowned neuropathologists periodically convenes for a consensus conference on brain tumor classification and grading. The results are then published. An update to the 2007 edition of the so-called "Blue Book" is scheduled for late 2016.

Brain tumors are both classified and graded. Although this is rapidly changing with the advent of molecular profiling, histological grading has been the primary means of predicting the biological behavior of tumors. While many different grading schemas have been proposed, the WHO classification and grading of CNS neoplasms is the most widely accepted and is utilized in this text.

Classification/Grading of CNS Neoplasms

General Considerations

CNS neoplasms are divided into primary and metastatic tumors. Primary neoplasms are divided into 6 major categories. The largest by far is tumors of neuroepithelial tissue, followed by tumors of the meninges. Tumors of cranial and spinal nerves, lymphomas and hematopoietic neoplasms, and germ cell tumors are less common but important groupings. The final category of primary neoplasms, tumors of the sellar region, is identified by geographic region rather than histologic type.

Tumors of Neuroepithelial Tissue

This category is huge, and therefore it is divided into several discrete tumor subtypes. Once thought to arise from dedifferentiation of mature neurons or glial cells (e.g., astrocytes, oligodendrocytes, ependymal cells, etc.), it is now recognized that most brain tumors arise from neural stem cells.

Astrocytomas: There are many histologic types and subtypes of astrocytomas, ranging in biological behavior from benign, relatively circumscribed tumors, such as pilocytic astrocytoma (PA) and subependymal giant cell astrocytoma (SGCA), to the highly malignant, diffusely infiltrating glioblastoma (GBM).

Two of the localized astrocytomas (PA and SGCA) are designated as WHO grade I neoplasms. Neither displays a tendency to malignant progression, although a variant of PA called pilomyxoid astrocytoma may behave more aggressively and is classified as a WHO grade II tumor.

Diffusely infiltrating astrocytomas have no distinct border between tumor and normal brain, even though the tumor may look relatively discrete on imaging. The lowest grade is simply called "diffuse astrocytoma" and is designated as WHO grade II. Anaplastic astrocytoma (AA) is WHO grade III and GBM is a grade IV neoplasm.

Patient age has a significant effect on astrocytoma type and location. For example, diffusely infiltrating astrocytomas are most common in the cerebral hemispheres of adults and the pons in children. PAs are tumors of children and young adults. They are common in the cerebellum and around the third ventricle but only rarely occur in the hemispheres.

Oligodendroglial tumors: These vary from a diffusely infiltrating, but relatively well-differentiated, WHO grade II neoplasm (oligodendroglioma) to anaplastic oligodendroglioma (WHO grade III).

Low grade gliomas (LGGs): LGGs have been distilled into 3 molecular subtypes, which yields a robust nonoverlapping, clinically relevant classification that is superior to traditional histologic methods in predicting biological behavior. LGG class is based on the FISH (fluorescence in situ hybridization) status of 3 important markers: *IDH1*, 1p19q (co-deletion of both 1p and 19q), and *ATRX* (α-thalassemia/mental retardation syndrome X-linked gene).

This molecular classification results in two diffusely infiltrating astrocytomas that are stratified primarily according to *IDH1* status. Astrocytomas with a more favorable prognosis exhibit *IDH* mutation (are *IDH1*[+]) &/or *ATRX* mutation (*ATRX*[+]). 1p19q is nondeleted. The second group is those that are *IDH1*(-) ("wild type"). Even though they may appear histologically "low grade" (WHO II), "wild type" tumors are aggressive neoplasms that behave more like GBMs. Oligodendrogliomas exhibit 1p19q codeletion are typically *IDH1*(+). *ATRX* is nonmutated.

O-6-methylguanine-DNA methyltransferase (MGMT) promoter profiling is important for glioma treatment stratification. MGMT(+) tumors are typically more chemosensitive than "wild type" neoplasms.

Gliomas in children vs. adults: Pediatric gliomas are often genetically different from their adult counterparts even though they appear identical under the microscope. Intrinsic pediatric pontine gliomas, aggressive neoplasms that are almost always fatal, exhibit histone (*H3*) and *ACVR1* mutations. In contrast to adult oligodendrogliomas, pediatric oligodendrogliomas rarely exhibit 1p19q codeletion.

Ependymal tumors: Classic histologic criteria divide ependymal neoplasms into grade I subependymomas or myxopapillary ependymomas, grade II ependymomas (further subdivided into cellular, papillary, clear cell, and tanycytic types), and grade III (anaplastic) ependymomas.

DNA methylation profiling has recently identified 9 molecular subgroups of ependymoma. This molecular classification outperforms the current histopathological grading in the risk stratification of patients for treatment.

Choroid plexus tumors: Choroid plexus tumors (CPTs) are papillary intraventricular neoplasms. Almost 80% are found in children. Classically, CPTs have been divided into choroid plexus papillomas (CPP) (WHO grade I), atypical choroid plexus papillomas (aCPP) (WHO grade III), and choroid plexus carcinomas (CPCa), designated as WHO grade III. Recent genomic analysis has shown aCPP is an immature variant of CPP with similar cytogenetic profiling and differs only by exhibiting increased proliferative activity. CPCa is a genetically distinct tumor group.

CPPs are 5-10x more common than CPCs. All choroid plexus tumors can spread diffusely through the CSF, so the entire neuraxis should be imaged prior to surgical intervention.

Other neuroepithelial tumors: These rare neoplasms include astroblastoma, chordoid glioma of the third ventricle, and angiocentric glioma.

Neuronal and mixed neuronal-glial tumors: Neuroepithelial tumors with ganglion-like cells, differentiated neurocytes, or poorly differentiated neuroblastic cells are included in this heterogeneous group. Ganglion cell neoplasms (gangliocytoma, ganglioglioma), desmoplastic infantile ganglioglioma or astrocytoma (DIG/DIA), neurocytoma

https://CafePezeshki.IR

(central as well as the newly described extraventricular variant), dysembryoplastic neuroepithelial tumor (DNET), papillary glioneuronal tumor, rosette-forming glioneuronal tumor (of the 4th ventricle), and cerebellar liponeuroblastoma are included.

Pineal region tumors: Pineal region neoplasms account for < 1% of all intracranial neoplasms and can be germ cell tumors or pineal parenchymal tumors. Pineal parenchymal tumors are less common than germ cell tumors. Because germ cell neoplasms occur in other intracranial sites as well as the pineal gland, they are considered separately.

Pineocytoma is a very slowly growing, well-delineated tumor that is usually found in adults. Pineocytomas are WHO grade I. Pineoblastoma is a highly malignant primitive embryonal tumor mostly found in children. Highly aggressive and associated with early CSF dissemination, pineoblastomas are WHO grade IV neoplasms.

Pineal parenchymal tumor of intermediate differentiation (PPTID) is intermediate in malignancy, probably WHO grade II or III. Many so-called aggressive pineocytomas would probably be reclassified as PPTIDs. A newly described neoplasm, papillary tumor of the pineal region (PTPR), is a rare neuroepithelia tumor of adults. No WHO grade has been assigned.

Embryonal tumors: This group includes medulloblastoma, CNS primitive neuroectodermal tumors (PNETs), and atypical teratoid-rhabdoid tumors (AT/RT). *SMARCB1* (*INI1/hSNF5*) mutation is diagnostic of AT/RT even in the absence of overtly rhabdoid cells.

Medulloblastoma (MB), which has 1 classic and 3 histologic variants, is now divided into 4 groups based on molecular profiling (the first step in risk stratifying MB patients for therapy). While all 4 groups are designated as WHO IV tumors, they behave quite differently and 1 specific subgroup (Wnt) is associated with an especially favorable prognosis.

Meningeal Tumors

Overview: Meningeal tumors are the second largest category of primary CNS neoplasms. They are divided into meningiomas and mesenchymal, nonmeningothelial tumors (i.e., tumors that are not meningiomas). Hemangiopericytomas, hemangioblastomas, and melanocytic lesions are also considered part of the meningeal tumor grouping.

Meningiomas: Meningiomas arise from meningothelial (arachnoid cap) cells. Most are attached to the dura but can occur in other locations (e.g., choroid plexus of the lateral ventricles). While meningiomas have many histologic subtypes (e.g., meningothelial, fibrous, psammomatous, etc.), the current WHO schema classifies them rather simply. Most meningiomas are benign and correspond to WHO grade I. Atypical meningioma, as well as the chordoid and clear cell variants, are WHO grade II tumors. Anaplastic (malignant) meningiomas correspond to WHO grade III.

Mesenchymal, nonmeningothelial tumors: Both benign and malignant mesenchymal tumors can originate in the CNS. Most correspond to tumors of soft tissue or bone. Generally, both a benign and malignant (sarcomatous) type occur. Lipomas and liposarcomas, chondromas and chondrosarcomas, osteomas and osteosarcomas are examples.

Hemangiopericytoma (HPC) is a highly cellular, vascular mesenchymal tumor that is almost always attache dura. HPCs are WHO II or III neoplasms. Hemangioblastoma (HGBL) is a WHO grade I neoplasm, consisting of stromal cells and innumerable small blood vessels. It occurs both sporadically and as a part of von Hippel-Lindau (VHL) syndrome. Primary melanocytic neoplasms of the CNS are rare. They arise from leptomeningeal melanocytes and can be diffuse or circumscribed, benign or malignant.

Tumors of Cranial (and Spinal) Nerves

Schwannoma: Schwannomas are benign, encapsulated nerve sheath tumors that consist of well-differentiated Schwann cells. They can be solitary or multiple. Multiple schwannomas are associated with neurofibromatosis type 2 and schwannomatosis, a syndrome characterized by multiple schwannomas but lacking other features of NF2. Intracranial schwannomas are almost always associated with cranial nerves (CN8 is by far the most common) but occasionally occur as a parenchymal lesion. Schwannomas do not undergo malignant degeneration and are designated as WHO grade I neoplasms.

Neurofibroma: Neurofibromas (NFs) are diffusely infiltrating, extraneural tumors that consist of Schwann cells and fibroblasts. Solitary scalp neurofibromas occur. Multiple NFs or plexiform NFs occur as part of neurofibromatosis type 1. Neurofibromas correspond histologically to WHO grade I. Plexiform neurofibromas may degenerate into malignant peripheral nerve sheath tumors (MPNSTs). MPNSTs are graded from WHO II to IV, an approach similar to sarcoma grading.

Lymphomas and Hematopoietic Tumors

Primary CNS lymphoma: As a result of HAART therapy in HIV/AIDS patients, as well as in other immunocompromised individuals, primary CNS lymphomas (PCNSL) are dramatically increasing in prevalence. PCNSL can occur as both focal parenchymal and intravascular (IVL) tumor. PCNSL can be single or multiple and is most commonly seen in the cerebral hemispheres. More than 95% of PCNSLs are diffuse large B-cell lymphomas.

Germ Cell Tumors

Intracranial germ cell tumors (GCTs) are morphologic homologues of germinal neoplasms that arise in the gonads and extragonadal sites. 80-90% occur in adolescents. Most occur in the midline (pineal region, around the third ventricle).

Sellar Region Tumors

Craniopharyngioma: Craniopharyngioma is a benign (WHO grade I), often partially cystic neoplasm that is the most common nonneuroepithelial intracranial neoplasm in children. It shows a distinct bimodal age distribution, with the cystic adamantinomatous type seen mostly in children and a second, smaller peak in middle-aged adults. The less common papillary type is usually solid and found almost exclusively in adults.

Miscellaneous sellar region tumors: Granular cell tumor of the neurohypophysis is a rare tumor of adults that usually arises from the infundibulum. Pituicytomas are glial neoplasms of adults that also usually arise within the infundibulum. Spindle cell oncocytoma of the adenohypophysis is a nonendocrine neoplasm of the adenohypophysis. These rare tumors are all WHO grade I.

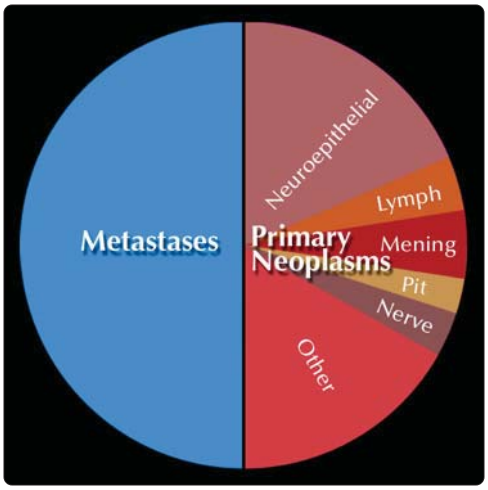
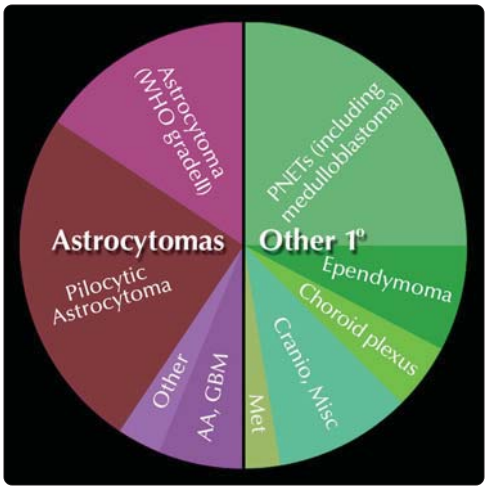
Malignant lymphoma				Spindle cell oncocytoma	I

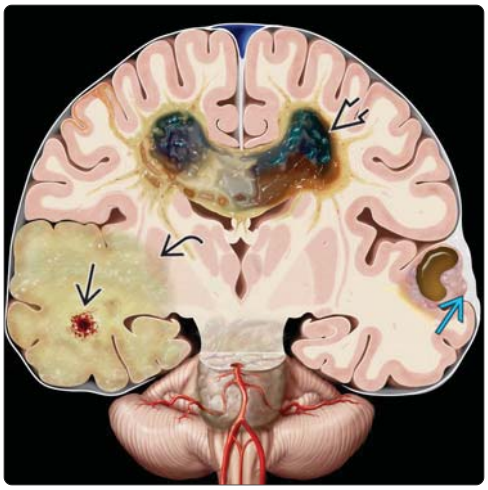
Tables modified, adapted to conform to 2007 World Health Organization Classification of Tumours of the Central Nervous System.

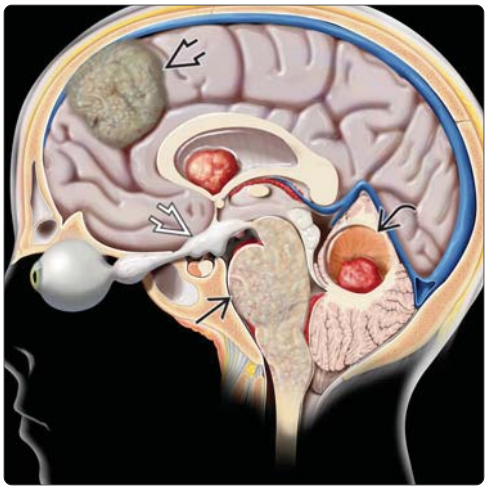
https://CafePezeshki.IR



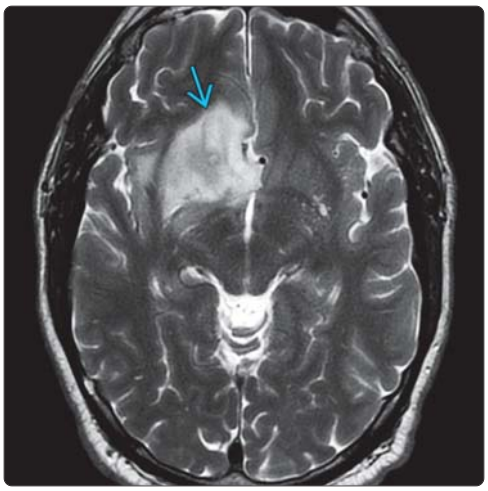


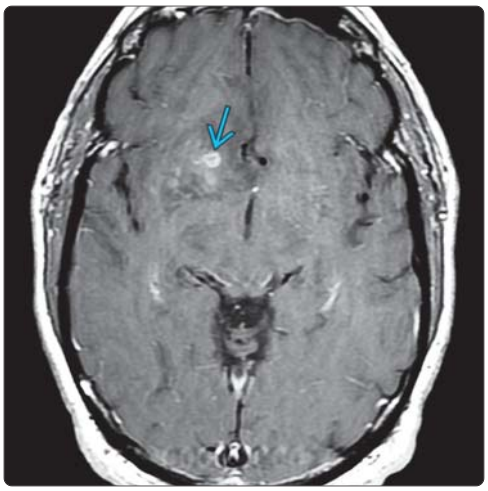
(Left) *Graphic depicts the relative prevalence of brain tumors in adults. Nearly 1/2 are metastases from systemic cancers; the other 1/2 are primary neoplasms.* **(Right)** *Graphic depicts brain tumors in children. Metastases, anaplastic astrocytoma (AA), and glioblastoma (GBM) are rare. Pilocytic astrocytoma and primitive neuroectodermal tumors (PNETs) in children are more common than in adults.*





(Left) *Graphic depicts adult astrocytomas. Low-grade astrocytoma ⇨ (WHO II) has an intrinsic tendency to become anaplastic ⇨. GBM ⇨ is the most common and is shown here in the corpus callosum. PXA is a cystic tumor with nodule abutting and thickening of the meninges ⇨.* **(Right)** *Graphic depicts astrocytomas in children. Brainstem "gliomas" ⇨ and pilocytic astrocytoma (PA) ⇨ are common. Except for PAs around the 3rd ventricle ⇨, supratentorial astrocytomas ⇨ are less frequent compared to adults.*





(Left) *Axial T2WI in a 58-year-old male with 2 seizures demonstrates a heterogeneously hyperintense mass ⇨ infiltrating the right basal ganglia, frontal lobe, external capsule, and posterior limb of the internal capsule.* **(Right)** *T1WI C+ MR in the same patient shows a few enhancing foci ⇨ in the center of the mass. Its location (frontal lobe) and large nonenhancing areas suggest this tumor is likely a secondary GBM. Biopsy disclosed IDH1(+), EGFR(-), MGMT(+), p53 70%(+), PTEN 25%(+), and MIB1 90%.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Well-differentiated but infiltrating neoplasm, slow growth pattern
- Primary brain tumor of astrocytic origin with intrinsic tendency for malignant progression, degeneration into anaplastic astrocytoma (AA)

IMAGING

- Focal or diffuse nonenhancing white matter mass
- T2 homogeneously hyperintense mass
- May expand adjacent cortex
- Usually no enhancement
  - Enhancement suggests progression to higher grade
- MRS: High choline, low NAA typical but not specific
- Perfusion: Relatively lower rCBV compared to AA
- Cerebral hemispheres most common location
  - Supratentorial 2/3: Frontal and temporal lobes
- Infratentorial 1/3: Brainstem (50% of brainstem "gliomas" are low-grade astrocytoma)
- Low-grade astrocytoma may be indistinguishable from other tumors, including AA and oligodendroglioma
- May appear circumscribed on imaging, but tumor cells are often found beyond imaged signal abnormality

TOP DIFFERENTIAL DIAGNOSES

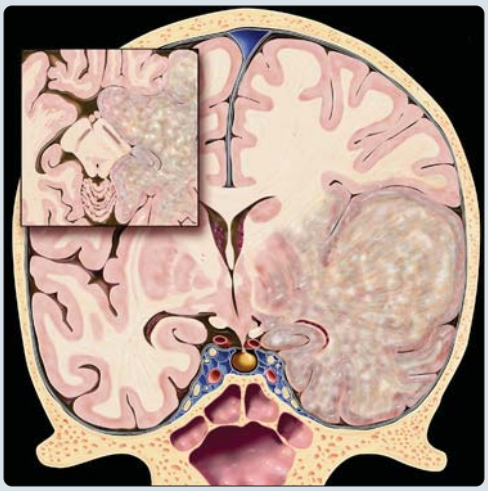
- Anaplastic astrocytoma (AA)
- Oligodendroglioma
- Ischemia
- Cerebritis

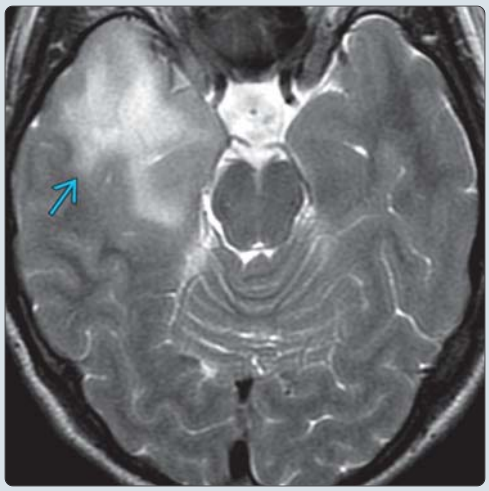
PATHOLOGY

- WHO grade II

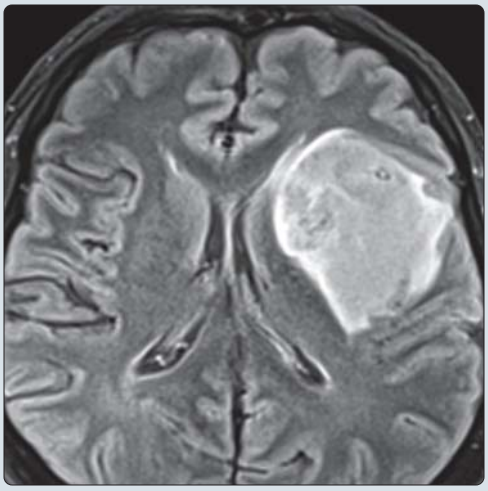
CLINICAL ISSUES

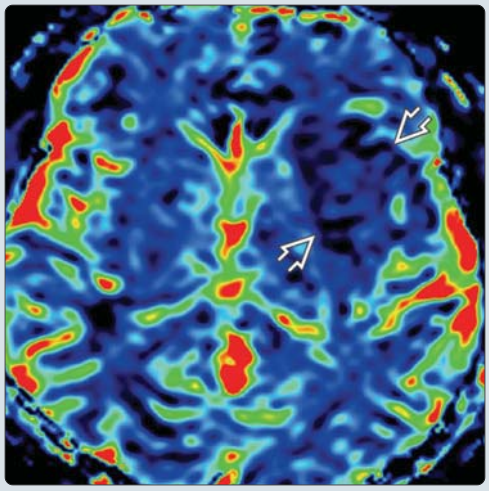
- Seizure is most common presenting feature
- Majority occur between ages of 20-45 years, mean: 34 years
- Median survival: 6-10 years
- Increased survival: Young age, gross total resection
- More favorable prognosis: *IDH1*(+), *ARTX*(+), MGMT(+)





(Left) *Coronal graphic shows an infiltrative mass centered in the white matter expanding the left temporal lobe. Axial insert shows mild mass effect upon the midbrain. Low-grade astrocytomas typically affect young adults.* **(Right)** *Axial T2 MR image in a 34-year-old man with seizures shows a hyperintense infiltrative mass ⇨ centered in the right temporal lobe white matter with extension to the overlying cortex. No enhancement was present on contrast-enhanced images. WHO grade II astrocytoma was diagnosed at resection.*





(Left) *Axial FLAIR MR shows a relatively homogeneous hyperintense mass with mild local mass effect, typical of a WHO grade II diffuse astrocytoma. These infiltrative tumors may be focal or diffuse. Fibrillary astrocytoma is the most frequent histologic variant.* **(Right)** *Axial MR perfusion in the same patient shows a low rCBV ⇨ in the frontotemporal mass, suggesting a low-grade tumor. Perfusion MR has been shown to be helpful in preoperative tumor grading, predicting survival, and guiding biopsy.*

TERMINOLOGY

Synonyms

- Diffuse astrocytoma, grade II astrocytoma, fibrillary astrocytoma, low-grade astrocytoma (LGA)

Definitions

- Primary brain tumor of astrocytic origin with intrinsic tendency for malignant progression, degeneration into anaplastic astrocytoma (AA)
- Well-differentiated but infiltrating neoplasm, slow growth pattern

IMAGING

General Features

- Best diagnostic clue
  - Focal or diffuse nonenhancing white matter (WM) mass
- Location
  - Cerebral hemispheres, supratentorial 2/3
    - Frontal lobes 1/3, temporal lobes 1/3
    - Relative sparing of occipital lobes
    - Tumors of white matter may extend into cortex
  - Infratentorial 1/3
    - Brainstem (50% of brainstem "gliomas" are low-grade astrocytoma)
    - Occur in pons and medulla of children/adolescents
    - Cerebellum is uncommon location
  - 20% involve deep gray matter structures: Thalamus and basal ganglia
  - Less commonly occur in spinal cord
- Size
  - Variable
- Morphology
  - Homogeneous mass with enlargement and distortion of affected structures
  - May appear circumscribed on imaging, but tumor cells are often found beyond imaged signal abnormality

CT Findings

- NECT
  - Ill-defined homogeneous hypodense/isodense mass
  - 20% Ca++; cysts are rare
  - Calvarial erosion in cortical masses (rare)
- CECT
  - No enhancement or very minimal
    - Enhancement should raise suspicion of focal malignant degeneration

MR Findings

- T1WI
  - Homogeneous hypointense mass
  - May expand white matter and adjacent cortex
  - Appears circumscribed, but infiltrates adjacent brain
  - Ca++ and cysts (uncommon)
  - Hemorrhage or surrounding edema (rare)
- T2WI
  - Homogeneous hyperintense mass
  - May appear circumscribed, but often infiltrates adjacent brain
  - Ca++ and cysts less common
  - Hemorrhage or surrounding edema are rare
  - May expand adjacent cortex
- FLAIR
  - Homogeneous hyperintense mass
- DWI
  - Typically no diffusion restriction
- T1WI C+
  - Usually no enhancement
  - Enhancement suggests progression to higher grade
- MRS
  - High choline, low NAA typical but not specific
  - High mI/Cr ratio (0.82 ± 0.25)
  - May delineate tumor extent better than conventional MR
- MR perfusion
  - Relatively lower rCBV compared to AA, GBM
  - Lower permeability values than high-grade tumors
  - Increase in rCBV helps predict time to progression

Nuclear Medicine Findings

- PET
  - Low-grade astrocytomas have FDG uptake similar to normal white matter
  - FDG uptake within astrocytoma has good correlation with histologic grade of tumor
  - FDG, 18F-choline, and 11C-choline PET useful for biopsy (most hypermetabolic area)

Imaging Recommendations

- Protocol advice
  - Contrast-enhanced MR
  - MRS and perfusion imaging may be helpful

DIFFERENTIAL DIAGNOSIS

Anaplastic Astrocytoma (AA)

- Hemispheric WM lesion, usually nonenhancing
- Focal or diffuse mass
- May be indistinguishable without biopsy
- MR perfusion may show elevated CBV

Oligodendroglioma

- Cortically based mass with variable enhancement
- Ca++ common
- May be indistinguishable

Ischemia

- Vascular territory (anterior, middle, and posterior cerebral arteries), acute onset
- Diffusion restriction (acute/early subacute)
- Often wedge-shaped, involves GM and WM

Cerebritis

- Edema, patchy enhancement characteristic
- Usually shows restricted diffusion
- Typically more acute onset

Herpes Encephalitis

- Confined to limbic system, temporal lobes
- Hemorrhage and enhancement are common
- Acute onset

https://CafePezeshki.IR

Status Epilepticus

- Active seizures may cause signal abnormalities and enhancement
- Clinical history of seizures

PATHOLOGY

General Features

- Etiology
  - Arise from differentiated astrocytes or astrocytic precursor cells
  - Astrocytic neoplasm characterized by high degree of cellular differentiation, slow growth, diffuse infiltration of adjacent structures
- Genetics
  - *TP53* mutation 25-50%
  - *IDH1*(+), *ATRX* mutations common (up to 85%)
  - Overexpression of platelet-derived growth factor receptor-α (*PDGFRA*)
  - Chromosomal abnormalities: Gain of 7q; 8q amplification; LOH 10p, 22q; chromosome 6 deletions
- Associated abnormalities
  - Associated with Li-Fraumeni syndrome and inherited multiple enchondromatosis type 1 (Ollier disease)

Staging, Grading, & Classification

- WHO grade II

Gross Pathologic & Surgical Features

- Enlargement and distortion of invaded structures
- Diffusely infiltrating mass with blurring of GM/WM interface
- May appear grossly circumscribed but diffusely infiltrates adjacent brain
- Occasional cysts, Ca++

Microscopic Features

- Well-differentiated fibrillary or gemistocytic neoplastic astrocytes
- Background of loosely structured, often microcystic tumor matrix
- Moderately increased cellularity
- Occasional nuclear atypia
- Mitotic activity generally absent or very rare
- No microvascular proliferation or necrosis
- MIB-1 (proliferation index) is low (< 4%)
- Immunohistochemistry: GFAP(+)
- Histologic variants
  - Fibrillary (most frequent)
  - Gemistocytic (most likely to progress to AA, GBM)
  - Protoplasmic (rare)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizures, increased intracranial pressure
  - Other signs/symptoms: Varies with tumor location
    - Seizure, focal neurologic deficit, behavior changes

Demographics

- Age
  - Majority occur between 20-45 years
  - Occur at all ages, mean: 34 years
- Gender
  - Slight male predominance
- Epidemiology
  - Represents 25-30% of gliomas in adults
  - 10-15% of all astrocytomas
  - 2nd most common astrocytoma of childhood (pilocytic is 1st)
  - ~ 1.4 new cases per 1,000,000/year

Natural History & Prognosis

- Patients rarely succumb to spread of low-grade tumor
- Median survival: 6-10 years
- Inherent tendency for malignant progression to AA and GBM = major cause of mortality
- Recurrent disease associated with malignant degeneration in 50-75% of cases
- Malignant progression tends to occur following mean interval of 4-5 years
- Increased survival: Young age, gross total resection
- Radiation therapy in patients with subtotal resection improves survival
- More favorable prognosis: *IDH1*(+), *ARTX*(+), MGMT(+)
- Prognosis worse for pontine, better for medullary tumors (especially dorsally exophytic)

Treatment

- Surgical resection is primary treatment
- Usually adjuvant chemotherapy and XRT at time of recurrence or progression

DIAGNOSTIC CHECKLIST

Consider

- Low-grade astrocytoma may be indistinguishable from other tumors including AA and oligodendroglioma
- Acute/subacute ischemia may mimic diffuse astrocytoma; DWI, history, and follow-up MR helpful

Image Interpretation Pearls

- Think low-grade astrocytoma if T2 hyperintense expansile mass largely confined to WM

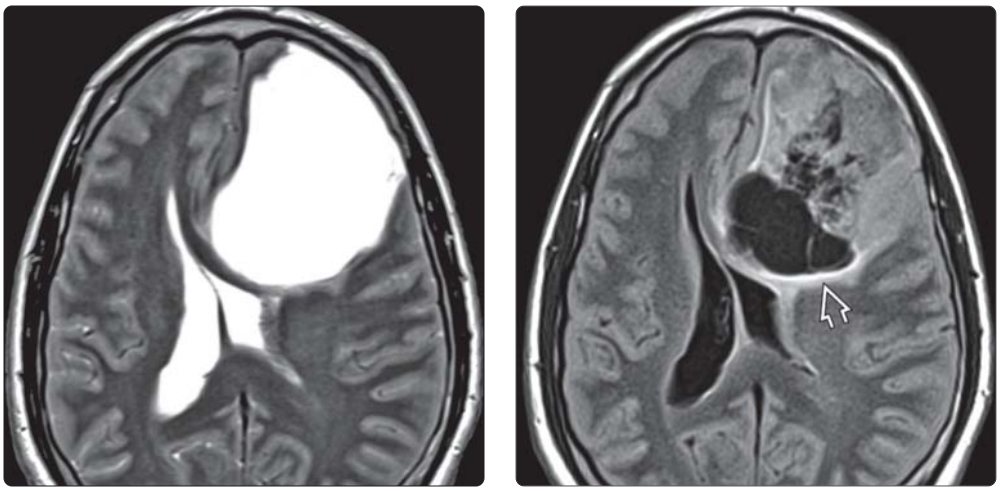
(Left) *Axial FLAIR MR in a 28-year-old woman shows a discrete-appearing posterior frontal lobe hyperintense mass ➡ centered in the white matter with extension to the overlying cortex. Increased survival is correlated with a younger age at presentation and complete surgical resection.* **(Right)** *Axial T1 C+ MR in the same patient shows no enhancement within the mass ➡, typical of a WHO grade II astrocytoma. Imaging mimics an oligodendroglioma. This tumor was IDH1(+), which also has a more favorable prognosis.*

(Left) *Sagittal T2 MR shows a dorsally exophytic medullary mass ➡ that projects into the 4th ventricle. Biopsy confirmed a low-grade astrocytoma. Most brainstem gliomas are diffuse grade II astrocytomas.* **(Right)** *Axial T1 MR shows a large isointense thalamic mass ➡ with associated severe hydrocephalus with interstitial edema (transependymal flow of CSF) ➡. Biopsy revealed a diffusely infiltrating fibrillary astrocytoma. Hydrocephalus is a rare complication of diffuse astrocytoma.*



(Left) *Axial T2WI MR shows a large, hyperintense frontal lobe mass with significant mass effect in this young man with seizures. Protoplasmic astrocytoma, WHO grade II, was found at resection.* **(Right)** *Axial FLAIR MR in the same patient shows the mass to be heterogeneous with minimal surrounding vasogenic edema ➡. Protoplasmic astrocytoma is a rare variant of diffuse astrocytoma. Mucoid degeneration and microcyst formation are common. The frontotemporal region is a classic location.*

KEY FACTS

TERMINOLOGY

- Diffusely infiltrating malignant astrocytoma with anaplasia and marked proliferative potential

IMAGING

- Infiltrating mass that predominately involves white matter with variable enhancement
- T2 heterogeneously hyperintense
- Neoplastic cells almost always found beyond areas of abnormal signal intensity
- May involve and expand overlying cortex
- Usually no enhancement
  - Focal, nodular, homogeneous, patchy enhancement less common
  - Ring enhancement is suspicious for glioblastoma (GBM)
- MRS: Increased Cho/Cr ratio, decreased NAA
- MRP: Elevated maximum rCBV
- AA have histologic and imaging characteristics along spectrum between low-grade astrocytoma and GBM

TOP DIFFERENTIAL DIAGNOSES

- Low-grade diffuse astrocytoma
- GBM
- Oligodendroglioma
- Cerebritis
- Ischemia

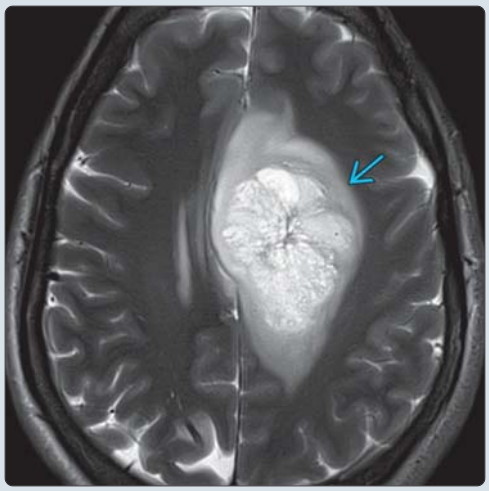
PATHOLOGY

- WHO grade III
- Usually evolves from low-grade (diffuse) astrocytoma (WHO grade II) (75%)

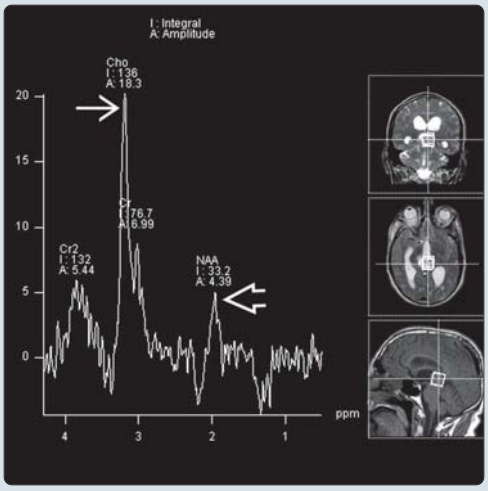
CLINICAL ISSUES

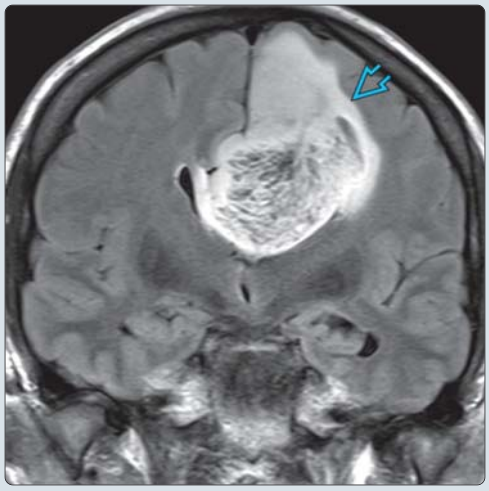
- Most common presentation: Marked clinical deterioration in patient with grade II astrocytoma
- Occurs at all ages, most common 40-50 years
- 1/3 of astrocytomas
- *IDH1*(+) and *MGMT*(+) associated with increased survival
- Median survival: 2-3 years

(Left) *Axial graphic shows an infiltrative white matter mass with extension along the corpus callosum, focal hemorrhage ➡, and local mass effect. White matter extension is typical of anaplastic astrocytoma (AA). They are most commonly located in the cerebral hemispheres.* **(Right)** *Axial T2 MR shows a heterogeneously hyperintense mass with local mass effect ⇨ in the frontal lobe. AA, WHO grade III, was diagnosed at resection. These high-grade gliomas have an intrinsic tendency to degenerate into GBM.*



(Left) *MRS image in a patient with a tectal anaplastic astrocytoma shows a typical malignant tumor spectrum with a high choline peak ➡ and a low NAA peak ⇦.* **(Right)** *Coronal FLAIR MR image in a 47-year-old male shows a heterogeneously hyperintense mass ⇨ centered in the frontal lobe white matter. Anaplastic astrocytomas represent 1/3 of all astrocytomas. Anaplastic astrocytomas are intermediate between low-grade (diffuse) astrocytoma (WHO grade II) and GBM (WHO grade IV).*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Anaplastic astrocytoma (AA)

Synonyms

- Grade III astrocytoma, malignant astrocytoma, high-grade astrocytoma

Definitions

- Diffusely infiltrating malignant astrocytoma with focal or diffuse anaplasia and marked proliferative potential

IMAGING

General Features

- Best diagnostic clue
  - Infiltrating mass that predominately involves white matter (WM) with variable enhancement
- Location
  - Hemispheric WM
    - Commonly involves frontal and temporal lobes
  - May involve pons, thalamus (pons common in children)
  - Less commonly involves brainstem, spinal cord
- Size
  - Variable
- Morphology
  - Ill-defined hemispheric WM mass typical
  - May appear well circumscribed
  - Neoplastic cells almost always found beyond areas of abnormal signal intensity

CT Findings

- NECT
  - Low-density, ill-defined mass
  - Ca++ and hemorrhage rare
- CECT
  - Majority do not enhance
  - Enhancement often focal, patchy, heterogeneous
  - If ring enhancement, consider malignant progression to glioblastoma multiforme (GBM)

MR Findings

- T1WI
  - Mixed isointense to hypointense WM mass
  - May involve and expand overlying cortex
  - Ca++, hemorrhage, cysts rare
- T2WI
  - Heterogeneously hyperintense
  - May appear discrete, but infiltrates adjacent brain
  - May involve and expand overlying cortex
  - Rarely, prominent flow voids are present, suggesting progression to GBM
- FLAIR
  - Heterogeneously hyperintense
- DWI
  - No diffusion restriction is typical
- T1WI C+
  - Usually no enhancement
  - Less common: Focal, nodular, homogeneous, patchy enhancement
  - Ring enhancement is suspicious for GBM
- MRS
  - Elevated Cho/Cr ratio, decreased NAA
- Dynamic contrast-enhanced T2-weighted imaging
  - Elevated maximum rCBV compared to low-grade astrocytoma
  - Increased permeability compared to low-grade astrocytoma
- Diffusion tensor imaging (DTI) of WM tracts may help surgical planning

Nuclear Medicine Findings

- PET
  - Higher metabolism than low-grade astrocytomas
  - FDG shows high-grade gliomas have uptake similar to or exceeding normal gray matter (GM)
  - Tumor:WM ratio > 1.5 and tumor:GM ratio > 0.6 suggest high-grade tumors
  - FDG has sensitivity of 81-86%, specificity of 50-94% in differentiation of recurrent tumor from radiation brain injury

Imaging Recommendations

- Protocol advice
  - Contrast-enhanced MR
  - MRS, MR perfusion, and DTI may be helpful

DIFFERENTIAL DIAGNOSIS

Low-Grade Diffuse Astrocytoma

- Focal or diffuse WM mass
- Typically nonenhancing hemispheric mass
- May be indistinguishable without biopsy

Glioblastoma Multiforme (GBM)

- 95% necrotic core, enhancing rim
- Extensive surrounding T2/FLAIR signal
- Hemorrhage not uncommon

Cerebritis

- T2 hyperintensity and patchy enhancement
- Diffusion restriction typical

Ischemia

- Vascular territory (MCA, ACA, PCA)
- Restricted diffusion if acute/subacute
- Often wedge-shaped, involves GM and WM
- Gyriform enhancement in subacute ischemia

Oligodendroglioma

- Cortical mass with variable enhancement
- Ca++ common
- May be indistinguishable

Status Epilepticus

- Active seizures may cause signal abnormalities and enhancement
- History of seizures
- Follow-up imaging may be necessary

Herpes Encephalitis

- Confined to limbic system, temporal lobes
- Blood products and enhancement common
- Typically acute onset

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Derived from precursor stem cells committed to astrocytic differentiation
  - Usually evolves from low-grade (diffuse) astrocytoma (WHO grade II) (~ 75%)
    - Progression from low-grade (diffuse) astrocytoma to AA is associated with multiple genetic alterations
  - Occasionally arises de novo
- Genetics
  - *TP53* mutations and LOH 17p may be seen
    - Overexpression of p53 is unfavorable
  - Abnormal cell cycle regulatory genes
  - Loss of heterozygosity: Chromosome 10q, 19q, 22q
  - Deletion of chromosome 6q (30%)
  - Majority are *IDH1*(+)
  - *MGMT* methylation common
- Biologically aggressive astrocytoma characterized by cytologic atypia and mitotic activity
  - Intrinsic tendency for progression to GBM

Staging, Grading, & Classification

- WHO grade III
- Intermediate between low-grade (diffuse) astrocytoma (WHO grade II) and GBM (grade IV)

Gross Pathologic & Surgical Features

- Infiltrating mass with poorly delineated margins
- Often expands invaded structures without frank destruction
- May appear discrete but tumor always infiltrates adjacent brain
- Cysts, hemorrhage uncommon

Microscopic Features

- Characterized by increased cellularity, marked mitotic activity, distinct nuclear atypia
- High nuclear/cytoplasmic ratio
- Nuclear/cytoplasmic pleomorphism
- No necrosis or microvascular proliferation (presence = grade IV)
- Immunohistochemistry: *GFAP*(+) common
- KI-67 (MIB-1): 5-10% (proliferation index)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acceleration in clinical deterioration in patient with low-grade (diffuse) astrocytoma (WHO grade II)
  - Varies with location
    - Seizures, focal neurologic deficit common
    - May have headache, drowsiness
    - Increased intracranial pressure
    - Personality or behavioral changes

Demographics

- Age
  - Occurs at all ages, most common 40-50 years
- Gender
  - M:F = 1.6:1
- Epidemiology
  - 1/3 of astrocytomas
  - 25% of gliomas
  - Diffusely infiltrating gliomas including WHO grades II, III, IV account for > 60% of all primary tumors

Natural History & Prognosis

- Median survival: 2-3 years
- Commonly arise as recurrence after resection of grade II tumor
  - Typically *IDH1*(+) (better prognosis)
- *IDH1*(-) (wild-type) are associated with poor prognosis (similar to GBM)
- Progression to secondary GBM very common
  - 2 years is typical time for progression
- Spreads along WM tracts commonly
  - May spread along ependyma, leptomeninges, and CSF
- Increased survival: Younger age, high Karnofsky score, gross total resection
- Other factors associated with longer survival
  - Absence of enhancement, proliferation index of 5.1% or lower, oligodendroglial component
  - *IDH1*(+), *MGMT* methylation (+)

Treatment

- Resection with adjuvant radiation therapy and chemotherapy (temozolomide)

DIAGNOSTIC CHECKLIST

Consider

- AA may mimic other tumors, particularly diffuse, low-grade astrocytomas (grade II)
- Nonneoplastic mimics, such as cerebritis, may be differentiated with help of clinical history
- AA have histologic and imaging characteristics along spectrum between low-grade astrocytoma and GBM

Image Interpretation Pearls

- AA are typically nonenhancing hemispheric masses
- If new areas of enhancement are seen, malignant degeneration is likely

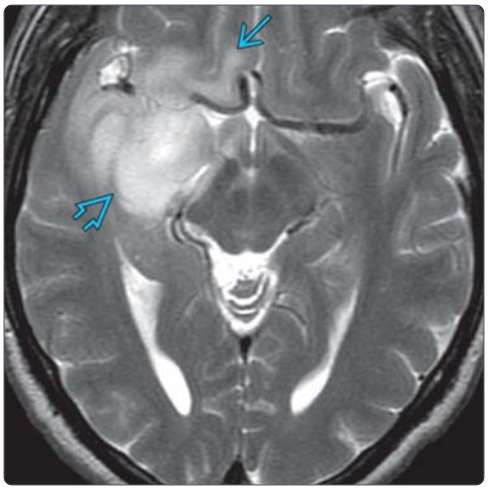
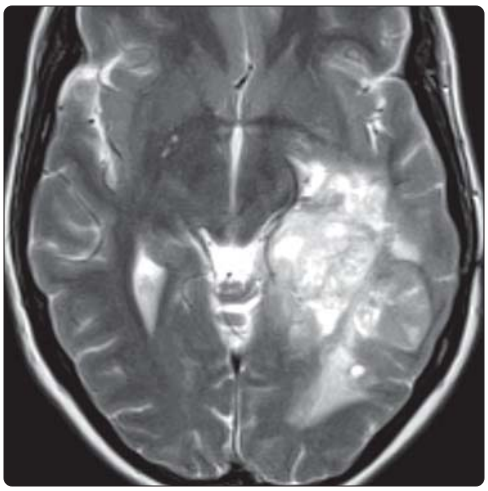
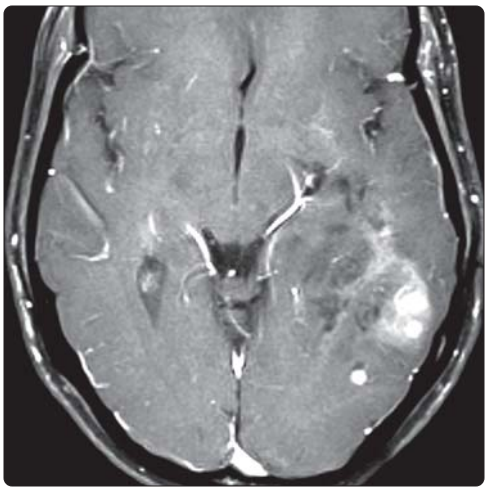
(Left) *Axial T2 MR in a 47-year-old female shows a heterogeneously hyperintense right frontal lobe mass* ⇨ *centered in the white matter with involvement of the overlying cortex. Although the mass appears discrete, tumor cells often extend beyond the signal abnormality.* **(Right)** *Coronal T1 C+ in the same patient shows focal enhancement* ⇨ *within the mass. The enhancement pattern of anaplastic astrocytoma is variable, from no enhancement to patchy or nodular enhancement. Most AAs do not enhance.*



(Left) *Axial T2 MR in a 62-year-old man shows an infiltrative, hyperintense mass in the right temporal lobe* ⇨ *with extension to the inferior frontal lobe* ⇨*. No enhancement was present on the enhanced images. Anaplastic astrocytoma often resembles the more benign diffuse astrocytoma.* **(Right)** *Axial NECT shows a hemorrhagic mass in the right frontal lobe with surrounding low density and mass effect. Hemorrhage is seen in both anaplastic astrocytoma and GBM but is more common in the grade IV GBM.*





(Left) *Axial T2WI MR shows a heterogeneously hyperintense mass in the left posterior temporal and occipital lobes in a patient with a previously treated low-grade (diffuse) astrocytoma.* **(Right)** *Axial T1WI C+ MR in the same patient shows heterogeneous enhancement of the mass, a new finding in this patient with a grade II astrocytoma and clinical deterioration. Repeat biopsy disclosed a grade III astrocytoma. New enhancement in a lower grade astrocytoma is almost always malignant degeneration.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Rapidly enlarging malignant astrocytic tumor characterized by necrosis and neovascularity
- Most common of all primary intracranial neoplasms

IMAGING

- Best imaging clue: Thick, irregularly enhancing rind of neoplastic tissue surrounding necrotic core
- Heterogeneous, hyperintense mass with adjacent tumor infiltration/vasogenic edema
- Necrosis, cysts, hemorrhage, fluid/debris levels, flow voids (neovascularity) may be seen
- Supratentorial white matter most common location
  - Cerebral hemispheres > brainstem > cerebellum
- Viable tumor extends far beyond signal changes

TOP DIFFERENTIAL DIAGNOSES

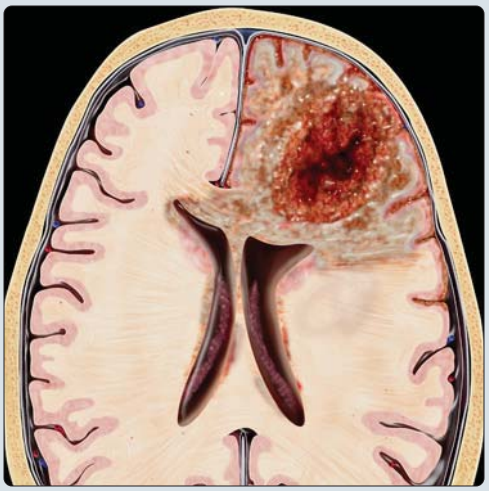
- Abscess
- Metastasis
- Primary CNS lymphoma
- Anaplastic astrocytoma
- Tumefactive demyelination
- Subacute ischemia

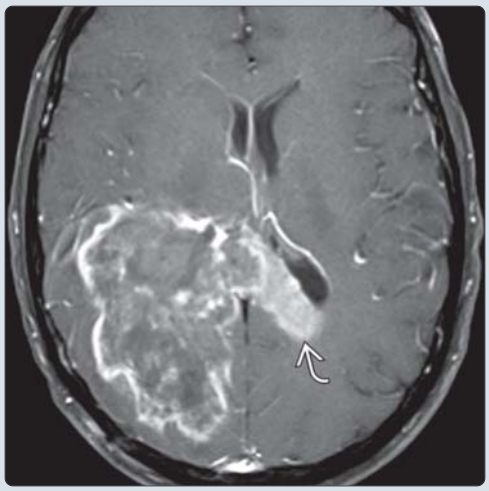
PATHOLOGY

- 2 types: Primary (de novo) and secondary (degeneration from lower grade astrocytoma)
- Necrosis and microvascular proliferation are hallmarks
- WHO grade IV

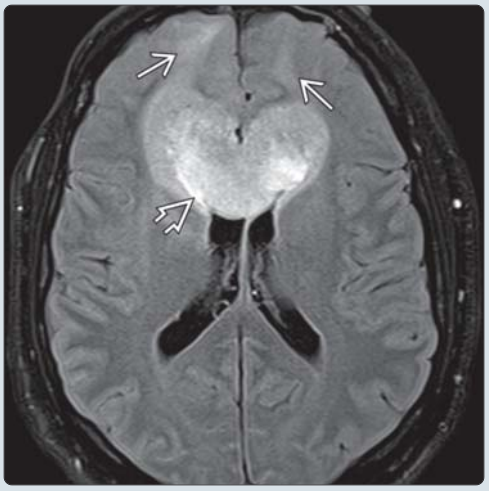
CLINICAL ISSUES

- Symptoms vary with location: Seizures, focal neurologic deficits common
- Peak: 45-75 years, but may occur at any age
- Represents 12-15% of all intracranial neoplasms
- 60-75% of astrocytomas
- Relentless progression, survival often < 1 year





(Left) *Axial graphic shows a centrally necrotic infiltrating mass with extension across the corpus callosum; a peripheral rind of tumor is seen surrounding the necrotic core, typical of GBM.* **(Right)** *Axial T1WI C+ FS MR in a 60-year-old man with acute onset of seizures shows a heterogeneously enhancing occipital lobe mass with central necrosis and extension across the splenium of the corpus callosum, characteristic of GBM. The frontal and temporal lobes are the most common locations for GBM.*



(Left) *Axial FLAIR MR shows a heterogeneously hyperintense mass crossing the corpus callosum genu with signal abnormality extending into the frontal lobe subcortical white matter. Viable tumor cells may extend beyond the area of MR signal abnormality.* **(Right)** *Axial T1 C+ FS MR in the same patient shows a thick enhancing rind of tumor that surrounds the necrotic tumor core, characteristic of GBM. Other lesions including lymphoma and demyelination may also involve the corpus callosum.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Grade IV astrocytoma, malignant astrocytoma, glioblastoma multiforme (GBM)

Definitions

- Rapidly enlarging malignant astrocytic tumor characterized by necrosis and neovascularity
- Most common of all primary intracranial neoplasms

IMAGING

General Features

- Best diagnostic clue
  - Thick, irregularly enhancing rind of neoplastic tissue surrounding necrotic core
- Location
  - Supratentorial white matter (WM) most common
    - Frontal, temporal, parietal > occipital lobes
  - Cerebral hemispheres > brainstem > cerebellum
  - Basal ganglia/thalamus less common
  - Brainstem, cerebellum more common in children
- Morphology
  - Poorly marginated, diffusely infiltrating necrotic hemispheric mass
  - Tumor typically crosses WM tracts to involve contralateral hemisphere
    - Corpus callosum ("butterfly" glioma)
    - Anterior and posterior commissures
  - Rarely may invade meninges
  - Rarely may be multifocal (~5%)

CT Findings

- NECT
  - Irregular isodense or hypodense mass with central hypodensity representing necrosis
  - Marked mass effect and surrounding edema/tumor infiltration
  - Hemorrhage not uncommon
  - Ca++ rare (related to low-grade tumor degeneration)
- CECT
  - Strong, heterogeneous, irregular rim enhancement

MR Findings

- T1WI
  - Irregular isointense, hypointense WM mass
  - Necrosis, cysts, and thick irregular margin common
  - May have subacute hemorrhage
- T2WI
  - Heterogeneous, hyperintense mass with adjacent tumor infiltration/vasogenic edema
  - Necrosis, cysts, hemorrhage, fluid/debris levels, flow voids (neovascularity) may be seen
  - Viable tumor extends far beyond signal changes
- FLAIR
  - Heterogeneous, hyperintense mass with adjacent tumor infiltration/vasogenic edema
- T2* GRE
  - Susceptibility artifact related to blood products
- DWI
  - Lower measured ADC than low-grade gliomas
  - Variable diffusion restriction in solid portions of tumor
- PWI
  - Elevated maximum relative cerebral blood volume compared to low grade
  - Elevated permeability compared to low grade
- T1WI C+
  - Thick, irregular rind of enhancement surrounding central necrosis typical
  - Enhancement may be solid, ring, nodular, or patchy
- MRS
  - Decreased NAA, myoinositol
  - Elevated choline, lactate/lipid peak (1.33 ppm)
- Diffusion tensor imaging (DTI) can improve surgical planning

Nuclear Medicine Findings

- PET
  - Malignant tumors have high glucose metabolism and avidly accumulate FDG
  - Tumor:WM > 1.5 and tumor:gray matter (GM) > 0.6 suggests high-grade tumors

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR is most sensitive
  - Newer techniques help improve diagnosis/biopsy accuracy: MRS, perfusion, hypoxia imaging, DTI

DIFFERENTIAL DIAGNOSIS

Abscess

- Ring enhancement typically thinner than GBM
- T2 hypointense rim, diffusion restriction is typical
- MRS may show succinate, amino acids

Metastasis

- Typically multiple lesions at gray-white junctions
- Round > infiltrating lesion
- Single lesion may be indistinguishable

Primary CNS Lymphoma

- Periventricular enhancing mass
- Often crosses corpus callosum
- Typically isointense/hypointense on T2WI
- Necrosis common in AIDS-related lymphoma

Anaplastic Astrocytoma

- Often nonenhancing WM mass
- Enhancement may indicate degeneration to GBM
- May be indistinguishable

Tumefactive Demyelination

- Often incomplete, horseshoe-shaped enhancement, open towards cortex
- Lesions in typical locations; younger patients

Subacute Ischemia

- Typical vascular territory (MCA, PCA, ACA)
- May have mass effect and enhancement (gyriform)
- Follow-up imaging may be helpful to differentiate

https://CafePezeshki.IR

Status Epilepticus

- Active seizures may cause signal abnormality and enhancement
- Enhancement often diffuse, affecting GM and WM
- Clinical history of seizures

Arteriovenous Malformation (AVM)

- Multiple flow voids with minimal mass effect
- If associated with hemorrhage, may mimic GBM

PATHOLOGY

General Features

- Etiology
  - 2 types: Primary (de novo) and secondary (degeneration from lower grade astrocytoma)
    - Genetically distinct, same appearance
  - Spreads by creating "permissive environment"
  - Rare cases related to irradiation
- Genetics
  - **Primary GBM** (de novo)
    - Older patients (mean = 62 years), biologically more aggressive
    - Develops de novo (without preexisting lower grade tumor), likely from neural stem cell
    - Amplification, overexpression of *EGFR*, *MDM2*
    - *PTEN* mutation (up to 40% of cases)
    - Chromosome 10p loss of heterozygosity (LOH)
    - Represent > 90% of GBMs
  - **Secondary GBM** (degeneration from lower grade)
    - Younger patients (mean = 45 years), less aggressive than primary GBM
    - Develops from lower grade astrocytoma (usually 4-5 years of progression)
    - *TP53, IDH1* mutations
    - *PDGFR* amplification, overexpression
    - Chromosomes 10q, 17p LOH
    - Increased telomerase activity and *hTERT* expression
    - Represent < 10% of GBMs
- Associated abnormalities
  - Occurs sporadically or as part of heritable tumor syndrome
    - Neurofibromatosis type 1, Li-Fraumeni syndrome (*TP53* mutation)
    - Turcot syndrome, Ollier disease, Maffucci syndrome
  - Giant cell glioblastoma, histologic variant of GBM (5%), slightly improved prognosis

Staging, Grading, & Classification

- WHO grade IV

Gross Pathologic & Surgical Features

- Reddish-gray "rind" of tumor surrounds necrotic core
  - Necrosis is hallmark of GBM
- Most GBMs have marked vascularity, ± gross hemorrhage

Microscopic Features

- Necrosis and microvascular proliferation are hallmarks
- Pleomorphic astrocytes, marked nuclear atypia, numerous mitoses
- High MIB-1 (proliferation index): > 10%

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Varies with location: Seizures, focal neurologic deficits common
  - Increased intracranial pressure, mental status change
  - Typically short duration of symptoms (< 3 months)

Demographics

- Age
  - Peak 45-75 years, but may occur at any age
- Gender
  - Male predominance (M:F = 1.3:1)
- Epidemiology
  - Most common primary brain tumor
  - Represents 12-15% of all intracranial neoplasms
  - 60-75% of astrocytomas
  - 3-4:100,000 per year
  - Multifocal in up to 20% (2-5% synchronous independent tumors)

Natural History & Prognosis

- Relentless progression
- Prognosis is dismal (death typically in 9-12 months)
- Patterns of dissemination
  - Most common: Along WM tracts
  - Less common: Ependymal/subpial spread, CSF metastases, perivascular spaces
  - Uncommon: Dural/skull invasion
  - Rare: Extraneural spread (lung, liver, nodes, bone)
- Independent predictors of longer survival
  - Age (younger: < 45 years), Karnofsky performance scale (higher), extent of resection (gross total vs. subtotal); MGMT methylation status
  - Degree of necrosis, enhancement on preoperative MR

Treatment

- Biopsy/tumor debulking followed by XRT, chemotherapy (temozolomide)
- Newer antiangiogenesis agents, particularly bevacizumab (vascular endothelial growth factor blocker) for recurrent disease

DIAGNOSTIC CHECKLIST

Consider

- Corpus callosum involvement may be seen in GBM, lymphoma, demyelination, or less commonly with metastases

Image Interpretation Pearls

- Viable tumor extends far beyond signal abnormalities

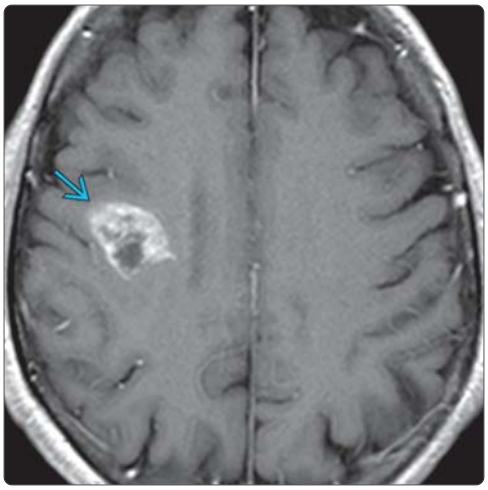
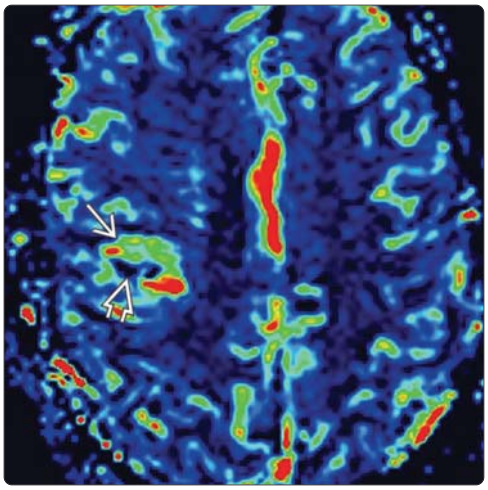
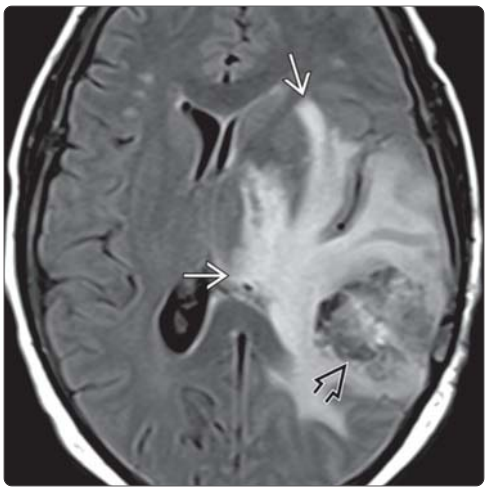
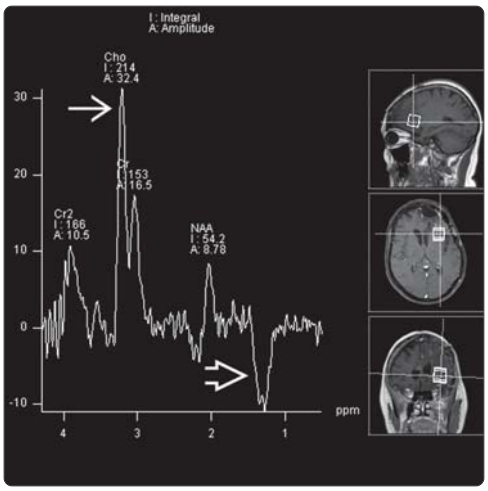
(Left) *Axial T1 MR in a 62-year-old female shows a hemorrhagic mass with areas of T1 shortening related to subacute blood products. Biopsy disclosed GBM. GBM should always be considered in an older adult with no history of hypertension and an unexplained intracranial hemorrhage.* **(Right)** *Axial T1 C+ MR in a 72-year-old male shows 3 separate areas of enhancement representing a multifocal GBM. This rare synchronous presentation of GBM occurs in up to 5% of cases.*





(Left) *Axial T1 C+ MR in a 42-year-old male with new onset seizure shows a peripherally enhancing mass with only mild associated mass effect.* **(Right)** *Axial MR perfusion in the same patient shows an increased rCBV in the solid parts of the tumor and a low rCBV in the necrotic center. Perfusion MR is helpful to provide an accurate preoperative diagnosis. In addition, it is often used to help guide a biopsy if the location of the tumor prevents the patient from undergoing a complete resection.*





(Left) *Axial FLAIR MR in a patient with GBM shows a heterogeneous mass and the typical extensive surrounding signal abnormality that represents a combination of tumor cells and vasogenic edema. Pathologically, tumor cells are found beyond the regions of signal abnormality.* **(Right)** *MRS in a patient with recurrent GBM shows a classic malignant tumor spectrum with a markedly elevated choline (Cho), a low NAA at 2.02 ppm, and an inverted lactate peak at 1.33.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Rare glioblastoma variant with both glial & mesenchymal elements
- May be primary or secondary (sarcomatous growth in recurrent glioblastoma [GBM])

IMAGING

- Heterogeneously enhancing mass with dural invasion, ± skull involvement
- May be indistinguishable from GBM
- Temporal > parietal > frontal > occipital lobes
- Heterogeneous mass related to hemorrhage, necrosis
- Heterogeneous, thick irregular enhancement with central necrosis

TOP DIFFERENTIAL DIAGNOSES

- Glioblastoma (GBM)
- Metastasis
- Hemangiopericytoma
- Malignant meningioma

PATHOLOGY

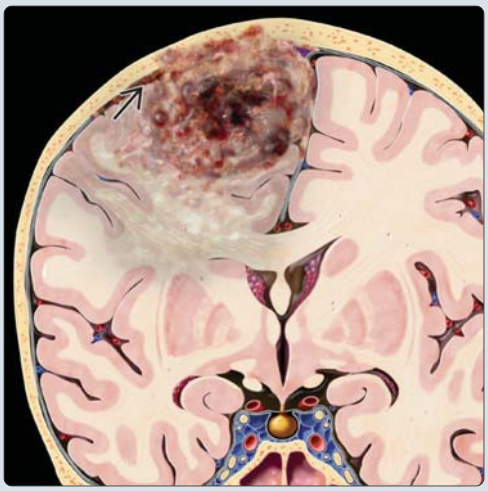
- Sarcomatous elements thought to arise from transformed vascular elements within GBM
- WHO grade IV

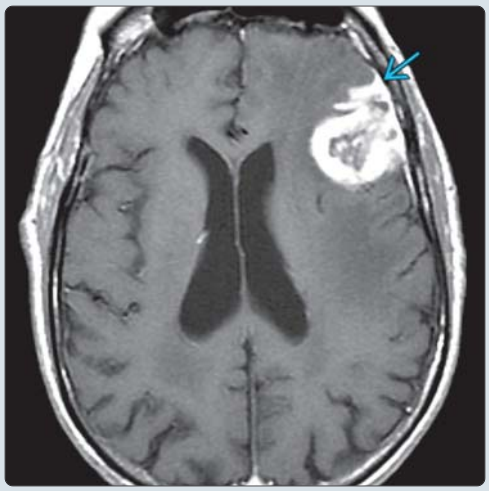
CLINICAL ISSUES

- Most common presenting symptoms: Headache, seizures, focal neurologic deficit
- Typically 5th to 6th decade
- Poor prognosis, median survival 6-12 months
- Extracranial metastases common (15-30%)
- Treatment: Surgery followed by adjuvant XRT, chemotherapy

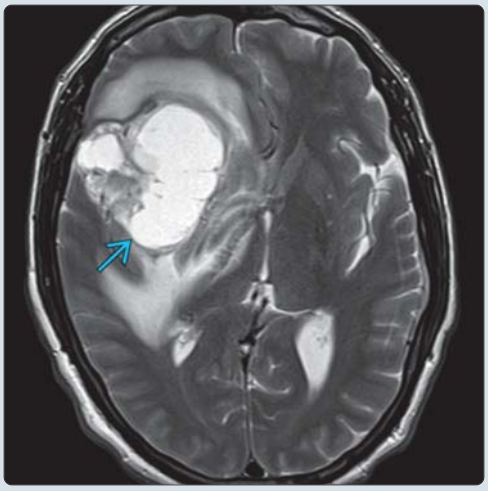
DIAGNOSTIC CHECKLIST

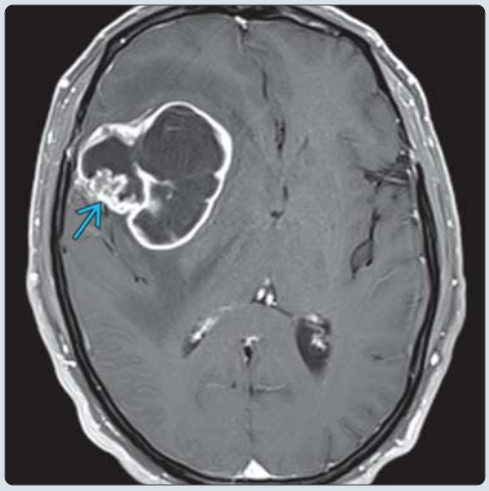
- Consider gliosarcoma in event of peripheral mass with dural invasion





(Left) *Coronal graphic shows a peripherally located, heterogeneous necrotic mass with invasion of the dura ⇨ and the adjacent skull, findings typical of gliosarcoma. The infiltrative tumor involves the corpus callosum as well. Dural invasion with or without skull involvement helps distinguish this glioblastoma (GBM) variant from a typical GBM.* **(Right)** *Axial T1 C+ MR shows a heterogeneous frontal mass with thick enhancement and dural invasion ⇨, typical for gliosarcoma.*





(Left) *Axial T2 MR in a 57-year-old man shows a heterogeneous right frontal lobe mass ⇨.* **(Right)** *Axial T1 C+ FS MR in the same patient shows heterogeneous rim enhancement ⇨ with central low signal related to necrosis. When there is no dural involvement, gliosarcoma is indistinguishable from a typical GBM. Both of these WHO grade IV tumors have a poor prognosis.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Rare glioblastoma variant with both glial and mesenchymal elements
- May be primary or secondary (sarcomatous growth in recurrent glioblastoma [GBM])

IMAGING

General Features

- Best diagnostic clue
  - Heterogeneously enhancing mass with dural invasion, ± skull involvement
  - May be indistinguishable from GBM
- Location
  - Cerebral hemispheres
    - Temporal > parietal > frontal > occipital lobes
  - Rarely posterior fossa or intraventricular
- Size
  - Variable, typically 3-8 cm
- Morphology
  - Infiltrating mass, may have discrete portion

CT Findings

- NECT
  - Heterogeneous mass with surrounding edema
  - Hemorrhage may be seen
- CECT
  - Heterogeneous, thick irregular enhancement
  - May see dural involvement ± skull involvement

MR Findings

- T1WI
  - Heterogeneous, hypointense mass
- T2WI
  - Heterogeneous mass related to hemorrhage, necrosis
  - Marked surrounding edema + infiltrative tumor
- T1WI C+
  - Heterogeneous, thick, irregular enhancement with central necrosis
  - May see dural involvement ± skull involvement

DIFFERENTIAL DIAGNOSIS

Glioblastoma

- Typically indistinguishable
- Heterogeneous mass with hemorrhage, necrosis
- No dural or skull involvement

Metastasis

- Multiple lesions common; primary often known

Hemangiopericytoma

- Extraaxial mass with dural and skull invasion

Malignant Meningioma

- Extraaxial mass with parenchymal invasion

Abscess

- Ring-enhancing lesion with central necrosis
- T2 hypointense rim and DWI+ is typical

PATHOLOGY

General Features

- Etiology
  - Sarcomatous elements thought to arise from transformed vascular elements within GBM
  - Reports suggest XRT induces sarcomatous change

Staging, Grading, & Classification

- WHO grade IV

Gross Pathologic & Surgical Features

- May mimic metastasis or meningioma at surgery
- Firm, lobular mass with central necrosis, ± meningeal invasion

Microscopic Features

- Malignant glial and mesenchymal elements

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Increased intracranial pressure: Headache
- Other signs/symptoms
  - Related to location: Seizure, focal neuro deficit

Demographics

- Age
  - Typically 5th to 6th decade
  - Congenital gliosarcoma has been reported (rare)
- Gender
  - M:F = 2:1
- Epidemiology
  - Rare, accounts for 2-8% of GBM

Natural History & Prognosis

- Poor prognosis, median survival 6-12 months
- Local recurrence typical
- Extracranial metastases common (15-30%)

Treatment

- Surgery followed by adjuvant XRT, ± chemotherapy

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Consider gliosarcoma in event of peripheral mass with dural invasion
- Gliosarcomas may mimic GBM and metastases
- Tumor cells extend beyond enhancing mass

KEY FACTS

TERMINOLOGY

- Diffusely infiltrating, frequently bilateral glial tumor involving at least 3 lobes
- Infiltrative extent of tumor is out of proportion to histologic and clinical features

IMAGING

- T2 hyperintense infiltrating mass with enlargement of involved structures
  - Typical cerebral hemispheres (75%)
  - Brain architecture enlarged, distorted, but preserved
- Typically no or minimal enhancement
- Enhancement may indicate malignant progression or focus of malignant glioma
- MRS: Increased choline, decreased NAA

TOP DIFFERENTIAL DIAGNOSES

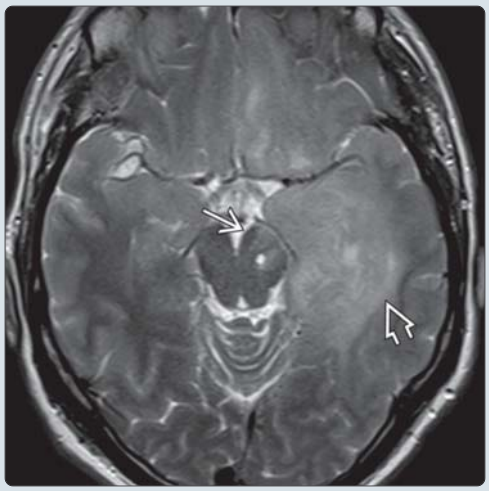
- Arteriolosclerosis
- Vasculitis
- Anaplastic astrocytoma
- Viral encephalitis
- Demyelination

PATHOLOGY

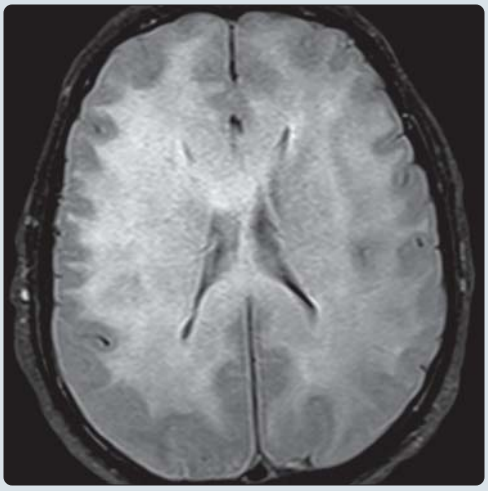
- Usually WHO grade III; range grade II-IV
- Shares many features of diffusely infiltrating astrocytoma
- Rarely, oligodendroglioma is predominant cell type
- Diagnosis typically made on basis of histology and imaging

CLINICAL ISSUES

- Presenting symptoms: Mental status changes, dementia, headaches, seizures, lethargy
- Treatment: Biopsy for diagnosis, ± radiation and chemotherapy
- Peak incidence between 40-50 years, occurs at all ages
- Relentless progression
- Survival ranges from weeks to years
  - Median survival ~ 14 months



(Left) *Axial graphic shows infiltrating tumor involving the frontal lobes, insulae, and basal ganglia with preservation of the underlying cerebral architecture. Note the focal malignant degeneration.* **(Right)** *Axial T2 MR shows abnormal hyperintensity in the left cerebral peduncle, left temporal and left frontal lobes with blurring of the corticomedullary junctions. There is subtle expansion of the involved structures with relative preservation of the underlying architecture, typical of gliomatosis cerebri.*



(Left) *Axial FLAIR MR in a 73-year-old male shows diffuse hyperintensity extending throughout the hemispheric supratentorial white matter. Gliomatosis cerebri may mimic a nonneoplastic white matter process, including arteriolosclerosis.* **(Right)** *Axial T1 C+ MR in the same patient shows no enhancement, typical of gliomatosis cerebri. Enhancement often correlates with focal anaplasia or disease progression. Mild sulcal effacement is present. These infiltrative tumors may be WHO grade II through IV.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Gliomatosis cerebri (GC)

Synonyms

- Gliomatosis, diffuse cerebral gliomatosis

Definitions

- Diffusely infiltrating, frequently bilateral glial tumor involving at least 3 lobes
- Infiltrative extent of tumor is out of proportion to histologic and clinical features

IMAGING

General Features

- Best diagnostic clue
  - T2 hyperintense infiltrating mass with enlargement of involved structures
- Location
  - Typically hemispheric white matter (WM) involvement (76%), may also involve cortex (19%)
  - 3 lobes, diffuse WM plus
    - Basal ganglia, thalami (75%)
    - Brainstem (52%)
    - Corpus callosum (50%)
    - Cerebellum (29%)
    - Spinal cord (9%)
  - May cross corpus callosum or massa intermedia
- Morphology
  - Infiltrates, enlarges yet preserves underlying brain architecture

CT Findings

- NECT
  - Poorly defined, asymmetric low density (often subtle)
  - Loss of gray-white differentiation with expansion and mild mass effect
- CECT
  - No enhancement typical

MR Findings

- T1WI
  - Isointense or hypointense infiltrating mass
  - Typically homogeneous
- T2WI
  - Homogeneous hyperintense infiltrating mass
  - Mass effect with mild diffuse sulcal and ventricular effacement
  - May cause hydrocephalus (rare)
- FLAIR
  - Homogeneous hyperintense infiltrating mass
- DWI
  - Usually no restriction
- T1WI C+
  - Typically no or minimal enhancement
  - Patchy enhancement rarely
  - Enhancement may indicate malignant progression or focus of malignant glioma
- MRS
  - Marked elevation of myoinositol (mI)
  - Increased choline
  - Decreased NAA
  - ± lactate, lipid peaks at 1.33 ppm (suggests decreased survival)
- Dynamic perfusion MR
  - Low rCBV: Correlates with no vascular hyperplasia
  - High rCBV: Suggests higher grade tumor
- Diffusion tensor imaging
  - Preservation of nerve fibers in GC compared to other tumors

Nuclear Medicine Findings

- FDG PET shows marked hypometabolism

Imaging Recommendations

- Protocol advice
  - Multiplanar contrast-enhanced MR
  - MRS and perfusion imaging may help further characterize

DIFFERENTIAL DIAGNOSIS

Arteriolosclerosis

- Aging brain, microvascular disease
- No mass effect; spares cortex
- Often associated volume loss
- Some cases may be indistinguishable without biopsy

Vasculitis

- Often multifocal areas of ischemia
- DWI positive acutely
- Patchy, multifocal enhancement may be seen
- May be indistinguishable without biopsy

Anaplastic Astrocytoma

- May appear discrete or infiltrating, often less diffuse
- Variable enhancement

Viral Encephalitis

- More acute presentation, history may distinguish
- ± meningeal involvement
- Herpes involves temporal lobes, limbic system

Demyelination

- Usually multiple lesions in typical locations
- Typically lack significant mass effect
- Often enhances, incomplete ring, open at cortex
- May involve WM and deep gray nuclei

Progressive Multifocal Leukoencephalopathy

- Asymmetric T2 hyperintensity in periventricular, subcortical WM
- No or minimal enhancement typical
- Often parietooccipital region, may cross corpus callosum
- Immunosuppressed patients, typically AIDS

