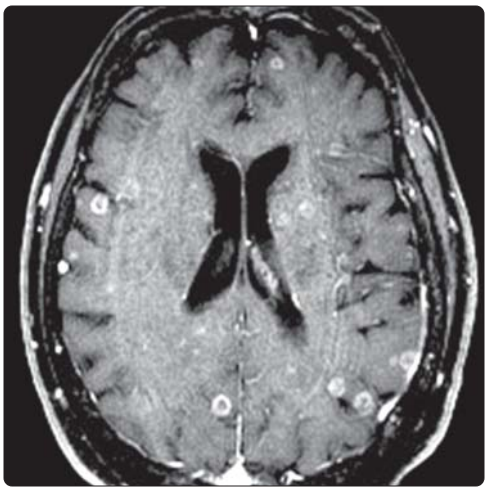
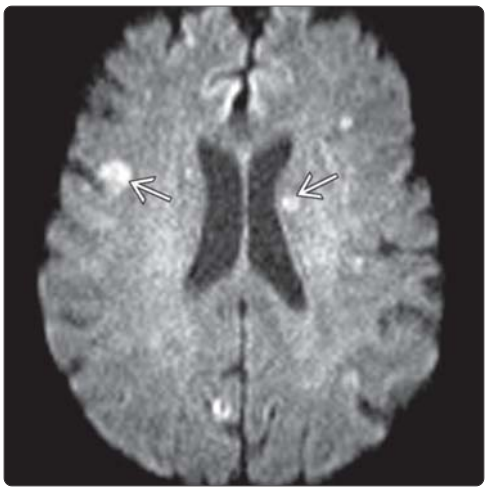
(Left) *Axial T2WI MR in a middle-aged patient with unexplained mental decline and normal neurologic examination shows multifocal white matter hyperintensities (WMHs) ➡. These are indistinguishable from the usual WMHs of small vessel disease, most commonly arteriolosclerosis.* **(Right)** *Axial T1WI C+ MR in the same patient demonstrates that several of the WMHs enhance ➡. Other images (not shown) revealed several subependymal enhancing foci. Further evaluation revealed breast carcinoma.*





(Left) *Axial T1WI C+ FS MR in a 70-year-old woman with breast cancer shows multiple punctate and ring-enhancing lesions.* **(Right)** *Axial DWI MR in the same patient shows several foci of restricted diffusion ➡ that were hypointense on ADC (not shown). Most neoplasms do not restrict, but metastases often have a high nuclear to cytoplasm ratio and sometimes show restricted diffusion.*

KEY FACTS

TERMINOLOGY

- Brain metastases in locations other than skull/meninges or parenchyma

IMAGING

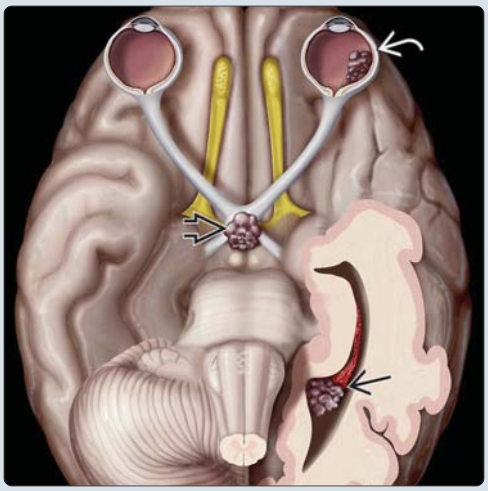
- General features
  - > 95% of brain metastases parenchymal
  - Only 1-2% in ventricles, pituitary gland, etc.
  - Sites generally very vascular
  - Extraventricular metastases more diffuse, infiltrative than parenchymal mets (usually round)
- Location
  - Choroid plexus ± ventricular ependyma
  - Pituitary gland infundibulum
  - Eye (choroid)
  - Cranial nerves
  - Pineal gland
  - Preexisting neoplasm ("collision tumor")
- Best imaging tool: MR with T1WI C+ FS
  - Metastases almost always enhance

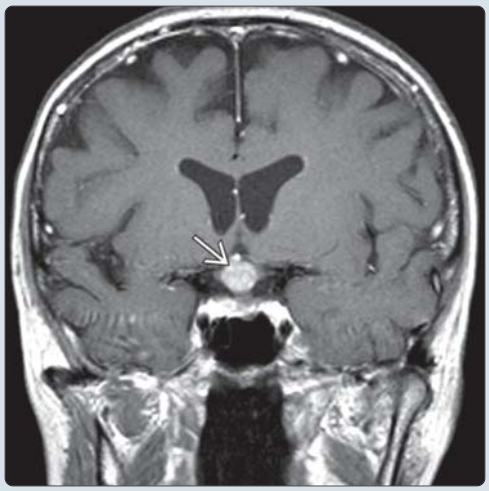
TOP DIFFERENTIAL DIAGNOSES

- Varies with location
- Choroid plexus, ventricle = meningioma
- Pituitary gland, infundibular stalk
  - Pituitary macroadenoma
  - Lymphocytic hypophysitis
  - Lymphoma
- Cranial nerves = NF2, lymphoma
- Eye (globe)
  - Ocular melanoma
  - Retinal or choroidal detachment
  - Choroidal hemangioma

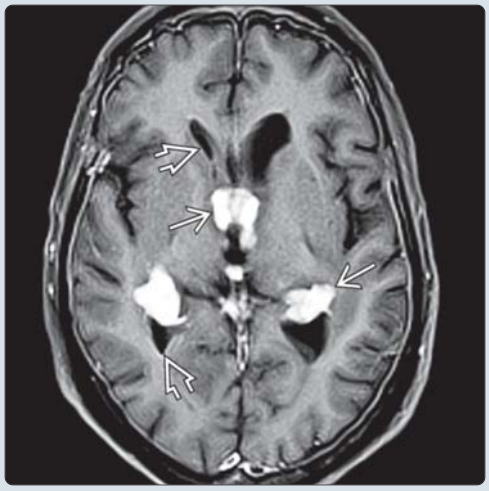
DIAGNOSTIC CHECKLIST

- Look for "secret sites" outside parenchyma when imaging brain for possible metastatic disease





(Left) *Submentovertex graphic shows the typical sites for miscellaneous nonparenchymal CNS metastases. These include the choroid plexus and ventricles ⇨, pituitary gland, infundibular stalk ⇨, and eye (choroid of the retina) ⇨.* **(Right)** *Coronal T1WI C+ MR in an elderly woman with known breast carcinoma shows a thickened, enhancing infundibular stalk ⇨. This was the only intracranial metastasis identified in this patient.*



(Left) *Axial T1 C+ FS in a patient with diplopia and known esophageal cancer shows an enhancing nodule on the left 3rd cranial nerve ⇨, as well as on the left optic nerve/sheath ⇨. Cranial nerve metastases from extracranial tumors are less common than from hematopoietic neoplasms (e.g., lymphoma).* **(Right)** *Axial T1 C+ FS in a patient with systemic B-cell lymphoma shows multiple metastases to the choroid plexus ⇨. Subtle ependymal metastases ⇨ are present along with diffuse dura-arachnoid thickening.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Brain metastases in locations other than skull/meninges, parenchyma

IMAGING

General Features

- Best diagnostic clue
  - "Unusual" mass in patient with known systemic primary neoplasm
- Location
  - In general, sites very vascular
  - Choroid plexus ± ventricular ependyma
  - Pituitary gland, infundibulum
  - Cranial nerves
  - Eye (uvea)
    - Usually late stage, disseminated disease, poor prognosis
  - Pineal gland
  - Preexisting neoplasm ("collision tumor")
    - 2 unique tumor types within single lesion
    - Metastasis to meningioma most common
- Morphology
  - Often more diffuse, infiltrative than round parenchymal metastases

Imaging Recommendations

- Best imaging tool
  - MR with T1WI C+ FS

DIFFERENTIAL DIAGNOSIS

Choroid Plexus, Ventricle

- Meningioma
- Choroid plexus cyst (xanthogranuloma)
- Ventriculitis/choroid plexitis

Pituitary Gland, Infundibular Stalk

- Pituitary macroadenoma
- Lymphocytic hypophysitis
- Lymphoma

Cranial Nerves (Multiple Enhancing)

- Lymphoma
  - May be indistinguishable from other metastases
  - CNs, brain surface often coated
- Neurofibromatosis type 2
- Lyme disease
- Chronic inflammatory demyelinating polyneuropathy

Eye (Globe)

- Ocular melanoma
  - Most ocular melanomas are choroidal
  - Ciliary body, iris lesions less common
- Retinal or choroidal detachment
  - Retina is V-shaped
  - Choroid is ovoid, parallel to choroidal plane
- Choroidal hemangioma
  - Middle-aged/elderly patients
  - Lenticular mass in juxtapapillary or macular region
  - Can be solitary or diffuse
  - Avid enhancement (> metastasis, melanoma)

PATHOLOGY

General Features

- Etiology
  - Extracranial primary sources
    - Breast carcinoma most common
    - Others include lung, kidney, colon
  - Intracranial sources of "brain-to-brain" metastases
    - Glioblastoma multiforme, anaplastic astrocytoma most common
      - White matter > extraparenchymal sites
- Associated abnormalities
  - Other CNS metastases (often multifocal)
    - Parenchyma
    - Pia-subarachnoid space
    - Skull, meninges
  - Systemic metastases
    - Often multiorgan
    - In 10% of cases, brain is only metastatic site

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Varies with location

Demographics

- Age
  - Middle-aged, older patients
- Epidemiology
  - > 95% of brain metastases parenchymal
  - Only 1-2% found in ventricles, pituitary gland, etc.

DIAGNOSTIC CHECKLIST

Consider

- Metastasis in middle-aged or older patient with intraventricular or intraocular mass

Image Interpretation Pearls

- Look for "secret sites" outside parenchyma when imaging brain for possible metastatic disease

KEY FACTS

TERMINOLOGY

- Secondary involvement of CNS in patients with systemic lymphoma

IMAGING

- Secondary CNS lymphoma: Skull, dura, leptomeninges >> parenchymal mass
- Best diagnostic clue: Diffusely enhancing dural mass ± bone involvement
  - May see leptomeningeal enhancement or nonsupression of CSF on FLAIR; CT hyperdensity
- Lower rCBV than other tumors

TOP DIFFERENTIAL DIAGNOSES

- Meningioma
- Meningeal metastases
- Primary CNS lymphoma
- Leptomeningeal disease
- Hemangiopericytoma

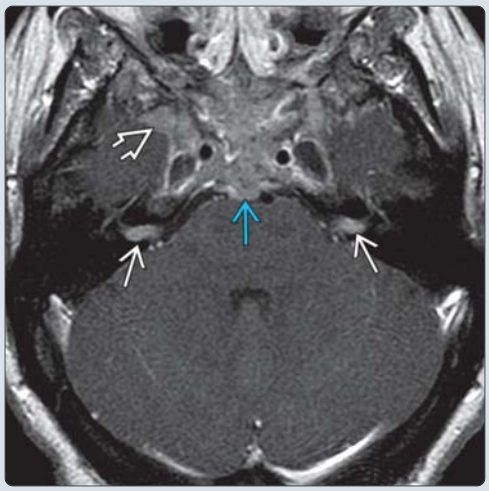
CLINICAL ISSUES

- Prognostic markers suggestive of CNS relapse
  - Elevated serum lactate dehydrogenase (LDH) levels
  - Presence of B symptoms
  - Extranodal involvement at more than 1 site
  - Advanced stage
- Aggressive histologic features increase risk for SCNSL
- Involvement of liver, bladder, testis, or adrenals increases risk of CNS spread
- CNS involvement of lymphoma almost always fatal
- Prophylactic CNS chemotherapy recommended for patients considered at high risk of CNS recurrence

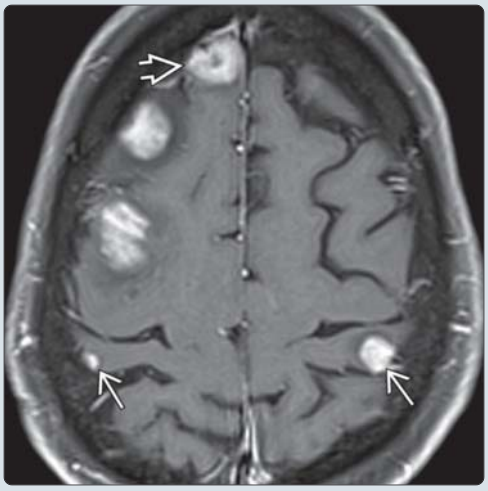
DIAGNOSTIC CHECKLIST

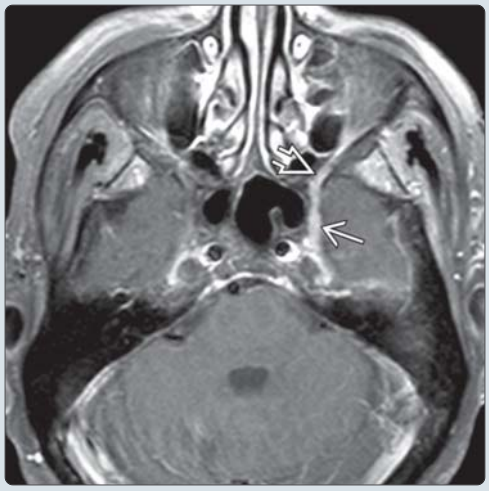
- Occult lymphoma found in 8% of patients presenting with CNS lymphoma
- SCNSL commonly mimics meningioma or other metastatic disease

(Left) *Axial CECT shows extensive dural enhancement related to metastatic intracranial lymphoma. Secondary lymphoma has a propensity for the meninges. About 1/3 of systemic lymphoma patients develop CNS disease.* **(Right)** *Axial T1 C+ MR shows an enhancing central skull base mass with associated dural and leptomeningeal enhancement within the internal auditory canals. The clivus is often involved by metastatic disease, particularly breast cancer and lymphoma.*



(Left) *Axial T1 C+ MR in a 54-year-old man with systemic lymphoma shows multiple enhancing masses. Some lesions involve the dura, while others are parenchymal. Metastatic intracranial lymphoma often involves the dura and may mimic a meningioma.* **(Right)** *Axial T1WI C+ FS MR shows enhancement along the maxillary division (V2) of CN5, extending from the cavernous sinus into the pterygopalatine fossa, in this patient with systemic lymphoma and new facial paresthesias.*





https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Secondary CNS lymphoma (SCNSL)

Definitions

- Secondary involvement of CNS in patients with systemic lymphoma

IMAGING

General Features

- Best diagnostic clue
  - Enhancing dural mass ± bone involvement
- Location
  - Typically involves dura or leptomeninges
  - Parenchymal lesions may occur
  - Peripheral nerve = neurolymphomatosis
  - Spine involvement: ~ 3-5%
- Morphology
  - Solitary mass or multiple lesions
  - May be circumscribed or infiltrative

Imaging Recommendations

- Protocol advice
  - Contrast-enhanced MR

MR Findings

- T1WI
  - Single or multiple iso- or hypointense mass(es)
- T2WI
  - Homogeneously iso- or hypointense to cortex
- FLAIR
  - Leptomeningeal: Nonsuppression of CSF in sulci
- PWI
  - Lower rCBV than other tumors
- T1WI C+
  - Diffusely enhancing dural mass ± bone changes
  - May see leptomeningeal enhancement

DIFFERENTIAL DIAGNOSIS

Meningioma

- Enhancing mass with dural tail in older women
- Often solitary
- May be indistinguishable

Meningeal Metastases

- Prostate and breast primaries may cause dural metastases
- Calvarial erosion may be seen

Primary CNS Lymphoma

- Periventricular or basal ganglia-enhancing mass
- Typically DWI+
- May rarely present as dural mass

Leptomeningeal Disease

- Infectious meningitis usually diagnosed clinically
- Carcinomatous meningitis indistinguishable

Hemangiopericytoma

- Lobular extraaxial mass ± skull erosion
- Heterogeneous enhancement typical

PATHOLOGY

General Features

- Etiology
  - Secondary involvement of CNS in patients with systemic lymphoma (typically systemic B-cell lymphomas 80%)
  - CNS involvement occurs in 22% of post-transplantation lymphomas

Staging, Grading, & Classification

- Highly aggressive lymphomas (i.e., lymphoblastic and Burkitt) carry high risk of CNS relapse
- Intermediately aggressive subtypes (i.e., diffuse large B-cell lymphoma) carry lower risk of CNS relapse
- Hodgkin disease uncommon

Gross Pathologic & Surgical Features

- Typically firm dural mass
- Parenchymal mass less common

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, altered mental status
- Clinical profile
  - Polymerase chain reaction (PCR) and flow cytometry assays of CSF useful for correct diagnosis

Demographics

- Age
  - Typically 6th-7th decade

Natural History & Prognosis

- Prognostic markers suggestive of CNS relapse of lymphoma
  - Elevated serum lactate dehydrogenase (LDH) levels
  - Presence of B symptoms
    - Fever, night sweats, weight loss
  - Extranodal involvement at more than 1 site
  - Advanced stage
- Aggressive histologic features increase risk for SCNSL
- Involvement of liver, bladder, testis, or adrenals increases risk of CNS spread
- CNS involvement is almost always fatal

Treatment

- Prophylactic CNS chemotherapy for patients considered at high risk of CNS recurrence

DIAGNOSTIC CHECKLIST

Consider

- Occult systemic lymphoma found in 8% of patients presenting with CNS lymphoma

KEY FACTS

TERMINOLOGY

- Remote neurological effects of cancer, associated with extra-CNS tumors
  - Most common tumor: Small cell lung carcinoma
- Limbic encephalitis (LE) is most common clinical paraneoplastic syndrome

IMAGING

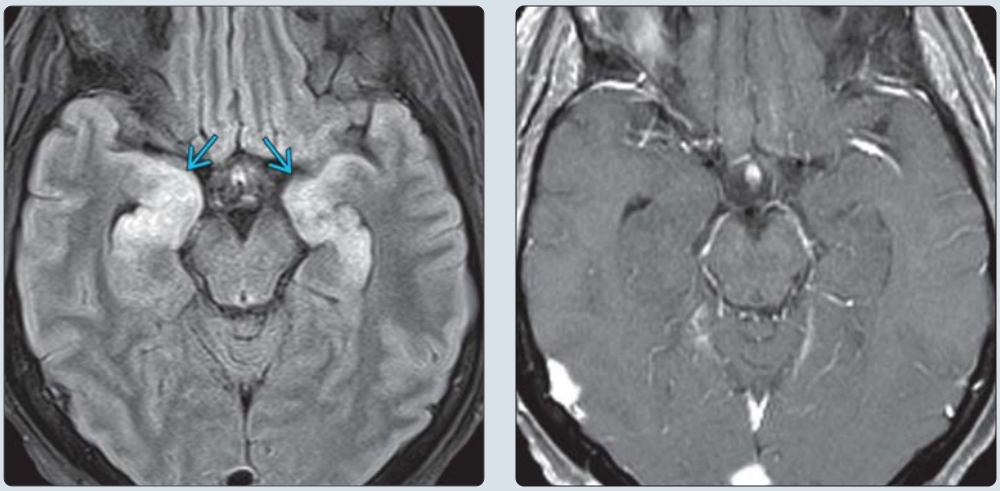
- Limbic encephalitis: Hyperintensity in mesial temporal lobes, limbic system
  - Mimics herpes encephalitis but subacute/chronic
- Paraneoplastic cerebellar degeneration (PCD): Cerebellar atrophy
- Brainstem encephalitis: T2 hyperintensity in midbrain, pons, cerebellar peduncles, basal ganglia
- Most paraneoplastic syndromes do not have associated imaging findings

TOP DIFFERENTIAL DIAGNOSES

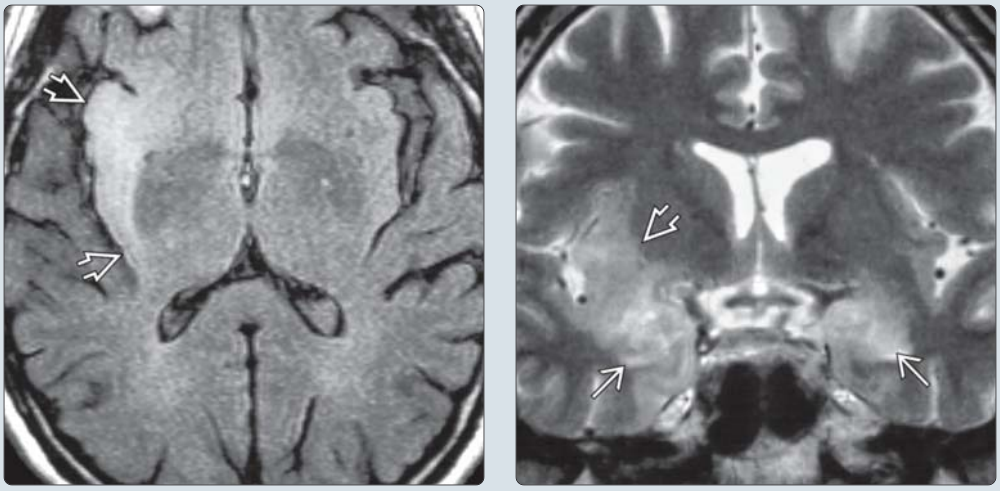
- Herpes encephalitis
- Low-grade (grade II) diffuse astrocytoma
- Status epilepticus
- Gliomatosis cerebri

CLINICAL ISSUES

- < 1% of patients with systemic cancers develop paraneoplastic syndrome
- Immune-mediated by autoantibodies or cytotoxic T cell-related mechanisms
  - 60% have circulating serum autoantibodies
- LE: Memory loss, cognitive dysfunction, dementia, psychological features, seizures
- PCD: Ataxia, incoordination, dysarthria, nystagmus
- Brainstem encephalitis: Brainstem dysfunction including cranial nerve palsies, visual changes
- Treatment of primary tumor may improve symptoms



(Left) *Axial FLAIR MR shows abnormal hyperintensity in the bilateral medial temporal lobes, characteristic of limbic encephalitis, the most common paraneoplastic syndrome. Bilateral involvement is typical of limbic encephalitis.* **(Right)** *Axial T1WI C+ MR in the same patient shows no significant enhancement in the medial temporal lobes. Enhancement is often present in limbic encephalitis. The patient's symptoms often improve after treatment of the primary tumor.*



(Left) *Axial FLAIR MR in an older adult with small cell lung cancer and subacute dementia shows striking hyperintensity in the right insula.* **(Right)** *Coronal T2WI in the same patient shows abnormal hyperintensity in both medial temporal lobes and right insular cortex. Imaging of limbic encephalitis mimics that of herpes encephalitis; however, patients with limbic encephalitis have a subacute presentation. Hemorrhage suggests herpes rather than limbic encephalitis.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Paraneoplastic syndromes (PS), paraneoplastic disease

Definitions

- Remote neurological effects of cancer, associated with extra-CNS tumors
  - Most common tumor: Small cell lung carcinoma
- Limbic encephalitis (LE) is most common clinical paraneoplastic syndrome
  - Only PS with clearly defined imaging features

IMAGING

General Features

- Best diagnostic clue
  - Limbic encephalitis: Hyperintensity in mesial temporal lobes, limbic system
    - Looks like herpes encephalitis but different clinical course (subacute vs. chronic)
  - Initial study normal in 20-40%
- Location of LE: Hippocampus, amygdala, cingulate gyrus, pyriform cortex, subfrontal cortex, insula

CT Findings

- NECT: Initial CT scan normal in > 95%
  - Rare: Low density within mesial temporal lobes
- CECT: Usually no visible enhancement

MR Findings

- T1WI
  - Hypointensity in mesial temporal lobes (hippocampus, amygdala), insula, cingulate gyrus, subfrontal cortex, inferior frontal white matter (WM)
  - May see minimal mass effect
  - May see atrophy in chronic cases
  - No hemorrhage
- DWI
  - Diffusion restriction rare
- T2WI: Hyperintensity in mesial temporal lobes (hippocampus, amygdala), insula, cingulate gyrus, subfrontal cortex, inferior frontal WM
  - May see minimal mass effect
- FLAIR: Hyperintensity in temporal lobes, insula, cingulate gyrus, subfrontal cortex, inferior frontal WM
- T2* GRE: No hemorrhage
  - If blood products seen, consider herpes encephalitis
- T1WI C+: Patchy enhancement common
- Brainstem encephalitis: T2 hyperintensity in midbrain, pons, cerebellar peduncles, basal ganglia
- Paraneoplastic cerebellar degeneration (PCD): Cerebellar atrophy

Nuclear Medicine Findings

- FDG PET: Increased glucose metabolism in medial temporal lobes in LE patients

Imaging Recommendations

- Protocol advice
  - Contrast-enhanced MR with coronal T2 or FLAIR
  - Consider repeat MR if initial scan normal with high clinical suspicion

DIFFERENTIAL DIAGNOSIS

Herpes Encephalitis

- T2 hyperintensity in temporal lobes, limbic system
- Mass effect common; restricted DWI common
- Rapid onset, febrile illness
- HSV titers (CSF, serum) may be negative early
- Late acute/subacute may hemorrhage
- May be indistinguishable from limbic encephalitis

Low-Grade (Grade II) Diffuse Astrocytoma

- Unilateral T2 hyperintense mass
- May involve medial temporal lobe
- No enhancement typical

Status Epilepticus

- Seizures may cause abnormal T2/FLAIR of mesial temporal lobes
- Cortical enhancement with DWI is typical
- Clinical history of seizures

Gliomatosis Cerebri

- Diffuse process, no predilection for limbic system
- T2 hyperintensity in multiple contiguous lobes
- Enlarges affected area

Parenchymal Metastases

- Typically multifocal enhancing lesions
- Primary tumor often known

PATHOLOGY

General Features

- Etiology
  - Immune-mediated by **autoantibodies** or cytotoxic T cell-related mechanisms
  - 60% of patients have circulating serum **autoantibodies**
    - **Anti-Hu** (lung cancer): Limbic encephalitis
    - **Anti-Ta** (testicular germ cell tumors): Limbic encephalitis, brainstem encephalitis
    - **Anti-Yo** (breast and ovarian): Paraneoplastic cerebellar degeneration
    - **Anti-Tr** (Hodgkin disease): Paraneoplastic cerebellar degeneration
    - **Anti-Ri** (lung, breast, ovarian): Opsoclonus myoclonus
  - Reversible extralimbic paraneoplastic encephalopathy
    - Associated with breast cancer and lung cancer
    - Reversible when primary tumors controlled
  - New **cell surface antigens** reported: Voltage-gated potassium channels (**VGKC**) and N-methyl-D-aspartate receptor (**NMDAR**)
    - Associated with other tumors (thymoma, teratoma, Hodgkin lymphoma)
    - Appear to be antibody-mediated and respond better to immunotherapy (90%)
    - Patients may present with limbic encephalitis; more frequently manifest severe psychiatric symptoms, seizures, dyskinesias, autonomic instability, or hypoventilation
  - New antibody to α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (**AMPAR**)
    - Associated with limbic encephalitis

https://CafePezeshki.IR

- – May occur with other antibodies

Staging, Grading, & Classification

- PSs divided into disorders of CNS, peripheral NS, CNS/PNS, neuromuscular junction
  - CNS: Paraneoplastic cerebellar degeneration (PCD), opsoclonus myoclonus, retinopathy
  - Peripheral NS: Sensory-motor neuropathy, autonomic neuropathy
  - Both CNS/PNS: Encephalomyelitis (limbic encephalitis, brainstem encephalitis, myelitis, motor neuron disease)
  - Neuromuscular junction: Lambert-Eaton myasthenic syndrome
- Limbic encephalitis most common PS
  - Nonparaneoplastic limbic encephalitis reported
- PCD is 2nd most common PS
- Multiple PSs may occur in same patient

Gross Pathologic & Surgical Features

- LE: Ill-defined softening, discoloration of gray matter (GM)
  - Hippocampus, cingulate gyrus, pyriform cortex, frontal orbital surface of temporal lobe, insula, amygdala; typically bilateral
- PCD: Cerebellar atrophy, gyral thinning
- Brainstem encephalitis: Brainstem softening

Microscopic Features

- Limbic encephalitis
  - Neuronal loss, reactive gliosis, perivascular infiltration of lymphocytes, microglial nodules
  - No neoplasm and no viral inclusions
- PCD: Purkinje cell loss, microglial proliferation, Bergmann glia hyperplasia, decrease in granule cells
- Brainstem encephalitis: Perivascular inflammatory infiltrates, glial nodules, neuronophagia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - LE: Memory loss, cognitive dysfunction, dementia, psychological features (anxiety, depression, hallucinations), seizures; subacute presentation
  - PCD: Ataxia, incoordination, dysarthria, nystagmus
    - In patients > 50 years, cerebellar degeneration is paraneoplastic in 50% of cases, often precedes remote malignancy
  - Brainstem encephalitis: Brainstem dysfunction including cranial nerve palsies, visual changes
  - In patients with known primary tumor, must exclude other complications
    - Metastases, infection, metabolic disorder, chemotherapy effects
- Clinical profile
  - Up to 60% have no known primary tumor at presentation, many have no tumor found at work-up
  - Identification of antineuronal antibodies in serum or CSF facilitates diagnosis of PS and primary cancer
  - Primary neoplasms
    - Limbic encephalitis
      - Most common: Small cell lung carcinoma
      - Other = GI, GU (ovary > renal > uterus), lymphoma, breast, testicular, thymus, neuroblastoma (pediatric)
      - 90% have positive CSF (pleocytosis, ↑ protein, oligoclonal bands)
      - EEG reveals involvement of temporal lobes
    - Paraneoplastic cerebellar degeneration
      - GU (ovary), breast, lung, lymphoma
    - Opsoclonus myoclonus
      - Neuroblastoma, lung cancer
    - Lambert-Eaton myasthenic syndrome
      - Small cell lung cancer

Demographics

- Age: Occurs at all ages, most commonly adults
- Epidemiology: < 1% of patients with systemic cancers develop paraneoplastic syndrome

Natural History & Prognosis

- Relates to primary neoplasm
- Some reports suggest patients with PSs have more indolent primary tumor growth than those without
- Relates to type of paraneoplastic syndrome
  - Slow long-term cognitive decline (LE)
  - Progressive ataxia, weakness (PCD, spinal cord degeneration)

Treatment

- Treatment of primary malignancy may improve neurologic symptoms of PSs (25-45%)
- Primary neoplasm resected, ± chemoradiation
- Treatment of paraneoplastic syndromes is variable
  - Treatment of primary tumor is best therapy
  - ± steroids, immunoglobulins, plasmapheresis

DIAGNOSTIC CHECKLIST

Consider

- LE is only PS with defined imaging features
- Paraneoplastic syndromes are often clinically evident before diagnosis of primary tumor
- Repeat MR if initial scan normal and high clinical suspicion, as initial MR often normal in LE

Image Interpretation Pearls

- Herpes encephalitis mimics LE on imaging but has acute presentation
  - Patients often initially treated with antiviral therapy until HSV titers final
- Hemorrhage suggests herpes rather than LE

Porencephalic Cyst	646
Neurenteric Cyst	650
Nonneoplastic Tumor-Associated Cysts	652

https://CafePezeshki.IR

General Approach to Brain Cysts

General Considerations

Overview: Cysts are common findings on MR and CT brain scans. There are many types of intracranial cysts, some significant, some incidental. In this section, we exclude cystic neoplasms (such as pilocytic astrocytoma and hemangioblastoma), solid neoplasms that commonly have intratumoral cysts (such as ependymoma), and tumors that often display central necrosis (e.g., glioblastoma).

We also exclude parasitic cysts (neurocysticercosis, hydatid disease) and cystic brain malformations (Dandy-Walker spectrum) from the discussion. Thus, the focus of this particular section is primary nonneoplastic cysts.

Because the etiology, pathology, and clinical importance of nonneoplastic cysts is so varied, classifying them presents a real challenge. Some neuropathologists typically classify cysts according to the histology of the cyst wall. Others group them according to putative origin or pathogenesis.

In a schema based on pathogenesis, cysts may occur as normal anatomic variants (e.g., enlarged perivascular [Virchow-Robin] spaces), congenital inclusion cysts (e.g., dermoid and epidermoid cysts), or lesions derived from embryonic ecto-/endoderm (colloid and neurenteric cysts). Of course, there is a group of miscellaneous cysts (such as choroid plexus cysts and nonneoplastic tumor-associated cysts [TACs]) that does not fit nicely into any category.

Neuroimagers face a very real dilemma: A cystic-appearing lesion is identified on MR or CT. What is it? What else could it be? Histopathology of the cyst wall isn't a practical consideration. What **is** readily apparent is (1) the anatomic location of the cyst; (2) its imaging characteristics (density/signal intensity, presence or absence of calcification, enhancement, etc.); and (3) the patient's age. The recommended initial approach to analyzing brain cysts is anatomy-based.

Anatomy-Based Approach to Brain Cysts

General Considerations

Key features: Four features help the diagnostic approach to cystic-appearing intracranial lesions. The 1st step is to determine if the cyst is intra- or extraaxial. If it is extraaxial, is the cyst supra- or infratentorial? Is it midline or off midline? If a cyst is intraaxial, is it supra- or infratentorial? Is it parenchymal or intraventricular? While many intracranial cysts certainly may occur in more than 1 location, some sites are "preferred" by certain cysts.

Extraaxial Cysts

Supratentorial extraaxial cysts: Nonneoplastic, noninfectious extraaxial cysts can occur in the midline or off midline. Pineal and Rathke cleft cysts occur only in the midline. While dermoid cysts seem to prefer a midline location like the suprasellar cistern, they also occur off midline. Look for rupture with fatty "droplets" in the subarachnoid cisterns.

Arachnoid cysts (AC) are usually off midline. In the supratentorial compartment, midline ACs are relatively rare. The most frequent midline locations are the suprasellar cistern, followed by the quadrigeminal cistern and velum interpositum. Large suprasellar ACs usually present in children and may cause obstructive hydrocephalus.

The most common off midline extraaxial supratentorial cyst is an arachnoid cyst. While these can occur virtually anywhere, the middle cranial fossa is the location of at least 50% of all ACs. Occasionally ACs occur over the cerebral convexities, most commonly over the parietal lobe. ACs follow CSF on all sequences and are differentiated from epidermoid cysts using FLAIR and DWI. ACs suppress completely on FLAIR and do not show diffusion restriction.

Extraaxial tumors, such as meningioma, schwannoma, pituitary macroadenoma, and craniopharyngioma, may be associated with prominent extratumoral cysts. These nonneoplastic TACs occur in both the supra- and infratentorial compartments.

TACs are benign collections of fluid that vary from clear and CSF-like to proteinaceous. TACs are typically positioned between at the tumor-brain interface, between the mass and adjacent cortex. Whether TACs are true arachnoid cysts, obstructed PVSs, or fluid collections mostly lined by gliotic brain is debatable.

Scalp and skull cysts are less common than intracranial cysts. Sebaceous cysts (more accurately termed trichilemmal cysts [TCs]) are a common scalp mass in middle-aged and older patients. Most are identified incidentally on MR and CT scans. TCs can be solitary or multiple, are well-delineated, and vary in size from a few millimeters to several centimeters. The classic finding is a subepidermal scalp tumor in a female over the age of 60 years.

Leptomeningeal cysts, also known as "growing fractures," are a rare but important extraaxial cyst that is most commonly found in the parietal bone. An enlarging calvarial fracture adjacent to post-traumatic encephalomalacia is typical. The vast majority of patients are under 3 years of age. They present with an enlarging, palpable soft tissue mass. Fluid and encephalomalacic brain extrude through torn dura and arachnoid and then through the enlarging linear calvarial fracture. Leptomeningeal cysts are seen as linear lucent skull lesions with rounded, scalloped margins.

Infratentorial extraaxial cysts: Most nonneoplastic cysts in the posterior fossa occur off midline. The 2 major cyst types found in this location are epidermoid and arachnoid cysts.

The cerebellopontine angle (CPA) is by far the most common posterior fossa sublocation of an epidermoid cyst (EC). Occasionally, an EC occurs in the 4th ventricle. A 4th ventricular EC can mimic a trapped, dilated 4th ventricle, but ECs do not suppress on FLAIR and usually exhibit some degree of restricted diffusion.

The next most common posterior fossa cyst is AC. While ACs can also occur in the midline cisterna magna, the cerebellopontine angle is the most common site. TACs sometimes occur in the CPA cistern. Most are associated with vestibular schwannoma, but a CPA meningioma may also cause formation of a TAC.

Neurenteric cysts (NE) are congenital endodermal cysts that are much more commonly found in the spinal canal. Intracranial NE cysts occur in the cerebromedullary cistern and are usually midline or slightly off midline, lying just anterior to the pontomedullary junction. Sometimes NE cysts occur off midline, in the lower CPA (cerebromedullary) cistern. Bony skull defects can occur but are rare.

An anatomic variant that can be confused with a posterior fossa NE cyst is retroclival ecchordosis physaliphora (EP), found in about 2% of autopsies. EP is a gelatinous notochordal remnant that can occur anywhere from the dorsum sellae to

https://CafePezeshki.IR

the sacrococcygeal region. Intracranial EPs typically occur in the prepontine cistern and are attached to a defect in the dorsal clivus by a thin, stalk-like pedicle. NE cysts and EPs are both hyperintense on T2WI. Chordomas are the malignant counterparts of ecchordosis.

Intraaxial Cysts

Supratentorial intraaxial cysts: Here, anatomic sublocation is key to the differential diagnosis. Parenchymal cysts represent a completely different group than intraventricular cysts. The most common parenchymal cysts in the brain are enlarged perivascular (Virchow-Robin) spaces (PVSs). PVSs have a distinct predilection for the basal ganglia, where they tend to cluster around the anterior commissure. The midbrain is another common site. When they occur here, enlarged PVSs may cause obstructive hydrocephalus. Prominent PVSs also occur in the subcortical and deep white matter. They are pial-lined, interstitial fluid-containing structures that tend to occur in clusters of variably sized cysts. Most PVSs suppress completely; 75% are surrounded by normal-appearing brain, which helps distinguish them from porencephalic cysts.

Hippocampal sulcus remnant cysts are common normal variants, seen as a "string" of small CSF-like cysts lying in the hippocampus just medial to the temporal horn of the lateral ventricle. They are caused by defective or incomplete fusion of the embryonic cornu ammonis and dentate gyrus and are of no clinical significance.

Porencephalic cysts are the 3rd most common supratentorial parenchymal cysts. They may communicate with the ventricles and are typically lined by gliotic white matter, not ependyma, and are caused by brain destruction (e.g., peri- or antenatal insult). The brain surrounding a porencephalic cyst is typically hyperintense on T2WI and FLAIR.

Periventricular cysts of newborns encompasses a wide, overlapping variety of periventricular cystic lesions that ranges from cystic periventricular leukomalacia to connatal and germinolytic cysts.

Neuroglial cysts, sometimes called neuroepithelial cysts, are benign glial-lined cavities buried within the cerebral white matter. While they can occur anywhere, the frontal lobe is the most common site. They tend to be solitary, whereas PVSs are usually collections of multiple cysts of different sizes. A choroid fissure cyst is a neuroglial cyst that occurs anywhere along the infolded choroid fissure. Most are found medial to the temporal horn of the lateral ventricle. Hippocampal sulcus remnant cysts (HSRCs) occur when there is incomplete fusion of the cornu ammonis and the dentate gyrus. HSRCs are often multiple, appearing like a string of small CSF-containing cysts along the lateral margin of the hippocampus.

Supratentorial intraventricular cysts are most often found in the atria of the lateral ventricles and foramen of Monro. Choroid plexus cysts (CPCs) are the most common of all intracranial neuroepithelial cysts, occurring in up to 50% of autopsies. Most CPCs are actually xanthogranulomas. Lipid accumulates in the choroid plexus from degenerating &/or desquamating choroid epithelium. CPCs are common incidental imaging findings in middle-aged and older adults. They are usually bilateral and are often multicystic. Most CPCs are small, measuring 2-8 mm in diameter. They typically do not suppress completely on FLAIR and may show moderately high signal intensity on DWI.

Ependymal cysts (EC) are rare, benign, ependymal-lined cysts of the lateral ventricles. Most ECs, even large ones, are asymptomatic and incidental. EC patients presenting with headache, seizure, &/or obstructive hydrocephalus have been reported in the literature. They contain clear serous CSF-like fluid secreted from ependymal cells. ECs typically follow CSF on all sequences and suppress completely on FLAIR.

Colloid cysts (CCs) occur almost exclusively in the foramen of Monro, attached to the anterosuperior portion of the 3rd ventricular roof. They are wedged into the foramen and are typically straddled by the fornices. CCs are endodermal in origin and contain viscous gelatinous material consisting of mostly mucin. CCs may also contain blood degradation products, foamy cells, and cholesterol crystals. Even relatively small CCs may suddenly obstruct the foramen of Monro, causing acute hydrocephalus. Occasionally brain herniation with rapid clinical deterioration ensues. The imaging appearance of a well-delineated, hyperdense mass at the foramen of Monro on NECT is virtually pathognomonic of a CC.

Infratentorial intraaxial cysts: Parenchymal infratentorial cysts are rare; most are PVSs. The only common site is in and around the dentate nuclei. Most are asymptomatic. Occasionally, large PVSs occur in the pons and can be a rare cause of cranial neuropathy.

Nonneoplastic, nonparasitic cysts in the 4th ventricle are uncommon. The most common cause is not a true cyst but an enlarged, "encysted" 4th ventricle. Infection or aneurysmal subarachnoid hemorrhage may cause outlet foraminal obstruction. When combined with superior obstruction near the aqueduct, the 4th ventricle can become completely encysted. Choroid plexus continues to produce CSF. With egress blocked, the 4th ventricle enlarges. Epidermoid cysts can arise in the 4th ventricle, a much less common posterior fossa location than the CPA. Some ECs are so similar to CSF that only FLAIR and DWI permit distinction of an EC from CSF in an enlarged but otherwise normal-appearing 4th ventricle.

Intracranial Cystic-Appearing Lesions

Extraaxial	Intraaxial
Supratentorial	Supratentorial
Midline	Parenchymal
Pineal cyst	Enlarged perivascular spaces (PVSs)
Dermoid cyst	Neuroglial cyst
Rathke cleft cyst	Porencephalic cyst
Arachnoid cyst (suprasellar)	Connatal, germinolytic cysts
	Hippocampal sulcus remnants
Off midline	Intraventricular
Arachnoid cyst (middle cranial fossa, convexity)	Choroid plexus cysts
Epidermoid cyst	Ependymal cyst
TACs (macroadenoma, meningioma)	Colloid cyst
Sebaceous cyst (scalp)	
Leptomeningeal cyst ("growing fracture")	
Infratentorial	Infratentorial
Midline	Parenchymal
Neurenteric cyst	Enlarged PVSs (dentate nuclei)
Arachnoid cyst	
Off midline	Intraventricular
Epidermoid (CPA)	Epidermoid (4th ventricle, cisterna magna)
Arachnoid cyst (CPA)	Cystic ("trapped") 4th ventricle
TACs (schwannoma, meningioma)	

Nonneoplastic, noninfectious cystic brain lesions are classified by common anatomic locations. The 1st division is extra- vs. intraaxial, then supra- vs. infratentorial. Extraaxial cysts are further subdivided into midline and off midline lesions. Intraaxial cysts are subdivided into parenchymal and intraventricular. CPA = cerebellopontine angle; PVSs = perivascular (Virchow-Robin) spaces; TACs = tumor-associated cysts.

Intracranial Cysts by Type, Most Common Location(s)

Cyst Type	Common Location(s)
Arachnoid cyst	Middle cranial fossa; cerebellopontine angle (CPA); suprasellar cistern
Choroid fissure cyst	Choroid fissure, between temporal horn and suprasellar cistern
Choroid plexus cyst	Choroid plexus glomus
Colloid cyst	Interventricular foramen/anterosuperior 3rd ventricle
Connatal cyst(s)	Peri- or intraventricular, adjacent to frontal horn, body of lateral ventricle
Dermoid cyst	Suprasellar, frontonasal (anteroinferior interhemispheric fissure)
Enlarged perivascular spaces (PVSs)	Basal ganglia, midbrain, cerebral white matter, dentate nuclei
Epidermoid cyst	Cerebellopontine angle (CPA)
Ependymal cyst	Lateral ventricle (atrium most common)
Germinolytic pseudocyst(s)	Periventricular, subependymal along caudothalamic groove
Hippocampal sulcus remnants	Hippocampus, just medial to lateral ventricle
Leptomeningeal cyst ("growing fracture")	Parietal bone
Neurenteric cyst	Prepontine at pontomedullary junction
Neuroglial cyst	Frontal/temporal subcortical WM, choroid fissure
Pineal cyst	Pineal gland
Porencephalic cyst	Cerebral hemispheres, adjacent to lateral ventricles
Rathke cleft cyst	Suprasellar, intrasellar
Sebaceous (trichilemmal) cyst	Scalp (dermis or subcutaneous tissues)
Tumor-associated cyst	Between schwannoma, meningioma, macroadenoma, and brain

KEY FACTS

TERMINOLOGY

- Intraarachnoid CSF-filled sac that does not communicate with ventricular system

IMAGING

- General findings
  - Sharply demarcated round/ovoid extraaxial cyst
  - Isodense/isointense with CSF
- Location
  - Middle cranial fossa (50-60%)
  - Cerebellopontine angle (10%)
  - Suprasellar (10%)
  - Miscellaneous (10%) (convexity, quadrigeminal)
- MR
  - Isointense with CSF on all sequences
  - Suppresses completely with FLAIR
  - No restriction on DWI
  - CISS, FIESTA: Use to delineate cyst wall, adjacent structures
  - 2D cine PC: Use to detect communication between AC, adjacent subarachnoid space

TOP DIFFERENTIAL DIAGNOSES

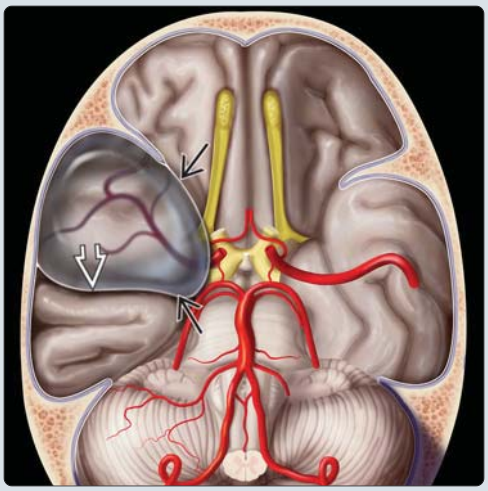
- Epidermoid cyst
- Other nonneoplastic cysts (e.g., porencephalic)
- Chronic subdural hematoma
- Subdural Hygroma

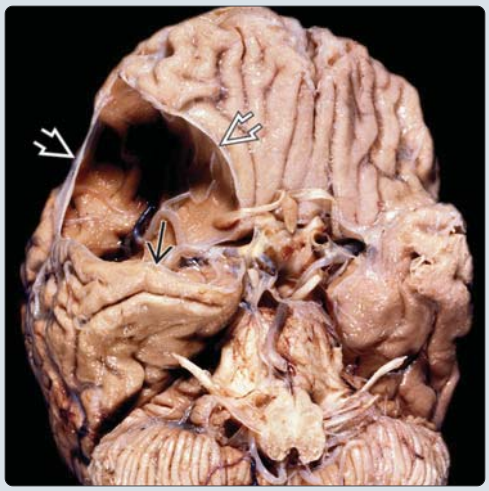
CLINICAL ISSUES

- Most common congenital intracranial cystic abnormality
- 1% of all intracranial masses
- Can be found at any age (75% in children)
- Usually an incidental finding

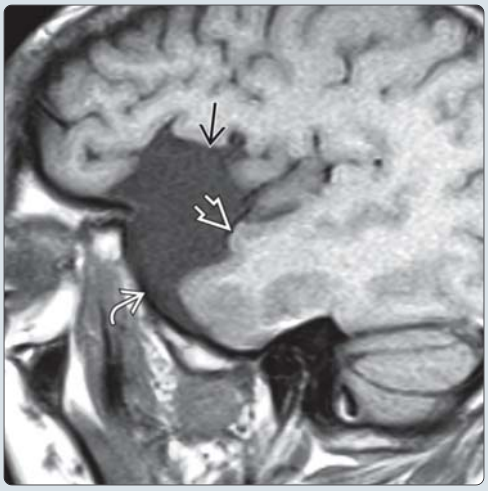
DIAGNOSTIC CHECKLIST

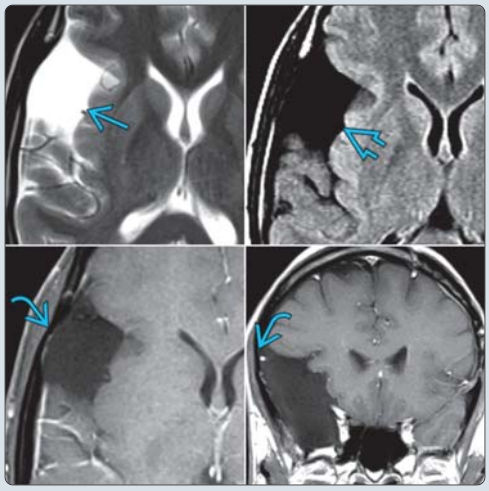
- FLAIR, DWI best for AC vs. epidermoid





(Left) *Graphic depicts the middle cranial fossa AC. Note the arachnoid ⇨ splits and encloses CSF. The middle fossa is expanded, and the overlying bone is thinned. Note that the temporal lobe ⇨ is displaced posteriorly.* **(Right)** *Submentovertex view shows autopsied brain with incidental finding of middle cranial fossa AC. Note "splitting" of arachnoid ⇨ containing a large CSF collection (drained during removal). The temporal lobe is displaced posteriorly ⇨, and the middle fossa is expanded. (Courtesy J. Townsend, MD.)*





(Left) *Sagittal T1WI MR shows a classic middle fossa arachnoid cyst ⇨. Note the expansion of the greater sphenoid wing ⇨ and posteriorly displaced temporal lobe ⇨.* **(Right)** *Composite of axial T2, FLAIR, post-contrast T1WI, and coronal T1C+ images show the scalloped margins characteristic of ACs. ACs are CSF-like on T2WI ⇨, suppress completely on FLAIR ⇨, remodel the adjacent calvaria ⇨, and do not enhance.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Arachnoid cyst (AC)

Synonyms

- Meningeal cyst

Definitions

- Intraarachnoid CSF-containing sac that does not communicate with ventricular system

IMAGING

General Features

- Best diagnostic clue
  - Sharply demarcated round/ovoid extraaxial cyst that follows CSF attenuation/signal
- Location
  - Middle cranial fossa (MCF) (50-60%)
  - Cerebellopontine angle (CPA) (10%)
  - Suprasellar arachnoid cyst (SSAC), variable types (10%)
    - Noncommunicating = cyst of membrane of Liliequist
    - Communicating = cystic dilation of interpeduncular cistern
  - 10% miscellaneous
    - Cerebral convexity
    - Quadrigeminal plate
    - Retrocerebellar
- Size
  - Varies from few mm to 5 cm or more
- Morphology
  - Sharply delineated translucent cyst
  - Displays features of extraaxial mass
    - Displaces cortex
    - "Buckles" gray-white interface

CT Findings

- NECT
  - Usually CSF density
    - Hyperdense if intracyst hemorrhage present (rare)
  - May expand, thin/remodel bone
- CECT
  - Does not enhance
- CTA
  - Posterior displacement of middle cerebral artery (MCA) in MCF ACs
- Cisternography may demonstrate communication with subarachnoid space

MR Findings

- T1WI
  - Sharply marginated extraaxial fluid collection isointense with CSF
- T2WI
  - Isointense with CSF
- PD/intermediate
  - Isointense with CSF
- FLAIR
  - Suppresses completely
- T2* GRE
  - No "blooming" unless hemorrhage present (rare)
- DWI
  - No restriction; nearly identical to ventricles
- T1WI C+
  - Does not enhance
- MRA
  - Cortical vessels displaced away from calvaria
- MRV
  - Can demonstrate anomalies of venous drainage
- MRS
  - Can predict pathology in > 90% of similar-appearing intracranial cystic lesions

Ultrasonographic Findings

- Grayscale ultrasound
  - Useful for demonstrating sonolucent ACs in infants < 1 year

Angiographic Findings

- MCA, sylvian triangle displaced posteriorly in MCF ACs

Nuclear Medicine Findings

- SPECT
  - May show hypoperfusion in brain adjacent to cyst

Imaging Recommendations

- Best imaging tool
  - MR with FLAIR, DWI
- Protocol advice
  - Consider adding
    - Magnetic resonance cisternography
      - CISS, FIESTA (high-resolution sequences to delineate cyst wall, adjacent anatomic structures); particularly in suprasellar cyst
      - Can help distinguish AC from enlarged subarachnoid space
    - MR CSF flow imaging, quantification
      - 2D cine PC (to look for communication between AC, adjacent subarachnoid space)

DIFFERENTIAL DIAGNOSIS

Epidermoid Cyst

- Scalloped margins
- Insinuating growth pattern
  - Creeps along into CSF cisterns
  - Surrounds, engulfs vessels/nerves
    - ACs displace, but usually do not engulf vessels, cranial nerves
- Does not suppress on FLAIR
- Restricted diffusion (bright) on DWI

Chronic Subdural Hematoma

- Signal not identical to CSF
- Often bilateral, lentiform-shaped
- ± enhancing membrane
- Look for foci of "blooming" on T2*
  - < 5% of ACs hemorrhage

Subdural Hygroma

- Often bilateral
- Crescentic or flat configuration

https://CafePezeshki.IR

Other Nonneoplastic Cysts

- Porencephalic cyst
  - Surrounded by gliotic brain, not compressed cortex
  - History of trauma, stroke common
- Neurenteric cyst
  - Rare; spine, posterior fossa = most common locations
  - Often proteinaceous fluid
- Neuroglial (glioependymal) cyst
  - Rare
  - Usually intraaxial

PATHOLOGY

General Features

- Etiology
  - Old concept = "splitting" or diverticulum of developing arachnoid
  - New concept (middle fossa ACs)
    - Frontal, temporal embryonic meninges (endomeninx) fail to merge as Sylvian fissure forms
    - Remain separate, forming "duplicated" arachnoid
  - Possible mechanisms
    - Active fluid secretion by cyst wall
    - Slow distention by CSF pulsations
    - CSF accumulates by 1-way (ball-valve) flow
  - Rare: ACs may form as shunt complication
- Genetics
  - Usually sporadic, nonsyndromic, rarely familial
  - Inherited disorders of metabolism
    - "Sticky" leptomeninges: Mucopolysaccharidoses
- Associated abnormalities
  - Temporal lobe may appear (or be) hypoplastic (MCF ACs)
  - Subdural hematoma
    - 5% in middle fossa ACs
  - Syndromic ACs
    - Acrocallosal (cysts in 1/3), Aicardi, Pallister-Hall syndromes
  - Periventricular giant ACs may cause hydrocephalus, may be associated with
    - Foramen of Monro stenosis
    - Aqueductal stenosis/occlusion

Staging, Grading, & Classification

- Galassi classification for middle fossa ACs: Increases with ↑ size/mass effect and ↓ communication with basal cisterns
  - Type 1: Small, spindle-shaped; limited to anterior MCF
  - Type 2: Superior extent along Sylvian fissure; temporal lobe displaced
  - Type 3: Huge, fills entire MCF; frontal/temporal/parietal displacement

Gross Pathologic & Surgical Features

- Fluid-containing cyst with translucent membrane
- Arachnoid layers bulge around, contain CSF collection

Microscopic Features

- Wall has variable histology; may explain why some grow
  - 50% have arachnoid-like tissue
  - 17% have thicker wall with mostly fibrous connective tissue
  - 33% have ciliated cells
- No inflammation, neoplastic change

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Often asymptomatic, found incidentally
  - Symptoms vary with size and location of cyst
    - Headache, dizziness, sensorineural hearing loss, hemifacial spasm/tic
    - SSACs may cause obstructive hydrocephalus
- Other signs/symptoms
  - Rarely, ruptured MCF ACs cause increased intracranial pressure requiring shunting

Demographics

- Age
  - ACs can be found at any age
  - 75% in children (symptom onset, if any, may be delayed)
- Gender
  - M:F = 3-5:1; especially middle cranial fossa
- Ethnicity
  - None reported
- Epidemiology
  - Most common congenital intracranial cystic abnormality
  - 1% of all intracranial masses
  - 2% incidental finding on imaging for seizure

Natural History & Prognosis

- May (but usually do not) slowly enlarge
- Occasionally decompress spontaneously

Treatment

- Usually none
  - Majority of ACs are found incidentally
- Resection (may be endoscopic)
- Fenestration/marsupialization
- Shunt (cystoperitoneal is common option)

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- FLAIR, DWI best sequences for distinguishing etiology of cystic-appearing intracranial masses

KEY FACTS

TERMINOLOGY

- Unilocular mucin-containing 3rd ventricular cyst

IMAGING

- > 99% are wedged into foramen of Monro
  - Pillars of fornix straddle, drape around cyst
  - Majority are hyperdense on NECT
  - Density correlates inversely with hydration state
- MR signal more variable
  - Generally reflects water content
  - Majority isointense to brain on T2WI (small cysts may be difficult to see)
  - 25% mixed hypo/hyper ("black hole" effect)
  - May show mild rim enhancement (rare)

TOP DIFFERENTIAL DIAGNOSES

- Neurocysticercosis
- CSF flow artifact (MR "pseudocyst")
- Vertebrobasilar dolichoectasia (VBD)/aneurysm
- Subependymoma
- Craniopharyngioma

PATHOLOGY

- From embryonic endoderm, not neuroectoderm
- Similar to other foregut-derived cysts (neurenteric, Rathke)

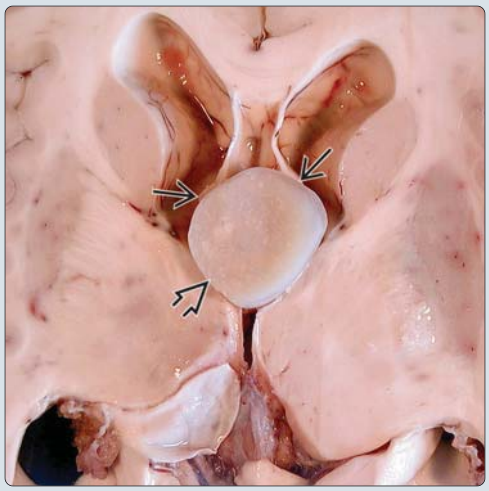
CLINICAL ISSUES

- 40-50% asymptomatic, discovered incidentally
- Headache (50-60%)
  - Acute foramen of Monro obstruction may lead to rapid onset hydrocephalus, herniation, death
- Peak age = 3rd to 4th decade (rare in children)
- 90% stable or stop enlarging
- 10% enlarge

DIAGNOSTIC CHECKLIST

- Beware of flow artifact in 3rd ventricle mimicking CC

(Left) *Axial graphic shows a classic CC at the foramen of Monro causing mild/moderate obstructive hydrocephalus. Note that the fornices and choroid plexus are elevated and stretched over the cyst* ⇨. **(Right)** *Axial gross pathology in a patient who suddenly and inexplicably died shows a large colloid cyst* ⇨ *causing moderate obstructive hydrocephalus. A small cavum septi pellucidi is present. Fornices* ⇨ *are draped over the cyst. (Courtesy R. Hewlett, MD.)*



(Left) *Axial NECT in a 65-year-old man with "thunderclap" headache, obtained to look for a subarachnoid hemorrhage, shows a classic colloid cyst, seen here as a hyperdense mass* ➡ *wedged into the foramen of Monro and upper 3rd ventricle.* **(Right)** *Sagittal T2WI MR in the same patient shows the mass* ⇨ *to be very hypointense, indicating inspissated proteinaceous contents. Note the markedly enlarged lateral ventricle with a normal-sized 3rd ventricle. The colloid cyst was removed emergently.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Colloid cyst (CC)

Synonyms

- Paraphyseal cyst, endodermal cyst

Definitions

- Unilocular, mucin-containing 3rd ventricular cyst

IMAGING

General Features

- Best diagnostic clue
  - Hyperdense foramen of Monro mass on NECT
- Location
  - > 99% are wedged into foramen of Monro
    - Attached to anterosuperior 3rd ventricular roof
    - Pillars of fornix straddle, drape around cyst
    - Posterior part of frontal horns splayed laterally around cyst
  - < 1% found at other sites
    - Lateral, 4th ventricles
    - Extraventricular CCs (very rare)
      - Parenchyma (cerebellum)
      - Extraaxial (prepontine, meninges, olfactory groove)
- Size
  - Variable (few mm to 3 cm)
  - Mean: 15 mm
- Morphology
  - Well-demarcated round > ovoid/lobulated mass

CT Findings

- NECT
  - Density correlates inversely with hydration state
    - 2/3 hyperdense
    - 1/3 iso-/hypodense
  - ± hydrocephalus
  - Rare
    - Hypodense
    - Change in density/size
    - Hemorrhage (cyst "apoplexy"), Ca++ rare
- CECT
  - Usually does not enhance
  - Rim enhancement (rare)

MR Findings

- T1WI
  - Signal correlates with cholesterol concentration
    - 2/3 hyperintense on T1WI
    - 1/3 isointense
      - Small CCs may be difficult to see
  - May have associated ventriculomegaly
- T2WI
  - Signal more variable
    - Generally reflects water content
    - Majority isointense to brain on T2WI
      - Small CCs may be difficult to see
  - Less common findings
    - 25% mixed hypo/hyper ("black hole" effect)
    - Fluid-fluid level
- FLAIR
  - Does not suppress
- DWI
  - Does not restrict
- T1WI C+
  - Usually no enhancement
  - Rare: May show peripheral (rim) enhancement
- MRS
  - Normal brain metabolites absent

Imaging Recommendations

- Protocol advice
  - NECT + contrast-enhanced MR
  - ± serial imaging for asymptomatic cysts < 1 cm, no hydrocephalus

DIFFERENTIAL DIAGNOSIS

Neurocysticercosis

- Multiple lesions within parenchyma and cisterns
- Associated ependymitis or basilar meningitis common
- Ca++ common
- Look for scolex

CSF Flow Artifact (MR "Pseudocyst")

- Multiplanar technique confirms artifact
- Look for phase artifact

Vertebrobasilar Dolichoectasia (VBD)/Aneurysm

- Extreme VBD can cause hyperdense foramen of Monro mass
- Look for flow void, phase artifact on MR

Neoplasm

- Subependymoma
  - Frontal horn of lateral ventricle
  - Attached to septum pellucidum
  - Patchy/solid enhancement
- Craniopharyngioma
  - 3rd ventricle rare location
  - Usually not wedged into foramen of Monro, fornix
  - Ca++, rim/nodular enhancement common
- Pituitary adenoma
  - Rare in 3rd ventricle
  - Enhances (usually strongly, uniformly)

Choroid Plexus Mass

- Choroid plexus papilloma
  - Rare in 3rd ventricle
  - Tumor of early childhood
- Xanthogranuloma
  - Rare in 3rd ventricle
  - Ovoid > round
  - Can be hyper- or hypodense ± Ca++
  - Can obstruct foramen of Monro
  - Can be indistinguishable on imaging studies
- Choroid plexus cyst
  - Usually found in infants
  - Anechoic at ultrasound

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - From embryonic endoderm, not neuroectoderm
    - Similar to other foregut-derived cysts (neurenteric, Rathke)
    - Ectopic endodermal elements migrate into embryonic diencephalic roof
  - Contents accumulate from mucinous secretions, desquamated epithelial cells
- Genetics
  - None known
- Associated abnormalities
  - Variable hydrocephalus

Gross Pathologic & Surgical Features

- Smooth, spherical/ovoid well-delineated cyst
  - Thick gelatinous center, variable viscosity (mucinous or desiccated)
  - Rare = evidence for recent/remote hemorrhage
- Gross appearance, location virtually pathognomonic

Microscopic Features

- Outer wall = thin fibrous capsule
- Inner lining
  - Simple or pseudostratified epithelium
  - Interspersed goblet cells, scattered ciliated cells
  - Rests on thin connective tissue layer
- Cyst contents
  - PAS + gelatinous ("colloid") material
  - Variable viscosity
  - ± necrotic leukocytes, cholesterol clefts
- Immunohistochemistry
  - ± epithelial antigen reactivity (cytokeratins, EMA)
  - Neuroepithelial markers negative
- Electron microscopy
  - Resembles mature respiratory epithelium
  - Nonciliated or tall columnar cells
  - Basal cells contain dense core vesicles

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache (50-60%)
  - Less common = nausea, vomiting, memory loss, altered personality, gait disturbance, visual changes
  - Acute foramen of Monro obstruction may lead to rapid onset hydrocephalus, herniation, death
  - 40-50% asymptomatic, discovered incidentally
    - 3-, 5-, and 10-year incidence of developing cyst-related symptoms = 0, 0, and 8%, respectively
- Clinical profile
  - Adult with headache

Demographics

- Age
  - 3rd to 4th decade
    - Peak: 40
    - Rare in children (only 8% < 15 at diagnosis)
- Gender
  - M = F
- Epidemiology
  - 0.5-1.0% primary brain tumors
  - 15-20% intraventricular masses
  - Few familial cases reported

Natural History & Prognosis

- Varies with presence/rate of growth, development of CSF obstruction
- 90% stable or stop enlarging
  - Older age
  - Small cyst
  - No hydrocephalus
  - Hyperdense on NECT, hypointense on T2-weighted MR
- 10% enlarge
  - Younger patients
  - Larger cyst, hydrocephalus
  - Iso-/hypodense on NECT, often hyperintense on T2WI
  - May enlarge rapidly, cause coma/death
- Prognosis excellent when CCs diagnosed early and excised

Treatment

- Most common = complete surgical resection
  - Neuronavigation-guided endoscopic approach increasingly common
  - 50% experience short-term memory disturbance (usually resolves)
  - Recurrence rare if resection complete
- Options
  - Precoronal, paramedian minicraniotomy
  - Stereotactic aspiration (difficult with extremely viscous/solid cysts)
  - Imaging features that may predict difficulty with percutaneous therapy
    - Hyperdensity on CT/hypointensity on T2WI suggest high viscosity
  - Ventricular shunting
  - Observation (rare; not recommended as sudden obstruction can occur with even small CCs)

DIAGNOSTIC CHECKLIST

Consider

- Consider CT or MR in patient with longstanding history of intermittent headaches
- Notify referring MD immediately if CC identified (especially if hydrocephalus is present)

Image Interpretation Pearls

- Beware of flow artifact in 3rd ventricle mimicking CC

Dermoid Cyst

KEY FACTS

TERMINOLOGY

- Benign, ectopic, squamous epithelial cyst containing dermal elements, including hair follicles and sebaceous and sweat glands

IMAGING

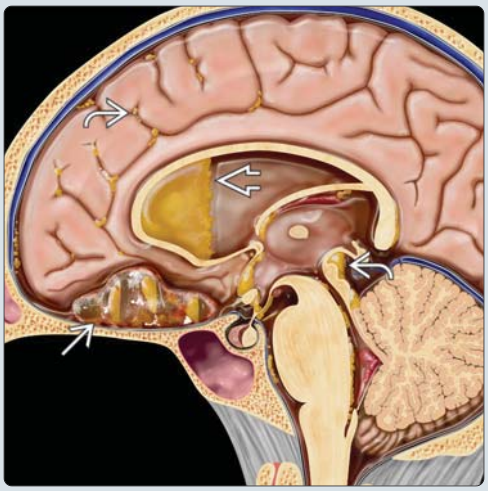
- Midline unilocular cystic lesion with fat
  - Subarachnoid fatty droplets if ruptured
- Suprasellar or posterior fossa most common intracranial sites
- Extracranial sites = spine, orbit
  - May have fistulous connections to skin (dermal sinus tract)
- CT hypodensity and negative Hounsfield units (fat)
  - 20% capsular Ca++
- MR: T1 hyperintense
  - Fat-suppression sequence confirms lipid elements
  - Fat-fluid level in cyst and in ventricles (if ruptured)
- With rupture: Extensive leptomeningeal enhancement possible from chemical meningitis

TOP DIFFERENTIAL DIAGNOSES

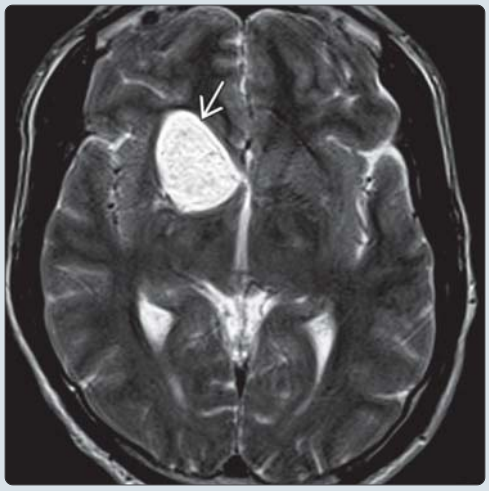
- Epidermoid cyst
- Craniopharyngioma
- Teratoma
- Lipoma

CLINICAL ISSUES

- Rare: < 0.5% of primary intracranial tumors
- Intradural dermoid cysts 4-9x less common than epidermoid cysts
- Rupture can cause significant morbidity/mortality
- Dermoid + dermal sinus may cause meningitis, hydrocephalus
- Treatment: Complete surgical excision ± shunt for hydrocephalus



(Left) *Sagittal graphic of an inferior frontal dermoid shows a discrete, heterogeneous fat-containing mass with squamous epithelium and dermal appendages. There is a ventricular fat-fluid level and fat within the subarachnoid spaces related to the rupture.* **(Right)** *Axial NECT shows a hypodense midline fatty mass with focal calcification charateristic for ruptured dermoid cyst. Note fatty hypodense droplets in the sylvian fissures and subarachnoid spaces.*



(Left) *T1WI shows classic dermoid cyst is hyperintense. Note fatty droplets in adjacent sylvian fissure typical for ruptured dermoid.* **(Right)** *Axial FSE T2WI in the same patient shows the mass is hyperintense, but internally heterogeneous. Ruptured dermoid cyst was confirmed at surgery.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Dermoid inclusion cyst, ectodermal inclusion cyst

Definitions

- Benign, ectopic, squamous epithelial cyst containing dermal elements, including hair follicles and sebaceous and sweat glands

IMAGING

General Features

- Best diagnostic clue
  - Midline nonenhancing unilocular cystic lesion with fat
    - Subarachnoid fatty droplets if ruptured
- Location
  - Suprasellar, parasellar
  - Less common in posterior fossa: Cisterna magna, 4th ventricle, and basal cisterns
  - Extracranial sites = spine, orbit
    - May have fistulous connections to skin (dermal sinus tract)
    - Orbit: Dermolipoma at zygomatico-frontal suture
  - Ruptured: Subarachnoid/intraventricular spread of contents
- Size
  - Variable
- Morphology
  - Well-circumscribed, lipid-containing mass

CT Findings

- NECT
  - Round/lobulated, well-delineated, unilocular cystic mass
  - Hypodensity and negative Hounsfield units from fat
  - Capsular Ca++ (20%)
  - With rupture, droplets of fat disseminate in cisterns, may cause fat-fluid level within ventricles
  - Skull/scalp dermoid expands diploë
  - Frontonasal dermoid sinus tract: Bifid crista galli, large foramen cecum + sinus tract
  - Rare dense dermoid: Hyperattenuating
- CECT
  - Generally no enhancement in absence of infection

MR Findings

- T1WI
  - Unruptured: Hyperintense
  - Ruptured: Droplets very hyperintense
    - Fat-suppression sequence confirms lipid elements
    - Fat-fluid level in cyst; if ruptured, in ventricles as well
  - Rare dense dermoid: Very hyperintense
- T2WI
  - Unruptured: Heterogeneous, hypo- to hyperintense
    - Chemical shift artifact in frequency encoding direction with long TR
  - Ruptured: Typically hyperintense droplets
  - Rare dense dermoid: Very hypointense
  - With hair: Fine curvilinear hypointense elements
- T1WI C+
  - ± mild enhancement of capsule without central enhancement
  - With rupture: Extensive leptomeningeal enhancement possible from chemical meningitis
  - With infection: May see rim enhancement
- MRS
  - Elevated lipid peak from 0.9-1.3 ppm

Angiographic Findings

- Vasospasm with chemical meningitis from rupture
  - May relieve vasospasm with angioplasty
- Dermoid-encased vessels may have ↑ rupture risk

Imaging Recommendations

- Best imaging tool
  - MR with fat saturation
- Protocol advice
  - Use fat-suppression sequence to confirm diagnosis
  - Chemical shift-selective sequence useful to detect tiny droplets

DIFFERENTIAL DIAGNOSIS

Epidermoid Cyst

- Most epidermoid cysts resemble cerebrospinal fluid (CSF), no fat
- Restricted diffusion on DWI is classic
- Cyst lined with squamous epithelium without dermal elements
- 4-9x more common than dermoid
- Off midline > midline: In CPA (40-50%), parasellar/middle fossa (10-15%), diploic (10%)

Craniopharyngioma

- Also suprasellar/midline, often with intrasellar component
- CT: Multilocular with solid enhancing tissue (> 90%), nodular Ca++ in majority
- MR: Commonly T1 hypointense, T2 hyperintense, enhances strongly
- More common than dermoid (3-5% of primary intracranial tumors)

Teratoma

- Location similar, but usually pineal region
- 90% have all 3 embryologic layers: Ectoderm, mesoderm, endoderm
- Often multicystic/multiloculated
- Heterogeneous appearance containing calcification, CSF, lipid, and soft tissue components
- Does not have fat-fluid level

Lipoma

- Homogeneous midline fat
- Dermoids more likely heterogeneous
- Ca++ less frequent than in dermoid

PATHOLOGY

General Features

- Etiology
  - Embryology (2 theories)

https://CafePezeshki.IR

  - Sequestration of surface ectoderm at lines of epithelial fusion/along course of normal embryonic invaginations
  - Inclusion of cutaneous ectoderm at time of neural tube closure; 3rd to 5th week of embryogenesis
  - Can also arise at any age from traumatic implantation (i.e., lumbar puncture)
  - Similar etiology with epidermoid, which is thought to be later in development and off midline
- Genetics
  - Usually sporadic
  - Association with Goldenhar syndrome
  - Possible association with Klippel-Feil syndrome
- Associated abnormalities
  - Occipital/nasofrontal dermal sinus may be present; 89% of dermal sinuses associated with inclusion cysts
  - Goldenhar syndrome (a.k.a. oculoauriculovertebral dysplasia); congenital condition includes
    - Cranial lipomas and dermoids
    - Ocular dermoids
    - Anomalies of 1st and 2nd branchial arch derivatives
    - Cardiovascular, facial, oral, auricular, visceral, and spinal defects

Gross Pathologic & Surgical Features

- Unilocular cyst with thick wall
- Contents = lipid and cholesterol elements from sebaceous secretions floating on proteinaceous material

Microscopic Features

- Outer wall of squamous epithelium
- Inner lining contains dermal elements of hair follicles, sebaceous and apocrine glands
- Rare squamous cell carcinoma (SCCa) degeneration
  - Squamous cell predominance with some glandular differentiation
  - Suggestive of poorly differentiated squamous cell carcinoma with adenomatous component

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Uncomplicated dermoid: Headache (32%), seizure (30%) are most common symptoms
    - Large cyst can cause obstructive hydrocephalus
    - Less commonly hypopituitarism, diabetes insipidus, or cranial nerve (CN) defects
    - Suprasellar may present with visual symptoms
  - Cyst rupture causes chemical meningitis (6.9%)
- Other signs/symptoms
  - Recurrent meningitis when associated with sinus tract

Demographics

- Age
  - 2nd-3rd decade
- Gender
  - Slight male predilection
- Epidemiology
  - Rare: < 0.5% of primary intracranial tumors
  - Intradural dermoid cysts 4-9x less common than epidermoid cysts

Natural History & Prognosis

- Benign, slow growing
- Larger lesions associated with higher rupture rate
- Rupture can cause significant morbidity/mortality
  - Relatively rare and typically spontaneous
  - Seizure, coma, vasospasm, infarction, death
- Dermoid + dermal sinus may cause meningitis, hydrocephalus
- Rare malignant transformation into SCCa
  - Postulated prolonged or reparative process from foreign material leads to cellular atypia and neoplasia
  - May occur years after surgical resection

Treatment

- Complete surgical excision
  - Residual capsule may lead to recurrence
  - Rare SCCa degeneration within surgical remnants
- Subarachnoid dissemination of contents may occur during operative/postoperative course
  - Cause aseptic meningitis or other complications (hydrocephalus, seizures, CN deficits)
    - May require shunt placement for hydrocephalus
  - Alternatively, disseminated fat particles can remain silent without radiological/neurological change
    - Justifies "wait and see" approach
    - Regular MR and clinical exams are necessary to avoid complications

DIAGNOSTIC CHECKLIST

Consider

- When possible dermoid is seen near glabella or crista galli, look for sinus tract

Image Interpretation Pearls

- Follows fat characteristics on NECT and T1WI fat-suppressed MR

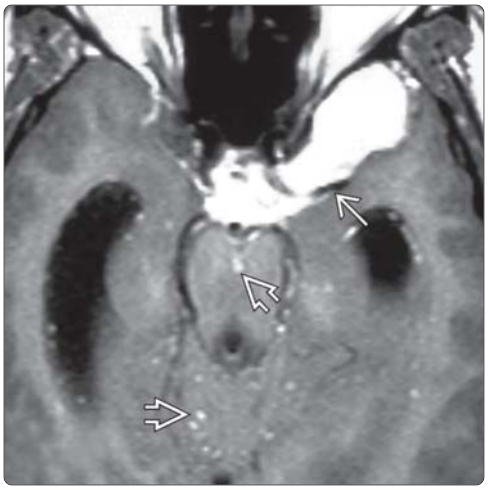
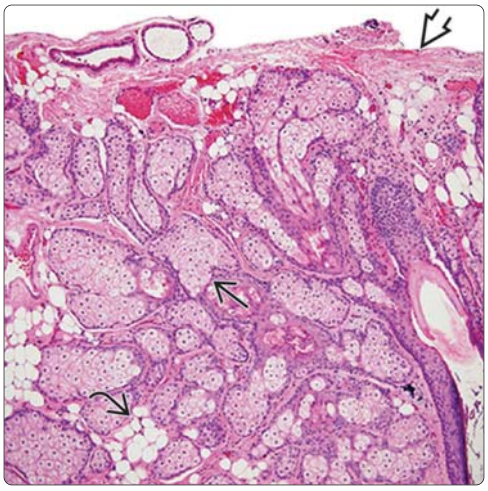
https://CafePezeshki.IR



(Left) *Axial NECT shows a large, heterogeneous fatty mass in the left parasellar region. Note the typical fat-fluid level ⇨ within the dermoid cyst and minimal calcification ⇨.* **(Right)** *Axial T1WI MR in the same patient shows a hyperintense mass ⇨ with scattered foci of hyperintensity throughout the subarachnoid space ⇨. Chemical meningitis from a ruptured dermoid, while uncommon, can cause significant morbidity from seizures, vasospasm, infarction, and even death.*



(Left) *Axial T1WI C+ FS MR in the same patient shows complete suppression of the fatty mass with minimal capsular enhancement ⇨. The severe communicating hydrocephalus is caused by a chemical meningitis ⇨. Patients with a ruptured dermoid are typically treated with resection of the cyst and ventricular decompression.* **(Right)** *High-power micropathology shows typical dermoid cyst features with keratin lining ⇨, multiple sebaceous glands ⇨, and fat ⇨.*

(Left) *Axial NECT shows a large, mixed fatty and calcified, suprasellar and subfrontal mass. Low-density fat droplets ⇨ are seen in the adjacent sylvian fissure, related to dermoid rupture. Headaches and seizures are the most common presenting features of these cysts. Rupture may cause a chemical meningitis.* **(Right)** *Axial CECT shows a fat-containing orbital mass in a young adult. Dermoids of the orbit are most commonly "dermolipomas" and are associated with the zygomatico-frontal suture.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Intracranial epidermoids: Congenital inclusion cysts

IMAGING

- CSF-like mass that insinuates cisterns and encases neurovascular structures
- Morphology: Lobulated, irregular, cauliflower-like mass with "fronds"
- FLAIR: Usually does not completely null
- DWI: Diffusion hyperintensity definitively distinguishes from arachnoid cyst

TOP DIFFERENTIAL DIAGNOSES

- Arachnoid cyst
- Inflammatory cyst (i.e., neurocysticercosis)
- Cystic neoplasm
- Dermoid cyst

PATHOLOGY

- Arise from ectodermal inclusions during neural tube closure, 3rd to 5th week embryogenesis

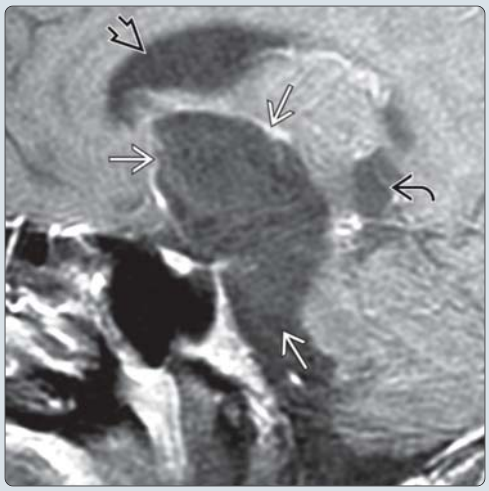
CLINICAL ISSUES

- Symptoms depend on location and effect on adjacent neurovascular structures
  - Most common symptom: Headache
  - Cranial nerve 5, 7, 8 neuropathy common
- 0.2-1.8% of all primary intracranial tumors
- Rare malignant degeneration into squamous cell carcinoma
- Treatment: Microsurgical resection
  - Recurrence common if incompletely removed

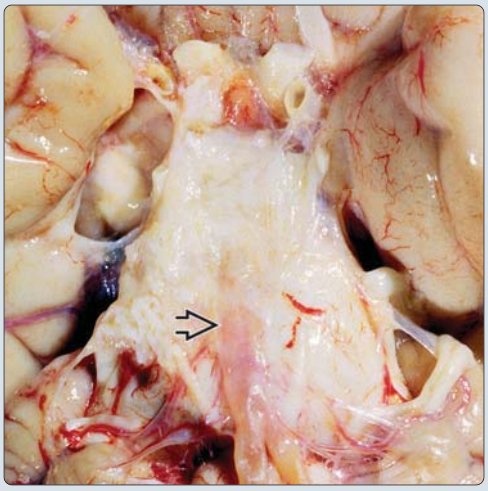
DIAGNOSTIC CHECKLIST

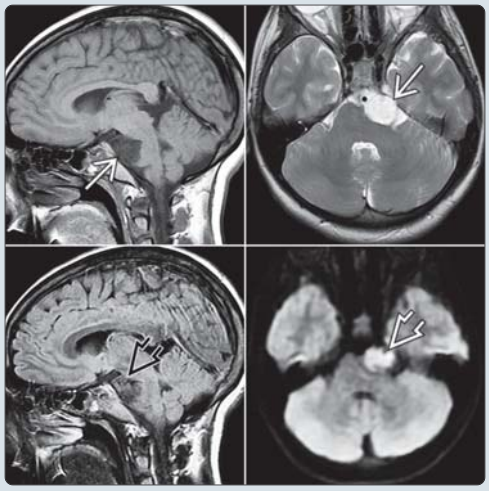
- Insinuates and surrounds rather than displaces
- Incomplete nulling on FLAIR; DWI hyperintense

(Left) *Sagittal graphic illustrates a multilobulated epidermoid primarily within the prepontine cistern. Significant mass effect displaces the pons, cervicomedullary junction, and upper cervical spine.* **(Right)** *Sagittal T1WI C+ MR shows a nonenhancing epidermoid ➡ arising from the prepontine cistern with extensive mass effect upon the pons, midbrain, and hypothalamus. Its intensity is slightly greater than normal CSF ⇨, and it has insinuated itself around the pons into the ambient cistern ⇨.*



(Left) *Gross pathology shows an epidermoid cyst extending anterosuperiorly from the CPA cistern, insinuating within the prepontine cistern and encasing the basilar artery ⇨. Note its typical pearly appearance. (Courtesy E. Hedley-Whyte, MD.)* **(Right)** *Collage of images illustrates cerebellopontine angle epidermoid cyst that resembles CSF on T1- and T2WI ➡ but typically does not suppress on FLAIR ⇨ and demonstrates moderate restricted diffusion ➡.*





https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Ectodermal inclusion cyst

Definitions

- Intracranial epidermoids: Congenital inclusion cysts

IMAGING

General Features

- Best diagnostic clue
  - CSF-like mass that insinuates cisterns and encases neurovascular structures
- Location
  - Intradural (90%), primarily in basal cisterns
    - Cerebellopontine angle (CPA) (40-50%)
    - 4th ventricle (17%)
    - Parasellar/middle cranial fossa (10-15%)
    - Cerebral hemispheres (rare) (1.5%)
    - Brainstem location exceedingly rare
    - Intraventricular within tela choroidea of temporal horn, 3rd or 4th ventricles
  - Extradural (10%): Skull (intradiploic within frontal, parietal, occipital, sphenoid skull) as well as spine
- Morphology
  - Lobulated, irregular, cauliflower-like mass with "fronds"
  - Insinuates without mass effect unless large

Radiographic Findings

- Radiography
  - Diploic space epidermoids
    - May alter scalp, outer/inner skull tables, and epidural space appearance
    - Typically round or lobulated
    - Well delineated with sclerotic rim

CT Findings

- NECT
  - Round/lobulated mass
  - > 95% hypodense, resembling CSF
  - 10-25% contain calcifications
  - Rare variant = "dense" epidermoid
    - 3% of intracranial epidermoids
    - Secondary to hemorrhage, high protein, saponification of cyst debris to calcium soaps or iron-containing pigment
- CECT
  - Usually none, though margin of cyst may show minimal enhancement
- Bone CT
  - May have bony erosion; sharply corticated margins when intradiploic

MR Findings

- T1WI
  - Often (~ 75%) slightly hyperintense to CSF
  - Lobulated periphery may be slightly more hyperintense than center
  - Uncommonly hyperintense to brain ("white epidermoid") due to high triglycerides and unsaturated fatty acids
  - Uncommonly hypointense to CSF ("black epidermoid")
    - Presence of solid crystal cholesterol and keratin
    - Lack of triglycerides and unsaturated fatty acids
- T2WI
  - Often isointense (65%) to slightly hyperintense (35%) to CSF
  - Very rarely hypointense due to calcification, ↓ hydration, viscous secretions, and iron pigments
- FLAIR
  - Usually does not completely null
- DWI
  - Characteristic hyperintensity
    - High fractional anisotropy due to diffusion along 2D geometric plane
      - Attributed to microstructure of parallel-layered keratin filaments and flakes
    - In comparison to white matter, which also shows high fractional anisotropy, due to diffusion along single direction
  - ADC = brain parenchyma
- T1WI C+
  - Usually none, though margin of cyst may show minimal enhancement (25%)
  - Enhancing tumor is sign of malignant degeneration
- MRS
  - Resonances from lactate
  - No NAA, choline, or lipid

Angiographic Findings

- Conventional
  - Depending on location and size, may show avascular mass effect

Nonvascular Interventions

- Myelography
  - Cisternography contrast delineates irregular lobulated tumor borders, extends into interstices

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - FLAIR will often distinguish whereas conventional sequences may not
  - Diffusion hyperintensity definitively distinguishes from arachnoid cyst

DIFFERENTIAL DIAGNOSIS

Arachnoid Cyst

- Usually isointense to CSF on all standard sequences
  - Completely nulls on FLAIR
  - Hypointense diffusion: Contains highly mobile CSF, ADC = stationary water
- Rather than insinuate and engulf local structures, arachnoid cysts displace them
- Smooth surface, unlike lobulations of epidermoids

Inflammatory Cyst

- i.e., neurocysticercosis
- Often enhances
- Density/signal intensity usually not precisely like CSF
- Adjacent edema, gliosis common

https://CafePezeshki.IR

Cystic Neoplasm

- Attenuation/signal intensity not that of CSF
- Often enhances

Dermoid Cyst

- Usually at or near midline
- Resembles fat, not CSF, and contains dermal appendages; often ruptured

PATHOLOGY

General Features

- Etiology
  - Congenital: Embryology
    - Arise from ectodermal inclusions during neural tube closure, 3rd to 5th week embryogenesis
    - Congenital intradural CPA epidermoids derived from cells of 1st branchial groove
  - Acquired: Develop as result of trauma
    - Uncommon etiology for intracranial tumors
    - More common as spine etiology following LP
- Genetics
  - Sporadic
- Associated abnormalities
  - May have occipital/nasofrontal dermal sinus tract

Gross Pathologic & Surgical Features

- Outer surface often has shiny, glistening mother of pearl appearance ("beautiful tumor")
- Soft and pliable
  - Conforms to shape of adjacent local structures/spaces
- Lobulated excrescences
  - May invaginate into brain
- Insinuating growth pattern, extends through cisterns, surrounds and encases vessels/nerves
- Cyst filled with soft, waxy, creamy, or flaky material

Microscopic Features

- Cyst wall = internal layer of simple stratified cuboidal squamous epithelium covered by fibrous capsule
- Cyst contents = solid crystalline cholesterol, keratinaceous debris; no dermal appendages
- Grows by progressive desquamation with conversion to keratin/cholesterol crystals, forming concentric lamellae

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Symptoms depend on location and effect on adjacent neurovascular structures
    - Most common symptom: Headache
    - Cranial nerve 5, 7, 8 neuropathy common
    - 4th ventricular cerebellar signs common, yet increased intracranial pressure rare
    - Less commonly hypopituitarism, diabetes insipidus
    - Seizures if in sylvian fissure/temporal lobe
  - May remain clinically silent for many years

Demographics

- Age
  - Presents between 20-60 years with peak at 40 years
  - Presentation is uncommon in childhood
- Gender
  - M = F
    - CT hyperdense variant lesions have female predominance (M:F = 1:2.5)
- Epidemiology
  - Epidermoids make up 0.2-1.8% of all primary intracranial tumors
  - Much more common than dermoid cyst (4-9x higher incidence)
  - Most common congenital intracranial tumor
  - 3rd most common CPA/IAC mass, after vestibular schwannoma and meningioma

Natural History & Prognosis

- Grows slowly: Epithelial component growth rate commensurate to that of normal epithelium
- Chemical meningitis possible from content leakage
- Rare malignant degeneration into squamous cell carcinoma (SCCa) reported
  - Postulated prolonged or reparative process from foreign material leads to cellular atypia and neoplasia
  - Often predated by frequent recurrences
  - May occur years after surgical resection
  - Mean age at presentation: 52 years with male preponderance

Treatment

- Microsurgical resection
  - Complicated by investment of local structures
  - Recurrence common if incompletely removed
  - Subarachnoid dissemination of contents may occur during operative/postoperative course
    - May cause chemical meningitis
    - CSF seeding and implantation reported
- Rare malignant degeneration of resection bed into SCCa reported

DIAGNOSTIC CHECKLIST

Consider

- Epidermoid if insinuates and surrounds rather than displaces

Image Interpretation Pearls

- Resembles CSF on imaging studies, except usually incomplete nulling on FLAIR
- DWI hyperintensity is diagnostic

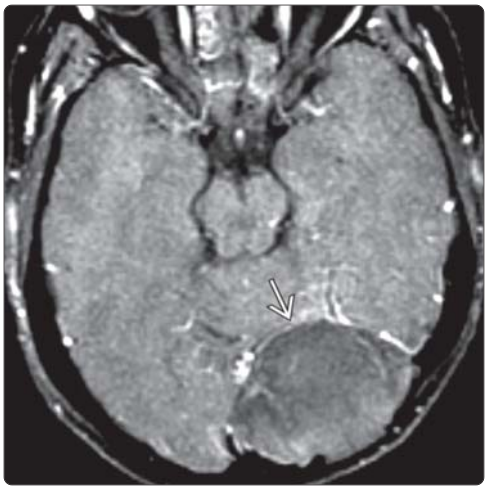
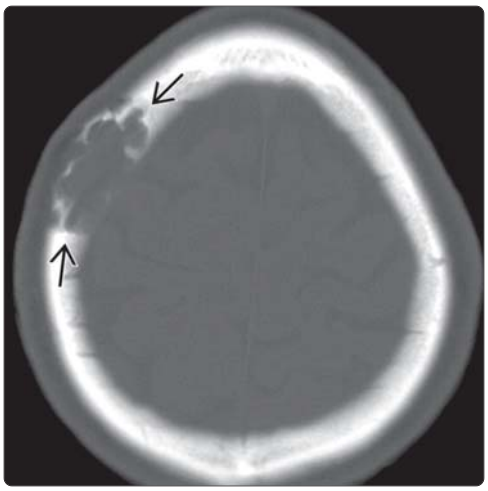
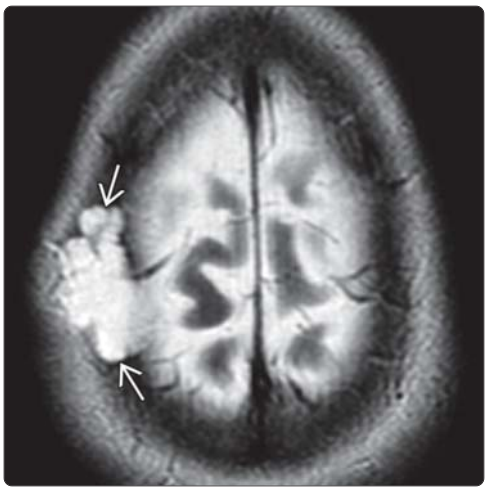
(Left) *Axial T2WI MR demonstrates "scalloped" expansion of an epidermoid within the 4th ventricle ➡. This is the 2nd most common location for epidermoids yet is statistically uncommon at only 17%.* **(Right)** *Axial T2WI MR shows a hyperintense, lobulated mass in the ambient cistern ➡. Most epidermoid cysts are laterally located, but this one is unusually extensive and has a large suprasellar component as well ➡.*



(Left) *Axial T2WI MR shows an extraaxial left occipital mass that scallops the skull ➡ and displaces the dura inwardly ➡.* **(Right)** *Axial T1WI C+ FS MR in the same patient shows the mass does not enhance ➡. DWI (not shown) clinched the diagnosis as an epidermoid cyst. This is an atypical location for epidermoid.*





(Left) *Axial bone CT demonstrates the typical appearance of an intradiploic epidermoid as an expansile lesion with sharply corticated margins ⇨.* **(Right)** *Axial T2WI MR in the same patient shows lobulated hyperintense mass scallops the skull ➡. Intradiploic epidermoid cyst was removed at surgery.*

https://CafePezeshki.IR

Neuroglial Cyst

KEY FACTS

TERMINOLOGY

- Neuroglial cyst (NGC), a.k.a. glioependymal cyst
- Benign, glial-lined, fluid-containing cavity buried within cerebral white matter
  - May occur anywhere throughout neuraxis
  - Frontal lobe most common site
  - Size varies from few mm up to several cm

IMAGING

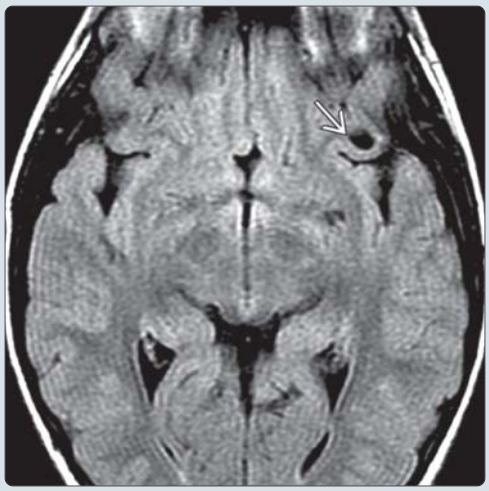
- CT
  - Well-delineated, low-density, unilocular parenchymal cyst
  - No Ca++ or enhancement
- MR
  - T1 hypo-/T2 hyperintense (resembles CSF)
  - Usually suppresses on FLAIR
  - Does not restrict on DWI
  - No enhancement
  - Minimal/no surrounding signal abnormality

TOP DIFFERENTIAL DIAGNOSES

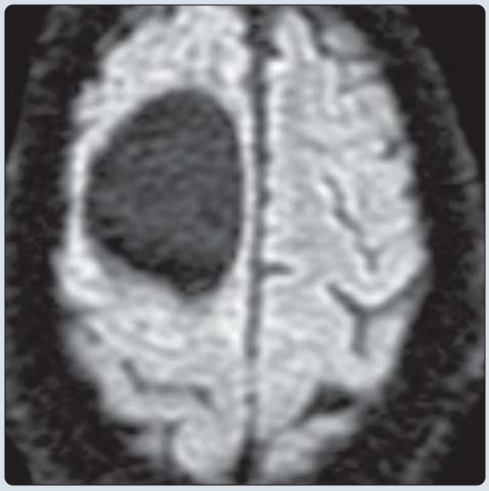
- Porencephalic cyst
- Enlarged perivascular spaces (PVSs)
- Arachnoid cyst
- Ependymal cyst
- Epidermoid cyst
- Infectious cyst (e.g., neurocysticercosis, echinococcosis)

DIAGNOSTIC CHECKLIST

- Parenchymal cysts that do not communicate with ventricular system and have minimal/no surrounding gliosis may be NGC
- Use FLAIR, DWI to help distinguish between different types of intracranial cysts



(Left) *Axial graphic shows a classic neuroglial cyst. This well-delineated, unilocular lesion does not communicate with the ventricles and contains clear fluid. The surrounding brain is normal. Neuroglial cysts are lined with glial cells, astrocytes, and rarely ependymal cells.* **(Right)** *Axial FLAIR MR in a child shows incidental finding of a benign-appearing cyst in the left frontal subcortical white matter ➡. The cyst followed CSF on all sequences and did not enhance.*



(Left) *Axial FLAIR MR in a young adult with headaches shows a large right frontal CSF-like cyst ➡.* **(Right)** *Axial DWI MR in the same patient shows no restriction. The cyst was biopsied and drained. Histological examination showed the cyst lining was glial tissue with no evidence for epithelial elements.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neuroglial cyst (NGC)

Synonyms

- Glioependymal cyst

Definitions

- Benign, glial-lined, fluid-containing cavity buried within cerebral white matter

IMAGING

General Features

- Best diagnostic clue
  - Nonenhancing CSF-like parenchymal cyst with minimal/no surrounding signal abnormality
- Location
  - May occur anywhere throughout neuraxis
    - Frontal lobe most common site
    - Intraparenchymal > extraparenchymal
- Size
  - Varies from few mm up to several cm
- Morphology
  - Smooth, rounded, unilocular, benign-appearing cyst

CT Findings

- NECT
  - Well-delineated, low-density cyst
    - Unilocular; no Ca++
- CECT
  - Wall does not enhance

MR Findings

- T1WI
  - Usually hypointense, resembles CSF
- T2WI
  - Hyperintense
- PD/intermediate
  - May be slightly hyperintense to CSF
- FLAIR
  - Usually suppresses
- DWI
  - Typically no diffusion restriction
- T1WI C+
  - No enhancement

Imaging Recommendations

- Best imaging tool
  - MR with T1WI C+, FLAIR, DWI

DIFFERENTIAL DIAGNOSIS

Porencephalic Cyst

- Communicates with ventricles
- Adjacent brain usually shows gliosis, spongiosis

Enlarged Perivascular Spaces (PVSs)

- Clusters of variable-sized cysts > single, unilocular cyst

Arachnoid Cyst

- Extraaxial

Ependymal Cyst

- Intraventricular

Epidermoid Cyst

- Does not suppress on FLAIR, restricts on DWI

Infectious Cyst

- e.g., neurocysticercosis, echinococcosis

PATHOLOGY

Gross Pathologic & Surgical Features

- Rounded, smooth, unilocular cyst usually containing clear fluid resembling CSF

Microscopic Features

- Varies from columnar (ependymal type) epithelium to low cuboidal cells resembling choroid plexus
  - Variable expression of GFAP
  - Cytokeratin, EMA expression absent

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache
- Other signs/symptoms
  - Seizures
  - Neurologic deficit (depends on cyst size, location)

Demographics

- Age
  - Any age; adults > children
- Gender
  - M = F
- Epidemiology
  - Uncommon (< 1% of intracranial cysts)

Natural History & Prognosis

- Varies with cyst size, location
- May be stable over many years

Treatment

- Observation vs. fenestration/drainage of cyst

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Use FLAIR, DWI to help distinguish between different types of intracranial cysts

KEY FACTS

TERMINOLOGY

- Periventricular cysts (PCs) of newborn
  - Encompasses wide variety of periventricular cystic lesions

IMAGING

- Anterior choroid plexus cysts (ACPC)
  - Posterior to caudothalamic groove, within choroid plexus or protruding into lateral ventricle
- Subependymal pseudocysts (SEPC)
  - Nonhemorrhagic: Anterior to caudothalamic groove
  - Posthemorrhagic: Commonly in caudothalamic notch
- Connatal cyst (CS)
  - At or just below superolateral angles of frontal horns &/or body of lateral ventricles
- Cystic periventricular leukomalacia (cPVL)
  - At or above superolateral angle of frontal horn
  - Along margins of lateral ventricles

CLINICAL ISSUES

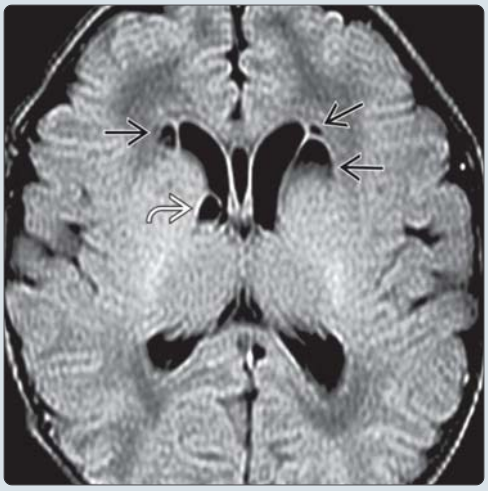
- Bilateral ACPC or SEPC → look for systemic disease
  - Inborn error of metabolism, TORCH, cocaine, etc.
- cPVL: More common in association with cytokine damage
  - Neonatal enterovirus
  - Maternal chorioamnionitis
  - Sepsis
- SEPC &/or ACPC detected in up to 5% of neonates
  - Frequently involute over time

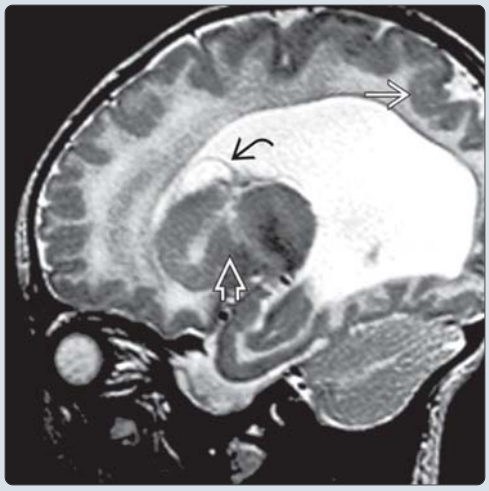
DIAGNOSTIC CHECKLIST

- Isolated SEPCs detected at prenatal US should prompt further investigation in following conditions
  - Cysts ≥ 9 mm diameter
  - SEPC located posterior to caudothalamic notch
  - SEPC with atypical morphology
  - SEPC facing temporal horns

(Left) *Coronal ultrasound in a newborn with intrauterine growth retardation demonstrates a round cyst in the anterior horn of the left lateral ventricle.* **(Right)** *Longitudinal ultrasound in the same infant shows the cyst behind the caudothalamic groove. The cyst may "bounce" on ultrasound.*

(Left) *Axial FLAIR MR in newborn with mitochondrial depletion syndrome and lactic acidosis demonstrates multiple periventricular cysts (PCs). Large paraventricular cysts adjacent to the frontal horns were noted in utero. Additionally, a subependymal cyst is anterior to the caudothalamic groove.* **(Right)** *Sagittal T2WI MR in a newborn with Zellweger syndrome reveals ventriculomegaly, focal cortical dysplasia, and a large subependymal cyst anterior to the caudothalamic groove.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neonatal periventricular cysts (PCs)

Definitions

- Periventricular cysts of newborn: Encompasses wide variety of periventricular cystic lesions
  - Anterior choroid plexus cyst (ACPC)
    - Cyst of anterior portion of choroid plexus in body of lateral ventricles
  - Subependymal pseudocyst (SEPC)
    - Subependymal cyst in region of caudate nucleus; may be congenital (germinolytic) or acquired (posthemorrhagic)
  - Connatal cyst (CS), a.k.a. coarctation of anterior horns
    - Controversial, some authors consider CS to be germinolytic cysts (GC)
  - Cystic periventricular leukomalacia (cPVL), previously known as paraventricular cysts
- Considerable overlap and confusion in literature

IMAGING

General Features

- Best diagnostic clue
  - ACPC
    - Spherical, thick or double walled
    - On US, look for "bouncing" of ACPC with pulsation to confirm location within choroid plexus
  - SEPC
    - Teardrop-shaped, thin walled
    - Nonhemorrhagic
      - Anterior to caudothalamic groove
    - Hemorrhagic
      - In caudothalamic groove, blood products identifiable during acute phase
  - cPVL
    - Local loss of brain volume
- Location
  - ACPC
    - Posterior to caudothalamic groove
    - Within choroid plexus or protruding into lateral ventricle
  - SEPC
    - Nonhemorrhagic
      - Anterior to caudothalamic groove
    - Posthemorrhagic
      - Commonly in caudothalamic notch
    - Slightly more common on left side
  - CS
    - At or just below superolateral angles of frontal horns &/or body of lateral ventricles
    - Anterior to foramina of Monro
  - cPVL
    - At or above superolateral angle of frontal horn
    - Along margins of lateral ventricles, anterior to posterior
    - Cysts may communicate with ventricles (porencephaly) or be separated from ventricles by ependyma
- Size
  - SEPC: 2-11 mm
  - Cysts in cystic periventricular leukomalacia are most variable in size, may be several centimeters in diameter
- Morphology
  - ACPC: Spherical, may exhibit double wall, nonseptate
  - SEPC: Teardrop-shaped, thin walled

CT Findings

- NECT: Hemorrhage within cysts may give clue to etiology

Ultrasonographic Findings

- ACPC: Double wall, may "bounce" with pulsation

Imaging Recommendations

- Best imaging tool
  - High-resolution sonography/linear array
- Protocol advice
  - Include gradient sequences with MR to exclude or confirm hemorrhagic etiology

DIFFERENTIAL DIAGNOSIS

Arachnoid Cyst

- Giant arachnoid cysts of foramen of Monro
- Distinguished by location
  - Not along caudothalamic groove
  - Not at superolateral frontal horn
  - Not along ventricular margins

Choroid Plexus Papilloma

- Rarely, choroid plexus papillomas can be purely cystic
- Intra- rather than periventricular

Hippocampal Sulcus Remnant Cysts

- Cornu ammonis, dentate gyrus normally fuse
- Defects leave remnant cysts within primitive hippocampal fissure
- Seen medial to temporal horn of lateral ventricle
- CSF-like "string of pearls" along hippocampus

Leukoencephalopathy With Calcifications and Cysts

- Distinguished genetically from Coats plus by absence of *CTC1* mutations
- Dense Ca++ in basal ganglia, thalami, dentate, brainstem, deep WM, pericystic distribution
- Diffuse leukoencephalopathy, usually symmetrical and periventricular
- Cysts in basal ganglia, thalami, deep WM, cerebellum, brainstem

PATHOLOGY

General Features

- Etiology
  - SEPC: Subependymal germinal matrix of neuronal and glial proliferation
    - Metabolically active and richly vascular
    - Insult (infection, hemorrhage, genetic) → lysis of cells

Gross Pathologic & Surgical Features

- Subependymal cyst
  - Cystic cavity bounded by pseudocapsule

https://CafePezeshki.IR

- Pseudocapsule consists of aggregates of germinal cells and glial tissue, not epithelium
- ± hemorrhage or reactive astrocytes, cystic necrosis
- CS: Ependymal lined
- cPVL: Cavitary white matter necrosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - SEPC vs. ACPC
    - SEPC somewhat more likely than ACPC to be associated with anomalies or systemic disease
    - Unilateral ACPC or SEPC
      - Low likelihood of associated anomalies
    - Bilateral ACPC or SEPC
      - Look for systemic disease
- Other signs/symptoms
  - ACPC very occasionally causes obstruction at foramina of Monro

Natural History & Prognosis

- SEPC &/or ACPC detected in up to 5% of neonates, frequently involute over time
  - Neurodevelopment of newborns with SEPC normal when no underlying disease present (exclude CMV infection)
  - Postnatal acquired SEPC (hemorrhagic) in very low-birth-weight infants = risk factor for impaired motor development
- cPVL prognosis generally poor, dependent upon amount of destroyed tissue that becomes incorporated into ventricle over time

Treatment

- None unless obstruction of lateral ventricles occurs

DIAGNOSTIC CHECKLIST

Consider

- Bilateral SEPCs are markers for systemic disease
  - Aneuploidy and multiple congenital anomaly syndromes
  - Growth disorders: Intrauterine growth restriction, large for gestational dates, Soto syndrome
  - TORCH: CMV, rubella
  - Intrauterine exposure to cocaine
  - Inborn error of metabolism
    - Peroxisomal biogenesis disorders (Zellweger)
    - Congenital lactic acidoses, PDH deficiency
    - Holocarboxylase synthetase deficiency
    - D-2OH and L-2OH glutaric aciduria
- Isolated SEPCs detected at prenatal US should prompt further investigation in following conditions
  - Cysts ≥ 9 mm diameter
  - SEPC facing temporal horns
  - SEPC located posterior to caudothalamic notch
  - SEPC with atypical morphology

Image Interpretation Pearls

- CT or gradient sequences may aid in differentiation

Reporting Tips

- May be extremely difficult or even impossible to differentiate SEPC and ACPC

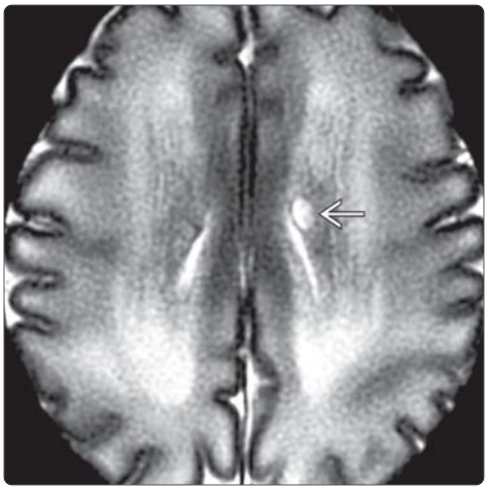
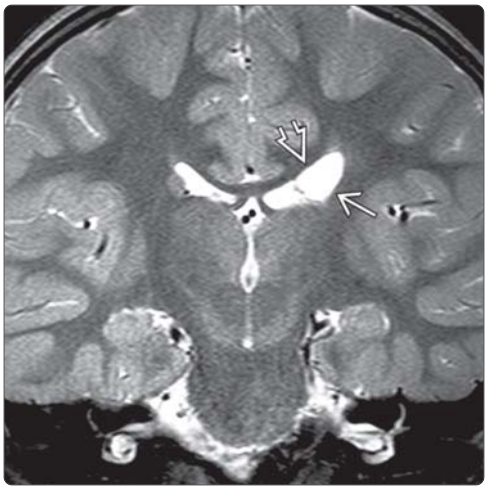
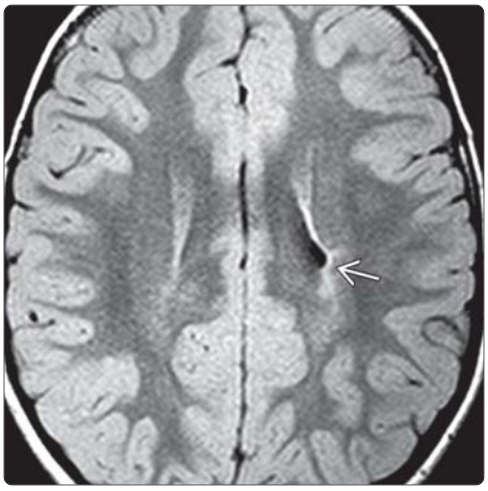
https://CafePezeshki.IR



(Left) *Coronal ultrasound 1 day after birth in a 31-week gestational infant demonstrates a cyst ⇨ adjacent to the lateral corner of the anterior horn. It is formed by a web-like adhesion ⇨ or coaptation of the anterior horn, representing a connatal cyst (CS).* **(Right)** *Axial T2WI MR in the same infant shows the CS ⇨. As is typical, the cyst was not present on follow-up ultrasound or MR.*





(Left) *Coronal T2WI MR in a toddler with a history of congenital hemiparesis demonstrates an apparent cyst of the anterior horn ⇨. However, note the loss of the body of the caudate nucleus ⇨ in this child with a paraventricular volume loss following neonatal ischemia.* **(Right)** *Axial FLAIR MR in the same child reveals focal atrophy in the body of the caudate nucleus and surrounding white matter gliosis ⇨.*

(Left) *Coronal T2WI MR in a preterm infant with a history of maternal chorioamnionitis reveals large paraventricular cysts ⇨. This pattern is more commonly called extensive cystic periventricular leukomalacia (cPVL).* **(Right)** *Sagittal T2WI MR reveals extensive cystic white matter damage ⇨. Lesions do not communicate with the ventricles, an appearance reported in term and pre-term infants who present with neonatal enterovirus or who have had exposure to maternal chorioamnionitis.*

https://CafePezeshki.IR

Choroid Fissure Cyst

KEY FACTS

TERMINOLOGY

- Extraaxial neuroepithelial cyst arising in or near choroid fissure

IMAGING

- Best imaging clue
  - Cystic lesion of medial temporal lobe, choroid fissure
  - Well-circumscribed round or ovoid on axial, "spindle-shaped" on sagittal MR
- NECT
  - CSF-like along medial temporal lobe, posteromedial to temporal horn
- MR
  - Follows CSF on all sequences
    - FLAIR: Complete suppression
    - DWI: No restricted diffusion
    - T1 C+: No enhancement
  - Sagittal MR shows typical "spindle" shape
  - Coronal T2 shows relationship to choroid fissure

TOP DIFFERENTIAL DIAGNOSES

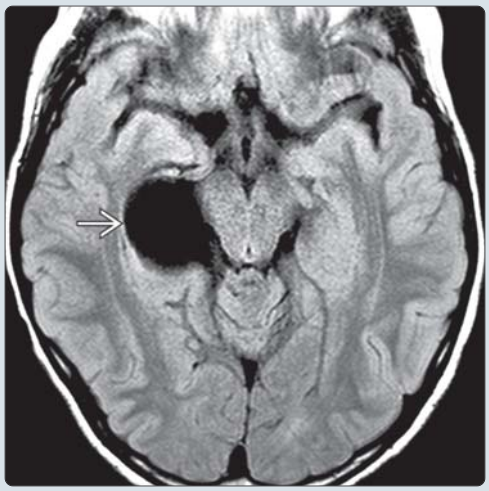
- Arachnoid cyst
- Epidermoid cyst
- Dermoid cyst
- Cystic tumor

PATHOLOGY

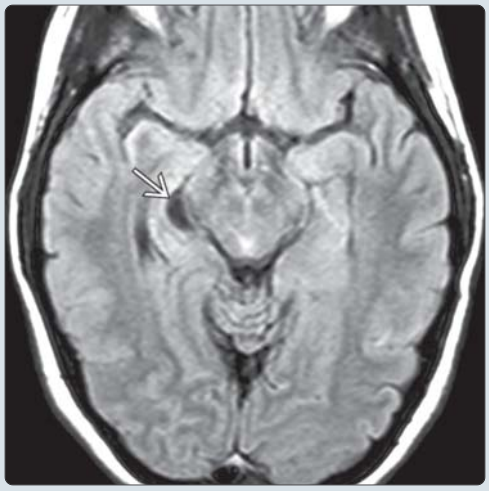
- Likely etiology = maldevelopment of embryonic tela choroidea
- Choroid fissure anatomy
  - Choroid fissure is CSF space between fimbria of hippocampus, diencephalon
  - Shallow fissure that curves posterosuperiorly from anterior temporal lobe to atrium of lateral ventricle

CLINICAL ISSUES

- Incidental benign finding
- Most commonly asymptomatic



(Left) *Sagittal T1WI MR shows a large choroidal fissure cyst ➡ with mass effect on the adjacent hippocampus. While these are most commonly incidental, there are case reports suggesting an association with complex partial seizures.* **(Right)** *Axial FLAIR MR in the same patient shows the isointense choroid fissure cyst ➡ just posterior to the uncus. The cyst displaces the temporal horn and distorts the normal hippocampus. Choroid fissure cysts follow CSF on all sequences.*



(Left) *Coronal T2WI MR shows a choroid fissure cyst displacing the temporal horn and causing hippocampal and parahippocampal gyrus flattening and distortion ➡.* **(Right)** *Axial FLAIR MR shows an incidental choroid fissure cyst ➡, medial to the temporal horn, in a young adult with headaches. These benign cysts follow CSF signal intensity on all sequences, including DWI, and do not enhance. These cysts usually require no treatment unless associated with medically refractory epilepsy.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Synonyms: Hippocampal remnant cyst, hippocampal sulcal cavities
- Cyst or string of cysts along residual cavity of primitive hippocampal sulcus

IMAGING

- String of cysts along lateral margin of hippocampus
- Cysts follow CSF signal on all MR sequences
  - T2: Hyperintense
  - FLAIR: Complete suppression
  - T1WI C+: No enhancement

TOP DIFFERENTIAL DIAGNOSES

- Mesial temporal sclerosis
- Choroid fissure cyst
- Arachnoid cyst
- DNET

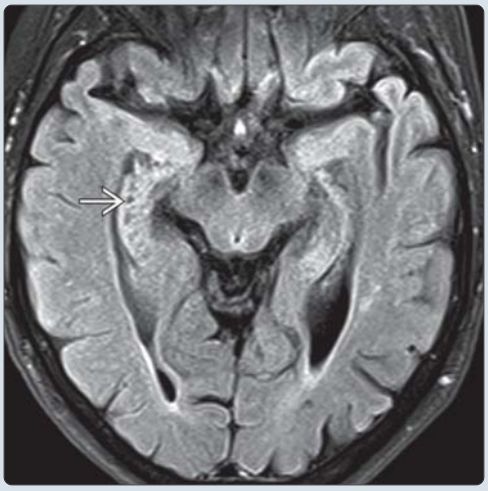
PATHOLOGY

- Represent partially unfused hippocampal sulcus
- Embryology
  - Primitive hippocampal fissure is formed as cornu ammonis and dentate gyrus fold on each other to form cleft
  - Cornu ammonis and dentate gyrus then fuse, leaving shallow hippocampal sulcus
  - Defects in this fusion cause remnant cysts within primitive sulcus

CLINICAL ISSUES

- Incidental finding, not associated with pathology
- Often observed on high-resolution imaging for evaluation of seizure patients (10-15%)
- Have been noted to enlarge with temporal lobe atrophy in Alzheimer disease

(Left) *Axial graphic of the normal temporal lobe shows a string of cysts within the lateral hippocampus, along the residual cavity of the primitive hippocampal sulcus ⇨, representing hippocampal sulcus remnant cysts. These incidental findings have a characteristic appearance.* **(Right)** *Axial T2WI in an asymptomatic patient shows prominent hippocampal sulcus remnants ⇨ in both medial temporal lobes.*



(Left) *Axial T2WI MR shows small hyperintense cysts in the hippocampus ⇨. These unfused remnants of the embryonic hippocampal sulcus present as CSF-like cysts, appearing as a "string of beads" coursing through the hippocampus.* **(Right)** *Axial FLAIR MR in the same patient shows complete suppression of the hippocampal sulcus remnant cysts ⇨. The "string of beads" appearance is typical of these common normal variants. They have been found to enlarge in patients with temporal lobe atrophy.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Pial-lined interstitial fluid (ISF) -filled structures
  - Accompany penetrating arteries
  - Do not communicate with subarachnoid space

IMAGING

- Clusters of variable-sized, well-delineated nonenhancing cysts
- PVSs occur in all locations, at all ages; easily seen in most patients on 3T imaging
- Most common site for normal PVSs = basal ganglia (clustered around anterior commissure)
  - Midbrain, thalami
  - Deep white matter (including corpus callosum, subinsular cortex, extreme capsule)
  - Almost never involve cortex (PVSs expand within subcortical white matter)
- PVSs usually 5 mm or less
  - Occasionally expand, attain large size
  - Most common location for expanded ("giant" or "tumefactive") PVSs = midbrain
  - May cause mass effect, obstructive hydrocephalus
- Isodense/isointense with CSF

TOP DIFFERENTIAL DIAGNOSES

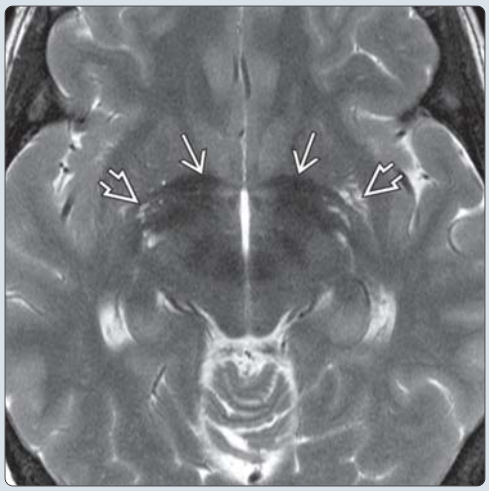
- Lacunar infarcts
- Cystic neoplasm (e.g., DNET, cystic astrocytoma)
- Infectious/inflammatory cysts

CLINICAL ISSUES

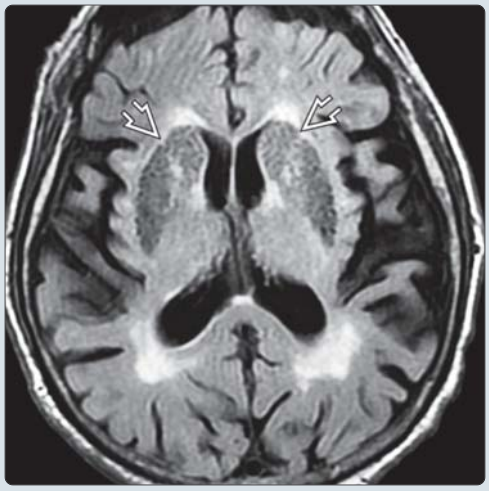
- Should not be mistaken for serious disease
- Usually remain stable in size over years

DIAGNOSTIC CHECKLIST

- Prominent, but normal, PVSs are identified in nearly all patients, in virtually every location at 3T imaging



(Left) *Coronal graphic shows normal perivascular spaces (PVSs) as they accompany penetrating arteries into the basal ganglia and subcortical white matter. Normal PVSs cluster around the anterior commissure but occur in all areas.* **(Right)** *Axial T2WI 3T MR with thin sections shows multiple small perivascular spaces ➔ clustered around the anterior commissure ➔ in the inferior 1/3 of the basal ganglia. These are normal findings.*



(Left) *Axial T2WI in an 88-year-old female with mild cognitive decline shows innumerable tiny CSF-like cysts in both basal ganglia ➔.* **(Right)** *Axial FLAIR in the same patient shows almost all the basal ganglia cysts ➔ suppress, indicating they are filled with fluid similar to CSF. The symmetry of the cysts and absence of FLAIR hyperintensity indicate these are enlarged perivascular spaces, sometimes called "état criblé" (cribriform state), and not lacunar infarcts.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Perivascular spaces (PVSs)

Synonyms

- Virchow-Robin spaces

Definitions

- Pial-lined interstitial fluid (ISF) -filled structures that accompany penetrating arteries but do not communicate directly with subarachnoid space

IMAGING

General Features

- Best diagnostic clue
  - Clusters of variable-sized fluid-filled spaces resembling CSF
    - Surround/accompany penetrating arteries
    - Found in virtually all locations, in patients of all ages
- Location
  - Most common site for normal PVSs = basal ganglia (clustered around anterior commissure)
  - Other common locations
    - Midbrain/thalami
    - Deep white matter
    - Subinsular cortex, extreme capsule
  - Less common sites
    - Dentate nuclei
    - Corpus callosum, cingulate gyrus
  - Most common location for expanded ("giant" or "tumefactive") PVSs = midbrain
    - Can be found almost anywhere
    - Almost never involve cortex (PVSs expand within subcortical white matter)
- Size
  - PVSs usually 5 mm or less
    - Occasionally expand, attain large size (up to several cm)
    - May cause focal mass effect, hydrocephalus
    - Widespread dilatation of PVSs may look very bizarre
- Morphology
  - Clusters of well-demarcated, variable-sized parenchymal cysts
  - Multiple > solitary cysts

CT Findings

- NECT
  - Clusters of round/ovoid/linear/punctate cyst-like lesions
    - Low density (attenuation = CSF)
    - No Ca++
- CECT
  - Do not enhance

MR Findings

- T1WI
  - Multiple well-delineated cysts isointense with CSF
  - Focal mass effect common
    - Expand overlying gyri
    - Thalamomesencephalic enlarged PVSs may compress aqueduct/3rd ventricle, cause hydrocephalus
- T2WI
  - Appear isointense with CSF
    - Signal intensity within PVSs actually measures slightly < CSF
  - No edema in adjacent brain; may have ↑ SI
- PD/intermediate
  - Isointense with CSF
- FLAIR
  - Suppress completely
  - 25% have minimal increased signal in brain surrounding enlarged PVSs
- T2* GRE
  - No "blooming"
- DWI
  - No restricted diffusion
- T1WI C+
  - No enhancement
  - ± visualization of penetrating arteries with contrast
- MRS
  - Spectra in adjacent brain typically normal

Imaging Recommendations

- Best imaging tool
  - Routine MR + FLAIR, DWI
- Protocol advice
  - Contrast optional

DIFFERENTIAL DIAGNOSIS

Lacunar Infarcts

- Older patients
- Common in basal ganglia, white matter
- Adjacent parenchymal hyperintensity

Cystic Neoplasm

- Usually in pons, cerebellum, thalamus/hypothalamus
- Single > multiple cysts
- Signal not quite like CSF
- Parenchymal signal abnormalities common
- May enhance

Infectious/Inflammatory Cysts

- Neurocysticercosis
  - Cysts often have scolex
  - Most are < 1 cm
  - Can be multiple but do not typically occur in clusters
  - Cyst walls often enhance
  - Surrounding edema often present
- Other parasites
  - Hydatid cysts often unilocular, almost all in children
  - Multilocular parasitic cysts typically enhance, mimic neoplasm more than PVSs

PATHOLOGY

General Features

- Etiology
  - Theory: ISF accumulates between penetrating vessel, pia
  - Egress of ISF blocked, causing cystic enlargement of PVS
    - Enlarged cystic-appearing spaces
    - Actually contain interstitial fluid, not CSF
- Genetics

https://CafePezeshki.IR

- Usually normal unless PVSs expanded by undegraded mucopolysaccharides (Hurler, Hunter disease)
- PVSs expand in some congenital muscular dystrophies
- Associated abnormalities
  - Hydrocephalus (midbrain expanding PVSs can obstruct aqueduct)
  - "Cysts" caused by enlarged/obstructed PVSs reported with pituitary adenomas, large aneurysms
  - PVSs provide entry site into CNS in inflammatory, neoplastic disorders
    - Transmigration across capillaries, venules into PVSs
    - Progress across glia limitans into parenchyma
  - May be associated with increased risk of microvascular disease

Gross Pathologic & Surgical Features

- Smoothly demarcated, fluid-filled cyst(s)

Microscopic Features

- Single or double layer of invaginated pia
- Pia becomes fenestrated, disappears at capillary level
- PVSs usually very small in cortex, often enlarge in subcortical white matter
- Surrounding brain usually lacks gliosis, amyloid deposition

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually normal, discovered incidentally at imaging/autopsy
  - Nonspecific symptoms (e.g., headache)
  - Reported association with increased risk of hypertensive hemorrhages, cerebral small vessel disease
- Clinical profile
  - Patient with nonspecific, nonlocalizing symptoms and bizarre, alarming multicystic-appearing brain mass initially diagnosed as "cystic neoplasm"

Demographics

- Age
  - Occur in all locations, at all ages
    - Easily seen on 3T imaging
  - Present in 25-30% of children (benign normal variant)
  - Enlarged PVSs
    - Mean age = mid 40s
    - May occur in children
- Gender
  - Giant PVSs: M:F = 1.8:1
- Epidemiology
  - Common nonneoplastic brain "cyst"
  - Common cause of multifocal hyperintensities on T2WI

Natural History & Prognosis

- Usually remain stable in size over many years
- Rarely continue to expand
- Rare spontaneous regression of "tumefactive" PVS reported

Treatment

- "Leave me alone" lesion that should not be mistaken for serious disease
- Shunt ventricles if midbrain lesions cause obstructive hydrocephalus
  - Cystoventriculoperitoneal shunt has been reported as alleviating symptoms

DIAGNOSTIC CHECKLIST

Consider

- Could multicystic, nonenhancing mass on MR or CT be cluster of enlarged PVSs

Image Interpretation Pearls

- Prominent, but normal, PVSs are identified in nearly all patients, in virtually every location at 3T imaging

No enhancement was seen on T1WI C+ MR.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Nonneoplastic intrapineal glial-lined cyst

IMAGING

- CT
  - Sharply demarcated, smooth cyst behind 3rd ventricle
  - 80% < 10 mm (can be large; reported up to 4.5 cm)
  - Fluid iso-/slightly hyperdense to CSF
  - 25% Ca++ in cyst wall
- MR
  - Slightly hyperintense to CSF (55-60%) on most sequences
  - Isointense (40%)
  - 1-2% hemorrhage (heterogeneous signal intensity)
  - Does not suppress on FLAIR

TOP DIFFERENTIAL DIAGNOSES

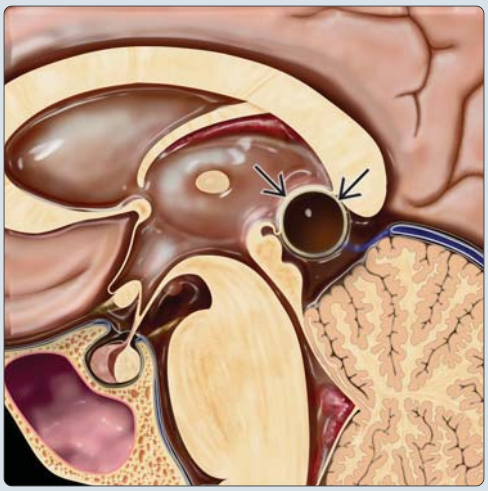
- Normal pineal gland
- Pineocytoma
- Epidermoid cyst
- Arachnoid cyst
- Pineal parenchymal tumor of intermediate differentiation

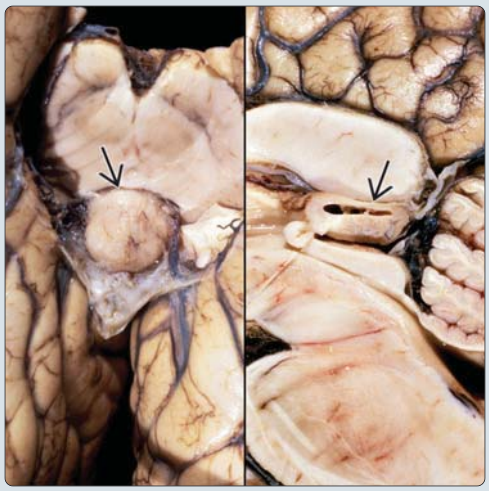
CLINICAL ISSUES

- Vast majority clinically silent, discovered incidentally
  - Occur at all ages
  - Found in 1-5% of normal MRs
  - May spontaneously resolve in children
- Headache (less common)
- "Pineal apoplexy" with intracystic hemorrhage (rare)
  - ± acute hydrocephalus, sudden death (very rare)

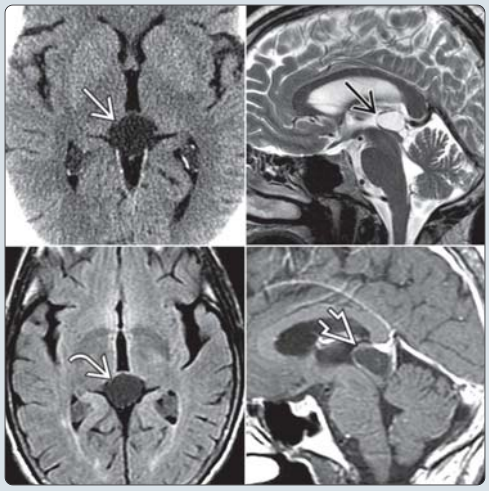
DIAGNOSTIC CHECKLIST

- Cannot distinguish benign PC from neoplasm (pineocytoma) on basis of imaging studies alone
  - Both may remain stable for many years
- Heterogeneous, nodular, or ring-like enhancing pineal mass may be benign cyst, not neoplasm





(Left) *Sagittal graphic shows a small cystic lesion within the pineal gland. Small benign pineal cysts (PCs) are often found incidentally at autopsy or imaging.* **(Right)** *Submentovertex (left) and sagittal midline section (right) show a benign, nonneoplastic pineal gland cyst found incidentally at autopsy. The cyst is very well delineated and has a moderately thick wall surrounding the cystic cavity. (Courtesy E. Tessa Hedley-Whyte, MD.)*



(Left) *Axial NECT scan in a patient with chronic nonspecific headaches and normal neurologic examination shows a 16 mm cystic pineal gland with rim calcifications. The lesion is stable over several years and is a presumed nonneoplastic pineal cyst.* **(Right)** *Collage of images shows a 20 mm pineal cyst on NECT that is slightly hyperdense to CSF in the adjacent 3rd ventricle. The lesion is hyperintense on T2WI and FLAIR. A thin enhancing rim is present on T1C+. This is a surgically proven pineal cyst.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pineal cyst (PC)

Synonyms

- Glial cyst of pineal gland

Definitions

- Nonneoplastic intrapineal glial-lined cyst

IMAGING

General Features

- Best diagnostic clue
  - Fluid-filled pineal region mass
- Location
  - Above, clearly distinct from tectum
  - Below velum interpositum, internal cerebral veins (ICVs)
- Size
  - Most are small (< 1 cm)
  - Occasionally up to 2 cm or more
- Morphology
  - Round/ovoid, relatively thin-walled cyst
    - 95% minimal/no compression of tectum, aqueduct
      - May be multilocular
    - 5% flatten tectum, occasionally compress aqueduct
    - Variable hydrocephalus (with large cysts or cyst apoplexy)
      - Enlarged 3rd, lateral ventricles
      - Normal 4th ventricle

CT Findings

- NECT
  - Sharply demarcated, smooth cyst behind 3rd ventricle
    - Fluid iso-/slightly hyperdense to CSF
    - Ca++ in cyst wall (25%)
    - Rare: Hyperdense cyst
      - Acute hemorrhage ("pineal apoplexy")
- CECT
  - Rim or nodular enhancement

MR Findings

- T1WI
  - Slightly hyperintense to CSF (55-60%)
  - Isointense (40%)
  - Hemorrhagic (heterogeneous signal intensity) (1-2%)
- T2WI
  - Iso-/slightly hyperintense to CSF
  - Multicystic/septated (20-25%)
- PD/intermediate
  - Hyperintense to CSF (85-90%)
- FLAIR
  - Does not suppress
  - Moderately hyperintense
- T2* GRE
  - Usually normal
  - Uncommon: Blooming (old or recent hemorrhage)
- DWI
  - Typically shows no restriction
- T1WI C+
  - Pineal gland always enhances (no blood-brain barrier)
    - Most common: Thin rim (≤ 2 mm)
      - Can be partial, eccentric, incomplete
    - Less common: Nodular, irregular enhancement
    - Cystic areas will always fill in on delayed scans, can resemble solid tumor
      - Differentiate from tumor by doing sagittal MR immediately after contrast administration
- MRV
  - ICVs may be elevated by large lesions
- MRS
  - Neuronal markers absent

Angiographic Findings

- Arterial phase almost always normal
- Venous phase
  - May show elevation, displacement of ICVs if large PC present
  - Thalamostriate veins splayed, bowed if hydrocephalus present

Imaging Recommendations

- Best imaging tool
  - MR ± contrast
    - DWI, T2*, MRS may be helpful
- Protocol advice
  - Use thin sections (≤ 3 mm) for detecting and defining lesions in this anatomically complex region

DIFFERENTIAL DIAGNOSIS

Normal Pineal Gland

- Can be cystic
- 3 anatomic appearances on contrast-enhanced imaging
  - Nodule (52%)
  - Crescent (26%)
  - Ring-like (22%)

Pineocytoma

- Usually solid or partially solid/cystic
- Purely cystic pineocytoma much less common
  - May be indistinguishable on imaging studies
  - Require histology for definitive diagnosis
- Both pineal cyst and pineocytoma may remain stable for many years without significant change on serial imaging

Epidermoid Cyst

- Quadrigeminal cistern relatively rare location
- "Cauliflower" configuration
- Mild/moderate restriction on DWI

Arachnoid Cyst

- Displaces normal gland; no Ca++, enhancement
- Follows CSF attenuation, signal intensity

Pineal Parenchymal Tumor of Intermediate Differentiation

- 20% of pineal parenchymal tumors
- Usually larger, more heterogeneous than pineal cyst or pineocytoma
  - Extension into adjacent structures common
  - CSF dissemination not uncommon

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Etiology/pathogenesis: 3 major theories
    - Enlargement of embryonic pineal cavity
    - Ischemic glial degeneration ± hemorrhagic expansion
    - Small preexisting cysts enlarge with hormonal influences
- Genetics
  - None known
- Associated abnormalities
  - Hydrocephalus (uncommon)
  - Embryology
    - Primitive pineal diverticulum divides into pineal recess, cavum pineal
    - Cavum pineal usually obliterated by glial fibers
    - Incomplete obliteration may leave residual cavity

Gross Pathologic & Surgical Features

- Smooth, soft, tan to yellow cyst wall
  - Cavity can be uni- or multilocular
  - Fluid contents vary
    - Clear yellow (most common) to hemorrhagic
- 80% < 10 mm
- Can be large (reported up to 4.5 cm)

Microscopic Features

- Delicate (usually incomplete) outer leptomeningeal layer
- Middle layer of attenuated pineal parenchyma
  - ± Ca++
- Inner layer of dense fibrillar glial tissue with
  - Variable granular bodies
  - ± hemosiderin-laden macrophages
- Compare with pineocytoma
  - Pseudolobular arrangement of small, round cells with pleomorphic nuclei
  - "Pinocytic" rosettes
  - Neuronal differentiation
    - Neuron-specific enolase, synaptophysin positive cells

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Vast majority clinically silent
    - Discovered incidentally at imaging/autopsy
  - Large cysts (> 1 cm) rarely become symptomatic
    - 50% headache (aqueduct compression, hydrocephalus)
    - 10% Parinaud syndrome (tectal compression)
    - Sx usually associated with hemorrhage
  - Rare: "Pineal apoplexy"
    - Severe headache (can be "thunderclap," mimic aneurysmal subarachnoid hemorrhage)
    - Intracystic hemorrhage, acute hydrocephalus, sudden death
- Clinical profile
  - Young female with nonfocal headache

Demographics

- Age
  - Can occur at **any** age
    - Older adults > children
  - Incidence among women between 21-30 years significantly higher than any other group
    - Incidence in women decreases with age
    - No change in males
- Gender
  - F:M = 3:1
- Ethnicity
  - None known
- Epidemiology
  - 1-5% of normal MRs
    - 2% in children, young adults
  - 25-40% of microscopic cysts within pineal gland found at autopsy

Natural History & Prognosis

- Size generally remains unchanged in males
- Cystic expansion of pineal in some females begins in adolescence, decreases with aging
- Rare: Sudden expansion, hemorrhage ("pineal apoplexy")

Treatment

- Usually none
- Atypical/symptomatic lesions may require stereotactic aspiration or biopsy/resection
  - Preferred approach = infratentorial supracerebellar

DIAGNOSTIC CHECKLIST

Consider

- PCs often asymptomatic, incidental MR finding
- MR appearance of PCs varies
  - Uncomplicated cystic mass
  - Mass with hemorrhage, enhancement, or hydrocephalus
- Heterogeneous, nodular, or ring-like enhancing pineal mass **may be benign cyst, not neoplasm**

Image Interpretation Pearls

- Cannot distinguish benign PC from neoplasm (pineocytoma) on basis of imaging studies alone
- Histopathology required for definitive diagnosis
  - May be complicated by tissue fragmentation, cyst collapse, reactive changes in adjacent tissue

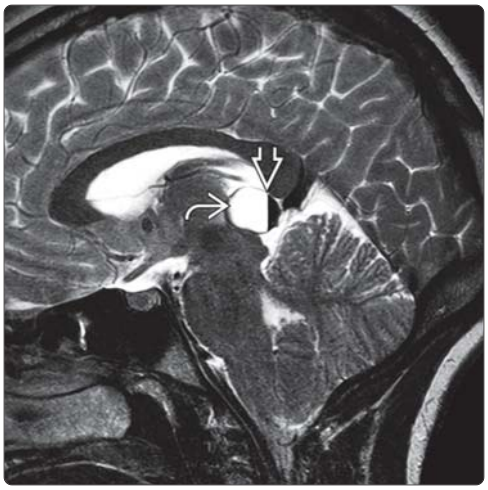
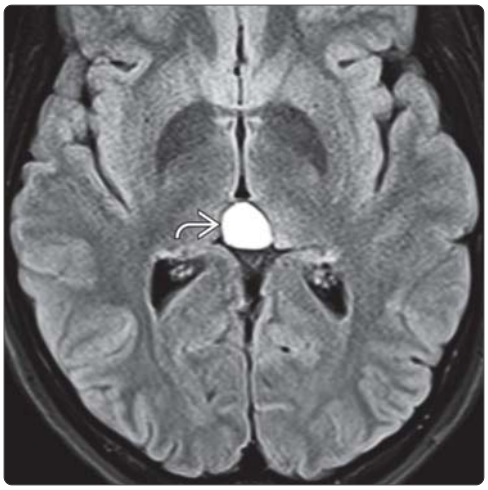
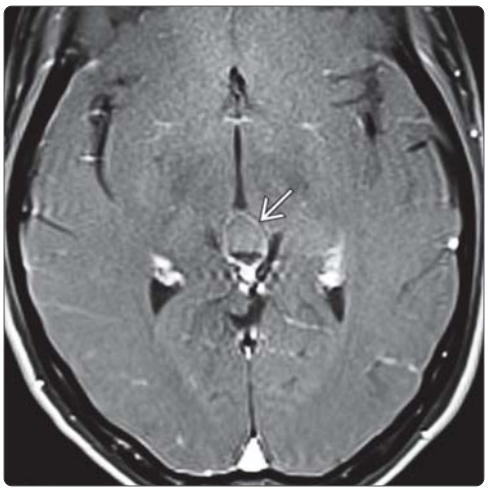
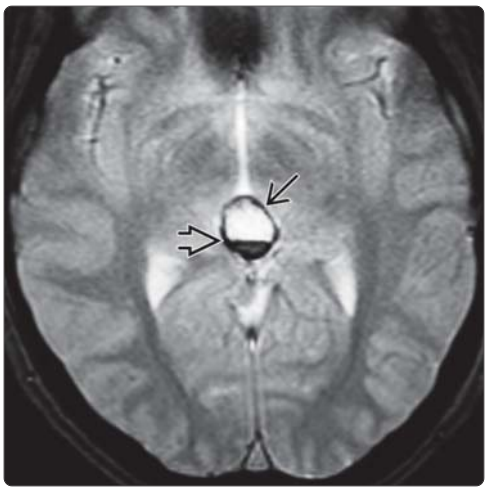
(Left) *Axial T2WI in a 52-year-old female with dizziness and double vision, but normal neurologic examination, shows a normal-sized, but multicystic-appearing, pineal gland* ➡. **(Right)** *T1C+FS in the same patient shows rim stippled enhancement of the pineal gland* ⇨. *Multicystic pineal glands are a normal variant.*





(Left) *Sagittal T2FS MR in a 17-year-old female with sudden onset of severe headache shows a cystic pineal gland* ⇨ *with a blood-fluid level* ➡. **(Right)** *Axial FLAIR in the same patient shows the fluid-filled pineal cyst* ⇨ *does not suppress. There is no evidence for obstructive hydrocephalus.*





(Left) *T1C+FS in the same patient shows a thin rim of enhancement in the cyst wall* ➡. **(Right)** *Axial T2* GRE scan shows blooming hemorrhage in the cyst wall* ⇨ *and a dependent blood-fluid level* ⇨ *in the cyst. Pineal cyst apoplexy is rare but can cause acute neurologic symptoms.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Nonneoplastic, noninflammatory cysts
  - Contained within choroid plexus
  - Lined by compressed connective tissue

IMAGING

- General
  - Typically in atria of lateral ventricle
  - Usually small (2-8 mm)
  - Rare: Large cysts (> 2 cm)
  - Usually multiple, often bilateral
- CT
  - Isodense or slightly hyperdense to CSF
  - Irregular, peripheral Ca++ common in adults
- MR
  - Isointense or slightly hyperintense compared to CSF on T1WI
  - 2/3 isointense, 1/3 hypointense on FLAIR
  - 60-80% "bright" on DWI
  - Enhancement (ring, nodular, solid) varies from none to strong

TOP DIFFERENTIAL DIAGNOSES

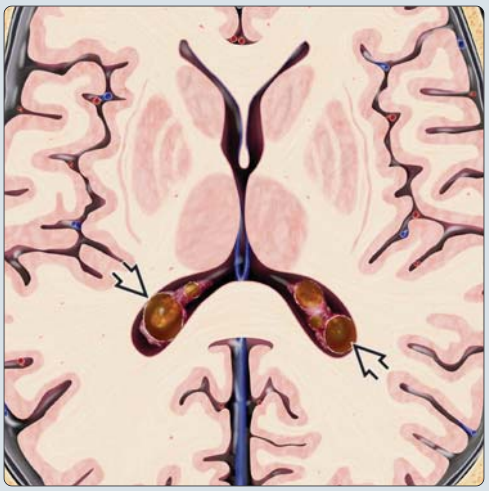
- Ependymal cyst
- Neurocysticercosis
- Epidermoid cyst
- Choroid plexus papilloma (CPP)
  - Purely cystic CPP very rare

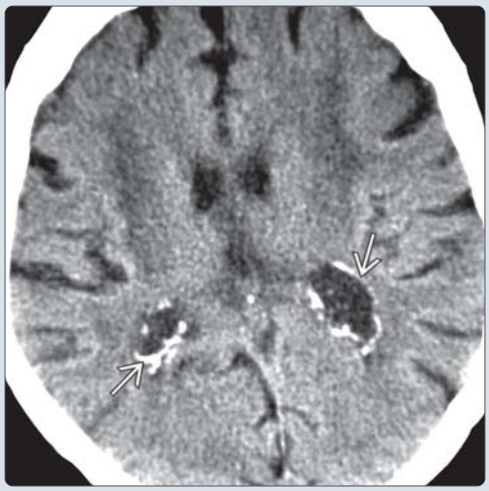
CLINICAL ISSUES

- Found at both ends of age spectrum
  - Common in fetus, infants, older adults
  - Less common in children, young adults
- Clinically silent, discovered incidentally
- Associations: Aicardi syndrome, trisomy 18

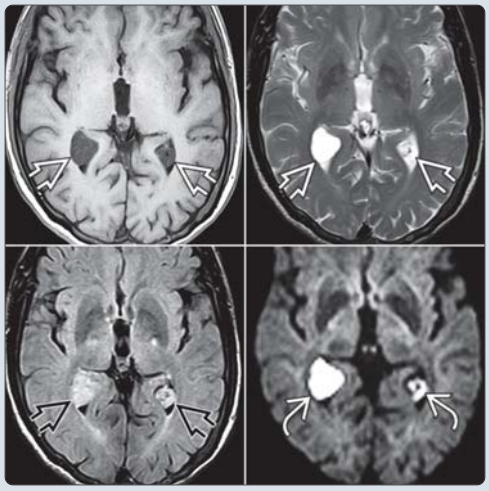
DIAGNOSTIC CHECKLIST

- Most common choroid plexus mass in adults = CPC





(Left) *Axial graphic shows multiple cystic masses in the choroid plexus glomi ⇨, often seen incidentally on scans of middle-aged and older adults. Most are degenerative xanthogranulomas.* **(Right)** *Axial NECT obtained in an elderly adult with minor head trauma and a normal neurological examination shows dense peripheral calcifications ➡ around cystic masses in the atria of both lateral ventricles. This was an incidental finding with no clinical significance.*



(Left) *Axial T1WI C+ FS MR in a 52-year-old man with headaches and no neurological abnormalities shows multiple mixed solid and ring-enhancing cysts in the atria of both lateral ventricles ➡.* **(Right)** *Series of axial MR scans show incidental finding of bilateral choroid plexus cysts in an older patient. Cysts are slightly hyperintense to CSF on T1- and T2WIs ➡, typically do not suppress on FLAIR ⇨ and frequently appear very bright on DWI ➡.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Choroid plexus cyst (CPC)
- Choroid plexus xanthogranuloma (CPX)

Definitions

- Nonneoplastic, noninflammatory cysts of choroid plexus
  - Lined by compressed connective tissue
  - Adult: CPC is common incidental finding on imaging studies in older patients (~ 40% prevalence)
  - Fetus: CPCs seen in 1% of 2nd trimester pregnancies

IMAGING

General Features

- Best diagnostic clue
  - Older patient with "bright" cysts in choroid plexuses on T2WI
  - Fetus or newborn with large (> 2 mm) choroid plexus cyst(s) on US
- Location
  - Most common: Atria of lateral ventricles
    - Attached to or within choroid plexus
    - > 2/3 bilateral
  - Less common: 3rd and 4th ventricles
- Size
  - Variable
    - Usually small (2-8 mm)
    - Often multiple
    - Rare: Large cysts (> 2 cm)
- Morphology
  - Cystic or nodular/partially cystic mass(es) in choroid plexus glomi

CT Findings

- NECT
  - Iso-/slightly hyperdense (due to presence of increased protein) to CSF
  - Irregular, peripheral Ca++ in majority of adult cases
- CECT
  - Varies from none to rim of solid enhancement

MR Findings

- T1WI
  - Isointense or slightly hyperintense (due to presence of increased protein) compared to CSF
- T2WI
  - Hyperintense compared to CSF
- PD/intermediate
  - Hyperintense
- FLAIR
  - 2/3 isointense, 1/3 hypointense
- T2* GRE
  - Foci of "blooming" common
    - Ca++ (intracystic hemorrhage rare)
- DWI
  - 60-80% show high signal on DWI
- T1WI C+
  - Enhancement varies from none to strong
  - Variable pattern (solid, ring, nodular)
  - Delayed scans may show filling in of contrast within cysts

Ultrasonographic Findings

- Grayscale ultrasound
  - Prenatal US
    - Cyst > 2 mm surrounded by echogenic choroid
    - In absence of other abnormalities, low risk for chromosomal abnormalities

Imaging Recommendations

- Best imaging tool
  - Adults: MR ± contrast
  - Fetus, newborn
    - Antenatal: Maternal US or MR
    - Postnatal: US of infant with anterior, posterior, mastoid fontanelles as acoustic windows
- Protocol advice
  - MR with contrast, FLAIR, DWI
  - US transverse view of lateral ventricle at atrial level

DIFFERENTIAL DIAGNOSIS

Ependymal Cyst

- Does not enhance
- Usually unilateral
- Attenuation, signal more like CSF
- Immunohistochemistry differentiates

Neurocysticercosis (NCC)

- Multiple cysts common (subarachnoid space, parenchyma ventricles)
- Not associated with choroid plexus
- Look for scolex, other signs of NCC (e.g., parenchymal Ca++)
- May be migratory

Epidermoid Cyst

- Intraventricular location rare (4th > > lateral ventricle)
- "Cauliflower," insinuating pattern

Choroid Plexus Papilloma (CPP)

- Children < 5 years
- Strong, relatively uniform enhancement
- Purely cystic CPP very rare

Villous Hyperplasia of Choroid Plexus

- Very rare
- Often overproduces CSF
- Causes hydrocephalus

Ultrasound Pseudolesion

- Tiny anechoic areas in fetal choroid are normal, not CPC
- Normal, fluid-filled atria can be confused with CPC on transverse view
- "Split" or "truncated" choroid can mimic CPC

Neoplasm

- Meningioma (usually solid)
- Metastasis (rarely cystic)
- Cystic astrocytoma (rare in older patients)

Sturge-Weber Syndrome

- Enlarged, angiomatous, choroid plexus ipsilateral to malformation

https://CafePezeshki.IR

Choroid Plexus Infarct

- Usually seen in choroid artery infarct
- May cause ↑ intraventricular signal on DWI

Choroid Plexus Cavernoma

- Rare mass most common in adults
- Mention when MR shows marked susceptibility

PATHOLOGY

General Features

- Etiology
  - CPCs
    - Lipid from desquamating, degenerating choroid epithelium accumulates in choroid plexus
    - Lipid provokes xanthomatous response
- Genetics
  - Large, fetal choroid plexus cysts associated with trisomy 21 or 18 in only 6% of cases
  - Presence of additional malformations increases risk factors for aneuploidy
- Associated abnormalities
  - Fetal CPC
    - Trisomy 18 (mildly increased risk < 2x baseline risk)
    - Trisomy 21 (only if other markers present)
  - Adult CPC: May cause obstructive hydrocephalus (rare)
  - Aicardi syndrome
    - Patients diagnosed by presence of retinal lacunae, severe corpus callosum hypo-/agenesis, polymicrogyria, heterotopia
    - Usually associated with choroid plexus papillomas, but may occur with choroid plexus cysts

Gross Pathologic & Surgical Features

- CPC commonly found at autopsy in middle-aged, older adults
  - Nodular, partly cystic, yellowish-gray masses in choroid plexus glomus
  - Contents often gelatinous, highly proteinaceous
  - Rare: Hemorrhage

Microscopic Features

- Neuroepithelial microcysts
- Trapped choroid plexus epithelium often associated
- Cysts contain nests of foamy, lipid-laden histiocytes
- Foreign body giant cells
- Chronic inflammatory infiltrates (lymphocytes, plasma cells)
- Cholesterol clefts, hemosiderin
- Peripheral psammomatous Ca++ common
- Immunohistochemistry positive for prealbumin, cytokeratins, GFAP, EMA, S100

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Adult CPC
    - Typical: Clinically silent, discovered incidentally at autopsy/imaging
    - Rare: Headache

Demographics

- Age
  - Found at both ends of age spectrum
    - Adult CPC: Prevalence increases with age
    - Fetal CPC: Prevalence decreases with age
- Gender
  - No known prevalence
- Ethnicity
  - No known prevalence
- Epidemiology
  - Most common type of neuroepithelial cyst
    - 1% of all pregnancies on routine US
    - 50% of fetuses with T18
    - Small, asymptomatic CPCs found incidentally in more than 1/3 of all autopsied adults

Natural History & Prognosis

- Fetal CPCs
  - Transient finding; typically resolve in 3rd trimester regardless of whether isolated or with associated anomalies
  - CPC + minor markers = 20% risk for chromosome abnormality
  - CPC + major markers = 50% risk for chromosome abnormality
- Adult CPCs
  - Usually remain asymptomatic, nonprogressive

Treatment

- Adult CPC: Usually none
  - Rare: Shunt for obstructive hydrocephalus
- Fetal CPC
  - In absence of other markers, none
  - With other markers, amniocentesis warranted

DIAGNOSTIC CHECKLIST

Consider

- Amniocentesis with karyotyping if CPCs + other anomalies (e.g., cardiac anomaly, clenched hands with overlapping fingers, clubfeet) present on fetal US

Image Interpretation Pearls

- Benign degenerative cyst (xanthogranuloma): Most common cause of choroid plexus mass in adults

https://CafePezeshki.IR

Ependymal Cyst

KEY FACTS

TERMINOLOGY
- Congenital, benign, ependymal-lined cyst of brain

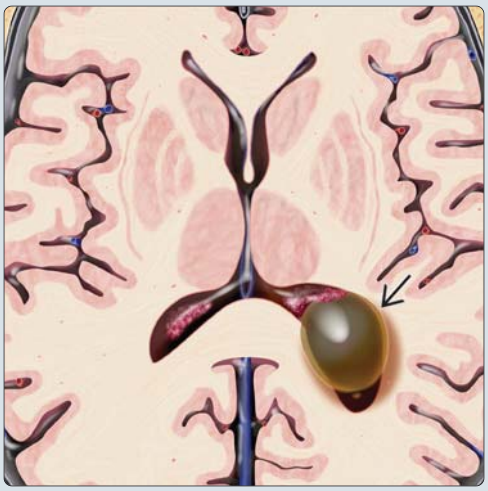
IMAGING
- Nonenhancing thin-walled cyst
  - CSF density/intensity
- Most common location = intraventricular (lateral; 3rd rare)
  - Less common: Parenchyma, subarachnoid space

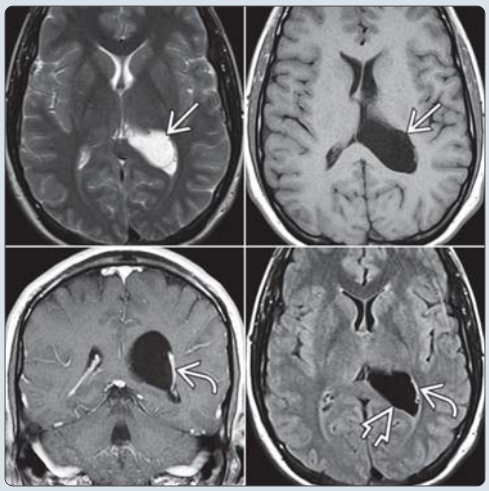
TOP DIFFERENTIAL DIAGNOSES
- Asymmetric lateral ventricles (normal variant)
- Choroid plexus cyst
- Arachnoid cyst
- Epidermoid cyst
- Neurenteric cyst
- Porencephalic cyst
- Neurocysticercosis

PATHOLOGY
- Thin-walled cyst filled with clear serous liquid
- Fluid-filled space lined by columnar or cuboidal cells

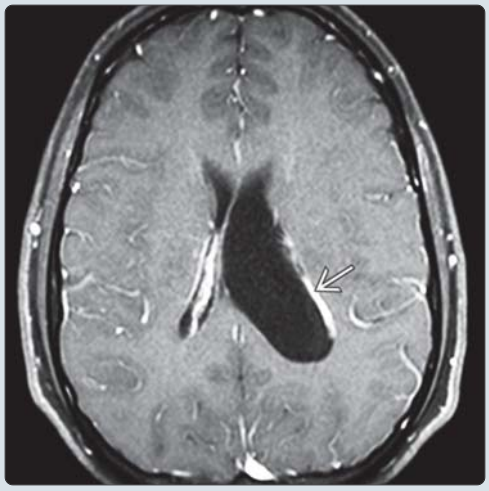
CLINICAL ISSUES
- Typically asymptomatic
- Headache, seizure, gait disturbance, dementia
- Symptoms related to CSF obstruction/↑ ICP
- Young adults (typically < 40 years old)
- Interval follow-up typically shows no clinical or imaging changes in asymptomatic lesions
- Symptomatic intraventricular cysts treated via neuronavigation-assisted fenestration

DIAGNOSTIC CHECKLIST
- Ependymal cysts may be indistinguishable from other benign intracranial cysts
- Ependymal cysts follow CSF on all MR sequences, including DWI; no enhancement





(Left) *Axial graphic depicts a typical ependymal cyst of the lateral ventricle ⇨, seen here as a CSF-containing simple cyst that displaces the choroid plexus around it. Ependymal cysts typically follow CSF signal on all sequences.* **(Right)** *MR scans demonstrate the typical appearance of an ependymal cyst in the atrium of the left lateral ventricle. The cyst ⇨ behaves exactly like CSF on all sequences, suppressing completely on FLAIR ⇨. Note the choroid plexus ⇨ displaced around the cyst. Incidental finding in this asymptomatic patient.*



(Left) *NECT in a 22 year old with headaches shows a CSF-like mass in the body of the left lateral ventricle ⇨. The large intraventricular cyst displaces the septum pellucidum across the midline ⇨ and displaces the calcified choroid plexus laterally ⇨.* **(Right)** *T1C+FS in the same patient shows the cyst does not enhance. The enhancing choroid plexus ⇨ is displaced laterally around the cyst. Neuronavigation-assisted endoscopic fenestration of the ependymal cyst was performed.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Ependymal cyst (EC)

Synonyms

- Neuroepithelial cyst, glioependymal cyst

Definitions

- Congenital, benign, ependymal-lined cyst of brain

IMAGING

General Features

- Best diagnostic clue
  - Nonenhancing, thin-walled, CSF density/intensity
- Location
  - Most common: Intraventricular (lateral > 3rd, 4th)
  - Less common: Cerebral parenchyma
- Size
  - Typically small (2-3 mm) but up to 8-9 cm reported
- Morphology
  - Smooth, thin-walled cyst

CT Findings

- NECT
  - Cyst is isodense to CSF; Ca++ extremely rare
- CECT
  - No enhancement

MR Findings

- T1WI
  - Isointense to CSF, cyst wall may be seen
- T2WI
  - Isointense to hyperintense to CSF (protein content)
- FLAIR
  - Isointense to CSF (suppresses)
- DWI
  - Isointense to CSF
- T1WI C+
  - No enhancement unless infected

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR with T1WI C+, DWI

DIFFERENTIAL DIAGNOSIS

Asymmetric Ventricles

- Lateral ventricle asymmetry, normal variant

Choroid Plexus Cyst

- Typically bilateral, arises in choroid plexus glomus

Neurocysticercosis

- Scolex present; does not suppress on FLAIR

Arachnoid Cyst

- May be indistinguishable; CSF intensity

Epidermoid Cyst

- Subarachnoid space > ventricles (4th most common)
- Heterogeneous on FLAIR, DWI hyperintensity

Neurenteric Cyst

- Extraaxial (typically posterior fossa) > parenchyma

PATHOLOGY

Gross Pathologic & Surgical Features

- Thin-walled cyst
- Filled with clear, serous liquid

Microscopic Features

- Fluid-filled space
  - May be lined by columnar or cuboidal cells

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Typically asymptomatic
- Other signs/symptoms
  - Rarely headache, seizure, gait disturbance, dementia
  - Symptoms related to CSF obstruction/↑ ICP

Demographics

- Age
  - Young adults (typically < 40 years old)
- Gender
  - Male predominance
- Epidemiology
  - Uncommon (< 25 symptomatic cases reported)

Natural History & Prognosis

- Uncommon so natural history unknown
- Follow-up typically shows no clinical or imaging changes in asymptomatic lesions
  - Imaging follow-up best with MR

Treatment

- If asymptomatic, conservative management
- Symptomatic intraventricular cysts treated via neuronavigation-assisted fenestration

DIAGNOSTIC CHECKLIST

Consider

- Ependymal cysts may be indistinguishable from other benign intracranial cysts

Image Interpretation Pearls

- Ependymal cysts follow CSF on all MR sequences, including DWI; no enhancement

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- CSF-filled parenchymal cavity
  - Deep, unilateral/bilateral cavity/excavation
  - Usually communicates with ventricle &/or subarachnoid space
  - Lined by reactive gliosis/astrocytic proliferation
- Congenital (perinatal brain destruction) or acquired (trauma, infection, etc)

IMAGING

- Best diagnostic clue: CSF-filled cavities with enlarged adjacent ventricle
- MR: Smooth-walled cavity; CSF isointense; lined by gliotic white matter

TOP DIFFERENTIAL DIAGNOSES

- Consider arachnoid, ependymal, neoplastic, or inflammatory cyst
- Agenesis of corpus callosum
- Encephalomalacia
- Schizencephaly
- Dandy-Walker malformation
- Hydranencephaly

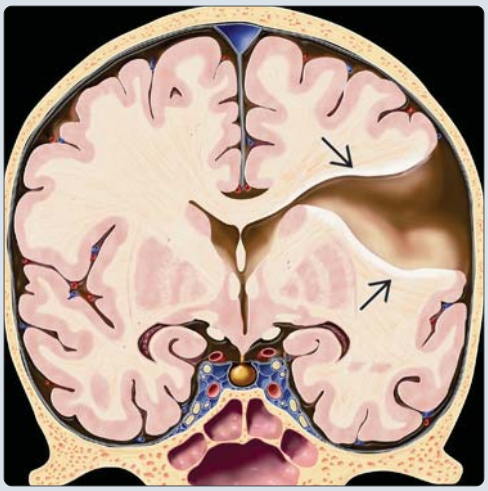
PATHOLOGY

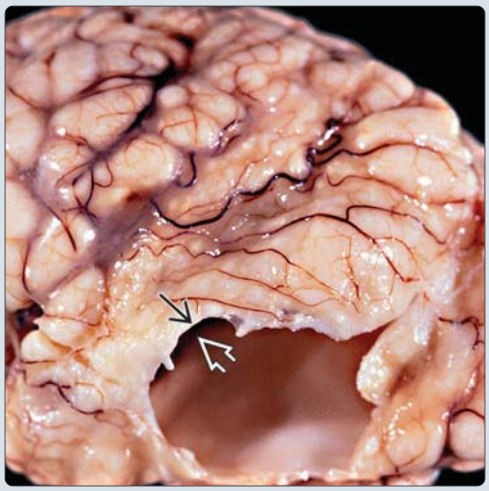
- Congenital: In utero destructive process caused by cerebral vascular events or infectious injury (CMV)
- Acquired: Injury later in life, following head trauma, surgery, vascular occlusion, or infection
- Genetics: Rare, autosomal dominant familial porencephaly → procollagen defect

CLINICAL ISSUES

- Spastic hemiplegia most common symptom
- Indications for therapy: Mass effect, localized/generalized refractory symptoms

(Left) *Coronal graphic illustrates an intraparenchymal CSF-filled cavity that communicates with the left lateral ventricle and subarachnoid space. Note the classic porencephalic cyst is lined with gliotic white matter ⇨.* **(Right)** *Lateral view of autopsied brain with a porencephalic cyst in the temporal lobe shows a CSF-filled cavity that extends from the brain surface ⇨ to the ventricular ependyma of the temporal horn ⇨. The cyst is lined with gliotic white matter. (Courtesy J. Townsend, MD.)*





(Left) *Axial FLAIR of a porencephalic cyst reveals a CSF intensity parenchymal defect, which was isointense to CSF on all sequences, including FLAIR nulling ⇨. Also note the small amount of associated white matter gliosis ⇨. Susceptibility artifact is secondary to a ventriculostomy shunt ⇨.* **(Right)** *Coronal T1 C+ MR in the same patient shows a CSF-density parenchymal defect ⇨, which communicates with the atrium of the left lateral ventricle with dilatation of the occipital horn ⇨. Classic porencephalic cyst is also seen.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Porencephaly

Definitions

- Various definitions of porencephaly
  - Congenital/acquired CSF-filled cavity that usually communicates with ventricular system
    - Deep, unilateral/bilateral cavities or excavations
    - Lined by reactive gliosis/astrocytic proliferation
  - Presence of cysts/cavities in brain parenchyma
    - Communicating by "pore" with arachnoid space
  - Cavities arising in fetal life or early infancy
    - Brain destruction during perinatal period
    - Frequently communicate with subarachnoid space &/or lateral ventricles

IMAGING

General Features

- Best diagnostic clue
  - CSF-filled cavities; enlarged adjacent ventricle
- Location
  - Often corresponds to territories supplied by cerebral arteries (ischemic injury in midgestation)
  - Cortical/subcortical cavity, unilateral/bilateral
  - Usually connected with a lateral ventricle
- Size
  - Varies from small to enormous

CT Findings

- NECT
  - Intraparenchymal smooth-walled cavity
    - Isodense with CSF
  - Directly communicates with ventricle
  - May see thin membrane separating cavity from ventricle
- CECT
  - No contrast enhancement of fluid-filled cavity
- Bone CT
  - Skull remodeling from chronic CSF pulsation
- CTA
  - Absence of vessels at site of porencephaly

MR Findings

- T1WI
  - Smooth-walled cavity; CSF isointense; lined by WM
- T2WI
  - Brain atrophy, gliosis common; CSF isointense; lined by white matter
- FLAIR
  - Accurately depicts CSF content of cyst and gliosis
- T1WI C+
  - Nonenhancing cyst

Ultrasonographic Findings

- Prenatal ultrasound for congenital porencephaly
  - Solitary or multiple echo-spared lesions(s)
  - Some cortical tissue may be preserved

Nonvascular Interventions

- Myelography
  - Contrast material injected into lumbar region may fill cystic space

Nuclear Medicine Findings

- PET
  - Area of absent glucose metabolism

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - FLAIR

DIFFERENTIAL DIAGNOSIS

Arachnoid Cyst

- CSF-isointense extraaxial cyst that exerts variable degrees of mass effect
- Unlike porencephalic cyst, extraaxial and displaces brain tissue away from adjacent skull

Ependymal Cyst

- Intraventricular; brain usually normal

Neoplastic Cyst

- Any cystic appearance of neoplastic processes

Inflammatory Cyst

- Mass effect, contrast enhancement if neoplastic

Agenesis of Corpus Callosum

- CSF-filled space extending cephalad from 3rd ventricle
- Parallel appearance of lateral ventricles
- Colpocephaly: Dilatation of occipital horns and posterior portions of temporal horns

Encephalomalacia

- Late gestational, perinatal, or postnatal injuries (thrombotic/embolic infarction, asphyxia, infection)
- May be slightly hyperdense/hyperintense to CSF (T1, T2, FLAIR)
- Cavity typically does not communicate with ventricle
  - Often contains septations and is lined by astrocytic proliferation

Schizencephaly

- Intraparenchymal cavity lined by gray matter, extending from ventricular surface to brain surface

Dandy-Walker Malformation

- Large median posterior fossa cyst widely communicating with 4th ventricle
- Rotated, raised, and small cerebellar vermis in contact with tentorium
- Upward displacement of tentorium and lateral sinuses

Hydranencephaly

- Early destructive process of developing brain caused by toxoplasmosis, CMV, or arterial occlusion
- Cortex and white matter destroyed and replaced by thin-walled CSF-filled sacs of leptomeninges

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Congenital: In utero destructive process caused by cerebral vascular events or infectious injury (CMV)
    - May be induced by antenatal trauma, even when mild or not directed at uterine wall
  - Acquired: Injury later in life, following head trauma, surgery, vascular occlusion, or infection
- Genetics
  - Most cases are sporadic
  - Inherited cases often result from bleeding
    - Rare, autosomal dominant familial porencephaly
      - Chromosome 13qter → mutation of gene encoding procollagen type IV α1
      - Encodes basement membrane protein expressed in all tissues
      - ↑ intracerebral hemorrhage risk for life
    - Inherited thrombophilia, most often heterozygosity for factor V Leiden mutation (gene *F5*)
- Associated abnormalities
  - Amygdala-hippocampal atrophy often coexists with congenital porencephaly (95% in some reports)
    - May be bilateral despite unilateral cysts
  - Syndromes: Septo-optic dysplasia, oro-facio-digital syndrome type I, encephalocraniocutaneous lipomatosis, Proteus syndrome, Delleman syndrome, DK-focomelia
  - Alloimmune thrombocytopenia
  - Coagulopathies (e.g., von Willebrand disease), factor V or X deficiency, maternal warfarin use
  - Multiple gestation associated with vascular disruption defects: Large intestinal atresia, transverse limb deficiency, porencephaly, and renal agenesis

Gross Pathologic & Surgical Features

- CSF-filled cavity with smooth walls
  - Lined by gliotic or spongiotic white matter
- Overlying skull
  - May be remodeled due to long-term transmission of CSF pulsations
  - May be thickened when intervening brain tissue precludes transmission of CSF pulsations

Microscopic Features

- Congenital porencephalic cyst
  - Gray and white matter necrosis
  - Fluid-filled, focal cavity with smooth walls and minimal surrounding glial reaction
- Acquired porencephalic cyst
  - Mature brain reacts to injury by significant astrocytic proliferation
  - Resulting cavity often has septations and irregular wall composed primarily of reactive astrocytes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Spastic hemiplegia most common feature
  - May be associated with severe neurological deficits
    - Mental retardation, medically intractable epilepsy
- Clinical profile
  - Cerebellar symptoms; ophthalmological signs
  - Various forms of cerebral paralysis
  - Seizures, psychomotor retardation

Demographics

- Age
  - Pediatric age most common; also occurs in adults
- Gender
  - Male > female infants, especially with mothers < 20 years
- Epidemiology
  - 2.5% incidence of porencephalic cysts among 1,000 congenital and acquired brain lesions
  - 0.035% prevalence per 10,000 live births

Natural History & Prognosis

- Narrow communication with ventricular system may ↑ pressure in cyst → mass effect
- Children with neonatal intraparenchymal echodensities and porencephaly have much worse long-term neurodevelopmental outcome

Treatment

- Usually no treatment required
- Indications for therapy: Mass effect, localized/generalized refractory symptoms
  - Cystoperitoneal shunt (preferred)
  - If no communication with ventricular system: Fenestration or partial resection of cyst wall
  - Children with intractable seizures benefit from uncapping and cyst fenestration to lateral ventricle
- Congenital porencephaly should prompt collagen *4A1* genetic screening

DIAGNOSTIC CHECKLIST

Consider

- Arachnoid cyst simulating porencephalic cyst

Image Interpretation Pearls

- Assess hippocampus in setting of seizures

KEY FACTS

TERMINOLOGY

- Congenital endodermal cyst
  - Like Rathke cleft, colloid cysts

IMAGING

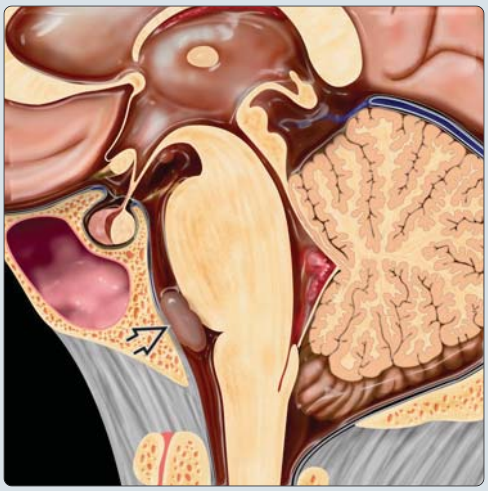
- General
  - Oblong nonenhancing, slightly hyperintense (to CSF) mass in front of medulla
- Location
  - More common in spine than brain (3:1)
  - 70-75% of intracranial NECs infratentorial, extraaxial
  - Anterior/lateral to pontomedullary junction
  - 25-30% supratentorial (suprasellar, cerebral hemispheres)
- CT
  - Hypo-/iso-/hyperdense, no Ca++
  - Bony anomalies usually absent
- MR
  - Almost always iso-/hyperintense to CSF on T1WI
  - 90% hyperintense to CSF, 10% hypointense on T2WI
  - Usually does not restrict on DWI
  - Usually no enhancement (mild rim in some)

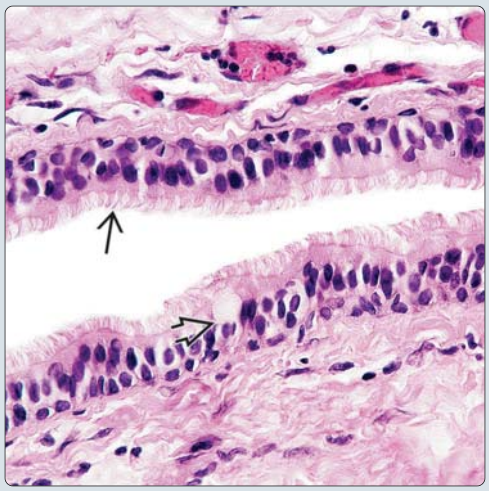
TOP DIFFERENTIAL DIAGNOSES

- Most common
  - Epidermoid
  - Arachnoid cyst
- Less common
  - Schwannoma (cystic)
- Rare
  - Ecchordosis physaliphora

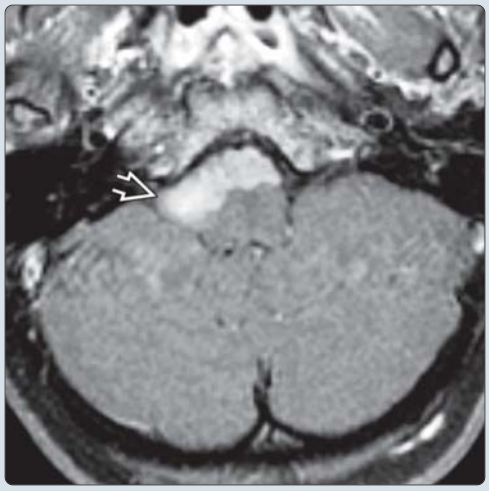
DIAGNOSTIC CHECKLIST

- Mass in front of brainstem, hyperdense/hyperintense to CSF may be neurenteric cyst





(Left) *Sagittal graphic shows a classic neurenteric (NE) cyst ⇨. Intracranial NE cysts are most often found near the midline, anterior to the brainstem.* **(Right)** *Neurenteric (endodermal) cysts are mostly lined with pseudostratified columnar epithelium with heavily ciliated cells ⇨. Variable numbers of mucin-secreting goblet cells ⇨ are present. (Courtesy P. Burger, MD.)*



(Left) *Sagittal T1WI shows typical neurenteric cyst as a well-delineated hyperintense ovoid paramedian mass ⇨ anterior to the pontomedullary junction.* **(Right)** *Axial T1C+FS MR in the same patient shows that the mass ⇨ extends inferolaterally in front of the lower medulla. The center of the mass is slightly off midline, a typical location for a posterior fossa neurenteric cyst.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neurenteric cyst (NEC)

Synonyms

- Neuroepithelial cyst. enterogenous cyst, enteric cyst

Definitions

- Rare benign malformative endodermal CNS cyst

IMAGING

General Features

- Best diagnostic clue
  - Oblong, nonenhancing, slightly T1/T2 hyperintense mass in front of medulla
- Location
  - More common in spine than brain (3:1)
  - 70-75% of intracranial NECs found in posterior fossa
    - > 95% extraaxial
    - Anterior/lateral to pontomedullary junction
    - 70% extend to midline
  - 25-30% supratentorial
    - Suprasellar, quadrigeminal cisterns
    - Cerebral hemispheres (frontal most common)
- Size
  - Posterior fossa usually < 2 cm; supratentorial often large
- Morphology
  - Smooth, lobulated, well demarcated

CT Findings

- NECT
  - Hypo-/iso-/hyperdense mass, no Ca++ or hemorrhage
  - Bony anomalies usually absent
- CECT
  - No enhancement

MR Findings

- T1WI
  - Almost always iso-/hyperintense to CSF
- T2WI
  - 90% hyperintense to CSF, 10% hypointense
- FLAIR
  - Hyperintense to CSF
- DWI
  - Usually none, but may show mild restriction
- T1WI C+
  - Usually none; occasionally mild rim

Imaging Recommendations

- Best imaging tool
  - MR with T1 C+, FLAIR, DWI

DIFFERENTIAL DIAGNOSIS

Epidermoid Cyst

- "White" epidermoid (rare) is hyperintense on T1WI
- Usually restricts on DWI

Dermoid Cyst

- Like fat; often Ca++

Arachnoid Cyst

- Like CSF on all sequences

Schwannoma

- Enhances strongly; usually not midline

Other Endodermal Cysts

- Rathke cleft, colloid cysts
- Excluded by location

Ecchordosis Physaliphora

- Notochordal remnant
- Often involves clivus

PATHOLOGY

General Features

- Etiology
  - Congenital endodermal cyst
  - Probably arises from persistent neurenteric canal

Gross Pathologic & Surgical Features

- Transparent, thin-walled, smooth, round/lobulated cyst
- Contents vary from clear, colorless fluid (like CSF) to thicker, more viscous/mucoid

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Brain = asymptomatic or headache

Demographics

- Age
  - Any age; peak 34 years
- Gender
  - M:F = 1:3
- Epidemiology
  - Rare (only 75 intracranial cases reported)

Natural History & Prognosis

- May be stable for years or grow very slowly

Treatment

- Observation vs. total surgical excision

DIAGNOSTIC CHECKLIST

Consider

- Mass in front of brainstem, hyperdense/hyperintense to CSF may be neurenteric cyst

KEY FACTS

TERMINOLOGY

- Nonneoplastic tumor-associated cysts (TACs)
- Benign fluid-containing cyst
  - Directly adjacent to, but not within neoplasm

IMAGING

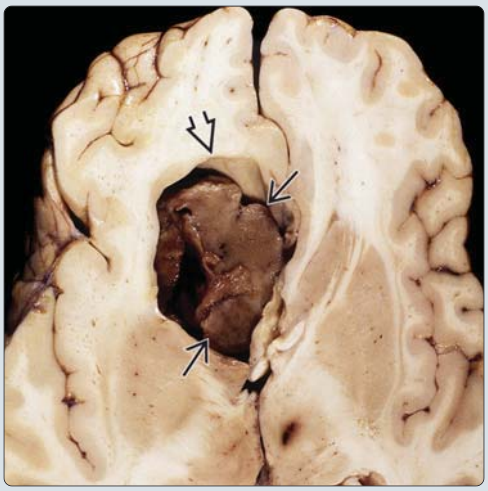
- General features of TAC
  - Smooth, well demarcated
  - Can be single, multiple, multiloculated
  - Abuts tumor directly
  - Usually lies between tumor, brain
  - Extraaxial > > intraaxial TACs
  - Size varies from small to very large
  - Neoplasms that cause TACs are typically large
- CT
  - Hypodense fluid collection adjacent to mass
  - No Ca++, hemorrhage
  - No enhancement
- MR
  - Variable signal (depending on protein content)
  - Often hyperintense to CSF
  - May suppress on FLAIR
  - Usually no restriction on DWI
  - Enhancement absent/minimal

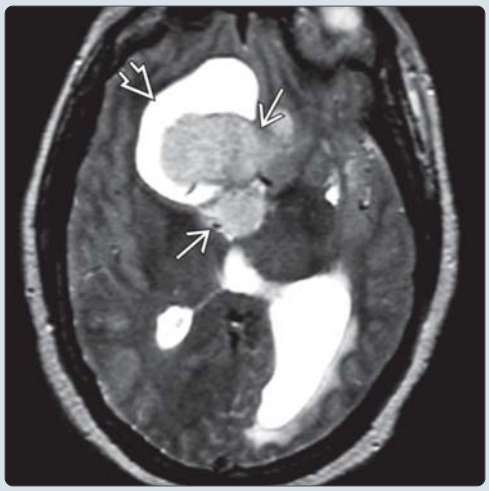
TOP DIFFERENTIAL DIAGNOSES

- Arachnoid cyst
- Enlarged perivascular spaces
- Cystic neoplasms

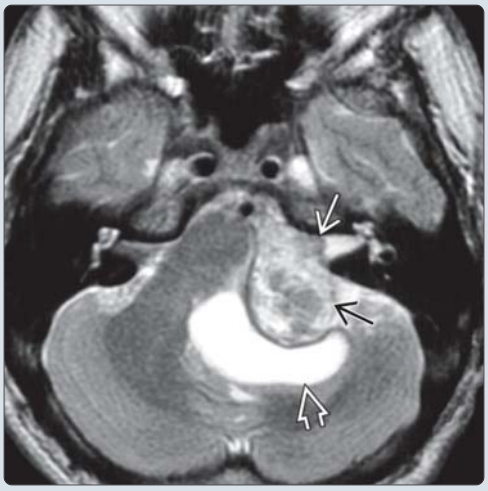
PATHOLOGY

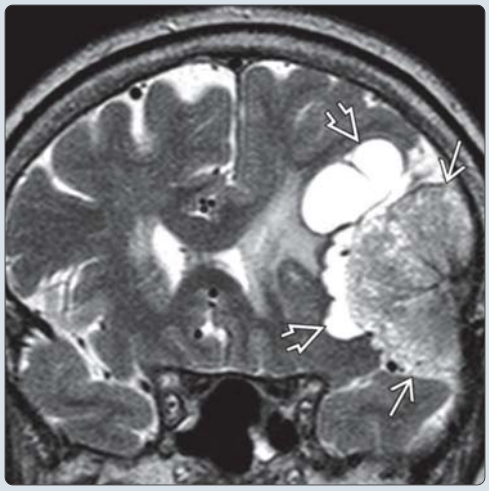
- Considered tumor "epiphenomenon"
- Most likely represent trapped, encysted pools of CSF adjacent to large extraaxial neoplasm
- As tumor grows, traps CSF between itself and adjacent brain





(Left) *Axial autopsy study shows giant pituitary macroadenoma ⇨ with a large, benign, nonneoplastic peritumoral cyst ⇨. (Courtesy R. Hewlett, MD.)* **(Right)** *Axial T2WI in a 58-year-old male with a giant pituitary macroadenoma and lobulated suprasellar extension ⇨ shows an associated benign, nonneoplastic peritumoral cyst ⇨. The cyst collapsed when the tumor was removed and did not recur.*





(Left) *Axial T2WI MR in a 33-year-old man with gradually increasing left-sided hearing loss shows a large, mixed signal intensity, CPA mass ⇨ that extends into the proximal IAC ⇨. Note the large nonneoplastic peritumoral cyst ⇨, hyperintense to CSF, associated with this vestibular schwannoma.* **(Right)** *Coronal T2WI MR shows a classic meningioma ⇨ with several large tumor-associated cysts ⇨. The neoplasm enhanced strongly, but heterogeneously, after contrast administration; the cysts showed no enhancement.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Nonneoplastic tumor-associated cysts (TACs)

Synonyms

- Peritumoral cyst
- "Herald" cyst (at surgery, may "herald" immediately adjacent mass)
- Tumor-associated arachnoid cyst (AC)
- Tumor-associated enlarged perivascular spaces (PVSs)

Definitions

- Benign fluid-containing cyst adjacent to, but not within, neoplasm

IMAGING

General Features

- Best diagnostic clue
  - Nonenhancing cyst immediately adjacent to neoplasm
- Location
  - Adjacent to tumor
    - Extraaxial TACs much more common than intraaxial
    - TACs generally between tumor, brain
- Size
  - TACs vary from small to very large
  - Neoplasms that cause TACs are typically large
- Morphology
  - Smooth, well demarcated
  - Can be single, multiple, multiloculated

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR
- Protocol advice
  - Include FLAIR, DWI

CT Findings

- NECT
  - Hypodense
  - No Ca++, hemorrhage
- CECT
  - No enhancement

MR Findings

- T1WI
  - Variable depending on protein content
    - Hypointense to brain
    - Iso- to hyperintense to CSF
- T2WI
  - Hyperintense
- FLAIR
  - May suppress
- DWI
  - Usually no restriction
  - May show mildly increased diffusivity
- T1WI C+
  - Usually none
  - Minimal/mild peripheral enhancement may occur
    - Secondary to reactive inflammatory changes, not neoplastic cells in cyst wall

DIFFERENTIAL DIAGNOSIS

Arachnoid Cyst

- Non-tumor-associated arachnoid cysts more common than TACs
- Typically behave **exactly** like CSF
  - Suppress on FLAIR
  - Does not restrict/show increased diffusivity on DWI

Enlarged Perivascular Spaces

- Intraparenchymal, not extraaxial
- Clustered variably-sized cysts > > solitary lesion
- Contain interstitial fluid but behave like CSF

Cystic Neoplasms

- Pilocytic astrocytoma
- Hemangioblastoma
- Schwannoma

PATHOLOGY

General Features

- Etiology
  - Precise etiology unknown
  - Considered tumor "epiphenomenon"
  - Most likely represent trapped, encysted pools of CSF adjacent to large extraaxial neoplasm
    - As tumor grows, traps CSF between itself and adjacent brain
  - Trapped PVSs less likely etiology
  - Some TACs may be true arachnoid cysts

Gross Pathologic & Surgical Features

- Thin cyst wall
- Fluid varies from clear to turbid, proteinaceous

Microscopic Features

- TAC cyst wall is generally gliotic brain ± reactive astrocytes, lymphocytes
- No tumor cells

Overview of CNS Infections

General Considerations

Classification: Infectious diseases can be classified into congenital/neonatal and acquired infections. They can be further subdivided by etiology, i.e., bacterial, viral, fungal, parasitic, and rickettsial diseases.

Infectious diseases can have different manifestations depending on disease acuity. Some diseases like herpes encephalitis are typically acute and fulminant. Others are subacute or chronic (e.g., subacute sclerosing panencephalitis (SSPE) and Rasmussen encephalitis).

Congenital/Neonatal Infections

General Considerations

Terminology: Congenital brain infections are often grouped together and simply called TORCH infections (for **to**xoplasmosis, rubella, **C**ytomegalovirus, and **h**erpes). If congenital syphilis is included, the grouping is called TORCH(S) or (S)TORCH.

Other congenital infections include human immunodeficiency virus (HIV) and lymphocytic choriomeningitis (LCM). Approximately 40% of HIV-positive mothers pass on their infection to the fetus which has shown to be dramatically reduced with HAART treatment of mothers and delivery by cesarean section.

Etiology: Most congenital infections are transmitted to the fetus through the transplacental route, except for herpes, which is acquired during parturition. With 2 exceptions, toxoplasmosis and syphilis, most are viral. All are relatively rare with the possible exceptions of cytomegalovirus (CMV) and herpes encephalitis.

Pathology: Transplacental transmission of various pathogens results in a spectrum of findings depending on both the agent and timing of infection. When infections occur early in fetal development (e.g., the 1st trimester), they tend to result in miscarriage or birth defects. Malformations, such as migrational defects and schizencephaly, are seen in surviving neonates. When infections occur later, encephaloclastic manifestations predominate. Microcephaly with frank brain destruction and widespread encephalomalacia occur. Dystrophic parenchymal calcifications are characteristic of CMV, toxoplasmosis, HIV, and congenital rubella infections.

Acquired Infectious/Inflammatory Diseases

Bacterial Infections

Bacterial pathogens that commonly cause meningitis include *Streptococcus pneumoniae*, *Neisseria meningitidis*, *Haemophilus influenzae*, *Listeria monocytogenes*, Group B *Streptococcus* and *E. coli*.

Meningitis: Purulent exudates, predominately in the basal cisterns, are the common pathologic feature of meningitis, regardless of the specific infectious agent. Exudates may fill the cisterns and subarachnoid spaces. Pia-subarachnoid enhancement is the most common imaging finding. Complications, such as hydrocephalus, empyema, and vasculitis, with or without cerebral infarction, are common.

Abscess: Abscesses develop in 4 general stages: Early and late cerebritis and early and late capsule. In early cerebritis, infection is focal but not yet localized. An unencapsulated mass of inflammatory cells, edema, necrotic foci, and petechial hemorrhage forms. In late cerebritis, the infection coalesces. Central necrosis with a poorly delineated rim of inflammatory cells, granulation tissue, and fibroblasts is seen. The early capsule stage follows late cerebritis. A well-defined collagenous capsule with a liquified necrotic core forms 2-4 weeks after the initial infection. Eventually the abscess cavity shrinks and collapses. This "late capsule" stage can last for months, with imaging findings still present long after symptoms resolve.

Ventriculitis: An abscess rim is thinnest on the paraventricular side. If the abscess ruptures into the ventricle, it causes ventriculitis ("pyocephalus") and choroid plexitis. Intraventricular abscess rupture is often fatal.

Viral Infections

Acute viral infections: Herpes simplex encephalitis (HSE) is the most common nonepidemic viral encephalitis. Over 95% are caused by HSV-1 (oral herpes virus). Currently the most common epidemic viral encephalitis is the West Nile virus.

Subacute and chronic viral infections: Many viruses have a slow incubation period and are characterized by symptoms that progress over months or even years. Subacute sclerosing panencephalitis (SSPE) is an example. Progressive multifocal leukoencephalopathy (PML), caused by JC virus (a ubiquitous polyomavirus), is another.

Miscellaneous Infections

Tuberculosis: With 8-10 million new cases each year and rising prevalence in developing countries, TB is a special public health concern. The emergence of multi-drug resistant TB (MDR TB) and extremely drug-resistant TB (XDR TB) make early recognition and urgent treatment of TB even more important. The "deadly intersection" between HIV and TB, with each disease amplifying the lethality of the other, is of special concern.

Parasites: Neurocysticercosis (NCC) has become the most common CNS parasitic infection in the world and the most common worldwide cause of epilepsy. Although most parasites rarely infect the brain, CNS lesions eventually develop in most patients infected with NCC.

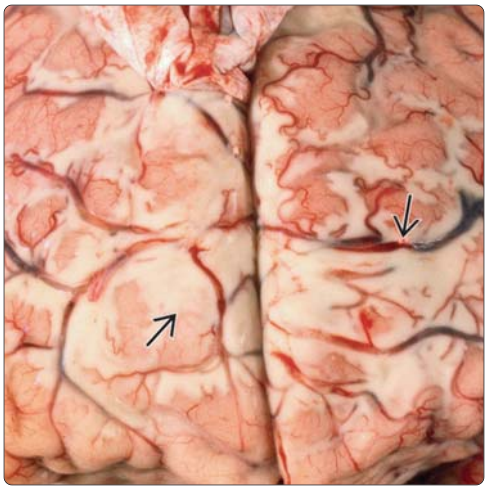
Fungal diseases: Fungi are ubiquitous organisms and endemic in many areas of the world. Most, such as *Aspergillus*, infect humans infrequently, usually through inhalation or puncture wounds. When fungal infections occur in immunocompetent patients, lung disease is more common than brain infection.

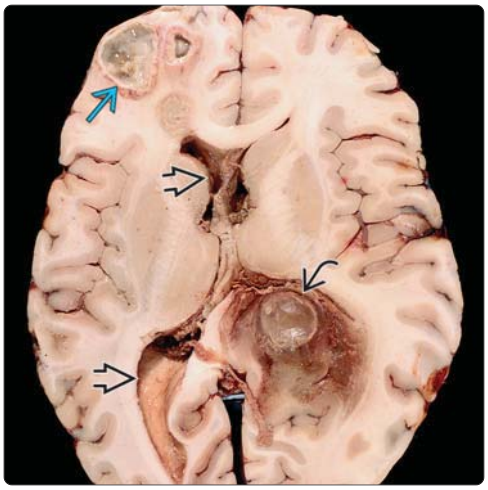
CNS and disseminated systemic fungal infections typically occur in immunocompromised patients. HIV/AIDS and immunosuppressive drugs are factors that increasingly predispose patients to opportunistic infections.

Rickettsial diseases: Rickettsial diseases, such as Rocky Mountain and Mediterranean spotted fever, usually have associated skin rashes. CNS infection is uncommon. When it occurs, Rickettsiae have a distinct predilection for the perivascular spaces and cause infarct-like lesions in the basal ganglia.

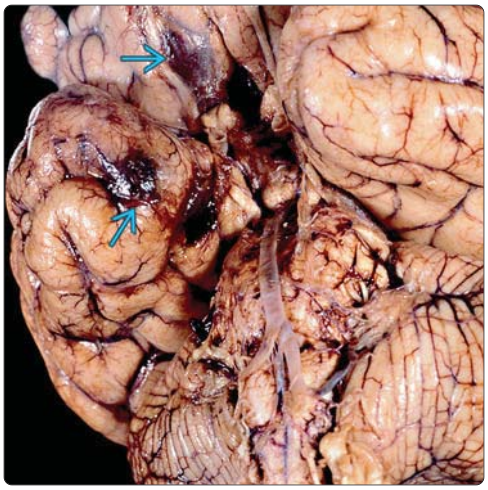
Spirochetes: Spirochetes are a phylum of gram-negative bacteria. Syphilis and Lyme disease which are caused by *Treponema pallidum* and *Borrelia burgdorferi*, respectively are them most common encountered diseases in this pathogen group. Lyme disease is the most common vector (tick) borne disease in the US. Lyme neuroborreliosis is neurologic involvement secondary to systemic infection by the spirochete *Borrelia burgdorferi*.

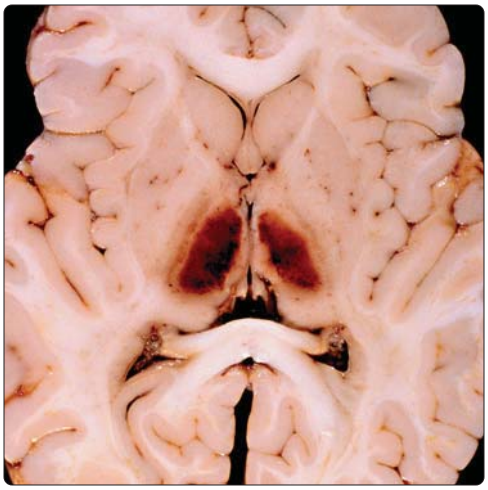
https://CafePezeshki.IR



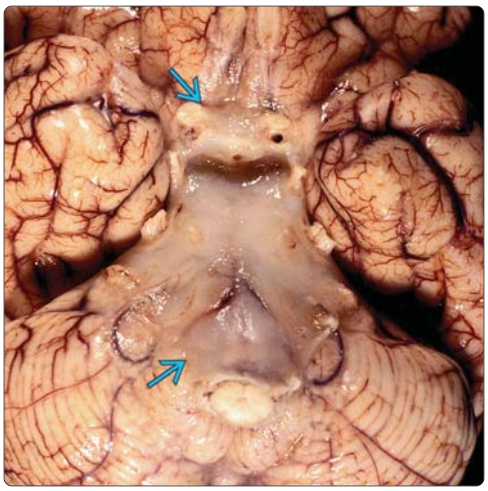


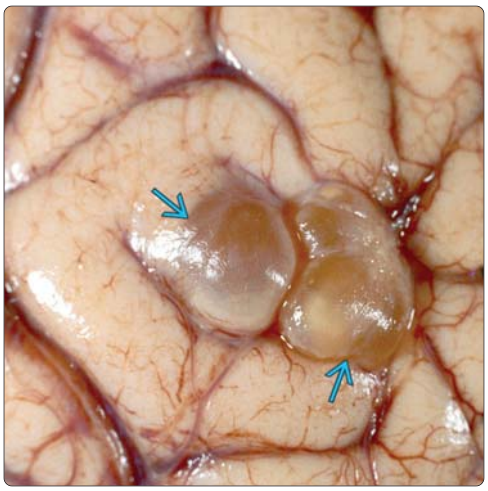
(Left) *Close-up view of the autopsied brain in a patient who died from acute bacterial meningitis. Note thick purulent exudate filling the sulci. The underlying gyri are edematous and diffusely swollen. The pia is inflamed and congested, with prominent cortical vessels. (Courtesy R. Hewlett, MD.)* **(Right)** *Autopsy case shows multiple pyogenic abscesses. A large abscess in the deep white matter has ruptured into the ventricles, causing ventriculitis. (Courtesy R. Hewlett, MD.)*





(Left) *Autopsied brain shows classic findings of acute herpes encephalitis. Note the predilection for the limbic system, seen here as hemorrhagic necrosis in the temporal lobe and subfrontal cortex. (Courtesy R. Hewlett, MD.)* **(Right)** *Autopsy case of acute hemorrhagic, necrotizing encephalitis, probably viral. Many nonepidemic viral encephalitides have a predilection for the basal ganglia, thalami, midbrain, and pons. (Courtesy R. Hewlett, MD.)*





(Left) *Autopsy case demonstrates tuberculous meningitis (TBM). TBM typically causes thick, purulent-appearing exudates with a predilection for the basal cisterns. The imaging and pathologic appearance of meningitis is generally similar, regardless of the etiology. (Courtesy R. Hewlett, MD.)* **(Right)** *Autopsy case shows 2 neurocysticercosis (NCC) cysts lodged within the superficial sulci. The subarachnoid spaces are the most common location for NCC cysts in the brain. (Courtesy R. Hewlett, MD.)*

KEY FACTS

TERMINOLOGY

- Acronym for congenital infections caused by transplacental transmission of pathogens
- TORCH(S), (S)TORCH, congenital infections, intrauterine infection

IMAGING

- CMV, toxo, lymphocytic choriomeningitis, HIV, and rubella all have parenchymal calcifications (Ca++)
- CMV → periventricular Ca++ ± cysts, cortical clefts, cortical dysplasia, WM abnormalities, and cerebellar hypoplasia
- Sonography for neonatal screening, MR for comprehensive evaluation, NECT to detect or confirm Ca++
- Rubella and HSV cause lobar destruction/encephalomalacia

TOP DIFFERENTIAL DIAGNOSES

- Pseudo-TORCH syndromes → basal ganglia Ca++, progressive demyelination
- Congenital lymphocytic choriomeningitis → micro- or macrocephaly; Ca++ precise mimic of CMV

PATHOLOGY

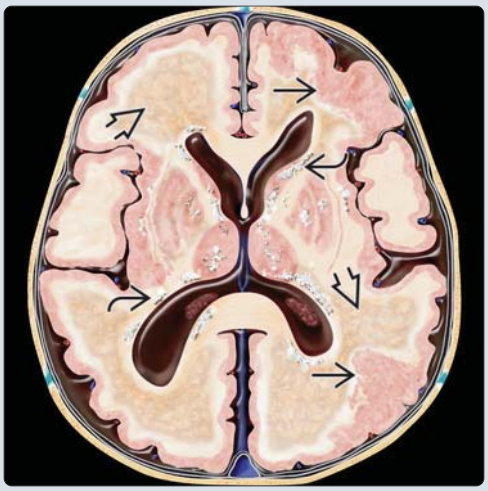
- CMV most common cause of intrauterine infection; DNA herpesvirus

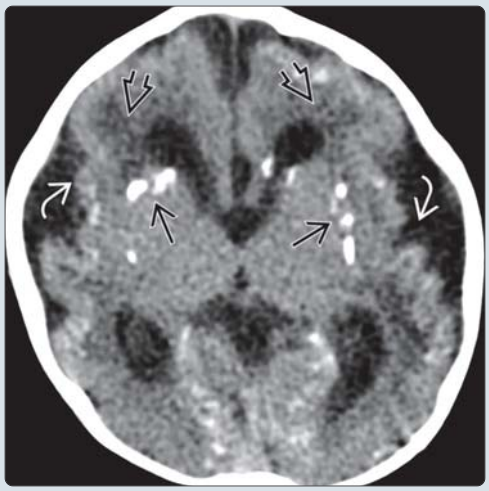
CLINICAL ISSUES

- CMV most common TORCH infection
- CMV can present at birth (10%) with microcephaly, hepatosplenomegaly, petechial rash
- Congenital toxoplasmosis is usually inapparent at birth, presenting at 2-3 months
- HSV acquired during delivery typically presents at 3-15 days with seizures, lethargy

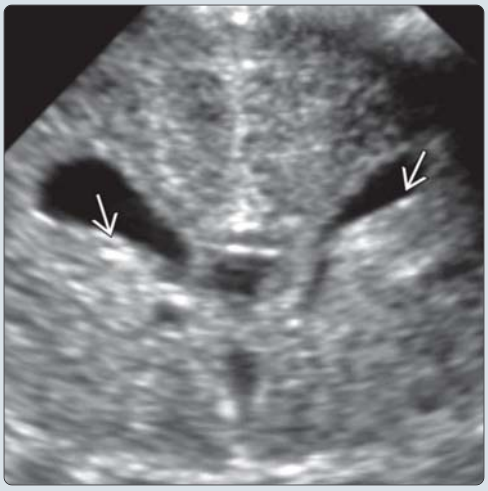
DIAGNOSTIC CHECKLIST

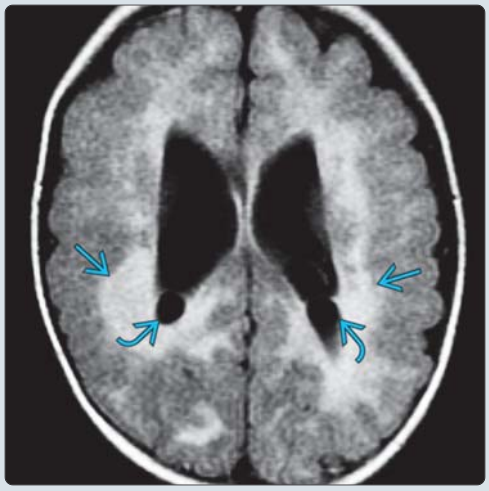
- CMV → microcephaly, cortical dysplasia, periventricular Ca++ and ± cysts, WM disease, and cerebellar hypoplasia





(Left) *Axial graphic shows periventricular parenchymal calcifications, damaged white matter, and dysplastic cortex, all characteristic of an in utero cytomegalovirus infection.* **(Right)** *Axial NECT in a microcephalic infant with cytomegalovirus shows extensive parenchymal Ca++. Note the open sylvian cisterns. MR (not shown) confirmed bilateral perisylvian polymicrogyria. Bilateral frontal white matter hypodensity corresponded to regions of demyelination.*





(Left) *Periventricular foci of hyperechogenicity correspond to Ca++ on a NECT in this patient with congenital CMV. Ultrasound may also detect cysts, clefts, and schizencephaly, all associated with congenital CMV.* **(Right)** *Axial FLAIR MR in congenital CMV infection shows periventricular germinolytic cysts and extensive white matter hyperintensities due to gliosis.*

TERMINOLOGY

Synonyms

- TORCH(S), (S)TORCH, congenital infections, intrauterine infection

Definitions

- Congenital infections caused by transplacental transmission of pathogens
  - Toxoplasmosis (toxo): *Toxoplasma gondii*
  - Rubella: Rubella virus
  - Cytomegalovirus (CMV): Most common TORCH infection
  - Herpes: Herpes simplex virus 2 (HSV-2)
  - Other: Human immunodeficiency virus (HIV), lymphocytic choriomeningitis (LCM), syphilis

IMAGING

General Features

- Best diagnostic clue
  - Toxo, CMV, HIV, and rubella all cause parenchymal calcifications (Ca++)
  - CMV causes periventricular cysts, clefts, schizencephaly, and migrational defects
  - HSV in neonates is diffuse and multifocal unlike adults (localize in frontal and temporal lobes)
  - Rubella and HSV cause lobar destruction/encephalomalacia
  - Syphilis causes basilar meningitis

CT Findings

- NECT
  - Cytomegalovirus
    - ~ 50% of patients have parenchymal &/or periventricular Ca++
    - Focal regions of white matter (WM) low attenuation, ± cysts
    - Migrational defects, cortical clefts, schizencephaly
    - Ventricular dilatation, cerebral volume loss, cerebellar hypoplasia
  - Toxoplasmosis
    - Parenchymal and periventricular Ca++ usually less extensive than CMV, scattered
  - Herpes simplex virus
    - Large regions of decreased attenuation, ± high attenuation foci of hemorrhage
  - HIV
    - Combination of volume loss, basal ganglia, and subcortical Ca++
- CECT
  - Lesions with meningeal inflammatory components (syphilis, HSV) may show enhancement

MR Findings

- T1WI
  - Cytomegalovirus
    - Periventricular subependymal foci of T1 shortening due to Ca++, hypointensity WM
  - Herpes simplex virus
    - Hemorrhagic regions may be hyperintense
- T2WI
  - Cytomegalovirus
    - Cortical abnormalities (polymicrogyria, schizencephaly), hippocampal dysplasia (vertical orientation)
  - Herpes simplex virus
    - Obliterated normal "dark cortex" on T2WI, diffusion restriction, ± hemorrhagic foci
- FLAIR
  - Cytomegalovirus
    - Focal, patchy, or confluent regions of increased signal due to gliosis and demyelination
- T2* GRE
  - Hypointense signal due to Ca++ in CMV, toxo, and HIV
  - Blooming blood in HSV and rubella
- T1WI C+
  - Thickened and enhancing basal meninges in syphilis
  - Patchy mild parenchymal enhancement in HSV
- MRS
  - Active lesions: ↑ myoinositol and excitatory amino acids
  - Chronic disease: ↓ N-acetylaspartate (NAA)

Ultrasonographic Findings

- Grayscale ultrasound
  - Echogenic periventricular foci (Ca++) in CMV, toxo
  - Branching basal ganglia and thalamic echoes: "Mineralizing vasculopathy"
    - Associated with CMV, toxo, syphilis, rubella, and trisomies
  - Periventricular pseudocysts and ventricular adhesions

Imaging Recommendations

- Best imaging tool
  - Cranial sonography for neonatal screening
  - MR brain to completely characterize abnormalities
- Protocol advice
  - T2* GRE &/or NECT to detect periventricular Ca++ or hemorrhage

DIFFERENTIAL DIAGNOSIS

Tuberous Sclerosis

- Subependymal Ca++ characteristic
- Peripheral tubers will mimic migrational abnormalities
- WM lesions can mimic gliosis in TORCH infections

Congenital Lymphocytic Choriomeningitis

- Produces necrotizing ependymitis → aqueductal obstruction; macrocephaly (43%), microcephaly (13%)
- NECT may perfectly mimic CMV

Pseudo-TORCH Syndromes

- Baraitser-Reardon, Aicardi-Goutières (cerebrospinal fluid [CSF] pleocytosis, ↑ CSF α interferon)
  - Progressive cerebral and cerebellar demyelination
  - Basal ganglia Ca++, ± periventricular Ca++

PATHOLOGY

General Features

- Etiology
  - Cytomegalovirus
    - Ubiquitous DNA virus of Herpesviridae family
    - Most common cause of intrauterine infection

https://CafePezeshki.IR

  - Mother has primary or reactivation infection during pregnancy
- Herpes encephalitis
  - HSV2
  - Active genital infection during delivery; transplacental infection less common
- Rubella
  - Togaviridae family of viruses; very rare in USA
  - High risk of miscarriage and birth defects with 1st trimester maternal infection
- Toxoplasmosis
  - Cats are definitive hosts for protozoan parasite
  - 50% of toxoplasmosis infections in USA are from contaminated meat
  - Active infection in pregnancy → 20-50% congenital infection
- HIV
  - Transmitted by transcervical route
  - 30% of pregnancies in HIV(+) women will result in transmission unless preventative measures taken
- Syphilis
  - Caused by spirochetal bacterium *Treponema pallidum*

Gross Pathologic & Surgical Features

- Microcephaly, schizencephaly, polymicrogyria in CMV
- Inflammation/destruction in toxo, rubella, HSV

Microscopic Features

- May find encysted parasites in toxo
- Ischemic necrosis in rubella
- Microglial nodules and cytomegalic cells in CMV

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - CMV can present at birth (10%) with microcephaly, hepatosplenomegaly, petechial rash
    - 55% with systemic disease have central nervous system (CNS) involvement
  - Congenital toxoplasmosis is usually inapparent at birth, presenting at 2-3 months
    - Leukokoria (chorioretinitis)
  - HSV acquired during delivery typically presents at 3-15 days with seizures, lethargy
    - HSV acquired in utero (5%) typically presents at birth with hydranencephaly and growth retardation
  - HIV typically diagnosed at 6-12 months with developmental delay
  - Rubella presents with petechial rash, low birth weight, and leukokoria (cataracts)
  - Syphilis → failure to thrive and irritability in newborn, bone pain in infant

Demographics

- Epidemiology
  - CMV most common TORCH infection
    - Incidence 30,000-40,000 per year in USA
  - In utero infection with *T. gondii* reported 1-6/1,000 births
  - HSV 2nd most common TORCH infection
    - Incidence 1/5,000 births
  - Congenital rubella very rare in US due to rubella vaccination program
  - Congenital syphilis varies with geographic region; highest reported incidences in South Africa

Natural History & Prognosis

- Timing of infection during pregnancy in toxo, CMV correlates with severity of disease
  - Infections in early gestation have worse prognosis
- Up to 95% of newborns with neurological symptoms from CMV have major neurodevelopmental sequelae

Treatment

- Ganciclovir may benefit CMV-infected infants
- No treatment for rubella
- Antiretroviral treatment in 2nd and 3rd trimesters and during labor can prevent transmission of HIV
- Pyrimethamine and sulfadiazine are used to treat neonatal toxo → improved outcomes compared to untreated infants
- HSV is treated with acyclovir
- All forms of syphilis are treated with penicillin

DIAGNOSTIC CHECKLIST

Consider

- TORCH infection in newborn and infant with microcephaly, ocular abnormalities, and intrauterine growth restriction

Image Interpretation Pearls

- Congenital CMV encephalitis should be considered when imaging shows
  - Microcephaly, polymicrogyria, periventricular Ca++ and cysts, cortical clefts, WM disease, and cerebellar hypoplasia

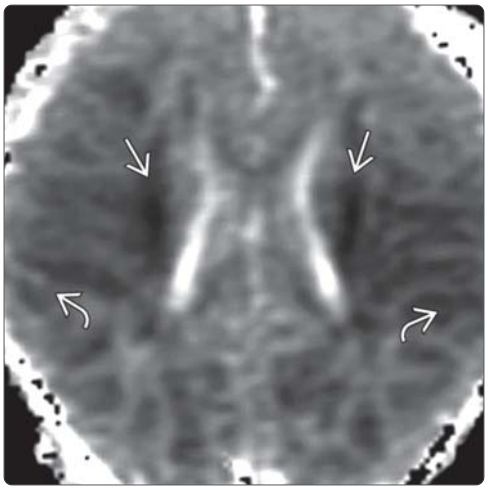
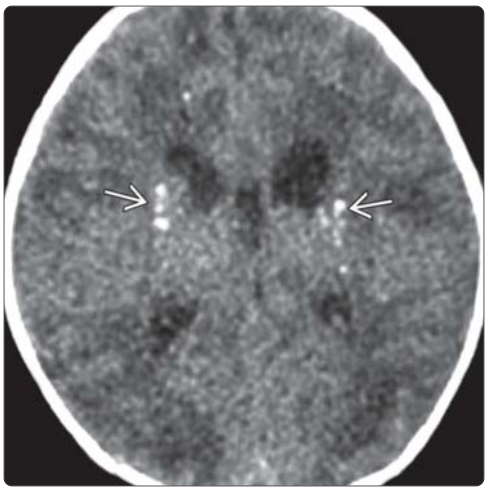
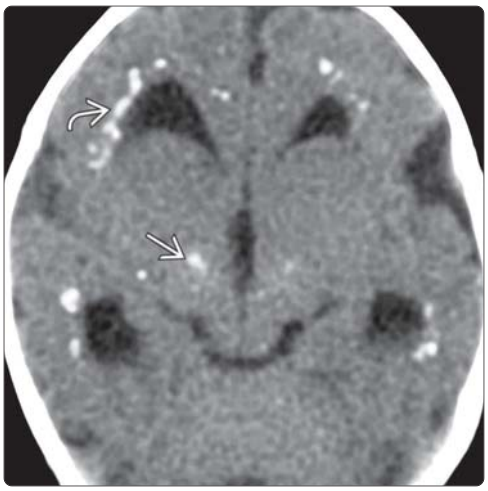
(Left) *Axial T2WI FSE MR in an infant with congenital CMV shows broad, sylvian cisterns due to perisylvian polymicrogyria. Confluent regions of periventricular white matter increased signal due to gliosis and demyelination* **(Right)** *Axial NECT in a patient with toxoplasmosis shows multiple scattered cerebral calcifications. Note the ventricular dilation and cerebral hemispheric volume loss. The infection is caused by the protozoan Toxoplasma gondii.*



(Left) *Axial ADC of an acutely infected, seizing neonate with herpes simplex virus type 2 sepsis shows widespread low diffusivity (hypointensity) within the periventricular white matter, cortex, and subcortical white matter.* **(Right)** *Axial NECT in an infant with congenital rubella and cataracts shows atrophy of the cerebral hemispheres. There is overlap of the cranial sutures, secondary to volume loss. Note the central basal ganglia calcification.*





(Left) *Axial NECT in a microcephalic infant with a lymphocytic choriomeningitis virus infection shows scattered basal ganglia calcifications. The clinical and imaging features of this disorder may precisely mimic congenital cytomegalovirus infection.* **(Right)** *Axial NECT in pseudo-TORCH shows basal ganglia calcification and periventricular calcification. Pseudo-TORCH states are autosomal recessive disorders showing mineralization and progressive demyelination.*

KEY FACTS

TERMINOLOGY

- Congenital cytomegalovirus (CMV)
  - Most common source of intrauterine infection in USA

IMAGING

- Microcephaly: Spectrum and severity of brain injury depends on timing of fetal infection
- Cranial sonography
  - Periventricular hyperechoic foci
  - Branching basal ganglia hyperechogenicities (lenticulostriate vasculopathy)
  - Ring-like regions of periventricular lucency may precede subependymal Ca++
- NECT when CMV is clinically suspected &/or to complement brain MR
  - Intracranial Ca++ (40-70%): Periventricular (subependymal) (germinolytic zones)
- MR brain to completely characterize abnormalities
  - Agyria ↔ pachygyria ↔ diffuse polymicrogyria ↔ focal cortical dysplasia ↔ schizencephalic clefting
  - WM abnormalities: Periventricular germinolytic cysts, demyelination, gliosis
  - Cerebellar hypoplasia

TOP DIFFERENTIAL DIAGNOSES

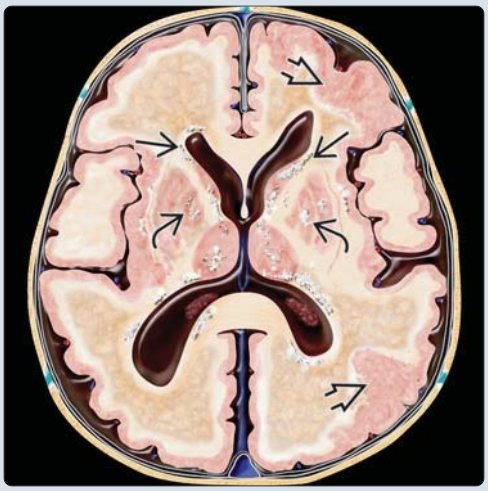
- Congenital lymphocytic choriomeningitis (LCM)
- Toxoplasmosis
- Pseudo-TORCH syndromes

PATHOLOGY

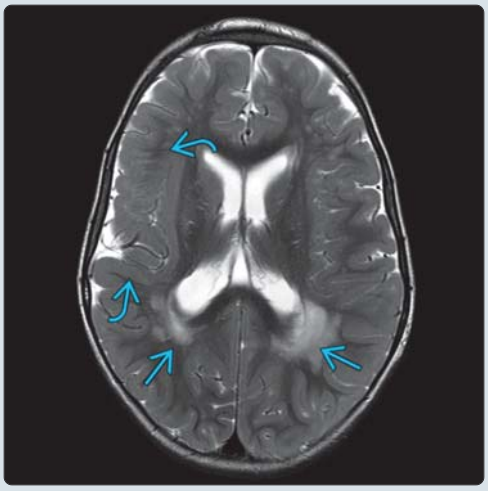
- Ubiquitous DNA virus of herpes virus family
- Hematogenously seeds choroid plexus, replicates in ependyma, germinal matrix, and capillary endothelia

CLINICAL ISSUES

- Most infected newborns appear normal
- 55% with systemic disease have CNS involvement



(Left) *Axial graphic shows numerous periventricular and basal ganglia calcifications. Note regions of cortical dysplasia (polymicrogyria). Ventricular dilation reflects adjacent white matter (WM) volume loss. The yellowish WM abnormalities reflect regions of edema, demyelination, &/or gliosis.* **(Right)** *Axial NECT shows extensive periventricular and parenchymal calcification. Note the open sylvian fissures and simplified perisylvian cortex. MR confirmed polymicrogyria.*



(Left) *Axial T2WI MR in a child with congenital CMV shows right perisylvian dysplastic cortex (likely polymicrogyria) and regions of abnormal WM signal predominantly in the parietal lobes, likely due to gliosis &/or demyelination. Ventricular dilation is secondary to WM volume loss.* **(Right)** *Axial SWI image in the same patient shows foci of low signal in the frontal periventricular region due to calcifications*

TERMINOLOGY

Abbreviations

- Congenital cytomegalovirus (CMV)

Definitions

- Congenital infection caused by transplacental transmission of CMV, a member of herpes virus family
  - Most common source of intrauterine infection in USA

IMAGING

General Features

- Best diagnostic clue
  - Microcephaly, spectrum of brain injury depending on timing of fetal infection
  - Intracranial calcifications (40-70%); periventricular (subependymal germinal matrix zones)
  - Migration abnormalities : Lissencephaly ↔ pachygyria ↔ polymicrogyria ↔ schizencephalic clefting
  - White matter (WM) abnormality: Delayed myelination, dysmyelination
  - Cerebral, cerebellar atrophy
  - Periventricular cysts, ventriculomegaly, ventricular adhesions, lenticulostriate vasculopathy
- Gestational age at time of infection determines pattern of CNS injury
  - Prior to 18 weeks → reduction in neurons and glia, lissencephaly, small cerebellum, ventriculomegaly
  - 18-24 weeks → migration anomalies, cerebellar hypoplasia, schizencephaly
  - 3rd trimester → Delayed myelination, dysmyelination, periventricular cysts
  - Perinatal infection → delay in myelin maturation, focal WM injury (astrogliosis)

CT Findings

- NECT
  - Intracranial Ca++ (40-70%): Periventricular (subependymal) (germinolytic zones)
  - WM volume loss , WM low attenuation, ± periventricular cysts, ventriculomegaly
  - Cortical gyral abnormalities
  - Cerebellar hypoplasia

MR Findings

- T1WI
  - Periventricular subependymal foci of T1 shortening secondary to Ca++
  - Ventricular dilatation and periventricular WM volume loss ± periventricular cysts
  - Cerebellar hypoplasia
- T2WI
  - Migration abnormalities : Lissencephaly, pachygyria, diffuse or focal polymicrogyria, schizencephaly
  - Myelination delay or destruction ± periventricular cysts (often at temporal tip)
  - Focal WM lesions with ↑ T2 intensity (gliosis/demyelination) predominantly in parietal deep WM
  - Hippocampal dysplasia (vertical orientation)
- FLAIR
  - Focal, patchy, or confluent regions of increased signal due to gliosis ± periventricular hypointense cysts
- T2* GRE
  - Periventricular ↓ signal due to Ca++
- MRS
  - ↓ NAA:Cr ratio due to loss of neuronal elements, ↑ myoinositol (gliosis)

Ultrasonographic Findings

- Grayscale ultrasound
  - Ring-like regions of periventricular lucency may precede subependymal Ca++
  - Branching basal ganglia and thalamic echoes (lenticulostriate vasculopathy)
  - Periventricular cysts and ventricular adhesions
  - Cerebellar hypoplasia

Imaging Recommendations

- Best imaging tool
  - Sonography for prenatal or neonatal screening
  - NECT rarely necessary
  - Brain MR to completely characterize abnormalities
- Protocol advice
  - High-resolution neonatal neurosonography
  - NECT or T2* GRE to detect subtle calcification or hemorrhage

DIFFERENTIAL DIAGNOSIS

Congenital Lymphocytic Choriomeningitis

- Rodent-borne arenavirus: Carried by feral house mouse and hamster
- Necrotizing ependymitis leading to aqueductal obstruction (macrocephaly in 43%, microcephaly in 13%)
- Appearance on NECT may perfectly mimic CMV

Toxoplasmosis

- Protozoan parasite
  - Maternal risk factors include
    - Exposure to cat excreta during pregnancy
    - Eating raw or undercooked meat
- 1/10 as common as CMV, macrocrania > microcrania, cortical dysplasia less common, random cerebral Ca++

Pseudo-TORCH Syndromes

- Baraister-Reardon, Aicardi-Goutières (CSF pleocytosis, ↑ CSF α-interferon)
  - Autosomal recessive, progressive cerebral and cerebellar demyelination and degeneration
  - Basal ganglia and brainstem Ca++, periventricular Ca++ less common
- Mutations of *OCLN* gene encoding occludin
  - Autosomal recessive microcephaly
  - Polymicrogyria with band of subcortical calcification

PATHOLOGY

General Features

- Etiology
  - CMV is ubiquitous DNA virus of herpesvirus family
  - Neurotropic virus that replicates in ependyma, germinal matrix, capillary endothelium

https://CafePezeshki.IR

- Chronic ischemia from placentitis leading to secondary perfusion insufficiency
- Most common cause of intrauterine infection
- Mechanisms of infection
  - Fetal infection
    - Mother with primary infection during pregnancy vs. mother with reactivation of latent infection
  - Neonatal infection
    - Mother infected at delivery, transmission of virus in breast milk, or by blood transfusion

Staging, Grading, & Classification

- Timing of gestational infection determines insult
  - Neuronal formation between 8-20 weeks
  - Neuron migration until 24-26 weeks
  - Astrocyte generation begins near end of neuronal production
  - Maximal size of germinal zones at 26 weeks
  - Oligodendrocytes produced during 1st half of 3rd trimester

Gross Pathologic & Surgical Features

- Microcephaly
- Early gestational infection
  - Germinal zone necrosis, diminished number of glia and neurons, WM volume loss

Microscopic Features

- Hallmark of CMV infection: Cytomegaly with viral nuclear and cytoplasmic inclusions
- Patchy and focal cellular necrosis (particularly germinal matrix cells)
- Vascular inflammation and thrombosis, vascular and subependymal dystrophic Ca++

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Most infected newborns appear normal
  - 10% have systemic signs of disease
    - Hepatosplenomegaly, petechiae, chorioretinitis, jaundice, intrauterine growth retardation
  - 55% with systemic disease have CNS involvement
    - Microcephaly, seizures, hypotonia or hypertonia, sensorineural hearing loss (SNHL)
- Clinical profile
  - Seronegative women are at greatest risk for vertical transmission
- Methods of diagnosis
  - Shell-vial assay for CMV (urine)
  - Late diagnosis with PCR for CMV-DNA from neonatal Guthrie card
  - Elevated CSF β-2 microglobulin levels, microcephaly, neuroimaging findings predictive of outcome

Demographics

- Epidemiology
  - Affects ~ 1% of all newborns (10% of whom have CNS or systemic signs and symptoms)
  - 40% of mothers who acquire infection during pregnancy transmit virus to fetus

Natural History & Prognosis

- 3 prognostic groups
  - Newborns with CNS manifestations (microcephaly, periventricular Ca++)
    - Up to 95% have major neurodevelopmental sequelae
  - Newborns with only systemic manifestations (hepatosplenomegaly, petechiae, jaundice)
    - Have better prognosis but still significantly affected
  - Infected newborns with neither CNS nor systemic manifestations
    - Best prognosis, yet still at risk for developmental delays, motor deficits, and SNHL
  - Overall mortality ~ 5%

Treatment

- Ganciclovir therapy may benefit infected infants

DIAGNOSTIC CHECKLIST

Consider

- Congenital CMV in developmentally delayed, microcephalic infant with SNHL

Image Interpretation Pearls

- Congenital CMV encephalitis should be considered when MR shows
  - Microcephaly, migration anomalies, periventricular cysts, WM abnormalities, and cerebellar hypoplasia
- When NECT is classic for CMV encephalitis but work-up for (S)TORCH infection is negative, consider
  - Lymphocytic choriomeningitis (LCM) and pseudo-TORCH syndromes

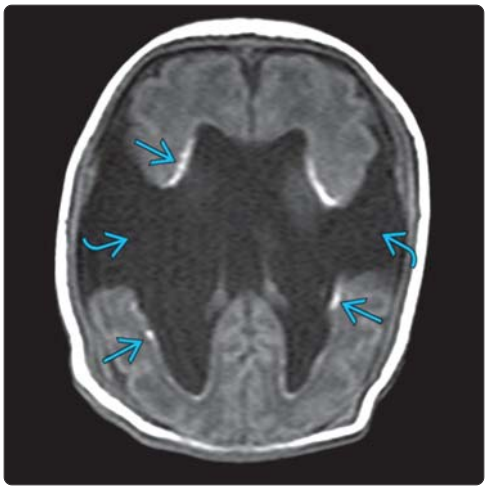
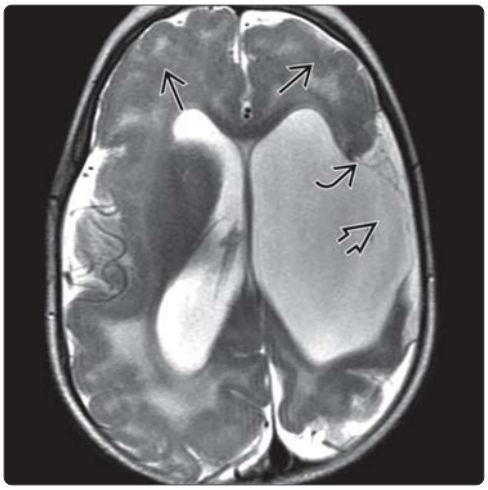
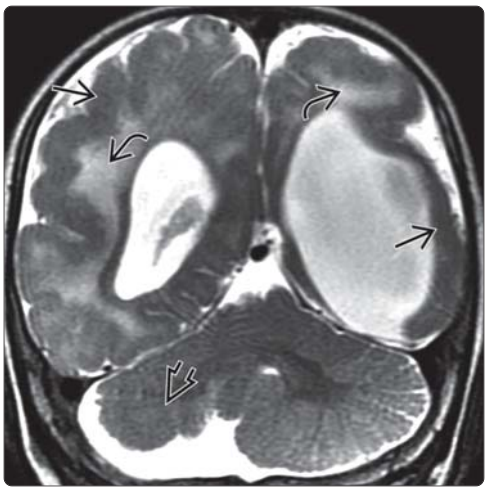
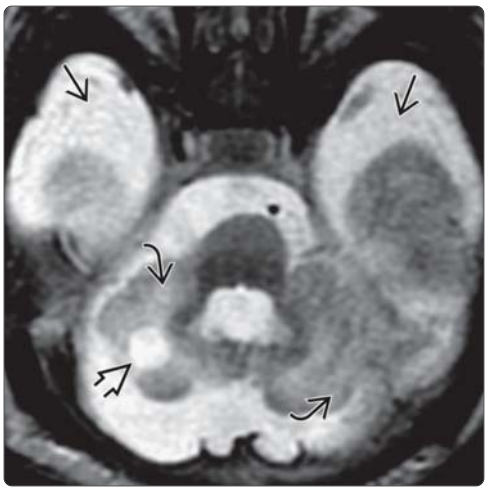
(Left) *Coronal T1WI MR in a microcephalic infant shows numerous periventricular cavitary germinolytic cysts. Detecting these cysts on US, CT, or MR imaging should prompt the consideration of possible congenital CMV infection.* **(Right)** *Coronal cranial ultrasound in congenital CMV shows periventricular foci of echogenicity consistent with calcification.*





(Left) *Axial T1WI in an infant with congenital CMV demonstrates bilateral open lip schizencephaly. Note the periventricular T1 hyperintense signal due to calcifications.* **(Right)** *Axial T2WI MR shows a left hemispheric "open-lip" schizencephaly lined by polymicrogyric cortex. Note the extensive bifrontal polymicrogyria. Patchy central WM hyperintensity reflects regions of demyelination or gliosis.*





(Left) *Coronal T2WI MR shows ventriculomegaly secondary to central WM volume loss; WM hyperintensities reflecting edema, gliosis, or demyelination; and polymicrogyria. Also note the hypoplastic right cerebellar hemisphere.* **(Right)** *Axial T2WI MR in a neonate demonstrates cerebellar hypoplasia and focal cystic injury of the cerebellum. Expansion of the middle cranial fossa subarachnoid spaces is indicative of temporal lobe atrophy.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Congenital AIDS, maternally transmitted AIDS

IMAGING

- Basal ganglia (BG) Ca++, cerebral atrophy
- Atrophy particularly frontal lobes
- Mineralizing microangiopathy: BG Ca++ (30-85%) > frontal WM > cerebellum
- Atrophy, ± T1 shortening within BG due to Ca++
- ± high signal in frontal subcortical WM, infarcts
- Fusiform vasculopathy (late)
- Include MRA with baseline NECT/MR

TOP DIFFERENTIAL DIAGNOSES

- Cytomegalovirus: Periventricular Ca++, microcephaly, cortical dysplasia
- Toxoplasmosis: Scattered Ca++, ± hydrocephalus
- Pseudo-TORCH: BG, brainstem, and parenchymal Ca++, neurodegeneration

PATHOLOGY

- HIV in microglial cells and macrophages
- Fibrosing and calcific vasculopathy, aneurysms, strokes, demyelination, ± hemorrhage

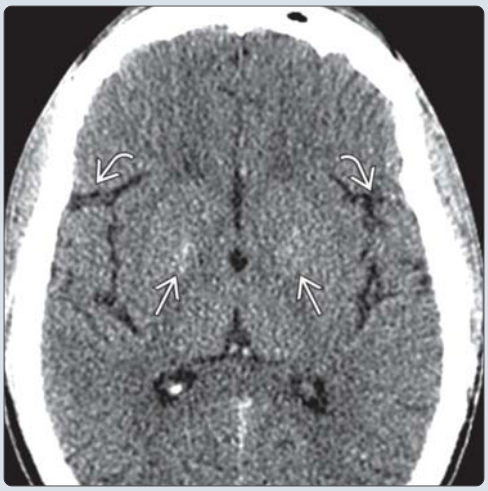
CLINICAL ISSUES

- Developmental delay, progressive encephalopathy, ↓ motor milestones, stroke
- Pediatric HIV: HIV cases in USA (2%), worldwide (5-25%); 90% are vertically transmitted (90%)
- Most acquired at birth, 3rd trimester, or via breastfeeding
- Opportunistic infections less common than in adult HIV

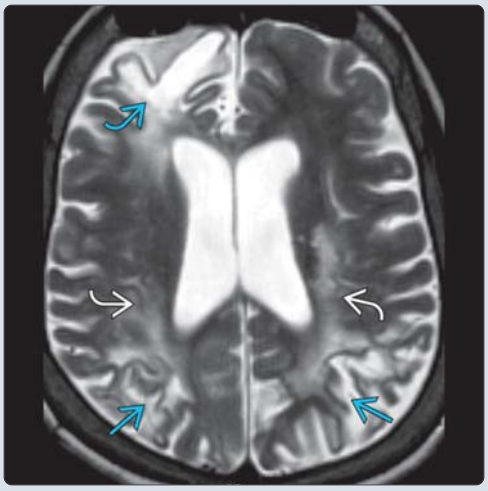
DIAGNOSTIC CHECKLIST

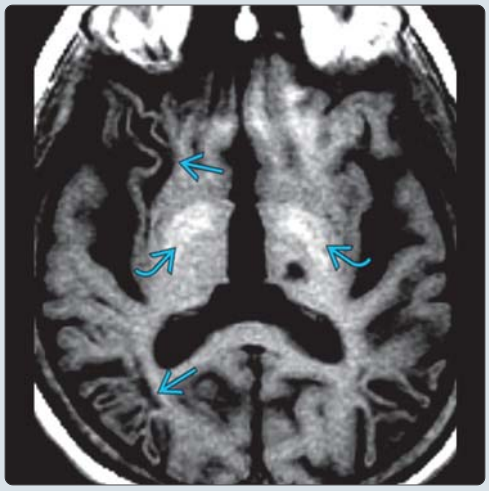
- Consider congenital HIV with bilateral symmetrical BG Ca++ in children > 2 months
- Consider congenital HIV when fusiform arteriopathy is detected

(Left) *Axial NECT in a 5-year-old girl with vertically transmitted HIV infection shows mild to moderate atrophy, most notable at the sylvian cisterns. Note the focal calcification involving the globus pallidus.* **(Right)** *Axial T2WI MR in a 12-year-old boy with a history of previous strokes and congenital HIV infection demonstrates fusiform aneurysmal dilation of the arteries of the circle of Willis. There is evidence of early atrophy involving the occipital lobes.*



(Left) *Axial T2WI in a 10 year old with congenital HIV demonstrates encephalomalacia due to old infarcts in the right frontal and both parietal lobes. Note diffuse volume loss as well as ill-defined T2 signal change in the deep white matter.* **(Right)** *Axial T1WI MR in the same patient shows T1 shortening in the basal ganglia due to calcifications. Cystic encephalomalacia due to old infarcts are also noted.*





https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Congenital AIDS, pediatric human immunodeficiency virus-1 infection

Definitions

- Infection early in utero/late pregnancy, at delivery, or by breast feeding

IMAGING

General Features

- Best diagnostic clue
  - Basal ganglia (BG) Ca++
  - Cerebral atrophy

CT Findings

- NECT
  - Atrophy, particularly frontal lobes
  - Mineralizing microangiopathy: BG Ca++ (30-85%) > frontal white matter (WM) > cerebellum
- CECT
  - ± faint enhancement of BG prior to appearance of Ca++
- CTA
  - Ectasia/fusiform enlargement of intracranial arteries (3-5%)

MR Findings

- T1WI
  - Atrophy, ± T1 shortening within BG due to Ca++
- T2WI
  - ± high signal in frontal subcortical WM, infarcts
- T2* GRE
  - May accentuate Ca++
- DWI
  - ± restricted diffusion for patients presenting with stroke
- T1WI C+
  - ± faint BG enhancement initially
- MRA
  - Fusiform vasculopathy (late)
- MRS
  - ↓ NAA, ↑ Cho:Cr, presence of excitatory neurotransmitters

Imaging Recommendations

- Best imaging tool
  - NECT
- Protocol advice
  - Include MRA with baseline NECT/MR

DIFFERENTIAL DIAGNOSIS

Cytomegalovirus

- Periventricular Ca++, microcephaly, cortical dysplasia

Toxoplasmosis

- Scattered Ca++, ± hydrocephalus

PATHOLOGY

General Features

- Etiology
  - HIV in microglial cells and macrophages

Gross Pathologic & Surgical Features

- Generalized brain volume loss
- Fibrosing and calcific vasculopathy, aneurysms, strokes, demyelination, ± hemorrhage
- Cerebrovascular disease found in 25% at autopsy (3-5% on imaging)

Microscopic Features

- Microglial nodules, multinucleated giant cells, Ca++ vasculopathy, myelin loss

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Encephalopathy, ↓ motor milestones
  - Stroke, microcephaly
- Clinical profile
  - Children become symptomatic after 3rd month of life
    - Hepatomegaly, lymphadenopathy, pneumonitis, infections, encephalopathy
    - High prevalence of congenital CMV when mothers have prenatal antiviral prophylaxis

Demographics

- Age
  - Symptoms begin at 12 weeks of life; some asymptomatic until 10 years
- Epidemiology
  - Pediatric HIV cases in USA (2%), worldwide (5-25%); 90% are vertically transmitted
    - Most acquired at birth, 3rd trimester, or via breastfeeding

Natural History & Prognosis

- If symptomatic in 1st year of life → 20% die in infancy
- Opportunistic infections less common than in adult HIV

Treatment

- Confirm diagnosis with polymerase chain reaction, HIV blood culture, p24-antigen assay
- Retroviral therapy improves survival

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Consider congenital HIV with bilateral symmetrical BG Ca++ in children > 2 months
- Consider HIV when fusiform arteriopathy is detected

SELECTED REFERENCES

KEY FACTS

TERMINOLOGY

- Neonatal herpes simplex encephalitis, HSV-2, neonatal HSV

IMAGING

- Early : Edema, DWI abnormality
- Late: Atrophy, cysts, ventriculomegaly, Ca++
- Variable brain involvement, early DWI abnormality
- Variable: WM, GM (cortical, BG), temporal lobe, brainstem, cerebellum, ± watershed
  - Unlike HSV encephalitis in adults & older children, infants with HSV have a diffuse, rather than temporal lobe predilection
- Early: CT normal (27%); variable distribution, low attenuation
- Early: Swelling, T1 hypointensity in affected regions
- Early: T2 hyperintensity (edema, neuronal necrosis), BG involved ~ 57%
- Hemorrhage less common than with HSV-1

TOP DIFFERENTIAL DIAGNOSES

- Peripartum &/or postnatal infection
- Stroke/ischemia, arterial or venous
- Vertically transmitted infection, TORCH
  - CMV → microcephaly, Ca++, cortical clefting or malformation
  - Toxoplasmosis → scattered Ca++, hydrocephalus

PATHOLOGY

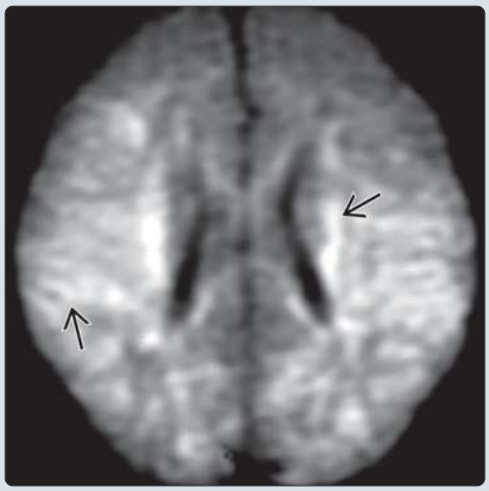
- Transmission: Peripartum (85%), postnatal (10%), in utero (5%)

CLINICAL ISSUES

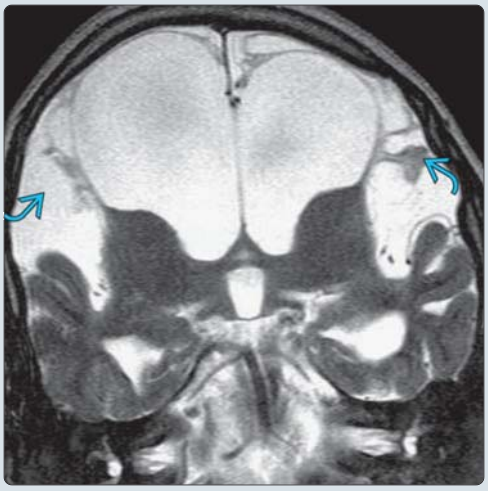
- C-section if active maternal infection, intravenous acyclovir

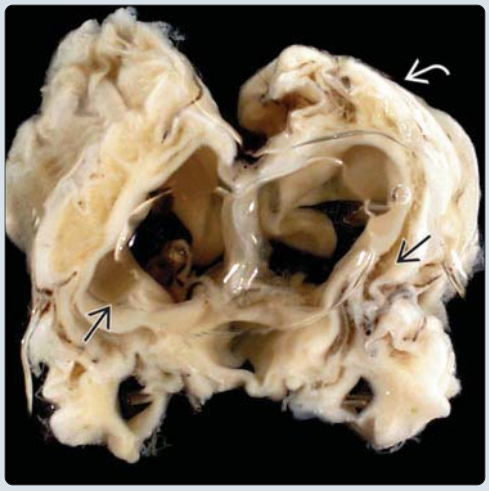
DIAGNOSTIC CHECKLIST

- Suspect HSV-2 in neonates with unexplained DWI abnormality



(Left) *Axial NECT in a neonate with HSV-2 encephalitis demonstrates widespread regions of gray and white matter hypoattenuation. The initial NECT will be negative in up to 27% of infected neonates.* **(Right)** *Axial DWI MR in a 2 week old with seizures & bulging fontanelle demonstrates extensive bihemispheric reduced diffusion involving gray and white matter structures in a random widespread manner. Increased IgM & positive PCR against HSV were detected. DWI is essential for early detection.*





(Left) *Coronal T2 MR in an infant who had HSV-2 peripartum encephalitis demonstrates extensive bihemispheric cystic encephalomalacia with marked ex vacuo dilatation of the lateral ventricles* **(Right)** *Coronal gross pathology section shows a neonatal brain with changes of vertically transmitted HSV-2 infection, including ventricular dilation, cystic encephalomalacia, and lack of normal cortical sulcation. About 5% of neonatal HSV-2 is acquired in utero.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neonatal HSV, HSV-2

IMAGING

General Features

- Best diagnostic clue
  - Variable brain involvement, early DWI abnormality
- Location
  - Variable: White matter (WM), gray matter (GM) (cortical, basal ganglia [BG]), temporal lobe, brainstem, cerebellum, ± watershed

CT Findings

- NECT
  - Early: Normal (27%), variable distribution, low attenuation
  - Late: Hydrocephalus, cysts, Ca++ (BG, thalami, cortex, or WM)

MR Findings

- T1WI
  - Early: Swelling, T1 hypointensity in affected regions
  - Late: Atrophy, cysts, ventriculomegaly, ± T1 shortening (Ca++)
- T2WI
  - Early: T2 hyperintensity (edema, neuronal necrosis), BG involved ~ 57%
  - Late: Cystic encephalomalacia, atrophy, WM hyperintensity
- T2* GRE
  - Hemorrhage less common than with HSV-1
- DWI
  - Restricted diffusion in affected regions
- T1WI C+
  - Patchy enhancement in affected regions, ± meningeal enhancement
- MRS
  - Acute: ↑ Cho, Glx, glutamine, ± lipid lactate, ↓ NAA
  - Chronic: All metabolites ↓

Ultrasonographic Findings

- Early: Linear echoes in BG
- Late: Multicystic encephalomalacia, ± Ca++

Imaging Recommendations

- Protocol advice
  - NECT, MR

DIFFERENTIAL DIAGNOSIS

Peripartum &/or Postnatal Infection

- Other bacterial and viral infections can mimic neonatal HSV

Stroke/Ischemia

- Arterial or venous infarction

Vertically Transmitted Infection, TORCH

- CMV → microcephaly, Ca++, cortical clefting or malformation
- Toxoplasmosis → scattered Ca++, hydrocephalus

PATHOLOGY

General Features

- Etiology
  - Transmission: Peripartum (85%), postnatal (10%), in utero (5%)

Staging, Grading, & Classification

- HSV infection acquired in the intrauterine, peripartum, or postnatal period is classified into the following types
  - Intrauterine infection
  - Disseminated disease
  - CNS disease

Gross Pathologic & Surgical Features

- Early: Meningoencephalitis, necrosis, ± hemorrhage, microglial proliferation
- Late: Atrophy, cysts, Ca++, ± hydranencephaly

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Postnatal: Lethargy, apnea, poor feeding, ± seizures, bulging fontanelle
  - In utero: Low birth weight, microcephaly, microphthalmia, ± mucous membrane ulceration
- Clinical profile
  - CSF: Pleocytosis (mononuclear cells), ↑ protein
  - EEG: Nonspecific

Demographics

- Age
  - Onset for peripartum infection → 2-4 weeks
- Epidemiology
  - Uncommon, estimated 1 in 3200 deliveries

Natural History & Prognosis

- Death in ~ 3 % of neonates with CNS disease and 29% with disseminated disease
- Survivors → cerebral palsy, seizures, mental retardation

Treatment

- C-section if active maternal infection, intravenous acyclovir

DIAGNOSTIC CHECKLIST

Consider

- HSV-2 in neonates with unexplained MR diffusion abnormalities

Image Interpretation Pearls

- Postnatal: Varied distribution, + DWI, ± hemorrhage
- In utero: Atrophy, scattered brain Ca++, cystic encephalomalacia, ventriculomegaly

KEY FACTS

TERMINOLOGY

- GBS meningitis, group B β-hemolytic streptococcal meningitis
- Leading cause of newborn meningitis in developed countries

IMAGING

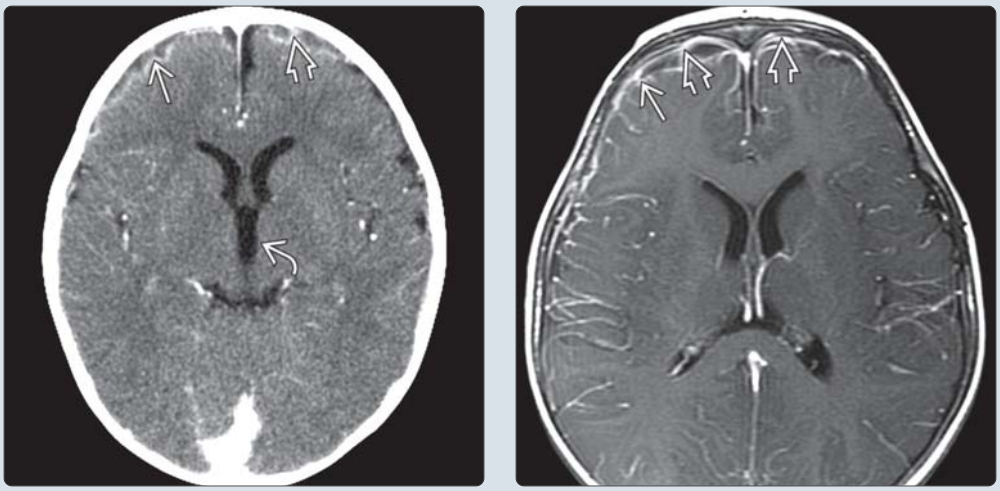
- Acute manifestations: Meningitis, cerebritis, vasculitis, ventriculitis, subdural effusion, empyema, arterial and venous infarction
- Arterial distributions often affected
- Variable: Dural, leptomeningeal, and parenchymal enhancement
- Ependymal enhancement and ventricular debris = ventriculitis
- Blurring/loss of gray-white matter junction → ± BG, thalamic, WM hyperintensities
- FLAIR hyperintensity in cortex, SAS, and subdural, cisternal, and ventricular spaces
- Diffusion restriction within infarcts and empyema
- Rim enhancement with subdural effusion (thinner) and empyema (thicker)
- Arterial narrowing, ± occlusions
- Dural venous sinus/cortical vein thrombosis ~ 30%
- MR with IV contrast, DWI, MRA, and MRV

TOP DIFFERENTIAL DIAGNOSES

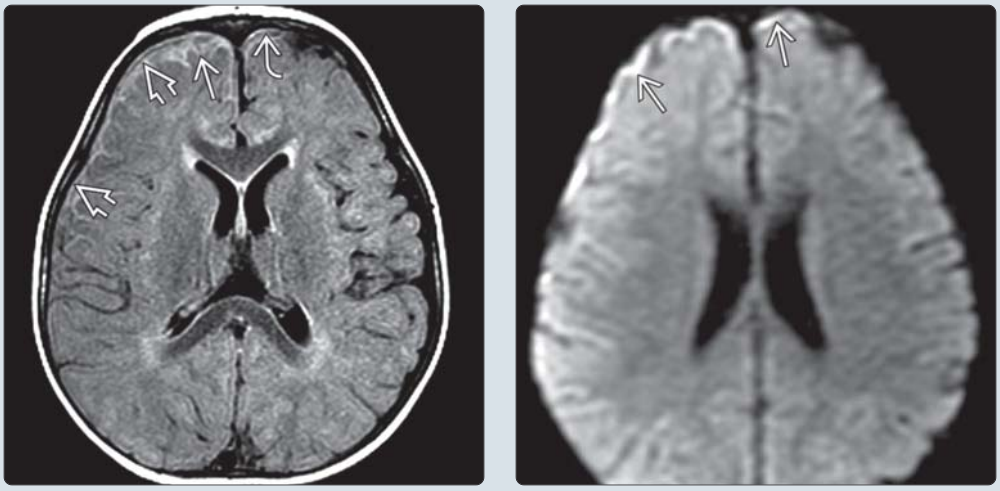
- Enteric, gram-negative meningitis
- *Escherichia coli*: Along with GBS meningitis, major cause of newborn meningitis in developed countries
- Listeria monocytogenes: Gram-positive rod
- *Enterobacter*: Most common cause of meningitis in 1st few months of life

DIAGNOSTIC CHECKLIST

- No imaging features distinguish GBS meningitis from other neonatal meningitides



(Left) *Axial CECT in an infant with group B streptococcal meningitis shows cortical enhancement ➡ and leptomeningeal enhancement ➡. Note the dilation of the frontal horns and 3rd ventricle ➡ reflecting impeded CSF circulation.* **(Right)** *Axial T1WI C+ MR of the same patient, performed for evaluation of status epilepticus 24 hours following CECT, more clearly shows the peripheral frontal cortical ➡ and leptomeningeal enhancement ➡. CSF Gram stain showed gram-positive diplococci.*



(Left) *Axial FLAIR MR is a sensitive tool to detect early complicated extraaxial fluid collections. FLAIR hyperintensity is seen in the right frontal cortex ➡ and within the right frontal temporal subarachnoid spaces ➡. Note the early involvement of the left frontal subarachnoid space ➡.* **(Right)** *Axial DWI MR in the same patient with meningitis helps to differentiate subdural effusions from subdural empyemas. These bifrontal hyperintense subdural collections ➡ showed low ADC values.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Group B streptococcal (GBS) meningitis

Synonyms

- Group B β-hemolytic streptococcal meningitis

Definitions

- Leading cause of newborn meningitis in developed countries
  - Early-onset disease (EOD): GBS sepsis presenting in 1st week of life
  - Late-onset disease (LOD): GBS sepsis presenting between 1-4 weeks of life

IMAGING

General Features

- Best diagnostic clue
  - Meningoencephalitis in newborn
- Location
  - Leptomeninges, cerebral hemispheres, and deep gray matter
- Morphology
  - Multifocal involvement
  - Arterial distributions often affected, particularly BG and thalami
- Acute manifestations: Meningitis, cerebritis, vasculitis, ventriculitis, subdural effusion, empyema, arterial and venous infarction
- Chronic sequelae: Loculated hydrocephalus, cystic encephalomalacia

CT Findings

- NECT
  - Hydrocephalus ± dependent debris in ventricles
  - Hypodensities in arterial distributions, BG, thalami, white matter (WM)
  - Occasional hyperdense foci = hemorrhagic venous infarcts, laminar necrosis
  - Hypodense subdural collections (effusion vs. empyema)
- CECT
  - Variable: Dural, leptomeningeal, and parenchymal enhancement
    - Rim enhancement around subdural effusions and empyemas
  - Ependymal enhancement/ventricular debris

MR Findings

- T1WI
  - Hypo- and hyperintense foci common
    - Multifocal hypointensities = edema, ischemia, infarction
    - Hyperintense foci cortex, BG, and WM = laminar necrosis, hemorrhagic venous infarction
- T2WI
  - Blurring/loss of gray-white matter junction, ± BG, thalamic and WM hyperintensity
- FLAIR
  - Hyperintensity in cortex and subarachnoid, subdural, cisternal, and ventricular spaces
- T2* GRE
  - Blooming of hemorrhagic foci
- DWI
  - Diffusion reduced in infarcts, pus collections
- T1WI C+
  - Variable: Dural, leptomeningeal, parenchymal, and ependymal enhancement
  - Rim enhancement with subdural effusion (thinner) and empyema (thicker)
- MRA
  - Arterial narrowing, ± occlusions
- MRV
  - Dural venous sinus/cortical vein thrombosis (in up to 30%)
- MRS
  - ↑ choline, ↓ NAA; increased lactate in areas of ischemia/infarction

Ultrasonographic Findings

- Grayscale ultrasound
  - ↑ echogenicity of sulci and parenchyma → hydrocephalus → ventricular debris

Imaging Recommendations

- Best imaging tool
  - MR with IV contrast, DWI, MRA, and MRV
- Protocol advice
  - CECT for rapid, initial assessment of hemodynamically unstable neonate

DIFFERENTIAL DIAGNOSIS

Other Neonatal Meningitides

- Enteric, gram-negative meningitis
  - Account for majority of early-onset meningitis in developing countries
  - Higher mortality than GBS meningitis
  - Specific pathogens
    - *Escherichia coli*: Major cause of newborn meningitis in developed countries (along with GBS meningitis)
    - *Enterobacter*: Most common cause of meningitis in 1st few months of life
    - *Citrobacter*: Rare; high morbidity/mortality secondary to frequent abscess formation
- Other meningitides
  - Listeria monocytogenes: Gram-positive rod

Congenital Infections (TORCH)

- CMV, toxoplasmosis, rubella: Infection occurs in utero with chronic sequelae present in neonate/infant
  - CMV: Periventricular Ca++, microcephaly, migrational abnormalities, encephalomalacia, cerebellar hypoplasia
  - Toxoplasmosis: Parenchymal Ca++, encephalomalacia, microphthalmia
- Herpes simplex virus type 2 (HSV-2): Infection acquired during vaginal birth; presents in 1st 2-4 weeks of life
  - Meningoencephalitis with extensive edema, necrosis, late cystic encephalomalacia

Hypoxic-Ischemic Encephalopathy

- Preterm: Injury to periventricular WM (mild) or thalami, basal ganglia, brainstem (severe)

https://CafePezeshki.IR

- Term: Injury to mature vascular watershed (mild) or areas of early myelination/metabolic activity (severe)

PATHOLOGY

General Features

- Etiology
  - EOD: Aspiration of infected amniotic fluid or birth canal secretions
  - LOD: As EOD or postnatal maternal contact, breast milk, nosocomial
  - Bacteremia facilitated by immature neonatal immune system
  - Development of meningitis related to magnitude/duration of bacteremia
  - Production of β-hemolysin facilitates access of GBS across blood-brain barrier
- GBS agalactiae serotype 3 responsible for majority of GBS meningitis
- GBS is potent activator of neonatal immune/inflammatory response

Gross Pathologic & Surgical Features

- Debris, exudates within subarachnoid spaces and ventricles
- Parenchymal infarction/encephalomalacia; luminal narrowing of vessels

Microscopic Features

- Inflammation of adventitia and vaso vasorum = vasculitis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Lethargy, poor feeding, irritability
  - Seizures (40%) and bulging fontanelle are typically late findings
- Clinical profile
  - Newborn with sepsis
  - Typical signs/symptoms of meningitis subtle or absent in neonate
- CSF analysis: ↑ WBCs, ↑ protein, ↓ glucose
- CSF/blood Gram stain: Gram-positive diplococci
- Maternal risk factors for EOD: GBS colonization, GBS chorioamnionitis/bacteruria, membrane rupture > 18 hours, intrapartum fever ≥ 38°C, previous newborn with EOD, delivery at < 37 weeks gestation

Demographics

- Age
  - 90% of newborns with GBS EOD present within 1st 24 hours of life
  - GBS LOD presents between 1-4 weeks after birth; occasionally up to 6 months
- Gender
  - Male, preterm infants (< 37 weeks) most at risk for EOD
- Ethnicity
  - Maternal GBS colonization rates highest in African American women
- Epidemiology
  - 10-30% of pregnant women have asymptomatic GBS colonization of genital/GI tract
    - < 1% of newborns born to colonized women develop EOD
  - EOD incidence: 0.5/1,000 live births
    - Incidence decreased by > 50% as result of maternal screening and intrapartum chemoprophylaxis
    - ↓ incidence of GBS EOD accompanied by ↑ incidence of neonatal gram-negative sepsis
    - Term infants account for 50% of GBS EOD secondary to preterm intrapartum chemoprophylaxis

Natural History & Prognosis

- Prognosis
  - Mortality of early-onset disease
    - Full-term newborns (2%), 34-36 weeks gestational age (10%), < 33 weeks gestational age (30%)
  - Morbidity meningitis: Neurological sequelae (12-30%) (cortical blindness, spasticity, global mental retardation)

Treatment

- Maternal
  - GBS screen: Rectovaginal swab at 35-37 weeks gestation
  - Positive maternal GBS screen or presence of other risk factors: Intrapartum IV penicillin
  - Future strategies
    - GBS PCR assay and rapid *Streptococcus* screen at onset of labor
    - GBS vaccine: Ideal prevention strategy; would prevent development of antibiotic-resistant pathogens
- Neonatal meningitis
  - High-dose IV penicillin → ± antiepileptics → CSF diversion may be required for complicated hydrocephalus

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- No imaging features distinguish GBS meningitis from other neonatal meningitides

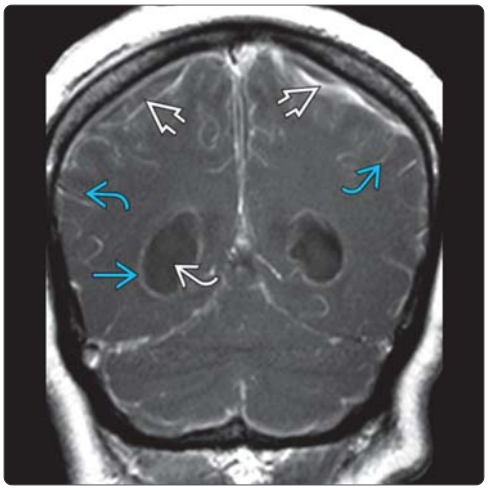
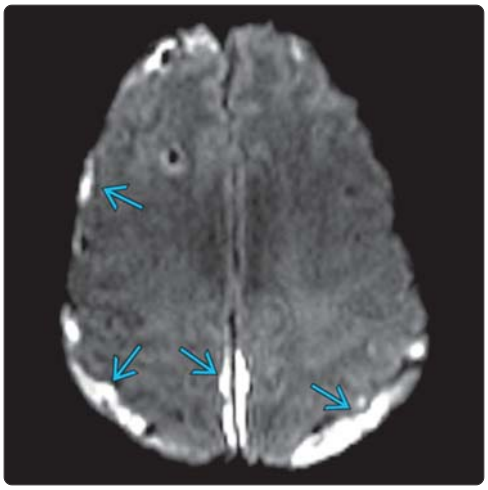
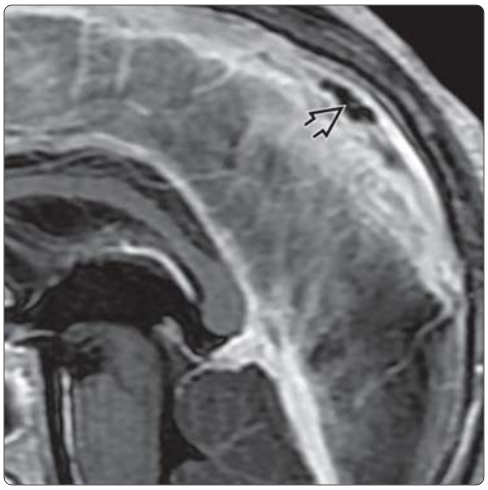
https://CafePezeshki.IR

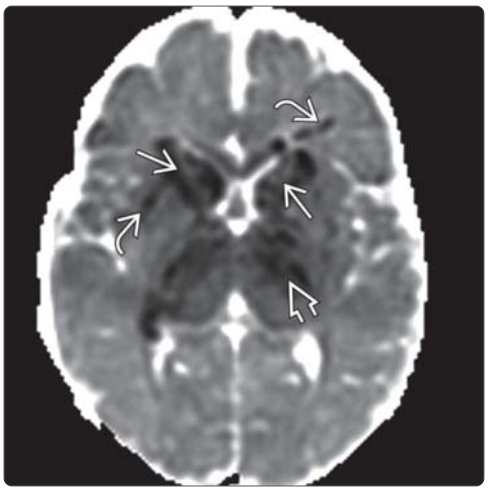




(Left) *Coronal T1 C+ MR in group B streptococcal meningitis shows extensive leptomeningeal enhancement. Ependymal enhancement with ventricular debris is due to a ventriculitis. Note extraaxial collections with rim enhancement.* **(Right)** *Axial DWI MR in the same patient shows restricted diffusion in the subdural collections consistent with empyemas. DWI helps to differentiate reactive subdural effusions from empyemas.*



(Left) *Axial T1WI C+ MR shows extensive leptomeningeal enhancement. Note the ventricular ependymal enhancement, dependent ventricular debris (ventriculitis), and basal ganglia enhancement due to perivascular space inflammation/arteritis. Ventricular dilation reflects early hydrocephalus.* **(Right)** *Sagittal MRV with contrast shows a hypointense clot within the sagittal sinus, creating a partial occlusion. Small clots were also detected in the transverse sinuses.*



(Left) *Axial T2WI MR demonstrates focal basal ganglia, thalamic, and white matter hyperintensities, reflecting infarction secondary to perivascular space inflammatory involvement/arteritis.* **(Right)** *Axial ADC in the same patient shows multiple basal ganglia and thalamic infarctions. Note the scattered white matter infarctions. Early detection of infarction is best achieved with diffusion imaging when T2 and FLAIR images may be "normal."*

https://CafePezeshki.IR

KEY FACTS

IMAGING

- Multiple, large, cystic white matter (WM) lesions
- Predilection for lobar white matter
- ± diffuse pneumocephalus (due to gas production)
- Square morphology of abscesses
- Rim or dot-like septal enhancement
- Best imaging tool: MR with contrast

TOP DIFFERENTIAL DIAGNOSES

- Other bacterial brain infections
- Periventricular white matter injury
- Cystic encephalomalacia
- White matter lacerations in nonaccidental head injury

PATHOLOGY

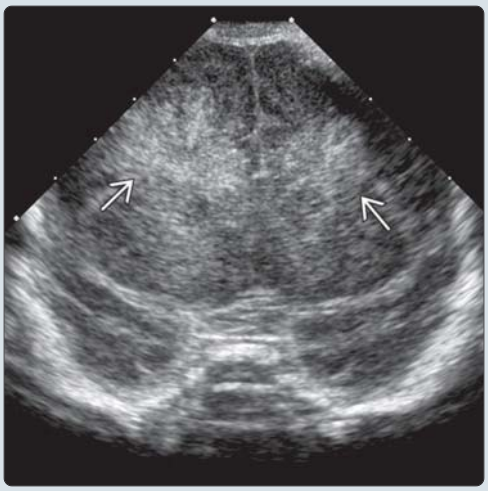
- Infection acquired: Horizontally (nosocomial) or vertically (maternal)
- Colonization (skin, umbilicus stump) → bacteremia → meningitis

CLINICAL ISSUES

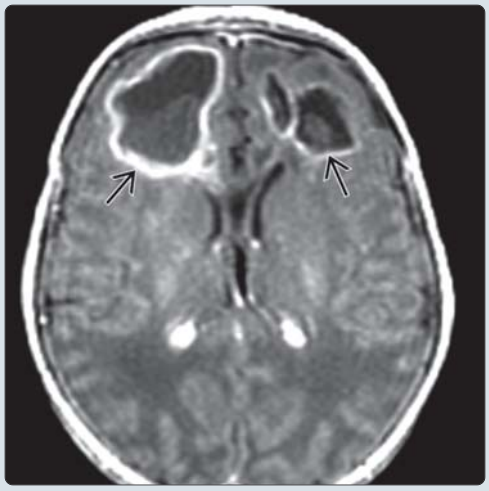
- Immunocompromised patients at higher risk
- Neonates & sick preterms are immunocompromised
- Preterm newborns are most susceptible
- 5% of neonatal (gram-negative) meningitis → 80% of neonatal brain abscesses
- Abscesses may only appear near completion of therapy
- 80% of neonates with *Citrobacter* meningitis develop brain abscesses

DIAGNOSTIC CHECKLIST

- Square WM abscesses with rim or dot-like septal enhancement



(Left) *Coronal cranial ultrasound in a newborn with Citrobacter sepsis shows bilateral frontal lobe white matter hyperechogenicity corresponding to regions of cerebritis on earlier MR (not shown). (Courtesy C. Glasier, MD.)* **(Right)** *Axial T1WI MR in a newborn with peripartum Citrobacter sepsis shows bifrontal "square" cavitary white matter abscesses. These cavitary lesions progressed from foci of cerebritis. Note the necrotic debris within the cavities. (Courtesy C. Glasier, MD.)*



(Left) *Axial DWI MR in the same patient demonstrates reduced diffusivity (increased signal intensity) within the dependent infected debris. (Courtesy C. Glasier, MD.)* **(Right)** *Axial T1 C+ MR in the same patient shows rim enhancement of the abscesses. Dot-like septal enhancement within the abscesses is another finding that may be seen on CECT or T1WI C+ MR. (Courtesy C. Glasier, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- *Citrobacter* cerebritis

Definitions

- Gram-negative enteric bacterium infection

IMAGING

General Features

- Best diagnostic clue
  - Multiple, large, cystic white matter (WM) lesions
  - "Polygonal" abscesses from complete replacement of WM; border parallels cortex
    - Increasing mass effect/edema more likely to have infected contents
    - "Rounding" of edges suggests increased pressure/active infection
- Location
  - Predilection for lobar white matter
- Size
  - Multiple large WM cysts
- Morphology
  - Polygonal abscesses

CT Findings

- NECT
  - Early (cerebritis)
    - Patchy, multilobar WM lesions
    - Low attenuation compared to unmyelinated brain
    - ± diffuse pneumocephalus (due to gas production)
  - Late (abscess)
    - Lobar WM cavities with septations
    - Square morphology of abscesses
    - Dot-like focus of septal Ca++
- CECT
  - Early (cerebritis)
    - Variable, often subtle parenchymal enhancement
  - Late (abscess)
    - Rim or dot-like septal enhancement
    - Multiple large cavities (± septations), replace WM

MR Findings

- T1WI
  - Early (cerebritis)
    - Patchy multilobar areas of T1 hypointensity
  - Late (abscess)
    - Multiple large cysts
    - Square morphology
    - Septations
    - T1 WM signal abnormality diminishes
- T2WI
  - Early (cerebritis)
    - Patchy multilobar T2 hyperintensity
  - Late (abscess)
    - Multiple, often septated cavities
    - Usually bilateral
    - Extensive T2 hyperintensity within WM
    - Variable edema, mass effect
    - Eventually, cavities may contract, causing profound WM loss
- FLAIR
  - Increased signal within lobar WM
- T2* GRE
  - Dot-like Ca++ within septal walls shows diminished signal
- T1WI C+
  - Early (cerebritis)
    - Subtle patchy WM enhancement
  - Late (abscess)
    - Patchy WM enhancement
    - Rim or septal wall enhancement
    - Dot-like focus of septal enhancement
- MRS
  - Products of fermentation
    - Lactate (1.3 ppm) , acetate (1.9 ppm), and succinate (2.4 ppm)
  - Proteolysis end products released from neutrophils
    - Valine and leucine (0.9 ppm)

Ultrasonographic Findings

- Grayscale ultrasound
  - Early (meningitis/cerebritis)
    - Sulcal thickening and increased sulcal echogenicity
    - Regions of WM hyperechogenicity
    - Loss of normal WM echo architecture
  - Late (abscess)
    - Multiple, septated, WM, anechoic, or hypoechoic cavities
- Color Doppler
  - Subtle flow within abscess septal walls

Imaging Recommendations

- Best imaging tool
  - MR with contrast best depicts location and severity of involvement
- Protocol advice
  - MR with contrast
    - Shows early parenchymal enhancement of cerebritis
    - Reveals dot-like foci of septal enhancement of "squared" abscesses
    - Detects complications of brain infection (vascular, extraaxial purulent collections)

DIFFERENTIAL DIAGNOSIS

Other Bacterial Brain Infections

- Usually with greater surrounding edema and mass effect
- Search for possible sinus, mastoid, or embolic/hematogenous sources of infection

Periventricular Leukomalacia

- Perifrontal and peritrigonal locations of WM cysts
- Slower progression of cystic change
- No rim or septal "dot" enhancement

Cystic Encephalomalacia

- Cortical and deep gray matter involved
- Thalamic and basal ganglia Ca++
- Cysts replaces WM
- Passive ventricular dilatation

https://CafePezeshki.IR

White Matter Lacerations in Nonaccidental Head Injury (NAHI)

- Frontal lobe WM
- Fluid level may be seen dependently within laceration
- Associated intracranial manifestations of NAHI
  - Parafalcine/convexity subdural hematoma, subarachnoid hemorrhage

PATHOLOGY

General Features

- Etiology
  - Neurovirulence factors of *Citrobacter* species
    - Unique 32-kD outer membrane protein
    - Resistance to phagocytosis
  - *Citrobacter* invades/transcytoses microvascular endothelial cells
    - Leads to hemorrhagic necrosis and abscess
  - Intracellular replication of *Citrobacter* in microvascular endothelial cells
    - Contributes to persistence of brain infection and cavitation
- Associated abnormalities
  - Infection acquired: Horizontally (nosocomial) or vertically (maternal)
  - Colonization (skin, umbilicus stump) → bacteremia → meningitis
  - *Citrobacter* is facultative anaerobe
    - Hydrolyzes urea and ferments glucose → produces gas

Gross Pathologic & Surgical Features

- Opaque leptomeninges, purulent exudate
- Diffuse ependymitis

Microscopic Features

- No well-formed fibrotic capsule
- Organisms in walls of congested vessels
- Neutrophils plus necrotic cell debris

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Septic newborn or preterm infant: Bulging fontanelle, apnea, seizures
- Clinical profile
  - In very premature neonates
    - Sepsis, irritability, poor feeding, bulging fontanelle
  - Immunocompromised patients at higher risk
    - Neonates, sick preterms are immunocompromised

Demographics

- Age
  - Predilection for very young, very old patients
    - Newborns → sepsis, meningitis, and cerebral abscesses
    - Elderly → causes urinary, upper respiratory tract infections
  - Mean age of sepsis onset: 5 days
  - Preterm newborns are most susceptible
  - Citrobacter CNS infection beyond 1 month of age is rare
- Epidemiology
  - *Citrobacter* infection
    - 5% of neonatal (gram-negative) meningitis → 80% of neonatal brain abscesses
    - Abscesses may only appear near completion of therapy
  - *Citrobacter* CNS infection
    - Most cases considered sporadic ↔ neonatal ICU outbreaks do occur

Natural History & Prognosis

- 30% of neonates and infants with *Citrobacter* CNS infection die
- 80% of neonates with *Citrobacter* meningitis develop brain abscesses
- 50% of *Citrobacter* meningitis/abscess survivors have significant CNS damage

Treatment

- Antibiotics are mainstay of therapy
- Late abscesses occur, and prolonged IV therapy is rule
- Adjunctive surgical drainage of abscesses
  - For enlarging cysts on optimized IV therapy
  - Poorly responsive to initial antibiotic therapy

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Minimal edema surrounding abscesses
- Square abscesses with focal septal enhancement
- Not all rim-enhancing cavities are abscesses
  - Some are WM necrosis and liquefaction
- *Citrobacter* species and *Cronobacter sakazakii* have similar imaging

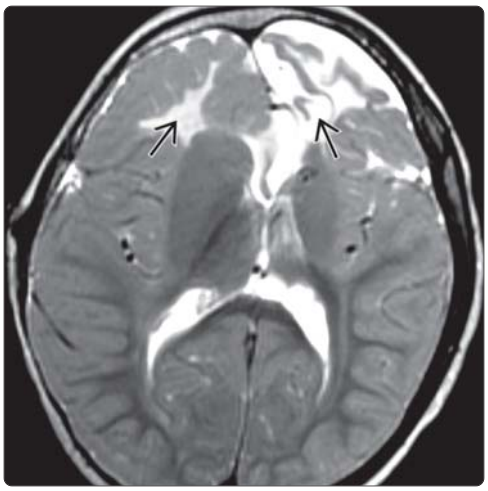
(Left) *Axial T2WI MR in a 1 month old with neonatal Citrobacter sepsis demonstrates a large cavitary right parietooccipital abscess ➡ with dependent debris ⇨. Note the developing small right frontal lobe abscess ➡, which is just starting to cavitate. (Courtesy L. Lowe, MD.)* **(Right)** *Rim enhancement ⇨ of a more mature parietooccipital and less mature frontal abscess is seen. Progression from meningitis to cerebritis to abscess is common (~ 80%). (Courtesy L. Lowe, MD.)*

(Left) *Axial T1WI C+ MR in an infant with "treated" Citrobacter meningitis demonstrates large bilateral parietooccipital rim-enhancing abscesses ➡. Note the associated ependymal thickening and enhancement reflecting ventriculitis ⇨. (Courtesy T. Booth, MD.)* **(Right)** *In this newborn with "treated" Citrobacter meningitis, bilateral frontal ➡ and right peritrigonal ⇨ rim-enhancing abscesses are seen. Long-term IV therapy is the rule in such cases. (Courtesy T. Feygin, MD.)*



(Left) *Axial T2WI MR in a 1 year old with refractory seizures remote from long-term IV therapy for Citrobacter brain abscesses shows bilateral frontal retraction cavities, gliosis, and atrophy ⇨. (Courtesy C. Glasier, MD.)* **(Right)** *Axial NECT in an infant originally diagnosed with Citrobacter sepsis and meningitis shows that the meningitis has progressed. Note the multifocal cerebral abscesses lead to macrocystic encephalomalacia and multiple septated cavities ➡. (Courtesy S. Gorges, MD.)*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Acute or chronic inflammatory infiltration of pia, arachnoid, and CSF
- Classified as acute pyogenic (bacterial), lymphocytic (viral), chronic (tuberculosis or granulomatous)

IMAGING

- Imaging best delineates complications: Empyema, ischemia, hydrocephalus, cerebritis/abscess, ventriculitis
- FLAIR MR: Hyperintense signal in sulci, cisterns
- T1WI C+: Exudate and brain surface (pia) enhance
- Delayed C+ FLAIR most sensitive sequence for leptomeningeal disease
- DWI: Invaluable for detecting complications
- Basilar meningitis typical of pyogenic infections, TB, cryptococcosis, neurosyphilis, sarcoid, lymphoma
- Meningitis is clinical/laboratory diagnosis, not imaging diagnosis
  - Can occur in presence of normal imaging

TOP DIFFERENTIAL DIAGNOSES

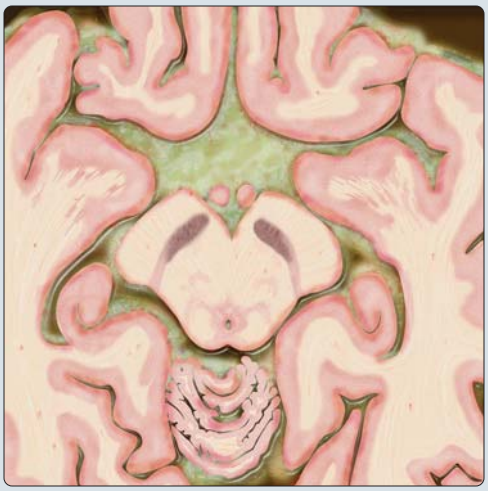
- Carcinomatous meningitis
- Neurosarcoidosis
- Increased FLAIR signal in CSF (SAH, high inspired oxygen, artifact, venous congestion from stroke)

PATHOLOGY

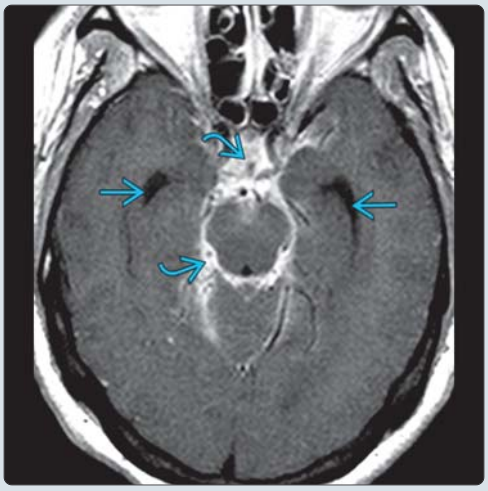
- Hematogenous spread from remote infection (i.e., heart, teeth) is most common etiology

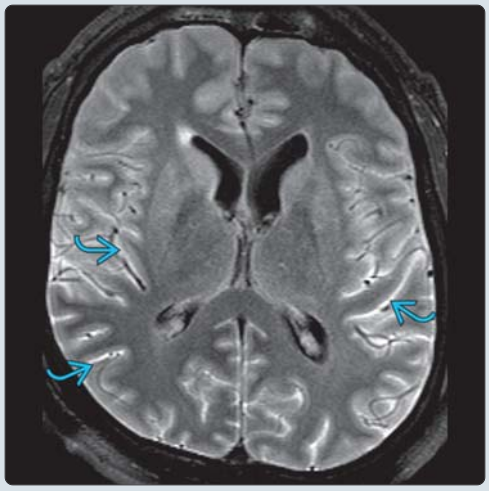
CLINICAL ISSUES

- Adults: Headache, fever, nuchal rigidity, ± altered mental status
- Children: Fever, irritability, nuchal rigidity
- Infants: Fever, lethargy, irritability
- Intravenous antibiotics are mainstay of therapy
- Empiric therapy based on age
- Specific therapy based on culture and sensitivity



(Left) *Axial graphic shows diffuse inflammatory exudate that involves the leptomeninges and fills the basal cisterns and sulci. This typically results in increased density on CT or T1 signal intensity on MR. It is important to remember that meningitis is a clinical/laboratory diagnosis, not an imaging diagnosis.* **(Right)** *Autopsy case shows changes of severe meningitis with dense purulent exudate covering the pons and filling the basal cisterns. (Courtesy R. Hewlett, MD.)*





(Left) *Axial T1WI C+ MR in a patient with TB meningitis shows extensive cisternal enhancement, as well as early hydrocephalus.* **(Right)** *Axial FLAIR MR in a 24-year-old man with headache, fever, and vomiting demonstrates extensive high signal in the sulci due to a pyogenic meningitis. Axial FLAIR, T1 +C and DWI are important sequences in evaluation of a patient with suspected meningitis.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Leptomeningitis; infectious meningitis

Definitions

- Acute or chronic inflammatory infiltration of pia, arachnoid, and CSF
- Classified as acute pyogenic (bacterial), lymphocytic (viral), chronic (tubercular or granulomatous)

IMAGING

General Features

- Best diagnostic clue
  - Positive CSF by lumbar puncture
- Location
  - Pia, arachnoid, and subarachnoid space of brain and spine
- Morphology
  - Typically smooth ± thick, intense sulcal-cisternal enhancement
  - Tuberculosis (TB), fungal meningitis often basilar/confluent; may be nodular
- Imaging may be normal early
- Imaging best delineates complications
  - Hydrocephalus: Mild transient communicating most common
  - Extraaxial fluid collections: Sterile (effusions) or infected/purulent (empyema)
  - Cerebritis/abscess
  - Ventriculitis
  - Arterial narrowing/occlusions, venous thrombosis & associated infarcts

CT Findings

- NECT
  - Most common = normal
  - Mild ventricular enlargement common
  - Sulci, basal cisterns may appear effaced
  - May see increased density in basilar cisterns or sylvian fissures related to inflammatory debris simulating subarachnoid hemorrhage
  - ± subdural effusion in pediatric patients
- CECT
  - Enhancing exudate in sulci, cisterns
  - Low-density areas related to ischemic complications
- CTA
  - Arterial narrowing, occlusion may be seen

MR Findings

- T1WI: Isointense exudate
- T2WI: Hyperintense exudate
- FLAIR: Hyperintense signal in sulci, cisterns (nonspecific)
  - May see hydrocephalus
- DWI: Useful to detect infarcts (2° to vascular complications), empyema, abscess, ventriculitis
- T1WI C+: Exudate and brain surface (pia) enhance
  - Characterizes complications
- MRA: May see arterial narrowing or occlusion
- MRV: May see venous thrombosis
- MRS: Helpful for evaluation of complications
  - e.g., cerebritis, abscess, infarct

Ultrasonographic Findings

- Sulcal enlargement, echogenic deposits in subarachnoid space in infants
- Ventricular dilatation and subdural collections

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR + DWI: Best to evaluate complications
- Protocol advice
  - MR with FLAIR, DWI, T1WI C+
  - Delayed enhanced FLAIR most sensitive sequence for leptomeningeal disease

DIFFERENTIAL DIAGNOSIS

Carcinomatous Meningitis

- Primary tumor often known (exception = lymphoma)
- Breast, lung most common extracranial sources
- Primary CNS tumors: GBM, medulloblastoma, pineal/choroid plexus tumors, PNET, ATRT, ependymoma

Neurosarcoidosis

- Lacy leptomeningeal enhancement
- May have ventricular or dural-based enhancing masses

Increased FLAIR Signal in CSF

- Nonspecific; many causes
  - Subarachnoid hemorrhage (SAH)
  - High inspired oxygen
  - Artifact
  - Acute stroke (parenchymal edema, vascular congestion)
  - Retained gadolinium in CSF: Dialysis-dependent patient with end-stage renal disease

PATHOLOGY

General Features

- Etiology
  - Hematogenous (most common)
    - Spread from remote infection (heart, teeth, etc.)
    - Some may enter CNS via choroid plexus (lacks blood-brain barrier)
  - Direct extension
    - Less common
    - Sinusitis, otitis media, orbital infection
    - Skull base fracture
  - Penetrating injury (least common)
  - Basilar meningitis typical of pyogenic infections, TB, cryptococcosis, neurosyphilis, sarcoid, lymphoma
- Associated abnormalities
  - Complications
    - Extraventricular obstructive hydrocephalus (EVOH)
    - Ventriculitis, choroid plexitis
    - Cerebritis, abscess
    - Subdural fluid collections (empyema, effusion)
  - Cerebrovascular complications
    - Venous and arterial thrombosis
    - Ischemia/infarct

https://CafePezeshki.IR

Gross Pathologic & Surgical Features

- Gross pathology generally same regardless of agent
- Cisterns, sulci filled with cloudy CSF, then purulent exudate
- Pia-arachnoid congested, may mimic SAH
- Cortex may be edematous

Microscopic Features

- Meningeal exudate: Neutrophils, fibrin, bacteria
- Vessels within exudate may show fibrinoid necrosis, thrombosis
- Infection may extend into perivascular spaces (PVSs), ventricles
  - PVSs may act as conduit for infection to reach brain parenchyma
- May spread by direct invasion of pia
- Subpial, microglial, astrocytic proliferation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Adults: Headache, fever, nuchal rigidity, ± altered mental status
    - Brudzinski sign: Hips and knees flex involuntarily when neck is flexed
    - Kernig sign: Flex hips and knees, try to extend knees = pain in hamstrings, patient resistance
  - Children: Fever, headache, photophobia, vomiting, irritability, nuchal rigidity
  - Infants: Fever, lethargy, irritability
  - Seizures in 30%
  - Meningitis is clinical/laboratory diagnosis, not imaging diagnosis
- Clinical profile
  - CSF shows increased white blood cells (leukocytosis)
    - Elevated CSF protein, decreased glucose typical of infectious meningitis
  - Purpuric rash may develop in *Neisseria meningitidis* (meningococcal) meningitis, highly morbid

Demographics

- Epidemiology
  - Bacterial meningitis increase in last 30 years related to nosocomial infection
    - ~ 3/100,000 in USA
  - Meningitis is most common form of CNS infection in children
  - Incidence of bacteria based on age
    - Elderly: *Listeria monocytogenes*, *S. pneumoniae*, *N. meningitidis*, gram-negative bacilli
    - Adults: *S. pneumoniae*, *N. meningitidis*, group B *Streptococcus*
    - Children: *N. meningitidis*
    - Infants: *S. pneumoniae*, *N. meningitidis*
    - Neonates: Group B *Streptococcus*, *Escherichia coli*, *Enterobacter*
  - Vaccine has markedly decreased incidence of *H influenzae* meningitis
  - Viral meningitis: Enteroviruses most common
  - Chronic meningitis
    - TB most common
    - High morbidity, mortality despite treatment
  - Fungal meningitis: *Cryptococcus neoformans* (AIDS) and *Coccidioides immitis* most common

Natural History & Prognosis

- Effective antimicrobial agents have reduced but not eliminated mortality, morbidity
- Impaired CSF resorption may cause hydrocephalus
- Elevated intracranial pressure, cerebral perfusion alterations can be early complications
- Complications occur in 50% of adult patients
  - Infectious: Cerebritis/abscess, ventriculitis, empyema, effusion
  - Vascular: Ischemia related to arterial spasm or infectious arteritis, dural venous thrombosis
  - Labyrinthine ossificans is uncommon complication
    - Infection of labyrinth via cochlear aqueduct from subarachnoid space
    - Typically results in bilateral hearing loss
- Mortality up to 25%

Treatment

- Intravenous antibiotics
  - Empiric therapy based on age
  - Specific therapy based on culture and sensitivity
  - Most bacterial meningitides: Ceftriaxone or cefotaxime ± vancomycin is treatment of choice
  - Fungal meningitis: Amphotericin B ± fluconazole or flucytosine
  - TB meningitis requires combination therapy: Isoniazid, pyrazinamide, rifampin
  - Viral meningitis: Supportive care, except for herpes meningitis (acyclovir)
- Surgery for complications (hydrocephalus, empyema)

DIAGNOSTIC CHECKLIST

Consider

- Imaging may be normal, most useful for complications

Image Interpretation Pearls

- Meningitis is clinical/laboratory diagnosis, not imaging diagnosis
  - Can occur in presence of normal imaging
- T1WI C+, FLAIR often complementary in diagnosis
- DWI invaluable for detecting complications of meningitis

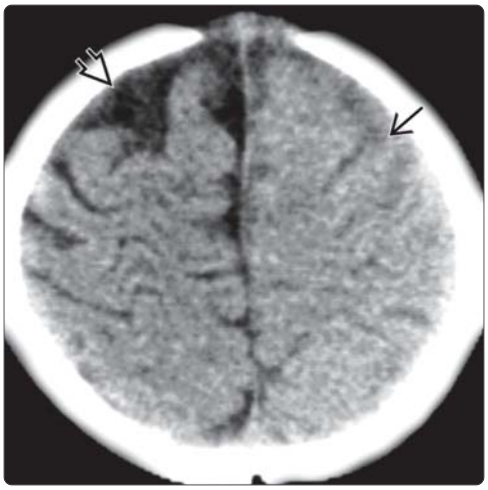
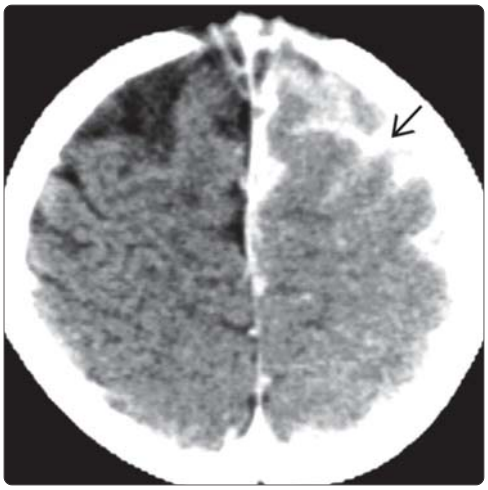
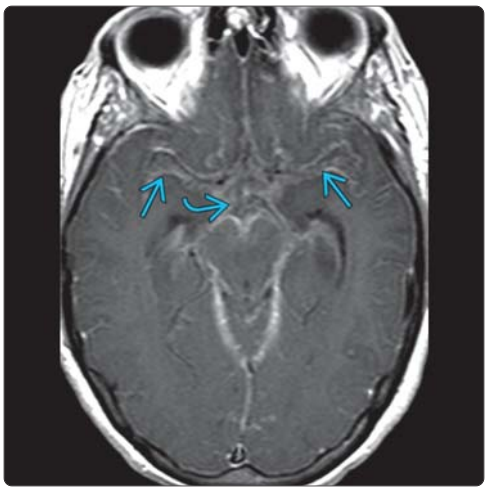
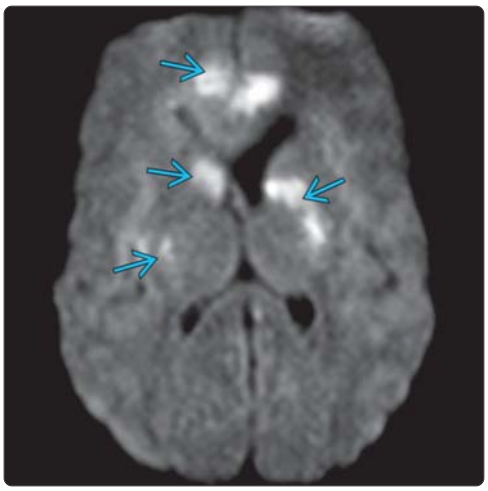
(Left) *NECT in a patient with pneumococcal meningitis shows communicating hydrocephalus* ⇨ *with periventricular low density* ⇨ *due to periventricular interstitial edema.* **(Right)** *Axial DWI MR in the same patient shows complications of meningitis. Restricted diffusion is seen in the 3rd ventricle* ⇨ *and occipital horns* ⇨ *due to ventriculitis. There is a small subdural empyema* ➡ *in the right occipital parasagittal region. Note high DWI signal due to exudates* ➡ *in the superior cerebellar cistern.*





(Left) *Axial NECT in an infant shows poor visualization of the left convexity sulci related to an inflammatory exudate due to bacterial meningitis. The pus-filled sulci* ⇨ *are nearly isodense with the underlying brain, making them difficult to see unless you compare them with the normal CSF-filled sulci* ⇨ *on the right.* **(Right)** *CECT scan in the same case shows intense enhancement of the left-sided exudate that completely fills the sulci* ⇨.