Lymphoma

- Periventricular/deep GM enhancing mass in primary CNS lymphoma
  - Corpus callosum involvement classic
  - Isointense/hypointense on T2WI
- Intravascular lymphoma may appear diffusely infiltrating

https://CafePezeshki.IR

Inherited/Acquired Metabolic Disorder

- Metachromatic leukodystrophy (MLD): Confluent periventricular WM T2 hyperintensity
- Alexander disease: Frontal lobe WM hyperintensity and enhancement

PATHOLOGY

General Features

- Etiology
  - Controversial, classified as neoplasm of unknown histogenesis
  - Shares some, but not all, features of diffusely infiltrating astrocytoma
  - Rarely oligodendroglioma is predominant cell type
- Genetics
  - *TP53* mutation similar to diffuse astrocytoma, lower frequency
  - In oligodendroglioma subtype, chromosome 1p and 19q deletions common
  - May have IDH1 mutation

Staging, Grading, & Classification

- Usually WHO grade III (range from grades II-IV)
- Dx typically made on basis of histology and imaging

Gross Pathologic & Surgical Features

- 2 gross pathologic GC types recognized
  - Type 1: Neoplastic overgrowth, expansion of existing structures without circumscribed tumor mass
  - Type 2: Diffuse lesion + focal neoplastic mass with malignant features (may develop from type 1)
- Blurring of gray-white junction borders ± distinct tumor nodule
- Underlying brain architecture preserved
- Diffuse neoplastic overgrowth

Microscopic Features

- Extensive tumor infiltration is disproportionate to histologic features
  - Necrosis and neovascularity typically absent
- Neuroepithelial neoplasm with diffuse invasion of parenchyma with tumor cells
- Elongated glial cells with hyperchromatic nuclei, variable mitoses
- Diffuse infiltration along/between myelinated nerve fibers
- Immunohistochemistry: Often *GFAP*(+), S100(+)
- Ki-67 (proliferation index) = 1-30%

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Mental status changes, dementia, headaches, seizures, lethargy
- Other signs/symptoms
  - Cranial nerve signs, increased intracranial pressure, personality changes
  - Rare: Hydrocephalus

Demographics

- Age
  - Peak incidence between 40-50 years
  - Occurs at all ages, reported in neonates to 83 years
- Gender
  - No gender predominance
- Epidemiology
  - Rare
  - Represents ~ 1% of all astrocytomas

Natural History & Prognosis

- Relentless progression
- Poor prognosis
  - 50% mortality by 1 year
  - 75% by 3 years
- Survival ranges from weeks to years, median survival ~ 14 months
- Karnofsky performance scale ≥ 70 correlates with increased survival
- Ki-67 labeling index may correlate with survival time
- IDH1 mutation correlates with increased survival
- Rarely complicated by hydrocephalus or herniation
- Very rarely GC is complicated by hemorrhage

Treatment

- Stereotaxic biopsy (enhancing nodule, if present)
- Mixed response to chemotherapy, radiation therapy
  - Some reports show increased survival with treatment
- Steroids may help as initial treatment
- Surgical decompression, ventricular shunting occasionally required

DIAGNOSTIC CHECKLIST

Consider

- GC = diffusely infiltrating glial tumor that can be mistaken for nonneoplastic WM disease

Image Interpretation Pearls

- Extensive MR findings and tumor infiltration are disproportionate to histologic features
- MR often underestimates extent of disease when correlated with postmortem findings
- 3 or more contiguous lobes of multiregional involvement characterizes GC

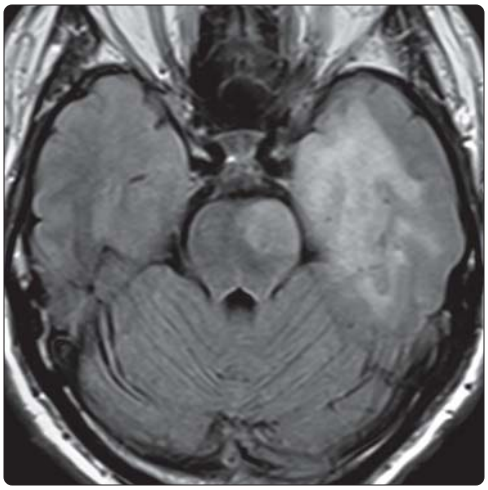
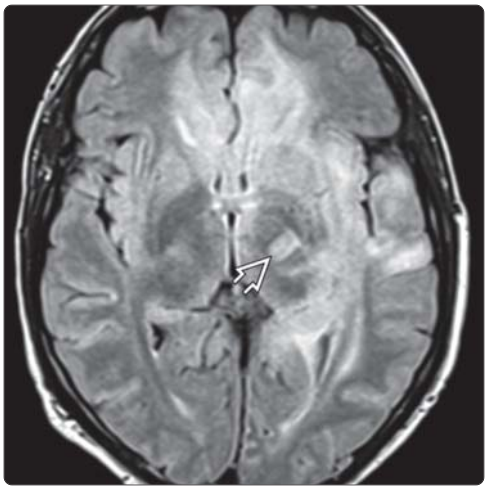
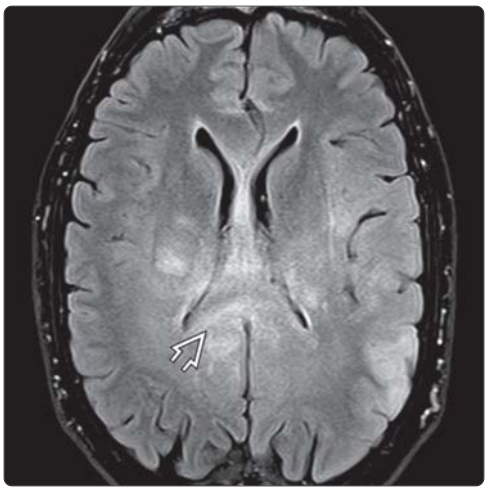
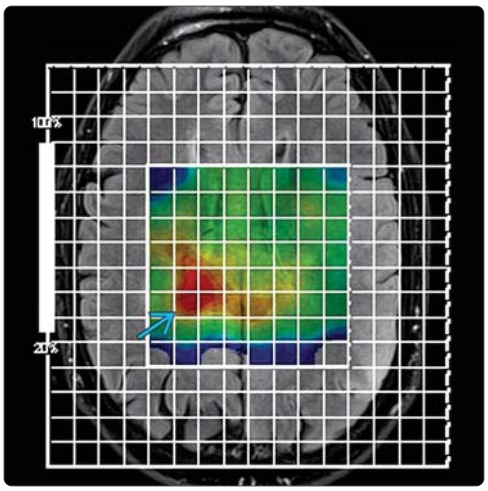
(Left) *Axial T2 MR shows abnormal hyperintensity throughout the pons ⇨ with associated enlargement. Imaging mimics a diffuse pontine glioma. Gliomatosis cerebri most commonly involves the bilateral cerebral hemispheres, though extension to the brainstem is present in approximately 50% of patients.* **(Right)** *Axial NECT shows loss of the normal gray-white interfaces and sulcal effacement ⇨. CT diagnosis of gliomatosis cerebri is difficult, as the study may appear normal.*





(Left) *Axial FLAIR MR shows abnormal hyperintensity in the left brainstem with extension into the temporal lobe. Note the subtle expansion of the involved structures with relative preservation of the underlying architecture, typical of gliomatosis cerebri.* **(Right)** *Axial FLAIR MR in the same patient shows hyperintensity in the left temporal and parietal lobes, corpus callosum, frontal lobes, & thalamus ⇨. Usually a WHO grade III tumor, biopsy revealed a grade IV tumor in this patient.*





(Left) *Axial FLAIR MR in a patient with gliomatosis cerebri, WHO grade III, shows hyperintensity in the left temporal and parietal lobes, corpus callosum ⇨, and bilateral basal ganglia.* **(Right)** *Axial MRS choline color map in the same patient shows elevated choline ⇨ as the red area in the right hemisphere. A biopsy in this region would likely reveal a higher grade tumor. MRS may appear normal or show elevated choline and decreased NAA. Elevated choline and presence of lactate correlates with decreased survival.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Pilocytic astrocytoma (PA): Well-circumscribed, slow-growing tumor, often with cyst and mural nodule

IMAGING

- Cystic cerebellar mass with enhancing mural nodule
  - Arises from cerebellar hemisphere and compresses 4th ventricle
- Enlarged optic nerve/chiasm/tract with variable enhancement
- Cerebellum (60%) > optic nerve/chiasm (25-30%) > adjacent to 3rd ventricle > brainstem
- Well circumscribed with little to no edema
- Aggressive appearance (enhancement and MRS) of tumor is misleading

TOP DIFFERENTIAL DIAGNOSES

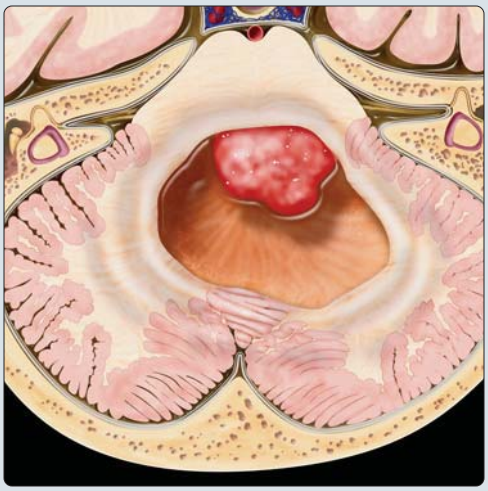
- Medulloblastoma (PNET-MB)
- Ependymoma
- Ganglioglioma
- Hemangioblastoma
- Demyelination

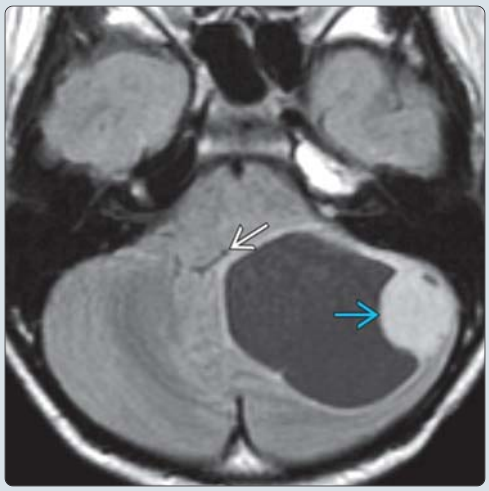
PATHOLOGY

- WHO grade I
- 15% of neurofibromatosis type 1 (NF1) patients develop PAs, most commonly in optic pathway
- Up to 1/3 of patients with optic PAs have NF1
- Most common primary brain tumor in children

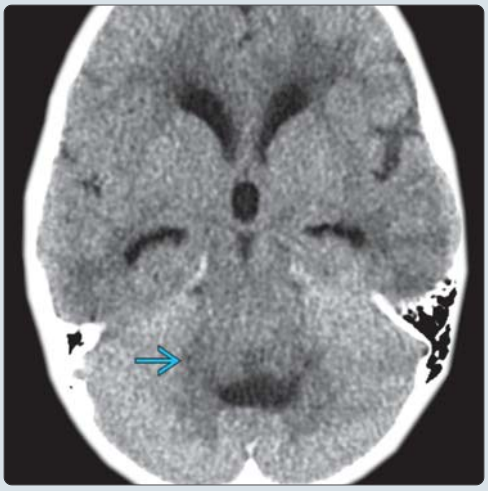
CLINICAL ISSUES

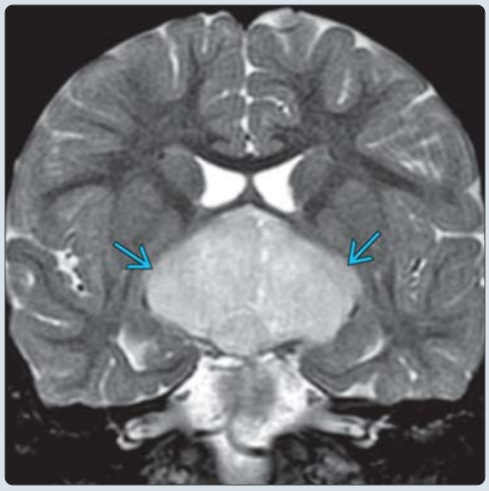
- Clinical presentation varies with location
  - Headache, nausea, vomiting most common
  - Visual loss (optic pathway lesions)
  - Ataxia, cerebellar signs (cerebellar lesions)
- Peak incidence: 5-15 years of age
- Slowly growing tumor with very good prognosis
- Median survival rates at 20 years > 70%





(Left) *Axial graphic shows the characteristic cyst with mural nodule appearance of a posterior fossa pilocytic astrocytoma (PA). These WHO grade I tumors most commonly arise in the cerebellar hemispheres and compress the 4th ventricle.* **(Right)** *Axial FLAIR MR shows a classic cyst with mural nodule appearance ⇨ of a cerebellar PA in a child. Note the typical lack of surrounding edema in the adjacent cerebellum. Mass effect on the 4th ventricle ➡ with associated hydrocephalus is common.*





(Left) *Axial NECT shows a cystic and solid isodense posterior fossa mass ⇨ causing obstructive hydrocephalus. The lack of increased density helps to differentiate this PA from a medulloblastoma.* **(Right)** *Coronal T2WI MR shows a hyperintense hypothalamic/chiasmatic mass ⇨ with no surrounding edema. PAs in this location have variable enhancement. Optic pathway PAs are highly associated with neurofibromatosis 1 (NF1): ≤ 1/3 of patients with an optic pathway PA have NF1.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pilocytic astrocytoma (PA), juvenile pilocytic astrocytoma (JPA)

Definitions

- Pilocytic astrocytoma: Well-circumscribed, slow-growing tumor, often with cyst and mural nodule
- Characterized by hair-like cytoplasmic (Rosenthal) fibers &/or eosinophilic granular bodies in stacked bipolar cells

IMAGING

General Features

- Best diagnostic clue
  - Cystic cerebellar mass with enhancing mural nodule
  - Enlarged optic nerve/chiasm/tract with variable enhancement
- Location
  - Cerebellum (60%) > optic nerve/chiasm (25-30%) > adjacent to 3rd ventricle > brainstem
- Size
  - Large lesions in cerebellum, often > 3 cm
  - Optic nerve lesions typically smaller
- Morphology
  - Overall morphology often determined by cystic component
  - Well circumscribed with little to no adjacent T2 prolongation
  - Optic nerve tumors elongate and widen nerve causing buckling in orbit: Dotted i appearance

CT Findings

- NECT
  - Discrete cystic-solid mass
  - May have little or no surrounding edema
  - Solid component hypo- to isodense to gray matter (GM)
  - Ca++ in 20%, hemorrhage uncommon
  - Often causes obstructive hydrocephalus, location dependent
- CECT
  - > 95% enhance (patterns vary)
    - 50% nonenhancing cyst, strongly enhancing mural nodule
    - 40% solid with necrotic center, heterogeneous enhancement
    - 10% solid, homogeneous
    - Cyst may accumulate contrast on delayed images
    - Cyst wall may have some enhancement

MR Findings

- T1WI
  - Solid portions iso-/hypointense to GM
  - Cyst contents iso- to slightly hyperintense to cerebrospinal fluid (CSF)
- T2WI
  - Solid portions hyperintense to GM
  - Cyst contents iso-/hyperintense to CSF
  - Optic pathway hyperintense to GM
- FLAIR
  - Solid portions hyperintense to GM
  - Cyst contents do not suppress: Hyperintense to CSF
  - Margins of chiasmatic/hypothalamic tumors in patients with neurofibromatosis type 1 (NF1) difficult to resolve
- DWI
  - Solid tumor has similar diffusivity to GM
- T1WI C+
  - Intense but heterogeneous enhancement of solid portion
  - Cyst wall occasionally enhances
  - Rare: Leptomeningeal metastases
  - Optic pathway: Variable enhancement
- MRS: Aggressive-appearing metabolite pattern
  - ↑ choline, ↓ NAA, ↑ lactate
  - Paradoxical finding: MRS does not accurately reflect clinical behavior of tumor

Ultrasonographic Findings

- Grayscale ultrasound
  - Solid components are hyperechoic relative to brain parenchyma
  - Cysts may contain debris

Angiographic Findings

- Conventional: Avascular mass
  - Occasional neovascularity seen in solid portion

Nuclear Medicine Findings

- PET
  - 18F-fluorodeoxyglucose (FDG) studies show increased tumor metabolism in PAs
  - Paradoxical finding: PET does not accurately reflect histologic behavior of tumor

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR
- Protocol advice
  - Multiplanar or 3D volume post-contrast imaging key to show structure of origin and degree of extension

DIFFERENTIAL DIAGNOSIS

Medulloblastoma (PNET-MB)

- Hyperdense enhancing midline mass fills 4th ventricle
- Solid components T2 isointense to GM; ↓ ADC
- Younger patient age (2-6 years)

Ependymoma

- "Plastic" tumor, extends out 4th ventricle foramina
- Ca++, cysts, hemorrhage common
- Heterogeneous enhancement

Ganglioglioma

- Cortically based cystic and solid enhancing mass
- Ca++ common
- Typically located in temporal or frontal lobes

Hemangioblastoma

- Large cyst with small enhancing mural nodule at periphery of cerebellum, associated with feeding vessel
- **Adult** tumor
- Associated with von Hippel-Lindau disease

https://CafePezeshki.IR

Pilomyxoid Astrocytoma

- Chiasmatic/hypothalamic tumor in infants
- Solid and enhancing
- More likely to disseminate, more aggressive

Demyelination/Inflammation

- Optic neuritis in acute multiple sclerosis, acute disseminated encephalitis, pseudotumor can mimic optic nerve glioma
- "Tumefactive" MS can mimic hemispheric PA

PATHOLOGY

General Features

- Etiology
  - Astrocytic precursor cell
- Genetics
  - Syndromic: Association with NF1
    - 15% of NF1 patients develop PAs, most commonly in optic pathway
    - Up to 1/3 of patients with optic pathway PAs have NF1
  - Sporadic: No definite loss of tumor suppressor gene
- Associated abnormalities
  - Major source of morbidity in NF1
  - Frequently causes obstructive hydrocephalus
  - Gross appearance and clinical impact varies with location

Staging, Grading, & Classification

- WHO grade I

Gross Pathologic & Surgical Features

- Well-circumscribed, soft, gray mass ± cyst

Microscopic Features

- Classic biphasic pattern of 2 astrocyte populations
  - Compacted bipolar cells with Rosenthal fibers
  - Loose-textured multipolar cells with microcysts, eosinophilic granular bodies
- Highly vascular with glomeruloid features
- May have aggressive features, but still grade I tumor
- MIB-1 proliferation index ~ 1%
- GFAP(+), IDH1(-)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, nausea, and vomiting (consequence of hydrocephalus and increased intracranial pressure)
  - Visual loss (optic pathway lesions)
  - Ataxia, cerebellar signs (cerebellar lesions)
  - Seizures, focal neurological deficit, mass effect (cerebral hemisphere lesion)
- Clinical profile
  - Children, 5-15 years old
  - Prolonged duration of symptoms on close inquiry: Months to years

Demographics

- Age
  - > 80% under 20 years
  - Peak incidence: 5-15 years of age
    - Older than children with medulloblastoma
- Gender
  - M = F
- Epidemiology
  - 5-10% of all gliomas
  - Most common primary brain tumor in children (up to 25% of total)
  - Represents 85% of posterior fossa astrocytomas in children

Natural History & Prognosis

- Slowly growing, mass effect accommodated
  - Rarely spontaneously involute without treatment or after partial resection or biopsy
- Tumor may spread through subarachnoid space in rare cases (but is still WHO grade I)
- 10-year survival > 90%
- Median survival rates at 20 years > 70%
- Rare reports of malignant features associated with prior radiation therapy

Treatment

- Cerebellar or hemispheric: Resection
  - Adjuvant chemotherapy or radiation only if residual progressive unresectable tumor
- Optic/chiasmatic/hypothalamic: Often none
  - Stable or slowly progressive tumors watched
  - Debulking or palliative surgery considered after vision loss
  - Radiation or chemotherapy for rapidly progressive disease

DIAGNOSTIC CHECKLIST

Consider

- Cerebellar or supratentorial cyst with enhancing nodule in child, most likely PA
- Generally not reasonable diagnostic consideration in adults
- Rarely presents with CSF metastatic disease or as hemorrhagic mass

Image Interpretation Pearls

- Differentiate cerebellar lesions from medulloblastoma
  - PA arises from hemisphere, compresses 4th ventricle, circumscribed, DWI similar to GM
- Aggressive appearance of PA is misleading
  - Enhancing intraaxial tumor with cystic change in child is most likely PA
- MRS pattern of PA is contradictory to clinical behavior

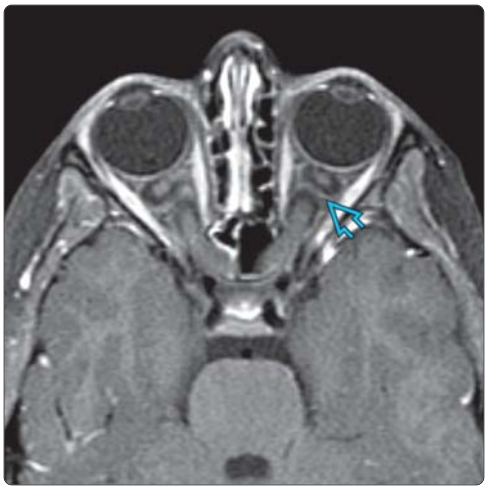
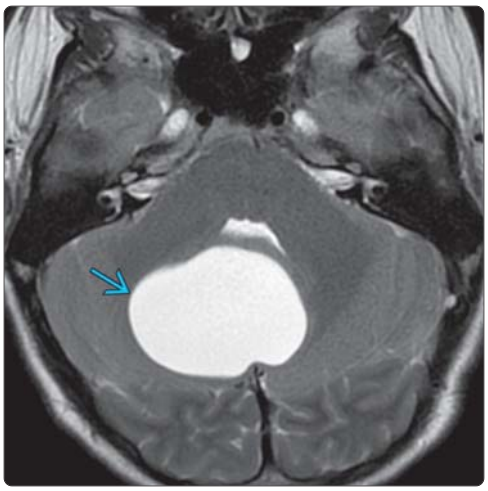
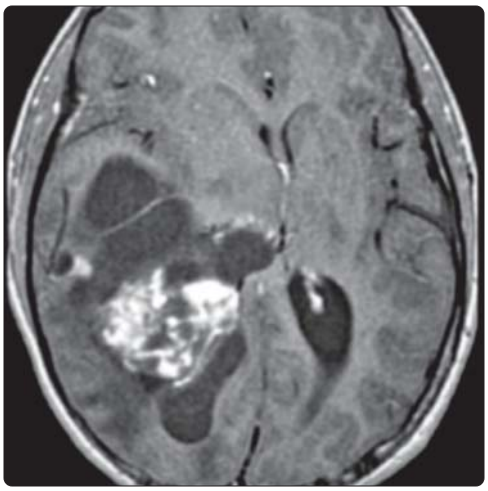
(Left) *Axial T2 MR shows a heterogeneously hyperintense frontal mass ⇨ with mild peritumoral edema ➡ in a 19-year-old female.* **(Right)** *Axial T1WI C+ MR in the same patient shows central enhancement ➡ of the tumor and a cystic portion. Pilocytic astrocytomas are most common in the posterior fossa (60%) and optic nerve/chiasm (25-30%). Within the supratentorial brain, PAs are commonly adjacent to the 3rd ventricle. Hemispheric PAs are rare. The cystic and solid appearance is typical of these WHO grade I tumors.*



(Left) *Axial T1WI C+ MR with fat saturation in an NF1 patient with bilateral optic nerve gliomas shows the characteristic dotted i appearance of the intraorbital optic nerves ⇨ caused by buckling of the elongated nerve just proximal to the globe.* **(Right)** *Coronal T1 C+ FS MR image shows a markedly enhancing optic nerve glioma ➡. Pilocytic astrocytomas of the optic nerve have variable enhancement, from none to striking enhancement. Optic pathway PAs are highly associated with NF1.*





(Left) *Axial T2 MR in a teenage male with cerebellar symptoms shows a discrete T2 hyperintense posterior fossa mass ⇨. The lack of surrounding edema is typical of pilocytic astrocytoma. An enhancing mural nodule was present on post-contrast images.* **(Right)** *Axial T1WI C+ MR shows a large, cystic and solid mass in a child. Note the associated mass effect. The large size and heterogeneous enhancement might suggest a more aggressive histology. At resection, this proved to be a WHO grade I PA.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Pilomyxoid astrocytoma (PMA): More aggressive, myxoid variant of pilocytic astrocytoma (PA)
  - High risk of local recurrence, cerebrospinal fluid (CSF) dissemination

IMAGING

- 60% suprasellar (large, bulky H-shaped mass in hypothalamus/optic chiasm, medial temporal lobes)
- 40% outside diencephalon (hemisphere, ventricles)
- Grossly well circumscribed, little/no edema
- Enhances strongly
- 20% show intratumoral hemorrhage

TOP DIFFERENTIAL DIAGNOSES

- Pilocytic astrocytoma
- Low-grade diffuse astrocytoma
- Glioblastoma multiforme

PATHOLOGY

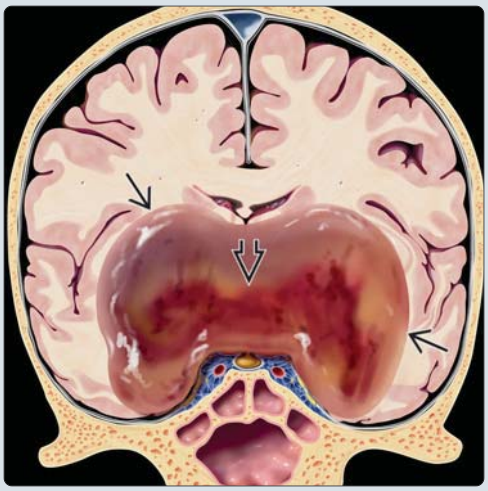
- WHO grade II (typical PA is WHO grade I)

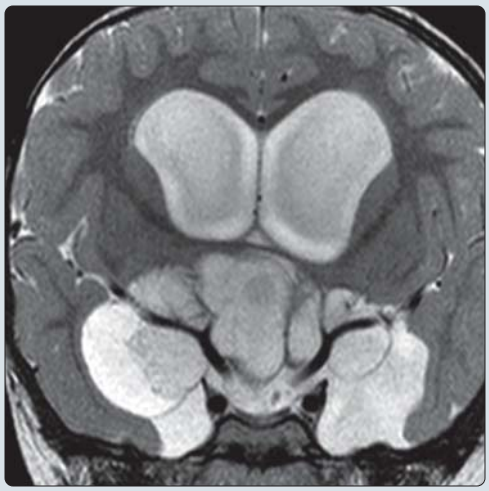
CLINICAL ISSUES

- Typical: Infants, young children (< 4 years)
- Less common: Older children, young adults
- 5-10% of cases initially diagnosed as PAs may actually be PMAs
  - Especially if tumor is hemorrhagic, presents in very young child, or shows CSF dissemination

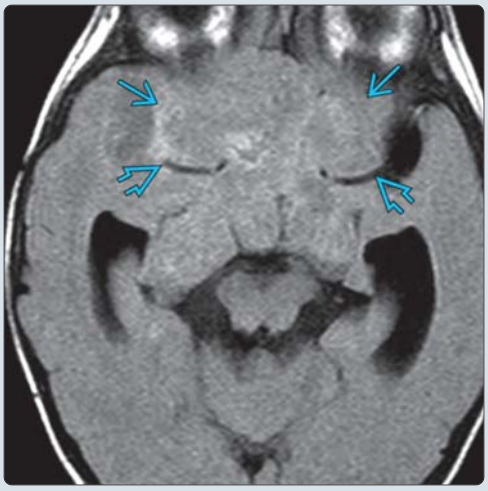
DIAGNOSTIC CHECKLIST

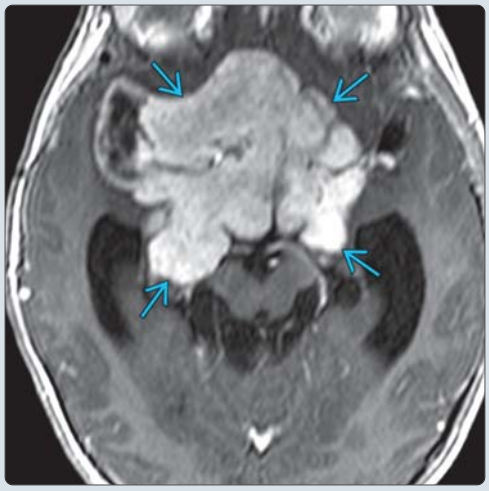
- Consider PMA if
  - Infant or young child has large/bulky or hemorrhagic H-shaped suprasellar mass
  - Presumed PA in any patient who has atypical imaging (e.g., hemorrhage, metastases)





(Left) *Coronal graphic depicts pilomyxoid astrocytoma (PMA). Note the large, bulky H-shaped mass ⇨ centered on the hypothalamic/chiasmatic region & extending into both temporal lobes. The tumor is relatively well circumscribed and shows little/no edema. Glistening myxoid matrix is typical. Hemorrhage ⇨ occurs in ~ 20% of PMAs but is unusual in classic pilocytic astrocytoma (PA).* **(Right)** *Coronal T2WI in an infant with a large head shows markedly enlarged lateral ventricles and a lobulated hyperintense suprasellar mass .*





(Left) *Axial FLAIR scan in the same patient shows the large mass ⇨ completely fills the suprasellar cistern, elevating and encasing both middle cerebral arteries ⇨. The mass is mildly hyperintense relative to cortex.* **(Right)** *Axial T1C+ SPGR scan in the same patient shows the mass ⇨ enhances intensely and quite uniformly. The H-shaped configuration centered in the suprasellar cistern is classic for pilomyxoid astrocytoma, which was confirmed at surgery. (Courtesy M. Thurnher, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pilomyxoid astrocytoma (PMA)
- Myxoid variant of pilocytic astrocytoma (PA)

Definitions

- Tumor with monomorphic piloid cells dispersed in mucopolysaccharide-rich matrix
  - More aggressive tumor than PA with high risk of local recurrence, dissemination

IMAGING

General Features

- Best diagnostic clue
  - Infant or young child with large, bulky H-shaped mass in hypothalamus/optic chiasm, medial temporal lobes
- Location
  - 60% suprasellar
    - Optic chiasm, hypothalamus
    - Extension into adjacent structures is common with larger tumors
    - Deep gray nuclei, temporal lobes, adjacent white matter often involved
  - 40% centered **outside** diencephalon
    - Cerebral hemispheres
      - 2nd most common general location
      - Temporal lobe most common
      - May be purely cortical
    - Less common sites reported
      - Midbrain
      - Cerebellum
      - 4th ventricle
      - Spinal cord
- Size
  - Variable
    - Mean: 4 cm
    - Often large, bulky (up to 12 cm)
- Morphology
  - Grossly well circumscribed

CT Findings

- NECT
  - Uniform hypodensity most common
  - 20% show intratumoral hemorrhage
    - Hyperdense
    - Mixed hypo-/hyperdense
  - Ca++ occurs but uncommon
- CECT
  - Strong but inhomogeneous enhancement
  - Irregular central nonenhancing area in 1/3

MR Findings

- T1WI
  - Typical: Uniformly hypointense (almost 2/3 of cases)
  - Less common: Mixed hypo-/hyperintensity (10-15%)
  - Uncommon: Blood-fluid level
- T2WI
  - 70% uniformly hyperintense
  - 15% inhomogeneously hyperintense
  - 10% hypointense center, hyperintense rim
- FLAIR
  - 50% uniformly hyperintense
  - 33% heterogeneously hyperintense
  - Relatively well-demarcated margins
  - Little or no peritumoral edema
- T2* GRE
  - Intratumoral hemorrhage in 20%
  - May be strikingly hypointense
- DWI
  - Typically does not restrict
- T1WI C+
  - Strong but heterogeneous enhancement
    - 50% heterogeneous (i.e., rim)
    - 40% solid, homogeneous
    - 10% no enhancement
  - Basilar/spinal meningeal enhancement is common and indicates cerebrospinal fluid (CSF) dissemination

Other Modality Findings

- MRS
  - ↑ Cho, ↓ Cr and NAA ± lactate
  - Some authors report low-metabolite pattern with ↓ Cho, Cr, NAA

Imaging Recommendations

- Best imaging tool
  - MR with T1WI C+, DWI, T2* (GRE or SWI), MRS

DIFFERENTIAL DIAGNOSIS

Pilocytic Astrocytoma

- Older children (mean age at diagnosis: 6 years)
- PMA usually more hyperintense on T2/FLAIR (mucoid matrix)
- Hemorrhage, CSF dissemination uncommon

Low-Grade Diffuse Astrocytoma

- Peak age: 20-45 years
- Cerebral hemispheres, brainstem > diencephalon
- Does not enhance

Glioblastoma Multiforme

- Hemorrhage, necrosis common
- Hypothalamus rare location
- Patients usually older
- May arise from lower grade astrocytoma

PATHOLOGY

General Features

- Genetics
  - PMA has significant differences in gene expression vs. PA
    - *H19*, *DACT2*, extracellular matrix collagens, IGF2BP3 (*IMP3*) overexpressed in PMAs
    - Variable tendencies toward maturation to PA
- Associated abnormalities
  - Few cases associated with neurofibromatosis type 1 have been reported

Staging, Grading, & Classification

- WHO grade II (PA is WHO grade I)

https://CafePezeshki.IR

- Grade III if anaplastic features
- Malignant transformation to glioblastoma multiforme (GBM) (IV) rare but does occur
- *MIB1* generally low (1-2%) but higher in anaplastic pleomorphic xanthoastrocytomas

Gross Pathologic & Surgical Features

- Large, grossly well-circumscribed mass
- Necrosis, hemorrhage may be present

Microscopic Features

- Lacks classic biphasic pattern seen in PAs
- Consists of monomorphic piloid tumor cells
  - Embedded in myxoid (mucopolysaccharide-rich) matrix
  - GFAP(+), vimentin (+)
- Conspicuous angiocentric growth pattern (perivascular rosettes)
  - Vascular proliferation may be marked
  - Infiltration of tumor cells into adjacent brain common
  - Necrosis rare

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Signs of ↑ intracranial pressure
    - Headache
    - Nausea, vomiting
  - Delayed development
  - Failure to thrive (so-called diencephalic syndrome)
  - Visual disturbances
  - Hypothalamic dysfunction
- Other signs/symptoms
  - Seizures
  - Focal neurologic deficit

Demographics

- Age
  - Typical: Infants, young children (< 4 years)
  - Less common: Older children, young adults
  - Rare: Middle-aged adult (up to 46 years)
- Gender
  - Slight male predominance (M:F = 4:3)
- Epidemiology
  - Rare; represent < 1% of astrocytomas
  - 5-10% of cases initially diagnosed as PAs may be PMAs, especially if hemorrhage is present or tumor presents in very young child

Natural History & Prognosis

- Higher recurrence rate than PA
- CSF dissemination common
- Bimodal pattern
  - Can mature to PA
  - May dedifferentiate into GBM

Treatment

- Partial resection with adjuvant therapy may prolong survival

DIAGNOSTIC CHECKLIST

Consider

- Pilomyxoid astrocytoma if
  - Infant or young child has large/bulky or hemorrhagic suprasellar mass
  - Imaging atypical for PA (i.e., hemorrhage)
- If "pilocytic astrocytoma" with repeated recurrences, CSF dissemination, review histopathology and consider PMA

Image Interpretation Pearls

- H-shaped suprasellar mass may be PMA

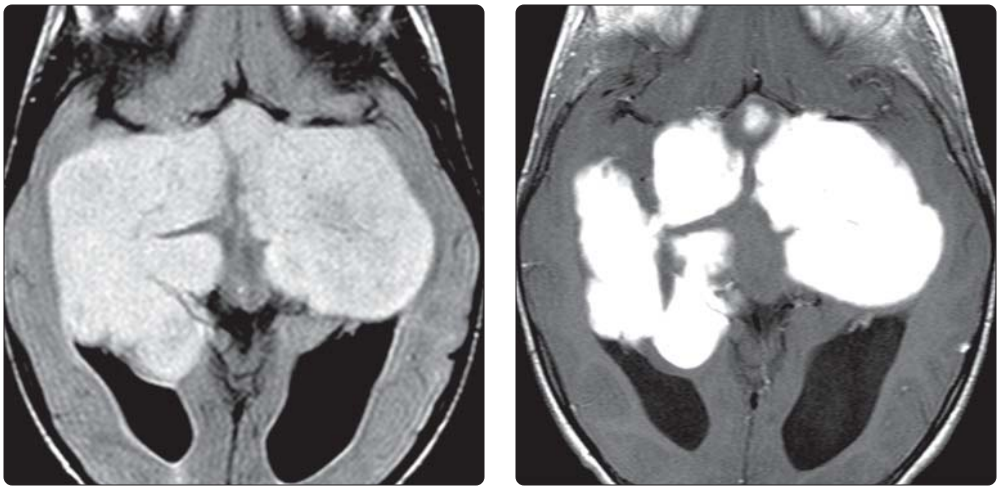
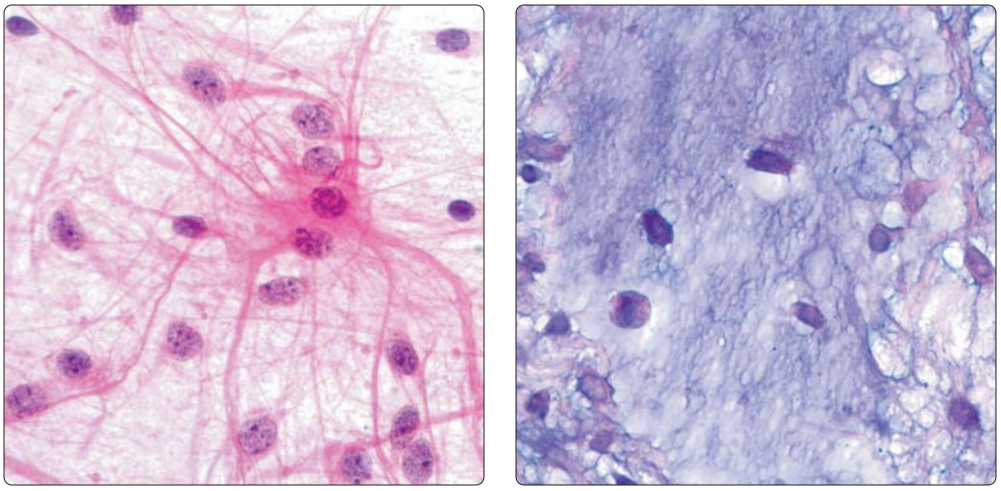
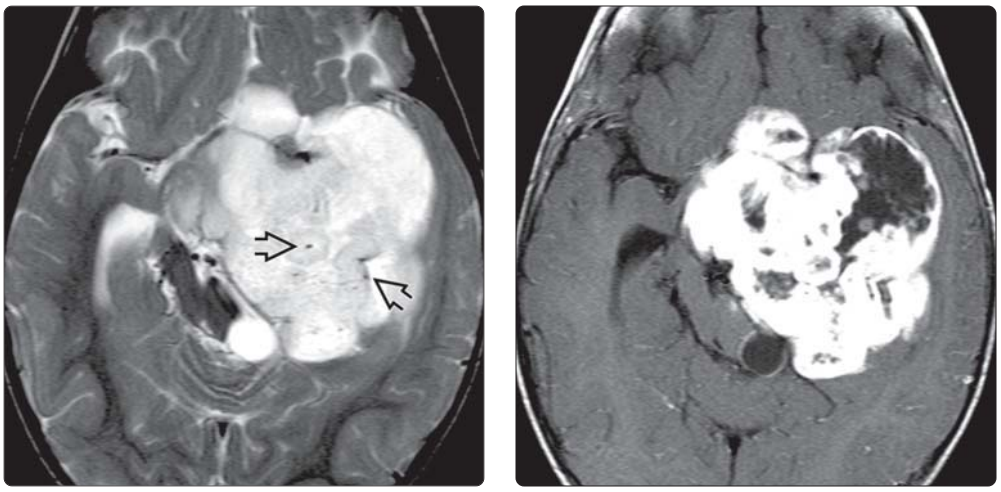
https://CafePezeshki.IR



(Left) *Axial FLAIR MR in a 3 year old shows a large H-shaped suprasellar mass with extension into the basal ganglia and both medial temporal lobes. The tumor is quite well delineated despite its size and shows no evidence for surrounding edema.* **(Right)** *Axial T1WI C+ MR in the same patient shows intense, uniform enhancement.*



(Left) *Micropathology biopsied from the same patient shows neoplastic, bipolar, "pilocytic" cells. No Rosenthal fibers are seen.* **(Right)** *High-power micropathology with mucin stain shows the mucinous matrix (blue) with embedded glial nuclei. MIB1 was elevated. Final diagnosis was pilomyxoid astrocytoma (WHO grade II). (Courtesy R. Hewlett, MD.)*



(Left) *Axial T2WI MR in a 20 month old shows a huge bulky suprasellar and medial temporal lobe mass. Scattered foci of T2 shortening within the mass ⇨ may represent hemorrhage (no T2* imaging was performed.)* **(Right)** *Axial T1WI C+ MR in the same patient shows mixed solid and rim enhancement. Biopsy disclosed elongated "piloid" cells in a mucin-rich matrix consistent with PMA. (Courtesy R. Hewlett, MD.)*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Astrocytic neoplasm with generally favorable prognosis in children and young adults

IMAGING

- Peripherally located hemispheric mass, often involves cortex and meninges
  - Temporal lobe most common
- Supratentorial cortical mass with adjacent enhancing dural "tail"
  - Cyst and enhancing mural nodule typical
  - Enhancing nodule often abuts pial surface

TOP DIFFERENTIAL DIAGNOSES

- Ganglioglioma
- Pilocytic astrocytoma
- Dysembryoplastic neuroepithelial tumor
- Oligodendroglioma
- Meningioma

PATHOLOGY

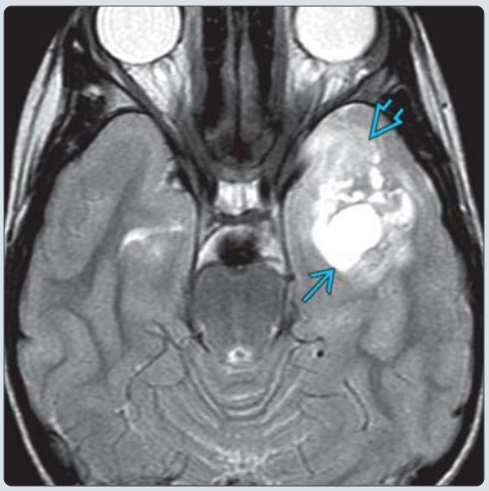
- WHO grade II
- "PXA with anaplastic features" also described

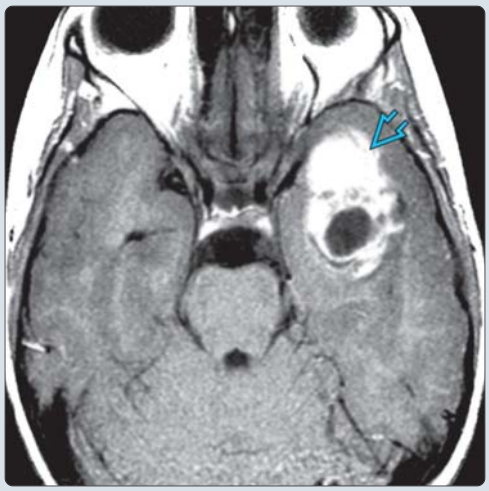
CLINICAL ISSUES

- Majority of patients have longstanding epilepsy, often partial complex seizures (temporal lobe)
  - Rare but important cause of temporal lobe epilepsy
- Tumor of children and young adults, majority < 18 years
- Represent < 1% of all astrocytomas
- Surgical resection is treatment of choice
- Survival 70% at 10 years
- Extent of resection and mitotic index are most significant predictors of outcome

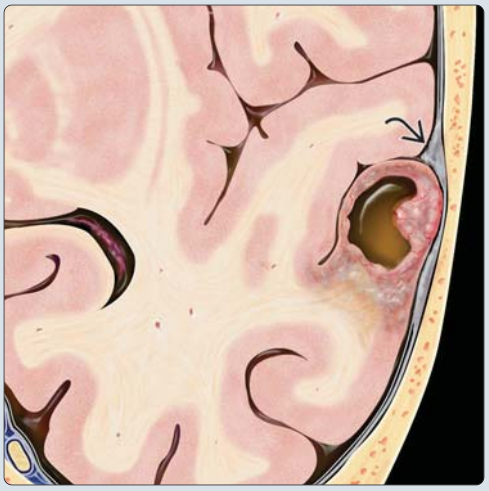
DIAGNOSTIC CHECKLIST

- If cortical mass and meningeal thickening in a young adult with long seizure history, think PXA
- Ganglioglioma may mimic PXA clinically and by imaging





(Left) *Axial T2WI MR shows a cystic ⇨ and solid ⇨ temporal lobe mass in a 6-year-old girl with epilepsy.* **(Right)** *Axial T1WI C+ MR in the same patient shows marked enhancement ⇨ of the solid portions of the mass. Note the relative lack of surrounding edema and mass effect, characteristic of PXA. The imaging differential diagnosis includes ganglioglioma and pilocytic astrocytoma. Enhancement along the meninges when present helps make an accurate preoperative diagnosis.*



(Left) *Coronal graphic shows a cystic and solid cortical mass with thickening of the adjacent meninges ⇨, characteristic of PXA. The mural nodule often abuts the pial surface and may result in a dural "tail." Thinning of the adjacent calvaria is rare.* **(Right)** *Axial T1 C+ MR image shows a peripherally located frontal lobe mass, which abuts the dura ➡ with mild local mass effect. Solid, enhancing mural nodules ⇨ are present. PXA was diagnosed at surgical resection. These WHO grade II tumors typically occur in the temporal lobes.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pleomorphic xanthoastrocytoma (PXA)

Definitions

- Astrocytic neoplasm with generally favorable prognosis in children and young adults
  - Superficial location in cerebral hemispheres with involvement of meninges

IMAGING

General Features

- Best diagnostic clue
  - Supratentorial cortical mass with adjacent enhancing dural "tail"
  - Cyst and enhancing mural nodule typical
- Location
  - Peripherally located hemispheric mass, often involves cortex and meninges
    - 98% supratentorial
  - Temporal lobe most common (40-50%)
    - Frontal and parietal > occipital lobes
  - Rarely found in cerebellum, sella, spinal cord, retina
- Size
  - Variable
- Morphology
  - 50-60% cyst with mural nodule that abuts meninges (may be solid)
  - Discrete, round to oval mass typical (may be ill defined)
  - Despite circumscribed appearance, tumor often infiltrates into brain and perivascular spaces

CT Findings

- NECT
  - Cystic/solid mass: Hypodense with mixed density nodule
  - Solid mass: Variable; hypodense, hyperdense, or mixed
  - Minimal or no edema is typical
  - Ca++, hemorrhage, frank skull erosion (rare)
- CECT
  - Strong, sometimes heterogeneous enhancement of tumor nodule

MR Findings

- T1WI
  - Mass is hypo- or isointense to gray matter
  - Mixed signal intensity may be seen
  - Cystic portion isointense to cerebrospinal fluid (CSF)
  - Associated cortical dysplasia may be seen (rare)
- T2WI
  - Hyperintense or mixed signal intensity mass
  - Cystic portion isointense to CSF
  - Surrounding edema (rare)
- FLAIR
  - Hyperintense or mixed signal intensity mass
  - Cystic portion isointense to CSF
- DWI
  - May show apparent diffusion coefficient (ADC) hypointensity in solid portions
  - Relatively low ADC values and ADC ratios (compared with pilocytic astrocytoma and ganglioglioma)
  - Mean ADC ratio of tumor to normal brain: 1.14 ± 0.26
- T1WI C+
  - Enhancement usually moderate/strong, well delineated
  - Enhancement of adjacent meninges, dural "tail" common (~ 70%)
    - Enhancing nodule often abuts pial surface
  - Rare: Deep tumor extension, distant metastases

Angiographic Findings

- Typically avascular
- Vascular blush may indicate necrotic or aggressive PXA

Nuclear Medicine Findings

- PET
  - FDG PET may show hypermetabolic foci even in low-grade PXA

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR is most sensitive
  - CT may be helpful for calvarial changes
- Protocol advice
  - Contrast-enhanced MR including coronal images to better evaluate temporal lobes

DIFFERENTIAL DIAGNOSIS

Ganglioglioma

- Cortically based hemispheric mass, solid/cystic, or solid
- Mural nodule typical, often not adjacent to meninges
- Variable enhancement, no enhancing dural "tail"
- Ca++ is common; may remodel calvaria

Pilocytic Astrocytoma

- Supratentorial location other than hypothalamus/chiasm is rare
- Typically solid and cystic or solid mass
- Enhancement but no dural "tail"

Dysembryoplastic Neuroepithelial Tumor (DNET)

- Superficial cortical tumor, well demarcated
- Multicystic bubbly appearance
- T2 hyperintense mass with rare, mild enhancement
- May remodel calvaria

Oligodendroglioma

- Heterogeneous, Ca++ mass
- Typically larger and more diffuse than PXA
- May remodel/erode calvaria

Meningioma

- Diffusely enhancing, dural-based mass with dural "tail"
- Usually older patients

Low-Grade Astrocytoma (Grade II)

- Demarcated but infiltrative white matter mass
- No enhancement

PATHOLOGY

General Features

https://CafePezeshki.IR

- May originate from cortical (subpial) astrocytes
- May arise from multipotential neuroectodermal precursor cells common to both neurons and astrocytes or from preexisting hamartomatous lesions

- Genetics
  - No definite association with hereditary tumor syndromes
  - Rare reports of PXA in neurofibromatosis type 1 and Sturge-Weber patients
  - PXA with *TP53* mutations reported (low incidence)
  - Tumors with *BRAF* mutation associated with overall longer survival
  - Frequent loss of chromosome 9
- Associated abnormalities
  - PXA may occur with ganglioglioma and oligodendroglioma (rare)
  - PXA reported with DNET and atypical teratoid-rhabdoid tumor
  - Synchronous, multicentric PXA lesions are rare
  - May be associated with cortical dysplasia

Staging, Grading, & Classification

- WHO grade II
- PXA with anaplastic features (10-15%)
  - Significant mitoses (5 or more per 10 HPF) &/or necrosis
  - Has been associated with poorer prognosis
    - Increased recurrence and decreased survival
  - Some classify these PXA as WHO grade III

Gross Pathologic & Surgical Features

- Cystic mass with mural nodule abutting meninges
- May be completely solid
- Leptomeningeal adhesion/attachment is common
- Dural invasion is rare
- Deep margin may show infiltration of parenchyma

Microscopic Features

- Superficial, circumscribed astrocytic tumor noted for cellular pleomorphism and xanthomatous change
- Pleomorphic appearance
  - Fibrillary and giant multinucleated neoplastic astrocytes
  - Large xanthomatous (lipid-containing) cells are GFAP positive
  - Dense reticulin network
  - Lymphocytic infiltrates
- Tumor sharply delineated from cortex, but infiltration may be seen
- Some positive for synaptophysin, neurofilament proteins, S100 protein
- CD34 antigen may help differentiate PXA from other tumors
- Necrosis, mitotic figures rare/absent
  - *MIB1* index generally < 1%

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Majority with longstanding epilepsy, often partial complex seizures (temporal lobe)
  - Other signs/symptoms: Headache, focal neurologic deficits

Demographics

- Age
  - Tumor of children and young adults
    - Typically first 3 decades
    - 2/3 < 18 years
    - Range: 2-82 years, mean: 26 years
- Gender
  - No definite gender predominance
- Epidemiology
  - < 1% of all astrocytomas
  - Rare but important cause of temporal lobe epilepsy

Natural History & Prognosis

- Usually circumscribed, slow growing
- Recurrence of tumor is uncommon
- Hemorrhage is rare complication
- Survival 70% at 10 years
- 5-year survival 75-80%
- Malignant transformation in 10-25% of cases
- Extent of resection and mitotic index are most significant predictors of outcome
- Younger age at diagnosis portends a better overall survival
- Aggressive PXA with malignant progression, dissemination may occur

Treatment

- Surgical resection is treatment of choice
- Repeat resection for recurrent tumors
- Radiation therapy and chemotherapy show mild improvement in outcome in some cases

DIAGNOSTIC CHECKLIST

Consider

- If cortical mass and meningeal thickening in young adult with long seizure history, think PXA
- Ganglioglioma may mimic PXA clinically and by imaging

Image Interpretation Pearls

- Meningioma-like lesion in young patient should raise suspicion of PXA

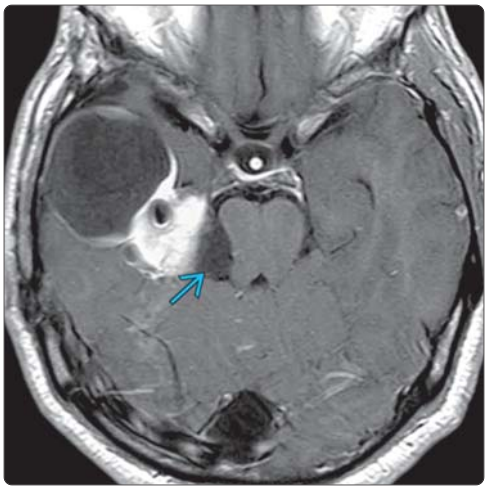
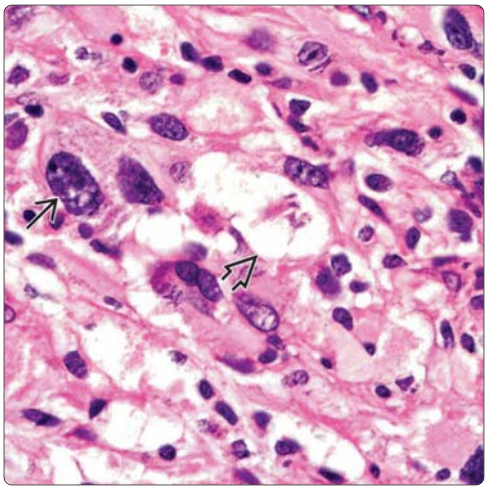
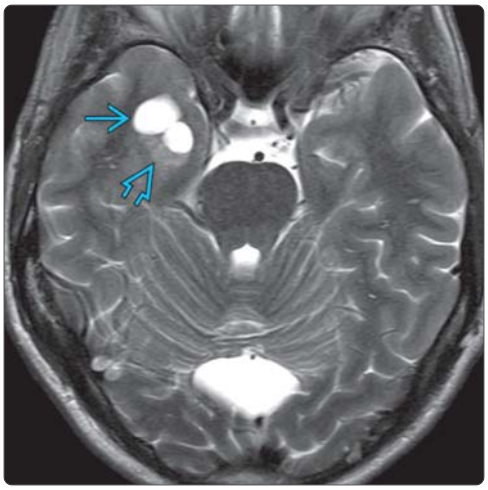
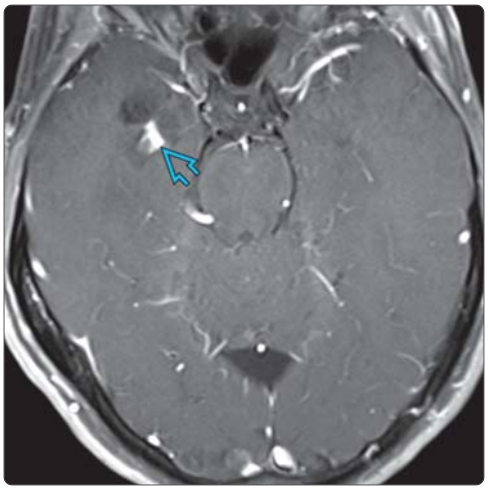
https://CafePezeshki.IR





(Left) *Axial T1WI C+ MR shows a solid and cystic temporal lobe mass related to a recurrent pleomorphic xanthoastrocytoma (PXA). Note the extraaxial portion ⇨ with mass effect on the adjacent midbrain.* **(Right)** *H&E micropathology from the same patient shows conspicuous pleomorphism of the tumor with multinucleated giant cells ⇨ and vacuolation ⇨, characteristic for PXA, WHO grade II. Malignant transformation occurs in 10-25% of cases. (Courtesy R. Hewlett, MD.)*





(Left) *Axial T2WI MR in an epilepsy patient shows a cystic ⇨ and solid ⇨ temporal lobe mass with no significant mass effect or surrounding edema.* **(Right)** *Axial T1 C+ FS MR in the same patient shows minimal nodular enhancement ⇨ of the mass. Imaging differential diagnosis includes ganglioglioma, pilocytic astrocytoma, PXA, and DNET. This was diagnosed as a PXA, WHO grade II, at resection. Coronal imaging is often helpful to better visualize the presence of meningeal involvement that is typical of PXA.*

(Left) *Axial T1 C+ FS MR shows a heterogeneously enhancing periventricular mass ⇨ in a 49-year-old male with local mass effect. PXA, WHO grade II, was diagnosed at resection. These tumors typically present in children or young adults.* **(Right)** *Axial CECT shows a large, mixed density, partially calcified, parietooccipital mass with patchy enhancement. This was classified as PXA with anaplastic features, WHO grade III, at resection, and the tumor had a high mitotic rate. These anaplastic tumors are uncommon and associated with a poor prognosis.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Subependymal giant cell astrocytoma (SGCA, SEGA)
- Benign, slow-growing glioneuronal tumor in patient with tuberous sclerosis complex (TSC)
  - Arises near foramen of Monro

IMAGING

- General findings
  - Enlarging, enhancing mass near foramen of Monro in patient with TSC
  - Other findings of TS (cortical tubers, SE nodules)

TOP DIFFERENTIAL DIAGNOSES

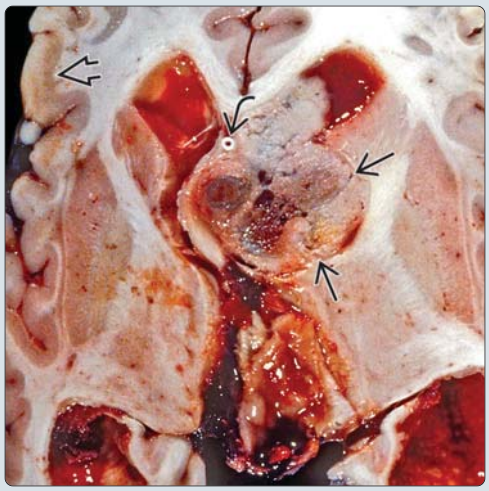
- Choroid plexus tumors
  - Choroid plexus papilloma > atypical choroid plexus papilloma, carcinoma
- Central neurocytoma
  - Body of lateral ventricle
- Astrocytoma
  - Pilocytic astrocytoma, chordoid glioma (rare)
- Subependymoma
  - Middle-aged, older adults
- Supratentorial PNET (rare)
  - Young child without TSC

PATHOLOGY

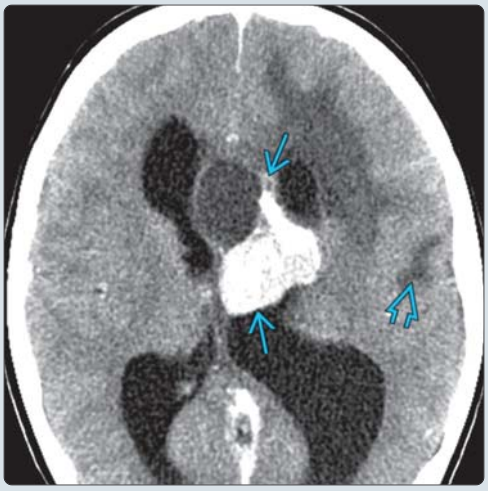
- SGCA probably arises from SE nodule in region of germinal matrix
- Likely represents disordered neuronal migration
- WHO grade I, curable with complete resection

CLINICAL ISSUES

- Most common CNS neoplasm in TSC
  - SGCA in up to 15% of patients with TSC
  - Rarely (if ever) arises in absence of TSC
- Typically occurs during first 2 decades
- Treatment with rapamycin (Everolimus)
  - Most TS patients have 50% ↓ in SEGA within 9 months



(Left) *Coronal graphic demonstrates hydrocephalus secondary to a subependymal giant cell astrocytoma (SGCA) arising near the left foramen of Monro. Note the subependymal tubers.* **(Right)** *Axial section through the ventricles in a patient with tuberous sclerosis complex (TSC) shows a large SGCA obstructing the foramen of Monro. Note the well-delineated tumor margins and cortical tuber. Despite emergent ventricular shunting, the ventricles were not decompressed successfully. (Courtesy R. Hewlett, MD.)*



(Left) *Axial CECT in a patient with TSC shows a large, partially calcified mass that obstructs the foramen of Monro. Note the hypodense white matter lesion underlying a cortical tuber.* **(Right)** *Axial FLAIR MR in the same patient shows that the mass is heterogeneously hyperintense. Note the cortical tubers and subcortical white matter hyperintensities. SGCA was found at surgery.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Subependymal giant cell astrocytoma (SGCA, SEGA)

Definitions

- Benign, slow-growing glioneuronal tumor arising near foramen of Monro in patient with tuberous sclerosis complex (TSC)

IMAGING

General Features

- Best diagnostic clue
  - Enlarging, enhancing foramen of Monro mass in patient with TSC
    - Other imaging findings of TSC (cortical tubers, subependymal nodules)
    - Subependymal giant cell astrocytoma in absence of clinical/genetic evidence of TSC reported but very rare
- Location
  - Subependymal nodules (SENs) in > 90% of tuberous sclerosis (TS) patients
    - Lateral ventricles adjacent to caudate nuclei
  - SEGAs may arise from SENs
    - Almost always near foramen of Monro
- Size
  - SEGAs variable, slowly growing
    - Often presents when 2-3 cm; causes obstructive hydrocephalus
  - SENs typically 5-10 mm
    - Larger SENs near foramen of Monro should be followed with serial imaging
      - SEGAs usually grow slowly while SENs remain stable
- Morphology
  - Well marginated, often lobulated
  - Frond-like margins

CT Findings

- NECT
  - Hypo- to isodense; heterogeneous
  - Ca++ variable
  - Hydrocephalus
- CECT
  - Heterogeneous, strong enhancement
  - Presence of interval growth suggests SGCA
  - Initially tumor is typically > 1 cm
- CT perfusion
  - May be mildly hypervascular

MR Findings

- T1WI
  - Hypointense to isointense to gray matter (GM)
  - ± Ca++ (hyperintense to hypointense)
- T2WI
  - Heterogeneous
    - Isointense to hyperintense
  - Ca++ foci hypointense
  - Hydrocephalus
- PD/intermediate
  - Hyperintense
- FLAIR
  - Heterogeneously hyperintense
  - Periventricular interstitial edema from ventricular obstruction
- T2* GRE
  - Low signal from Ca++
- DWI
  - Apparent diffusion coefficient (ADC) values are less than parenchymal hamartomas of TS
- T1WI C+
  - Robust enhancement
    - Enhancement alone does not allow discrimination from hamartoma
  - Enlarging, enhancing foramen of Monro mass > 1.2 cm suggests SGCA
  - CSF dissemination not seen
- MRS
  - Less than expected decrease in N-acetylaspartate (NAA) due to some neuronal elements in this primarily glial neoplasm

Imaging Recommendations

- Best imaging tool
  - MR demonstrates extent of mass, delineates associated TSC features
- Protocol advice
  - FLAIR MR to detect subtle CNS features of TSC
  - Recommend brain MR with contrast every 1-2 years for SGCA follow-up

DIFFERENTIAL DIAGNOSIS

Choroid Plexus Papilloma

- Atrium of lateral ventricle; foramen of Monro rare

Astrocytoma

- Origin: Septum pellucidum fornices or medial basal ganglia
  - Common pediatric intraaxial neoplasm
  - Variable enhancement, Ca++ rare

Germinoma

- Hugs midline, often arises near 3rd ventricle
- May originate from basal ganglia, resemble SGCA
- Early CSF spread

Subependymoma

- Tumor of middle-aged, elderly adults
- Inferior 4th/frontal horn of lateral ventricle

Central Neurocytoma

- Well-defined, variably vascularized, lobulated mass
- Body of lateral ventricle > foramen of Monro or septum pellucidum
- Necrosis, cyst formation are common
- Seen in young adults

Supratentorial PNET

- May exophytically extend into ventricle
- Lack of peritumoral edema
- Highly cellular tumor, isointense → slightly hyperintense on T2WI

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - SGCA probably arises from SEN in region of germinal matrix
  - Likely represents disordered neuronal migration complex
- Genetics
  - 50% of TSC patients have positive family history
    - High rate of de novo mutations
    - Inheritance: Autosomal dominant
    - High penetrance
    - Considerable phenotypic variability
  - Molecular genetics
    - 2 distinct TSC loci (chromosome 9q on *TSC1* and 16p on *TSC2*)
    - Protein products of *TSC1* (hamartin) and *TSC2* (tuberin)
      - Suppress mammalian target of rapamycin (mTOR), a major cell growth and proliferation controller
    - Mutation results in activation of mTOR
- Associated abnormalities
  - Other CNS, extraneural manifestations of TSC

Staging, Grading, & Classification

- WHO grade I

Gross Pathologic & Surgical Features

- Well-marginated mass arising from lateral ventricular wall near foramen of Monro
  - ± cysts, Ca++, and hemorrhage
- Does not seed CSF pathways

Microscopic Features

- Tumor cells of SGCAs show wide spectrum of astroglial phenotypes
  - Giant pyramidal ganglioid astrocytes
  - Perivascular pseudopalisading
- Histology may be indistinguishable from subependymal nodules
  - Diagnosis based on size and growth
- Immunohistochemistry
  - Variable immunoreactivity for GFAP, S100
  - Glial, neuronal antigen expression variable

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Increased intracranial pressure secondary to tumor obstructing foramen of Monro
    - Headache, vomiting, loss of consciousness
  - Other signs/symptoms
    - Worsening epilepsy
    - Massive spontaneous hemorrhage
- Clinical profile
  - Patient with TSC develops signs and symptoms of ventricular obstruction
  - Worsening of epilepsy

Demographics

- Age
  - SGCA typically occurs during first 2 decades
    - Mean age: 11 years
    - Rarely arise after 20-25 years of age
- Epidemiology
  - 1.4% of all pediatric brain tumors
  - Most common CNS neoplasm in TSC
    - Incidence of SGCA: 10-20% of patients with TSC
    - Rarely occurs in absence of TSC
- Uncommon reports of congenital cases
- No race or gender predilection

Natural History & Prognosis

- Solitary, slow-growing, benign tumor
- Symptoms from ventricular obstruction
- Good outcome and low recurrence rate with complete resection
- Rarely, massive spontaneous hemorrhage

Treatment

- Successful treatments reported with rapamycin (Everolimus)
  - Part of mTORC1 pathway
  - Restores pathway after inhibition by *TSC1* or *TSC2* mutation
- Surgery is no longer necessary in most cases

DIAGNOSTIC CHECKLIST

Consider

- SGCA in TSC patient with worsening seizures &/or symptoms of ventricular obstruction

Image Interpretation Pearls

- Enlarging, enhancing, intraventricular mass near foramen of Monro in TSC patient
- Foramen of Monro mass and associated intraventricular hemorrhage

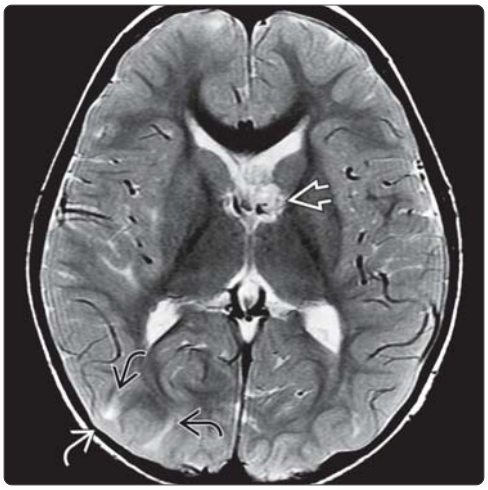
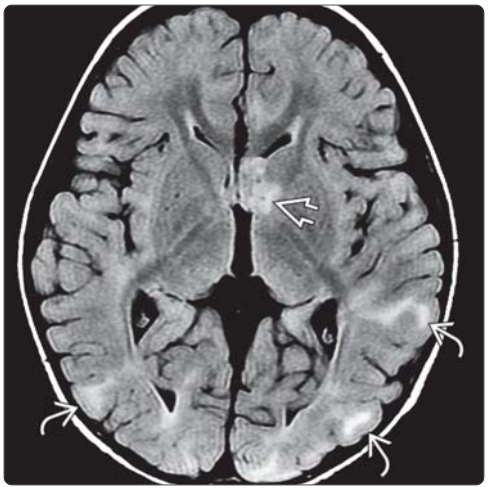
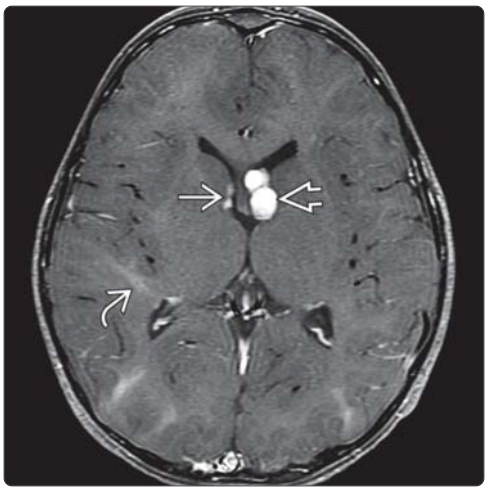
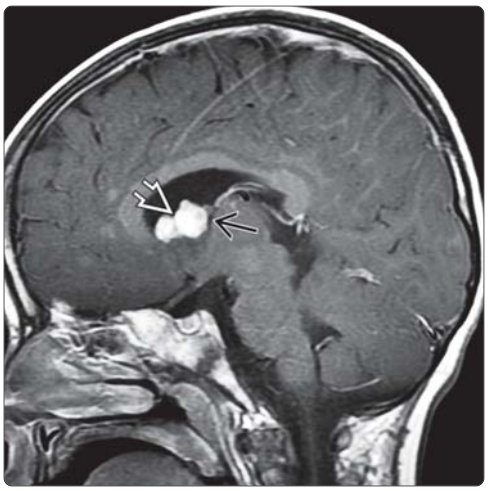
(Left) *Axial T1WI MR in a 13-year-old boy with TS shows 2 SENs along the right frontal horn. A bilobulated mixed signal intensity mass is present in the left frontal horn adjacent to the foramen of Monro. Note serial cortical tubers with widened gyri, indistinct gray matter-white matter interfaces.* **(Right)** *More cephalad axial T1WI MR in the same case shows additional SENs.*





(Left) *Axial T2WI MR in the same case shows the lobulated mass in the left frontal horn is hyperintense relative to both white matter, gray matter. Several flame-shaped white matter subcortical hyperintensities under the cortical tubers are present.* **(Right)** *Axial FLAIR MR in the same case shows the lobulated mass in the left frontal horn has not obstructed the lateral ventricle. The flame-shaped white matter hyperintensities under the cortical tubers are more apparent on this sequence.*





(Left) *T1 C+ FS MR in the same case shows the right frontal SENs enhance, as does the lobulated left frontal horn mass. The flame-shaped white matter hyperintensities are better seen on this image, with 1 radial band extending to the ventricular margin.* **(Right)** *Sagittal T1C+ MR in this case shows the lobulated mass in the left frontal horn is directly adjacent to the foramen of Monro but does not obstruct it. Presumed SGCA is being followed without surgery and has remained stable over several years.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Well-differentiated, slowly growing but diffusely infiltrating cortical/subcortical tumor

IMAGING

- Most common site is frontal lobe (50-65%)
- Best diagnostic clue: Partially calcified subcortical/cortical frontal mass in middle-aged adult
  - Typically T2 heterogeneous, hyperintense mass
- ~ 50% enhance
  - Heterogeneous enhancement is typical
- New enhancement in previously nonenhancing oligodendroglioma suggests malignant progression

TOP DIFFERENTIAL DIAGNOSES

- Anaplastic oligodendroglioma (AO)
- Low-grade diffuse astrocytoma
- Ganglioglioma
- Dysembryoplastic neuroepithelial tumor (DNET)
- Pleomorphic xanthoastrocytoma (PXA)
- Cerebritis
- Cerebral ischemia

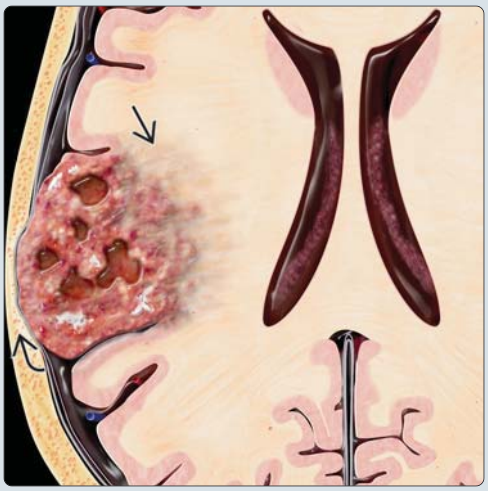
PATHOLOGY

- Loss of heterozygosity for 1p and 19q (50-70%)
- WHO grade II
- Anaplastic oligodendroglioma = WHO grade III
- Oligodendrogliomas carry better prognosis than astrocytomas of same grade

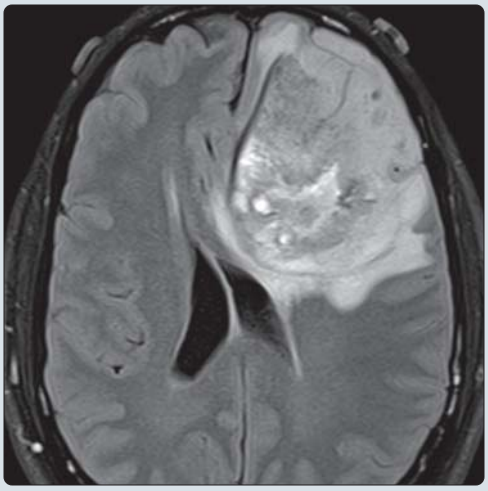
CLINICAL ISSUES

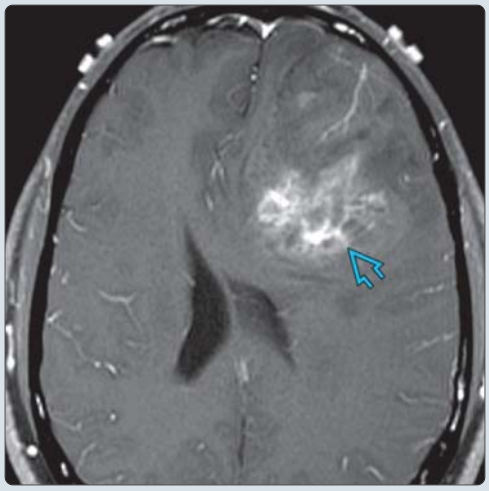
- 5-10% of primary intracranial neoplasms
- Seizures, headaches, and focal neurologic deficits are most common presentations
- Peak incidence: 4th and 5th decades
- Median survival time = 10 years
- 1p, 19q deletions and *IDH1*(+) associated with more favorable prognosis

(Left) *Axial graphic shows a heterogeneous cystic and solid mass involving the cortex and subcortical white matter, typical of oligodendroglioma. Note the deep infiltrative margin and calvarial remodeling.* **(Right)** *Axial NECT in a 20-year-old man shows a large, calcified, left frontal lobe mass, typical of oligodendroglioma. The vast majority (70-90%) of oligodendrogliomas show calcification. The calcification helps distinguish this tumor from other gliomas, particularly astrocytomas.*



(Left) *Axial FLAIR MR in the same patient shows a heterogeneous, hyperintense infiltrative mass expanding the frontal gyri. The frontal lobe location and involvement of both cortex and subcortical white matter are typical of oligodendroglioma.* **(Right)** *Axial T1WI C+ MR in the same patient shows heterogeneous enhancement in this grade II oligodendroglioma. Differentiating a grade II from a grade III oligodendroglioma is difficult on conventional imaging. MRS and MR perfusion may help predict the tumor grade preoperatively.*





https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Well-differentiated, slowly growing, but diffusely infiltrating, cortical/subcortical tumor

IMAGING

General Features

- Best diagnostic clue
  - Partially calcified subcortical/cortical mass in middle-aged adults
- Location
  - Typically involves subcortical white matter (WM) and cortex
  - Majority supratentorial (85%), hemispheric WM
    - Most common site is frontal lobe (50-65%)
    - May involve temporal, parietal, or occipital lobes
    - Rare: Posterior fossa
    - Extremely rare: Intraventricular, brainstem, spinal cord, primary leptomeningeal
- Morphology
  - Infiltrative mass that appears well demarcated

CT Findings

- NECT
  - Mixed density (hypo-/isodense) hemispheric mass that extends to cortex
  - Majority calcify, nodular or clumped Ca++ (70-90%)
  - Cystic degeneration common (20%)
  - Hemorrhage, edema are uncommon
  - May expand, remodel, erode calvaria
- CECT
  - ~ 50% enhance
  - Enhancement varies from none to striking

MR Findings

- T1WI
  - Hemispheric mass, hypo- to isointense to gray matter
  - Typically heterogeneous
  - Cortical and subcortical with cortical expansion
  - May appear well circumscribed with minimal associated edema
- T2WI
  - Typically heterogeneous, hyperintense mass
    - Heterogeneity related to Ca++, cystic change, less commonly blood products
  - May appear well circumscribed with minimal associated edema
  - Typically expands overlying cortex
  - Hemorrhage, necrosis are rare unless anaplastic
  - May expand, erode calvaria
- FLAIR
  - Typically heterogeneous, hyperintense
  - May appear well circumscribed but infiltrative
- T2* GRE
  - Ca++ seen as areas of "blooming"
- DWI
  - No diffusion restriction is typical
- T1WI C+
  - Heterogeneous enhancement is typical
  - ~ 50% enhance
  - Rarely, leptomeningeal enhancement is seen
- MRS
  - ↑ Cho, ↓ NAA
  - Absence of lipid/lactate peak helps differentiate from anaplastic oligodendroglioma
  - 2HG MRS has been found helpful to identify *IDH* status
- Perfusion MR
  - Relative cerebral blood volume (rCBV) can help differentiate grade II from grade III
  - Foci of elevated rCBV can mimic high-grade tumor

Nuclear Medicine Findings

- PET
  - FDG uptake similar to normal white matter
  - 11C-methionine studies show marked uptake differences between oligo and anaplastic oligo

Imaging Recommendations

- Best imaging tool
  - MR is most sensitive to delineate tumor
  - CT is helpful for identifying Ca++
- Protocol advice
  - Contrast-enhanced MR with T2* GRE or SWI ± MRS, perfusion

DIFFERENTIAL DIAGNOSIS

Anaplastic Oligodendroglioma (AO)

- May require biopsy to distinguish
- MRS, perfusion, or PET may be helpful

Low-Grade Diffuse Astrocytoma

- Calcification less common
- Usually involves white matter, cortex relatively spared
- May be indistinguishable

Ganglioglioma

- Usually temporal lobe, cortical
- Sharply demarcated, cyst with enhancing nodule
- Ca++ common
- Childhood, young adult tumor

Dysembryoplastic Neuroepithelial Tumor (DNET)

- Sharply demarcated cortical neoplasm
- Heterogeneous, bubbly appearance
- Variable enhancement
- Childhood, young adult tumor

Pleomorphic Xanthoastrocytoma (PXA)

- Supratentorial cortical mass, dural "tail" common
- Often cyst and mural nodule, may be solid
- Enhancing nodule abuts pial surface
- Childhood, young adult tumor

Cerebritis

- T2 hyperintensity and patchy enhancement
- Diffusion restriction typical

Cerebral Ischemia

- Typical vascular distribution (MCA, ACA, PCA)
- Diffusion restriction if acute/subacute
- Involves gray and white matter, often wedge-shaped

https://CafePezeshki.IR

- Cortical, gyriform enhancement if subacute

Arteriovenous Malformation (AVM)

- Typically multiple enlarged flow voids
- Often calcified
- If thrombosed, may be indistinguishable

Herpes Encephalitis

- Confined to limbic system, temporal lobes
- Blood products and enhancement common
- Acute onset is typical

PATHOLOGY

General Features

- Etiology
  - Arises from neoplastic transformation of mature oligodendrocytes or immature glial precursors
- Genetics
  - Loss of heterozygosity (LOH) for 1p and 19q (50-70%)
  - *IDH1* mutation (+) (80%)
  - Pediatric cases, often *IDH*(-) and *MGMT*(+)
  - *ATRX* is nonmutated
  - Familial cases have been reported
- Associated abnormalities
  - Oligoastrocytomas include neoplastic cell types of both oligodendroglioma and diffuse astrocytoma
    - Proposal to remove term oligoastrocytoma and stratify tumors based on *IDH1* status
  - Rarely occurs with other tumors, pleomorphic xanthoastrocytoma (PXA)
  - Rarely may be multifocal or multicentric
  - Oligodendroglial gliomatosis cerebri (rare)
  - Primary leptomeningeal oligodendrogliomatosis (extremely rare)

Staging, Grading, & Classification

- WHO grade II
- Anaplastic oligodendroglioma = WHO grade III
  - Mitoses, microvascular proliferation, ± necrosis
- Oligodendrogliomas carry better prognosis than astrocytomas of same grade

Gross Pathologic & Surgical Features

- Solid, infiltrative lesions of cortex/subcortical WM
- Well-defined, grayish pink, soft, unencapsulated mass
- Ca++ frequent; ± cystic degeneration, hemorrhage

Microscopic Features

- Moderately cellular tumors with occasional mitoses
- Rounded, homogeneous nuclei and clear cytoplasm
  - Fried egg and honeycomb patterns probably artifactual, perinuclear halos
- May have dense network of branching capillaries
- MIB-1 < 5% (proliferation index)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizures, headaches, focal neurologic deficits
  - Patients have relatively longstanding history of symptoms

Demographics

- Age
  - Peak incidence: 4th and 5th decades
- Gender
  - Slight male predominance
- Epidemiology
  - 5-10% of primary intracranial neoplasms
  - 5-20% of all gliomas
  - 3rd most common glial neoplasm

Natural History & Prognosis

- More favorable outcome correlated with younger age, frontal location, lack of enhancement, complete resection, radiation therapy after partial resection
- Worse prognosis correlated with necrosis, increased cellularity, mitotic activity, nuclear atypia, cellular pleomorphism, microvascular proliferation
- Median survival time = 10 years
- 5-year survival rate in 50-75% of cases
- Local recurrence is common; CSF seeding is uncommon
- 1p, 19q deletion and *IDH1*(+) associated with more favorable prognosis, better response to chemotherapy
- Tumors without *IDH1* mutation are considered wild type and behave more aggressively with poor survival

Treatment

- Surgical resection is primary treatment
- ± adjuvant radiation therapy & chemotherapy (temozolomide)

DIAGNOSTIC CHECKLIST

Consider

- If frontal lobe calcified mass, think oligodendroglioma
- Oligos may mimic cortically based masses (i.e., DNET), although these typically occur in younger patients

Image Interpretation Pearls

- Grade II oligos cannot be reliably differentiated from grade III (AO) on conventional imaging
- Oligos are most common intracranial tumor to calcify
- New enhancement in previously nonenhancing oligodendroglioma suggests malignant progression

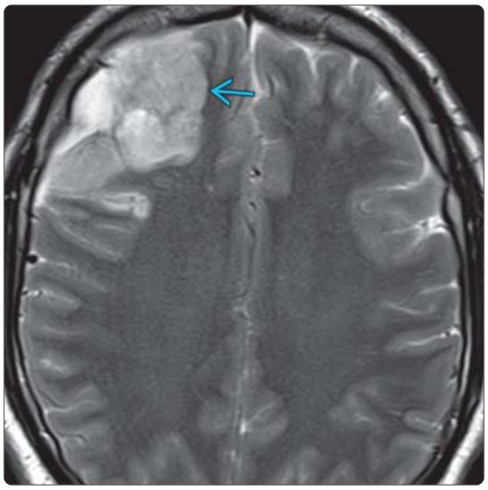
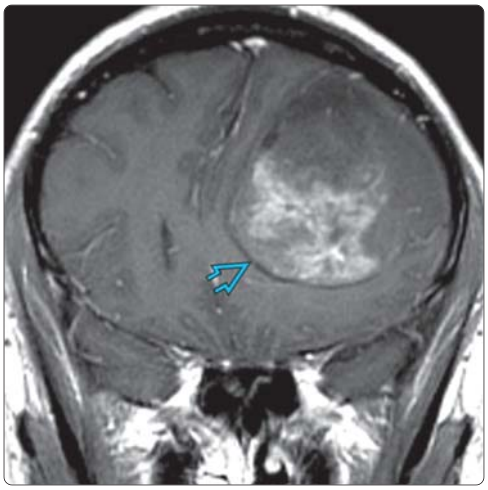
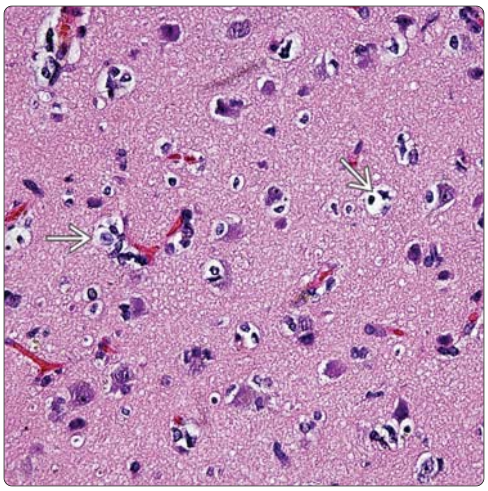
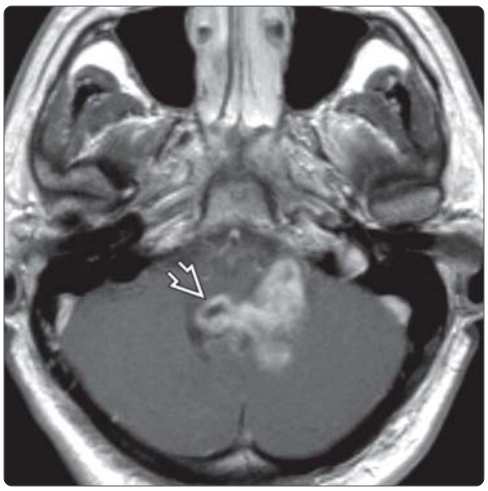
(Left) *Coronal T2 MR shows a discrete-appearing hyperintense white matter mass* ⇨ *with involvement of the overlying cortex. Grade II oligodendroglioma, 1p, 19q deletion was diagnosed at resection. 1p 19q deletions and IDH1 mutation are associated with improved survival.* **(Right)** *Axial T1 MR in the same patient shows a hypointense mass* ⇨ *involving the right frontoparietal cortex and deep white matter. No enhancement was present following contrast. About 50% of grade II oligodendrogliomas show enhancement.*





(Left) *Axial T2 MR shows a heterogeneous, hyperintense mass* ⇨ *with involvement of the cortex and subcortical white matter with mild associated mass effect. Imaging is highly suggestive of oligodendroglioma. Anaplastic oligodendroglioma was diagnosed at resection. Grade II oligodendrogliomas cannot be reliably differentiated from grade III on conventional imaging. MRS and MR perfusion may be helpful.* **(Right)** *Coronal T1 C+ MR shows a heterogeneously enhancing frontal lobe grade II oligodendroglioma* ⇨.





(Left) *High-power micropathology shows the classic histopathologic fried egg appearance* ➡ *related to a perinuclear halo, characteristic for oligodendroglioma. Oligodendrogliomas carry a better prognosis than astrocytomas of the same grade.* **(Right)** *Axial T1WI C+ MR shows a heterogeneously enhancing posterior fossa mass* ➡ *involving the 4th ventricle. Though imaging mimics an ependymoma, this was a grade II oligodendroglioma at resection.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Oligodendroglioma with focal or diffuse histologic features of malignancy

IMAGING

- Best diagnostic clue: Calcified frontal lobe mass involving cortex and subcortical white matter
  - Frontal lobe is most common location, followed by temporal lobe
- Majority have nodular or clumped calcification
- May see hemorrhage or necrosis
- Variable enhancement
  - Anaplastic oligodendroglioma more likely to enhance than low-grade oligo
- Neoplastic cells almost always found beyond areas of abnormal signal intensity
- MRS and MR perfusion may help distinguish grade II from grade III oligos

TOP DIFFERENTIAL DIAGNOSES

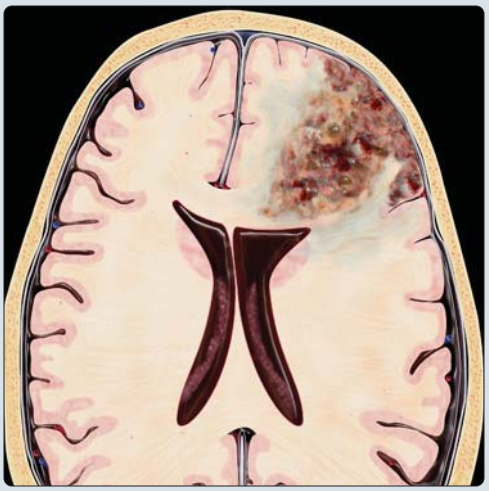
- Oligodendroglioma
- Anaplastic astrocytoma (AA)
- Glioblastoma multiforme (GBM)
- Cerebritis
- Ischemia

PATHOLOGY

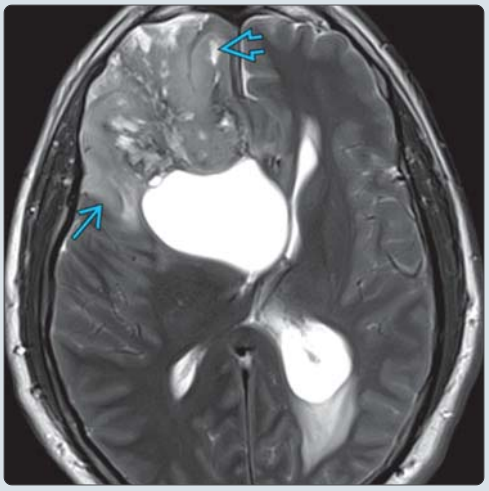
- WHO grade III
- Oligos: Better prognosis than astrocytomas of same grade

CLINICAL ISSUES

- Headache, seizures are most common presentations
- Occurs at all ages; mean is 49 years
- 20-50% of oligodendrogliomas are anaplastic
- Median survival: 4 years
- 5-year survival: 40-45%; 10-year survival: 15%
- 1p and 19q deletions associated with prolonged survival



(Left) *Axial graphic shows a heterogeneous frontal cortical and subcortical mass with areas of necrosis and hemorrhage. Note the mass effect and infiltrative margins, typical of anaplastic grade III oligodendroglioma. These malignant gliomas have a poor prognosis.* **(Right)** *Axial CT image in a 43-year-old man with seizures shows a calcified, cystic, and solid frontal lobe mass. There is associated intraventricular obstructive hydrocephalus with ventricular enlargement and transependymal CSF flow (interstitial edema).*



(Left) *Axial T2 MR in the same patient shows the heterogeneously hyperintense mass with significant mass effect and associated hydrocephalus. The T2 heterogeneity is related to cystic change and calcification. The calcification is better seen on CT or T2* MR.* **(Right)** *Axial T1 C+ MR in the same patient shows heterogeneous enhancement of the mass. WHO grade III anaplastic oligodendroglioma was diagnosed at resection. Enhancement is more common in grade III than in grade II oligodendrogliomas.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Anaplastic oligodendroglioma (AO), high-grade oligodendroglioma (oligo)

Definitions

- Highly cellular, diffusely infiltrating glioma
- Oligodendroglioma with focal or diffuse histologic features of malignancy

IMAGING

General Features

- Best diagnostic clue
  - Calcified frontal lobe mass involving cortex and subcortical white matter (WM)
- Location
  - Supratentorial hemispheric mass, involves cortex and subcortical WM
  - Frontal lobe most common, followed by temporal lobe
  - May involve parietal or occipital lobes
  - Often expands overlying cortex
- Morphology
  - Diffusely infiltrative mass
  - May appear discrete, but always infiltrative
  - Neoplastic cells almost always found beyond areas of abnormal signal intensity

CT Findings

- NECT
  - Mixed density (hypodense/isodense) mass
  - Majority calcify, nodular or clumped Ca++
    - May see gyriform Ca++
  - Cystic degeneration common
  - May see hemorrhage or necrosis
  - May expand, remodel, or erode calvaria

MR Findings

- T1WI
  - Heterogeneous hypointense infiltrative mass
  - May appear circumscribed
  - May see blood products, edema, necrosis
  - Cortical expansion may be seen
- T2WI
  - Heterogeneous hyperintense infiltrative mass
    - Heterogeneity related to Ca++, cystic change, blood products
  - Typically expands overlying cortex
  - May see hemorrhage, necrosis
- FLAIR
  - Heterogeneous hyperintense infiltrative mass
  - Typically expands overlying cortex
- T2* GRE
  - Ca++ &/or hemorrhage seen as areas of "blooming"
- DWI
  - No diffusion restriction is typical
- T1WI C+
  - Variable enhancement
  - New enhancement suggests malignant progression
  - 50% of all oligodendrogliomas enhance
  - AOs more likely to enhance than low-grade oligo
- MRS
  - ↑ Cho/Cr, ↓ NAA
  - Lipid/lactate peak at 1.33 ppm may be seen
- PWI
  - High relative cerebral blood volume (rCBV) common
  - Helpful to distinguish grade II from grade III
  - May help guide biopsy

Nuclear Medicine Findings

- PET
  - High glucose metabolism, accumulate FDG similar to or exceeding gray matter
  - FDG shows high-grade gliomas have uptake similar to or exceeding normal gray matter
  - Tumor/WM > 1.5 and tumor/GM > 0.6 suggest high-grade tumors
  - 11C-methionine studies show marked uptake differences between oligo, AO

Imaging Recommendations

- Best imaging tool
  - MR to delineate tumor; CT for Ca++
- Protocol advice
  - MR with contrast, GRE ± MRS and PWI

DIFFERENTIAL DIAGNOSIS

Oligodendroglioma

- Calcified mass involving gray and white matter
- May appear more circumscribed
- May be indistinguishable without biopsy
- MRS and perfusion may help preoperative diagnosis

Anaplastic Astrocytoma (AA)

- Infiltrative mass, predominantly involves white matter
- Often nonenhancing, Ca++ rare
- May be indistinguishable

Glioblastoma Multiforme (GBM)

- 95% necrotic core, enhancing rim
- Extensive surrounding T2/FLAIR signal
- Hemorrhage common

Cerebritis

- T2 hyperintensity and patchy enhancement
- Diffusion restriction is typical
- May appear mass-like
- Acute onset common

Ischemia

- Typical vascular distribution (MCA, ACA, PCA)
- Diffusion restriction if acute/subacute
- Involves GM and WM, often wedge-shaped
- Cortical, gyriform enhancement if subacute

Herpes Encephalitis

- Confined to limbic system, temporal lobes
- Blood products and enhancement common
- Acute onset is typical

Meningioma

- Enhancing extraaxial dural-based mass

https://CafePezeshki.IR

- Often calcified with broad dural base, dural "tail"
- Hyperostosis and Ca++ is characteristic
- Older patients

PATHOLOGY

General Features

- Etiology
  - May arise de novo or from malignant progression of preexisting grade II oligo
  - Arises from neoplastic transformation of mature oligodendrocytes or immature glial precursors
- Genetics
  - Loss of heterozygosity for 1p and 19q (30-40%)
  - Average number of chromosomes involved is higher in grade III than grade II oligo
- Associated abnormalities
  - Oligoastrocytoma (mixed tumor with 2 distinct neoplastic cell types) is common
    - Recent proposal to remove term oligoastrocytoma and stratify based on *IDH1* status
    - WHO grade II (oligoastrocytoma)
    - WHO grade III (anaplastic oligoastrocytoma)
    - Decreased survival compared with pure oligodendroglioma

Staging, Grading, & Classification

- WHO grade III
- May rarely be multifocal or multicentric
- Oligodendroglial gliomatosis cerebri rare

Gross Pathologic & Surgical Features

- Well-defined, grayish pink, soft unencapsulated mass
- Located in cortex and subcortical WM
- Ca++ is extremely common
- Cystic degeneration and hemorrhage common
- Necrosis may be present
- Rarely infiltrates overlying leptomeninges

Microscopic Features

- Rounded, homogeneous nuclei and clear cytoplasm
  - Perinuclear halos, fried egg and honeycomb patterns related to fixation artifact
- Microcalcifications, mucoid/cystic degeneration
- Dense network of branching capillaries
  - Chicken-wire pattern
- Increased cellularity, marked atypia
- High mitotic activity
- Microvascular proliferation and necrosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, seizures most common
  - Focal neurologic deficits
  - Duration of symptoms shorter than in grade II oligo

Demographics

- Age
  - Peak incidence: 4th through 6th decades
  - Occurs at all ages; mean is 49 years
  - Older on average than WHO grade II patients
- Gender
  - Slight male predominance
- Epidemiology
  - 20-50% of oligodendrogliomas are anaplastic
  - Oligos represent 5-25% of all gliomas

Natural History & Prognosis

- Poor prognosis, survival is months to years
- Median survival: 4 years
- 5-year survival: 40-45%; 10-year survival: 15%
- Local tumor recurrence common
- CSF metastasis uncommon
- Systemic metastasis rare
- Leptomeningeal oligodendrogliomatosis, spinal cord metastasis extremely rare
- Positive prognostic factors
  - Age: < 50 years
  - Karnofsky performance status (KPS): 90-100
  - Tumors ≤ 4 cm
  - Complete tumor resection
- *CDKN2A* tumor suppressor gene deletions associated with shorter survival
- 1p and 19q loss of heterozygosity associated with prolonged survival
- Oligos have better prognosis than astrocytomas of same grade

Treatment

- Surgical resection + adjuvant chemo and radiation therapy

DIAGNOSTIC CHECKLIST

Consider

- Many gliomas may mimic AO
- Presence of Ca++, cortical expansion may help distinguish AOs from other gliomas

Image Interpretation Pearls

- AOs cannot be reliably differentiated from grade II oligos on conventional MR
- Neoplastic cells are almost always found beyond areas of abnormal signal intensity
- New enhancement in previously nonenhancing oligo suggests malignant progression

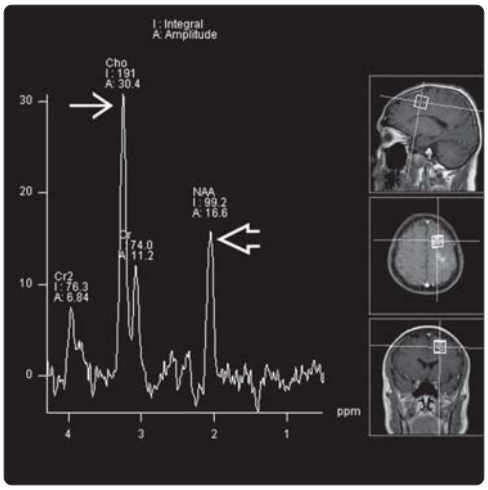
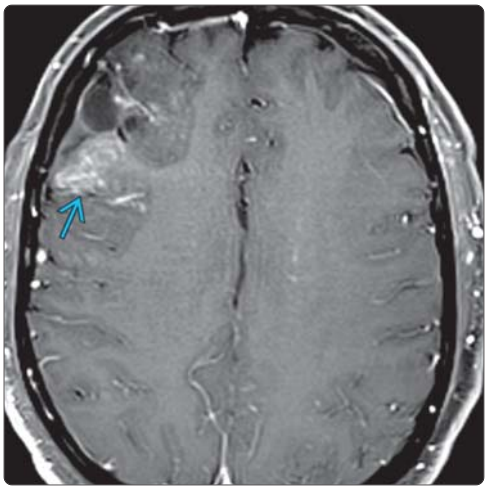
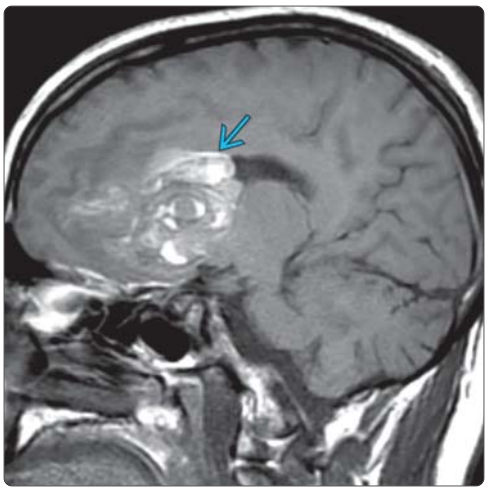
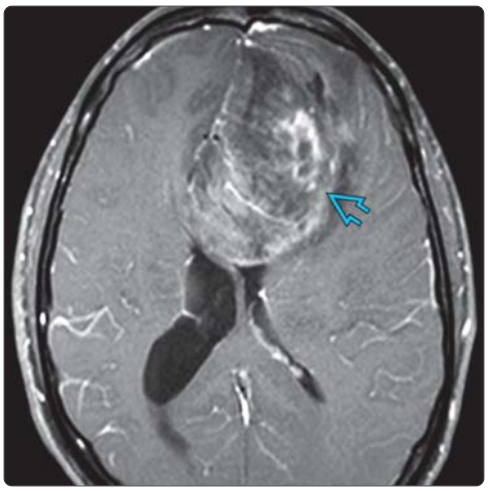
(Left) *Axial T1 C+ MR in a patient who was treated with surgery, radiation therapy, and temozolomide for her anaplastic oligodendroglioma shows new enhancement in the left frontal lobe. New enhancement in a previously nonenhancing mass is highly concerning for disease progression.* **(Right)** *Axial rCBV color map from a DSC MR perfusion study shows elevated relative cerebral blood volume in the regions of new enhancement related to progressive tumor.*





(Left) *MRS in the same patient shows a typical malignant tumor spectrum with marked elevation of choline and decreased NAA. MR perfusion and MRS may be helpful in the preoperative diagnosis as well as the post-treatment evaluation of patients with glial neoplasms.* **(Right)** *Axial T1WI C+ FS MR shows a heterogeneously enhancing frontal mass. Grade III oligodendrogliomas was found at resection. Oligodendrogliomas have a better prognosis than pure astrocytomas of the same grade.*





(Left) *Sagittal T1 MR shows a heterogeneous mass with areas of hyperintensity related to blood products and calcifications in this anaplastic oligodendroglioma.* **(Right)** *Axial T1WI C+ FS MR in a different patient with anaplastic oligodendroglioma shows heterogeneous enhancement of a large mass. Approximately 50% of all oligodendrogliomas enhance. Enhancement does not reliably differentiate between grade II and grade III oligodendrogliomas.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Rare glial neoplasm with perivascular pseudorosettes and variable biological behavior

IMAGING

- Well-delineated, mixed solid and cystic hemispheric mass with bubbly appearance
- Almost always supratentorial, usually within cerebral hemisphere
- Majority (up to 80%) have calcification
- T2WI: Solid and cystic mass with heterogeneous bubbly appearance of solid portion
- GRE/SWI: Hypointensity related to Ca++ or blood products
- Heterogeneous enhancement is typical (75%)
  - Mixed solid, rim-enhancing pattern
- MRS may show ↓ NAA, ↑ choline

TOP DIFFERENTIAL DIAGNOSES

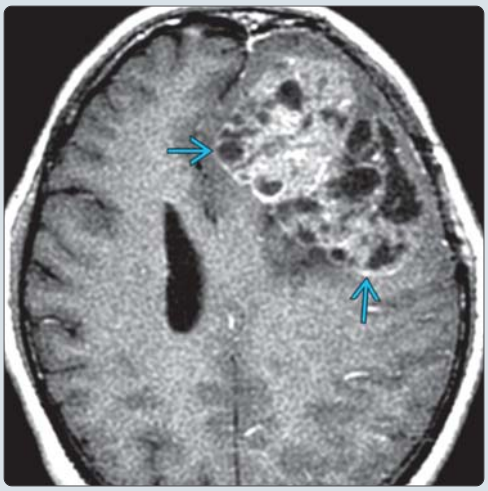
- Ependymoma
- Primitive neuroectodermal tumor
- Atypical teratoid-rhabdoid tumor
- Oligodendroglioma
- Pleomorphic xanthoastrocytoma

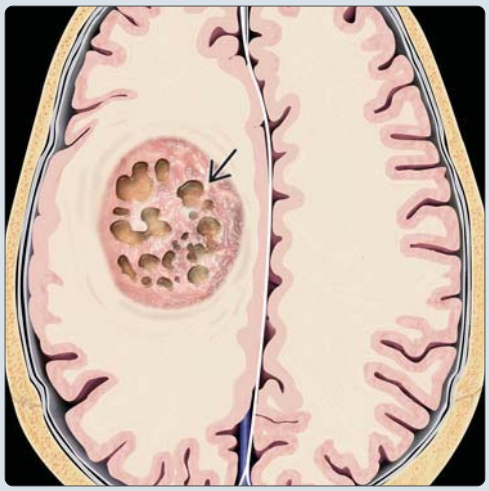
PATHOLOGY

- No WHO grade officially established
  - Low- and high-grade histologic features

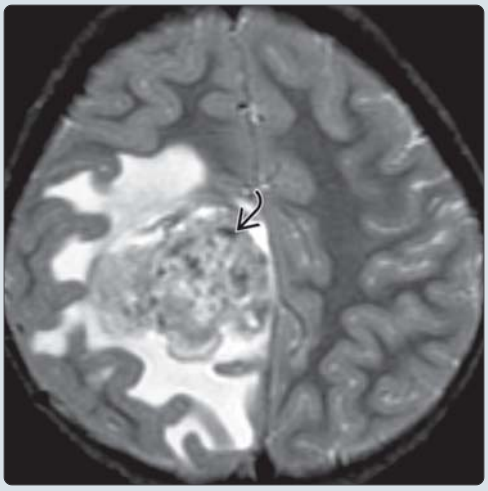
CLINICAL ISSUES

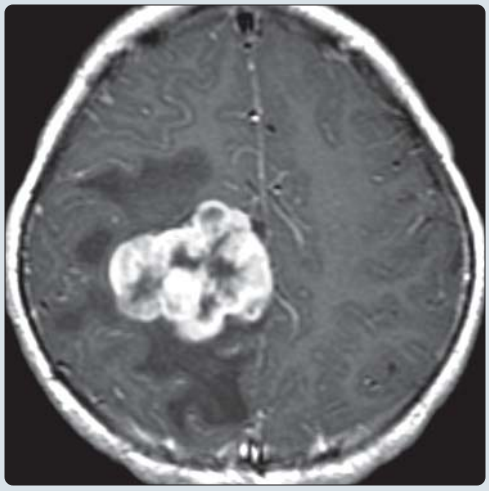
- Most common presentation: Headache, seizures, focal neurologic deficit
- Occurs at all ages; median is 11 years (peak: 10-30 years)
- Rare: 0.5-3% of primary gliomas
- Low-grade astroblastomas often have good long-term survival
- Surgical resection is treatment of choice
- Adjuvant radiation therapy and chemotherapy for high-grade (anaplastic) lesions





(Left) *Axial T1WI C+ MR shows a large frontal lobe mass with strong, heterogeneous enhancement. Note the multiple cysts surrounded by rims and solid masses of enhancing tissue. Note the relative lack of surrounding edema and mass effect for the size of the lesion, typical of astroblastoma.* **(Right)** *Axial graphic shows a well-delineated mixed solid and cystic hemispheric mass with calcification and a bubbly appearance characteristic of astroblastoma.*





(Left) *Axial T2WI MR shows a large heterogeneous mass in this 5 year old with seizures. The areas of low signal intensity are related to calcifications. These rare tumors typically occur in children and young adults.* **(Right)** *Axial T1WI C+ MR in the same patient shows strong, heterogeneous enhancement of the mass. Histology revealed a well-differentiated astroblastoma. Surgical resection is the primary treatment with adjuvant radiation and chemotherapy reserved for anaplastic tumors.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Rare glial neoplasm with perivascular pseudorosettes and variable biological behavior

IMAGING

General Features

- Best diagnostic clue
  - Well-delineated mixed solid and cystic hemispheric mass with bubbly appearance in child or young adult
- Location
  - Almost always supratentorial, usually within cerebral hemisphere
    - Parietal > frontal lobe
- Size
  - Range: 1-10 cm; mean: 4 cm
- Morphology
  - Circumscribed, lobular, solid and cystic mass with dominant solid component

CT Findings

- NECT
  - Mixed areas of hyperdensity, hypodensity, isodensity typical
  - Majority (up to 80%) have calcification (Ca++)

MR Findings

- T1WI
  - Solid and cystic mass with heterogeneous signal
- T2WI
  - Solid and cystic mass with heterogeneous bubbly appearance of solid portion
  - Hyperintense to white matter (80%)
  - 50% lack peritumoral hyperintensity
- T1WI C+
  - Heterogeneous enhancement (70-75%)
  - < 10% show no enhancement

Imaging Recommendations

- Best imaging tool
  - NECT best to identify calcification
  - Multiplanar contrast-enhanced MR best for tumor evaluation

DIFFERENTIAL DIAGNOSIS

Ependymoma

- Supratentorial (1/3): Heterogeneous parenchymal/periventricular enhancing mass
- Hemorrhage, necrosis, Ca++, and edema common

Primitive Neuroectodermal Tumor (PNET)

- Peripheral, heterogeneous parenchymal mass
- Hemorrhage, cysts, and Ca++ common

Atypical Teratoid-Rhabdoid Tumor (AT/RT)

- Heterogeneous solid mass with hemorrhage, necrosis, Ca++, cyst formation

Oligodendroglioma

- Peripheral, cortically based mass ± enhancement
- Ca++ common; minimal surrounding edema

Pleomorphic Xanthoastrocytoma

- Cyst with mural nodule in temporal lobe typical
- Enhancing nodule abuts dura with dural "tail"

Pilocytic Astrocytoma

- Enhancing solid component + cyst common

PATHOLOGY

Staging, Grading, & Classification

- No WHO grade officially established
- Some pathologists designate well differentiated (low grade) or anaplastic (high grade) based on histologic features

Gross Pathologic & Surgical Features

- Circumscribed, well-demarcated mass, cysts common
- Necrosis may be seen in low-grade or high-grade lesions

Microscopic Features

- Perivascular pseudorosettes
- Oval to elongated hyperchromatic nuclei; ± Ca++

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, seizures, focal neurologic deficit

Demographics

- Age
  - Most common in children and young adults
    - Median: 11 years
- Gender
  - Female predominance
- Epidemiology
  - Rare (0.5-3% of primary gliomas)

Natural History & Prognosis

- Gross total resection is associated with favorable outcome
- Low-grade astroblastomas often have good long-term survival
- Anaplastic histology is associated with tumor recurrence and progression

DIAGNOSTIC CHECKLIST

Consider

- "Bubbly" hemispheric mass in child or young adult may be astroblastoma

Image Interpretation Pearls

- Astroblastoma often shows lack of significant mass effect for size of lesion

SELECTED REFERENCES

KEY FACTS

TERMINOLOGY

- Rare glioma arising from anterior wall/roof of 3rd ventricle

IMAGING

- Adult with well-delineated, homogeneously enhancing 3rd ventricular mass
- CT: Moderately hyperdense anterior 3rd ventricular mass
- Ca++ may be present
- Hydrocephalus in 10-15% of cases

TOP DIFFERENTIAL DIAGNOSES

- Craniopharyngioma
- Pilocytic astrocytoma
- Germinoma
- Choroid plexus papilloma
- Colloid cyst

PATHOLOGY

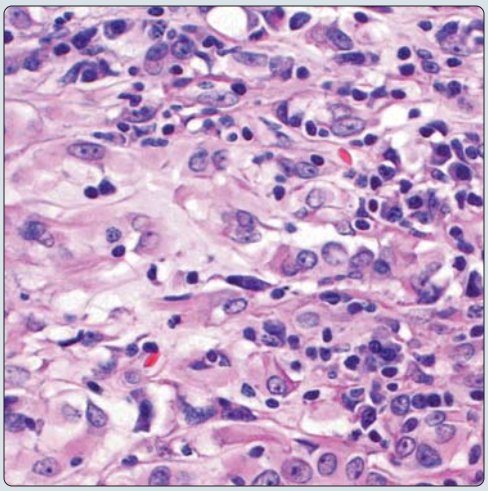
- WHO grade II
- Cords/clusters of oval/polygonal epithelioid cells within mucinous stroma
- Likely ependymal origin
  - From ependymal cells in/near lamina terminalis
  - May arise from subcommissural organ

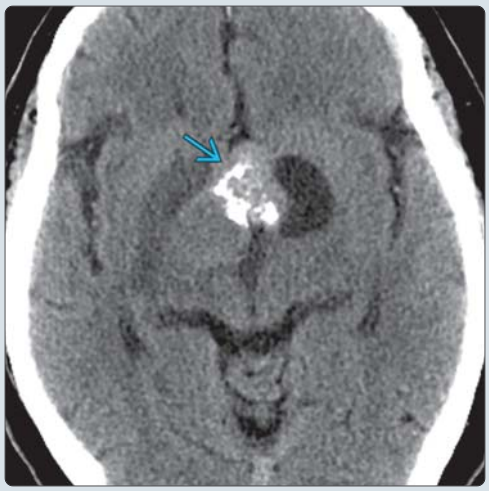
CLINICAL ISSUES

- Headache, nausea due to hydrocephalus most common symptom
  - Endocrine disturbances (hypothyroidism, diabetes insipidus, amenorrhea)
  - Dysautonomias
  - Visual disturbances
- Surgical excision is primary therapy

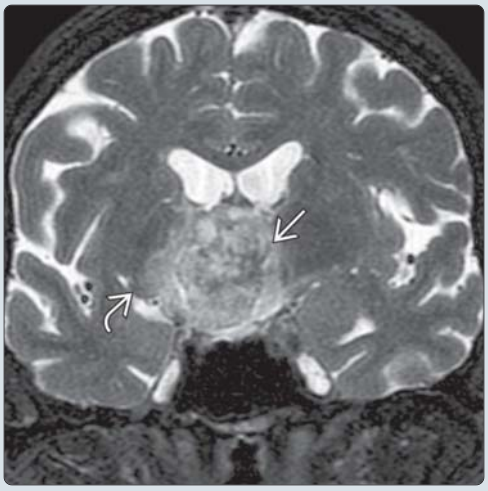
DIAGNOSTIC CHECKLIST

- Consider chordoid glioma of 3rd ventricle if adult with T2 hyperintense, enhancing, anterior 3rd ventricular mass





(Left) *High-power H&E stain of a classic chordoid glioma shows a neoplasm with clusters and cords of epithelioid cells with abundant eosinophilic cytoplasm in a mucinous stroma. GFAP (not shown) was strongly positive.* **(Right)** *Axial CT in a 48-year-old man with visual changes shows a calcified cystic and solid suprasellar/anterior 3rd ventricular region mass ⇨. Imaging mimics the more common craniopharyngioma. Chordoid glioma was diagnosed at resection. (Courtesy L. Shah, MD.)*



(Left) *Coronal T2 FS MR image in a 65-year-old woman with a 3-year history of weight gain and personality changes shows a lobulated heterogeneously hyperintense mass ⇨ mostly contained within the 3rd ventricle. The optic tract ⇨ is displaced laterally.* **(Right)** *Sagittal T1 C+ MR image in the same patient shows strong, uniform enhancement of the slightly lobulated 3rd ventricular mass ⇨. Chordoid glioma was diagnosed at histopathology. (Courtesy C. Glastonbury, MBBS.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Chordoid glioma of third ventricle (CGOTV)

Definitions

- Rare glioma arising from anterior wall/roof of 3rd ventricle

IMAGING

General Features

- Best diagnostic clue
  - Well-delineated, homogeneously enhancing anterior 3rd ventricular mass
- Location
  - Suspended from roof/anterior wall of 3rd ventricle
- Size
  - 1.5-7 cm
- Morphology
  - Rounded or ovoid, well circumscribed

MR Findings

- T1WI
  - 3rd ventricular mass isointense to brain
  - Hydrocephalus in 10-15% of cases
- T2WI
  - Iso-/hyperintense 3rd ventricular mass
- T1WI C+
  - Strong uniform enhancement

Imaging Recommendations

- Protocol advice
  - Thin section imaging through sella region
    - Thin sagittal, coronal T1WI, T2WI
    - T1WI C+ FS sagittal, coronal

DIFFERENTIAL DIAGNOSIS

Craniopharyngioma

- Heterogeneous, 90% cystic, 90% Ca++
- Suprasellar location most common
- Children > adults

Pilocytic Astrocytoma

- Optic tract, hypothalamus, 3rd ventricular floor
- Children, young adults, ± neurofibromatosis type 1

Germinoma

- Diabetes insipidus common
- Usually involves stalk, suprasellar or pineal region
- Hyperdense on CT, homogeneously enhancing
- Children, young adults

Choroid Plexus Papilloma

- Lobulated, enhancing lateral ventricular mass in child
- Rare in 3rd ventricle
- Typically child < 5 years

Colloid Cyst

- Wedged between fornices at foramen of Monro
- Round, nonenhancing

Ependymoma

- Enhancing 4th ventricular mass typical
- Uncommon in 3rd ventricle

PATHOLOGY

General Features

- Etiology
  - Likely ependymal origin
    - From ependymal cells in or around lamina terminalis
    - May arise from subcommissural organ

Staging, Grading, & Classification

- WHO grade II

Gross Pathologic & Surgical Features

- Grossly well circumscribed
- Occasional extension into adjacent hypothalamic tissue
- Variable calcifications, cystic regions; hemorrhage rare

Microscopic Features

- Cords/clusters of oval/polygonal epithelioid cells within mucinous stroma
  - Strongly GFAP(+); vimentin (+)
  - Mitotic figures uncommon

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache ± nausea due to hydrocephalus
- Other signs/symptoms
  - Visual field defect
  - Endocrine disturbances (10-15%)
    - Hypothyroidism, diabetes insipidus, amenorrhea
  - Dysautonomias (hyperhidrosis)

Demographics

- Age: Adults (35-60 years)
- Gender: Female predominance (M:F = 1:2)
- Epidemiology: Rare, represent < 1% of all gliomas

Natural History & Prognosis

- Slow enlargement

Treatment

- Surgical excision is primary therapy

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Bulky, well-circumscribed 3rd ventricular mass in adult

SELECTED REFERENCES

KEY FACTS

TERMINOLOGY

- Angiocentric glioma (AG) is also known as
  - Angiocentric neuroepithelial tumor (ANET)
  - Monomorphous angiocentric glioma
- Epilepsy-associated, slowly-growing, low-grade cortical neoplasm mainly affecting children and young adults

IMAGING

- Frontal, temporal lobes most common sites
- Nonenhancing, ill-defined cortical mass
  - Most commonly solid
  - Rarely mixed solid, cystic
  - Rim-like hyperintensity on T1WI
- Hyperintense on T2WI, FLAIR
  - Stalk-like extension toward ventricle common

TOP DIFFERENTIAL DIAGNOSES

- Dysembryoplastic neuroepithelial tumor (DNET)
- Ganglioglioma
- Oligodendroglioma

PATHOLOGY

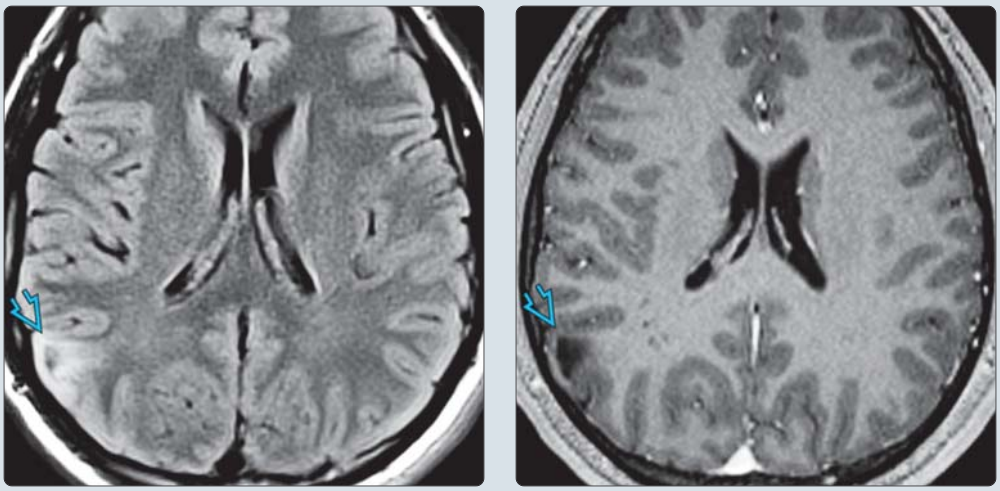
- WHO grade I
  - Angiocentric growth pattern
  - MIB-1 proliferation low (1-5%)
  - No malignant degeneration

CLINICAL ISSUES

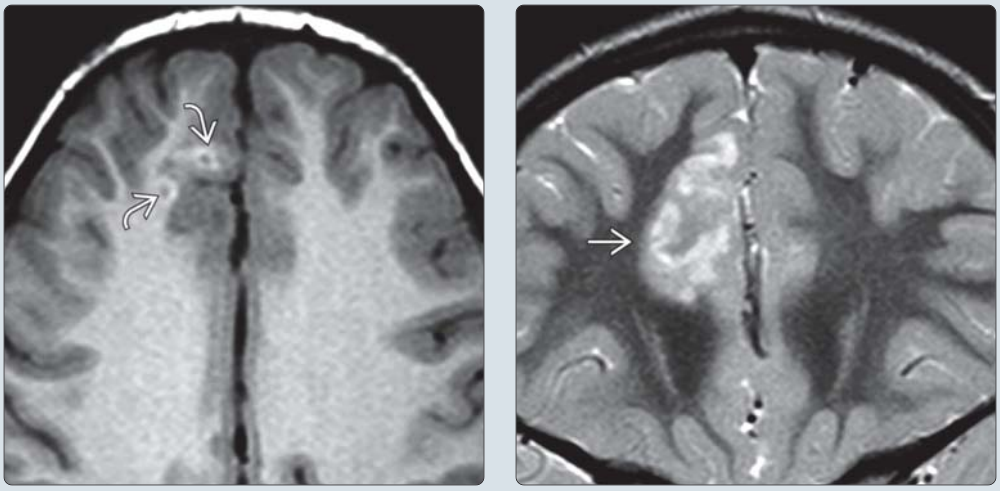
- Longstanding drug-resistant focal epilepsy
  - Typically starting in childhood
- Complete surgical resection curative

DIAGNOSTIC CHECKLIST

- Cortical neoplasm in child/young adult with refractory epilepsy
- Nonenhancing cortical mass with rim-like hyperintensity on T1 MR



(Left) *Axial FLAIR MR in a young adult with longstanding seizures shows a wedge-shaped hyperintense cortical and subcortical mass in the right parietal lobe. Note the lack of surrounding edema.* **(Right)** *Axial T1 C+ MR in the same patient shows no enhancement within the mass, a typical finding in angiocentric glioma. Focal cortical dysplasia is often present adjacent to the tumor and must be resected to prevent recurrent seizures. (Courtesy M Castillo, MD.)*



(Left) *Axial T1WI MR in 6-year-old child with refractory epilepsy shows an ill-defined, cortical and subcortical mass. Note the hyperintense ring-like areas, findings typical for an angiocentric glioma.* **(Right)** *Coronal T2 MR in the same patient shows high signal intensity of the cortical and subcortical right frontal lobe lesion. Angiocentric glioma was diagnosed at surgical resection. Imaging may mimic the more common DNET. (Courtesy A. Rossi, MD.)*

TERMINOLOGY

Abbreviations

- Angiocentric glioma (AG)

Synonyms

- Angiocentric neuroepithelial tumor (ANET)
- Monomorphous angiocentric glioma

Definitions

- Epilepsy-associated, slowly-growing, low-grade cortical neoplasm mainly affecting children and young adults

IMAGING

General Features

- Best diagnostic clue
  - Nonenhancing, ill-defined cortical/subcortical mass in child/young adult with seizures
- Location
  - Cortex or subcortical white matter
  - Frontal > temporal lobes most common sites
- Size
  - 3-4 cm (up to 10 cm)

Imaging Recommendations

- Best imaging tool
  - MR

CT Findings

- Solid, cortically-based tumor
- No calcification, hemorrhage, or necrosis

MR Findings

- T1WI
  - Ill-defined cortical/subcortical mass
  - Most commonly solid
    - Rarely mixed solid, cystic
  - Can be hypo-, iso-, or hyperintense
  - Rim-like hyperintensity may be seen
- T2WI
  - Hyperintense expansile cortical/subcortical mass
  - Stalk-like extension toward ventricle common
- FLAIR
  - Hyperintense
  - Stalk-like extension toward ventricle
- T1WI C+
  - Usually no enhancement

DIFFERENTIAL DIAGNOSIS

Dysembryoplastic Neuroepithelial Tumor (DNET)

- Cortical/subcortical cystic or "bubbly" T2 hyperintense mass
- May be wedge-shaped and point towards ventricle
- Enhancement uncommon

Ganglioglioma

- Cortical mass with cyst and mural nodule is common
- May be predominantly solid mass
- May see Ca++ (30-50%) and enhancement (50%)

Oligodendroglioma

- Round or ovoid T2 hyperintense cortical/subcortical mass
- Ca++ in ~ 80%, variable enhancement

PATHOLOGY

General Features

- Etiology
  - Uncertain origin: Astrocytic and ependymal lineages have been suggested
  - Dysembryoplastic theory
    - Radial glia suggested cell of origin
- Associated abnormalities
  - Adjacent focal cortical dysplasia is common

Staging, Grading, & Classification

- WHO grade I

Microscopic Features

- Small polygonal/spindle-shaped tumor cells with ependymal features
- Angiocentric growth pattern
- MIB-1 proliferation low (1-5%)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Drug-resistant focal epilepsy starting in childhood

Demographics

- Age
  - Children, young adults
- Epidemiology
  - AG represents up to 8% of tumors found at epilepsy surgery

Natural History & Prognosis

- Benign course
- No malignant degeneration

Treatment

- Complete surgical resection curative

DIAGNOSTIC CHECKLIST

Consider

- Cortical neoplasm in child/young adult with longstanding seizures

Image Interpretation Pearls

- Ill-defined nonenhancing cortical mass with rim-like hyperintensity on T1 MR

KEY FACTS

TERMINOLOGY

- Posterior fossa ependymoma (PF-EPN)

IMAGING

- Ependymoma can occur anywhere in neuraxis
- Most common site: Posterior fossa (2/3 of cases)
  - Lobulated mass in body/inferior 4th ventricle
    - Soft or "plastic" tumor
      - Accommodates to shape of ventricle
      - Squeezes through foramen of Magendie into cisterna magna
      - ± extension through foramina of Luschka into CPA cisterns
- NECT
  - Ca++ common (50%)
  - ± cysts, hemorrhage
  - Obstructive hydrocephalus common
- MR
  - Variable enhancement
  - Usually does not restrict on DWI

PATHOLOGY

- 3 posterior fossa ependymoma molecular subtypes
  - Posterior fossa ependymoma subtype A (PF-EPN-A)
    - Most common (50%)
    - Predominately infants
    - Poor prognosis
  - Posterior fossa ependymoma subtype B (PF-EPN-B)
    - 10% of PF-EPNs
    - Older children, adults
    - Better prognosis
  - Subependymoma (PF-SE; discussed in separate chapter)

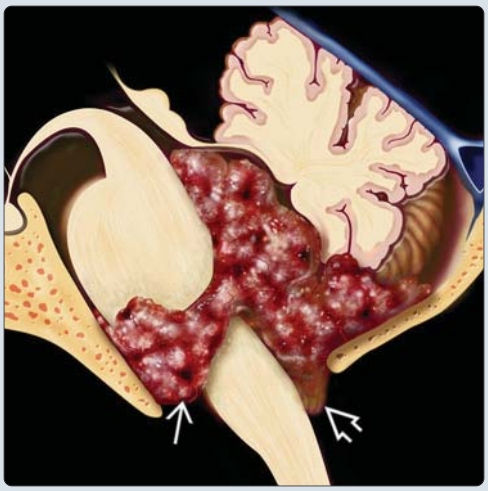
CLINICAL ISSUES

- Signs of increased intracranial pressure
- 3-17% CSF dissemination

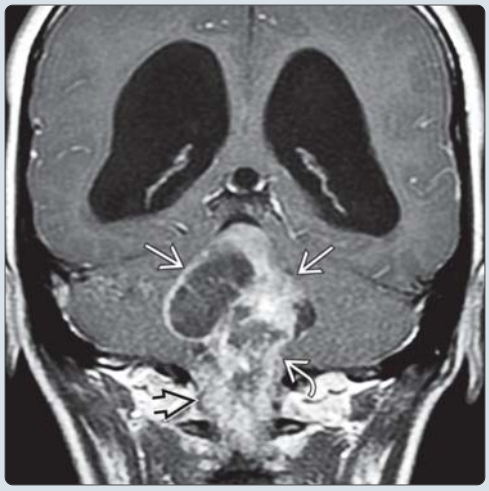
DIAGNOSTIC CHECKLIST

- Much less common than PNET-MB or pilocytic astrocytoma

(Left) *Sagittal graphic shows a posterior fossa ependymoma extending through the 4th ventricle outlet foramina into the cisterna magna ⇨ and CPA cistern ⇨. This "plastic" pattern of growth is typical of ependymoma in this location and increases the difficulty of surgical resection.* **(Right)** *Sagittal T1 C+ MR shows classic PF-EPN as a lobulated mixed cystic/solid enhancing mass displacing the brainstem anteriorly, expanding the 4th ventricle. Tumor extrudes posteroinferiorly through the foramen of Magendie ⇨ into the cisterna magna ⇨.*



(Left) *Axial T1 C+ FS MR scan in the same case shows the enhancing mixed cystic ⇨ and solid ⇨ tumor expanding, filling the 4th ventricle ⇨.* **(Right)** *Coronal T1 C+ MR scan in the same case again shows the mixed cystic/solid enhancing mass conforming to the shape of the expanded 4th ventricle ⇨. The tumor extrudes inferiorly through the enlarged foramen of Magendie ⇨ and extends into the upper cervical spinal canal ⇨. WHO II cellular ependymoma was found at surgery.*



https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Posterior fossa ependymoma (PF-EPN)
  - Slow-growing tumor of ependymal cells
  - Subtypes: Cellular, papillary, clear cell, tanycytic

IMAGING

General Features

- Best diagnostic clue
  - Soft "plastic" tumor squeezes out through 4th ventricle foramina into cisterns
  - Heterogeneous density, signal intensity
  - ± indistinct interface with floor of 4th ventricle
- Location
  - May arise along entire neuraxis (hemispheres, hindbrain, spinal cord)
  - 2/3 posterior fossa (most in 4th ventricle)
    - Usually from inferior 1/2 of 4th ventricle
    - Extends anterolaterally through foramina of Luschka
  - 1/3 supratentorial
    - Majority outside ventricles, in periventricular white matter (WM)
- Size
  - 2-4 cm
- Morphology
  - Accommodates to shape of ventricle
  - Typical = lobulated inferior 4th ventricle mass
    - Anterolateral extension through recess(es) into CPA cistern
    - Posteroinferior extension through foramen of Magendie into cisterna magna

CT Findings

- NECT
  - 4th ventricle mass
  - Ca++ common (50%); ± cysts, hemorrhage
  - Hydrocephalus common
- CECT
  - Variable heterogeneous enhancement

MR Findings

- T1WI
  - Heterogeneous, usually iso- to hypointense
  - Cystic foci slightly hyperintense to CSF
  - Hyperintense foci (Ca++, blood products) common
- T2WI
  - Heterogeneous, usually iso- to hyperintense
  - Hyperintense cystic foci
  - Hypointense foci (Ca++, blood products)
- FLAIR
  - Can show sharp interface between tumor, CSF
  - Tumor cysts very hyperintense to CSF
- T2* GRE
  - "Blooming" of Ca++, hemorrhage
- DWI
  - No restriction (relatively low cellularity)
  - Intratumoral hemorrhage may complicate appearance
- T1WI C+
  - Enhancement
    - Varies from none to mild/moderate
    - Typically heterogeneous
- MRS
  - ↓ NAA, ↑ Cho
    - NAA:Cho ratio higher than in primitive neuroectodermal tumor-medulloblastoma (PNET-MB)
  - ↑ lactate
  - MR spectroscopy alone does not reliably differentiate ependymoma from astrocytoma or PNET-MB

Imaging Recommendations

- Best imaging tool
  - NECT + MR with contrast, MRS
- Protocol advice
  - Image entire neuraxis before surgery
  - Need combination of imaging, clinical findings to distinguish from PNET-MB
  - High-quality sagittal imaging can distinguish point of origin as floor vs. roof of 4th ventricle

DIFFERENTIAL DIAGNOSIS

Medulloblastoma (PNET-MB)

- Hyperdense on NECT
- Homogeneous mass
- Arises from roof of 4th ventricle
- More distinct interface with floor
- Low ADC, high cellularity

Cerebellar Pilocytic Astrocytoma (PA)

- Heterogeneous tumor of cerebellar hemisphere
- Cyst with mural nodule
- Solid portion enhances vigorously

Brainstem Glioma

- Infiltrating mass expanding brainstem
- Homogeneous signal on MR
- May project dorsally into 4th ventricle

Atypical Teratoid/Rhabdoid Tumor (AT/RT)

- Large mass with cyst or necrosis
- Variable enhancement pattern

Choroid Plexus Papilloma

- Vigorously enhancing intraventricular tumor
- 4th ventricle location more common in adults

Oligodendroglioma

- Heterogeneous supratentorial mass in young adults
- Frontal lobe lesion with Ca++

Glioblastoma

- Older adults; rare in posterior fossa
- Heterogeneous malignant supratentorial mass
- Necrosis, hemorrhage common

PATHOLOGY

General Features

- Etiology
  - Thought to arise from regionally distinct radial glial cells
    - Differences between these cell populations carried forward in neoplasm

https://CafePezeshki.IR

- May account for part of observed heterogeneity
- Genetics
  - Gene amplifications almost totally absent
    - Gains or losses of whole chromosomes characteristic
    - Epigenetic abnormalities most important
  - DNA methylation profiling identifies 9 molecular ependymoma subgroups
  - 3 posterior fossa ependymoma subgroups
    - Subependymoma (PF-SE)
    - Posterior fossa ependymoma subtype A (PF-EPN-A)
      - Largest ependymoma subgroup (~ 50% of all cases)
      - Predominately infants
      - Stable genome ("genetically bland")
      - Epigenetically deregulated (CpG island methylator phenotype-positive [CIMP(+)])
      - Highly malignant with poor response to surgery, radiation therapy
      - **But** CIMP+ ("methylated") tumors may be responsive to drugs targeting DNA or H3K27 methylation
    - Posterior fossa ependymoma subtype B (PF-EPN-B)
      - Older children, adults
      - 10% of all cases
      - Most unstable genome of all ependymomas
      - Large-scale copy number alterations (often whole chromosome gains/losses)
      - Better prognosis
      - CIMP(-)
  - Molecular subgroups remain stable at relapse
  - Risk stratification by molecular subgrouping superior to histological grading

Staging, Grading, & Classification

- WHO grade II (low grade, well differentiated)
- WHO grade III (high grade, anaplastic)

Gross Pathologic & Surgical Features

- Well demarcated
- Soft, lobulated, grayish red mass
- ± cysts, necrosis, hemorrhage
- Extrudes through 4th ventricle outlet foramina into "plastic development"
- Typically displaces rather than invades adjacent brain parenchyma

Microscopic Features

- Despite being histologically identical, ependymomas from different anatomic regions are biologically and clinically distinct

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - ↑ intracranial pressure: Headache, nausea, vomiting
- Clinical profile
  - Age 1-5 years; headache, vomiting
- Other
  - Ataxia, hemiparesis, visual disturbances, neck pain, torticollis, dizziness
  - Infants: Irritability, lethargy, developmental delay, vomiting, macrocephaly

Demographics

- Age
  - PF-EPN-A
    - 1-5 years (mean: 3 years)
  - PF-EPN-B
    - Mean age at diagnosis: 30 years
- Gender
  - Slight male predominance
- Epidemiology
  - 3-5% of all intracranial tumors
  - 15% of posterior fossa tumors in children
    - 3rd most common posterior fossa tumor in children
      - Most common are PA and PNET-MB

Natural History & Prognosis

- Prognosis highly variable
  - PF-EPN-A 5-year overall survival: 50-60%
  - PF-EPN-B: 90-95% 5-year survival
- 3-17% CSF dissemination
- 5-year survival after recurrence: 15%

Treatment

- Maximal safe surgical resection, then XRT
  - Surgical resection often difficult due to adherence and infiltrating nature of tumor
  - Gross total resection + XRT correlates with improved survival
- Chemotherapy does not improve survival

DIAGNOSTIC CHECKLIST

Consider

- Much less common than PNET-MB or PA
- Gross total resection has greater impact on survival than in PNET-MB or PA
- Surveillance imaging to detect asymptomatic recurrence can increase survival

Image Interpretation Pearls

- Indistinct interface
  - With **floor** of 4th ventricle = ependymoma
  - With **roof** of 4th ventricle = PNET-MB

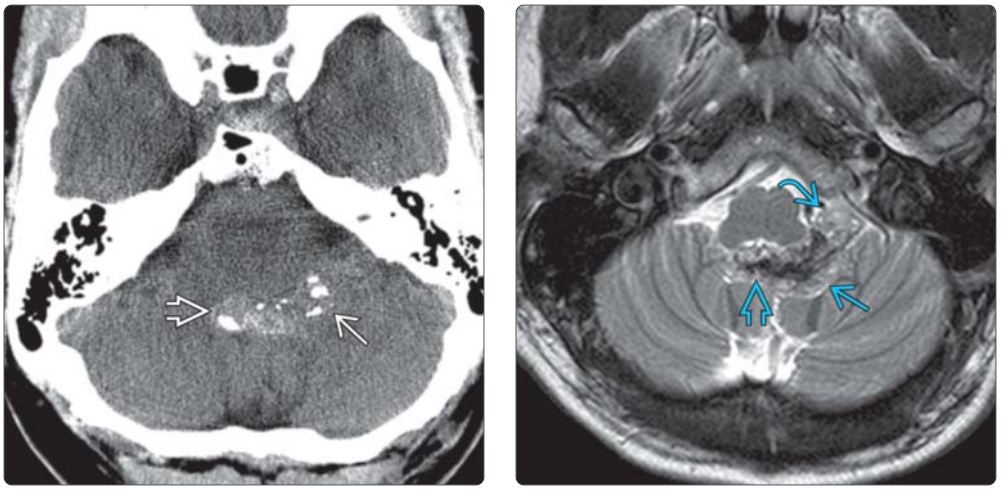
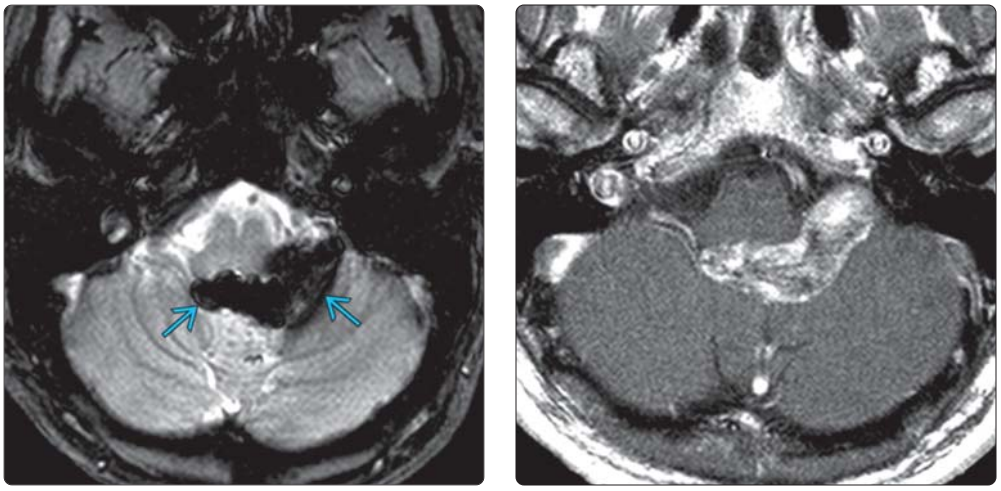
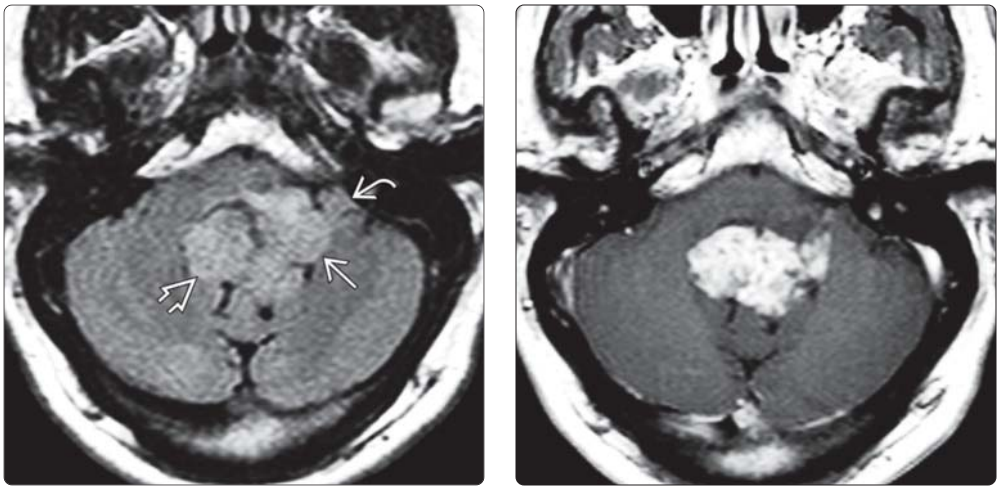
https://CafePezeshki.IR



(Left) *Axial NECT scan shows a partially calcified hyperdense mass in the inferior 4th ventricle. Note extension toward the right cerebellopontine angle cistern.* **(Right)** *Axial T2 MR in the same case shows that the mass is well-demarcated and extends from the midline of the inferior 4th ventricle through the left lateral recess and projects into the cerebellopontine angle cistern.*



(Left) *T2* GRE MR scan in the same case shows extensive "blooming", probably from both tumoral calcification and hemorrhage.* **(Right)** *Axial T1 C+ MR in the same case shows that the mass enhances moderately but heterogeneously. The lobulated, "plastic" appearance of the tumor "squeezing" out through the foramen of Luschka is characteristic of ependymoma.*



(Left) *Axial FLAIR MR in a 49-year-old man with suboccipital headaches shows a lobulated, slightly hyperintense mass in the 4th ventricle. Note anterolateral extension through the left foramen of Luschka into the left cerebellopontine angle cistern.* **(Right)** *Axial T1 C+ MR in the same case shows that the mass enhances strongly but somewhat heterogeneously. WHO grade II tanycytic ependymoma was found at surgery.*

https://CafePezeshki.IR

KEY FACTS

IMAGING

- General location of ependymomas
  - 2/3 infratentorial, 1/3 supratentorial
  - 45-65% of supratentorial ependymomas (STEs) are **extraventricular**
  - Common locations of STEs: Cerebral hemisphere > 3rd ventricle > lateral ventricle
- General features
  - Large, complex-appearing mixed solid/cystic hemispheric mass
  - Calcification, intratumoral hemorrhage common
  - Moderate but inhomogeneous enhancement

TOP DIFFERENTIAL DIAGNOSES

- Glioblastoma
- Ganglioglioma
- Astroblastoma
- Oligodendroglioma/anaplastic oligodendroglioma
- Pleomorphic xanthoastrocytoma
- Supratentorial PNET
- Atypical teratoid-rhabdoid tumor

PATHOLOGY

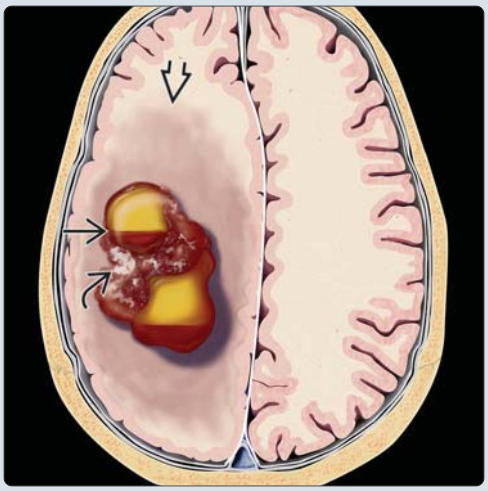
- Majority of adult STEs are WHO grade III tumors

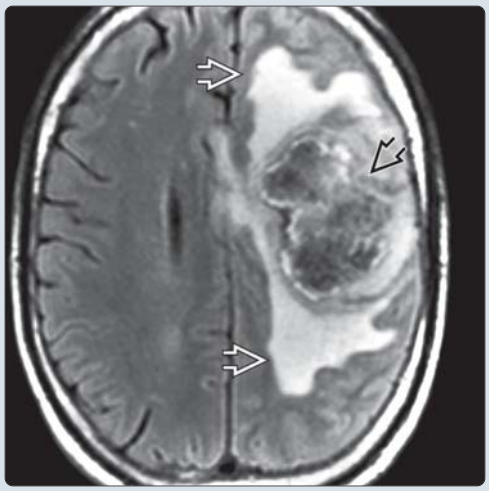
CLINICAL ISSUES

- Older children, adults
  - Seizures
- Most important prognostic factor: Location
- Children < 3 years have poor outcome

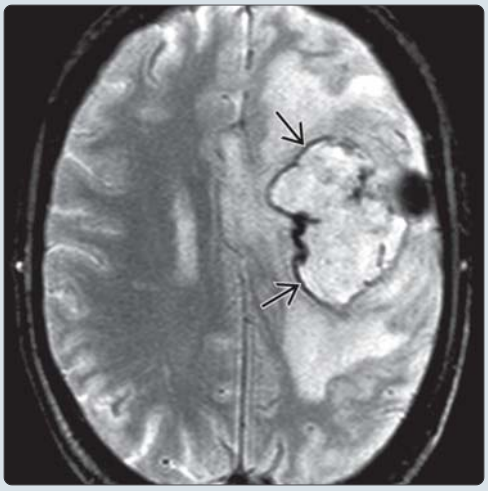
DIAGNOSTIC CHECKLIST

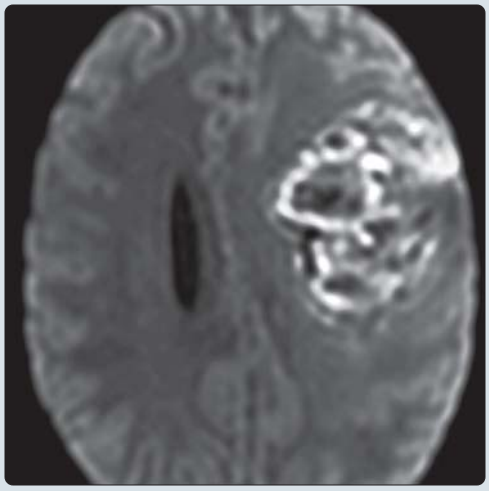
- If large, mixed solid-cystic, calcified hemispheric/cortical mass in older children or adult, think STE





(Left) *Graphic depicts supratentorial ependymoma (STE) as a large, hemorrhagic hemispheric mass with multiple cysts, fluid-fluid levels ⇨, calcifications ⇨, significant mass effect, and peritumoral edema ⇨.* **(Right)** *Axial FLAIR MR in a 47-year-old man with anaplastic (grade III) hemispheric STE shows an inhomogeneous extraventricular mass in the left frontal lobe ⇨ with perifocal edema ⇨.*





(Left) *Axial T2* GRE MR in the same patient demonstrates a rim of peripheral low signal intensity ⇨ indicating hemorrhage. STEs commonly demonstrate intratumoral hemorrhage.* **(Right)** *Axial DWI MR in the same patient reveals inhomogeneous high signal of the tumor, representing areas of elevated diffusion (dark) and areas of restricted diffusion due to hemorrhage (hyperintense).*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Supratentorial ependymoma (STE)

Synonyms

- Hemispheric STE (a.k.a. brain surface ependymoma)
- Supratentorial ectopic cortical ependymoma
- Cortical ependymoma

Definitions

- Ependymoma in supratentorial location

IMAGING

General Features

- Best diagnostic clue
  - Large, complex-appearing mixed solid/cystic hemispheric mass
- Location
  - General location of ependymomas
    - 2/3 infratentorial (ITE)
    - 1/3 supratentorial (STE)
  - 45-65% of STEs are **extraventricular**
    - Hemispheric white matter or cortex
      - Frontal lobe most common location of cortical STEs
      - In cortex or infiltrating cortex from white matter
    - Rare: Suprasellar region
  - Less common location = intraventricular
    - 3rd ventricle > lateral ventricle
- Size
  - STEs often larger size at presentation than ITEs
    - 95% > 4 cm

CT Findings

- NECT
  - Mixed iso-/hypodense
    - Hyperdense = solid portion
    - Hypodense = cystic component
    - Calcifications (44%)
      - Can be small scattered foci or very extensive
  - May show bone destruction (tumor invades meninges, dura, and bone)

MR Findings

- T1WI
  - Iso-/hypointense
  - Cysts follow CSF
- T2WI
  - Variable morphological features
    - Cystic with mural nodule
    - Solid mass
    - Huge, partially necrotic mass
  - Variable signal
    - Hyper-/hypointense (high cellularity, calcifications)
    - Cysts hyperintense (CSF)
- T2* GRE
  - Low signal indicates hemorrhage or calcifications
- DWI
  - High signal with low ADC in hypercellular solid portions
- T1WI C+
  - Moderately intense enhancing tumor (solid parts) with necrotic foci
  - Rarely nonenhancing
  - Pattern
    - Cystic + mural nodule appearance (often in hemispheric location)
      - Mural nodule moderate or intensely enhancing
      - Nonenhancing or rim-enhancing cysts
  - Continuity with ventricle may be present
  - Continuity with surface present in cortical STE

Imaging Recommendations

- Best imaging tool
  - MR ± contrast
  - T2* (hemorrhage, calcification)

DIFFERENTIAL DIAGNOSIS

Glioblastoma

- If STE presents as huge partially necrotic mass
- Less common: Low-grade anaplastic astrocytoma

Astrocytoma (Other)

- Anaplastic astrocytoma, anaplastic pleomorphic xanthoastrocytoma can be very complex, heterogeneous-appearing

Oligodendroglioma, Anaplastic Oligodendroglioma

- Cerebral hemispheres
- Cortical and subcortical locations
- Calcifications
- Scalloping of inner table of skull

Astroblastoma

- Older children and young adults
- Solid cystic mass
- Supratentorial location
- Calcifications

Supratentorial PNET

- Children < 5 years of age
- Clearly separated from ventricle

Atypical Teratoid-Rhabdoid Tumor

- Very young children

Ganglioglioma

- Most common in temporal lobe
- Not as complex-appearing (usually cyst + nodule)

Angiocentric Glioma

- Children, young adults
- Nonenhancing cortical mass
- Rim-like hyperintensity on T1WI
- Epilepsy since childhood

Papillary Glioneuronal Tumor

- Cortical mass, often with connection to ventricle
- Calcifications
- May be cystic or have nodule-cystic appearance

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - General: Ependymoma is glial-based neoplasm arising from ependymal lining of ventricular system
  - Extraventricular STEs arise either from
    - Fetal rests of ependymal cells located at angle of ventricles
    - Random distribution of fetal ependymal rests located periventricularly
- Genetics
  - Gains of 1q (associated with aggressive clinical behavior), 12q, 7q, 8, 9
  - Perinuclear LRIG3 proteins more highly expressed in STE than ITE
  - Complete and partial losses of chromosomes 22, 22q, 10q, 3, 6q, 9q
    - 9q contains P16 *INK4A* gene often seen in STE
  - Upregulation of components of EphB-ephrin and Notch signaling pathways in STE
  - New entity: **Trisomy 19 ependymoma**
    - WHO grade III
    - Occurs in 9% of ependymomas

Staging, Grading, & Classification

- WHO grade I includes subependymoma and myxopapillary ependymoma
- WHO grade II ependymoma
  - 4 variants: Cellular, papillary, clear cell, and tanycytic
- WHO grade III anaplastic ependymoma
  - Majority of adult STEs are WHO grade III tumors
  - Defined by presence of any 2 of 4 + factors
    - 4 mitoses per 10 high-power fields (brisk mitotic activity)
    - Hypercellularity
    - Endothelial proliferation
    - Necrosis (pseudopalisading necrosis)

Gross Pathologic & Surgical Features

- Well-delineated tumors
- Lobulated mass, grayish-red surface, hemorrhagic and calcified parts

Microscopic Features

- Histological hallmarks
  - Perivascular rosettes
  - Ependymal rosettes
  - GFAP(+)
- Nonrosetting angiocentric growth pattern
- Variable amount of solid tumor growth
- Low proliferative index
- Infiltrating brain parenchyma
  - Infiltration along axonal tracts, perineuronal satellitosis, subpial mounding

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizures most common symptom
  - Focal motor or sensory deficit, headache

Demographics

- Age
  - Bimodal
    - Most in children 1-5 years, smaller peak 20-30 years
- Gender
  - M > F
- Epidemiology
  - Ependymomas = 1.2-7.8% of all intracranial tumors
  - 3rd most common intracranial neoplasm in children

Natural History & Prognosis

- 5-year survival for supratentorial ependymomas (72%), significantly better than for infratentorial
- Higher recurrence rate for 3rd ventricular tumors (compared to hemispheric tumors)
- Most important prognostic factor: Location
- Children < 3 years have poor outcome

Treatment

- Gross total resection with adjuvant radiotherapy

DIAGNOSTIC CHECKLIST

Consider

- Large, solid-cystic, calcified mass in ventricular or cortical location in older children or adults

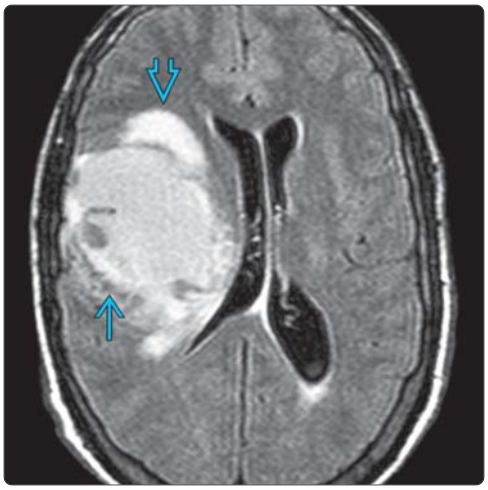
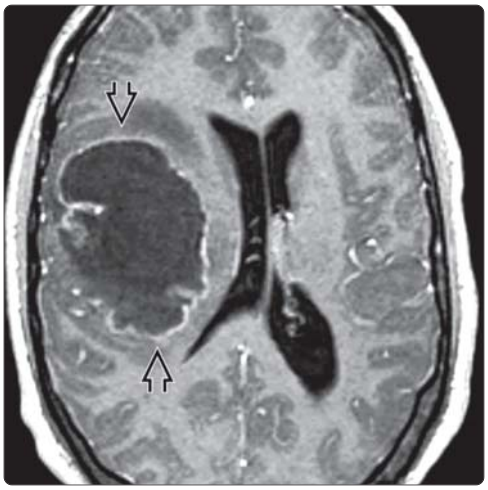
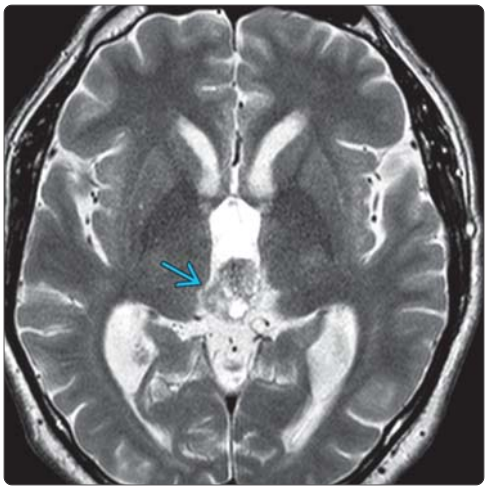
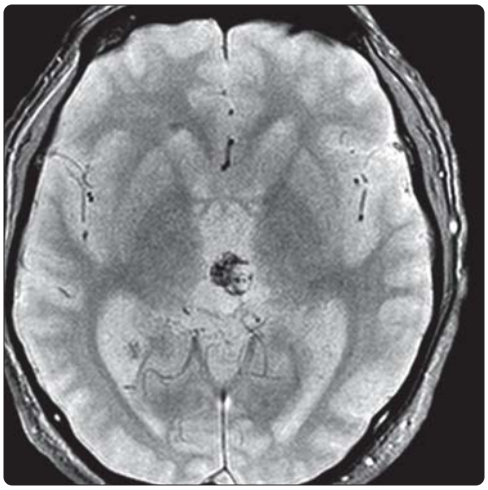
https://CafePezeshki.IR



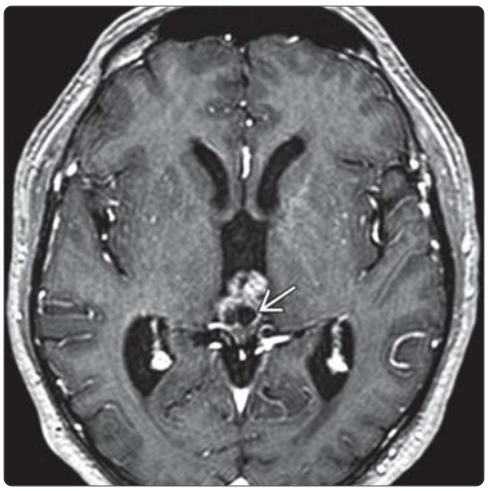


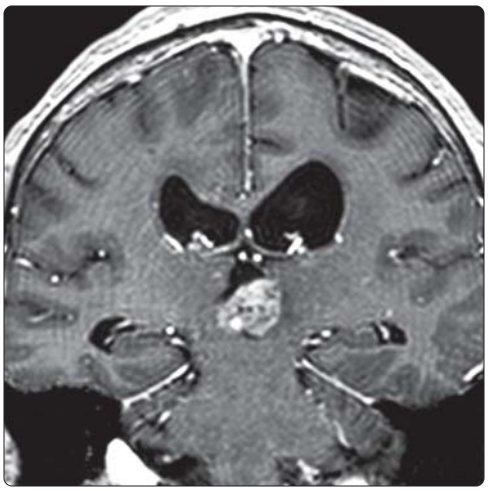
(Left) *Axial FLAIR MR shows a large, cystic mass in the right hemisphere with perifocal edema and compression of the right ventricle with minimal midline shift.* **(Right)** *Axial T1WI C+ MR in the same patient shows peripheral enhancement around a nonenhancing cystic component. STE was found at surgery. This STE does not show any contiguity with the ventricular system.*





(Left) *Axial T2WI MR in a patient with STE shows an inhomogeneous mass in the 3rd ventricle. Note the relatively low signal, small intratumoral cysts.* **(Right)** *Axial T2* GRE MR in the same case shows blooming, hypointense foci indicating calcification or hemorrhage.*





(Left) *Axial T1WI C+ MR in the same patient demonstrates marked but inhomogeneous enhancement. Note the solid portions, intratumoral cysts of various sizes, and a larger cyst with rim enhancement.* **(Right)** *Coronal T1WI C+ MR in the same patient demonstrates an inhomogeneously enhancing nodular mass within the 3rd ventricle.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Rare, benign, well-differentiated, intraventricular ependymal tumor, typically attached to ventricular wall