(Left) *Axial T1 +C MR in a patient with blastomycosis shows extensive leptomeningeal enhancement in the basal cisterns* ⇨ *and sylvian fissures* ⇨ *due to meningitis.* **(Right)** *Axial DWI MR in the same patient shows multiple focal areas of high signal* ⇨ *due to acute infarcts. Ischemia may be the result of arterial spasm/occlusion or true arteritis. DWI is invaluable in the evaluation of meningitis complications*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Focal pyogenic infection of brain parenchyma, typically bacterial; fungal or parasitic less common
- 4 pathologic stages: Early cerebritis, late cerebritis, early capsule, late capsule

IMAGING

- Ring-enhancing lesion with T2 hypointense rim and central diffusion restriction characteristic
- Imaging varies with stage of abscess development
  - Early cerebritis: Ill-defined T2 hyperintense mass
- Findings with contrast enhancement
  - Early cerebritis: Patchy enhancement
  - Late cerebritis: Intense, irregular rim enhancement
  - Early capsule: Well-defined, thin-walled, enhancing rim
  - Late capsule: Cavity collapses, capsule thickens
- MRS: Central necrotic area may show presence of amino acids (0.9 ppm), lactate (1.3 ppm), acetate (1.9 ppm), succinate (2.4 ppm)
- Multiplanar MR ± contrast, DWI, ± MRS, PWI
- Dual rim sign on SWI (hypointense outside, hyperintense inside) helpful in from other ring-enhancing lesions

TOP DIFFERENTIAL DIAGNOSES

- Glioblastoma
- Parenchymal metastases
- Demyelinating disease
- Resolving intracerebral hematoma
- Subacute cerebral infarction

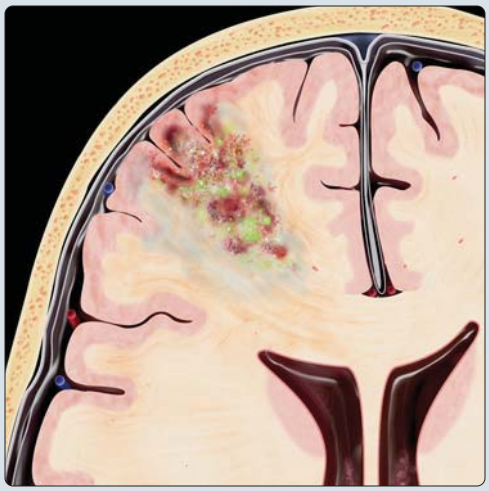
CLINICAL ISSUES

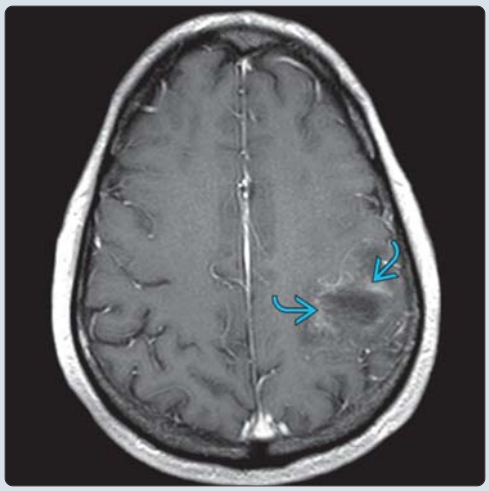
- Headache (up to 90%); may have seizures, altered mental status, focal deficits, nausea, vomiting
- Potentially fatal but treatable lesion

DIAGNOSTIC CHECKLIST

- DWI, MRS helpful to distinguish abscess from mimics

(Left) *Axial graphic shows early cerebritis, the initial phase of abscess formation, in the frontal lobe. There is a focal unencapsulated mass of petechial hemorrhage, inflammatory cells, and edema.* **(Right)** *Axial T1W C+ in a 24-year-old male with headache, fever, and altered sensorium shows early cerebritis with patchy enhancement. Imaging varies with stage of abscess development and may mimic a neoplasm, demyelination, or subacute infarct. DWI is often helpful to distinguish cerebritis from its mimics.*





(Left) *Axial graphic shows the early capsule formation of an abscess with central liquified necrosis and inflammatory debris. Collagen and reticulin form the well-defined abscess wall. Note the surrounding edema.* **(Right)** *Axial T1W +C demonstrates a ring-enhancing abscess with a central necrotic core and surrounding edema.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Localized infection of brain parenchyma, typically bacterial; fungal or parasitic less common
- 4 pathologic stages: Early cerebritis, late cerebritis, early capsule, late capsule

IMAGING

General Features

- Best diagnostic clue
  - Imaging varies with stage of abscess development
  - Early capsule: Well-defined, thin-walled enhancing rim
    - Ring-enhancing lesion: DWI high signal, low ADC
    - T2 hypointense rim with surrounding edema
- Location
  - Typically supratentorial; up to 14% infratentorial
  - Frontal lobe (sinusitis, odontogenic infection), temporal lobe (otomastoiditis)
  - Usually at gray-white junction (hematogenous)
  - Multiple lesions may represent septic emboli
- Size
  - 5 mm up to several cm
- Morphology
  - Thin-walled, well-delineated, ring-enhancing, cystic-appearing mass

CT Findings

- NECT
  - Early cerebritis: Ill-defined, hypodense subcortical lesion with mass effect; CT may be normal early
  - Late cerebritis: Central low-density area; peripheral edema, increased mass effect
  - Early capsule: Hypodense mass with moderate vasogenic edema and mass effect
  - Late capsule: Edema, mass effect diminish
  - Gas-containing abscess rare
- CECT
  - Early cerebritis: ± mild patchy enhancement
  - Late cerebritis: Irregular rim enhancement
  - Early capsule: Low-density center with thin, distinct enhancing rim
    - Medial or ventricular wall of capsule thinnest; thickest near cortex
  - Late capsule: Cavity shrinks, capsule thickens
    - May have "daughter" abscesses

MR Findings

- T1WI
  - Early cerebritis: Poorly marginated, mixed hypo-/isointense mass
  - Late cerebritis: Hypointense center, iso-/mildly hyperintense rim
  - Early capsule: Rim iso-/hyperintense to white matter (WM); center hyperintense to CSF
  - Late capsule: Cavity shrinks, capsule thickens
- T2WI
  - Early cerebritis: Ill-defined hyperintense mass
  - Late cerebritis: Hyperintense center, hypointense rim; hyperintense edema
  - Early capsule: Hypointense rim (due to collagen, hemorrhage, or paramagnetic free radicals)
  - Late capsule: Edema and mass effect diminish
- T2* GRE
  - Dual rim sign on SWI (hypointense outside, hyperintense inside) helpful in distinguishing from other ring-enhancing lesions
- DWI
  - Increased signal intensity in cerebritis and abscess
  - ADC map: Markedly decreased signal (low ADC) centrally within abscess
  - Elevated fractional anisotropy (FA) within abscess cavity
- T1WI C+
  - Early cerebritis: Patchy enhancement
  - Late cerebritis: Intense, irregular rim enhancement
  - Early capsule: Well-defined, thin-walled enhancing rim
  - Late capsule: Cavity collapses, capsule thickens
    - Capsule thinnest on ventricular side
- MRS
  - Central necrotic area may show presence of amino acids (0.9 ppm), lactate (1.3 ppm), acetate (1.9 ppm), succinate (2.4 ppm)
- PWI: Abscess capsule shows lower rCBV values than rims of enhancing tumors
- Resolving abscess: T2 hypointense rim resolves, central ADC increases, enhancement resolves last
  - Small ring/punctate enhancing focus may persist for months

Nuclear Medicine Findings

- PET: FDG and carbon-11-methionine show increased uptake in brain abscess

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR
- Protocol advice
  - Multiplanar MR ± contrast, DWI, ± MRS, PWI

DIFFERENTIAL DIAGNOSIS

Glioblastoma

- Thick, nodular > thin wall
- Low signal on DWI (rarely high, mimics abscess)
- Hemorrhage common
- Other cystic primary neoplasms can also mimic abscess

Parenchymal Metastases

- Thick-walled, centrally necrotic mass, often multiple, marked edema
- May be solitary ring-enhancing lesion
- DWI may be positive and mimic abscess

Demyelinating Disease

- Multiple sclerosis, ADEM
- Ring enhancement often incomplete ("horseshoe")
- Characteristic lesions elsewhere in brain
- Mass effect small for size of lesion

Resolving Intracerebral Hematoma

- History of trauma or vascular lesion
- Blood products present on MR

https://CafePezeshki.IR

Subacute Cerebral Infarction

- History of stroke, vascular distribution
- Gyriform > > ring enhancement (rare)

PATHOLOGY

General Features

- Etiology
  - Hematogenous from extracranial location (pulmonary infection, endocarditis, urinary tract infections)
  - Direct extension from calvarial or meningeal infection
    - Paranasal sinus, middle ear, teeth infections (via valveless emissary veins)
  - Postoperative
  - Penetrating trauma (bone fragments > metal)
  - Right-to-left shunts (congenital cardiac malformations, pulmonary arteriovenous fistulas)
  - Neonatal: 2/3 associated with meningitis
    - "Square abscess" associated with Citrobacter meningitis
  - 20-30% have no identifiable source (cryptogenic)
    - Often polymicrobial (streptococci, staphylococci, anaerobes)

Gross Pathologic & Surgical Features

- Early cerebritis (3-5 days)
  - Infection focal but not localized
  - Unencapsulated mass of PMNs, edema, scattered foci of necrosis, petechial hemorrhage
- Late cerebritis (4-5 days to 2 weeks)
  - Necrotic foci coalesce
  - Rim of inflammatory cells, macrophages, granulation tissue, and fibroblasts surrounds central necrotic core
  - Vascular proliferation, surrounding vasogenic edema
- Early capsule (begins at about 2 weeks)
  - Well-delineated collagenous capsule
  - Liquified necrotic core, peripheral gliosis
- Late capsule (weeks to months)
  - Central cavity shrinks
  - Thick wall (collagen, granulation tissue, macrophages, gliosis)

Microscopic Features

- Early cerebritis: Hyperemic tissue with PMNs, necrotic blood vessels, microorganisms
- Late cerebritis: Progressive necrosis, inflammatory cells, fibroblasts deposit an early reticulin matrix around periphery
- Early capsule: Granulation tissue proliferation around necrotic core
- Late capsule: Multiple layers of collagen and fibroblasts

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache (up to 90%); may have seizures, altered mental status, focal deficits, nausea, vomiting
  - Fever in only 50%
- Other signs/symptoms
  - Increased ESR (75%), elevated WBC count (50%), absence of leukocytosis does not exclude diagnosis

Demographics

- Age
  - Most common in 3rd and 4th decades; 25% in patients < 15 years
- Gender
  - M:F = 2:1
- Epidemiology
  - Uncommon; ~ 2,500 cases per year in USA
  - Bacterial: *Staphylococcus*, *Streptococcus*, *Pneumococcus*
  - Diabetic: *Klebsiella pneumoniae*
  - Post-transplant: *Nocardia*, *Aspergillus*, *Candida*
  - AIDS: *Toxoplasmosis*, *Mycobacterium tuberculosis*
  - Neonates: *Citrobacter*, *Proteus*, *Pseudomonas*, *Serratia*, *Staphylococcus aureus* (meningitis related)

Natural History & Prognosis

- Potentially fatal but treatable lesion
  - Stereotactic surgery + medical therapy have greatly reduced mortality
- Complications of inadequately or untreated abscesses
  - Meningitis, "daughter" lesions, mass effect, herniation
  - Intraventricular rupture, ventriculitis
    - Ventricular debris with irregular fluid level
    - Hydrocephalus and ependymal enhancement
- Factors affecting prognosis: Size, location, virulence of infecting organism(s), and immune status
- Mortality variable: 0-30%
- Epilepsy: Common complication in pediatric patients

Treatment

- Primary therapy: Surgical drainage &/or excision
- If < 2.5 cm or early-phase cerebritis: Antibiotics only
- Steroids to treat edema and mass effect
- Lumbar puncture hazardous if findings of ↑ ICP; pathogen often cannot be determined from CSF unless related to meningitis

DIAGNOSTIC CHECKLIST

Consider

- DWI, MRS helpful to distinguish abscess from mimics
- Dual rim sign on SWI (hypointense outside, hyperintense inside) helpful in from other ring-enhancing lesions

Image Interpretation Pearls

- Search for local cause (sinusitis, otitis media, mastoiditis)
- T2 hypointense abscess rim resolves before enhancement in successfully treated patients

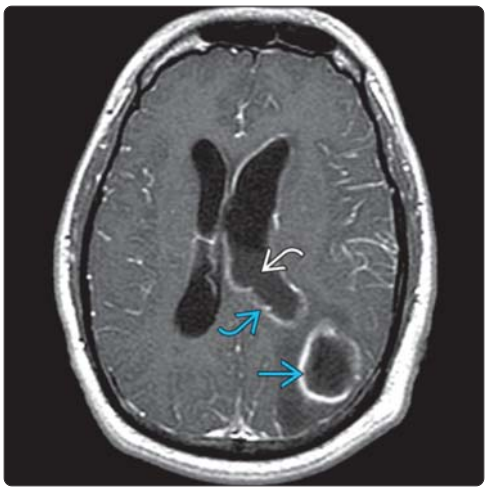
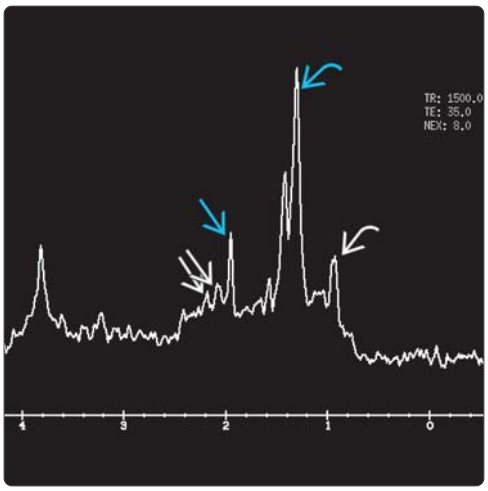
(Left) *Axial DWI MR in a 20-year-old male with an abscess shows a large, well-defined mass with restricted diffusion ⇨ in the right frontal lobe.* **(Right)** *Axial ADC map in the same patient shows very low ADC values ⇨. Restriction of water proton mobility within abscess cavity is due to necrotic debris, macromolecules, viscosity of pus. Studies suggest that persistent low ADC or recurrent low ADC in an abscess cavity following treatment indicates reactivation of infection or failed therapy.*

(Left) *Axial T2WI in the same patient as above shows a T2 hypointense rim ⇨ of abscess wall with extensive vasogenic edema ⇨. There is mass effect, subfalcine herniation to the left ⇨. T2 hypointensity of abscess capsule has been attributed to free radicals generated by phagocytic macrophages.* **(Right)** *Axial SWI MR in the same patient shows a characteristic dual rim sign. Abscess is bordered by 2 concentric rims, the outer one hypointense ⇨ and inner one hyperintense ⇨ relative to cavity content, forming the dual rim sign.*





(Left) *Axial T1WI MR C+ in the patient with pyogenic abscess and ventriculitis shows a rim-enhancing lesion ⇨, dependent ventricular debris ⇨, and ependymal enhancement ⇨.* **(Right)** *MRS (TR 1500, TE 35) shows typical spectrum for a bacterial brain abscess. There is a large lactate peak at 1.3 ppm ⇨, acetate at 1.9 ppm ⇨, amino acids (valine, leucine, isoleucine) at 0.9 ppm ⇨ and succinate at 2.4 ppm ⇨.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Ventricular ependyma infection related to meningitis, ruptured brain abscess, or ventricular catheter

IMAGING

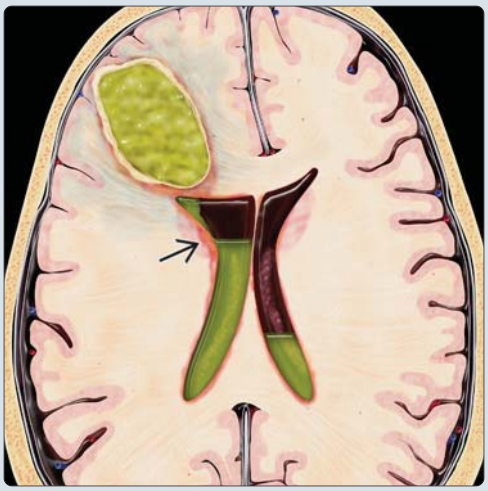
- Best imaging clue: Ventriculomegaly with debris level, abnormal ependyma, periventricular T2/FLAIR hyperintensity
- DWI: Restriction of layering debris with low ADC is characteristic
- T1WI C+: Marked ependymal enhancement with ventriculomegaly
- Ultrasound: Ventriculomegaly with echogenic ependyma and debris in infant
  - Can play important role in detection of postinfectious hydrocephalus

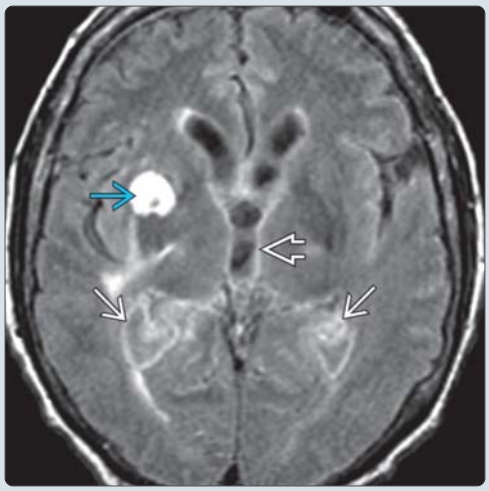
TOP DIFFERENTIAL DIAGNOSES

- Primary central nervous system lymphoma
- Ependymal tumor spread (e.g., glioblastoma multiforme, medulloblastoma, pineal and choroid plexus tumors, ependymoma)
- Intraventricular hemorrhage
- Prominent ependymal veins (e.g., arteriovenous malformation, developmental venous anomaly, cavernoma, Sturge-Weber)

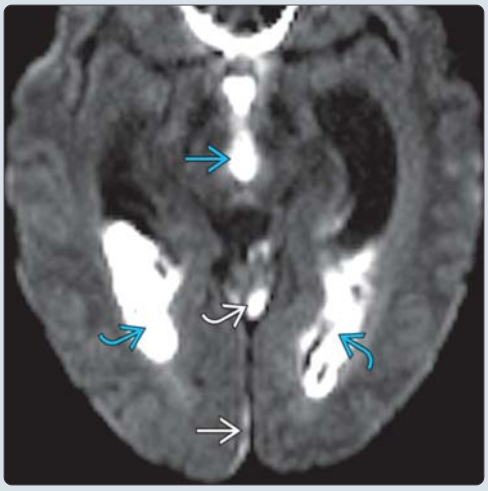
CLINICAL ISSUES

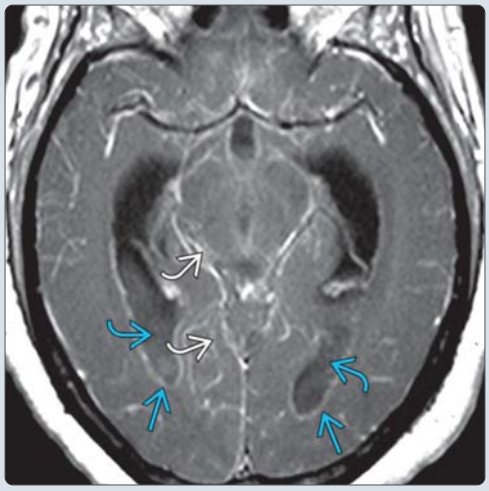
- Bacterial ventriculitis may occur in healthy individuals after trauma or neurosurgical procedure
- Fungal or viral ventriculitis occurs most commonly in immunosuppressed patients
- Ventriculitis occurs in 30% of meningitis patients; up to 80-90% in neonates/infants
- High mortality rate: 40-80%
- Treatment: Surgical irrigation, drainage, &/or IV antibiotics





(Left) *Axial graphic shows a right frontal abscess that has ruptured into the ventricular system, resulting in ventriculitis. Note the characteristic debris level within the ventricles and the inflammation along the ventricular margins.* **(Right)** *Axial FLAIR MR shows striking hyperintensity along the ventricular ependyma with hyperintense debris filling the atria of the lateral ventricles. FLAIR and DWI are the most sensitive sequences to identify ventriculitis. Note the right basal ganglia abscess.*





(Left) *Axial DWI MR in a patient with pneumococcal meningitis shows diffusion restriction in 3rd ventricle and lateral ventricular debris due an associated ventriculitis. Exudates in superior cerebellar cistern and a small subdural empyema. DWI is invaluable in the diagnosis of ventriculitis.* **(Right)** *Axial T1WI C+ MR in the same patient shows dependent ventricular debris, ependymal as well as leptomeningeal enhancement.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Ependymitis, ventricular abscess, pyocephalus

Definitions

- Ventricular ependyma infection related to meningitis, ruptured brain abscess, or ventricular catheter

IMAGING

General Features

- Best diagnostic clue
  - Ventriculomegaly with debris level, abnormal ependymal enhancement, periventricular T2/FLAIR hyperintensity

CT Findings

- NECT
  - Ventriculomegaly with dependent debris level
  - Subtle low density along ventricular margins
- CECT
  - Enhancement of ventricular walls

MR Findings

- T1WI
  - Ventriculomegaly with hyperintense debris
  - Subtle periventricular hypointensity
- T2WI
  - Hyperintensity along ventricular margins
- FLAIR
  - Hyperintensity along ventricular margins
  - Hyperintense debris layering dependently
- DWI
  - Diffusion restriction of layering debris, low ADC
- T1WI C+
  - Marked ependymal enhancement
  - May have associated choroid plexitis with enlarged, edematous choroid
  - Inflammatory septations and loculations (chronic)

Ultrasonographic Findings

- Ventriculomegaly with echogenic debris and echogenic ependyma, increased periventricular echogenicity, poor definition of choroid plexus in infant

Imaging Recommendations

- Best imaging tool
  - MR in adults, ultrasound in infants
- Protocol advice
  - Multiplanar MR with contrast, DWI, FLAIR

DIFFERENTIAL DIAGNOSIS

Primary Central Nervous System (CNS) Lymphoma

- Ependymal enhancement, typically nodular
- Parenchymal disease usually present

Ependymal Tumor Spread

- Primary brain tumors: GBM, medulloblastoma, pineal tumors, ependymoma, choroid plexus tumors
- Metastatic tumor from extracranial primary

Intraventricular Hemorrhage

- History of trauma; other sequelae seen
- Ventricles are typically not enlarged acutely

Prominent Ependymal Veins

- Vascular malformations: Arteriovenous malformation, developmental venous anomaly, cavernoma
- Abnormal venous drainage (i.e., Sturge-Weber)

PATHOLOGY

General Features

- Etiology
  - Complication of meningitis or cerebral abscess that ruptures into ventricular system
  - Complication of neurosurgical procedure, most commonly intraventricular catheter
  - Pathogens include bacteria, fungus, virus, parasites
    - Common bacterial organisms: *Staphylococcus*, *Streptococcus*, *Enterobacter*

Gross Pathologic & Surgical Features

- Intraventricular sedimentation levels with inflammation and proteinaceous debris

Microscopic Features

- Ependymal and subependymal inflammation with macrophages, lymphocytes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Dependent on etiology; often indolent
- Clinical profile
  - Cerebrospinal fluid (CSF) cytology, cultures may be normal

Demographics

- Epidemiology
  - Bacterial ventriculitis may occur in healthy individuals after trauma or neurosurgical procedure
  - Fungal or viral ventriculitis occurs most commonly in immunosuppressed patients
  - Ventriculitis occurs in 30% of meningitis patients; up to 80-90% in neonates/infants
  - Intrathecal chemotherapy, rarely associated

Natural History & Prognosis

- Mortality rate: 40-80%

Treatment

- Surgical irrigation, drainage, &/or IV antibiotics

KEY FACTS

TERMINOLOGY

- Collection of pus in subdural or epidural space, or both (15%); subdural much more common
- Subdural empyema (SDE), epidural empyema (EDE)

IMAGING

- Best diagnostic clue: Extraaxial collection with enhancing rim, DWI positive
- Supratentorial typical
  - EDE: Often adjacent to frontal sinus
  - SDE: Convexity in > 50%, parafalcine in 20%
- Infratentorial (up to 10%); related to mastoiditis
- T2 MR: Inwardly displaced dura seen as hypointense line between fluid and brain
- T1 C+ MR: Prominent enhancement at margin related to granulomatous tissue and inflammation
- MR with DWI best to demonstrate presence, nature, extent, and complications

TOP DIFFERENTIAL DIAGNOSES

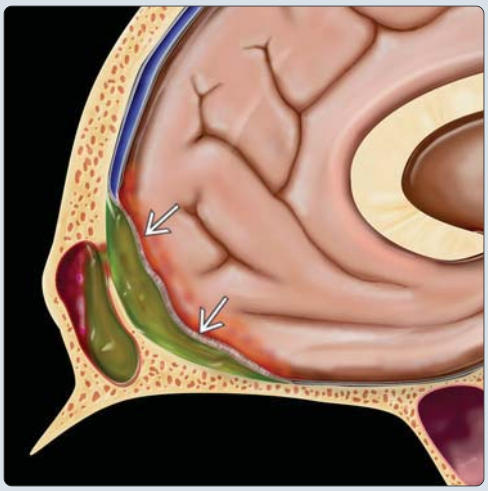
- Chronic subdural hematoma
- Subdural effusion, subdural hygroma

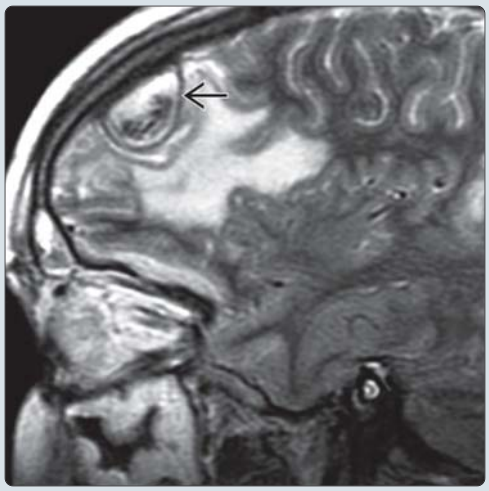
PATHOLOGY

- Infants, young children: Complication of bacterial meningitis
- Older children, adults: Related to paranasal sinus disease (> 2/3)

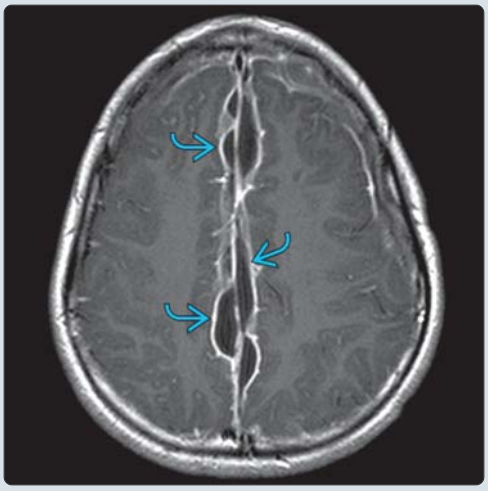
CLINICAL ISSUES

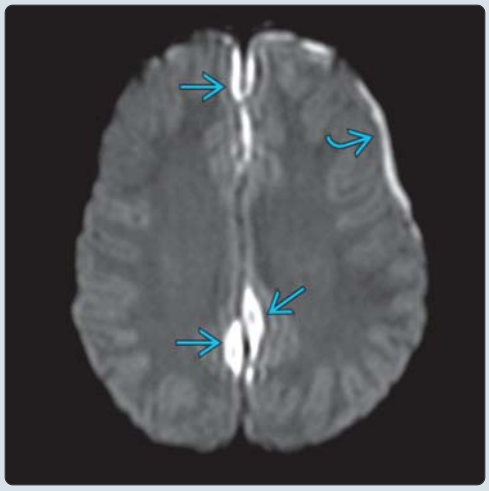
- Sinus or ear infection in > 75% of cases
- EDE, SDE rare, yet highly lethal
- Complications common: Cerebritis, abscess, venous thrombosis, ischemia, hydrocephalus
- Mortality: 10-15%
- Surgical drainage is primary treatment
- Sinus drainage + antibiotics: Small sinus-related EDE





(Left) *Sagittal graphic shows frontal sinus purulence and direct extension into the epidural space, resulting in an epidural empyema (EDE). Note the displaced dura ➡ and inflammation in the adjacent frontal lobe. EDE is often located adjacent to the frontal sinus.* **(Right)** *Sagittal T2WI MR shows an EDE with abnormal signal in the adjacent brain related to cerebritis. Note the inwardly displaced dura ⇨, seen as a hypointense line between the EDE and the brain, in this child with sinusitis.*





(Left) *Axial T1WI C+ FS MR in a patient presenting with headache and fever shows rim-enhancing parafalcine collections ⇨ related to subdural empyemas.* **(Right)** *Axial DWI MR in the same patient shows bright diffusion restriction in the parafalcine ⇨ and left frontal ⇨ subdural empyemas. DWI is an important sequence to demonstrate the presence, extent, and complications of a subdural or epidural empyema.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Subdural empyema (SDE), epidural empyema (EDE)

Synonyms

- Epidural empyema = epidural abscess

Definitions

- Collection of pus in subdural or epidural space or both; subdural much more common

IMAGING

General Features

- Best diagnostic clue
  - Extraaxial collection with enhancing rim
- Location
  - Supratentorial typical
    - SDE: Convexity in > 50%, parafalcine in 20%
    - EDE: Often adjacent to frontal sinus
  - Infratentorial (up to 10%)
    - Often associated with mastoiditis
    - > 90% associated with hydrocephalus
- Morphology
  - SDE: Crescentic typical; may be lens-shaped (lentiform) on coronal images
    - Can spread diffusely over hemispheres, along tentorium/falx
  - EDE: Biconvex, lentiform

CT Findings

- NECT
  - Extraaxial collection, iso- to hyperdense to CSF
  - SDE: Crescentic iso- to hyperdense collection, limited by dural reflections
    - Frequently bilateral
    - Warning: Can be small, easily overlooked
  - EDE: Biconvex low-density collection between dura, calvaria; contained by cranial sutures
    - Often continuous across midline
  - Posterior fossa EDE
    - Typically at sinodural angle
    - Tegmen tympani ± sigmoid plate eroded
    - Pus may extend into cerebellopontine angle
- CECT
  - Strong peripheral rim enhancement
  - Posterior fossa EDE: Look for venous thrombosis
- Bone CT
  - **Sinusitis** common in **supratentorial** SDE-EDE
  - **Otomastoiditis** common in **infratentorial** SDE-EDE

MR Findings

- T1WI
  - Extraaxial collection, hyperintense to CSF
  - SDE: Crescentic extraaxial collection
  - EDE: Lentiform bifrontal or convexity collection
    - May cross midline in frontal region
- T2WI
  - Iso- to hyperintense to CSF
  - SDE: Crescentic collection, underlying brain may be hyperintense
  - EDE: Lentiform bifrontal or convexity collection
    - Inwardly displaced dura seen as **hypointense line** between fluid and brain
- FLAIR
  - Hyperintense to CSF
  - SDE: Crescentic collection, underlying brain may be hyperintense
  - EDE: Lentiform bifrontal or convexity collection
  - Hyperintensity in underlying brain parenchyma may be caused by cerebritis or ischemia (venous or arterial)
- DWI
  - SDE: **Restricted diffusion** (↑ signal intensity) typical
  - EDE: Variable signal with some restricting components
- T1WI C+
  - Prominent enhancement at margin related to granulomatous tissue and inflammation
  - SDE: Encapsulating membranes enhance strongly, may be loculated with internal fibrous strands
  - EDE: Strong enhancement of collection margins
  - May see enhancement of adjacent brain parenchyma (cerebritis/abscess)
  - May see leptomeningeal enhancement due to associated meningitis
  - Frontal subgaleal phlegmon or abscess ("Pott puffy tumor")
- MRV: Venous thrombosis especially with SDE

Ultrasonographic Findings

- Useful in infants
- Heterogeneous echogenic convexity collection with mass effect
  - Hyperechoic fibrous strands
  - Thick, hyperechoic inner membrane
  - Increased echogenicity of pia-arachnoid and exudates in subarachnoid space

Imaging Recommendations

- Best imaging tool
  - **MR with DWI** best to demonstrate presence, nature, extent, and complications
- Protocol advice
  - Contrast-enhanced multiplanar MR with DWI
  - **DWI** helpful to evaluate extent and complications

DIFFERENTIAL DIAGNOSIS

Chronic Subdural Hematoma

- MR shows blood products; may be loculated
- Often enhances along edge; enhancement usually thinner than SDE
- May be indistinguishable; history may help

Subdural Effusion

- Sterile, CSF-like collection associated with meningitis
- Follows CSF on all MR sequences
- Usually nonenhancing; may enhance mildly
- Frontal and temporal regions common, often bilateral

Subdural Hygroma

- Nonenhancing CSF collection, often trauma/surgical history

https://CafePezeshki.IR

Dural Metastasis

- Primary tumor often known, typically breast, prostate
- Often diffuse, nodular enhancement
- May have associated bone metastases

PATHOLOGY

General Features

- Etiology
  - Infants, young children: Complication of **bacterial meningitis**
  - Older children, adults: Related to **paranasal sinus disease** (> 2/3)
    - Direct spread via posterior wall of frontal sinus
    - Retrograde spread through **valveless bridging emissary veins** of extra- and intracranial spaces
  - **Mastoiditis** (± cholesteatoma) in 20%
  - Complication of head trauma or neurosurgical procedure (rare)
  - Complication of meningitis in adults (very rare)
  - Causative organism: *Staphylococcus aureus*, *Staphylococcus epidermidis*, enteric gram-negative bacilli most common
  - Aerobic and microaerophilic streptococci (infection from paranasal sinuses)
- SDE much more common than EDE
- SDE more commonly complicated by abscess and venous thrombosis (> 10%)
- 15% of cases have both EDE and SDE

Gross Pathologic & Surgical Features

- Encapsulated, yellowish, purulent collection
- Spreads widely but may be loculated
- Often accompanying osteitis

Microscopic Features

- Inflammatory infiltrate & granulomatous tissue

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Majority have fever, headaches
  - Meningismus common, may mimic meningitis
  - Sinusitis often present
  - Cerebritis/brain abscess causes neurologic signs
- Clinical profile
  - Sinus or ear infection in > 75% of cases
  - Frontal subgaleal abscess ("Pott puffy tumor") in up to 1/3; typically adolescent males
  - Periorbital swelling may be seen
  - Confused with meningitis; delayed diagnosis
  - EDE, SDE rare, yet highly lethal

Demographics

- Age
  - Can occur at any age
- Epidemiology
  - SDE: 15-22%, EDE: 2-5% of focal intracranial infections
  - SDE: Sinusitis (67%), mastoiditis (10%)

Natural History & Prognosis

- Progresses rapidly, **neurosurgical emergency**
- Rapidly evolving, fulminant course
- EDE may occasionally have indolent course, as dura mater functions as barrier between infection and brain
  - Much better prognosis than SDE
- Can be fatal unless recognized and treated
  - **Lumbar puncture** can be **fatal**
  - CSF can be normal
- Complications common
  - Cerebritis and brain abscess: ~ 5%
  - Cortical vein, dural sinus thrombosis (venous ischemia)
  - Cerebral edema
  - Hydrocephalus (> 90% of infratentorial SDE)
- **Mortality: 10-15%**

Treatment

- Surgical drainage via wide craniotomy is gold standard
- Intravenous antibiotics
- Sinus drainage + antibiotics possible in small sinus-related EDE

DIAGNOSTIC CHECKLIST

Consider

- Chronic subdural hematoma may be difficult to differentiate from SDE; history may help
- Look for empyema in patient with sinusitis and neurologic symptoms
- If SDE or EDE discovered, look also for sinusitis, otomastoiditis, dural sinus thrombosis, brain abscess

Image Interpretation Pearls

- MR with contrast and **DWI** is most sensitive; CT may miss small collections
- DWI differentiates SDE from subdural effusions
- MR with DWI may be used to monitor treatment response

KEY FACTS

TERMINOLOGY

- Brain parenchyma infection caused by herpes simplex virus type 1 (HSV1)
- Typically reactivation in immunocompetent patients

IMAGING

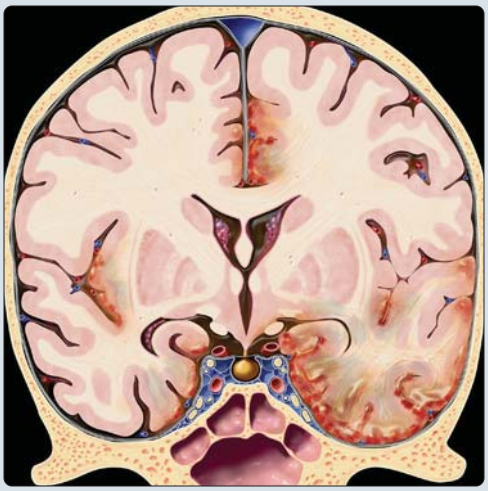
- Best imaging clue: T2/FLAIR hyperintensity of limbic system (medial temporal and inferior frontal cortex) with DWI restriction
  - Typically bilateral disease, but asymmetric
  - Deep gray nuclei usually spared
- CT often normal early
- MR with DWI most sensitive for early diagnosis
- T2/FLAIR: Cortical, subcortical hyperintensity with relative white matter sparing
- GRE: If hemorrhagic, hypointensity "blooms" within edematous brain
- DWI: Restricted diffusion in limbic system
- T1WI C+: May see mild, patchy enhancement early
  - Gyriform enhancement usually seen 1 week after initial symptoms

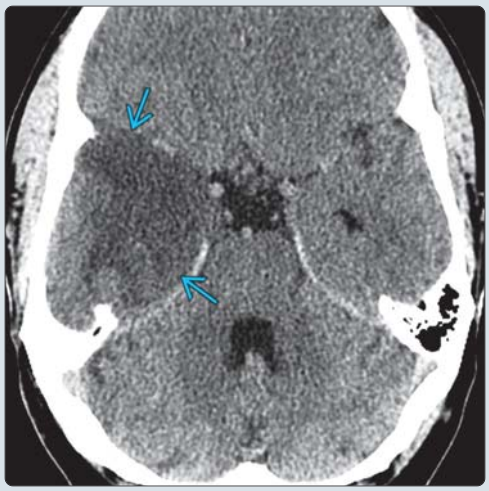
TOP DIFFERENTIAL DIAGNOSES

- Acute cerebral ischemia-infarction
- Status epilepticus
- Limbic encephalitis
- Infiltrating neoplasm

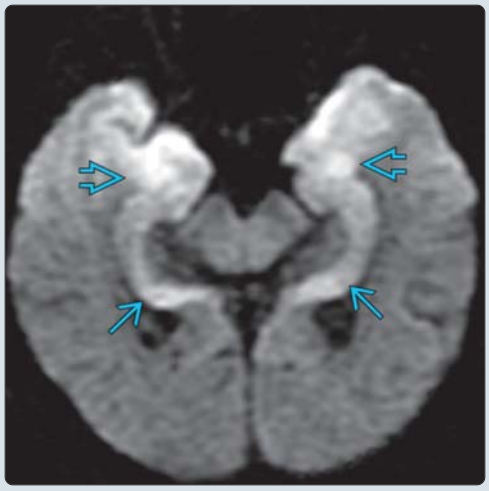
CLINICAL ISSUES

- Common presentation: Fever, headache, seizures, ± viral prodrome
- Children often present with nonspecific symptoms
- Polymerase chain reaction (PCR) of CSF most accurate diagnosis
- HSV1 causes 95% of all herpetic encephalitis
- Start IV acyclovir immediately if HSE suspected





(Left) *Coronal graphic shows the classic features of herpes encephalitis with bilateral but asymmetric involvement of the limbic system. There is inflammation involving the temporal lobes, cingulate gyri, and insular cortices.* **(Right)** *NECT in a 52-year-old man with herpes simplex encephalitis shows hypodensity ⇨ and mild mass effect in the right anteromedial temporal lobe. Hemorrhage and contrast enhancement appear 2-3 days later in the disease course.*



(Left) *Axial FLAIR MR shows classic bilateral but asymmetric abnormal hyperintense signal in the medial temporal lobes of this patient with herpes encephalitis. Note involvement of the hippocampi ⇨.* **(Right)** *Axial DWI MR in the same patient shows diffusion restriction as a bright signal in the medial temporal lobes ⇨ and hippocampi ⇨. DWI and FLAIR are the most sensitive sequences for detection of encephalitis. CT is often normal early in the course of herpes encephalitis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Herpes simplex encephalitis (HSE)

Definitions

- Brain parenchyma infection caused by herpes simplex virus type 1 (HSV1)
- Typically reactivation in immunocompetent patients

IMAGING

General Features

- Best diagnostic clue
  - Abnormal signal in medial temporal and inferior frontal cortex with DWI restriction
  - Involvement of cingulate gyrus and contralateral temporal lobe highly suggestive
- Location
  - Limbic system: Temporal lobes, insula, subfrontal area, cingulate gyri typical
  - Cerebral convexity, posterior occipital cortex may become involved
  - Typically bilateral disease, but asymmetric
  - Basal ganglia usually spared
  - Atypical patterns seen in infants and children (may be caused by HSV1 or HSV2)
    - May primarily affect cerebral hemispheres
  - Rarely affects midbrain and pons (mesenrhombencephalitis)

CT Findings

- NECT
  - CT often normal early
    - Low attenuation, mild mass effect in medial temporal lobes, insula
    - Hemorrhage typically late feature
  - Predilection for limbic system; basal ganglia spared
  - Earliest CT findings at 3 days after symptom onset
- CECT
  - Patchy or gyriform enhancement of temporal lobes (late acute/subacute feature)

MR Findings

- T1WI
  - Cortical swelling with loss of gray-white junction, mass effect
  - May see subacute hemorrhage as increased signal within edematous brain
  - Atrophy, encephalomalacia in late subacute/chronic cases
- T2WI
  - Cortical and subcortical hyperintensity with relative white matter sparing
  - May see subacute hemorrhage as increased signal within edematous brain
- FLAIR
  - Cortical and subcortical hyperintensity with relative white matter sparing
  - Often see changes earlier than on T2WI
- T2* GRE
  - If hemorrhagic, hypointensity "blooms" within edematous brain
- DWI
  - Restricted diffusion in limbic system
  - Look for bilateral disease
  - DWI findings may precede T2/FLAIR changes
- T1WI C+
  - May see mild, patchy enhancement early
  - Gyriform enhancement usually seen 1 week after initial symptoms
  - Meningeal enhancement occasionally seen
  - Enhancement seen in temporal lobes, insular cortex, subfrontal area, cingulate gyrus
- MRS
  - ↓ NAA, prominent lipid-lactate peak

Imaging Recommendations

- Best imaging tool
  - MR (positive 24-48 hours earlier than CT)
- Protocol advice
  - Multiplanar MR with coronal T2 &/or FLAIR, DWI, T2* GRE, contrast

DIFFERENTIAL DIAGNOSIS

Acute Cerebral Ischemia-Infarction

- Typical vascular distribution (MCA, ACA, PCA)
- Hyperacute symptoms vs. 2-3 day history of flu-like illness
- Reduced diffusivity in acute infarct
- ACA distribution ischemia may mimic HSE

Status Epilepticus

- Active seizures may disrupt blood-brain barrier, cause signal abnormalities and enhancement
- Temporal lobe epilepsy hyperperfusion may mimic HSE
- No hemorrhage in status epilepticus

Limbic Encephalitis

- Rare paraneoplastic syndrome associated with primary tumor, often lung
- Predilection for limbic system, often bilateral
- Nonhemorrhagic
- Imaging may be indistinguishable
- Symptom onset weeks to months (vs. acute in HSE)

Infiltrating Neoplasm

- Low-grade gliomas may involve medial temporal lobe and cause epilepsy
- Gliomatosis cerebri may involve frontal and temporal lobes, may be bilateral
- Onset usually indolent

Other Encephalitides

- Limbic system not typically involved
- Neurosyphilis can affect medial temporal lobes and mimic HSE
  - May involve meninges, blood vessels (obliterative endarteritis)
- West Nile can mimic HSE clinically, but typically involves basal ganglia &/or thalami

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Initial HSV1 infection usually occurs in oronasopharynx via contact with infected secretions
    - Invades along cranial nerves (via lingual nerve, division of trigeminal nerve) to ganglia
    - Remains dormant in trigeminal ganglion
    - Reactivation may occur spontaneously or be precipitated by various factors
      - Local trauma, immunosuppression, hormonal fluctuations, emotional stress

Staging, Grading, & Classification

- Herpes viruses include HSV1, HSV2, Epstein-Barr virus (EBV), cytomegalovirus (CMV), varicella-zoster virus (VZV), B virus, HSV6, HSV7
- HSV1 in adults, children
- HSV2 is more common in neonates
- HSV1 and HSV2 are DNA viruses
- Viruses are obligate intracellular pathogens

Gross Pathologic & Surgical Features

- Hemorrhagic, necrotizing encephalitis
  - Severe edema, massive tissue necrosis with hemorrhage typical
  - Involvement of temporal lobes, insular cortex, orbital surface of frontal lobes
  - Less frequent involvement of cingulate gyrus and occipital cortex

Microscopic Features

- Intense perivascular cuffing, interstitial lymphocytic inflammation
- Intranuclear inclusion bodies in infected cells (neurons, glia, endothelial cells)
  - Typically eosinophilic Cowdry A nuclear inclusions
- Immunohistochemistry shows viral antigens, antibodies to HSV1
- Chronic cases: Microglial nodules

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Fever, headache, seizures, ± viral prodrome
  - Children often present with nonspecific symptoms
    - Behavioral changes, fever, headaches, seizures
  - Patients typically immunocompetent
    - HSV1 uncommon in AIDS patients
- Other signs/symptoms
  - Altered mental status
  - Focal or diffuse neurologic deficit (< 30%)
- Clinical profile
  - CSF studies show lymphocytic pleocytosis, ↑ protein
  - Polymerase chain reaction (PCR) of CSF most accurate diagnosis
    - Sensitivity/specificity nearly 95-100%
    - False-negative PCR possible if CSF obtained < 72 hours after clinical onset
  - EEG: Temporal high voltage discharges in background of generalized slowing
  - Brain biopsy may be required for diagnosis

Demographics

- Age
  - May occur at any age
  - Highest incidence in adolescents and young adults
  - ~ 1/3 of all patients < 20 years old
- Gender
  - M = F
- Epidemiology
  - HSV1 causes 95% of all HSE
  - Most common cause of fatal sporadic encephalitis
  - Most common nonepidemic cause of viral meningoencephalitis
  - In adults, typically related to viral reactivation
  - In neonates, related to maternal infection
  - Incidence: 1-3/1 million

Natural History & Prognosis

- May progress to coma and death
  - 50-70% mortality rate
  - Rapid diagnosis, early treatment with antiviral agents can decrease mortality, may improve outcome
- Nearly 2/3 of survivors have significant neurological deficits, despite acyclovir therapy
- Survival complicated by memory difficulties, hearing loss, intractable epilepsy, personality changes

Treatment

- Antiviral therapy with intravenous acyclovir

DIAGNOSTIC CHECKLIST

Consider

- Start IV acyclovir immediately if HSE suspected
- Unilateral disease may mimic stroke or tumor; history often helpful
- Limbic encephalitis if all clinical HSE tests negative and subacute onset of symptoms
- Acute onset of HSE helps differentiate from other etiologies

Image Interpretation Pearls

- CT often normal early, MR with FLAIR/DWI most sensitive for early diagnosis
- Imaging often key in diagnosis

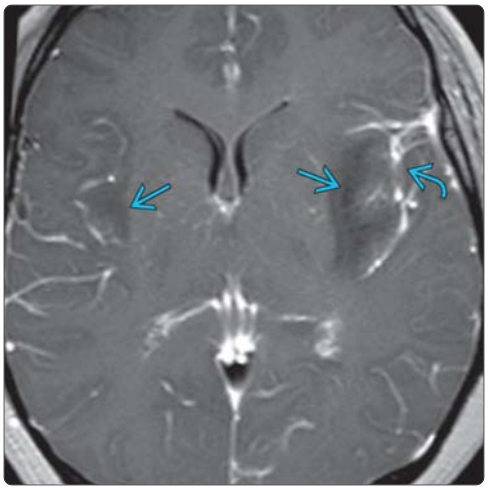
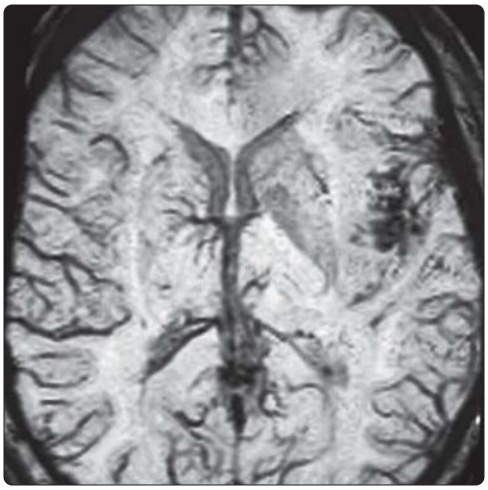
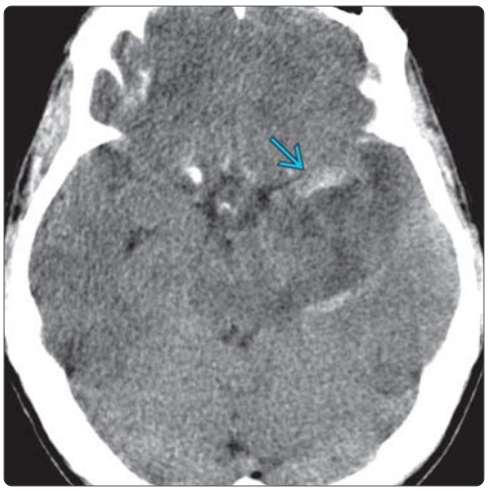
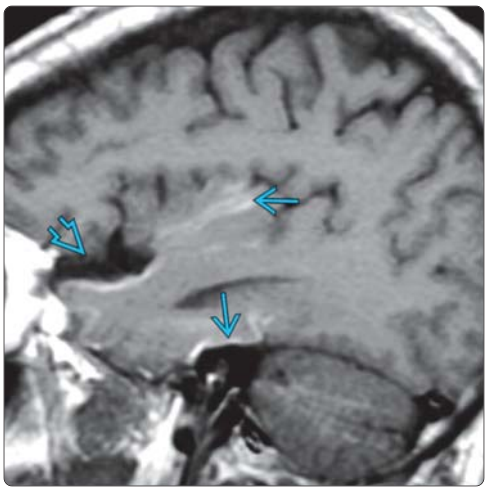
(Left) *Axial NECT in a 45 year old with fever and altered mental status shows questionable subtle low density changes in the right medical temporal lobe.* **(Right)** *Axial T2 WI MR in the same patient shows signal abnormality in right medical temporal lobe. CSF polymerase chain reaction (PCR) was positive for HSV-1. CT study may be normal in early stages of herpes encephalitis.*





(Left) *Axial T1C+ MR in subacute stage of herpes encephalitis shows bilateral but asymmetric hypointensities in the insular regions. There is associated pial enhancement in the left insular region. Pial, leptomeningeal, diffuse, ring-like enhancement patterns have been reported in herpes encephalitis.* **(Right)** *Axial SWI MR in the same patient shows patchy hemorrhage in the left insular region. Following the acute stage (> 1 week), MR is superior to CT in detecting hemorrhage.*





(Left) *Axial NECT shows edema and hemorrhage in the left temporal lobe in this young adult with altered mental status. Despite early acyclovir therapy, the patient succumbed to his disease. Mortality ranges from 50-70% in HSE patients.* **(Right)** *Sagittal T1WI in a patient 2 weeks after the initial presentation of herpes encephalitis shows volume loss in the temporal lobe and linear gyriform T1 shortening within the temporal lobe cortex, characteristic of subacute cortical hemorrhage.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Diffuse brain parenchymal inflammation caused by variety of pathogens, most commonly viruses
- Location dependent on etiology

IMAGING

- Abnormal T2 hyperintensity of gray matter ± white matter or deep gray nuclei
- Large, poorly delineated areas of involvement common, ± patchy hemorrhage
- Imaging is often nonspecific, mimics other etiologies

TOP DIFFERENTIAL DIAGNOSES

- Acute ischemia
- Autoimmune encephalitis
- Herpes encephalitis
- Status epilepticus
- Toxic/metabolic lesions

PATHOLOGY

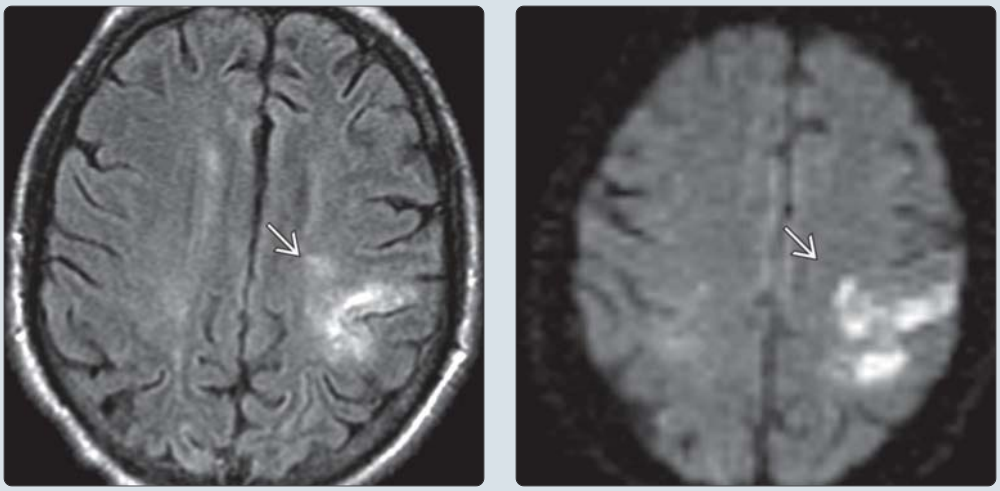
- Most (but not all) are caused by viruses
- Spread of virus to CNS is hematogenous or neural

CLINICAL ISSUES

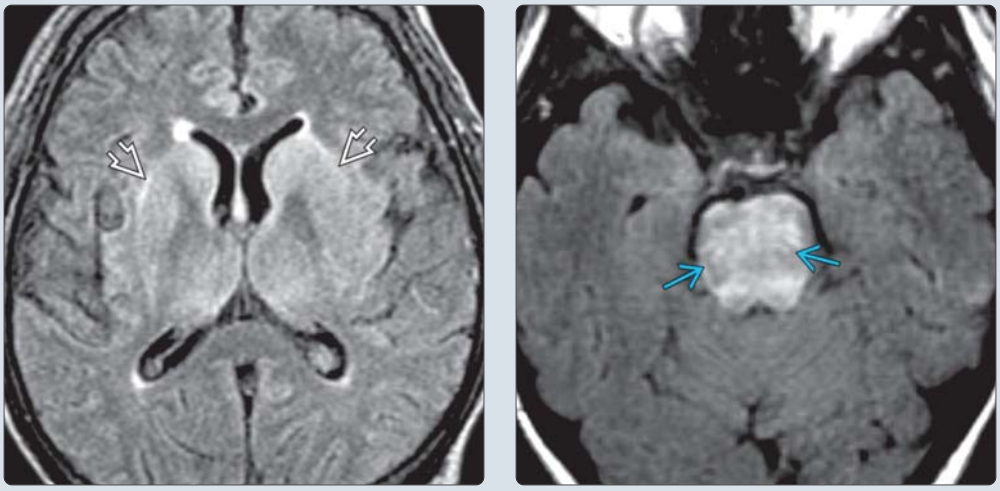
- Herpes: Most common cause of sporadic (nonepidemic) viral encephalitis
- Japanese encephalitis: Most common endemic encephalitis in Asia
- Many encephalitides have high morbidity, mortality
- Rapid diagnosis and early treatment with antiviral or antibacterial agents can decrease mortality, may improve outcome

DIAGNOSTIC CHECKLIST

- Clinical history often helpful for accurate diagnosis
- DWI may detect lesions earlier than conventional MR



(Left) *Axial FLAIR MR shows hyperintense signal primarily in the left posterior frontal lobe ⇨ in an immunosuppressed patient with CMV meningoencephalitis. CMV typically involves the periventricular white matter.* **(Right)** *Axial DWI MR in the same patient shows restricted diffusion in the left posterior frontal lobe ⇨ with involvement of the gray and white matter. DWI is often positive in encephalitis and may be the most sensitive MR sequence.*



(Left) *Axial FLAIR MR shows symmetric abnormal hyperintensity in the basal ganglia ⇨ and thalami in this patient with West Nile virus encephalitis. Symmetric appearance of deep gray nuclei involvement mimics toxic and metabolic etiologies.* **(Right)** *Axial FLAIR MR in a patient with ataxia shows diffuse hyperintensity and enlargement of brainstem ⇨. Rhombencephalitis is often caused by viruses; other pathogens include Listeria monocytogenes, Legionnaire, Mycoplasma, Lyme disease.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Diffuse brain parenchymal inflammation caused by variety of pathogens, most commonly viruses
- Location dependent on etiology

IMAGING

General Features

- Best diagnostic clue
  - Abnormal T2 hyperintensity of gray matter (GM) ± white matter (WM) or deep gray nuclei
  - Large, poorly delineated areas of involvement common, ± patchy hemorrhage
  - Imaging is often nonspecific
- Location
  - Herpes simplex virus type 1 (**HSV1**): Limbic system
  - Cytomegalovirus (**CMV**): Deep periventricular WM
  - Epstein-Barr virus (**EBV**)
    - Multifocal, diffuse involvement of brain and spinal cord
    - Splenium of corpus callosum
  - Varicella-zoster virus (**VZV**)
    - Varicella: May affect multifocal areas of cortex
    - Zoster: Brainstem/cortical GM, cranial nerves
  - **Cerebellitis**: Bilateral cerebellar hemispheres
  - Eastern equine encephalitis (**EEE**): BG and thalami
  - **Enteroviral** encephalomyelitis
    - **Enterovirus (EV) 71**: Posterior medulla, pons, midbrain, dentate nuclei, spinal cord
    - **Polio, Coxsackie**: Midbrain, anterior spinal cord
  - **Hantavirus**: Pituitary gland hemorrhage
  - **HIV-1**: Cerebral WM, brainstem, thalamus, BG
  - **Japanese encephalitis**: Bilateral thalami, brainstem, cerebellum, spinal cord, cerebral cortex
  - Murray Valley encephalitis (**MVE**): Bilateral thalami; may affect midbrain, cervical spinal cord
  - **Nipah viral encephalitis**: Multifocal WM
  - **Rabies encephalitis**: Brainstem, hippocampi, hypothalamus, WM, GM
  - **Rhombencephalitis**: Brainstem and cerebellum
  - **St. Louis encephalitis**: Substantia nigra
  - West Nile virus (**WNV**): BG &/or thalami; may affect brainstem, cerebral WM, substantia nigra, cerebellum, spinal cord

CT Findings

- NECT: Initial CT negative in vast majority of patients
  - Japanese encephalitis: May see thalamic hemorrhage

MR Findings

- T1WI
  - **Japanese encephalitis**: Low signal foci in WM, brainstem, BG, thalami bilaterally
  - **Rabies encephalitis**: Hyperintense bilateral BG (rare)
- T2WI
  - **CMV**: Deep periventricular WM patchy increased signal
  - **EBV**: Hyperintensity in BG, thalamus, cortex
  - **Varicella**: Multifocal increased cortical signal
  - **Zoster**: Increased signal in brainstem, cortex
  - **Cerebellitis**: Hyperintense cerebellar signal
  - **EEE**: Increased signal in BG and thalami; may involve brainstem, cortex, periventricular WM
  - Enteroviral encephalomyelitis (**EV71**): Hyperintense lesions in posterior medulla, pons, midbrain, dentate nuclei of cerebellum
    - Less common: Cervical cord, thalamus, putamen
  - **Japanese encephalitis**: High signal foci in WM, brainstem, BG, thalami bilaterally
  - **MVE**: Hyperintensity in bilateral thalami; may involve midbrain, cerebral peduncles
  - **Nipah viral encephalitis**: Multifocal WM hyperintensities; may affect GM
  - **Rabies encephalitis**: Ill-defined mild hyperintensity in brainstem, hippocampi, thalami, WM, BG
    - Paralytic rabies: Medulla and spinal cord hyperintensity
  - **Rhombencephalitis**: Patchy hyperintensity in pons, medulla, midbrain
  - **St. Louis encephalitis**: May see hyperintensity of substantia nigra, often normal
  - **WNV**: Hyperintensity in deep gray nuclei ± cerebral WM
- FLAIR
  - **Nipah encephalitis**: Discrete high-signal lesions in subcortical, deep WM ± GM
    - Confluent cortical involvement in relapsed and late-onset encephalitis
- T2* GRE
  - Japanese encephalitis: Thalamic hemorrhage
- DWI: Diffusion restriction is commonly seen
- T1 C+: Variable enhancement, none to intense
  - Meningeal enhancement can be seen
  - Herpes zoster oticus (Ramsay Hunt syndrome): Enhancing CN7, CN8, membranous labyrinth
- MRS: May help distinguish encephalitis from infarct

Imaging Recommendations

- Protocol advice
  - Multiplanar MR with FLAIR, DWI, and contrast

DIFFERENTIAL DIAGNOSIS

Acute Ischemia

- Typical vascular distribution, DWI positive

Autoimmune Encephalitis

- Often mediated by anti-NMDA receptors antibodies; subcortical white matter

Herpes Encephalitis

- Limbic system and temporal lobe involvement

Status Epilepticus

- Active seizures with cerebral hyperperfusion, BBB disruption causes abnormal signal and enhancement

Toxic/Metabolic Lesions

- Symmetric BG or thalamic involvement common

PATHOLOGY

General Features

- Etiology

https://CafePezeshki.IR

- Most (but not all) are caused by viruses
  - Viruses are obligate intracellular parasites
  - Replicate in skin or mucous membranes of respiratory, GI tracts
  - Spread of virus to CNS is hematogenous or neural
  - Some invade along CNS (i.e., HSV1 via lingual nerve to trigeminal ganglia)
  - Latent infections may reactivate, spread along meningeal branches
- **Herpes viruses** include HSV1, HSV2, CMV, EBV, VZV, B virus, HSV6, HSV7
  - HSV2: Neonatal encephalitis
- **Varicella:** Meningoencephalitis, cerebellar ataxia, and aseptic meningitis (< 1% of patients)
- **Zoster infection:** Encephalitis, neuritis, myelitis, or herpes ophthalmicus
  - Latent virus in ganglia of CN (often CN5 and CN7) can reactivate, spread to brainstem
  - Immunocompetent patients: Cranial and peripheral nerve palsies
  - Immunosuppressed patients: Diffuse encephalitis
  - Herpes zoster ophthalmicus can cause internal carotid artery necrotizing angiitis
- **EBV:** Agent in infectious mononucleosis
  - Diffuse encephalitis seen in < 1% of patients
  - Associated with meningoencephalitis, Guillain-Barré syndrome, transverse myelitis
- **Enteroviruses** include Coxsackie viruses A and B, poliovirus, echoviruses, enteroviruses 68 to 71
- **Arboviruses** (arthropod-borne viruses) include Eastern, Western, and Venezuelan equine encephalitis, St. Louis encephalitis, Japanese B encephalitis, California encephalitis, tick-borne encephalitis
- **Nipah encephalitis**: Paramyxovirus related to close contact with infected pigs
  - Nipah encephalitis: Inflammation of small blood vessels with thrombosis and microinfarction
- **Rhombencephalitis:** Viruses (most commonly) , Listeria monocytogenes, Legionnaire disease, Mycoplasma, Lyme disease

Gross Pathologic & Surgical Features

- Vascular congestion, generalized or local edema, ± hemorrhage, necrosis

Microscopic Features

- Infiltration by polymorphonuclear cells (PMNs), lymphocytes, plasma cells, and mononuclear cells
- Perivascular cuffing characteristic
- May see inclusion bodies (i.e., Negri bodies in rabies)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Varies widely: Slight meningeal to severe encephalitic symptoms, ± fever, prodrome
  - Varicella and herpes zoster: Different clinical manifestations of infection by same virus (VZV)
    - **Varicella encephalitis**: Fever, headache, vomiting, seizures, altered mental status days to weeks after onset of (chicken pox) rash
    - **Zoster**: Immunocompetent, CN and peripheral nerve palsies in dermatomes involved by skin lesions
      - CN5, ophthalmic branch most affected (herpes zoster ophthalmicus)
  - **Zoster**: Immunosuppressed patient with fever, meningismus, altered mental status
  - **Cerebellitis**: Sudden onset of limb &/or gait ataxia after infectious prodrome
  - Enterovirus encephalitis (**EV 71**)
    - Hand, foot, and mouth disease (HFMD): Fever, vesicles on hands, feet, elbows, knees, lips
    - Cranial neuropathies, ocular disturbance, dyspnea, tachycardia if brainstem involved
  - **Nipah virus**: Fever, headache, dizziness, vomiting; segmental myoclonus, areflexia, hypotonia, hypertension
  - **MVE**: Fever, headache, confusion, tremors; may progress to paralysis, coma, respiratory failure
  - **Rabies** (encephalitic): Fever, malaise, altered mental status, limbic dysfunction, autonomic stimulation
    - Paralytic: Weakness of all extremities
  - **Rhombencephalitis**: Areflexia, ataxia, ophthalmoplegia
  - **St. Louis encephalitis**: Tremors, fevers

Demographics

- Epidemiology
  - Herpes: Most common cause of sporadic (nonepidemic) viral encephalitis
  - Japanese encephalitis: Most common endemic encephalitis in Asia
  - CNS involvement in EBV is uncommon (< 10% of cases)
  - VZV: < 1% have CNS involvement
  - Marked seasonal variation in USA

Natural History & Prognosis

- Many encephalitides have high morbidity, mortality
- Rapid diagnosis, early treatment with antiviral or antibacterial agents can decrease mortality, may improve outcome

DIAGNOSTIC CHECKLIST

Consider

- Imaging often nonspecific, mimics other etiologies
- Clinical and travel history often helpful

Image Interpretation Pearls

- DWI may detect lesions earlier than conventional MR

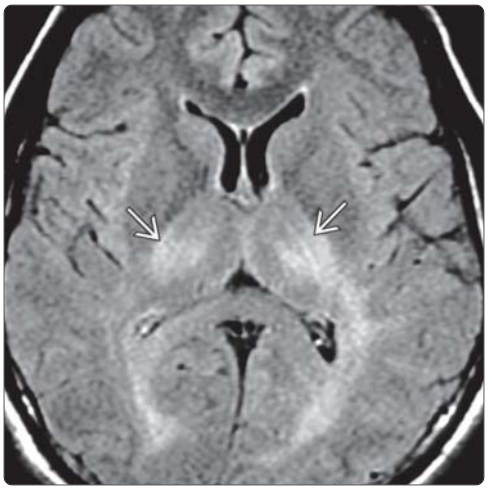
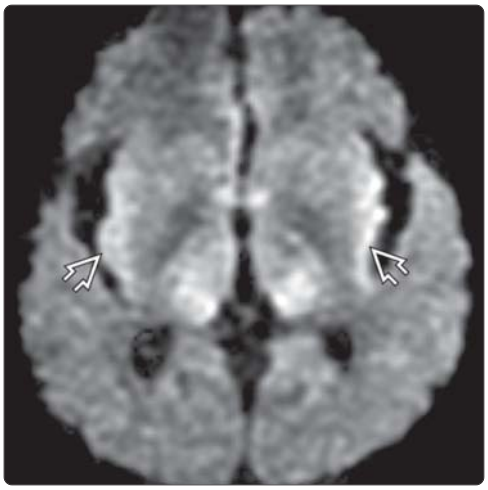
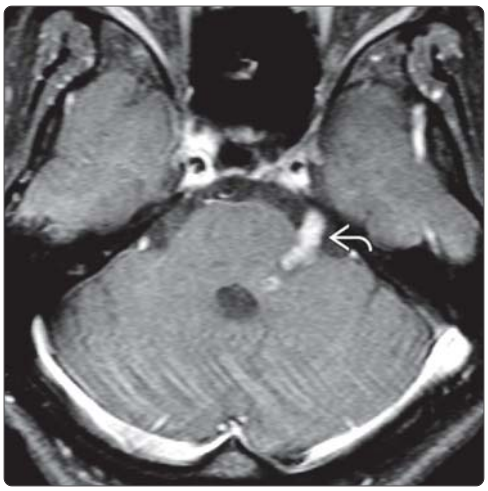
(Left) *Sagittal STIR MR in a patient with acute enterovirus encephalitis shows extensive T2 hyperintensity involving the medulla and cervical cord.* **(Right)** *Axial FLAIR MR in the same patient shows hyperintense signal in the medulla and dentate nuclei. Enterovirus encephalitis can involve the pons, medulla, midbrain, dentate nuclei, thalami, basal ganglia, and cervical spinal cord. Enteroviruses include Coxsackie viruses, poliovirus, echovirus, and enteroviruses 68-71.*





(Left) *Axial FLAIR MR shows symmetric hyperintense signal in the thalami in this patient with a history of infectious mononucleosis. EBV commonly involves the basal ganglia, thalami, cortex, &/or brainstem.* **(Right)** *Axial DWI MR shows symmetric diffusion restriction in the thalami and insular cortex in this patient with West Nile virus encephalitis. Basal ganglia and thalamic involvement is classic for West Nile virus encephalitis. DWI may help detect lesions earlier than conventional MR imaging.*



(Left) *Axial T1WI C+ MR shows enhancement of CN5, cisternal segment, root entry zone, and brachium pontis in this patient with trigeminal neuralgia. The ophthalmic branch (V1) is most affected in herpes zoster. Zoster commonly affects cranial nerves in immunocompetent patients. VZV encephalitis is rare.* **(Right)** *Sagittal T2WI MR shows diffuse enlargement and hyperintensity of the cervical spinal cord in this paralytic rabies patient. Paralytic rabies often affects the medulla and spinal cord.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- West Nile virus (WNV), West Nile fever (WNF), West Nile neuroinvasive disease (WNND)
- Mosquito-transmitted acute meningoencephalitis

IMAGING

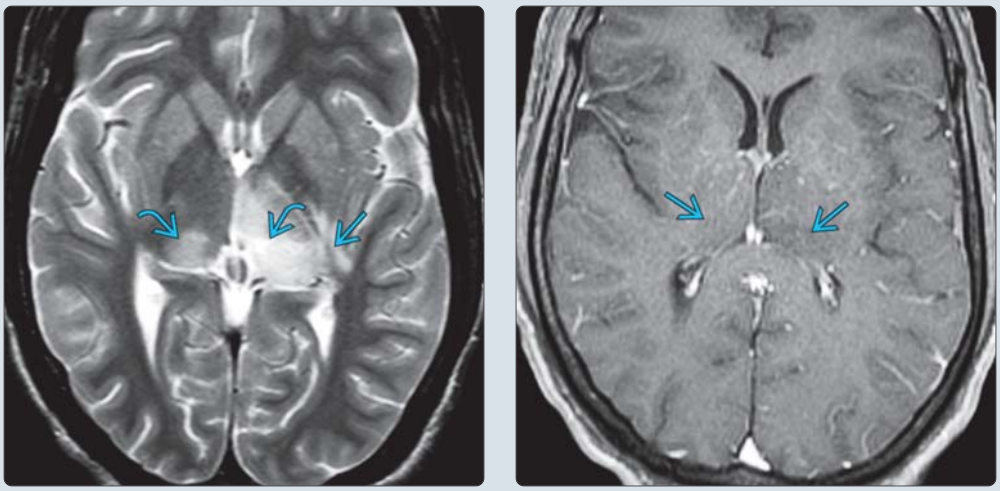
- Head CT usually normal
- MR with DWI, T1 C+
  - Classic: Bilateral basal ganglia, thalamic hyperintensity
  - Patchy, poorly demarcated hyperintense foci in cerebral WM on T2WI/FLAIR
  - Enhancement usually absent (has been reported)
  - DWI may show restricted diffusion
- Other sites of involvement
  - Brainstem
  - Corpus callosum splenium
  - Mesial temporal lobes
  - Cerebellum
  - Spinal cord, cauda equina

PATHOLOGY

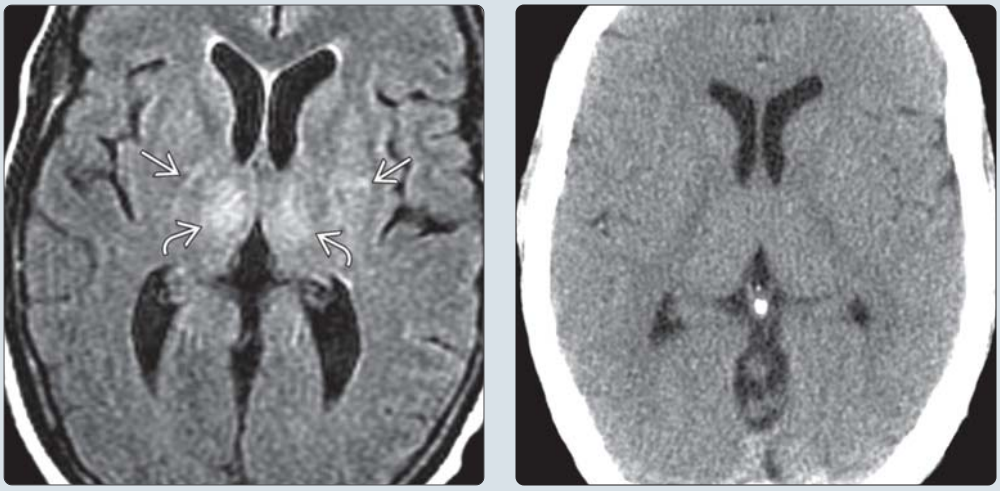
- WNV: Flavivirus (like Japanese encephalitis)
- Arthropod-transmitted (mosquito)

CLINICAL ISSUES

- Approximately 1/140 patients infected with WNV develop CNS symptoms
  - Incubation period: 3-14 days
- ~ 80% of infected individuals asymptomatic
  - Mild febrile syndrome (West Nile fever) in 20%
  - Meningoencephalitis in < 1%
  - Rare: Anterior myelitis
- CNS symptoms more common in diabetics, immunocompromised
- Treatment is supportive; hydration, antipyretics, airway and seizure management as indicated
- No human vaccine
  - Best way to prevent infection? Fight the bite
- Mortality rate is approximately 10%



(Left) *Axial T2WI MR in a 24-year-old man with West Nile encephalitis demonstrates asymmetric T2 hyperintensity in the thalami. Posterior limb of left internal capsule is also involved.* **(Right)** *Axial T1 C+ MR in the same patient shows low signal in the thalami, more pronounced on the left with no abnormal enhancement. Anatomic areas commonly affected in West Nile encephalitis are basal ganglia, thalami, brainstem, mesial temporal structures, and cerebellum.*



(Left) *Axial FLAIR MR in a patient with West Nile virus meningoencephalitis shows bilaterally symmetric high signal intensity in the thalami. There is subtle hyperintensity in the basal ganglia and right internal capsule.* **(Right)** *Axial NECT in the same patient performed 6 hours prior to the MR exam is normal. No edema is seen in the thalami or white matter. Indeed, early in the disease course, CT scans are frequently unremarkable.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- West Nile virus (WNV), West Nile fever (WNF), West Nile neuroinvasive disease (WNND)

Definitions

- Mosquito-transmitted acute meningoencephalitis caused by West Nile arbovirus

IMAGING

General Features

- Best diagnostic clue
  - Bilateral basal ganglia &/or thalamic lesions
- Location
  - Classic: Bilateral basal ganglia, thalami
  - Cerebral white matter
  - Other
    - Brainstem
    - Corpus callosum splenium
    - Mesial temporal lobes
    - Cerebellum
    - Spinal cord, cauda equina

Imaging Recommendations

- Best imaging tool
  - Standard MR; include T1 C+, DWI

CT Findings

- Frequently normal

MR Findings

- Bilateral, frequently symmetric T2-hyperintense signal in basal ganglia, thalami, and brainstem
- Patchy, poorly demarcated foci of T2 signal in cerebral white matter on T2 and FLAIR sequences
- DWI may show restricted diffusion
- Enhancement usually absent (though has been reported)

DIFFERENTIAL DIAGNOSIS

Encephalitis (Other Infectious Etiologies)

- Herpes usually affects mesial temporal lobe(s)

Demyelinating Diseases

- e.g., ADEM, multiple sclerosis, Susac
- ADEM often (but not always) spares deep gray matter

PATHOLOGY

General Features

- Etiology
  - WNV: Flavivirus (like Japanese encephalitis)
    - Arthropod-transmitted (mosquito)
      - *Culex pipiens* is vector in eastern USA
      - *Culex quinquefasciatus* species in southeastern USA
      - *Culex tarsalis* species in western, midwestern USA
    - Mosquitos infect birds ("amplifying hosts")
      - Birds transmit infection to other biting mosquitos
      - Uncommonly infects humans/other mammals
    - Human-to-human transmission rare but reported
      - Blood transfusions, transplant recipients
      - Intrauterine exposure, conjunctival exposure
      - Breastfeeding, occupational exposure
- Genetics
  - Increased susceptibility to WNV disease in carriers with 2 mutated copies of gene *CCR5*

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - ~ 80% of infected individuals asymptomatic
  - Mild febrile syndrome (WNF) in 20%
    - Fever, headache, fatigue, lymphadenopathy, arthralgia typical
    - May develop GI symptoms including nausea, vomiting, and diarrhea
    - Occasional truncal maculopapular rash
    - Incubation period: 3-14 days
  - Meningoencephalitis (WNND) in < 1%
    - Symptoms of mild febrile syndrome plus
      - Seizures, altered mental status, coma
      - Extrapyramidal signs (brisk followed by ↓ DTRs)
- Other signs/symptoms
  - Rare associations
    - Anterior myelitis ± encephalitis
      - Guillain-Barré syndrome
    - Multifocal chorioretinitis
    - Nephritis, hepatitis, myocarditis

Demographics

- Age
  - WNND more common in elderly
- Epidemiology
  - Approximately 1/140 patients infected with WNV develop CNS symptoms
  - CNS symptoms more common in diabetics, immunocompromised

Natural History & Prognosis

- Prolonged convalescent period with fatigue common
- Mortality rate is approximately 10%

Treatment

- No human vaccine
- Best way to prevent infection? Fight the bite
  - Wear light clothing that covers extremities
  - Use insect repellents
- Treatment is supportive
  - Hydration, antipyretics, airway and seizure management as indicated

HHV-6 Encephalitis

KEY FACTS

TERMINOLOGY
- Encephalitis caused by human herpes virus 6 (HHV-6)

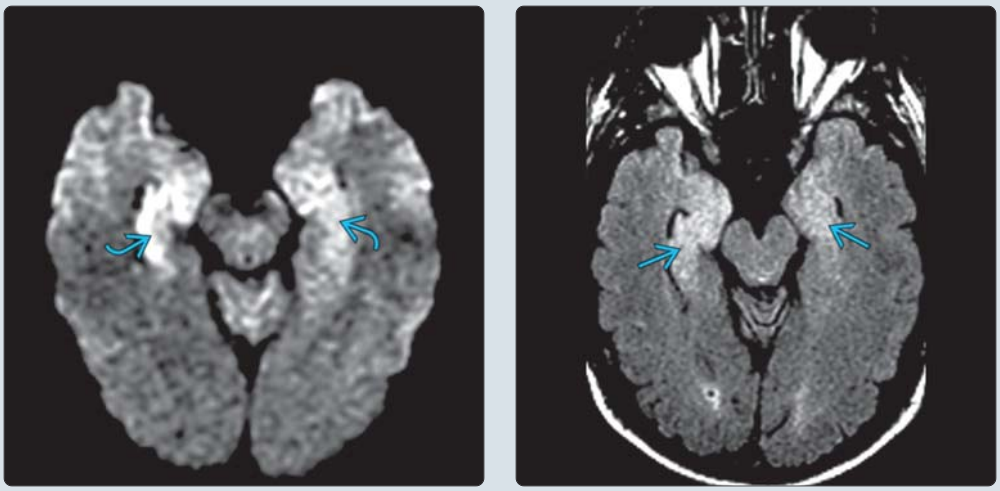
IMAGING
- Immunocompromised patient with abnormal signal medial temporal lobe(s)
  - Limbic system: Hippocampus, amygdala, parahippocampal gyrus
  - Insular region, inferior frontal lobe involvement less common than herpes simplex encephalitis
- Atypical pattern in infants/children (basal ganglia, thalami, cerebellum, brainstem)
- Best imaging: MR (coronal T2/FLAIR, DWI, T1 C+)

TOP DIFFERENTIAL DIAGNOSES
- Herpes simplex virus (HSV) encephalitis
- Paraneoplastic limbic encephalitis
- Status epilepticus

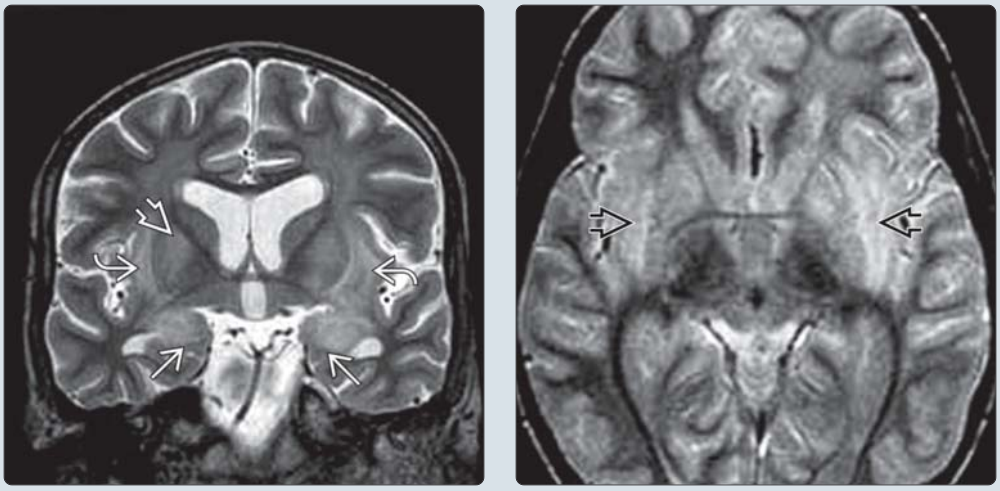
PATHOLOGY
- HHV-6: DNA virus belongs to herpes virus family
- 2 variants: HHV-6A and HHV-6B
- Reactivation in immunocompromised patients

CLINICAL ISSUES
- Mental status changes, short-term memory loss, fever, seizure, headache
- Febrile seizures in infants
- Post hemopoietic stem cell transplant, lung/liver transplant
- Antiviral drugs: Ganciclovir and foscarnet
- Mortality of HHV-6 encephalitis > 50%

DIAGNOSTIC CHECKLIST
- Consider HHV-6 encephalitis in immunocompromised patients with CNS symptoms + unilateral/bilateral medial temporal lobe signal changes



(Left) *Axial DWI MR in a 42-year-old patient post stem cell transplant who presented with altered sensorium demonstrates restricted diffusion in the hippocampi bilaterally, more pronounced on the right.* **(Right)** *Axial FLAIR MR in the same patient shows corresponding high signal in the hippocampi bilaterally, again more pronounced on the right. In this patient with immunosuppression, imaging findings are very typical for HHV-6 encephalitis*



(Left) *Coronal T2WI MR in a 37-year-old man with immunosuppression, fever, and seizures shows hyperintense signal in the medial temporal lobes, basal ganglia, and subinsular white matter.* **(Right)** *Axial T2WI MR in the same patient shows asymmetric hyperintense signal in the subinsular white matter. Extrahippocampal involvement in HHV-6 encephalitis is less common than Herpes simplex encephalitis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Human herpes virus 6 (HHV-6) encephalitis

Definitions

- Encephalitis caused by HHV-6

IMAGING

General Features

- Best diagnostic clue
  - Immunocompromised patient with abnormal signal in medial temporal lobe(s)
- Location
  - Limbic system: Hippocampus, amygdala
  - Insular region, inferior frontal lobe involvement less common than herpes simplex encephalitis
  - Atypical patterns seen in infants and children
    - Basal ganglia, thalami, cerebellum, brainstem

CT Findings

- NECT
  - CT often negative
- CECT
  - No abnormal enhancement

MR Findings

- T1WI
  - Decreased signal in medial temporal lobes
- T2WI
  - ↑ signal hippocampus, amygdala, typically bilateral but asymmetric
    - Insular region, inferior frontal lobe involvement less common
  - Early volume loss in hippocampus
- FLAIR
  - Hyperintense cortex/subcortical white matter
- DWI
  - May show restricted diffusion
- T1WI C+
  - Usually no enhancement

Imaging Recommendations

- Best imaging tool
  - MR (coronal T2/FLAIR, DWI, T1 C+)

DIFFERENTIAL DIAGNOSIS

Herpes Simplex Virus (HSV) Encephalitis

- Similar anatomic distribution
- Enhancement, DWI restriction more common

Paraneoplastic Limbic Encephalitis

- Paraneoplastic syndrome associated with primary tumor
- Symptom onset insidious

Status Epilepticus

- Medial temporal signal abnormalities with enhancement

PATHOLOGY

General Features

- Etiology
  - HHV-6: DNA virus belongs to herpes virus family
  - 2 variants: HHV-6A and HHV-6B
    - 90% general population seropositive for HHV-6 by 2 years of age
  - Primary infection < age 2, febrile exanthem (Roseola infantum/6th disease) or asymptomatic
  - Virus enters body through salivary gland, remains latent; salivary glands, WBC cells, and brain
  - Reactivation in immunocompromised patients

Gross Pathologic & Surgical Features

- Small necrotic changes in limbic structures

Microscopic Features

- Severe neuronal loss, reactive astrocytosis, detection of HHV-6 P41/P101 protein in astrocytes & neurons

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Mental status changes, short-term memory loss, fever, seizure, headache
  - Febrile seizures in infants
- Clinical profile
  - CSF: Lymphocytic pleocytosis and ↑ protein
  - PCR detection HHV-6 DNA in CSF: High specificity

Demographics

- Epidemiology
  - Most children primary infection < 2 years old
  - Reactivation in immunocompromised
    - Post hemopoietic stem cell transplant, lung/liver transplant

Natural History & Prognosis

- Mortality of HHV-6 encephalitis > 50%

Treatment

- Antiviral drugs: Ganciclovir and foscarnet
- Acyclovir (treatment for HSV encephalitis) ineffective

DIAGNOSTIC CHECKLIST

Consider

- HHV-6 encephalitis in immunocompromised patients with CNS symptoms + unilateral/bilateral medial temporal lobe signal changes

Image Interpretation Pearls

- MR (FLAIR, T2 most sensitive)

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Acute cerebellitis

IMAGING

- Bilateral cerebellar hemispheric gray and white matter low attenuation (NECT), T2/FLAIR hyperintensity (MR); unilateral involvement less common
- Confluent regions of T2 prolongation, affecting gray and white matter
- ± pial or subtle parenchymal enhancement
- DWI/ADC → affected regions typically show increased diffusivity

TOP DIFFERENTIAL DIAGNOSES

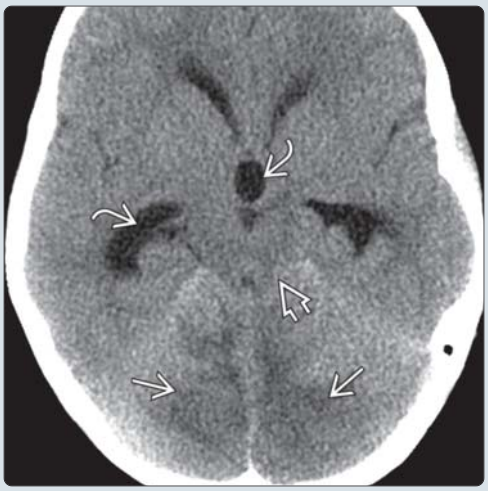
- Acute disseminated encephalomyelitis
- Infiltrating cerebellar neoplasm
- Cerebellar infarct

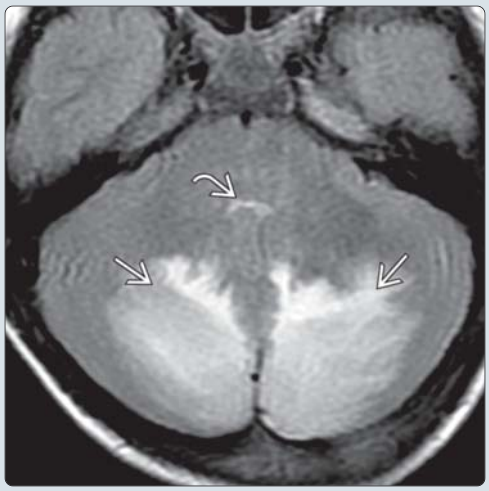
PATHOLOGY

- Reported in association with varicella, Epstein-Barr, enterovirus, rotavirus, HHV-7, mumps, measles, influenza & mycoplasma pneumoniae
- In most cases, definite etiology remains unknown
- Moderate to severe cerebellar swelling → vascular compression, upward transtentorial herniation, tonsillar herniation, brainstem compression, obstructive hydrocephalus

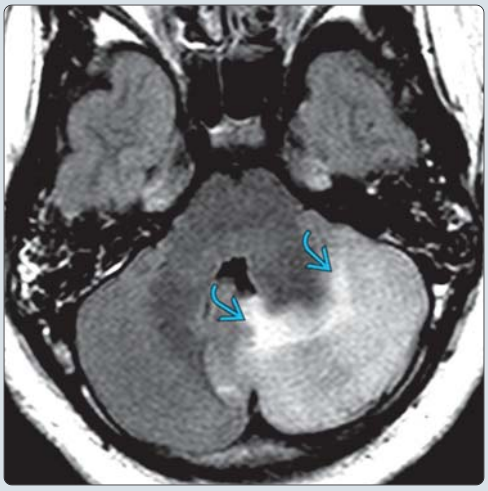
CLINICAL ISSUES

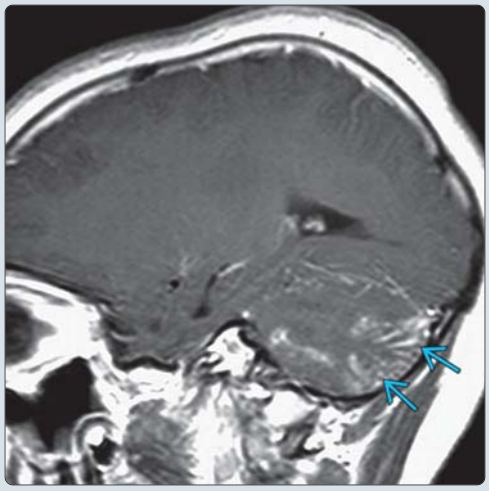
- Truncal ataxia, dysmetria, & headache
- Symptoms of ↑ ICP: Irritability, occipital headache and vomiting may overshadow manifestations of cerebellar dysfunction
- Most symptoms and signs resolve completely over weeks to months
- Surgery rarely necessary to decompress herniating cerebellum, ventricular drain for hydrocephalus





(Left) *Axial NECT in a 4-year-old girl with proven influenza A infection shows cerebellar hemispheric edema (low attenuation) involving both gray and white matter. The edema causes upward cerebellar herniation and effacement of the quadrigeminal plate cistern. The resultant aqueductal compression causes hydrocephalus.* **(Right)** *Axial T2WI MR demonstrates cerebellar edema (T2 hyperintensity) involving both gray and white matter. Note the compressed 4th ventricle.*





(Left) *Axial FLAIR MR in a 12 year old with acute onset of cerebellar ataxia demonstrates high signal in the left cerebellar hemisphere. Note mild mass effect on the 4th ventricle.* **(Right)** *Sagittal T1+C MR in the same patient shows patchy areas of pial enhancement along the left cerebellar hemisphere. In acute cerebellitis, unilateral involvement is far less common than bilateral.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Acute cerebellitis

Definitions

- Parainfectious, postinfectious, or postvaccination cerebellar inflammation

IMAGING

General Features

- Best diagnostic clue
  - Bilateral cerebellar hemispheric gray and white matter low attenuation (NECT), T2/FLAIR hyperintensity (MR); unilateral involvement less common
- Location
  - Cerebellar gray and white matter, typically bilateral

Imaging Recommendations

- Best imaging tool
  - MR, including C+, DWI, MRS

CT Findings

- NECT
  - Bilateral or less commonly unilateral low attenuation involving gray and white matter of cerebellar hemispheres

MR Findings

- T1WI
  - Regions of T1 hypointensity in cerebellum
- T2WI
  - T2 hyperintensity affecting gray and white matter of cerebellum
- DWI
  - Typically shows increased diffusivity
- T1WI C+
  - ± pial or subtle parenchymal enhancement
- MRS
  - Acutely: ↑ excitatory neurotransmitters, ↑ choline, ± lactate and lipid, NL to ↓ NAA

DIFFERENTIAL DIAGNOSIS

Acute Disseminated Encephalomyelitis (ADEM)

- Look for supratentorial peripheral white matter, basal ganglia (BG), and brainstem lesions

Cerebellar Neoplasm (Infiltrating)

- Typical bilateral involvement of gray and white matter in cases of cerebellitis is helpful
- Use MRS as adjunct when tumor is considered (↓ NAA, ± ↓ creatine, ↑ choline, myoinositol, ± lactate and lipid)

Cerebellar Infarct

- Typical vascular distribution, DWI positive

PATHOLOGY

General Features

- Etiology
  - Reported in association with varicella, Epstein-Barr, enterovirus, rotavirus, HHV-7, mumps, measles, influenza & mycoplasma pneumoniae
  - Post varicella vaccine
  - In most cases, definite etiology remains unknown
- Associated abnormalities
  - Moderate to severe cerebellar swelling → vascular compression, upward transtentorial herniation, tonsillar herniation, brainstem compression, obstructive hydrocephalus

Gross Pathologic & Surgical Features

- Acutely, cerebellar edema, nonhemorrhagic involving gray and white matter

Microscopic Features

- Acute: Edema with lymphocytic & eosinophilic infiltrates
- Chronic: ± cerebellar atrophy

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Truncal ataxia, dysmetria & headache
  - Symptoms of ↑ ICP: Irritability, occipital headache, and vomiting may overshadow manifestations of cerebellar dysfunction

Demographics

- Age
  - Usually in younger children
- Epidemiology
  - Typically follows viral infection
    - Delayed presentation may occur after varicella zoster infection (chicken pox or herpes zoster ophthalmicus)

Natural History & Prognosis

- Most symptoms and signs resolve completely over weeks to months
- Severe cases with herniation & hydrocephalus: Variable outcome from full recovery to death

Treatment

- Typically supportive, ± steroids, ± antivirals if specific diagnosis is confirmed
- Surgery rarely necessary to decompress herniating cerebellum, ventricular drain for hydrocephalus

DIAGNOSTIC CHECKLIST

Consider

- Acute cerebellitis when bihemispheric GM and WM cerebellar involvement

Image Interpretation Pearls

- Bilateral cerebellar hemispheric gray and white matter edema; unilateral involvement less common

SELECTED REFERENCES

KEY FACTS

TERMINOLOGY

- Chronic focal (localized) encephalitis
- Chronic, progressive, unilateral brain inflammation of uncertain etiology
- Characterized by drug-resistant focal epilepsy, progressive hemiplegia, cognitive decline

IMAGING

- Unilateral progressive cortical atrophy
- CT/MR: Normal → cortical swelling → atrophy
- Usually unilateral, predominantly frontoinsular
- Best imaging tools: MR with contrast, ± PET (FDG)

TOP DIFFERENTIAL DIAGNOSES

- Sturge-Weber syndrome
- Other autoimmune encephalitides (often bilateral)
- Hemispheric infarction (Dyke-Davidoff-Masson)

PATHOLOGY

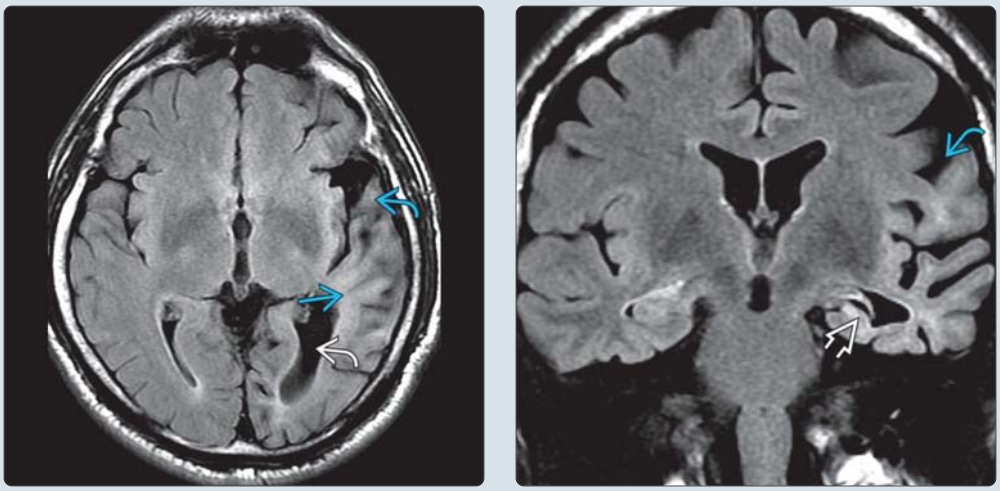
- Hemispheric cortical atrophy
- Cortical inflammation, neuronal loss, gliosis

CLINICAL ISSUES

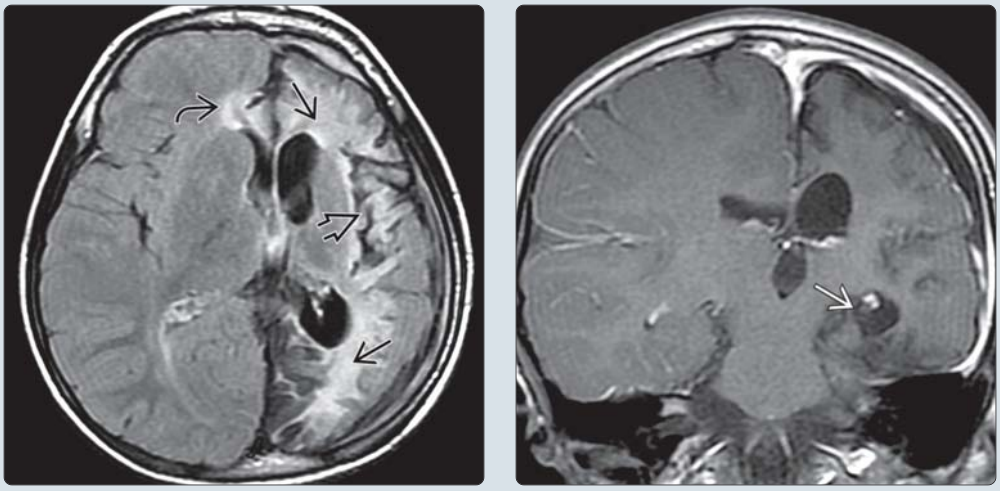
- Intractable partial epilepsy, clonic movements
  - Other: Hemiparesis, visual and sensory deficits, dysarthria, dysphasia, personality changes
- Partial complex seizures that increase in frequency → 20% present in status epilepticus
- Surgery only definitive treatment of seizures in RE

DIAGNOSTIC CHECKLIST

- Consider Rasmussen encephalitis when/if
  - ↑ frequency of partial complex seizures, postictal deficit in patients (1-15 years) with initial "normal" imaging
  - Intractable epilepsy with progressive atrophy of 1 hemisphere showing high T2 signal



(Left) *Axial FLAIR MR in a patient with Rasmussen encephalitis demonstrates left perisylvian and posterior temporal volume loss with subcortical gliosis. Note ex vacuo dilatation of the posterior horn of the left lateral ventricle.* **(Right)** *Coronal FLAIR MR in the same patient demonstrates left perisylvian and temporal volume loss. Note the profound left hippocampal volume loss.*



(Left) *Axial FLAIR MR shows atrophy of the left hemisphere. Gliosis is manifested as FLAIR hyperintensity. Note the insular cortical and subcortical atrophy and the involvement of the right frontal cortex.* **(Right)** *Coronal T1WI C+ MR shows extensive atrophy of the left hemisphere. Note the profound left hippocampal volume loss. Rasmussen encephalitis is distinguished on T1WI C+ MR from Sturge-Weber syndrome by the lack of enhancing leptomeningeal angiomatosis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Rasmussen encephalitis (RE)

Synonyms

- Chronic focal (localized) encephalitis

Definitions

- Chronic, progressive, unilateral brain inflammation of uncertain etiology
- Characterized by hemispheric volume loss and difficulty controlling focal seizure activity

IMAGING

General Features

- Best diagnostic clue
  - Unilateral progressive cerebral atrophy
  - CT/MR often normal initially
    - Early cortical swelling, then cortical/subcortical T2/FLAIR hyperintensity with atrophy ensues
    - Most cerebral damage occurs in first 8-12 months after clinical onset of disease
- Location
  - Cerebral hemisphere
  - Usually unilateral, predominantly frontal/insular and parietal
    - Precentral, inferior frontal atrophy
      - Contralateral cerebellar volume loss (crossed cerebellar diaschisis)
- Size
  - Variable, usually lobar, occasionally entire hemisphere affected
- Morphology
  - Focal abnormality, "spreads across hemisphere"
  - Becomes progressively more diffuse

CT Findings

- NECT
  - Initially normal, → atrophy
- CECT
  - Usually no enhancement
  - **Rare** transient pial &/or cortical enhancement

MR Findings

- T1WI
  - Sulcal effacement due to early swelling
- T2WI
  - Early focal swelling of gyri
    - Gray-white matter (GM-WM) "blurring" and T2 prolongation
    - ± basal ganglia, hippocampi involvement
  - Late: Atrophy of involved cerebral hemisphere or lobe
- FLAIR
  - Cortical and subcortical areas of hyperintensity that progressively increase over time
  - Late: Atrophy, encephalomalacia/gliosis
- T2* GRE
  - Typically normal
  - Nonhemorrhagic
- DWI
  - Subtle high signal on trace images; ↑ diffusivity
- T1WI C+
  - Usually does not enhance
    - Occasionally, subtle pial &/or cortical enhancement
- MRS
  - ↓ N-acetyl-aspartate (NAA) and choline; ↑ myoinositol, ↑ glutamine/glutamate

Nuclear Medicine Findings

- Tc-99m HMPAO scintigraphy: ↓ perfusion even if normal MR
- PET/SPECT
  - ↓ diffuse hemispheric metabolism/perfusion
  - Crossed cerebellar diaschisis
  - Transient hypermetabolism may be related to recent seizures (rare)
    - C-11-methionine shows increased multifocal uptake

Imaging Recommendations

- Best imaging tool
  - MR + clinical signs/symptoms + appropriate EEG findings
- Protocol advice
  - MR with contrast, ± PET (FDG)

DIFFERENTIAL DIAGNOSIS

Sturge-Weber Syndrome

- Port wine facial nevus and enhancement of pial angioma
- Progressive hemispheric atrophy
- Cortical Ca++

MELAS (Mitochondrial Encephalopathy, Lactic Acidosis, and Stroke-Like Episodes)

- Acute: May cause cortical hyperintensity (parietooccipital most common), + DWI
- Chronic: Cortical atrophy, lacunes (basal ganglia, thalami)

Dyke-Davidoff-Masson (Prenatal/Neonatal Hemispheric Infarction)

- Unilateral brain atrophy
- Compensatory calvarial thickening
- Elevation of petrous ridge and hyperaeration of paranasal sinuses
- Following in utero or perinatal infarct

Focal Cortical Dysplasia

- May cause hemispheric status epilepticus, resulting in unilateral volume loss

Other Autoimmune Inflammatory Disorders

- Unilateral cerebral vasculitis, paraneoplastic syndromes, onconeural antibodies

PATHOLOGY

General Features

- Etiology
  - Etiology & pathogenesis of RE remains unkown
  - Evidence for immunopathological basis is growing
    - Antibody-mediated, T-cell cytotoxicity & microglial-induced degeneration
- Genetics

https://CafePezeshki.IR

- Possibly viral trigger of genetic predisposition to immunodysfunction
- Associated abnormalities
  - 3 potentially overlapping factors may initiate or perpetuate events leading to injury
    - Viral infection
    - Autoimmune antibodies
    - Autoimmune cytotoxic T lymphocytes

Staging, Grading, & Classification

- 3 disease stages of RE
  - Prodromal stage: Nonspecific, low seizure frequency, & mild hemiplegia
  - Acute stage: Frequent seizures, often epilepsia partialis continua, progressive hemiparesis, cognitive deterioration
  - Residual stage: Permanent and stable neurological deficits & continuing seizures
- Classification and staging: MR (T2WI)
  - Stage 1: Swelling/hyperintense signal
  - Stage 2: Normal volume/hyperintense signal
  - Stage 3: Atrophy/hyperintense signal
  - Stage 4: Progressive atrophy and normal signal

Gross Pathologic & Surgical Features

- Hemispheric cortical atrophy
- Area of damage often surrounded by normal cortex or mild inflammation
  - Biopsy can be misleading

Microscopic Features

- Robitaille classification describes cortical inflammation, neuronal loss, and gliosis confined to 1 hemisphere
  - Group 1 (pathologically active): Ongoing inflammatory process
    - Microglial nodules, ± neuronophagia, perivascular round cells
  - Group 2 (active and remote disease): Acute on chronic
    - Above plus ≥ 1 gyral segment of complete necrosis and cavitation including full thickness cortex
  - Group 3 (less active "remote" disease)
    - Neuronal loss/gliosis and fewer microglial nodules
  - Group 4 (burnt out)
    - Nonspecific scarring with little active inflammation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Intractable epilepsy, clonic movements
  - Progresses to epilepsia partialis continua
  - Other: Hemiparesis, visual and sensory deficits, dysarthria, dysphasia, personality changes
- Clinical profile
  - Young child with progressive partial epilepsy unresponsive to medical therapy
- Clinical course
  - Partial complex seizures that increase in frequency
  - 20% present in status epilepticus
  - Followed by worsening seizures, progressive hemiparesis, cognitive deterioration, death
- EEG: Initial normal to persistent unilateral slowing ± epileptiform activity
- CSF: ± oligoclonal bands

Demographics

- Age
  - Usually begins in childhood (6-8 years)
  - 10% present as adolescent or adult
- Gender
  - M = F
- Ethnicity
  - No predilection
- Epidemiology
  - Preceded by inflammatory episode (50%)
    - Tonsillitis, upper respiratory infection, otitis media

Natural History & Prognosis

- Hemiplegia and cognitive deterioration in most cases
- Older patients have longer prodromal stage and protracted course
- Prognosis is poor
- Hemiplegia is inevitable ± treatment

Treatment

- Refractory to antiepileptic medications
- ± transient improvement with plasma exchange, IVIG therapy, steroids, B-cell & T-cell directed agents
- Surgery only definitive treatment of seizures in RE
  - Functional hemispherectomy/central disconnection
  - Hemispherotomy

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Consider Rasmussen encephalitis
  - ↑ frequency of partial complex seizures + postictal deficit in patients (1-15 years) with initial "normal" imaging
  - Intractable epilepsy with progressive atrophy of 1 hemisphere showing high T2 signal

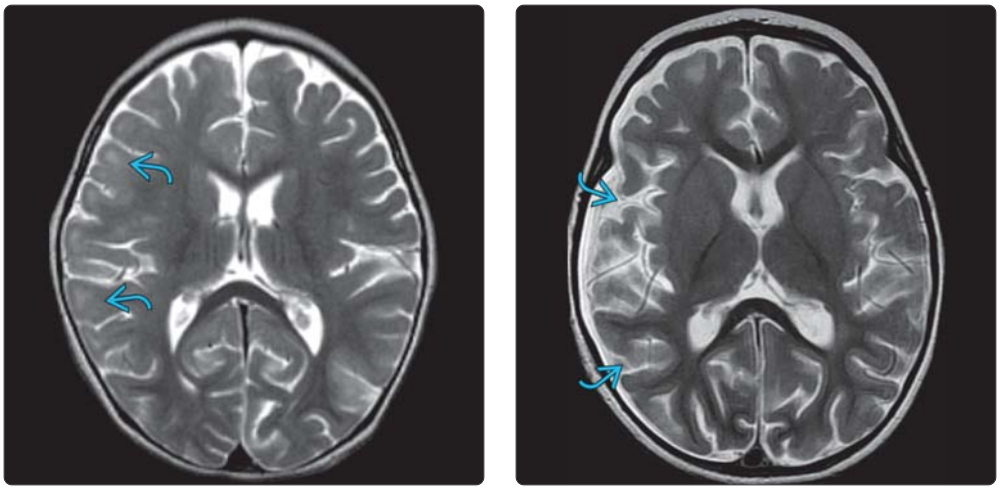
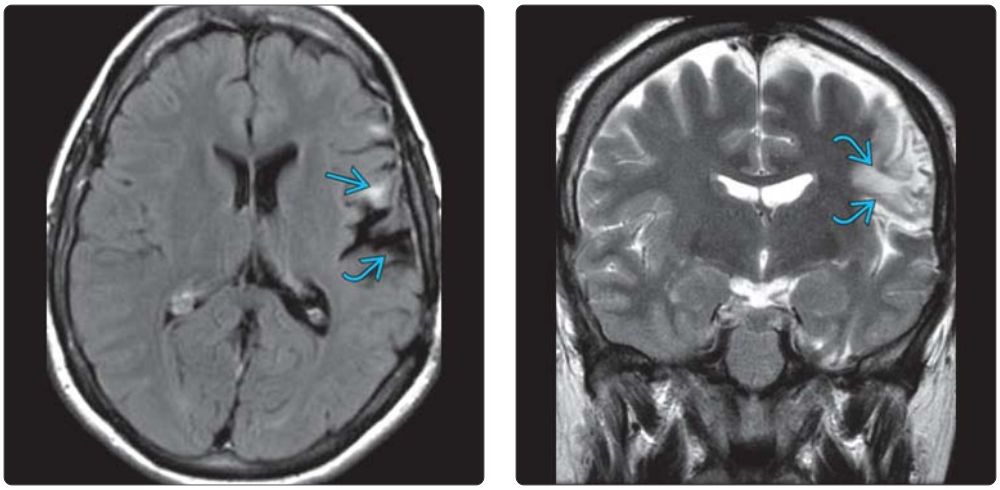
https://CafePezeshki.IR



(Left) *Axial T2WI MR in a 1 year old with drug-resistant focal seizures and progressive left hemiparesis demonstrates subtle T2 hyperintensity in the right hemisphere subcortical white matter.* **(Right)** *Axial T2WI MR in the same patient after 1 month shows marked right hemisphere volume loss with prominence of the sulci. Serial MR in Rasmussen encephalitis shows progression of atrophy and cortical/subcortical signal change.*



(Left) *Axial FLAIR MR in a patient with Rasmussen encephalitis (biopsy proven) shows prominence of the left perisylvian fissure due to volume loss.There is associated subcortical gliosis in the frontal operculum.* **(Right)** *Coronal T2WI MR in the same patient demonstrates left frontal opercular volume loss and gliosis.*

(Left) *Axial T1WI MR in a 4-year-old girl with chronic localized Rasmussen encephalitis demonstrates marked atrophy of the frontal lobe. Note the ex vacuo dilation of the left frontal horn and the enlargement of the circular sulcus reflecting insular volume loss.* **(Right)** *Axial FLAIR MR in the same patient shows atrophy of the superior frontal and middle frontal gyrus. Atrophy and subcortical gliosis extends into the left inferior frontal gyrus.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Definition: Rare, progressive, measles virus-mediated encephalitis

IMAGING

- CT: Imaging often initially normal; cortical swelling, cortical/subcortical hypoattenuation
- MR: Ill-defined T2 hyperintensities in periventricular or subcortical white matter
  - Frontal > parietal > occipital; no mass effect
- MRS: Increased choline and myoinositol; decreased NAA (may precede MR abnormalities)

TOP DIFFERENTIAL DIAGNOSES

- Acute disseminated encephalomyelitis
- Tumefactive multiple sclerosis
- Human immunodeficiency virus
- Progressive multifocal leukoencephalopathy

PATHOLOGY

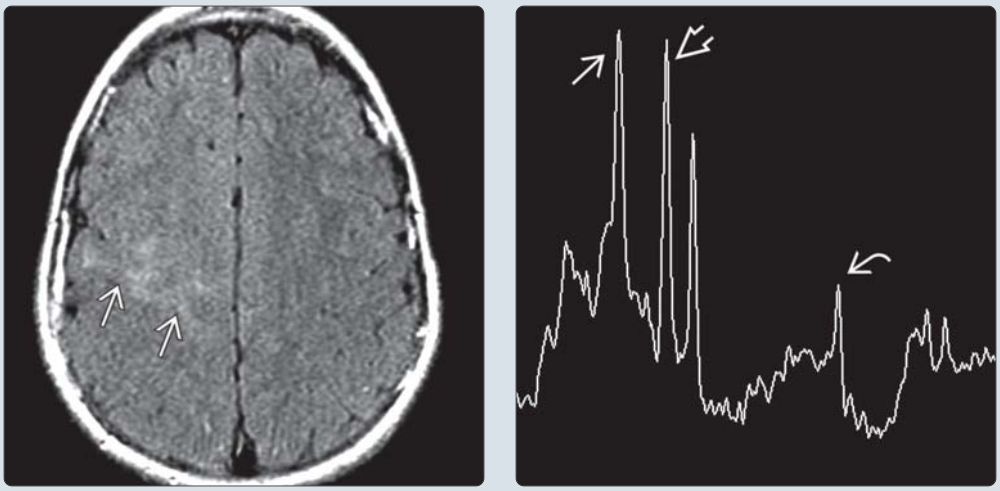
- Postinfectious progressive encephalitis years after measles infection

CLINICAL ISSUES

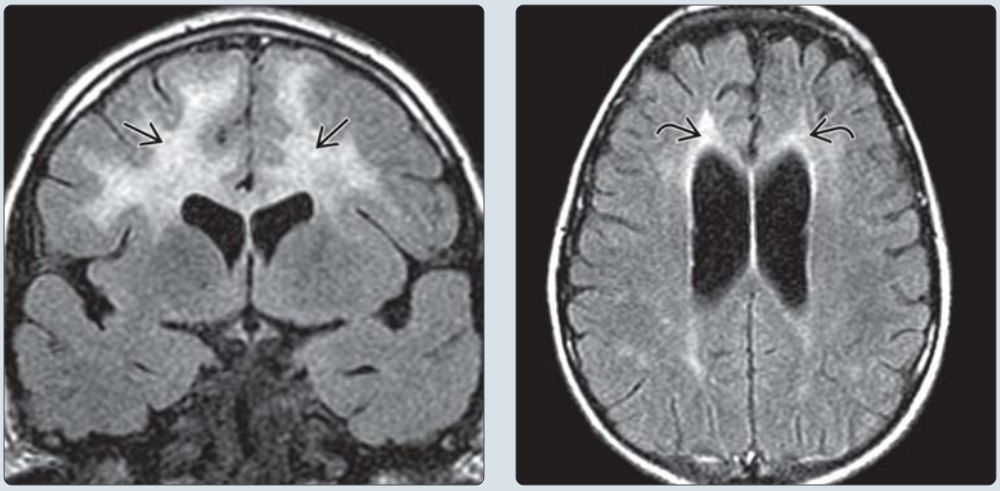
- Behavioral changes, mental deterioration, ataxia, myoclonus & visual disturbances
- Begins insidiously; subacute course; death (1-3 years after symptom onset)
- Positive CSF, plasma complement fixation test for measles; CSF plus oligoclonal bands

DIAGNOSTIC CHECKLIST

- Consider subacute sclerosing panencephalitis in immigrant child with behavioral changes and multifocal white matter disease



(Left) *Axial FLAIR MR in a 7-year-old boy with worsening gait disturbance and myoclonic jerks shows subtle right posterior frontal lobe cortical and subcortical white matter FLAIR hyperintensity* ⇨. **(Right)** *Single voxel proton MRS (TE = 35 ms) from the right parietal subcortical white matter in the same patient shows increased choline* ⇨ *and myoinositol* ⇨ *and a marked decrease in NAA* ⇨. *These metabolic changes were present with only subtle FLAIR and T2 signal abnormality.*



(Left) *Coronal FLAIR MR in a 7-year-old boy 6 months after initial presentation (following confirmatory CSF complement fixation test for measles) demonstrates progressive frontal lobe white matter FLAIR hyperintensity* ⇨. **(Right)** *Axial FLAIR MR in the same patient (10 months after initial clinical presentation with progressive cognitive deterioration and worsening myoclonus) shows bilateral frontal lobe white matter volume loss and FLAIR hyperintensity* ⇨ *(demyelination and gliosis).*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Subacute sclerosing panencephalitis (SSPE)

Synonyms

- Dawson encephalitis

Definitions

- Progressive measles virus-mediated encephalitis

IMAGING

General Features

- Best diagnostic clue
  - T2 hyperintensities in periventricular, deep, or subcortical white matter (WM)
- Location
  - Frontal > parietal > occipital lobes

CT Findings

- NECT
  - Imaging often initially normal; cortical swelling, cortical/subcortical hypoattenuation

MR Findings

- T1WI
  - Areas of ↓ signal in WM, corpus callosum
- T2WI
  - ↑ signal in WM, frontal > parietal > occipital, generally symmetric and eventually leading to diffuse atrophy
- T1WI C+
  - No enhancement
- MRS
  - ↑ choline and myoinositol; ↓ NAA (may precede MR abnormalities)

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - MR + IV contrast + MRS

DIFFERENTIAL DIAGNOSIS

Acute Disseminated Encephalomyelitis

- Prior viral illness, peripheral areas of ↑ T2 signal

Tumefactive Multiple Sclerosis

- Mass-like lesions in periventricular WM, perimeter enhancement

Human Immunodeficiency Virus

- Atrophy, ill-defined areas of ↑ T2 signal in WM
- ↑ attenuation of basal ganglia (NECT)

Progressive Multifocal Leukoencephalopathy

- Areas of ↑ T2 signal, immunocompromised (AIDS, cancer) patients

PATHOLOGY

General Features

- Etiology
  - Postinfectious progressive encephalitis years after measles infection

Gross Pathologic & Surgical Features

- Early diffuse cerebral swelling; subcortical & periventricular white matter, basal ganglia
- Rapidly progressive diffuse cortical atrophy

Microscopic Features

- Leptomeningeal, parenchymal, and perivascular inflammation
- Reactive gliosis with white matter demyelination, intranuclear inclusions in neurons & oligodendroglia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Behavioral changes, mental deterioration, ataxia, myoclonus, & visual disturbances
- Clinical profile
  - Positive CSF, plasma complement fixation test for measles; CSF plus oligoclonal bands
  - EEG: Periodic complexes with generalized polyspike, high-voltage slow waves

Demographics

- Age
  - Childhood, early adolescence; rare in adults
- Epidemiology
  - History of measles before age 2 in most patients → 16x risk of developing SSPE

Natural History & Prognosis

- Minor behavioral changes; motor dysfunction (myoclonic jerks); death (1-3 years after symptom onset)

Treatment

- No treatment, but there are some benefits from intraventricular α-interferon and Isoprinosine

DIAGNOSTIC CHECKLIST

Consider

- SSPE in immigrant child with behavioral changes and multifocal WM disease

Image Interpretation Pearls

- MR findings correlate poorly with clinical stage

KEY FACTS

TERMINOLOGY

- Typically causes tuberculous meningitis (TBM) &/or localized CNS infection, tuberculoma

IMAGING

- Basilar meningitis + extracerebral TB (pulmonary)
- Meningitis + parenchymal lesions highly suggestive
- Tuberculomas
  - Supratentorial parenchyma most common
  - Usually T2 hypointense
  - Enhances strongly (solid or ring enhancing)
- Tuberculous abscess: Multiloculated ring enhancement
- MR with FLAIR, DWI, T1 C+, ± MRA, MRS
- TB abscess has prominent lipid, lactate but no amino acid resonances

TOP DIFFERENTIAL DIAGNOSES

- Meningitis
- Neurosarcoidosis
- Abscess
- Neoplasm

PATHOLOGY

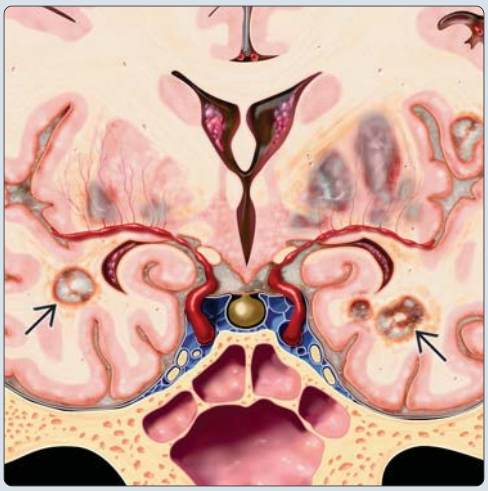
- CNS TB almost always secondary (often pulmonary source)
- Meningitis = most frequent manifestation of CNS TB
  - More common in children

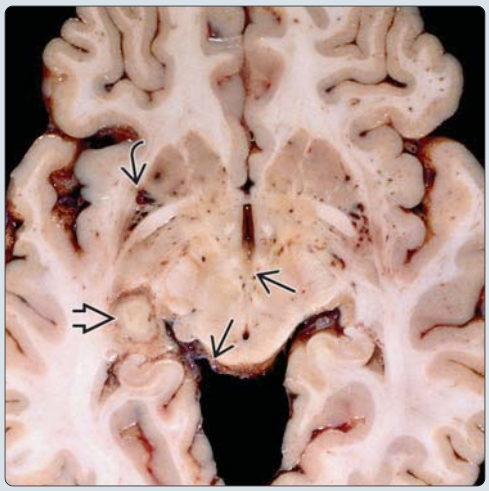
CLINICAL ISSUES

- Varies from mild meningitis with no neurologic deficit to coma
- Long-term morbidity in up to 80%: Mental retardation, paralysis, seizures, rigidity, speech or visual deficits
- Mortality in 25-30% of patients; higher in AIDS patients
- Reemerging disease (immigration from endemic areas, AIDS, drug-resistant strains)

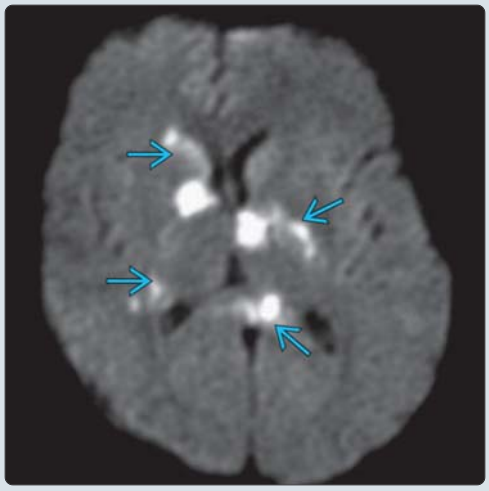
DIAGNOSTIC CHECKLIST

- TB often mimics other diseases, such as neoplasm





(Left) *Coronal graphic shows basilar TB meningitis and tuberculomas, which often coexist. Note the vessel irregularity and early basal ganglia ischemia related to arteritis.* **(Right)** *Axial gross pathology section shows numerous features of CNS TB. Exudates with meningitis in the basilar cisterns, tuberculoma, and vasculitic changes are all present in this autopsy specimen. (Courtesy R. Hewlett, MD.)*



(Left) *Axial T1WI C+ MR in a child with documented tuberculous meningitis shows thick, linear enhancement along the midbrain and temporal lobes. Note the enlarged lateral ventricles and cerebral aqueduct.* **(Right)** *Axial DWI MR in a patient with tuberculous meningitis shows multiple acute infarcts in the basal ganglia, thalami, internal capsules, and splenium of the corpus callosum. Vasculitis is a common complication of TBM involving small and medium-sized vessels and causing cerebral infarction.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Tuberculosis (TB)

Definitions

- Infection by acid-fast bacillus *Mycobacterium tuberculosis*
- CNS TB almost always secondary to hematogenous spread (often pulmonary)
  - Manifestations include tuberculous meningitis (TBM)
  - Localized parenchymal infection: Tuberculoma (common), TB abscess (rare)

IMAGING

General Features

- Best diagnostic clue
  - Basilar meningitis + extracerebral TB (pulmonary)
  - Meningitis + parenchymal lesions highly suggestive
- Location
  - Meningitis (basal cisterns > superficial sulci)
  - Tuberculomas
    - Typically parenchymal: Supratentorial most common
    - Dural tuberculomas may occur
- Size
  - Tuberculomas range from 1 mm to 6 cm
  - Tuberculous abscess: Usually > 3 cm
- Morphology
  - TBM: Thick basilar exudate
  - Tuberculoma: Round or oval mass
    - Solitary or multiple (more common)
  - Tuberculous abscess: Large, solitary frequently multiloculated
- Associated findings
  - Spine is most frequent osseous site: TB spondylitis (Potts disease)
  - Less common sites: Calvaria (± dura), otomastoid
  - TB cervical adenitis
    - Conglomerate nodal neck mass

CT Findings

- NECT
  - TBM: May be normal early (10-15%)
    - Isodense to hyperdense exudate effaces CSF spaces, fills basal cisterns, sulci
  - Tuberculoma
    - Hypodense to hyperdense round or lobulated nodule/mass with moderate to marked edema
    - Ca++ uncommon (approximately 20%)
- CECT
  - TBM: Intense basilar meningeal enhancement
  - Tuberculoma: Solid or ring enhancing
    - Target sign: Central focus of enhancement + ring of peripheral enhancement
  - Tuberculous abscess: Solitary often multiloculated ring-enhancing

MR Findings

- T1WI
  - TBM: Exudate isointense or hyperintense to CSF
  - Tuberculoma
    - Noncaseating granuloma: Hypointense to brain
    - Caseating granuloma
      - Solid center: Hypointense or isointense
      - Necrotic center: Central hypointensity
      - May have hyperintense rim (paramagnetic material)
- T2WI
  - TBM: Exudate is isointense or hyperintense to CSF; may see low-signal nodules (rare)
  - Tuberculoma
    - Noncaseating granuloma: Hyperintense to brain
    - Caseating granuloma: Hypointense rim
      - Solid center: Usually hypointense
      - Necrotic center: Hyperintense
    - Surrounding edema common
  - Tuberculous abscess: Hyperintense lesion with hypointense rim & marked vasogenic edema
- FLAIR
  - TBM: Increased intensity in basal cisterns, sulci
  - Tuberculoma & tuberculous abscess: Similar to T2 characteristics
- DWI
  - May show hyperintense center of tuberculoma
  - Restricted diffusion in tuberculous abscess
  - Helpful for detecting complications (stroke, cerebritis)
- T1WI C+
  - TBM: Marked meningeal enhancement, basilar prominence; may be nodular
    - Punctate/linear basal ganglia enhancement = vasculitis
    - Rare: Ventriculitis, choroid plexitis
    - Rare: Pachymeningitis with dural thickening, enhancement (may mimic meningioma)
  - Tuberculomas
    - Noncaseating granuloma: Nodular, homogeneous enhancement
    - Caseating granuloma: Peripheral rim enhancement
      - Necrotic center will show low signal
  - Tuberculous abscess: Multiloculated ring enhancement
- MRA
  - May see vessel narrowing, irregularity, occlusion
- MRS
  - TB abscess has prominent lipid, lactate but no amino acid resonances
    - Lipids at 0.9 ppm, 1.3 ppm, 2.0 ppm, 2.8 ppm
- **Complications**: Hydrocephalus, ischemia
- **Chronic changes**: Atrophy, Ca++, chronic ischemia

Imaging Recommendations

- Best imaging tool
  - MR with FLAIR, DWI, T1 C+, ± MRA, MRS

DIFFERENTIAL DIAGNOSIS

Meningitis

- Infectious meningitis (bacterial, fungal, viral, parasitic)
  - Coccidioidomycosis, cryptococcosis often basilar
- Carcinomatous meningitis (CNS or systemic primary) or lymphoma

Neurosarcoidosis

- Typically leptomeningeal &/or dural enhancement

https://CafePezeshki.IR

- Rarely causes parenchymal nodules

Abscess

- Other granuloma, parasite (neurocysticercosis), bacteria
- Pyogenic abscess often more edema, MRS helpful

Neoplasm

- Primary or metastatic tumors may be indistinguishable
- Thick, nodular enhancing wall, variable diffusivity

PATHOLOGY

General Features

- Etiology
  - CNS TB almost always secondary to hematogenous spread (often pulmonary; rarely GI or GU tract)
    - Hyperemia, inflammation extend to meninges
    - May involve perivascular spaces, cause vasculitis
  - TBM pathophysiology
    - Penetration of meningeal vessel walls by hematogenous spread
    - Rupture of subependymal or subpial granulomata into CSF
  - Tuberculoma pathophysiology
    - Hematogenous spread (gray-white matter junction lesions)
    - Extension of meningitis into parenchyma via cortical veins or small penetrating arteries
  - Arteries directly involved by basilar exudate or indirectly by reactive arteritis (up to 40% of patients)
    - Infection causes arterial spasm resulting in thrombosis and infarct
    - Lenticulostriate arteries, MCA, thalamoperforators most often affected
    - Infarcts most common in basal ganglia, cerebral cortex, pons, cerebellum

Gross Pathologic & Surgical Features

- TBM: Thick, gelatinous, cisternal exudate
- Tuberculoma: Noncaseating, caseating with solid center, or caseating with necrotic center
  - Rarely progresses to TB abscess
    - Lobulated mass with thick rim, occurs in parenchyma, subarachnoid space, dura
- Tuberculous abscess: Encapsulated collection of pus with abundant viable tubercle bacilli

Microscopic Features

- TBM: Inflammatory cells, fragile neocapillaries
  - Caseous necrosis, chronic granulomas, endarteritis, perivascular inflammatory changes
- Tuberculoma
  - Early capsule: Peripheral fibroblasts, epithelioid cells, Langerhans giant cells, lymphocytes
  - Late capsule: Thick collagen layer, central liquefied caseating material in mature tuberculoma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Varies from mild meningitis with no neurologic deficit to coma
  - TBM: Fevers, confusion, headache, lethargy, meningismus
  - Tuberculoma: Seizures, increased intracranial pressure, papilledema
- Clinical profile
  - LP: Increased protein, pleocytosis (lymphocytes), low glucose, negative for organisms
    - CSF positive on initial LP in < 40%
    - Mycobacteria grow slowly, culture 6-8 weeks
    - PCR for TB may help confirm diagnosis earlier
  - TB skin test may be negative, particularly early
  - Elevated erythrocyte sedimentation rate common

Demographics

- Age
  - Occurs at all ages, but more often in 1st 3 decades
- Epidemiology
  - Worldwide: 8-10 million cases annually
  - Reemerging disease (immigration from endemic areas, AIDS, drug-resistant strains)
  - CNS tuberculosis: 1% of all TB, 10-15% of all extrapulmonary TB

Natural History & Prognosis

- Long-term morbidity in up to 80%: Mental retardation, paralysis, seizures, rigidity, speech or visual deficits
- Mortality in 25-30% of patients; higher in AIDS patients
- Complications: Hydrocephalus (70%), stroke (up to 40%), cranial neuropathies (CN3, CN4, CN6 common), syrinx
- Tuberculomas may take months to years to resolve

Treatment

- Untreated TBM can be fatal in 4-8 weeks
- Multidrug therapy required: Isoniazid, rifampin, pyrazinamide, ± ethambutol or streptomycin
- Despite therapy, lesions may develop or increase
- Hydrocephalus typically requires CSF diversion

DIAGNOSTIC CHECKLIST

Consider

- TB often mimics other diseases, such as neoplasm

Image Interpretation Pearls

- Combination of meningitis and parenchymal lesions suggests TB

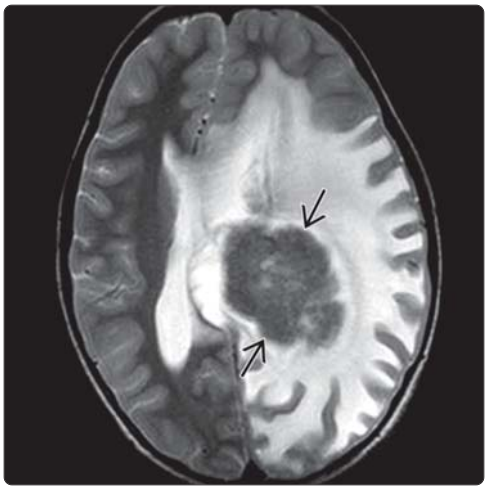
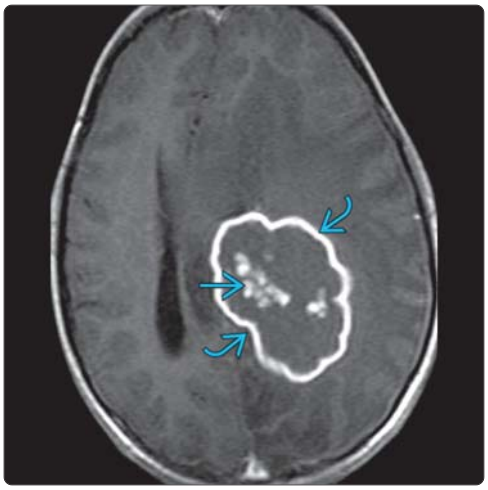
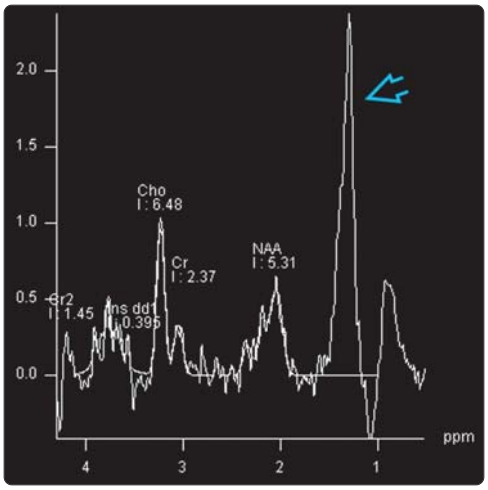
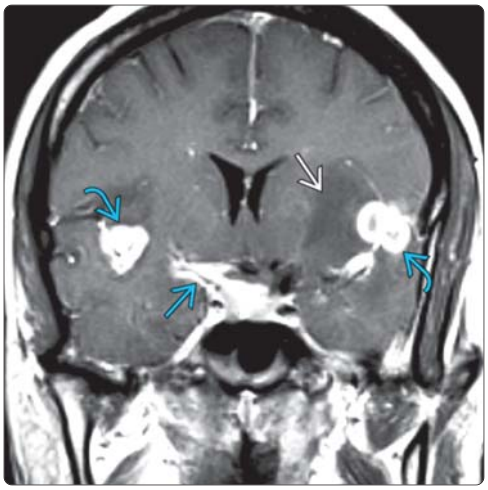
https://CafePezeshki.IR



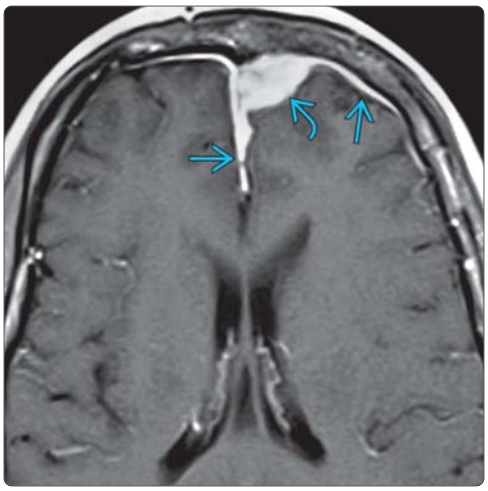


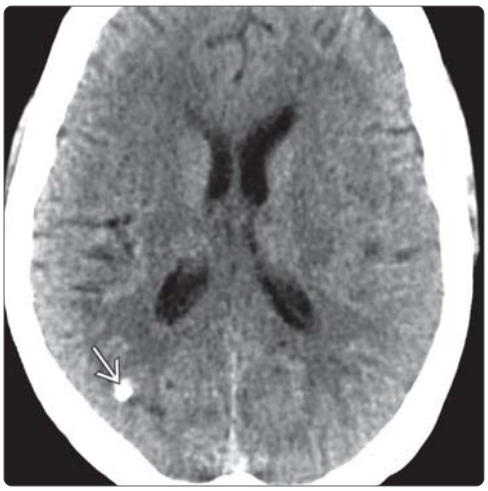
(Left) *Axial T2WI MR in a patient with tuberculoma shows a large, mostly hypointense left parietal lesion ⇨ with edema affecting almost the entire hemisphere. Note the extension into the subcortical U-fibers with sparing of the overlying cortex.* **(Right)** *Axial T1WI C+ MR in the same patient shows ring enhancement ⇨ with some central punctate enhancing foci ⇨. Giant tuberculomas can mimic CNS neoplasms on standard MR imaging.*





(Left) *MRS (PRESS, intermediate echo) in the same patient shows diminished NAA and a large lipid peak ⇨ (1.3 ppm), a common finding in tuberculosis.* **(Right)** *Coronal T1WI C+ MR in tuberculous meningitis shows basilar meningitis ⇨ surrounding the MCA and enhancing tuberculomas ⇨ adjacent to the sylvian fissures. Note subtle low signal ➡ in left basal ganglia related to arteritis/ischemia.*





(Left) *Axial T1WI C+ MR demonstrates an enhancing dural-based mass ⇨ with adjacent dural tails ⇨. After surgical resection the final diagnosis was a dural tuberculoma. CNS TB may involve the dura causing a pachymeningitis which may be focal or diffuse. MR imaging is nonspecific in TB pachymeningitis and may mimic a large number of inflammatory and noninflammatory conditions.* **(Right)** *Axial NECT shows a calcified, healed tuberculous granuloma ➡.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Intracranial parasitic infection caused by pork tapeworm *Taenia solium*
  - 4 pathologic stages: Vesicular, colloidal vesicular, granular nodular, and nodular calcified

IMAGING

- Best diagnostic clue: Cyst with "dot" inside
- Convexity subarachnoid spaces most common location
  - Inflammatory response around cyst may seal sulcus, making lesions appear intraaxial
- May involve cisterns > parenchyma > ventricles
- Intraventricular cysts are often isolated
- Basal cistern cysts may be racemose (grape-like)
- Imaging varies with development stage and host response
- Lesions may be at different stages in same patient
- FLAIR and T1 MR helpful to identify scolex and intraventricular lesions
- GRE/SWI helpful in young adults presenting with seizures

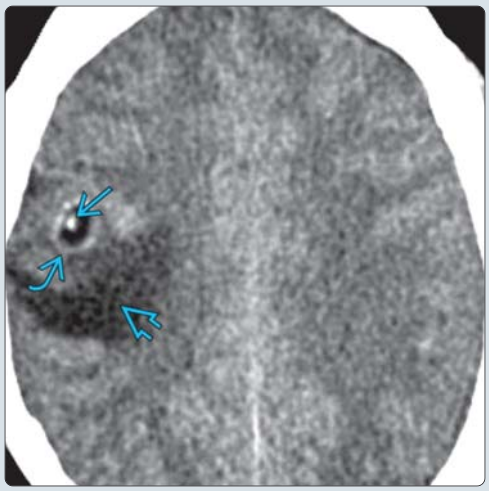
TOP DIFFERENTIAL DIAGNOSES

- Abscess
- Tuberculosis
- Neoplasm
- Arachnoid cyst
- Enlarged perivascular spaces

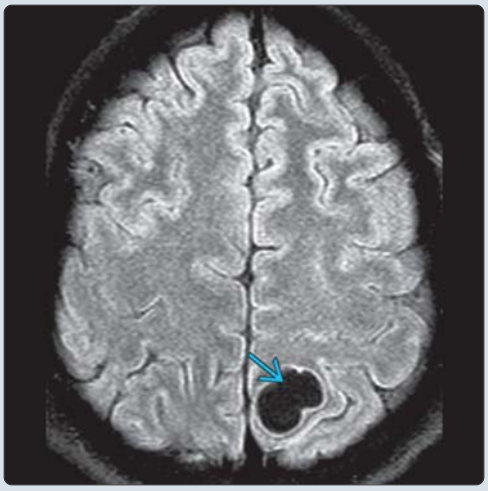
CLINICAL ISSUES

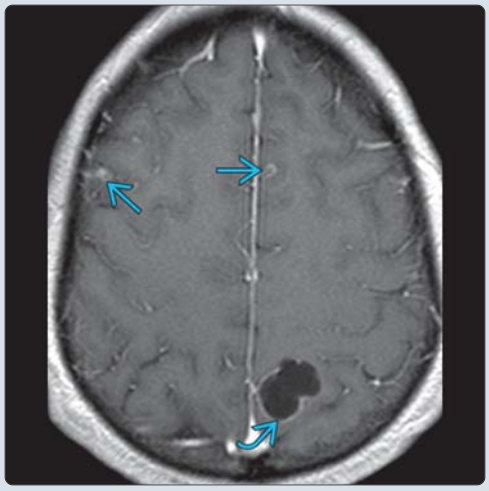
- Seizure, headaches, hydrocephalus common
  - NCC asymptomatic until larvae degenerate
- Cysticercosis is most common parasitic infection worldwide
  - CNS involved in 60-90% of cysticercosis cases
- Most common cause of epilepsy in endemic areas
- Increased travel, immigration have spread disease
- Diagnosis confirmed by ELISA of serum or CSF
- Oral albendazole (reduces parasitic burden, seizures)
- Steroids often required to decrease edema
- Consider excision or drainage of parenchymal lesions

(Left) *Coronal graphic shows subarachnoid and ventricular cysts. The convexity cysts have a scolex and surrounding inflammation. Note that the inflammation around the largest cyst "seals" the sulcus ⇨ and makes it appear parenchymal. Racemose cysts ⇨ are multilocular, nonviable, seen in the basal cisterns and typically lack a scolex.* **(Right)** *Axial CECT in a young male with first episode of seizure demonstrates a ring enhancing lesion ⇨ with an eccentric hyperdense "dot" ⇨ typical for NCC. Note surrounding edema ⇨.*



(Left) *Axial FLAIR MR shows a well-defined cyst in left parietal lobe ⇨, which follows CSF signal. There is no edema surrounding this cyst.* **(Right)** *Axial T1+C MR in the same patient shows minimal rim enhancement ⇨ of the cyst. Findings are typical for vesicular stage of NCC. Note nodular enhancing lesions ⇨ in the frontal lobes due to granular nodular stage of NCC. It is important to remember that NCC lesions may be at different stages in same patient.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neurocysticercosis (NCC)

Synonyms

- Cysticercosis

Definitions

- Intracranial parasitic infection caused by pork tapeworm *Taenia solium*
  - 4 pathologic stages: Vesicular, colloidal vesicular, granular nodular, and nodular calcified

IMAGING

General Features

- Best diagnostic clue
  - Cyst with "dot" inside
- Location
  - Convexity subarachnoid spaces most common
  - May involve cisterns > parenchyma > ventricles
  - Parenchymal cysts often hemispheric, at gray-white junction
  - Intraventricular cysts are often isolated
    - 4th ventricle is most common
  - Basal cistern cysts may be racemose (grape-like)
- Size
  - Cysts variable, typically 1 cm, range from 5-20 mm; contain scolex (1-4 mm)
  - Parenchymal cysts ≤ 1 cm
  - Subarachnoid cysts may be larger
- Morphology
  - Round or ovoid cyst, solitary in 20-50%
  - Disseminated form (a.k.a. miliary NCC): Rare
- Imaging varies with development stage and host response
- Lesions may be at different stages in same patient
- Inflammatory response around cyst may seal sulcus, making lesions appear intraaxial

CT Findings

- NECT
  - **Vesicular** stage (viable larva): Smooth, thin-walled cyst, isodense to CSF, no edema
    - Hyperdense "dot" within cyst = protoscolex
  - **Colloidal vesicular** stage (degenerating larva): Hyperdense cyst fluid with surrounding edema
  - **Granular nodular** stage (healing): Mild edema
  - **Nodular calcified** stage (healed): Small, calcified nodule
- CECT
  - **Vesicular** stage: No (or mild) wall enhancement
  - **Colloidal vesicular** stage: Thicker, ring-enhancing fibrous capsule
  - **Granular nodular** stage: Involuting, enhancing nodule
  - **Nodular calcified** stage: Shrunken, Ca++ nodule
- Subarachnoid lesions: Multiple isodense cysts without scolex; may cause meningitis, vasculitis, or hydrocephalus
- Intraventricular cysts not well seen on CT, may see hydrocephalus

MR Findings

- T1WI
  - **Vesicular** stage: Cystic lesion isointense to CSF
    - May see discrete, eccentric scolex (hyperintense)
  - **Colloidal vesicular** stage: Cyst is mildly hyperintense to CSF
  - **Granular nodular** stage: Thickened, retracted cyst wall; edema decreases
  - **Nodular calcified** stage: Shrunken, Ca++ lesion
  - Useful to detect intraventricular cysts
- T2WI
  - **Vesicular** stage: Cystic lesion isointense to CSF
    - May see discrete, eccentric scolex
    - No surrounding edema
  - **Colloidal vesicular** stage: Cyst is hyperintense
    - Surrounding edema, mild to marked
  - **Granular nodular** stage: Thickened, retracted cyst wall; edema decreases
  - **Nodular calcified** stage: Shrunken, Ca++ lesion
- FLAIR
  - **Vesicular** stage: Cystic lesion isointense to CSF
    - May see discrete, eccentric scolex (hyperintense to CSF); no edema
  - **Colloidal vesicular** stage: Cyst is hyperintense
    - Surrounding edema, mild to marked
  - Useful to detect intraventricular cysts (hyperintense)
  - 100% inspired oxygen increases conspicuity
- T2* GRE
  - Useful to demonstrate calcified scolex
  - May show "multiple black dot" appearance
- DWI
  - Cystic lesion typically isointense to CSF
  - Scolex detectable as a hyperintense nodule
- T1WI C+
  - **Vesicular** stage: No enhancement typical, may see mild enhancement
    - May see discrete, eccentric scolex enhancement
  - **Colloidal vesicular** stage: Thick cyst wall enhances
    - Enhancing marginal nodule (scolex)
  - **Granular nodular** stage: Thickened, retracted cyst wall; may have nodular or ring-like enhancement
  - **Nodular calcified** stage: Small calcified lesion, rare minimal enhancement
- MRS
  - ↑ lactate, alanine, succinate, choline; ↓ NAA and Cr
- In children, may see "encephalitic cysticercosis" with multiple small enhancing lesions and diffuse edema
- Steady state sequences (CISS) for intraventricular cysts
- **Cisternal** NCC may appear **racemose** (multilobulated, grape-like), typically lacks scolex

Imaging Recommendations

- Best imaging tool
  - MR is most sensitive
  - Calcified lesions may be better seen on CT
- Protocol advice
  - MR with T1, T2, FLAIR, GRE/SWI, contrast

DIFFERENTIAL DIAGNOSIS

Abscess

- Typically T2-hypointense rim and DWI positive
- Multiple lesions may occur related to septic emboli

https://CafePezeshki.IR

Tuberculosis
- Tuberculomas often occur with meningitis
- Typically not cystic

Neoplasm
- Primary or metastatic (primary often known)
- Thick, irregular margin enhancement typical
- May have cyst and mural nodule (e.g., pilocytic astrocytoma, hemangioblastoma)

Arachnoid Cyst
- Solitary lesion with CSF density/intensity
- No enhancement

Enlarged Perivascular Spaces
- Follow CSF on all MR sequences, no enhancement

Other Parasitic Infection
- May be cystic, but no scolex seen

PATHOLOGY

General Features
- Etiology
  - Caused by larval form of pork tapeworm *Taenia solium*
  - Man is intermediate host in life cycle of tapeworm
    - Fecal-oral most common route of infection
    - Ingestion of eggs from contaminated water, food
    - From GI tract, primary larvae (oncospheres) disseminate into CNS and skeletal muscle
    - Once intracranial, primary develop into secondary larvae, cysticerci
  - Man may also be definitive host (infected with tapeworm)
    - Typically from uncooked pork
    - Viable larvae ingested, attach in GI tract

Staging, Grading, & Classification
- 4 pathologic stages
  - Vesicular, colloidal vesicular, granular nodular, and nodular calcified
- **Vesicular** stage: Larva is small marginal nodule projecting into small cyst with clear fluid
  - Viable parasite with little or no inflammation
  - May remain in this stage for years or degenerate
- **Colloidal vesicular** stage: Larva begins to degenerate
  - Scolex shows hyaline degeneration, slowly shrinks
  - Cyst fluid becomes turbid, and capsule thickens
  - Surrounding edema and inflammation
- **Granular nodular** stage: Cyst wall thickens and scolex is mineralized granule; surrounding edema regresses
- **Nodular calcified** stage: Lesion is completely mineralized and small; no edema

Gross Pathologic & Surgical Features
- Usually small translucent cyst with invaginated scolex

Microscopic Features
- Cyst wall has 3 distinct layers: Outer (cuticular) layer, middle cellular (pseudoepithelial) layer, inner reticular (fibrillary) layer
- Scolex has rostellum with hooklets, muscular suckers

CLINICAL ISSUES

Presentation
- Most common signs/symptoms
  - Seizure, headaches, hydrocephalus
  - NCC asymptomatic until larvae degenerate
  - Other signs/symptoms: Syncope, dementia, visual changes, focal neurologic deficits, stroke
- Clinical profile
  - Diagnosis confirmed by ELISA of serum or CSF

Demographics
- Epidemiology
  - Cysticercosis is most common parasitic infection
  - CNS infection in 60-90% of cysticercosis cases
  - Endemic in many countries (Latin America, parts of Asia, India, Africa, eastern Europe)
    - USA: Incidence rising in CA, AZ, NM, TX
  - Increased travel, immigration have spread disease
- Age: Any; commonly young, middle-aged adults
- Ethnicity: In USA, Latin American patients common

Natural History & Prognosis
- Most common cause of epilepsy in endemic areas
- Variable time from initial infection until symptoms: 6 months to 30 years; typically 2-5 years
- Variable time to progress through pathologic stages: 1-9 years; mean: 5 years
- Subarachnoid disease may be complicated by meningitis, vasculitis, and hydrocephalus
- Intraventricular NCC has increased morbidity and mortality (↑ morbidity related to acute hydrocephalus)

Treatment
- Oral albendazole (reduces parasitic burden, seizures)
  - Steroids often required to decrease edema
- Consider excision or drainage of parenchymal lesions
- Consider endoscopic resection of ventricular lesions
- CSF diversion often required to treat hydrocephalus

DIAGNOSTIC CHECKLIST

Consider
- Complex parasitic cysts may mimic brain tumor

Image Interpretation Pearls
- FLAIR and T1WI helpful to identify scolex and intraventricular lesions
- GRE/SWI helpful in young adults presenting with seizures

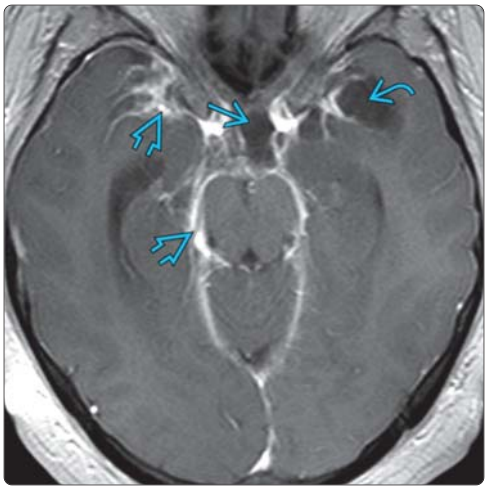
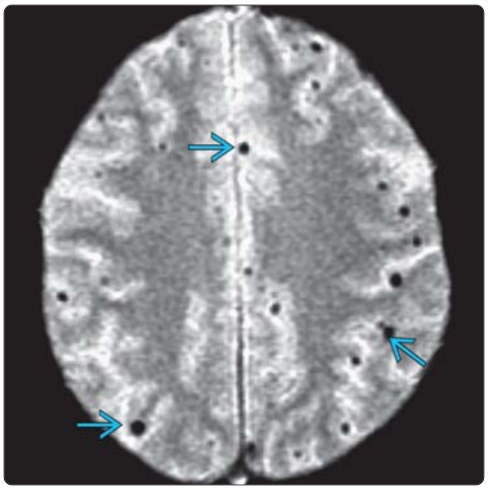
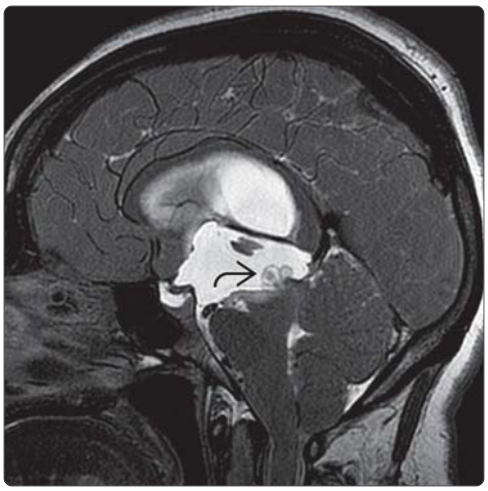
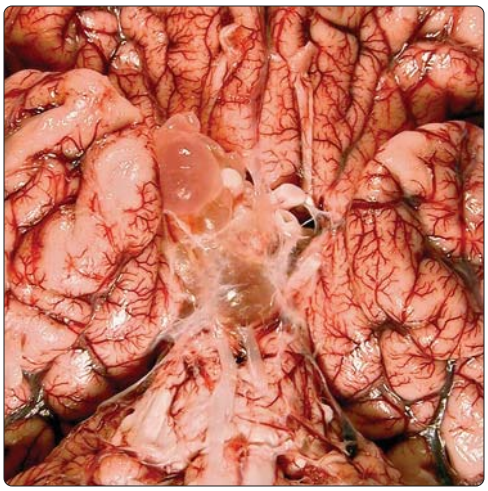
(Left) *Axial FLAIR MR in a patient with NCC shows a large CSF signal intensity cyst ⇨ with extensive surrounding vasogenic edema ⇨. In the colloidal vesicular stage of NCC the larvae begin to degenerate, which incites a striking inflammatory response and leads to prominent perilesional edema.* **(Right)** *MRS at TR 1500 TE 144 within the cyst cavity shows peaks of Cho ⇨ (3.2 ppm), succinate ⇨ (2.4 ppm), and lactate ⇨ (1.3 ppm).*





(Left) *Axial T1+ C MR demonstrates multiple cysts within the suprasellar cistern ⇨ and left sylvian fissure ⇨. There is extensive leptomeningeal enhancement ⇨ in the basal cisterns and sylvian fissures. Cisternal NCC also termed "racemose" (grape-like) may cause meningeal inflammation, communicating hydrocephalus,vasculitis, and infarcts.* **(Right)** *Axial T2* GRE MR in a patient with seizures shows multifocal "black dots" ⇨ in the sulci and parenchyma related to the nodular calcified stage of NCC.*





(Left) *Sagittal FIESTA MR scan shows hydrocephalus due to intraventricular cysticercosis. Note the presence of cysts ⇨ blocking the flow of CSF from the 3rd ventricle to the aqueduct. Steady-state free precession sequences are useful to show intraventricular cysts.* **(Right)** *Inferior view of the brain at autopsy shows multiple racemose NCC cysts. Basal cistern cysts are commonly complicated by meningitis, hydrocephalus, and vasculitis. (Courtesy R. Hewlett, MD.)*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Hydatid disease (HD), hydatid cyst (HC)
- *Echinococcus granulosus* (EG)
- *Echinococcus multilocularis/alveolaris* (EM/EA)

IMAGING

- General: Child/young adult with large, supratentorial, unilocular, thin-walled cyst
  - No Ca++ or surrounding edema
  - CSF density/intensity
- MR
  - EG: Well-defined, T2-hypointense rim; no enhancement
  - EM/EA: Small irregular cysts with nodular/ring enhancement, edema
  - Lactate, alanine, acetate, pyruvate (at 2.4 ppm)

TOP DIFFERENTIAL DIAGNOSES

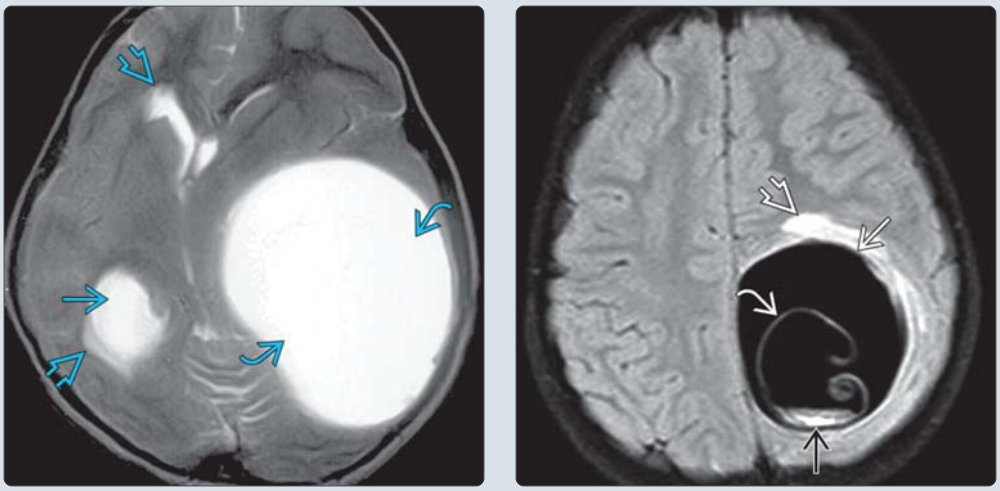
- Arachnoid cyst
- Epidermoid cyst
- Neuroglial cyst
- Porencephalic cyst

PATHOLOGY

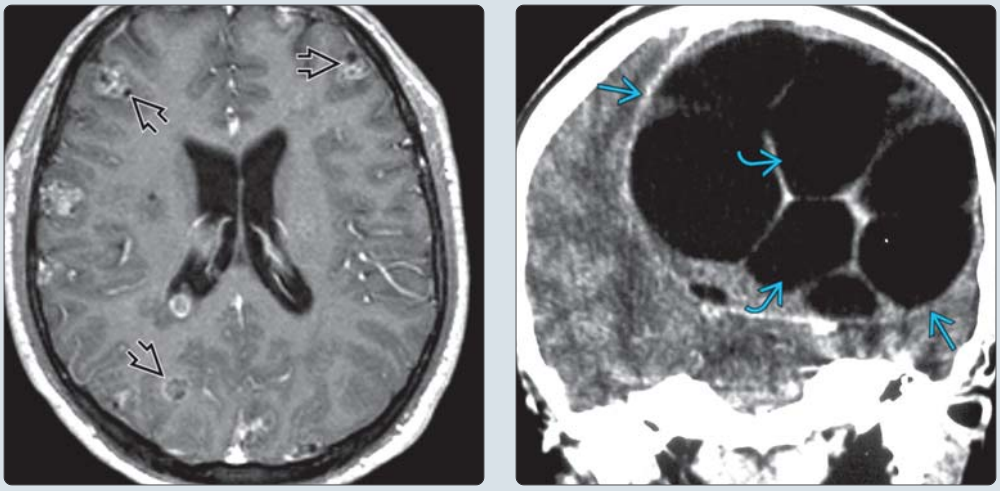
- Parasitic infection by *Echinococcus* tapeworms
  - Definitive host = dog (or other carnivore)
  - Intermediate host = sheep (most commonly)
  - Humans may become intermediate hosts
- CNS involvement: 1-2% in EG, 3-5% EM/EA
- HC has 3 layers: Outer (pericyst), middle laminated membrane (ectocyst), and inner germinal (endocyst)

CLINICAL ISSUES

- Surgical excision = treatment of choice
- Caution: Avoid cyst rupture
- Spillage of cyst contents can lead to anaphylactic reaction or recurrence



(Left) *Axial T2 MR demonstrates a huge, unilocular, CSF signal intensity hydatid cyst in the left hemisphere.There is no edema surrounding the cyst. There is mass effect with obstruction of the right lateral ventricle and periventricular interstitial edema.* **(Right)** *Axial FLAIR MR demonstrates a large left parietal hydatid cyst with an internal membrane representing detached germinal membrane and dependent hyperintense "hydatid sand". There is very mild surrounding edema.*



(Left) *Axial T1WI C+ MR demonstrates clusters of small cysts with peripheral ring enhancement. Alveolar echinococcosis (AE) with CNS involvement was finally diagnosed. AE is composed of numerous irregular cysts (between 1 and 20 mm in diameter), not sharply demarcated. Necrosis with liquefaction causes the cystic central areas.* **(Right)** *Coronal CECT shows a variant manifestation of hydatid disease. Multiple "daughter" cysts are present within a very large cyst. (Courtesy S. Nagi, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hydatid disease (HD), hydatid cyst (HC)
- *Echinococcus granulosus* (EG)
- *Echinococcus multilocularis/alveolaris* (EM/EA)

Synonyms

- Echinococcosis, hydatid cyst

IMAGING

General Features

- Best diagnostic clue
  - Large, unilocular, thin-walled cyst
    - No Ca++ or surrounding edema
    - CSF density/intensity
- Location
  - Majority of HCs occur in liver, lungs
  - CNS involvement: 1-2% of EG, 3-5% of EM/EA
    - Most commonly supratentorial (MCA territory)
      - Parietal lobe most frequently involved
- Size
  - EG: Large cysts
  - EM/EA: Smaller, partially solid/cystic (1-20 mm)
- Morphology
  - EG: Generally solitary; may be multiple if ruptured
  - Multivesicular cysts uncommon in brain

CT Findings

- NECT
  - EG: Unilocular cyst isodense to CSF
    - Ca++ < 1% (more common with EM/EA)
- CECT
  - Normally no enhancement

MR Findings

- T1WI
  - EG: Unilocular cyst, isointense to CSF
- T2WI
  - EG: Cyst with well-defined hypointense rim
  - EM/EA: Small irregular cysts with edema
- T1WI C+
  - EG: None (rim only if superinfected)
  - EM/EA: Nodular/ring-like enhancement
- MRS
  - Lactate (1.3 ppm), alanine (1.48 ppm), acetate (1.92 ppm), succinate (2.4 ppm)

DIFFERENTIAL DIAGNOSIS

Arachnoid Cyst

- Extraaxial cysts follow CSF signal/attenuation

Epidermoid Cyst

- Does not suppress on FLAIR, ↑ DWI

Neuroglial Cyst

- Difficult to differentiate (travel history helps for EG)

Porencephalic Cyst

- Cystic space with adjacent enlarged ventricle

PATHOLOGY

General Features

- Etiology
  - Parasitic infection by *Echinococcus* tapeworm
    - Usually caused by EG, less frequently EM/EA
  - Life cycle
    - Definitive host = dog (or other carnivore)
    - Intermediate host = sheep (most commonly)
  - Humans may become intermediate hosts via
    - Contact with definitive host
    - Ingestion of contaminated water/vegetables

Gross Pathologic & Surgical Features

- Vesicles resemble "bunch of grapes"

Microscopic Features

- HC has 3 layers
  - Outer layer (pericyst): Modified host cells form dense, fibrous protective zone
  - Middle laminated membrane (ectocyst): Acellular and permits passage of nutrients
  - Inner germinal layer (endocyst): Produces daughter vesicles
    - Scolices (larval stage of parasite) are seen within daughter vesicles

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, seizures, focal deficits, nausea, vomiting, papilledema (↑ ICP)

Demographics

- Age
  - Usually child, young adult
- Epidemiology
  - EG: Endemic in Australia, New Zealand, Middle East, Mediterranean, South America
  - EM/EA: Endemic in North America, central Europe, Russia, China, Turkey

Natural History & Prognosis

- Rupture, infection: Important complications of HC

Treatment

- Surgical excision = treatment of choice
  - Caution: Avoid cyst rupture
  - Spillage of cyst contents can lead to anaphylactic reaction or recurrence
- Antihelmintic therapy (praziquantel, albendazole)

DIAGNOSTIC CHECKLIST

Consider

- HC if large, unilocular, noncalcified parietal cyst without edema, enhancement
  - Residence in or travel to endemic regions

SELECTED REFERENCES

1. Teke M et al: Imaging features of cerebral and spinal cystic echinococcosis. Radiol Med. ePub, 2014

KEY FACTS

TERMINOLOGY

- Parasitic infection caused by free-living amebae
  - *Entamoeba histolytica* (EH), *Naegleria fowleri* (NF), *Acanthamoeba* (Ac)
  - Primary amebic meningoencephalitis (PAM)
  - Granulomatous amebic encephalitis (GAE)

IMAGING

- EH: Ring-enhancing lesion(s)
- NF: (PAM) enhancing leptomeninges, cisterns (most prominent around olfactory bulbs)
- Ac: (GAE) Ring, linear & superficial gyriform enhancement
- Deep gray matter infarcts in PAM

TOP DIFFERENTIAL DIAGNOSES

- Pyogenic abscess
- Other encephalitides

PATHOLOGY

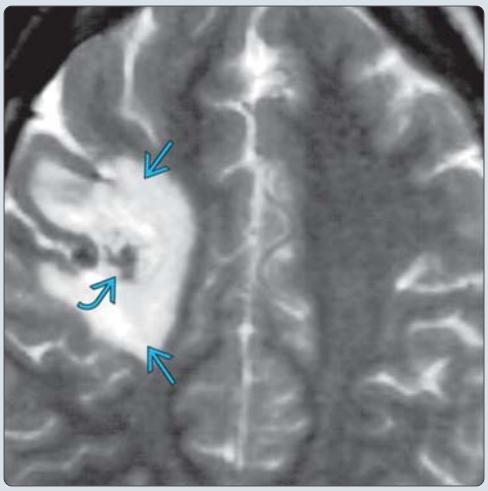
- *E. histolytica*, *N. fowleri*, *Acanthamoeba* frequent
  - *N. fowleri* causes PAM
  - *Acanthamoeba* causes GAE

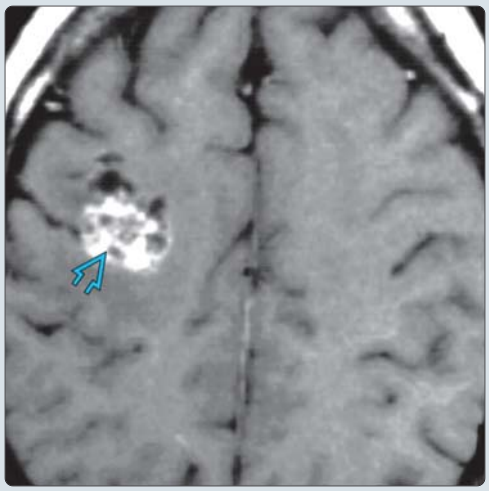
CLINICAL ISSUES

- Endemic to southern USA, South America, Latin America, Southeast Asia, Africa
  - GAE: Patients often debilitated, immunocompromised
  - Ac: Insidious (headache, low-grade fever, seizures)
- Symptoms: Headache, nausea, vomiting, lethargy, seizures

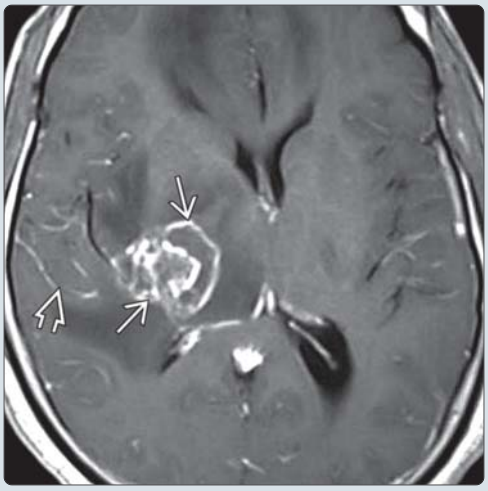
DIAGNOSTIC CHECKLIST

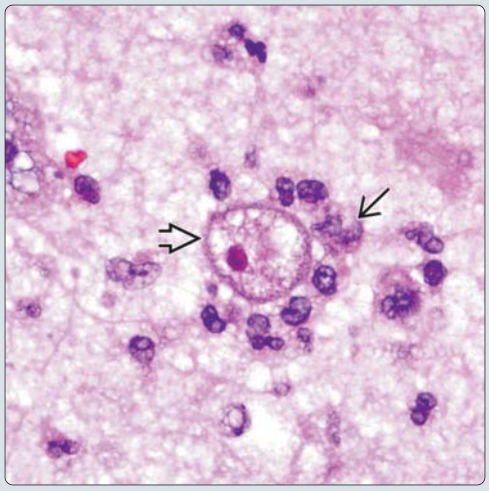
- "Odd-looking" lesion(s); can mimic neoplasm
- Consider amebic infection in setting of meningoencephalitis with travel to endemic areas





(Left) *Axial T2 FS MR in a patient with recent travel to Africa demonstrates a mixed signal intensity mass with significant surrounding edema.* **(Right)** *Axial T1 C+ MR in the same patient shows a lobulated enhancing lesion. Biopsy in this case showed granulomatous amebic encephalitis. This case demonstrates the useful dictum that if a patient comes from an endemic area where parasitic infestations are common, the possibility should be considered when an "odd-looking" intracranial mass is identified on imaging.*





(Left) *Axial T1WI C+ MR shows inhomogeneous ring-like enhancement in a right thalamic mass. Note the leptomeningeal enhancement, consistent with meningoencephalitis.* **(Right)** *Hematoxylin & eosin micropathology obtained from biopsy in this case shows an ameba surrounded by inflammatory cells. Note the complex nucleolus with an eosinophilic rim, pyknotic core. This proves necrotizing amebic meningoencephalitis is caused by free-living forms of Acanthamoeba. (Courtesy R. Hewlett, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- *Entamoeba histolytica* (EH), *Naegleria fowleri* (NF), *Acanthamoeba* (Ac)
- Primary amebic meningoencephalitis (PAM)
- Granulomatous amebic encephalitis (GAE)

Synonyms

- Central nervous system amebiasis

Definitions

- Parasitic infection caused by free-living amebic organisms

IMAGING

General Features

- Best diagnostic clue
  - Meningoencephalitis, ring-enhancing lesion(s) in patients who traveled to endemic areas
- Location
  - EH: Meninges, cortical/deep gray matter
  - NF: (PAM) meninges in region of olfactory bulb, cerebral cortex at base of brain
  - Ac: (GAE) meninges, thalamus, brainstem, cerebral hemispheres

CT Findings

- NECT
  - Hypodense lesion(s) with surrounding edema
    - Cortical, deep gray matter
- CECT
  - Single/multiple ring-enhancing lesions
  - Gyriform, leptomeningeal enhancement (PAM)

MR Findings

- T1WI
  - Hypointense edema, focal lesions
- T2WI
  - EH: Hyperintense lesions with edema
  - PAM: Ill-defined areas of ↑ T2 signal, mass effect
- FLAIR
  - Meningitis may cause ↑ signal in CSF
- T2* GRE
  - Lesions may show ↓ signal due to hemorrhage
- DWI
  - Deep gray matter infarcts in PAM
- T1WI C+
  - EH: Ring-enhancing lesion(s)
  - NF: (PAM) enhancing leptomeninges, cisterns (most prominent around olfactory bulbs)
  - Ac: (GAE) ring, linear & superficial gyriform enhancement

DIFFERENTIAL DIAGNOSIS

Pyogenic Abscess

- High signal on DWI, low ADC

Other Encephalitides

- Difficult to differentiate

PATHOLOGY

General Features

- Etiology
  - Caused by free-living amebae
  - *E. histolytica*, *N. fowleri*, and *Acanthamoeba* frequent
    - *N. fowleri* causes PAM
    - *Acanthamoeba* causes GAE
- Most are transmitted by fecal-oral contamination
  - EH & Ac by hematogenous dissemination
- NF: Organisms in stagnant freshwater
  - Nasal mucosa → olfactory neuroepithelium → CNS

Gross Pathologic & Surgical Features

- EH: Single/multiple, 2-60 mm in size, central necrosis
- NF: Purulent exudate, hyperemic meninges (region of olfactory bulbs), necrosis frontal/temporal lobes
- Ac: Multifocal hemorrhagic necrosis, edema, abscess

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, nausea, vomiting, lethargy, seizures
  - Ac: Insidious, headache, low-grade fever, seizures

Demographics

- Age
  - EH: 20-40 years; NF in children
- Gender
  - M > F
- Epidemiology
  - Endemic to southern USA, South America, Latin America, southeast Asia, Africa
  - GAE in debilitated/immunocompromised patients

Natural History & Prognosis

- PAM: Rapid progression (fatal if untreated)
- GAE: More insidious, prolonged duration

Treatment

- Surgical intervention, drugs (miconazole, metronidazole, amphotericin B, clotrimazole)

DIAGNOSTIC CHECKLIST

Consider

- Amebic infection in clinical setting of meningoencephalitis with travel to endemic areas

Image Interpretation Pearls

- "Odd-looking" lesion(s); can mimic neoplasm

KEY FACTS

TERMINOLOGY

- Cerebral malaria (CM)
- *Plasmodium*-infected RBCs sequester in cerebral microvasculature → multiple infarcts
  - Only 2% of infected patients develop CM
  - **But** CM most common cause of death from parasitic infection

IMAGING

- Multiple cortical, thalamic infarcts ± hemorrhages
  - Cortex, deep WM, basal ganglia, thalami > cerebellum
  - May show restriction on DWI
  - Diffuse petechial hemorrhages on T2* (GRE/SWI)

TOP DIFFERENTIAL DIAGNOSES

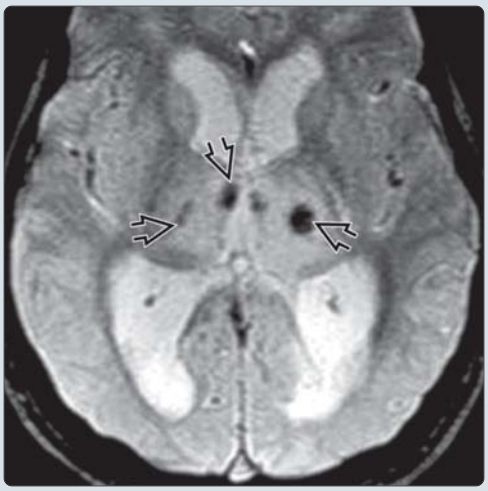
- Multiple cerebral emboli/infarction
- Acute infantile bilateral striatal necrosis

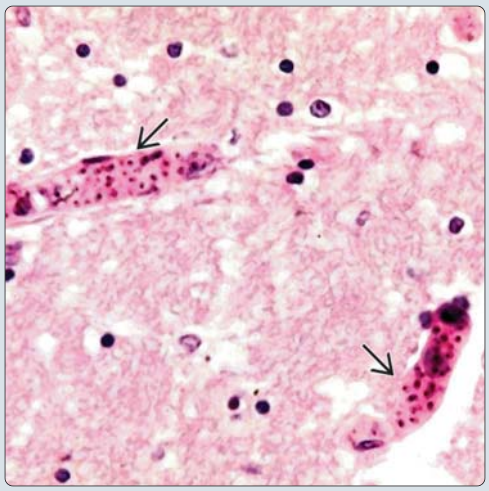
PATHOLOGY

- Malaria caused by 4 species of *Plasmodium*
  - > 95% *P. falciparum, P. vivax*
  - Carrier is *Anopheles* mosquito
- Infected erythrocytes sequestered in microvasculature
  - Vascular occlusions → infarcts ± hemorrhages
- Petechial hemorrhages in cortex, subcortical WM, basal ganglia
- Parasitized RBCs may become ghost-like, contain malaria parasites

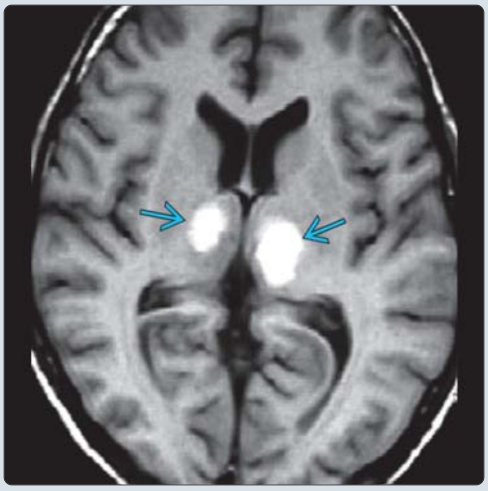
CLINICAL ISSUES

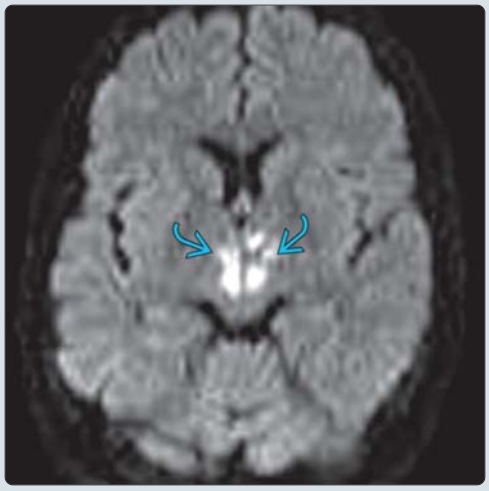
- Usually young children/adults visiting endemic areas
- Incubation period 1-3 weeks
  - Fever, headache
  - Altered sensorium, seizures
- 25-50% mortality despite appropriate therapy
- Sickle cell trait confers some protection





(Left) *Axial T2* GRE MR in a child with known malaria who had altered sensorium, then lapsed into coma, shows hyperintensity in both thalami with numerous hemorrhagic foci. DWI and ADC (not shown) disclosed multiple areas of restriction consistent with infarcts. Autopsy showed bithalamic infarcts. (Courtesy R. Ramakantan, MD.)* **(Right)** *Hematoxylin & eosin in the same patient shows pale-staining ischemic parenchyma and capillary plugging from RBCs containing innumerable parasites. (Courtesy R. Ramakantan, MD.)*





(Left) *Axial T1 MR in a 12 year old with high-grade fever and altered sensorium shows symmetric T1 hyperintensity in the thalami due to hemorrhagic infarcts. Sequestration of infected RBCs in capillaries may cause infarction often with hemorrhagic foci. (Courtesy Anagha K, MD.)* **(Right)** *Axial DWI MR in a patient with cerebral malaria and altered sensorium shows bilateral foci of diffusion restriction indicating acute thalamic infarcts. (Courtesy R. Ramakantan, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Cerebral malaria (CM)

Definitions

- Parasitic infection caused by different species of genus *Plasmodium*

IMAGING

General Features

- Best diagnostic clue
  - Multiple cortical, thalamic infarcts ± hemorrhages in patient with known *Plasmodium* infection
- Location
  - Cortex, deep white matter, basal ganglia, thalami

CT Findings

- NECT
  - Findings vary from normal to striking
    - Diffuse edema
    - Focal infarcts, often multiple
      - Cortex, thalami, basal ganglia
      - White matter, cerebellum

MR Findings

- T1WI
  - Variable hypointensity
- T2WI
  - Focal hyperintensities
    - Bilateral thalami
    - Periventricular WM including corpus callosum splenium
- FLAIR
  - Multifocal hyperintensities in WM, thalami
- T2* GRE
  - Diffuse petechial hemorrhages
- DWI
  - Variable; may show restriction
- T1WI C+
  - Generally none

Imaging Recommendations

- Best imaging tool
  - MR with FLAIR, T2* (GRE/SWI), DWI

DIFFERENTIAL DIAGNOSIS

Multiple Cerebral Emboli/Infarction

- Peripheral (gray-white junction) > > basal ganglia

Acute Infantile Bilateral Striatal Necrosis

- Usually follows respiratory illness, influenza
- Also associated with HHV-6, rotavirus gastroenteritis

PATHOLOGY

General Features

- Etiology
  - Malaria caused by 4 species of *Plasmodium*
    - > 95% *P. falciparum, P. vivax*
    - Less common: *P. malariae, P. ovale*
  - Carrier is *Anopheles* mosquito
    - Inoculates malaria sporozoites
    - Carried via blood stream to liver
    - Penetrate hepatocytes, become merozoites
    - Hepatocytes rupture → merozoites enter blood stream
    - Invade RBCs, become trophozoites then schizonts
  - Infected erythrocytes sequestered in microvasculature
    - Vascular occlusions → infarcts ± hemorrhages

Gross Pathologic & Surgical Features

- Grossly swollen brain
  - Cortex may appear dusky pink (marked congestion) or slate gray (malarial pigment related to hematin)
  - Petechial hemorrhages in cortex, subcortical WM, basal ganglia

Microscopic Features

- Parasitized RBCs may become ghost-like, contain malaria parasites

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Incubation period 1-3 weeks
    - Fever, headache
    - Altered sensorium, seizures
    - Decreased consciousness, coma
- Other signs/symptoms
  - Backache
  - Photophobia, nausea, vomiting

Demographics

- Age
  - Young children, adult visitors to endemic areas
- Ethnicity
  - Sickle cell trait confers some protection
- Epidemiology
  - Only 2% of patients infected by *Plasmodium falciparum* develop CM
  - CM most common cause of death from parasitic infection

Natural History & Prognosis

- 25-50% mortality despite appropriate therapy

DIAGNOSTIC CHECKLIST

Consider

- Malaria in adult with travel to endemic area

KEY FACTS

IMAGING

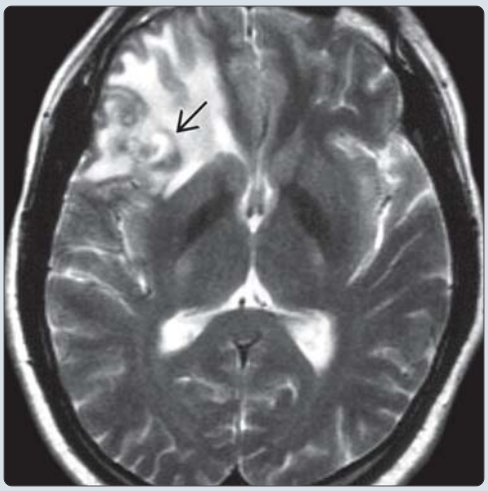
- Enhancing supratentorial mass, may be multiloculated
- Majority of parasitic infections are supratentorial
- **Paragonimiasis**: Acutely may cause hemorrhage or infarct followed by granuloma formation
  - Conglomerated, multiple ring-enhancing lesions
- **Schistosomiasis**: Granulomatous encephalitis, hyperintense mass, enhancing dots
  - Central linear enhancement surrounded by multiple punctate nodules "arborize" appearance
- **Sparganosis**: Conglomerate, multicystic hemispheric mass with surrounding edema
  - May cause "tunnel" sign (worm migration)
  - Conglomerate ring enhancement
- **Trichinosis**: Eosinophilic meningoencephalitis, vascular thrombi, infarcts
- **Trypanosomiasis**: Meningoencephalitis, organisms in PVS → edema, congestion, petechial hemorrhages

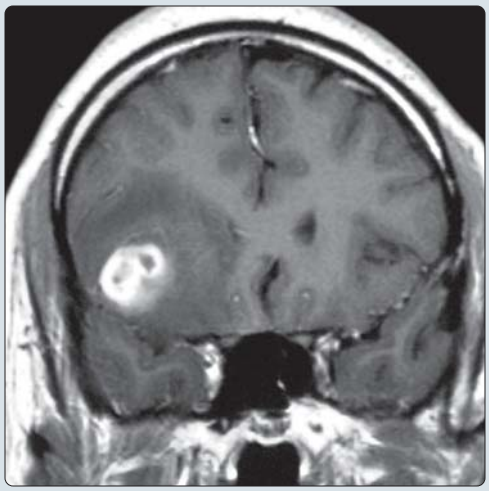
TOP DIFFERENTIAL DIAGNOSES

- Neoplasms (glioblastoma multiforme, metastases)
- Abscess
- Neurocysticercosis
- Neurosarcoid

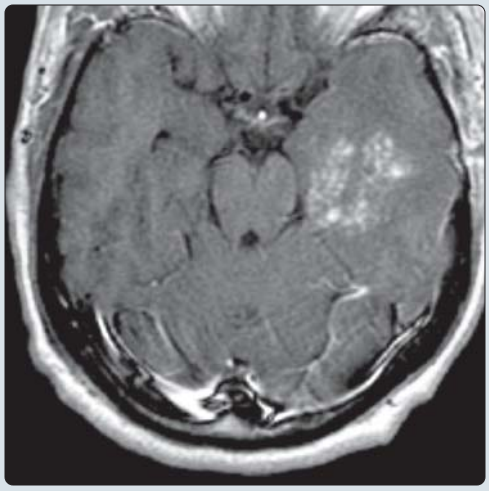
PATHOLOGY

- **Paragonimiasis**: Ingestion of undercooked fresh water crabs or crayfish contaminated with *Paragonimus westermani* flukes (lung fluke)
- **Schistosomiasis**: Infestation from trematode worms
- **Sparganosis**: Ingestion of contaminated water or food (snake, frogs)
- **Trichinosis**: Ingestion of uncooked meat containing infective encysted larvae
- **Trypanosomiasis**: African (tsetse fly) and American (Chagas disease, reduviid bugs)





(Left) *Axial T2WI MR shows a heterogeneous lesion in the right frontal lobe with mass effect and surrounding edema in this patient from east Asia. Note the hypointense rim ⇨, typical of paragonimiasis.* **(Right)** *Coronal T1WI C+ MR in the same patient shows conglomerated, ring-enhancing lesions with marked surrounding edema. Paragonimiasis may acutely cause hemorrhage or infarct followed by granuloma formation. Imaging mimics a neoplasm. Chronically, calcifications and atrophy will develop.*



(Left) *Axial CECT shows diffuse brain atrophy with ventriculomegaly and basal ganglia hyperdensity ⇨ in this patient with a remote history of paragonimiasis. Acutely, these parasites may cause brain infarction.* **(Right)** *Axial T1WI C+ MR shows patchy, nodular enhancement in the left temporal lobe. The enhancement has a mildly arborized appearance, characteristic of schistosomiasis. This parasite often causes a granulomatous encephalitis and presents as encephalopathy or seizures.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Rare parasitic infection affecting CNS
- Includes paragonimiasis, schistosomiasis, sparganosis, trichinosis, trypanosomiasis

IMAGING

General Features

- Best diagnostic clue
  - Enhancing supratentorial mass, may be multiloculated
- Location
  - Majority of parasitic infections are supratentorial
  - **Paragonimiasis**: Hemispheric, commonly posterior
  - **Schistosomiasis**: Cerebrum, cerebellum, brainstem, choroid plexus
  - **Sparganosis**: Cerebral white matter, basal ganglia, insula, and cerebellum
  - **Trichinosis:** Cerebral cortex and white matter (WM)
  - **Trypanosomiasis:** Periventricular white matter, corpus callosum, cerebral peduncles, cerebellum
- Morphology
  - **Paragonimiasis**: Acutely may cause hemorrhage or infarct followed by granuloma formation
    - In chronic stage, round and ovoid Ca++ in mass
  - **Schistosomiasis**: Granulomatous encephalitis, hyperintense mass, enhancing dots
  - **Sparganosis**: Conglomerate, multicystic mass with surrounding edema
    - May cause "tunnel" sign related to worm migration
  - **Trichinosis**: Eosinophilic meningoencephalitis, vascular thrombi, infarcts
  - **Trypanosomiasis**: Meningoencephalitis, organisms in perivascular spaces (PVS) cause brain edema, congestion, petechial hemorrhages

CT Findings

- NECT
  - **Paragonimiasis**: Multiple conglomerated granulomas, ± hemorrhage
    - Multiple round or oval calcifications, surrounding low density, cortical atrophy, ventriculomegaly
  - **Schistosomiasis**: Single or multiple hyperdense lesion(s) with edema, mass effect
  - **Sparganosis**: Conglomerate, multicystic mass with surrounding edema
    - Typically unilateral, hemispheric
    - Atrophy, calcification,ventricular dilatation in chronic cases
  - **Trichinosis**: Hypodense white matter lesions, cortical infarcts
  - **Trypanosomiasis**: Edema with scattered petechial hemorrhage
- CECT
  - **Paragonimiasis**: Ring enhancement
  - **Trichinosis**: Multiple microinfarcts with ring enhancement

MR Findings

- T2WI
  - **Paragonimiasis**: Heterogeneous mass with surrounding edema, ± hemorrhage
    - May have isointense or hypointense rim
  - **Schistosomiasis**: Hyperintense mass with surrounding edema
  - **Sparganosis**: Conglomerate, multicystic mass with surrounding edema, ± hemorrhage
    - May see mixed-signal lesion, central low signal and peripheral high signal
    - Unilateral white matter degeneration, cortical atrophy in chronic cases
  - **Trichinosis**: Multiple hyperintense microinfarcts
    - Border zones of major vascular territories, periventricular white matter and corpus callosum
  - **Trypanosomiasis**: Multiple hyperintense lesions
    - Corpus callosum, periventricular white matter, subcortical regions, deep gray matter
- T1WI C+
  - **Paragonimiasis**: Conglomerated multiple ring-enhancing lesions
    - "Grape cluster" or "soap bubble" forms of enhancement
    - Chronic: Atrophy and calcification
  - **Schistosomiasis**: Central linear enhancement surrounded by multiple punctate nodules "**arborized**" appearance
  - **Sparganosis**: Variable; pattern may change on follow-up related to worm migration
    - **"Tunnel" sign**: Peripherally enhancing hollow tube
    - Conglomerate ring or bead-shaped enhancement
  - **Trichinosis**: Multiple microinfarcts with ring enhancement
  - **Trypanosomiasis**: Nodular or annular enhancement seen in American trypanosomiasis

Imaging Recommendations

- Best imaging tool
  - Contrast MR is most sensitive for detection
  - CT may be helpful to identify associated Ca++
- Protocol advice
  - Contrast-enhanced MR

DIFFERENTIAL DIAGNOSIS

Glioblastoma Multiforme

- Thick, irregular margin enhancement with central necrosis typical
- Often involves corpus callosum
- Typically in older adult

Parenchymal Metastases

- Enhancing mass at corticomedullary junctions
- Multiple lesions common
- Primary tumor often known

Abscess

- T2-hypointense rim and DWI(+) typical
- Ring enhancement, thinner on ventricular margin

Neurocysticercosis

- Cyst with marginal scolex
- Multiple lesions common

https://CafePezeshki.IR

Neurosarcoid

- Enhancing lesions involving dura, leptomeninges, and subarachnoid space
- Rarely affects brain parenchyma
  - Hypothalamus > brainstem > cerebral hemispheres > cerebellar hemispheres

Arachnoid Cyst

- Nonenhancing solitary lesion with CSF density/intensity
- Anterior middle cranial fossa most commonly

PATHOLOGY

General Features

- Etiology
  - **Paragonimiasis**: Ingestion of undercooked fresh water crabs or crayfish contaminated with *Paragonimus westermani* flukes (lung fluke)
    - Worms penetrate skull base foramina and meninges and directly invade brain parenchyma
    - Elicits granulomatous inflammatory reaction
  - **Schistosomiasis**: Infestation from trematode (fluke) worms
    - Host is freshwater snail
    - Releases *Schistosoma* larvae (cercariae) into water
    - Humans affected through skin
    - Migrate to lungs and liver, reach venous system
  - **Sparganosis**: Ingestion of contaminated water or food (snake, fish, frogs)
    - Larvae migrate through skull base foramina to reach brain
  - **Trichinosis**: Ingestion of uncooked meat containing infective encysted larvae
  - **Trypanosomiasis**: African (sleeping sickness) and American (Chagas disease)
    - African: Transmitted to humans by tsetse fly; invade meninges, subarachnoid, PVS
    - American: Transmitted by reduviid bugs

Gross Pathologic & Surgical Features

- **Paragonimiasis**: Cystic lesions elaborate toxins that result in infarction,hemorrhage, meningitis, adhesions
- **Schistosomiasis**: Granulomatous encephalitis, eggs seen at microscopy
- **Sparganosis**: Live worm or degenerated worm with surrounding granuloma found at surgery
- **Trichinosis**: Eosinophilic meningoencephalitis, ischemic lesions, petechial hemorrhage, necrosis
- **Trypanosomiasis**: Edema, congestion, hemorrhage

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - **Paragonimiasis**: Headache, focal neurologic deficit
  - **Schistosomiasis**: Encephalopathy, seizures, paresis, headache, visual changes
  - **Sparganosis**: Headache, seizure, neurologic signs
  - **Trichinosis**: Fever, headache, delirium, seizures, focal neurologic deficits
  - **African trypanosomiasis**: Behavior change, indifference, daytime somnolence
  - **American trypanosomiasis**: Acute (fever, swollen face, conjunctivitis), chronic (neurologic)
- Clinical profile
  - Varies with organism, development stage, host immune response
  - ELISA studies can be helpful in some diseases

Demographics

- Age
  - Most parasitic infections occur at all ages, but commonly affect children and young adults
- Gender
  - Most parasitic infections have male predominance
- Epidemiology
  - Neurocysticercosis most common parasitic infection worldwide
  - Increased travel, immigration have spread diseases
  - **Paragonimiasis**: Brain involvement in 2-27% of cases
    - Endemic to East and Southeast Asia including Korea, China, and Japan
  - **Schistosomiasis**: 2% of cases have CNS complications
    - Endemic to tropical Africa, northeastern South America, and Caribbean islands
  - **Sparganosis**: Extremely rare
    - High incidence in Southeast Asia, Japan, China, and Korea
  - **Trichinosis**: CNS involvement in 10-24% of cases

Natural History & Prognosis

- Some parasitic infections (e.g., echinococcosis) develop slowly over many years
- **Schistosomiasis**: Anthelmintic treatment improves patient condition within 6 weeks with complete resolution within 6 months
- **Trichinosis**: Mortality in 5-10% of affected individuals
- **American trypanosomiasis**: Mortality in 2-10% of meningoencephalitis patients

Treatment

- Variable, ranges from oral therapy to lesion resection

DIAGNOSTIC CHECKLIST

Consider

- Complex conglomerated parasitic cysts of any etiology may mimic brain tumor
- Patient travel history is often key to diagnosis

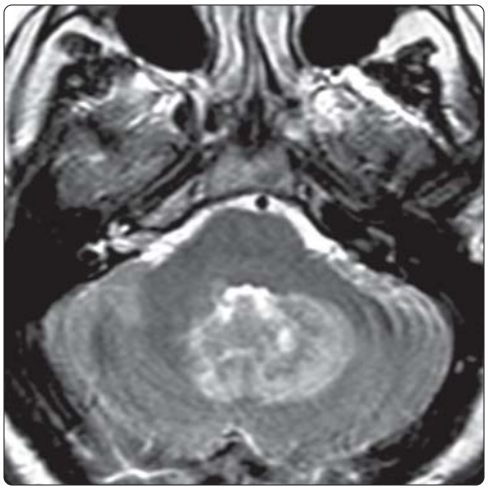
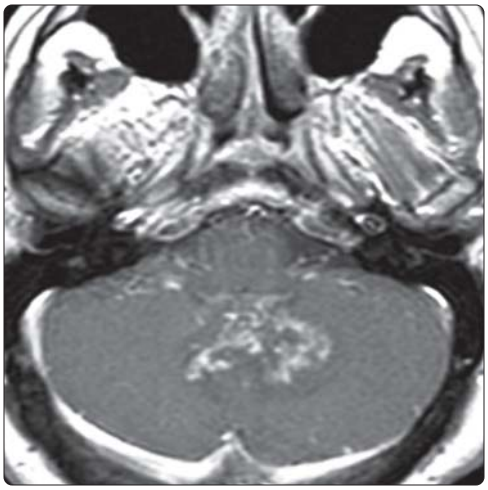
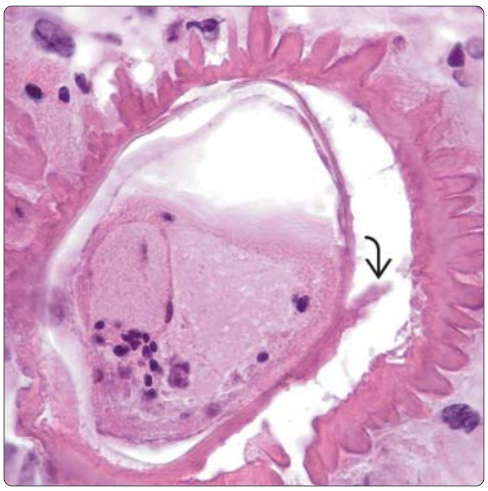
(Left) *Axial T2WI MR shows multiple round hyperintense lesions scattered in the hemispheres and right brainstem ➡. Some of the lesions have mixed signal with hypointense foci or a hypointense rim ➡.* **(Right)** *Axial T1WI C+ MR in the same patient with sparganosis shows ring enhancement of the lesions. Imaging mimics other parasites, including the much more common neurocysticercosis. Sparganosis is extremely rare and is related to ingestion of contaminated water or food. (Courtesy M. Castillo, MD.)*





(Left) *Axial T2WI MR shows hyperintensity in the cerebellum related to edema in this young adult male with schistosomiasis.* **(Right)** *Axial T1WI C+ MR in the same patient shows patchy, mildly nodular enhancement in the cerebellum with surrounding edema. Imaging mimics granulomatous disease or neoplasm. Schistosomiasis often has central linear enhancement surrounded by multiple punctate nodules, causing an arborized appearance.*



(Left) *Coronal T1WI C+ MR shows irregular punctate and nodular enhancement in the posterior fossa related to schistosomiasis. Schistosomiasis most commonly affects the cerebral hemispheres or the cerebellum.* **(Right)** *Microscopic pathology in the same patient shows a Schistosomiasis mansoni egg with a characteristic lateral spine ➡. Schistosomiasis infection is related to infestation from a trematode (fluke) worm and is very uncommon. (Courtesy D. Kremens MD., S. Galetta, MD.)*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Coccidioidomycosis, histoplasmosis (common)
- Invasive fungal infection (immunocompromised)
  - Candidiasis (common)
  - Aspergillus, mucormycosis are angioinvasive

IMAGING

- General features
  - Meningeal enhancement
  - Ring-enhancing brain lesions
  - Infarctions (both lacunar, territorial)
  - Diffuse brain edema, herniation, hydrocephalus
  - Hemorrhage(s)
  - Vasculitis, occlusions, mycotic aneurysms

TOP DIFFERENTIAL DIAGNOSES

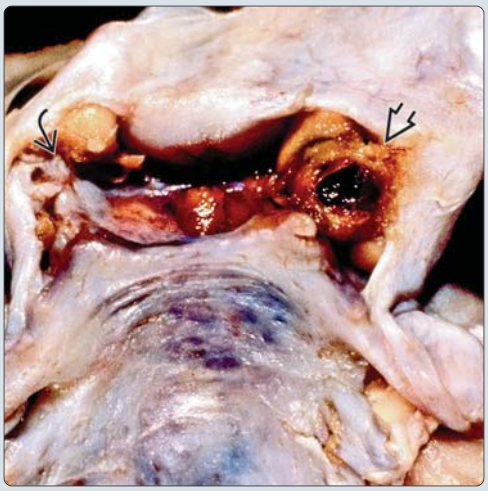
- Invasive skull base neoplasm (e.g., SCCa)
  - Fungus often angioinvasive → ICA occlusion
  - Vessel occlusion rare in SCCa
- Ring-enhancing lesions (immunocompetent)
  - Metastases, pyogenic abscesses, septic emboli
- Ring-enhancing lesions (immunocompromised)
  - TB, toxoplasmosis, lymphoma

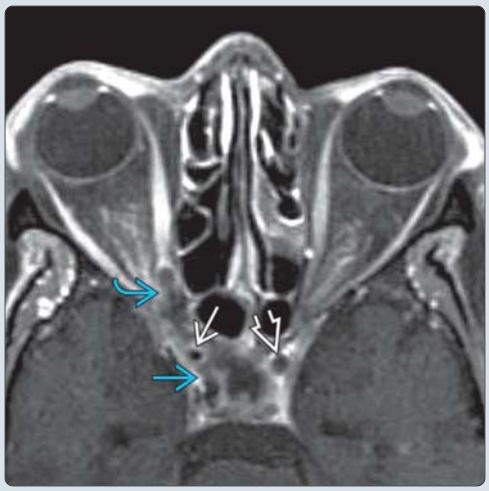
PATHOLOGY

- General
  - Congested meninges, swollen brain
  - Focal granulomas, abscesses
- Angioinvasive fungi
  - Vasculitis, infarcts
  - Hemorrhages, mycotic aneurysm

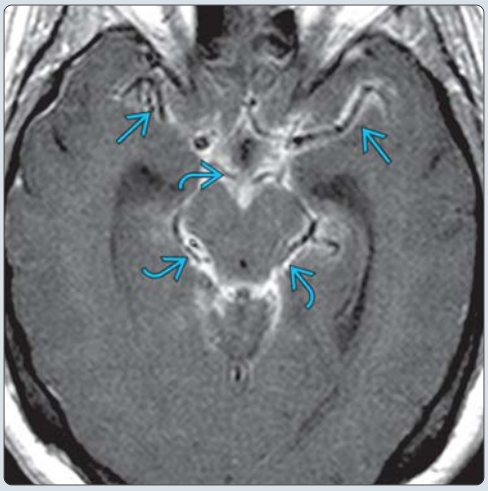
DIAGNOSTIC CHECKLIST

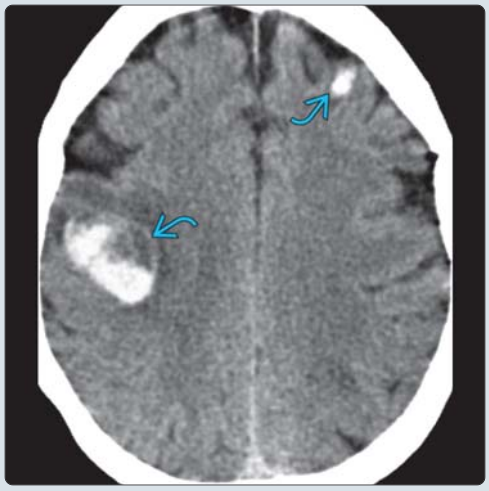
- Consider fungus in immunocompromised when
  - Acute neurologic deficit
  - Multiple brain lesions
  - Stroke, vascular occlusion





(Left) *Autopsy specimen shows aspergillosis invading the paranasal sinuses and skull base. One internal carotid artery is encased by fungus ⇨ while the other has been occluded ⇨. (Courtesy R. Hewlett, MD.)* **(Right)** *Axial T1+ C MR in a diabetic patient with invasive mucormycosis demonstrates necrotic soft tissue in the superior orbital fissure ⇨ with extension to cavernous sinus ⇨. Note narrowing of the right internal carotid artery ➡ with normal left internal carotid artery ➡.*





(Left) *Axial T1 C+ MR in a patient with coccidioidomycosis meningitis demonstrates extensive leptomeningeal enhancement in the basal cisterns ⇨ and sylvian fissures ⇨. Meningitis is the most common presentation of coccidioidomycosis.* **(Right)** *Axial NECT in an immunosuppressed patient shows multifocal parenchymal hemorrhages ⇨ at the gray-white matter interface. Hemorrhagic mycetomas from angioinvasive aspergillosis were documented at surgery.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Coccidioidomycosis
  - Sporadic, relatively common
- Histoplasmosis
  - Common
- Blastomycosis
  - Rare, sporadic, generally affects lungs/skin
- Invasive CNS fungal infections
  - Patients usually immunocompromised
  - Agents
    - Hyphae: Aspergillosis, mucormycosis
    - Pseudo-hyphae/yeast: Candidiasis

IMAGING

General Features

- Best diagnostic clue
  - Meningeal enhancement, enhancing lesions in brain in immunosuppressed patient
  - Coccidioidomycosis: Meningitis
  - Blastomycosis and histoplasmosis: Rare infections with parenchymal abscesses or meningitis
  - Angioinvasive aspergillosis: Multifocal hemorrhagic lesions with reduced diffusion
  - Mucormycosis: Frontal lobe lesions with markedly reduced diffusion
  - Candidiasis: Numerous microabscesses < 3 mm at corticomedullary junction, basal ganglia, or cerebellum
- Location
  - Meninges, brain, spinal cord
- Size
  - Variable (mm to cm)
- Morphology
  - Many lesions are ring-like

CT Findings

- NECT
  - Areas of low density = infection, lacunar infarctions, territorial infarcts
  - Diffuse brain edema, herniation, hydrocephalus
  - Hemorrhages
- CECT
  - Foci of enhancement, some ring-like

MR Findings

- T1WI
  - Ill-defined areas of low signal intensity
- T2WI
  - Focal or diffuse areas of high signal intensity
  - May have peripheral hypointense rim
  - Fungal abscess characteristic feature: Intracavitary projections
- T2* GRE
  - Blooming due to blood products
- DWI
  - May have restricted diffusion
  - Fungal abscess: Wall and intracavitary projections show restricted diffusion with ↓ ADC, cavity of abscess may show ↑ ADC
- T1WI C+
  - Thick meningeal enhancement
  - Cerebral enhancement may be ring-like, solitary to miliary
  - Fungal abscess: Intracavitary projections do not enhance
- MRA
  - Vasculitis, occlusions, mycotic aneurysms
- MRS
  - Mildly ↑ Cho, ↓ NAA, ↑ lactate
  - Fungal abscess: ↑ amino acids (valine, leucine, isoleucine), ↑ lactate as well as multiple peaks between 3.6 and 4.0 ppm

Angiographic Findings

- Vasculitis, mycotic aneurysms

Nuclear Medicine Findings

- PET
  - ↓ metabolism and ↓ blood flow to lesions

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Contrast-enhanced MR essential
  - MRS (infection vs. neoplasm)

DIFFERENTIAL DIAGNOSIS

Locally Invasive Skull Base Neoplasm

- e.g., SCCa
- Look for soft tissue mass in nasopharynx
- Fungal infection often angioinvasive with ICA occlusion (extremely rare in SCCa)

Multiple Ring-Enhancing Brain Lesions

- Immunocompetent patients
  - Metastases
  - Pyogenic abscesses
  - Parasites (e.g., neurocysticercosis)
  - Septic emboli
- Immunocompromised patients
  - Tuberculosis
  - Toxoplasmosis
  - Primary CNS lymphoma

PATHOLOGY

General Features

- Etiology
  - Blastomycosis: *B. dermatitidis*
    - Inhalation, may be acquired by pet bites
  - Coccidioidomycosis: *C. immitis*
    - Inhalation, then hematogenous spread
  - Histoplasmosis: *H. capsulatum*
    - Inhalation, then hematogenous spread
  - Candidiasis: *C. albicans*
    - Initially involves gastrointestinal &/or respiratory systems
    - Then spreads hematogenously
  - Aspergillosis: *A. fumigatus*
    - Inhalation of spores, hypersensitivity reaction

https://CafePezeshki.IR

  - Hematogenous dissemination in immunosuppressed
  - Angioinvasive
  - Mucormycosis: Phycomycetes (*Mucor*, *Rhizopus*)
    - Enter via nasopharynx
    - Can be inhaled into lungs
    - Can have rhinocerebral extension
    - Angioinvasive
- Associated abnormalities
  - Histoplasmosis
    - Calcified/cavitating lung lesions
    - Mediastinal nodes
  - Coccidioidomycosis
    - Generally affects lungs

Gross Pathologic & Surgical Features

- All: Congested meninges, swollen brain, focal granulomas, abscesses
- Coccidioidomycosis
  - Involvement of CNS in 30%
  - Meningitis most common
  - Vasculitis (40%), infarcts, hemorrhages
- Candidiasis
  - Hemorrhagic infarcts
  - Abscess, granulomas (may be miliary)

Microscopic Features

- Granulomas or small abscesses
  - Caseous necrosis, giant cells, neutrophils, lymphocytes
- Identification of specific organism needed for diagnosis
- Fibropurulent meningitis → meningeal fibrosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Initially for all
    - Weight loss, fever, malaise, fatigue
  - Meningitis
    - Acute focal neurological deficits from stroke/hemorrhage
- Clinical profile
  - Many fungal infections have associated lung lesions (granulomas, airspace disease) in immunocompetent patients
  - CSF usually shows pleocytosis, ↓ glucose, ↑ protein

Demographics

- Age
  - More common in young and older individuals
  - Seen at any age if immunocompromised
- Gender
  - M > F (more outdoor activities)
- Ethnicity
  - No predilection
- Epidemiology
  - Blastomycosis
    - Fungus lives in damp places, rotting wood
    - Endemic in Africa, USA (Mississippi, Arkansas, Kentucky, Tennessee, Wisconsin)
  - Coccidioidomycosis
    - Fungus lives in damp places, rotting wood
    - Southwestern USA, northern Mexico, South America
    - 60,000-80,000 new cases/year in USA
  - Histoplasmosis
    - Fungus in chicken, pigeon, bat feces
    - Worldwide distribution
    - ~ 25% of USA population infected
    - Disseminated disease usually seen in infancy/childhood, immunosuppression
  - Candidiasis
    - Worldwide distribution
    - Most common nosocomial fungal infection
    - Higher incidence in diabetics, immunocompromised
    - Occasionally seen in immunocompetent individuals
  - Mucormycosis
    - Ubiquitous; found in organic matter, soil
    - Mostly affects immunocompromised
  - Aspergillosis
    - Ubiquitous; found in damp places
    - Mostly affects immunocompromised
    - Occasionally becomes invasive in immunocompetent

Natural History & Prognosis

- Delay in diagnosis and treatment → poor prognosis

Treatment

- Options, risks, complications
  - Survival depends on early diagnosis, prompt initiation of antifungal therapy
    - Amphotericin B in immunocompromised, life-threatening cases
  - Survival depends on management of underlying disease process

DIAGNOSTIC CHECKLIST

Consider

- Consider fungal infection when acute neurologic deficit in immunocompromised patient

Image Interpretation Pearls

- Consider fungal infection with multiple brain lesions in immunocompromised patient
- Consider fungal infection with associated stroke, vascular occlusion

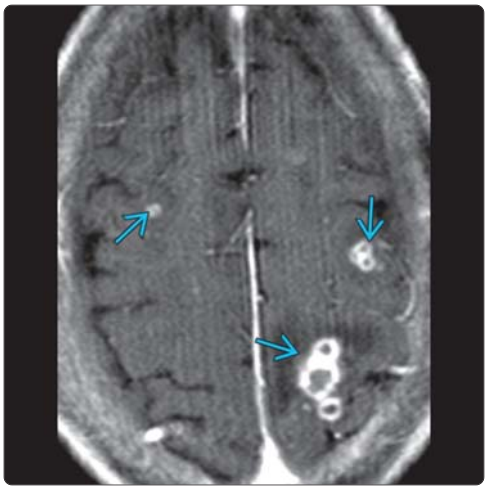
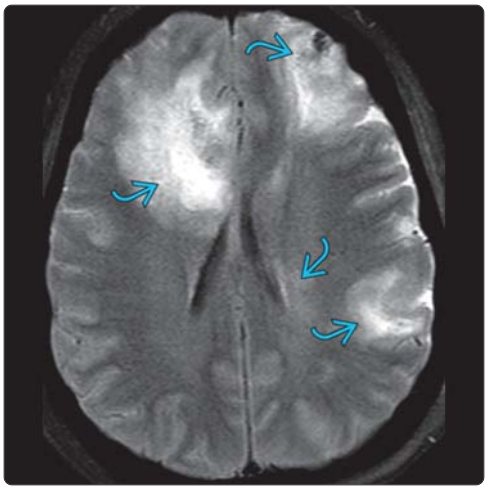
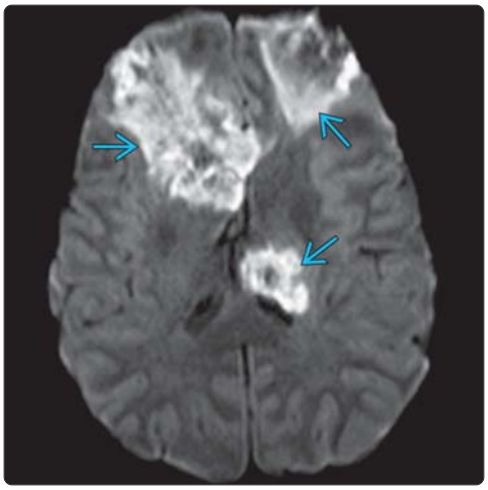
https://CafePezeshki.IR

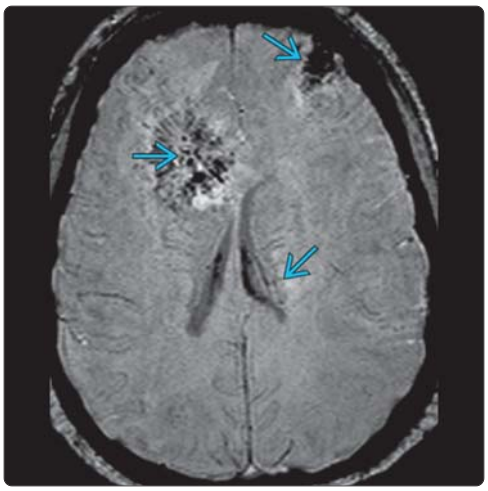


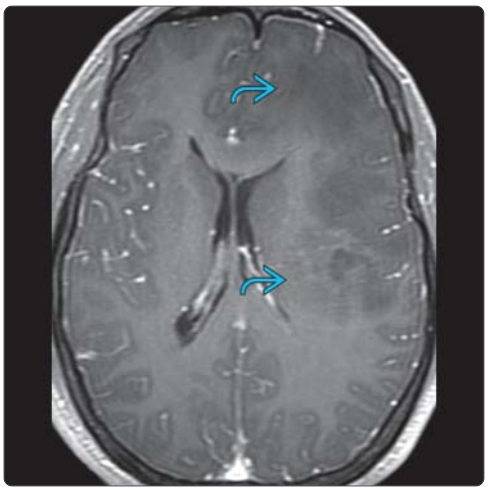
(Left) *Axial CECT in an immunosuppressed patient shows a large, low-density mass in the right frontal lobe and deep basal ganglia with irregular rim enhancement* ⇨ *and surrounding edema* ➡ *with local mass effect. Aspergilloma abscess was found at surgery.* **(Right)** *Axial T1+C MR in a patient with disseminated candidiasis demonstrates multiple small ring enhancing lesions* ⇨*. Candidiasis usually manifests by numerous microabscesses occurring at the corticomedullary junction, basal ganglia, or cerebellum.*





(Left) *Axial FLAIR MR in a patient with ALL status post stem cell transplant demonstrates large hyperintense areas* ⇨ *involving the cortex, subcortical white matter, and basal ganglia. There is mass effect on the lateral ventricles greater on the right.* **(Right)** *Axial DWI in the same patient shows corresponding large areas of restricted diffusion* ⇨ *due to infarction.*





(Left) *Axial SWI MR in the same patient shows multiple punctate "blooming" foci* ⇨ *within the areas of FLAIR signal abnormality consistent with petechial hemorrhages.* **(Right)** *Axial T1+C MR in the same patient does not show any significant enhancement* ⇨*. Angioinvasive mucormycosis was found at surgery. Angioinvasive fungi (Mucor, Aspergillus) produce enzyme elastase which compromises blood vessel wall leading to inflammatory reaction, vasculitis, thrombosis, and eventual infarction.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Rocky Mountain spotted fever (RMS), Q fever, epidemic typhus (ET)
- Zoonotic infections of squirrels and other animals → ticks carrying *Rickettsia* → humans
  - Exception is *Coxiella burnetii* (causes Q fever) transmitted by inhalation

IMAGING

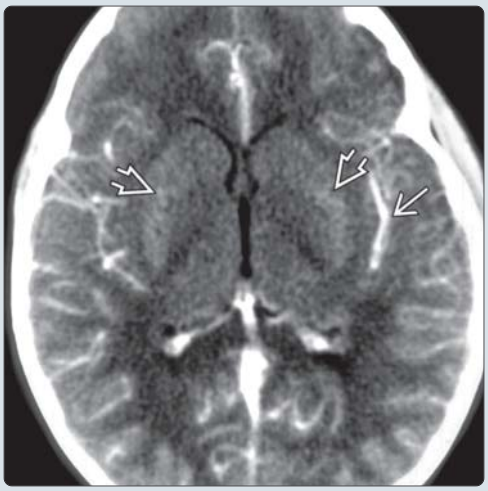
- ~ 20% of patients with RMS have abnormal imaging
  - End artery infarct-like lesions (especially BG)
  - Ill-defined hypodensities on CT
  - T2 hyperintensities in perivascular spaces, deep gray nuclei
  - ± diffuse brain swelling
  - Perivascular lesions, meninges may enhance
- Cauda equina, low spinal cord may be abnormal

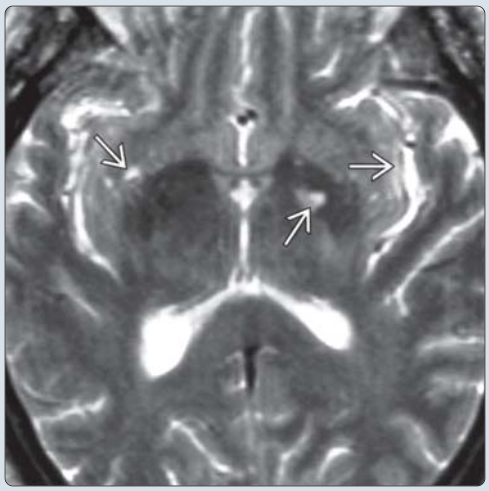
PATHOLOGY

- RMS caused by *Rickettsia rickettsii*
  - Dog or wood tick bite
- ET caused by *Rickettsia prowazekii*
  - Transmitted to humans via the louse
- Q fever caused by *Coxiella burnetii*
  - Transmission from inhalation of dust contaminated with *Coxiella burnetii*

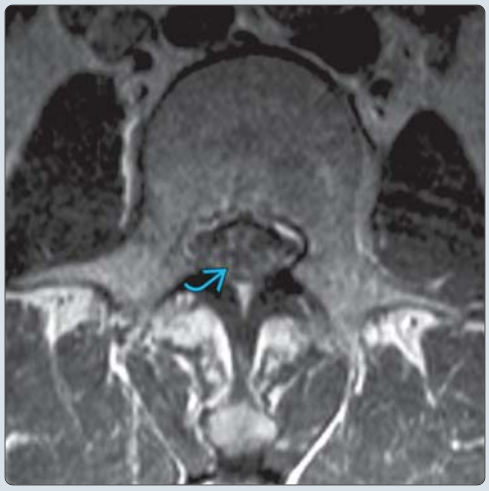
CLINICAL ISSUES

- RMS: Most frequently reported life-threatening tick-borne infection
- RMS: Sudden onset fever, myalgias, headache
  - Petechial rash then develops (palms, soles, then spreads to trunk in 90%)
- RMS can be difficult to diagnose in early stages
- RMS: Mortality 2-10% even under adequate therapy
- Normal MR is favorable prognostic sign





(Left) *Axial CECT in a patient with Rocky Mountain spotted fever shows pial enhancement, especially striking along the left insula. Some faint enhancement in the basal ganglia is present.* **(Right)** *Axial T2WI MR in the same patient shows punctate areas of increased signal intensity in the basal ganglia and subinsular white matter. RMS is caused by Rickettsia rickettsii and transmitted by dog or wood tick bite. Vasculitis is a characteristic appearance on pathology.*



(Left) *Sagittal T1 C+ MR shows enhancement of ventral and dorsal nerve roots in the distal spinal cord and conus medullaris regions.* **(Right)** *Axial T1 C+ MR in the same patient shows the nerve roots enhancing. Rocky Mountain spotted fever (RMS) can involve the brain, spinal cord, and cauda equina. RMS is still the most frequently reported life-threatening tick-borne infection. Mortality ranges from 2-10% even under adequate antibiotic therapy.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Rocky Mountain spotted fever (RMS), Q fever, epidemic typhus (ET)

Definitions

- Zoonotic infections of squirrels and other animals → ticks carrying *Rickettsia* → humans
  - Exception is Q fever (caused by *Coxiella burnetii*) transmitted by inhalation

IMAGING

General Features

- Best diagnostic clue
  - Ill-defined areas of low density on CT, high signal on T2WI along perivascular spaces and deep gray matter
  - Associated skin rash
- Location
  - RMS: Perivascular spaces, meninges, cauda equina, lower spinal cord
  - Q fever: Meninges, cerebellum, spinal cord
- Morphology
  - End artery infarct-like lesions

CT Findings

- NECT
  - Small, ill-defined WM low-density foci
  - Infarct-like lesions in deep gray matter
  - Lesions may have small focal hemorrhages

MR Findings

- T2WI
  - Hyperintense lesions in distribution of perivascular spaces, deep gray nuclei, pons
  - Diffuse brain swelling
- DWI
  - Some lesions show restricted diffusion
- T1WI C+
  - Some lesions and meninges enhance
  - Enhancement in cauda equina nerve roots and lower thoracic spinal cord

Imaging Recommendations

- Best imaging tool
  - MR (only 20% of patients have abnormal MR)
- Protocol advice
  - Brain MR with DWI, T1 C+

DIFFERENTIAL DIAGNOSIS

Cryptococcosis and Lyme Disease

- No associated rash

Vasculitis

- Segmental arterial narrowing on DSA
- Multiple infarcts of different ages on DWI

Sarcoidosis

- Suprasellar region, orbit also frequently involved

PATHOLOGY

General Features

- Etiology
  - RMS caused by *Rickettsia rickettsii*
    - Dog or wood tick bite
    - Spreads via blood stream, proliferates, injures endothelial & vascular smooth muscle cells
  - ET caused by *Rickettsia prowazekii*
    - Transmitted to humans via louse
  - Q fever caused by *Coxiella burnetii*
    - Transmission from inhalation of dust contaminated with *Coxiella burnetii*

Microscopic Features

- RMS: Vasculitis, typhus nodules, perivascular infiltrates
- Confirmation of RMS by histologic examination of skin biopsy

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - RMS: Sudden onset fever, myalgias, headache
    - Petechial rash (90% in palms, soles) develops later
  - Can be difficult to diagnose in early stages
- Clinical profile
  - RMS: Anemia, thrombocytopenia, coagulopathy, abnormal liver function tests, ↑ BUN

Demographics

- Epidemiology
  - RMS: Most frequently reported life-threatening tick-borne infection
  - RMS: 25% of cases in North Carolina, > 50% cases reported in South Atlantic region of USA
  - ET: Typically seen in overcrowded populations living in poor & unsanitary conditions
  - Q fever: Seen around world; occurs mainly in people in contact with goats, sheep, and dairy cattle

Natural History & Prognosis

- RMS: Early antibiotics → effective
  - If not treated → rapidly progressive
- RMS: Mortality 2-10% even under adequate therapy

Treatment

- RMS: Tetracyclines, chloramphenicol

DIAGNOSTIC CHECKLIST

Consider

- Normal MR does not exclude diagnosis but is favorable prognostic sign

SELECTED REFERENCES

KEY FACTS

TERMINOLOGY

- Lyme disease (LD), Lyme neuroborreliosis (LNB)
- Multisystem inflammatory disease
  - Caused by spirochete *Borrelia burgdorferi* (USA)
  - Transmitted by *Ixodes* tick bite
  - Reservoirs = white tail deer/field mouse

IMAGING

- MS-like WM lesions (may enhance)
  - 2-8 mm (large "tumefactive" lesions rare)
- ± multiple enhancing cranial nerves
- ± cauda equina, meningeal enhancement

TOP DIFFERENTIAL DIAGNOSES

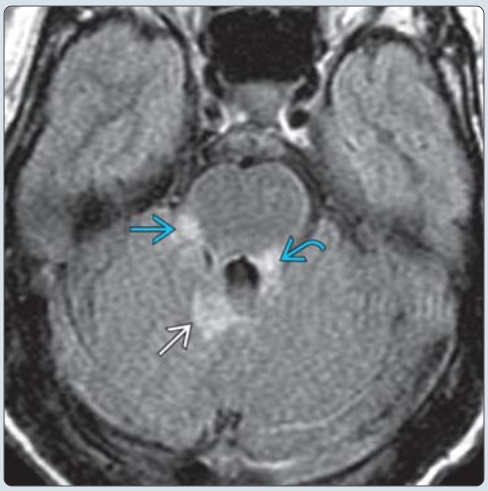
- Demyelinating disease
- Vasculitis
- Sarcoidosis
- Chronic fatigue syndrome

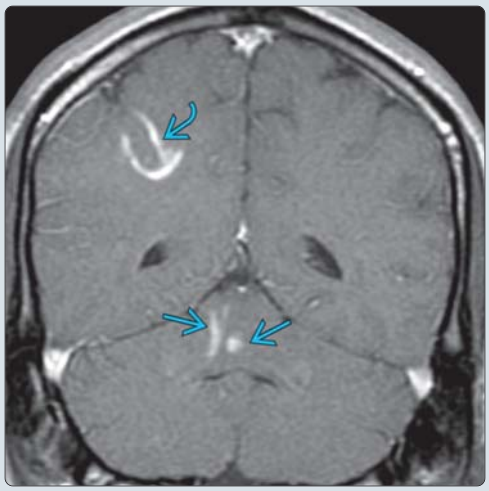
CLINICAL ISSUES

- Most common vector-borne disease in USA
  - Round, bull's-eye skin rash
  - ± flu-like symptoms
  - Meningopolyneuritis, radiculitis common
- Confirm with ELISA, PCR
- Peak incidence: May through July
- Incubation period varies from days to weeks
- Progressive debilitating disorder if not treated early
- 10-15% of untreated patients develop neurologic manifestations

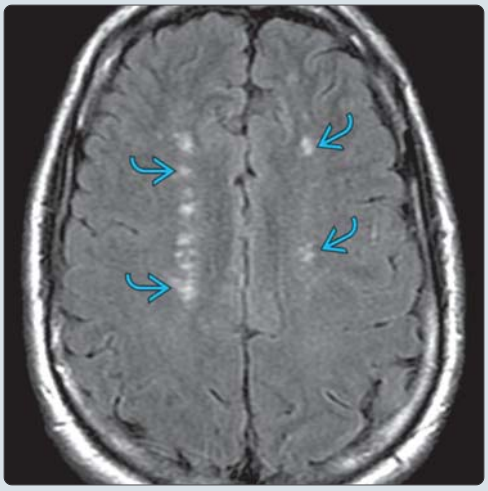
DIAGNOSTIC CHECKLIST

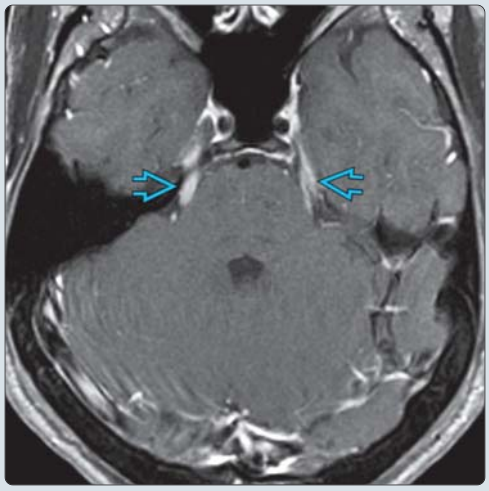
- Consider geography, recreational/travel history, season
- Consider LNB if MS-like lesions in patient with erythema migrans
  - ± enhancing CNs, cauda equina





(Left) *Axial FLAIR MR in a patient with serologically documented Lyme disease shows multiple hyperintense foci in the left superior cerebellar peduncle, right lateral pons, and cerebellum.* **(Right)** *Coronal T1WI C+ MR in the same patient shows enhancement of a right cerebral white matter lesion, as well as posterior fossa lesions. Lyme disease generally manifests as foci of T2 hyperintensities, nerve root, or meningeal enhancement.*





(Left) *Axial FLAIR in a patient with history of tick bite and erythema migrans demonstrates multiple white matter hyperintensities in the deep white matter. WM lesions in Lyme may resemble multiple sclerosis plaques although involvement of callososeptal interface is less common.* **(Right)** *Axial T1 C+ MR in a 24-year-old man with recent history of camping shows enhancement of the cisternal segment of both trigeminal nerves. Third, 5th, and 7th cranial nerve enhancement can be seen in Lyme neuroborreliosis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Lyme disease (LD), Lyme neuroborreliosis (LNB)

Definitions

- Multisystem inflammatory disease
  - Caused by spirochete *Borrelia burgdorferi* (different subspecies in Europe)
  - Transmitted by hard-bodied tick bite

IMAGING

General Features

- Best diagnostic clue
  - Multiple sclerosis-like lesions + cranial neuritis
  - Meningoradiculoneuritis (Bannwarth syndrome) in Europe
- Location
  - Periventricular white matter (WM)
  - Cranial nerves (CN7 > CN3 and CN5)
  - Cauda equina, leptomeninges
- Size
  - 2-8 mm (large "tumefactive" lesions rare)

CT Findings

- NECT
  - Usually normal

MR Findings

- T2WI
  - Hyperintensities in periventricular WM, spinal cord
- DWI
  - Some lesions may show restriction
- T1WI C+
  - Variable enhancement
    - WM lesions/meninges/cauda equina
    - ± cranial nerve enhancement (including CN7 root exit zone, fundal tuft)

Imaging Recommendations

- Protocol advice
  - Brain MR (include T1 C+, DWI)

DIFFERENTIAL DIAGNOSIS

Demyelinating Disease

- WM lesions; lesions in optic nerve, spinal cord, callosal-septal interface more common in MS

Vasculitis

- T2 lesions ± arterial narrowing (DSA)

Sarcoidosis

- Meningeal, perivascular spaces, infundibulum

PATHOLOGY

General Features

- Etiology
  - Spirochete *Borrelia burgdorferi* (USA)
  - Transmitted by hard-bodied ticks of genus *Ixodid*

Microscopic Features

- Perivascular lymphocyte/plasma cell infiltrates
  - Endo-/peri-/epineurial blood vessels
  - Causes endarteritis obliterans
- Axonal degeneration
- Lymphocytes, plasma cells accumulate in autonomic ganglia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Early local: Round, outwardly expanding rash ("bull's-eye")
    - ± flu-like symptoms, lymphadenopathy
  - Early disseminated: Erythema migrans (may develop at sites different from tick bite)
    - Neurologic symptoms: Facial nerve palsy, meningitis, mild encephalitis, memory loss
  - Late disseminated: Brain, nerves, eyes, joints, heart
    - Knee most common joint involved
  - CNS symptoms in about 15-20% of patients with characteristic skin rash
- Clinical profile
  - Confirmation of diagnosis: ELISA, PCR

Demographics

- Epidemiology
  - Most common vector-borne disease in USA
    - US incidence 9.7 cases per 100,000
    - Coastal Northeast states, Midwest & the West
    - Peak incidence: May through July
  - White tail deer/white-footed mouse most important reservoirs

Natural History & Prognosis

- Progressive debilitating disorder if not treated early
- 10-15% of untreated patients develop neurologic manifestations
- Most recover with minimal or no residual deficits

Treatment

- Adults: Doxycycline, tetracycline, chloramphenicol
- Children: Amoxicillin
- Ketolides (new, experimental)

DIAGNOSTIC CHECKLIST

Consider

- Lyme neuroborreliosis if MS-like lesions in patient with erythema migrans
  - ± enhancing CNs, cauda equina
- Geography, recreational/travel history, season of year

SELECTED REFERENCES

1. Hansen K et al: Lyme neuroborreliosis. Handb Clin Neurol. 115:559-75, 2013

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- HIV-1 encephalitis/HIV-1 encephalopathy (HIVE)
- HIV-associated neurocognitive disorders (HAND)
- Moderate cognitive impairment common despite good virologic response to therapy
- Direct HIV infection of brain
  - Opportunistic infections absent
  - Cognitive, behavioral, motor abnormalities in 25-70%
  - Most frequent neurological manifestation of HIV infection

IMAGING

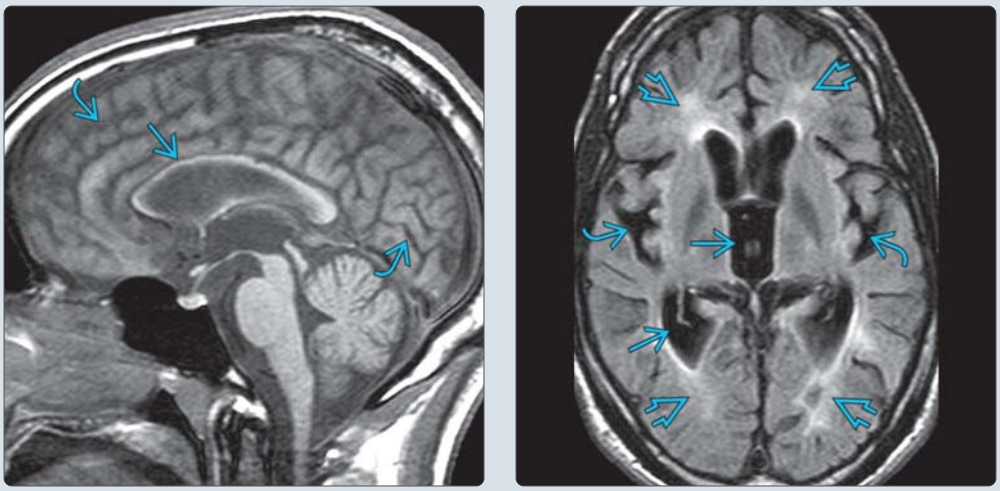
- CT
  - Atrophy
  - Bilateral periventricular/diffuse WM hypointensities
  - Basal ganglia, cerebellum, brainstem hypodensity
- MR
  - Diffuse "hazy" hyperintense WM on T2/FLAIR
  - Nonenhancing (if enhancement present, consider opportunistic infections, IRIS)
- MRS
  - AIDS dementia complex: ↑ myo-inositol, ↑ choline, ↓ N-acetyl aspartate
  - Asymptomatic patients with normal cognition: Mild ↑ myo-inositol

PATHOLOGY

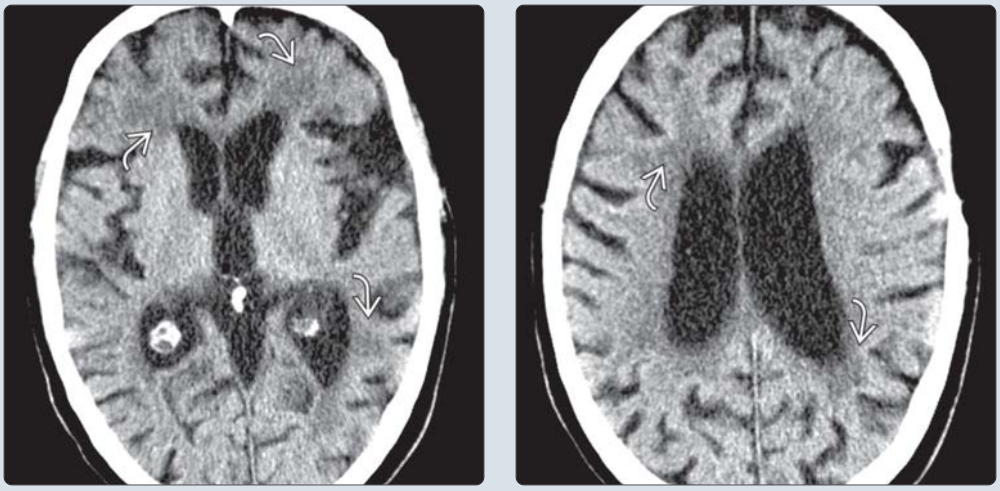
- HIV has ability to cause neurologic disease
  - Does not replicate within neural/glial cells
  - Microglial nodules with multinucleated giant cells
- WM pallor early, neocortical infection/atrophy late

DIAGNOSTIC CHECKLIST

- Evidence of "cerebral atrophy" by CT/MR does not indicate AIDS dementia complex in HIV positive patient
- Consider reversible causes 1st (dehydration, malnutrition, protein depletion, alcoholism)



(Left) *Sagittal T1WI MR in a 35-year-old man with HIV shows generalized atrophy, enlarged sulci, and severe atrophy of the corpus callosum.* **(Right)** *Axial FLAIR MR in the same patient shows enlarged ventricles and sylvian fissures due to diffuse atrophy. There are hazy periventricular white matter hyperintensities. These imaging findings are characteristic of HIV encephalitis.*



(Left) *Axial NECT in a 38-year-old man with longstanding HIV/AIDS, who was receiving HAART, was obtained for decreasing cognitive function. Note the gross atrophy and low density within the subcortical white matter.* **(Right)** *Axial NECT in the same patient shows characteristic low density in the periventricular white matter along with diffusely enlarged sulci and lateral ventricles.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- HIV-1 encephalitis/encephalopathy (HIVE)
- Direct HIV infection of brain
  - Opportunistic infections absent
  - Cognitive, behavioral, motor abnormalities in 25-70%
  - HIV-associated neurocognitive disorders (HAND) = most frequent neurological manifestations of HIV infection
- Moderate cognitive impairment common despite good virologic response to therapy

IMAGING

General Features

- Best diagnostic clue
  - Atrophy + bilateral diffuse white matter (WM) abnormalities
    - Pathology/imaging varies with patient age, acuity of onset
- Location
  - Bilateral periventricular/centrum semiovale WM, basal ganglia, cerebellum, brainstem
- Size
  - Variable, often diffuse
- Morphology
  - Extends to gray-white matter junction

CT Findings

- NECT
  - Children: Atrophy and diffuse WM hypodensity
    - In utero HIV infection: Characteristic bilateral and symmetrical calcifications in basal ganglia and frontal WM with eventual contrast enhancement
  - Adults: Normal or mild atrophy, WM hypodensity
  - No mass effect
- CECT
  - Usually no contrast enhancement

MR Findings

- T1WI
  - WM abnormality may not be evident
- T2WI
  - 2 imaging patterns
    - Focal abnormalities of high signal intensity
    - Diffuse moderate-high signal WM changes
  - Distribution and extent of WM lesions does not always correlate with clinical picture
- FLAIR
  - Same imaging patterns as T2WI
  - Allows early detection of small lesions in cortical/subcortical and deep WM locations
  - Greater overall lesion conspicuity (when compared to T2)
- T1WI C+
  - No enhancement in involved regions
- MRS
  - AIDS dementia complex
    - ↑ myo-inositol, ↑ choline in white matter and basal ganglia
    - ↓ N-acetyl aspartate (NAA) in white matter
  - Asymptomatic patients with normal cognition
    - Mild ↑ myo-inositol in white matter
- 2 major consequences of brain tissue HIV infection
  - Atrophy of brain parenchyma due to neuronal death
  - Alterations of deep WM (usually periventricular regions) → high signal intensity on T2WI
- **Magnetization transfer ratio (MTR)**
  - MTR allows differentiation of HIVE from progressive multifocal leukoencephalopathy (PML)
    - Dramatic ↓ in MTR for PML lesions (as compared to HIVE lesions) likely due to demyelination
- **Diffusion tensor imaging**
  - May show early ↓ fractional anisotropy in HIV-associated cognitive impairment

Imaging Recommendations

- Best imaging tool
  - MR better than CT for WM lesion detection
  - MRS may detect changes in WM even during asymptomatic stage
- Protocol advice
  - CT scan should be performed when
    - New seizure, new onset of headache, depressed, or altered orientation
  - MR scan should be performed when
    - CT shows focal mass

DIFFERENTIAL DIAGNOSIS

Progressive Multifocal Leukoencephalopathy (PML)

- Patchy WM lesions
  - May be unilateral but more often bilateral, asymmetric
  - Parietooccipital locations most common
  - Subcortical U-fibers affected (unlike HIV or CMV)
- No enhancement; if present, consider immune reconstitution inflammatory syndrome (IRIS)

CMV-Associated CNS Disease

- Encephalitis (diffuse WM hyperintensities)
- Ventriculitis (ependymal enhancement)

Herpes Virus Encephalitis

- Herpes simplex virus (HSV), human herpes virus 6 (HHV-6): Initially hippocampal and medial temporal lesions

Toxoplasmosis

- Ring-enhancing mass(es)
- Hyperintense lesions on T2WI/FLAIR, DWI

Primary CNS Lymphoma

- Solitary/multifocal lesions, deep > subcortical lesions
- Marked predilection for basal ganglia, cerebellar hemispheres, thalamus, brainstem, corpus callosum, and subependymal region
- CECT: Usually rim enhancement in HIV positive patients
- Positive thallium-201 SPECT

Cryptococcosis

- "Gelatinous" pseudocysts within perivascular spaces
- Meningoencephalitis ± vasculitis, infarction

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - During primary infection, HIV is transported into brain by monocyte/macrophage system
  - HIV has ability to cause neurologic disease but does not replicate within neural/glial cells
  - Myelin destruction is not typical; T2WI WM hyperintensities may be due to ↑ water content
  - Inflammatory (T-cell) reaction with vasculitis, leptomeningitis
- Genetics
  - HIV genomic → more neurovirulent strains
  - Dementia affects only some patients depending on whether critical mutations occur in HIV strain
- Associated abnormalities
  - HIVE can occur in conjunction with other AIDS-related abnormalities (e.g., other infections)
  - Progressive encephalopathy in children is frequently associated with myelopathy
- Hallmark of HIVE: Microglial nodules with multinucleated giant cells (MGCs)
- Reactive gliosis, focal necrosis, and demyelination
- Mild neuronal loss; minor inflammatory changes
- Viral entry into brain occurs very early after systemic infection

Staging, Grading, & Classification

- 3 types of neuropathological findings
  - Finding 1: HIV encephalitis
    - Multiple disseminated foci of microglia, macrophages, and MGCs; if no MGCs found, HIV antigen/nucleic acids required
  - Finding 2: HIV leukoencephalopathy
    - Diffuse and symmetric WM damage (myelin loss, reactive astrogliosis, macrophages, and MGCs); if no MGCs found, HIV antigen/nucleic acids required
  - Finding 3: HIV giant cells
    - PAS(+) mono- or multinuclear macrophages
- Mild HIVE: Finding 1 without MGCs
- Moderate HIVE: Finding 1, 2, or 3
- Severe HIVE: Cerebral atrophy with finding 1 or 2

Gross Pathologic & Surgical Features

- Early: WM pallor
- Late: Neocortical infection, atrophy

Microscopic Features

- HIVE
  - Infected cells: Mostly macrophages and microglia; few astroglia; rarely oligodendrocytes
  - Neurons undergo secondary damage
  - Minor inflammatory changes: Perivascular macrophage infiltrates and microglial nodules
- Progressive encephalopathy in pediatric AIDS population
  - Inflammatory infiltrates with MGCs
  - Extensive calcific vasculopathy primarily in small vessels of basal ganglia, also cerebral WM and pons
  - Atrophy from impaired development of myelin or myelin loss

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Subcortical dementia with cognitive, motor, and behavioral deficits
- Clinical profile
  - HIV cognitive syndrome: Minor or major (dementia)
  - Deficits of central motor function
  - Behavioral: Pseudodementia (depression), delirium, and confusion
  - Pediatric: Microcephaly, cognitive defects, weakness, pyramidal signs, ataxia, and seizures

Demographics

- Age
  - Both pediatric and adult HIV positive patients
- Gender
  - No preference; gender distribution of HIVE reflects that of HIV infection
- Epidemiology
  - 33-67% of adult AIDS patients and 30-50% of pediatric AIDS patients are affected by HIVE
  - HIVE occurs before opportunistic infections and neoplasms; prevalence unrelated to disease stage

Natural History & Prognosis

- Cognitive decline occurs once patients become immunocompromised
- Slowly progressive impairment of fine motor control, verbal fluency, and short-term memory
- After few months: Severe deterioration and subcortical dementia with near vegetative state as final stage

Treatment

- Highly active antiretroviral therapy (HAART) cannot prevent occurrence of HIVE but ↓ HIVE severity
  - HAART era: ↓ frequency of severe HIVE, but ↑ frequency of mild-moderate HIVE

DIAGNOSTIC CHECKLIST

Consider

- Evidence of "cerebral atrophy" by CT/MR does not indicate AIDS dementia complex in HIV positive patient
  - Consider reversible causes 1st (dehydration, malnutrition, protein depletion, alcoholism)

Image Interpretation Pearls

- Characteristic parenchymal changes often missed by CT, but detected by MR (T2, FLAIR)

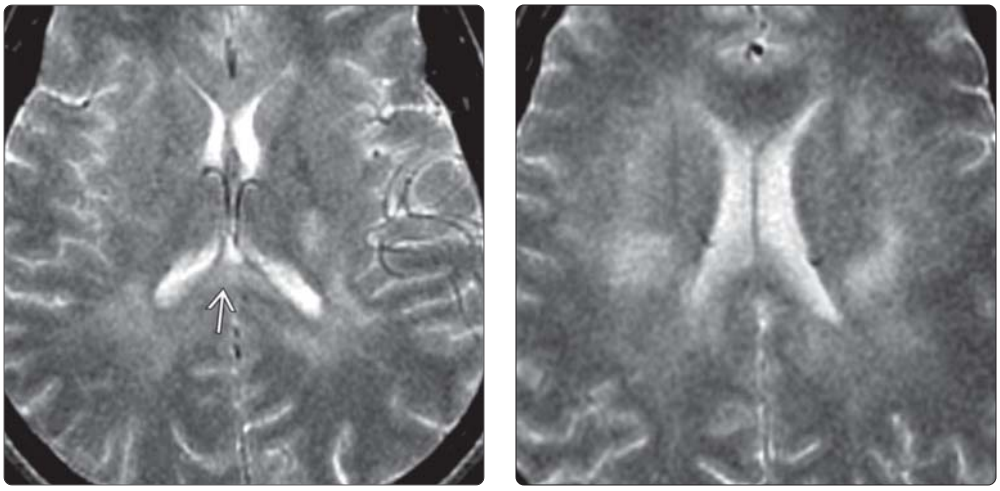
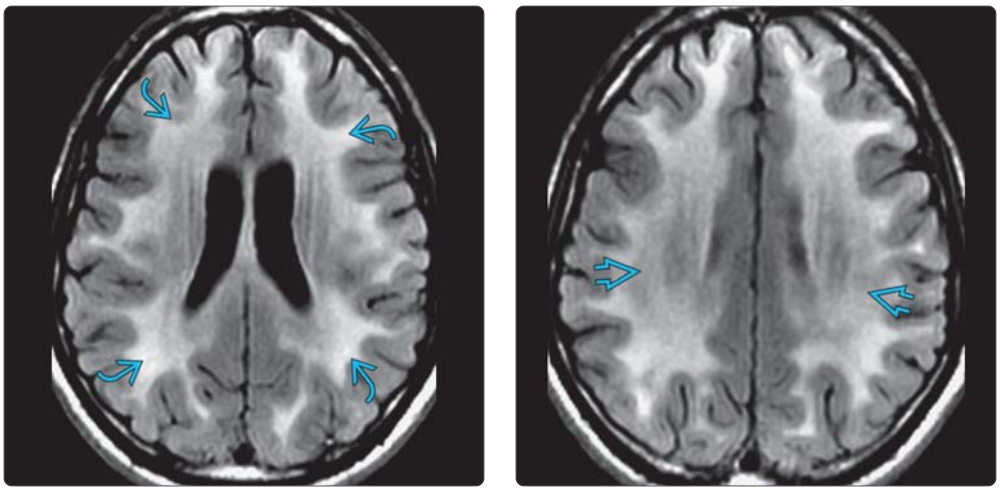
(Left) *Axial T2WI MR in an HIV-positive patient with early signs of subcortical dementia shows a variant appearance. Atrophy is obvious near the vertex with an increase in the CSF spaces around the brain ⇨. HIV encephalitis most commonly presents on imaging as diffuse "hazy" white matter abnormality in association with atrophy. However, occasionally atrophy may be the dominant feature, as in this case.* **(Right)** *FLAIR MR in the same patient reveals mild atrophy without significant white matter disease.*



(Left) *White matter changes may appear in the brains of HIV/AIDS patients before atrophy and dementia ensue, as happened in this 34-year-old HIV-positive man with headaches. The ventricles appear normal, but bilateral "hazy" white matter hyperintensity is present, including abnormality in the corpus callosum ⇨.* **(Right)** *Axial T2WI MR in the same patient shows ill-defined, multifocal, bilateral, asymmetric, "hazy," hyperintense white matter signal intensity.*



(Left) *Axial FLAIR MR in a 25-year-old HIV-positive man who presented with cognitive and behavioral abnormalities demonstrates extensive confluent relatively symmetric white matter hyperintensities ⇨ and mild atrophy.* **(Right)** *Axial FLAIR MR in the same patient shows similar diffuse white matter hyperintensities ⇨. Findings are typical for HIV encephalitis, which does not result in mass effect or enhancement. If either if these findings are present, another diagnosis must be considered.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Opportunistic infection
  - Caused by parasite *Toxoplasma gondii*
  - Most common opportunistic CNS infection in AIDS patients

IMAGING

- CT
  - Ill-defined, hypodense lesions + edema
  - Basal ganglia, corticomedullary junction, thalamus, cerebellum
  - Rim, nodular, target enhancement
- MR
  - T2 hypointense
  - T1 C+ target sign highly suggestive
- Thallium-201 SPECT and 18F-FDG PET: Toxoplasmosis lesions are hypometabolic

TOP DIFFERENTIAL DIAGNOSES

- Lymphoma
  - Solitary mass in patient with HIV/AIDS?
    - Lymphoma > toxoplasmosis
- Other opportunistic infections
  - Cryptococcosis, PML (usually does not enhance)

PATHOLOGY

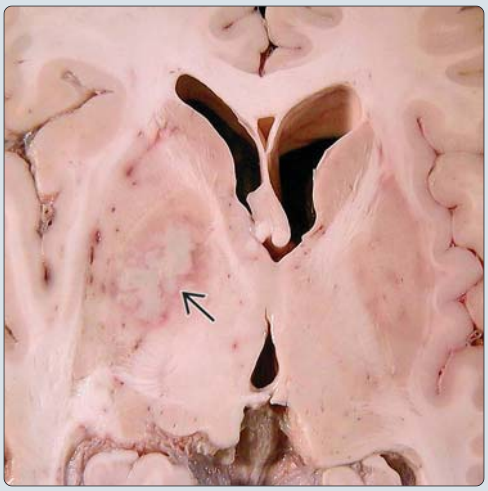
- 20-70% of USA population seropositive for *T. gondii*
  - Usually reactivation of latent infection

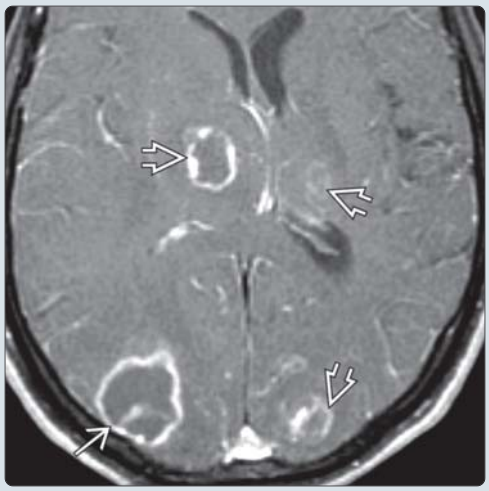
CLINICAL ISSUES

- Fever, malaise, headache

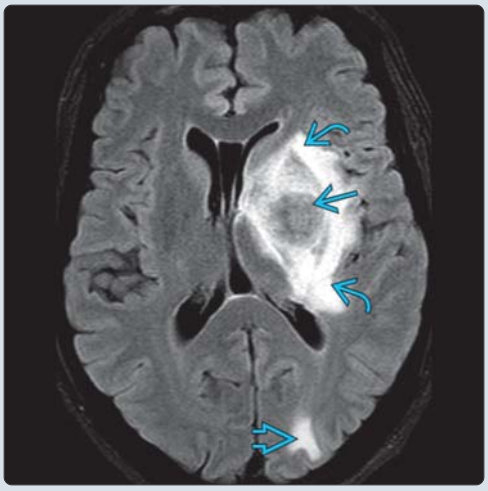
DIAGNOSTIC CHECKLIST

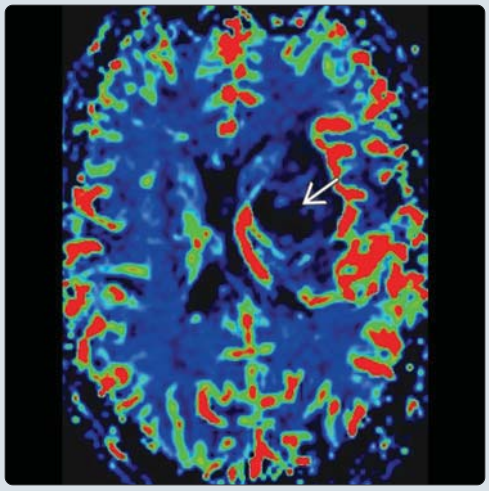
- Multiple target lesions on T1WI C+ that are dark on T2WI?
  - Consider TE
- TE lesions usually resolve in 2-4 weeks





(Left) *Axial gross pathology specimen sectioned through the ventricles in a patient with HIV/AIDS shows a toxoplasmosis abscess in the right lentiform nucleus. The lesion is necrotic and poorly demarcated. (Courtesy R. Hewlett, MD.)* **(Right)** *Axial T1WI C+ MR shows several ring-enhancing lesions in the thalami and left occipital lobe. Note the large lesion showing a classic target appearance. These lesions were hypointense on T2WI.*





(Left) *Axial FLAIR MR in patient with HIV demonstrates a large, hypointense lesion in the left basal ganglia with extensive surrounding edema. Another smaller lesion is seen in the left occipital region. The left basal ganglia lesion showed rim and "target" enhancement on T1WI C+ MR. The most important differential consideration is toxoplasmosis vs. lymphoma.* **(Right)** *Axial CBV map from MR perfusion demonstrates low rCBV suggesting an infection (toxoplasmosis) rather than lymphoma.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Toxoplasmosis encephalitis (TE)

Definitions

- Opportunistic parasitic infection caused by *Toxoplasma gondii*
  - Most common opportunistic CNS infection in patients with AIDS

IMAGING

General Features

- Best diagnostic clue
  - T2-hypointense lesion with peripheral nodular enhancement
- Location
  - Basal ganglia, corticomedullary junction, thalamus, cerebellum most common sites
- Size
  - Variable but generally 2-3 cm in diameter
- Morphology
  - Round or oval

Imaging Recommendations

- Best imaging tool
  - MR for sensitivity; thallium-201-SPECT for specificity
- Protocol advice
  - MR with T2WI, FLAIR, T1 C+ plus DWI, MRS

CT Findings

- NECT
  - Ill-defined, hypodense lesions with edema
- CECT
  - Multiple rim-/nodular-enhancing masses

MR Findings

- T1WI
  - Ill-defined, hypointense lesions
  - Occasionally lesions are hyperintense
    - Not due to hemorrhage or calcification
    - May be coagulative necrosis/proteins
- T2WI
  - Hypointense + hyperintense peripheral edema
  - Edema is often disproportionately larger relative to lesion size
- FLAIR
  - May see target sign
- DWI
  - Increased diffusivity in necrotic centers
- PWI
  - Extremely hypovascular
- T1WI C+
  - Rim, nodular, punctate enhancement
  - Target sign highly suggestive of TE
    - Enhancing nodule within enhancing rim
- MRS
  - Prominent lipid & lactate peaks

Nuclear Medicine Findings

- Thallium-201 SPECT and 18F-FDG PET: Toxoplasmosis lesions are hypometabolic

DIFFERENTIAL DIAGNOSIS

Lymphoma

- Solitary mass in patient with HIV/AIDS?
  - Lymphoma > toxoplasmosis

Other Opportunistic Infections

- Cryptococcosis, PML (usually does not enhance)

PATHOLOGY

General Features

- Etiology
  - 20-70% of USA population seropositive for *T. gondii*
    - Usually reactivation of latent infection
  - Definitive host = cat
    - Any mammal can be carrier (intermediate host)
      - Transmitted to humans primarily by ingestion of cysts

Microscopic Features

- 3 distinct zones in parenchymal toxoplasma lesions
  - Central avascular zone reflecting coagulative necrosis
  - Intermediate zone engorged with blood vessels containing tachyzoites (corresponds to enhancing ring)
  - Peripheral zone with more encysted bradyzoites (corresponds to edema on imaging)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Fever, malaise, headache

Demographics

- Epidemiology
  - CNS TE occurs in 3-10% of AIDS patients in USA
    - 35-50% of AIDS patients in Europe and Africa
  - More common when CD4(+) counts are < 200 cells/μL

Treatment

- Pyrimethamine plus sulfadiazine; trimethoprim sulfamethoxazole is acceptable alternative
- TE lesions usually resolve in 2-4 weeks; lack of resolution suggests another etiology

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Multiple target lesions on T1WI C+; dark on T2WI

Reporting Tips

- Know whether therapy has been administered; if poor response, suggest alternative diagnosis

SELECTED REFERENCES

1. Ho EL et al: Central nervous system diseases due to opportunistic and coinfections. Semin Neurol. 34(1):61-9, 2014

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Acquired CNS cytomegalovirus infections: Meningitis, encephalitis, ventriculitis, transverse myelitis, radiculomyelitis, chorioretinitis
- Immunocompromised (AIDS, organ transplant) patients are at risk → reactivation of previously silent infection

IMAGING

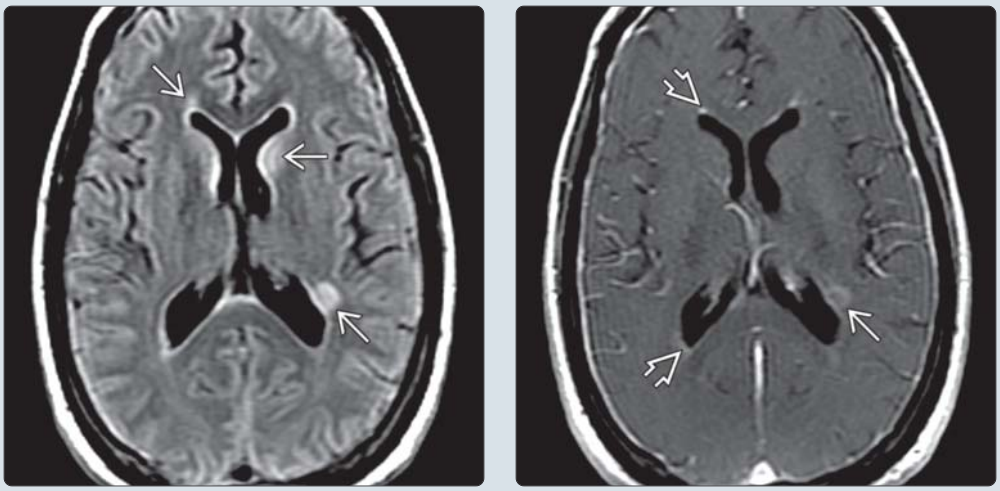
- Best diagnostic clue: Ventriculitis with fluid-debris level and ependymal enhancement in an immunocompromised patient
- Encephalitis: Ill-defined T2-hyperintense area, variable enhancement
- May mimic HIV encephalitis with patchy nonspecific T2-hyperintense lesions
- Contrast should be used for imaging of all immunocompromised patients

TOP DIFFERENTIAL DIAGNOSES

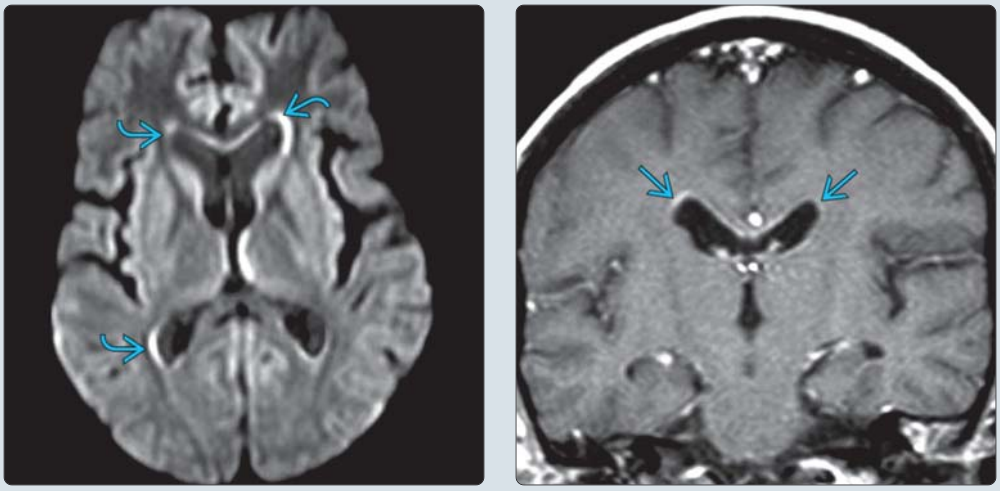
- HIV encephalitis
- PML
- Toxoplasmosis
- ADEM

CLINICAL ISSUES

- Primary CMV infection is generally asymptomatic
- Infection may occur 2° to reactivation of latent viral infection or newly acquired via organ or bone marrow transplant from seropositive donor
  - CMV disseminates to CNS in late stages of HIV infection, low CD4(+) count
  - Clinically may mimic HIV encephalitis
- Disease manifestations vary in severity depending on degree of host immunosuppression
- HAART: Markedly ↓ incidence of CMV disease in AIDS; ↑ immunocompetence against CMV



(Left) *Axial FLAIR MR shows mild ventriculomegaly and periventricular hyperintensities related to ventriculo-encephalitis.* **(Right)** *Axial T1WI C+ MR in the same patient shows ependymal and periventricular enhancement. This patient was immunocompromised, with ventriculitis and associated encephalitis. CMV encephalitis is commonly a ventriculo-encephalitis, involving the periventricular white matter. However, CMV may also cause hemorrhagic or necrotic lesions.*



(Left) *Axial DWI MR in a 35-year-old HIV-positive patient with very low CD4(+) cell count demonstrates thin hyperintense rim along the ventricular margins. There is mild enlargement of the ventricles and mild cortical atrophy.* **(Right)** *Coronal T1WI C+ MR in the same patient shows subtle ependymal enhancement along the frontal horns. Imaging findings are characteristic of CMV ventriculitis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Cytomegalovirus (CMV) infection

Definitions

- Acquired CNS infections: Meningitis, encephalitis, ventriculitis, retinitis, polyradiculopathy, myelitis
- Primary CMV infection: Generally asymptomatic in healthy adults
- Immunocompromised (AIDS, organ transplant) patients at risk → reactivation of previously silent infection

IMAGING

General Features

- Best diagnostic clue
  - Ventriculitis in immunocompromised patient
    - Enlarged ventricles with ependymal enhancement
  - Absent periventricular Ca++ (seen in congenital CMV)
  - Encephalitis may occur, commonly deep periventricular white matter
- Location
  - Ventricles (ependymal and subependymal)
  - Periventricular white matter (WM)
- Morphology: Encephalitis may cause "mass" lesion

Imaging Recommendations

- Best imaging tool: MR with contrast

MR Findings

- T1WI
  - Encephalitis: Ill-defined hypointense area
  - Ventriculitis: Enlarged ventricles with debris level
- T2WI
  - Encephalitis: Ill-defined periventricular hyperintensity
  - Ventriculitis: Enlarged ventricles with surrounding hyperintensity
- FLAIR
  - Encephalitis: Ill-defined periventricular hyperintensity
  - Ventriculitis: Enlarged ventricles with surrounding hyperintensity
  - May cause nonspecific, multifocal, periventricular WM hyperintensity
- T1WI C+
  - Encephalitis: Typically no significant enhancement
    - May become necrotizing with enhancement
  - Ventriculitis: Ependymal and periventricular enhancement
- MRS: Necrotizing encephalitis may show ↑ Cho, ↑ Lac , ↓ NAA
- PWI: Lower rCBV than tumor

DIFFERENTIAL DIAGNOSIS

HIV Encephalitis

- Periventricular patchy WM T2 hyperintensity with atrophy; no enhancement

PML

- T2-hyperintense WM lesions involving subcortical U-fibers; often frontal/parietooccipital
- Subcortical U-fibers > periventricular WM > gray matter

Toxoplasmosis

- Multiple ring-enhancing lesions
- Deep gray nuclei and cerebral hemispheres

ADEM

- Patchy periventricular WM T2 hyperintensities with enhancement; 10-14 days after infection/vaccination

PATHOLOGY

General Features

- Etiology
  - Vast majority of adults are infected with CMV
  - Transmission of CMV chiefly via contact with infected secretions
  - CNS disease primarily in immunosuppressed host
    - Reaches brain hematogenously
- Associated abnormalities
  - HHV-6 reactivation associated with CMV infection in patients post liver transplant
  - JC virus may be transactivated by CMV

Microscopic Features

- Cytomegalic inclusion cell: Enlarged cells with intranuclear inclusions, histologic "owl's eyes"

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - CMV encephalitis: Confusion, gait disturbance, cranial neuropathies, hyperreflexia

Demographics

- Epidemiology
  - Most children acquire CMV infection early in life, with adult seroprevalence approaching 100%
  - CMV disseminates to CNS in late stages of HIV infection, low CD4(+) count
  - Prior to advent of highly active antiretroviral therapy (HAART) for HIV, CMV retinitis was most common cause of blindness in AIDS (> 90%)

Natural History & Prognosis

- Primary infection is generally asymptomatic; acute febrile illness rare, termed CMV mononucleosis
- Infection may occur 2° to reactivation of latent viral infection or be newly acquired via organ or bone marrow transplant (BMT) from seropositive donor

Treatment

- Ganciclovir and other antiviral drugs for severe disease
- HAART: ↓ incidence of CMV disease in AIDS

SELECTED REFERENCES

1. Bilgrami M et al: Neurologic diseases in HIV-infected patients. Handb Clin Neurol. 121:1321-44, 2014

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- *Cryptococcus neoformans* infection
- Opportunistic fungal infection that typically affects HIV and other immunosuppressed patients
- Cryptococci spread along PVS to deep brain: Basal ganglia (BG), thalamus, brainstem, cerebellum, dentate nucleus, periventricular white matter (WM)

IMAGING

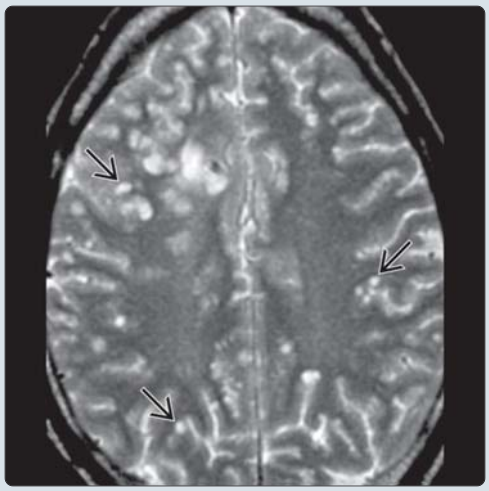
- Dilated perivascular spaces in deep gray nuclei of AIDS patient, often no enhancement
  - Degree of enhancement depends on cell-mediated immunity of host
- May see miliary or leptomeningeal enhancing nodules + gelatinous pseudocysts
- Cryptococcoma: Ring-like or solid enhancement
- Dilated PVS in AIDS patients → consider Cryptococcus infection
- 4 imaging patterns: Miliary enhancing parenchymal nodules, leptomeningeal-cisternal nodules, cryptococcoma, gelatinous pseudocysts

TOP DIFFERENTIAL DIAGNOSES

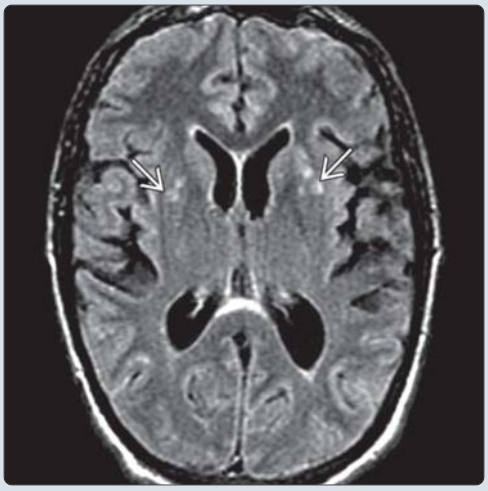
- Acquired toxoplasmosis
- Tuberculosis
- Primary CNS lymphoma

CLINICAL ISSUES

- CNS infection related to hematogenous dissemination from lungs
- Headache most common symptom
- Most common fungal infection in AIDS patients
- 3rd most common infection seen in AIDS patients (HIV > toxoplasmosis > crypto)
- Indian ink test: Highly specific
  - Antigen titers correspond to severity of illness



(Left) *Coronal graphic shows multiple dilated perivascular (Virchow-Robin) spaces ⇨, filled with fungi and mucoid material, resulting in gelatinous pseudocysts which are characteristic of cryptococcal infection in AIDS.* **(Right)** *Axial T2WI MR shows multiple dilated perivascular spaces ⇨ in this immunocompromised patient with cryptococcal meningitis. Gelatinous pseudocysts are most commonly located in the basal ganglia and thalami but may be seen in the brainstem, cerebellum, and cerebral hemispheres.*



(Left) *Axial FLAIR MR shows bilateral dilated perivascular spaces ⇨ with hyperintense rims in this AIDS patient with Cryptococcus meningitis. Hydrocephalus is a common complication of this infection.* **(Right)** *Axial T1WI C+ MR in the same patient shows subependymal enhancement ⇨ along the frontal horns of the lateral ventricles as well as nodular leptomeningeal enhancement ⇨. Enhancement in Cryptococcus infection is dependent on the cell-mediated immunity of the host.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- *Cryptococcus neoformans* infection
- Opportunistic fungal infection that typically affects HIV and other immunocompromised patients
- Pulmonary infection with subsequent transfer of circulating *Cryptococci* into subarachnoid spaces, perivascular spaces = leptomeningitis

IMAGING

General Features

- Best diagnostic clue
  - Dilated perivascular spaces in deep gray nuclei of AIDS patient, no enhancement
  - Degree of enhancement depends on cell-mediated immunity of host
    - Immunocompromised: Typically no enhancement
  - May see leptomeningeal, miliary enhancing nodules or cryptococcomas
- Location
  - Perivascular spaces (PVS)
  - Cryptococci spread along PVS to deep brain: Basal ganglia (BG), thalamus, brainstem, cerebellum, dentate nucleus, white matter (WM)
- Size: 2-3 mm nodules, up to 3-4 cm
- Morphology: Small round or oval-shaped lesions
  - May become confluent and form gelatinous pseudocysts or "soap bubbles"

Imaging Recommendations

- Best imaging tool: Contrast-enhanced MR

CT Findings

- CECT: Often normal
  - Subtle meningeal or miliary enhancement rare

MR Findings

- T2WI: PVS filled with fungi, isointense to CSF
- FLAIR: Multiple bilateral, small, cystic lesions
  - Follow CSF, may see small hyperintense rim
  - May form gelatinous pseudocysts
    - BG, thalamus, brainstem, cerebellum, periventricular and subcortical WM
  - Cryptococcoma: Hyperintense lesion
- T1 C+: Enhancement depends on host immune status
  - No enhancement is typical
  - May see leptomeningeal enhancement
  - Cryptococcoma: Ring-like or solid enhancement
  - Rare: Miliary or leptomeningeal enhancing nodules

DIFFERENTIAL DIAGNOSIS

Acquired Toxoplasmosis

- Multiple ring-enhancing masses + surrounding edema
- Typically BG and cerebral hemispheres

Tuberculosis

- Basal meningitis + parenchymal lesions (tuberculoma)
- Tuberculomas may be T2 hypointense

Primary CNS Lymphoma

- Enhancing lesion(s), often along ependymal surface
- T2-hypointense tumor

Neurosarcoid

- Leptomeningeal enhancement ± dural lesions

Enlarged Perivascular Spaces

- Typical locations, near anterior commissure
- Follow CSF on all MR sequences
- May be indistinguishable

PATHOLOGY

General Features

- Etiology
  - *Cryptococcus* is found in mammal and bird feces
  - In AIDS, CNS infection related to hematogenous dissemination from lungs

Gross Pathologic & Surgical Features

- Gelatinous mucoid material (pseudocysts) in or near prominent PVS in BG, midbrain, WM

Microscopic Features

- Large polysaccharide capsules stain with Indian ink

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache most common
- Other signs/symptoms
  - Seizure, blurred vision, focal neuro deficits (rare)
- Clinical profile
  - Lumbar puncture: ↑ CSF pressure, ↓ glucose, ↑ protein, mild to moderate leucocytosis
  - Indian ink test: Highly specific

Demographics

- Epidemiology
  - 3rd most common infection seen in AIDS patients (HIV > toxoplasmosis > crypto)
    - 10% of AIDS patients have Cryptococcus infection
    - Usually occurs when CD4 counts < 50-100 cells/μL
  - Cryptococcus meningitis > > > cryptococcoma

Treatment

- Antifungal treatment (i.e., amphotericin B)

DIAGNOSTIC CHECKLIST

Consider

- In AIDS patients with dilated PVS

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Progressive multifocal leukoencephalopathy (PML)
- Subacute opportunistic infection caused by DNA virus JC polyomavirus (JCV)
- JC polyomavirus infects oligodendrocytes, causes demyelination in immunocompromised patients
- Associated with immunosuppression, often AIDS
  - Organ transplant, cancer, chemotherapy, myeloproliferative disease, and steroid treatment
  - Reported in treatment for multiple sclerosis (MS) and in rheumatic diseases

IMAGING

- Multifocal T2-hyperintense demyelinating plaques involve subcortical white matter (WM), extend to deep WM; gray matter often spared until late stage
- Characteristic involvement of **subcortical U-fibers**
- Generally no contrast enhancement or mass effect
- Late: Confluent WM disease, cystic changes
- Propensity for frontal and parietooccipital region, thalamus
  - May involve brainstem and cerebellum
- May be solitary, multifocal, or widespread confluent

TOP DIFFERENTIAL DIAGNOSES

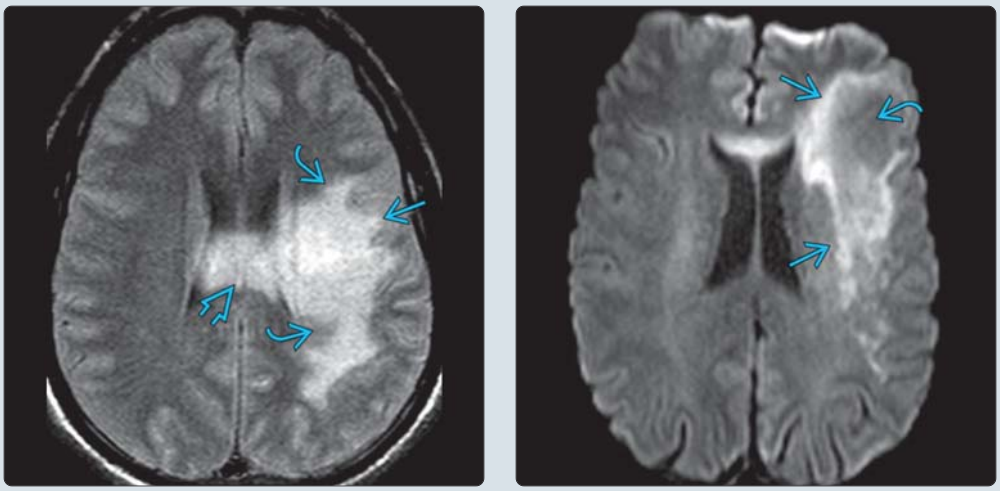
- HIV encephalitis
- ADEM
- Acquired CMV
- Immune reconstitution inflammatory syndrome

CLINICAL ISSUES

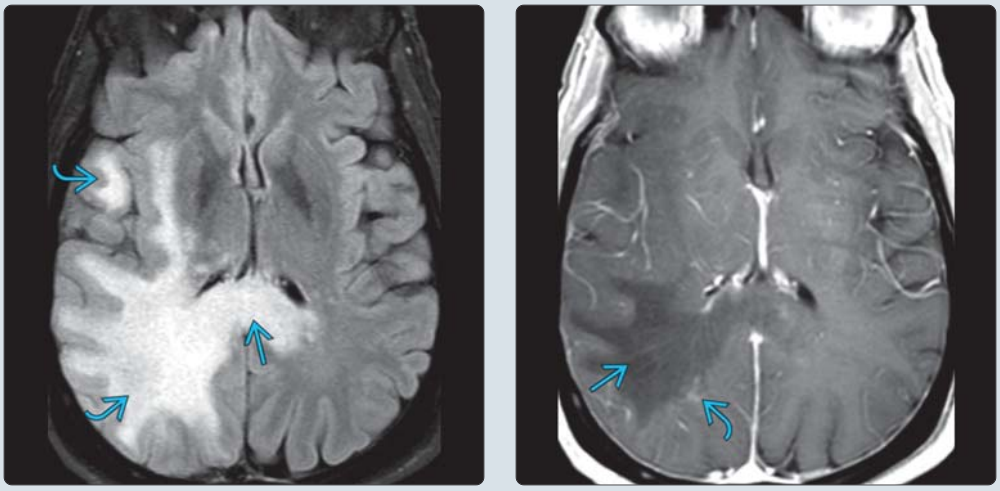
- Without treatment poor prognosis, death in 2.5-4 months
- Highly active antiretrovirus therapy (HAART) reported to improve survival

DIAGNOSTIC CHECKLIST

- If multifocal subcortical white matter lesions without mass effect or enhancement in AIDS patients, consider PML over HIV encephalopathy



(Left) *Axial FLAIR MR in an AIDS patient who was somnolent at presentation shows scalloped hyperintensity in the left frontoparietal white matter. There is involvement of the subcortical U-fibers, characteristic of PML. Note involvement of the corpus callosum, but lack of mass effect.* **(Right)** *Axial DWI in an HIV patient with very low CD4(+) counts and PML demonstrates central core of low signal surrounded by rim of higher signal. Appearance of PML on DWI varies with disease stage.*



(Left) *Axial FLAIR MR in a patient with multiple sclerosis on natalizumab and developed PML demonstrates infiltrating hyperintensity involving the right temporal, parietal, and occipital white matter as well as the splenium.* **(Right)** *Axial T1C+ MR in the same patient shows white matter hypointensity with very faint enhancement at the margins. Monoclonal antibody therapy (like natalizumab) used in a wide spectrum of immunologic diseases may depress the immune system and predispose the patient to PML.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Progressive multifocal leukoencephalopathy (PML)

Definitions

- Subacute opportunistic infection caused by DNA virus JC polyomavirus (JCV)

IMAGING

General Features

- Best diagnostic clue
  - T2-hyperintense, multifocal, demyelinating plaques involve subcortical white matter (WM), extend to deep WM; gray matter often spared until late stage
  - Typically bilateral, but asymmetric; no mass effect or contrast enhancement
  - Late stage: Confluent WM lesions with cavitary changes
- Location
  - Propensity for parietooccipital region, thalamus
  - Cerebellum & brainstem may be involved
- Size
  - Variable, small subcortical lesions to confluent hemispheric lesions
- Morphology
  - May be solitary, multifocal, or widespread hemispheric WM lesions

Imaging Recommendations

- Best imaging tool
  - MR with contrast

MR Findings

- T1WI: Hypointense lesions → aggressive forms and burnt out PML lesions
- T2WI: Hyperintensity predominantly in subcortical and periventricular WM
  - Involves **subcortical U-fibers** → **scalloped** appearance
- FLAIR: Hyperintensity in subcortical and periventricular WM
- DWI: Newer lesion has slightly restricted diffusion along its margins; older lesion is unrestricted
- T1WI C+: Typically no enhancement
  - Faint peripheral enhancement may rarely be seen, typically in patients with long-term survival
  - Increasing enhancement, mass effect & edema attributable to immune reconstitution
- MRS: ↓ NAA; ↑ lactate, Cho, lipids
- Magnetization transfer: ↓ ratio compared to HIV encephalitis

DIFFERENTIAL DIAGNOSIS

HIV Encephalitis

- Atrophy and symmetric periventricular or diffuse WM disease; affects subinsular and peritrigonal WM

Acquired CMV

- May see ventriculitis, encephalitis, retinitis, or polyradiculopathy

Immune Reconstitution Inflammatory Syndrome (IRIS)

- Most often associated with PML (JC virus)

ADEM

- Post-infection/vaccination immune-mediated inflammatory demyelination

PATHOLOGY

General Features

- Etiology
  - By age 65 years, 50-70% of individuals have antibodies to JCV
  - Hematogenous spread of virus from periphery or reactivation of latent brain lesion
  - PML destroys oligodendrocytes

Gross Pathologic & Surgical Features

- Multiple confluent foci of grayish discoloration in white matter or gray-white junction

Microscopic Features

- Demyelination, oligodendroglia with large basophilic inclusion
- Bizarre reactive astrocytes with hyperchromatic nuclei resembling neoplastic cells

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Altered mental status, progressive neurological symptoms, headache, lethargy

Demographics

- Epidemiology
  - AIDS, organ transplantation, cancer patients undergoing chemotherapy
  - Reported in multiple sclerosis patients treated with α-integrin inhibitor (natalizumab) and in patients with rheumatic diseases

Natural History & Prognosis

- Without treatment poor prognosis, death in 2.5-4 months

Treatment

- Highly active antiretrovirus therapy (HAART) reported to improve survival

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- If multifocal subcortical WM lesions without mass effect or enhancement in AIDS patients, consider PML over HIV encephalitis

SELECTED REFERENCES

1. Berger JR: Progressive multifocal leukoencephalopathy. Handb Clin Neurol. 123:357-76, 2014

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Immune reconstitution inflammatory syndrome (IRIS)
  - Atypical/worsening opportunistic infection
  - HIV/AIDS patients following commencement of HAART
  - Patients with MS, immunomodulatory therapy

IMAGING

- PML-IRIS
  - WM hypodensities with ↑ mass
  - Patchy atypical enhancement
- TB-IRIS
  - ↑ leptomeningeal enhancement
  - ↑ size of ring-/nodular-enhancing tuberculomas
- Crypto-IRIS
  - ↑ nodular meningeal/subependymal enhancement
  - ↑ in size of "gelatinous" pseudocysts

TOP DIFFERENTIAL DIAGNOSES

- Diffuse/patchy WM abnormalities in AIDS
  - HIV encephalitis, PML, CMV infection
- Focal/multifocal brain lesions in AIDS
  - Lymphoma, toxo, tuberculoma, cryptococcosis

PATHOLOGY

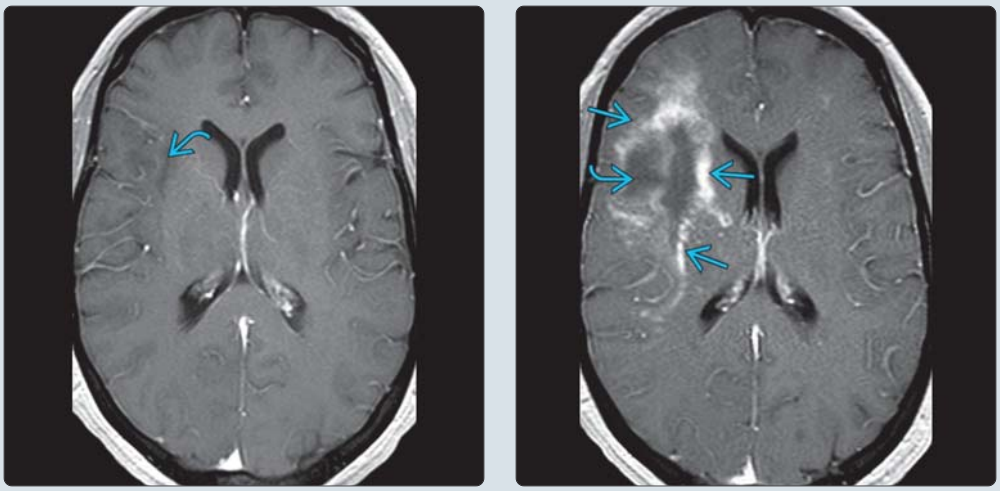
- Reconstitution of immunity → abnormal immune response to infectious/noninfectious antigens
- IRIS is **not** caused by relapse/recurrence of preexisting disease

CLINICAL ISSUES

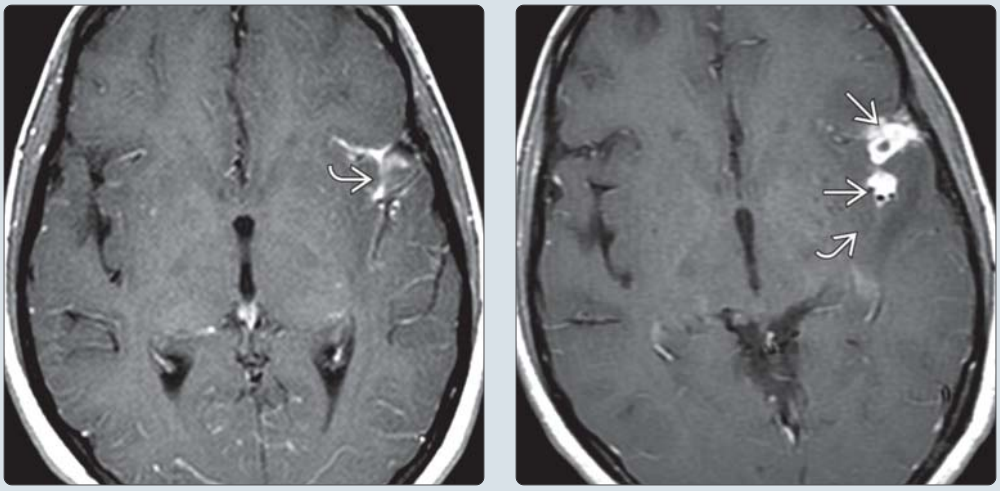
- 1/4 to 1/3 HIV-infected patients develop IRIS
- PML, TB common IRIS-associated pathogens

DIAGNOSTIC CHECKLIST

- IRIS if worsening/enhancing lesions in
  - HIV patient who recently started HAART
  - MS patient on immunomodulatory therapy



(Left) *Axial T1WI C+ MR in a patient with HIV and PML shows subtle hypodensity in the right insular region without any abnormal enhancement. FLAIR images (not shown) demonstrated multifocal confluent white matter hyperintensities.* **(Right)** *Axial T1 C+ MR in the same patient after initiation of HAART therapy and significant clinical deterioration shows patchy nodular and linear foci of enhancement as well as worsening of the underlying hypodensity. Finding are typical for PML with IRIS.*



(Left) *Axial T1WI C+ MR demonstrates meningeal enhancement in the left sylvian fissure in an HIV-positive patient with tuberculous meningitis.* **(Right)** *Axial T1WI C+ MR shows worsening of imaging appearance after placement on HAART. There is an increase in enhancement, which appears more nodular, and there is development of surrounding edema. This worsening of disease could be due to drug resistance; however, the time course after starting HAART makes IRIS most likely.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Immune reconstitution inflammatory syndrome (IRIS)

Synonyms

- Immune restoration disease (IRD)
- Immune restitution syndrome (IRS)

Definitions

- Paradoxical worsening of opportunistic infection
  - After starting highly active antiretroviral therapy (HAART)
  - Patients with MS, immunomodulatory therapy

IMAGING

General Features

- Best diagnostic clue
  - Atypical/worsening imaging appearance of infection in HIV/AIDS following commencement of HAART
  - Other: Patient on immunomodulation therapy
    - MS with monoclonal antibody therapy
- Location
  - PML: Frontal/parietooccipital lobes most common
    - Less common: Posterior fossa
  - TB: Meninges, brain parenchyma
  - Cryptococcosis: Virchow-Robin spaces (VRSs), meninges

CT Findings

- NECT
  - PML-IRIS: White matter (WM) hypodensities with ↑ mass effect
- CECT
  - PML-IRIS: Atypical heterogeneous enhancement
  - TB-IRIS: Increased size of tuberculomas

MR Findings

- T1WI
  - PML-IRIS: Hypointense lesions become confluent
- T2WI
  - PML-IRIS: Hyperintense WM lesions ↑
    - Enlarge, become confluent, exert mass effect
  - TB-IRIS: ↑ edema around tuberculomas
- T1WI C+
  - PML-IRIS: Patchy atypical enhancement
  - TB-IRIS: ↑ pial enhancement
    - ↑ size of ring-/nodular-enhancing tuberculomas
  - Crypto-IRIS: ↑ nodular meningeal/subependymal enhancement, ↑ in size of "gelatinous" pseudocysts

Imaging Recommendations

- Best imaging tool
  - MR with T1 C+, T2WI, FLAIR

DIFFERENTIAL DIAGNOSIS

Diffuse/Patchy WM Abnormalities in AIDS

- HIV encephalitis, PML, CMV infection

Focal/Multifocal Brain Lesions in AIDS

- Lymphoma, toxo, TB, cryptococcosis

PATHOLOGY

General Features

- Etiology
  - Reconstitution of immunity → heightened but dysregulated immune response to infectious/noninfectious antigens
  - IRIS is **not** caused by relapse/recurrence of preexisting disease
  - Paradoxical clinical deterioration as CD4 counts ↑, viral load ↓
  - Typical in 1st 2-12 weeks after starting HAART
  - Unmasking of preexisting disease can occur
  - Pathogens: TB, CMV, crypto, JC virus (PML), and others
  - Can occur in non-HIV immunocompromised
    - MS patient on monoclonal antibody therapy