IMAGING

- Intraventricular, inferior 4th ventricle typical (60%)
- Other locations: Lateral > 3rd ventricle > spinal cord
- T2/FLAIR hyperintense intraventricular mass
  - Heterogeneity related to cystic changes; blood products or Ca++ may be seen in larger lesions
- Variable enhancement, typically none to mild
- T2WI and FLAIR are often most sensitive sequences

TOP DIFFERENTIAL DIAGNOSES

- Ependymoma
- Central neurocytoma
- Subependymal giant cell astrocytoma
- Choroid plexus papilloma (CPP)
- Hemangioblastoma
- Metastases

PATHOLOGY

- WHO grade I

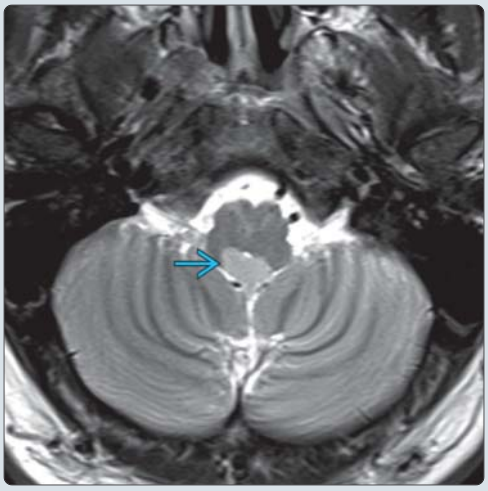
CLINICAL ISSUES

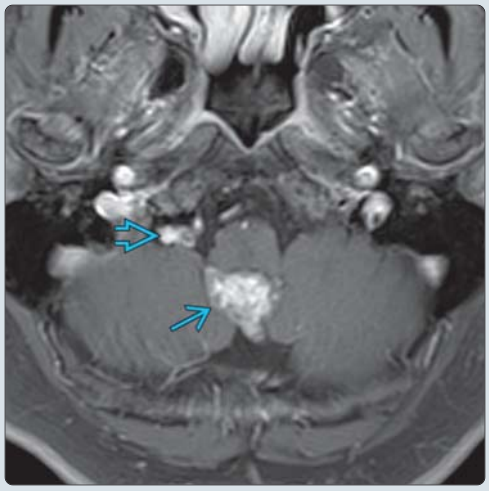
- 40% become symptomatic, often supratentorial
  - Related to increased intracranial pressure, hydrocephalus
- Present in middle-aged/elderly adults (typically 5th-6th decades)
- Treatment: Conservative management with serial imaging if asymptomatic patient
- Surgical resection is curative in most cases
- Excellent prognosis for supratentorial lesions
  - Recurrence is extremely rare

DIAGNOSTIC CHECKLIST

- If 4th or lateral ventricular hyperintense mass in elderly man, think subependymoma

(Left) *Sagittal graphic shows a solid, well-circumscribed mass arising from the floor of the 4th ventricle with mild mass effect. Note the lack of hydrocephalus, typical of subependymoma.* **(Right)** *Sagittal FLAIR MR shows a solid, hyperintense mass along the inferior 4th ventricle in a 64-year-old man with headaches. Subependymoma was found at resection. These 4th ventricular tumors are often asymptomatic. T2 and FLAIR are typically the most sensitive sequences to identify this WHO grade I tumor.*





(Left) *Axial T2WI MR shows a hyperintense mass along the inferior 4th ventricle at the level of the medulla (classic imaging of a subependymoma).* **(Right)** *Axial T1 C+ MR shows an enhancing mass in the 4th ventricular outflow tract. The moderate enhancement is uncommon. Subependymomas classically have no or minimal enhancement. They can protrude through the foramen of Magendie. In this case, tumor is also present anterior to the cerebellar hemisphere through the foramen of Luschka.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Older literature: Subependymal glomerulate astrocytoma, subependymal astrocytoma, subependymal mixed glioma

Definitions

- Rare, benign, well-differentiated, intraventricular ependymal tumor, often attached to ventricular wall

IMAGING

General Features

- Best diagnostic clue
  - T2-hyperintense, lobular, nonenhancing, intraventricular mass
- Location
  - Typical: Intraventricular, inferior 4th ventricle (60%)
    - Often protrudes through foramen of Magendie
  - Other locations: Lateral > 3rd ventricle > spinal cord (cervical or cervicothoracic)
    - Lateral ventricle: Attached to septum pellucidum or lateral wall
  - Rare: Periventricular
- Size
  - Typically small, 1-2 cm
  - May become large, > 5 cm
    - More commonly symptomatic when large
- Morphology
  - Well-defined, solid, lobular mass
  - When large, may see cysts, hemorrhage, Ca++

CT Findings

- NECT
  - Iso- to hypodense intraventricular mass
  - Cysts or Ca++ may be seen in larger lesions
  - Rarely hemorrhage
- CECT
  - No or mild enhancement typical
  - Heterogeneous enhancement may be seen

MR Findings

- T1WI
  - Intraventricular mass, hypo- or isointense to white matter
  - Typically homogeneous solid mass
  - Heterogeneity may be seen in larger lesions
- T2WI
  - Hyperintense intraventricular mass
  - Heterogeneity related to cystic changes; blood products or Ca++ may be seen in larger lesions
  - No edema seen in adjacent brain parenchyma
- FLAIR
  - Hyperintense intraventricular mass
  - No edema seen in adjacent brain parenchyma
- T2* GRE
  - May see Ca++ "bloom" in larger lesions and 4th ventricle location
- T1WI C+
  - Variable enhancement, typically none to mild
  - Marked enhancement may be seen: More common in 4th than lateral ventricular subependymomas

Nuclear Medicine Findings

- PET
  - Rare reports show exceedingly low rates of glucose metabolism and kinetic constants
    - Hypometabolism indicates low cellular density and slow growth

Imaging Recommendations

- Best imaging tool
  - MR is most sensitive
  - CT may be useful for calcification
- Protocol advice
  - Multiplanar contrast-enhanced MR including T2WI, FLAIR

DIFFERENTIAL DIAGNOSIS

Ependymoma

- Younger patients
- Heterogeneous, enhancing mass with edema
- Typically 4th ventricular mass with hydrocephalus
- Often parenchymal when supratentorial

Central Neurocytoma

- Typical bubbly appearance, Ca++ common
- Lateral ventricle, attached to septum pellucidum
- Moderate to strong enhancement

Subependymal Giant Cell Astrocytoma

- Enhancing mass at foramen of Monro
- Ca++ common
- Tuberous sclerosis patients: Subependymal nodules, cortical tubers, white matter lesions

Choroid Plexus Papilloma (CPP)

- Typically pediatric tumors, lateral ventricle
- In adults, 4th ventricle
- Enhancing papillary mass, hydrocephalus common

Hemangioblastoma

- Cystic mass with enhancing mural nodule
- Typically cerebellar hemispheres, often at pial surface
- Rarely intraventricular

Metastases

- Primary tumor often known
- Often multiple lesions at gray-white junctions
- Typically involve choroid plexus if intraventricular

Cavernous Malformation

- Rarely intraventricular, 2.5-11% of cases
- Ca++ and T2 hypointense hemosiderin rim common
- Enhancement variable

PATHOLOGY

General Features

- Etiology
  - Proposed cells of origin: Subependymal glia, astrocytes of subependymal plate, ependymal cells
    - Development from subependymal glial precursors appears likely

https://CafePezeshki.IR

- Genetics
  - Most are sporadic
  - Rare familial cases have been reported
- Associated abnormalities
  - Contains both astrocytes and ependymal elements
  - Occasionally coexists with cellular ependymomas
  - Rare: Multiple lesions

Staging, Grading, & Classification

- WHO grade I

Gross Pathologic & Surgical Features

- Solid, well-delineated, white to grayish, avascular mass
- Firmly attached to site of origin
  - 4th ventricle: Floor typical
  - Lateral ventricle: Septum pellucidum or lateral wall
- Larger lesions are lobulated, more often Ca++; hemorrhage, cyst formation common
- 4th ventricular lesions often protrude out of foramen of Magendie

Microscopic Features

- Highly fibrillar, low cellularity with nuclei clustering
- Microcystic change common in tumors near foramen of Monro
- Ca++ is commonly seen in 4th ventricle tumors
- Mitoses are rare or absent, MIB < 1%
- Hemorrhage is rare
- Immunohistochemistry: Strongly GFAP(+)
- Electron microscopy: Closely packed cell processes filled with glial intermediate filaments

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Most asymptomatic
  - 40% become symptomatic, often supratentorial
    - Related to increased intracranial pressure, hydrocephalus
      - Headache, gait ataxia, visual disturbance, cranial neuropathy, nystagmus, vertigo, nausea, vomiting

Demographics

- Age
  - Middle-aged/elderly adult (typically 5th-6th decades)
    - Asymptomatic patients: Mean age = 60 years
    - Symptomatic patients: Mean age = 40 years
  - Rare in children
- Gender
  - Male predominance
- Epidemiology
  - Reported in 0.5-1% of autopsies
  - Account for 0.7% of intracranial neoplasms
  - Represent ~ 8% of ependymal tumors

Natural History & Prognosis

- Excellent prognosis for supratentorial lesions
- Recurrence is extremely rare
- Complications include hydrocephalus and rarely hemorrhage
- Rare, benign, slow-growing tumors often found incidentally at imaging or autopsy

Treatment

- Surgical resection is curative in most cases
  - Lateral ventricle lesions: Complete resection
  - 4th ventricle lesions: Subtotal resection more common
- Perioperative mortality low but increased by attachment of tumor to adjacent structures
- If hydrocephalus, CSF diversion may be required
- Adjuvant radiation therapy is controversial
- Conservative management with serial imaging if asymptomatic

DIAGNOSTIC CHECKLIST

Consider

- Other intraventricular tumors tend to enhance more prominently
- May be indistinguishable from ependymoma or central neurocytoma
- Differential diagnosis varies with age
  - Adults: Central neurocytoma, choroid plexus papilloma, metastases, hemangioblastoma
  - Children: Ependymoma, choroid plexus papilloma, subependymal giant cell astrocytoma

Image Interpretation Pearls

- If 4th or lateral ventricular hyperintense mass in an elderly man, think subependymoma
- T2WI and FLAIR are often most sensitive

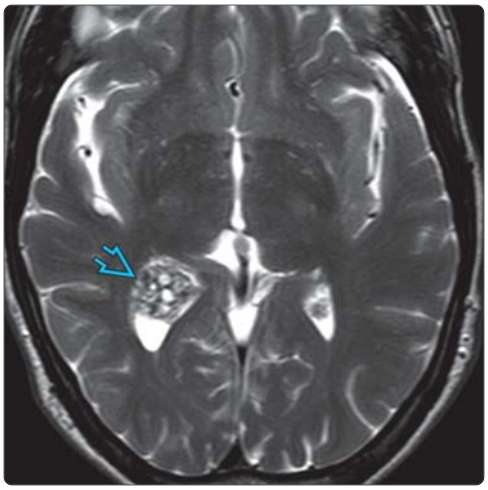
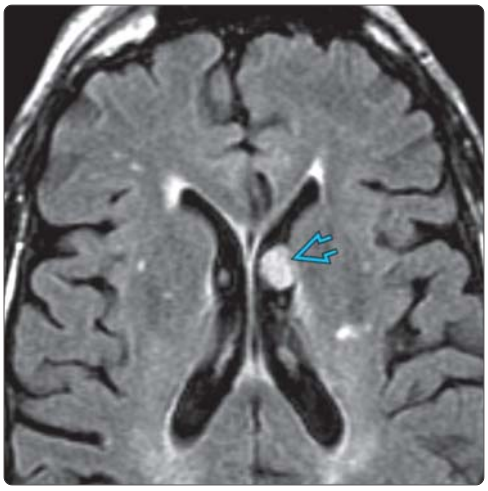
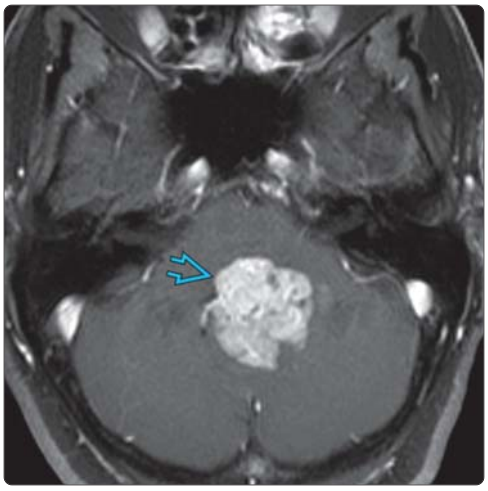
https://CafePezeshki.IR



(Left) *Axial T2 MR shows a heterogeneous right lateral ventricle mass in a 58-year-old man. Subependymoma was found at resection. Imaging mimics a cavernous malformation.* **(Right)** *Sagittal T1WI C+ MR shows a mildly enhancing mass. Subependymomas are most commonly found in the inferior 4th ventricle (50-60%). The lateral ventricle is the next most common location (30-40%). These tumors are primarily treated conservatively or with surgical resection, which is typically curative.*



(Left) *Coronal graphic shows a solid, well-circumscribed, intraventricular mass attached to the septum pellucidum with neither mass effect nor hydrocephalus. Subependymomas are typically asymptomatic, but they may cause hydrocephalus and increased intracranial pressure.* **(Right)** *Axial FLAIR MR shows a hyperintense lateral ventricle mass at the level of the septum pellucidum. When in the lateral ventricle, subependymomas are typically attached to the septum pellucidum or lateral wall.*



(Left) *Axial T1 C+ MR shows a markedly enhancing 4th ventricular mass. Differential considerations include ependymoma and choroid plexus papilloma. Subependymoma was diagnosed at resection.* **(Right)** *Sagittal T2WI MR shows a heterogeneous mass filling the 4th ventricle with inferior extension. Enhancement was present on contrast images of this WHO grade I subependymoma. Cysts, blood, and calcification may be seen in larger lesions. Imaging mimics ependymoma and hemangioblastoma.*

https://CafePezeshki.IR

Typical Choroid Plexus Papilloma

KEY FACTS

TERMINOLOGY

- Choroid plexus tumor (CPT)
  - 3 types of CPTs
    - Choroid plexus papilloma (CPP)(WHO grade I)
    - Atypical choroid plexus papilloma (aCPP)(grade II)
    - Choroid plexus carcinoma (CPCa)(grade III)

IMAGING

- Classic: Child with enhancing lobulated (cauliflower-like) mass in atrium of lateral ventricle
- CPPs occur in proportion to amount of choroid plexus
  - 50% in lateral ventricle (usually atrium)
  - 40% in 4th ventricle &/or foramina of Luschka
  - 5% in 3rd ventricle (roof)
- Hydrocephalus (overproduction, obstructive)

TOP DIFFERENTIAL DIAGNOSES

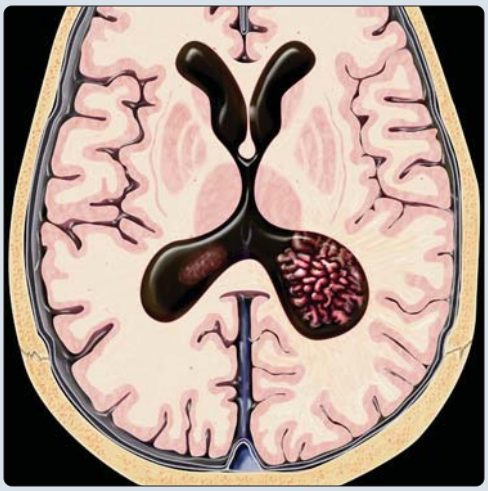
- Atypical choroid plexus papilloma
- Choroid plexus carcinoma
- Physiologic choroid plexus enlargement
- Choroid plexus xanthogranuloma
- Meningioma
- Intraventricular metastasis
- Medulloblastoma
- Ependymoma

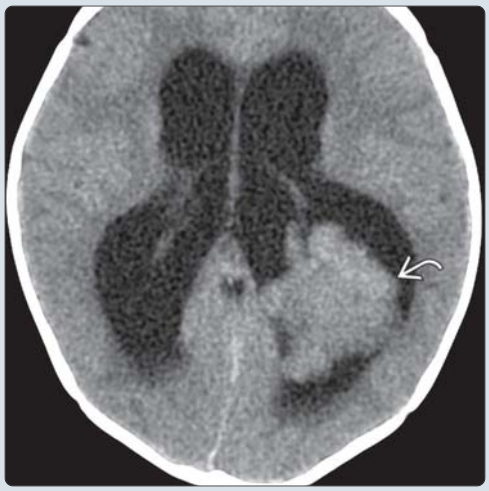
CLINICAL ISSUES

- Most common brain tumor in children < 1 year old
  - 13.1% of all brain tumors in 1st year of life
  - 7.9% of fetal brain tumors diagnosed by ultrasound
- Benign, slowly growing
  - ± CSF spread (does not distinguish CPP from CPCa)
  - Malignant progression rare

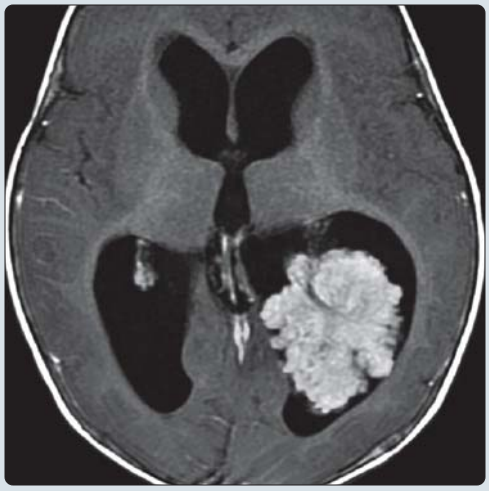
DIAGNOSTIC CHECKLIST

- Consider CPP if intraventricular mass in child < 2 years old
- Imaging cannot reliably distinguish CPP from aCPP, CPCa





(Left) *Axial graphic shows a choroid plexus papilloma (CPP) arising from the glomus of the left lateral ventricular trigone. Note the characteristic frond-like surface projections. CPPs are most common in the lateral ventricles of a child.* **(Right)** *Axial NECT in a child with macrocephaly shows hydrocephalus with a lobulated mass ⇄ in the atrium of the left lateral ventricle.*



(Left) *Axial T2WI MR in the same patient shows a heterogeneously hyperintense lateral ventricle mass with scattered hypointense flow voids ⇨ indicating high vascularity. The lobulated nature of the mass is striking.* **(Right)** *Axial T1WI C+ MR shows marked enhancement of the lobular mass with frond-like projections, characteristic of CPP. CPP cannot be reliably differentiated from atypical choroid plexus papilloma (aCPP) by conventional imaging alone.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Choroid plexus tumor (CPT)
  - 3 recognized subtypes of CPTs
    - Choroid plexus papilloma (CPP)
    - Atypical choroid plexus papilloma (aCPP)
    - Choroid plexus carcinoma (CPCa)

Definitions

- Benign (WHO grade I) papillary neoplasm derived from choroid plexus epithelium

IMAGING

General Features

- Best diagnostic clue
  - Child with strongly enhancing lobulated (cauliflower-like) intraventricular mass
- Location
  - CPPs occur in proportion to amount of normally present choroid plexus
    - 50% → atrium of lateral ventricle, left > right
    - 40% → 4th ventricle (posterior medullary velum) and foramina of Luschka
    - 5% → 3rd ventricle (roof)
    - 5% → multiple sites (synchronous lesions at diagnosis)
    - Rare: Cerebellopontine angle, suprasellar, intraparenchymal
- Size
  - Varies from tiny to huge
- Morphology
  - Cauliflower-like mass

CT Findings

- NECT
  - Intraventricular lobular mass
  - 75% iso- or hyperattenuating
  - Ca++ in 25%
  - Hydrocephalus
    - Overproduction of CSF → obstruction
    - Can be as much as 800-1,500 mL/day
- CECT
  - Intense, homogeneous enhancement
    - Heterogeneous enhancement suggests choroid plexus carcinoma
  - No or minimal parenchymal invasion

MR Findings

- T1WI
  - Well-delineated iso- to hypointense lobular mass
- T2WI
  - Iso- to hyperintense mass
  - ± internal linear and branching vascular flow voids
  - Large CPP may bury itself within brain parenchyma
    - Extensive invasion suggests CPCa
  - Hydrocephalus common
- FLAIR
  - Bright periventricular signal
    - Periventricular interstitial edema due to ventricular obstruction common
    - Asymmetric ipsilateral T2 hyperintensity may suggest invasion and CPCa
- T2* GRE
  - ± foci of diminished signal if Ca++ &/or blood products are present
- T1WI C+
  - Robust homogeneous enhancement
  - Occasional cysts and small foci of necrosis
  - Look for CSF dissemination
- MRA
  - Flow-related signal within mass
  - Enlarged choroidal artery (trigonal mass)
- MRS
  - NAA absent, mild ↑ choline, lactate if necrotic
  - Myoinositol (mI) elevation in CPP may help to distinguish from CPCa

Ultrasonographic Findings

- Grayscale ultrasound
  - Hyperechoic mass with frond-like projections
  - Mass echogenicity similar to normal choroid plexus
  - Hydrocephalus

Angiographic Findings

- Conventional
  - Enlarged choroidal arteries
  - Prolonged vascular stain
  - Arteriovenous shunting

Imaging Recommendations

- Best imaging tool
  - MR with contrast
- Protocol advice
  - Perform contrast-enhanced MR of entire neuraxis before surgery

DIFFERENTIAL DIAGNOSIS

Atypical Choroid Plexus Papilloma

- Neuropathologic diagnosis
  - WHO grade II based on ↑ proliferation, cellular atypia
    - > 2 mitoses/10 high-power fields
  - Indistinguishable from CPP on imaging alone
    - CPP:aCPCa = 10:1
  - Cytogenetic profiles similar to CPP

Choroid Plexus Carcinoma

- Difficult to distinguish from CPP by imaging
- CPP:CPCa = 2:1
- More heterogeneous, more likely to invade brain

Physiologic Choroid Plexus Enlargement

- Collateral venous drainage (Sturge-Weber)
- Enlargement of choroid following hemispherectomy

Villous Hypertrophy (VH)

- Rare (many presumed VH cases may be bilateral CPPs)
- Proliferation index (MIB-1) is useful to distinguish

Meningioma

- Older adults
- Enhancing, circumscribed, intraventricular mass
- Consider neurofibromatosis type 2

https://CafePezeshki.IR

Intraventricular Metastasis
- Rare in children
- Known history of primary tumor

Medulloblastoma
- Hyperdense 4th ventricular mass in child
- More spherical than CPP

Ependymoma
- More common in 4th ventricle in children
- Heterogeneous enhancing mass

Subependymoma
- Nonenhancing intraventricular mass

Choroid Plexus Xanthogranuloma
- Multiloculated cysts in enhancing choroid plexus of atrium
- Middle-aged, older adults
- Benign, incidental finding
- Usually bilateral

PATHOLOGY

General Features
- Genetics
  - Genetic changes common (> 90% of CPPs)
    - Hyperdiploidy, focal chromosomal gains common
    - High expression of *TWIST1* (transcription factor that inhibits p53)
    - Association with Aicardi, Li-Fraumeni syndromes
- Associated abnormalities
  - Diffuse hydrocephalus from
    - CSF overproduction
    - Mechanical obstruction
    - Impaired CSF resorption (due to hemorrhage)

Staging, Grading, & Classification
- WHO grade I

Gross Pathologic & Surgical Features
- Well-circumscribed, lobulated, intraventricular mass
  - ± cysts, necrosis, and hemorrhage

Microscopic Features
- Fibrovascular connective tissue fronds
  - Covered by cuboidal or columnar epithelium
- Mitotic activity, necrosis, and brain invasion typically absent
- Resembles nonneoplastic choroid plexus (CP)
- Immunohistochemistry
  - Transthyretin may help distinguish from normal CP
  - GFAP reactivity can distinguish from normal CP
  - Kir7.1 and stanniocalcin-1 reactivity differentiates normal CP and CPT from other cell origins

CLINICAL ISSUES

Presentation
- Most common signs/symptoms
  - Macrocrania, bulging fontanelle, vomiting, headache, ataxia, seizure
- Clinical profile
  - Child < 2 years with signs and symptoms of elevated intracranial pressure

Demographics
- Age
  - Lateral ventricular CPPs: 80% < 20 years
  - 4th ventricular CPPs: More common in adults
- Gender
  - Lateral ventricle: M:F = 1:1
  - 4th ventricle: M:F = 3:2
- Epidemiology
  - < 1% of all adult brain tumors
  - 2-4% of all pediatric brain tumors
  - 1 of most common brain tumors in children < 1 year
    - 50% manifest in 1st decade
    - 86% present by 5 years
    - 13.1% of all brain tumors in 1st year of life
    - 7.9% of fetal brain tumors diagnosed by ultrasound

Natural History & Prognosis
- Benign, slowly growing
  - Malignant progression rare
- 5-year survival ~ 100%

Treatment
- Total surgical resection (recurrence rare)

DIAGNOSTIC CHECKLIST

Consider
- CPP if intraventricular mass in child under 2 years

Image Interpretation Pearls
- Imaging alone cannot reliably distinguish CPP from aCPP or CPCa
  - Final diagnosis is histologic
- Lobulated intraventricular mass with intense enhancement in young child most likely represents CPT

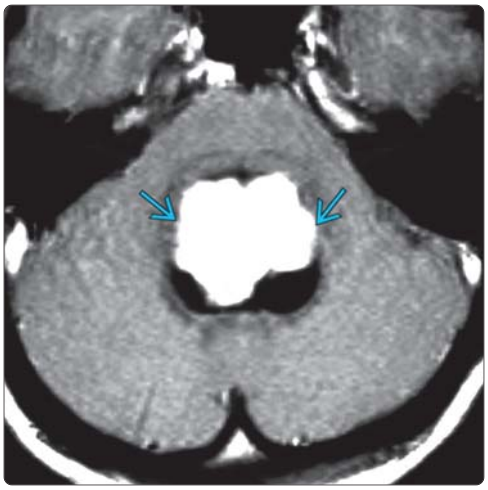
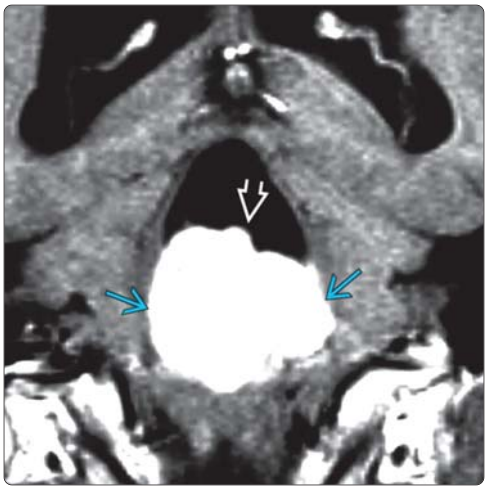
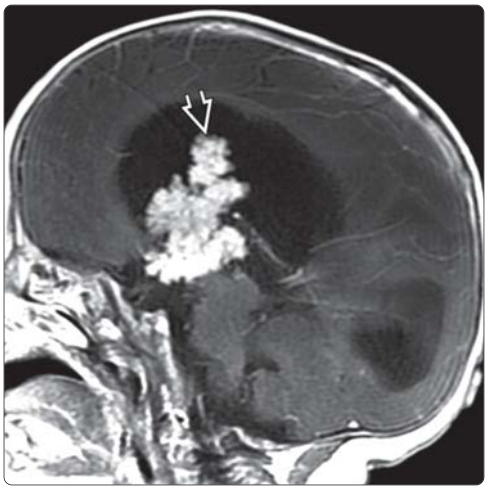
https://CafePezeshki.IR

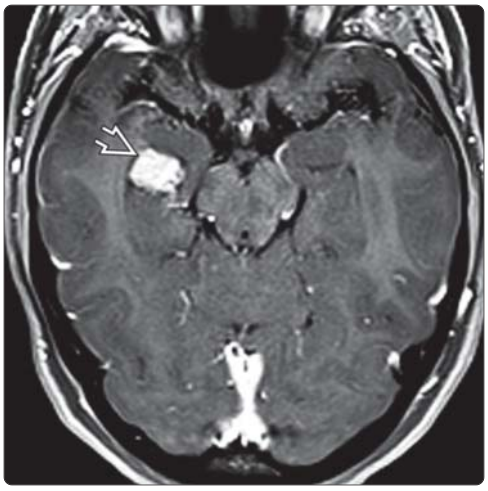


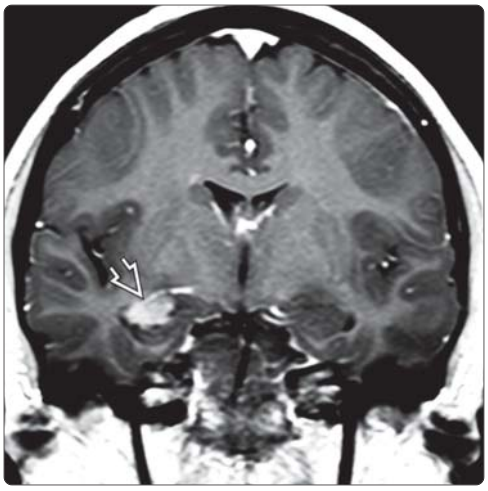
(Left) *Sagittal T1 C+ MR in an adult with headaches demonstrates the 4th ventricular presentation of CPP. Note the lobulated, cauliflower-like morphology of the mass ⇨. Choroid plexus tumors in adults are more likely to involve the choroid plexus within the 4th ventricle. These tumors may be centered in the 4th ventricle or at the lateral recess.* **(Right)** *Axial T1 C+ MR in the same patient shows the robust enhancement of the mass ⇨.*





(Left) *Coronal T1 C+ MR in the same patient shows the lobulated, well-demarcated character of the mass ⇨ and the intense, uniform enhancement ⇨.* **(Right)** *Sagittal T1WI C+ MR in a child with a large head and papilledema shows a lobular, markedly enhancing 3rd ventricle mass with distinct frond-like projections ⇨. The 3rd ventricle is an uncommon location for choroid plexus tumors. Note the cephalad extension through the foramen of Monro and the associated hydrocephalus.*





(Left) *Axial T1 C+ FS MR in a 19-year-old woman with headaches, nausea, and vomiting shows a strongly enhancing mass in the temporal horn of the right lateral ventricle ⇨.* **(Right)** *Coronal T1 C+ scan in the same patient shows the intraventricular mass ⇨ is lobulated and well delineated. Preoperative diagnosis was meningioma. Pathology disclosed a typical CPP. The temporal horn is an unusual location for a CPP, but the appearance, in this case, is consistent with the diagnosis.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Malignant tumor originating from epithelium of choroid plexus (WHO grade III)

IMAGING

- Best imaging clue: Child < 5 years with enhancing intraventricular mass and ependymal invasion, ± prominent flow voids
  - Asymmetric periventricular white matter edema suggests invasion
- MR may not distinguish papilloma from carcinoma
  - Heterogeneity, brain invasion, CSF spread favors CPCa
- Important to image spine prior to surgery

TOP DIFFERENTIAL DIAGNOSES

- Choroid plexus papilloma (CPP)
- Ependymoma
- Subependymal giant cell astrocytoma

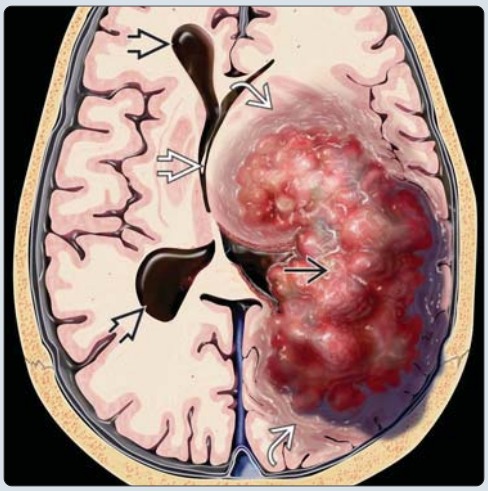
PATHOLOGY

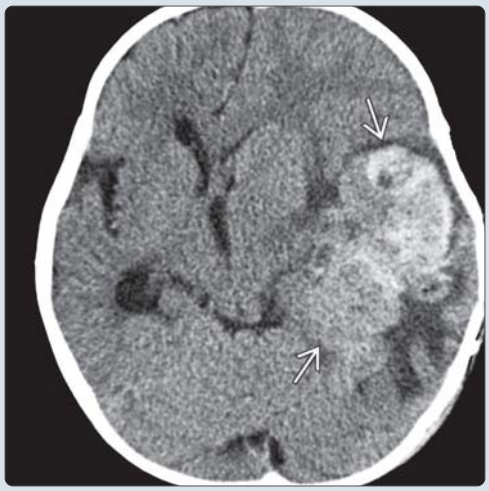
- WHO grade III
- Microscopic features: Hypercellularity, pleomorphism, increased mitotic activity
  - Cysts, necrosis, hemorrhage, microcalcifications
  - Brain invasion common
- Increased incidence in Li-Fraumeni and Aicardi syndromes

CLINICAL ISSUES

- Occurs in infants and young children
  - 70% occur before 2 years of age
- Nausea, vomiting, headache, obtundation most common presenting features
- CPCa represent 20-40% of all choroid plexus tumors
- Grows rapidly
- 30-50% 5-year survival
- Poor outcome with brain invasion or CSF seeding

(Left) *Axial graphic demonstrates a lobular mass centered in the atria of the left lateral ventricle. Note the invasion and expansion of the surrounding parenchyma, more characteristic of a choroid plexus carcinoma. There is associated midline shift and entrapment of the right lateral ventricle.* **(Right)** *Axial NECT in a 2-year-old female with a large head and papilledema shows a predominately hyperdense mass in the left cerebral hemisphere.*





(Left) *Axial T2WI in the same case shows the lobulated mass is extremely heterogeneous in signal intensity. The lesion appears to arise within the atrium of the left lateral ventricle and invades the adjacent brain extensively.* **(Right)** *Axial post-contrast T1WI shows the mass enhances strongly but heterogeneously. Choroid plexus carcinoma (WHO grade III) was found at surgery.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Choroid plexus carcinoma (CPCa)
- Choroid plexus tumor (CPT)

Definitions

- Malignant tumor originating from epithelium of choroid plexus

IMAGING

General Features

- Best diagnostic clue
  - Child (< 5 years) with enhancing intraventricular mass and ependymal invasion
  - Differentiation from choroid plexus papilloma (CPP) is histologic, not radiologic
- Location
  - Almost always arise in lateral ventricle
- Size
  - Variable
- Morphology
  - Cauliflower-like mass
  - Necrosis, cysts, and hemorrhage common

CT Findings

- NECT
  - Iso- to hyperattenuating mass with irregular contours
  - Necrosis, cysts, and hemorrhage common
  - Hydrocephalus common
  - Calcification (Ca++) in 20-25%
- CECT
  - Heterogeneous, strong enhancement
  - Peritumoral edema
  - ± CSF tumor seeding

MR Findings

- T1WI
  - Iso- to hypointense intraventricular mass
  - Lobulated or irregularly marginated, papillary appearance
  - Heterogeneous (necrosis, cysts, hemorrhage)
- T2WI
  - Mixed signal mass, hypo-/iso-/hyperintense
  - Heterogeneous related to necrosis, cysts, hemorrhage, Ca++
  - ± prominent flow voids
  - Many invade brain and cause edema
- PD/intermediate
  - Heterogeneous mass with vascular flow voids
- FLAIR
  - Heterogeneous intraventricular mass
  - Periventricular white matter edema suggests invasion
  - Transependymal CSF flow from hydrocephalus
- T2* GRE
  - Low signal from hemorrhage or calcification
- DWI
  - Low ADC values in solid portions of tumor
- T1WI C+
  - Heterogeneous enhancement, ± CSF seeding
- MRS
  - NAA absent; ↑ choline ± ↑ lactate

Angiographic Findings

- Conventional
  - Enlarged choroidal artery and vascular stain

Nuclear Medicine Findings

- PET
  - 11C-methionine → ↑ tumor: Normal brain ratios
- Tc-99m sestamibi → ↑ in CPTs

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR of brain and spine
- Protocol advice
  - Enhanced MR of entire neuraxis prior to surgery

DIFFERENTIAL DIAGNOSIS

Choroid Plexus Papilloma (CPP)

- MR may not distinguish CPCa from typical or atypical CPP
- Aggressive CPP may seed through CSF pathways
- CPP rarely shows minimal brain invasion

Ependymoma

- Heterogeneous 4th ventricular mass
- Classically squeezes out 4th ventricular foramina into cisterns
- Supratentorial ependymoma often extraventricular

Subependymal Giant Cell Astrocytoma

- Associated CNS findings of tuberous sclerosis
- Characteristic location near foramen of Monro
- Rarely cause edema

Astrocytic Tumors

- May arise from periventricular tissues (septum pellucidum, thalamus)
- Smooth or lobular masses, no papillary margins
- High-grade tumor may cause periventricular edema

Medulloblastoma

- Hyperdense, round 4th ventricular mass
- Arises from roof of 4th ventricle (superior medullary velum)

Central Neurocytoma

- "Bubbly" intraventricular mass in adult
- Often attached to septum pellucidum

Meningioma

- Delineated, oval enhancing mass
- Uncommon in children, associated with neurofibromatosis type 2

Primitive Neuroectodermal Tumor (PNET)

- Heterogeneous tumor can be lobulated within lateral ventricle
- May arise deep in hemisphere
- Peritumoral edema often minimal

Atypical Teratoid/Rhabdoid Tumor (AT/RT)

- Heterogeneous tumor with cysts or hemorrhage

https://CafePezeshki.IR

- Common in posterior fossa, may occur in lateral ventricle, often intraaxial
- Typically present in patients < 2 years of age
- INI1 protein negative on immunohistochemistry
  - Most CPCa positive

Vascular Lesions

- Arteriovenous malformation
- Cavernous malformation

Metastases

- History of previous tumor often known
- Multiple lesions common
- Rare in children

PATHOLOGY

General Features

- Etiology
  - SV40 virus DNA sequences in 50% of CPTs
- Genetics
  - Increased incidence in Li-Fraumeni and Aicardi syndromes
    - Li-Fraumeni *TP53* mutation/deletion
      - Autosomal dominant tumor predisposition syndrome
  - Overlap with rhabdoid tumors and *SNF5(INI1)* mutation
- Associated abnormalities
  - Diffuse hydrocephalus → mechanical obstruction, increased CSF production, decreased resorption

Staging, Grading, & Classification

- WHO grade III

Gross Pathologic & Surgical Features

- Well-circumscribed lobulated intraventricular mass
- Ependymal invasion

Microscopic Features

- Hypercellular, pleomorphic, increased mitotic activity
- Cysts, necrosis, hemorrhage, microcalcifications
- Brain invasion common
- May have CSF seeding
- Ki-67 (MIB-1) proliferation indices high (~ 14-20%)

Immunochemistry

- Kir7.1 and Stanniocalcin-1 may distinguish choroid plexus origin from other tumors
- CPC express cytokeratins
- Transthyretin, S100(+) (less than CPP)

Genetic Alterations

- Recurrent copy number losses and gains of multiple chromosomes, varying with age

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Nausea, vomiting, headache, obtundation
  - Focal neurologic signs and symptoms
- Clinical profile
  - Infant or child with elevated ICP and focal neuro deficits

Demographics

- Age
  - Infants and young children (typically < 5 years)
  - Median: 26-32 months
- Gender
  - M = F
- Epidemiology
  - 80% arise in children
  - 70% before 2 years of age
  - 20-40% of all CPTs
  - ~ 5% of supratentorial tumors in children
  - < 1% of all pediatric intracranial tumors

Natural History & Prognosis

- Small percentage may be malignant progression from WHO grade I and II papillomas
- Grows rapidly
- 30-50% 5-year survival
- Poor outcome with brain invasion, CSF seeding

Treatment

- "Head Start" (HS) irradiation-avoiding strategy has improved survival, minimized neurocognitive sequelae
  - Maximal surgical resection 1st
  - High dose consolidation myeloablative chemotherapy next
    - With autologous hematopoietic stem cell rescue
  - ± post-chemo irradiation (based on patient age, evidence of residual disease)

DIAGNOSTIC CHECKLIST

Consider

- CPCa in child with invasive intraventricular mass and focal neurologic signs

Image Interpretation Pearls

- MR may not distinguish papilloma from carcinoma
- Heterogeneity, brain invasion, CSF spread favors CPCa
- Image spine prior to surgery

https://CafePezeshki.IR

Ganglioglioma

KEY FACTS

TERMINOLOGY

- Well-differentiated, slowly growing neuroepithelial tumor composed of neoplastic ganglion cells and neoplastic glial cells
- Most common neoplastic cause of temporal lobe epilepsy (TLE)

IMAGING

- Best diagnostic clue: Partially cystic, enhancing, cortically based mass in child/young adult with TLE
- Can occur anywhere, but most commonly superficial hemispheres, temporal lobe (> 75%)
- Circumscribed cyst with mural nodule most common
- May be solid and appear well circumscribed
- Calcification is common (up to 50%)
- Superficial lesions may expand cortex, remodel bone
- ~ 50% enhance
- Protocol advice: Contrast-enhanced MR to include coronal T2 images for better evaluation of temporal lobes

TOP DIFFERENTIAL DIAGNOSES

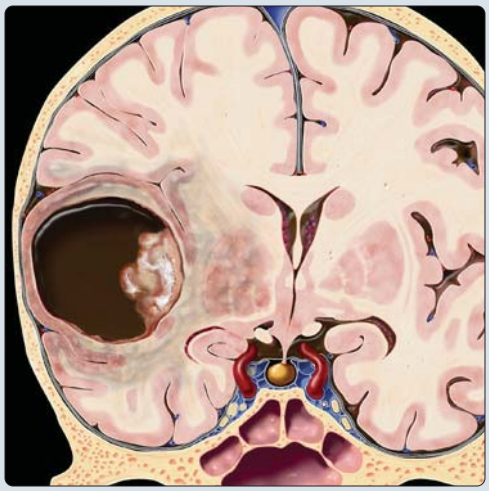
- Pleomorphic xanthoastrocytoma (PXA)
- Dysembryoplastic neuroepithelial tumor (DNET)
- Astrocytoma
- Oligodendroglioma
- Neurocysticercosis

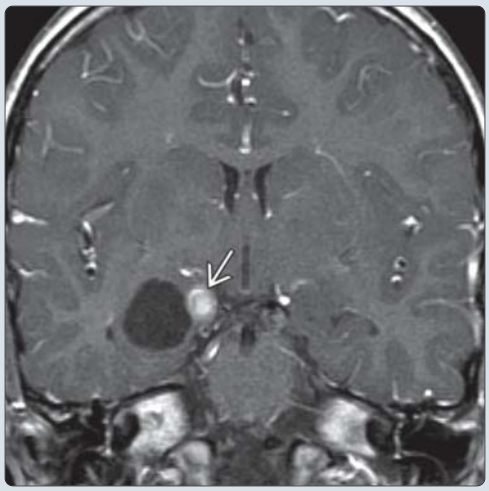
PATHOLOGY

- WHO grade I or II (80% grade I)
- Uncommon: Anaplastic ganglioglioma (WHO III)
- Rare: Malignant with glioblastoma multiforme (GBM)-like glial component (WHO IV)

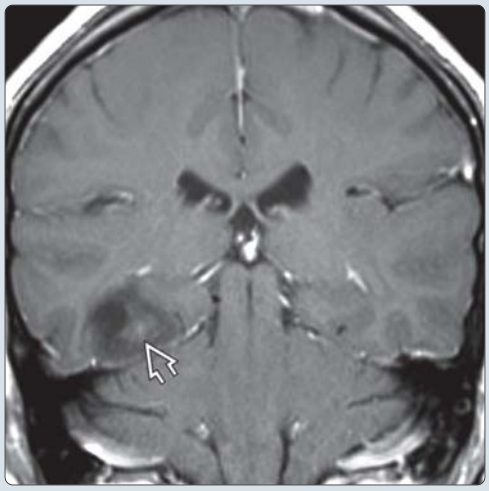
CLINICAL ISSUES

- Occurs at all ages (peak: 10-20 years)
- Most common mixed neuronal-glial tumor
- Cortical dysplasia is commonly associated with GG
- Excellent prognosis if surgical resection complete





(Left) *Coronal graphic shows a discrete cystic and solid temporal lobe mass expanding the overlying cortex. Calvarial remodeling is seen, typical of a superficially located ganglioglioma. Gangliogliomas are the most common tumors to cause temporal lobe epilepsy.* **(Right)** *Coronal T1WI C+ MR in a young adult with temporal lobe epilepsy shows a circumscribed, cystic, and solid temporal lobe mass with intense enhancement of the mural nodule. This is the classic enhancement pattern of a ganglioglioma.*



(Left) *Axial CT image shows a partially calcified frontal lobe mass in a 25 year old with headaches and seizures. The lack of surrounding edema is typical for ganglioglioma. Imaging mimics an oligodendroglioma. Calcification is seen in 30-50% of gangliogliomas.* **(Right)** *Coronal T1WI C+ MR shows subtle enhancement within a right temporal lobe ganglioglioma in a female patient with seizures. The differential diagnosis for this lesion includes DNET, astrocytoma, PXA, and oligodendroglioma.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Ganglioglioma (GG)

Definitions

- Well-differentiated, slowly growing neuroepithelial tumor composed of neoplastic ganglion cells and neoplastic glial cells
- Most common neoplasm to cause temporal lobe epilepsy (TLE)

IMAGING

General Features

- Best diagnostic clue
  - Partially cystic, enhancing, cortically based mass in child/young adult with TLE
- Location
  - Can occur anywhere, but most commonly superficial hemispheres, temporal lobe (> 75%)
    - Frontal and parietal lobes next most common
  - Rare locations: Brainstem, cerebellum, pineal region, optic nerve/chiasm, intraventricular, pituitary axis, spinal cord, cranial nerves
- Size
  - Variable in adults, typically 2-3 cm
  - Larger in children, typically > 4 cm
  - Up to 6 cm reported
- Morphology
  - 3 patterns
    - Most common: Circumscribed cyst with mural nodule
    - Solid tumor (often thickens, expands gyri)
    - Uncommon: Infiltrating, poorly delineated mass
  - Calcification is common (up to 50%)
  - In younger patients (< 10 years), gangliogliomas are larger and more cystic

CT Findings

- NECT
  - Variable density
    - 40% hypodense
    - 30% mixed hypodense (cyst), isodense (nodule)
    - 15% isodense or hyperdense
  - Ca++ common (35-50%)
  - Superficial lesions may expand cortex, remodel bone
  - Hemorrhage is rare
- CECT
  - ~ 50% enhance
    - Variable; moderate and uniform to heterogeneous
    - Can be solid, rim, or nodular
    - Often shows cyst with enhancing nodule

MR Findings

- T1WI
  - Mass is hypointense to isointense to gray matter
    - Rarely hyperintense
  - Ca++ has variable signal intensity
  - May see associated cortical dysplasia
- T2WI
  - Hyperintense mass typical
  - May be heterogeneous
  - No surrounding edema
- T2* GRE
  - May show Ca++ as areas of "blooming"
- T1WI C+
  - Variable enhancement, usually moderate but heterogeneous
    - May be minimal, ring like, homogeneous
    - Some GG do not enhance
  - Meningeal enhancement rarely seen
- MRS
  - Elevated Cho has been described

Nuclear Medicine Findings

- PET
  - Typically decreased activity with FDG PET indicating tumor hypometabolism
  - May have some hypermetabolic foci
- Th-201 SPECT: Increased activity in high-grade gangliogliomas (grade III, IV)
  - Typical gangliogliomas have decreased or normal SPECT activity

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR
- Protocol advice
  - Contrast-enhanced MR to include coronal T2 images for better evaluation of temporal lobes

DIFFERENTIAL DIAGNOSIS

Pleomorphic Xanthoastrocytoma (PXA)

- Supratentorial cortical mass, dural "tail" common
- Often cyst and mural nodule, may be solid
- Enhancing nodule abuts pial surface
- Temporal lobe most common location

Dysembryoplastic Neuroepithelial Tumor (DNET)

- Superficial cortical tumor, well demarcated
- Multicystic bubbly appearance
- T2-hyperintense mass with rare, mild enhancement
- May remodel calvaria

Pilocytic Astrocytoma

- Supratentorial location other than hypothalamus/chiasm rare
- Typically solid and cystic or solid mass
- Enhancement typical

Low-Grade Astrocytoma (Grade II)

- Circumscribed but infiltrative white matter mass
- No enhancement

Oligodendroglioma

- Calcified, heterogeneous mass
- Typically more diffuse than ganglioglioma
- May remodel/erode calvaria

Neurocysticercosis

- Cyst with "dot" inside
- Often calcified
- Multiple lesions common

https://CafePezeshki.IR

- Imaging varies with pathologic stage, host response

PATHOLOGY

General Features

- Etiology
  - 2 theories
    - Origin from dysplastic, malformative glioneuronal precursor lesion with glial element neoplastic transformation
    - Neoplastic transformation of glial hamartoma or subpial granule cells
- Genetics
  - Gain of chromosome 7 and 12 reported
  - Deletions of 22q in neoplastic glial cells
  - Sporadic
    - *TP53* mutations found in malignant degeneration
  - Syndromic
    - Ganglioglioma has been reported in Turcot syndrome, NF1, and NF2
- Associated abnormalities
  - Gangliogliomas have been found in association with oligodendroglioma, DNET, tanycytic ependymoma
  - Malignant transformation into GBM, neuroblastoma has been reported
  - Cortical dysplasia is commonly associated
    - Possibly related to mutations affecting mTORC1 pathway

Staging, Grading, & Classification

- Common: WHO grade I 80% or II
- Uncommon: Anaplastic ganglioglioma (WHO grade III)
- Rare: Malignant with GBM-like glial component (WHO grade IV)

Gross Pathologic & Surgical Features

- Solid or cystic mass with mural nodule
- Firm, well-circumscribed mass, often expands cortex
- Ca++ is common

Microscopic Features

- Mix of mature but neoplastic ganglion cells and neoplastic glial cells (usually astrocytes)
- Dysmorphic, occasionally binucleate neurons
  - Immunohistochemistry of neuronal cells
    - Synaptophysin and neurofilament protein are positive
    - Majority exhibit CD34 immunoreactivity (70-80% of gangliogliomas)
- Electron microscopy shows dense core granules, variable synapses
- Neoplastic glial cells are GFAP(+)
- Mitoses rare (75% have Ki-67 < 1%, low MIB [1-3%])

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Chronic temporal lobe epilepsy (~ 90%)
    - Often partial complex seizures
  - Other signs/symptoms: Headache and signs of increased intracranial pressure

Demographics

- Age
  - Tumor of children, young adults
  - 80% of patients < 30 years
  - Occurs at all ages
  - Peak: 10-20 years
- Gender
  - Slight male predominance
- Epidemiology
  - 1% of primary intracranial neoplasms
  - Most common mixed neuronal-glial tumor
  - Represents ~ 5% of pediatric CNS neoplasms
  - Most common tumor to cause TLE (> 45%)
    - Ganglioglioma (40%) > DNET (20%) > pilocytic astrocytoma > low-grade astrocytoma > oligodendroglioma > PXA

Natural History & Prognosis

- Excellent prognosis if surgical resection complete
- 94% have 7.5-year recurrence-free survival
- Vast majority of patients seizure-free after surgery (80%)
- Well-differentiated tumor with slow growth pattern
- Malignant degeneration is rare (~ 5-10% glial component)

Treatment

- Surgical resection is treatment of choice
- Radiation therapy &/or chemotherapy for aggressive or unresectable tumors

DIAGNOSTIC CHECKLIST

Consider

- Ganglioglioma in young patient with history of TLE
- In children < 10 years old, gangliogliomas are larger and more cystic

Image Interpretation Pearls

- Cyst with enhancing mural nodule is classic, but not specific for ganglioglioma

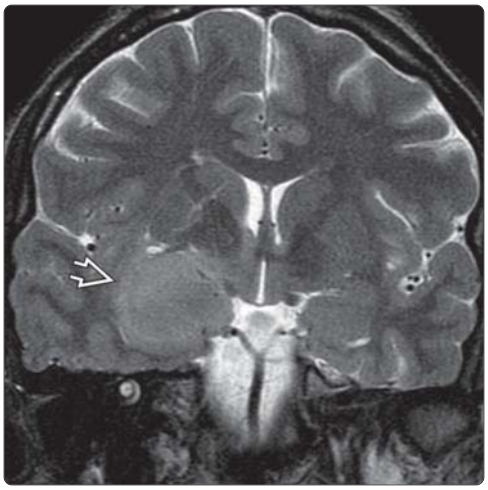
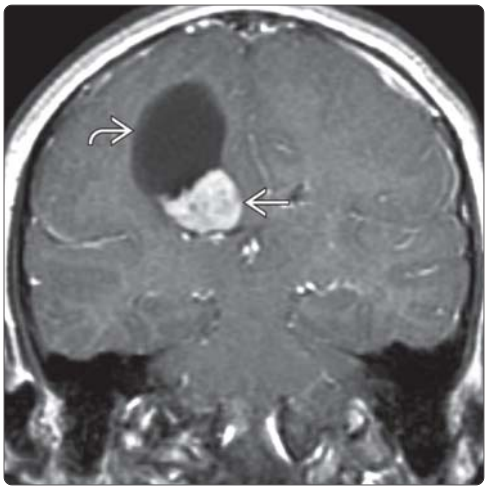
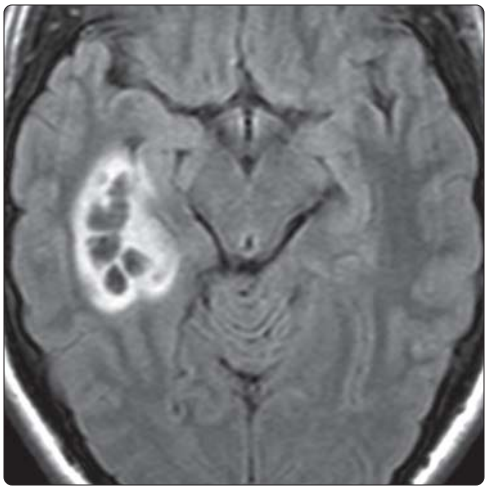
https://CafePezeshki.IR

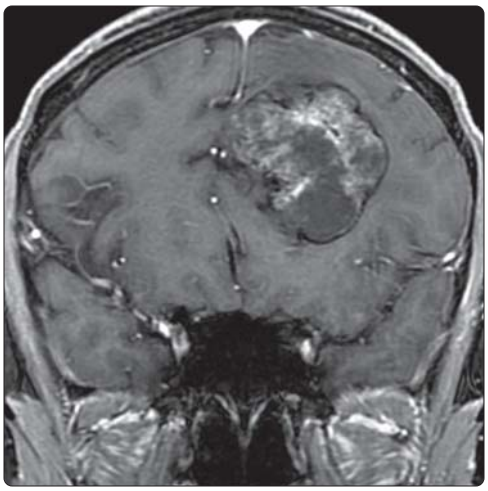


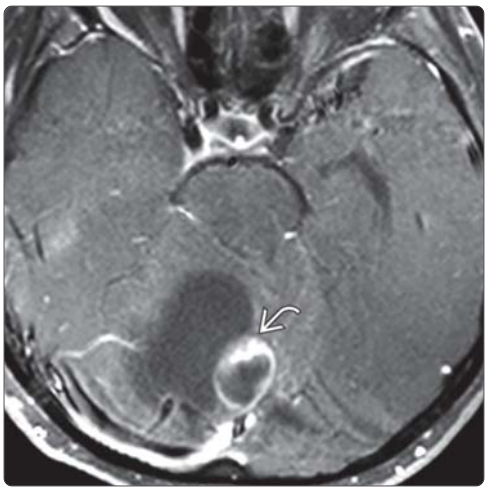


(Left) *Coronal T2WI MR shows a discrete, hyperintense mass ➡ in this 25-year-old temporal lobe epilepsy patient. Thin-section T2 imaging is very helpful for evaluation of patients with temporal lobe epilepsy. This nonenhancing mass proved to be ganglioglioma at resection.* **(Right)** *Coronal T1WI C+ MR shows a well-circumscribed frontal lobe mass with a sharply demarcated cystic portion ➡ and an enhancing deep soft tissue nodule ➡ that indents the ventricle. This deep white matter location is atypical of ganglioglioma.*



(Left) *Axial FLAIR MR shows a discrete, multiseptated temporal lobe mass. The lack of surrounding edema and lack of significant mass effect is typical of ganglioglioma. This WHO grade I tumor has a very good prognosis with resection.* **(Right)** *Axial T2WI MR shows a hyperintense, cystic parietal lobe mass ➡ with remodeling of the overlying calvaria. This mass showed a cyst with an enhancing mural nodule, classic for ganglioglioma. Superficial tumors often have associated bone remodeling.*





(Left) *Coronal T1WI C+ MR in a young adult with seizures shows a heterogeneously enhancing frontal lobe mass. Ganglioglioma was diagnosed at resection. The frontal lobe is the 2nd most common location for a ganglioglioma.* **(Right)** *Axial T1WI C+ FS MR shows an enhancing cyst and mural nodule along the medial border of a large cystic mass ➡. The posterior fossa is an uncommon location for a ganglioglioma. Differential considerations would include hemangioblastoma and pilocytic astrocytoma in this young adult.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Large cystic tumors of infants involving superficial cerebral cortex and leptomeninges
- Desmoplastic infantile ganglioglioma (DIG/DIGG)
  - Prominent desmoplastic stroma + neoplastic astrocytes, variable neuronal component
- Desmoplastic infantile astrocytoma (DIA)
  - Desmoplastic stroma + neoplastic astrocytes

IMAGING

- Best diagnostic clue: Peripheral supratentorial tumor with cyst and nodule in infant < 2 years
  - Large cyst + cortical-based tumor nodule
  - Enhancement of adjacent meninges
  - T2 hypointense solid portion
- Frontal and parietal > temporal > occipital
- Cysts may be very large, cause macrocephaly and bulging fontanelles in infants

TOP DIFFERENTIAL DIAGNOSES

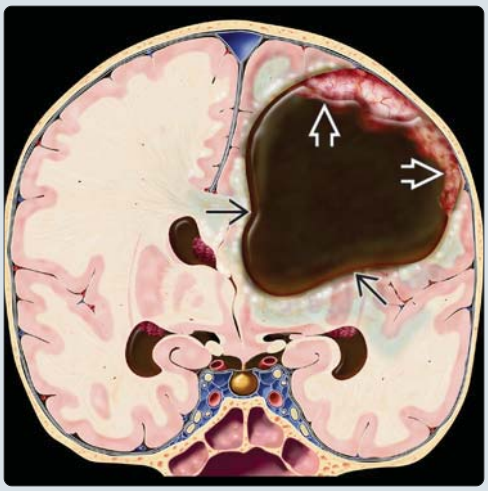
- Primitive neuroectodermal tumor (PNET)
- Supratentorial ependymoma
- Pleomorphic xanthoastrocytoma (PXA)
- Hemangioblastoma
- Ganglioglioma
- Pilocytic astrocytoma

PATHOLOGY

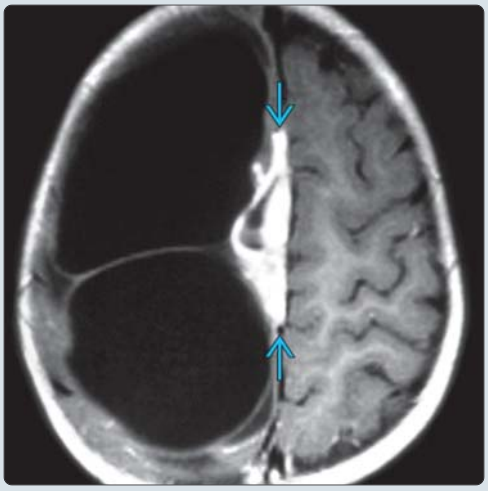
- WHO grade 1
- Areas of cellular proliferation, mitoses, and necrosis may cause misdiagnosis as higher grade tumor

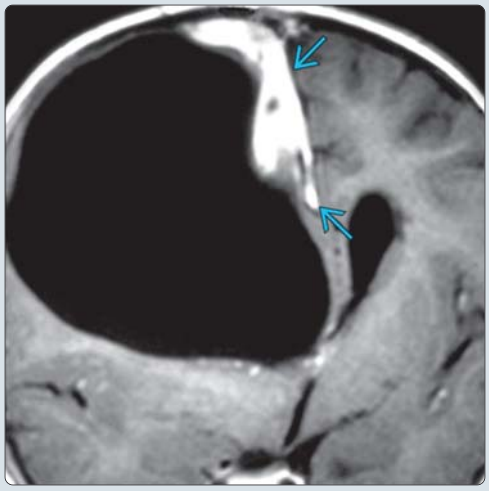
CLINICAL ISSUES

- Most are found at 1-24 months (peak: 3-6 months)
- 16% of intracranial tumors in 1st year of life
- Median survival rate is > 75% at 15 years
- Surgical resection typically curative



(Left) *Coronal graphic shows an infant with an enlarged head caused by desmoplastic infantile ganglioglioma and astrocytoma (DIG/DIA). Note the dominant cystic component ⇨ with a dural-based plaque of desmoplastic stroma ⇨. Mild surrounding edema and hydrocephalus is present.* **(Right)** *Coronal T2WI MR shows a large cystic and solid mass with a T2 hypointense, peripheral plaque-like solid component ⇨, characteristic of DIG/DIA. Note the significant associated mass effect and hydrocephalus ⇨.*





(Left) *Axial T1WI C+ MR shows a large cystic and solid mass with a markedly enhancing solid component along the falx ⇨.* **(Right)** *Coronal T1WI C+ MR in the same patient shows the large cystic and solid mass with a dural-based enhancing solid portion ⇨, characteristic of DIG/DIA. Involvement of the adjacent dura is typical. DIG/DIA should be considered in supratentorial tumors demonstrating cysts and peripheral nodules in the 1st year of life. (Courtesy M. Sage, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Desmoplastic infantile ganglioglioma (DIG/DIGG)
- Desmoplastic infantile astrocytoma (DIA)

Synonyms

- Desmoplastic supratentorial neuroepithelial tumors of infancy
- Superficial cerebral astrocytoma ± neuronal elements attached to dura

Definitions

- Large cystic tumors of infants involving superficial cerebral cortex and leptomeninges, often attached to dura
- DIG: Prominent desmoplastic stroma + neoplastic astrocytes, variable neuronal component
- DIA: Desmoplastic stroma + neoplastic astrocytes

IMAGING

General Features

- Best diagnostic clue
  - Large cyst + cortical-based enhancing tumor nodule/plaque in infant < 2 years
  - Enhancement of adjacent pia plus reactive dural thickening
  - T2 hypointense solid portion
- Location
  - Supratentorial: Frontal/parietal > temporal > occipital
- Size
  - Cysts may be very large, cause macrocephaly and bulging fontanelles in infants
- Morphology
  - Solid and cystic mass usually with dural attachment

CT Findings

- NECT
  - Large heterogeneous solid and cystic mass
  - Well-demarcated hypodense cyst (isodense to CSF)
  - Solid tumor nodule(s) isodense/slightly hyperdense to GM
  - Calcification extremely rare
- CECT
  - Cyst → no enhancement
  - Nodule → marked enhancement
- CTA
  - Hypovascular; supply from intra- and extraparenchymal vessels
  - Vessels markedly stretched around large cyst

MR Findings

- T1WI
  - Cyst: Hypointense, often multilobulated
    - May contain septa
  - Solid portion: Nodule or plaque-like areas → heterogeneous
- T2WI
  - Cyst is hyperintense
  - Lobular, solid tumor nodule is hypointense
  - Degree of surrounding edema dependent upon local ventricular obstruction
- FLAIR
  - Cysts are isointense to CSF
  - Solid portions usually isointense to GM
- T2* GRE
  - No hemorrhage or calcification
- DWI
  - Usually no restriction
- T1WI C+
  - Solid tumor nodule(s) enhance markedly, homogeneously
  - Enhancement of leptomeninges, dura adjacent to solid tumor is typical
  - Cyst typically more central than enhancing solid nodule, ± wall enhancement
- MRS
  - ↓ NAA, ↑ choline

Ultrasonographic Findings

- Grayscale ultrasound
  - Large, multicystic mass
  - Hypoechoic tumor nodule, if identified

Imaging Recommendations

- Best imaging tool
  - Multiplanar contrast-enhanced MR

DIFFERENTIAL DIAGNOSIS

Primitive Neuroectodermal Tumor (PNET)

- Solid tumor is hyperdense on CT, isointense to GM on T2, contains cysts, Ca++, edema
- Large heterogeneously enhancing hemispheric mass
- Large cyst less common than in DIG/DIA

Supratentorial Ependymoma

- Nonspecific imaging findings but commonly contains Ca++
- Solid portion usually less peripherally located than DIG/DIA
- Cysts are often less complex than DIG/DIA

Pleomorphic Xanthoastrocytoma (PXA)

- May appear identical to DIG
- Occurs in older patients, children, and young adults
- Temporal lobe most common location

Hemangioblastoma

- Cyst with mural nodule appearance in posterior fossa
- Solid nodule is vascular, flow void may be seen
- Older patients
- Imaging features similar to DIG but rare above tentorium

Ganglioglioma

- Similar appearance to DIG but generally smaller in size
- Ca++ is common
- Older patients, children, and young adults
- Temporal lobe most common location

Pilocytic Astrocytoma

- Rare in infancy
- Uncommon in cerebral hemispheres
- Cyst is usually smaller; nodule hyperintense on T1WI

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Possibly related to progenitor cells in subcortical zone along with mature subpial astrocytes
- Genetics
  - DIA, DIG represent histologic spectrum of same tumor rather than 2 separate entities
  - Large chromosomal alterations rare, inconsistent
  - BRAF V600E mutation rare; affects subset of DIA/DIGs

Staging, Grading, & Classification

- WHO grade I

Gross Pathologic & Surgical Features

- 2 distinct components
  - Cortical-based solid tumor nodule with adjacent dural thickening
  - Large associated cyst compresses adjacent ventricular system
- Large cyst(s) containing xanthochromic fluid
- Firm attachment to dura and brain parenchyma
- No necrosis within solid component of tumor, no hemorrhage

Microscopic Features

- DIA: Astrocytes are sole tumor cell
- DIG: Astrocytes + neoplastic neurons
  - Intense desmoplasia with mixture of astroglial and neuronal cells
  - Immature neuronal component and neoplastic astrocytes
- Spindle cells in collagenous stroma forming whorled patterns
- Ki-67 (MIB-1) proliferation indices < 2-5%
  - Rare: ↑ Ki-67, malignant histologic features, behaves in aggressive clinical manner

Immunohistochemistry

- GFAP and vimentin positive
- Synaptophysin (+) if neuronal elements (DIG)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - ↑ head size, bulging fontanelles, paresis, and seizures
  - Older children: Seizures and focal neurologic signs/symptoms
- Clinical profile
  - Infant with rapidly progressive macrocephaly

Demographics

- Age
  - Most are found at 1-24 months (peak: 3-6 months)
  - Children, < 24 months, usually ≤ 12 months; occasionally older patients (5-17 years)
- Gender
  - Slightly more common in males (M:F = 2:1)
- Epidemiology
  - 1.25% of intracranial tumors in childhood
  - 16% of intracranial tumors in 1st year of life

Natural History & Prognosis

- Median survival rate is > 75% at 15 years after diagnosis
- Spontaneous disappearance rare
- Anaplasia is very rare
- Leptomeningeal metastasis rare

Treatment

- Surgical resection curative, no recurrence with complete resection
- Chemotherapy if brain invasion or recurrence

DIAGNOSTIC CHECKLIST

Consider

- Large cystic mass in infant with plaque-like or nodular component along meninges, think DIG/DIA
- Important to mention DIG/DIA in report as pathologists may initially misinterpret as highly malignant tumor

Image Interpretation Pearls

- Solid portion is peripheral involving cortex, often invades adjacent meninges
- Solid portion is T2 hypointense

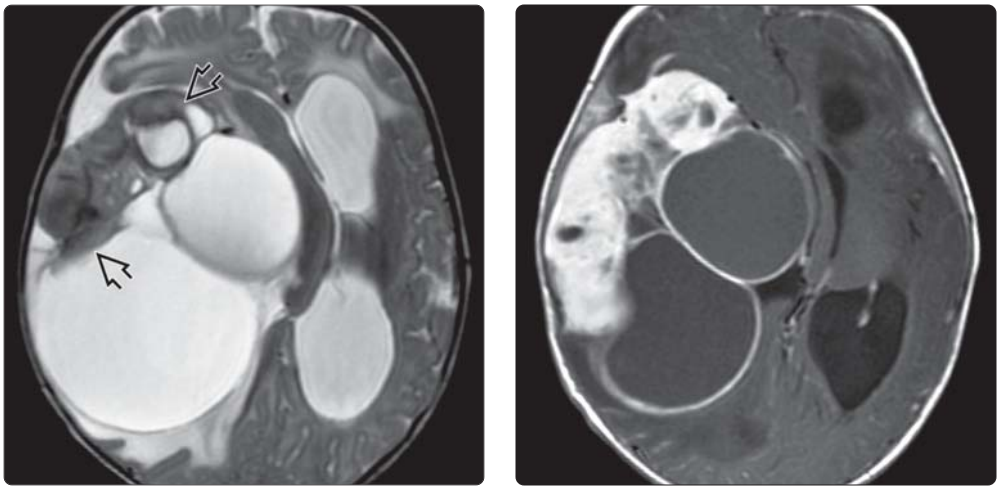
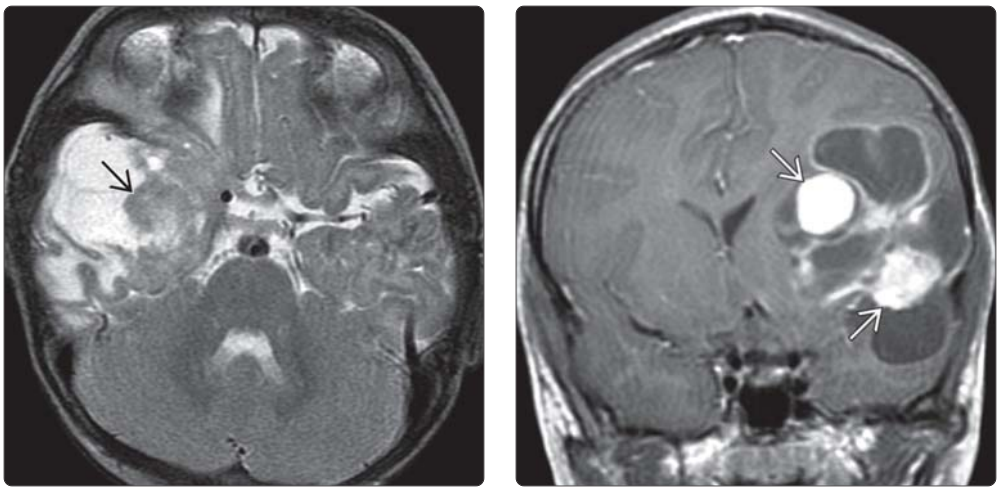
(Left) *Axial T1WI C+ MR shows a cystic and solid mass in the temporal lobe with intense enhancement of the solid portion* ⇨. **(Right)** *Coronal T1WI C+ MR in the same patient shows the cystic and solid mass with internal septations* ⇨ *present in the cystic portion of the tumor. There is mild associated mass effect. DIAs and DIGs are often very large at presentation. Enhancement of the cortically based solid portion with involvement of the adjacent pia and dura is characteristic of these rare tumors.*



(Left) *Axial T2WI MR shows a large multicystic and solid mass of the right hemisphere. The cortically based T2 hypointense solid portion* ⇨ *is typical of DIG/DIA.* **(Right)** *Axial T1WI C+ MR in the same patient shows marked enhancement of the solid elements with mild cyst wall enhancement. DIA and DIG presents in infants as large tumors, often approaching 13 cm. Macrocephaly with seizures are the most common presenting features.*



(Left) *Axial T2WI MR shows a heterogeneous cystic and solid mass with a hypointense cortically based* ⇨ *medial solid portion. Diagnosis was DIA/DIG.* **(Right)** *Coronal T1WI C+ MR shows a heterogeneous cystic and solid frontal mass with marked enhancement of the multiple solid nodules* ⇨. *Typically, the solid portion is peripheral and dural-based in DIA/DIG. These WHO grade I tumors are important to recognize, as the initial pathology may suggest a more malignant tumor.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Dysembryoplastic neuroepithelial tumor (DNET)
  - Benign mixed glial-neuronal neoplasm
  - Frequently associated with cortical dysplasia

IMAGING

- May occur in any region of supratentorial cortex
  - Temporal lobe most common, followed by frontal lobe
  - Mass frequently "points" toward ventricle
- Sharply demarcated, wedge shaped
  - Cystic ("bubbly") intracortical mass
  - Minimal/no mass effect
  - No surrounding edema
- Slow growth over years
- Usually does not enhance
- Faint focal punctate or ring enhancement in 20-30%
  - Higher rate of recurrence if enhancement

TOP DIFFERENTIAL DIAGNOSES

- Focal cortical dysplasia type II (Taylor type)
- Neuroepithelial cyst
- Ganglioglioma
- Pleomorphic xanthoastrocytoma (PXA)
- Angiocentric glioma (a.k.a. ANET)

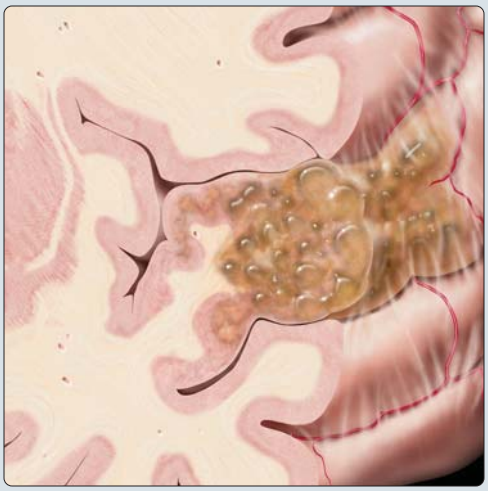
PATHOLOGY

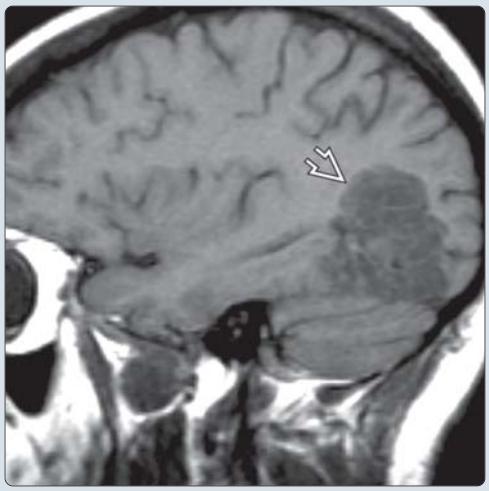
- WHO grade I
- Hallmark = specific glioneuronal element (SGNE)

CLINICAL ISSUES

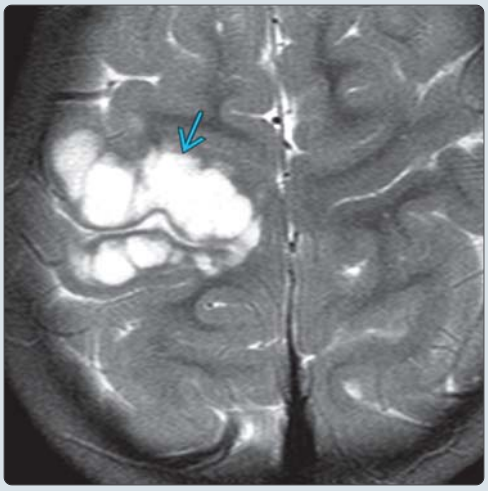
- Longstanding drug-resistant partial complex seizures in child/young adult
- Surgical resection usually curative
- Histology usually remains benign even if tumor recurs, enhances

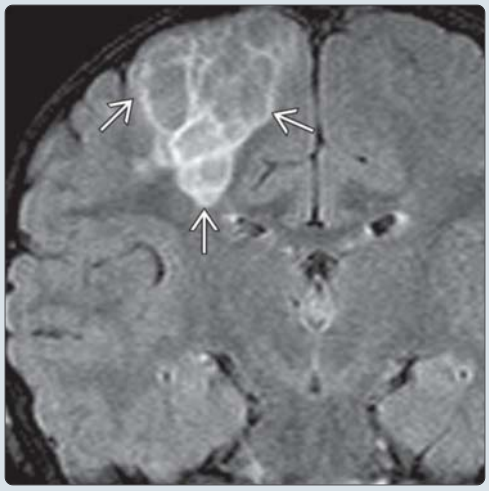
(Left) *Coronal oblique graphic shows the typical appearance of a cystic cortical DNET. The gyrus is expanded by the multicystic-appearing tumor. DNETs typically present in children or young adults with seizures.* **(Right)** *Sagittal T1 MR image in a young adult with seizures shows the characteristic "bubbly" appearance of a DNET. Note the low T1 signal within the wedge-shaped cortical mass ➡. These WHO grade I neoplasms have an excellent prognosis with surgical resection.*





(Left) *Axial T2WI MR shows a multilobular, wedge-shaped cystic cortically based mass ➡ in the right posterior frontal lobe. Note the lack of edema and mass effect, given the size of the tumor, which is typical of a DNET.* **(Right)** *Axial FLAIR MR image in the same patient shows the characteristic appearance of a DNET. Note the cortically based, sharply demarcated, wedge-shaped mass with a hyperintense rim ➡. The tumor points toward the ventricle, and there is no surrounding edema.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Dysembryoplastic neuroepithelial tumor (DNET)

Synonyms

- Mixed glial-neuronal neoplasm

Definitions

- Benign, highly epileptogenic tumor frequently associated with cortical dysplasia

IMAGING

General Features

- Best diagnostic clue
  - Demarcated, wedge-shaped/ovoid, cystic/multicystic cortical mass in young patients with longstanding partial complex seizures
- Location
  - May occur in any region of supratentorial cortex
    - Temporal lobe is most common (45-68%)
      - Often amygdala/hippocampus
    - Frontal lobe is also common (1/3 of cases)
    - Basal ganglia, septum pellucidum are less frequent sites
  - Cortical mass frequently "points" toward ventricle
- Size
  - Variable: Small (involving part of gyrus)
  - Large (several cm) lesions involving large portion of lobe have been reported
- Morphology
  - Circumscribed, wedge shaped, cystic
  - Minimal or no mass effect relative to size of lesion
  - No associated surrounding edema
  - Slow growth over many years
    - May remodel overlying bone

CT Findings

- NECT
  - Wedge shaped/ovoid
    - Cortical/subcortical
    - Scalloped inner table in 44-60%
  - Low density
    - May resemble stroke on initial CT
      - **But** no temporal evolution to atrophy
  - Calcification in 20-36%
- CECT
  - Usually nonenhancing
  - Faint nodular or patchy enhancement in 20%
    - Higher incidence of recurrence if enhancement
- CTA
  - Avascular CTA, MRA, conventional angiography

MR Findings

- T1WI
  - Multilobular, hypointense "bubbly" mass
    - Cortex; may extend into subcortical WM and (rarely) basal ganglia
- T2WI
  - Multilobular or septated appearance
  - Very hyperintense on T2
  - "Pseudocystic" or multicystic appearance
    - True cysts uncommon
- PD/intermediate
  - Hyperintense rim
- FLAIR
  - Variable
    - Mixed hypo-/isointense signal
    - Well-defined, complete or incomplete, hyperintense ring(s) surrounding mass
  - No peritumoral edema
- T2* GRE
  - Bleeding into DNET is uncommon but does occur
    - Possibly in association with microvascular abnormalities
    - May simulate cavernoma
- DWI
  - High diffusivity
- T1WI C+
  - Usually does not enhance
  - Focal punctate or ring enhancement in up to 30%
- MRS
  - Nonspecific, but lactate present in some
  - Often spectroscopy is normal

Nuclear Medicine Findings

- PET
  - FDG-18 PET demonstrates glucose hypometabolism
  - Lower 11C-methionine (MET) uptake in DNET than in ganglioglioma or gliomas
- Tc-99m-HMPAO SPECT
  - Ictal may show hyperperfusion
  - Interictal hypoperfusion typical

Imaging Recommendations

- Best imaging tool
  - MR with T1WI C+, FLAIR ± MRS

DIFFERENTIAL DIAGNOSIS

Focal Cortical Dysplasia Type II

- Single tuberous sclerosis-like cortical lesion
- Expands single gyrus
- Looks like tuber, nonenhancing

Neuroepithelial Cyst

- Nonenhancing single or complex cystic structure
- No bright rim on FLAIR

Ganglioglioma

- Ca++ common
- Frequently solid and cystic components
- Solid components avidly enhance

Pleomorphic Xanthoastrocytoma (PXA)

- Enhancing nodule abuts pia
- May have pial enhancement
- Look for dural "tail"

Angiocentric Glioma

- a.k.a. angiocentric neuroepithelial tumor (ANET)
- Rare superficial cortical lesion, usually frontoparietal
- Child/young adult with longstanding epilepsy

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Embryology: Likely dysplastic cells in germinal matrix
  - Extend along migratory path of neurons toward cortex
  - Associated with cortical dysplasia
  - Contain gelatinous cysts
- Genetics
  - Sporadic
  - Nonneoplastic focal cortical dysplasias may be syndrome related
  - Reported cases with NF1; most are sporadic

Staging, Grading, & Classification

- WHO grade I

Gross Pathologic & Surgical Features

- Neocortical lesion
- Thick gyrus
- Glioneuronal component of tumor is viscous in consistency
- Firm nodules represent more stromal components

Microscopic Features

- Hallmark = specific glioneuronal element (SGNE)
  - Characterized by columns of bundled axons oriented perpendicular to cortex
  - Columns lined by oligodendroglia-like cells
  - Other cells show astrocytic, neuronal differentiation
- Several histological types
  - Complex form
    - Multinodular architecture
    - Mixed cellular composition
    - Foci of cortical disorganization
    - SGNE
  - Simple form with SGNE only
  - 3rd nonspecific form has no SGNE
    - But has same neuroimaging characteristics as complex form
- Microcystic degeneration
  - Neurons "float" in pale, eosinophilic mucoid matrix
- Calcification and leptomeningeal involvement are common
- Adjacent cortical dysplasia is common
- Low proliferative potential with variable MIB-1 index

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Partial complex seizures
- Clinical profile
  - Longstanding frequently drug-resistant partial complex seizures in child or young adult

Demographics

- Age
  - Children and young adults
    - 2nd-3rd decades
    - Majority present by 20 years
- Gender
  - Slight male predominance
- Ethnicity
  - None established
- Epidemiology
  - < 1% of all primary brain tumors
  - ~ 1% of primary neuroepithelial brain tumors in patients < 20 years
  - Represents 0.2% of neuroepithelial tumors in patients > 20 years
  - Reported in 5-80% of epilepsy specimens

Natural History & Prognosis

- Benign lesions
  - Rare malignant transformation or spinal drop metastases
- No to very slow increase in size over time
- Rare recurrence
  - Beware of atypical features (enhancement) on preoperative imaging
  - Malignant transformation described but extremely rare
    - Imaging may look alarming (e.g., new ring-enhancing mass)
    - Histology usually remains benign

Treatment

- Seizures may become intractable
  - Glutamate receptors shown within tumor and margins may explain typical, difficult-to-control seizures
- Surgical resection of epileptogenic foci (may include cortical dysplasia)
- Surgical resection usually curative

DIAGNOSTIC CHECKLIST

Consider

- DNET if T2 hyperintense, "bubbly" cortical mass in child/young adult with longstanding partial complex epilepsy

Image Interpretation Pearls

- Beware of enhancing lesions; they may represent more ominous lesion than DNET

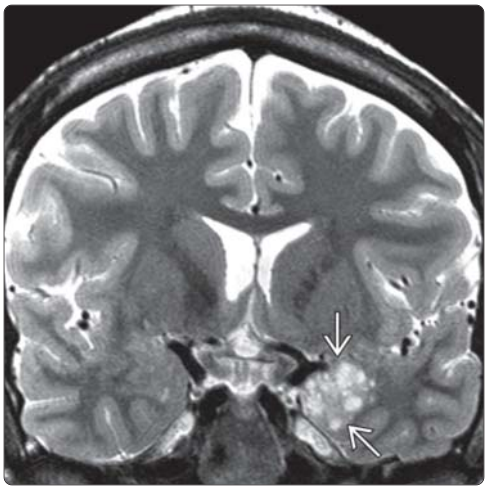
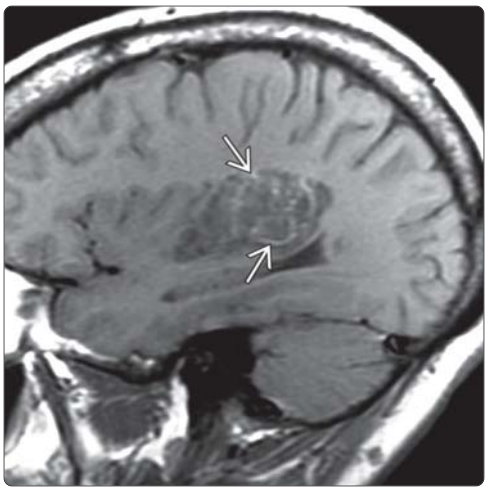
(Left) *Sagittal T2 MR image in a young patient with temporal lobe epilepsy shows the bubbly cortical and subcortical mass ⇨ with no surrounding edema, typical of DNET. Surgical resection is curative in the vast majority of patients.* **(Right)** *Axial FLAIR MR in an older adult shows the classic hyperintense rim ⇨ surrounding the cortically based frontal lobe DNET. This FLAIR hyperintense rim is present in ~ 75% of DNET cases. Lack of peritumoral edema is also characteristic of these WHO I tumors.*



(Left) *Coronal T2WI MR shows a demarcated, "bubbly" mass ⇨ in the medial left temporal lobe. The tumor is heterogeneous with both cystic and more solid areas. There is no associated surrounding edema.* **(Right)** *Coronal T1WI C+ MR in the same patient shows the cortically based mass with cystic areas ⇨. There is no enhancement of the solid portion of the tumor. Enhancement is uncommon in these tumors and is generally nodular or punctate.*



(Left) *Sagittal T1WI MR in a patient with DNET and multiple resections shows a "bubbly," cortically based temporal lobe mass, mostly hypointense and with a few scattered areas of T1 shortening ⇨.* **(Right)** *Sagittal T1WI C+ MR in the same patient shows foci of heterogeneous enhancement ⇨ mostly around the cystic-appearing components. DNETs with atypical features may behave more aggressively. This tumor continued to show benign histology despite multiple recurrences.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Intraventricular neuroepithelial tumor with neuronal differentiation, typically in young adult

IMAGING

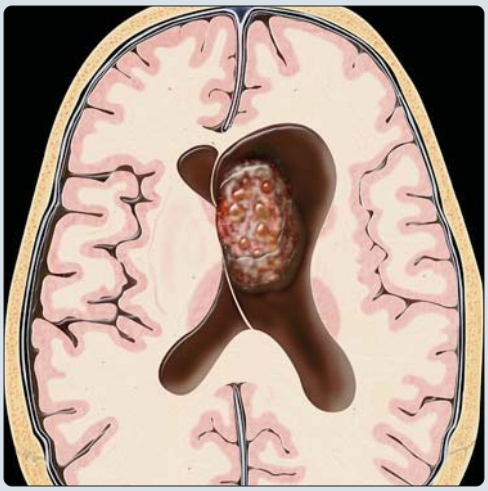
- Best diagnostic clue: "Bubbly" mass in frontal horn or body of lateral ventricle
  - May involve 3rd ventricle
- CT: Usually mixed solid and cystic mass with calcification
  - Hydrocephalus common
  - Rarely complicated by hemorrhage
- MR: Heterogeneous, T2 hyperintense, "bubbly" appearance
  - May be a predominantly solid mass
  - Moderate to strong heterogeneous enhancement
- MRS: ↑ Cho, ↓ NAA
  - Glycine peak at 3.55 ppm
- Consider central neurocytoma if "bubbly," "feathery," or solid intraventricular mass near foramen of Monro in young adult

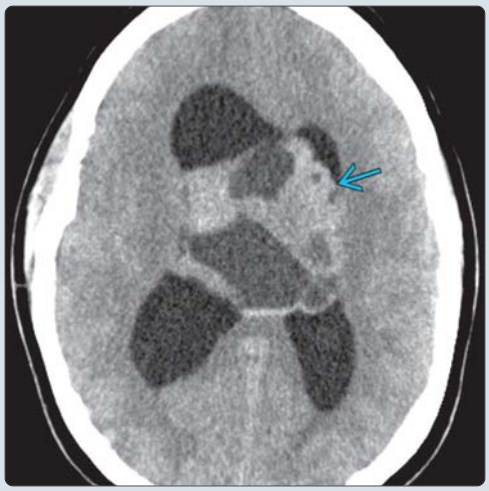
TOP DIFFERENTIAL DIAGNOSES

- Subependymoma
- Subependymal giant cell astrocytoma
- Intraventricular metastasis
- Ependymoma
- Choroid plexus papilloma

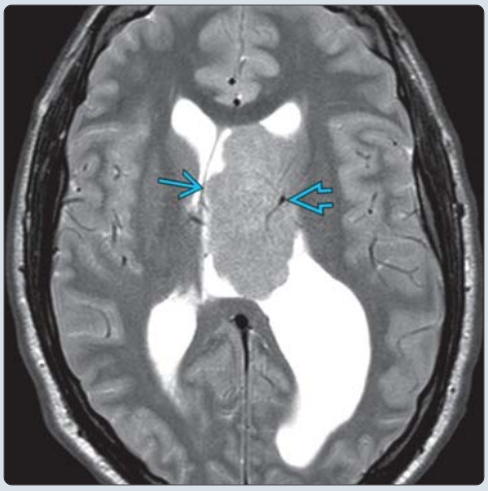
CLINICAL ISSUES

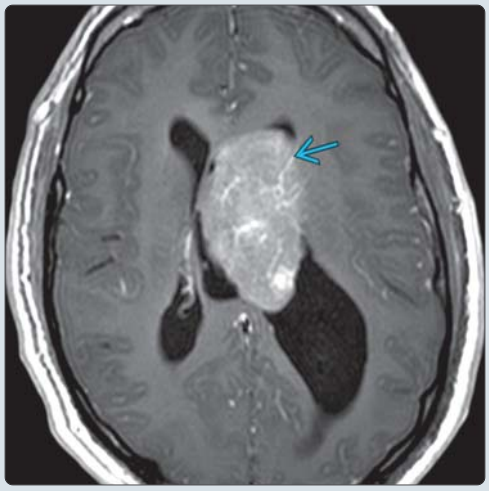
- Young adults, commonly 20-40 years of age
- Usually benign, local recurrence is uncommon
  - Surgical resection is typically curative
  - If incomplete resection, radiation therapy, chemotherapy, &/or radiosurgery may be helpful
- 5-year survival rate: 90%
- MIB-1 > 2-3% associated with poorer prognosis
- Headache, increased intracranial pressure, mental status changes, seizure are most common presenting features
  - Hydrocephalus secondary to foramen of Monro obstruction





(Left) *Axial graphic shows a circumscribed, lobular, "bubbly" mass attached to the septum pellucidum. Ventricular dilatation is related to foramen of Monro obstruction. This is the classic appearance of a central neurocytoma. Complete surgical resection is often curative for these WHO grade II tumors.* **(Right)** *Axial NECT shows a heterogeneous, cystic, and solid mass in the lateral ventricles attached to the septum pellucidum. There is associated hydrocephalus, typical for central neurocytoma.*





(Left) *Axial T2WI MR in a 20 year old with headaches shows a predominantly solid ventricular mass in the body of the lateral ventricle attached to the septum pellucidum with prominent flow voids.* **(Right)** *Axial T1WI C+ MR in the same patient shows diffuse enhancement. Central neurocytoma was diagnosed at resection. Imaging differential considerations include subependymal giant cell astrocytoma, subependymoma, and meningioma. (Courtesy S. van der Westhuizen, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Central neurocytoma (CN)

Synonyms

- Neurocytoma

Definitions

- Intraventricular neuroepithelial tumor with neuronal differentiation
- Well-demarcated, intraventricular, neurocytic neoplasm located in foramen of Monro region

IMAGING

General Features

- Best diagnostic clue
  - "Bubbly" mass in frontal horn or body of lateral ventricle
- Location
  - Typically supratentorial, intraventricular
  - Intraventricular mass attached to septum pellucidum
    - > 50% in frontal horn/body of lateral ventricle, near foramen of Monro
    - 15% extend into 3rd ventricle
  - Both lateral ventricles: 13%
  - 3rd ventricle only: ~ 5%
  - 4th ventricle: Extremely rare
  - Rare extraventricular tumors with neurocytoma features (extraventricular neurocytoma)
    - Brain parenchyma, cerebellum, brainstem, spinal cord
- Morphology
  - Circumscribed, lobulated mass with intratumoral "cysts"
  - Characteristic bubbly appearance on imaging studies
  - May be predominantly solid

CT Findings

- NECT
  - Usually mixed solid and cystic (iso-/hyperdense)
  - Ca++ common (50-70%)
  - Hydrocephalus common
  - Rarely complicated by hemorrhage
- CECT
  - Moderate heterogeneous enhancement

MR Findings

- T1WI
  - Heterogeneous, mostly isointense to gray matter
  - Cysts are hypointense
  - Prominent flow voids may be seen
  - Hemorrhage is rare
- T2WI
  - Heterogeneous, hyperintense bubbly appearance
  - Associated hydrocephalus is common
  - Ca++ often hypointense
  - Prominent flow voids may be seen
- FLAIR
  - Heterogeneous, predominantly hyperintense mass
- T2* GRE
  - Ca++ seen as areas of "blooming"
- T1WI C+
  - Moderate to strong heterogeneous enhancement
- MRS
  - Elevated Cho peak, decreased NAA typical
  - Glycine peak at 3.55 ppm typical
  - Alanine peak may be seen

Angiographic Findings

- DSA: Variable appearance
  - Avascular mass to marked vascularity

Nuclear Medicine Findings

- PET
  - Typically characterized by decreased metabolism on FDG PET
  - Hypermetabolic activity has been described in atypical central neurocytoma

Imaging Recommendations

- Protocol advice
  - Multiplanar contrast-enhanced MR, + coronal T2

DIFFERENTIAL DIAGNOSIS

Subependymoma

- May be indistinguishable
- Older patients
- Usually faint or no enhancement
- 4th > lateral ventricle

Subependymal Giant Cell Astrocytoma

- Mass at foramen of Monro, Ca++ common
- Look for stigmata of tuberous sclerosis
  - Subependymal nodules, cortical tubers, white matter lesions

Intraventricular Metastasis

- Uncommon, usually older patients
- Primary tumor often known

Ependymoma

- Supratentorial ependymomas rarely intraventricular
- Heterogeneous enhancing mass with edema
- Aggressive features

Choroid Plexus Papilloma

- Typically younger patients, lateral ventricle
- In adults, 4th ventricle
- Intensely enhancing papillary mass, hydrocephalus common

Meningioma

- Circumscribed, intensely enhancing mass
- Typically at trigone of lateral ventricle
- Older patients

Cavernous Malformation

- Rarely intraventricular (up to 11%)
- Ca++, T2-hypointense hemosiderin rim common

Oligodendroglioma

- Typically cortical mass with variable enhancement
- Main histologic differential

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Likely arise from neuroglial or bipotential progenitor cells
- Genetics
  - Chromosomal abnormalities on 7, 2p, 10q, 18q, 13q reported
- Associated abnormalities
  - "Central neurocytoma" describes typical intraventricular tumors
    - Parenchymal invasion is rare, found in more aggressive tumors
  - Central neurocytoma rarely found in association with medulloblastoma

Staging, Grading, & Classification

- WHO grade II
- "Atypical central neurocytoma" (aggressive variant)
  - MIB-1 index > 2%
  - Vascular proliferation

Gross Pathologic & Surgical Features

- Grayish, friable, circumscribed, intraventricular mass
- Moderately vascular, may calcify, hemorrhage rare
- Typically attached to septum pellucidum or lateral ventricular wall

Microscopic Features

- Resembles oligodendroglioma
  - Many central neurocytomas misdiagnosed in past
- Uniform round cells with neuronal differentiation
  - Stippled nuclei, perinuclear halos
- Various architectural patterns (can resemble other neoplasms)
  - Monotonous sheets of cells
  - Perivascular pseudorosettes (ependymoma)
  - Honeycomb appearance (oligodendroglioma)
  - Large fibrillary areas (pineocytoma)
- Benign (low proliferation rate, mitoses rare)
  - MIB-1 usually low (< 2%)
- Anaplasia, necrosis rare
  - May have brisk mitotic activity, MIB-1 > 2-3%
  - Microvascular proliferation
- Synaptophysin and neuron-specific enolase positive; rarely GFAP positive
- Electron microscopy: Finely speckled chromatin, small distinct nucleolus, cell processes with neuritic features (microtubules)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, increased intracranial pressure, mental status changes, seizure
- Other signs/symptoms
  - Hydrocephalus secondary to foramen of Monro obstruction
  - Tumors of septum, 3rd ventricle, hypothalamus may have visual disturbances, hormonal dysfunction
  - Acute ventricular obstruction and death reported
  - Rarely asymptomatic

Demographics

- Age
  - Young adults, commonly 20-40 years (70%)
  - Range: 1-67 years; mean: 29 years
- Gender
  - No gender predominance
- Epidemiology
  - < 1% of all primary intracranial neoplasms
  - ~ 10% of intraventricular neoplasms
  - Represents 50% of intraventricular tumors in patients 20-40 years

Natural History & Prognosis

- Usually benign, local recurrence is uncommon
  - Surgical resection is typically curative
- Rarely complicated by hemorrhage
- 5-year survival rate: 90%
- MIB-1 > 2-3% associated with poorer prognosis
- Craniospinal dissemination extremely rare
- Tumors with extraventricular extension have poorer clinical outcome

Treatment

- Complete surgical resection is treatment of choice
- If incomplete resection, radiation therapy, chemotherapy, &/or radiosurgery may be helpful
- Radiosurgery may improve local control rates and increase survival

DIAGNOSTIC CHECKLIST

Consider

- Subependymoma and giant cell astrocytoma mimic central neurocytoma, clinical information may help
- May mimic other tumors pathologically, so imaging correlation is important

Image Interpretation Pearls

- Think central neurocytoma if "bubbly," "feathery," intraventricular mass near foramen of Monro in young adult
- Central neurocytoma is typically attached to septum pellucidum

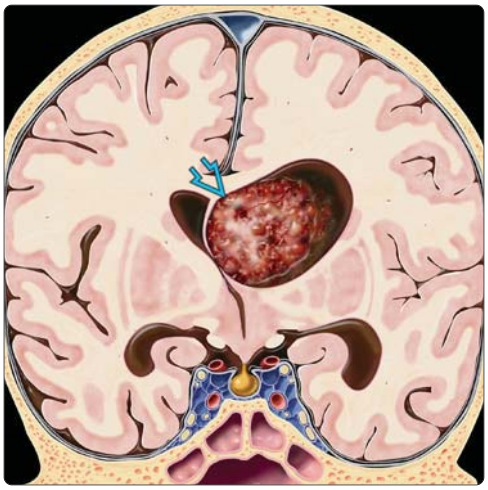
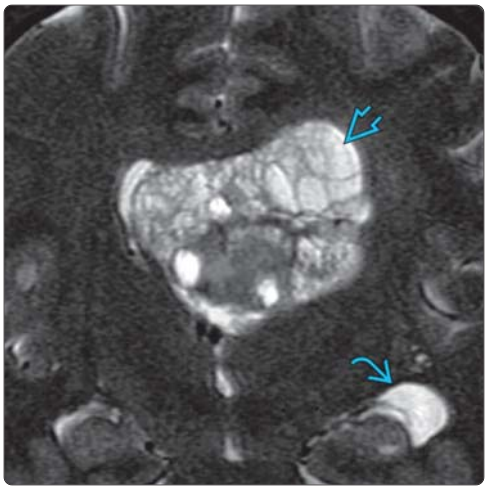
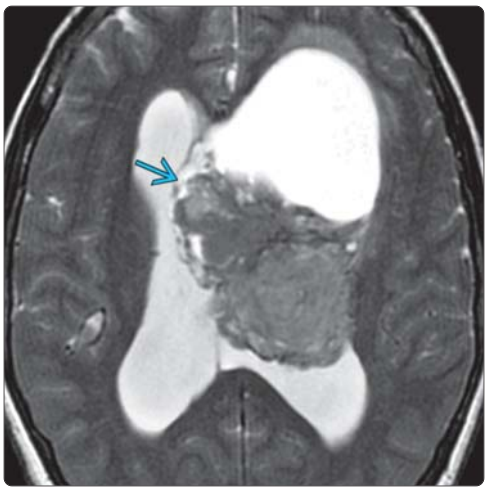
(Left) *Sagittal T1 C+ MR in a 36-year-old woman shows a heterogeneously enhancing cystic and solid intraventricular mass. WHO grade II central neurocytoma was diagnosed at resection. Surgical resection is typically curative of these tumors.* **(Right)** *Axial FLAIR MR shows a heterogeneously hyperintense mass ⇨ in the lateral ventricles. There is associated hydrocephalus, typical for central neurocytoma. (Courtesy M. Michel, MD.)*





(Left) *Coronal graphic shows a "bubbly," lobular, intraventricular central neurocytoma ⇨ with bowing of the septum pellucidum and associated ventricular dilatation.* **(Right)** *Coronal T2WI MR shows the characteristic bubbly appearance of this lateral ventricle central neurocytoma ⇨ with septum pellucidum bowing and temporal horn dilatation ⇨. Strong heterogeneous enhancement is typical. These tumors typically present in young adults between 20 and 40 years old.*



(Left) *Axial T2WI MR shows a heterogeneous, "bubbly" lateral ventricular mass with attachment to the septum pellucidum ⇨ and hydrocephalus, typical for central neurocytoma.* **(Right)** *Axial T1WI C+ MR in the same patient shows marked enhancement of the lobular mass with a large cyst filling the frontal horn. The imaging features of subependymoma and subependymal giant cell astrocytoma may mimic a central neurocytoma. Clinical features can help differentiate.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Neuroepithelial tumor located outside ventricular system, commonly in brain parenchyma

IMAGING

- Best diagnostic clue: Well-circumscribed, enhancing, cystic and solid parenchymal mass in young adult
- Majority are supratentorial involving cerebral hemispheres
  - Frontal and parietal lobes most common
  - Deep gray nuclei less common
- Ca++ in 10-15%
- T2 MR: Heterogeneously hyperintense mass
- T2* GRE: May show "blooming" related to blood products or Ca++
- T1WI C+: Variable enhancement of solid portions
  - May have cyst with mural nodule appearance

TOP DIFFERENTIAL DIAGNOSES

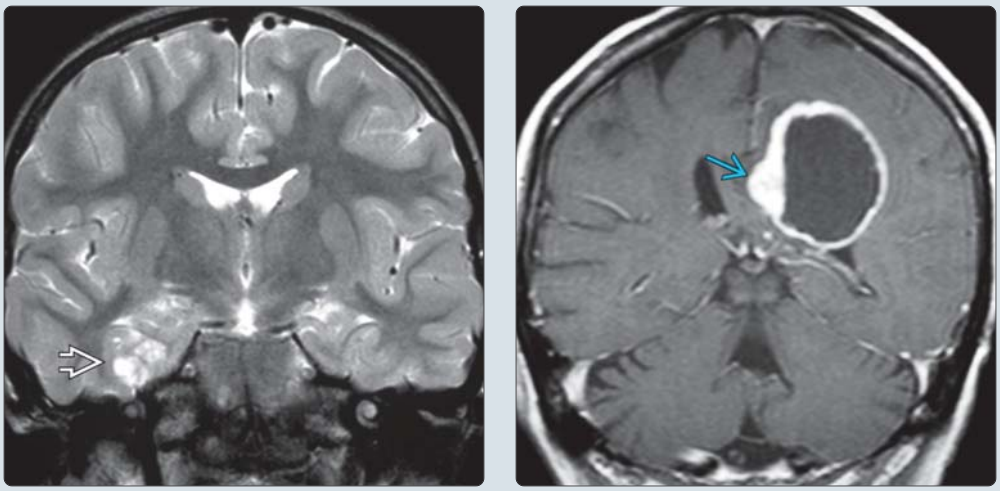
- Oligodendroglioma
- Pilocytic astrocytoma
- Ganglioglioma
- DNET
- Glioblastoma

PATHOLOGY

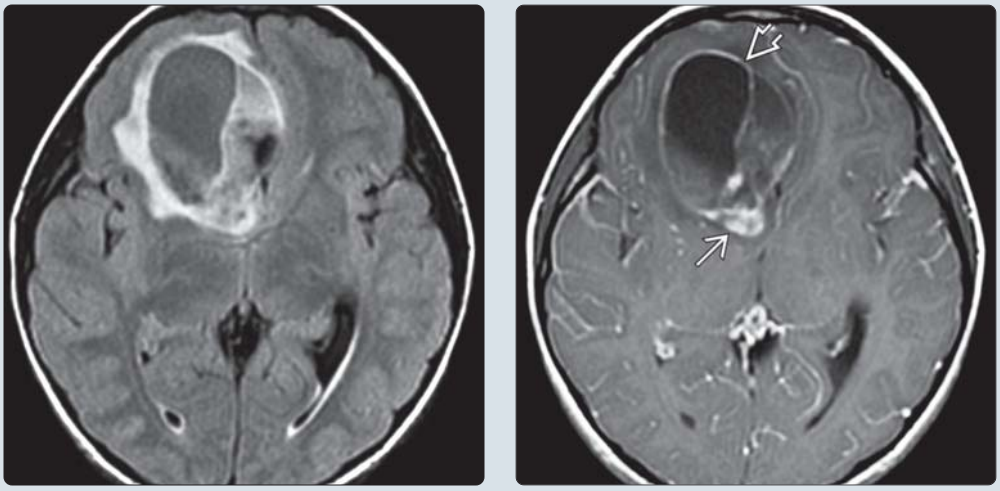
- WHO grade II
- May be identical to central neurocytoma
  - Often contain ganglion cells or ganglioid cells

CLINICAL ISSUES

- Seizures, headaches, hemiparesis are most common presenting features
- Occur in children and young adults (median: 34 years)
- Rare: < 0.5% of primary CNS tumors
- Surgical resection is typically curative
- Subtotal resection, atypical histologic features, and high cell proliferation rates correlate with recurrence



(Left) *Coronal T2WI MR shows a heterogeneously hyperintense superficial temporal lobe mass. The bubbly appearance mimics a DNET, but this proved to be an extraventricular neurocytoma. (Courtesy A. Rossi, MD.)* **(Right)** *Coronal T1WI C+ MR in a 61-year-old woman with weakness shows a peripherally nodular enhancing parietal lobe mass. Extraventricular neurocytoma was diagnosed at histopathology. (Courtesy J. Boxerman, MD.)*



(Left) *Axial FLAIR MR shows a cystic and solid mass in the frontal lobe with mild surrounding vasogenic edema. (Courtesy N. Fischbein, MD.)* **(Right)** *Axial T1WI C+ MR in the same patient shows heterogeneous enhancement of the solid portion and rim enhancement of the cystic portion. The lack of significant vasogenic edema is typical for extraventricular neurocytoma. Imaging differential considerations include oligodendroglioma, astrocytoma, and ganglioglioma. (Courtesy N. Fischbein, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Extraventricular neurocytoma (EVN)

Definitions

- Neuroepithelial tumor located outside of ventricular system, commonly in brain parenchyma

IMAGING

General Features

- Best diagnostic clue
  - Well-circumscribed, enhancing, cystic and solid parenchymal mass in young adult
- Location
  - Majority are supratentorial involving cerebral hemispheres
    - Frontal and parietal lobes most common
    - Deep gray nuclei less common
  - Cerebellum and brainstem rare
  - Sella, pineal region, spinal cord reported
- Morphology
  - Cystic and solid masses
  - May have cyst with mural nodule appearance

Imaging Recommendations

- Protocol advice
  - Contrast-enhanced MR with GRE, ± MRS

CT Findings

- NECT
  - Circumscribed, complex, cystic and solid mass
  - Ca++ in 10-15%
  - Vasogenic edema variable

MR Findings

- T1WI: Cystic, heterogeneously solid mass
  - Usually involve deep white matter (WM), may involve cortex
- T2WI: Heterogeneously hyperintense mass
  - Mild vasogenic edema typical
- T2* GRE: May show "blooming" related to blood products or Ca++
- T1WI C+: Variable enhancement of solid portions
  - May see cyst and mural nodule
- MRS: ↓ NAA and ↑ choline (Cho)

DIFFERENTIAL DIAGNOSIS

Oligodendroglioma

- Calcified, heterogeneous mass
- Variable enhancement

Pilocytic Astrocytoma

- Solid-cystic or solid enhancing mass
- Typically posterior fossa or chiasmatic/hypothalamic

Ganglioglioma

- Enhancing cystic and solid, cortically based mass in child or young adult
- Temporal lobe commonly > parietal, frontal

DNET

- Cortical "bubbly" mass in young adult

Glioblastoma

- Heterogeneous mass with central necrosis
- Typically older patients

PATHOLOGY

General Features

- Etiology
  - May arise from neuroglial precursor cells
- Associated abnormalities
  - Single case reported in patient with neurofibromatosis type 1

Staging, Grading, & Classification

- WHO grade II

Gross Pathologic & Surgical Features

- Cysts, necrosis, Ca++ may be seen
- Hemorrhage rare

Microscopic Features

- May be identical to central neurocytoma
  - Densely cellular, cytologically monomorphous
- Often contain ganglion cells or ganglioid cells
- Hyalinized vessels and dense Ca++ common
- Synaptophysin positive, often GFAP positive

CLINICAL ISSUES

Presentation

- Most common signs: Seizures, headaches, hemiparesis

Demographics

- Age
  - Typically children, young adults (median: 34 years)
- Gender
  - No gender predominance
- Epidemiology
  - Rare: < 0.5% of primary CNS tumors

Natural History & Prognosis

- Surgical resection is typically curative
- Subtotal resection, atypical histologic features, and high cell proliferation rates correlate with recurrence

Treatment

- Surgical resection ± adjuvant therapy
- Radiation therapy in recurrent tumors

KEY FACTS

TERMINOLOGY

- Cerebellar liponeurocytoma (CLN)
- Rare cerebellar parenchymal neoplasm of adults
  - Consistent neuronal, variable astrocytic and lipomatous elements

IMAGING

- CT
  - Hypodense (fat density)
- MR
  - Hyperintense on T1WI
  - Inhomogeneously hyperintense on T2WI
  - Lipomatous component suppresses with fat saturation
  - Heterogeneous enhancement

TOP DIFFERENTIAL DIAGNOSES

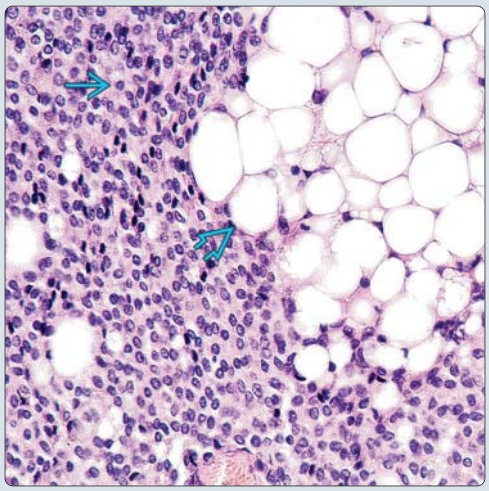
- Medulloblastoma with lipidized cells
- Teratoma
- Anaplastic oligodendroglioma
- Ependymoma

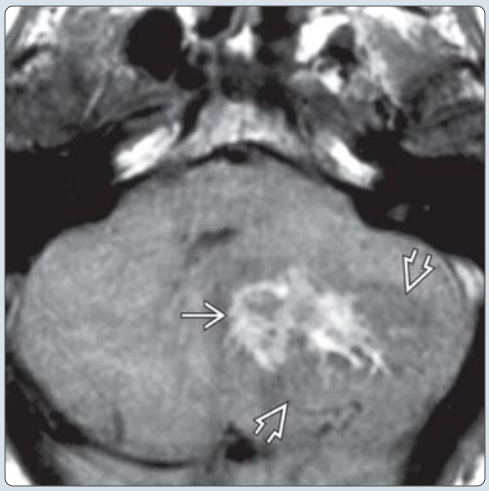
PATHOLOGY

- *TP53* missense mutations
- WHO grade II
- Moderate to low mitotic index
  - MIB-1 mean: 2.5%

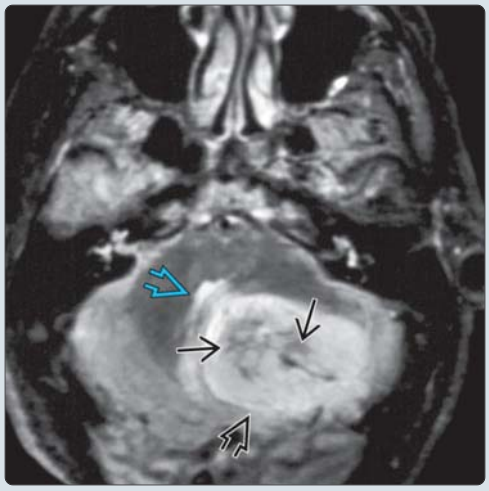
CLINICAL ISSUES

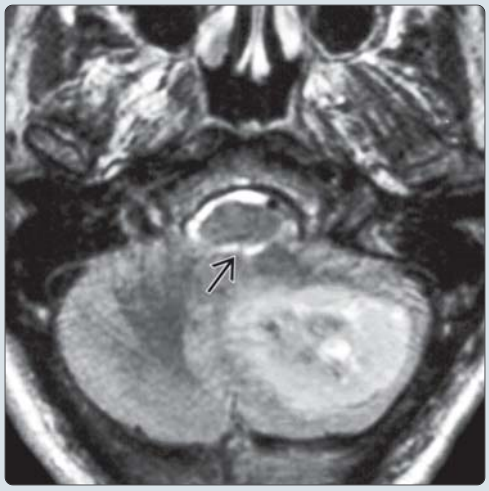
- Headache is most common presenting symptom
  - More focal cerebellar symptoms depending on location
- Age range: 24-77 years; mean: 50 years
- M = F
- ~ 2/3 recur after resection within 1-12 years
  - 5-year survival: 48%
- Consider cerebellar liponeurocytoma in fat-containing cerebellar mass in adult





(Left) *The principal components of a cerebellar liponeurocytoma include classic neurocytes ⇨ and distinctive, variably lipidized cells ⇨ resembling adipose tissue. (From DP: Neuro.)* **(Right)** *Precontrast axial T1 MR image shows irregular areas of high signal intensity ➡ within a left cerebellar mass due to areas of fatty tissue that cause T1 shortening. The majority of the mass is isointense with poorly defined borders ➡. (Courtesy AFIP.)*





(Left) *Axial T2 MR image in the same patient shows the left cerebellar mass as a discrete lesion with the fatty component ⇨ slightly hypointense compared to the larger, more cellular, nonfatty, hyperintense portion of the tumor ⇨. Note the significant mass effect upon the 4th ventricle ⇨. (Courtesy AFIP.)* **(Right)** *Axial T2 MR image shows the mass effect from the tumor significantly effacing the inferior 4th ventricle ⇨ resulting in the supratentorial hydrocephalus. (Courtesy AFIP.)*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Indolent glioneuronal tumor
  - Previously considered ganglioglioma subtype
  - Also described as pseudopapillary neurocytoma with glial differentiation

IMAGING

- General features
  - Cerebral hemispheres most common site
    - Temporal lobe predilection
  - Parenchymal mass with solid, cystic, or cyst/mural nodule architecture
- CT
  - Partially calcified mass ± cystic regions
- MR
  - Isointense ± hypointense cysts on T1WI
  - Inhomogeneously hyperintense on T2WI
  - Inhomogeneously hyperintense nodule on FLAIR (cyst may suppress)
  - Strong, heterogeneous enhancement on T1WI C+
- Imaging may be indistinguishable from ganglioglioma

TOP DIFFERENTIAL DIAGNOSES

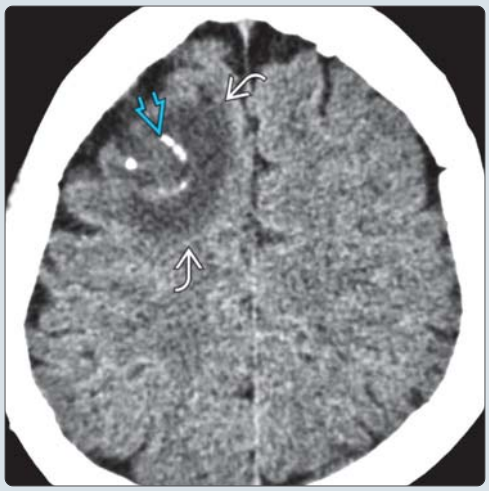
- Ganglioglioma
- Oligodendroglioma
- Neurocysticercosis
- Ependymoma

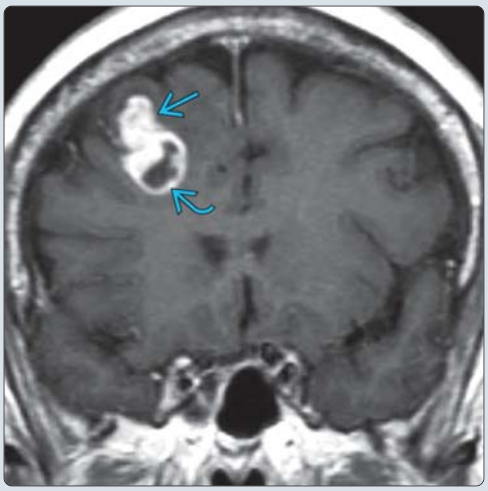
PATHOLOGY

- "Biphasic" neurocytic, glial components
- WHO grade I with low MIB-1 index (1-2%)

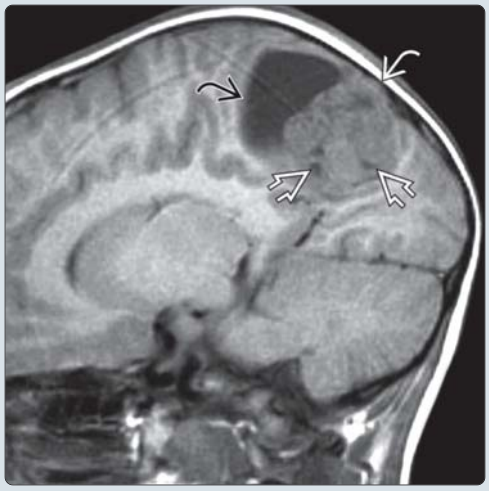
CLINICAL ISSUES

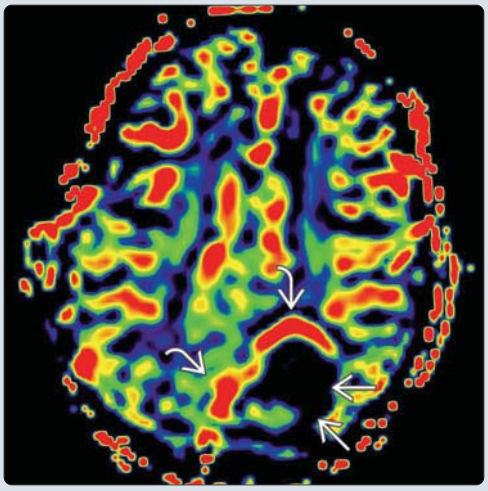
- Seizures, headache most common symptoms
- Affects children, young adults (range: 4-75 years)
- Potentially curable with complete resection
- Generally indolent course although aggressive papillary glioneuronal tumors reported





(Left) *Axial NECT in a recently arrived immigrant with seizures shows a right frontal mass with incomplete ring calcification and moderate perilesional edema. The imaging differential diagnosis includes both neoplasm and parasitic infection.* **(Right)** *Coronal T1WI C+ MR in the same patient shows an intensely, but heterogeneously, enhancing mass with a larger cystic area with rim enhancement. Stereotaxic biopsy disclosed a papillary glioneuronal tumor.*





(Left) *Sagittal T1WI MR in an 8-year-old boy with seizures shows a solid and cystic parietal lobe mass. The solid component shows lobulations with some intratumoral cystic-appearing spaces. PGNT are most common in the temporal lobes. (Courtesy M. Castillo, MD.)* **(Right)** *Axial perfusion MR in the same patient shows a parietal lobe mass with relatively decreased perfusion surrounded by a rim of relatively increased perfusion. Papillary glioneuronal tumor was found at surgery. (Courtesy M. Castillo, MD.)*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Rosette-forming glioneuronal tumor (RGNT)
- Rare, slowly growing benign tumor of young adults
  - 4th ventricle most common site > cerebellum
  - Rarely in pineal region, cerebellopontine angle, brain hemispheres

IMAGING

- Midline cerebellar neoplasm
  - Mixed solid-cystic appearance
  - Variable Ca++, hemorrhage
  - Hyperintense on T2WI
- Variable enhancement

TOP DIFFERENTIAL DIAGNOSES

- Ependymoma
- Medulloblastoma (PNET-MB)
- Pilocytic astrocytoma
- Metastases

PATHOLOGY

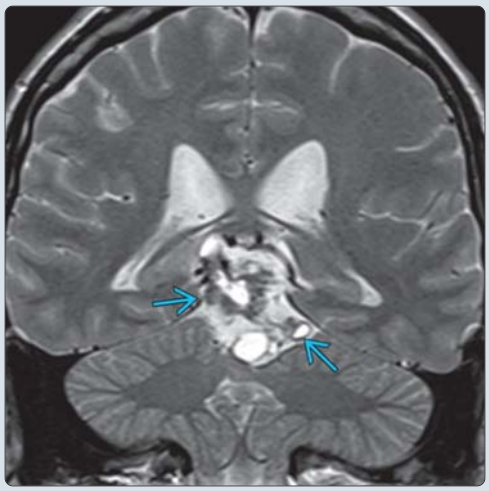
- WHO grade I
- 2 components
  - Neurocytic: Neurocytes forming neurocytic/perivascular pseudorosette
  - Astrocytic: Resembles pilocytic astrocytoma

CLINICAL ISSUES

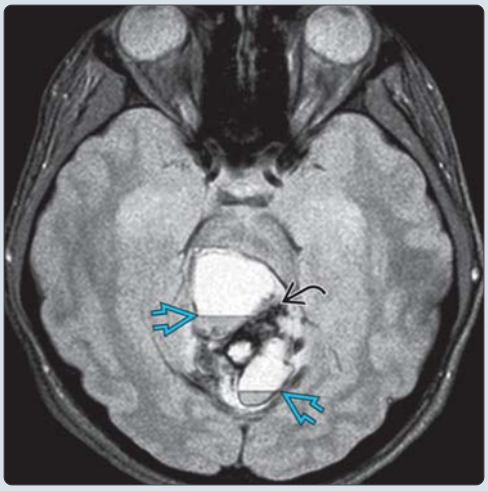
- Young/middle-aged adults
- Headache (60% associated hydrocephalus) and ataxia are common presenting symptoms
- Benign, no malignant transformation
  - CSF dissemination into ventricular system has been reported

DIAGNOSTIC CHECKLIST

- Suspect RGNT when young adult presents with well-circumscribed 4th ventricle mass with combined cystic-nodule appearance, no edema



(Left) *Sagittal T1WI MR in a young adult with headaches shows a mixed signal intensity mass filling the 4th ventricle. Foci of T1 shortening represent hemorrhage. No enhancement was seen on T1WI C+ scans. Pathology showed a RGNT.* **(Right)** *Coronal T2 MR in a 31-year-old man with headaches shows a heterogeneous pineal region mass with mass effect but no surrounding edema. RGNT was diagnosed at resection. These tumors are most commonly in the posterior fossa, within the 4th ventricle or cerebellar vermis.*



(Left) *Axial T2* GRE MR in a patient with headaches and papilledema on physical examination demonstrates a large, multicystic midline mass in the posterior fossa. Note the fluid-fluid levels and regions of low signal intensities representing calcifications.* **(Right)** *Axial T1WI C+ in the same patient shows mild heterogeneous enhancement of the 4th ventricle mass. Note the dilated optic nerve sheaths and elevated optic discs from papilledema. A RGNT was found at surgery.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Rosette-forming glioneuronal tumor (RGNT)

Synonyms

- 1st described as dysembryoplastic neuroepithelial tumor (DNT) of cerebellum
- Also formerly called cerebellar DNT

Definitions

- Rare, slowly growing benign tumor
  - 4th ventricle most common (sometimes called RGNT of 4th ventricle)

IMAGING

General Features

- Best diagnostic clue
  - Midline cerebellar mass with solid-cystic appearance without edema in young/middle-aged adult
- Location
  - Majority in cerebellar midline around 4th ventricle (posterior fossa)
  - Rarely in pineal region, cerebellopontine angle, brain hemispheres
- Size
  - Varies between 1.5 and 10 cm

Imaging Recommendations

- Best imaging tool
  - MR with T1WI C+, T2* (hemorrhage, Ca++)

CT Findings

- NECT
  - Midline posterior fossa cystic/solid mass
  - Variable Ca++, hemorrhage

MR Findings

- T1WI
  - Iso-/hypointense mass
- T2WI
  - Hyperintense, heterogeneous
- T2* GRE
  - Hemorrhage common
- T1WI C+
  - Variable enhancement (none to heterogeneous)

DIFFERENTIAL DIAGNOSIS

Ependymoma

- Usually tumor of childhood
- "Squeezes" out through lateral recesses
- Strong but heterogeneous enhancement

Medulloblastoma (PNET-MB)

- Children > adults
- Typically strong enhancement
- Gross hemorrhage, cyst formation less common

Pilocytic Astrocytoma (PA)

- Children > adults
- Cyst with nodule appearance
  - Nodule enhances strongly
  - If cyst wall enhances, may resemble RGNT

Metastases

- Older adult > young adult
- Primary tumor often known

PATHOLOGY

General Features

- Etiology
  - Derives from pluripotential cells of subependymal plate

Staging, Grading, & Classification

- WHO grade I

Gross Pathologic & Surgical Features

- Cystic/nodular appearance

Microscopic Features

- 2 components
  - Neurocytic: Neurocytes forming neurocytic/perivascular pseudorosette
  - Astrocytic: Resembles pilocytic astrocytoma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, ataxia
- Other signs/symptoms
  - Nausea, vertigo
  - 60% of patients present with obstructive hydrocephalus

Demographics

- Age
  - Young/middle-aged adults
    - Mean: ~ 30 years old
- Gender
  - M:F = 1:2

Natural History & Prognosis

- Benign; no malignant transformation

Treatment

- Surgical removal, ± adjuvant therapy

DIAGNOSTIC CHECKLIST

Consider

- Suspect RGNT when young adult presents with well-circumscribed 4th ventricle mass with combined cystic-nodule appearance, no edema

https://CafePezeshki.IR

Pineocytoma

KEY FACTS

TERMINOLOGY

- Pineocytoma (PC), pineal parenchymal tumor (PPT)
- PCs are composed of small, uniform, mature cells
  - Cells resemble pineocytes

IMAGING

- General features: Circumscribed, enhancing pineal mass
  - May mimic benign pineal cyst or pineal parenchymal tumor of intermediate differentiation (PPTID)
  - Typically < 3 cm
  - May compress adjacent structures
  - Rarely extends into 3rd ventricle, rarely invasive
  - Can compress aqueduct → hydrocephalus
- CT
  - Circumscribed iso-/hypodense pineal region mass
  - Peripheral ("exploded") Ca++ common
  - CECT: Enhances (solid, ring, nodular)
- MR (most sensitive)
  - Cystic change may be present
  - Enhancement may be solid or peripheral

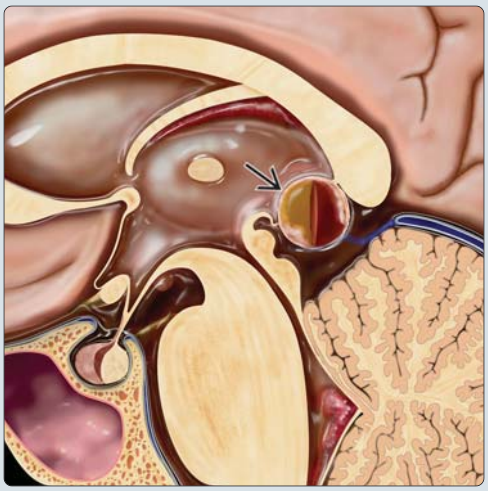
TOP DIFFERENTIAL DIAGNOSES

- Nonneoplastic pineal cyst
- PPTID
- Pineoblastoma
- Germinoma, other germ cell tumors

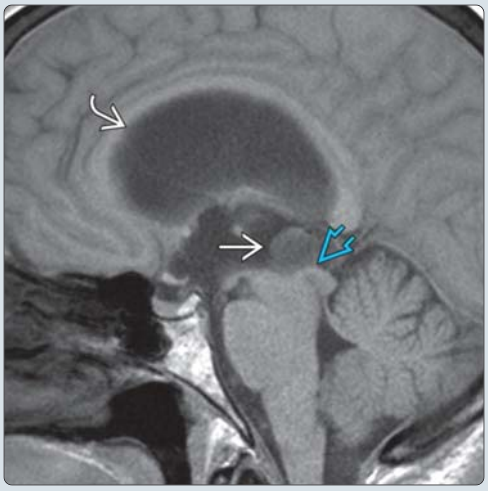
CLINICAL ISSUES

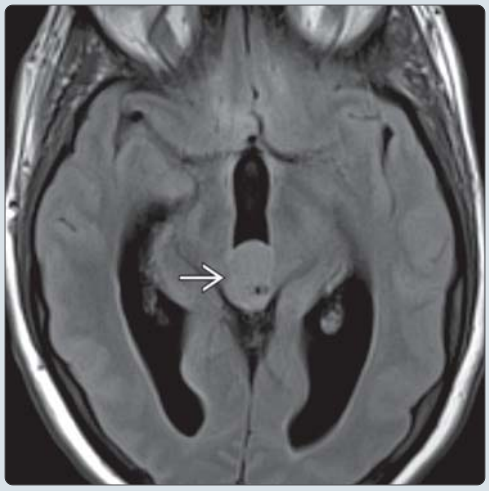
- Headache, Parinaud syndrome (paralysis of upward gaze) are most common features
- Increased intracranial pressure, ataxia, hydrocephalus, mental status changes may occur
- Most common in adults, mean 40 years
- Stable- or slow-growing tumor
- Germ cell markers (α-fetoprotein, hCG) absent
- Surgical excision or stereotactic biopsy is primary treatment
  - Complete surgical resection generally curative

(Left) *Sagittal graphic shows a cystic pineal gland mass with a fluid-fluid level and nodular tumor along the periphery of the mass, typical of pineocytoma. No significant mass effect is present. Pituicytomas may be found incidentally or present with hydrocephalus.* **(Right)** *Axial NECT shows a classic example of a pineocytoma. Note the "exploded" peripheral calcification in this small mass that arises from the pineal region. The tumor is just over 1 cm in size. There is no hydrocephalus.*



(Left) *Sagittal T1 MR image of a 50-year-old woman with headache shows a cystic pineal region mass with associated ventriculomegaly and local mass effect on the tectum. Mass effect on the superior tectum often results in Parinaud syndrome, paralysis of upward gaze.* **(Right)** *Axial FLAIR MR in the same patient shows the hyperintense, lobular pineal region mass with associated ventriculomegaly. Pineocytoma was diagnosed at resection. These WHO grade I tumors are often stable for years.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pineocytoma (PC)

Definitions

- Slow-growing pineal parenchymal tumor (PPT) of young adults
  - Composed of small, uniform, mature cells resembling pineocytes

IMAGING

General Features

- Best diagnostic clue
  - Circumscribed pineal mass that "explodes" pineal calcification peripherally
  - May mimic pineal cyst, pineal parenchymal tumor of intermediate differentiation (PPTID)
- Location
  - Pineal region
  - Rarely extends into 3rd ventricle
  - Rarely invasive
  - May compress adjacent structures
    - Rarely, associated hydrocephalus if aqueduct compression
- Size
  - Typically < 3 cm
- Morphology
  - Demarcated round or lobular mass

CT Findings

- NECT
  - Iso-/hypodense mass
  - Peripheral ("exploded") Ca++
  - Cystic change may be present
- CECT
  - Enhancement present, often heterogeneous

MR Findings

- T1WI
  - Iso- to hypointense round or lobular mass
- T2WI
  - Hyperintense round or lobular mass
- FLAIR
  - Hyperintense round or lobular pineal mass
- T2* GRE
  - May see Ca++
    - Areas of "blooming" at periphery/within mass
  - May hemorrhage (less common)
- T1WI C+
  - Avid enhancement is typical
  - Enhancement may be solid or peripheral

Imaging Recommendations

- Best imaging tool
  - MR imaging most sensitive
  - CT helpful to confirm Ca++
- Protocol advice
  - MR: Include post-contrast coronal and sagittal images

DIFFERENTIAL DIAGNOSIS

Nonneoplastic Pineal Cyst

- Round, smooth, cystic mass
- Typically < 1 cm, may be up to 2 cm
- Variable calcification and cyst fluid
- No/minimal rim enhancement
  - Compressed enhancing gland often seen posteriorly
- May be indistinguishable from PC on imaging

Pineal Parenchymal Tumor of Intermediate Differentiation (PPTID)

- Often middle-aged, older patients
- PPTIDs have more aggressive appearance than PC
  - Intermediate between PC, pineoblastoma
  - WHO grade II or III

Pineoblastoma

- Younger patients
- Large, lobulated, heterogeneous
- Mass effect, parenchymal invasion, CSF spread
- May be seen in patients with retinoblastoma ("trilateral retinoblastoma")

Germinoma

- "Engulfs" calcified pineal gland
- Intensely enhancing, often homogeneous
- CSF spread often present at diagnosis
- Hyperdense on CT
- Typically young male patients

Papillary Tumor of Pineal Region (PTPR)

- Rare
- Enhancing pineal region mass
- May be indistinguishable from PC, PPTID on imaging

Astrocytoma

- Infiltrative, T2 hyperintense mass
- Significant mass effect
- Variable enhancement

Other Germ Cell Tumors (GCT)

- Teratoma
- Choriocarcinoma, endodermal sinus (yolk sac) tumor, embryonal carcinoma, mixed GCT
- May have fat, hemorrhage, cystic change
- Lab studies may help (i.e., α-fetoprotein, hCG)

Meningioma

- Avidly enhancing, homogeneous mass with dural tail
- Middle-aged, older female patients

PATHOLOGY

General Features

- Etiology
  - Derived from pineal parenchymal cells (pineocytes) or their embryonic precursors
  - Pineocytes have photosensory and neuroendocrine function
- Genetics
  - No *TP53* mutations
  - Inconsistent reports of chromosomal gains/deletions

https://CafePezeshki.IR

Staging, Grading, & Classification

- WHO grade I
- Grading system for PPTs
  - Based on mitoses, neurofilament (NF) protein staining
    - Grade 1: Classic PC with no mitoses, NF(+)
    - Grade 2: < 6 mitoses/10 high-power fields, NF(+) (PPTID)
    - Grade 3: < 6 mitoses, NF(-) or ≥ 6 mitoses, NF(+) (PPTID)
    - Grade 4: Variable mitoses ± NF (pineoblastoma)

Gross Pathologic & Surgical Features

- Well-circumscribed, gray-tan mass
  - Homogeneous or granular cut surface
- Cysts, small hemorrhagic foci may be present
- Compresses, does not invade adjacent structures
- Rarely extends into 3rd ventricle

Microscopic Features

- Well-differentiated tumor
  - Small, uniform, mature cells
    - Resemble pineocytes
  - Sheets/lobules of tumor
  - Separated by mesenchymal septa
  - Variable neuronal, ganglionic, astrocytic differentiation
- Large fibrillary "pineocytomatous rosettes" characteristic
  - Large rosettes surround a fine network of processes
- Mitoses, necrosis absent
- Immunohistochemistry
  - Synaptophysin strongly positive
  - Neuron-specific enolase (NSE) strongly positive
- Electron microscopy
  - Microtubules
  - Clear-core or dense-core vesicles
  - Synapses
- Pleomorphic subset (probably PPTID)
  - Mixed/intermediate differentiation, mitoses
  - Occasional areas of necrosis, endothelial hyperplasia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache
  - Parinaud syndrome (paralysis of upward gaze)
- Other signs/symptoms
  - ↑ intracranial pressure, hydrocephalus
  - Ataxia
  - Mental status changes
- Clinical profile
  - Germ cell markers
    - α-fetoprotein, hCG absent

Demographics

- Age
  - May occur at any age, including children
  - Mean: 35-40 years
- Gender
  - M = F
- Epidemiology
  - < 1% of primary brain tumors
  - Pineal region tumors ~ 3-8% of pediatric tumors
  - Pineal parenchymal tumors (PPT) account for ~ 15-30% of pineal gland tumors
    - PPT: Pineocytoma, pineal parenchymal tumor of intermediate differentiation (PPTID), pineoblastoma
  - Germ cell neoplasms account for ~ 40% of pineal gland tumors
    - Germinoma > > PPTs
  - Pineocytomas: ~ 45% of PPTs

Natural History & Prognosis

- Stable or slow-growing tumor
- Overall 5-year survival ~ 85-100%
  - 90% (grade II) to 100% (grade I) 5-year survival
- Rarely complicated by hemorrhage

Treatment

- Surgical excision or stereotactic biopsy is primary treatment
- Complete surgical resection generally curative
  - CSF diversion may be necessary
- Postoperative radiation therapy is controversial
- Some reports suggest stereotactic radiosurgery may be used as primary therapy or adjuvant therapy

DIAGNOSTIC CHECKLIST

Consider

- Pineocytoma may be cystic, mimic pineal cyst
- May appear aggressive, mimic pineoblastoma or PPTID
- Clinical information often helpful to differentiate pineal region masses
- GCTs often have positive serum markers

Image Interpretation Pearls

- Pineocytomas have peripheral Ca++
  - Germinomas "engulf" gland Ca++
- Enhancement often solid, may be peripheral

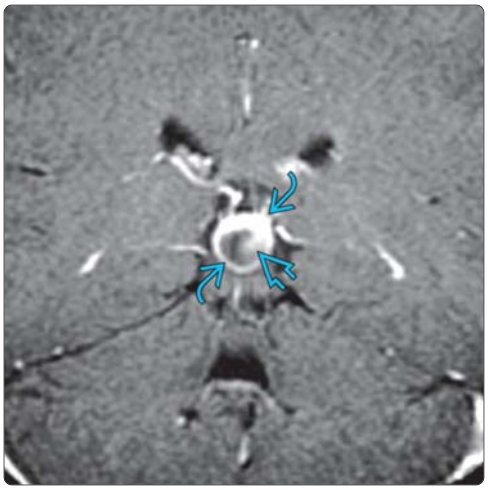
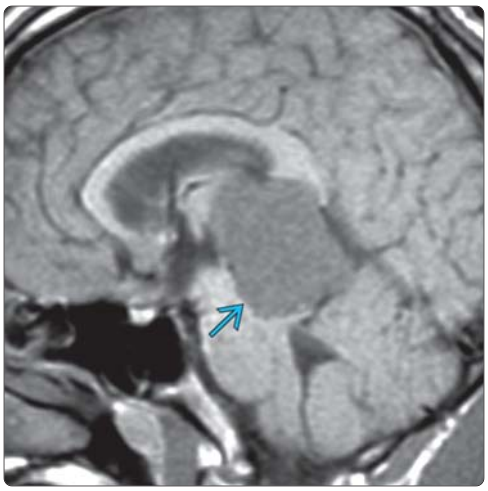
(Left) *Sagittal T1WI MR shows a demarcated mass of the pineal gland, isointense to the brain parenchyma. It exerts mild mass effect on the tectum, but the aqueduct is patent and there is no hydrocephalus. The pineal tumor sits underneath the internal cerebral veins and splenium of the corpus callosum.* **(Right)** *Sagittal T1WI C+ MR in the same patient shows the heterogeneously enhancing nature of the pineocytoma, with avid enhancement of the superior nodular component.*



(Left) *Axial T1 C+ MR image of a pineocytoma shows a lobular, partially enhancing, partially cystic pineal region mass. Pineocytoma is the most common pineal parenchymal tumor. When cystic, these tumors may mimic a benign pineal cyst. (Courtesy C. Glastonbury MBBS.)* **(Right)** *Coronal T1WI C+ MR in a patient with pineocytoma shows both peripheral and more solid enhancement of a cystic pineal mass. A small central "target" of enhancement is also present.*



(Left) *Sagittal T1WI MR shows a variant appearance of a pineocytoma. There is a large, lobular, circumscribed tumor that causes obstructive hydrocephalus due to compression of the cerebral aqueduct. The tumor is slightly hyperintense relative to CSF and mildly hypointense relative to brain.* **(Right)** *Coronal T1WI C+ MR shows avid enhancement of the tumor with mild heterogeneity. "Variant" cases of presumed pineocytoma must be distinguished from PPTID, a more aggressive tumor.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Primary parenchymal neoplasm of pineal gland
  - Intermediate in malignancy between pineoblastoma and pineocytoma

IMAGING

- General features
  - Aggressive-looking pineal mass in adult
  - Extension into adjacent structures (ventricles, thalami) is common
  - Lobulated, moderately vascular
  - Size varies from small (< 1 cm) to large (~ 6 cm)
- CT
  - Hyperdense mass centered in pineal region
  - Engulfs pineal gland Ca++
  - Hydrocephalus
- MR
  - T1: Mixed iso-/hypointense mass
  - T2: Isointense with gray matter, + small hyperintense foci
  - FLAIR: Hyperintense
  - Strong, heterogeneous enhancement
  - MRS: Elevated Cho, decreased NAA
- If aggressive-looking pineal region tumor in middle-aged, older adult, consider PPTID

TOP DIFFERENTIAL DIAGNOSES

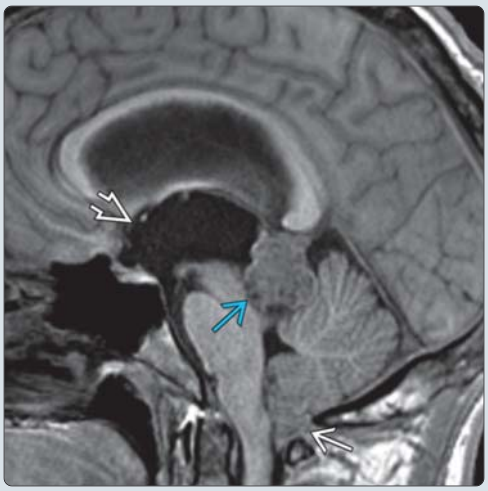
- Germinoma
- Pineocytoma
- Pineoblastoma
- Papillary tumor of pineal region (PTPR)

PATHOLOGY

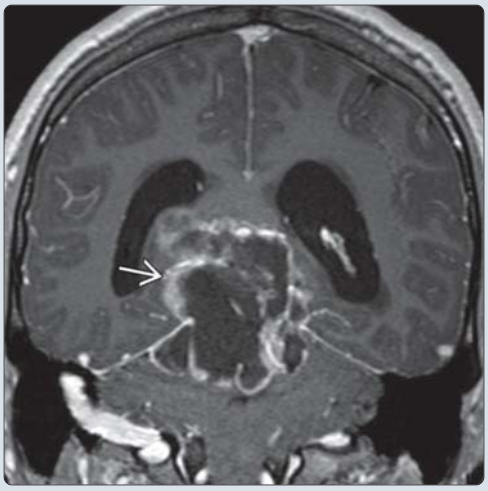
- Neuroepithelial neoplasm
  - Arises from pineocytes or their precursors
- WHO grade II or III

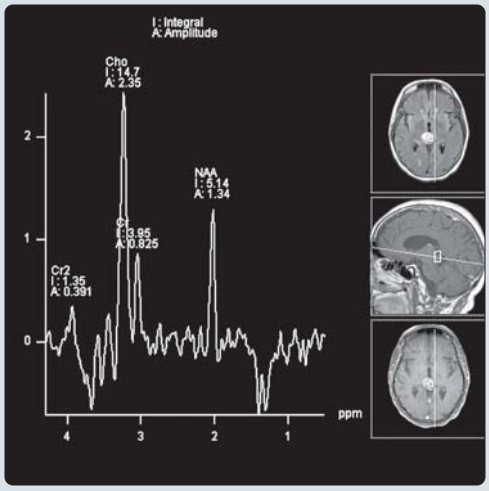
CLINICAL ISSUES

- Presenting features: Diplopia, Parinaud syndrome, headache



(Left) *Sagittal T1WI MR in a 21-year-old man with headache shows a pineal region mass ⇨ with obstructive hydrocephalus, enlargement of the 3rd ventricle ⇨, and cerebellar tonsillar descent ⇨. Imaging differential considerations include PPTID, pineoblastoma, and germinoma.* **(Right)** *Axial T2WI MR shows a very large PPTID ⇨ with extension into the ventricular system. Note the heterogeneous T2 appearance of the mass with multiple cystic regions ⇨, typical of PPTID. (Courtesy L. Loevner, MD.)*





(Left) *Coronal T1WI C+ MR shows a large, peripherally enhancing pineal mass ⇨ in a 24-year-old male. PPTID was diagnosed at resection.* **(Right)** *MRs in a 48-year-old woman patient shows elevated choline, decreased NAA, and a lactate doublet. Imaging is too aggressive for a pineocytoma. Germinomas are rare in middle-aged females. Imaging is most suggestive of a PPTID, although a papillary tumor of the pineal region would be a possible diagnosis. PPTID was confirmed at histologic examination.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pineal parenchymal tumor of intermediate differentiation (PPTID)

Definitions

- Primary parenchymal neoplasm of pineal gland
  - Intermediate in malignancy between pineocytoma and pineoblastoma
    - Pineocytoma: Slow-growing neoplasm with small mature cells that resemble pineocytes
    - Pineoblastoma: Highly malignant primitive embryonal tumor of pineal gland

IMAGING

General Features

- Best diagnostic clue
  - Aggressive-looking pineal mass in adult
- Location
  - Pineal gland mass
  - Extension into adjacent structures common: Ventricles, tectum, thalamus
  - CSF dissemination (rare)
- Size
  - Varies from small (< 1 cm) to ~ 6 cm

CT Findings

- NECT
  - Hyperdense mass centered in pineal region, ± hydrocephalus
  - Engulfs pineal gland Ca++

MR Findings

- T1WI
  - Mixed iso-/hypointense lobulated mass
- T2WI
  - Isointense with gray matter
  - Small, intratumor, hyperintense, cystic-appearing foci common
- T2* GRE
  - May show foci of "blooming"
- T1WI C+
  - Strong, heterogeneous enhancement

Imaging Recommendations

- Protocol advice
  - Pre-, post-contrast sagittal/axial/coronal T1WI
    - T2WI, FLAIR, T2* (GRE, SWI), DWI
  - Perform complete imaging of entire neuraxis prior to surgery to look for CSF dissemination

DIFFERENTIAL DIAGNOSIS

Germinoma

- Most common pineal neoplasm
- M > > F; mostly children, young adults < 25 years
- Engulfs pineal gland Ca++
- Intraventricular, distant CSF spread is common

Pineocytoma

- Most common pineal parenchymal neoplasm
- Generally tumor of adults (mean: 35-40 years)
- "Explodes" pineal gland Ca++
- Solid or solid and cystic, enhancement of solid portion

Pineoblastoma

- Most common in children but can occur at any age; M = F
- May require biopsy to distinguish from large PPTID
- CSF spread common, early

Papillary Tumor of Pineal Region (PTPR)

- Rare neuroepithelial tumor with papillary architecture
- Indistinguishable on imaging, gross pathology from PPTID, pineocytoma

PATHOLOGY

General Features

- Etiology
  - Neuroepithelial neoplasm
- Historical background
  - PPTID not generally recognized as distinct entity until 2007
  - Neoplasms diagnosed as "pineocytoma vs. pineoblastoma" or "atypical pineocytoma" prior to 2007 may be PPTIDs

Staging, Grading, & Classification

- WHO grade II or III

Gross Pathologic & Surgical Features

- Circumscribed, soft tumor without gross hemorrhage or necrosis

Microscopic Features

- Diffuse sheets of relatively uniform small cells
- Moderate to high cellularity; mild to moderate nuclear atypia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Diplopia, Parinaud syndrome, headache
- Other signs/symptoms
  - Signs of elevated intracranial pressure, ataxia

Demographics

- Pineal region tumors uncommon as a group
  - 1% of all intracranial neoplasms
  - Germinomas > > pineal parenchymal neoplasms
  - PPTIDs probably represent ~ 20% of pineal parenchymal tumors

Treatment

- Stereotaxic biopsy, surgical resection common treatment

Pineoblastoma

KEY FACTS

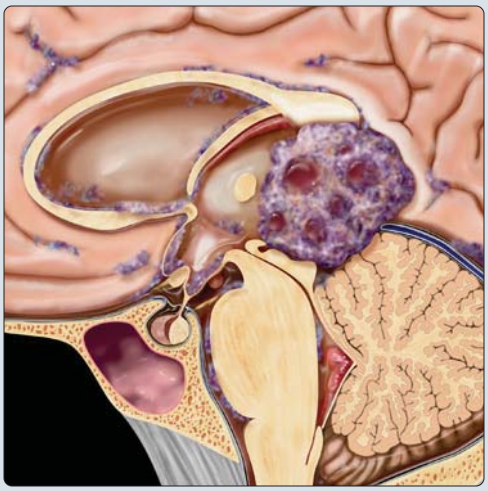
TERMINOLOGY
- Pineoblastoma (PB)
  - Neoplasm of pineal parenchyma (not germ cells)
  - Highly malignant, primitive embryonal tumor (PNET)

IMAGING
- General features
  - Large, heterogeneous pineal mass
  - Lobulated with poorly delineated margins
- Invasion into adjacent brain common
  - Corpus callosum, thalamus, midbrain, vermis
- Solid portion
  - NECT
    - Hyperdense with peripheral Ca++
  - MR
    - Iso- to hypointense on T2WI
    - Often shows restricted diffusion
    - Variable heterogeneous enhancement

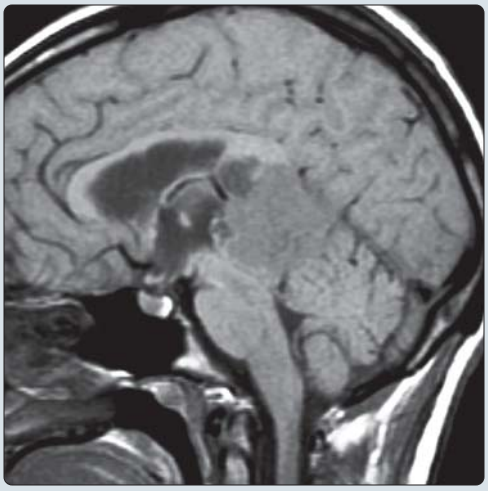
TOP DIFFERENTIAL DIAGNOSES
- Germ cell tumors
- Other pineal parenchymal tumors

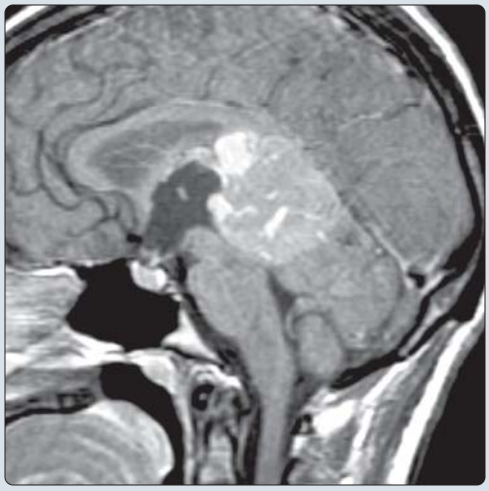
PATHOLOGY
- WHO grade IV
  - Embryonic precursors of pineal parenchymal cells (pinealocytes)
- Common phylogenetic origin of retina and pineal gland as light-sensing organs
- Germline mutations in retinoblastoma gene *RB1* → "trilateral" retinoblastomas
- Germline LOE mutations in *DICER1* → distinctive autosomal dominant tumor/dysplasia predisposition syndrome (DICER1 syndrome) that includes PB

DIAGNOSTIC CHECKLIST
- Image **entire neuraxis** preoperatively
  - Up to 45% CSF dissemination on MR or in CSF



(Left) *Sagittal graphic shows a large, heterogeneous pineal mass with areas of hemorrhage and necrosis. Note the compression of adjacent structures, hydrocephalus, and diffuse CSF seeding, which is typical of pineoblastoma.* **(Right)** *Axial NECT shows a large, hyperdense, pineal region mass with peripheral calcification; it proved to be a pineoblastoma. Germinomas have a similar appearance, but calcification, when identified, is usually central (engulfed).*





(Left) *Sagittal T1WI MR shows a mildly heterogeneous pineal region tumor with invasion of the midbrain tectum and posterior corpus callosum, typical of pineoblastoma.* **(Right)** *Sagittal T1WI C+ MR in the same patient shows moderate heterogeneous enhancement of the pineal region tumor and demonstrates the typical enhancement pattern of pineoblastoma.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pineoblastoma (PB)

Synonyms

- Primitive neuroectodermal tumor (PNET) of pineal gland

Definitions

- Highly malignant primitive embryonal tumor of pineal gland

IMAGING

General Features

- Best diagnostic clue
  - Child with large, heterogeneous hyperdense pineal mass with peripheral Ca++
- Location
  - Pineal gland
    - Pineal masses lie below corpus callosum splenium
    - Elevate internal cerebral veins
    - Flatten/compress tectal plate
  - Frequent invasion of adjacent brain common
    - Corpus callosum, thalami, midbrain, vermis
- Size
  - Large (most ≥ 3 cm)
- Morphology
  - Irregular, lobulated mass with poorly delineated margins

CT Findings

- NECT
  - Mixed density; solid portion frequently hyperdense
  - Peripheral Ca++ common
  - Nearly 100% have obstructive hydrocephalus
- CECT
  - Weak to avid but heterogeneous enhancement

MR Findings

- T1WI
  - Heterogeneous; solid portion iso-/hypointense
- T2WI
  - Heterogeneous
    - Solid portion iso-/hypointense more common than minimally hyperintense to cortex
    - Frequent necrosis/hemorrhage, cysts
  - Mild peritumoral edema characteristic
- T2* GRE
  - Ca++ and hemorrhage may "bloom"
- DWI
  - Solid portion frequently restricts
  - ADC values lower than germ cell tumors (GCTs)
- T1WI C+
  - Heterogeneous enhancement
- MRS
  - ↑ Cho, ↓ NAA
  - Prominent glutamate and taurine peak (~ 3.4 ppm) described at TE 20 msec

Other Modality Findings

- No elevation of serum tumor markers

Imaging Recommendations

- Best imaging tool
  - MR with T1WI C+, DWI
- Protocol advice
  - Image entire neuraxis preoperatively
    - 15-45% present with **CSF dissemination**
  - Sagittal images ideal for pineal region anatomy

DIFFERENTIAL DIAGNOSIS

Germ Cell Tumors (GCTs)

- Germinoma: Cannot be differentiated from PB by imaging
- Mature teratoma
  - 2nd most common GCT and pineal region tumor
  - Heterogeneous, multicystic mass with foci of Ca++ and fat
- Choriocarcinoma, endodermal sinus tumor, embryonal cell carcinoma
  - Uncommon, highly malignant
  - Characteristic elevation of serum tumor markers
    - Choriocarcinoma: β-hCG
    - Endodermal sinus tumor: α-fetoprotein (AFP)
    - Embryonal cell carcinoma: β-hCG and AFP
- 10% of GCTs are mixed histology (mixed GCT)

Other Pineal Parenchymal Tumors (PTTs)

- Pineocytoma (WHO grade I), pineal parenchymal tumor of intermediate differentiation (PPTID; WHO II-III)
- Arise from pineal gland parenchymal cells
- Well-defined mass "explodes" pineal Ca++
- Older age group compared to pineoblastomas
- Cone-rod homeobox gene (*CRX*) expressed in pineal parenchymal tumors, retinoblastomas as well as some medulloblastomas and PNETs

Papillary Tumor of Pineal Region

- Rare; usually older

Trilateral Retinoblastoma

- Some authors consider primitive round cell pineal tumor associated with retinoblastoma to be P
- Look for ocular lesions

Astrocytoma

- Rarely arise from pineal gland
- More commonly from thalamus or midbrain tectum
- Pilocytic astrocytoma (WHO grade I) most common
- Tectal astrocytoma
  - Nonenhancing, well-defined, expansile tectal mass
- Thalamic astrocytoma
  - T2-hyperintense, paramedian mass or cyst with enhancing mural nodule

Meningioma

- Females (5th-7th decades)
- Well-defined, round, dural-based mass isointense to cortex on all sequences with intense, homogeneous enhancement
- Pineal region meningiomas arise from tentorium cerebelli, falx
- Dural "tail" (35-80%)

https://CafePezeshki.IR

Metastases

- Pineal gland metastases uncommon
- Adenocarcinoma reported

PATHOLOGY

General Features

- Etiology
  - Derived from embryonic precursors of pineal parenchymal cells (pinealocytes)
  - Pinealocytes have photosensory and neuroendocrine function
  - Common phylogenetic origin of retina and pineal gland as light-sensing organs
- Genetics
  - Germline LOE mutations in *DICER1* → distinctive autosomal dominant tumor/dysplasia predisposition syndrome (DICER1 syndrome)
    - *DICER1* is important susceptibility gene for PB, ciliary body medulloepithelioma
  - Some reports of chromosome 11 deletions
  - Germline mutations in retinoblastoma gene *RB1* → "trilateral" retinoblastomas
    - Bilateral retinoblastomas + PNET-like PB
    - Incidence of PB 10x in bilateral vs. unilateral retinoblastomas

Staging, Grading, & Classification

- WHO grade IV
- New prognostic grading system for PPTs
  - Grade 1 = pineocytoma
  - Grade 2 and 3 = PPTs with intermediate differentiation
    - Grade 2 if < 6 mitoses and immunolabeling positive for neurofilaments
    - Grade 3 if ≥ 6 mitoses or if < 6 mitoses but immunolabeling negative for neurofilaments
  - Grade 4 = PB

Gross Pathologic & Surgical Features

- Soft, friable, poorly marginated, infiltrative
- Compresses/invades cerebral aqueduct, leading to hydrocephalus
- CSF dissemination at autopsy frequent

Microscopic Features

- Highly cellular tumor
  - Mitoses common, MIB-1 elevated

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - ↑ intracranial pressure (hydrocephalus)
    - Headache, nausea, vomiting, lethargy
    - Papilledema, abducens nerve palsy
- Other signs/symptoms
  - Parinaud syndrome, ataxia
- Clinical profile
  - Toddler with Parinaud syndrome, signs/symptoms of ↑ intracranial pressure

Demographics

- Age
  - Children > young adults (rare tumors up to 5th decade)
  - Mean age at diagnosis in children = 3 years
- Gender
  - M:F = 1:2
- Epidemiology
  - PPTs comprise 0.5-1% of primary brain tumors and 15% of pineal region neoplasms
  - PBs comprise 30-45% of PPTs

Natural History & Prognosis

- CSF seeding common
  - Up to 45% of patients present with spinal dissemination on MR &/or CSF analysis
- Rare reports of hematogenous metastases to bone
- Dismal; median survival 16-25 months from presentation

DIAGNOSTIC CHECKLIST

Consider

- Could pineal region mass be GCT (more common than PPTs)
  - Does patient have elevated serum tumor markers
  - Is patient male
  - Is there a coexistent suprasellar mass (germinoma)