Gross Pathologic & Surgical Features

- PML-IRIS: Multifocal discoloration of WM
- TB-IRIS: Granulomas, basal exudates

Microscopic Features

- ↑ CD8(+) T cells: Parenchymal, leptomeningeal and perivascular lymphocytic inflammatory infiltrates

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - PML-IRIS: Headache, visual disturbance, dementia
  - TB-IRIS: Fever, lymphadenopathy, seizures

Demographics

- Epidemiology
  - IRIS risk factor at HAART initiation
    - Lower CD4 cell count/cell %, ↓ CD4:CD8 ratio
    - Higher HIV RNA
  - TB common reported copathogen associated with IRIS

Natural History & Prognosis

- May progress to death in severe cases

Treatment

- Continue primary therapy for opportunistic infection
- Continue HAART + anti-inflammatory agents

DIAGNOSTIC CHECKLIST

Consider

- HIV patient who recently started HAART + worsening/unmasking of preexisting opportunist infection

KEY FACTS

TERMINOLOGY

- HIV/AIDS-related opportunistic infections and neoplasms

IMAGING

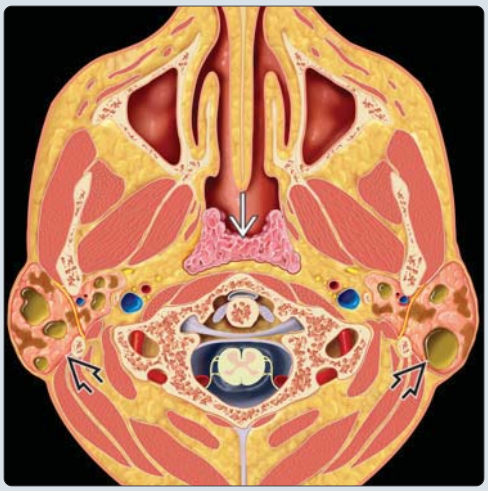
- Findings
  - Primary CNS lymphoma (PCNSL): Enhancing lesions, often hemorrhagic/necrotic within basal ganglia, periventricular WM
  - Kaposi sarcoma (KS): Intense enhancing soft tissue mass in scalp
  - Bacterial abscesses (BA): Ring-enhancing lesion with ↑ signal on DWI
  - Aspergillosis (As): Multiple ring-enhancing lesions
  - Neurosyphilis (NS): Cortical/subcortical infarcts, granulomas, leptomeningeal enhancement
  - Benign lymphoepithelial lesions of HIV (BLL-HIV): Multiple cystic masses enlarging both parotid glands
- MR is most sensitive
- PET or thallium-201 SPECT helpful to differentiate from toxoplasmosis
- Immune reconstitution inflammatory syndrome (IRIS): "Wild" looking enhancing lesion(s)

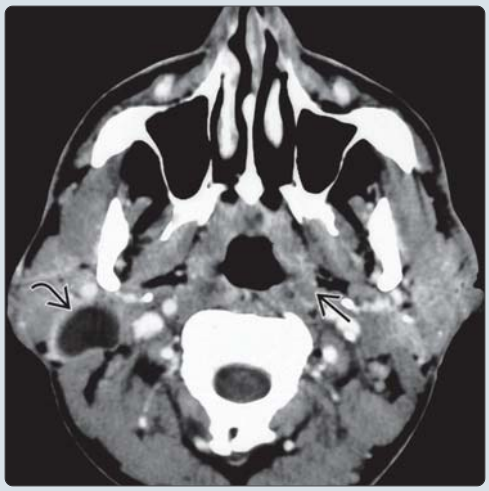
TOP DIFFERENTIAL DIAGNOSES

- Toxoplasmosis
- Metastases
- Tuberculosis

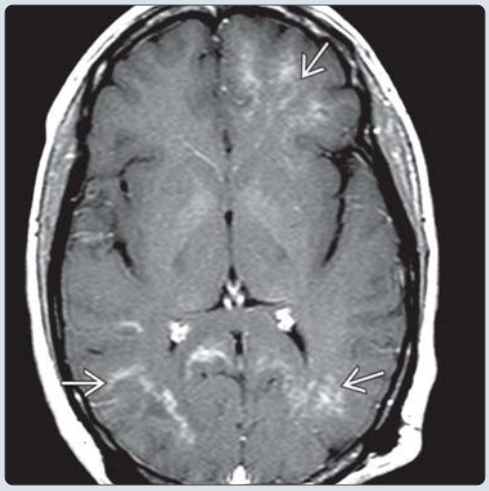
DIAGNOSTIC CHECKLIST

- Consider using DWI, MRS, PET/SPECT to differentiate opportunistic infections from malignant lesions
- Bacterial abscess, aspergillosis, neurosyphilis may need surgical biopsy for diagnosis





(Left) *Axial graphic shows typical lymphoid and lymphoepithelial lesions of HIV/AIDS. Note hyperplastic tonsils ➡ and multiple cysts in both parotid glands ⇨.* **(Right)** *Axial CECT scan in a 33-year-old man with HIV/AIDS shows a large right parotid cyst with enhancing rim ⇨ and enlarged Waldeyer ring ⇨.*



(Left) *T1 C+ scan in an HIV(+) man obtained prior to beginning HAART shows some nonenhancing periventricular hypointensities ➡.* **(Right)** *The patient deteriorated 3 weeks following institution of HAART. T1 C+ scan now shows extensive patchy enhancing lesions ➡. CSF was positive for JC virus in this case of PML-IRIS. (Courtesy T. Hutchins, MD.)*

TERMINOLOGY

Definitions

- HIV/AIDS-related opportunistic infections, neoplasms

IMAGING

General Features

- Best diagnostic clue
  - Primary CNS lymphoma (PCNSL): Enhancing lesions, often hemorrhagic/necrotic within basal ganglia, periventricular white matter (WM)
  - Kaposi sarcoma (KS): Intense enhancing, soft tissue mass in scalp
  - Bacterial abscesses (BA): Ring-enhancing lesion with ↑ signal on DWI
  - Aspergillosis (As): Multiple ring-enhancing lesions
  - Neurosyphilis (NS): Cortical/subcortical infarcts, granulomas, leptomeningeal enhancement
  - Benign lymphoepithelial lesions of HIV (BLL-HIV): Multiple cystic masses enlarging both parotid glands
- Location
  - PCNSL: 90% supratentorial; deep gray nuclei, periventricular white matter commonly affected
  - KS: Face, scalp, and skin of neck
  - BA: Typically supratentorial, frontal, and parietal
  - As: Distribution of MCA, cortical/subcortical, basal ganglia/thalami perforating arteries
  - NS: Cortical/subcortical, meninges
  - BLL-HIV: Parotid glands
- Morphology
  - PCNSL: Solitary mass or multiple lesions
  - KS: Infiltrating soft tissue mass
  - BA: Smooth, ring-enhancing lesion
  - As: Multiple lesions, often in distribution of MCA

CT Findings

- NECT
  - PCNSL: Hypodense or hyperdense, ± hemorrhage, necrosis
  - KS: Soft tissue thickening in scalp, face
  - BA: Hypodense mass with edema and mass effect
  - As: Multiple cortical/subcortical, low-attenuation lesions; may be associated with hemorrhage
  - NS: Peripherally located lesions isointense to cortex
  - BLL-HIV: Multiple bilateral, well-circumscribed, cystic masses within enlarged parotid glands
- CECT
  - PCNSL: Ring enhancement in HIV patients
  - KS: Marked enhancing scalp soft tissue mass
  - BA: Thin ring enhancement
  - As: Multiple ring-enhancing lesions
    - Enhancement may be subtle or well defined related to immune status
  - NS: Enhancing cortical lesions ± dural thickening
  - BLL-HIV: Thin rim enhancement of cystic lesions

MR Findings

- T1WI
  - PCNSL: Iso-/hypointense to cortex
  - KS: Localized thickening scalp isointense to muscle
  - BA: Early poorly marginated hypo-/isointense mass, late hypointense center
  - As: Hypointense masses
    - Hemorrhage ↑ T1 signal
- T2WI
  - PCNSL: Iso-/hypointense to cortex, mild surrounding edema
    - May be heterogeneous due to hemorrhage, necrosis
  - KS: Scalp mass hyperintense to muscle
  - BA: Capsule with characteristic T2 hypointense rim
  - As: Heterogeneous if hemorrhage present
  - NS: Hyperintense cortical/subcortical lesions, infarcts
- DWI
  - PCNSL: Variable restricted diffusion
  - BA: ↑ signal DWI, low ADC
  - As: Restricted diffusion in wall of abscess
- T1WI C+
  - PCNSL: Peripheral enhancement with central necrosis more common in HIV patients than homogeneous enhancement
  - KS: Intensely enhancing soft tissue mass in scalp
  - BA: Early patchy enhancement, late capsule with well-defined, thin rim enhancement
  - As: Multiple ring-enhancing lesions
  - NS: Lesions enhance; overlying leptomeningeal/dural enhancement also seen
  - BLL-HIV: Well-defined, rim-enhancing, cystic lesions in parotid glands
  - Immune reconstitution inflammatory syndrome (IRIS): "Wild" looking enhancing lesion(s)
- MRS
  - PCNSL: ↓ NAA, ↑ choline
  - BA: Central necrotic area may show acetate, lactate, alanine, succinate, and amino acids

Imaging Recommendations

- Best imaging tool
  - MR is most sensitive
- Protocol advice
  - PCNSL: Contrast-enhanced MR
    - PET or Tl-201 SPECT helpful to differentiate from toxoplasmosis
  - BA: MR C+, DWI, MRS

Nuclear Medicine Findings

- PCNSL: FDG PET/Tl-201 SPECT hypermetabolic

DIFFERENTIAL DIAGNOSIS

Toxoplasmosis

- Enhancing lesions, "eccentric target" sign
- PET, SPECT helpful to differentiate from PCNSL

Metastases

- Multiple lesions common, significant vasogenic edema, primary tumor often known

Tuberculosis

- Ring/nodular enhancing lesions in cortex, gray-white junction; Ca++ in chronic cases

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - PCNSL: Typically diffuse, large B-cell non-Hodgkin lymphoma
    - Associated with CD4(+) counts < 100 cells/mm³
    - EBV plays major role in immunosuppressed
  - KS: Caused by herpesvirus HHV-8
    - Classified as AIDS-defining cancers (ADCs)
  - BA: *Staphylococcus* and *Streptococcus* most common causative organisms
  - As: *Aspergillus* species = hyaline septate molds
    - *Aspergillus fumigatus* most common agent
    - Hematogenous spread from pulmonary focus or direct extension via sinus
    - Infectious vasculopathy: Acute infarction, hemorrhage, infectious cerebritis/abscess
  - NS: Sexually transmitted disease results from infection with spirochete *Treponema pallidum*
  - IRIS: Restored immunity (a few weeks after HAART) → exaggerated immune response
    - JC virus most common pathogen (PML-IRIS)

Gross Pathologic & Surgical Features

- PCNSL: Single multiple masses in cerebral hemispheres, central necrosis/hemorrhage in HIV
- BA: Depends on stage; necrotic foci, rim of inflammatory cells, granulation tissue, surrounding vasogenic edema
- As: Hemorrhagic infarcts with variable inflammation
- NS: Syphilitic gummas; well-circumscribed necrotic masses of granulation tissue (avascular)

Microscopic Features

- PCNSL: Small, noncleaved, and large immunoblastic type
  - High nuclear to cytoplasmic ratio
  - Angiocentric: Surrounds, infiltrates vessels and perivascular spaces
- KS: Diffuse positivity for vimentin; pedunculated, ulcerated, or both
- BA: Granulation tissue about necrotic core
- As: Septate hyphae branch at acute angles
  - Invade blood vessels, spread along internal elastica and lamina
- NS: Leptomeningitis, multifocal arteritis
  - Cerebral gummas; infiltration of meninges and brain by lymphocytes and plasma cells

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - PCNSL: Lethargy, confusion, headache, seizures, focal weakness
  - KS: Usually asymptomatic; symptoms may appear when lesions ulcerate or produce local mass effect
  - BA: Headache most common symptom
    - Seizures, focal neurologic deficits
  - As: Seizures, altered mental status, focal deficits
  - NS: Often asymptomatic
    - Headaches, seizures, personality changes, confusion
  - BLL-HIV: Bilateral parotid space masses
- Clinical profile
  - PCNSL: CD4(+) < 100 cells/mm³
    - CSF: Pleocytosis, ↑ proteins, cytology (+) for monoclonal, malignant-appearing lymphocytes
    - PCR amplification of EBV DNA in CSF
  - KS: Low CD4 count (i.e., < 150–200 cells/mm³)
  - NS: CSF ↑ WBC count, reactive CSF VDRL &/or positive CSF *T. pallidum* antibody index

Demographics

- Epidemiology
  - PCNSL: 2nd most common mass lesion after toxoplasmosis in patients with AIDS
    - 2-6% of AIDS patients
  - KS: Prevalence of AIDS-related KS has ↓, presumably due to use of HAART
  - BA: Relatively uncommon in AIDS patients
  - NS: Affects approximately 1.5% of AIDS population
  - BLL-HIV: 5% of HIV(+) patients
  - IRIS: 25-35% of HIV(+) patients beginning HAART

Treatment

- PCNSL: Definitive diagnosis requires stereotactic brain biopsy
  - HAART with radiation
- KS: Radiotherapy is primary therapy
- BA: Surgical drainage, antibiotics
- As: Surgery, antifungals
- NS: Penicillin ± steroids
- BLL-HIV: HAART therapy tends to completely or partially treat

DIAGNOSTIC CHECKLIST

Consider

- Consider using DWI, MRS, PET/SPECT to differentiate opportunistic infections from malignant lesions

Image Interpretation Pearls

- In HIV patients, difficult to differentiate between PCNSL and toxoplasmosis
  - PET/SPECT studies may be helpful
- Bacterial abscess, aspergillosis, neurosyphilis may need surgical biopsy for diagnosis

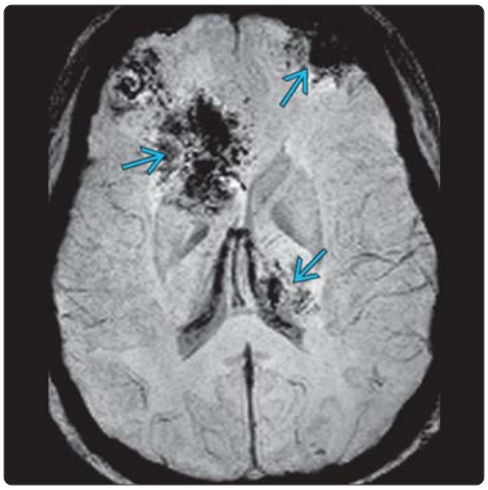
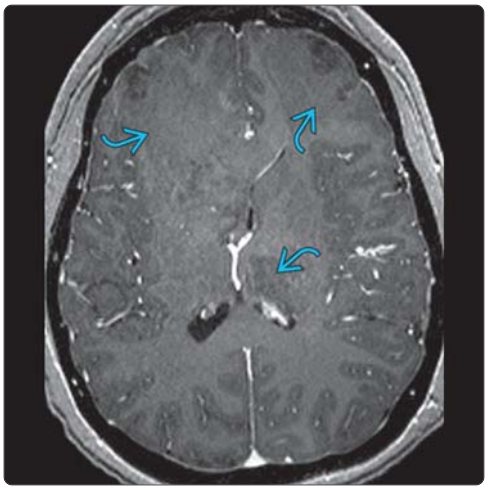
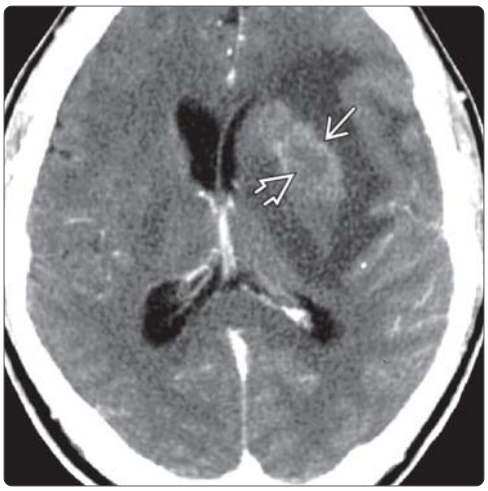
(Left) *Axial CECT in an HIV positive patient with scalp swelling shows an infiltrating soft tissue mass with adjacent skin thickening in the left frontal scalp. On biopsy this was a Kaposi sarcoma. Kaposi sarcoma is classified as AIDS-defining cancers (ADCs).* **(Right)** *Axial DWI MR in an HIV-positive patient who presented with altered sensorium and seizures demonstrates large areas of restricted diffusion in the frontal lobes and left thalamus.*





(Left) *Axial SWI image in the same patient shows areas of hemorrhage in the regions of diffusion abnormality.* **(Right)** *Axial T1+C MR in the same patient does not demonstrates any abnormal enhancement in the frontal lobes or left thalamus. Biopsy of the right frontal lobe lesion revealed invasive aspergillosis. Aspergillus infections leads to an infectious vasculopathy resulting in acute infarction, hemorrhage, and cerebritis/abscess.*



(Left) *CECT in an HIV(+) patient with a solitary basal ganglia mass shows some poorly defined enhancement around a necrotic center.* **(Right)** *Axial T1WI in the same patient shows the hyperintensity of subacute hemorrhage around a necrotic core. CNS lymphoma rarely hemorrhages or undergoes necrosis except in immunocompromised patients.*

https://CafePezeshki.IR

KEY FACTS

IMAGING

- Multiple perpendicular callososeptal T2 hyperintensities characteristic of multiple sclerosis (MS)
  - Perivenular extension: "Dawson fingers"
- Bilateral, asymmetric linear/ovoid FLAIR hyperintensities
  - > 85% periventricular/perivenular
  - 50-90% callososeptal interface
  - May also commonly involve subcortical U-fibers, brachium pontis, brainstem, spinal cord common
- Transient enhancement during active demyelination
  - > 90% disappear within 6 months
- Rare: Large tumefactive enhancing rings
- T1: Hypointense lesions suggest worse prognosis
  - Correlate with disability, atrophy, progressive disease
- Advanced imaging techniques show disease in normal-appearing white matter

TOP DIFFERENTIAL DIAGNOSES

- Acute disseminated encephalomyelitis (ADEM)
- Neuromyelitis optica
- Autoimmune-mediated vasculitis
- CADASIL
- Lyme disease
- Susac syndrome

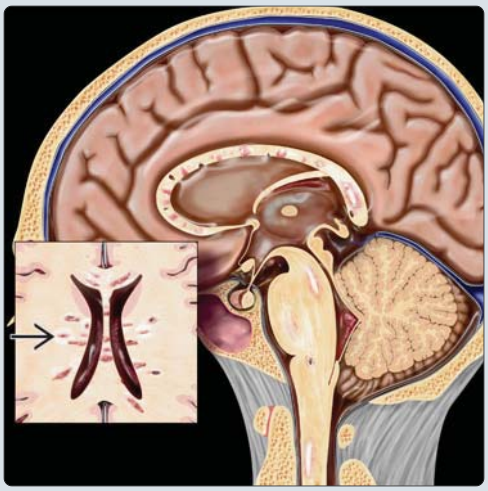
CLINICAL ISSUES

- Estimated 2.5 million people in world have MS
- Most common disabling CNS disease of young adults; 1:1,000 in Western world
- Age: 20-40 years
  - Peak onset = 30; 3-5% < 15, 9% > 50
- Adults: M:F = 1:2; adolescents: M:F = 1:3-5

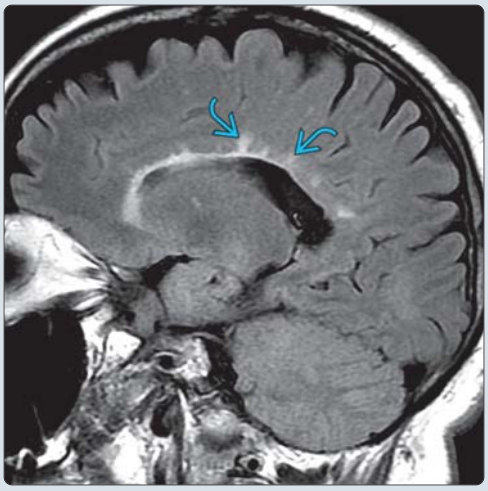
DIAGNOSTIC CHECKLIST

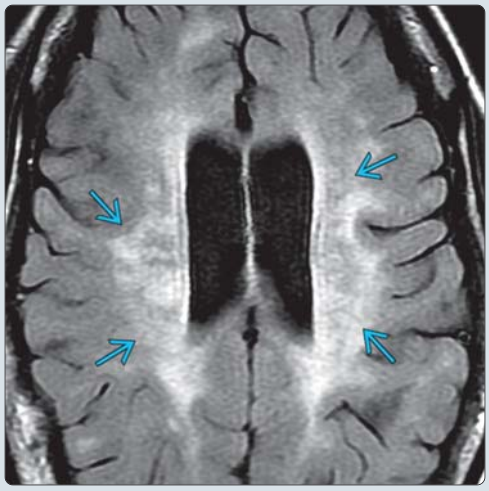
- Requires dissemination in time and space in central nervous system for diagnosis
- McDonald criteria: Consensus statement for diagnostic criteria, last revised in 2010

(Left) *Sagittal graphic illustrates multiple sclerosis (MS) plaques involving the corpus callosum, pons, and spinal cord. Note the characteristic perpendicular orientation of the lesions ⇨ at the callososeptal interface along penetrating venules.* **(Right)** *Axial T1WI C+ MR shows numerous enhancing MS plaques that were present throughout the infratentorial and supratentorial brain. Lesions may show homogeneous enhancement, but may also exhibit ring or an incomplete ring pattern of enhancement.*



(Left) *Sagittal FLAIR shows callososeptal hyperintensities ⇨ radiating from the lateral ventricles with a typical perpendicular orientation, characteristic of multiple sclerosis.* **(Right)** *Axial FLAIR in a 35-year-old female with multiple sclerosis shows extensive confluent periventricular hyperintense lesions ⇨ typical of advanced, longstanding MS with loss of discrete, linear, periventricular lesions. Note prominence of the ventricles and cortical sulci due to diffuse atrophy.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Multiple sclerosis (MS)

Definitions

- Probable autoimmune-mediated demyelination in which environmental factors act upon genetically susceptible individuals

IMAGING

General Features

- Best diagnostic clue
  - Multiple perpendicular callososeptal T2 hyperintensities
- Location
  - > 85% periventricular/perivenular
  - 50-90% callososeptal interface
  - Subcortical U-fibers, brachium pontis, brainstem, spinal cord
  - Infratentorial (< 10% in adults, more common in children)
- Size
  - Small 5-10 mm, tumefactive lesions several cm
- Morphology
  - Linear, round, or ovoid; beveled, target, lesion-in-a-lesion appearance

CT Findings

- CECT
  - Iso-/hypodense ± mild/moderate enhancement
  - Both solid and ring enhancement patterns

MR Findings

- T1WI
  - Typically hypo- or isointense
  - Hypointensity correlates with axonal destruction ("black holes")
  - T1 hypointense lesions suggest worse prognosis
    - Correlated with disability, atrophy, progressive disease
  - Hyperintense dentate nuclei seen in secondary progressive form
- T2WI
  - Hyperintense, linear foci radiating from ventricles
  - Also prevalent in subcortical U-fibers, brachium pontis, brainstem, and spinal cord
  - High cortical disease burden can be predictor of primary progressive MS
  - Hypointense basal ganglia 10-20% of chronic MS
- FLAIR
  - Earliest finding: Alternating linear hyperintensity along ependyma on sagittal FLAIR
    - Ependymal "dot-dash" sign
  - Bilateral, asymmetric, linear/ovoid hyperintensities
  - Perivenular extension; "Dawson fingers"
    - Along path of deep medullary veins
  - Hyperintensities become confluent with severity
- DWI
  - Majority of acute plaques: Normal or ↑ diffusivity
  - Few acute MS plaques may show restricted diffusion
    - Often at the margins of acute plaque
  - Subacute/chronic plaques show ↑ diffusivity
  - DTI: Reduced longitudinal diffusivity in areas of axonal injury
- T1WI C+
  - Transient enhancement during active demyelination (> 90% disappear within 6 months)
    - Nodular (68%) or ring (23%)
    - Semilunar, incomplete, horseshoe-shaped (9%)
    - Rare: Large tumefactive enhancing rings
- MRS
  - ↓ NAA (NAA/Cr), ↑ choline (Cho/Cr), ↑ myoinositol
  - MRS abnormalities found in normal-appearing white matter (NAWM)
  - Only secondary progressive MS shows ↓ NAA in normal-appearing gray matter (NAGM)
    - May allow early distinction between relapsing-remitting and secondary-progressive
- Perfusion MR (contrast-enhanced T2*): Low rCBV
  - Can separate tumefactive MS from neoplasm
- Magnetization transfer (MT)
  - ↓ MT ratio (MTR) in lesions/NAWM
- Functional connectivity MR (fcMR)
  - ↓ functional connectivity between right/left hemisphere primary visual and motor cortices
- 3.0 T vs. 1.5 T: 21% ↑ number of contrast-enhancing lesions, 30% ↑ enhancing lesion volume, 10% ↑ total lesion volume

Imaging Recommendations

- Protocol advice
  - Contrast-enhanced MR with sagittal FLAIR
  - Fat saturation to assess for optic neuritis

DIFFERENTIAL DIAGNOSIS

Acute Disseminated Encephalomyelitis (ADEM)

- Viral prodrome, monophasic illness, more common in children
- Can mimic MS; gray matter often involved
- ADEM lesions tend to be larger, more edematous, and often symmetric

Neuromyelitis Optica

- Optic neuritis and spinal cord lesions
- Brain lesions look atypical for MS, tend to border midline CSF spaces

Autoimmune-Mediated Vasculitis

- Enhancing lesions spare callososeptal interface
- "Beaded" angiogram appearance

CADASIL

- Premature dementia and recurrent strokes with *NOTCH3* mutations
- Tends to spare corpus callosum, subcortical U-fibers

Lyme Disease

- Can be identical to MS (skin rash common)

Susac Syndrome

- Classic triad: Encephalopathy, branch retinal artery occlusions, hearing loss

https://CafePezeshki.IR

McDonald Criteria (2010 Revisions) for Diagnosis of MS

Dissemination in Space by MR	Dissemination in Time by MR
≥ 1 T2 hyperintense lesion(s)	**Either** new T2 or Gd-enhancing lesion(s) on follow-up MR
In at least 2 of the following 4 areas	**Or** simultaneous presence of
Periventricular	Asymptomatic Gd-enhancing **and**
Juxtacortical	Nonenhancing lesions at any time
Infratentorial	
Spinal cord	

PATHOLOGY

General Features

- Etiology
  - Unknown; probably virus &/or autoimmune-mediated in genetically susceptible individuals
  - Activated T cells attack myelinated axons
  - Cox-2, iNOS may cause excitotoxic death of oligodendrocytes
- Genetics
  - Multifactorial; ↑ incidence in 1st-order relatives

Staging, Grading, & Classification

- Major clinical subtypes
  - **Relapsing-remitting** (RR) 85% initial presentation
  - **Secondary-progressive** (SP), a.k.a. relapsing progressive
    - By 10 years 50%, and by 25 years 90% of RR patients enter SP phase
  - **Primary-progressive** (PP), a.k.a. chronic progressive
    - 5-10% of MS population progressive from start
  - **Progressive-relapsing** (PR)
    - Rare; defined as progressive disease with clear acute relapses ± full recovery
    - Periods between relapses characterized by continuing disease progression
  - **Radiologically isolated syndrome** (RIS)
    - MR findings suggestive of MS without typical MS symptoms and normal neurological exam
- MS variants/subtypes
  - **Malignant/Marburg disease**: Younger patients, febrile prodrome, clinically fulminant, death in months
  - **Schilder** type ("diffuse sclerosis"): Extensive, confluent, asymmetric demyelination in bilateral supra-/infratentorial parenchyma
  - **Baló** type ("concentric sclerosis"): Large lesions with alternating zones of demyelinated/myelinated WM

Gross Pathologic & Surgical Features

- Acute: Poorly delineated, yellowish-white, periventricular plaques
- Chronic: Gray, granular, well-demarcated plaques ± generalized volume loss

Microscopic Features

- Perivenous demyelination, oligodendrocyte loss
  - Active: Foamy macrophages with myelin fragments, lipids; reactive astrocytes + perivascular inflammation; atypical reactive astrocytes, mitoses (mimic tumor)
  - Chronic: Marked loss of myelin, oligodendrocytes; dense astrogliosis; minimal/no perivascular inflammation
- Axonal transection
- CSF positive for oligoclonal bands

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Variable; initially impaired/double vision of acute optic neuritis (50% with positive MR develop MS)
  - Weakness, numbness, tingling, gait disturbances
  - ↓ sphincter control, blindness, paralysis, dementia
  - Cranial nerve palsy; usually multiple, 1-5% isolated (CN5, 6 most common)
  - Spinal cord symptoms in 80%

Demographics

- Age
  - 20-40; peak onset is 30; 3-5% < 15, 9% > 50
- Gender
  - Adults: M:F = 1:2
  - Adolescents: M:F = 1:3-5
- Ethnicity
  - All groups, but white most common
  - Most often occurs in temperate zones
- Epidemiology
  - Estimated 2.5 million people in world have MS
  - Most common disabling CNS disease of young adults; 1:1,000 in Western world

Natural History & Prognosis

- 1/3 patients have initial episode followed by normal or near-normal function
- > 80% with "probable" MS, positive MR progress to clinically definite MS
- Majority: Protracted course with progression of deficits
- Late: Severe disability, cognitive impairment

Treatment

- Immunomodulators &/or immunosuppressants

DIAGNOSTIC CHECKLIST

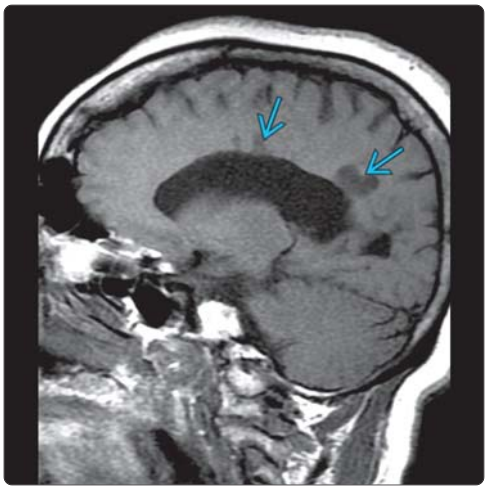
Image Interpretation Pearls

- 95% with clinically definite MS have positive MR

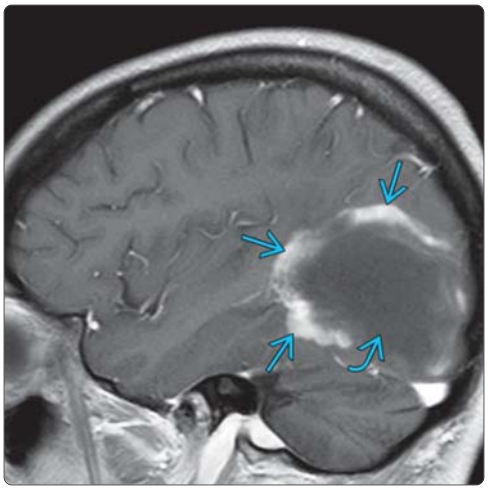
SELECTED REFERENCES

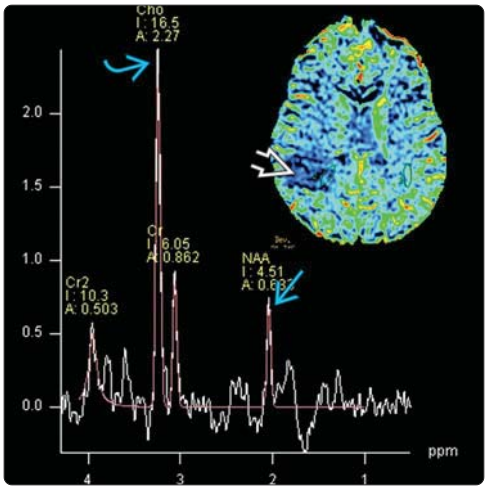
1. Roosendaal SD et al: Imaging phenotypes in multiple sclerosis. Neuroimaging Clin N Am. 25(1):83-96, 2015

https://CafePezeshki.IR

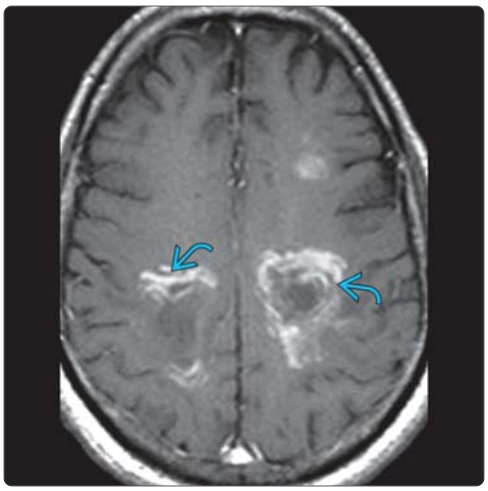


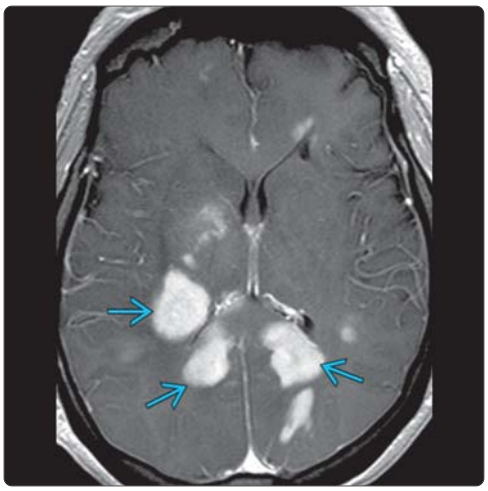
(Left) *Axial SWI image demonstrates characteristic perivenular location of a demyelinating plaque* ⇨ *with the medullary vein* ⇨ *coursing through it.* **(Right)** *Sagittal T1WI MR shows multiple hypointense lesions ("black holes") in the periventricular white matter* ⇨ *related to axonal destruction. Note the associated moderate ventricular and sulcal enlargement. T1 "back holes" are correlated with greater tissue damage and increased axonal destruction on histopathology.*





(Left) *Sag T1WI C+ MR shows a large hypointense mass* ⇨ *with a peripheral crescent of incomplete or "open ring" enhancement* ⇨*. This enhancement pattern is classic for a tumefactive demyelinating disease, most commonly MS.* **(Right)** *MRS at 144 TE in the same patient demonstrates a large choline peak* ⇨ *with ↓ in NAA* ⇨*. MRS in a tumefactive demyelinating lesion is not specific and can mimic a tumor profile. MR DSC perfusion (insert) shows marked ↓ rCBV* ⇨*, which goes more in favor of a demyelinating lesion.*





(Left) *Axial T1+C MR demonstrates concentric laminated "onion bulb" enhancement* ⇨ *characteristic of acute Baló concentric sclerosis. Baló concentric sclerosis is a rare aggressive MS variant characterized by acute onset and rapid deterioration.* **(Right)** *Axial T1+ MR in a young male with rapid onset of visual disturbance demonstrates large enhancing demyelinating lesions* ⇨ *in the deep and periventricular white matter. Marburg disease is an acute fulminant MS variant.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Neuromyelitis optica (NMO)
- Neuromyelitis optica spectrum disorders (NMOSD)
- Idiopathic inflammatory demyelinating disorder of CNS characterized by severe attacks of optic neuritis and myelitis

IMAGING

- Hyperintense, mildly enlarged optic nerves
- Expansile, hyperintense cord signal, ≥ 3 segments
- Brain lesions in NMO or NMOSD are quite characteristic and distinct from lesions in multiple sclerosis (MS)
- Long segment optic nerve enhancement
- Acute cord lesions show patchy enhancement
- Patchy enhancement with blurred margins ("cloud-like" enhancement) in cerebral lesions
- "Pencil-thin" ependymal enhancement

TOP DIFFERENTIAL DIAGNOSES

- Multiple sclerosis
- Optic neuritis
- Transverse myelitis
- Syringomyelia
- Spinal cord neoplasm

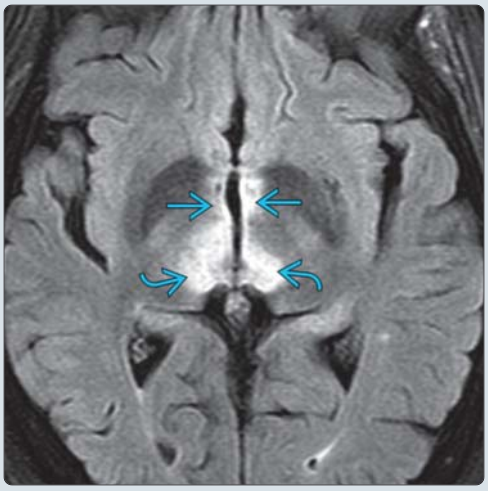
PATHOLOGY

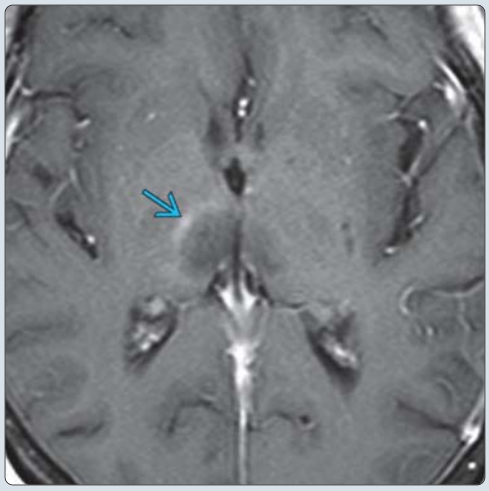
- Serum marker: **NMO-IgG**, targets water channel aquaporin-4 (AQP4)
- Seen in 70% of NMO patients, **99% specificity**

CLINICAL ISSUES

- Impaired or double vision, myelopathy
- 20% present with brainstem symptoms at disease onset
- Relapsing course in 90% of patients
- Anti-AQP4 antibody positivity established prognostic marker
- Acute exacerbation: IV corticosteroid treatment

(Left) *Axial T1WI C+ FS MR shows a markedly enhancing prechiasmatic right optic nerve and chiasm, consistent with acute optic neuritis.* **(Right)** *Sagittal T2 DP FSE MR in the same patient shows a long segment of cord enlargement with hyperintensity. Ill-defined enhancement was also present in the cervical cord in this patient with myelopathy and vision loss. Patients with neuromyelitis optica (NMO) have a worse prognosis with more severe disability than multiple sclerosis, despite lack of brain involvement.*





(Left) *Axial FLAIR MR in a patient with neuromyelitis optica spectrum disorder (NMOSD) shows characteristic periependymal lesions surrounding the 3rd ventricle, involving the thalamus and hypothalamus.* **(Right)** *Axial T1+C MR in the same patient shows subtle rim enhancement in the lesion in the right thalamus. Brain lesions in NMO/NMOSD are typically localized in the periependymal regions where aquaporin-4 (AQP4) is highly expressed.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neuromyelitis optica (NMO)
- Neuromyelitis optica spectrum disorders (NMOSD)

Synonyms

- Devic syndrome

Definitions

- Idiopathic inflammatory demyelinating disorder of CNS characterized by severe attacks of optic neuritis and myelitis

IMAGING

General Features

- Best diagnostic clue
  - Optic neuritis and myelitis
  - Spectrum of brain lesions atypical for multiple sclerosis (MS)
- Location
  - Most common in cervical spinal cord, optic nerves
    - More posterior involvement of optic nerve including chiasm and simultaneous bilateral disease
  - Brain lesions: Deep white matter, periependymal regions, corpus callosum, corticospinal tracts, brainstem, and cerebellum
- Size
  - Spinal lesions typically expansile, multisegment
  - Brain lesions punctate or small (< 3 mm) to large confluent in cerebral white matter

MR Findings

- T2WI
  - Hyperintense, mildly enlarged optic nerves
    - More posterior involvement of optic nerve including chiasm and simultaneous bilateral disease
  - Expansile, hyperintense cord signal, ≥ 3 segments
    - May have heterogeneous areas of brighter (fluid) T2 signal
    - Predominantly involves central gray matter of spinal cord
  - Brain lesions with morphology and location not typical for MS
- STIR
  - Hyperintense optic nerve
  - Hyperintense cord signal ≥ 3 segments
    - Predominantly involves central gray matter of spinal cord
- FLAIR
  - Brain lesions in NMO or NMOSD are quite characteristic and distinct from lesions in MS
  - Distribution of NMO-characteristic brain lesions correspond to sites of high aquaporin-4 (AQP4) expression
    - Adjacent to ventricular system at any level
  - **Periependymal hyperintense lesions surrounding 3rd ventricle and cerebral aqueduct**
    - Thalamus, hypothalamus, ventral midbrain
  - **Dorsal brainstem hyperintense lesions adjacent to 4th ventricle**
    - Including area postrema and nucleus tracts solitarius
  - **Periventricular hyperintense lesions surrounding lateral ventricles**
    - NMO lesions follow ependymal lining in disseminated pattern
    - Often edematous and heterogeneous, creating "marbled" pattern unlike MS
    - Sometimes involving complete thickness of splenium in unique "arch bridge" pattern
    - Chronic phase lesions tend to reduce in size and intensity; may even disappear
      - Cystic changes and atrophy of corpus callosum
  - **Hyperintense lesions involving corticospinal tracts**
    - Unilateral or bilateral, posterior limb internal capsule, cerebral peduncle
    - Contiguous, often longitudinally extensive, following pyramidal tracts
    - Corticospinal tract lesions in 23% to 44% in NMOSD
  - **Extensive hemispheric hyperintense lesions**
    - Tumefactive (> 3 cm), long spindle-like, or radial shaped
    - Occasionally mimicking posterior reversible encephalopathy syndrome (PRES)
  - **Nonspecific lesions: Not unique, but most common**
    - Nonspecific punctate or small (< 3 mm) dots or patches of hyperintensities in subcortical or deep white matter
- DWI
  - Higher diffusivity, lower fractional anisotropy than MS patients or controls
  - Patient with NMO and normal brain MR
    - DTI shows increased mean diffusivity in corticospinal tract and optic radiation, but not in cingulum or corpus callosum
- T1WI C+
  - Long segment optic nerve enhancement unilateral or bilateral, often extending posterior to optic chiasm
  - Acute lesions in cord show patchy enhancement
  - Most NMO brain lesions do not show enhancement
  - Patchy enhancement with blurred margins ("cloud-like" enhancement) in cerebral lesions
    - Relatively specific for NMO
  - "Pencil-thin" ependymal enhancement
  - Rarely, well-marginated nodular enhancement or meningeal enhancement
- MRS
  - In NMO metabolites are normal in normal-appearing white matter (NAWM) and normal-appearing gray matter (NAGM) compared to patients with MS
  - In MS, NAA ↓ and choline ↑ in NAWM

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR of brain, spine, and orbits
- Protocol advice
  - Orbits: Axial or coronal STIR or T2 FS and T1 C+ FS
  - Spine: Sagittal STIR or T2, T1WI C+
  - Brain: Axial and Sagittal FLAIR, T1WI C+

https://CafePezeshki.IR

DIFFERENTIAL DIAGNOSIS

Multiple Sclerosis

- Radially oriented, well-demarcated perivenular lesions (Dawson fingers)
- Optic neuritis and spinal involvement may be seen
- Multisegment, expansile cord lesion more common in neuromyelitis optica

Optic Neuritis

- 1 component of NMO
- Consider NMO-IgG in case of 1st optic neuritis, but otherwise normal brain MR

Transverse Myelitis

- 1 component of NMO
- Idiopathic inflammatory or postinfectious myelitis
- Differentiation of spinal NMO and other immune-mediated myelitis like Sjögren disease or SLE difficult

Syringomyelia

- Enlargement and T2 hyperintensity of spinal cord
- May appear similar to NMO

Spinal Cord Neoplasm

- Astrocytoma or ependymoma can show similar multisegment cord T2 hyperintensity and enhancement

PATHOLOGY

Staging, Grading, & Classification

- **Diagnostic criteria for diagnosis of NMO**
  - Optic neuritis
  - Transverse myelitis
  - At least 2 of following 3 supportive criteria
    - Contiguous spinal cord MR lesion extending over at least 3 vertebral segments
    - Onset brain MR not meeting diagnostic criteria for MS
    - NMO-IgG seropositive status

Gross Pathologic & Surgical Features

- Cavitation of spinal cord

Microscopic Features

- Serum marker: **NMO-IgG**, targets water channel AQP4
  - Seen in 70% of NMO patients, **99% specificity**
  - AQP4 is most abundant cell membrane water channel in CNS
  - Expressed in foot processes of astrocytes in contact with blood vessels throughout brain, spinal cord, and optic nerves
  - Periventricular area, hypothalamus, and brainstem also sites of high expression of AQP4
- Evolving lesions show fragmentation and loss of astrocytes that precede demyelination
- Granulocyte infiltration with perivascular immunoglobulin and complement deposition

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Optic neuritis: Impaired or double vision
  - Myelitis: Myelopathy
  - 20% present with brainstem symptoms at disease onset
    - Nystagmus, dysarthria, dysphagia, ataxia, or ophthalmoplegia
  - Symptomatic narcolepsy or acute diencephalic syndrome
  - Aphasia, seizures, disturbance of consciousness, cognitive symptoms
- Clinical profile
  - CSF: Neutrophilic pleocytosis, negative oligoclonal bands

Natural History & Prognosis

- Relapsing course in 90% of patients
- Worse prognosis with more severe disability than MS
- Anti-AQP4 antibody positivity established prognostic marker
  - Indicates high risk of further relapses of optic neuritis and myelitis
- Early and aggressive immunosuppression required to prevent or reduce severe disability
- Routine imaging surveillance necessary to monitor complications of immunosuppression

Treatment

- Acute exacerbation: IV methylprednisone treatment followed by oral prednisone and then gradual tapering over 6-12 months
  - Plasma exchange in relapses not responding to steroids
- Prevention of relapses: Low dose corticosteroids, azathioprine, rituximab, methotrexate
- Symptom management and rehabilitation

DIAGNOSTIC CHECKLIST

Consider

- NMO in patient with optic neuritis and myelitis
- NMOSD in patient with characteristic brain lesions involving periependymal regions, corpus callosum, corticospinal tracts, brainstem

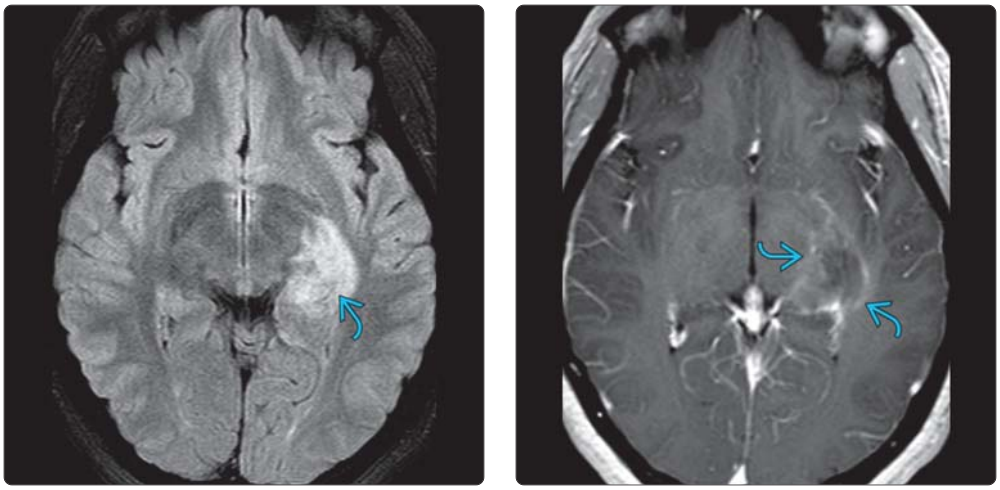
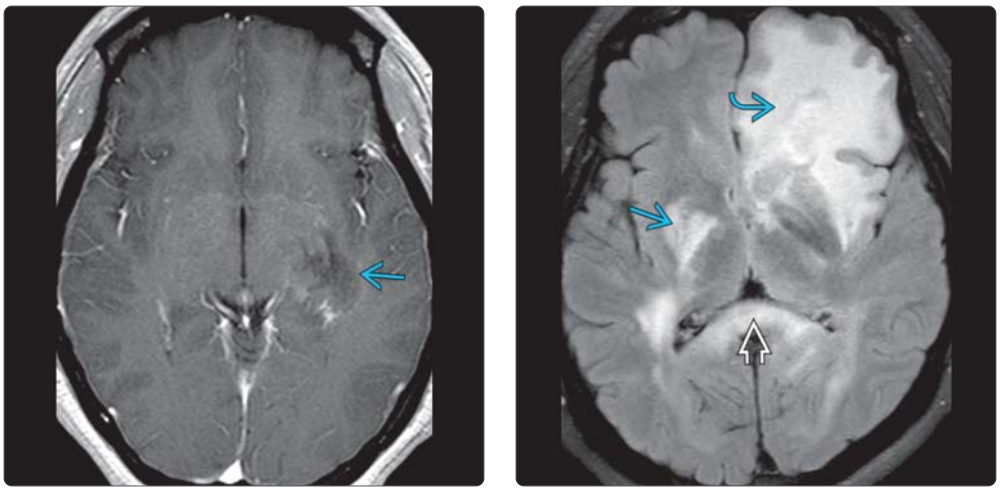
(Left) *Sagittal T2 (left) and T1WI C+ FS (right) images show multilevel T2 hyperintensity with irregular posterior enhancement* ➡ *in the cervical cord in a patient with a previous history of optic neuritis.* **(Right)** *Sagittal T2WI MR in the same patient 1 year after treatment shows near complete resolution of the T2 signal abnormality. Enhancement was no longer seen in the cervical cord. The cord lesions seen in NMO typically extend over 3 or more segments.*



(Left) *Axial FLAIR MR in a patient who presented with altered sensorium demonstrates a large hyperintense lesion in the left medial temporal lobe* ⇨*.* **(Right)** *Axial T1+ C MR in the same patient shows patchy enhancement* ⇨ *with blurred margins ("cloud-like" enhancement). NMO-immunoglobulin G antibody in serum was positive in this patient. This pattern of enhancement has been reported as relatively specific for NMO.*



(Left) *Axial T1+C MR in the same patient 4 days after IV steroid therapy shows almost complete resolution of the enhancement* ⇨*.* **(Right)** *Axial FLAIR MR in a patient with NMO shows multiple characteristic brain lesions. A large tumefactive lesion with ill-defined borders is seen in the left frontal lobe* ⇨*. An ill-defined hyperintense lesion is seen involving the posterior limb of right internal capsule* ⇨ *and there involvement of the splenium of corpus callosum* ➡ *in a unique "arch bridge" pattern.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Autoimmune-mediated white matter (WM) demyelination of brain &/or spinal cord, usually with remyelination

IMAGING

- Best diagnostic clue: Multifocal WM and deep gray lesions days to weeks following infection/vaccination
- May involve both brain and spinal cord; white matter > gray matter, but usually both affected
- Deep/juxtacortical WM > periventricular WM
- Both supratentorial and infratentorial lesions
- Multifocal punctate to large flocculent FLAIR hyperintensities
- Do not usually involve callososeptal interface
- Most lesions show increased signal on DWI (T2 shine through)
- Punctate, ring, incomplete ring, peripheral enhancement
- Absence of enhancement does not exclude diagnosis
- MRS: ↓ NAA within lesions; may see ↑ Cho, ↑ lactate

TOP DIFFERENTIAL DIAGNOSES

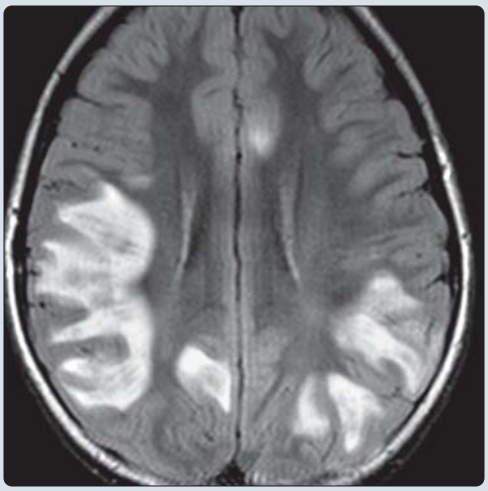
- Multiple sclerosis (MS)
- Autoimmune-mediated vasculitis
- Acute hypertensive encephalopathy, PRES
- Fabry disease
- Behçet disease

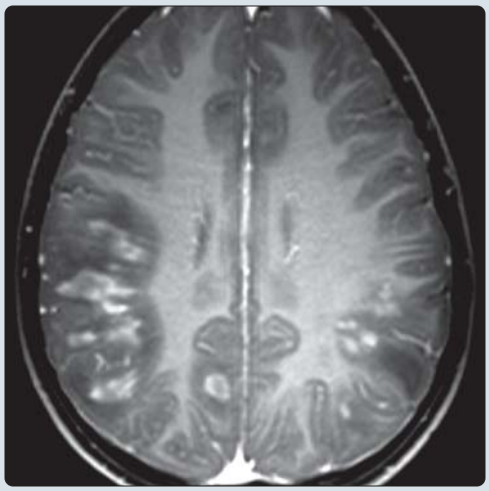
PATHOLOGY

- Over 30 different infectious agents and immunizations reported

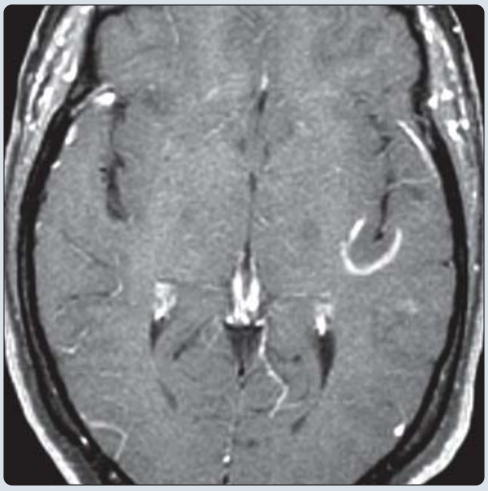
CLINICAL ISSUES

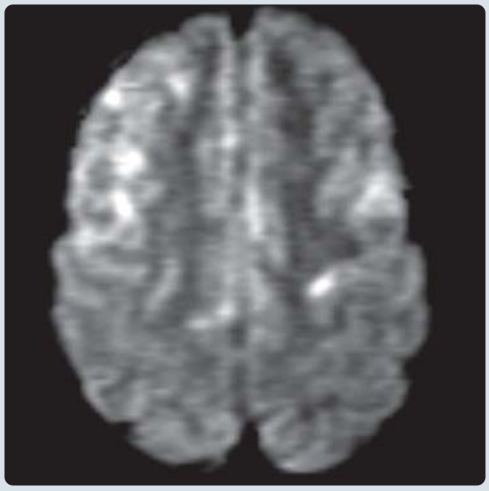
- Mean age is 5-8 years, but can occur at any age
- Male predominance (M:F = 1:0.6-0.8), unlike MS
- Usually monophasic, self-limited
- Complete recovery within 1 month: 50-60%
- Mortality: 10-30%





(Left) *Axial FLAIR MR shows peripheral, confluent areas of hyperintensity predominantly involving the subcortical white matter in this child with ADEM. The bilateral but asymmetric pattern is typical of ADEM.* **(Right)** *Axial T1WI C+ MR in the same patient shows marked, irregular enhancement of nearly all of the lesions. As ADEM is a monophasic illness, enhancement of the majority of lesions is typical, as the lesions all have a similar time course. Enhancement of MS lesions is more variable.*





(Left) *Axial T1WI C+ MR shows an incomplete ring of peripheral enhancement, typical of a demyelinating process. Other contrast enhancement patterns include ovoid or punctate homogeneous enhancement.* **(Right)** *Axial DWI MR shows increased signal in areas of FLAIR hyperintensity. The foci were hypointense on ADC images, indicating diffusion restriction. Both white and gray matter involvement is present. Diffusion restriction is an uncommon imaging finding and is associated with a worse prognosis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Acute disseminated encephalomyelitis (ADEM)

Definitions

- Autoimmune-mediated white matter (WM) demyelination of brain &/or spinal cord, usually with remyelination

IMAGING

General Features

- Best diagnostic clue
  - Multifocal WM/basal ganglia lesions days to weeks following infection/vaccination
    - 93% within 3 weeks of infection, 5% within 1 month of vaccination
- Location
  - May involve both brain and spinal cord; white matter > gray matter, but usually both affected
  - Deep/juxtacortical WM > periventricular WM
  - Both supratentorial and infratentorial lesions
- Size
  - Tumefactive lesions may be large, but with less mass effect than expected from tumor size
- Morphology
  - Punctate to "flocculent"
  - Tumefactive, mass-like lesions possible

CT Findings

- NECT
  - Initial CT normal in 40%
- CECT
  - Multifocal punctate or ring-enhancing lesions

MR Findings

- T2WI
  - Hyperintensities may be better visualized in brainstem and posterior fossa on T2
- FLAIR
  - Multifocal punctate to large flocculent FLAIR hyperintensities
    - Bilateral but asymmetric
  - Involve peripheral white-gray matter junction subcortical WM
  - Thalami & basal ganglia frequently involved, typically symmetric
  - Can involve brainstem and posterior fossa
  - Do not usually involve callososeptal interface
- DWI
  - Variably hyperintense lesions on DWI (trace) images
  - Apparent diffusion coefficient (ADC) may be increased or decreased
    - Most lesions show increased signal (T2 shine through)
    - Diffusion restriction uncommon, suggests worse prognosis
    - Diffusivity normal within normal-appearing white matter (NAWM), unlike MS
- T1WI C+
  - Punctate, ring, incomplete ring, peripheral enhancement
  - Cranial nerve(s) may enhance
  - Absence does not exclude diagnosis
- MRS
  - NAA low within lesions, lactate may be elevated
  - Choline often elevated in acute lesions
  - NAA normalizes with resolution of symptoms/MR abnormalities
- Magnetization transfer ratio (MTR)
  - ADEM MTR normal within NAWM, unlike MS

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR
    - Initial imaging often normal but more sensitive than CT
    - May appear identical to MS; repeat MR necessary to distinguish with certainty
- Protocol advice
  - Limited rapid interval follow-up may be provided by FLAIR alone

DIFFERENTIAL DIAGNOSIS

Multiple Sclerosis (MS)

- Predilection for periventricular WM (callososeptal interface), involves subcortical U-fibers, commonly in posterior fossa
- Lesions often more symmetric than ADEM
- Relapsing-remitting course common

Autoimmune-Mediated Vasculitis

- Multifocal GM-WM lesions
  - Bilateral, usually cortical/subcortical, basal ganglia/thalami
  - Ring-enhancing lesions may mimic infection

Acute Hypertensive Encephalopathy, PRES

- Typically posterior circulation in cortex/subcortical WM
- May affect deep gray nuclei

Aging Brain With Hyperintense WM Lesions

- Atherosclerotic brain changes in 50% patients > 50 years old
- Found in normotensive patients; more common in hypertensives
- Present in 10-30% of cognitively normal elderly patients
- MR: Scattered, asymmetric WM lesions, without enhancement
  - Often periatrial; posterior fossa uncommon
  - Spares callososeptal interface, subcortical U-fibers

Fabry Disease

- Deficiency α-galactosidase A; overaccumulation of glycosphingolipids within lysosomes
- MR: Scattered, asymmetric WM lesions, without enhancement
  - May involve brainstem and posterior fossa
  - Spares callososeptal interface and subcortical U-fibers
  - Cranial MR sensitive to identify neurologic involvement in asymptomatic patients
- Present with renal failure/heart disease

Behçet Disease

- MR: Scattered, asymmetric, subcortical WM lesions without cortical involvement

https://CafePezeshki.IR

- Nodular enhancement in acute phase
- Predilection for midbrain
- ADC ↑, similar to ADEM
- Classic triad: Oral & genital ulcerations with uveitis

PATHOLOGY

General Features

- Etiology
  - Autoimmune-mediated severe acute demyelination
  - Following nonspecific upper respiratory tract infection, often viral
    - Over 30 different infectious agents and immunizations reported
  - After specific viral illness: Epstein-Barr, influenza A, mumps, coronavirus
  - Especially after exanthematous diseases of childhood (chickenpox, measles)
  - After vaccination: Diphtheria, influenza, rabies, smallpox, tetanus, typhoid
  - Spontaneously (no known cause)
- Genetics
  - ADEM associated with DRB1*01 and DRB1*017(03) in Russian population
- Associated abnormalities
  - Acute hemorrhagic leukoencephalopathy variant associated with ulcerative colitis and asthma

Gross Pathologic & Surgical Features

- None, unless hemorrhage (rare) or tumefactive edema

Microscopic Features

- Acute myelin breakdown
- Perivenous inflammation; lymphocytic infiltrates
- Relative axonal preservation; atypical astrogliosis
- Virus generally not found, unlike viral encephalitides
- Similar to experimental allergic encephalomyelitis, supporting autoimmune-related etiology

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually preceded by prodromal phase: Fever, malaise, myalgia
  - Multifocal neurological symptoms, 2 days to 4 weeks after viral illness/immunization
    - Initial symptoms: Headache, fever, drowsiness
    - Cranial nerve palsies, seizures, hemiparesis
    - Decreased consciousness (from lethargy to coma)
    - Behavioral changes
- Other signs/symptoms
  - Seizures in 10-35%
- Clinical profile
  - CSF normal in 60 %
  - If abnormal (lymphocyte pleocytosis, elevated protein)
    - Usually lacks CSF oligoclonal bands

Demographics

- Age
  - Children > adults
  - Mean age is 5-8 years but can occur at any age
- Gender
  - Male predominance (M:F = 1.0:0.6-0.8), unlike MS
- Epidemiology
  - Rare, yet most common para-/post-infectious disorder
  - Most common in winter and spring
  - Exact epidemiology unknown, but increasingly reported

Natural History & Prognosis

- Usually monophasic, self-limited
- Variable prognosis
  - Complete recovery within 1 month (50-60%)
  - Neurologic sequelae (most commonly seizures) (20-30%)
  - Mortality (10-30%)
  - Relapses are rare
    - "Relapsing disseminated encephalomyelitis"
    - May not be separate entity from relapsing-remitting MS
- Typically delay between symptom onset and imaging findings
- Varicella and rubella ADEM have preferential patterns
  - Varicella ADEM characterized by cerebellar ataxia and mild pyramidal dysfunction
  - Rubella ADEM characterized by acute explosive onset, seizures, coma, and moderate pyramidal signs
- Rare manifestations of ADEM
  - Acute hemorrhagic leukoencephalopathy (2%)
    - Young patients with abrupt symptom onset
    - Fulminant, often ending in death
  - Bilateral striatal necrosis (usually in infants, may be reversible)

Treatment

- Immunosuppressive/immunomodulatory therapy
  - MR may show prompt improvement after therapy
- Plasma exchange therapy
  - 40% of patients failing steroid treatment may show marked improvement

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Imaging findings often lag behind symptom onset, resolution

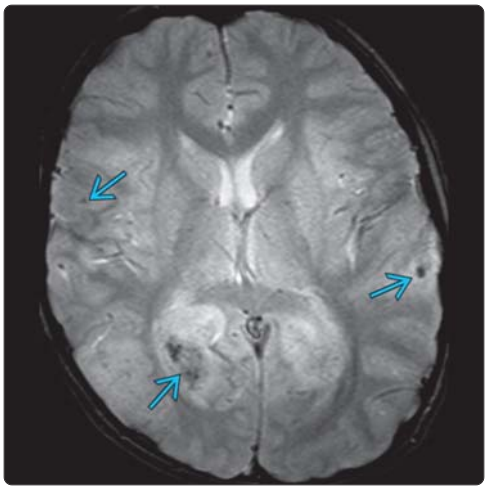
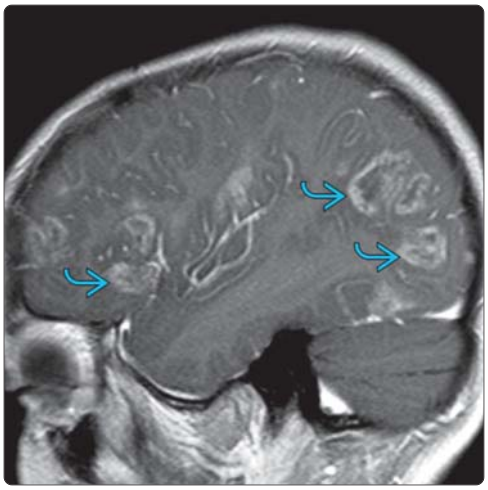
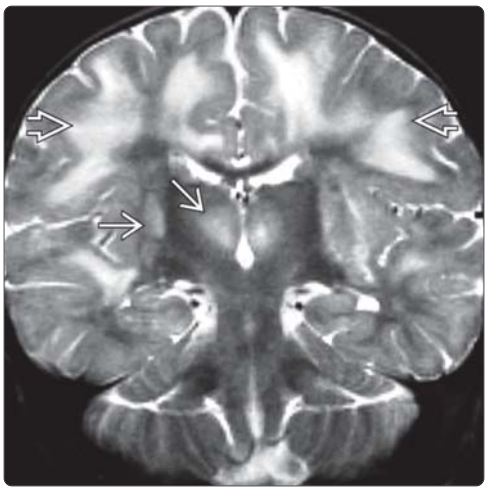
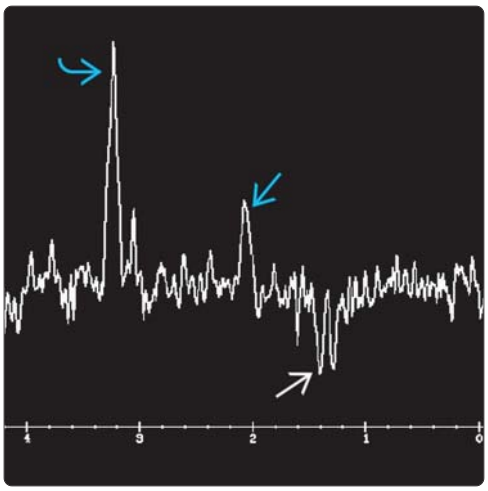
(Left) *Axial T2WI MR shows hyperintense lesions in the brachium pontis bilaterally, typical for demyelination. The right-sided lesion shows a targetoid ➡ appearance. Enhancement of several of the lesions was present on post-contrast T1 images (not shown).* **(Right)** *Axial FLAIR shows large confluent regions of hyperintense signal ⇨ in the periventricular and subcortical white matter in a 14 year old who presented with neck stiffness, fatigue, and seizures.*





(Left) *Axial SWI in the same patient shows petechial hemorrhages ⇨ in regions of FLAIR signal abnormality.* **(Right)** *Sagittal T1+C in the same patient shows extensive irregular ring enhancement ⇨ involving the multiple subcortical white matter lesions. Acute hemorrhagic leukoencephalopathy (AHL) is a rare manifestation of ADEM occurring in 2% of cases. AHL is associated with a very poor prognosis. Aggressive therapeutic management is a prerequisite to avoid usual disease course with fatal outcome.*





(Left) *Coronal T2WI MR shows large confluent regions of hyperintense signal in the white matter ➡ and deep gray nuclei ➡ of a child with ADEM. Although ADEM predominantly involves white matter, gray matter is often affected.* **(Right)** *MRS at long TE in a patient with acute lesions in ADEM demonstrates an ↑ choline ⇨, ↓ NAA ⇨, and the presence of a lactate doublet ➡. Increase in choline with corresponding reductions in NAA normalize as the clinical and conventional neuroimaging abnormalities resolve.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Hyperacute, fulminant hemorrhagic perivascular demyelinating disorder
- Usually viral or immunization related

IMAGING

- Best imaging: MR with T2*GRE, SWI
- CT: May be normal if only microbleeds present
- MR
  - Multifocal scattered or confluent white matter (WM) hyperintensities on T2/FLAIR
  - T2* shows multifocal "blooming" microbleeds in WM (often striking sparing of cortex)
    - Most striking in corpus callosum
    - Less common: Large lobar confluent hemorrhages
  - SWI significantly more sensitive than GRE

TOP DIFFERENTIAL DIAGNOSES

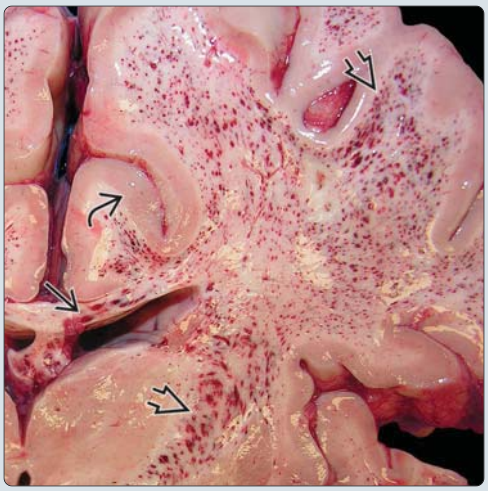
- Acute disseminated encephalomyelitis (ADEM)
- Multiple sclerosis
- Acute necrotizing encephalopathy
- Other brain "microbleeds"
  - Trauma (DAI), fat emboli, HUS/TTP
  - Sepsis, vasculitis, hemorrhagic viral fevers
  - High altitude cerebral edema

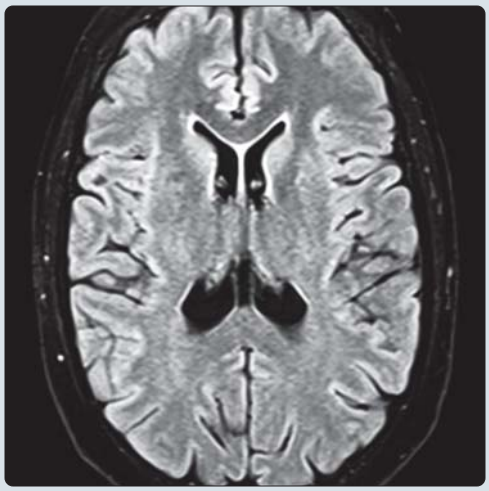
CLINICAL ISSUES

- Demographics
  - AHLE represents ~ 2% of ADEM cases
  - All ages but children, young adults most common
- Presentation and course
  - Fever, then rapid neurological deterioration
  - 60-80% mortality without treatment

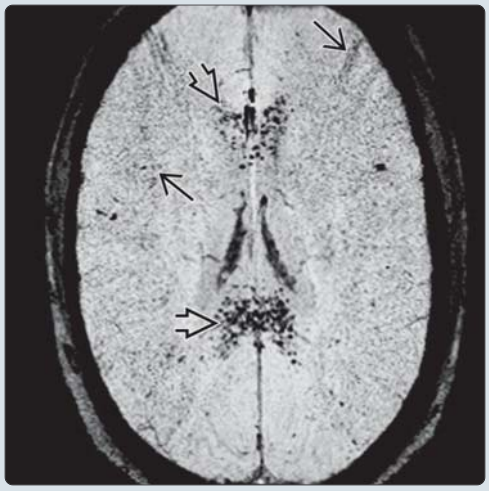
DIAGNOSTIC CHECKLIST

- Do T2* (GRE or SWI) in all febrile CNS illnesses with rapid clinical deterioration





(Left) *Close-up view of autopsied brain in a patient with acute hemorrhagic leukoencephalitis (AHLE) shows innumerable tiny microbleeds in the subcortical and deep white matter (WM) ⇨, corpus callosum ⇨. Note the overlying cortex is almost completely spared ⇨. (Courtesy E. Rushing, MD.)* **(Right)** *Axial FLAIR MR in a 25-year-old man with fever and rapidly decreasing mental status shows no definite abnormalities.*



(Left) *T2* GRE in the same patient shows a few punctate "blooming" foci in the corpus callosum genu ⇨ and splenium ⇨. The remainder of the WM appears normal.* **(Right)** *Axial SWI in the same patient shows innumerable tiny "blooming" microbleeds in the corpus callosum ⇨, as well as the subcortical and deep WM ⇨. The cortex is largely spared. These imaging findings are characteristic of AHLE.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Acute hemorrhagic leukoencephalitis (AHLE)

Synonyms

- Acute hemorrhagic encephalomyelitis (AHEM)
- Weston Hurst disease

Definitions

- Hyperacute, fulminant hemorrhagic perivascular demyelinating disorder
  - Usually viral or immunization related
- May be exceptionally severe form of acute disseminated encephalomyelopathy (ADEM)

IMAGING

General Features

- Best diagnostic clue
  - T2* shows multifocal petechial white matter (WM) microhemorrhages with striking sparing of cortex
  - Less common: Large, lobar confluent hemorrhages
- Location
  - White matter
    - Corpus callosum, subcortical WM (U-fibers)
  - Less common: Basal ganglia, midbrain, pons, cerebellum
- Size
  - Punctate microbleeds > large lobar hemorrhages

CT Findings

- NECT
  - May be normal if only microbleeds present
  - ± WM edema with hypodensity

MR Findings

- T1WI
  - Often normal
- T2WI
  - Multifocal scattered or confluent WM hyperintensities
    - Most striking in corpus callosum
- T2* GRE
  - Multifocal "blooming" microbleeds
  - SWI significantly more sensitive than GRE

Imaging Recommendations

- Best imaging tool
  - MR with T2*GRE, SWI

DIFFERENTIAL DIAGNOSIS

Acute Disseminated Encephalomyelitis (ADEM)

- AHLE may be most severe form of ADEM
- ADEM usually less fulminant
- ADEM lacks lobar or perivascular hemorrhages of AHLE

Multiple Sclerosis (MS)

- Acute fulminant MS (Marburg type)
  - Lacks hemorrhage, high fever, marked leukocytosis

Acute Necrotizing Encephalopathy

- Rare complication of acute viral infection, such as influenza A
- Children < 4 years most common
- Bilateral, symmetric lesions in thalami typical
- WM predominance rare

Other Etiologies of Brain "Microbleeds"

- Diffuse traumatic vascular injury
- Fat emboli
- HUS/TTP
- Sepsis, vasculitis
- Hemorrhagic infections (viral fevers, malaria, rickettsial diseases)
- High altitude cerebral edema

PATHOLOGY

Gross Pathologic & Surgical Features

- Predominately involves WM of brain ± spinal cord
- May affect basal ganglia but usually spares cortical GM
- Focal confluent &/or multifocal petechial WM hemorrhages

Microscopic Features

- Fibrinoid necrosis of vessel walls
- Perivascular demyelination, hemorrhages

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Fever, then rapid neurological deterioration
  - Somnolence, impaired consciousness
- Other signs/symptoms
  - Long-tract signs

Demographics

- AHLE represents ~ 2% of ADEM cases
- All ages but children, young adults most common

Natural History & Prognosis

- Rapid clinical deterioration; death within days typical course
- Mortality: 60-80%

Treatment

- Aggressive IV steroids, immunoglobulin, plasmapheresis

DIAGNOSTIC CHECKLIST

Consider

- Do T2* (GRE or SWI) in all febrile CNS illnesses with rapid clinical deterioration

Image Interpretation Pearls

- Corpus callosum, subcortical WM microbleeds with striking sparing of overlying cortex typical for AHLE

SELECTED REFERENCES

KEY FACTS

TERMINOLOGY

- Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids
  - Predominantly involving brainstem, adjacent rhombencephalic structures
  - Shows clinical, imaging response to glucocorticosteroids

IMAGING

- Location: Predominately pons
  - May extend laterally into cerebellar peduncles or hemispheres
  - Caudally into medulla, spinal cord
  - Rostrally into midbrain
- MR
  - Classic: Enhancing punctate/curvilinear lesions "peppering" the pons
    - May exhibit subtle radiating pattern
  - ± faint, patchy or "speckled" punctate hyperintensities on T2/FLAIR
  - Beware: May begin as isolated, enhancing mass in pons/cerebellar peduncle before exhibiting typical pattern of multifocal punctate pontine lesions

TOP DIFFERENTIAL DIAGNOSES

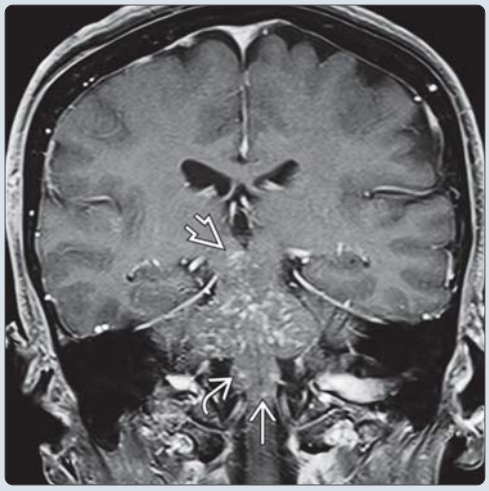
- Angiocentric (intravascular) lymphoma
- Neurosarcoidosis
- Demyelinating disease (MS, NMO spectrum)
- Vasculitis (primary, secondary, Behçet)
- Lymphomatoid granulomatosis
- CNS histiocytosis (LCH, Erdheim-Chester, hemophagocytic)

CLINICAL ISSUES

- Brainstem symptoms, gait ataxia, diplopia
  - Often relapsing-remitting course (without treatment)
  - Mean age at onset 40-50 years (reported range 13-86 years)
- Keep in mind: CLIPPERS is diagnosis of exclusion

(Left) *Sagittal FLAIR MR in a 56-year-old female with weight loss and 3-week history of diplopia and disequilibrium shows confluent and punctate hyperintensities in the pons ⇨ and medulla ⇨.* **(Right)** *Axial T1C+ scan in the same patient shows multiple punctate and curvilinear enhancing foci "peppering" the pons ⇨. Additional lesions are present in both cerebellar peduncles, vermis, and the left cerebellar hemisphere.*

(Left) *More cephalad T1C+ scan in the same patient shows the punctate ⇨ and curvilinear ⇨ lesions involving the upper pons.* **(Right)** *Coronal T1C+FS scan in the same patient shows the lesions "peppering" the pons. Note cephalad extension into the cerebral peduncles ⇨ and inferior extension into the medulla ⇨ and upper cervical cord ⇨. DSA (not shown) was negative. The lesions resolved with corticosteroids, so this is a presumed case of CLIPPERS.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS)

Definitions

- Recently described inflammatory CNS disorder
- Predominantly involving brainstem, adjacent rhombencephalic structures
- Clinical, imaging response to glucocorticosteroids

IMAGING

General Features

- Best diagnostic clue
  - Enhancing punctate/curvilinear lesions "peppering" the pons
    - May exhibit subtle radiating pattern
- Location
  - Predominately pons
  - May extend laterally into cerebellar peduncles or hemispheres
  - Caudally into medulla, spinal cord
  - Rostrally into midbrain
  - Sometimes involves basal ganglia, cerebral WM
  - May begin as isolated, enhancing mass in pons/cerebellar peduncle before exhibiting typical pattern of multifocal punctate pontine lesions
- Morphology
  - Typically small, punctate or curvilinear

CT Findings

- Usually normal

MR Findings

- T1WI
  - Usually normal
  - Pontocerebellar/cerebellar, cord, cerebral atrophy may be late changes
- T2WI
  - ± faint, patchy or "speckled" punctate hyperintensities on T2/FLAIR
  - Minimal or no mass effect, vasogenic edema
- T2* GRE
  - May show blooming foci
- T1WI C+
  - Punctate &/or curvilinear enhancing foci ("peppering the pons")

Angiographic Findings

- DSA normal without evidence for vasculitis

Imaging Recommendations

- Best imaging tool
  - MR ± contrast (include coronal T1C+), DWI, T2*

DIFFERENTIAL DIAGNOSIS

Lymphoma, Angiocentric (Intravascular)

- Hemorrhage, foci of restricted diffusion common

Neurosarcoidosis

- Dura, leptomeningeal lesions common

Demyelinating Disease

- MS, ADEM

Vasculitis

- PACNS; ANCA, polyarteritis nodosa, Churg-Strauss
- Systemic vasculitides (SLE, RA)

Glioblastoma

- Primary brainstem GBM rare in adults

Lymphomatoid Granulomatosis

- Brain often more diffusely involved

Paraneoplastic Syndromes

Neuromyelitis Optica/NMO Spectrum Disorders

- Brain less commonly involved; AqP4(+) common

CNS Histiocytosis

- Langerhans cell, Erdheim-Chester, hemophagocytic lymphohistiocytosis

PATHOLOGY

General Features

- Etiology
  - Immune-mediated inflammation (precise etiology unknown)

Microscopic Features

- Perivascular tropism with adjacent parenchymal inflammatory infiltrate

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Brainstem symptoms, gait ataxia, diplopia
  - Systemic symptoms common

Demographics

- Age
  - Mean age at onset 40-50 years (reported range 13-86 years)
- Gender
  - Both; slight male preponderance

Natural History & Prognosis

- Generally subacute presentation
  - Often relapsing-remitting course (without treatment)
- Diagnosis of exclusion
  - Requires careful exclusion of alternative diagnoses

Treatment

- Corticosteroids (clinical, imaging response key to diagnosis)

Overview

Inherited metabolic disorders (IMD) are very difficult to diagnose. Affected patients can present at any age; symptoms vary depending upon age of onset and severity of the biochemical defect. Completely different parts of the brain may be involved in less severely affected patients as compared to more severely affected patients. The same enzyme may perform different functions, in different parts of the brain, as the person matures from infancy to childhood to adulthood. Clearly, patients will have different symptoms if different parts of the brain are involved.

Adding to the confusion, IMDs have been **classified** in many different ways: Biochemical characteristics, the biochemical pathway that is affected, the cellular organelle in which the affected protein or affected biochemical pathway is located, characteristics of clinical presentation, and the gene that is affected. None of these classifications have been very successful, and it is likely that classification by the biochemical pathways affected will, ultimately, be the most useful.

The imaging features of inherited metabolic disorders can be equally confusing, particularly if not approached methodically. The imaging appearances of many disorders overlap and often vary with the stage and the variant of the disease. Imaging is most helpful early in the course of the disease, when it can help to narrow the differential diagnosis and reduce the amount of testing needed. From a neuroimaging perspective, it is most useful to classify disorders based on the **pattern of brain involvement on MR early in the course of the disease**. This pattern can be supplemented by the use of metabolic data (obtained from proton MR spectroscopy), diffusion data (obtained from diffusion-weighted imaging), and, occasionally, magnetization transfer.

First Analysis: White vs. Gray Matter

The first important determination is whether the disease involves primarily gray matter, primarily white matter, or both gray and white matter.

If the gray matter is primarily involved, scrutinize both the cortex and deep nuclei to determine whether involvement is primarily cortical, primarily deep nuclear, or both. Sometimes disorders that primarily affect cortical gray matter will show cortical swelling with effaced sulci early in the course of the disease; more commonly, diagnosis is made later and cortical thinning is found, with prominent cortical sulci, In later stages, cortical thinning is the rule in all such disorders. The cerebral white matter will often have an abnormal appearance in patients with primary cortical disorders, as Wallerian degeneration of axons causes diminished white matter volume and sometimes mild hyperintensity on FLAIR and T2-weighted images. This appearance can be differentiated from that of primary white matter disorders if the study is performed early in the course of the disease; primarily affected white matter will typically be edematous and, therefore, brighter and more voluminous (causing compressed, smaller sulci) than the white matter that has undergone secondary degeneration. In the acute phase, disorders primarily affecting deep gray matter will typically show edema (FLAIR hyperintensity and prolonged T1 and T2 relaxation times) in the involved structures. In the chronic phase, volume loss with gliosis (resulting in T2 hyperintensity) is more typical.

Disorders primarily affecting white matter cause marked signal abnormality before any volume loss is apparent. Some white matter disorders cause spongiform changes, result in intramyelinic edema, or have an inflammatory component in the early stages. These conditions cause edema with accompanying mass effect upon adjacent structures. Diffusion-weighted images can add specificity as spongiform changes typically cause increased diffusivity, while intramyelinic edema and inflammation cause reduced diffusivity. Alternatively, many white matter disorders, such as X-linked adrenoleukodystrophy and fibrinoid leukodystrophy (Alexander disease), start locally and expand to involve adjacent areas. Neither of these appearances are seen in the white matter of gray matter disorders. White matter diseases can result in necrosis and cavitation of the affected regions and subsequent ex vacuo dilation of the ventricles, whereas the abnormal white matter in gray matter disorders appears less severely damaged.

Gray Matter Disorders

Gray matter disorders need to be further analyzed to determine whether the disorder primarily involves the cerebral cortex or the deep gray matter nuclei. If the pattern of the imaging study indicates that the metabolic disorder is **primarily one of cortical involvement** (cortical thinning with enlarged cortical sulci), consideration should be given to disorders such as the neuronal ceroid lipofuscinoses, the mucolipidoses, glycogen storage diseases, or GM1 gangliosidosis.

When **only deep gray matter is involved**, it is important to identify the specific structures that are affected and their signal intensities. Involvement of the striatum (caudate and putamen) is typically seen in mitochondrial disorders (primarily Leigh syndrome, mitochondrial encephalopathy with lactic acidosis and stroke-like symptoms [MELAS], and the glutaric acidurias), propionic acidemia, Wilson disease, juvenile Huntington disease, molybdenum cofactor deficiency, asphyxia, and childhood or adult hypoglycemia.

Associated white matter or cortical injury may be present in many disorders. If globi pallidi show isolated T2 prolongation, succinate semialdehyde dehydrogenase deficiency, methylmalonic academia (cavitation of globi pallidi), guanidinoacetate methyltransferase deficiency (a creatine synthesis disorder), isovaleric acidemia, pyruvate dehydrogenase deficiency (due to mutation of the dihydrolipoamide acetyltransferase [E2] component), carbon monoxide poisoning, or the chronic phase of kernicterus should be considered. If T2 or FLAIR hyperintensity of the globi pallidi is associated with subcortical white matter demyelination, sparing of the periventricular white matter, and involvement of the cerebellar dentate nuclei, L-2-hydroxyglutaricaciduria and Kearns-Sayre syndrome should be considered. When the MR shows atrophy of the dorsal brainstem, cerebellar nuclei, and subthalamic nuclei, one should consider Leigh syndrome secondary to *SURF1* mutation. If T1 hyperintensity of the globi pallidi is associated with normal T2 signal, and the patient is not receiving hyperalimentation, consider chronic hepatic disease. If both T1 and T2 hyperintensity are seen in a neonate or young infant, consider acute hyperbilirubinemia of infancy, systemic lupus erythematosus, and hemolytic-uremic syndrome; in the presence of edema involving the external and extreme capsules and the claustrum, hemolytic-uremic syndrome is the most likely. If the globi pallidi, the insula, and perirolandic

https://CafePezeshki.IR

cortex are all hyperintense on T2-weighted or FLAIR images, the diagnosis of hyperammonemia (frequently due to a urea cycle disorder) should be suggested. If the involvement of the globus pallidus is manifested on MR as T2 hypointensity with central T2 hyperintensity, the diagnosis of pantothenate kinase-associated neuropathy (formerly called Hallervorden-Spatz disease) can be made with some confidence.

White Matter Disorders

White matter disorders can be divided into disorders in which white matter never myelinates completely (**hypomyelination**) and disorders in which myelin forms and breaks down (demyelination) with or without cavitation of white matter. The pattern of a lack of myelination, or hypomyelination, is seen in very few disorders, called the hypomyelinating leukoencephalopathies. These should be differentiated from delayed myelination, which has a very different differential diagnosis. If a follow-up MR in 6 months shows no change or minimal change in myelination, a hypomyelinating disorder can be diagnosed. The appearance of the brain in these disorders is often that of a normal, much more immature brain. For example, the MR of a 5-year-old child with hypomyelination might be mistaken for that of a 5-month-old infant; diffusivity is normal, while magnetization transfer is reduced. Such disorders include Pelizaeus-Merzbacher and like diseases, leukodystrophies with trichothiodystrophy and photosensitivity, Tay syndrome, 18q syndrome (deletion of a large portion of the long arm of chromosome 18), sialic acidemia (Salla disease), hypomyelination with atrophy of basal ganglia and cerebellum, and hypomyelination with congenital cataracts. Cerebral or cerebellar atrophy may develop over time in many of these patients.

When myelin develops but is subsequently damaged, the condition is called **demyelination** to differentiate it from breakdown of abnormal myelin, sometimes called **dysmyelination**. By the use of diffusion tensor imaging, it may eventually be possible to differentiate these 2 entities, but the differentiation cannot currently be made. Myelin destruction can, however, be differentiated from white matter cavitation (cystic degeneration). Cystic degeneration has much lower signal on FLAIR sequences, significantly less magnetization transfer, and greater diffusivity than areas of myelin destruction without cavitation. In disorders where inflammation is associated with demyelination (typically peroxisomal disorders), the inflammatory infiltrate causes reduced diffusivity and blood-brain barrier breakdown (resulting in regions of contrast enhancement). When myelin breakdown occurs, the white matter becomes more hypointense on T1-weighted images and more hyperintense on T2-weighted images. In these situations, analyze the brain to determine whether the region primarily affected is the periventricular white matter, the deep white matter, or the subcortical white matter.

Disorders Affecting Gray and White Matter

Disorders involving both gray and white matter are first separated by the type of gray matter involvement: Those involving only the cerebral cortex and those involving deep gray matter (with or without cortical involvement).

Disorders involving only cortical gray matter can be subdivided depending on the involvement of long bones and the spinal column. If the long bones are normal, the cortex should be analyzed for malformations of cortical development (MCD). If an MCD is present in addition to a lack of myelination, the differential diagnosis includes the generalized peroxisomal disorders, congenital cytomegalovirus disease, and the so-called cobblestone cortical malformations. If no MCD is found, differential considerations include Alpers disease and Menkes disease, both of which cause considerable cerebral cortical destruction. If the bones are abnormal, the differential diagnoses include primarily storage diseases, such as the mucopolysaccharidoses and lipid storage disorders.

If deep gray matter is involved, determine precisely which nuclei are affected. If thalami are involved, differential considerations include Krabbe disease and the GM1 and GM2 gangliosidoses; the thalami in these disorders display high attenuation on CT and short T1 and T2 relaxation times (hyperintense on T1-weighted images and hypointense on T2-weighted images) on MR. Krabbe disease is distinguished by the early presence of abnormal T2 hyperintensity along the corticospinal tracts and in the cerebellar dentate nuclei.

Another disorder with thalamic involvement is profound neonatal hypoxic-ischemic injury, which typically involves the ventrolateral thalami, posterior putamina, and perirolandic cortex; a characteristic history of perinatal distress and neonatal encephalopathy simplifies the diagnosis. Another consideration when thalamic involvement is identified is autosomal dominant acute necrotizing encephalitis, particularly if T2 hyperintensity is also seen in the dorsal brainstem. Thalami may also be affected in mitochondrial disorders, Wilson disease, and Canavan disease; typically other deep gray matter nuclei will be affected as well (e.g., putamina in mitochondrial disorders and Wilson disease, globi pallidi in Canavan disease). Globus pallidus involvement in association with diffuse white matter disease including the subcortical, deep, and periventricular regions suggests a diagnosis of Canavan disease, particularly if associated with macrocephaly. Association of globus pallidus involvement with affected subcortical white matter but sparing of periventricular white matter suggests a later phase of Kearns-Sayre syndrome or L-2-hydroxyglutaric aciduria; the latter will often show involvement of the cerebellar dentate nuclei.

Globus pallidus injury with sparing of subcortical white matter in early stages suggests methylmalonic academia (look for cavitation), maple syrup urine disease, carbon monoxide toxicity, or cyanide toxicity. MR of maple syrup urine disease during the acute neonatal phase of the disease shows involvement of the centrum semiovale, internal capsules, cerebral peduncles, dorsal pons, and cerebellar white matter, reduced diffusivity in the affected regions, and a peak at 0.9 ppm on proton MR spectroscopy. Carbon monoxide and cyanide toxicity typically involve the cerebral cortex, globi pallidi, and cerebellum. White matter disease associated with striatal involvement suggests Leigh syndrome, MELAS, propionic acidemia, glutaric aciduria type 1, molybdenum cofactor deficiency, isolated sulfite oxidase deficiency, hypomyelination with atrophy of the basal ganglia and cerebellum, toxic exposure, later infantile or childhood profound hypoxic-ischemic injury, or childhood hypoglycemia. Proper analysis of the MR scans using this pattern system can facilitate the work-up of patients with inborn errors of metabolism.

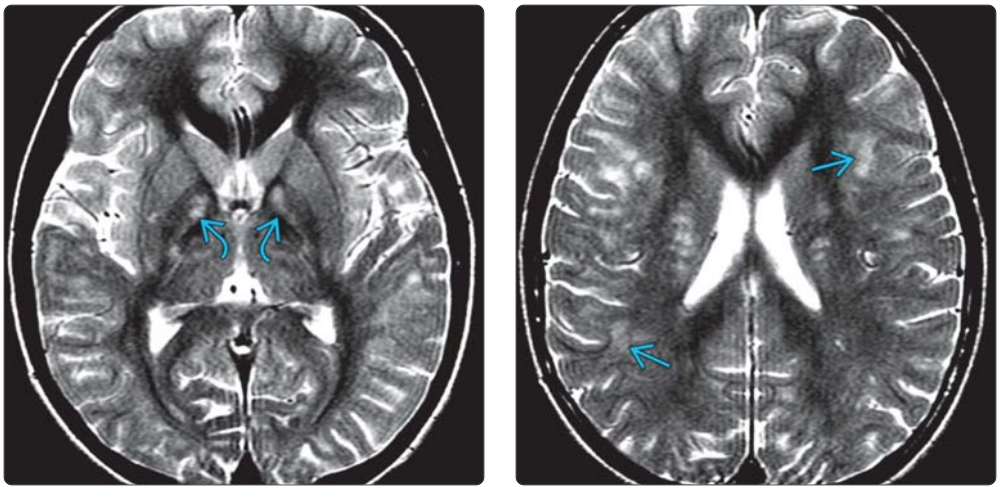
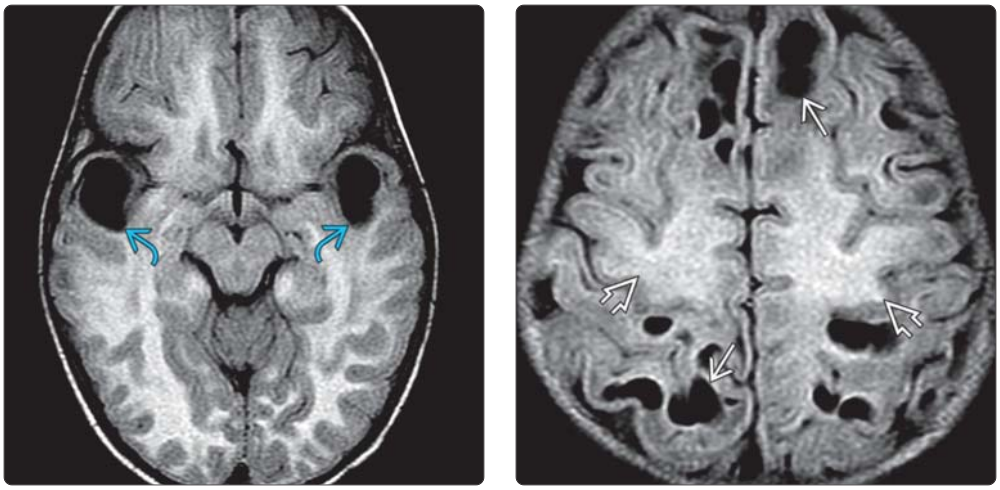
Imaging Patterns

Metabolic Disorders With
T2 or FLAIR Hyperintensity of the Corpus Striatum
Leigh syndrome (includes pyruvate dehydrogenase deficiency, respiratory complex I and complex II disorders)
Wilson disease
Glutaric aciduria type 1
Juvenile Huntington disease
Molybdenum cofactor deficiency
Propionic acidemia
T2 or FLAIR Hyperintensity of Globi Pallidi
Methylmalonic acidemia
Succinic semialdehyde dehydrogenase deficiency
Urea cycle disorders
Guanidinoacetate methyltransferase deficiency
Pyruvate dehydrogenase (E2) deficiency
Systemic lupus erythematosus
Hemolytic-uremic syndrome
Bilirubin toxicity
Isovaleric acidemia
Carbon monoxide or cyanide toxicity
Early Involvement of Subcortical White Matter
Alexander disease
Kearns-Sayre syndrome
Galactosemia
Mitochondrial disorders
Early Involvement of Periventricular and Deep White Matter With Sparing of Subcortical White Matter
X-linked adrenoleukodystrophy
Krabbe disease (globoid cell leukodystrophy)
Metachromatic leukodystrophy
GM2 gangliosidoses
Childhood ataxia with CNS hypomyelination (vanishing white matter disease)
Merosin-deficient congenital muscular dystrophy with cortical malformation
Damage from radiation or chemotherapy
Globus Pallidus and White Matter Involvement
Canavan disease
Methylmalonic acidemia
Kearns-Sayre syndrome
L-2-hydroxyglutaric aciduria
Maple syrup urine disease
Carbon monoxide or cyanide poisoning
Striatal (Caudate and Putaminal) and White Matter Involvement
Leigh syndrome
Mitochondrial encephalopathy with lactic acidosis and stroke-like symptoms (MELAS)
Other mitochondrial leukoencephalopathies
Propionic acidemia
Glutaric acidemia type 1
Isolated sulfite oxidase deficiency
Late infantile/childhood profound hypoxic-ischemic injury
Childhood hypoglycemia

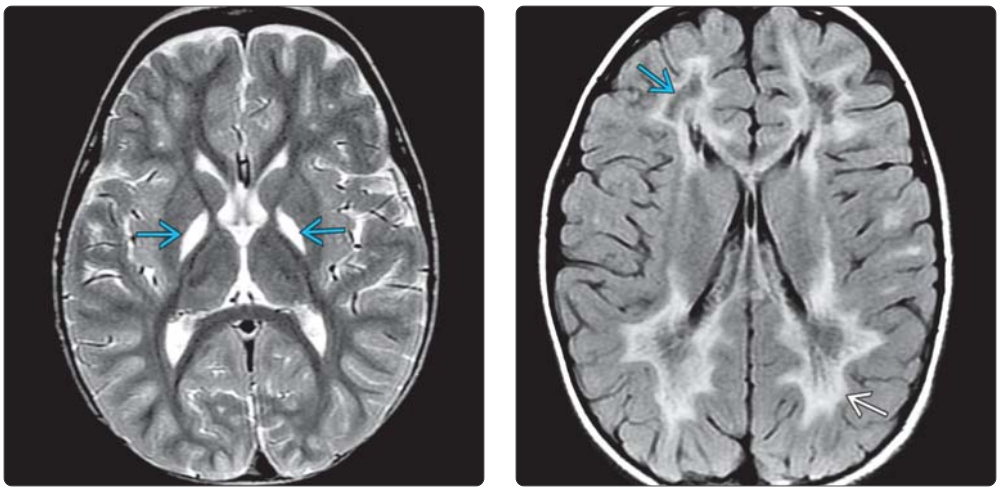
https://CafePezeshki.IR



(Left) *Axial T2WI MR in a patient with Kearns-Sayre syndrome shows bilateral globus pallidus hyperintensity* ⇨. **(Right)** *More cephalad T2WI MR in the same case shows involvement of subcortical white matter* ⇨ *with sparing of periventricular regions.*



(Left) *Axial FLAIR MR in a 22-month-old child with macrocephaly and decreasing acquisition of developmental milestones shows large, bilateral temporal lobe cysts* ⇨ *typical of megalencephaly with leukoencephalopathy and cysts (MLC). The hypomyelinated white matter is swollen and diffusely hyperintense.* **(Right)** *Axial FLAIR MR in a 2-year-old child with MLC shows swollen, hyperintense hypomyelinated WM* ➡ *and numerous subcortical cysts* ➡.



(Left) *Axial T2WI MR in a child with methylmalonic acidemia shows abnormal hyperintensity* ⇨ *of the bilateral globi pallidi. The white matter is unaffected in this patient.* **(Right)** *Axial FLAIR MR shows multiple areas of hypointense cavitation* ⇨ *in the cerebral white matter in this patient with vanishing white matter disease. The less affected subcortical white matter* ➡ *is hyperintense.*

KEY FACTS

TERMINOLOGY

- Diminished or absent degree of white matter (WM) myelination for age
- May be primary hypomyelination syndrome or secondary to other pathology

IMAGING

- T1 shortening reflects presence of mature oligodendrocytes with proteolipid protein
  - Myelination on T1WI is complete by 1 year of age
- T2 shortening reflects displacement of interstitial water by myelin wrapping on axons
  - Myelination on T2WI is complete by 3 years of age, usually by 2 years of age

TOP DIFFERENTIAL DIAGNOSES

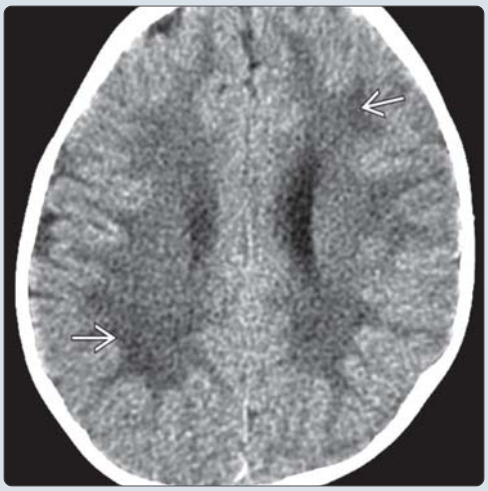
- Hypomyelinating leukodystrophies (Pelizaeus-Merzbacher disease, 4H syndrome)
- Mucopolysaccharidoses, mitochondrial encephalopathies
- Gray matter disease with secondary myelin loss

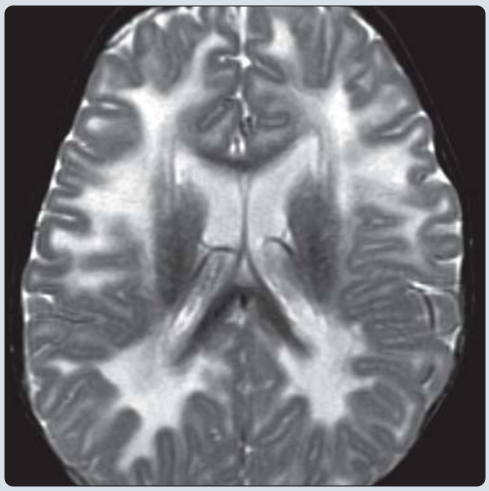
PATHOLOGY

- Hypomyelination often reflects impaired oligodendrocyte maturation/survival
  - Immature oligodendrocytes do not produce myelin
  - Without myelin, axons are not properly nourished

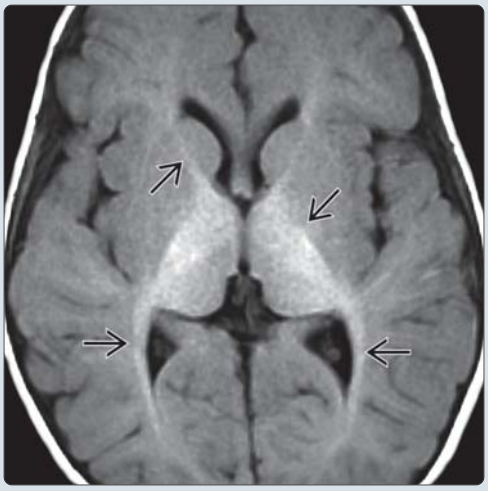
DIAGNOSTIC CHECKLIST

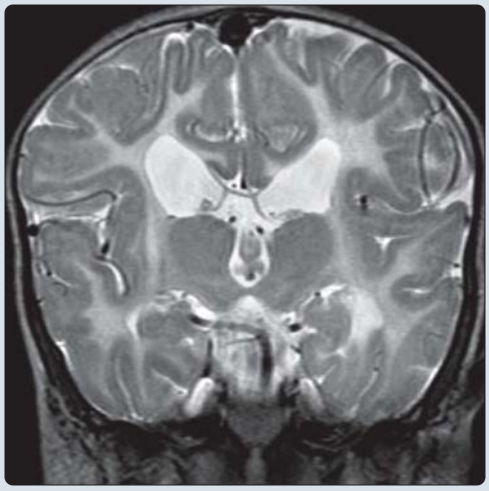
- Hypomyelination does not have bright T2/FLAIR signal like dys- or demyelination
- Define degree of myelination by age at which it would be appropriate → "degree of myelination appropriate for x months of age"
  - Assess myelination prior to learning chronologic age of patient





(Left) *Axial NECT in a 1 year old with Jacobsen syndrome (11q-chromosomal deletion) shows irregular hypoattenuation that is most severe in the subcortical cerebral white matter* ⇨. **(Right)** *Axial T2WI MR in the same patient confirms that the decreased attenuation on CT correlates with marked and diffuse hypomyelination. Hypomyelination has been described in numerous chromosomal deletion syndromes, although the prevalence is difficult to gauge.*





(Left) *Axial T1WI MR in a 9 month old with 18q-syndrome shows only faint T1 shortening that is limited to the internal capsules and optic radiations* ⇨. *At 9 months, only the most distal rami of white matter should be without bright signal on T1WI.* **(Right)** *Coronal T2WI MR in a 14 year old shows hypomyelination and atrophy of the basal ganglia and cerebellum (H-ABC). Note absence of visible caudate nuclei and corpus callosum in addition to the abnormal hyperintense signal of unmyelinated white matter.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Delayed myelin maturation, undermyelination

Definitions

- Diminished or absent degree of white matter (WM) myelination for age
- Myelin "milestones" not achieved
- May be primary hypomyelination syndrome or secondary to other pathology

IMAGING

General Features

- Best diagnostic clue
  - Poor gray-white differentiation on T1WI in children > 1 year
  - Poor gray-white differentiation on T2WI in children > 2 years
- Location
  - Key areas to assess are internal capsule, pyramidal tracts, and peripheral frontal lobe WM rami
- Size
  - Hypomyelination will result in reduced brain volume
    - Thin corpus callosum evident on sagittal images
- Morphology
  - Typically normal

CT Findings

- NECT
  - Lack of myelin generally too subtle to identify on CT

MR Findings

- T1WI
  - Myelinated WM is hyperintense
    - T1 shortening reflects presence of mature oligodendrocytes with proteolipid protein
  - WM structures become hyperintense in stereotypical order
  - Myelination on T1WI is essentially complete by age 1 year
- T2WI
  - Myelinated WM is hypointense
    - T2 shortening reflects displacement of interstitial water by myelin wrapping on axons
  - Hypointensity on T2WI lags hyperintensity on T1WI by 4-8 months
  - Myelination on T2WI is complete by 3 years of age (usually by 2 years of age)
  - "Terminal zones"
    - Regions of persistent hyperintense signal on T2WI in otherwise normal brains
    - Typically around trigones of lateral ventricles
    - Likely due to concentration of interstitial water migrating to ventricles in these areas
    - Must be distinguished from periventricular leukomalacia or perivascular spaces
- PD/intermediate
  - Key for distinguishing gliosis from undermyelination
    - Gliosis is more hyperintense
- FLAIR
  - Not recommended in children < 2 years
    - Heterogeneous signal makes assessment of myelination and distinction of pathology more difficult
- DWI
  - ADC values predate T1- and T2-weighted signal changes
    - ADC, radial diffusivity decrease with maturation
  - Fractional anisotropy increases with brain maturation
- T1WI C+
  - Some leukodystrophies have abnormal enhancement
    - Not strictly hypomyelination
- MRS
  - Choline decreases as myelination progresses
  - Relative increases in myoinositol, choline, and lipid resonances with hypomyelination
  - Significant increases in choline may indicate demyelination or dysmyelination

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - T1WI most helpful in children < 10 months
  - T2WI most helpful in children > 10 months

DIFFERENTIAL DIAGNOSIS

Primary Hypomyelination Syndromes

- Pelizaeus-Merzbacher disease (PMD)
- Spastic paraplegia type 2 (SPG2)
- 18q-syndrome
- *TUBB4A*-related hypomyelinating disorders (with or without atrophy of basal ganglia &/or cerebellum)
- 4H syndrome (hypomyelination, hypodontia, hypogonadotropic hypogonadism)
- Oculodentodigital dysplasia
- Hypomyelination with congenital cataracts
- Hypomyelination with brainstem, spinal cord involvement/leg spasticity
- Fucosidosis
- Sialic acid storage disease
- Aicardi-Goutieres syndrome

Prematurity

- Use of normal milestones assumes full-term gestation
- Adjust chronologic age for degree of prematurity

External Stresses

- Chronic debilitating conditions in infancy
  - Congenital vascular malformations (AVF)
  - Malnutrition
- Treatments for diseases in neonate
  - Organ transplantation
  - Chemotherapy
- Myelination typically rebounds with treatment of primary illness

Syndromes With Hypomyelination and Other Findings

- Typically cause dysmyelination, not hypomyelination
- Mucopolysaccharidoses
  - Hunter, Hurler

https://CafePezeshki.IR

- Mitochondrial encephalopathies
  - Electron transport chain (ETC) defects
  - Mitochondrial membrane abnormalities
- Leukodystrophies
  - Metachromatic leukodystrophy
  - Globoid leukodystrophy (Krabbe)
- Trichothiodystrophy
  - Group of disorders of DNA repair
  - Osteosclerosis of axial skeleton
  - "Tiger-band hair" under polarized light
- Neurodegenerative disorders
  - Neuronal ceroid lipofuscinoses may have hypomyelination as cortical degeneration proceeds

PATHOLOGY

General Features

- Etiology
  - Hypomyelination often reflects deficiency of mature oligodendrocytes
  - Duplication of *PLP1* gene causes folded protein response, oligodendrocyte death
    - Result is nearly complete absence of myelin
  - Nutritional disorders, neurodegeneration are other causes
- Genetics
  - 10-30% of PMD and SPG2 caused by defects in proteolipid protein (*PLP*) gene (Xq21-q22)
  - 18q-syndrome causes hemizygous deletion (1 copy of gene missing) of *MBP* gene
- Associated abnormalities
  - Craniofacial-facial malformations associated with 18q-syndrome
  - PMD and 18q-syndrome are prototypes of hypomyelination

Microscopic Features

- Pelizaeus-Merzbacher disease
  - Diffuse myelin deficiency: Looks like much less mature brain
  - Islands of persistent perivascular myelin result in classic tigroid appearance
  - Absent or deficient compact myelin sheaths, "redundant myelin balls"

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Developmental delay, hypotonia
- Other signs/symptoms
  - Classic PMD: Head titubation, hypotonia, only 50% able to sit
  - 18q-syndrome: Developmental delays, short stature, delayed bone age, limb anomalies
  - Trichothiodystrophy: Short stature, osteosclerosis

Demographics

- Age
  - Primary hypomyelination syndromes typically present in infancy
- Gender
  - Classic PMD is X-linked recessive and thus exclusive to males
  - Other forms of PMD are autosomal recessive and equally distributed

Natural History & Prognosis

- Late progression of symptoms may occur in some

Treatment

- No treatment yet for heritable disorders of hypomyelination

DIAGNOSTIC CHECKLIST

Consider

- Hypomyelination may be difficult to distinguish from dys- and demyelination
- Remember to adjust chronologic age for degree of prematurity when imaging infants

Image Interpretation Pearls

- Assess myelination prior to learning chronologic age of patient
  - Avoid predetermination bias
- Correlate imaging findings with clinical history and neurological exam to narrow scope of differential

Reporting Tips

- Define degree of myelination by age at which it would be appropriate → "degree of myelination appropriate for x months of age"

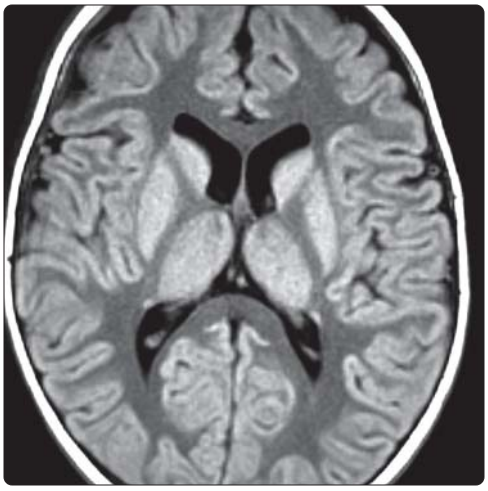
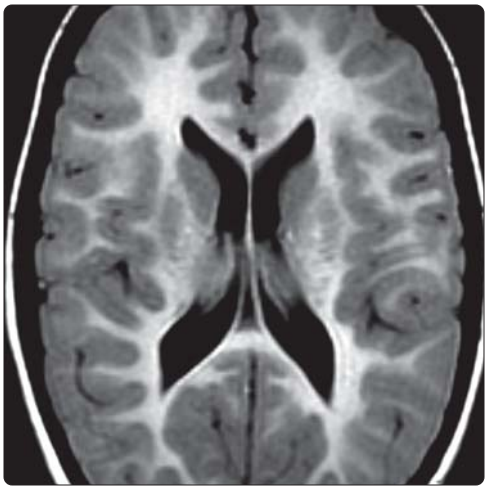
(Left) *Axial T2WI MR in this 12 year old with trichothiodystrophy shows essentially complete absence of myelination throughout the brain. Examination of the hair under polarized light demonstrated characteristic "tiger-tail" bands, and radiographs showed central osteosclerosis.* **(Right)** *Sagittal T1WI MR in the same child shows absence of myelin deposition throughout the brain, making the corpus callosum difficult to define on this midline image. Note the thickened skull posteriorly.*





(Left) *Axial T1WI MR shows a 26 month old with nystagmus and head titubation, diagnosed with Pelizaeus-Merzbacher disease. The homogeneous absence of myelin deposition causes the appearance to mimic a normal FLAIR image in a mature brain.* **(Right)** *Conversely, this axial FLAIR image in a 6 year old with Pelizaeus-Merzbacher disease resembles a normal T1WI, with hyperintense signal of the white matter relative to gray matter throughout.*

(Left) *Axial T1WI MR in a 2 year old with nystagmus shows minimal T1 shortening in the posterior limb of internal capsule (PLIC); myelination should appear complete on T1WI at this age. Chromosomal analysis showed a mutation of PLP, confirming a diagnosis of Pelizaeus-Merzbacher disease.* **(Right)** *Axial T2WI MR in a 14 month old with an arteriovenous fistula shows hypointense signal of myelin maturation in the genu and internal capsules only. Concomitant illness is a common cause of delayed myelin maturation.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Genetically heterogeneous mitochondrial disorder characterized by progressive neurodegeneration

IMAGING

- Best imaging: MR with DWI/MRS
  - Bilateral, symmetric ↑ T2/FLAIR corpora striata (putamen > caudate) > globi pallidi (GP), periaqueductal gray matter (PAG), substantia nigra/subthalamic nuclei, dorsal pons, cerebellar nuclei
  - Reduced diffusion in regions of acute disease
  - Lactate peak often present; may be large
  - Uncommon appearance: Predominant WM disease (simulates leukodystrophy)

TOP DIFFERENTIAL DIAGNOSES

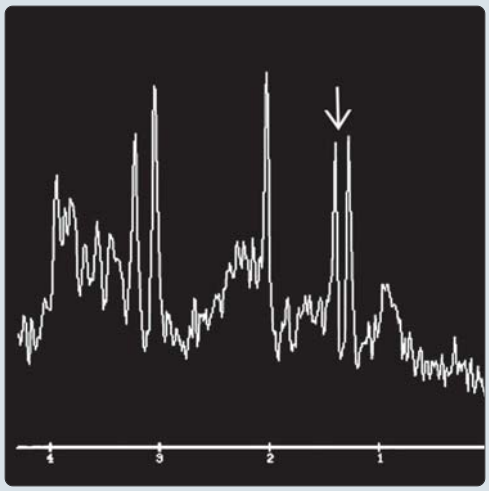
- Profound perinatal asphyxia
- Mitochondrial encephalopathy, lactic acidosis, stroke-like episodes (MELAS)
- Glutaric aciduria type 1 (GA1)
- Wilson disease

PATHOLOGY

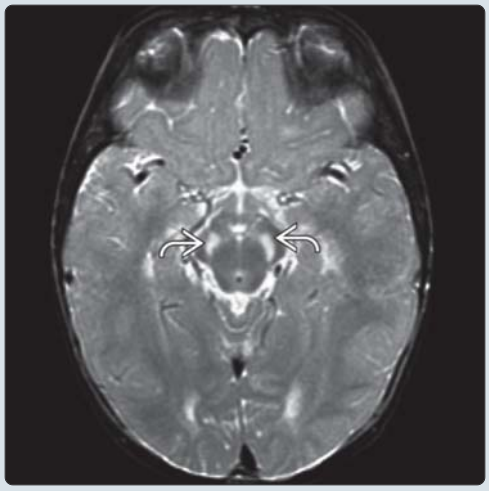
- Bioenergetic failure (ATP loss) and production of reactive oxygen species likely key factors in mitochondria-mediated cell apoptosis
- 50-75% of patients with LS have detectable biochemical or molecular abnormality

CLINICAL ISSUES

- Presentation: Psychomotor delay/regression, hypotonia
- Prenatal diagnosis: Chorionic villus sampling (mutations and biochemical defects)
- Majority present by age 2 years



(Left) *Axial FLAIR MR shows swelling and abnormal hyperintensity in the caudate heads and putamina. Foci of hyperintensity are also present in the medial thalami, a typical location of involvement in Leigh syndrome.* **(Right)** *Single voxel proton MR spectroscopy (TE = 26 ms) of the same patient shows a large lactate doublet at 1.3 ppm. The identification of a lactate peak supports the diagnosis of mitochondrial disease, but is variably present.*



(Left) *Axial T2WI MR shows T2 hyperintensity and some swelling of the lentiform nuclei bilaterally. In addition, the genu and splenium of the corpus callosum are affected. Note that foci of unaffected tissue are present in the putamina; heterogeneous involvement is common.* **(Right)** *Axial T2WI MR in the same patient shows T2 hyperintensity of the cerebral peduncles. This is another common site of involvement in Leigh syndrome.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Leigh syndrome (LS)

Synonyms

- Subacute necrotizing encephalomyelopathy

Definitions

- Genetically heterogeneous mitochondrial disorder characterized by progressive neurodegeneration

IMAGING

General Features

- Best diagnostic clue
  - Bilateral, symmetric, ↑ T2/FLAIR putamina and periaqueductal gray matter (PAG)
- Location
  - Common
    - Basal ganglia (BG): Corpora striata (putamina > caudate heads) > globi pallidi (GP)
    - Brainstem (BS): PAG, substantia nigra/subthalamic nuclei, pons, medulla
    - Thalami, dentate nuclei
  - Infrequent: White matter (WM) (cerebral > cerebellar, may be cavitary), spine, cortical gray matter
- Size
  - BS: Small, discrete foci (< 1 cm)
    - Involvement of central WM tracts typical
  - BG: Involvement of posterior putamina classic but variable; may affect entire lentiform nuclei
  - Thalami: Focal involvement of dorsomedial nuclei classic but variable
- Morphology
  - Except WM, lesions are bilaterally symmetric
  - Edema, expansion characteristic of early disease; volume loss characteristic of late disease
    - PAG edema may cause hydrocephalus
  - Involvement of lower BS (pons, medulla) and lack of BG involvement characteristic of LS secondary to *SURF1* mutation
  - Uncommon appearance
    - Predominant WM disease (simulates leukodystrophy)

CT Findings

- NECT
  - Hypodense; occasionally normal
- CECT
  - Enhancement uncommon

MR Findings

- T1WI
  - Hypointense
    - Variable foci hyperintensity = blood or necrosis
- T2WI
  - Hyperintense
- FLAIR
  - Hyperintense
    - Resolution of signal abnormality or cystic encephalomalacia (hypointense) may be seen in chronic disease
- DWI
  - Reduced diffusion in regions of acute disease
- MRS
  - ↑ choline, ↓ NAA
  - Lactate peak often present; may be large

Ultrasonographic Findings

- Hyperechoic deep gray structures, WM

Imaging Recommendations

- Best imaging tool
  - MR with DWI/MRS

DIFFERENTIAL DIAGNOSIS

Profound Perinatal Asphyxia

- ↑ T2 & T1 dorsolateral putamina, lateral thalami, dorsal BS, perirolandic cortex
  - T2 hyperintensity difficult to identify in unmyelinated brain
  - T1 hyperintensity seen subacutely (3-10 days)
- History of perinatal asphyxia

Mitochondrial Encephalopathy, Lactic Acidosis, Stroke-Like Episodes (MELAS)

- ↑ T2/FLAIR putamina (Ca++ in chronic disease)
  - May be asymmetric or unilateral
- Stroke-like signal abnormality in parietooccipital lobes
  - Nonvascular distribution and (-) DWI typical

Glutaric Aciduria Type 1 (GA1)

- ↑ T2/FLAIR corpora striata, GP, ± WM disease
- Characteristic opercular widening

Wilson Disease

- ↑ T2/FLAIR putamina, GP, midbrain, thalami
  - T2 changes evident in older children, teens
- T1-hyperintense GP 2° to hepatic failure

PATHOLOGY

General Features

- Etiology
  - Exact mechanistic relationship between mitochondrial dysfunction and neurodegeneration unknown
  - Bioenergetic failure (ATP loss) and production of reactive oxygen species likely key factors in mitochondria-mediated cell apoptosis
  - Coenzyme Q10 deficiency and mitochondrial depletion also implicated in LS
- Genetics
  - LS characterized by extreme genetic heterogeneity
  - Autosomal recessive (AR), X-linked, and maternal inheritance of mutated proteins involved in mitochondrial energy production
    - Mutations frequently involve electron transport chain complexes (COs) I-V
    - AR: Mutation of *SURF1* gene (9q34) is most frequent cause of LS due to CO IV (cytochrome C oxidase, COX) deficiency

https://CafePezeshki.IR

  - Other AR mutations: *NDUFV1/NDUFS8* (11q13), *NDUFS4* (5q11.1), *NDUFS7* genes → CO I deficiency; *NDUFS3* gene → NADH dehydrogenase deficiency; *SDHA* gene (5p15) → CO II deficiency; *BCS1L* gene (2q33) → CO III deficiency, and non-*SURF1* mutations → COX deficiency
  - X-linked: *PDHA1* gene (Xp22.2-p22.1) → pyruvate dehydrogenase CO deficiency
  - Maternally inherited (mtDNA mutations): *MT-ATP6* gene → CO V deficiency (causes LS if mutation load > 90%), NARP (neuropathy, ataxia, retinitis pigmentosa) if load 70-90%); *MT-ND5*, *MT-ND6* genes → CO I deficiency; *MT-CO3* gene → COX deficiency; *MT-TK*, *MT-TV* tRNA genes
- Associated abnormalities
  - 50-75% of patients with LS have detectable biochemical or molecular abnormality
  - Embryology-anatomy
    - Main role of mitochondria = production of ATP via oxidative phosphorylation
    - Mitochondria contain own DNA (mtDNA, average of 5 mtDNA per mitochondrion)
    - mtDNA contribution to zygote exclusively from oocyte (maternal inheritance)
    - Mitochondria/mtDNA randomly distributed among daughter cells
    - mtDNA & nuclear DNA (nDNA) encode subunits of electron transport chain complexes (COs) I, III-V; nDNA encodes subunits CO II
  - Brain & striated muscle highly dependent on oxidative phosphorylation → most severely affected in mitochondrial disorders
  - Variable number of mitochondria/cell, random distribution of mitochondria/mtDNA into daughter cells → phenotypic heterogeneity typical of all mitochondrial disorders

Gross Pathologic & Surgical Features

- Brownish-gray, gelatinous or cavitary foci in corpora striata, GP, BS, dentate nuclei, thalami, spinal cord, white matter

Microscopic Features

- Spongiform degeneration, gliosis, neuronal loss, demyelination, capillary proliferation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Presentation: Psychomotor delay/regression, hypotonia
    - LS is a clinical diagnosis; many mitochondrial disorders can cause it
  - Other signs/symptoms
    - Progressive BS & BG dysfunction
      - Ataxia, ophthalmoplegia, ptosis, vomiting, swallowing and respiratory difficulties, dystonia
  - Early presentation, BS dysfunction, peripheral neuropathy, & rapid neurologic deterioration typical of LS 2° to *SURF1* mutation
  - Metabolic stressors (e.g., infection) may unmask disease or cause deterioration
  - Elevated CSF, serum, urine lactate classic but not invariable
  - Clinical diagnosis
    - Progressive neurodegeneration
    - Signs/symptoms of BS & BG dysfunction
    - ↑ lactate in blood + CSF
    - Biochemical defect identified by mitochondrial analysis of muscle biopsy or cultured skin fibroblasts
    - MR → characteristic BG or BS lesions
  - Prenatal diagnosis: Chorionic villus sampling (mutations and biochemical defects)
- Clinical profile
  - Infant with psychomotor regression, hypotonia

Demographics

- Age
  - Majority present by age 2
  - Childhood & adult presentations uncommon
- Gender
  - No predilection
- Ethnicity
  - No predilection
- Epidemiology
  - Mitochondrial disorders = 1:8,500
  - LS in children < 6 years = 1:32,000 (most common mitochondrial disease in this age group)

Natural History & Prognosis

- Natural history: Progressive neurodegeneration leading to respiratory failure and death in childhood
- Prognosis: Dismal (particularly *SURF1*); childhood/adult LS more slowly progressive

Treatment

- No curative treatment
- Potential role of antioxidants and inhibitors in mtDNA replication

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Putaminal involvement classic but variable
- Thalamic and PAG involvement simulates Wernicke encephalopathy; however, mammillary bodies spared in Leigh syndrome
- Only brainstem involvement in *SURF1* mutations

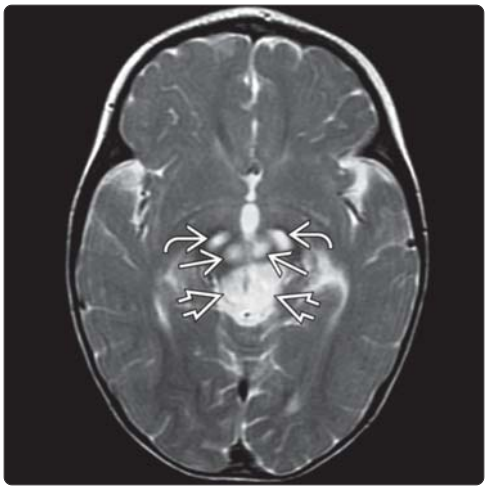
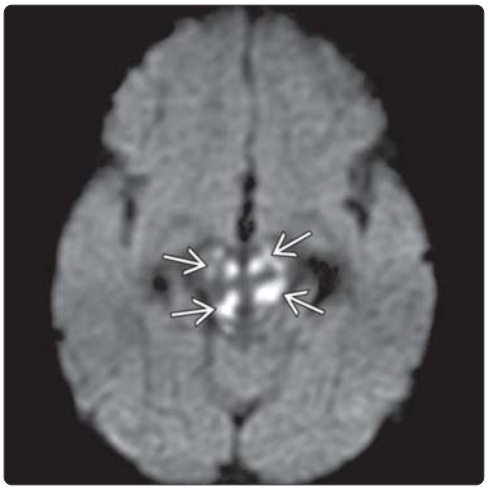
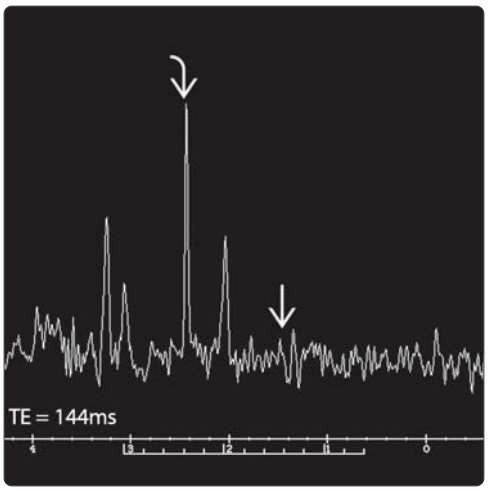
https://CafePezeshki.IR

(Left) *Axial T2WI FSE MR in an infant with hypotonia and encephalopathy shows hyperintensity of caudate heads and putamina. Note involvement of most posterior putamina. Central putamina have increased hyperintensity.* **(Right)** *Axial ADC map in the same patient shows that the caudate heads and most of the affected putamina have reduced diffusivity, whereas the central putamina have increased diffusivity, indicating prior injury with cavitation.*





(Left) *Axial T2WI MR shows hyperintensity of cerebral peduncles, red nuclei, and midbrain tegmentum (including periaqueductal gray matter). These are common locations of brainstem involvement in Leigh syndrome.* **(Right)** *Axial DWI MR shows reduced diffusivity (hyperintense areas) in portions of the affected midbrain. The reduced diffusivity indicates acute injury, while normal or increased diffusivity indicates more chronic injury.*



(Left) *Axial T2WI MR shows hyperintensity in the callosal genu and splenium, which extends into the periventricular and deep white matter, as well as the posterior limbs of the internal capsules.* **(Right)** *Single voxel proton MRS (TE = 144 ms) in the same patient shows minimal lactate at 1.33 ppm and an abnormal peak at 2.4 ppm, which corresponds to succinate. The diagnosis was succinate dehydrogenase deficiency from SDHA mutation.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke-like episodes (MELAS)
- Inherited disorder of intracellular energy production caused by point mutation in mtDNA

IMAGING

- Stroke-like cortical lesions crossing vascular territories
  - Posterior location most common
- "Shifting spread" (appearance, disappearance, reappearance elsewhere) is classic
- Lactate (Lac) "doublet" at 1.3 ppm in 60-65%
  - Elevated lactate in CSF, "normal" brain on MRS
- Basal ganglia (BG) lesions and calcifications

PATHOLOGY

- mtDNA contribution to zygote exclusively maternal inheritance
- Caution: Relationship of phenotype to genotype complex, variable
- Mutations may present as MELAS but also as other mitochondrial phenotypes

CLINICAL ISSUES

- Classic MELAS triad: Lactic acidosis, seizures, stroke-like episodes
  - Onset of stroke-like episodes usually occurs in childhood/early adulthood
  - Also: Sensorineural hearing loss, diabetes, short stature

DIAGNOSTIC CHECKLIST

- Think MELAS in patient with acute stroke-like cortical lesion that crosses usual vascular territories
- Consider MELAS in adult presenting with unusual and recurrent stroke-like episodes

(Left) *Axial graphic shows pathology of MELAS. The acute onset of gyriform cortical swelling that crosses vascular territories is depicted ⇨. Note old lacunes, generalized/focal atrophy.* **(Right)** *Axial FLAIR MR in an 8-year-old girl with short stature and new-onset stroke-like symptoms reveals a focus of abnormally increased signal intensity in the right thalamus ⇨ and extensive hyperintensity and abnormal thickening of the cerebral cortex ⇨ in the right occipital lobe. The underlying WM is largely spared.*

(Left) *Axial T2WI MR in the same patient shows similar abnormal signal hyperintensity lesions in the same thalamic focus of signal increase ⇨ and in the edematous right occipital cortex ⇨. Note the prominent subarachnoid spaces, which may result from malnutrition, medications, or the disease process itself.* **(Right)** *Axial DWI MR demonstrates reduced diffusion in the affected regions of the brain ⇨, confirming the acuity of the lesion.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke-like episodes (MELAS)

Definitions

- Inherited disorder of intracellular energy production caused by point mutations in mitochondrial DNA (mtDNA)

IMAGING

General Features

- Best diagnostic clue
  - Acute: Stroke-like cortical lesions
    - "Shifting spread" (appearance, disappearance, reappearance elsewhere) is classic
    - Lesions cross typical vascular territories
- Location
  - Stroke-like: Parietooccipital > temporoparietal
  - Calcifications: Basal ganglia (BG)
- Size
  - Variable, progressive, multifocal
- Morphology
  - Acute: Gyral swelling
  - Chronic: Supra- and infratentorial atrophy, deep white matter (WM), & BG lacunar infarcts

CT Findings

- NECT
  - Symmetric BG calcification
- CECT
  - Variable gyral enhancement

MR Findings

- T1WI
  - Acute: Swollen gyri, compressed sulci
  - Subacute: Band of cortical hyperintensity consistent with laminar necrosis
  - Chronic: Progressive atrophy of BG, temporal-parietal-occipital cortex with preservation of hippocampal, entorhinal structures
- T2WI
  - Acute: Hyperintense cortex/subcortical WM
  - Chronic: Multifocal BG, deep WM hyperintensities
- FLAIR
  - Infarct-like swelling and mass effect
- T2* GRE
  - No hemorrhage; SWI may show cortical hypointensity
- DWI
  - Acute: DWI positive, ADC variable
- T1WI C+
  - Acute: Gyral enhancement
- MRA
  - Often normal; may show cerebral artery vasodilatation, hyperperfusion in acute states
- MRS
  - Lactate (Lac) "doublet" at 1.3 ppm in 60-65%
  - Caution: Lac presence variable
    - Lac may be elevated in CSF but not brain (measure ventricular Lac)
    - Lac not always elevated and may precede imaging changes of brain
    - Other causes of elevated CNS Lac (e.g., hypoxia, ischemia, neoplasm, infection) must be excluded

Angiographic Findings

- Conventional
  - Acute: Dilated cortical arteries, prominent capillary blush without arterial occlusion

Nuclear Medicine Findings

- SPECT
  - Acute: Tc-99m-HMPAO SPECT shows striking increase in tracer accumulation

Other Modality Findings

- Xenon CT shows focal hyperperfusion during acute stroke-like episode, hypoperfusion later
- Electromyographic findings consistent with myopathy found in majority of cases
- EEG may show focal periodic epileptiform discharges

Imaging Recommendations

- Best imaging tool
  - MR with multivoxel MRS
- Protocol advice
  - Confirm lactate in normal regions of brain

DIFFERENTIAL DIAGNOSIS

Myoclonic Epilepsy With Ragged-Red Fibers (MERRF)

- Propensity for BG, caudate nuclei
- Watershed ischemia/infarcts common

Leigh Disease

- Mutations commonly involve electron transport chain complexes (COs) I-V
- Subacute necrotizing encephalomyopathy
- *SURF1* gene mutation
  - Involvement of subthalamic nuclei, lower brainstem characteristic

Kearns-Sayre Syndrome (KSS)

- Ataxia, ophthalmoplegia, retinitis pigmentosa
- Diffuse symmetric Ca++ in BG, caudate nuclei, subcortical WM
- Hyperintense BG on T1 & T2WI; cerebellar WM, posterior columns of medulla often involved

Status Epilepticus

- May cause transient gyral swelling, enhancement
- No Lac elevation in normal unaffected brain, CSF

Maternally Inherited Diabetes and Deafness (MIDD)

- Also *A3243G* mutation of mitochondrial DNA
- Diabetes mellitus, sensorineural hearing loss, short stature, ± spontaneous abortion
- No stroke-like episodes
- NECT: Diffuse atrophy and BG calcification

PATHOLOGY

General Features

- Etiology

https://CafePezeshki.IR

- Pathophysiology remains unclear
  - Impaired oxidative cerebral metabolism
  - Mitochondrial angiopathy of small cerebral arteries, arterioles, capillaries
- May also be hyperperfusion, vasogenic edema with blood-brain barrier disruption during acute stroke-like episodes
- Genetics
  - mtDNA contribution to zygote exclusively maternal inheritance
  - Caution: Relationship of phenotype to genotype complex, variable
    - Mutations may present as MELAS, but also as other phenotypes
      - *MTT1*: A-to-G translation at nucleotide 3243 of mtDNA most common
    - Polygenetic: *MTTQ*, *MTTL1*, *MTTH*, *MTTK*, *MTTC*, *MTTS1*, *MTND1*, *MTND5*, *MTND6*, *MTTS2*
    - MELAS overlap syndromes with Leigh syndrome, MERRF, KSS, others
- Associated abnormalities
  - Some cortical malformations associated with *A3243G* mutations

Gross Pathologic & Surgical Features

- Diffuse generalized atrophy
- Multiple focal cortical, deep WM/BG infarcts
- Prominent mineralization of BG

Microscopic Features

- Trichrome stain shows increased numbers of ragged-red fibers in skeletal/cardiac muscle
- Perivascular Ca++ in both gray matter (GM), WM may occur
- Immunohistochemistry: COX(+) ragged-red fibers (may help distinguish from MERRF)
- Electron microscopy: Swelling, increase in number of dysfunctional mitochondria in smooth muscle, endothelial cells of small arteries, and pial arterioles

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Triad: Lactic acidosis, seizures, stroke-like episodes
  - Common: Sensorineural hearing loss, diabetes, short stature
  - Cognitive deficits, depression, psychosis, dementia
  - Ataxia, muscle weakness (myopathy), peripheral neuropathy
  - Acute-onset headache, migraines, episodic vomiting, intermittent dystonia, alternating hemiplegia
- Other signs/symptoms
  - Heteroplasmy and random mitotic mtDNA segregation, tissue-to-tissue variability → phenotypic heterogeneity and "overlap" with other mitochondrial syndromes
    - Cardiac: Cardiomyopathy, cardiac conduction defects
    - Ocular findings: Scotomata, hemianopsia, ophthalmoplegia, maculopathy (progressive macular retinal pigment epithelial atrophy)
    - Renal dysfunction (including Fanconi syndrome and focal segmental glomerular sclerosis)
    - GI dysmotility, gastroparesis, intestinal pseudo-obstruction
- Clinical profile
  - Older child or young adult with muscle weakness and epilepsy or acute stroke-like syndrome

Demographics

- Age
  - Onset of stroke-like episodes usually occurs in childhood/early adulthood
    - Mean age onset = 15 years
    - 90% symptomatic by 40 years
- Epidemiology
  - Uncommon but important cause of stroke in pediatric cases
  - Carrier prevalence of *m.3243A > G* mutation 0.6% or 60 per 100,000 individuals
  - Incidence (Finland): *3243A > G* =18.4 per 100,000 individuals

Natural History & Prognosis

- Recurrent stroke-like events with either permanent or reversible neurologic deficits
- Progressive course with periodic acute exacerbation

Treatment

- Cofactor and supplement therapy

DIAGNOSTIC CHECKLIST

Consider

- Think MELAS in patient with acute stroke-like cortical lesion that crosses usual vascular territories
- Consider MELAS in adult presenting with unusual and recurrent stroke-like episodes

Image Interpretation Pearls

- Obtain MRS in CSF, "uninvolved" brain

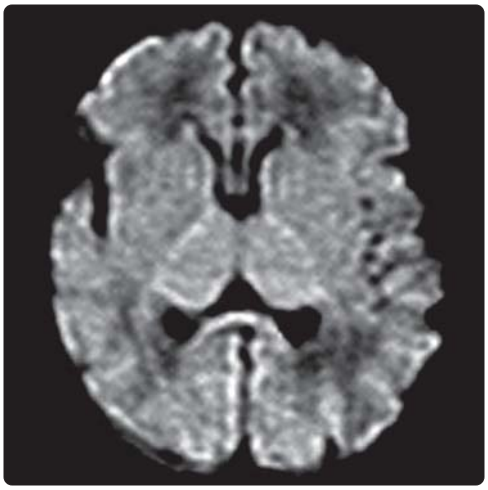
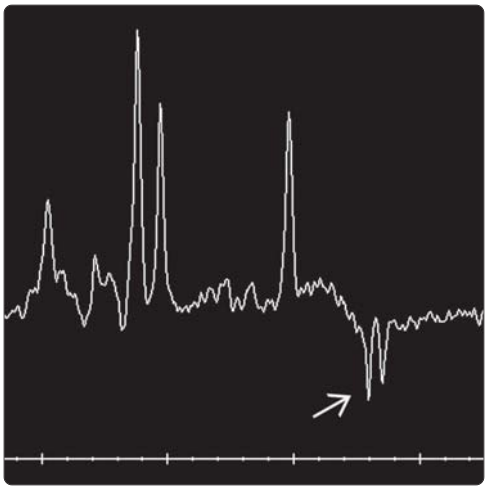
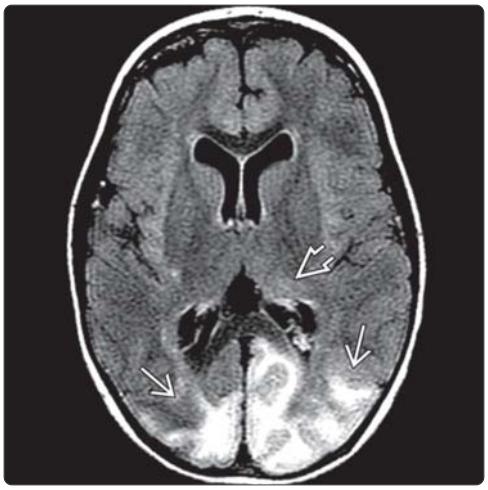
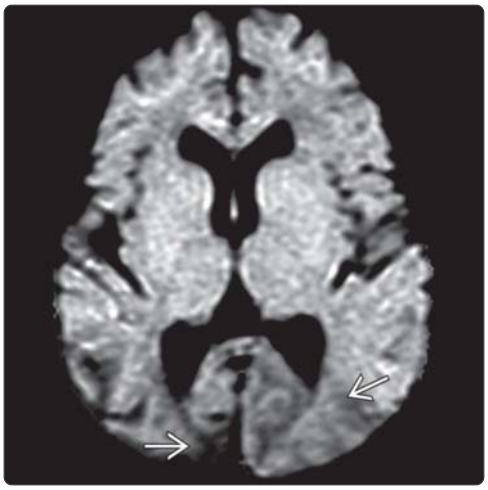
https://CafePezeshki.IR



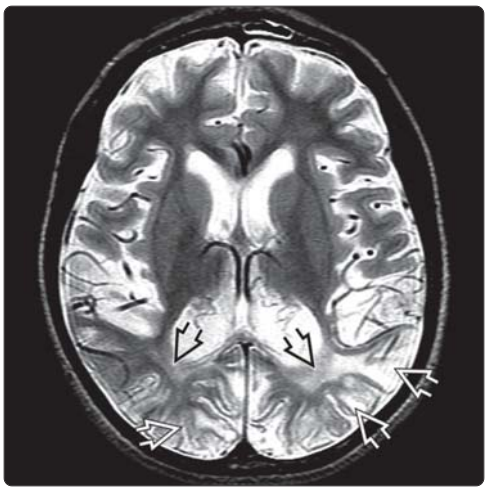


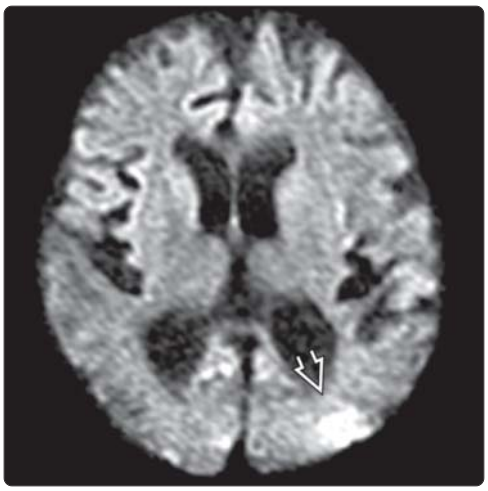
(Left) *Axial DWI MR in a 22-day-old girl with microcephaly and lactic acidosis is essentially normal; it fails to reveal any areas of reduced diffusion.* **(Right)** *Proton MRS with an echo time of 144 msec localized to the basal ganglia of the same patient confirms a lactate doublet ➡ at 1.3 ppm. Note that the lactate peak is inverted at an echo time of 135-144 msec. Proton MRS with this echo time can be a useful finding to distinguish lactate from lipid.*





(Left) *Follow-up axial FLAIR MR in the same patient, now 3.5 years old, demonstrates a new subtle signal increase in the left thalamus ➡ as well as extensive new bilateral occipital cortical/subcortical hyperintensity and swelling ➡.* **(Right)** *Axial DWI MR shows hypointensity ➡ in the affected regions, indicating that the lesions are subacute. Proton MRS (not shown) showed the presence of lactate, often seen in the subacute phase.*





(Left) *Axial T2WI MR in a 12-year-old girl with longstanding diagnosis of MELAS reveals extensive volume loss in the cerebral cortex and subcortical white matter, in addition to increased signal intensity of peritrigonal white matter ⇨ and of the parietooccipital subcortical white matter/cortex ➡.* **(Right)** *Axial DWI MR in the same 12 year old demonstrates reduced diffusivity ➡ in the left occipital pole, indicating an acute exacerbation in superimposed upon chronic changes.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Clinical phenotypes associated with single large-scale mtDNA deletions (SLSMDs)
  - Progressive external ophthalmoplegia (PEO)
  - Kearns-Sayre syndrome (KSS)
  - Pearson syndrome
    - Multisystem disorder characterized by bone marrow failure, pancreatic insufficiency
    - Children who survive develop KSS later in life
- Overlapping spectrum of disease
  - Multisystem disease with anemia, renal impairment, endocrine disturbance most frequent extraneurological features

IMAGING

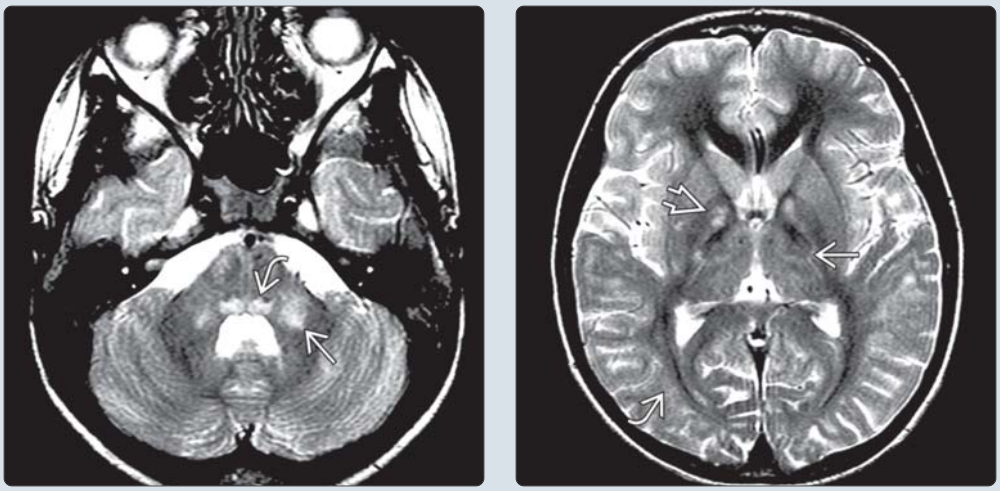
- Diffuse symmetric Ca++ in BG on NECT
- ↑ T2 signal in peripheral subcortical WM, U-fibers, cerebellar WM, corpus callosum, globi pallidi, substantia nigra, posterior brainstem
- Early sparing of periventricular WM
- Occasional radial stripes in hyperintense WM

PATHOLOGY

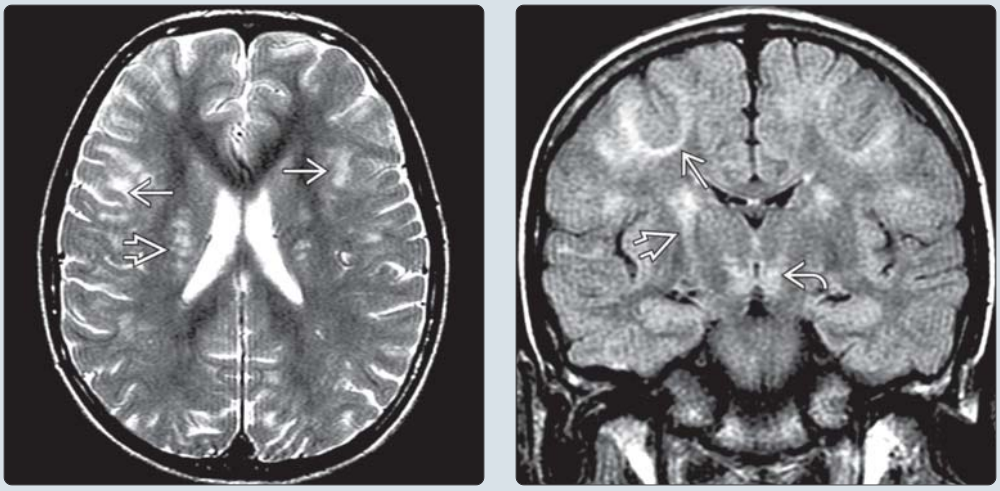
- Polygenetic: Caused by various mtDNA rearrangements
- Status spongiosus, spongy myelinopathy
- Cerebellar atrophy
- Ragged-red fibers on muscle biopsy

CLINICAL ISSUES

- Common symptoms: Ophthalmoplegia, ataxia, retinitis pigmentosa, heart block present before 20 years old
- Additional symptoms: Dementia, sensorineural hearing loss, muscle weakness, short stature, diabetes
- Age of onset usually before 20 years
- Cardiac conduction problems may manifest during anesthetic care



(Left) *Axial T2WI MR in a teenager with symptomatic Kearns-Sayre syndrome demonstrates abnormal increased signal intensity bilaterally in the brachium pontis ⇨ and the dorsal pons ⇨. Widening of the interfoliate sulci results from mild cerebellar atrophy.* **(Right)** *Axial T2WI MR in the same teenager demonstrates foci of abnormal signal bilaterally within the globi pallidi ⇨ and the corticospinal tracts ⇨. Note the subtle loss of myelin arborization into the subcortical U-fibers ⇨.*



(Left) *Axial T2WI MR in the same teenager with symptomatic Kearns-Sayre syndrome reveals linear hyperintense white matter "stripes" in the corona radiata ⇨ and multifocal areas of abnormal hyperintense subcortical U-fibers ⇨. No lactate was identified on proton MRS (not shown) obtained at the same time as the routine MR imaging.* **(Right)** *Coronal FLAIR MR in the same patient shows abnormal hyperintense signal in corticospinal tracts ⇨, subcortical U-fibers ⇨, and thalami ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Clinical phenotypes associated with single large-scale mtDNA deletions (SLSMDs)
  - Progressive external ophthalmoplegia (PEO)
  - Kearns-Sayre syndrome (KSS)
  - Pearson syndrome
    - Multisystem disorder characterized by bone marrow failure, pancreatic insufficiency
    - Children who survive develop KSS later in life
- Overlapping spectrum of disease
  - Multisystem disease with anemia, renal impairment, endocrine disturbance most frequent extraneurological features

IMAGING

General Features

- Best diagnostic clue
  - Diffuse symmetric Ca++ BG
  - Hyperintense GP on T1 & T2WI
  - WM signal increase on T2/FLAIR involves subcortical WM
- Morphology
  - Spongy myelinopathy

CT Findings

- NECT
  - Basal ganglia calcifications

MR Findings

- T2WI
  - Occasional radial stripes in hyperintense WM
  - ↑ signal in peripheral subcortical WM, U-fibers, cerebellar WM, corpus callosum, globi pallidi, substantia nigra, posterior brainstem
  - Early sparing of periventricular WM
- DWI
  - Abnormal white matter (T2-DWI match) has reduced diffusion
  - DTI demonstrates brainstem white matter alterations

DIFFERENTIAL DIAGNOSIS

Other Mitochondrial (mtDNA) Deletion Syndromes

- MELAS
  - Stroke-like episodes
    - Parietooccipital lobe involvement common (rare in KSS)
  - Lactic acidosis
  - Seizures
- Chronic progressive external ophthalmoplegia (CPEO)
  - Upper eyelid ptosis
  - Progressive weakness of extraocular muscles
  - Normal imaging or atrophy common, lactate uncommon
    - Severe phenotype: Pyramidal tract T2/FLAIR hyperintensity
- Pearson marrow-pancreas syndrome
  - Refractory anemia, vacuolization of bone marrow cells, exocrine pancreatic dysfunction
  - Mild phenotype or progression to KSS

PATHOLOGY

General Features

- Genetics
  - Polygenetic: Caused by multiple mtDNA rearrangements
  - Identical mutations reported in KSS, MELAS, Pearson, and CPEO; however, mutant mtDNA tissue distribution is different in these disorders

Gross Pathologic & Surgical Features

- Status spongiosus, spongy myelinopathy
  - Spongy degeneration and vacuolization
- Cerebellar atrophy
- Ragged-red fibers on muscle biopsy

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Ophthalmoplegia, ataxia, retinitis pigmentosa, heart block
- Other signs/symptoms
  - Dementia, sensorineural hearing loss
  - Short stature, diabetes
  - Proximal muscle weakness, fatigue
  - ↑ CSF protein, ± ↑ lactate

Natural History & Prognosis

- Age of onset usually before 20 years
- Cardiac conduction problems may manifest during anesthetic care

Treatment

- Vitamins and cofactors
- Pacemaker or cochlear implant may be required

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- White matter involvement spares periventricular WM, involves "subcortical U-fibers"
- SLSMDs should be considered in all children presenting with ptosis

KEY FACTS

TERMINOLOGY

- Mucopolysaccharidoses (MPS): 1-9
- Group of lysosomal storage disorders
  - Characterized by inability to break down glycosaminoglycans (GAGs)
  - Undegraded GAGs toxic, accumulate in multiple organs
  - Each type of MPS causes accumulation of particular GAG in lysosomes, extracellular matrix
  - 11 known enzyme deficiencies, resulting in 7 distinct forms of MPS
    - Prototype MPS = MPS 1H (Hurler)

IMAGING

- Perivascular spaces (PVS) dilated by accumulated GAG
- Favored sites of dilated VRS in MPS: Corpus callosum (CC), peritrigonal white matter (WM)
  - Can occur in other lobes
- Single to too many to count
- Dysostosis multiplex, broad ribs, trident hands
- Progressive odontoid dysplasia → risk atlantoaxial subluxation; some correction follows BMT

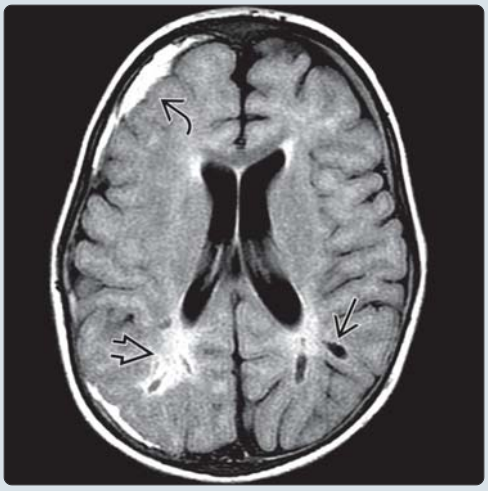
CLINICAL ISSUES

- Prognosis, deterioration rate depends upon specific enzyme deficiency
- Treatment: BMT or IV recombinant human enzyme (e.g., MPS 1H: α-L-iduronidase)
- Significant correlation exists between WM alterations and mental retardation

DIAGNOSTIC CHECKLIST

- Always visualize foramen magnum on any CNS study to seek CVJ compression
- Airway: Major sedation and anesthesia risk
- Not all MPS have typical facial features, dilated VRS may still signal less common MPS
- Look at upper cervical spine on sagittal images; aids in making diagnosis

(Left) *Axial graphic of a prototype mucopolysaccharidosis shows multiple dilated perivascular spaces that are radially oriented in the white matter of the brain. Note the posterior predominance and involvement of the corpus callosum.* **(Right)** *Axial T1WI MR in a toddler with MPS 1H demonstrates prominent perivascular spaces involving the white matter, including the corpus callosum. Note the posterior predominance of involvement, which is typical in MPS.*



(Left) *Axial FLAIR MR in a male child with MPS 2 reveals a few dilated perivascular spaces surrounded by gliotic white matter. Note the unilateral subdural hematoma. Extraaxial bleeds, while uncommon, have been reported in MPS with vasculopathy, trauma, or large subdural effusions.* **(Right)** *Axial FLAIR MR in a different school-aged male with MPS 2 demonstrates dilated perivascular spaces, hyperintense white matter, and hydrocephalus. Note the typical anterior beaking.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Mucopolysaccharidoses (MPS)

Definitions

- Group of lysosomal storage disorders
  - Characterized by inability to break down glycosaminoglycans (GAGs)
  - Undegraded GAGs toxic, accumulate in multiple organs
  - Each type of MPS causes accumulation of particular GAG in lysosomes, extracellular matrix
  - 11 known enzyme deficiencies, resulting in 7 distinct forms of MPS
    - Prototype MPS = MPS 1H (Hurler)

IMAGING

General Features

- Best diagnostic clue
  - Perivascular spaces (PVS), a.k.a. Virchow-Robin spaces (VRS), dilated by accumulated GAG
- Location
  - Favored sites of dilated VRS in MPS: Corpus callosum (CC), peritrigonal white matter (WM)
    - Can occur in other lobes
- Size
  - Variably-sized dilated VRS, usually < 5 mm; occasional large obstructed VRS occur
  - Range: 1 to too many to count
- Morphology
  - Round, oval, spindle, parallel to veins

Radiographic Findings

- Radiography
  - Dysostosis multiplex, broad ribs, trident hands, J-shaped sella, "rosette" formation of multiple impacted teeth in single follicle

CT Findings

- NECT
  - Metopic beaking despite macrocrania
  - Macrocrania, ↓ density WM, dilated VRS rarely visible on CT
  - Progressive hydrocephalus **and** atrophy
    - MPS 1: Hydrocephalus is early finding in 25%
    - MPS 3B: Severe atrophy
- CECT
  - Enhancing pannus associated with ligaments and dura at craniocervical junction (CVJ)

MR Findings

- T1WI
  - Cribriform appearance WM, CC, basal ganglia (BG)
    - Dilated VRS filled with GAG: "Hurler holes"
    - Especially in severe MPS (MPS 1H, 2 > > other MPS types)
    - Except MPS 4 (Morquio): CNS spared
  - Occasional arachnoid cysts (meningeal GAG deposition)
- T2WI
  - ↑ signal of WM surrounding dilated VRS: Gliosis, edema, de- or dysmyelination
  - ± additional patchy WM signal
- FLAIR
  - VRS isointense with CSF
  - ↑ signal surrounds VRS
- T1WI C+
  - CV junction pannus enhances
- MRS
  - ↓ NAA, ↑ Cho/Cr ratio; ↑ peak at 3.7 ppm contains signals from MPS
    - Improvement in presumptive MPS peaks following bone marrow transplant (BMT)
- Spinal MR
  - Compression CVJ in majority of MPS
    - C2 meningeal hypertrophy
    - Progressive odontoid dysplasia → risk atlantoaxial subluxation; some correction reported following BMT
    - Short C1 posterior arch
  - ↑ T2 signal cord in 50% of CVJ compression
  - Upper lumbar gibbus
    - MPS 1H (Hurler): Inferior beaking
    - MPS 4 (Morquio): Middle beaking

Imaging Recommendations

- Best imaging tool
  - MR brain
- Protocol advice
  - Baseline MR/MRS
  - Follow-up: Complications (CVJ compression, hydrocephalus), therapeutic response to BMT
  - Always visualize foramen magnum on any CNS study to seek CVJ compression

DIFFERENTIAL DIAGNOSIS

Velocardiofacial Syndrome (22q11DS)

- Dilated VR spaces and plaques, typical frontal predominance
- Deviated carotid arteries in pharynx is clue

Macrocephaly With Dilated VRS

- Lacks typical beaked metopic suture and foramen magnum compression

Hypomelanosis of Ito

- Periventricular signal change (brighter and more persistent than MPS) with large VRS
- May also have hemimegalencephaly
- Typical whorled skin lesions
- Lack "beaked" metopic suture present in MPS

Perinatal Hypoxic-Ischemic Encephalopathy

- Transient phase of cystic change following hypoxic-ischemic encephalopathy → atrophy

Normal VR Spaces

- Vary in number and prominence

PATHOLOGY

General Features

- Etiology
  - Ganglioside accumulation (toxic to neurons)
- Genetics

https://CafePezeshki.IR

- Autosomal recessive (exception: X-linked MPS 2)
- Associated abnormalities
  - Dermal melanocytosis (mongolian-like spots)
    - Extensive, blue skin pigmentation differs from typical mongolian spots in persistence or progression
  - GAG accumulates in most organs/ligaments
    - Hepatosplenomegaly (HSM), umbilical hernia
    - Skeletal dysostosis multiplex, joint contractures
    - Arterial wall (mid aortic stenosis) and cardiac valve thickening
    - Thick dura (cord compressed at foramen magnum)
    - Coarse facies (formerly "gargoylism")
    - Upper airway obstruction (38%): Submucosal deposition → small, abnormally shaped trachea (difficult intubation); abnormal configuration vocal cords
  - Embryology-anatomy
    - Dilated VR spaces may be seen in utero

Staging, Grading, & Classification

- Diagnosis depends on specific enzyme deficiency
  - MPS 1H, 1HS (Hurler/Hurler-Scheie): α-L-iduronidase (4p16.3)
  - MPS 2 (Hunter): Iduronate 2-sulfatase (Xq28)
  - MPS 3A (Sanfilippo): Heparin N-sulfatase (17q25.3)
  - MPS 4A (Morquio): Galactose 6-sulfatase (16q24.3)
  - MPS 6 (Maroteaux-Lamy): Arylsulfatase B (5q11-q13)

Gross Pathologic & Surgical Features

- Thick meninges
- Cribriform appearance to cut surface of brain

Microscopic Features

- MPS: Glycosaminoglycans accumulate in leptomeninges and VR spaces

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Typical coarse facies develop (mild in MPS 3, 6, 7)
    - Macroglossia, bushy eyebrows, flat nasal bridge
- Clinical profile
  - Prototype MPS 1H, appear normal at birth
    - Corneal clouding (except MPS 2): Proteoglycans in keratocytes
    - Mental retardation (except MPS 2b, 4, 1HS)
    - Joint contractures, dysostosis multiplex, short stubby fingers, carpal tunnel syndrome
    - Loss of walking skills: Spinal claudication/myelopathy C1-2 and vascular claudication from mid-aortic stenosis
    - Recurrent upper respiratory infection, nasal discharge, ear infections, sleep apnea, sensorineural deafness
    - Middle ear effusions (73%), otolaryngologist notes this prediagnosis MPS
    - Cardiac valvular disease: Mitral > aortic
    - Skin blistering in MPS 3
  - MPS 7 may present with fetal nuchal translucency, hydrops fetalis, or isolated ascites

Demographics

- Age
  - MPS 1H presents in infancy
- Gender
  - MPS 2 (Hunter) is X-linked: Male
- Ethnicity
  - Geographic variability in prevalence of specific MPS disorders
- Epidemiology
  - 1:29,000 live births (series from Australia)
    - MPS 1H = 1:107,000 live births
    - MPS 2 = 1:165,000 male live births
    - MPS 3 = 1:58,000 live births
    - MPS 4A = 1:640,000 live births
    - MPS 6 = 1:320,000 live births

Natural History & Prognosis

- Significant correlation exists between WM alterations and mental retardation
- Rate of deterioration depends upon specific deficiency
  - MPS 1H death by 10 years, without therapy
  - MPS 2A death in late teens (cardiac)
  - Others variable

Treatment

- Enzyme replacement therapy (e.g., α-L-iduronidase for MPS 1H), hematopoietic stem cell transplantation, substrate reduction therapy, gene therapy, anti-inflammatory drugs
  - Goal: ↓ visceral accumulation MPS; ameliorate some manifestations

DIAGNOSTIC CHECKLIST

Consider

- Airway: Major sedation and anesthesia risk

Image Interpretation Pearls

- Not all MPS have typical facial features; dilated VRS may still signal less common MPS
- Not all dilated VRS are MPS
- Always look for CVJ compression
  - Treatable cause of morbidity in MPS
  - Lack of CVJ compression suggests there may be different etiology of dilated VRS than MPS

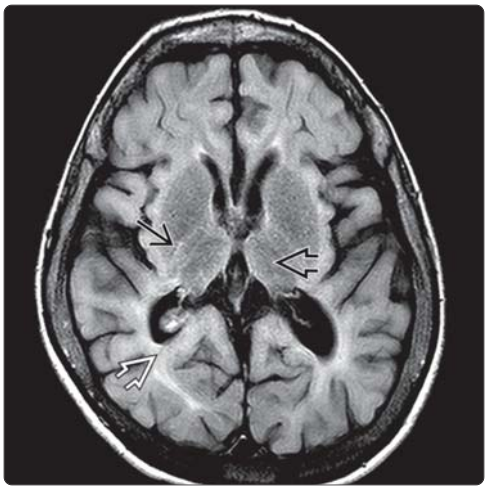
(Left) *Axial micropathology with Luxol fast blue stain in a teenager with MPS 1HS reveals dilated perivascular spaces filled by mucopolysaccharide. (Courtesy P. Shannon, MD.)* **(Right)** *Sagittal T2WI MR in a 10-year-old boy with MPS 2 demonstrates ventriculomegaly due to hydrocephalus, scaphocephaly, and numerous dilated perivascular spaces. Characteristic dilated perivascular spaces within the corpus callosum can be seen.*



(Left) *Axial FLAIR MR in a child with MPS 3 reveals increased signal in the abnormal myelin of the peritrigonal white matter and the internal capsules. The thalami are dark and small. Thalamic findings are uncommon in the other MPS disorders but can be seen in MPS 3 and other lysosomal disorders.* **(Right)** *Axial T2WI MR in a 2-year-old child with MPS 3 reveals similar thalamic hypointensity. Notice the hypomyelination of the white matter manifested as abnormal hyperintensity.*

(Left) *Sagittal T2WI MR in a child with MPS 6 demonstrates dilated perivascular spaces in the corpus callosum (a typical location), scaphocephaly, and an abnormal sella turcica. The upper cervical spinal cord is significantly compressed by prominent pannus dorsal to the odontoid and by a short posterior arch of C1.* **(Right)** *Sagittal T2WI MR in MPS 1 demonstrates severe acute thoracolumbar kyphosis due to abnormal thoracic vertebra. Note the compression of the conus medullaris.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Tay-Sachs disease (TS), Sandhoff disease (SD)
- Inherited lysosomal storage disorder characterized by GM2 ganglioside accumulation in brain
- TS & SD exist in infantile, juvenile, and adult forms

IMAGING

- Infantile: T2-hypointense, T1-hyperintense (CT hyperdense) thalami
- Juvenile/adult: Cerebellar atrophy

TOP DIFFERENTIAL DIAGNOSES

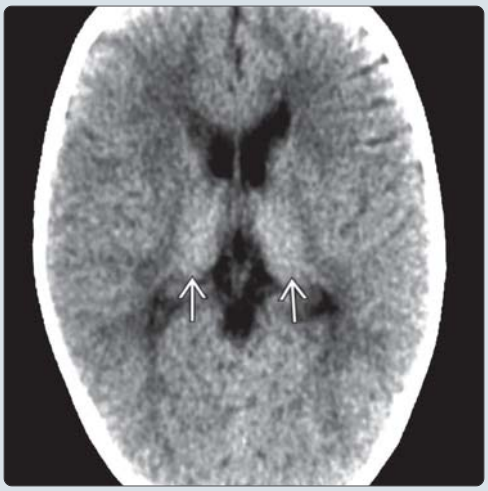
- Krabbe disease
- Juvenile GM1 gangliosidosis
- Neuronal ceroid lipofuscinosis
- Status marmoratus

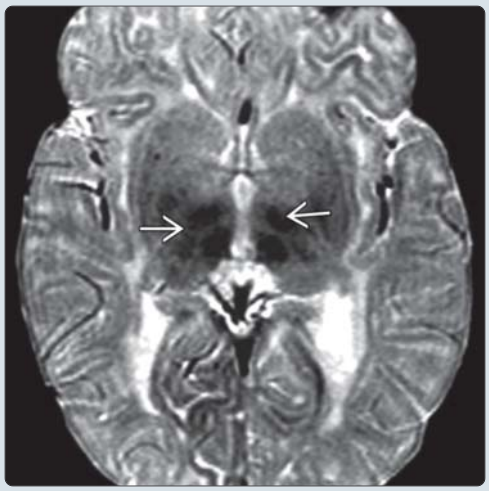
PATHOLOGY

- Autosomal recessive inheritance
- Accumulation of GM2 ganglioside in neuronal lysosomes causes neuronal degradation, apoptosis with secondary hypo-/demyelination

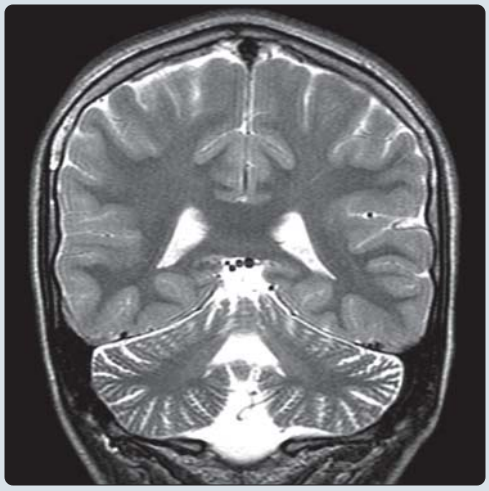
CLINICAL ISSUES

- TS: 1:30 carrier frequency in Ashkenazi Jewish and French Canadians
- SD, GM2 variant AB, juvenile/adult GM2 = pan-ethnic (↑ in small gene pools)
- Presentation
  - Infant: Psychomotor retardation/regression
  - Juvenile/adult: Atypical spinocerebellar ataxia
- Poor prognosis for infantile onset GM2
  - Typically death by age 4 years
- Treatment: Supportive, seizure control; promising new therapies on horizon





(Left) *Axial NECT shows classic hyperdense thalami ➡ in this developmentally delayed 1 year old with infantile Tay-Sachs disease. The basal ganglia appear small and were hypodense on lower images (not shown).* **(Right)** *Axial T2WI MR in a patient with infantile Tay-Sachs disease shows thalamic hypointensity limited to the ventral nuclei ➡, findings in contrast to those in patients with Sandhoff disease. The dorsal thalamus (not shown) is often mildly hyperintense.*



(Left) *Sagittal T1WI MR in an older child with psychosis and extrapyramidal symptoms shows enlarged vermian fissures, indicating volume loss. Cerebellar atrophy is the main finding in patients with juvenile or adult onset GM2.* **(Right)** *Coronal T2WI MR in a 15 year old with juvenile onset GM2 shows cerebellar atrophy. The supratentorial brain is normal. The cerebral WM is variably affected in juvenile/adult GM2. Rarely, deep gray structure and mass-like brainstem involvement can occur.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Gangliosidosis (GM2)

Synonyms

- Tay-Sachs (TS) disease, Sandhoff disease (SD)

Definitions

- Inherited lysosomal storage disorder
  - Characterized by GM2 ganglioside accumulation in brain
- 3 major biochemically distinct, but clinically indistinguishable types
  - TS disease
  - SD
  - GM2 variant AB (rare)
- TS and SD exist in infantile, juvenile, and adult forms
- GM2 variant AB exists in infantile form only

IMAGING

General Features

- Best diagnostic clue
  - Infantile
    - T2-hypointense, T1-hyperintense (CT hyperdense) thalami
    - Mild T2 hyperintensity striatum
  - Juvenile/adult
    - Cerebellar atrophy
- Location
  - Infantile: Thalami, striatum, cerebral > > cerebellar white matter (WM)
    - Corpus callosum (CC) spared
  - Juvenile/adult: Cerebellum, cerebral WM
    - Rare striatal and mass-like brainstem involvement
- Morphology
  - Symmetric involvement of deep gray structures
  - Late: Atrophy

CT Findings

- NECT
  - Infantile
    - Hyperdense thalami (classic but variable)
    - Hypodense striatum, WM
  - Juvenile/adult
    - Cerebellar atrophy
    - ± cerebral WM hypodensity
- CECT
  - No abnormal enhancement

MR Findings

- T1WI
  - Hyperintense thalami
  - Striatal intensity variable
  - Hypointense cerebral WM
- T2WI
  - TS: **Hypo**intense ventral thalami, **hyper**intense dorsal thalami
  - SD: Thalami diffusely hypointense
  - Mild striatal and cerebral WM hyperintensity
- DWI
  - Variably ↓ diffusivity ventral thalami (TS)
- T1WI C+
  - No abnormal enhancement
- MRS
  - Infantile: ↓ NAA, ↑ choline, ↑ myoinositol
  - Juvenile/adult: ↓ NAA; normal-appearing thalami, cerebral WM reported

Ultrasonographic Findings

- Infantile: Echogenic thalami

Imaging Recommendations

- Best imaging tool
  - MR (CT may confirm thalamic abnormality)

DIFFERENTIAL DIAGNOSIS

Krabbe Disease

- Hyperdense thalami, caudate and dentate nuclei
- T2-hyperintense cerebral, cerebellar WM
- CC involved

Juvenile GM1 Gangliosidosis

- Imaging findings identical to SD
- GM1 ganglioside accumulates in brain & viscera

Neuronal Ceroid Lipofuscinosis

- Thalami, globi pallidi hyperdense, T2 hypointense
- Cerebral, cerebellar atrophy

Status Marmoratus

- Hyperdense, atrophic thalami
- Atrophy putamina, perirolandic region
- History of profound perinatal ischemia

PATHOLOGY

General Features

- General pathology comments
  - Neuronal accumulation of GM2 ganglioside caused by deficient lysosomal enzyme, β-hexosaminidase A
- Embryology-anatomy
  - GM2 ganglioside resides in neuronal membranes; plays role in cell-cell recognition, synaptogenesis
  - β-hexosaminidase A (HexA) and GM2 activator protein (GMAP) required for lysosomal GM2 ganglioside catabolism
  - HexA is 1 of 3 isoenzymes of β-hexosaminidase formed by dimerization α and β subunits
    - HexA = αβ dimer, HexB = ββ, HexS = αα
  - HexA and HexB are major forms; HexS is minor form with unclear physiologic function
  - *HEXA*, Chr 15q23-24, encodes α subunit
  - *HEXB*, Chr 5q13, encodes β subunit
  - *GM2A*, Chr 5q31.3-q33.1, encodes GMAP
- Genetics
  - Autosomal recessive inheritance
  - > 100 different mutations of *HEXA* cause TS
  - > 30 different mutations of *HEXB* cause SD
  - ~ 4 mutations of *GM2A* cause GM2 variant AB
  - Mutations allowing residual HexA activity (0.5-4% normal activity) account for milder juvenile/adult phenotypes
- Etiology

https://CafePezeshki.IR

- Accumulation of GM2 ganglioside in neuronal lysosomes causes neuronal degradation, apoptosis with secondary hypo-/demyelination
  - GM2 ganglioside accumulation in myelin membrane may also contribute to demyelination
- Exact mechanism by which GM2 ganglioside accumulation → neuronal apoptosis is unknown
  - Activation microglia, macrophages, and astrocytes suggest inflammatory component
  - Identification of autoantibodies in mouse models of SD suggests autoimmune component

Gross Pathologic & Surgical Features

- Infantile: Early megalencephaly, late atrophy
  - Gelatinous, hemispheric WM, ± cavitation
- Juvenile/adult: Cerebellar atrophy

Microscopic Features

- GM2 ganglioside accumulation in cerebral neurons
- Less severe GM2 ganglioside accumulation in glial, Purkinje, anterior horn, and retinal ganglion cells
- EM: GM2 ganglioside contained in membranous cytoplasmic bodies (MCBs) in neuronal cytoplasm, proximal nerve processes, axons
  - MCBs in cytoplasm cause distortion and ballooning
  - MCBs in proximal nerve processes form meganeurites
- Hypomyelination, demyelination, wallerian degeneration
- Juvenile/adult GM2: Ganglioside accumulation in anterior horn cells, cerebellar neurons, basal ganglia, brainstem
  - MCBs occasionally absent
- SD: Additional storage of GM2 (and globoside) in viscera

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Infantile
    - Psychomotor retardation/regression
  - Juvenile/adult
    - Atypical spinocerebellar ataxia
  - Other signs/symptoms
    - Infantile: Macrocranium, hypotonia, seizures, blindness (90% with cherry-red spot macula), exaggerated startle response to noise
    - Juvenile/adult: Dysarthria, extrapyramidal and pyramidal dysfunction, peripheral neuropathy, stuttering, psychosis/depression (late, 30%)
- Clinical profile
  - Diagnosis: Documentation HexA deficiency in serum leukocytes, cultured skin fibroblasts, amniotic fluid, or chorionic villus sample
  - Abnormal results should be followed by DNA analysis to detect mutation &/or exclude pseudodeficiency allele

Demographics

- Age
  - Infantile
    - Symptom onset in 1st year
  - Juvenile
    - Symptom onset by 2-6 years old
  - Adult
    - Symptom onset in 1st-3rd decades
- Gender
  - No predilection
- Epidemiology
  - TS
    - 1:30 carrier frequency in Ashkenazi Jewish and French Canadians
    - ↑ incidence in Cajuns, French Canadians
    - Normal carrier frequency in general population
  - SD, GM2 variant AB, juvenile/adult GM2 = pan-ethnic (↑ in small gene pools)
    - 1:1,000 Jewish, 1:600 non-Jewish
    - 1:16-29 Creole population of Cordoba, Argentina
    - 1:7 Maronite Christian Cypriots
  - Incidence of TS in USA and Canada has decreased by > 90% since 1970 due to carrier screening and prenatal diagnosis

Natural History & Prognosis

- Infantile: Rapidly progressive psychomotor regression culminating in paralysis, blindness, deafness; death typically by 4 years of age
- Juvenile: More slowly progressive with death between 5-15 years of age
  - Death often 2° to respiratory infection
  - Often several years of decerebrate rigidity in vegetative state precede death
- Adult: Prolonged survival to age 60-80 can occur

Treatment

- Supportive therapy, seizure control
- Promising new therapies: Substrate deprivation, enzyme replacement, bone marrow transplantation, gene therapy, pharmacologic chaperone therapy

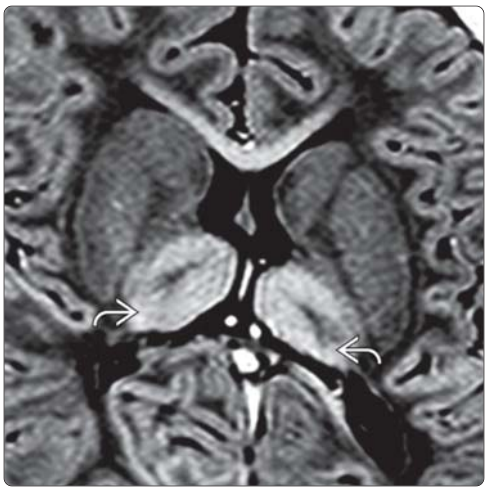
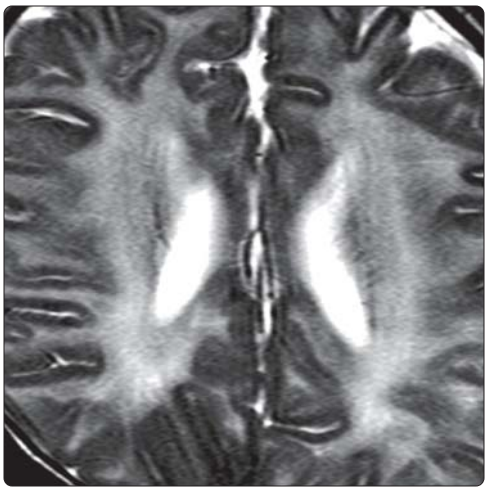
https://CafePezeshki.IR

(Left) *Axial FLAIR MR in a 1 year old with infantile Sandhoff disease shows diffusely hypointense thalami. The striatum is diffusely hyperintense. Evaluation of the cerebral WM on FLAIR MR is difficult at this age.* **(Right)** *Axial T1WI MR in the same patient shows symmetric thalamic hyperintensity and diffusely hypointense (hypo-/demyelinated) cerebral WM. WM should appear completely myelinated on T1WI at this age. Note the spared (hyperintense) corpus callosum.*

(Left) *Coronal T2WI MR in a 1 year old with infantile Sandhoff disease shows diffusely hypointense thalami. The striatum is abnormally hyperintense, particularly the caudate nuclei. The cerebral WM is also mildly hyperintense.* **(Right)** *Axial T2WI MR shows symmetric hypointense thalami in this 7 month old with infantile Sandhoff disease. The putamina are mildly hyperintense, more so posteriorly than anteriorly. Myelination appears within a normal range.*





(Left) *Axial T1WI MR in a 2 year old with infantile Sandhoff disease shows symmetric thalamic hyperintensity. The central hypointense foci are atypical. The cerebral WM is grossly hypointense, with sparing of the corpus callosum.* **(Right)** *Axial T2WI MR in the same patient shows diffuse WM hyperintensity, confirming extensive hypo-/demyelination. The cerebral cortex has a normal appearance.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Lysosomal storage disorder
  - Caused by ↓ arylsulfatase A (ARSA)
  - Results in CNS, PNS demyelination
- 3 clinical forms
  - Late infantile (most common), juvenile, adult

IMAGING

- Best diagnostic clue: Confluent butterfly-shaped ↑ T2 signal in deep cerebral hemispheric white matter (WM)
  - Early: Spares subcortical U-fibers
    - Corpus callosum splenium, parietooccipital WM initially
    - Rapid centrifugal spread to frontal, temporal WM
  - Late: Involves subcortical U-fibers
- Sparing of perivenular myelin = tigroid or leopard pattern
- No WM enhancement
  - Reports cranial nerve, cauda equina enhancement

TOP DIFFERENTIAL DIAGNOSES

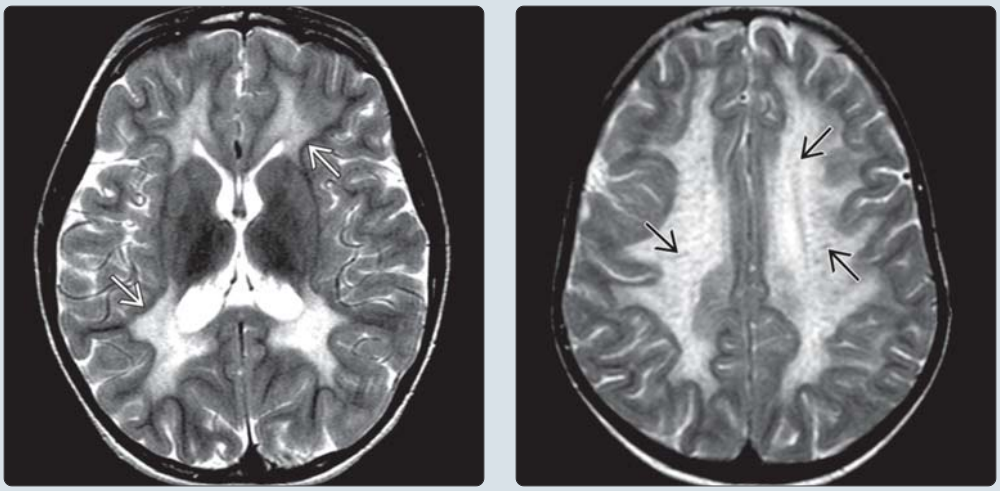
- Pelizaeus-Merzbacher disease
- TORCH
- Pseudo-TORCH
- Periventricular leukomalacia
- Sneddon syndrome (arylsulfatase A pseudodeficiency)
- Krabbe disease
- Megalencephaly with leukoencephalopathy and cysts

CLINICAL ISSUES

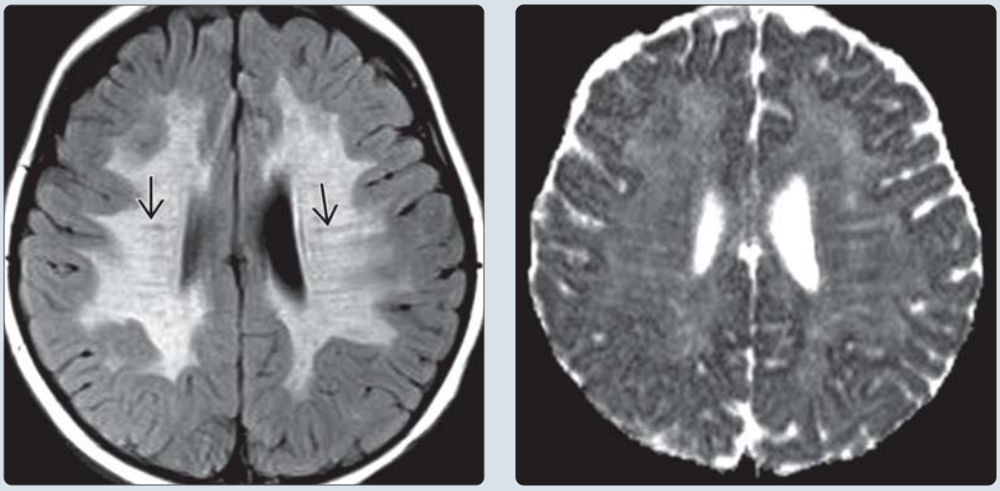
- Clinical profile: Toddler with visuomotor impairment and abdominal pain

DIAGNOSTIC CHECKLIST

- Adult patients presenting with cryptic spasticity of legs should be screened for X-linked adrenoleukodystrophy/adrenomyeloneuropathy, lysosomal disorders (e.g., MLD)



(Left) *Axial T2WI MR shows typical butterfly-shaped pattern of white matter (WM) involvement in metachromatic leukodystrophy (MLD). Note the sparing of internal/external capsules and subcortical U-fibers ⇨, typical of early disease.* **(Right)** *Axial T2WI MR shows confluent, symmetric WM hyperintensity with sparing of subcortical U-fibers. Perivenular myelin sparing causes the hypointense lines and dots within the WM ⇨, the characteristic tigroid or leopard pattern of MLD.*



(Left) *Axial FLAIR MR demonstrates the characteristic confluent, symmetric, central WM involvement of MLD. The tigroid or leopard pattern of lines ⇨ and dots within the cerebral hemispheric WM is evident.* **(Right)** *Axial ADC map in the same patient shows high signal intensity within the affected WM consistent with increased diffusivity and probable interstitial edema. Reduced diffusivity (cytotoxic edema) is sometimes seen in areas of active demyelination.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Metachromatic leukodystrophy (MLD)

Synonyms

- Sulfatide lipoidosis

Definitions

- Lysosomal storage disorder
  - Caused by ↓ arylsulfatase A (ARSA)
  - Results in CNS, PNS demyelination
- 3 clinical forms: Late infantile (most common), juvenile, adult

IMAGING

General Features

- Best diagnostic clue: Confluent butterfly-shaped ↑ T2 signal in deep cerebral hemispheric white matter (WM)
- Location: Deep cerebral hemispheric WM
  - Early: Spares subcortical U-fibers
    - Corpus callosum, parietooccipital WM initially
    - Rapid centrifugal spread to frontal, temporal WM
  - Late: Involves subcortical U-fibers
- Morphology: Symmetric, confluent periventricular (PV) and deep WM high T2 signal

CT Findings

- NECT: Symmetric ↓ attenuation central cerebral hemispheric WM; late atrophy
- CECT: No enhancement (lacks inflammation)
- CT perfusion: ↓ perfusion hemispheric WM

MR Findings

- T1WI
  - Early: ↓ T1 signal within PV/deep WM
  - Late: Atrophy
- T2WI
  - Early
    - Confluent PV hyperintensity (butterfly shaped)
    - Sparing of perivenular myelin = tigroid or leopard pattern
    - Sparing of subcortical U-fibers
  - Late
    - Progressive subcortical WM extension
    - Involvement of U-fibers, corpus callosum, descending pyramidal tracts, internal capsules
    - Atrophy
- PD/intermediate: ↑ signal within PV/deep WM
- FLAIR: Butterfly-shaped periventricular hyperintensity
- T2* GRE: No petechial hemorrhage
- DWI: Reduced diffusivity in areas of active demyelination
- T1WI C+: No WM enhancement
  - Reports cranial nerve, cauda equina enhancement
- MRS: ↑ choline, ± ↑ myoinositol

Imaging Recommendations

- Best imaging tool
  - Early MR and MRS in presymptomatic enzyme-deficient siblings
- Protocol advice
  - MR: Include FLAIR
  - MRS: Sample central hemispheric WM

DIFFERENTIAL DIAGNOSIS

Pelizaeus-Merzbacher Disease

- Usually manifests in neonates and infants
- Lack of myelination without myelin destruction
- Cerebellum may be markedly atrophic

TORCH

- Variable WM hyperintensity (demyelination and gliosis)
- Not progressive
- Varied patterns of Ca++ depending on etiology

Pseudo-TORCH

- Progressive cerebral and cerebellar demyelination
- Brainstem, basal ganglia, and PV Ca++
- Elevated CSF neurotransmitters

Periventricular Leukomalacia

- Usually symmetric PV bright T2 signal
- PV volume loss (nonprogressive)
- Static spastic diplegia or quadriplegia

Sneddon Syndrome (Arylsulfatase A Pseudodeficiency)

- Demyelination
  - May be precipitated by hypoxic event
- PV WM bright T2 signal
- Confirmed by skin biopsy

Krabbe Disease

- Early involvement of cerebellar WM
- CT shows ↑ attenuation of thalami

Megalencephaly With Leukoencephalopathy and Cysts

- Slowly progressive, sparing of cognition, macrocephaly

PATHOLOGY

General Features

- General path comments
  - ↓ ARSA results in systemic storage of sulfatide
    - Symptomatic storage: CNS, PNS, gallbladder
    - Asymptomatic: Kidneys, adrenals, pancreas, liver
  - Diagnosis confirmed by
    - Excess urine sulfatide
    - Absent or deficient ARSA activity in fibroblasts &/or leukocytes
- Genetics: Autosomal recessive
  - *ARSA* gene located at 22q13.31-qter
  - > 110 different mutations
  - Late infantile form caused by mutations resulting in extremely low levels of ARSA
  - Juvenile/adult forms associated with residual ARSA activity
- Etiology
  - Absent or ↓ ARSA → increased lysosomal storage sulfatide → lethal demyelination
- Associated abnormalities: Gallbladder disease

https://CafePezeshki.IR

Gross Pathologic & Surgical Features

- Early
  - Enlarged brain and demyelination
  - Lack of inflammatory component to WM
- Late
  - Progressive cerebral hemispheric demyelination
  - Cerebral atrophy

Microscopic Features

- Central nervous system
  - PAS(+) metachromatic material accumulates in glial cells, neurons, Schwann cells, macrophages
  - Sulfatide deposition within plasma membranes
  - Sulfatide membrane-bound inclusions at inner layer of myelin sheaths
  - Demyelination may be extensive, yet inflammatory component is lacking
  - Sulfatide content in WM is considerably higher in late infantile form

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Late infantile
    - Insidious onset 2nd year of life
    - Strabismus, gait disturbance, ataxia, weakness, hypotonia
    - ± cherry-red macular spot
    - Bulbar signs → progressive hypotonia → decerebrate posturing → optic atrophy
    - Death frequently within 4 years of diagnosis
  - Juvenile
    - Appears between 5 and 10 years of age
    - Impaired school performance (nonverbal learning disability)
    - Spastic gait, ataxia, intellectual impairment
    - Brisk deep tendon reflexes
    - Progressive spasticity → progressive dementia → decerebrate posturing → seizures
    - Rare to survive longer than 20 years
  - Adult form
    - Can manifest as late as 6th decade
    - Presentation
      - May present as MS
      - Dementia, schizophrenia
      - Cryptic spasticity of legs
      - Progressive corticobulbar, corticospinal, and cerebellar changes
- Clinical profile: Toddler with visuomotor impairment and abdominal pain

Demographics

- Age: Variable depending on clinical form
- Gender: No predilection
- Epidemiology of all forms in USA: 1:100,000
  - ↑ in Habbanite Jewish (1:75 live births)
  - ↑ in Navajo Indians (1:2,500 live births)

Natural History & Prognosis

- Variable depending on clinical form

Treatment

- Hematopoietic stem cell, bone marrow, and umbilical cord blood transplant
  - May arrest motor and intellectual deterioration
  - Hematopoietic stem cell transplant shown to stabilize and even improve WM abnormalities
  - Mixed reports of effectiveness of bone marrow/cord blood transplants
    - Considered only in early phases of late infantile and juvenile/early adult forms
- Experimental: Lentivector-mediated *ARSA* gene transfer

DIAGNOSTIC CHECKLIST

Consider

- If WM involvement appears as "worst case MLD," involving internal capsule and brainstem → MLD look-alike, consider
  - Pseudo-TORCH
  - Megalencephaly with leukoencephalopathy and cysts
- Adult patients presenting with cryptic spasticity of legs should be screened for X-linked adrenoleukodystrophy/adrenomyeloneuropathy, lysosomal disorders (e.g., MLD)

Image Interpretation Pearls

- Butterfly pattern of cerebral hemispheric WM
- Tigroid or leopard pattern on T2WI
- Early sparing of subcortical U-fibers
- Lack of WM enhancement

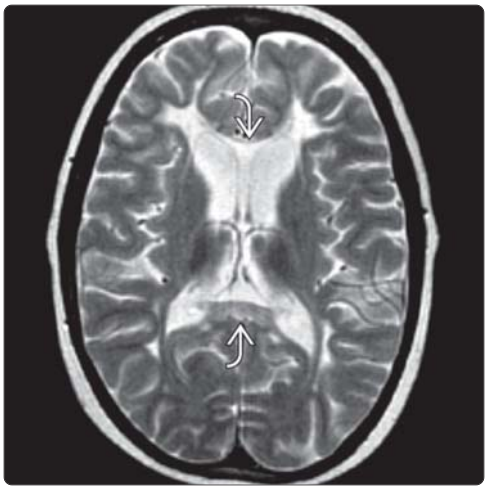
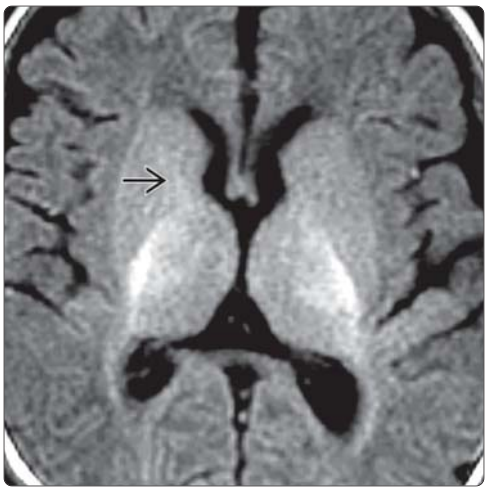
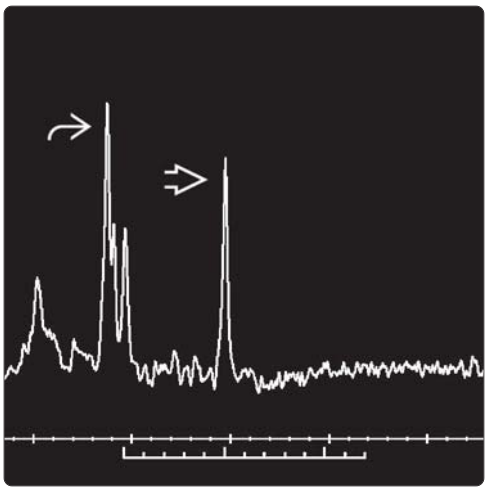
(Left) *Sagittal T1WI MR shows confluent hypointense signal in the periventricular and deep WM with sparing of the subcortical U-fibers ➡. Although less well evaluated in the sagittal plane, dot-like areas of spared perivenular myelin can be identified ➡.* **(Right)** *Axial T2WI MR shows the butterfly-shaped pattern of WM involvement typical in more advanced MLD. Although the subcortical U-fibers remain spared, the posterior limbs of the internal capsules ➡ are involved.*



(Left) *In this axial T2WI MR of a patient with late MLD, the characteristic butterfly-shaped pattern of disease can be recognized despite severe loss of WM volume. Lateral ventricles are enlarged (ex vacuo), and the basal ganglia are atrophic. Hyperintense signal is present in the corpus callosum ➡.* **(Right)** *Axial T2WI MR in the same patient shows confluent hyperintense signal and severe volume loss of the WM. Although spared in this patient, the subcortical U-fibers are often affected in late disease.*





(Left) *Axial T1WI MR shows a 4-month-old infant with affected older siblings status post bone marrow transplant (BMT). Excepting mild myelin maturation delay in the anterior limbs of the internal capsule ➡, the conventional images were normal.* **(Right)** *Single voxel MRS (TE = 288 msec) obtained from the periventricular WM of the same patient shows increase in the choline peak ➡. The NAA peak ➡ should be the dominant peak at this age.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Progressive autosomal recessive degenerative leukodystrophy of central (CNS) and peripheral (PNS) nervous systems

IMAGING

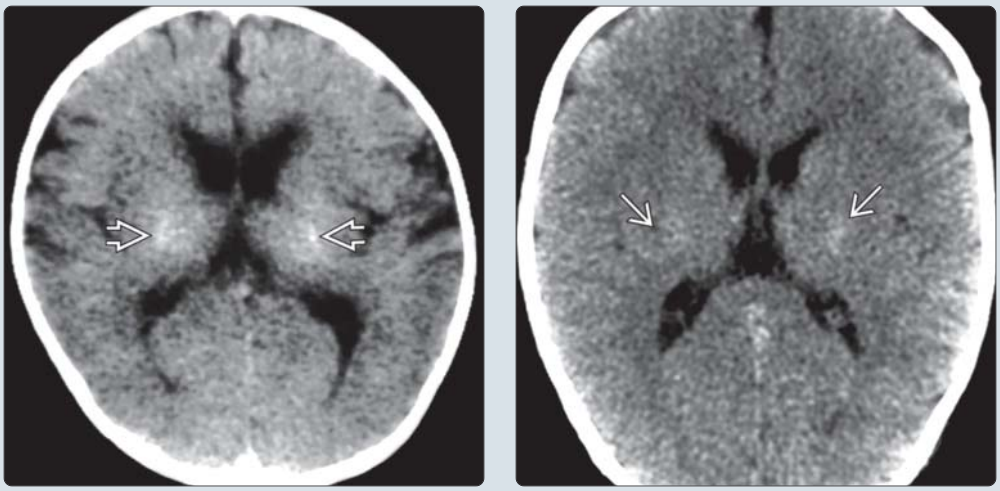
- Symmetric hyperdensity in thalami, basal ganglia on CT
- Enlargement of optic nerves and cranial nerves
- Confluent symmetric deep periventricular white matter (WM) hyperintensity
- Cerebellar WM hyperintense signal on T2WI
  - Ring-like appearance around dentate nuclei
- Fractional anisotropy values in corticospinal tracts are low compared to controls
- Enhancement of lumbar nerve roots
- MRS: Pronounced ↑ choline, myoinositol; moderate NAA reduction; mild lactate accumulation

PATHOLOGY

- Deficiency of lysosomal galactocerebroside β-galactosidase (GALC)
  - Accumulation of psychosine 100x normal concentrations
  - Psychosine is toxic to brain
- Infantile form is most common and most severe
- "Globoid" cells = macrophages containing PAS(+) galactocerebrosides
  - Identified in enlarged optic nerves

CLINICAL ISSUES

- Most common symptom is extreme irritability
- Neonatal screening has been instituted in New York and Illinois
- Stem cell transplant can halt disease progression



(Left) *Axial NECT in a 6 month old with irritability and feeding difficulties shows abnormal increased attenuation in the thalami* ⇨. **(Right)** *The hyperdensities are more punctate* ⇨ *in this axial NECT from an 18 month old with Krabbe disease. Infantile Krabbe is 1 of the few leukodystrophies in which CT features may be apparent before MR findings; however, DTI shows promise in detecting decreased fractional anisotropy in the corticospinal tracts in presymptomatic neonates.*

(Left) *Axial T1WI MR in an 8-month-old boy with Krabbe shows abnormal hypointensity* ⇨ *in the hila of the cerebellar nuclei bilaterally. Regions of increased density on CT often have hyperintense signal on T1WI.* **(Right)** *Axial T2WI MR in the same patient shows correlating alternating hyper- (edema in hila* ⇨*), hypo- (nuclei* ⇨*), and hyperintense (cerebellar white matter* ⇨*) signal around the cerebellar nuclei. Krabbe is 1 of the few leukodystrophies that has early cerebellar imaging findings.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Globoid cell leukodystrophy (GLD)

Synonyms

- Krabbe disease

Definitions

- Progressive autosomal recessive degenerative leukodystrophy of central (CNS) and peripheral (PNS) nervous systems

IMAGING

General Features

- Best diagnostic clue
  - Hyperdensity on CT in thalami, corona radiata, and body of caudate nuclei in irritable infant
- Location
  - Thalami, basal ganglia (BG), white matter (WM), corticospinal and pyramidal tracts, PNS

CT Findings

- NECT
  - Symmetric hyperdensity in thalami, BG, corona radiata, cerebellum
    - Globoid cell accumulation with calcifications
    - Fades over time
  - Deep, periventricular WM hypodensity
  - Atrophy develops, leads to 2° microcephaly

MR Findings

- T1WI
  - Deep, periventricular WM hypointensity
  - Faint hyperintensity in thalami and BG
  - Enlargement of optic nerves and cranial nerves
- T2WI
  - Confluent symmetric deep periventricular WM hyperintensity
    - Spares subcortical U-fibers
    - Starts in corticospinal tracts, becomes diffuse over time
    - Hypointense thalami
  - Cerebellar WM hyperintense signal
    - Ring-like appearance around dentate nuclei
  - Corpus callosum frequently involved in adult-onset disease
- FLAIR
  - Better delineates WM hyperintensities in older children
- DWI
  - Fractional anisotropy (FA) values in corticospinal tracts are significantly lower in neonates with Krabbe disease than in controls
  - Diffusion tensor-derived anisotropy maps → loss of diffusion anisotropy
    - Relative anisotropy (RA) differences found in BG, middle cerebellar peduncles, internal capsule, corpus callosum, periventricular WM
    - After stem cell transplantation, RA of untreated patients < mean RA treated < RA of control subjects
- T1WI C+
  - Enhancement of cranial nerves, lumbar nerve roots
- MRS
  - Infantile: Pronounced ↑ choline, myoinositol; moderate NAA reduction; mild lactate accumulation
  - Late infantile-juvenile: ↑ choline, myoinositol; mild NAA reduction
  - Adult: Mild ↑ choline and myoinositol, may be close to normal

Imaging Recommendations

- Best imaging tool
  - MR + contrast and DTI
- Protocol advice
  - Pay attention to cranial nerves
  - Consider NECT to look for hyperdense thalami

DIFFERENTIAL DIAGNOSIS

Neuronal Ceroid Lipofuscinosis

- Batten disease
- Hyperdense thalami on CT
- Progressive cerebral atrophy

GM2 Gangliosidoses

- e.g., Tay-Sachs disease
- Lysosomal lipid storage disorders caused by mutations in ≥ 1 of 3 recessive genes: *HEXA*, *HEXB*, *GM2A*
- Hypointense/hyperdense thalami; patchy hyperintense WM

Neurofibromatosis Type 1

- Optic nerve enlargement (optic nerve glioma)
- Patchy WM signal abnormalities
- Not progressive; does not present with irritability in infant

Metachromatic Leukodystrophy (MLD)

- Progressive WM hyperintensity on T2WI
- Initial sparing of subcortical U-fibers

PATHOLOGY

General Features

- Etiology
  - Gene defects result in deficiency of lysosomal galactocerebroside β-galactosidase (GALC)
    - Normally aids in cleavage of galactose from psychosine and galactosylceramide, leaving sphingosine and ceramide, respectively
      - Galactosylceramidase 2 and 3 can catalyze galactosylceramide but not psychosine
    - Results in accumulation of psychosine 100x normal concentrations
      - Psychosine is toxic to brain, especially oligodendroglia → destruction of oligodendrocytes
    - Accumulation of psychosine causes
      - Upregulation of AP-1 (proapoptotic pathway)
      - Downregulation of NF-κB pathway (antiapoptotic pathway)
  - Sulfotransferase may also be deficient; suggests that galactosylceramide degradation may be complex
- Genetics
  - Autosomal recessive lysosomal disorder
  - Gene mapped to chromosome 14 (14q24.3 to 14q32.1) and has been cloned

https://CafePezeshki.IR

  - Different mutations associated with differing severity for both age of onset and progression
  - 65 mutations and polymorphic changes described

Staging, Grading, & Classification

- Infantile: Before age 2
  - Most common and most severe
- Late infantile-juvenile: After age 2
- Adult: After age 10
  - Corticospinal, pyramidal tract symptoms
  - Mimics peripheral neuropathy
  - Often undiagnosed for many years

Gross Pathologic & Surgical Features

- Small, atrophic brain

Microscopic Features

- Myelin loss with astrogliosis and dysmyelination
  - Severe oligodendrocyte loss
- Perivascular large multinucleated "globoid" and mononuclear epithelioid cells in demyelinated zones
  - "Globoid" cells = macrophages containing PAS(+) galactocerebrosides
- Demyelination is marked within cerebrum, cerebellum, brainstem, spinal cord with segmental involvement of peripheral nerves
- "Globoid" cells identified in enlarged optic nerves
- "Globoid" cell inclusions in sweat gland epithelial cells

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Neonatal: Most common symptom is extreme irritability
    - Seizures result in medical attention
    - Hypersensitivity to sensory stimuli (e.g., hyperacusis), fevers, feeding problems, failure to thrive, optic atrophy, cortical blindness
  - Infantile-juvenile
    - Visual failure, cerebellar ataxia, spasticity, polyneuropathy, dementia, psychosis
  - Adult
    - Hemiparesis, spastic paraparesis, cerebellar ataxia, intellectual impairment, visual failure, peripheral polyneuropathy, talipes cavus
- Clinical profile
  - Diagnosis made from leukocyte or skin fibroblast β-galactosidase assay
  - Molecular assay available for genetic counseling, prenatal testing
  - Universal neonatal screening has been instituted in New York and Illinois

Demographics

- Gender
  - M = F
- Ethnicity
  - Most reported patients have European ancestry, but it can affect all populations
- Epidemiology
  - 1:100,000 in USA and Europe
  - 1:25-50,000 in Sweden
  - 6:1,000 in Druze community in Israel

Natural History & Prognosis

- Neonatal: Rapidly progressive, few live > 2 years
  - Motor deterioration → quadriparesis
  - Hypertonicity becomes flaccidity as PNS is involved
  - Blindness
- Infantile-juvenile: More protracted course, slower rate of progression
- Adult: Heterogeneous, progresses more slowly
  - MR may remain normal for many years, even in presence of symptoms
- Sequelae (e.g., infection) cause most deaths

Treatment

- Hematopoietic stem cell transplantation
  - Halts disease progression in mild forms of Krabbe
  - Both clinical and radiologic manifestations may reverse or retard

DIAGNOSTIC CHECKLIST

Consider

- Use contrast on MR when considering leukodystrophies
- Think of Krabbe when dealing with hyperirritable infant

Image Interpretation Pearls

- Look for faint hyperdensity on CT in deep cerebral nuclei

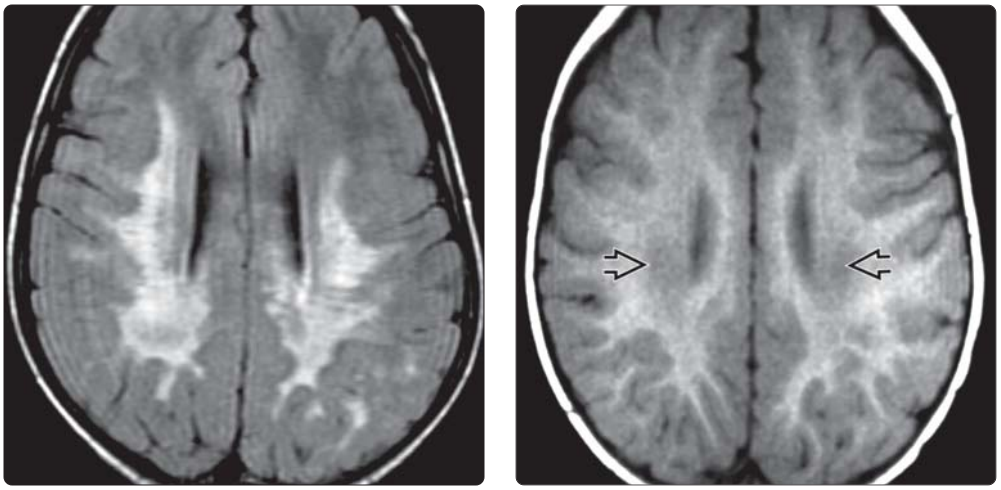
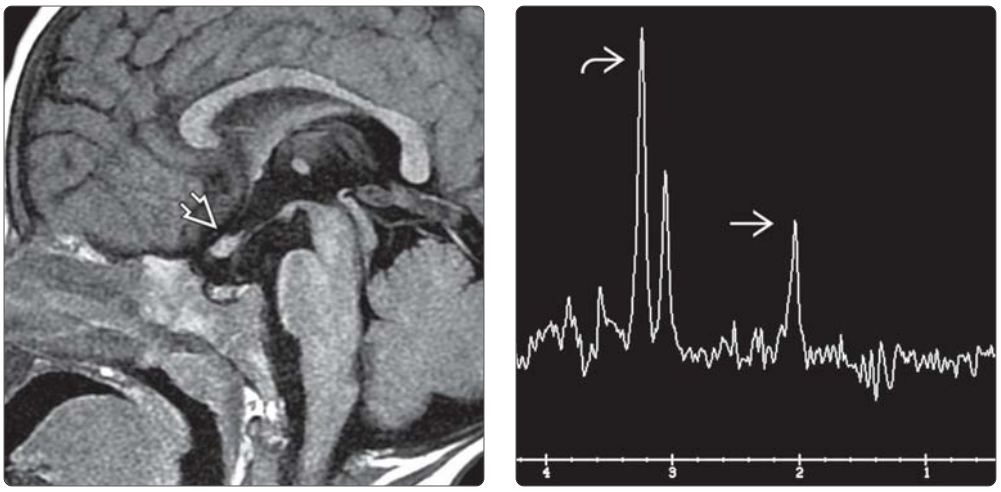
https://CafePezeshki.IR



(Left) *Axial FLAIR MR in a 4 year old with Krabbe disease treated with stem cell transplantation shows confluent abnormal hyperintense signal in the periventricular white matter, primarily affecting the posterior frontal and parietal lobes.* **(Right)** *Axial T1WI MR in the same child shows subtle hypointense signal ⇨ that appears less extensive but is in the same distribution. These findings did not progress after the stem cell transplant.*

(Left) *Axial FLAIR MR in a 30 year old with juvenile-onset Krabbe disease demonstrates abnormal hyperintense signal ⇨ in the corona radiata on each side. Symmetric corticospinal tract involvement is a hallmark of globoid cell leukodystrophy.* **(Right)** *Axial FLAIR MR in the same patient shows focal symmetric hyperintensity in the capsular portion of the corticospinal tracts ⇨. The infantile juvenile-onset form is characterized by a more protracted course with a slower rate of progression.*



(Left) *Sagittal T1WI MR clearly shows focal enlargement of the optic chiasm ⇨ in this child with Krabbe disease. A unique feature of this leukodystrophy is the occasional enlargement of optic nerves described by Krabbe in his original paper on the condition.* **(Right)** *Axial MRS in the affected WM of a child with Krabbe shows elevated choline ⇨ and diminished NAA ⇨. Although nonspecific, this pattern is typical of Krabbe disease, and these alterations will worsen without treatment.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY
- Fabry disease (FD)

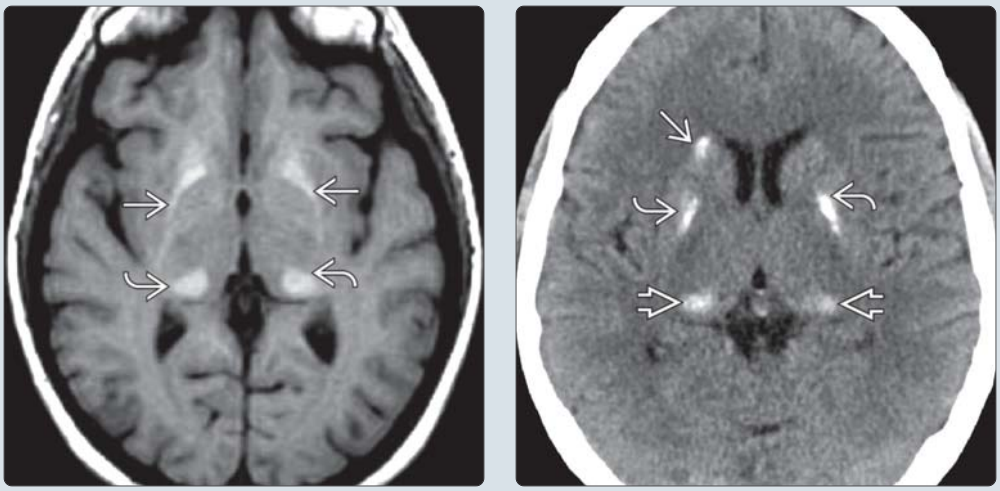
IMAGING
- NECT
  - Ca++ in lateral pulvinar, globus pallidus, putamen, substantia nigra, dentate nuclei
- MR may show earlier changes
  - ↑ T1 signal in deep gray nuclei
  - T1 lateral pulvinar hyperintensity considered pathognomonic of FD
  - T2/FLAIR hyperintensities in periventricular WM, deep gray matter

TOP DIFFERENTIAL DIAGNOSES
- Endocrinologic disorders
  - Hyperparathyroidism, hypoparathyroidism, pseudohypoparathyroidism, hypothyroidism
- HIV-associated mineralizing calcific microangiopathy
- Fahr disease

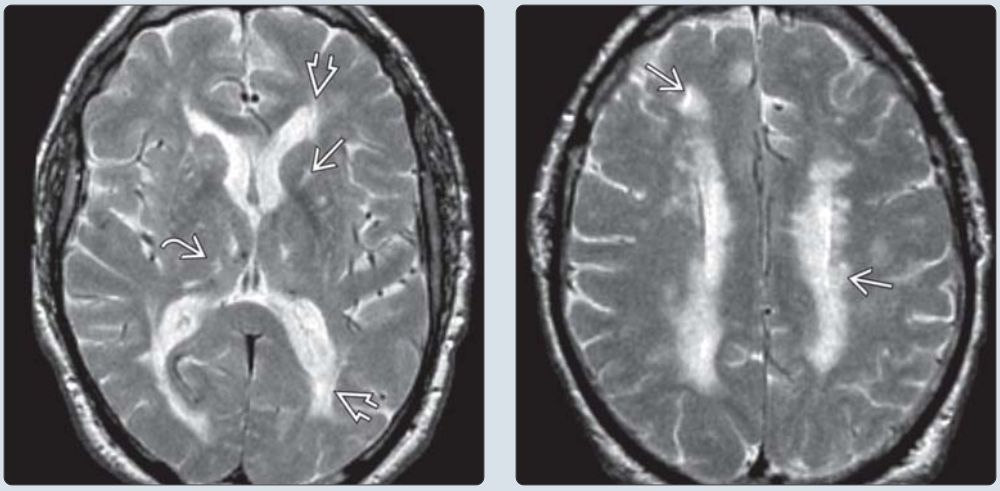
PATHOLOGY
- X-linked disorder of glycosphingolipid metabolism
- Deficient activity of α-galactosidase A
- Endothelial accumulation of glycosphingolipids
  - Compromises vessel lumen size
  - Leads to vascular events (myocardial ischemia, strokes)

CLINICAL ISSUES
- Neurologic complications in 4th/5th decades
- Enzyme replacement therapy may help

DIAGNOSTIC CHECKLIST
- Consider FD in young males with white matter disease, basal ganglia/pulvinar calcification



(Left) *Axial T1WI MR in a patient with Fabry disease shows bilateral hyperintense lesions in the lateral putamina ➡ and lateral aspects of both pulvinars ➡. T1 hyperintensity in the lateral pulvinar is considered a virtually pathognomonic sign of Fabry disease.* **(Right)** *Axial NECT in the same patient shows calcifications in the right caudate ➡, both putamina ➡, and lateral pulvinars ➡, corresponding to the T1 hyperintensities seen on the previous MR scan.*



(Left) *Axial T2WI MR in a 50-year-old man with Fabry disease shows multifocal lacunar infarcts in the basal ganglia ➡ and thalami ➡, as well as confluent hyperintensities in the deep periventricular white matter ➡.* **(Right)** *Axial T2WI MR in the same patient shows multifocal, discrete, and confluent white matter hyperintensities in the deep cerebral white matter ➡. Deep white matter and basal ganglia infarcts are due to large and small vessel involvement in Fabry disease.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Fabry disease (FD)

Synonyms

- Anderson-Fabry disease

Definitions

- X-linked disorder of glycosphingolipid metabolism
- Deficient activity of α-galactosidase A

IMAGING

General Features

- Best diagnostic clue
  - Lateral pulvinar ↑ T1 signal (MR), Ca++ (CT)
- Location
  - Typical: Lateral pulvinar, globus pallidus, putamen
  - Other: Substantia nigra, dentate nuclei

Imaging Recommendations

- Best imaging tool
  - CT: Sensitive for small quantities of calcification
  - MR may show earlier changes, T1 hyperintensity
- Protocol advice
  - NECT + MR (T1-, T2WI; FLAIR best)

MR Findings

- T1WI
  - Increased T1 signal in deep gray nuclei
    - Lateral pulvinar ↑ T1 signal considered pathognomonic
  - T1 hyperintensity varies
    - Depends on stage, volume of Ca++
- T2WI
  - Patchy hyperintensities in WM, deep gray nuclei
    - ↑ in intensity, coalesce over time
- T2* GRE
  - Microbleeds (10%)

DIFFERENTIAL DIAGNOSIS

Fahr Disease

- Bilateral dense, thick Ca++ in BG/thalami
- Cortical atrophy

Endocrinologic Disorders

- Hyperparathyroidism, hypoparathyroidism, pseudohypoparathyroidism, hypothyroidism
  - Lacks multifocal infarcts but Ca++ similar to FD
  - Serum Ca, PTH, T3/T4, TSH levels helpful

HIV-Associated Mineralizing Calcific Microangiopathy

- Ca++ in basal ganglia (BG) and cerebral atrophy

PATHOLOGY

General Features

- Etiology
  - Disorder of glycosphingolipid metabolism
  - α-galactosidase A deficient activity
    - Causes progressive accumulation of glycosphingolipids (ceramide trihexoside)
      - Vascular endothelium and smooth muscle cells affected
      - Endothelial accumulation causes ↓ vessel lumen
      - Parenchymal cells in kidney, heart, and brain affected
    - Leads to myocardial ischemia and stroke
- Genetics
  - X-linked inheritance, abnormality in *GLA* gene
- Associated abnormalities
  - Left ventricular hypertrophy, short PR interval, AV block
  - Renal cysts (subcapsular predilection)

Microscopic Features

- Glycosphingolipid deposits
  - Form lamellate membrane-like structure (myeloid or "Zebra bodies")
  - Neurons (basal ganglia, brainstem, amygdala, hypothalamus)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Cardiovascular (emboli, large vessel arteriopathy, microvascular disease)
    - Causes 1.5% of unexplained strokes in young patients
    - Angina, heart block, renal failure/HTN
  - Other
    - Acroparesthesias, neuropathic pain
    - Cutaneous angiokeratomas (infants)
      - Corneal inclusions, cataracts

Demographics

- Age
  - Neurologic complications in 4th/5th decades
    - Present in 4-5% of men with cryptogenic stroke or unexplained left ventricular hypertrophy
  - Hemizygous men: Onset in adolescence
- Gender
  - Heterozygous females are normally healthy carriers but may develop symptoms of FD

Treatment

- Recombinant human alpha-galactosidase A

DIAGNOSTIC CHECKLIST

Consider

- FD in young males with white matter disease, basal ganglia/pulvinar calcification

Image Interpretation Pearls

- T1 hyperintensity in pulvinar is pathognomonic

KEY FACTS

TERMINOLOGY

- Zellweger syndrome: Cerebrohepatorenal syndrome
- Zellweger syndrome spectrum (ZSS): ZS + neonatal adrenoleukodystrophy + infantile Refsum disease
- Peroxisome biogenesis disorders: ZSS (80%) + rhizomelic chondrodysplasia punctata

IMAGING

- Microgyria, pachygyria, hypomyelination, germinolytic (caudothalamic) cysts
  - Microgyria most severe in perisylvian region (especially posterior insula)
  - Pachygyria most common frontoparietal
- Central volume loss common
- MRS: ↓ NAA, ↑ Cho
- Short TE MRS: Mobile lipid peaks at 0.9 and 1.33 ppm
- Diffuse hypomyelination, cerebellum, and brainstem may be involved especially if present > 1 year

TOP DIFFERENTIAL DIAGNOSES

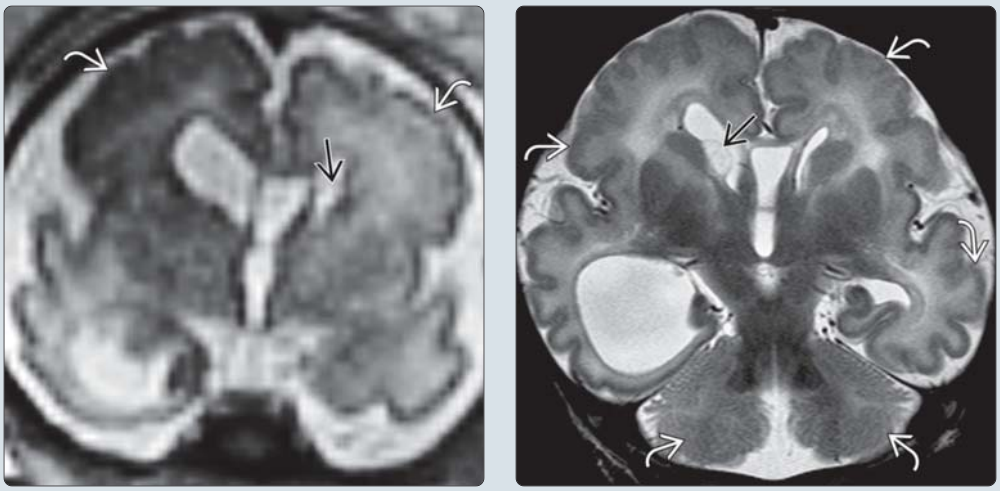
- Congenital CMV
- Pseudo-TORCH
- Single peroxisomal enzyme deficiencies

PATHOLOGY

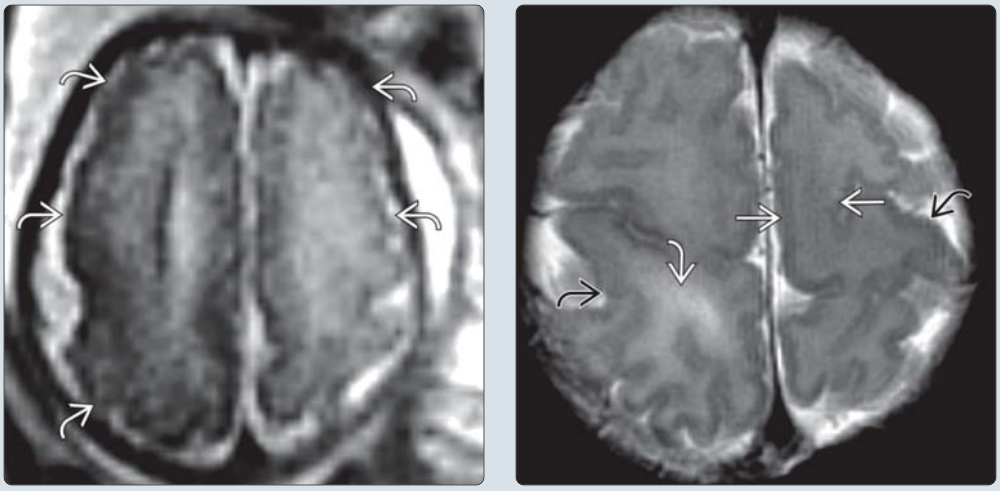
- Defect in biogenesis of peroxisomes
- Autosomal-recessive phenotype resulting from defect in any of at least 12 *PEX* genes

CLINICAL ISSUES

- Severe hypotonia, seizures, poor sucking
- Large fontanelle + sutures, high forehead, broad nasal bridge, hypertelorism
- Elevated liver enzymes, hepatomegaly
- Cataract, nystagmus, retinitis pigmentosa, or optic atrophy



(Left) *Coronal T2WI MR of a fetus at 32 weeks gestational age shows right ventricular enlargement (30 mm), a subtle germinolytic cyst ⇨ in the left frontal horn, diffuse microgyria ⇨, and abnormal variation of white matter signal intensity.* **(Right)** *Coronal T2WI MR in the same patient 2 days after term delivery shows right ventricular enlargement, a germinolytic cyst ⇨ in the right frontal horn, diffuse cerebral and cerebellar microgyria ⇨, and abnormally increased signal in the deep white matter.*



(Left) *Axial T2WI MR of the same fetus shows diffusely abnormal signal intensity in the cerebral hemispheric white matter, in addition to extensive cerebral microgyria ⇨.* **(Right)** *Axial T2WI MR in the same patient 2 days after term delivery shows the presence of diffuse cerebral cortical microgyria ⇨ along with areas of decreased sulcation ⇨, in addition to abnormally increased signal in the white matter ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Zellweger syndrome (ZS)

Synonyms

- Cerebrohepatorenal syndrome
- Zellweger syndrome spectrum (ZSS)

Definitions

- ZSS: ZS + neonatal adrenoleukodystrophy + infantile Refsum disease
- Peroxisome biogenesis disorders: ZSS (80%) + rhizomelic chondrodysplasia punctata (RCDP)

IMAGING

General Features

- Best diagnostic clue
  - Microgyria, pachygyria, hypomyelination, germinolytic cysts
  - Leukoencephalopathy; volume loss > 1 year
- Location
  - Microgyria most severe in perisylvian region, especially posterior insula
  - Pachygyria most common frontoparietal
  - Diffuse hypomyelination; cerebellum and brainstem may be involved, especially if present > 1 year
- Size
  - Central volume loss common
- Morphology
  - ± heterotopia (periventricular or subcortical)

MR Findings

- T1WI
  - Microgyria, pachygyria, germinolytic cysts (near foramina of Monro), ↓ white matter (WM) signal
  - ± ↑ globus pallidus signal from hyperbilirubinemia
- T2WI
  - Microgyria, pachygyria, germinolytic cysts, ↑ WM signal
- T1WI C+
  - May see enhancement of corticospinal tracts in brainstem
- MRS
  - Use short TE: ↓ NAA; ↑ Cho; lipid peaks at 0.9 and 1.33 ppm

Imaging Recommendations

- Best imaging tool
  - MR + MRS
- Protocol advice
  - Volumetric T1/FLAIR for cysts, TE = 20-30 ms for MRS

DIFFERENTIAL DIAGNOSIS

Congenital CMV

- Ca++, periventricular cysts usually not caudothalamic

Pseudo-TORCH

- Basal ganglia, thalamic, and periventricular Ca++

Single Peroxisomal Enzyme Deficiencies

- Brain MR may be similar; biochemistry different

PATHOLOGY

General Features

- Etiology
  - Defect in biogenesis of peroxisomes
    - Defective transport of proteins into peroxisomal matrix → accumulation of very long chain fatty acids
- Genetics
  - AR defect in any of at least 12 *PEX* genes
- Associated abnormalities
  - Eye: Brushfield spots, retinal pigment degeneration
  - Hepatomegaly, renal cortical cysts
  - Skeletal: Stippled chondral calcification

Gross Pathologic & Surgical Features

- Leukoencephalopathy, germinolytic cysts, cortical and cerebellar malformations
- Subcortical heterotopia, cerebellar hypoplasia

Microscopic Features

- Pachygyria, polymicrogyria, or microgyria
- Sudanophilic leukodystrophy

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Severe hypotonia, seizures, poor sucking
  - Large fontanelle + sutures, high forehead, broad nasal bridge, hypertelorism
- Other signs/symptoms
  - Elevated liver enzymes, hepatomegaly
  - Cataract, nystagmus, retinitis pigmentosa, or optic atrophy
- Clinical profile
  - Low Apgar scores; very floppy, dysmorphic facies

Demographics

- Age
  - Severe at birth, milder at < 6 months, rare adult

Natural History & Prognosis

- Most severely affected die < 3 months, milder may live > 20 years

Treatment

- Supportive, no proven therapy

KEY FACTS

TERMINOLOGY

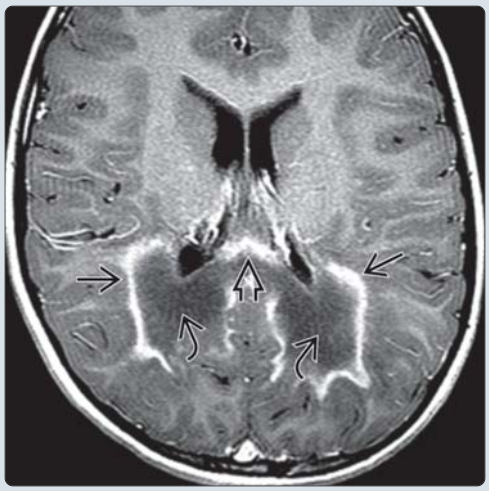
- Abbreviations
  - X-linked adrenoleukodystrophy (X-ALD, ALD)
  - Classic childhood ALD (CCALD)
- Inherited peroxisomal disorder
  - *ABCD1* mutation → impaired β-oxidation (β-ox) of very long chain fatty acids (VLCFA)
  - Accumulation of VLCFAs in white matter (WM) causes severe inflammatory demyelination
- Several clinical forms of ALD and related disorders
  - Classic X-linked adrenoleukodystrophy (X-ALD)
    - Severe form almost exclusively in males 5-12 years
  - At least 6 variants other than classic childhood X-ALD
    - Presymptomatic X-ALD, adolescent (AdolCALD), adult (ACALD), adrenomyeloneuropathy (AMN), Addison only, symptomatic female carriers
  - AMN
    - "Mild" adult (spinocerebellar) form, cerebral involvement in up to 50%
    - X-ALD and AMN account for 80% of cases

IMAGING

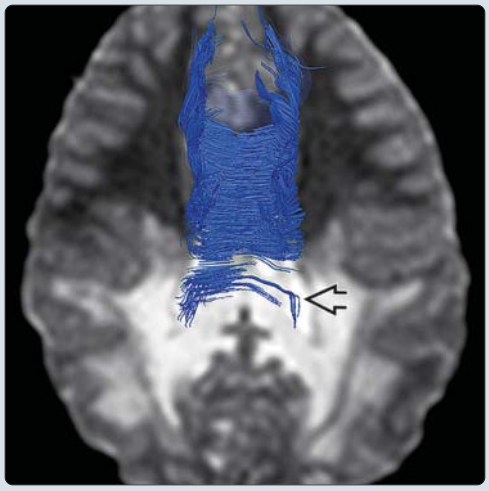
- Three zones of myelin loss in CCALD
  - Innermost: Necrotic astrogliotic core
  - Intermediate: Enhancing active demyelination, inflammation
  - Peripheral: Advancing demyelination without inflammation

DIAGNOSTIC CHECKLIST

- X-ALD presenting at atypical ages
  - Atypical appearances common
    - Lacks enhancement, may have frontal (rather than posterior) "gradient"
- Always enhance unknown leukodystrophy



(Left) *Axial graphic demonstrates multiple layers of demyelination. The layers correspond to 3 zones histopathologically. The outer layer ⇨ consists of active destruction and the middle layer ⇨ of active inflammation. Note that the central area ⇨ is burnt out.* **(Right)** *Axial T1WI C+ MR reveals marked rim enhancement ⇨ surrounding the most severely damaged parietal white matter (WM) ⇨ and the splenium of the corpus callosum ⇨ in a preteen male with typical CCALD (Loes pattern 1).*



(Left) *Axial T2WI MR distinguishes the active inflammation of the outer zone ⇨ from the innermost "burnt-out" zone of WM destruction ⇨ in this preteen male who presented with well-developed brain involvement.* **(Right)** *Axial tractograph of the corpus callosum from a DTI sequence demonstrates significant loss of WM tracts crossing the splenium of the corpus callosum ⇨ and forceps major in another preteen symptomatic male with CCALD.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- X-linked adrenoleukodystrophy (X-ALD, ALD)
  - Classic childhood ALD (CCALD)

Definitions

- Inherited peroxisomal disorder
  - *ABCD1* mutation → impaired β-oxidation (β-ox) of very long chain fatty acids (VLCFA)
  - Accumulation of VLCFAs in white matter (WM) causes severe inflammatory demyelination
- Several clinical forms of ALD and related disorders
  - Classic X-ALD
    - Severe progressive form almost exclusively in males 5-12 years
  - At least 6 variants other than classic childhood X-ALD exist: Presymptomatic X-ALD, adolescent (AdolCALD), adult (ACALD), adrenomyeloneuropathy (AMN), Addison only, symptomatic female carriers
    - AMN
      - "Mild" adult (spinocerebellar) form, cerebral involvement in up to 50%
  - X-ALD and AMN account for 80% of cases

IMAGING

General Features

- Best diagnostic clue
  - CCALD: Enhancing peritrigonal demyelination
- Location
  - Classic CCALD: Peritrigonal WM
    - Pattern: Splenium → peritrigonal WM → corticospinal tracts/fornix/commisural fibers/visual and auditory pathways
    - Typically spares subcortical U-fibers
- Morphology
  - Usually symmetrical, confluent, posterior involvement; rare frontal pattern occurs
  - Central (splenium) to peripheral gradient is usual

CT Findings

- NECT
  - ↓ density splenium/posterior WM
  - ± Ca++ of involved WM
- CECT
  - CCALD: Linear enhancement of intermediate zone

MR Findings

- T1WI
  - ↓ T1 signal of involved WM
- T2WI
  - ↑ T2 signal of involved WM
    - CCALD: Splenium → peritrigonal WM → corticospinal tracts/fornix/commisural fibers/visual and auditory pathways
    - AMN: Cerebellum, spinal cord; most common intracranial feature is corticospinal involvement but may resemble CCALD
- FLAIR
  - Same as T2WI
- DWI
  - Reduced diffusion in actively involved WM, increased in chronically involved WM
  - DTI: Reduced brain "connectivity," ↑ isotropic diffusion, and loss of fractional anisotropy in obvious WM change **and** in presymptomatic WM
- T1WI C+
  - Leading edge (intermediate zone) enhances
    - Enhancement strongly linked to progression
- MRS
  - Peaks between 0.9 and 1.4 ppm probably represent VLCFA macromolecules
  - X-ALD: ↓ NAA even in normal-appearing WM predicts progression; ↑ CHO, myoinositol, lactate
- Spinal MR: Spinal atrophy in AMN

Nuclear Medicine Findings

- PET
  - Hypometabolism of occipital lobes
- Tc-99m-HMPAO SPECT: ↑ regional cerebral blood flow in enhancing zone (decreased elsewhere)

Imaging Recommendations

- Best imaging tool
  - MR + contrast
- Protocol advice
  - DWI/DTI and MRS may predict onset of presymptomatic disease

DIFFERENTIAL DIAGNOSIS

Neonatal Hypoglycemia (Acute and Follow-Up)

- May involve splenium, calcar avis, and posterior peritrigonal WM but does not enhance

White Matter Disease With Lactate (WML)

- Involves splenium, peritrigonal WM, and corticospinal tracts but does not enhance

Alexander Disease

- Enhances, but frontal not peritrigonal WM

PATHOLOGY

General Features

- Etiology
  - Peroxisomes: Ubiquitous organelles involved in catabolic pathways
    - Involved with myelin formation/stabilization
    - Defect in VLCFA importer → impaired β-ox of VLCFA
    - VLCFA accumulate in WM → brittle myelin
- Genetics
  - X-ALD: X-linked recessive
    - Mutations of *ABCD1* gene at Xq28 (> 300 described)
    - ABCD1 is ATPase transporter protein: "Traffic" ATPase
    - Required for transport hydrophilic molecules across peroxisomal membrane
  - Phenotypic variability: CCALD, AMN, or presymptomatic presentations even within same family
  - Clinical heterogeneity attributed (in part) to specific mutations, modifying factors
    - Insertion allele of CBS c.844_845ins68 protects against CNS demyelination

https://CafePezeshki.IR

  - G allele of Tc2 c.776C > G more common in demyelinating forms (CCALD)
- Associated abnormalities
  - VLCFA accumulates in all tissues of body
  - Symptomatic accumulation: CNS myelin, adrenal cortex, Leydig cell testes
    - Adrenal failure: Skin bronzing
    - Testes: Early androgenetic alopecia in adults

Staging, Grading, & Classification

- Loes MR scoring system: Severity score based upon location, extent of disease, and atrophy
  - Pattern 1: Parietooccipital WM (rapid progression if contrast-enhancement present and very young)
  - Pattern 2: Frontal WM (same as pattern 1)
  - Pattern 3: Corticospinal tract (adults, slower progression)
  - Pattern 4: Corticospinal tract and cerebellar WM (adolescents, slower progression)
  - Pattern 5: Concomitant parietooccipital and frontal WM (mainly childhood, extremely rapid)

Gross Pathologic & Surgical Features

- Atrophy, WM softened

Microscopic Features

- Complete myelin loss (U-fibers preserved), astrogliosis
- Zone-specific features
  - Innermost zone of necrosis, gliosis ± Ca++
  - Intermediate zone of active demyelination and inflammation
  - Peripheral zone of demyelination without inflammation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Skin bronzing, behavioral difficulties, hearing problems
- Clinical profile
  - Phenotypes unpredictable (even intrafamilial)
- Classic childhood cerebral X-ALD (CCALD): 35-50%, but percentage ↓ as new forms diagnosed
  - Preteen male (3-10 years): Behavioral, learning, gait, hearing, vision difficulties
  - Addison/adrenal insufficiency (skin bronzing, nausea and vomiting, fatigue) may predate X-ALD diagnosis
- AMN (25%)
  - 14-60 years
  - Spinal involvement > > brain involvement; peripheral nerve involvement
  - Brain inflammatory reaction eventually in 50%; variable demyelination/enhancement
- Presymptomatic ALD (12%)
  - Abnormal genetic testing (due to known symptomatic brother or maternal uncle)
- 20-50% female carriers develop AMN-like symptoms (milder, age related)
- Other presentations less common
  - AdolCALD: 10-20 years, symptoms and course similar to CCALD
  - ACALD: May be misdiagnosed as psychiatric disorder, very rapid progression, diffuse rather than posterior pattern

Demographics

- Age
  - CCALD: Preteen males
- Gender
  - Males in classic X-ALD
  - Female carriers may show AMN-like symptoms
- Ethnicity
  - CCALD predominates in North America and France
  - AMN predominates in Netherlands
- Epidemiology
  - X-ALD and variants = 1:16,800 North American births

Natural History & Prognosis

- CCALD: Progresses to spastic quadriparesis, blindness, deafness, vegetative state
- AMN: Spastic, weak legs; sphincter/sexual dysfunction

Treatment

- CCALD: Vegetative state, death in 2-5 years without bone marrow transplant (BMT)
  - Lorenzo oil delays symptoms in presymptomatic ALD
  - Early BMT stabilizes demyelination: RARE reversal demyelination

DIAGNOSTIC CHECKLIST

Consider

- X-ALD presenting at atypical ages → atypical appearances (may lack enhancement or have frontal rather than posterior "gradient")

Image Interpretation Pearls

- Always enhance unknown leukodystrophy

Reporting Tips

- Loes scoring aids pattern analysis

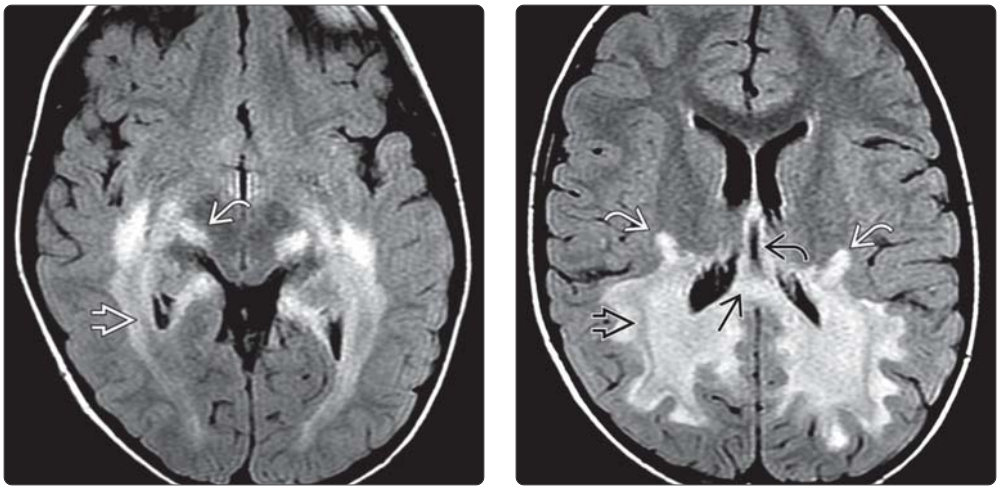
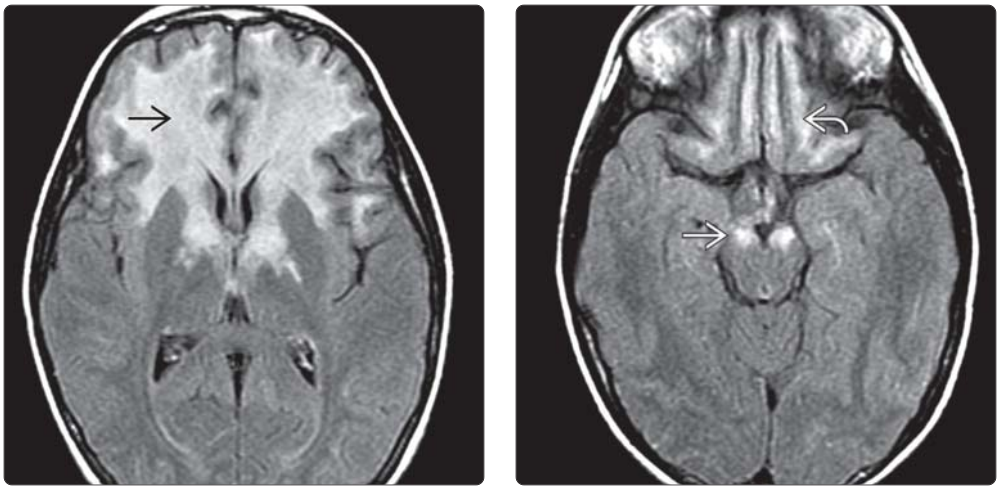
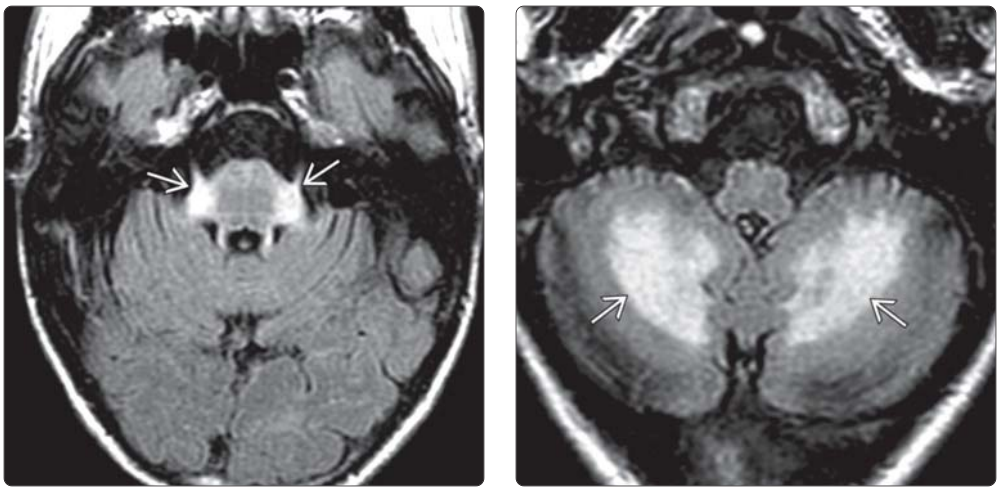
https://CafePezeshki.IR



(Left) *Axial FLAIR MR in CCALD (ALD pattern 1) demonstrates hyperintensity of the medial geniculate body along with the periventricular and deep WM of the temporal and occipital lobes.* **(Right)** *Axial FLAIR MR in the same child with CCALD reveals hyperintensity of the posterior columns of the fornices, the splenium of the corpus callosum, and multilayered involvement in the peritrigonal WM and external/extreme capsules.*



(Left) *Axial FLAIR shows confluent bifrontal white matter hyperintensity. Abnormal signal extends into the caudate heads, globi pallidi, and anterior limbs of internal capsules in this frontal variant case (Loes pattern 2) of proven X-ALD in a school-aged male.* **(Right)** *Axial FLAIR in the same patient shows symmetrical WM hyperintensities in the internal capsules as they extend into the cerebral peduncles and in the juxtacortical frontal WM.*



(Left) *Axial FLAIR MR through the mid pons shows striking demyelination in the lateral pons/root entry zones and both CN5s in an adult with Loes pattern 4.* **(Right)** *Axial FLAIR MR at the level of the medulla and lower cerebellum in the same adult with trigeminal nerve involvement shows symmetric hyperintensity in the cerebellar WM (Loes pattern 4 of ALD).*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Peroxisomal disorders; peroxisomal biogenesis or assembly disorders (PBD); single peroxisomal enzyme (transporter) deficiencies (PED)
- PBD: Zellweger syndrome (ZS), neonatal adrenoleukodystrophy (NALD), infantile Refsum disease (IRD), rhizomelic chondrodysplasia punctata (RCDP) type 1
- PED composed of ≥ 16 disorders with gene mutation affecting single protein in peroxisomal function
- Peroxisomes: Membrane-bound subcellular organelles involved in catabolic and anabolic pathways

IMAGING

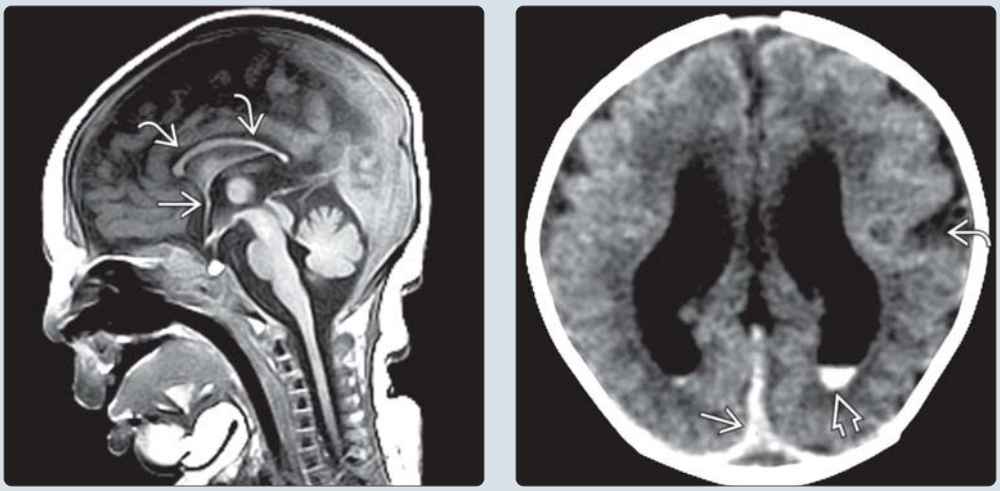
- ZSD continuum: ZS most severe, NALD intermediate, IRD least severe
- D-bifunctional protein and Acyl-CoA oxidase deficiencies: ZS like
  - Look for WM disease in corticospinal tracts
  - Look for posterior perisylvian PMG
- RCDP: ↑ intensity periventricular white matter (WM), centrum semiovale, delayed occipital myelination

PATHOLOGY

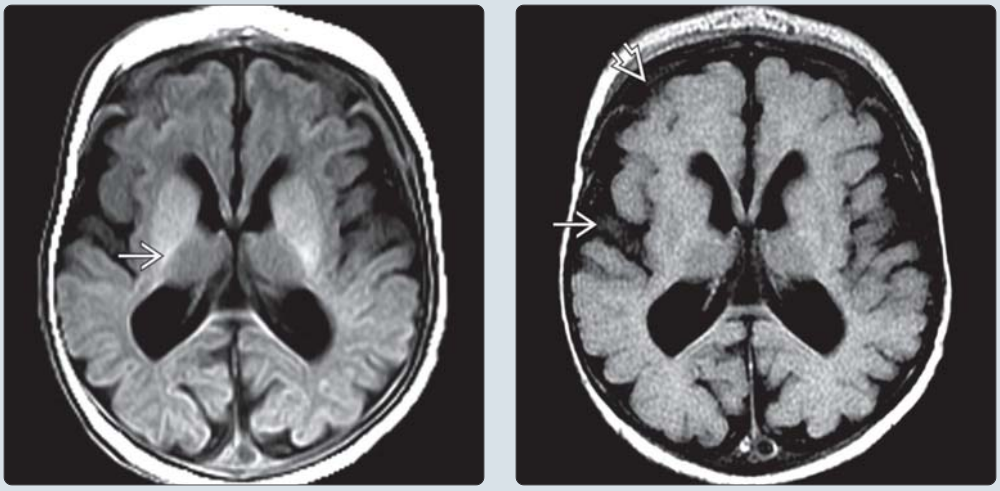
- Intact peroxisomal function required for normal brain formation, deficiency → neocortical dysgenesis
- Peroxisomes normally located near developing myelin sheaths in oligodendroglial cells at peak of myelin formation
- Genetics: Phenotype depends on both gene mutated and effect of mutation on gene function

DIAGNOSTIC CHECKLIST

- Use MR with DWI, MRS



(Left) *Sagittal T1WI MR in a 28 day old with non-Zellweger peroxisomal biogenesis disorder and facial dysmorphism reveals flat face, significant retrognathia, microcephaly, thin corpus callosum ⇄, and small anterior commissure ⇒.* **(Right)** *Axial NECT in a 5 day old with non-Zellweger peroxisomal biogenesis disorder and hepatic dysfunction reveals primitive sylvian fissures ⇄, small subdural collection ⇒, and blood layering ⇒ within the posterior horns of the lateral ventricles.*



(Left) *Axial T1WI MR in a full-term infant with non-Zellweger peroxisomal biogenesis disorder demonstrates mild ventriculomegaly, enlarged subarachnoid spaces, and failure of myelin maturation within the posterior limb of the internal capsule ⇒. Lentiform nuclei are abnormally hyperintense.* **(Right)** *Axial FLAIR MR in the same microcephalic infant demonstrates prominent pericerebral fluid spaces ⇒ and underoperculized sylvian fissures ⇒.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Peroxisomal biogenesis or assembly disorders (PBD)
- Single peroxisomal enzyme (transporter) deficiencies (PED)
- PBD: Zellweger syndrome (ZS), neonatal adrenoleukodystrophy (NALD), infantile Refsum disease (IRD), rhizomelic chondrodysplasia punctata (RCDP) type 1, other nonspecific phenotypes
  - Zellweger spectrum disorders (ZSD): Triad of ZS, NALD, IRD (but not RCDP) phenotypes
  - RCDP type 1: Normal β-oxidation of very long chain fatty acids (VLCFA), therefore different profile
- PED composed of ≥ 16 disorders with gene mutation affecting single protein in peroxisomal function
  - Peroxisomal fatty acid β-oxidation
    - Adrenoleukodystrophy protein (X-ALD); deficiencies of alkyl-DHAP-synthase (RCDP type 3); Acyl-CoA oxidase, D-bifunctional protein (D-BP), sterol carrier protein X (SCPx), and 2-methylacyl CoA racemase (AMACR)
  - Ether phospholipid biosynthesis (especially plasmalogens)
    - DHAP-alkyl transferase (DHAPAT; RCDP type 2)
  - Phytanic acid α-oxidation: Adult Refsum disease (ARD)
  - Glyoxylate detox: Primary hyperoxaluria type 1
  - Hydrogen peroxide metabolism: Acatalasemia
  - Degradation of methy-branched phytanic acid: Phytanic acid accumulation

Definitions

- Peroxisomes: Membrane-bound subcellular organelles involved in catabolic and anabolic pathways, collaborate with other organelles
  - > 50 enzymes are contained within peroxisomes, majority in lipid metabolism

IMAGING

General Features

- Best diagnostic clue
  - PBD: Abnormal myelin in corticospinal tracts ± dentate nuclei, ± cortical dysplasia
- Location
  - Corticospinal tracts ± dentate nuclei

Radiographic Findings

- Radiography
  - ZS and RCDP: Rhizomelia, stippled epiphyses
  - RCDP and DHAP deficiencies: Coronal vertebral clefts
  - ARD: Short metacarpals/metatarsals (30%)

CT Findings

- NECT
  - X-ALD: Occasional punctate white matter (WM) calcifications

MR Findings

- T2WI
  - ZSD continuum: ZS most severe, NALD intermediate, IRD least severe
    - ZS: ↑ intensity WM/myelin delay, neocortical dysplasia/polymicrogyria (PMG), atrophy, late cerebral and cerebellar demyelination
      - PMG most common in posterior insula, posterior perisylvian cortex
    - NALD: PMG, progressive WM disease
    - IRD: No neuronal migration anomalies, WM nonprogressive ± improvement
  - D-BP and Acyl-CoA oxidase deficiencies: ZS like
    - D-BP: Occasional thalami and globus pallidus involvement (unlike PBD)
  - RCDP: ↑ intensity periventricular WM, centrum semiovale, delayed occipital myelination
  - SCPx: Thalamic, pons, occipital ↑ intensity
  - AMACR: Deep WM ↑ intensity
- DWI
  - X-ALD: Intermediate zone ↓ ADC
  - PBD: ↑ ADC values
- T1WI C+
  - X-ALD: Leading edge enhancement
  - Acyl-CoA oxidase deficiency: Enhancing centrum semiovale lesions

Ultrasonographic Findings

- ZS: Renal cysts
- ZSD and D-BP: Hepatomegaly

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - MR, DWI, MRS, C+

DIFFERENTIAL DIAGNOSIS

ZSD Mimics

- Bilateral perisylvian polymicrogyria
- Congenital cytomegalovirus infection

RCDP 1 Mimics

- X-linked dominant chondrodysplasia punctata: Conradi–Hünermann–Happle syndrome
- Warfarin embryopathy

PATHOLOGY

General Features

- Etiology
  - VLCFA and phytanic acid incorporated into cell membranes → cell dysfunction, atrophy, and death
- Genetics
  - Phenotype severity varies with nature of mutation
    - *PEX1*: G843D does not abolish peroxisomal protein import completely → mild (NALD, IRD), while c.2097-2098insT mutation abolishes import completely → severe (ZS)
    - *PEX7*: L292X → classical, severe RCDP phenotype, while A218V → milder RCDP
  - PED may clinically resemble PBD
    - D-BP and Acyl-CoA oxidase deficiencies: ZS like

https://CafePezeshki.IR

  - Defects involving first 2 steps of plasmalogens (DHAP-alkyl transferase, DHAP-synthase deficiencies): RCDP/*PEX7* like
- PBD: Organelle fails to form, multiple peroxisomal functions defective
- PBD have *PEX* gene mutations; disorder depends on both gene affected and specific mutation
  - *PEX1*, PEX*6*, *PEX12*, *PEX26*: ZS, NALD, IRD
  - *PEX2*: ZS, IRD
  - *PEX5*, *PEX10*, *PEX13*: ZS, NALD
  - *PEX3*, *PEX14*, *PEX16*, PEX *19*: ZS
  - *PEX 7*: RCDP 1
- PED: Single peroxisomal enzyme deficiency
  - ARD: Phytanoyl-CoA hydroxylase
  - X-ALD: *ABCD1* gene mutation
  - Acyl-CoA oxidase: ZS-like phenotype (less severe)
  - D-BP: ZS-like phenotype (severe)
  - SCPx: Sterol carrier protein X, single family
  - PH1: *AGXT* gene mutation, glyoxylate aminotransferase 1 (AGT) deficient (catalyzes transamination of glyoxylate to glycine) → ↑ glyoxylate oxidation to oxalate → renal stones ± systemic hyperoxaluria
  - Acatalasemia: Impaired hydrogen peroxide detoxification → ↑ risk of diabetes

Staging, Grading, & Classification

- Marked genetic heterogeneity complicates genotype-phenotype correlation

Gross Pathologic & Surgical Features

- Intact peroxisomal function required for normal brain formation, deficiency → neocortical dysgenesis
- Peroxisomes located near developing myelin sheaths in oligodendroglial cells at peak of myelin formation
  - Deficiency → defect in central WM formation/maintenance and myelin lipid reduction

Microscopic Features

- Neuropathologic lesions
  - Abnormalities in neuronal differentiation/migration
  - Inflammatory dysmyelination or noninflammatory demyelination
- Postdevelopmental neuronal degeneration
  - Adrenomyeloneuropathy (AMN): Spinal cord axonopathy
  - IRD, RCDP: Cerebellar atrophy
- PH1: Rare reports of oxalate crystals in brain
- ZS: Additional olivary dysplasia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - CNS involvement manifests during development &/or later in life
- Other signs/symptoms
  - BPD
    - ZSD: Frontal bossing, marked hypotonia, hepatomegaly, perinatal apnea, seizures, jaundice, cataracts, retinopathy, deafness
    - RCDP: Rhizomelia, dwarfism/short stature, broad nasal bridge (koala bear face), epicanthus, microcephaly, mental retardation, cataracts
  - PED
    - D-BP and Acyl-CoA oxidase deficiencies: ZS like
    - ARD: Classic tetrad of peripheral polyneuropathy, cerebellar ataxia, ↑ CSF protein, retinitis pigmentosa; also ichthyosis, psychiatric disorders, cardiac arrhythmias, anosmia, deafness
    - X-ALD: Behavioral, learning, and hearing difficulties, skin bronzing
    - SCPx: Dystonia, azoospermia/hypogonadism, hyposmia
    - AMACR: Rare, variable findings (tremor, pyramidal signs, seizures, sensory motor neuropathy)
    - PH1: Renal stones or renal failure with systemic oxalosis (bone pain, fractures, myocarditis, embolic stroke, retinopathy)

Demographics

- Age
  - Most: Neonatal
  - X-ALD, classic Refsum: Childhood or adult onset
- Epidemiology
  - Peroxisomal disorders in 1:5,000 births

Natural History & Prognosis

- PBD: Variable neurodevelopmental delays, retinopathy, deafness, liver disease
  - ZSD and look-alikes share imaging and clinical phenotype; most fail to gain milestones, severe phenotypes die within 1st year of life
  - RCDP and look-alikes: Severe and mild phenotypes
- PED: Variable
  - X-ALD: Progression to vegetative state if untreated
  - PH1: Progression to systemic oxalosis (myocardium, bone marrow, eyes, peripheral nerves); rapidly progressive (death in 1st year) and mild phenotypes

Treatment

- PBD: Limited by multiple malformations and metabolic defects originating in utero
- PED: X-ALD (cholesterol lowering drugs, VLCFA restriction, bone marrow transplant), ARD (phytanic acid restriction), PH1 (pyridoxine → ↓ production oxalate; alkalinize urine to ↑ oxalate solubility

DIAGNOSTIC CHECKLIST

Consider

- Plasma biochemical abnormalities may be absent
- Analysis of cultured skin fibroblasts indicated if strong imaging and clinical suspicion

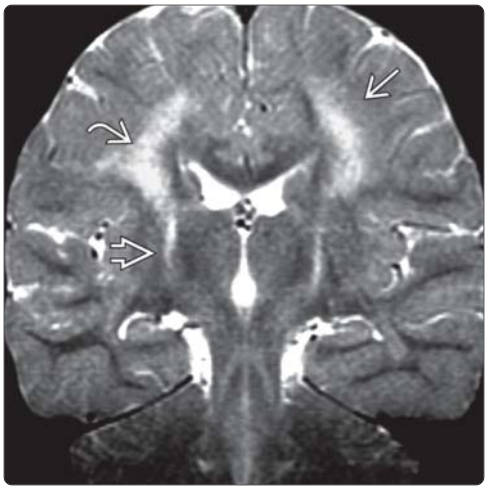
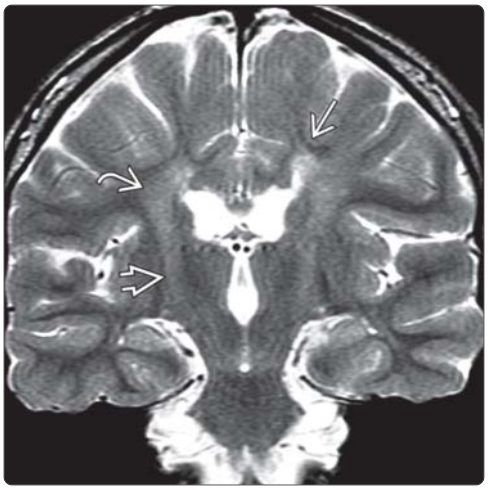
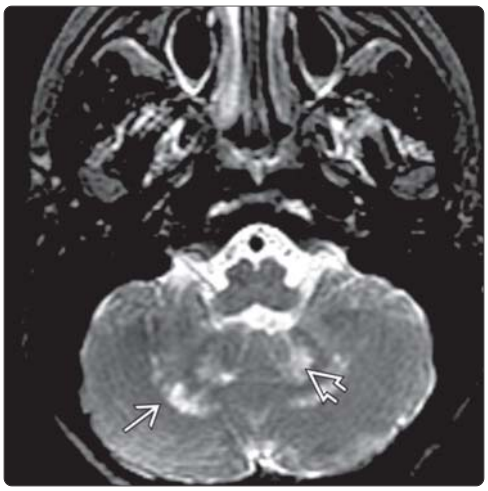
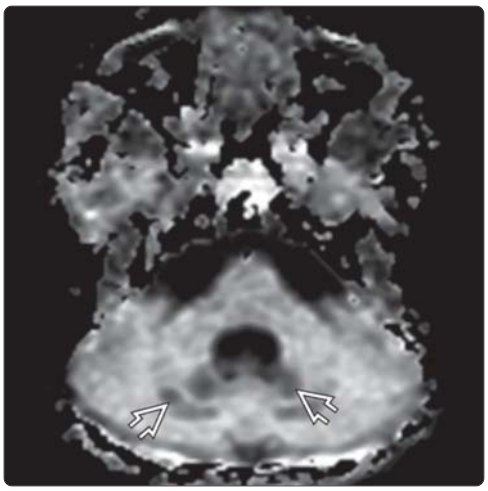
(Left) *Axial FLAIR MR in a 3 year old with peroxisomal chondrodysplasia punctata demonstrates increased signal intensity in the peritrigonal white matter ➡ and periventricular white matter (WM) of the right frontal horn ➡, as well as scattered foci of abnormal increased signal ➡.* **(Right)** *Anteroposterior radiograph in a 2 year old with peroxisomal chondrodysplasia punctata demonstrates coxa vara with stippling of the triradiate cartilage ➡. Bone radiographs can help to specify diagnosis.*





(Left) *Coronal T2WI MR in a 4 year old with infantile Refsum demonstrates abnormal signal intensity within the corticospinal tracts ➡ and periventricular white matter ➡. Note the poor myelin maturation in the subcortical U-fibers ➡.* **(Right)** *Follow-up coronal T2WI MR in the same patient at age 16 shows partial resolution of findings. Note the progressive myelin maturation of the subcortical U-fibers ➡ and (incomplete) improvement of periventricular white matter ➡ and corticospinal tracts ➡.*





(Left) *Axial T2WI MR in the same patient demonstrates persistent and typical abnormal signal intensity in the cerebellar white matter ➡ and hila of the deep cerebellar nuclei ➡. The brainstem appears normal.* **(Right)** *Axial DWI MR in the same patient fails to demonstrate any evidence of reduced diffusion in the abnormal foci ➡, suggesting that the injury is subacute or chronic.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Maple syrup urine disease (MSUD)
- Inherited disorder of branched-chain amino acid (BCAA) metabolism
- Typically presents at 4-10 days of age with neurologic deterioration, ketoacidosis, hyperammonemia

IMAGING

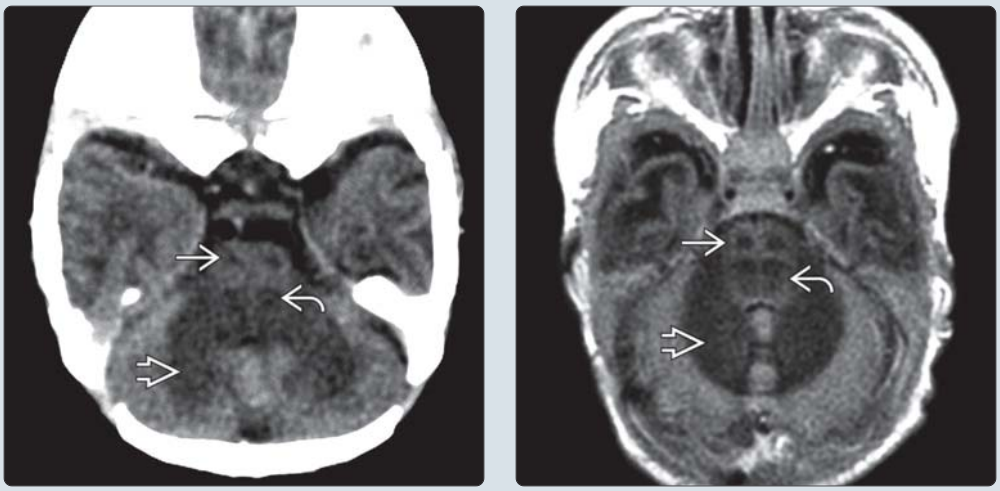
- MR with DWI best, but CT can make diagnosis in critically ill infant
- Classic MSUD edema/restriction pattern
  - Cerebellar white matter, dorsal brainstem, cerebral peduncles, thalami, globi pallidi
  - Pyramidal and tegmental tracts
  - Infratentorial > > > supratentorial edema
- Broad peak at chemical shift of 0.9 ppm

PATHOLOGY

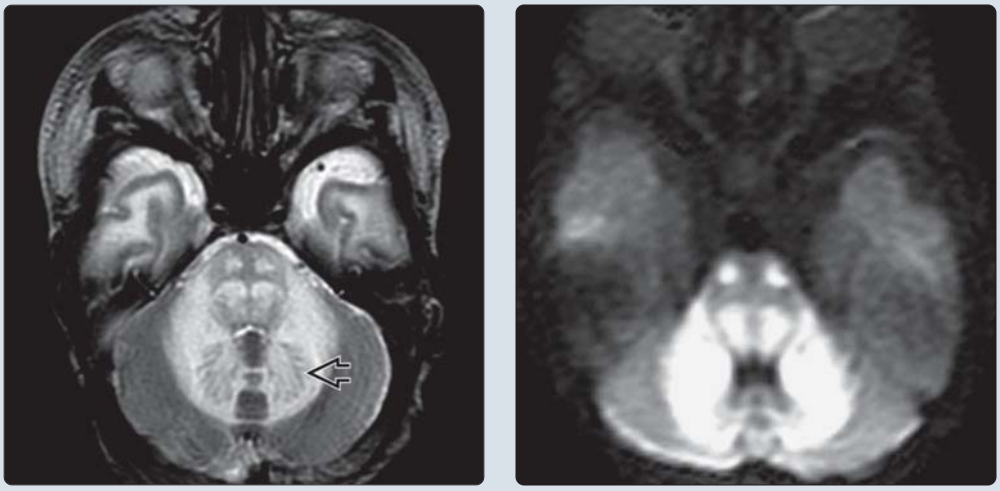
- MSUD: ↓ activity branched-chain α-keto acid dehydrogenase complex (BCKD) → accumulation of branched-chain L-amino (BCAA) and metabolites (neuro- and leukotoxic)

CLINICAL ISSUES

- Initial symptoms of classic MSUD: Poor feeding, vomiting, poor weight gain, increasing lethargy, encephalopathy, seizures
- Patients in crisis often (but not always) smell like maple syrup (or burnt sugar)
- 1:850,000 in general population but as frequent as 1:170 in population isolates
- MSUD has potentially favorable outcome with strict dietary control and aggressive treatment of metabolic crises
- Response to therapy; however, can be variable



(Left) *Axial NECT in a seizing newborn who returned to the hospital at 10 days of age demonstrates classic MSUD edema pattern. Note hypodensity in cerebellar white matter ⇨, dorsal pons, and 4 foci in the anterior and middle pons, which are paired pyramidal ⇨ and tegmental tracts ⇨.* **(Right)** *Axial T1WI MR in a different infant with lethargy and feeding difficulty shows the same MSUD pattern: Hypointensity in the cerebellar white matter ⇨ and paired pyramidal ⇨ and tegmental tracts ⇨.*



(Left) *Axial T2WI MR demonstrates crisp margins of the signal abnormality of the cerebellar white matter. Again seen are the paired tracts (4 bright pontine foci) superimposed on signal abnormality in the pons. The dentate nuclei ⇨ stand out against the abnormal MSUD edema.* **(Right)** *Axial DWI MR confirms intramyelinic edema in a MSUD pattern, showing reduced diffusivity (hyperintensity). DWI is extremely useful in the acute and subacute phase of MSUD.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Maple syrup urine disease (MSUD)

Synonyms

- Leucine encephalopathy

Definitions

- Inherited disorder of branched-chain amino acid (BCAA) metabolism presenting in newborns with neurologic deterioration, ketoacidosis, and hyperammonemia
- Intermediate form presents later with developmental delay and failure to thrive
- Intermittent form presents in late infancy (or later) with episodic decompensation
  - Ataxia, disorientation, altered behavior

IMAGING

General Features

- Best diagnostic clue
  - Radiologist may be 1st to suggest diagnosis based on classic-appearing MSUD edema
    - Cerebellar white matter, brainstem, thalamus, globus pallidus
    - Pyramidal and tegmental tracts
- Location
  - Cerebellar and brainstem edema > > > supratentorial hemispheres
    - Most prominent in dorsal brainstem, cerebellar white matter
    - Edema of corticospinal tracts
    - These areas show reduced diffusivity on ADC maps

CT Findings

- NECT
  - Early: Diffuse edema **not** sparing brainstem and cerebellum
    - Recognize here for best neurocognitive outcome
  - Subacute: Rapid formation of typical (classic) MSUD edema pattern
    - Cerebellar white matter, dorsal brainstem, cerebral peduncles, thalami, pyramidal, and tegmental tracts > supratentorial hemispheres
    - Margins become sharp during subacute phase

MR Findings

- T1WI
  - ↓ signal intensity; margins may be sharp
- T2WI
  - Late: Generalized and MSUD edema disappear
    - Resolve to "pallor" and volume loss
- FLAIR
  - Insensitive to fluid shifts in newborns
- DWI
  - Marked restriction (↑ intensity) and ↓ ADC (MSUD edema = cytotoxic/intramyelinic)
  - DTI: ↓ anisotropy
- MRS
  - Broad peak at chemical shift of 0.9 ppm; this is present with both short-echo and long-echo spectra

Ultrasonographic Findings

- Grayscale ultrasound
  - ↑ echogenicity of globi pallidi, periventricular white matter, brainstem, cerebellar white matter

Imaging Recommendations

- Best imaging tool
  - DWI during hyperacute and acute phases
- Protocol advice
  - MR with diffusion-weighted imaging best, but CT can make diagnosis in critically ill infant

DIFFERENTIAL DIAGNOSIS

Disorders Causing Brainstem and Cerebellar Swelling

- Mitochondrial *SURF1* mutations: Lactate may be seen in this **and** in MSUD during crisis
- Alexander disease: Abnormal signal and enhancement of brainstem and aqueduct
- Vanishing white matter: Findings are persistent

Hypoxic-Ischemic Encephalopathy

- No symptom-free interval, usually positive history
- Cerebellum, brainstem relatively spared (MSUD involves these areas)

Marchiafava-Bignami

- Myelin splitting disorder of adult red wine drinkers
- Splits corpus callosum

PATHOLOGY

General Features

- Etiology
  - MSUD: ↓ activity branched-chain α-keto acid dehydrogenase complex (BCKD) → accumulation of branched-chain L-amino (BCAA) and metabolites (neuro- and leukotoxic)
  - ↑ brain leucine displaces other essential amino → neurotransmitter depletion, disrupted brain growth and development
  - Branched-chain ketoacid accumulation → thought to disrupt Krebs cycle
- Genetics
  - > 50 different mutations in genes governing enzyme components of BCKD
    - e.g., E1α (33%), E1β (38%), E2 (19%)
  - Autosomal recessive
- Associated abnormalities
  - ↑ plasma isoleucine associated with maple syrup odor
  - Maternal ingestion of fenugreek during labor gives false impression of MSUD
    - Shares component and smell with MSUD urine

Staging, Grading, & Classification

- Classical, intermediate, and intermittent forms of MSUD; thiamine-responsive MSUD

Gross Pathologic & Surgical Features

- Brainstem edema
- Spongy degeneration: White matter, basal ganglia

https://CafePezeshki.IR

Microscopic Features

- ↓ oligodendrocytes and astrocytes
- Alterations in neuronal migration, maturation
  - Aberrant orientation of neurons
  - Abnormal dendrites/dendritic spines

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Initial symptoms of classic MSUD: Poor feeding, vomiting, poor weight gain, increasing lethargy
    - In neonates, develops within 4-7 days
  - Patients in crisis often (but not always) smell like maple syrup (or burnt sugar)
    - Resuscitation with non-protein-containing oral or IV hydrating fluids may "clear" odor
    - Maple syrup odor may be difficult to identify in 1st days of life unless urine-soaked diaper allowed to dry
    - Maple syrup odor of cerumen "more predictable"
  - Neonates in communities with known high MSUD risk diagnosed within hours of blood sampling
    - If tested **and** receive immediate results **and** therapy is instituted, then may have excellent outcome
    - Tandem mass spectrometry of whole blood filter paper shortens diagnosis time
    - Guthrie test insensitive before 24 hours, requires incubation period and has high false-positive rate
- Clinical profile
  - Normal at birth
  - Presents after disease-free interval, usually within 1st 48 hours to 2 weeks of life
  - Mimic of sepsis: Acute encephalopathy, vomiting, seizures, neurological distress, lethargy, coma, leukopenia/thrombopenia
    - Additionally, free water retention, renal salt wasting and hyponatremia, dehydration
  - Plasma detection of alloisoleucine diagnostic
    - May not appear until 6th day of life
  - Ketosis or ketoacidosis and hyperammonemia
  - Typical EEG: Comb-like rhythms
  - Prenatal diagnosis can be performed on cultured amniocytes or chorion villus cells

Demographics

- Age
  - May be diagnosed on day 1 of life if MSUD suspected
- Ethnicity
  - 1/170 live births in certain population isolates (founder effect in Old Order Mennonites)
  - High carrier rate in Middle East and Ashkenazi Jewish descendants
- Epidemiology
  - 1:850,000 in general population but as frequent as 1:170 in population isolates

Natural History & Prognosis

- Breastfeeding may delay onset of symptoms to 2nd week of life
- MSUD has potentially favorable outcome with strict dietary control and aggressive treatment of metabolic crises
  - Response to therapy, however, can be variable
  - Exposure to high levels, BCAAs and their metabolites neurotoxic
  - Uncontrolled BCAA levels → profound cognitive impairment/death
  - Pretreatment plasma leucine > 40 mg/100 mL **or** encephalopathy > days associated with poor cognitive outcome
- May survive to adulthood if well controlled
  - Metabolic "intoxication" **at any age** may be provoked by infection, injury, stress, fasting, or even pregnancy
- Reports of late (adulthood) development of peripheral neuropathy
- Exfoliative skin and corneal lesions from inadequate amino-acid intake

Treatment

- Acute "metabolic rescue" to reverse cerebral edema
- May require hemodialysis during acute crisis to limit neurotoxicity/damage
- Metabolically appropriate diet (protein modified) minimizes severity
  - Inhibit endogenous protein catabolism while sustaining protein synthesis
  - Prevent deficiencies of essential amino acids
  - Maintain normal serum osmolarity
  - Commercially available formulas, foods are available without BCAAs or with reduced levels of BCAAs
  - Dietary therapy must be lifelong
- Neonatal screening (tandem mass spectrometry) can diagnose
- Orthotopic liver transplantation increases availability of BCKD (rarely used)
- Gene therapy experimental

DIAGNOSTIC CHECKLIST

Consider

- Neonatal testing for MSUD is **not** universal
- Not all MSUD occurs in population isolates
- Even if testing performed, results may be available only after 1-2 weeks in nonendemic areas

Image Interpretation Pearls

- Neonatal brain edema that includes posterior fossa and brainstem is highly suggestive of MSUD

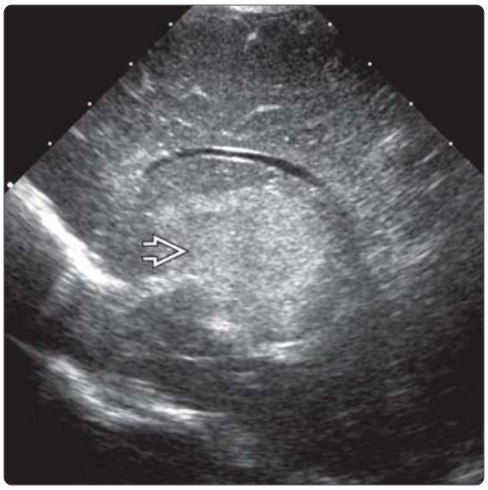
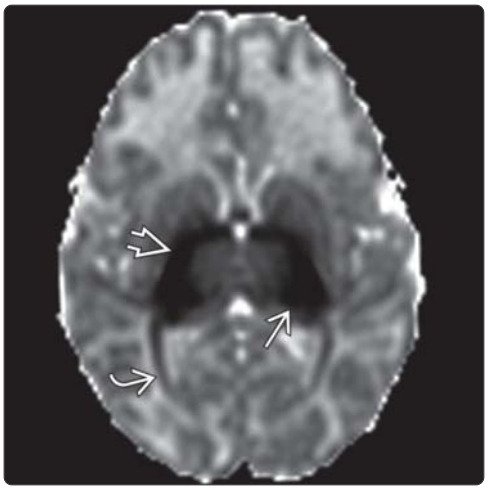
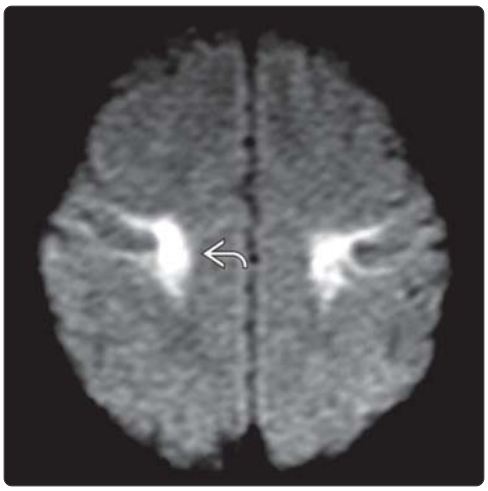
https://CafePezeshki.IR

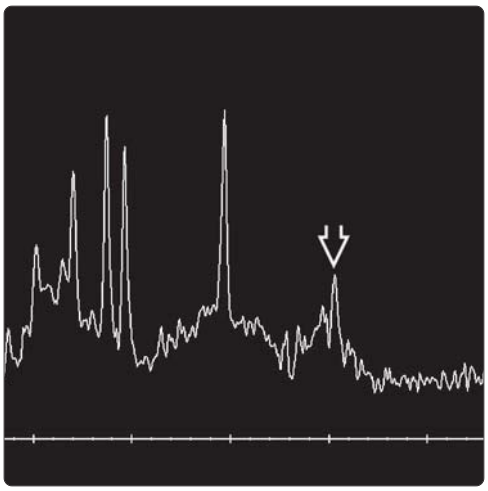


(Left) *Sagittal T1WI MR in an encephalopathic newborn reveals marked swelling of the entire brainstem. Low signal of the involved brainstem, cerebellar white matter, and subcortical cerebral white matter is also present.* **(Right)** *Parasagittal ultrasound in another symptomatic newborn with maple syrup urine disease (MSUD) demonstrates markedly increased echogenicity of the thalami due to the severe edema.*



(Left) *Axial DWI MR shows markedly reduced diffusivity (hyperintensity) of the posterior limbs of the internal capsules and of the internal medullary lamina of the thalami during the acute phase of MSUD.* **(Right)** *Axial diffusivity (ADC) map in the same infant confirms reduced diffusivity of the posterior limbs of the internal capsules and of the internal medullary lamina of the thalami as well as the optic tracts.*





(Left) *Axial DWI MR demonstrates extension of intramyelinic edema (manifest as reduced diffusivity) in the corticospinal tracts as they extend upward to the perirolandic cortex.* **(Right)** *Peaks at 0.9-1.0 ppm on MRS with a TE of 30 milliseconds represent branched-chain α-keto acid peaks, which can be seen during acute metabolic decompensation in MSUD. They are also seen at longer echo times, a finding that helps to confirm the diagnosis.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- 6 disorders of urea cycle
  - Ornithine transcarbamylase deficiency (OTCD)
  - Carbamoyl phosphate synthetase 1 deficiency
  - Citrullinemia or argininosuccinate synthetase deficiency
  - Argininosuccinate aciduria or argininosuccinate lyase deficiency
  - Argininemia or arginase deficiency (AD)
  - N-acetylglutamate synthase deficiency

IMAGING

- Neonates: Deep gray nuclei, depths of sulci in frontal, parietal, and insular > temporal cortex
- Older: As above or asymmetric cortical/subcortical white matter mimicking stroke
- Posterior fossa spared
- Acute/subacute: ↑ T2 signal, swelling areas involved
- Acute/subacute: Iso/↑ DWI signal, iso/↓ ADC
- Acute/subacute: ↓ myoinositol (MI), ↑ glutamine-glutamate (glx), ↑ lipids/lactate

TOP DIFFERENTIAL DIAGNOSES

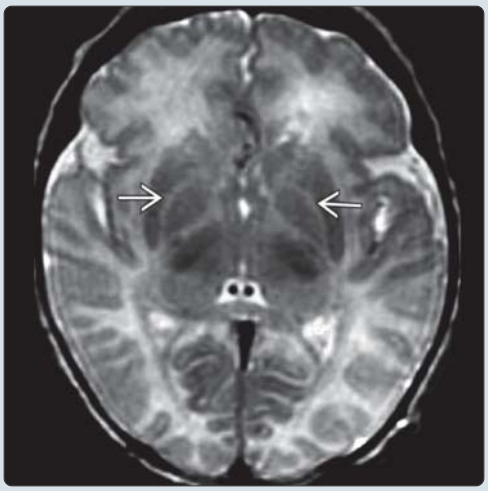
- Hypoxic-ischemic encephalopathy
- Arterial ischemic stroke
- Mitochondrial disorders
- Organic acidemias
- Nonketotic hyperglycinemia

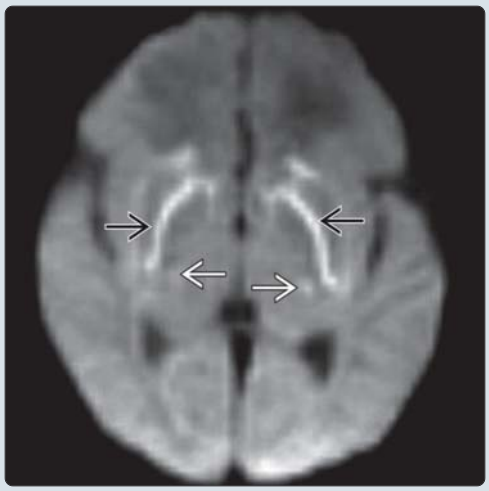
PATHOLOGY

- Urea cycle incorporates nitrogen → urea → urine, prevents accumulation of toxic nitrogen products
- ↑ ammonia → ↑ glutamate → ↑ glutamine in astrocytes → swelling + dysfunction

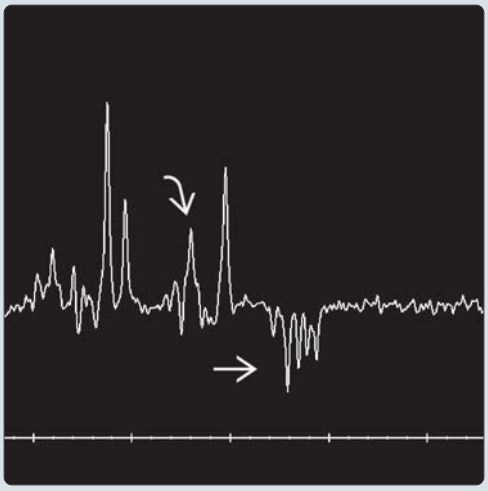
CLINICAL ISSUES

- Triad of hyperammonemia, encephalopathy, respiratory alkalosis





(Left) *Axial T2WI MR shows abnormally increased signal ⇨ between lateral nuclei of the globi pallidi and the putamina in a 2-day-old boy neonate presenting acutely with ornithine transcarbamylase deficiency (OTCD).* **(Right)** *Axial DWI MR in the same patient shows reduced diffusivity (abnormally increased signal ⇨) in the same location between the globi pallidi and putamina, extending into the caudates; this corresponded to decreased ADC. More subtle thalamic hyperintensity ⇨ (and low ADC) is also seen.*



(Left) *Axial proton MRS (TE = 144 msec) in a neonate presenting acutely demonstrates 2 inverted doublets ⇨ of lactate (at 1.33 ppm) and 1,2-propene-diol (found in anticonvulsants, at 1.1 ppm). Also noted is a large glutamine-glutamate (glx) peak ⇨ at 2.1-1.4 ppm.* **(Right)** *Coronal FLAIR MR in the chronic stage of another child with OTCD shows cortical and subcortical posterior insular and temporoparietal increased signal ⇨ that is most marked at the depths of the sulci.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- 6 disorders of urea cycle
  - Ornithine transcarbamylase deficiency (OTCD)
  - Citrullinemia or argininosuccinate synthetase deficiency
  - Carbamoyl phosphate synthetase 1 deficiency
  - Argininosuccinate aciduria or argininosuccinate lyase deficiency
  - Argininemia or arginase deficiency (AD)
  - N-acetylglutamate synthase deficiency

IMAGING

General Features

- Best diagnostic clue
  - Neonate presenting 24-48 hours with basal ganglia (BG) and cortical ↑ DWI signal
- Location
  - Neonates: Deep gray nuclei, depths of sulci in frontal, parietal, and insular > temporal cortex
  - Older: As above or asymmetric cortical/subcortical white matter (WM) mimicking stroke
  - Posterior fossa spared

CT Findings

- NECT
  - ↓ attenuation deep gray nuclei, WM + cortex with swelling → atrophy when chronic

MR Findings

- T1WI
  - Subacute/chronic: ↑ signal in cortical, deep gray nuclei areas involved
- T2WI
  - Acute/subacute: ↑ signal, swelling areas involved
  - Chronic: Volume loss, gliosis ± cystic change
- DWI
  - Acute/subacute: Iso/↑ DWI signal, iso/↓ ADC
- MRS
  - Acute/subacute: ↓ myoinositol, ↑ glutamine-glutamate, ↑ lipids/lactate

Imaging Recommendations

- Best imaging tool: MR
- Protocol advice: T1WI, T2WI, DWI, MRS

DIFFERENTIAL DIAGNOSIS

Hypoxic-Ischemic Encephalopathy

- Lateral putamen and ventrolateral thalamus involved; difficult to differentiate in chronic state

Arterial Ischemic Stroke

- Vascular distribution

Metabolic Disorders

- Mitochondrial disorders
- Organic acidemias: Globi pallidi but not cortex; metabolic acidosis/ketosis
- Nonketotic hyperglycinemia: No basal ganglia involvement

PATHOLOGY

General Features

- Etiology
  - Urea cycle incorporates nitrogen → urea → urine; prevents accumulation of toxic nitrogen products
  - ↑ ammonia → ↑ glutamate → ↑ glutamine in astrocytes → swelling + dysfunction
- Genetics
  - All autosomal recessive except OTCD (X-linked)

Gross Pathologic & Surgical Features

- Brain swelling in acute; atrophy + ulegyria in chronic

Microscopic Features

- GM Alzheimer type 2 astrocytes; GM, WM spongiosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Triad of hyperammonemia, encephalopathy, respiratory alkalosis
  - Progressive lethargy, hypothermia, vomiting, apnea
  - Neonates develop encephalopathy > 24-48 hours
  - Episodic in older patients (often when ↑ protein intake or ↑ catabolism)
- Clinical profile
  - ↑ ammonium blood levels (except AD)
  - Diagnosis: Liver cell enzyme assessment/DNA

Demographics

- Age
  - Neonate if severe, older if less severe
- Epidemiology
  - Whites > African Americans
  - OTCD most common

Natural History & Prognosis

- Improved with treatment but most mentally retarded
- Neonates: Worst prognosis with high mortality

Treatment

- Hemodialysis in acute crisis
- Liver transplant in severe cases
- ↓ protein intake, adequate caloric intake, supplements
- Sodium benzoate/phenylbutyrate/phenylacetate
- Valproate contraindicated; can cause death

KEY FACTS

TERMINOLOGY

- Glutaric acidemia type 1 (GA1), mitochondrial glutaryl-coenzyme A dehydrogenase (GCDH) deficiency
- Inborn error of metabolism characterized by encephalopathic crises and resultant severe dystonic-dyskinetic movement disorder

IMAGING

- Large sylvian fissures (from hypoplastic frontal/temporal opercula) and bright T2/FLAIR basal ganglia
  - Common: ↑ signal caudate/putamina > globus pallidus
  - Occasional: Pallidal and dentate signal change may occur even in absence of crisis
  - Severe: White matter, thalami, dentate nuclei may be involved
  - Significant basal ganglia atrophy in late phases of disease
- Child abuse mimic: Easily torn bridging veins within enlarged cerebrospinal fluid spaces → subdural hematomas