Image Interpretation Pearls

- Both PBs and germinomas frequently hyperdense on CT (hypointense on T2WI) and prone to CSF dissemination
- Peripheral "exploded" Ca++ in PB and central "engulfed" Ca++ in classic germinoma

Clinical Pearl

- Pineal region astrocytomas typically do not present with Parinaud syndrome

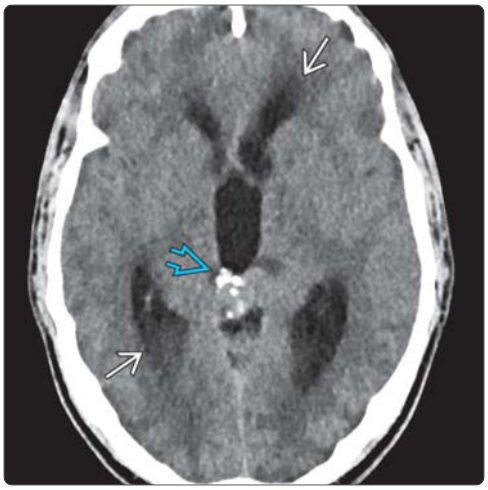
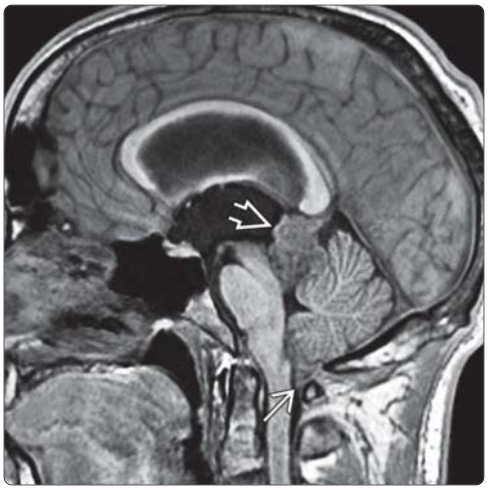
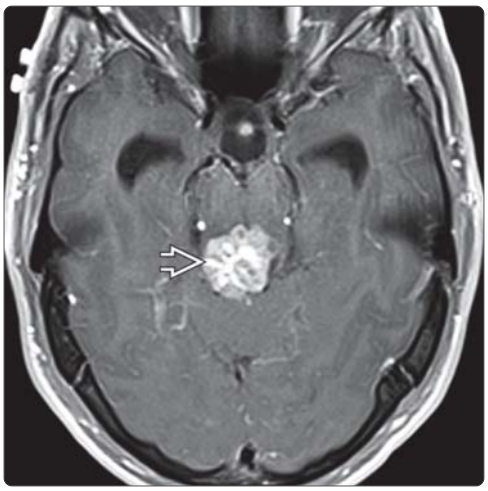
(Left) *Axial NECT shows a poorly demarcated, infiltrative, mildly hyperdense mass centered in the pineal region. Note the peripheral calcifications. On close evaluation there is invasion of the adjacent brain parenchyma. There is compression of the aqueduct of Sylvius and resultant hydrocephalus.* **(Right)** *Axial DWI MR shows restricted diffusion in the solid mass and better delineates the neoplasm and the invasion of the adjacent brain parenchyma.*





(Left) *Axial NECT scan in a 23-year-old man in the ER who presented with several weeks of headache and recent onset of blurred vision shows a calcified mass in the pineal region. Moderate obstructive hydrocephalus is present with "blurred" margins around the enlarged lateral ventricles.* **(Right)** *Sagittal T1-weighted MPRAGE scan in the same patient shows a lobulated mass in the pineal region. The 3rd/lateral ventricles are moderately enlarged and there is downward displacement of the cerebellar tonsils.*



(Left) *T2WI in the same patient shows the mass is heterogeneously hyperintense with numerous intratumoral cysts. Papilledema is present with intraoptic protrusion of the optic nerve head and dilated optic nerve sheaths.* **(Right)** *T1 C+ FS MR in the same patient shows the mass enhances strongly but heterogeneously. Preoperative diagnosis was pineal parenchymal tumor of intermediate differentiation vs. papillary tumor of the pineal region. Final diagnosis was pineoblastoma, WHO grade IV.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Papillary tumor of pineal region (PTPR)

IMAGING

- Enhancing, often well-circumscribed pineal mass
- T1: May be heterogeneously hyperintense
- T2: Cystic regions common
- Moderate heterogeneous enhancement
- Imaging often mimics other pineal parenchymal neoplasms

TOP DIFFERENTIAL DIAGNOSES

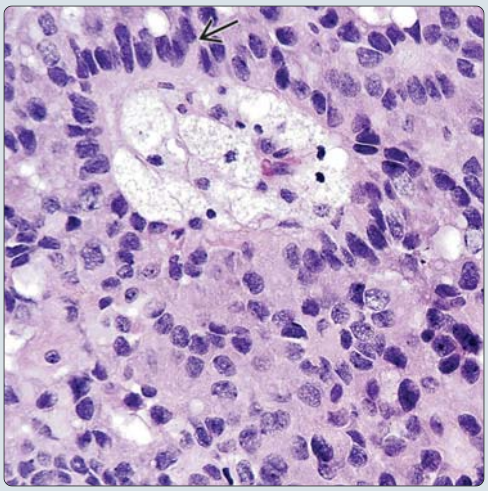
- Germinoma
- Pineocytoma
- Pineoblastoma
- Pineal parenchymal tumor of intermediate differentiation (PPTID)
- Teratoma

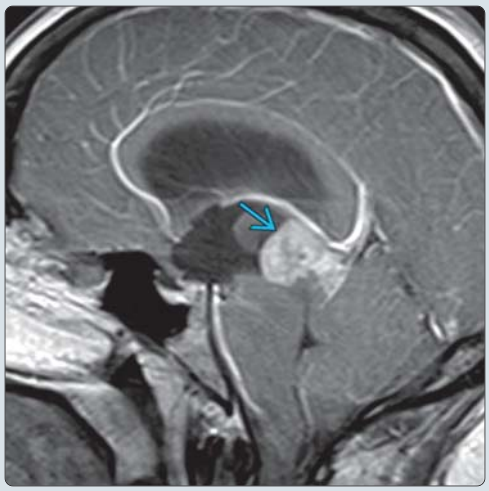
PATHOLOGY

- May derive from specialized ependymocytes of subcommissural organ
- WHO grade II-III
- Epithelial tumor
  - Papillary regions with large cuboidal/columnar cells
  - Cytokeratin (+), EMA(-)

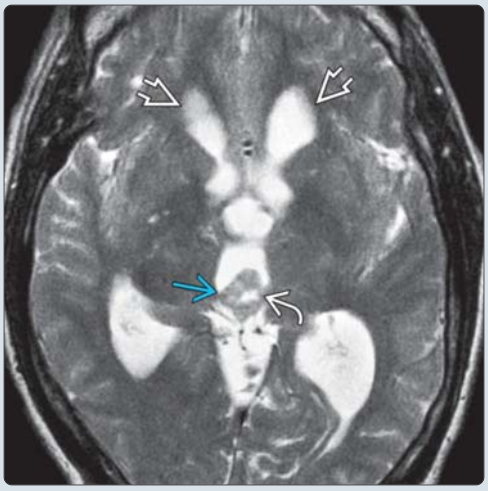
CLINICAL ISSUES

- Most common symptoms related to increased intracranial pressure, headache
- Primarily tumor of adults, typically 30-50 years
- > 5 mitoses per 10 high-power fields correlates with decreased survival and increased likelihood of recurrence
- Frequent local recurrence
- CSF dissemination common
- Treatment: Surgical resection ± adjuvant radiation therapy
- Complete resection affords highest chance of cure





(Left) *H&E micrograph shows the typical epithelial features ⇨ of a papillary tumor of the pineal region. (From DP: Neuropathology.)* **(Right)** *Sagittal T1 C+ MR image shows a heterogeneously enhancing pineal region mass ⇨. The mass obstructs the aqueduct of Sylvius causing hydrocephalus. Imaging differential considerations include pineal parenchymal tumors and germ cell tumors. Papillary tumor of the pineal region was diagnosed at surgical resection. (Courtesy P. Burger, MD.)*



(Left) *Axial T2WI in a 66-year-old man with headaches shows a small heterogeneous mass in the pineal region ⇨. The mass is primarily isointense with the brain but contains a small, more focal, cystic-like area ⇨. Note the hydrocephalus with transependymal CSF flow (interstitial edema) seen here as "blurred" ventricular margins ⇨. (Courtesy J. Rees, MD.)* **(Right)** *Axial T1WI C+ MR in the same patient shows the pineal region mass ⇨ enhances diffusely but somewhat heterogeneously. (Courtesy J. Rees, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Papillary tumor of pineal region (PTPR)

IMAGING

General Features

- Best diagnostic clue
  - Enhancing pineal mass in adult
- Size
  - Variable, ~ 1-6 cm
- Morphology
  - Well circumscribed, ± cystic regions

Imaging Recommendations

- Best imaging tool
  - MR ± gadolinium
- Protocol advice
  - Pre-/post-contrast thin section sagittal T1WIs

MR Findings

- T1WI
  - Variable but can be heterogeneously hyperintense
- T2WI
  - Heterogeneously iso-/hyperintense
- FLAIR
  - Hyperintense
- T1WI C+
  - Moderate heterogeneous enhancement

DIFFERENTIAL DIAGNOSIS

Germinoma

- Most common pineal neoplasm
- Adolescent males > middle-aged adults
- Engulfs pineal gland Ca++
- Intraventricular, distant CSF spread is common

Pineocytoma

- Most common pineal parenchymal neoplasm
- Arises from pineal gland; "explodes" pineal gland Ca++
- Solid or solid and cystic, enhancement of solid portion

Pineoblastoma

- Most common in children but can occur at any age; M = F
- Enhancing pineal mass
- CSF spread common, early

Pineal Parenchymal Tumor of Intermediate Differentiation (PPTID)

- Enhancing, aggressive pineal mass in adult
- Can be indistinguishable from PTPR
- Histologic diagnosis

Teratoma

- Heterogeneous pineal mass with fat density/signal intensity
- Suppresses with FS sequences

PATHOLOGY

General Features

- Etiology
  - May derive from specialized ependymocytes of subcommissural organ, in posterior wall of 3rd ventricle
  - May be related to ependymal cells in pineal recess
- Genetics
  - Most show losses on chromosomes 10 and 22q
  - Gains on chromosomes 4, 8, 9, and 12
- Associated abnormalities
  - No other anomalies or syndromal associations

Staging, Grading, & Classification

- WHO grade II-III

Gross Pathologic & Surgical Features

- Moderate to large well-circumscribed mass

Microscopic Features

- Epithelial tumor with characteristic papillary regions with large cuboidal or columnar cells or, less commonly, smaller cells
- Some ependymal-type rosettes and tubular regions as well as perivascular pseudorosettes
- Immunohistochemistry
  - Strongly positive for cytokeratin, S100, NSE, vimentin
  - Weak or nonreactive to GFAP
- Occasional areas of necrosis, variable mitotic figures

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Nonspecific CNS symptoms, headache

Demographics

- Age
  - Reported in ages 5-66 but primarily tumor of adults, mean 32 years

Natural History & Prognosis

- Variable: 5-year survival (73%); progression free (27%)
- > 5 mitoses per 10 high-power fields correlates with decreased survival and increased likelihood of recurrence
- Frequent local recurrence
- CSF dissemination common

Treatment

- Complete resection affords highest chance of cure
- Adjuvant radiotherapy for subtotal resection of tumor
- Role of chemotherapy unclear

KEY FACTS

TERMINOLOGY

- Medulloblastoma (MB)
  - Malignant, invasive, highly cellular embryonal tumor
- Four distinct MB molecular subgroups
  - WNT (wingless)
  - SHH (sonic hedgehog)
  - Group 3
  - Group 4

IMAGING

- MB subgroups arise in different locations
  - Midline (4th ventricle)
    - Predominately (but not exclusively) groups 3 and 4
  - Cerebellar peduncle/CPA cistern: WNT
  - Cerebellar hemispheres (lateral): SHH
- NECT: 90% hyperdense (Ca++ uncommon, hemorrhage rare)
- MR: > 90% enhance (group 4 minimal/no enhancement)
  - Restricted diffusion, low ADC
  - T1C+ essential to detect CSF dissemination

TOP DIFFERENTIAL DIAGNOSES

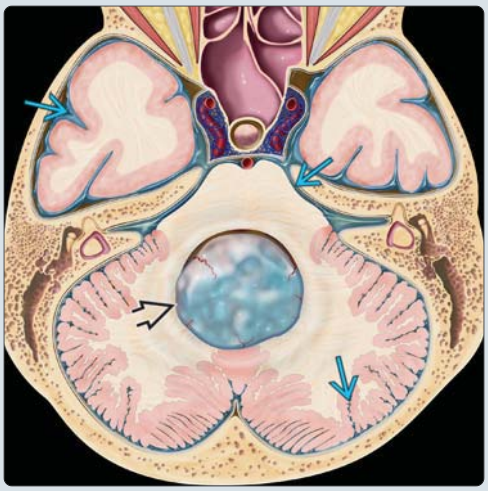
- Atypical teratoid/rhabdoid tumor (AT/RT)
- Ependymoma
- Cerebellar pilocytic astrocytoma (PA)

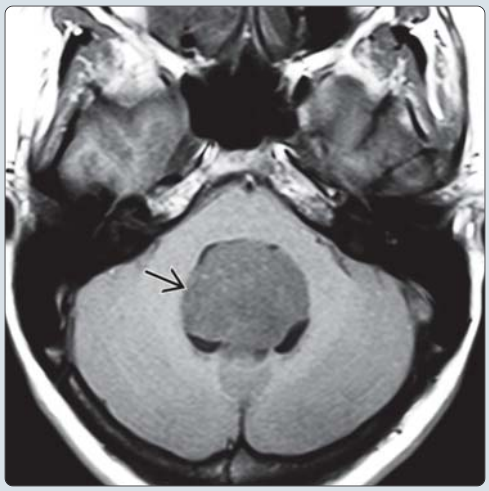
PATHOLOGY

- WHO grade IV (overstates risk of WNT MB)
- Histologic subtypes
  - Classic
  - Desmoplastic
  - MB with extensive nodularity (MBEN)
  - Large cell/anaplastic (LC/A)

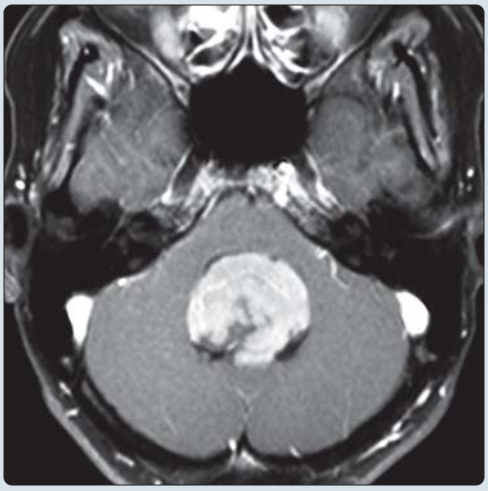
CLINICAL ISSUES

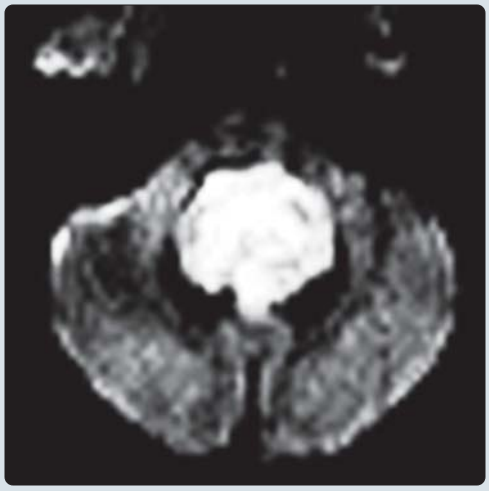
- Most common malignant pediatric brain tumor
- Prognosis varies with subgroup, mutations
  - WNT best, group 3 worst





(Left) *Axial graphic shows a spherical tumor centered in the 4th ventricle ⇨, typical of classic medulloblastoma. CSF dissemination ("sugar icing") is common at initial diagnosis and is shown in blue ⇨.* **(Right)** *Axial T1WI shows imaging findings of classic medulloblastoma, with a rounded, slightly hypointense mass ⇨ in the 4th ventricle.*





(Left) *Axial T1 C+ FS in the same patient shows strong, slightly heterogeneous enhancement in the mass. No definite CSF spread is identified.* **(Right)** *DWI in the same patient shows strongly restricted diffusivity. Surgery disclosed medulloblastoma, desmoplastic subtype. The midline 4th ventricle is the 2nd most common location for desmoplastic medulloblastomas (MBs) and the most common site for classic MBs. Histopathology disclosed desmoplastic medulloblastoma, SHH subtype.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Medulloblastoma (MB)

Synonyms

- PNET-MB

Definitions

- Malignant, invasive, highly cellular embryonal tumor
  - Not single-disease entity
  - 4 distinct molecular subgroups
    - Each has distinct cells of origin
    - Each has distinct molecular and clinical features
    - Each has different therapeutic approach
    - Subgroup maintained in relapse/recurrence
  - MB subgroups
    - WNT (wingless)
    - SHH (sonic hedgehog)
    - Group 3
    - Group 4

IMAGING

General Features

- Best diagnostic clue
  - Most common: Round, dense 4th ventricle mass
- Location
  - MB subgroups arise in distinct regions of cerebellum, associated with subgroup-specific genetic aberrations and cells of origin
    - Midline (4th ventricle)
      - Predominately (but not exclusively) groups 3 and 4
    - Cerebellar peduncle/cerebellopontine angle cistern
      - WNT most common
    - Cerebellar hemispheres (lateral)
      - SHH (slightly > 50%, remainder mostly midline)

CT Findings

- NECT
  - Solid mass in 4th ventricle
    - 90% hyperdense
    - Ca++ (up to 20%), hemorrhage rare
    - Small intratumoral cysts/necrosis in 40-50%
  - Hydrocephalus common (95%)
- CECT
  - > 90% enhance
    - Relatively homogeneous
    - Occasionally patchy (may fill in slowly)

MR Findings

- T1WI
  - Hypointense to gray matter (GM)
- T2WI
  - Near GM intensity, or slightly hyperintense to GM
- FLAIR
  - Hyperintense to brain
  - Good differentiation of tumor from CSF in 4th ventricle
- DWI
  - Restricted diffusion, low ADC
- T1WI C+
  - > 90% enhance (group 4 minimal/no enhancement)
  - Often heterogeneous
  - Contrast essential to detect CSF dissemination
    - Linear icing-like enhancement over brain surface: "Zuckerguss"
    - Extensive grape-like tumor nodules common in desmoplastic or medulloblastoma with extensive nodularity (MBEN)
    - May have dural tail and resemble meningioma (cerebellar hemispheres)
  - Contrast-enhanced MR of spine (entire neuraxis)
    - Up to 1/3 have subarachnoid metastatic disease at presentation
    - Image preoperatively to avoid postoperative false-positive: Blood in spinal canal may mimic or mask metastases
- MRS
  - ↓ ↓ NAA
  - ↑ ↑ choline
  - Lactate usually present
  - Elevation in Tau (short TE)
  - Cr/Cho < 0.75 and mI/NAA < 2.1 indicative for MB (resembles ependymoma)

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR

DIFFERENTIAL DIAGNOSIS

Atypical Teratoid/Rhabdoid Tumor (AT/RT)

- Top differential diagnosis (indistinguishable by imaging)

Pilocytic Astrocytoma (PA)

- Cerebellar hemisphere > 4th ventricle
- Cyst with enhancing nodule

Ependymoma

- Extrudes through 4th ventricle foramina/foramen magnum
- Heterogeneous (Ca++, hemorrhage more common)
- Higher ADC values (less cellular)

Choroid Plexus Papilloma (CPP)

- 4th ventricle less common, mostly adults

PATHOLOGY

General Features

- Etiology
  - WNT, SHH
    - WNT, SHH signaling regulate neural stem cell self-renewal, differentiation
  - Group 3
    - Cerebellar granule neuron precursors at weeks 10-15
      - Abnormal neuronal differentiation
      - Resemble rod precursor cells at week 15
  - Group 4
    - Cerebellar glutamatergic granule neuron precursors (GNPs) at weeks 20-30
      - Deregulation of synaptic pruning apoptosis
      - Dopamine, semaphorin signaling, and cell cycle deregulation
- Genetics

https://CafePezeshki.IR

- WNT
  - *DKK1*, *DKK2*, *DKK3*; *WNT16*, etc.
- SHH
  - *PTCH1*, *PTCH2*, and *SUFU* (infants)
  - *TP53*, *GLI2*, and *MYCN* amplifications (children)
  - *SMO* (adults)
- Group 3
  - Transient rod precursor gene *NRL*
  - *CRX* (normally regresses to pineal gland at week 15) and over expressed *SAG*
  - Group 3 MB, pineoblastoma often histologically indistinguishable
- Group 4
  - Late granule neuron markers, reelin pathway expressed
  - *SNCAIP* overexpressed exclusively in group 4
    - GNP proliferation promoted, protected from apoptosis
- Associated abnormalities
  - Some familial cancer syndromes (e.g., Gorlin)

Staging, Grading, & Classification

- WHO grade IV (overstates risk of WNT MB)

Microscopic Features

- Histologic subtypes
  - Classic
  - Desmoplastic
  - MBEN
  - Large cell/anaplastic (LC/A)
- MB diagnosis based on molecular subtype + histology, immunohistochemistry
  - WNT: Classic (90%)
  - SHH: All 4 histologic subtypes represented
    - Most all desmoplastic MBs are SHH
    - Subgroups
  - Group 3: Most are classic or LC/A (desmoplastic rare)
    - Further stratification into subgroups based on *MYC* amplification, chr 8
  - Group 4: All types except desmoplastic
    - Recurs with metastases

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Ataxia, signs of increased intracranial pressure
  - Macrocephaly in infants with open sutures
- Clinical profile
  - Relatively short (average 2 months) of symptoms
  - Symptoms reflect local mass effect &/or ↑ ICP
    - Nausea and vomiting, ataxia
    - Cranial nerve palsies (less common than in brainstem astrocytomas)
  - Gastrointestinal work-up for nausea, vomiting may precede diagnostic neuroimaging

Demographics

- Age
  - 75% < 10 years
  - Most diagnosed by 5 years
- Gender
  - M:F = 2-4:1
- Epidemiology
  - Most common malignant pediatric brain tumor
    - 15-20% of all pediatric brain tumors
    - 30-40% of posterior fossa tumors in children
    - Leading cause of childhood cancer-related mortality
  - Rare in adults

Natural History & Prognosis

- Varies with subgroup, mutations
  - WNT best (only MB categorized as low risk)
  - Group 3 worst
    - Higher risk if *MYC* amplified or iso17q or M(+)
  - SHH intermediate
    - Adults do better than children/infants
    - Low risk if M0, *GLI2* not amplified, no 14q loss
  - Group 4 intermediate
    - High risk if M(+), low risk with chr11 loss or 17 gain
- Risk also varies with histology
  - Generally desmoplastic > classic > LC/A

Treatment

- Surgical excision, adjuvant chemotherapy
- Craniospinal irradiation if > 3 years
- Low risk MB (WNT) may warrant reduced therapeutic intensity

DIAGNOSTIC CHECKLIST

Consider

- AT/RT in patients under 3 years
- Preoperative evaluation of entire neuraxis and postoperative evaluation of surgical bed are key to prognosis

Image Interpretation Pearls

- 4th ventricle tumor arising from roof = PNET-MB
- 4th ventricle tumor arising from floor = ependymoma
- If thinking of MB in childhood posterior fossa tumor, include AT/RT

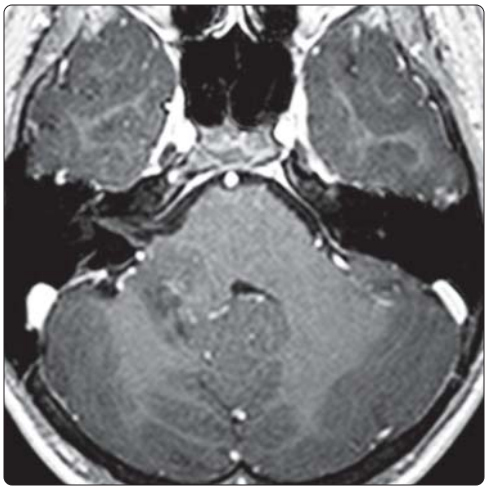
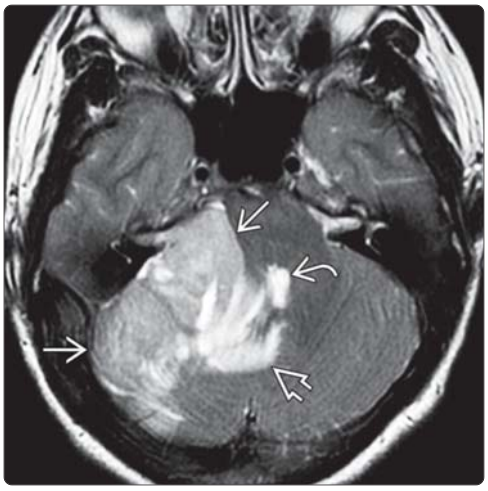
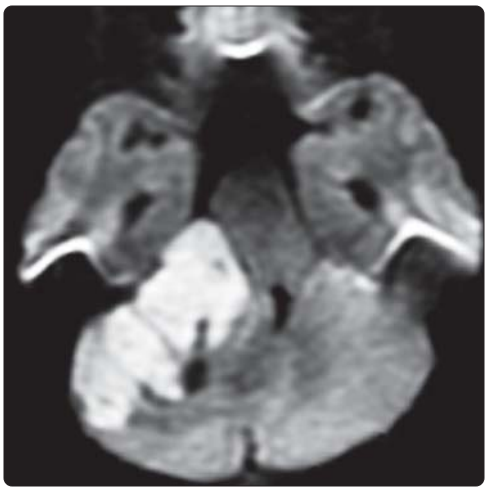
(Left) *Axial FLAIR MR in an 11-year-old woman with hearing loss, facial droop, and loss of balance shows a hyperintense right cerebellopontine mass ➡ predominately centered within the brachium pontis.* **(Right)** *DWI in the same case shows the mass ➡ exhibits strong, uniform restricted diffusion.*





(Left) *Axial T1 C+ SPGR MR shows the mass has minimal enhancement. The preoperative diagnosis of medulloblastoma was documented at surgery. Molecular profiling disclosed WNT subtype. (Courtesy S. Blaser, MD.)* **(Right)** *Axial T2WI in a 27-year-old woman with headaches shows a hyperintense mass ➡ in the lateral aspect of the right cerebellar hemisphere. Moderate edema ➡ is present adjacent to the mass. The lesion compresses and displaces the 4th ventricle ➡.*



(Left) *T1 C+ FS MR in the same patient shows moderately intense, uniform enhancement. No CSF spread is apparent.* **(Right)** *DWI in the same patient shows the mass exhibits restricted diffusion (and was also hypointense on ADC, not shown). SHH-type desmoplastic MB was confirmed at surgery and subsequent molecular profiling.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- CNS supratentorial primitive neuroectodermal tumor (S-PNET)
  - Embryonal tumor composed of undifferentiated neuroepithelial cells

IMAGING

- Large, complex-appearing hemispheric mass in infant/young child
- Variable size, based on location
  - Hemispheric PNETs larger (mean diameter: 5 cm)
  - Suprasellar, pineal PNETs smaller
- Sharply delineated to diffusely infiltrative
  - Minimal peritumoral edema
- Calcification common (50-70%)
- Heterogeneous density/signal intensity, enhancement
  - Restricted diffusion common

TOP DIFFERENTIAL DIAGNOSES

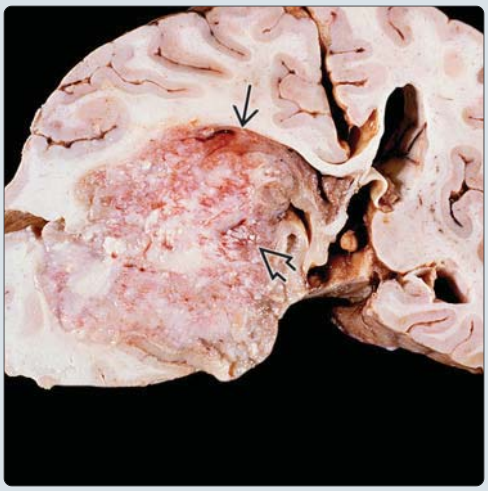
- Atypical teratoid/rhabdoid tumor (AT/RT)
- Astrocytoma
- Ependymoma

PATHOLOGY

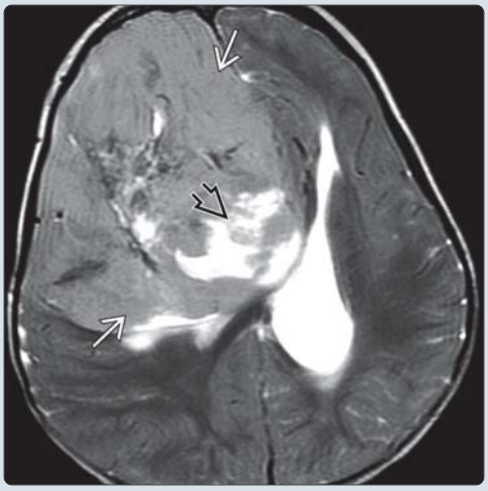
- WHO grade IV
- Some histologic subtypes now combined into single common diagnostic entity
  - Characterized by *C19MC* amplified/LIN28(+)
  - Enriched for primitive neural features
  - 75% in cerebral hemispheres

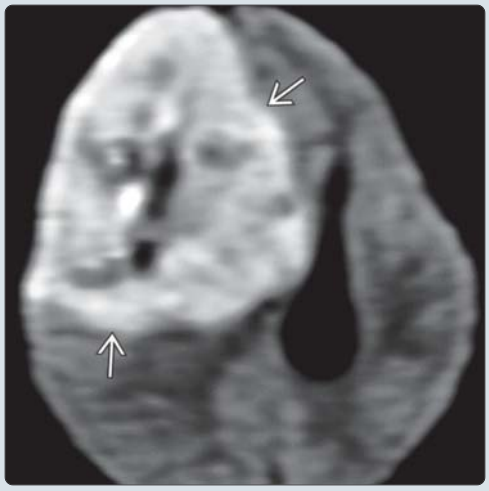
DIAGNOSTIC CHECKLIST

- If large bulky hemispheric mass with sparse edema in infant, think PNET or AT/RT
- Perform enhanced MR of entire neuraxis before surgery
  - Enhanced FLAIR detects subarachnoid seeding



(Left) *Coronal gross pathology shows a cerebral PNET as a large, bulky hemispheric mass. Note the heterogeneous appearance, foci of hemorrhage, and necrosis. (Courtesy Rubinstein Collection, AFIP.)* **(Right)** *Axial T1WI MR shows a typical, very large, solid, intraaxial mass with distinctive lack of peritumoral edema. The mass is overall mildly hypointense relative to gray matter, though regions of hemorrhage are hyperintense. Ventricular obstruction with dilatation results from subfalcine herniation.*





(Left) *Axial T2WI MR shows a large, mildly hyperintense, right frontal lobe mass. Note that the signal intensity is just slightly greater than gray matter. Also note the lack of peritumoral edema. Central and medial tumoral heterogeneity and hyperintensity represent necrosis.* **(Right)** *Axial DWI MR shows restricted diffusion within this highly cellular mass. Restricted diffusion was confirmed on corresponding ADC maps (not shown).*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- CNS supratentorial primitive neuroectodermal tumor (S-PNET)

Definitions

- CNS PNET: Generic designation comprising histologically diverse group of tumors
  - Composed of undifferentiated neuroepithelial cells
  - Broad capacity for divergent differentiation
    - Astrocytic, ependymal, neuronal, muscular, melanotic elements

IMAGING

General Features

- Best diagnostic clue
  - Large, complex-appearing hemispheric mass with minimal peritumoral edema in infant/young child
- Location
  - Cerebral hemisphere
    - Cortical/subcortical
    - Thalamic
  - Suprasellar
  - Pineal
- Size
  - Variable, based on location
    - Cerebral hemispheric PNETs are larger at diagnosis (mean diameter: ~ 5 cm)
      - Hemispheric lesions in infants often huge
    - Suprasellar PNETs tend to be smaller
      - Earlier symptoms (e.g., neuroendocrine and visual disturbances) due to mass effect on adjacent structures
    - Pineal PNETs cause hydrocephalus and gaze/convergence difficulties
- Morphology
  - Sharply delineated to diffusely infiltrative

Radiographic Findings

- Radiography
  - Macrocephaly and widened sutures (neonate and infant)

CT Findings

- NECT
  - Iso- to hyperattenuating
  - Calcification (50-70%)
  - Hemorrhage and necrosis common
- CECT
  - Heterogeneous enhancement
  - Prone to subarachnoid tumor seeding

MR Findings

- T1WI
  - Hypo- to isointense to gray matter
  - Homogeneous to heterogeneous
- T2WI
  - Solid elements isointense to slightly hyperintense to gray matter
  - No or minimal peritumoral edema; margins may appear sharp
  - Ca++ → hypointense foci
  - Blood products → mixed signal intensity
- PD/intermediate
  - Slightly hyperintense
- FLAIR
  - Solid components hyperintense
  - Little peritumoral edema
  - Post-contrast enhancement FLAIR detects leptomeningeal metastases
- T2* GRE
  - Dephasing from blood products
- DWI
  - Restricted diffusion common
- T1WI C+
  - Heterogeneous enhancement
  - Subarachnoid seeding common
  - Subtraction imaging helpful with hemorrhagic masses
- MRS
  - ↓ NAA, ↓ creatine, ↑ choline, + lipid and lactate

Ultrasonographic Findings

- Congenital S-PNET (antenatal sonography)
  - Large hyperechoic hemispheric mass
  - Hydrocephalus

Imaging Recommendations

- Best imaging tool
  - MR with T1WI C+, FLAIR, DWI, MRS
- Protocol advice
  - Perform T1WI C+ MR of entire neuraxis before surgery
  - Adding post-contrast enhancement FLAIR aids in detecting leptomeningeal metastases

DIFFERENTIAL DIAGNOSIS

Atypical Teratoid/Rhabdoid Tumor

- Posterior fossa > 50%, supratentorial 39%
- Necrosis, cysts, and vasogenic edema common
- Subarachnoid seeding common

Astrocytoma (AA, GBM)

- Extensive vasogenic edema
- Ca++

Ependymoma

- When supratentorial (30%), usually intraaxial
  - Only 15-25% arise within 3rd or lateral ventricle
- Necrosis and hemorrhage not uncommon

Choroid Plexus Carcinoma

- Parenchymal invasion can be dramatic
- Extensive vasogenic edema
- Avid enhancement

Cavernous Malformation

- Can be huge (almost holohemispheric) in newborn, infant
- Mimics hemorrhagic tumor

PATHOLOGY

General Features

- Etiology
  - Tumor suppressor gene aberrations may play role

https://CafePezeshki.IR

- Deregulation of epigenetic processes contributes to heterogeneity in tumor phenotypes, drivers of cancer initiation/progression
- C19MC amplified/LIN28(+)
- Genetics
  - Unlike medulloblastoma (PNET-MB), chromosome 17 aberrations (rare)
  - Somatic mutations in tumor suppressor genes
    - *ASCL1*
    - *SMARCB1* on chromosome 22
  - Other chromosome anomalies in S-PNETs
    - TTYH1-C19MC gene fusion
    - Aberrations of short arm of chromosome 11
    - Trisomies of chromosomes 9,13,1q, and 18p telomere maintenance
- Associated abnormalities
  - Hereditary syndromes
    - Gorlin syndrome
    - Turcot syndrome
    - Hereditary retinoblastoma and risk for secondary malignancies
    - Rubinstein-Taybi syndrome

Staging, Grading, & Classification

- All PNETs are WHO grade IV
- 2007 WHO classification
  - CNS PNET and embryonal tumors not otherwise specified (CNS PNET, NOS)
  - CNS PNET histologic subtypes
    - Neuroblastoma
    - Ganglioneuroblastoma
    - Ependymoblastoma (EPB)
    - Embryonal tumor with abundant neuropil and true rosettes (ETANTR)
    - Medulloepithelioma (MEP)
- EPB, ETANTR, MEP now combined into single common diagnostic entity (as yet unnamed)
  - These histologic subclasses are closely related molecular entities
    - Characterized by *C19MC* amplified/LIN28(+)
      - LIN23(+) (but not *C19MC*) also seen in other malignant pediatric brain tumors (e.g., rhabdoid brain tumors, some malignant gliomas)
    - Enriched for primitive neural features
    - Occur in children < 4 years
    - 75% in cerebrum
- New: "Group 1 CNS-PNETs"
- "CNS-PNET" now uncommon diagnosis of molecular exclusion

Gross Pathologic & Surgical Features

- Variable consistency
  - Solid and homogeneous → cystic, necrotic, hemorrhagic, and partially calcified
  - Solid portions and soft pink-red coloration, unless prominent desmoplasia
  - Demarcation between tumor and brain may range from indistinct to sharp

Microscopic Features

- Similar to medulloblastoma (PNET-MB)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Vary with site of origin and size of tumor
    - Hemispheric → seizures, altered mental status, motor deficit, elevated intracranial pressure
    - Suprasellar → visual disturbance, endocrine dysfunction
    - Pineal → hydrocephalus, Parinaud syndrome
- Other signs/symptoms
  - Cranial neuropathies due to herniation or diffuse CSF metastases
- Clinical profile
  - Infant presenting with macrocephaly, seizures, large hemispheric mass

Demographics

- Age
  - Most common in younger children
    - Median age at diagnosis: 30-35 months
- Gender
  - M:F = 2:1
- Ethnicity
  - No ethnic predilection
- Epidemiology
  - S-PNETs constitute 1% of pediatric brain tumors
  - Of all CNS PNETs, 5-6% are supratentorial

Natural History & Prognosis

- Compared to posterior fossa PNET (PNET-MB), S-PNETs have poorer survival
  - S-PNET: 5-year survival: 30-35%
  - PNET-MB: 5-year survival: 80-85%
- Heavily calcified S-PNETs have slightly better prognosis

Treatment

- Aggressive surgical resection, chemotherapy, craniospinal radiation
- mTOR inhibitors may be helpful in LIN28(+) tumors

DIAGNOSTIC CHECKLIST

Consider

- S-PNET in newborn, infant, or young child with
  - Hemispheric tumor lacking edema
  - Suprasellar or pineal mass

Image Interpretation Pearls

- Large hemispheric mass with sparse peritumoral edema

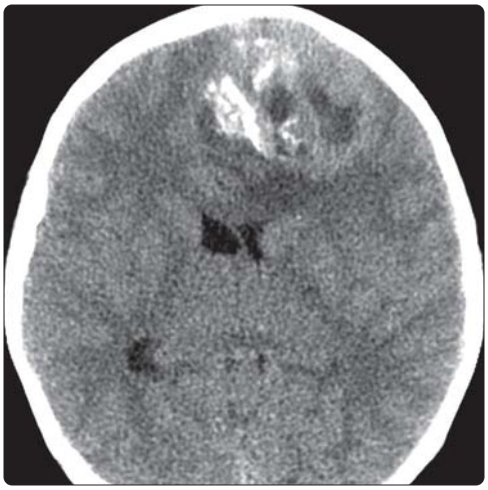
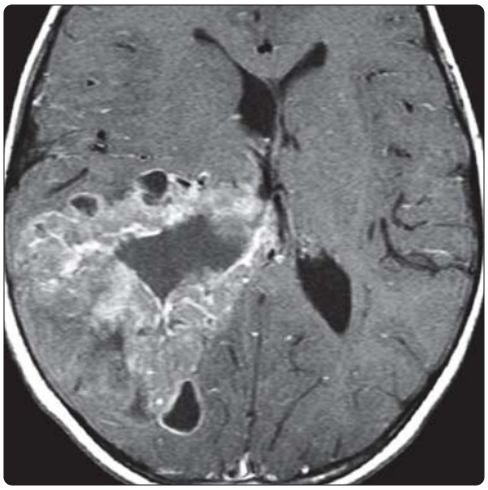
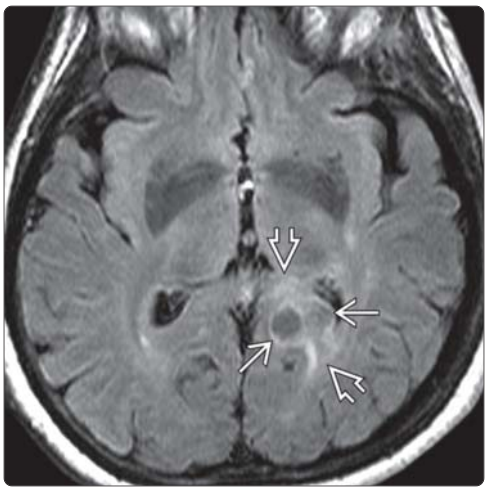
https://CafePezeshki.IR

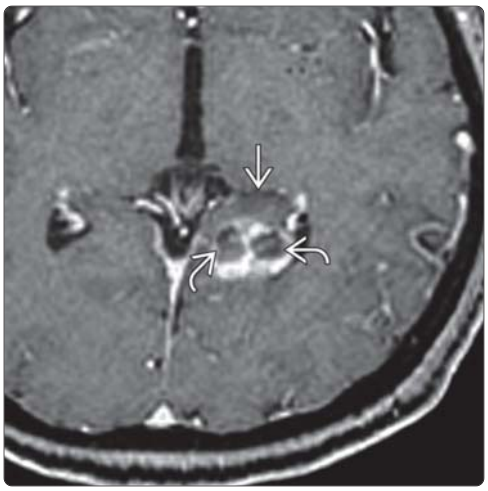


(Left) *Axial NECT shows a typical, intraaxial, frontal lobe cerebral PNET with heterogeneity, features of high cellularity and little or no peritumoral edema. The tumor is largely hyperattenuating with scattered calcifications.* **(Right)** *Axial T2WI in a 7-year-old boy with seizures shows a large heterogeneous mixed iso- and hyperintense mass ➡ in the right parietal lobe. Note the absence of peritumoral edema.*



(Left) *FLAIR scan in the same patient shows a hyperintense area of central necrosis ⇨, solid portions of the tumor ➡, and several intratumoral cysts ➡ that do not suppress completely.* **(Right)** *T1 C+ MR in the same patient shows heterogeneous enhancement in the solid portions of the mass and around the intratumoral cysts. The central necrotic area does not enhance. PNET was found at surgery.*





(Left) *Axial FLAIR MR shows a lobular, heterogeneous mass ➡ medial to the trigone of the left lateral ventricle at the parietooccipital junction. More subtle areas of hyperintensity in the surrounding white matter ➡ proved to be an infiltrating tumor.* **(Right)** *Axial T1WI C+ MR in the same patient shows heterogeneous enhancement of the lobular portion with regions of central necrosis ➡. The infiltrating portions do not enhance ➡. Final diagnosis was a supratentorial PNET.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Lethal (usually childhood) cancer with *SMARCB1/hSNF5* mutations
- Loss of INI1 protein expression hallmark of CNS AT/RT

IMAGING

- Heterogeneous intracranial mass in infant
- Hyperattenuating mass on CT
- Commonly contains cysts or hemorrhage
- Relatively little edema for size of tumor
- Heterogeneous enhancement
- Leptomeningeal spread common
- Solid portions have reduced diffusivity on DWI, show decreased ADC
  - Cystic/necrotic regions show increased diffusivity, increased ADC

TOP DIFFERENTIAL DIAGNOSES

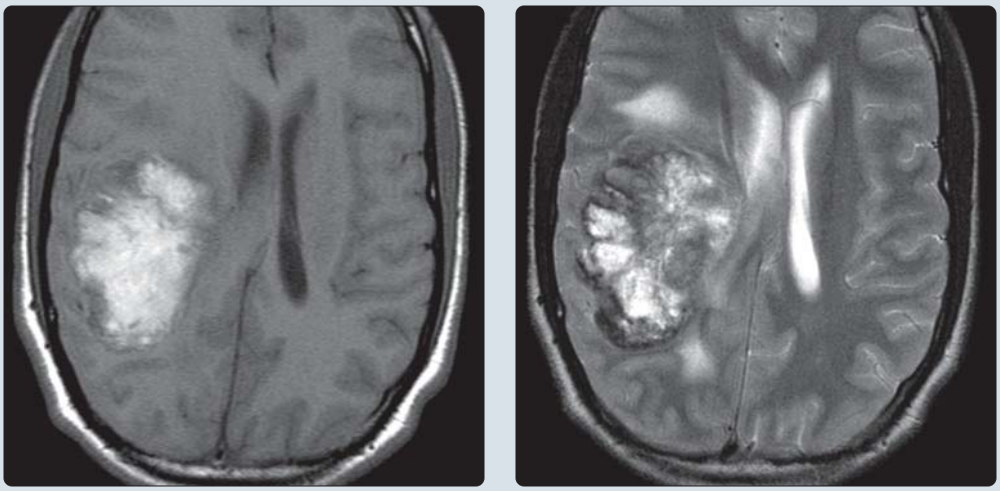
- Medulloblastoma, other PNETs

PATHOLOGY

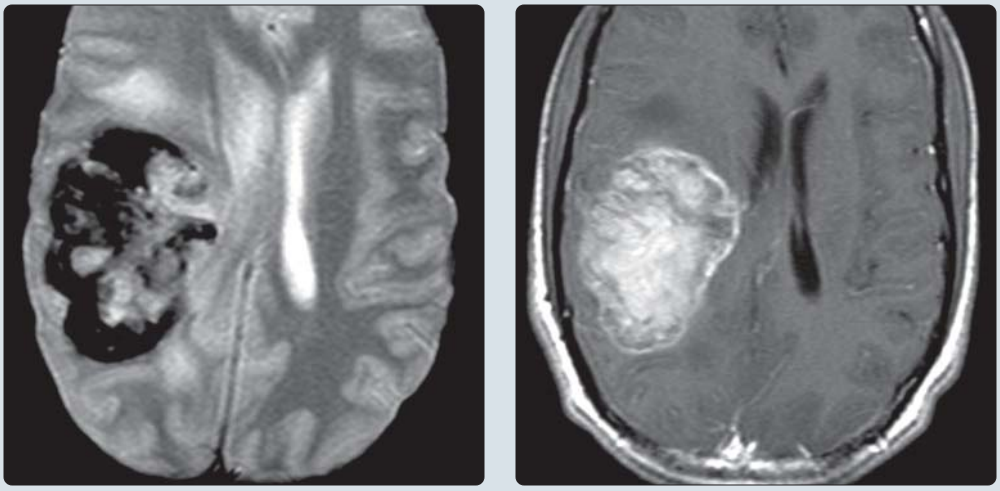
- WHO grade IV
- Extreme morphological, immunophenotypic heterogeneity
- Divergent differentiation along mesenchymal, neuronal, glial, or epithelial lines
  - Accounts for "teratoid" label
  - Rhabdoid cells common but not invariably present
  - Often contains primitive neuroectodermal cells that resemble PNET
- Lack of immunostaining for INI1 protein correlates with *hSNF5/INI1* mutation
  - Required for definitive diagnosis of AT/RT

DIAGNOSTIC CHECKLIST

- Always consider AT/RT when large tumor found in child younger than 3 years
- Include AT/RT whenever medulloblastoma (PNET-MB) is diagnostic consideration



(Left) *Axial T1WI shows a large right parietal mass with predominately high signal intensity, suggesting hemorrhage.* **(Right)** *Axial T2WI in the same case shows a very heterogeneous lesion with mixed hyper-, hypo-, and isointense regions. Peripheral edema is relatively minimal in this case.*



(Left) *Axial T2*GRE shows markedly hypointense "blooming" in the mass, consistent with hemorrhage.* **(Right)** *Axial T1C+ MR in the same case shows some enhancement around the periphery of the mass. AT/RT was found at surgery. (Courtesy R. Hewlett, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Atypical teratoid/rhabdoid tumor (AT/RT)

Synonyms

- Malignant rhabdoid tumor of brain
- Rhabdoid brain tumor

Definitions

- Lethal (usually childhood) cancer with *SMARCB1/hSNF5* mutations
  - Loss of INI1 protein expression hallmark of CNS AT/RT

IMAGING

General Features

- Best diagnostic clue
  - Heterogeneous mass in infant/young child
  - Moderately large, bulky tumor with mixed solid cystic components
- Location
  - Infratentorial (47%)
    - Most off midline
    - Cerebellopontine angle (CPA)
    - Cerebellum &/or brainstem
  - Supratentorial (41%)
    - Hemispheric or suprasellar
  - Both infra- and supratentorial (12%)
  - 15-20% present with disseminated tumor at time of initial diagnosis
- Size
  - Most 1-3 cm at presentation (can be very large)
- Morphology
  - Roughly spherical, irregular/lobulated

CT Findings

- NECT
  - Hyperattenuating mass
  - Commonly contains cysts &/or hemorrhage
  - May contain Ca++
  - Obstructive hydrocephalus common
- CECT
  - Strong but heterogeneous enhancement typical

MR Findings

- T1WI
  - Heterogeneous
    - Isointense to brain
    - ± hyperintense hemorrhagic foci
    - Cysts slightly hyperintense to CSF
- T2WI
  - Heterogeneous
    - Hypointense foci (hemorrhage)
    - Hyperintense foci (cysts)
- FLAIR
  - Solid tumor isointense to hyperintense
  - Cysts hyperintense to CSF
  - Transependymal edema from hydrocephalus
  - Relatively little edema for size of tumor
- T2* GRE
  - Hypointense "blooming" of hemorrhagic foci
- DWI
  - May restrict because of cellularity
  - Decreased apparent diffusion coefficient (ADC)
- T1WI C+
  - Heterogeneous enhancement
  - Leptomeningeal spread common (15-20%)
    - Diffuse linear
    - Multiple nodular
  - "Brain-to-brain" parenchymal metastases
- MRA
  - May show narrowing of encased vessels
- MRS
  - Aggressive metabolite pattern
    - Elevated choline
    - Low or absent N-acetylaspartate (NAA), creatine
    - Lipid/lactate peak common

Imaging Recommendations

- Best imaging tool
  - MR with contrast
- Protocol advice
  - Entire CNS must be imaged at presentation to identify subarachnoid spread of tumor

DIFFERENTIAL DIAGNOSIS

Medulloblastoma (PNET-MB)

- Posterior fossa tumor
- AT/RT more likely to have cysts than PNET-MB
- Heterogeneous CPA tumors statistically more likely to be PNET-MB but more typical of AT/RT

Ependymoma

- "Plastic" tumor, extends out 4th ventricle foramina
- Ca++, cysts, hemorrhage common
- Strong, heterogeneous enhancement

Choroid Plexus Papilloma

- Intraventricular mass
- Homogeneous enhancement

Glioblastoma/Sarcoma

- High-grade glioma
- Exophytic from brainstem

Teratoma

- More often pineal or parasellar in location
- Heterogeneous on imaging due to Ca++, hemorrhage

PATHOLOGY

General Features

- Genetics
  - *SMARCB1* mutation with INI1 loss of expression/mutation diagnostic of AT/RT
    - Core member of SWI/SNF chromatin remodeling complex
  - 2 AT/RT molecular subgroups, each with distinct clinicopathological and survival features
    - Group 1: *ASCL1* (regulator of NOTCH signaling, marker of primitive neural lineage) upregulated
      - 60% supratentorial, 40% infratentorial

https://CafePezeshki.IR

- Neural differentiation = 5-year survival
  - *ASCL1* negative tumor (infratentorial, poor survival)
    - Mesenchymal differentiation, BMP/MAPK signaling pathways enriched
    - 70% infratentorial, 30% supratentorial
    - Infratentorial location, BMP signaling = worse outcome
- Familial cases occur in rhabdoid tumor predisposition syndrome (RTPS)
  - When mutation in *SMARCB1* gene, called RTPS1
  - *SMARCB4* gene mutation → RTPS2

Staging, Grading, & Classification

- WHO grade IV
  - Without molecular information, diagnosis is "embryonal tumor with rhabdoid features"

Gross Pathologic & Surgical Features

- Frequently unresectable at presentation
- Poorly defined tumor margins
- Infiltration into parenchyma

Microscopic Features

- Extreme morphological, immunophenotypic heterogeneity
- Divergent differentiation along mesenchymal, neuronal, glial, or epithelial lines
  - Accounts for "teratoid" label
  - Rhabdoid cells common but not invariably present
    - Large, pale, bland cells with moderate eosinophilic cytoplasm
  - Often contains primitive neuroectodermal cells that resemble PNET
- Lack of immunostaining for INI1 protein correlates with *hSNF5/INI1* mutation
  - Required for definitive diagnosis of AT/RT

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Signs of increased intracranial pressure
    - Lethargy
    - Vomiting
    - Increased head circumference
  - Other signs/symptoms
    - Torticollis
    - Seizure
    - Regression of skills
    - Acute facial nerve palsy in infant

Demographics

- Age
  - < 3 years; smaller peak in adults
    - Adult tumors often in atypical locations (e.g., pineal, suprasellar, spine)
- Gender
  - M = F
- Epidemiology
  - Rare > 3 years
  - Up to 20% of primitive CNS tumors in children < 3 years of age

Natural History & Prognosis

- Median survival = 16 months with leptomeningeal disease, 149 months without
- Death rate = 64%

Treatment

- Aggressive resection and chemoradiation have increased survival times but still remains poor
- Radiation has shown to increased survival time, especially in older children
  - Controversial in younger children due to damage to developing brain
- Chemotherapy regimens designed for PNET-MB largely ineffectual

DIAGNOSTIC CHECKLIST

Consider

- Always consider AT/RT when large tumor found in child < 3 years of age
- Include AT/RT whenever medulloblastoma (PNET-MB) is diagnostic consideration

Image Interpretation Pearls

- Imaging appearance is nonspecific
- More likely to be heterogeneous or supratentorial than PNET-MB

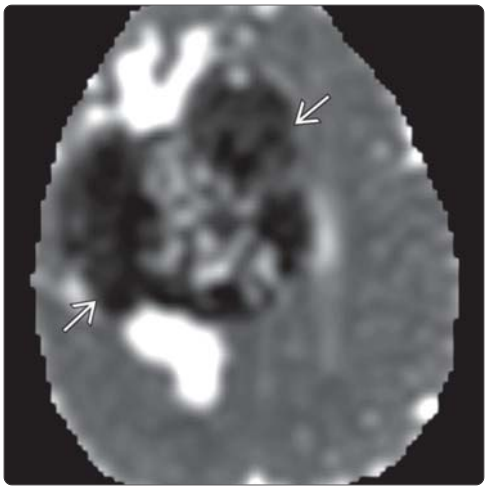
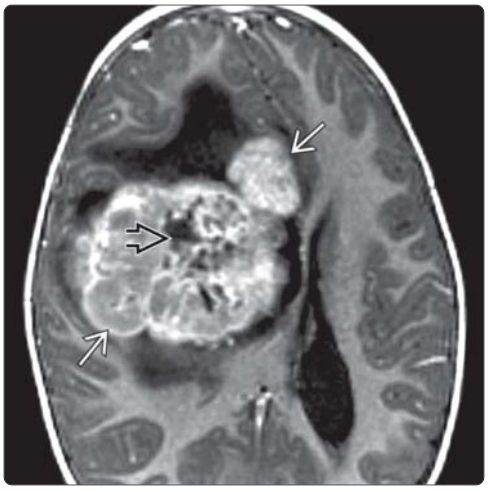
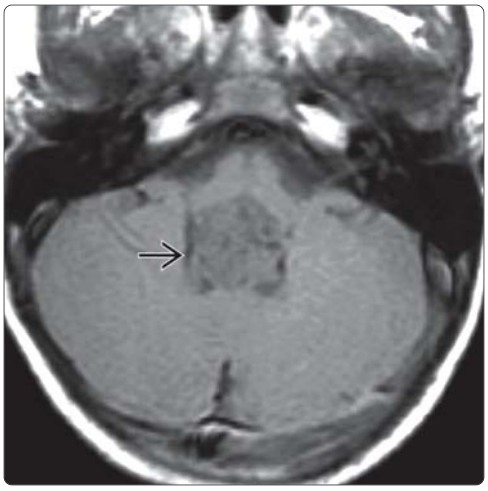
https://CafePezeshki.IR

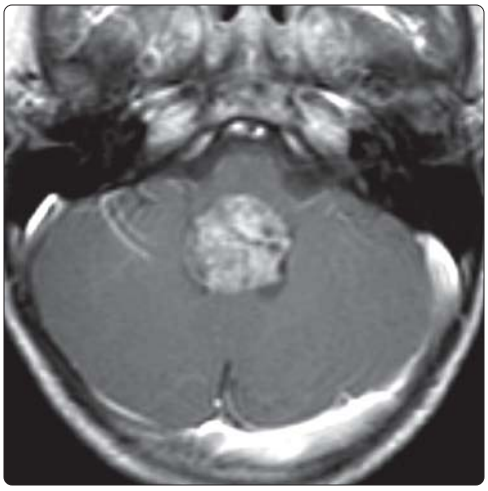


(Left) *Axial T2WI MR shows a large, bulky, supratentorial, heterogeneous tumor ⇨ with central hemorrhage and mass effect. Although some edema is present ⇨, it is less than expected given the size of the tumor.* **(Right)** *Axial ADC in the same case shows decreased apparent diffusion coefficient ⇨ compatible with the hypercellular nature of the tumor.*



(Left) *Axial T1WI C+ MR in the same patient shows strong but rather heterogeneous enhancement ⇨. Some central areas of necrosis ⇨ can be seen within the generally solid mass.* **(Right)** *Sagittal T1WI C+ MR demonstrates "drop" metastases ⇨. Preoperative contrast-enhanced scans of the entire neuraxis should be obtained in all cases of posterior fossa neoplasms in children to rule out subarachnoid metastases, as in this example.*





(Left) *Axial T1WI MR in a 3-year-old male with history of morning emesis for 4-6 weeks shows a mass in the fourth ventricle ⇨.* **(Right)** *Axial T1 C+ MR in the same case shows the mass enhances moderately but heterogeneously. The preoperative diagnosis was medulloblastoma. The final pathological diagnosis was AT/RT.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Malignant tumor of sympathetic nervous system arising from embryonal neural crest cell derivatives

IMAGING

- Classic imaging appearance:
  - "Hair on end" spiculated periostitis of orbits and skull ± bone destruction
- Cranial metastases
  - Nearly always extradural, calvarial-based mass
- Brain metastases rare
  - ↑ prevalence with improved treatment protocols, stage IV metastatic disease
  - Most parenchymal NB mets supratentorial, hemorrhagic

TOP DIFFERENTIAL DIAGNOSES

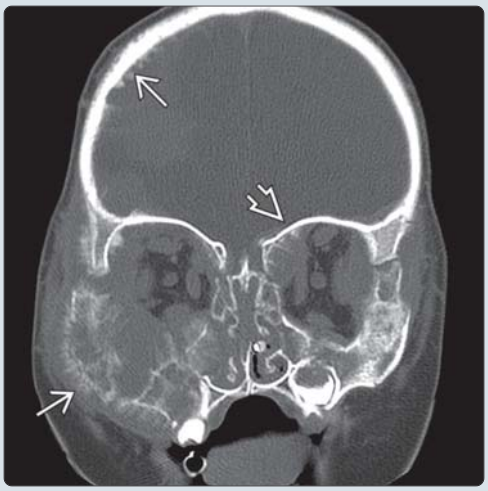
- Leukemia
- Langerhans cell histiocytosis (LCH)
- Extraaxial hematoma
- Ewing sarcoma

PATHOLOGY

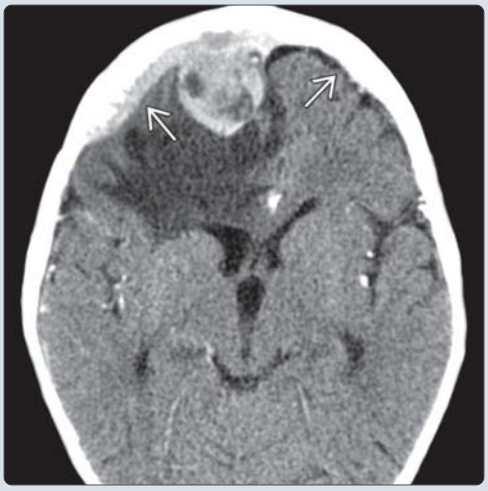
- Calvarial metastases indicate stage IV disease
  - 60-75% < 1-year survival
  - 15% > 1-year survival despite aggressive treatment

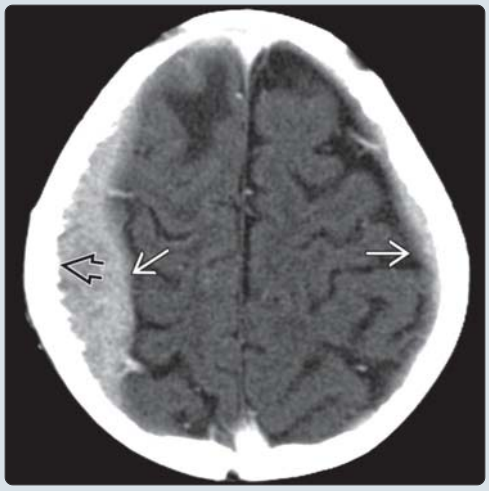
CLINICAL ISSUES

- Most common solid extracranial tumor in children < 5 years of age
  - 8-10% of all childhood cancers
- Most common tumor in neonates/infants < 1 month of age (congenital)
  - Median age at diagnosis = 22 months
  - Ophthalmic manifestation in 20-55%
    - Proptosis and "raccoon eyes"
- Metastasis to bone most common, 2/3 of patients at diagnosis
  - Stage IV disease



(Left) *Coronal NECT of a child with an abdominal mass reveals orbital, facial bone, and calvarial spiculated periostitis giving rise to a "hair on end" appearance ➡ with associated large soft tissue masses. Note bilateral disease ➡. Metastatic stage IV neuroblastoma typically involves the skull and bony orbits.* **(Right)** *Axial NECT in the same patient shows the "hair on end" appearance. Involvement of the orbits often gives rise to proptosis and ecchymosis "raccoon eyes," which may be mistaken for abuse.*





(Left) *Axial CECT in a 2-year-old male with neuroblastoma shows strong, heterogeneously enhancing epidural masses ➡ with mass effect and edema in frontal lobe.* **(Right)** *Cephalad CECT scan in the same case shows strongly enhancing epidural masses ➡. Irregularity of overlying skull ⇨ indicates calvarial involvement. Intracranial involvement in neuroblastoma is typically from adjacent calvarial metastases with dural invasion. Brain parenchymal metastases are rare.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neuroblastoma (NB), neuroblastic tumors (NBT)

Definitions

- Malignant tumor of sympathetic nervous system arising from embryonal neural crest cell derivatives

IMAGING

General Features

- Best diagnostic clue
  - Spiculated periorbital bone mass causing proptosis in child with "raccoon eyes"
- Location
  - Cranial metastases nearly always extradural calvarial-based masses
    - Calvaria, orbit, skull base
  - Brain metastases rare but ↑ with improved treatment protocols, stage IV metastatic disease
    - CNS NB is sole site of disease recurrence in 64% of high-risk patients
    - CNS may represent "sanctuary site" for NB
    - Most parenchymal NB mets supratentorial, hemorrhagic
    - Leptomeningeal, intraventricular lesions also occur
- Morphology
  - Crescentic or lenticular, following contour of bone
  - Typically poorly defined
- Classic imaging appearance: "Hair on end" spiculated periostitis of orbits and skull, ± bony destruction

Radiographic Findings

- Coronal suture widening and periosteal new bone

CT Findings

- NECT
  - Best for showing fine spicules of periosteal bone projecting off skull or sphenoid wings
  - Soft tissue mass typically iso- to hyperdense to brain
    - May mimic epidural or subdural hematoma
  - Mass projects into orbit (extraconal), with extension to surrounding spaces, not preseptal space
  - May project through inner and outer tables of skull
  - May be bilateral
- CECT
  - Enhancing dural metastasis if intracranial
  - Rare ring-enhancing brain parenchymal metastasis

MR Findings

- T1WI
  - Slightly heterogeneous
  - Hypointense to muscle
- T2WI
  - Heterogeneous
  - Hypointense to brain
  - Slightly hyperintense to muscle
- FLAIR: Heterogeneous; hyperintense to muscle
- T2* GRE: Hypointense
- T1WI C+: Vigorously enhances, may be heterogeneous
- MRV: May narrow or invade adjacent dural sinuses

Nuclear Medicine Findings

- Bone scan
  - MIBG (meta-iodobenzylguanidine)
    - Catecholamine analog
    - Labeled with iodine-131 or iodine-123
    - Avid uptake by neural crest tumors
      - NB, ganglioneuroblastoma, ganglioneuroma, carcinoid, medullary thyroid carcinoma
    - 99% specific for NBT
    - Caveat: Up to 30% of NB not MIBG positive
      - Misses 50% of recurrent tumors
    - Cannot distinguish marrow disease from bone disease
  - Tc-99m-MDP (methylene diphosphonate)
    - Increased uptake from calcium metabolism of tumor not specific to neural crest tissue
    - 74% sensitivity for bony metastases
    - May distinguish marrow from bone disease
    - Bone scan essential for differentiating stage IV disease from stage IV-S in children < 1 year
  - In111 pentetreotide
    - Somatostatin analog
    - Not specific to NBT; not superior to MIBG
- PET
  - FDG PET has shown high sensitivity and specificity for recurrent tumor in small numbers of cases
  - FDG PET may identify recurrence when MIBG negative due to dedifferentiation

Imaging Recommendations

- Best imaging tool
  - CT/MR to evaluate primary tumor
  - Nuclear medicine MIBG & Tc-99m-MDP bone scan
  - Brain/orbit CT if scintigraphy indicates metastases
- Protocol advice
  - MR C+ and FS complementary to CT

DIFFERENTIAL DIAGNOSIS

Leukemia

- Dural- or calvarial-based masses
- More frequent parenchymal masses
- Less heterogeneous on MR

Langerhans Cell Histiocytosis (LCH)

- Lytic bone lesions without periosteal new bone
- Often associated with diabetes insipidus

Extraaxial Hematoma

- Subdural or epidural hematoma
- Bleeding disorder or child abuse to be considered

Ewing Sarcoma

- < 1% of cases involve skull
- Aggressive bone destruction
- Spiculated periosteal reaction

Osteosarcoma

- Rarely primary in calvaria

Rhabdomyosarcoma

- Most common soft tissue malignancy of pediatric orbit
- Less likely bilateral; may invade preseptal space

https://CafePezeshki.IR

Beta Thalassemia Major

- Classic "hair on end" calvarial expansion
- Not focal or destructive like neuroblastoma

PATHOLOGY

General Features

- Etiology
  - Arises from pathologically maturing neural crest progenitor cells
  - Primary tumors arise at sites of sympathetic ganglia
  - No known causative factor
- Genetics
  - Multiple gene loci associated with NB 1p, 4p, 2p, 12p, 16p, 17q
    - *Myc-N* oncogene (chromosome 2) important marker
    - 35% have chromosome 1 short arm deletion
  - 1-2% of cases inherited
- Associated abnormalities
  - Rarely associated with Beckwith-Wiedemann syndrome, neurofibromatosis type 1
  - Some association with neurocristopathy syndromes
    - Hirschsprung disease, congenital central hypoventilation, DiGeorge syndrome

Staging, Grading, & Classification

- Calvarial metastases indicate stage IV disease
- International Neuroblastoma Staging System
  - Stage I: Confined to primary organ
  - Stage IIA: Unilateral tumor, no positive lymph nodes (LN)
  - Stage IIB: Unilateral tumor, unilateral positive LN
  - Stage III: Contralateral involvement
  - Stage IV: Distal metastases
  - Stage IV-S: < 1 year at diagnosis, stage I or II + metastatic disease confined to skin, liver, or bone marrow

Gross Pathologic & Surgical Features

- Grayish-tan soft nodules
- Infiltrating or circumscribed without capsule
- Necrosis, hemorrhage, and calcifications variable

Microscopic Features

- Undifferentiated round blue cells with scant cytoplasm, hyperchromatic nuclei
- May form Homer Wright rosettes
- Ganglioneuroblastoma has interspersed mature ganglion cells
  - Different regions of same tumor may have ganglioneuroblastoma or NB

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - "Raccoon eyes" (periorbital ecchymosis)
  - Palpable calvarial masses
- Other signs/symptoms
  - Palpable abdominal or paraspinal mass
  - Cranial metastatic disease rarely occurs in isolation
- Clinical profile
  - Ophthalmic manifestation in 20-55% at presentation
    - Proptosis and "raccoon eyes," 50% bilateral
    - Horner syndrome
    - Opsoclonus, myoclonus, and ataxia
      - Myoclonic encephalopathy of infancy
      - Paraneoplastic syndrome (not metastatic)
      - Up to 2-4% of NB patients; more favorable prognosis
  - Elevated vasoactive intestinal peptides (VIP)
    - Up to 7% of NBT patients
    - Diarrhea, hypokalemia, achlorhydria
  - Elevated homovanillic acid and vanillylmandelic acid in urine (> 90%)

Demographics

- Age
  - Median at diagnosis: 22 months
  - 40% diagnosed by 1 year
  - 35% between 1-2 years
  - 25% > 2 years
  - 89% by 5 years
- Gender
  - M:F = 1.2:1
- Epidemiology
  - Most common solid extracranial tumor in patients < 5 years
  - 8-10% of all childhood cancers
  - Most common tumor in patients < 1 month (congenital)
  - Bony metastasis most common, 2/3 of patients at diagnosis
  - 1-2% spontaneously regress in 6-12 months, mostly stage IV-S
  - NB is most common and aggressive of NBT

Natural History & Prognosis

- Stage I, II, and IV-S have 3-year event-free survival (EFS) of 75-90%
- Stage III: < 1 year old (80-90%) 1-year EFS; > 1 year old (50%) 3-year EFS
- Stage IV: < 1 year old (60-75%) 1-year EFS; > 1 year old (15%) 3-year EFS
- Poor prognostic indicators: Deletion of 1p, translocation of 17q, *Myc-N* amplification
- Good prognostic indicators: Localized disease, stage IV-S, decreased *Myc-N* amplification

Treatment

- Surgical resection + chemotherapy, radiation
- Bone marrow transplant
- Stage IV-S may spontaneously regress

DIAGNOSTIC CHECKLIST

Consider

- Abdominal imaging to identify primary tumor site

Image Interpretation Pearls

- CT without contrast can help identify bone spicules, eliminating LCH from differential

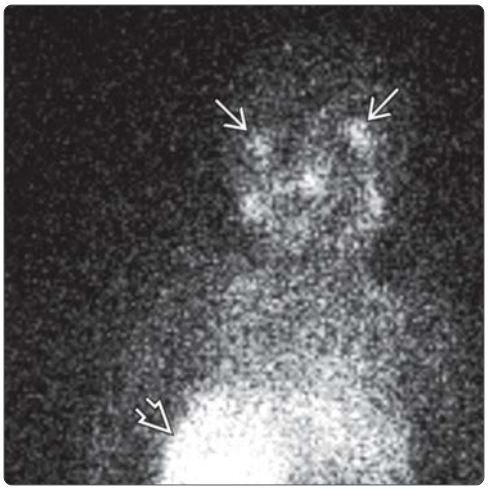
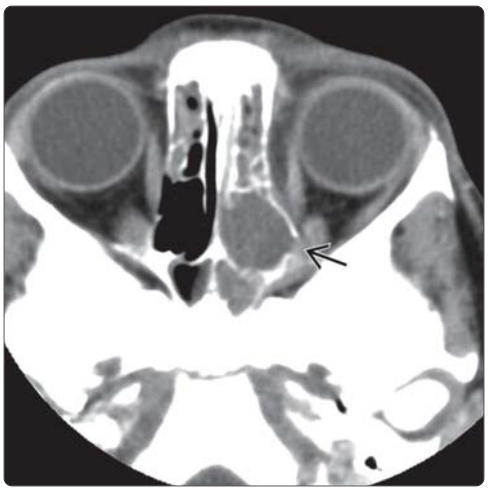
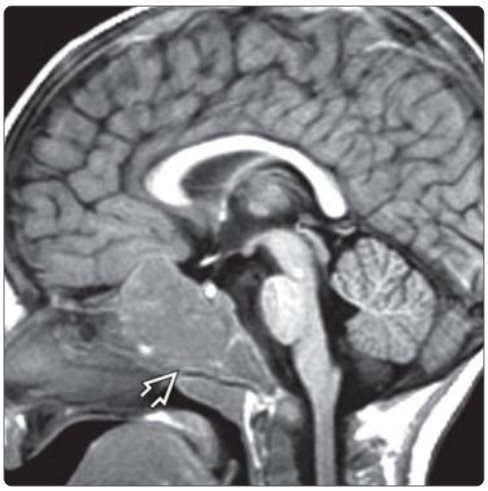
(Left) *Axial FLAIR MR shows heterogeneous signal in a patient with extradural metastatic neuroblastoma. Little reactive change is seen in the underlying brain parenchyma despite significant mass effect.* **(Right)** *Axial T2WI MR in the same case shows heterogeneous and hypointense signal in this metastatic neuroblastoma. T2 hypointensity is characteristic of densely cellular masses with high nuclear to cytoplasmic ratio.*



(Left) *Coronal I-123-labeled MIBG scan shows areas of increased uptake in the orbits related to neuroblastoma metastases. Note the large area of uptake in the right abdomen from the primary tumor. Although MIBG scanning is highly specific for neuroblastic tumors, up to 30% of primary and 50% of recurrent neuroblastomas do not take up MIBG.* **(Right)** *Coronal T1WI C+ MR shows an enhancing convexity mass centered at the diploic space with subperiosteal and epidural components in a child with neuroblastoma.*





(Left) *Axial NECT in a child with neuroblastoma shows an ethmoid mass. There is a small focus of bony erosion suggesting the correct diagnosis of neuroblastoma metastasis.* **(Right)** *Sagittal T1WI MR shows a mildly heterogeneous, large, central skull base mass with marked expansion of the clivus in this 2 year old with stage IV neuroblastoma. Imaging mimics other malignancies. Neuroblastoma metastases most commonly involve the calvaria or orbital region.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Benign encapsulated nerve sheath tumor composed of differentiated neoplastic Schwann cells
  - 99% of all schwannomas associated with cranial nerves
  - 95% involve CN8
  - < 1% of all intracranial schwannomas are intraparenchymal

IMAGING

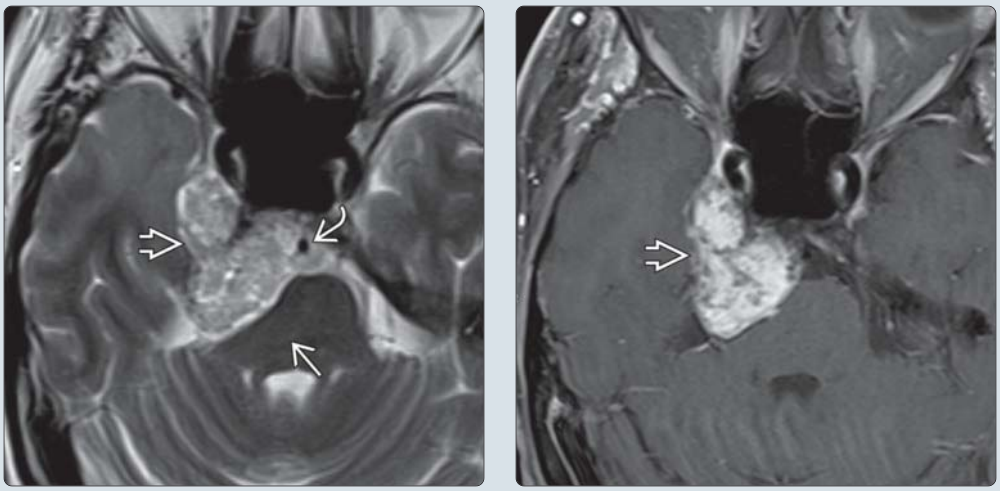
- CT
  - Iso- to slightly hyperdense compared to brain
  - Adjacent bone, foramina may show smooth, scalloped enlargement
  - Avid, sometimes heterogeneous enhancement
- MR
  - Heterogeneously hyperintense on T2WI, FLAIR
  - 100% enhance (avid, heterogeneously)

TOP DIFFERENTIAL DIAGNOSES

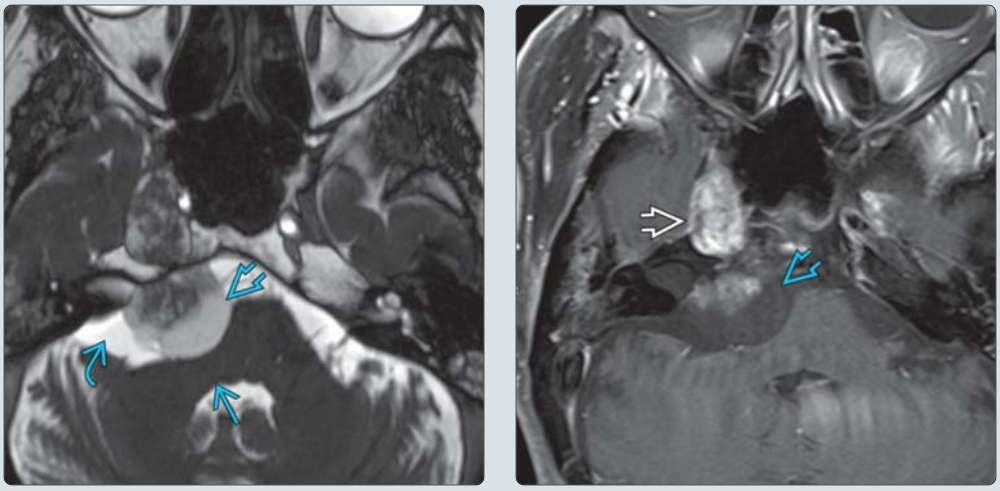
- CN schwannoma (enlarged, enhancing cranial nerve[s])
  - Metastases
  - Lymphoma
  - Multiple sclerosis
  - Neurofibromatosis type 2
  - Schwannomatosis
- Parenchymal schwannoma (rare)
  - Ganglioglioma
  - Pleomorphic xanthoastrocytoma
  - Pilocytic astrocytoma

PATHOLOGY

- Spindle-shaped neoplastic Schwann cells
- Single cell type with 2 basic histologic patterns
  - High cellularity (Antoni A pattern)
  - Low cellularity ± lipidization ± cystic degeneration (Antoni B pattern)



(Left) *Right trigeminal nerve schwannoma in a 58-year-old man. Axial T2WI shows a heterogeneously hyperintense mass ⇨ extending from the cisternal segment through trigeminal cave, effacing the pons ⇨ and contacting the basilar artery ⇨.* **(Right)** *Heterogeneous, but avid enhancement is seen in solid portions of the tumor ⇨.*



(Left) *Axial CISS MR imaging in the same patient demonstrates a tumor-associated cyst ⇨, which is hyperintense to brain, but hypointense relative to CSF ⇨. This contributes to mass ⇨ effect upon the pons and brachium pontis.* **(Right)** *The tumor-associated cyst is non-enhancing ⇨, in contradistinction to the solid portions of the schwannoma ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Nonvestibular schwannoma (nVS)

Synonyms

- Neurilemmoma, neurinoma

Definitions

- Benign encapsulated nerve sheath tumor composed of differentiated neoplastic Schwann cells