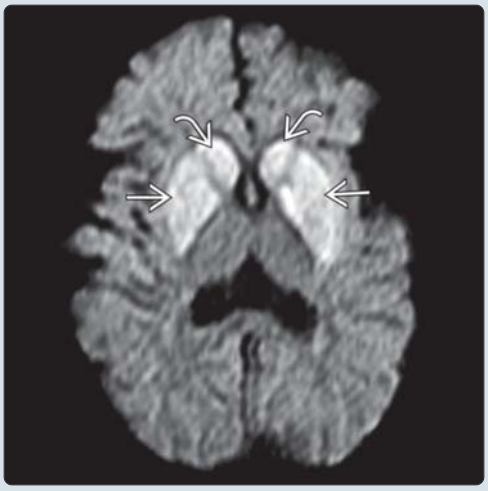
TOP DIFFERENTIAL DIAGNOSES

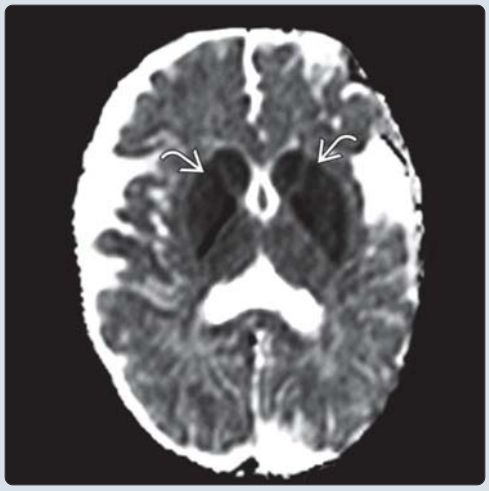
- Nonaccidental injury
- Disorders with bilateral middle fossa cyst-Like spaces
  - Mucopolysaccharidoses
  - "Idiopathic" middle cranial fossae arachnoid cysts
- Other causes of macrocephaly
  - Hydrocephalus
  - Idiopathic enlargement of subarachnoid spaces (SAS) during 1st year of life
  - Benign familial macrocephaly

CLINICAL ISSUES

- Episodic crises follow trigger (infection, immunization, surgery)
- Hyperintensity/atrophy of basal ganglia worsens after each crisis
- Generally manifests during 1st year of life
- 10% carrier rate in Old Order Amish

(Left) *Axial graphic demonstrates the pattern of involvement in glutaric acidemia type 1 (GA1). The sylvian fissures are enlarged, and the basal ganglia are diffusely and symmetrically abnormal in signal.* **(Right)** *Axial T2WI in a 7 month old reveals enlarged sylvian fissures. Note the swelling and abnormally increased signal intensity of the basal ganglia, including the heads of caudate nuclei, the putamina, and the globi pallidi bilaterally. Myelination is delayed.*





(Left) *Axial diffusion weighted MR of an infant in the midst of a severe metabolic crisis shows hyperintense signal resulting from reduced diffusion within the heads of the caudate nuclei and putamina bilaterally.* **(Right)** *ADC map shows hypointensity in the same areas, the caudates and putamina, confirming the presence of acute brain injury with resultant reduced diffusivity, rather than T2 shine through.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Glutaric acidemia type 1 (GA1)
- Mitochondrial glutaryl-coenzyme A dehydrogenase (GCDH) deficiency

Definitions

- Inborn error of metabolism characterized by encephalopathic crises and resultant severe dystonic-dyskinetic movement disorder

IMAGING

General Features

- Best diagnostic clue
  - Wide sylvian fissures and bright basal ganglia (BG)
- Location
  - Sylvian fissures, BG
- Size
  - Enlarged sylvian fissures
- Morphology
  - Small frontal and temporal opercula → bat wing dilatation of sylvian fissures

CT Findings

- NECT
  - > 95% have wide, cyst-like cerebrospinal fluid (CSF) spaces in middle cranial fossae
    - Sylvian fissure widening (93%), mesencephalic cistern widening (86%)
    - Frontal, temporal opercula, which normally cover insula, are hypoplastic
  - Striatal hypodensity
  - Early macrocephaly, late atrophy (mostly ventricular enlargement)
  - Subdural hematoma with minimal trauma
- CECT
  - No enhancement

MR Findings

- T1WI
  - Sylvian fissure cyst-like spaces isointense to CSF
    - May decrease in size over time
  - Subependymal pseudocysts (disappear by 6 months)
  - Frontotemporal hypoplasia
  - Delayed myelination
  - Occasional mild, immature-appearing gyral pattern
- T2WI
  - Common: ↑ signal caudate/putamina > globus pallidus
  - Occasional: Pallidal and dentate signal change may occur even in absence of crisis
    - May predate involvement of caudate & putamina
  - Striatal atrophy over time
  - If severe: White matter (WM), thalami, dentate nuclei may be involved
- FLAIR
  - Same as T2WI
- DWI
  - Acute phase: Reduced diffusion in BG and selected WM tracts; may show more extensive disease than apparent on either CT or MR
- T1WI C+
  - No enhancement
- MRS
  - ↑ Cho/Cr ratio, ↓ NAA
  - During crisis: ± increased lactate

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - MRS, DWI

DIFFERENTIAL DIAGNOSIS

Nonaccidental Injury

- Opercular hypoplasia may mimic atrophy
- GA1 does not cause fractures
- Subdural hematoma (SDH) in GA1 from torn-bridging veins in presence of large CSF, atrophy
- SDH in GA1 does not occur without enlarged CSF spaces
- Head trauma = most common cause of death
  - SDH most common finding, often interhemispheric
  - Skull fracture subarachnoid, epidural hemorrhage
  - Cerebral edema, contusion(s), shear injuries

Other Disorders With Bilateral Middle Cranial Fossa Cyst-Like Spaces

- Mucopolysaccharidoses
  - Types 1-4: Hurler, Hunter, Sanfilippo, Scheie, Maroteaux-Lamy, Sly
  - CSF-like mucopolysaccharide pachymeningeal deposition in all but Morquio type 4
- "Idiopathic" middle cranial fossae arachnoid cysts
  - 5% may be bilateral, usually asymptomatic
  - CSF intensity; may be slightly different on FLAIR
  - No DWI restriction

Causes of Macrocephaly

- Hydrocephalus
  - Congenital, post-traumatic, or obstructive
  - Ventricular prominence out of proportion to sulci
  - Enlarged temporal horns, rounded frontal horns, transependymal CSF flow
- Idiopathic enlargement of subarachnoid spaces (SAS) during 1st year of life
- Benign familial macrocephaly
  - Family tendency toward large head size

PATHOLOGY

General Features

- Etiology
  - GCDH required for metabolism of lysine, hydroxylysine, and tryptophan
  - ↓ GCDH → accumulation glutaric, glutaconic, and 3-OH-glutaric acid
  - Accumulated substances toxic to striate cells and white matter
- Genetics
  - Autosomal recessive
  - *GCDH* gene mutations (Chr 19p13.2) result in amino acid substitutions

https://CafePezeshki.IR

- Multiple mutations govern varied clinical presentation
  - European variant (most common): Arg402-to-trp
  - Amish variant, riboflavin sensitive: Ala421-to-val
  - Severe, 1% residual enzyme, symptoms despite treatment (Tx): Glu365-to-lys
- Rare adult onset: Compound heterozygosity with deletion and novel missense mutation
- Associated abnormalities
  - Embryology: Toxic effects in utero impede operculization during 3rd trimester
  - Mild hepatocellular dysfunction during crisis

Staging, Grading, & Classification

- Symptomatic: Frontotemporal atrophy, BG signal changes
- Presymptomatic: Symptom-free, lack BG changes, but CSF spaces still enlarged

Gross Pathologic & Surgical Features

- Macrocrania, frontotemporal atrophy/hypoplasia; ↑ CSF spaces ± SDH
- Hypo- and demyelination

Microscopic Features

- Myelin vacuolation and splitting, excess intramyelinic fluid
- Spongiform changes, neuronal loss BG

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Initially normal development
  - Acute encephalopathy, seizures, dystonia, choreoathetosis, mental retardation
- Acute onset group: Majority
  - Episodic crises follow trigger (infection, immunization, surgery)
    - Acute Reye-like encephalopathy, ketoacidosis, ↑ NH4, vomiting
    - Dystonia, opisthotonus, seizures, excessive sweating
    - Follow-up: Alert child (intellect preserved > > motor); rapid infantile head growth → frontal bossing; severe dystonia
- Insidious onset (25%): Dystonia without crisis
- Presymptomatic may remain asymptomatic: Diagnose, treat, avoid catabolic stress
- Rare asymptomatic without treatment: Still frontotemporal atrophy but normal BG
- Diagnosis: Frequent long interval between presentation and diagnosis
  - Tandem mass spectrometry of newborn filter-paper blood specimens
    - Chromatography of mass; spectroscopy of urine
  - Deficient or absent GCDH activity in fibroblasts
  - Laboratory (may be relatively normal between crises)
    - Metabolic acidosis/ketosis, hypoglycemia, ↓ carnitine
    - Urinary organic acids: ↑ glutaric, glutaconic, and 3-OH-glutaric acid

Demographics

- Age
  - Generally manifests during 1st year of life
- Gender
  - No predilection
- Ethnicity
  - 10% carrier rate in old order Amish
- Epidemiology
  - 1:30,000 newborns

Natural History & Prognosis

- Symptomatic: Most severely handicapped, 20% die before 5 years
- Presymptomatic: Many (not all) remain asymptomatic with diagnosis and therapy
- Treat before 1st encephalopathic crisis; avoiding catabolic crises may improve outcome
- Prognosis poor if has already presented with encephalopathic crisis

Treatment

- Intrauterine diagnosis available
  - DNA analysis: Cultured amniotic fluid cells and chorionic villi biopsy
  - Fetal sonography and MR: Dilated perisylvian CSF in 3rd trimester
- Early treatment may prevent or ameliorate symptoms and imaging
  - Low-protein diet (reduced tryptophan and lysine), synthetic protein drink
  - Riboflavin (vitamin B2) to ensure cofactor supply for GCDH
  - Oral carnitine replacement; gamma aminobutyric acid (GABA), analog (baclofen)

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Consider GA1 in young children with bilateral enlargement of sylvian fissures and abnormal basal ganglia
- Pallidal and dentate signal change may occur even in absence of crisis; may predate involvement of caudate and putamina

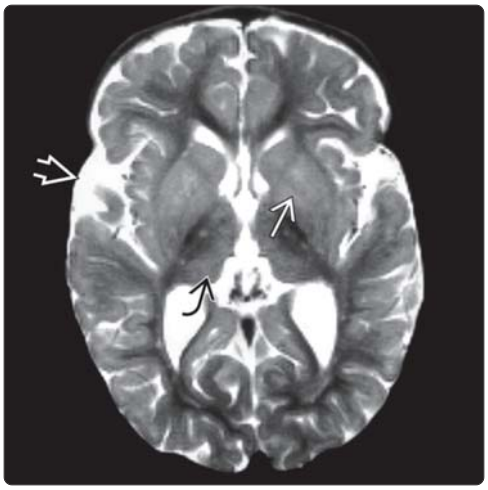
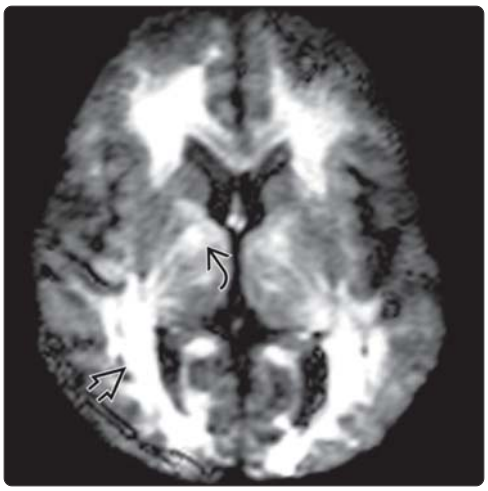
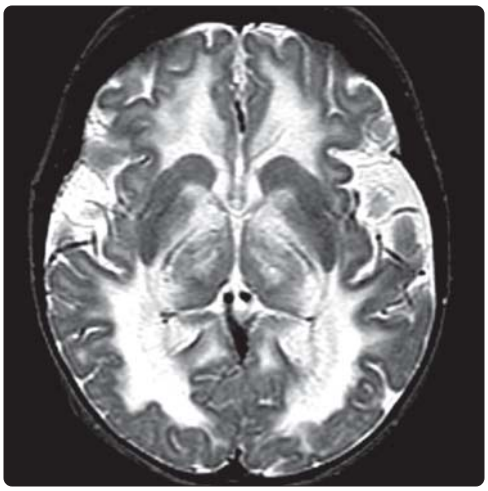
https://CafePezeshki.IR



(Left) *Axial T2WI MR shows mild prominence of the sylvian fissures ➡ and mottled, early signal abnormalities in the basal ganglia ➡ and thalami ⇨. The presence of macrocrania is an additional clue when imaging findings are subtle in cases of GA1.* **(Right)** *Axial T2WI MR in a child 21 months of age, long after resolution of metabolic crisis, reveals slit-like atrophy, gliosis of the basal ganglia ⇨, and persistence of the sylvian fissure enlargement ➡.*

(Left) *Axial FLAIR MR demonstrates typical enlargement of the sylvian fissures ➡ in a 7-month-old child. Abnormal signal is identified within the globi pallidi ➡, as expected, and in cerebral white matter ➡. The latter finding is unusual and is felt to reflect the combination of GA1 and dihydropteridine reductase (DHPR) deficiency in this child.* **(Right)** *T2WI MR in the same child shows diffusely abnormal white matter ➡, abnormal signal within the globi pallidi ⇨, and thalami ⇨.*





(Left) *Follow-up DWI MR in the same child at nearly 2 years of age shows reduced diffusivity, which confirms active disease and marked progression of disease, particularly within the white matter ⇨. There is also reduced diffusivity within the involved globi pallidi ⇨.* **(Right)** *T2WI MR at the same time as the DWI shows marked progression of white matter abnormality. White matter is now isointense to CSF. The prominent sylvian fissures remain a strong clue to the diagnosis of GA1.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Progressive autosomal-recessive spongiform leukodystrophy

IMAGING

- White matter: Involves subcortical U-fibers, sparing internal capsule, and corpus callosum
- Thalami, globi pallidi (GP), ± dentate nuclei, sparing caudate, and putamen
- ↑ T2 + DWI signal, normal to ↓ ADC in involved areas
- ↑ NAA/Cr, ↓Ch/Cr

TOP DIFFERENTIAL DIAGNOSES

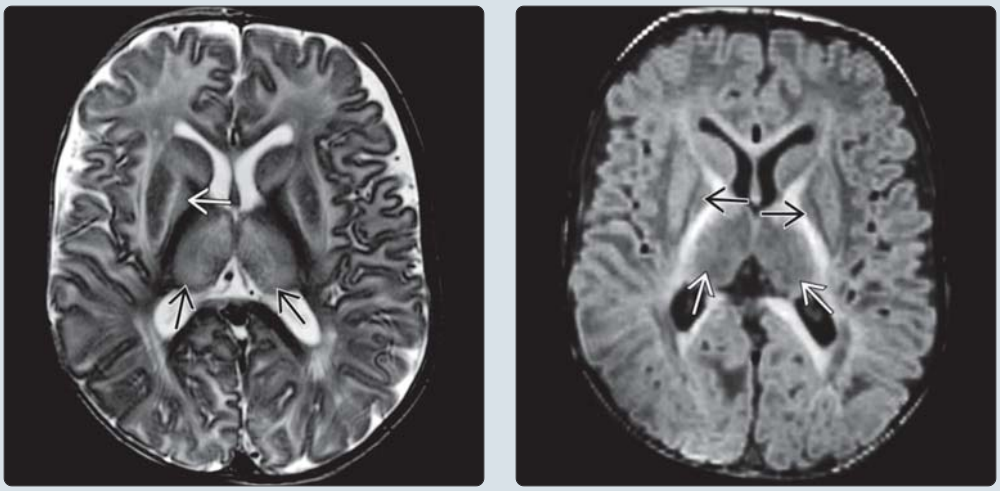
- Maple syrup urine disease
- Pelizaeus-Merzbacher disease
- Merosin-deficient congenital muscular dystrophy
- Alexander disease

PATHOLOGY

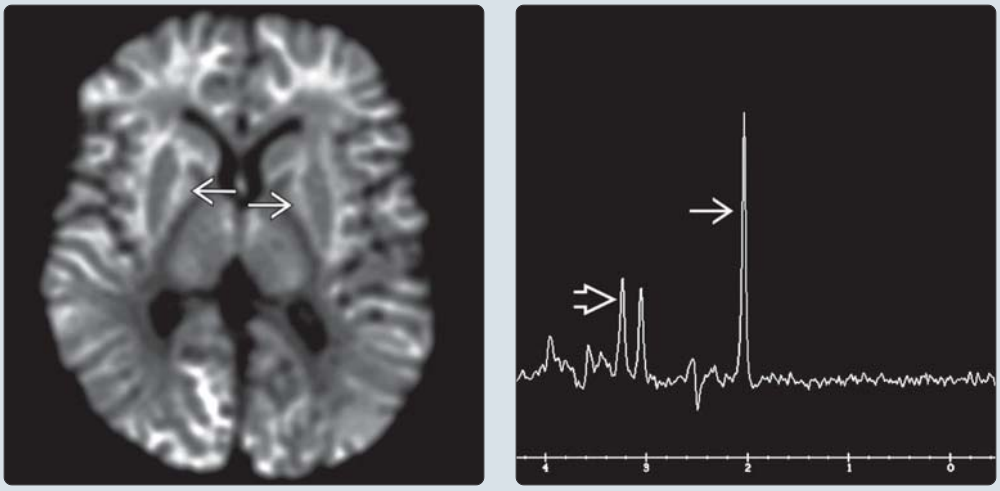
- Deficiency of aspartoacylase → N-acetyl aspartic acid ↑ in brain and urine
- Spongiform degeneration of white matter; GP and thalami with swollen astrocytes

CLINICAL ISSUES

- Early severe hypotonia and macrocephaly
- Evident by 4 months
- ↑ risk for Ashkenazi Jewish (1 in 40 carriers)
- Relentless, progressive neurodegenerative disorder: Chronic vegetative state with autonomic crises → death by end of 1st decade
- No proven treatment (gene therapy and acetate supplementation under evaluation)



(Left) *Axial T2WI MR in a 6-month-old infant boy shows diffusely increased signal in the cerebral white matter, thalami ⇨, and right globus pallidus ➡ with relative sparing of the internal capsule, corpus callosum, caudate, and putamen.* **(Right)** *Axial T1WI MR in the same 6-month-old infant shows diffusely decreased signal in the white matter, thalami ➡, and globi pallidi ⇨. Normal signal intensity is present within the internal capsule, corpus callosum, caudates, and putamina.*



(Left) *Axial DWI MR in the same 6-month-old infant shows diffusely increased signal (reduced diffusivity) in the cerebral white matter and globi pallidi ➡. Normal diffusivity is seen in the myelinated internal capsule and corpus callosum. Caudates and putamina appear unaffected.* **(Right)** *Axial long echo (TE = 144 msec) proton MRS acquired in the centrum semiovale at 1.5T shows a marked relative increase in NAA ➡ and decrease in choline ➡ relative to Cr for age.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Canavan disease (CD)

Synonyms

- Spongiform leukodystrophy, spongy degeneration of CNS, Canavan-van Bogaert-Bertrand disease, aspartoacylase deficiency, *ASPA* deficiency, *ASP* deficiency, aminoacylase 2 deficiency, *ACY2* deficiency

Definitions

- Progressive fatal autosomal-recessive spongiform leukodystrophy

IMAGING

General Features

- Best diagnostic clue
  - Megalencephaly with diffuse ↑ white matter T2 and DWI signal and ↑ NAA
- Location
  - White matter (WM): Involves subcortical U-fibers, sparing internal capsule, and corpus callosum
  - Thalami, globi pallidi (GP), ± dentate nuclei, sparing caudate and putamen

CT Findings

- NECT
  - Diffuse ↓ attenuation in involved areas

MR Findings

- T1WI
  - Hypointense in involved areas
- T2WI
  - Hyperintense in involved areas
- DWI
  - Bright DWI signal, normal to ↓ ADC in involved areas
- T1WI C+
  - No enhancement
- MRS
  - ↑ NAA/Cr, ↓ Ch/Cr

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - T2WI, DWI, and MRS

DIFFERENTIAL DIAGNOSIS

Maple Syrup Urine Disease

- ↑ branched-chain AA + ketoacids

Pelizaeus-Merzbacher Disease

- ↑ ADC, spares GP and thalami

Merosin-Deficient Congential Muscular Dystrophy

- ↑ ADC, spares GP and thalami

Alexander Disease

- Predilection for frontal WM, enhances

PATHOLOGY

General Features

- Etiology
  - Deficiency of aspartoacylase (which metabolizes N-acetyl aspartate [NAA]) → ↑ ↑ NAA in brain and urine
- Genetics
  - Autosomal recessive → *ASPA* gene = long arm chromosome 17

Staging, Grading, & Classification

- Earlier onset → more rapid progression

Gross Pathologic & Surgical Features

- Swollen brain

Microscopic Features

- Spongiform degeneration of white matter; GP and thalami with swollen astrocytes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 3 clinical variants (according to age at presentation)
    - Congenital (1st few days of life)
      - Hypotonia, rapid death
    - Infantile (3-6 months); most common form
      - Most common form
      - Hypotonia, head lag, macrocephaly → seizures, spasticity, visual loss
    - Juvenile
      - Onset at 4-5 years; most slowly progressive form of CD
- Clinical profile
  - Early severe hypotonia and macrocephaly

Demographics

- Ethnicity
  - ↑ risk for Ashkenazi Jewish (1 in 40 carriers)

Natural History & Prognosis

- Relentless, progressive neurodegenerative disorder: Chronic vegetative state with autonomic crises → death by end of 1st decade

Treatment

- No proven treatment (ablating NAA synthesis by disrupting Nat8l in mouse model)

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Swollen brain with ↑ T2, ↑ DWI signal in white matter, involvement of GP and thalami

SELECTED REFERENCES

1. Guo F et al: Ablating N-acetylaspartate prevents leukodystrophy in a Canavan disease model. Ann Neurol. 77(5):884-8, 2015

3. van der Knaap MS et al: Defining and categorizing leukoencephalopathies of unknown origin: MR imaging approach. Radiology. 213(1):121-33, 1999

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Rare leukoencephalopathy characterized by Rosenthal fibers (RFs), intracytoplasmic astrocytic inclusions
- 3 clinical forms: Infantile (most common), juvenile, adult

IMAGING

- Infantile: Symmetric, ↑ T2 signal bifrontal WM
- Juvenile/adult: ↑ T2 signal brainstem (especially medulla), cerebellum, cervical cord
- Other findings: ↓ T2, ↑ T1 enhancing nodular periventricular rim
  - One of few metabolic disorders that enhances

TOP DIFFERENTIAL DIAGNOSES

- Canavan disease
- Megaloencephalic leukoencephalopathy with subcortical cysts (MLC)
- Glutaric aciduria type 1 (GA1)
- Mucopolysaccharidoses (MPS)

PATHOLOGY

- Dominant mutations *GFAP* (17q21) (> 95% of cases)

CLINICAL ISSUES

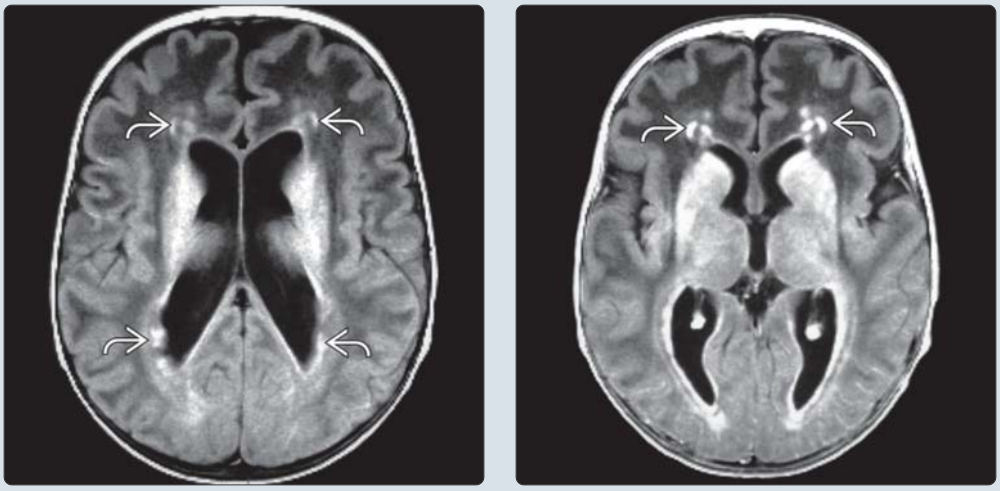
- Clinical profile: Infant with macrocephaly, seizures
- Natural history: Variable rate of progression ultimately leading to death in all forms
- Treatment: Supportive

DIAGNOSTIC CHECKLIST

- Consider adult Alexander disease (AD) if ↑ T2 signal and atrophy in medulla (inferior olives and gracile nuclei) & cervical cord
- Enhancing, symmetric bifrontal WM disease in macrocephalic infant highly characteristic of AD

(Left) *Axial NECT shows the typical appearance of infantile Alexander disease (AD). The striatum and periventricular rim ⇨ are hyperdense. Note the symmetric, frontal predominant, white matter (WM) hypodensity.* **(Right)** *Axial T2WI MR shows a nodular, hypointense, periventricular rim ⇨ with symmetric, mild hyperintensity in the striata and thalami ⇨. The cerebral white matter is diffusely hyperintense, greatest in the frontal lobes, where it extends from the ventricular margin to the subcortical U-fibers.*

(Left) *Axial T1WI MR shows diffusely hypointense, swollen-appearing WM with a frontal to occipital gradient. Only the occipital WM appears myelinated. The nodular periventricular rim ⇨ is hyperintense. The lateral ventricles are abnormally enlarged.* **(Right)** *Axial T1WI C+ MR shows enhancement of the periventricular rim, the caudate heads, and the putamina bilaterally. The nodular, rabbit ear appearance of the frontal periventricular rim ⇨ is typical of Alexander disease.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Alexander disease (AD)

Synonyms

- Fibrinoid leukodystrophy

Definitions

- Rare leukoencephalopathy characterized by Rosenthal fibers (RFs), intracytoplasmic astrocytic inclusions
- 3 clinical forms: Infantile (most common), juvenile, adult
- Caused by dominant mutations in gene endocing GFAP

IMAGING

General Features

- Best diagnostic clue
  - Macrocephalic infant with
    - Symmetric, ↑ T2 signal bifrontal white matter (WM)
    - ↓ T2, ↑ T1, enhancing, nodular periventricular rim
  - Juvenile: Enhancing, ↑ T2 signal brainstem (BS), cerebellum
    - One of the few metabolic disorders that enhances
  - Adult: ↑ T2 signal, atrophy medulla, cervical cord
- Other findings
  - Infantile
    - ↑ T2 signal, enhancement striatum
    - Variable ↑ T2 signal, enhancement in BS (especially periaqueductal), dentate nuclei, optic chiasm, fornix
    - ± hydrocephalus (periaqueductal disease)
  - Juvenile/adult
    - Characterized by BS, cerebellar, spinal cord involvement
      - Inferior olives, gracile nuclei in medulla
    - Involvement cerebral WM, periventricular rim, striatum variable (usually mild)
  - Enhancement, swelling early in frontal WM, basal ganglia (infantile AD)
  - Atrophy, cystic encephalomalacia (infantile) late
- Location
  - WM
    - Frontal: Periventricular → subcortical
    - External/extreme capsules, ± callosal genu
  - Periventricular rim
  - Basal ganglia (BG), thalami, BS, cerebellum, fornix, optic chiasm, spinal cord
- Morphology
  - Posterior extension WM changes frequent with disease progression
  - Rostral caudal gradient less pronounced in juvenile/adult disease

CT Findings

- NECT
  - Hypodense frontal WM
  - Dense periventricular rim, caudate heads
- CECT: Intense enhancement typical of early disease

MR Findings

- T1WI
  - Hypointense frontal WM
  - Hyperintense periventricular rim, ± basal ganglia
- T2WI
  - Hyperintense frontal WM (subcortical WM included), caudate heads
  - Hypointense periventricular rim
  - Juvenile/adult: Hyperintense foci BS, ± cervical cord
- FLAIR
  - Cystic encephalomalacia frontal WM (late infantile)
- DWI: Normal to increased diffusivity
- T1WI C+: Intense enhancement typical of early disease
  - Infantile: Frontal periventricular WM, striatum, periventricular rim; rare BS, fornix, optic chiasm
  - Juvenile/adult: BS and cerebellar enhancement may mimic tumor
- MRS: ↓ NAA, ↑ myoinositol; ± ↑ choline, lactate

Nuclear Medicine Findings

- FDG-18 fluorodeoxyglucose PET
  - Hypometabolism in affected frontal white matter
  - Preserved overlying normal glucose metabolism

Imaging Recommendations

- Best imaging tool: MR C+/MRS
- Protocol advice: Enhance all "unknown" cases of hydrocephalus and abnormal WM
- Proposed MR criteria for infantile AD (4/5 required)
  - Extensive cerebral WM change with frontal predominance
  - ↓ T2, ↑ T1 periventricular rim
  - Abnormal signal basal ganglia, thalami
  - Abnormal signal BS
  - Enhancement of frontal WM, periventricular rim, BG, thalami, BS, dentate nuclei, cerebellum, optic chiasm, or fornix

DIFFERENTIAL DIAGNOSIS

Canavan Disease

- WM: Diffuse; subcortical U-fibers involved early
- Deep gray matter: Globi pallidi, thalami
- No enhancement
- Characteristic ↑ ↑ NAA peak on MRS

Megalencephaly With Leukoencephalopathy and Cysts (MLC)

- WM: Diffuse with subcortical U-fiber involvement
- No involvement deep gray structures
- No enhancement
- Characteristic temporal, frontoparietal, subcortical cysts

Glutaric Aciduria Type 1

- WM: Periventricular WM involved in severe disease
- Deep gray: Symmetric basal ganglia
- No enhancement
- Characteristic widened opercula

Mucopolysaccharidoses

- WM: Mild periventricular
- No involvement of deep gray structures
- Characteristic cribriform WM, corpus callosum

https://CafePezeshki.IR

PATHOLOGY

General Features

- General pathology comments
  - AD characterized by accumulation of Rosenthal fibers (RFs) in astrocytes and hypo-/demyelination
- Embryology and anatomy
  - Astrocytes play role in myelin formation by oligodendrocytes
  - Astrocytic end-feet form part of blood-brain barrier
  - Glial fibrillary acidic protein (GFAP): Major intermediate filament protein in astrocytes
- Genetics
  - Dominant mutations *GFAP* (17q21) (> 95% of cases)
    - > 80 different mutations identified
    - Same mutation may be seen in all clinical forms → additional epigenetic or environmental factors influence phenotype
    - Majority of mutations arise de novo; familial cases seen in adult AD
    - Mutations cause gain in function
- Etiology
  - RFs: Abnormal intracellular protein aggregates containing GFAP, αβ-crystalline, hsp27, & ubiquitin
  - Mechanism by which *GFAP* mutation induces RF formation uncertain
  - Mechanism by which RF accumulation leads to hypo-/demyelination uncertain
    - Theory: RF accumulation causes cell dysfunction
      - Includes blood-brain barrier disruption and loss of normal cell-cell interaction with oligodendrocytes
  - RFs also seen in astrocytomas, hamartomas, gliosis

Gross Pathologic & Surgical Features

- Megaloencephalic, heavy brain with large ventricles
- Swollen, gelatinous WM with cortical thinning
- Frontal WM cavitation
- BG swelling early; atrophy and cystic change late

Microscopic Features

- RFs: Eosinophilic, electron-dense, cytoplasmic inclusions in fibrous astrocytes
  - Greatest concentration in subependymal, subpial, and perivascular astrocytic end-feet areas of enhancement
- Hypomyelination/myelin loss frontal lobes > caudal brain, ± cerebellar WM, dentate nucleus, brainstem
- Generalized astrocytosis ± neuraxonal degeneration
- Abnormalities of muscle mitochondria reported

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Infantile: Macrocephaly, seizures, developmental delay/arrest, spasticity
  - Juvenile: Developmental regression, bulbar/pseudobulbar signs, ataxia, spasticity
  - Adult: Bulbar/pseudobulbar signs, ataxia
    - Palatal myoclonus (40%) is highly suggestive
- Other signs/symptoms in juvenile/adult
  - Bowel/bladder dysfunction, sleep disturbance, dysautonomia
- Clinical profile: Infant with macrocephaly, seizures
- CSF: Variable ↑ protein, αβ-crystalline, hsp27, lactate
- Diagnosis: MR findings & *GFAP* gene blood analysis

Demographics

- Age
  - Infantile: Birth to 2 years
  - Juvenile: 2-12 years
  - Adult: > 12 years old
- Gender: Slight male predominance in infantile AD
- Epidemiology: Rare; incidence unknown
  - Adult AD more common than previously thought

Natural History & Prognosis

- Natural History
  - Variable rate of progression ultimately leading to death in all forms
    - Neonatal variant of infantile form is most rapidly fatal; infantile form is next most severe
    - Juvenile form is more slowly progressive
    - Adult form is mildest
- Prognosis
  - Infantile: Average survival 3 years after disease onset
  - Juvenile: Average survival 8 years after disease onset
  - Adult: Average survival 15 years after disease onset

Treatment

- Supportive; hydrocephalus may respond to shunting
- Potential future therapeutic role for agents causing down-regulation of *GFAP* expression

DIAGNOSTIC CHECKLIST

Consider

- Adult AD if ↑ T2 signal, atrophy in medulla & cervical cord
- Infantile AD if macrocephaly with frontal predominant leukodystrophy

Image Interpretation Pearls

- Enhancing, symmetric bifrontal WM disease in macrocephalic infant highly characteristic of AD

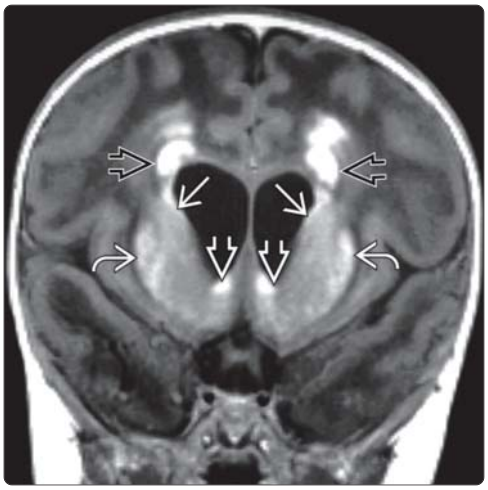
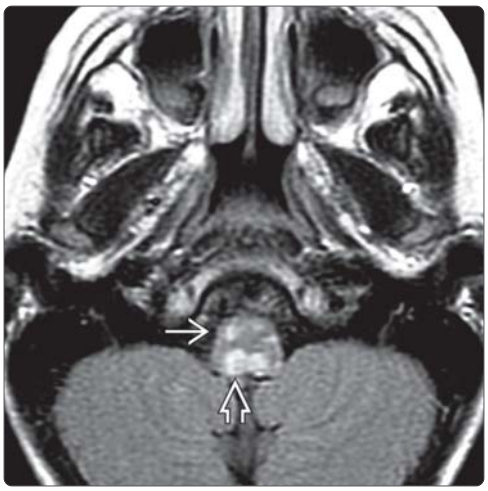
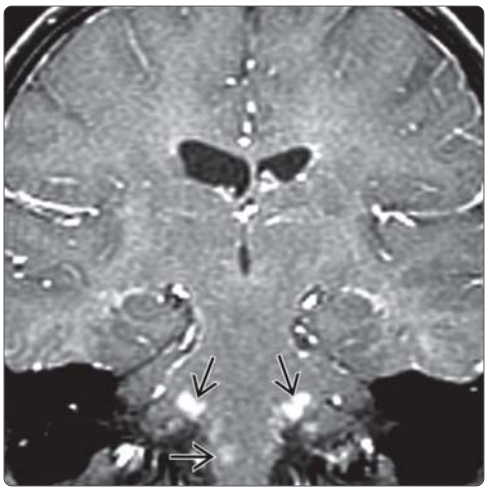
https://CafePezeshki.IR



(Left) *Axial NECT shows swollen, hypodense, cerebral WM with frontal predominance. The hyperdense, nodular periventricular rim is made more conspicuous by the adjacent hypodense WM.* **(Right)** *Coronal T1WI C+ MR shows intense enhancement in the frontal periventricular rims and adjacent frontal WM. Enhancement is also present over the surface of the caudate heads and in the putamina and fornix. Note the symmetric, hypointense, swollen frontal and temporal lobe WM.*

(Left) *Axial T2WI MR in this more advanced case shows symmetric, hyperintense cerebral WM and deep gray structures with greatest hyperintensity in the frontal WM and striata. Note the swollen caudate heads and fornices. WM hyperintensity extends into the external and extreme capsules, causing the claustra to stand out.* **(Right)** *Axial T1WI C+ MR in the same patient shows intense enhancement of the fornices and mild enhancement over the surface of the caudate heads.*





(Left) *Axial FLAIR MR in an older child shows multiple foci of hyperintensity within the inferior olives and gracile nuclei in the medulla.* **(Right)** *Coronal T1WI C+ MR in the same patient shows focal enhancement in the medulla and middle cerebellar peduncles. Note the normal cerebral WM. Juvenile and adult AD are characterized by involvement of the brainstem (especially medulla), cerebellum, and cervical cord (particularly adults), with little to no supratentorial involvement.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

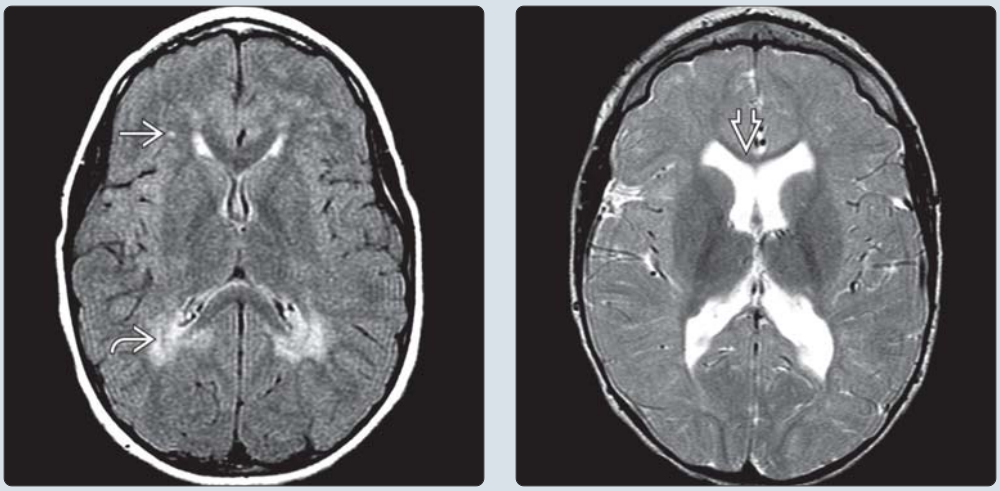
- PKU
  - Most common inborn error of amino acid metabolism
  - Results in ↑ phenylalanine (Phe)
- Hyperhomocysteinemia (HHcy)
  - Multiple disorders
    - Results in ↑ plasma homocysteine (Hcy) > 12 μmol/L
  - Risk factor for arteriosclerotic disease > venous thrombosis

IMAGING

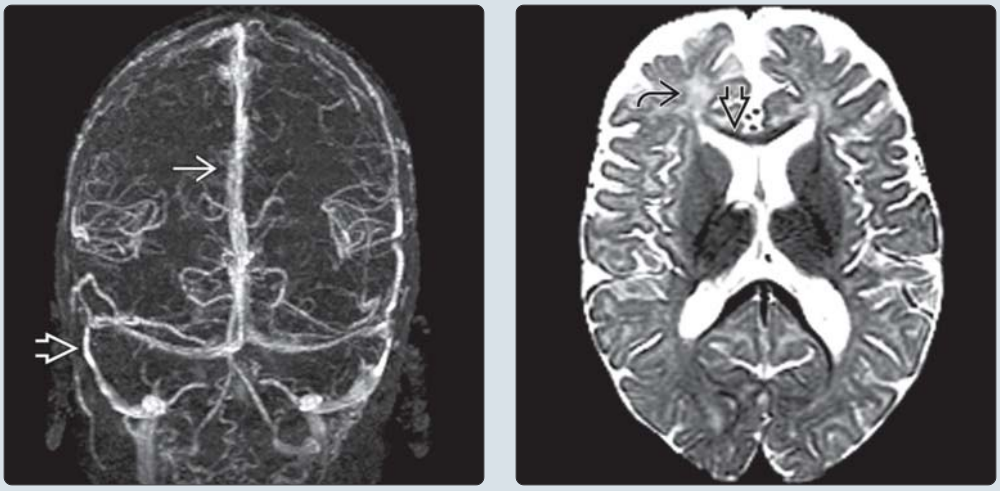
- PKU, HHcy
  - ↑ T2 periventricular/deep cerebral WM
- CBSD, MTHFRD, late-onset Cbl-C
  - Arterial > venous infarcts

CLINICAL ISSUES

- Presentation
  - PKU
    - Severe mental retardation (untreated)
    - Subtle cognitive impairment (early-treated disease)
  - HHcy
    - Variable phenotype
  - Late-treated CBSD
    - Mental retardation, thrombosis
  - Untreated CBSD
    - 12-27% have thromboembolic event by age 15
    - 4-23% die by age 30
- Diagnosis
  - PKU, CBSD, MAT I/IIID = newborn screen
- Treatment
  - PKU treatment
    - Phe-free diet starts 1st month of life
    - Strict diet during childhood improves outcome
  - CBSD/MTHFRD
    - Vit B6, folate, betaine; Cbl-C: IM/IV Vit B12
  - MAT I/IIID: Most have normal development



(Left) *Axial FLAIR MR in a 10 year old with PKU. Note the increased signal in the peritrigonal and frontal white matter. As is typical of PKU, the parietal white matter lesions are more pronounced than those in the frontal or temporal lobes.* **(Right)** *Axial T2WI MR in a 4 year old with MTHFRD. There is marked central white matter volume loss with associated ex vacuo ventricular enlargement and callosal thinning. Note the white matter is hypomyelinated for age.*



(Left) *Coronal maximum intensity projection from MR venogram in 4 year old with MTHFRD demonstrates irregular, recanalized sigmoid sinus and superior sagittal sinus several years following acute sinovenous thrombosis.* **(Right)** *Axial T2WI MR in an 8 month old with Cbl-C shows diffusely diminished white matter volume with increased signal in the periventricular and deep frontal white matter. Note mild ex vacuo ventricular enlargement and callosal thinning.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Phenylketonuria (PKU)
- Hyperhomocysteinemia (HHcy)
- Cystathionine β-synthase deficiency (CBSD)
- 5,10 methylenetetrahydrofolate reductase deficiency (MTHFRD)
- Methionine adenosyltransferase deficiency (MAT I/IIID)
- Cobalamin C (Cbl-C), disorder vitamin B12 metabolism

Definitions

- PKU: Most common inborn error of amino acid metabolism resulting in ↑ phenylalanine (Phe)
- Hyperhomocysteinemia: Multiple disorders resulting in ↑ plasma homocysteine (Hcy) > 12 μmol/L
  - ↑ risk arteriosclerotic disease > venous thrombosis
  - Caused by inborn errors of Hcy, folate, or vitamin B12 metabolism; ↓ vitamin B12/folate intake; renal failure
  - 4 most recognized metabolic disorders: CBSD, MTHFRD, Cbl-C, MAT I/IIID
  - Variable phenotype among & within each disorder

IMAGING

General Features

- PKU: ↑ T2 periventricular white matter (PVWM)
  - Posterior > anterior PVWM
  - Subcortical WM, corpus callosum late
- CBSD: Small foci ↑ T2 cerebral WM > cortical infarct > sinovenous thrombosis (SVT)
- MTHFRD: ↑ T2 PV/deep WM > arterial infarct, SVT
- Early onset Cbl-C: Swollen, ↑ T2 cerebral WM; ± hydrocephalus, ↑ T2 basal ganglia; Late: WM atrophy
- Late-onset Cbl-C: ↑ T2 PV/deep WM, atrophy > arterial infarct; ± ↑ T2 posterior spinal cord columns
- MAT I/IIID: Reversible ↑ T2 PV/deep WM, dorsal pons during severe hypermethioninemia (also with CBSD)
- PKU & HHcy: Imaging may be normal

CT Findings

- NECT
  - ↓ density cerebral WM, infarct

MR Findings

- T1WI: Variable ↓ signal cerebral WM
- T2WI/FLAIR: ↑ signal affected structures
- DWI: ↓ ADC PVWM reported PKU, HHcy
  - HHcy: ↓ ADC acute infarct, dorsal pons MAT I/IIID
- MRS: PKU: Phe peak 7.37 ppm; Cbl-C: (+) lactate

Imaging Recommendations

- PKU: MR/MRS; HHcy: MR/MRS/MRA

DIFFERENTIAL DIAGNOSIS

Metachromatic Leukodystrophy

- ↑ T2 central cerebral WM with tigroid appearance

Periventricular Leukomalacia

- ↑ T2 signal, volume loss PVWM, and positive hypoxia-ischemia history

PATHOLOGY

General Features

- General pathology comments
  - PKU: ↓ phenylalanine hydroxylase (PAH) → ↑ Phe
    - ↑ Phe toxic to developing brain
  - HHcy: ↑ Hcy → oxidative stress, ↓ methylation, vascular endothelial damage
- Genetics: Autosomal recessive
  - PKU: > 450 mutations *PAH* gene 12q24.1
  - CBSD: > 100 mutations *CBS* gene 21q22.3
  - MTHFRD: > 50 mutations *MTHFR* gene 1p36.3
  - MAT I/IIID: > 27 mutations *MAT1A* gene 10q22
- Associated abnormalities
  - CBSD: Ectopia lentis, marfanoid, ↓ bone density

CLINICAL ISSUES

Presentation

- Signs/symptoms
  - Untreated PKU: Severe mental retardation
    - Early treated: Subtle cognitive impairments
  - Late-treated CBSD: Mental retardation, thrombosis
  - MTHFRD: Developmental delay, gait difficulties, seizures, psychiatric symptoms > thrombotic events
  - Early-onset Cbl-C (infant): Neurologic, hematologic, renal, GI impairments
    - Late onset: Neurologic deterioration as adult
  - MAT I/IIID: Most normal, rare neurologic signs
- Diagnosis: PKU, CBSD, MAT I/IIID = newborn screen

Demographics

- Epidemiology
  - PKU: 1:8,000 Caucasians in USA (↓ African Americans)
  - 5-7% population have ↑ Hcy (from all causes)
  - 5-15% Caucasians homozygous *MTHFR* C667T allele

Natural History & Prognosis

- PKU: Strict diet during childhood improves outcome
- Untreated CBSD: 12-27% have thromboembolic event by age 15; 4-23% die by age 30
- MTHFRD/Cbl-C: Significant neurologic impairment, early death if late diagnosis/poor therapy compliance
- MAT I/IIID: Most have normal development

Treatment

- PKU: Phe-free diet begins 1st month of life
- CBSD/MTHFRD: Vit B6, folate, betaine; Cbl-C: IM/IV Vit B12; MAT I/IIID: None typically necessary

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Megalencephaly with leukoencephalopathy and subcortical cysts (MLC)
- Inherited leukodystrophy

IMAGING

- Swollen white matter
  - Early white matter swelling decreases over time; atrophy ensues
- Subcortical temporal and frontoparietal cysts
- Cysts increase in size and number over time
- No contrast enhancement or reduced diffusion

PATHOLOGY

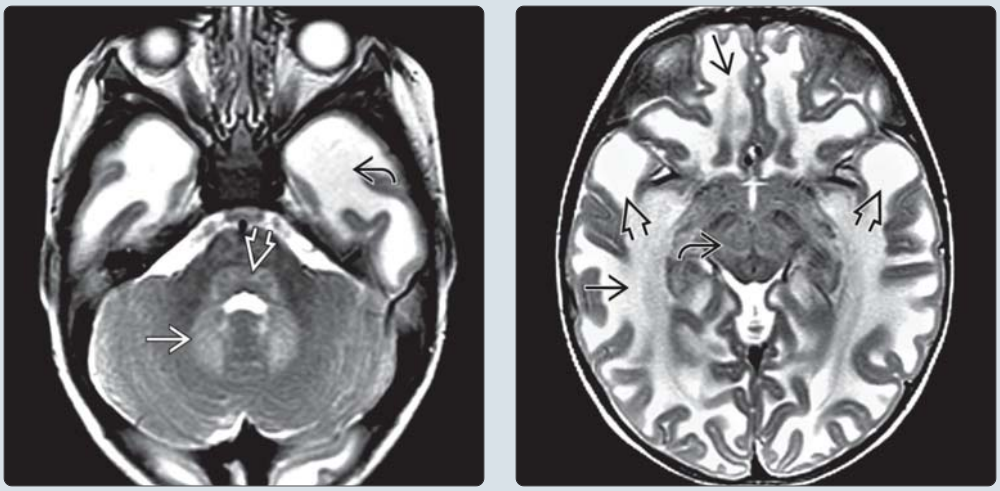
- Genetics
  - Autosomal recessive; mutations of *MLC1* or *GLIALCAM* gene
  - Mutations mostly private mutations
  - Founder effect occurs in population subisolates

CLINICAL ISSUES

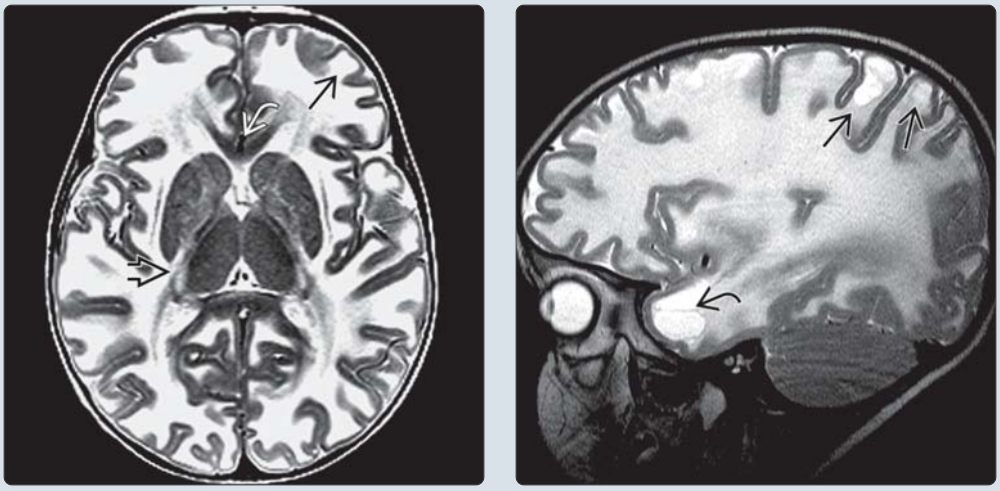
- Delayed onset of slow motor deterioration (despite very abnormal MR)
- Macrocephaly
- Seizures/deterioration after mild trauma
- Even slower cognitive decline
- Cerebellar ataxia
- Pyramidal tract involvement
- Rare disorder, but carrier rate in some communities with high levels of consanguinity as high as 1/40
- Prenatal diagnosis is option in families with known mutations

DIAGNOSTIC CHECKLIST

- Consider 1 of "new" leukodystrophies, such as MLC, when imaging features are more severe than metachromatic leukodystrophy



(Left) *Axial T2WI MR in a 10-month-old infant, with increasing head circumference but normal development, reveals abnormally increased signal intensity of the cerebellar white matter, dorsal brainstem, and anterior temporal lobes.* **(Right)** *Axial T2WI MR in the same infant confirms extensive swelling and increased signal of white matter of the cerebrum and the white matter tracts surrounding the red nuclei in the midbrain. Note the anterior temporal lobe cysts.*



(Left) *Axial T2WI MR of the same 10-month-old infant reveals sparing (normal myelination) of the corpus callosum, diminished myelination of portions of the posterior limb of the internal capsule, and definitely impaired myelination of the subcortical U-fibers throughout the cerebral hemispheres.* **(Right)** *Sagittal T2WI MR in the same infant nicely confirms the presence of temporal and frontoparietal cysts, as well as extensive hypomyelination.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Megalencephaly with leukoencephalopathy and subcortical cysts (MLC)

Synonyms

- Formerly
  - Vacuolating megaloencephalic leukoencephalopathy with benign, slowly progressive course
  - Infantile-onset leukoencephalopathy with swelling and discrepantly mild course
  - van der Knaap disease
    - 1 of many disorders eponymously named after that author
  - Indian Agarwal megaloencephalic leukodystrophy

Definitions

- Autosomal recessive disorder of astrocytic volume-regulated anion currents
  - Characterized by macrocephaly, motor/cognitive decline, ataxia, spasticity

IMAGING

General Features

- Best diagnostic clue
  - Diffusely abnormal, swollen hemispheric white matter (WM)
  - Subcortical cysts predominately anterior temporal, frontoparietal
- Location
  - Diffuse WM, includes subcortical U-fibers
    - Subcortical cysts
      - Anterotemporal most common
      - Frontoparietal also common
    - ± involvement of posterior internal capsules
    - Cerebellar WM involvement subtle
- Size
  - Cysts increase in size and number over time

CT Findings

- NECT
  - Involved WM ↓ attenuation
- CECT
  - No contrast enhancement

MR Findings

- T1WI
  - Involved WM ↓ signal on T1WI
- T2WI
  - Involved WM ↑ signal on T2WI
    - Cerebral white matter
      - Relative sparing of corpus callosum
    - Posterior 1/3 of posterior limb of internal capsule ± involvement
    - WM tracts of brainstem ± involvement in very young
- FLAIR
  - Involved WM ↑ signal on FLAIR
  - Subcortical cysts
    - Anterotemporal and frontoparietal most common
    - Cysts approximate CSF signal
- DWI
  - DTI shows ↓ anisotropy, ↑ ADC values
    - Results from ↑ water in interstitial space
- T1WI C+
  - No contrast enhancement
  - Probably not necessary
- MRS
  - All metabolites ↓ in cystic regions
  - ↓ NAA in WM
  - Normal myoinositol
  - ± lactate signal

Imaging Recommendations

- Best imaging tool
  - MR with MRS
    - ± contrast administration (to exclude enhancing leukodystrophies)

DIFFERENTIAL DIAGNOSIS

Other Leukodystrophies, Nonenhancing

- Metachromatic leukodystrophy (MLD)
  - Look for WM "stripes" on T2WI
- Hypomyelination
- Canavan
  - Subcortical U-fibers involved early
  - Markedly elevated NAA on MRS
- Cree leukoencephalopathy
  - Involvement of WM
  - Deep structures
    - Involves globus pallidus, thalami, medulla
    - Spares olives, red nuclei, and caudate nuclei

Other Leukodystrophies, Enhancing

- Alexander disease
  - Abnormal signal + enhancement of frontal WM and ependymal surfaces
  - Basal nuclei involved
- X-linked adrenoleukodystrophy
  - Abnormal signal and enhancement of peritrigonal WM and splenium

PATHOLOGY

General Features

- Etiology
  - Inborn genetic errors
  - Disturbed water homeostasis and osmotic balance to abnormal function of volume-regulated anion channels (VRACs)
    - VRACs in astrocytes respond to changes in extracellular osmolarity
    - Display prominent cell volume changes as part of osmoregulatory process
    - MLC1 important in VRAC activity; GlialCAM is a chaperone of MLC1 in ion channels
- Genetics
  - Autosomal recessive; gene localized on Chr 22q(tel)
    - Many different mutations of *MLC1* and *GLIALCAM* genes
    - Mutations distributed along whole gene, types include

https://CafePezeshki.IR

        - Splice-site mutations
        - Nonsense mutations
        - Missense mutations
        - Deletions and insertions
    - Mutations identified in 80%; 2nd locus suspected
    - Mutations mostly private mutations
    - Founder effect occurs in population subisolates
- Associated abnormalities
    - *MLC1* in CNS expressed in astrocytic end-feet at blood-brain and CSF-brain barriers
        - GlialCAM is a chaperone for MLC1 in ion channels of astrocytes
    - *MLC1* also expressed in peripheral white blood cells, spleen
        - But no systemic or other organ involvement

Gross Pathologic & Surgical Features

- Spongiform leukoencephalopathy
    - Vacuolization in subcortical white matter

Microscopic Features

- Myelin splitting at intraperiod line
- Vacuolization of outermost lamellae of myelin sheaths

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
    - Macrocephaly at birth or within 1st year of life
    - Delayed onset of slow motor deterioration (even slower cognitive decline) despite very abnormal MR
        - Development during 1st year often normal
- Other signs/symptoms
    - Rare early presentation with developmental delay
    - Rare transient coma following minor head trauma
- Clinical profile
    - Macrocephaly
    - Very slow cognitive decline
        - Eventual learning problems in 50%
    - Cerebellar ataxia and pyramidal tract involvement
    - Motor deterioration
        - Late loss of ability to walk
        - Occasional delayed autonomous walking
    - Minor head trauma → seizures and temporary deterioration

Demographics

- Age
    - Macrocephaly before 1 year of age
- Ethnicity
    - Increased in population isolates
        - Common *MLC* mutations in
            - Specific Indian community (Agarwal)
            - Libyan Jewish community
            - Turkish community
            - Some Japanese families due to founder effect
        - Agarwal community mutation
            - Insertion (c.135_136insC) usual, phenotypic variation occurs
- Epidemiology
    - Rare
    - Carrier rate in some communities with high levels of consanguinity as high as 1/40

Natural History & Prognosis

- Early white matter swelling
    - Swelling decreases over time
    - Atrophy ensues
- Clinical features progress slowly

Treatment

- Treat symptoms (seizures, spasticity)
- Prenatal diagnosis is option in families with known mutations

DIAGNOSTIC CHECKLIST

Consider

- 1 of "new" leukodystrophies when imaging involvement more severe than metachromatic leukodystrophy

Image Interpretation Pearls

- Always enhance unknown leukoencephalopathy

Reporting Tips

- Differentiation from MLD
    - Involvement of subcortical U-fibers
    - Subcortical cysts
- Differentiate from Canavan
    - No basal ganglia involvement in MLC
    - Normal NAA in MLC

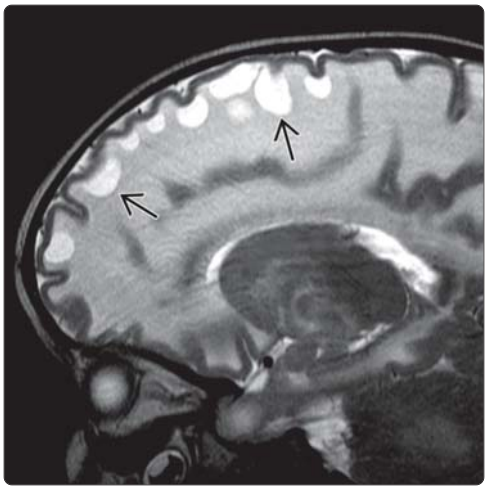
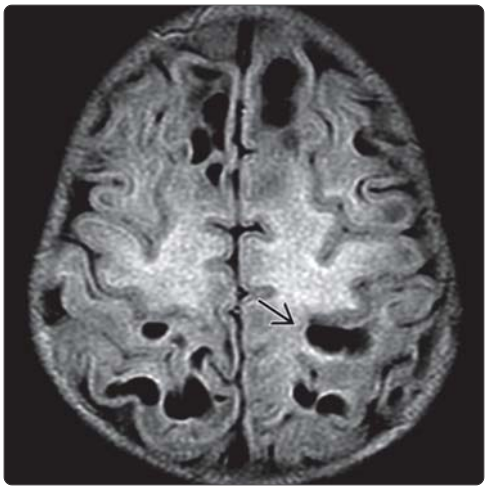
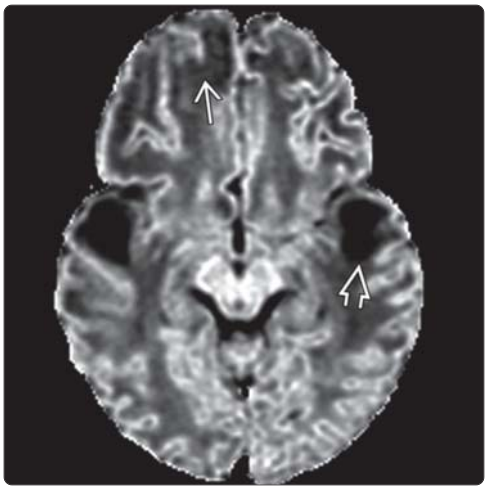
https://CafePezeshki.IR

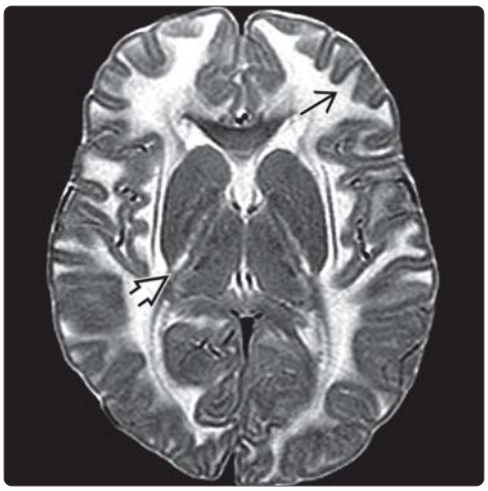




(Left) *Sagittal T2WI MR in a 2-year-old patient with megalencephaly and slowing of acquisition of developmental milestones shows swollen white matter, as well as fairly extensive subcortical cysts involving the frontal lobe.* **(Right)** *Axial FLAIR MR in the same 2-year-old patient shows white matter with abnormally high signal intensity due to hypomyelination, as well as extensive, bilateral, frontal and frontoparietal subcortical cysts.*



(Left) *Axial FLAIR MR in a 22-month-old child with macrocephaly and decreasing acquisition of developmental milestones shows large, bilateral temporal lobe cysts, typical of megalencephaly with leukoencephalopathy and cysts (MLC), on a background of swollen, abnormally hyperintense white matter.* **(Right)** *Axial DWI MR in the same 22-month-old infant confirms markedly increased diffusivity in the cysts and, less dramatically, in the subcortical white matter.*



(Left) *Axial T2WI MR in a 6-year-old child with MLC shows less pronounced white matter swelling, although the posterior limbs of the internal capsules and subcortical U-fibers show persistence of abnormal signal hyperintensity.* **(Right)** *Axial T2WI MR in a 14-year-old patient with MLC demonstrates sulcal widening due to atrophy, a common finding as the disease progresses. Note the persistent hyperintensity of the cerebral white matter with involvement of the subcortical U-fibers.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Group of neurodegenerative disorders characterized by dystonia, parkinsonism, and spasticity
  - Caused by mutations in L-ferritin gene *FTL1*
  - All characterized by abnormal Fe accumulation in basal ganglia
    - Lewy bodies, axonal swellings, hyperphosphorylated tau in some subtypes
  - Includes PKAN, INAD, aceruloplasminemia, etc.

IMAGING

- Globus pallidus T2 hypointensity with central hyperintensity of GP: Eye of the tiger sign
  - Specific to classic PKAN (*PANK2* mutations)
  - May also be seen in neuroferritinopathy
- GP ± SN, DN, cortex, striatum, & thalamus T2 dark without "eye of the tiger" = other NBIA
- Caution: Globus pallidus normally hypointense on T2 at 3T or above

PATHOLOGY

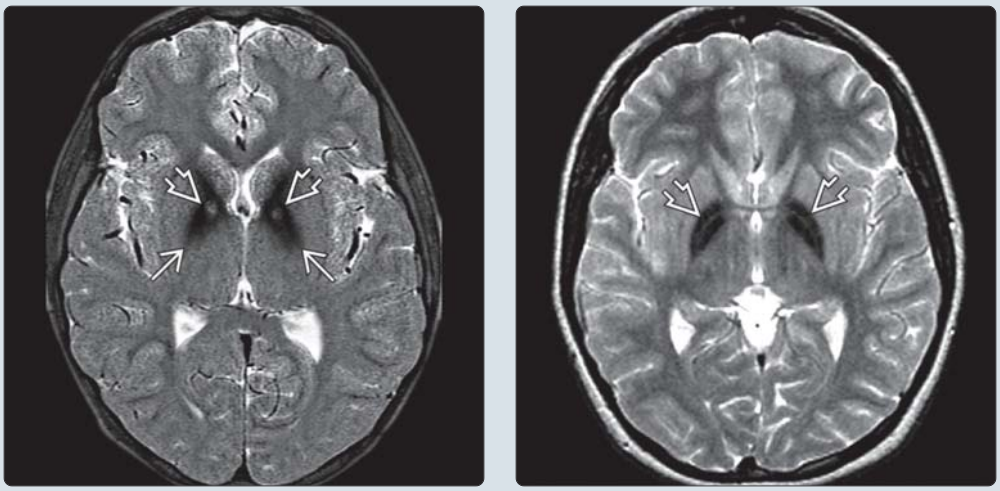
- Iron directly causes or facilitates cellular injury, or is a consequence of axonal disruption

CLINICAL ISSUES

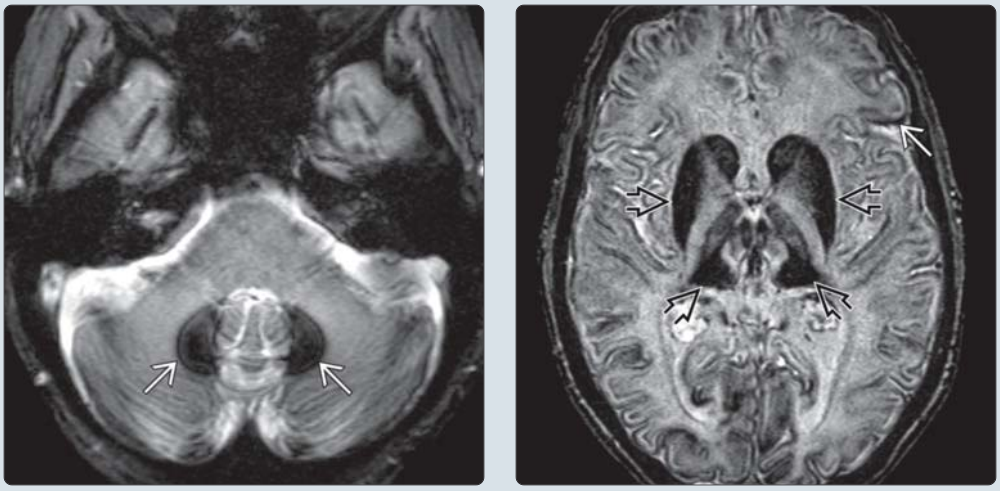
- PKAN
  - Classic < 6 years, atypical during teenage years
- INAD
  - Classic < 2 years, atypical at 4-6 years
- Aceruloplasminemia and neuroferritinopathy
  - Mean age 40 years

DIAGNOSTIC CHECKLIST

- Look for: T2 hypointensity of globus pallidus in patient with movement disorder
- Consider: T2* (gradient echo) or susceptibility weighted imaging (SWI) in patients with movement disorders



(Left) *Axial T2WI FS MR shows classic imaging of PKAN (Hallervorden-Spatz syndrome), which is within the spectrum of NBIA. Note the globus pallidi hypointensity related to iron deposition with central hyperintensity, consistent with the eye of the tiger sign, highly specific for the PANK2 mutation.* **(Right)** *Axial T2WI MR shows symmetric hypointensity within the globus pallidi. The eye of the tiger sign is absent; therefore, this is not PKAN. These findings are characteristic of NBIA.*



(Left) *Axial T2* GRE MR shows marked hypointensity related to iron deposition in the dentate nuclei of the cerebellum in this patient with aceruloplasminemia. Aceruloplasminemia and neuroferritinopathy occur in adults and have a similar imaging appearance.* **(Right)** *Axial T2* SWI MR in the same patient shows diffuse linear hypointensity in the cortex with marked "blooming" in the basal ganglia and thalami related to iron deposition. Substantia nigra involvement is also typical.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pantothenate kinase-associated neurodegeneration (PKAN)
- Infantile neuroaxonal dystrophy (INAD)
- Neurodegeneration with brain iron accumulation (NBIA)

Definitions

- Group of neurodegenerative disorders characterized by dystonia, parkinsonism, and spasticity
  - Caused by mutations in L-ferritin gene *FTL1*
  - All characterized by abnormal Fe accumulation in basal ganglia
  - Includes PKAN, INAD, aceruloplasminemia, etc.
    - Lewy bodies, axonal swellings, hyperphosphorylated tau in some subtypes

IMAGING

General Features

- Best diagnostic clue
  - T2 hypointensity in globus pallidus (GP)
- Location
  - PKAN and INAD
    - GP, substantia nigra (SN), ± dentate nuclei (DN)
  - Neuroferritinopathy and aceruloplasminemia
    - GP, SN, DN, cortex, striatum, and thalamus

Imaging Recommendations

- Best imaging tool
  - MR with T2* (gradient echo) or susceptibility weighted imaging (SWI)

CT Findings

- NECT
  - Cerebral and cerebellar atrophy in non-*PANK2* NBIA

MR Findings

- T2WI
  - GP hypointensity with central hyperintensity of GP interna: Eye of the tiger sign
    - Specific to classic PKAN (*PANK2* mutations)
    - Can see only T2 hyperintensity early in disease
    - May also be seen in neuroferritinopathy
  - GP, ± SN, DN, cortex, striatum, and thalamus dark without "eye of the tiger" = other NBIA
  - GP normally hypointense on T2 at 3T or above
- T2* GRE
  - Accentuation of hypointense T2 findings
- Imaging findings do not always correlate with clinical symptoms

DIFFERENTIAL DIAGNOSIS

Normal Iron Deposition

- Imaging at 3T
- Seen in normal aging process

Parkinson and Alzheimer Diseases

- No "eye of the tiger"; older patients

Multiple Sclerosis

- Iron accumulation in basal ganglia associated with MS
- Should have other classic demyelinating lesions

Superficial Siderosis

- Iron overload from transfusions or recurrent CNS hemorrhage

Hemochromatosis

- Liver and spleen usually affected before CNS

PATHOLOGY

General Features

- Genetics
  - Autosomal recessive *PANK2*, *PLA2G6*, and *CP*
  - Autosomal dominant *FTL* mutation

Gross Pathologic & Surgical Features

- Iron accumulation, rust brown pigmentation

Microscopic Features

- Iron accumulation in GP and SN, neuronal loss, axonal swellings (spheroids)
- "Eye of the tiger" may represent cystic degeneration
- Neurofibrillary tangles and Lewy bodies suggest shared pathway with Alzheimer and Parkinson diseases

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Ataxia, dysarthria, dystonia
  - Retinal degeneration and optic atrophy
- Other signs/symptoms
  - Aceruloplasminemia: Adult onset triad of diabetes, retinal degeneration, and movement disorder
  - Neuroferritinopathy: Adult onset chorea or dystonia

Demographics

- Age
  - PKAN: Classic < 6 years, teenage atypical
  - INAD: Classic < 2 years, 4-6 years atypical
  - Adult onset NBIA: Mean age = 40 years

Natural History & Prognosis

- PKAN & INAD: Death is variable, usually from secondary causes such as malnutrition & aspiration
- Adult onset NBIA: Progressive motor decline

Treatment

- Symptom palliation: Medications and deep brain stimulator
- Aceruloplasminemia: Iron chelation with desferrioxamine and ceruloplasmin from fresh frozen plasma

KEY FACTS

TERMINOLOGY

- Pantothenate kinase-associated neurodegeneration (PKAN)
  - Most common form of neurodegeneration with brain iron accumulation (NBIA)
  - Caused by mutation pantothenate kinase 2 gene (*PANK2*)

IMAGING

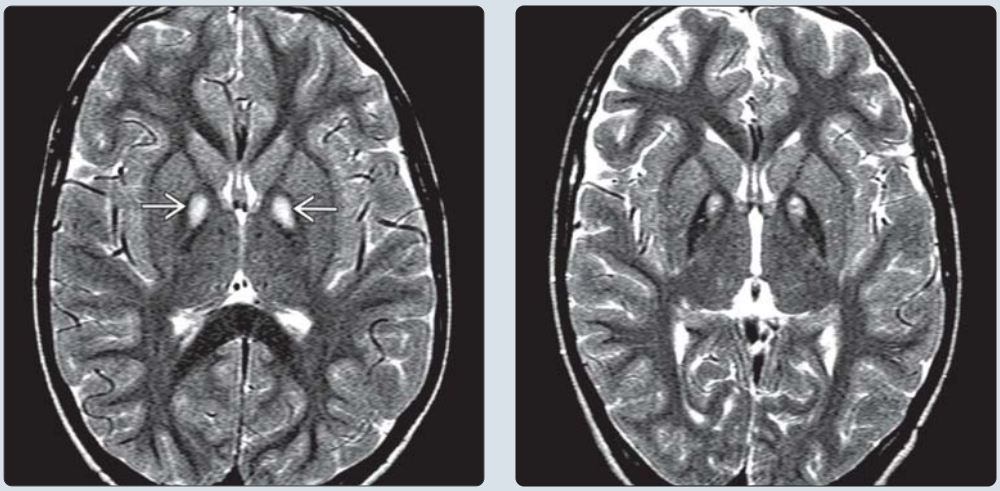
- Best diagnostic clue: Eye of the tiger sign = diffuse pallidal T2 hypointensity with medial foci ↑ T2 signal
  - Highly suggestive of PKAN

TOP DIFFERENTIAL DIAGNOSES

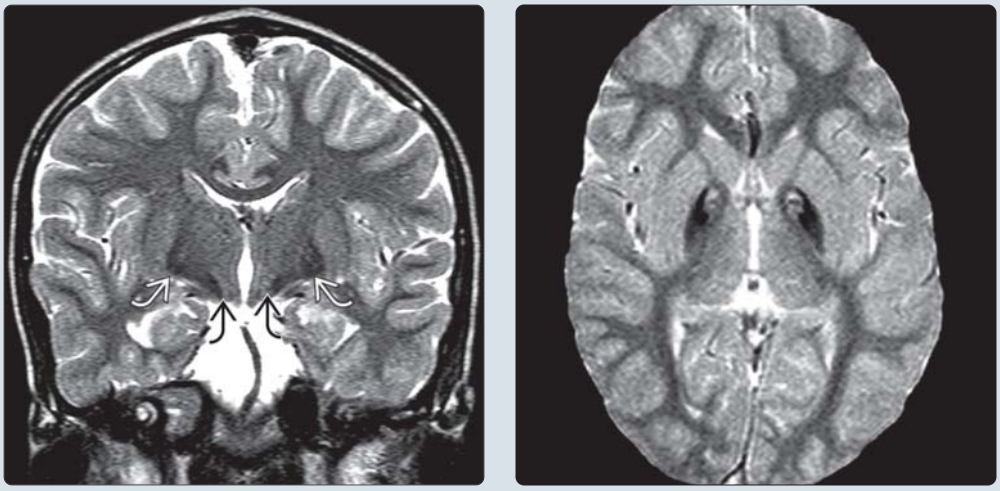
- Disorders with ↑ T2 signal globus pallidus
  - Metabolic: Methylmalonic acidemia, Kearns-Sayre, L-2-Hydroxyglutaric aciduria, Canavan, neuroferritinopathy
  - Ischemic/toxic: Anoxic encephalopathy, carbon monoxide/cyanide poisoning, kernicterus

CLINICAL ISSUES

- Classic PKAN
  - Dystonia, dysarthria, rigidity, choreoathetosis in young child
- Atypical PKAN
  - Psychiatric, speech, pyramidal/extrapyramidal disturbances in older child/teenager
- Epidemiology
  - Rare; incidence unknown
- Prognosis
  - Classic PKAN: Fatal; mean disease duration after symptom onset is 11 years
  - Atypical PKAN: Eventual severe impairment/death
- No curative treatment



(Left) *Axial T2WI MR in a 5 year old with a diagnosis of cerebral palsy demonstrates an "eye of the tiger" sign typical of PKAN: Symmetric areas of high T2 signal within the medial globus pallidus with surrounding pallidal hypointensity.* **(Right)** *Four years later, dystonia prompted repeat MR imaging in the same patient. Axial T2WI MR shows that the "eyes" have diminished in size and intensity with greater surrounding pallidal hypointensity. Volume loss is now evident, particularly frontal.*



(Left) *Coronal T2WI MR of the same patient at 9 years of age shows abnormal hypointense signal in the globus pallidus and substantia nigra.* **(Right)** *Axial T2* GRE MR in same patient at 9 years of age shows "blooming" of hypointense signal in the globus pallidus secondary to the paramagnetic effect of iron. The findings in this patient are typical of the evolution of classic PKAN: Diminishing caliber of the "eye," increasing surrounding pallidal hypointensity, and progressive volume loss.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pantothenate kinase-associated neurodegeneration (PKAN)

Synonyms

- Neurodegeneration with brain iron accumulation type 1 (NBIA-1)
- Hallervorden-Spatz syndrome
  - PKAN and NBIA-1 = preferred terms

Definitions

- Neurodegeneration with brain iron accumulation (NBIA) = umbrella term for neurodegenerative disorders characterized by brain iron accumulation
  - Known causes include PKAN (most common), aceruloplasminemia, neuroferritinopathy, and infantile neuroaxonal dystrophy
- PKAN caused by mutation pantothenate kinase 2 gene (*PANK2*)

IMAGING

General Features

- Best diagnostic clue: Eye of the tiger sign = diffuse pallidal T2 hypointensity with medial foci ↑ T2 signal
  - Highly suggestive of PKAN
  - Hyperintense "eye" may predate surrounding pallidal hypointensity
  - "Eye" caliber and intensity ↓ as disease progresses
  - Pallidal hypointensity increases as disease progresses
  - Eye of the tiger sign has been described in neuroferritinopathy
- Variable ↓ T2 signal substantia nigra > > dentate nuclei
- Atrophy in advanced diseases
- Location: Globus pallidus (GP), substantia nigra (SN), dentate nuclei (DN)
- Morphology: Signal alteration of globus pallidus resembles tiger eyes
- Iron deposition (ferritin bound) responsible for T2 hypointense imaging appearance

CT Findings

- NECT: Variable; hypodense, hyperdense, normal GP
- CECT: No abnormal enhancement

MR Findings

- T1WI: Variable (ferritin bound iron has > T1 shortening than hemosiderin bound)
- T2WI
  - Eye of the tiger sign = diffuse pallidal hypointensity with medial foci ↑ signal
  - Variable ↓ signal SN; more common in older patients
- FLAIR: "Eye" persists
- T2* GRE: ↓ T2 signal GP, SN "blooms" due to paramagnetic effect iron
- Susceptibility weighted imaging (SWI): Greater "blooming" artifact than T2* GRE
- T1WI C+: No abnormal enhancement
- MRS: ↓ NAA GP (neuronal loss)

Nuclear Medicine Findings

- Tc-99m SPECT: ↑ activity in medial GP
  - Possible chelation Tc-99m by pallidal cysteine

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Consider SWI or T2* GRE sequence for mineralization
  - T2 hypointensity more conspicuous on spin-echo (vs. fast spin-echo) and high field strength magnets

DIFFERENTIAL DIAGNOSIS

Disorders With ↑ T2 Signal Globus Pallidus

- Metabolic
  - Methylmalonic acidemia (MMA): ↑ T2 signal GP ± periventricular white matter (WM)
  - Kearns-Sayre/L-2-hydroxyglutaric aciduria: ↑ T2 GP (> than other deep gray) and peripheral WM
  - Canavan: ↑ T2 GP (> than other deep gray) and subcortical WM; macrocephaly; ↑ NAA
  - Neuroferritinopathy: Variable-sized foci ↑ T2 signal GP, putamen, caudate heads with ↓ T2 SN, DN; disease of adults
  - Guanidinoacetate methyltransferase deficiency (impairs creatine synthesis)
- Ischemic/toxic
  - Anoxic encephalopathy: ↑ T2 GP (and other deep gray) and cortex
  - Carbon monoxide poisoning: ↑ T2 GP (± other deep gray, cortex, WM)
  - Cyanide poisoning: ↑ T2 basal ganglia followed by hemorrhagic necrosis
  - Kernicterus: ↑ T2/T1 globus pallidus in neonate

PATHOLOGY

General Features

- Iron accumulation likely secondary phenomenon in PKAN
  - Serial MRs in PKAN patients show hyperintense foci in GP predating surrounding hypointensity
- Embryology, anatomy
  - Progressive, physiologic brain iron accumulation occurs in GP, SN > red and dentate nuclei
  - ↓ T2 signal GP identified in majority of normal patients by age ≥ 25, but never before age 10
- Genetics
  - Autosomal recessive (50% sporadic)
  - > 100 *PANK2* mutations Chr 20p12.3-p13 identified
    - MR eye of the tiger sign highly correlative with *PANK2* mutation
    - *PANK2* gene encodes mitochondrial-targeted pantothenate kinase 2, key enzyme in biosynthesis of coenzyme A (CoA)
      - CoA essential to energy and fatty acid metabolism, among other functions
    - Null mutations are more common in early onset, rapidly progressive disease
    - Missense mutations more common in late onset, more slowly progressive disease
      - Suggests residual pantothenate kinase 2 activity in late onset (less severe) disease

https://CafePezeshki.IR

- HARP: **H**ypoprebetalipoproteinemia, **a**canthocytosis, **r**etinitis pigmentosa, and **p**allidal degeneration
  - Allelic with PKAN
  - Prominent orofacial dystonia; early onset parkinsonism
- Etiology
  - Leading theory
    - *PANK2* mutation → CoA deficiency → energy and lipid dyshomeostasis → production of oxygen free radicals → phospholipid membrane destruction
    - Basal ganglia and retina vulnerable to oxidative damage secondary to high metabolic demand
  - Additional factors
    - Cysteine accumulation in GP secondary to ↓ phosphopantothenate causes iron chelation and peroxidative cell membrane damage
    - Axonal spheroids further compromise glial and neuronal function

Gross Pathologic & Surgical Features

- Symmetric, rust-brown pigmentation GP (interna > externa), and pars reticulata SN
  - In addition to iron, intra-/extraneuronal ceroid lipofuscin and melanin contribute to pigmentation
- Variable atrophy

Microscopic Features

- Classic features
  - ↑ iron GP interna and pars reticulata SN
    - Iron located in astrocytes, microglial cells, neurons, and around vessels
  - Neuronal loss, gliosis, and glial inclusions primarily involving GP interna and pars reticulata SN
  - Round or oval, nonnucleated, axonal swellings ("spheroids") in GP, SN, cortex, and brainstem
- "Loose" tissue (consisting of reactive astrocytes, dystrophic axons, and vacuoles in anteromedial GP) corresponds to "eye" in eye of the tiger sign on MR
- Variably present acanthocytes (on blood smear)

CLINICAL ISSUES

Presentation

- Clinical classification into classic and atypical disease
  - Classic PKAN: Early onset, more rapidly progressive disease, uniform phenotype
  - Atypical PKAN: Late onset, more slowly progressive disease, heterogeneous phenotype
- Most common signs/symptoms
  - Classic PKAN: Dystonia
    - Other extrapyramidal signs/symptoms: Dysarthria, rigidity, choreoathetosis
    - Upper motor neuron signs/symptoms and cognitive decline are frequent
    - Pigmentary retinopathy (66%)
  - Atypical PKAN: Psychiatric and speech disturbances
    - Other signs/symptoms: Pyramidal/extrapyramidal disturbances (including freezing), dementia
- Clinical profile
  - Classic PKAN: Young child with gait, postural deficits
  - Atypical PKAN: Teenager with speech, psychiatric disturbance
- Normal serum and CSF iron levels
- Confirmatory *PANK2* mutation analysis should be performed in all suspected cases of PKAN

Demographics

- Age
  - Classic PKAN: Majority present before 6 years of age
  - Atypical PKAN: Mean age at presentation is 13 years
- Epidemiology: Rare; incidence unknown

Natural History & Prognosis

- Natural History
  - Classic PKAN: Rapid, nonuniform progression with periods of deterioration interspersed with stability, leading to early adulthood death
  - Atypical PKAN: More slowly progressive with loss of ambulation 15-40 years after disease onset
- Prognosis
  - Classic PKAN: Fatal; mean disease duration after symptom onset is 11 years
  - Atypical PKAN: Eventual severe impairment, ± death, adulthood

Treatment

- No curative treatment; iron chelation ineffective
- Palliative therapy
  - Baclofen, trihexyphenidyl frequently ineffective
  - Stereotactic pallidotomy
  - Promising initial results with pallidal deep brain stimulation

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Eye of the tiger sign highly suggestive of PKAN
- Physiologic GP hypointensity difficult to distinguish from pathologic hypointensity in teenager/adult

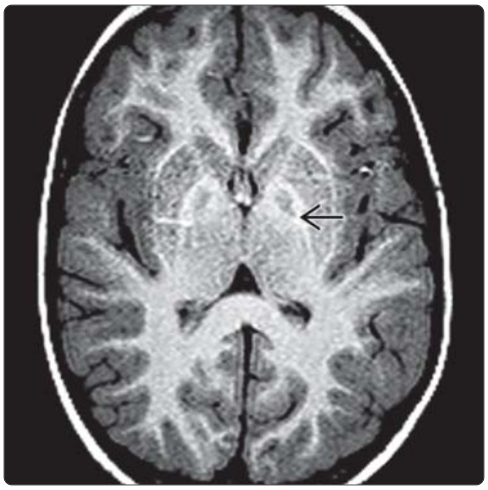
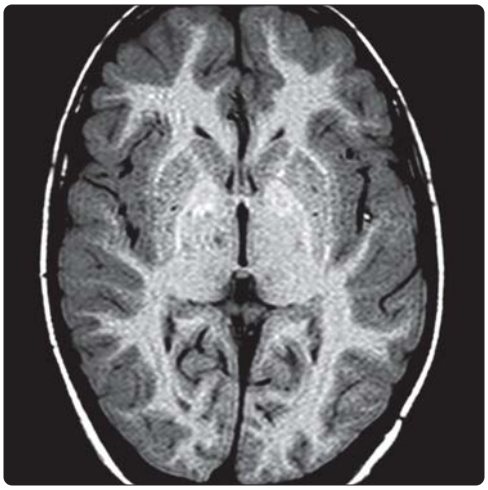
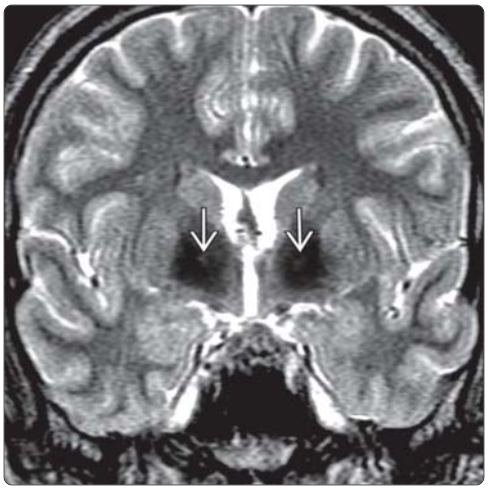
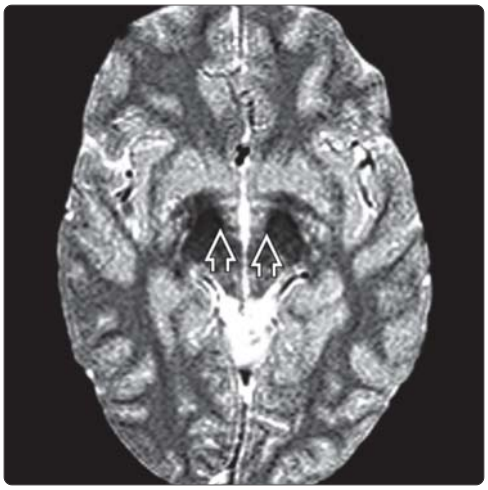
https://CafePezeshki.IR



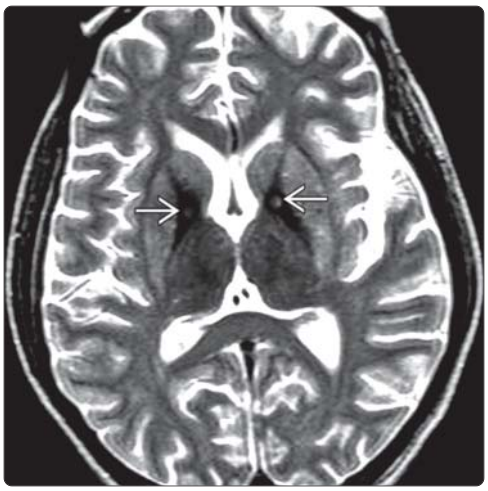


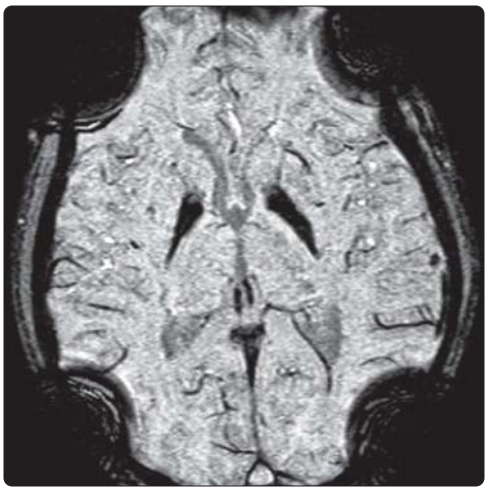
(Left) *Axial T1WI MR in a 5 year old with classic PKAN shows that the "eye" in the "eye of the tiger" is hypointense with few punctate areas of surrounding hyperintensity* ⇨. **(Right)** *Axial T1WI MR in the same patient at 9 years old shows the "eye" as mostly hyperintense. The appearance of the "eye" in "eye of the tiger" is variable depending on the stage of the disease. Progressive iron deposition within the globus pallidus likely accounts for greater T1 shortening seen in later disease.*





(Left) *Coronal T2WI MR in a patient with classic PKAN shows the classic "eye of the tiger" sign with small foci of increased T2 signal in the medial globi pallidi* ⇨ *surrounded by abnormal pallidal hypointensity.* **(Right)** *Axial T2* GRE MR in a patient with classic PKAN shows "blooming" of hypointense signal in the inferior globus pallidus and substantia nigra* ⇨. *Abnormal iron accumulation within the substantia nigra is more conspicuous on imaging as the disease progresses.*





(Left) *Axial T2WI MR in a 12 year old with advanced classic PKAN undergoing preoperative imaging for pallidotomies shows globi pallidi hypointense and atrophic with subtle "eye of the tiger" signs* ⇨. *Note also the diffuse volume loss.* **(Right)** *Axial SWI in the same patient shows "blooming" of hypointense signal within the globi pallidi. The "eyes of the tiger" are no longer seen, obscured by the "blooming" effect. SWI is more sensitive than T2* GRE due to magnetic susceptibility effects.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Autosomal dominant neurodegenerative disease
  - Loss of GABAergic neurons of basal ganglia (BG)

IMAGING

- Diffuse cerebral atrophy
- Atrophy of caudate nucleus → frontal horns enlarged
- ↑ CC:IT ratio (bicaudate ratio)
  - Shrinkage of caudate nucleus (CN) and ↑ intercaudate distance (CC)
  - Increased intercaudate distance (CC) between medial aspects of CN
  - Most specific & sensitive measure for HD
- Hyperintense signal in CN, putamina in juvenile HD
- ↓ FDG uptake in BG before any detectable atrophy
- ± frontal lobe hypometabolism

TOP DIFFERENTIAL DIAGNOSES

- Leigh disease
- Wilson disease
- Pantothenate kinase-associated neurodegeneration (formerly called Hallervorden-Spatz)
- Carbon monoxide poisoning

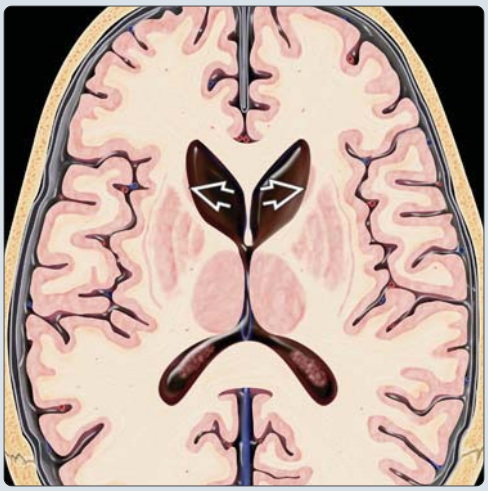
PATHOLOGY

- Autosomal dominant with complete penetrance
- CAG trinucleotide repeat disease affecting HD gene on chromosome 4p16.3

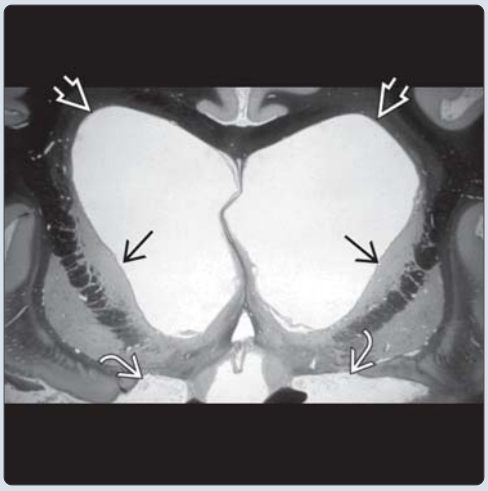
DIAGNOSTIC CHECKLIST

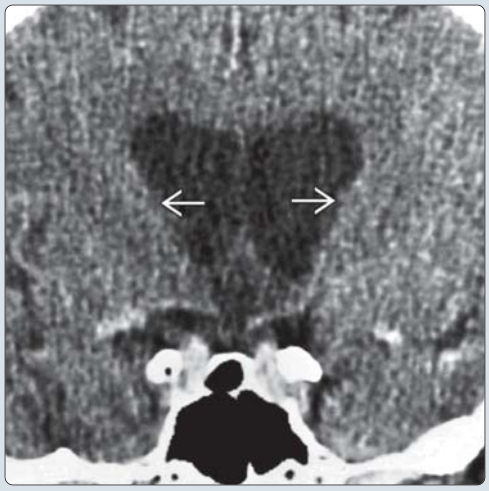
- Rule out reversible dementias, movement disorders
- Caudate atrophy is main radiologic feature of HD
- ↑ bicaudate diameter: Sensitive for CN atrophy
- Decline in size of GP, putamen correlates with disease progression
- Consider HD in child with ↑ signal in CN/putamina on PD-/T2WI

(Left) *Axial graphic shows the convex margins of the frontal horns due to atrophy of the heads of the caudate nuclei.* **(Right)** *Axial T2WI MR in a patient with juvenile Huntington disease shows generalized volume loss and striking atrophy and hyperintensity of both caudate nuclei. The frontal horns of the lateral ventricles are enlarged, and there is atrophy and hyperintensity in the putamina.*



(Left) *Autopsy specimen sectioned in the coronal plane shows enlarged lateral ventricles and basal cisterns. Both caudate nuclei appear thinned and atrophic.* **(Right)** *Coronal CECT, cut in same plane to correspond to the autopsy specimen in the previous image, shows straightening of the lateral borders of the lateral ventricles due to caudate atrophy and increased intercaudate (CC) distance, which are characteristic findings of Huntington disease.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Huntington disease (HD), huntingtin (HTT)

Synonyms

- Huntington chorea

Definitions

- Autosomal dominant neurodegenerative disease
  - Loss of GABAergic neurons of basal ganglia (BG)
- Clinical triad: Early onset dementia, choreoathetosis, psychosis

IMAGING

General Features

- Best diagnostic clue
  - Atrophy of caudate nucleus (CN) → frontal horns enlarged
- Location
  - Primarily striatum (especially CN, putamen)
  - Cerebral cortex, globus pallidus (GP), thalamus
  - Substantia nigra (SN), brainstem
- Size
  - Decreased caudate nucleus size
- Morphology
  - Loss of convex surface of caudate head

CT Findings

- NECT
  - Atrophy of CN, putamen, and (lesser degree) GP
  - Compensatory enlargement of frontal horns of lateral ventricles
  - Diffuse cerebral atrophy (reported to be predominantly frontal in some studies)
  - CN atrophy is measured on axial images at level of 3rd ventricle
    - Increased intercaudate distance (CC) between medial aspects of CN
    - CC can be compared with distance between inner tables (IT) of skull (CC:IT ratio)
    - In HD, CC is typically > 20 mm & often > 25 mm (compared to 10-14 mm in normal individuals)
    - CC:IT (bicaudate) ratio ↑ in HD; considered most specific & sensitive HD measurement
    - In HD, CC:IT ratio usually ranges from 0.175-0.185 compared to ~ 0.12 in normal individuals
    - CC compared with distance across lateral margins of frontal horns (FH) provides FH:CC ratio
    - In HD, FH:CC ratio typically ranges from 1.3-1.8 compared to 2.3-2.8 in normal individuals
- CECT
  - No contrast enhancement of affected structures

MR Findings

- T1WI
  - Shrinkage of CN and increased CC
  - MR measurements: ↓ volume in all BG structures
    - Reported even in presymptomatic stage of HD
  - Diffuse cerebral atrophy
- T2WI
  - Hyperintense signal in CN, putamina in juvenile HD
    - Related to gliosis
  - Shrinkage of CN; ↑ CC
  - Striatum may have ↓ signal due to iron deposition
  - Susceptibility weighted imaging (SWI) suggests iron accumulation
- MRS
  - ↑ lactate concentration in occipital cortex of symptomatic HD, also in BG in some patients
  - ↓ N-acetylaspartate to creatine ratio in BG (neuronal loss)
  - ↑ ↑ choline to creatine ratio in BG due to gliosis

Nuclear Medicine Findings

- PET
  - ↓ FDG uptake in BG precedes detectable atrophy
  - ± frontal lobe hypometabolism
- SPECT: Perfusion defects in motor cortex, prefrontal cortex, and BG correlate with clinical disease

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - T2WI

DIFFERENTIAL DIAGNOSIS

Leigh Disease

- Many metabolic causes
- Onset usually < 2 years old, but juvenile/adult forms also exist
- Changes in putamen, CN, and tegmentum
  - T1 hypointensities, T2 hyperintensities (infarcts)
  - No atrophy of CN and putamina
- Focal involvement of white matter, thalamus, brainstem, and cerebellum

Wilson Disease

- Rigidity, tremor, dystonia, gait difficulty, dysarthria
- T2WI: Symmetrical signal hyperintensity in CN, putamen, midbrain, and pons (gliosis and edema)
  - Asymmetrical hypointensity in frontal white matter
  - Characteristic irregular areas of hypointensity in CN and putamen
- Atrophy of CN and brainstem on CT, MR

Pantothenate Kinase-Associated Neurodegeneration

- Neurodegeneration with brain iron accumulation (formerly called Hallervorden-Spatz)
- Involuntary movements (choreoathetosis), spasticity
- Progressive dementia in young adults
- Characteristic iron deposition in GP, red nuclei, SN
  - "Eye of the tiger" sign: Central high signal in T2-hypointense GP
- GP atrophy, ± cortical, CN atrophy

Carbon Monoxide Poisoning

- Bilateral CT hypodensity, T2 hyperintensity in GP

Other Neurodegenerative Disorders, Adults

- Multiple system atrophy
- Corticobasal degeneration

https://CafePezeshki.IR

- Frontotemporal lobar degeneration

PATHOLOGY

General Features

- Etiology
  - Polyglutamine expansion → HTT fragments accumulate in nucleus; cytoplasm → aggregates in axonal terminals
- Genetics
  - Autosomal dominant with complete penetrance
  - CAG trinucleotide repeat disease affecting HD gene on chromosome 4p16.3
  - Genetic anticipation: ↑ severity or ↓ age of onset in successive generations
    - More commonly in paternal transmission of mutated allele
  - Homozygosity for HD mutation (very rare)
    - Associated with more severe clinical course

Staging, Grading, & Classification

- Based on gross striatal pathology, neuronal loss, gliosis
- Grade 0: Normal gross, histologic examination
- Grade 1: No gross striatal atrophy (only histologic changes)
- Grade 2: Striatal atrophy, convex CN
- Grade 3: More severe striatal atrophy, flat CN
- Grade 4: Most severe striatal atrophy, concave CN

Gross Pathologic & Surgical Features

- Diffuse cerebral atrophy (marked in CN, putamen)
- Juvenile HD: Involvement of GP, cerebellum (typically not involved in adults)

Microscopic Features

- Neuropathological hallmarks of HD
  - Intranuclear inclusions containing Huntington protein
  - Perinuclear aggregates in cortex, striatum

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Classic triad
    - Movement disorder (choreoathetosis)
    - Dementia of subcortical type
    - Behavioral changes/psychosis
- Other signs/symptoms
  - Dysarthria, dysphagia, abnormal eye movements
- Clinical profile
  - Pathognomonic feature of HD: Movement disorder
    - Chorea: Often facial twitching or writhing and twitching of distal extremities; ballism later on
    - Progressive cytoplasmic → impaired gait ("dancing" gait)
    - Rigidity and dystonia in later stages (adult HD)
  - Juvenile HD: Rigidity > chorea
    - Rigidity & dystonia may occur as initial symptoms
    - Cerebellar signs, dyslalia, rapid cognitive decline
    - Seizures, parkinsonism, dystonia, long-tract signs

Demographics

- Age
  - Mean at onset: 35-44 years in adult-onset HD
  - Juvenile HD (5-10% of cases): Onset at < 20 years
- Gender
  - M = F; gender-related factor affecting disease onset
    - Earlier onset, faster progression of HD in offspring of male patients
    - 70% of juvenile cases have affected father
- Ethnicity
  - Less common in African/Asian populations
- Epidemiology
  - Worldwide prevalence: 5-10/100,000 people
  - 3-7/100,000 in populations of Western European descent

Natural History & Prognosis

- Early symptoms: Personality changes and subtle movement disturbances
- Progression to choreoathetosis and dementia
- Behavioral disorganization, depression, suicidal behavior, psychotic features (visual hallucinations)
- Adult HD: Progressive deterioration until death 15-20 years after onset
- Higher degree of volume loss ↔ earlier age of onset
- Juvenile HD: More progressive clinical course

Treatment

- Antidepressants, high-potency antipsychotics
- Tetrabenazine (Dopamine depleters)
- Antiglutamatergic drugs (amantadine, memantine, riluzole)
- Ubiquinone (coenzyme Q10) → normalization of lactate levels in cortex and striatum
- Bilateral neural transplantation
- Experimental: Grafting of trophic factor-producing cell lines

DIAGNOSTIC CHECKLIST

Consider

- Reversible dementias & movement disorders

Image Interpretation Pearls

- Caudate atrophy is main radiologic feature of HD
  - Bicaudate diameter: Sensitive for CN atrophy
- Consider HD in child with ↑ signal in CN/putamina on PD-/T2WI

KEY FACTS

TERMINOLOGY

- Wilson disease (WD), hepatolenticular degeneration
- Autosomal recessive inherited copper metabolism disorder characterized by
  - Abnormal accumulation of copper in various tissues
  - Particularly in liver and brain (basal ganglia)

IMAGING

- Usually normal MR in presymptomatic patients
- SI improvement correlated with clinical response to copper-chelating therapy
- Symmetrical T2 hyperintensity or mixed intensity in putamina (with hyperintense peripheral putaminal rim), caudate nuclei, thalami, and globus pallidi (GP)
- Characteristic "face of giant panda" sign on axial sections at midbrain level

TOP DIFFERENTIAL DIAGNOSES

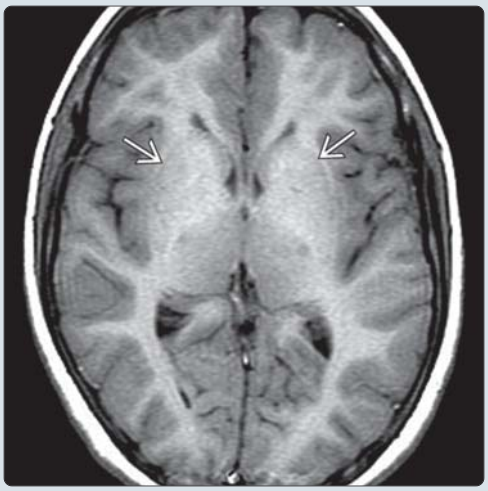
- Leigh disease
- Creutzfeldt-Jakob disease
- Japanese encephalitis
- Organic aciduria
- Hypoxic-ischemic encephalopathy

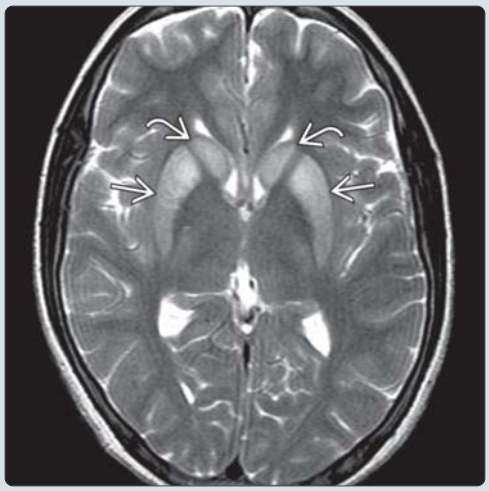
CLINICAL ISSUES

- Kayser-Fleischer ring in cornea
- Neurologic: Asymmetric tremor, ataxia, dyskinesia, dysarthria, dystonia (mainly face), incoordination
  - Chelation therapy prevents progression

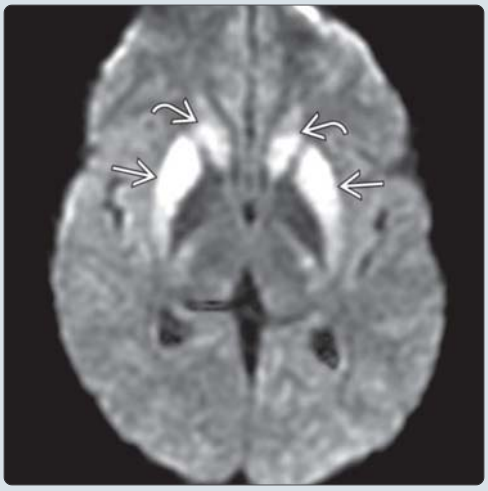
DIAGNOSTIC CHECKLIST

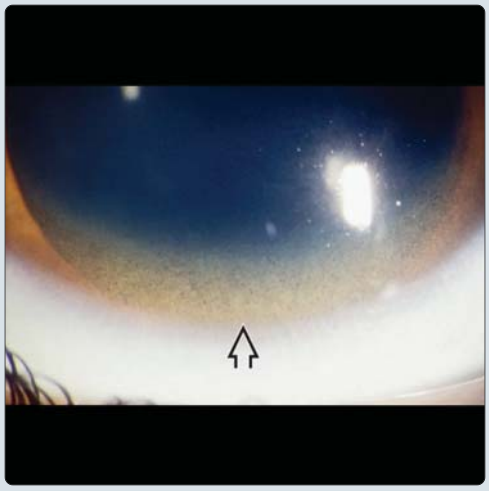
- MR improvement correlated with clinical recovery





(Left) *Axial T1WI in a patient with Wilson disease shows basal ganglia hyperintensity* ➡. **(Right)** *Axial T2WI in the same case shows hyperintensity in the caudate nuclei* ➡ *and putamen* ➡. *The globi pallidi are spared.*





(Left) *Axial DWI in the same case shows restricted diffusion in the caudate nuclei* ➡ *and putamina* ➡. *The lesions did not enhance on T1C+ imaging. (Courtesy M. Ayadi, MD.)* **(Right)** *Slit-lamp examination shows a Kayser-Fleischer ring of the cornea* ⇨, *an important marker in Wilson disease that is almost always present in patients with neurological involvement.*

TERMINOLOGY

Abbreviations

- Wilson disease (WD)

Synonyms

- Progressive hepatolenticular degeneration

Definitions

- Autosomal recessive inherited copper metabolism disorder characterized by abnormal accumulation of copper in various tissues

IMAGING

General Features

- Best diagnostic clue
  - Symmetrical T2 hyperintensity or mixed intensity in putamina, caudate nuclei, thalami, and globus pallidi (GP)
- Location
  - Most common: Putamen (predilection for outer rim)
  - Caudate nuclei, GP, thalami (ventrolateral nuclei)
  - Midbrain, pons, cerebellum (vermis and dentate nucleus)
  - Cortical and subcortical lesions (mostly frontal lobe)
- Size
  - Initially ↑ (swelling of basal ganglia [BG]), then ↓ (atrophy)
- Morphology
  - No change in shape of affected structures

CT Findings

- NECT
  - Widening of frontal horns of lateral ventricles; diffuse brain atrophy
  - ± hypodensity in lentiform nuclei and thalami
- CECT
  - Lesions do not contrast enhance

MR Findings

- T1WI
  - T1 signal generally reduced in BG
  - Signal intensity may ↑ in affected BG (paramagnetic effects of copper)
- T2WI
  - Usually normal MR in presymptomatic patients
  - Hyper-/hypo-/mixed intensity in putamen, GP, caudate, thalamus
    - Bilateral symmetric concentric-laminar T2 putaminal hyperintensity
    - BG can be hypointense due to ↑ iron content
  - Characteristic face of giant panda sign; normal signal intensity in red nucleus against background of hyperintense signal in tegmentum
  - ± hyperintensity in periaqueductal gray matter, pontine tegmentum, medulla oblongata, dentate nucleus, and cerebral and cerebellar white matter (WM), especially frontal lobe
  - Clinical response to copper-chelating therapy correlates with improvement in signal abnormalities
  - In adults, BG lesions may differ from those in children
    - Putaminal lesions may be absent; GP and substantia nigra may be hypointense on T2WI
- PD/intermediate
  - Symmetrical high signal intensity in affected BG
- DWI
  - Abnormally low ADC values immediately after onset of neurologic symptoms; subsequently high ADC values (necrosis, spongiform degeneration)
- T1WI C+
  - No contrast enhancement is typically seen
- MRS
  - ↓ N-acetyl aspartate to creatine ratio (neuronal loss) in BG, parietooccipital cortex, frontal WM
  - ↓ myoinositol to creatine ratio in BG and ↓ choline:creatine ratio in GP
  - ↓ myoinositol to creatine ratio in WD with portosystemic shunting (pattern of hepatic encephalopathy)

Nuclear Medicine Findings

- PET
  - ↓↓ glucose metabolism in cerebellum, striatum, and, to lesser extent, in cortex and thalamus
  - ↓↓ dopa-decarboxylase activity (impaired nigrostriatal dopaminergic pathway)
- SPECT
  - (I-123)2β-carbomethoxy-3β-(4(I-123)iodophenyl)tropane binds to presynaptic striatal dopamine carriers
  - (I-123)iodobenzamide binds to postsynaptic striatal dopamine D2R
  - In symptomatic WD patients
    - ↓↓ striatal binding ratios of both tracers
  - In all WD patients, highly correlated binding ratios of both tracers corresponding to severity of neurologic features

Imaging Recommendations

- Best imaging tool
  - MR more sensitive than CT for detection of early lesions
- Protocol advice
  - T2WI, FLAIR, DWI

DIFFERENTIAL DIAGNOSIS

Leigh Disease

- Subacute necrotizing encephalomyelopathy
- Symmetrical spongiform brain lesions with onset in infancy/early childhood
- Lesions predominantly bilateral and symmetrical, in brainstem, BG (particularly putamen), and cerebral WM

Hypoxic-Ischemic Encephalopathy

- Bilateral symmetric hyperintense lesions with restricted diffusion in putamen, caudate, thalamus, and cortex

Creutzfeldt-Jakob Disease

- Progressively hyperintense changes in BG, thalamus, and cerebral cortices on T2WI

Japanese Encephalitis (JE)

- Homogeneous T2 hyperintensities in BG and posteromedial thalami (very characteristic of JE, spared in WD)

Organic Aciduria

- Symmetrical diffuse WM changes, wide CSF spaces

https://CafePezeshki.IR

- BG changes (↑ T2 signal ± volume loss in caudate &/or lentiform nuclei)

Methanol Poisoning

- Bilateral symmetric T2 hyperintensity in putamen, caudate ± WM

Osmotic Demyelination Syndrome

- Involvement of pons (central median raphe), basal ganglia, and, rarely, midbrain

PATHOLOGY

General Features

- Etiology
  - Defective incorporation of copper into ceruloplasmin and impaired biliary copper excretion
  - Brain lesions caused by accumulation of copper, chronic ischemia, vasculopathy, or demyelination
- Genetics
  - Autosomal recessive: ATPase copper transporting β-polypeptide (*ATP7B*) gene on chromosome 13q14.3-q21.1
- General comments
  - Excess copper throughout brain (lesions often bilateral and symmetrical), with unexplained tendency for extensive BG damage

Staging, Grading, & Classification

- Stage 1: Initial period of accumulation of copper by hepatic binding sites
- Stage 2: Acute redistribution of copper within liver and release into circulation
- Stage 3: Chronic accumulation of copper in brain and other extrahepatic tissues

Gross Pathologic & Surgical Features

- Ventricular enlargement, sulcal widening

Microscopic Features

- Edema, necrosis, and spongiform degeneration of BG; gliosis and demyelination in WM
- Opalski cells = PAS(+) altered glial cells
- Deep pyramidal cell layers of cerebral cortex involved

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Neurologic: Asymmetric tremor, ataxia, incoordination, dyskinesia, dysarthria, dystonia (mainly facial)
    - Parkinsonian symptoms: Rigidity, bradykinesia
  - Psychiatric: Hyperkinetic behavior, irritability, emotional lability, difficulty in concentration, depression, psychosis, mania, personality change
  - Acute hepatitis
  - Kayser-Fleischer ring in cornea due to abnormal copper accumulation in Descemet membrane
- Clinical profile
  - 40-50% of patients present with liver disease
  - 40-50% present with neurological or psychiatric symptoms (corneal rings almost always present)
  - ↓ ceruloplasmin and total serum copper levels, ↑ 24-hour urinary copper excretion, and ↑ ↑ hepatic copper content

Demographics

- Age
  - Onset of liver disease usually at age 8-16 years
  - Neurological symptoms often 1st recognized in 2nd-3rd decade (rarely, age < 12 years)
- Gender
  - Generally M = F, but M:F = 1:4 for fulminant WD, i.e., liver failure, encephalopathy, coagulopathy
- Epidemiology
  - Prevalence: 1 in 30,000-40,000 people
  - Carrier frequency in USA: 1 in 90 individuals

Natural History & Prognosis

- Children: Liver disease most common presentation
- Older individuals: Neuropsychiatric symptoms
  - ↑ symptom severity with ↑ brain copper deposition
- Once symptomatic, WD is fatal if untreated; 70% mortality for patients with fulminant liver failure
- Good prognosis with early chelation treatment
  - Prevents progression; may improve symptoms
- Best prognosis: Treated asymptomatic siblings

Treatment

- Restriction of food abundant in copper (e.g., chocolate, liver, nuts, mushrooms, shellfish)
- Early administration of chelating therapy can ↓ brain damage
  - Penicillamine (side effect of initial neurological deterioration in 20-50%)
  - Other treatments: Trientine (better alternative chelator), ammonium tetrathiomolybdate, zinc (especially for presymptomatic and asymptomatic patients)
- Liver transplant (for severe hepatic decompensation)

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- T2 hyperintensity in striatum with neurologic dysfunction
- T1 hyperintensity in BG with hepatic dysfunction
- MR improvement correlated with clinical recovery

Approach to Toxic and Metabolic Disorders

Acquired toxic and metabolic disorders of the brain result from a wide variety of agents, including toxic exposures, substance abuse, radiation, and chemotherapy, as well as metabolic alterations, including hypertension, hepatic failure, hypoglycemia, and osmotic demyelination. The vast majority of toxic and metabolic disorders of the brain involve the deep gray nuclei (basal ganglia and thalamus) or the cerebral white matter. Typically, there is symmetric abnormality of the involved structures, which can provide a clue to the correct diagnosis. MR shows damage at both early and delayed phases of toxic and metabolic disorders. DWI and FLAIR are extremely valuable in differentiating among the various pathologies in this group and can help arrive at a correct diagnosis. Of course, clinical history of possible exposure or substance abuse is often the key to the patient's diagnosis.

Imaging Anatomy

Basal Ganglia

The basal ganglia (BG) are symmetric paired deep gray matter nuclei in cerebral hemispheres and form the core of the extrapyramidal system and regulate motor activity. The BG consists of caudate nucleus, putamen, and globus pallidus (GP). Caudate nucleus and putamen form the corpus striatum. The putamen and GB together are called the lentiform nuclei.

- **Caudate nucleus** is a C-shaped nucleus with a large head, tapered body, and down-curving tail. The head forms the floor and lateral wall of the anterior horn of the lateral ventricle. The caudate body parallels the lateral ventricles. The anterior limb of the internal capsule separates the caudate head from the putamen and GP.
- **Putamen** is the outermost part of the BG located lateral to GP and is separated by the lateral or external medullary lamina.
- **GP** consists of 2 segments, lateral (external) and medial (internal), separated by a thin layer of myelinated axons, the internal medullary lamina.

Thalamus

The thalamus is comprised of paired ovoid nuclear complexes that act as relay stations for most of the sensory pathways. The thalami extend from the foramen of Monro to the quadrigeminal plate of the midbrain. The medial aspect of the thalami form the 3rd ventricle lateral walls. The posterior limb of the internal capsule forms the lateral border of the thalami. The thalamus is subdivided into several nuclear groups, the anterior, medial, lateral, medial geniculate nuclei (part of the auditory system), lateral geniculate nuclei (part of the visual system), and pulvinar. These nuclear groups are further subdivided into 10 additional nuclei. The pulvinar is easily identified as it is the most posterior of the thalamic nuclei and overhangs the superior colliculus. The subthalamic nucleus is small, lens-shaped, lies superolateral to the red nucleus, and is rarely involved in toxic or metabolic disorders.

Pathologic Issues

The mechanisms for various toxic and metabolic lesions of the brain are complex and often represent a combination of various pathways. Since the deep gray nuclei are highly metabolically active and require significant oxygenation, they are commonly affected by toxins, metabolic abnormalities, and hypoxic-ischemic injury. Often, as in carbon monoxide (CO) and cyanide poisoning, there is a component of hypoxic injury that helps explain the predilection for involvement of the GP, which is extremely sensitive to hypoxia. Selective vulnerability of the deep gray nuclei is also related to dysfunction of selected excitatory neuronal circuits, inhibition of mitochondrial function, and selective loss of dopaminergic neurons.

Differential Diagnosis

Most of the pathologies that affect the brain have a characteristic location, which helps the radiologist arrive at a correct diagnosis. The following differential diagnosis considerations will provide clues to the common toxic and metabolic processes that affect the deep gray nuclei and white matter.

Basal Ganglia Calcification

Basal ganglia calcification is the end result of many toxic, metabolic, inflammatory, and infectious insults. Fahr disease is a rare neurodegenerative disorder that results in extensive bilateral BG calcifications. The GP is most commonly involved, followed by the putamen, caudate, and thalamus. Additionally, there may be involvement of the cerebellum, particularly the dentate nuclei and cerebral white matter.

Other endocrinologic disorders, including hypothyroidism and hypoparathyroidism, may cause calcification, particularly involving the GP, putamen, dentate nuclei, thalami, and subcortical white matter. Radiation and chemotherapy may result in mineralizing microangiopathy that commonly causes BG and subcortical white matter calcifications and atrophy. Physiologic calcification as part of the normal aging brain typically occurs in the GP more than the putamen.

T1 Hyperintense Basal Ganglia

Basal ganglia T1 hyperintensity is usually symmetric, related to calcification or other mineralization. T1 hyperintensity is often seen in the GP and substantia nigra in patients with a history of liver disease or hyperalimentation related to abnormal manganese metabolism. Kernicterus, related to toxic unconjugated bilirubin in a newborn, results in increased T1 signal in the GP, as well as the substantia nigra, hippocampus, and dentate nucleus.

Many endocrine disorders that result in BG calcification will also cause T1 hyperintensity. These include hypothyroidism, hyperparathyroidism, hypoparathyroidism, and pseudohypoparathyroidism. Fahr disease also results in T1 hyperintensity, particularly in the GP.

T2 Hyperintense Basal Ganglia

T2 hyperintensity within the BG is typically symmetric in toxic and metabolic disorders. Often DWI helps to differentiate the various lesions of the BG. CO poisoning classically causes symmetric GP hyperintensity but occasionally also involves the putamen, thalamus, and white matter. DWI may be positive acutely. Methanol toxicity typically results in putaminal necrosis and may be hemorrhagic. Drug abuse is another cause for abnormalities of the basal ganglia, often in young adults. Often, drug abuse results in strokes or vasculitis. Heroin and MDMA (ecstasy) often result in GP ischemia. Osmotic demyelination syndrome is acute demyelination caused by rapid shifts in serum osmolality, often in the setting of rapid correction of hyponatremia. Extrapontine myelinolysis commonly affects the caudate and putamen, as well as the white matter.

Wilson disease causes symmetric hyperintensity in the putamen, GP, caudate, and thalami. It also results in a face of

https://CafePezeshki.IR

the giant panda sign at the midbrain level with T2 hyperintense white matter tracts. Acute hypertensive encephalopathy (PRES) is a caused by hypertension and may be related to chemotherapy. PRES typically affects the cortex and subcortical white matter of the posterior circulation. However, involvement of the BG may occur. The main considerations besides toxic and metabolic insults that may cause T2 hyperintense BG are hypoxic-ischemic encephalopathy, deep venous occlusion, and infectious etiologies.

Globus Pallidus Lesions

Lesions that often only involve the GP include CO poisoning, cyanide poisoning, heroin and MDMA (ecstasy) abuse, kernicterus, neurodegeneration with brain iron accumulation (NBIA)-pantothenate kinase-associated neurodegeneration (PKAN), hyperalimentation, hepatic encephalopathy, and methylmalonic acidemia. NBIA is a group of progressive neurodegenerative disorders with extrapyramidal motor impairment and brain iron accumulation, resulting in GP T2 hypointensity. PKAN, also known as Hallervorden-Spatz syndrome or NBIA-1, has a classic eye of the tiger appearance with bilateral, symmetric GP T2 hyperintensity surrounded by hypointensity.

Other disorders that commonly affect the GP more prominently than the other BG nuclei include Fahr disease, hypothyroidism, and Wilson disease. As with other lesions of the BG, hypoxic-ischemic encephalopathy should also be considered.

Bilateral Thalamic Lesions

Thalamic lesions are most commonly caused by arterial or venous ischemia or hypoxic-ischemic encephalopathy. However, they are also involved in many toxic and metabolic processes. Alcoholic encephalopathy, particularly Wernicke encephalopathy, typically results in T2 hyperintense medial thalami, mammillary bodies, hypothalamus, and periaqueductal gray matter. Wernicke encephalopathy results from a vitamin B1 deficiency and is frequently associated with alcohol abuse. T1 hyperintensity in the pulvinar is a common and sensitive finding for Fabry disease and is considered by many as the T1 pulvinar sign. Fabry disease is a rare multisystem X-linked disorder that includes renal and cardiac dysfunction and strokes. Although Fahr disease most commonly causes extensive bilateral calcification of the BG, the thalami are frequently affected.

Other diseases that affect the thalami include PRES, vasculitis, osmotic demyelination, and acute disseminated encephalomyelitis. Additionally, many of the encephalitides affect the thalami, including Ebstein-Barr virus, Japanese encephalitis, and West Nile virus. Creutzfeldt-Jakob disease (CJD) often affects the basal ganglia and thalami symmetrically.

Diffuse White Matter Abnormality

Toxic and metabolic disorders often cause a confluent T2 hyperintense leukoencephalopathy. Radiation and chemotherapy classically causes a leukoencephalopathy with T2 hyperintensity throughout the cerebral white matter. Sparing of the subcortical U-fibers is typical. A diffuse necrotizing leukoencephalopathy may also result, commonly from a combination of radiation and chemotherapy, which causes white matter necrosis in addition to leukoencephalopathy. Heroin vapor inhalation, a.k.a. chasing the dragon syndrome, causes a toxic leukoencephalopathy that results in T2 hyperintense cerebellar white matter and the posterior limb of the internal capsule showing involvement of the posterior cerebral white matter, with relative sparing of the subcortical white matter.

Hypothyroidism related to Hashimoto thyroiditis may result in a diffuse confluent white matter encephalopathy that typically affects the anterior cerebral white matter. There is involvement of the subcortical U-fibers but relative sparing of the posterior hemispheres. Acute liver failure may also result in diffuse edema with T2 hyperintensity in the periventricular and subcortical white matter. Cortex involvement is typical. PRES typically involves the cortex and subcortical white matter in a posterior circulation. Alcoholic encephalopathy may rarely result in diffuse white matter T2 hyperintensity related to acute demyelination.

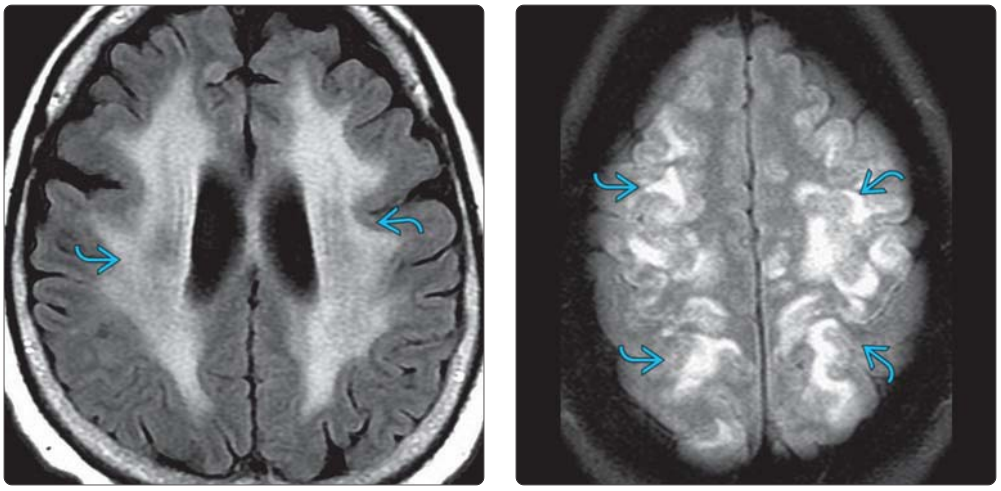
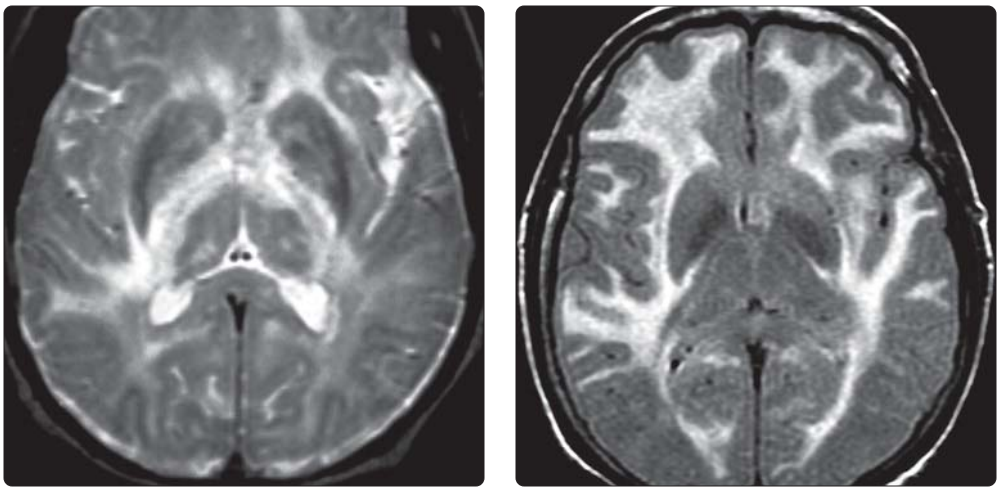
(Left) *Axial DWI MR shows hyperintensity in the internal capsule posterior limbs, corpus callosum splenium, and occipital white matter related to heroin-induced leukoencephalopathy, a.k.a. chasing the dragon syndrome.* **(Right)** *Axial FLAIR MR shows extensive, symmetric hyperintensity in the basal ganglia, cortex, and subcortical white matter related to profound hypoglycemia. Predilection for the parietal and occipital lobes is typical.*



(Left) *Axial FLAIR MR in a patient with history of whole brain radiation shows extensive hyperintensity throughout the white matter* ⇨ *and sparing of the subcortical U-fibers, typical of treatment-related leukoencephalopathy. Radiation and chemotherapy cause a variety of toxic injuries to the brain, with leukoencephalopathy being the most common.* **(Right)** *Axial FLAIR MR shows bilateral cortical and subcortical hyperintensities* ⇨ *related to acute hypertensive encephalopathy or PRES.*



(Left) *Axial T2WI MR shows diffuse white matter hyperintensity related to severe alcohol poisoning from binge drinking and acute demyelination.* **(Right)** *Coronal FLAIR MR shows diffuse, symmetric white matter hyperintensity with involvement of the subcortical U-fibers. There is relative sparing of the occipital lobes, typical of Hashimoto encephalopathy, a rare complication of Hashimoto thyroiditis.*

https://CafePezeshki.IR

KEY FACTS

IMAGING

- Consider if bilateral occipital/parietal bright DWI signal in neonate with seizures
- Occipital > parietal > frontal, temporal lobe
- ± basal ganglia, thalamus, brainstem involvement
- White matter injury common, may be predominantly periventricular in premature
- Increased DWI signal corresponds to normal to low ADC acutely, DWI normalizes after 1st week
- Normal to low NAA, ± lactate

TOP DIFFERENTIAL DIAGNOSES

- Term hypoxic-ischemic injury
- Preterm hypoxic-ischemic injury
- MELAS
- Venous Infarct
- Acute Hypertensive Encephalopathy (PRES)

PATHOLOGY

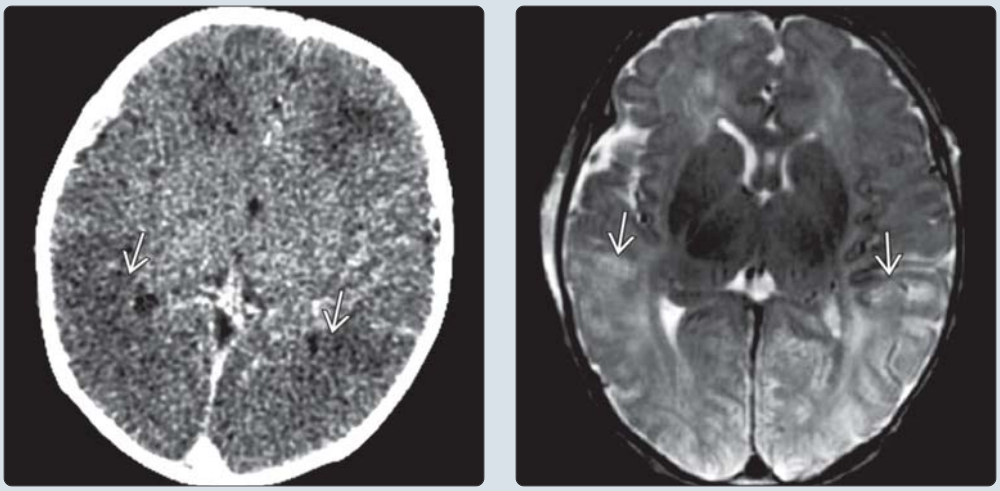
- Upper cortical layers involved, not intermediate and deep layers as in hypoxic-ischemic injury
- No selective involvement of watershed areas

CLINICAL ISSUES

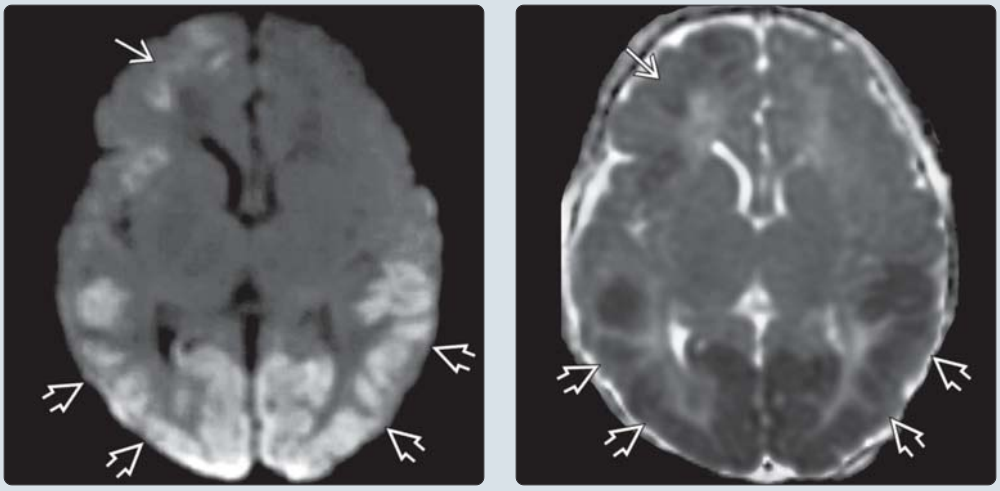
- Stupor, jitteriness, seizures, apnea, irritability, hypotonia
- Usually presents within first 3 days of life
- Threshold for injury unknown but likely a factor of severity and duration as well as associated insults
- M > F
- Prognosis depends on prompt recognition & treatment of hypoglycemia
- Long-term prognosis correlated with WM damage on MR

DIAGNOSTIC CHECKLIST

- Do not equate DWI abnormalities with infarcts (pan necrosis) as acute DWI abnormalities may result in only mild volume loss, especially if ADC not decreased



(Left) *Axial CECT in a 3 day old with severe hypoglycemia shows decreased attenuation in the posterior cerebrum involving the occipital, parietal (not shown), and posterior temporal lobes bilaterally with loss of gray-white differentiation.* **(Right)** *Axial T2WI MR in the same patient 1 day later shows posterior T2 cortical and subcortical hyperintensity involving occipital, parietal (not shown), and posterior temporal lobes bilaterally. Note the loss of gray-white differentiation.*



(Left) *Axial DWI MR in the same patient shows increased signal in the occipital, parietal (not shown), and posterior temporal lobe bilaterally, with less severe right frontal lobe and insular cortex involvement.* **(Right)** *Axial ADC in the same patient shows markedly decreased signal intensity in the posterior regions of the cerebral hemispheres. The right frontal lobe is actually reduced diffusivity and not a result of T2 effects "shining through."*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Significant hypoglycemia
  - Plasma glucose level < 30-35 mg/dL in the first 24 hours of life
  - < 40- 45 mg/dL (after 24 hours)

IMAGING

General Features

- Best diagnostic clue
  - Bilateral occipital/parietal bright DWI in neonate with seizures
- Location
  - Occipital > parietal > frontal, temporal lobes
  - ± basal ganglia, thalamus, brainstem involvement
  - White matter injury common; may be predominantly periventricular in premature
  - Hypoglycemia that is less severe can accentuate watershed zone injuries in neonate hypoxic-ischemic injury

CT Findings

- NECT
  - Decreased attenuation with loss of gray-white differentiation in acute and subacute phase
  - Cortical Ca++ in chronic phase

MR Findings

- T1WI
  - Cortical ± deep gray hyperintensity in subacute phase
  - ± foci of increased T1 signal in white matter
- T2WI
  - Increased signal in gray and white matter with loss of gray-white distinction in acute phase
  - Increased signal in gray and white matter with variable cortical low signal in subacute phase
  - Volume loss ± gliosis that may be subtle to cystic encephalomalacia in chronic phase
- DWI
  - Increased DWI signal corresponds to low ADC acutely
  - DWI normalizes after 1st week
  - DWI most sensitive to identify parietal-occipital injury
- MRS
  - Normal to low NAA
  - ± lactate

Ultrasonographic Findings

- Grayscale ultrasound
  - Increased echogenicity

Imaging Recommendations

- Best imaging tool
  - MR with DWI
- Protocol advice
  - Higher b values (b = 1,000-1,500 s/mm²) make areas of decreased diffusion more conspicuous

DIFFERENTIAL DIAGNOSIS

Term Hypoxic-Ischemic Injury

- Hypoglycemia and hypoxic-ischemic injury (HII) often coexist & potentiates extent of brain injury
- HII causes hypoglycemia
- DWI in partial HII with hypoglycemia may be indistinguishable from posterior predominant normoglycemic partial HII

Preterm Hypoxic-Ischemic Injury

- Hypoglycemia potentiates periventricular leukomalacia

MELAS

- MELAS- mitochondrial encephalopathy with lactic acidosis & stroke-like episodes
- Consider if marked elevation in lactate or if no history of hypoglycemia

Status Epilepticus

- Seizures are typical response of newborn brain to injury
  - DWI abnormalities in newborns more likely to be cause (not consequence) of seizures
- Vicious cycle may develop where cerebral injury is exacerbated by seizures

Venous Infarct

- Often associated hemorrhage and edema; MRV to rule out

Acute Hypertensive Encephalopathy (PRES)

- Cortical & subcortical T2/FLAIR hyperintensity with predominant posterior distribution
- Predominantly increased ADC, older patients

PATHOLOGY

General Features

- Etiology
  - Inadequate energy substrate (oxygen, glucose, lactate) availability/reserve: IUGR, preeclampsia, maternal hypoglycemia, prolonged fasting, prematurity
  - ↑ glucose utilization: Hypoxia, stress
  - Hyperinsulinemia
    - Uncontrolled maternal diabetes
    - Hyperinsulinemic hypoglycemia, familial, 1 or 2 (HHF1 or HHF2)
  - Beckwith-Wiedemann syndrome (BWS)
    - Inherited disorder with macrosomia, macroglossia, visceromegaly, omphalocele, embryonal tumors, & renal abnormalities
    - BWS- associated hypoglycemia are mild & transient
  - Other endocrine abnormalities: Panhypopituitarism, hypothyroidism, adrenal insufficiency
  - Other: Polycythemia, congenital heart disease
  - Excitatory amino acids (glutamate) and oxidative stress are thought to play central role in neuronal death
- Glucose metabolism
  - Glucose primary metabolic fuel for brain
  - Brain is major determinant of hepatic glucose production
  - Neonates have disproportionally high glucose production relative to body size due to disproportionately large neonatal brain

https://CafePezeshki.IR

- Immature brain more resilient to hypoglycemia than adult
  - Lower absolute demand
  - Increased ability to increase cerebral blood flow
  - Utilization of other substrates (i.e., lactate)
  - Resistance of neonatal heart to hypoglycemia
- Hypoglycemia potentiates hypoxic-induced damage

Staging, Grading, & Classification

- Clinical categories
  - Transitional adaptive hypoglycemia
    - Very early onset; mild, brief hypoglycemia
    - Responds rapidly to treatment
    - Diabetic mothers, erythroblastosis, difficulty transitioning to extrauterine life
  - Secondary associated hypoglycemia
    - Early 1st day; mild, short-duration hypoglycemia
    - Responds rapidly to treatment
    - Associated CNS disorder (HII, intracranial hemorrhage, sepsis)
  - Classic transient hypoglycemia
    - End of 1st day; moderate to severe, often prolonged hypoglycemia
    - Requires large amounts of glucose
    - IUGR, ↓ substrate/impaired gluconeogenesis
  - Severe recurrent hypoglycemia
    - Variable onset; severe, prolonged hypoglycemia
    - May persist despite treatment
    - Most have primary disorder of glucose metabolism
      - e.g., BWS, HHF1 or HHF2/persistent hyperinsulinemia hypoglycemia of infancy (PHHI)/nesidioblastosis, β-cell hyperplasia, endocrine deficiencies, inborn errors in metabolism

Gross Pathologic & Surgical Features

- Pale, edematous brain; blurred gray-white junction

Microscopic Features

- Widespread injury to cerebral cortex, hippocampus, basal ganglia, thalamus, brainstem, spinal cord
- Upper cortical layers involved, not intermediate and deep layers as in hypoxic-ischemic injury
- No selective involvement of watershed areas
- Severe degeneration of glial cells
- Periventricular white matter injury may be prominent

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Stupor, jitteriness, seizures, apnea, irritability, hypotonia
  - May have no symptoms
  - When associated with neonatal HIE, may present with neonatal encephalopathy
- Clinical profile
  - Small or large neonates

Demographics

- Age
  - Usually presents within first 3 days of life
- Gender
  - M > F

Natural History & Prognosis

- Cerebral glucose metabolism probably flow limited, so dependent on CBF
- Threshold for injury unknown but likely a factor of severity and duration as well as associated insults
- < 45 mg/dL may have deleterious long-term effects even if no neonatal signs
- Epilepsy (may have intractable seizures), developmental delay, motor delay, learning and behavior problems, hyperactivity and attention difficulties, autistic features, microcephaly, cortical blindness
- DWI abnormalities associated with later deficits (occipital lobe low ADC associated with later cortical visual loss)
- Regions of bright DWI and minimal ADC decrease may have minimal to no volume loss on follow-up
- Prognosis depends on prompt recognition & treatment of hypoglycemia
- Long-term prognosis correlated with WM damage on MR

Treatment

- Glucose level to treat controversial; consider if 40-45 mg/dL
- Glucose infusion to restore normal glucose levels, often even if asymptomatic
- Frequent feeds, increased caloric density, continuous NG feeds ± cornstarch, continuous IV dextrose, hydrocortisone, diazoxide, octreotide, glucagon, Ca++ channel blocker, partial pancreatectomy

Prevention

- Control maternal diabetes, preeclampsia/eclampsia, nutrition, prevention/rapid treatment of perinatal asphyxia
- Identify high-risk infant, temperature control, oral feeds in 1st hours of life, glucose test when indicated

DIAGNOSTIC CHECKLIST

Reporting Tips

- Do not equate DWI abnormalities with infarcts (pan necrosis), as acute DWI abnormalities may result in only mild volume loss, especially if ADC not decreased

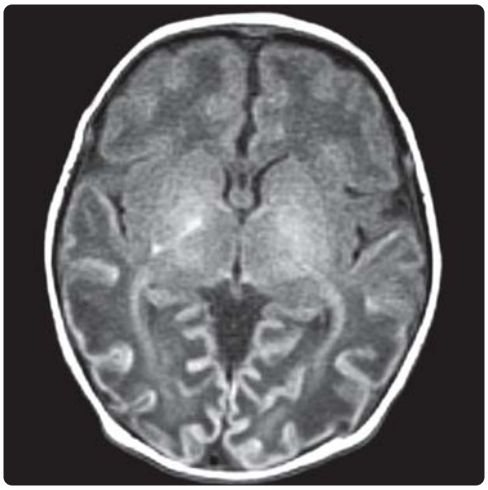
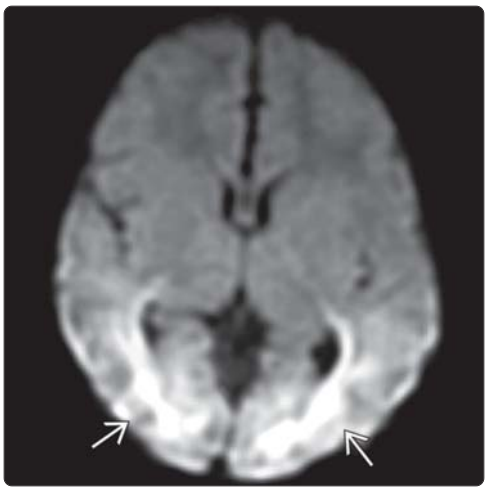
(Left) *Axial T2WI MR in a 5-day-old hypoglycemic infant shows increased signal in the parietal cortex ➡ and underlying parietal white matter ⇨ with loss of gray-white distinction. Note the extension of hyperintensity ⇨, probably representing interstitial edema, into the splenium of the corpus callosum.* **(Right)** *Axial ADC in the same infant shows reduced diffusivity in the parietal cortex and white matter ➡, as well as in the posterior corpus callosum ⇨.*



(Left) *Axial T2WI MR in the same patient at 7 days shows the evolution of hypoglycemic injury, with increased signal in the posterior white matter, including posterior limb of the internal capsules and pulvinar thalamus ⇨. The overlying cortex shows patchy increased and decreased signal.* **(Right)** *Axial T1WI MR at 7 days shows evolving injury: Decreased signal in the posterior white matter and pulvinar thalamus, increased signal in the overlying cortex and posterior limb internal capsule.*



(Left) *Axial DWI MR at 7 days in the same patient with hypoglycemic injury shows increased signal ➡ in the posterior white matter and overlying cortex. At this stage, diffusivity is pseudonormalizing, so the increased signal is likely a result of T2 shine through.* **(Right)** *Axial T2WI MR in the same patient at 1 year of age shows chronic injury with marked volume loss and gliosis involving the cortex and white matter of the posterior temporal lobes, parietal lobes (not shown), and occipital lobes.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Adult hypoglycemic encephalopathy (AHE)
- Imbalance between glucose supply, utilization → brain injury
- Hypoglycemia: Sudden decrease in serum glucose level < 50 mg/dL

IMAGING

- Stroke/coma in adult diabetic on insulin replacement therapy (IRT)
- Parietal/temporal/occipital lobes, basal ganglia, ± hippocampi
- Hyperintensity in parietooccipital cortex and basal ganglia
- Thalami, subcortical/deep white matter and cerebellum generally spared
- Restricted diffusion, ↓ ADC (may be transient)
- ↓ NAA, ↑ lactate

TOP DIFFERENTIAL DIAGNOSES

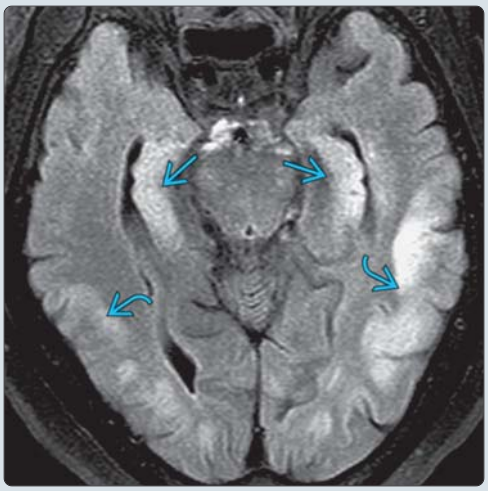
- Acute cerebral ischemia/infarction
- Hypoxia, hypoperfusion
- Acute hypertensive encephalopathy (PRES)

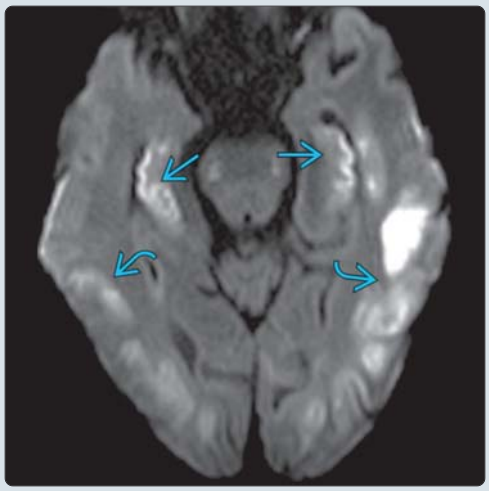
PATHOLOGY

- Caused by IRT either without adequate glucose intake or excessive glucose utilization
- Ingestion of oral hypoglycemic medication, either accidental or intentional
- Accumulation/release of excitatory neurotransmitters increases glucose utilization
- Patchy or diffuse laminar necrosis
  - Varying severity, WM generally spared

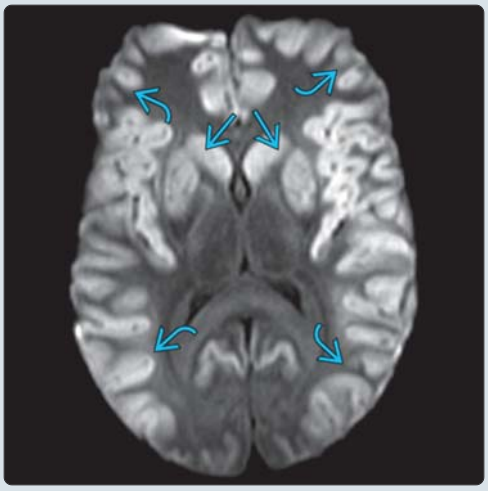
CLINICAL ISSUES

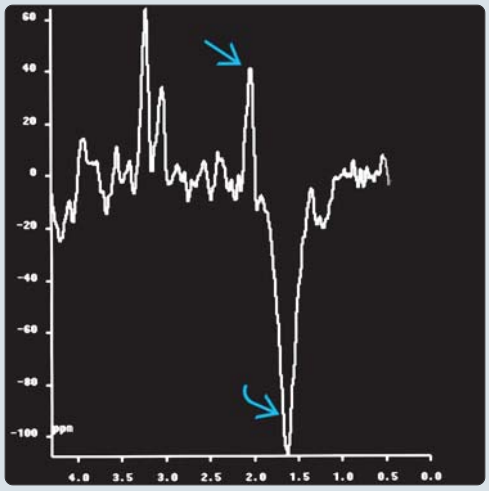
- Often elderly diabetic, altered dietary glucose intake
- Coma, depressed level of consciousness
- May be preceded by seizures





(Left) *Axial FLAIR MR in a diabetic patient with altered sensorium and a blood glucose of 36 mg/DL shows symmetric hyperintensity involving the hippocampus, temporal and occipital cortex bilaterally.* **(Right)** *Axial DWI image in the same patient shows corresponding areas of restricted diffusion in the hippocampus, temporal and occipital cortex. Prognosis in adult hypoglycemic encephalopathy varies with severity and duration of hypoglycemia, as well as extent of brain injury.*





(Left) *Axial DWI images in patient with overdose of glipizide (sulfonylureas class of oral diabetes medicine) and blood glucose level of 20 mg/DL shows severe changes of hypoglycemic encephalopathy. There is extensive symmetric diffusion restriction in the basal ganglia and cerebral cortex.* **(Right)** *Intermediate TE MR spectroscopy in the a patient with hypoglycemia shows a relatively low NAA peak, as well as a prominent lactate peak.*

TERMINOLOGY

Abbreviations

- Adult hypoglycemic encephalopathy (AHE)

Synonyms

- Hypoglycemic brain injury
- Diabetic coma (nonspecific; term may include AHE)

Definitions

- Imbalance between glucose supply, utilization → brain injury
- Hypoglycemia: Sudden decrease in serum glucose level < 50 mg/dL

IMAGING

General Features

- Best diagnostic clue
  - Stroke/coma in adult diabetic on insulin replacement therapy (IRT)
- Location
  - Parietal/temporal/occipital lobes, basal ganglia, ± hippocampi
  - Thalami usually spared

CT Findings

- NECT
  - Hypodense parietal, occipital lobes
    - Superimposed on diffuse edema

MR Findings

- T1WI
  - Early: Gyral swelling, sulcal effacement
  - Subacute and chronic: Curvilinear gyral hyperintensity (laminar necrosis)
- T2WI
  - Hyperintensity in parietooccipital cortex and basal ganglia
  - Thalami, subcortical/deep white matter and cerebellum generally spared
- DWI
  - Restricted diffusion, ↓ ADC (may be transient)
- MRS
  - ↓ NAA, ↑ lactate

Imaging Recommendations

- Best imaging tool
  - MR + DWI

DIFFERENTIAL DIAGNOSIS

Acute Cerebral Ischemia/Infarction

- Wedge-shaped, vascular distribution (MCA > PCA)
- Both cortex and underlying WM involved
- Patchy focal hemorrhage common
  - Uncommon in AHE

Hypoxia, Hypoperfusion

- Post cardiac arrest, global hypoperfusion
- Bilateral symmetric thalamic injury
  - Uncommon in AHE

Acute Hypertensive Encephalopathy (PRES)

- Uncontrolled HTN or immunosuppressive medication
- Usually no restriction on DWI

PATHOLOGY

General Features

- Etiology
  - Cellular glucose needs, supply imbalance
    - IRT without adequate dietary intake
    - Accidental/intentional ingestion of oral hypoglycemic agents
    - β-cell hypertrophy (nesidioblastosis)
      - Post gastric bypass similar to persistent hyperinsulinemic hypoglycemia of infancy (PHHI)
      - May require subtotal pancreatectomy
  - Glucose insufficiency-impaired oxygen utilization
    - Accumulation/release of excitatory neurotransmitters

Gross Pathologic & Surgical Features

- Pale/edematous brain, blurred GM-WM boundary
- Cortical ± basal ganglia injury

Microscopic Features

- Variable patchy/diffuse laminar necrosis
- WM generally spared

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Coma, depressed level of consciousness
  - May be preceded by seizures
- Clinical profile
  - Elderly diabetic with altered dietary intake
    - Due to deprivation or other factors (e.g., EtOH)

Natural History & Prognosis

- Prognosis varies with severity and duration of hypoglycemia as well as extent of brain injury
- Correlates with basal ganglia (BG) injury
  - If BG significantly involved, meaningful neurologic recovery diminished
  - If no/minimal BG injury, residual deficits are determined by extent and severity of cortical injury

Treatment

- Intravenous glucose, monitoring, supportive care

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- WM sparing, lack of hemorrhage help differentiate from hypoxic-ischemic injury
- Bilateral thalamic injury more typical of hypoperfusion/hypoxia

KEY FACTS

TERMINOLOGY

- Kernicterus or bilirubin encephalopathy: Pathological bilirubin staining of basal ganglia, brainstem, and hippocampi associated with hyperbilirubinemia

IMAGING

- Acute: ↑ T1 signal in globus pallidus (GP), subthalamic nuclei (STN), hippocampi, substantia nigra (SN)
- Chronic: ↑ T2 signal in GP, hippocampi
- MRS: ↑ Tau/Cr, ↑ Glx/Cr, ↑ mI/Cr, ↓ Cho/Cr

TOP DIFFERENTIAL DIAGNOSES

- Hyperalimentation, liver failure: ↑ T1 signal GP, SN
- Toxic: CO poisoning
- Metabolic: Methylmalonic acidemia, creatine deficiency, succinic semialdehyde dehydrogenase deficiency, L2-hydroxyglutaric aciduria
- Term hypoxic-ischemic injury

PATHOLOGY

- Encephalopathy due to ↑ unconjugated bilirubin crossing immature blood-brain barrier (BBB)
- Neurons > glia, neuropil spongiosis
- Yellow staining > MR abnormality

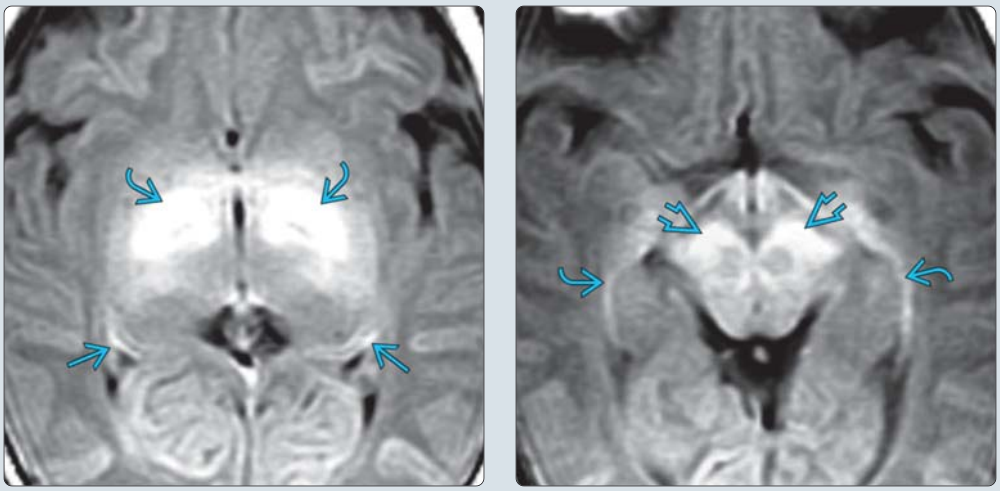
CLINICAL ISSUES

- Stupor, hypotonia, poor suckling, high-pitched cry
- Incidence ↑ with early discharge, ↑ breastfeeding
- Specific damage to brainstem auditory nuclei, ± deafness or abnormal auditory processing (most common)
- Athetosis, gaze abnormal in most; intellectual deficits in few

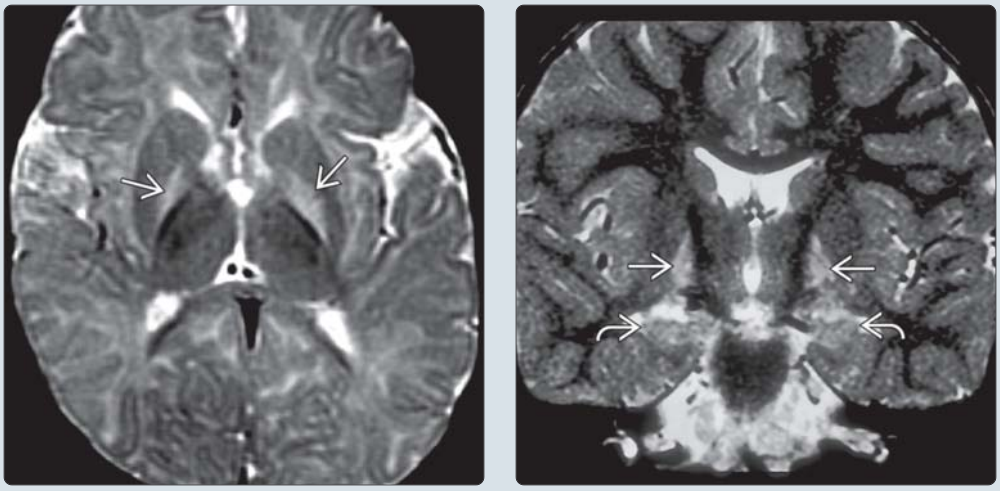
DIAGNOSTIC CHECKLIST

- Normal MR does not rule out long-term sequelae
- ↑ T1 signal in GP can be normal in neonates; look for other areas of involvement
- Findings may resolve with therapy

(Left) *Axial T1 MR in a neonate with hyperbilirubinemia, stupor, hypotonia, and increased irritability shows increased signal with the globi pallidi and hippocampal tails.* **(Right)** *Axial T1 MR in the same neonate shows abnormally increased signal within the substantia nigra and hippocampus bilaterally. The cerebral cortex and the underlying white matter have a normal appearance.*



(Left) *Axial T2WI MR of the same infant at the age of 6 months shows high T2 signal intensity and volume loss in globus pallidus bilaterally. The volume of the cerebral white matter is somewhat diminished.* **(Right)** *Coronal T2WI MR in a young child who had severe neonatal hyperbilirubinemia shows increased T2 signal and volume loss in the bilateral globi pallidi, as well as in the hippocampal heads bilaterally.*



https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Bilirubin (BR) or posticteric encephalopathy

Definitions

- Kernicterus or bilirubin encephalopathy: Pathological bilirubin staining of basal ganglia, brainstem, and hippocampi associated with hyperbilirubinemia

IMAGING

General Features

- Best diagnostic clue
  - Acute: ↑ T1 signal in globus pallidus (GP), subthalamic nuclei (STN), hippocampi, substantia nigra (SN)
  - Chronic: ↑ T2 signal in GP, hippocampi

MR Findings

- T1WI
  - Acute: ↑ T1 signal in GP > STN > hippocampi > SN
    - Deposition of unconjugated BR (UBR) or ↑ manganese (Mn)
- T2WI
  - Subacute & chronic: ↑ T2 signal/volume loss in GP, hippocampi, ± SN
- MRS
  - ↑ Tau/Cr, Glx/Cr, mI/Cr, ↓ NAA/Cho,NAA/Cr, Cho/Cr

Imaging Recommendations

- Best imaging tool
  - MR

DIFFERENTIAL DIAGNOSIS

T1 Hyperintense Globus Pallidus

- Hyperalimentation, liver failure, asphyxia, neurofibromatosis

T2 Hyperintense Globus Pallidus

- Toxic: CO poisoning
- Metabolic: Methylmalonic acidemia, creatine deficiency, succinic semialdehyde dehydrogenase deficiency, L2-hydroxyglutaric aciduria
- Normotensive hypoxia

Term Hypoxic-Ischemic Injury

- Acute: ↑ T2 signal; subacute/chronic: ↑ T1 signal in ventrolateral thalamus, corticospinal tract

PATHOLOGY

General Features

- Etiology
  - Encephalopathy due to ↑ UBR crossing immature blood-brain barrier (BBB)
  - Risk factors for ↑ BR
    - Hemolytic disorders (especially erythroblastosis fetalis), breastfeeding, > 10% loss of birth weight, polycythemia, dehydration
  - Risk factors for ↑ susceptibility to brain damage at ~ normal BR levels
    - Drugs compete for albumin binding of bilirubin
    - Sulphonamides, ceftriaxone, salicylates, Na benzoate, hormones
    - Renal hypoalbuminemia, hepatic failure, ↓ thyroidism
    - Prematurity, asphyxia, sepsis
    - ↑ cerebral blood flow; abnormal BBB
- Genetics
  - Some 2q37 (Crigler-Najjar syndrome, etc.)

Gross Pathologic & Surgical Features

- Yellow staining > MR abnormality
  - GP, SN, STN, hippocampi > thalamus, striatum, cranial nerve nuclei (3, 8), dentate nuclei, reticular formation, spinal cord
  - Also Purkinje cells (premature infants)

Microscopic Features

- Neurons > glia, neuropil spongiosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Stupor, hypotonia, poor suckling, high-pitched cry
  - Over days, may develop stupor, irritability, ↑ tone
  - May have no or equivocal neurological signs

Demographics

- Age
  - Preterm > term; 1st days of life
- Gender
  - M > F
- Ethnicity
  - More prevalent in Asians, Hispanics
- Epidemiology
  - Incidence ↑ with early discharge, ↑ breastfeeding

Natural History & Prognosis

- Specific damage to brainstem auditory nuclei → ± deafness or abnormal auditory processing (common)
- Athetosis, gaze abnormality; intellectual deficits in few

Treatment

- Maternal screen, anti-Rh; fetal blood transfusion
- Hydration, phototherapy for moderate + exchange transfusion for severe
- Other, e.g., heme oxygenase inhibitors

DIAGNOSTIC CHECKLIST

Consider

- Normal MR does not rule out long-term sequelae

Image Interpretation Pearls

- ↑ T1 signal in GP can be normal in neonates; look for other areas; findings may resolve with therapy

KEY FACTS

TERMINOLOGY

- Hashimoto encephalopathy (HE)
- HE synonym: Steroid-responsive encephalopathy associated with autoimmune thyroiditis (SREAT)

IMAGING

- Pituitary hyperplasia (PH): Symmetrical pituitary enlargement that is reversible with thyroid hormone replacement therapy (THRT)
- Basal ganglia variably hyperintense (Ca++)
- HE: Bilateral patchy or confluent subcortical and periventricular white matter (WM) T2 hyperintensity with relative sparing of occipital lobes, bilateral and symmetric or unilateral mesial temporal lobe edema

TOP DIFFERENTIAL DIAGNOSES

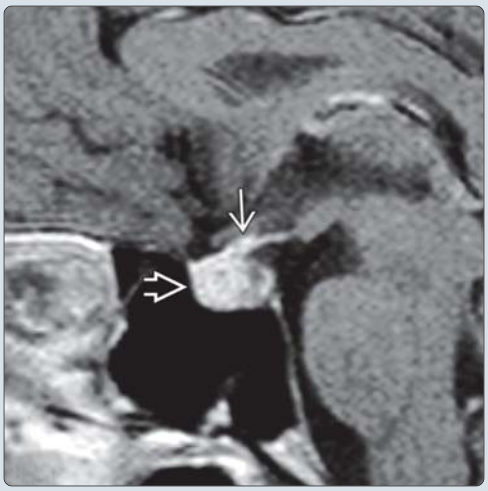
- Pituitary macroadenoma
- Physiologic pituitary hyperplasia
- Confluent white matter lesions

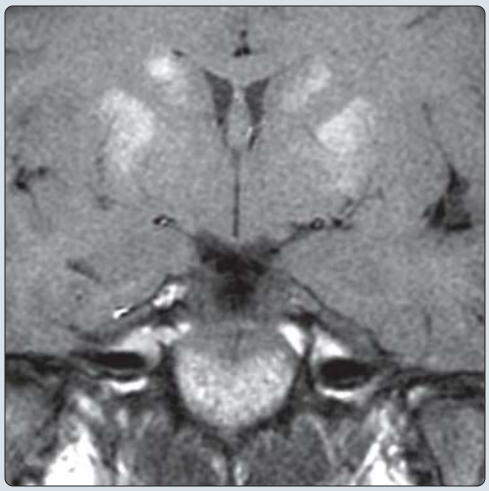
PATHOLOGY

- Diffuse hyperplasia of anterior pituitary responds to treatment
- **HE**
  - High titers of antithyroglobulin or anti-TPO (antimicrosomal) antibodies
  - Various studies reported no evidence of pathogenic role of antibodies in HE

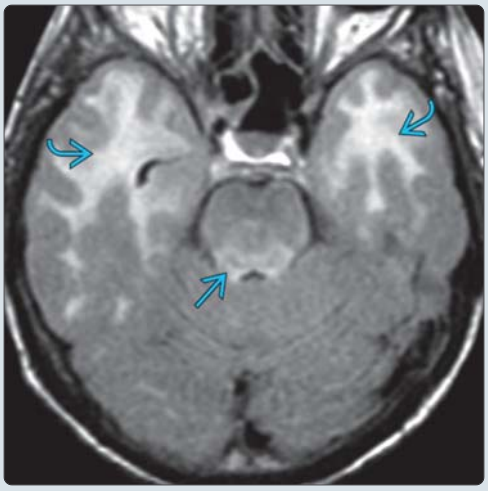
CLINICAL ISSUES

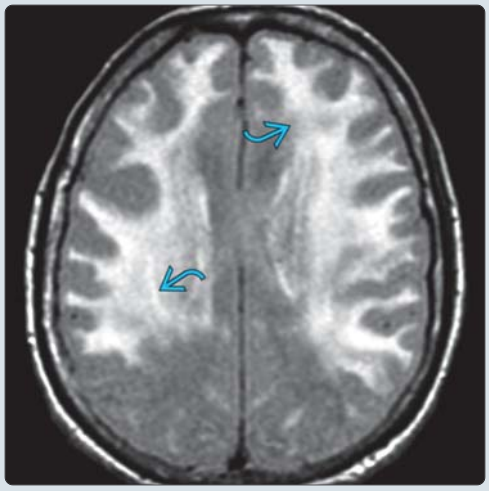
- Hypothyroidism: Poor memory, psychomotor slowing, depression, reversible dementia
- In congenital hypothyroidism, thyroid hormone replacement ASAP (< 13 days)
- HE: 2 types of initial clinical presentation, acute stroke-like (vasculitic type) episode and gradual cognitive impairment
  - Confusion, focal/generalized seizure, focal neurological deficit, cognitive decline, dementia





(Left) *Sagittal T1WI C+ MR shows an enlarged homogeneously enhancing pituitary gland* ⇨ *with infundibular thickening* ⇨ *related to hypothyroid-induced pituitary hyperplasia. The hyperplasia resolves with thyroid replacement therapy.* **(Right)** *Axial T1WI MR shows a focal T1 hyperintensity related to hypothyroidism, involving the caudate heads and globus pallidus bilaterally. These changes are related to mineralization of the basal ganglia, which are hyperdense on CT.*





(Left) *Axial FLAIR MR shows extensive hyperintensity throughout the anterior temporal white matter* ⇨ *and dorsal pons* ⇨ *related to leukoencephalopathy in a patient with Hashimoto encephalopathy.* **(Right)** *Axial FLAIR MR in the same patient shows extensive involvement of the white matter* ⇨ *with relative sparing of the posterior cerebral hemispheres. Involvement of the subcortical U-fibers is typical of Hashimoto encephalopathy.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hashimoto encephalopathy (HE)
- Pituitary hyperplasia (PH)

Synonyms

- HE: Steroid-responsive encephalopathy associated with autoimmune thyroiditis (SREAT)

Definitions

- Thyroid hormone deficiency affecting multiorgan systems

IMAGING

General Features

- Best diagnostic clue
  - PH: Symmetrical pituitary enlargement that is reversible with thyroid hormone replacement therapy (THRT)
  - HE: Bilateral patchy or confluent subcortical and periventricular white matter (WM) T2 hyperintensity with relative sparing of occipital lobes, bilateral and symmetric or unilateral mesial temporal lobe edema
- Location
  - PH: Pituitary enlarged, variable suprasellar extension/mass effect
  - HE: Subcortical and periventricular WM, mesial temporal lobe
- Size
  - Correlates with circulating thyrotropin levels, ↑ with hyperthyroid and ↓ with hypothyroid

CT Findings

- NECT
  - Sellar mass ± suprasellar extension
  - Basal ganglia (BG), variable cerebellar Ca++
  - HE: Subcortical and periventricular WM hypodensities
- CECT
  - Enhancing intra-/suprasellar mass

MR Findings

- T1WI
  - Enlarged pituitary isointense to cerebral WM
  - With THRT: Brain size ↑, ventricular size ↓
  - BG variably hyperintense (Ca++)
  - In endemic neurological cretinism
    - Bilateral globi pallidi, substantia nigra hyperintensity
    - Mild generalized atrophy
    - Enlargement of sylvian fissures
- T2WI
  - Pituitary hyperplasia
    - Homogeneous diffuse enlargement of pituitary gland, ± suprasellar extension, ± partial or complete obliteration of infundibulum, ± compression of optic chiasm
    - Enlarged pituitary gland is isointense to cerebral WM
  - Hashimoto encephalopathy
    - Diffuse/focal subcortical and periventricular WM T2 hyperintensity with relative sparing of occipital lobes
    - Bilateral or unilateral mesial temporal lobe edema
  - In patients with HT-associated ataxia
    - Cerebellar vermis or olivopontocerebellar atrophy
  - In endemic neurological cretinism
    - Hypointensity in area of globus pallidus and substantia nigra bilaterally
    - Mild generalized atrophy and enlarged sylvian fissures with hypothyroidism
- T1WI C+
  - Enlarged pituitary enhances homogeneously, intensely, similar to cavernous sinuses
  - No focal hypointensity (suggestive of adenoma)
  - HE: Typically no enhancement
- MRS
  - ↑ Cho in untreated congenital hypothyroidism reflecting blocked myelin maturation

Nuclear Medicine Findings

- PET
  - Severe hypothyroidism (short duration): Generalized ↓ regional CBF, glucose metabolism

Other Modality Findings

- Tc-99m HMPAO SPECT: Reversible cerebral hypoperfusion (25% ↓ mean CBF) in reversible dementia caused by hypothyroidism

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Coronal T1WI C+, axial and coronal T2/FLAIR for white matter, temporal lobe

DIFFERENTIAL DIAGNOSIS

Pituitary Macroadenoma

- Difficult to differentiate adenoma from pituitary hyperplasia
- T1WI
  - Adenomas may be homogeneous or heterogeneous, typically with lower signal than normal pituitary gland
  - Isointense signal if hemorrhage or necrosis within adenoma
- T1WI C+: Focal hypointensity suggests macro- or microadenoma

Physiologic Pituitary Hyperplasia

- Puberty, pregnancy, post partum (1st week)
- Can be indistinguishable on imaging studies

Enlargement of Pituitary Gland With Spontaneous Intracranial Hypotension

- Look for diffuse dural thickening, "slumping midbrain," tonsillar herniation

Confluent White Matter Lesions

- Arteriosclerosis: Usually multiple T2 hyperintensities but can become confluent in late elderly
- Chronic hypertensive encephalopathy: BG lacuna, deep periventricular confluent T2 hyperintensities
- Cerebral amyloid disease: Multifocal juxtacortical small infarcts and hemorrhages of varying ages common, with little to no BG involvement

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Primary hypothyroidism
    - Most common cause in North America: Autoimmune disease
    - Iatrogenic hypothyroidism (2nd most common): Post-thyroidectomy, post-radioactive I-131 therapy
    - Congenital hypothyroidism: Aplasia/hypoplasia or ectopic gland, enzymatic defects in thyroid hormone synthesis
    - Goitrous hypothyroidism: Endemic iodine deficiency; extinct in USA, but major cause of mental deficiency worldwide
  - Secondary hypothyroidism: Uncommon cause
    - Hypothalamic-pituitary axis failure (↓ thyroid releasing hormone [TRH]/thyroid stimulating hormone [TSH])
  - Lack of inhibition of hypothalamic TRH, pituitary TSH caused by insufficient quantity of thyroid hormones
  - High TRH levels increase TSH and prolactin release from pituitary
  - 2 mechanisms of cerebellar dysfunction in hypothyroidism
    - Endocrine disorder, reversible with THRT
    - Autoimmune-mediated HT, not reversed by THRT
  - **HE**
    - Rare disease with no specific known cause
    - High titers of antithyroglobulin or anti-TPO (antimicrosomal) antibodies
    - High titers of antithyroid antibodies not sufficient for diagnosis
    - Various studies reported no evidence of pathogenic role of antibodies in HE
    - Combination of encephalopathy, high serum antithyroid antibody concentrations, and responsiveness to steroid therapy seen in almost every case
- Associated abnormalities
  - Hypothyroidism is associated with other autoimmune diseases
    - Rheumatoid arthritis, systemic lupus erythematosus (SLE), insulin-dependent diabetes mellitus, ulcerative colitis, myasthenia gravis, MS, pernicious anemia
  - Cretinism
    - Malformed convolution, poor differentiation of cortical layers, reduction in quantity of WM, delayed myelination

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Hypothyroidism: Poor memory, psychomotor slowing, depression, reversible dementia
  - Acquired cerebellar ataxia
  - HE
    - 2 types of initial clinical presentation: Acute stroke-like (vasculitic type) episode and gradual cognitive impairment
    - Confusion, focal/generalized seizure, focal neurological deficit, cognitive decline, dementia
  - Other: Headache, visual impairment (bitemporal hemianopsia) if enlarged pituitary

Demographics

- Age
  - In acquired hypothyroidism, prevalence ↑ with age
  - HE reported in pediatric and adult patients
- Gender
  - Females commonly affected in acquired hypothyroidism
- Epidemiology
  - Acquired hypothyroidism affects 8-9 million Americans
  - Congenital hypothyroidism: 1:2,000-4,000 newborns

Natural History & Prognosis

- Rapid progression (3 weeks) of hyperplasia of anterior pituitary proven in acute development of hypothyroidism
- In congenital hypothyroidism: Main developmental delay originates during first 3 months after birth

Treatment

- Prompt regression of pituitary enlargement with THRT
- ↑ in brain size and ↓ in ventricular size with treatment correlate with changes in levels of circulating thyroid hormones
- In congenital hypothyroidism, thyroid hormone replacement ASAP (< 13 days)
  - Patients with early treated congenital hypothyroidism often develop subnormally and display subtle neurological defects
- Endemic cretinism is determined in utero, irreversible by postnatal treatment
- Acquired cerebellar ataxia is typically reversible with THRT
  - In few patients: Ataxia persists despite THRT
- HE: Responsive to corticosteroid

DIAGNOSTIC CHECKLIST

Consider

- Urgent thyroid function tests should be performed in all patients with pituitary enlargement prior to surgery to exclude hypothyroid-induced pituitary swelling
- Consider hypothyroidism in child (especially male) with diagnosis of "pituitary adenoma"
- HE: Exclude other toxic metabolic or infectious etiologies, high antithyroid antibodies

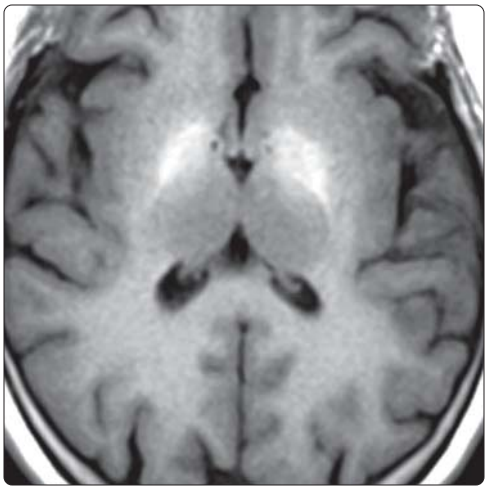
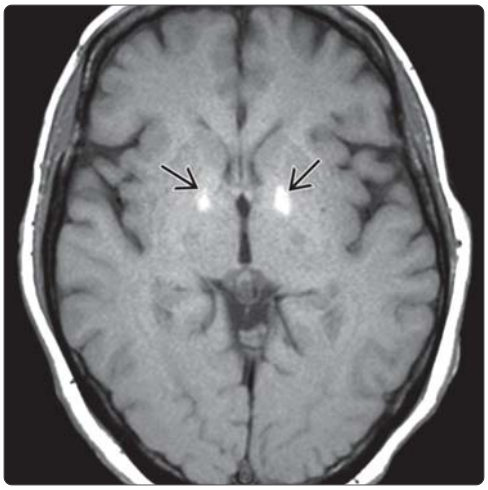
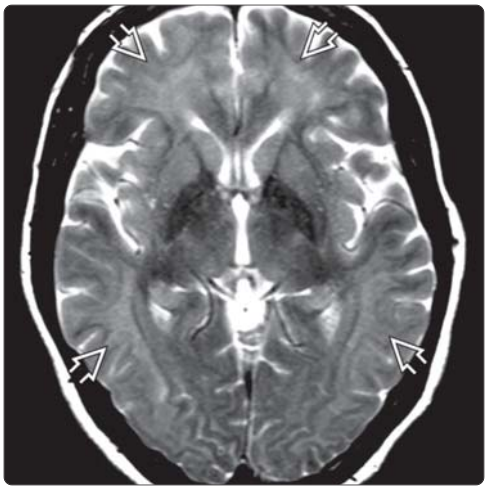
https://CafePezeshki.IR

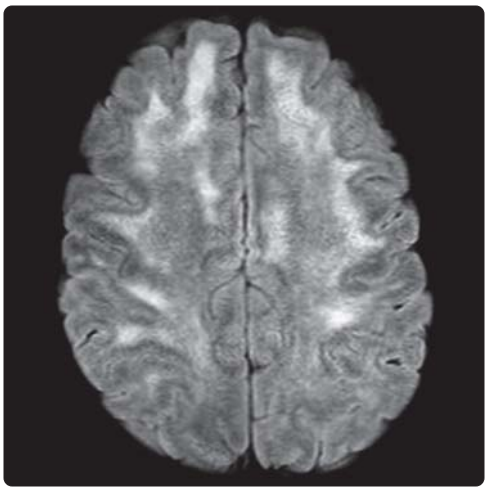


(Left) *Axial NECT shows diffuse calcifications within the basal ganglia and subcortical white matter in a patient with hypothyroidism. Imaging mimics that of other thyroid and parathyroid disorders.* **(Right)** *Axial T1WI MR shows focal hyperintensity in both globi pallidi related to longstanding hypothyroidism. NECT scan (not shown) disclosed dense calcifications in the basal ganglia, especially in the globi pallidi, typical of hypothyroidism.*





(Left) *Axial T1WI shows bilateral hyperintensities in the medial globi pallidi ⇨ in a patient status post thyroidectomy.* **(Right)** *Axial T2WI MR shows striking confluent, symmetric hyperintensity throughout the white matter ⇨ with involvement of the subcortical U-fibers. This diffuse white matter hyperintensity is a very rare but recognized manifestation of hypothyroidism. Sometimes called "myxedema madness," it is also known as Hashimoto encephalopathy.*



(Left) *Axial FLAIR MR in a 40-year-old woman who presented with altered mental status, hallucinations, and seizures shows diffuse confluent white matter hyperintensity ⇨ with relative sparing of the occipital lobes.* **(Right)** *Axial FLAIR in the same patient shows diffuse white matter hyperintensity extending to involve the subcortical U-fibers. Note the relative sparing of the occipital lobes.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- CNS manifestations related to parathyroid hormone (PTH) metabolic abnormalities

IMAGING

- Bilateral symmetric calcifications in globi pallidi, putamen, caudate nuclei
- Diffuse patchy "salt and pepper" lesions in skull in 1° HPTH
- Plaque-like dural calcification, "pipestem" calcifications of carotid arteries in 2° HPTH
- Brown tumors: Focal expansile lytic lesions with nonsclerotic margins in 1° HPTH and 2° HPTH
- T2WI: Hypointensity involving BG, cerebral cortex, or dentate nucleus due to Ca++ deposition

TOP DIFFERENTIAL DIAGNOSES

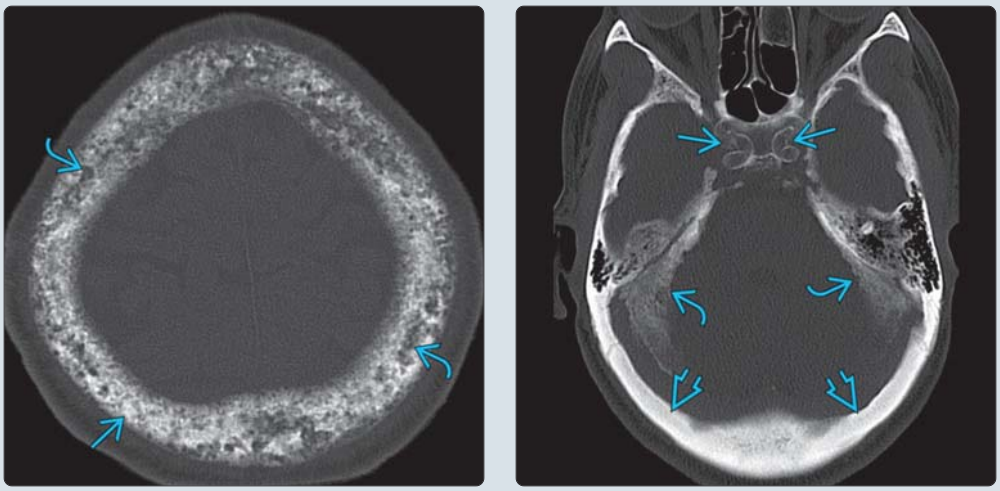
- Fahr disease
- Physiologic calcification
- Congenital HIV
- Hypoxic-ischemic encephalopathy

PATHOLOGY

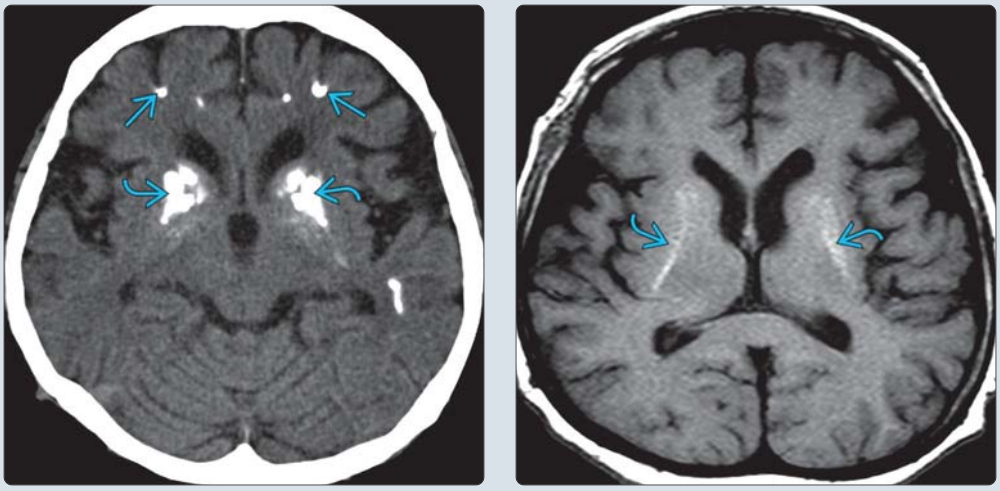
- 1° HPTH: Parathyroid adenoma (75-85 %) , parathyroid hyperplasia (10-20 %), carcinoma (1-5%), ↑ PTH, ↑ Ca++
- 2° HPTH: Chronic renal failure, kidney fails to convert vitamin D to active form and excrete phosphate
- HP: Parathyroids are absent or atrophied; genetic autoimmune syndrome or DiGeorge syndrome (total absence of PT glands at birth)
- PHP: Insensitivity of end-organ to PTH, rather than decreased production of PTH

CLINICAL ISSUES

- HPTH: ↑ Ca++ affects transsynaptic nerve conduction, fatigue, pain, nausea, osteoporosis
- HP: Carpal-pedal spasm, tetany, seizure, and hyperreflexia



(Left) *Axial NECT in 1° hyperparathyroidism shows extensive patchy lytic and sclerotic areas involving the calvaria. This gives a classic "salt and pepper" appearance of the calvaria.* **(Right)** *Axial NECT in a patient with a long history of dialysis for chronic renal failure demonstrates classic changes in skull due to 2° hyperparathyroidism. There is extensive calcification of the tentorium, sclerosis of calvaria, and pipe-like calcification of the internal carotid arteries.*



(Left) *Axial NECT in a patient with hypoparathyroidism shows symmetric bilateral basal ganglia calcifications. Focal calcifications are also seen in the subcortical white matter.* **(Right)** *Axial T1 MR in the same patient shows T1 shortening in the basal ganglia due to calcifications. Calcium deposition in the basal ganglia is seen in both hyper- and hypoparathyroidism. Additional sites for calcium deposition include thalamus, subcortical white matter, dentate nuclei, and dura.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- CNS manifestations related to parathyroid hormone (PTH) metabolic abnormalities
  - 1° and 2° hyperparathyroidism (HPTH)
  - Hypoparathyroidism (HP)
  - Pseudohypoparathyroidism (PHP)
  - Pseudo-pseudohypoparathyroidism (PPHP)

IMAGING

General Features

- Best diagnostic clue
  - Calcium (Ca++) deposition in basal ganglia (BG) in HPTH and HP
  - "Salt and pepper" skull in 1° HPTH
- Location
  - Ca++ in globus pallidi (GP), putamen, caudate, thalamus, subcortical WM, dentate nucleus, dura
  - Skull

Imaging Recommendations

- Best imaging tool: CT and MR (T2WI and T2* GRE)

CT Findings

- NECT
  - Bilateral symmetric calcifications in globi pallidi, putamen, caudate nuclei
    - Thalami, subcortical WM, and dentate nuclei may be affected
  - Diffuse patchy "salt and pepper" lesions in skull in 1° HPTH
  - Plaque-like dural calcification, "pipestem" calcifications of carotid arteries in 2° HPTH
  - Brown tumors: Focal expansile lytic lesions with nonsclerotic margins in 1° HPTH and 2° HPTH

MR Findings

- T1WI: BG hyperintensity
- T2WI: Hypointensity involving BG, cerebral cortex, or dentate nucleus due to Ca++ deposition
- T2* GRE: "Blooming" artifact related to Ca++
- Brown tumors: Variable signal intensity

DIFFERENTIAL DIAGNOSIS

T1 Hyperintense Basal Ganglia

- Hepatic encephalopathy, hyperalimentation, Wilson disease, nonketotic hyperglycemia

Fahr Disease

- Symmetric Ca++ in BG, thalamus, and dentate nucleus

Physiologic Calcification

- Almost always GP, ↑ incidence with age

Congenital HIV

- Microangiopathy and infarction → Ca++ and atrophy

Hypoxic-Ischemic Encephalopathy

- GP, thalamus, and brainstem Ca++

PATHOLOGY

General Features

- Etiology
  - 1° HPTH: Parathyroid adenoma (75-85 %), parathyroid hyperplasia (10-20 %), carcinoma (1-5%), ↑ PTH, ↑ Ca++
    - Sporadic 1° HPTH more common than hereditary
    - Inherited syndromes associated with 1° HPTH : Multiple endocrine neoplasia (MEN) type 1, MEN type 2A, and familial isolated HPTH
  - 2° HPTH: Chronic renal failure commonly → kidneys fail to convert vitamin D to active form and excrete phosphate (P): ↑ PTH, normal or ↓ Ca++, ↑ P
    - Parathyroid hyperplasia less common
  - HP: Parathyroid glands are absent or atrophied; surgically removed; genetic autoimmune syndrome or DiGeorge syndrome (total absence of parathyroid glands at birth)
  - PHP: Insensitivity of end-organ to PTH, rather than ↓ production of PTH; dysfunction of G protein (Gs alpha subunit): ↓ Ca++, ↑ P, ↑ PTH
  - PPHP: Incomplete expression of PHP, normal Ca++ and P
- Associated abnormalities
  - Dialysis-associated encephalopathy: Dementia (aluminum accumulation), renal osteodystrophy, brown tumor
  - HP could be due to hemochromatosis or magnesium deficiency

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 1° HPTH: ↑ Ca++ affects transsynaptic nerve conduction; fatigue, pain, nausea, osteoporosis
    - "Stones, bones, abdominal groans, and psychic moans"
  - 2° HPTH: Progressive cranial nerve involvement due to massive thickening of calvaria and skull base
  - HP: Carpal-pedal spasm, tetany, seizure, and hyperreflexia
- Other signs/symptoms
  - HPT: Excessive secretion of PTH: ↑ Ca++ (1° HPTH) or response to low Ca++ level (2° HPTH)
  - HP: Dry, puffy, coarse skin, brittle nails, cataract, ↓ Ca++

Treatment

- Primary HPTH: Remove parathyroid adenoma
- Secondary HPTH: Calcimimetics → mimics Ca++ in body, reduce PTH secretion, lowering Ca++
- HP: Intravenous calcium with vitamin D3

DIAGNOSTIC CHECKLIST

Consider

- Excessive Ca++ in BG or heterotopic Ca++, consider PTH abnormality and other toxic-metabolic disorders

Fahr Disease

KEY FACTS

TERMINOLOGY

- Fahr disease (FD)
  - a.k.a. cerebrovascular ferrocalcinosis, bilateral striopallidodentate calcification
- Rare degenerative neurological disorder
  - Extensive bilateral basal ganglia (BG) calcifications (Ca++)
  - ± progressive dystonia, parkinsonism, neuropsychiatric manifestations

IMAGING

- Bilateral symmetric Ca++ in BG, thalami, dentate nuclei, and cerebral white matter on CT

TOP DIFFERENTIAL DIAGNOSES

- Normal (physiologic)
  - Symmetrical BG Ca++ in middle-aged, elderly
- Pathologic BG Ca++ (e.g., endocrinological)

PATHOLOGY

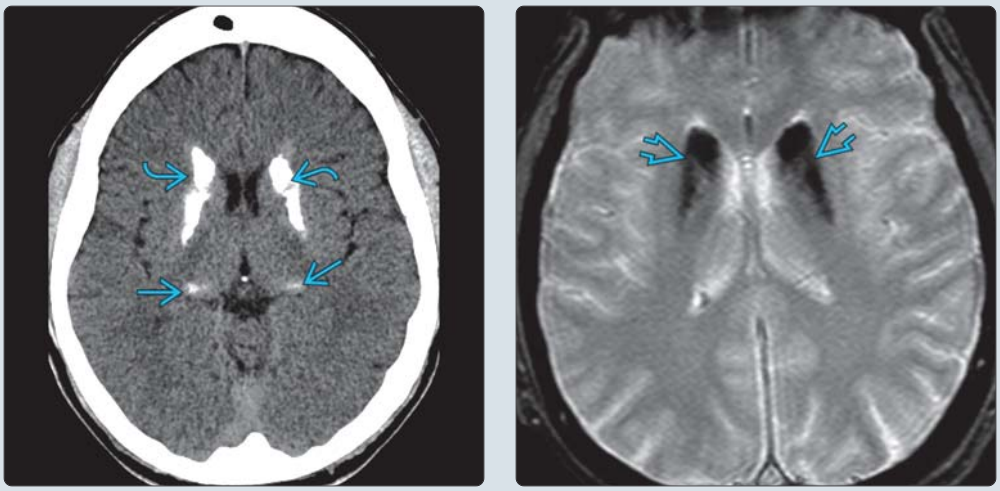
- FD is often familial, yet heterogeneous
- Characteristic feature: Diffuse neurofibrillary tangles with calcification (a.k.a. Fahr-type calcification)

CLINICAL ISSUES

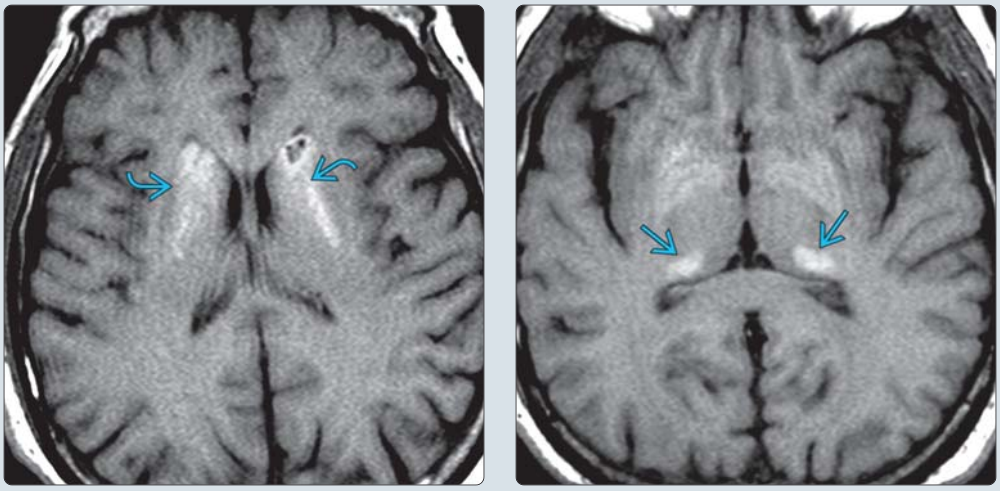
- Most common signs/symptoms
  - Neuropsychiatric disturbance
  - Cognitive impairment (subcortical dementia)
  - Extrapyramidal movement disorders
- Ca++/P metabolism, PTH levels normal
- Bimodal pattern of clinical onset
  - Early adulthood (schizophrenic-like psychosis)
  - 6th decade (extrapyramidal syndrome, subcortical dementia)

DIAGNOSTIC CHECKLIST

- BG Ca++ if < 50 years old merits investigation



(Left) *Axial NECT in patient with Fahr disease demonstrates classic extensive calcifications in the basal ganglia and thalami.* **(Right)** *Axial T2* GRE MR image in the same patient shows low signal in the basal ganglia. This appearance on T2* GRE is due to a combination of calcification and iron deposition.*



(Left) *Axial T1 MR image in the same patient shows T1 shortening in the basal ganglia. T1 shortening is typical and is secondary to the presence of Fahr-type calcification.* **(Right)** *Axial T1 MR in the same patient shows similar T1 shortening in the thalami. This corresponds to the calcification seen on CT. Fahr disease is a degenerative neurological disorder that manifests as bilateral symmetric calcifications in the basal ganglia, thalami, dentate nuclei, and cerebral white matter.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Fahr disease (FD)

Synonyms

- Familial idiopathic basal ganglia calcification
- Bilateral striopallidodentate calcification
- Idiopathic familial cerebrovascular ferrocalcinosis

Definitions

- Rare degenerative neurological disorder
  - Extensive bilateral basal ganglia (BG) calcifications (Ca++)
  - Can lead to progressive dystonia, parkinsonism, neuropsychiatric manifestations

IMAGING

General Features

- Best diagnostic clue
  - Bilateral symmetric Ca++ in BG, thalami, dentate nuclei, and cerebral white matter on CT
- Location
  - Globus pallidus = most common site of Ca++
    - Lateral pallidum > medial pallidum
  - Also putamen, caudate, thalami, cerebellum (especially dentate), internal capsule, cerebral white matter
- Morphology
  - Variable extent
  - Dense Ca++ often conforms to outline of BG

CT Findings

- NECT
  - Bilateral symmetric Ca++ in typical locations
- CECT
  - No enhancement

MR Findings

- T1WI
  - Varying signal intensities related to
    - Stage of disease, volume of calcium deposit
    - Differences in calcium metabolism
  - Ca++ usually hyperintense on T1WI
- T2WI
  - Dense Ca++ can appear hypo-/hyperintense
  - T2 hyperintense areas in white matter
    - Do not correspond to any calcification
    - May reflect metabolic or inflammatory brain process, which subsequently becomes calcified
    - Entire centrum semiovale may appear hyperintense in patients with dementia
    - Focal internal capsule hyperintense foci may correlate with contralateral hemiparesis
- FLAIR
  - Same as T2WI
- SWI
  - Marked hypointensity
  - SWI may prove to be more sensitive than CT

Nuclear Medicine Findings

- PET
  - May show ↓ bilateral FDG uptake in BG
    - Also seen in frontal and temporoparietal cortices and hippocampal area
  - Functional abnormalities may precede morphological changes in FD process
- SPECT with Tc-99-ethyl-cysteinate-dimer (ECD)
  - ↓ perfusion to calcified lesions
    - Especially in setting of dementia
    - Not associated with volume of calcium deposits
  - May see ↑ perfusion if acquired during symptomatology
    - Especially temporal lobes with auditory hallucinations

Imaging Recommendations

- Best imaging tool
  - NECT
- Protocol advice
  - MR SWI may prove to be superior

DIFFERENTIAL DIAGNOSIS

Normal

- Symmetrical BG Ca++ in middle-aged, elderly
- Localized in globus pallidus
- Usually punctate but can be quite heavy
- Detected on CT scan, no clinical significance
- Extremely common finding in older age group
- If accompanied by other calcifications, consider pathologic condition

Inherited, Acquired BG Ca++

- In children/young adults
- Associated with Down syndrome
- Trisomy 5
- Mitochondrial encephalopathies
  - Kearns-Sayre, MELAS, MERRF
  - T2 hyperintense lesions in BG
  - BG Ca++ can occur but not prominent feature
- Aicardi-Goutières syndrome
  - Autosomal recessive
  - Encephalopathy after birth → developmental arrest
- HIV encephalitis
  - BG Ca++ and cerebral atrophy
- Cockayne syndrome
  - Autosomal recessive disorder of DNA repair
  - CT: Cortico-subcortical atrophy, BG, and dentate nuclei Ca++
  - T2WI: Hyperintensity of periventricular white matter and subcortical U-fibers
  - T2WI hypointense putamina and caudate nuclei
  - Atrophy of cerebellar vermis and brainstem
  - Dwarfism, microcephaly, mental retardation
  - Photosensitivity, ocular abnormalities
  - Gait disturbance, progeroid appearance
- Long-term complications of radiation for childhood brain tumors and intrathecal chemotherapy
  - Bilateral BG Ca++, leukoencephalopathy
- Phakomatoses: Tuberous sclerosis and neurofibromatosis

Pathologic BG Ca++

- Endocrinologic disorders

https://CafePezeshki.IR

- Hyperparathyroidism, hypoparathyroidism, pseudohypoparathyroidism, pseudopseudohypoparathyroidism, post thyroidectomy
- Similar distribution of calcifications to FD
- Hypoparathyroidism: ↑ ionic calcium in interstitial tissues with ↓ levels of circulating calcium
- Calcification in primary hypoparathyroidism is more diffuse than in other etiologies of calcification
- Post-thyroidectomy hypoparathyroidism calcifications are more focal

- Neuropsychiatric (e.g., lupus, motor neuron disease)
- Postinfectious (e.g., TB, toxoplasmosis, cysticercosis)
- Toxic (e.g., carbon monoxide, lead intoxication)

PATHOLOGY

General Features

- Etiology
  - CNS Ca++ in FD could represent
    - Metastatic deposition secondary to local blood-brain barrier disruption
    - Disorder of neuronal calcium metabolism
  - Defective iron transport and free radicals → tissue damage → calcification
- Genetics
  - Autosomal dominant in most families with FD
    - Occasionally autosomal recessive
  - FD is often familial, yet heterogeneous
    - Variable expressivity and reduced penetrance can be found in same family, but most patients are symptomatic
    - "Genetic anticipation" = age of onset ↓ with each transmission in multigenerational family
    - In some kindreds, most individuals are largely asymptomatic
  - 1st locus identified: IBGC1 on chromosome 14q
    - IBGC1 region contains over 100 known genes, expressed sequence tags, and predicted genes
    - Now known not to be the main locus

Staging, Grading, & Classification

- Fahr disease = idiopathic calcifications with cognitive and neurobehavioral manifestations
  - Diagnosis of exclusion; requires normal calcium, phosphorous, and parathyroid hormone levels
- Fahr syndrome = same appearance as FD but secondary to underlying disorder (e.g., hypoparathyroidism)

Microscopic Features

- Characteristic feature: Diffuse neurofibrillary tangles with calcification (a.k.a. Fahr-type calcification)
  - Neurofibrillary tangles comprised of tau and phosphorylated-tau protein
- Predominant element is calcium
  - Other elements (Zn, P, Fe, Mg, Al, K) also present
- Ca++ in extracellular, extravascular space, often surrounding capillaries
  - Ca++ of medial walls and adventitia
  - Ca++ in areas of demyelination, lipid deposition
  - Ca++ incorporated into proteins or bound to polysaccharides

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Neuropsychiatric disturbance
  - Cognitive impairment (subcortical dementia)
  - Extrapyramidal movement disorders
- Clinical profile
  - Calcium–phosphorus metabolism and parathyroid hormone levels are normal
  - Usually asymptomatic in 1st 2 decades of life, despite presence of multiple brain calcifications
  - Neurological manifestations vary, but movement disorders are most common
    - Parkinsonism most common, usually permanent and progressive
    - Childhood transient parkinsonism also reported
    - Paroxysmal dystonic choreoathetosis

Demographics

- Age
  - Onset of clinical symptoms is typically 30-60 years
  - Infantile form also described
  - Bimodal pattern of clinical onset
    - Early adulthood (schizophrenic-like psychosis)
    - 6th decade (extrapyramidal syndrome, subcortical dementia)
- Gender
  - No gender predominance
- Epidemiology
  - Rare

Natural History & Prognosis

- Characterized by very slow progression
- Mental deterioration and loss of motor skills
  - Degenerative rather than developmental disorder
- Adult-onset FD: Calcium deposition begins in 3rd decade with neurological deterioration 2 decades later
- Symmetrical spastic paralysis and sometimes athetosis appear, progressing to decerebrate state
- Commonly develop neuropsychiatric disturbances
- Proposed disruption in thalamo-cortico-striatal circuit leads to disconnection syndrome, termed "cognitive dysmetria," producing symptoms of schizophrenia

DIAGNOSTIC CHECKLIST

Consider

- FD in parkinsonian patients with dementia and cerebellar signs
- Discovery of BG Ca++ if < 50 years old merits investigation

Image Interpretation Pearls

- Symmetric BG Ca++ in middle-aged/older adults
  - Common, of no clinical significance

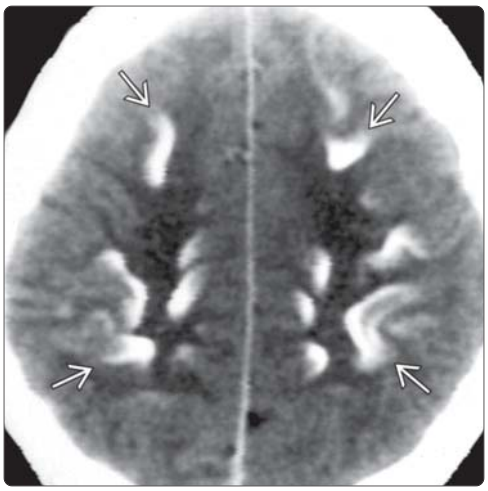
(Left) *Axial T1WI MR demonstrates the typical MR appearance of Fahr disease with T1 hyperintense basal ganglia calcifications ➡. These calcifications were also documented on head CT (not shown).* **(Right)** *Axial PD/intermediate MR in the same patient reveals the typical pattern of basal ganglia calcifications as T1 hyperintensity within a larger region of T2 hyperintense abnormality ⇨. Note that the T2 technique reveals that the caudate nuclei are also involved ⇨.*

(Left) *Axial NECT of a patient with Fahr disease shows extensive calcifications involving the periventricular deep white matter ➡. Patients with extensively affected centrum semiovale are more likely to present with dementia.* **(Right)** *Axial FLAIR MR in the same patient shows T2 hyperintensity within the areas of calcification ➡. In advanced cases, hyperintense abnormality may affect the entire centrum semiovale.*



(Left) *Axial NECT demonstrates extensive Fahr-type calcifications at subcortical gray-white junctions ➡.* **(Right)** *Axial NECT illustrates both the typical dentate ➡, as well as atypical and extremely dense midbrain ➡ calcifications of Fahr disease, which is often familial, as in this case.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Acute/subacute/chronic toxic effects of EtOH on CNS

IMAGING

- EtOH: Disproportionate superior vermian atrophy, enlargement of lateral ventricles, sulci with chronic EtOH
- WE: Mammillary body, medial thalamus, hypothalamus, periaqueductal gray abnormal signal/enhancement/diffusion restriction
- MBD: Abnormal signal and later necrosis in corpus callosum
- Protocol advice: Contrast-enhanced MR + DWI

TOP DIFFERENTIAL DIAGNOSES

- Nonalcoholic atrophy
- Diffuse demyelination
  - Toxic demyelination
  - Acquired/inherited metabolic disorders
- Corpus callosal hyperintensity
  - Status epilepticus
  - Drug toxicity
  - Encephalitis
  - Hypoglycemia

PATHOLOGY

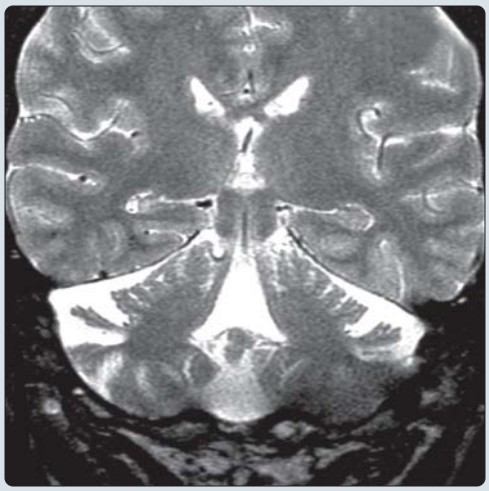
- EtOH: Causes both direct/indirect neurotoxicity
- WE: Thiamine (vitamin B_1) deficiency
- WE can be alcoholic or nonalcoholic
- MBD: Chronic EtOH abuse, anecdotal association with red wine

CLINICAL ISSUES

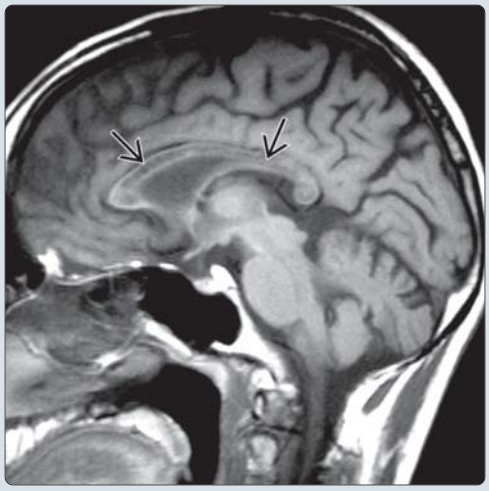
- WE: Triad of ataxia, oculomotor abnormalities, confusion
- Classic clinical triad present in only a minority of patients
- EtOH: Cessation, establishment of adequate nutrition
- WE: Immediate administration of IV thiamine → quick response

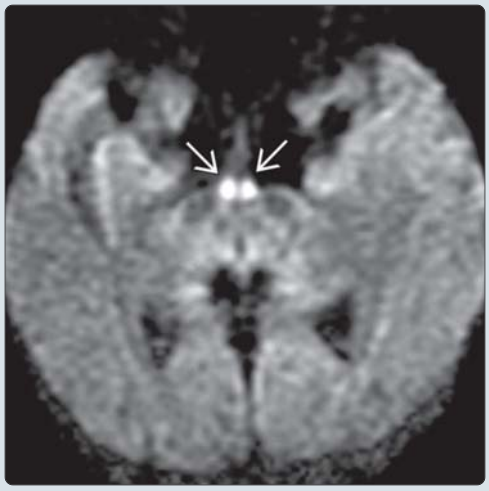
DIAGNOSTIC CHECKLIST

- 50% of WE cases occur in nonalcoholics, including children



(Left) *Sagittal graphic shows generalized and superior vermian atrophy, as well as necrosis in the corpus callosum related to alcoholic toxicity. Mammillary body, periaqueductal gray necrosis is seen with Wernicke encephalopathy.* **(Right)** *Coronal T2WI MR demonstrates pronounced cerebellar atrophy.*





(Left) *Sagittal T1WI MR shows a classic finding for Marchiafava-Bignami disease with a thinned corpus callosum and hypointensity in the middle layers ⇨. Note that the genu, body, and splenium are all involved. (Courtesy A. Datir, MD.)* **(Right)** *Axial DWI MR shows restricted diffusion in the mammillary bodies ➡ in this patient with acute Wernicke encephalopathy.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Alcoholic (EtOH) encephalopathy
- Wernicke encephalopathy (WE)
- Marchiafava-Bignami disease (MBD)

Definitions

- Acute, subacute, or chronic toxic effects of EtOH on CNS
- Can be primary (direct) or secondary (indirect)
  - Primary (direct) effects of EtOH = neurotoxicity
    - Cortical/cerebellar degeneration, peripheral polyneuropathy
  - Secondary (indirect) effects
    - Trauma, malnutrition, coagulopathy
- Rare treatable complication = WE

IMAGING

General Features

- Best diagnostic clue
  - EtOH: Disproportionate superior vermian atrophy
  - WE: mammillary body, medial thalamus, hypothalamus, periaqueductal gray abnormal signal/enhancement
  - MBD: Abnormal signal and later necrosis in corpus callosum
- Location
  - EtOH
    - Cerebral hemispheres, especially frontal lobes
    - Cerebellum, superior vermis
    - Diffuse toxic demyelination = unusual manifestation of alcoholic encephalopathy
    - Basal ganglia (associated liver disease)
  - WE
    - Mammillary bodies, periaqueductal gray matter, hypothalamus
    - Thalami (adjacent to 3rd ventricle)
  - MBD
    - Corpus callosum ± lateral extension into adjacent white matter

CT Findings

- NECT
  - EtOH: Generalized atrophy; superior vermis atrophy
  - WE (acute): Often normal
    - May see hypodensity in periaqueductal gray matter, mammillary bodies, and medial thalamus
  - MBD: Hypodensity in corpus callosum

MR Findings

- T1WI
  - EtOH
    - Symmetric enlargement of lateral ventricles, sulci with chronic EtOH
    - ↑ size of cerebral sulci, interhemispheric/sylvian fissures
    - ± hyperintensity in basal ganglia (liver dysfunction)
  - WE
    - May see hypointensity in periaqueductal gray matter, mammillary bodies, hypothalamus, and medial thalamus
    - Chronic: Atrophic mammillary bodies (sagittal scan) and 3rd ventricular enlargement
- T2WI
  - EtOH
    - Nonspecific multifocal white matter hyperintensities
    - Less common: Diffuse white matter hyperintensity from toxic demyelination
  - WE
    - Hyperintensity around 3rd ventricle, mammillary bodies, hypothalamus, medial thalamus, midbrain (tectal plate and periaqueductal gray)
    - Atypical findings: Hyperintensity in cerebellum, cranial nerve nuclei, red nuclei, dentate nuclei, splenium, and cerebral cortex
  - MBD
    - Acute: Hyperintense corpus callosum (middle layers) virtually pathognomonic
    - Chronic: Callosal necrosis
- FLAIR
  - Lesions all typically hyperintense
- DWI
  - WE: Restriction in or around 3rd ventricle, periaqueductal region, bilateral dorsomedial thalami, and brainstem
  - MBD: Restricted diffusion in splenium of corpus callosum
- T1WI C+
  - WE: Enhancement of mammillary bodies, periaqueductal gray, medial thalamus
  - MBD: Acute phase white matter lesions may enhance
- MRS
  - EtOH: NAA/Cr, Cho/Cr decreased in frontal lobes, cerebellum; recover after detoxification

Nuclear Medicine Findings

- PET
  - EtOH
    - 18F-FDG PET: Significant decrease in whole-brain metabolism with chronic EtOH
  - WE: 18F-FDG PET: Diencephalic, medial temporal, limbic, and retrosplenial hypometabolism

Imaging Recommendations

- Best imaging tool
  - NECT for complications, such as subdural hematoma, related to trauma/coagulopathy
  - MR for possible Wernicke encephalopathy
    - Lack of imaging abnormalities does not exclude WE
- Protocol advice
  - Contrast-enhanced MR + DWI

DIFFERENTIAL DIAGNOSIS

Nonalcoholic Atrophy

- Alzheimer dementia (AD) = hippocampal, temporal atrophy, hypometabolism
- Multi-infarct dementia pattern = focal infarcts ± generalized atrophy
- Malnutrition, eating disorders = generalized
- Remote trauma = atrophy + cortical/axonal hemorrhages common
- Inherited cerebellar degeneration syndromes (Marie ataxia, olivopontocerebellar degeneration, etc.)

https://CafePezeshki.IR

- Longstanding phenytoin (Dilantin) use = cerebellar atrophy + thick skull

Diffuse Demyelination

- Toxic demyelination, including chemotherapy, CO poisoning, and inhaled heroin ("chasing the dragon")
- Acquired/inherited metabolic disorders
  - Osmotic demyelination syndrome = pontine > putamen, cortical involvement

Corpus Callosal Hyperintensity

- Status epilepticus
- Drug toxicity
- Encephalitis
- Hypoglycemia

PATHOLOGY

General Features

- Etiology
  - EtOH
    - Alcohol readily crosses blood-brain barrier
    - Causes both direct/indirect neurotoxicity
  - WE
    - Thiamine (vitamin B_1) deficiency impairs dependent enzymes, results in glutamate accumulation/cell damage
    - WE can be alcoholic or nonalcoholic
    - **Alcoholic WE**: Chronic thiamine deficiency due to associated malnourishment
    - **Nonalcoholic WE**: Same pathophysiology but different etiology
      - Malabsorption secondary to GI neoplasm/surgery
      - Hyperemesis (hyperemesis gravidarum, chemotherapy)
      - Malnutrition (starvation, anorexia nervosa)
      - Prolonged hyperalimentation
  - MBD
    - Chronic EtOH abuse, anecdotal association with red wine
- Associated abnormalities
  - EtOH
    - May ↑ stroke risk (especially in putamen, anterior cerebral artery)
    - Hepatic encephalopathy
  - Chronic EtOH
    - Brain shrinkage, cortical atrophy reflect lifetime consumption
    - EtOH modulates GABAergic neurotransmission

Gross Pathologic & Surgical Features

- EtOH
  - Atrophy (especially frontal), ↑ ventricles, sulci
  - Atrophy of folia of superior vermis & anterosuperior aspects of cerebellar hemispheres
- WE
  - Mammillary bodies; periventricular midbrain/brainstem
    - Petechial hemorrhage (acute)
    - Mammillary body atrophy (chronic)
  - Dorsal medial thalamic nuclei (may cause Korsakoff psychosis)
- MBD
  - Callosal necrosis, atrophy

Microscopic Features

- Axonal degeneration, demyelination (alcoholic polyneuropathy)
- Purkinje cell loss (alcoholic cerebellar degeneration)
- WE: Demyelination, neuronal loss in affected areas
- MBD: Demyelination middle layers of corpus callosum

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Chronic EtOH
    - Cognitive problems, impaired memory
    - Most common neurologic abnormality = polyneuropathy
    - Gait abnormalities, nystagmus (cerebellar degeneration)
  - WE: Triad of ataxia, oculomotor abnormalities, confusion
    - Classic clinical triad present in only a minority of patients
    - 50% nonalcoholic
    - Korsakoff psychosis (amnestic syndrome) may complicate WE
  - MBD: Sudden onset of altered mental status, seizures, dysarthria, ataxia, hypertonia, pyramidal signs

Demographics

- Age
  - Any age (Neuroblastoma: WE can occur in children)
- Epidemiology
  - EtOH, brain atrophy = dose dependent, independent of gender/ethnicity

Natural History & Prognosis

- EtOH: Ventricular, sulcal enlargement often reversible
- WE: Ocular palsies respond 1st to thiamine; ataxia, apathy, and confusion clear more slowly
  - High mortality if untreated
  - Only 25% of Korsakoff patients achieve full recovery
- MBD: Severe neurologic sequelae

Treatment

- EtOH: Cessation, establishment of adequate nutrition
- WE: Immediate administration of IV thiamine → quick response
- MBD: Vitamin B complex and steroids may reverse course in acute MBD

DIAGNOSTIC CHECKLIST

Consider

- 50% of WE cases occur in nonalcoholics, including children

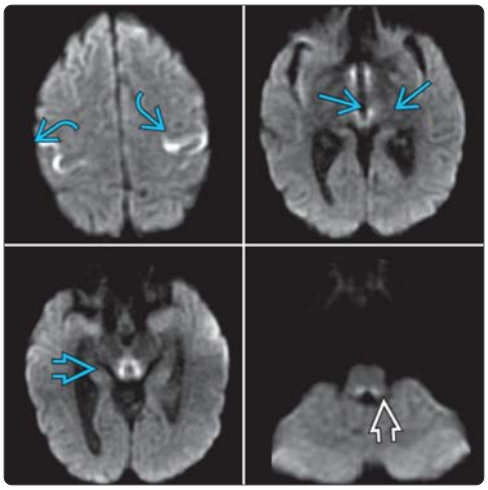
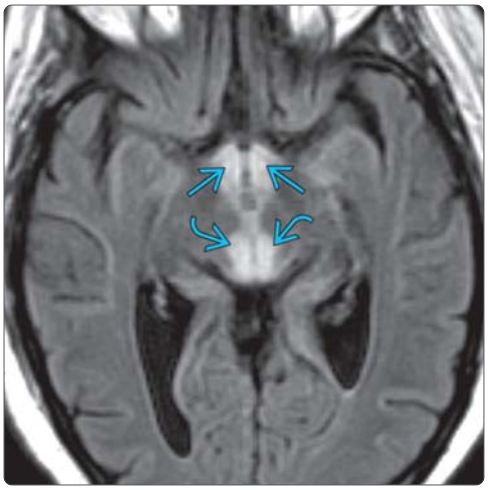
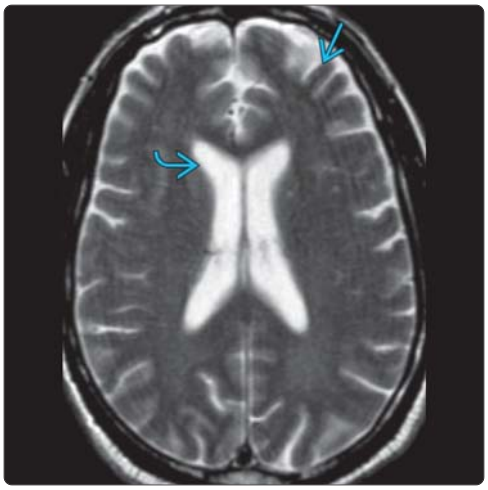
4. Manzo G et al: MR imaging findings in alcoholic and nonalcoholic acute Wernicke's encephalopathy: a review. Biomed Res Int. 2014:503596, 2014

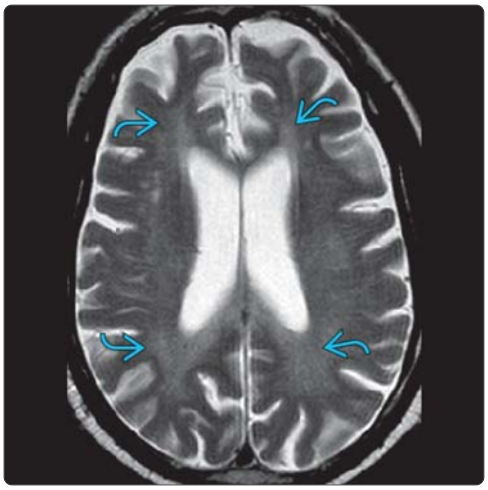
https://CafePezeshki.IR



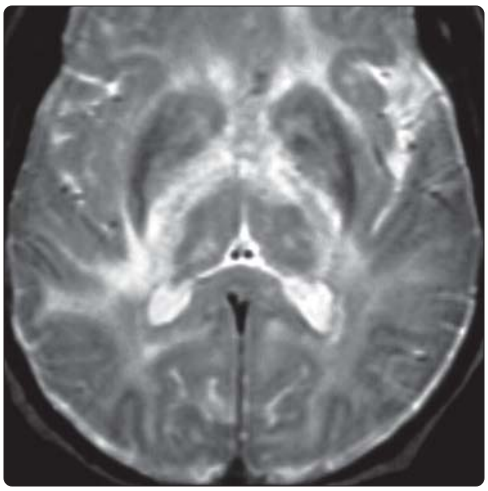


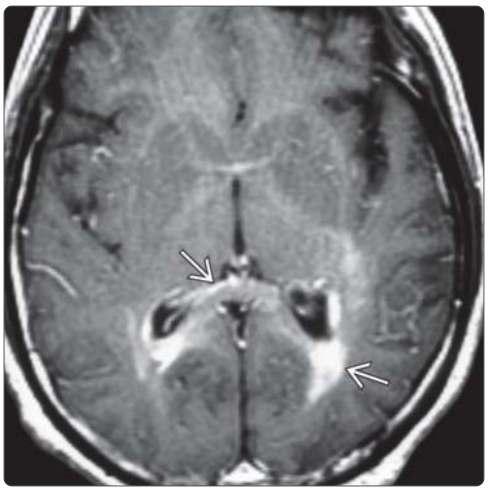
(Left) *Axial DWI MR images in a patient with acute Wernicke encephalopathy demonstrates restricted diffusion involving the perirolandic cortex, dorsomedial thalami, periaqueductal gray matter, and dorsal medulla.* **(Right)** *Axial FLAIR MR in the same patient shows hyperintensity in the dorsomedial thalami as well as the mammillary bodies. Acute Wernicke encephalopathy is caused by thiamine deficiency.*





(Left) *Axial T2 MR in a 45-year-old patient with a history of chronic alcoholism shows prominence of the ventricles and cortical sulci due to diffuse atrophy.* **(Right)** *Axial T2 MR in the same patient after 4 years shows progression of the diffuse atrophy with development of periventricular and deep white matter hyperintensities. Alcohol readily crosses the blood-brain barrier and causes both direct/indirect neurotoxicity.*





(Left) *Axial T2WI MR in a patient with acute alcohol poisoning caused by binge drinking shows symmetric, confluent white matter hyperintensity in the internal capsules, corpus callosum, and hemispheric white matter. Acute alcohol toxicity may induce striking demyelination, as occurred in this case.* **(Right)** *Axial T1WI C+ MR in the same patient with acute alcohol-induced demyelination shows enhancement in the corpus callosum splenium and forceps major.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Functional, potentially reversible clinical syndrome during acute or chronic liver disease
- Characterized by psychiatric, cognitive, and motor components

IMAGING

- AHE
  - High T2 signal in most of cerebral cortex (preferential insular cortex and cingulate gyri) with diffusion restriction
  - Perirolandic/occipital regions relatively spared
- CHE
  - Bilateral T1WI hyperintensity in basal ganglia (BG), particularly globus pallidus (GP)
  - ↑ T1WI signal intensity in pituitary gland and hypothalamus less common
- FLAIR: Diffuse high signal intensity along hemispheric white matter in or around corticospinal tract

TOP DIFFERENTIAL DIAGNOSES

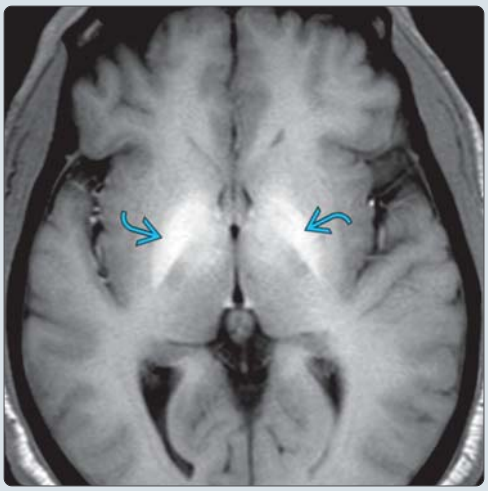
- Cholestatic diseases
- Liver copper overload
- Hyperalimentation
- Other causes of T1 hyperintense BG
  - Hypoxic-ischemic encephalopathy
  - Fahr disease (idiopathic calcification of BG)
  - Carbon monoxide poisoning
  - Neurofibromatosis type 1

PATHOLOGY

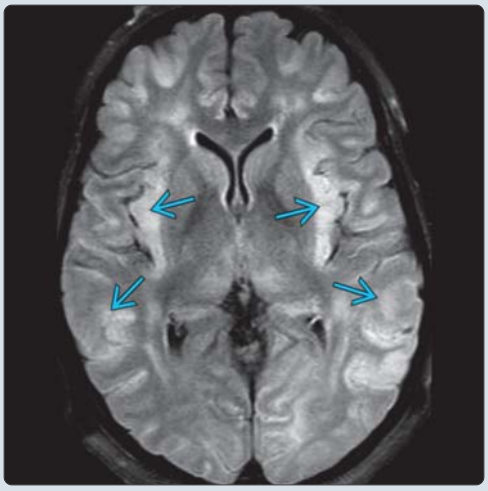
- Brain accumulation of neurotoxic &/or neuroactive substances
- Ammonia, manganese, aromatic amino acids

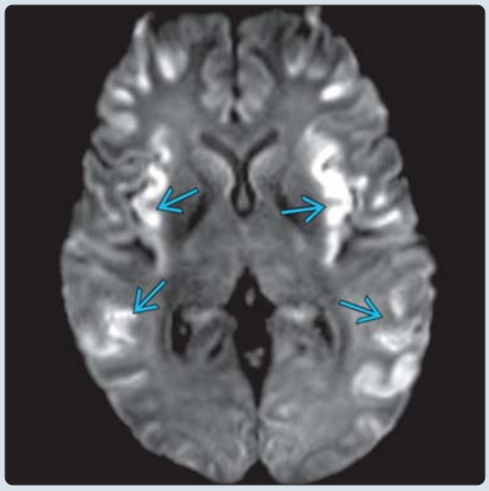
DIAGNOSTIC CHECKLIST

- After therapy, clinical features and MRS abnormalities improve 1st, followed 3-6 months later by normalization of BG signal



(Left) *Axial T1 MR in a patient with chronic liver disease demonstrates high T1 signal in the globus pallidus.* **(Right)** *Sagittal T1 MR in the same patient shows a hyperintense anterior pituitary gland. In patients with chronic liver disease, T1 hyperintensity is most commonly seen in the globus pallidus. The anterior pituitary and hypothalamus may also show similar T1 hyperintensity but is less common. T1 hyperintensity is thought to be due to manganese deposition.*





(Left) *Axial FLAIR MR in a patient with acute liver failure shows extensive cortical swelling and hyperintensity. There is relative sparing of the occipital cortex.* **(Right)** *Axial DWI MR in the same patient shows corresponding high signal due to diffusion restriction. Acute hepatic encephalopathy is caused by hyperammonemia. It is a life-threatening disorder with high morbidity and mortality.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hepatic encephalopathy (HE)
- Acute hepatic encephalopathy (AHE)
- Chronic hepatic encephalopathy (CHE)

Synonyms

- Hepatic coma

Definitions

- Functional, potentially reversible clinical syndrome during acute or chronic liver disease
- Characterized by psychiatric, cognitive, and motor components

IMAGING

General Features

- Best diagnostic clue
  - AHE: Bilateral swollen T2/FLAIR hyperintense gyri (most severe insular cortex, cingulate gyri) with diffusion restriction
  - CHE: Bilateral T1WI hyperintensity in basal ganglia (BG), particularly globus pallidus (GP)
- Location
  - BG, particularly GP
  - Insular cortex, cingulate gyri in AHE
  - White matter in or around corticospinal tract

CT Findings

- NECT
  - AHE: Severe diffuse cerebral edema
  - CHE: Cerebral atrophy
- CECT
  - No enhancement of affected BG

MR Findings

- T1WI
  - Bilateral T1 hyperintensity in BG, particularly GP
    - Reported in 80-90% of chronic liver failure patients
    - Probably caused by manganese accumulation
    - Slow reversal following restoration of liver function
  - ↑ T1WI signal intensity in pituitary gland and hypothalamus less common
  - Atrophy, especially affecting cerebellum
  - AHE: Blurring of gray-white matter junction
- T2WI
  - AHE: Bilateral symmetric T2 hyperintensity in insular cortex, cingulate gyri, and basal ganglia
    - Relative sparing of perirolandic and occipital regions
  - Periventricular WM hyperintensity
- FLAIR
  - Diffuse high signal intensity along hemispheric white matter in or around corticospinal tract
    - Decreased to nearly normal after liver transplantation
  - WM hyperintensities similar to those seen in small vessel cerebrovascular disease and healthy elderly population
    - Partially reversible
- DWI
  - AHE: Restricted diffusion involving cortex (insular, cingulate gyri) & basal ganglia, corresponding ↓ ADC, ↓ mean diffusivity (MD), ↓ fraction anisotropy (FA)
  - ↑ MD, ↑ ADC in cirrhotic patients with minimal HE
- T1WI C+
  - No contrast enhancement
- MRS
  - ↓ myoinositol (mI), ↑ glutamine/glutamate (Glx), ↓ choline (Cho)
    - Brain glutamine concentrations ↑ in direct correlation with severity of HE in patients with chronic liver failure
    - Brain ammonia removal relies primarily on formation of glutamine
  - ↓ mI/Cr and Cho/Cr ratios and ↑ Glx/Cr ratios
    - After correction of hepatic dysfunction, these ratios normalize or may reverse
    - mI/Cr: Most sensitive (80-85%) indicator of HE
  - May play role in monitoring lactulose therapy

Nuclear Medicine Findings

- PET
  - NH_3-13-PET in chronic liver failure with mild HE
    - ↑ cerebral metabolic rate for ammonia
    - ↑ "permeability-surface area" product (measure of blood-brain barrier permeability to ammonia)
  - Redistribution of cerebral blood flow from cortical to subcortical areas (including BG)

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR+DWI

DIFFERENTIAL DIAGNOSIS

Liver Copper Overload

- Wilson disease
  - Symmetrical hyperintensity in putamina, GP, caudate nuclei, and thalami on T2WI
  - Hyperintensity in dentatorubrothalamic, pontocerebellar, and corticospinal tracts on T2WI
  - Lesions appear hypointense (occasionally hyperintense) on T1WI, without enhancement
- Cholestatic disease
- Inefficient biliary excretion of copper in newborn

Hyperalimentation

- Bilateral hyperintense signal in GP and subthalamic nuclei on T1WI, without contrast
  - Caused by manganese deposition, astrogliotic reaction to such deposition, or both
- No corresponding abnormalities on T2WI or CT

Other Causes of T1 Hyperintense BG

- Microangiopathy and infarcts in AIDS patients
- Chorea-ballism associated with hyperglycemia
  - T1 hyperintense putamen, caudate nucleus: Unilateral
- Endocrine disorders leading to BG calcifications
  - Hyperparathyroidism, hypothyroidism
  - Hypoparathyroidism, pseudohypoparathyroidism, pseudopseudohypoparathyroidism
- Fahr disease (idiopathic calcification of BG)
- Hypoxic-ischemic encephalopathy

https://CafePezeshki.IR

- BG, parasagittal cortical areas most frequently involved
  - Hyperintense BG lesions on T1/T2WI
  - Diffuse laminar cortical hyperintensity on T1WI in subacute stage
  - Laminar cortical, BG enhancement
- Carbon monoxide poisoning
  - Most specific findings: GP hypodensity on CT and hyperintensity on T2WI
- Langerhans cell histiocytosis
- Neurofibromatosis type 1
  - Hyperintensities in BG (usually GP), internal capsule bilaterally on T1WI
  - Smaller foci of hyperintensity in brainstem, cerebellar WM, dentate nucleus, BG, and periventricular WM on T2WI

PATHOLOGY

General Features

- Etiology
  - Underlying cirrhosis, acute fulminant viral hepatitis
  - Drugs and toxins
  - Shock &/or sepsis
  - Childhood hepatic diseases associated with bright hypothalamus and pituitary gland
  - Portosystemic shunting through collateral vessels
  - Brain accumulation of neurotoxic &/or neuroactive substances
    - Ammonia, manganese, aromatic amino acids
  - Alterations in neurotransmission, blood-brain barrier permeability, and energy metabolism
  - Proinflammatory cytokines (TNF α, interleukin 1α) may affect brain by production of nitric oxide in endothelial or neural cells after crossing defective blood-brain barrier
  - HE precipitated by ammoniagenic situations
- Associated abnormalities
  - Parkinsonian signs especially with midbrain involvement
  - Hepatic myelopathy in chronic liver disease with extensive shunts

Staging, Grading, & Classification

- Based on mechanism causing hepatic condition, HE classified into 3 types
  - **Type A**: HE associated with acute liver failure
  - **Type B**: HE associated with portal-systemic bypass without intrinsic hepatocellular disease
  - **Type C**: HE associated with cirrhosis & portal hypertension (most common)

Gross Pathologic & Surgical Features

- Laminar and pseudolaminar necrosis of cerebral cortex
- Polymicrocavitation at gray-white matter junction

Microscopic Features

- AHE: Severe cytotoxic edema in astrocytes with anoxic neuronal damage
- HE in chronic liver failure
  - Astrocytosis: Alzheimer type 2 astrocytes
  - Neuronal degeneration

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Altered mental status leading to stupor and coma
  - Motor abnormalities: Tremor, bradykinesia, asterixis, ataxia, apraxia, hyperreflexia
  - Seizures: Rare manifestation of HE
- Clinical profile
  - HE classified into 3 main groups based on length or characteristics of neurological changes
    - **Episodic/acute**: Use neuroimaging to exclude other diseases
    - **Chronic HE**
      - Relapsing HE: Similar to episodic with completely normal neurocognition between attacks
      - Persistent HE: No reversal of manifestations despite treatment
    - **Minimal HE** (a.k.a. latent or subclinical HE)
      - Abnormalities that cannot be detected by standard examination

Demographics

- Age
  - Both pediatric and adult patients with severe hepatic dysfunction
- Gender
  - No gender preference
- Epidemiology
  - Occurs in > 50% of all cirrhosis cases

Natural History & Prognosis

- Acute HE: Severe brain edema may ↑ intracranial pressure → cerebral herniation → death
- Neuropsychologic signs of HE follow ^{1}H-MRS rather than MR changes

Treatment

- Identify and remove/treat precipitating factors
- Nonabsorbable disaccharides (lactulose, lactitol)
- Antibiotics (neomycin) with oto-/nephrotoxicity
- L-ornithine-L-aspartate
- Molecular adsorbents recirculating system (MARS) albumin dialysis: Improves encephalopathy grade

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- After therapy, clinical features and MRS abnormalities improve 1st, followed 3-6 months later by normalization of BG signal
- BG signal abnormality typically normalizes within 1 year of liver transplantation

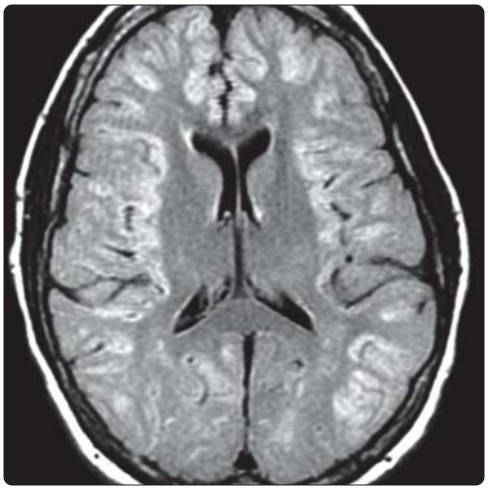
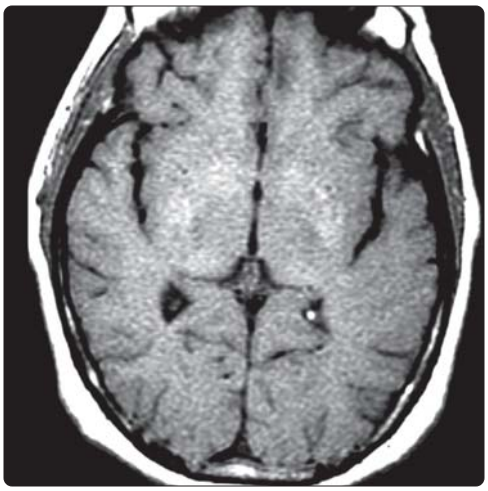
(Left) *Axial FLAIR MR in a patient with liver cirrhosis during an episode of hepatic encephalopathy shows symmetric areas of increased signal intensity along the corticospinal tract in both cerebral hemispheres. This signal abnormality reversed on a follow-up study obtained few months later (not shown).* **(Right)** *Coronal T2WI MR shows the typical T2 hypointense appearance of basal ganglia in a patient with chronic hepatic encephalopathy.*



(Left) *Axial NECT shows diffuse cerebral edema in a patient with acute hepatic encephalopathy manifested by loss of gray-white matter distinction and obliteration of the sulci.* **(Right)** *Axial FLAIR MR in a patient with acute hepatic encephalopathy shows diffuse cortical hyperintensity with relative sparing of the occipital regions.*



(Left) *Axial T1WI MR obtained prior to liver transplant shows bilateral symmetric hyperintensity in the globi pallidi, typical findings for chronic hepatic encephalopathy.* **(Right)** *Axial T1WI MR in the same patient obtained 14 months after transplant shows nearly complete interval resolution of the hyperintensity. The patient's movement disorder also resolved. Both clinical and imaging findings of hepatocerebral degeneration are potentially reversible. (Courtesy P. Hildenbrand, MD.)*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Cerebrovascular autoregulatory disorder
- Many etiologies with HTN as common component
  - Preeclampsia, eclampsia
  - Drug toxicity (e.g., chemotherapy)
  - Uremic encephalopathies

IMAGING

- General
  - Patchy parietooccipital cortical/subcortical edema in patient with severe acute/subacute HTN
- CT
  - Bilateral nonconfluent hypodense foci
  - ± symmetric lesions in basal ganglia
- MR
  - Parietooccipital T2/FLAIR hyperintensities in 95%
  - ± basal ganglia, pontine, cerebellar involvement
  - 3 patterns of hemorrhage: Focal parenchymal hemorrhage, microhemorrhages, convexity SAH
  - Generally no restriction on DWI
  - Variable patchy enhancement
  - However, atypical imaging patterns common

TOP DIFFERENTIAL DIAGNOSES

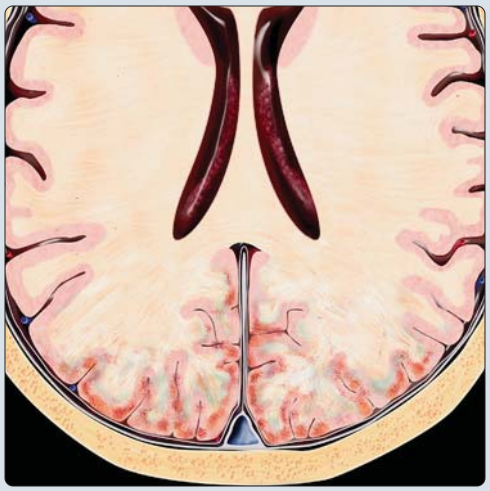
- Acute cerebral ischemia-infarction
- Status epilepticus
- Hypoglycemia
- Thrombotic microangiopathies (DIC, TTP, mHTN)

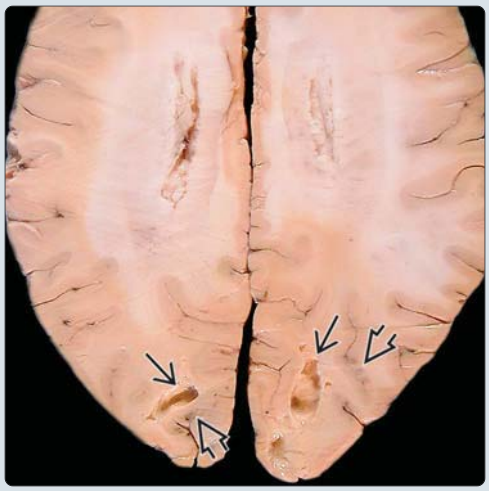
PATHOLOGY

- Acute HTN damages vascular endothelium
- Failed autoregulation causes blood-brain barrier disruption
- Result = vasogenic (not cytotoxic) edema

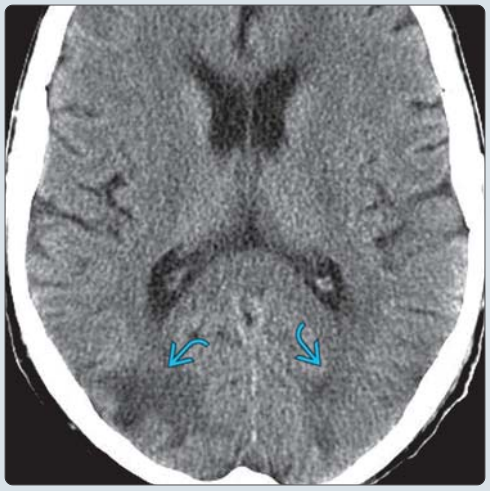
CLINICAL ISSUES

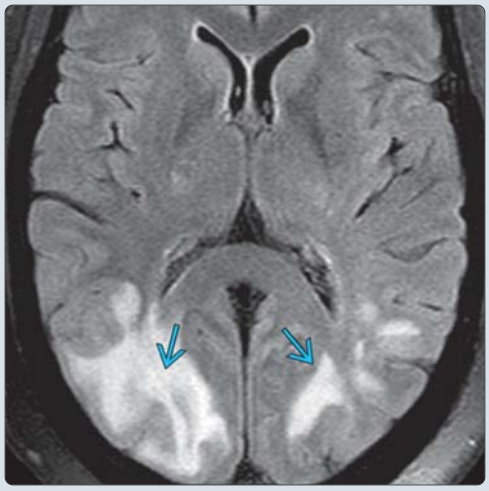
- Headache, seizure, ↓ mental status, visual symptoms
- Caution: Some patients may be normotensive or have only minimally elevated BP





(Left) *Axial graphic shows the classic posterior circulation cortical/subcortical vasogenic edema characteristic of posterior reversible encephalopathy syndrome (PRES). Petechial hemorrhage occurs in some cases.* **(Right)** *Gross pathology of a patient with complicated PRES demonstrates diffuse cerebral edema with swollen gyri. Multifocal petechial microhemorrhages are present in the occipital cortex ⇨ with several areas of focal encephalomalacia secondary to infarction ⇨. (Courtesy R. Hewlett, MD.)*





(Left) *Axial NECT in a 54-year-old patient with liver transplant on Tacrolimus FK 506 who presented with seizures demonstrates asymmetric subcortical edema in the occipital lobes bilaterally ⇨. Findings are typical of PRES.* **(Right)** *Axial FLAIR MR in a 20-year-old eclamptic woman who presented with severe hypertension, seizures, and altered sensorium shows classic findings of PRES with occipital cortical/subcortical edema ⇨. Her BP at presentation was 210/140.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Posterior reversible encephalopathy syndrome (PRES)

Synonyms

- Hypertensive encephalopathy
- Reversible posterior leukoencephalopathy syndrome (RPLS)

Definitions

- Variant of hypertensive encephalopathy characterized by headache, visual disturbances, altered mental function
- Cerebrovascular autoregulatory disorder
  - Multiple etiologies
  - Most caused by acute hypertension (HTN)

IMAGING

General Features

- Best diagnostic clue
  - Patchy parietooccipital cortical/subcortical edema in patient with severe acute/subacute HTN
- Location
  - Most common: Cortex, subcortical white matter
    - Parietooccipital lobes (85-95 %)
    - Frontal lobes (75-77%), temporal lobes (65%), cerebellum (50-55%)
    - At junctions of vascular watershed zones
    - Usually bilateral, often somewhat asymmetric
  - Less common: Basal ganglia
  - Rare: Predominant/exclusive brainstem involvement
- Size
  - Extent of abnormalities highly variable
- Morphology
  - Patchy > confluent; atypical patterns common

CT Findings

- NECT
  - May be normal or subtly abnormal
    - If PRES suspected, perform MR to confirm
  - Common: Bilateral nonconfluent hypodense foci
    - Posterior parietal, occipital lobes
    - Cortical watershed zones
  - Less common: Petechial cortical/subcortical or basal ganglionic hemorrhages
  - Uncommon: Thalamic, basal ganglia, brainstem, cerebellar hypodensities
- CECT
  - Usually no enhancement
  - Occasionally mild patchy/punctate enhancement
- CTA
  - Major vessels usually normal
  - Distal vessels may show diffuse vasoconstriction, focal irregularity, and beaded appearance

MR Findings

- T1WI
  - Hypointense cortical/subcortical lesions
- T2WI
  - **Typical** PRES: Hyperintense cortical/subcortical lesions
    - Parietooccipital lobes, cortical watershed zones
  - **Atypical** PRES: Almost as common as **typical** PRES
    - Frontal lobe, basal ganglia involvement
    - Extensive brainstem, cerebellar edema
- FLAIR
  - **Typical** PRES: Parietooccipital hyperintense cortical/subcortical lesions in 95%
  - **Atypical** PRES: Frontal lobe, basal ganglia, brainstem, cerebellar edema
  - "Leaky" blood-brain barrier may cause gadolinium accumulation in CSF, FLAIR hyperintensity
- T2* GRE
  - 3 patterns of hemorrhage: Focal parenchymal hemorrhage, microhemorrhages, convexity subarachnoid hemorrhage (SAH)
- DWI
  - Most common: No restriction
  - Less common: Hyperintense on DWI with "pseudonormalized" ADC
    - May indicate irreversible infarction
- PWI
  - May show ↑ rCBV
- T1WI C+
  - Variable patchy enhancement
- MRS
  - May show widespread metabolic abnormalities
    - ↑ Cho, Cr, mildly ↓ NAA
    - Usually return to normal within 2 months
- DTI
  - Shows foci of increased diffusivity and anisotropy loss
  - Vasogenic edema due to cerebrovascular autoregulatory dysfunction

Nuclear Medicine Findings

- SPECT
  - Variable findings reported; more common hypoperfusion in affected areas

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR + DWI
- Protocol advice
  - Repeat scan after blood pressure normalized

DIFFERENTIAL DIAGNOSIS

Acute Cerebral Ischemia-Infarction

- MCA distribution > > PCA
- Infarcts restrict on DWI; PRES usually does not

Status Epilepticus

- May cause transient gyral edema, enhancement
- Can mimic PRES, stroke, infiltrating neoplasm
- Unilateral (PRES often bilateral)

Hypoglycemia

- Severe parietooccipital edema
- Can resemble PRES, so history important

Thrombotic Microangiopathies

- Malignant hypertension, disseminated intravascular coagulation DIC, HUS, TTP
- Significant overlap as PRES common imaging manifestation

https://CafePezeshki.IR

Cerebral Hyperperfusion Syndrome

- Postcarotid endarterectomy, angioplasty, or stenting
  - Hyperperfusion syndrome occurs in 5-9% of cases
  - Perfusion MR imaging or CT scans show elevated rCBF
  - Aggressive control of blood pressure associated with clinical, radiological improvement

Gliomatosis Cerebri

- Entire lobe(s) involved
- Occipital lobe involvement less common
- Can mimic brainstem PRES

PATHOLOGY

General Features

- Etiology
  - Not yet completely understood
  - Diverse causes and clinical entities with acute HTN as common component
  - Acute HTN damages vascular endothelium
  - Failed autoregulation causes blood-brain barrier disruption
  - Result = vasogenic (not cytotoxic) edema
    - Arteriolar dilatation with cerebral hyperperfusion
    - Hydrostatic leakage (extravasation, transudation of fluid/macromolecules through arteriolar walls)
    - Interstitial fluid accumulates in cortex, subcortical white matter
    - Posterior circulation sparsely innervated by sympathetic nerves
      - Predilection for parietal, occipital lobes
  - Frank infarction with cytotoxic edema rare in PRES
- Associated abnormalities
  - Acute/subacute systemic HTN
  - Preeclampsia, eclampsia
    - Typically occurs after 20 weeks gestation
    - Rare: Headache, seizures up to several weeks post partum
  - Drug toxicity ± tumor lysis syndrome
    - Chemotherapeutic agents
      - e.g., cyclosporine, cisplatin
  - Thrombotic microangiopathies (DIC, TTP, malignant hypertension)
  - Uremic encephalopathies
    - Acute glomerulonephritis, lupus nephropathy, etc.
  - Severe infection
    - 25% of septic patients in shock develop PRES
    - Blood pressure can be normal or elevated

Gross Pathologic & Surgical Features

- Common
  - Cortical/subcortical edema
  - ± petechial hemorrhage in parietal, occipital lobes
- Less common
  - Anterior frontal lobes, basal ganglia, brainstem, cerebellum
- Uncommon
  - Lobar hemorrhage
  - Frank infarction

Microscopic Features

- Autopsy in severe cases shows microvascular fibrinoid necrosis, ischemic microinfarcts, variable hemorrhage
- Chronic: Demyelination, laminar necrosis, older hemorrhage

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, seizure, ↓ mental status, visual disturbances
  - Caution: Some patients, especially children, may be normotensive or have only minimally elevated BP
- Clinical profile
  - Pregnant female with acute systemic HTN, headache ± seizure
  - Middle-aged, older adult on chemotherapy
  - Child with kidney disease or transplant

Demographics

- Age
  - Any, but young > old
- Gender
  - F >> M
- Epidemiology
  - Preeclampsia in 5% of pregnancies
  - Eclampsia has lower rate (< 1%)

Natural History & Prognosis

- Usually no residual abnormalities after HTN corrected
  - Reversibility related to blood pressure normalization
  - Brainstem, deep white matter lesions less reversible than cortical/subcortical
  - Eclampsia more reversible than drug-related PRES
- In rare cases, may be life threatening
- Permanent infarction rare
- 4% of patients develop recurrent PRES

Treatment

- Control blood pressure, remove precipitating factors
- Delayed diagnosis/therapy can result in chronic neurologic sequelae

DIAGNOSTIC CHECKLIST

Consider

- Patchy bilateral parietooccipital hypodensities may be earliest NECT manifestation of PRES

Image Interpretation Pearls

- Major DDx of PRES is cerebral ischemia; DWI is positive in latter, usually negative in former

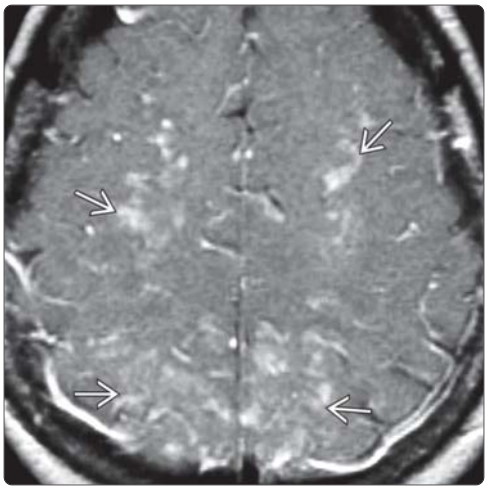
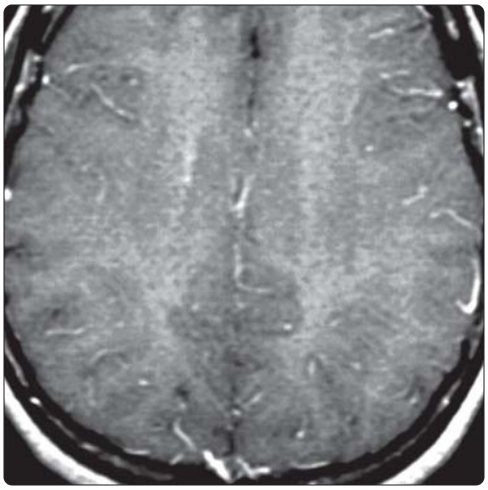
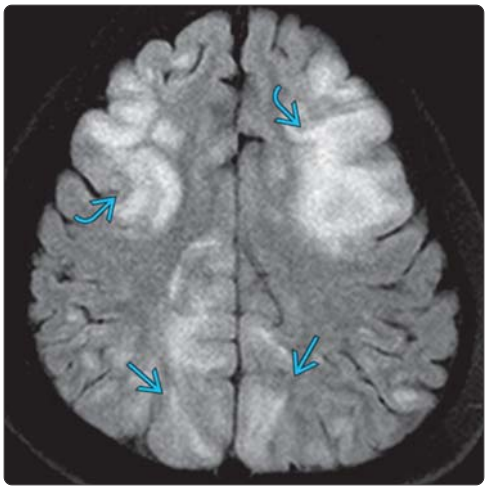
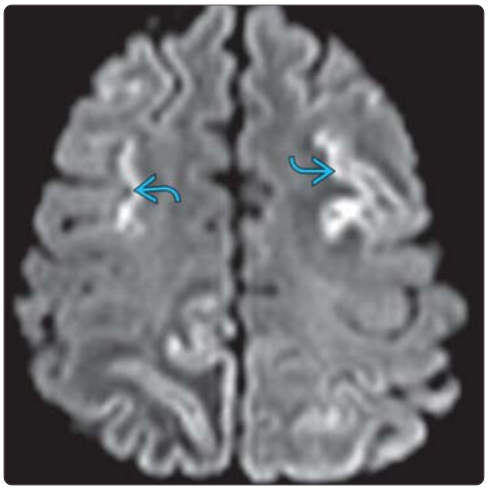
https://CafePezeshki.IR



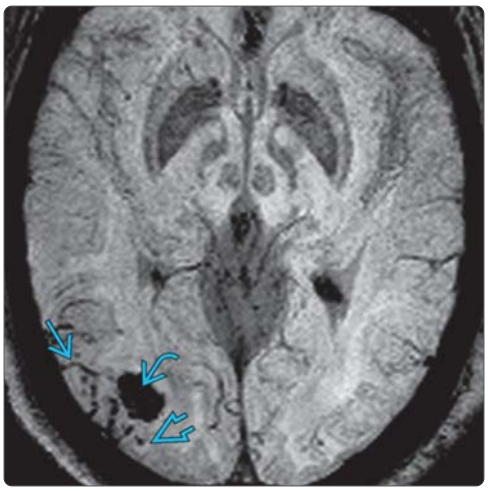


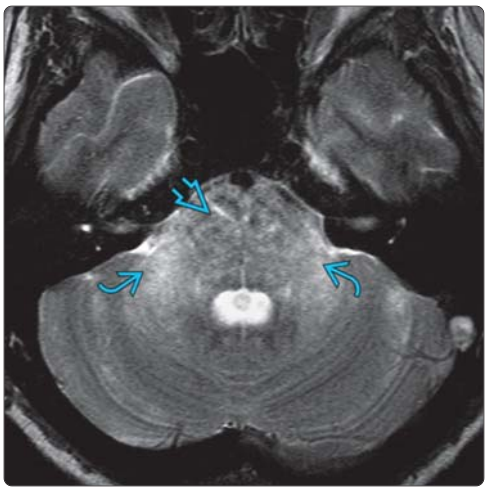
(Left) *Axial T1WI C+ MR in a patient with eclampsia shows numerous patchy cortical and subcortical enhancing foci in both occipital lobes and along the watershed zones. T2WIs (not shown) demonstrated hyperintensities in the same areas.* **(Right)** *Repeat scan was obtained 2 days after delivery and normalization of BP. MR is normal with the disappearance of the enhancing foci previously seen. Even florid MR changes of PRES usually resolve without clinical or imaging residua.*





(Left) *Axial FLAIR MR in a patient with systemic lupus erythematosu (SLE) and renal failure demonstrates cortical/subcortical edema in the frontal and parietal lobes. The frontal lobes are involved in 75-7 % of PRES cases.* **(Right)** *Axial DWI in the same patient shows some patchy areas of frontal cortical restricted diffusion. Because most cases of PRES are caused by vasogenic and not cytotoxic edema DWI is usually negative. Diffusion restriction has been reported like in this case and may lead to residual abnormalities.*





(Left) *Axial SWI in a hypertensive patient who presented with visual disturbances, headache, and seizures demonstrates the 3 pattern of hemorrhages which can be seen in PRES. This case shows lobar hemorrhage, cortical SAH, and microhemorrhages in the right occipital lobe.* **(Right)** *Axial T2 MR in a patient with sepsis and slightly elevated BP shows atypical findings of PRES. There is extensive edema involving the pons and both the middle cerebellar peduncles.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Chronic hypertensive encephalopathy (CHE)
- Subcortical arteriosclerotic encephalopathy

IMAGING

- General features
  - Lacunae (lenticular nuclei, pons, thalamus, internal capsule, caudate)
  - Cerebral hemorrhage (basal ganglia/external capsule, thalamus)
  - Confluent WM disease (centrum semiovale, corona radiata)
- CT
  - Diffuse WM hypodensity on CT
  - Lacunar infarcts (BG, thalamus/brainstem)
- MR
  - Hyperintense lesions within corona radiata, centrum semiovale, basal ganglia
  - Multiple microhemorrhages (GRE, SWI)
    - Predilection for BG/thalami, brainstem, cerebellum
  - Acute WM lesions may restrict

TOP DIFFERENTIAL DIAGNOSES

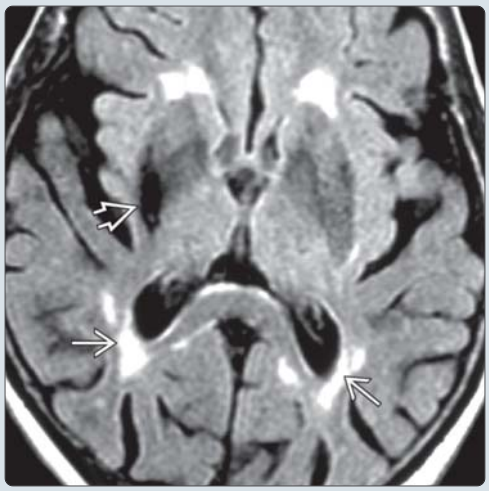
- Amyloid angiopathy
- CADASIL
- Dementing disorders
  - Alzheimer dementia
  - Multi-infarct dementia
- Antiphospholipid antibody syndrome
- Neuropsychiatric systemic lupus erythematosus
- Vasculitis

PATHOLOGY

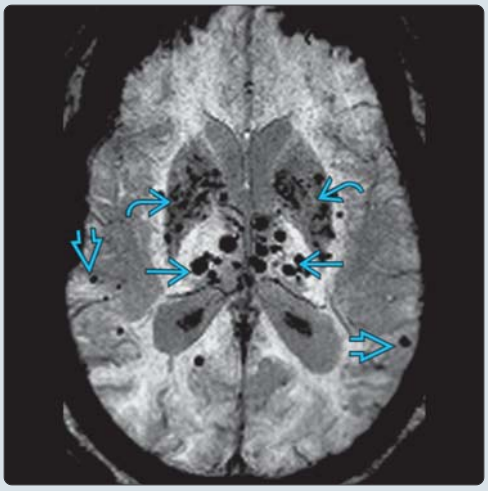
- Chronic HTN is associated with hyaline deposition within small arteries (so-called lipohyalinosis)

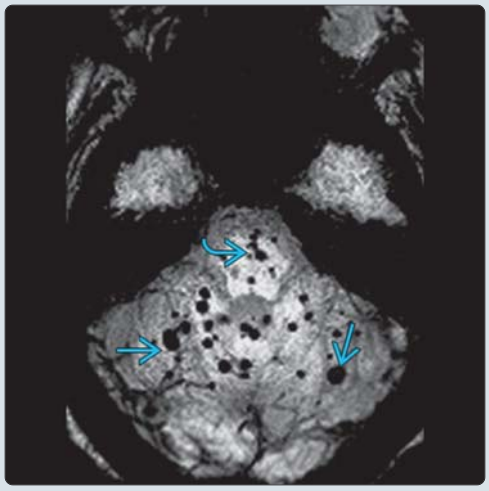
CLINICAL ISSUES

- Stepwise/gradual mental deterioration
- Acute strokes, lacunar syndrome



(Left) *Axial NECT shows the typical appearance of chronic hypertensive encephalopathy, seen here as diffuse confluent periventricular white matter hypodensity* ➡. **(Right)** *Axial FLAIR in a 72-year-old woman with longstanding systemic HTN demonstrates multifocal discrete and confluent hyperintensities scattered throughout the deep periventricular white matter, especially near the atria and occipital horns* ➡. *Note the old, hypertensive, basal ganglionic hemorrhage* ➡.





(Left) *Axial SWI image in a patient with long standing poorly controlled hypertension shows numerous microhemorrhages in the basal ganglia* ➡ *and thalami* ➡. *A few microhemorrhages are also seen in the subcortical white matter* ➡. **(Right)** *Axial SWI image in the same patient shows more microhemorrhages in the brainstem* ➡ *and both cerebellar hemispheres* ➡. *The distribution of these microhemorrhages is typical for chronic hypertensive encephalopathy.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Chronic hypertensive encephalopathy (CHE)

Synonyms

- Subcortical arteriosclerotic encephalopathy
  - a.k.a. Binswanger disease
- Hypertension-related microvascular disease

Definitions

- Brain parenchymal changes due to longstanding effects of untreated or poorly treated systemic hypertension (HTN)
  - CHE is most common cause of leukoaraiosis (diffuse rarefaction of white matter)
    - Others include diabetes
- CHE: Important cause of cognitive deficits caused by vascular disease (i.e., vascular dementia)

IMAGING

General Features

- Best diagnostic clue
  - 2 major features
    - Diffuse white matter (WM) lesions (hypodense on CT, hyperintense on T2WI)
    - Microhemorrhages ("bloom" on T2*)
- Location
  - WM lesions
    - Centrum semiovale, corona radiata
    - Brainstem, cerebellum
  - Gray matter lesions
    - Basal ganglia (BG), thalami, brainstem
  - Microhemorrhages
    - Basal ganglia/thalami, brainstem, cerebellum, subcortical WM
- Size
  - WM lesions initially small; may become confluent over time
- Morphology
  - Rounded or patchy, discrete or confluent

CT Findings

- NECT
  - Focal hypodensities (usually multiple)
    - BG, thalamus, brainstem
    - Often due to lacunar infarcts
  - Diffuse periventricular hypodensity
  - ± hyperdense lesions
    - Focal/confluent petechial hemorrhages

MR Findings

- T1WI
  - Lesions usually hypointense
    - Less conspicuous than on T2WI or FLAIR
- T2WI
  - Hyperintense lesions within corona radiata, centrum semiovale, basal ganglia
- FLAIR
  - Hyperintense or central hypointensities + peripheral hyperintensity
- T2* GRE
  - Multifocal hypointense lesions (microhemorrhages)
    - Predilection for BG/thalami, cerebellum
    - Subcortical WM (especially posterior brain regions)
- DWI
  - Acute WM lesions may restrict
  - ADC lower (acute) or higher (chronic)
- PWI
  - ↓ perfusion measurements in patients with confluent lesions
- T1WI C+
  - Generally no enhancement
- MRS
  - Older HTN patients have ↑ myoinositol to creatine ratio
    - Similar to patients with Alzheimer disease (AD)
  - Lower NAA levels in chronic hypertension
- DTI
  - ↑ mean diffusivity (MD), ↓ fractional anisotropy (FA)
    - Seen in both T2WI hyperintensities, normal-appearing WM

Nuclear Medicine Findings

- Frontal lobe (cingulate, superior frontal gyri) predominantly affected
- Regional CBF Tc-99m-HMPAO SPECT
  - Mild CHE: Reduced frontal CBF
  - Severe CHE: Diffuse cerebral hypoperfusion

Imaging Recommendations

- Best imaging tool
  - FLAIR (WM lesions) + T2* (GRE, SWI) for microhemorrhages

DIFFERENTIAL DIAGNOSIS

Amyloid Angiopathy

- Amyloid deposition in small/medium arteries of cerebral leptomeninges, cerebral cortex
- Recurrent cerebral hemorrhages, most common in frontal and parietal lobes, involving cortex and subcortical WM
- Rarely cerebellar, putaminal, thalamic, or brainstem

CADASIL

- Nonarteriosclerotic, amyloid-negative hereditary angiopathy primarily affecting leptomeningeal and long perforating arteries
- Characteristic subcortical lacunar infarcts and leukoencephalopathy in young adults
- Anterior temporal WM and external capsule lesions are highly suggestive of CADASIL

Various Dementias

- Alzheimer disease
  - Parietal and temporal cortical atrophy, volume loss in hippocampi, entorhinal cortex
  - Often coexisting microvascular disease, WM hyperintensities
- Multi-infarct dementia
  - Hyperintense lesions on T2WI and focal atrophy suggestive of chronic infarcts

Antiphospholipid Antibody Syndrome

- Early stroke, recurrent arterial and venous thromboses, spontaneous fetal loss, thrombocytopenia

https://CafePezeshki.IR

Systemic Lupus Erythematosus (SLE)

- Most common: Small multifocal WM lesions; usually diagnosed in 3rd or 4th decade (earlier than in CHE)
- Periventricular or more diffuse WM changes

Other Vasculitides

- Primary angiitis of CNS
- Granulomatous angiitis
- Polyarteritis nodosa, Behçet disease

Pseudoxanthoma Elasticum

- Systemic HTN, subcortical leukoencephalopathy, multiple strokes, and dementia in 3rd and 4th decades (younger than CHE patients)

PATHOLOGY

General Features

- Etiology
  - Chronic HTN is associated with hyaline deposition within small arteries (so-called lipohyalinosis)
  - 2 major mechanisms postulated for leukoaraiosis related to lipohyalinosis
    - Chronic hypoperfusion may cause ischemia of small brain regions, which later coalesce into large abnormal WM regions
    - Increased permeability of blood vessels may allow leakage of plasma contents
  - Chronic HTN impairs dilatation of collateral vessels in cerebral circulation
    - Impaired cerebral autoregulation and decreased vasodilatory capacity; ↑ susceptibility to cerebral infarction
- Associated abnormalities
  - Over time, lesions continue to accumulate, principally within subcortical WM
  - Various genetic factors, including DNA sequence variations occurring within single nucleotide (single-nucleotide polymorphisms), appear to place some patients at increased risk
  - Patients with HTN may also develop large parenchymal hemorrhages

Gross Pathologic & Surgical Features

- Demyelination of periventricular and central WM
- Multiple lacunae and infarctions
- Tortuosity of small arteries and small artery occlusions

Microscopic Features

- Multiple petechial microhemorrhages
- Leukoaraiosis: Partial loss of myelin, axons, oligodendroglia, glial cells
- Alterations of small penetrating arteries leading to luminal stenosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually seen in middle-aged or elderly
    - Memory loss, depression, various features of dementia
  - Long tract findings, pseudobulbar syndrome
- Other signs/symptoms
  - Risks: Hypertensive hemorrhage, acute hypertensive encephalopathy (posterior reversible encephalopathy syndrome)
- Clinical profile
  - Stepwise or gradual progression of mental deterioration
  - Acute strokes, lacunar syndrome
  - Subacute onset of focal, pseudobulbar, and extrapyramidal signs

Demographics

- Age
  - Incidence increases with age
- Gender
  - HTN more prevalent in men than women
- Ethnicity
  - HTN more prevalent in African Americans
- Epidemiology
  - In addition to HTN, higher prevalence in patients with diabetes mellitus and peritoneal dialysis for renal failure

Natural History & Prognosis

- Arteriolosclerosis associated with systemic HTN and increasing age
  - Small vessel occlusive changes are primary factor in pathogenesis of hyperintense WM lesions on T2WI in elderly
- Periventricular hyperintense WM lesions
  - Increased in patients with untreated systemic HTN
- Age, smoking, and HTN are independent predictors of hyperintense lesions on T2WI
- Untreated or poorly controlled systemic HTN → intracranial hemorrhages usually involving BG, thalamus, brainstem, or dentate nucleus of cerebellum
- CHE eventually causes vascular-type dementia

DIAGNOSTIC CHECKLIST

Consider

- Is history of chronic hypertension present
  - Many disease states have imaging findings like CHE

Image Interpretation Pearls

- SWI superior sensitivity for chronic microhemorrhages compared to T2*GRE

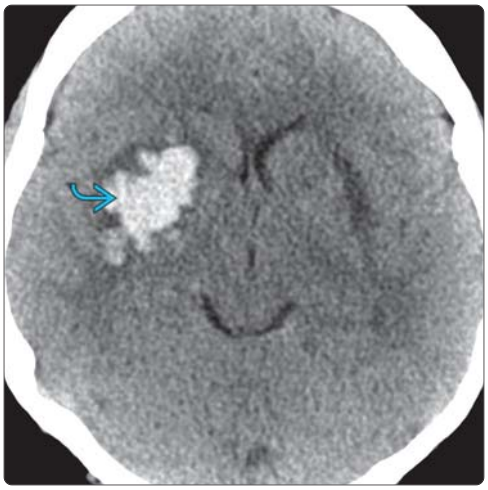
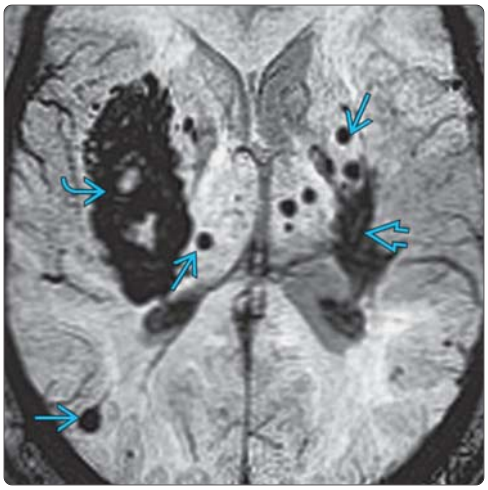
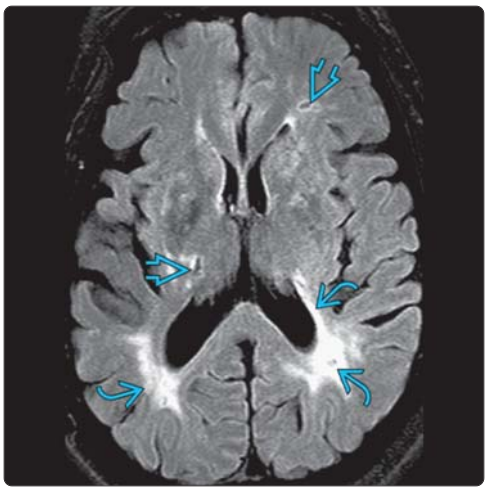
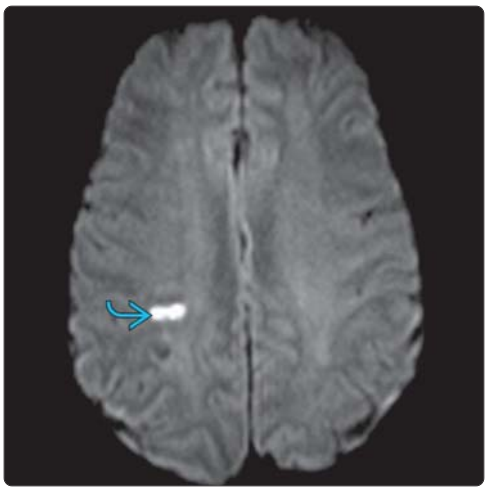
(Left) *Axial NECT demonstrates frontal and parietal periventricular confluent white matter hypodensities* ➡ *in a patient with chronic hypertensive encephalopathy and clinical Binswanger disease.* **(Right)** *Axial NECT slice through corona radiata in the same patient shows bilateral confluent hypodense lesions* ➡. *These findings are sometimes termed "subcortical arteriosclerotic encephalopathy."*





(Left) *Axial NECT shows classic location of an acute hypertensive hemorrhage* ➡ *involving the lateral aspect of the putamen and external capsule.* **(Right)** *Axial SWI in the same patient shows the acute right basal ganglionic hemorrhage* ➡ *and in addition findings of chronic hypertensive encephalopathy. There are microhemorrhages* ➡ *in the basal ganglia, thalami and subcortical white matter. Hemosiderin staining due to an old hemorrhage is seen in the left basal ganglia* ➡.





(Left) *Axial FLAIR MR in a patient with chronic hypertensive encephalopathy shows focal and confluent hyperintensities* ➡ *involving periventricular and deep white matter regions. Also noted are multiple old lacunar infarcts* ➡. **(Right)** *Axial DWI in the same patient shows a focal area of restricted diffusion in the right centrum semiovale* ➡ *consistent with a small acute infarct.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Idiopathic intracranial hypertension (IIH)
- Pseudotumor cerebri
- Benign intracranial hypertension
- ↑ intracranial pressure (ICP) without identifiable cause

IMAGING

- Empty or partially empty sella
- Posterior globe flattening
- Intraocular protrusion of optic nerve head
- Optic nerve sheath enlargement: Widened ring of CSF around optic nerve
- Optic nerve tortuosity
- Slit-like ventricles, rare: Poor neuroimaging sign of IIH
- MRV: Often shows transverse sinus stenosis and "flow gaps"
  - Whether this is cause or consequence of raised ICP is controversial
- Best imaging tool: MR brain + T2 coronal fat-sat orbit + MRV

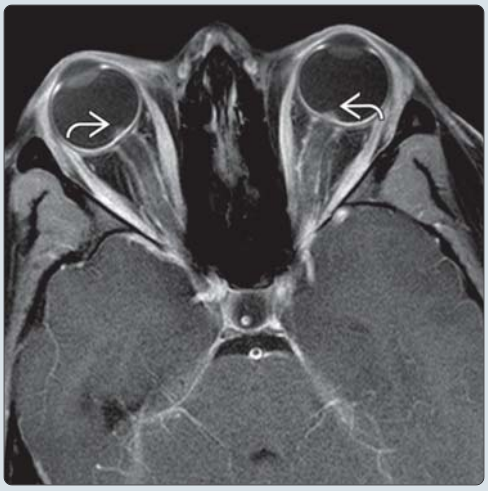
TOP DIFFERENTIAL DIAGNOSES

- Secondary pseudotumor syndromes
- Idiopathic or post-inflammatory (i.e., multiple sclerosis) optic nerve atrophy
- Idiopathic empty sella (normal variant)

CLINICAL ISSUES

- Obese woman age 20-44 years with headache and papilledema most common presentation
  - Headache in 90-95%
  - Papilledema (bilateral optic nerve head swelling) virtually universal
- Progressive visual loss ± CN6 paresis, diplopia
- Chief hazard: Vision loss from chronic papilledema
- Treatment: Medical or surgical (LP, shunt, optic nerve sheath fenestration)

(Left) *Axial T2WI MR shows dilated CSF spaces around the optic nerves ⇨ and protrusion of the optic nerve papilla into the posterior globes ⇨. Opening CSF pressure in this 32-year-old woman was 45 cm of H_2O. Prominent CSF space in the suprasellar cistern represents an empty sella ⇨. Note the tortuosity of the left optic nerve.* **(Right)** *Sagittal T1WI MR in the same patient shows a partially empty sella ⇨, suggesting high CSF pressure in this young obese woman with headaches.*



(Left) *Axial T1WI C+ MR in the same patient demonstrates enhancement, as well as protrusion of prelaminar optic nerves bilaterally ⇨. Mild diffuse optic nerve sheath enhancement is also present.* **(Right)** *Coronal T1WI C+ FS MR in the same patient shows diffuse enhancement of the optic nerve sheaths ⇨ associated with prominent subarachnoid spaces along the optic nerves. Treatment for pseudotumor cerebri includes weight loss and medications, as well as lumbar punctures, shunt, and optic nerve fenestration.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Idiopathic intracranial hypertension (IIH)
- Pseudotumor cerebri (PTC)

Synonyms

- Pseudotumor cerebri
- Benign intracranial hypertension

Definitions

- ↑ intracranial pressure (ICP) without identifiable cause
- Association of any medication or condition with IIH better termed "secondary pseudotumor syndrome"

IMAGING

General Features

- Best diagnostic clue
  - Flattening of posterior sclera, intraocular optic nerve protrusion, enlarged optic nerve sheath, increased tortuosity of optic nerve, partially empty sella, and venous sinus stenosis in patient with clinical findings of IIH
- Imaging in IIH
  - Exclude identifiable causes of ↑ ICP
  - Detect findings associated with IIH

CT Findings

- NECT
  - Usually normal
  - Enlarged optic nerve sheaths ± empty sella
  - Less common: Slit ventricles

MR Findings

- T1WI
  - Partially empty sella turcica
  - Enlarged/tortuous optic nerve sheaths
  - Posterior sclera flattened
  - Small "pinched" ventricles
  - Midline sagittal: Cerebellar tonsillar ectopia may mimic Chiari malformation type I
- T2WI
  - Empty or partially empty sella
  - Posterior globe flattening
  - Intraocular protrusion of optic nerve head
  - Optic nerve sheath enlargement: Widened ring of CSF around an optic nerve
  - Optic nerve tortuosity
  - Slit-like ventricles, rare: Poor neuroimaging sign of IIH
- T1WI C+
  - Enhancement of prelaminar optic nerve
- MRV
  - Often shows transverse sinus stenosis and "flow gaps"
  - Whether this is cause or consequence of raised ICP is controversial
- CTV
  - CT venogram helpful to differentiate hypoplastic sinus segment from thrombosis

Imaging Recommendations

- Best imaging tool
  - MR brain + T2 coronal fat-sat orbit + MRV

DIFFERENTIAL DIAGNOSIS

Secondary Pseudotumor Syndromes

- Cerebral venous abnormalities
  - Dural venous sinus thrombosis, bilateral jugular vein thrombosis, superior vena cava syndrome, arteriovenous fistula
  - Decreased CSF absorption from previous intracranial infection or subarachnoid hemorrhage, hypercoagulable states
- Medications and exposures
  - Tetracycline, minocycline, vitamin A, lithium, retinoids, anabolic steroids, withdrawal from chronic corticosteroids
- Medical conditions
  - Endocrine disorders (Addison disease, hypoparathyroidism), hypercapnia, sleep apnea, SLE

Idiopathic or Post-Inflammatory Optic Nerve Atrophy

- Small optic nerves without scleral flattening

Idiopathic Empty Sella

- Normal variant; normal optic nerve sheaths

Chiari I Malformation

- Peg-like tonsils ≥ 5 mm below the foramen magnum
- Low cerebellar tonsils in IIH may mimic Chiari I: Look for other neuroimaging signs of IIH and clinical findings (papilledema)

PATHOLOGY

General Features

- Etiology
  - Precise etiology of IIH unknown
  - 5 different proposed mechanisms resulting in ↑ ICP
    - ↑ cerebral volume
      - Possible etiology: ↑ interstitial fluid, ↑ blood volume, ↑ tissue volume
    - ↑ CSF volume
      - Possible etiology: ↑ CSF production rate, ↑ CSF outflow resistance
    - ↑ cerebral arterial pressure
      - Possible etiology: Loss of cerebral autoregulation
    - ↑ venous blood volume and interstitial fluid
      - Possible etiology: ↑ cerebral venous pressure
    - ↓ CSF outflow and ↑ CSF volume

Gross Pathologic & Surgical Features

- Bilateral papilledema

Microscopic Features

- Normal CSF cytology, chemistry

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache in 90-95%

https://CafePezeshki.IR

Diagnostic Criteria for Pseudotumor Cerebri Syndrome

1. Required for Diagnosis of Pseudotumor Cerebri Syndrome
A. Papilledema
B. Normal neurologic examination except for cranial nerve abnormalities
C. Neuroimaging: Normal brain parenchyma without evidence of hydrocephalus, mass, or structural lesion and no abnormal meningeal enhancement on MR, ± gadolinium, for typical patients (female and obese), and MR, ± gadolinium, and magnetic resonance venography for others; if MR is unavailable or contraindicated, contrast-enhanced CT may be used
D. Normal CSF composition
E. Elevated lumbar puncture opening pressure (> 250 mm CSF in adults and > 280 mm CSF in children [250 mm CSF if the child is not sedated and not obese]) in properly performed lumbar puncture
2. Diagnosis of Pseudotumor Cerebri Syndrome Without Papilledema
In absence of papilledema, a diagnosis of pseudotumor cerebri syndrome can be made if B–E from above are satisfied, and in addition the patient has unilateral or bilateral abducens nerve palsy
In absence of papilledema or 6th nerve palsy, diagnosis of pseudotumor cerebri syndrome can be suggested but not made if B–E from above are satisfied, and in addition at least 3 of the following neuroimaging criteria are satisfied
i. Empty sella
ii. Flattening of posterior aspect of globe
iii. Distention of perioptic subarachnoid space ± tortuous optic nerve
iv. Transverse venous sinus stenosis
Diagnosis of pseudotumor cerebri syndrome is definite if patient fulfills criteria A-E. The diagnosis is considered probable if criteria A-D are met, but the measured CSF pressure is lower than specified for a definite diagnosis.

Liguori C et al. Revised diagnostic criteria for the pseudotumor cerebri syndrome in adults and children. Neurology. 2014 May 13;82(19):1752-3.

  - Generalized, episodic, throbbing, aggravated by Valsalva
  - Papilledema (bilateral optic nerve head swelling) virtually universal
  - Progressive visual loss ± CN6 paresis, diplopia
  - Uncommon: Vertigo, tinnitus, occasional pituitary disfunction
  - In children: Irritability, "sunset" sign, bulging anterior fontanelle
- Clinical profile
  - Obese, young to middle-aged woman with headache, papilledema

Demographics

- Age
  - Peak = 15-40 years (occasionally seen in children)
- Gender
  - M:F = 1:4-8
- Epidemiology: ↑ prevalence with obesity

Natural History & Prognosis

- Chief hazard: Vision loss from chronic papilledema

Treatment

- Goal: Prevent visual loss, improve associated symptoms
- Options
  - Medical
    - Weight loss
    - Carbonic anhydrase inhibitors: cetazolamide
  - Therapeutic lumbar puncture
  - Surgical: Reserved for patients who continue to experience vision loss despite conservative management and those initially presenting with rapid vision loss
    - Lumboperitoneal shunt
    - Optic nerve sheath fenestration
  - Venous stent placement
    - Stent placement in transverse sinus stenosis with significant pressure differentials across stenosis has shown to improve symptoms and reduce papilledema
    - ↓ cerebral venous pressure, improve CSF resorption in venous system: ↓ intracranial (CSF) pressure, improving symptoms of IIH and ↓ papilledema
    - Venous stent placement is controversial

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Must exclude venous thrombosis/space-occupying lesion

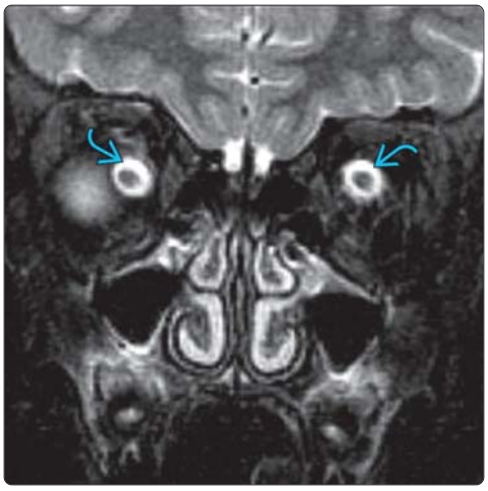
(Left) *Sagittal T1 MR in a patient with idiopathic intracranial hypertension shows a partially empty sella with the pituitary gland flattened along the floor of the sella.* **(Right)** *MIP image of a post-contrast MR venogram study in the same patient shows stenosis of the distal transverse sinuses bilaterally. Transverse sinus stenosis is common in patients with IIH.*



(Left) *Coronal T2 FS MR of orbits in a 6 year old with papilledema and opening CSF pressure of 32 of H_2O shows dilated optic nerve sheaths bilaterally.* **(Right)** *Sagittal T2 FS MR in the same patient shows tortuosity of the optic nerve, dilated optic nerve sheath, flattening of the posterior sclera, and mild bulging of the optic nerve disc head due to papilledema. Findings are typical of idiopathic intracranial hypertension (IIH). Childhood obesity has a strong association with an increased risk of pediatric IIH.*

(Left) *Axial T2WI MR in a young obese female with headaches and visual symptoms shows mild dilatation of the CSF spaces around the optic nerves. There is mild flattening of the posterior sclera and minimal protrusion of the optic nerve papilla into the posterior globe.* **(Right)** *3D TOF-MR venogram image in the same patient shows stenosis in the distal transverse sinuses bilaterally. Stent placement in sinus stenosis with significant pressure differentials has shown to reduce papilledema.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Anoxic-ischemic encephalopathy, usually with bilateral lesions, caused by inhalation of carbon monoxide (CO) gas

IMAGING

- Best diagnostic clue: Globi pallidi (GP) T2/FLAIR hyperintensity
- T1 MR: Both hypointensity in GP (likely necrosis) and hyperintensity in GP (likely hemorrhage) reported
- T2 MR: Ischemia/infarct of GP
  - Cerebral hemispheric WM: Bilateral confluent hyperintense WM (periventricular, centrum semiovale)
  - Cortical hyperintensity (commonly temporal lobe)
  - Medial temporal lobe hyperintensity (uncommon despite frequent pathologic findings)
- DWI MR: Acute restriction is common
- MRS: Progressively ↓ NAA/Cr with time; ↑ Cho/Cr
  - Progressively ↑ Lac/Cr with time

TOP DIFFERENTIAL DIAGNOSES

- Wilson disease
- Japanese encephalitis (JE)
- Creutzfeldt-Jakob disease (CJD)

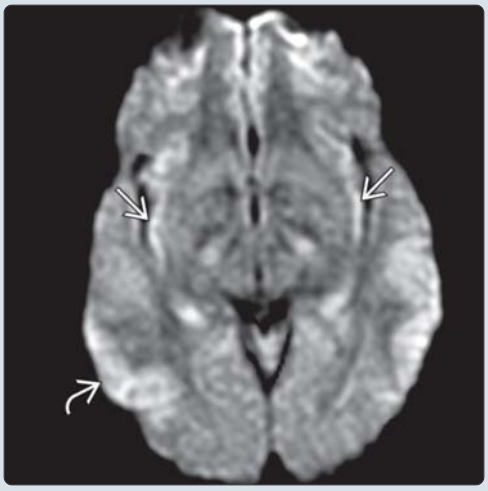
PATHOLOGY

- Impairs the ability of erythrocytes to transport oxygen, causing hypoxia and reducing cellular oxygen metabolism
- CO-induced parkinsonism
- Demyelination, edema, and hemorrhagic necrosis

CLINICAL ISSUES

- Acute toxicity: Nausea, vomiting, headache
- Neuropsychological sequelae
- Hyperbaric oxygen (HBO) therapy: Treatment of choice in acute carbon monoxide poisoning (COP) (within 6 hours for best effect)
- Delayed neurologic sequelae (10-30% of victims)

(Left) *Axial graphic shows the typical involvement of the brain by CO poisoning. The globi pallidi (GP) ⇨ are most affected, followed by the cerebral white matter. Pathologically, there is necrosis of the GP with variable areas of necrosis and demyelination in the white matter.* **(Right)** *Axial FLAIR MR in this patient with acute CO poisoning shows the classic appearance with symmetric GP hyperintensity. Note the additional involvement of the posterior temporal cortex ⇨ and hippocampi ⇨, a less common finding.*



(Left) *Axial DWI MR in the same patient shows areas of restricted diffusion involving the posterior temporal cortex ⇨, hippocampal tail, and insular cortex ⇨ bilaterally. DWI often shows the affected areas more readily than corresponding T2 or FLAIR MR images.* **(Right)** *Axial FLAIR MR in the same patient shows symmetric hyperintensity involving the bilateral hippocampi ⇨ and posterior temporal cortex ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Carbon monoxide (CO) poisoning (COP)

Definitions

- Anoxic-ischemic encephalopathy, usually with bilateral lesions, caused by inhalation of CO gas

IMAGING

General Features

- Best diagnostic clue
  - Globi pallidi (GP) hyperintensity on T2WI or hypodensity on CT
- Location
  - GP: Most common site of abnormality
  - Cerebral white matter (WM): 2nd most common
  - Putamen, caudate nucleus, thalamus, substantia nigra, corpus callosum, fornix, hippocampus: Less common
- Morphology
  - Typically oval lesions confined to GP
  - Severe changes show loss of gray-white differentiation due to diffuse edema

CT Findings

- NECT
  - Symmetric hypodensity in GP and symmetric diffuse hypodensity in cerebral WM

MR Findings

- T1WI
  - In GP, both T1 hypointensity (likely due to necrosis) and T1 hyperintensity (likely due to hemorrhage) reported
- T2WI
  - Ischemia/infarct of GP
    - Bilateral T2 hyperintensities of GP surrounded by hypointense rim (likely due to hemosiderin)
    - Caudate nucleus and putamen may be affected, either alone or in addition to GP abnormality
  - Cerebral hemispheric WM: Bilateral, confluent, T2 hyperintense WM (periventricular, centrum semiovale)
    - Reflects diffuse demyelination
  - Abnormal signal in cerebral cortex (less frequent)
    - Cortical hyperintensity: Most common pattern, with predilection for temporal lobe
    - Abnormalities in perisylvian cortex, anterior temporal lobe, and insular cortex
    - Asymmetrical, diffuse cortical hyperintensity affecting parietal and occipital lobes also possible
  - Medial temporal lobe in region of hippocampus may show signal abnormality
    - Uncommon despite frequent pathological findings
  - Diffuse, bilateral high signal within cerebellar hemispheres, affecting cortex and WM
    - Not seen in acute setting; develops later
  - Delayed encephalopathy 2-3 weeks after recovery
    - Additional high intensity in corpus callosum, subcortical U-fibers, internal and external capsules
    - Associated with low intensity in thalamus and putamen (due to iron deposition)
- FLAIR
  - Same as T2WI
  - Additional periventricular high signal in acute COP
    - May not be visible on conventional T2 FSE
- DWI
  - Early (acute) stage of COP
    - Diffuse symmetric DWI hyperintensity in subcortical hemispheric WM (restricted diffusion due to cytotoxic edema)
      - WM may appear normal on FLAIR, particularly in low-dose exposure
    - Corresponding ADC maps: Low ADC values in same regions
  - Delayed stage of COP (weeks post exposure)
    - High signal area in cerebral WM
    - ± abnormal WM findings on T2WI
    - Low ADC values persist at this stage
  - Chronic stage of COP
    - Gradual increase in ADC values, consistent with macrocystic encephalomalacia
    - Hyperintense WM areas on T2WI and symmetric bright lesions in GP
  - Diffusion tensor imaging (DTI): FA values decreased in deep white matter including centrum semiovale
    - High correlation between FA and Mini-Mental State Examination
- T1WI C+
  - Variable enhancement in GP, often in patients with acute COP
- MRS
  - Serial ^{1}H-MRS scans performed after appearance of delayed sequelae in COP, disturbances of neuronal function, membrane metabolism, and anaerobic energy metabolism
    - Persistently ↑ Cho/Cr at DWI abnormal WM site
    - Progressively ↓ NAA/Cr with time
      - ↓ NAA suggests neuron and axon degeneration
    - Progressively ↑ Lac/Cr with time, often seen in high-dose exposure cases

Nuclear Medicine Findings

- SPECT studies show cerebral hypoperfusion deficits
  - ↓ regional cerebral blood flow in frontal and temporal cortices and diffuse hypoperfusion defects have been reported

Imaging Recommendations

- Best imaging tool
  - MR more sensitive than CT for detection of brain abnormalities following COP
  - DWI best for lesion detection in acute stage of COP
- Protocol advice
  - Multiplanar MR including DWI

DIFFERENTIAL DIAGNOSIS

Wilson Disease

- WM/GM lesions, involving BG, dentate nucleus, pons, mesencephalon
- T1 hypointense (occasionally hyperintense) lesions
- Variably T2 hyperintense/hypointense

https://CafePezeshki.IR

Japanese Encephalitis (JE)

- Homogeneous T2 hyperintensities in BG and thalami
- Most characteristic finding in JE
  - Bilateral thalamic hyperintensities ± hemorrhage
- JE is meningoencephalitis → meningeal enhancement

Creutzfeldt-Jakob Disease (CJD)

- Progressively symmetric hyperintense changes in BG, thalami, cerebral cortex
- DWI and FLAIR most sensitive

Leigh Syndrome

- Symmetrical spongiform brain lesions with onset in infancy/early childhood
- Lesions predominantly in brainstem, BG (particularly putamen), and cerebral WM
- Focal, bilateral, and symmetric T2 hyperintense lesions

PATHOLOGY

General Features

- Etiology
  - CO: Colorless, odorless, tasteless gas
  - 200x affinity for hemoglobin than O_2
  - Brain and heart damage once CO-Hgb level exceeds 20%
  - Mechanisms of brain injury
    - Impairs ability of erythrocytes to transport oxygen, causing hypoxia and reducing cellular oxygen metabolism
    - Lipid peroxidation leading to oxidative injury
    - Damage to vascular endothelium due to deposition of peroxynitrite
    - Excitotoxicity, apoptosis
- Associated abnormalities
  - CO-induced parkinsonism
    - GP lesions after COP or periventricular and deep WM hyperintensities without BG lesions
    - Extrapyramidal syndrome may be due to lesions of WM areas containing BG output &/or input
    - Improvement usually accompanied by ↓ extent and signal intensity of WM abnormalities, especially in frontoparietal centrum semiovale

Staging, Grading, & Classification

- 4 main pathological types
  - GP lesions: Variable degree of necrosis
  - WM lesions: Scattered/focal areas of necrosis or confluent areas of demyelination
  - Cortical lesions: Spongy changes, intense capillary proliferation, degeneration, and loss of neurons
  - Hippocampal lesions: Coagulation necrosis

Gross Pathologic & Surgical Features

- GP necrosis, WM pallor

Microscopic Features

- Demyelination, edema, and hemorrhagic necrosis
  - Necrotic lesions in GP, other BG, hippocampus, cortex, and cerebellum
  - WM lesions: Foci of necrosis or demyelination

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Nonspecific symptoms; controversial association of specific symptoms with known CO-Hgb levels
  - Acute toxicity: Nausea, vomiting, headache
    - Confusion, cognitive impairment, loss of consciousness, seizures, coma, death
  - Neuropsychological sequelae
    - Dementia, memory deficits, decreased attention, irritability, mood and personality disturbance
    - Gait disturbance, parkinsonian-like symptoms, apraxia, convulsive disorders, visual-spatial and speech impairment
- Clinical profile
  - Depends on duration and intensity of exposure

Demographics

- Age
  - Equivalent age-specific fatality rates in adults, death rates from COP: ↑ in patients > 65 years
- Epidemiology
  - Most common cause of accidental poisoning in Europe and North America
  - Causes 2-6,000 deaths/year in USA, from both accidental and nonaccidental overdoses
  - ↑ prevalence of COP during winter months

Natural History & Prognosis

- Persistent neurologic sequelae: Occur immediately following COP and persist over time
- Delayed neurologic sequelae (10-30% of victims)
  - Occur weeks after initial recovery from acute COP
- 2 categories with regard to outcome
  - Normal/mild functional impairment: No or minimal abnormality on brain MR
  - Death/severe functional impairment (coma): Diffuse brain damage on MR

Treatment

- Hyperbaric oxygen (HBO) therapy: Treatment of choice in acute COP (within 6 hours for best effect)
- Early administration of 100% oxygen or HBO may prevent long-term neuropsychiatric sequelae

DIAGNOSTIC CHECKLIST

Consider

- MR to monitor progression/resolution of lesions

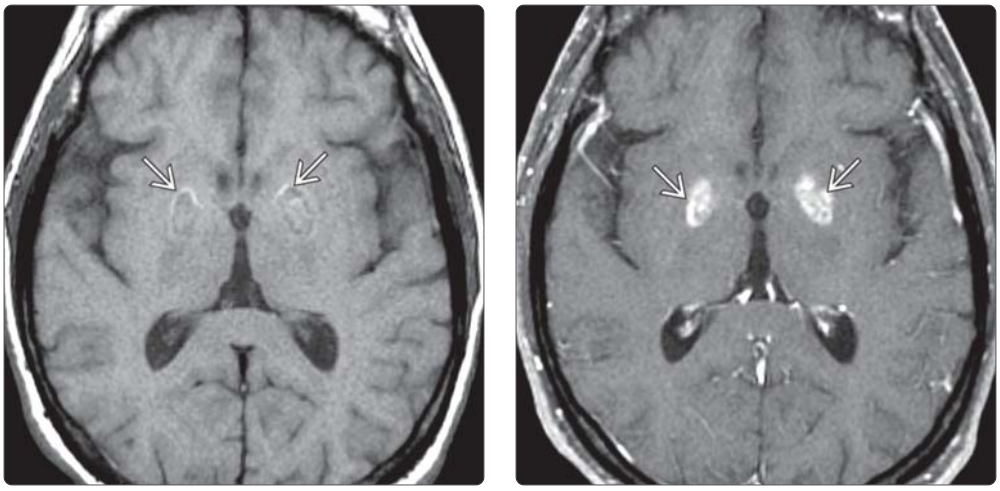
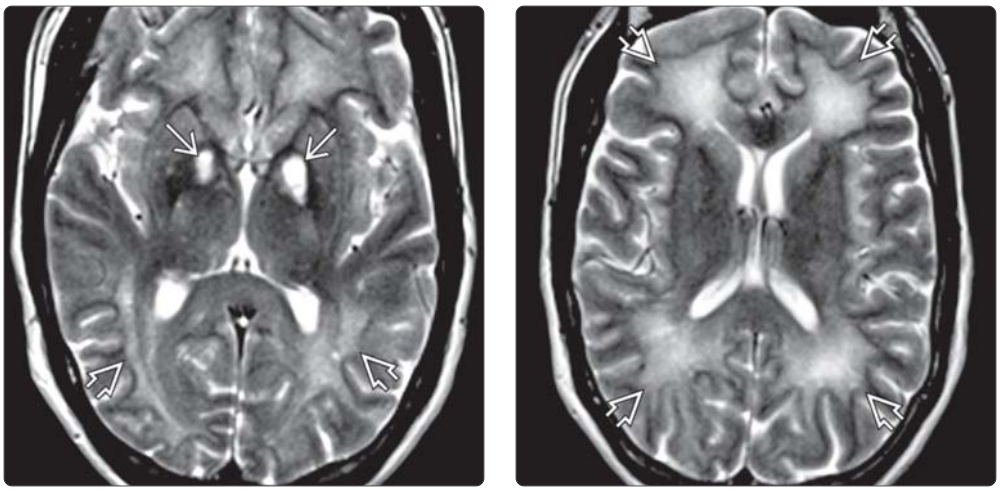
(Left) *Axial T1WI MR shows the appearance of chronic CO poisoning involving the basal ganglia. There are bilateral, nonenhancing, CSF intensity lesions present within the globi pallidi* ⇨. **(Right)** *Axial T2WI MR in the same patient shows symmetric, bilateral, CSF intensity lesions within the globi pallidi* ➡. *Often, there is a rim of hypointensity related to hemosiderin surrounding the injured deep gray nuclei. Up to 30% of patients with CO poisoning have delayed neurologic sequelae.*



(Left) *Axial T1WI MR of a patient with acute CO poisoning shows heterogeneous signal in the globus pallidus bilaterally with areas of central hypointensity with a surrounding rim of hyperintensity* ➡. *The hyperintensity is likely related to blood products.* **(Right)** *Axial T1WI C+ FS MR in the same patient shows heterogeneous enhancement of the globus pallidus bilaterally* ➡. *Enhancement is variably seen in CO poisoning.*



(Left) *Axial T2WI MR shows symmetric, bilateral, globus pallidus hyperintensities* ➡ *and diffuse hyperintensity throughout the white matter* ➡ *with sparing of the subcortical U-fibers.* **(Right)** *Axial T2WI MR in the same patient shows bilateral diffuse hyperintensity throughout the white matter* ➡ *with typical sparing of the subcortical U-fibers. The white matter hyperintensity is related primarily to demyelination with variable amounts of necrosis. The hyperintensity typically shows diffusion restriction.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Many drugs (prescription, illicit, or street) have adverse CNS effects
  - Illicit drug use often causes cerebrovascular disease
  - Amphetamines, cocaine > opioids, cannabis
- Polydrug abuse (including EtOH) is common
- Nitrous oxide (NO_2) abuse → vitamin B12 inactivation → subacute combined degeneration

IMAGING

- Best imaging clue: Young/middle-aged adult with ischemic or hemorrhagic stroke in close temporal proximity to drug administration
  - Hemorrhage: Intracranial, subarachnoid, intraventricular
  - Nonhemorrhagic ischemic stroke: MCA territory most common
- Heroin, MDMA: Globus pallidus ischemia
- Amphetamines: Hemorrhage, vasculitis, pseudoaneurysm, infarcts
- NECT for suspected hemorrhage indicated: If NECT reveals hemorrhage, consider CTA/MRA/DSA
- Consider drug abuse or dissection in young or middle-aged patient with stroke

TOP DIFFERENTIAL DIAGNOSES

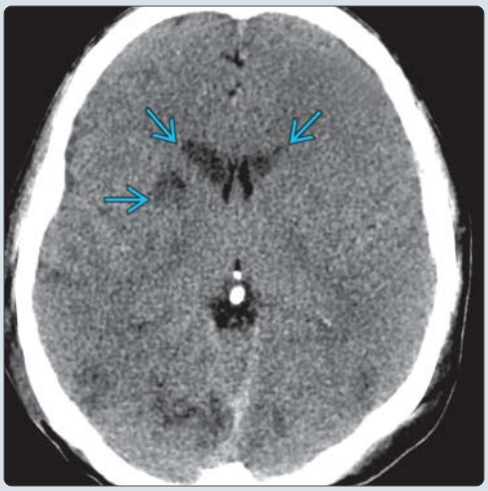
- Intracranial hemorrhage in young adults
  - Vascular malformations
  - Dural sinus thrombosis with hemorrhagic infarct
  - Severe posterior reversible encephalopathy syndrome with secondary hemorrhage
- Vasculitis

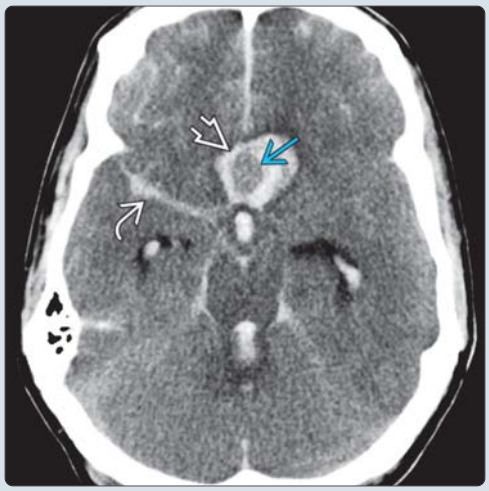
PATHOLOGY

- 40-50% of drug-related ICH is related to underlying vascular malformation (cerebral aneurysm, AVM)

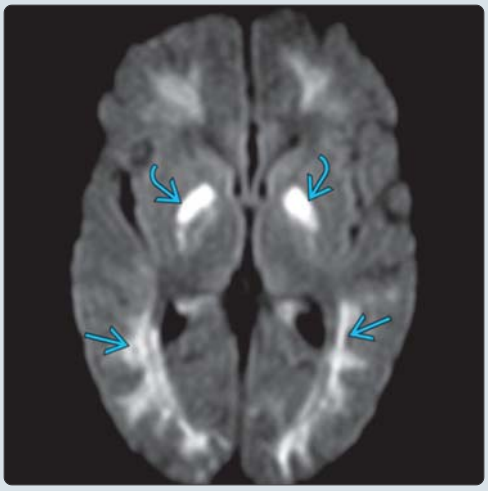
CLINICAL ISSUES

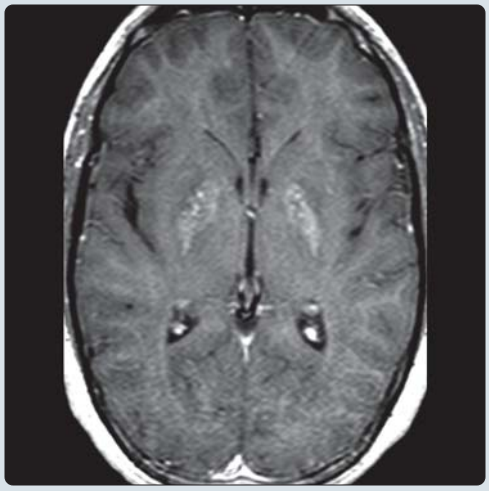
- 30% of strokes in patients < 45 years old are drug related
- Cocaine, MDMA, amphetamines: Stroke, headache, seizures





(Left) *Axial NECT in a comatose patient after cocaine abuse shows focal hypodensities in the basal ganglia related to ischemia. Note also the diffuse loss of the corticomedullary differentiation due to severe anoxia.* **(Right)** *A 32-year-old female methamphetamine abuser had sudden severe headache followed by coma. NECT shows diffuse subarachnoid, intraventricular hemorrhage. A focal interhemispheric hematoma surrounds a ruptured ACoA aneurysm.*





(Left) *Axial DWI MR in a young male patient following ingestion of ecstasy (MDMA) shows symmetric diffusion restriction in the globi pallidi and deep white matter.* **(Right)** *Axial T1 C+ MR in the same patient shows enhancement within the globi pallidi due to necrosis. MDMA causes rapid release of 5-hydroxytryptamine, which is 1 of the most potent vasoconstrictors in the brain and it ultimately leads to necrosis of the involved regions of the brain. The occipital cortex and globi pallidi are most vulnerable.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Many drugs (prescription, illicit, or street) have adverse effects on CNS
  - Major pathology is generally vascular or metabolic
  - Polydrug abuse (including EtOH) is common
- Cerebrovascular disease caused by illicit drug use
  - Amphetamines and derivatives
    - Cocaine
      - Cocaine hydrochloride (HCl) is water soluble, ingested via mucosal membrane
      - Alkaloid form (freebase, crack) is smokable
    - 3,4-methylenedioxymethamphetamine (MDMA, ecstasy)
  - Opioids and derivatives
    - Heroin: IV use, inhaled ("chasing the dragon")
    - Other derivatives include morphine, hydrocodone, oxycodone, codeine
  - Cannabis/marijuana
  - EtOH abuse: Interference with normal clotting increases risk of spontaneous hemorrhage and extent of hemorrhage due to primary pathology
    - Traumatic brain injury
    - Hypertensive cerebral vascular disease
- May interfere with critical metabolic pathways
  - Nitrous oxide (NO_2) abuse → vitamin B12 inactivation → subacute combined degeneration
- May lead to nutritional deficiencies
  - Chronic EtOH abuse → thiamine deficiency → Wernicke encephalopathy
- Organ damage from chronic drug abuse
  - EtOH → liver failure → manganese deposition in basal ganglia (BG)

IMAGING

General Features

- Best diagnostic clue
  - Young/middle-aged adult with ischemic or hemorrhagic stroke in close temporal proximity to drug administration
- Location
  - Hemorrhage: Intracranial (ICH), subarachnoid (SAH), intraventricular (IVH)
  - Nonhemorrhagic ischemic stroke: Usually, middle cerebral artery (MCA) territory
  - Vascular: Vasculitis, pseudoaneurysm
  - Cocaine: Infarctions in cerebrum, thalamus, brainstem, cerebellum, retina
  - Heroin, MDMA: Globus pallidus (GP) ischemia

CT Findings

- NECT
  - Cocaine: ICH, SAH, IVH
  - Heroin inhalation: Symmetric hypodensity in cerebellar and posterior cerebral white matter (WM), posterior limb of internal capsule, GP
- CTA
  - May show segmental narrowing in vasculitis

MR Findings

- T1WI
  - Heroin vapor inhalation: Leukoencephalopathy
- T2WI
  - Cocaine: May have severe T2-hyperintense lesions
    - Cerebral, insular subcortex WM lesions, transient arterial occlusion in MCA territory: Small infarctions
  - MDMA: Ischemic necrosis in occipital cortex and globus pallidus
  - Heroin vapor inhalation
    - Hyperintense cerebral, cerebellar tracts
    - WM cerebellum, posterior cerebral, posterior limb of internal capsule, sparing of subcortical WM
  - Cannabis
    - T2-hyperintense lesions in basal ganglia, periventricular white matter, striatocapsular region, cerebellum
  - Wernicke encephalopathy
    - Hyperintensity in medial thalami, tectum, periaqueductal gray matter, mammillary bodies, rarely cortex
  - Subacute combined degeneration
    - Hyperintensity in posterior spinal cord (cervical and thoracic)
- T2* GRE
  - Hemorrhagic lesions have decreased signal
  - Cocaine: Hemorrhage in basal ganglia and thalami
- DWI
  - Restricted diffusion in acute ischemic and metabolic lesions
- MRA
  - Arterial spasm &/or vasculitis
    - Vasculitis is difficult to diagnose on MRA unless high quality; 3T MRA > 1.5T MRA

Other Modality Findings

- Cerebral angiography may show irregularity of medium-sized intracranial vessels consistent with amphetamine-induced vasculitis

Imaging Recommendations

- Protocol advice
  - NECT for suspected hemorrhage
    - If CT reveals hemorrhage, consider CTA/MRA/DSA
  - MR: Include DWI, GRE, T1WI C+

DIFFERENTIAL DIAGNOSIS

Spontaneous ICH in Young Adults

- Hypertension: BG hemorrhages
- Vascular malformations
  - Cavernous angiomas
  - Arteriovenous malformations (AVMs)
- Intratumoral hemorrhage
  - Incomplete hemosiderin rings, enhancing nodule, persistent mass effect
- Dural sinus thrombosis with hemorrhagic infarct
  - Underlying coagulable state is often present
- Severe posterior reversible encephalopathy syndrome (PRES) with secondary hemorrhage
- Mycotic aneurysm with parenchymal hemorrhage

https://CafePezeshki.IR

- Often related to infectious endocarditis

Vasculitis

- Inflammation and necrosis of vessel walls
- Multiple etiologies: Infectious, granulomatous, autoimmune, collagen vascular disease
- Drug-induced differentiated by history

PATHOLOGY

General Features

- Etiology
  - Amphetamines: Cocaine, MDMA
    - Systemic vasoconstriction → acute arterial hypertension → hemorrhagic stroke (rupture of preexisting aneurysms, bleeding from AVM)
    - Cerebral vasoconstriction, vasculitis → infarction
  - Cocaine
    - ↑ platelet aggregation with thrombosis
    - Heart disease: Source of emboli
  - MDMA abuse: Loss of serotoninergic neurons
  - Parenteral drugs
    - Infective endocarditis (IE) → emboli → cerebral infarction, hemorrhage, abscess, mycotic aneurysm
    - Bacteremia in absence of IE: Brain abscess
  - Heroin: Toxic leukoencephalopathy, hypoxic brain injury, ischemic stroke, brain abscess
    - Generalized hypoxia and hypotension
    - Possible immunologic-mediated vasculitis
    - Nephropathy → severe hypertension
  - Concomitant alcohol use may potentiate illicit drug effects (↓ hepatic metabolism)
- Associated abnormalities
  - 40-50% of drug-related ICH is related to underlying vascular malformation (cerebral aneurysm, AVM)
  - Drug-induced IE, vasculitis
  - Alkaloidal cocaine (crack): Hemorrhagic = ischemic stroke
  - Cocaine hydrochloride: Hemorrhagic > ischemic stroke
  - Heroin: Cerebral infarctions (MCA area, not watershed distribution), toxic leukoencephalopathy

Gross Pathologic & Surgical Features

- Amphetamine, cocaine: Arterial spasm/vasculitis
- Amphetamine, cocaine, MDMA: ICH, SAH
- MDMA: Bilateral GP necrosis (secondary prolonged vasospasm)

Microscopic Features

- Amphetamines: Inflammatory vasculitis with vessel wall necrosis (speed arteritis) similar to polyarteritis nodosa
- Cocaine: Vasculitis affecting CNS
- Heroin: Vasculitis (rare), probably related to drug contaminants
  - Inhaled heroin vapors: Symmetric spongiform degeneration in cerebral/cerebellar WM, corticospinal tracts

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Cocaine, MDMA, amphetamines: Stroke, headache, seizures
  - Heroin: BG damage (parkinsonism, hemiballismus)
    - Toxic leukoencephalopathy: Cerebellar, pyramidal, and pseudobulbar signs, spasms, death
- Clinical profile
  - Cerebral infarcts, TIAs, ICH, SAH
    - Temporal proximity of stroke to drug use

Demographics

- Age
  - 85-90% of drug-related strokes in 4th-5th decades
- Epidemiology
  - 30% of strokes in patients < 45 are drug related
  - Estimated relative risk for stroke among drug abusers (after controlling for other stroke risk factors): 6.5 out of 10
  - Subacute combined degeneration
    - Individuals with access to medical NO_2
    - Abuse of NO_2 canisters (poppers)

Natural History & Prognosis

- Time interval between drug use and stroke onset: ≤ 1 week
  - Stroke risk is highest within first 6 hours after drug use
- IE-related strokes may be delayed
- Cocaine worsens presentation and outcome of aneurysmal SAH patients

Treatment

- Management of drug-related stroke largely supportive
- Antibiotics for embolic stroke due to IV-drug-induced IE ↓ risk of recurrent infarction
- Aggressive addiction rehabilitation
- Experimentally, magnesium reverses cocaine-induced vasospasm
- Wernicke encephalopathy: Supplementary thiamine
- Subacute combined degeneration: B12 injection

DIAGNOSTIC CHECKLIST

Consider

- Drug abuse in young/middle-aged patient with hemorrhagic or ischemic stroke
- Vascular imaging CTA/MRA/DSA in drug-related hemorrhages

Image Interpretation Pearls

- Drug-related hemorrhages may indicate underlying vascular abnormality
- Vasculitis can be very difficult to distinguish from drug-related vasospasm

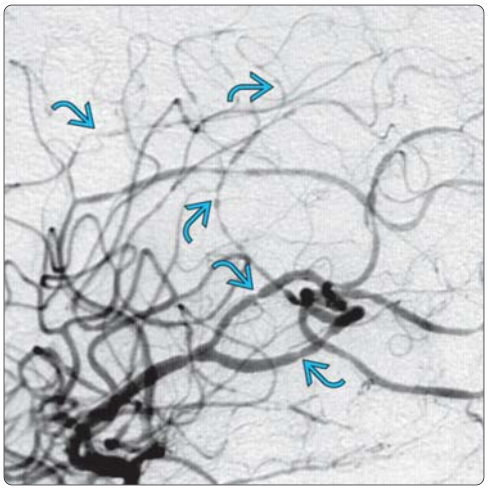
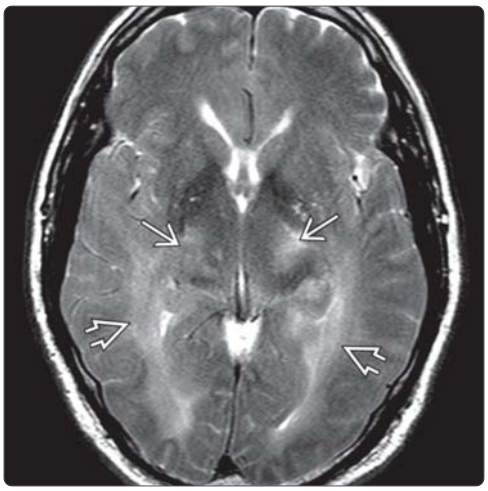
(Left) *A 57-year-old man developed acute leukoencephalopathy after "chasing the dragon." MR shows diffuse WM hyperintensity on T2/FLAIR (L) and acute diffusion restriction (R). (Courtesy M. Michel, MD.)* **(Right)** *A 32-year-old woman overdosed on methadone. MR scans show symmetric hyperintensity on T2/FLAIR with acute diffusion restriction on DWI.*



(Left) *Axial NECT in a 42-year-old man presenting with history of recurrent severe headache and longstanding history of amphetamine abuse shows hyperdensity related to lobar hemorrhage with surrounding edema in the right frontal lobe.* **(Right)** *Lateral DSA of a right internal carotid artery injection shows an irregularity and a beaded appearance of the medium to small-sized vessels in the MCA and anterior cerebral artery distributions. Findings are consistent with drug-induced vasculitis.*



(Left) *Axial FLAIR MR in a patient with intravenous heroin abuse who presented with right hemiparesis shows an infarct in the left precentral gyrus. There was corresponding diffusion restriction (not shown). Ischemia is the most common acute neurovascular complication caused by heroin.* **(Right)** *T2WI MR in a comatose patient who drank a gallon of vodka or whisky daily for a full week shows diffuse brain swelling, hyperintense white matter, and bithalamic lesions, indicative of acute alcohol poisoning.*

KEY FACTS

TERMINOLOGY

- Acute toxic effects of methanol on CNS

IMAGING

- Bilateral hemorrhagic putaminal necrosis
- Putamen, hemispheric white matter
  - Caudate nuclei may be involved
  - Uncommon: Corpus callosum, brainstem, cerebellum
- Cerebral and intraventricular hemorrhage
- DWI: Restriction in putamina ± white matter
- Protocol: MR (including GRE + DWI)

TOP DIFFERENTIAL DIAGNOSES

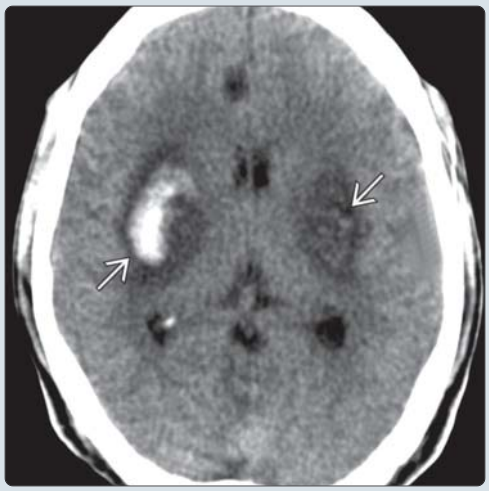
- Hypertensive intracranial hemorrhage
- Anoxic infarcts
- Carbon monoxide (CO) poisoning
- Osmotic demyelination syndrome
- Wilson disease
- Leigh disease
- Creutzfeldt-Jakob disease (CJD)
- Huntington disease

PATHOLOGY

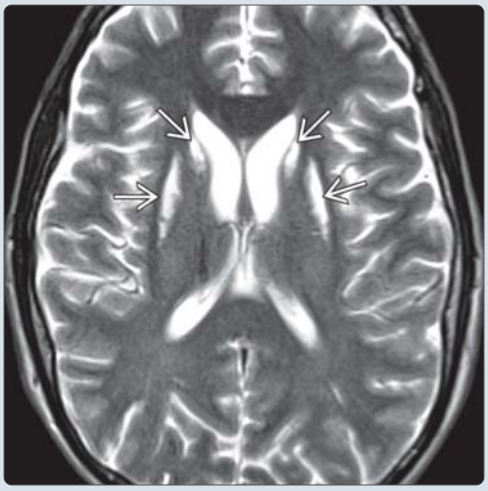
- Methanol metabolized to formaldehyde, formic acid
- Causes "anion gap acidosis"

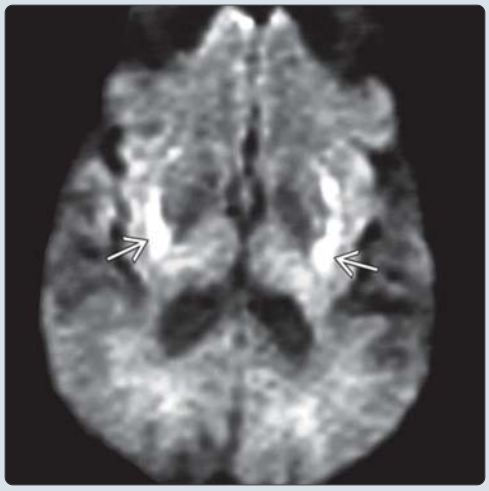
CLINICAL ISSUES

- Blurred vision
- Drowsiness, confusion, seizure, coma
- Nausea/vomiting, abdominal pain
- Respiratory arrest → death
- Untreated methanol poisoning
  - Visual deficits in ~ 1/3
  - Death rate of ~ 1/3
- Treatment: Fomepizole or ethanol
- General supportive care (e.g., intravenous fluids, correction of electrolytes and acidemia)



(Left) *Axial gross pathology specimen sectioned through the basal ganglia in a patient who died from methanol poisoning shows bilateral hemorrhagic necrosis of both basal ganglia and the right caudate. The putamina are most severely affected. Note sparing of the thalami. (Courtesy R. Hewlett, MD.)* **(Right)** *Axial NECT shows mixed density lesions in the basal ganglia in a patient who had been drinking methanol. Note gross and petechial hemorrhage in the putamen ➡, typical of acute methanol toxicity.*





(Left) *Axial T2WI MR shows striking hyperintensities in the putamina and caudate nuclei ➡ in a 37-year-old man with longstanding abuse of both ethanol and methanol. Generalized volume loss is consistent with a history of chronic substance abuse.* **(Right)** *Axial DWI MR in a patient with acute methanol poisoning shows restricted diffusion in both putamina ➡. Follow-up NECT scans obtained 1 week later (not shown) demonstrated symmetrical low density in the putamina, as well as subcortical WM.*

TERMINOLOGY

Abbreviations

- Methanol (MtOH) encephalopathy

Definitions

- Acute toxic effects of MtOH on CNS

IMAGING

General Features

- Best diagnostic clue
  - Bilateral hemorrhagic putaminal necrosis
- Location
  - Putamen, hemispheric white matter
    - Caudate nuclei may be involved
    - Uncommon: Corpus callosum, brainstem, cerebellum

CT Findings

- NECT
  - Bilateral hemorrhagic putaminal necrosis
  - White matter hypodensity may be seen
  - Cerebral and intraventricular hemorrhage

MR Findings

- T1WI
  - Bilateral hemorrhagic putaminal necrosis is characteristic
  - Hemorrhagic subcortical necrosis
  - White matter hypointense lesions (confluent hemispheric ± optic nerves)
- T2WI
  - Lesions typically hyperintense
  - Acute hemorrhagic necrosis may cause hypointense foci
- FLAIR
  - Lesions all typically hyperintense
- T2* GRE
  - Hypointense foci in putamina
  - Cerebral and intraventricular hemorrhage
- DWI
  - Restriction (high signal) in putamina ± white matter
- T1WI C+
  - Enhancement of necrotic lesions

Imaging Recommendations

- Best imaging tool
  - NECT initially
- Protocol advice
  - MR (including GRE + DWI)

DIFFERENTIAL DIAGNOSIS

Hypertensive Intracranial Hemorrhage

- Usually unilateral

Anoxic Infarcts

- Most are nonhemorrhagic vs. hemorrhagic necrosis in MtOH
- Symmetric ↑ T2 in basal ganglia (BG) typical

Carbon Monoxide (CO) Poisoning

- ↑ T2 in globus pallidus (GP) > putamen typical ± hemispheric WM

Osmotic Demyelination Syndrome

- Extrapontine myelinolysis results in ↑ T2 in BG
- High signal in central pons common

Wilson Disease

- ↑ T2 in the BG, brainstem typical

Leigh Disease

- ↑ T2 lesions (brainstem, BG, and WM) with onset in infancy/early childhood

Creutzfeldt-Jakob Disease (CJD)

- Progressive ↑ T2 of BG (putamen and caudate > GP), thalamus, and cerebral cortex

Huntington Disease

- Caudate atrophy, ↑ T2 caudate/putamen

PATHOLOGY

General Features

- Etiology
  - Methanol metabolized to formaldehyde, formic acid
  - Causes "anion gap acidosis"
  - Select toxic effect on putamen, optic nerves
  - Commercial products containing methanol include antifreeze, paint remover, photocopying fluid

Gross Pathologic & Surgical Features

- Pallidal necrosis
- Optic nerve demyelination and atrophy

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Blurred vision
    - May progress to blindness
  - Drowsiness, confusion, seizure, coma
  - Nausea/vomiting, abdominal pain
  - Respiratory arrest → death

Natural History & Prognosis

- Latency period between ingestion and symptoms because of time required for enzymatic oxidation
- Untreated methanol poisoning
  - Visual deficits in ~ 1/3 of survivors
  - Death rate of ~ 1/3

Treatment

- Fomepizole or ethanol
  - Inhibit alcohol dehydrogenase
  - Prevents metabolism of methanol to formic acid
- General supportive care (e.g., intravenous fluids, correction of electrolytes, and acidemia)

KEY FACTS

TERMINOLOGY

- Anoxic encephalopathy caused by exposure to cyanide (CN)

IMAGING

- Hemorrhagic striatal, cortical laminar necrosis
  - Basal ganglia (BG)
  - Cortex (especially sensorimotor)
- T2/FLAIR hyperintense foci in BG, cortex
- Restricted diffusion in BG, cortex
- May see T1 hyperintensity, enhancement in BG/cortex

TOP DIFFERENTIAL DIAGNOSES

- Hypoxic-ischemic encephalopathy
- Toxic exposure, especially carbon monoxide (CO)
- Inherited/metabolic disease
- Infectious etiologies

PATHOLOGY

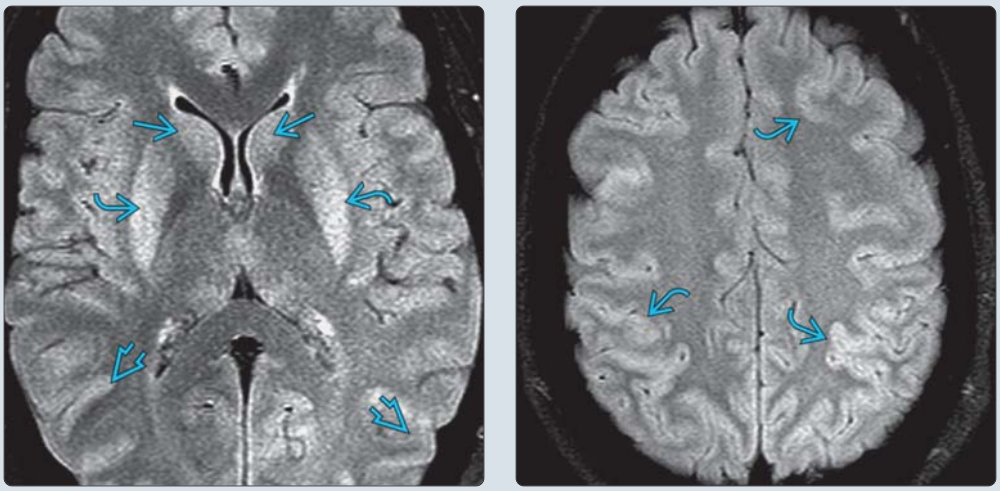
- Inhibits mitochondrial cytochrome c oxidase
  - Compromises aerobic oxidative metabolism, phosphorylation
  - Cellular hypoxia, lactic acidosis ensues

CLINICAL ISSUES

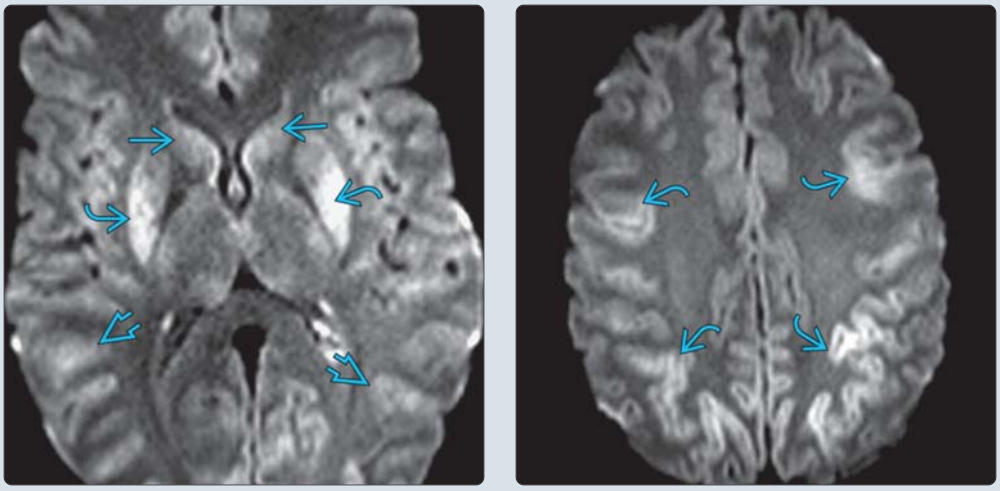
- Odor of bitter almond
- Tachypnea, tachycardia, hypertension
  - Cardiorespiratory collapse ensues
- Seizure ± coma ± death
- Often overlaps with signs/symptoms of CO exposure
- Smoke inhalation, ingestion, or dermal absorption
- Accidental exposure (work-related)
- Nonaccidental exposure

DIAGNOSTIC CHECKLIST

- May have overlapping features related to CN and CO poisoning, especially in smoke inhalation



(Left) *Axial FLAIR MR in a 22-year-old woman found unconscious after smoke inhalation in a residential fire demonstrates increased signal in the putamina, caudate nuclei, and cortex.* **(Right)** *Axial FLAIR MR in the same patient shows extensive cortical swelling and subtle hyperintensity.*



(Left) *Axial DWI shows corresponding areas or restricted diffusion in the putamina, caudate nuclei, and cortex.* **(Right)** *Axial DWI in the same patient shows extensive cortical restricted diffusion. Findings are more pronounced on DWI as compared to FLAIR. Although these imaging findings are nonspecific, the bilateral symmetric appearance should raise the possibility of a global hypoxic/toxic/metabolic insult. Clinical history is vital to confirm the diagnosis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Cyanide (CN) poisoning

Definitions

- Anoxic encephalopathy caused by exposure to CN

IMAGING

General Features

- Best diagnostic clue
  - Hemorrhagic striatal, cortical laminar necrosis
- Location
  - Basal ganglia (BG)
    - Bilateral involvement typical
      - Putamen, caudate nucleus can involve globus pallidus
  - Cortex
    - Multifocal lesions, especially sensorimotor cortex
  - Cerebellum

CT Findings

- NECT
  - Hypodense foci in BG

MR Findings

- T1WI
  - Early: Hypointense BG foci
  - Late: Hyperintensity in BG, curvilinear cortical hyperintensity
- T2WI
  - Hyperintense foci in BG
  - Cortical hyperintensity
- FLAIR
  - Same as T2WI
- DWI
  - Restricted diffusion in BG, cortex
- T1WI C+
  - May see enhancement in BG, cortex

Imaging Recommendations

- Best imaging tool
  - MR with FLAIR, DWI

Nuclear Medicine Findings

- PET
  - 18F-fluorodopa: ↓ striatal uptake
  - 18F-FDG PET: ↓ metabolism in putamen, temporo-parietooccipital, and cerebellar cortices

DIFFERENTIAL DIAGNOSIS

Hypoxic-Ischemic Encephalopathy

- Includes anoxia, hypoxia, near drowning, and cerebral hypoperfusion injury

Toxic Exposure

- Methanol, alcohol, carbon monoxide (CO), heroin

Inherited/Metabolic Disease

- Wilson disease, Leigh disease, Huntington disease

Infectious Etiologies

- Japanese encephalitis, Creutzfeldt-Jakob disease (CJD), etc.

PATHOLOGY

General Features

- Etiology
  - Inhibits mitochondrial cytochrome c oxidase
    - Compromised aerobic oxidative metabolism, phosphorylation
    - Cellular hypoxia, lactic acidosis ensue

Gross Pathologic & Surgical Features

- Hemorrhagic BG necrosis
- Cortical laminar necrosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Often overlaps with signs/symptoms of CO exposure
  - Odor of bitter almond
  - Tachypnea, tachycardia, hypertension
    - Cardiorespiratory collapse
  - Seizure, coma, death

Demographics

- Epidemiology
  - Smoke inhalation, ingestion, or dermal absorption
  - Accidental exposure (work-related)
    - Metal industry, mining, jewelry manufacture, inhaling smoke
  - Nonaccidental exposure
    - Suicide and murder attempts

Natural History & Prognosis

- Symptom onset varies with exposure type
  - Gaseous hydrocyanic acid → seconds
  - Solid or liquid cyanide salts → minutes
  - Some cyanogenic compound (nitriles and nitroprusside) → hours
- Range of outcomes
  - From full recovery to death
  - Permanent neurological disability
    - Extrapyramidal syndromes and vegetative state

Treatment

- Decontamination, supportive
- Oxygen therapy: Normobaric and hyperbaric
- Cyanide antidotes

DIAGNOSTIC CHECKLIST

Consider

- May have overlapping features related to CN and CO poisoning, especially in smoke inhalation

SELECTED REFERENCES

KEY FACTS

TERMINOLOGY

- Osmotic demyelination syndrome (ODS)
  - Formerly called central pontine myelinolysis (CPM) &/or extrapontine myelinolysis (EPM)
- Acute demyelination from rapid shifts in serum osmolality
  - Classic setting: Rapid correction of hyponatremia
  - ODS may occur in normonatremic patients

IMAGING

- Central pons T2 hyperintensity with sparing of periphery
- 50% in pons (CPM); 50% in extrapontine sites (EPM)
  - Central fibers involved; peripheral fibers spared
  - Basal ganglia (BG)
  - Cerebral white matter (WM)
- CPM + EPM = almost pathognomonic for ODS
- Acute: Confluent hyperintensity in central pons with sparing of periphery and corticospinal tracts
- Round, triangular, or batwing-shaped
- DWI earliest and sensitive for ODS
- Subacute: Hyperintensity often normalizes
- Best imaging tool: MR > > CT

TOP DIFFERENTIAL DIAGNOSES

- Pontine ischemia/infarction
- Demyelinating disease
- Pontine neoplasm (astrocytoma, metastasis)
- Metabolic disease (Wilson, Leigh, diabetes, hypertensive encephalopathy)

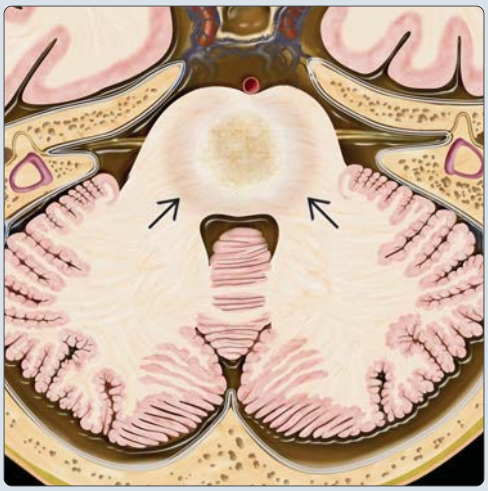
PATHOLOGY

- Heterogeneous disorder with common etiology: Osmotic stress

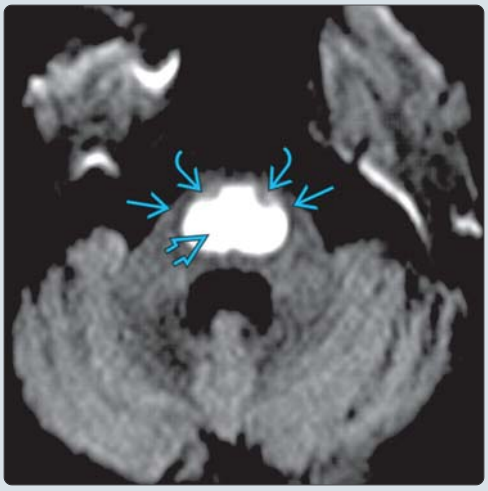
CLINICAL ISSUES

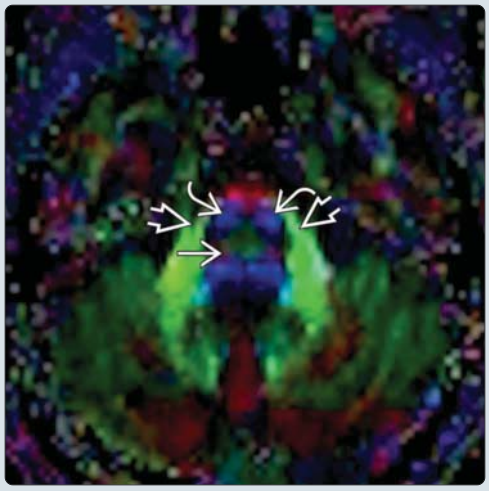
- Alcoholic, hyponatremic patient with rapid correction of serum sodium
- ODS symptoms emerge 2-8 days (occasionally weeks) after correction of hyponatremia
- "Comorbid" conditions common, poorer prognosis

(Left) *Axial graphic shows acute osmotic demyelination affecting the central pons. The pons is slightly swollen with mild mass effect on the 4th ventricle.* **(Right)** *Axial NECT in a chronic alcoholic patient who presented with altered sensorium demonstrates central pontine hypodensity due to osmotic demyelination syndrome. Osmotic demyelination syndrome is an acute demyelination caused by rapid shifts in serum osmolality.*



(Left) *Axial DWI in the same patient shows restricted diffusion in the pons corresponding to the hypodensity on CT. There is sparing of the corticospinal tracts and peripheral pontine pons.* **(Right)** *Axial DTI in the same patient shows disruption of the central pontine white matter with preservation of the corticospinal tracts and peripheral pontine fibers. Pontine osmotic demyelination is round, triangular, or batwing-shaped.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Osmotic demyelination syndrome (ODS)

Synonyms

- Formerly called central pontine myelinolysis (CPM) &/or extrapontine myelinolysis (EPM)

Definitions

- Acute demyelination caused by rapid shifts in serum osmolality
- Classic setting: Rapid correction of hyponatremia
  - ODS may occur in normonatremic patients

IMAGING

General Features

- Best diagnostic clue
  - Central pons T2 hyperintensity with sparing of periphery
- Location
  - 50% in pons (CPM)
    - Central fibers involved; peripheral fibers spared
  - 50% in extrapontine sites (EPM)
    - Cerebellum (middle cerebellar peduncles)
    - Lateral geniculate bodies
    - Basal ganglia (BG), external capsule, thalamus
    - Cerebral white matter (WM)
    - Uncommon: Peripheral cortex, hippocampi
  - CPM + EPM = almost pathognomonic for ODS
- Morphology
  - Round or triangular (pons)
  - Regardless of site, demyelination often bilateral/symmetric
  - Rare: Gyriform (cortical involvement)

CT Findings

- NECT
  - Low density in affected areas (pons, BG, etc.)
  - Hypodensity in the central pons may be obscured by beam-hardening artifact
  - Look for other abnormalities (e.g., vermian atrophy)
  - No hemorrhage
- CECT
  - Classic: No enhancement
  - Early, acute/severe demyelination may show intense enhancement

MR Findings

- T1WI
  - Acute
    - Classic: Mildly/moderately hypointense
    - Less common: Can be isointense with surrounding normal brain
    - Findings may be transitory, resolve completely
    - Initial study may be normal
  - Subacute
    - May resolve completely
    - Less common: Hyperintensity at 1-4 months (coagulative necrosis)
- T2WI
  - Acute: Confluent hyperintensity in central pons with sparing of periphery and corticospinal tracts
    - Round, triangular, or batwing-shaped
    - Symmetric hyperintensity in BG, white matter (EPM)
  - Subacute: Hyperintensity often normalizes, may resolve completely
- PD/intermediate
  - Hyperintense
- FLAIR
  - Hyperintense
- T2* GRE
  - Hemorrhage, "blooming" rare
- DWI
  - Acute
    - DWI: Hyperintense (restricted); ↓ ADC
    - DWI earliest and sensitive for ODS
    - DWI changes occur within 24 hours of symptoms, improves significantly within 1st week
  - Delayed
    - DWI: Isointense
    - ADC values to baseline within 3-4 weeks
- T1WI C+
  - Common: Usually does not enhance
  - Less common: Moderate confluent/peripheral enhancement
- MRS
  - Acute: ↓ NAA, ↑ choline , ↑ Cho:Cr ratio

Nuclear Medicine Findings

- PET
  - Early metabolic stress = variable hypermetabolism
  - Late = hypometabolic areas in affected sites

Imaging Recommendations

- Best imaging tool
  - MR > > CT
- Protocol advice
  - FLAIR, DWI, T1WI C+
  - Repeat imaging as needed

DIFFERENTIAL DIAGNOSIS

Pontine Ischemia/Infarction

- Often asymmetric
- Usually involves both central, peripheral pontine fibers
- Caution: Perforating basilar artery infarct(s) may involve central pons; imaging can mimic CPM (including DWI)

Demyelinating Disease

- Look for typical lesions elsewhere
- Horseshoe (incomplete ring) enhancement pattern in acute multiple sclerosis common

Pontine Neoplasm (Astrocytoma, Metastasis)

- Primary neoplasm (e.g., pontine "glioma")
  - Typically pediatric/young adult patients
- Pons is rare site for solitary metastasis

Metabolic Disease

- e.g., Wilson, Leigh, diabetes, hypertensive encephalopathy
- Basal ganglia > pons in Wilson disease
- Basal ganglia, midbrain in Leigh disease

https://CafePezeshki.IR

- Parietooccipital lobes = most common site in hypertensive encephalopathy
- Pontine hypertensive encephalopathy
  - Typically does not spare peripheral fibers
  - Other lesions common

PATHOLOGY

General Features

- Etiology
  - Heterogeneous disorder with common etiology: Osmotic stress
    - Osmotic stress: Any change in osmotic gradient
  - Most common: Iatrogenic correction of hyponatremia
  - Less common: Osmotic derangement with azotemia, hyperglycemia, hypokalemia, ketoacidosis
  - Precise mechanism of osmotic stress-related myelinolysis unknown
    - Osmotic insult, change in serum osmolality
    - Relative intracellular hypotonicity
    - Serum osmolality change causes endothelial damage
    - Organic osmolyte deficiency predisposes to endothelial breakdown
    - Endothelial cells shrink, causing blood-brain barrier breakdown
    - Accumulation of hypertonic sodium-rich fluid in extracellular fluid (ECF)
    - Hypertonic ECF, release of myelin toxins damages WM
    - Cell death ensues
  - Oligodendrocytes particularly vulnerable to osmotic changes
  - Astrocytic AQP (aquaporin water channels) loss in a subset of human CPM cases suggests AQP1 and AQP4 may be involved in pathogenesis of CPM
- Associated abnormalities
  - Demyelination without associated inflammation

Gross Pathologic & Surgical Features

- Bilateral/symmetrical, soft, gray-tan discoloration

Microscopic Features

- Extensive demyelination, gliosis
- Macrophages contain engulfed myelin bits and fragments
- Axis cylinders, nerve cells preserved
- Reactive astrocytes, abundant foamy, lipid-laden macrophages

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizures, altered mental status
  - Often biphasic when hyponatremia present
    - ODS symptoms emerge 2-8 days (occasionally weeks) after correction of hyponatremia
    - Changing level of consciousness, disorientation
    - Pseudobulbar palsy, dysarthria, dysphagia (CPM)
    - Movement disorder (EPM)
  - Symptoms may resolve with increase in serum osmolality
- Clinical profile
  - Alcoholic, hyponatremic patient with rapid correction of serum sodium
  - "Comorbid" conditions that may exacerbate ODS
    - Hepatic, renal, adrenal, pituitary, paraneoplastic disease
    - Nutritional (alcohol, malnutrition, vomiting)
    - Burn, transplantation, other surgery

Demographics

- Age
  - Occurs at all ages
    - Most common: Middle-aged patients
    - Uncommon: Pediatric patients (diabetes, anorexia)
- Gender
  - M > F
- Epidemiology
  - Autopsy prevalence in alcoholic individuals varies from < 1% to 10%

Natural History & Prognosis

- Spectrum of outcomes
  - Complete recovery may occur
  - Minimal residual deficits
    - Memory, cognitive impairment
    - Ataxia, spasticity, diplopia
  - May progress to
    - Spastic quadriparesis
    - "Locked in," may progress to coma, death
  - Variable behavioral and psychiatric disorders, movement disorders, seizures, depression, polyradiculopathy, and neuropathy
- "Comorbid" conditions common, poorer prognosis
- Mortality ranging from 6% to 90%

Treatment

- No consensus; no "optimal" correction rate for hyponatremia
- Self-correction (fluid restriction, discontinue diuretics) if possible
- Supportive treatment

DIAGNOSTIC CHECKLIST

Consider

- Diagnosis of ODS in alcoholic patient with basal ganglia, white matter disease (EPM)

Image Interpretation Pearls

- Classic CPM spares peripheral pontine fibers
- EPM can occur without CPM
- Repeat MR may be necessary as initial study may be normal

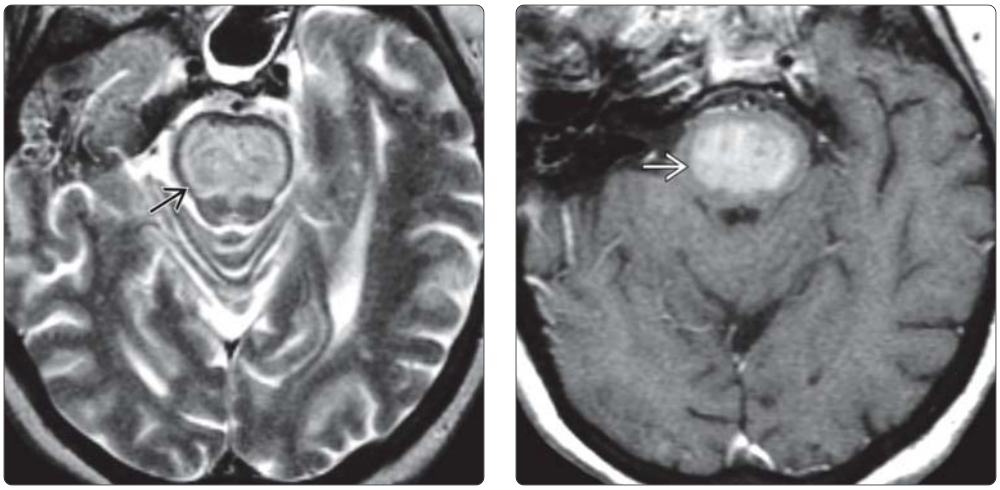
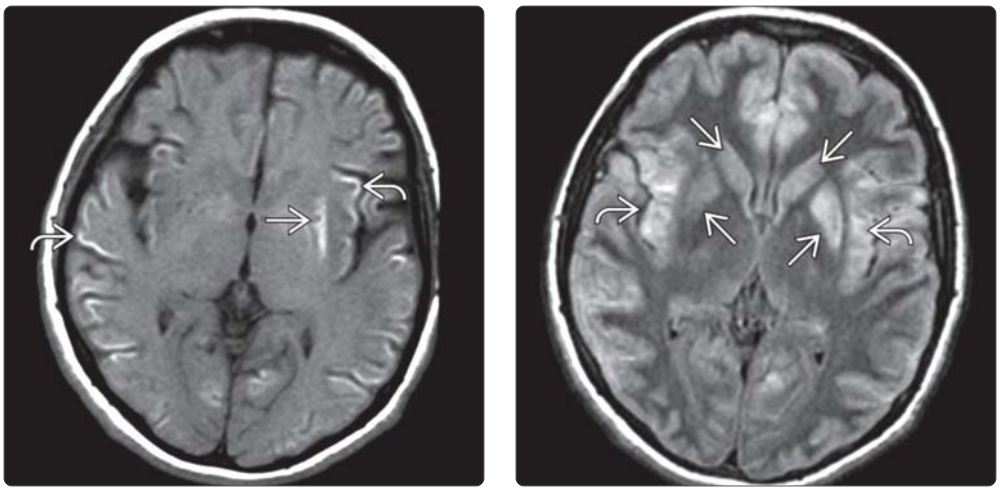
(Left) *Axial FLAIR MR shows abnormal signal intensity in the pons* ➡. **(Right)** *Axial FLAIR MR in the same patient demonstrates abnormal signal intensity in the putamina* ➡ *and in the caudate nuclei* ➡. *Osmotic demyelination syndrome may have manifestations of both central pontine and extrapontine myelinolysis.*



(Left) *Axial T2WI MR demonstrates striking hyperintensity within the central pons* ⇨, *which is a classic finding in osmotic demyelination syndrome.* **(Right)** *T1WI C+ MR in the same patient shows enhancement of the acutely demyelinating area* ➡.



(Left) *Axial T1WI MR in a patient with hyponatremia shows diffuse high signal in the cortex* ➡ *and left putamen* ➡. **(Right)** *Axial FLAIR MR in the same patient shows diffuse high signal in the cortex* ➡ *and striatum* ➡. *Frank cortical laminar necrosis is an atypical manifestation of osmotic demyelination syndrome. Some cases, such as this one, spare the pons (not shown) completely and affect only the basal ganglia &/or cortex. The hemispheric white matter is not involved in this case.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Radiation-induced injury may be divided into acute, subacute/early delayed, late injury

IMAGING

- **Radiation injury**: Mild vasogenic edema to necrosis
- **Radiation necrosis**: Irregular enhancing lesion(s)
  - MRS: Markedly ↓ metabolites (NAA, Cho, Cr), ± lactate/lipid peaks
  - Perfusion MR: ↓ rCBV compared with tumor
- **Leukoencephalopathy**: T2 white matter (WM) hyperintensity, spares subcortical U-fibers
- **Mineralizing microangiopathy**: Basal ganglia (BG), subcortical WM Ca++, atrophy
- **Necrotizing leukoencephalopathy**: WM necrosis
- **PRES**: Posterior circulation subcortical WM edema
- MRS, MR perfusion, PET, or SPECT may help delineate recurrent tumor from radiation necrosis

TOP DIFFERENTIAL DIAGNOSES

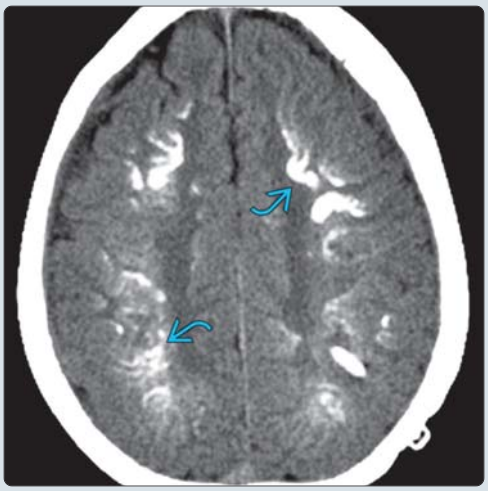
- Neoplasm
- Abscess
- Multiple sclerosis
- Vascular dementia
- Progressive multifocal leukoencephalopathy

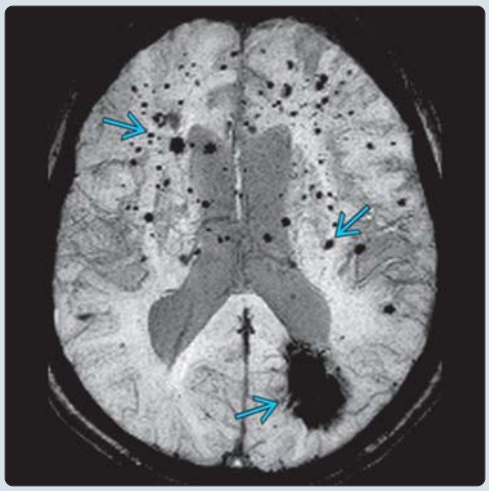
PATHOLOGY

- 2nd neoplasms: Meningiomas (70%), gliomas (20%), sarcomas (10%)
  - More aggressive tumors, highly refractory
  - Incidence: 3-12%
- Radiation-induced vascular malformations: Capillary telangiectasias ± cavernomas (CM)

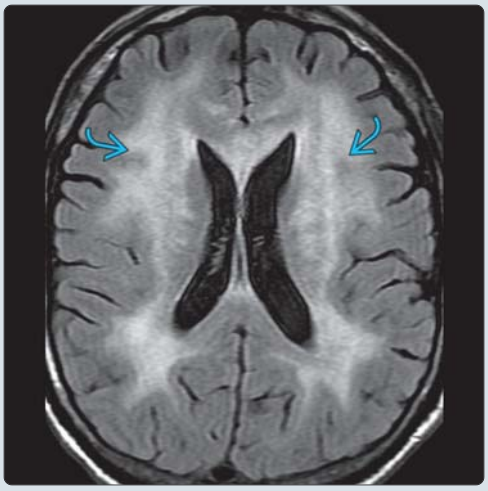
CLINICAL ISSUES

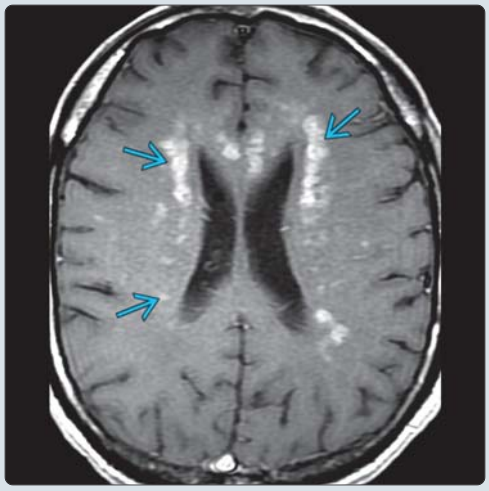
- Overall incidence of radionecrosis: 3-9%
- Worse prognosis: Younger patient at treatment





(Left) *Axial NECT shows extensive calcification in the subcortical white matter (WM) in a 20-year-old patient. Mineralizing microangiopathy usually results after a combination of radiation therapy and chemotherapy 2 or more years after treatment.* **(Right)** *Axial SWI in an adult patient with neurofibromatosis and optic nerve glioma status post radiation therapy in childhood shows innumerable "blooming" hypointense foci consistent with radiation-induced vascular malformations.*





(Left) *Axial FLAIR MR in a 22 year old with acute leukemia treated with intrathecal methotrexate shows confluent periventricular and deep white matter hyperintensities with sparing of the subcortical white matter.* **(Right)** *Axial T1 C+ MR in the same patient shows multiple nodular enhancing lesions in the WM. Findings are consistent with chemotherapy-induced necrotizing leukoencephalopathy. Leukoencephalopathy is a potentially serious complication of chemotherapy.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Radiation-induced injury (RII)

Synonyms

- Radiation (XRT) changes, chemotherapy effects, treatment-related changes

Definitions

- RII may be divided into acute (during or shortly after radiation), subacute/early delayed (typically up to 12 weeks after radiation), and late (months to years after completion of radiation)
- Includes radiation injury (edema, arteritis), radiation necrosis, leukoencephalopathy, mineralizing microangiopathy, necrotizing leukoencephalopathy, posterior reversible encephalopathy syndrome (PRES), radiation-induced tumors

IMAGING

General Features

- Best diagnostic clue
  - Radiation injury: Mild vasogenic edema to necrosis
  - Radiation necrosis: Irregular enhancing lesion(s)
  - Leukoencephalopathy: T2 white matter (WM) hyperintensity, spares subcortical U-fibers
  - Mineralizing microangiopathy: Basal ganglia (BG), subcortical WM Ca++, atrophy
  - Necrotizing leukoencephalopathy (NLE): WM necrosis ± Ca++
  - PRES: Posterior circulation subcortical WM edema
- Location
  - Radiation injury occurs in radiation port
  - Periventricular WM especially susceptible
  - Subcortical U-fibers and corpus callosum spared

CT Findings

- NECT
  - Subacute/early delayed RII: Confluent WM low-density edema
  - Late RII: Focal/multiple WM low density
  - **Leukoencephalopathy**: Symmetric WM hypodensity
  - **Mineralizing microangiopathy**: BG, subcortical WM Ca++, atrophy
  - **NLE**: Extensive areas of WM necrosis, Ca++
  - **PRES**: Subcortical WM edema, posterior circulation

MR Findings

- T1WI
  - Subacute/early delayed RII: Periventricular WM hypointense edema
  - Late RII: Focal or multiple WM hypointensities
  - **Leukoencephalopathy**: Diffuse, symmetric WM hypointensity; spares subcortical U-fibers
  - **Mineralizing microangiopathy**: Putamen hyperintensity, atrophy
- T2WI
  - Acute RII: Usually normal or transient diffuse brain swelling
  - Subacute/early delayed RII: Focal or multiple hyperintense WM lesions with edema, demyelination
    - Spares subcortical U-fibers and corpus callosum
  - Late RII: Diffuse WM injury or necrosis
    - Hyperintense WM lesion(s), ± hypointense rim
    - Mass effect and edema
  - **Leukoencephalopathy**: Diffuse, symmetric involvement of central and periventricular WM, relative sparing of subcortical U-fibers
  - **Mineralizing microangiopathy**: ↓ signal
  - **NLE**: Extensive WM necrosis
  - **PRES**: Confluent, symmetric hyperintensity in subcortical WM, ± cortex, posterior circulation
    - Occipital, parietal, posterior temporal lobes, cerebellum typical
    - May involve frontal lobes, BG, brainstem
- T2* GRE
  - **Radiation-induced vascular malformations**: "Blooming" related to blood products
- DWI
  - Recurrent tumor lower ADC values than radiation necrosis
- T1WI C+
  - Subacute/early delayed RII: ± patchy enhancement
  - Late RII: Enhancement often resembles residual/recurrent tumor
    - May see nodular, linear, curvilinear, "soap bubble," or "Swiss cheese" enhancement
    - May have multiple lesions remote from tumor site
  - **NLE**: Marked enhancement, possibly ring
- **MRS**: Markedly ↓ metabolites (NAA, Cho, Cr), ± lactate/lipid peaks in radiation necrosis
- **Perfusion MR**: ↓ rCBV in radiation necrosis

Angiographic Findings

- Radiation-induced vasculopathy: Progressive narrowing of supraclinoid ICA and proximal anterior circulation vessels; may develop moyamoya pattern

Nuclear Medicine Findings

- FDG PET: Radiation necrosis is hypometabolic
- Th-201 SPECT: Radiation necrosis is hypometabolic, ↓ uptake

Imaging Recommendations

- Protocol advice
  - Enhanced MR ± MRS, MR perfusion, PET if question of RII vs. recurrent neoplasm

DIFFERENTIAL DIAGNOSIS

Recurrent Glioblastoma Multiforme (GBM)

- Enhancing mass with central necrosis, mass effect
- MRS shows ↑ Cho, ↓ NAA, ± lactate

Metastasis

- Typically multiple lesions at gray and white matter junctions, significant edema
- MRS shows ↑ Cho, ↓ NAA, ± lactate
- Ring-enhancing mass may mimic radiation necrosis

Abscess

- Ring-enhancing mass, thinner margin along ventricle

https://CafePezeshki.IR

- T2-hypointense rim, diffusion restriction characteristic
- MRS shows metabolites, such as succinate, amino acids

Multiple Sclerosis

- Often incomplete, horseshoe-shaped enhancement, open toward cortex
- Other lesions in typical locations, young patients

Vascular Dementia

- Large and small infarcts, WM disease
- Typically older patients, clinical diagnosis

Progressive Multifocal Leukoencephalopathy

- WM T2 hyperintensity, involves subcortical U-fibers
- May cross corpus callosum; usually no enhancement
- Immunosuppressed patients

Foreign Body Reaction

- Granulomatous reaction (i.e., to gelatin sponge)
- Can mimic tumor recurrence, radiation necrosis

PATHOLOGY

General Features

- Etiology
  - **Radiation-induced vascular injury**
    - Permeability alterations, endothelial and basement membrane damage, accelerated atherosclerosis, telangiectasia formation
  - **Radiation-induced neurotoxicity**
    - Glial and WM damage (sensitivity of oligodendrocytes > > neurons)
  - **Radiation-induced tumor** (i.e., sarcoma)
    - Increased risk in patients with XRT ≤ 5 years old, those with genetic predisposition (NF1, retinoblastoma), bone marrow transplant survivors
  - **Radiation-induced cryptic vascular malformations**: Predominantly capillary telangiectasias ± cavernomas
  - **Mineralizing microangiopathy**: Common with chemotherapy and XRT, appears ≥ 2 years after XRT
  - **Necrotizing leukoencephalopathy**: Combined XRT and chemotherapy, progressive disease
  - **PRES**: Related to elevated blood pressure that exceeds autoregulatory capacity of brain vasculature
  - Many chemotherapy agents cause CNS effects: Methotrexate, cytarabine, carmustine, cyclophosphamide, cisplatin
  - **RII variables**: Total dose, field size, fraction size, number/frequency of doses, adjuvant therapy, survival duration, patient age

Staging, Grading, & Classification

- Neurotoxic reaction to radiation therapy divided into acute, early, and late delayed injury
  - **Acute** injury: Mild and reversible, vasogenic edema
  - **Subacute/early delayed** injury: Edema and demyelination
  - **Late** injury: More severe, irreversible

Gross Pathologic & Surgical Features

- XRT: Spectrum from edema to cavitating WM necrosis
- Radiation necrosis: Coagulation necrosis that favors WM, may extend to deep cortex

Microscopic Features

- Acute RII: WM edema from capillary damage
- Subacute/early delayed RII: Vasogenic edema, demyelination, perivascular lymphocytic infiltrates, gliosis
- Late RII: WM necrosis, demyelination, astrocytosis, vasculopathy,
- Radiation necrosis: Confluent coagulative necrosis, Ca++, hyaline thickening and fibrinoid necrosis of vessels, thrombosis
- Mineralizing microangiopathy: Hyalinization and fibrinoid necrosis of small arteries and arterioles with endothelial proliferation, Ca++ deposition

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Highly variable
  - Acute RII: Signs of ↑ intracranial pressure with headache, nausea/vomiting, &/or mental status changes
  - Subacute/early delayed RII: Somnolence syndrome characterized by fatigue and lethargy
  - Radiation necrosis: Usually seen 2-32 months after therapy
    - 85% of cases occurring within 2 years

Demographics

- Epidemiology
  - Overall incidence of radionecrosis: 3-9%
    - < 5% with 60 Gy of radiation in daily 2 Gy fractions
  - Radiation-induced neoplasms: 3-12%
    - Meningiomas (70%), gliomas (20%), sarcomas (10%)

Natural History & Prognosis

- Younger patient at time of treatment: Worse prognosis
- Radiation necrosis is dynamic pathophysiological process; often progressive, irreversible

Treatment

- Biopsy if imaging does not resolve tumor vs. radionecrosis
- Surgery if mass effect, edema
- Acute radiation injury may respond to steroids

DIAGNOSTIC CHECKLIST

Consider

- Distinguishing residual/recurrent neoplasm from XRT necrosis difficult using morphology alone

Image Interpretation Pearls

- MRS, MR perfusion, PET, or SPECT may help delineate recurrent tumor from radiation necrosis

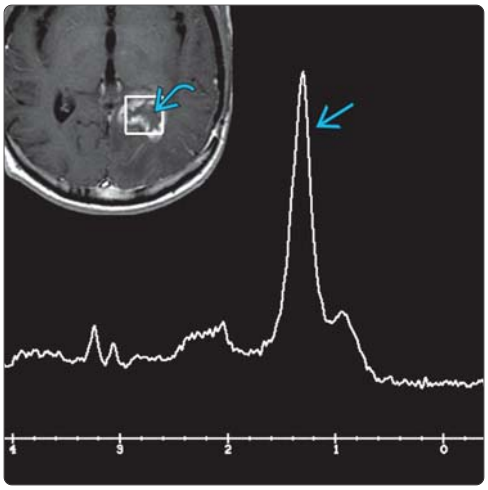
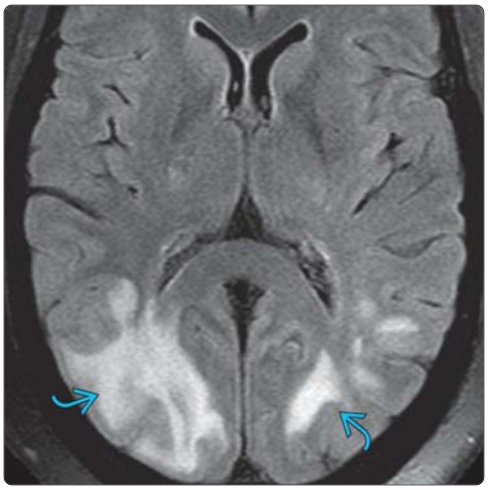
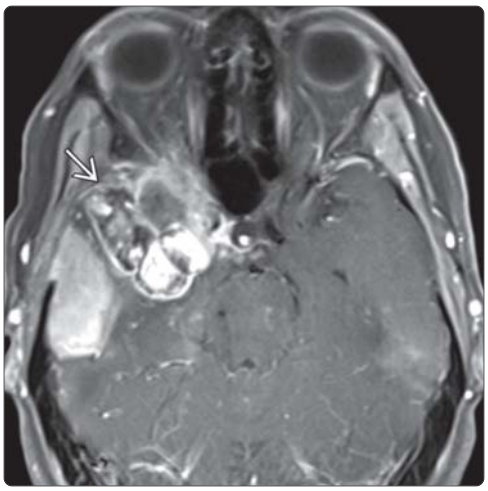
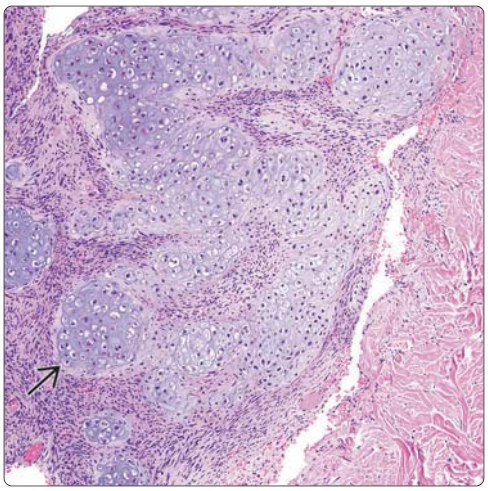
(Left) *Axial T1WI C+ MR in a patient with esthesioblastoma 6 months post radiation shows masses in the inferior frontal lobes with a spreading wavefront enhancement pattern.* **(Right)** *MR perfusion rCBV map in the same patient does not show any significant increase in the relative cerebral volume in the regions of enhancement. Findings are typical of radiation necrosis. Radiation necrosis can occur months to years after radiation therapy. More than 85% of cases occur within 2 years.*





(Left) *Single-voxel MR spectroscopy at 35 TE in a patient status post resection of a metastasis and radiation therapy who developed a necrotic enhancing lesion in the left parietal lobe shows markedly elevated lipid/lactate peak with reduction in the rest of the metabolites.* **(Right)** *Axial FLAIR MR in a patient status post renal transplant on cyclosporine shows characteristic changes of PRES with asymmetric occipital cortical/subcortical edema.*





(Left) *Axial T1WI C+ FS MR shows a heterogeneous mass in the anterior middle cranial fossa in a patient with prior surgery and radiation therapy for a WHO grade I meningioma.* **(Right)** *High-power micropathology (same patient) shows chondrosarcoma elements at repeat resection. A 2nd neoplasm occurs in 3-12% of patients treated with radiation therapy. Though radiation-induced tumors are rare (seen in 3-12% of cases), they are most commonly meningiomas (70%), gliomas (20%), or sarcomas (10%).*

https://CafePezeshki.IR

Pseudoprogression

KEY FACTS

TERMINOLOGY

- Treatment-related increase in contrast enhancement mimics tumor progression
- Classically described after treatment with chemoradiation (temozolomide with radiation therapy)
- Typically occurs within 3-6 months after conclusion of radiation therapy (XRT)

IMAGING

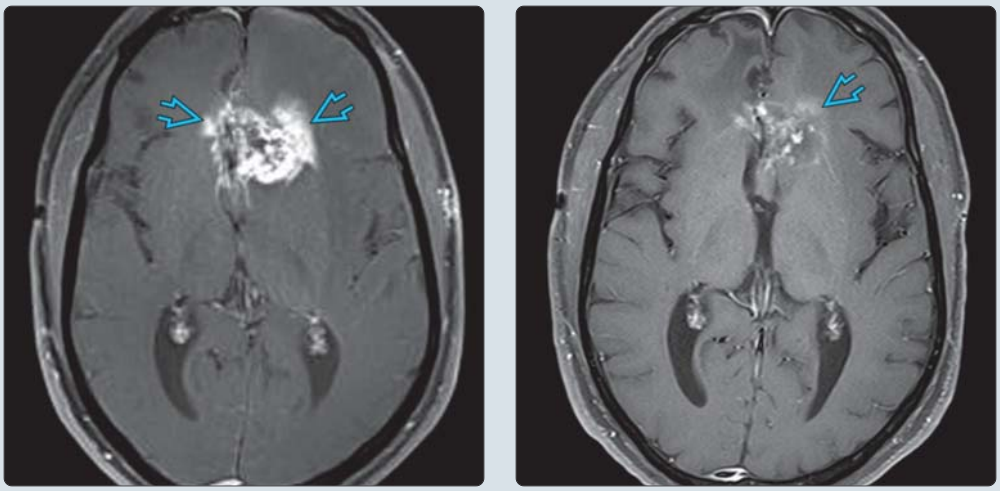
- New enhancing lesion + ↑ FLAIR hyperintensity in treated malignant glioma at 3-4 months after XRT completion
- T2/FLAIR: Increased hyperintensity with mass effect
- DWI: Higher ADC values in PsP compared with tumor
- DSC: Lower mean rCBV values in PsP compared with tumor
- DCE: Mean K trans (volume transfer constant) is lower in PsP compared with true progression
- MRS: No significant elevation of choline in Psp
- Best Imaging: Contrast-enhanced MR, DWI, ± MRS, MRP
- Follow-up studies may be necessary to make accurate diagnosis of PsP
- Knowing clinical history and timing of therapy is key to accurate brain tumor imaging

TOP DIFFERENTIAL DIAGNOSES

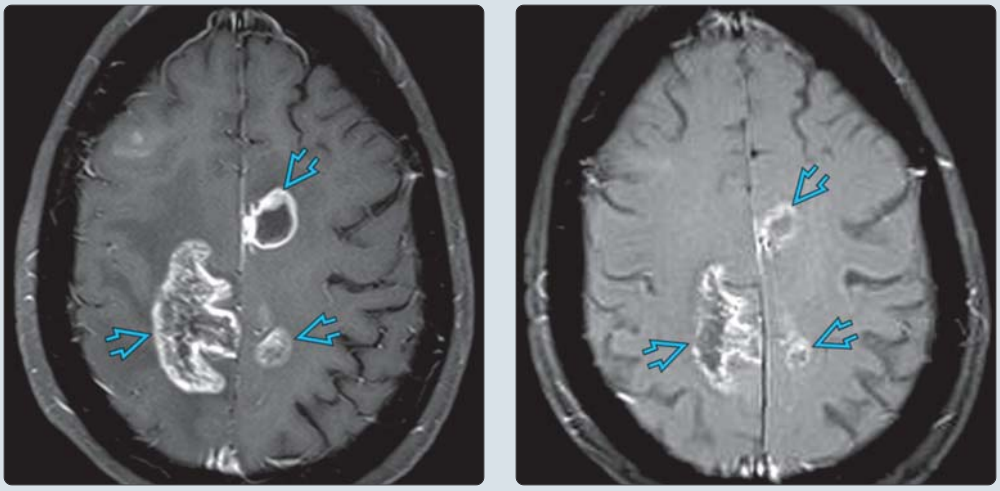
- Recurrent malignant glioma
- Radiation necrosis

CLINICAL ISSUES

- Current standard of care for malignant gliomas is surgical resection followed by concurrent XRT and chemotherapy with temozolomide (Temodar)
  - PsP occurs in ~ 35-50% of patients
- PsP is self-limited, enhancing lesions resolve without new treatment
- PsP has been associated with **improved survival**
- Important to recognize that not all new enhancement in a patient with a treated GBM is progressive tumor



(Left) *Axial T1 C+ MR in a 48-year-old man treated with radiation therapy and Temodar for 3 months for his malignant glioma shows new enhancement in the frontal lobes bilaterally. His initial postoperative MR study showed no enhancement. He was clinically doing well.* **(Right)** *Axial T1 C+ MR in the same patient 4 weeks later shows a marked decrease in the enhancement without a change in therapy. Imaging findings are related to pseudoprogression, not true progression, likely related to an inflammatory response.*



(Left) *Axial T1 C+ MR in a 62-year-old woman with a multifocal glioblastoma (GBM) treated with Temodar and radiation therapy shows new enhancement in the hemispheres on her 4-month scan, concerning for progressive tumor.* **(Right)** *Axial T1 C+ MR in the same patient 8 weeks later with no therapy change shows a marked decrease in the enhancing lesions. The new enhancement was related to pseudoprogression (PsP), which is associated with an increased survival.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pseudoprogression (PsP)

Synonyms

- Treatment-related enhancement

Definitions

- Treatment-related increase in contrast enhancement mimicking tumor progression
  - Classically described after treatment with chemoradiation (temozolomide with radiation therapy)
- Typically occurs within 3-6 months after conclusion of radiotherapy (XRT)
- Self-limited, enhancing lesions resolve without new treatment

IMAGING

General Features

- Best diagnostic clue
  - New enhancement with ↑ FLAIR hyperintensity in treated glioblastoma (GBM) at 3-4 months after XRT completion
- Location
  - Region of previously treated neoplasm or in adjacent brain
  - Typically within radiation field

MR Findings

- T1WI
  - Typically hypointense
- T2WI
  - Hyperintense with mass effect, ± focal mass
- FLAIR
  - Hyperintense with mass effect, ± focal mass
- DWI
  - Higher ADC values and ratios in PsP compared with tumor
- PWI
  - DSC: Lower mean rCBV values in PsP compared with recurrent tumor
    - Significant overlap in values
  - DCE: Mean K trans (volume transfer constant) is lower in PsP compared with true progression
  - Extravascular extracellular space per unit volume of tissue (Ve) is lower in PsP
- T1WI C+
  - Enhancing mass

DIFFERENTIAL DIAGNOSIS

Recurrent Malignant Glioma

- New enhancement in previously treated neoplasm
- Subependymal spread is suggestive of recurrent tumor
- DWI: Low ADC values
- PWI: High CBV suggestive of recurrent tumor

Radiation Necrosis

- Enhancement in region of previously treated neoplasm or vascular lesion
- T2/FLAIR hyperintensity with mass effect
- Imaging overlap with pseudoprogression
- MRS, MR perfusion may help differentiate
- Typically occurs ≥ 12-18 months to many years after therapy

Pseudoresponse

- Decreased enhancement related to antiangiogenic agents (i.e., Avastin) rather than true response
- Tumor typically hyperintense on FLAIR and DWI
- Related to reduced vascular permeability
- Often results in growth of nonenhancing infiltrative tumor

PATHOLOGY

General Features

- Etiology is thought to be related to vascular and oligodendroglial injury leading to inflammation and increased permeability of blood-brain barrier

Gross Pathologic & Surgical Features

- Vascular dilation, fibrinoid necrosis, endothelial damage of normal cerebral vasculature

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Typically asymptomatic
  - May have symptoms related to increased mass effect

Natural History & Prognosis

- Current standard of care for malignant gliomas is surgical resection followed by concurrent XRT and chemotherapy with temozolomide (Temodar)
  - Incidence of PsP is 30-50% of treated patients
- Likely increases with increasing radiation dose
- PsP has been associated with **improved survival**
  - May be related to favorable correlation with methylated O6-methylguanine-DNA methyltransferase (MGMT) promoter status

Treatment

- No change in therapy is required
- Some oncologists treat with steroids

DIAGNOSTIC CHECKLIST

Consider

- New enhancement and mass effect in a malignant glioma does not always mean disease progression
- Follow-up studies may be necessary to make accurate diagnosis of pseudoprogression

SELECTED REFERENCES

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Antiangiogenic agents may substantially reduce contrast enhancement in GBM related to reduced vascular permeability rather than actual tumor response
  - **Bevacizumab** (Avastin): An anti-VEGF is main antiangiogenic agent currently used for treatment of recurrent malignant gliomas
  - **Cediranib**: VEGF receptor tyrosine kinase inhibitor, has been tested in recent high-grade glioma treatment trials

IMAGING

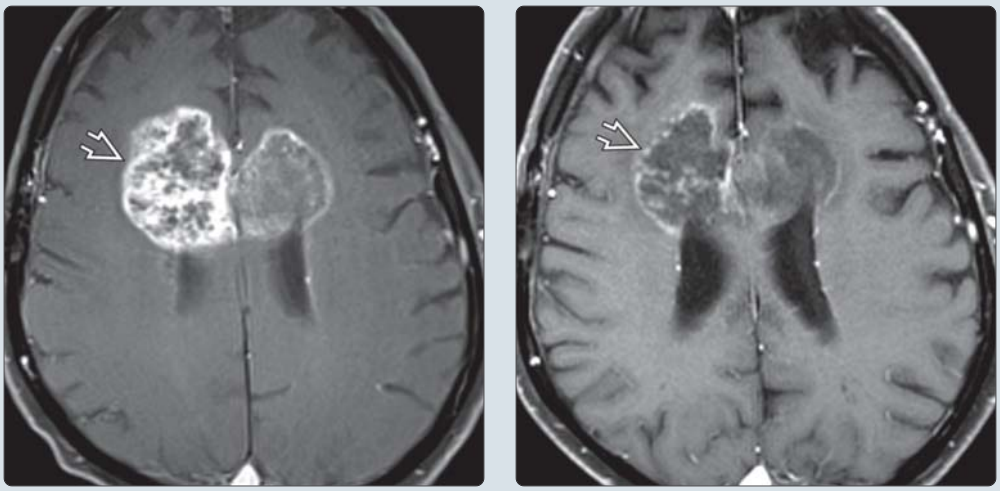
- Decreased enhancement in a patient with malignant glioma treated with anti-VEGF agent
  - May see persistent FLAIR and diffusion restriction, despite decreased enhancement
- DWI and ADC have been proposed as imaging markers for tumor response in presence of antiangiogenic agents to address pseudoresponse
- Beware, decreased enhancement in tumor follow-up study may be true treatment response or pseudoresponse in setting of newer therapies
- DSC: Early changes in rCBV after initiation of antiangiogenic therapy may distinguish pseudoresponse from true treatment response

TOP DIFFERENTIAL DIAGNOSES

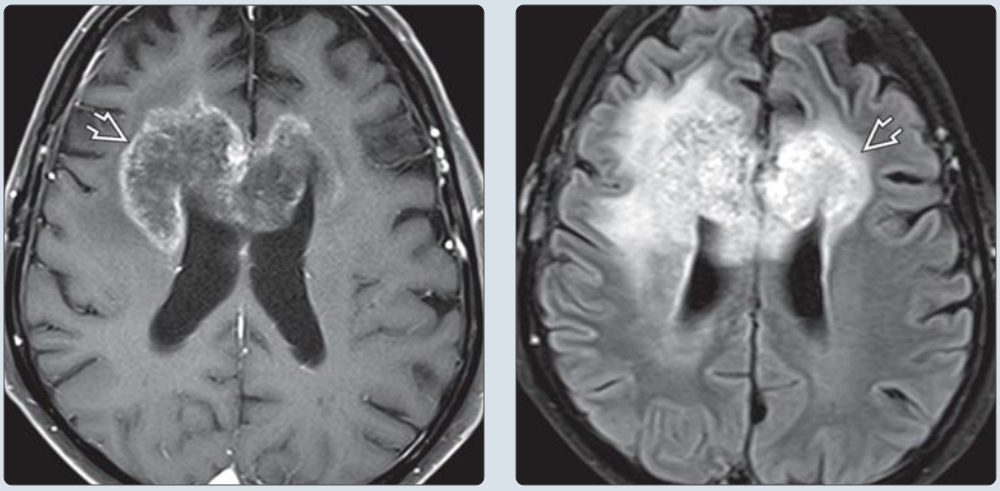
- Treatment response
- Steroid effect

CLINICAL ISSUES

- Antiangiogenic agents normalize hyperpermeable tumor vasculature and restore blood-brain barrier
- Local response to tumor growth is controlled, but diffuse infiltration and distant metastases are common
- Antiangiogenic agents significantly improve 6-month progression-free survival, but may not affect overall survival



(Left) *Axial T1 C+ MR in a GBM patient who progressed on standard therapy with radiation and Temodar shows there is a heterogeneously enhancing mass involving the genu of the corpus callosum ⇨. Avastin therapy was started immediately after this MR examination.* **(Right)** *Axial T1 C+ MR in the same patient 4 weeks after the start of Avastin shows a marked decrease in the enhancing mass involving the genu of the corpus callosum ⇨. The FLAIR and DWI image showed stable hyperintensity and mass effect.*



(Left) *Axial T1 C+ MR in the same patient 8 weeks later shows an increase in the size of the corpus callosum enhancing mass ⇨.* **(Right)** *Axial FLAIR MR in the same patient shows a marked increase in the size ⇨ and associated mass effect of the corpus callosum mass related to progressive tumor. Decreased enhancement on the prior MR is a result of pseudoresponse from the antiangiogenic therapy, rather than true tumor response. Diffuse tumor infiltration is common after antiangiogenic therapy.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Vascular endothelial growth factor (VEGF)

Synonyms

- Treatment effect, Avastin effect

Definitions

- Antiangiogenic agents may substantially reduce contrast enhancement in glioblastoma multiforme (GBM) related to reduced vascular permeability rather than actual tumor response
  - **Bevacizumab** (Avastin): An anti-VEGF antibody is the main antiangiogenic agent currently used for treatment of recurrent malignant gliomas
  - **Cediranib**: A VEGF receptor tyrosine kinase inhibitor, has been tested in recent high-grade glioma treatment trials with similar effects

IMAGING

General Features

- Best diagnostic clue
  - Decreased enhancement +/- decreased FLAIR in patient with malignant glioma treated with anti-VEGF agent, typically bevacizumab
  - May see persistent FLAIR and diffusion restriction, despite decreased enhancement

MR Findings

- T2WI
  - Hyperintense, +/- focal mass
- FLAIR
  - Hyperintense, +/- focal mass
- DWI
  - Diffusion restriction with low ADC in actual tumor
  - Some suggest increased ADC in patients with favorable response to therapy
  - Decreased ADC suggest poor prognosis
- PWI
  - DSC: Early changes in rCBV after initiation of antiangiogenic therapy may distinguish pseudoresponse from true treatment response
    - Greater decrease in rCBV of the tumor microvessels associated with increased overall survival
    - Increased CBF may be associated with favorable survival
  - DCE: Greater reduction in Ktrans seen in patients with increased survival
  - Use of indices, such as the vascularization normalization index (VNI), may help predict those patients who will respond better to treatment
- T1WI C+
  - Decreased enhancement

DIFFERENTIAL DIAGNOSIS

Treatment Response

- True reduction in tumor volume
- Decreased enhancement
- Decreased FLAIR hyperintensity, mass effect

Steroid Effect

- Steroids reestablish blood-brain barrier
- May decrease enhancement of tumor without decrease in actual tumor
- Imaging similar to pseudoresponse

Pseudoprogression

- Increased enhancement and mass effect without actual change in tumor
- Typically seen at 3-4 months following temozolomide, external radiation therapy (XRT)

PATHOLOGY

General Features

- Decrease in contrast enhancement from antiangiogenic therapy results in change in vascular permeability, with "normalization" of blood brain barrier
  - Not true tumor reduction
- Local response to tumor growth is controlled, but diffuse infiltration and distant metastases are common
- Antiangiogenic agents improve 6-month progression-free survival, may not change overall survival

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - No corresponding clinical response

Natural History & Prognosis

- Antiangiogenic agents produce rapid ↓ in contrast enhancement with high response rate and 6-month progression-free survival, with modest effects on overall survival
- Tendency for growth of nonenancing infiltrative tumor prior to emergence of contrast enhancement in ~ 30-40%

DIAGNOSTIC CHECKLIST

Consider

- Significant rapid improvement in imaging appearance of tumor without affecting biologic activity of tumor itself is related to pseudoresponse

Image Interpretation Pearls

- DWI and ADC have been proposed as imaging markers for tumor response in presence of antiangiogenic agents to address this issue of pseudoresponse
- Beware, decreased enhancement in tumor follow-up study may be true treatment response or pseudoresponse in setting of newer therapies (bevacizumab)

KEY FACTS

TERMINOLOGY

- Seizure-associated neuronal loss and gliosis in hippocampus and adjacent structures

IMAGING

- Primary features: Abnormal T2 hyperintensity, hippocampal volume loss/atrophy, obscuration of internal architecture
- Secondary signs: Ipsilateral fornix and mammillary body atrophy, enlarged ipsilateral temporal horn, and choroidal fissure
- ↑ hyperintensity on DWI (T2 shine through)
- ↓ NAA in hippocampus, temporal lobe

TOP DIFFERENTIAL DIAGNOSES

- Status epilepticus
- Low-grade astrocytoma
- Choroidal fissure cyst
- Hippocampal sulcus remnant

PATHOLOGY

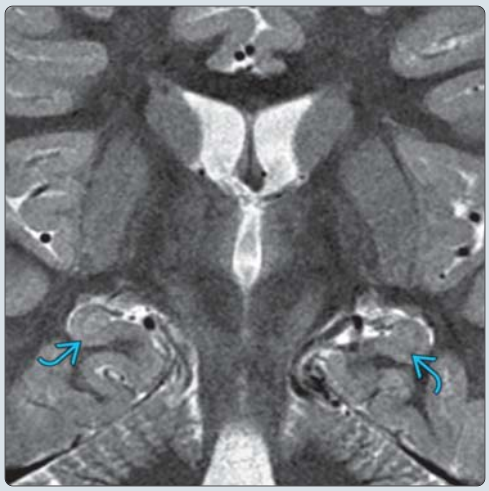
- Prolonged febrile seizures may produce acute hippocampal injury → subsequent atrophy
- Coexistent 2nd developmental lesion in 15% of mesial temporal sclerosis (MTS) patients

CLINICAL ISSUES

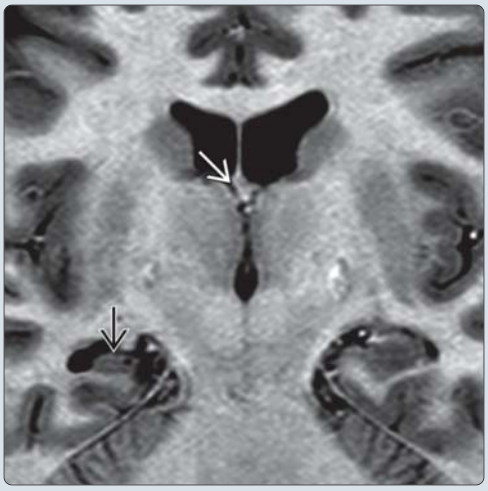
- Partial complex seizures
- Often history of childhood febrile or medically intractable seizures
- Surgical temporal lobectomy reserved for medically intractable seizures, intolerable drug side effects

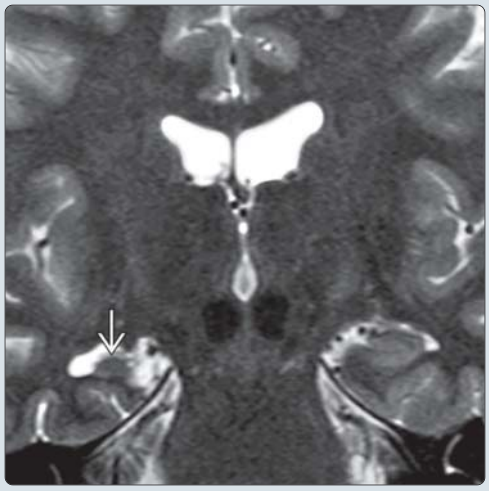
DIAGNOSTIC CHECKLIST

- Most common cause of partial complex epilepsy in adult age group
- Low-grade neoplasms and cortical dysplasia more common causes of partial complex epilepsy than MTS in pediatric age group



(Left) *Coronal graphic depicts the characteristic appearance of mesial temporal sclerosis (MTS). The right hippocampus ➡ is small (atrophic) with loss of normal internal architecture reflecting neuronal loss and gliosis. Note concordant atrophy of the ipsilateral fornix ⇨ and widening of the ipsilateral temporal horn and choroidal fissure.* **(Right)** *Coronal STIR MR at 3.0 tesla in a normal nonepileptic patient imaged for headaches demonstrates normal bilateral hippocampal anatomy ⇨, size, and signal intensity.*





(Left) *Coronal T1-weighted true inversion recovery MR at 3.0 tesla shows asymmetric right hippocampal volume loss ⇨ and obscuration of normal internal gray-white differentiation. The ipsilateral fornix ➡ is smaller than the normal left fornix.* **(Right)** *Coronal T2-weighted MR at 3.0 tesla in the same patient with right hippocampal sclerosis (HS) ➡ shows hippocampal volume loss and obscuration of normal internal architecture, but normal T2 signal intensity. FLAIR better shows the increase in signal intensity.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Mesial temporal sclerosis (MTS)

Synonyms

- Ammons horn sclerosis, hippocampal sclerosis (HS)

Definitions

- Seizure-associated neuronal loss and gliosis in hippocampus and adjacent structures

IMAGING

General Features

- Best diagnostic clue
  - Primary features: Abnormal T2 hyperintensity, hippocampal volume loss/atrophy, obscuration of internal architecture
  - Secondary signs: Ipsilateral fornix and mammillary body atrophy, enlarged ipsilateral temporal horn, and choroidal fissure
  - Additional findings: Loss of ipsilateral hippocampal head (pes) digitations, parahippocampal gyrus white matter atrophy, ↑ T2 signal in anterior temporal white matter
- Location
  - Mesial temporal lobe(s), 10-20% bilateral
  - Hippocampus > amygdala > fornix > mammillary bodies
- Size
  - Slight to marked ↓ in hippocampal volume
- Morphology
  - Abnormal shape, size of affected hippocampus

CT Findings

- NECT
  - Usually normal; CT insensitive to MTS

MR Findings

- T1WI
  - ↓ hippocampal size
  - Loss of normal hippocampal gray-white differentiation
  - ± ipsilateral fornix, mammillary body atrophy
  - Quantitative hippocampal volumetry: ↑ sensitivity of MTS detection (particularly bilateral MTS)
- T2WI
  - Hippocampal atrophy
  - Obscuration of normal internal architecture
  - ↑ hippocampal signal intensity
  - ± ipsilateral fornix, mammillary body atrophy, dilatation of ipsilateral temporal horn
  - ± abnormal hyperintensity, volume loss in ipsilateral anterior temporal lobe
- FLAIR
  - Hyperintense signal in abnormal hippocampus
- DWI
  - ↑ hyperintensity on DWI (T2 shine through)
  - ↑ diffusivity on ADC
- T1WI C+
  - No enhancement
- MRS
  - ↓ NAA in hippocampus, temporal lobe
  - ↓ NAA/Cho and ↓ NAA/Cho+Cr suggests MTS
  - ± lactate/lipid peaks after 24 hours of continual seizure

Angiographic Findings

- Presurgical Wada testing: Neuropsychological testing after intracarotid amobarbital (Amytal) injection
  - Lateralize memory and language functions
  - Predict postoperative memory loss, feasibility of surgery
  - May help lateralize seizure onset
- fMRI mapping replacing Wada testing

Nuclear Medicine Findings

- FDG PET: Hypometabolism in abnormal mesial temporal lobe
- SPECT: Hypoperfusion (interictal) or hyperperfusion (ictal) in epileptogenic zone
  - Sensitivity of ictal > interictal

Imaging Recommendations

- Best imaging tool
  - High-resolution MR imaging
  - MRS, quantitative volumetry may help lateralize MTS in difficult cases
- Protocol advice
  - Thin-section coronal T2WI and FLAIR (3 mm), angled perpendicular to long axis of hippocampus
  - Thin-section coronal 3D SPGR (1-2 mm), angled perpendicular to long axis of hippocampus

DIFFERENTIAL DIAGNOSIS

Status Epilepticus

- Clinical history of multiple seizures or status epilepticus
- Temporary T2 hyperintensity ± gyriform enhancement in affected cortex, hippocampus

Low-Grade Astrocytoma

- Hyperintense temporal lobe white matter mass (usually nonenhancing)
- ± seizures, young adults typical

Choroidal Fissure Cyst

- Asymptomatic CSF signal cyst in choroidal fissure distorts normal hippocampus
  - Round on axial, coronal images
  - Oval, parallels temporal lobe long axis on sagittal imaging
- No abnormal T2 hyperintensity in mesial temporal lobe

Hippocampal Sulcus Remnant

- Failure of normal hippocampal sulcus involution → asymptomatic cyst between dentate gyrus, cornu ammonis
- Common normal variant (10-15%)

Cavernous Malformation

- Heterogeneous hyperintense "popcorn" lesion with dark complete hemosiderin rim
- ± seizures

Dysembryoplastic Neuroepithelial Tumor (DNET)

- Demarcated "bubbly," variably enhancing cortical mass ± regional cortical dysplasia
- Partial complex seizures

https://CafePezeshki.IR

Cortical Dysplasia

- Most common dual pathology associated with MTS
- T2 hyperintensity in anterior temporal white matter

PATHOLOGY

General Features

- Etiology
  - Controversial whether acquired or developmental
    - Acquired: Follows complicated febrile seizures, status epilepticus, encephalitis
    - Developmental: 2nd developmental lesion identified in 15%
    - "Two-hit" hypothesis: 1st an initial precipitating injury (like complicated seizures), 2nd an increased vulnerability (such as genetic predisposition or developmental anomaly)
    - Most likely MTS represents common outcome of both acquired and developmental processes
  - Febrile seizures (FS) most common childhood seizure disorder (2-5%)
    - Prolonged FS may produce acute hippocampal injury → subsequent atrophy
- Genetics
  - Familial cases of mesial temporal lobe epilepsy (TLE), FS reported
  - Recent studies suggest relationship between FS and later epilepsy development may be genetic
  - Syndrome-specific genes for FS (channelopathies) account for small proportion of FS cases
- Associated abnormalities
  - Coexistent 2nd developmental lesion (15%)

Gross Pathologic & Surgical Features

- Normal hippocampus divided anatomically into head (pes), body, tail
  - Subdivision into Ammons horn, dentate gyrus, hippocampal sulcus, fimbria, alveus, subiculum, parahippocampal gyrus, collateral sulcus
- Mesial temporal lobe atrophy: Hippocampal body (88%), tail (61%), head (51%), amygdala (12%)
- Absence of hemorrhage or necrosis

Microscopic Features

- Chronic astrogliosis with fine fibrillary background of bland astrocytic nuclei and decreased residual neurons
- Ammons horn, cornu ammonis (CA), contains 4 zones of granular cells: CA1, CA2, CA3, CA4
  - CA1, CA4 pyramidal cell layers most susceptible to ischemia
  - All hippocampal regions may show varying neuronal cell loss

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Partial complex seizures, automatisms
    - Simple at younger ages and increasingly complex and discrete with age
- Other signs/symptoms
  - May progress to generalized tonic-clonic seizures
- Clinical profile
  - Often history of childhood febrile or medically intractable seizures
    - History of complex or prolonged febrile seizures ↑ risk for development of hippocampal injury, MTS
  - Surface electro- (EEG) or magneto- (MEG) encephalogram helpful for localization (60-90%)
  - Intracranial EEG (subdural or depth electrodes) may be indicated if noninvasive studies discordant

Demographics

- Age
  - Disease of older children, young adults
- Gender
  - No gender predominance
- Epidemiology
  - MTS accounts for majority of epilepsy patients undergoing temporal lobe seizure surgery

Natural History & Prognosis

- Anterior temporal lobectomy 70-95% successful if MR findings are of MTS
- Success of anterior temporal lobectomy 40-55% if MR normal
- ↓ surgical success when amygdala involved

Treatment

- Clinical management based on phenotypic features of initial febrile and subsequent seizures
- Medical treatment initial approach
- Surgical temporal lobectomy reserved for medically intractable seizures, intolerable drug side effects
  - Resection includes anterior temporal lobe, majority of hippocampus, variable portions of amygdala

DIAGNOSTIC CHECKLIST

Consider

- Most common cause of partial complex epilepsy in adults
- Bilateral in 10-20%; difficult to detect without quantitative volumetry unless severe

Image Interpretation Pearls

- Coronal high-resolution T2WI, FLAIR MR most sensitive for MTS
- Dual pathology in 15%
- In pediatric age group, low-grade neoplasms and cortical dysplasia more common causes of partial complex epilepsy than MTS

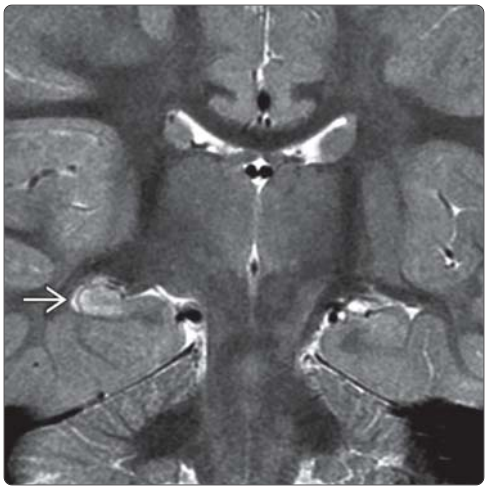
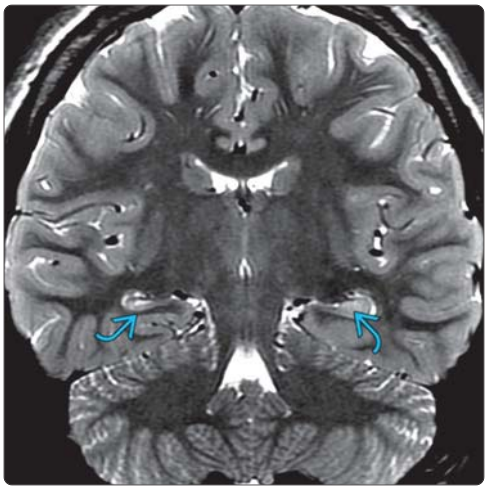
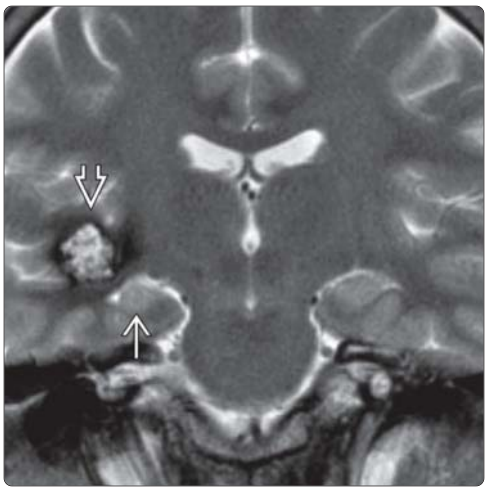
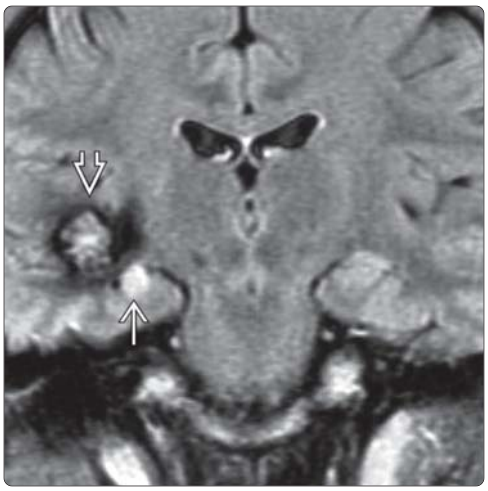
(Left) *Coronal T2 MR in a patient with temporal lobe epilepsy demonstrates primary and secondary imaging features of mesial temporal sclerosis. There is severe left hippocampal atrophy and signal alteration. Note secondary features such as atrophy of the left fornix and mammillary body as well as dilation of temporal horn.* **(Right)** *Coronal T2 MR in a patient with epilepsy shows a vertical left collateral sulcus and a globular hippocampus. This common variation can be mistaken for hippocampal sclerosis.*





(Left) *Coronal T2-weighted MR at 3.0 tesla in a patient with prolonged febrile seizure shows abnormal enlargement and T2 hyperintensity in the right hippocampus. DWI (not shown) revealed reduced diffusion. The patient later developed hippocampal sclerosis.* **(Right)** *Coronal T2 MR in a patient with longstanding partial complex epilepsy shows bilateral hyperintense hippocampi with volume loss, right greater than left, consistent with bilateral mesial temporal sclerosis.*





(Left) *Coronal T2WI MR in a chronic seizure patient with large right temporal lobe cavernous malformation demonstrates all 3 primary determinants of right hippocampal sclerosis (volume loss, T2 hyperintensity, and loss of internal architecture).* **(Right)** *Coronal FLAIR MR in the same patient with right temporal lobe cavernous malformation better shows hippocampal sclerosis. Hyperintensity is usually more conspicuous on FLAIR, while T2 is better for depicting internal structure.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Status epilepticus: > 30 minutes of continuous seizures or ≥ 2 seizures without full recovery of consciousness between seizures
- Synonyms: Transient seizure-related MR changes, reversible postictal cerebral edema

IMAGING

- Best diagnostic clue: T2 hyperintensity in gray matter &/or subcortical white matter (WM) with mild mass effect
  - Supratentorial, related to epileptogenic focus
  - Typically cortex &/or subcortical WM
  - May involve hippocampus, corpus callosum, thalamus (particularly pulvinar nucleus)
- Swelling and increased volume of involved cortex
- DWI: Restricted diffusion acutely
- T1WI C+: Variable enhancement, none to marked
- PWI: Marked hyperemia, ↑ rCBF and rCBV

TOP DIFFERENTIAL DIAGNOSES

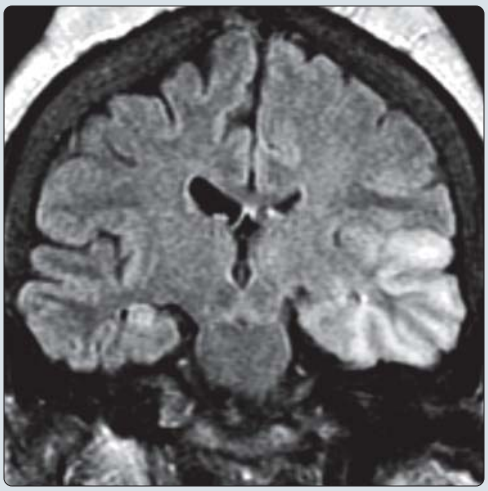
- Cerebritis
- Cerebral ischemia-infarction
- Herpes encephalitis
- Astrocytoma

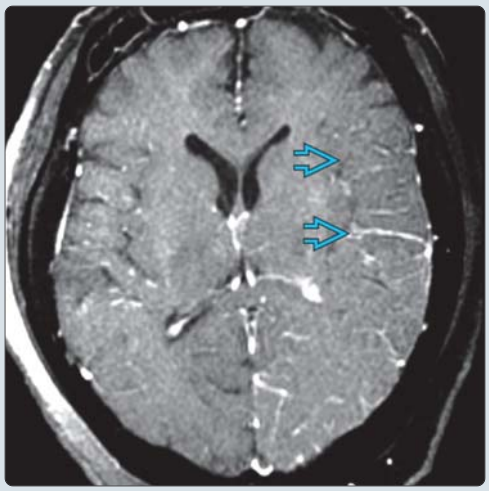
CLINICAL ISSUES

- Active seizures &/or status epilepticus
- Other signs/symptoms: Location dependent

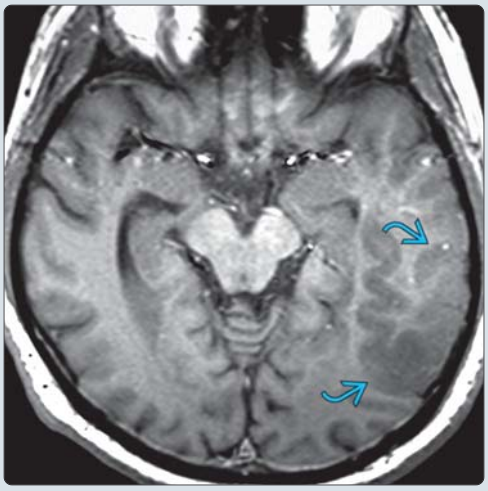
DIAGNOSTIC CHECKLIST

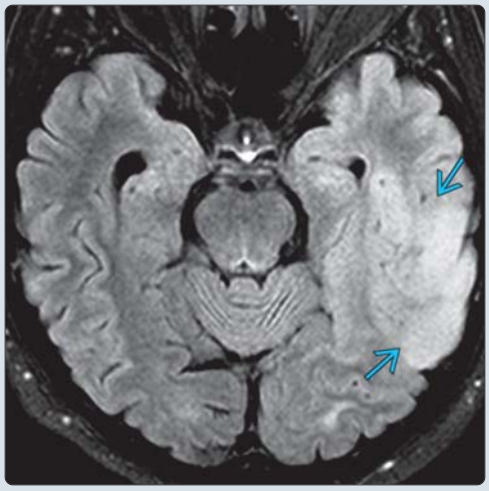
- Acute seizures or status epilepticus may mimic other pathology, such as tumor progression or cerebritis
- Clinical information and follow-up imaging often differentiates from other etiologies
- Look for underlying mass that may have caused seizures/status epilepticus
- Seizure-related changes usually resolve within days to weeks





(Left) *Coronal FLAIR MR performed shortly after a long episode of status epilepticus shows increased signal involving the left temporal lobe cortex and associated subcortical white matter.* **(Right)** *Axial T1WI C+ FS MR in the same patient shows mild edema and vascular congestion in the left temporal lobe. Imaging 1 month later showed near complete resolution of the signal abnormalities. Status epilepticus may result in MR changes that are likely related to transient cerebral edema.*





(Left) *Axial T1WI MR in a patient with status epilepticus shows mild thickening of the left temporal cortex.* **(Right)** *Axial FLAIR MR in the same patient shows cortical and subcortical white matter edema. MR signal abnormalities are related to transient vasogenic &/or cytotoxic edema. Follow-up imaging in such cases usually shows resolution of the acute imaging abnormalities in treated patients. Atrophy may be seen chronically.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Status epilepticus (SE)

Synonyms

- Transient seizure-related MR changes, reversible postictal cerebral edema

Definitions

- Status epilepticus: > 30 minutes of continuous seizures or ≥ 2 seizures without full recovery of consciousness between seizures
- MR changes associated with seizures likely related to transient cerebral edema

IMAGING

General Features

- Best diagnostic clue
  - T2 hyperintensity in gray matter (GM) &/or subcortical white matter (WM) with mild mass effect
  - May focally involve hippocampus, corpus callosum, thalamus (particularly pulvinar nucleus)
- Location
  - Supratentorial, related to epileptogenic focus
    - Typically cortex &/or subcortical WM
  - May involve focal structures
    - Hippocampus (febrile or partial complex seizures)
    - Splenium of corpus callosum
    - Pulvinar of thalamus
  - Occasionally cerebellar involvement

CT Findings

- NECT
  - Hypodensity in cortex &/or subcortical WM
  - Blurring of corticomedullary junction
  - Hippocampus, splenium of corpus callosum, thalamus (particularly pulvinar nucleus) may be involved
  - No hemorrhage
- CECT
  - Variable enhancement: None to marked

MR Findings

- T1WI
  - Hypointensity in cortex &/or subcortical WM
    - Swelling and increased volume of involved cortical gyri
  - Blurring of corticomedullary junction
  - Mild mass effect
  - Hippocampus, splenium of corpus callosum, thalamus (particularly pulvinar nucleus) may be involved
  - Rarely cerebellar involvement due to crossed cerebellar diaschisis
- T2WI
  - Hyperintensity in cortex &/or subcortical WM
    - Swelling and increased volume of involved cortical gyri
  - Mild edema and mass effect
  - Hippocampus, corpus callosum splenium, thalamus (particularly pulvinar nucleus) may be involved
  - No hemorrhage
- FLAIR
  - Hyperintensity in cortex &/or subcortical WM
  - Mild edema and mass effect
  - Hippocampus, splenium of corpus callosum, pulvinar may be involved
- DWI
  - Restricted diffusion with decrease in ADC map acutely
  - ADC maps normal interictally, elevated in chronic seizures
- T1WI C+
  - Variable enhancement: None to marked
  - May see gyriform or leptomeningeal enhancement
- MRS
  - Lipids &/or lactate shown in hippocampi of temporal lobe epilepsy (TLE) patients within 24 hours of last seizure
  - Follow-up MRS after seizures under control show no lipids/lactate
- Perfusion imaging (PWI): Marked hyperemia on side of epileptic focus, elevated rCBF and rCBV maps

Nuclear Medicine Findings

- Seizures: Increased metabolism and perfusion
- PET: Increased glucose metabolism and metabolic rate
- HMPAO SPECT: High uptake in affected cerebral lobe during or immediately after seizure

Imaging Recommendations

- Best imaging tool
  - MR is most sensitive
- Protocol advice
  - Contrast-enhanced MR with DWI
  - MRS may be helpful in TLE patients

DIFFERENTIAL DIAGNOSIS

Cerebritis

- T2 hyperintense "mass" with mass effect
- Typically DWI positive
- Patchy enhancement typical

Cerebral Ischemia-Infarction

- Typical vascular distribution (ACA, MCA, PCA)
- Acute/subacute DWI positive
- Wedge-shaped, involves GM and WM
- Gyriform enhancement in subacute ischemia

Herpes Encephalitis

- Confined to limbic system, temporal lobes
- Blood products, enhancement typical
- Acute onset, often with fever
- May present with seizures

Astrocytoma

- Infiltrating WM mass
- May extend to involve cortex
- Variable enhancement in anaplastic (grade III)
- May cause epilepsy

MELAS

- Mitochondrial encephalopathy, lactic acidosis, and stroke-like episodes
- Multifocal bilateral T2 hyperintensities
- Predominantly GM involvement, may involve subcortical WM

https://CafePezeshki.IR

- Ischemia in > 1 vascular territory
- MRS shows lactate peak

Mesial Temporal Sclerosis

- Abnormal T2 hyperintensity in mesial temporal lobe
- Hippocampal volume loss and architectural distortion

Vasculitis

- Multiple small areas of T2 hyperintensity in deep and subcortical WM, often bilateral, ± enhancement
- GM involvement may be seen

Demyelination

- Multifocal WM lesions, deep gray nuclei
- Incomplete rim or horseshoe-shaped enhancement
- Lesions often in typical locations

PATHOLOGY

General Features

- Etiology
  - SE evolves through initiation phase to maintenance phase
    - Initiation phase: Triggering stimuli evoke discrete seizures, tend to abate as soon as stimulus is removed
    - Maintenance phase: Discrete seizures coalesce, triggering stimuli no longer required to sustain seizures
    - Intensity and duration of stimulation has direct influence on transition from initiation to maintenance phase
    - Signaling molecules: GABA-A (γ-aminobutyric acid) antagonists, glutamate agonists, cholinergic agonists found to be involved in initiation phase
    - Molecules that block maintenance phase: NMDA (N-methyl-D aspartate) antagonists, substance P antagonist
  - MR signal abnormalities related to transient vasogenic &/or cytotoxic edema
    - Redistribution of intracellular and extracellular water, related to alteration in cell membrane permeability or cytotoxic edema
  - Hippocampus involvement by SE may result in mesial temporal sclerosis
  - Involvement of corpus callosum splenium, 2 theories
    - Transient focal edema related to transhemispheric connection of seizure activity
    - Reversible demyelination related to antiepileptic drugs
- Anatomic considerations
  - Portions of brain most vulnerable to damage from SE
    - CA1, CA3 of hippocampus, amygdala, piriform cortex, cerebellar cortex, thalamus, cerebral cortex

Staging, Grading, & Classification

- SE classified broadly as convulsive and nonconvulsive
  - Convulsive SE further classified
    - Tonic–clonic
    - Tonic
    - Clonic
    - Myoclonic
  - Nonconvulsive SE

Gross Pathologic & Surgical Features

- Acutely
  - Swelling of cortex &/or subcortical WM or hippocampus
- Chronic
  - Atrophy of involved cortex &/or subcortical WM

Microscopic Features

- Acutely
  - Reactive astrocytes with swollen cytoplasm and neuropil, consistent with cytotoxic edema
- Chronic
  - Marked neuronal loss with intense astrocytic reaction; reactive astrocytes replacing absent neurons
- Gliosis and neuronal loss affecting GM-WM matter junction with extension to cortex

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Active seizures &/or status epilepticus
  - Other signs/symptoms: Location dependent
  - Nonconvulsive SE: Abnormal mental status, unresponsiveness, ocular motor abnormalities
- Clinical profile
  - EEG shows seizure activity

Demographics

- Age
  - Occurs at all ages, commonly young adults
- Gender
  - No gender predominance

Natural History & Prognosis

- Typically complete resolution with treatment of seizures
- May be complicated by infarction related to hypoxemia

Treatment

- Treatment of underlying seizure disorder
  - Antiepileptic medicines primary therapy
- Surgical resection in patients with intractable epilepsy

DIAGNOSTIC CHECKLIST

Consider

- Acute seizures or SE may mimic other pathology, such as tumor progression or cerebritis
- Clinical information and follow-up imaging often differentiates seizure-related MR changes from other etiologies

Image Interpretation Pearls

- Look for underlying mass that may have caused seizures/SE
- Seizure-related changes will usually resolve within days to weeks on follow-up imaging

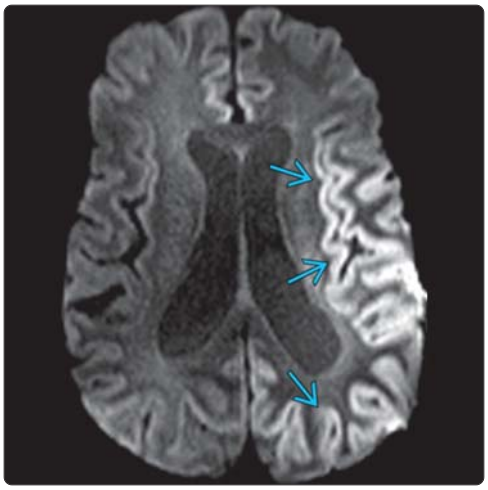
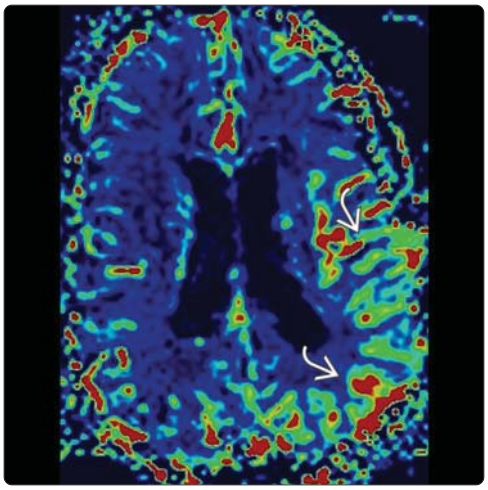
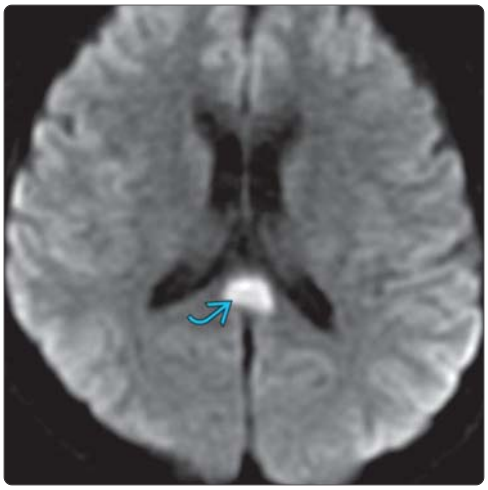
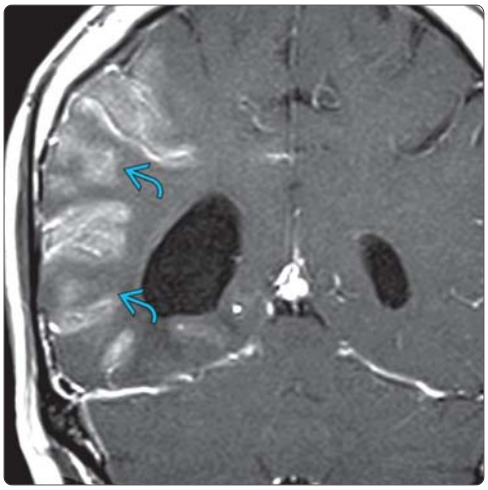
https://CafePezeshki.IR



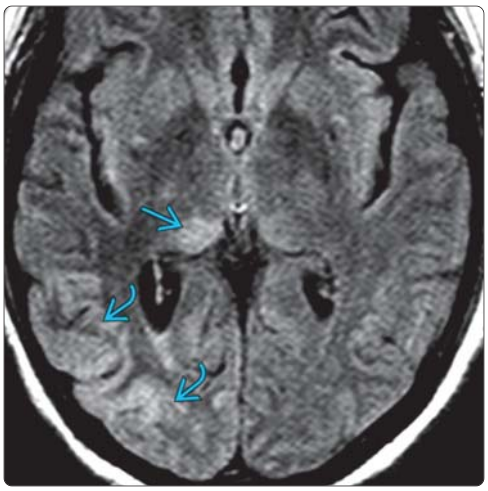


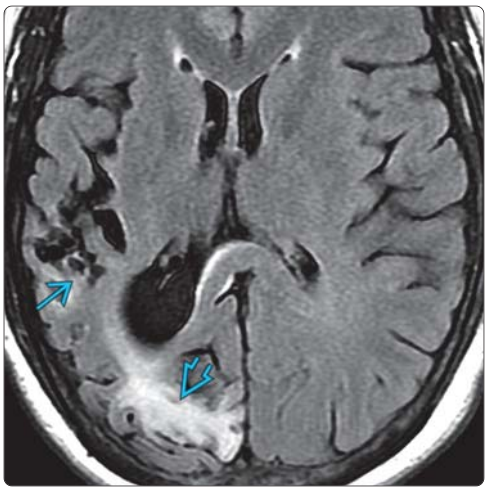
(Left) *Axial DWI MR shows cortical restricted diffusion in a patient with status epilepticus. Transient diffusion changes related to seizures can involve the cortex/subcortical white matter, corpus callosum, hippocampus, and pulvinar nucleus of thalamus.* **(Right)** *Axial rCBV map in the same patient shows increased CBV in the same region as the diffusion abnormality. Cerebral hyperperfusion may occur after seizures, particularly with status epilepticus.*





(Left) *Axial DWI MR shows restricted diffusion in the splenium of the corpus callosum. Follow-up MR showed complete resolution. A transient splenial lesion can be seen with seizures, antiepileptic medications, PRES, viral infections, and hypoglycemia.* **(Right)** *Coronal T1 C+ MR shows gyriform and meningeal enhancement related to status epilepticus. After treatment, the MR changes completely resolved. This enhancement pattern is often seen in subacute stroke and encephalitis.*





(Left) *Axial FLAIR MR in a patient with status epilepticus shows right temporal and parietal cortex/subcortical hyperintensity. Note high signal in the pulvinar nucleus of right thalamus.* **(Right)** *Axial FLAIR MR in the same patient after 1 year shows cystic encephalomalacia, gliosis, and volume loss in the same regions. Although in most cases imaging findings of status epilepticus are reversible, persistent imaging abnormalities such as focal atrophy due to permanent neuronal damage can occur as in this case.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Sudden memory loss without other signs of cognitive or neurologic impairment that recovers completely within 24 hours

IMAGING

- NECT, CECT almost invariably normal
- MR
  - T2/FLAIR usually normal
  - DWI: Focal dot-like area of diffusion restriction in hippocampus
    - Single (55%)
    - Multiple (45%)
    - Unilateral (50-55%)
    - Bilateral (45-50%)
  - DWI abnormalities increase with time
    - From 35% at 0-6 hours to 65-70% by 12-24 hours
    - Complete resolution by day 10
- PWI, PET/CT may show hippocampal hypoperfusion/hypometabolism

TOP DIFFERENTIAL DIAGNOSES

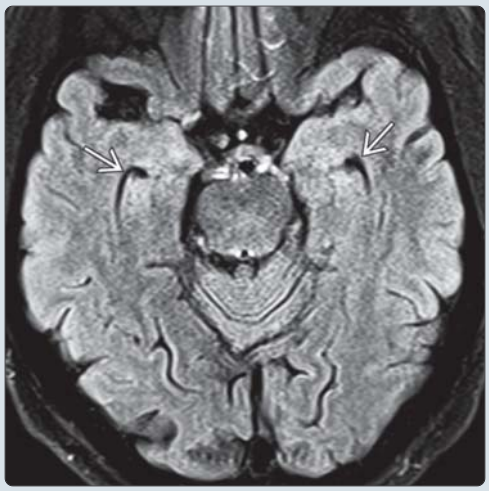
- Cerebral ischemia-infarction
- Seizure/postictal state
- Hypoglycemia

PATHOLOGY

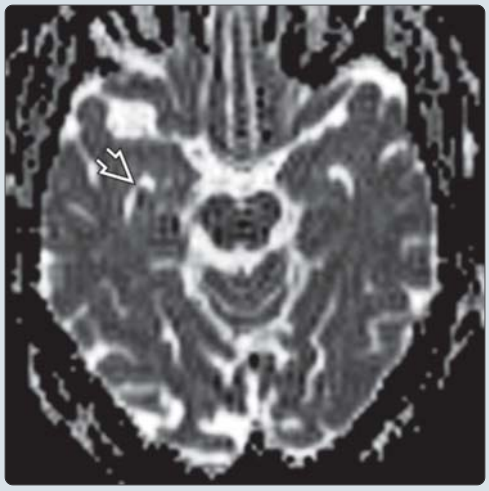
- Underlying pathophysiology still unknown
- Functional, reversible modification of hippocampus

CLINICAL ISSUES

- Most common in middle aged, elderly (rare < 40 years)
- Abrupt onset of massive episodic memory impairment
  - Both anterograde and retrograde
  - Often accompanied by repetitive questioning
  - Other neurologic functions intact
- Self-limited (spontaneous resolution within 24 hours)



(Left) *Axial T2WI in a 54-year-old male with sudden onset of amnesia is normal.* **(Right)** *Axial FLAIR MR shows no abnormalities. Both temporal horns ⇨ are well visualized and are normal. The hippocampi, just medial to the CSF-filled temporal horns, also appear completely normal.*



(Left) *Axial DTI trace image in the same patient shows a dot-like focus of restricted diffusion in the right hippocampus ⇨, just inside the temporal horn of the lateral ventricle.* **(Right)** *The hyperintense focus seen on the DTI trace image is dark on ADC (hypointense to the adjacent parenchyma) ⇨, confirming the reduced diffusivity. The patient's memory recovered within a few days. This is a classic case of transient global amnesia with the classic findings on DWI.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Transient global amnesia (TGA)

Definitions

- Sudden memory loss without other signs of cognitive or neurologic impairment that recovers completely within 24 hours
  - Both antero- and retrograde amnesia

IMAGING

General Features

- Best diagnostic clue
  - Focal dot-like area of diffusion restriction in hippocampus
- Location
  - Hippocampus
    - Body most common site, followed by head
  - Number
    - Single (55%)
    - Multiple (45%)
    - Unilateral (50-55%)
    - Bilateral (45-50%)
- Size
  - Between 1-2 mm
- Morphology
  - Rounded dot-like foci

CT Findings

- NECT, CECT almost invariably normal

MR Findings

- T1WI
  - Normal
- T2WI
  - T2/FLAIR usually normal
  - Small hyperintense foci occasionally identified but are typically reversible
- DWI
  - Tiny "dot" of restricted diffusion in hippocampus (just inside temporal horn) in 80%
    - Abnormalities increase with time
      - 0-6 hours: 35%
      - 6-12 hours: 60%
      - 12-14 hours: 65-70%
      - 3 days: 75%
      - 10 days: Complete resolution
- DSC perfusion-weighted imaging (PWI)
  - Negative to visual inspection
  - Hypoperfusion
    - Lower rCBF, rCBV in both hippocampus, thalamus compared to normal
    - Inconsistently present, reversible

Nuclear Medicine Findings

- May show hippocampal hypoperfusion, hypometabolism on PET/CT

Imaging Recommendations

- Best imaging tool
  - MR with DWI

DIFFERENTIAL DIAGNOSIS

Cerebral Ischemia-Infarction

- TIA or stroke
- Not in clear arterial territory

Seizure/Postictal State

- Shorter in duration than TGA
- Recur more frequently
- No epileptiform abnormalities during/after TGA

Hypoglycemia

- Cortex, usually parietooccipital

PATHOLOGY

General Features

- Etiology
  - Underlying pathophysiology still unknown
    - Possible etiologies
      - Spreading depression in hippocampus (similar to cortical spreading depression in migraine with aura)
      - Ischemic stroke
      - Venous congestion/hypertension
    - Functional, reversible modification of hippocampus
      - Specifically the CA1 area
      - Vascular vs. neurochemical

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Abrupt onset of massive episodic memory impairment
    - Both anterograde and retrograde
    - Often accompanied by repetitive questioning
  - Other neurologic functions intact

Demographics

- Age
  - Middle aged, elderly
    - Rare < 40 years
- Epidemiology
  - 23.5/100,000 per year in population > 50 years

Natural History & Prognosis

- Self-limited, with spontaneous resolution within 24 hours of onset
  - Rarely recur (5-10%/year)

SELECTED REFERENCES

KEY FACTS

TERMINOLOGY

- ↓ overall brain volume with advancing age
  - Reflected in relative ↑ CSF spaces

IMAGING

- Broad spectrum of "normal" on imaging in elderly
- "Successfully aging brain"
  - Smooth, thin, periventricular, high signal rim on FLAIR is normal
  - White matter hyperintensities (WMHs) absent/few
- Decreased total brain volume
  - Selective atrophy of white matter (not gray matter) predominates
- WMHs ↑ in number/size after 50 years
  - Approximately universal after 65 years
- GRE/SWI
  - Increasing mineralization of basal ganglia with age
  - Microbleeds are not characteristic of successful aging brain
- Age-related shift from anterior to posterior cortical metabolism

TOP DIFFERENTIAL DIAGNOSES

- Mild cognitive impairment
- Alzheimer disease
- Sporadic subcortical arteriosclerotic encephalopathy
- Vascular dementia
- Frontotemporal lobar degeneration (Pick disease)

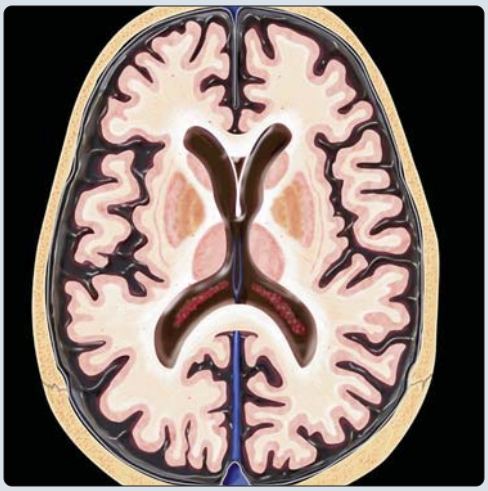
CLINICAL ISSUES

- WMHs correlate with age, silent stroke, hypertension, female sex

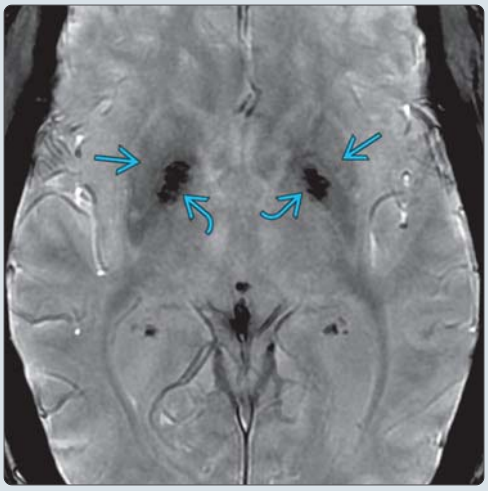
DIAGNOSTIC CHECKLIST

- Cannot predict cognitive function from CT/MR
  - Imaging only roughly correlates with cognitive function
  - Significant overlap with dementias

(Left) *Axial graphic depicts a normally aging brain in an 80-year-old patient. Note the widening of sulci and ventricles in the absence of any brain parenchymal abnormalities.* **(Right)** *Axial NECT demonstrates mild sulcal enlargement and mild ventriculomegaly in a 70-year-old patient. The white matter appears completely normal, without periventricular hypodensities or white matter lacunar infarcts.*



(Left) *Axial SWI in a 67-year-old woman shows striking hypointensity in the globi pallidi ⇨ with less prominent hypointensity in the putamina ⇨ due to iron deposition.* **(Right)** *Axial FLAIR MR in a 79-year-old man shows enlargement of ventricles and sulci due to age-related volume loss. Smooth, thin, periventricular hyperintense rim ⇨ and subtle hyperintensity in the splenium ⇨ of corpus callosum is common and normal.*



https://CafePezeshki.IR

TERMINOLOGY

Definitions

- ↓ overall brain volume with advancing age
  - Reflected in relative ↑ CSF spaces

IMAGING

General Features

- Best diagnostic clue
  - "Successfully aging brain"
    - Thin, periventricular, high signal rim
    - Absent/few white matter hyperintensities (WMHs)
    - Mild shrinkage of selected cerebellar regions
- Location
  - Selective atrophy of white matter (WM) predominates, not gray matter (GM)
  - Striatum (primarily caudate nucleus, putamen)
- Size
  - Decreased total brain volume
  - Absolute striatal size
    - Caudate decreases linearly with age
    - Putamen remains relatively stable
- Morphology
  - Brain tissue ↓, CSF volume ↑
    - Reflects overall WM volume loss > focal WMHs
    - Rounded appearance of dilated ventricles, sulci ↑

CT Findings

- NECT
  - Enlarged ventricles, widened cortical sulci
  - Patchy periventricular low densities
  - ± symmetrical, punctate calcifications in globi pallidi (GP)
  - ± curvilinear vascular Ca++

MR Findings

- T1WI
  - Mild but symmetric ventricular enlargement, proportionate prominence of subarachnoid spaces
  - Mild but significant age-related shrinkage of
    - Posterior vermis (lobules 6, 7, and 8-10)
    - Cerebellar hemispheres
  - Dilated perivascular Virchow-Robin spaces
    - Isointense to CSF on all sequences
    - Conform to course of penetrating arteries
    - Round/oval/curvilinear
    - Smooth, well-defined margins
    - Bilateral, often symmetrical; usually no mass effect
    - Increase in number, size (> 2 mm) with age
    - Can be found in most all areas
      - Tend to cluster around anterior commissure
      - Inferior 1/3 of putamen, external capsule
- T2WI
  - Focal/confluent periventricular WMHs
    - Number/size ↑ after 50 years; ~ universal after 65 years
    - Only rough correlation with cognitive function
    - Significant overlap with dementias
  - Infarct-like T2-hyperintense lesions
    - Seen in 1/3 of asymptomatic patients > 65 years
    - Mostly in basal ganglia (BG), thalami
    - Probably represent clinically silent lacunar infarcts
  - T2 shortening
    - "Black line" in visual, motor/sensory cortex
      - Common, normal in older patients
    - Ferric iron deposition
      - Normal in GP, abnormal in thalamus
    - With aging, hypointensity in caudate/putamen ↑
      - Putamen hypointensity may equal GP in 8th decade
- FLAIR
  - Smooth, thin, periventricular hyperintense rim normal
  - BG and thalamic foci
    - Perivascular spaces suppress
    - Lacunar infarcts hyperintense
- T2* GRE
  - SWI: Increasing mineralization of BG with age
    - Can see linear "waves" or conglomerate mineralization in GP
    - Putaminal hypointensity less prominent until 8th decade
  - Microbleeds are common in aging brain
    - SWI demonstrates microbleeds in 20% of patients > 60 of age years and in 1/3 of patients > 80 years old
    - Microbleeds are not characteristic of successful aging brain
    - Basal ganglia, brainstem and cerebellar microbleeds indicative of chronic hypertensive encephalopathy
    - Lobar and cortical microbleeds typical of amyloid angiopathy
- DWI
  - Small but significant increased water diffusibility
    - ADC increases
  - DTI: Loss of fractional anisotropy in "normal-appearing" WM
- T1WI C+
  - Age-related WMHs do not enhance
  - If enhancing, consider acute lacunar infarct or metastases
- MRS
  - Metabolite distribution varies among different brain regions
    - Choline (Cho) content ↑ with aging
    - Creatine (Cr) ↑ with aging
    - N-acetyl aspartate (NAA) ↓ in cortex, centrum semiovale, temporal lobes

Nuclear Medicine Findings

- PET
  - Metabolic alterations common
    - Global, regional changes in CBF
  - Gradual ↓ in regional cerebral blood flow (CBF) of GM, WM
    - Particularly in frontal lobes
  - Age-related shift from anterior to posterior cortical metabolism
  - Relative glucose metabolic rate (rGMR) measured by FDG PET
    - With age, rGMR ↑ in putamen and ↓ in caudate
  - ↓ pre-/postsynaptic dopamine markers in BG
- Tc-99m HMPAO SPECT, Xe-133 inhalation show regional, global reduction in CBF

https://CafePezeshki.IR

Imaging Recommendations

- Best imaging tool
  - MR with FLAIR, DWI, T2* GRE/SWI

DIFFERENTIAL DIAGNOSIS

Mild Cognitive Impairment

- Overlap with normal on standard imaging studies
- ↓ NAA

Alzheimer Disease

- Parietal and temporal cortical atrophy
- Striking volume loss in hippocampi, entorhinal cortex
- ↓ NAA, ↑ myoinositol (mI)

Sporadic Subcortical Arteriosclerotic Encephalopathy

- Numerous WMHs (overlap with normal)
- Multiple lacunar infarcts

Vascular Dementia

- Hyperintense lesions on T2WI and focal atrophy suggestive of chronic infarcts

Frontotemporal Lobar Degeneration

- Asymmetric frontal, anterior temporal atrophy

PATHOLOGY

General Features

- Etiology
  - Previous conception of aging: Substantial cortical neuronal loss with age
  - New: Predominant neuroanatomic changes
    - WM alterations, subcortical neuronal loss
    - Reduction in cell size > cell number
  - Neuronal dysfunction rather than loss of neurons/synapses
    - ↓ neuronal viability or function associated with accelerated membrane degradation &/or ↑ glial cell numbers
    - Loss of synapses and dendritic pruning in selected areas rather than globally
  - Some investigators consider accumulation of neurofibrillary tangles (NFTs) may be responsible for memory loss associated with aging
- Genetics
  - Clearly affect aging of brain
  - Apolipoprotein E (ApoE) and 6 novel risk-associated single nucleotide polymorphisms (SNPs) on chromosome 17q25 associated with brain pathology in aging

Gross Pathologic & Surgical Features

- Widened sulci, proportionate large ventricles
- Minor thinning of cortical mantle, predominant changes in subcortical WM

Microscopic Features

- Degeneration of neurons and oligodendrocytes
- Decreased myelinated fibers in subcortical WM
- Increased extracellular space, gliosis
- Iron deposition in globus pallidus, putamen
- WM capillaries lose pericytes, have thinner endothelium
- Dilated perivascular spaces of Virchow-Robin
  - Extension of subarachnoid space that accompanies penetrating vessels into brain to level of capillaries
- Senile plaques
  - Extracellular amyloid deposits in cerebral gray matter
- Lewy bodies
  - Intraneuronal clumps of α-synuclein and ubiquitin proteins
  - Found in 5-10% of cognitively intact individuals
- Neurofibrillary tangles (NFTs)
  - Tau phosphorylation, mitochondrial dysfunction may precede full NFT formation
  - NFTs appear in small numbers in entorhinal and transentorhinal cortices early in aging (patients ~ 60 years old)
  - NFTs may induce neural dysfunction, destruction of synapses, and, eventually, neuronal death

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Normal cognitive function
  - Mild cognitive impairment correlates with ↑ risk of Alzheimer disease

Demographics

- Age
  - > 60 years old
- Gender
  - Differences in striatal size
    - Relatively constant across lifespan in men
    - Variable across lifespan in women: Smaller in women aged 50-70 years than in men
- Epidemiology
  - WMHs correlate with age, silent stroke, hypertension, female sex

Natural History & Prognosis

- Parenchymal volume ↓, CSF spaces ↑ progressively
- WMHs progressively ↑ with age

DIAGNOSTIC CHECKLIST

Consider

- Striatum may mediate age-associated cognitive decline
  - ↓ volume, functional activity with age

Image Interpretation Pearls

- Broad spectrum of "normal" on imaging in elderly
- Cannot predict cognitive function from CT/MR

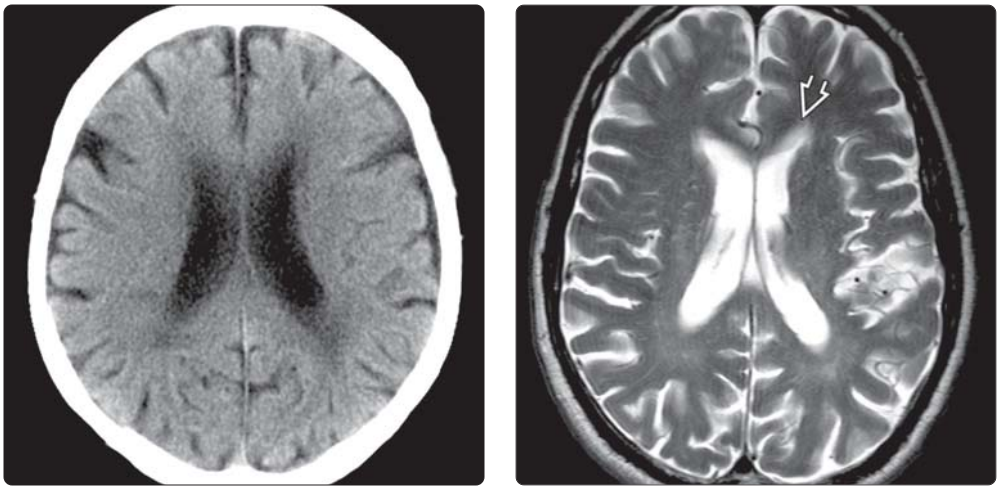
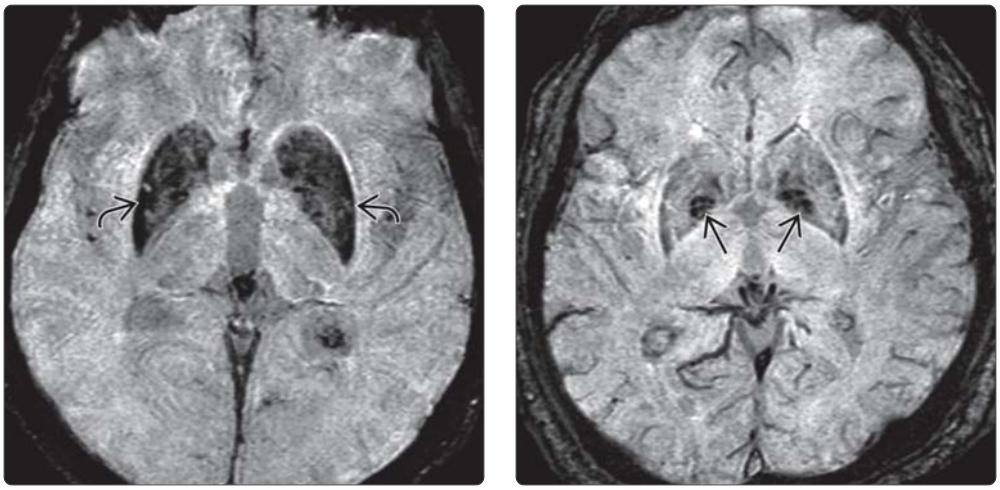
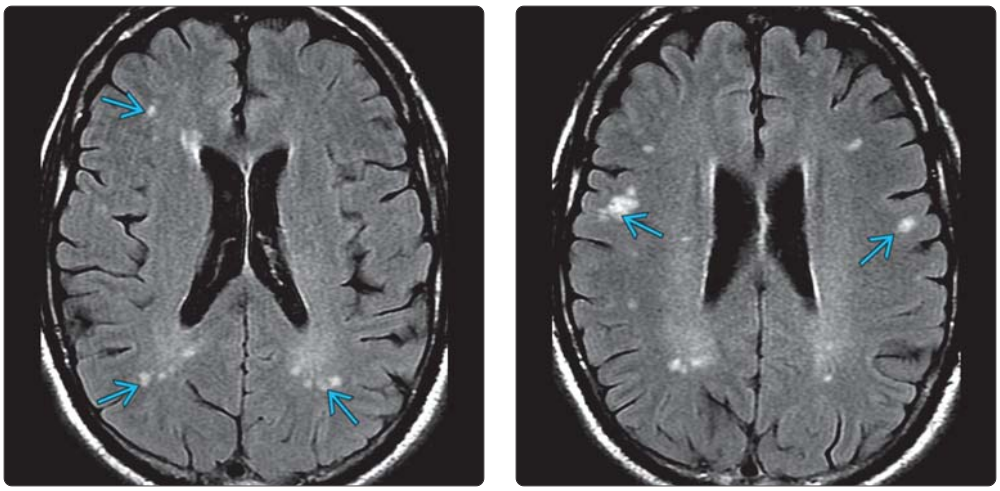
https://CafePezeshki.IR



(Left) *Axial NECT in an 85-year-old patient without cognitive impairment shows wide sulci and lateral ventricles, as well as moderate periventricular hypodense white matter.* **(Right)** *Axial T2WI 3T MR in a 76-year-old patient shows mild periventricular hyperintensity ⇨, mild ventriculomegaly, and mild sulcal enlargement.*



(Left) *Axial T2* SWI MR demonstrates marked hypointensity in the basal ganglia ⇨ related to normal mineralization with age.* **(Right)** *Axial T2* SWI MR demonstrates horizontal linear "waves" of mineralization in the globus pallidi ⇨, a normal finding in the aging brain.*



(Left) *Axial FLAIR in a 72-year-old man shows scattered white matter hyperintensities ⇨. Aging brains may demonstrate a few scattered nonconfluent white matter hyperintensities. Increased prevalence of white matter hyperintensities with cardiovascular risk factors such as diabetes and hyperlipidemia is shown.* **(Right)** *Axial FLAIR in the same patient shows additional subcortical white matter hyperintensities ⇨.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Alzheimer disease (AD)
  - Slowly progressive neurodegenerative disease

IMAGING

- Current role of imaging in AD
  - Exclude other causes of dementia
  - Identify region-specific patterns of brain volume loss
  - Identify imaging markers of coexistent disease such as amyloid angiopathy
  - Identify early AD for possible innovative therapy
- Best imaging = volumetric MR, FDG-18 PET
- Thinned gyri, widened sulci, and enlarged ventricles
- Medial temporal lobe particularly hippocampus and entorhinal cortex disproportionately affected
- FDG-18 PET
  - Early stage AD: ↓ metabolism in parietotemporal association cortices, posterior cingulate, and precuneus regions
  - Moderate to severe AD: Additional frontal lobe involvement
- Amyloid PET imaging: High sensitivity in detecting amyloid plaques and vascular amyloid in vivo

TOP DIFFERENTIAL DIAGNOSES

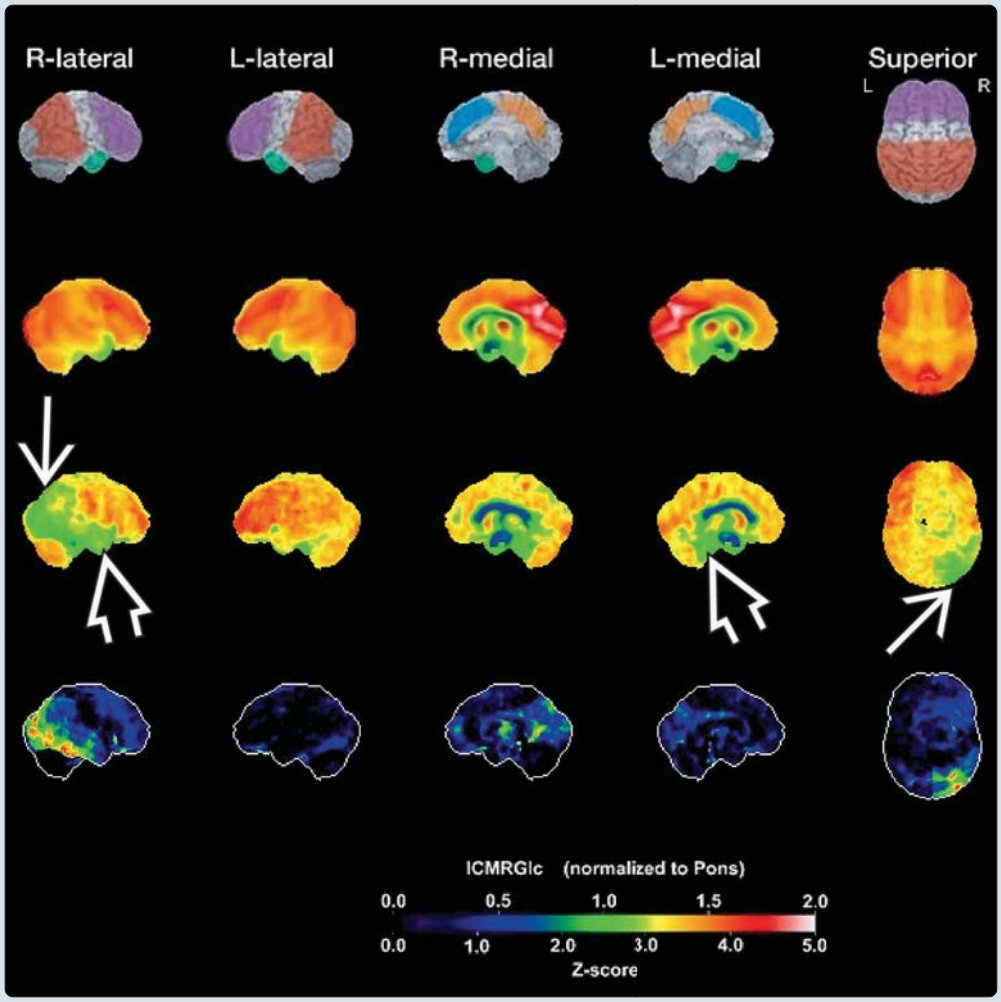
- Frontotemporal lobar degeneration
- Dementia with Lewy bodies
- Normal pressure hydrocephalus
- Vascular dementia
- Normal aging

CLINICAL ISSUES

- Most common cause of dementia over age 65
- Age is biggest risk factor
  - 1-2% prevalence at age 65
  - Incidence doubles every 5 years after age of 60

DIAGNOSTIC CHECKLIST

- Look for reversible causes of dementia



Sagittal FDG-18 PET with stereotaxic surface projections in a 70-year-old woman with possible Alzheimer disease (AD) is shown. Standard MR (not shown) disclosed no definite abnormalities. The top row shows a reference map. The 2nd row shows glucose metabolism in the normal elderly control group (n = 27). The 3rd row shows the patient's glucose metabolism map. Note the decrease in medial temporal ➡ and parietal lobes ➡ with sparing of the frontal, occipital lobes. The bottom row shows a Z-score map. (Courtesy N. Foster, MD.)

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Alzheimer disease (AD)

Synonyms

- Senile/presenile dementia of Alzheimer type

Definitions

- AD is progressive neurodegenerative condition characterized by progressive cognitive decline, memory impairment, and adverse impact on activities of daily living
- National Institute on Aging and Alzheimer's Association workgroup recommendations 2011
  - Phases of AD pathophysiological processes
    - Preclinical AD
    - Mild cognitive impairment (MCI) in AD
    - AD dementia

IMAGING

General Features

- Best diagnostic clue
  - MR: Temporal/parietal cortical atrophy
    - Disproportionate hippocampal volume loss
  - FDG PET: Regional ↓ glucose metabolism
    - Temporoparietal lobes, posterior cingulum
- Current role of imaging in AD
  - Exclude other structural abnormalities
  - Evaluate degree and location of atrophic changes
  - Evaluate metabolic abnormalities
    - When structural abnormalities absent/uncharacteristic (i.e., early in disease course)
  - Identify preclinical and MCI in AD for possible innovative therapy

CT Findings

- NECT
  - Screening to exclude potentially reversible or treatable causes of dementia
  - Medial temporal lobe atrophy earliest finding on CT
  - Late finding: Generalized cortical atrophy

MR Findings

- Current role of MR
  - Exclude other causes of dementia
  - Identify region-specific patterns of brain volume loss
  - Identify imaging markers of coexistent disease such as amyloid angiopathy
- T1WI (assess structure, atrophy patterns)
  - High resolution (MP-RAGE or SPGR) for volumetric analysis
  - Thinned gyri, widened sulci, and enlarged ventricles
  - Medial temporal lobe particularly hippocampus and entorhinal cortex disproportionately affected
    - May help distinguish patients with MCI from normal elderly
    - Average hippocampal volume reduction 20-25% in AD and 10-15% in MCI
- T2* GRE for microhemorrhages, amyloid angiopathy
- MRS
  - ↓ NAA and ↑ mI in AD even in early stage
  - NAA:mI ratio relatively sensitive and highly specific in differentiating AD from normal elderly
  - NAA:Cr ratio in posterior cingulate gyrus & left occipital cortex predicts conversion of MCI to probable AD
- DTI: ↓ FA in multiple regions especially superior longitudinal fasciculus and splenium
- Perfusion MR: ↓ rCBV in temporal, parietal regions

Nuclear Medicine Findings

- FDG-18 PET
  - Early stage AD
    - ↓ metabolism in parietotemporal association cortices, posterior cingulate, and precuneus regions
    - Most reliable early changes in posterior cingulate
  - Moderate to severe AD
    - Additional frontal lobe involvement
  - MCI in AD
    - Same pattern of ↓ metabolism as AD
  - Higher accuracy than MR for diagnosing early AD and predicting rapid conversion of MCI to early AD
- Amyloid PET imaging
  - High sensitivity in detecting amyloid plaques and vascular amyloid in vivo
  - 11C-Pittsburg compound-B (PiB): High affinity to amyloid β peptide (Aβ) aggregates
  - 18F-labeled amyloid tracers like 18F-AV-45 (florbetapir) becoming more widely used
  - Criteria for appropriate use of amyloid PET
    - Persistent or progressive unexplained MCI
    - Possible AD with unclear presentation
    - Progressive dementia and atypically early age of onset

Imaging Recommendations

- Best imaging tool
  - Volumetric MR
  - 18F-FDG PET
- Protocol advice
  - MP-RAGE or SPGR for volumetric measurement

DIFFERENTIAL DIAGNOSIS

Causes of Reversible Dementia

- Alcohol abuse (thiamine deficiency)
- Endocrinopathies (e.g., hypothyroidism)
- Vitamin B12 deficiency
- Depression ("pseudodementia")
- Normal pressure hydrocephalus
- Mass lesions (chronic subdural hematoma, tumor, etc.)

Frontotemporal Lobar Degeneration

- Frontal &/or anterior temporal atrophy

Vascular Dementia

- 2nd most common dementia (15-30%)
- Parenchymal hyperintensities, focal atrophy (infarcts)

Dementia With Lewy Bodies

- Hypometabolism of entire brain

Corticobasal Degeneration

- Prominent extrapyramidal, cortical symptoms
- Asymmetric severe frontoparietal atrophy

https://CafePezeshki.IR

Creutzfeldt-Jakob Disease

- Dementia with myoclonus, EEG abnormalities
- Hyperintensity in anterior basal ganglia, cortex

Cerebral Amyloid Angiopathy

- Often coexists with AD
- Microhemorrhages on T2* GRE/SWI

PATHOLOGY

General Features

- Etiology
  - Extracellular β-amyloid plaques
    - Located in cerebral cortex
  - Intracellular accumulation of neurofibrillary tangles (NTs)
    - Initially around hippocampus, later spread to other cortical areas
- Genetics
  - Most cases late onset sporadic AD
    - Deterministic genetic mutation not found
    - Apolipoprotein E (*ApoE*) ε4 allele is major genetic risk factor
  - Rare early-onset AD
    - Mutations in 1 of 3 genes
      - Amyloid precursor protein gene on chromosome 21
      - Presenilin-1 (*PSEN1*) gene on chromosome 14
      - Presenilin-2 (*PSEN2*) gene on chromosome 1

Gross Pathologic & Surgical Features

- Shrunken gyri, widened sulci

Microscopic Features

- 2 abnormal protein aggregates characterize AD pathologically
- Neurofibrillary tangles
  - Intracellular aggregates in neurons due to hyperphosphorylation of tau protein
  - Begins in entorhinal cortex, progresses to hippocampus, paralimbic system, and adjacent medial-basal temporal lobe
- Aβ deposition
  - Hallmark of Aβ peptide deposit in AD is neuritic plaque
  - Dense Aβ core with inflammatory cells and dystrophic neurites in its periphery
- Neurodegeneration: Synapse loss, neuron loss

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Slowly progressive neurodegenerative disease
  - Initially affects episodic memory
    - Then at least 1 other area of cognition
- Clinical profile
  - Clinical subtypes
    - Mild cognitive impairment: Early, mild memory impairment; no deficits in cognitive domains other than memory, not impairing daily function
    - Possible AD: Dementia features in presence of 2nd disease that could cause memory deficit but is not likely cause
    - Probable AD: Memory deficits on neuropsychological testing, progressive worsening of memory and ≥ 2 cognitive functions
    - Definite AD: Pathologic diagnosis
  - 5 major biomarkers for AD
    - Amyloid accumulation: CSF Aβ 42, PET amyloid plaque imaging
    - Neurogeneration or neuronal injury: CSF tau (total and phosphorylated), structural MR, FDG PET

Demographics

- Age
  - Biggest risk factor
    - 1-2% prevalence at age 65
    - Incidence doubles every 5 years after age of 60
- Gender
  - Women more commonly affected
- Epidemiology
  - AD most common neurodegenerative dementia
  - Currently ~ 5.3 million in US
  - 1/8, or 13% of individuals, in US > 65 years and > 50 % of individuals older than 85

Natural History & Prognosis

- Chronic, progressive
- Patients live average 8-10 years after diagnosis

Treatment

- No established treatments to prevent or reverse AD
- May transiently improve cognitive function
  - Cholinesterase inhibitors, NMDA receptor antagonists
- Many current disease-modifying drugs focus on reducing Aβ

DIAGNOSTIC CHECKLIST

Consider

- Look for
  - Reversible causes of dementia
  - Ventricular enlargement, sulcal widening proportionate
  - ↑ temporal horns of lateral ventricle
  - Hippocampal, entorhinal cortex volume loss

Image Interpretation Pearls

- MR volumetric analysis helps distinguish MCI in AD from normal elderly subjects
  - Measure change hippocampus/parahippocampal gyri over time
- FDG-18 PET
  - Helps distinguish AD from frontotemporal dementia
  - May identify early AD when MR normal

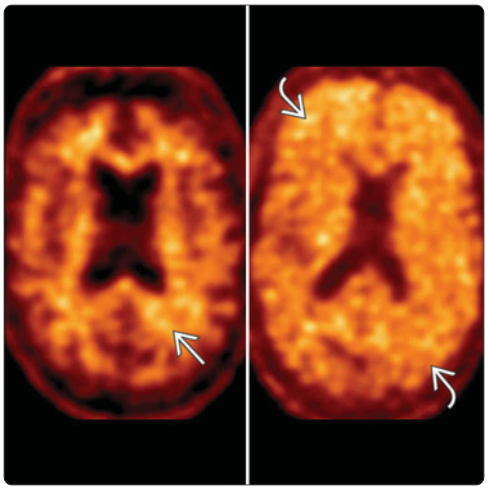
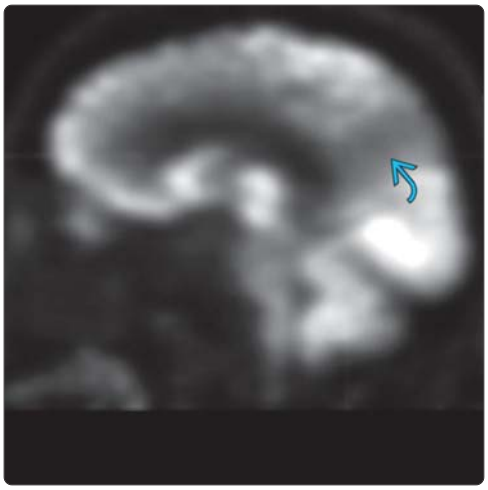
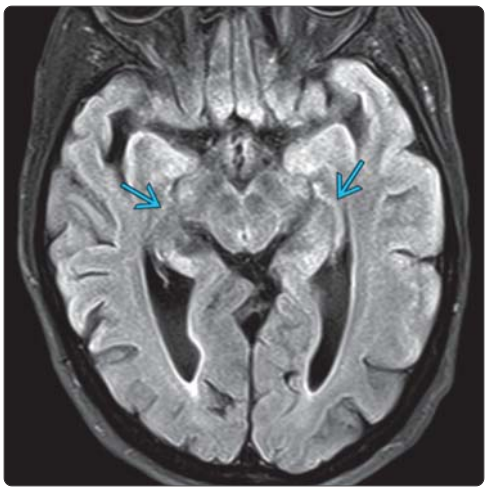
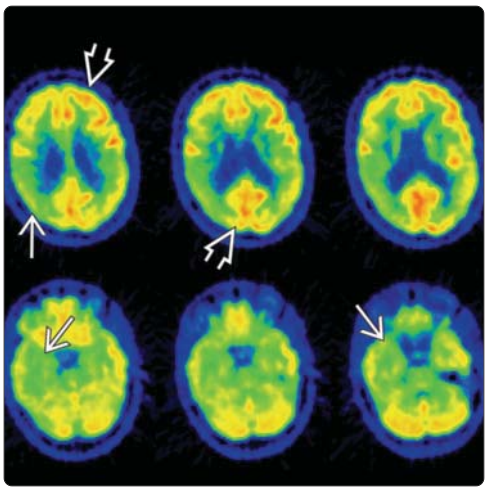
(Left) *Sagittal T1WI MR in a 72-year-old patient with suspected AD shows marked enlargement of the sylvian fissure compared to the other subarachnoid spaces. Cortical atrophy of structures around the sylvian fissures can be striking, as in this case.* **(Right)** *Axial T2 MR in a patient with AD demonstrates enlarged temporal horns disproportionate volume loss in the temporal lobes as compared to the normal appearing occipital lobes.*





(Left) *18F-AV-45 (florbetapir) PET in a healthy control (left) demonstrates nonspecific white matter uptake and preserved gray-white matter differentiation. In a patient with AD (right), there is marked cerebral gray matter uptake due to Aβ deposition that makes gray-white matter differentiation difficult. (Courtesy C. Singh, MD, A. Ali, MD.)* **(Right)** *Sagittal PET in early AD shows a classic pattern of hypometabolism in the posterior cingulate gyrus and precuneus. (Courtesy S. Nayak, MD.)*





(Left) *Axial FLAIR scan in a 54-year-old woman with possible AD. While the sylvian fissures are slightly enlarged and the lateral ventricles are prominent for the patient's age, the hippocampi appear normal with no evidence for parenchymal ischemic lesions.* **(Right)** *Selected axial images from a FDG-18 PET study in the same patient show a subtle decrease in glucose metabolism in the temporal and parietal lobes compared to the frontal and occipital lobes.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Vascular dementia (VaD), multi-infarct dementia (MID)
- Stepwise progressive ↓ in cognitive function
- Heterogeneous group of disorders with varying etiologies, pathologic subtypes
  - VaD often mixed etiology
  - Can occur alone or in association with AD
  - MID secondary to repeated cerebral infarctions

IMAGING

- General features
  - Multifocal infarcts (cortical GM, subcortical WM)
  - Basal ganglia (BG), pons
  - Territorial as well as lacunar lesions
  - Coexisting microvascular WM disease common
  - Multiple remote microhemorrhage
- CT
  - Multifocal infarcts
  - Single or multiple, lacunar to territorial
  - WM hypointensities (discrete to confluent)
- FDG PET
  - Multifocal regions ↓ metabolism in cortex, WM

TOP DIFFERENTIAL DIAGNOSES

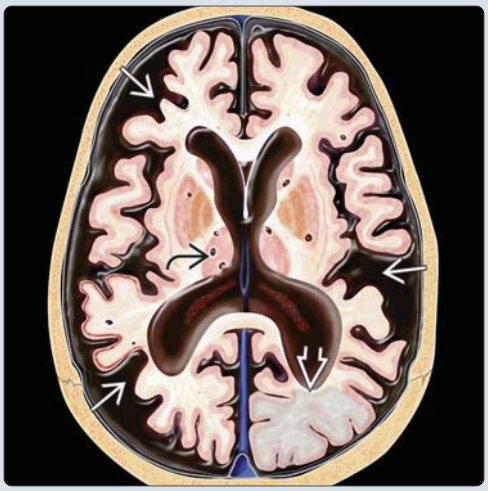
- Alzheimer disease (AD)
- Frontotemporal lobar degeneration
- CADASIL
- Dementia with Lewy bodies

CLINICAL ISSUES

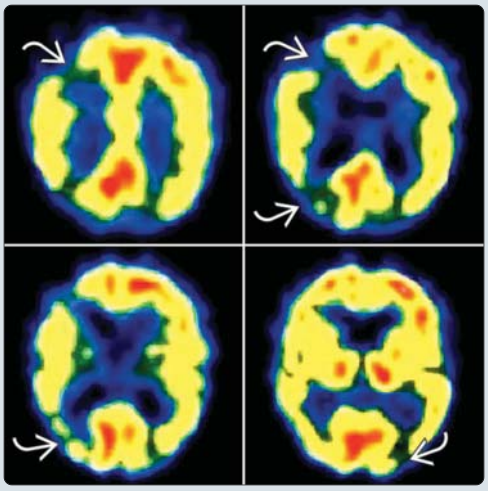
- 2nd most common dementia (after AD)
- Mood and behavioral changes more typical than memory loss

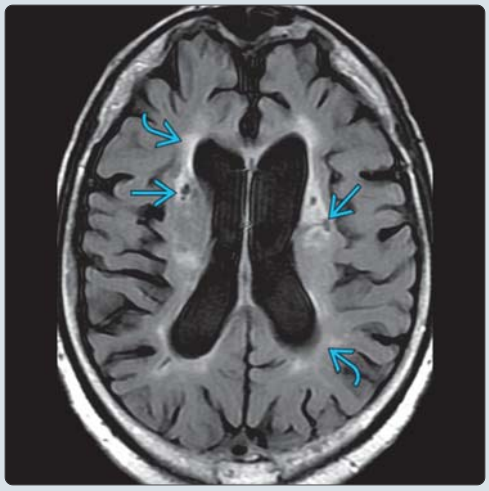
DIAGNOSTIC CHECKLIST

- Report strategically placed infarcts
- Look for hemorrhage, DWI abnormalities



(Left) *Axial diagram of vascular dementia shows diffuse cerebral atrophy, focal volume loss due to multiple chronic infarcts, an acute left occipital lobe infarct, and small lacunar infarcts in the basal ganglia/thalami.* **(Right)** *Axial NECT demonstrates periventricular white matter hypodensity, as well as bilateral MCA and right PCA infarcts, in a patient with vascular dementia. The clinical history plus findings of infarcts in multiple separate vascular distributions is consistent with vascular dementia (VaD).*





(Left) *Axial FDG PET in a patient with multi-infarct dementia demonstrates multiple wedge-shaped areas of hypometabolism due to chronic infarcts. (Courtesy A. Ali, MD.)* **(Right)** *Axial FLAIR MR in a 72-year-old man with chronic hypertension and diabetes presenting with mood and behavioral changes shows confluent white matter hyperintensities in the periventricular regions. Note the multiple chronic lacunar infarcts in the basal ganglia as well as enlargement of the ventricles and cortical sulci.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Vascular dementia (VaD)

Synonyms

- Multi-infarct dementia (MID)
- Vascular cognitive disorder (VCD)
- Vascular cognitive impairment (VCI)
- Subcortical ischemic vascular dementia
- Poststroke dementia

Definitions

- Stepwise progressive deterioration of cognitive function
  - VaD: Heterogeneous group of disorders with varying etiologies, pathologic subtypes
    - Often mixed etiology
  - Can occur alone or in association with Alzheimer disease (AD)
  - MID secondary to repeated cerebral infarctions

IMAGING

General Features

- Best diagnostic clue
  - Multifocal infarcts
    - Cortical gray matter (GM), subcortical white matter (WM)
    - Basal ganglia (BG), pons
    - Territorial as well as lacunar infarcts
    - Changes of microvascular WM ischemia common
- Location
  - Typically involve cerebral hemispheres and BG
  - Usually bilateral but may be unilateral
- Size
  - Vary from single to multiple, punctate to large/confluent
- Morphology
  - Small infarcts are rounded or oval; large confluent abnormalities are ill defined

CT Findings

- NECT
  - Hypodensity in periventricular WM
  - Cortical, subcortical, BG infarcts
  - Generalized atrophy with focal cortical infarcts typical

MR Findings

- T1WI
  - Generally have hypointense BG lacunar infarcts
  - Atrophy with enlargement of ventricles and sulci
- T2WI
  - Punctate or confluent regions of hyperintense WM
  - Central pontine infarcts
  - Large areas of volume loss with widened sulci
- FLAIR
  - Hyperintense foci within BG
  - Multifocal diffuse and confluent WM hyperintensities
- T2* GRE
  - Multiple "blooming" hypointensities in cortex and along pial surface
- DWI
  - ↓ FA and ↑ ADC within lesions, normal-appearing WM (NAWM) ↓
  - Increase in mean diffusivity of NAWM correlates with disability found on tests of executive function
- MRA
  - Most abnormalities in small arteries, generally not well seen on MRA
- MRS
  - ↓ NAA in both cortical and WM regions
  - Frontal cortex NAA negatively correlated with volume of WM signal hyperintensity

Ultrasonographic Findings

- Transcranial Doppler sonography: Pulsatility indices in large arteries are increased compared to AD

Nuclear Medicine Findings

- FDG PET
  - Multiple areas of hypometabolism without specific lobar predominance
  - Severity of MID neuropsychiatric symptoms correlates with extent of ↓ metabolism in cortex and WM
- SPECT
  - Iodine-123-iodoamphetamine: ↓ frontal and BG CBF, which correlates with low cognitive scores
  - Tc-99m hexamethyl propyleneamine oxime: CBF heterogeneity more prominent in anterior portion of brain
    - Unlike pattern in Alzheimer disease, in which posterior abnormalities predominate

Imaging Recommendations

- Best imaging tool
  - MR
  - PET/SPECT may also provide specificity
- Protocol advice
  - Axial FLAIR to detect white matter infarcts
  - Axial and coronal T2WI to assess regions of atrophy
  - T2* GRE/SWI to identify hemorrhage

DIFFERENTIAL DIAGNOSIS

Alzheimer Disease

- Striking hippocampus and amygdala atrophy
- PET: Bilateral temporoparietal hypoperfusion/hypometabolism (BG spared)
- Often coexists with VaD

Frontotemporal Lobar Degeneration

- Characterized by early onset of behavioral changes with intact visual, spatial skills
- Frontal, temporal lobe atrophy
- Marked atrophy → knife-like gyri

Alcoholic Encephalopathy

- 3rd most common cause of dementia
- Generalized > focal atrophy; superior vermis atrophy

CADASIL

- Most common heritable cause of stroke, VaD in adults
- Earlier age of onset
- Imaging looks like "small vessel" disease

https://CafePezeshki.IR

Dementia With Lewy Bodies

- Hypometabolism of entire brain
- Without infarcts or significant atrophy

PATHOLOGY

General Features

- Etiology
  - MID is usually due to multiple small infarctions
    - Infarcts involving entire major vessel territories are usually absent
    - Minority may be secondary to single or a few large infarctions
  - ~ 75% of all MID patients exhibit small vessel disease rather than thromboembolism
  - Growing evidence exists for involvement of cholinergic system in VaD
    - Cholinergic deficits well documented in VaD, independent of concomitant AD pathology
    - Cholinergic neuron loss in 70% of AD, 40% of VaD
- Genetics
  - Apolipoprotein E (*APOE*)
    - Serum protein involved in lipid metabolism
    - Encoded at single gene locus on chromosome 19 by 3 alleles: ε2, ε3, ε4
    - Frequency of ε4 allele significantly higher among patients with AD and VaD compared to controls
    - Odds of developing AD or VaD are 4.4x and 3.7x higher (respectively) in presence of even a single ε4 allele
  - Paraoxonase (*PON1*)
    - Component of high-density lipoproteins with antioxidative potential
    - 2 *PON1* polymorphisms (Gln192Arg associated with enzyme activity and T-107C associated with enzyme concentration) are independent risk factors for VaD, particularly in *APOE* (ε4)

Staging, Grading, & Classification

- 8 subtypes of VaD
  - Multi-infarct dementias: Due to large cerebral emboli, usually readily identifiable
  - Strategically placed infarctions causing dementia
  - Multiple subcortical lacunar lesions: Develop VaD 5-25x more frequently than age-matched controls
  - Binswanger disease: Small vessel disease → widespread incomplete infarction of WM
  - Mixtures of 2 or more VaD subtypes
  - Hemorrhagic lesions causing dementia
  - Subcortical dementias due to other causes (e.g., cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy [CADASIL])
  - Hybrid forms of Alzheimer dementia and VaD

Gross Pathologic & Surgical Features

- Multifocal infarctions with atrophy

Microscopic Features

- Arteriosclerosis and amyloid angiopathy major underlying pathologies in small vessel vascular disease
- Vessels display atheromata, lipohyalinosis, subintimal thickening, fibrinoid necrosis
- Infarcted tissue undergoes necrosis → gliotic wall surrounding CSF cavity
- Myelin and axonal loss with astrocytosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Infarcts with transient focal neurologic deficits
    - Most deficits persist
  - Mood and behavioral changes
  - Deterioration of executive function and attention, changes in personality (rather than memory loss) predominate
  - Severe depression is more common in VaD than AD
- Clinical profile
  - Main risk factors
    - Advanced age, hypertension, diabetes, smoking
    - Hypercholesterolemia, hypercoagulable states

Demographics

- Age
  - Generally earlier age than AD
  - Incidence ↑ with age
- Gender
  - M > F
- Epidemiology
  - 10 % of dementias
  - 2nd most common dementia (after AD)
  - ~ 25% of elderly stroke patients meet VaD criteria

Natural History & Prognosis

- Progressive, episodic, stepwise downward course
- Intervals of clinical stabilization ± limited recovery
- 5-year survival with VaD ~ 50% of age-matched controls

Treatment

- Prevent further vascular insult
  - Control precipitating factors (e.g., HTN, diabetes)

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Not a single entity, but a large group of conditions with variable clinical and imaging findings

Reporting Tips

- Report strategically placed infarcts, hemorrhagic components, DWI abnormalities, pattern of cortical volume loss if present

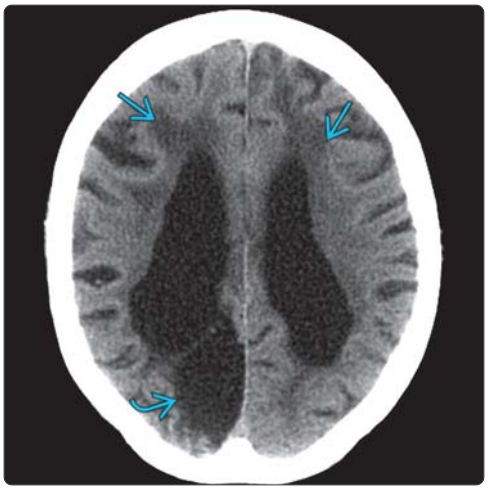
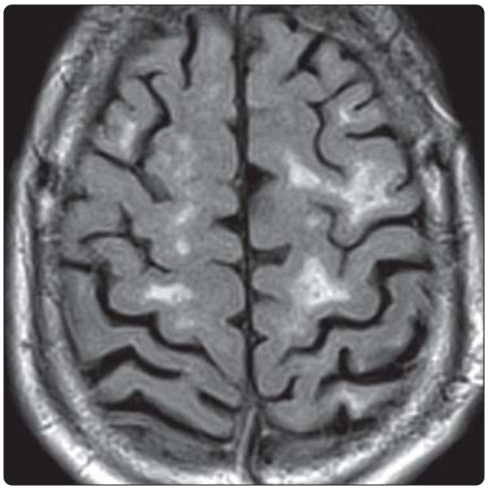
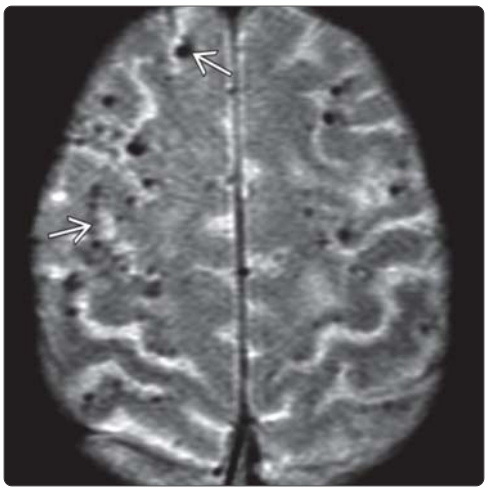
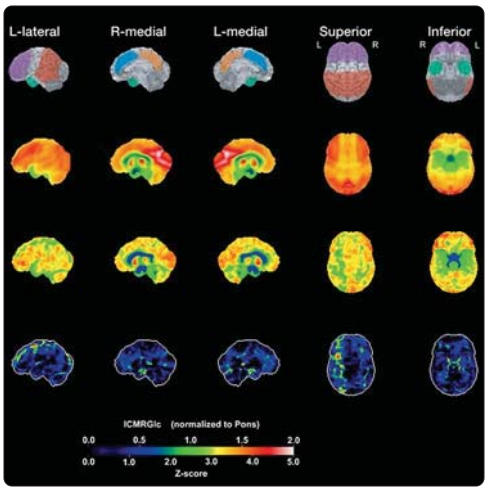
(Left) *Axial FLAIR MR in a patient with vascular dementia shows confluent periventricular white matter hyperintensities with volume loss.* **(Right)** *Axial SWI image in the same patient shows multiple "blooming" hypointense foci due to remote microhemorrhages in the basal ganglia, thalami, and cerebral cortex. This patient had long-standing uncontrolled hypertension and the distribution of the microhemorrhages predominantly in the deep gray nuclei supports that.*





(Left) *Axial NECT in a 81-year-old woman with MID shows cystic encephalomalacia in the right parietal lobe due to an old infarct. There is marked volume loss with ventricular enlargement. There are confluent white matter hypodensities consistent with arteriolosclerosis and lipohyalinosis.* **(Right)** *Axial FLAIR MR shows multiple subcortical hyperintensities in a 76-year-old normotensive man with clinical diagnosis of vascular dementia. No focal infarcts are seen.*





(Left) *Axial T2* GRE MR in the same patient shows multifocal cortical/subcortical blooming "black dots". The cerebellum and basal ganglia were spared, suggesting amyloid angiopathy as the most likely diagnosis.* **(Right)** *PET scan in the same patient shows multifocal areas of diminished glucose metabolism (3rd row) compared to normal age-matched controls (2nd row). Z-score maps (bottom row) confirm the multifocal, diffuse nature of this patient's vascular disease. (Courtesy N. Foster, MD.)*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Clinical subtypes
  - Behavioral-variant frontotemporal dementia (bvFTD)
  - Primary progressive aphasia syndromes (PPA)
    - Semantic variant (sv-PPA): Previously known as semantic dementia
    - Nonfluent/agrammatic variant (nfv-PPA): Previously known as progressive nonfluent aphasia
    - Logopenic variant (lv-PPA)
  - Frontotemporal dementia with motor symptoms

IMAGING

- Early
  - PET shows frontotemporal ↓ glucose metabolism
- Late: Frontotemporal atrophy with knife-like gyri on MR
- Subtypes have characteristic cortical atrophy patterns

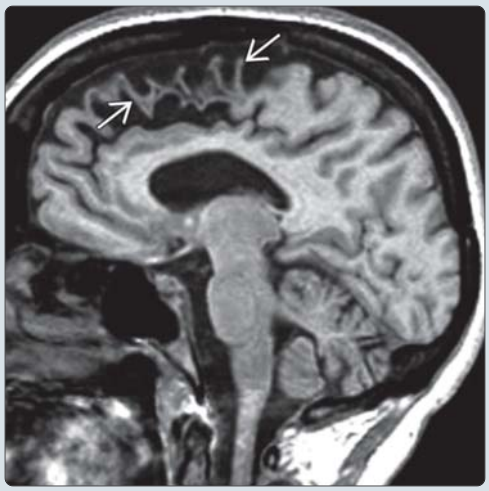
TOP DIFFERENTIAL DIAGNOSES

- Alzheimer dementia (AD)
- Vascular dementia
- Corticobasal ganglionic degeneration (CBD)
- Dementia with Lewy bodies (DLB)

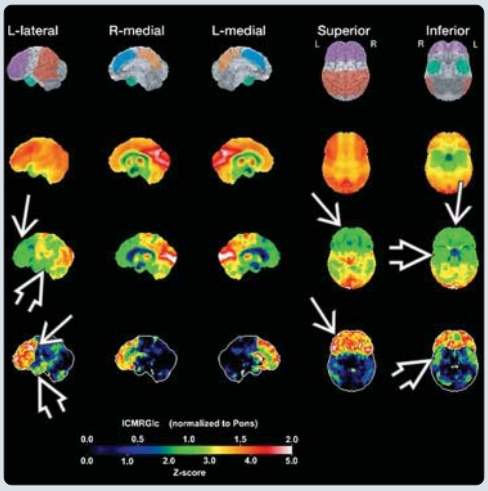
CLINICAL ISSUES

- Clinical syndromes (some overlap)
  - **bvFTD**: Marked changes in personality & behavior, mixture of apathy & disinhibition
  - **sv-PPA**: Progressive loss of "semantic" knowledge about words, objects & concepts, fluent speech
  - **nfv-PPA**: Effortful speech production & orofacial apraxia
  - **lv-PPA**: Word finding pauses & poor sentence repetition
- Younger age group than Alzheimer disease
- FTLD most common cause of early-onset age (< 65 years) dementia
- Median survival: 6-11 years from symptom onset & 3-4 years from diagnosis

(Left) *Graphic depicts the classic disproportionate frontal lobe atrophy of late-stage frontotemporal dementia (FTD). The sulci are widened and gyri are knife-like ⇨. Parietal occipital lobes are spared. Gyri around the central sulcus are normal.* **(Right)** *Parasagittal image (3D-MPRAGE) was obtained as part of the initial evaluation in a patient with suspected FTD. Note the frontal lobe knife-like gyri ⇨ with markedly widened sulci and preservation of the parietal and occipital lobes.*



(Left) *Sagittal SSP FDG PET scan in a 72-year-old man with FTD shows a normal elderly control map (2nd row), the patient's glucose metabolism (3rd row), and Z-score statistical map (bottom row). The frontal lobes ⇨ are strikingly hypometabolic. The temporal lobes ⇨ are somewhat less severely affected.* **(Right)** *Axial T2WI MR in a patient with semantic dementia subtype of FTLD shows marked atrophy of anterolateral temporal lobes ⇨. Note the relative preservation of the hippocampi ⇨.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Frontotemporal lobar degeneration (FTLD)
- Clinical subtypes
  - Behavioral-variant frontotemporal dementia (bvFTD)
  - Primary progressive aphasia syndromes (PPA)
    - Semantic variant (sv-PPA): Previously known as semantic dementia
    - Nonfluent/agrammatic variant (nfv-PPA): Previously known as progressive nonfluent aphasia
    - Logopenic variant (lv-PPA)
- Frontotemporal dementia with motor symptoms
  - Corticobasal degeneration (CBD)
  - Progressive supranuclear palsy (PSP)
  - FTD with motor neuron disease
  - FTD with amyotrophic lateral sclerosis (ALS)

Synonyms

- Pick disease no longer used
  - Referred to pathologic variant with Pick bodies

Definitions

- Heterogenous family of neurodegenerative disorders characterized by focal lobar degeneration of frontal &/or temporal lobes

IMAGING

General Features

- Best diagnostic clue
  - PET scan showing frontotemporal ↓ glucose metabolism
  - Anterior frontotemporal atrophy with knife-like gyri
- Location
  - Anterior temporal/frontal lobes, orbital frontal lobe, medial temporal lobes
  - Relative sparing of
    - Parietal, occipital lobes
- Morphology
  - Knife blade appearance of atrophic gyri
  - ± marked asymmetry
    - May have worst atrophy in dominant hemisphere

CT Findings

- NECT
  - Frontal lobe atrophy often most prominent feature
    - Increased size of frontal horns (larger than rest of lateral ventricles)

MR Findings

- T1WI
  - Atrophy of frontal & temporal lobes, often asymmetric
  - Knife-like gyri with normal signal
  - Dilated frontal sulci reflecting atrophy
  - Relative sparing of parietal & occipital lobes
- T2WI
  - ± hyperintensity in frontotemporal WM
- MRS
  - ↓ NAA and glutamate-plus-glutamine (neuronal loss), ↑ myoinositol (↑ glial content) in frontal lobes
    - Reflects ↓ neuronal population, viability
  - ± lactate peak in frontal lobes
- MR voxel based morphometry
  - Subtypes have characteristic cortical atrophy patterns
  - Frontal vs. temporal, L vs. R help discriminate
  - **bvFTD**: Atrophy of frontal & temporal lobes
    - Asymmetric right frontal &/or right temporal atrophy may occur
  - **sv-PPA**: Typically atrophy of left anterior inferior temporal lobe
    - Entire temporal lobe can be involved
    - Ventromedial & superior frontal lobes
    - Right temporal atrophy as disease progresses
  - **nfv-PPA**: Selective left perisylvian & frontal atrophy
  - **lv-PPA**: Atrophy mainly left-sided & more posterior involving angular & middle temporal gyri
- DTI
  - Wide spread damage to WM tracts reported
  - **bvFTD**: Uncinate fasciculus, inferior longitudinal fasciculus, & anterior commissural fibers
  - **sv-PPA**: Inferior longitudinal & uncinate fasciculi
  - **nfv-FTD**: Left superior longitudinal fasciculus
  - **lv-PPA**: Widespread dorsal & ventral WM tracts

Nuclear Medicine Findings

- PET
  - FDG PET: ↓ metabolic activity in frontotemporal cortex
  - Amyloid imaging (11C-labeled Pittsburgh compound-B) helps differentiate FTLD from Alzheimer disease
- HMPAO-SPECT
  - Sensitive technique for early detection of FTD
    - Occurs before atrophy is evident
  - **bvFTD**: ↓ perfusion frontal & anterior temporal lobes
    - Asymmetric, left or right dominant
  - **sv-PPA**: Prominent anterior temporal hypoperfusion, L > R
  - **nfv-PPA**: Asymmetric frontal hypoperfusion often involving insular cortex
  - **lv-PPA**: ↓ perfusion in left parietal inferior lobule & posterolateral temporal lobe
- SPECT perfusion deficits predominantly in frontal and anterior temporal lobes with preserved perfusion posteriorly
  - Helps distinguishes FTD from Alzheimer disease
- Reduced frontal perfusion is not specific to FTD but also occurs in some cases of schizophrenia, depression, HIV encephalopathy, Creutzfeldt-Jakob disease, Alzheimer disease

Imaging Recommendations

- Best imaging tool
  - PET/SPECT; MR voxel-based morphometry
- Protocol advice
  - Routine T1WI, T2WI, coronal T2WI

DIFFERENTIAL DIAGNOSIS

Alzheimer Disease (AD)

- Parietal and temporal cortical atrophy with disproportionate hippocampal volume loss
- Increased rate of atrophy in FTD compared to AD

https://CafePezeshki.IR

- Often coexisting microvascular disease, white matter hyperintensities, microhemorrhages
- Amyloid imaging (11C-labeled Pittsburgh Compound-B) helps to differentiate AD from other dementias

Vascular Dementia

- 2nd most common dementia (15-30%)
- White matter and deep gray lacunae
- Hyperintense lesions on T2WI and focal atrophy is suggestive of chronic infarcts

Corticobasal Degeneration

- Prominent extrapyramidal, cortical symptoms
- Severe frontoparietal atrophy contralateral to more severely affected clinically
- Atrophy of paracentral structures

Dementia With Lewy Bodies (DLB)

- Hypometabolism of entire brain, especially visual cortex
- Visual and auditory hallucinations, paranoid delusions

PATHOLOGY

General Features

- Etiology
  - Tau protein (hyperphosphorylated microtubular protein) or TDP-43 (TAR DNA-binding protein-43)
  - Rare cases change on fused-in-sarcoma (FUS) protein
- Genetics
  - 25-40% of FTD is familial
  - Most common: Mutations in tau gene (microtubule-associated protein tau [MAPT])
  - Progranulin gene (*PGRN*) results in TDP-43 pathology

Staging, Grading, & Classification

- Histopathologic classification of FTLD
  - FTLD- tau: Tau inclusion
  - FTLD-TDP: Tau-negative & TDP-43-positive inclusions
  - FTLD-FUS: Tau/TDP-negative & FUS-positive inclusions
  - FTLD-UPS: Positive immunohistochemistry against proteins of ubiquitin protease system (UPS)
  - FTLD-ni: No inclusions

Gross Pathologic & Surgical Features

- Gross atrophy of frontal & anterior temporal lobes
- Firm cortical gray matter (gliosis)
- Soft, retracted subcortical white matter

Microscopic Features

- Loss of pyramidal neurons & microvacuolar degeneration in layer II & III of frontal & temporal cortex
- Subjacent WM shows axonal & myelin loss
- FTLD-related tauopathies
  - Pick disease: Prototypical tauopathy of FTLD
  - Characterized by Pick bodies: Solitary, round or oval, argyrophilic inclusions in cytoplasm of neurons
  - Commonly found in dentate gyrus of hippocampus, amygdala, frontal & temporal neocortex

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Personality, behavior, and language changes
  - Memory loss, confusion, cognitive and speech dysfunction, apathy, and abulia
- Clinical profile
  - **bvFTD**: Marked changes in personality & behavior, mixture of apathy & disinhibition
    - Repetitive motor behaviors, cognitive decline
  - **sv-PPA**: Progressive loss of "semantic" knowledge about words, objects & concepts, fluent speech
  - **nfv-PPA**: Effortful speech production & orofacial apraxia
  - **lv-PPA**: Word finding pauses & poor sentence repetition

Demographics

- Age
  - Younger age group than Alzheimer disease
    - Onset usually < 70 years
    - Peak incidence 45-65 years
- Gender
  - bvFTD & sv-FTD: Male preponderance
  - nfv-PPA: Female predominance
- Ethnicity
  - Familial forms of Pick-complex dementias particularly common in people of Scandinavian origin
- Epidemiology
  - FTLD most common cause of early-onset (age < 65 years) dementia
  - Age > 65 years account for 20-25 % of cases of FTLD
  - Prevalence: 2.7-15.1/100,000

Natural History & Prognosis

- Insidious onset of behavioral and cognitive dysfunction
- Speech and language disturbance are often more profound than memory disorder
- Median survival 6-11 years from symptom onset & 3-4 years from diagnosis

DIAGNOSTIC CHECKLIST

Consider

- Other common forms of dementia (AD, DLB)

Image Interpretation Pearls

- Bilateral frontal lobe atrophy should cause diagnosis of FTD to be considered
- Bilateral asymmetric anterior temporal lobe atrophy: sv-FTD

Reporting Tips

- Report pattern of cortical volume loss

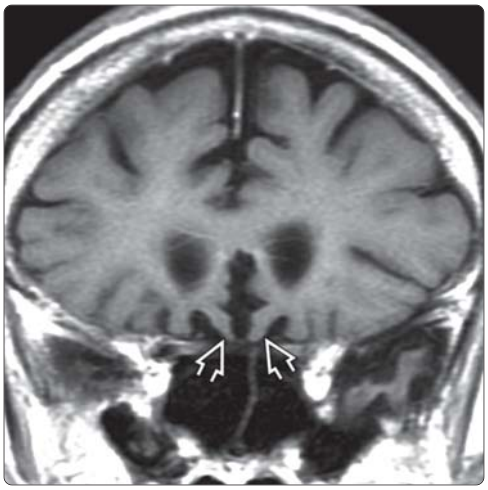
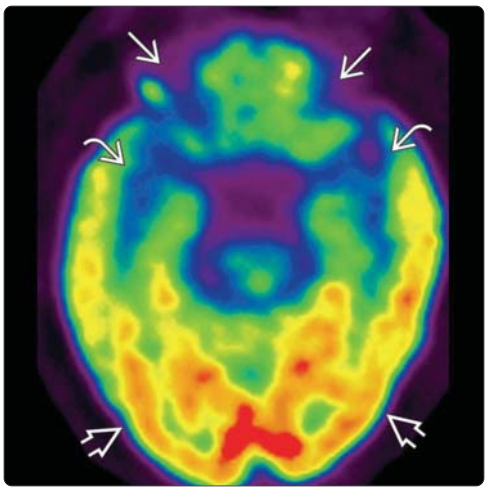
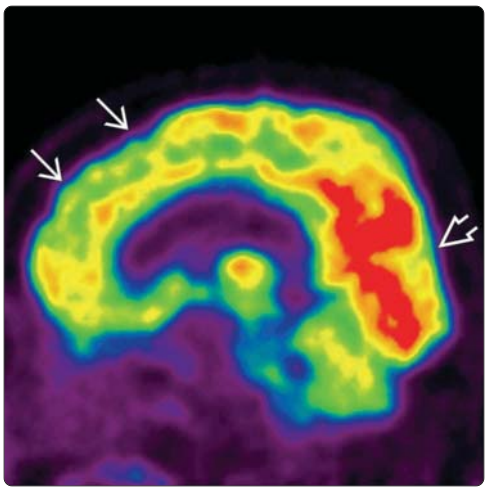
(Left) *Axial NECT in a 78-year-old patient diagnosed with late-stage FTD through the upper lateral ventricles shows striking frontal lobar atrophy, with classic knife-like gyri characteristic of FTD. In contrast, the parietal and occipital lobes appear relatively spared.* **(Right)** *FDG PET in a patient with frontotemporal dementia shows marked hypometabolism in the frontal and temporal lobes. There is relative preservation of glucose metabolism in the occipital and parietal lobes.*



(Left) *Axial T2WI MR in a patient with classic FTD shows predominantly frontal lobar atrophy with knife-like gyri. In this case, an associated region of hyperintense white matter is present.* **(Right)** *Coronal T1WI MR in the same patient shows focal atrophy of the olfactory gyri. This finding was initially overlooked, and the patient was given the imaging diagnosis of Alzheimer disease. Review and subsequent clinical evaluation confirmed frontotemporal dementia.*





(Left) *Axial FDG PET in a patient with FTD shows decreased glucose metabolism in frontal and temporal lobes. The parietal and occipital lobes are spared.* **(Right)** *Sagittal FDG PET in the same patient with FTD depicts glucose hypometabolism in the frontal lobes. The occipital lobes are normal.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Progressive neurodegenerative dementia
  - Parkinsonism, visual hallucinations prominent
  - Caused by abnormal accumulation of α-synuclein protein

IMAGING

- MR may differentiate Alzheimer disease (AD) from dementia with Lewy bodies (DLB)
- PET, SPECT most useful for DLB diagnosis
- Voxel-based morphometry
  - Relatively preserved hippocampal/medial temporal lobe volume in DLB compared to AD
  - Reduced volume of hypothalamus, substantia innominata and putamen in DLB compared to AD
- FDG PET
  - ↓ in glucose metabolism in occipital cortex, especially primary visual cortex
  - 18F-fluorodopa-PET: ↓ striatal dopamine uptake in DLB vs. AD
- SPECT: Occipital lobe hypoperfusion, especially visual cortex
- 123FP-CIT-SPECT: ↓ uptake in striatum in DLB vs. AD

TOP DIFFERENTIAL DIAGNOSES

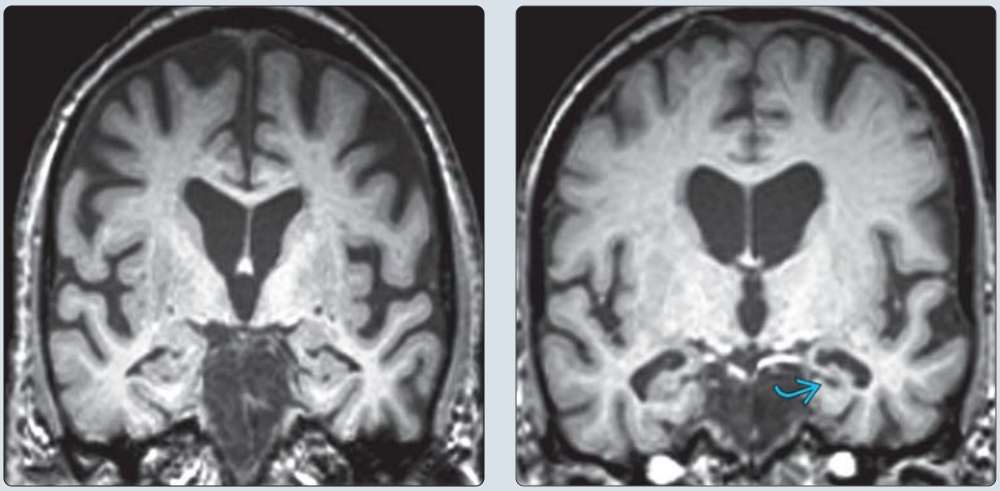
- Parkinson disease-associated dementia (PDD)
  - Similar clinical, pathological, imaging features with DLB
- Alzheimer disease (AD)
- Frontotemporal lobar degeneration (FTLD)
- Vascular dementia

PATHOLOGY

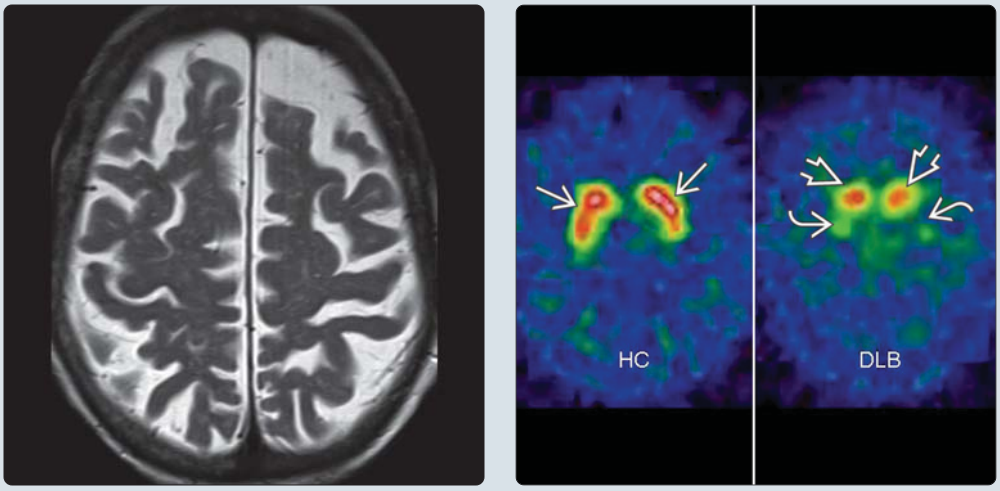
- Pathologic aggregation of α-synuclein protein in neurites (Lewy bodies)

DIAGNOSTIC CHECKLIST

- Unlike Alzheimer disease, medial temporal lobe atrophy not a prominent feature



(Left) *Coronal T1WI MR in a patient with dementia with Lewy bodies shows prominent frontal lobe volume loss with relative sparing of hippocampal volume. (Courtesy M.J. Firbank, MD, and J.T. O'Brien, MD.)* **(Right)** *Coronal T1WI MR in a patient with Alzheimer disease (AD) shows marked hippocampal volume loss and relative sparing of frontal lobes. (Courtesy M.J. Firbank, MD, and J.T. O'Brien, MD.)*



(Left) *Axial T2WI MR in a patient with DLB shows nonspecific diffuse cortical atrophy. Conventional MR findings are frequently nonspecific in DLB.* **(Right)** *123FP-CIT-SPECT, DAT imaging (dopamine transporter) shows normal symmetric uptake in the striatum of a healthy control (HC). In DLB, there is marked reduced update in the putamen and mild in the caudate nuclei. Using DAT imaging it is not possible to distinguish DLB from atypical parkinsonian syndromes like MSA, PSP, and CBD.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Dementia with Lewy bodies (DLB)

Definitions

- Neurodegenerative dementia characterized by cognitive fluctuations, visual hallucinations, and motor parkinsonism
  - Caused by pathologic aggregation of α-synuclein protein in neurites (Lewy bodies)

IMAGING

General Features

- Best diagnostic clue
  - MR may differentiate Alzheimer disease (AD) from DLB
  - PET, SPECT most useful for DLB diagnosis

Imaging Recommendations

- Best imaging tool
  - PET or SPECT

MR Findings

- T1WI
  - Mild generalized atrophy
- T2WI
  - Nonspecific white matter (WM) hyperintensities
- MRS
  - ↓ WM NAA/Cr in DLB compared to healthy controls (HC)
  - ↑ Cho/Cr ratios in DLB compared to HC
  - Normal levels of NAA/Cr and myoinositol in DLB compared to AD
- Voxel-based morphometry
  - Relatively preserved hippocampal/medial temporal lobe volume in DLB compared to AD
  - Reduced volume of hypothalamus, substantia innominata, and putamen in DLB compared to AD
  - Reduced gray matter in temporal, parietal, and occipital regions compared to HC
- DTI
  - ↑ mean diffusivity in amygdala
  - ↓ FA in pons and left thalamus compared to AD
  - ↓ FA in inferior longitudinal fasciculus and inferior occipitofrontal fasciculi compared to HC

Nuclear Medicine Findings

- PET
  - FDG PET: ↓ in glucose metabolism in occipital cortex and visual association cortex with relative preservation of posterior cingulate
  - 18F-fluorodopa-PET: ↓ striatal dopamine uptake in DLB vs. AD
- SPECT
  - Occipital lobe hypoperfusion, especially visual cortex
  - 123FP-CIT-SPECT: To visualize DAT (dopamine transporter) loss
    - ↓ uptake in striatum in DLB vs. AD (caudate, anterior, and posterior putamen)

DIFFERENTIAL DIAGNOSIS

Parkinson Disease-Associated Dementia

- Similar clinical, pathological, imaging features to DLB
- Less pronounced atrophy in temporal, occipital, and parietal lobes compared to DLB

Alzheimer Disease (AD)

- Parietal/temporal cortical atrophy
  - Disproportionate hippocampal volume loss
- More severe, faster rate of progression than DLB

Frontotemporal Lobar Degeneration (FTLD)

- Asymmetric frontal, anterior temporal lobar atrophy

Vascular Dementia

- 2nd most common dementia (15-30%)
- Infarcts of different ages

PATHOLOGY

General Features

- Etiology
  - Accumulation of α- synuclein protein (Lewy bodies)
- Genetics
  - Majority of DLB is sporadic; some are familial

Microscopic Features

- Lewy bodies in substantia nigra, neocortex, limbic system
  - α-synuclein protein aggregates: Pale eosinophilic inclusions

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Cognitive decline, fluctuations in level of alertness
  - Visual hallucinations, parkinsonian features

Demographics

- Age
  - 55-85 years; age is only risk factor
- Gender
  - Men more commonly affected
- Epidemiology
  - 15-20% of dementia cases
  - 2rd most common neurodegenerative dementia (after AD)

Natural History & Prognosis

- Average survival after diagnosis = 8 years

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- No characteristic features on standard MR

KEY FACTS

TERMINOLOGY

- Creutzfeldt-Jakob disease (CJD): Rapidly progressing, fatal, potentially transmissible dementia caused by prion

IMAGING

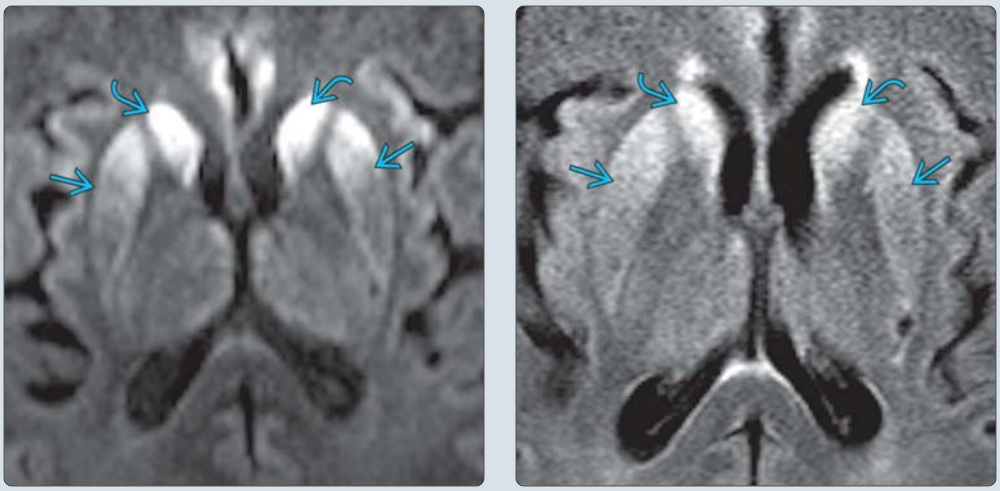
- Best imaging clue: Progressive T2 hyperintensity of basal ganglia (BG), thalamus, and cerebral cortex
- Predominantly gray matter (GM): Caudate and putamen > globus pallidus (GP)
  - Thalamus: Common in variant CJD (vCJD)
  - Cerebral cortex: Frontal, parietal, and temporal
- Heidenhain variant: Occipital lobe
- 2 signs seen in 90% of vCJD but can also occur in sporadic CJD (sCJD)
  - "Pulvinar" sign: Symmetric T2 hyperintensity of pulvinar of thalamus
  - "Hockey stick" sign: Symmetric pulvinar and dorsomedial thalamic nuclear hyperintensity
- Best imaging tool: MR with DWI

TOP DIFFERENTIAL DIAGNOSES

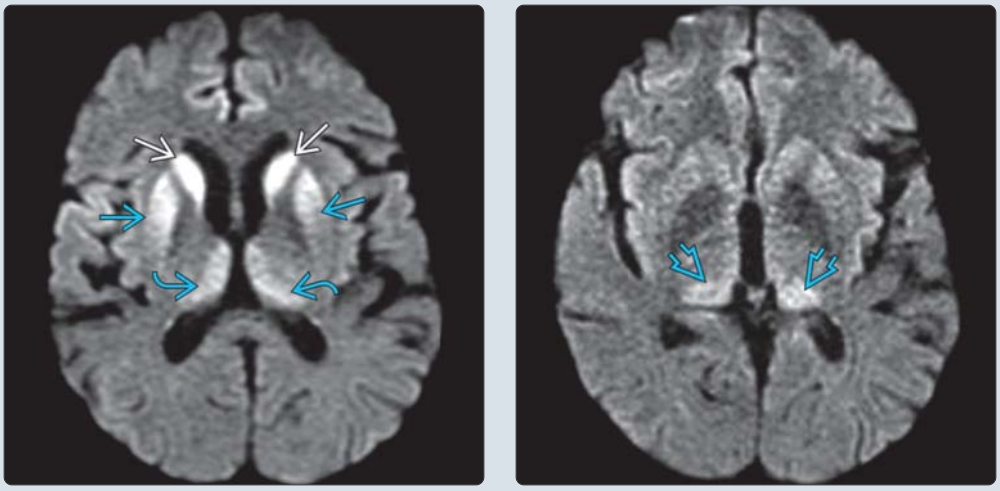
- Hypoxic-ischemic injury
- Osmotic demyelination syndrome
- Other causes of dementia
  - Alzheimer, frontotemporal, multi-infarct dementia, dementia in motor neuron disease
- Leigh syndrome
- Corticobasal degeneration

CLINICAL ISSUES

- Definite CJD diagnosed by brain biopsy or autopsy
- Progressive dementia associated with myoclonic jerks and akinetic mutism; variable constellation of pyramidal, extrapyramidal, and cerebellar signs
- CSF protein biomarkers: 14-3-3 protein, total tau (t-tau) and neuron-specific enolase (NSE)
- DWI MR has higher diagnostic accuracy, 97% than any or all of these 3 CSF biomarkers
- Death usually ensues within months of onset



(Left) *Axial DWI in a 67-year-old man with rapidly progressing dementia shows typical findings of sporadic Creutzfeldt-Jakob disease (sCJD). There is symmetric restricted diffusion involving the caudate nuclei and putamina.* **(Right)** *Axial FLAIR MR in the same patient shows corresponding high signal in the caudate nuclei and putamina. Creutzfeldt-Jakob disease (CJD) is a rapidly progressing, fatal, neurodegenerative disorder caused by a prion. MR with DWI is the imaging procedure of choice.*



(Left) *Axial DWI in a patient with sCJD demonstrates restricted diffusion involving the caudate nuclei and putamina. There is also involvement of the posteromedial thalami giving the classic "hockey stick" sign.* **(Right)** *Axial DWI in a patient with variant CJD (vCJD) shows classic "pulvinar" sign with symmetric hyperintensity in the posterior thalami. The "hockey stick" and "pulvinar" signs are seen in 90% of vCJD but can also occur in sCJD.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Creutzfeldt-Jakob disease (CJD)
- Sporadic Creutzfeldt-Jakob disease (sCJD)
- Variant Creutzfeldt-Jakob disease (vCJD)

Definitions

- Rapidly progressing, fatal, neurodegenerative disorder caused by prion (proteinaceous infectious particle devoid of DNA and RNA)
  - Transmissible spongiform encephalopathy

IMAGING

General Features

- Best diagnostic clue
  - Progressive T2 hyperintensity of basal ganglia (BG), thalamus, and cerebral cortex
- Location
  - Predominantly gray matter (GM)
    - BG: Caudate and putamen > globus pallidus (GP)
    - Thalamus (common in vCJD)
    - Cerebral cortex (most commonly frontal, parietal, and temporal lobes)
      - Cortical involvement often asymmetric
      - Heidenhain variant: Occipital lobe
      - Brownell-Oppenheimer: Cerebellum
  - White matter (WM) usually not involved

CT Findings

- NECT: Usually normal
  - May show rapidly progressive atrophy and ventricular dilatation on serial CT

MR Findings

- T1WI
  - Normal
- T2WI
  - Hyperintense signal in BG, thalami, cortex
  - Cerebral atrophy
  - With time, hyperintense foci may develop in WM
- FLAIR
  - 2 signs seen in 90% of vCJD but can also occur in sCJD
    - "**Pulvinar**" sign: Bilateral symmetrical hyperintensity of **pulvinar** (posterior) nuclei of **thalamus**
    - "**Hockey stick**" sign: Symmetrical **pulvinar and dorsomedial thalamic** nuclear hyperintensity
  - Periaqueductal GM hyperintensity
  - Cortical hyperintensity (common in sCJD)
- DWI
  - Progressive hyperintensity in striatum and cortex
  - Gyriform hyperintense areas in cerebral cortex ("cortical ribbon" sign)
    - Correspond to localization of periodic sharp-wave complexes on EEG
  - DWI hyperintensity may disappear late in disease
- T1WI C+: No enhancement of lesions

Nuclear Medicine Findings

- PET: Regional glucose hypometabolism correlates with sites of neuropathologic lesions
- SPECT with N-isopropyl-p-(I-123) iodoamphetamine
  - ↓ uptake of tracer and ↓ absolute values of rCBF in various parts of cerebral cortex

Imaging Recommendations

- Best imaging tool: MR with DWI and FLAIR

DIFFERENTIAL DIAGNOSIS

Hypoxic-Ischemic Injury

- BG and parasagittal cortical areas involved
- Hyperintense BG lesions on T1WI and T2WI
- DWI + symmetric GM involvement

Osmotic Demyelination Syndrome

- Extrapontine: T2 hyperintense putamen and caudate
- DWI positive acutely

Leigh Syndrome

- Primarily seen in pediatric patients
- T2 hyperintensity in putamen and GP

Other Causes of Dementia

- Alzheimer disease
- Dementia in motor neuron disease
- Frontotemporal dementia
- Multi-infarct dementia

Corticobasal Degeneration

- Neuronal loss in substantia nigra, frontoparietal cortex, and striatum (BG atrophy may be subtle)
- MR: Symmetric/asymmetric atrophy of pre- and postcentral gyri; prominent parasagittal involvement
- Subcortical gliosis: High intensity on T2WI

Wilson Disease

- WM and deep GM lesions (BG, dentate nucleus, brainstem); variably T2 hyperintense
- T1 hypointense (rarely hyperintense) lesions

Arteriolosclerosis

- BG involvement: Typically asymmetric and multifocal (rather than diffuse as in CJD)
- Focal hyperintensities in deep WM
- DWI negative, unless acute

PATHOLOGY

General Features

- Etiology
  - Prion protein is misfolded isoform (PrPSc) of normal host-encoded protein (PrPc)
  - PrPSc introduced into healthy cells → initiates self-perpetuating vicious cycle: PrPc → PrPSc
  - sCJD : Spontaneous PrPc → PrPSc or somatic mutation
  - Familial CJD (fCJD): Mutations in *PRNP*
  - Iatrogenic CJD: Infection from prion-containing material
    - Surgical instruments, dura mater grafts
    - Cadaveric corneal transplants, human growth hormone preparations
  - vCJD: Bovine spongiform encephalopathy in cattle is transmitted to humans through infected beef
    - a.k.a. new variant CJD (nvCJD)
- Genetics

https://CafePezeshki.IR

CDC Diagnostic Criteria for CJD 2010

(I) Clinical Signs	(II) Tests
(1) Dementia	(1) PSWCs on EEG
(2) Cerebellar or visual	(2) 14-3-3 detection in CSF (disease duration < 2 years)
(3) Pyramidal or extrapyramidal	(3) High signal abnormalities in caudate and putamen or at least 2 cortical regions (temporal-parietal-occipital) either on DWI or FLAIR
(4) Akinetic mutism	
Probable CJD: 2 out of 1 clinical signs and at least 1 out of 2 tests	
Probable CJD: 2 out of 1 clinical signs and at least 1 out of 2 tests	

Updated clinical diagnostic criteria for sporadic Creutzfeldt-Jakob disease. Zerr I et al: Updated clinical diagnostic criteria for sporadic Creutzfeldt-Jakob disease. Brain. 132(Pt 10):2659-68, 2009

- Can be inherited, sporadic, or acquired (infectious)
- 10-15% of human prion disease cases associated with dominant mutations in autosomal prion protein (PrPc) gene (*PRNP*) on chromosome 20
- Associated abnormalities
  - EEG: Periodic [high-voltage] sharp waves complexes (PSWCs) on background of low-voltage activity

Gross Pathologic & Surgical Features

- Mild cortical atrophy
- Ventricular enlargement

Microscopic Features

- Spongiform encephalopathy: GM most affected
  - Marked neuronal loss with reactive astrocytosis
  - Replacement gliosis
  - Neuronal vacuolation with spongiform changes
- 10% of patients with CJD have amyloid plaques in cerebellum or cerebral hemispheres
- Variable accumulation of PrPSc in brain tissue

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Rapidly progressive dementia associated with myoclonic jerks and akinetic mutism
  - Variable constellation of pyramidal, extrapyramidal, and cerebellar signs
- Clinical profile
  - **sCJD**: Cerebellar dysfunction, rapidly progressive cognitive impairment, both
    - 6 molecular subtypes: MM1, MM2, MV1, MV2, VV1, and VV2
      - Vary with respect to age at onset, disease duration, early symptoms, and neuropathology
  - **vCJD**: Psychiatric and sensory symptoms
    - **Heidenhain variant** of CJD
      - Isolated visual signs/symptoms (initially)
      - Predominantly occipital lobe degeneration
    - **Brownell-Oppenheimer**: Cerebellar signs/symptoms
    - Extrapyramidal type of CJD
      - May show ↑ signal intensity in BG
    - Pyramidal involvement with disease progression
  - **CSF studies**
    - CSF protein biomarkers: 14-3-3 protein, total tau (t-tau) and neuron-specific enolase (NSE)
    - DWI MR has higher diagnostic accuracy than any or all 3 CSF biomarkers
  - Real-time quaking induced conversion (RT-QUIC) testing of CSF to detected PrPsc
    - More sensitive using olfactory epithelium (nasal brushing) than CSF

Demographics

- Age
  - Young in vCJD, older in sCJD (6th to 7th decades)
- Ethnicity
  - sCJD occurs throughout world, in all races
  - vCJD limited to Europe (~ all cases in UK)
- Epidemiology
  - Incidence 1-1.5 per million in US
  - sCJD (85%), familial (15%), infectious/iatrogenic (less than 1%)

Natural History & Prognosis

- Long incubation period but rapidly progressive once clinical symptoms begin
- Rapidly progressing dementia, with death usually ensuing within months of onset
  - Median survival from time of onset of symptoms to death is 4.5 months
  - 90% live < 1 year

Treatment

- No effective treatment

DIAGNOSTIC CHECKLIST

Consider

- Heidenhain variant of CJD in patients with visual disorders of unclear origin and dementia

Image Interpretation Pearls

- Lack of BG findings does not rule out CJD

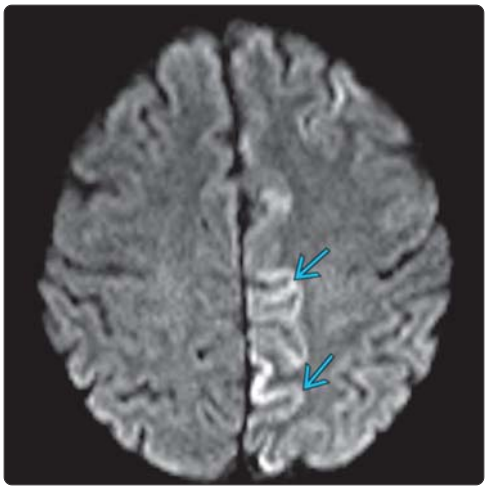
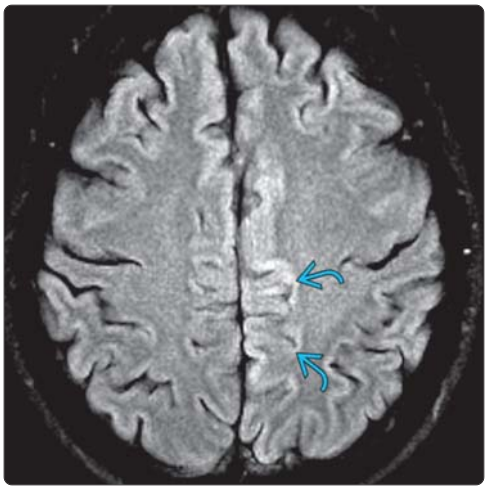
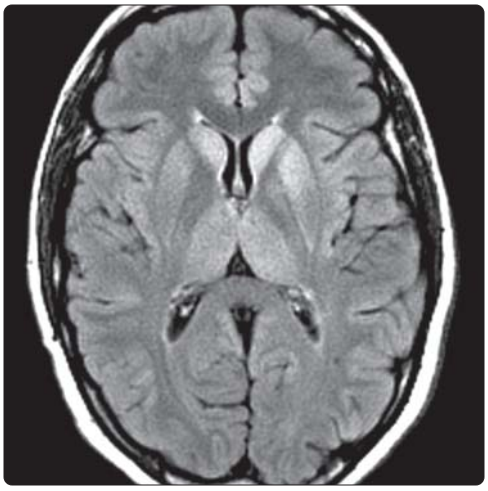
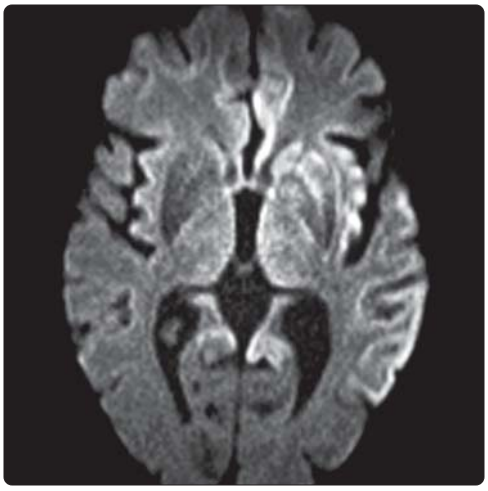
https://CafePezeshki.IR



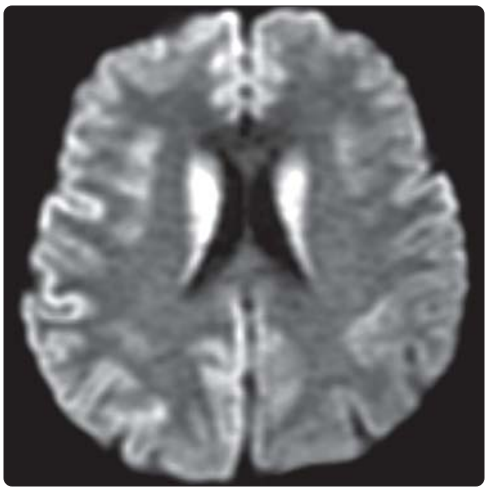


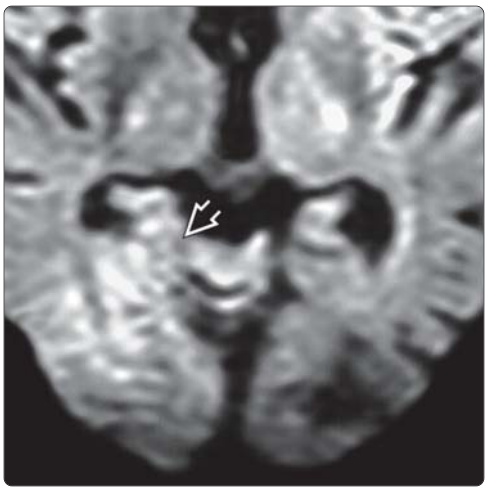
(Left) *Axial DWI in a patient with sCJD shows cortical restricted diffusion* ⇨ *also called "cortical ribbon" sign.* **(Right)** *Axial FLAIR in the same patient shows subtle corresponding cortical hyperintensity* ⇨*. The cortical signal abnormality corresponds to localization of periodic sharp-wave complexes on EEG. DWI MR has higher diagnostic accuracy, 97% than any or all of the 3 CSF biomarkers: 14-3-3 protein, total tau (t-tau), and neuron-specific enolase (NSE).*





(Left) *Axial FLAIR MR shows asymmetric hyperintensity in the caudate heads, left greater than right, and the left putamen.* **(Right)** *Axial DWI MR in the same patient a few weeks later shows asymmetric hyperintensity in the basal ganglia, left greater than right, and the cerebral cortex. Asymmetric cortical involvement is more common than asymmetric basal ganglia involvement in CJD. This elderly man had rapidly progressive dementia and probable CJD, as EEG showed characteristic features.*





(Left) *Axial DWI MR shows marked hyperintensity related to decreased diffusivity in the caudate nuclei and cortex in this patient with CJD. DWI is the most sensitive sequence for diagnosis of CJD.* **(Right)** *Axial DWI MR shows marked hyperintensity in the right occipital lobe* ⇨ *and left insula in a patient with primarily visual complaints. The Heidenhain variant of CJD is characterized by isolated visual signs and symptoms initially. Occipital lobe involvement predominates on imaging.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Parkinson disease (PD)
  - Progressive neurodegenerative disease
  - Primarily affects pars compacta of substantia nigra (SNpc)

IMAGING

- MR
  - SNpc narrowed/inapparent (T2WI)
  - SNpc progressively loses normal hyperintensity (from lateral to medial)
  - Border between SNpc, red nucleus blurred on PD
  - ↑ R2' relaxation at 3T in SNpc, caudal putamen (reflects ↑ iron content)
  - DWI may differentiate PD from PSP, MSA-P
  - MRS: Nonspecific, ↓ NAA/Cr and NAA/choline ratios in basal ganglia
- PET/SPECT helpful for distinction from "Parkinson-plus" syndromes
- ↑ ADC in putamen and caudate nucleus

TOP DIFFERENTIAL DIAGNOSES

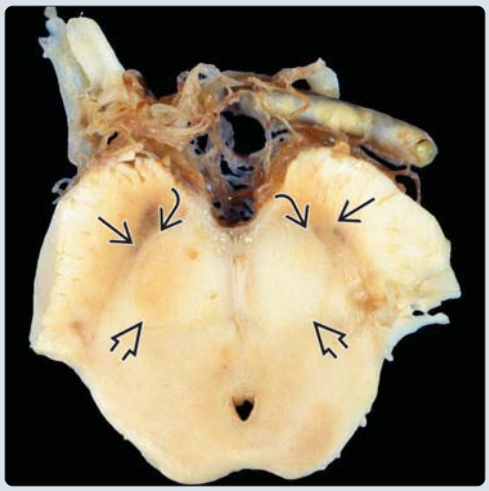
- Multiple system atrophy (MSA)
  - Parkinsonian variant of MSA (MSA-P)
- Progressive supranuclear palsy
- Corticobasal ganglionic degeneration
- Dementia with Lewy bodies

PATHOLOGY

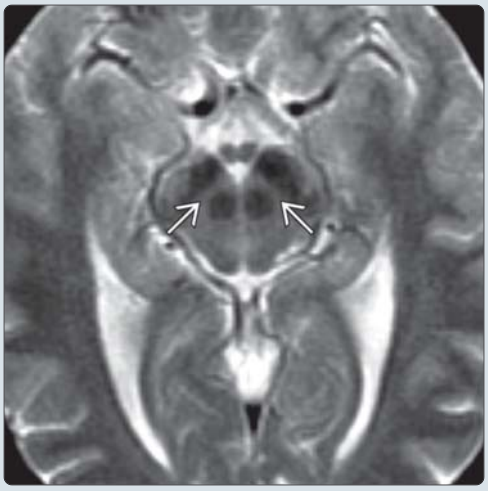
- Lewy bodies (eosinophilic intracytoplasmic inclusions with peripheral halos and dense cores), gliosis

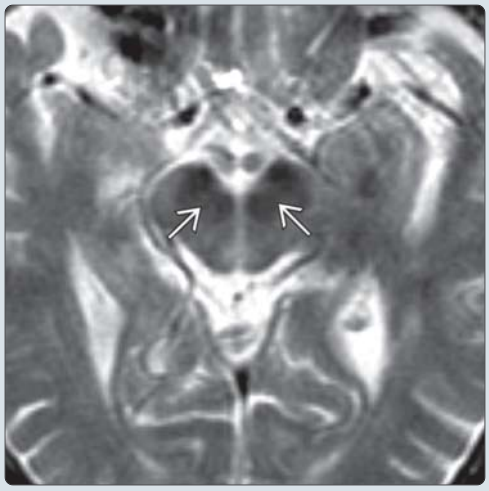
CLINICAL ISSUES

- Resting tremor
- "Cogwheel" rigidity
- Bradykinesia
- Shuffling gate
- "Masked" facies



(Left) *Axial midbrain diagram shows narrowing and depigmentation of the substantia nigra in Parkinson disease (upper) relative to normal anatomy (lower).* **(Right)** *Axial slice through the midbrain of a patient with severe Parkinson disease shows gross pathologic changes. Note the striking narrowing and depigmentation of the pars reticulata of the substantia nigra. The pars compacta, which is the region between the pars reticulata and the red nucleus, is markedly narrowed.*





(Left) *Axial T2WI MR in a normal individual shows the appropriate width of the pars compacta, a striking contrast to the abnormal findings seen in a patient with Parkinson disease.* **(Right)** *Axial T2WI MR in a patient with Parkinson disease shows classic midbrain findings. Note the "blurring" and thinning of pars compacta between 2 hypointense structures (i.e., the pars reticulata of substantia nigra and red nucleus). As a result, the red nuclei and substantia nigra are almost touching.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Idiopathic Parkinson disease (PD), paralysis agitans

Definitions

- Progressive neurodegenerative disease predominantly caused by primary disorder of pars compacta of substantia nigra (SNpc)
- Parkinsonism: Syndrome characterized by rigidity, tremor, bradykinesia, and postural imbalance
  - Idiopathic PD (typically responsive to L-dopa therapy)
  - "Parkinson-plus" syndrome: Parkinsonism combined with other clinical signs
    - e.g., dementia with Lewy bodies, multiple system atrophy, progressive supranuclear palsy, corticobasal degeneration

IMAGING

General Features

- Best diagnostic clue
  - Thinning of pars compacta of substantia nigra
- Location
  - Substantia nigra (SN), caudate nucleus, and putamen
- Size
  - Decreased (atrophy)

CT Findings

- NECT
  - Nonspecific cerebral atrophy

MR Findings

- T1WI
  - Most commonly, generalized enlargement of sulci, ventricles, which is nonspecific
  - Voxel-based morphometry
    - Nonspecific gray matter (GM) loss of limbic, paralimbic and prefrontal cortices
- T2WI
  - In normal subjects, SN is 2-layered GM structure at upper midbrain level
    - Hypointense area in posterior region of crus cerebri = pars reticulata of SN (SNpr)
    - Relatively hyperintense area between SNpr and red nucleus (RN) = SNpc
      - Some authors maintain this is best seen on PD images rather than T2WI
    - Hypointense area normally seen on axial T2WI corresponds to anterosuperior aspect of SN, adjacent crus cerebri (upper midbrain), anteromedial part of peduncular fibers (lower midbrain)
  - SNpc narrows in PD, difficult to distinguish from adjacent SNpr and RN
  - T2 hyperintense foci can be seen in putamen and globus pallidus (GP) in some PD patients; in addition, volume of putamen is decreased
  - At 3.0T imaging, increased R2 relaxation rates, indicative of increased iron content, are seen in SNpc and caudal portion of putamen in PD
- PD/intermediate
  - Axial intermediate-weighted SE images in normal subjects: Anatomic location of SN can be accurately identified
    - SN seen as area of hyperintense GM surrounded by hypointense RN and crural fibers at upper midbrain level
    - SNpr and SNpc cannot be distinguished
  - Axial intermediate TE images in PD
    - Progressive loss of normal signal of SNpc from lateral to medial; SNpc no longer appears hyperintense
    - Indistinct border between SNpr and RN, which reflects neuronal loss and iron deposition
- STIR
  - Fast STIR images: Same findings as proton density-weighted images
- DWI
  - Significantly ↑ putaminal ADC in Parkinson variant of multiple system atrophy (MSA-P) compared to PD
  - ↑ ADC in putamen and caudate nucleus
    - vs. progressive supranuclear palsy (PSP) and Parkinson variant of multiple system atrophy (MSA-P), which have ↑ putaminal ADC values
  - ↑ ADC of olfactory tracts in PD compared to healthy controls
- MRS
  - Nonspecific, ↓ NAA/Cr and NAA/choline ratios in basal ganglia
- DTI
  - ↓ FA in SN and along path of nigrostriatal projection
    - FA values correlate inversely with clinical severity of PD
  - ↓ FA in frontal lobe (supplementary motor area, presupplementary motor area, cingulum)
- T2 or T2* mapping
  - Sensitive to iron content in brain; ↑ ↑ R2' relaxation rate in SN of PD correlates with patient's motor symptoms but not with disease duration

Ultrasonographic Findings

- Brain parenchyma sonography: Hyperechoic appearance of SN in PD
  - Hypointense appearance of putamen (iron accumulation) in Parkinson-plus syndromes (PSP, MSA), not in PD

Nuclear Medicine Findings

- PET
  - May be used to study functional status of dopaminergic neurons in SN, dopamine D2 receptors in basal ganglia, or opiate receptors in basal ganglia
  - Dopaminergic neurons in SN
    - 18F-fluorodopa PET: ↓ striatal uptake proportional to decreased number of dopaminergic neurons; correlated with clinical severity
      - More pronounced reduction in striatal uptake in putamen than in caudate nucleus
      - May diagnose early/relatively asymptomatic PD
  - Dopamine D2 receptors in basal ganglia
    - 11C-raclopride PET; putaminal dopamine terminals are normal or increased in early stages of PD but normalize in advanced PD, reduced in MSA
  - Opiate receptors in basal ganglia

https://CafePezeshki.IR

  - 11C-diprenorphine; reduced uptake in putamen, thalamus, and anterior cingulate in PD patients with dyskinesias, normal in nondyskinetic PD patients
- SPECT: Like PET, may be used to study dopaminergic neurons in SN or dopamine D2 receptors in basal ganglia
  - Dopaminergic neurons in SN
    - I-123-FP-CIT SPECT findings in putamen similar to those seen with 18F-fluorodopa PET
  - Dopamine D2 receptors in basal ganglia
    - I-123 SPECT findings similar to those seen with 11C-raclopride PET

Imaging Recommendations

- Best imaging tool
  - Proton density-weighted SE MR and PET/SPECT
- Protocol advice
  - Proton density-weighted SE, fast STIR images allow direct visualization of SN as GM structure

DIFFERENTIAL DIAGNOSIS

Multiple System Atrophy (MSA)

- MSA-P: Prominent T2 hypointensity in putamen and caudate nucleus (abnormal iron deposition), putamen may show rim of ↑ T2 signal
- MSA-C: ↑ T2 signal in middle cerebellar peduncles, pontine transverse fibers (hot cross bun sign)

Progressive Supranuclear Palsy (PSP)

- Sag T1 MR: Tectal atrophy with a hummingbird appearance
- Concave posterolateral borders of atrophic midbrain giving morning glory flower appearance

Corticobasal Degeneration

- Thinning of pre-/postcentral gyri with central sulcus dilatation with marked parasagittal involvement

Dementia With Lewy Bodies

- Lewy bodies found diffusely in brain
- Brainstem, SN, and cortical atrophy

Parkinsonism-Dementia-Amyotrophic Lateral Sclerosis Complex

- Corticospinal tract abnormalities

PATHOLOGY

General Features

- Etiology
  - Various genetic markers are under study for increased susceptibility to developing PD
  - Environmental exposure: MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine); possibly pesticide exposure
  - Aging: Normal aging is associated with decrease of neurons in SNpc
- Genetics
  - Sporadic (3-5% of cases familial)
- Associated abnormalities
  - Increased iron content in SNpc

Gross Pathologic & Surgical Features

- Loss of pigmentation in SN and locus ceruleus

Microscopic Features

- Loss of dopaminergic neurons in SN (especially SNpc), locus ceruleus, dorsal vagal nucleus, and substantia innominata
- Lewy pathology: Misfolded α-synuclein aggregates to form intracellular inclusions within cell bodies (Lewy bodies) and processes of neurons (Lewy neurites)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Resting tremor with frequency of 3-5 Hz (pill-rolling tremor), "cogwheel" rigidity, bradykinesia, shuffling gate, masked facies, later dementia in 40%
- Other signs/symptoms
  - Autonomic dysfunction, depression, sleep disturbance

Demographics

- Age
  - Onset typically between 50-60 years
- Gender
  - M:F = 1.5:1
- Epidemiology
  - Idiopathic PD is most common movement disorder
  - PD is 2nd most common neurodegenerative disorder after Alzheimer disease
  - Prevalence: 1% of population > 50 years old

Natural History & Prognosis

- Onset of PD is typically asymmetric
- Slowly progressive course of bradykinesia, rigidity, and gait difficulty → eventual disability after several years

Treatment

- Medical (favored for some younger patients): Levodopa, bromocriptine, amantadine, selegiline
- Surgical (for medically refractive cases): Stereotactic pallidotomy or deep brain stimulation for subthalamic nucleus, thalamus, globus pallidus

DIAGNOSTIC CHECKLIST

Consider

- Parkinson-plus syndromes

Image Interpretation Pearls

- Role of imaging in parkinsonism: Exclude treatable bradykinesia (tumor, hematoma, hydrocephalus)
- Minimal correlation between hypointense areas on T2WI and SN location on anatomical specimens/PD-weighted/fast STIR images

KEY FACTS

TERMINOLOGY

- Adult onset fatal neurodegenerative disease
- Multiple system atrophy (MSA) has 3 clinical subtypes
- Cerebellar (MSA-C)
  - Sporadic olivopontocerebellar atrophy (sOPCA)
- Extrapyramidal (MSA-P)
  - Striatonigral degeneration (SND)
- Autonomic (MSA-A)
  - Shy-Drager syndrome (SDS)

IMAGING

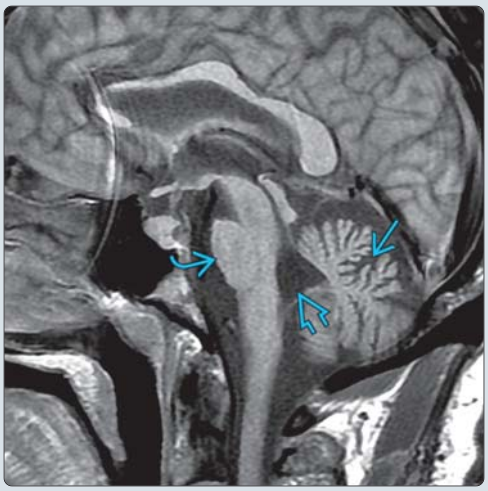
- General findings
  - ↓ ("flat") pons/medulla
  - Cerebellar vermis/hemispheres atrophic
- MSA-C
  - Selective atrophy of lower portion of basis pontis, medulla, MCPs, and cerebellar hemispheres
  - Corresponding ↑ T2 signal in pons, MCPs, and cerebellar white matter
  - Cruciform pontine hyperintensity ("hot cross bun" sign)
- MSA-P
  - ↓ T2 signal in dorsolateral putamen
  - ± ↑ T1 signal in lateral putamen rim
- FDG PET shows ↓ metabolism in putamen in MSA-P & ↓ FDG activity in cerebellar hemispheres and MCPs in MSA-C

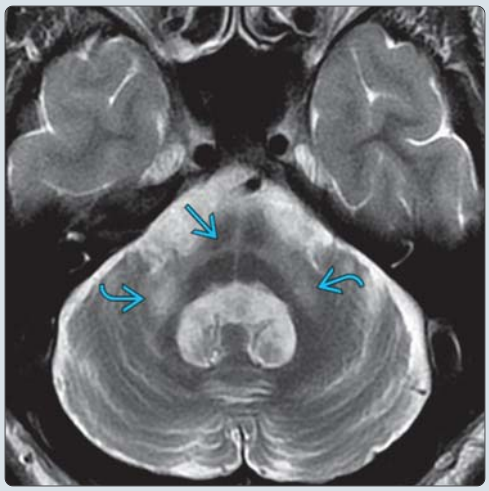
TOP DIFFERENTIAL DIAGNOSES

- Parkinson, Parkinson-plus syndromes
- Friedreich ataxia (spinocerebellar ataxia)
- Progressive nonfamilial adult onset cerebellar degeneration
- Hereditary olivopontocerebellar atrophy (OPCA)
- Hereditary cerebellar atrophy

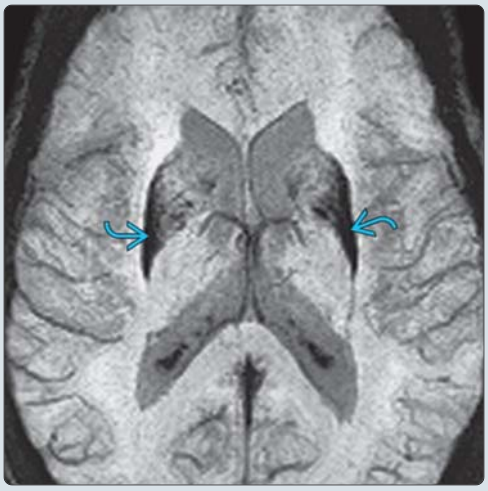
DIAGNOSTIC CHECKLIST

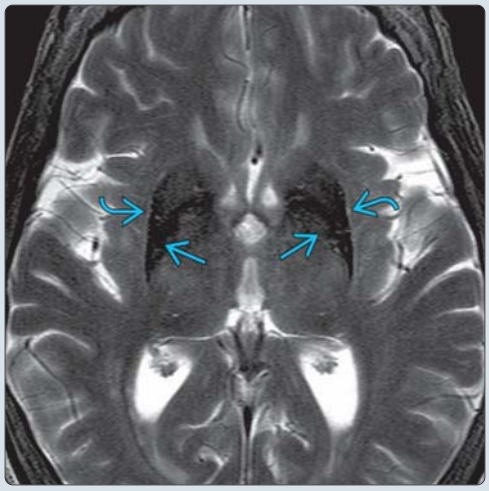
- MR features may overlap
- All MR findings may be observed in every MSA subtype





(Left) *Sagittal T1 MR in a patient with MSA-C type shows atrophy with flattening of the belly of pons. There is atrophy of the cerebellar vermis with prominence of the 4th ventricle.* **(Right)** *Axial T2 MR in the same patient shows characteristic pontine "hot cross bun" sign as well as symmetric hyperintensity in the middle cerebellar peduncles. The "hot cross bun" sign is caused by loss of myelinated transverse pontocerebellar fibers in the pontine raphe.*





(Left) *Axial SWI in a patient with MSA-P type shows abnormal putaminal hypointensity with greater involvement of the lateral putamen. This is caused by higher iron deposition in MSA.* **(Right)** *Axial T2 MR in the same patient shows putaminal hypointensity due to iron deposition. In addition there is subtle T2 hyperintensity at the lateral margin of the putamen "hyperintense putaminal rim" sign.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Multiple system atrophy (MSA)
  - Adult onset fatal neurodegenerative disease, unknown etiology
  - Various combination of cerebellar/pyramidal/extrapyramidal/autonomic features
- 3 clinical subtypes characterized by signs and symptoms
  - Predominantly cerebellar (MSA-C)
    - a.k.a. sporadic olivopontocerebellar atrophy (sOPCA)
  - Extrapyramidal (MSA-P)
    - a.k.a. striatonigral degeneration (SND)
  - Autonomic (MSA-A)
    - a.k.a. Shy-Drager syndrome (SDS)
- 2 distinct imaging subtypes: MSA-C and MSA-P

IMAGING

General Features

- Best diagnostic clue
  - MSA-C: Cruciform shape of hyperintense signal in pons on T2WI; atrophy of pons, inferior olives, and cerebellum
  - MSA-P: Putamen atrophy, ↓ T2 signal in dorsolateral putamen ± ↑ T2 signal in lateral rim of putamen
- Location
  - Striatum (mainly putamen), middle cerebellar peduncles (MCP), pons, cerebellum
- Size
  - Decreased (atrophy)

CT Findings

- NECT
  - Pontine atrophy, enlarged 4th ventricle (4th V)
  - Cerebellar atrophy (hemispheres > vermis)
  - Cortical atrophy (especially frontal and parietal lobes)

MR Findings

- T1WI
  - On sagittal images
    - ↓ size of pons and medulla with flat ventral surface of pons
    - Atrophy of cerebellar vermis and hemispheres
  - On axial images
    - ↓ anteroposterior diameter of pons
    - ↓ width of MCP
    - Enlargement of 4th V and cerebellopontine angle
    - Cerebellar atrophy
  - Atrophy of MCP and cerebellum is greater in MSA-C than other MSA subtypes
  - Lateral putaminal T1 hyperintensity in MSA-P
  - Frontal, parietal atrophy
- T2WI
  - MSA-C type
    - Selective atrophy of lower portion of basis pontis, medulla, MCPs, and cerebellar hemispheres
    - Corresponding ↑ T2 signal in pons, MCPs, and cerebellar white matter (WM)
    - Hyperintense signal in cruciform shape in pons ("hot cross bun" sign)
      - Reflects degeneration of pontine neurons and transverse pontocerebellar fibers (TPF)
  - MSA-P type
    - Atrophy of putamen
    - ↓ signal in dorsolateral putamen ± ↑ signal in lateral rim of putamen
    - ↑ signal lateral rim putamen normal finding at 3.0 T
  - Atrophy of cerebral hemispheres
    - Especially frontal and parietal lobes
    - Not significantly different in various subtypes
  - All MR findings may be observed in every MSA subtype
- T2* GRE
  - SWI: Severe putaminal hypointensity in MSA-P type
- DWI
  - ↑ ADC in MCP helps differentiating MSA-C from PD and progressive supranuclear palsy
  - ↑ ADC in putamen helps differentiating MSA-P from Parkinson disease
  - Diffusion tensor MR (DTI)
    - MSA-C: ↓ FA in MCP, TPF, and cerebellum
- MRS
  - ^{1}H-MRS: Significantly ↓ pontine and cerebellar NAA/Cr, Cho/Cr ratios in MSA-C
    - Pontine NAA/Cr ratio correlates with disability
  - Phosphorus MRS: ↓ phosphocreatine, ↑ phosphate
- MR volumetry
  - Volumetry and voxel-based morphometry show striatal and cerebellar volume loss in MSA-P compared to PD and healthy controls
  - MCP width < 8 mm: In MSA compared to PD and healthy controls

Ultrasonographic Findings

- Transcranial ultrasound in MSA-P
  - Hyperechogenicity of lentiform nucleus and normal appearance of substantia nigra (SN) helps differentiating MSA-P from PD

Nuclear Medicine Findings

- PET
  - FDG PET in MSA-P: Relatively symmetric ↓ putaminal FDG activity
    - 11C-raclopride PET shows ↓ postsynaptic D2 receptor density in putamen
  - FDG PET in MSA-C: ↓ FDG activity in cerebellar hemispheres and MCPs
- SPECT
  - Dopamine transporter (DaT) selective radiotracers 123 I β CIT and 123 I ioflupane most widely used
  - 123 I ioflupane SPECT shows varying degree of unilateral or bilateral ↓ striatal uptake in MSA
  - DaT-SPECT shows no discernible difference in pattern of nigrostriatal degeneration between MSA and PD
  - D2 receptor SPECT may demonstrate reduction in D2 receptors in MSA compared to PD

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Axial T2WI or FLAIR for "hot cross bun" sign, SWI

https://CafePezeshki.IR

DIFFERENTIAL DIAGNOSIS

Parkinson Disease

- Thinned pars compacta
- ↓ width of MCP in MSA but not in PD
- Putaminal iron deposition appears earlier and more prominent in MSA-P compared to PD

Other Parkinson-Plus Syndromes

- Progressive supranuclear palsy
- Corticobasal degeneration
- MCP widths are normal

Friedreich Ataxia (Spinocerebellar Ataxia)

- Severe atrophy of spinal cord (flat posterior aspect) and medulla oblongata
- Mild atrophy of vermian and paravermian structures

Progressive Nonfamilial Adult Onset Cerebellar Degeneration

- May occur in association with many conditions
  - Hashimoto thyroiditis (even in euthyroid state)
  - Paraneoplastic syndromes
  - Nutritional deficiency, alcohol abuse
  - Prolonged phenytoin/phenobarbital use
- Midline cerebellar atrophy on MR

Hereditary Olivopontocerebellar Atrophy (OPCA)

- Dominant OPCA
  - "Fine comb" type of cerebellar atrophy, involving hemispheres > vermis; atrophy of pons and MCP
- Recessive OPCA: Marked atrophy in lateral part of cerebellar hemispheres with "fish-mouth deformity"

Hereditary Cerebellar Atrophy

- Middle-aged patients; severe superior vermian atrophy

PATHOLOGY

General Features

- Etiology
  - Unknown; genetic and environmental factors contribute
- Genetics
  - Genetic factors play an etiological role in some families
  - Mutations in *COQ2* gene in familial and sporadic cases

Gross Pathologic & Surgical Features

- Variable degrees of olivopontocerebellar atrophy and striatonigral degeneration
- Frontal and parietal lobe atrophy

Microscopic Features

- Proteinaceous oligodendroglial cytoplasmic inclusions (glial cytoplasmic inclusion [GCIs]) are hallmark of MSA
  - Also called Papp-Lantos bodies
  - Main constituent of GCLs is misfolded α-synuclein
- Loss of cerebellar Purkinje cells
- Severe degeneration and gliosis in deep cerebellar WM
- ↑ accumulation of intracellular ferritin in basis pontis and putamen

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Parkinsonian features predominate in 80% of patients (MSA-P subtype)
    - Bradykinesia, rigidity, postural and rest tremor, unsteady gait, dysequilibrium
    - Differentiation from Parkinson disease is important
      - MSA-P more rapidly progressing, nonresponsive to L-Dopa
  - Cerebellar symptoms predominate in 20% of patients (MSA-C subtype)
    - Gait ataxia, limb akinetic ataxia, dysarthria, cerebellar oculomotor disturbance
  - Autonomic failure (MSA-A)
    - Symptomatic orthostatic hypotension
    - Erectile and urologic disturbance, constipation, hypo-/anhidrosis
  - Neuropsychological dysfunction, particularly in memory and other higher order cognitive functions
    - Cognitive dysfunction correlated with frontal, parietal atrophy

Demographics

- Age
  - Onset of MSA: Usually 6th decade
- Gender
  - No gender preference
- Epidemiology
  - Prevalence of MSA in USA: 3-5/100,000
  - Incidence rate of MSA: 0.6-3/100,000 per year
  - Associated with history of high exposure to exogenous toxins, organic solvents, plastic monomers, pesticides and metals

Natural History & Prognosis

- Progressive neurodegenerative disease
- Death usually occurs within 10 years from onset

Treatment

- Options, risks, complications
  - 90% of MSA-P patients are unresponsive to L-dopa

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- "Hot cross bun" sign (cruciform shape of hyperintense signal in pons on T2WI) suggests diagnosis of MSA-C

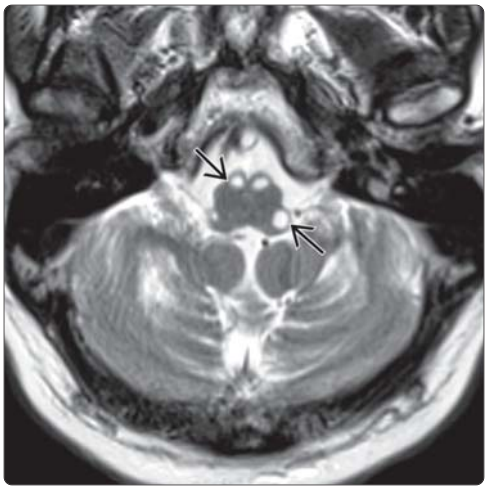
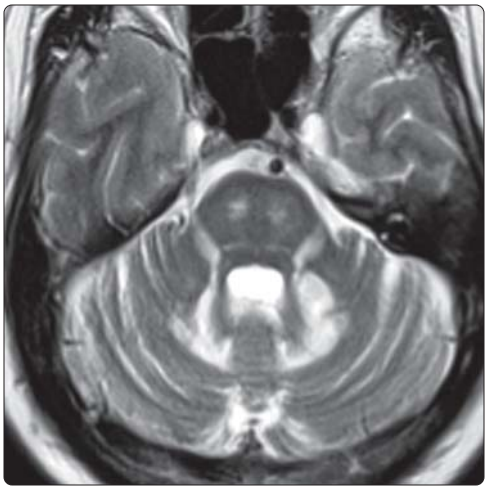
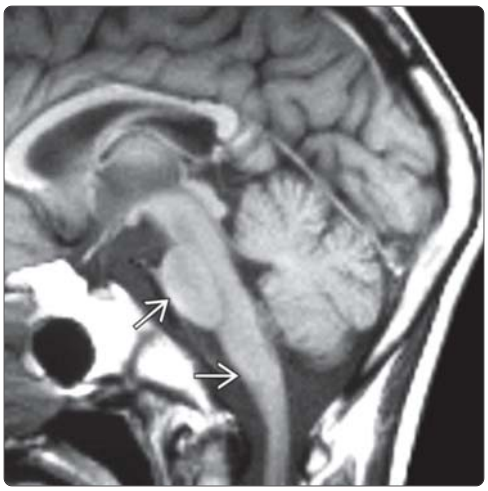
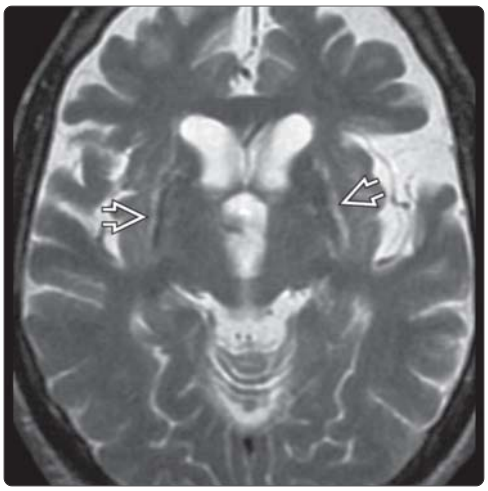
(Left) *Axial NECT in a 62-year-old woman with multiple system atrophy of the cerebellar type shows cerebellar cortical atrophy demonstrated by the prominence of the horizontal fissure ⇨ and enlargement of the 4th ventricle ⇨.* **(Right)** *Axial T2WI MR through the lower pons in the same patient confirms cerebellar atrophy. The most striking feature is the cruciform region of the hyperintense signal ➡ within the atrophic pons, the "hot cross bun" sign.*





(Left) *Axial T2WI MR in a 55-year-old woman with sporadic olivopontocerebellar atrophy shows striking, symmetric high signal intensity in the pyramids and inferior cerebellar peduncles ⇨.* **(Right)** *Axial T2WI MR in the same patient shows hyperintensity in the middle cerebellar peduncles, dentate nuclei, and pons. The cerebellum appears moderately atrophic for the patient's age. The basal ganglia and cerebral hemispheres (not shown) were normal.*





(Left) *Sagittal T1WI MR shows relatively "flat" pons and medulla ➡.* **(Right)** *Axial T2WI MR also demonstrates that the putamina appear small and hypointense, with a thin peripheral rim of high signal intensity ➡. The white matter (WM) appears quite normal compared to the overall degree of sulcal and ventricular enlargement.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Corticobasal degeneration (CBD)
  - Progressive neurodegenerative disease
  - Presents with cognitive dysfunction, "asymmetrical" parkinsonism

IMAGING

- Severe focal asymmetric cortical atrophy
  - Perirolandic (posterior frontal, parietal cortex)
  - Relative sparing of temporal, occipital regions
- ↑ signal intensity in frontal &/or parietal subcortical white matter
- Marked T2 hypointensity
  - Putamen, globus pallidi
- 18F-FDG PET decreased uptake in cortical and subcortical regions (frontal, temporal, sensorimotor, and parietal association cortices), caudate, lentiform nucleus, and thalamus
- SPECT: Asymmetric hypoperfusion in frontoparietal lobes, basal ganglia (putamen), thalamus, and cerebellar hemispheres

TOP DIFFERENTIAL DIAGNOSES

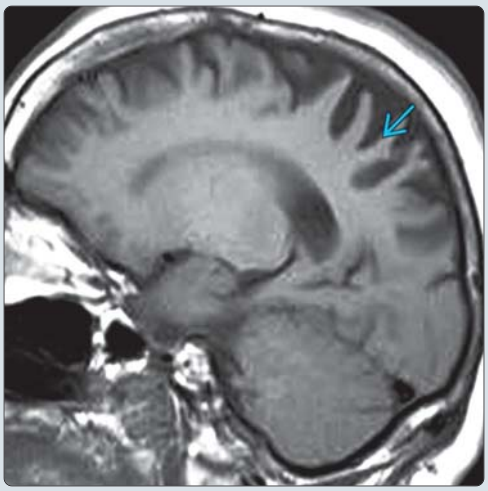
- Progressive supranuclear palsy
- Frontotemporal lobar dementia/degeneration
- Alzheimer disease
- Dementia with Lewy bodies
- Amyotrophic lateral sclerosis (ALS)

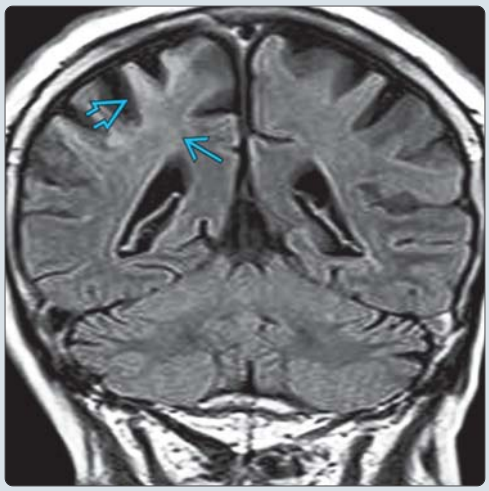
PATHOLOGY

- Hyperphosphorylated tau/abnormal filamentous inclusions accumulate in neurons/glia

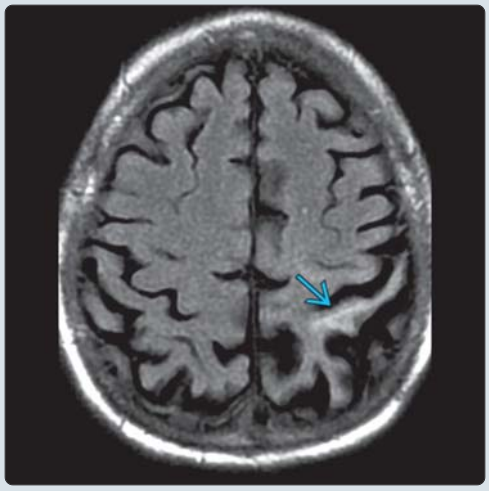
CLINICAL ISSUES

- Unilateral or asymmetrical parkinsonism
  - Dystonia, tremor
  - Ideomotor apraxia, "alien limb" phenomenon
- Cognitive decline





(Left) *Parasagittal T1WI MR through the right hemisphere in a 63-year-old man with corticobasal degeneration shows prominent volume loss in the posterior frontal and parietal cortex. The anterior frontal lobe cortex is normal in appearance.* **(Right)** *Coronal FLAIR MR in the same patient shows asymmetric parietal atrophy, worse on the right, with subcortical white matter hyperintensity. (Courtesy A. Erbetta, MD.)*



(Left) *Axial T2 MR in a 71-year-old male with corticobasal degeneration demonstrates asymmetric atrophy and thin cortex in the left perirolandic region.* **(Right)** *Axial FLAIR MR in the same patient shows subcortical white matter hyperintensity in the region of perirolandic atrophy. In CBD the dorsal prefrontal and perirolandic cortex, striatum, and midbrain tegmentum are most severely involved. Asymmetric frontoparietal atrophy is contralateral to the side that is more severely affected clinically.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Corticobasal degeneration (CBD)

Synonyms

- Corticobasal ganglionic degeneration (CBGD)
- Corticodentatonigral degeneration with neuronal achromasia

Definitions

- Progressive neurodegenerative disease
  - Presents with cognitive dysfunction, "asymmetrical" parkinsonism
  - Characterized pathologically by cortical and striatal tau protein accumulation

IMAGING

General Features

- Best diagnostic clue
  - Asymmetric cerebral atrophy (frontoparietal cortex ± cerebral peduncle)
- Size
  - Atrophy

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Axial and coronal T2WI and FLAIR

CT Findings

- NECT
  - Asymmetric cerebral atrophy

MR Findings

- T1WI
  - Asymmetric cerebral atrophy
    - Posterior frontal, parietal cortex
    - ± cerebral peduncle, midbrain tegmentum, corpus callosum
- T2WI
  - Asymmetric hyperintensity in subcortical white matter (SCWM)
  - Marked hypointensity in putamen, globus pallidi
- FLAIR
  - Asymmetric ↑ signal intensity in frontal &/or parietal subcortical white matter
    - Seen more frequently in more cephalad brain regions
- MRS
  - Marked ↓ in N-acetylaspartate (NAA)/creatine ratio compared with controls in centrum semiovale
  - ↓ NAA/choline ratio in lentiform nucleus and parietal cortex
- DTI
  - Corticospinal tract atrophy on tractography
  - ADC
    - ↑ in motor (lateral) thalamus, precentral/postcentral gyri (ipsilateral to affected frontoparietal cortex) and bilaterally in the caudate and supplementary motor area (SMA)
  - FA
    - ↓ in precentral gyrus, SMA, postcentral gyrus, cingulum

Nuclear Medicine Findings

- PET
  - 18F-FDG decreased uptake in cortical and subcortical regions (frontal, temporal, sensorimotor, and parietal association cortices), caudate, lentiform nucleus, and thalamus
  - 18F-dopa-PET: Decreased uptake in putamen, caudate
- SPECT
  - Asymmetric hypoperfusion in frontoparietal lobes, basal ganglia (putamen), thalamus, and cerebellar hemispheres
  - Site of hypoperfusion is contralateral to side more severely affected clinically
  - DaT (dopamine transporters) SPECT: ↓ presynaptic dopamine transporter binding in striatum
  - Dopamine D2 receptor SPECT: Limited value, normal or slightly reduced D2 receptor binding

DIFFERENTIAL DIAGNOSIS

Progressive Supranuclear Palsy

- Prominent atrophy of midbrain ± pons ("penguin silhouette" sign)
- Postural instability, vertical gaze palsy
- Most common Parkinson-plus syndrome
- No subcortical hyperintense regions

Frontotemporal Lobar Degeneration

- Abnormalities of behavior and personality
- Bilateral frontal, anterior temporal lobar atrophy
- No subcortical hyperintense regions

Alzheimer Disease

- Parietotemporal lobar atrophy (entorhinal cortex, hippocampus)
- Major dysfunction in memory and cognition
- No subcortical hyperintense regions
- Amyloid PET: Uptake of radiotracer Pittsburgh compound-B (PiB) in temporoparietal cortex

Dementia With Lewy Bodies

- Mild diffuse brain atrophy
- No subcortical hyperintense regions
- PET: Hypometabolism in occipital cortex

Amyotrophic Lateral Sclerosis (ALS)

- No significant brain atrophy
- Abnormal high signal intensity of corticospinal tracts on T2WI/FLAIR

PATHOLOGY

General Features

- Etiology
  - Accumulation of hyperphosphorylated tau
  - Abnormal filamentous inclusions in neurons, glia
- Genetics
  - Tau gene is located on chromosome 17 (13 exons)

https://CafePezeshki.IR

Clinical Phenotypes Associated With Corticobasal Degeneration

Syndrome	Features
Probable corticobasal syndrome	Asymmetric presentation of 2 of the following: (a) limb rigidity or akinesia, (b) limb dystonia, &/or (c) limb myoclonus, plus 2 of the following: (d) orobuccal or limb apraxia, (e) cortical sensory deficit, &/or (f) alien limb phenomena (more than simple levitation)
Possible corticobasal syndrome	May be asymmetric with 1 of the following: (a) limb rigidity or akinesia, (b) limb dystonia, or (c) limb myoclonus, plus 1 of the following: (d) orobuccal or limb apraxia, (e) cortical sensory deficit, or (f) alien limb phenomena (more than simple levitation)
Frontal behavioral-spatial syndrome (FBS)	2 of the following: Executive dysfunction, behavioral or personality changes, visuospatial deficits
Nonfluent/agrammatic variant of primary progressive aphasia (naPPA)	Effortful, agrammatic speech plus at least 1 of the following: Impaired grammar/sentence comprehension with relatively preserved single-word comprehension, groping &/or distorted speech production (apraxia of speech)
Progressive supranuclear palsy syndrome (PSPS)	3 of the following: Axial or symmetric limb rigidity or akinesia, postural instability or falls, urinary incontinence, behavioral changes, supranuclear vertical gaze palsy, or decreased velocity of vertical saccades

Armstrong MJ, Litvan I, Lang AE, et al. Criteria for the diagnosis of corticobasal degeneration. Neurology 2013;80:496–503.