IMAGING

General Features

- Best diagnostic clue
  - T2 hyperintense, avid but heterogeneously enhancing cranial nerve mass
- Location
  - Extraaxial
    - 99% of all intracranial schwannomas are extraaxial
      - Arise from a cranial nerve
    - 95% associated with CN8 (vestibular schwannoma [VS])
      - VS = 2nd most common extraaxial tumor in adults (meningioma is most common)
      - VS accounts for ~ 90% of all CPA-IAC masses
    - Between 1-5% of intracranial schwannomas are nonvestibular schwannomas
    - Relative incidence of nVSs
      - Trigeminal nerve (CN5) 2nd most common schwannoma
      - Schwannomas of all other CNs are uncommon
      - CN9 > 10 > 7 > 11 > 12
      - Nonvestibular schwannomas of CN3, 4, 6 rare in absence of neurofibromatosis type 2
      - Multiple nVSs should raise suspicion for Schwannomatosis
  - Intraparenchymal
    - < 1% of all intracranial schwannomas
  - Schwannomas can be solitary or multiple
    - Solitary (sporadic) schwannoma
    - Multiple schwannomas
      - Neurofibromatosis type 2
      - Schwannomatosis
- Size
  - Varies from tiny to enormous
    - Small schwannomas along oculomotor CNs (3, 4, 6)
    - Largest along CN8, 5
- Morphology
  - Smooth, well-demarcated, often lobulated

CT Findings

- NECT
  - Iso- to slightly hyperdense compared to brain
  - Look for effect on adjacent bone, foramina
    - **Smooth enlargement**
    - Thin, sclerotic but well-demarcated margins
    - CN5 schwannoma often extends into (or originates from) trigeminal cave
    - Extracranial extension of nVS (e.g., CN5, 9) more common than with VS
  - Nonneoplastic tumor-associated cyst between tumor, brain in ~ 5%
  - Ca++, gross hemorrhage uncommon
- CECT
  - Strong, sometimes heterogeneous enhancement

MR Findings

- T1WI
  - Isointense to brain
  - Tumor-associated cyst hypointense
- T2WI
  - Inhomogeneously hyperintense
  - Tumor-associated cyst very hyperintense
- FLAIR
  - Both nodule, tumor-associated cyst may be hyperintense
- T2* GRE
  - May show small "blooming" hemorrhagic foci
- DWI
  - No restriction (iso- to hyperintense to brain parenchyma on ADC)
  - May help differentiate from high cellularity malignant neoplasm (low ADC relative to brain parenchyma)
- T1WI C+
  - 100% enhance
    - Avid, usually heterogeneous
    - 10-15% have intramural cysts (nonenhancing)
    - Nonneoplastic tumor-associated cysts do not enhance

Imaging Recommendations

- Best imaging tool
  - Precontrast T1-, T2WIs; whole brain FLAIR with axial, coronal T1WI C+ FS
- Protocol advice
  - For suspected cranial nerve schwannoma
    - Add thin-section high-resolution T2WI, CISS, or 3D T2 turbo spin echo with variable flip angles (SPACE or CUBE)

DIFFERENTIAL DIAGNOSIS

CN Schwannoma

- Enlarged, enhancing cranial nerve(s)
  - Metastases
  - Lymphoma
  - Multiple sclerosis
  - Neurofibromatosis type 2
  - Neurosarcoid
  - Chronic inflammatory demyelinating polyneuropathy (CIDP)

Parenchymal Schwannoma (Rare)

- Ganglioglioma
- Pleomorphic xanthoastrocytoma
- Pilocytic astrocytoma
- Hemangioblastoma

PATHOLOGY

General Features

- Etiology

https://CafePezeshki.IR

- Benign cranial nerve tumor
  - Arises from glial-Schwann cell junction
  - Distance from brain to glial-Schwann cell junction varies according to CN
- Parenchymal schwannoma may arise from dedifferentiated neural crest cells
- Genetics
  - Inactivating **somatic** mutations of *NF2* tumor suppressor gene in 60% of sporadic schwannomas
    - Loss of remaining wild-type allele on chromosome 22q
    - Encodes Merlin (schwannomin) protein
  - Germline mutation of *SMARCB1* tumor suppressor/chromatin remodeling gene in Schwannomatosis
    - AKA *INI1*, *hSNF5*, and *BA547*
    - Located on chromosome 22, centromeric to *NF2* gene
    - Complex, multi-hit mutation interplay between SMARCB1 and NF2 in affected somatic tissues of schwannomatosis patients

Staging, Grading, & Classification

- WHO grade I

Gross Pathologic & Surgical Features

- Yellowish tan, rubbery
  - Round/ovoid
  - Encapsulated by epineurium, well delineated
- Arises eccentrically from cranial nerve
  - Nerve often appears "splayed" over schwannoma
- 15-20% have associated fluid-filled cysts
  - Most are small, intratumoral
  - Occasionally large, nonneoplastic, fluid-containing collections form between tumor and brain
- Hemorrhage
  - Small hemorrhagic foci occur but are uncommon
  - Gross hemorrhage rare (< 1%)

Microscopic Features

- Spindle-shaped neoplastic Schwann cells
- Single cell type with 2 basic histologic patterns
  - High cellularity and spindle-shaped nuclei (*Antoni A pattern*)
    - Frequent "Verocay bodies" = foci of prominent nuclear palisades separated by nuclear free zones
  - Low cellularity, disorganized matrix with common cystic degeneration (*Antoni B pattern*)
    - May represent spectrum of degenerated Antoni A
- Immunohistochemistry
  - S100 protein strongly expressed
  - Vimentin variably expressed
  - Usually GFAP negative
- Rare variant = melanotic schwannoma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Cranial nerve schwannoma
    - Vestibular schwannoma
      - Unilateral sensorineural hearing loss
      - Small VS: Tinnitus, disequilibrium common
      - Large VS: Trigeminal ± facial neuropathy
    - Symptoms of nVS vary depending on which nerve is affected
  - Parenchymal schwannoma
    - Much less common
    - Seizure
    - Headache
    - Focal neurologic deficit uncommon

Demographics

- Age
  - Adult (unless neurofibromatosis type 2)
    - Age range = 30-70 years
    - Peak = 40-60 years
- Epidemiology
  - Schwannomas account for 8% of all intracranial tumors
  - Vestibular schwannoma accounts for 90% of all CPA masses
  - 90% of schwannomas are solitary
  - 5% associated with neurofibromatosis type 2
  - 5% associated with Schwannomatosis

Natural History & Prognosis

- Benign, slowly growing
- Malignant change extremely rare

Treatment

- Vestibular schwannoma
  - Resection
  - Fractionated/stereotaxic neurosurgery
- Other (nonvestibular schwannoma)
  - Varies with location

DIAGNOSTIC CHECKLIST

Consider

- Patient may have NF2 if
  - nVS in unusual location
  - > 1 schwannoma
  - Coexisting meningioma identified
- Patient may have Schwannomatosis if
  - > 1 schwannoma
  - No VS
  - Age > 35

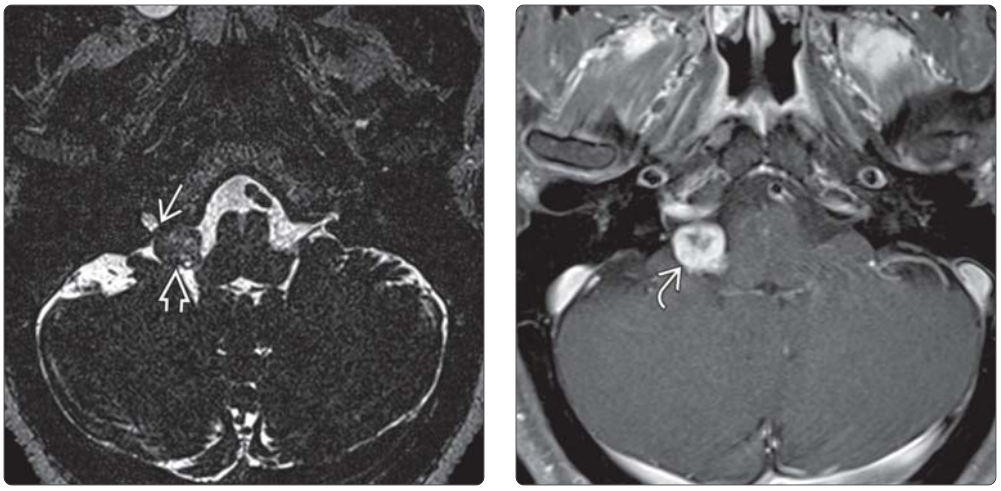
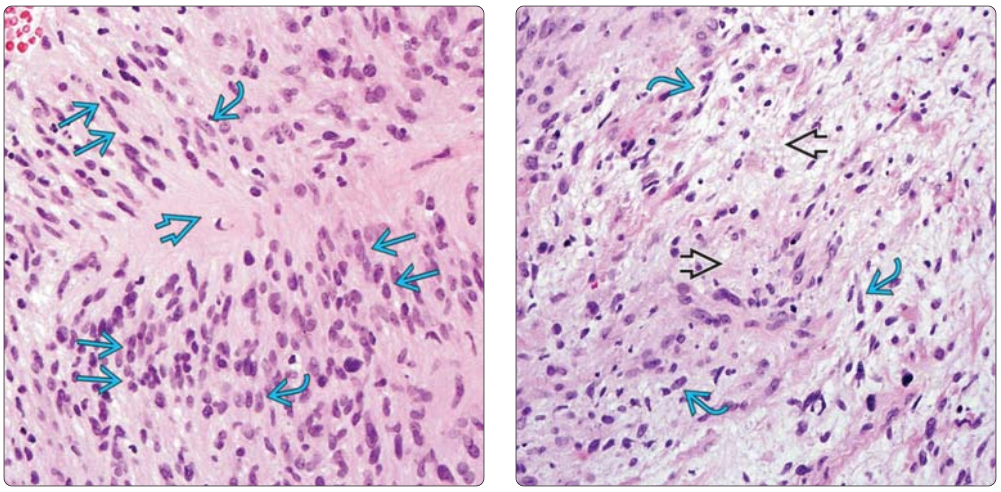
(Left) *Axial T2WI MR demonstrates a cystic mass ⇨ with a mural nodule ⇨ in the right inferior frontal lobe. Note the benign remodeling (scalloping) ⇨ of the adjacent calvaria, characterizing this as a slow-growing mass.* **(Right)** *Axial T1WI C+ MR shows avid enhancement of the mural nodule ⇨. Most intracranial schwannomas are extraaxial, associated with cranial nerves. Parenchymal schwannomas are rare (< 1% of schwannomas), commonly seen as a cyst with a mural nodule.*



(Left) *Axial T2 SPACE of a 57-year-old man with schwannoma demonstrates a heterogeneously hypointense mass ⇨ in the right cerebellopontine angle, extending just to the jugular foramen ⇨.* **(Right)** *There is avid, targetoid enhancement ⇨, consistent with schwannoma. Given location and extension, this may be of CN 9, 10, or 11 origin. Central non-enhancement corresponds to an area of T2 hyperintensity (not shown), often seen in Antoni B regions of hypocellularity and myxoid stroma.*



(Left) *Photomicrograph (H&E, 400x) demonstrates typical features of a high cellularity (Antoni A) region within a schwannoma. Spindle-shaped nuclei ⇨ are arranged in palisades ⇨ surrounding a nuclear-free zone ⇨, a so-called Verocay body that is characteristic of an Antoni A region.* **(Right)** *In contrast, Antoni B pattern is a low-cellularity region characterized by a spindle-shaped nuclei ⇨ in a background of myxoid stroma ⇨, often manifesting higher T2 signal on MR imaging.*

KEY FACTS

TERMINOLOGY

- PNF: Infiltrative extraneural tumor
  - Occurs exclusively in neurofibromatosis type 1 (NF1)
- SNF: Round/ovoid subcutaneous mass
  - Usually solitary, not associated with NF1

IMAGING

- General features
  - PNF: NF1 patient with poorly delineated, infiltrating, worm-like, soft tissue mass
  - PNF: Orbit (CNV1), scalp, parotid gland
  - SNF: Well-circumscribed, round/oval scalp mass
  - SNF: Skin, spinal, or peripheral nerve roots (rarely, if ever, involves cranial nerves [CN])
- CT
  - PNF infiltrates CNV1
  - May enlarge superior orbital fissure
  - May extend intracranially into cavernous sinus
  - Almost never extends beyond Meckel (trigeminal) cave
  - Moderate to avid enhancement
- MR
  - Isointense, infiltrating on T1WI
  - Hyperintense on T2WI
  - Avid, somewhat heterogeneous enhancement

TOP DIFFERENTIAL DIAGNOSES

- Schwannoma
- Metastasis
- Malignant peripheral nerve sheath tumor (MPNST)
- Sarcoma

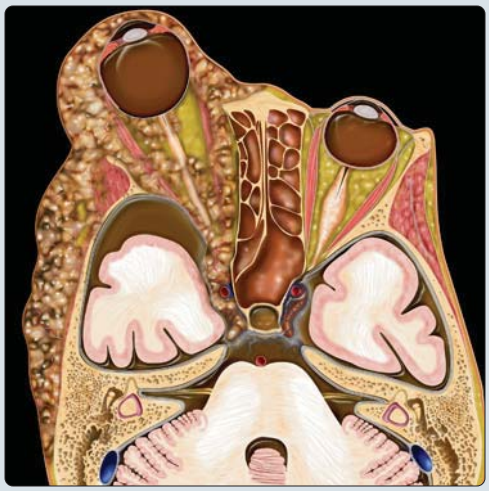
CLINICAL ISSUES

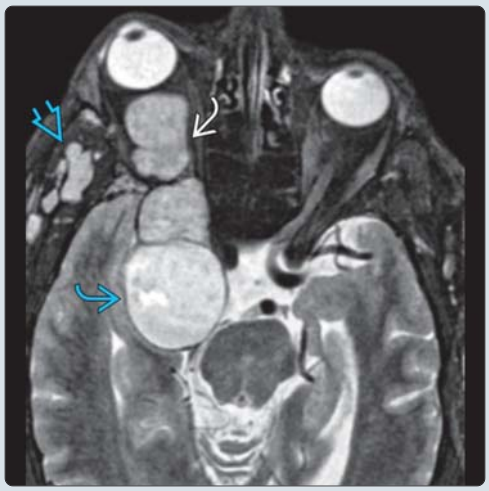
- 2-12% of PNFs degenerate into MPNST

DIAGNOSTIC CHECKLIST

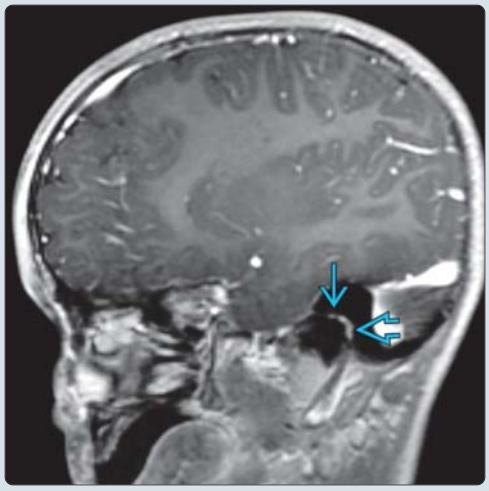
- Look for other imaging stigmata of NF1 (optic nerve/pathway glioma, skeletal and vascular dysplasias, WM lesions, spinal dural ectasia, lateral spinal meningocele, etc.)

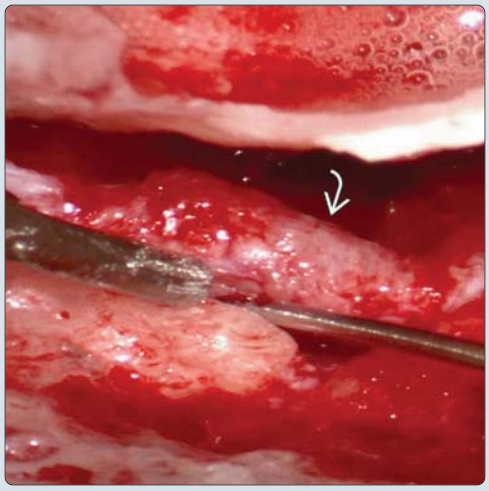
(Left) *Axial graphic shows extensive plexiform neurofibroma of the right face and orbit, resulting in proptosis.* **(Right)** *Axial T2WI FS MR shows a large, multilobulated, right cavernous sinus mass ⇨ with extension through markedly enlarged superior orbital fissure into the retrobulbar space ⇨. Note the right temporal scalp involvement ⇨. Plexiform neurofibromas in and around the orbit and scalp rarely have this degree of intracranial involvement.*





(Left) *A 4-year-old boy with progressive left facial weakness is shown. Sagittal oblique reconstruction of T1 C+ SPGR MR demonstrates abnormal enhancement along the tympanic ⇨ and descending mastoid ⇨ segments of the left facial nerve.* **(Right)** *Intraoperative photograph of subsequent resection of a symptomatic left facial nerve neurofibroma is shown. The patient has undergone left middle cranial fossa approach mastoidectomy & the enlarged facial nerve ⇨ is identified prior to en bloc resection.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neurofibroma (NF)

Definitions

- Plexiform neurofibroma (PNF): Infiltrative extraneural tumor
  - Occurs exclusively in patients with NF1
- Solitary neurofibroma (SNF): Round/ovoid subcutaneous mass
  - Not associated with NF1

IMAGING

General Features

- Best diagnostic clue
  - PNF: NF1 patient with poorly delineated, worm-like, soft tissue mass infiltrating scalp, orbit, or parotid gland
  - SNF: Well-circumscribed, round/oval scalp mass
- Location
  - PNF: Orbit (CNV1) most common head/neck site
    - Scalp, parotid gland (CN7)
    - Spinal, peripheral nerve roots
  - SNF: Skin, spinal, or peripheral nerve roots
    - Rarely (if ever) involves cranial nerves
- Morphology
  - Can be small or large; well demarcated (SNF) or diffusely infiltrating (PNF)

CT Findings

- NECT
  - Plexiform NF
    - Mass infiltrates CNV1
    - PNFs may enlarge orbital fissure, extend into cavernous sinus (almost never posterior to trigeminal cave)
    - Other sites: Scalp, skull base (e.g., parotid gland, pterygopalatine fossa)
- CECT
  - Moderate/strong enhancement

MR Findings

- T1WI
  - Plexiform NF = isointense infiltrating mass
- T2WI
  - Hyperintense
- T1WI C+
  - Enhances strongly, sometimes heterogeneously

Imaging Recommendations

- Best imaging tool
  - MR ± contrast
- Protocol advice
  - PNF: Scan entire neuraxis to detect other manifestations of NF1

DIFFERENTIAL DIAGNOSIS

Schwannoma

- Usually solitary, well circumscribed
- May involve CN, spinal nerve roots (rare in scalp)

Metastasis

- Scalp lesions rare without underlying bone/dura involvement

Malignant Peripheral Nerve Sheath Tumor

- Infiltrative, invasive

Sarcoma of Skull/Scalp

- Kaposi sarcoma (usually in AIDS patients)
- Ewing sarcoma (metastatic)

Lymphoma

- Skull, dura often involved

Vascular Malformation of Scalp

- Can be seen in patients with NF1

PATHOLOGY

General Features

- Genetics
  - Neurofibromatosis type 1 = Germline *NF1* mutation (neurofibromin tumor suppressor) with loss of remaining wild-type allele
    - Autosomal dominant, 50% new mutations
- Associated abnormalities
  - PNFs = other stigmata of NF1

Staging, Grading, & Classification

- NF = WHO grade I

Gross Pathologic & Surgical Features

- Plexiform NF may look like infiltrating bag of worms
- Solitary NF is ovoid/fusiform circumscribed nodule

Microscopic Features

- Neoplastic Schwann cells with all other cellular substrates of the nerve (fibroblasts, axons, perineurium, and mast cells)
- Matrix of collagen fibers, mucoid substances

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Painless scalp or skin mass

Natural History & Prognosis

- Slow growth
- 2-12% of PNFs and NFs of major nerves degenerate into malignant peripheral nerve sheath tumor

Treatment

- ± surgical resection (PNFs have high recurrence rate)

DIAGNOSTIC CHECKLIST

Consider

- Look for other imaging stigmata of NF1

SELECTED REFERENCES

1. Riccardi VM: Ketotifen suppression of NF1 neurofibroma growth over 30 years. Am J Med Genet A. ePub, 2015

KEY FACTS

TERMINOLOGY

- Hemangioblastoma (HGBL): Highly vascular tumor of adults most commonly found in cerebellum, brainstem, spinal cord
  - 25-40% of HGBLs occur in patients with VHL

IMAGING

- Best diagnostic clue: Adult with a cerebellar mass with cyst and enhancing mural nodule
- General features
  - Adult with intraaxial posterior fossa mass
  - 50-60% cyst + "mural" nodule; 40% solid enhancing mass
  - 90-95% in posterior fossa
  - 5-10% supratentorial (around optic pathways, hemispheres; usually in VHL)

TOP DIFFERENTIAL DIAGNOSES

- Metastasis (adult)
- Pilocytic astrocytoma (child)
- Cavernous malformation (CM)
- Hereditary hemorrhagic telangiectasia (HHT)

PATHOLOGY

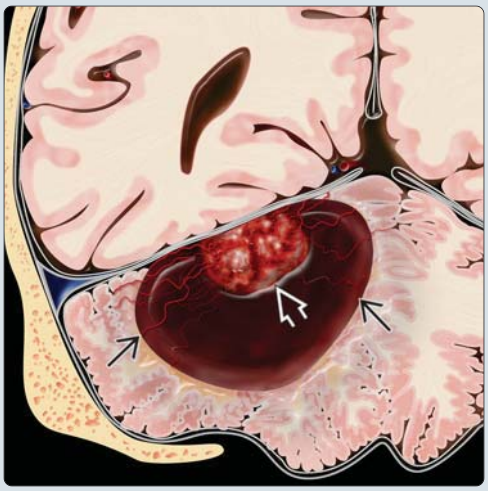
- WHO grade I
- Red or yellowish, well-circumscribed, unencapsulated, highly vascular mass that abuts leptomeninges
- Histology shows stromal cells, innumerable small vessels

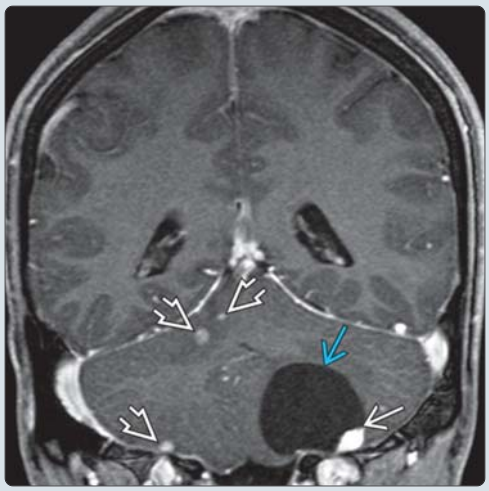
CLINICAL ISSUES

- Headache is most common presenting symptom
- Primary therapy = surgical resection
- Begin MR screening of patients from VHL families after 10 years of age

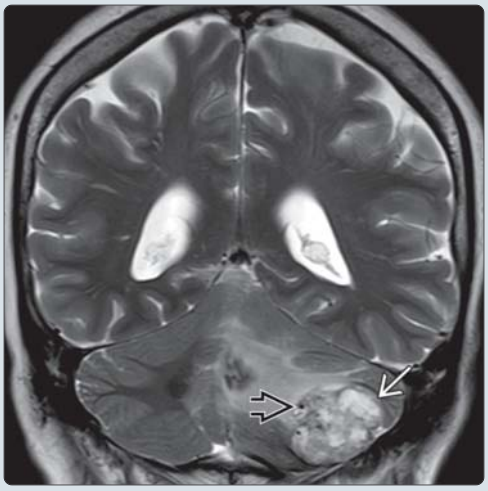
DIAGNOSTIC CHECKLIST

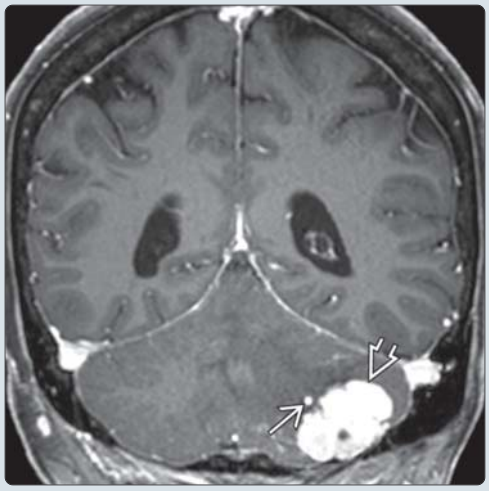
- Most common posterior fossa intraaxial mass in middle-aged/older adult is metastasis, not HGBL
- Most common posterior fossa primary tumor in middle-aged/older adult is HGBL





(Left) *Coronal graphic shows a classic cerebellar hemangioblastoma as largely cystic mass ⇨ with a vascular tumor nodule ➡ that abuts the pial surface. These low-grade tumors are the most common primary posterior fossa tumor in adults.* **(Right)** *Coronal T1 C+ MR shows a large cyst and mural nodule ➡ in a VHL patient with multiple hemangioblastomas. Note the lack of enhancement ⇨ of the cyst wall, which consists of compressed but normal cerebellum. The other hemangioblastomas ➡ have a solid enhancing appearance.*





(Left) *Coronal T2 MR image in a 60-year-old woman with headaches shows a heterogeneous cerebellar mass ➡ with prominent flow voids ⇨ and surrounding edema.* **(Right)** *Coronal T1 C+ MR image in the same patient shows marked enhancement of the mass ➡ and a prominent adjacent vessel ➡. Hemangioblastoma was found at surgical resection. The main imaging differential diagnosis in this adult was metastatic disease. These WHO grade I tumors have an excellent prognosis in sporadic cases.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hemangioblastoma (HGBL)

Synonyms

- Capillary hemangioma

Definitions

- Slow-growing, highly vascular tumor of adults most commonly found in cerebellum, brainstem, spinal cord

IMAGING

General Features

- Best diagnostic clue
  - Adult with a cerebellar mass with cyst and enhancing mural nodule abutting pia
- Location
  - Posterior fossa (90-95%)
    - Cerebellar hemispheres (80%)
    - Vermis (15%), other, e.g., medulla, 4th ventricle (5%)
  - Supratentorial (5-10%) (around optic pathways, hemispheres; usually in von Hippel-Lindau)
  - Spinal cord, typically dorsal surface
  - Rarely extraaxial dural-based mass
    - May also rarely be extramedullary in spine
- Size
  - Size varies from tiny to several cms
- Morphology
  - 50-60% cyst + "mural" nodule; 40% solid

CT Findings

- NECT
  - Low-density cyst + isodense to hyperdense nodule
  - No calcification
  - Hemorrhage is rare
- CECT
  - Nodule enhances intensely, relatively uniformly
  - Cyst wall usually does not enhance
- CTA
  - May demonstrate arterial feeders

MR Findings

- T1WI
  - Nodule isointense with brain ± flow voids
  - Cyst slightly/moderately hyperintense compared to CSF
- T2WI
  - Both nodule, cyst are hyperintense to brain
  - Prominent flow voids in some cases
- FLAIR
  - Both cyst and nodule hyperintense
- T2* GRE
  - May "bloom" if blood products present
- DWI
  - Cyst slightly or markedly low signal
- T1WI C+
  - Common: Nodule enhances strongly, intensely
  - Less common: Solid tumor enhancement
  - Rare: Ring-enhancing mass

Angiographic Findings

- Rarely performed as diagnosis is established by MR, preoperative embolization uncommon
  - Large avascular mass (cyst)
  - Highly vascular nodule
    - Prolonged blush
    - ± arteriovenous shunting (early draining vein)

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR (sensitivity > > CT for small HGBLs)
- Protocol advice
  - Begin MR screening of patients from von Hippel-Lindau families after 10 years of age
  - Screen complete spine, as cord lesions are common

DIFFERENTIAL DIAGNOSIS

Pilocytic Astrocytoma

- Cyst and mural nodule
- Imaging mimics HGBL
- Child or young adult

Metastasis

- Solitary posterior fossa metastasis uncommon
  - **But** most common parenchymal posterior fossa mass in > 40 year old is metastasis
- May be very vascular
- Solid > cystic
- Multiple > single
- Vascular mets (renal cell carcinoma) do not express inhibin A or GLUT1; HGBL does

Cavernous Malformation (CM)

- Heterogeneous mass with blood products
- Hemosiderin rim common
- Enhancement uncommon
- May acutely hemorrhage
- Complete hemosiderin rim typical in CMs

Glioblastoma

- Adults with irregular ring-enhancing mass
- Posterior fossa uncommon location

Vascular Neurocutaneous Syndromes

- Hereditary hemorrhagic telangiectasia (HHT)
- Wyburn-Mason
- Multiple intracranial AVMs may mimic HGBLs

PATHOLOGY

General Features

- Etiology
  - Precise histogenesis unknown
  - Presence of 2 cell types suggests undifferentiated precursor cell with angiogenic and stromal potential
  - Alternative theory: Stromal cells are neoplastic and vascular cells are nonneoplastic response to stromal VEGF
- Genetics
  - Familial HGBL (von Hippel-Lindau disease)

https://CafePezeshki.IR

  - Autosomal dominant
  - Chromosome 3p mutation
  - Suppressor gene product (VHL protein) causes neoplastic transformation
  - VEGF highly expressed in stromal cells
  - Other *VHL* gene mutations common
  - Sporadic HGBL
    - Upregulation of erythropoietin common in both sporadic, VHL-related HGBL
- Associated abnormalities
  - Secondary polycythemia (may elaborate erythropoietin)
  - 25-40% of patients with HGBL have VHL
  - Multiple HGBLs are rule in VHL
  - Other VHL markers (visceral cysts, renal clear cell carcinoma), + family history

Staging, Grading, & Classification

- WHO grade I
- Low MIB-1 index, typically < 1
- No difference between sporadic, VHL-associated HGBLs

Gross Pathologic & Surgical Features

- Red or yellowish, well-circumscribed, unencapsulated, highly vascular mass that abuts leptomeninges
  - ± cyst with yellow-brown fluid

Microscopic Features

- Nodule
  - Large vacuolated stromal cells
    - Neoplastic component
    - Lipid-containing vacuoles ("clear cell" morphology)
  - Immunohistochemistry
    - Negative for cytokeratin, EMA
    - Positive for inhibin A, GLUT1
    - Overexpress VEGF protein
  - Rich capillary network
- Cyst wall
  - Usually compressed brain (not neoplasm)
  - Variable intratumoral hemorrhage

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Sporadic HGBL
    - Headache (85%), dysequilibrium, dizziness
  - Familial
    - Retinal HGBL: Ocular hemorrhage often 1st manifestation of VHL
    - Other: Symptoms due to renal cell carcinoma, polycythemia, endolymphatic sac tumor

Demographics

- Age
  - Sporadic HGBL
    - Peak 40-60 years
    - Rare in children
  - Familial
    - VHL-associated HGBLs occur at younger age (rare < 15 years)
    - Retinal HGBL: Mean onset 25 years
- Gender
  - Slight male predominance
- Epidemiology
  - VHL seen in 1:36-40,000
  - < 1/2 (25-40%) HGBLs associated with VHL
  - 1-2% of primary intracranial tumors
    - 7-10% of posterior fossa tumors in adults
  - 2nd most common posterior fossa tumor in adults (after metastases)
  - 3-13% of spinal cord tumors

Natural History & Prognosis

- Usually benign tumor with slow growth pattern
  - Symptoms usually associated with cyst expansion (may occur rapidly)
  - Rare: Leptomeningeal tumor dissemination, leptomeningeal hemangioblastomatosis
- 2/3 with a single VHL-associated HGBL develop additional lesions
  - Average: 1 new lesion every 2 years
  - Require periodic screening, lifelong follow-up
  - Periods of intermixed growth, relative quiescence common with VHL-associated HGBL
  - Median life expectancy in patients with VHL: 49 years

Treatment

- En bloc surgical resection (piecemeal may result in catastrophic hemorrhage)
  - 10-year survival rate: 85%
  - Recurrence rate: 15-20%
- Preoperative embolization: Limited efficacy and usage
- Expectant management without surgery may occasionally be considered if lesion is stable and nonsymptomatic
- Some reports show good results with radiosurgery
- Evolving medical and gene target therapies

DIAGNOSTIC CHECKLIST

Consider

- Screen entire neuraxis for other HGBLs in a VHL patient

Image Interpretation Pearls

- Most common posterior fossa intraaxial mass in middle-aged/older adult is metastasis, not HGBL
- Most common posterior fossa primary tumor in middle-aged/older adult is HGBL

Reporting Tips

- Degree of mass effect
- Presence of hemorrhage
- Extent of additional screening needed

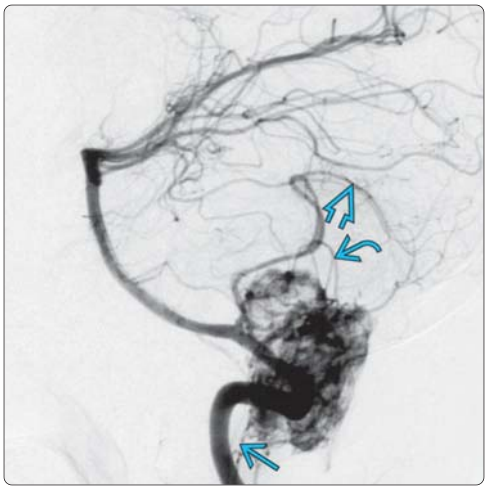
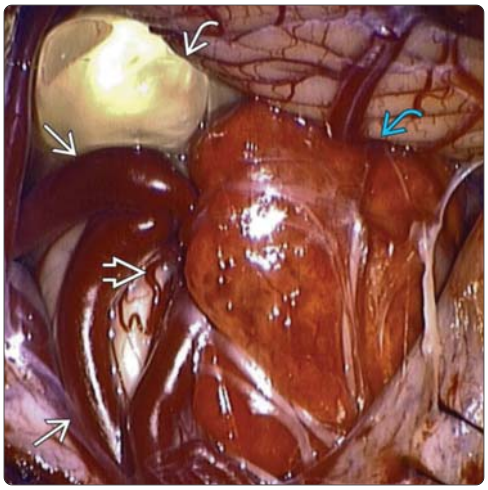
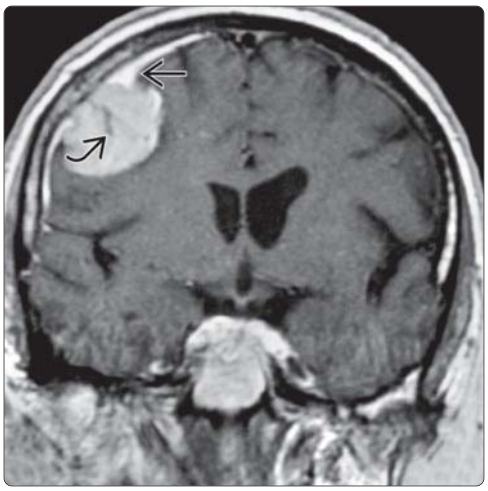
(Left) *Sagittal T2 MR in a 29-year-old woman shows a cystic ⇨ and solid ⇨ posterior fossa mass with surrounding edema.* **(Right)** *Axial T1 C+ FS MR in the same patient shows the classic cyst and mural nodule ⇨ appearance of this hemangioblastoma. In a child or young adult, the main imaging differential consideration would be a pilocytic astrocytoma.*





(Left) *Lateral DSA shows a highly vascular tumor nodule supplied by PICA ⇨ and branches of the vertebral and anterior spinal arteries ⇨. Avascular mass effect caused by the large associated cyst displaces the hemispheric branches superiorly ⇨.* **(Right)** *Intraoperative photograph of the same lesion shows the solid, highly vascular tumor nodule ⇨, the cystic component with yellowish fluid ⇨, and a markedly enlarged PICA ⇨ with prominent dilated feeding vessels ⇨.*



(Left) *Axial T1 C+ MR in a 35-year-old man shows a cystic and solid enhancing posterior fossa hemangioblastoma ⇨.* **(Right)** *Rare extraaxial dural-based hemangioblastoma shows diffuse enhancement with a visible central flow void ⇨. A slight enhancing dural tail is present ⇨. Imaging findings in this variant case mimic meningioma. Most supratentorial hemangioblastomas cluster around the optic nerves and chiasm. (Courtesy J. Rees, MD.)*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Highly cellular and vascularized mesenchymal tumor, nearly always attached to dura

IMAGING

- Lobular enhancing extra-axial mass with dural attachment, ± skull erosion
  - Mimics meningioma, but no Ca++ or hyperostosis
- Typically supratentorial heterogeneous, extraaxial mass; occipital region most common
- Commonly involve falx, tentorium, or dural sinuses
- Marked enhancement, often heterogeneous
- Dural "tail" seen in ~ 50%

TOP DIFFERENTIAL DIAGNOSES

- Meningioma
- Dural metastases
- Lymphoma
- Gliosarcoma

PATHOLOGY

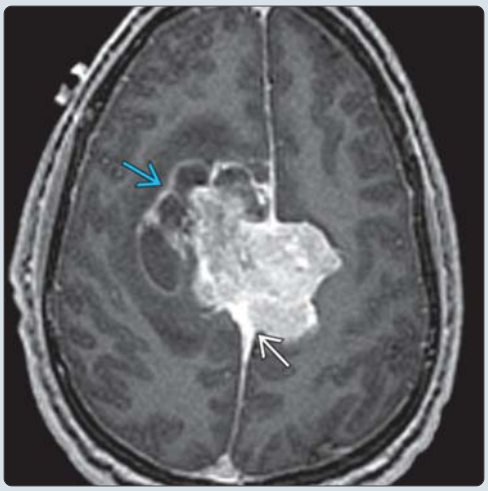
- WHO grade II and WHO grade III (anaplastic)
- Hemangiopericytoma (HPC): Distinctive mesenchymal neoplasm unrelated to meningioma
  - Arises from primitive mesenchymal cells throughout body

CLINICAL ISSUES

- Headache is most common presenting feature
- Commonly occur in 4th-6th decades, mean: 43 years
- Represents < 1% of primary CNS tumors
- Surgical resection with radiation therapy or radiosurgery is treatment of choice
- Local recurrence common (50-90%)

DIAGNOSTIC CHECKLIST

- Consider HPC when "meningioma" has atypical features (frank bone erosion, multiple flow voids)



(Left) *Axial T1 C+ MR image shows a large heterogeneous, enhancing mass ⇨ attached to the falx ➡. Imaging mimics the much more common atypical meningioma. Hemangiopericytoma was diagnosed at surgical resection.* **(Right)** *Axial T1WI C+ MR shows a lobular, heterogeneously enhancing mass with central low signal ⇨, likely related to necrosis. Extension through the calvaria ⇨ is common in hemangiopericytomas. These rare tumors are typically attached to the falx, tentorium, or dural sinuses.*

(Left) *Axial T1WI C+ FS MR shows an enhancing extraaxial mass along the greater sphenoid wing that extends into the orbit. Although this mimics a meningioma, the associated bone erosion ➡, not hyperostosis, helps with the diagnosis of the more aggressive hemangiopericytoma.* **(Right)** *Gross pathology cut section shows a lobulated, circumscribed vascular mass with multiple enlarged vascular channels characteristic of hemangiopericytoma. (Courtesy R. Hewlett, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hemangiopericytoma (HPC), meningeal hemangiopericytoma

Synonyms

- In older literature called "angioblastic meningioma," hemangiopericytic type
- New literature supports the term solitary fibrous tumor (SFT), hemangiocytoma type, cellular SFT or malignant SFT

Definitions

- Highly cellular and vascularized mesenchymal tumor, nearly always attached to dura
- Sarcoma related to neoplastic transformation of pericytes, contractile cells about capillaries
  - Occur in any region of body where capillaries are found

IMAGING

General Features

- Best diagnostic clue
  - Lobular enhancing extraaxial mass with dural attachment, ± skull erosion
  - May mimic meningioma, but without Ca++ or hyperostosis
- Location
  - Supratentorial: Occipital region most common
  - Typically involve falx, tentorium, or dural sinuses
  - Rare reports of intraparenchymal, skull base, cranial nerve, intraventricular involvement
- Size
  - Variable; 2-9 cm, often > 4 cm
- Morphology
  - Lobular dural-based extraaxial mass
    - Dural attachment may be narrow pedicle or broad based
  - Dural "tail" commonly seen, ~ 50%
  - Rarely may appear intraaxial

CT Findings

- NECT
  - Hyperdense extraaxial mass with surrounding edema
    - Low-density cystic or necrotic areas are common
  - Calvarial erosion may be seen
  - No Ca++ or hyperostosis
- CECT
  - Strong, heterogeneous enhancement

MR Findings

- T1WI
  - Heterogeneous mass, isointense to gray matter
  - Flow voids may be seen
- T2WI
  - Heterogeneous isointense mass
  - Prominent flow voids are common
  - Surrounding edema, mass effect typical
  - Hydrocephalus may be seen
- T1WI C+
  - Marked enhancement, often heterogeneous
  - Dural "tail" seen in ~ 50%
  - Central necrosis may be seen
- MRV
  - May show occlusion of dural sinuses

Angiographic Findings

- Hypervascular mass with irregular tumor vessels and prolonged, dense tumor stain
- Extensive arteriovenous shunting
- Mixed dural-pial vascular supply typical
- Preoperative embolization has been shown helpful

Nuclear Medicine Findings

- Bone scan
  - Helpful to detect extracranial metastases
- PET
  - Early FDG studies show lower metabolic rate in HPC than gray matter

Imaging Recommendations

- Best imaging tool
  - CT helpful to evaluate bone erosion
  - Multiplanar MR is most sensitive
- Protocol advice
  - Multiplanar contrast-enhanced MR, ± MRS
  - Bone scan useful in patient follow-up as extracranial metastases are common

DIFFERENTIAL DIAGNOSIS

Meningioma

- May be indistinguishable
- Enhancing extraaxial dural based mass
- Often calcified with broad dural base, dural "tail"
- Hyperostosis and Ca++ is characteristic

Dural Metastases

- Dural metastases with calvarial invasion may be indistinguishable
- Typically multiple lesions
- Primary tumor often known
  - Breast and prostate cancer most common

Gliosarcoma

- Rare glial tumor often with dural involvement
- Heterogeneously enhancing parenchymal mass

Lymphoma

- Dural involvement by lymphoma may mimic HPC
  - Diffusely enhancing dural mass, often multifocal
  - T2 low signal related to hypercellularity
- Calvarial involvement uncommon
- Flow voids usually absent

Neurosarcoidosis

- Dural-based masses can occur, often multifocal
- No calvarial involvement
- Typically leptomeningeal enhancement

Solitary Fibrous Tumor

- Circumscribed enhancing dural-based mass
- May have associated hyperostosis
- Extremely rare, < 20 reported cases

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Distinctive mesenchymal neoplasm unrelated to meningioma
    - Considered a fibroblastic sarcoma
  - Uncertain histogenesis
    - Considered as morphological continuum with SFT
  - Arises from primitive mesenchymal cells throughout body
    - Most commonly involves soft tissues of lower extremities, pelvis, and retroperitoneum
    - ~ 15% occur in head and neck region (scalp, face, neck, sinonasal)
    - Less favorable prognosis in CNS
- Genetics
  - No consistent chromosomal losses or gains
  - Reports of abnormalities of chromosomes 12 and 3

Staging, Grading, & Classification

- WHO grade II
  - IIa: High cellularity, no necrosis, ≤ 5 mitoses/10 HPF
  - IIb: High cellularity, no necrosis, > 5 mitoses/10 HPF
- WHO grade III (anaplastic)
  - High cellularity, necrosis, and > 5 mitoses/10 HPF

Gross Pathologic & Surgical Features

- Extremely vascular with tendency to bleed at surgery
- Well-circumscribed, encapsulated firm mass with dural attachment
- Cut surface is gray to red-brown with visible vascular spaces

Microscopic Features

- Highly cellular, monotonous tumor with randomly oriented plump cells in dense reticulin network
- "Staghorn" vascular pattern characteristic
  - Lobules of tumor cells surrounding wide, branching capillaries
- Immunohistochemistry: Antibodies to factor XIIIa, Leu-7, and CD34 may help differentiate from other tumors
  - Vimentin positive
  - Epithelial membrane antigen (EMA) negative, S100 negative
- Prominent mitotic activity, median Ki-67 index (MIB-1) of 5-10%

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache
- Other signs/symptoms
  - Related to tumor location: Focal neurologic deficit, seizure

Demographics

- Age
  - Most common 4th to 6th decade, mean = 43 years
  - Occur at all ages, uncommon in children
- Gender
  - Slight male predominance
- Epidemiology
  - Represents < 1% of primary CNS tumors, ~ 0.4%
  - Represents 2-4% of all meningeal tumors
  - HPC to meningioma ratio = 1:50

Natural History & Prognosis

- Local recurrence common (50-90%)
  - Recurrence usually within 40-70 months
  - 65% recurrence at 5 years, 90% at 12 years
- Extracranial metastases common (up to 30%)
  - Commonly liver, lungs, lymph nodes, bones
  - Mean survival after metastases: 2 years
- Complications
  - Invasion of dural sinuses, bone, and cranial nerves
  - Hemorrhage (rare)
- May cause oncogenic osteomalacia
  - Rare paraneoplastic syndrome associated with mesenchymal tumors
- 5-year survival rate has improved (up to 93%)
- Complete resection and adjuvant radiation therapy improves overall survival

Treatment

- Preoperative embolization may be helpful, tumors are highly vascular
- Surgical resection with radiation therapy or radiosurgery is treatment of choice
  - Reduces risk of local recurrence
- Radiosurgery may be effective alternative to repeated surgical resection in recurrent tumors
- Chemotherapy shows some improved survival in recurrent tumors in recent reports
- Careful long-term follow-up is mandatory
  - Potential for local recurrence and metastases many years after initial diagnosis

DIAGNOSTIC CHECKLIST

Consider

- Bone erosion is most commonly seen in metastatic disease, but can suggest HPC
- Dural "tail" is nonspecific and is much more common in meningioma

Image Interpretation Pearls

- Consider HPC when "meningioma" has atypical features (frank bone erosion, multiple flow voids)

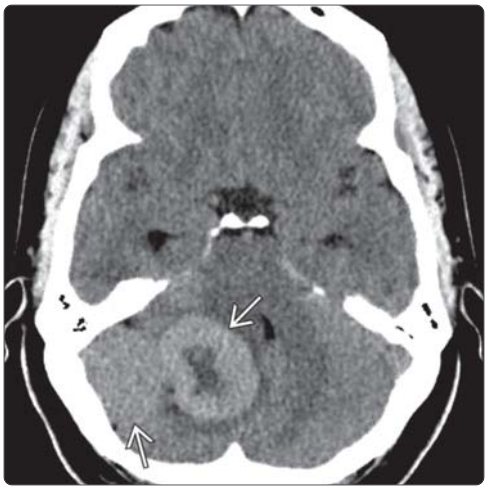
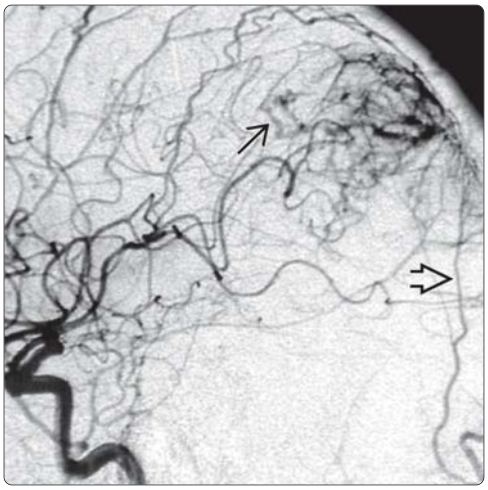
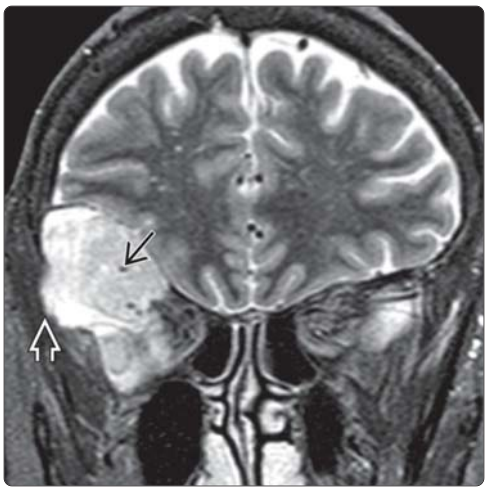
https://CafePezeshki.IR

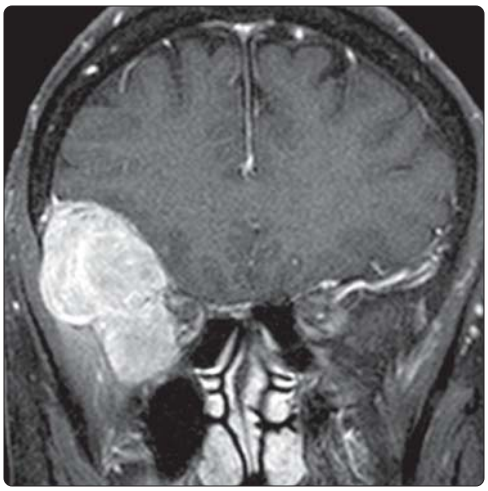


(Left) *Axial NECT shows a hyperdense posterior fossa mass* ⇨ *with local mass effect. Anaplastic hemangiopericytoma, WHO grade III was diagnosed at resection.* **(Right)** *Axial CECT shows a heterogeneously enhancing mass* ⇨ *in the occipital region with extensive bone erosion. Note the surrounding edema and mass effect. Location and appearance are typical of hemangiopericytoma. These rare tumors have a high rate of recurrence and often metastasize outside the CNS.*



(Left) *Coronal T2 FS MR image shows a large, heterogeneous mass* ⇨ *centered in the right cerebellopontine angle, attached to the dura. Hemangiopericytoma was diagnosed at resection.* **(Right)** *Lateral ICA injection DSA shows arteriovenous shunting with early draining veins* ⇨*. An additional dural feeding vessel, a branch of the occipital artery* ⇨*, is also seen. A mixed dural-pial vascular supply is typical of hemangiopericytoma. Preoperative embolization is often helpful prior to surgical resection.*





(Left) *Coronal T2WI FS MR shows a heterogeneous hyperintense mass in the inferior frontal region with central flow voids* ⇨ *and bone erosion* ⇨*, characteristic of hemangiopericytoma.* **(Right)** *Coronal T1WI C+ FS MR in the same patient shows diffuse enhancement of the lobular mass. Imaging mimics a meningioma. CT can be helpful to further define bone erosion. Other imaging differential considerations would include a dural metastasis and lymphoma.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Malignant primary CNS neoplasm primarily composed of B lymphocytes

IMAGING

- Best diagnostic clue: Enhancing lesion(s) within basal ganglia &/or periventricular white matter
- 60-80% supratentorial
  - Often involve, cross corpus callosum
  - Frequently contact, extend along ependymal surfaces
- Classically hyperdense on CT (helpful for diagnosis)
- Diffusely enhancing periventricular mass in immunocompetent
- May see hemorrhage or necrosis in immunocompromised
- DWI: Low ADC values
- PWI: Low rCBV ratios
- Periventricular location and subependymal involvement is characteristic of PCNSL
- Corpus callosum involvement may be seen with PCNSL, glioblastoma (GBM), and rarely metastases or demyelination

TOP DIFFERENTIAL DIAGNOSES

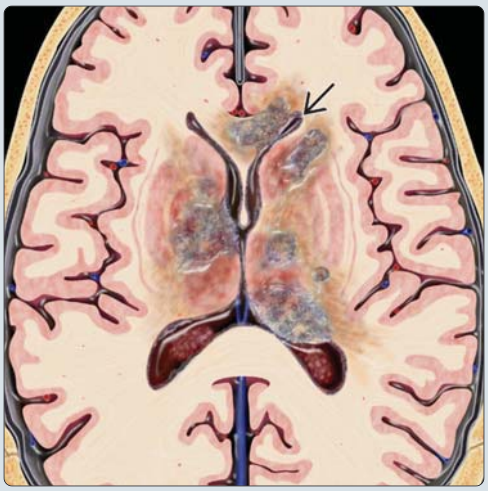
- Acquired toxoplasmosis
- Glioblastoma (GBM)
- Abscess
- Progressive multifocal leukoencephalopathy (PML)

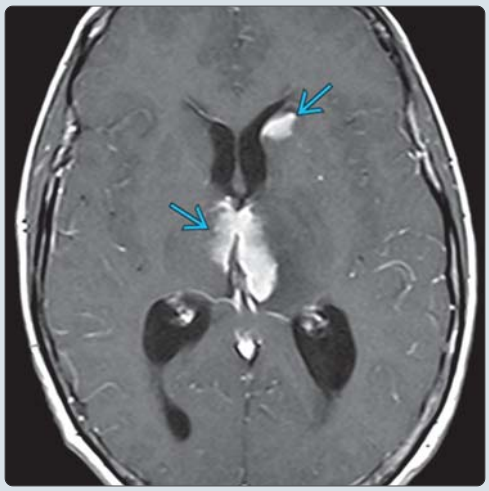
PATHOLOGY

- 98% diffuse large B-cell, non-Hodgkin lymphoma

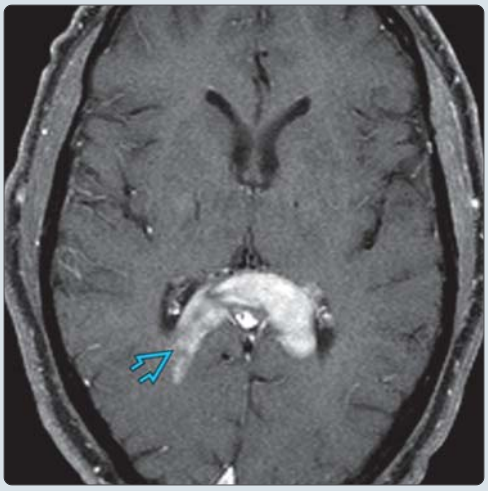
CLINICAL ISSUES

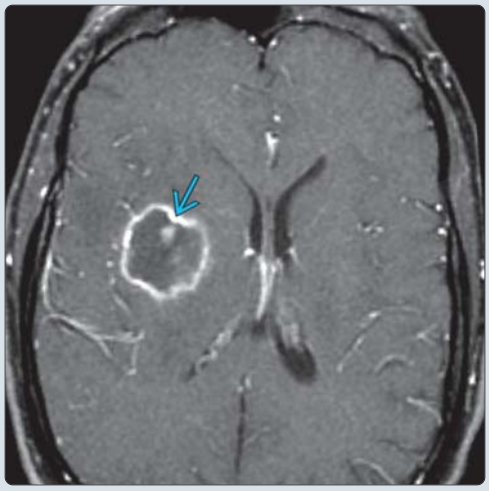
- Imaging and prognosis varies with immune status
- 6.6% of primary brain tumors, incidence rising
- Poor prognosis
- Stereotactic biopsy, followed by XRT and chemotherapy is treatment of choice
- Stereotactic biopsy, followed by chemotherapy, ± XRT





(Left) *Axial graphic shows multiple periventricular lesions with involvement of the basal ganglia, thalamus, and corpus callosum, typical of primary CNS lymphoma (PCNSL). Note the extensive subependymal spread of the disease. PCNSL typically extends along ependymal surfaces.* **(Right)** *Axial T1 C+ MR image in a 63 year old shows the classic appearance of PCNSL. Note the multiple homogeneously enhancing masses in the basal ganglia along the ependymal lining of the ventricular system.*





(Left) *Axial T1 C+ MR shows a homogeneously enhancing mass crossing the corpus callosum splenium typical of PCNSL in this 76-year-old man with a headache. The main differential consideration would be a glioblastoma, which typically has a more heterogeneous appearance.* **(Right)** *Axial T1WI C+ MR in an AIDS patient shows a ring-enhancing mass with a "target" sign, suggestive of toxoplasmosis. Hemorrhage, necrosis, and ring-enhancing lesions are typical of PCNSL in AIDS patients.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Primary central nervous system lymphoma (PCNSL)

Definitions

- Extranodal malignant lymphoma arising in CNS in absence of systemic lymphoma

IMAGING

General Features

- Best diagnostic clue
  - Enhancing lesion(s) within basal ganglia, periventricular white matter (WM)
- Location
  - 60-80% supratentorial
    - Frontal, temporal, and parietal lobes most common
  - Deep gray nuclei commonly affected (10%)
  - Lesions cluster around ventricles, gray-white matter junction
  - Often involve, cross corpus callosum (5-10%)
  - Frequently abut, extend along ependymal surfaces
  - Posterior fossa, sella, pineal region uncommon
  - Spine involvement rare (1%)
  - May involve leptomeninges or dura (more common in secondary lymphoma)
- Morphology
  - Solitary mass or multiple lesions
  - May be circumscribed or infiltrative

CT Findings

- NECT
  - Classically hyperdense; may be isodense
  - ± hemorrhage, necrosis (immunocompromised)
- CECT
  - Common: Moderate, uniform (immunocompetent)
  - Less common: Ring (immunocompromised)
  - Rare: Nonenhancing (infiltrative)

MR Findings

- T1WI
  - Immunocompetent: Homogeneously iso-/hypointense to cortex
  - Immunocompromised: Iso-/hypointense
    - May be heterogeneous from hemorrhage, necrosis
- T2WI
  - Immunocompetent: Homogeneously iso-/hypointense to cortex
    - Hypointensity related to high nuclear to cytoplasmic ratio
  - Immunocompromised: Iso-/hypointense
    - May be heterogeneous from hemorrhage, necrosis
    - Ca++ may rarely be seen, usually after therapy
  - Mild surrounding edema is typical
- FLAIR
  - Homogeneously iso-/hypointense
  - Immunocompromised: Iso-/hypointense
  - May be hyperintense
- T2* GRE
  - May see blood products or calcium as areas of "blooming" (immunocompromised)
- DWI
  - May show restricted diffusion
  - Low ADC values compared to malignant glioma
    - Minimal ADC lower than glioblastoma
- PWI
  - Relative CBV ratios are lower than malignant glioma
    - Relative CBV much lower than glioblastoma
- T1WI C+
  - Immunocompetent: Strong homogeneous enhancement
  - Immunocompromised: Peripheral enhancement with central necrosis or homogeneous enhancement
  - Nonenhancement extremely rare
- MRS
  - NAA ↓, Cho ↑
  - Lipid and lactate peaks reported
- Diffusion tensor imaging (DTI)
  - Low fractional anisotropy (FA) and ADC
    - FA and ADC of PCNSL significantly lower than glioblastoma (GBM)

Nuclear Medicine Findings

- FDG PET and Tl-201 SPECT: Hypermetabolic

Imaging Recommendations

- Protocol advice
  - Contrast-enhanced MR ± DWI, PWI, DTI
  - PET or Tl-201 SPECT may be helpful when toxoplasmosis is considered

DIFFERENTIAL DIAGNOSIS

Acquired Toxoplasmosis

- Involves basal ganglia, corticomedullary junction
- Enhancing lesions, "eccentric target" sign
- No ependymal spread
- Often indistinguishable on standard MR
  - DWI, DTI, perfusion may be helpful
  - SPECT, PET helpful (iso-/hypometabolic)

Glioblastoma (GBM)

- "Butterfly glioma" involving corpus callosum
- Hemorrhage common
- Enhancement typically heterogeneous
- Necrosis with ring enhancement in 95%

Abscess

- T2 hypointense rim, diffusion restriction typical
- Peripheral enhancement with central necrosis
- Enhancement often thinner on ventricular side
- MRS: Elevated amino acids in cystic cavity (low TE)

Progressive Multifocal Leukoencephalopathy

- White matter T2 hyperintensity, nonenhancing
- Involves subcortical U-fibers and corpus callosum

Demyelination

- May involve corpus callosum
- Often incomplete, horseshoe-shaped enhancement, open toward cortex

https://CafePezeshki.IR

- Other lesions in characteristic locations
- Younger patients

Metastases

- Multiple lesions common
- Significant associated vasogenic edema

Neurosarcoidosis

- "Lacy" leptomeningeal enhancement typical
- Dural, leptomeningeal > > parenchymal disease
- Most patients have systemic disease

Secondary CNS Lymphoma

- Lymphomatous meningitis or dural disease common
- Can have single/multiple deep, periventricular lesions

PATHOLOGY

General Features

- Etiology
  - Site of origin controversial as CNS does not have lymphoid tissue or lymphatic circulation
  - Inherited or acquired immunodeficiency predisposes
- Genetics
  - Clonal abnormalities in chromosomes 1, 6, 7, and 14
  - Translocations reported in (1;14), (6;14), (13;18), and (14;21)
- Associated abnormalities
  - Epstein-Barr virus (EBV) plays major role in immunocompromised (95%)
  - 8% of PCNSL patients have had prior malignancy, commonly leukemia or adenocarcinoma
  - Rarely PCNSL is preceded by demyelinating lesions

Staging, Grading, & Classification

- Majority are diffuse large B-cell, non-Hodgkin lymphoma

Gross Pathologic & Surgical Features

- Single or multiple mass(es) in cerebral hemispheres
- Well-circumscribed > infiltrative mass
- Central necrosis, hemorrhage in HIV-positive patients

Microscopic Features

- Cells surround, infiltrate vessels and perivascular spaces
- High nuclear:cytoplasmic ratio (high electron density)
- MIB-1, proliferation index, usually high (50-70%)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Altered mental status, focal neurologic deficits
- Other signs/symptoms
  - Cognitive, neuropsychiatric disturbance
  - Headache, increased intracranial pressure, seizure
- Clinical profile
  - Cytology positive in 5-30% of PCNSL

Demographics

- Age
  - Immunocompetent: 6th-7th decades, mean 60 years
  - Immunocompromised
    - AIDS: Mean age 39 years
    - Transplant recipients: Mean age 37 years
    - Inherited immunodeficiency: Mean age 10 years
- Gender: Male predominance
- Epidemiology
  - 6.6% of primary brain tumors
  - Represents ~ 1% of lymphomas
  - PCNSL is present in 0.4% of AIDS patients
    - PCNSL is AIDS-defining condition
    - Highly effective antiviral therapy (HAART) has reduced occurrence of all NHL in AIDS patients
  - In post-transplant lymphoma, CNS involvement occurs in 22%

Natural History & Prognosis

- Poor prognosis
- Median survival
  - 50 months in immunocompetent
  - 36 months in AIDS patients
    - Marked improvement with HAART and XRT
- Favorable prognostic factors
  - Single lesion
  - Absence of meningeal or periventricular disease
  - Immunocompetent patient
  - Age < 60 years
    - Patients < 61 years: 5-year survival 75%
- Dramatic but short-lived response to steroids and XRT
- Rarely, PCNSL is complicated by systemic disease

Treatment

- Stereotactic biopsy, followed by chemotherapy, ± XRT
- Treatment with enhanced chemotherapy delivery with blood-brain barrier disruption may be helpful

DIAGNOSTIC CHECKLIST

Consider

- Corpus callosum involvement may be seen with PCNSL, GBM and rarely metastases, demyelination
- Steroids may dramatically ↓ mass, enhancement; mask biopsy results
- Occult systemic disease present in up to 8% of PCNSL, systemic staging helpful

Image Interpretation Pearls

- Imaging and prognosis varies with immune status
- PCNSL is characteristically hyperdense on NECT
- Periventricular location and subependymal involvement is characteristic of PCNSL

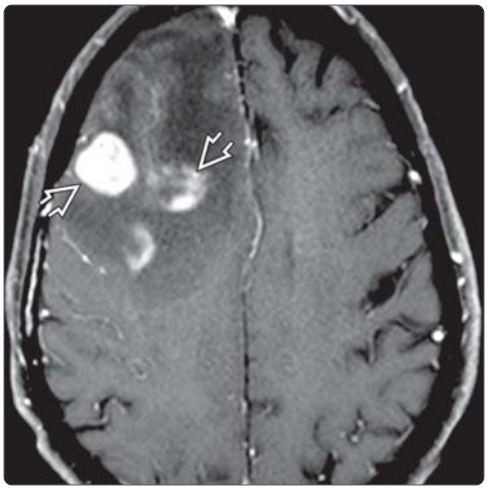
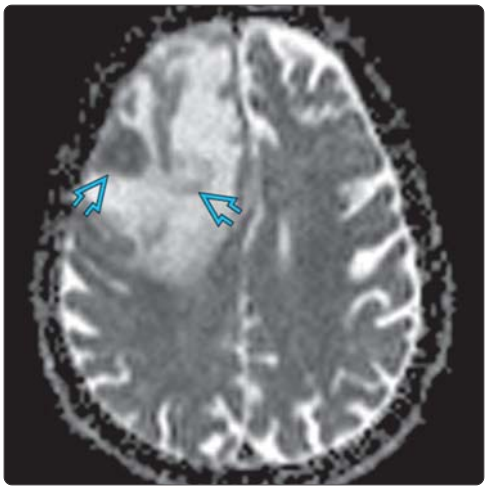
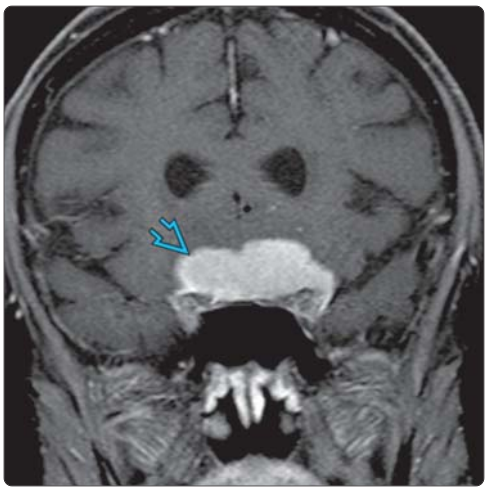
(Left) *Axial T1 C+ MR shows several enhancing masses in the periventricular white matter ➡ typical of PCNSL. It is important to recognize PCNSL as the preoperative diagnosis, as a biopsy rather than a resection is the initial treatment of choice.* **(Right)** *Axial T2 MR in the same patient shows hypointensity ⇨ within the lesions related to the high nuclear to cytoplasmic ratio within the tumor, a common finding in primary CNS lymphoma. The vast majority of primary CNS lymphoma are diffuse large, B-cell, non-Hodgkin lymphoma.*





(Left) *Axial T1 C+ MR shows several enhancing masses in the right frontal lobe with smooth homogeneous enhancement ➡ typical of PCNSL. PCNSL is increasing in prevalence related to the increased number of immunocompromised patients.* **(Right)** *Axial DWI ADC map in the same patient shows the characteristic diffusion restriction within these tumors as a low ADC value ⇨. DWI has been shown to be helpful in differentiating PCNSL from other tumors and demyelinating lesions.*



(Left) *Axial NECT shows a hyperdense mass ➡ with surrounding vasogenic edema. CT hyperdensity is characteristic of PCNSL and is helpful for an accurate preoperative diagnosis.* **(Right)** *Coronal T1 C+ FS MR shows a dural-based mass ⇨ along the anterior cranial fossa in a female patient with optic neuropathy. Imaging mimics a meningioma, but PCNSL was found at biopsy. Dural involvement is more common in secondary CNS lymphoma.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Rare malignancy characterized by intravascular proliferation of lymphoid cells with predilection for CNS and skin

IMAGING

- T2/FLAIR multifocal hyperintensities in deep white matter, cortex, and basal ganglia
  - May mimic infarct
- Diffusion restriction common
- GRE/SWI: Multifocal hemorrhage often seen
- Linear and punctate enhancement typical
  - May see meningeal &/or dural enhancement
- Often mimics vasculitis

TOP DIFFERENTIAL DIAGNOSES

- Vasculitis
- Multi-infarct dementia
- Primary CNS lymphoma (PCNSL)
- Neurosarcoid

PATHOLOGY

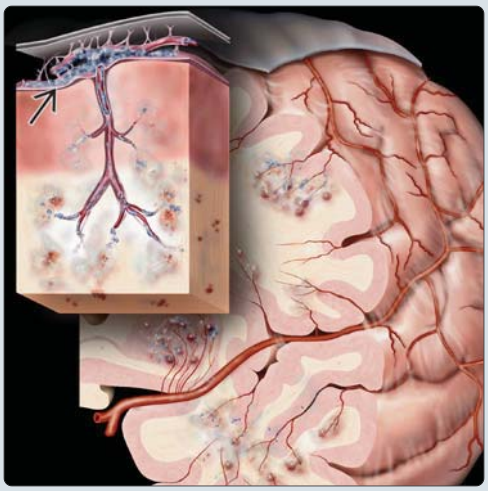
- Malignant lymphoid cells occlude and distend small arteries, veins, and capillaries

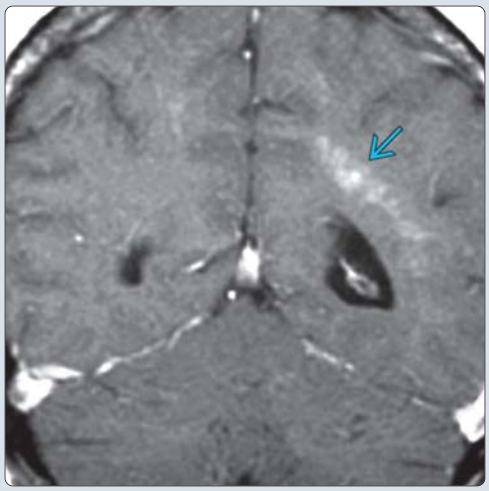
CLINICAL ISSUES

- Dementia is most common presenting feature
- May present with multiple stroke-like episodes
- Presents in 5th-7th decades; mean: 60-65 years
- Diagnosis may be made by skin or brain biopsy
- Rapidly progressive disease with high mortality rate
  - Mean survival: 7-13 months
- Rare, but underdiagnosed
  - CNS involved in up to 75% of cases

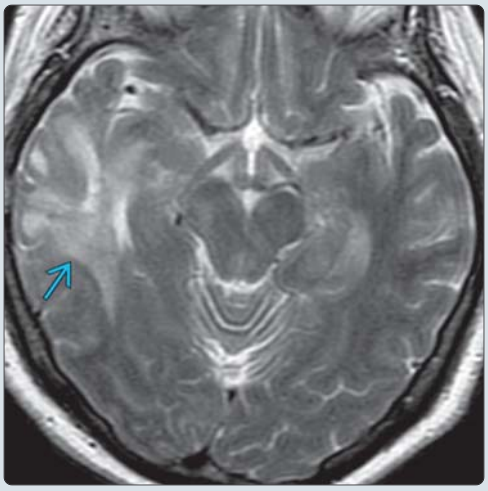
DIAGNOSTIC CHECKLIST

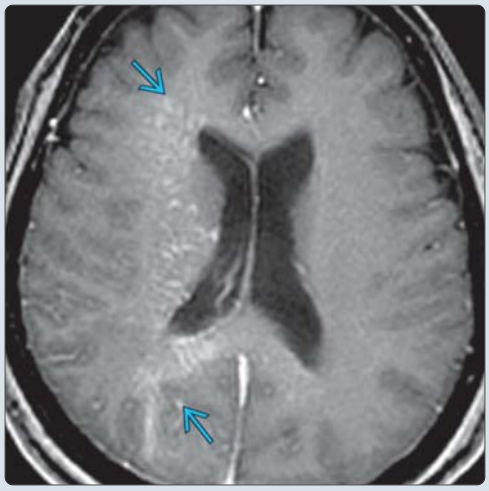
- Imaging of intravascular lymphoma (IVL) is nonspecific, but IVL should be considered in patients with dementia, multifocal lesions, and enhancement





(Left) *Graphic shows malignant lymphoid cells occluding and distending small arteries, veins, and capillaries, resulting in ischemic regions. Note also the meningeal involvement ⇨ typical of intravascular lymphoma (IVL).* **(Right)** *Coronal T1WI C+ MR shows a classic multifocal linear and patchy enhancement pattern in the deep white matter ⇨ related to IVL in this patient with dementia. The enhancement occurs in regions of T2/FLAIR hyperintensity and is often the key to a correct preoperative diagnosis.*





(Left) *Axial T2 MR shows confluent areas of hyperintensity in the right temporal periventricular and subcortical white matter ⇨ in this elderly patient. The T2 hyperintensities seen in IVL are nonspecific and mimic other disease processes, including chronic small vessel ischemia and vasculitis. Cortical lesions are also commonly seen.* **(Right)** *Axial T1 C+ MR in the same patient shows multifocal linear and nodular enhancement ⇨ in the periventricular and subcortical white matter, typical of IVL.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Intravascular (angiocentric) lymphoma (IVL)

Synonyms

- Intravascular malignant lymphomatosis
- Angioendotheliotropic lymphoma
- Malignant angioendotheliomatosis
- Angiotropic large cell lymphoma
- Intravascular B-cell lymphoma

Definitions

- Rare malignancy characterized by intravascular proliferation of lymphoid cells with predilection for CNS and skin
- Form of non-Hodgkin lymphoma (NHL) characterized by angiotropic growth

IMAGING

General Features

- Best diagnostic clue
  - Multifocal abnormal T2 hyperintensities in deep white matter (WM), cortex, or basal ganglia with enhancement
  - Linear and nodular enhancement commonly
  - No pathognomonic criteria for IVL
- Location
  - Supratentorial
    - Periventricular/deep WM, gray-white junction
  - May involve basal ganglia, brainstem, cerebellum
  - Spinal cord involvement reported

CT Findings

- NECT
  - Often normal or nonspecific
  - Focal, bilateral, asymmetric, low-density lesions in WM, cortex, or basal ganglia
- CECT
  - Variable enhancement
    - None to moderate

MR Findings

- T1WI
  - Multifocal hypointense lesions
  - May see blood products
- T2WI
  - Majority show hyperintensities in deep WM
    - e.g., edema, gliosis
  - May see cortex hyperintensity, infarct-like lesions (1/3 of cases)
  - Hyperintense basal ganglia lesions common
  - May see hemorrhagic transformation
- T2* GRE
  - May see blood products "blooming"
- DWI
  - Diffusion restriction common
  - Often mimics acute stroke or vasculitis
- T1WI C+
  - Variable enhancement
    - Linear, punctate, patchy, nodular, ring like, gyriform, homogeneous
  - Meningeal &/or dural enhancement
- SWI
  - Multifocal blood products related to microhemorrhage

Angiographic Findings

- Often mimics vasculitis
  - Alternating stenoses and dilatation, "beading," primarily involving 2nd and 3rd order branches

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR
- Protocol advice
  - Contrast-enhanced MR with DWI

Nuclear Medicine Findings

- PET
  - FDG PET helpful in diagnosing IVL in bone marrow and kidneys

DIFFERENTIAL DIAGNOSIS

Vasculitis

- Multifocal subcortical ischemia, ± enhancement
- DWI positive in acute setting
- DSA suggests diagnosis (IVL may mimic)
- Enhancement pattern may mimic IVL (particularly granulomatous angiitis)
- Imaging and clinical features may mimic IVL

Multi-Infarct Dementia

- Large and small infarcts, WM disease
- Deep gray nuclei typically involved
- Clinical diagnosis can mimic IVL

Primary CNS Lymphoma (PCNSL)

- Enhancing lesions in basal ganglia, periventricular WM
- Corpus callosum often involved
- Ependymal involvement characteristic

Neurosarcoid

- Dural or leptomeningeal enhancement
- Brain parenchyma typically spared
- Patients often have systemic disease

Viral Encephalitis

- T2/FLAIR hyperintense lesion
- Often DWI hyperintensity, ± enhancement
- May mimic IVL on pathologic specimen

PATHOLOGY

General Features

- Etiology
  - Aggressive, malignant B-cell non-Hodgkin lymphoma, angiotropic
    - May arise from T cells or rarely NK cells
  - IVL typically affects CNS and skin
    - May affect any organ
      - Reported in kidneys, bone marrow, breast, uterus, testes, lungs, larynx, adrenal gland
- Associated abnormalities
  - Possible association with Epstein-Barr virus (EBV)
    - NK-IVL is typically EBV positive

https://CafePezeshki.IR

Gross Pathologic & Surgical Features

- Small infarcts of varying ages throughout cortex and subcortical WM
  - May be hemorrhagic, petechial > confluent macroscopic bleeds
- May appear macroscopically normal
- May cause cerebral masses (rare)

Microscopic Features

- Accumulations of large B cells typical
- Malignant lymphoid cells occlude and distend small arteries, veins, and capillaries
- Minimal perivascular extension into adjacent brain parenchyma
- CD20(+), CD19(+), CD22(+), CD79a(+)
- Ki-67 high proliferative activity

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Dementia, confusion, memory loss
  - Multiple stroke-like episodes
  - Patients in Asia often present with hemophagocytic syndrome (Asian variant)
- Other signs/symptoms
  - Cognitive failure, focal deficits, seizure, fever
  - Myelopathy reported with spinal cord involvement
- Clinical profile
  - Skin changes
    - Raised plaques or nodules over abdomen and thighs (50%)
  - CSF studies may show elevated protein
  - No malignant cells in peripheral blood smear or bone marrow
  - Laboratory studies often inconclusive
  - Absence of lymphadenopathy is typical

Demographics

- Age
  - 5th-7th decades; mean: 60-65 years
- Gender
  - Slight male predominance
- Epidemiology
  - Rare, but underdiagnosed
  - CNS involved in up to 75% of IVL cases

Natural History & Prognosis

- Rapidly progressive disease with high mortality rate
- Mean survival: 7-13 months
  - Mildly improved survival in recent reports
- Mortality rate: > 80%
- Rarely, spontaneous regression of symptoms occurs
- Diagnosis often made postmortem
- Risk of recurrence at 1 year: 25%
- Duration of diagnosis to CNS recurrence short

Treatment

- Diagnosis may be made by skin or brain biopsy
- Treatment primarily includes steroids and chemotherapy (rituximab, methotrexate)
- Variable results with radiation therapy

DIAGNOSTIC CHECKLIST

Consider

- In evaluation of patients with dementia, contrast-enhanced MR may be helpful
- IVL often mimics vasculitis and vascular dementia clinically and by imaging
- Stereotactic biopsy often required for definitive diagnosis

Image Interpretation Pearls

- Imaging of IVL is nonspecific, but IVL should be considered in patients with dementia, multifocal lesions, and enhancement
- Linear enhancement along perivascular spaces suggests diagnosis of IVL
- Ischemic foci are most common imaging finding in IVL, often acute foci of ischemia present

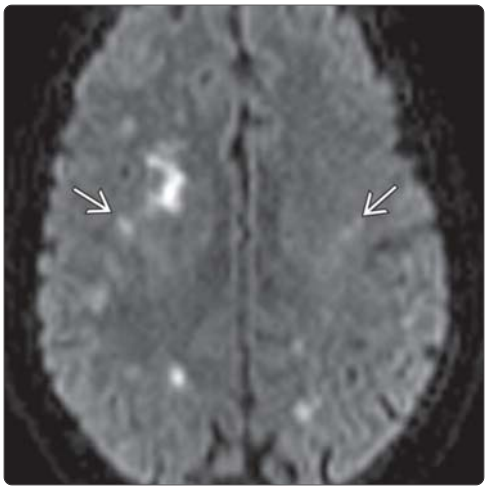
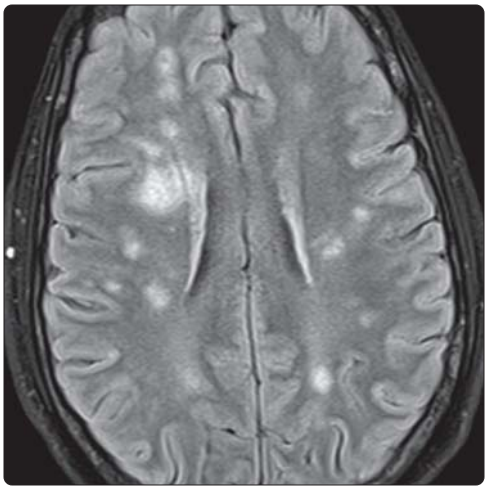
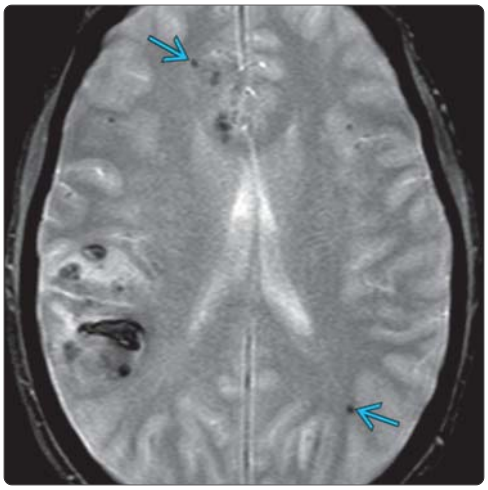
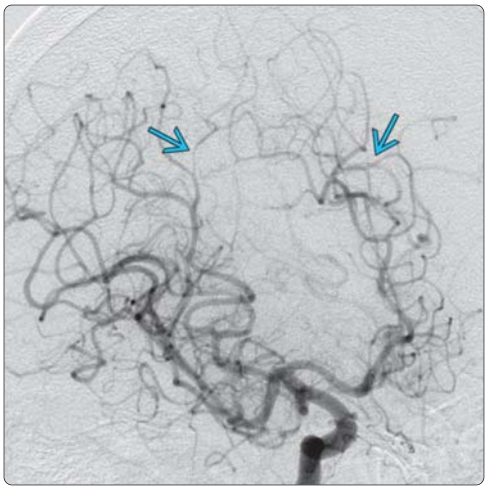
https://CafePezeshki.IR