- Selective aggregation of 4R tau occurs in BG, cerebral cortex
- Tau haplotype H1 associated with both CBD, progressive supranuclear palsy
  - Suggests tau abnormality on chromosome 17 causes both diseases

Gross Pathologic & Surgical Features

- Severe focal cortical atrophy
  - Perirolandic (posterior frontal, parietal cortex)
  - Relative sparing of temporal and occipital regions
- Striatonigral degeneration: Atrophy and discoloration of substantia nigra

Microscopic Features

- Core features
  - Focal cortical neuronal loss, substantia nigra neuronal loss
  - Tau-positive neuronal, glial lesions
    - Astrocytic plaques and threads
    - In cortex, corpus striatum
- Supportive features
  - Cortical atrophy, commonly with superficial spongiosis
  - Ballooned neurons, typically mainly in atrophic cortices
  - Tau-positive oligodendroglial coiled bodies

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Unilateral or asymmetrical parkinsonism (typically in arm), dystonia, tremor
  - Ideomotor apraxia, "alien limb" phenomenon, cognitive decline
- Other signs/symptoms
  - Depression, apathy

Demographics

- Age
  - Typically 50-70 years old
    - Mean age = 63 years
- Gender
  - No gender preference
- Epidemiology
  - True prevalence unknown (but likely ~ 5-7 per 100,000)
  - ~ 5% of cases of parkinsonism

Natural History & Prognosis

- Mean survival of 8 years after diagnosis
- Most common initial presentations: "Useless arm" (55%), gait disorder (27%) are common
- Subsequent development of unilateral limb rigidity or dystonia, bradykinesia, dementia

Treatment

- No curative treatment is available
- Motor symptoms: Levodopa and other dopaminergic drugs may help; botulinum toxin injections for dystonic clenched fist

DIAGNOSTIC CHECKLIST

Consider

- Consider CBD in case of asymmetric parkinsonism and cortical dysfunction

Image Interpretation Pearls

- Asymmetry atrophy of brain cortex and cerebral peduncle can be helpful MR findings

KEY FACTS

TERMINOLOGY

- Neurodegenerative disease characterized by supranuclear palsy, postural instability, mild dementia

IMAGING

- Midbrain atrophy ("penguin" or "hummingbird" sign)
  - Sagittal T1WI shows concave/flat upper border of midbrain (normally convex)
  - Axial T1WIs show abnormal concavity of lateral margins of midbrain tegmentum ("morning glory" or "Mickey Mouse" sign)
  - Thinning of superior colliculus
- Midsagittal 3D-MPRAGE or FSPGR images
  - Voxel-based morphometry used to calculate ratio of midbrain to pons area
  - Midbrain area < 70 mm² (50% of normal)
  - Midbrain to pons ratio < 0.15 strongly suggests PSP
  - MR Parkinsonism index: Allows discrimination of PSP from MSA-P, PD, and control

TOP DIFFERENTIAL DIAGNOSES

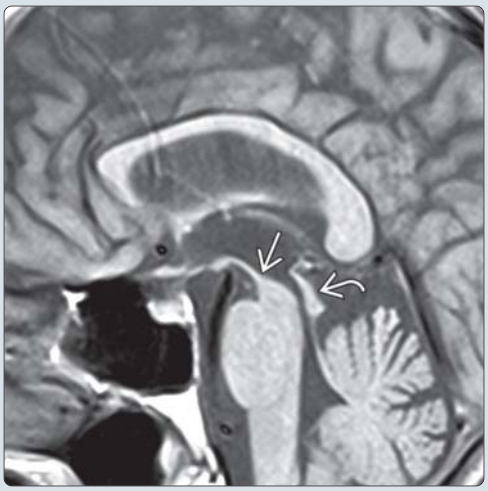
- Multiple system atrophy, Parkinsonian type
- Corticobasal degeneration
- Dementia with Lewy bodies
- Parkinson disease

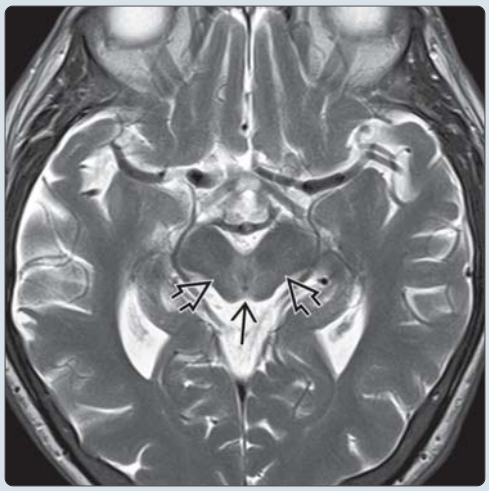
PATHOLOGY

- Neurofibrillary tangles and neuropil threads in globus pallidus, subthalamic nucleus, substantia nigra; cerebral cortex relatively preserved except for perirolandic cortex
- Neuronal loss, gliosis

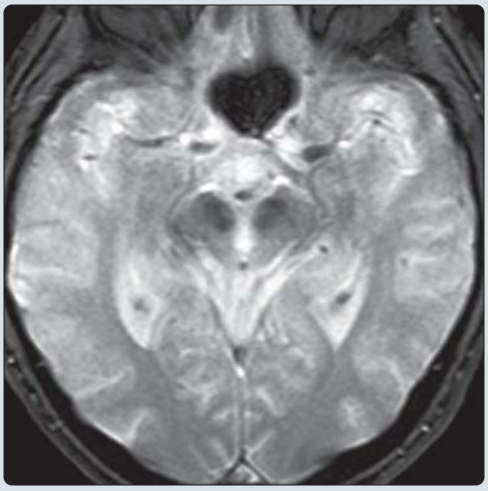
CLINICAL ISSUES

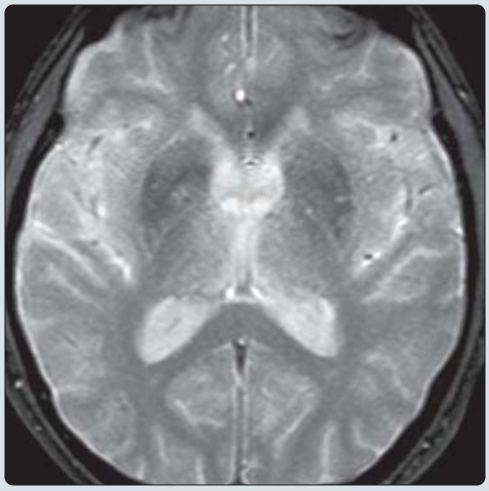
- PSP-RS (Richardson syndrome)
- Lurching gait, axial dystonia, vertical supranuclear palsy
- PSP-P (Parkinsonian type)
- Bradykinesia, rigidity, normal eye movements
- 2nd most common neurodegenerative cause of Parkinsonism overall





(Left) *Sagittal T1WI MR in a patient with bradykinesia and suspected Parkinson disease shows the classic "penguin" or "hummingbird" sign of progressive supranuclear palsy (PSP). Note thinning of the midbrain ⇨ with atrophy of the tectum ⇨, also consistent with PSP. In contrast to the strikingly abnormal midbrain findings, here the pons appears normal.* **(Right)** *Axial T2WI MR in the same patient shows volume loss of the midbrain with thinned tectum ⇨ and concave lateral midbrain margins ⇨.*





(Left) *Axial T2* GRE MR in the same patient shows no evidence for abnormal iron accumulation in the midbrain, which helps to distinguish PSP from Parkinson disease.* **(Right)** *Axial T2* GRE MR shows no evidence for abnormal iron accumulation in the striatum, another location in which iron is commonly found in Parkinson disease.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Progressive supranuclear palsy (PSP)

Synonyms

- Steele-Richardson-Olszewski syndrome

Definitions

- Neurodegenerative disease characterized by supranuclear palsy, Parkinsonism, postural instability, pseudobulbar syndrome, & dementia

IMAGING

General Features

- Best diagnostic clue
  - Midbrain tegmentum atrophy ("penguin" or "hummingbird" sign)
  - Most accurate: Calculation of midbrain area/pons area ratio
    - Distinguishes PSP from other conditions
      - PSP vs. Parkinsonian form of multisystem atrophy (MSA-P)
- Location
  - Midbrain
    - Tegmentum
    - Tectum (superior colliculus)
- Morphology
  - Prominent midbrain volume loss
    - Pons normal

Imaging Recommendations

- Best imaging tool
  - MR
  - PET
- Protocol advice
  - Midsagittal T1WI
  - 3D MP-RAGE or FSPGR images
    - Use voxel-based morphometry to calculate ratio of midbrain to pons area

CT Findings

- NECT
  - Atrophy of midbrain with prominent mesencephalic cisterns and enlarged 3rd ventricle

MR Findings

- T1WI
  - Sagittal T1WI helpful in detecting midbrain tectal atrophy ("penguin" or "hummingbird" sign)
    - Concave or flat profile of cephalad surface of midbrain (as opposed to normal convex superior profile)
    - Thinning of superior colliculus
  - Axial T1WIs show abnormal concavity of lateral margins of midbrain tegmentum ("morning glory" or "Mickey Mouse" sign)
  - Atrophic superior cerebellar peduncles
  - Midbrain area approximately 1/2 that of normal individuals
  - Ratio of area of midbrain to area of pons in PSP (0.124) was significantly smaller than in Parkinson Disease (PD) (0.208), MSA-P (0.266), and normal control (0.237)
  - Sagittal midbrain area < 70 mm², ratio of midbrain tegmentum to pons area < 0.15 → diagnostic of PSP
    - Sensitivity: 100%; specificity: 91-100%
  - MR Parkinsonism index = (pons area/midbrain area x middle cerebellar peduncle width/superior cerebellar peduncle width)
    - Allows discrimination of patients with PSP from MSA-P, PD, and control with 100% sensitivity, 100 % specificity, and 100% PPV
  - AP midbrain diameter < 17 mm
- T2WI
  - Decreased AP diameter of midbrain on axial T2WI < 17 mm, 75% positive predictive value in differentiating PSP from MSA
  - Hyperintense signal in midbrain tegmentum = periaqueductal
  - Prominent mesencephalic cisterns and enlarged 3rd ventricle
  - Occasionally abnormal hypointense signal in striatum
- DWI
  - ↑ ADC in putamen might discriminate PSP from PD
  - ↑ ADC in decussation of superior cerebellar peduncles
- DTI
  - ↑ mean diffusivity in decussation of superior cerebellar peduncle
  - DTI indices (fractional anisotropy, mean diffusivity) demonstrate widespread white matter abnormalities
  - ↑ mean diffusivity in midbrain of PSP patients compared with PD & MSA

Nuclear Medicine Findings

- PET
  - 18 F-FDG ↓ in putamen, thalamus, medial frontal cortex, & midbrain
  - 11C-raclopride PET ↓ striatal dopamine receptor binding
  - Fluorodopa-PET: Reduction of F-dopa uptake in caudate, putamen (more severe than in PD)
- SPECT
  - I-123-IBZM SPECT: Reduced dopamine receptor binding in striatum

DIFFERENTIAL DIAGNOSIS

Multiple System Atrophy, Parkinsonian Type (MSA-P)

- T2 hypointensity in putamen without prominent midbrain atrophy
- Cerebellar and pontine atrophy
- Prominent cerebellar symptoms, autonomic dysfunction, parkinsonism

Corticobasal Degeneration

- Severe frontoparietal atrophy in asymmetrical pattern
- Unilateral parkinsonism
- "Alien limb" phenomenon, cortical sensory deficit

Dementia With Lewy Bodies

- Cortical atrophy without prominent midbrain atrophy
- Hallucinations, cortical dementia with aphasia, Parkinsonism

Parkinson Disease

- No prominent midbrain atrophy

https://CafePezeshki.IR

- Tremor-dominant clinical symptoms, good response to levodopa

PATHOLOGY

General Features

- Etiology
  - PSP is a tauopathy
  - Abnormal accumulation of phosphorylated tau protein in brain
    - Pallidum, subthalamic nucleus, red nucleus, substantia nigra, pontine tegmentum, striatum, oculomotor nucleus, medulla, dentate nucleus
- Genetics
  - Associated with tau, *MTAP* gene on chromosome 17
- Tau haplotype H1 associated with both PSP and corticobasal degeneration
  - Suggests that gene on chromosome 17 for tau abnormality causes both diseases

Gross Pathologic & Surgical Features

- Atrophy of subthalamic nucleus and brainstem (midbrain tectum and superior cerebellar peduncle)
- Loss of pigmentation in substantia nigra → nigrostriatal dopaminergic degeneration

Microscopic Features

- Neuronal loss, astrocytic gliosis
- Neurofibrillary tangles and neuropil threads in globus pallidus, subthalamic nucleus, substantia nigra; cerebral cortex relatively preserved except for perirolandic cortex
- Tau pathology is also noted in glia: Tufted astrocytes, coiled bodies of oligodendrocyte

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 2 PSP phenotypes
  - PSP-RS (Richardson syndrome)
    - Classic, more common presentation of lurching gait, axial dystonia, vertical supranuclear palsy
  - PSP-P (Parkinsonian type) 1/3 patients
    - Bradykinesia, rigidity, normal eye movements, & transient response to levodopa
  - Personality change, memory problems, sleep disturbance, apathy
- Most common cause of atypical parkinsonian syndrome
  - 2nd most common neurodegenerative cause of parkinsonism overall
- Clinical criteria for "probable" PSP
  - Gradually progressive bradykinetic disorder
  - Onset at age 40 or later
  - No evidence for competing diagnostic possibilities
  - Vertical gaze palsy
  - Slowing of vertical saccades and prominent postural instability with falls in 1st year
  - Exclusion criteria
    - Recent encephalitis, alien limb syndrome, cortical sensory defects or temporoparietal atrophy, psychosis unrelated to dopaminergic treatment, important cerebellar signs, severe, asymmetric parkinsonian signs, relevant structural abnormality of basal ganglia on neuroimaging

Demographics

- Age
  - Generally 45-75 years
  - Peak onset: 63 years
- Gender
  - Slight male predominance
- Epidemiology
  - 5-6 cases per 100,000

Natural History & Prognosis

- Disease course variable
- Survival from time of symptom onset in PSP ranges from 5.3 to 9.7 years
- Neuropsychiatric symptoms develop > 50 % patients within 2 years of disease onset

Treatment

- Symptomatic
- Levodopa may help the rigidity and bradykinesia of PSP
- Mitochondrial nutrient coenzyme Q10 can give modest benefit

Variant PSP Syndrome

- PSP-parkinsonism
- PSP-pure akinesia with gait freezing
- PSP-corticobasal syndrome
- PSP-progressive nonfluent aphasia

DIAGNOSTIC CHECKLIST

Consider

- Consider PSP when MR shows marked midbrain atrophy in patients with atypical parkinsonism, vertical gaze palsy, and cognitive dysfunction

Image Interpretation Pearls

- Sagittal images helpful in identifying "penguin silhouette" sign
- Minimal or no lobar atrophy

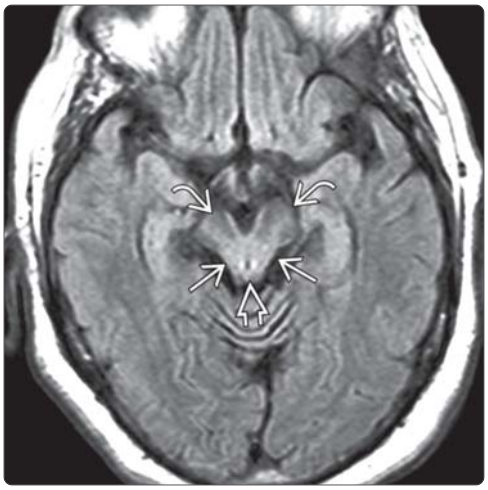
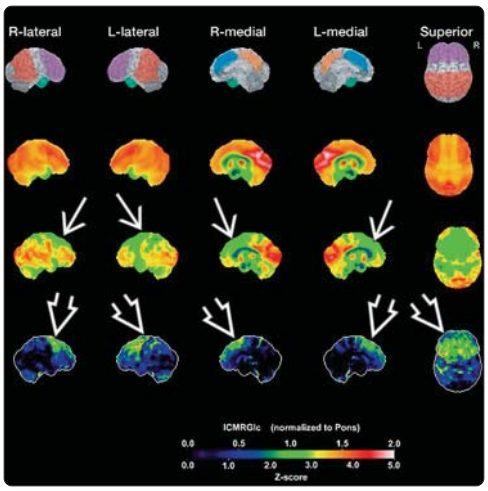
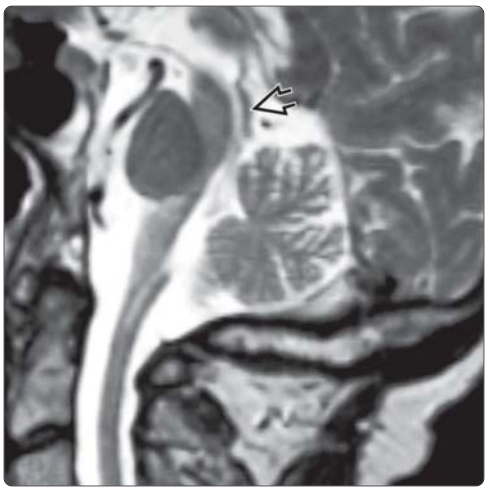
(Left) *Sagittal T1WI MR in a patient with progressive supranuclear palsy shows markedly atrophy of the midbrain relative to pons. There is upper concavity of the midbrain tegmentum with a "penguin" or "hummingbird" sign and thinning of superior tectum.* **(Right)** *Axial T2 MR in the same patient shows abnormal concavity of the lateral margin of midbrain tegmentum referred to as the " morning glory" or "Mickey Mouse" sign.*



(Left) *Sagittal T1WI MR (3D MP-RAGE) in an 80-year-old woman with PSP shows striking midbrain volume loss, with the "penguin" or "hummingbird" sign manifested by a concave upper border of the midbrain. Note extreme thinning of the tectal plate. An incidental subependymoma was found.* **(Right)** *Axial FLAIR MR in the same patient shows the tectal plate is extremely thin, the lateral aspects of the midbrain are concave ("morning glory" sign), and the cerebral peduncles are atrophic.*





(Left) *PET scan with stereotaxic surface projections in the same patient: The top row is the reference map. The 2nd row illustrates glucose metabolism in elderly normal controls (n = 27). The 3rd row is the patient's glucose metabolism map. The 4th row is the Z-score map. The glucose metabolism and Z-score maps show markedly reduced metabolism in both frontal lobes. (Courtesy N. Foster, MD.)* **(Right)** *Sagittal T2WI MR in a patient with PSP shows diminished midbrain volume and thinned tectum.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Amyotrophic lateral sclerosis (ALS)
- Selective degeneration of somatic motor neurons of brainstem/spinal cord and large pyramidal neurons of motor cortex
  - Eventual loss of corticospinal tract (CST) fibers

IMAGING

- Small percentage demonstrate CST hyperintensity
- As CST is normally slightly hyperintense especially at 3.0 T, this finding lacks sensitivity & specificity
- T2 hyperintense CST may be specific for ALS when seen on corresponding PD images
- Consider FLAIR and PD in suspected ALS
- DWI hyperintensity (↓ diffusivity) in CST
- Hypointense GM in precentral gyrus (motor cortex)

TOP DIFFERENTIAL DIAGNOSES

- Primary lateral sclerosis
- Wallerian degeneration
- Hypertrophic olivary degeneration
- Metabolic diseases involving bilateral CSTs
- Demyelinating and inflammatory diseases
- Neoplasms: Brainstem glioma, malignant lymphoma
- CST can appear hyperintense on 3T MR normally

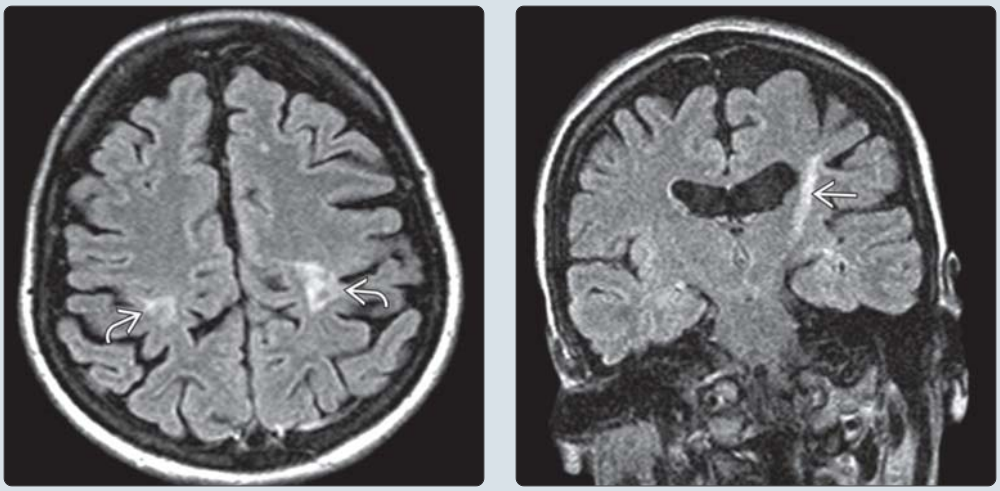
PATHOLOGY

- Majority of ALS cases are sporadic (sALS)
- 15-20% are familial (fALS)

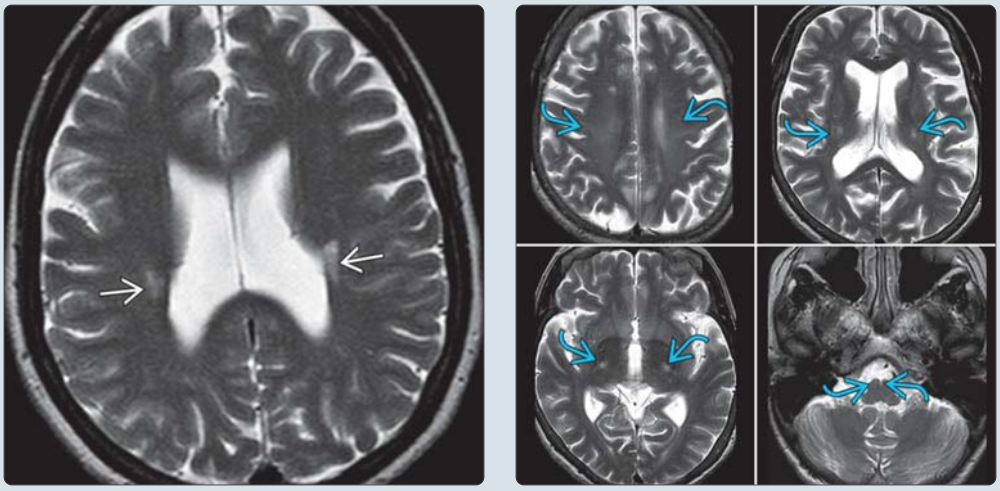
CLINICAL ISSUES

- UMN signs: Babinski sign, spasticity, hyperreflexia
- LMN signs: Asymmetric muscle weakness, atrophy, fasciculations, hyporeflexia
- Bulbar signs: Slurred speech, dysphagia
- Onset usually between 4th-7th decades of life
- Complete disability and death within a decade

(Left) *Axial FLAIR MR shows increased signal in the precentral gyri in this ALS patient. There is also atrophy of bilateral motor cortices.* **(Right)** *Coronal FLAIR MR shows linear hyperintensity along the corticospinal tract (CST) from the precentral gyrus to the cerebri crus. Right CST signal abnormality is out of this imaging slice. Hyperintensity of the precentral gyrus subcortical white matter on FLAIR is a potentially useful and specific sign of ALS that is not seen in healthy, asymptomatic patients.*



(Left) *Axial T2WI FS MR demonstrates ovoid hyperintensity along the CSTs bilaterally. The atrophy and hyperintensity are due to myelin loss and gliosis. There is frequently involvement of the prefrontal motor neurons, which play a role in planning or orchestrating the work of the upper and lower motor neurons.* **(Right)** *Axial T2 MR in a patient with ALS shows hyperintensity along the course of the corticospinal tracts (CST) bilaterally. Important to note that CST is typically slightly hyperintense on T2 especially at 3.0 T.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Amyotrophic lateral sclerosis (ALS)

Synonyms

- Lou Gehrig disease, motor neuron disease (MND)

Definitions

- Selective degeneration of somatic motor neurons of brainstem/spinal cord (lower motor neurons [LMN]) and large pyramidal neurons of motor cortex (upper motor neurons [UMN])
  - Eventual loss of corticospinal tract (CST) fibers

IMAGING

General Features

- Best diagnostic clue
  - Bilateral hyperintensities along CST extending from corona radiata to brainstem on T2WI/PD/FLAIR
- Location
  - Hallmark is CST and LMN degeneration
    - LMN in anterior horn of spinal cord and brainstem
    - Corticospinal UMN in precentral gyrus (motor cortex)
  - White matter (WM) and gray matter (GM)
- Size
  - Atrophy of motor system, particularly pyramidal tract, in advanced stages of ALS
- Morphology
  - Oval or thin curvilinear hyperintensities conforming to CST

CT Findings

- NECT
  - Serial CT exams may show progressive atrophy
    - Frontal, anterior temporal lobes → precentral gyrus → postcentral gyrus, anterior cingulate gyrus, corpus callosum, tegmentum

MR Findings

- T1WI
  - Different T1 appearances of CST
    - Isointensity (most common) may reflect ↑ content of free radicals
    - Hypointense or mild hyperintense signal
- T2WI
  - Small percentage demonstrate CST hyperintensity
  - Hyperintensity can occur anywhere from subcortical white matter of precentral gyrus to posterior limb internal capsules, cerebral peduncles, & pons
  - As CST is normally slightly hyperintense especially at 3.0 T, this finding lacks sensitivity & specificity
  - T2 hyperintense CST may be specific for ALS when seen on corresponding PD images
  - Hypointense GM in precentral gyrus (motor cortex)
    - Nonspecific; may be due to iron and heavy metals accumulation in cortex of aged patients
- PD/intermediate
  - Hyperintense CST
- FLAIR
  - More sensitive and less specific than T2 FSE for detecting hypointensity in precentral gyrus
  - Hyperintense CST
- DWI
  - Hyperintensity in CST
    - May be seen in the absence of T2 hyperintensity
- Diffusion tensor imaging (DTI)
  - ROI-based approaches & tractography demonstrates significant changes in diffusion parameters along CST
  - Most common finding: ↓ fractional anisotropy (FA) in CST due to neuronal degeneration of UMN
  - FA ↓ demonstrated at all levels of CST; most significant reduction in posterior limb internal capsule
  - FA correlates with UMN involvement, disease severity
  - ↑ mean diffusivity (MD) along CST
  - MD more constant over different levels of CST; tends to be elevated at cranial level of CST
    - MD positively correlates with disease duration
- ^{1}H-MRS useful for assessing UMN involvement
  - ↓ NAA, ↓ NAA/Cr, ↓ NAA/Cho, & ↓ NAA/(Cr + Cho) in motor cortex
  - NAA present primarily in neurons; these metabolic changes reflect loss or dysfunction of motor neurons
  - ↓ NAA/Cr & NAA/Cho ratio along CST; most pronounced in precentral gyrus & corona radiata
  - ↓ NAA in pons & upper medulla in patients with prominent UMN or bulbar signs
  - ↑ Cho in posterior limb internal capsule
  - ↑ myo-inositol in motor cortex
- Magnetization-transfer ratio (MTR) measurements
  - ↓ MTR in posterior limb of IC in ALS
  - CST hyperintensity on T1 MT contrast-enhanced images: 80% sensitivity, 100% specificity
  - May detect CST degeneration of ALS at early stage
- Voxel-based morphometry (VBM)
  - Regional gray matter loss in motor cortex, frontal, temporal, parietal & limbic regions
  - Frontal severe atrophy in ALS & frontotemporal dementia
  - WM loss in corpus callosum, cerebellum, frontotemporal & occipital regions
  - Global brain atrophy relatively mild
- Functional MR
  - Pattern of cortical reorganization
  - ↑ activation of contralateral sensorimotor cortex, supplementary motor area, basal ganglia, & cerebellum during motor tasks

Nuclear Medicine Findings

- PET, Tc-99m-HMPAO SPECT
  - ↓ regional cerebral metabolism or perfusion throughout brain
  - ↑ ALS severity correlated with ↓ gray matter perfusion

Imaging Recommendations

- Best imaging tool: MR with T2, PD, FLAIR, DTI

DIFFERENTIAL DIAGNOSIS

Primary Lateral Sclerosis

- Neurodegeneration restricted to UMN
  - T2WI shows changes in motor pathways

https://CafePezeshki.IR

- Autosomal recessive disease with juvenile onset

Wallerian Degeneration

- Dynamic signal intensities change along CST in patients with various cortical/subcortical lesions

Hypertrophic Olivary Degeneration

- Secondary degeneration of inferior olivary nucleus (ION), usually caused by primary lesions in dento-rubro-olivary pathway

Conditions With T2 Hyperintense Lesions Along CST

- Metabolic diseases may involve CST bilaterally
  - X-linked adrenoleukodystrophy, Wilson disease
  - Hypoglycemic coma: Reversible CST changes
- Demyelinating and inflammatory diseases
  - Multiple sclerosis, ADEM, Behçet disease, AIDS, cervical myelopathy
- Neoplasms: Brainstem glioma, malignant lymphoma

Normal Individuals

- CST can appear hyperintense on 3T MR (normal fully myelinated brain at any age) and mimic ALS

PATHOLOGY

General Features

- Etiology
  - Etiology of sporadic ALS (sALS) is largely unknown
  - Pathological hallmarks include loss of MNs with intraneuronal ubiquitin-immunoreactive inclusions in UMN and TDP-43 immunoreactive inclusions in degenerating LMN
  - Increased expression of cyclooxygenase-2 in spinal cord, frontal cortex, and hippocampus
  - Apoptosis, free radical-mediated oxidative stress, excessive glutamate-mediated excitotoxicity
  - Biochemical studies have shown ↓ glutamate levels in CNS tissue and ↑ levels in CSF
- Genetics
  - Majority of ALS cases are sporadic (sALS)
  - 15-20% of ALS cases are familial (fALS)
    - 10-20% of fALS cases are caused by mutations in copper/zinc superoxide dismutase 1 gene (*SOD1*) on chromosome 21q
  - Rare autosomal recessive juvenile-onset ALS
    - *ALS2* gene on chromosome 2q encodes alsin
- Associated abnormalities
  - ALS-plus syndrome: Typical ALS phenotype associated with dementia, parkinsonism, or both
    - 2–3% of cases, ALS is accompanied by frontotemporal dementia
    - ~ 50% of cases show cognitive impairment
  - ALS-like motor neuron disease can occur as paraneoplastic syndrome

Gross Pathologic & Surgical Features

- Focal atrophy of motor cortex & along course of CST
- Atrophy of anterior & lateral portions of spinal cord

Microscopic Features

- Loss of cortical pyramidal motor neurons and astrocytosis
- Histologically uneven involvement of CST showing variable patterns of degeneration
- "Senescent changes" with lipofuscin pigment atrophy
- Proximal and distal axonopathy with axonal spheroids
- Surviving motor neurons are smaller and abnormal

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - UMN signs: Babinski sign, spasticity, hyperreflexia
  - LMN signs: Asymmetric muscle weakness, atrophy, fasciculations, hyporeflexia
  - Bulbar signs: Slurred speech, dysphagia
  - Difficulty walking, unexplained weight loss
- Clinical profile
  - Classic ALS: Both UMN and LMN affected
  - UMN-dominant ALS can be difficult to distinguish from primary lateral sclerosis
  - Predominantly bulbar form usually leads to more rapid deterioration and death
  - fALS associated with *SOD1* abnormality has mean age at 42 years limb onset, slow evolution

Demographics

- Age
  - Onset usually between 4th-7th decades of life
- Gender
  - M:F = 1.5:1
- Epidemiology
  - Incidence: 1-2 cases/100,000 persons
  - Prevalence: 5.2/100,000 persons

Natural History & Prognosis

- Progressive (distal to proximal)
  - Median survival from diagnosis to death: 3-4 years
  - 10% of patients survive > 10 years
- Some patients with familial, juvenile-onset ALS survive for longer periods (2-3 decades)

Treatment

- Riluzole (glutamate release inhibitor and insulin-like growth factor) may prolong survival
  - ↑ NAA/Cr in precentral gyrus and supplementary motor area after riluzole therapy

DIAGNOSTIC CHECKLIST

Consider

- FLAIR and PD in all patients with suspected ALS

Image Interpretation Pearls

- High-signal intensity in posterior limb of IC is suggestive for ALS when also visible on PD
- T1- and PD-weighted images differentiate real degeneration from normal areas
- DTI can assess CST lesions before pyramidal symptoms

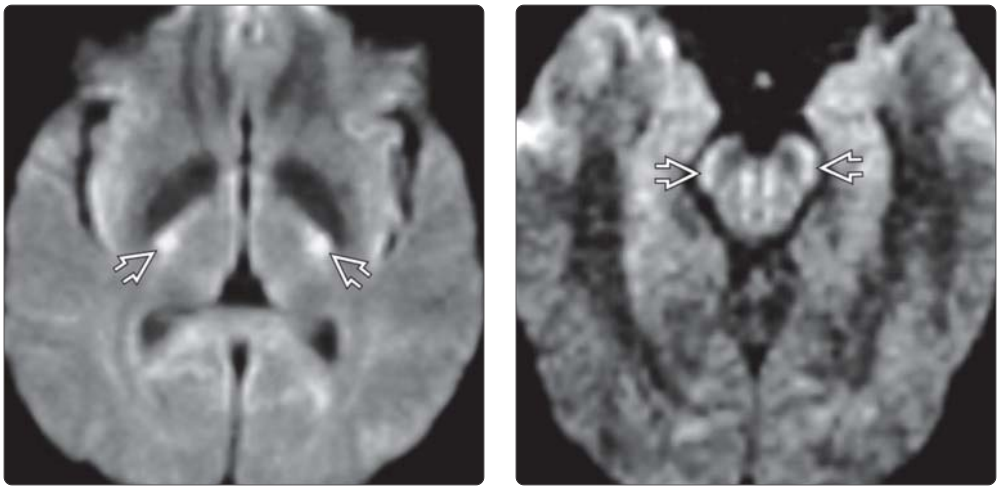
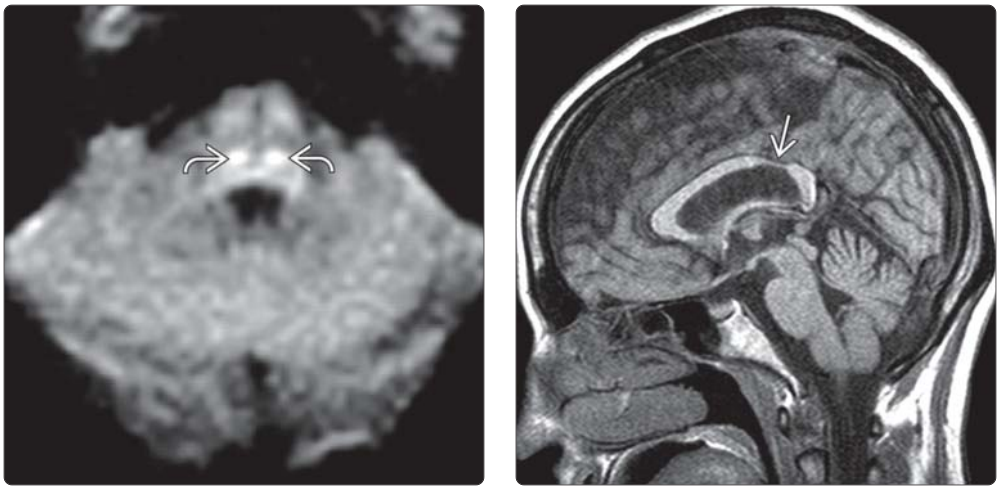
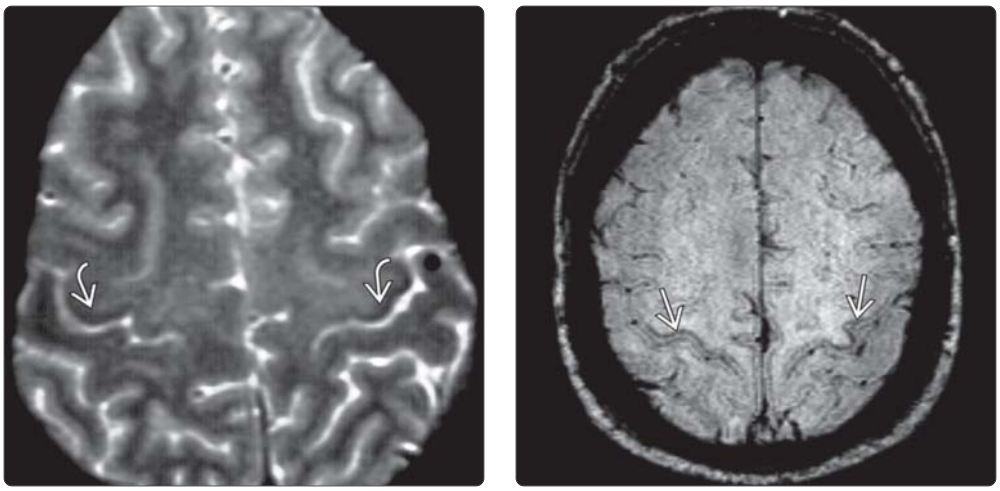
https://CafePezeshki.IR



(Left) *Axial DTI trace image shows symmetric hyperintensity in the internal capsule posterior limbs ⇨. Fractional anisotropy (FA) correlates with measures of disease severity and UMN involvement, whereas the mean diffusivity correlates with disease duration.* **(Right)** *Axial DWI MR shows round hyperintensities in bilateral cerebral peduncles ⇨. Signal abnormality can be seen in the precentral gyrus, centrum semiovale, posterior 3rd of posterior limb of internal capsules, cerebral peduncles, and ventral brainstem.*



(Left) *Axial DWI MR shows oval hyperintensities corresponding to CSTs in the pons ⇨. DWI/DTI can help differentiate progressive muscular atrophy (no change in FA or MD) from ALS (↑ MD, ↓ FA), which can be clinically difficult.* **(Right)** *Sagittal T1WI MR shows atrophy of the posterior corpus callosum body ⇨. DTI showed ↓ FA in the corpus callosum. Voxel-based morphometry has a high sensitivity in detecting local tissue atrophy in the motor cortex and along the corticospinal tracts.*



(Left) *Axial T2WI FS MR shows central cortical hypointense signal intensity ⇨ in the precentral gyri due to iron deposition. While this is common in ALS patients, it is nonspecific and may be seen in aged patients due to iron and heavy metals accumulation.* **(Right)** *Axial T2* SWI MR demonstrates curvilinear hypointensity along the cortical gray matter of bilateral precentral gyri ⇨. The T2* SWI technique accentuates the T2 hypointensity seen in the precentral gyrus gray matter of ALS patients.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

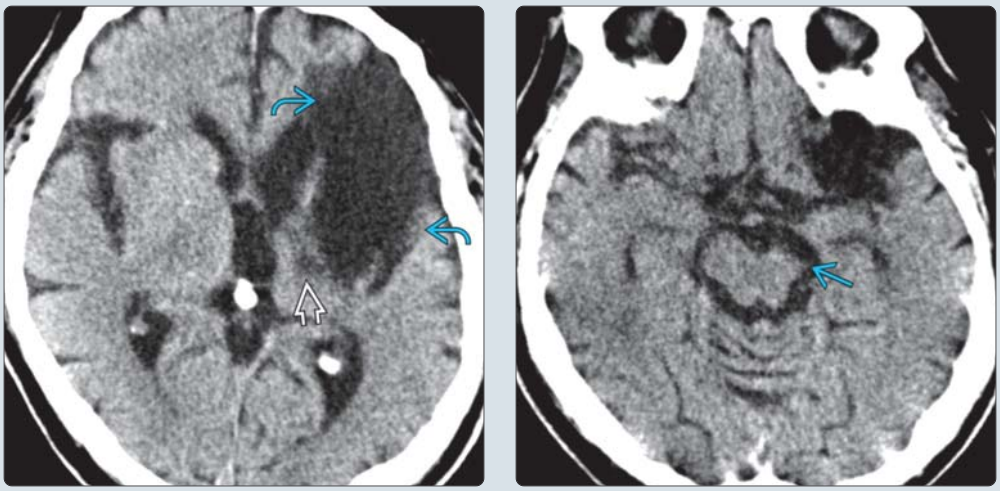
- Wallerian degeneration (WaD)
- Secondary anterograde degeneration of axons and their myelin sheaths caused by interruption of the axonal integrity or damage to the neuron

IMAGING

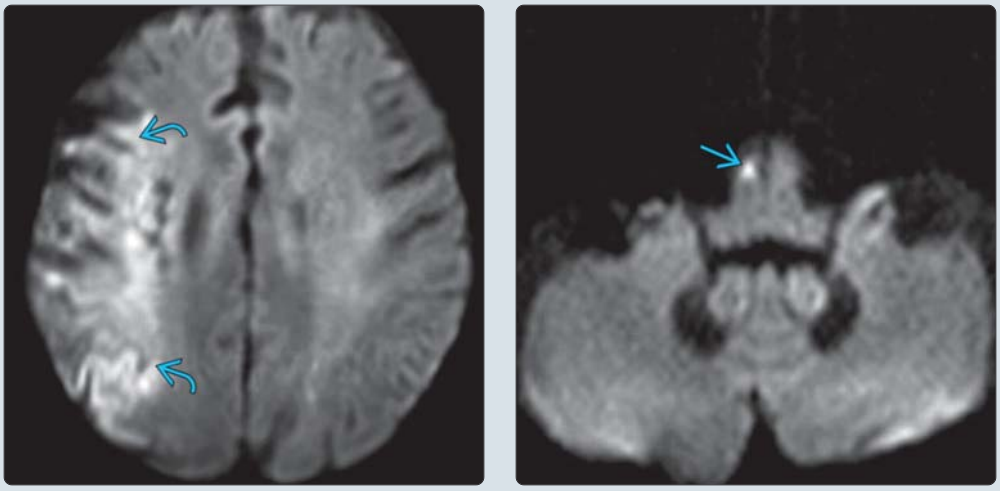
- Primary lesion is cortical or subcortical with WaD in descending white matter (WM) tracts ipsilateral to neuronal injury
  - WaD can be seen in fibers crossing the corpus callosum, fibers of optic radiations, fornices, and cerebellar peduncles
- CT is not sensitive for WaD in acute-subacute stages
  - Detects atrophy of CSTs in chronic stage
- Time-dependent changes in CSTs on MR
  - Strong correlation between WaD detected on T2WI and DWI and long-term morbidity
  - DWI findings precede development of WaD assessed by conventional MR
- DTI may distinguish between primary lesion and associated WaD
  - Reduced fractional anisotropy (FA) with increased mean diffusivity (MD) in infarct
  - Reduced FA with preserved MD in CST

TOP DIFFERENTIAL DIAGNOSES

- Neurodegenerative diseases
- Brainstem glioma
- Demyelinating and inflammatory diseases
- Hypertrophic olivary degeneration
- Metabolic diseases
- Intoxication (heroin inhalation)
- Normal appearance of hyperintensity on high field strength MR



(Left) *Axial NECT shows encephalomalacia in the left frontal and temporal opercula related to a chronic stroke. Hypodensity and volume loss in the thalamus is likely due to wallerian degeneration of the corticothalamic fibers.* **(Right)** *Axial NECT in the same patient shows atrophy of the left cerebral peduncle due to chronic wallerian degeneration of the corticospinal tracts. NECT is not sensitive for acute-subacute stages but detects atrophy of the pyramidal tracts in the chronic stage of wallerian degeneration.*



(Left) *Axial DWI image demonstrates restricted diffusion in the right frontal and parietal lobes due to an acute infarct in the right MCA distribution.* **(Right)** *Axial DWI image in the same patient demonstrates restricted diffusion in the ventral medulla in the region of the corticospinal tract due to acute wallerian degeneration. DWI is more sensitive at detecting early Wallerian degeneration when compared to standard MR sequences.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Wallerian degeneration (WaD)

Definitions

- Secondary anterograde degeneration of axons and their myelin sheaths caused by interruption of the axonal integrity or damage to the neuron

IMAGING

General Features

- Best diagnostic clue
  - Contiguous T2 hyperintensity along topographic distribution of corticospinal tract (CST) in internal capsule (IC) and brainstem in patients with various cerebral pathologies
- Location
  - Primary lesion: Cortical or subcortical
  - WaD: Descending white matter (WM) tracts ipsilateral to neuronal injury
    - CST, corticobulbar, corticopontine tracts
  - WaD can be seen in corpus callosum, optic radiations, fornices, and cerebellar peduncles
  - Corpus callosum has been shown to be susceptible to atrophy in Alzheimer disease mainly as correlate of wallerian degeneration of commissural nerve fibers of neocortex
  - Seizure-induced damage may cause secondary white matter degeneration along tapetum and through splenium of corpus callosum
- Morphology
  - Signal changes conforming to WM tract shape
    - Oval regions in posterior limb of IC and cerebral peduncle; thin curvilinear regions in pons

CT Findings

- NECT
  - Not sensitive for WaD in acute-subacute stages
  - Detects atrophy of CSTs in chronic stage
    - ↓ size of corresponding aspect of brainstem

MR Findings

- T1WI
  - Time-dependent changes in descending WM tracts
    - Stage 1: No changes
    - Stage 2: T1 hyperintense
    - Stage 3: T1 hypointense
    - Stage 4: Ipsilateral brainstem atrophy ± hypointensity
- T2WI
  - Time-dependent changes in descending WM tracts
    - Stage 1: No changes in adult CNS
    - Stage 2: T2 hypointense
    - Stage 3: T2 hyperintense
    - Stage 4: Atrophy, best seen in brainstem
      - Sometimes, T2 hyperintense signal may persist
  - Neonates and infants: Identification of WaD by T2WI complicated by high water content and lack of myelination in immature WM
  - Adults: Strong correlation between T2WI detected WaD and long-term morbidity
- FLAIR
  - Same as T2WI
- DWI
  - Neonates and infants: Indicates acute WM injury
    - DWI findings precede development of WaD assessed by conventional MR
    - May portend poor clinical outcome
  - Adults: Correlation of DW changes in descending motor pathways at presentation with long-term neurologic disability
  - Extent and severity of territorial ischemia is related to development of descending WM tract injury detectable by DWI
  - Hyperintense DW signal intensity and ↓ ADC values within territorial infarct and ipsilateral CST
    - DW and ADC time courses in region of territorial injury and CST injury may be different
      - Relatively delayed development of diffusion abnormality in descending WM tracts
  - DW signal intensity abnormality in descending WM tracts may persist, even as DW hyperintensity in ipsilateral cerebral hemisphere fades
- T1WI C+
  - No contrast enhancement of degenerated tracts
- MRS
  - ^{1}H-MRS enables in vivo assessment of axonal injury based on signal intensity of N-acetyl aspartate (NAA)
  - ↓ NAA concentration in normal-appearing WM in pons and cerebellar peduncles in early stages of relapsing-remitting multiple sclerosis (MS)
    - Correlates best with disability, MS duration, and relapse rate
- Diffusion tensor imaging (DTI)
  - Myelin breakdown leads to ↓ diffusion anisotropy
  - Reduced FA with increased mean diffusivity (MD) in infarct
  - Reduced FA with preserved MD in CST
  - In patients with motor pathway infarction, diffusion indices in degenerated CST stabilize within 3 months and early changes in CST FA may predict long-term clinical outcomes

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - DWI allows early detection (stage 1)
  - T2WI detects changes after 4 weeks

DIFFERENTIAL DIAGNOSIS

Neurodegenerative Diseases

- Amyotrophic lateral sclerosis (upper &/or lower motor neuron involvement)
  - Bilateral hyperintensities along CST extending from corona radiata to brainstem on T2WI/PD/FLAIR
- Primary lateral sclerosis and infantile-onset hereditary spastic paraplegia
  - Upper motor neuron degeneration only

Brainstem Glioma

- T2 hyperintense mass ± enhancement

https://CafePezeshki.IR

Demyelinating and Inflammatory Diseases

- Multiple sclerosis: Periventricular T2 hyperintensity
- ADEM: Asymmetric T2 hyperintensity in white and gray matter after viral prodrome
- Behçet disease: Enlarged, T2 hyperintense brainstem ± thalamus

Hypertrophic Olivary Degeneration

- Secondary degeneration of inferior olivary nucleus (ION), usually caused by primary lesions in dentato-rubro-olivary pathway

Metabolic Diseases

- X-linked adrenoleukodystrophy: Enhancing peritrigonal demyelination
- Wilson disease: White and gray matter lesions involving basal ganglia, dentate nucleus, brainstem
- Hypoglycemic coma: Reversible CST changes

Heroin Inhalation

- Symmetric T2 hyperintensity in posterior WM, including posterior limb of internal capsule

Normal Individuals

- CST can appear T2/FLAIR hyperintense on 3T MR (normal fully myelinated brain)

PATHOLOGY

General Features

- Etiology
  - Infarction, hemorrhage, neoplasm, encephalitis
  - Demyelinating disease, trauma, AV malformations
  - Reported also in patients with movement disorder
- Genetics
  - Process of axonal degeneration is genetically regulated
- Associated abnormalities
  - Primary lesion/disorder that caused secondary WM tract degeneration

Staging, Grading, & Classification

- Stage 1 (0-4 weeks): Degradation of axon; mild changes in myelin
- Stage 2 (4-14 weeks): Myelin protein breakdown; lipids remain intact
- Stage 3 (> 14 weeks): Myelin lipid breakdown, gliosis, changes in water content and structure
- Stage 4 (after months to years): Atrophy of ipsilateral brainstem

Gross Pathologic & Surgical Features

- Brainstem asymmetry due to atrophy in chronic stage

Microscopic Features

- Stage 1: Beginning of myelin and axon breakdown
  - Myelin sheaths break up into ellipsoids and spheres but retain myelin staining properties
- Stage 2: Decreased protein:lipid ratio
- Stage 3: Increased edema and further lipid breakdown
- Stage 4: Atrophy due to volume loss; removal of axonal debris by microglia continues for 2 years (vs. completed in 3 weeks in peripheral nervous system)
- Expression of transcription factors ATF3 and c-Jun by nonneuronal cells during WaD
- In CNS, astrocyte-dominated matrix fails to accommodate new axonal growth

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - WaD in CST is associated with persistent hemiparesis

Demographics

- Age
  - Reported in all ages
- Gender
  - No gender preference
- Epidemiology
  - WaD commonly follows CNS lesions
    - WaD in pyramidal tract reported in 78.6% of cases of capsular infarct

Natural History & Prognosis

- WaD may begin within 1 week of fiber tract damage
- Demyelination can continue during next 6 months
- Signifies irreversible loss of neuronal function
- Extent of WaD is related to severity of motor deficit
  - Abnormal DWI signal in CST can be acute predictor of motor outcome in childhood infarction

Treatment

- No specific therapy

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- In ischemic stroke: Important to differentiate DWI abnormality related to WaD from additional infarction
- Time-specific signal intensity changes of WaD → able to ascertain age of primary lesion

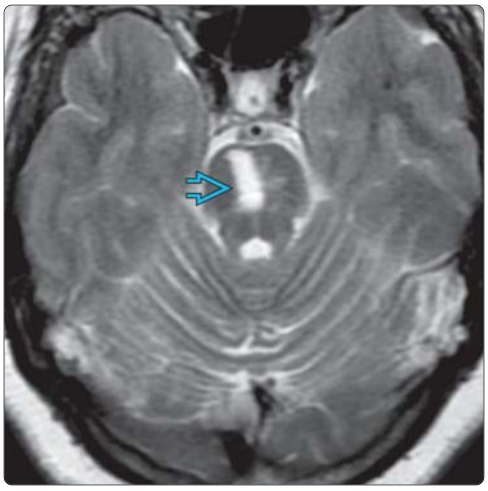
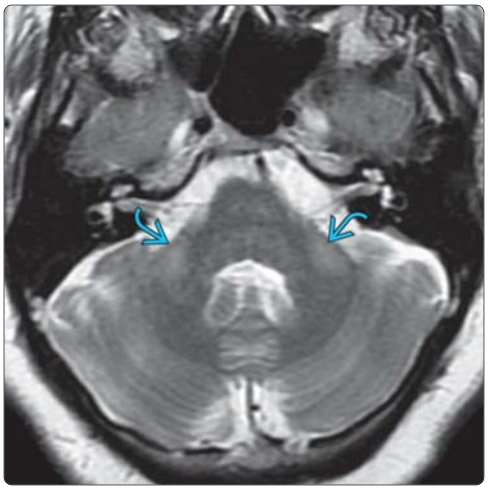
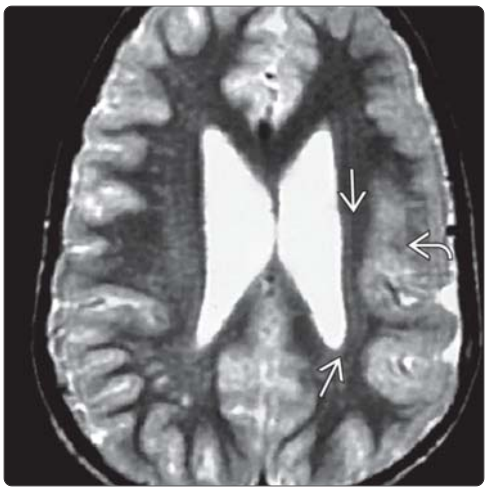
(Left) *Axial T2 MR images demonstrate an old infarct in the distribution of the left MCA. There is T2 hyperintensity with atrophy of the left cerebral peduncle due to wallerian degeneration of the corticospinal tract. T2 hyperintensity is also noted along the entire course of the corticospinal tract.* **(Right)** *Coronal T1WI C+ MR shows an infiltrative, enhancing mass along the left corona radiata. Note T1 hypointensity along the corticospinal tract due to wallerian degeneration caused by lipid breakdown and edema.*





(Left) *Axial T2 MR shows an old infarct involving the right half of the pons.* **(Right)** *Axial T2 MR in the same patient shows mild atrophy of both middle cerebellar peduncles (MCP) with T2 hyperintensity due to wallerian degeneration. This is as a result of the decussation of fibers in the pons. An infarct in the pons affects the nuclei and the tracts in the pons at the site of the infarct which pass to the contralateral middle cerebellar peduncle and also the tracts passing across from the contralateral nuclei.*



(Left) *Axial T2WI MR shows a left hemispheric lissencephaly with pachygyria. When due to toxins or infections, as in this case, reactive gliosis with macrophage infiltration disturbs neuronal migration, resulting in abnormal cortex and sparse underlying white matter.* **(Right)** *Axial T1WI MR in the same patient shows a diminutive left cerebral peduncle. This neuronal migrational abnormality results in 4-layer cortex with sparse underlying white matter. There is consequent hypoplasia of the corticospinal tract.*

KEY FACTS

TERMINOLOGY

- Diaschisis = sudden loss of function in brain connected to (but at distance from) damaged area
- CCD = decreased blood flow/metabolism in cerebellar hemisphere contralateral to supratentorial infarct

IMAGING

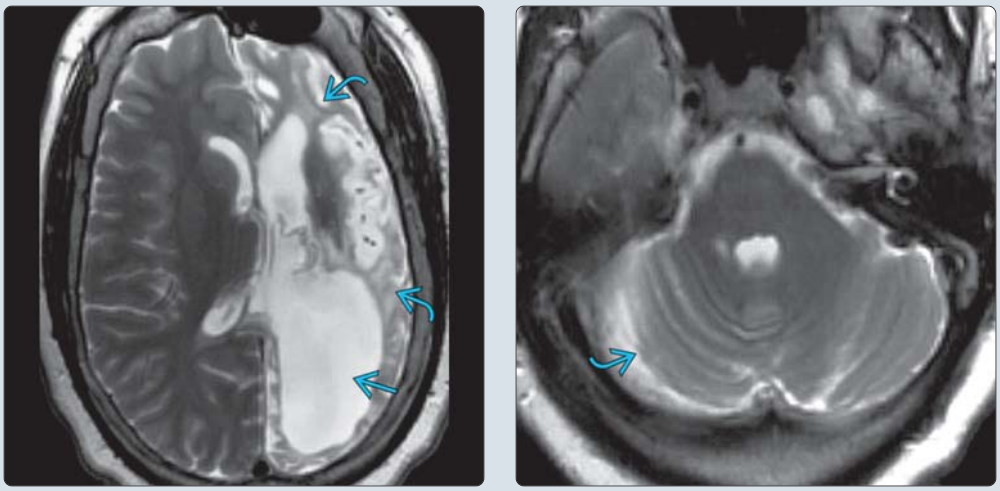
- Acute: CT/MR perfusion shows ↓ CBF in cerebellar hemisphere opposite acute hemispheric infarct
  - ↑ TTP, ↓ CBF in cerebellum contralateral to infarct
  - Add DTI as subtle cases may show ↓ FA when conventional MR normal
  - 18F-FDG PET/CT shows diffusely reduced uptake in contralateral cerebellar hemisphere
- Chronic: CT or MR shows atrophic cerebellar hemisphere opposite old cerebral hemispheric infarct

TOP DIFFERENTIAL DIAGNOSES

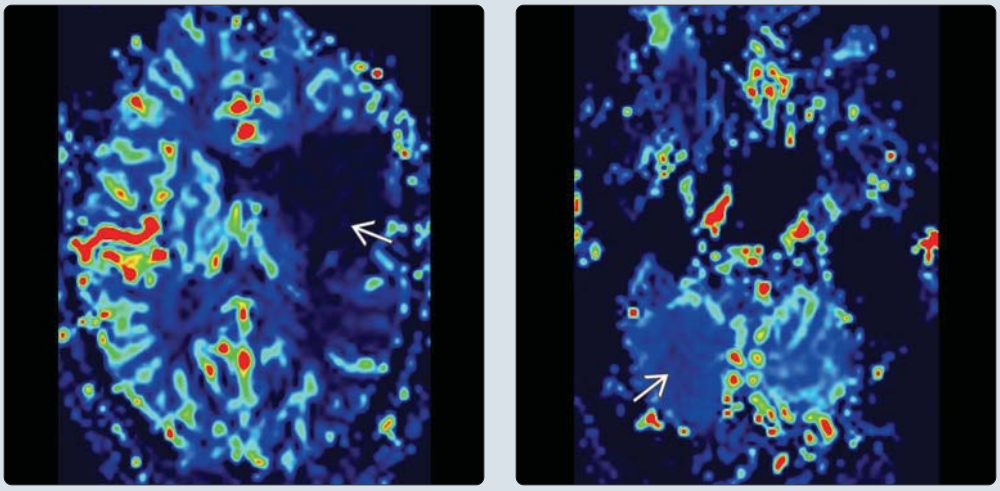
- Superior cerebellar artery infarct
  - CCD involves > just SCA territory
- Encephalomalacia
  - Trauma, infection, surgery
- Cerebellitis
  - Cerebellum swollen, hyperintense (not shrunken, atrophic)

PATHOLOGY

- Corticopontocerebellar (CPC) tract
  - Input to cerebellum via corticopontocerebellar tracts 40x all other afferent sources combined
  - Injury at any point along CPC can result in ↓ CBF, metabolism in contralateral cerebellar hemisphere
  - Most common cause = MCA infarct
  - Others = status epilepticus, neoplasm, trauma, surgery,migraine, Rasmussen encephalitis, etc.



(Left) *Axial T2WI MR in a patient with a remote left middle cerebral artery infarct shows the typical changes of encephalomalacia and volume loss. The ipsilateral ventricle is enlarged.* **(Right)** *Axial T2 MR in the same patient shows volume loss with enlarged horizontal sulci in the contralateral cerebellar hemisphere. These findings are consistent with chronic crossed cerebellar diaschisis.*



(Left) *MR perfusion study CBF (cerebral blood flow) map in a patient with acute right hemiparesis shows diminished blood flow (blue area) in the left middle cerebral artery distribution.* **(Right)** *CBF map in the same patient demonstrates reduced CBF in the right cerebellar hemisphere consistent with acute crossed cerebellar diaschisis (CCD). CCD is caused by an interruption of the corticopontocerebellar fibers. As a result of ↓ afferent input, there is a ↓ in cerebellar metabolism, coupled with a ↓ in cerebellar perfusion.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Crossed cerebellar diaschisis (CCD)

Definitions

- Diaschisis = sudden loss of function in brain connected to (but at distance from) damaged area
- CCD = decreased blood flow/metabolism in cerebellar hemisphere contralateral to supratentorial infarct
  - Caused by interrupted input through corticopontocerebellar tract (CPC)
- CCD occurs in both acute and chronic phases
  - Acute CCD results from functional deafference
  - Subacute, chronic CCD reflects transneuronal degeneration

IMAGING

General Features

- Best diagnostic clue
  - Acute: CT/MR perfusion shows ↓ cerebral blood flow (CBF) in cerebellar hemisphere opposite acute cerebral hemispheric infarct
  - Chronic: CT or MR shows atrophic cerebellar hemisphere opposite old cerebral hemispheric infarct
- Location
  - Cerebellar hemisphere opposite cerebral hemispheric infarct

Imaging Recommendations

- Best imaging tool
  - Acute: CT or MR perfusion
    - PET/CT also effective but expensive; variable availability
  - Chronic: MR with T2WI, FLAIR, DTI
- Protocol advice
  - Add DTI as subtle cases may show ↓ fractional anisotropy when conventional MR normal

CT Findings

- NECT
  - Acute: Normal
  - Chronic: Cerebellar atrophy contralateral to supratentorial infarct
- CTA
  - MCA occlusion
  - Cerebellar vessels appear normal
- CT perfusion
  - ↑ TTP, ↓ CBF in cerebellum contralateral to infarct

MR Findings

- T1WI
  - Unilateral cerebellar atrophy
- T2WI
  - Folia shrunken, fissures enlarged
- FLAIR
  - Except for atrophy, cerebellum usually normal
- MRA
  - Posterior fossa vasculature normal
- DTI
  - Shows ↓ FA in middle cerebellar peduncle
  - Visualizes altered CPC in chronic CCD that may not be seen on conventional MR

Nuclear Medicine Findings

- PET/CT
  - 18F-FDG PET/CT shows diffusely reduced uptake in contralateral cerebellar hemisphere
  - L-(methyl-11C) methionine (MET) uptake not reduced
- Tc-99m sulfur colloid
  - Tc-99m ECD, HMPAO SPECT can demonstrate distant areas of ↓ CBF, metabolism (diaschisis)

DIFFERENTIAL DIAGNOSIS

Superior Cerebellar Artery Infarct

- CCD involves most of cerebellum, not just SCA territory
- Contralateral MCA infarct absent

Encephalomalacia

- No history of trauma, contralateral MCA infarct

Cerebellitis

- Cerebellum swollen, not shrunken

PATHOLOGY

General Features

- Etiology
  - Corticopontocerebellar (CPC) tract
    - Large afferent pathway derived from very extensive areas of cortex
    - Input to cerebellum via corticopontocerebellar tracts 40x all other afferent sources combined
      - 1st-order neurons arrive in ipsilateral pons
      - Synapse with 2nd-order neurons
      - Then cross to opposite cerebellar hemisphere via middle cerebellar peduncle
  - Injury at any point along CPC can result in ↓ CBF, metabolism in contralateral cerebellar hemisphere
    - Most common cause = MCA infarct
    - Others = status epilepticus, neoplasm, trauma, surgery, migraine, Rasmussen encephalitis, etc.

CLINICAL ISSUES

Natural History & Prognosis

- CCD represents temporal continuum
  - Early, reversible functional hypometabolism
    - Cerebellum recovers (typical)
  - Irreversible degeneration in up to 20%
    - Cerebellar atrophy
    - Can be seen decades after initial insult

KEY FACTS

TERMINOLOGY

- Inferior olivary nucleus (ION) degeneration
  - Unique type of trans-synaptic neuronal degeneration
  - Olivary deafferentation thought to be source of ensuing hypertrophic olivary degeneration (HOD)
- Usually caused by primary lesions in dento-rubro-olivary pathway (anatomical triangle of Guillain-Mollaret)
- Triangle of Guillain-Mollaret defined by 3 anatomic structures
  - Dentate nucleus (DN) of cerebellum
  - Ipsilateral red nucleus (RN)
  - ION ipsilateral to RN

IMAGING

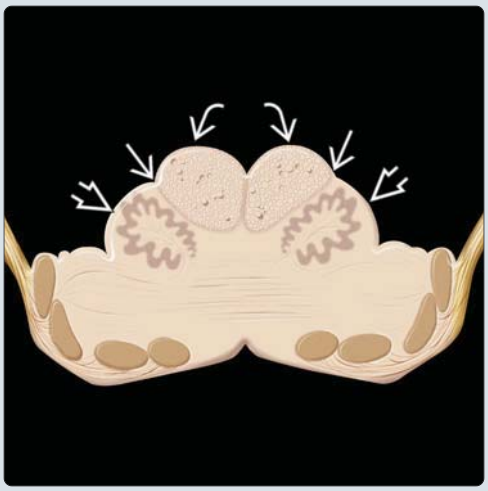
- ION initially hypertrophies rather than atrophies
- 3 distinct MR stages in HOD
  - Hyperintense signal without hypertrophy of ION: Within 1st 6 months of ictus
  - Increased signal + ION hypertrophy: Between 6 months and 3-4 years after ictus
  - Only ION hyperintensity: Begins when hypertrophy resolves (can persist indefinitely)
- MR also detects primary lesion located in ipsilateral central tegmental tract or contralateral DN

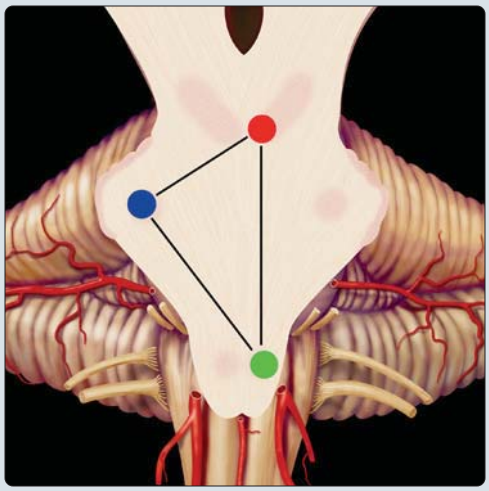
TOP DIFFERENTIAL DIAGNOSES

- Vertebrobasilar perforating artery infarct
- Demyelination (MS, microvascular disease)
- Amyotrophic lateral sclerosis
- HIV/AIDS
- Rhombencephalitis

CLINICAL ISSUES

- Palatal myoclonus (palatal "tremor")
- Usually develops 10-11 months after primary lesion
- Clinical symptoms (tremors) rarely improve





(Left) *Axial graphic of the upper medulla shows the medullary pyramids on each side of the ventral median fissure. The olives lie just posterior to the preolivary sulci.* **(Right)** *Coronal graphic of the midbrain, pons, and medulla is sectioned to depict the Guillain-Mollaret triangle. The triangle of Guillain-Mollaret is composed of the ipsilateral inferior olivary nucleus (green), dentate nucleus (blue) of the contralateral cerebellum, and the ipsilateral red nucleus (red).*

(Left) *Axial T2WI MR (CISS) shows the normal shape of the medullary olives.* **(Right)** *Axial T2WI MR in a patient who developed palatal myoclonus approximately 6 months after resection of a midbrain cavernous malformation shows hyperintensity and enlargement of both olives. This pattern is typical in the subacute stage of hypertrophic olivary degeneration, which typically appears between 6 months and 3-4 years after injury to the dento-rubro-olivary pathway.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hypertrophic olivary degeneration (HOD)

Synonyms

- Pseudohypertrophy of inferior olivary nucleus

Definitions

- Secondary degeneration of inferior olivary nucleus (ION), usually caused by primary lesions in dento-rubro-olivary pathway (anatomical triangle of Guillain and Mollaret)

IMAGING

General Features

- Best diagnostic clue
  - T2 hyperintense, nonenhancing enlargement of ION
- Location
  - Triangle of Guillain and Mollaret defined by 3 anatomic structures
    - Red nucleus (RN)
    - ION ipsilateral to RN
    - Contralateral dentate nucleus (DN) of cerebellum
  - Central tegmental tract connects RN to ipsilateral ION
  - Superior cerebellar peduncle (dentatorubral tract) connects DN to contralateral RN
  - Inferior cerebellar peduncle connects ION to contralateral cerebellar cortex and contralateral DN
  - 3 patterns of HOD in relation to primary lesion
    - Ipsilateral HOD: Primary lesion is limited to brainstem (central tegmental tract)
    - Contralateral HOD: Primary lesion is in cerebellum (DN or superior cerebellar peduncle)
    - Bilateral HOD: Primary lesion involves both central tegmental tract and superior cerebellar peduncle
- Size
  - Variable (time-dependent) size of affected ION
    - Normal in acute stage
    - Increased (hypertrophy) between 6 months to 3-4 years
    - Decreased (atrophy) in advanced stage (> 3-4 years)
- Morphology
  - Unique type of trans-synaptic neuronal degeneration
    - ION initially hypertrophies rather than atrophies

CT Findings

- NECT
  - May show acute primary injury (e.g., hemorrhage) in tegmentum
  - HOD typically not depicted on CT

MR Findings

- T1WI
  - Acute phase: Normal ION
    - Shows primary lesion in brainstem (cerebellum or tegmentum)
  - After HOD ensues
    - Enlargement confined to ION, isointense to slightly hypointense to gray matter
    - Slightly increased olivary T1 signal also reported
    - ± residual primary lesion
- T2WI
  - 3 distinct MR stages in HOD
    - Hyperintense signal without hypertrophy of ION: Within 1st 6 months of ictus
    - Both increased signal and hypertrophy of ION: Between 6 months and 3-4 years after ictus
    - Increased signal only in ION: Begins when hypertrophy resolves and can persist indefinitely
  - Axial MR: Disappearance of pre- and postolivary sulci in hypertrophic stage
  - MR also detects primary lesion located in ipsilateral central tegmental tract or contralateral DN
    - Old hematomas: Low signal areas on T2WI revealing hemosiderin deposition
  - ± decreased size of contralateral ION, with higher than normal signal intensity
  - ± mild to severe atrophic changes of cerebellar cortex contralateral to HOD
- PD/intermediate
  - High signal intensity of ION better detected on PD images than on T2WI
- FLAIR
  - Similar to T2WI
- T1WI C+
  - No contrast enhancement of degenerated ION

Nuclear Medicine Findings

- PET
  - Hypermetabolism of glucose in medulla in patients with HOD

Imaging Recommendations

- Best imaging tool
  - MR imaging
- Protocol advice
  - T2WI (include coronal or sagittal sections)

DIFFERENTIAL DIAGNOSIS

Other Causes of High T2 Signal Intensity in Anterior Part of Medulla

- Demyelination related to multiple sclerosis
- Tumor (astrocytoma, metastasis, lymphoma)
- Lesions involving corticospinal tract
  - Wallerian degeneration, adrenoleukodystrophy
  - Amyotrophic lateral sclerosis
- Vertebrobasilar perforating artery infarct
  - Most medullary infarctions occur in posteroinferior cerebellar artery territory and involve posterolateral medulla (e.g., vertebral artery dissection)
  - Alternatively, medullary infarcts could be related to perforating branches of anterior spinal or vertebral arteries and have paramedial location
- Infectious/inflammatory processes
  - Tuberculosis
  - Sarcoidosis
  - HIV/AIDS
  - Rhombencephalitis

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Transsynaptic degeneration caused by interruption of pathways composing Guillain-Mollaret triangle
  - Olivary deafferentation thought to be source of ensuing HOD
  - Primary lesions usually located in contralateral DN or ipsilateral central tegmental tract
  - Focal brainstem insults that may lead to dentatorubral-olivary pathway interruption
    - Ischemic infarction, demyelination
    - Hemorrhage (related to hypertensive disease, occult cerebrovascular malformation, or diffuse axonal injury following severe head trauma)
    - Cavernous malformation
- Associated abnormalities
  - Primary brainstem insult
    - Most commonly pontine hemorrhage from trauma (including surgery), hypertension, tumor, and infarction
- Olivary enlargement: Histologically unusual vacuolar cytoplasmic degeneration → hypertrophy related in part to ↑ number of astrocytes
- After onset of primary lesion
  - Vacuolar cytoplasmic degeneration in 6-15 months
  - Gliosis follows at 15-20 months

Staging, Grading, & Classification

- 6 phases of pathologic change
  - No olivary changes within 1st 24 hours
  - Degeneration of olivary amiculum (white matter capsule at olive periphery) at 2-7 days or more
  - Olivary hypertrophy (mild enlargement with neuronal hypertrophy, no glial reaction) at 3 weeks
  - Maximal olivary enlargement (hypertrophy of neurons and astrocytes) at 8.5 months
  - Olivary pseudohypertrophy (neuronal dissolution with gemistocytic astrocytes) after 9.5 months
  - Olivary atrophy (neuronal disappearance with olivary atrophy and prominent degeneration of amiculum olivae) after a few years

Gross Pathologic & Surgical Features

- Focal swelling of ION
- Unilateral HOD
  - Asymmetric enlargement of anterior medulla
  - "Pallor" in contralateral DN
  - Atrophy of contralateral cerebellar cortex
- Bilateral HOD: More difficult to observe
  - No left-right asymmetry

Microscopic Features

- Changes in hypertrophic degenerated ION
  - Hypertrophic, thickened neurites
  - Vacuolation of neurons
  - Fibrillary gliosis
  - Demyelination and astrocytic proliferation of WM
- In contralateral cerebellar cortex
  - Decreased number of Purkinje cells
- Contralateral DN reduced in size, possibly due to
  - Iron depletion secondary to axonal iron transport block
  - Loss of cells in nucleus

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Symptomatic palatal tremor/myoclonus
    - Rhythmic involuntary movement of soft palate, uvula, pharynx, and larynx
  - Severe myoclonus may also affect cervical muscles and diaphragm
  - ± dentatorubral tremor (Holmes tremor)
    - 2-5 Hz rest, postural, and kinetic tremor of upper extremity
    - May occur before onset of palatal tremor
  - Symptoms of cerebellar or brainstem dysfunction
    - Associated with acute lesion within triangle of Guillain-Mollaret
- Clinical profile
  - Palatal myoclonus (palatal "tremor")
    - Usually develops 10-11 months after primary lesion
    - Virtually all patients who develop palatal myoclonus after brain insult will have HOD
    - Not all HOD patients develop palatal myoclonus
    - May result from hypermetabolism of ION

Demographics

- Age
  - Rare; reported in all ages, both genders

Natural History & Prognosis

- After primary brainstem injury, olivary hypertrophy typically appears in delayed fashion
  - May occur between 3 weeks to 11 months (usually within 4-6 months)
- Maximum hypertrophy at 5-15 months
- Olivary hypertrophy typically resolves in 10-16 months
- Olivary hyperintensity on T2WI may persist for years after resolution of hypertrophy
- Finally ION undergoes atrophy
- Clinical symptoms (tremors) rarely improve

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Avoid misdiagnosis of tumor or multiple sclerosis
- Bilateral and symmetrical lesions in ION argue against subacute infarct and vertebral artery dissection

Gross and Imaging Anatomy

Ventricles and Choroid Plexus

Basic embryology: Early in embryonic development, the forebrain cavity divides into two lateral ventricles, which develop as outpouchings from the rostral third ventricle and are connected to it by the interventricular foramen (a.k.a. foramen of Monro). In the coronal plane, these form a central H-shaped "monoventricle." The cerebral aqueduct develops from the midbrain vesicle. The fourth ventricle develops from a cavity within the hindbrain and merges caudally with the central canal of the spinal cord.

Anatomic overview: The brain CSF spaces include both the ventricular system and subarachnoid spaces (SAS). The ventricular system is comprised of four interconnected CSF-filled, ependymal-lined cavities that lie deep within the brain. The paired **lateral ventricles** communicate with the third ventricle via the Y-shaped **foramen of Monro**. The **third ventricle** communicates with the fourth ventricle via the **cerebral aqueduct** (of Sylvius). In turn, the **fourth ventricle** communicates with the SAS via its outlet foramina (the midline **foramen of Magendie** and the two lateral **foramina of Luschka**).

Lateral ventricles: Each lateral ventricle has a body, atrium, and three projections ("horns"). The roof of the **frontal horn** is formed by the corpus callosum genu. It is bordered laterally and inferiorly by the head of the caudate nucleus. The septi pellucidi is a thin, bilayered membrane that extends from the corpus callosum genu anteriorly to the foramen of Monro posteriorly and forms the medial borders of both frontal horns.

The **body** of the lateral ventricle passes posteriorly under the corpus callosum. Its floor is formed by the dorsal thalamus and its medial wall is bordered by the fornix. Laterally, it curves around the body and tail of the caudate nucleus.

The **atrium** contains the choroid plexus glomus and is formed by the confluence of the body with the temporal and occipital horns. The **temporal horn** extends anteroinferiorly from the atrium and is bordered on its floor and medial wall by the hippocampus. Its roof is formed by the tail of the caudate nucleus. The **occipital horn** is surrounded entirely by white matter fiber tracts, principally the geniculocalcarine tract and the forceps major of the corpus callosum.

Foramen of Monro is a Y-shaped structure with two long arms extending towards each lateral ventricle and a short inferior common stem that connects with the roof of the third ventricle.

Third ventricle: The third ventricle is a single, slit-like, midline, vertically oriented cavity that lies between the thalami. Its roof is formed by the tela choroidea, a double layer of invaginated pia. The lamina terminalis and anterior commissure lie along the anterior border of the third ventricle.

The floor of the third ventricle is formed by several critical anatomic structures. From front to back these include the optic chiasm, hypothalamus with the tuber cinereum and infundibular stalk, mammillary bodies, and roof of the midbrain tegmentum.

The third ventricle has two inferiorly located CSF-filled projections: The slightly rounded **optic recess** and the more pointed **infundibular recess**. Two small recesses, the **suprapineal and pineal recesses**, form the posterior border of the third ventricle. A variably sized interthalamic adhesion (also called the **massa intermedia**) lies between the lateral walls of the third ventricle. The massa intermedia is not a true commissure.

Cerebral aqueduct is an elongated tubular conduit that lies between the midbrain tegmentum and the quadrigeminal plate. It connects the third ventricle with the fourth ventricle.

Fourth ventricle: The fourth ventricle is a roughly diamond-shaped cavity that lies between the pons anteriorly and the cerebellar vermis posteriorly. Its roof is covered by the anterior (superior) medullary velum above and the inferior medullary velum below.

The fourth ventricle has five distinctly shaped recesses. The **posterior superior recesses** are paired, thin, flat, CSF-filled pouches that cap the cerebellar tonsils. The **lateral recesses** curve anterolaterally from the fourth ventricle, extending under the brachium pontis (major cerebellar peduncle) into the lower cerebellopontine angle cisterns. The lateral recesses transmit choroid plexus through the foramina of Luschka into the adjacent subarachnoid spaces. The **fastigium** is a triangular, blind-ending, dorsal midline outpouching that points towards the cerebellar vermis. The fourth ventricle gradually narrows as it courses inferiorly, forming the **obex**. Near the cervicomedullary junction, the obex becomes continuous with the central canal of the spinal cord.

Choroid plexus and the production of CSF: The choroid plexus is comprised of highly vascular papillary excrescences with a central connective tissue core coated by an ependyma-derived secretory epithelium. The embryonic choroid plexus forms where the infolded tela choroidea contacts the ependymal lining of the ventricles, thus developing along the entire choroidal fissure.

The largest mass of choroid plexus, the **glomus**, is located in the atrium of the lateral ventricles. The choroid plexus extends anteriorly along the floor of the lateral ventricle, lying between the fornix and thalamus. It then dives through the interventricular foramen (of Monro) and curves posteriorly along the roof of the third ventricle. The choroid plexus, in the body of the lateral ventricle, curls around the thalamus into the temporal horn, where it fills the choroidal fissure and lies superomedial to the hippocampus.

CSF is predominantly, but not exclusively, secreted by the choroid plexuses. Brain interstitial fluid, ependyma, and capillaries may also play a poorly defined role in CSF secretion. The choroid plexus epithelium secretes CSF at the rate of about 0.2-0.7 mL/minute or 600-700 mL/day. The mean CSF volume is 150 ml, with 25 ml in the ventricles and 125 ml in subarachnoid spaces. CSF flows through the ventricular system and passes through the exit foramina of the fourth ventricle into the SAS. The bulk of CSF resorption is through the arachnoid villi along the superior sagittal sinus. CSF also drains into lymphatic vessels around the cranial cavity and spinal canal.

Not all CSF is produced in the choroid plexus. Drainage of brain interstitial fluid is a significant extrachoroidal source.

CSF plays an essential role in the maintenance of brain interstitial fluid homeostasis and regulation of neuronal functioning.

Cisterns and Subarachnoid Spaces

Overview: The SASs lie between the pia and arachnoid. The sulci are CSF-filled spaces between the gyral folds. Focal

https://CafePezeshki.IR

expansions of the SASs form the brain CSF cisterns. These cisterns are found at the base of the brain around the brainstem, tentorial incisura, and foramen magnum. Numerous pial-covered septa cross the SAS from the brain to the arachnoid. All SAS cisterns communicate with each other and the ventricular system, providing natural pathways for disease spread (e.g., meningitis, neoplasms).

The brain cisterns are conveniently grouped into supra-, peri-, and infratentorial cisterns. All contain numerous important critical structures, such as vessels and cranial nerves.

Supratentorial/peritentorial cisterns: The **suprasellar cistern** lies between the diaphragma sellae and the hypothalamus. Critical contents include the infundibulum, optic chiasm, and circle of Willis.

The **interpeduncular cistern** is the posterior continuation of the suprasellar cistern. Lying between the cerebral peduncles, it contains the oculomotor nerves as well as the distal basilar artery and proximal segments of the posterior cerebral arteries. Important perforating arteries, the thalamoperforating and thalamogeniculate arteries, arise from the top of the basilar artery and cross the interpeduncular cistern to enter the midbrain.

The **perimesencephalic(ambient) cisterns** are thin wings of CSF that extend posterosuperiorly from the suprasellar cistern to the quadrigeminal cistern. They wraparound the midbrain and contain the trochlear nerves, P2 PCA segments, superior cerebellar arteries, and basal vein of Rosenthal.

The **quadrigeminal cistern** lies under the corpus callosum splenium, behind the pineal gland and tectal plate. It connects with the ambient cisterns laterally and the superior cerebellar cistern inferiorly. The quadrigeminal cistern contains the pineal gland, trochlear nerves, P3 PCA segments, proximal choroidal arteries, and vein of Galen. An anterior extension, the **velum interpositum**, lies below the fornix and above the third ventricle. The velum interpositum contains the internal cerebral veins and medial posterior choroidal arteries.

Infratentorial cisterns: The unpaired posterior fossa cisterns that lie in the midline are the prepontine, premedullary, and superior cerebellar cisterns, as well as the cisterna magna. The lateral cisterns are paired and include the cerebellopontine and cerebellomedullary cisterns.

The **prepontine cistern** lies between the upper clivus and the "belly" of the pons. It contains numerous important structures including the basilar artery, the anterior inferior cerebellar arteries (AICAs), and the trigeminal and abducens nerves (CN5 and CN6).

The **premedullary cistern** is the inferior continuation of the prepontine cistern. It lies between the lower clivus in front and the medulla behind. It extends inferiorly to the foramen magnum and contains the vertebral arteries and branches (e.g., PICAs) and the hypoglossal nerve (CN12).

The **superior cerebellar cistern** lies between the straight sinus above and the vermis below. It contains the superior cerebellar arteries and veins. It connects superiorly through the tentorial incisura with the quadrigeminal cistern and inferiorly with the cisterna magna. The **cisterna magna** lies below the inferior vermis between the medulla and the occiput. It contains the cerebellar tonsils and the tonsillohemispheric branches of posterior inferior cerebellar artery (PICA). The cisterna magna merges imperceptibly with the SAS of the upper cervical spinal canal.

The **cerebellopontine angle cisterns** (CPAs) lie between the pons/cerebellum and the petrous temporal bone. Their most important contents are the trigeminal, facial, and vestibulocochlear nerves (CN5, CN7, and CN8). Other structures found here include the petrosal veins and AICAs. The CPA cisterns are contiguous inferiorly with the cerebellomedullary cisterns, sometimes termed the "lower" cerebellopontine angle cisterns.

The **cerebellomedullary cisterns** extend laterally around the medulla and are continuous with the cisterna magna below and the CPAs above. They contain the vagus, glossopharyngeal, and spinal accessory nerves (CN9, CN10, and CN11). A tuft of choroid plexus exits each foramen of Luschka into the cerebellomedullary cistern. The flocculus of the cerebellum that projects into this cistern can appear very prominent. The flocculus and choroid plexus are normal contents of the cerebellomedullary cisterns and should not be mistaken for pathology.

Imaging Recommendations

MR: Thin-section 3D T2WI or FIESTA/CISS best detail CSF within the ventricular system, SASs, and basal cisterns, and exquisitely delineates their contents. Whole brain FLAIR is especially useful for evaluating potential abnormalities in the SASs. Spin dephasing with pulsatile CSF flow is common and can mimic intraventricular pathology, especially in the basal cisterns and around the interventricular foramen. Incomplete CSF suppression with "bright" CSF can mimic pathologic SASs.

Differential Diagnosis Approach

Ventricles and Choroid Plexus

Overview: Approximately 10% of intracranial neoplasms involve the cerebral ventricles, either primarily or by extension. An anatomy-based approach is most effective, as there is a distinct predilection for certain lesions to occur in one ventricle or cistern and not others. Age is also a helpful consideration. Specific imaging findings, such as signal intensity, enhancement, and the presence or absence of calcification are relatively less important than location and age.

Normal variants: Asymmetry of the lateral ventricles is a common normal variant, as is flow-related CSF pulsation artifact. A cavum septi pellucidi (CSP) is a common normal variant, seen as a CSF cleft between the two leaves of the septum pellucidum. An elongated, finger-like posterior continuation of the CSP between the fornices, a cavum vergae (CV), may be associated with a CSP.

Lateral ventricle mass:Choroid plexus cysts (xanthogranulomas) are a common, generally age-related, degenerative finding with no clinical significance. They are nonneoplastic noninflammatory cysts, usually bilateral with rim calcification. They may be hyperintense on FLAIR and 60-80% appear quite bright on DWI. A strongly enhancing choroid plexus mass in a child is most likely a choroid plexus papilloma. With the exception of the fourth ventricle, a choroid plexus mass in an adult is usually meningioma or metastasis, not a choroid plexus papilloma.

Some lateral ventricle lesions display a distinct predilection for specific sublocations within the lateral ventricles. An innocent-appearing frontal horn mass in a middle-aged or older adult is

https://CafePezeshki.IR

most often a subependymoma. A bubbly mass in the body of the lateral ventricle is usually a central neurocytoma. Neurocysticercosis cysts can occur in all ages and in virtually every CSF space.

Foramen of Monro mass: The most common "abnormality" here is a pseudolesion caused by CSF pulsation artifact. Colloid cyst is the only relatively common pathology here. It is rare in children and typically a lesion of adults. Flow artifact can mimic a colloid cyst, but mass effect is absent. In a child with an enhancing mass in the interventricular foramen, tuberous sclerosis with subependymal nodule &/or giant cell astrocytoma should be a consideration. Masses such as ependymoma, papilloma, and metastasis are rare.

Third ventricle mass: Again, the most common "lesion" in this location is either CSF flow artifact or a normal structure (the massa intermedia). Colloid cyst is the only common lesion that occurs in the third ventricle; 99% are wedged into the foramen of Monro. Extreme vertebrobasilar dolichoectasia can indent the third ventricle, sometimes projecting upward as high as the interventricular foramen, and should not be mistaken for colloid cyst.

Primary neoplasms in children are uncommon here but include choroid plexus papilloma, germinoma, craniopharyngioma, and a sessile-type tuber cinereum hamartoma. Primary neoplasms of the third ventricle in adults are also uncommon, though an intraventricular macroadenoma and chordoid glioma are examples. Neurocysticercosis occurs here but is uncommon.

Cerebral aqueduct: Other than aqueductal stenosis, intrinsic lesions of the cerebral aqueduct are rare. Most are related to masses in adjacent structures (e.g., tectal plate glioma).

Fourth ventricle mass: Pediatric masses are the most common intrinsic abnormalities of the fourth ventricle. Medulloblastoma, ependymoma, and astrocytoma predominate. Atypical teratoid/rhabdoid tumor (AT/RT) is a less common neoplasm that may occur here. It usually occurs in children under the age of three and can mimic medulloblastoma.

Metastases to the choroid or ependyma are probably the most common fourth ventricle neoplasm of adults. Primary neoplasms are rare. Choroid plexus papilloma does occur here, as well as in the CPA cistern. Subependymoma is a lesion of middle-aged adults that is found in the inferior fourth ventricle, lying behind the pontomedullary junction. A newly described rare neoplasm, rosette-forming glioneuronal tumor, is a midline mass of the fourth ventricle. It has no particular distinguishing imaging features and, although it may appear aggressive, it is a benign (WHO grade I) lesion. Hemangioblastomas are intraaxial masses but may project into the fourth ventricle. Epidermoid cysts and neurocysticercosis cysts can be found in all ages.

Subarachnoid Spaces and Cisterns

Overview: The subarachnoid spaces are a common site of pathology that varies from benign congenital lesions (such as arachnoid cyst) to infection (meningitis) and neoplastic involvement ("carcinomatous meningitis"). Anatomic location is key to the differential diagnosis, as imaging findings, such as enhancement and hyperintensity on FLAIR, are often nonspecific. Patient age is also helpful though generally of secondary importance.

Normal variants: CSF flow-related artifacts are common, especially in the basal cisterns on FLAIR imaging. Mega cisterna magna may be considered a normal variant, as is a cavum velum interpositum (CVI). A CVI is a thin, triangular-shaped CSF space between the lateral ventricles that lies below the fornices and above the third ventricle. Occasionally a CVI may become quite large.

Suprasellar cistern mass: Common masses in adults are upward extensions of macroadenoma, meningioma, and aneurysm. The two most common suprasellar masses in children are astrocytoma of the optic chiasm/hypothalamus and craniopharyngioma.

Cerebellopontine angle mass: In adults, vestibular schwannoma accounts for almost 90% of all CPA-IAC masses. Meningioma, epidermoid cyst, aneurysm, and arachnoid cyst **together** represent about 8% of lesions in this location. All other less common entities, such as lipoma, schwannomas of other cranial nerves, metastases, neurenteric cysts, etc., account for about 2%.

In the absence of neurofibromatosis type 2, vestibular schwannomas are very rare in children. CPA epidermoid and arachnoid cysts may occur in children. Extension of ependymoma laterally through the foramina of Luschka may involve the CPA.

Cystic-appearing CPA masses comprise their own special differential diagnosis. While vestibular schwannoma with intramural cysts can occur, it is less common than epidermoid and arachnoid cysts. Neurocysticercosis may occasionally involve the CPA. Large endolymphatic sac anomaly (IP-2) shows a CSF-like mass within the posterior wall of the temporal bone. Hemangioblastoma and neurenteric cysts are other less common cystic masses that occur in the CPA.

Cisterna magna mass: Tonsillar herniation, whether congenital (Chiari 1) or secondary to posterior fossa mass effect or intracranial hypotension, is the most common "mass" in this location. Nonneoplastic cysts (arachnoid, epidermoid, dermoid, neurenteric) may also occur here.

Neoplasms in and around the cisterna magna, such as meningioma and metastasis, are typically anterior to the medulla. Subependymoma of the fourth ventricle originates in the obex and lies behind the medulla.

FLAIR hyperintensity: Hyperintense sulci and subarachnoid spaces are seen with MR artifacts, as well as a variety of lesions. Pathologic FLAIR hyperintensity is typically related to blood (e.g., subarachnoid hemorrhage), protein (meningitis), or cells (pia-subarachnoid space metastases). Less commonly, gadolinium-based contrast agents in patients with blood-brain barrier leakage or renal failure can cause FLAIR hyperintensity.

Rare causes of FLAIR hyperintensity include ruptured dermoid cyst, moyamoya ("ivy" sign), and acute cerebral ischemia. Contrast enhancement helps distinguish meningitis and metastases from subarachnoid hemorrhage and CSF artifacts.

KEY FACTS

TERMINOLOGY

- Cystic CSF cavity of septum pellucidum (SP)
  - Occurs ± cavum vergae (CV)

IMAGING

- Elongated finger-shaped CSF collection between lateral ventricles
  - Cavum septi pellucidi (CSP): Between frontal horns of lateral ventricles
  - CV: Posterior extension between fornices
- Size varies from slit like to several mm, occasionally > 1 cm
- SP invariably cystic in fetus
  - Width of fetal CSP increases between 19-27 weeks
  - Plateaus at 28 weeks
  - Gradually closes in rostral direction between 28 weeks and term
  - CSP present in 100% of premature, 85% of term infants
- CSP seen in up to 15-20% of adults

TOP DIFFERENTIAL DIAGNOSES

- Asymmetric lateral ventricles
- Cavum velum interpositum
- Ependymal cyst
- Absent SP

PATHOLOGY

- CSP forms if fetal SP fails to obliterate
- CSP is not "5th ventricle"
- CV is not "6th ventricle"

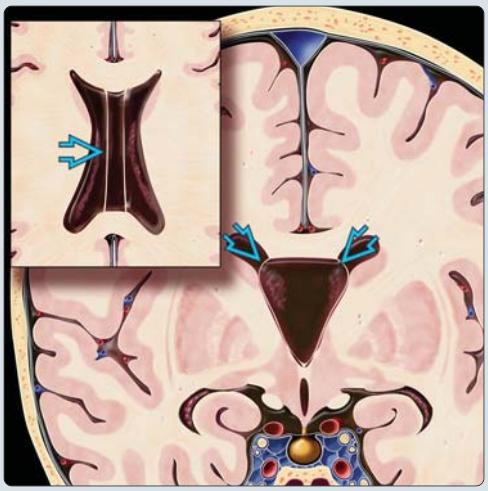
CLINICAL ISSUES

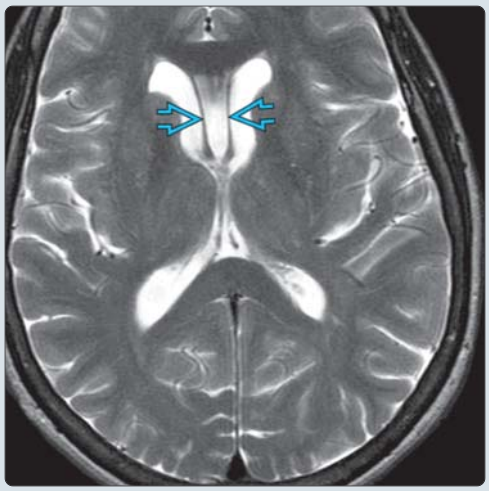
- Usually asymptomatic, incidental
- Headache (relationship to cyst unclear)
- CSP frequent among athletes with history of repeated traumatic brain injury, such as boxers

DIAGNOSTIC CHECKLIST

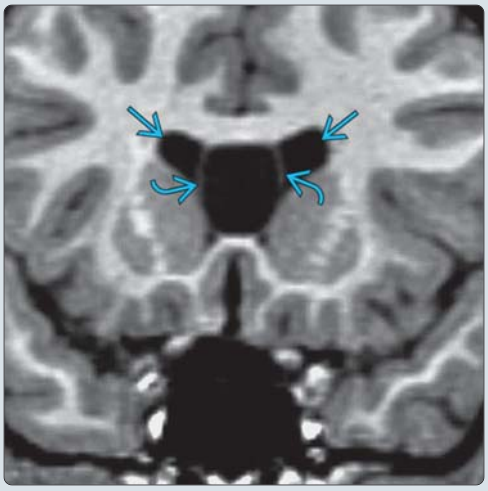
- CV almost never occurs without CSP

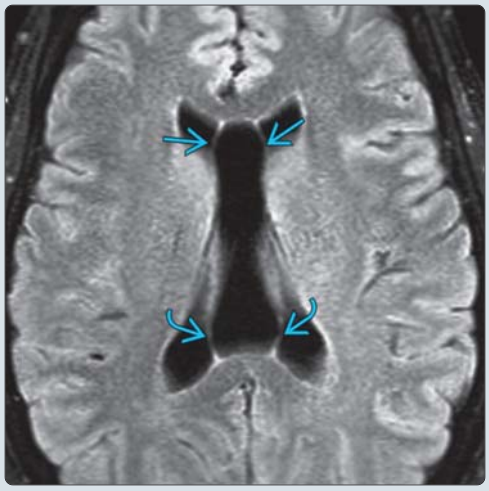
(Left) *Coronal graphic with axial insert shows classic cavum septi pellucidi (CSP) with cavum vergae (CV).* *Note the finger-like CSF collection between the lateral ventricles.* **(Right)** *Axial T2WI MR shows cavum septi pellucidi as a CSF collection between the leaves of the septum pellucidum.* *Although seen incidentally, some studies have report that CSP is frequent among athletes with a history of repeated traumatic brain injury (TBI), such as boxers, and American professional football players.*





(Left) *Coronal T1WI MR shows a classic large CSP between the frontal horns bowing the leaves of the septum pellucidum laterally.* **(Right)** *Axial FLAIR MR shows a large CSP with CV as a large CSF collection between the leaves of the septum pellucidum continuing directly posteriorly with the CSF collection, splaying the fornices laterally.*





https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Cavum velum interpositum (CVI); cyst of velum interpositum (VI)

IMAGING

- Triangular CSF space
  - Between lateral ventricles, over thalami
  - Apex points toward foramen of Monro
  - Elevates, splays fornices
  - Flattens, displaces internal cerebral veins inferiorly
- Size varies from slit-like linear to triangular to round/ovoid CSF collection
- Isodense/isointense with CSF
  - Suppresses completely on FLAIR
  - Does not restrict on DWI
  - Does not enhance
- US shows hypoechoic midline interhemispheric cyst

TOP DIFFERENTIAL DIAGNOSES

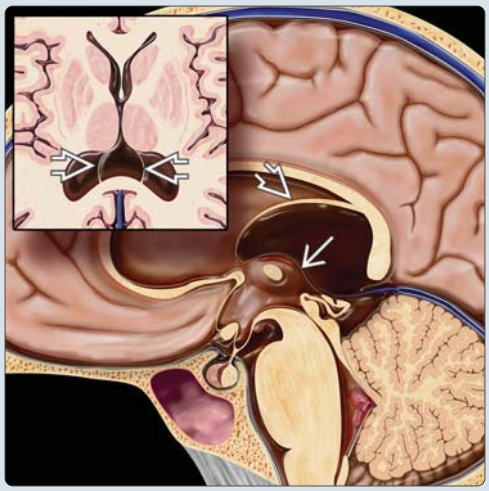
- Normal cistern of velum interpositum
- Cavum septi pellucidi, cavum vergae
- Arachnoid cyst
- Epidermoid cyst

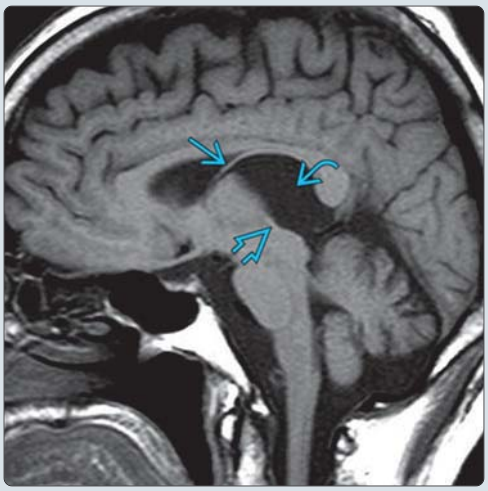
CLINICAL ISSUES

- Can be found at any age
  - Common in infants, rare in adults
- Symptoms
  - Usually asymptomatic, found incidentally
  - Headache (relationship to cyst unclear)
  - Large CVI can obstruct normal CSF flow; treated by endoscopic fenestration

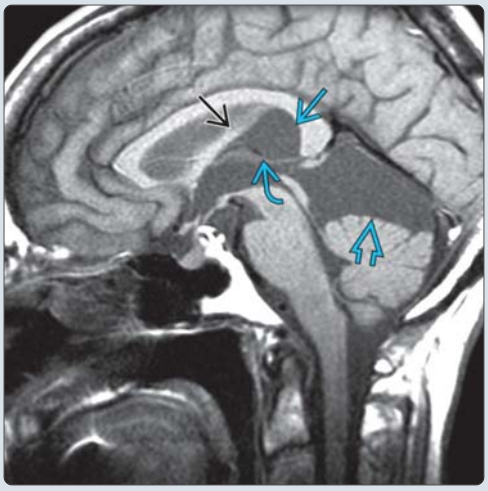
DIAGNOSTIC CHECKLIST

- CSF-like "cyst" could be epidermoid
- Include FLAIR and DWI to distinguish between CVI, epidermoid cyst





(Left) *Sagittal graphic with axial insert shows a cavum velum interpositum (CVI). Note the elevation and splaying of the fornices. Also noted is the inferior displacement of the internal cerebral veins and 3rd ventricle.* **(Right)** *Sagittal T1WI MR shows a classic CVI as a CSF-like enlargement that elevates the fornix and flattens and displaces the internal cerebral vein inferiorly. These are usually asymptomatic, however large ones can cause CSF obstruction and can be treated by fenestration.*



(Left) *Axial T2WI MR in a 37-year-old man with headaches shows a classic cavum velum interpositum with a triangular-shaped CSF collection between the lateral ventricles spreading the fornices laterally.* **(Right)** *Sagittal T1WI MR shows a variant CVI that elevates the fornix, flattens the internal cerebral vein, and extends into the quadrigeminal and suprasellar cisterns. This case probably represents an arachnoid cyst of the cavum velum interpositum.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Idiopathic enlargement of SAS during 1st year of life

IMAGING

- Enlarged SAS and ↑ head circumference (> 95%)
- CSF space follows (not flattens) gyral contour
- Right and left subarachnoid spaces are symmetric
- Macrocephaly, frontal bossing on radiography
- CECT demonstrates veins traversing SAS
- Spaces must follow CSF signal on all MR sequences

TOP DIFFERENTIAL DIAGNOSES

- Atrophy
- Acquired extraventricular obstructive hydrocephalus (EVOH)
- Nonaccidental trauma (NAT)

PATHOLOGY

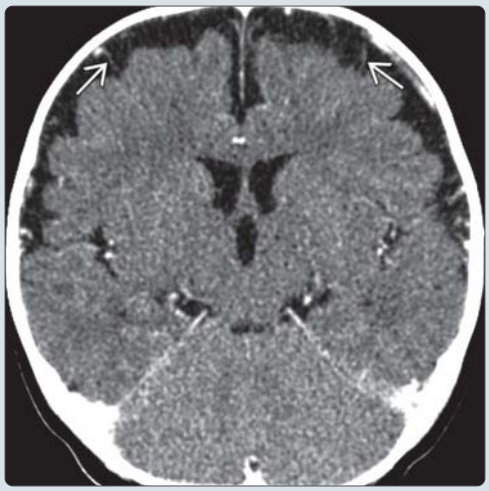
- Underlying mechanism poorly understood
- Disproportion between rapidly increasing CSF secretion rate and immature CSF drainage pathways is most commonly held theory

CLINICAL ISSUES

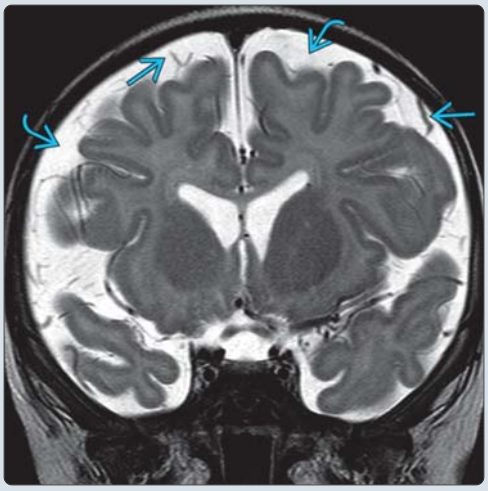
- Increasing neurological signs or lack of development is not consistent with benign enlarged SAS
- No signs of elevated intracranial pressure; normal pressure on lumbar puncture
- Self-limited; SAS enlargement resolves without therapy by 12-24 months
- No treatment necessary
- Majority are physically, neurologically, & developmentally normal on follow-up

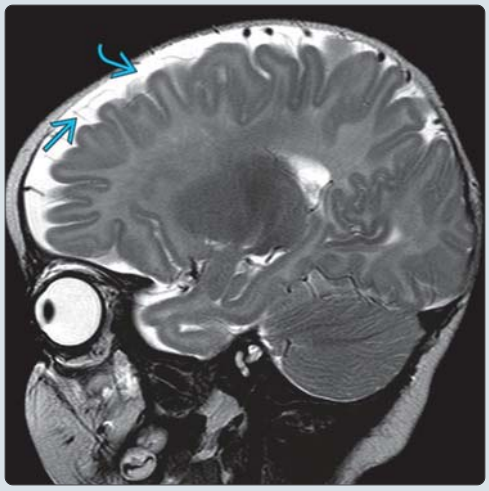
DIAGNOSTIC CHECKLIST

- Consider nonaccidental trauma if enlarged SAS atypical in any way
- Crucial: Know head circumference



(Left) *Axial graphic shows classic enlarged subarachnoid spaces in a macrocephalic infant with symmetric bifrontal enlargement, multiple bridging veins ➡, and mild ventriculomegaly. The craniocortical distance between the brain and calvaria is ≥ 5 mm.* **(Right)** *Axial CECT shows enlarged subarachnoid spaces with enhancing traversing veins ➡ and mildly enlarged ventricles in a macrocephalic infant. This benign condition usually peaks at 7 months and resolves spontaneously by 12-24 months of age.*





(Left) *Coronal T2 MR shows enlarged subarachnoid spaces ⇨ overlying the frontal lobes. Note the flow voids ⇨ of the traversing vessels in the subarachnoid space. This helps to distinguish from enlarged subdural spaces.* **(Right)** *Sagittal MR in the same patient again demonstrates enlarged frontal subarachnoid spaces ⇨ and multiple bridging vessels ⇨. The definition of normal subarachnoid space width varies in literature and there is no consensus. Craniocortical width > 10 mm is considered an absolute sign of pathology.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Subarachnoid space (SAS) enlargement

Synonyms

- Benign subarachnoid space enlargement
- Benign external hydrocephalus, benign extracerebral fluid collections of infancy
- Benign communicating hydrocephalus, physiologic extraventricular obstructive hydrocephalus
- Benign macrocrania of infancy

Definitions

- Idiopathic enlargement of SAS during 1st year of life

IMAGING

General Features

- Best diagnostic clue
  - Enlarged SAS and increased head circumference (> 95%)
- Location
  - Subarachnoid space
- Size
  - Definition of normal SAS width varies in literature: No consensus
  - Craniocortical width (CCW): Widest vertical distance between brain and calvaria
    - CCW upper limits range from 3 to 5 mm
    - Infants < 1 year range from 4 to 10 mm
    - > 10 mm considered absolute sign of pathology
  - Sinocortical width (SCW): Widest distance between lateral wall of superior sagittal sinus and brain surface
    - Normal range 2-10 mm
  - Interhemispheric: Widest distance between hemispheres
    - Enlargement defined as > 8.5 mm
  - **Note**: Normal maximum width peaks at 28 postnatal weeks (7 months) of life
- Morphology
  - CSF space follows (not flattens) gyral contour
  - Right and left subarachnoid spaces are symmetric

Radiographic Findings

- Radiography
  - Macrocephaly, frontal bossing

CT Findings

- NECT
  - Widening bifrontal/anterior interhemispheric SAS
  - Enlarged cisterns (especially suprasellar/chiasmatic)
  - Normal or mildly enlarged ventricles
  - Sulci generally normal (especially posteriorly)
  - Postural unilateral lambdoid flattening is common
  - Posterior fossa normal
- CECT
  - Demonstrates veins traversing SAS
  - No abnormal enhancement of meninges

MR Findings

- T1WI
  - Similar to NECT
- T2WI
  - No abnormal brain tissue or signal abnormalities
  - Single layer of fluid (SAS) with traversing vessels
  - Normal flow void in aqueduct
  - Normal or mildly enlarged ventricles
- FLAIR
  - Homogeneous hypointense fluid in SAS (follows normal CSF signal)
- T2* GRE
  - No blood products
- DWI
  - No restriction, normal diffusivity
- T1WI C+
  - Enhancing veins traverse SAS
- Fetal MR: Distribution of fluid/ventricular prominence related to positioning of fetus
  - Usually frontal prominence after birth due to position of child lying on back for scan

Ultrasonographic Findings

- Grayscale ultrasound
  - Enlarged frontal subarachnoid space
  - CCW and sinocortical width (SCW) < 10 mm in neurologically normal infants
  - Veins as "dots" floating in SAS
- Pulsed Doppler
  - Increased cerebral blood flow may identify "progressive" cases
- Color Doppler
  - Veins traverse SAS

Angiographic Findings

- Conventional
  - Widened space between skull and arteries of brain surface

Nonvascular Interventions

- Myelography
  - Cisternography confirms communication of SAS, but not necessary

Imaging Recommendations

- Best imaging tool
  - MR to exclude chronic subdural collections
- Protocol advice
  - Doppler sonography: Documents veins traversing SAS
  - MR or CECT: To exclude underlying etiology
  - MR: To exclude chronic subdural collections
    - SAS isointense with CSF on all sequences if benign
  - Phase-contrast MR shows normal intraventricular CSF flow
  - After diagnosis, best follow-up = tape measure and assess for normal development; not imaging

DIFFERENTIAL DIAGNOSIS

Atrophy

- Small head circumference (HC)
  - Forehead "pointed" due to metopic fusion
- Patients with benign SAS enlargement have large head
  - Forehead "flat" due to frontal bossing
- Knowledge of HC critical for diagnosis

https://CafePezeshki.IR

Acquired Extraventricular Obstructive Hydrocephalus (EVOH)

- Often hemorrhagic/postinflammatory/neoplastic
  - Density of extraaxial collection greater than CSF
- Achondroplasia and other skull base anomalies
  - Coarctation of foramen magnum (narrow)
- Intermittent intracranial pressure waves

Nonaccidental Trauma (NAT)

- Predisposition to bleed with minor trauma is controversial
  - Venous "stretching" implicated

Glutaric Aciduria Type 1

- Enlarged sylvian fissures with delayed myelination
- T2-hyperintense basal ganglia

Elevated Venous Pressures

- May be due to cardiac issues or bilateral transverse sinus/jugular vein thrombosis

PATHOLOGY

General Features

- Etiology
  - Underlying mechanism poorly understood
  - Disproportion between rapidly increasing CSF secretion rate and immature CSF drainage pathways is most commonly held theory
    - CSF primarily drained via extracellular space → capillaries
    - Arachnoid granulations (AGs) do not mature until 18 months
    - AGs are then displaced into veins (as Starling-type resistors)
    - AGs regulate pulse pressure/venous drainage CSF when fontanels close
    - Benign SAS enlargement usually resolves at that time
- Genetics
  - No documented genetic predisposition, although common in benign familial macrocrania
    - Family history of macrocephaly > 80%
- Associated abnormalities
  - Possibility of increased risk for bridging vein injury and resultant subdural hematoma in absence of trauma
  - May constitute a significant risk factor for development of de novo arachnoid cysts

Staging, Grading, & Classification

- Danger signs
  - Elevated intracranial pressure (ICP)
  - Rapid enlargement of head circumference
  - Increasing lack of development or neurological signs
  - Onset or persistence > 1 year old

Gross Pathologic & Surgical Features

- Deep/prominent but otherwise normal-appearing SAS
- No pathologic membranes

Microscopic Features

- Ependymal damage not seen in benign SAS enlargement

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Macrocrania: Head circumference > 95%
  - Frontal bossing
  - No signs of elevated ICP; normal pressure on lumbar puncture
- Other signs/symptoms
  - Possible mild developmental delay (50%), which usually resolves
- Clinical profile
  - Family history of benign macrocephaly common
  - Male infants, sometimes late to walk

Demographics

- Age
  - Usually present at 3-8 months
- Gender
  - 80% male
- Epidemiology
  - Reported on 2-65% of neuroimaging for macrocrania < 1 year old

Natural History & Prognosis

- Enlarged SAS → ↑ suture/calvarial malleability/compliance → predisposes to posterior plagiocephaly
- Self-limited; SAS enlargement resolves without therapy by 12-24 months
  - Spontaneous resolution of spaces and symptoms
- Calvaria outgrows brain, brain eventually catches up
- Macrocephaly often persists
- Majority are physically, neurologically, and developmentally normal on follow-up

Treatment

- No treatment necessary
- Normal outcome (developmental delay resolves as prominent SAS resolves)

DIAGNOSTIC CHECKLIST

Consider

- Nonaccidental injury if enlarged SAS atypical in any way

Image Interpretation Pearls

- Crucial: Know head circumference
- Consider enhanced CT or MR to confirm veins traversing SAS and search for membranes or nonisointense fluid collections (chronic subdural)

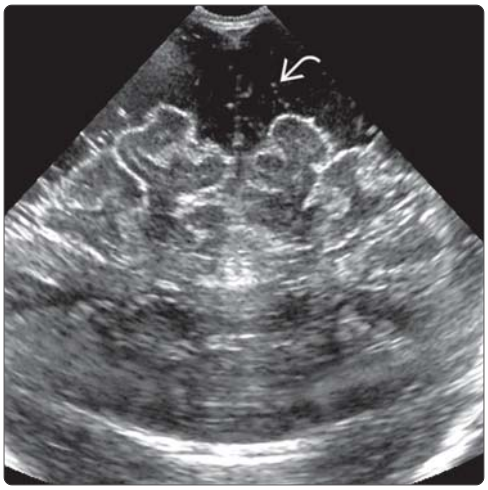
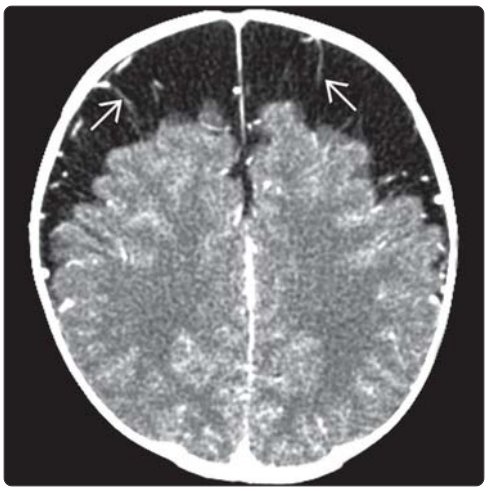
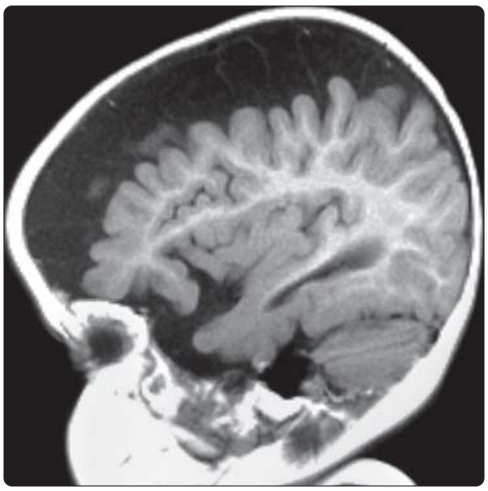
(Left) *Axial T2WI MR shows enlarged frontal and anterior interhemispheric pericerebral fluid spaces, mild ventriculomegaly, and right-sided posterior plagiocephaly in a 7-month-old male with macrocephaly.* **(Right)** *Axial T2WI MR follow-up of the same patient at 17 months of age shows that the pericerebral and anterior interhemispheric fluid spaces have normalized. A family history of benign macrocephaly is common in these patients.*



(Left) *Coronal brain ultrasound shows increased sinocortical distance in this case of markedly enlarged subarachnoid spaces in this young infant with macrocephaly. Echogenic foci within the CSF collection correspond to bridging veins. CSF spaces are most prominent at 7 months of life.* **(Right)** *Coronal color Doppler ultrasound demonstrates venous structures traversing the dilated subarachnoid space. Enlarged subarachnoid spaces are related to immature CSF drainage pathways.*





(Left) *Axial CECT shows markedly enlarged frontal subarachnoid spaces with traversing bridging veins. The distance between the brain surface and the dura is 1.5 cm.* **(Right)** *Sagittal T1WI MR shows markedly enlarged subarachnoid spaces. Note the large calvarial size compared to the face, related to macrocephaly. Bridging veins traverse the enlarged subarachnoid spaces. It is important to ensure that the fluid follows CSF on all sequences to exclude nonaccidental trauma.*

KEY FACTS

TERMINOLOGY

- Intraventricular obstructive hydrocephalus (IVOH) = obstruction proximal to foramina of Luschka, Magendie
  - Acute (aIVOH)
  - Chronic "compensated" (cIVOH)

IMAGING

- aIVOH = "ballooned" ventricles plus indistinct ("blurred") margins
  - "Fingers" of CSF extend into periventricular WM
  - Most striking around ventricular horns (periventricular "halos")
  - After decompression, corpus callosum may show hyperintensity
- cIVOH = "ballooned" ventricles without periventricular "halo"

TOP DIFFERENTIAL DIAGNOSES

- Ventricular enlargement 2° to parenchymal loss
- Normal pressure hydrocephalus
- Extraventricular obstructive hydrocephalus
- Choroid plexus papilloma
- Longstanding overt ventriculomegaly in adults

PATHOLOGY

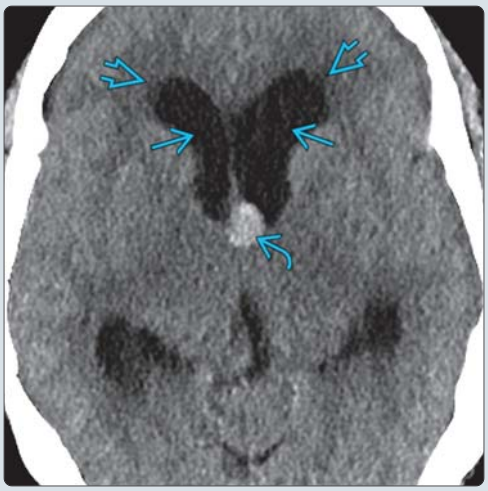
- Intraventricular obstruction to CSF flow
  - CSF production continues, ventricular pressure ↑
- Ventricles expand, compress adjacent parenchyma
- Periventricular interstitial fluid increases
  - Leads to myelin vacuolization, destruction
- Pathology varies depending on obstruction etiology

CLINICAL ISSUES

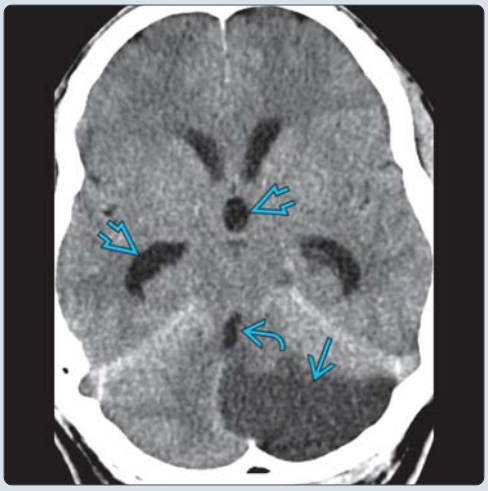
- Headache, papilledema (aIVOH)
- Nausea, vomiting, diplopia (6th nerve palsy)

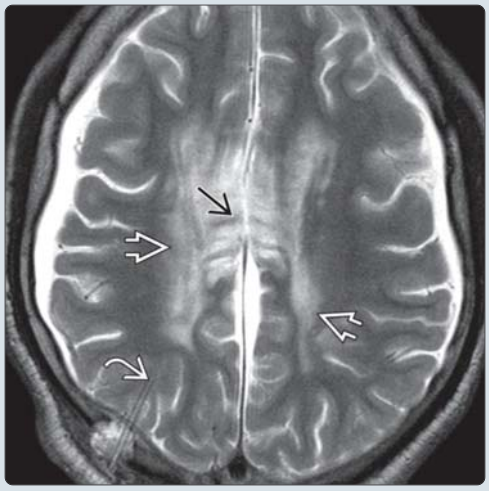
DIAGNOSTIC CHECKLIST

- Size of ventricles generally correlates poorly with intracranial pressure



(Left) *Axial NECT in a patient with headache demonstrates a classic colloid cyst at the foramen of Monro causing intraventricular obstructive hydrocephalus with dilatation of both lateral ventricles. Note the periventricular hypodensities due to transependymal leakage of CSF.* **(Right)** *Axial FLAIR in a patient with tuberous sclerosis shows large subependymal giant cell astrocytoma causing obstructive hydrocephalus with mild periventricular edema. Note the subtle hyperintensity in the occipital lobe tuber.*





(Left) *Axial CECT demonstrates a subacute left posterior inferior cerebellar infarct causing mass effect on the 4th ventricle and resulting in obstructive hydrocephalus.* **(Right)** *Axial T2WI MR in a patient with corpus callosum impingement syndrome, after shunting for severe IVOH, shows a shunt tube, bilateral subdural fluid collections, and "striated" hyperintensity in the corpus callosum with somewhat less striking changes in the periventricular WM. (Courtesy S. Candy, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Intraventricular obstructive hydrocephalus (IVOH)
  - Acute IVOH (aIVOH)
  - Chronic "compensated" IVOH (cIVOH)

Synonyms

- "Noncommunicating" hydrocephalus

Definitions

- Enlarged ventricles caused by obstruction proximal to 4th ventricular outflow foramina (of Luschka, Magendie)

IMAGING

General Features

- Best diagnostic clue
  - aIVOH
    - "Ballooned" ventricles with indistinct ("blurred") margins
  - cIVOH
    - "Ballooned" ventricles without periventricular "halo"
- Size
  - Bifrontal horn to intracranial diameter ratio > 0.33
  - Temporal horn width > 3 mm
- Morphology
  - Varies with site, duration of blockage
  - Global/focally enlarged ventricle(s) ± elevated ICP
  - Ventricles proximal to obstruction enlarge, appear more rounded
  - Look for enlarged anterior recesses of 3rd ventricle

CT Findings

- NECT
  - Large ventricles proximal to obstruction
    - aIVOH
      - "Ballooned" ventricles with periventricular low-density "halo"
    - cIVOH
      - "Ballooned" ventricles, periventricular "halo"
  - Basal cisterns, sulci compressed/obliterated

MR Findings

- T1WI
  - Lateral ventricles enlarged
  - Corpus callosum (CC) thinned, stretched upward
    - May be impinged against falx
    - Impaction may cause pressure necrosis
  - Fornix, internal cerebral veins (ICV) displaced downward
  - Enlarged 3rd ventricle often herniated into expanded sella
  - Funnel-shaped aqueduct of Sylvius in aqueductal stenosis
- T2WI
  - aIVOH
    - "Fingers" of CSF-like hyperintensity extend into periventricular white matter (WM), most striking around ventricular horns (periventricular "halos")
    - Disturbed/turbulent CSF flow
    - Absent aqueductal "flow void" common
    - CC may appear hyperintense
  - cIVOH
    - Large ventricles, normal CSF pressure
    - No periventricular "halo"
    - CC may show hyperintensity after decompression (15% of shunted IVOH cases)
  - Thin section T2WI, FIESTA or CISS sequences
    - exquisitely delineate CSF spaces
    - May demonstrate subtle abnormalities not detected on standard images
- T1WI C+
  - Neoplasm causing IVOH may enhance
  - aIVOH may cause leptomeningeal vascular stasis, enhancement
    - Can mimic meningitis, metastases

Other Modality Findings

- Contrast-enhanced ventriculography
  - MR/CT used to identify site of obstruction, status of 3rd ventriculostomies
  - MR can be used for assessing CSF flow
- Cardiac-gated phase contrast MR
  - May show absent aqueductal CSF flow

Imaging Recommendations

- Best imaging tool
  - MR with contrast to evaluate cause of CSF obstruction
- Protocol advice
  - 3D FEISTA/CISS
    - Decreases CSF flow artifact
    - Allows better delineation of ventricular contour, septa

DIFFERENTIAL DIAGNOSIS

Ventricular Enlargement Secondary to Parenchymal Loss

- Old term: Ex vacuo hydrocephalus (not used)
- Age related (ventricular volume increases 1.2-1.4 mL/after 60 years)
  - Ischemia/infarction, trauma, infection, toxic
- Obtuse frontal angle (> 110°)
- Diffuse/focal enlargement of sulci, cisterns
- Normal lateral ventricles can be asymmetric (related to handedness, not gender)
- May correlate with some psychiatric disorders (e.g., schizophrenia)

Normal Pressure Hydrocephalus

- Progressive dementia, gait disturbance, incontinence
- Ventricular dilation with normal CSF pressure
- Sulci normal/minimally enlarged
- Increased CSF displacement through aqueduct
- MRS shows lactate peak

Extraventricular Obstructive Hydrocephalus (EVOH)

- Dilated ventricles due to mismatch between CSF formation, absorption
- Decreased CSF absorption through arachnoid villi
- Subarachnoid hemorrhage most common cause
  - Others: Meningitis, carcinomatosis, granulomatous disease

https://CafePezeshki.IR

Choroid Plexus Papilloma

- Accounts for 2-5% of childhood intracranial tumors
- Child < 5 years with ↑ ICP
- Most common lateral ventricle trigone
- May "overproduce" CSF
- Hemorrhage, tumor spread may cause IVOH

Longstanding Overt Ventriculomegaly in Adults

- Early childhood onset or longstanding progression of hydrocephalus into adulthood
- Markedly enlarged ventricles, high ICP

Benign Enlargement of Subarachnoid Spaces and Ventricles

- Seen in association with macrocephaly in infants
- Not associated with developmental delay

PATHOLOGY

General Features

- Etiology
  - Normal CSF production = 0.20-0.35 mL/min
    - Capacity of lateral, 3rd ventricles in adult = 20 mL
    - Total volume of CSF in adult = 120 mL
  - Intraventricular obstruction to CSF flow; as CSF production continues, ventricular fluid pressure ↑
  - Ventricles expand, compress adjacent parenchyma; stretching may rupture/open ependymal cell junctions
  - Periventricular interstitial fluid increases → myelin destruction
  - Etiology depends on site
    - Foramen of Monro
      - Colloid cyst
      - Subependymal nodule, tuberous sclerosis complex
      - Subependymal giant cell astrocytoma
    - 3rd ventricle
      - Pituitary macroadenoma
      - Craniopharyngioma
    - Aqueduct of Sylvius
      - Aqueductal stenosis
      - Tectal glioma
      - Pineal region tumors
    - 4th ventricle
      - Medulloblastoma, ependymoma
      - Glioma, pilocytic astrocytoma, hemangioblastoma
      - Cerebellar infarct
      - Congenital anomalies (Chiari malformations, Dandy-Walker malformations, rhombencephalosynapsis)
    - Metastasis, neurocysticercosis, or meningioma can occur at multiple intraventricular locations
- Genetics
  - Cell adhesion molecule L1 (*L1CAM*) only gene recognized to cause human hydrocephalus
    - Located on X chromosome (Xq28)

Gross Pathologic & Surgical Features

- Focal/generalized ventricular enlargement
- Ependyma, adjacent WM are secondarily injured
- Variable pathology depending on causative factor

Microscopic Features

- Increased periventricular extracellular space
- Ependymal lining damaged or lost; surrounding WM becomes pale and rarefied

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, papilledema (aIVOH)
  - Nausea, vomiting, diplopia (6th nerve palsy)
- Clinical profile
  - Varies with etiology, severity, age of onset

Demographics

- Age
  - May be any age from in utero (congenital hydrocephalus) to adult
- Epidemiology
  - Epidemiological data varies widely, depending upon etiology and type of hydrocephalus

Natural History & Prognosis

- Usually progressive unless treated

Treatment

- Medical management to delay surgical intervention
- CSF diversion (shunt), endoscopic intervention, and ventriculostomy
- Surgery to alleviate primary cause of obstruction
- Most common neurosurgical procedure in children = CSF shunting for hydrocephalus

DIAGNOSTIC CHECKLIST

Consider

- Longstanding aqueductal stenosis can be caused by slow-growing tectal tumor

Image Interpretation Pearls

- Size of ventricles generally correlates poorly with intracranial pressure
- Pulsatile CSF may create confusing signal intensity, even mimic intraventricular mass
- Ventricular asymmetry can be normal variant
- If seen with absent septum pellucidum in fetus/neonate, look for vermis (r/o rhombencephalosynapsis)

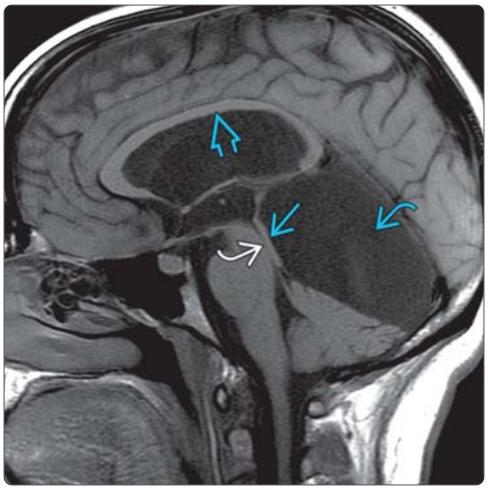
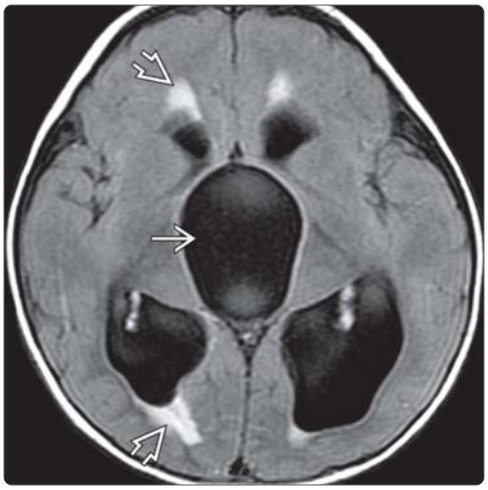
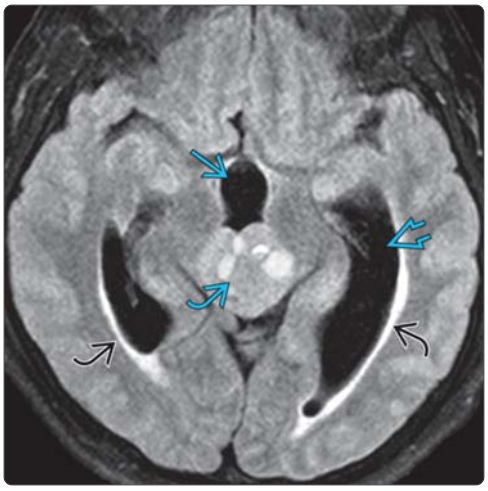
https://CafePezeshki.IR

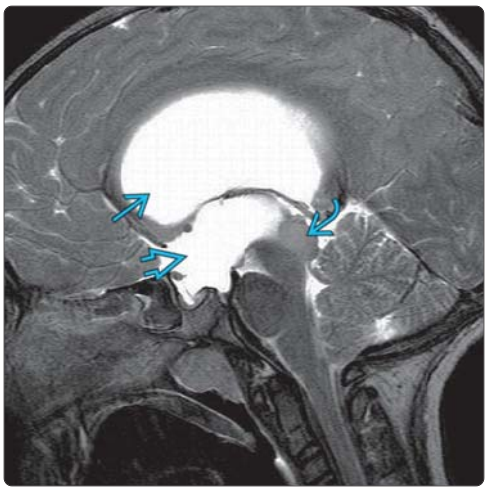


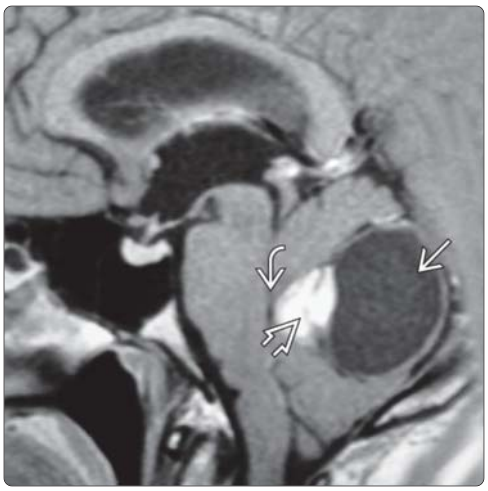


(Left) *Sagittal T1 MR shows a large arachnoid cyst in the superior cerebellar cistern causing severe mass effect on the tectal plate and aqueduct. There is dilatation of the 3rd and lateral ventricles with thinning of the corpus callosum.* **(Right)** *Axial FLAIR MR shows massive enlargement of the 3rd and lateral ventricles by a CSF-like mass within the 3rd ventricle. There is periventricular interstitial edema. At surgery, an ependymal cyst of the 3rd ventricle was found and fenestrated.*



(Left) *Axial FLAIR MR in a patient with a pineal region germinoma shows intraventricular obstructive hydrocephalus with dilatation of the 3rd and lateral ventricles. Note the periventricular FLAIR hyperintensity due to transependymal CSF leakage.* **(Right)** *Sagittal T1WI MR reveals typical findings in aqueductal stenosis: Funnel-shaped aqueduct of Sylvius, normal 4th ventricle, thinned and stretched corpus callosum, and downward displacement of the floor of the 3rd ventricle.*





(Left) *Sagittal T2 MR demonstrates an enlarged T2 hyperintense tectal plate glioma, which causes obstruction at the aqueduct and dilatation of the lateral and 3rd ventricles.* **(Right)** *Sagittal T1WI C+ MR shows a cyst with an enhancing mural nodule of hemangioblastoma in the vermis, causing severe effacement of the 4th ventricle and obstructive hydrocephalus.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Extraventricular obstructive hydrocephalus (EVOH): Enlarged ventricles due to mismatch between CSF formation, absorption
- Synonym: "Communicating" hydrocephalus

IMAGING

- Impaired absorption of CSF distal to 4th ventricle outlet foramina
- Ventricular size varies with duration of obstruction
- All ventricles enlarged with no intraventricular obstructive cause
- Lateral, 3rd, and 4th ventricles dilated
- ± periventricular white matter interstitial edema
- ± abnormal density/intensity of cisternal CSF ± leptomeningeal enhancement

TOP DIFFERENTIAL DIAGNOSES

- Intraventricular obstructive hydrocephalus
- Ventricular enlargement 2° to parenchymal loss
- Normal pressure hydrocephalus

PATHOLOGY

- Hemorrhage → fibrosis/obstruction of subarachnoid space
  - Most common cause of EVOH
- Other etiologies include suppurative meningitis, neoplastic or inflammatory exudates
- Subarachnoid hemorrhage (SAH), exudates may fibrose/occlude subarachnoid space, reduce CSF pulsations

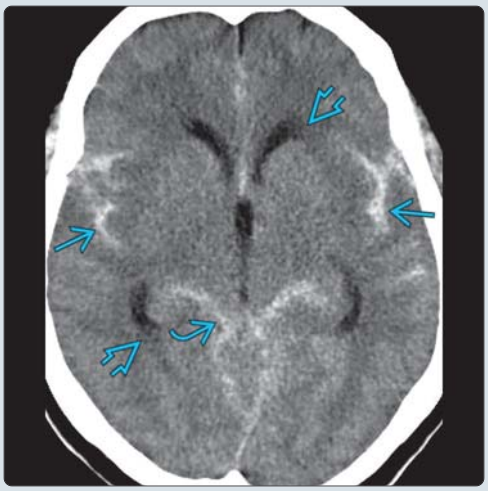
CLINICAL ISSUES

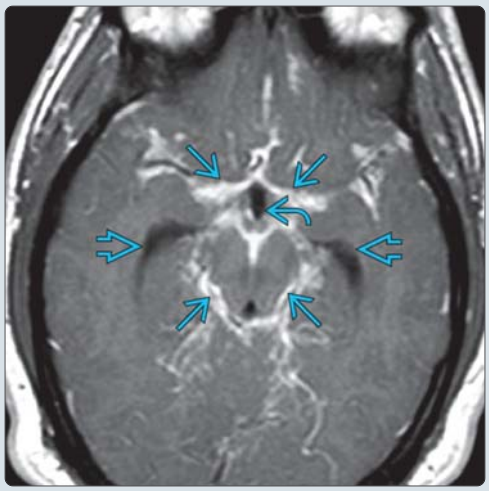
- Headache, papilledema
- Nausea, vomiting, diplopia (cranial nerve palsy)

DIAGNOSTIC CHECKLIST

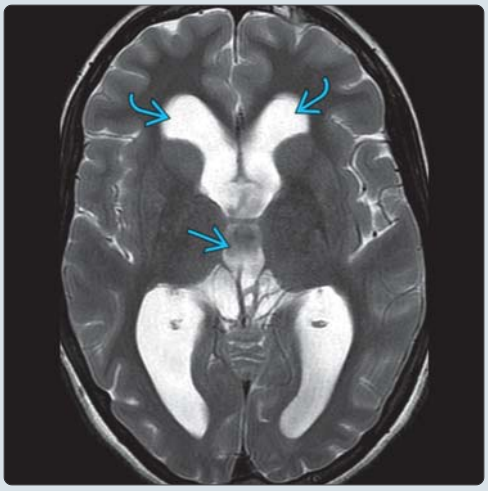
- EVOH: Generalized ventricular enlargement with abnormal density/intensity in basal cisterns ± leptomeningeal enhancement

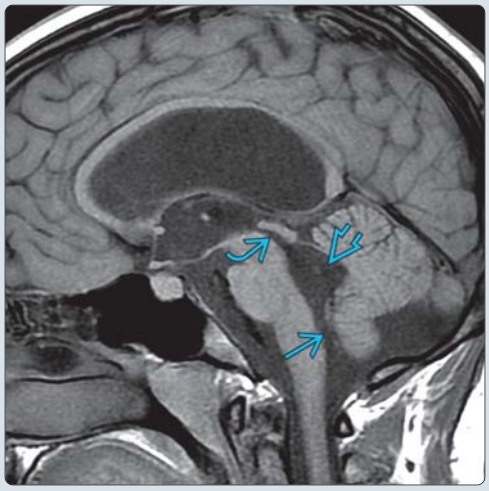
(Left) *Axial NECT shows acute subarachnoid hemorrhage in the basal cisterns and sylvian fissures. There is early extraventricular obstructive hydrocephalus with mild periventricular hypodensity due to interstitial edema.* **(Right)** *Axial T1WI C+ MR shows extensive leptomeningeal enhancement of the basal cisterns in neurosarcoidosis. Notice the early communicating hydrocephalus with the dilated 3rd ventricle and temporal horns.*





(Left) *Axial T2 MR in a 21-year-old patient with a remote history of meningitis shows chronic "compensated" extraventricular communicating hydrocephalus with marked dilatation of the lateral and 3rd ventricles.* **(Right)** *Sagittal T1 MR in the same patient shows a patent widened cerebral aqueduct and foramen of Magendie with dilatation 4th ventricle. In long standing "compensated" hydrocephalus, there is no periventricular interstitial edema around the ventricles, as in this case.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Extraventricular obstructive hydrocephalus (EVOH)

Synonyms

- "Communicating" hydrocephalus

Definitions

- Enlarged ventricles due to mismatch between CSF formation, absorption

IMAGING

General Features

- Best diagnostic clue
  - Lateral, 3rd, and 4th ventricles all dilated
  - ± abnormal density/intensity of cisternal CSF ± leptomeningeal enhancement
- Location
  - Obstruction distal to 4th ventricle outlet foramina
- Size
  - Bifrontal horn to intracranial diameter ratio > 0.33
  - Temporal horn width > 3 mm
- Morphology
  - All ventricles enlarged
    - Generally proportionate, symmetrical increase
    - No intraventricular obstructive cause

CT Findings

- NECT
  - Variable ventricular dilatation ± basal cisterns effaced
  - If subarachnoid hemorrhage (SAH), look for hyperdense CSF
- CECT
  - Look for sulcal/cisternal enhancement

MR Findings

- T1WI
  - "Dirty" CSF, ventricular dilatation
- T2WI
  - Dilated ventricles ± periventricular white matter interstitial edema
  - Effacement of cortical sulci
  - Hyperintense CSF-SAH, exudates
- FLAIR
  - ± periventricular white matter interstitial edema better delineated than T2
- T1WI C+
  - ± enhancement of basal cisterns/sulci
    - Meningitis, carcinomatosis, etc.
- 3D CISS/FIESTA
  - Exquisitely delineates CSF spaces and helps to exclude intraventricular obstruction

Imaging Recommendations

- Best imaging tool
  - MR with T1WI C+
  - 3D CISS/FIESTA

DIFFERENTIAL DIAGNOSIS

Intraventricular Obstructive Hydrocephalus

- Global/focal enlarged ventricles due to obstruction proximal to 4th ventricle outflow

Ventricular Enlargement Secondary to Parenchymal Loss

- Neurodegenerative disease, cerebritis, hypoxia/ischemia
- Diffuse/focal enlargement of sulci, cisterns

Normal Pressure Hydrocephalus

- Ventricular enlargement with normal CSF pressure
- Sulci normal/minimally enlarged
- Progressive dementia, gait disturbance, incontinence

PATHOLOGY

General Features

- Etiology
  - Obstruction to CSF flow at level of basal cisterns or arachnoid villi
    - Also reduced CSF pulsations reduce venous resorption of CSF
  - SAH: Most common cause of EVOH
  - Other etiologies include suppurative meningitis, neoplastic inflammatory exudates
    - All lead to subarachnoid scarring, reduced CSF pulsations

Gross Pathologic & Surgical Features

- SAH, exudates may fibrose/occlude subarachnoid space
- Generalized ventricular dilatation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, papilledema
  - Nausea, vomiting, diplopia (cranial nerve palsy)

Natural History & Prognosis

- Usually progressive unless shunted and primary cause treated

Treatment

- CSF diversion (shunt)
- Directed to primary cause

DIAGNOSTIC CHECKLIST

Consider

- EVOH: Generalized ventricular enlargement with abnormal density/intensity in basal cisterns ± leptomeningeal enhancement

KEY FACTS

TERMINOLOGY

- Focal reduction of cerebral aqueduct diameter

IMAGING

- Ventriculomegaly of lateral and 3rd ventricles with normal-sized 4th ventricle
- ± periventricular interstitial edema (uncompensated hydrocephalus)
- Multiplanar MR with sagittal 3D heavily T2WI sequences and sagittal cardiac-gated cine MR

TOP DIFFERENTIAL DIAGNOSES

- Obstructing extraventricular pathology
  - Neoplasm
  - Vein of Galen malformation
  - Quadrigeminal cistern arachnoid cyst
- Obstructing intraventricular (aqueductal) pathology
- Postinflammatory gliosis (aqueductal gliosis)
- Rhombencephalosynapsis

PATHOLOGY

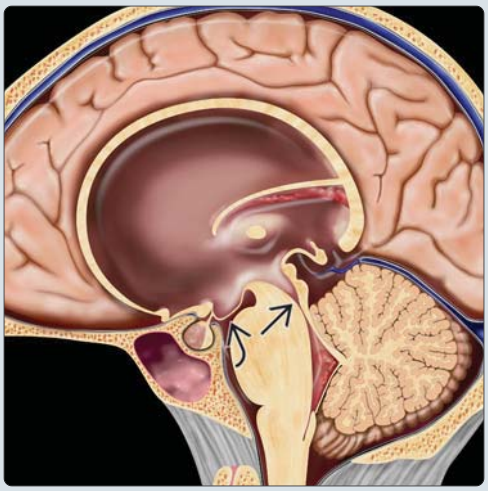
- Congenital aqueductal stenosis (AS) is common cause of fetal hydrocephalus
- Aqueductal web and fork are pathological subsets

CLINICAL ISSUES

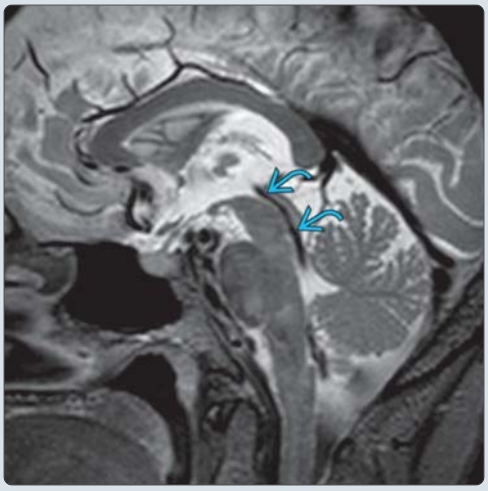
- Symptoms depend upon patient age at time of diagnosis
- Onset often insidious, may occur at any time from birth to adulthood
- Headache, papilledema, 6th nerve palsy, bulging fontanelle
- Parinaud syndrome (sun-setting eyes, lid retraction, and tonic downgaze)

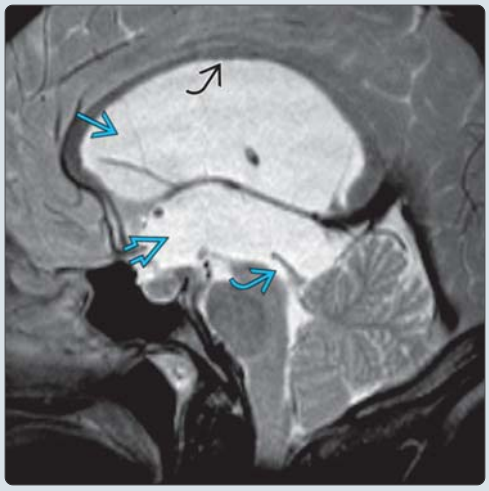
DIAGNOSTIC CHECKLIST

- Consider postinflammatory gliosis (aqueductal gliosis), particularly if history of prematurity or meningitis
- Carefully scrutinize posterior 3rd ventricle, tectum, and tegmentum for obstructing neoplastic mass



(Left) *Sagittal graphic shows obstructive hydrocephalus with markedly enlarged lateral and 3rd ventricles, stretched (thinned) corpus callosum, and a funnel-shaped cerebral aqueduct ⇨ related to distal obstruction. Note the normal size of the 4th ventricle and herniation of the floor of the 3rd ventricle ⇨ from the hydrocephalus.* **(Right)** *Sagittal T1WI C+ MR demonstrates aqueductal web ➡ causing dilation of the proximal cerebral aqueduct and lateral 3rd ventriculomegaly. The 4th ventricle is normal.*





(Left) *Sagittal T2 SPACE MR demonstrates a normal aqueduct with a "flow void" ⇨ due to CSF flow from the 3rd ventricle into the 4th ventricle.* **(Right)** *Sagittal T2 SPACE MR demonstrates classic findings of aqueductal stenosis. There is an enlarged, funnel-shaped cerebral aqueduct ⇨ and marked dilatation of the lateral ⇨ and 3rd ventricles ⇨ with thinning and upward bowing of the corpus callosum ⇨. Note the normal size of the 4th ventricle*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Aqueductal stenosis (AS)

Definitions

- Focal reduction of cerebral aqueduct diameter with concomitant lateral and 3rd ventriculomegaly

IMAGING

General Features

- Best diagnostic clue
  - Ventriculomegaly of lateral and 3rd ventricles, foramina of Monro proximal to obstruction
  - Normal size of 4th ventricle, basilar foramina (Luschka, Magendie) distal to obstruction
- Location
  - Cerebral aqueduct; most commonly at superior colliculi or intercollicular sulcus level
- Size
  - Normal mean aqueductal cross-sectional area at birth is 0.2-1.8 mm²
- Morphology
  - Funnel-shaped enlargement of proximal cerebral aqueduct or diffuse ↓ caliber of entire aqueduct

CT Findings

- NECT
  - Ventriculomegaly of lateral and 3rd ventricles, normal-sized 4th ventricle
    - Caveat: 4th ventricle is (near) normal size in many patients with communicating hydrocephalus
  - ± periventricular interstitial edema from uncompensated hydrocephalus (HCP)
  - No obstructing midbrain/thalamic mass
    - Tectal tumors may be occult on CT; asymmetry of posterior 3rd ventricle prompts MR imaging
- CECT
  - No pathologic brain enhancement
  - ± tectal tumor enhancement

MR Findings

- T1WI
  - Ventriculomegaly of lateral and 3rd ventricles, foramina of Monro
    - Corpus callosum (CC) thinned, stretched upward
    - Fornix, internal cerebral veins, 3rd ventricle floor displaced downward
    - Enlarged rounded optic and infundibular recesses of 3rd ventricle
  - Normal size of 4th ventricle, basilar foramina
  - Aqueductal narrowing commonly proximal in more severe hydrocephalus, distal in milder hydrocephalus
  - Aqueductal web: Thin tissue membrane separating dilated aqueduct from normal-sized 4th ventricle
- T2WI
  - Aqueductal "flow void" diminished or absent
  - Disturbed/turbulent CSF flow in lateral and 3rd ventricles
  - ± periventricular interstitial edema
- T1WI C+
  - Tumor enhancement differentiates neoplastic from benign AS
  - Hydrocephalus may induce leptomeningeal venous stasis → mimics meningitis or CSF metastases
- MRA
  - Upward displacement of anterior cerebral artery branches secondary to hydrocephalus
- MRV
  - Downward displacement of internal cerebral veins secondary to hydrocephalus
- MR cine
  - Phase contrast imaging: Absent or diminished CSF flow in aqueduct

Ultrasonographic Findings

- Grayscale ultrasound
  - Use mastoid (posterolateral) fontanelle window to supplement standard views in newborn
  - Obstetrical ultrasound may permit prenatal diagnosis

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR with sagittal 3D heavily T2WI sequences and sagittal cardiac-gated cine MR

DIFFERENTIAL DIAGNOSIS

Obstructing Extraventricular Pathology

- Neoplasm
  - Tectal astrocytoma
  - Pineal region tumor
  - Thalamic tumor
- Vein of Galen malformation
- Quadrigeminal cistern arachnoid cyst

Obstructing Intraventricular (Aqueductal) Pathology

- Neurocysticercosis with aqueductal cyst

Postinflammatory Gliosis (Aqueductal Gliosis)

- Destruction of aqueductal ependymal lining → fibrillary gliosis of adjacent tissue
- Perinatal infection or hemorrhage (ICH)
  - Increasing prevalence reflects improved neonatal survival following bacterial meningitis or ICH
- Difficult to distinguish congenital AS from aqueductal gliosis on imaging
  - GRE MR can detect hemosiderin deposition from previous interventricular hemorrhage

Rhombencephalosynapsis

- Developmental midline anomaly of unknown cause
  - Continuity of cerebellar hemispheres with partial or complete absence of vermis
  - Other midline anomalies include fusion of inferior/superior colliculi, aqueductal stenosis, absence of septum pellucidum
  - When associated with trigeminal anesthesia, parietal alopecia, or brachy/turricephaly, consider Gomez-Lopez-Hernandez syndrome
- Consider this diagnosis in severe congenital HCP; carefully assess cerebellum

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Aqueductal stenosis
    - Common cause of fetal hydrocephalus
    - May be congenital or acquired, benign or neoplastic
    - AS pathologically obstructs CSF flow into 4th ventricle, basilar foramina
    - CSF production in choroid plexus continues → lateral/3rd ventricular fluid ↑ pressure, ventriculomegaly
    - Ventricles expand, compress adjacent parenchyma, stretch corpus callosum
      - May rupture/open ependymal cell junctions → transependymal CSF flow
  - Aqueductal web
    - Subset of aqueductal stenosis
    - Thin membrane of brain tissue within distal aqueduct restricts CSF flow into 4th ventricle
  - Aqueductal fork
    - Branching of aqueduct into dorsal and ventral channels
- Genetics
  - Cell adhesion molecule L1 (*L1CAM*) gene recognized cause of human hydrocephalus
    - *L1CAM* expression is essential during normal embryonic development of nervous system
    - Mutations in *L1CAM* gene responsible for 4 related disorders (X-linked hydrocephalus/HSAS, MASA, X-linked complicated spastic paraplegia type 1, and X-linked agenesis of corpus callosum)
      - Now collectively CRASH syndrome: **C**allosal hypoplasia, mental **r**etardation, **a**dducted thumbs, **s**pastic paraplegia, and X-linked **h**ydrocephalus)
      - Site of mutation within L1 protein correlates with disease severity
- Associated abnormalities
  - CRASH syndrome
    - Absence/diminution of corticospinal tracts, thalamic fusion, collicular fusion, absence of septum pellucidum, corpus callosum dysgenesis
    - Thin cerebral mantle, malformations of cortical development, hypoplastic white matter
  - Aqueductal fork
    - Fusion of quadrigeminal bodies and cranial nerve 3 nuclei, tectal molding (beaking)

Microscopic Features

- Malformations of cortical development with poor differentiation and maturation of cortical neurons on histology
- Aqueductal fork shows branching of aqueduct into dorsal and ventral channels
  - Dorsal channel usually divided into several ductules

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Symptoms depend upon patient age at time of diagnosis
  - Onset often insidious, may occur at any time from birth to adulthood
- Other signs/symptoms
  - Headache, papilledema, 6th nerve palsy, bulging fontanelles
  - Macrocrania, especially if sutures open
  - Parinaud syndrome (sun-setting eyes, lid retraction, and tonic downgaze)
  - Bobble-head doll syndrome (rare)

Demographics

- Age
  - Age at presentation depends on severity of stenosis, hydrocephalus
- Gender
  - M:F = 2:1
- Epidemiology
  - 0.5-1 per 1,000 births, recurrence rate of 1-4.5% in siblings
  - AS responsible for ~ 20% of congenital hydrocephalus

Natural History & Prognosis

- Hydrocephalus usually progressive unless treated
  - May stabilize as "arrested" or compensated hydrocephalus
- Neonates with aqueductal stenosis and normal development ~ 24-86%

Treatment

- CSF shunt diversion
- Endoscopic 3rd ventriculostomy
- Cerebral aqueductoplasty for membranous and short-segment aqueductal stenoses (selected cases)

DIAGNOSTIC CHECKLIST

Consider

- Postinflammatory gliosis (aqueductal gliosis), particularly if history of prematurity or meningitis
- Carefully scrutinize posterior 3rd ventricle, tectum, and tegmentum for neoplastic mass

Image Interpretation Pearls

- Tectal astrocytomas large enough to obstruct aqueduct may be missed on routine CT scanning
  - MR more sensitive than CT for detecting obstructing mass lesion
  - Consider neurofibromatosis type 1 when tectal astrocytoma is identified
- Consider rhombencephalosynapsis in severe congenital AS

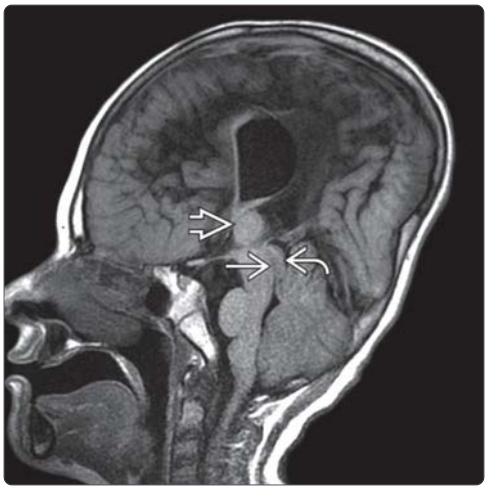
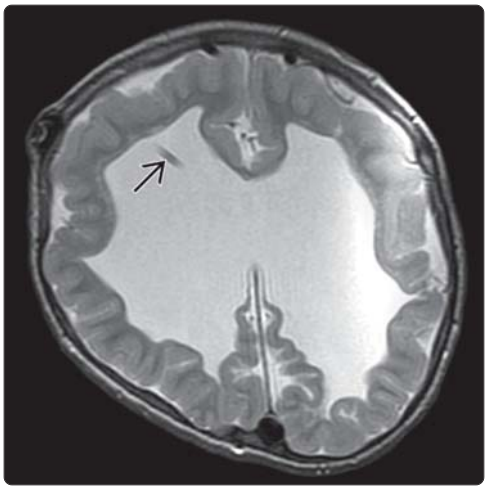
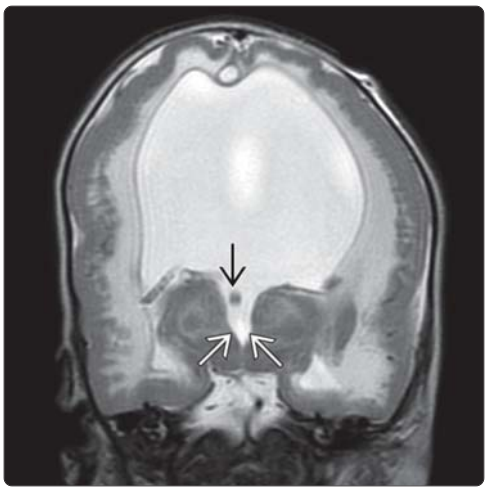
(Left) *Sagittal T1 MR demonstrates acquired aqueductal stenosis secondary to a lipoma of the quadrigeminal plate. There is marked dilatation of the lateral ventricles with thinning and upward bowing of the corpus callosum.* **(Right)** *Sagittal T1WI MR depicts proximal aqueductal stenosis producing enlargement of the lateral and 3rd ventricles with depression of the fornices in conjunction with normal 4th ventricle size. Tectum is dysplastic and thickened with collicular fusion.*





(Left) *Sagittal T1WI MR (CRASH syndrome) shows characteristic marked aqueductal stenosis with small 4th ventricle size, dysplastic tectal thickening, callosal dysgenesis, and large massa intermedia from thalamic fusion.* **(Right)** *Axial T2WI MR (CRASH syndrome) confirms marked ventriculomegaly of the lateral ventricles with abnormal cortical sulcation, striking white matter volume loss, and absent septum pellucidum. A VP shunt was placed for treatment of hydrocephalus.*



(Left) *Sagittal T1WI MR in a patient with Walker-Warburg syndrome shows severe tectal dysgenesis with aqueductal occlusion. Marked enlargement of the lateral > 3rd ventricle is present. "Zigzag" brainstem and very small cerebellum are characteristic of this syndrome.* **(Right)** *Coronal T2WI MR in the same patient with Walker-Warburg syndrome confirms marked ventriculomegaly, funnel-shaped cerebral aqueductal stenosis, fused fornices, and classic cobblestone lissencephaly.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Ventriculomegaly with normal CSF pressure, altered CSF dynamics

IMAGING

- Enlarged lateral & 3rd ventricles, 4th ventricle relatively normal
- Ventricular enlargement out of proportion to cortical sulcal enlargement
- Disproportionately enlarged subarachnoid space hydrocephalus (DESH) (particularly sylvian fissures and basal cisterns) with effacement of subarachnoid space over convexity
- ± aqueductal flow void
- Periventricular high signal transependymal CSF flow
- 18F-FDG PET shows decreased regional cerebral metabolism

TOP DIFFERENTIAL DIAGNOSES

- Normal aging brain
- Alzheimer disease
- Multi-infarct dementia (MID)
- Subcortical arteriosclerotic encephalopathy

PATHOLOGY

- Pathogenesis of NPH poorly understood
- Leading theory: Poor venous compliance in superior sagittal sinus impairs CSF pulsations and CSF absorption through arachnoid granulations

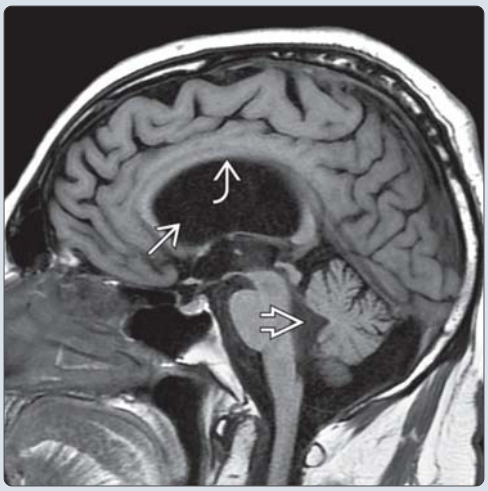
CLINICAL ISSUES

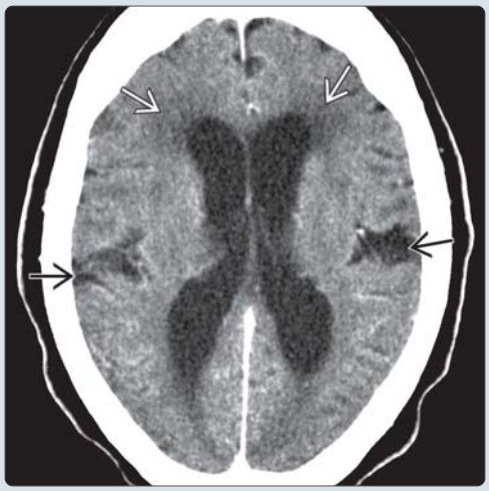
- Heterogeneous syndrome (classic clinical triad = dementia, gait apraxia, urinary incontinence)

DIAGNOSTIC CHECKLIST

- Is ventricular dilation solely due to atrophy?
- Diagnostic challenge = identify shunt-responsive NPH

(Left) *Sagittal T1WI MR shows large lateral ventricles ⇨, thinning of the corpus callosum ⇨, and a relatively normal 4th ventricle ⇨ in a patient with NPH.* **(Right)** *Axial CECT demonstrates typical findings suggestive of NPH. There is enlargement of the lateral ventricles and sylvian fissures ⇨ out of proportion to the amount of general sulcal enlargement. The frontal horns show a characteristic rounded appearance. Periventricular hypodensities ⇨ could reflect transependymal migration of CSF.*





(Left) *Axial FLAIR MR shows enlarged ventricles out of proportion to the sulcal enlargement. Notice that periventricular hyperintensity is also present ⇨.* **(Right)** *Axial T2WI MR in the same patient shows dilated ventricles. Normal pressure hydrocephalus accounts for approximately 5-6 % of all dementias. The classic Hakim triad of dementia, gait apraxia, and urinary incontinence is present in a minority of patients.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Normal pressure hydrocephalus (NPH)

Synonyms

- Idiopathic adult hydrocephalus syndrome

Definitions

- Ventriculomegaly with normal CSF pressure, altered CSF dynamics

IMAGING

General Features

- Best diagnostic clue
  - Enlarged lateral & 3rd ventricles, 4th ventricle relatively normal
  - Ventricular enlargement out of proportion to cortical sulcal enlargement
  - Disproportionately enlarged subarachnoid space hydrocephalus (DESH) (particularly sylvian fissures and basal cisterns) with effacement of subarachnoid space over convexity
- Location
  - Ventriculomegaly involves all 3 horns of lateral ventricles, plus 3rd ventricle
    - 4th ventricle relatively spared
- Size
  - Increased ventricular volume
  - Evans index (ratio of widest diameter of frontal horns to widest diameter of brain on same axial slice) ≥ 0.3
  - Callosal angle (angle between lateral ventricles on coronal image) ≤ 90°
  - Dilatation of sylvian fissures
- Morphology
  - Diffuse expansion of ventricles

CT Findings

- NECT
  - Ventriculomegaly with rounded frontal horns, out of proportion to sulcal atrophy (ventriculosulcal disproportion)
  - Frontal/occipital periventricular hypodensities (representing transependymal CSF flow) may be present
  - Corpus callosal thinning (nonspecific)
  - Prominent basal cisterns & sylvian fissures

MR Findings

- T1WI
  - Lateral ventricles enlarged with rounded frontal horns
  - Moderately dilated 3rd ventricle, relatively normal 4th ventricle
  - ± aqueductal flow void
- T2WI
  - Periventricular high signal, primarily anterior to frontal horns or posterior to occipital horns of lateral ventricles (transependymal CSF flow)
  - 50-60% have periventricular and deep white matter lesions
    - More frequent, severe compared to age-matched controls
    - Positive outcome after shunting and should not exclude patients from surgery
- Enlarged basal cisterns, sylvian fissures
- Dilatation of optic and infundibular recesses of anterior 3rd ventricle and downward displacement of hypothalamus
- Focal bulging of roof of lateral ventricles
- Corpus callosum bowed upward (may be impinged by falx)
- Aqueductal flow void sign
  - Reflects increased CSF velocity through cerebral aqueduct
    - May be reduced if flow compensation, FSE techniques used
- Cortical and subcortical lacunar infarctions (basal ganglia, internal capsule)
- Diffusion tensor imaging
  - ↑ fractional anisotropy (FA) values in posterior limb of internal capsule

Nuclear Medicine Findings

- PET
  - FDG-18 PET shows decreased regional cerebral metabolism
- SPECT: Cerebral blood flow ↓ in patients with NPH
- In-111 DTPA cisternography
  - Prominent ventricular reflux, with no flow over convexities at 24-48 hours
  - High false-positive rate

Other Modality Findings

- Phase-contrast cine MR imaging
  - Cardiac gated CSF flow studies to detect increased velocity ("hyperdynamic" flow)
  - Aqueduct stroke volume (ASV): Lack of correlation between ASV and symptom severity
  - Some patients with normal CSF flow values also improve
- ICP monitoring: Wave amplitude > 9 mm Hg correlates with post-shunt cognitive improvement

Imaging Recommendations

- Best imaging tool
  - MR with CSF flow studies
  - CT helpful

DIFFERENTIAL DIAGNOSIS

Normal Aging Brain

- Thin periventricular high signal rim is normal
- Few/no white matter hyperintensities ("successfully aging brain")

Alzheimer Disease

- Dementia out of proportion to gait disturbance
- Large parahippocampal fissures, small hippocampi, sulcal enlargement

Multi-Infarct Dementia (MID)

- Multiple infarcts on imaging

Subcortical Arteriosclerotic Encephalopathy (Binswanger Disease)

- Continuous, irreversible ischemic degeneration of periventricular and deep white matter

https://CafePezeshki.IR

- MR shows extensive periventricular and deep white matter hyperintensities, enlarged ventricles
  - Reflect microinfarctions and demyelination

PATHOLOGY

General Features

- Etiology
  - Pathogenesis of NPH poorly understood
  - 50% idiopathic
  - 50% other (e.g., subarachnoid hemorrhage, meningitis, neurosurgery, or head trauma)
  - Age-related changes in CSF formation/absorption
    - Increased resistance to CSF outflow
    - May be exacerbated in NPH
  - Dysfunctional CSF dynamics
    - Reduced absorption through arachnoid villi
    - Compensatory CSF flow into periventricular white matter
    - Transcapillary CSF resorption
  - NPH: Reduced CBF, altered CSF resorption without increased CSF pressure
    - Brain expands in systole, causes CSF displacement
    - Loss of parenchymal compliance, altered viscoelastic properties of ventricular wall
    - Increased interstitial fluid
    - Pulsation pressure directed toward ventricles
    - "Water hammer" effect
    - May be further complicated by microangiopathy (including venous compromise), atrophy
  - Leading theory: Poor venous compliance in superior sagittal sinus impairs CSF pulsations and CSF absorption through arachnoid granulations

Gross Pathologic & Surgical Features

- Enlarged ventricles, normal CSF pressure
- Periventricular white matter stretched, dysfunctional
  - Inadequate perfusion without frank infarction

Microscopic Features

- Arachnoid fibrosis (50%)
- Periventricular tissue
  - Disruption of ependyma
  - Edema, neuronal degeneration, and gliosis
- Cerebral parenchyma
  - Almost 50% show no significant pathology
  - 20% neurofibrillary tangles, other Alzheimer disease changes
  - 10% arteriosclerosis, ischemic encephalomalacia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Heterogeneous syndrome (classic clinical triad = dementia, gait disorder, urinary incontinence)
  - Gait disorder: Disturbed postural and locomotor reflexes in absence of primary sensorimotor deficits
  - Bladder dysfunction: Urinary urgency with difficulty inhibiting bladder emptying
  - Dementia: Apathy or amotivation, daytime sleepiness, psychomotor slowing
- Clinical profile
  - Reversible cause of dementia

Demographics

- Age
  - Most common in patients > 60 years
  - Idiopathic form of NPH tends to present in elderly
- Gender
  - M > F
- Ethnicity
  - No racial predilection
- Epidemiology
  - Accounts for ~ 5-6 % of dementias

Natural History & Prognosis

- Continuing cognitive and motor decline, akinetic mutism, and eventual death
- Potentially reversible cause of dementia when shunted

Treatment

- Large-volume lumbar puncture (also known as the tap test) has high positive predictive value
  - Test is used to assess patient's response to CSF removal
  - Patient must be examined before and after LP
  - Typical "tap test" protocols remove 30–50 mL of CSF and observe change in gait & cognition 30 minutes to 4 hours afterward
- Shunt surgery indicated for patients who respond to CSF drainage or have CSF hydrodynamic variables consistent with NPH
- Recent studies have suggested positive effect of endoscopic 3rd ventriculostomy
- Predictors of positive response to shunting remains elusive
- After shunt surgery, variable outcome
  - Clinical response to shunting ranges from 29% to 90%
  - Gait disturbance is clinical symptom most likely to respond to surgery
  - Irregular periventricular hyperintensities seem to be key reversible white matter change at MR imaging

DIAGNOSTIC CHECKLIST

Consider

- Whether ventricular dilation is solely due to atrophy
- Diagnostic challenge = identify shunt-responsive NPH

Image Interpretation Pearls

- Intraventricular lactate level may be useful in differentiating NPH from other types of dementia

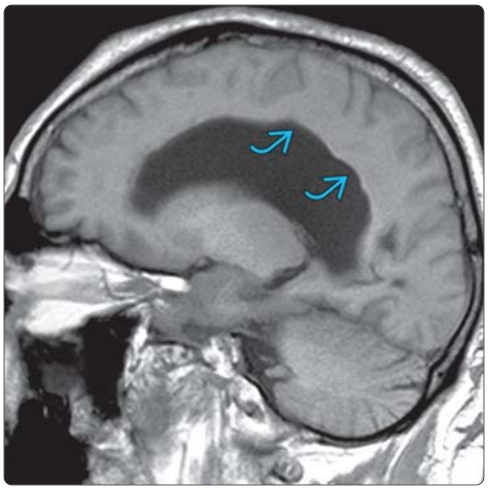
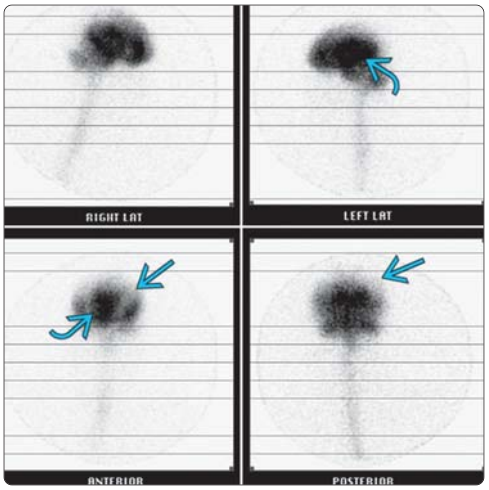
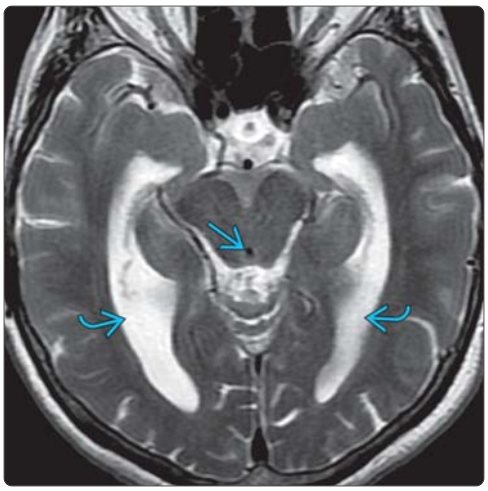
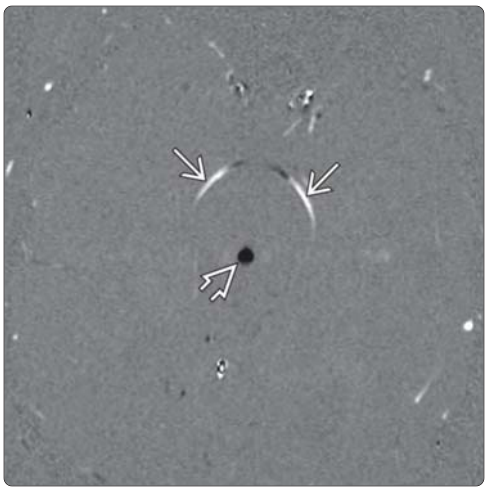
(Left) *Axial NECT shows large ventricles out of proportion to the sulcal prominence with a rounded appearance of the frontal horns.* **(Right)** *Axial T2WI MR in the same patient shows ventriculomegaly. The patient presented with the classic clinical triad of normal pressure hydrocephalus (NPH): Dementia, gait apraxia, and urinary incontinence. One treatment option is ventricular shunting. The favorable response to shunting varies from 29% to 90%.*





(Left) *Sagittal T1 MR in a patient with NPH demonstrates focal bulging of the roof of the lateral ventricles, which has been recently described.* **(Right)** *24-hour multiplanar In-111 DTPA cisternography in a patient with NPH shows radiotracer in the lateral ventricles with lack of activity over the convexity. Normally, there should be radiotracer movement over the convexities at 24-hour. (Courtesy C. Singh, MD, A. Ali, MD.)*





(Left) *Axial T2WI MR in 65 year old with NPH shows dilated temporal horns and low signal flow void in the aqueduct caused by hyperdynamic flow of CSF.* **(Right)** *Axial MR phase contrast cine CSF flow study shows increased velocity of CSF through the dilated aqueduct. There is more hyperdynamic flow through the aqueduct than the cisterns, where no high velocity signal change is seen. Flow is incidentally noted in the posterior cerebral arteries.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Hydrocephalus
  - Enlargement of cerebral ventricles secondary to abnormal CSF formation, flow, or absorption resulting in ↑ CSF volume

IMAGING

- Shunt failure → dilated ventricles + edema around ventricles, along catheter and reservoir
- Use CT or MR to evaluate ventricle size, plain radiograph shunt series to identify mechanical shunt failure
- Baseline CT/MR following shunt insertion, follow-up at 1 year and as clinically needed
- Shunt radionuclide studies: Used to confirm distal obstruction

TOP DIFFERENTIAL DIAGNOSES

- Shunt failure with normal ventricle size or lack of interstitial edema
- Noncompliant ("slit") ventricle syndrome
- Acquired Chiari 1 malformation/tonsillar ectopia

PATHOLOGY

- Obstructive hydrocephalus: Secondary to physical blockage by tumor, adhesions, cyst
- Communicating hydrocephalus: Secondary to ↓ CSF absorption across arachnoid granulations

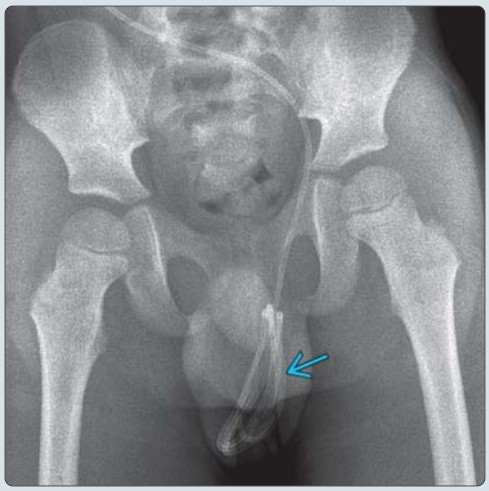
CLINICAL ISSUES

- Older children/adults: Headache, vomiting, lethargy, seizure, neurocognitive symptoms
- Infants: Bulging fontanelle, ↑ head circumference, irritability, lethargy

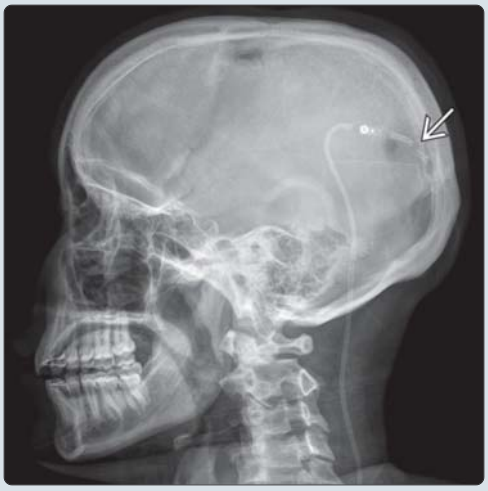
DIAGNOSTIC CHECKLIST

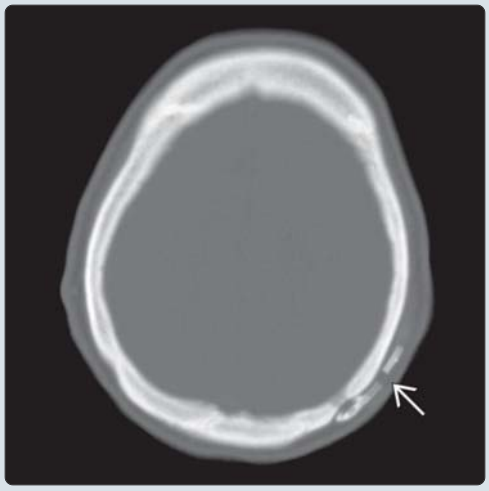
- Shunt + headache not always shunt failure
- Confirm programmable shunt valve setting after MR
- Compare current CT with prior studies to detect subtle changes in ventricle size

(Left) *Lateral radiograph from a plain film shunt series in an infant with acute shunt failure demonstrates that the ventricular catheter has pulled out of the head and is laying along the distal catheter within the scalp (tip ➡).* **(Right)** *AP radiograph of the pelvis in a 4 year old with a ventriculoperitoneal shunt who presented with left scrotal swelling demonstrates a coiled distal shunt catheter ⇨ in the left scrotum. The migration of the catheter to the scrotum is due to a patent processes vaginalis.*



(Left) *Lateral skull radiograph of acute VP shunt failure from a plain radiograph shunt series demonstrates a mechanical shunt catheter disconnection ➡ between the programmable valve and the reservoir.* **(Right)** *Axial bone CT in the same patient reveals the mechanical catheter disconnection ➡ between the reservoir and the programmable shunt valve. This finding had not appeared on the most recent comparison CT scan (not shown).*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Shunt types: Ventriculoperitoneal (VP), ventriculoatrial (VA), ventriculopleural (VPL), lumboperitoneal (LP)

Definitions

- Ventriculomegaly
  - General term for enlargement of cerebral ventricles
- Hydrocephalus (HCP)
  - Enlargement of cerebral ventricles secondary to abnormal CSF formation, flow, or absorption resulting in ↑ CSF volume
    - Onset over days (acute), weeks (subacute), or months to years (chronic)

IMAGING

General Features

- Best diagnostic clue
  - Shunt failure: Dilated ventricles + edema ("blurring") around ventricles and along catheter, reservoir
- Location
  - VP shunt common; VA and VPL used rarely unless VP contraindicated
- Size
  - Ventricular size is relative → ventriculomegaly may indicate shunt failure in 1 patient and be stable finding in another
    - Change in ventricular size in individual patient probably significant
    - Conversely, some patients manifest shunt failure with minimal to no change in ventricular size
  - Distal catheter must be sized long enough to permit somatic growth, prevent retraction out of abdomen or chest
- Morphology
  - Shunt system components
    - Proximal catheter in ventricles, subarachnoid space, syrinx cavity, or thecal sac
    - Unidirectional valve prevents reflux into ventricles
    - Reservoir used to sample CSF, acutely relieve pressure
    - Distal catheter tunneled through subcutaneous tissues → tip in peritoneal cavity, cardiac atrium, or pleural cavity

Radiographic Findings

- Radiography
  - Evaluate shunt catheter system integrity
    - Shunt fracture, separation, migration
    - Distal catheter may retract out of abdomen if significant somatic growth since shunt placement

CT Findings

- NECT
  - Ventricular dilatation (diffuse or loculated)
    - "Isolated" ventricle after infection, hemorrhage → interventricular synechia
    - Periventricular interstitial edema ("blurred" ventricle margins) → acute hydrocephalus
  - Small, "slit" ventricles → noncompliant ventricle syndrome, chronic overdrainage
  - ± subdural hematoma (CSF overdrainage)

MR Findings

- T1WI
  - Assess ventricular size, characterize brain anatomy
- T2WI
  - ± interstitial parenchymal edema (transependymal CSF flow) → acute shunt failure
- FLAIR
  - Interstitial edema more conspicuous than on T1WI or T2WI
- T1WI C+
  - ± enhancement with ventriculitis, abscess, neoplasm
  - Pachymeningeal enhancement due to low intracranial pressure
- MRA
  - Stretched, displaced arteries around dilated ventricles secondary to ventriculomegaly
- MRV
  - Venous thrombosis may precede hydrocephalus or follow shunting
    - Leads to increased intraventricular/intracranial pressure (ICP)
- MR cine
  - Evaluate patency of normal CSF pathways, 3rd ventriculostomy

Ultrasonographic Findings

- Grayscale ultrasound
  - Useful in neonates for serial assessment of ventricular size (requires open fontanelle)

Nonvascular Interventions

- Interventricular contrast injection through shunt plus NECT→ detect ventricular isolation needing additional catheter

Nuclear Medicine Findings

- Shunt radionuclide studies
  - Radiotracer injected into shunt reservoir, serial imaging to document timing of radiotracer egress from distal catheter tip
  - Used to confirm distal obstruction

Imaging Recommendations

- Best imaging tool
  - Brain NECT to assess for acute ventricular size change
  - Fast MR imaging protocols (HASTE, SSFSE) used in many centers with 24-hour MR availability to avoid cumulative radiation exposure
- Protocol advice
  - Brain CT or MR to evaluate ventricle size
  - Plain film shunt series to identify mechanical shunt fracture or disconnection

DIFFERENTIAL DIAGNOSIS

Shunt Failure With Normal Ventricle Size or Lack of Interstitial Edema

- Look for fluid along shunt catheter or reservoir as only sign of malfunction
- May require diagnosis on clinical grounds

https://CafePezeshki.IR

Noncompliant ("Slit") Ventricle Syndrome

- Usually older child (shunted in infancy)
- Small ventricles plus intermittent signs of shunt obstruction
- Ventricles normal/small even if shunt malfunctioning

Acquired Chiari 1 Malformation/Tonsillar Ectopia

- Functioning LP shunt produces tonsillar descent through foramen magnum
- More common with valveless systems

PATHOLOGY

General Features

- Etiology
  - Impairment of CSF circulation
    - Obstructive
      - Usually at narrowest points in CSF circulation (aqueduct, foramina of Monro)
      - Tumor, web/synechia, congenital aqueductal stenosis
    - Inadequate reabsorption across arachnoid granulations into venous sinuses
      - Arachnoid granulations "clogged" after hemorrhage, inflammation
      - Diminished pressure gradient from subarachnoid space to venous sinuses secondary to venous hypertension
      - Impaired CSF absorption → CSF accumulation, ↑ ICP
  - CSF shunt establishes accessory drainage pathway to bypass obstructed natural CSF flow pathways
    - Restores or maintains normal intracranial pressure
  - Each shunt, valve, device carries its own set of complications
    - All types → material degradation/fatigue, mechanical stress (especially craniocervical junction, inferior ribs)
    - VP → abdominal complications (CSF pseudocyst, ascites, bowel perforation)
    - VPL → symptomatic pleural effusion
    - VA → shunt nephritis, cor pulmonale, pulmonary embolus
    - LP → arachnoiditis, cerebellar tonsillar herniation, high catheter migration rate
    - Programmable shunt → unintentional reprogram during MR imaging
- Associated abnormalities
  - Shunts placed with CSF blood/protein > 1 g/dL prone to early blockage, failure
  - Shunt infection
  - Ventricular loculation or isolation
  - Overshunting

Gross Pathologic & Surgical Features

- Ventricular ependymal adhesions ("scar")
- Extracranial shunt tubing calcification

Microscopic Features

- Gliosis along intracranial shunt tract

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Children, adults
    - Headache, vomiting, lethargy, seizure
    - Neuropsychologic, cognitive, or behavioral
  - Infants
    - Bulging fontanelle, increasing head circumference, irritability, lethargy

Demographics

- Epidemiology
  - 160,000 shunts implanted each year worldwide
  - CSF shunts in USA ~ 125,000 total
    - 33,000 placed per year (~ 50% revisions)

Natural History & Prognosis

- Acute shunt obstruction in shunt-dependent patients may lead to death
- Majority of shunts eventually fail, complication rate 25-37%
  - ≤ 40% shunts fail in 1st year, 80% fail by 10 years
  - 50% of patients need multiple revisions, progressively shorter time interval to next failure

Treatment

- Shunt revision
  - Replace intraventricular component/valve for proximal obstruction
  - Alter valve pressure setting/type if over- or underdraining
    - Programmable shunt valves permit transcutaneous adjustment of pressure setting
  - Lengthen distal shunt as child grows
- 3rd ventriculostomy to avoid indwelling shunt if blockage is distal to 3rd ventricle
- Laparoscopic or open abdominal procedure for distal obstruction related to CSF pseudocyst

DIAGNOSTIC CHECKLIST

Consider

- Shunt + headache does not always mean shunt failure
  - Consider sinusitis, trauma, sinovenous thrombosis, viral infection
- Confirm programmable shunt valve setting after MR
- Plain film shunt series has extremely low yield in absence of clinical evidence for mechanical shunt failure

Image Interpretation Pearls

- Compare with prior studies to detect subtle ventricular size changes
- Fluid tracking along shunt may be only sign of failure, possible even if ventricles normal or unchanged size

Gross Anatomy

Sella

Bony anatomy: The sella turcica ("Turkish saddle") is a concave, midline depression in the basisphenoid that contains the pituitary gland (also called the hypophysis). The anterior borders of the sella are formed by the anterior clinoid processes of the lesser sphenoid wing and the tuberculum sellae, while the posterior border is formed by the dorsum sellae. The top of the dorsum sellae expands to form the posterior clinoid processes, which in turn form the upper margin of the clivus. The floor of the sella is part of the sphenoid sinus roof, which is partially or completely aerated. The cavernous segments of the internal carotid artery lie in shallow grooves, called the carotid sulci, which are located inferolateral to the sella.

Meninges: The meninges in and around the sella turcica form important anatomic landmarks. Dura covers the bony floor of the sella itself. A thin dural reflection borders the pituitary fossa laterally and forms the medial cavernous sinus wall. A small circular dural shelf, the diaphragma sellae, forms a roof over the sella turcica that, in most cases, almost completely covers the pituitary gland. The diaphragma sella has a variably sized central opening that transmits the pituitary stalk. In some cases, this dural opening is large and gapes widely. In such cases, arachnoid with or without accompanying CSF may protrude from the suprasellar cistern inferiorly through the diaphragma sellae opening into the sella turcica and cause the imaging appearance of an empty sella.

Pituitary Gland

Overview: The pituitary gland, also called the hypophysis cerebri, consists of three major parts: The adenohypophysis (AH), the neurohypophysis (NH), and the pars intermedia (PI) plus the infundibulum, which are generally considered together as a unit.

Adenohypophysis: The AH, also called the anterior lobe, wraps anterolaterally around the NH in a U-shaped configuration. The AH contains acidophil, basophil, and chromophobe cells, as well as other cells, such as tanycytes. Cells of the AH secrete trophic hormones (TSH, ACTH, LH, and FSH) as well as growth hormones (GHs). The AH forms 80% of the pituitary gland by volume.

Pars intermedia: The PI is derived from the buccal ectoderm of the embryonic Rathke pouch. It is relatively small (less than 5% of the pituitary volume). Axons from the hypothalamus carry granules of releasing hormones to the AH.

Neurohypophysis: The NH, sometimes called the pars nervosa, consists of the posterior lobe of the pituitary gland, infundibular stem, and median eminence of the hypothalamus. The NH is formed from the embryonic diencephalon (forebrain) as a downward extension of the hypothalamus. Vasopressin and oxytocin are formed within the hypothalamus, pass inferiorly along the hypothalamohypophysial tract, and are stored in the NH. The NH comprises approximately 20% of the pituitary gland.

Imaging Recommendations

MR

MR is generally the imaging procedure of choice. Recommended sequences include pre-contrast thin-section, small FOV sagittal and coronal T1- and T2WIs followed by post-contrast sagittal and coronal T1WI C+ FS images. Whole-brain FLAIR is a useful sequence to add. T2*/SWI may be helpful in detecting pituitary hemorrhage. If microadenoma is suspected, dynamic imaging with coronal thin-section T1WIs obtained at 5-10 second intervals following rapid bolus injection of contrast are recommended. At least three sections (3 mm or less with no interslice gap), sorted by slice, are typically obtained. Some 20-30% of microadenomas are detected only on dynamic contrast-enhanced MR imaging.

CT

Thin-section coronal CT with sagittal/coronal reconstruction may be a useful imaging adjunct when lesions affecting the sella &/or cavernous sinus arise in the basisphenoid.

Imaging Anatomy

Size: The overall height of the pituitary gland varies with both gender and age. In prepubescent children, 6 mm or less is considered normal. Physiologic hypertrophy, with a normal height of up to 10 mm, is common in young menstruating females. An upwardly convex gland is common in these patients. Pregnant and lactating females can have an even larger gland with a height of 12 mm. The upward limit of normal in adult males and postmenopausal females is 8 mm.

Signal intensity: Pituitary gland signal varies. With the exception of neonates (in whom the AH can be large and very hyperintense), the AH is typically isointense to gray matter on pre-contrast T1WIs. A dark or black pituitary gland seen on T2* is found in iron overload states (thalassemia, hemochromatosis). A uniformly white pituitary gland on T1WI is uncommon and can be seen in liver failure.

The NH usually has a short T1 (posterior pituitary "bright spot" or PPBS) likely caused by vasopressin/oxytocin neurosecretory granules. The "bright spot" does not suppress with FS as it does not contain fat. Although the absence of a PPBS is common in central diabetes insipidus, up to 20% of normal imaged patients lack a PPBS.

Enhancement: The pituitary gland does not have a blood-brain barrier so it enhances rapidly and strongly following contrast administration. Enhancement is typically slightly less intense than that of venous blood in the adjacent cavernous sinuses.

Pituitary "incidentalomas" are common on T1WI C+ scans (found in 15-20% of cases). Seen as focal areas of hypointensity within the intensely enhancing pituitary gland, they can be caused by intrapituitary cysts as well as nonfunctioning microadenomas. Both are very common at autopsy. If a pituitary "incidentaloma" does not enhance at all, then a benign nonneoplastic cyst (such as a pars intermedia or Rathke cleft cyst) is more likely than a microadenoma.

Differential Diagnosis Approach

Overview: Because the sellar region is anatomically very complex, at least 30 different lesions occur in and around the pituitary gland. They can arise from the pituitary gland or any adjacent structure (brain, third ventricle, meninges, cavernous sinus, arteries, cranial nerves, etc.). At least 75-80% of all sellar/juxtasellar masses are in the "Big 5": Macroadenoma, meningioma, aneurysm, craniopharyngioma, and astrocytoma. All other lesions (e.g., Rathke cleft and arachnoid cysts, germinoma, lymphoma, metastasis, etc.) are each 1-2% or less.

Keys to diagnosis: Anatomic sublocation is the most important key to establishing an appropriate differential diagnosis. Initially dividing lesions into three categories, (1) intrasellar (2) suprasellar and (3) infundibular, is the first step.

https://CafePezeshki.IR

The key to determining anatomic sublocation accurately is asking the question, "Can I find the pituitary gland separate from the mass?" If the gland **is** the mass, it is most likely a macroadenoma. Less likely pathologies that can enlarge the pituitary gland and sometimes appear indistinguishable from macroadenoma include infiltrating lesions, such as sarcoidosis, histiocytosis, hypophysitis, lymphoma, germinoma, and metastasis. If the mass can indeed be identified as separate from the pituitary gland, it is most likely not macroadenoma and arises from structures other than the hypophysis.

Clinical considerations: Patient age is an important consideration in differential diagnosis. Lesions that are common in children (craniopharyngioma and astrocytoma of the optic chiasm/hypothalamus) are less common in adults, in whom the most common masses are macroadenoma, meningioma, and aneurysm. Macroadenomas are very common in adults but, with the exception of adolescent females, are quite rare in children. Beware: A lesion in a prepubescent male that looks like a macroadenoma usually isn't; it is more often nonphysiologic nonneoplastic hyperplasia from end-organ failure.

Imaging appearance: Imaging appearance can be very helpful in evaluating a sellar/juxtasellar lesion. Is the lesion calcified? Does it appear cystic? Does it contain blood products? Is it focal or infiltrating? Does it enhance?

Intrasellar Lesions

Empty sella: Empty sella is seen in 5-10% of patients as an intrasellar CSF collection that flattens the pituitary gland against the sellar floor. Other than empty sella, most intrasellar masses are lesions of the pituitary gland itself.

Pituitary hyperplasia: Diffuse pituitary enlargement or hyperplasia is common and can be physiologic in young menstruating females and postpartum/lactating women. Less commonly, pituitary hyperplasia occurs as a result of end-organ failure, such as hypothyroidism. Rarely, intracranial hypotension and dAVFs cause pituitary enlargement, probably due to passive venous congestion.

Macro- and microadenomas: The most common "real" intrasellar masses are pituitary microadenomas (defined as < 10 mm) and macroadenomas. Macroadenomas may extend superiorly through the diaphragma sella opening into the suprasellar compartment. Occasionally macroadenomas can appear very aggressive and extremely invasive, extending into the cavernous sinus and eroding the skull base. Pituitary carcinoma is exceptionally rare, typically diagnosed at the time of metastatic spread.

Miscellaneous lesions: A number of neoplastic and nonneoplastic processes can infiltrate the pituitary gland and adjacent structures, such as neurosarcoid, lymphoma, and metastases.

Suprasellar Lesions

Children vs. adults*:* Once a lesion is defined as suprasellar, patient age is key to the differential diagnosis. Pediatric suprasellar masses are most often either craniopharyngiomas or pilocytic astrocytomas (hypothalamus, optic chiasm). All other lesions, such as germinoma and histiocytosis, are much less common.

At least 1/2 of all suprasellar masses in adults are upward extensions of macroadenomas through the diaphragma sella. Macroadenomas are typically heterogeneously enhancing masses that may contain cysts or blood products. Macroadenomas often enlarge or remodel the sella turcica. Meningioma and aneurysm are common in adults, accounting for approximately 10% each of all adult suprasellar masses. Both are rare in children. Meningiomas are homogeneously enhancing masses, separate from the pituitary gland. Aneurysms may be identified on MR by a flow void or pulsation artifact. If thrombosed, an aneurysm may have a laminated appearance. CTA or MRA may be helpful in further characterizing a sellar region aneurysm.

Imaging appearance: Cystic-appearing suprasellar masses are often nonneoplastic (enlarged third ventricle, Rathke cleft cyst [RCC], suprasellar arachnoid cyst, and inflammatory cysts, such as neurocysticercosis). RCCs may be intrasellar (40%) or suprasellar (60%). RCCs may be asymptomatic or present with pituitary dysfunction, visual changes, or headache. RCCs are noncalcified, nonenhancing, cystic lesions on CT and MR. A helpful clue on MR is the presence of an intracystic nodule. Craniopharyngioma is the most common suprasellar mass in a child and is often known as the 90% tumor; 90% are cystic, 90% are calcified, and 90% enhance. With the exception of craniopharyngioma, cystic-appearing neoplasms are rare in this location. Pilocytic astrocytoma is the overall most common pediatric glial neoplasm in this area. Pilocytic astrocytomas of the optic chiasm/hypothalamus are solid, not cystic (as they often are when they occur in the posterior fossa).

The presence of calcification is helpful. In older patients, atherosclerosis (cavernous and supraclinoid internal carotid arteries), saccular aneurysm, and meningioma are common lesions that calcify. In children, a calcified suprasellar mass is most often a craniopharyngioma. Neurocysticercosis (NCC) can calcify and may be found in both children and adults, but the suprasellar cistern is a rare location for NCC cysts.

Hemorrhage into a sellar/suprasellar mass can be detected with T2* imaging or SWI. Hemorrhagic macroadenoma, pituitary apoplexy, and thrombosed aneurysm can show "blooming." The pilomyxoid variant of pilocytic astrocytoma is a rare but important cause of a hemorrhagic suprasellar mass in a child or young adult.

Infundibular Stalk Lesions

Infundibular stalk lesions are a distinct differential diagnosis. The normal infundibular stalk should be 2 mm or less in transverse diameter and taper gradually from top to bottom.

A "thick stalk" in a child is usually histiocytosis or germinoma. In an adult, neurosarcoid, lymphocytic hypophysitis, lymphoma, and metastasis are more common. Lesions of the infundibulum often present with diabetes insipidus. Enhancement is often unhelpful as the normal infundibulum lacks a blood-brain barrier and enhances intensely following contrast administration. Neurosarcoid may affect the infundibulum only and appear as a thickened, enhancing stalk, but more commonly presents with other CNS lesions. Hypophysitis may be related to an autoimmune inflammatory disorder, granulomatous disease, IgG4 related, or drug related. A recent cancer immunotherapy (ipilimumab) has been associated with lymphocytic hypophysitis, which may affect the gland &/or only the infundibulum.

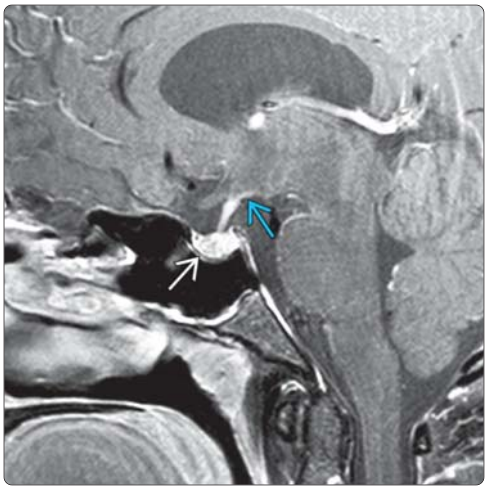
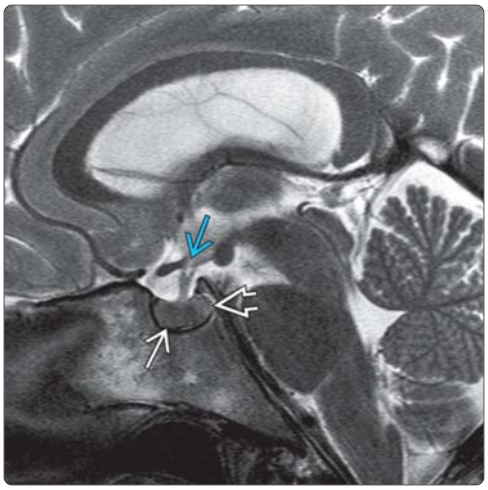
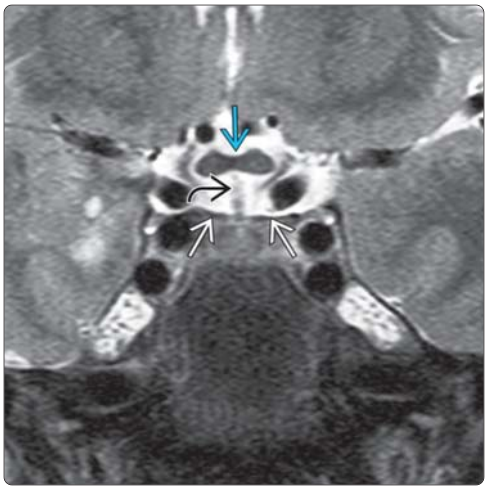
(Top) *Lateral graphic of a normal pituitary shows the adenohypophysis composed of the pars tuberalis, pars intermedia, and pars distalis. The neurohypophysis is composed of the median eminence of the hypothalamus, infundibulum, and pars nervosa. Periosteal dural layer covers the sellar floor.* **(Bottom)** *Coronal graphic depicts the cavernous sinus contents. The cranial nerves that traverse the cavernous sinus within the lateral wall, from superior to inferior, are oculomotor (CN3), trochlear (CN4), and the 1st (ophthalmic or V1) and 2nd (maxillary or V2) divisions of trigeminal (CN5) nerves. The only cranial nerve actually within the venous sinusoids of the cavernous sinus is the abducens nerve (CN6). The abducens nerve is often the 1st cranial nerve affected by a cavernous carotid artery aneurysm.*

https://CafePezeshki.IR

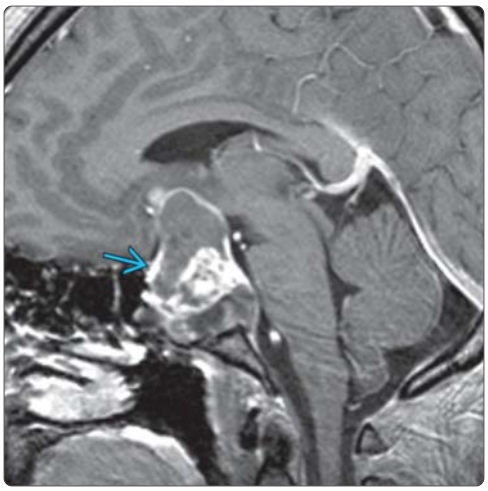


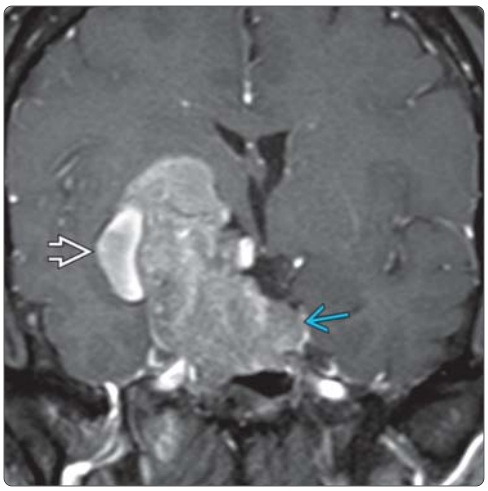
(Left) *Sagittal 3T T1WI with FS MR shows the normal adenohypophysis is isointense with gray matter; the posterior pituitary is hyperintense. This posterior pituitary "bright spot" does not suppress on FS sequences. Note the gradual top-to-bottom tapering of the infundibulum.* **(Right)** *Sagittal T1 C+ FS MR in the same patient shows intense, slightly inhomogeneous enhancement of the pituitary gland. The stalk enhances, as does the tuber cinereum of the hypothalamus, anterior to the mammillary bodies.*





(Left) *Sagittal T2WI MR shows the adenohypophysis (AH) is isointense with brain. The neurohypophysis is slightly hyperintense compared to the AH. Note the infundibular recess of the 3rd ventricle.* **(Right)** *Coronal T2WI MR shows the infundibular stalk passing inferiorly through a small discontinuity in the thin shelf of dura, the diaphragma sellae, seen here as thin black lines forming the roof of the pituitary fossa. The optic chiasm is present superiorly within the suprasellar cistern and is often affected by suprasellar masses.*





(Left) *Sagittal T1 C+ MR in a child shows a complex, cystic, and solid sellar and suprasellar mass related to an adamantinomatous craniopharyngioma. These masses represent > 50% of pediatric suprasellar neoplasms.* **(Right)** *Coronal T1 C+ MR in an adult with visual symptoms shows a complex sellar and suprasellar macroadenoma with regions of hemorrhage. Macroadenomas are among the most common of all CNS neoplasms, accounting for 10-15% of primary intracranial neoplasms.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Congenital anomalies of pituitary stalk → potential hypothalamic/pituitary axis malfunction

IMAGING

- Posterior pituitary ectopia (PPE)
- Duplicated pituitary gland/stalk (DP)
- PPE: No (or tiny) pituitary stalk, ectopic posterior pituitary (EPP) on midline sagittal T1WI MR
  - Look for associated anomalies: Heterotopia, optic nerve hypoplasia, corpus callosum anomalies
- DP: 2 pituitary stalks on coronal view, thick tuber cinereum on midline sagittal view

TOP DIFFERENTIAL DIAGNOSES

- Posterior pituitary ectopia (PPE)
  - Surgical or traumatic stalk transection
  - Central diabetes insipidus
  - Hypothalamic lipoma (in tuber cinereum)
- Duplicated pituitary gland/stalk (DP)
  - Dilated infundibular recess of 3rd ventricle ("pseudoduplication")
  - Tuber cinereum hamartoma

PATHOLOGY

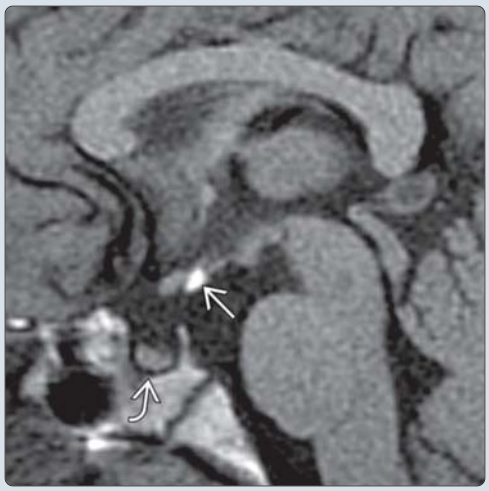
- PPE: Genetic mutation → defective neuronal migration during embryogenesis
- DP: Genetic mutation unknown; may constitute polytopic field defect due to splitting of notochord

CLINICAL ISSUES

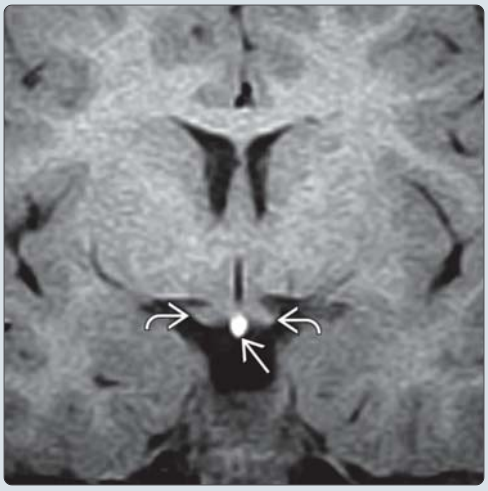
- PPE: Short stature
- DP: Unsuspected finding on craniofacial imaging for other indications

DIAGNOSTIC CHECKLIST

- PPE: Assess optic and olfactory nerves, frontal cortex
- DP: Oral tumors compromise airway patency



(Left) *Sagittal graphic demonstrates ectopia of the posterior pituitary gland located at the distal end of a truncated pituitary stalk along the median eminence of the hypothalamus. The sella turcica and adenohypophysis are both small.* **(Right)** *Sagittal T1WI MR shows an ectopic posterior pituitary gland located at the median eminence. The pituitary infundibulum is absent, the anterior pituitary gland is small, and the normal bright posterior pituitary gland is not identified in its typical location.*



(Left) *Coronal T1WI MR depicts the ectopic posterior pituitary gland location at the median eminence. A pituitary stalk is not visualized below the ectopic posterior pituitary. The septum pellucidum is present, and the optic tracts are of normal size.* **(Right)** *Sagittal T2 MR in a patient with complete absence of the posterior pituitary bright spot shows a small sella turcica and pituitary gland. The optic apparatus is also hypoplastic. A clearly defined pituitary stalk is present.*

TERMINOLOGY

Definitions

- Congenital anomalies of pituitary stalk → potential hypothalamic/pituitary axis malfunction

IMAGING

General Features

- Best diagnostic clue
  - Posterior pituitary ectopia (PPE): No (or tiny) pituitary stalk, ectopic posterior pituitary (EPP) on midline sagittal T1WI MR
  - Duplicated pituitary gland/stalk (DP): 2 pituitary stalks on coronal view, thick tuber cinereum on midline sagittal view
    - Tuberomammillary fusion: Tuber cinereum/mammillary bodies fused into single mass
  - Pituitary hypoplasia: Small sella turcica and adenohypophysis
- Location
  - PPE: EPP located along median eminence of tuber cinereum or truncated pituitary stalk
  - DP: Paired lateral stalks, pituitary glands, bony fossae
- Size
  - PPE: Anterior pituitary (adenohypophysis) is small
  - DP: Each pituitary gland is normal in size
- Morphology
  - PPE: Small adenohypophysis and osseous sella
  - DP: Each pituitary gland and osseous sella is normal in morphology but laterally located

Radiographic Findings

- Radiography
  - PPE: Small sella turcica on lateral radiography
  - DP: Craniofacial/craniocervical anomalies common; may observe 2 fossae on AP view

CT Findings

- NECT
  - PPE: Narrow pituitary fossa and skull base structures and clivus, ± persistent sphenopharyngeal foramen
  - DP: 2 widely separated pituitary fossae, ± midline basisphenoid cleft or frontonasal dysplasia
- CTA
  - PPE: Medial deviation of juxtasellar/supraclinoid carotid arteries ("kissing" carotids)
  - DP: Duplicated basilar artery, ± widely separated juxtasellar/supraclinoid carotid arteries

MR Findings

- T1WI
  - PPE: Absent, truncated, or thread-like pituitary stalk; small adenohypophysis
    - EPP located along truncated stalk or median eminence of tuber cinereum
      - Usually ↑ signal on T1WI (phospholipids/secretory granules)
      - Posterior pituitary may "dim" as patient outgrows available hormone levels
  - DP: Mass-like thickening of tuber cinereum on sagittal view portends duplicated pituitary axis
    - Mammillary bodies fused with tuber cinereum into thickened 3rd ventricle floor
    - 2 lateralized but otherwise normal pituitary glands/stalks
- T2WI
  - PPE: Variable signal of posterior pituitary
  - DP: Normal signal of glands, stalk, tuberomammillary fusion mass
- T1WI C+
  - Both: Stalks and remnants enhance (absent blood-brain barrier)
  - PPE: Hyperintensity absent if multiple endocrine anomalies/diabetes insipidus; contrast enhancement helps find neurohypophysis
- MRA
  - PPE: Supraclinoid carotid arteries medially deviated, "kiss" in midline; rare absent carotid artery/canal
  - DP: Fenestration (common) or total duplication (rare) of basilar artery (BA); widely separated juxtasellar carotid arteries

Imaging Recommendations

- Best imaging tool
  - Multiplanar T1WI MR
- Protocol advice
  - Both: Sagittal and coronal T1WI of hypothalamic/pituitary axis
  - PPE: Assess olfactory nerves, anterior frontal lobes with coronal FSE T2WI
    - 3D T1WI SPGR can identify small posterior pituitaries, occult on conventional 2D sagittal T1WI
  - DP: 3D CT of skull base and face in selected patients

DIFFERENTIAL DIAGNOSIS

Posterior Pituitary Ectopia

- Central diabetes insipidus
  - Hyperintensity of posterior pituitary lobe is absent but normal location of stalk and gland
- Surgical or traumatic stalk transection
  - Permits build-up of neurosecretory granules along stump
- Hypothalamic lipoma (located at tuber cinereum)
  - Posterior pituitary is not suppressed by fat saturation; lipoma is suppressed

Duplicated Pituitary Gland/Stalk

- Dilated infundibular recess of 3rd ventricle ("pseudoduplication")
  - Simulates duplicated stalk but only 1 gland and 1 pituitary fossa
- Tuber cinereum hamartoma
  - Round mass of 3rd ventricle floor but 1 midline pituitary stalk/gland

PATHOLOGY

General Features

- Etiology
  - PPE: Genetic mutation → defective neuronal migration during embryogenesis

https://CafePezeshki.IR

  - Adenohypophysis (anterior pituitary) grows up from stomodeal ectoderm (Rathke pouch)
    - Hypothalamic releasing hormones reach adenohypophysis via infundibular portal system
    - Anterior pituitary dysfunction thought to be related to absent infundibulum
  - Neurohypophysis (posterior pituitary) grows down from diencephalic neuroectoderm, remains attached by stalk
    - Antidiuretic hormone and oxytocin transported to neurohypophysis via neurosecretory cells along infundibulum
  - DP: Congenital anomaly, presumed genetic duplication of stomodeal origin structures 2° to aberrant ventral induction
    - Theory: Duplication prechordal plate and tip of rostral notochord leads to duplicated pituitary primordium
- Genetics
  - PPE: Mutations in genes encoding developmental transcription factors allow maldevelopment
    - *HESX1* (homeobox gene), *PIT1*, *PITX2*, *LHX3*, *LHX4*, *PROP1*, *SF1*, and *TBX19 (TPIT)*
  - DP: Gene mutation unknown; may constitute polytopic field defect due to splitting of notochord
- Associated abnormalities
  - Duplicated pituitary gland/stalk
    - Midline tumors in oral, nasopharyngeal, palate
      - Epignathus, hamartomas, teratomas, dermoids, lipomas
    - Spinal anomalies include segmentation/fusion anomalies, schisms, hydromyelia, enteric cysts
    - Rib and cardiac anomalies, Pierre-Robin anomaly
  - **Both**: Common midline CNS anomalies
    - Posterior pituitary ectopia
      - ± anomalies of structures formed at same time (anterior pituitary lobe, forebrain, eyes, olfactory bulbs)
      - ± lobar holoprosencephaly, septo-optic dysplasia, Joubert syndrome
    - Duplicated pituitary gland/stalk
      - Callosal dysgenesis, Dandy-Walker spectrum, frontonasal dysplasia
      - Craniofacial clefting and duplication anomalies: Frontonasal dysplasia; clefts/duplication of skull base, face, mandible, nose, palate
  - Pituitary hypoplasia associated with Kallmann syndrome

Gross Pathologic & Surgical Features

- PPE: Hypoplastic anterior lobe, stalk truncation or aplasia
  - Sella may be covered over with dura
- DP: Tuberomammillary fusion, 2 normal glands/stalks

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - PPE: Short stature
  - DP: Unsuspected finding on craniofacial imaging for other indications
- Other signs/symptoms
  - PPE: Multiple pituitary hormone deficiencies common
  - DP: Rarely symptomatic from pituitary causes
- Clinical profile
  - PPE: Short stature (growth hormone deficiency), ± multiple endocrine deficiencies
    - Peak growth hormone levels < 3 g/L more likely to have abnormal MR
    - ± anosmia, poor vision, seizures (cortical malformations)
    - Neonatal hypoglycemia or jaundice, micropenis, single central incisor
  - DP: ± facial midline anomalies, oral or nasal mass (hamartoma or teratoma)
    - Face: ± hypertelorism or frontonasal dysplasia
    - Craniocervical segmentation and fusion anomalies
    - Airway or oral obstruction from pharyngeal tumor

Demographics

- Age
  - PPE: Early growth failure apparent in childhood
  - DP: Usually discovered in early infancy during imaging for complicated facial anomalies
- Gender
  - PPE: M > F
  - DP: M < F
- Epidemiology
  - PPE: Prevalence 1:4,000 to 1:20,000 births
  - DP: Extremely rare (reported in 20+ reported cases)

Natural History & Prognosis

- PPE: Stable if no pituitary/hypothalamic crises; growth may be normal for a while
  - Severity and number of hormone deficiencies predicted by degree of stalk and gland hypoplasia
- DP: Usually significant intracranial, upper airway, or craniocervical malformations (some lethal)
  - Clinical outcome unrelated to pituitary function

Treatment

- Assess/treat endocrine malfunction

DIAGNOSTIC CHECKLIST

Consider

- PPE: Assess optic and olfactory nerves, frontal cortex
- DP: Oral tumors compromise airway patency

Image Interpretation Pearls

- PPE & DP: Can miss findings/diagnosis if thick sections (MR) are used or osseous structures (bone CT) not evaluated

KEY FACTS

TERMINOLOGY

- a.k.a. hypothalamic hamartoma (HH)
- Nonneoplastic; congenital gray matter heterotopia

IMAGING

- Hypothalamic mass contiguous with tuber cinereum
  - Located between mammillary bodies and infundibulum
  - Can be sessile or pedunculated ("collar button")
  - Size ranges from few mm to several centimeters
- Isointense with GM on T1WI
  - Can be slightly hyperintense on T2/FLAIR
  - Large lesions can be heterogeneous, contain cysts
  - No enhancement on T1C+

TOP DIFFERENTIAL DIAGNOSES

- Chiasmatic/hypothalamic astrocytoma
- Craniopharyngioma
- Ectopic posterior pituitary
- Lipoma
- Germinoma
- Langerhans cell histiocytosis

PATHOLOGY

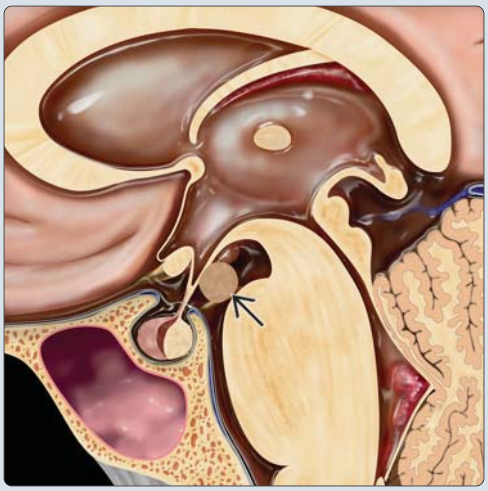
- Mature but dysplastic neuronal ganglionic tissue

CLINICAL ISSUES

- Infant with epilepsy or precocious puberty
  - Cognitive, neuropsychiatric comorbidities common
- Older children with precocious puberty
  - Often tall, overweight, with advanced bone age
- Shape, size of hamartoma often predicts symptoms, presentation
  - Large sessile lesions → seizures
  - Small pedunculated lesions → central precocious puberty

DIAGNOSTIC CHECKLIST

- If hypothalamic mass in seizure imaging, think HH



(Left) *Sagittal graphic shows a classic pedunculated tuber cinereum hamartoma interposed between the infundibulum anteriorly and the mammillary bodies posteriorly. The mass resembles gray matter.* **(Right)** *Sagittal T1WI MR in an 8-year-old female with precocious puberty shows a classic pedunculated "collar button" hypothalamic hamartoma. The lesion is interposed between the infundibular stalk anteriorly and the mammillary bodies posteriorly. HHs are classically isointense with gray matter.*

(Left) *Sagittal T2WI MR in a patient presenting with precocious puberty reveals a pedunculated hypothalamic mass located between the median eminence and mammillary bodies. The mass is isointense with cortex.* **(Right)** *Sagittal T1WI C+ MR in the same case shows the mass does not enhance. This is classic pedunculated hypothalamic hamartoma (HH).*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Hypothalamic hamartoma (HH), diencephalic hamartoma

Definitions

- Nonneoplastic congenital gray matter heterotopia in region of tuber cinereum

IMAGING

General Features

- Best diagnostic clue
  - Nonenhancing hypothalamic mass contiguous with tuber cinereum
- Location
  - Tuber cinereum of hypothalamus
  - Located between pons/mammillary bodies and hypothalamic infundibulum
- Size
  - Variable, few mm to giant (3-5 cm)
- Morphology
  - Sessile or pedunculated mass
  - Similar in density/intensity to gray matter

Radiographic Findings

- Radiography
  - ± suprasellar calcifications, eroded dorsum, enlarged sella (rare)

CT Findings

- NECT
  - Homogeneous suprasellar mass
    - Isodense → slightly hypodense
    - Cysts and calcification are uncommon
    - ± patent craniopharyngeal canal (very rare)
- CECT
  - No pathologic enhancement

MR Findings

- T1WI
  - Mass located between mammillary bodies and infundibulum
  - Isointense → slightly hypointense to gray matter
- T2WI
  - Isointense → slightly hyperintense (secondary to fibrillary gliosis)
- FLAIR
  - Isointense → slightly hyperintense to gray matter
- T1WI C+
  - Nonenhancing; if enhances, consider other diagnosis
- MRS
  - ↓ NAA and NAA/Cr, mild ↑ choline (Cho) and Cho/Cr, ↑ myoinositol (mI) and mI/Cr
    - ↓ NAA and ↑ Cho indicate reduced neuronal density and relative gliosis, respectively, compared to normal gray matter
    - ↑ mI/Cr correlates with ↑ glial component and lesion T2 hyperintensity

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR imaging
- Protocol advice
  - Thin-section sagittal and coronal T2, T1WI C+ MR

DIFFERENTIAL DIAGNOSIS

Craniopharyngioma

- Most common suprasellar mass in children
- Variable signal intensity cysts (90%), calcifications (90%), and enhancement (90%)
- Longstanding lesion, frequently with short stature and pituitary abnormalities

Chiasmatic/Hypothalamic Astrocytoma

- 2nd most common pediatric suprasellar mass (± NF1)
- Hyperintense on T2WI MR ± contrast enhancement (heterogeneous, often vigorous)
- Optic pathway or hypothalamus ± optic tract extension

Ectopic Posterior Pituitary

- Ectopic hyperintense focus on T1WI MR
- No normal orthotopic posterior pituitary hyperintensity

Germinoma

- Thickening, abnormal enhancement of pituitary stalk rather than tuber cinereum
- Diabetes insipidus common
- ± multicentric: Suprasellar, pineal, thalamus, basal ganglia
- Early leptomeningeal metastatic dissemination

Langerhans Cell Histiocytosis

- Thickening, abnormal enhancement of pituitary stalk rather than tuber cinereum
- Diabetes insipidus common
- Look for lytic bone lesions in typical locations

Lipoma

- Hyperintense fat signal on T1WI MR
- Hypointense on STIR or fat-saturated sequences

PATHOLOGY

General Features

- Etiology
  - Neuronal migration anomaly (occurs between gestational days 33-41)
  - Affects normal hypothalamic regulation of autonomic, endocrine, neurological, behavioral functions
  - Shape and size of hamartoma postulated to predict symptoms
    - Large sessile lesions → seizures
    - Small pedunculated lesions → central precocious puberty (CPP)
    - Presentation with both seizures and CPP common
- Genetics
  - *GLI3* mutation
    - Pallister-Hall syndrome (PHS)
      - Hamartoma or hamartoblastoma of tuber cinereum; often large mass
      - Digital malformations (short metacarpals, syndactyly, polydactyly)
      - Other midline (epiglottis/larynx) and cardiac/renal/anal anomalies

https://CafePezeshki.IR

- Greig cephalopolysyndactyly syndrome (GCPS)

Staging, Grading, & Classification

- Valdueza classification
  - Pedunculated, central precocious puberty or asymptomatic
    - Originates in tuber cinereum
    - Originates in mammillary bodies
  - Sessile, hypothalamus displaced, seizures
    - More hypothalamic dysfunction and abnormal behavior

Gross Pathologic & Surgical Features

- Mature neuronal ganglionic tissue projecting from hypothalamus, tuber cinereum, or mammillary bodies
- Pedunculated or sessile, rounded or nodular

Microscopic Features

- Well-differentiated neurons interspersed with glial cells, myelinated/unmyelinated axons, variable amounts of fibrillary gliosis
  - Hamartoblastomas include primitive undifferentiated cells

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Luteinizing hormone-releasing hormone (LHRH) dependent CPP presenting at very young age
  - Refractory symptomatic mixed seizure types, including gelastic seizures
    - Gelastic seizures are recurrent automatic bursts of laughter without mirth
    - Rarely occur in conjunction with focal cortical dysplasia or hypothalamic astrocytoma
  - Other seizure types frequent with HH; always look for HH in child with epilepsy
- Clinical profile
  - Infant with gelastic seizures or precocious puberty
  - Older children with precocious puberty; tall, overweight, and advanced bone age

Demographics

- Age
  - Usually present between 1-3 years of age
- Gender
  - No predilection; some reports M > F
- Ethnicity
  - No predilection
- Epidemiology
  - Of histologically verified lesions, 3/4 have precocious puberty and 1/2 seizures
  - Up to 33% of patients with central precocious puberty have HH

Natural History & Prognosis

- Size should remain stable; if growth is detected, surgery/biopsy is indicated
- Symptomatic lesions: Sessile >> pedunculated

Treatment

- Medical: Hormonal-suppressive therapy, treat seizures
- Surgical: If medical therapy failure or rapid lesion growth

DIAGNOSTIC CHECKLIST

Consider

- If hypothalamic mass identified in seizure imaging, think HH

Image Interpretation Pearls

- Classic = nonenhancing hypothalamic mass
  - Isointense to gray matter on T1WI, slightly ↑ signal on T2WI/FLAIR

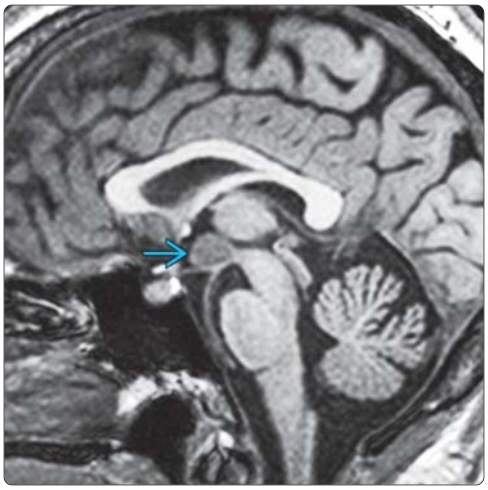
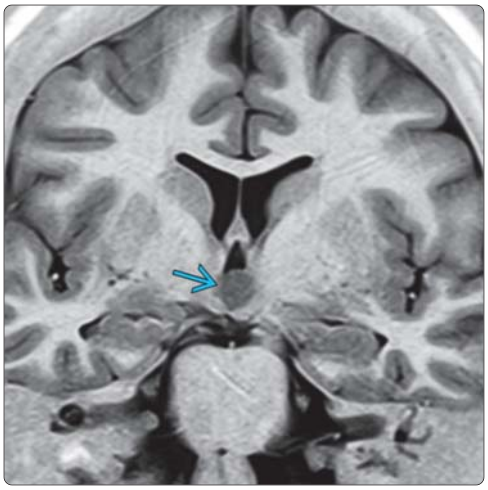
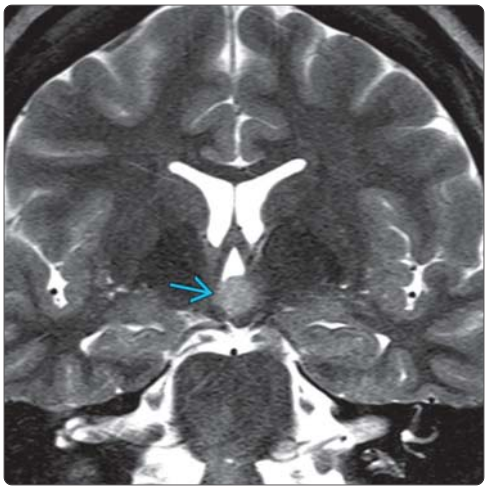
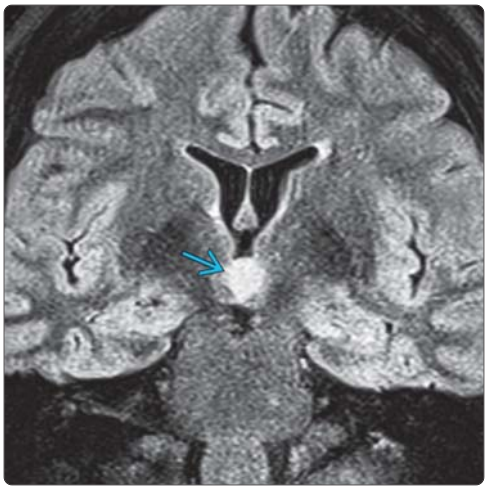
https://CafePezeshki.IR



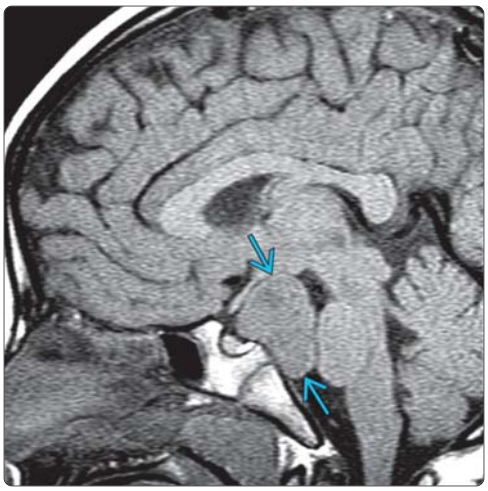


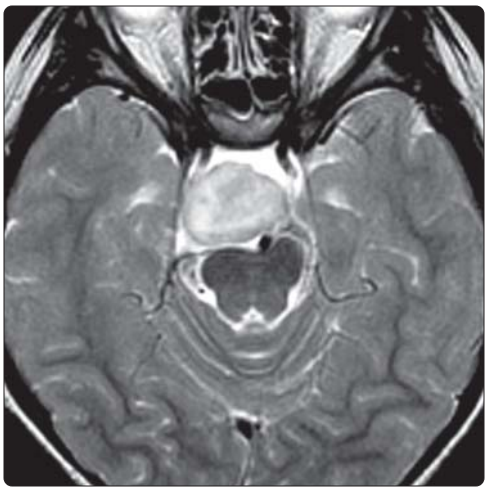
(Left) *Sagittal T1WI MR in a 36-year-old woman being evaluated for seizures shows a well-delineated suprasellar mass* ⇨ *that appears to lie within the 3rd ventricle.* **(Right)** *Coronal thin-section IR shows the mass* ⇨ *is actually in the hypothalamus. The mass is clearly isointense with gray matter.*





(Left) *Coronal T2WI MR in the same patient shows the mass* ⇨ *remains isointense with gray matter and elevates, but does not obstruct, the 3rd ventricle.* **(Right)** *Coronal FLAIR in the same patient shows the lesion* ⇨ *appears slightly hyperintense relative to cortex. The mass did not enhance following contrast administration. This is a classic sessile HH.*





(Left) *Sagittal T1WI in a child with precocious puberty shows a large lobulated suprasellar mass* ⇨ *that is isointense with cortex & is clearly separate from the pituitary gland & optic chiasm. The mass is so large it displaces the brainstem posteriorly.* **(Right)** *Axial T2WI in the same patient shows the mass is heterogeneously hyperintense compared to cortex. HHs can be huge, measuring up to several centimeters in diameter. A mass of dysplastic, disorganized gray matter was removed at surgery and was consistent with HH.*

https://CafePezeshki.IR

Rathke Cleft Cyst

KEY FACTS

TERMINOLOGY

- Nonneoplastic cyst arising from remnants of embryonic Rathke cleft
- Benign sellar region endodermal cyst lined by ciliated, mucus-producing epithelium

IMAGING

- Nonenhancing, noncalcified, intrasellar &/or suprasellar cyst with intracystic nodule
  - Completely intrasellar (40%), suprasellar extension (60%)
  - Density/signal intensity varies with cyst content (serous vs. mucoid)
- Most symptomatic RCCs: 5-15 mm in diameter
- Occasionally RCCs can become very large
- Claw sign = enhancing rim of compressed pituitary surrounding nonenhancing cyst
- No internal enhancement

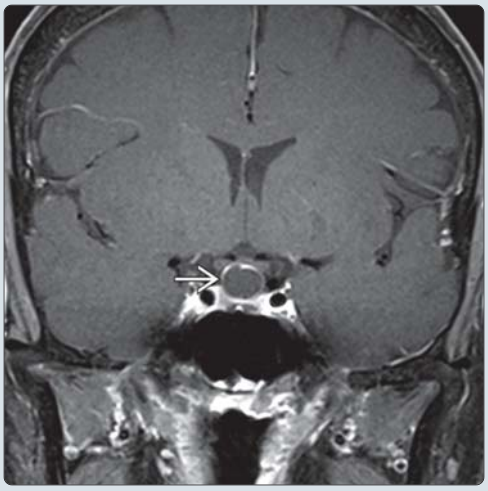
TOP DIFFERENTIAL DIAGNOSES

- Craniopharyngioma
- Cystic pituitary adenoma
- Arachnoid cyst
- Other nonneoplastic cyst (pars intermedia, colloid cyst)

CLINICAL ISSUES

- Most are asymptomatic, found incidentally at imaging or autopsy
- Common presenting features when symptomatic: Headache, pituitary dysfunction, visual changes
- Rare but important: Apoplexy, cavernous sinus syndrome
  - Can be indistinguishable from pituitary apoplexy
- Conservative management if asymptomatic
  - Have been reported to resolve without therapy
- Surgical aspiration, partial excision, or resection if symptomatic
  - Recurrence rates in up to 18% of patients

(Left) *Coronal graphic shows a typical suprasellar Rathke cleft cyst interposed between the pituitary gland ⇨ and the optic chiasm ⇨.* **(Right)** *Sagittal T1WI MR in a 32-year-old woman with amenorrhea shows a hyperintense mass within the pituitary gland ⇨ anterior to the normal T1-hyperintense neurohypophysis ⇨. Imaging mimics a hemorrhagic pituitary microadenoma. Rathke cleft cyst was found at resection. Small Rathke cleft cysts are most commonly asymptomatic and may be managed conservatively.*



(Left) *Coronal T1WI C+ MR in a 62-year-old woman with headaches shows a cystic suprasellar mass ⇨ with mild peripheral enhancement, a claw sign related to compression of the adjacent normal pituitary gland by the Rathke cleft cyst. Note the lack of enhancement within the cyst.* **(Right)** *Coronal T2WI MR in the same patient shows a hyperintense cyst with a hypointense intracystic nodule ⇨. An intracystic nodule may be seen in up to 75% of Rathke cleft cysts and is a helpful clue to the correct diagnosis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Rathke cleft cyst (RCC)

Definitions

- Nonneoplastic cyst arising from remnants of embryonic Rathke cleft
- Benign sellar region endodermal cyst lined by ciliated, mucus-producing epithelium

IMAGING

General Features

- Best diagnostic clue
  - Nonenhancing, noncalcified, intrasellar &/or suprasellar cyst with intracystic nodule
  - Uncommon but pathognomonic = posterior ledge sign
    - Upward extension through diaphragma sellae
    - Ledge of tissue overlies posterior lobe
- Location
  - Completely intrasellar (40%), suprasellar extension (60%)
  - Most Rathke cleft cysts are limited to sella
    - Between anterior, intermediate lobes
  - Symptomatic Rathke clef cysts involve suprasellar location
- Size
  - Most symptomatic Rathke cleft cysts are between 5-15 mm in diameter
  - Occasionally become very large
    - May cause expansile intrasellar/suprasellar mass
    - Rare: Erode skull base
  - Size usually constant, does not enlarge
    - Transient decrease reported in response to glucocorticoids
- Morphology
  - Well defined, round/ovoid

CT Findings

- NECT
  - Well-delineated, round/lobulated, intra-/suprasellar mass
    - Hypodense (75%), mixed iso-/hypodense (20%)
    - Hyperdense (5-10%)
    - Ca++ (10-15%), curvilinear, in cyst wall
  - Rare: May cause sphenoid sinusitis
- CECT
  - Does not enhance
  - Occasionally see claw sign with normal pituitary gland surrounding the cyst

MR Findings

- T1WI
  - Varies with cyst content (serous vs. mucoid)
    - Hyperintense (50%), hypointense (50%)
    - Hyperintense intracystic nodule (75%)
    - Mixed (5-10%), may have fluid-fluid level
- T2WI
  - Varies with cyst content
    - Hyperintense (70%), iso-/hypointense (30%)
    - Hypointense intracystic nodule (75%)
- FLAIR
  - Hyperintense
- T2* GRE
  - Rarely blooms
- T1WI C+
  - No internal enhancement
    - Claw sign = enhancing rim of compressed pituitary surrounding nonenhancing cyst
    - Small nonenhancing intracystic nodule (75%)
    - If enhancing nodule present, likely a craniopharyngioma

Imaging Recommendations

- Best imaging tool
  - MR
- Protocol advice
  - Thin-section high-resolution imaging of sellar region
  - Sagittal, coronal pre-contrast T1/T2WI
  - "Dynamic" contrast-enhanced coronal T1WI through sella
  - Sagittal, coronal thin-section T1WI C+

DIFFERENTIAL DIAGNOSIS

Craniopharyngioma

- Histologic continuum between Rathke cleft cyst, craniopharyngioma
- Floccular Ca++ common in craniopharyngioma, rare in Rathke cleft cyst
- Noncalcified RCC can be indistinguishable from craniopharyngioma on imaging
- Rim or nodular enhancement (90%)
- Cytokeratin profile helps distinguish from Rathke cleft cyst
  - RCCs express cytokeratins 8, 20

Cystic Pituitary Adenoma

- Ca++ rare
- Signal intensity often heterogeneous
- Rim or rim with nodular enhancement common

Arachnoid Cyst

- Follows CSF signal intensity
- Does not occur within pituitary gland
- No intracystic nodule

Other Nonneoplastic Cyst

- Dermoid cyst
  - May have short T1 signal related to fat or Ca++
  - Look for evidence of rupture
- Epidermoid cyst
  - Mild irregular enhancement, Ca++ (25%)
  - DWI hyperintensity, FLAIR lack of suppression
  - Otherwise follow CSF signal
- Miscellaneous intrasellar cyst
  - Pars intermedia, colloid cysts
- Rare: Sellar/hypophyseal neurocysticercosis (NCC)
  - May see racemose NCC in sellar/suprasellar region
  - May rarely see scolex

PATHOLOGY

General Features

- Etiology

https://CafePezeshki.IR

- One of spectrum of midline sellar/juxtasellar endodermal cysts
- Arises from embryonic remnants of fetal Rathke pouch
  - Rathke cleft normally regresses by 12th gestational week
- Genetics
  - No known heritable conditions
- Associated abnormalities
  - Sphenoid sinusitis (rare)
  - Compression of optic chiasm, pituitary gland, hypothalamus
    - May cause hyperintensity on T2WI/FLAIR along optic chiasm, tracts
  - Embryology
    - Persistence of Rathke pouch
    - Stomodeum (primitive oral cavity) invaginates
    - Extends dorsally, forms craniopharyngeal duct
    - Meets infundibulum (outgrowth of 3rd ventricle) by 11th fetal week, gives rise to hypophysis
    - Anterior wall of pouch forms anterior lobe, pars tuberalis
    - Posterior wall forms pars intermedia
    - Lumen forms narrow cleft (Rathke cleft) that normally regresses by 12th week of gestation
    - Persistence, expansion gives rise to RCC

Gross Pathologic & Surgical Features

- Smoothly lobulated, well-delineated, intrasellar/suprasellar cystic mass
  - Content varies from clear CSF-like fluid to thick mucoid material

Microscopic Features

- Wall = single layer of ciliated cuboidal/columnar epithelium ± goblet cells
  - Changes of mixed acute, chronic inflammation may be present
- May see squamous metaplasia (associated with increased rates of recurrent cysts)
- Variable cyst content
  - Clear or serous
  - ± hemorrhage, hemosiderin
  - Amorphous, inspissated, eosinophilic, mucicarmine(+) colloid ± cholesterol clefts
  - Firm, waxy, yellow, inspissated material
  - Rare: Hemorrhage (cyst apoplexy)
- Immunohistochemical stains positive for cytokeratin
  - Express cytokeratins 8, 20

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Most are asymptomatic, found incidentally at imaging or autopsy
    - Found in up to ~ 20% of autopsy cases
  - Symptomatic Rathke cleft cyst
    - Larger lesions, typically > 1 cm
    - Pituitary dysfunction (70%)
      - Amenorrhea/galactorrhea, diabetes insipidus, panhypopituitarism, hyperprolactinemia
    - Visual disturbances (45-55%)
    - Headache (50%)
  - Other signs/symptoms
    - Head pain, visual disturbance
    - Hypopituitarism
    - Central diabetes insipidus
  - Rare but important: Apoplexy, cavernous sinus syndrome
    - Cyst apoplexy
      - Can occur ± intracystic hemorrhage
      - Can be indistinguishable from pituitary apoplexy
    - Cavernous sinus syndrome
      - Caused by lateral extension of Rathke cleft cyst into cavernous sinus
- Clinical profile
  - Asymptomatic most commonly

Demographics

- Age
  - Mean: = 45 years
- Gender
  - Slight female predominance
- Epidemiology
  - Common intrasellar/suprasellar nonneoplastic cyst
  - Usually incidental, found in up to 20% of all autopsies

Natural History & Prognosis

- Most are stable, do not change in size/signal intensity
- Some cysts may shrink/disappear spontaneously
- Iso-/hyperintense cysts on T1WI more often cause symptoms
- Rathke cleft cysts do not undergo neoplastic degeneration
- Some authors propose a continuum from RCC to craniopharyngioma

Treatment

- Conservative if asymptomatic
- Surgical aspiration/partial excision/resection if symptomatic
  - Persistent/recurrent cyst formation occurs in approximately 15-18% of patients
  - May occur many years after surgery

DIAGNOSTIC CHECKLIST

Consider

- Obtaining endocrine profile

Image Interpretation Pearls

- Look for hypointense intracystic nodule on T2WI

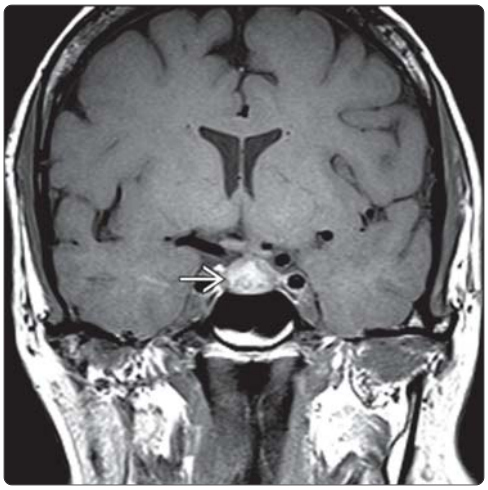
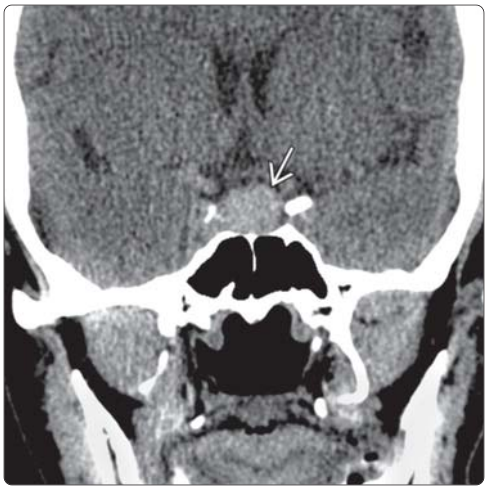
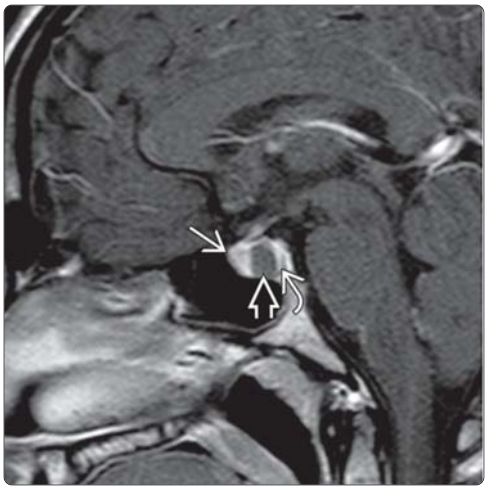
https://CafePezeshki.IR



(Left) *Coronal T1 MR in a 48-year-old man with headache shows a hypertense sellar mass ⇨ with normal surrounding pituitary tissue.* **(Right)** *Coronal T2 MR in the same patient shows the mass is hypointense ⇨ and enlarges the pituitary gland. There is no compression of the optic chiasm ⇨. No enhancement of the lesion was present on post-contrast imaging (not shown). Rathke cleft cyst was confirmed at resection.*





(Left) *Coronal NECT in a patient with a headache shows a hyperdense intrasellar mass with minimal suprasellar extension ⇨. Rathke cleft cysts are most commonly hypodense on CT imaging. Note the lack of calcification, which helps distinguish RCC from craniopharyngiomas, which are typically calcified (90%).* **(Right)** *Sagittal T1 C+ MR shows the typical imaging of a nonenhancing Rathke cleft cyst ⇨ between the normal adenohypophysis anteriorly ⇨ and the neurohypophysis posteriorly ⇨.*

(Left) *Sagittal T1 C+ MR shows a sellar and suprasellar Rathke cleft cyst with a classic claw sign of compressed pituitary gland ⇨ surrounding the nonenhancing mass. Rathke cleft cyst was confirmed at surgery.* **(Right)** *Coronal T2 MR in the same patient shows marked hypointensity throughout the cyst ⇨. There is mild mass effect and superior displacement of the optic chiasm ⇨ in this male patient who presented with visual changes.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Microadenoma: ≤ 10 mm in diameter

IMAGING

- Intrasellar mass is typical location
  - Rare: Ectopic origin outside pituitary fossa
- Best technique = dynamic contrast-enhanced thin-section T1-weighted MR
  - Generally enhance more slowly than adjacent normal pituitary
  - Beware: 10-30% can be seen only on dynamic contrast-enhanced scans
  - Occasionally, the adenoma may be cystic or hemorrhagic
- Intrapituitary "filling defect" may be benign nonneoplastic cyst, as well as incidental microadenoma

TOP DIFFERENTIAL DIAGNOSES

- Rathke cleft cyst
- Craniopharyngioma
- Pituitary hyperplasia
- Other nonneoplastic cyst (e.g., pars intermedia cyst)

PATHOLOGY

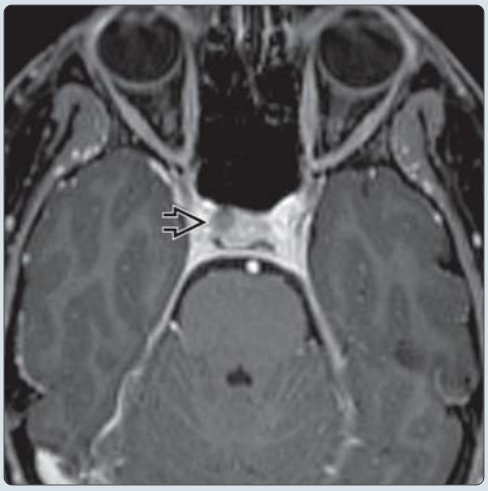
- Adenomas are almost always WHO grade I
  - Pituitary carcinoma exceedingly rare (diagnosed when metastatic disease identified)
- Can occur as part of MEN type 1, Carney complex, or McCune-Albright syndrome

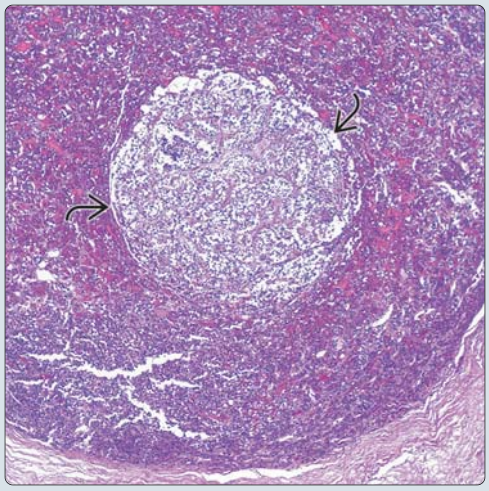
CLINICAL ISSUES

- Symptoms of secreting tumors vary according to type
  - Prolactinoma is most common functional adenoma
  - Asymptomatic/nonfunctioning adenoma most common
- ~ 20-25% incidental finding at autopsy
- Medical therapy (bromocriptine, cabergoline) reduces PRL secretion to normal in 80%
- Surgical (transsphenoidal) curative in 60-90%

(Left) *Coronal graphic shows a small microadenoma that slightly enlarges the right side of the pituitary gland and deviates the infundibulum toward the left.* **(Right)** *Coronal T1 C+ MR in a 41-year-old woman with amenorrhea and elevated prolactin levels shows a mass in the left pituitary gland with displacement of the infundibulum to the right. Prolactin-secreting microadenoma was found at resection. The microadenoma enhances less than the normal pituitary gland.*

(Left) *Axial T1 C+ MR in a 31-year-old woman with elevated prolactin shows a discrete mass related to a microadenoma in the anterior right pituitary gland. Prolactinomas are typically located laterally within the adenohypophysis as the prolactin secreting cells are present laterally within the normal gland.* **(Right)** *Coronal microscopic image shows a normal pituitary gland surrounding a small nonfunctioning microadenoma that was found incidentally at autopsy. (Courtesy J. Townsend, MD.)*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pituitary microadenoma

Synonyms

- Prolactinoma, adenoma

Definitions

- Microadenoma: ≤ 10 mm in diameter

IMAGING

General Features

- Best diagnostic clue
  - Intrapituitary lesion that enhances less rapidly than surrounding normal gland
- Location
  - Intrasellar
  - Rare: Ectopic origin outside pituitary fossa
    - Sphenoid sinus, cavernous sinus, clivus
    - Pituitary stalk, 3rd ventricle
    - Nasopharynx
- Size
  - By definition, microadenomas ≤ 10 mm in diameter
- Morphology
  - Circumscribed, well-demarcated mass surrounded by crescentic rim of compressed anterior pituitary
- Occasionally, microadenomas may be hemorrhagic or cystic

CT Findings

- NECT
  - If uncomplicated (no hemorrhage, cyst), microadenomas are isodense, invisible
- CECT
  - 2/3 are hypodense to normal pituitary on dynamic scans

MR Findings

- T1WI
  - Variable signal intensity
    - Usually isointense with normal pituitary gland
    - May be slightly hypointense to gland
    - Can be hyperintense if hemorrhage, necrosis
- T2WI
  - Typically isointense to normal pituitary gland
  - May be hypointense (blood products) or hyperintense (cystic)
- T2* GRE
  - May show "blooming" if hemorrhagic
- T1WI C+
  - 70-90% relatively hypointense compared to intensely enhancing pituitary gland, cavernous sinus
    - Generally enhance more slowly than normal pituitary
  - Beware: 10-30% can be seen only on dynamic contrast-enhanced scans

Other Modality Findings

- Cavernous/inferior petrosal sinus sampling (10% false-negative) in patients with ACTH-dependent Cushing syndrome

Imaging Recommendations

- Best imaging tool
  - Dynamic contrast-enhanced thin-section T1 MR
- Protocol advice
  - Coronal thin-section T1WI obtained during contrast infusion
    - Scans obtained at 5-10 second intervals following rapid bolus injection
    - At least 3 sections (3 mm or less, no interslice gap) through pituitary gland

DIFFERENTIAL DIAGNOSIS

Rathke Cleft Cyst

- Hypo-/hyperintense to normal gland on T1-/T2WI
- No enhancement
- Up to 75% have intracystic nodule

Craniopharyngioma

- Completely intrasellar craniopharyngioma is uncommon
- May have Ca++
- Displaces/compresses normal pituitary

Pituitary Hyperplasia

- Gland appears slightly, diffusely enlarged
- May appear slightly inhomogeneous, but usually no discrete foci of hypointensity seen on contrast-enhanced scans

Other Nonneoplastic Cyst (e.g., Pars Intermedia Cyst)

- Variable signal intensity
- Nonenhancing
- Indistinguishable from intrasellar Rathke cleft cyst

PATHOLOGY

General Features

- Etiology
  - 1 possible model of pituitary tumorigenesis
    - Hypophysiotrophic hormone excess, suppressive hormone insufficiency, or growth factor excess leads to hyperplasia
    - Increased proliferation predisposes to genomic instability; adenoma forms
  - 5 endocrine cell types in anterior pituitary (each secretes specific hormone, may develop into microadenoma or macroadenoma)
    - Lactotrophs: Prolactin (PRL)
      - 30% of adenomas
      - Prolactin secreting cells are located laterally
    - Somatotrophs: Growth hormone (GH)
      - 20% of adenomas
      - GH secreting cells are located laterally
    - Corticotrophs: Adrenocorticotrophic hormone (ACTH)
      - 10% of adenomas
      - ACTH secreting cells are located centrally
    - Thyrotrophs: Thyroid-stimulating hormone (TSH)
      - 1-2% of adenomas
      - TSH secreting cells are located centrally
    - Gonadotrophs: Gonadotropins, luteinizing hormone (LH), follicle-stimulating hormone (FSH)
      - FSH/LH (10%); located diffusely through gland
      - PRL/GH (5%)
  - Null cell (nonfunctional): 20-30% of adenomas

https://CafePezeshki.IR

- Genetics
  - No consistent allelic losses or point mutations identified
    - 2 normal copies of POU transcription factor Pit-1 (*POU1F1*) gene necessary for normal anterior pituitary lobe function
  - Can occur as part of MEN type 1, Carney complex, McCune-Albright syndrome
    - MEN1-associated adenomas often plurihormonal, larger, more invasive
    - Pituitary tumors occur in up to 40% of MEN1 patients
  - Familial isolated pituitary adenoma syndrome
    - Recently described
    - Family members develop only pituitary tumors
    - Prolactinomas in 40% of patients, somatotropinomas in 30%, nonsecreting in 13%
- Associated abnormalities
  - Growth hormone secreting adenoma
    - Acromegaly in adults
    - Gigantism in adolescents

Staging, Grading, & Classification

- Adenomas are almost always WHO grade I
- Pituitary carcinoma exceedingly rare
- Modified Kovacs and Horvath classification (cell type with tinctorial characteristics and hormones produced)
  - Growth hormone cell adenoma
  - Prolactin cell adenoma
  - Mixed GH, prolactin cell adenoma
  - Acidophil cell adenoma
  - Mammosomatotroph cell adenoma
  - Corticotroph cell adenoma
  - Thyrotroph cell adenoma
  - Gonadotroph cell adenoma
  - Nonfunctioning adenoma
  - Plurihormonal adenoma

Gross Pathologic & Surgical Features

- Small reddish-pink nodule

Microscopic Features

- Monotonous sheets of uniform cells
- Cell type varies, has variable trichrome staining, specific immunohistochemical stains

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic/nonfunctioning most common
  - Symptoms of secreting tumors vary according to type
    - Hyperprolactinemia: Amenorrhea, galactorrhea, infertility
    - Symptoms can also occur with non-prolactin-secreting tumors
      - Elevated prolactin related to mass effect on pituitary stalk ("stalk effect")
      - Macroprolactinemia may be idiopathic
- Clinical profile
  - Young female with primary or secondary amenorrhea and infertility, galactorrhea
- Noninvasive laboratory tests: Dexamethasone suppression, metyrapone stimulation, peripheral ovarian corticotropin-releasing hormone (CRH) stimulation

Demographics

- Age
  - Prolactinoma: 20-35 years
  - GH-secreting adenoma: 30-50 years
- Gender
  - Prolactinomas typically in females but can occur in males with delayed puberty, primary hypogonadism
  - Prolactinomas in men usually larger, more often cystic/hemorrhagic
- Epidemiology
  - 10-15% of all intracranial tumors (increasing due to improved imaging techniques)
    - ~ 20-25% incidental finding at autopsy
    - 1% of microadenomas are multiple
  - Prolactin-secreting = 30-40% of symptomatic adenomas
  - Pathologically, microadenoma > > macroadenoma
    - Most found incidentally (autopsy or imaging)
    - Pituitary "incidentaloma" seen in 6-27% of MR scans (common even in children)
    - 10-20% prevalence in general population (most are nonfunctioning)

Natural History & Prognosis

- Benign, slow growing
- Majority found incidentally

Treatment

- "Incidentaloma": Conservative (clinical, imaging follow-up unless change in size, ophthalmological/endocrinological evaluation)
- Functioning microadenomas
  - Medical (bromocriptine, other dopamine agonists, such as cabergoline) reduces PRL secretion to normal in 80%
  - Surgical (transsphenoidal) curative in 60-90%
- Radiation therapy for incompletely resected or recurrent tumors
  - Also helpful for patients not able to undergo surgery

DIAGNOSTIC CHECKLIST

Consider

- Intrapituitary filling defect may be benign nonneoplastic cyst, as well as incidental microadenoma

Image Interpretation Pearls

- Microadenomas **do** enhance but more slowly than normal pituitary, so dynamic studies are very helpful

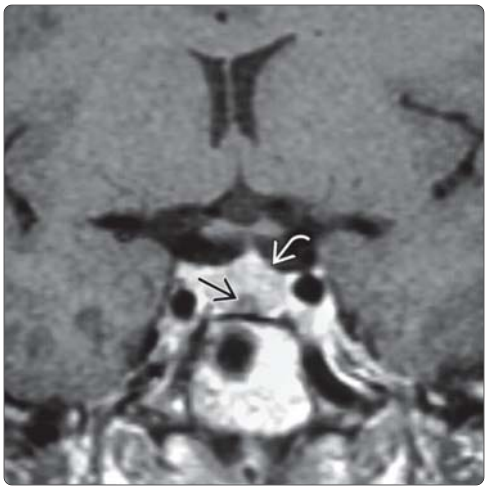
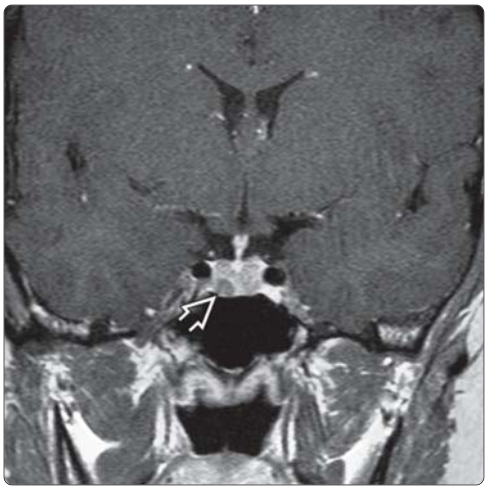
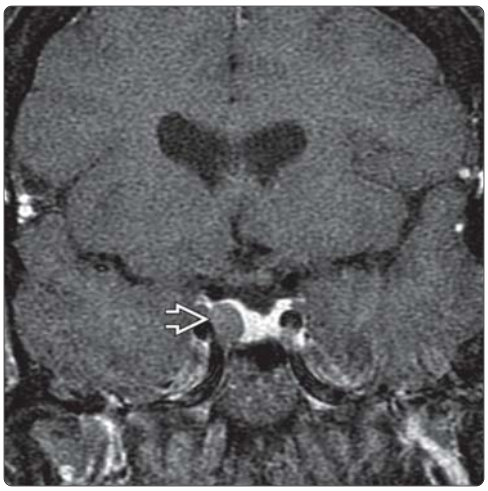
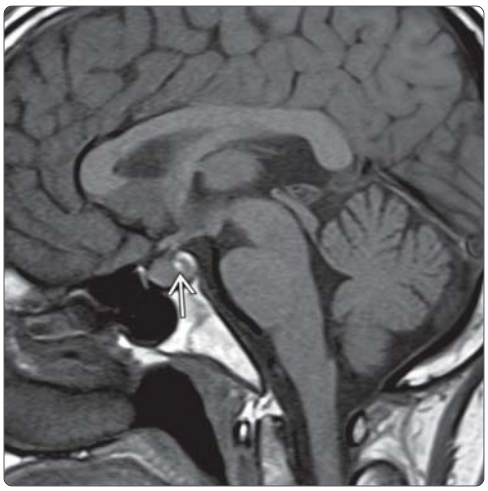
(Left) *Coronal T1 MR in a 32-year-old woman with elevated prolactin and galactorrhea shows subtle enlargement of the right pituitary gland* ⇨ *with mild thinning of the sella turcica floor* ⇨. **(Right)** *T1 C+ MR in the same patient shows a focal mass in the right anterior gland* ⇨ *that enhances less than the normal left gland. The infundibulum is in its normal midline location* ⇨. *The patient underwent trans-sphenoidal surgical resection after the tumor grew on medical therapy. Prolactin secreting adenoma found at resection.*





(Left) *Coronal T1WI C+ MR shows a focus of less enhancement* ⇨ *within a mildly enlarged pituitary gland* ⇨. *The patient was asymptomatic, and this was an incidental finding. Pituitary "incidentalomas" are common and may represent nonfunctioning adenomas or nonneoplastic cysts.* **(Right)** *Coronal T1 C+ MR in a 36-year-old patient with Cushing syndrome shows a mass* ⇨ *in the right gland related to her ACTH-secreting pituitary adenoma. ACTH secreting tumors are often centrally located within the gland.*





(Left) *Coronal T1 C+ MR in a patient with acromegaly shows a microadenoma* ⇨ *as a less enhancing mass in the right adenohypophysis. Growth-hormone secreting adenoma found at resection.* **(Right)** *Sagittal T1 MR in a young adult male shows a T1-hyperintense lesion* ⇨, *separate from the bright neurohypophysis, likely related to a hemorrhagic nonfunctional microadenoma in this patient with mild elevation of prolactin. A Rathke cleft cyst could have a similar appearance.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Benign neoplasm of the adenohypophysis

IMAGING

- Upward extension of macroadenoma = most common suprasellar mass in adults
- Best imaging technique
  - MR with sagittal/coronal thin-section imaging through sella + T1 C+ with FS
- Sellar mass without separate identifiable pituitary gland = macroadenoma
- Mass **is** the pituitary gland
- Usually isointense with gray matter
- Enhance strongly, often heterogeneously
- Cavernous sinus invasion difficult to determine

TOP DIFFERENTIAL DIAGNOSES

- Pituitary hyperplasia
- Saccular aneurysm
- Meningioma (diaphragma sellae)
- Metastasis
- Lymphocytic hypophysitis
- Craniopharyngioma

PATHOLOGY

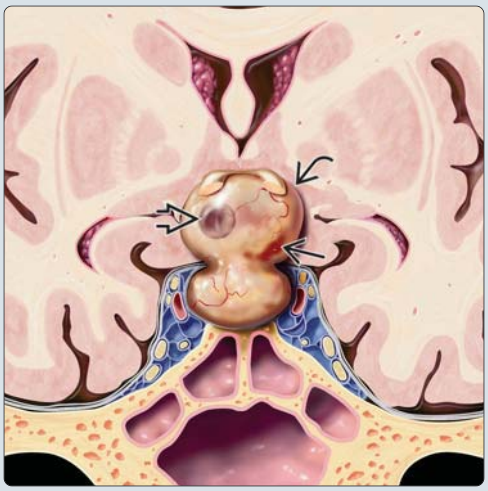
- WHO grade I
- MIB-1 > 1% suggests early recurrence, rapid regrowth
- Invasive adenoma > > pituitary carcinoma (rare)

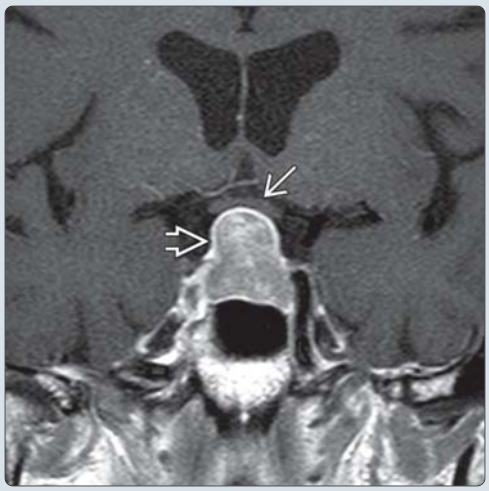
CLINICAL ISSUES

- Beware: Adenoma-like mass in adolescent/prepubescent males may represent hyperplasia secondary to end-organ failure
- Prolactin-secreting adenoma is most common functional adenoma

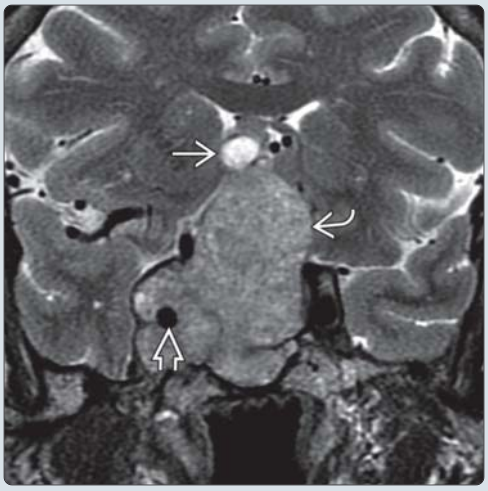
DIAGNOSTIC CHECKLIST

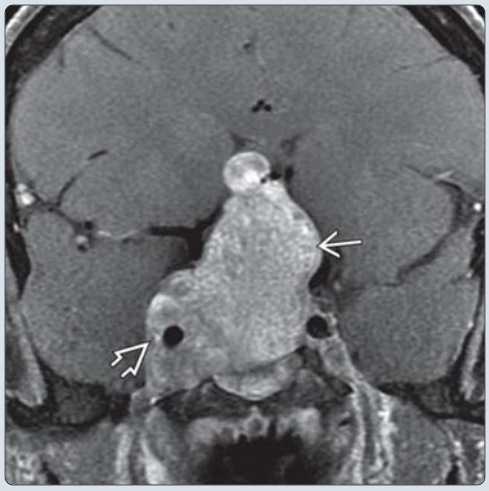
- No matter how aggressive/invasive it looks, pituitary tumors are almost never malignant





(Left) *Coronal graphic shows a snowman-shaped or "figure 8" sellar/suprasellar mass. Small foci of hemorrhage and cystic change are present within the lesion. The pituitary gland cannot be identified separate from the mass; indeed, the gland is the mass.* **(Right)** *T1 C+ MR in a 68-year-old male patient with elevated prolactin shows a classic "figure 8" or "snowman" appearance of the pituitary macroadenoma. There is mild displacement of the optic chiasm. The pituitary gland cannot be separated from the mass.*





(Left) *Coronal T2 MR in a 64-year-old woman with visual changes shows a large adenoma with cystic change filling the sella and suprasellar region. Note the patent cavernous carotid artery.* **(Right)** *Coronal T1 C+ MR image in the same patient shows heterogeneous enhancement of the macroadenoma. There is tumor lateral to the cavernous carotid artery representing cavernous sinus invasion. Nonfunctional adenoma found at resection. The cavernous sinus disease was treated with radiation therapy.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Macroadenoma, pituitary adenoma, prolactinoma

Definitions

- Benign neoplasm of adenohypophysis

IMAGING

General Features

- Best diagnostic clue
  - Sellar mass without separate identifiable pituitary gland; mass is gland
- Location
  - Most common: Intra- or combined intra-/suprasellar
    - Upward extension of macroadenoma = most common suprasellar mass in adults
  - Uncommon: Giant adenoma
    - May invade skull base, extend into anterior/middle/posterior fossae
    - Can mimic metastasis or other malignant neoplasm
  - Rare: "Ectopic" pituitary adenoma
    - Sphenoid sinus most common
    - Cavernous sinus, clivus, 3rd ventricle, infundibulum
- Size
  - > 10 mm
  - "Giant": > 4 cm in diameter (< 0.5%)
- Morphology
  - Most common: "Figure 8" or "snowman"
    - Indentation: Dural constriction caused by diaphragma sellae
  - Less common: Multilobulated margins

CT Findings

- NECT
  - Variable attenuation
    - Usually isodense with gray matter (typical)
    - Cysts, necrosis common (15-20%)
    - Hemorrhage (10%), Ca++ (1-2%)
- CECT
  - Moderate, heterogeneous enhancement
- Bone CT
  - Large adenomas expand sella, may erode floor
  - Aggressive adenomas extend inferiorly, invade sphenoid, may destroy upper clivus

MR Findings

- T1WI
  - Usually isointense with gray matter
    - Subacute hemorrhage (T1 shortening)
    - Fluid-fluid levels may occur, especially with pituitary apoplexy (acute hemorrhage or infarct of adenoma)
  - Posterior pituitary "bright spot" displaced into supradiaphragmatic level in 80% of cases
    - Posterior pituitary "bright spot" absent in 20% of large adenomas
  - Cavernous sinus invasion difficult to determine (medial wall is thin, weak)
    - If tumor exists between cavernous carotid artery and lateral dura = invasion
- T2WI
  - Most common: Isointense with gray matter
  - Less common
    - Cysts (hyperintense), hemorrhage (signal varies with age)
    - Densely granulated, growth-hormone-producing adenomas often hypointense
  - Uncommon: High signal along optic tracts
    - Seen with 15-20% of adenomas that touch/compress optic pathway
- T2* GRE
  - Susceptibility artifact (blooming) if hemorrhage present
- T1WI C+
  - Most enhance strongly but heterogeneously
    - Some macroadenomas (thyrotropin-secreting adenomas, necrotic adenomas) are hypoenhancing
    - Subtle/mild dural thickening ("tail") may be seen
- MRA
  - Internal carotid arteries (ICAs) often displaced and encased (20%) but rarely occluded

Angiographic Findings

- Suprasellar extension splays supraclinoid ICAs, anterior choroidal arteries laterally
- Pituitary normally "blushes"
  - With macroadenoma, meningohypophyseal trunk may enlarge, causing prominent vascular staining

Other Modality Findings

- Cavernous/inferior petrosal sinus sampling may be helpful in evaluating ACTH-dependent Cushing syndrome

Imaging Recommendations

- Best imaging tool
  - MR with sagittal/coronal thin-section imaging through sella
    - Pre- and post-contrast imaging with T1WI C+ FS

DIFFERENTIAL DIAGNOSIS

Pituitary Hyperplasia

- 25-50% of females 18-35 years have upwardly convex pituitary
  - Usually ≤ 10 mm unless pregnant, lactating
  - Homogeneous enhancement
  - Pituitary function normal
- Can occur with end-organ failure (e.g., ovarian, thyroid)
- If prepubescent female or young male has adenoma-looking pituitary, do endocrine work-up

Saccular Aneurysm

- Usually eccentric, not directly suprasellar
- Pituitary gland visible, identified separate from mass
- Flow void common on MR; MRA/CTA shows vessel of origin
- Ca++ more common (rare in adenoma)

Meningioma (Diaphragma Sellae)

- Pituitary gland visible, can be identified **separate** from mass
  - Diaphragma sellae identifiable as thin, dark line between mass (above) and pituitary gland (below)
- Dural thickening more extensive than with adenoma

https://CafePezeshki.IR

Metastasis

- Diffuse skull base invasion by adenoma may mimic more ominous disease
- May see systemic metastases to stalk or pituitary gland

Lymphocytic Hypophysitis

- Can mimic adenoma clinically on imaging studies
- Most common in peripartum female

Craniopharyngioma

- Ca++, cysts; children > adults
- Rim/nodular > solid enhancement

PATHOLOGY

General Features

- Etiology
  - Genetic, epigenetic factors, hormonal stimulation, growth factors and their receptors implicated in pituitary tumorigenesis
- Genetics
  - Allelic loss of chromosome 11q in *MEN1* region
  - *MEN1* gene (probably tumor suppressor) involved in adenoma formation
- Associated abnormalities
  - Acromegaly, gigantism (growth-hormone-secreting macroadenomas)
  - MEN type 1 (parathyroid, pancreatic tumors with multicentric pituitary adenomas in 50%)
  - May also be associated with McCune-Albright syndrome, Carney complex, familial isolated pituitary adenoma or isolated familial somatotropinoma syndrome

Staging, Grading, & Classification

- WHO grade I
- MIB-1 > 1% suggests early recurrence, rapid regrowth

Gross Pathologic & Surgical Features

- Reddish-brown, lobulated mass
- "Capsule" of macroadenoma is normal compressed pituitary gland
- Usual growth pattern: Bulges upward into suprasellar cistern
- Gross cavernous sinus invasion at autopsy in 5-10%, microscopic in 45%
- Invasive benign adenoma > > pituitary carcinoma (exceedingly rare)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Endocrine abnormalities
    - 75% endocrinologically active (symptoms vary)
  - Visual field defect
    - 20-25% visual defect/cranial nerve palsy
    - Bitemporal hemianopsia
  - Rare: Nelson syndrome
    - Macroadenoma with elevated ACTH, MSH develops after bilateral adrenalectomy
- Clinical profile
  - Middle-aged female with bitemporal hemianopsia
  - Less common: Male with impotence, decreased libido, visual disturbance
  - Rare: Pituitary apoplexy (can be acute, life threatening)

Demographics

- Age
  - Peak: 20-40 years
  - Uncommon: Presentation in childhood/adolescence
    - Pituitary adenomas account for < 6% of intracranial tumors in adolescents, even rarer in children
    - ~ 60% are macroadenomas, 40% are microadenomas
    - Adenoma-like mass in adolescent/prepubescent males may represent hyperplasia secondary to end-organ failure
- Gender
  - Varies with secretory type; prolactin-secreting tumors much more common in females
- Epidemiology
  - 10-15% of intracranial neoplasms
  - Prolactin-secreting: Most common (prevalence ~ 500 cases per million)

Natural History & Prognosis

- Benign; usually slow but highly variable growth rate
  - Malignant transformation exceedingly rare
- "Giant" adenoma
  - Prolactin often > 1,000 ng/mL
- Metastasizing pituitary adenoma (pituitary carcinoma)
  - Occurs but very rare (both CSF, extra-CNS)
  - Carcinoma diagnosed only if metastases present
- Some adenomas (e.g., clinically silent corticotroph adenomas) behave in more aggressive manner with high recurrence rate
  - Apoptosis-related proteins (Bcl-2, BAX, p53) related to local control, recurrence

Treatment

- Resection is primary therapy (15% recurrence at 8 years, 35% at 20 years)
- Other: Medical, stereotaxic radiosurgery, conventional XRT

DIAGNOSTIC CHECKLIST

Consider

- Could sellar mass be nonneoplastic (e.g., hyperplasia, hypophysitis, etc.)
- Check prolactin levels in male with giant invasive skull base mass; it may be giant adenoma

Image Interpretation Pearls

- No matter how aggressive/invasive it looks, pituitary tumors are almost never malignant

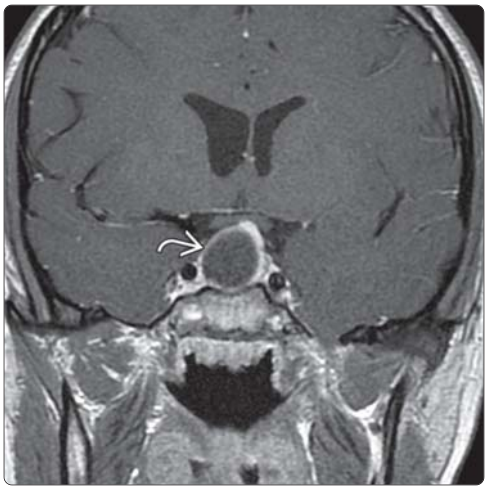
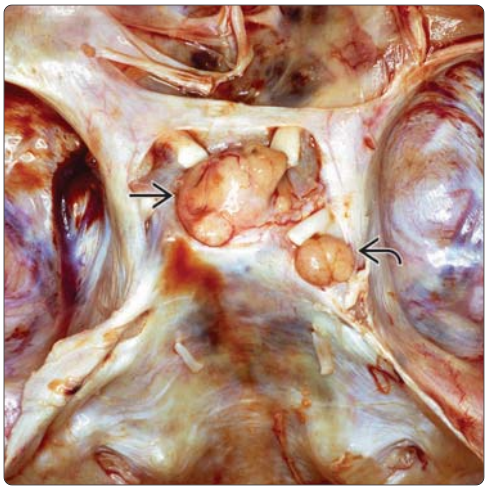
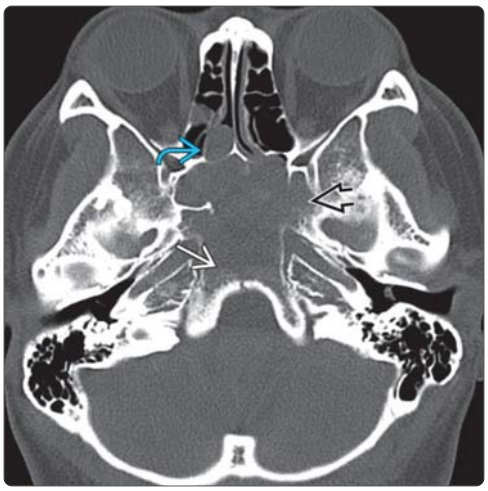
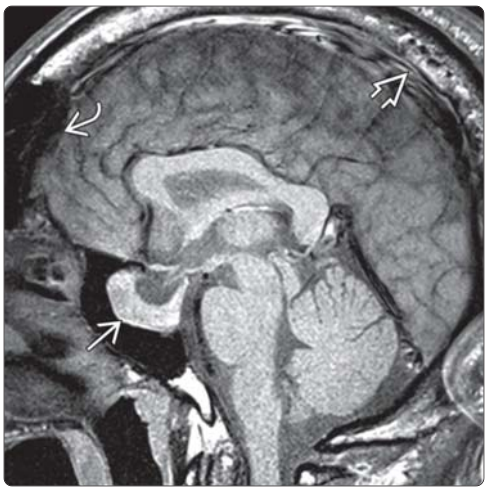
(Left) *Sagittal T1 MR in a 28-year-old woman with visual changes & elevated prolactin shows an invasive pituitary macroadenoma ➡ that has eroded the clivus ➡, extending into sphenoid sinus and nasopharynx. Imaging differential considerations on pre-contrast imaging include skull base lesions, such as chordoma, metastases, or myeloma.* **(Right)** *Coronal T1 C+ MR in the same patient shows strong, heterogeneous enhancement of the macroadenoma ➡. There is compression of the optic chiasm ➡.*





(Left) *Coronal T1 C+ MR in a 19-year-old woman with amenorrhea and markedly elevated prolactin shows a cystic macroadenoma ➡ with left lateral displacement of the infundibulum and remaining normal gland. Imaging mimics a Rathke cleft cyst.* **(Right)** *Gross pathology shows a pituitary macroadenoma that extends upward through the diaphragma sellae into the suprasellar cistern ➡ and laterally into the cavernous sinus ➡, which is partially unroofed. (Courtesy R. Hewlett, MD.)*





(Left) *Axial CT shows erosion of the anterior clivus ➡ from a large, invasive macroadenoma that extends anteriorly to fill the sphenoid sinus ➡ and posterior ethmoids ➡.* **(Right)** *Sagittal T1 MR in a 30-year-old man with longstanding acromegaly shows a pituitary macroadenoma enlarging the sella turcica and invading the sphenoid sinus ➡. Note the thick skull ➡ and enlarged frontal sinuses ➡ seen in acromegaly. Growth-hormone secreting adenoma was found at resection.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Acute clinical syndrome with headache, visual defects/ophthalmoplegia, altered mental status, variable endocrine deficiencies
- Caused by either hemorrhage or infarction of pituitary gland
- Preexisting pituitary macroadenoma common

IMAGING

- CT
  - Sellar/suprasellar mass with patchy or confluent hyperdensity
  - Peripheral enhancement, ± hemorrhage
  - May be associated with subarachnoid hemorrhage
- MR
  - Enlarged, hypointense (hemorrhagic), or hyperintense (nonhemorrhagic) pituitary on T2WI
  - "Blooming" if blood products present
  - Restricted diffusion within adenoma may be early sign of apoplexy
- Associated findings
  - Adjacent dural thickening, enhancement in 50%
  - Thickening of sphenoid sinus mucosa in 80%

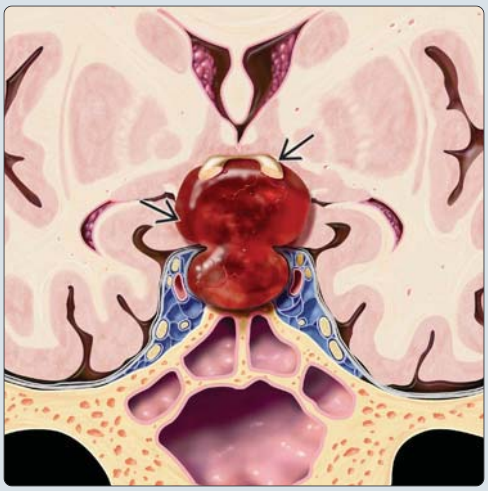
TOP DIFFERENTIAL DIAGNOSES

- Pituitary macroadenoma (nonhemorrhagic)
- Craniopharyngioma
- Rathke cleft cyst
- Lymphocytic hypophysitis
- Giant thrombosed intrasellar aneurysm
- Pituitary abscess
- Primary intrapituitary hemorrhage

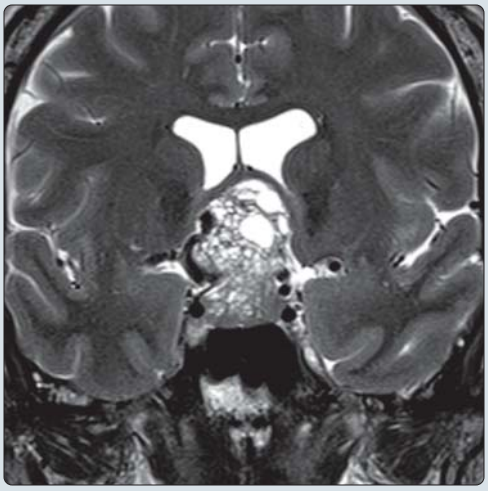
DIAGNOSTIC CHECKLIST

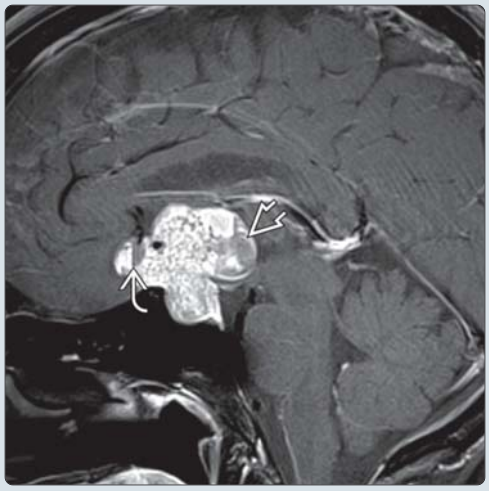
- Rim enhancement or fluid level in snowman-shaped sellar/suprasellar mass may represent PA

(Left) *Coronal graphic shows a macroadenoma with acute hemorrhage ⇨ causing pituitary apoplexy. Superior displacement of the optic chiasm is common.* **(Right)** *Coronal T1 MR shows a hemorrhagic sellar and suprasellar macroadenoma in a 58-year-old woman with acute onset of headache and ophthalmoplegia. Note the T1 shortening ➡ in the superior aspect of the macroadenoma related to subacute blood products.*



(Left) *Coronal T2 MR in the same patient shows heterogeneous signal throughout the sellar and suprasellar mass, typical of pituitary apoplexy.* **(Right)** *Sagittal T1 C+ FS MR in the same patient shows heterogeneous enhancement of the mass with a blood-fluid level ➡ and regions of nonenhancement ⇨ related to necrotic adenoma. A necrotic, hemorrhagic, nonfunctional adenoma was found at surgery. A preexisting macroadenoma is present in the vast majority of patients with pituitary apoplexy.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Pituitary apoplexy (PA)

Synonyms

- Pituitary necrosis; hemorrhage into pituitary mass

Definitions

- Acute clinical syndrome with headache, visual defects/ophthalmoplegia, altered mental status, variable endocrine deficiencies
  - Caused by either hemorrhage or infarction of pituitary gland
  - Preexisting pituitary macroadenoma common

IMAGING

General Features

- Best diagnostic clue
  - Pituitary mass with peripheral or heterogeneous enhancement, ± hemorrhage
- Location
  - Intrasellar or combined sellar and suprasellar
- Size
  - Variable but typically > 1 cm
- Morphology
  - "Snowman" or "figure of eight" sellar and suprasellar mass

CT Findings

- NECT
  - Acute
    - Sellar/suprasellar mass with patchy or confluent hyperdensity (20-25%)
    - May rarely be associated with subarachnoid hemorrhage
  - May be normal acutely
  - Chronic: Empty sella
- CECT
  - Minimal or no enhancement
    - Rim enhancement suggestive (but not diagnostic) of pituitary apoplexy
- CTA
  - Avascular or hypovascular mass effect on adjacent vessels
  - Done to exclude aneurysm

MR Findings

- T1WI
  - Early acute: Enlarged gland, iso-/hypointense with brain
  - Late acute/subacute: Hyperintense
  - Chronic: Hypointense
    - Empty sella (filled with CSF)
    - Small isointense pituitary remnant
- T2WI
  - Acute
    - Enlarged, heterogeneous pituitary mass
    - May see fluid level
    - Acute compression of hypothalamus, optic chiasm may cause hyperintensity along optic tracts
  - Subacute: Hyperintense
  - Chronic: Hyperintense (empty sella filled with CSF)
- FLAIR
  - Acute: Hyperintense, heterogeneous mass
  - Chronic: Hypointense (CSF in empty sella suppresses)
- T2* GRE
  - "Blooming" if blood products present
- DWI
  - Restricted diffusion within adenoma may be early sign of apoplexy
  - ADC map: Markedly decreased signal intensity
- T1WI C+
  - Rim enhancement common
  - May have heterogeneously enhancing mass with areas of nonenhancement
  - Adjacent dural thickening and enhancement in 50% of cases
  - Thickening of sphenoid sinus mucosa in 80% of cases

Imaging Recommendations

- Best imaging tool
  - MR of central skull base
- Protocol advice
  - MR ± dynamic contrast-enhanced sequences; add GRE sequence
  - Consider adding GRE/SWI, DWI sequences

DIFFERENTIAL DIAGNOSIS

Pituitary Macroadenoma (Nonhemorrhagic)

- Clinical course usually subacute/chronic
- Predominately suprasellar, rather than intrasellar
- Cysts, small hemorrhagic foci may occur without necrosis

Craniopharyngioma

- Ca++, multiple cysts with variable contents, and mixed signal intensity common
- Can usually identify normal/compressed pituitary distinct from mass

Rathke Cleft Cyst

- Proteinaceous fluid may be hyperintense, mimic hemorrhage
- Cyst usually identifiable as separate from pituitary gland
- No enhancement
- Clinical symptoms subacute/chronic

Giant Thrombosed Sellar Aneurysm

- Acute thrombosis can present with panhypopituitarism, subarachnoid hemorrhage
- Patent aneurysm shows typical "flow void" on MR
- Partially/completely thrombosed aneurysm may show mixed-age laminated clot
- CTA helpful to determine vascular etiology
- Rare

Lymphocytic Hypophysitis

- Typically only modest gland enlargement
- Acute inflammation of gland
- Typically occurs in pregnancy or post-partum females

Pituitary Abscess

- Rare
- Clinical signs of infection may be absent

https://CafePezeshki.IR

- May be difficult to distinguish from bland (ischemic) infarction on imaging studies
- T1 shortening along rim > center of mass
- Both apoplexy, abscess may restrict on DWI

Primary Intrapituitary Hemorrhage

- Hemorrhage into nonadenomatous tissue is rare
- Has been reported with infection (hantavirus), other neoplasms (germinoma)

PATHOLOGY

General Features

- Etiology
  - Hemorrhagic or ischemic pituitary infarction
  - Preexisting macroadenoma common, but PA can occur with normal pituitary gland or microadenoma
- Genetics
  - Rare, MEN1 syndrome
- Associated abnormalities
  - Preexisting macroadenoma in 65-90% of PA cases
  - Multiple acute endocrine insufficiencies (pituitary, adrenal)
  - Both hemorrhagic and ischemic pituitary apoplexy typically occur in preexisting macroadenoma

Gross Pathologic & Surgical Features

- Hemorrhagic sellar/suprasellar mass
- Nonhemorrhagic (bland) pituitary infarction = swollen, edematous pituitary gland

Microscopic Features

- Pituicytes uniform but shrunken with dark pyknotic nuclei
- Most common adenoma affected by PA = nonfunctioning (null-cell type)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache in nearly 100%
    - Nausea (~ 80%)
    - Panhypopituitarism (~ 80%)
    - Visual impairment, ophthalmoplegia common (~ 70%)
    - Occasionally can present with sudden-onset ptosis, diplopia
  - Other signs/symptoms
    - Life-threatening pituitary insufficiency, acute adrenal crisis
    - Hypovolemia, shock, disseminated intravascular coagulation
    - Rarely complicated by subarachnoid hemorrhage or acute intracranial ischemia (from carotid compression or vasospasm)
  - Rare: Sheehan syndrome
    - Common: Loss of anterior pituitary hormone function long after index pregnancy (up to 15-20 years later)
    - Less common: Acute (peripartum) presentation
  - Rarely associated with HELLP syndrome
    - PA with panhypopituitarism and diabetes insipidus may develop in patient with hemolysis, elevated liver enzymes, and low platelet count syndrome (HELLP)
- Clinical profile
  - Male with pituitary adenoma and acute headache, nausea, and ophthalmoplegia
  - Post-/peripartum female with hypovolemia, shock

Demographics

- Age
  - Mean: 57 years (50-60 years old, typically)
  - Rare < 15 years
- Gender
  - M:F = 2:1
- Epidemiology
  - PA occurs in approximately 1% of macroadenomas
  - Other reported clinical risk factors
    - Anticoagulation
    - Endocrinologic testing (dynamic pituitary function tests)
    - Radiation, bromocriptine or cabergoline (dopamine agonist) therapy for existing macroadenoma
    - Trauma, surgery (especially cardiac)
    - Peri- or postpartum state
    - Elevated estrogen levels (pregnancy, exogenous hormones)
    - Diabetes

Natural History & Prognosis

- Varies from clinically benign event to catastrophic presentation with permanent neurologic deficits or death
- Long-term pituitary insufficiency common in survivors

Treatment

- Early diagnosis, treatment of acute PA necessary to prevent morbidity/mortality
  - Best results with surgical decompression
  - Steroids, fluid/electrolyte replacement

DIAGNOSTIC CHECKLIST

Consider

- Could a high-density/hyperintense intrasellar mass represent something other than PA?
  - Giant intrasellar aneurysm
  - Craniopharyngioma or Rathke cleft cyst with high protein content

Image Interpretation Pearls

- Look for pituitary gland separate/distinct from mass (PA unlikely)
- Rim enhancement in snowman-shaped sellar/suprasellar mass may represent PA

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Benign, often partially cystic sellar region tumor derived from Rathke pouch epithelium
- 2 types
  - Adamantinomatous (cystic mass in childhood)
  - Papillary (solid mass in older adults)

IMAGING

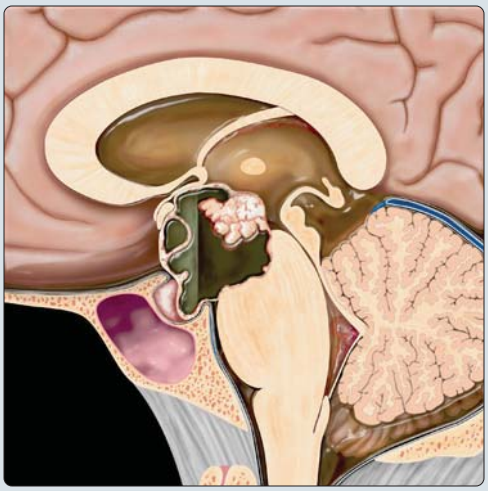
- General features
  - Multilobulated, often large (> 5 cm)
  - Occasionally giant, multicompartmental
- CT
  - Cystic (90%), Ca++ (90%), enhancing (90%)
- MR: Signal varies with cyst contents
  - Cysts variably hyperintense on T1WI and T2WI
  - Solid portions enhance heterogeneously; cyst walls enhance strongly
  - Cyst contents show broad lipid peak (0.9-1.5 ppm) on MR spectroscopy

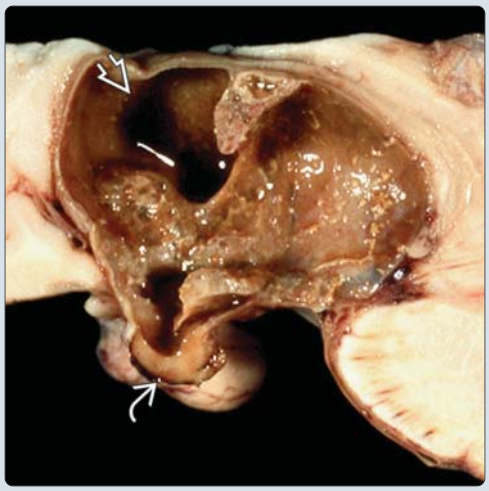
PATHOLOGY

- Most common pediatric intracranial tumor of nonglial origin
- WHO grade I
- Craniopharyngiomas arise from remnants of craniopharyngeal duct

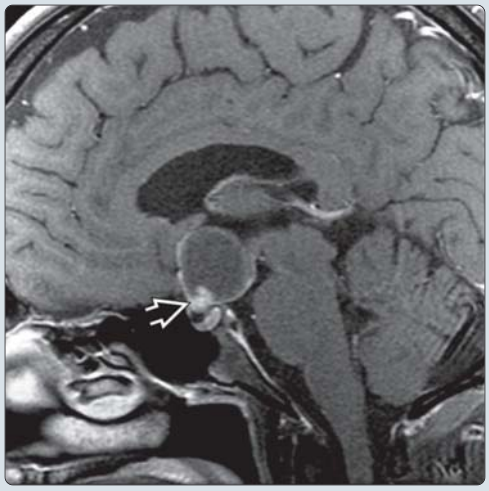
CLINICAL ISSUES

- Bimodal age distribution
  - Peak 5-15 years; papillary craniopharyngioma > 50 years
- Pediatric patient with morning headache, visual defect, short stature
  - Endocrine disturbances include growth hormone (GH) deficiency
  - Others = hypothyroidism > adrenal failure > diabetes insipidus
- Surgical resection is primary therapy
- Surgery, radiation therapy, or cyst aspiration for recurrent tumors





(Left) *Sagittal graphic shows a predominantly cystic, partially solid, suprasellar mass with focal rim calcifications. Note the small intrasellar component and fluid-fluid level. Craniopharyngiomas are the 90% tumors (90% cystic, 90% calcified, and 90% enhancing).* **(Right)** *Sagittal gross pathology shows classic adamantinomatous craniopharyngioma with mixed solid, cystic components. The classic machine or "crank case oil" ⇨ is present. Note the intrasellar extension ⇨. (Courtesy R. Hewlett, MD.)*



(Left) *T2 MR in a 48-year-old man who presented with visual changes shows a cystic suprasellar mass ⇨ with a focal T2-hypointense nodule ⇨. The T2 imaging mimics a Rathke cleft cyst.* **(Right)** *Sagittal T1 C+ MR in the same patient shows the enhancing nodule ⇨, which distinguishes this cystic lesion as a craniopharyngioma, not a Rathke cleft cyst. Surgical resection is the primary therapy for this WHO grade I neoplasm. However, the recurrence rate at 10 years approaches 20%.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Craniopharyngioma (CP)

Synonyms

- Craniopharyngeal duct tumor, Rathke pouch tumor, adamantinoma

Definitions

- Benign, often partially cystic sellar region tumor derived from Rathke pouch epithelium
  - 2 histologies: Adamantinomatous and papillary

IMAGING

General Features

- Best diagnostic clue
  - CT: Partially Ca++ mixed solid/cystic suprasellar mass in child
  - MR: Complex signal intensity suprasellar mass
- Location
  - Surgical division of CPs into 3 groups
    - Sellar
    - Prechiasmatic
    - Retrochiasmatic
  - Imaging locations of CPs (adamantinomatous type)
    - Suprasellar (75%)
    - Suprasellar + intrasellar component (21%)
    - Entirely intrasellar (4%)
    - Often extends into multiple cranial fossae: Anterior (30%), middle (23%), posterior, &/or retroclival (20%)
  - Rare ectopic locations
    - Optic chiasm, 3rd ventricle
    - Other: Nasopharynx, paranasal sinuses, pineal gland, sphenoid (clivus), cerebellopontine angle
- Size
  - Variable; often large at presentation (> 5 cm)
    - Occasionally giant, multicompartmental
- Morphology
  - Multilobulated, multicystic

CT Findings

- NECT
  - Adamantinomatous type (90% rule)
    - 90% mixed solid (isodense), cystic (hypodense)
    - 90% calcify
    - 90% enhance (solid = nodule; rim = capsule)
  - Papillary type: Often solid, isodense, rarely calcifies

MR Findings

- T1WI
  - Signal varies with cyst contents
    - Short T1 due to high protein content
    - Classic (adamantinomatous type)
      - Hyperintense cyst + heterogeneous nodule
    - Less common (papillary type)
      - Isointense solid component
- T2WI
  - Cysts are variably hyperintense
  - Solid component = heterogeneous (iso-/hyperintense, Ca++ portions hypointense)
  - Hyperintense signal in brain parenchyma adjacent to tumor may indicate
    - Gliosis, tumor invasion, irritation from leaking cyst fluid
    - Edema from compression of optic chiasm/tracts
    - Hypointense T2* = Ca++
- FLAIR
  - Cyst contents typically hyperintense
- DWI
  - Variable depending upon character of cyst fluid
- T1WI C+
  - Solid portions enhance heterogeneously; cyst walls enhance strongly
- MRA
  - Vascular displacement &/or encasement
- MRS
  - Cyst contents show broad lipid spectrum (0.9-1.5 ppm)

Imaging Recommendations

- Best imaging tool
  - MR with thin sagittal, coronal sequences
- Protocol advice
  - Pre-/post-contrast T1WI, T2, FLAIR, GRE, DWI, MRS

DIFFERENTIAL DIAGNOSIS

Rathke Cleft Cyst (RCC)

- Noncalcified, less heterogeneous
- Look for intracystic nodule on T2
- Does not enhance
  - Claw sign (enhancing pituitary draped around cyst)
- Small RCC may be indistinguishable from rare intrasellar CP
- RCCs express CK8 and CK20 (CPs generally do not)

Suprasellar Arachnoid Cyst

- No Ca++, enhancement

Hypothalamic/Chiasmatic Astrocytoma

- Solid or with small cystic/necrotic components
- Ca++ is rare; robust enhancement is common

Pituitary Adenoma

- Rare in prepubescent children
- Isointense with brain
- Enhances strongly
- Can mimic CP when cystic and hemorrhagic

Epidermoid/Dermoid Tumors

- Minimal or no enhancement

Thrombosed Aneurysm

- Contains blood products; use SWI
- Look for residual patent lumen, phase artifact

Germinoma or Mixed Germ Cell Tumor With Cystic Component(s)

- CSF spread is common, Ca++ is rare

PATHOLOGY

General Features

- Etiology
  - 2 proposed theories

https://CafePezeshki.IR

- CPs arise from remnants of craniopharyngeal duct
- CPs arise from squamous epithelial cells in pars tuberalis of adenohypophysis

- Genetics
  - No known genetic susceptibility (rare reports of siblings, parent-child)
  - Small subset of CPs are monoclonal tumors that arise from oncogenes at specific loci
  - β-catenin gene mutations found in adamantinomatous CP (genetically distinctive)

Staging, Grading, & Classification

- WHO grade I
- MIB-1 labeling index > 7% predicts recurrence

Gross Pathologic & Surgical Features

- Solid tumor with variable cysts
- Adamantinomatous cysts often contain thick "crankcase oil" fluid
- Epithelial fronds penetrate adjacent hypothalamus/chiasm

Microscopic Features

- Adamantinomatous (mostly pediatric)
  - Multi-stratified squamous epithelium with nuclear palisading
  - Nodules of "wet" keratin
  - Dystrophic Ca++
- Papillary (mostly adults)
  - Sheets of squamous epithelium form pseudopapilla
  - Villous fibrovascular stroma
- Malignant transformation, distant metastases rare
  - May occur with varied histologies, resulting in poor prognosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Symptoms vary with location, size of tumor, age of patient
  - Visual disturbances
    - Bitemporal hemianopsia
- Other signs/symptoms
  - Endocrine disturbances
    - Growth hormone (GH) deficiency > hypothyroidism > adrenal failure > diabetes insipidus
    - Headaches
- Clinical profile
  - Pediatric patient with morning headache, visual defect, short stature

Demographics

- Age
  - Bimodal distribution (peak 5-15 years, with smaller peak > 65 years)
    - Papillary CP > 50 years
- Gender
  - M = F
- Ethnicity
  - More common in Japanese children
- Epidemiology
  - Most common pediatric intracranial tumor of nonglial origin
  - Comprise 1.2-4% of all intracranial tumors across all ages
    - 6-9% of all pediatric intracranial tumors
    - Incidence = 0.5-2.5 new cases per 1 million per year
  - ~ 54% of all pediatric sellar/chiasmatic region tumors are CPs

Natural History & Prognosis

- Typically slow-growing benign neoplasm
- Prognosis based upon size, extent of tumor at presentation
  - < 5 cm, recurrence rate: 20%
  - > 5 cm, recurrence rate: 83%
  - Overall 10-year survival: 64-96%

Treatment

- Methods of primary treatment
  - Radical surgery = gross total resection
    - Complications = hypothalamic injury, endocrine symptoms, vasa vasorum injury, and pseudoaneurysm
  - Surgery may occur via craniotomy, transnasal, transorbital, or endoscopic routes
  - Limited surgery = subtotal resection plus radiation therapy
  - Biopsy, cyst drainage, and radiation therapy
- Treatment for residual or recurrent tumor
  - Surgery, radiation therapy, or cyst aspiration
  - Cyst instillation with intracavitary radioisotopes, bleomycin, or other sclerosing agents

DIAGNOSTIC CHECKLIST

Consider

- Preoperative ophthalmologic and endocrine evaluations

Image Interpretation Pearls

- Use NECT to detect Ca++ if MR diagnosis is in question
- Adamantinomatous craniopharyngioma = 90% rule (90% cystic, calcified, enhancing)
- Papillary craniopharyngioma is typically solid and primarily an adult neoplasm

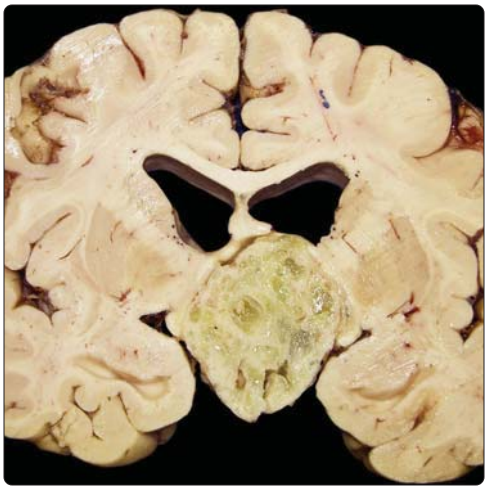
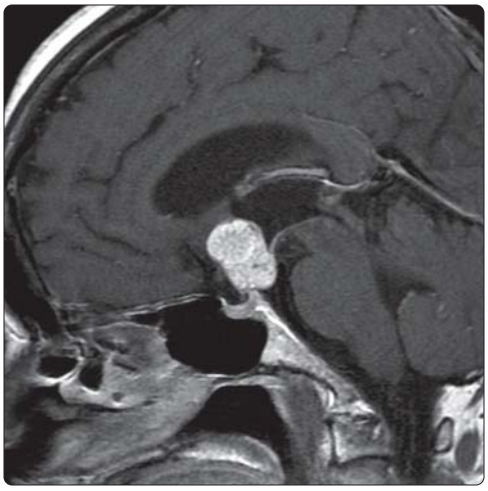
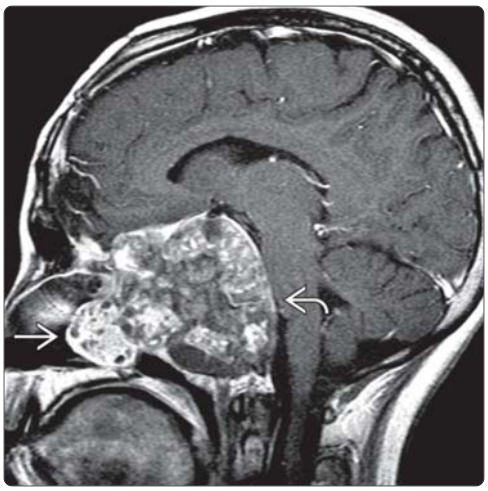
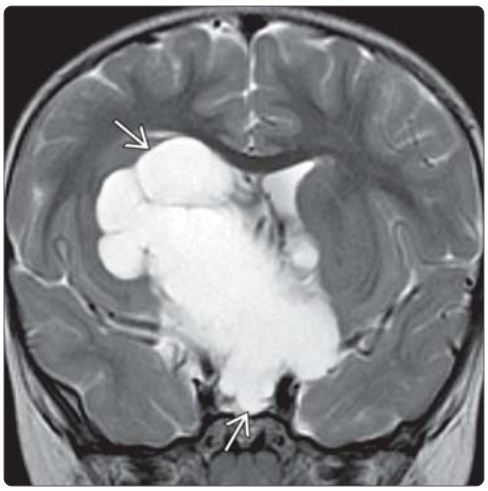
(Left) *Axial NECT shows classic findings of craniopharyngioma. Note the large suprasellar cyst with a fluid-fluid level ➡, rim ➡, and globular ➡ calcifications.* **(Right)** *Sagittal T1WI C+ MR shows a complex cystic suprasellar mass with an enhancing rim ➡ and solid components ➡. The cysts contain fluid of different signal intensities. Note the large suprasellar, smaller intrasellar ➡ components in this classic craniopharyngioma.*





(Left) *Gross pathologic specimen displays a typical solid and cystic composition of an adamantinomatous craniopharyngioma. The cystic spaces contain a thick gelatinous material. (Courtesy AFIP.)* **(Right)** *Sagittal T1 C+ MR in this 45-year-old patient who presented with visual changes shows a solid enhancing suprasellar mass. Papillary craniopharyngioma was diagnosed at resection. Papillary craniopharyngiomas are WHO grade I tumors. However, they are more commonly solid, noncalcified lesions.*





(Left) *Sagittal T1WI C+ MR shows a large recurrent adamantinomatous craniopharyngioma in the sella, suprasellar, nasopharyngeal ➡, & prepontine space ➡ with typical heterogeneous cystic & solid morphology. Note mass effect on the optic chiasm, hypothalamus, & pons. (Courtesy S. Blaser, MD.)* **(Right)** *Coronal T2WI MR in a 2 year old with a huge suprasellar mass shows multiple hyperintense cysts ➡. The intrasellar component is relatively small.*

KEY FACTS

TERMINOLOGY

- Rare tumor arising from pituicytes, specialized glial cells in neurohypophysis and infundibulum

IMAGING

- Enhancing sellar or suprasellar mass arising from neurohypophysis or infundibulum
- Location is typically suprasellar (infundibular); pure intrasellar less common
- MR: Isointense to hypointense solid mass
  - Posterior pituitary "bright spot" often absent
  - Variable enhancement, typically strong & uniform
- Best imaging tool: High-resolution MR of sella (2.5-3 mm slice thickness)
  - Sagittal & coronal T1, coronal T2, post-contrast sagittal, & coronal T1 with fat saturation

TOP DIFFERENTIAL DIAGNOSES

- Pituitary adenoma
- Lymphocytic hypophysitis
- Pituitary hyperplasia
- Granular cell tumor

PATHOLOGY

- Distinct from granular cell tumor (WHO 2007)
- WHO grade I
- Well-demarcated, round or oval solid mass
- Hypervascular tumor at surgery

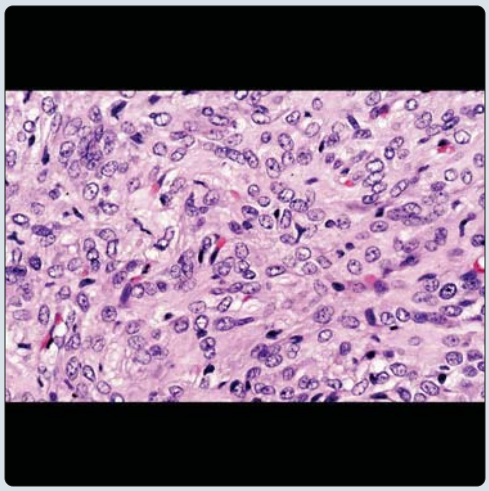
CLINICAL ISSUES

- Visual and endocrine dysfunction common symptoms
- May be asymptomatic
- Surgical resection: Primary therapy; transsphenoidal approach difficult given tumor vascularity

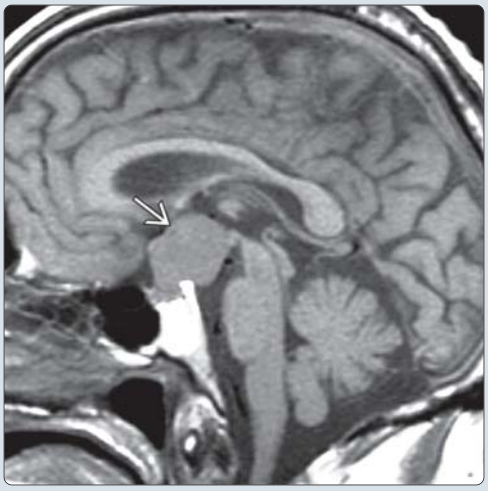
DIAGNOSTIC CHECKLIST

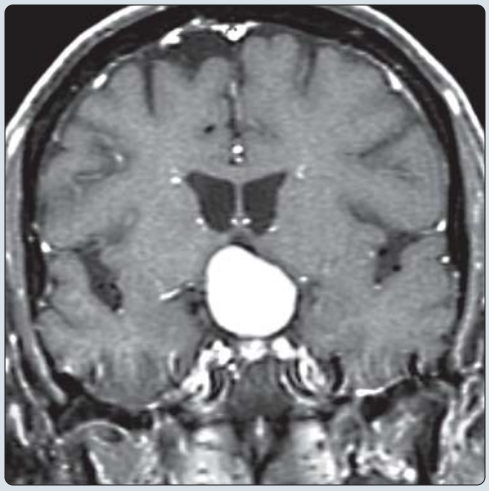
- If mass is present posteriorly within gland, is intrasellar but separate from gland, or involves stalk, consider pituicytoma

(Left) *Sagittal graphic shows a pituicytoma involving the infundibular stalk and neurohypophysis. A lobular suprasellar mass without significant compression of the adjacent structures is typical for this rare, low-grade, spindle cell glial neoplasm.* **(Right)** *H&E histopathology shows the typical benign features of a pituicytoma with bipolar spindle cells with abundant eosinophilic cytoplasm. Nuclear atypia and mitoses are absent. GFAP (not shown) showed strong staining, indicating the astrocytic origin of the tumor.*



(Left) *Sagittal T1WI MR shows a well-delineated suprasellar mass ➡ extending into the posterior sella. Note the lack of a normal pituitary "bright spot," a common feature of pituicytoma.* **(Right)** *Coronal T1WI C+ MR in the same patient shows strong uniform enhancement of this large pituicytoma. Such enhancement is typical of these rare tumors of the neurohypophysis or infundibulum. These vascular tumors are WHO grade I. (Courtesy A.V. Hasso, MD.)*





https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Less preferred terms include infundibuloma and posterior pituitary astrocytoma

Definitions

- Rare tumor arising from pituicytes, specialized glial cells in neurohypophysis and infundibulum

IMAGING

General Features

- Best diagnostic clue
  - Enhancing sellar or suprasellar mass arising from neurohypophysis or infundibulum
- Location
  - Typically suprasellar (infundibular); pure intrasellar less common
- Size
  - Variable (1-2 mm to 4 cm)
- Morphology
  - Well-demarcated, round or oval solid mass

CT Findings

- NECT
  - Hyperdense sellar &/or suprasellar mass; Ca++ rare

MR Findings

- T1WI
  - Isointense to hypointense solid mass
  - Posterior pituitary "bright spot" often absent
- T2WI
  - Heterogeneously hypo- to isointense
- T1WI C+
  - Variable enhancement, typically strong & uniform

Imaging Recommendations

- Best imaging tool
  - High-resolution MR of sella (2.5-3 mm slice thickness)
- Protocol advice
  - Sagittal & coronal T1, coronal T2, post-contrast sagittal & coronal T1 with fat saturation through sella

DIFFERENTIAL DIAGNOSIS

Pituitary Adenoma

- May be indistinguishable; typically anterior gland
- Sellar &/or suprasellar enhancing mass

Lymphocytic Hypophysitis

- May involve gland (anterior > posterior) or stalk
- Typically pregnant or peripartum females

Pituitary Hyperplasia

- Typically diffuse gland enlargement

Metastasis

- Primary tumor often known; multiple lesions common

Granular Cell Tumor

- Glial neoplasm originating in neurohypophysis or infundibulum

PATHOLOGY

General Features

- Etiology
  - Arise from pituicytes in neurohypophysis or infundibulum
  - Distinct from granular cell tumor (WHO 2007)

Staging, Grading, & Classification

- WHO grade I

Gross Pathologic & Surgical Features

- Well-circumscribed, soft to firm mass
  - Necrosis & cystic degeneration are uncommon
  - Rarely, tumor infiltrates surrounding structures including optic chiasm & cavernous sinus
- Hypervascular tumor at surgery

Microscopic Features

- Elongate, bipolar spindle cells with abundant cytoplasm
- Perivascular lymphocytic aggregates common
- Vimentin (+), S100 protein (+), GFAP(+)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Visual and endocrine dysfunction common
    - Headache, amenorrhea, galactorrhea, decreased libido, infertility, diabetes insipidus, hypopituitarism
  - May be asymptomatic

Demographics

- Age
  - Peak incidence: 5th decade
  - No cases reported in patients younger than 20 years old
- Gender
  - M:F = 1.6:1
- Epidemiology
  - Rare (< 50 symptomatic cases have been reported)

Natural History & Prognosis

- Benign, slow-growing tumor
- Regrowth after subtotal resection not uncommon

Treatment

- Surgical resection: Primary therapy; transsphenoidal approach difficult given tumor vascularity
- Inconsistent data regarding radiation therapy
- Preoperative embolization may be helpful

DIAGNOSTIC CHECKLIST

Consider

- If mass is present posteriorly within gland, is intrasellar but separate from gland, or involves stalk, consider pituicytoma

SELECTED REFERENCES

KEY FACTS

TERMINOLOGY

- Rare nonadenomatous, nonendocrine, nonfunctioning sellar tumor
- Thought to arise from folliculostellate cells of anterior pituitary

IMAGING

- Indistinguishable from macroadenoma on imaging
- Sellar and suprasellar mass
- CT: Iso- to hyperdense sellar/suprasellar mass
- MR: Mostly isointense with white matter
  - Strong, typically uniform enhancement

TOP DIFFERENTIAL DIAGNOSES

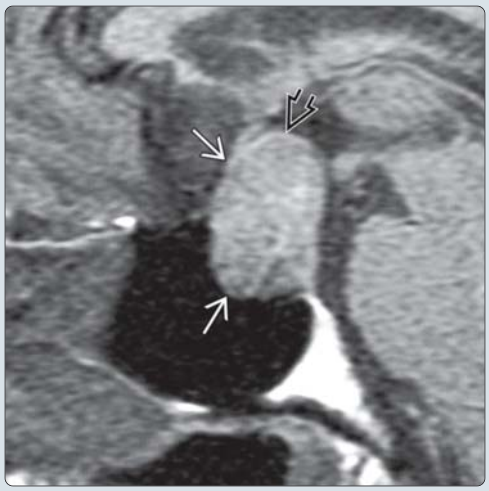
- Pituitary macroadenoma
- Lymphocytic hypophysitis
- Pituicytoma
- Granular cell tumor of neurohypophysis
- Metastasis

PATHOLOGY

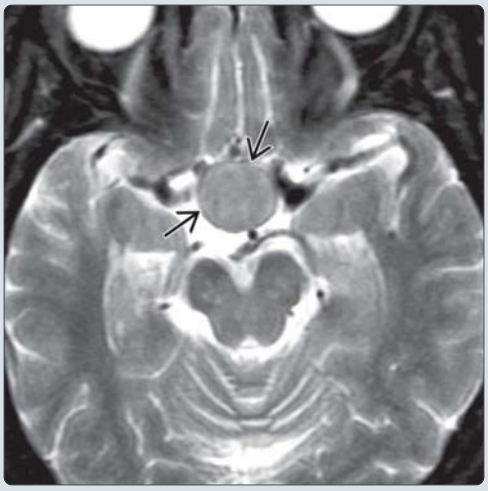
- Gross appearance indistinguishable from macroadenoma
- Microscopic features
  - Interwoven fascicles of elongated spindled cells
  - Eosinophilic "oncocytic" cytoplasm
  - Mitotic rate typically low
- WHO grade I

CLINICAL ISSUES

- Tumor of adults (mostly 5th/6th decades)
- Symptoms indistinguishable from nonfunctioning pituitary macroadenoma
  - Visual defects
  - Panhypopituitarism
  - Headache
  - Less common symptoms reported include nausea and vomiting
- Treatment: Surgical resection
- Generally benign clinical course



(Left) *Axial NECT in a 69-year-old woman with headaches and bitemporal hemianopsia shows a well-delineated, slightly hyperdense mass ⇨ in the suprasellar cistern.* **(Right)** *Sagittal T1WI MR in the same patient shows a sellar and suprasellar mass ➡ that appears isointense with white matter with superior displacement of the optic chiasm ⇨. Note that the pituitary gland cannot be identified separate from the mass, nor can the infundibular stalk be distinguished from the rest of the lesion.*



(Left) *Axial T2WI MR in the same patient shows that the mass ⇨ is sharply circumscribed and remains isointense with white matter.* **(Right)** *Coronal T1 C+ MR shows the tumor ➡ enhances strongly and uniformly. Preoperative diagnosis was pituitary macroadenoma. Oncocytoma was found at surgery. Although imaging and clinical findings are indistinguishable from macroadenomas, oncocytomas are readily distinguished on histologic, immunohistochemical, and fine structural features.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Neoplasms that arise from pituicytes, specialized glial cells of the neurohypophysis or infundibulum
- Rare low-grade, nonendocrine neoplasms of sellar region
- Formerly called pituicytoma; granular cell tumor of the neurohypophysis

IMAGING

- Enhancing, well-circumscribed sellar/suprasellar or infundibular mass
- 1.5 -6.0 cm
- CT: Sellar/suprasellar mass with hyperattenuation
  - Rarely calcification may be present
- Best imaging tool: MR C+ with high-resolution imaging through sellar region
- Consider granular cell tumor if sellar/suprasellar mass appears separate from anterior pituitary gland

TOP DIFFERENTIAL DIAGNOSES

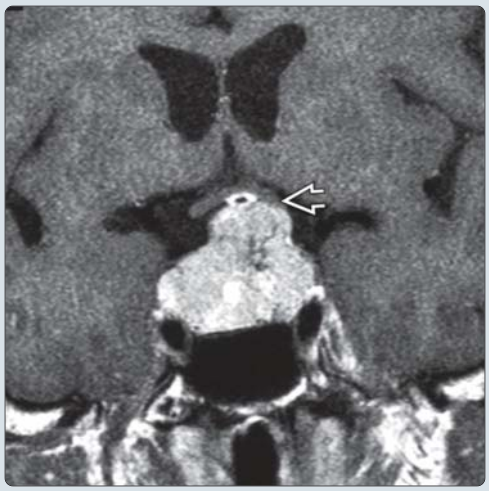
- Pituitary macroadenoma
- Lymphocytic hypophysitis
- Pituicytoma
- Spindle cell oncocytoma
- Rathke cleft cyst

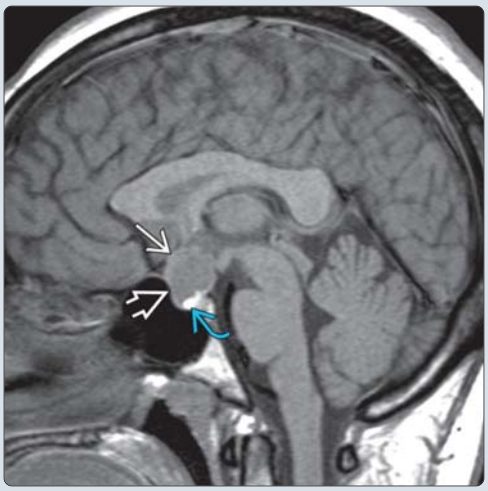
PATHOLOGY

- WHO grade I

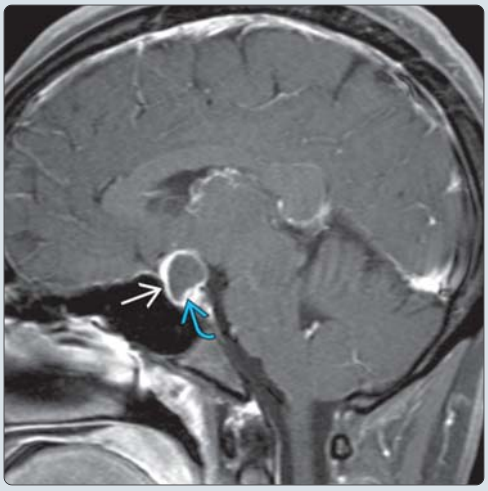
CLINICAL ISSUES

- Commonly asymptomatic (small lesions)
- Visual field deficit related to optic chiasm compression is most common presenting feature
- Less common symptoms: Panhypopituitarism, galactorrhea, amenorrhea, decreased libido, neuropsychological changes
- Typically present in adulthood, 5th-6th decades
- Generally benign clinical course





(Left) *Coronal T1 C+ MR shows a large sellar and suprasellar enhancing mass contacting the left optic chiasm ➡. Granular cell tumor was diagnosed at resection. Imaging mimics the much more common pituitary macroadenoma.* **(Right)** *Sagittal T1 MR in a 31-year-old woman with headache and visual complaints shows a sellar & suprasellar mass ➡ with superior displacement of the optic chiasm ➡. There is a hyperintense focus ⇨ along the inferior aspect of the mass.*



(Left) *Coronal T1 C+ MR in the same patient shows peripheral enhancement of the mass ➡.* **(Right)** *Sagittal T1 C+ MR in the same patient shows peripheral enhancement ➡ and central low signal within the mass. The region of T1 hyperintensity is also seen, resembling an intracystic nodule ⇨, typically seen in a Rathke cleft cyst. Pathology revealed a granular cell tumor of the neurohypophysis at resection. Granular cell tumor was recognized as a separate tumor entity by the 2007 WHO classification system.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Sella partially filled with arachnoid-lined CSF collection
- Primary empty sella
  - Common normal, incidental finding (15% of brain MRs)
  - Can be normal variant
  - Normal or increased CSF pressure
  - Near normal volume of compressed pituitary tissue
- Secondary empty sella
  - Prior pituitary surgery, radiation, or injury

IMAGING

- Intrasellar CSF, pituitary flattened against sellar floor
  - Bony sella may be normal or moderately enlarged (secondary to pulsatile CSF)
  - Bony margins intact, not eroded/demineralized
  - Infundibular stalk, pituitary gland enhance normally
- Fluid exactly like CSF
  - Suppresses completely on FLAIR
  - Does not restrict on DWI

TOP DIFFERENTIAL DIAGNOSES

- Idiopathic intracranial hypertension
- Secondary intracranial hypertension
- Arachnoid cyst
- Pituitary apoplexy

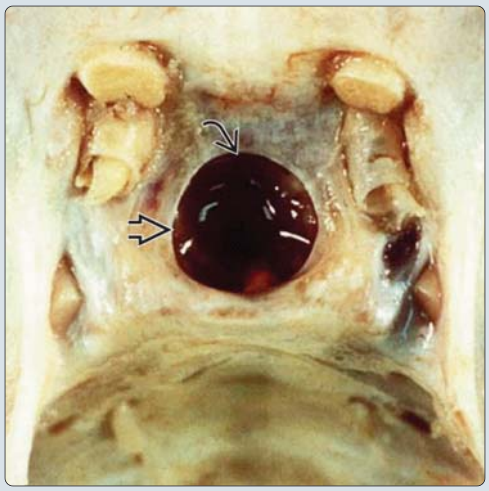
PATHOLOGY

- "Deficient" diaphragma sellae
  - Dural covering of sella is incomplete (widened)
  - Leaves large opening for infundibular stalk
  - Allows intrasellar herniation of arachnoid with CSF from suprasellar subarachnoid cistern above

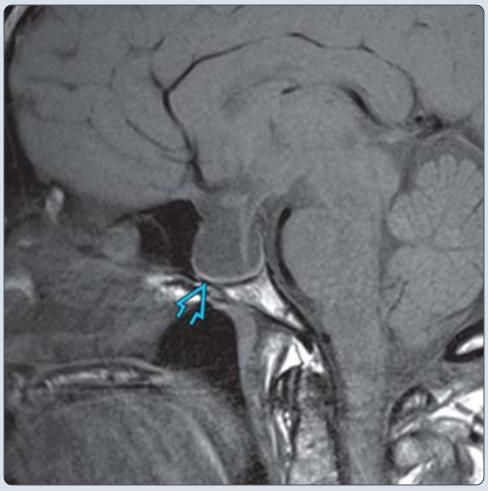
CLINICAL ISSUES

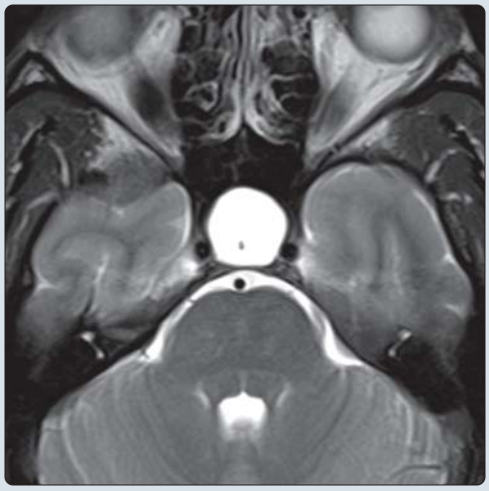
- Mostly incidental, asymptomatic (adults)
  - F:M = 5:1
- Headache, visual disturbances if related to intracranial hypertension
- Frequent endocrine abnormalities in children

(Left) *Sagittal graphic shows an empty sella (ES). The extension of arachnoid with CSF through the diaphragma sellae ➡ flattens and displaces the pituitary gland ⇨ posteroinferiorly against the sellar floor.* **(Right)** *Axial gross pathology shows a primary empty sella found incidentally at autopsy. Note the wide opening of the diaphragma sellae ⇨ and CSF ⇨ largely filling the bony sella. (Courtesy M. Sage, MD.)*



(Left) *Sagittal T1WI MR shows a 40-year-old man with incidentally found partially empty sella. No endocrine laboratory abnormalities. Notice enlarged bony sella with thin rim of pituitary tissue ⇨.* **(Right)** *This T2WI MR was taken from the same 40-year-old man with incidental partially empty sella. The bony sella is expanded and filled with CSF. A normal pituitary infundibulum is present in the midline.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Empty sella (ES)

Definitions

- Herniation of suprasellar arachnoid and CSF through wide diaphragma sellae into bony sella turcica
- Sella turcica is partially filled with CSF
  - Rarely completely empty
  - Pituitary gland
    - Almost never completely absent
    - Thin, flattened rim of residual pituitary tissue
    - Generally at posteroinferior sellar floor
- Primary or secondary
  - Primary empty sella
    - Common normal variant (15% of MRs), incidental finding
    - Normal or increased CSF pressure
    - Near normal volume of compressed pituitary tissue
    - No history of trauma, surgery, radiation
    - Patients typically endocrinologically normal
  - Secondary empty sella
    - Many etiologies
      - Surgery
      - Radiation
      - Bromocriptine therapy
      - Trauma
      - Sheehan syndrome (postpartum pituitary necrosis)
      - Pituitary apoplexy
      - Pituitary abscess

IMAGING

General Features

- Best diagnostic clue
  - Intrasellar CSF with pituitary gland flattened against sellar floor
  - Bony sella may be normal or large
- Location
  - Intrasellar CSF
- Size
  - Variable

Imaging Recommendations

- Best imaging tool
  - Sagittal T1WI
  - Coronal T2WI

CT Findings

- NECT
  - CSF-like herniation of CSF into bony sella
    - Bony sella typically appears normal
  - May also be moderately enlarged (secondary to pulsatile CSF)
    - Bony margins intact, not eroded/demineralized
- CECT
  - Infundibular stalk and pituitary gland enhance normally
  - Occasionally intrasellar CSF collection may be asymmetric
    - Stalk may appear tilted to 1 side

MR Findings

- T1WI
  - Primary empty sella
    - Fluid looks exactly like CSF
    - Stalk usually midline
      - Stalk may be tilted to 1 side if intrasellar CSF herniation is asymmetric
    - 3rd ventricle, hypothalamus usually normal
      - Rare: Herniation of optic chiasm, anterior 3rd ventricle into sella
  - Secondary empty sella
    - Look for changes of transsphenoidal hypophysectomy
      - Defect in sellar floor
      - Fat packing
    - May cause distortion of stalk, chiasm
      - Stalk and pituitary remnant(s) may be scarred/adhesed to side or bottom of sella turcica
- T2WI
  - Fluid exactly like CSF
- FLAIR
  - Intrasellar fluid suppresses completely on FLAIR
- DWI
  - No restriction
- T1WI C+
  - Primary empty sella
    - Stalk, gland enhance normally
    - No other abnormalities
  - Secondary empty sella
    - Gland and stalk may be adhesed/distorted

DIFFERENTIAL DIAGNOSIS

Idiopathic Intracranial Hypertension

- "Pseudotumor cerebri"
- Usually obese female, 20-40 years
- Headache, papilledema
- Enlarged optic nerve sheaths ± empty sella
- Ventricles may appear slit-like
- Subarachnoid spaces (cisterns, surface sulci) may be small

Secondary Intracranial Hypertension

- Increased intracranial pressure caused by
  - Obstructive hydrocephalus (intra-/extraventricular)
  - Mass (neoplasm, etc.)
- Dilated anterior recesses of 3rd ventricle herniate into sella
- Look for mass, evidence for transependymal CSF migration

Arachnoid Cyst

- Suprasellar arachnoid cyst may herniate into bony sella
  - Bony sella often enlarged, eroded/expanded
- Look for 3rd ventricle or optic chiasm displaced by CSF-containing mass
- Cyst walls may be visible on thin-section imaging

Pituitary Apoplexy

- Acute: Pituitary gland usually enlarged, not small
  - Usually hemorrhagic
  - Look for rim enhancement around periphery of enlarged, nonenhancing gland
- Chronic: May cause empty sella

https://CafePezeshki.IR

Pituitary Anomalies

- Ectopic posterior pituitary "bright spot"
  - May cause small pituitary gland
  - Infundibular stalk short, "stubby"
  - Bony sella often small, shallow appearing
  - Sella can appear partially empty
- Persisting embryonal infundibular recess of 3rd ventricle
  - Can mimic empty sella (rare)
- Pituitary stalk duplication
  - Rare
  - Look for 2 thin stalks
  - Sella may appear partially empty

Sheehan Syndrome

- Original clinical description
  - Postpartum hemorrhage
  - Pituitary necrosis
  - Lactation failure
  - Hypopituitarism
- Anterior pituitary necrosis
  - Leaves small residual pituitary gland
  - Result = empty sella
- May occur years after pregnancy
- Slow clinical progression over years suggests factors other than ischemia may be involved
- Necrosis may be caused by antihypothalamus, antipituitary antibodies
- Pituitary autoimmunity may perpetuate hypopituitarism

Epidermoid Cyst

- True intrasellar epidermoid cyst very rare
  - Off midline > midline
  - Usually extension from cerebellopontine angle epidermoid

PATHOLOGY

General Features

- Etiology
  - Primary empty sella
    - Deficient diaphragma sellae
      - Dural covering of sella is incomplete (widened)
      - Leaves widened dural opening for infundibular stalk
      - Allows intrasellar herniation of arachnoid with CSF from suprasellar subarachnoid cistern above
    - Pulsatile CSF may gradually enlarge sella
  - Secondary empty sella
    - Common: Surgery, bromocriptine therapy, radiation
    - Less common/rare: Pituitary apoplexy, pituitary abscess

Gross Pathologic & Surgical Features

- Diaphragma sellae appears widened, gaping
- Intrasellar herniation of arachnoid-containing CSF

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Incidental, asymptomatic
  - Headache, visual disturbances if caused by idiopathic intracranial hypertension (IIH)
  - Endocrine disturbances
    - 20% of adults have subtle laboratory abnormalities
    - Majority (70%) of children with ES have endocrine abnormalities

Demographics

- Age
  - Peak incidence between 50-60 years
  - Increased CSF pressure presents earlier, 30-40 years
- Gender
  - F:M = 5:1
- Epidemiology
  - 10-15% found incidentally on imaging

Natural History & Prognosis

- Both primary and secondary empty sella usually benign, do not require treatment
- If related to IIH, can result in vision loss or CSF leak
- Hormonal replacement therapy may be required in some cases
- Surgery (rare)
  - "Chiasmapexy" to elevate optic chiasm if severe visual disturbances caused by inferior displacement of optic chiasm into empty sella
  - CSF rhinorrhea may require surgical intervention

DIAGNOSTIC CHECKLIST

Consider

- Incidental, normal variant in older adults
- Additional findings of IIH in younger females (e.g., dilated optic nerve sheaths, papilledema, dural venous sinus narrowing)
- Look for endocrine abnormalities in children

Image Interpretation Pearls

- Intrasellar fluid follows CSF **exactly** on all sequences

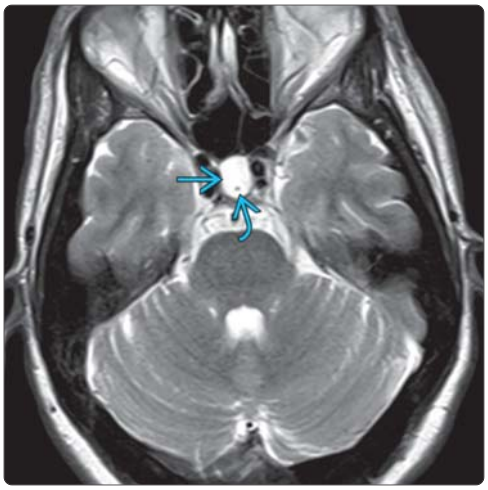
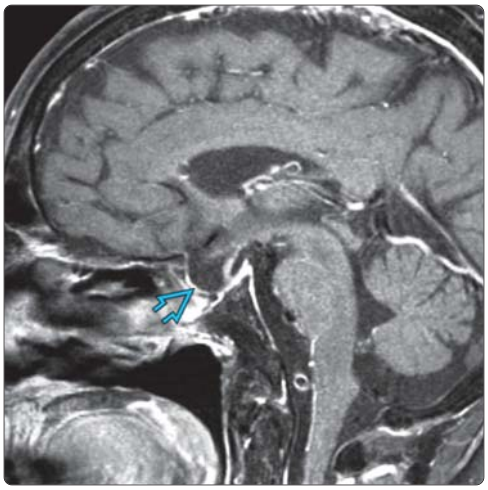
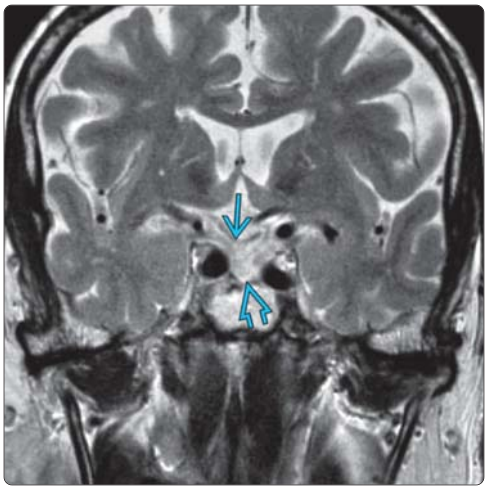
https://CafePezeshki.IR

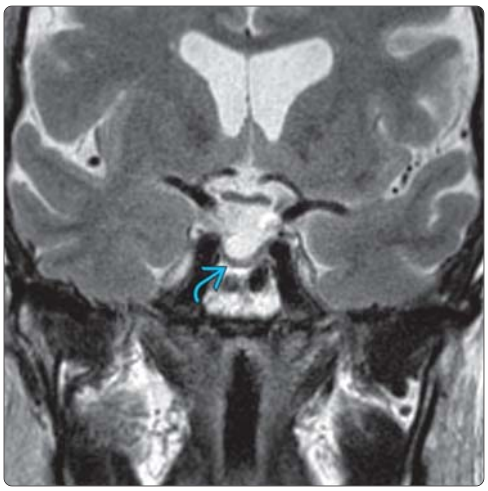


(Left) *Sagittal T1WI MR shows the incidental finding of a primary partially empty sella, mostly filled with CSF. Note the absence of a posterior pituitary "bright spot," which is found in 15-20% of endocrinologically normal patients.* **(Right)** *Axial T2WI MR in the same patient shows the sella mostly filled with CSF from intrasellar herniation of the suprasellar subarachnoid space. Note that the infundibular stalk within the mostly empty sella is normally positioned.*





(Left) *Sagittal T1WI C+ FS MR shows an empty sella secondary to surgery for pituitary macroadenoma. Little pituitary tissue is apparent along the enlarged sellar floor.* **(Right)** *Coronal T2WI MR of a secondary empty sella in the same patient demonstrates that the sella is filled with CSF. Note the thinned optic chiasm retracted downward toward the sella.*



(Left) *T1WI C+ MR was taken from a 71-year-old woman with a sellar and suprasellar arachnoid cyst mimicking the appearance of an empty sella. Note the normally enhancing pituitary infundibulum and pituitary tissue displaced anteriorly by the CSF intensity arachnoid cyst.* **(Right)** *T2WI MR was taken from a 40-year-old man formerly treated with bromocriptine for elevated testosterone levels with a secondary empty sella. A small amount of residual pituitary tissue remains along the inferior margin of the normal-sized sella.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Upper limit of normal pituitary height varies with age, gender
  - Pregnant/lactating females: 12 mm
  - Young menstruating females: 10 mm
  - Males, postmenopausal females: 8 mm
  - Infants, children: 6 mm
- Nonphysiologic hyperplasia seen with
  - Hypothyroidism, Addison disease, or other end-organ failure
  - Some neuroendocrine neoplasms

IMAGING

- Enlarged homogeneously enhancing pituitary gland with convex superior margin
- Best technique: High-resolution MR
  - Sagittal/coronal T1; coronal T2
  - Dynamic coronal T1WI
  - Post-contrast T1 FS sagittal/coronal T1
  - 3-4 mm slice thickness

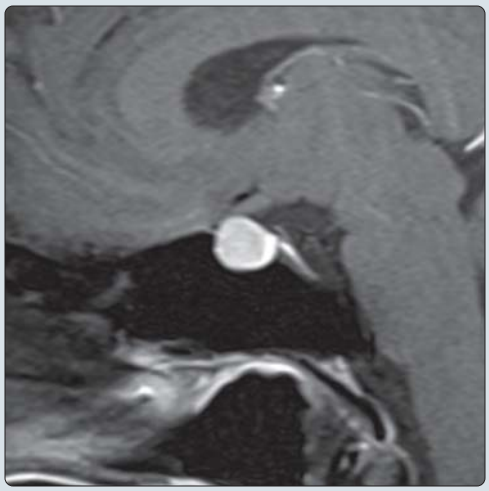
TOP DIFFERENTIAL DIAGNOSES

- Pituitary macroadenoma
- Pituitary microadenoma
- Lymphocytic hypophysitis
- Venous congestion (intracranial hypotension, dural arteriovenous fistula)

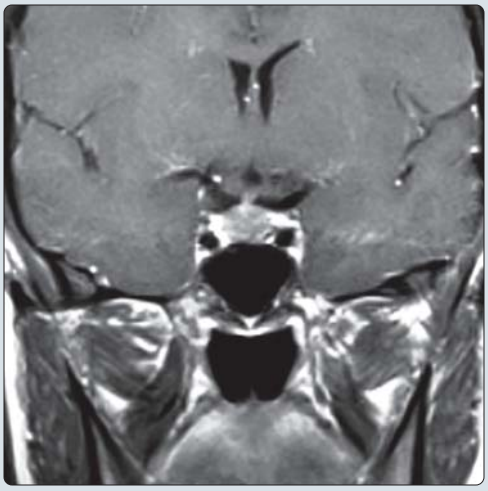
PATHOLOGY

- Growth hormone cell hyperplasia usually diffuse, occurs with neuroendocrine tumors
- Prolactin cell hyperplasia: Diffuse > nodular
- Corticotroph hyperplasia: Nodular or diffuse
- Thyrotroph hyperplasia
  - Longstanding primary hypothyroidism, may have associated prolactin hyperplasia
- Gonadotroph hyperplasia (e.g., Turner, Klinefelter syndrome)

(Left) *Coronal graphic shows physiologic pituitary hyperplasia. The gland is uniformly enlarged and has a mildly convex superior margin.* **(Right)** *Sagittal T1W C+ MR in a 38-year-old woman undergoing infertility treatment imaged for headache shows a homogeneously enhancing pituitary measuring 12 mm.*



(Left) *Coronal T1WI C+ MR shows typical physiologic pituitary hyperplasia in a 28-year-old lactating woman. The gland has a mildly convex superior margin and measures nearly 14 mm in height.* **(Right)** *At follow-up 1 year later, coronal T1WI C+ MR reveals normal appearance to the pituitary gland with interval resolution of the postpartum physiologic enlargement.*



https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Upper limit of normal pituitary height varies with age, gender
  - Pregnant/lactating females: 12 mm
  - Young menstruating females: 10 mm
  - Males, postmenopausal females: 8 mm
  - Infants, children: 6 mm
- Nonphysiologic hyperplasia seen with
  - Longstanding hypothyroidism, Addison disease, end-organ failure, or some neuroendocrine neoplasms

IMAGING

General Features

- Best diagnostic clue
  - Enlarged homogeneously enhancing pituitary gland with convex superior margin
  - May be nodular, mimic pituitary adenoma
- Location
  - Sella; may extend into suprasellar region, compress adjacent structures
- Size
  - > 10 mm up to 15 mm

CT Findings

- NECT
  - Noncalcified pituitary gland enlargement
- CECT
  - Homogeneous enhancement

MR Findings

- T1WI
  - Isointense with remainder of pituitary gland
- T2WI
  - Isointense with remainder of pituitary gland
- T1WI C+
  - Diffusely enhancing gland is typical
  - May cause focal nodular enlargement
  - Dynamic MR: Enhances similar to remainder of gland

Imaging Recommendations

- Best imaging tool
  - MR with 3 mm slices, small FOV
- Protocol advice
  - Sagittal/coronal T1; coronal T2
  - Dynamic enhanced coronal T1WI
  - Post-contrast T1 FS sagittal/coronal

DIFFERENTIAL DIAGNOSIS

Pituitary Macroadenoma

- May be indistinguishable

Pituitary Microadenoma

- May be indistinguishable
- Enhances slower than normal gland on dynamic study

Lymphocytic Hypophysitis

- Enlarged gland &/or stalk
- Pregnant or postpartum females

Venous Congestion

- Can occur with intracranial hypotension
- Dural arteriovenous fistulas

PATHOLOGY

General Features

- Etiology
  - Response to endocrinologic stimulation by orthotopic or ectopic production of hypothalamic releasing hormones
    - Orthotopic: Response to end-organ failure
    - Ectopic: Related to neuroendocrine tumors
  - Physiologic hyperplasia occurs in pregnancy and lactation

Microscopic Features

- Nodular hyperplasia characterized by marked expansion of acini, architectural distortion
- Diffuse hyperplasia requires formal cell count
- Growth hormone cell hyperplasia usually diffuse, occurs with neuroendocrine tumors
  - Pancreatic islet cell tumor, pheochromocytoma, bronchial and thyroid carcinoid tumor
  - Associated with McCune-Albright syndrome, multiple endocrine neoplasia syndrome, and Carney complex
- Prolactin cell hyperplasia: Diffuse > nodular
  - May be seen with pregnancy and lactation, estrogen treatment, primary hypothyroidism, Cushing disease
- Corticotroph hyperplasia: Nodular or diffuse
  - Associated with Cushing disease, neuroendocrine tumors, untreated Addison disease
- Thyrotroph hyperplasia
  - Longstanding primary hypothyroidism, may have associated prolactin hyperplasia
- Gonadotroph hyperplasia (e.g., Turner, Klinefelter syndrome)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Varies with cell type of hyperplasia

Treatment

- If related to hypothyroidism, regression after thyroid hormone therapy common
- Treat end-organ failure or neuroendocrine tumor

DIAGNOSTIC CHECKLIST

Consider

- Hyperplasia may mimic adenoma
  - Clinical information can help differentiate
- If imaging looks like adenoma in prepubescent male, consider end-organ failure

KEY FACTS

TERMINOLOGY

- Lymphocytic hypophysitis (LH)
- Synonyms: Adenohypophysitis, primary hypophysitis, stalkitis
- Idiopathic inflammation of pituitary gland &/or stalk

IMAGING

- Thick stalk (> 2 mm + loss of normal "top to bottom" tapering)
- ± enlarged pituitary gland
- 75% show loss of posterior pituitary "bright spot"
- Enhances intensely, uniformly
- May have adjacent dural or sphenoid sinus mucosal thickening

TOP DIFFERENTIAL DIAGNOSES

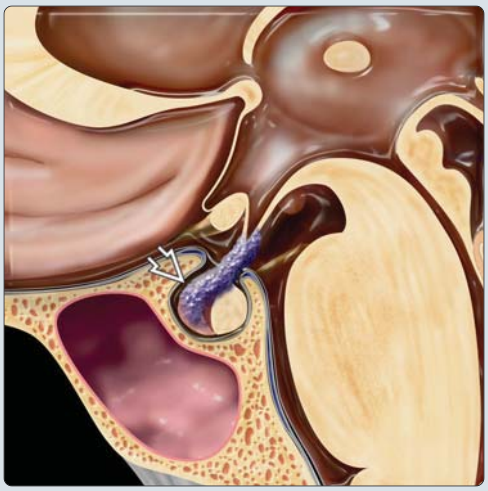
- Macroadenoma
- Pituitary hyperplasia
- Adolescent pituitary gland
- Granulomatous disease
- Pituitary "dwarf"
- Ectopic posterior pituitary gland

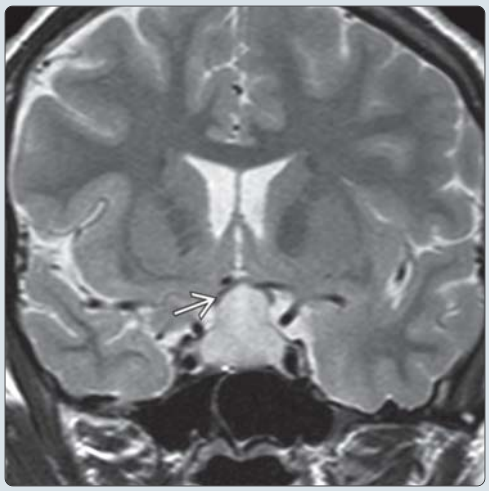
CLINICAL ISSUES

- Peripartum woman with headache, multiple endocrine deficiencies
- Middle-aged man with diabetes insipidus (lymphocytic infundibuloneurohypophysitis)
- Mean in women = 35 years, men = 45 years
- M:F = 1:8-9
- Often self-limited
- Unrecognized, untreated LH can result in death from panhypopituitarism
- Conservative care (steroids, hormone replacement)

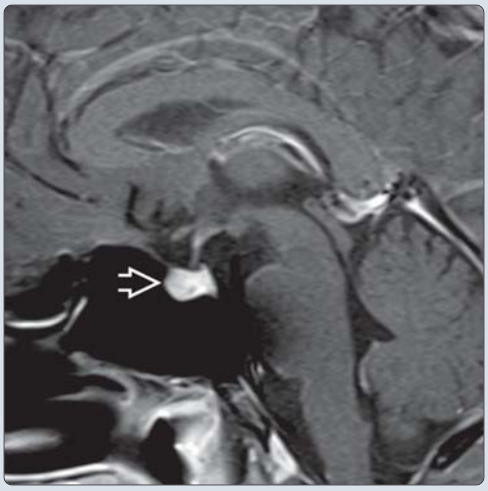
DIAGNOSTIC CHECKLIST

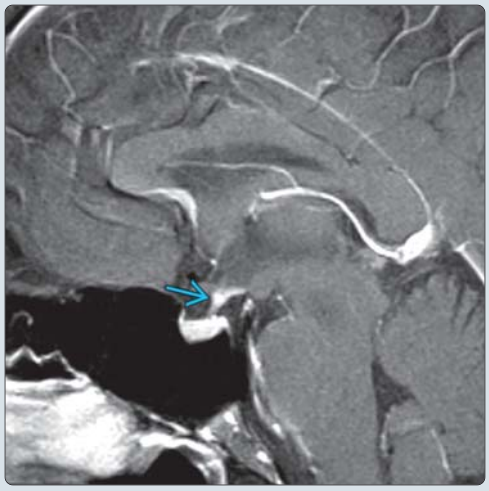
- LH can mimic pituitary adenoma





(Left) *Sagittal graphic shows lymphocytic hypophysitis. Note thickening of the infundibulum with loss of the normal "top to bottom" tapering as well as infiltration into the anterior lobe of the pituitary gland* ⇨. **(Right)** *Coronal T2 MR in a pregnant woman with visual changes and endocrine abnormalities shows a hyperintense sellar/suprasellar mass with superior displacement of the optic chiasm* ⇨. *Surgery for optic chiasm decompression disclosed lymphocytic hypophysitis. Imaging mimics pituitary macroadenoma.*





(Left) *Sagittal T1 C+ MR shows a prominent pituitary gland* ⇨ *in a 37-year-old man with panhypopituitarism during treatment with ipilimumab for metastatic melanoma. The gland had doubled in size since MR 6 weeks prior. Findings are consistent with drug-induced hypophysitis* **(Right)** *Sagittal T1 C+ MR in a 50 year old with diabetes insipidus shows focal enlargement of the pituitary infundibulum* ⇨ *related to lymphocytic infundibuloneurohypophysitis.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Lymphocytic hypophysitis (LH)

Synonyms

- Adenohypophysitis, primary hypophysitis, stalkitis

Definitions

- Idiopathic inflammation of pituitary gland or stalk

IMAGING

General Features

- Best diagnostic clue
  - Thick nontapered stalk, ± pituitary mass
- Location
  - Suprasellar, intrasellar
- Size
  - Usually < 10 mm but may reach 2-3 cm
- Morphology
  - Rounded pituitary gland with infundibulum that appears thickened, nontapering, or bulbous

MR Findings

- T1WI
  - Thick stalk (> 2 mm + loss of normal tapering)
  - ± enlarged pituitary gland
  - 75% show loss of posterior pituitary "bright spot"
- T2WI
  - Iso-/hypointense
- T1WI C+
  - Enhances intensely, uniformly
  - May see dural or sphenoid sinus mucosal thickening

Imaging Recommendations

- Protocol advice
  - MR: Pre-contrast thin-section (< 3 mm) sagittal, coronal T1WI and T2WI
  - Coronal dynamic T1WI C+ (may show delayed pituitary enhancement)

DIFFERENTIAL DIAGNOSIS

Macroadenoma

- Sellar and suprasellar mass
- Sella turcica enlarged/eroded
- Diabetes insipidus common in LH, rare with adenoma

Pituitary Hyperplasia

- Stalk usually normal
  - In young females, late pregnancy/peripartum
- May be seen with hypothyroidism, Addison disease, end-organ failure, neuroendocrine neoplasms

Adolescent Pituitary

- Enlarged gland with uniform enhancement

Granulomatous Disease

- Sarcoid, Langerhans cell histiocytosis (LCH), granulomatosis with polyangiitis; systemic disease often present

Pituitary "Dwarf"

- Stalk may appear short and stubby

Ectopic Posterior Pituitary

- Hyperintense focus at tuber cinereum or truncated stalk

PATHOLOGY

General Features

- Etiology
  - Autoimmune, inflammatory disorder
  - Other types of hypophysitis include
    - Granulomatous (sarcoid, LCH, infectious, etc.)
    - IgG4-related hypophysitis
    - Drug-related (cancer immunotherapy [e.g., ipilimumab])

Gross Pathologic & Surgical Features

- Diffusely enlarged stalk/pituitary gland

Microscopic Features

- Acute
  - Dense infiltrate of B-/T-lymphocytes, plasma cells, occasionally eosinophils; ± lymphoid follicles
  - No granulomas, giant cells, or organisms; no neoplasm
- Chronic may demonstrate extensive fibrosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache, visual impairment
- Clinical profile
  - Peripartum woman with headache, multiple endocrine deficiencies
  - Middle-aged man with diabetes insipidus (lymphocytic infundibuloneurohypophysitis)

Demographics

- Age
  - Mean in women = 35 years, men = 45 years
- Gender
  - M:F = 1:8-9
- Epidemiology
  - Rare (1-2% of sellar lesions)

Natural History & Prognosis

- Often self-limited
- Unrecognized, untreated LH can result in death from panhypopituitarism

Treatment

- Conservative (steroids, hormone replacement)

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- LH can mimic pituitary adenoma

Terminology

The contents of the cerebellopontine angle (CPA) and internal auditory canal (IAC) cisterns include the facial nerve (CN7), the vestibulocochlear nerve (CN8), and the anterior inferior cerebellar artery (AICA) loop. The bony IAC, its fundal crests (vertical and horizontal), and its opening in the porus acusticus are also included as part of this discussion.