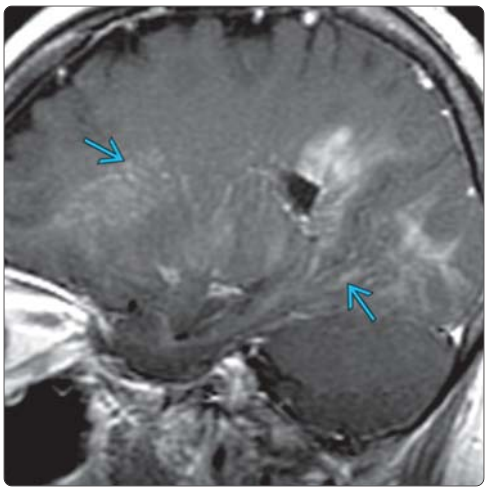


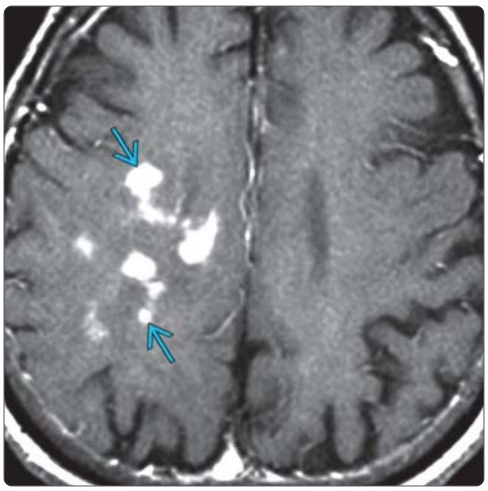
(Left) *Axial DWI shows multiple foci of diffusion restriction of varying ages* ⇨ *in the cerebral hemispheres in a 60 year old with increasing confusion.* **(Right)** *Axial FLAIR MR in the same patient shows multiple nonspecific foci of hyperintensity in the periventricular and subcortical white matter. Without contrast, the imaging is nonspecific, and this patient may have been diagnosed with thromboembolic disease, chronic small vessel ischemia, or vasculitis. IVL often mimics vasculitis clinically and on imaging.*





(Left) *Axial GRE in the same patient shows multiple foci of susceptibility artifact* ⇨ *or "blooming" related to multiple hemorrhages throughout the hemispheres. IVL was diagnosed at autopsy. GRE and SWI MR are helpful to identify the microhemorrhages often seen in IVL.* **(Right)** *AP view of a right internal carotid artery injection DSA in the same patient shows multifocal narrowing in small- and medium-sized vessels* ⇨*. This pattern may be seen in both vasculitis and IVL. Biopsy is typically required for definitive diagnosis.*





(Left) *Sagittal T1 C+ MR image in a patient with IVL shows the classic linear and punctate enhancement* ⇨ *often seen in IVL. When enhancement is oriented along perivascular spaces, IVL can be suggested.* **(Right)** *Axial T1WI C+ MR shows multifocal areas of enhancement in the hemispheric white matter* ⇨ *in this IVL patient. Enhancement patterns of IVL are variable and may be linear, punctate, patchy, nodular, ring-like, gyriform, or homogeneous. Meningeal &/or dural enhancement has also been described.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Extramedullary leukemic tumors (EML)
- Synonyms: Granulocytic sarcoma, chloroma

IMAGING

- Best diagnostic clue: Homogeneous enhancing tumor(s) in patients with known or suspected myeloproliferative disorder
- Meningeal (dural-based or pial) > intraparenchymal lesions
- NECT: Hyperdense
- CECT: Moderate uniform enhancement
- MR
  - T2/FLAIR iso- to hypointense
  - Restricted diffusion on DWI

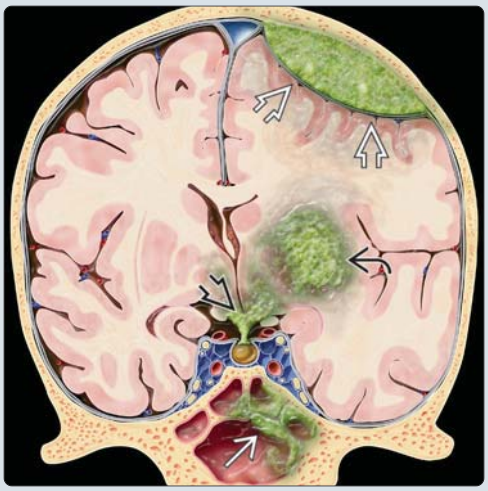
TOP DIFFERENTIAL DIAGNOSES

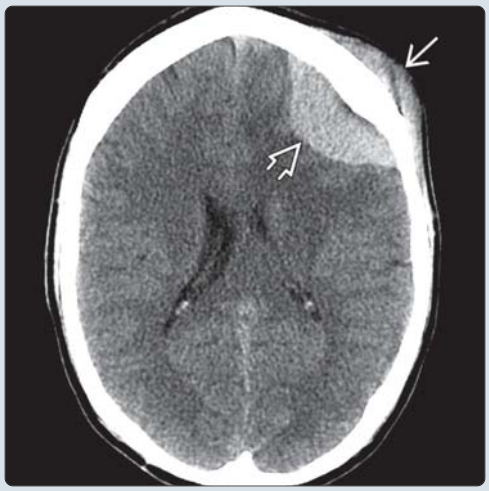
- Metastatic neuroblastoma (NBT)
- Meningioma
- Extraaxial hematoma
- Extramedullary hematopoiesis
- Langerhans cell histiocytosis (LCH)

PATHOLOGY

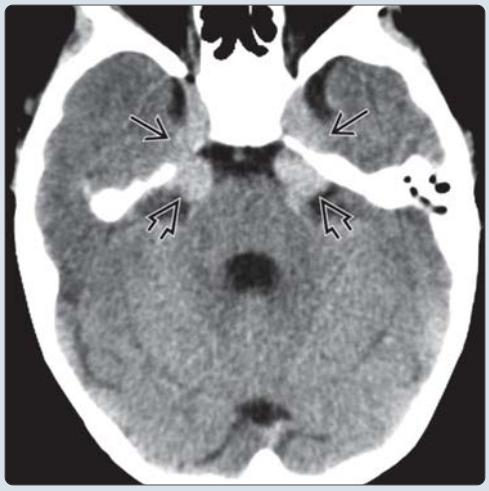
- CNS leukemia presents in 3 forms
  - Meningeal disease (usually with ALL)
  - Intravascular aggregates (leukostasis): Can rupture, hemorrhage with markedly ↑ leukocyte counts
  - Tumor masses (chloroma)
- Multiple other intracranial manifestations, complications of leukemia/treatment
  - Posterior reversible encephalopathy syndrome (PRES)
  - Post-transplant lymphoproliferative disease (PTLD) after bone marrow transplantation
  - Invasive fungal infection
  - Venous thrombosis associated with chemotherapy
  - Late development of cavernous angiomas after radiation therapy

(Left) *Coronal graphic shows multiple foci of leukemic infiltrates in the skull base/paranasal sinuses ➡, hypothalamus/infundibulum ⇨, basal ganglia ⇨, and dura ➡. Green color observed at pathology results in the name "chloroma." The accepted term is "granulocytic sarcoma."* **(Right)** *Axial NECT scan in a child with acute myelogenous leukemia (AML) and a palpable scalp mass shows a hyperdense intra- ➡ and extracranial mass ➡ that centers on the calvaria.*





(Left) *Axial T2WI in a child with AML demonstrates a hypointense parietal mass ➡ surrounded by a collar of edema ⇨. AML with parenchymal metastasis (cerebral granulocytic sarcoma) is rare.* **(Right)** *NECT scan in a 5-year-old girl with AML shows chloroma infiltrating both trigeminal nerves, enlarging the cisternal ⇨ and Meckel cave segments ⇨. (Courtesy N. Aggarwal, MD.)*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Extramedullary leukemic tumors (EML)
- Extramedullary myeloblastoma, extramedullary myeloid cell tumors (EmMCT)

Synonyms

- Granulocytic sarcoma, chloroma

Definitions

- Solid tumor of myeloblasts/myelocytes/promyelocytes
  - In patients with myeloproliferative disorder
- Multiple other intracranial manifestations of leukemia/treatment complications
  - Posterior reversible encephalopathy syndrome (PRES)
  - Invasive fungal infection
  - Late development of cavernous angiomas after radiation therapy
  - Post-transplantation lymphoproliferative disease (PTLD) after bone marrow transplantation
  - Venous thrombosis associated with chemotherapy (L-asparaginase)
  - Vasculitis
    - Primary manifestation of leukemia
    - Secondary to treatment (trans retinoic acid)
    - Secondary to infection (e.g., *Aspergillus*)

IMAGING

General Features

- Best diagnostic clue
  - Homogeneous enhancing tumor(s) in patients with known or suspected myeloproliferative disorder
  - Most often complication of acute myelogenous leukemia (AML)
- Location
  - Meningeal (dural-based or pial) > intraparenchymal lesions

CT Findings

- NECT
  - Iso-/hyperdense to brain
    - May rapidly become hypodense (necrosis, liquefaction)
  - May present with (or mimic) hematoma
  - Look for skull base/paranasal sinus involvement
- CECT
  - Homogeneous enhancement
    - Hyperdensity or presence of hemorrhage may mask enhancement
  - May have rim enhancement, mimic abscess

MR Findings

- T1WI
  - Hypo-/isointense to brain
  - Can distinguish between acute hematoma, nonhemorrhagic mass
- T2WI
  - Variable; may be hypointense
  - Pial disease may extend into perivascular spaces, appear as patchy WM hyperintensities
- FLAIR
  - More sensitive than T2WI for leptomeningeal disease
- T2* GRE
  - Helpful for identifying cavernous angiomas as very late complication of leukemia treatment
- DWI
  - May restrict (hyperintense on DWI, hypointense on ADC)
  - Helps distinguish ischemic complications from PRES
- T1WI C+
  - Homogeneous enhancement
    - May become heterogeneous with necrosis/liquefaction
  - Leptomeningeal or perivascular space enhancement
  - Fat-saturation technique essential for assessment of skull base disease
- MRA
  - May show vasospasm in cases of PRES
  - May identify medium-vessel vasculitis
- MRV
  - Essential in evaluation of hemorrhagic lesions
  - Identify presence or extent of venous thrombosis

Nuclear Medicine Findings

- Bone scan
  - Tc-99m MDP commonly used for bone disease in leukemia
  - Soft tissue uptake typically reflects hypercalcemia, not chloroma
- PET
  - Avid uptake on FDG PET exams

Imaging Recommendations

- Best imaging tool
  - MR with contrast
- Protocol advice
  - Use T1WI C+ FS

DIFFERENTIAL DIAGNOSIS

Metastatic Neuroblastoma (NBT)

- Rarely occurs without extracranial disease
- Characteristic "raccoon eyes" clinical presentation
- Spiculated periostitis

Meningioma

- May be very difficult to distinguish
- Dural "tail" may be more common in meningioma

Extraaxial Hematoma

- Extracranial soft tissue swelling or skull fracture
- If no appropriate history, consider possibility of child abuse

Extramedullary Hematopoiesis

- Markedly hypointense on T2WI
- Same at-risk patient population

Langerhans Cell Histiocytosis (LCH)

- Destruction of adjacent bone without periosteal reaction
- Diabetes insipidus

Ewing Sarcoma

- Aggressive pattern of growth
- Destruction of adjacent bone

https://CafePezeshki.IR

Neurosarcoidosis

- Mimic of leptomeningeal disease
- Less commonly presents as dural-based masses

PATHOLOGY

General Features

- Etiology
  - Some association with exposures
    - Ionizing radiation, hydrocarbons, benzene, alkylating agents
- Genetics
  - CNS involvement have higher incidence of 11q23 abnormalities compared to those without CNS disease
  - Chromosomal t(8;21) translocations reported in cases of AML with chloroma
  - AML has higher incidence in some genetic syndromes
    - Down, Bloom, Fanconi syndromes
- Associated abnormalities
  - Less common in non-AML myeloproliferative disorders
    - Myeloid metaplasia
    - Hypereosinophilic syndrome
    - Polycythemia vera
- CNS leukemia presents in 3 forms
  - Meningeal disease
    - Usually with acute lymphoblastic leukemia (ALL)
  - Intravascular aggregates (leukostasis)
    - May rupture, hemorrhage (with markedly high leukocyte counts)
  - Focal tumor masses (chloroma)
- Chloroma
  - Leukemic masses first described in 1811
  - "Chloroma" coined in 1853
  - Renamed granulocytic sarcoma in 1966

Gross Pathologic & Surgical Features

- Called chloroma because of green color in 70% of cases
  - Caused by high levels of myeloperoxidase

Microscopic Features

- Moderate to large cells
- Pleomorphic nuclei
- Multiple mitoses give "starry sky" appearance

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - May precede marrow diagnosis of leukemia
  - 50% of cases diagnosed only at autopsy
  - CNS lesions more likely symptomatic
  - Focal signs from local mass effect
  - Headache from hemorrhage
- Clinical profile
  - Child with AML develops new neurological signs or symptoms

Demographics

- Age
  - 60% of patients < 15 years
- Gender
  - M:F = 1.38:1
- Ethnicity
  - Hispanic children < 19 years have highest rates of leukemia
  - Incidence in Americans of European descent > African descent
- Epidemiology
  - 5-10% of patients with AML; 1-2% with CML
  - Risk factors for CNS disease = age < 45 years, WBC counts > 50,000/μL, 11q23 translocations

Natural History & Prognosis

- Overall survival rates for AML (40-50%)
- Chloroma in setting of other myeloproliferative syndrome
  - Implies blastic transformation
  - Poor prognostic sign

Treatment

- Chemotherapy for induction
  - Cytarabine (Ara-C)
  - Anthracycline
- Bone marrow transplant for consolidation
- Note: Methotrexate treatment can cause stroke-like symptoms
  - MR → round WM lesions with reduced diffusion

DIAGNOSTIC CHECKLIST

Consider

- Extramedullary hematopoiesis can present in same patient population with similar appearance
- Hemorrhagic lesions in children with AML can be manifestation of chloroma or complication of therapy

Image Interpretation Pearls

- Multiple lesions at multiple sites suggestive of diagnosis
- Chloromas with enhancing rim (rare) can mimic abscess

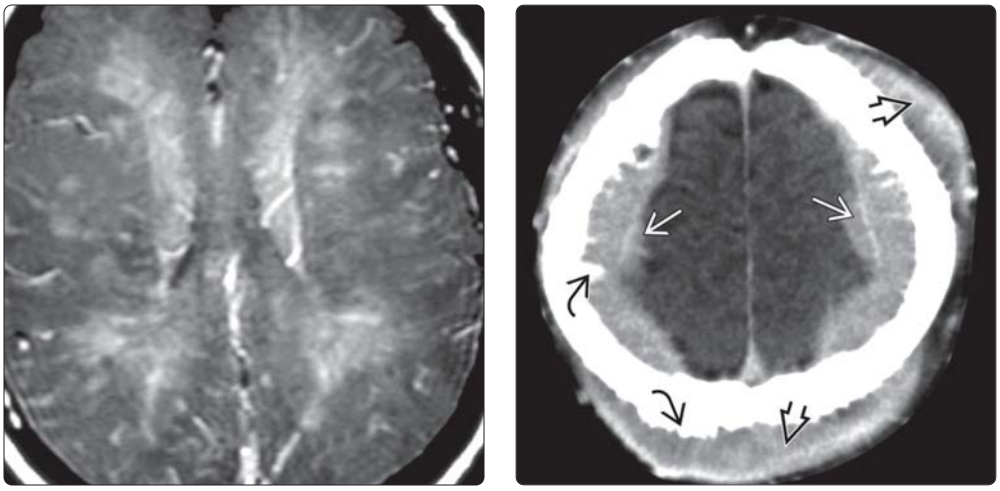
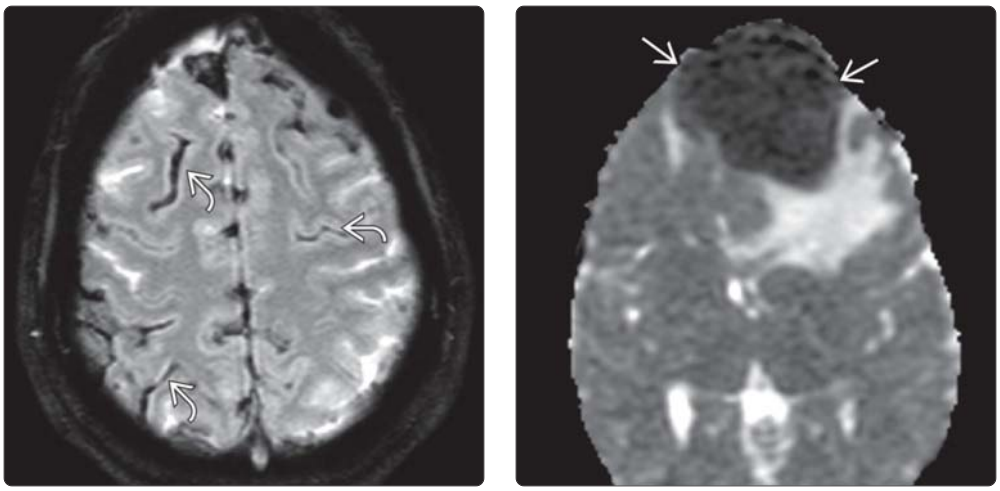
(Left) *Axial NECT demonstrates a hyperdense dural-based mass mimicking a subdural hematoma in a patient with acute myelocytic leukemia* ➡. **(Right)** *Axial CECT shows homogeneous enhancement in the dural-based mass* ➡, *thus excluding simple hemorrhage. Small areas of nonenhancement* ➡ *are due to necrosis/liquefaction rather than rapid bleeding. These are typical findings in dural-based leukemic infiltrates in patients with AML.*



(Left) *Axial T1WI C+ MR in a patient with leukemia and progressive encephalopathy shows multiple, enhancing intra- and perivascular infiltrates. Carcinomatous encephalitis is a rare complication of leukemia.* **(Right)** *Axial CECT in a patient with leukemic disease and skull involvement shows large, bilateral, convexity epidural leukemic masses* ➡. *Note the subperiosteal accumulations of tumor* ⇨. *The spiculated appearance of the outer and inner calvaria* ⇨ *speaks to the extensive marrow involvement.*



(Left) *Axial T2* GRE MR shows leptomeningeal low signal* ➡ *in a patient with AML and blast crisis. CSF analysis showed hemorrhage and leukemic cell infiltrates.* **(Right)** *Axial ADC in a 13-year-old girl with sinusitis and scalp swelling shows a restricting, profoundly hypointense mass* ➡ *that was hyperdense on CT and hyperintense and strongly enhancing on DWI (not shown). Biopsy and blood studies showed high-risk ALL.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Intracranial germ cell tumor (iGCT)
- iGCTs are intracranial homologue of gonadal germinomas (ovarian dysgerminoma, testicular seminoma)

IMAGING

- Most common: In/near midline (80-90%)
  - Pineal region ~ 50-65%
  - Suprasellar ~ 25-35%
- Less common: Basal ganglia/thalami ~ 5-10%
- 20% multiple
  - Most common = pineal with suprasellar
- NECT (pineal germinoma)
  - Hyperdense pineal region mass engulfs pineal Ca++
- MR (suprasellar germinoma)
  - Absent posterior pituitary "bright spot"
  - "Fat" stalk/pituitary gland
  - Strong, relatively uniform enhancement
  - May have cysts, hemorrhage (rare)

TOP DIFFERENTIAL DIAGNOSES

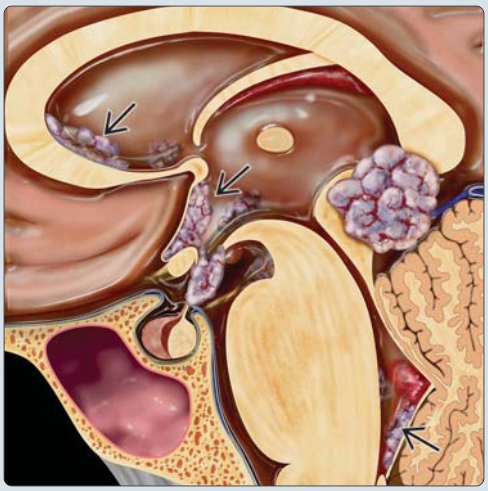
- Pineal germinoma
  - Pineocytoma
  - Other pineal GCTs
- Suprasellar germinoma ("fat" infundibulum)
  - Adult
    - Neurosarcoid
    - Metastases
  - Child
    - Langerhans cell histiocytosis (LCH)

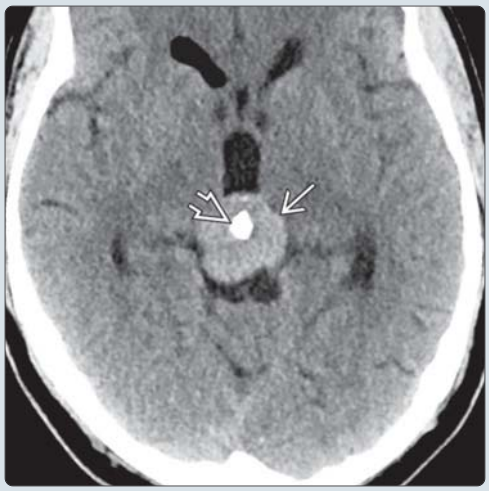
CLINICAL ISSUES

- 90% of patients < 20 years old
- Pineal region germinoma: M:F ~ 10:1

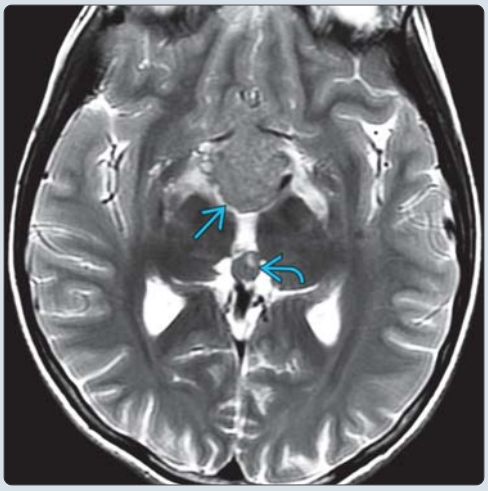
DIAGNOSTIC CHECKLIST

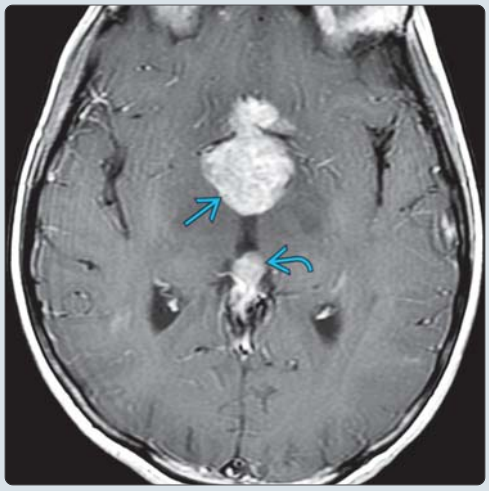
- If young patient presents with diabetes insipidus, think germinoma or LCH





(Left) *Sagittal graphic shows synchronous germinomas in the suprasellar and pineal regions. Note the CSF spread of tumor in the lateral, 3rd, and 4th ventricles.* **(Right)** *Axial NECT scan shows typical findings of pineal germinoma with a well-demarcated slightly hyperdense mass engulfing the calcified pineal gland.*





(Left) *Axial T2WI in a 14-year-old boy with visual symptoms shows a suprasellar mass that is slightly hypointense relative to gray matter. A 2nd, smaller mass is present in the pineal gland.* **(Right)** *T1 C+ MR in the same patient shows the lobulated suprasellar mass enhances strongly. The pineal mass also enhances uniformly. The combination of suprasellar and pineal mass (sometimes called "double midline" germinoma) occurs in ~ 20% of cases.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Intracranial germ cell tumor (iGCT)

Synonyms

- Dysgerminoma, extragonadal seminoma

Definitions

- iGCTs are intracranial homologue of gonadal germinomas (ovarian dysgerminoma, testicular seminoma)

IMAGING

General Features

- Best diagnostic clue
  - Hyperdense pineal region mass that engulfs pineal Ca++
  - Suprasellar mass with diabetes insipidus (DI)
  - BG mass with ipsilateral hemiatrophy
- Location
  - Most common: In/near midline (80-90%)
    - Pineal region ~ 50-65%
    - Suprasellar ~ 25-35%
  - Less common: Basal ganglia/thalami ~ 5-10%
  - Other sites: Intraventricular (3rd), intrasellar, bulbar, intramedullary, midbrain, hemispheric
- Size
  - Varies with location
    - Pineal: Can be large if no hydrocephalus, midbrain compression ± invasion
    - Infundibular stalk: Early presentation with DI common
      - Mass can initially be tiny/imperceptible
- Number
  - 20% multiple; most common = pineal with suprasellar

CT Findings

- NECT
  - Lobulated hyperdense mass
    - Pineal: Mass drapes around posterior 3rd ventricle or engulfs Ca++ pineal gland
    - Suprasellar: "Fat" infundibulum
    - Basal ganglia: Often no abnormality in early stage, later iso-/hyperdense lesions without mass effect
      - Single calcified spot may be seen on NECT in early stage
  - ± cysts
  - ± hemorrhage (especially in basal ganglia germinomas)
  - ± hydrocephalus
- CECT
  - Strong uniform enhancement, ± CSF seeding
    - Pineal region: Look for posterior 3rd ventricle, midbrain/thalami infiltration
    - Suprasellar: Look for thick stalk, infiltration of 3rd ventricular floor, lateral walls, and anterior columns of fornices

MR Findings

- T1WI
  - Iso-/hyperintense to GM
  - "Fat" stalk/pituitary gland
    - Absent posterior pituitary "bright spot"
      - Pituitary "bright spot" present in 99.7% of normal patients
  - Basal ganglia/thalami: 20-33% associated ipsilateral hemiatrophy
- T2WI
  - Iso- to hyperintense to GM (high nuclear to cytoplasmic ratio)
    - Cystic/necrotic foci (high T2 signal)
      - Multiple cysts common in germinoma and all GCTs (up to 44%)
    - Less common: Hypointense foci (hemorrhage)
- FLAIR
  - Slightly hyperintense to GM
- T2* GRE
  - Calcification, hemorrhage "bloom"
- DWI
  - Reduced diffusion due to high cellularity
- T1WI C+
  - Strong, homogeneous enhancement, ± CSF seeding, ± brain invasion
  - BG and thalami: Ill-defined enhancement
    - Later cystic changes (due to previous hemorrhage and tumor progression)
- MRS
  - ↑ choline, ↓ NAA, ± lactate

Imaging Recommendations

- Best imaging tool
  - Enhanced MR of brain and spine
- Protocol advice
  - MR evaluation of entire neuraxis before surgery

DIFFERENTIAL DIAGNOSIS

Other Pineal GCTs

- Malignant mixed germ cell, yolk sac, choriocarcinoma, embryonal carcinoma
- Immature teratoma, mature teratoma, mixed mature/immature

Pineoblastoma

- Large, heterogeneous pineal mass; peripheral Ca++
- Obstructive hydrocephalus

Pineocytoma

- Mass "explodes" rather than engulfs pineal Ca++

Pineal Parenchymal Tumor of Intermediate Differentiation

- Pineal mass with histology between pineocytoma and pineoblastoma

Pineal Cyst (Atypical)

- Often > 15 mm, rim enhancing, variable signal of cyst contents, ± tectal compression

Other Pineal Region Masses

- Astrocytoma
- Metastasis
- Meningioma
- Retinoblastoma
  - Trilateral → evaluate orbits and suprasellar regions
- Papillary tumor of pineal region

https://CafePezeshki.IR

"Fat" Infundibulum

- Child
  - Langerhans cell histiocytosis (LCH)
  - Tuber cinereum hamartoma (isointense with GM, nonenhancing)
- Adult
  - Neurosarcoid
  - Metastases

PATHOLOGY

General Features

- Etiology
  - Genetics
    - Frequent aberrations of *CCND2* (12p13)
    - *KIT* alterations also common in pure germinomas
- Associated abnormalities
  - Klinefelter syndrome (47XXY)
  - Down syndrome
  - Neurofibromatosis type 1
  - Laboratory derangements
    - Elevated placental alkaline phosphatase (PLAP)
    - Most germinomas have elevated serum, CSF β-HCG irrespective of histology

Staging, Grading, & Classification

- Multiple site involvement (pineal, suprasellar, BG, thalamus) considered metastatic in USA, synchronous in Canada and Europe
- Pure germinoma: WHO grade II
- Germinoma with syncytiotrophoblastic giant cells (STGCs): WHO grade II-III

Gross Pathologic & Surgical Features

- Soft and friable, tan-white mass, ± necrosis

Microscopic Features

- Sheets of large polygonal primitive germ cells
- Lymphocytic infiltrates along fibrovascular septa
- IHC shows PLAP, c-kit, OCT3/4 highly expressed

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pineal region germinoma
    - Parinaud syndrome (upward gaze paralysis and altered convergence)
    - Headache due to tectal compression or invasion (hydrocephalus)
  - Suprasellar germinoma
    - Diabetes insipidus (DI)
    - Visual loss
    - Hypothalamic-pituitary dysfunction (↓ growth, precocious puberty)
  - Off-midline germinoma
    - Slow, progressive hemiparesis (due to involvement of internal capsule and subsequent Wallerian degeneration)
    - Progressive mental deterioration, personality change, fever of unknown origin
    - Precocity, diabetes insipidus, hemianopsia, speech disturbance
    - Choreoathetoid movements

Demographics

- Age
  - CNS GCTs primarily in young patients
    - 90% < 20 years
    - Peak: 10-12 years
- Gender
  - Pineal region germinoma: M:F ~ 10:1
  - Suprasellar germinoma: More common in women
  - For all CNS germinomas: M:F = 1.5-2:1
- Ethnicity
  - CNS GCTs far more prevalent in Asia (9-15%)
- Epidemiology
  - Germinomas → 1-2% of all CNS tumors
    - 2/3 of all iGCTs
    - 50% of pineal region tumors
    - 2-4% of pediatric CNS tumors (9-15% of CNS tumors in Japanese children)

Natural History & Prognosis

- Pure germinoma has favorable prognosis
  - Moderate elevation of β-HCG → favorable
- CSF dissemination and invasion of adjacent brain common

Treatment

- Biopsy to confirm histology, "pure" germinomas have best outcome
- Reduced dose and volume of XRT ± adjuvant chemotherapy

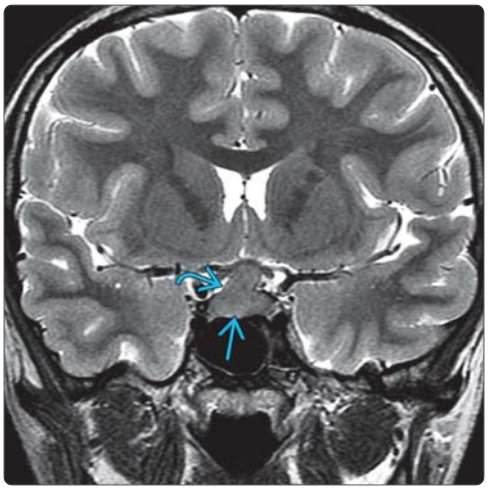
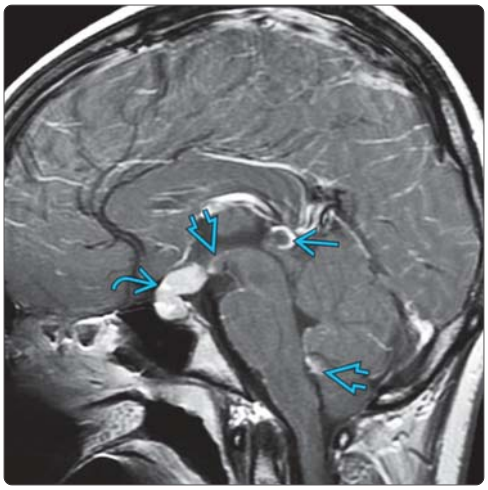
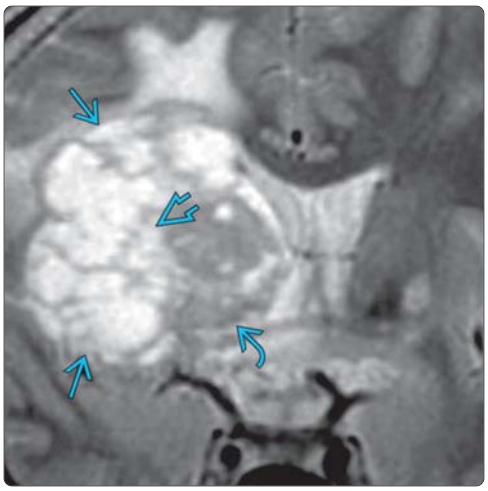
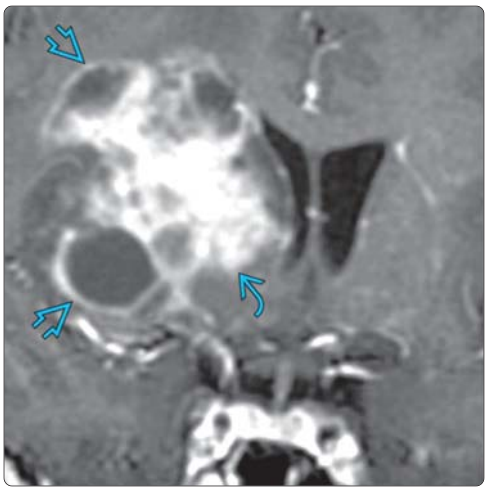
(Left) *Sagittal T1WI in a 14-year-old girl with diabetes insipidus shows absence of the posterior pituitary "bright spot." A lobulated mass that is isointense with the cortex thickens the infundibular stalk ⇨ and extends superiorly into the hypothalamus and 3rd ventricle ⇨.* **(Right)** *Sagittal T2WI in the same patient shows the mass in the pituitary stalk ⇨ and hypothalamus/inferior 3rd ventricle ⇨ remains isointense with gray matter. Note the benign-appearing pineal cyst ⇨.*





(Left) *Coronal T2WI in the same patient shows the mass ⇨ seems to be infiltrating both the infundibular stalk and pituitary gland ⇨.* **(Right)** *Sagittal T1 C+ in the same patient shows the mass ⇨ enhances strongly and uniformly. Note the enhancing rim around the benign pineal cyst ⇨. Subtle CSF spread is present ⇨ and was documented by lumbar puncture. Biopsy showed germinoma.*





(Left) *Coronal T2WI shows a mixed signal intensity mass in the right basal ganglia ⇨. Note the numerous intratumoral cysts ⇨. The solid portion of the tumor ⇨ is isointense with gray matter.* **(Right)** *Coronal T1 C+ shows enhancement in the cyst walls ⇨ & the solid portion of the mass ⇨. Biopsy disclosed germinoma. Primary germinomas in the basal ganglia & thalami are uncommon. They are often atypical in appearance. Intratumoral hemorrhage and cysts are common. (Courtesy R. Babbel, MD).*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Teratoma: Nongerminomatous germ cell tumor
  - Arises from multipotential germ cells
  - Tridermic (contains tissues derived from all 3 germ cell layers)
- Types
  - Mature teratoma (most common; well differentiated)
  - Immature teratoma (some incompletely differentiated tissue)
  - Teratoma with malignant transformation

IMAGING

- NECT
  - Midline mass containing Ca++, soft tissue, cysts, and fat
- T1WI
  - Fat → ↑ signal, Ca++ → variable signal
  - Soft tissue components iso- to hyperintense, enhancing
- T2WI: ↓ signal from Ca++
- DWI: Restriction in solid (high cellular) parts
- Anatomic location indeterminate in 50%
  - Huge holocranial mass in newborns or fetus
  - Anatomic landmarks effaced
- Fetal US: Macrocephaly
  - Rapidly ↑ mass, mixed hyper-, hypoechoic features

TOP DIFFERENTIAL DIAGNOSES

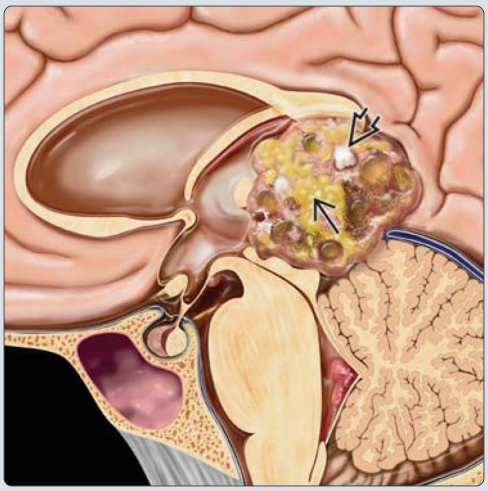
- Germinoma
- Other nongerminomatous germ cell tumor
- PNET, AT/RT
- Dermoid
- Craniopharyngioma

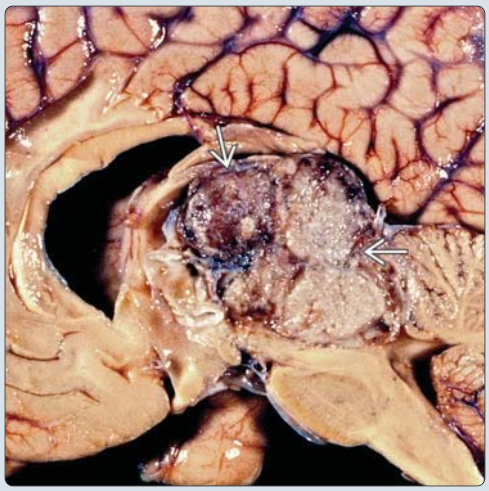
CLINICAL ISSUES

- Often detected in utero or as neonate
- M:F = 4:1

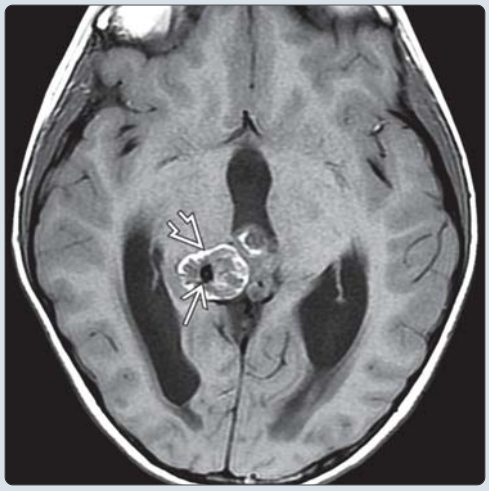
DIAGNOSTIC CHECKLIST

- If newborn with holocranial tumor, think teratoma





(Left) *Sagittal graphic shows a heterogeneous pineal teratoma with a solid, calcific ⇨, and fatty ⇨ composition.* **(Right)** *Sagittal gross pathology section shows a pineal teratoma ⇨ with obstructive hydrocephalus. (Courtesy B. Alvord, MD.)*



(Left) *Axial NECT scan in an 8-year-old boy who presented with headaches, morning nausea, and vomiting shows a mixed density mass in the pineal region. Note the fat-like ⇨ tissue calcifications, including one that resembles a tooth ⇨. The lateral ventricles are moderately enlarged, consistent with obstructive hydrocephalus.* **(Right)** *T1WI in the same patient shows mixed hyper- ⇨, isointense lobulated soft tissue mass with a central hypointense focus ⇨ from the tooth-like structure.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Teratoma: Nongerminomatous germ cell tumor
  - Arises from multipotential germ cells
  - Tridermic (contains tissues derived from all 3 germ cell layers)
- Types
  - Mature teratoma (most common; well differentiated)
  - Immature teratoma (some incompletely differentiated tissue)
  - Teratoma with malignant transformation

IMAGING

General Features

- Best diagnostic clue
  - Midline mass containing Ca++, soft tissue, cysts, fat
  - Huge holocranial mass in newborn or fetus
- Location
  - Midline
    - Pineal gland
      - Tectum, mesencephalon commonly involved
    - Sellar/suprasellar
      - Hypothalamus, optic chiasm
      - Less common: Parasellar (cavernous sinuses or mesial middle cranial fossa)
    - Basal ganglia, thalami
    - Spine (thoracolumbar junction)
  - Rare locations
    - Brain hemispheres
    - Ventricles
    - ~ 50% so large that anatomic origin indeterminate
- Size
  - Variable; infantile teratomas often huge ("holocranial")

CT Findings

- NECT
  - Fat, soft tissue, Ca++
  - Cystic components common
  - Often large (may fill entire cranium)
- CECT
  - Soft tissue components enhance
- Bone CT
  - Look for tooth-like configuration of Ca++

MR Findings

- T1WI
  - Increased signal from fat
  - Variable signal from Ca++
- T2WI
  - Soft tissue components iso- to hyperintense
  - Perifocal edema
    - Usually minimal or absent (mature teratoma)
    - Common in immature (malignant) teratoma
- FLAIR
  - ↓ signal from cysts, ↑ signal from solid tissue
- T2* GRE
  - Decreased signal from Ca++
- DWI
  - Restricted diffusion in solid (high cellular) parts
  - Useful in differentiating high- vs. low-grade neoplasms for large bulky supratentorial tumors in 1st year of life
    - ADC values negatively correlated with tumor grade
- T1WI C+
  - Soft tissue enhancement
- Fetal MR
  - Extremely heterogeneous mass containing fat, fluid, bone, and soft tissue
  - Usually midline, may fill and expand cranium
  - When small, often midline
    - Suprasellar vs. pineal region vs. 4th ventricle

Ultrasonographic Findings

- Neonates: Heterogeneous mass with internal shadowing (Ca++)
- In utero ultrasound
  - Intracranial mass (often huge)
  - Hydrocephalus, polyhydramnios

Imaging Recommendations

- Best imaging tool
  - CT to demonstrate soft tissue, fat, Ca++
  - MR best characterizes relationship of teratoma to midline structures
- Protocol advice
  - MR with and without fat suppression

DIFFERENTIAL DIAGNOSIS

Germinoma

- Homogeneous appearance

Other Nongerminomatous Germ Cell Tumor

- Includes embryonal carcinoma, yolk sac tumor, choriocarcinoma, mixed germ cell tumor
- Heterogeneous suprasellar or pineal mass

Craniopharyngioma

- Cystic and solid, calcifications

Dermoid

- Minimal/no enhancement
- Calcifications common
- Look for rupture with fat "droplets"

Pineoblastoma

- Large pineal mass with "exploded" Ca++
- Hydrocephalus present in 100%

Supratentorial PNET

- Ca++, hemorrhage, necrosis common
- Does not contain fat

Atypical Teratoid/Rhabdoid Tumor (AT/RT)

- Large, bulky AT/RT in newborn difficult to distinguish

Astrocytoma

- Newborn GBM can be large, bulky, very heterogeneous

Lipoma

- Contains fat, calcifications but no soft tissue component
- Uncommon in suprasellar location

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Originates during 3rd or 4th week of fetal development
  - Anomalous development of primitive streak or its derivatives
- Genetics
  - Gains of hypomethylated, active X chromosomes occur in all intracranial germ cell tumors (ICGCTs)
- Associated abnormalities
  - Increased serum carcinoembryonic antigen (CEA)
  - Increased α-fetoprotein if tumor contains enteric glandular elements (yolk sac cells)

Staging, Grading, & Classification

- WHO classification
  - Mature teratoma (WHO grade I)
  - Immature teratoma
  - Teratoma with malignant transformation (TMT)
    - Usually arises from immature teratoma
    - Contains somatic-type cancers (e.g., rhabdomyosarcoma)

Gross Pathologic & Surgical Features

- Mature teratomas → fully differentiated tissue
  - Cystic component frequent in mature teratoma
- Immature or malignant teratoma → resembles fetal tissues
- Teratomas may be part of mixed tumors, with germinomas or nongerminomatous ICGCT

Microscopic Features

- Contain elements representing 3 germinal layers
  - Ectoderm
  - Mesoderm
  - Endoderm

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Macrocephaly → congenital teratoma
  - Parinaud syndrome → pineal lesions
- Other signs/symptoms
  - Increased serum carcinoembryonic antigen (CEA)
- Clinical profile
  - In utero demonstration of hydrocephalus, macrocephaly, and heterogeneous mass
  - Congenital teratomas
    - Diffuse intracranial form: Large tumors replacing intracranial content
    - Small tumors causing hydrocephalus
    - Massive form: Extension in orbits, pharynx, neck

Demographics

- Age
  - Average age at diagnosis = 15 years
  - Range: Newborn-6th decade
  - Often detected in utero or as neonate
- Gender
  - M > F
- Ethnicity
  - More common among Asians
- Epidemiology
  - 2-4% of intracranial tumors in children
  - Leading perinatal brain tumor (42%)

Natural History & Prognosis

- 5-year survival for malignant teratomas: 18%
- Congenital teratoma
  - May be seen on fetal ultrasound or MR
  - Majority stillborn or die within 1st week of life
- Lowest survival rate of all fetal brain tumors
- Pineal mature teratomas have good prognosis
- CSF metastases common in malignant (immature) teratoma

Treatment

- Surgical removal
  - Operative mortality in 1st year: 20%

DIAGNOSTIC CHECKLIST

Consider

- Think teratoma in newborn with holocranial tumor
- Heterogeneous midline mass, young age, male predominance, pineal preferential location

Image Interpretation Pearls

- Midline tumor predominantly in sellar and pineal region containing fat, soft tissue, and Ca++

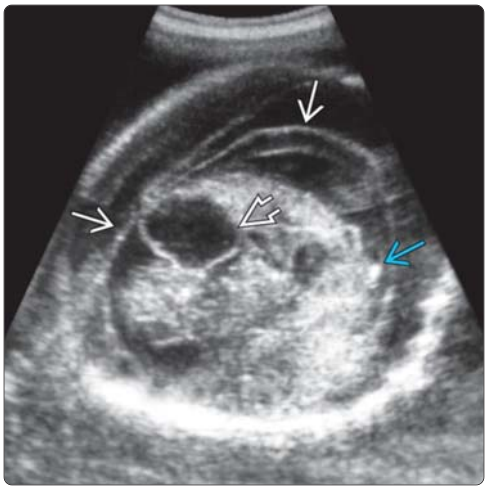
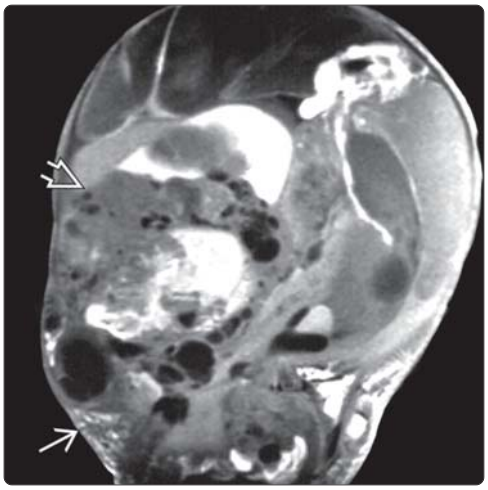
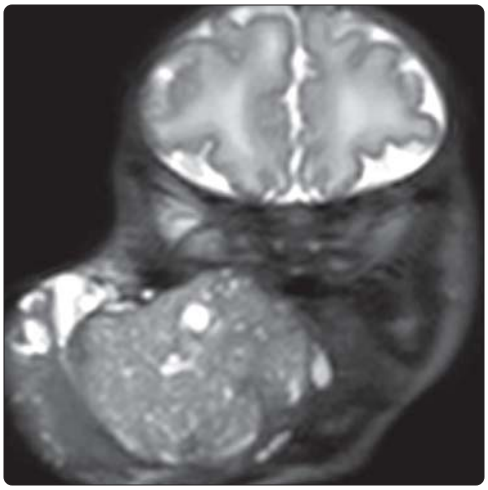
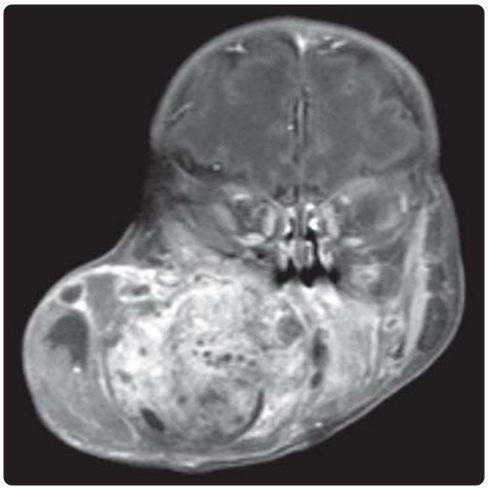
https://CafePezeshki.IR



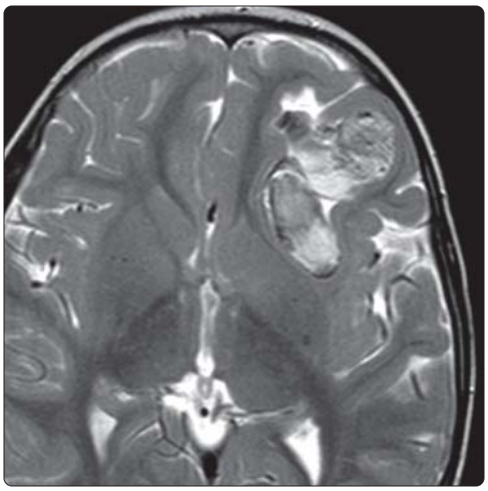


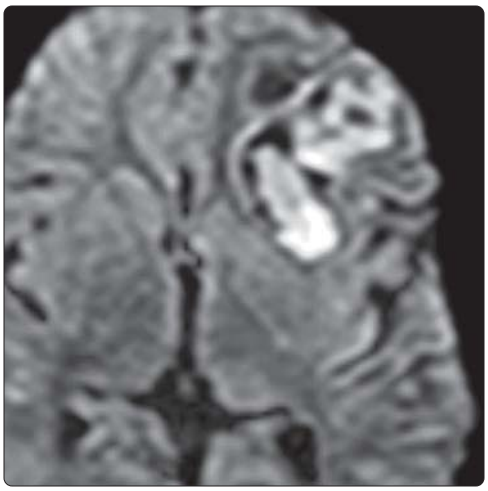
(Left) *Fetal ultrasound shows a fetus with a large head* ➔ *that is almost completely filled with mixed hyper-* ➔ *and hypoechoic* ➔ *tissue. No normal anatomic structures are recognizable. Stillborn fetus with immature teratoma was found.* **(Right)** *Postmortem T1WI of a stillborn infant shows replacement of all brain tissue by a complex mixed signal intensity mass* ➔ *that also extends into the face* ➔*. Immature teratoma with primitive neural ectodermal tissue was identified at autopsy.*





(Left) *Coronal T2WI MR in a newborn infant shows a huge neck mass with relatively low signal intensity (indicating high cellularity) without extension into the brain.* **(Right)** *Coronal T1WI C+ FS MR in the same patient shows the huge mass enhances heterogeneously. Immature teratoma with foci of malignant transformation was found at surgery.*





(Left) *Axial T2WI MR shows a significant interval increase in the size of the lesion.* **(Right)** *On axial DWI MR, the left frontal mass appears hyperintense, indicating high cellularity. At surgery, mature teratoma was found.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- 2 major types of germ cell tumor (GCTs)
  - Most common = germinoma (50-70%)
  - Nongerminomatous GCTs
- Nongerminomatous malignant GCTs
  - Teratoma with malignant transformation
  - Embryonal carcinoma
  - Yolk sac tumor (endodermal sinus tumor)
  - Choriocarcinoma

IMAGING

- Location
  - Pineal region most common location
  - May occur in suprasellar location
  - Propensity to hug midline
- MR features
  - Hypo-/isointense to gray matter
  - T1 shortening common (protein, blood, or fat)
  - Heterogeneous enhancement ± CSF spread

TOP DIFFERENTIAL DIAGNOSES

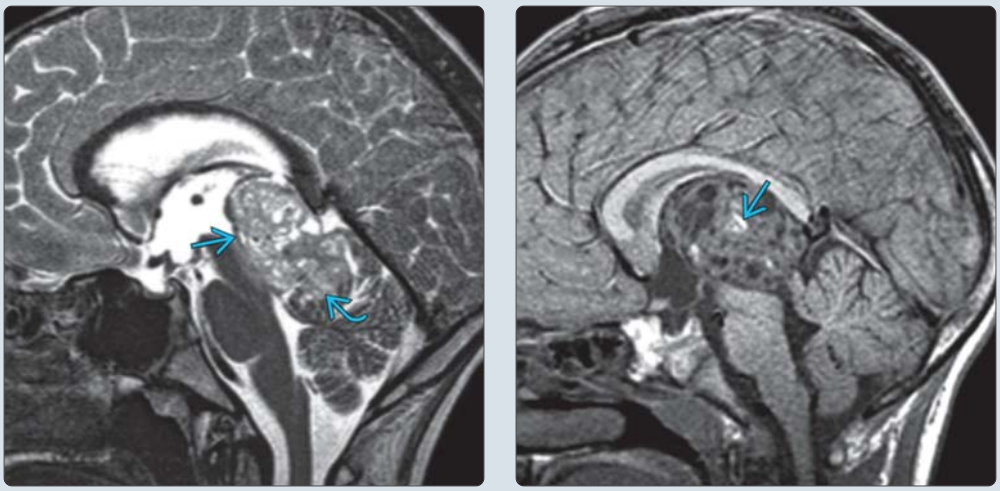
- Germinoma
- Pineoblastoma
- Pineal parenchymal tumor of intermediate differentiation (PPTID)
- Pineocytoma
- Astrocytoma

CLINICAL ISSUES

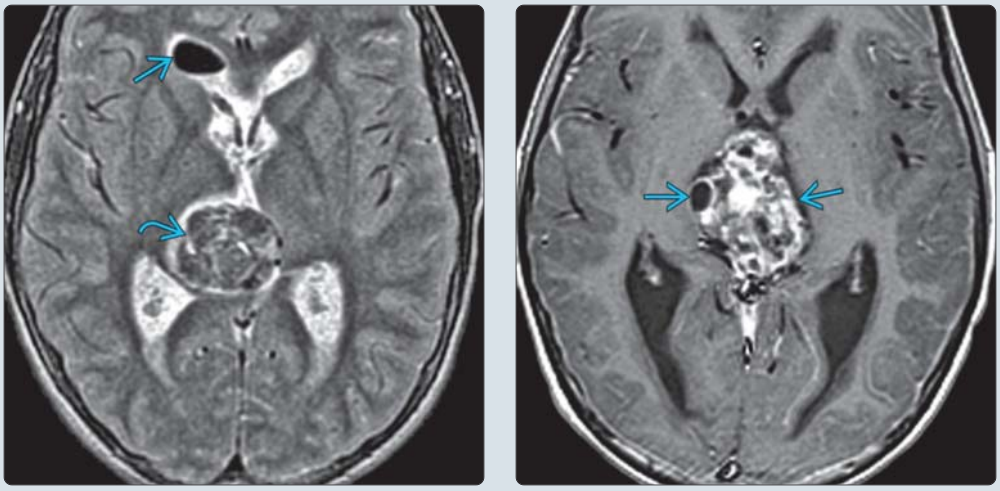
- Peak incidence 10-15 years
- Peripubertal patients (rare < 4 years)
- M:F = 14:1 (purely pineal tumors)
- Visual/endocrine symptoms, Parinaud syndrome
- Signs of hypothalamic/pituitary dysfunction (suprasellar)

DIAGNOSTIC CHECKLIST

- Difficult to differentiate from germinoma on imaging alone



(Left) *Sagittal T2WI FS MR in a 13-year-old boy shows a mixed germ cell tumor (GCT) presenting as a lobulated mixed solid-cystic pineal region mass ⇨ with focal invasion of the vermis ⇨.* **(Right)** *Sagittal T1WI MR in an 8-year-old boy with Parinaud syndrome and embryonal carcinoma shows a heterogeneous mass with foci of T1 shortening that represent hemorrhage ⇨. This tumor, like other intracranial GCTs, tends to hug the midline and may occur as a component of a histologically mixed GCT.*



(Left) *Axial T2 MR of a patient with embryonal carcinoma shows a heterogeneous, hypointense, pineal region mass ⇨. Relatively low signal intensity is due to the high nuclear:cytoplasmic ratio in the cells of this highly malignant neoplasm. Also note the air within the frontal horn following ventricular catheter placement ⇨.* **(Right)** *Axial T1WI C+ MR shows heterogeneous enhancement within a pineal embryonal carcinoma ⇨. Embryonal cell carcinomas often have a worse prognosis than a mixed GCT.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Germ cell tumor (GCT)

Synonyms

- Malignant GCT
- Primary GCT (PGCT)
- Intracranial GCT

Definitions

- Malignant tumor composed of undifferentiated epithelial cells
- Morphological, immunophenotypic homologues of gonadal/extraneuraxial GCTs but in CNS
- 2 major types of GCTs
  - Germinoma (50-70%)
  - Nongerminomatous GCTs (NGGCTs)
    - Embryonal carcinoma
    - Yolk sac tumor (YST)
    - Choriocarcinoma
    - Teratoma
    - Mixed GCT

IMAGING

General Features

- Best diagnostic clue
  - Heterogeneous pineal or suprasellar mass in adolescent
- Location
  - Hugs midline as do other CNS GCTs
  - Brainstem GCT (rare)
- Size
  - Suprasellar, pineal region GCTs usually smaller than hemispheric tumors
- Morphology
  - Typically lobulated, well circumscribed

CT Findings

- NECT
  - Heterogeneous (mixed iso- to hyperdense)
  - ± hydrocephalus
- CECT
  - Enhancing, ± cysts, hemorrhage

MR Findings

- T1WI
  - Hypo- to isointense to gray matter
  - Short T1 due to protein, blood, or fat
- T2WI
  - Iso- to slightly hyperintense to gray matter
- FLAIR
  - Hyperintense solid elements
- T2* GRE
  - Susceptibility artifact (dephasing) from hemorrhagic foci
- DWI
  - ± restriction within solid components
- T1WI C+
  - Heterogeneous enhancement
  - Variable CSF spread
- MRS
  - ↑ choline, lipid, and lactate
  - ↓ NAA

Angiographic Findings

- Variable (can be very vascular)

Imaging Recommendations

- Best imaging tool
  - C+ MR ± MRS
  - Contrast helpful for majority of tumors
- Protocol advice
  - Preoperative MR of **entire** neuraxis

DIFFERENTIAL DIAGNOSIS

Germinoma

- Typically at midline: Pineal, suprasellar, basal ganglia
- Pineal region mass engulfs pineal gland
- Hyperdense on CT
- Strongly enhancing

Pineoblastoma

- Large, lobulated enhancing pineal mass
- Mass effect, parenchymal invasion, CSF spread
- All ages, but commonly in child or adolescent

Pineal Parenchymal Tumor of Intermediate Differentiation (PPTID)

- Often middle-aged, older patients
- Heterogeneous pineal mass
- WHO grade II or III

Pineocytoma

- Enhancing pineal mass in young adult
- Typically < 3 cm
- May be cystic, solid, or mixed
- May mimic pineal cyst or PPTID

Astrocytoma

- May occur in tectum, splenium of corpus callosum
- T2/FLAIR hyperintense
- Variable enhancement, depending on grade

Supratentorial PNET

- Minimal peritumoral edema
- Heterogeneous, enhancing parenchymal mass

PATHOLOGY

General Features

- Etiology
  - Aberrations in
    - Histogenesis
    - Germ cell migration
    - Stem cells
  - 2 possible theories
    - "Germ cell" theory
      - GCTs arise from primordial germ cells that have migrated aberrantly during embryonic development with subsequent malignant transformation
    - "Embryonic cell" theory

https://CafePezeshki.IR

- Mismigrational pluripotent embryonic cells give rise to GCTs
- Genetics
  - Reports of near triploid complex karyotypes
  - *p14* and *KIT* gene alterations in germinomas
  - Homozygous deletion or frameshift mutation of CDKN2A (71% of ICGCTs)
  - Overexpression of CDKN2A
    - Associated with poor prognosis in intracranial GCTs
- Associated abnormalities
  - Klinefelter syndrome (47XXY)
  - Down syndrome

Staging, Grading, & Classification

- Several types of nongerminomatous GCTs
  - Teratoma (mature, immature, malignant transformation)
  - Yolk sac tumor (endodermal sinus)
  - Embryonal carcinoma
  - Choriocarcinoma
- Malignant GCTs often histologically mixed
  - May exist with both germinomatous, other nongerminomatous GCTs
  - Prognosis correlated with most malignant component
    - Choriocarcinoma, yolk sac tumor, embryonal carcinoma elements have worst prognosis

Gross Pathologic & Surgical Features

- Soft, often friable mass

Microscopic Features

- Undifferentiated epithelial cells
- YST: Delicate fibrovascular projections forming distinct papillae (Schiller-Duval bodies)
- Embryonal carcinoma: Large anaplastic cells with epithelial features and abundant mitoses
- Choriocarcinoma: Extraembryonic differentiation
- Other GCTs usually mixed

Special Immunohistochemical Markers

- Human chorionic gonadotropin (hCG): Choriocarcinoma
- α-fetoprotein (AFP): Teratoma, yolk sac tumor
- Human placental alkaline phosphatase (PLAP): Germinoma, embryonal carcinoma, ± YST, choriocarcinoma
- Cytokeratin: May be seen in all GCTs
- C-Kit (CD117): Germinoma, ± teratoma
- OCT4 (POU5F1): Germinoma, embryonal carcinoma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Signs of hypothalamic/pituitary dysfunction
  - ↑ intracranial pressure from suprasellar or pineal region mass
  - Other signs/symptoms
    - Visual, endocrine symptoms
    - Parinaud syndrome (paralysis of upward gaze)
  - Brainstem GCT: Pulmonary complaints, cranial neuropathies
- Other signs/symptoms
  - Choriocarcinoma: High serum and CSF hCG
- Clinical profile
  - Adolescent with obstructing midline mass in vicinity of 3rd ventricle, ± focal neuro deficits

Demographics

- Age
  - Strong predilection for peripubertal patients
    - Peak incidence 10-15 years
    - Rare < 4 years
- Gender
  - Males show slight increased incidence for pineal region
    - When purely pineal tumors, M:F = 14:1
  - Female predominance in suprasellar cases
- Ethnicity
  - More common in Asians
    - In Japan 1.8-3% of all primary brain tumors are GCT (in patients < 15 years, 15%)
- Epidemiology
  - Rare (0.3-3.4% of all CNS tumors)
  - Teratoma is leading perinatal brain tumor
    - Accounts for 42% of fetal brain tumors

Natural History & Prognosis

- Locally invasive with metastatic potential
- Follow-up: PLAP, cytokeratin markers
- Yolk sac tumor
  - Median survival: < 2 years
  - 5-year survival rate: < 25%
- Choriocarcinoma is most malignant intracranial GCT
  - High risk of hemorrhage
  - Extraneural/CSF dissemination

Treatment

- Surgical resection → chemotherapy → neuraxis radiation
- Combination of pre- and postirradiation chemotherapy: Improved survival

DIAGNOSTIC CHECKLIST

Consider

- Embryonal carcinoma if heterogeneous pineal region or suprasellar mass in adolescent
- Metastasis of embryonal carcinoma from testicular source
- Metastasis of choriocarcinoma from other source in patients with cerebral hemorrhage and multiple pseudoaneurysms

Image Interpretation Pearls

- Difficult to differentiate from other CNS GCTs on imaging alone

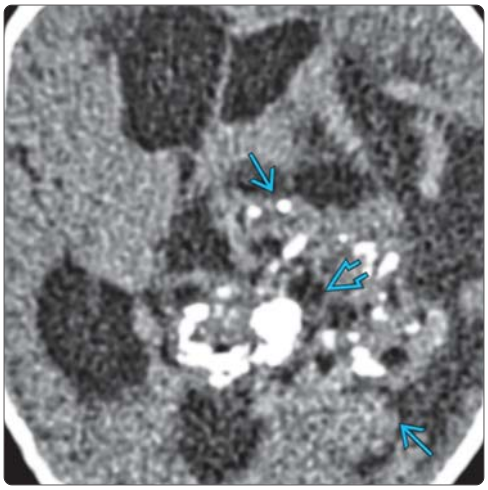
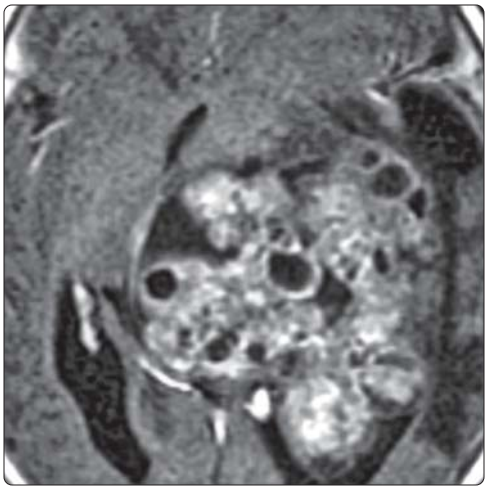
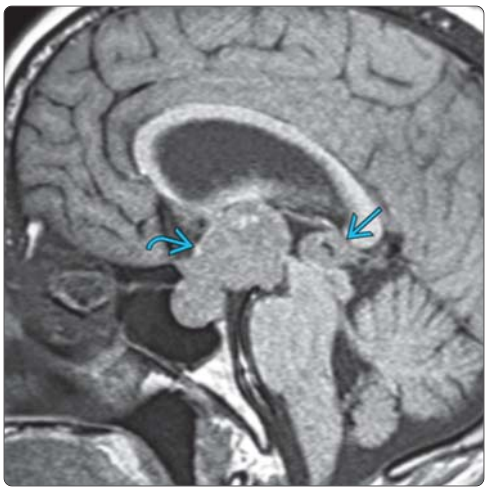
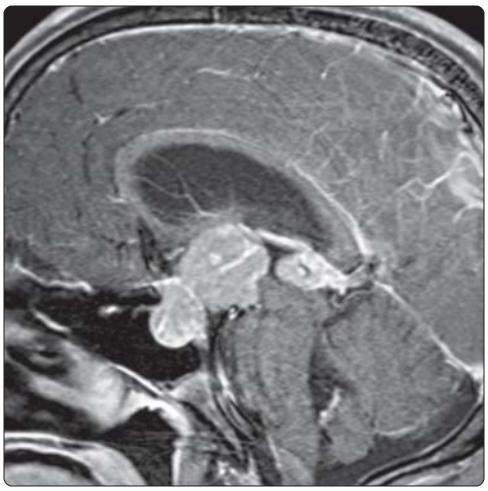
(Left) *Sagittal T1WI MR in a 5-year-old boy shows a well-circumscribed, lobulated, low signal intensity, midline, pineal region mass with a small cystic component. (Courtesy A. Rossi, MD.)* **(Right)** *Axial T1WI C+ MR in the same patient shows intense, but heterogeneous enhancement of the mass. No evidence of CSF dissemination was identified on preoperative evaluation of the entire neuraxis. Histopathology revealed a yolk sac tumor. (Courtesy A. Rossi, MD.)*





(Left) *Axial NECT shows a lobulated heterogeneous mass centered in the left hypothalamus and causing obstructive hydrocephalus. Note the multiple calcifications, intratumoral cysts and surrounding edema.* **(Right)** *Axial T1WI MR in the same patient demonstrates the very heterogeneous nature of the mass. Foci of enhancing solid tumor intermixed with cysts characterize this neoplasm. An immature teratoma was found at histopathological examination.*





(Left) *Sagittal T1WI MR in a 22-year-old man with headaches, diabetes insipidus, and a hyperdense suprasellar mass on NECT (not shown) reveals a "double midline" mass with a small pineal lesion and a larger sellar and suprasellar mass.* **(Right)** *Sagittal T1WI C+ FS MR in the same patient shows intense but heterogeneous enhancement. Preoperative diagnosis was germinoma. Biopsy disclosed embryonal carcinoma, a highly malignant neoplasm.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Secondary brain tumors (metastases) arise from
  - Tumors outside CNS spreading to CNS (usually via hematogenous dissemination)
  - Primary CNS neoplasms spreading from one site to another (usually geographic extension, e.g., along WM tracts)

IMAGING

- General features
  - Round enhancing lesion(s) at gray-white interface (arterial border zones)
  - Most metastases are circumscribed/discrete > > infiltrating, spherical > > linear
  - 50% are solitary; 20% have 2 metastases
  - 30% of patients have 3 or more
- MR signal intensity varies with
  - Cellularity, nuclear:cytoplasmic ratio
  - Presence/absence of hemorrhage
- Usually no restriction on DWI
  - Exception: Densely cellular metastases may restrict

TOP DIFFERENTIAL DIAGNOSES

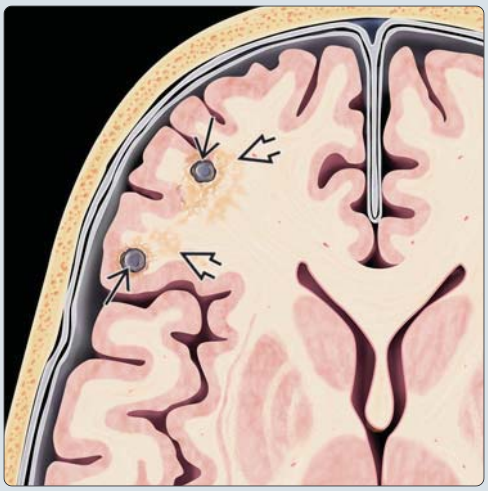
- Abscess (solitary or multiple)
- Glioblastoma multiforme
- Cerebral infarction (multiple embolic)
- Demyelinating disease (e.g., tumefactive MS)

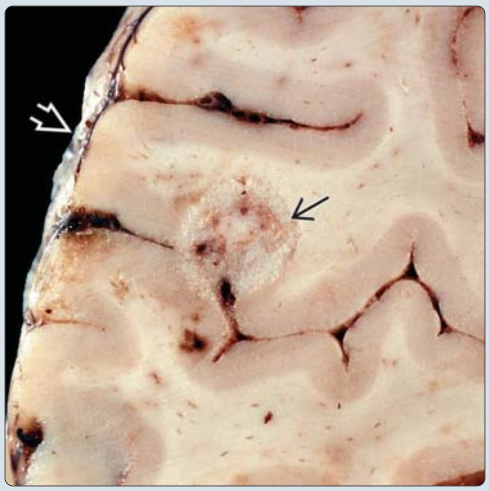
PATHOLOGY

- Metastases represent at least 50% of all brain tumors
- In 10% of cases, brain is only site

CLINICAL ISSUES

- Progressive increase in size and numbers is typical
- Median survival with whole brain XRT = 3-6 months
- Stereotactic radiosurgery alone > whole brain XRT
- Survival advantage if 1-4 metastases, avoids deleterious effects of whole brain XRT on quality of life, cognition
- Resection of solitary metastasis may improve survival





(Left) *Axial graphic shows parenchymal metastases ⇨ with surrounding edema ⇨. The gray-white matter junction is the most common location. Most metastases are round, not diffusely infiltrating.* **(Right)** *Close-up view of an axial section through an autopsied brain shows a classic metastasis ⇨ in the classic location, the gray-white matter junction. Note the round shape, central necrosis, and relative lack of edema. Diffuse leptomeningeal metastatic spread ⇨ is also present.*

(Left) *Axial T2WI MR in a 52-year-old man with a seizure, history of melanoma, shows multiple lesions ⇨ at the gray-white matter interfaces. Moderate edema surrounds the lesions. One of the lesions has a hypointense nodule ⇨ suggesting at least one is a hemorrhagic metastasis.* **(Right)** *Axial T1 C+ FS MR in the same patient shows the parenchymal lesions enhance ⇨. Note small metastasis ⇨ in the choroid plexus of the right lateral ventricle that was not appreciated on T2WI.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Parenchymal metastases (mets)

Definitions

  - Tumors outside CNS that spread to CNS (usually via hematogenous dissemination)
  - Primary CNS neoplasms that spread from one site to another (usually geographic spread, e.g., along white matter [WM] tracts)

IMAGING

General Features

- Best diagnostic clue
  - Discrete enhancing lesion(s) at gray-white interface
- Location
  - Common: At arterial border zones/gray-white matter (GM-WM) junctions
    - 80% hemispheres
    - 15% cerebellum
    - 3% basal ganglia
    - < 1% midbrain, pons, medulla
  - Uncommon
    - Only 5% deep white matter
  - Rare
    - Diffusely infiltrating tumors ("carcinomatous encephalitis")
      - Perivascular (e.g., intravascular lymphoma)
      - Perineural (e.g., adenocystic carcinoma along CN5 to pons)
- Morphology
  - Most mets are circumscribed/discrete > > infiltrating, spherical > > linear
  - 50% of metastases are solitary
  - 20% 2 metastases
  - 30% 3 or more

CT Findings

- NECT
  - Iso-/hypodense mass(es) at GM-WM interface
  - Variable peritumoral edema (none to striking)
  - Variable intracranial hemorrhage (ICH)
    - Mets may cause "spontaneous" ICH in elderly
- CECT
  - Intense, punctate, nodular, or ring enhancement
  - Conspicuity, number, volume of tumors may increase on delayed scans

MR Findings

- T1WI
  - Most common: Iso-/hypointense
  - Less common: Hyperintense
    - Some nonhemorrhagic mets (e.g., melanoma) have intrinsically short T1
    - Hemorrhagic metastases
      - Disordered/bizarre appearance, evolution (compared to nonneoplastic ICH)
- T2WI
  - Signal varies depending on
    - Cellularity, nuclear:cytoplasmic ratio
    - Presence/absence of hemorrhage
  - Multifocal hyperintense mets mimic vascular WM disease
- FLAIR
  - Usually moderately hyperintense with strikingly hyperintense adjacent edema
- T2* GRE
  - "Blooms" if hemorrhage present
- DWI
  - Usually no restriction on DWI
    - Exception: Densely cellular mets may restrict
- T1WI C+
  - Almost all mets enhance
    - Enhancement usually strong
    - Patterns variable
      - Solid, uniform
      - Nodular
      - Ring-like
  - Dynamic susceptibility contrast-enhanced MR
    - May show elevated rCBV
    - Can be difficult to distinguish metastasis from high-grade glioma on standard imaging
      - rCBV in adjacent brain higher for glioma than metastasis
- MRS
  - Elevated Cho
  - Lipid or lipid/lac peak often present
  - 80-85% lack Cr peak
- DTI
  - Fractional anisotropy helpful in distinguishing met from glioblastoma multiforme (GBM)
  - Tractography may help detect WM tract invasion

Nuclear Medicine Findings

- PET
  - PET/CT helpful for systemic mets
    - Not as sensitive as MR for brain parenchymal lesions
  - PET/MR
    - May be superior for melanoma staging

Imaging Recommendations

- Best imaging tool
  - MR with DWI, T2*, T1WI C+
- Protocol advice
  - T1WI C+ with FS enhances lesion conspicuity
  - 3D MP-RAGE sequence may improve detection
  - T2 C+ FLAIR may show more small (< 3 mm) lesions
  - Delayed sequences at 20-30 minutes often show additional lesions
  - Double- or triple-contrast dose increases sensitivity but of questionable value on routine basis

DIFFERENTIAL DIAGNOSIS

Abscess

- Usually restricts on DWI
- MRS: Elevated amino acids, lactate in cystic component; no Cho elevation

https://CafePezeshki.IR

Glioblastoma Multiforme

- Tends to be infiltrating, deep location (rather than discrete gray-white junction masses)
- Solitary > multifocal
  - Solitary met can mimic GBM

Multiple Embolic Cerebral Infarction

- Arterial border-zone location common
- Ring-enhancing pattern uncommon
- Multiple acute embolic strokes usually show restricted diffusion
- Chronic-appearing hyperintensities
  - If they do not enhance, they are not metastases

Multiple Sclerosis

- Periventricular > gray-white junction
- Incomplete ring, horseshoe-shaped enhancement
- Younger patients

PATHOLOGY

General Features

- Etiology
  - Hematogenous spread from systemic primary neoplasm
    - Lung, breast, melanoma most common primary malignancies
    - 10% unknown source
- Genetics
  - Metastasis formation is complex, often genetically mediated event
    - Inactivation of tumor suppressor genes
    - Activation of protooncogenes
- Associated abnormalities
  - Other organs often involved
  - In 10% of cases, brain is only site
  - Limbic encephalitis
    - Paraneoplastic syndrome (remote effect of cancer)
    - Resembles herpes encephalitis (subacute clinical presentation)

Gross Pathologic & Surgical Features

- Round/confluent, relatively discrete, tan or grayish-white mass
- Edema, mass effect varies from little to striking
- Hemorrhage common with some mets (melanoma, choriocarcinoma, lung/renal cell carcinomas)

Microscopic Features

- Usually similar to primary neoplasm
- Metastases usually displace rather than infiltrate tissue
- Necrosis, neovascularity common
- Marked mitoses; labeling index may be greater than primary

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizure, focal neurologic deficit
- Clinical profile
  - Middle-aged/elderly patient with known systemic cancer, new onset of neurological symptoms

Demographics

- Age
  - Incidence increases with age
    - Rare in children (skull/dura more common site than parenchyma)
    - Peak prevalence over 65 years
- Gender
  - Slight male predominance
- Epidemiology
  - With better treatment, patients with systemic cancers are surviving longer
    - Mets now most common CNS tumors in adults
  - Result
    - Prevalence of metastases vs. primary CNS neoplasms increasing
    - Now account for up to 50% of all brain tumors
    - Brain involvement is found in 25% of systemic cancer patients at autopsy

Natural History & Prognosis

- Progressive increase in size and numbers is typical
- Median survival with whole brain XRT = 3-6 months
  - Younger age, high Karnofsky performance status associated with longer survival

Treatment

- Stereotactic radiosurgery alone > whole brain XRT
  - Survival advantage if 1-4 mets, avoids deleterious effects of whole brain XRT on quality of life, cognition
- Resection of solitary metastasis may improve survival

DIAGNOSTIC CHECKLIST

Consider

- Spontaneous ICH or new onset seizures in elderly patient may be caused by metastasis

Image Interpretation Pearls

- White matter disease (UBOs) in elderly patient can be caused by multifocal metastases
- Consider T1WI C+ in patients with WM disease, unexplained mental decline

(Left) *Axial T2WI MR shows a solitary metastasis from lung carcinoma in the right frontal lobe ⇨. A large amount of edema surrounds the lesion and there is significant subfalcine herniation of the lateral ventricle secondary to the mass effect.* **(Right)** *Axial T1 C+ FS in the same patient shows the solitary parenchymal metastasis has a cyst ➡ + nodule ➡ configuration. Close inspection of the image shows ependymal enhancement along the wall of the right lateral ventricle ➡.*