Embryology

The temporal bone forms as 3 distinct embryological events: (1) The external and middle ear, (2) the inner ear, and (3) the IAC. The practical implications of these 3 related but separate embryological events is that the presence or absence of the IAC is independent of the development of the inner, middle, or external ear.

The IAC develops in response to formation and migration of the facial and vestibulocochlear nerves through this area. IAC size depends on the number of migrating nerve bundles. The fewer the nerve bundles, the smaller the IAC. If the IAC is very small and only 1 nerve is seen, it is usually the facial nerve.

Imaging Anatomy of Cochlea, IAC, and CPA

The cochlear nerve portion of the vestibulocochlear nerve begins in the modiolus of the cochlea where the bipolar **spiral ganglia** are found. Distally projecting axons reach the organ of Corti within the scala media. Proximally projecting axons coalesce to form the cochlear nerve itself within the fundus of the IAC.

CN8 in the IAC and CPA cisterns is made up of vestibular (balance) and cochlear (hearing) components. The cochlear nerve is located in the anteroinferior quadrant of the IAC. In the region of the porus acusticus, the cochlear nerve joins the superior and inferior vestibular nerve bundles to become the vestibulocochlear nerve in the CPA cistern.

The vestibulocochlear nerve crosses the CPA cistern as the posterior nerve bundle (CN7 is the anterior nerve bundle) to enter the brainstem at the junction of the medulla and pons. The entering cochlear nerve fibers pierce the brainstem and bifurcate to form synapses with both the **dorsal** and the **ventral cochlear nuclei**. These 2 nuclei are found on the lateral surface of the inferior cerebellar peduncle. Their location can be accurately determined by looking at high-resolution T2 axial images and identifying the contour of the inferior cerebellar peduncle. The entering vestibular nerve fibers divide into 4 branches to form synapses with the superior, inferior, medial, and lateral nuclei. The vestibular nuclei are clustered in the inferior cerebellar peduncle just anteromedial to the cochlear nuclei.

Remembering the normal orientation of nerves within the IAC cistern is assisted by the mnemonic "7-up, Coke down." CN7 is found in the anterosuperior quadrant whereas the cochlear nerve is confined to the anteroinferior quadrant. Given this information, it is simple to remember that the superior vestibular nerve (SVN) is posterosuperior while the inferior vestibular nerve (IVN) is posteroinferior.

Other normal structures to be aware of in the IAC include the **horizontal crest** (crista falciformis) and the **vertical crest** ("Bill's bar"). The horizontal crest is a medially projecting horizontal bony shelf in the IAC fundus that separates the CN7 and SVN above from the cochlear nerve and IVN below. The vertical crest is found between CN7 and the SVN along the superior fundal bony wall. The horizontal crest is easily seen on both bone CT and high-resolution MR. The vertical crest is more readily seen on bone CT.

Openings from the IAC fundus into the inner ear are numerous. The largest is the anteroinferior **cochlear nerve canal**, which conveys the cochlear nerve from the modiolus to the IAC fundus. Anterosuperiorly, the **meatal foramen** opens into the labyrinthine segment of CN7. The **macula cribrosa** is the multiply perforated bone that separates the vestibule of the inner ear from the IAC fundus.

Other non-neural normal anatomy of interest in the CPA cistern includes the AICA loop, flocculus, and choroid plexus. The **AICA** arises from the basilar artery, courses superolaterally into the CPA cistern, and then travels into the IAC cistern. Within the IAC, the AICA feeds the internal auditory artery of the cochlea. The AICA loop in the IAC or CPA cisterns may mimic a cranial nerve bundle on high-resolution T2WI MR. AICA vascular territory includes the cochlea, flocculus of the cerebellum, and anterolateral pons in the area of cranial nerve nuclei for CN5, CN7, and CN8. The **flocculus** is a lobule of the cerebellum that projects into the posterolateral CPA cistern. The 4th ventricle **choroid plexus** typically passes through the foramen of Luschka in the CPA cistern.

Imaging Techniques & Indications

The principal clinical indication requiring radiologists to examine the CPA-IAC is **sensorineural hearing loss (SNHL)**. Three principal parameters must be satisfied when completing the MR study in SNHL: (1) Use contrast-enhanced T1 fat-saturated thin-section sequences through the CPA-IAC to identify enhancing lesions in this location, (2) utilize high-resolution T2-weighted sequences to answer presurgical questions when a mass lesion is found, and (3) screen the brain for intraaxial causes, such as multiple sclerosis.

The gold standard for imaging patients with acquired SNHL is enhanced thin-section (≤ 3 mm) axial and coronal fat-saturated MR through the CPA-IAC. With these enhanced sequences, it is highly unlikely that a lesion causing SNHL will be missed. Be sure to obtain an axial or coronal pre-contrast T1 sequence and use fat saturation when contrast is applied to avoid the rare but troublesome mistake of calling a CPA-IAC lipoma a vestibular schwannoma. In the absence of fat saturation, the inherent high signal of lipoma will appear to enhance, leading to the misdiagnosis of vestibular schwannoma.

High-resolution T2-weighted thin-section (≤ 1 mm) MR sequences (CISS, FIESTA, T2 space) in the axial and coronal planes can be used as a screening exam without contrast to identify patients with mass lesions in the CPA-IAC area. However, these sequences are currently more commonly used as supplements when vestibular schwannoma is found on the enhanced T1 sequences to answer specific surgically relevant questions: What size is the fundal cap? What is the nerve of origin? Does the lesion enter the cochlear foramen?

Whenever MR is ordered for SNHL, remember to include whole-brain FLAIR, GRE, and DWI sequences. FLAIR will identify the rare multiple sclerosis patient presenting with SNHL as well as other intraaxial causes. GRE will demonstrate micro- or macrohemorrhage within a vestibular schwannoma and may help with aneurysm diagnosis when blooming of blood products or calcium in an aneurysm wall is seen. When

https://CafePezeshki.IR

CPA Mass Differential Diagnosis

Pseudolesions	**Vascular**
Asymmetric cerebellar flocculus	Aneurysm (vertebrobasilar, PICA, AICA)
Asymmetric choroid plexus	Arteriovenous malformation
High jugular bulb	**Benign tumor**
Jugular bulb diverticulum	Choroid plexus papilloma
Marrow foci around IAC	Facial nerve schwannoma
Congenital	Hemangioblastoma, cerebellum
Arachnoid cyst	IAC hemangioma (venous malformation)
Epidermoid cyst	Meningioma
Lipoma	Vestibular schwannoma
Neurofibromatosis type 2	**Malignant tumor**
Infectious	Brainstem glioma, pedunculated
Cysticercosis	Ependymoma, pedunculated
Meningitis	Melanotic schwannoma
Inflammatory	Metastases, systemic or subarachnoid spread ("drop")
Idiopathic intracranial pseudotumor	
Sarcoidosis	

DWI shows restricted diffusion in a CPA mass, the diagnosis of **epidermoid** is easily made.

Approaches to Imaging Issues of CPA-IAC

Approach to Sensorineural Hearing Loss in an Adult

Unilateral SNHL in an otherwise healthy adult is evaluated with enhanced thin-section fat-saturated T1WI MR of the CPA-IAC area, with high-resolution T2WI sequences providing help in surgical planning if a lesion is identified. Despite audiometric and brainstem-evoked response testing in the otolaryngology clinic, positive MR studies for lesions causing the SNHL are infrequent (< 5% even in highly screened patient groups). **Vestibular schwannoma** is by far the most common cause of unilateral SNHL (about 90% of lesions found with MR). It is important for the radiologist to become familiar with the wide range of appearances of vestibular schwannoma, including intramural cystic change, micro- and macroscopic hemorrhage, and associated arachnoid cyst.

Meningioma, epidermoid cyst, and CPA aneurysm are responsible for about 8% of lesions found in adult patients with SNHL. A long list of rare lesions, including otosclerosis, facial nerve, labyrinthine and jugular foramen schwannomas, IAC hemangioma, CPA metastases, labyrinthitis, sarcoidosis, lipoma, and superficial siderosis, make up < 2% of lesions causing unilateral SNHL in an adult that are found by MR.

Approach to Sensorineural Hearing Loss in a Child

When a child presents with unilateral or bilateral SNHL, the emphasis in the imaging work-up veers away from the typical adult tumor causes. Instead, congenital inner ear or CPA-IAC lesions are sought as the cause of the hearing loss. Complications of suppurative labyrinthitis (labyrinthine ossificans) are also included in the differential diagnosis.

When the child's presentation is bilateral profound SNHL, imaging is usually obtained as part of the work-up for possible **cochlear implantation**. High-resolution T2 MR imaging is obtained in the axial and **oblique sagittal** planes to look for inner ear anomalies and labyrinthine ossificans as well as the presence or absence of a cochlear nerve in the IAC. If complex congenital inner ear disease is found, bone CT is often obtained to further define the inner ear fluid spaces and look for an absent cochlear nerve canal.

In reviewing the MR and CT in a child with SNHL, it is important to accurately describe any inner ear congenital anomaly, if present. If there is a history of meningitis, labyrinthine ossificans may be present. Look for bony encroachment on the fluid spaces of the inner ear. In particular, make sure the basal turn of the cochlea is open because occlusion by bony plaque may thwart successful cochlear implantation. Check the T2 oblique sagittal MR images for the presence of a normal cochlear nerve. If absent, cochlear implantation results may be negatively affected. Finally, look carefully at the IAC and CPA for signs of epidermoid cyst (restricted diffusion on DWI), lipoma (high signal on T1 pre-contrast sequences), and neurofibromatosis type 2 (bilateral CPA-IAC vestibular or facial schwannoma).

KEY FACTS

TERMINOLOGY

- Lipoma in CPA-IAC: Nonneoplastic mass of adipose tissue in CPA-IAC area

IMAGING

- Focal benign-appearing CPA-IAC mass, which follows fat density (CT) and intensity (MR)
- Concurrent intralabyrinthine deposit may be seen in association with CPA-IAC lipoma
- MR: Hyperintense CPA mass (parallels subcutaneous and marrow fat intensity)
  - Becomes **hypointense** with **fat saturation**
  - Caveat: Fat-saturated MR sequences avoid mistaking lipoma for enhancing CPA mass

TOP DIFFERENTIAL DIAGNOSES

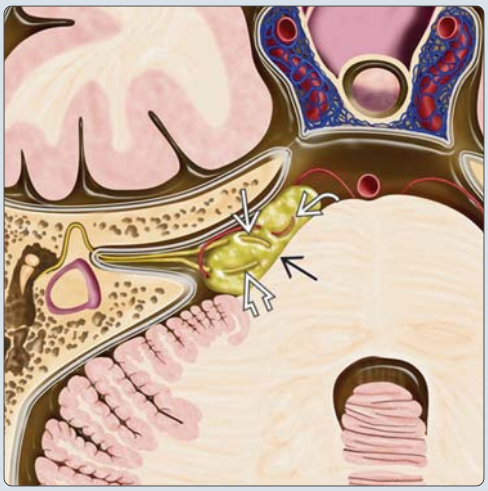
- Hemorrhagic vestibular schwannoma
- Aneurysm in CPA-IAC
- Neurenteric cyst
- Ruptured dermoid cyst

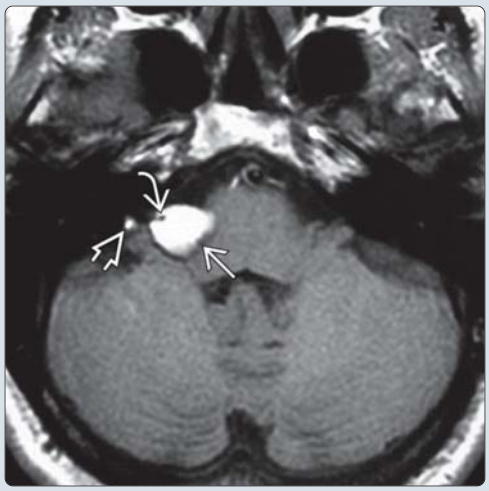
PATHOLOGY

- Aberrant differentiation of embryonic meninx primitiva (meningeal precursor tissue)
- Lipoma composed of mature lipocytes (fat cells)

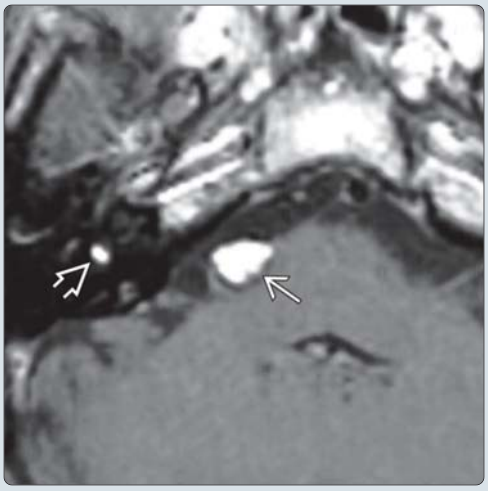
CLINICAL ISSUES

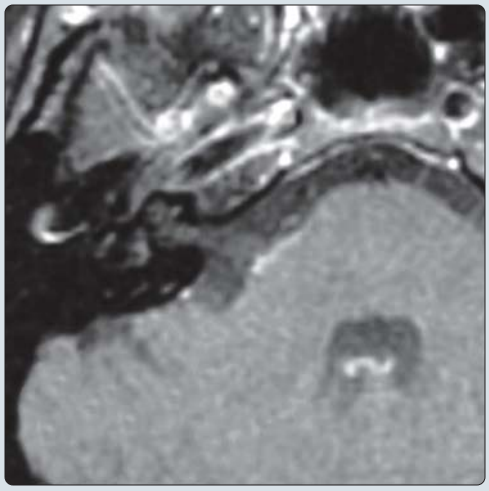
- Most common presentation: Adult presenting with unilateral sensorineural hearing loss
  - CN8 compression: Tinnitus (40%), vertigo (45%)
  - Compression of CN5 root entry zone: Trigeminal neuralgia (15%)
  - Compression of CN7 root exit zone: Hemifacial spasm, facial nerve weakness (10%)
  - Incidentally seen on brain CT or MR completed for unrelated reasons (33%)
- Treatment: **No treatment** is best treatment
  - If surgery required (cranial neuropathy), subtotal resection (debulking) only recommended





(Left) *Axial graphic demonstrates a CPA lipoma ⇨ abutting the lateral pons. Notice that the facial nerve ⇨, vestibulocochlear nerve ⇨, and AICA loop ⇨ all pass through the lipoma on their way to the internal auditory canal.* **(Right)** *Axial T1WI MR shows a right CPA lipoma ⇨ adherent to the lateral pontine pial surface. Note the 2nd smaller lipoma ⇨ along the lateral margin of the internal auditory canal. A portion of the AICA loop ⇨ passes through the anterolateral lipoma.*





(Left) *Axial T1WI MR reveals a hyperintense CPA lipoma ⇨ abutting the lateral pons. Note the 2nd ⇨ focus of hyperintensity representing a small intravestibular lipoma. Such intralabyrinthine lipomas are very rare and may exist with or without CPA lipoma.* **(Right)** *Axial T1WI C+ FS MR in the same patient shows both lesions have disappeared. Fat-saturation MR sequences are key to confirming the diagnosis of lipoma and to avoid mistaking a lipoma for an enhancing CPA mass.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Congenital lipoma, lipomatous hamartoma

Definitions

- Lipoma in CPA-IAC: **Nonneoplastic** mass of adipose tissue in CPA-IAC area
  - Congenital malformation; not true neoplasm

IMAGING

General Features

- Best diagnostic clue
  - Focal benign-appearing CPA-IAC mass, which follows fat density (CT) and intensity (MR)
- Location
  - 20% of intracranial lipomas are infratentorial
  - Primary location = CPA cistern
    - May be in IAC only
    - Concurrent **intralabyrinthine lipoma** may be present
      - Isolated intralabyrinthine lipoma also possible
- Size
  - Range: 0.5-5 cm in maximum diameter
    - May be as small as a few millimeters
- Morphology
  - Lobulated pial-based fatty mass
    - Characteristically encases facial nerve (CN7), vestibulocochlear nerve (CN8), anterior inferior cerebellar artery (AICA) loop
  - Small lesions
    - Linear along course of CN7 and CN8 in CPA
    - Ovoid within CPA cistern; tubular within IAC
  - Large lesions
    - Broad-based hemispherical shape adherent to lateral pontine pial surface

CT Findings

- NECT
  - **Low-density** CPA-IAC mass
  - Measure mass using Hounsfield units (HU) if uncertain
    - Hounsfield unit range: **-50 to -100 HU**
  - IAC lipoma may create bulbous bone CT appearance
- CECT
  - Lesion does **not** enhance

MR Findings

- T1WI
  - **Hyperintense** CPA-IAC mass (parallels subcutaneous and marrow fat intensity)
    - Noncontiguous 2nd fatty lesion in inner ear may be present
  - Becomes **hypointense** with fat-saturation MR sequences
- T2WI
  - Intermediate "fat intensity" lesion
  - Conspicuous **chemical shift artifact** (frequency-encoding direction)
  - Signal parallels subcutaneous and marrow fat
- STIR
  - Hypointense due to STIR inherent fat suppression
- FLAIR
  - Hyperintense compared to cisternal CSF
- T1WI C+
  - Lesion already hyperintense on pre-contrast images
  - Use fat-saturated T1WI C+ sequence
    - Lesion **"disappears"** secondary to **fat saturation** aspect of this MR sequence
    - No enhancement in region of lesion is present

Imaging Recommendations

- Best imaging tool
  - **MR** is 1st study ordered when symptoms suggest possibility of CPA-IAC mass
  - CT can easily confirm diagnoses by measuring HU if some confusion on MR images persists
- Protocol advice
  - When T1WI C+ MR focused to CPA area is anticipated, need at least 1 **pre-contrast T1 sequence**
    - Helps distinguish fatty and hemorrhagic lesions from enhancing lesions
    - Fatty lesions include lipoma and dermoid
    - Hemorrhagic lesions with methemoglobin high signal include aneurysm and venous varix
  - Once high signal is seen on pre-contrast T1 sequence, **fat-saturated sequences** distinguish fat from hemorrhage
    - **Caveat**: Fat saturation avoids mistaking lipoma for enhancing CPA mass (vestibular schwannoma)

DIFFERENTIAL DIAGNOSIS

Hemorrhagic Vestibular Schwannoma

- Rare manifestation of common lesion
- Patchy intraparenchymal hyperintensity on T1WI MR
- Hyperintensities persist with fat-saturated sequences
- T2* GRE shows "blooming" of intralesional hemorrhage

Aneurysm in CPA-IAC

- CPA aneurysm may have complex signal
  - PICA aneurysm most common > VA > AICA
- Rarely enters IAC (AICA)
- Ovoid CPA mass with calcified rim (CT) and complex layered signal (MR)
- MR signal complex with high signal areas from methemoglobin in aneurysm lumen or wall
  - Does not fat saturate

Neurenteric Cyst

- Most common in prepontine cistern
- Contains proteinaceous fluid (hyperintense on T1WI MR)
- Does not fat saturate

Ruptured Dermoid Cyst

- Ectodermal inclusion cyst
- Original location usually midline
- Rupture spreads fat droplets into subarachnoid space
- Rupture may lead to chemical meningitis

PATHOLOGY

General Features

- Etiology
  - Best hypotheses for congenital lipoma

https://CafePezeshki.IR

  - Aberrant differentiation of meninx primitiva (neural crest derived mesenchymal anlage)
    - Responsible for development of pia, arachnoid, dura, and subarachnoid cisterns
    - Maldifferentiates into fat instead
  - Hyperplasia of fat cells normally **within pia**
- Genetics
  - No known defects in sporadic CPA lipoma
  - Epidermal nevus syndrome has CPA lipomas as part of complex congenital anomalies
- Associated abnormalities
  - 2nd fatty lesion may occur in inner ear

Gross Pathologic & Surgical Features

- Soft, yellowish mass attached to leptomeninges
  - Sometimes adherent to lateral pontine pia
- May incorporate CN7 and CN8 with dense adhesions
  - AICA loop may also be engulfed

Microscopic Features

- Histologically normal lipocytes in atypical location
- Highly vascularized adipose tissue
- Mature lipocytes; mitoses rare

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Unilateral sensorineural hearing loss (60%)
- Clinical profile
  - Adult presenting with slowly progressive unilateral sensorineural hearing loss
- Other signs/symptoms
  - Incidentally on brain CT or MR (33%)
  - Cerebellopontine angle lipoma symptoms
    - CN8 compression: Sensorineural hearing loss (60%), tinnitus (40%), vertigo (40%)
    - Compression of CN5 root entry zone: **Trigeminal neuralgia** (15%)
    - Compression of CN7 root exit zone: **Hemifacial spasm**, facial nerve weakness (10%)
  - Internal auditory canal lipoma symptoms
    - SNHL, tinnitus, and vertigo only

Demographics

- Age
  - Range at presentation: 8-60 years
  - Mean at presentation: 45 years
- Epidemiology
  - Lipomas occur less frequently in CPA than epidermoid and arachnoid cysts
    - Epidermoid cyst > arachnoid cyst > > lipoma
  - CPA lipoma represents 10% of all intracranial lipomas
    - Interhemispheric (45%), quadrigeminal/superior cerebellar (25%), suprasellar/interpeduncular (15%), sylvian cisterns (5%)

Natural History & Prognosis

- Usually does not grow over time
  - Lesion consists of mature lipocytes
  - Growth has been seen in pediatric lesions
  - Growth reported in obese or steroid treated patients
- Stability confirmed with follow-up examinations

Treatment

- Primum non nocere ("first, do no harm") is guiding principle
  - **No treatment** is best treatment
- Conservative therapy recommendations
  - Medical therapy: Trigeminal neuralgia, hemifacial spasm
  - Discontinue steroid treatment if present; weight loss
- **Surgical removal** is **no longer recommended**
  - Injury to CN7, CN8, or AICA common
  - Historically, 70% of postoperative patients had new postoperative deficits
- Surgical intervention if CN5 or CN7 decompression needed
  - Subtotal removal (debulking) only recommended

DIAGNOSTIC CHECKLIST

Consider

- When high signal lesion is seen in CPA-IAC on T1WI unenhanced MR, 3 explanations to consider
  - Fatty lesion
    - Lipoma most common (will fat saturate)
  - Hemorrhagic lesion
    - Aneurysm wall clot or clotted venous varix (dural AVF)
    - Rare hemorrhagic acoustic schwannoma
    - Hemorrhage will not fat saturate
  - Highly proteinaceous fluid
    - Neurenteric cyst (usually in prepontine cistern)
    - High protein hyperintensity will not fat saturate

Image Interpretation Pearls

- Once high signal lesion is seen in CPA on pre-contrast T1WI MR, use **fat-saturation** sequences to confirm diagnosis

Reporting Tips

- Report size and extent of lipoma
  - Check inner ear for 2nd lesion
- Report CN7, CN8, and AICA loop engulfed by lipoma

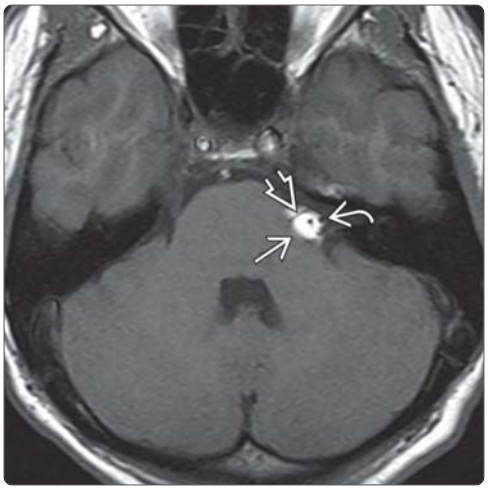
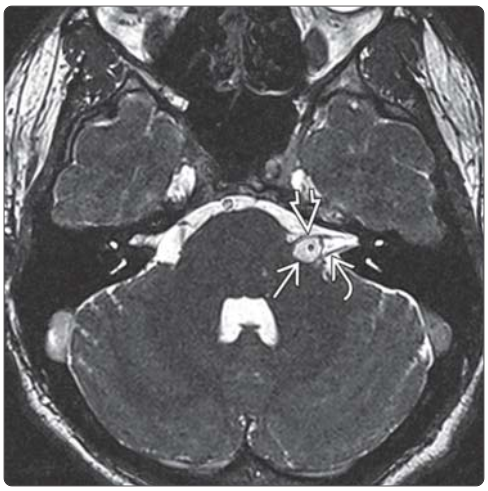
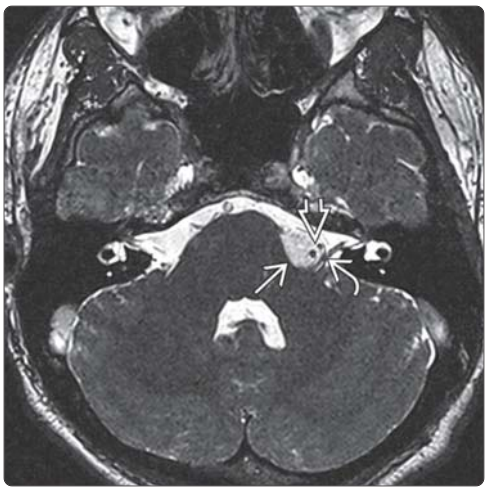
(Left) *Axial CECT reveals a fat-density lesion ⇨ in the fundus of the right internal auditory canal. The bone shape in this area is bulbous in comparison to the opposite normal IAC suggesting a congenital origin of the lesion.* **(Right)** *Axial T1WI MR in the same patient shows the expected hyperintense fundal intracanalicular congenital lipoma ⇨. Lipoma of the CPA-IAC area may be found in the CPA, IAC, and, rarely, in the inner ear.*



(Left) *Axial T2WI FS MR in the same patient shows the lipoma in the IAC fundus as a low signal filling defect ⇨ in the high signal surrounding CSF.* **(Right)** *Axial T1WI MR in a 30-year-old patient with sensorineural hearing loss and trigeminal neuralgia shows a hyperintense CPA lipoma abutting the lateral pons ⇨. The linear hypointense line ⇨ is the proximal facial nerve (CN7) while the hypointense dots within the lateral aspect of the lipoma ⇨ are anterior inferior cerebellar artery (AICA) loops.*





(Left) *Axial CISS MR in the same patient better demonstrates the lipoma adherent to the lateral pons ⇨. Note the lesion engulfs the proximal CN7 ⇨ and superior vestibular CN8 ⇨. The AICA loop is the hypointense dot in the center of the lipoma.* **(Right)** *Axial CISS MR in the same patient slightly inferior to the previous image shows the lipoma ⇨ surrounding the AICA loops ⇨ and superior vestibular branch of the CN8 ⇨. The possibility of CN7 and CN8 injury and AICA stroke preclude surgery in this patient.*

KEY FACTS

TERMINOLOGY

- Definition: Congenital inclusion of ectodermal epithelial elements during neural tube closure

IMAGING

- CPA cisternal **insinuating** mass with high signal on DWI MR
  - 90% intradural, 10% extradural
  - Margins usually scalloped or irregular
  - Cauliflower-like margins with "fronds" possible
- TI and T2: Isointense or slightly hyperintense to CSF
- DWI: **Restricted diffusion** makes diagnosis

TOP DIFFERENTIAL DIAGNOSES

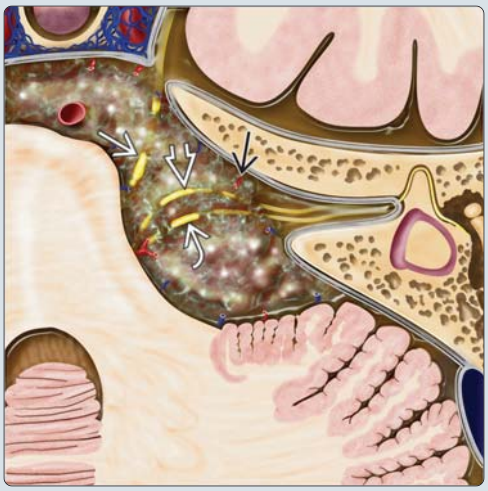
- Arachnoid cyst in CPA
- Cystic neoplasm in CPA
  - Cystic vestibular schwannoma
  - Cystic meningioma
  - Infratentorial ependymoma
  - Pilocytic astrocytoma
- Neurenteric cyst
- Neurocysticercosis, CPA

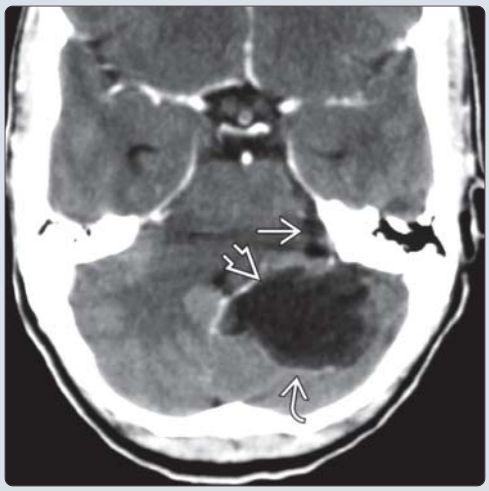
PATHOLOGY

- Surgical appearance: Pearly white CPA cistern mass
- Cyst wall: Internal layer of stratified squamous epithelium covered by fibrous capsule

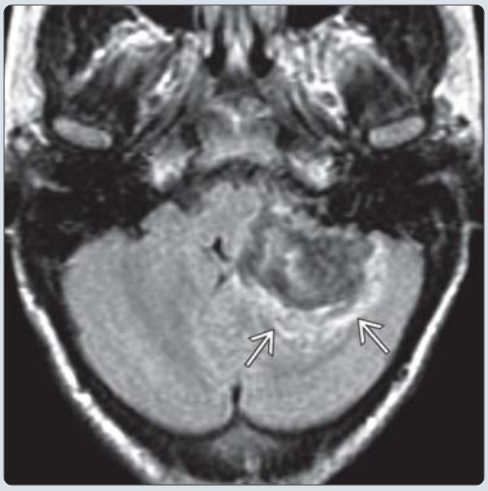
CLINICAL ISSUES

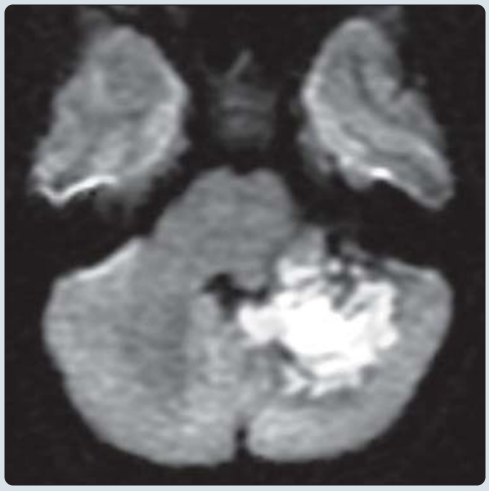
- Clinical presentation
  - Principal presenting symptom: Dizziness and headache
    - Sensorineural hearing loss also common
  - If extends to lateral pons: Trigeminal neuralgia
  - Rarer symptoms: Facial palsy, seizure
- Treatment: Complete surgical removal is goal
  - If adherent to neural structures, complete removal may not be possible
  - If recurs, takes many years to grow
  - DWI MR key to diagnosing recurrence





(Left) *Axial graphic shows a large CPA epidermoid cyst within a typical "bed of pearls" appearance. Note that the 5th ➡, 7th ➡, and 8th ➡ cranial nerves along with the AICA loop ⇨ are characteristically engulfed by this insinuating mass.* **(Right)** *Axial CECT shows a large CPA epidermoid cyst ➡. Note that this nonenhancing low-density lesion appears to invade the left cerebellar hemisphere ➡. Minimal rim enhancement is visible along the posterior margin of the cyst ➡.*





(Left) *Axial FLAIR MR of the same patient shows "incomplete" or partial nulling of the signal of this large epidermoid cyst. Associated high signal ➡ along the deep margins of the lesion is most likely due to gliosis of the cerebellar hemisphere.* **(Right)** *Axial DWI MR in the same patient reveals the expected high signal from epidermoid cyst diffusion restriction. DWI sequence allows straightforward differentiation of this epidermoid cyst from an arachnoid cyst.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Epidermoid tumor, primary cholesteatoma, or epithelial inclusion cyst

Definitions

- Congenital **inclusion** of ectodermal epithelial elements during neural tube closure

IMAGING

General Features

- Best diagnostic clue
  - CPA cistern **insinuating** mass with high signal on DWI MR
    - Engulfs cranial nerves (7th and 8th) and anterior inferior cerebellar artery (AICA) loop
- Location
  - 90% intradural,10% extradural
    - Posterior fossa location most common
      - CPA ~ 40%; 4th ventricle ~ 20%
- Size
  - Wide range: 1-8 cm or more in diameter
- Morphology
  - Insinuating mass in cisterns
  - Margins usually scalloped or irregular
    - Cauliflower-like margins with "fronds" possible
  - When large, compresses or invades brainstem ± cerebellum

CT Findings

- NECT
  - Similar density to cerebrospinal fluid (CSF)
  - Calcification in 20%, usually margins
  - Pressure erosion of T-bone and skull base may occur
  - Rare variant: "Dense epidermoid"
    - 3% of intracranial epidermoids
    - From protein, cyst debris saponification to calcium soaps or iron-containing pigment
- CECT
  - No enhancement is rule
    - Sometimes margin of cyst minimally enhances

MR Findings

- T1WI
  - Isointense or slightly hyperintense to CSF
  - If hyperintense, term "dirty CSF" has been applied
  - Rare variant: "White epidermoid" with high T1 compared to brain
    - Secondary to high triglycerides and unsaturated fatty acids
    - Caveat: If lesion in prepontine cistern, consider neuroepithelial cyst diagnosis
  - Epidermoid with hemorrhage
    - Mixed low and high signal areas
    - High signal secondary to methemoglobin
- T2WI
  - Isointense to hyperintense to CSF
  - "White epidermoid": Low T2 signal
- FLAIR
  - Does not null (attenuate) like CSF or arachnoid cyst
- DWI
  - **Restricted diffusion** on DWI or DTI **makes diagnosis**
    - Secondary to high fractional anisotropy from diffusion along 2D geometric plane
      - Due to microstructure of parallel-layered keratin filaments and flakes
  - Apparent diffusion coefficient (ADC) = low signal
  - High signal foci on DWI trace images in surgical bed indicates recurrence
- T1WI C+
  - No enhancement is rule
  - Subtle marginal enhancement may occur (25%)
- MRA
  - Vessels of CPA may be displaced or engulfed
  - Artery wall dimension not affected
- MRS
  - Resonances from lactate
  - No NAA, choline, or lipid

Imaging Recommendations

- Best imaging tool
  - Brain MR with FLAIR, DWI, and T1WI C+ sequences
- Protocol advice
  - DWI sequences make diagnosis
  - If looking for recurrence, DWI (DTI) is best sequence

DIFFERENTIAL DIAGNOSIS

Arachnoid Cyst in CPA

- Displaces, does not engulf, adjacent structures
- Isointense to CSF on all standard MR sequences
  - T2 higher signal possible; if no CSF pulsations
- Completely nulls on FLAIR (low signal)
- Hypointense (no restricted diffusion) on DWI trace MR
  - Contains highly mobile CSF
  - ADC = stationary water

Cystic Neoplasm in CPA

- Cystic vestibular schwannoma
- Cystic meningioma in CPA
- Infratentorial ependymoma
  - Pedunculates from 4th ventricle
- Pilocytic astrocytoma
  - Pedunculates from cerebellum
- All show some areas of enhancement on T1WI C+ MR

Neurenteric Cyst

- Most common prepontine cistern in location
- T1 high signal (might mimic "white epidermoid")
- T2 signal often low

Neurocysticercosis in CPA

- Partially enhances
- Density/signal intensity does not precisely follow CSF
- Adjacent brain edema or gliosis common

PATHOLOGY

General Features

- Etiology
  - Congenital **inclusion of ectodermal elements** during neural tube closure

https://CafePezeshki.IR

  - 3rd to 5th week of embryogenesis
  - CPA lesion derived from 1st branchial groove cells

Gross Pathologic & Surgical Features

- **Pearly white mass** in CPA
- Surgeons refer to it as the "beautiful tumor"
- Lobulated, cauliflower-shaped surface features
- Insinuating growth pattern in cisterns
  - Engulfs cisternal vessels and nerves
    - May become adherent
- Lesion filled with soft, waxy, creamy, or flaky material

Microscopic Features

- Cyst wall: Internal layer of stratified squamous epithelium covered by fibrous capsule
- Cyst contents: Solid crystalline cholesterol, keratinaceous debris
  - **No** dermal appendages (hair follicles, sebaceous glands, or fat)
  - If any of these present, consider dermoid
- Grows in successive layers by desquamation of squamous epithelium from cyst wall
  - Conversion to keratin/cholesterol crystals forms concentric lamellae

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Principal presenting symptoms: Dizziness
  - Other symptoms depend on location, growth pattern
    - Sensorineural hearing loss: Common symptom
    - Trigeminal neuralgia (tic douloureux): If extends to lateral pontine CN5 root entry zone
    - Seizures: If extends superiorly through incisura to temporomesial location
  - Symptoms usually present for > 4 years before diagnosis
- Clinical profile
  - 40-year-old patient with minor symptoms and large lesion discovered in CPA on MR
  - Asymptomatic patient shows incidental hyperintense lesion in CPA on DWI MR sequence

Demographics

- Age
  - Although congenital, presents in adult life
  - Broad presentation: 20-60 years
    - Peak age: 40 years
- Epidemiology
  - 3rd most common CPA mass
  - 1% of all intracranial tumors

Natural History & Prognosis

- Slow-growing congenital lesions that remain clinically silent for many years
- Smaller cisternal lesions are readily cured with surgery
- Larger lesions with upward supratentorial herniation are more difficult to completely remove
  - Larger lesions have more significant surgical complications

Treatment

- Complete surgical removal is goal
  - If large, near-total removal is prudent surgical choice
    - Aggressive total removal may cause significant cranial neuropathy
    - Used when capsule is adherent to brainstem and cranial nerves
- If recurs, takes many years to grow
  - DWI MR key to diagnosing recurrence

DIAGNOSTIC CHECKLIST

Consider

- MR diagnosis based on
  - Insinuating CPA lesion
  - Low signal on T1, high on T2 (similar but not identical to CSF)
  - No or partial nulling on FLAIR
  - Hyperintense on DWI trace images

Image Interpretation Pearls

- **Diffusion MR** imaging sequence is **key to correct diagnosis**

Reporting Tips

- Be sure to report prepontine or medial middle cranial fossa extension if present

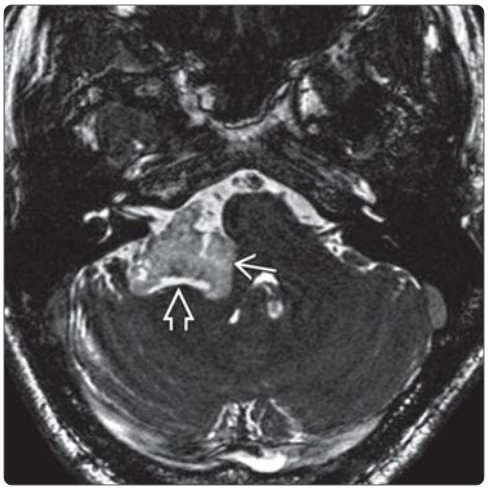
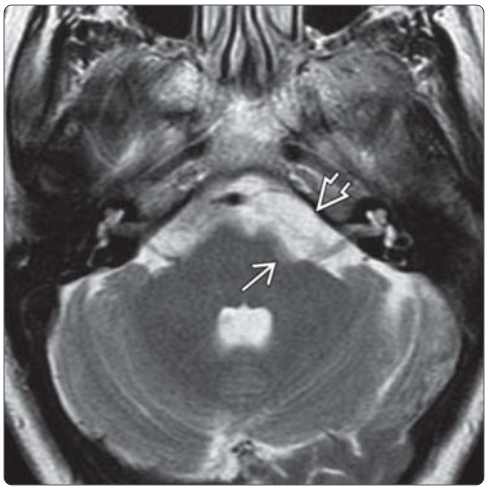
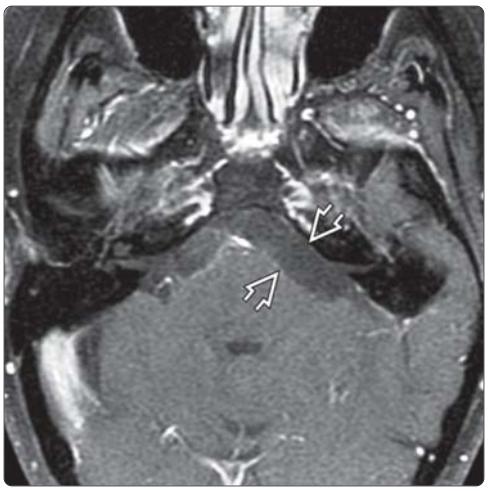
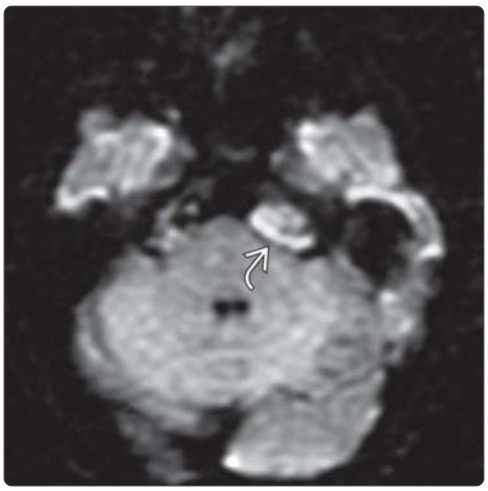
(Left) *Axial T1WI C+ MR demonstrates a large, insinuating, right CPA cistern epidermoid cyst ➡. Note the low signal with lack of enhancement of the lesion. The cyst insinuates into the cerebellar hemisphere and foramen of Luschka ➡.* **(Right)** *Axial T2WI MR in the same patient reveals a large, insinuating epidermoid cyst with typical high T2 signal and invagination into the cerebellar hemisphere ➡ and foramen of Luschka ➡.*





(Left) *Axial T2 FS thin-section high-resolution MR shows a right CPA epidermoid cyst. Note the cauliflower-like surface architecture. This lesion is compressing the brachium pontis ➡ and adjacent cerebellar hemisphere ➡.* **(Right)** *Axial T2WI MR shows slight widening of the left CPA cistern ➡ with minimal mass effect on the brachium pontis ➡, but no definite lesion is visible. In a patient with left sensorineural hearing loss, arachnoid cyst or epidermoid cyst should be considered.*





(Left) *Axial T1WI C+ FS MR in the same patient again reveals a widened CPA cistern ➡ but no evidence of enhancing tumor. If an epidermoid cyst is present in the enlarged cistern, DWI sequences will be positive with restricted diffusion making the diagnosis.* **(Right)** *Axial DWI MR in the same patient demonstrates the characteristic restricted diffusion of the epidermoid cyst ➡ in the left CPA cistern. Without DWI information, the lesion could have been missed altogether.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Arachnoid cyst (AC): Developmental arachnoid duplication anomaly creating CSF-filled sac

IMAGING

- Sharply demarcated ovoid extraaxial cisternal cyst with imperceptible walls with CSF density (CT) or intensity (MR)
- AC signal parallels (is isointense to) CSF on **all** MR sequences
- Complete fluid attenuation on FLAIR MR
- **No** diffusion restriction on DWI MR

TOP DIFFERENTIAL DIAGNOSES

- Epidermoid cyst in CPA
- Cystic vestibular schwannoma
- Neurenteric cyst
- Cystic meningioma in CPA
- Cystic infratentorial ependymoma
- Cerebellar pilocytic astrocytoma

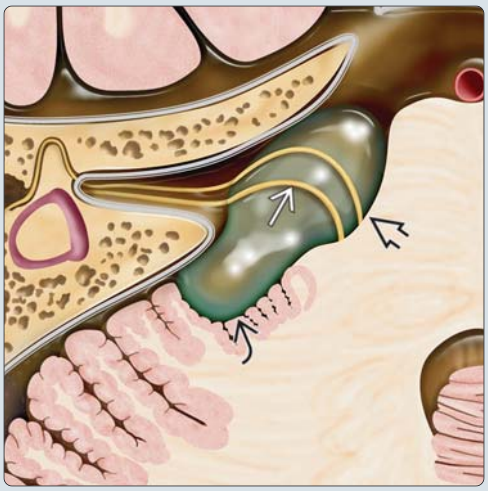
CLINICAL ISSUES

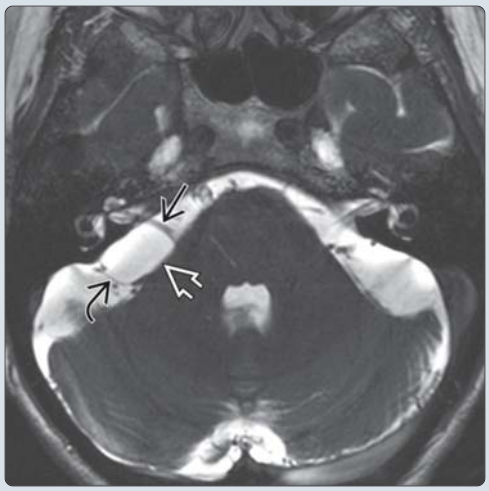
- Clinical presentation
  - Small AC: Asymptomatic, incidental finding (MR)
  - Large AC: Mostly asymptomatic
    - Symptoms may arise from direct compression ± ↑ intracranial pressure
- Natural history
  - Vast majority of ACs **do not** enlarge over time
- Treatment options
  - Most cases require **no** treatment
  - Treatment is highly selective process

DIAGNOSTIC CHECKLIST

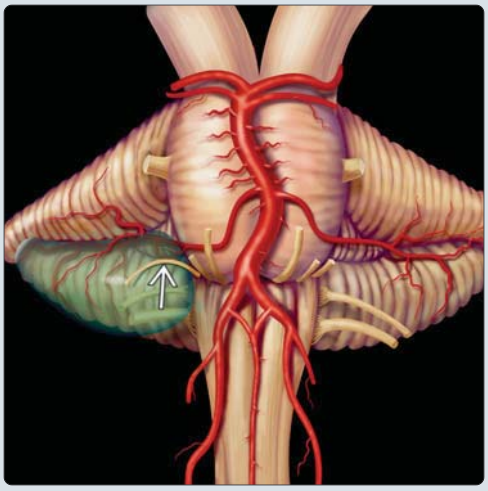
- Differentiate AC from epidermoid cyst
- AC: No restriction on DWI = best clue
- Reporting tip: Since AC is usually not treated surgically, avoid offering any differential diagnosis when imaging findings diagnose AC

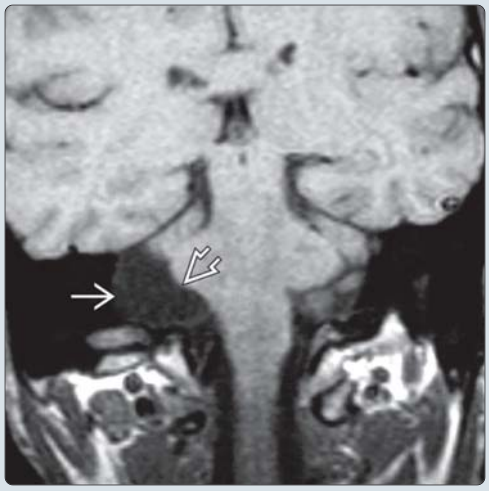
(Left) *Axial graphic of an arachnoid cyst in the CPA shows a thin, translucent wall. Notice the cyst bowing the 7th and 8th cranial nerves anteriorly ➡ and effacing the brainstem ⇨ and cerebellum ⇨.* **(Right)** *Axial T2WI MR reveals a right CPA arachnoid cyst causing bowing of the facial and vestibulocochlear nerves anteriorly ⇨, small bridging veins posteriorly ⇨, and flattening of the lateral margin of the brachium pontis ➡.*





(Left) *Coronal graphic of a CPA arachnoid cyst depicts a typical translucent cyst wall. CN7 and CN8 are pushed by the cyst ➡ without being engulfed by it. In epidermoid cyst, cranial nerves are usually engulfed.* **(Right)** *Coronal T1WI MR demonstrates a small CSF intensity CPA arachnoid cyst ➡ with subtle mass effect on the adjacent brainstem ➡. Complete fluid attenuation on FLAIR MR helps differentiate this lesion from an epidermoid cyst, which is the primary imaging differential diagnosis.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Arachnoid cyst (AC)

Synonyms

- Primary or congenital AC, subarachnoid cyst

Definitions

- Developmental arachnoid duplication anomaly creating **intraarachnoid** CSF-filled sac

IMAGING

General Features

- Best diagnostic clue
  - Sharply demarcated ovoid or lentiform extraaxial cisternal cyst with imperceptible walls with CSF density (CT) or signal intensity (MR)
  - AC signal parallels CSF (is isointense to CSF) on all MR sequences
    - **Complete fluid attenuation** on FLAIR MR
    - **No diffusion restriction** on DWI MR imaging
- Location
  - 10-20% of all ACs occur in posterior fossa
    - Cerebellopontine angle (CPA) = most common infratentorial site
    - **10%** found in CPA
  - Spread patterns
    - Most remain confined to CPA (60%)
    - May spread dorsally along brainstem (25%)
    - Rarely spread into internal auditory canal (IAC)
- Size
  - Broad range: 1 cm to giant (> 8 cm)
  - In posterior fossa, when very large may be symptomatic
  - When large, will exert mass effect on vestibulocochlear and facial nerves, adjacent brainstem and cerebellum
- Morphology
  - Sharply demarcated with broad-arching margins
  - Displaces, does not engulf, surrounding structures
  - Pushes cisternal structures but does not insinuate
    - Epidermoid cyst insinuates adjacent structures

CT Findings

- NECT
  - Density same as CSF
  - Rare high density from hemorrhage or proteinaceous fluid
- CECT
  - No enhancement of cavity or wall
- Bone CT
  - Rarely causes expansile remodeling of bone
    - Seen mostly in children
- CT cisternography
  - May show connection to subarachnoid SPACE

MR Findings

- T1WI
  - Low signal AC is isointense to CSF
- T2WI
  - High signal lesion isointense to CSF
    - May have brighter signal than CSF
    - Cyst fluid lacks CSF pulsations
  - Well-circumscribed lesion
    - Compresses adjacent CN7-8 bundle, brainstem, and cerebellum when large
- FLAIR
  - Suppresses AC fluid completely
- DWI
  - No diffusion restriction
- T1WI C+
  - No enhancement seen
- High-resolution, thin-section MR (CISS, FIESTA, T2 space)
  - Help define cyst wall, relationship to adjacent structures (CN7, CN8, AICA, etc.)
- Phase-contrast cine MR
  - Flow quantification can sometimes distinguish AC from subarachnoid space
  - May rarely show connection between AC and cistern

Ultrasonographic Findings

- Grayscale ultrasound
  - Shows hypoechoic AC in infants < 1 year of age
  - Larger AC diagnosed in utero

Imaging Recommendations

- Best imaging tool
  - MR ± contrast
- Protocol advice
  - Add FLAIR (suppresses)
  - Add DWI (no restricted diffusion)

DIFFERENTIAL DIAGNOSIS

Epidermoid Cyst in CPA

- Major lesion of differential concern in setting of AC
- FLAIR: Incomplete fluid attenuation
- DWI: Restricted diffusion (high signal)
- Morphology: Insinuates into adjacent CSF spaces

Cystic Vestibular Schwannoma in CPA-IAC

- Intramural or marginal cysts seen in larger lesions
- Foci of enhancing tumor always present on T1WI C+ MR
- Rarely, larger lesions have associated AC

Cystic Meningioma in CPA-IAC

- Rare meningioma variant
- Dural "tails," asymmetry to IAC still present with mixed enhancement on T1WI C+ MR

Neurenteric Cyst

- Rare prepontine cistern near midline
- Often contains proteinaceous fluid (↑ on T1WI MR)

Cystic Infratentorial Ependymoma

- Ependymoma pedunculates from 4th ventricle via foramen of Luschka
- 50% calcified
- Cystic and solid enhancing components

Cerebellar Pilocytic Astrocytoma

- Cystic tumor in cerebellar hemisphere
- Enhancing mural nodule

https://CafePezeshki.IR

PATHOLOGY

General Features

- Etiology
  - Embryonic meninges fail to merge
    - Remain separate as **duplicated** arachnoid
    - Split arachnoid contains CSF
  - 2 types
    - Noncommunicating; most common type
    - Communicating with subarachnoid space/cistern
- Genetics
  - Usually sporadic; rarely familial
  - Inherited disorders of metabolism
    - "Sticky" leptomeninges: Mucopolysaccharidoses
- Associated abnormalities
  - Vestibular schwannoma has AC associated in 0.5%

Gross Pathologic & Surgical Features

- Fluid-containing cyst with translucent membrane
- Displaces adjacent vessels or cranial nerves

Microscopic Features

- Thin wall of flattened but normal arachnoid cells

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Small AC: **Asymptomatic, incidental** finding (MR)
  - Large AC: Symptoms from direct compression ± ↑ intracranial pressure
  - Pediatric AC associated with higher symptom rate
- Other signs/symptoms
  - Defined by location and size
    - Headache
    - Dizziness, tinnitus ± sensorineural hearing loss
      - Rarely facial nerve symptoms
    - Hemifacial spasm or trigeminal neuralgia
- Clinical profile
  - Adult undergoing brain MR for unrelated symptoms

Demographics

- Age
  - May be initially seen at any age
    - 75% of AC identified in childhood
- Gender
  - M:F = 3:1
- Epidemiology
  - Most common congenital intracranial cystic lesion
  - Accounts for 1% of intracranial masses

Natural History & Prognosis

- Most ACs **do not enlarge** over time
  - Infrequently enlarge via CSF pulsation through ball-valve opening into AC
  - Hemorrhage with subsequent ↓ in size reported
- If surgery is limited to AC where symptoms are clearly related, prognosis is excellent
- Radical cyst removal may result in cranial neuropathy ± vascular compromise

Treatment

- Most cases require **no treatment**
  - Pediatric AC more commonly treated than adult AC
- Surgical intervention is highly selective process
  - Reserved for cases where clear symptoms can be directly linked to AC anatomic location
  - Endoscopic cyst decompression via fenestration
    - Least invasive initial approach

DIAGNOSTIC CHECKLIST

Consider

- Differentiate AC from epidermoid cyst
  - AC: No restriction on DWI = best clue
- Determine if symptoms match location of AC before considering surgical treatment

Image Interpretation Pearls

- AC signal follows CSF on all MR sequences
  - Remember T2 signal may be higher than CSF from lack of CSF pulsation
- **DWI** sequence shows AC as **low signal**
- **FLAIR** sequence shows AC as **low signal**
- **No** enhancement of AC, including wall, is expected
  - Nodular enhancement suggests alternative diagnosis

Reporting Tips

- Since AC is usually not treated surgically, avoid offering any differential diagnosis when imaging findings diagnose AC

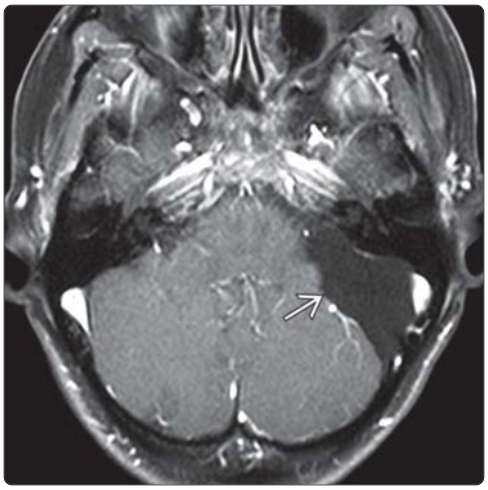
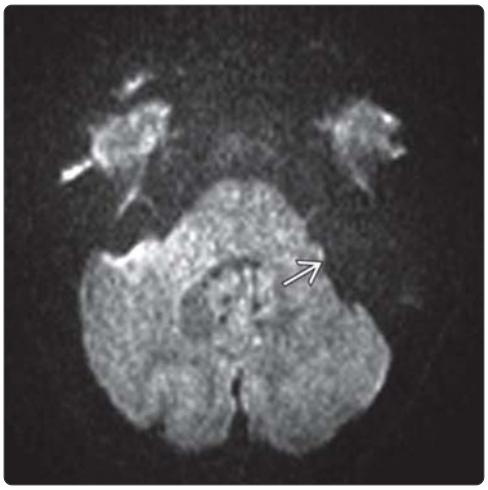
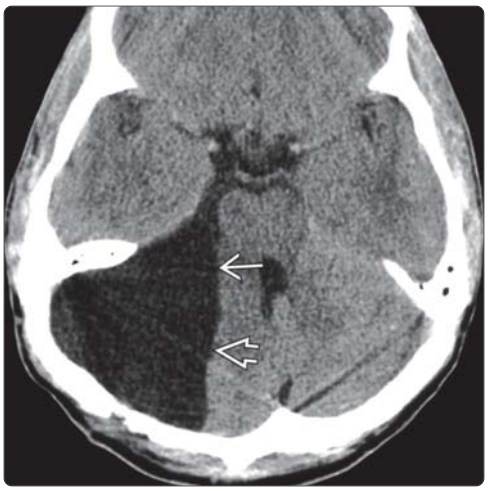
https://CafePezeshki.IR

(Left) *Axial T2WI MR shows a high signal large arachnoid cyst enlarging the left cerebellopontine angle cistern. The facial and vestibulocochlear nerves are visible bowing over the anteromedial surface of the arachnoid cyst* ➡. **(Right)** *Axial FLAIR MR in the same patient shows the low signal arachnoid cyst* ➡ *and complete fluid attenuation. FLAIR suppression is expected as the arachnoid cyst is essentially CSF collecting between arachnoid layers.*





(Left) *Axial T1WI C+ FS MR in the same patient demonstrates that the CPA arachnoid cyst* ➡ *does not enhance.* **(Right)** *Axial DWI MR in the same patient shows that the arachnoid cyst* ➡ *has no associated signal (no restricted diffusion). If this were an epidermoid cyst, high signal on DWI (restricted diffusion) would be present. DWI is the best way to differentiate an arachnoid cyst from an epidermoid cyst.*



(Left) *Axial NECT through the upper CPA cistern shows a large low-density arachnoid cyst causing flattening of the lateral brachium pontis* ➡ *and cerebellar hemisphere* ➡. **(Right)** *Axial T2WI FS MR demonstrates an incidental hyperintense CPA arachnoid cyst* ➡ *found at the time of imaging for headache. This lenticular-shaped lesion displaces the glossopharyngeal nerve (CN9) anteriorly* ➡. *These small lesions require no additional imaging or treatment.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Bell palsy (BP): Herpetic peripheral facial nerve paralysis secondary to herpes simplex virus

IMAGING

- T1WI C+ fat-saturated MR: Fundal "tuft" and labyrinthine segment CN7 show intense asymmetric enhancement
  - Entire intratemporal CN7 may enhance
- Imaging note: Classic rapid-onset BP requires **no imaging** in initial stages
- If **atypical Bell palsy**, search with imaging for underlying lesion

TOP DIFFERENTIAL DIAGNOSES

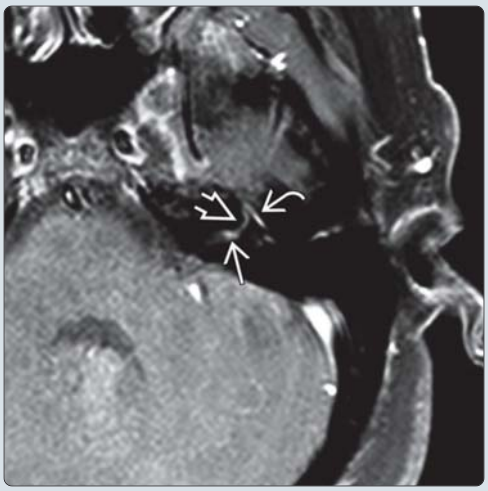
- Normal enhancement of intratemporal CN7
- Ramsay Hunt syndrome
- Facial nerve schwannoma
- Facial nerve venous malformation (hemangioma)
- Perineural tumor from parotid

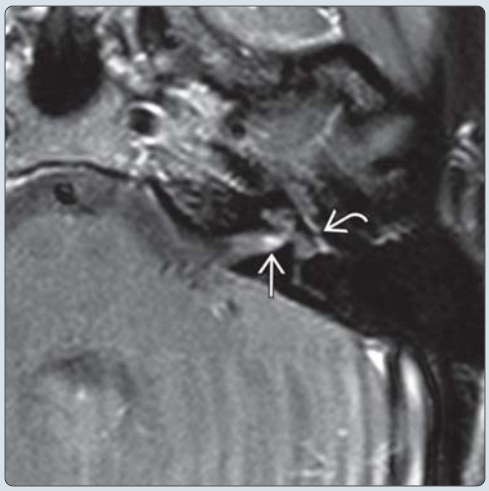
PATHOLOGY

- Etiology-pathogenesis (current hypothesis)
  - Latent **herpes simplex** infection of geniculate ganglion with reactivation and spread of inflammatory process along proximal and distal intratemporal facial nerve fibers

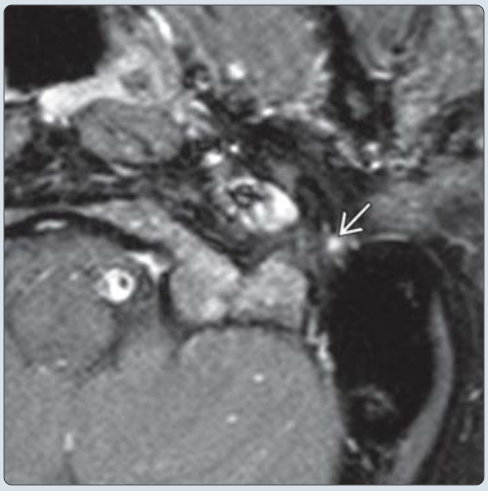
CLINICAL ISSUES

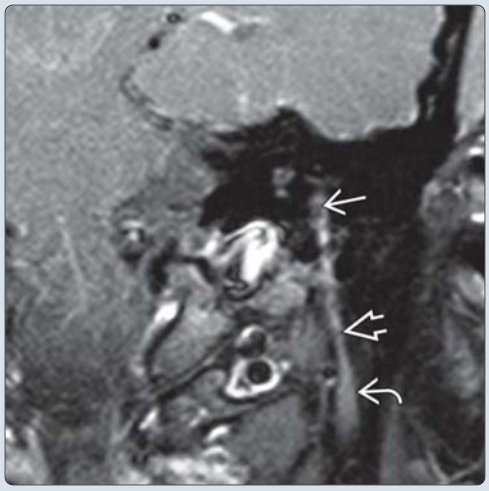
- Classic clinical presentation
  - Acute-onset peripheral CN7 paralysis (36-hr onset)
- Medical therapy for BP
  - Tapering course of prednisone; begin within 3 days of symptoms for best result
  - Antiviral agents no longer used
- Surgical therapy for BP is controversial
  - Profound denervation (> 95%) treated with facial nerve decompression from internal auditory canal fundus to stylomastoid foramen





(Left) *Axial T1WI C+ FS MR shows classic findings of Bell palsy with the internal auditory canal fundal "tuft" sign ⇨, labyrinthine ⇨, and tympanic ⇨ facial nerve segment enhancement.* **(Right)** *Axial T1WI C+ FS MR in the same patient again shows the IAC fundal "tuft" sign ⇨ and tympanic segment of the facial nerve enhancement ⇨. Remember that the geniculate ganglion and posterior genu/upper mastoid segment of the facial nerve may normally enhance.*





(Left) *Axial T1WI C+ FS MR in the same patient through the stylomastoid foramen demonstrates an enhancing, slightly enlarged facial nerve ⇨. Swelling of the facial nerve is possible outside the bony facial nerve canal within the temporal bone.* **(Right)** *Coronal T1WI C+ FS MR in the same patient reveals avid enhancement in the mastoid ⇨, stylomastoid ⇨, and extracranial facial nerve ⇨ in this patient with typical Bell palsy.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Bell palsy (BP)

Synonyms

- Herpetic facial paralysis

Definitions

- BP (original definition): Idiopathic acute onset of lower motor neuron facial paralysis
- BP (modern definition): Herpetic facial paralysis secondary to herpes simplex virus

Other Facts

- Named after Sir Charles Bell (1774-1842), who 1st described BP syndrome

IMAGING

General Features

- Best diagnostic clue
  - Fundal **"tuft"** and labyrinthine segment CN7 intense asymmetric enhancement on T1WI C+ MR
- Location
  - Fundal and labyrinthine segment CN7 most affected
  - Often involves entire intratemporal CN7
    - Intraparotid segment less commonly affected
- Size
  - CN7 swells within facial nerve canal

CT Findings

- Bone CT
  - Normal facial nerve canal
    - If enlargement present, **not** Bell palsy

MR Findings

- T2WI
  - Brain normal; no high signal lesions
  - High-resolution thin-section T2 or T2* GRE may show internal auditory canal (IAC) CN7 enlargement
- T1WI C+
  - Uniform, contiguous CN7 enhancement
    - CN7: Normal in size within bony canal
    - CN7: Conspicuous high signal appears slightly enlarged
    - Enhancement pattern is linear, not nodular
  - Enhancement usually present from distal IAC through labyrinthine segment, geniculate ganglion, and anterior tympanic segment
    - **Tuft** of enhancement in IAC fundus (premeatal segment) along with C+ of labyrinthine segment of CN7 are distinctive MR findings
    - Mastoid CN7 enhances less frequently
    - Enhancement of intraparotid CN7 infrequent

Imaging Recommendations

- Best imaging tool
  - Thin-section fat-saturated T1WI C+ MR focused to IAC and temporal bone
  - T-bone CT: Only used if MR creates suspicion of enlarged CN7 canal or focal lesion
- Classic rapid-onset BP requires **no imaging** in initial stages
  - 90% of BP recover spontaneously in < 2 months
  - If decompressive surgery is anticipated, MR imaging is warranted to ensure that no other lesion is causing CN7 paralysis
- If **atypical Bell palsy**, search for underlying lesion
  - Atypical Bell palsy
    - Slowly progressive CN7 palsy
    - Facial hyperfunction (spasm) preceding BP
    - Recurrent CN7 palsies
    - BP with any other associated cranial neuropathies
    - CN7 paralysis persisting or deepening > 2 months

DIFFERENTIAL DIAGNOSIS

Normal Enhancement of Intratemporal CN7

- Clinical: No facial nerve symptoms
- T1WI C+ MR: Mild, linear, discontinuous enhancement of anterior and posterior genus of intratemporal CN7
  - IAC and labyrinthine CN7 segments normal

Ramsay Hunt Syndrome

- Clinical: Peripheral CN7 paralysis with CN8 associated symptoms
  - External auditory canal (EAC) hemorrhagic vesicular rash
  - Varicella-zoster virus infection = cause
- T1WI C+ MR: Linear, continuous enhancement of fundal IAC and intratemporal CN7
  - Enhancement of inner ear structures and vestibulocochlear nerve variable

Facial Nerve Schwannoma

- Clinical: Hearing loss more common than CN7 palsy
- T1WI C+ MR: Well-circumscribed, tubular, C+ mass within enlarged CN7 canal most commonly centered on geniculate ganglion

Facial Nerve Venous Malformation ("Hemangioma")

- Clinical: CN7 paralysis occurs when lesion is small
- Bone CT: May show intratumoral bone spicules
- T1WI C+ MR: Poorly circumscribed, enhancing mass commonly found in geniculate fossa

Perineural Tumor from Parotid

- Clinical: Parotid malignancy usually palpable
- Imaging: Invasive parotid mass is present
  - Tissue-filled stylomastoid foramen
  - CN7 is enlarged from distal to proximal with associated mastoid air cell invasion

PATHOLOGY

General Features

- Etiology
  - Etiology-pathogenesis (current hypothesis)
    - Latent herpes simplex infection of geniculate ganglion with reactivation and spread of inflammatory process along proximal and distal CN7 fibers
    - Pathophysiology: Formation of intraneural edema in neuronal sheaths caused by breakdown of blood-nerve barrier and by venous congestion in epineural and perineural venous plexus
- Intratemporal CN7 normal anatomy
  - CN7 normal C+ at its anterior and posterior genus

https://CafePezeshki.IR

Brackman Facial Nerve Grading System

Grade	Description of Facial Paralysis	Measurement**	Function %	Estimated Function %
I	Normal	8/8	100	100
II	Slight	7/8	76-99	80
III	Moderate	5/8-6/8	51-75	60
IV	Moderately severe	3/8-4/8	26-50	40
V	Severe	1/8-2/8	1-25	20
VI	Total	0/8	0	0

*** Facial nerve injury is measured by the superior movement of the mid portion of the upper eyebrow and the lateral movement of the oral commissure. For each 0.25 cm of upward motion for both eyebrow and oral commissure, a scale of 1 is assigned up to 1 cm. The points are then added together. A total of 8 points can be obtained if both the eyebrow and the oral commissure both move 1 cm.*

Adapted from House JW et al: Facial nerve grading system. Otolaryngol Head Neck Surg. 93(2):146-7, 1985.

- C+ from robust circumneural arteriovenous plexus
- Familiarity with normal patterns of intratemporal CN7 C+ allows radiologist to identify abnormal enhancement seen with BP

Gross Pathologic & Surgical Features

- CN7 edema peaks at 3 weeks after symptom onset

Microscopic Features

- Herpes simplex DNA recovered from CN7

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute-onset peripheral CN7 paralysis (36-hour onset)
- Clinical profile
  - Healthy adult with acute unilateral CN7 paralysis
    - More common in diabetic patients
- Other signs/symptoms
  - Viral prodrome often reported before BP onset
  - 70%: Taste alterations days before CN7 paralysis
  - 50%: Pain around ipsilateral ear (not severe)

Demographics

- Age
  - All ages affected; incidence peaks in 5th decade
- Epidemiology
  - Herpetic facial paralysis thought to be responsible for ~ 75% of peripheral CN7 paralysis cases
  - Annual BP incidence: 10-50/100,000 persons

Natural History & Prognosis

- 80% of BP patients spontaneously recover all of CN7 function without therapy in 1st 2 months
  - 15% partially recover; 5% show no recovery

Treatment

- Test for diabetes and Lyme disease
- Medical therapy for BP
  - Tapering course of prednisone; begin within 3 days of symptoms for best result
  - Acyclovir or valacyclovir (antivirals) no longer used
- Surgical therapy for BP is controversial
  - Profound denervation (> 95%) treated with CN7 decompression, fundus to stylomastoid foramen
  - Decompression performed within 2 weeks of onset of total paralysis for maximal effect
- Intensity, pattern ± location of enhancement on T1WI C+ MR **not** helpful in predicting individual patient outcome
- Older patients: Lower rate of complete CN7 recovery

DIAGNOSTIC CHECKLIST

Consider

- **No** imaging necessary for typical BP
  - MR imaging reserved for **atypical** BP
- Abnormal CN7 C+ on MR may persist well beyond clinical improvement or full recovery
- Not all intratemporal facial nerves enhance in BP
  - < 10 days following onset of BP, CN7 often normal

Image Interpretation Pearls

- "Tuft" of IAC fundal C+ associated with labyrinthine segment CN7 C+ without associated focal lesion is highly suggestive of BP

Reporting Tips

- Remember to comment on parotid as normal
- Also note absence of focal CN7 lesions

KEY FACTS

TERMINOLOGY

- Trigeminal neuralgia (TN) definition: Vascular loop compressing trigeminal nerve (CN5) at its root entry zone (REZ) or preganglionic segment (PGS)

IMAGING

- High-resolution MR: Serpiginous asymmetric signal void (vessel) in CPA CN5 REZ or PGS
  - CN5 PGS atrophy: Severe, prolonged compression
  - Compressing vessel will bow PGS
- Offending vessels: **Superior cerebellar artery** (55%) > AICA (10%) > basal artery (5%) > variant vein (5%) > other

TOP DIFFERENTIAL DIAGNOSES

- Aneurysm in CPA-IAC
- Arteriovenous malformation in CPA
- Developmental venous anomaly in posterior fossa

PATHOLOGY

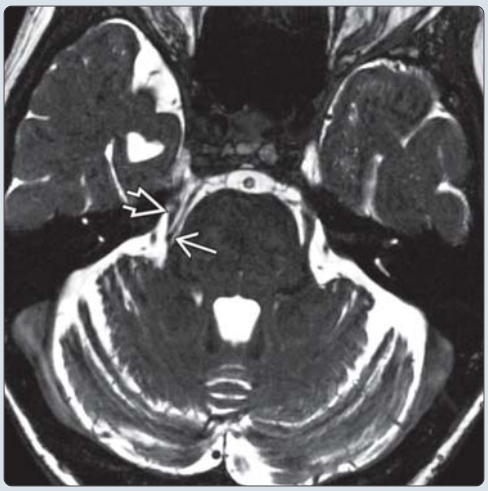
- CN5 REZ or PGS experiences "irritation" from vessel

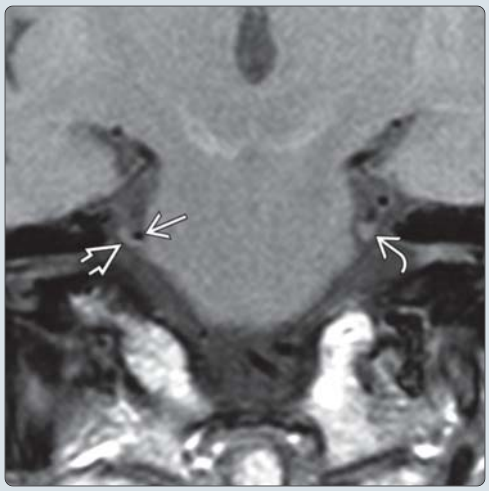
CLINICAL ISSUES

- Trigeminal neuralgia symptoms
  - Lancinating pain following V2 ± V3 distributions
  - May occur spontaneously or in response to "trigger" from tactile stimulation
- Treatment
  - Begin with conservative drug therapy
  - Microvascular decompression or focused radiotherapy (~ 70% long-term success rate)

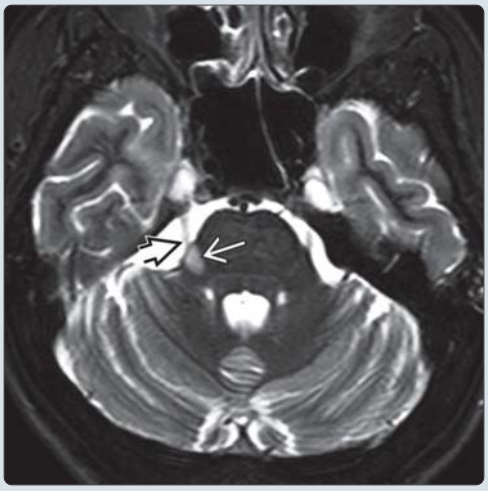
DIAGNOSTIC CHECKLIST

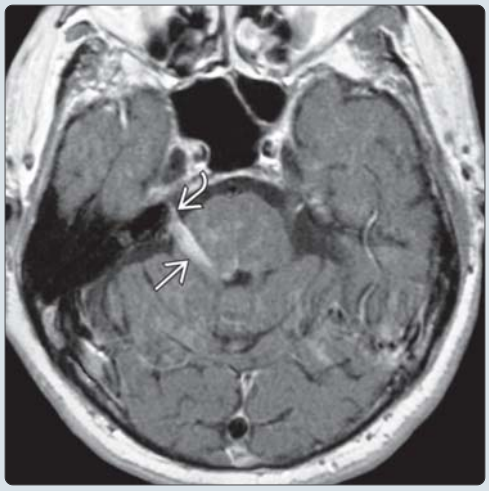
- 1st look for multiple sclerosis or DVA with draining vein along PGS
  - Also check for cisternal mass: Schwannoma, meningioma, epidermoid
- Next follow CN5 distally into cavernous sinus and face
  - Exclude perineural tumor, malignancies of face
- Last view high-resolution thin-section MR for causal vessel
  - Causal vessel will bow PGS or deform REZ





(Left) *Axial T2WI MR in this patient with right trigeminal neuralgia shows the low signal superior cerebellar artery ➡ impinging on the root entry zone of the preganglionic segment ➡ of the trigeminal nerve.* **(Right)** *Coronal T1WI MR in the same patient reveals the superior cerebellar artery ➡ compressing and deforming the right proximal preganglionic segment of CN5 ➡. Notice the larger, normal left preganglionic CN5 ➡ indicating that atrophy is a feature of the affected right side.*





(Left) *Axial T2WI FS MR in a patient with right trigeminal neuralgia reveals a multiple sclerosis lesion ➡ involving the lateral pons at the root entry zone of the trigeminal nerve ➡. Rarely, cisternal masses or MS may present with trigeminal neuralgia.* **(Right)** *Axial T1WI C+ MR in a patient with right TN shows a developmental venous anomaly of the cerebellum draining through the lateral pons ➡ and root entry zone ➡ of CN5. Less than 5% of patients with TN have a venous explanation for their symptoms.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Trigeminal neuralgia (TN)

Synonyms

- Tic douloureux, trigeminal nerve vascular loop syndrome, trigeminal nerve hyperactive dysfunction syndrome

Definitions

- Vascular loop compressing trigeminal nerve at its root entry zone (REZ) or preganglionic segment (PGS)

IMAGING

General Features

- Best diagnostic clue
  - High-resolution MR shows serpentine asymmetric signal void (vessel) in CPA CN5 REZ or PGS
- TN offending vessels: Superior cerebellar artery (SCA) > AICA > basal artery > petrosal vein

MR Findings

- FLAIR
  - Multiple sclerosis (MS) may present with TN
- DWI
  - Hyperintense cisternal mass diagnoses epidermoid
- T1WI C+
  - In vascular loop-caused TN, CN5 PGS does **not** enhance
  - May show rare venous cause of TN or perineural tumor
  - Rare cisternal mass possible
- High-resolution MR (CISS, FIESTA, T2 space, other)
  - Causal vessel compressing CN5 REZ or PGS
    - Vessel bows PGS or deforms REZ if cause of neurovascular conflict
  - CN5 PGS atrophy: When compression severe, prolonged
- MRA: Source images most helpful

Imaging Recommendations

- Best imaging tool
  - High-resolution MR for imaging of causal vascular loop

DIFFERENTIAL DIAGNOSIS

Aneurysm in CPA-IAC

- AICA or vertebral artery aneurysm
- Oval complex signal mass
- Rarely causes TN

Arteriovenous Malformation in CPA

- Much larger vessels (arteries and veins) with nidus
- Rare in posterior fossa

Developmental Venous Anomaly in Posterior Fossa

- Larger vessels (veins)
- CPA rare as venous drainage route
- Rarely causes venous compression-induced TN

PATHOLOGY

General Features

- Etiology
  - CN5 REZ or PGS vascular compression → **atrophy**
  - Atrophy secondary to axonal loss and demyelination
  - Atrophy → abnormal contacts among nerve fibers
    - Abnormal contacts cause paroxysmal pain of TN

Microscopic Features

- Myelin cover of proximal CN5 is breached

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Lancinating pain following V2 ± V3 distributions
  - Spontaneous or in response to tactile stimulation

Demographics

- Age
  - Older patients (usually > 65 years)
- Epidemiology
  - 5:100,000

Natural History & Prognosis

- Prognosis
  - ~ 70% pain-free 10 years after surgery or radiotherapy

Treatment

- Begin with conservative drug therapy
- Other treatments if conservative therapy fails
  - Focused radiotherapy (Gamma knife)
  - Microvascular decompression

DIAGNOSTIC CHECKLIST

Consider

- Many normal vessels in CPA cistern
- Look for asymmetric vessel with visible compression

Image Interpretation Pearls

- 1st look for MS, pontine DVA, cisternal masses
- Follow CN5 distally into cavernous sinus and face
  - Exclude perineural tumor, malignancies of face
- View high-resolution MR for neurovascular conflict

KEY FACTS

TERMINOLOGY

- Definition: Vascular loop compressing facial nerve at its root exit zone within cerebellopontine angle cistern causing hemifacial spasm

IMAGING

- High-resolution T2WI MR or source MRA images show serpentine asymmetric signal void (vessel) in medial CPA
  - AICA (50%) > PICA (30%) > VA (15%) > vein (5%)

TOP DIFFERENTIAL DIAGNOSES

- Aneurysm, CPA-IAC
- Arteriovenous malformation, CPA
- Developmental venous anomaly, posterior fossa

PATHOLOGY

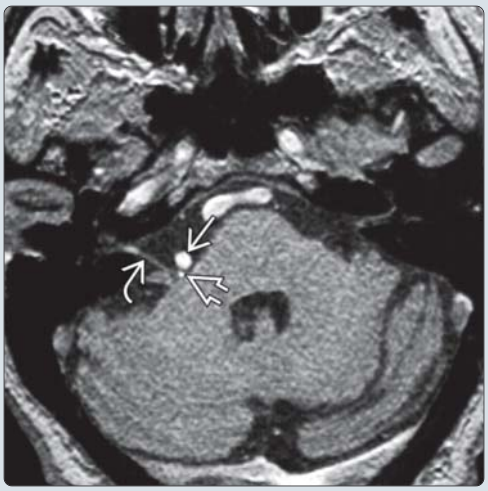
- CN7 bundle experiences "irritation" from vessel
- Rare, nonvascular causes of HFS
  - Multiple sclerosis
  - Cisternal masses
    - Epidermoid, meningioma, schwannoma
  - T-bone and parotid lesions
    - Perineural CN7 malignancy

CLINICAL ISSUES

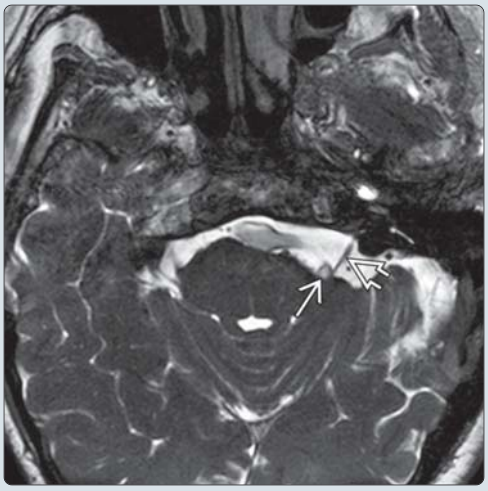
- Clinical presentation
  - Unilateral involuntary facial spasms (HFS)
  - HFS begins with orbicularis oculi spasms
  - Tonic-clonic bursts become constant over time

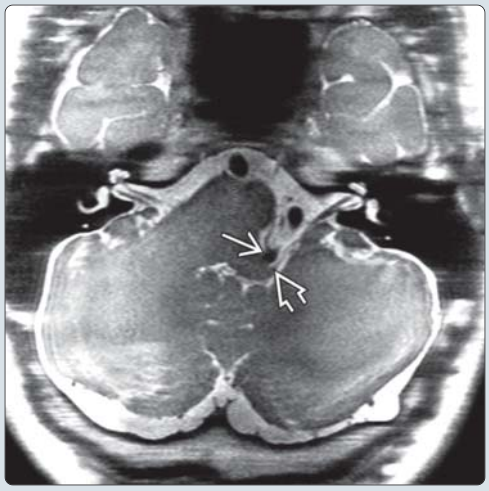
DIAGNOSTIC CHECKLIST

- Positive MR findings present in ~ 50% HFS patients
- 1st look for cisternal mass lesions, multiple sclerosis
- Then follow CN7 distally into T-bone and parotid
  - Exclude CN7 venous malformation, parotid malignancy
- Determine if MRA source images or high-resolution T2WI images identify causal vessel
  - Negative MR does not preclude surgical therapy



(Left) *Axial MRA source image in a patient with right hemifacial spasm shows a tortuous right vertebral artery ➡ and associated PICA ➡ pushing on the root exit zone of the facial nerve. The facial nerve is visible in the CPA cistern ➡.* **(Right)** *Axial CISS MR through the CPA cisterns in a patient with right hemifacial spasm demonstrates a PICA loop ➡ pushing the cisternal CN7 and CN8 posteriorly, causing them to drape over the posterior margin of the porus acusticus ➡.*





(Left) *Axial CISS MR in a patient with left hemifacial spasm reveals the left vertebral artery ➡ looping into the CPA cistern where it impinges on the proximal facial nerve ➡ at the root exit zone.* **(Right)** *Axial T2WI MR reveals a dolichoectatic vertebral artery ➡ impinging on the root exit zone ➡ of the facial nerve in the medial CPA cistern in this patient with hemifacial spasm. Approximately 50% of patients with hemifacial spasm have positive MR findings, typically on thin-section T2 or MRA sequences.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Hemifacial spasm (HFS)

Synonyms

- Facial nerve vascular loop syndrome, facial nerve hyperactive dysfunction syndrome

Definitions

- Vascular loop compressing facial nerve at its root exit zone within CPA cistern causing hemifacial spasm

IMAGING

General Features

- Best diagnostic clue
  - High-resolution T2WI MR shows serpentine asymmetric signal void (vessel) in medial CPA
- Location
  - Loop in medial CPA cistern at CN7 root exit zone
- HFS offending vessels: AICA (50%), PICA (30%), VA (15%), vein (5%)

MR Findings

- T2WI
  - High-resolution T2WI: Vessel best seen as low signal tube coursing through high signal CSF
- FLAIR
  - Adjacent brain most commonly normal
  - Multiple sclerosis may present with HFS
- MRA
  - Source images most helpful

Imaging Recommendations

- Best imaging tool
  - Thin-section high-resolution T2WI MR of CPA allows best vascular loop visualization
- Protocol advice
  - Begin with whole brain T2 or FLAIR sequence to exclude multiple sclerosis
  - Follow with axial and coronal T1WI C+ FS of brainstem and CPA cistern, including deep face
    - Look for asymmetric venous cause
    - Look for cisternal or perineural tumor, cranial neuritis
  - High-resolution T2WI of brainstem and CPA cistern next
    - Best sequence to look for causal artery

DIFFERENTIAL DIAGNOSIS

CPA-IAC Aneurysm

- PICA or vertebral artery aneurysm
- Oval complex signal mass

CPA Arteriovenous Malformation

- Larger vessels (arteries and veins) with nidus
- Rare in posterior fossa

Posterior Fossa Developmental Venous Anomaly

- Larger vessels (veins)
- CPA rare as venous drainage route
- Rarely causes venous compression with HFS

PATHOLOGY

General Features

- Etiology
  - CN7 bundle experiences "irritation" from vessel
    - Brainstem nuclei secondarily affected
    - Abnormal brainstem response (ABR)

Microscopic Features

- Myelin cover on proximal CN7 breached

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - HFS: Unilateral involuntary facial spasms
    - Begins with orbicularis oculi spasms
    - **Tonic-clonic bursts** become constant

Demographics

- Age
  - Older patients (usually > 65 years)
- Epidemiology
  - < 1:100,000

Natural History & Prognosis

- 90% symptom-free ≥ 5 years after surgery

Treatment

- Local injections of botulinum toxin
  - 85% of patients obtain significant relief from local injections
  - Repeat treatment every 4 months
- **Microvascular decompression** as needed
  - Provides permanent relief in 90% of patients

DIAGNOSTIC CHECKLIST

Consider

- Positive MR findings present in ~ 50% of HFS patients

Image Interpretation Pearls

- 1st look for cisternal mass lesions, multiple sclerosis
- Follow CN7 distally into T-bone and parotid
  - Exclude CN7 hemangioma, parotid malignancy
- Review MRA and high-resolution T2WI for causal vessel
  - Negative MR does **not** preclude surgical therapy

KEY FACTS

TERMINOLOGY

- Vestibular schwannoma (VS): Benign tumor from Schwann cells that wrap vestibular CN8 branches in CPA-IAC

IMAGING

- T1WI fat-saturated enhanced MR = gold standard
  - Focal, enhancing mass of CPA-IAC cistern centered on porus acusticus
  - Small VS: Ovoid enhancing intracanalicular mass
  - Large VS: "Ice cream on cone" shape in CPA and IAC
  - 15% with intramural cysts (low signal foci)
  - 0.5% with associated arachnoid cyst/"trapped" CSF
- High-resolution T2 space, CISS, or FIESTA: "Filling defect" in hyperintense cerebrospinal fluid of CPA-IAC cistern
- FLAIR: ↑ cochlear signal from ↑ protein
- T2* GRE: Microhemorrhages ↓ signal foci (common)
  - Characteristic VS finding when present
  - Not seen in meningioma

TOP DIFFERENTIAL DIAGNOSES

- Meningioma in CPA-IAC
- Epidermoid cyst in CPA
- Aneurysm in CPA
- Facial nerve schwannoma in CPA-IAC
- Metastases in CPA-IAC

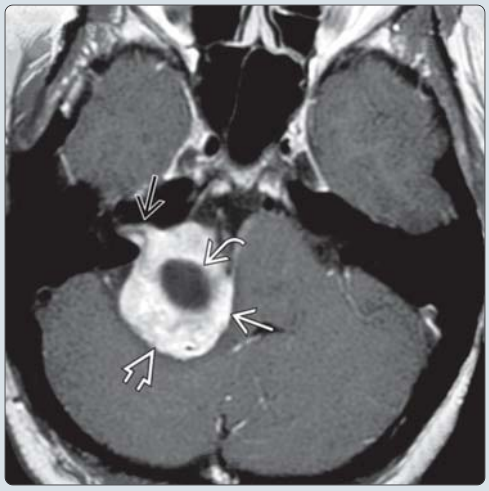
PATHOLOGY

- Benign tumor arising from vestibular portion of CN8 at glial-Schwann cell junction

CLINICAL ISSUES

- Demographics and symptoms
  - Adults with unilateral SNHL
- Surgical approaches
  - Translabyrinthine resection if no hearing
  - Middle cranial fossa approach for IAC VS
  - Retrosigmoid approach when CPA involved
- Fractionated or stereotactic radiosurgery

(Left) *Axial graphic shows small intracanalicular vestibular schwannoma ➡ arising from the superior vestibular nerve. Notice that the cochlear nerve canal is uninvolved ➡.* **(Right)** *Axial T2WI MR reveals a small intracanalicular vestibular schwannoma ➡ visualized as a soft tissue intensity mass surrounded by high intensity cerebrospinal fluid. The cochlear nerve canal ➡ is not involved, and an 8 mm fundal cap ➡ is present.*



(Left) *Axial graphic of a large vestibular schwannoma reveals the typical "ice cream on cone" CPA-IAC morphology. Mass effect on the middle cerebellar peduncle ➡ and cerebellar hemisphere ➡ is evident.* **(Right)** *Axial T1WI C+ MR demonstrates a large CPA-IAC vestibular schwannoma compressing the middle cerebellar peduncle ➡ and cerebellar hemisphere ➡. Enhancement within the IAC ➡ and the large intramural cyst ➡ makes the imaging diagnosis certain.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Vestibular schwannoma (VS)

Synonyms

- Acoustic schwannoma, acoustic neuroma, acoustic tumor
  - Uncommon names: Neurinoma, neurilemmoma

Definitions

- Benign tumor arising from Schwann cells that wrap vestibular branches of CN8 in CPA-IAC

IMAGING

General Features

- Best diagnostic clue
  - Avidly enhancing cylindrical (IAC) or "**ice cream on cone**" (CPA-IAC) mass
- Location
  - Small lesions: Intracanalicular
  - Large lesions: Intracanalicular with CPA cistern extension
- Size
  - Small lesions: 2-10 mm
  - Larger lesions: Up to 5 cm in maximum diameter
- Morphology
  - Small and intracanalicular VS: Ovoid mass
  - Large VS: "Ice cream" (CPA) "on cone" (IAC)

CT Findings

- CECT
  - Well-delineated, enhancing mass of CPA-IAC cistern
  - Calcification not present (compared to CPA meningioma)
  - May flare IAC when large
  - Smaller intracanalicular lesions (< 5 mm) may be missed with CECT

MR Findings

- T1WI
  - Usually isointense with brain
  - ↑ signal foci if rare hemorrhage present
    - Microhemorrhages more common but not seen on T1
- T2WI FS
  - High-resolution T2 space, CISS, or FIESTA: "Filling defect" in ↑ signal cerebrospinal fluid (CSF) of CPA-IAC cistern
    - Small lesion: Ovoid filling defect in ↑ signal CSF of IAC
    - Large lesion: "Ice cream on cone" filling defect in CPA-IAC
- FLAIR
  - ↑ cochlear signal from ↑ perilymph protein
- T2* GRE
  - **Microhemorrhage** low-signal foci common
    - Not seen in meningioma unless sufficient intramural calcifications present to cause "blooming"
- T1WI C+ FS
  - Focal, enhancing mass of CPA-IAC cistern centered on porus acusticus
  - 100% enhance strongly
  - **15%** with **intramural cysts** (low signal foci)
  - Dural "tails" rare (compared to meningioma)
- Other MR findings
  - < 1%: Macroscopic intratumoral hemorrhage
  - 0.5% with associated arachnoid cyst/"trapped" CSF

Imaging Recommendations

- Best imaging tool
  - Gold standard is full brain FLAIR MR with axial and coronal thin-section T1WI C+ FS MR of CPA-IAC
- Protocol advice
  - High-resolution T2 space, CISS, or FIESTA MR of CPA-IAC is only screening exam for VS
    - Used for uncomplicated unilateral sensorineural hearing loss (SNHL) in adult
    - Not useful for postoperative follow-up imaging

DIFFERENTIAL DIAGNOSIS

Meningioma in CPA-IAC

- Intracanalicular meningioma may mimic VS (rare)
- CECT: Calcified dural-based mass eccentric to porus acusticus
- T1WI C+ MR: Broad dural base with associated dural "tails"
- T2* GRE: Typically **no** microhemorrhages seen

Epidermoid Cyst in CPA

- May mimic rare cystic VS
- Insinuating morphology
- T1WI C+ MR: Nonenhancing CPA mass
- DWI: **Diffusion restriction** (high signal) diagnostic

Arachnoid Cyst in CPA

- Well-marginated CPA lesion: Does not enter IAC
- Follows CSF signal on all MR sequences
- DWI: No restricted diffusion

Aneurysm in CPA

- Ovoid to fusiform **complex signal** CPA mass

Facial Nerve Schwannoma in CPA-IAC

- When confined to CPA-IAC, may exactly mimic VS
- Look for labyrinthine segment "**tail**" to differentiate

Metastases in CPA-IAC

- May have bilateral meningeal involvement
  - Beware of misdiagnosing as neurofibromatosis type 2 (NF2)

PATHOLOGY

General Features

- Etiology
  - Benign tumor arising from vestibular portion of CN8 at glial-Schwann cell junction
    - Rare in cochlear portion CN8
- Genetics
  - Inactivating mutations of *NF2* tumor suppressor gene in 60% of sporadic VS
  - Loss of chromosome 22q also seen
  - Multiple or bilateral schwannomas = NF2
- Associated abnormalities
  - Arachnoid cyst (0.5%)
  - At surgery may be arachnoid cyst or "trapped" CSF

Staging, Grading, & Classification

- WHO grade I lesion

https://CafePezeshki.IR

Gross Pathologic & Surgical Features

- Tan, round-ovoid, encapsulated mass
- Arises eccentrically from CN8 at glial-Schwann cell junction
  - Glial-Schwann cell junction usually at porus acusticus

Microscopic Features

- Differentiated Schwann cells in collagenous matrix
- Areas of compact, elongated cells = Antoni A
  - Most VS composed mostly of Antoni A cells
- Areas less densely cellular with tumor loosely arranged, ± clusters of lipid-laden cells = Antoni B
- Strong, diffuse expression of S100 protein
- No necrosis; instead intramural cysts
- < 1% hemorrhagic

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Adults with unilateral SNHL
- Clinical profile
  - Slowly progressive SNHL
  - Laboratory
    - Brainstem electric response audiometry (BERA) most sensitive preimaging test for VS
    - Screening MR could replace BERA
- Other symptoms
  - Small VS: Tinnitus (ringing in ear); disequilibrium
  - Large VS: Trigeminal ± facial neuropathy possible

Demographics

- Age
  - Adults (rare in children unless NF2)
  - Peak age: 40-60 years
  - Age range: 30-70 years
- Epidemiology
  - Most common lesion in unilateral SNHL (**> 90%**)
  - Most common CPA-IAC mass (85-90%)
  - 2nd most common extraaxial neoplasm in adults

Natural History & Prognosis

- 60% of VS are slow growing (< 1 mm/year)
- 10% of VS grow rapidly (> 3 mm/year)
- 60% of VS grow slowly; can be followed with imaging
  - Used in > 60 years old, poor health, small tumor size, patient preference
- Successful surgical removal of VS will not restore any hearing already lost
- Negative prognostic imaging findings for hearing preservation
  - Size > 2 cm
  - VS involves IAC fundus ± cochlear aperture

Treatment

- **Translabyrinthine** resection if no hearing preservation possible
- **Middle cranial fossa** approach for intracanalicular VS
  - Especially lateral IAC location
- **Retrosigmoid approach** when CPA or medial IAC component present
- Fractionated or stereotactic radiosurgery
  - Gamma knife: Low dose, sharply collimated, focused cobalt-60 treatment
  - Used when medical contraindications to surgery and residual postoperative VS
  - Can be used as 1st treatment

DIAGNOSTIC CHECKLIST

Consider

- Consider using high-resolution T2 space, CISS, or FIESTA MR as "screening" for VS
- Thin-section, T1WI C+ enhanced, fat-saturated axial and coronal MR = gold standard imaging approach

Image Interpretation Pearls

- Unilateral well-circumscribed IAC or CPA-IAC mass should be considered VS until proven otherwise
- Always make sure there is no labyrinthine "tail" on all VS to avoid misdiagnosing facial nerve schwannoma

Reporting Tips

- Comment on tumor size ± CPA involvement
- Does VS involve cochlear nerve canal or IAC fundus?
- How large in millimeters is "fundal cap"?
- Is hemorrhage, intramural cyst, or arachnoid cyst/"trapped" CSF present within or associated with VS?
- When small, comment on nerve of origin if possible

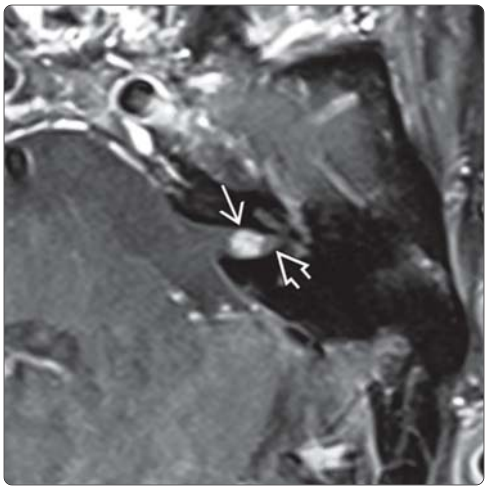
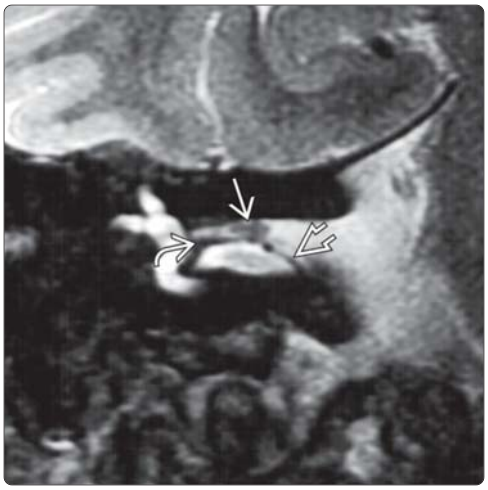
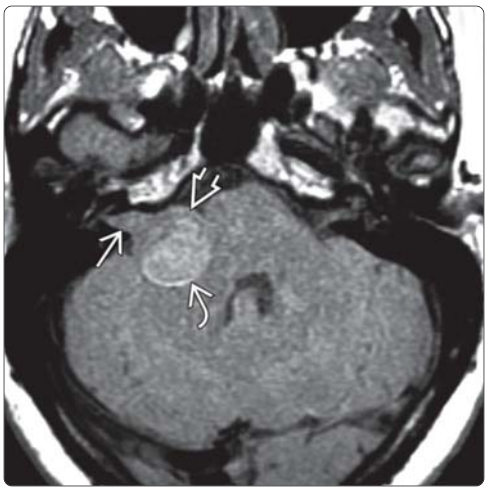
https://CafePezeshki.IR

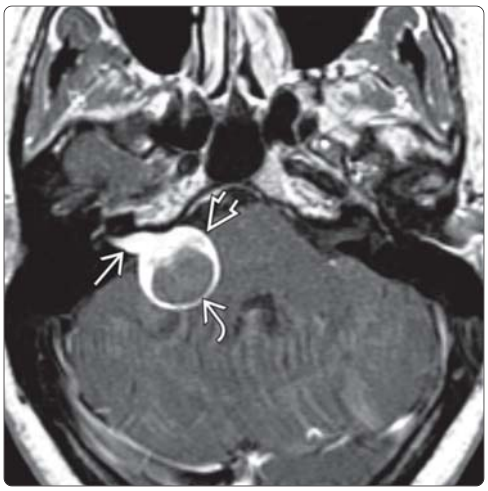


(Left) *Axial T1WI C+ FS MR in a patient with left sensorineural hearing loss shows a small enhancing vestibular schwannoma within the internal auditory canal with a 3 mm fundal CSF cap lateral to the tumor.* **(Right)** *Axial CISS MR in the same patient reveals a "filling defect" within the high signal CSF in the IAC. The vestibular schwannoma is easily diagnosed with CISS imaging. The fundal CSF cap is more readily seen with T2 or CISS MR.*



(Left) *Coronal high-resolution thin-section T2WI MR demonstrates a 2 mm superior vestibular schwannoma. The lesion is seen superior to the crista falciformis with the anterior inferior cerebellar artery loop visible in the lateral IAC.* **(Right)** *Axial T2* GRE MR reveals punctate microhemorrhages in the CPA component of a larger vestibular schwannoma. When present this finding is highly suggestive of vestibular schwannoma.*





(Left) *Axial T1WI MR reveals the IAC and CPA components of a larger vestibular schwannoma. Increased signal in the medial CPA portion of this tumor is due to methemoglobin from a subacute intratumoral hemorrhage.* **(Right)** *Axial T1WI C+ MR in the same patient shows an enhancing vestibular schwannoma with IAC and CPA components. The medial CPA intramural cystic change is due to hemorrhage.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Definition: Benign, unencapsulated neoplasm arising from meningothelial arachnoid cells of CPA-IAC dura

IMAGING

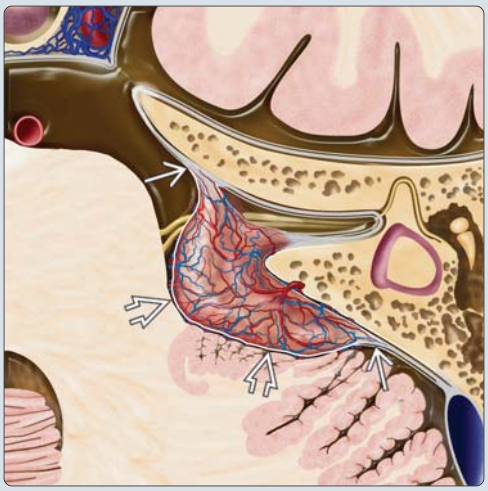
- 10% occur in posterior fossa
- When in CPA, asymmetric to IAC porus acusticus
- NECT: 25% calcified; 2 types seen
  - Homogeneous, sand-like (psammomatous)
  - Focal "sunburst," globular, or rim pattern
- Bone CT: Hyperostotic or permeative-sclerotic bone changes possible (en plaque type)
- T2WI MR: Pial blood vessels seen as surface flow voids between tumor and brain
  - High signal crescent from CSF ("CSF cleft")
- T1WI C+ MR: Enhancing dural-based mass with dural "tails" centered along posterior petrous wall
  - When IAC tail present, usually dural reaction, not tumor

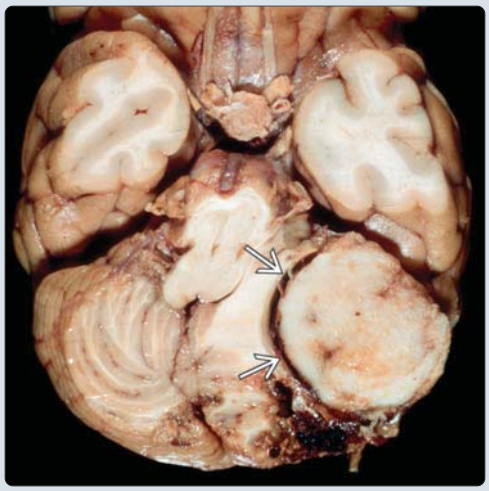
TOP DIFFERENTIAL DIAGNOSES

- Vestibular schwannoma
- Epidermoid cyst, CPA-IAC
- Dural metastases, CPA-IAC
- Sarcoidosis, CPA-IAC
- Idiopathic inflammatory pseudotumor

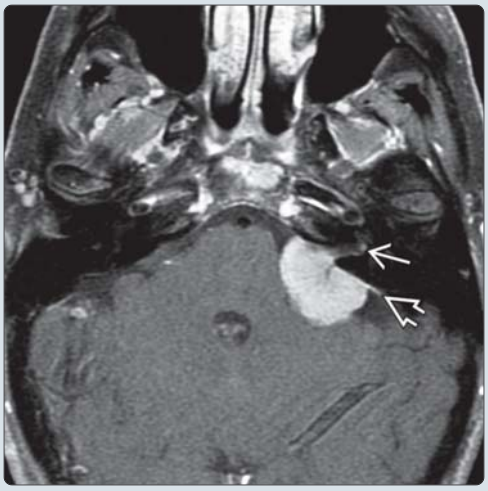
CLINICAL ISSUES

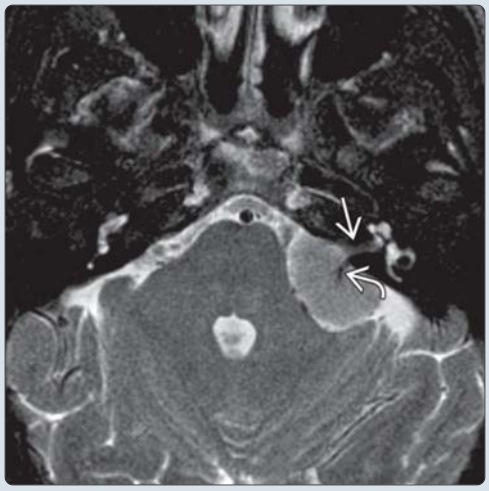
- 2nd most common CPA tumor
- Slow-growing tumor, displacing adjacent structures
- Often found as incidental brain MR finding
- < 10% symptomatic
  - Usually do not cause sensorineural hearing loss
- Treatment
  - Follow with imaging if smaller size and older patient
  - Surgical removal if medically safe
  - Adjunctive radiation therapy with incomplete surgery





(Left) *Axial graphic at level of the IAC shows a large CPA meningioma causing mass effect on the brainstem and cerebellum. Notice the broad dural base creating the shape of a mushroom cap. Dural "tails" ⇨ are present in ~ 60% of cases, typically representing reactive rather than neoplastic change. CSF-vascular cleft is also visible ⇨.* **(Right)** *Gross pathologic section viewed from below shows a large CPA meningioma with a broad dural base compressing the cerebellum. The specimen demonstrates a CSF-vascular cleft ⇨.*





(Left) *Axial T1WI C+ FS MR through the IAC shows a meningioma overlying the porus acusticus. Note the dural "tail" ⇨ extending along the temporal bone posterior wall. A dot of enhancement in the IAC fundus ⇨ suggests that the low signal area in the IAC is a nonenhancing meningioma.* **(Right)** *Axial T2WI FS MR in the same patient reveals a high-velocity flow void ⇨ representing a dural artery feeder penetrating the meningioma core. Low signal in the IAC ⇨ is a intracanalicular meningioma.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Benign, unencapsulated neoplasm arising from meningothelial arachnoid cells of CPA-IAC dura

IMAGING

General Features

- Best diagnostic clue
  - CPA dural-based enhancing mass with **dural "tails"**
- Location
  - 10% occur in posterior fossa
  - When in CPA, **asymmetric** to IAC porus acusticus
- Size
  - Broad range; usually 1-8 cm but may be larger
  - Generally significantly larger than vestibular schwannoma at presentation
- Morphology
  - 3 distinct morphologies
    - "Mushroom cap" (hemispherical) with broad base toward posterior petrous wall (75%)
    - Plaque-like (en plaque), ± bone invasion with hyperostosis (20%)
    - Ovoid mass mimics vestibular schwannoma (5%)
  - Larger lesions often herniate superiorly through incisura into medial middle cranial fossa

CT Findings

- NECT
  - 25% isodense, 75% hyperdense
  - 25% calcified; 2 types seen
    - Homogeneous, sand-like (psammomatous)
    - Focal "sunburst," globular, or rim pattern
- CECT
  - > 90% have strong, uniform enhancement
- Bone CT
  - Hyperostotic or permeative-sclerotic bone changes possible (en plaque type)
  - IAC widening is rare (seen with vestibular schwannoma)

MR Findings

- T1WI
  - Isointense or minimally hyperintense to gray matter
  - When tumor has calcifications or is highly fibrous, hypointense areas are visible
- T2WI
  - Wide range of possible signals on T2 sequence
    - Isointense or hypointense CPA mass (compared to gray matter) is most likely meningioma
    - Focal or diffuse parenchymal low signal seen if calcified or highly fibrous
  - **CSF-vascular cleft**
    - Pial blood vessels seen as surface flow voids between tumor and brain
    - High-signal crescent from CSF
  - Tumor arterial feeders seen as arborizing flow voids
  - High signal in adjacent brainstem or cerebellum
    - Represents peritumoral brain edema
    - Correlates with pial blood supply
    - Signals problems with safe removal
- T2* GRE
  - Calcifications may "bloom"
- T1WI C+
  - Enhancing **dural-based mass** with **dural "tails"** centered along posterior petrous wall
    - > 95% enhance strongly
    - Heterogeneous enhancement when large
  - Dural "tail" in ~ 60%
    - Represents **reactive** rather than neoplastic change in most cases
    - When extending into IAC, may mimic IAC component of vestibular schwannoma
  - En plaque: Sessile, thickened enhancing dura

Angiographic Findings

- Digital subtraction angiography
  - Dural vessels supply tumor center, **pial vessels** supply **tumor rim**
  - "Sunburst" pattern: Enlarged dural feeders
  - Prolonged vascular "stain" into venous phase
- Interventional: Preoperative embolization
  - ↓ operative time and blood loss
  - Particulate agents favored (e.g., polyvinyl alcohol)
  - Optimal interval between embolization and surgery is 7-9 days
    - Allows for greatest tumor softening

Imaging Recommendations

- Best imaging tool
  - Enhanced MR focused to posterior fossa
  - Bone CT if bone invasion suspected on MR
- Protocol advice
  - Full brain T2 ± FLAIR shows brain edema best

DIFFERENTIAL DIAGNOSIS

Vestibular Schwannoma

- Intracanalicular 1st, then CPA extension
- Intracanalicular meningioma may mimic

Epidermoid Cyst, CPA-IAC

- Near CSF signal insinuating mass on MR
- DWI high signal characteristic

Dural Metastases, CPA-IAC

- May be bilateral in CPA area
- Multifocal meningeal involvement

Sarcoidosis, CPA-IAC

- Often multifocal, dural-based foci
- Look for infundibular stalk involvement

Idiopathic Inflammatory Pseudotumor

- Diffuse or focal meningeal thickening
- CPA involvement is rare

PATHOLOGY

General Features

- Etiology
  - Arises from arachnoid ("cap") meningothelial cells
  - Radiation therapy (XRT) predisposes

https://CafePezeshki.IR

  - Most common radiation-induced tumor; latency 20-35 years
- Genetics
  - Long arm deletions of chromosome 22 are common
  - *NF2* gene inactivated in 90% of sporadic cases
  - May have progesterone, prolactin receptors; may express growth hormone
- Associated abnormalities
  - Neurofibromatosis type 2 (NF2)
    - 10% of multiple meningiomas have NF2
    - Meningioma + schwannoma = NF2
    - Multiple inherited schwannomas, meningiomas, and ependymomas (MISME)

Staging, Grading, & Classification

- WHO grading classification (grades I-III)
  - Typical meningioma (grade I, benign) = 90%
  - Atypical meningioma (grade II) = 9%
  - Malignant (anaplastic) meningioma (grade III) = 1%

Gross Pathologic & Surgical Features

- "Mushroom cap" (globose, hemispherical) morphology most common (75%)
- En plaque morphology (20%) also seen in CPA
- Sharply circumscribed, unencapsulated
- Adjacent dural thickening (collar or "tail") is usually reactive, not neoplastic

Microscopic Features

- Subtypes (wide range of histology with little bearing on imaging appearance or clinical outcome)
  - Meningothelial (lobules of meningothelial cells)
  - Fibrous (parallel, interlacing fascicles of spindle-shaped cells)
  - Transitional (mixed; "onion-bulb" whorls and lobules)
  - Angiomatous (↑ vascular channels), not equated with obsolete term "angioblastic meningioma"
  - Lipoblastic: Metaplasia into adipocytes; large triglyceride fat droplets
  - Miscellaneous forms (microcystic, chordoid, clear cell, secretory, lymphoplasmacyte-rich, etc.)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Incidental brain MR finding
  - < 10% symptomatic
- Clinical profile
  - Adult undergoing brain MR for unrelated indication

Demographics

- Age
  - Middle-aged, elderly; peak = 60 years old
  - If found in children, consider possibility of NF2
- Gender
  - M:F = 1:1.5-3
- Ethnicity
  - More common in African Americans
- Epidemiology
  - Accounts for ~ 20% of primary intracranial tumors
    - Most common primary nonglial tumor
  - 1-1.5% prevalence at autopsy or imaging
  - 10% multiple (NF2; multiple meningiomatosis)
  - 2nd most common CPA-IAC mass

Natural History & Prognosis

- Slow-growing tumor
- Compresses rather than invades structures
- Negative prognostic findings on MR
  - Peritumoral edema in adjacent brainstem
  - Significant subjacent bone invasion

Treatment

- Asymptomatic: Follow with serial imaging if smaller tumor or older patient
- Surgical removal if medically safe
  - Complete surgical removal possible in 95% when tumor does not invade skull base
- Radiation therapy
  - Adjunctive therapy with incomplete surgery
  - Primary therapy if extensive skull base invasion

DIAGNOSTIC CHECKLIST

Consider

- Meningioma when MR shows hemispherical, dural-based enhancing CPA mass with dural "tails"
- Meningioma when CPA mass is large but asymptomatic

Image Interpretation Pearls

- Focal or diffuse hypointensity on T2 in CPA mass suggests meningioma
- Dural "tail" in IAC suggests meningioma

Reporting Tips

- Report extent of meningioma, including intraosseous component
  - Mention cranial nerves in area of involvement
  - Note any brainstem or brain edema indicating pia-arachnoid involvement

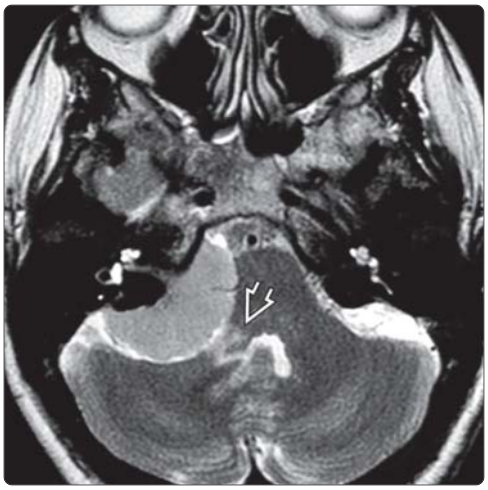
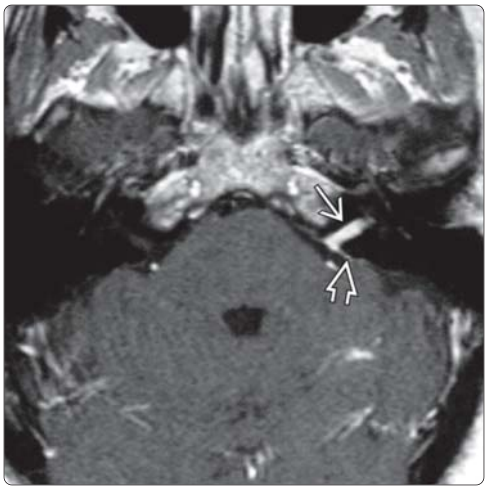
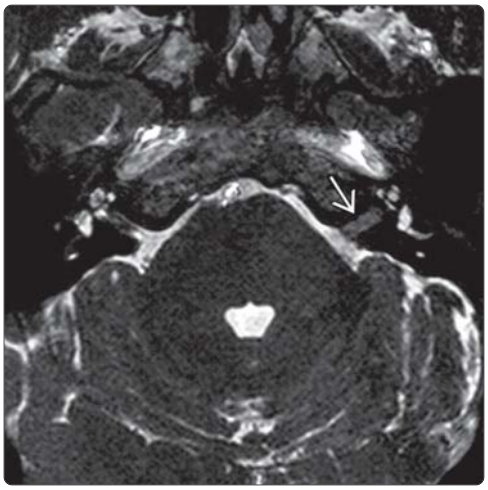
https://CafePezeshki.IR

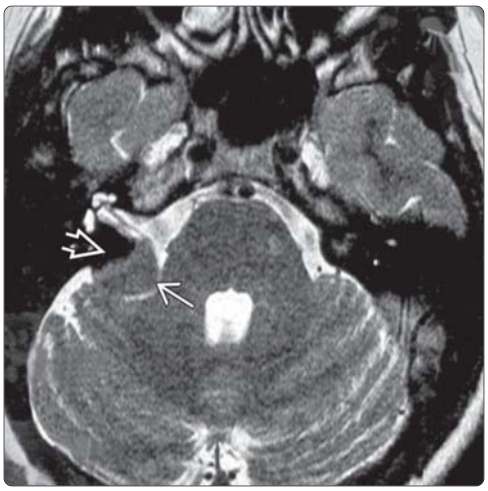


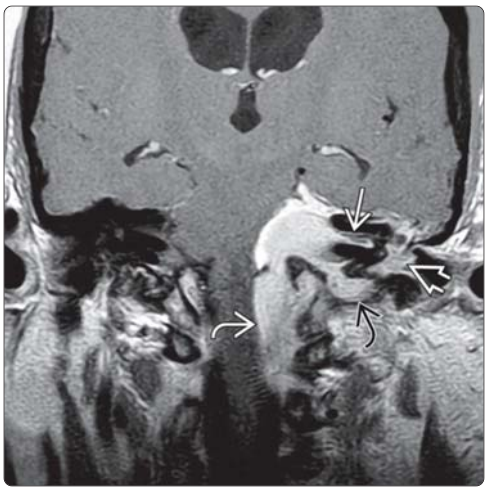
(Left) *Axial T1WI C+ MR demonstrates a large CPA meningioma with an IAC component. This degree and depth of IAC enhancement usually signifies tumor rather than dural reaction.* **(Right)** *Axial T2WI MR in the same patient reveals high signal in the adjacent brachium pontis. Pial invasion by the meningioma is likely. This MR finding is predictive of an increased risk of complications when surgical removal occurs.*





(Left) *Axial T1WI C+ MR shows an enhancing intracanalicular mass. Subtle dural "tails" along the posterior margin of the porus acusticus suggest but do not definitively diagnose meningioma.* **(Right)** *Axial T2WI MR in the same patient reveals the intracanalicular meningioma as low signal tissue filling the IAC. Often IAC meningioma cannot be reliably distinguished from IAC vestibular schwannoma, the most common lesion in this location.*





(Left) *Axial T2WI MR shows a gray matter signal intensity meningioma abutting the posterior wall of the temporal bone. Note the underlying dark signal of bony hyperostosis. Despite the tumor abutting CN7-8 along the posterior margin of the porus acusticus, the patient did not have hearing loss.* **(Right)** *Coronal T1WI C+ MR shows a large enhancing CPA meningioma. Note that the IAC, middle ear, and jugular foramen are filled with tumor. Tumor extends through the foramen magnum.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Definition: CPA-IAC metastases refers to systemic or CNS neoplasia affecting area of CPA-IAC

IMAGING

- 4 major sites: Leptomeningeal (pia-arachnoid), dura, flocculus, and choroid plexus
- T1WI C+ MR
  - **Leptomeningeal metastases**: Diffuse thickening and enhancement of cranial nerves in IAC
  - **Dural metastases**: Thickened enhancing dura; may be diffuse or focal
  - **Floccular metastases**: Enhancing floccular mass extends into CPA cistern
  - **Choroid plexus metastases**: Enhancing nodular lesion along normal course of choroid plexus
  - Focal, enhancing brain metastases may be present
- FLAIR MR
  - Parenchymal brain metastases usually high signal

TOP DIFFERENTIAL DIAGNOSES

- Bilateral vestibular schwannoma (NF2)
- Sarcoidosis
- Meningitis
- Ramsay Hunt syndrome

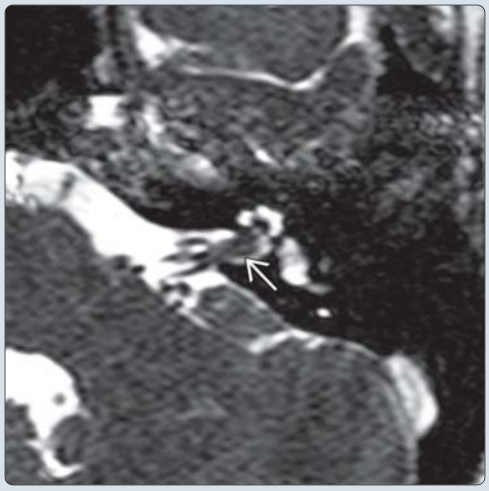
CLINICAL ISSUES

- Rapidly progressive unilateral or bilateral facial nerve paralysis and sensorineural hearing loss
- Patient with past history of treated malignancy

DIAGNOSTIC CHECKLIST

- If trying to diagnose bilateral "vestibular schwannoma" in adult as NF2, probably CPA metastases instead
- Rapidly progressive 7th & 8th cranial nerve palsies + CPA mass suggests metastatic focus
  - Vestibular schwannoma rarely causes CN7 palsy

(Left) *Axial graphic depicts the 4 major types of CPA-IAC area metastases. Along the posterolateral margin of the IAC, thickened dural metastases ⇨ are visible. Within the IAC metastatic leptomeningeal (pia-arachnoid) ⇨ involvement is present. Choroid plexus ⇨ and floccular ⇨ metastases are also depicted.* **(Right)** *Axial T1WI C+ MR shows bilateral leptomeningeal breast carcinoma metastases ⇨ within the internal auditory canals. The left-sided disease is more subtle than the right.*



(Left) *Axial T2WI MR demonstrates right IAC leptomeningeal metastatic foci as thickening of the branches of CN7 and CN8 ⇨ within the internal auditory canal.* **(Right)** *Axial T2WI MR reveals left IAC metastatic disease as subtle thickening of the branches of CN7 and CN8 ⇨ within the internal auditory canal. In an adult patient with suspected "bilateral vestibular schwannoma," consider metastatic disease rather than NF2.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Metastases (mets)

Synonyms

- Leptomeningeal carcinomatosis, meningeal carcinomatosis, carcinomatous meningitis
  - All of the above terms are misnomers for the following reasons
    - Neoplasms are not always carcinomas
    - Pachymeninges (dura) and leptomeninges (pia + arachnoid) are often both involved
    - Usually does not contain inflammatory component
      - -itis suffix makes no sense

Definitions

- CPA-IAC metastases: Systemic or central nervous system (CNS) neoplasia affecting area of CPA-IAC

IMAGING

General Features

- Best diagnostic clue
  - Multiple enhancing masses on T1WI C+ MR
- Location
  - 4 major sites: **Leptomeningeal (pia-arachnoid), dura, flocculus, and choroid plexus**
  - Primary site locations
    - Primary tumors: Breast, lung, and melanoma
    - Meningeal lymphoproliferative malignancy
      - Lymphoma and leukemia
    - Primary CNS tumor seeds basal cisterns via cerebrospinal fluid (CSF) pathways: "Drop" metastases
- Size
  - Often small (< 1 cm)
    - Metastases cause symptoms early
- Morphology
  - Leptomeningeal: Thickened CN7 and CN8 in IAC
  - Dura: Diffuse dural thickening (pachymeninges)
  - Flocculus: Enlarged flocculus with associated brain edema; mass extends into CPA cistern
  - Choroid plexus: Nodular thickening

CT Findings

- CECT
  - Unilateral or bilateral dural enhancement along CPA
  - CT shows metastases only when larger ± multiple

MR Findings

- T1WI
  - Focal dural thickening isointense to gray matter
- T2WI
  - High-resolution T2 MR
    - Leptomeningeal metastases: CN7 and CN8 thickening
    - Floccular metastases: ↑ signal edema associated
- FLAIR
  - Larger CPA-IAC metastases may cause ↑ signal in adjacent brainstem ± cerebellum
  - Floccular metastases seen as ↑ signal
- T1WI C+
  - **Leptomeningeal metastases**: Diffuse thickening and enhancement of cranial nerves in IAC
    - Late finding shows plug of enhancing tissue in IAC
    - Unilateral or bilateral
  - **Dural metastases**: Thickened enhancing dura; may be focal or diffuse
    - Associated with other dural or skull lesions
  - **Floccular metastases**: Enhancing floccular mass
  - **Choroid plexus metastases**: Enhancing nodular lesion along normal course of choroid plexus
    - Lateral recess 4th ventricle → foramen of Luschka → inferior CPA cistern
  - Focal, enhancing brain metastases may be present

Imaging Recommendations

- Best imaging tool
  - T1WI C+ MR of posterior fossa is best imaging tool and sequence
  - Whole-brain FLAIR and T1WI C+ for associated brain metastases
- Protocol advice
  - Axial and coronal planes recommended

DIFFERENTIAL DIAGNOSIS

Bilateral Vestibular Schwannoma (NF2)

- Younger patients; no history of malignancy
- T1WI C+ MR shows bilateral CPA-IAC enhancing masses
  - Mimics bilateral leptomeningeal metastases
- Other cranial nerve schwannoma ± meningiomas possible

Sarcoidosis, CPA-IAC

- ↑ erythrocyte sedimentation rate (ESR) and serum angiotensin converting enzyme (ACE)
- T1WI C+ MR may be identical to metastases when multifocal meningeal type
  - May be bilateral CPA lesions mimicking neurofibromatosis 2 (NF2) or metastases
  - May be single, en plaque focus mimicking meningioma
- Look for infundibular stalk involvement

Meningitis, CPA-IAC

- Bacterial meningitis
- Fungal meningitis
- Tuberculous meningitis
- T1WI C+ MR may be identical to CPA-IAC metastases
- Clinical information and CSF evaluation are key

Ramsay Hunt Syndrome

- External ear vesicular rash
- T1WI C+ MR shows enhancement in IAC fundus and inner ear ± 7th cranial nerve
  - Mimics unilateral leptomeningeal metastasis

PATHOLOGY

General Features

- Etiology
  - Metastatic tumor involves leptomeningeal or dural surfaces of CPA-IAC
    - Leptomeningeal metastases follow CN7 and CN8 into IAC
  - Metastatic tumor deposits in flocculus or choroid plexus

https://CafePezeshki.IR

- Routes of spread
  - Extracranial neoplasm spreads hematogenously to meninges
  - CSF spread from intracranial or intraspinal neoplasm is less common
- Associated abnormalities
  - Multiple other pial or dural metastatic foci
  - Parenchymal brain metastases also possible
    - Pia + arachnoid = **leptomeninges**
- Key anatomy: Meninges has 3 discrete layers
  - **Dura** (pachymeninges): Dense connective tissue attached to calvaria
  - **Arachnoid**: Interposed between pia and dura
  - **Pia**: Clear membrane firmly attached to surface of brain; extends deeply into sulci

Gross Pathologic & Surgical Features

- Diffuse, nodular ± discrete

Microscopic Features

- Common tissue types found
  - Solid tumors = breast, lung, and melanoma
    - All involve both leptomeninges and pachymeninges
  - Lymphoproliferative malignancy = lymphoma and leukemia
    - Involve both leptomeninges and pachymeninges
  - "Drop" metastases from CNS tumors
    - Medulloblastoma, ependymoma, glioblastoma multiforme

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - **Rapidly progressive** unilateral or bilateral facial nerve (CN7) paralysis and sensorineural hearing loss (CN8)
- Other signs/symptoms
  - Vertigo and polycranial neuropathy
- Clinical profile
  - Patient with past history of treated malignancy

Demographics

- Age
  - Older adults
- Epidemiology
  - Increasingly more common neurologic complication of systemic cancer
    - Due to increase in survival rate of cancer patients

Natural History & Prognosis

- Meningeal metastases usually late-stage finding
- Poor prognosis as patients have advanced, incurable disease by definition

Treatment

- No curative treatments available
- Therapies aimed at preserving neurologic function and improving quality of life
- Treatments are same as for underlying neoplasm
  - Radiotherapy ± chemotherapy depending on tissue type
- Surgery will rarely play role at this stage
  - Solitary melanoma metastases may be exception
- If any question of diagnosis, excisional biopsy necessary

DIAGNOSTIC CHECKLIST

Consider

- If trying to diagnose bilateral "vestibular schwannoma" in adult as NF2, probably CPA metastases instead
- Rapidly progressive 7th cranial nerve palsy + sensorineural hearing loss with CPA mass suggests metastatic focus
  - Vestibular schwannoma rarely causes CN7 palsy

Image Interpretation Pearls

- If suspect CPA-IAC metastasis from T1WI C+ MR appearance or history of known malignancy, make sure to review
  - Extracranial and calvarial structures for other lesions to confirm diagnosis
  - Look for involvement of other meningeal sites, such as parasellar, other basal meninges
  - Parenchymal brain for abnormal FLAIR high signal ± enhancing lesions on T1WI C+ sequences

Overview

Understanding the anatomy of the skull, scalp, and meninges is key to formulating a correct imaging diagnosis. Several important differential diagnoses are based on location. Yet each of these locations requires a different imaging approach.

For example, CT is often the best imaging modality for lesions of the skull and scalp. When faced with a complex skull base lesion, a combination of bone CT and contrast-enhanced MR images is often required for optimal imaging. MR with contrast is the best imaging modality for meningeal processes.

Scalp

The scalp is made up of 5 layers including the dermis (skin), subcutaneous fibro-adipose tissue, epicranium and muscles, subaponeurotic areolar tissue, and pericranium. The first three layers are firmly connected and surgically act as a single layer.

The majority of scalp lesions are not imaged, as the area is easily accessible to both visual and manual inspection. Imaging becomes important when a scalp lesion is malignant or has a vascular component that could alter the surgical approach.

Skull Vault (Calvaria)

The calvaria is composed of 5 bones: Frontal, parietal, occipital, temporal, and sphenoid (greater wings) bones that are primarily connected by the major sutures, including the coronal, sagittal, and lambdoid sutures. The metopic suture is variably seen in adults.

There are many normal variants of the skull. These must be recognized to prevent misdiagnosis and unnecessary biopsy. Some of the most common skull normal variants include arachnoid granulations, vascular grooves from the meningeal arteries and veins, venous lakes, emissary veins, parietal thinning, asymmetric marrow (particularly in the petrous apex), aerated clinoid processes, and accessory sutures.

Meninges

Dura

The dura (or pachymeninges) is a thick, dense, fibrous connective tissue that is made up of 2 layers: An outer (peri- or endosteal) layer and an inner (meningeal) layer. These outer and inner layers are closely adherent and apposed except where they separate to enclose the venous sinuses.

The outer layer forms the periosteum of the calvaria, tightly attached to the inner table, particularly at the sutures. The inner layer folds to form the falx cerebri, tentorium, and diaphragma sellae. It also divides the cranial cavity into compartments. On imaging, the dura usually shows smooth, thin enhancement (< 2 mm).

The dura forms 2 important potential spaces. First, the epidural space is located between the dura and the inner table of the calvaria. Important lesions of the epidural space include hemorrhage related to trauma and infection causing an empyema, a rare but potentially lethal complication of sinusitis. Second, the subdural space is the potential space between the inner (meningeal) layer of the dura and the arachnoid. A traumatic subdural hematoma is the most common process to affect the subdural space (more accurately, it probably collects within the border cell layer along the inner margin of the dura). The subdural space may also be affected by infection, either a subdural effusion related to meningitis or a subdural empyema related to meningitis in a child or sinusitis in an adult.

Leptomeninges

The leptomeninges are formed by the arachnoid and pia. The arachnoid is loosely attached to the dural border cell layer. Pathologies often affect both the arachnoid and dura together, and the 2 areas cannot be easily differentiated on imaging.

The arachnoid is a thin, nearly transparent layer of meninges closely applied to the inner (meningeal) dura. It forms the outer margin of the subarachnoid space (SAS). It does not enter the sulci or fissures except along the falx where it dips into the interhemispheric fissure. Trabeculae extend from the arachnoid across the SAS to the pia and are invested with a thin pia-like layer. The SAS is a CSF-filled space between the arachnoid and pia.

The pia is a thin, delicate membrane closely applied to the brain. It covers vessels and trabeculae in the SAS and lines the perivascular spaces.

Perivascular (Virchow-Robin) spaces are normal variants. They appear as interstitial fluid-filled, pial-lined spaces that accompany penetrating arteries and veins.

Arachnoid Granulations

Arachnoid granulations are normal extensions of the SAS and arachnoid through the dural wall and into the venous sinuses. They are covered with arachnoid cap cells and venous sinus endothelium. CSF drains through the endothelium into the venous sinus. The most common locations for arachnoid granulations are the superior sagittal sinus and transverse sinuses. These normal variants are important "pseudolesions" to recognize, as they may be misdiagnosed as pathology. They are CSF density or intensity on imaging and do not enhance. They are often associated with bone changes on CT, particularly in the occipital bone.

Differential Diagnosis

The following differential diagnosis lists are provided to help organize the most common scalp, skull, and meningeal lesions.

Scalp Masses

- Subgaleal hematoma, foreign body (most common)
- Trichilemmal ("sebaceous") cyst
- Lipoma
- Dermoid
- Metastases (extension from calvaria)
- Vascular malformation (sinus pericranii in a child)
- Skin cancer (basal cell or squamous cell)

Calvarial Thickening

- Normal variant (most common)
- Chronic phenytoin (Dilantin) therapy
- Shunted hydrocephalus
- Paget disease
- Fibrous dysplasia
- Hyperparathyroidism
- Acromegaly
- Anemias

Calvarial Thinning

- Normal variants (parietal thinning) (most common)
- Arachnoid cyst
- Mega cisterna magna
- Peripherally located tumors (oligodendroglioma, DNET)

https://CafePezeshki.IR

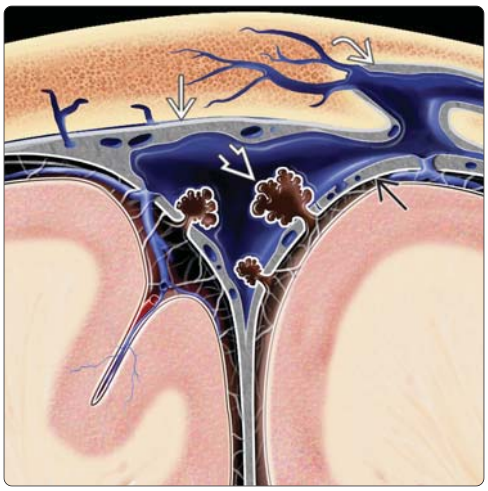
"Hair on End"
- Classic appearance of anemias: Thalassemia, sickle cell disease, hereditary spherocytosis
- Skull hemangioma
- Metastases (commonly neuroblastoma and prostate cancer)

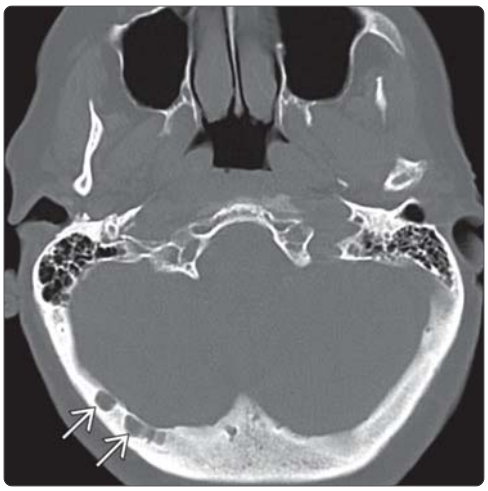
Lytic Skull Lesion
- Normal variant or surgical defects (most common)
- Metastases
- Epidermoid cyst
- Eosinophilic granuloma
- Hemangioma
- Paget disease
- Plasmacytoma
- Osteomyelitis

Sclerotic Skull Lesion
- Metastasis (most common)
- Osteoma
- Fibrous dysplasia
- Meningioma-associated
- Paget disease

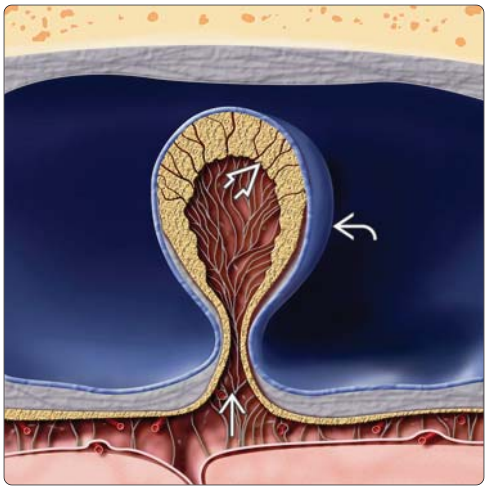
Diffuse Dura-Arachnoid Enhancement
- Postoperative or post procedure (i.e., lumbar puncture)
- Chronic subdural hematoma
- Meningitis (leptomeningeal enhancement common)
- Neoplasm
- Neurosarcoid
- Intracranial hypotension (venous congestion)
- Hypertrophic pachymeningitis (may be IgG4-related)
- Dural sinus thrombosis

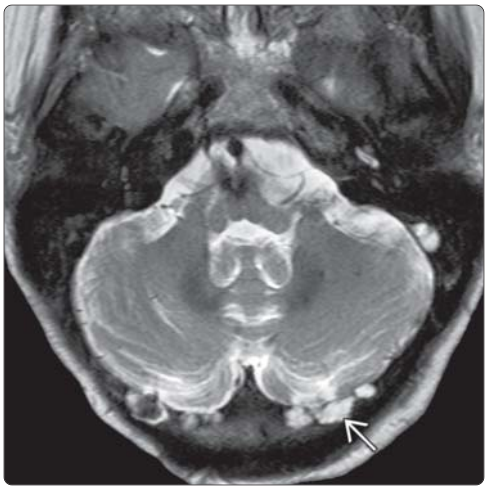
Pial Enhancement
- Meningitis (infectious or neoplastic); neurosarcoid





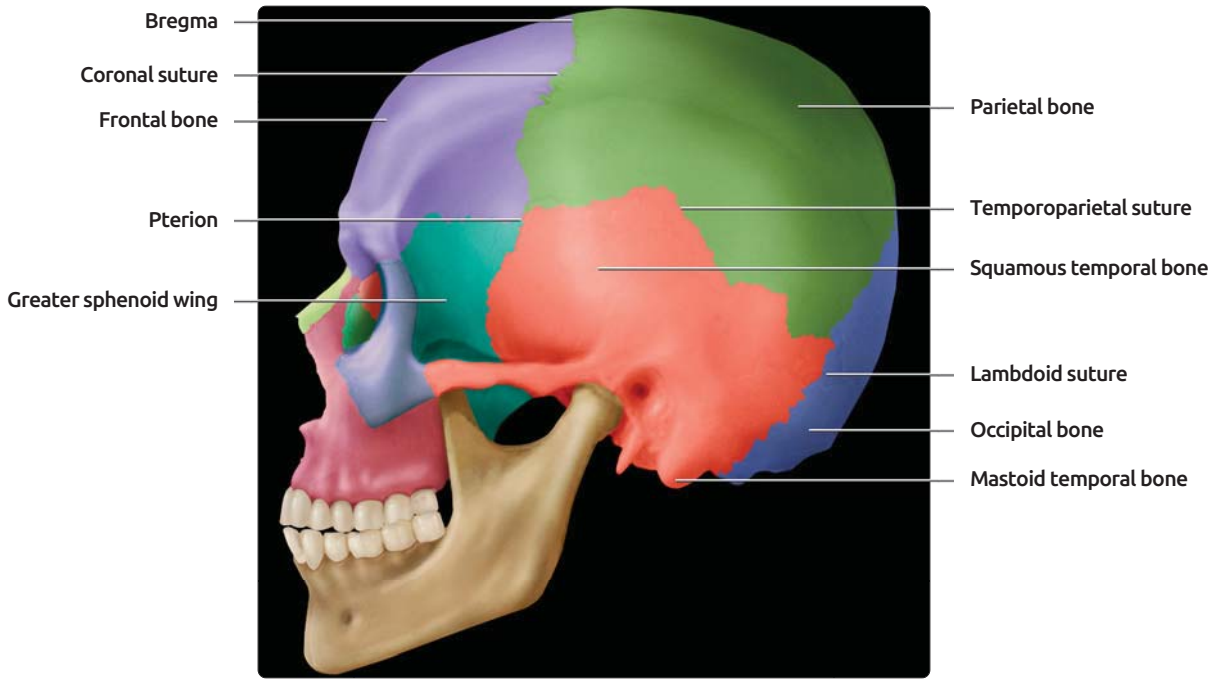
(Left) *Coronal graphic shows the calvarial apex with the superior sagittal sinus (SSS) and a venous lake. The SSS is formed by 2 dural layers, an outer (periosteal) layer and inner (meningeal) layer. Arachnoid granulations extend from the arachnoid into the SSS. The arachnoid is closely applied to the inner layer of dura.* **(Right)** *Axial bone CT shows multiple sharply marginated, lucent, occipital bone lesions adjacent to the transverse sinus, characteristic of arachnoid granulations.*

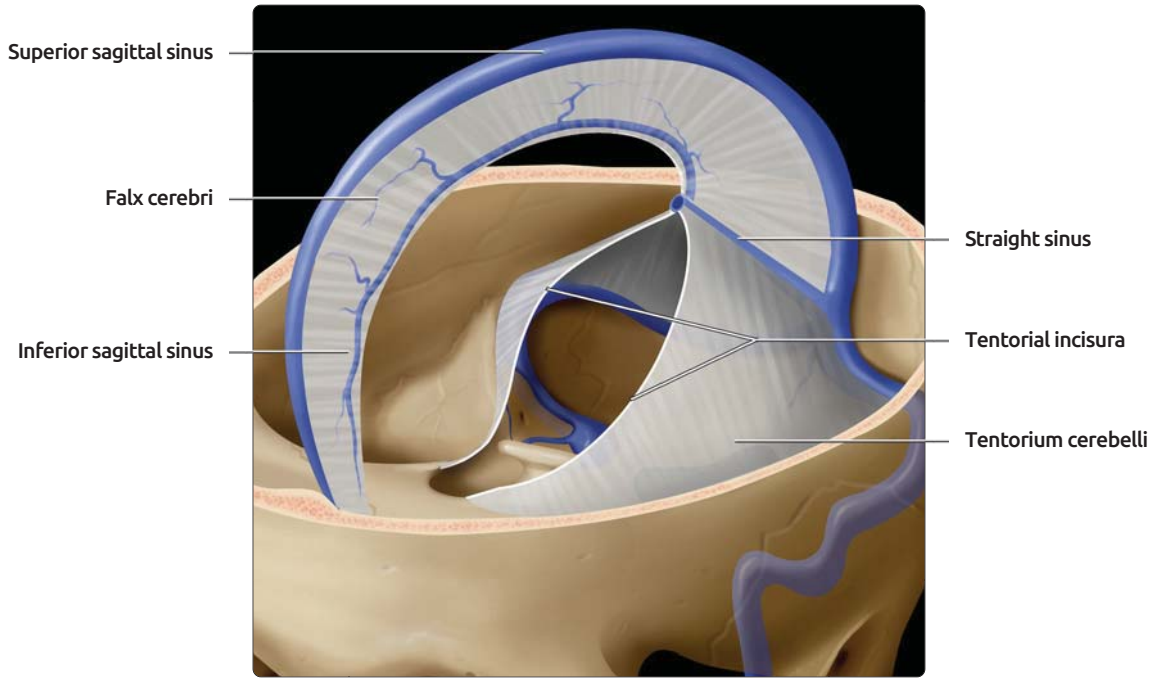




(Left) *Coronal graphic shows an arachnoid granulation projecting from the subarachnoid space (SAS) into the SSS. A CSF core extends into the arachnoid granulation and is separated by arachnoid cap cells from the venous sinus endothelium. Arachnoid granulations allow drainage of CSF into the venous circulation.* **(Right)** *Axial T2WI FS MR shows multiple CSF signal intensity lesions representing arachnoid granulations in the occipital bone, a typical location.*

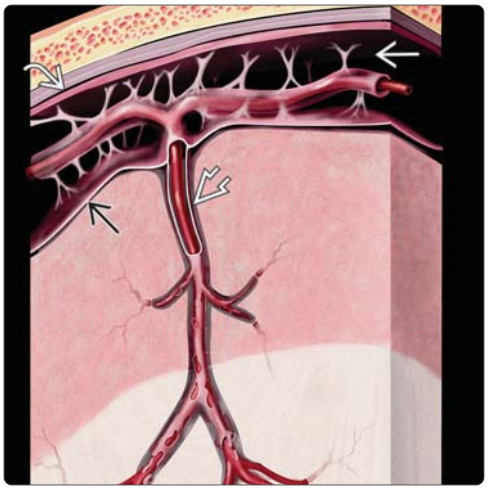
https://CafePezeshki.IR

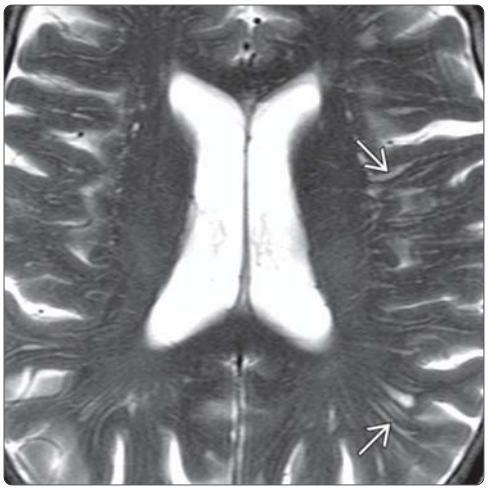




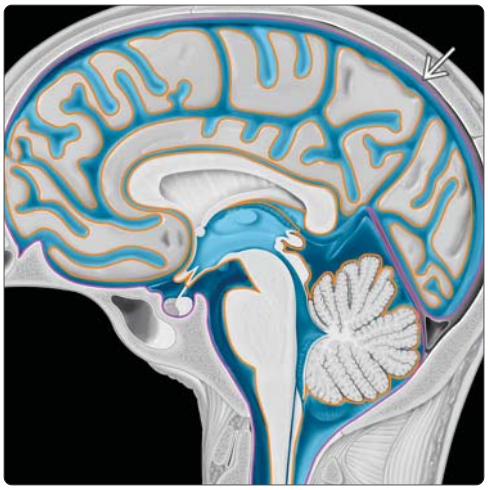
(Top) *Lateral view shows calvarial vault components. The pterion, an important surgical landmark, is a small area on the lateral skull at the intersection of the frontal, parietal, sphenoid, and squamosal temporal bones.* **(Bottom)** *Graphic shows the major dural sinuses as they relate to the falx cerebri and tentorium cerebelli. The falx inserts on the crista galli anteriorly and sweeps backwards in the midline to the straight sinus, becoming taller as it passes posteriorly. The tentorium meets the falx at the tentorial apex and curves downwards to contain the transverse sinuses. The leaves of the tentorium insert anteriorly on the petrous apex and fibers extend forward to the anterior clinoid processes.*

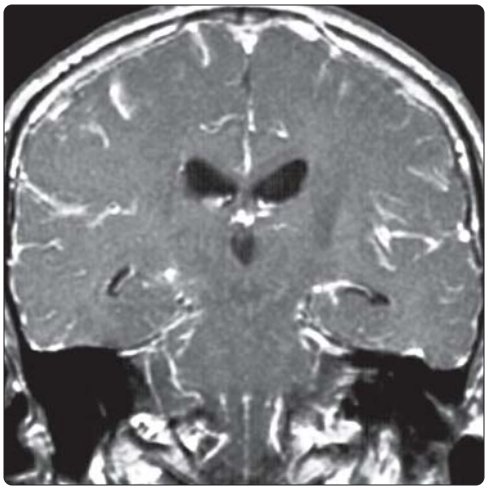
https://CafePezeshki.IR



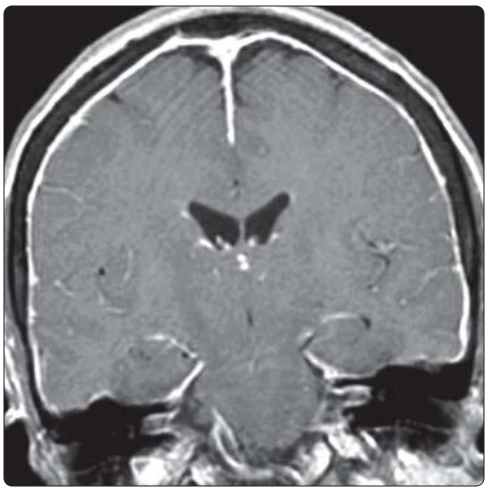


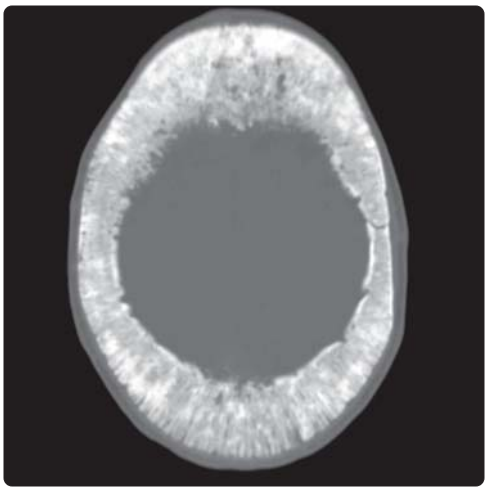
(Left) *Coronal graphic shows the cranial meninges and SAS ➡. The pia is a thin delicate membrane that covers the brain ⇨ as well as the vessels and trabeculae in the SAS. The pia also invaginates along a penetrating cortical artery to form a perivascular space ➡. The arachnoid ➡ forms the outer margin of the SAS and is loosely attached to the dura.* **(Right)** *Axial T2WI MR at 3T shows multiple normal perivascular spaces ➡ in the subcortical and deep white matter.*





(Left) *Sagittal graphic depicts the cranial leptomeninges as they enclose the CSF cisterns, shown in blue. The arachnoid ➡ (purple) follows the dura around the inner calvaria but does not invaginate into the sulci. The pia (orange) is the innermost layer of leptomeninges and follows the brain surface and dips into the sulci. The SAS lies between the pia and arachnoid.* **(Right)** *Coronal T1 C+ MR shows extensive abnormal leptomeningeal enhancement related to infectious meningitis.*





(Left) *Coronal T1 C+ MR shows diffuse dural enhancement related to intracranial hypotension in this patient with a CSF leak. Diffuse dural enhancement is commonly related to a prior procedure, infection, or inflammatory etiology. Venous congestion is the cause in intracranial hypotension.* **(Right)** *Axial bone CT shows diffuse calvarial thickening with widening of the diploic marrow resulting in a "hair on end" appearance. Thalassemia major is the most common cause of this classic imaging finding.*

KEY FACTS

TERMINOLOGY

- Parietal foramina
  - Nonossification of medial parietal bone embryonal rest
- Sinus pericranii
  - Abnormal communication between intracranial and extracranial venous systems through calvarial defect
- Aplasia cutis congenita
  - Congenital skin malformation; may have underlying skull defect
- Cleidocranial dysplasia
  - Defective membranous and endochondral bone formation → delayed skull ossification
- Amniotic band syndrome
  - Strands of amniotic sac (bands) from ruptured amnion entangle digits, limbs, or other fetal parts
- Cranium bifidum occultum

IMAGING

- Symmetry, location best clues for diagnosis
- CT for calvaria, MR for underlying brain

TOP DIFFERENTIAL DIAGNOSES

- Epidermoid/dermoid
- Hemangioma
- Langerhans cell histiocytosis
- Metastasis
- Lacunar skull (Lückenschädel)

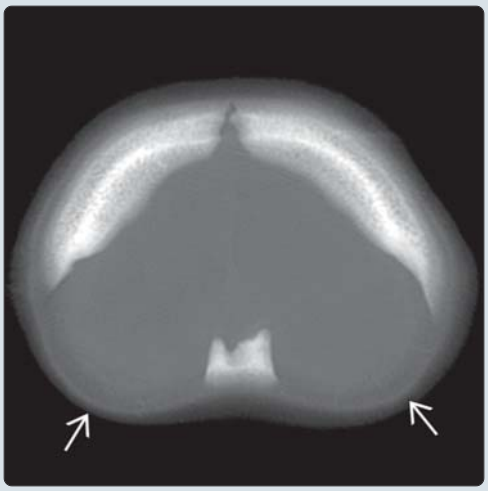
CLINICAL ISSUES

- Incidental finding on imaging or palpable scalp/calvarial mass that may protrude with crying, ↑ ICP

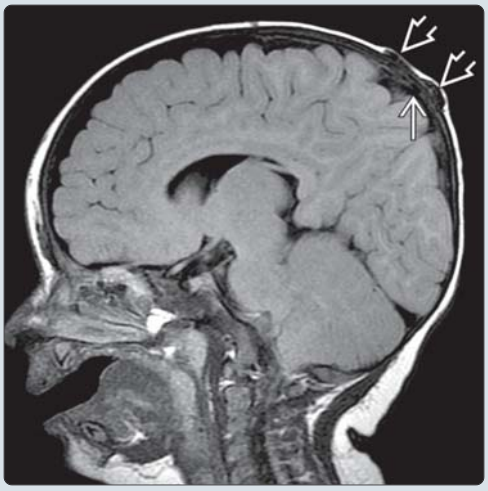
DIAGNOSTIC CHECKLIST

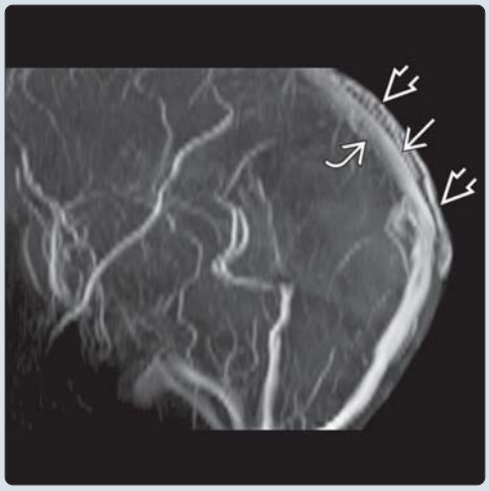
- Patients with EPF (> 5 mm) warrant imaging of brain parenchyma and vasculature

(Left) *Axial bone CT of the calvaria in a patient with a bilateral enlarged parietal foramina shows soft tissue extension through symmetrical, smooth, sharply demarcated osseous calvarial defects* ⇨. **(Right)** *Axial NECT in the same patient shows soft tissue windows with bilateral enlarged parietal foramina and otherwise normal brain parenchyma* ⇨ *protruding through the large, well-demarcated bilateral calvarial defects.*



(Left) *Sagittal T1WI MR in a patient with sinus pericranii shows dilated parietal scalp veins* ⇨ *in contiguity with the superior sagittal sinus through a small calvarial defect* ⇨. **(Right)** *Sagittal MRV MIP reconstruction in the same patient confirms the presence of large parietal scalp veins* ⇨ *in contiguity with the superior sagittal sinus* ⇨ *via a small transcalvarial vein* ⇨. *These are the classic imaging findings of sinus pericranii.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Enlarged parietal foramen (EPF), aplasia cutis congenita (ACC)

Definitions

- Parietal fissure (common)
  - Small, residual, "incomplete" medial parietal bone suture
- Parietal foramina (common; 60-70% of normal skulls)
  - Nonossification of medial parietal bone embryonal rest
  - Emissary vein portal between superior sagittal sinus and extracranial scalp veins
- Enlarged parietal foramina (rare; prevalence 1:15,000-25,000)
  - Delayed/incomplete ossification of membranous parietal bone → round or oval parietal bone defects
  - Calvarial defect may be large, palpable
- Sinus pericranii
  - Abnormal communication between intracranial, extracranial venous systems through calvarial defect
  - Soft (often red or blue) scalp mass near superior sagittal or transverse dural sinuses
  - ↑ size with ↑ ICP (Valsalva, dependent positioning)
- Craniolacunia (venous lakes)
  - Patulous calvarial diploic veins
  - Irregular, geographic, well-demarcated contour
  - Variable size and number
- Arachnoid (pacchionian) granulations
  - Located within 3 cm of superior sagittal sinus
  - Often multiple, irregular contour
- Abnormally large fontanelle
  - Secondary to ↑ intracranial pressure (suture spreading) or skeletal dysplasia
  - Search for ventriculomegaly, skeletal anomalies
- Cleidocranial dysplasia (uncommon)
  - Defective membranous and endochondral bone formation → delayed skull ossification
  - Enlarged sagittal and metopic sutures, wide anterior and posterior fontanelles, broad cranial diameter, multiple wormian bones along lambdoid sutures
- Cranium bifidum occultum ("cleft skull")
  - Delayed ossification of parietal bones → large midline skull defects
  - Progressive parietal bone ossification fills defects; may persist as parietal foramina
    - Persistence in adulthood rare (< 1%)
  - Brain covered by dura, intact scalp
- Amniotic band syndrome
  - Occurs when inner amnion membrane ruptures or tears without disruption of outer chorion
  - Strands of amniotic sac (bands) from ruptured amnion entangle digits, limbs, or other fetal parts
- Aplasia cutis congenita (uncommon)
  - Congenital skin malformation; may have underlying skull defect
  - Skin defects most frequent on midline scalp > trunk, face, limbs
- Acalvaria (rare)
  - Absent superior osseous cranial vault, dura mater
  - Normal skull base, facial bones, brain (usually)
- Acrania (rare)
  - Partial or complete absence of cranial vault bones, abnormal cerebral hemisphere development

IMAGING

General Features

- Best diagnostic clue
  - Symmetry, location best clues for diagnosis
- Size
  - Variable; small → large

CT Findings

- NECT
  - Variable soft tissue component
  - Intracranial extent may not be well demonstrated
- Bone CT
  - Characterize osseous margins as sharp or destructive, sclerotic or nonsclerotic, inner or outer table

MR Findings

- Variable; depends on composition of soft tissue component, size and etiology of calvarial defect

Imaging Recommendations

- Best imaging tool
  - Bone CT with 3D shaded surface reformats best demonstrates calvarial defect, bone margins
  - MR best demonstrates soft tissue component composition, intracranial extension, brain anomalies

DIFFERENTIAL DIAGNOSIS

Epidermoid/Dermoid

- Most common childhood benign calvarial tumor
- Sharp, slightly sclerotic osseous margins
- Most common along frontal, parietal bone sutures or adjacent to fontanelles

Hemangioma

- "Honeycomb" or "sunburst" pattern of bony spicules, avid enhancement
- Outer > inner table, nonsclerotic, nonbeveled margins
- ± prominent vascular grooves

Langerhans Cell Histiocytosis

- Lytic lesion(s) with nonsclerotic rim
- Beveled (outer > inner table)
- Predilection for calvaria, temporal bone

Metastasis

- Multiple poorly defined destructive osteolytic lesions
- Advanced leukemia, neuroblastoma most common
  - Neuroblastoma ± "hair on end" appearance
- Look for additional appendicular skeletal lesions, hepatosplenomegaly (leukemia)

Lacunar Skull (Lückenschädel) of Newborn

- Membranous bone dysplasia present at birth
- Well-defined calvarial lucencies = nonossified fibrous bone surrounded by normally ossified bone
- Resolve spontaneously by ~ 6 months, unrelated to hydrocephalus severity

https://CafePezeshki.IR

- Associated with myelomeningocele or encephalocele, Chiari 2 malformation

Leptomeningeal Cyst

- "Growing fracture" with adjacent encephalomalacia
- 0.6% of skull fractures (usually in child < 3 years)

Convolutional Markings

- True convolutional markings occur after sutural closure → differentiate from Lückenschädel

Osteomyelitis

- Lytic, poorly defined infiltrating margins, overlying soft tissue edema, fever or ↑ serum inflammatory markers

Cephalocele

- Osseous defect in characteristic location
- Brain anomalies, soft tissue component often clinically obvious

PATHOLOGY

General Features

- Etiology
  - Variable; many developmental and present early in life
  - Fortunately, majority of pediatric skull masses are histologically and clinically benign
- Genetics
  - Enlarged parietal foramina
    - Isolated autosomal dominant or syndromal
      - Chromosome 11p deletion with *ALX4* gene mutation
    - No causative mutation identified in nonsyndromic cases
  - Cleidocranial dysplasia
    - Autosomal dominant, locus on chromosome 6p21
      - Mutation in *RUN2* (also called *CBFA1*) gene coding for transcription factor activating osteoblastic differentiation
    - Variable expression, high penetrance
  - Cranium bifidum
    - Autosomal dominant, strong genetic heterogenicity
- Associated abnormalities
  - Enlarged parietal foramina
    - Scalp defects, cleft lip/palate, structural brain malformations
    - Vascular anomalies, including persistent falcine venous sinus ± adjacent focal encephalomalacia, occipital cortical infolding variations, atretic occipital encephalocele
  - Abnormally large fontanelles
    - Variable; depends on etiology or syndrome
  - Cleidocranial dysplasia
    - Absent/hypoplastic clavicles, small bell-shaped thorax, widened pubic symphysis, spinal anomalies, hypoplastic middle and distal phalanges, delayed deciduous dentition, hearing loss (38%)
  - Cranium bifidum
    - Midline neural tube malformations (myelomeningocele, meningoencephalocele, dermal sinus)
  - Amniotic band syndrome
    - ± constriction bands around limbs, congenital amputations, abdominal wall defects, and facial clefting
  - Acrania
    - Amniotic bands, anencephaly

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Palpable scalp or calvarial mass may bulge with crying, ↑ ICP
  - Incidental finding detected during imaging for other reasons
- Other signs/symptoms
  - Abnormally large anterior fontanelle (seen in osteogenesis imperfecta, cleidocranial dysplasia)

Natural History & Prognosis

- Dependent on severity of associated anomalies (especially orthopedic, neurological)

Treatment

- Surgical closure of calvarial defect with autologous bone or alloplastic material
- Multidisciplinary supportive care

DIAGNOSTIC CHECKLIST

Consider

- Patients with EPF (> 5 mm) warrant imaging of brain parenchyma and vasculature

Image Interpretation Pearls

- Confirm presence or absence of skull base, vascular, skeletal anomalies

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Synonyms: Craniosynostosis, sutural synostosis, cranial dysostosis, craniofacial dysostosis
- Heterogeneous group with abnormal head shape, premature sutural closure and fusion

IMAGING

- Calvarial (and facial) distortion predictable based on suture(s) involved
- Fibrous or bony "bridging" ± "beaking" along suture

TOP DIFFERENTIAL DIAGNOSES

- Postural flattening or positional molding
- Secondary craniosynostosis

PATHOLOGY

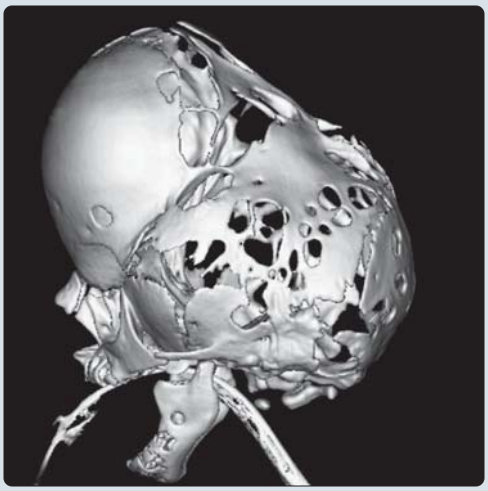
- Premature upregulation of growth factors signaling sutural fusion → craniostenosis
- Head shape may be abnormal before osseous sutural changes detectable on imaging
- Some single sutural and nonsyndromic synostoses are genetic
- Syndromic synostoses usually autosomal dominant

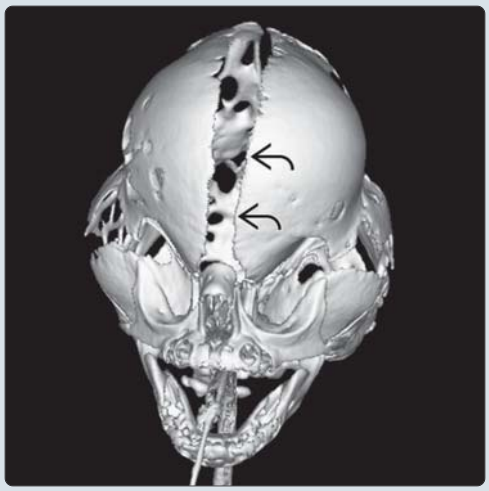
CLINICAL ISSUES

- Asymmetric face/cranium, ↓ head growth, extremity anomalies, developmental delay
- Patients with more severe anomalies often present at time of birth

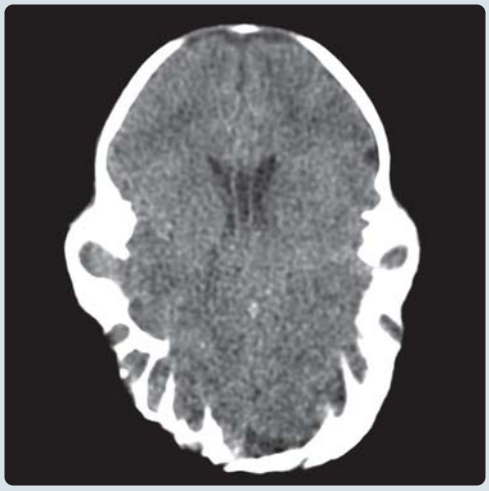
DIAGNOSTIC CHECKLIST

- Nonsyndromic does not necessarily mean nongenetic; single sutural synostoses also governed by genes
- Look for venous drainage anomalies or occlusion (particularly with multisutural synostosis)





(Left) *Sagittal bone CT 3D shaded surface reformat of the calvaria in a 1 day old with Carpenter syndrome shows an abnormal head shape and frontal bossing with facial hypoplasia and premature closure of the squamosal, coronal, lambdoid, and sagittal sutures.* **(Right)** *Anterior coronal bone CT 3D shaded surface reformat in the same patient shows a very wide metopic suture ⇨ and anterior fontanelle with harlequin eyes and a small face due to premature closure of the facial sutures.*



(Left) *Posterior coronal bone CT 3D shaded surface reformat in the same patient shows an abnormal head shape with occiput flattening, partial or complete closure of the lambdoid, sagittal sutures, and apparent holes ⇨ due to focal calvarial thinning.* **(Right)** *Axial NECT in the same patient reveals marked irregularity of the calvaria. The intracranial compartment is small, producing brain compression with posterior effacement of the convexity sulci.*

TERMINOLOGY

Synonyms

- Craniosynostosis, sutural synostosis, cranial dysostosis, craniofacial dysostosis

Definitions

- Heterogeneous group with abnormal head shape, premature sutural closure and fusion
  - Nonsyndromic (85%); isolated, classified according to involved suture(s)
    - Simple (single) suture (75-80%)
      - Abnormal head shape, (usually) normal intelligence
      - Usually sporadic, operated for cosmetic reasons
    - Multiple sutures (20-25%)
      - Oxycephaly (40-50%), brachycephaly (30-40%), unclassified (20%)
  - Syndromic (> 180 syndromes [15%]); multiple anomalies with (frequent) developmental delay
    - Association with craniofacial, skeletal, nervous system, other anomalies
    - Syndrome description based on clinical features
      - Acrocephalosyndactyly type 1 (Apert)
      - Acrocephalosyndactyly type 2 (Apert-Crouzon)
      - Acrocephalosyndactyly type 3 (Saethre-Chotzen)
      - Acrocephalosyndactyly type 4 (Waardenburg)
      - Acrocephalosyndactyly type 5 (Pfeiffer)
      - Acrocephalopolysyndactyly type 2 (Carpenter)

IMAGING

General Features

- Best diagnostic clue
  - Head shape predicts abnormal suture(s)
- Size
  - Part or all of abnormal suture may be fused
- Morphology
  - Classic imaging appearance: Calvarial (and facial) distortion predictable based on suture(s) involved
    - Scaphocephaly (dolichocephaly): ↓ transverse, ↑ AP, forehead bossing → sagittal synostosis
    - Trigonocephaly: Wedge-shaped forehead, hypotelorism → metopic synostosis
    - Plagiocephaly: Asymmetry → unilateral single or asymmetric multiple sutures
      - Unilateral coronal synostosis: Unilateral harlequin orbit, hemicalvarium shortened and pointed
      - Lambdoid synostosis: Trapezoid skull, ipsilateral posterior ear displacement, occipital flattening
    - Brachycephaly: ↑ transverse, ↓ AP → bicoronal or bilambdoid synostosis
      - Bilateral coronal synostosis: Bilateral harlequin orbit, brachycephaly, skull base and craniofacial aberrations
    - Turricephaly: "Towering skull" → bicoronal or bilambdoid synostosis
    - Oxycephaly: Coronal, sagittal, lambdoid sutures
    - Kleeblattschädel: "Cloverleaf skull," bulging temporal bone, shallow orbits → bicoronal and bilambdoid synostosis
    - Unclassified: Multiple assorted sutural synostoses

CT Findings

- Bone CT
  - Fibrous or bony "bridging" ± "beaking" along suture
  - Head shape determined by involved suture(s)

MR Findings

- T1WI
  - Syndromic: Abnormal head shape ± cerebellar tonsillar ectopia, hydrocephalus, agenesis corpus callosum
  - Nonsyndromic: Abnormal head shape, brain (usually) normal
- T2WI
  - Same as T1WI
- MRV
  - ± congenital venous drainage anomalies
  - Postoperative dural venous occlusion

Imaging Recommendations

- Best imaging tool
  - Low-dose 3D bone CT reconstruction for sutural status
  - MR for brain abnormalities

DIFFERENTIAL DIAGNOSIS

Postural Flattening or Positional Molding

- Sutures normal

Secondary Craniosynostosis

- Brain growth arrest (myriad causes) → premature sutural fusion (especially metopic or universal craniosynostosis)

PATHOLOGY

General Features

- Etiology
  - Normal sutures permit skull growth perpendicular to long axis, close when brain growth slows
    - Order of closure: Metopic > coronal > lambdoid > sagittal
  - Premature upregulation of growth factors signaling sutural fusion → anomalous skull base development, craniostenosis
    - Transforming growth factor (TGF), fibroblast growth factor/receptor (FGF/FGFR) mutations expressed in face, skull base, limb buds
  - Abnormal head shape before osseous sutural changes apparent
    - Identifiable as early as 13 weeks gestation
    - Only part of suture needs to close → craniosynostosis
  - ↓ growth of 1 suture compensated by ↑ growth of other sutures
    - Skull growth ↓ perpendicular, ↑ parallel to fused suture → abnormal head shape
- Genetics
  - Some single sutural and nonsyndromic synostoses are genetic
    - Gene expression often suture specific
  - Syndromic synostoses usually autosomal dominant
    - *FGFR1* (Pfeiffer syndrome)
    - *FGFR2* (Apert, Pfeiffer, Crouzon, Jackson-Weiss)
    - *FGFR3* (Thanatophoric dysplasia types 1 and 2, Crouzon)

https://CafePezeshki.IR

  - *TWIST* (Saethre-Chotzen syndrome)
  - *MSX2* (Boston-type craniosynostosis)
- Associated abnormalities
  - Limb anomalies (syndactyly and polysyndactyly [30%], deficiencies [22%])
  - Neurological abnormalities/complications
    - ↑ intracranial pressure: Mechanical brain distortion, hydrocephalus, dural and collateral venous outflow obstruction at skull base
    - Tonsillar herniation ± syringohydromyelia
    - Exophthalmos, visual loss, mental retardation (secondary to ↑ ICP)

Gross Pathologic & Surgical Features

- Fibrous or osseous "bridging," "beaking" along suture

Microscopic Features

- ↑ osteoblastic cell differentiation/maturation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymmetric face/cranium, ↓ head growth
  - Affected patients with more severe abnormalities often present at birth
- Other signs/symptoms
  - Extremity anomalies, developmental delay
- Clinical profile
  - Craniofacial asymmetry ± extremity anomalies
  - More common in twins (mechanical forces?)

Demographics

- Age
  - Usually present at birth or in infancy
- Gender
  - Overall (M:F = 4:1)
  - Scaphocephaly (M:F = 3.5:1)
  - Trigonocephaly (M:F = 2-3.3:1)
  - Coronal synostosis (M:F = 1:2)
  - Apert (M:F = 1:1)
- Epidemiology
  - Overall (1:2,500)
  - Sagittal (55-60%), coronal (20-30%), plagiocephaly (5-10%), metopic (1-2%)

Natural History & Prognosis

- Single suture → cosmetic only or secondary mandibular/maxillary deformities (suture dependent)
- Multiple suture → cosmetic with secondary mandibular/maxillary deformities, ↑ ICP, ↓ CBF; airway/aural/visual compromise
  - Craniofacial deformity socially stigmatizing
- Nonsyndromic → normal cognitive and motor development (debated)
- Syndromic ± midline brain anomalies → developmental delay

Treatment

- Mild deformity or positional molding
  - Aggressive physiotherapy, head repositioning, orthotic headband/helmet therapy
- Moderate to severe deformity
  - Surgical cranial vault reconstruction or cranial vault distraction osteogenesis

DIAGNOSTIC CHECKLIST

Consider

- Nonsyndromic does not mean nongenetic; single sutural synostoses also governed by genes
- Venous drainage anomalies (multisutural synostosis)

Image Interpretation Pearls

- Positional lambdoid flattening: Long axis of skull is oblique (forehead to contralateral occiput)
- Unilateral lambdoid synostosis: Long axis of skull remains unilateral A-P (forehead to ipsilateral occiput)

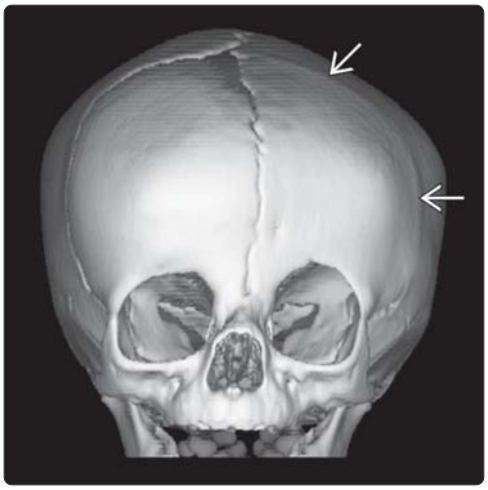
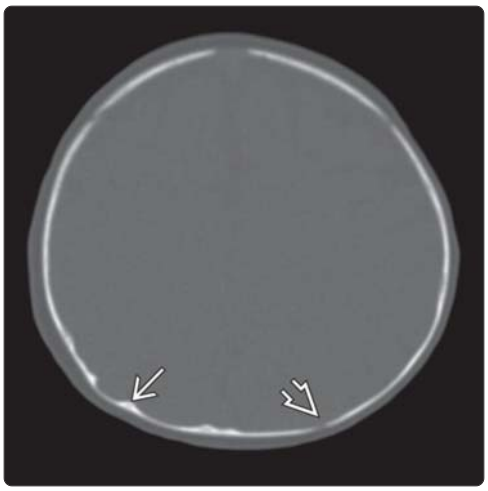
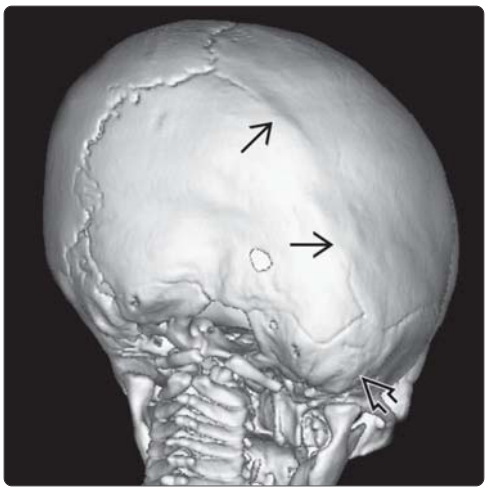
(Left) *Axial bone CT of the calvaria in a patient presenting with severe scaphocephaly shows sagittal synostosis. Note the straightening and narrowing of the sagittal suture ⇨ with prominent ridges, osseous bridging, and bony fusion ➡ across the sagittal suture.* **(Right)** *Sagittal 3D bone CT of the calvaria in the same patient shows prominent dolichocephaly and confirms characteristic findings of isolated sagittal synostosis. The coronal, lambdoid, and squamosal sutures are normal.*



(Left) *Axial bone CT of the calvaria in a patient with plagiocephaly reveals abnormal flattening of the left forehead and pointed configuration ➡ at the left coronal suture from premature closure and fusion of the suture. The right coronal and lambdoid sutures are open.* **(Right)** *Coronal 3D bone CT reformat of the skull in the same patient confirms closure of left coronal suture ➡ with characteristic flattening of the ipsilateral forehead and retrusion of lateral superior orbit ("harlequin eye").*





(Left) *Axial bone CT of the head in a patient with unilateral lambdoid synostosis demonstrates a fused right lambdoid suture ➡ producing asymmetric occipital flattening. The left lambdoid ➡ suture is normal.* **(Right)** *Coronal oblique 3D bone CT shaded surface reformat of the same patient confirms obliteration of the right lambdoid suture ⇨ producing occipital flattening and protrusion of the right mastoid bone ("mastoid bump") ⇨. The left lambdoid and sagittal sutures are open.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Cephalocele is generic term for intracranial content protrusion through calvarial or skull base defect
  - Meningoencephalocele (encephalocele): Brain tissue, meninges, CSF
  - Meningocele: Meninges, CSF only
- Cephalocele types
  - Basal
  - Cranial vault
  - Frontoethmoidal (sincipital)
  - Nasopharyngeal
  - Occipital
  - Parietal
  - Temporal bone

IMAGING

- Meninges ± brain tissue protruding through osseus skull defect
- Heterogeneous signal intensity reflecting brain tissue composition, CSF

TOP DIFFERENTIAL DIAGNOSES

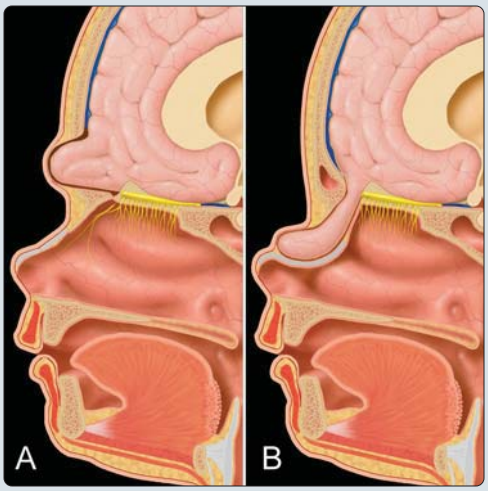
- Atretic parietal cephalocele
- Nasal dermoid/epidermoid
- Nasal glioma (nasal cerebral heterotopia)
- Calvarial dermoid

CLINICAL ISSUES

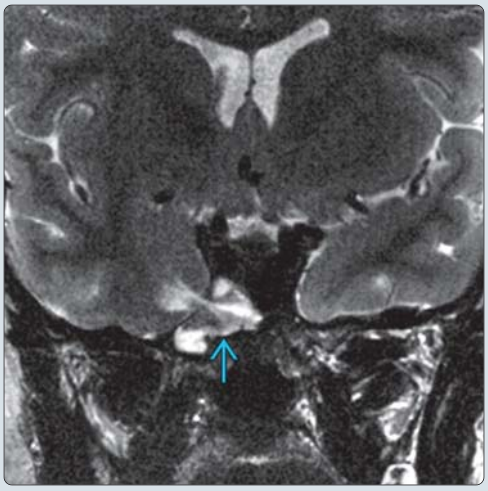
- Most cephaloceles (except nasopharyngeal) present at birth

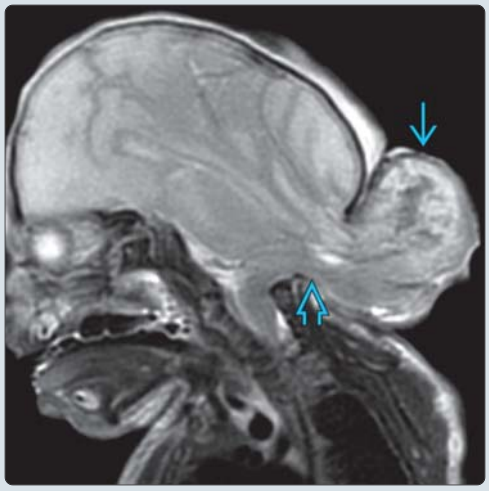
DIAGNOSTIC CHECKLIST

- Location determines risk of associated anomalies, predicates prognosis
- Evaluation of cartilaginous nasofrontal region in infants using CT problematic; consider MR



(Left) *Sagittal graphics show 2 variants of sincipital encephalocele. In the frontonasal type (A), the brain extends through the frontonasal suture into the glabellar region. In the nasoethmoidal type (B), the encephalocele extends through the foramen cecum into the nasal cavity.* **(Right)** *Sagittal T2WI MR demonstrates the nasoethmoidal type of sincipital encephalocele ⇨ extending through the foramen cecum and anterior skull base defect ⇨ into the nasal cavity.*





(Left) *Coronal T2WI MR shows a sphenoid encephalocele ⇨ extending through a small right lateral sphenoid bone defect identified during evaluation for temporal lobe epilepsy. EEG localized to the right mesial temporal lobe.* **(Right)** *Sagittal T2WI MR shows a low occipital cephalocele containing both occipital lobes ⇨ and the cerebellum ⇨ with severe traction distortion of the brainstem. Note the involvement of the foramen magnum. The herniated occipital lobe is dysmorphic and disorganized.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Generic term for intracranial content protrusion through calvarial or skull base defect
  - Named for roof and floor of bone defect
  - Open or skin covered, dura attenuated or dehiscent
  - Congenital or post-traumatic
- Cephalocele contents
  - Meningoencephalocele (encephalocele): Brain tissue, meninges, CSF
  - Meningocele: Meninges, CSF only
- Cephalocele types
  - Basal (10%)
    - Midline basal cephalocele
      - Sphenopharyngeal: Sphenoid body
      - Sphenoethmoidal: Sphenoid, ethmoid bones
      - Transethmoidal: Cribriform plate
    - Lateral basal cephalocele
      - Sphenomaxillary: Maxillary sinus, orbital fissure into pterygopalatine fossa
      - Sphenoorbital: Sphenoid bone into orbit
    - May include pituitary gland, hypothalamus, optic nerves/chiasm, anterior 3rd ventricle
  - Frontoethmoidal (sincipital) (10-15%)
    - Midface, dorsum of nose, orbits, forehead
    - Subtypes (may be mixed 10%)
      - Frontonasal (40-60%): Foramen cecum, fonticulus frontalis into glabella
      - Nasoethmoidal (30%): Foramen cecum into nasal cavity
      - Nasoorbital: Maxilla, lacrimal bone into orbit
  - Nasopharyngeal (very uncommon)
    - Occult cephalocele through ethmoid, sphenoid, or basiocciput → nasal cavity or pharynx
  - Occipital (75%)
    - Occipitocervical: Occipital bone, foramen magnum, upper cervical posterior arches
    - Low occipital: With foramen magnum
    - High occipital: Without foramen magnum
  - Parietal (10%)
    - Usually associated with significant brain anomalies → poor prognosis
  - Temporal bone
    - Inferior extension through middle ear/mastoid, petrous apex
  - Cranial vault
    - Anterior fontanelle, interfrontal, lateral (coronal or lambdoid sutures), temporal, interparietal, posterior fontanelle

IMAGING

General Features

- Best diagnostic clue
  - Meninges ± brain tissue protruding through osseous skull defect

CT Findings

- NECT
  - Contrast resolution limits ability to distinguish encephalocele from paranasal sinus opacification
- Bone CT
  - Excellent delineation of bone margins
  - Nasofrontal lesions problematic in infants because of cartilaginous anterior skull base
    - By 24 months, 84% of anterior skull base ossified; CT more reliable
- CTA
  - CTV characterizes venous vascular anatomy and relationship to encephalocele

MR Findings

- T1WI
  - Heterogeneous signal intensity reflecting brain tissue composition, CSF
- T2WI
  - Heterogeneous signal intensity reflecting brain tissue composition, CSF
  - Best contrast resolution, signal properties for CSF, characterizing gliosis in dysplastic brain tissue
- MRV
  - Characterize venous vascular anatomy, relationship to encephalocele

Ultrasonographic Findings

- Grayscale ultrasound
  - Will identify many cephaloceles in fetuses
    - Allows for early treatment post delivery
  - May have limited use in neonates

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR to delineate soft tissues and intracranial relationships
  - Bone CT to define osseous anatomy (except nasofrontal region in infants)
- Protocol advice
  - Multiplanar MR; contrast usually not necessary
  - Thin-section bone CT with multiplanar reformats

DIFFERENTIAL DIAGNOSIS

Atretic Parietal Cephalocele

- Small midline parietal mass, sharply marginated calvarial defect ± associated brain anomalies
- Cephalocele form fruste containing dura, fibrous tissue, dysplastic brain tissue

Nasal Dermoid/Epidermoid

- Failure of normal regression of dural projection through embryologic foramen cecum
- Small skin dimple or pit on external nose ± intracranial dermal sinus, (epi)dermoid cyst

Nasal Glioma (Nasal Cerebral Heterotopia)

- Congenital nonneoplastic heterotopia composed of dysplastic glial tissue
- Lack of normal regression of dural projection through embryologic foramen cecum
- Extranasal (60%), intranasal (30%), or mixed (10%)

https://CafePezeshki.IR

Calvarial Dermoid

- Usually near sutures
- Signal intensity reflects ectodermal, skin elements

Chiari 3

- Cephalocele through foramen magnum + cervical dysraphism
- Many cases of Chiari 3 are occipital cephaloceles (no cervical dysraphism)

Exencephaly

- Absence of cranial vault bones, protrusion of brain tissue into amniotic cavity

PATHOLOGY

General Features

- Etiology
  - General theories for cephalocele formation
    - Membranous calvaria: Defective bone induction, focal dural dysgenesis, bone erosion by cephalocele, local failure of neural tube closure
    - Endochondral skull base: Faulty neural tube closure, failure of basilar ossification center unification
  - Specific cephaloceles
    - Occipital encephalocele
      - Abnormal primary neural tube closure failure
      - Association with other neural tube defects
    - Frontal encephaloceles
      - Cutaneous ectoderm, neuroectoderm at anterior neuropore fail to detach ~ 3rd week
      - Genetic, toxic, environmental causes
      - No relationship to neural tube defects
    - Basal encephaloceles
      - Developmental failure of skull base ossification → migration of neural crest cells, tissue herniation through defect
      - Persistent craniopharyngeal canal theory out of favor
- Associated abnormalities
  - Basal: Hypertelorism, optic nerve hypoplasia, coloboma, midline facial anomalies, cleft lip/palate
  - Frontoethmoidal: Microcephaly, hypertelorism, eye anomalies, hydrocephalus, seizures
  - Nasopharyngeal: Callosal dysgenesis, optic hypoplasia, hypothalamic-pituitary axis dysfunction
  - Occipital: Cerebellar and cerebral gray matter migrational anomalies, dural venous anomalies, callosal dysgenesis, Chiari 2 malformation, Dandy-Walker malformation
  - Parietal: Callosal dysgenesis, Chiari 2 malformation, Dandy-Walker malformation, Walker-Warburg syndrome, holoprosencephaly spectrum

Gross Pathologic & Surgical Features

- Bone dehiscence occurs at suture or synchondrosis
- Smoothly marginated rim of cortical bone

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually clinically obvious
  - Soft, bluish (skin covered) or moist red (nonskin covered) discoloration over soft tissue mass
- Other signs/symptoms
  - CSF rhinorrhea → meningitis
  - Airway obstruction, nasal stuffiness/mouth breathing (basal, nasopharyngeal)
  - Occult mass in oro-/nasopharynx → change in size with Valsalva (basal, nasopharyngeal)
  - Hypertelorism, broad nasal bridge (frontoethmoidal)

Demographics

- Age
  - Most cephaloceles present at birth
  - Nasopharyngeal present by end of 1st decade
- Gender
  - Frontoethmoidal (M = F)
  - Occipital (M:F = 1:2.4)
- Ethnicity
  - Occipital most common location in European, North American Caucasians
  - Frontoethmoidal most common location in South/Southeast Asia, Latin America
- Epidemiology
  - 1:4,000 live births
  - 7% of neural tube defects
  - Usually sporadic but can be syndromic (e.g., Meckel syndrome)

Natural History & Prognosis

- Varies depending on type and location
- Cephalocele relationship to dural venous sinuses important for operative planning

Treatment

- Complete surgical resection of dysplastic herniated brain tissue to prevent CSF leakage, meningitis

DIAGNOSTIC CHECKLIST

Consider

- Location determines risk of associated anomalies, predicates prognosis

Image Interpretation Pearls

- Evaluation of cartilaginous nasofrontal region in infants using CT problematic; consider MR
  - Absence of ossified bone in crista galli/cribriform plate region does not = cephalocele
- MR + MR venography best for operative planning

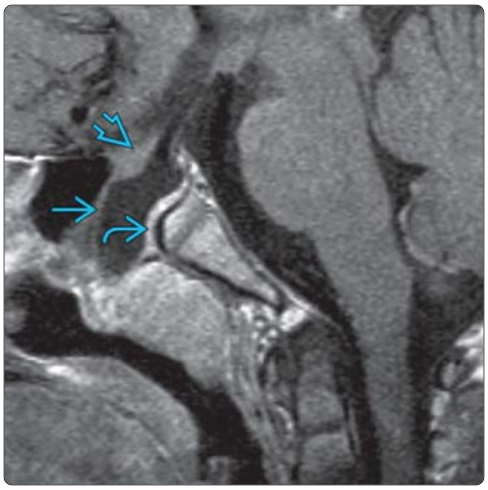
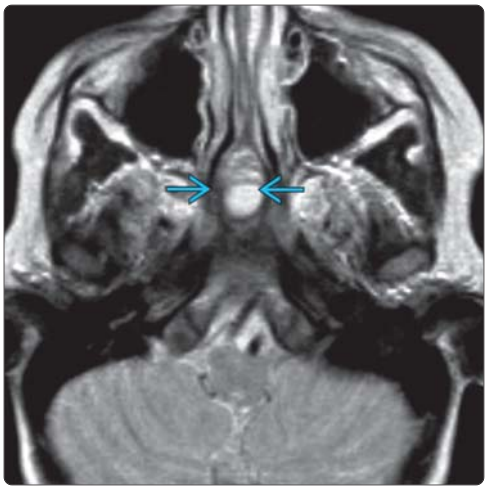
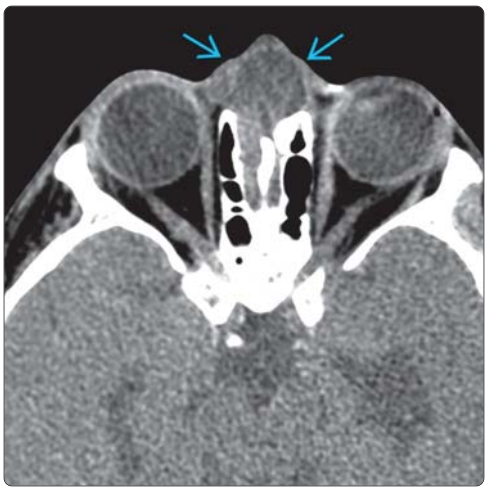
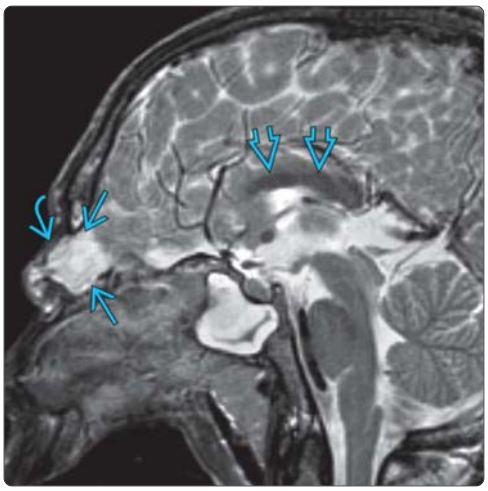
(Left) *Sagittal T1WI MR in an infant with nasal obstruction shows midline basal cephalocele containing CSF, meninges, and probably olfactory tracts. Note the associated callosal agenesis, abnormal palate, and dysmorphic nose.* **(Right)** *Axial T2WI MR in a newborn presenting with nasal obstruction reveals a large midline basal (sphenoethmoidal) encephalocele. Note the associated marked hypertelorism and left ocular coloboma, suggesting "morning glory" syndrome.*





(Left) *Sagittal T1WI C+ FS MR shows a large transsphenoidal cephalocele, with CSF and meninges extending through a large midline defect in the sphenoid bone. Optic chiasm is under traction, optic nerves are stretched, and pituitary is compressed.* **(Right)** *Axial T2WI MR depicts an area of hyperintensity in the midline, anterior to the sphenooccipital synchondrosis. This proved to be a midline sphenoidal cephalocele.*

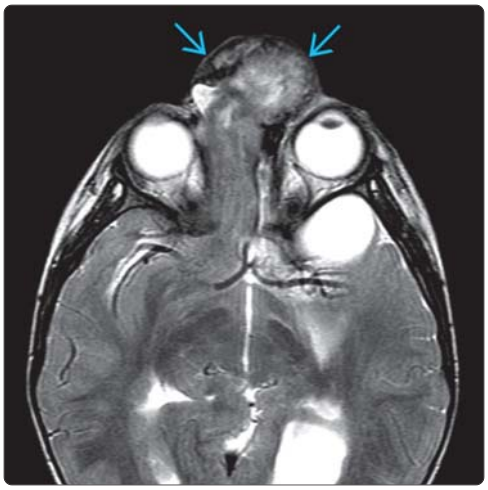


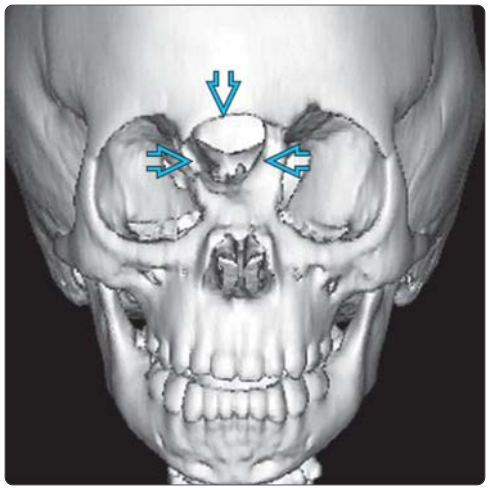


(Left) *Axial NECT in a boy with a glabellar mass (frontonasal cephalocele) shows absence of nasal bones and nasal processes of frontal bones and a fluid-intensity mass in the glabellar region. Mild hypertelorism is present. The left temporal horn is dilated.* **(Right)** *Sagittal T2WI MR in the same patient shows a bone defect near the frontonasal suture with a CSF-intensity mass, findings compatible with a cephalocele protruding through the defect. The corpus callosum is dysmorphic.*

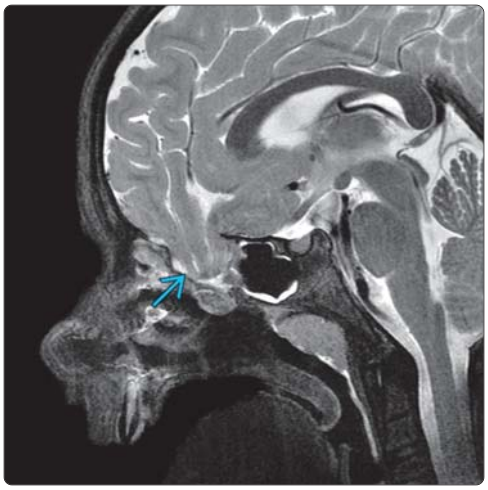
https://CafePezeshki.IR

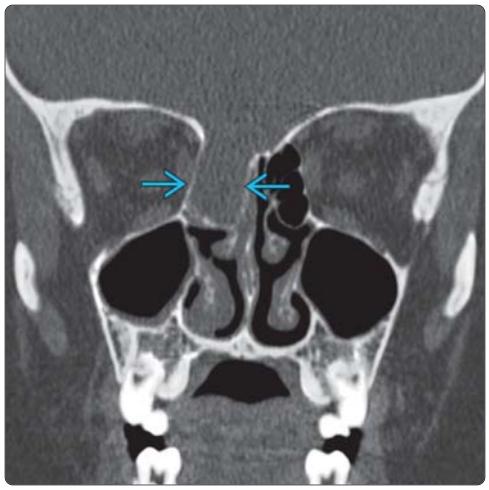
(Left) *Axial T2WI MR (frontonasal sincipital cephalocele) shows herniated brain ⇨ extending through a large bone defect at the junction of the frontal and nasal bones. Signal intensity of the dysplastic herniated brain tissue is heterogeneous and slightly hyperintense to normal parenchyma.* **(Right)** *Coronal 3D bone CT (frontonasal sincipital cephalocele) demonstrates a large midline osseous defect ⇨ correlating with the abnormally wide fonticulus frontalis.*



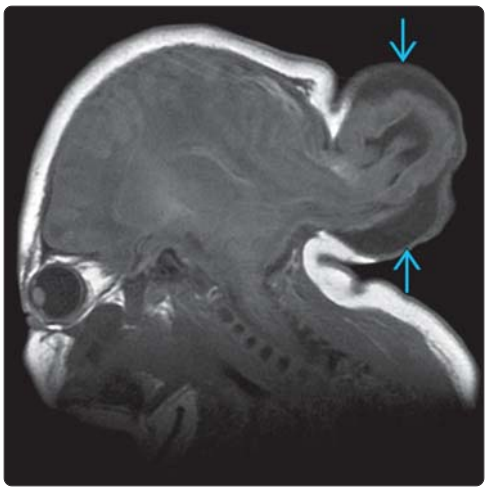


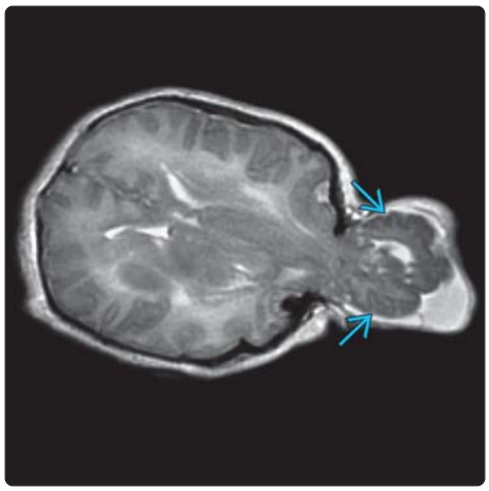
(Left) *Sagittal T2WI MR (acquired frontoethmoidal encephalocele) depicts extension of inferior frontal lobes ⇨ through anterior skull base defect into the ethmoid sinuses. The initial injury was a bungee cord hook through the nose into the frontal fossa, treated nonsurgically.* **(Right)** *Coronal bone CT (acquired frontoethmoidal encephalocele) in a patient with post-traumatic CSF rhinorrhea reveals a midline osseous defect ⇨ in the cribriform plate/frontal fossa.*



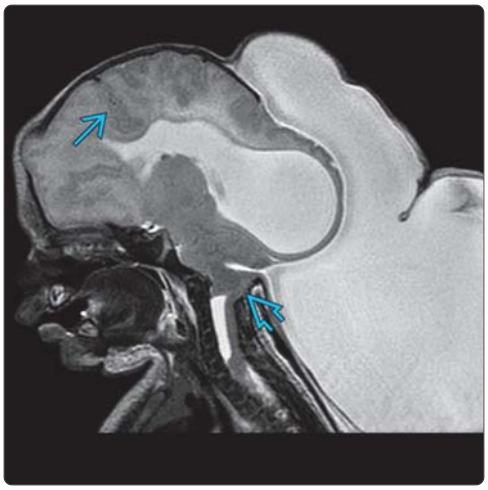


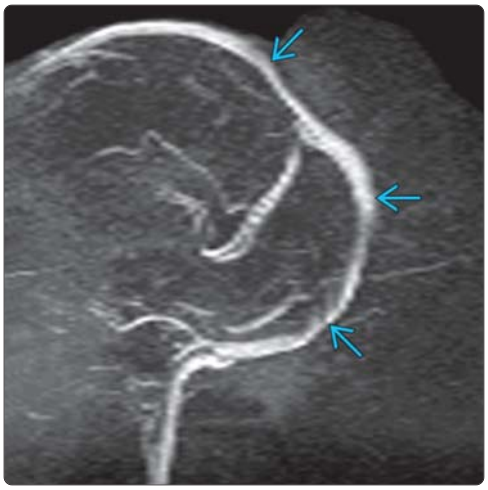
(Left) *Sagittal T1WI MR (occipital encephalocele) demonstrates extension of the dysmorphic occipital lobes into the posterior cephalocele sac ⇨. The cerebellum is distorted but not included within the sac. Bone defect sparing the foramen magnum indicates the high occipital variant.* **(Right)** *Axial T2WI MR in the same patient depicts displacement of both occipital lobes through the occipital bone defect into the cephalocele sac. The cortex in the cephalocele ⇨ appears dysplastic.*





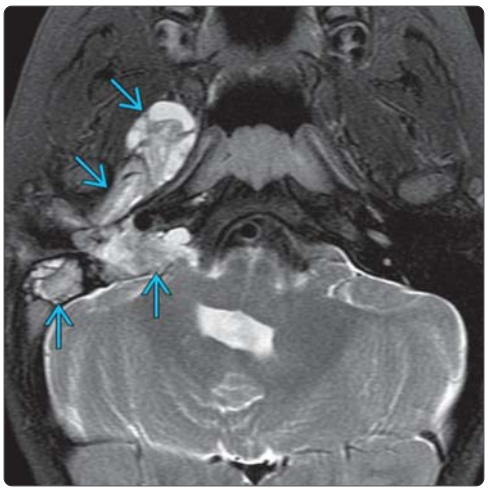
https://CafePezeshki.IR

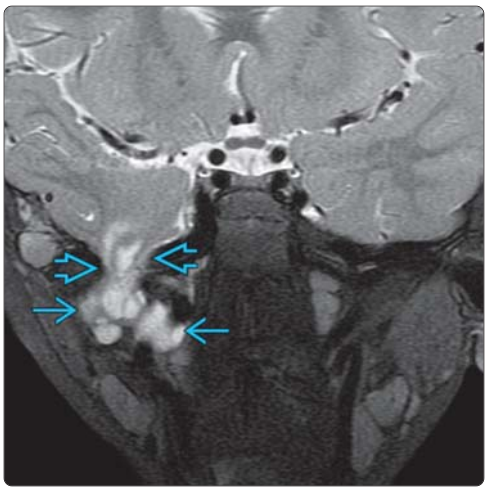




(Left) *Sagittal T2WI MR (occipital encephalocele) shows extension of both the posterior parietal and occipital lobes, as well as the cerebellum into the large fluid-filled cephalocele sac. Note traction deformity of the brainstem and upper cervical cord ⇨ and associated frontal lobe cortical dysplasia ⇨.* **(Right)** *Sagittal MRV in the same patient shows posterior displacement of the patent posterior superior sagittal sinus and venous confluence ⇨ into the cephalocele sac.*

(Left) *Sagittal T2WI MR in a newborn with parietal encephalocele and multiple severe congenital anomalies shows more brain parenchyma residing in the cephalocele than within the cranium. Brain tissue appears dysplastic within the cranium and the cephalocele.* **(Right)** *Coronal T2WI MR (parietal encephalocele) shows a combination of severe congenital brain malformation (bilateral cortical dysplasia) and acquired intraparenchymal hemorrhage ⇨ within the cephalocele.*





(Left) *Axial T2WI FS MR shows a large right post-traumatic encephalocele with multiple areas of temporal bone osseous dehiscence ⇨. The patient presented with right hearing loss and a remote history of head injury. Note the traction distortion of the medulla and cerebellum.* **(Right)** *Coronal T2WI FS MR of a post-traumatic temporal encephalocele reveals extension of the inferior right temporal lobe ⇨ through a post-traumatic bone defect ⇨ into the right middle ear and mastoid bone.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Atretic parietal cephalocele (APC)
- Cephalocele "form fruste" consisting of dura, fibrous tissue, and dysplastic brain tissue

IMAGING

- Heterogeneous subcutaneous scalp mass with intracranial extension
- Focal fenestration of superior sagittal sinus at APC
- CSF tract and vertical falcine vein "point" to subcutaneous scalp mass
- Cephalocele itself may be very small

TOP DIFFERENTIAL DIAGNOSES

- Dermoid or epidermoid cyst
- Proliferating (infantile) hemangioma
- Sinus pericranii
  - Often associated with APC
- Cephalohematoma or subgaleal hematoma
- Sebaceous cyst
- Metastasis

PATHOLOGY

- Considered involuted true cephalocele (meningocele or encephalocele) connected to dura mater via fibrous stalk
- Syndromic patients have increased incidence of associated intracranial anomalies

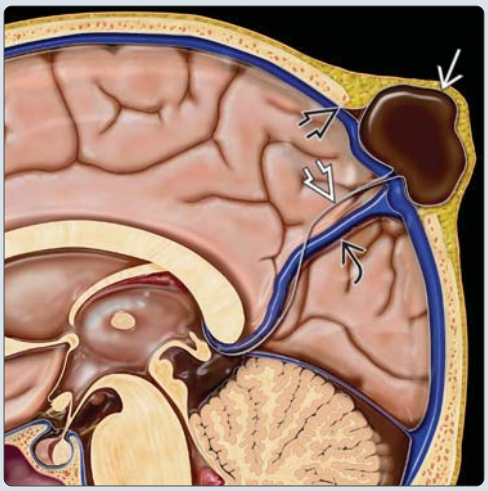
CLINICAL ISSUES

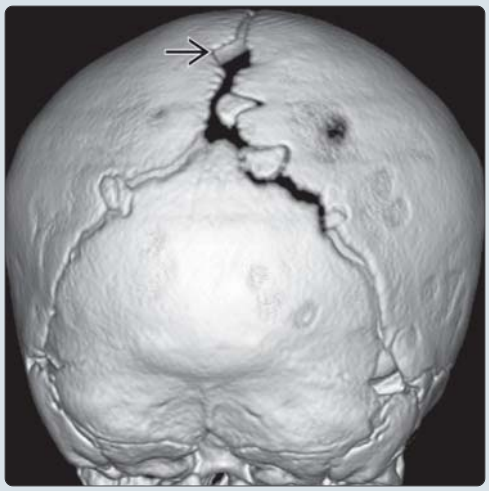
- Soft palpable interparietal subgaleal mass
- Usually identified in infants and young children
  - M ≤ F

DIAGNOSTIC CHECKLIST

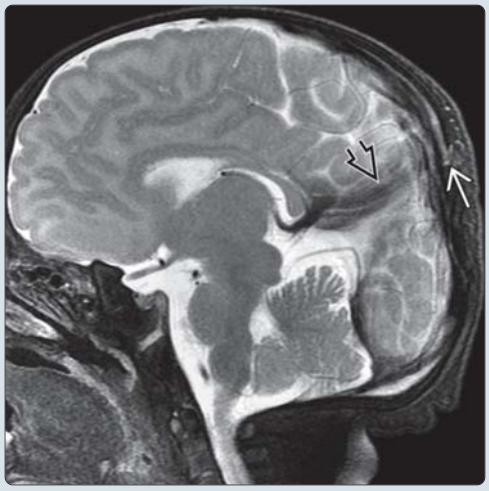
- Consider APC in differential diagnosis for child with midline parietal skin-covered subgaleal mass
- Prognosis depends more on associated "occult" brain anomalies than existence of cephalocele itself

(Left) *Sagittal graphic shows a skin-covered midline atretic parietal cephalocele ➡ protruding through a sharply demarcated skull defect ⇨. The atretic cephalocele is associated with a dura-lined sinus tract ➡ and a persistent falcine sinus ⇨.* **(Right)** *3D rendered bone CT in a child with an atretic parietal cephalocele demonstrates a small, sharply delineated midline skull defect ⇨.*





(Left) *Sagittal CTA in the same case shows a persistent falcine sinus ⇨, atretic cephalocele ➡ passing between a split superior sagittal sinus ⇨.* **(Right)** *Sagittal T2WI MR in the same case demonstrates the persistent falcine sinus ⇨ and a tiny atretic cephalocele ➡.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Atretic parietal cephalocele (APC)

Definitions

- Cephalocele "form fruste" consisting of dura, fibrous tissue, and dysplastic brain tissue

IMAGING

General Features

- Best diagnostic clue
  - Fibrous tract and vertical falcine vein "point" to subcutaneous scalp mass (APC)
- Location
  - Midline interparietal most common, occasionally occipital
- Size
  - Usually small (5-15 mm)
- Morphology
  - Skin-covered subgaleal mass with sharply marginated calvarial defect

Radiographic Findings

- Radiography
  - Cranium bifidum at obelion
    - May be difficult to appreciate

CT Findings

- NECT
  - Subgaleal soft tissue mass
  - Small cranium bifidum superior to lambda
  - "Spinning top" configuration of tentorial incisura (axial)
- CECT
  - Extension of subcutaneous scalp mass through dura delineated by enhancing veins
  - Fenestration of superior sagittal sinus, vertically oriented primitive falcine vein
- CTA
  - Vertical embryonic positioning of straight sinus equivalent (falcine sinus)
  - Fenestration of superior sagittal sinus

MR Findings

- T1WI
  - Heterogeneous subcutaneous scalp mass with intracranial extension
  - ± cigar-shaped CSF tract within interhemispheric fissure
  - Prominent superior cerebellar cistern and suprapineal recess
  - Characteristic appearance of tentorial incisura
    - "Spinning top" (axial) and "peaked" (coronal) configuration
  - Tissue are stretched in direction of defect and may "point" to lesion
- T2WI
  - Subcutaneous scalp mass representing APC is usually hyperintense
  - Other findings similar to T1WI
- STIR
  - Fat suppression better delineates subgaleal hyperintense cephalocele
- T1WI C+
  - Subcutaneous scalp mass usually shows heterogeneous enhancement
  - APC fibrous tract delineated by adjacent enhancing veins
- MRV
  - Vertically positioned straight sinus equivalent (persistent falcine vein)
  - Focal fenestration or lateral displacement of superior sagittal sinus at APC

Ultrasonographic Findings

- Grayscale ultrasound
  - Scalp mass with heterogeneous echotexture
  - Cranium bifidum osseous defect usually too small to identify

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR with intravenous contrast + MRV
- Protocol advice
  - MR: Thin section, small field of view, sagittal T1 and T2 with fat saturation
  - Intravenous contrast with fat saturation to define sagittal sinus and falcine vein; exclude sinus pericranii

DIFFERENTIAL DIAGNOSIS

Dermoid or Epidermoid Cyst

- Often located near sutures
- Scallops outer table of calvaria
- + marginal enhancement, no internal enhancement

Proliferating (Infantile) Hemangioma

- Lobulated soft tissue mass with internal flow voids
- + avid contrast enhancement

Sinus Pericranii

- Often associated with APC
- Abnormal communication between intracranial and extracranial venous systems through osseous calvarial defect
- Soft red or blue scalp mass adjacent to superior sagittal or transverse dural sinuses
- ↑ size with ↑ intracranial pressure (Valsalva, dependent positioning)
- Internal venous flow, robust enhancement

Cephalohematoma or Subgaleal Hematoma

- Fluid in subgaleal space adjacent to intact calvaria
- Consider in newborn post trauma or following vaginal delivery

Sebaceous Cyst

- Dermal inclusion in scalp
- No calvarial defect or venous anomalies

Metastasis

- Destructive calvarial lesion + soft tissue mass
- Consider neuroblastoma in infant or toddler

https://CafePezeshki.IR

Heterotopic Scalp Nodule

- Neuroectodermal malformation containing heterotopic leptomeningeal or glial tissue
- Focal alopecia surrounded by ring of long coarse hair ("hair collar" sign) ± surrounding capillary stain
  - May have rudimentary stalk with intracranial communication
- Clinically resembles dermoid cyst

PATHOLOGY

General Features

- Etiology
  - Considered involuted true cephalocele (meningocele or encephalocele)
  - Originates from overdistended rhombencephalic vesicle at 7-10 weeks of fetal life
    - Presence of persistent midline neural crest cells may prevent mutual induction of ectoderm and mesoderm
  - Postulated link to folate deficiency, valproic acid exposure
- Genetics
  - Typically sporadic, some cases syndromic
  - Syndromic more likely to have associated intracranial anomalies
- Associated abnormalities
  - Variable incidence
    - Most APC are incidentally identified without additional intracranial anomalies
    - Holoprosencephaly, callosal agenesis, eye anomalies, and interhemispheric cyst most common

Gross Pathologic & Surgical Features

- Hamartomatous subgaleal mass with adjacent focal cranium bifidum
- Connects to dura mater via fibrous stalk terminating in falx or tentorium
- CSF tract to supracerebellar, suprapineal, and quadrigeminal cisterns

Microscopic Features

- Meningeal and vestigial neural tissue rests
- CSF tract ependymal lined

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Soft palpable interparietal subgaleal mass
  - Overlying skin may be abnormally thin (cutis aplasia) and hairless (alopecia)
- Other signs/symptoms
  - APC may enlarge with crying
- Clinical profile
  - Subgaleal mass identified incidentally or during imaging evaluation for other anomalies

Demographics

- Age
  - Infants and young children
- Gender
  - M ≤ F
- Epidemiology
  - APC 10x more common than large parietal cephalocele
  - More common in Western hemisphere

Natural History & Prognosis

- Outcome determined more by associated anomalies than presence of APC
  - Children with no associated intracranial anomalies usually have normal clinical outcome
  - Additional intracranial anomalies (more common in syndromic patients) → worse outcome

Treatment

- Surgical resection of cephalocele with dural repair

DIAGNOSTIC CHECKLIST

Consider

- APC in differential diagnosis for child with midline parietal skin-covered subgaleal mass
- Prognosis depends more on associated occult brain anomalies than existence of cephalocele itself

Image Interpretation Pearls

- Persistent falcine sinus points to cephalocele
- Lack of abnormally dilated scalp veins, absence of falcine vein, and characteristic fibrous tract distinguish from sinus pericranii

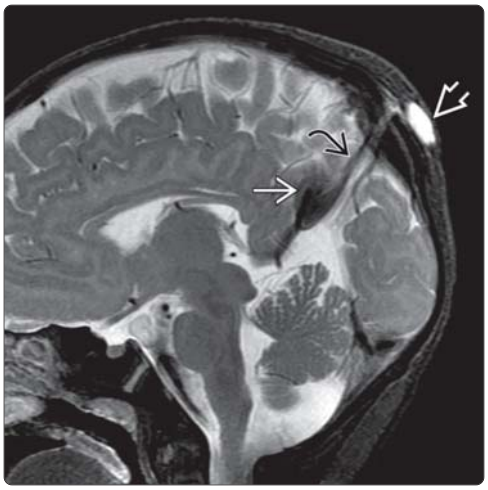
(Left) *Sagittal T1WI MR shows a typical small, subscalp, fluid-filled atretic parietal cephalocele* ➡. **(Right)** *Axial 3D bone CT of the calvaria in the same case demonstrates a small, focal, midline, interparietal calvarial defect* ⇨ *representing the focal cranium bifidum through which the cephalocele communicates intracranially via the fibrous stalk.*



(Left) *Sagittal T1WI FS MR shows a classic atretic parietal cephalocele with falcine vein* ➡ *and fluid collection* ➡. *The fibrous stalk* ⇨ *connecting the cephalocele through the calvarial defect is difficult to distinguish from the venous flow void.* **(Right)** *Sagittal T1WI C+ MR in the same patient shows a persistent falcine vein* ➡ *and a fluid-filled, skin-covered cephalocele* ➡. *The fibrous stalk* ⇨ *connecting the cephalocele through the calvarial defect is clearly visible next to the enhancing falcine vein.*

(Left) *Axial 2D time-of-flight MRV source image clearly demonstrates a focal split of the superior sagittal sinus* ➡ *surrounding the atretic cephalocele fibrous stalk* ⇨. **(Right)** *Sagittal T1WI C+ FS MR demonstrates the uncommon occipital variant of atretic cephalocele. As in the parietal variant, there is an aberrant vein* ➡ *and fibrous tract* ⇨ *"pointing" to the atretic cephalocele* ➡.

https://CafePezeshki.IR

Leptomeningeal Cyst ("Growing Fracture")

KEY FACTS

TERMINOLOGY
- Enlarging calvarial fracture adjacent to post-traumatic encephalomalacia

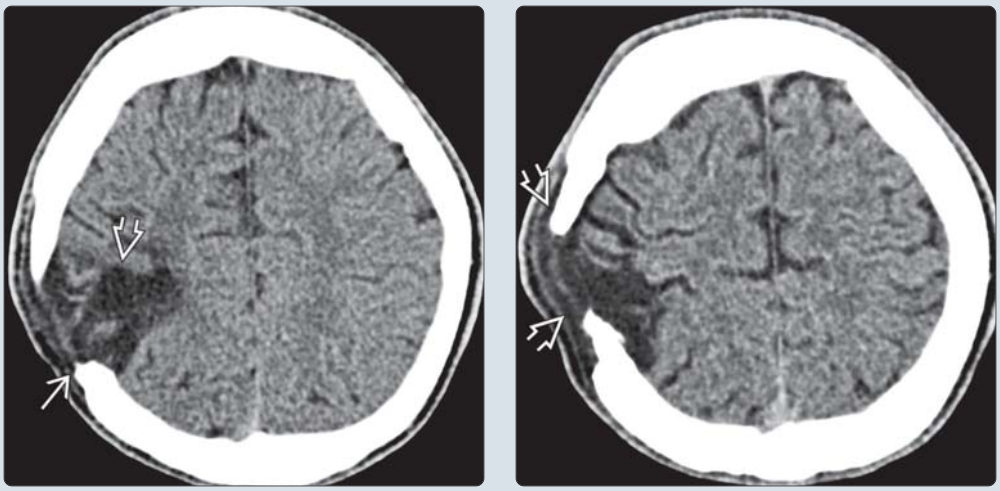
IMAGING
- Linear lytic skull lesion with scalloped margins
- Brain tissue and cerebrospinal fluid (CSF) extending between bone edges acutely
- Subsequent development of encephalomalacia underlying fracture

TOP DIFFERENTIAL DIAGNOSES
- Epidermoid
- Parietal foramina/fissures
- Langerhans cell histiocytosis
- Calvarial metastasis
- Osteomyelitis

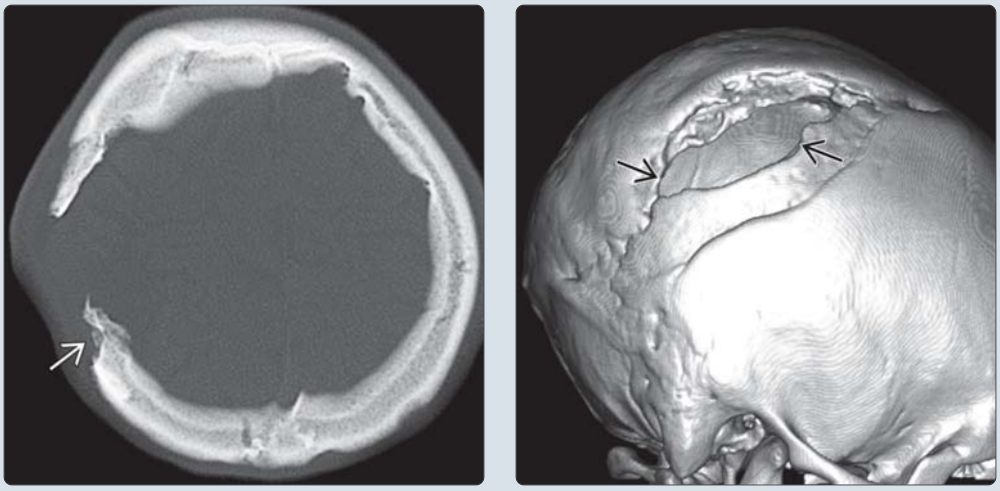
PATHOLOGY
- Scalloped fracture margins with differential erosion of inner, outer tables
- Absence of leptomeninges along inner surface of torn dura, over adjacent brain
- Brain necrosis, gliosis

CLINICAL ISSUES
- Infant or child: Enlarging palpable soft scalp mass
- Adults: Usually discovered as nontender, nonpulsatile, subcutaneous mass
- 90% occur in patients < 3 years

DIAGNOSTIC CHECKLIST
- Consider diagnosis in all infants with radiographic skull defect or palpable scalp mass
- Increasing fracture diastasis over time rather than healing



(Left) *A routine follow-up axial NECT scan in a 14-year-old male was obtained 2 months after a football injury with concussion led to evacuation of a subdural hematoma. The study shows a skull defect ➡ and post-traumatic encephalomalacia ➡.* **(Right)** *Two years later, the same patient noticed a gradually increasing "lump" on the side of his head. Repeat NECT scan shows the edges of the skull defect protrude outwards with a CSF-like mass ➡ extending through the defect under the galea.*



(Left) *Axial bone CT shows the margins of the skull defect are well corticated. Note the scalloping of the outer table of the calvaria ➡.* **(Right)** *3D reformatted image of the bone CT scan with shaded surface display shows widened, scalloped bone defect ⇨. A "growing" skull fracture with leptomeningeal cyst was surgically repaired.*

https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Enlarging calvarial fracture adjacent to post-traumatic encephalomalacia

IMAGING

General Features

- Best diagnostic clue
  - Persistent or widening calvarial fracture line following head trauma
- Location
  - Parietal bone most common

Imaging Recommendations

- Protocol advice
  - Routine NECT viewed in brain and bone algorithm

Radiographic Findings

- Radiography
  - Linear lytic skull lesion with scalloped margins

CT Findings

- NECT
  - Brain tissue, cerebrospinal fluid (CSF) extending between bone edges acutely
  - Subsequent encephalomalacia under fracture

MR Findings

- T1WI
  - Cyst isointense with CSF, communicates with subarachnoid space
  - Subsequent development of encephalomalacia underlying fracture
- T2WI
  - Same as T1WI

DIFFERENTIAL DIAGNOSIS

Epidermoid Cyst

- Well-defined sclerotic margins, + diffusion restriction

Congenital Calvarial Defects

- Look for bilateral symmetry, characteristic location to suggest diagnosis

Langerhans Cell Histiocytosis

- Classic beveled edge appearance unusual in infants prior to development of diploic layer

Calvarial Metastasis

- Consider leukemia, neuroblastoma

Osteomyelitis

- Overlying soft tissue edema, poorly defined infiltrating destructive margins

PATHOLOGY

General Features

- Etiology
  - Skull fracture + dural tear → herniation of pia, arachnoid (leptomeninges) through dural tear
  - Leptomeninges disappear from inner surface of torn dura and over adjacent brain
  - CSF pulsations → progressive skull erosion around fracture
  - Interposition of brain tissue prevents osteoblast migration, inhibits fracture healing
  - Damaged brain becomes necrotic or gliotic → encephalomalacia

Gross Pathologic & Surgical Features

- Absence of leptomeninges along inner surface of torn dura, over adjacent brain

Microscopic Features

- Brain necrosis, gliosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Infant or child: Enlarging palpable soft scalp mass
    - Predisposing fracture may not have been clinically recognized
  - Adults: Usually discovered as nontender subcutaneous mass
    - History of childhood trauma rarely remembered or difficult to elicit

Demographics

- Age
  - 90% occur in patients < 3 years
- Epidemiology
  - Rare: 0.6% of pediatric skull fractures
  - Falling is most frequent injury mechanism

Natural History & Prognosis

- Increasing fracture diastasis over time
- ± progressive neurologic deficits (seizures, paresis), particularly in adult presentation

Treatment

- Surgical repair of dura, cyst resection

DIAGNOSTIC CHECKLIST

Consider

- Consider diagnosis in all infants with radiographic skull defect or palpable scalp mass

Image Interpretation Pearls

- Increasing fracture diastasis over time rather than healing

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Headache caused by ↓ intracranial CSF pressure

IMAGING

- Classic imaging
  - Diffuse dural thickening/enhancement
    - Smooth, not nodular or "lumpy-bumpy"
  - Downward displacement of brain through incisura ("slumping" midbrain)
  - Veins, dural sinuses distended
  - ± subdural hygromas/hematomas
- Lack of 1 or more of 4 classic findings does not preclude diagnosis

TOP DIFFERENTIAL DIAGNOSES

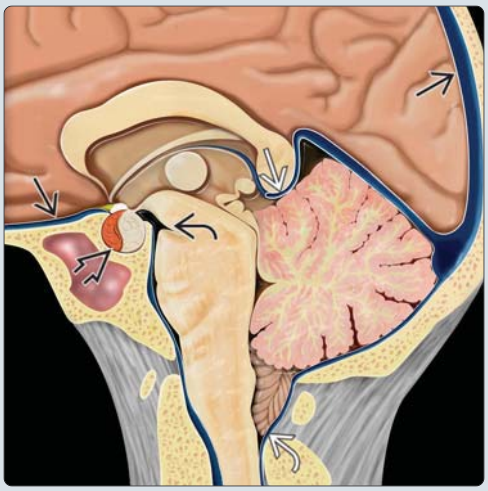
- Meningitis
- Meningeal metastases
- Chronic subdural hematoma
- Dural sinus thrombosis
- Postsurgical dural thickening
- Idiopathic hypertrophic cranial pachymeningitis

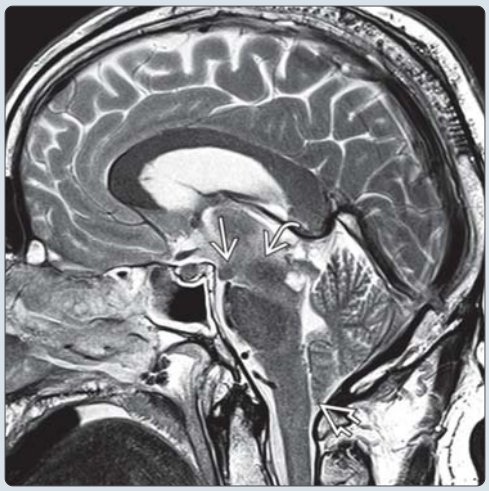
CLINICAL ISSUES

- Severe headache (orthostatic, persistent, pulsatile, or even associated with nuchal rigidity)
- Uncommon: CN palsy (e.g., abducens), visual disturbances
- Rare: Severe encephalopathy with disturbances of consciousness
- Profile: Young/middle-aged adult with orthostatic headache

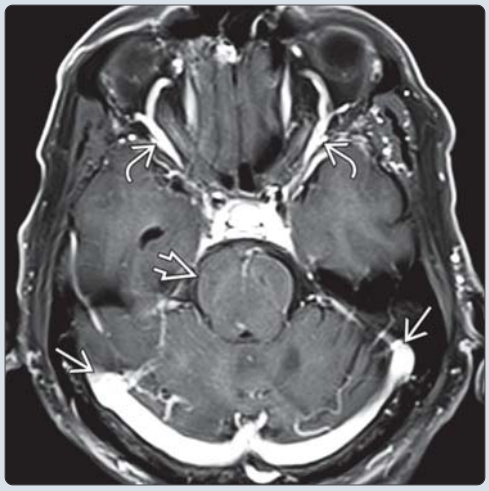
DIAGNOSTIC CHECKLIST

- Frequently misdiagnosed clinically; imaging is key to diagnosis
  - Do not misdiagnose intracranial hypotension as Chiari 1
  - Surgery can exacerbate symptoms; in rare cases can be fatal
- Only rarely are **all** classic findings of IH present in same patient





(Left) *Graphic shows IH with distended dural sinuses, enlarged pituitary, & herniated tonsils. Central brain descent causes midbrain slumping, inferiorly displaced pons, closed pons-midbrain angle, & splenium depressing ICV/vein of Galen junction.* **(Right)** *Sagittal T2 WI in a 57-year-old man treated for "migraine" headaches shows severe midbrain slumping, downwardly displaced cerebellar tonsils, draping of hypothalamus over dorsum sellae with mammillary bodies below dorsum.*



(Left) *Sagittal T1 C+ FS MR scan in the same case shows the severe midbrain "slumping" and inferiorly displaced tonsils. In addition, the pituitary gland appears "fat" and the dural venous sinuses are engorged.* **(Right)** *Axial T1 C+ FS scan in the same case shows a "fat" midbrain/pons, prominent superior ophthalmic veins, and engorged, outwardly convex transverse/sigmoid sinuses. No subdural hematomas were identified. Severe intracranial hypotension was treated successfully with blood patch.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Intracranial hypotension (IH)

Definitions

- Headache caused by ↓ intracranial CSF pressure

IMAGING

General Features

- Best diagnostic clue
  - Classic imaging quartet
    - Downward displacement of brain through incisura ("slumping" midbrain)
    - Diffuse dural thickening/enhancement
    - Veins, dural sinuses distended
    - Subdural hygromas/hematomas
  - Lack of 1 or more of 4 classic findings does not preclude diagnosis
- Location
  - Pachymeninges (dura)
    - Both supra- and infratentorial
    - May extend into internal auditory canals
    - Spinal dura, epidural venous plexuses may be involved
- Morphology
  - Dural enhancement is smooth, not nodular or "lumpy-bumpy"

CT Findings

- NECT
  - Relatively insensitive; may appear normal
  - Look for effaced suprasellar/basilar cisterns, "fat" midbrain/pons
  - ± thick dura
  - ± subdural fluid collections
    - Usually bilateral
    - CSF (hygroma) or blood (hematoma)
  - Atria of lateral ventricles may appear deviated medially, abnormally close ("tethered") to midline
- CECT
  - Diffuse dural thickening, enhancement

MR Findings

- T1WI
  - Sagittal view shows brain descent in 40-50% of cases
    - "Sagging" midbrain
      - Midbrain displaced inferiorly below level of dorsum sellae
      - Pons may be compressed against clivus
    - Decreased angle between peduncles, pons
    - Caudal displacement of tonsils in 25-75%
    - Optic chiasm, hypothalamus draped over sella
    - Pituitary enlarged above sella in 50%
    - Veins/dural sinuses distended (convex margins)
    - Decreased angle between ICVs, vein of Galen
  - Axial
    - Suprasellar cistern crowded/effaced
    - Midbrain, pons appear elongated ("fat" midbrain)
    - Temporal lobes herniated over tentorium, into incisura
    - Lateral ventricles small, often distorted
      - Atria pulled medially by downward displacement of midbrain
  - Coronal
    - Severe cases show decreased venous angle (< 120°) between roofs of lateral ventricles
  - Bilateral subdural fluid collections in 15%
    - 70% hygromas (clear fluid collects within dural border cell layer)
    - 10% hematomas (blood of variable signal intensity)
- T2WI
  - Thickened dura usually hyperintense
  - Subdural fluid (variable signal)
- FLAIR
  - Hyperintense dura, subdural fluid
- T2* GRE
  - May bloom if hemorrhage present
- T1WI C+
  - Diffuse, intense dural enhancement in 85%
  - Often extends into CPAs

Ultrasonographic Findings

- Color Doppler
  - Enlarged superior ophthalmic veins with higher mean maximum flow velocity

Angiographic Findings

- Cortical, medullary veins may be diffusely enlarged

Nonvascular Interventions

- Myelography
  - May demonstrate epidural contrast accumulation at site of CSF leak
    - Dynamic CT myelogram may show "fast" high-flow leaks
  - Caution: Myelography may facilitate CSF leak, worsen symptoms

Nuclear Medicine Findings

- Radionuclide cisternography (RNC)
  - Direct findings: Focal accumulation of radioactivity outside of subarachnoid space at leakage site
  - Indirect findings
    - Rapid washout from CSF space
    - Early appearance of activity in kidneys, urinary bladder
    - Poor migration of isotope over convexities

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced cranial MR for diagnosis
  - Radionuclide cisternography if localization required
- Protocol advice
  - Search for actual leakage site only if
    - 2 technically adequate blood patches fail
    - Post-traumatic leak is suspected

DIFFERENTIAL DIAGNOSIS

Meningitis

- Pia-subarachnoid enhancement > dura-arachnoid

Meningeal Metastases

- Enhancement usually thicker, irregular ("bumpy")

https://CafePezeshki.IR

Chronic Subdural Hematoma

- Look for enhancing membranes with blood products

Dural Sinus Thrombosis

- Look for thrombosed sinus (empty delta sign, etc.)

Postsurgical Dural Thickening

- Look for other postoperative findings (e.g., burr holes)
- May occur almost immediately after surgery, persist for months/years

Idiopathic Hypertrophic Cranial Pachymeningitis

- Headache usually not orthostatic
- May cause bone invasion

PATHOLOGY

General Features

- Etiology
  - Dural thickening, enhancement due to venous engorgement
  - Common cause of IH = spontaneous spinal CSF leak
    - Weak dura ± arachnoid diverticulae common
    - Aberrant extracellular matrix with abnormalities of fibrillin-containing microfibrils
  - Most (but not all) cases caused by reduced CSF pressure precipitated by
    - Surgery (CSF overshunting) or trauma (including trivial fall)
    - Vigorous exercise or violent coughing
    - Diagnostic lumbar puncture
    - Spontaneous dural tear, ruptured arachnoid diverticulum
    - Severe dehydration
    - Disc herniation or osteophyte (rare)
  - Pathophysiology = Monro-Kellie doctrine
    - CSF, intracranial blood volume vary inversely
    - In face of low CSF pressure, dural venous plexuses dilate
- Associated abnormalities
  - Dilated cervical epidural venous plexus, spinal hygromas, retrospinal fluid collections
  - Typical
    - Low opening pressure (OP), < 6 cm H_2O
    - CSF frequently shows pleocytosis, ↑ protein
  - Variant
    - OP occasionally normal (CSF hypovolemia rather than hypotension)
  - Stigmata of systemic connective tissue disorder found in up to 2/3 of patients
    - Marfan, Ehlers-Danlos type 2
    - Clinical findings = minor skeletal features, small joint hypermobility, etc.; may be subtle

Gross Pathologic & Surgical Features

- Surgical specimen generally unremarkable with grossly normal-appearing dura
- Spinal meningeal diverticula (often multiple), dural holes/rents common
- No specific leakage site identified at surgery in at least 50%

Microscopic Features

- Meningeal surface normal
  - No evidence for inflammation or neoplasia
- Inner surface
  - Layer of numerous delicate, thin-walled dilated, vessels often attached to inner surface
  - Nests of meningothelial cells may be prominent, should not be misinterpreted as meningioma
  - May show marked arachnoidal, dural fibrosis if longstanding

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Severe headache (orthostatic, persistent, pulsatile, or even associated with nuchal rigidity)
  - Uncommon: CN palsy (e.g., abducens), visual disturbances
  - Rare: Severe encephalopathy with disturbances of consciousness
- Clinical profile
  - Young/middle-aged adult with orthostatic headache

Demographics

- Age
  - Peak in 3rd, 4th decades

Natural History & Prognosis

- Most IH cases resolve spontaneously
  - Dural thickening, enhancement disappears; midline structures return (ascend) to normal position
- Rare: Coma, death from severe intracranial herniation

Treatment

- Epidural blood patching
- Surgery if blood patch fails (usually large dural tear) or SDHs with acute clinical deterioration

DIAGNOSTIC CHECKLIST

Consider

- Frequently misdiagnosed clinically; imaging is key to diagnosis
  - Do not misdiagnose intracranial hypotension as Chiari 1
    - Surgery can exacerbate symptoms; in rare cases can be fatal

Image Interpretation Pearls

- Only rarely are **all** classic findings of IH present in the same patient
- Look for enlarged spinal epidural venous plexuses

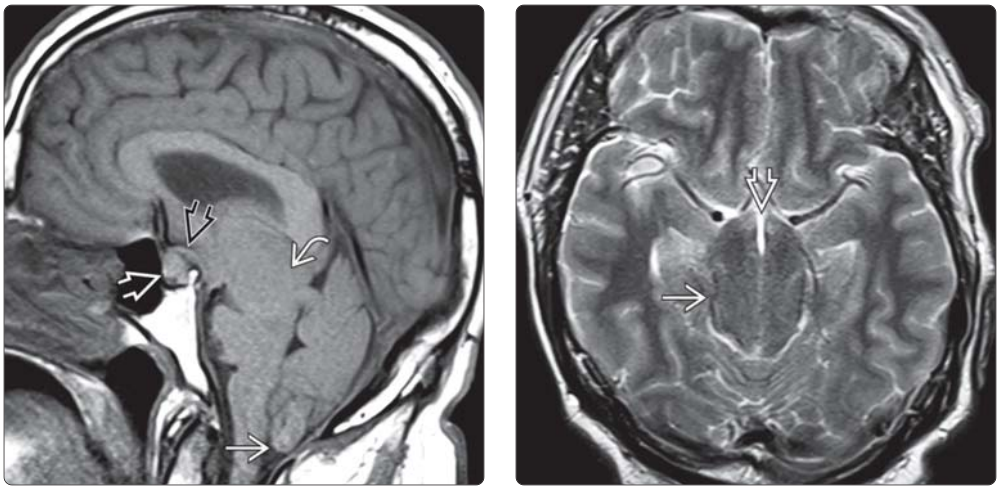
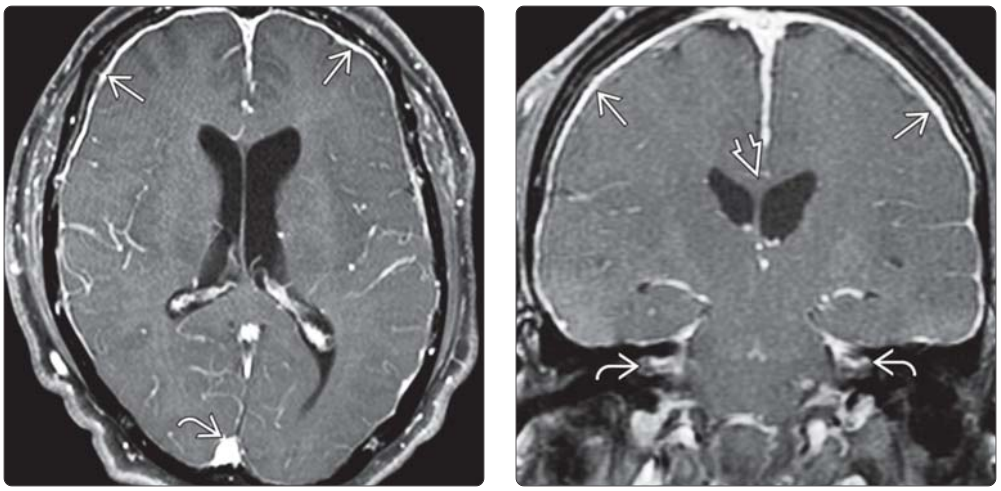
(Left) *Axial NECT in a 55-year-old man with severe headache in the ER shows downward herniation of both cerebellar tonsils through the foramen magnum.* **(Right)** *More cephalad NECT in the same patient shows effacement of all basal cisterns, especially the suprasellar cistern. The midbrain appears "fat". The imaging findings are suggestive of intracranial hypotension.*



(Left) *Sagittal T1WI MR in the same patient shows changes of severe intracranial hypotension, with midbrain "slumping", downward tonsillar displacement, "fat" pituitary gland, and draping of the optic chiasm/hypothalamus over the dorsum sellae.* **(Right)** *Axial T2WI MR in the same patient shows the inferiorly displaced hypothalamus and third ventricle obliterating the suprasellar cistern. The midbrain appears "fat" and elongated.*



(Left) *Axial T1 C+ FS MR in the same patient shows smooth, diffuse dura-arachnoid enhancement and an engorged, outwardly convex superior sagittal sinus.* **(Right)** *Coronal T1 C+ FS MR in the same patient shows the diffuse dura-arachnoid enhancement extends into both internal auditory canals. The lateral ventricles have a more acute angle and appear "pulled down" toward the incisura. Epidural blood patch relieved the symptoms.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Definition: Nonspecific, nonneoplastic benign inflammatory lesion without identifiable local or systemic causes characterized by polymorphous lymphoplasmacytic infiltrate
- Idiopathic orbital inflammation (IOI)
  - May involve any part(s) of orbit
- Idiopathic extraorbital inflammation (IEI)
  - **Intracranial involvement**: Spread through superior orbital fissure (SOF) or optic canal (OC)
    - Cavernous sinus, dura, Meckel cave
  - **Skull base-extracranial involvement**: Spreads from inferior orbital fissure (IOF) or through orbital wall
    - Anterior skull base, sinuses, nasopharyngeal spaces
- IgG4-related disease: Subgroup of idiopathic inflammation with systemic involvement
  - Intracranial noncontiguous sites: Pituitary, infundibulum
  - Extracranial noncontiguous H&N sites: Parotid, submandibular glands, thyroid

IMAGING

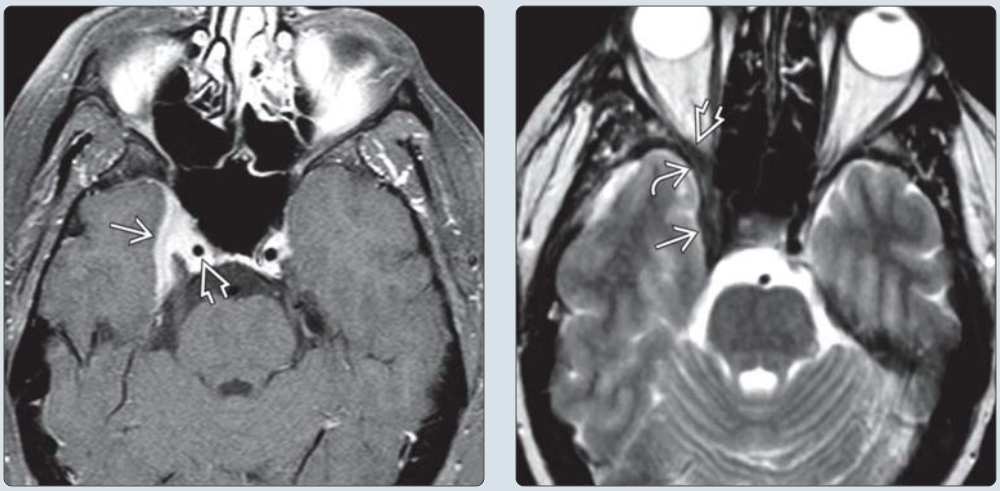
- T1WI C+ FS MR: Diffusely enhancing, infiltrating mass
  - Extends from orbit through SOF ± OC to cavernous sinus, dura, Meckel cave
  - Extends through IOF to pterygopalatine fossa, nose, deep nasopharyngeal spaces
- T2: Iso- to **hypointense** lesion; ↑ fibrosis, ↓ intensity

TOP DIFFERENTIAL DIAGNOSES

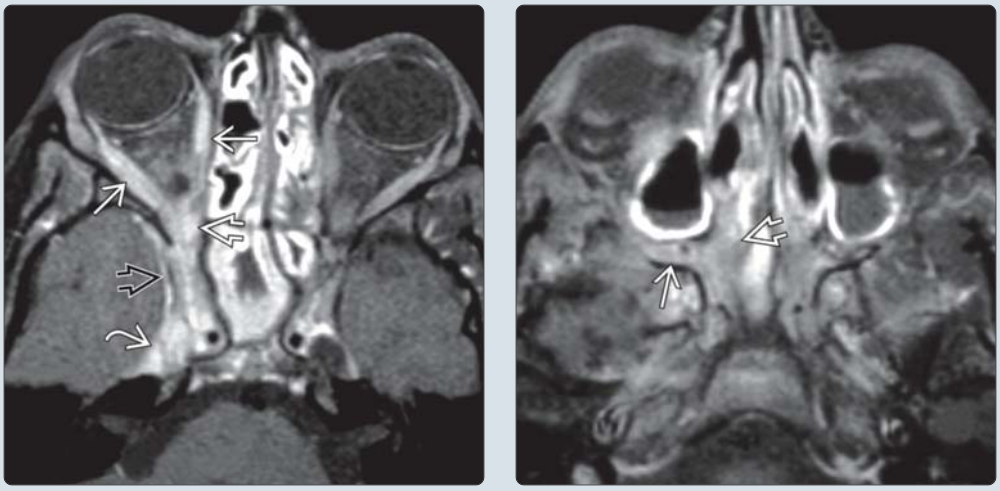
- En plaque meningioma
- Meningeal non-Hodgkin lymphoma
- Nasopharyngeal carcinoma
- Neurosarcoid

CLINICAL ISSUES

- Symptoms: Painful proptosis ± headaches ± cranial neuropathies
- Diagnosis of exclusion; must be biopsied
- Treatment: High-dose systemic **steroids**



(Left) *Axial T1WI C+ FS MR shows a focus of enhancing idiopathic extraorbital inflammation (IEI) involving the right cavernous sinus ⇨ with subtle narrowing ⇨ of the intracavernous internal carotid artery.* **(Right)** *Axial T2WI MR in the same patient reveals a idiopathic orbital inflammation (IOI) lesion ⇨ connects to the cavernous sinus IEI ⇨ through the superior orbital fissure ⇨. Both areas of idiopathic inflammation are hypointense due to the fibrosis often found within this lesion.*



(Left) *Axial T1WI C+ FS MR through the orbits shows enlarged, enhancing orbital rectus muscles ⇨ connecting through the SOF ⇨ with the cavernous sinus ⇨ and Meckel cave ⇨. The initial impression of adenoid cystic carcinoma gave way to biopsy-proven idiopathic inflammation with both intraorbital and intracranial components.* **(Right)** *Axial T1WI C+ FS MR in the same patient shows the lesion invading inferiorly through the inferior orbital fissure into the pterygopalatine fossa ⇨ and nose ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Idiopathic extraorbital inflammation (IEI)

Synonyms

- Idiopathic inflammatory disease, Tolosa-Hunt syndrome, hypertrophic cranial pachymeningitis, plasma cell granuloma

Definitions

- Nonspecific, nonneoplastic benign inflammatory lesion without identifiable local or systemic causes characterized by polymorphous lymphoplasmacytic infiltrate
  - IgG4-related disease (IgG4-RD): Subgroup of idiopathic orbital inflammation (IOI) IEI lesions where multisystem manifestation are present with positive cell immunostain showing IgG4-rich plasma cells

IMAGING

General Features

- Best diagnostic clue
  - IOI combined with contiguous extraorbital (intracranial, skull base, or extracranial) idiopathic inflammation
- Location
  - IOI
    - May involve any part(s) of orbit
  - IEI
    - **Intracranial involvement**: Spread through superior orbital fissure (SOF) or optic canal (OC)
      - Cavernous sinus
      - Dural thickening (previously called "pachymeningitis")
      - Meckel cave area
      - Noncontiguous IgG4-RD: Pituitary, infundibulum
    - **Skull base-extracranial involvement**: Spreads from inferior orbital fissure (IOF) or through orbital wall
      - Pterygopalatine fossa, nose, sinuses
      - Anterior skull base, sinuses
      - Deep spaces of nasopharynx
      - Noncontiguous IgG4-RD: Parotid, submandibular glands, thyroid
- Size
  - Small, subtle to very extensive extraorbital involvement
  - Skull base and extracranial soft tissue masses may be large (many centimeters)
- Morphology
  - Soft tissue infiltrating lesions mimic invasive malignancy

CT Findings

- CECT
  - Orbital enhancing, infiltrating mass with extension through SOF or OC to cavernous sinus, dura, skull base
    - If extension through IOF, lesion reaches pterygopalatine fossa, nose, sinuses, deep spaces
    - If extension through orbital wall, sinuses or anterior skull base affected
- Bone CT
  - Associated bone erosion unusual
- CTA
  - If cavernous internal carotid artery (ICA) involved, often narrowed

MR Findings

- T1WI
  - Lesion isointense to gray matter
- T2WI
  - Iso- to **hypointense** infiltrating mass
    - Increased **fibrosis** yields increased hypointensity
- FLAIR
  - No adjacent brain edema
- T1WI C+
  - Orbital enhancing, infiltrating lesion spread to intra- ± extracranial contiguous sites
    - Extends though SOF-OC to cavernous sinus, local dura, Meckel cave
    - Extends through IOF to pterygopalatine fossa, nose, sinuses, deep spaces
    - If extension through orbital wall, sinuses or anterior skull base affected
- MRA
  - If cavernous sinus involved, **ICA narrowing** common

Imaging Recommendations

- Protocol advice
  - Begin with MR, including full brain FLAIR and T1WI C+ with fat saturation
    - Fat-saturated T1 C+ best sequence
  - Bone CT may help differentiate this lesion from en plaque meningioma

DIFFERENTIAL DIAGNOSIS

En Plaque Meningioma

- Enhancing meningeal mass with dural "tails"
- Permeative-sclerotic invasive bone changes typical
- May exactly mimic intracranial IEI

Meningeal Non-Hodgkin Lymphoma (NHL)

- More diffuse, multifocal with underlying bone involvement
- "Great pretender" (can mimic many intracranial diseases)

Nasopharyngeal Carcinoma

- Arises in nasopharyngeal mucosal space
- Invades cephalad into skull base, sinuses
- Orbit usually spared

Neurosarcoid

- Systemic manifestations abound
- Increased erythrocyte sedimentation rate (ESR) and serum angiotensin converting enzyme (ACE)

Skull and Meningeal Metastases

- Simultaneous orbital metastases unusual
- Nodular meningeal carcinomatosis less common than diffuse carcinomatosis
- Cranial neuropathy occurs early

PATHOLOGY

General Features

- Etiology
  - Benign inflammatory process of unknown origin

https://CafePezeshki.IR

- Immune-autoimmune pathophysiology suspected
- IgG4-RD is now recognized as subgroup of IOI-IEI

Microscopic Features

- Characteristic histopathologic features of IOI and IEI
  - Diffuse lymphoplasmacytic infiltration
  - Varying degrees of **fibrosis** present

IgG4-Related Disease Subtype Additional Features

- Microscopic features
  - IgG4-RD subgroup: IgG4-rich plasma cells
  - IgG4-RD subgroup: Mild to moderate eosinophil infiltrate
- Immunohistochemical features
  - Semiquantitative analysis of **IgG4 immunostaining** may provide compelling features
    - > 30 IgG4-positive cells per high-power field
    - IgG4:IgG ratio > 50%
    - Lower values of IgG4-positive cells acceptable for diagnosis when characteristic microscopic appearance is present
- Serum IgG4 levels
  - Serum IgG4 is not by itself sufficient to diagnose IgG4-related disease
  - Serum IgG4 is elevated in majority (can reach ≥ 25x normal) but can be seen in 20-40% of normals

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - IOI and IEI
    - Orbital lesion: **Painful proptosis**
    - Intracranial lesion only: Chronic headaches
    - Cavernous sinus: Cranial neuropathy (CN3, 4, 5, 6)
    - Extracranial soft tissues: Focal or diffuse mass
      - Sinonasal, nasopharyngeal space mass
  - IgG-RD subtype: Other sites involved
    - Tumor-like lesion with indolent disease course (develops over months to years)
    - Head and neck: Salivary glands > thyroid gland, lymph nodes, laryngeal disease
      - Orbit: Bilateral > unilateral proptosis ± CN2 symptoms from optic nerve compression
      - Suprahyoid neck: Chronic sialoadenitis (submandibular = Küttner tumor; parotid = Mikulicz disease)
      - Infrahyoid neck: Hypothyroidism ± goiter (Hashimoto and Riedel thyroiditis); lymph nodes
    - Involvement outside of head and neck
      - Brain: Pituitary hypophysitis
      - Chest: Lung lesions; fibrosing mediastinitis and pleuritis
      - Abdomen: Type 1 autoimmune pancreatitis, sclerosing cholangitis, cholecystitis, renal lesions, retroperitoneal fibrosis
      - Vascular: Aortitis, arteritis
- Clinical profile
  - Adult presenting with painful proptosis, headaches, and cranial nerve palsies

Demographics

- Age
  - Extraorbital: Adults (40-65 years of age)

Natural History & Prognosis

- Idiopathic intraorbital and extraorbital inflammation
  - Rapid response to steroid therapy common
  - When extensive extraorbital involvement present, may be resistant to all therapies
    - May cause severe disability or death

Treatment

- Options, risks, complications
  - **Diagnosis of exclusion**
    - Extraorbital disease must be biopsied
    - Biopsy excludes infectious and neoplastic (meningioma, NHL) causes of focal dural thickening
  - **High-dose systemic steroids** with slow taper is principal treatment option
    - 70% success rate
  - Steroid-resistant cases ± cases with extensive skull base involvement
    - Radiotherapy ± chemotherapy
    - Surgical resection as possible

DIAGNOSTIC CHECKLIST

Consider

- IEI is diagnosis of exclusion
  - 1st exclude infection and malignancy with biopsy

Image Interpretation Pearls

- If infiltrating mass in orbit with contiguous dural and cavernous sinus lesion, consider IEI
- IOI alone > > IOI + IEI > > IEI alone (rare)
- If IOI + IEI with noncontiguous head and neck lesions of salivary glands, thyroid, lymph nodes ± systemic disease, consider subgroup IgG-RD
  - Recommend IgG4 immunostaining of tissue biopsy and serum IgG4 analysis

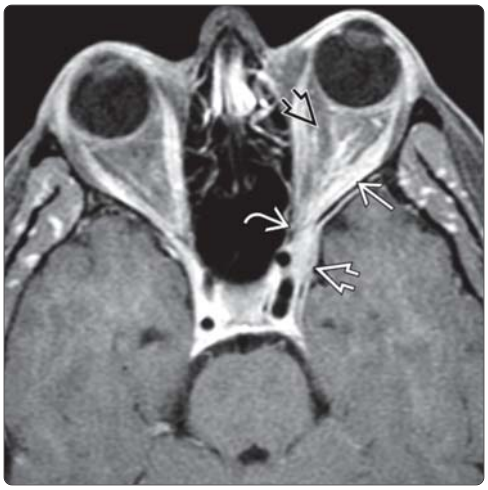
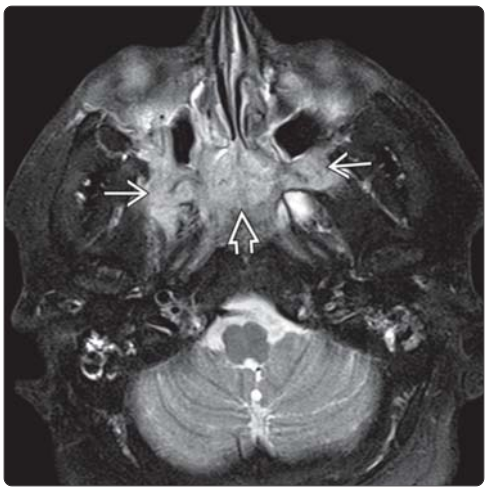
8. Bencherif B et al: Intracranial extension of an idiopathic orbital inflammatory pseudotumor. AJNR Am J Neuroradiol. 14(1):181-4, 1993

https://CafePezeshki.IR



(Left) *In this patient with painful proptosis, axial T1WI C+ FS MR shows an intraorbital lateral rectus ⇨ and intraconal ⇨ lesion. Note the idiopathic inflammation spreads through the superior orbital fissure (SOF) ⇨ to the anterior cavernous sinus ⇨.* **(Right)** *Coronal T1WI C+ FS MR in the same patient shows the intracranial extension of the lesion into the left cavernous sinus ⇨. Idiopathic orbital inflammation extending into the cavernous sinus is the most common form of extraorbital extension.*

(Left) *Axial T1WI C+ FS MR shows extensive orbital apex ⇨, ethmoid sinus ⇨, and foramen rotundum ⇨ infiltrating, enhancing idiopathic inflammation.* **(Right)** *On a more inferior slice in the same patient, axial T1WI C+ FS MR reveals bilateral pterygopalatine fossa ⇨ involvement with continuous intranasal IEI ⇨. Both inferior orbital fissures are also affected ⇨. Large IOI-IEI deposits often respond poorly to steroid treatment.*



(Left) *Axial T2WI FS MR in the same patient shows an infiltrating idiopathic inflammation in the orbital apex ⇨, ethmoid sinus ⇨, and foramen rotundum ⇨. Hyperintense obstructed sinuses are easily differentiated from the IOI-IEI. Hypointensity results from diffuse fibrosis often seen within larger lesions.* **(Right)** *Axial T2WI FS MR in the same patient shows extensive idiopathic extraorbital inflammation involving of the pterygopalatine fossae ⇨ and posterior nose ⇨.*

https://CafePezeshki.IR

IgG4-Related Disease

KEY FACTS

TERMINOLOGY

- IgG4-related disease (IgG4-RD)
- Chronic fibroinflammatory disease characterized by IgG4(+) plasma cell infiltrates

IMAGING

- Diffusely infiltrating enhancing mass
  - Orbital adnexae (lacrimal gland most common)
  - Dura-arachnoid (IgG4-related hypertrophic pachymeningitis)
  - Pituitary gland, stalk (hypophysitis)
  - Other: Cranial nerves (especially infraorbital nerve), brain (autoimmune-like encephalopathy)
- MR
  - Isointense to brain on T1WI, hypointense on T2WI
  - Enhances strongly, uniformly

TOP DIFFERENTIAL DIAGNOSES

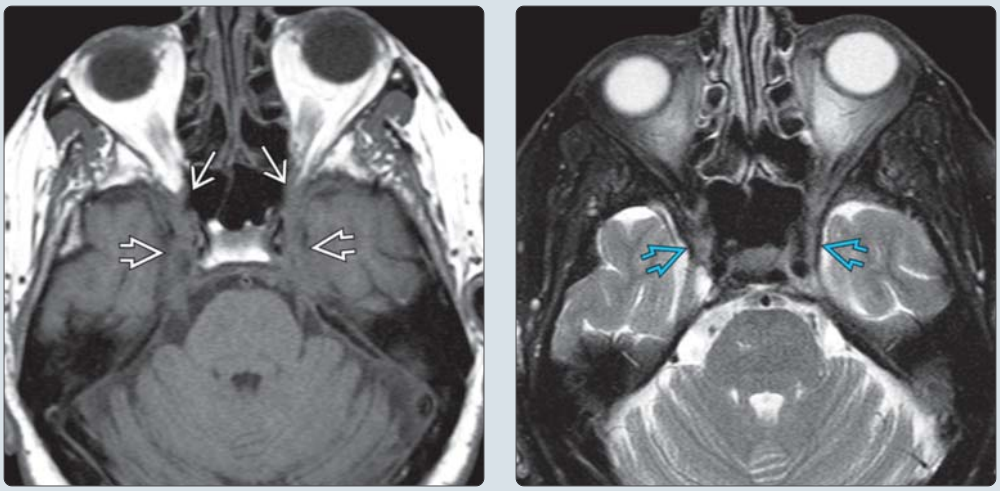
- Idiopathic inflammatory pseudotumor
- Meningioma
- Neurosarcoid
- Lymphoma

CLINICAL ISSUES

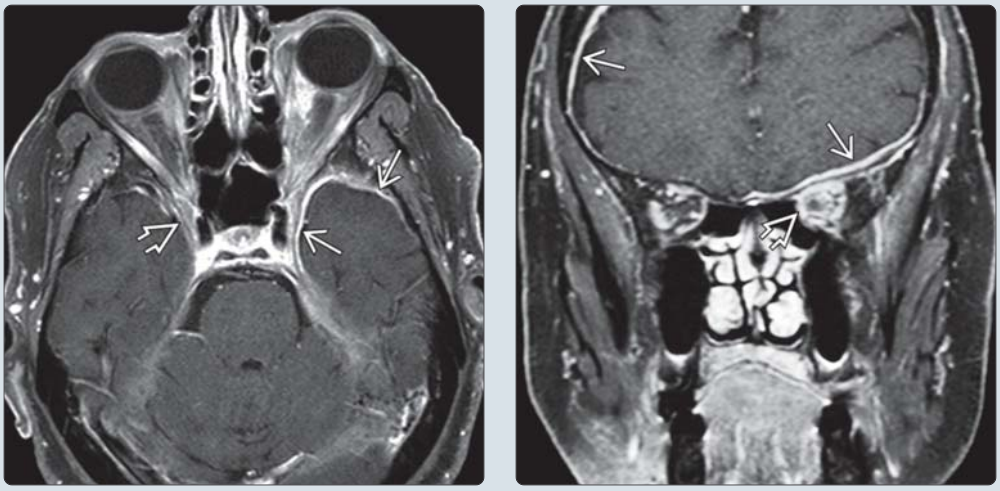
- All ages, but 6th-7th decades most common
  - Exophthalmos, headache
  - Cranial neuropathy
- Clinical course
  - Glucocorticosteroids → improvement/remission (relapses common if tapered/discontinued)
- Between 3-30% of IgG4-RD patients have normal serum IgG4 concentrations
- Elevated serum IgG4 is **not** diagnostic of IgG4-RD (neither sensitive nor specific)

DIAGNOSTIC CHECKLIST

- Best diagnostic clue is combination of clinical history, physical examination, laboratory, imaging



(Left) *Axial T1WI MR in an 81-year-old man with decreasing vision in his left eye shows diffuse infiltration of the cavernous sinus ⇨ and orbital apices ⇨ by soft tissue that is isointense relative to the brain. The lacrimal glands are not affected.* **(Right)** *Axial T2 FS MR in the same patient shows the infiltrates ⇨ are hypointense relative to the brain.*



(Left) *T1 C+ FS MR in the same patient shows the cavernous sinus ⇨ and orbital apex infiltrates enhance strongly. In addition, note thickened, enhancing dura-arachnoid ⇨ in the left middle cranial fossa.* **(Right)** *Coronal T1 C+ FS scan in the same case shows that the dura-arachnoid enhancement is bilateral ⇨, and the posterior orbit is filled with enhancing soft tissue ⇨ that surrounds and encases the left optic nerve. Biopsy disclosed IgG4-related disease.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- IgG4-related disease (IgG4-RD)

Synonyms

- Organ-specific conditions now related to IgG4
  - Mikulicz disease (lacrimal, parotid, submandibular glands)
  - Autoimmune pancreatitis (AIP)
  - Ormond disease (retroperitoneal fibrosis)
  - IgG4-related ophthalmic disease
- "Idiopathic" pseudotumor (generic)

Definitions

- Chronic fibroinflammatory disease characterized by IgG4(+) plasma cell infiltrates

IMAGING

General Features

- Best diagnostic clue
  - Diffusely infiltrating, enhancing mass involving orbit, cavernous sinus, dura
- Location
  - Can affect nearly any organ
    - Pancreas, kidney, retroperitoneum most common
    - Can cause granulomatosis with polyangiitis (formerly Wegener)
  - Head and neck
    - Salivary glands
    - Orbital adnexal structures (lacrimal gland most common)
      - Bilateral disease common
    - Otologic involvement occurs but less common
  - CNS
    - Dura-arachnoid (IgG4-related hypertrophic pachymeningitis)
    - Pituitary gland, stalk (hypophysitis)
    - Other: Cranial nerves (especially infraorbital nerve enlargement), brain (autoimmune-like encephalopathy)

CT Findings

- May be normal if no orbital involvement
- Bone erosion if involves skull base

MR Findings

- T1WI
  - Infiltrative mass isointense with brain
- T2WI
  - Hypointense
- T1WI C+
  - Enhances strongly, uniformly
    - Dura-arachnoid thickening ± focal mass-like lesion
    - Pituitary stalk, cranial nerves may be infiltrated

Nuclear Medicine Findings

- Hypermetabolic on FDG PET/CT
  - May delineate multiorgan involvement (e.g., aorta)

Imaging Recommendations

- Best imaging tool
  - Thin-section T1-, T2WI; contrast-enhanced axial, coronal

DIFFERENTIAL DIAGNOSIS

Idiopathic Inflammatory Pseudotumor

- Many "idiopathic" pseudotumors may be IgG4-RD
- "Idiopathic" hypertrophic pachymeningitis may be IgG4-RD

Meningioma

- En plaque meningioma of greater sphenoid wing can mimic IgG4-RD
- Bone thickening, erosion more common

Neurosarcoid

- May require biopsy for diagnosis

Lymphoma

- Metastatic > primary CNS lymphoma
- Skull ± "lumpy-bumpy" dura-arachnoid

PATHOLOGY

Gross Pathologic & Surgical Features

- "Tumefactive" mass-like lesion
- Variable fibrosis

Microscopic Features

- IgG4(+) plasma infiltrate

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Exophthalmos, headache
- Other signs/symptoms
  - Cranial neuropathy

Demographics

- Age
  - 6th-7th decades most common

Natural History & Prognosis

- Relapsing, remitting

Treatment

- Steroids (improve; relapses common)

DIAGNOSTIC CHECKLIST

Consider

- Best diagnostic clue is combination of clinical history, physical examination, laboratory, and imaging
  - 3-30% of IgG4-RD patients have normal serum IgG4 concentrations
  - Elevated serum IgG4 is **not** diagnostic of IgG4-RD (neither sensitive nor specific)
- Biopsy recommended for diagnosis, excluding malignancy
  - Immunohistochemistry shows IgG4(+) plasma cells
    - Caution: Occur in conditions other than IgG4-RD

SELECTED REFERENCES

KEY FACTS

TERMINOLOGY

- Fibrous dysplasia (FD)
  - Synonyms: Craniofacial fibrous dysplasia (CFD), osteitis fibrosa, osteodystrophy fibrosa
- McCune-Albright syndrome (MAS)
  - One of the most common FD syndromes
- Congenital disorder characterized by expanding lesion(s)
  - Defect in osteoblastic differentiation, maturation
  - Contains mixture of fibrous tissue, woven bone

IMAGING

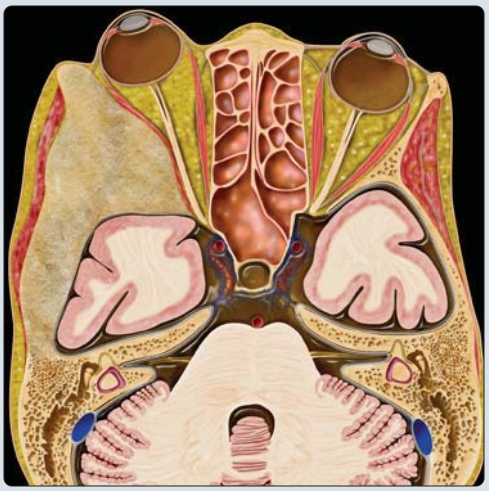
- Best diagnostic clue: Ground-glass matrix in bone lesion on CT
- CFD: Majority have > 1 bone involved
- MR: ↓ T2WI signal throughout (if solid) or in rim (if cystic)
  - Variable enhancement
  - Rim, diffuse, or none

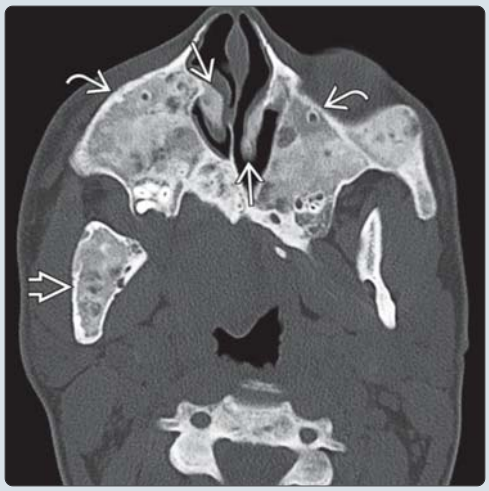
TOP DIFFERENTIAL DIAGNOSES

- Paget disease
- Garré sclerosing osteomyelitis
- Meningioma

CLINICAL ISSUES

- Most common signs/symptoms: Painless swelling or deformity
- Demographics
  - < 6 years (39%), 6-10 years (27%), > 10 years (39%)
  - MAS usually (but not exclusively) female
  - Monostotic FD 6x more common than polyostotic FD
  - Monostotic FD (75%): 25% found in skull, face
  - Polyostotic FD (25%): 50% found in skull, face
  - Calvarial involvement differs: Polyostotic FD (50%) > monostotic FD (25%)
- RARE progression to fibro-, osteo-, chondro-, and mesenchymal sarcoma





(Left) *Axial graphic shows expansion of the lateral orbital rim, sphenoid wing, and temporal squamosa by fibrous dysplasia. Note the exophthalmos and stretching of the optic nerve on the ipsilateral side.* **(Right)** *Axial bone CT in a 16-year-old male with McCune-Albright syndrome shows classic findings of polyostotic fibrous dysplasia (FD). The typical expansile lesions with ground-glass appearance are seen in the right mandible, both maxillary sinuses, and even the bony nasal turbinates.*

(Left) *Another cephalad scan in the same patient shows the basisphenoid, sphenoid alae, and frontal bones are expanded with mottled ground-glass pattern intermixed with more heterogeneous areas of radiopacity and radiolucency. Note the narrowing of the right optic canal.* **(Right)** *More cephalad scan in the same patient shows the classic multifocal areas of bony expansion with characteristic ground-glass appearance of FD.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Fibrous dysplasia (FD)

Synonyms

- Craniofacial fibrous dysplasia (CFD), osteitis fibrosa, osteodystrophy fibrosa
- McCune-Albright syndrome (MAS): One of the most common FD syndromes
- Jaffe-Lichtenstein dysplasia (monostotic FD)

Definitions

- Congenital disorder characterized by expanding lesions with mixture of fibrous tissue and woven bone
- Defect in osteoblastic differentiation and maturation
- One of the most common fibroosseous lesions

IMAGING

General Features

- Best diagnostic clue
  - Ground-glass matrix in bone lesion on CT
- Location
  - May involve any aspect of skull
  - CFD: Majority have > 1 bone involved
    - Maxilla, orbit, and frontal bones most common in one series; ethmoids and sphenoids in another

Radiographic Findings

- Radiography
  - Expanded bone with ground-glass appearance
  - CFD: Dental malocclusions in 20%

CT Findings

- NECT
  - Imaging patterns relate to relative content of fibrous and osseous tissue
  - Expansile bone lesion, widened diploic space
  - Ground-glass, sclerotic, cystic, or mixed bone changes
    - If cystic, may have thick sclerotic rind

MR Findings

- T1WI
  - Usual: ↓ signal
- T2WI
  - Usual: ↓ signal (if solid) or in rind (if cystic)
  - ↑ clinical-pathologic activity leads to ↑ signal
- T1WI C+
  - Variable enhancement depends on lesion pattern (rim, diffuse, or none)

Nuclear Medicine Findings

- Bone scan
  - Variable radionuclide uptake: Perfusion/delayed phases
  - Nonspecific; sensitive to extent of skeletal lesions in polyostotic FD
- PET
  - Accumulation of 11C-MET
  - Can be variably hot on FDG PET
    - Should not be mistaken for metastasis
    - Correlation with radiograph, CT helps

Imaging Recommendations

- Best imaging tool
  - Bone CT
- Protocol advice
  - CT or MR to define local extent
  - Bone scan to search for additional lesions

DIFFERENTIAL DIAGNOSIS

Paget Disease

- Pagetoid ground-glass FD mimics Paget disease
- Paget: Calvaria, not craniofacial; "cotton wool" CT

Garré Sclerosing Osteomyelitis

- Bony expansion, but inhomogeneous sclerotic pattern; ± dehiscent bone cortex; ± periosteal reaction

Jaffe-Campanacci (J-C) Syndrome

- Nonossifying fibromas, axillary freckling, and café au lait (lacks neurofibromas)
- Mimics polyostotic forms of FD
  - J-C café au lait: Coast of California (like neurofibromatosis type 1)
  - McCune-Albright café au lait: Coast of Maine

Craniometaphyseal Dysplasia

- Hyperostosis and sclerosis of craniofacial bones → facial distortion, cranial nerve compression
- Abnormal modeling of long bone metaphyses; paranasal "bossing"

Meningioma

- Resulting hyperostosis mimics FD
- MR spectroscopy: Characteristic alanine peak

Other Disorders With Expanded Bone and Abnormal Bony Density

- Thalassemia: Maxillary sinus involvement typical; "hair on end" skull
- Osteopetrosis: Involvement of all bones
- Neurocutaneous disorders: Osteitis fibrosa cystica in
  - Tuberous sclerosis
  - Neurofibromatosis type 1
- Chronic renal failure: Renal osteodystrophy may simulate leontiasis ossea
- Morgagni syndrome of hyperostosis frontalis interna
  - Postmenopausal women, limited to frontal bone

PATHOLOGY

General Features

- Etiology
  - Mutation of Gsα protein in osteoblastic progenitor cells leads to ↑ proliferation; abnormal differentiation
- Genetics
  - Numerous up-/down-regulated genes described
    - Mutations in regulatory Gsα protein (encoded by *GNAS1* gene) common to monostotic, polyostotic, and MAS
    - *ADAMTS2* significantly overexpressed in FD tissues

Staging, Grading, & Classification

- Monostotic vs. polyostotic

https://CafePezeshki.IR

- Specific lesion type (pagetoid, sclerotic, cystic) relates to disease activity
  - Cystic, pagetoid, and sclerotic FD believed to represent (in order) most to least active
    - Cystic FD (11-21%): Hypodense (CT) except rind
    - Pagetoid mixed FD (56%): Ground-glass plus cystic change
    - Homogeneous sclerotic FD (23-34%)

Gross Pathologic & Surgical Features

- Fibrous, tan to gray gritty tissue
- Variable consistency depends upon fibrous vs. osseous components
- Woven bone immature, structurally weak, prone to fractures
- Hemorrhage, cystic change may be present

Microscopic Features

- Fibrous stroma, usually avascular, low cellularity
- Osseous metaplasia: Bone trabeculae made up of immature, woven bone seen as peculiar shapes floating in fibrous stroma
  - Looks like "Chinese letters" or "alphabet soup"

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Swelling &/or deformity, pain
- Clinical profile
  - Proptosis, cranial neuropathy (diplopia, hearing loss, blindness), atypical facial pain or numbness, headache
  - Multiple endocrine disorders typically with severe polyostotic FD
- Presentations: Monostotic, polyostotic, craniofacial (CFD), syndromic (many known syndromes)
  - Monostotic FD
    - 70% of all FD cases; single osseous site affected
      - Skull, face involved in 27%
      - Most common: Maxilla (especially zygomatic process), mandible (molar area)
      - Less common: Frontal > ethmoid, sphenoid > temporal > occipital bones
    - Older children/young adults (75% present < 30 years)
  - Polyostotic FD
    - 30% of all FD cases; involves ≥ 2 separate sites
    - Skull, face involved in 50%
    - Younger group, 2/3 have symptoms by age 10
  - CFD
    - Autosomal dominant, stabilizes with skeletal maturity
  - McCune-Albright syndrome
    - Subtype of unilateral polyostotic FD: Clinical triad of polyostotic FD, hyperfunctioning endocrinopathies, café au lait spots
    - 5% of FD cases; appears earlier; affects more bones more severely
    - Renal phosphate wasting (50%) associated with elevation of circulating factor FGF-23; may result in rickets and osteomalacia
  - Mazabraud syndrome
    - Polyostotic FD, intramuscular myxoma
  - Cherubism: Familial bilateral FD of jaw
  - "Mulibrey" nanism: Severe, progressive growth failure; pericardial constriction; primarily Finland
    - **Mu**scle, **li**ver, **br**ain, **ey**e = triangular face, yellow ocular fundi pigment, hypoplastic tongue, peculiar high voice, nevi flammei (65%)
    - FD of long bones in 25%

Demographics

- Age
  - < 6 years (39%), 6-10 years (27%), > 10 years (39%)
- Gender
  - MAS usually (but not exclusively) female
- Epidemiology
  - Actual incidence unknown
    - Monostotic FD is 6x more common than polyostotic FD
    - Calvarial involvement differs: Polyostotic FD (50%) > monostotic FD (25%)
    - Monostotic FD (75%): 25% found in skull, face
    - Polyostotic FD (25%): 50% found in skull, face

Natural History & Prognosis

- **Rare** progression to osteo-, fibrous-, chondro-, and mesenchymal sarcoma
  - Usually polyostotic/syndromic forms
  - Nearly 1/2 arise following irradiation (marked increase in malignant potential)
- Monostotic craniofacial FD has excellent prognosis
- Most spontaneously "burn out" in teens, 20s

Treatment

- Aggressive resection reserved for visual loss, severe deformity ("vault" more accessible than skull base)
- No radiation therapy → malignant progression
- Alendronate treatment doesn't change pain scores, skeletal disease burden scores, or functional parameters

DIAGNOSTIC CHECKLIST

Consider

- Monostotic and polyostotic FD likely on same spectrum of phenotypic expression; consider checking for gene to predict complications

Image Interpretation Pearls

- Ground-glass appearance on plain films or CT, homogeneously decreased signal on T2WI characteristic

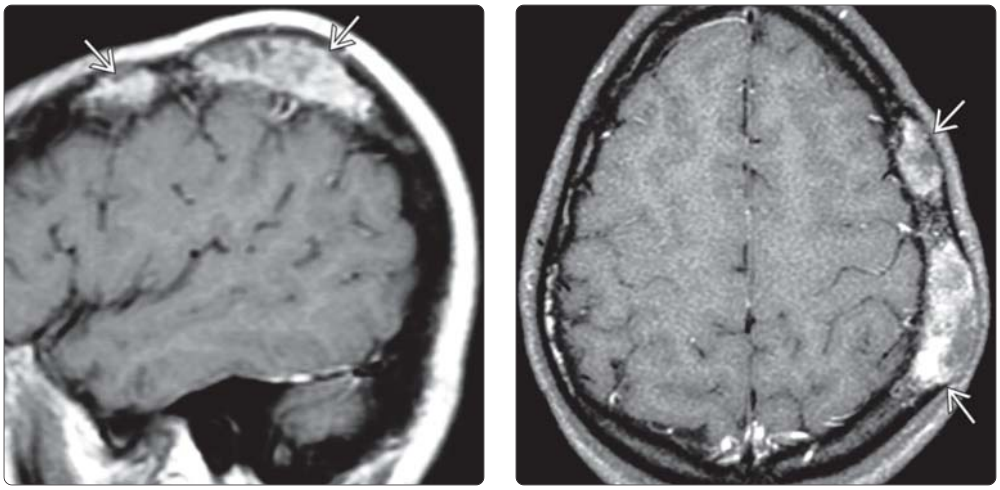
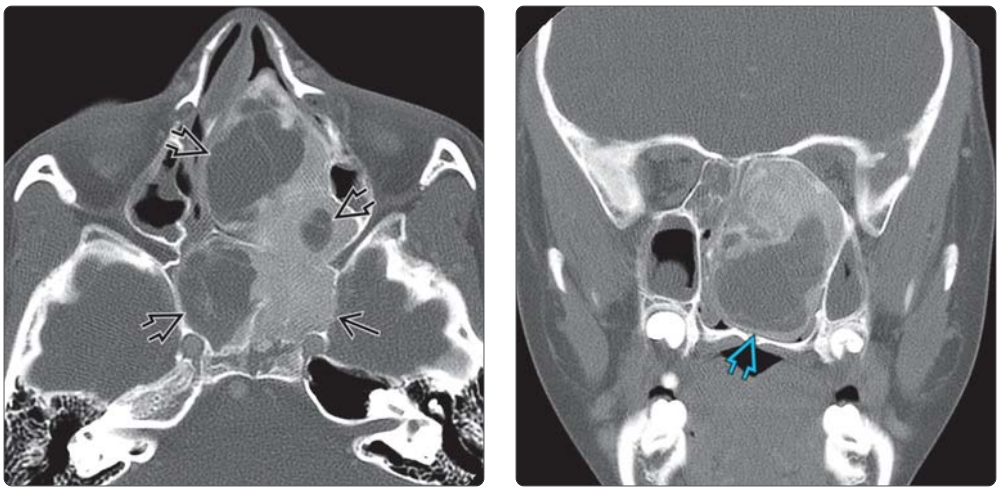
(Left) *Sagittal T1WI MR in a 17-year-old male with a slowly enlarging "scalp bump" shows an expansile calvarial mass* ➡ *that is moderately hypointense.* **(Right)** *Axial T2WI FS MR in the same patient shows the lesion* ➡ *is slightly heterogeneously hypointense.*



(Left) *Sagittal T1WI C+ MR in the same patient shows 2 calvarial lesions* ➡ *that enhance moderately strongly but heterogeneously.* **(Right)** *Axial T1WI C+ FS shows the lesions* ➡ *exhibit avid but heterogeneous enhancement. The imaging findings are characteristic of active fibrous dysplasia.*



(Left) *Axial bone CT in a 9-year-old female shows the cystic variant of fibrous dysplasia. Note the areas of frank cystic formation* ⇨ *within and adjacent to more characteristic ground-glass appearance* ⇨. **(Right)** *Coronal bone CT in the same patient shows the expansile nasoethmoidal FD with the internal cystic changes characterized by thin but sclerotic borders* ⇨.

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Chronic metabolic skeletal disorder
- Characterized by bony expansion with variable destruction ± sclerosis

IMAGING

- Well-circumscribed, sharply marginated defects &/or marked thickening + sclerosis
- Skull in 25-65% (may be isolated to skull base)
  - Diploic widening, coarse trabecula, thick cortices
  - "Tam-o'-shanter" skull: Marked ↑ diploic space, particularly inner table
  - "Cotton wool" skull: Focal sclerosis within previous areas of "osteoporosis circumscripta"
- Platybasia
- Typically "hot" throughout all bone scan acquisitions (blood flow, blood pool, static)
- Bone scans + radiographs abnormal in 56-86%

TOP DIFFERENTIAL DIAGNOSES

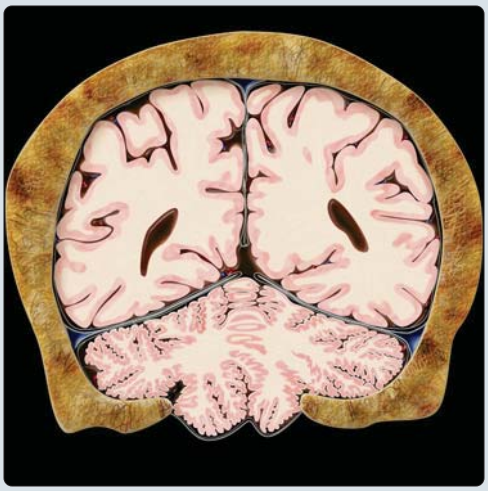
- Osteosclerotic metastases
- Osteolytic metastases
- Fibrous dysplasia
- Other causes of calvarial thickening

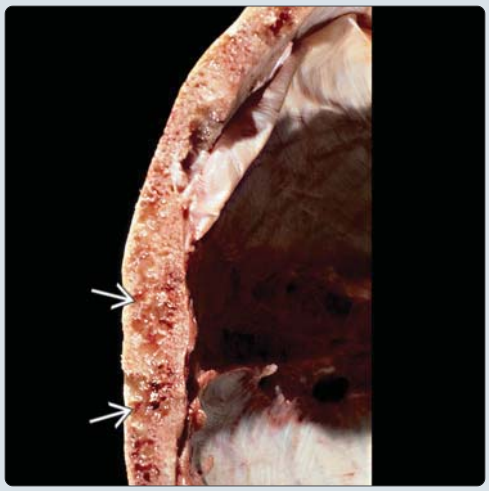
PATHOLOGY

- Excessive and abnormal remodeling of bone, with both active and quiescent phases
  - Localized areas of ↑ bone resorption + exuberant but aberrant new bone formation
- Individual sites progress at variable rates
  - PD of differing phases may be seen within same patient

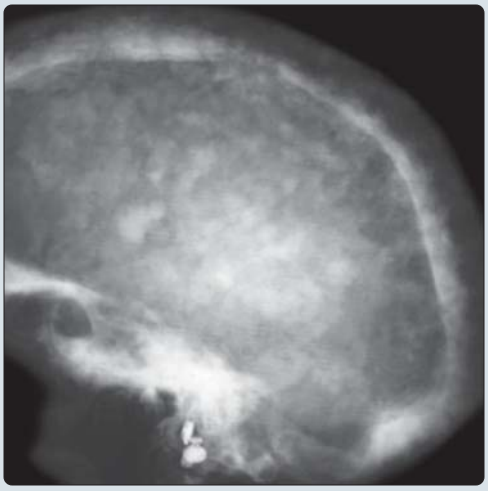
CLINICAL ISSUES

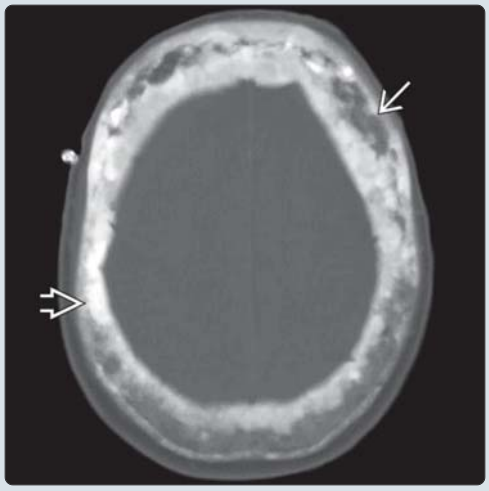
- 20% asymptomatic; pain, tenderness, ↑ hat size
- New pain/swelling → malignant transformation





(Left) *Coronal graphic illustrates diffuse Paget disease of the skull with severe diploic widening.* **(Right)** *Autopsy specimen shows pagetoid changes in the calvaria with diffuse thickening, replacement of fatty marrow with fibrovascular tissue ➡. (Courtesy E.T. Hedley-Whyte, MD.)*





(Left) *Lateral radiograph shows classic "cotton wool" appearance of mixed active stage Paget disease, with enlarged bone (thickened calvaria), mixed lytic and sclerotic foci, and confluent nodular calcifications.* **(Right)** *Axial bone CT shows the mixed areas of bony lysis ➡ and sclerosis ➡ that produces the "cotton wool" appearance seen on digital radiographs of mixed active stage Paget disease.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Paget disease (PD)

Synonyms

- Osteitis deformans

Definitions

- Chronic metabolic skeletal disorder
- Characterized by bony expansion with variable destruction ± sclerosis

IMAGING

General Features

- Best diagnostic clue
  - Well-circumscribed, sharply marginated defects &/or marked thickening + sclerosis
- Location
  - Monostotic (10-35%): Often axial skeleton
  - Polyostotic (65-90%)
  - Skull (25-65%): May be isolated to skull base

Radiographic Findings

- Radiography
  - Diploic widening, coarse trabecula, thick cortices
  - 3 phases identified
    - Early destructive phase
      - Well-defined lysis; commonly frontal > occipital
      - Osteoporosis/osteolysis circumscripta
      - Inner and outer tables involved; inner > outer
    - Intermediate phase
      - Both lytic and blastic lesions
      - Trabeculae and cortices coarsening and thickening
    - Late sclerotic phase
      - Blastic lesions, often crossing sutures
      - "Tam o' shanter" skull: Marked ↑ diploic space, particularly inner table
      - "Cotton wool" skull: Focal sclerosis within previous areas of osteoporosis circumscripta
  - Platybasia with variable basilar invagination

CT Findings

- NECT
  - Bones: 3 phases (same as radiography)
  - Platybasia with basilar invagination (BI)
  - Sarcomatous transformation
    - Aggressive osteolysis, cortical destruction, soft tissue mass without periosteal reaction
  - Giant cell tumor (GCT) transformation
    - Lytic lesion without periosteal reaction or mass
    - Marrow replacement distinguishes from PD lysis
    - Cystic and hemorrhagic regions possible
  - PD pseudomass
    - "Soft tissue mass" 2° periosteal lifting by active PD
    - Significant absence of lysis
- CECT
  - ↑ enhancement reflecting pathologic ↑ vascularity
  - Sarcomatous transformation: Mass enhancement, often with central necrosis, aggressive lysis, cortical destruction
  - GCT transformation: Enhancing solid tumor areas

MR Findings

- T1WI
  - Yellow marrow hyperintensity usually maintained
    - Occasionally have more fat than uninvolved bone
  - Early destructive to early intermediate phase
    - ↓ marrow intensity 2° to marrow replacement
    - Residual normal yellow marrow foci → excludes malignant transformation
  - Late sclerotic phase: Marrow hypointensity from sclerosis of coarse trabeculae and cortical thickening
  - PD pseudomass: Maintained areas of yellow marrow
- T2WI
  - Marrow changes with marrow replacement
- T1WI C+
  - ↑ enhancement reflecting pathologic ↑ vascularity
- MR findings of PD complications
  - Distortion and flattening of brain
  - Brainstem impingement from basilar invagination
  - Acquired Chiari 1 malformation
  - Sarcomatous transformation
    - Marrow replacement, focal bone destruction, soft tissue mass
  - GCT transformation
    - Lytic lesion without periosteal reaction/mass
    - Marrow replacement allows it to be distinguished from normal lytic phase of PD
    - Cystic and hemorrhagic regions possible

Nuclear Medicine Findings

- Bone scan
  - Marked uptake throughout all phases of PD
    - Typically "hot" throughout all bone scan acquisitions (blood flow, blood pool, static)
    - Findings may precede radiographic changes
  - Can be "cold" or normal in late sclerotic stage
  - Findings that suggest recurrence
    - New uptake, extension beyond initial boundaries
    - Cold foci in areas of ↑ activity of bone destruction
- Sulfur colloid scan: ↓ uptake = marrow replacement

Imaging Recommendations

- Best imaging tool
  - Radiography + bone scan
    - Bone scans + radiographs abnormal in 56-86%
    - Bone scan alone abnormal in 2-23%
    - Radiographs alone abnormal in 11-20%
  - NECT defines detail/extent, especially PD of skull base
  - MR for imaging PD complications
- Protocol advice
  - NECT: High-resolution, thin cuts through skull base
  - MR
    - Coronal + sagittal sequences for BI
    - T1WI C+ to evaluate for malignant transformation

DIFFERENTIAL DIAGNOSIS

Osteosclerotic Metastases

- Classically prostate, breast, lymphoma

Osteolytic Metastases

- Most metastases, including lung, renal, thyroid

https://CafePezeshki.IR

Fibrous Dysplasia

- Ground-glass appearance, outer > inner table involved

Causes of Calvarial Thickening

- Hyperostosis frontalis interna, meningioma, chronic calcified subdural hematoma

PATHOLOGY

General Features

- Etiology
  - Unknown
  - Viral theory
    - Probable chronic paramyxoviral infection, possibly measles
    - Intranuclear inclusion bodies found in osteoclasts
  - Genetic theory supported by findings listed above
  - Familial, as well as geographic "foci," clustering support both environmental and genetic factors
    - 15-30% have family history, autosomal dominant pattern of inheritance
- Genetics
  - Only gene mutation linked to PD is sequestosome-1 (*SQSTM1*), which encodes p62 protein
    - Elevated cytokine activation in osteoclasts; does not induce pagetic osteoclast phenotype
    - Probably insufficient to cause PD

Gross Pathologic & Surgical Features

- Localized areas of ↑ bone resorption + exuberant but aberrant new bone formation
  - Abnormally soft new bone causes deformity

Microscopic Features

- Early destructive phase: Giant osteoclasts with numerous nuclei show intense activity and aggressive bone resorption
  - Fibrovascular tissue with large vascular channels replaces normal yellow marrow
- Intermediate phase: ↓ osteoclastic and ↑ osteoblastic activity; gradual return of yellow marrow
- Late sclerotic phase: ↓ osteoblastic activity, bone turnover, and vascularity
- General histopathologic findings
  - Cement lines along coarsened/enlarged trabeculae characteristic; denotes bone resorption and formation
  - Trabecular thickening lacks normal interconnections and are weak; a.k.a. "pumice" bone
  - Cortices thickened, have most active bone turnover and repair
  - Areas of resorption and formation are hypervascular
  - Often ↑ in marrow fat ("atrophic marrow")

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 20% asymptomatic
  - Fatigue, pain, tenderness, ↑ hat size
  - Hyperthermia from hypervascularity
  - Cranial nerve deficit(s), pulsatile tinnitus
  - New pain/swelling → malignant transformation
- Clinical profile
  - Older patients
  - ↑ serum alkaline phosphatase (mixed and blastic phase)
  - ↑ serum/urine hydroxyproline (lytic phase)

Demographics

- Age
  - > 55 years (usually late 60s); unusual < 40 years
- Gender
  - M:F = 2:1, onset slightly younger in men
- Ethnicity
  - Caucasians > African Americans > Africans
  - Ashkenazi Jewish have ↑ prevalence
- Epidemiology
  - 3-4% > 40 years; 10-11% > 80 years
- Geographic distribution
  - Overall ↑ prevalence in northern latitudes
  - ↑ in Great Britain: Lands settled by British (Australia, New Zealand, USA) share ↑ prevalence
  - Rare in Asia and Africa (excluding South Africa)

Natural History & Prognosis

- 10% develop secondary hyperparathyroidism from hypercalcemia related to aggressive bone remodeling
- Skull base thickening → CN deficit(s), sensorineural hearing loss (cochlear involvement), mixed hearing loss (stapes fixation to oval window)
- BI in up to 30%; more common in women → brainstem compression, syrinx, obstructive hydrocephalus
- Malignant transformation
  - Sarcomatous transformation (1% or less)
    - M:F = 2:1; 55-80 years
    - Osteosarcoma (50-60%), fibrosarcoma/malignant fibrous histiocytoma (20–25%), chondrosarcoma (10%)
    - Metastasizes frequently, most commonly to lung
  - GCT
    - Skull/facial GCT almost always associated with PD
    - M:F = 1.6:1; 32-85 years
    - Solitary or multiple; 91% in polyostotic PD
    - Rarely cause mortality; generally do not metastasize

Treatment

- Medical
  - Goal: Control, reduction, and alleviation of pain, rather than return to normal bone
    - Calcitonin, bisphosphonates, mithramycin
    - NSAIDs and acetaminophen for pain management
    - Radiography may or may not improve/normalize
- Biopsy with CT guidance needed to diagnose sarcomatous transformation

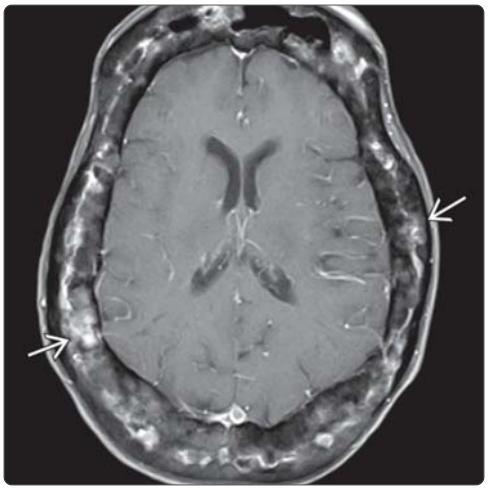
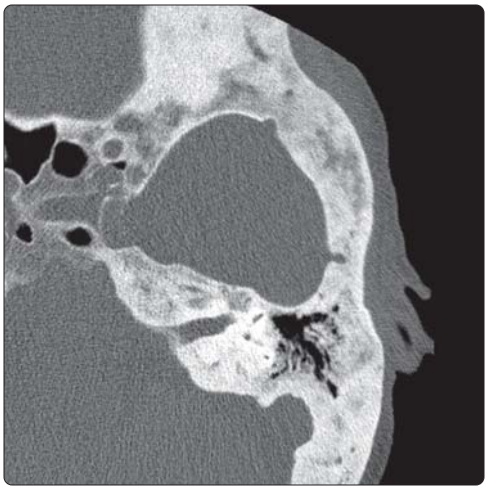
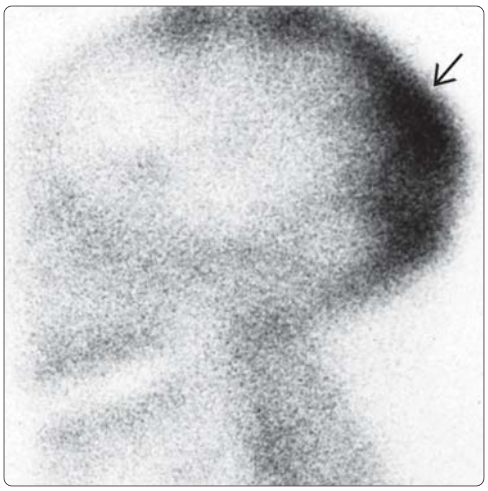
(Left) *Axial T1WI MR in a patient with mixed lytic, sclerotic Paget shows intermixed hyper-* ➡ *and hypointense* ⇨ *diploic lesions in a massively expanded calvaria in this elderly patient.* **(Right)** *Axial T2WI MR in the same patient shows the extremely "mottled" heterogeneous appearance of calvarial Paget disease.*





(Left) *Axial T1 C+ FS MR in the same patient shows patchy enhancement* ➡*, indicating that some active disease is present in this longstanding case.* **(Right)** *Axial close-up bone CT shows classic sclerotic Paget disease of the temporal bone. The bone is thickened and densely sclerotic.*



(Left) *Lateral skull radiograph shows the lytic phase of Paget disease, osteoporosis circumscripta,* ⇨ *together with an area of sclerotic skull thickening* ➡*.* **(Right)** *Bone scan in the same patient shows an area of abnormal uptake in the occiput* ⇨*, a typical location of Paget disease in the calvaria.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Extramedullary compensatory formation of blood elements due to decreased medullary hematopoiesis

IMAGING

- Skull (epidural, dura matter, sinuses), spine (paraspinal, epidural)
  - Too thick or dense skull
  - May show findings of underlying disease
- Contrast-enhanced MR
  - Smooth juxtaspinal or cranial homogeneous masses in patients with chronic anemias or marrow depletion
- Look for local complication
  - Cranial foramina, nerves
  - Spinal nerve involvement
  - Cord compression

TOP DIFFERENTIAL DIAGNOSES

- Meningioma
- Metastases
- Subdural collections
- Intracranial hypotension

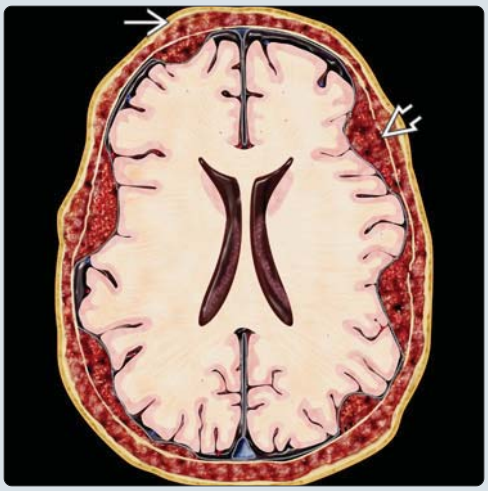
PATHOLOGY

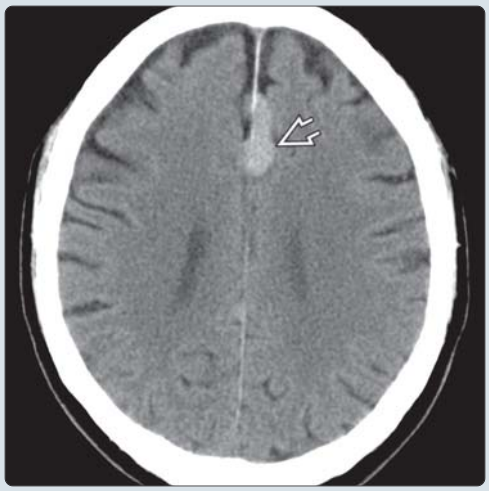
- "Trilineage" hyperplasia: Erythroid, myeloid, and megakaryocytic elements
- Primarily patients with congenital hemoglobinopathies
  - Thalassemia, sickle cell disease
- May be secondary to any depleted, infiltrated, or hyperactive bone marrow
  - Myelofibrosis/myelodysplastic syndromes
  - Leukemia

DIAGNOSTIC CHECKLIST

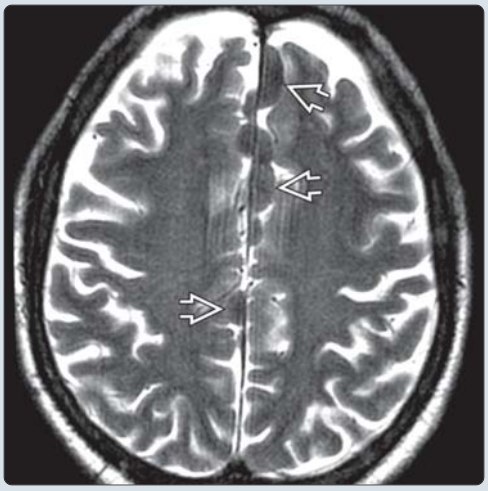
- EMH is dural &/or subdural hematoma mimic
- Think of EMH in unexplained extraaxial "collections" or perivertebral masses in child with congenital anemia or other hematological disorder

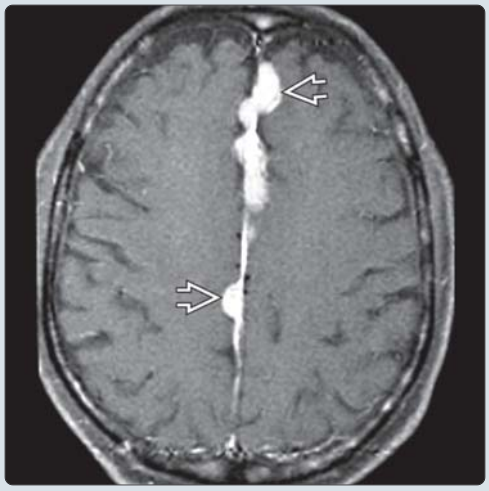
(Left) *Graphic depicts cranial manifestations of extramedullary hematopoiesis (EMH). The diploic space converts from fatty to hematopoietic ("red") marrow ⇨. Multiple lobulated extraaxial masses ⇨, usually subdural, can occur in severe cases.* **(Right)** *Axial NECT in a patient with myelofibrosis shows a well-delineated, lobulated hyperdense mass ⇨ adjacent to the falx cerebri.*





(Left) *Axial T2WI MR in the same patient shows multiple extra-axial, dural-based hypointense masses ⇨ along the falx.* **(Right)** *Axial T1 C+ FS MR in the same patient shows the masses enhance intensely and uniformly ⇨. Myelofibrosis/myelodysplastic syndromes are second only to anemia as the most common underlying cause of extramedullary hematopoiesis.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Extramedullary hematopoiesis (EMH)

Synonyms

- Extramedullary erythropoiesis

Definitions

- Extramedullary compensatory formation of blood elements due to decreased medullary hematopoiesis

IMAGING

General Features

- Best diagnostic clue
  - Smooth juxtaspinal or cranial homogeneous masses in patients with chronic anemia or marrow depletion
- Location
  - Skull (epidural, dura matter, sinuses), spine (paraspinal, epidural)
  - May be seen in multiple other organs: Kidneys, adrenals, thyroid, liver, spleen, lymph nodes, peritoneum
- Size
  - Variable, sometimes huge
- Morphology
  - Smooth, juxtaosseous circumscribed masses
  - Hypercellular tissue

Radiographic Findings

- Radiography
  - May show findings of underlying disease
    - Thalassemia → "hair-on-end" skull
    - Osteopetrosis → dense bone obliterating medullary space

CT Findings

- NECT
  - Smooth, homogeneous, isodense masses
    - May mimic subdural hematoma, lymphoma
    - Also simulates en plaque meningioma
  - May show osseous findings of underlying disease
    - Too thick or dense skull
    - Enlarged diploe
    - Changes of vertebral structure
  - Soft tissue filling paranasal sinus(es), orbits, juxtasellar regions
- CECT
  - Homogeneous enhancement

MR Findings

- T1WI
  - Isointense to slightly hyperintense to cortex
- T2WI
  - Slightly hypointense to cortex
- FLAIR
  - Hyperintense
  - No underlying parenchymal edema
- T1WI C+
  - Homogeneous enhancement
  - Simulates en plaque meningioma

Nuclear Medicine Findings

- Uptake by Tc-99m sulfur colloid

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR
- Protocol advice
  - Investigate bone as well as soft tissue masses
    - Etiological context usually known
    - CT: Thickening of diploe, erosions, paranasal sinus disease
    - MR: Bone marrow changes in vertebral bodies
  - Look for local complication
    - Cranial foramina, nerves
    - Spinal nerve involvement
    - Cord compression

DIFFERENTIAL DIAGNOSIS

Meningioma

- Different context, different bony findings
- MRS (often impossible in masses adjacent to bone): Characteristic alanine peak

Metastases

- Often multifocal, infiltrative, skull invasion

Subdural Collections

- Trauma history
- Enhancement of limiting membranes, not diffuse

Intracranial Hypotension

- Thick skull, thick enhancing dura
- May have associated subdural hematomas
- Enlarged venous dural sinuses
- Tonsillar descent, bulging pituitary
- ± history of CSF diversion or leak

Neurosarcoid

- Abnormal chest radiograph, labs

Other Paraspinal Masses

- Spondylitis, abscesses: Bone, disk involved, peripheral abscesses
- Lymphoma

PATHOLOGY

General Features

- Etiology
  - Hematogenous stem cell spread to different organs
    - Liver and spleen
    - Kidneys
    - Lungs
    - Peritoneum
    - Juxtaosseous also common
      - Face
      - Skull
      - Spine
  - Primarily patients with congenital hemoglobinopathies
    - Thalassemia
    - Sickle cell disease

https://CafePezeshki.IR

  - Hereditary spherocytosis
  - Hemorrhagic thrombocytopenia
  - Leukemia
  - Lymphoma
  - Myeloid metaplasia
- Others
  - May be secondary to any depleted, infiltrated, or hyperactive bone marrow
    - Can be seen after granulocyte colony-stimulating factor therapy
  - May be seen in any myelofibrosis/myelodysplastic syndrome
    - Hematological disorders (e.g., polycythemia vera)
    - Bone diseases
    - Exposure to ionizing radiation, benzene
- Occasionally no etiology found
- Genetics
  - Causal disease
    - Congenital hemoglobinopathies
    - Genetic hemopathies
    - Myelosclerosis of genetic causes
- Associated abnormalities
  - Secondary subdural hemorrhage from EMH involvement of dura reported

Gross Pathologic & Surgical Features

- Periosseous soft tissue masses
- Epidural EMH may compress underlying neural tissue
- Associated bony changes

Microscopic Features

- "Trilineage" hyperplasia
  - Erythroid elements
  - Myeloid elements
  - Megakaryocytic elements

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic
  - Seizures
  - Cranial nerve deficit(s) at skull base
  - Increased intracranial pressure if compressing dural sinuses
  - Myelopathy if compressing spinal cord
- Clinical profile
  - Generally older adults with myelofibrosis
  - Younger patients with congenital hemolytic anemias

Demographics

- Age
  - Generally in older patients, but EMH has its own specific pediatric causes
- Gender
  - Equal
- Epidemiology
  - Rare

Natural History & Prognosis

- Evolution dependent on primary underlying disease
- Compensatory for bone marrow failure
- Uncommonly, local complications related to compression

Treatment

- Treat primary disease
- Low-dose radiotherapy is treatment of choice
  - Remember that hematopoietic tissue is extremely sensitive to irradiation
- Surgical resection

DIAGNOSTIC CHECKLIST

Consider

- Think of EMH in unexplained extraaxial "collections" or perivertebral masses in child with congenital anemia or other hematological disorder

Image Interpretation Pearls

- EMH is dural &/or subdural hematoma mimic

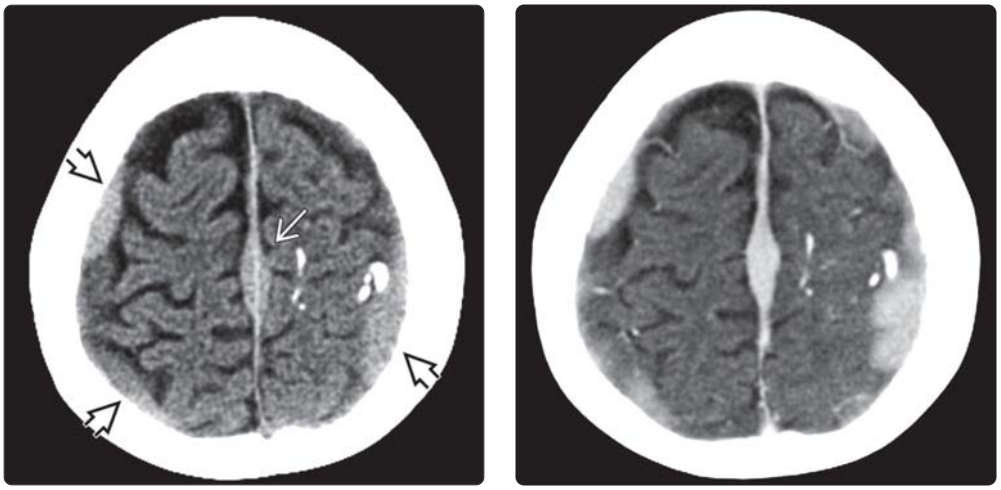
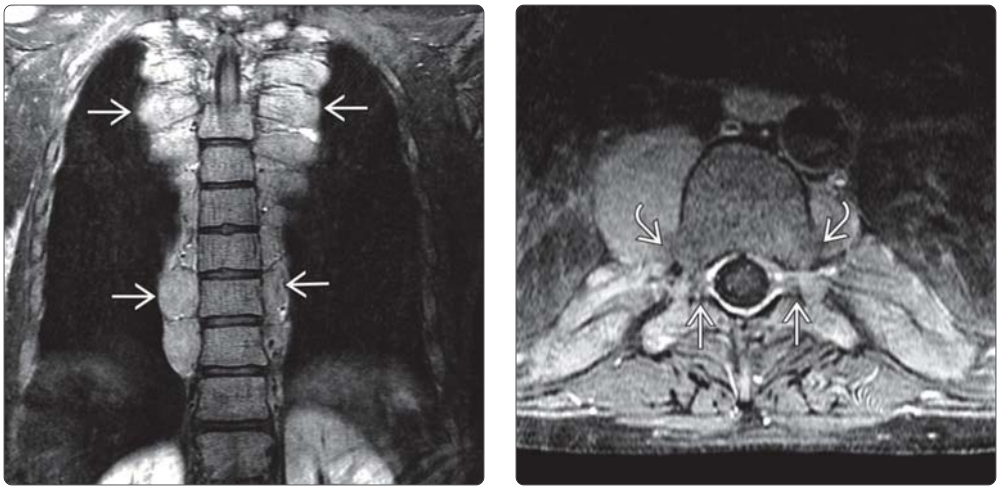
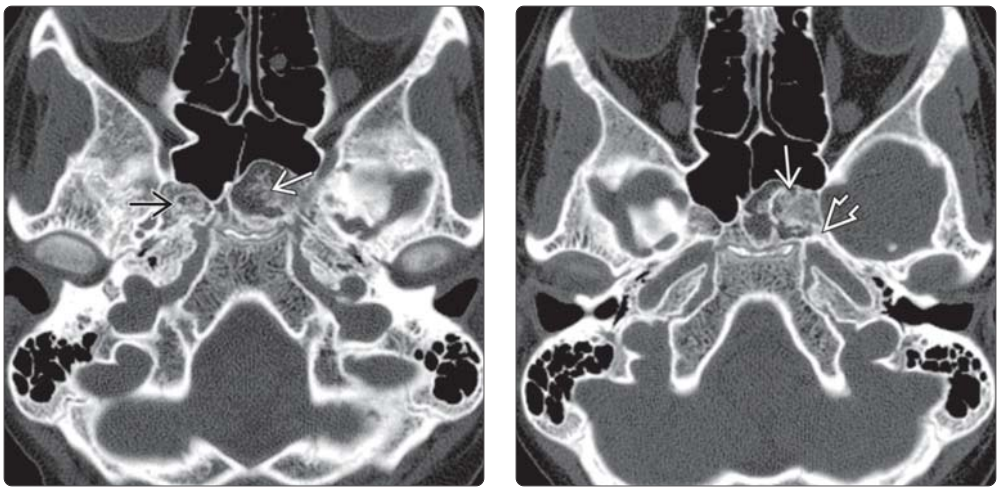
https://CafePezeshki.IR



(Left) *Axial NECT in an 8-year-old girl with myelofibrosis shows multiple extraaxial masses ⇨, most likely due to dural, epidural, &/or subdural intramedullary hematopoiesis. Note the falx ➡ where the mass is shown on both sides of the dural layer. The masses are slightly denser than brain, with (probably) dural calcifications, consistent with EMH.* **(Right)** *Axial CECT in the same patient demonstrates diffuse, rather homogeneous enhancement of the lesions, again in keeping with EMH. This was confirmed by biopsy.*



(Left) *Coronal T1WI C+ FS MR in a 17 year old with thalassemia shows multiple paravertebral masses ➡ along the thoracic vertebral, extending into intercostal spaces. Given the context, appearances, and homogeneous enhancement, they likely represent EMH.* **(Right)** *Axial T1WI C+ FS MR demonstrates in-plane extension of the masses, especially into the intervertebral foramina bilaterally ➡, where they involve the spinal nerves. Note the absence of cortical bone ⇨.*



(Left) *Axial bone CT in a 13 year old with thalassemia shows asymptomatic masses within the body of the sphenoid ➡ and the base of the right pterygoid plate ⇨ with bone expansion but preservation of the cortex, suggestive of, but not specific for, EMH.* **(Right)** *Axial bone CT at a higher level shows the proximity of the sphenoid body lesion ➡ to the carotid canal ⇨. This patient had multiple sites of proven EMH in other locations; therefore, this is the most likely diagnosis.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Skull thickening (ST)
  - Diploic space expanded ± thickened cortex

IMAGING

- Widened calvaria (skull width)
  - Can be diffuse or focal
- NECT best for most causes of ST
  - Thin-section MDCT for detailed skull base evaluation
- MR C+ contrast: Look for adjacent dural involvement

TOP DIFFERENTIAL DIAGNOSES

- Normal variation (most common cause)
- Shunted hydrocephalus or infantile brain injury
  - Neonatal meningitis or cerebritis
  - Hypoxia/ischemia/hypoglycemia in neonatal period
  - Metabolic/genetic disease with infantile brain atrophy
  - ± phenytoin
- Metastases (diffuse sclerotic)
- Microcephaly
- Chronic anemias

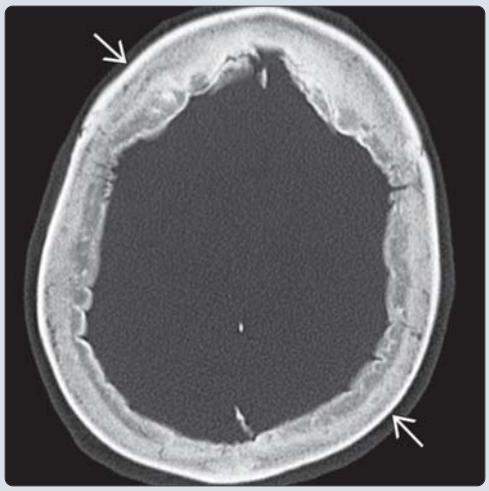
CLINICAL ISSUES

- Often asymptomatic
- Patients with skull base ST
  - Look for foraminal/canal overgrowth/encroachment
  - May cause cranial neuropathy
- In many cases, evaluation of underlying brain can help to establish diagnosis
- Many tests can help discriminate among etiologies
- Skull findings often harbinger of underlying disease
- Therapy aimed at treating underlying etiology

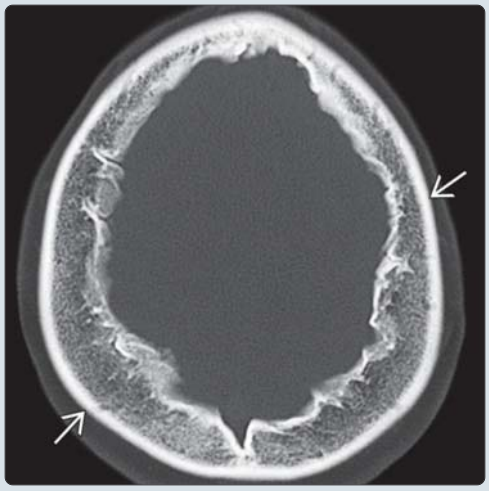
DIAGNOSTIC CHECKLIST

- What is underlying cause of skull thickening
  - Keep in mind: Most often it's normal variant

(Left) *Bone CT in a 64-year-old woman with nonspecific headaches, normal neurologic examination, and shows a diffuse, circumferentially thickened calvaria. The most common cause of diffusely thickened skull is a normal variant.* **(Right)** *The skull may thicken if the underlying brain is abnormally small. Due to the severe perinatal brain injury in this child, the brain is atrophic with ventriculomegaly, the calvaria is massively thickened, and the frontal sinuses are massively enlarged.*



(Left) *The calvaria can be thickened in a spectrum of inherited disorders. In this 19-year-old man with known craniometaphyseal dysplasia, the occipital bone (including the clivus) is markedly thickened, as are the maxillary sinuses.* **(Right)** *More cephalad image in the same patient shows the calvarial vault is also diffusely and symmetrically thickened, most strikingly in the parietal bones.*



https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Skull thickening (ST), calvarial thickening

Definitions

- Diploic space expansion ± adjacent cortical thickening

IMAGING

General Features

- Best diagnostic clue
  - Diffuse/focal increased skull width; variable size
- Location
  - Any bone can be involved; calvaria > skull base > occipital squamae
- Morphology
  - Generalized, regional or focal, depending on etiology

Radiographic Findings

- Radiography
  - Not useful for diffuse unless thickening is striking
  - Focal thickening more easily appreciated

CT Findings

- NECT
  - Thick skull: Findings may be classic/pathognomic
    - Local brain atrophy: Ipsilateral compensatory osseous hypertrophy/hyperpneumatization of paranasal sinuses
    - β-thalassemia: "Hair-on-end" skull
    - Shunted hydrocephalus: Thick skull + shunt + chronic collapsed ventricles
    - Fibrous dysplasia: Medullary expansion with ground-glass appearance

MR Findings

- T1-, T2WI may show diploic widening; depends on etiology
- Any sequence: Dural sinus displacement in focal thickening

Nuclear Medicine Findings

- Bone scan
  - Variable, dependent on cause of skull thickening
- PET
  - Rarely useful in children

Imaging Recommendations

- Best imaging tool
  - NECT for most causes of skull thickening
  - MR for brain assessment
- Protocol advice
  - Thin-section, high-resolution MDCT
    - Coronal and sagittal reformats
    - Goal: Thoroughly evaluate foramina and canals

DIFFERENTIAL DIAGNOSIS

Normal Anatomic Variation

- Normal skulls may have symmetric areas of thickening

Microcephaly

- Skull overgrowth occurs secondary to decreasing brain size in child

Many Others

- Shunted hydrocephalus
- Localized atrophy (e.g., Sturge-Weber disease)
- Chronic anemias

PATHOLOGY

General Features

- Etiology
  - Generalized ST: Drugs (phenytoin), microcephaly, hyperparathyroidism, osteopetrosis
  - Regional ST: Calcified cephalohematoma, localized cerebral atrophy, epidermal nevus syndrome, fibrous dysplasia
- Associated anomalies vary with genetic involvement/predisposition and systemic causes

Microscopic Features

- Specific histopathology varies greatly, dependent on underlying cause

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Most often asymptomatic; varies with etiology
  - Without skull base disease: Most symptoms referable to disease affecting systems outside skull
  - Patients with skull base ST may be symptomatic from foraminal or canal encroachment
    - Manifests as cranial nerve (CN) deficit(s)
    - Sinoorbital and auditory complications

Natural History & Prognosis

- Aggressive lesions, especially those involving skull base, have associated morbidity; usually CN deficit(s)

Treatment

- Usually no treatment required

DIAGNOSTIC CHECKLIST

Consider

- What is underlying cause of skull thickening

Reporting Tips

- Focal vs. diffuse, other bones, intracranial findings

KEY FACTS

TERMINOLOGY

- Langerhans cell histiocytosis (LCH)
- LCH now best understood as a neoplastic disease
  - Activating somatic *BRAF* mutations, LCH cell clonality

IMAGING

- NECT
  - Sharply marginated lytic skull defect
    - Beveled edges
  - Mastoid: Geographic destruction, soft tissue mass
- MR
  - Absent posterior pituitary "bright spot" on T1WI
  - Thick enhancing infundibulum
  - Enhancing masses in choroid plexus, leptomeninges, basal ganglia
  - Sometimes cerebellar WM disease

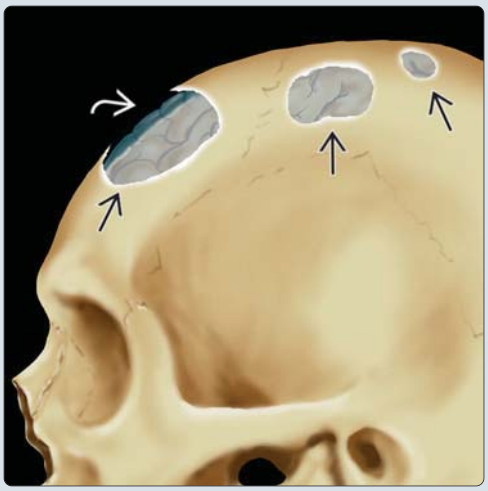
TOP DIFFERENTIAL DIAGNOSES

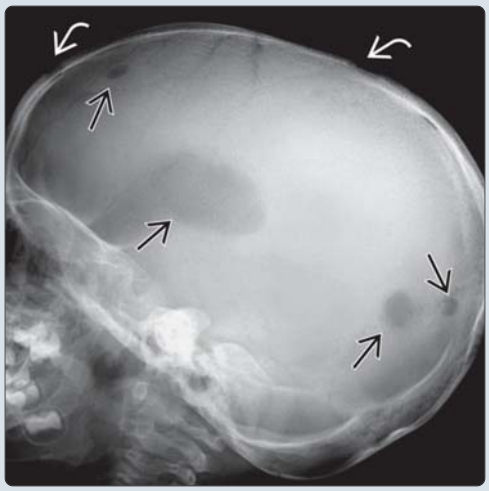
- Lytic calvarial lesions
  - Surgical (burr hole, shunt, surgical defect)
  - Epidermoid
  - Dermoid
- Pituitary infundibular/hypothalamic thickening, enhancement
  - Germinoma
  - Metastasis
  - Pituicytoma
  - Neurosarcoid

DIAGNOSTIC CHECKLIST

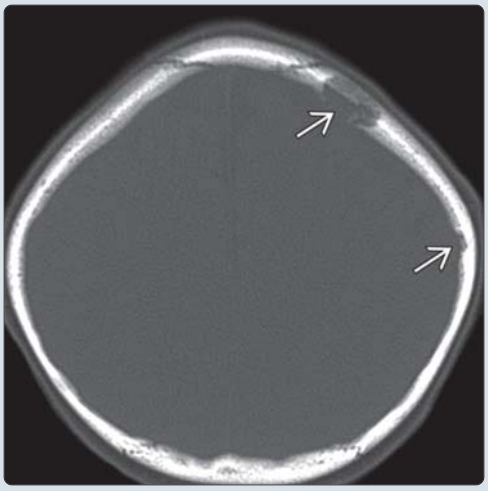
- Calvaria is most frequent bony site involved by LCH
- Thick enhancing pituitary stalk is most common CNS manifestation of LCH
  - If initially "normal" MR in patient with DI, repeat in 2-3 months
- Consider LCH for ataxic patient with choroid plexus masses, cerebellar WM demyelination

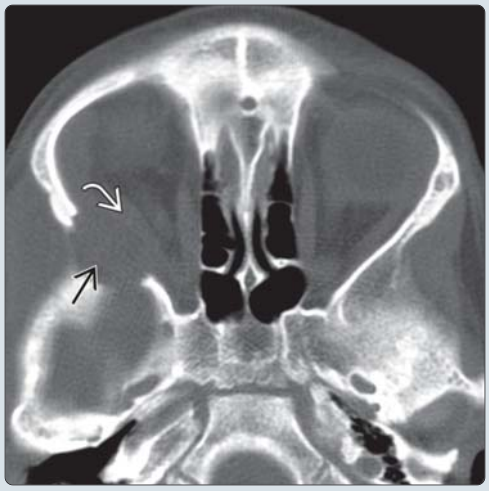
(Left) *Lateral graphic demonstrates 3 sharply defined lytic lesions ⇨ of the membranous calvaria with geographic destruction. Note the beveled margins of the bony lysis ⇨.* **(Right)** *Lateral radiograph in a 3-year-old boy with several subcutaneous masses and central diabetes insipidus demonstrates multiple lytic lesions of the skull ⇨. Note the "cookie cutter" sharp pattern of bony lysis and the beveled edge pattern ⇨ of differential inner and outer table calvarial involvement.*





(Left) *Axial NECT in a 5-year-old girl with multiple scalp masses demonstrates 2 lytic lesions ⇨ of the left frontal bone. Both lesions show the characteristic pattern of sharply defined geographic bony lysis. Note the unequal inner and outer table involvement creating a beveled edge appearance.* **(Right)** *Axial NECT in a proptotic 10-year-old boy shows a sharply defined lytic lesion of the lateral orbital wall ⇨. Note the soft tissue mass displacing the lateral rectus muscle ⇨.*





https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Langerhans cell histiocytosis (LCH)
  - Several entities (eosinophilic granuloma, Hand-Schuller-Christian disease, Letterer-Siwe disease, and "histiocytosis X" now under single designation of LCH

Definitions

- LCH now best understood as neoplastic disease
  - Activating somatic *BRAF* mutations, LCH cell clonality
  - Inflammatory myeloid neoplasia
- Divided into 3 groups (based on number of lesions, systems involved)
  - Unifocal (localized) form
    - 70% of cases
    - Limited to single or a few bones, may involve lung
  - Multifocal unisystem
    - 20% of cases
    - Chronic, recurring
    - Multiple bones, reticuloendothelial system, pituitary/hypothalamus
  - Multifocal, multisystem
    - 10% of cases
    - Fulminant (often fatal)

IMAGING

General Features

- Best diagnostic clue
  - Calvaria: Sharply marginated lytic skull defect with beveled margins
  - Skull base (mastoid most common): Geographic destruction ± soft tissue mass
  - Brain: Thick enhancing infundibulum, absent posterior pituitary bright spot on T1WI
- Location
  - Calvaria
    - Most common bony site
      - Frontal, parietal bones > temporal, occipital
    - Also mastoid portion of temporal bone, mandible, orbit, facial bones
  - Brain: Pituitary gland/infundibulum, hypothalamus
    - Rare: Choroid plexus, leptomeninges, basal ganglia, cerebellar white matter (WM), and brain parenchyma
- Size
  - Skull and facial bones: May grow, coalesce
  - Pituitary infundibulum: Small lesions due to early endocrine dysfunction (central DI)
- Morphology
  - Variable patterns of bony lysis ("geographic" skull)
  - Soft tissue masses vary from discrete ↔ infiltrative

CT Findings

- NECT
  - Calvaria
    - Lytic defect, "beveled" edge (inner table > outer table)
    - Small soft tissue mass, no periosteal reaction
  - Mastoid
    - Bone destruction, often bilateral, soft tissue mass
- CECT
  - Calvaria/mastoid: Enhancing soft tissue in lytic defect
  - Brain: Enhancing, thick pituitary stalk, ± hypothalamic mass or enhancement

MR Findings

- T1WI
  - Soft tissue mass at site of bony lysis (± T1 shortening due to lipid-laden histiocytes)
  - Brain
    - Pituitary/infundibulum: Absent posterior pituitary bright spot, thick stalk, ± soft tissue mass
- T2WI
  - Skull, mastoid, orbital/facial lesions: Soft tissue masses show slight T2 hyperintensity
  - Brain
    - Infundibulum/hypothalamus: Slightly hyperintense
    - ± cerebellar WM hyperintensity (autoimmune-mediated demyelination)
- FLAIR
  - Rare: Hyperintense cerebellar white matter demyelination
- T1WI C+
  - Skull, mastoid, orbital/facial: Enhancing soft tissue masses (defined or infiltrating)
  - Brain
    - Infundibulum: Thick, strongly enhancing stalk
    - Parenchyma: Enhancing masses in choroid plexus, leptomeninges, and basal ganglia

Nuclear Medicine Findings

- Bone scan
  - Tc-99m bone scan: Variable (cold ↔ warm)
- PET
  - F-18 FDG: ↑ uptake in proliferating lesions, ↓ uptake for "burned-out" lesions

Imaging Recommendations

- Best imaging tool
  - Skull: NECT (with CECT for mastoid disease)
  - Brain: MR with contrast
- Protocol advice
  - Skull: CT using bone algorithm; include coronal and sagittal reconstructions
  - Brain MR
    - Pituitary MR: Small field of view, thin section, no gap, sagittal and coronal T1WI with contrast
      - If initially "normal" in patient with DI, repeat in 2-3 months

DIFFERENTIAL DIAGNOSIS

Lytic Calvarial Lesions

- Surgical (burr hole, shunt, surgical defect)
- Epidermoid
- Dermoid
- Leptomeningeal cyst
- Metastases

Temporal Bone Destructive Processes

- Severe mastoiditis: Infection usually spares bony labyrinth
- Rhabdomyosarcoma: Often with large ipsilateral cervical nodes

https://CafePezeshki.IR

Pituitary Infundibular/Hypothalamic Thickening or Masses

- Germinoma
- Pituicytoma
- Metastasis
- Lymphocytic hypophysitis
- Neurosarcoid

PATHOLOGY

General Features

- Genetics
  - Pathologic LCH cells are clonal
  - Activating *BRAF* mutations
  - Activation of ERK signaling pathway in myeloid differentiation as essential/universal driver of LCH pathology
- Associated abnormalities
  - ↑ risk of LCH: Family history of thyroid disease, underimmunization, penicillin use, solvent exposure

Staging, Grading, & Classification

- Formerly classified into 1 of 3 overlapping forms
  - Eosinophilic granuloma
    - Localized, calvaria most common (70%)
  - Hand-Schüller-Christian
    - Chronic disseminated form, multifocal (20%)
  - Letterer-Siwe
    - Acute disseminated form, onset at < 2 years of age, ± skeletal involvement (10%)
- Now classified according to risk factors: Young age, multifocal involvement, multiorgan dysfunction, relapse

Gross Pathologic & Surgical Features

- Yellow, gray, or brown tumor mass

Microscopic Features

- Monoclonality of Langerhans cells
  - Presence of CD1a and Birbeck granules needed to establish diagnosis
- Accumulation of CD1A(+)/CD207(+) mononuclear phagocytes in granulomatous lesions

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Calvarial: Pain, subscalp mass, bony defect
  - Mastoid destruction: Pain, chronic otitis externa, retroauricular subscalp mass
  - Retroorbital mass: Exophthalmos, ± painful ophthalmoplegia
  - Pituitary infundibular involvement: Central DI, ± visual disturbance, ± hypothalamic dysfunction
- Clinical profile
  - Child < 2 years with diabetes insipidus, ± lytic calvarial lesion

Demographics

- Age
  - LCH typically presents at < 2 years
- Gender
  - M:F = 2:1
- Ethnicity
  - More common among Caucasians
- Epidemiology
  - Affects 4 in 1,000,000
  - Peak age at onset 1 year (isolated), 2-5 years (multifocal disease)
  - Inverse relation between severity of involvement and age
  - 50% of LCH cases are monostotic
  - Familial LCH < 2%
  - Lytic bone lesions are most common manifestations of LCH (seen in 80-95% of children with LCH)

Natural History & Prognosis

- Variable depending on age of onset and extent of involvement
  - Multifocal and systemic LCH: Mortality may approach 18%
- Rarely, may spontaneously hemorrhage → epidural hematoma

Treatment

- Therapeutic options depend on symptoms, location, and extent of disease
  - Observation, excision/curettage, sclerotherapy/injection, radiation/chemotherapy
- Solitary eosinophilic granuloma has best prognosis with spontaneous remission common
  - Painful: Curettage
  - Asymptomatic: Observe
- LCH patients with DI: Oral or nasal vasopressin, ± chemotherapy and radiation

DIAGNOSTIC CHECKLIST

Consider

- CNS LCH for ataxic patient with choroid plexus masses and cerebellar WM demyelination

Image Interpretation Pearls

- Skull is most frequent bony site involved by LCH
- Thick enhancing pituitary stalk is most common CNS manifestation of LCH

KEY FACTS

TERMINOLOGY

- Multisystem inflammatory disease characterized by noncaseating epithelioid-cell granulomas

IMAGING

- Solitary or multifocal CNS mass(es) ± abnormal CXR
  - Chest x-ray abnormal in > 90% with NS
- Wide spectrum of MR manifestations
  - Dura-arachnoid thickening (diffuse or focal))
  - May coat pia, CNs, fill internal auditory canals
  - Pituitary stalk/hypothalamus thickening
  - Can thicken, infiltrate choroid plexi
  - Can infiltrate orbital adnexae, optic nerve
  - Rare
    - Small vessel vasculitis/angiitis in white matter
    - Focal parenchymal mass

TOP DIFFERENTIAL DIAGNOSES

- Meningitis
- Meningioma
- Metastases
- Lymphocytic hypophysitis

PATHOLOGY

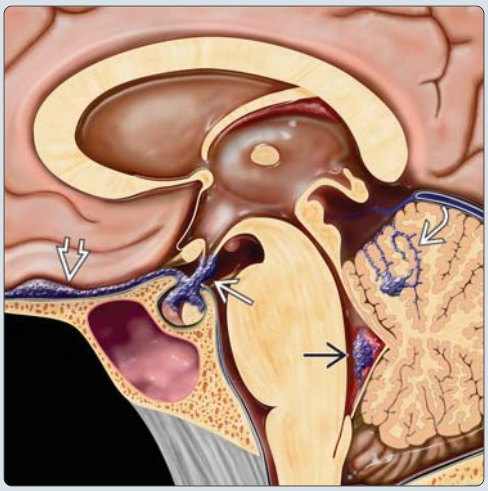
- Etiology remains unknown
- May infiltrate along perivascular spaces into brain

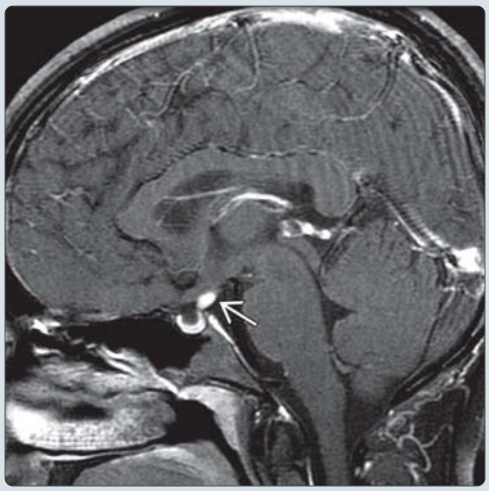
CLINICAL ISSUES

- Often indolent disease (up to 50% asymptomatic)
- CNS involved in 5% (clinical) to 27% (autopsy)
  - Most common CNS symptom: CN deficit(s), most often facial nerve palsy
- Natural history
  - 2/3 of NS self-limited monophasic illness; remainder have chronic remitting-relapsing course

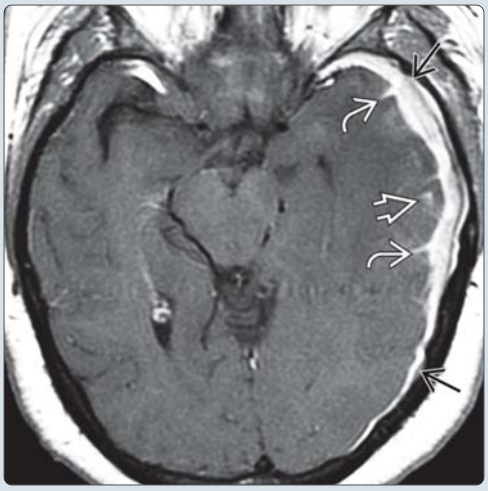
DIAGNOSTIC CHECKLIST

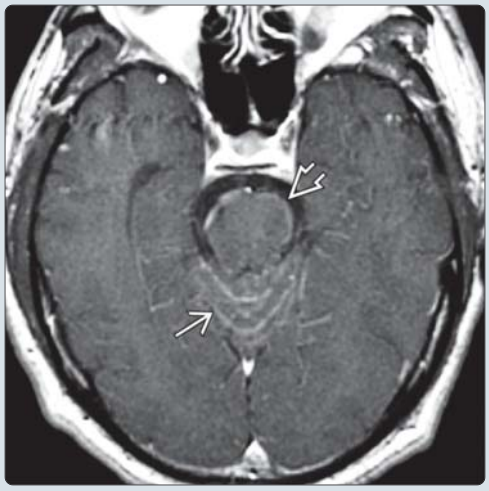
- Protean manifestations make NS "great mimicker"





(Left) *Sagittal graphic illustrates common neurosarcoid locations: (1) enveloping the infundibulum and extending into the parasellar region ➡; (2) contiguous disease wrapping the inferior frontal lobes ➡; and (3) synchronous lesions of the superior vermis ➡ and 4th ventricle choroid plexus ➡.* **(Right)** *Sagittal T1 C+ FS MR in a patient with neurosarcoidosis and diabetes insipidus demonstrates thickening of the infundibulum and hypothalamus ➡.*





(Left) *Axial T1 C+ MR in a 44-year-old woman with worsening headaches and diplopia shows diffuse dura-arachnoid thickening over the left hemisphere ➡. Extension into the sulci ➡ and underlying brain ➡ is present. Biopsy disclosed neurosarcoid with brain invasion.* **(Right)** *Axial T1 C+ MR in a case of proven neurosarcoid demonstrates diffuse pial enhancement over the surface of the upper pons ➡ and cerebellum ➡.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Neurosarcoid (NS)

Definitions

- Chronic multisystem inflammatory disease characterized by noncaseating epithelioid-cell granulomas

IMAGING

General Features

- Best diagnostic clue
  - Solitary or multifocal CNS mass(es) + abnormal CXR
- Location
  - Dura (29-50%), leptomeninges (31%), subarachnoid/perivascular spaces
    - Preferential involvement of basal cisterns
    - Optic chiasm, hypothalamus, infundibulum
  - Cranial nerves (CNs) (34-50%); optic nerve (28%)
  - Brain parenchyma (22%): Hypothalamus > brainstem > cerebral hemispheres > cerebellum
  - Choroid plexus
  - Spine (25%)
- Morphology
  - Focal or diffusely infiltrating granulomas
  - Absence of pathological enhancement does not rule out diagnosis of neurosarcoid

Radiographic Findings

- Radiography
  - Chest x-ray abnormal in > 90% with NS
    - Hilar adenopathy ± parenchymal involvement

CT Findings

- CECT
  - May show basilar leptomeningeal enhancement

MR Findings

- T1WI
  - Hydrocephalus
  - Lacunar infarcts (brainstem, basal ganglia)
  - Isointense material within subarachnoid spaces
  - Isointense dural lesion(s)
- T2WI
  - Lacunar infarcts (brainstem, basal ganglia)
  - Hypointense material within subarachnoid spaces
  - Hypointense dural lesion(s)
  - Sellar disease may appear cystic
- FLAIR
  - ~ 50% have periventricular T2-hyperintense lesions
    - Can infiltrate perivascular (Virchow-Robin) spaces
    - May cause vasculitis/angiitis of white matter
- DWI
  - Distinguish restricted (acute ischemic cytotoxic edema) from nonrestricted NS (vasogenic) edema
- T1WI C+
  - Wide spectrum of MR enhancement
    - 10% seen as solitary intraaxial mass
    - Slightly > 1/3 have multiple parenchymal lesions
    - Slightly > 1/3 have leptomeningeal involvement; nodular &/or diffuse
    - 5-10% hypothalamus, infundibular thickening
    - 5% solitary dural-based extraaxial mass
    - Other: Vasculitic or ependymal enhancement
    - May coat CN, fill internal auditory canals

Nuclear Medicine Findings

- PET: High pulmonary sarcoidosis FDG uptake
- Gallium scan: ↑ uptake at systemic sites of inflammation, including NS (as high as 85%)

Imaging Recommendations

- Best imaging tool
  - MR C+
- Protocol advice
  - Multiplanar, fat saturation, T1WI C+

DIFFERENTIAL DIAGNOSIS

Dural, Leptomeningeal, Subarachnoid NS

- Meningitis: CSF shows infection/organism
- Meningioma: Not parenchymal or subarachnoid space
- Infundibular histiocytosis: Age of onset: 6-14 years

Brain Parenchymal NS

- Metastases: Labs different, negative CXR
- Periventricular white matter disease: Different symptomatology and lab results, negative CXR

PATHOLOGY

General Features

- Etiology
  - Etiology remains unknown
    - Possibly stimulation of immune system by 1 or more antigens &/or abnormal immune response
  - DNA and RNA of *Mycobacterium*, *Propionibacterium* detected in some lesions, suggesting a possible cause
- Genetics
  - Sarcoidosis may occur in families
  - Genetic polymorphisms of MHC are associated with ↑ risk of disease or affect disease presentation
    - HLA-DRB1 (*11 & *14), HLA-DQB1*0201 alleles
    - Number of HLA genes involved unknown, but clear HLA region strongly implicated
  - Genetic polymorphisms of cytokines are associated with ↑ risk of disease or affect disease presentation
- Associated abnormalities
  - Löfgren syndrome (a.k.a. acute pulmonary sarcoid)
    - All: Fever, malaise, bilateral hilar adenopathy
    - Erythema nodosum and large joint arthralgia
    - May have uveitis, parotitis
  - Heerfordt syndrome (a.k.a. salivary gland sarcoidosis)
    - Fever, parotitis, uveitis, and facial nerve paralysis

Gross Pathologic & Surgical Features

- Granulomatous leptomeningitis (most common) or dural-based solitary mass (diffuse > nodular)
- May infiltrate along perivascular spaces

Microscopic Features

- Noncaseating granuloma: Compact, radially arranged epithelioid cells with pale-staining nuclei

https://CafePezeshki.IR

- Large, multinucleated giant cells in arc/circle around central granular zone
- Arterial wall invasion by epithelioid cell granuloma causing disruption of media and internal elastica
  - Tissue may then cause luminal stenosis or occlusion
- Fibrocollagenous tissue accumulates in dural lesions
  - Correlates with T2-hypointense lesions
- Inflammatory infiltration
  - Correlates with T2-hyperintense lesions

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Neurologic manifestations frequently presenting symptoms of systemic sarcoid
  - Imaging findings often do not have correlating symptoms at time of presentation
    - Nonetheless, post-therapy imaging shows excellent correlation with clinical improvement/worsening
  - Most common symptom: CN deficit(s), most often facial nerve palsy
    - Bell palsy 14x ↑ compared to general population
  - By imaging, optic nerve ± chiasm most affected
    - Clinical and imaging CN findings often disparate
  - Symptoms vary with location, size of granulomas
    - Other CN: Hearing loss, diplopia
    - Headache, fatigue, seizures, encephalopathy, dementia
    - Weakness, paresthesias
    - Pituitary/hypothalamic dysfunction
  - 5-10% occur without pulmonary/systemic sarcoid
  - Progressive encephalopathy, confusion, and dementia
    - Ascribed to longstanding microvascular changes of presumed granulomatous angiitis
  - Systemic involvement
    - Lung hilar nodes most often involved
    - Skin lesions 2nd (up to 1/3)
    - Eye (iritis, uveitis); polyarthritis
  - Children present differently
    - More likely: Seizures, space-occupying lesion
    - Less likely: Cranial nerve palsies
- Clinical profile
  - Kveim-Siltzbach skin test positive in 85%
  - Serum ACE levels elevated in < 50% of cases with NS
    - Normal CSF ACE levels do not rule out NS
  - Hypercalcemia + hypercalciuria in up to 15%
  - Serum CD4:CD8 ratio often ↓
  - ↑ CSF protein &/or cells insensitive, nonspecific
  - Use modified Zajicek criteria for diagnosis
    - Divides into "confirmed," "probable" and "possible" NS

Demographics

- Age
  - Bimodal: Initial peak at 20-29 years, later peak in women > 50 years
- Gender
  - M:F = 2:1
- Ethnicity
  - In USA, lifetime risk in African Americans is nearly 3x higher than Caucasians
  - In Europe, Caucasians mostly affected
- Epidemiology
  - In USA
    - Women: 6.3 per 100,000 person-years
    - Men: 5.9 per 100,000 person-years
  - CNS involved between 5% (clinical) and 27% (autopsy)
    - Primary, isolated CNS sarcoidosis rare (< 1%)
    - Imaging detects neurologic disease in 10% of all patients with sarcoidosis
- Geographic predilection
  - Temperate > tropical climates (< 10/100,000)
  - Swedes and Danes commonly affected
  - Rare in Chinese, Southeast Asians, Inuits, Canadian Indians, New Zealand Maoris, and Spanish

Natural History & Prognosis

- Often indolent disease; up to 50% asymptomatic
- 67% with NS have self-limited monophasic illness; remainder have chronic remitting-relapsing course
  - Most respond rapidly to steroids; others refractory
- Simultaneous expression of new and old granulomas suggest process may wax and wane
- Hydrocephalus
  - Direct obstruction (most common complication)
  - Also by loss/reduction of brain tissue compliance resulting from parenchymal infiltration
- Vasculitis may cause small vessel ischemia, lacunes, cortical infarcts
- Indicators of poor prognosis: Seizures; enhancing leptomeningeal, parenchymal, and spinal lesions
- Indicators of good prognosis: Nonenhancing dural, CN, and parenchymal lesions
- Death in 5%, mostly from pulmonary complications

Treatment

- No known cure; goal to alleviate symptoms
- Corticosteroids useful in most cases; immunosuppressive drugs occasionally
- In NS ~ 50% progress despite corticosteroid and immunosuppressive therapy
- MR imaging resolution lags clinical symptom resolution

DIAGNOSTIC CHECKLIST

Consider

- Look for abnormal CXR

Image Interpretation Pearls

- Protean manifestations make NS "great mimicker"
- CN deficit(s) and pituitary dysfunction often have normal MR C+ imaging; conversely MR findings may be clinically silent

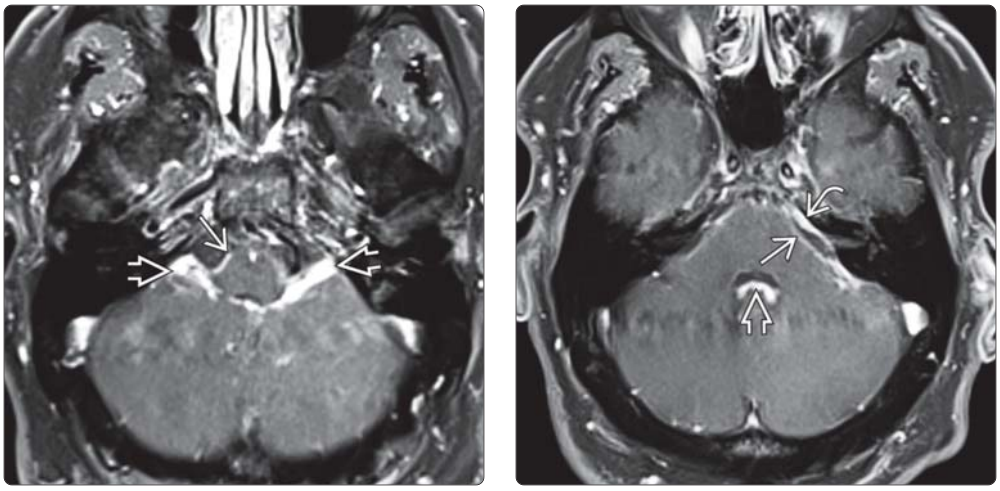
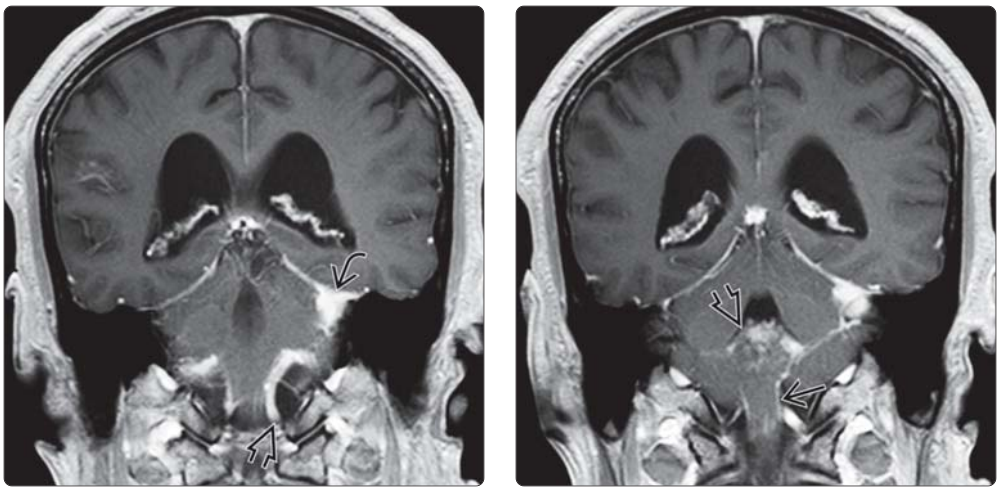
(Left) *Axial T2 MR in a 43-year-old woman with Tolosa-Hunt syndrome shows a thickened right lateral rectus muscle* ⇨ *and hypointense mass extending through the orbital apex into the cavernous sinus* ⇨. **(Right)** *Axial T1 C+ FS MR shows the infiltrating mass* ➡ *enhances intensely and uniformly. Subtle dura-arachnoid enhancement is also present* ➡. *Biopsy disclosed neurosarcoid.*



(Left) *Axial T1 C+ FS MR in a 56-year-old woman with neurosarcoid shows diffuse enhancement over the pial surface of the medulla* ➡, *as well as thickening of the choroid plexi* ➡ *in the 4th ventricle and lateral recesses.* **(Right)** *More cephalad T1 C+ FS MR in the same patient shows diffuse enhancement over the surface of the pons* ➡. *Note the enhancing choroid plexus mass in the floor of the 4th ventricle* ➡. *A dural-based cerebellopontine angle mass* ➡ *is also present.*



(Left) *Coronal T1 C+ MR in the same patient shows the left cerebellopontine angle mass* ⇨ *and enhancement extending over the brainstem into the upper cervical spine* ⇨. **(Right)** *Coronal MR in the same patient shows the extensive involvement of the 4th ventricle choroid plexus* ⇨. *The pia of the medulla and upper cervical spinal cord is thickened and enhancing* ⇨. *Mild enlargement of both lateral ventricles is also present. Obstructive hydrocephalus is a relatively uncommon complication of neurosarcoidosis.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Non-Langerhans cell histiocytoses
  - Four major disorders
    - Rosai-Dorfman disease (RDD)
    - Erdheim-Chester disease (ECD)
    - Hemophagocytic lymphohistiocytosis (HLH)
    - Juvenile xanthogranuloma (JXG)

IMAGING

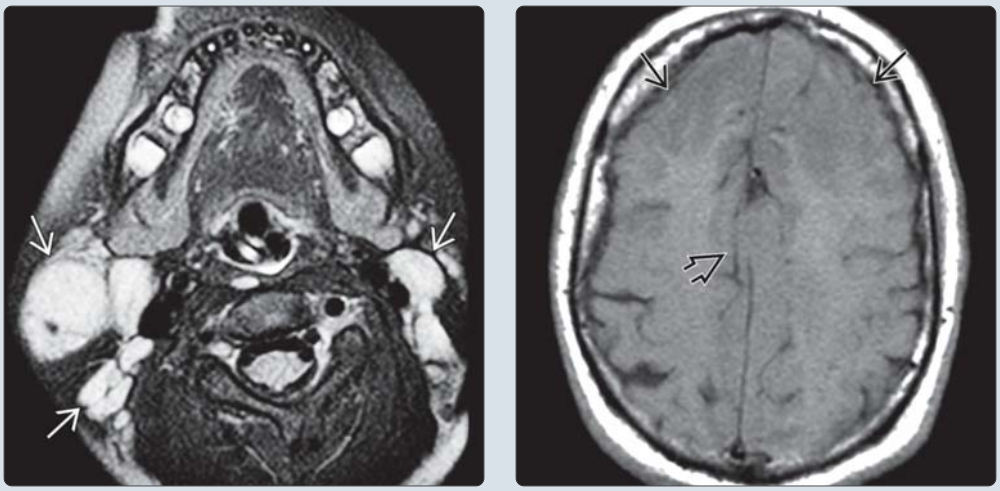
- RDD: Massive, painless cervical lymphadenopathy
- CNS: T2-hypointense orbital or dural masses that mimic meningioma
- HLH: Hyperintense, enhancing WM lesions (cerebellum, hemispheres), often with leptomeningeal disease
- JXG: Uncommon in brain (WM lesions resemble HLH; sellar, choroid plexus, orbit)

TOP DIFFERENTIAL DIAGNOSES

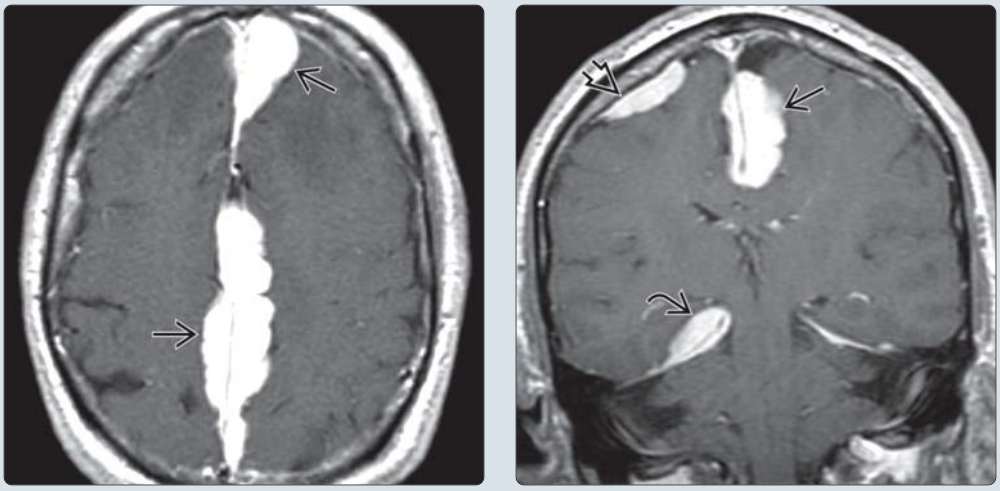
- Orbit: Lymphoma, pseudotumor, sarcoid
- Dural-based mass(es): Meningioma, sarcoid, lymphoma, extramedullary hematopoiesis, metastases

CLINICAL ISSUES

- RDD
  - Children and young adults (peak 20 years)
  - Good prognosis (usually benign, slowly progressive disease
- ECD
  - Any age but older adults/elderly (5th, 6th decades) most common
  - Poor prognosis (5-year survival 40%)
- HLH
  - Infants (most < 1 year), young children
  - Generally poor outcome
- JXG
  - Usually limited to skin
  - Disseminated WM lesions; sellar, pituitary/hypothalamus, choroid plexus lesions



(Left) *Axial T2 FS MR scan in a 42-year-old woman with cervical adenopathy shows multiple enlarged, hyperintense lymph nodes ➡. Biopsy disclosed Rosai-Dorfman disease (RDD).* **(Right)** *Axial T1 MR in the same patient was obtained after the patient complained of headaches. Note effacement of the sulci, gray-white interfaces in both frontal lobes ⇨ and along the interhemispheric fissure ⇨.*



(Left) *Axial T1 C+ MR in the same patient shows multifocal, intensely enhancing, lobulated extraaxial dural-based masses ⇨ along the falx.* **(Right)** *Coronal T1 C+ MR in the same patient shows the dural-based enhancing masses also involve the convexity ⇨ and tentorium ⇨, as well as both sides of the falx ⇨.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Non-Langerhans cell histiocytoses (non-LCH)

Definitions

- Non-Langerhans cell histiocytoses
  - 4 major disorders
    - Rosai-Dorfman disease (RDD)
    - Erdheim-Chester disease (ECD)
    - Hemophagocytic lymphohistiocytosis (HLH)
    - Juvenile xanthogranuloma (JXG)
- RDD: Rare, benign, idiopathic histioproliferative disorder generally (but not always) restricted to lymph nodes
- ECD: Rare, non-Langerhans form of histiocytosis of unknown etiology that affects multiple organs
- HLH: Syndrome of pathologic activation of macrophages, T cells with "hemophagocytosis" (engulfment of RBCs and leukocytes)
  - May affect multiple organ systems, including central nervous system (CNS)
- "Malignant histiocytosis" now considered histiocytic sarcoma, not true histiocytic lesion

IMAGING

General Features

- Best diagnostic clue
  - RDD: Massive, painless cervical lymphadenopathy
    - CNS: T2-hypointense orbital or dural masses that mimic meningioma
  - ECD: Enhancing brainstem and cerebellar lesions
  - HLH: T2 Hyperintense, enhancing WM lesions (cerebellum, hemispheres), often with leptomeningeal disease
  - JXG: Usually just skin, sometimes brain and choroid plexus lesions
- Location
  - RDD: Cervical lymph nodes, orbits, meninges, skin, paranasal sinuses, nasal cavity, bone, salivary glands
  - ECD: Bones, visceral organs, systemic fatty spaces
    - CNS: Cerebral hemispheres, hypothalamus, cerebellum, brainstem, orbits
  - HLH: Brain parenchyma, leptomeninges
  - JXG: Cerebellum, hemispheric WM, choroid plexus
- Morphology
  - RDD: Homogeneous orbital mass; nodular dural-based masses
  - ECD: Parenchymal nodules or masses ± meningeal thickening or masses
  - HLH: Nodular or linear parenchymal lesions

CT Findings

- NECT
  - RDD: Iso/hyperdense orbit, dural-based masses
  - ECD: Hypodense parenchymal lesions typical
    - Rarely see hyperdense lesions
  - HLH: Hypodense lesions
    - May see diffuse brain edema
  - JXG: Hypodense WM lesions
- CECT
  - RDD: Cervical lymphadenopathy
    - Orbital mass with diffuse enhancement
    - Nodular dural mass with diffuse enhancement

MR Findings

- T1WI
  - RDD: Isointense dural-based lesions
  - HLH: Ventriculomegaly; hypointense lesions
- T2WI
  - RDD: Variable; usually hypointense
  - ECD: Hyperintense lesions
  - HLH: Laminated, nodular hyperintense lesions; may become confluent
  - JXG: Patchy, confluent WM lesions in cerebellum, cerebral WM
- T1WI C+
  - RDD: Dural-based masses with diffuse, homogeneous enhancement
  - ECD
    - Hypothalamic-pituitary axis (loss of posterior pituitary "bright spot", thickened mass-like lesion in stalk/hypothalamus
    - Other
      - 3 patterns: Infiltrative (44%), meningeal (37%), or composite (infiltrative and meningeal lesions [19%])
  - HLH: Nodular, linear, or ring-enhancing lesions ± meningeal enhancement
  - JXG: Often minimal or no enhancement; enhancing choroid plexus mass

Imaging Recommendations

- Best imaging tool
  - Enhanced MR best for CNS manifestations
  - WG: Sinus CT; consider MR to evaluate for intracranial involvement if disease is extensive

DIFFERENTIAL DIAGNOSIS

Rosai-Dorfman Disease

- Orbital mass: Lymphoma, inflammatory pseudotumor, sarcoid, granulomatosis with polyangiitis (formerly known as Wegener granulomatosis)
- Meningeal masses: Meningiomas (most common), sarcoid, lymphoma, extramedullary hematopoiesis, metastases
- Cervical lymphadenopathy: Lymphoma, reactive lymph nodes, tuberculosis

Erdheim-Chester Disease and Hemophagocytic Lymphohistiocytosis

- LCH: Sharply marginated, lytic skull lesion; thick enhancing infundibulum; parenchymal lesions rare
- TB: Meningeal and parenchymal enhancing lesions
- Metastases: Multiple enhancing nodules; primary tumor often known

PATHOLOGY

General Features

- RDD
  - S100(+) histiocytes in fibrous stroma
  - Chronic inflammatory cells (T, B lymphocytes)
  - Lymphophagocytosis common (70% of cases)

https://CafePezeshki.IR

- ECD
  - Xanthogranulomatous infiltrate with lipid-laden, foamy histiocytes
  - CD68(+), factor VIII(+), CD1a(-), S100(-)
- HLH
  - Severe hyper-inflammation
  - Starts as leptomeningeal process → perivascular infiltration with astrocytic proliferation affecting mainly white matter → areas of necrosis and focal demyelination
  - Benign-appearing histiocytes with hemophagocytosis (mostly RBCs, neutrophils)
- JXG
  - Histiocytes
    - CD68(+)
    - Touton giant cells (vacuolated foamy histiocytes) classic but not universal

Staging, Grading, & Classification

- World Health Organization classifies histiocytic disorders according to type of histiocyte involved
  - Dendritic cell disorders (LCH, ECD, JXG)
  - Macrophage-related disorders (RDD, HLH)
  - Malignant histiocytic disorders (some leukemias, malignant neoplasms)
- HLH: Consequence of uncontrolled, dysregulated cellular immune reactivity caused by number of different underlying diseases
  - 2 forms of HLH identified
    - Genetic (primary) form
      - Familial (autosomal recessive or X-linked) with clinical HLH syndrome as only manifestation; usually in early infancy
      - Immune deficiencies (e.g., Chediak-Higashi)
    - Acquired (secondary) HLH
      - All ages
      - Usually in immunocompromised individuals
      - Infection-associated hemophagocytic syndrome (EBV, CMV, *Leishmania*)
      - Can occur in reaction to malignancies
      - Can be life-threatening

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - RDD: Painless lymphadenopathy most common
    - Sinonasal disease: Progressive nasal obstruction
    - Orbit: Proptosis
    - CNS: Headache
  - ECD
    - Most common: Bone pain, fever, weight loss
      - Bilateral, symmetrical osteosclerosis (long bones most common)
    - CNS manifestations
      - Most common = central DI (can be longstanding, only symptom), orbits
      - Cerebellar (41%) and pyramidal (45%) syndromes
      - Other: Seizures, headaches, neuropsychiatric or cognitive troubles, sensory disturbances, cranial neuropathy
  - HLH
    - Fever, hepatosplenomegaly most common in familial HLH
    - Neurologic (seizures, irritability, cranial neuropathy, coma)
  - JXG
    - Most common: Limited skin disease
    - Can be systemic (eye, brain, other organs)

Demographics

- Age
  - RDD: Children and young adults (peak 20 years)
  - ECD: Any age but older adults/elderly (5th, 6th decades) most common
  - HLH: Infants (most < 1 year), young children

Natural History & Prognosis

- RDD: Benign, progressive disease
- ECD: Poor prognosis (5 year survival 40%)
- HLH: Generally poor outcome

DIAGNOSTIC CHECKLIST

Consider

- When orbital or dural mass has T2 hypointensity, consider inflammatory pseudotumor (including IgG4-related disease) and RDD
- Brainstem or cerebellar lesions in patient with bone lesions or diabetes insipidus, consider ECD
- Infant or child with enhancing parenchymal and meningeal lesions, consider HLH

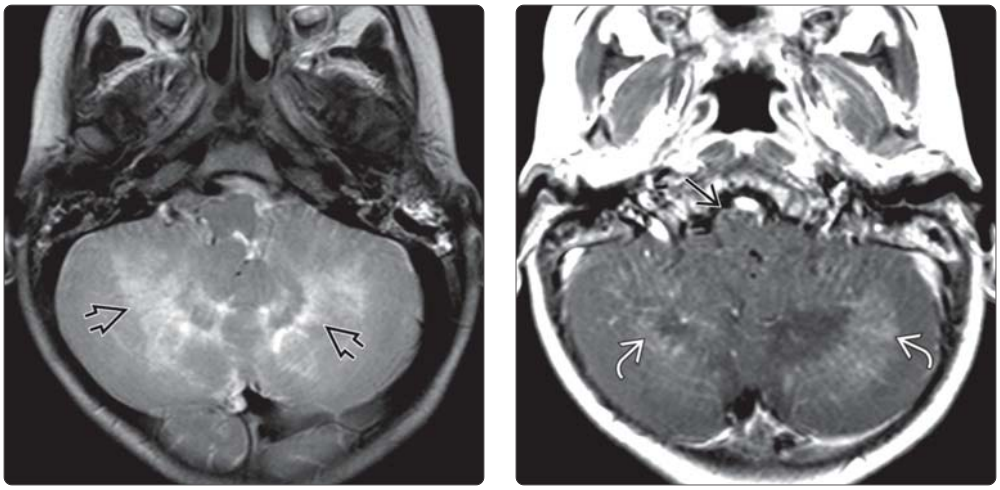
(Left) *Axial T1 C+ MR in a patient with biopsy-proven Erdheim-Chester disease shows enhancing lesions in both cerebellar hemispheres ➡, as well as the cavernous sinus ➡.* **(Right)** *More cephalad T1 C+ MR in the same patient shows additional lesions in the superior cerebellum ➡ and orbits ⇨. (Courtesy M. Warmuth-Metz, MD.)*



(Left) *Axial T2WI MR in a child with hemophagic lymphohistiocytosis shows bilateral patchy and confluent hyperintensities ⇨ in both cerebellar hemispheres.* **(Right)** *Axial T1 C+ MR in the same patient shows patchy and linear enhancement of the extensive cerebellar infiltrates ➡. Subtle pial enhancement over the medulla is also present ⇨. (Courtesy D. Phillips, MD.)*

(Left) *Axial FLAIR MR in a patient with juvenile xanthogranuloma (JXG) shows bilateral confluent and patchy white matter lesions in the subcortical and deep periventricular white matter.* **(Right)** *T1 C+ MR in the same patient shows an enhancing mass in the choroid plexus ➡. Diagnosis of JXG was proven by skin biopsy.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Trichilemmal cyst (TC) is preferred term
  - "Sebaceous cyst" (SC) commonly used but incorrect
  - Variant = proliferating trichilemmal tumor (PTT)
- Keratin-containing cyst
  - Lined by stratified squamous epithelium
  - Pathology looks like root sheath of hair follicle

IMAGING

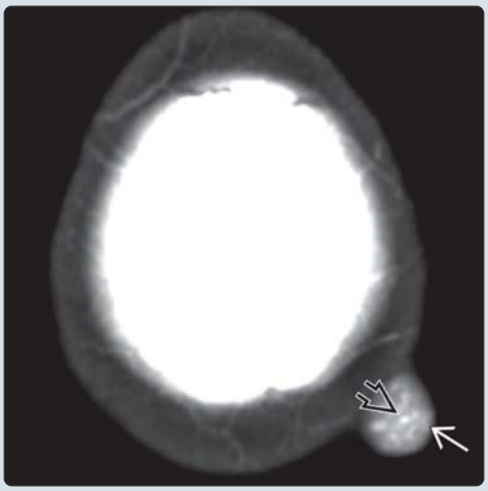
- General features
  - Most within dermis or subcutaneous tissue
  - Size varies (few mm to several cm)
  - Can be single or multiple
- CT
  - Round/ovoid, well-delineated scalp mass
  - Multifocal punctate/curvilinear/coarse Ca++
- MR
  - Isointense with brain, muscle on T1WI
  - Inhomogeneously hypointense on T2WI
  - Does not suppress on FLAIR
  - Multifocal "blooming" foci common on T2*
  - Simple sebaceous cysts usually do not enhance

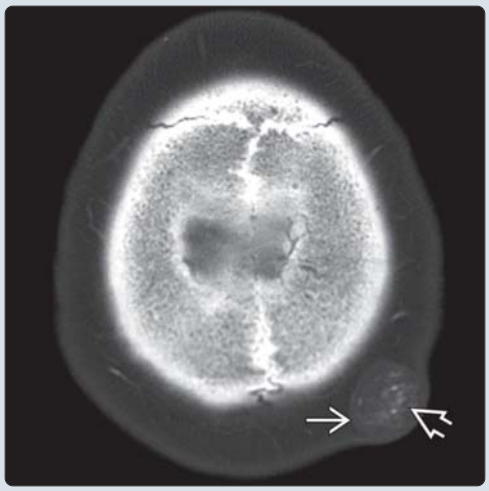
TOP DIFFERENTIAL DIAGNOSES

- Basal cell, SCCa
- Dermoid cyst
- Epidermoid cyst
- Metastasis
- Cephalocele

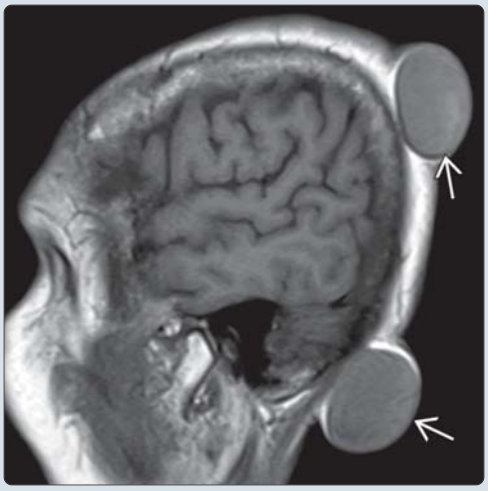
CLINICAL ISSUES

- Classic presentation
  - Subepidermal scalp mass in woman > 60 years of age
  - Hairless, rubbery, nontender, mobile subcutaneous scalp mass(es)
  - Usually nonpainful





(Left) *Axial NECT in a 63-year-old man was obtained for trauma evaluation. A superficial scalp mass ⇨ that contained several hyperintense foci suggesting calcifications ⇨ was incidentally noted.* **(Right)** *Axial bone CT in the same patient shows that the scalp mass ⇨ is sharply delineated. Multiple punctate and curvilinear calcifications ⇨ within the mass can be seen. Note the lack of bone erosion or invasion. The remainder of the scalp appears normal. This was presumed to be a sebaceous cyst.*



(Left) *Sagittal T1WI MR in a 68-year-old woman with headaches shows 2 large but very well-circumscribed scalp masses ⇨. The masses are incompletely surrounded by fat and isointense with brain and muscle.* **(Right)** *Axial T2WI MR in the same patient shows the mass ⇨ to be inhomogeneously hypointense. Both lesions demonstrated some internal "blooming" on T2* that suggested calcifications. These lesions had been slowly enlarging over many years and are benign proliferating trichilemmal cysts.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Trichilemmal cyst (TC) is preferred terminology
  - "Sebaceous cyst" (SC) commonly used but incorrect
- Variant = proliferating trichilemmal tumor (PTT)

Synonyms

- PTT also called "pilar" or "turban" tumor

Definitions

- Keratin-containing cyst
  - Lined by stratified squamous epithelium

IMAGING

General Features

- Best diagnostic clue
  - Nontender scalp mass in older woman
- Location
  - Soft tissues of scalp
    - Most within dermis or subcutaneous tissue
- Size
  - Varies from few mm to several cm
    - Can become huge
  - Can be single or multiple
- Morphology
  - Round/ovoid, well delineated

Imaging Recommendations

- Best imaging tool
  - CT with soft tissue, bone windows

CT Findings

- NECT
  - Solid or cystic scalp mass(es)
  - Sharply delineated
  - Hyperdense to fat
  - Multifocal punctate, curvilinear, and coarse Ca++
    - May layer in dependent portion of larger cysts
- CECT
  - No enhancement

MR Findings

- T1WI
  - Isointense with brain, muscle
- T2WI
  - Inhomogeneously hypointense
- FLAIR
  - Does not suppress
- T2* GRE
  - Multifocal "blooming" foci common
  - Ca++, not hemorrhage
- T1WI C+
  - Simple sebaceous cysts usually do not enhance
  - PTTs may show significant enhancement with solid lobules, cystic cavities

DIFFERENTIAL DIAGNOSIS

Basal Cell, SCCa

- Basal cell carcinomas are ill defined, invade locally
- Primary scalp SCCas rare

Dermoid Cyst

- Skull > > scalp

Epidermoid Cyst

- Skull > > scalp

Hemangioma

- Skull > > scalp

Metastasis

- Ill defined, invasive

Cephalocele

- Young patient
- Usually complex, containing brain/meninges/vessels

PATHOLOGY

Gross Pathologic & Surgical Features

- Elevated, slightly reddish scalp mass

Microscopic Features

- Resembles external root sheath of hair follicle
  - Lined by stratified squamous epithelial cells
- Cyst contents: Keratin, Ca++ frequent
- Malignant transformation rare

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Hairless, rubbery, nontender, mobile subcutaneous scalp mass
  - Usually nonpainful

Demographics

- Age
  - Any age
  - Proliferating trichilemmal cysts most common in elderly women
    - Classic is subepidermal scalp tumor in female > 60 years of age
- Gender
  - Female predominance

Natural History & Prognosis

- Usually slow growth
- May become locally aggressive
- Malignant transformation of trichilemmal cysts is rare
  - Proliferating trichilemmal cystic carcinoma (PTCC)

Treatment

- Surgical excision

KEY FACTS

TERMINOLOGY

- Typical ("benign") meningioma (TM) = WHO grade 1

IMAGING

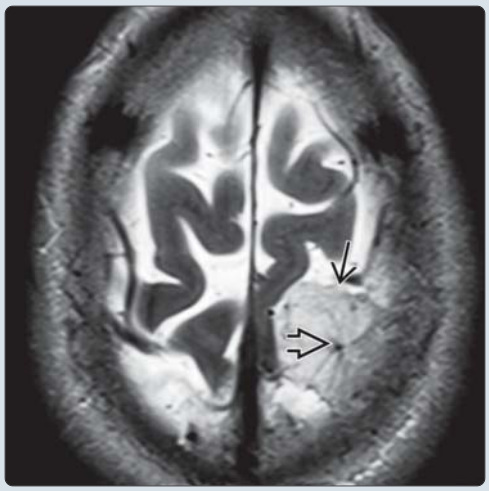
- Location
  - Supratentorial (90%)
    - Parasagittal/convexity (45%), sphenoid (15-20%)
    - Olfactory groove (5-10%), parasellar (5-10%)
  - Infratentorial (8-10%) (CPA most common site)
  - Multiple meningiomas in 1-9% of cases
- General features
  - Extraaxial mass with broad-based dural attachment
  - > 90% enhance homogeneously, intensely
- CT
  - Hyper- (70-75%), iso- (25%), hypodense (1-5%)
  - Hyperostosis, irregular cortex, ↑ vascular markings
  - Ca++ (20-25%) (diffuse, focal, sand-like, "sunburst," globular, rim)
  - Necrosis, cysts common; hemorrhage rare
- MR
  - Look for CSF/vascular "cleft" between tumor, brain
  - Dural "tail" (35-80% but nonspecific)
- Correlation between imaging, ↑ tumor grade
  - Indistinct tumor-brain interface
  - Capsular enhancement
  - Heterogeneous tumor enhancement

TOP DIFFERENTIAL DIAGNOSES

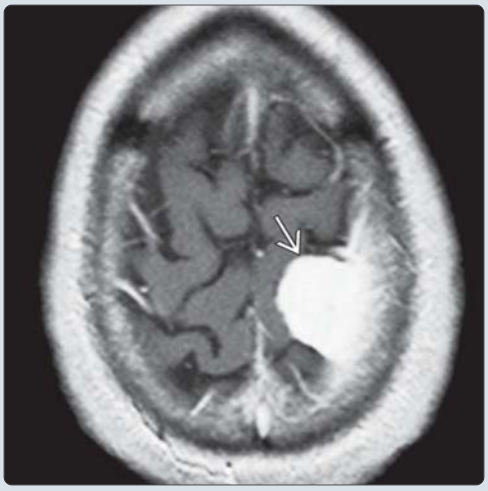
- Dural metastasis
- Granuloma (TB, sarcoid)
- Idiopathic hypertrophic pachymeningitis
- Extramedullary hematopoiesis
- Hemangioma, dura/venous sinuses

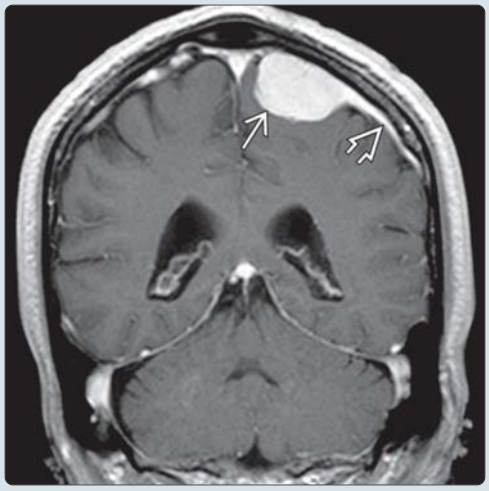
CLINICAL ISSUES

- Most common adult 1° intracranial neoplasm (20-35%)
- Peak age = 40-60 years (rare in children unless NF2)
- Often asymptomatic, incidentally found, grow slowly



(Left) *Coronal graphic depicts classic meningioma with broad base toward dura with reactive dural tail ⇨. Note the CSF-vascular cleft ⇨ between invaginating tumor and brain. Typical "sunburst" of dural vessels ⇨ (in this case, the middle meningeal artery) supplies center of lesion, while pial vessels supply periphery.* **(Right)** *Axial T2 FS MR in a 59-year-old man with headaches shows a moderately hyperintense extraaxial mass ⇨ with "sunburst" of vessels (flow voids) supplying center of tumor ⇨.*





(Left) *Axial T1 C+ MR in the same patient shows the mass ⇨ enhances strongly and uniformly.* **(Right)** *Coronal T1 C+ MR shows the enhancing mass ⇨ with slightly more intensely enhancing dural tail ⇨. A WHO grade I meningioma was removed at surgery. The dural tail was not involved by tumor.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Typical meningioma (TM)
- Atypical meningioma (AM), malignant meningioma (MM)

Definitions

- TM = WHO grade 1 meningioma

IMAGING

General Features

- Best diagnostic clue
  - Dural-based enhancing mass → cortical buckling, trapped CSF/vessels in "cleft" between tumor and brain
- Location
  - Supratentorial (90%)
    - Parasagittal/convexity (45%), sphenoid ridge (15-20%)
    - Olfactory groove (5-10%), parasellar (5-10%)
    - Other (5%): Intraventricular, optic nerve sheath (ONSM), pineal region
    - Rare: Intraparenchymal without dural attachment
  - Infratentorial (8-10%): CPA most common
  - Extradural (mostly intraosseous, calvaria) > 2%
  - Extracranial (head/neck)
    - Most common: Paranasal sinuses
    - Less common: Nasal cavity, parotid, skin
  - Multiple meningiomas: Seen in 1-9% of cases
    - 16% at autopsy (M < F)
- Morphology
  - Extraaxial mass with broad-based dural attachment

CT Findings

- NECT
  - Sharply circumscribed smooth mass abutting dura
    - Hyperdense (70-75%), isodense (25%)
      - Hypodense (1-5%), fat density (rare lipoblastic subtype)
    - Calcified (20-25%)
      - Can be diffuse, focal, sand-like ("psammomatous")
      - "Sunburst," globular, rim patterns
      - Calcification correlates with slow growth in asymptomatic meningiomas
    - Necrosis, cysts, hemorrhage (8-23%)
  - Trapped CSF pools, cysts in adjacent brain common
  - Peritumoral hypodense vasogenic edema (60%)
  - Bone CT
    - Hyperostosis, irregular cortex, ↑ vascular markings
- CECT
  - > 90% enhance homogeneously, intensely
- CTA
  - May be helpful prior to DSA, embolization
  - Delineates arterial supply, venous drainage

MR Findings

- T1WI
  - Typically iso- to slightly hypointense with cortex
  - Necrosis, cysts, hemorrhage (8-23%)
  - Look for gray matter "buckling"
- T2WI
  - Variable ("sunburst" pattern may be evident)
  - 8-23% of intratumoral cysts (common; can be almost microcystic), hemorrhage (rare)
  - Best sequence for
    - Visualizing CSF/vascular cleft between tumor, brain (80%)
    - Identifying vascular flow voids (80%)
    - Predicting "hard" meningioma at surgery (hypointense)
- FLAIR
  - Hyperintense peritumoral edema, dural tail
- T2* GRE
  - Ca++ common, hemorrhage rare
- DWI
  - DWI, ADC maps for TM variable in appearance
  - Lower ADC in MM and AM compared to TM
- T1WI C+
  - > 95% enhance homogeneously, intensely
  - Dural tail (35-80% of cases) nonspecific
    - Other neoplasms (schwannoma, adenoma, metastases), nonneoplastic dural-based masses
  - En plaque: Sessile thickened enhancing dura
- MRV
  - Evaluate sinus involvement
- MRS
  - Elevated levels of alanine at short TE
    - Triplet-like spectral pattern at 1.3-1.5 ppm (overlapping of Ala, Lac)
    - Elevated Glx alfa/glutathione
- Perfusion MR
  - rCBV and rMTE values of peritumoral edema differentiate TM and MM
    - High rCBV in peritumoral edema of anaplastic meningiomas
- Correlation between imaging, ↑ tumor grade
  - Indistinct tumor-brain interface
  - Capsular enhancement
  - Heterogeneous tumor enhancement

Angiographic Findings

- DSA
  - "Sunburst" or radial appearance
    - Dural vessels supply lesion core
    - Pial vessels may be parasitized, supply periphery
  - Prolonged vascular "stain"
  - Venous phase vital to evaluate sinus involvement

Nuclear Medicine Findings

- Thallium-201 SPECT better than FDG PET at predicting tumor grade

Other Modality Findings

- Imaging predictors of difficult, extrapial surgical cleavage plane
  - Peritumoral edema on MR/CT → may obscure pial invasion by tumor
  - Tumor pial vascularization on DSA = pial invasion
  - Tumor/cortex interface is not reliable predictor

Imaging Recommendations

- Best imaging tool
  - MR C+

https://CafePezeshki.IR

- Protocol advice
  - Consider MRS → look for alanine, glu:cr ratio

DIFFERENTIAL DIAGNOSIS

Dural Metastasis

- Skull often infiltrated; multifocal
- Breast most common primary

Granuloma

- Sarcoid
- TB

Idiopathic Hypertrophic Pachymeningitis

- Dural biopsy essential to confirm diagnosis
- Often IgG4-related disease

Extramedullary Hematopoiesis

- Known hematologic disorder
- Often multifocal

Hemangioma, Dura/Venous Sinuses

- Can be indistinguishable from TM
- Venous sinus (e.g., cavernous) > dural-based mass

PATHOLOGY

General Features

- Etiology
  - Arise from arachnoid meningothelial ("cap") cells
  - Loss of chromosome 22 (40-60% of sporadic meningiomas)
  - NF2 meningiomas
    - Genomic instability
    - More likely to be atypical
    - Cerebral, cerebellar hemispheres, lateral skull base, spine
  - Non-NF2 meningiomas
    - Nearly always benign
    - Chromosomal stability, SMO mutations common
    - Medial skull base
  - *SMARCB1* mutations common in multiple meningiomas
- Associated abnormalities
  - Neurofibromatosis type 2 (NF2)
    - Multiple inherited schwannomas, meningiomas, and ependymomas (MISME)
    - 50-75% of patients with NF2 develop meningioma
    - 10% of patients with multiple meningiomas have NF2
  - Metastases to meningioma ("tumor to tumor" sometimes called "collision tumor")
    - CM are most common primary intracranial tumor to harbor metastases; majority are lung or breast
- Slow growing, benign

Gross Pathologic & Surgical Features

- 2 basic morphologies
  - Globose = globular, well-demarcated neoplasm with wide dural attachment (dural tail)
    - 60% of tumors demonstrate local invasion into dural tail
  - En plaque = sheet-like extension covering dura without parenchymal invagination
- Homogeneous reddish-brown translucent pale surface
- Soft to tough, occasionally gritty
  - Depends on fibrous tissue, Ca++ calcium content
- TMs usually invaginate into brain, do not invade it

Microscopic Features

- TM (WHO grade I) has wide range of subtypes
  - Meningothelial: Uniform tumor cells, collagenous septa, psammomatous calcifications (most common)
  - Fibrous: Interlacing fascicles of spindle-shaped cells, collagen/reticulin matrix
  - Transitional (mixed): "Onion bulb" whorls, psammoma bodies
  - Psammomatous
  - Angiomatous
  - Microcystic
  - Secretory
  - Lymphoplasmacyte rich
  - Metaplastic

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - < 10% of all meningiomas are symptomatic
  - Symptoms depend on tumor site

Demographics

- Age
  - Middle decades
- Gender
  - M:F = 1:1.5-3
- Epidemiology
  - Most common 1° adult intracranial tumor (20-35%)
    - 1-1.5% autopsy prevalence

Natural History & Prognosis

- Generally grow slowly, compress adjacent structures
- Parasagittal often grow into and occlude superior sagittal sinus
- Metastases rare (0.1-0.2%): Histology, location do NOT correlate with metastases

Treatment

- Asymptomatic followed with serial imaging
- Surgical goals
- Radiotherapy infrequently utilized for CM

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Preoperatively define **entire** extent of tumor
- Could patient be syndromic (e.g., NF2)

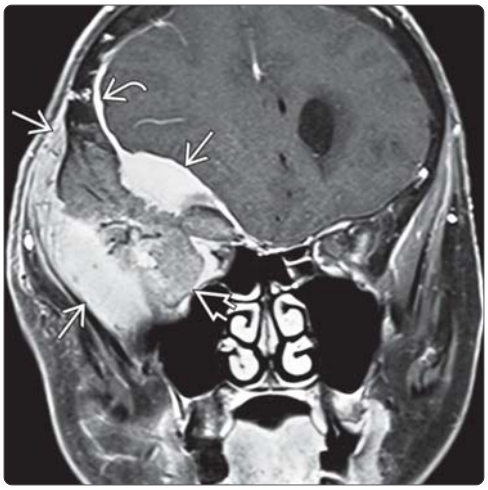
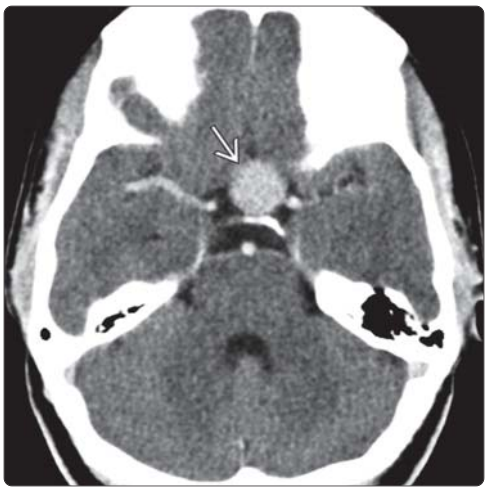
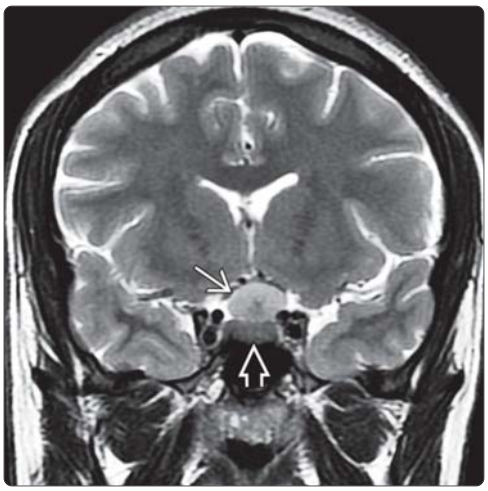
(Left) *Axial T2 FS MR in a 66-year-old woman with severe proptosis shows massive thickening of the greater sphenoid wing ➡ surrounded by a mildly hyperintense soft tissue mass ➡ involving the orbit, high deep masticator space, and middle cranial fossa.* **(Right)** *The marked hyperostosis of the sphenoid wing ➡ is well shown on this coronal STIR MR. There is a distinct dural tail ➡ that is noticeably more hyperintense than the soft tissue component of the mass ➡.*



(Left) *Axial T1 C+ FS MR in the same patient shows the soft tissue component of the mass ➡ enhances strongly and uniformly. The hyperostotic bone ➡ enhances mildly.* **(Right)** *Coronal T1 C+ FS MR shows the intensely enhancing soft tissue mass ➡, the markedly thickened, hyperostotic and vascularized sphenoid wing ➡, and the adjacent dural tail ➡. WHO grade I meningioma with tumor cells in the resected sphenoid bone was found at surgery.*

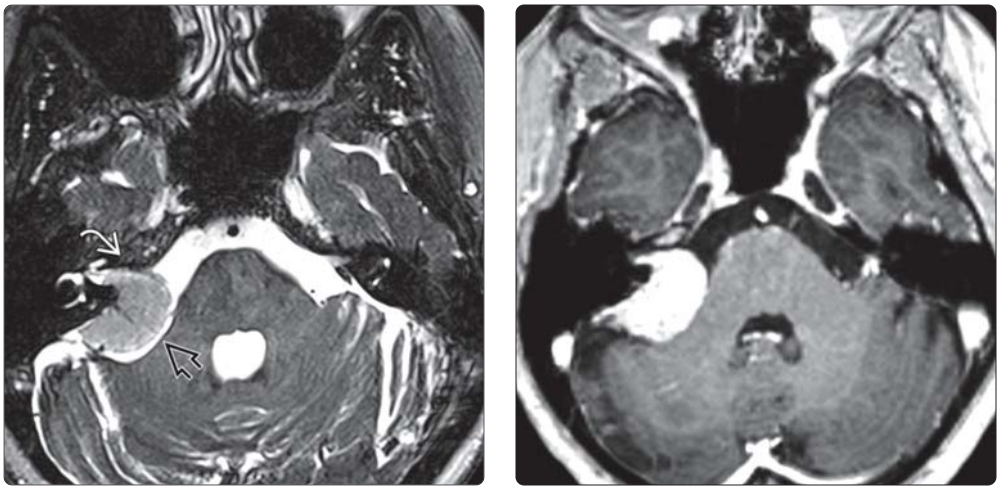




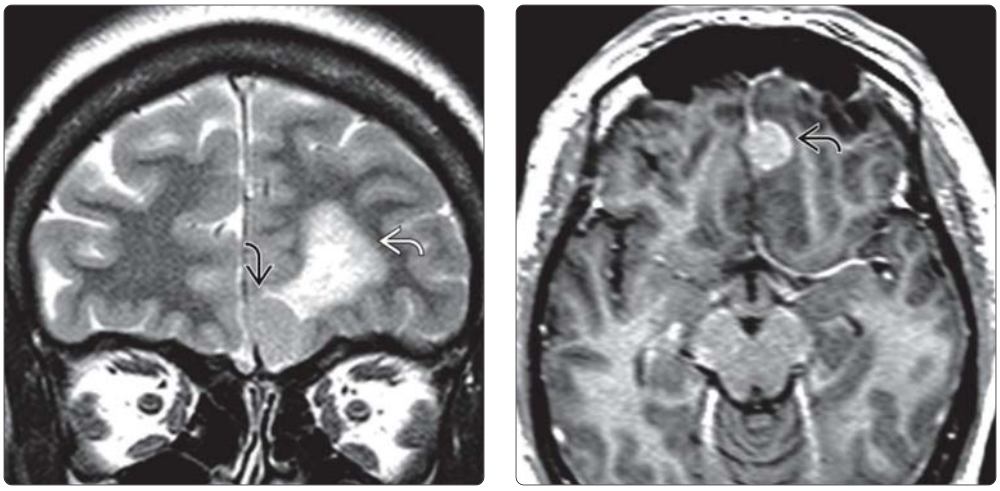
(Left) *Axial CECT in a 26-year-old pregnant woman with sudden visual loss shows an enhancing suprasellar mass ➡.* **(Right)** *Because of the concern for hemorrhagic pituitary neoplasm, an MR was obtained for further evaluation. Coronal T2WI shows a normal pituitary gland ➡ with a well-delineated hyperintense mass ➡ above it that arises from the diaphragma sellae and is clearly separate from the gland. Classic diaphragma sellae meningioma was found at surgery, proven to be a WHO grade I tumor.*

https://CafePezeshki.IR

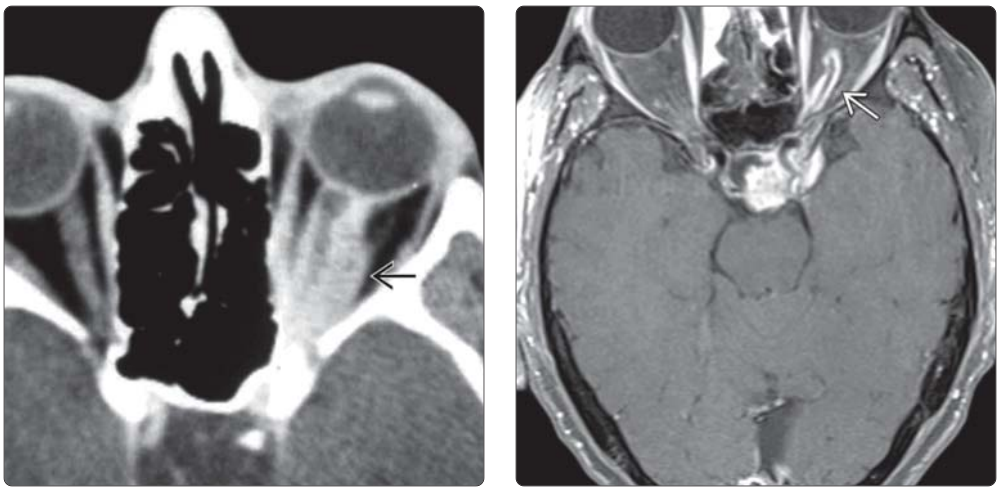
(Left) *Axial T2WI MR shows a well-defined mass in the right cerebellopontine angle ⇨ with extension into the right auditory canal ⇨.* **(Right)** *Axial T1WI C+ MR demonstrates marked and homogeneous enhancement of the CPA meningioma.*



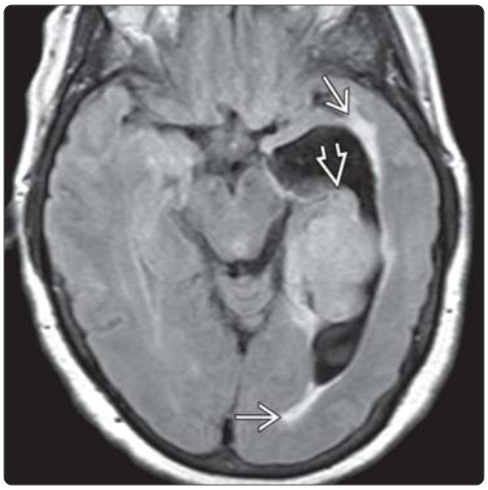
(Left) *Coronal T2WI MR shows a cortex isointense mass ⇨ in the region of the left olfactory bulb with perifocal edema ⇨.* **(Right)** *Axial T1WI C+ MR shows marked and homogeneous enhancement of the mass ⇨ representing olfactory meningioma.*

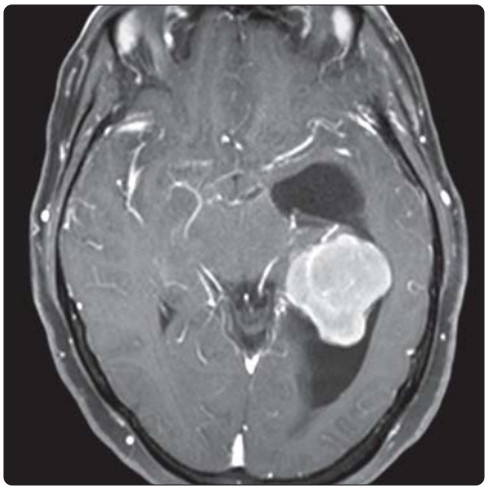


(Left) *Axial CECT in a patient with primary optic nerve sheath meningioma shows marked enhancement along the left optic nerve, described as a "tram-track" sign ⇨.* **(Right)** *Axial T1WI C+ MR in this patient with secondary optic nerve sheath meningioma shows meningioma arising from the sphenoid ridge around the anterior clinoid, narrowing the cavernous internal carotid, extending through the optic canal, and infiltrating the optic nerve sheath ⇨.*



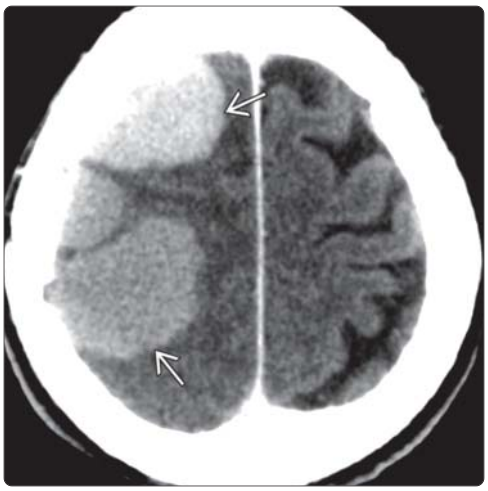
https://CafePezeshki.IR

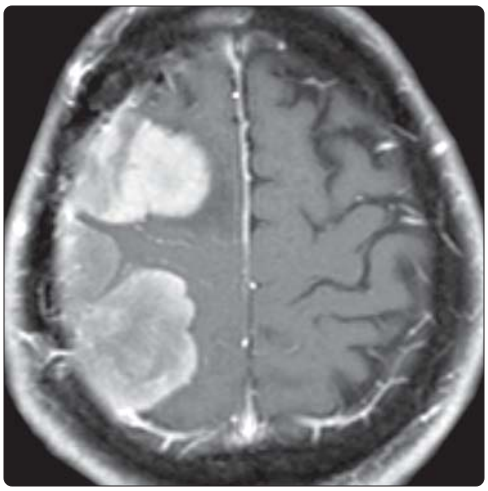




(Left) *Axial FLAIR MR shows a lobulated, mildly hyperintense intraventricular mass* ➡ *arising from the choroid plexus glomus. Note the enlarged temporal horn of left lateral ventricle with periventricular accumulation of interstitial fluid migration* ➡. **(Right)** *Axial T1 C+ FS MR shows a strongly, uniformly enhancing mass. Intraventricular meningioma was found at surgery. About 1% of intracranial meningiomas are intraventricular; this is the most common location as arachnoid rests may persist within choroid plexus.*

(Left) *Axial NECT shows marked hyperostosis* ➡ *and calcification* ➡ *in this plaque-like meningioma extending along the left inner table of the skull.* **(Right)** *Axial T1WI MR in the same patient demonstrates the characteristic hypointense appearance of calcification/ossification* ➡.





(Left) *Axial CECT shows multiple well-delineated, right-sided extraaxial masses* ➡ *that were moderately hyperdense on NECT (not shown) and enhance strongly.* **(Right)** *Axial T1WI C+ MR shows strongly enhancing masses. Multiple meningiomas are more common in female patients and patients with NF2.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Typical (benign) meningioma = WHO grade 1
- Atypical meningioma (AM) = WHO grade 2
- Malignant meningioma (MM) = WHO grade 3

IMAGING

- CT triad of MM: Extracranial mass, osteolysis, intracranial tumor
- MR
  - Dural-based locally invasive lesion with areas of necrosis, marked brain edema
  - Indistinct tumor margins (tumor invades, interdigitates with brain)
  - Prominent tumor pannus extending away from mass = "mushrooming"
  - Marked peritumoral edema
  - DWI, ADC correlate with hypercellular histopathology (high signal on DWI, low ADC)

TOP DIFFERENTIAL DIAGNOSES

- Meningioma (typical)
- Dural metastasis
- Lymphoma
- Sarcoma (osteosarcoma, Ewing, gliosarcoma, etc.)

PATHOLOGY

- AM: High mitotic activity
- MM: AM features + findings of frank malignancy

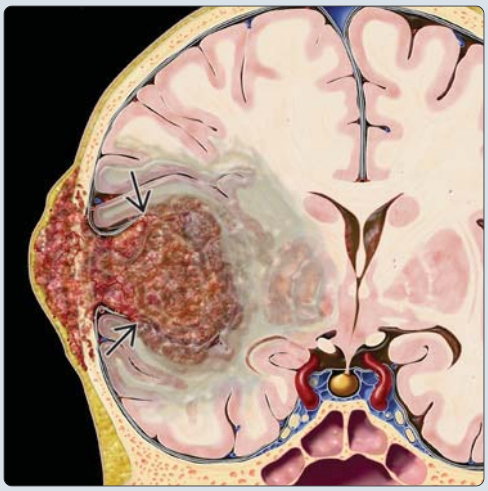
CLINICAL ISSUES

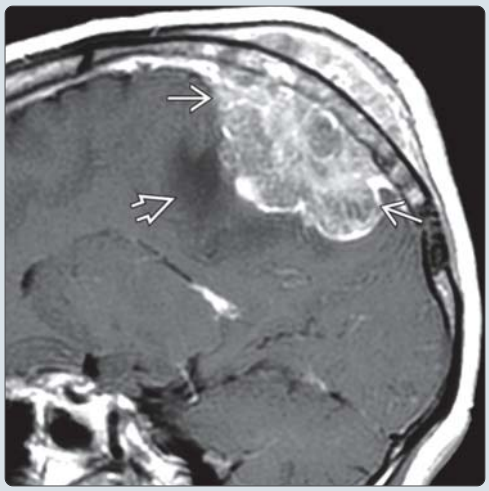
- AM 29% recurrence (26% become MM)
- MM 50% recurrence

DIAGNOSTIC CHECKLIST

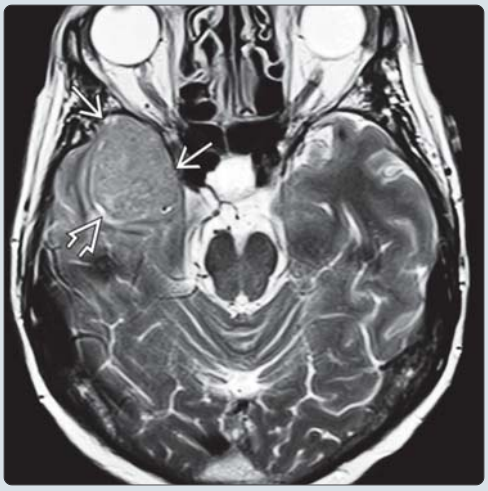
- Difficult to predict meningioma tumor grade on imaging
- Imaging findings of typical meningioma do not exclude atypical, malignant variants

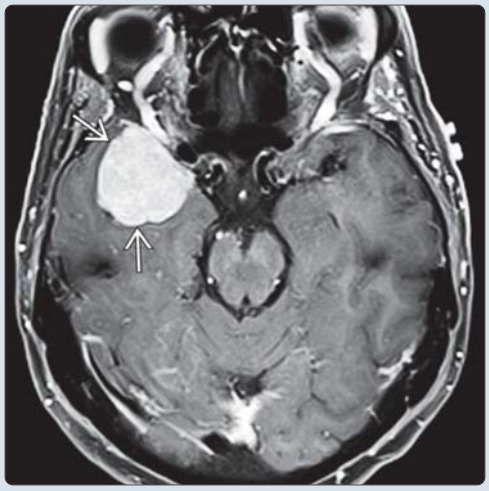
(Left) *Coronal graphic illustrates a malignant meningioma infiltrating the scalp, skull, and underlying brain. Extensive vasogenic edema (in gray) is present. Note osteolysis, invasion through dura/arachnoid, tumor "mushrooming" ⇨, and interdigitation with the brain.* **(Right)** *Sagittal T1WI C+ MR of malignant meningioma shows enhancing tumor involving the scalp, skull, and underlying brain. Note "mushrooming" of tumor through the dura ⇨, prominent hypointense brain edema ⇨.*





(Left) *Axial T2WI MR in a 71-year-old man shows well-demarcated dural-based mass along right greater sphenoid wing ⇨. Mass is isointense with cortex & distinct CSF-vascular cleft ⇨ with no evidence for focal brain invasion.* **(Right)** *Axial T1 C+ FS MR scan shows intense, uniform enhancement ⇨. At surgery there was no evidence for invasion of adjacent parenchymal. Pathology disclosed WHO grade II meningioma. This case illustrates the difficulty of predicting meningioma tumor grade on imaging.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Atypical meningioma (AM), malignant meningioma (MM)

Definitions

- Typical (benign) meningioma = WHO grade 1
  - Common meningioma (CM)
- Atypical meningioma = WHO grade 2
  - Papillary, clear cell meningiomas (CCM)
- Malignant meningioma = WHO grade 3
  - Anaplastic meningioma

IMAGING

General Features

- Best diagnostic clue
  - Dural-based, locally invasive lesion with areas of necrosis, marked brain edema
- Location
  - May occur anywhere in neuraxis (brain > > spine)
  - AM (clear cell variant)
    - Frequent in CPA, along tentorium
  - MM
    - Parasagittal (44%), cerebral convexities (16%) most common sites
    - Both AM, MM far less frequent in spine, skull base

CT Findings

- NECT
  - CT triad of MM: Extracranial mass, osteolysis, intracranial tumor
  - Hyperdense; minimal or no Ca++
    - Calcified = generally lower growth rate
  - Marked perifocal edema, bone destruction
- CECT
  - Enhancing tumor mass
  - Prominent tumor pannus extending away from mass = "mushrooming"

MR Findings

- T1WI
  - Indistinct tumor margins
  - Infiltrating tumor interdigitates with brain
- FLAIR
  - Marked peritumoral edema
- DWI
  - Markedly hyperintense on DWI, hypointense on ADC
- T1WI C+
  - Enhancing tumor mass
    - May extend into brain, skull, scalp
    - Often plaque-like ± "mushrooming"
- MRV
  - Look for dural sinus invasion
- MRS
  - Elevated levels of alanine at short TE (peak ranges from 1.3-1.5 ppm)
- Perfusion MR
  - Good correlation between volume transfer constant (K-trans), histologic grade

Angiographic Findings

- Conventional
  - Dural supply → central "sunburst" appearance
  - Intense vascular stain appears early, persists late
  - Venous phase vital to evaluate sinus involvement

Nuclear Medicine Findings

- PET
  - F-18 FDG: AM, MM ↑ ↑ glucose utilization
  - High glucose metabolism present in radiation-induced meningiomas

Imaging Recommendations

- Best imaging tool
  - MR C+, ± MRS

DIFFERENTIAL DIAGNOSIS

Meningioma (Typical)

- Usually noninvasive but may need histology for definitive diagnosis

Dural Metastasis

- Often known extracranial primary neoplasm
- Osteolytic & destructive or osteoblastic & sclerotic

Lymphoma (Metastatic Intracranial)

- Lytic bone lesion with epidural and extracranial component

Osteosarcoma

- Osteolytic with soft tissue mass and poorly defined margins
- Tumoral calcification may be "sunburst"

Ewing Sarcoma

- Affects children
- CT: Laminated periosteal "onion skin" appearance

Primary Meningeal Sarcoma

- Extremely rare nonmeningothelial tumor of meninges

Gliosarcoma

- GBM with meningeal sarcoma

PATHOLOGY

General Features

- Etiology
  - CM: 90% inactivation of *NF2* gene product "Merlin"
  - AM & MM: After *NF2* inactivation, additional events occur and are related to greater aggressiveness
  - Occasionally no genetic defect found as etiology
- Genetics
  - Loss of 1 copy of chromosome 22 is most common chromosomal change in meningioma
  - 2nd most frequent genetic abnormalities are 1p and 14q deletions, more aggressive behavior
  - Chromosome 10 abnormalities shared with nonmeningioma tumors
  - Chromosome 9p losses important in AM and MM
  - Multiple meningiomas
    - Many display expected *NF2* gene mutations
    - Some have normal *NF2* genes: Suggests 2nd tumor-suppressor gene is also on chromosome 22
  - Radiation-associated meningiomas (RAM)

https://CafePezeshki.IR

- No significant differences between RAM and non-RAM in chromosome 1 and 22 losses
- Genetic effects on location and histology
  - Strong correlations found among anterior skull base location, intact 22q, and meningothelial; convexity location, disrupted 22q, transitional, fibrous
- **Summary**: Significant correlation between number of chromosomal imbalances and tumor grade
  - CM: 22q loss (47%), 1p deletion (33%)
  - AM: 1p (86%), 22q (71%), 10q (57%), 14q and 18q (43%) losses; 15q and 17q (43%) gains
  - MM: 1p loss (100%); also losses on 9p, 10q, 14q, 15q, 18q, and 22q and gains on 12q, 15q & 18p
  - Combined 1p/14q deletions in CM (13%), AM (43%), and MM (67%)

Staging, Grading, & Classification

- Immunohistochemical staining with MIB-1 antibody (Ki-67) correlates with recurrence
  - MIB-1 = nuclear, nonhistone protein expressed during cell-cycle proliferation but not resting
  - Staining with MIB-1 yields labeling index (LI) for quantification of number of dividing cells
    - LI < 4.4% → 82% recurrence free at 6 years
    - LI > 4.4% → 32% recurrence free at 6 years

Microscopic Features

- AM features (WHO criteria)
  - ↑ mitotic activity (4 or more mitoses/10 HPFs)
  - 3 or more
    - Small cells with high nuclear:cytoplasmic ratio
    - Prominent nucleoli
    - Uninterrupted patternless or sheet-like growth
    - Foci of spontaneous or geographic necrosis
- MM features (WHO criteria)
  - AM features with findings of frank malignancy
    - Malignant cytology, high mitotic index

CLINICAL ISSUES

Demographics

- Age
  - Middle decades
  - AM occurs about 10 years earlier than typical meningioma
- Gender
  - M:F = 1:1.3-1.5
- Ethnicity
  - More common in African Americans
- Epidemiology
  - Meningioma 1 of most common primary adult intracranial neoplasms (13-20%)
    - AM: 10-30% of all meningiomas (frequency rising)
    - MM: 1-3% of meningiomas (rare)
  - ~ 6 in 100,000 population
  - Familial predilection for meningioma = *NF2*
- Geographic predilection
  - In Africa, meningioma nears 30% of adult primary intracranial tumors

Natural History & Prognosis

- Recurrence-free survival, median time to recurrence longer for typical meningioma vs. AM vs. MM
  - Typical benign meningioma = only 9% recurrence
  - AM recurrence: 28%
    - 5-year survival: 86%; 10-year survival: 61%
    - 5-year recurrence-free survival: 48%
    - Median time to recurrence: 3 years
  - MM recurrence: 75%
    - 5-year survival: 35%
    - 5-year recurrence-free survival: 29%
    - Median time to recurrence: 2 years
  - MicroRNA-224 contributes to malignant progression of meningioma

Treatment

- Preoperative embolization
  - Particulate agents (e.g., polyvinyl alcohol) favored
  - ↓ operative time, blood loss
- Surgical goals
  - Resection of tumor and involved dura/dural tail (with tumor-free margins) with duraplasty
  - Resection of involved or hyperostotic bone
  - Preoperative knowledge whether tumor is AM or MM may alter neurosurgery preoperative plan
    - More aggressive to achieve complete resection
    - Complication: CSF seeding
- Radiotherapy: Frequently used for AM, MM
  - Fractionated external beam irradiation
  - Stereotactic radiosurgery
- Recurrence treatments
  - Repeat surgery
  - External beam irradiation, stereotactic radiosurgery

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Preoperatively define **entire** tumor extent
- Typical imaging findings do not exclude atypical variants

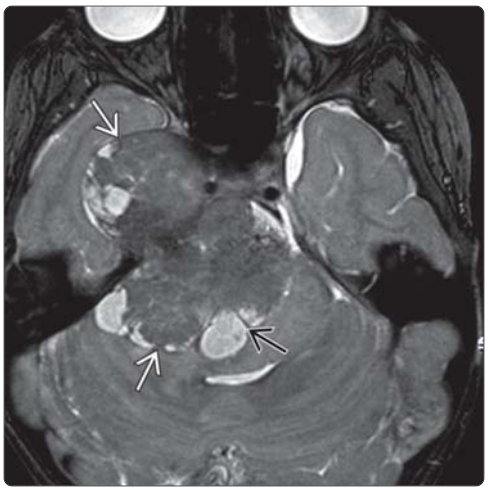
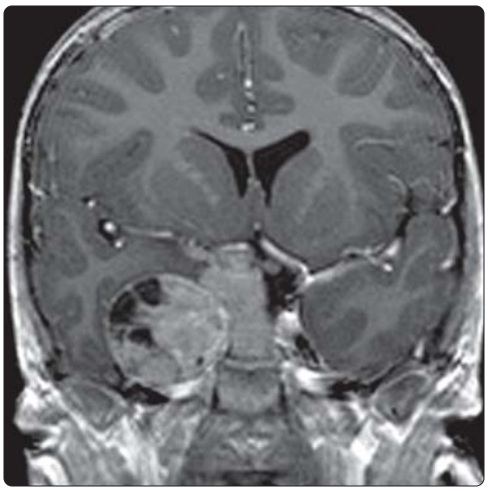
(Left) *Coronal T2WI MR in a 47-year-old man demonstrates a well-defined, homogeneous, extraaxial mass with minimal edema* ➡. **(Right)** *Axial T1 C+ MR in the same patient shows marked, relatively homogeneous enhancement. Note the compression of the left trigonum* ➡. *Surgical resection and histological evaluation revealed malignant meningioma (WHO grade III) despite the lack of aggressive features on imaging. Biopsy is necessary for definitive histologic type and grade of meningioma.*

(Left) *Axial NECT demonstrates a lobulated hyperdense mass along the right tentorium.* **(Right)** *Axial FLAIR MR in the same patient shows a hypointense, multilobulated mass* ➡ *with perifocal edema* ➡ *and mass effect on the 4th ventricle.*





(Left) *High-resolution axial T2WI MR in the same patient nicely demonstrates a well-defined, low signal mass* ➡ *with cystic components* ➡. *Hypodensity indicates a high cellular matrix of the tumor.* **(Right)** *Coronal T1WI C+ SPGR MR shows enhancement of the solid tumor parts. Surgical removal was performed, and histological diagnosis was a mixture of clear cell meningioma (WHO grade II) and a whorling sclerosing variant of meningioma.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Nonmenigotheliomatous benign mesenchymal tumor (BMT)
  - Typically dura, skull, &/or scalp lesion
  - Examples = chondroma, osteochondroma, osteoma, etc.

IMAGING

- Lesion of dura, skull, skull base, scalp without malignant features
- Use NECT, bone CT for most
- T1WI C+ MR to image noncalcified cartilage, brain involvement, malignant transformation

TOP DIFFERENTIAL DIAGNOSES

- Benign meningothelial tumors
- Malignant meningothelial tumors
- Malignant nonmeningothelial tumors

PATHOLOGY

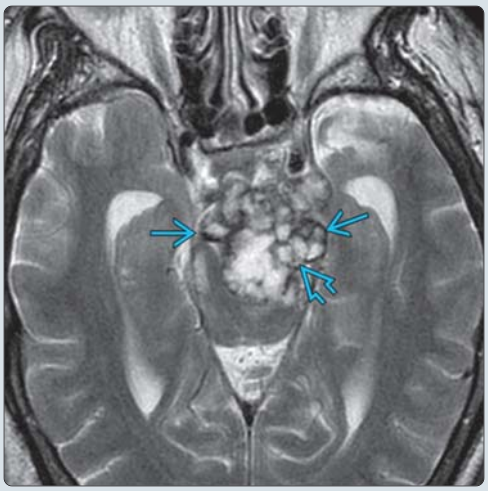
- Meninges contain primitive multipotential mesenchymal cells
  - May give rise to broad spectrum of nonmeningothelial neoplasms

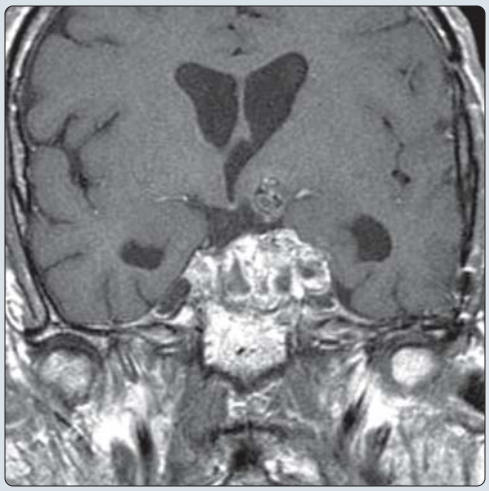
CLINICAL ISSUES

- BMT are most often asymptomatic
- BMT are rare to very rare
- Asymptomatic lesions require no treatment
- Surgical indications: Relief of symptoms, cosmesis

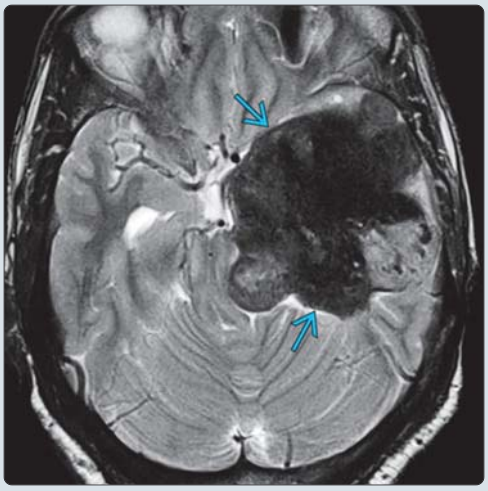
DIAGNOSTIC CHECKLIST

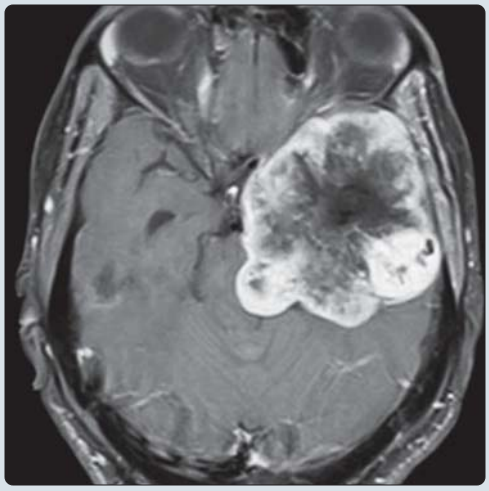
- Look for evidence of syndromic BMTs
  - Gardner: Multiple osteomas
  - Maffucci: Multiple enchondromas with hemangiomas
  - Ollier: Enchondromatosis





(Left) *Axial T2WI MR shows a well-delineated suprasellar mass with hypointense arcs surrounding hyperintense lobulated areas.* **(Right)** *Coronal T1 WI C+ MR in the same case shows that the mass involves the left cavernous sinus and enhances strongly but heterogeneously. Enchondroma was the histologic diagnosis. (Courtesy P. Sundgren, MD.)*





(Left) *Axial T2 WI MR shows a well-demarcated, lobulated, very hypointense mass in the left middle cranial fossa.* **(Right)** *Axial T1 WI C+ FS MR in the same case shows the strong but heterogeneous enhancement is mostly in the periphery of the mass. Solitary fibrous tumor was found at surgery. (Courtesy R. Hewlett, MD.)*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Benign mesenchymal tumors (BMT)
  - Includes chondroma (CD), osteochondroma (OCD), osteoma (OST), and many others

Synonyms

- Benign nonmeningothelial tumors

Definitions

- Nonmenigotheliomatous mesenchymal benign neoplasm
  - Typically dura, skull, &/or scalp lesion

IMAGING

General Features

- Best diagnostic clue
  - Dura, skull, skull base, or scalp lesion without malignant features
- Location
  - BMT: Dura, skull, skull base, scalp
    - CD: Sellar/parasellar most common; dura/falx rare
    - OCD: Usually arises from skull base; dura/falx, rare
    - OST: Involves outer table; inner table rare

Radiographic Findings

- Radiography
  - CD: Expansile lesion containing matrix calcification with scalloped endosteum
  - OCD: Sessile or pedunculated bone-like projection
  - OST: Dense lesions without diploic involvement

CT Findings

- NECT
  - Chondroma
    - Expansile, lobulated, soft tissue mass
    - Contains curvilinear matrix calcification
    - Scalloped endosteal bone resorption → "saucerization"
    - No stalk or peduncle as in OCD
  - Osteochondroma
    - May see calcified matrix in cap atop cortical bone
    - Parent bone contiguous with cortex of OCD
  - Osteoma
    - Dense lesions without diploic involvement
- CECT
  - CD: May have slight enhancement
  - OCD: ± cartilaginous cap enhancement
  - OST: No enhancement

MR Findings

- T1WI
  - CD: Intermediate intensity
  - OCD: Mixed intensity; may see hypointense calcified matrix within cap atop cortical bone
  - OST: Hypointense
- T2WI
  - CD: Hyper- to hypointense
  - OCD: Mixed intensity; may see hypointense calcified matrix within cap atop cortical bone
  - OST: Variable intensity
- T1WI C+
  - CD: Enhancement of curvilinear septae (ring-and-arc pattern), scalloped margins
  - OCD: May have peripheral cartilaginous cap enhancement
  - OST: No enhancement

Nuclear Medicine Findings

- Bone scan
  - CD: Uptake if actively making bone
  - OCD: Varies
  - OST: Uptake during active growth phase, diminishing to background levels

Imaging Recommendations

- Best imaging tool
  - NECT + bone CT for most
  - MR C+ for imaging noncalcified cartilage, affects on soft tissues, evaluating for malignant transformation
- Protocol advice
  - CT: Axial and coronal thin sections at skull base
  - MR: Fat saturation to confirm fat content or to optimize imaging of scalp lesions

DIFFERENTIAL DIAGNOSIS

Benign Meningothelial Tumors

- Common meningioma
  - Characteristic MR appearance with dural tail

Malignant Meningothelial Tumors

- Atypical/malignant meningioma
  - Infiltrative, destructive lesion

Malignant Nonmeningothelial Tumors

- Osteosarcoma
  - Osteolytic + soft tissue mass & ill-defined margins
  - Tumoral calcification may be "sunburst"
- Primary meningeal sarcoma
  - Extremely rare nonmeningothelial tumor of meninges
- Many other sarcomas

PATHOLOGY

General Features

- Etiology
  - Meninges contain primitive multipotential mesenchymal cells
    - May give rise to spectrum of nonmeningothelial neoplasms
  - CD
    - From clivus/skull base cartilage synchondroses
    - Ectopic embryologic cartilage cell rests; perhaps perivascular mesenchymal tissue metaplasia
  - OCD
    - Most common radiation-associated benign tumor
    - Arise from fragment of growth plate; in skull most likely from congenital defect
  - OST: Uncertain; found in auditory canals of cold water swimmers → may be inflammatory reaction
- Associated abnormalities
  - Gardner syndrome: Multiple osteomas, skin tumors, colon polyps

https://CafePezeshki.IR

- Maffucci syndrome: Multiple enchondromas associated with soft tissue hemangiomas
- Multiple hereditary exostoses: Multiple OCD
- Ollier disease: Enchondromatosis

Staging, Grading, & Classification

- 2007 WHO classification
  - Tumors of meninges
    - Tumors of meningothelial cells
      - Meningioma (15 subtypes listed)
    - Mesenchymal tumors
      - 23 subtypes listed
      - Includes both benign **and** malignant nonmeningothelial mesenchymal tumors
    - Primary melanocytic lesions (4 subtypes listed)
    - Other neoplasms related to meninges: Only hemangioblastoma listed

Gross Pathologic & Surgical Features

- General comment: Skull vs. skull base ossification
  - Skull develops by intramembranous ossification → origin of membranous tumors (e.g., OST)
  - Clivus and skull base develop by endochondral ossification → origin for cartilaginous tumors (e.g., CD and OCD)
- CD
  - Benign osteocartilaginous tumor
  - "Enchondroma" if within bone or cartilage
  - Multiple tumors = chondromatosis or enchondromatosis
  - No stalk or peduncle as in OCD
  - Gross path: Cartilage and ossified cartilage
- OCD
  - Benign osteocartilaginous tumor
  - Cartilage-capped bony exostosis; sessile or pedunculated
  - Gross path: Irregular bony mass with cartilage cap ± calcification
- OST: Benign membranous tumor
  - Gross path: Appears as mature lamellar bone

Microscopic Features

- CD
  - Benign chondrocytes in scattered lacunae
  - Abundant hyaline cartilage matrix
  - May exhibit cellular atypia
  - Immunohistochemical staining positive for vimentin and S100 protein
- OCD: Cartilaginous cap over bony excrescence with cortex, trabeculae, marrow identical to normal bone
- OST: 2 types
  - Compact or "ivory": Made of mature lamellar bone; no Haversian canals or fibrous components
  - Trabecular: Composed of cancellous trabecular bone with marrow surrounded by cortical bone margin

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - BMT are most often asymptomatic
  - OCD and OST: May present as "bony lump"
  - CD and OCD: May have cranial nerve deficit(s) if at clivus/skull base; very rarely seizure

Demographics

- Age
  - CD: Occur at any age, peak in 2nd to 4th decades
  - OCD: Mean age for multiple = 21 years, solitary = 30 years
  - OST: Highest incidence in 6th decade
- Gender
  - CD: M:F = 1-2:1
  - OCD: M:F = 1.5-2.5:1
  - OST: M:F = 1:3
- Epidemiology
  - BMT are rare to very rare
  - CD: Most common benign osteocartilaginous tumor of clivus/skull base; 0.1-1% of intracranial tumors
  - OCD
    - Most common benign skeletal tumor (8-9% of primary bone tumors, 36% of those benign)
    - Most common cartilaginous tumor (12% multiple)
  - OST: Most common primary calvarial tumors → 0.4% of population

Natural History & Prognosis

- CD: Malignant transformation is rare
- OCD: Malignant transformation rare
  - Sessile, large cartilage cap more likely to degenerate
  - Risk increases as number and size of OCD increases
  - Malignant transformation in osteochondromatosis 25-30% compared to ~ 1% for solitary
- OST
  - Slow-growing lesions normally asymptomatic
  - Secondary mucocele invading intracranial vault

Treatment

- Asymptomatic lesions require no treatment
- Surgical indications: Relief of symptoms, cosmesis
- Surgical goals: Complete excision, curettage if tumors cannot be resected completely

DIAGNOSTIC CHECKLIST

Consider

- Patient may be syndromic

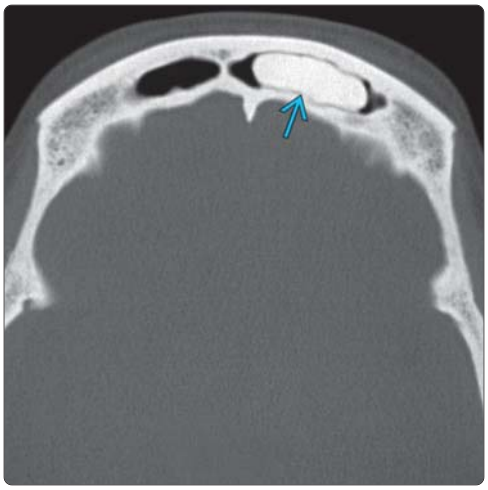
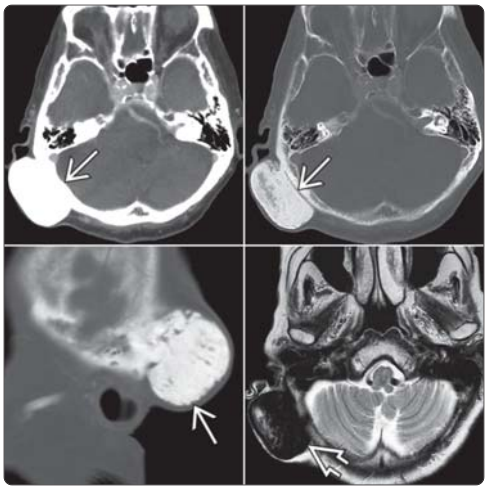
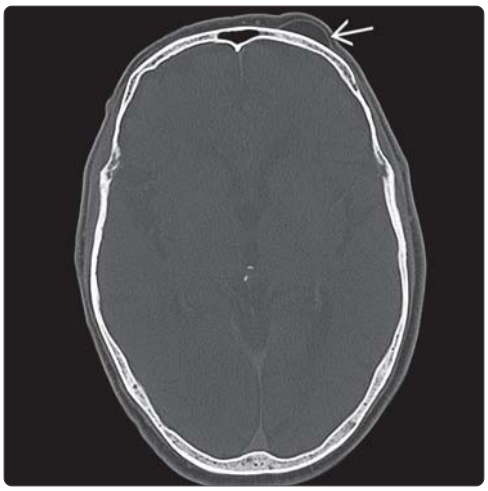
https://CafePezeshki.IR

(Left) *Coronal NECT demonstrates matrix calcification within a chondroma. There was no stalk connecting it to the parent bone.* **(Right)** *Axial T2WI MR shows primarily hypointensity from calcifications within the cartilaginous cap of an osteochondroma.*





(Left) *Axial bone CT shows a typical osteoma of the left frontal sinus.* **(Right)** *Collage of imaging studies shows a classic osteoma arising from the occipital bone. Note very hypointense signal on T2WI. In the head, the paranasal sinuses and calvaria are the most common sites for these benign tumors.*



(Left) *Axial NECT in an 81-year-old man in the ER with altered mental status shows a very hypointense scalp lesion over the left frontal bone.* **(Right)** *Bone CT in the same case shows the lesion is the same density as the subcutaneous fat. Incidental scalp lipomas are not uncommon. Intracranial lipomas are generally considered malformative, not neoplastic, lesions.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Nonmenigotheliomatous malignant mesenchymal neoplasms
  - Correspond histologically to extracranial tumors of soft tissue or bone
  - Most are sarcomas

IMAGING

- Highly aggressive dural, skull, skull base, scalp, lesions invading locally
- Amorphous, ill-defined, rapidly enlarging mass, often with both intra- and extraaxial components
- Best imaging tool: T1WI C+ FS MR; CT for matrix

TOP DIFFERENTIAL DIAGNOSES

- Benign meningothelial tumors
- Malignant meningothelial tumors
- Metastases

PATHOLOGY

- Accepted theory: Meninges contain primitive multipotential mesenchymal cells capable of giving rise to different histological types of nonmeningothelial neoplasms

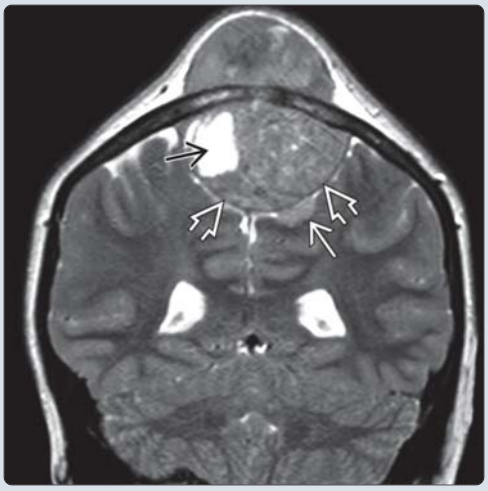
CLINICAL ISSUES

- Prognosis of MMT patients is generally very poor
- Biopsy is crucial to establish histiologic diagnosis and guide treatment plan
- Primary treatment: Wide radical surgical extirpation
- XRT: Prevent local recurrence, ↓ risk of metastasis
- Chemotherapy, brachytherapy often considered

DIAGNOSTIC CHECKLIST

- No characteristic radiologic findings that distinguish from other neoplasms

(Left) *Axial T1WI C+ MR in a patient with chondrosarcoma shows a lobulated dural-based mass with intense enhancement* ➡ *and minimal reaction within the underlying brain parenchyma.* **(Right)** *Axial CECT demonstrates a very rare primary meningeal sarcoma as a strikingly infiltrative lesion with heterogeneous enhancement, skull destruction* ➡*, and scalp infiltration* ➡*.*



(Left) *Coronal T2WI MR in a patient with primary calvarial Ewing sarcoma shows a predominantly hypointense, extradural cellular mass with hyperintense cystic/necrotic components* ⇨*, appearing to arise from the calvaria. Note the displaced dura* ➡*, transdural extension* ➡*, and large subgaleal component.* **(Right)** *Coronal T1WI C+ MR in the same patient reveals strong but inhomogeneous enhancement, better demonstrating the transdural component* ➡*.*

https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Malignant mesenchymal tumors (MMT)

Synonyms

- Malignant nonmeningothelial tumors

Definitions

- Nonmenigotheliomatous malignant mesenchymal neoplasms
  - Histologically correspond to extracranial tumors of soft tissue or bone
  - Most are sarcomas
    - Angiosarcoma (ANGIO), chondrosarcoma (CHON), fibrosarcoma (FIBRO)
    - Osteosarcoma (OSTEO), rhabdomyosarcoma (RHAB)
    - Meningeal sarcoma (MENSARC), Ewing sarcoma (EWING), etc.

IMAGING

General Features

- Best diagnostic clue
  - Highly aggressive dural, skull, skull base, scalp, lesions invading locally
- Morphology
  - Amorphous, ill-defined, rapidly enlarging mass, often with both intra- & extraaxial components

Radiographic Findings

- Radiography
  - Usually radiolucent lesions → ill-defined lytic borders, no periosteal reaction (except EWING)

CT Findings

- NECT
  - Usually radiolucent lesions → ill-defined lytic borders, no periosteal reaction (except EWING)
  - ANGIO: Reactive ossification, necrosis possible
  - CHON: May have stippled or rings & arcs Ca++
  - MENSARC: May be dense, biconvex, mimicking acute subdural hematoma
  - OSTEO: Calcified "sunburst" matrix possible
  - EWING: Often hyperdense (cellular)
- CECT
  - Most enhance
  - ANGIO: Very marked enhancement
  - EWING: Heterogeneous with periosteal reaction (but not "onion peel" for skull lesions)

MR Findings

- T1WI
  - Variably hypointense
  - Very hypointense (fibrous, chondroid, osteoid tissue)
  - Usually infiltrate brain
- T2WI
  - Most are predominantly hyperintense with heterogeneous signal and brain infiltration
  - May see extremely low signal from fibrous, chondroid, and osteoid tissue
  - EWING: Often hypointense (cellular)
- FLAIR
  - Best to evaluate edema, brain infiltration
- T1WI C+
  - Most enhance, often intensely
  - May have dural tail, necrotic foci
  - ANGIO: Very marked enhancement
  - CHON: May show "honeycomb" pattern
  - EWING: Heterogeneous with necrosis

Angiographic Findings

- DSA
  - Most have high degree of neovascularity
  - Others show avascular mass effect
- Interventional: Preoperative embolization to ↓ operative time and bleeding

Imaging Recommendations

- Best imaging tool
  - T1WI C+ FS MR; CT for matrix

DIFFERENTIAL DIAGNOSIS

Benign Meningothelial Tumors

- Common meningioma
  - Characteristic MR appearance
  - Not infiltrative

Malignant Meningothelial Tumors

- Atypical/malignant meningioma
  - Infiltrative, destructive lesion
  - Much more common than MMT

Metastases

- Often known extracranial malignancy
- Frequently multifocal
- Much more common than MMT

PATHOLOGY

General Features

- Etiology
  - Accepted theory: Meninges contain primitive multipotential mesenchymal cells capable of giving rise to different histological types of nonmeningothelial neoplasms
  - Exact cause is uncertain; 2 theories
    - Sarcomatous component may arise from mesenchymal elements of perivascular sheaths (fibroblasts, endothelium, smooth muscle, pericytes) or from arachnoid
    - Most likely from pluripotential meningeal mesenchymal cells
  - Radiation is known cause, most commonly FIBRO, with latency of 5-12 years
  - EWING: Uncertain histogenesis, belonging to family of neuroectodermal tumors
- Genetics
  - EWING: Cytogenetic translocation between chromosome 22 and 11 (80%)

Staging, Grading, & Classification

- 2007 WHO 4th edition classification
  - Tumors of meninges

https://CafePezeshki.IR

  - Tumors of meningothelial cells
    - Meningioma (15 subtypes listed)
  - Mesenchymal tumors (23 subtypes listed)
    - Includes both benign **and** malignant nonmeningothelial mesenchymal tumors
  - Primary melanocytic lesions (4 subtypes listed)
  - Other neoplasms related to meninges: Only hemangioblastoma listed

Gross Pathologic & Surgical Features

- CHON: Bluish-white glistening external surface of homogeneous tan cartilaginous tissue
- FIBRO: Pinkish, meaty
- MENSARC: Diffuse leptomeningeal involvement (10%) or large discrete lesions
- OSTEO: Soft tissue with hemorrhage, Ca++, necrosis

Microscopic Features

- Given lack of clinical/radiologic findings specific for MMT, diagnosis nearly always made by histopathology
- ANGIO
  - Irregular anastomosing vascular channels lined by anaplastic endothelial cells and pericytes
  - Cytokeratin, vimentin, ulex europaeus agglutinin, antihuman endothelial cell marker CD31(+)
- CHON
  - Undifferentiated mesenchymal cells, islands of hyaline cartilage, vimentin, & S100 protein positive
  - Scant material mainly of monomorphic small round cells with granular cytoplasm and central round nuclei in a background of myxoid matrix
  - Occasional giant cells; periodic acid-Schiff (-)
- FIBRO
  - Highly cellular with spindle-shaped cells in sheets or interlacing fascicles with herring-bone pattern
  - Cells contain elongated nuclei with mild hyperchromasia and high mitotic activity
  - Bone, osteoid, cartilage are absent
- MENSARC
  - Polymorphocellular sarcoma
- OSTEO
  - Single or multinucleated atypical polygonal cells in lacunae surrounded by immature osteoid
  - Osteoblastic, chondroblastic, & small-cell subtypes
- RHAB
  - Malignant undifferentiated tumor
    - Foci of muscular differentiation
  - Electron microscopy: Intracytoplasmic filamentous striations of poorly formed myofibrils
  - Positive for actin, desmin, myoglobin, vimentin
- EWING
  - Small round-cell tumor
  - High nuclear:cytoplasmic ratio

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Highly variable dependent on tumor location
  - Convexity: Most commonly hemiparesis, seizure
  - Skull base: Cranial nerve deficit(s)
  - Often rapidly growing mass with swelling
  - Headache, pain, fever, malaise, emesis

Demographics

- Age
  - More highly differentiated tumors appear in childhood whereas poorly differentiated in adults
  - ANGIO: Any age
  - CHON: 2nd and 3rd decade, mean: 37 years
  - FIBRO: Usually middle-aged adults
  - MENSARC: Children > adults
  - OSTEO: > 30 years; peak in 6th decade
  - RHAB: Children > > adults
  - EWING: 75% < 20 years; peak at 5-13 years
- Gender
  - Most have no sex predilection
  - FIBRO, MENSARC, and EWING: M > F
- Epidemiology
  - MMT: 0.5-2.7% of intracranial neoplasms
  - CHON: 0.15% of all intracranial tumors
  - MENSARC: 0.7–4.3% of pedi intracranial tumors
  - RHAB: < 1% of all intracranial tumors

Natural History & Prognosis

- Prognosis of MMT patients is generally very poor
  - CHON of dura & meninges have good prognosis; recurrence-free survival rate 65% after 5 years
  - EWING: Majority have good prognosis as can be fully or partially resected; 5-year survival (57.1%)
- Most have relentless tendency for local recurrence and metastases outside CNS
  - May recur years after diagnosis & initial treatment

Treatment

- Goal of treatment is to control disease locally
- Biopsy is crucial to establish histiologic diagnosis and guide treatment plan
- Primary treatment: Wide radical surgical extirpation
- Postoperative radiation therapy: Prevent local recurrence, ↓ risk of metastasis
- Chemotherapy, brachytherapy often considered

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- No characteristic radiologic findings that distinguish MMT from other neoplasms

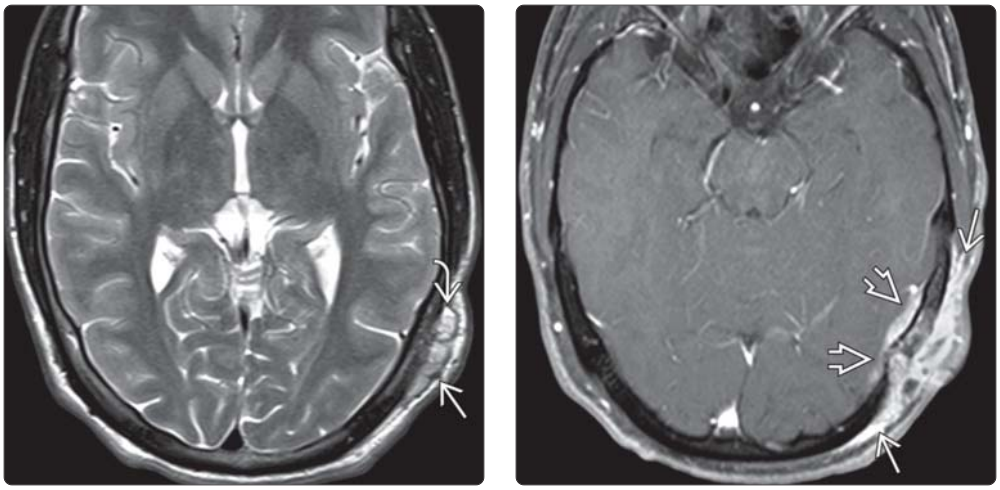
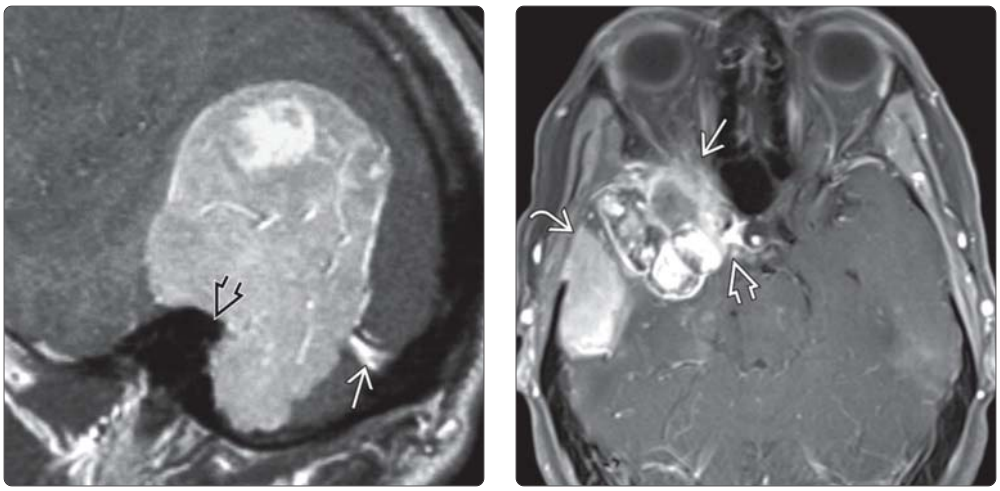
(Left) *Coronal T1WI C+ MR in a patient with primary calvarial Ewing sarcoma demonstrates striking scalp involvement ⇨, a mottled appearance of the expanded underlying calvaria ⇨, and thickening of the underlying dura ⇨.* **(Right)** *Axial T2WI MR in the same patient shows superficial ulceration, seen as disruption of the cutis ⇨. Note the expansion and mottled appearance of the underlying calvaria ⇨.*



(Left) *Axial T2WI MR demonstrates a left parietal scalp mass ⇨ infiltrating the underlying skull and containing a blood-fluid level ⇨. Histology revealed a high-grade chondroblastic osteosarcoma (WHO III).* **(Right)** *Axial T1WI C+ FS MR in the same patient shows the true extent of the mass ⇨ and more clearly delineates intracranial extension with calvarial penetration and dural infiltration ⇨.*



(Left) *Sagittal T1WI C+ MR shows a fibrosarcoma arising from the petrous apex ⇨ and occluding the transverse sinus ⇨.* **(Right)** *Axial T1WI C+ FS MR shows an aggressive inhomogeneously enhancing mass invading the orbit ⇨ and cavernous sinus ⇨, extending through a craniotomy defect into the scalp ⇨. Histology confirmed chondrosarcoma & osteosarcoma intermixed with atypical meningotheliomatous meningioma, arising as a complication from radiation therapy of a previously resected meningioma.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Benign intraosseous skull lesion with predominantly vascular and some avascular components

IMAGING

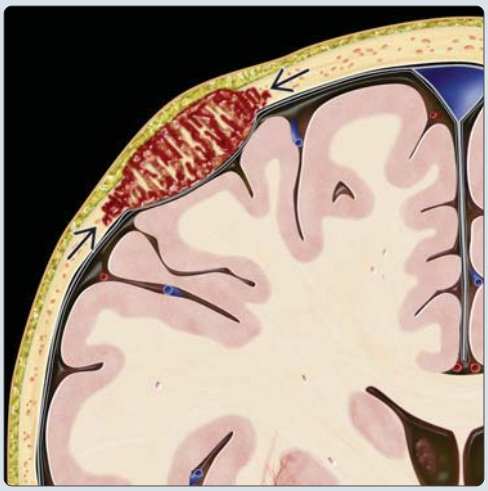
- Best clue: Sharply marginated expansile skull lesion
- Frontal, temporal, parietal bone in decreasing order
- Most often solitary, but multiple in 15%
- Best imaging tool: Bone CT
  - Sharply marginated expansile lesion
  - Thin peripheral sclerotic rim in 1/3
  - Intact inner and outer table
  - Outer table often more expanded than inner table
  - Trabecular thickening with radiating spicules
- MR signal characteristics dependent on
  - Quantity of slow-moving venous blood
  - Ratio of red marrow to converted fatty marrow
  - Hypointense trabeculae
- T1WI
  - Hypo- to isointense
- T2WI
  - Usually heterogeneously hyperintense ("light bulb bright")
- T1 C+
  - Enhances diffusely and heterogeneously
  - "Fills in" with delayed imaging
  - May have dural tail

PATHOLOGY

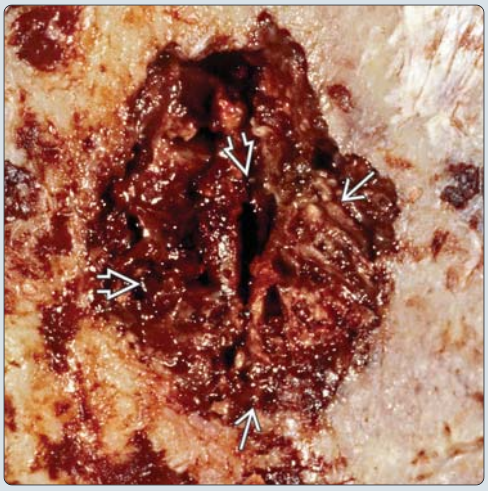
- Classified on basis of dominant vessels: Capillary, cavernous, or mixed

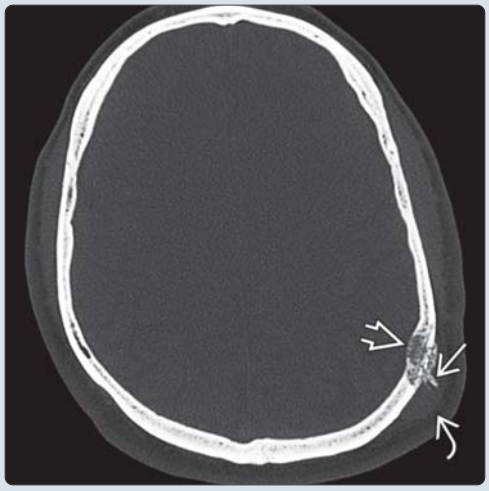
CLINICAL ISSUES

- Most often asymptomatic
- Calvarial hemangiomas rare: 0.2% of bone tumors
- Rarely requires treatment



(Left) *Coronal graphic illustrates a sharply marginated expansile skull lesion with a slight honeycomb-appearing pattern from intradiploic trabecular thickening.* **(Right)** *Coronal T1WI C+ MR shows diffuse yet heterogeneous enhancement of an expansile calvarial hemangioma. Heterogeneity is a result of vascular enhancement combined with hypointense bony trabeculae.*





(Left) *Image shows a close-up view of resected calvarial hemangioma. Note the radiating spicules of lamellar bone interspersed with vascular channels of varying sizes.* **(Right)** *Axial bone CT shows a scalp mass with the spiculated bone of an underlying calvarial hemangioma.*

https://CafePezeshki.IR

TERMINOLOGY

Synonyms

- Osseous hemangioma, intraosseous hemangioma

Definitions

- Benign intraosseous skull lesion with predominantly vascular and some avascular components

IMAGING

General Features

- Best diagnostic clue
  - Sharply marginated expansile skull lesion
- Location
  - Skull: 20% of intraosseous hemangiomas
    - Diploic space
    - Frontal, temporal, parietal in decreasing order
    - Less commonly occipital or sphenoid
  - Vertebra: 28% of intraosseous hemangiomas
- Size
  - 1-4 cm
- Morphology
  - Solitary but multiple in 15%; round or oval

Radiographic Findings

- Radiography
  - Sharply marginated expansile lesion
  - May have thin peripheral sclerotic rim
  - "Honeycomb" or "sunburst" pattern

CT Findings

- CECT
  - Enhances
- Bone CT
  - Sharply marginated expansile lesion
    - Thin peripheral sclerotic rim in 1/3
  - Intact inner and outer table
    - Outer table often more expanded than inner table
      - Erosion of both tables unusual (3%)
    - Scalloped nonsclerotic margins
  - "Spoke-wheel," "reticulated," or web-like pattern
    - Intradiploic trabecular thickening with radiating spicules
  - Also "soap bubble" or "honeycomb" appearance

MR Findings

- T1WI
  - Hypo- to isointense
    - Small lesions may appear hyperintense: Fatty tissue is main cause of T1WI hyperintensity
    - Larger lesions typically hypointense secondary to presence of thickened trabeculae
  - May be hemorrhagic
    - Signal dependent on hemoglobin stage
- T2WI
  - Usually heterogeneously hyperintense ("light bulb bright")
    - Slow flow or venous stasis is main cause of T2WI hyperintensity
    - May see hypointense spicules
  - May be hemorrhagic
    - Signal dependent on hemoglobin stage
- T1WI C+
  - Enhances diffusely and heterogeneously
    - "Fills in" with delayed imaging
- MR signal characteristics dependent on
  - Quantity of slow-moving venous blood
  - Ratio of red marrow to converted fatty marrow
  - Hypointense trabeculae

Nuclear Medicine Findings

- Bone scan
  - From photopenia to moderate increased activity

Imaging Recommendations

- Best imaging tool
  - Bone CT defines trabecular and cortical detail
- Protocol advice
  - MR C+ to characterize interstices

DIFFERENTIAL DIAGNOSIS

"Holes in Skull," Solitary (Common)

- Normal anatomic variant: Fissure, foramen, canal, emissary venous channel, pacchionian (arachnoid) granulation, parietal thinning
  - CT reveals normal anatomy
- Surgical: Burr holes, shunt, surgical defect
  - Surgical history
- Trauma, fracture
  - Fracture confirmed on CT
- Dermoid
  - Well-circumscribed unilocular cyst containing fat
- Eosinophilic granuloma
  - < 5 years; "beveled edge," "hole-within-a-hole," "button sequestrum"
  - Involves inner/outer tables
- Metastases
  - Older patients, often history of cancer
- Low-grade hemangioendothelioma
  - Can be indistinguishable

"Holes in Skull," Solitary (Uncommon)

- Osteoporosis circumscripta
  - Hypointense on T1WI and T2WI from cortical thickening, coarse trabeculation
- Epidermoid
  - Nonenhancing lesion with dense sclerotic borders
- Cephalocele
  - Very young; bony defect with tissue herniation
- Intradiploic arachnoid cyst
  - CSF isointensity on both T1WI and T2WI
- Intradiploic meningioma
  - Homogeneously enhances
  - May have inner/outer table destruction
- Leptomeningeal cyst
  - Appears as "growing fracture" on radiography/NECT
- Malignant mesenchymal tumors, miscellaneous
  - Very rare, large, highly aggressive tumors

https://CafePezeshki.IR

"Holes in Skull," Multiple (Common)

- Normal anatomic variants: Fissure, foramen, canal, emissary venous channel, pacchionian (arachnoid) granulation, parietal thinning
  - CT reveals normal anatomy
- Surgical
  - Burr holes, surgical defects
- Metastases
  - Older patients, often history of cancer
- Lymphoma
  - History of systemic lymphoma
- Osteoporosis
  - Older; osteopenia, trabecular loss, cortical thinning

"Holes in Skull," Multiple (Uncommon)

- Hyperparathyroidism
  - "Salt and pepper" skull
- Myeloma
  - Multiple, well-circumscribed, lytic, "punched-out"
  - Involves both inner and outer tables
- Osteomyelitis
  - 2-12 years; M:F = 3:1; mixed lytic/proliferative lesion
  - Characteristically "moth-eaten"/permeative medullary and cortical destruction with new bone formation

PATHOLOGY

General Features

- Etiology
  - Congenital or related to previous trauma
- Genetics
  - Nearly all sporadic
  - In rare congenital hemangiomatosis, skull, vertebra, muscle, skin, and subcutaneous tissues may all be involved

Staging, Grading, & Classification

- Classified on basis of dominant vessels: Capillary, cavernous, or mixed

Gross Pathologic & Surgical Features

- Brownish-red, nonencapsulated, under periosteum

Microscopic Features

- 3 histopathologic types
  - Capillary (classically in spine)
    - Abundant vessels ~ 10-100 μm in diameter with walls 1-3 cells thick
    - Vessels tend to run in parallel
  - Cavernous (classically in skull)
    - Large, dilated sinusoidal vessels separated by fibrous septi
    - Single layer of endothelial cells
    - Intravascular thrombosis with dystrophic calcification may be seen
  - Mixed capillary/cavernous
- There may be reactive new bone formation, which can appear similar to osteoblastoma
- Radiating, web-like, or "spoke-wheel" trabecular thickening caused by intramembranous bone formation adjacent to angiomatous channels

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic
  - Other signs/symptoms
    - Longstanding palpable lump, tender to pressure, spontaneous pain, deformity
    - Rarely epidural, subdural, or subarachnoid hemorrhage
- Clinical profile
  - Freely mobile skin above lump

Demographics

- Age
  - Usually adults: 4th-5th decades
  - Any age can be affected
- Gender
  - M:F = 1:2-4
- Epidemiology
  - Osseous hemangiomas: 0.7-1% of bone tumors
    - Calvarial hemangiomas (rare): 0.2% of bone tumors
  - 10% benign primary neoplasms of skull

Natural History & Prognosis

- Benign slow-growing neoplasms
- Increase in size may be due to repeated hemorrhage

Treatment

- Rarely requires treatment
- Indications for surgery include correction of mass effect, control of hemorrhage, cosmesis
  - En bloc surgical excision with rim of normal bone
  - Usually definitive treatment; recurrence is rare
- Radiotherapy may be considered when surgical access is difficult or as complement to subtotal resections
  - Complications may include scar formation, impairment of regional bone growth in children, rarely malignant transformation

DIAGNOSTIC CHECKLIST

Consider

- Hemangiomas are just 1 of large "holes in skull" diagnosis that require exclusion of others
- **Beware**: Routine bone biopsy and curettage may result in severe hemorrhage
  - Prior imaging diagnosis can prevent complications

Image Interpretation Pearls

- Intact inner/outer tables, thickened trabeculae, best aid in diagnosis

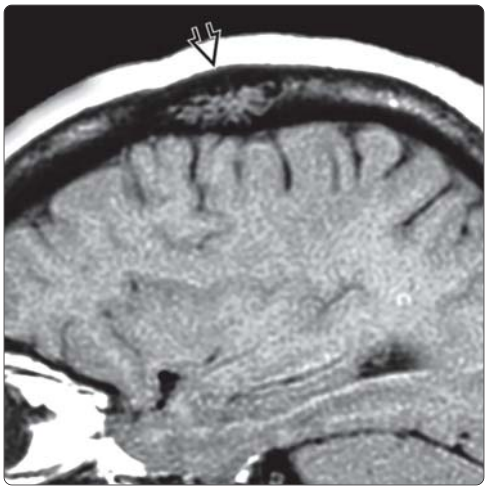
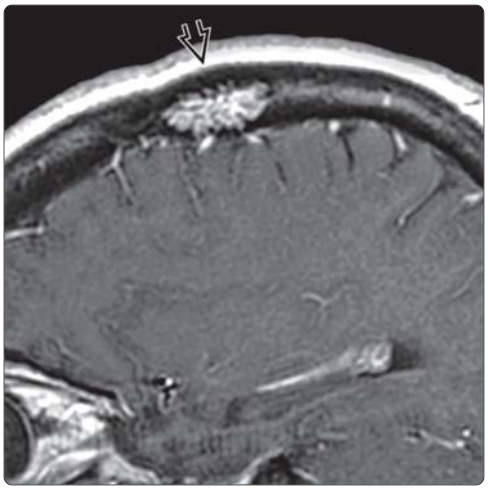
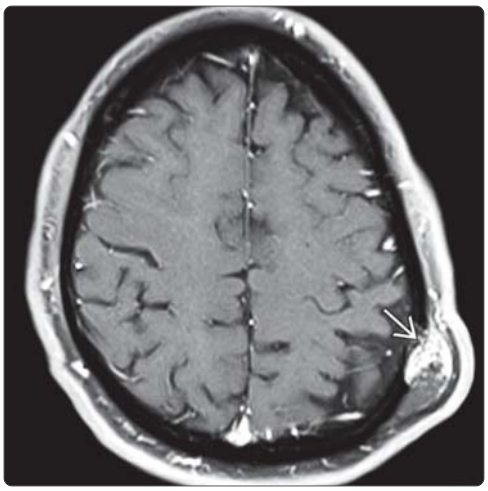
(Left) *Axial bone CT demonstrates the benign appearance of a hemangioma as a sharply marginated expansile lesion with scalloped margins, a "honeycomb" or web-like pattern from thickened trabeculae, as well as intact inner and outer tables* ➡. **(Right)** *Axial T2WI MR in the same patient demonstrates hyperintense components, mainly the result of slow flow or venous stasis with a contribution from fat* ➡. *Note the "honeycomb" or web-like hypointensities from thickened trabeculae.*





(Left) *Sagittal T1WI MR in the same patient shows the hemangioma as a mostly isointense lesion* ⇨, *which is less bright than the overlying fatty scalp.* **(Right)** *Sagittal T1WI C+ MR in the same patient demonstrates diffuse yet heterogeneous enhancement* ⇨, *the latter a result of intense vascular enhancement combined with hypointense bony trabeculae.*



(Left) *Axial T1WI MR in a 47-year-old man with a scalp "lump" for 10 years shows a calvarial mass that scallops the adjacent calvaria* ➡ *and has broken through the outer table to extend under the galea* ➡. *The mass was very hyperintense on T2WI (not shown).* **(Right)** *Early post-contrast scan in the same patient shows partial "filling in"* ➡ *of the intensely enhancing mass characteristic of hemangioma. Slightly delayed scan (not shown) demonstrated complete enhancement of the lesion.*

https://CafePezeshki.IR

KEY FACTS

TERMINOLOGY

- Benign nonmeningothelial mesenchymal neoplasm
  - Typically presents as extraaxial vascular mass of dura &/or venous sinus

IMAGING

- Best diagnostic clue: Marked T2 hyperintensity; delayed "filling in" with dynamic T1WI C+
- Location: Cavernous sinus, CPA, other dura
- Bone CT: Erosion or remodeling, not hyperostosis
- T1 C+: May be heterogeneous with slow centripetal "filling in" (analogous to liver hemangiomas)
- Best imaging tool: Dynamic T1WI C+ MR

TOP DIFFERENTIAL DIAGNOSES

- Cavernous sinus: Meningioma, nerve sheath tumor, granuloma
- CPA: Schwannoma, meningioma, epidermoid
- Dural based: Meningioma, metastases, granuloma, mesenchymal tumor

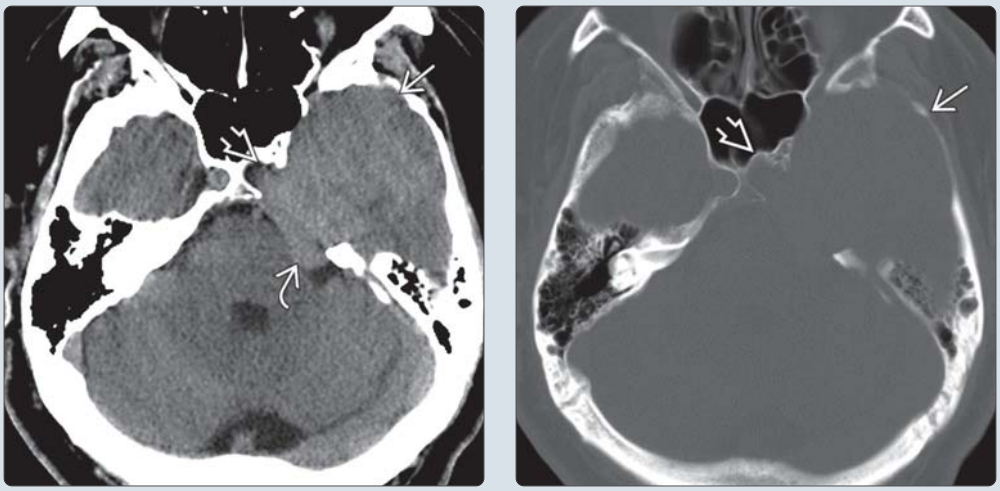
CLINICAL ISSUES

- Grows very slowly; no malignant degeneration
- Dural-based treatment: Surgical resection, avoided unless tumor growth demonstrated
- Cavernous sinus treatment much more difficult
  - Complete resection difficult due to location, bleeding, and relationship to vital neurovascular structures
  - Complete resection rates as low as 16%; overall surgical mortality up to 25%
  - Preoperative radiation therapy has been used to reduce hemorrhage with doses up to 30 Gy
  - γ knife radiosurgery may be effective, safe alternative treatment

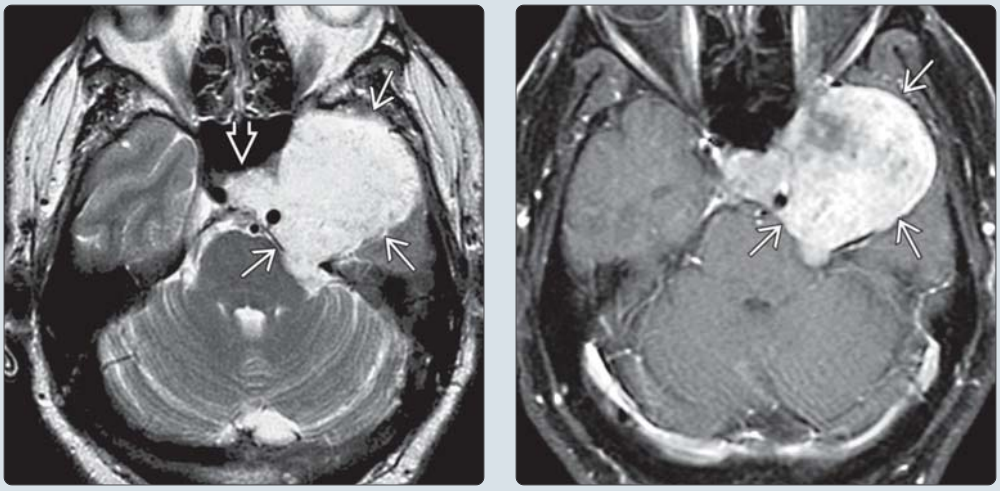
DIAGNOSTIC CHECKLIST

- Frequently misdiagnosed as meningioma on imaging
- Dynamic T1 C+ may show "edge to center" enhancement

(Left) *Axial NECT shows the left middle cranial fossa is expanded, and the overlying calvaria is thinned by a well-demarcated, slightly hyperdense mass ➡. The mass almost completely fills the middle fossa, extending into the posterior fossa ➡ and the sella/cavernous sinus ➡.* **(Right)** *Bone CT in the same case shows the expanded left middle fossa and extensively thinned overlying calvaria ➡. The bony sella turcica also appears remodeled ➡.*



(Left) *Axial T2WI MR in same case shows the mass ➡ is markedly hyperintense, almost completely filling the left middle fossa and extending into the sella/cavernous sinus ➡.* **(Right)** *Axial T1 C+ FS MR in the same case shows the mass enhances strongly and uniformly after contrast administration ➡. Hemangioma of the cavernous sinus was found at surgery. Hemangioma should be included in the differential diagnosis of strongly enhancing cavernous sinus masses that appear to be completely extradural.*



https://CafePezeshki.IR

TERMINOLOGY

Definitions

- Benign, nonmeningothelial mesenchymal neoplasm
  - Typically presents as extraaxial vascular mass of dura &/or venous sinus

IMAGING

General Features

- Best diagnostic clue
  - Marked T2 hyperintensity
  - Delayed "filling in" on dynamic contrast-enhanced MR
- Location
  - Cavernous sinus, CPA, other dura

CT Findings

- NECT: Iso- to hyperdense mass
- CECT: Marked homogeneous enhancement
- Bone CT: Erosion or remodeling, not hyperostosis

MR Findings

- T1WI
  - Hypo- to isointense
- T2WI
  - Marked hyperintensity
- T1WI C+
  - Dynamic may show "edge to center" enhancement
  - Homogeneous enhancement if delayed
- MRV
  - Assess sinus &/or flow involvement

Angiographic Findings

- Variable: Avascular to staining with feeder arteries
- Consider preoperative embolization to decrease intraoperative blood loss

Nuclear Medicine Findings

- Tc-99m labeled red cell scintigraphy
  - Slow progressive accumulation
  - Persistent increased activity on delayed images

Imaging Recommendations

- Best imaging tool
  - Dynamic T1WI C+ MR for centripetal "filling in"

DIFFERENTIAL DIAGNOSIS

Cavernous Sinus

- Meningioma, nerve sheath tumor, granuloma

CPA

- Schwannoma, meningioma, epidermoid

Dural Based

- Meningioma, mets, granuloma, mesenchymal tumor

PATHOLOGY

Staging, Grading, & Classification

- WHO grade I

Gross Pathologic & Surgical Features

- Soft mass often with pseudocapsule formed by dura

Microscopic Features

- Honeycomb of multiple, thin-walled vascular channels
- Single endothelial cell layer with no elastic membrane or smooth muscle cells
- Contiguous walls of collagen & flattened endothelium
- Vascular channels separated by fibroconnective stroma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headaches, retroorbital pain
- Other signs/symptoms
  - Cranial neuropathies, anisocoria, proptosis
  - Intracranial hypertension if sinus flow involved
  - Kasabach-Merritt syndrome (consumptive coagulopathy)
  - May occur as part of POEMS syndrome
  - Symptoms may appear or worsen during pregnancy or after hormone administration

Demographics

- Age
  - Cavernous sinus: Mean is 44 (range: 22–64)
- Gender
  - Cavernous sinus: M:F = 1:7
- Epidemiology
  - Lesions very rare

Natural History & Prognosis

- Grows very slowly; no malignant degeneration

Treatment

- Dural based: Surgical resection, avoided unless tumor growth demonstrated
- Cavernous sinus much more difficult
  - Complete resection difficult due to location, bleeding, & relationship to neurovascular structures
  - Major intraoperative bleeding in 42%; massive or severe in 75% of these
  - Complete resection rates as low as 16%; overall surgical mortality up to 25%
  - γ knife radiosurgery may be effective, safe alternative treatment

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Frequently misdiagnosed as meningioma on imaging
  - Dynamic may show "edge to center" enhancement

KEY FACTS

TERMINOLOGY

- Clonal B-lymphocyte neoplasm of terminally differentiated plasma cells
  - Solitary = plasmacytoma (PC)
    - Brain/CNS is extramedullary plasmacytoma
  - Multifocal = multiple myeloma (MM)

IMAGING

- Intracranial MM rare (1% of MM)
- Can occur as solitary (primary) plasmacytoma or manifestation of systemic MM (secondary)
  - **Secondary**
    - Extension from osteolytic skull lesion > hematogenous spread
  - **Primary** CNS myeloma rare
    - Extraaxial dural-based nonosseous lesions
    - CNS "myelomatosis" involving leptomeninges &/or cranial nerves
    - Parenchymal masses (discrete nodules)
- Best overall imaging tool: Radiography (skeletal survey)
  - Detects 80% of sites in 90% of patients
  - Up to 20% of radiographs & MR may be "normal"
- CNS disease
  - Bone CT for calvaria, skull base
  - MR ± T1 C+ FS for nonosseous intracranial lesions

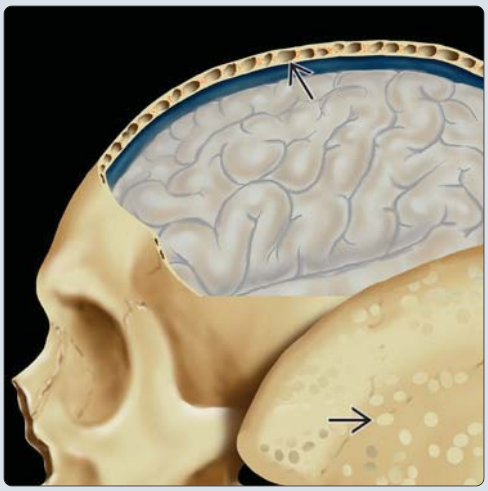
TOP DIFFERENTIAL DIAGNOSES

- Surgical defect
- Lytic metastasis
- Hemangioma
- Hyperparathyroidism

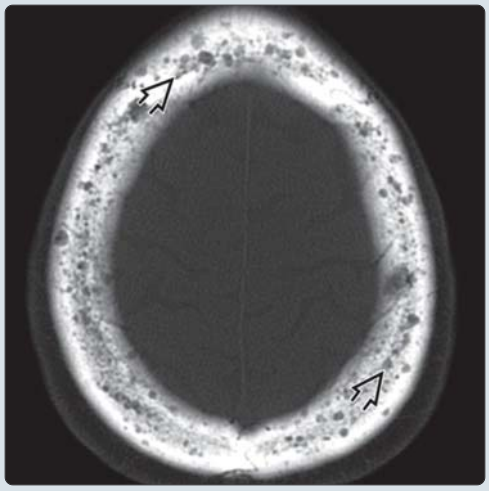
CLINICAL ISSUES

- Peak onset = 65-70 years
  - Most common symptom: Bone pain (68%)
- Prognosis
  - 70% of plasmacytomas progress to MM

(Left) *Sagittal graphic depicts the multiple "punched-out" lesions ⇨ of multiple myeloma in the calvaria.* **(Right)** *Lateral digital radiograph in a patient with multiple myeloma shows the classic "salt and pepper" appearance of the skull caused by innumerable "punched-out" lesions ⇨.*



(Left) *Axial NECT in a 50-year-old man with altered mental status, "possible TIA," shows no abnormalities.* **(Right)** *Axial bone CT with bone algorithm reconstruction in the same patient shows innumerable well-defined lytic lesions ⇨ in the calvaria. Further evaluation disclosed metastatic multiple myeloma.*



https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Solitary = plasmacytoma (PC)
  - Solitary plasmacytoma of bone
  - Extramedullary plasmacytoma (includes brain/CNS)
- Multifocal = multiple myeloma (MM)

Definitions

- Clonal B-lymphocyte neoplasm of terminally differentiated plasma cells

IMAGING

General Features

- Best diagnostic clue
  - Osteolytic skull lesion
- Location
  - Intracranial MM rare (1% 0f MM)
    - Can occur as solitary (primary) plasmacytoma or manifestation of systemic MM (secondary)
      - In Waldenström macroglobulinemia (a.k.a. Bing-Neel syndrome)
      - Often widely disseminated at time of diagnosis
    - **Secondary** (extension from osseous lesions in calvaria, skull base, nose/paranasal sinuses > hematogenous spread) most common
    - **Primary** CNS myeloma rare
      - Extraaxial dural-based nonosseous lesions
      - CNS "myelomatosis" involving leptomeninges &/or cranial nerves
      - Parenchymal masses (discrete nodules)
- Morphology
  - Focal, round or oval lesion(s)

Radiographic Findings

- Radiography
  - "Punched-out" lytic lesion(s) (90%)
  - Osteopenia/osteoporosis (10%)
  - Rarely sclerotic, except following therapy

CT Findings

- NECT
  - "Punched-out" lytic lesion(s)
  - Meningeal myelomatosis: Marked hyperdensity
- CECT
  - MM renal failure (RF) after contrast (0.6-1.25%)
    - 0.15% in general population
    - Thus, not 100% risk-free but may be performed if necessary and patient well hydrated
  - Meningeal myelomatosis: Uniform enhancement

MR Findings

- T1WI
  - Osseous lesions: Focal hypointensity (25%)
    - Diffuse marrow infiltration less common
  - Meningeal myelomatosis: Iso- to hyperintense
- T2WI
  - Osseous: Focal hyperintensity (53%)
  - Meningeal myelomatosis: Markedly hypointense
- T1WI C+
  - Marked lesional enhancement
  - Meningeal myelomatosis: Uniform enhancement, diffuse or focal

Nuclear Medicine Findings

- Bone scan
  - Scintigraphy insensitive
- PET
  - 18-fluorodeoxyglucose (FDG) > bone scan
  - Conflicting reports of FDG PET vs. radiography
  - Residual or recurrent FDG activity after therapy is poor prognostic factor

Other Modality Findings

- Sensitivity of imaging detection for diagnosis
  - Radiography detects 90% of patients, 80% of sites
  - Bone scan detects 74% of patients, 24-54% of sites
  - Gallium scan detects 55% of patients, 40% of sites
- Up to 20% radiographs and MR may be "normal"
- MR → about 10% understaging of stage III disease
- Whole-body MDCT = lower detection rate and staging compared to whole-body MR

Imaging Recommendations

- Best imaging tool
  - Radiography (skeletal survey)
  - Bone CT > MR for evaluation of skull lesions
  - MR best for delineating dural, leptomeningeal, parenchymal disease

DIFFERENTIAL DIAGNOSIS

Surgical Defects

- Burr hole, shunt, postoperative defect

Lytic Metastasis

- Commonly lung, breast, renal, thyroid

Hemangioma

- Sharply marginated expansile lesion often with "honeycomb" or "sunburst" appearance

Hyperparathyroidism

- Local destructive lesions ("brown tumor"), ↑ PTH

Other Causes of "Holes in Skull"

- Normal foramina, fissures, venous lakes

PATHOLOGY

General Features

- Etiology
  - Etiology remains unknown
  - Possible associations and supporting evidence
    - Immune system decline: More common in elderly
    - Genetic factors: Slight ↑ risk among children and siblings of MM patients; also definite ↑ racial risk
    - Certain occupations/chemicals: Agriculture, petroleum, leather industry, cosmetology, herbicides, insecticides, petroleum products, heavy metals, plastics, dusts (including asbestos)
    - Radiation: ↑ in Japanese atomic bomb survivors
    - Viral: Kaposi sarcoma-associated herpes virus found in marrow cells of some MM patients
- Genetics

https://CafePezeshki.IR

- 80-90% of patients have cytogenetic abnormalities
  - Chromosome 13 deletion is most common
- Associated abnormalities
  - "POEMS" syndrome: **P**olyneuropathy, **o**rganomegaly, **e**ndocrine abnormalities, **m**yeloma (usually sclerotic lesions), **s**kin changes
  - PC = early/initial MM stage; precedes by 1-20 years
  - Underlying pathology is single plasma cell lineage expansion that replaces normal marrow and produces monoclonal immunoglobulins

Staging, Grading, & Classification

- Durie-Salmon staging system
  - Stage I: All of following
    - Hemoglobin value < 10 g/dL
    - Serum calcium value normal or ≤ 12 mg/dL
    - No anemia, hypercalcemia, bone lesions
    - Low M-component: IgG value < 5 g/dL, IgA value < 3 g/dL, Bence Jones protein < 4 g/24 hours
    - Low myeloma cell mass: < 0.6 cells x 10^{12}/m2
  - Stage II: Fitting neither stage I nor stage III
    - Intermediate cell mass: 0.6-1.2 cells x 10^{12}/m2
  - Stage III: 1 or more of following
    - Hemoglobin value < 8.5 g/dL
    - Serum calcium value > 12 mg/dL
    - Advanced lytic bone lesions
    - IgG value > 7 g/dL, IgA value > 5 g/dL, Bence Jones protein > 12 g/24 hours
    - High myeloma cell mass: > 1.2 cells x 10^{12}/m2
  - Subclassification (either A or B)
    - A = relatively normal renal function
    - B = abnormal renal function

Gross Pathologic & Surgical Features

- Marrow replacement with gelatinous red-brown tissue

Microscopic Features

- Pleomorphic, enlarged plasma cells, often in sheets
  - Admixed with normal hematopoietic cells
  - Contain round/oval eccentric nuclei with clumped chromatin and perinuclear "halo" or pale zone
  - May have cytoplasmic inclusions: Mott, morula, or grape cells; Russell bodies
  - Cell clone produces excess monoclonal (M proteins) and free light-chain proteins
    - M proteins may be IgA, IgD, IgG, IgE or, IgM; depends on heavy chain class
    - Light-chain proteins may be κ or λ

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Most common symptom: Bone pain (68%)
  - Rare signs
    - Hyperviscosity syndrome: Shortness of breath, confusion, and chest pain
    - Cryoglobulinemia: Precipitating particles cause pain/numbness in fingers/toes during cold weather
    - Amyloidosis: Amyloid protein deposition, ↓ blood pressure, and kidney, heart, or liver failure
    - Bing-Neel syndrome: CNS involvement by lymphoplasmacytic lymphoma
- Clinical profile
  - Diagnosis often made with routine labs
  - Diagnosis confirmed by marrow aspirate/biopsy

Demographics

- Age
  - Peak onset: 65-70 years
  - Recent statistics: ↑ incidence and earlier age of onset
- Gender
  - Slight male predilection
- Ethnicity
  - African Americans and Native Pacific islanders have highest reported incidence; Asians lowest
- Epidemiology
  - 2nd most prevalent blood cancer (1st = NHL)
  - Incidence: ↑ with age
  - 1st primary bone malignancy in 4th-8th decades
    - Solitary PC without MM rare; solitary skull PC very rare (0.7% of all PC)

Natural History & Prognosis

- Solitary skull PC: No difference in prognosis between PC originating from bone vs. dura mater
- Multiple myeloma
  - 70% of plasmacytomas progress to MM
  - Renal insufficiency frequent
  - Leukopenia leads to frequent pneumonias
  - Secondary amyloidosis (6-15%)
- 5-year survival (20%); death not from MM, but renal disease, infection, thromboembolism
  - Median survival is ~ 3 years with conventional chemotherapy
- Good prognosis indicators
  - Stage I or II disease
  - Normal chromosome 13
    - Abnormal cytogenetics is most important factor
    - Chromosome 13 or 11q deletions, or any translocation, predict poor prognosis
- Biphosphonate treatment related osteonecrosis of mandible

Treatment

- Treatment dependent on disease status

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- "Old-fashioned" skeletal survey still highest sensitivity imaging modality

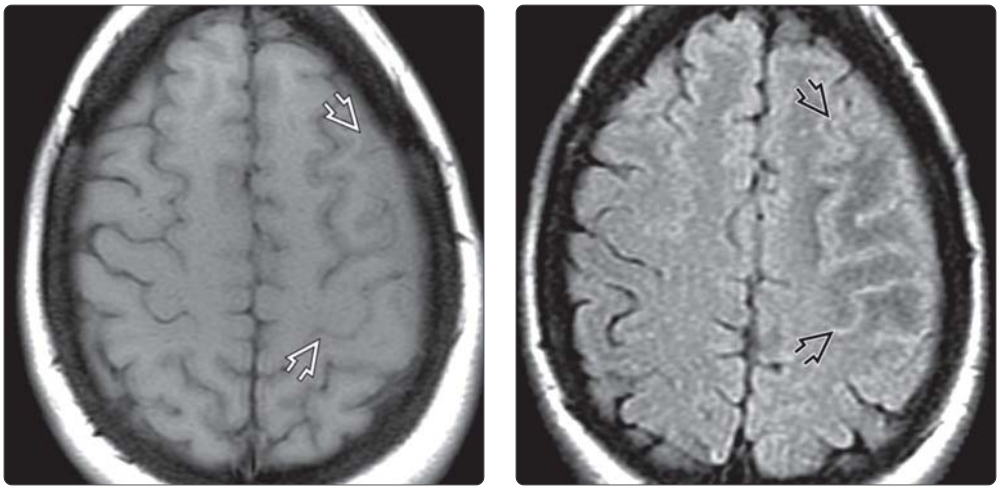
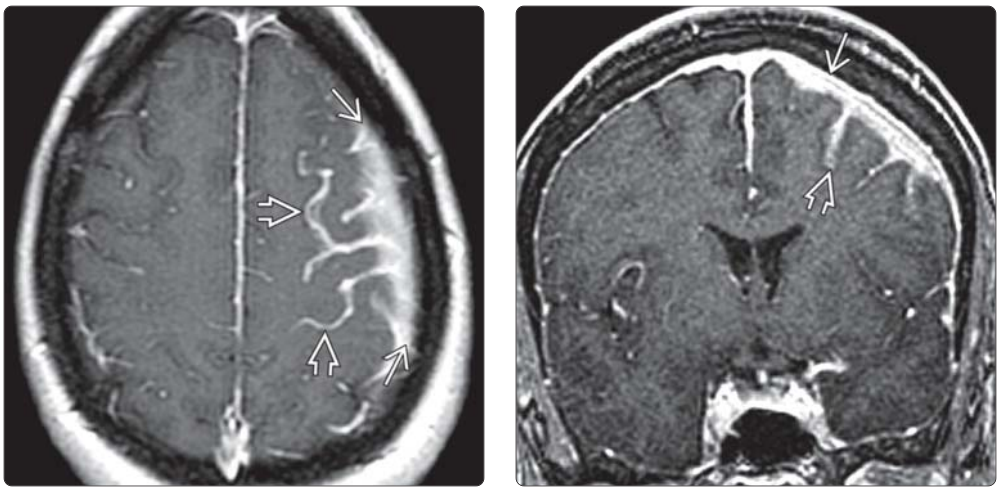
(Left) *Axial NECT in an elderly man who noted a progressively enlarging scalp "bump" shows a destructive lesion ⇨ arising from the calvaria and extending into the scalp ⇨.* **(Right)** *Axial CECT in the same patient shows the lesion ⇨ enhances strongly uniformly. Further evaluation disclosed multiple myeloma. This was the only lesion in the head and neck.*



(Left) *Axial T1WI MR in a patient with Waldenstrom macroglobulinemia and right-sided weakness shows subtle effacement of the left convexity sulci ⇨.* **(Right)** *Axial FLAIR MR in the same patient shows hyperintensity ⇨ in the effaced sulci.*



(Left) *Axial T1 C+ MR in the same patient shows an enhancing dural mass ⇨ with extension into the underlying subarachnoid spaces and pia ⇨.* **(Right)** *Coronal T1 C+ FS MR demonstrates the dural-based mass ⇨ and extension into the adjacent sulci ⇨. Plasma cells in his CSF were consistent with Waldenstrom macroglobulinemia. (Courtesy P. Hildenbrand, MD.)*

https://CafePezeshki.IR

KEY FACTS

IMAGING

- Enhancing lesion(s) with skull/meningeal destruction/infiltration
- Skull, dura, leptomeninges, arachnoid/subarachnoid, pia, and subgaleal
- Many manifestations: Smooth thickening, nodularity, loculation, lobulation, fungating masses

TOP DIFFERENTIAL DIAGNOSES

- SM: Surgical defect (burr hole, craniectomy), myeloma
- DM: Epidural/subdural hematoma, meningioma
- LM: Subarachnoid hemorrhage, sarcoidosis, infectious meningitis

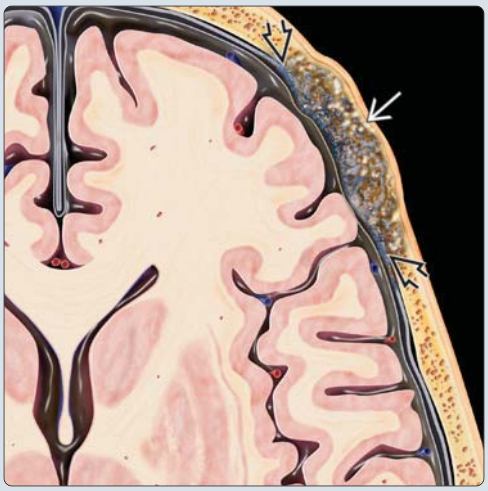
CLINICAL ISSUES

- 18% patients with extracranial and intracranial malignancies
- Primary tumor never identified in 2-4%
- All metastases: May be asymptomatic and unsuspected clinically
- Headache is most common symptom (50%)
- CSF cytology often falsely negative
- Accuracy of single lumbar puncture (LP) is 50-60% but 90% after 3 attempts
- Bimodal → children (medulloblastoma & leukemia); adults (breast, lung, melanoma, prostate)
- Average age ~ 50 years (relatively young secondary pediatric cancer and young women with breast cancer)
- Entire neuraxis must be treated as tumor cells are often widely disseminated throughout CSF

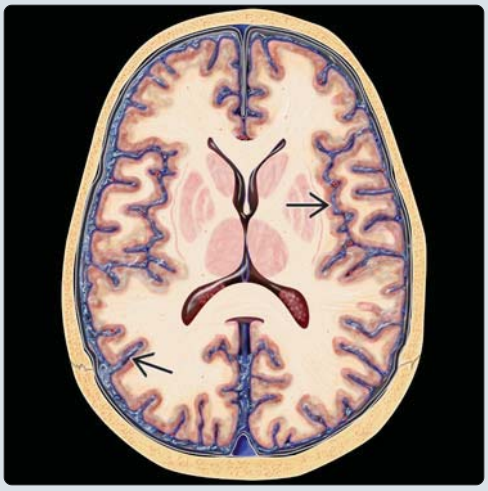
DIAGNOSTIC CHECKLIST

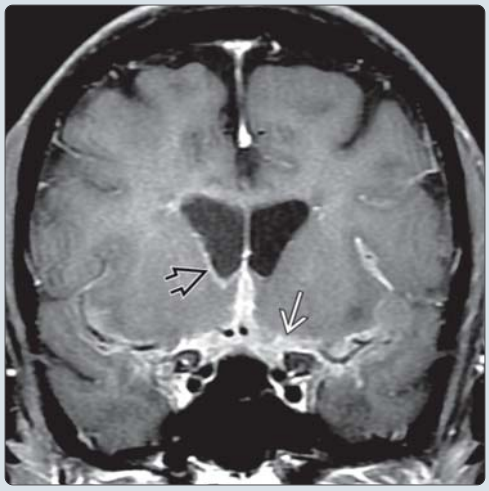
- Both enhanced MR and LP should be performed, especially if initial test is negative

(Left) *Axial graphic illustrates a destructive skull metastasis ➡ expanding the diploic space and invading/thickening the underlying dura (light blue linear structure) ⇨.* **(Right)** *Axial T1WI C+ MR shows skull metastasis with enhancement of the diploic space ➡. There is associated small subgaleal soft tissue ⇨ and extensive nodular dural thickening ⇨.*



(Left) *Axial graphic illustrates diffuse leptomeningeal metastases, shown here as abnormal blue material ⇨ coating the pial surface of the brain and filling the subarachnoid spaces between interdigitating sulci.* **(Right)** *Carcinomatous "meningitis" can be indistinguishable on imaging from pyogenic meningitis. In this case of diffuse CSF spread from glioblastoma, there is both sulcal-cisternal ➡ and ependymal ⇨ spread of tumor.*





https://CafePezeshki.IR

TERMINOLOGY

Abbreviations

- Skull metastases (SM), dural metastases (DM), arachnoid/subarachnoid metastases (ASAM), pial metastases (PM), leptomeningeal (pia + arachnoid) metastases (LM)

Definitions

- Metastatic disease from extracranial primary tumor to tissues overlying brain

IMAGING

General Features

- Best diagnostic clue
  - Enhancing lesion(s) with skull/meningeal destruction/infiltration
- Location
  - Skull, dura, leptomeninges, arachnoid/subarachnoid, pia, and subgaleal
- Morphology
  - Many manifestations: Smooth thickening, nodularity, loculation, lobulation, fungating masses

Radiographic Findings

- Radiography
  - SM: Focal lytic or blastic lesions lacking "benign" sclerotic border

CT Findings

- NECT
  - Any metastases: May find hemorrhagic hyperdensity
  - Subgaleal space: Relatively dense lesion
- CECT
  - SM: Enhancing mass centered in bone with osseous destruction, lacking "benign" sclerotic border
    - Most are lytic, though a few are sclerotic (e.g., prostate)
  - DM and LM: Both may appear as enhancing biconvex masses displacing brain
    - DM characterized by calvarial involvement
  - Carcinomatosis: CT is insensitive; however, hydrocephalus may be early sign

MR Findings

- T1WI
  - SM: Hypointense marrow lesion
  - DM and LM: Most masses hypointense to gray matter (GM)
  - Subgaleal space: Relative hypointense lesion
  - Any metastases: May find hemorrhagic signal
- T2WI
  - SM: Hyperintense marrow lesion; dura usually intact
  - DM between skull & elevated hypointense dura
  - DM and LM: Most hyperintense relative to GM
  - Any metastases: May find hemorrhagic signal
- FLAIR
  - LM and ASAM: Diffuse hyperintense CSF
  - ASAM infiltrating perivascular spaces (PVS): Loss of normal PVS-CSF suppression → hyperintensity
  - Carcinomatosis: Hyperintense thickening; affects adjacent sulcal nulling → hyperintensity
  - Brain infiltration: Hyperintense vasogenic edema
- DWI
  - Dural metastasis may show restricted diffusion due to high cellularity
  - DWI sensitive in picking subtle calvarial lesions
- T1WI C+
  - SM: Lesion may enhance to "normal" T1 marrow signal → requires fat saturation
    - Usually some dural thickening & enhancement
  - DM and LM: Both appear as enhancing biconvex masses displacing brain
    - DM often has calvarial involvement
    - LM often invades underlying brain
  - LM, ASAM, PM: Diffuse enhancing tissue ± nodularity
  - ASAM infiltrating perivascular spaces: Tiny enhancing nodules with miliary appearance
  - Carcinomatosis: Enhancing and thickened tissue ± nodules
    - May coat ependymal surfaces, cranial nerves
- MRV
  - May be helpful in evaluation of sinus displacement, compression, thrombosis

Nuclear Medicine Findings

- Bone scan
  - SM: Usually intensely positive
- PET
  - 18-fluorodeoxyglucose (FDG) PET may detect small calvarial metastases not seen by MR
  - Caveat: Adjacent activity from normal gray matter may limit detection of SM

Imaging Recommendations

- Best imaging tool
  - SM: NECT/bone algorithm for osseous evaluation
    - MR with contrast if dura, scalp involved
  - DM, ASAM, PM, LM: MR + Gd, although sensitivity still only ~ 70%
    - 90% for extracranial solid tumor metastases
    - 55% when hematologic (lymphoma, leukemia)
- Protocol advice
  - Fat saturation necessary to distinguish enhancement from normal hyperintense marrow and scalp fat

DIFFERENTIAL DIAGNOSIS

Skull Metastases

- Surgical defect: Burr hole, craniectomy
- Myeloma: Characteristic labs

Dural Metastases

- Epidural hematoma: Distinctive MR
- Subdural hematoma: Distinctive MR
- Meningioma

Arachnoid/Subarachnoid Metastases

- Subarachnoid hemorrhage: Typical NECT appearance

https://CafePezeshki.IR

Leptomeningeal Metastases (LM)

- Sarcoidosis: CXR → hilar adenopathy + Kveim-Siltzbach skin test
- Infectious meningitis: CSF → infection/organism

PATHOLOGY

General Features

- Etiology
  - SM: Hematogenous (most commonly breast, lung, prostate, kidney) or by direct extension (SCCa)
  - DM: Hematogenous (most commonly breast > lymphoma > prostate > neuroblastoma)
  - LM, ASAM, PM: Hematogenous (most commonly lung, gastric, breast, ovary, melanoma, leukemia, lymphoma) or direct extension (primary CNS tumors)
- Associated abnormalities
  - Limbic encephalitis
- Dura and leptomeninges provide considerable barriers to contiguous spread of metastasis
  - General mechanisms of spread
    - Arterial hematogenous: Arterial transfer (e.g., breast, lung, melanoma, prostate)
    - Venous hematogenous: Via choroid plexus or through arachnoid vessels (classic for leukemia)
    - Direct extension: From primary brain tumors (e.g., GBM, PNET, ependymoma)
    - Perineural spread: H&N cancers (SCCa)
    - Iatrogenic: Following initial resection/debulking of primary brain tumors

Gross Pathologic & Surgical Features

- DM: Well-defined dural masses often invading skull
  - Necropsy → nodules on inner dura (subdural)
- LM, ASAM, PM: Gray-white or yellow thickening

Microscopic Features

- SM and DM: Metastatic cell infiltrates
- LM and ASAM: Metastatic cell infiltrates, often along perivascular spaces extending into brain

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - All metastases: May be asymptomatic and unsuspected clinically
  - Headache is most common symptom (50%)
  - Less common signs/symptoms
    - N/V, pain, sensory deficit, weakness (33%)
    - Mental status change (25%)
    - Seizures (20%)
    - ↑ ICP from CSF obstruction
    - Cranial nerve deficit(s)
  - Symptoms from brain compression → highly dependent on locale
- Clinical profile
  - CSF cytology often falsely negative
    - Accuracy of single lumbar puncture (LP) is 50-60% but 90% after 3 attempts

Demographics

- Age
  - Bimodal → children (medulloblastoma and leukemia); adults (breast, lung, melanoma, prostate)
  - Average age ~ 50 years (relatively young 2° pediatric cancer and young women with breast cancer)
- Epidemiology
  - 18% patients with extra- and intracranial malignancies
  - 6-18% of CNS metastases also involve arachnoid/subarachnoid space, pia, or both
  - Carcinomatosis in up to 25% of cancer patients
    - Primary tumor never identified in 2-4%
    - Occurs in breast (35%), lung small cell (25%), melanoma cancer (25%) patients

Natural History & Prognosis

- Dural sinus thrombosis from invasion or compression
- Obstructive hydrocephalus
  - Noncommunicating: Normal CSF flow obstructed, usually by cisternal metastases
  - Communicating: Normal CSF flow, ↓ arachnoid villi absorption, obstruction 2° tumor cells, blood, debris
  - Important to evaluate presence prior to LP to prevent downward herniation and death
  - Up to 70% of carcinomatosis patients have some degree of CSF obstruction
- Pachymeningitis interna hemorrhagica
  - Rare, usually bilateral, spontaneous, subdural hematomas from meningeal metastasis
  - Commonly from breast but also prostate, melanoma
- Untreated malignant meningeal metastases decreases survival time to 1-2 months

Treatment

- Early detection of meningeal metastases is crucial
  - MR often provides 1st clue
- Usually radiation with chemotherapy (intrathecal &/or systemic) initiated to slow progression
  - Entire neuraxis must be treated as tumor cells are often widely disseminated throughout CSF
- Biopsy may be necessary if no evidence of primary tumor
- Ventriculoperitoneal shunt may be necessary in patients with symptomatic CSF obstruction

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Both enhanced MR and LP should be performed, especially if initial test is negative

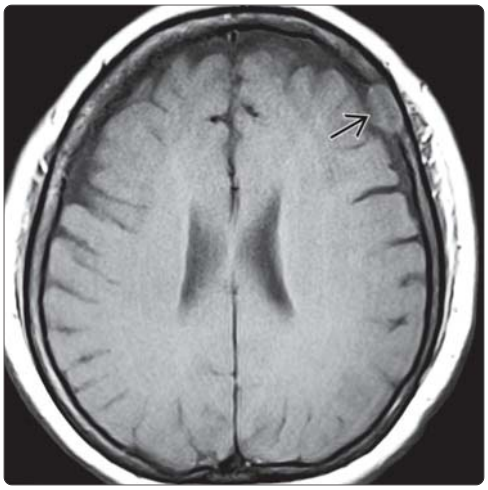
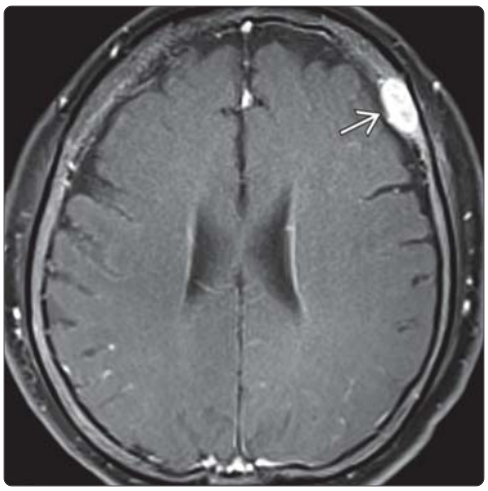
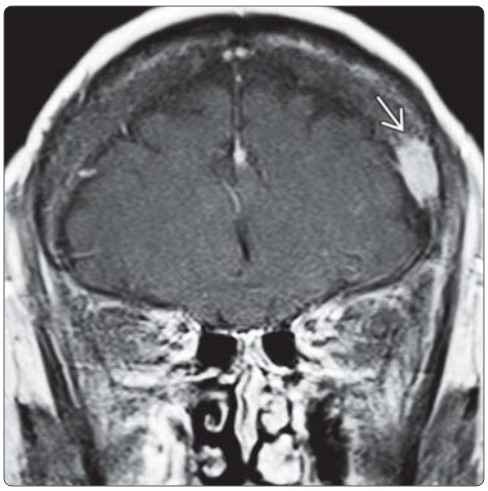
(Left) *Skull metastases can be difficult to see on routine NECT scans performed with soft tissue algorithm reconstructions. Axial NECT in this case shows very subtle erosions along the inner table of the calvaria* ⇨. **(Right)** *Axial NECT in the same case with bone algorithm reconstruction clearly shows the erosive, destructive lesion* ⇨. *In this case, this was the first manifestation of this patient's metastatic breast cancer.*



(Left) *Solitary calvarial metastases* ⇨ *are often well-seen on non-fat-saturated T1WI because the tumor replaces fatty marrow in the diploic space.* **(Right)** *Axial T2WI MR in the same case shows the lesion* ⇨ *is mixed iso- to hyperintense compared to the adjacent normal diploic space.*





(Left) *Axial T1 C+ FS MR in the same case shows the lesion* ➡ *clearly.* **(Right)** *Coronal T1 C+ MR shows the lesion margins are slightly irregular* ➡. *While the lesion has penetrated the inner table of the skull, there is no evidence for involvement of the underlying dura. This lesion was the only metastasis from the patient's known breast cancer.*

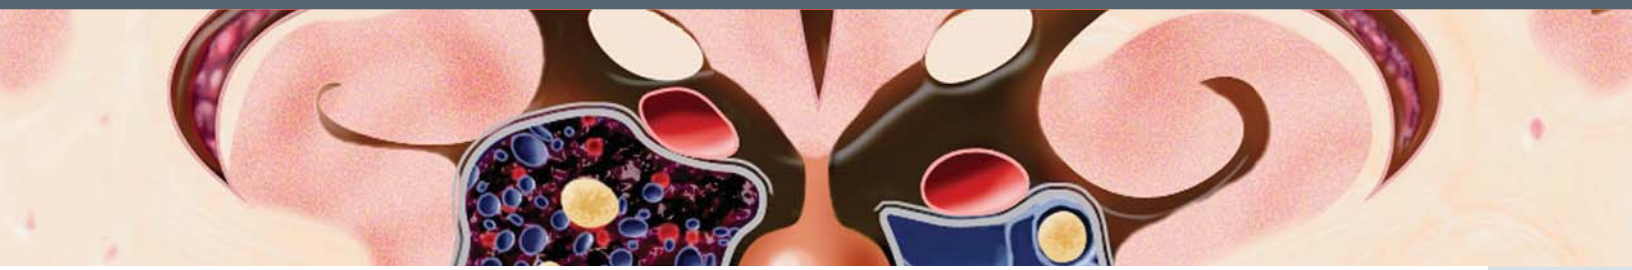
INDEX



A

Abscess, **682–685**
- differential diagnosis, **683–684**
- pituitary gland, pituitary apoplexy vs., **1045–1046**
- radiation and chemotherapy complications vs., **917–918**

Abusive head trauma, **188–191**
Adrenoleukodystrophy
- X-linked, **812–815**
  - diagnostic checklist, **814**
  - differential diagnosis, **813**
  - megalencephaly with leukoencephalopathy and cysts vs., **839**
  - staging, grading, and classification, **814**
  - Wallerian degeneration vs., **978**

Aging brain
- normal, **934–937**

Aicardi-Goutières syndrome, Fahr disease vs., **877**
Aicardi syndrome, **126–127**
AIDS
- miscellaneous manifestations, **752–755**

Alcoholic encephalopathy, **880–883**
- differential diagnosis, **881–882**

Alexander disease, **832–835**
- X-linked adrenoleukodystrophy vs., **814**

Alzheimer disease, **938–941**
- Creutzfeldt-Jakob disease vs., **953**
- differential diagnosis, **939–940**
- frontotemporal lobar degeneration vs., **947–948**

Amebic disease, **722–723**
Aminoacidopathies, miscellaneous, **836–837**
Amyloid angiopathy
- chronic hypertensive encephalopathy vs., **893–894**

Amyotrophic lateral sclerosis (ALS), **972–975**
- differential diagnosis, **973–974**

Anderson-Fabry disease. *See* Fabry disease.
Aneurysm, **218–219**
- blood blister-like, **218, 244–245**
  - diagnostic checklist, **245**
  - differential diagnosis, **245**
- cerebellopontine angle-internal auditory canal
  - hemifacial spasm vs., **1089**
  - lipoma vs., **1071**
  - trigeminal neuralgia vs., **1087**
  - vestibular schwannoma vs., **1091**
- fusiform
  - arteriosclerotic vascular disease, **240–241**
  - non-ASVD, **242–243**
- saccular, **232–235**
  - atypical, non-ASVD fusiform aneurysm vs., **243**
  - blood blister-like aneurysm vs., **245**
  - differential diagnosis, **233–234**

Angiocentric glioma (AG), **480–481**
Angiocentric (intravascular) lymphoma, **570–573**
Anoxic encephalopathy
- post-traumatic brain swelling vs., **198**

Antiphospholipid antibody syndrome
- non-SLE, systemic lupus erythematosus vs., **313**

Aqueductal stenosis, **1006–1009**
Arachnoid cyst, **608–611**
- cerebellopontine angle-internal auditory canal, **1078–1081**
  - diagnostic checklist, **1080**
  - differential diagnosis, **1079**
  - vestibular schwannoma vs., **1091**
- differential diagnosis, **609–610**
- nonneoplastic tumor-associated cyst vs., **653**
- posterior fossa, Dandy-Walker continuum vs., **27–28**

Arachnoid granulation
- aberrant, **388–391**

Arteriolosclerosis, **280–283**
- Creutzfeldt-Jakob disease vs., **953**
- differential diagnosis, **281–282**

Arteriovenous fistula
- dural, **400–403**
- pial, **404–405**

Arteriovenous malformations (AVMs), **396–399**
- cerebellopontine angle-internal auditory canal
  - hemifacial spasm vs., **1089**
  - trigeminal neuralgia vs., **1087**
- multiple, in vascular neurocutaneous syndrome, von Hippel-Lindau syndrome vs., **93**

Arteritis
- central nervous system, primary, **298–301**

Astroblastoma, **476–477**
Astrocytoma
- anaplastic, **438–441**
  - low-grade diffuse astrocytoma vs., **435**
- cerebellar pilocytic
  - arachnoid cyst of cerebellopontine angle-internal auditory canal vs., **1079**
- desmoplastic infantile, **506–509**
- low-grade (grade II)
  - ganglioglioma vs., **503**
  - mesial temporal sclerosis vs., **925**
  - pleomorphic xanthoastrocytoma vs., **461**
- low-grade diffuse, **434–437**
  - anaplastic astrocytoma vs., **439**
  - diagnostic checklist, **436**
  - differential diagnosis, **435–436**
  - oligodendroglioma vs., **469**
  - paraneoplastic syndromes vs., **599**
  - pilomyxoid astrocytoma vs., **457**
  - staging, grading, and classification, **436**

https://CafePezeshki.IR

- pilocytic, **452–455**
  differential diagnosis, **453–454**
  nonneoplastic tumor-associated cyst vs., **653**
  rosette-forming glioneuronal tumor vs., **523**
  von Hippel-Lindau syndrome vs., **93**
- pilomyxoid, **456–459**
  staging, grading, and classification, **457–458**
- subependymal giant cell, **464–467**

Atherosclerosis
- extracranial, **276–279**
- intracranial, **272–275**
  differential diagnosis, **273–274**

Atherosclerotic fusiform aneurysm (ASVD FA), **240–241**
Atherosclerotic vascular disease (ASVD)
- blood blister-like aneurysm vs., **245**

Atrophy
- multiple system, **960–963**
  differential diagnosis, **960–963**
- nonalcoholic, alcoholic encephalopathy vs., **881–882**
- optic nerve, idiopathic or post-inflammatory, intracranial hypertension vs., **897**

Atypical teratoid/rhabdoid tumor (AT/RT). *See* Teratoid-rhabdoid tumor, atypical.
Autoimmune-mediated vasculitis, acute disseminated encephalomyelitis vs., **765**
Autoimmune pancreatitis (AIP). *See* IgG4-related disease.
Axonal injury, diffuse, **176–179**
- traumatic, cerebral amyloid disease vs., **317–318**

B

Basal cell nevus syndrome, **106–109**
- Li-Fraumeni syndrome vs., **129**

Basal ganglia, **4–5, 858–861**
- T2 hyperintense, **858–859**

Basal ganglia calcification
- pathologic, Fahr disease vs., **877–878**

Behçet disease, **324–325**
- acute disseminated encephalomyelitis vs., **765–766**

Bell palsy, **1082–1085**
"Black dots"
- multifocal, cerebral amyloid disease vs., **317–318**

Blood blister-like aneurysm, **244–245**
- diagnostic checklist, **245**
- differential diagnosis, **245**

Blue rubber bleb nevus syndrome, Sturge-Weber syndrome vs., **101–102**
Bourneville-Pringle syndrome. *See* Tuberous sclerosis complex.
Brain
- aging
  normal, **934–937**
- cysts
  anatomy-based approach, **604–605**
- lesions
  multiple ring-enhancing, fungal disease vs., **731**
- malformations, general imaging approach, **4–5**

Brain death, **204–205**
Brain swelling, post-traumatic, **196–199**
- diagnostic checklist, **198**
- differential diagnosis, **198**

Brainstem glioma
- Wallerian degeneration vs., **977–978**

C

CADASIL (cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy), **320–323**
- arteriolosclerosis vs., **281–282**

Callosal dysgenesis, **18–21**
- differential diagnosis, **19–20**

Calvarial defects, congenital, **1108–1111**
- differential diagnosis, **1109–1110**

Calvarium (calvaria)
- hemangioma, **1184–1187**
  differential diagnosis, **1185–1186**

Canavan disease, **830–831**
Canavan-van Bogaert-Bertrand disease. *See* Canavan disease.
Capillary hemangioma, capillary telangiectasia vs., **425–426**
Capillary telangiectasias, **424–427**
- differential diagnosis, **425–426**

Carbon monoxide poisoning, **900–903**
- differential diagnosis, **901–902**

Carney complex, Li-Fraumeni syndrome vs., **129**
Carotid artery, internal
- aberrant, **284–287**
  differential diagnosis, **285–286**

Carotid basilar anastomoses, persistent, **288–289**
Carotid cavernous fistula
- traumatic, **212–213**

Cavernous malformations, **420–423**
Central nervous system (CNS)
- primary arteritis, **298–301**

Cephalocele, **1116–1121**
- atretic, **1122–1125**
  differential diagnosis, **1123–1124**
- differential diagnosis, **1117–1118**

Cerebellar disorders
- crossed cerebellar diaschisis, **980–981**
- remote hemorrhage, **266–267**

Cerebellar dysplasias
- unclassified, **34–35**
  Lhermitte-Duclos disease vs., **119**

Cerebellar infarction
- subacute, Lhermitte-Duclos disease vs., **119**

Cerebellar neoplasms
- pilocytic astrocytoma
  arachnoid cyst of cerebellopontine angle-internal auditory canal vs., **1079**

Cerebellitis, **704–705**
- Lhermitte-Duclos disease vs., **119**

Cerebellopontine angle (CPA) masses
- neurofibromatosis type 2 vs., **89–90**

Cerebellopontine angle-internal auditory canal (CPA-IAC)
- aneurysm
  hemifacial spasm vs., **1089**
  lipoma vs., **1071**
  trigeminal neuralgia vs., **1087**

https://CafePezeshki.IR

vestibular schwannoma vs., **1091**
- arachnoid cyst, **1078–1081**
  differential diagnosis, **1079**
  vestibular schwannoma vs., **1091**
- Bell palsy, **1082–1085**
- dura/venous sinus hemangioma vs., **1189**
- epidermoid cyst, **1074–1077**
  diagnostic checklist, **1076**
  differential diagnosis, **1075**
- hemifacial spasm, **1088–1089**
- lipoma, **1070–1073**
  diagnostic checklist, **1072**
  differential diagnosis, **1071**
- meningioma, **1094–1097**
- metastases, **1098–1101**
- overview, **1066–1069**
- trigeminal neuralgia, **1086–1087**

Cerebral amyloid disease, **316–319**
- differential diagnosis, **317–318**

Cerebral contusion, **172–175**
Cerebral hemiatrophy, **352–353**
Cerebral hyperperfusion syndrome, **372–375**
- differential diagnosis, **373–374**

Cerebral infarction
- chronic, **362–365**
- hypotensive, **344–347**
  differential diagnosis, **345–346**
- subacute, **358–361**

Cerebral ischemia
- oligodendroglioma vs., **469–470**

Cerebral ischemia-infarction
- acute, **354–357**
  acute hypertensive encephalopathy/PRES vs., **889**
  adult hypoglycemia vs., **867**
  adult hypoxic ischemic injury vs., **341**
  cerebral hyperperfusion syndrome vs., **373**
  diagnostic checklist, **356**
  differential diagnosis, **356**
  fat emboli cerebral infarction vs., **367**
  herpes encephalitis vs., **693**
- status epilepticus vs., **929**
- transient global amnesia vs., **933**
- traumatic, **200–203**
  diagnostic checklist, **202**
  differential diagnosis, **201**

Cerebral malaria, **724–725**
Cerebral vasoconstriction syndrome, reversible, **306–307**
Cerebritis
- low-grade diffuse astrocytoma vs., **435**

Cerebrospinal fluid (CSF) shunts and complications, **1014–1017**
Chiari 1, **8–11**
Chiari 2, **12–15**
Chiari 3, **16–17**
Childhood stroke, **348–351**
Chordoid glioma of third ventricle (CGOTV), **478–479**
Choroid plexus carcinoma, **498–501**
- differential diagnosis, **499–500**

Choroid plexus cyst, **640–643**
- differential diagnosis, **641–642**

Choroid plexus papilloma
- atypical teratoid-rhabdoid tumor vs., **545**
- typical, **494–497**
  differential diagnosis, **495–496**

Chronic progressive external ophthalmoplegia (CPEO), Kearns-Sayre syndrome vs., **791**
Chronic traumatic encephalopathy, **214–215**
Cisterns, overview, **988–993**
Citrobacter meningitis, **674–677**
- differential diagnosis, **675–676**

CLIPPERS (chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids), **770–771**
"Closed-lip" schizencephaly, heterotopic gray matter vs., **65**
Colloid cyst, **612–615**
Congenital lipoma. *See* Lipoma, cerebellopontine angle-internal auditory canal.
Congenital malformations
- Aicardi-Goutières syndrome, Fahr disease vs., **877**
- Aicardi syndrome, **126–127**
- basal cell nevus syndrome, **106–109**
- callosal dysgenesis, **18–21**
  differential diagnosis, **19–20**
- cerebellar dysplasias, unclassified, **34–35**
- Chiari 1, **8–11**
- Chiari 2, **12–15**
- Chiari 3, **16–17**
- Dandy-Walker continuum, **26–29**
  differential diagnosis, **27–28**
- encephalocraniocutaneous lipomatosis, **114–117**
- hemimegalencephaly, **80–83**
  differential diagnosis, **81–82**
- hereditary hemorrhagic telangiectasia, **110–113**
- Lhermitte-Duclos disease, **118–121**
  differential diagnosis, **119**
- Li-Fraumeni syndrome, **128–129**
- lissencephaly, **72–75**
- meningioangiomatosis, **104–105**
- muscular dystrophy, **60–63**
- neurocutaneous melanosis, **122–125**
- neurofibromatosis type 1, **84–87**
- neurofibromatosis type 2, **88–91**
  differential diagnosis, **89–90**
- overview, **4–7**
- polymicrogyria, **68–71**
  differential diagnosis, **69–70**
- rhombencephalosynapsis, **30–33**
- schwannomatosis, **130–131**
- septooptic dysplasia, **52–55**
- Sturge-Weber syndrome. *See* Sturge-Weber syndrome.
- von Hippel-Lindau syndrome, **92–95**
  differential diagnosis, **93**

Conradi-Hünermann-Happle syndrome, peroxisomal disorders vs., **817**
Cortical venous thrombosis, **380–383**
Corticobasal degeneration, **964–967**
- Creutzfeldt-Jakob disease vs., **953**

Cranial fossa, bilateral middle cyst-like spaces, glutaric aciduria type 1, **827**

https://CafePezeshki.IR

Craniopharyngioma, **1048–1051**
Craniostenoses, **1112–1115**
Craniovertebral junction, fracture, **135–136**
Creutzfeldt-Jakob disease (CJD), **952–955**
- adult hypoxic ischemic injury vs., **342**
- Alzheimer disease vs., **940**
- carbon monoxide poisoning vs., **902**
- cyanide poisoning vs., **911**
- diagnostic checklist, **954**
- differential diagnosis, **953**
- methanol poisoning vs., **909**
- Wilson disease vs., **853**

Crossed cerebellar diaschisis, **980–981**
Cryptococcosis, **746–747**
Cyanide poisoning, **910–911**
Cystic neoplasms
- nonneoplastic tumor-associated cyst vs., **653**

Cysts
- choroid plexus, **640–643**
  differential diagnosis, **641–642**
- colloid, **612–615**
- hydatid, **720–721**
- leptomeningeal
  "growing fracture," **1126–1127**
- neuroglial, **624–625**
- nonneoplastic
  primary, overview, **604–607**
- periventricular, **626–629**
- pineal, **636–639**
- tumor-associated nonneoplastic, **652–653**

Cytomegalovirus infection
- acquired, **744–745**
- congenital, **662–665**

Cytotoxic edema. *See* Brain swelling, post-traumatic.

D

Dandy-Walker continuum, **26–29**
- diagnostic checklist, **28**
- differential diagnosis, **27–28**
- molar tooth malformations vs., **37**
- staging, grading and classification, **28**

Dandy-Walker malformation, **4**
- porencephalic cyst vs., **647**

Dandy-Walker spectrum, Dandy-Walker continuum vs., **27**
Degenerative disorders
- amyotrophic lateral sclerosis, **972–975**
  differential diagnosis, **973–974**
- corticobasal degeneration, **964–967**
  Creutzfeldt-Jakob disease vs., **953**
- crossed cerebellar diaschisis, **980–981**
- Fahr disease, **876–879**
  differential diagnosis, **877–878**
- hypertrophic olivary degeneration, **982–985**
- Parkinson disease, **956–959**
  progressive supranuclear palsy vs., **969–970**
- progressive supranuclear palsy, **968–971**
  differential diagnosis, **969–970**
- Wallerian degeneration, **976–979**
  differential diagnosis, **977–978**

Dementia
- Creutzfeldt-Jakob disease. *See* Creutzfeldt-Jakob disease (CJD).
- multi-infarct. *See* Multi-infarct dementia.

Dementia with Lewy bodies, **950–951**
Demyelinating disease
- neuromyelitis optica, **760–763**
- Susac syndrome, **326–327**

Demyelination
- primary CNS lymphoma vs., **567–568**

Demyelination syndrome, osmotic, **912–915**
- Creutzfeldt-Jakob disease vs., **953**
- differential diagnosis, **913–914**

Dermoid cyst, **616–619**
Dermoid tumors
- T1-hyperintense, neurocutaneous melanosis vs., **123**

Desmoplastic infantile astrocytoma (DIA), **506–509**
Desmoplastic infantile ganglioglioma (DIG/DIGG), **506–509**
Developmental venous anomalies, **410–415**
- differential diagnosis, **411–412**

Diffuse astrocytoma. *See* Astrocytoma, low-grade diffuse.
Diffuse axonal injury, **176–179**
- traumatic, cerebral amyloid disease vs., **317–318**

Diffuse brain swelling. *See* Brain swelling, post-traumatic.
Diffuse dura-arachnoid enhancement, **1104**
Dissection
- intracranial atherosclerosis vs., **273–274**
- traumatic, intracranial arterial, **208–211**

Dolichoectasia
- vertebrobasilar, **238–239**

Drug abuse, **904–907**
Dura/venous sinus hemangioma, **1188–1189**
Dural neoplasms
- metastases
  cerebellopontine angle-internal auditory canal, meningioma vs., **1095**

Dural sinus
- granulations, **388–391**
- hypoplasia-aplasia
  dural sinus and aberrant arachnoid granulations vs., **389**
  dural sinus thrombosis vs., **378**

Dural sinus thrombosis, **376–379**
Dyke-Davidoff-Masson syndrome. *See* Cerebral hemiatrophy.
Dysembryoplastic neuroepithelial tumor (DNET), **510–513**
- of cerebellum. *See* Rosette-forming glioneuronal tumor (RGNT).

E

Eclampsia (pregnancy-induced hypertension), traumatic subarachnoid hemorrhage vs., **169**
Empty sella, **1056–1059**
- differential diagnosis, **1057–1058**

Empyema
- epidural, **688–691**
  differential diagnosis, **689–690**

https://CafePezeshki.IR

INDEX

Encephalitis
- herpes simplex virus, human herpes virus 6 (HHV-6) encephalitis vs., **703**
- HIV
  acquired, **738–741**
- human herpes virus 6 (HHV-6), **702–703**
- limbic
  paraneoplastic, human herpes virus 6 (HHV-6) encephalitis vs., **703**
- miscellaneous, **696–699**
- post-traumatic brain swelling vs., **198**
- Rasmussen, **706–709**
- subacute sclerosing panencephalitis, **710–711**
- West Nile virus, **700–701**

Encephalocraniocutaneous lipomatosis, **114–117**
Encephalomalacia
- postoperative/post-traumatic, chronic cerebral infarction vs., **363**

Encephalomyelitis, acute disseminated, **764–767**
- differential diagnosis, **765–766**

Encephalopathy
- alcoholic, **880–883**
  differential diagnosis, **881–882**
- anoxic, post-traumatic brain swelling vs., **198**
- chronic traumatic, **214–215**
- hepatic, **884–887**
  differential diagnosis, **885–886**
- metabolic, post-traumatic brain swelling vs., **198**
- subcortical arteriosclerotic, normal pressure hydrocephalus vs., **1011–1012**

Encephalotrigeminal angiomatosis. *See* Sturge-Weber syndrome.
Enlarged subarachnoid spaces, **996–999**
- differential diagnosis, **997–998**

Ependymal cyst, **644–645**
Ependymoma
- atypical teratoid-rhabdoid tumor vs., **545**
- infratentorial, **482–485**
- neurofibromatosis type 2 vs., **89–90**
- rosette-forming glioneuronal tumor vs., **523**
- supratentorial, **486–489**

Epidermoid cyst, **620–623**
- cerebellopontine angle-internal auditory canal, **1074–1077**
  arachnoid cyst vs., **1079**
  diagnostic checklist, **1076**
  differential diagnosis, **1075**
  meningioma vs., **1095**
  vestibular schwannoma vs., **1091**
- differential diagnosis, **621–622**

Epidermoid tumors. *See also* Cerebellopontine angle-internal auditory canal, epidermoid cyst.
Epidural empyema, **688–691**
- differential diagnosis, **689–690**

Epidural hematoma
- classic, **148–151**
  differential diagnosis, **149–150**
- variant, **152–155**

Epilepsy, myoclonic, with ragged-red fibers, MELAS vs., **787**
Epithelial inclusion cyst. *See* Cerebellopontine angle-internal auditory canal, epidermoid cyst.
Erdheim-Chester disease, **1161**
Extraaxial cysts, **604–605**
Extracranial atherosclerosis, **276–279**
Extramedullary hematopoiesis, **1146–1149**
Extraventricular neurocytoma (EVN), **518–519**

F

Fabry disease, **808–809**
Fahr disease, **876–879**
- differential diagnosis, **877–878**

Fat-containing lesions, evolution of intracranial hemorrhage vs., **255**
Fibrillary astrocytoma. *See* Astrocytoma, low-grade diffuse.
Fibromuscular dysplasia, **328–329**
Fibrous dysplasia, skull, **1138–1141**
- staging, grading, and classification, **1139–1140**

Frontotemporal lobar degeneration, **946–949**
- Creutzfeldt-Jakob disease vs., **953**
- differential diagnosis, **947–948**

Fungal diseases, **730–733**
Fusiform aneurysm
- ASVD, **240–241**
- non-ASVD, **242–243**
  diagnostic checklist, **243**
  differential diagnosis, **243**

G

Ganglioglioma, **502–505**
- desmoplastic infantile, **506–509**
- differential diagnosis, **503–504**
- Lhermitte-Duclos disease vs., **119**

Gangliosidosis, **796–799**
Germ cell neoplasms, miscellaneous malignant, **586–589**
Germinal matrix hemorrhage, **268–271**
Germinoma, **578–581**
- differential diagnosis, **579–580**

Giant aneurysm
- serpentine
  non-ASVD fusiform aneurysm vs., **243**

Glioblastoma, **442–445**
- atypical teratoid-rhabdoid tumor vs., **545**
- differential diagnosis, **443–444**

Glioma
- angiocentric, **480–481**
- brainstem
  Wallerian degeneration vs., **977–978**
- chordoid, of third ventricle, **478–479**
- low-grade, **430**
  herpes encephalitis vs., **693**

Gliomatosis cerebri, **448–451**
- differential diagnosis, **449–450**

Glioneuronal tumor
- rosette-forming, **522–523**
  diagnostic checklist, **523**

https://CafePezeshki.IR

differential diagnosis, **523**
staging, grading, and classification, **523**
Gliosarcoma, **446–447**
Glutaric aciduria type 1, **826–829**
Gorlin-Goltz syndrome. *See* Basal cell nevus syndrome.
Grade II astrocytoma. *See* Astrocytoma, low-grade diffuse.
Granulomatous disease
- meningeal, Lhermitte-Duclos disease vs., **119**
Gray matter, heterotopic, **64–67**
Gray matter disorders, **774–775**
Group B b-hemolytic streptococcal meningitis. *See* Meningitis, group B streptococcal.

H

Hallervorden-Spatz syndrome. *See* Pantothenate kinase-associated neurodegeneration (PKAN).
Hamartoma
- syndrome, multiple. *See* Lhermitte-Duclos disease.
- tuber cinereum, **1028–1031**
Hemangioblastoma, **558–561**
- nonneoplastic tumor-associated cyst vs., **653**
- solitary, von Hippel-Lindau syndrome vs., **93**
Hemangioendothelioma, low-grade, calvarial hemangioma vs., **1185**
Hemangioma
- calvarial, **1184–1187**
- capillary, capillary telangiectasia vs., **425–426**
- dura/venous sinuses, **1188–1189**
Hemangiopericytoma, **562–565**
Hematoma
- epidural
  classic, **148–151**
    differential diagnosis, **149–150**
  variant, **152–155**
Hematopoiesis, extramedullary, **1146–1149**
Hemifacial spasm, **1088–1089**
Hemimegalencephaly, **80–83**
- differential diagnosis, **81–82**
Hemorrhage
- cerebellar, remote, **266–267**
- germinal matrix, **268–271**
- spontaneous, coagulopathy-related, remote cerebellar hemorrhage vs., **267**
- T1-hyperintense, neurocutaneous melanosis vs., **123**
Hemorrhagic leukoencephalitis, acute, **768–769**
Hemorrhagic telangiectasia, hereditary, **110–113**
Hepatic encephalopathy, **884–887**
- differential diagnosis, **885–886**
"Herald" cyst. *See* Nonneoplastic tumor-associated cysts.
Herniation
- intracranial herniation syndromes, **192–195**
Herpes encephalitis, **692–695**
- low-grade diffuse astrocytoma vs., **435**
- neonatal, **668–669**
Herpes simplex virus type 2 (HSV-2) infection, group B streptococcal meningitis vs., **671**
Heterotopia
- subependymal, X-linked, tuberous sclerosis complex vs., **97**
Heterotopic gray matter, **64–67**
High-grade astrocytoma. *See* Astrocytoma, anaplastic.
High-grade oligodendroglioma (oligo). *See* Oligodendroglioma, anaplastic.
Histiocytosis
- miscellaneous, **1160–1163**
  non-Langerhans cell, **1161**
HIV-associated mineralizing calcific microangiopathy, Fabry disease vs., **809**
HIV encephalitis
- acquired, **738–741**
HIV infections
- congenital, **666–667**
- miscellaneous manifestations, **752–755**
Holoprosencephaly, **40–43**
- differential diagnosis, **41–42**
- middle interhemispheric variant (syntelencephaly), **48–51**
  differential diagnosis, **49–50**
- variants, **44–47**
Human herpes virus 6 (HHV-6) encephalitis, **702–703**
- diagnostic checklist, **703**
- differential diagnosis, **703**
Huntington disease, **848–851**
Hydatid disease, **720–721**
Hydranencephaly, **330–331**
Hydrocephalus
- extraventricular obstructive, **1004–1005**
- intraventricular obstructive, **1000–1003**
  differential diagnosis, **1001–1002**
- normal pressure, **1010–1013**
  differential diagnosis, **1011–1012**
Hyperdense vessel mimics, acute cerebral ischemia-infarction vs., **356**
Hyperglycemia, chorea-ballism associated with, hepatic encephalopathy vs., **885**
Hypertension
- intracranial
  idiopathic, **896–899**
Hypertension-related microvascular disease. *See* Hypertensive encephalopathy, chronic.
Hypertensive encephalopathy
- acute/PRES, **888–891**
  differential diagnosis, **889–890**
- chronic, **892–895**
  differential diagnosis, **893–894**
  normal pressure hydrocephalus vs., **1011–1012**
Hypertensive intracranial hemorrhage, **262–265**
- differential diagnosis, **263–264**
Hypertrophic olivary degeneration, **982–985**
Hypoglycemia
- adult, **866–867**
- neonatal, X-linked adrenoleukodystrophy vs., **814**
- pediatric, **862–865**
Hypomyelination, **778–781**
- differential diagnosis, **779–780**
Hypotension, intracranial, **1128–1131**
- differential diagnosis, **1129–1130**
Hypotensive cerebral infarction, **344–347**
- differential diagnosis, **345–346**

https://CafePezeshki.IR

Hypoxic-ischemic encephalopathy
- cyanide poisoning vs., **911**
- group B streptococcal meningitis vs., **671–672**
- hepatic encephalopathy vs., **885**
- maple syrup urine disease vs., **821**
- parathyroid disorders vs., **875**
- perinatal, mucopolysaccharidoses vs., **793**
- urea cycle disorders vs., **825**
- Wilson disease vs., **853**

Hypoxic-ischemic injury
- adult, **340–343**
  - Creutzfeldt-Jakob disease vs., **953**
  - diagnostic checklist, **342**
  - differential diagnosis, **341–342**
- neonatal, **775**
- preterm, pediatric hypoglycemia vs., **863**
- term, **336–339**
  - diagnostic checklist, **338**
  - differential diagnosis, **337–338**
  - kernicterus vs., **869**
  - pediatric hypoglycemia vs., **863**

I

"Idiopathic" pseudotumor. *See* IgG4-related disease.

IgG4-related disease, **1136–1137**
- diagnostic checklist, **1137**
- differential diagnosis, **1137**

IgG4-related ophthalmic disease. *See* IgG4-related disease.

Immune reconstitution inflammatory syndrome (IRIS), **750–751**

Infantile-onset leukoencephalopathy with swelling and discrepantly mild course. *See* Megalencephaly with leukoencephalopathy and cysts.

Infarction
- lacunar, **368–371**
- traumatic. *See* Cerebral ischemia-infarction, traumatic.

Infections
- central nervous system, overview, **656–657**
- cerebral malaria, **724–725**
- cryptococcosis, **746–747**
- fungal, **730–733**
- immune reconstitution inflammatory syndrome (IRIS), **750–751**
- Lyme disease, **736–737**
- miscellaneous parasites, **726–729**
- rickettsial diseases, **734–735**
- ventriculitis, **686–687**

Inflammatory pseudotumor, intracranial idiopathic, **1132–1135**

Infratentorial extraaxial cysts, **604–605**

Intracranial arterial dissection, traumatic, **208–211**

Intracranial atherosclerosis, **272–275**
- differential diagnosis, **273–274**

Intracranial cystic-appearing lesions, **606**

Intracranial hemorrhage
- evolution of, **254–257**
- hypertensive, **262–265**
  - differential diagnosis, **263–264**
- spontaneous nontraumatic, **258–261**
  - differential diagnosis, **259–260**

Intracranial herniation syndromes, **192–195**

Intracranial hypertension
- idiopathic, **896–899**

Intracranial hypotension, **1128–1131**

Intravascular B-cell lymphoma. *See* Angiocentric (intravascular) lymphoma.

Ischemia
- low-grade diffuse astrocytoma vs., **435**
- traumatic. *See* Cerebral ischemia-infarction, traumatic.

J

Jaffe-Campanacci (J-C) syndrome, fibrous dysplasia vs., **1139**

Jaffe-Lichtenstein dysplasia. *See* Fibrous dysplasia, skull.

K

Kaplan-Grumbach-Hoyt syndrome. *See* Septooptic dysplasia.

Kearns-Sayre syndrome, **790–791**
- diagnostic checklist, **791**
- differential diagnosis, **791**
- MELAS vs., **787**
- PKAN vs., **845**

Kernicterus, **868–869**

Klippel-Trenaunay-Weber syndrome, Sturge-Weber syndrome vs., **102**

Krabbe disease, **804–807**

L

L-2 hydroxyglutaric aciduria, PKAN vs., **845**

Lacunar infarction, **368–371**

Lacunar skull of newborn, congenital calvarial defects vs., **1109–1110**

Langerhans cell histiocytosis (LCH), **1152–1155**
- differential diagnosis, **1153–1154**

Lateral sclerosis, primary
- amyotrophic lateral sclerosis vs., **973–974**

Leigh syndrome, **782–785**
- Creutzfeldt-Jakob disease vs., **953**

Leptomeningeal carcinomatosis. *See* Metastasis (metastatic disease), cerebellopontine angle-internal auditory canal.

Leptomeningeal cyst
- "growing fracture," **1126–1127**

Leptomeningeal enhancement
- Sturge-Weber syndrome vs., **102**

Leukemia, **574–577**
- differential diagnosis, **575–576**

Leukodystrophy
- metachromatic, **800–803**

Leukoencephalitis, acute hemorrhagic, **768–769**

https://CafePezeshki.IR

Leukoencephalopathy
- megalencephalic, with cysts, **838–841**
- progressive multifocal, **748–749**
Lhermitte-Duclos disease, **118–121**
- diagnostic checklist, **120**
- differential diagnosis, **119**
- rhombencephalosynapsis vs., **31**
- staging, grading and classification, **120**
Li-Fraumeni syndrome, **128–129**
- diagnostic checklist, **129**
- differential diagnosis, **129**
- staging, grading and classification, **129**
Limbic encephalitis
- paraneoplastic, human herpes virus 6 (HHV-6) encephalitis vs., **703**
Lipoma, **22–25**
- cerebellopontine angle-internal auditory canal, **1070–1073**
  diagnostic checklist, **1072**
  differential diagnosis, **1071**
- differential diagnosis, **23–24**
- T1-hyperintense, neurocutaneous melanosis vs., **123**
Lipomatosis, encephalocraniocutaneous, **114–117**
Lipomatous hamartoma. *See* Lipoma, cerebellopontine angle-internal auditory canal.
Lissencephaly, **72–75**
Low-grade astrocytoma (LGA). *See* Astrocytoma, low-grade diffuse.
Lyme disease, **736–737**
Lymphocytic hypophysitis, **1062–1063**
Lymphoma
- IgG4-related disease vs., **1137**
- intravascular (angiocentric), **570–573**
- metastatic intracranial, **596–597**
- primary CNS, **566–569**
  deep cerebral venous thrombosis vs., **385–386**
  differential diagnosis, **567–568**

M

Malaria, cerebral, **724–725**
Malignant rhabdoid tumor of brain. *See* Teratoid-rhabdoid tumor, atypical.
Maple syrup urine disease, **820–823**
Marchiafava-Bignami disease. *See also* Alcoholic encephalopathy.
- maple syrup urine disease vs., **821**
McCune-Albright syndrome (MAS). *See* Fibrous dysplasia, skull.
Medulloblastoma, **536–539**
- atypical teratoid-rhabdoid tumor vs., **545**
- hemispheric, von Hippel-Lindau syndrome vs., **93**
- Lhermitte-Duclos disease vs., **119**
- rosette-forming glioneuronal tumor vs., **523**
"Mega-corpus callosum," callosal dysgenesis vs., **20**
Megalencephaly with leukoencephalopathy and cysts, **838–841**
Melanoma-astrocytoma syndrome, Li-Fraumeni syndrome vs., **129**
Melanosis, neurocutaneous, **122–125**
MELAS (mitochondrial encephalopathy with lactic acidosis and stroke-like episodes), **786–789**
- adult hypoxic ischemic injury vs., **342**
- CADASIL vs., **321**
- cerebral hyperperfusion syndrome vs., **373**
- diagnostic checklist, **788**
- differential diagnosis, **787**
- Kearns-Sayre syndrome vs., **791**
- Leigh syndrome vs., **783**
- pediatric hypoglycemia vs., **863**
- Rasmussen encephalitis vs., **707**
- status epilepticus vs., **929**
Meningeal carcinomatosis. *See* Metastasis (metastatic disease), cerebellopontine angle-internal auditory canal.
Meningeal granulomatous disease, Lhermitte-Duclos disease vs., **119**
Meningeal neoplasms
- metastases, **1194–1197**
  differential diagnosis, **1195–1196**
  Lhermitte-Duclos disease vs., **119**
- non-Hodgkin lymphoma, intracranial idiopathic inflammatory pseudotumor vs., **1133**
Meningeal tumors, **431–432**
Meninges
- overview, **1104–1107**
Meningioangiomatosis, **104–105**
- Sturge-Weber syndrome vs., **102**
Meningioma, **1166–1171**
- anaplastic oligodendroglioma vs., **473–474**
- atypical and malignant, **1172–1175**
- cerebellopontine angle-internal auditory canal, **1094–1097**
  diagnostic checklist, **1096**
  differential diagnosis, **1095**
  staging, grading, and classification, **1096**
  vestibular schwannoma vs., **1091**
- IgG4-related disease vs., **1137**
- malignant
  and atypical, **1172–1175**
Meningitides
- neonatal, gram-negative meningitis, group B streptococcal meningitis vs., **671**
Meningitis, **678–681**
- cerebellopontine angle-internal auditory canal, metastases vs., **1099**
- *Citrobacter*, **674–677**
- group B streptococcal, **670–673**
- post-traumatic brain swelling vs., **198**
Merosin-deficiency congenital muscular dystrophy, Canavan disease vs., **831**
Mesenchymal tumors
- benign, **1176–1179**
- malignant, **1180–1183**
Mesial temporal sclerosis, **924–927**
- differential diagnosis, **925–926**
Metabolic disorders
- acquired
  overview, **858–861**
- Fabry disease, **808–809**

https://CafePezeshki.IR

- gangliosidosis, **796–799**

- mucopolysaccharidoses, **792–795**
- neurodegeneration with brain iron accumulation (NBIA), **842–843**
- organic/aminoacidopathies, miscellaneous, **836–837**
- osmotic demyelination syndrome vs., **913–914**
- pantothenate kinase-associated neurodegeneration, Huntington disease vs., **849**
- parathyroid disorders, **874–875**
- PKAN, **844–847**
  genetics, **845–846**
- thyroid disorders, **870–873**
- urea cycle disorders, **824–825**
- X-linked adrenoleukodystrophy, **812–815**
  differential diagnosis, **813**
  megalencephaly with leukoencephalopathy and cysts vs., **839**
  Wallerian degeneration vs., **978**
- Zellweger syndrome spectrum, **810–811**

Metabolic encephalopathy, post-traumatic brain swelling vs., **198**
Metastasis (metastatic disease)
- cerebellopontine angle-internal auditory canal, **1098–1101**
  diagnostic checklist, **1100**
  differential diagnosis, **1099**
  vestibular schwannoma vs., **1091**
- intracranial, miscellaneous, **594–595**
- meningeal
  differential diagnosis, **1195–1196**
  Lhermitte-Duclos disease vs., **119**
- neuroblastoma, **548–551**
  differential diagnosis, **549–550**
- parenchymal, **590–593**
  differential diagnosis, **591–592**
- rosette-forming glioneuronal tumor vs., **523**
- skull, **1194–1197**
  differential diagnosis, **1195–1196**
- vascular, von Hippel-Lindau syndrome vs., **93**

Metastatic intracranial lymphoma, **596–597**
Methanol poisoning, **908–909**
Microangiopathy
- HIV-associated mineralizing calcific, Fabry disease vs., **809**

Microcephaly, **56–59**
Mikulicz disease. *See* IgG4-related disease.
Missile and penetrating injury, **144–147**
Mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke-like episodes. *See* MELAS.
Mixed glial-neuronal neoplasm. *See* Dysembryoplastic neuroepithelial tumor (DNET).
Mixed neuronal-glial tumors, **430–431**
Molar tooth malformations (Joubert), **36–39**
- Dandy-Walker continuum vs., **28**

Moyamoya, **294–297**
Mucopolysaccharidoses, **792–795**
Multi-infarct dementia
- alcoholic encephalopathy vs., **881**
- chronic hypertensive encephalopathy vs., **893**
- Creutzfeldt-Jakob disease vs., **953**
- intravascular (angiocentric) lymphoma vs., **571**
- normal pressure hydrocephalus vs., **1011**

Multiple hamartoma syndrome. *See* Lhermitte-Duclos disease.
Multiple sclerosis, **756–759**
Multiple system atrophy, **960–963**
Muscular dystrophy, congenital, **60–63**
- merosin-deficiency, Canavan disease vs., **831**

Myeloma, **1190–1193**
Myoclonic epilepsy with ragged-red fibers (MERRF), MELAS vs., **787**

N

Neoplasms, **430–433**
- classification, **430–431**
- grading, **430–431**
- low-grade, cerebral contusion vs., **173**
- underlying, spontaneous nontraumatic intracranial hemorrhage vs., **259–260**

Neurenteric cyst, **650–651**
- arachnoid cyst of cerebellopontine angle-internal auditory canal vs., **1079**

Neuro-Behçet disease. *See* Behçet disease.
Neuroblastoma
- metastatic, **548–551**
  differential diagnosis, **549–550**

Neurocutaneous melanosis, **122–125**
Neurocutaneous syndromes, Sturge-Weber syndrome vs., **101–102**
Neurocysticercosis, **716–719**
- differential diagnosis, **717–718**
- ganglioglioma vs., **503–504**

Neurocytoma
- central, **514–517**
- extraventricular, **518–519**

Neurodegeneration with brain iron accumulation (NBIA), **842–843**
- type 1. *See* Pantothenate kinase-associated neurodegeneration (PKAN).

https://CafePezeshki.IR

Neurofibroma (NF), **556–557**
Neurofibromatosis type 1, **84–87**
- Li-Fraumeni syndrome vs., **129**
Neurofibromatosis type 2, **88–91**
- differential diagnosis, **89–90**
Neuroglial cyst, **624–625**
Neuromyelitis optica, **760–763**
Neuronal tumors, **430–431**
Neurosarcoid, **1156–1159**
- IgG4-related disease vs., **1137**
Neurosarcoidosis
- tuberculosis vs., **713–714**
Non-Hodgkin lymphoma, meningeal, intracranial idiopathic inflammatory pseudotumor vs., **1133**
Nonneoplastic tumor-associated cysts, **652–653**
- differential diagnosis, **653**

O

Odontoid fractures, **135–136**
Oligodendroglioma, **468–471**
- anaplastic, **472–475**
  differential diagnosis, **473–474**
- differential diagnosis, **469–470**
- low-grade diffuse astrocytoma vs., **435**
Olivary degeneration, hypertrophic, **982–985**
Ophthalmoplegia, chronic progressive external , Kearns-Sayre syndrome vs., **791**
Optic-infundibular dysplasia, septooptic dysplasia vs., **53**
Optic nerve atrophy, idiopathic or post-inflammatory, intracranial hypertension vs., **897**
Ormond disease. *See* IgG4-related disease.
Osler-Weber-Rendu syndrome. *See* Hemorrhagic telangiectasia, hereditary.
Osmotic demyelination syndrome, **912–915**
- differential diagnosis, **913–914**
Oxygen, high-inspired, traumatic subarachnoid hemorrhage vs., **169**

P

Pachygyria-agyria complex. *See* Lissencephaly.
Pachymeningopathies (thickened dura)
- chronic subdural hematoma vs., **165–166**
- subacute subdural hematoma vs., **161–162**
Paget disease, **1142–1145**
- differential diagnosis, **1143–1144**
Palsy
- Bell palsy, **1082–1085**
- progressive supranuclear, **968–971**
  differential diagnosis, **969–970**
Panencephalitis, subacute sclerosing, **710–711**
Pantothenate kinase-associated neurodegeneration (PKAN), **844–847**. *See also* Neurodegeneration with brain iron accumulation (NBIA).
- diagnostic checklist, **846**
- differential diagnosis, **845**
- genetics, **845–846**
- Huntington disease vs., **849**
Papillary tumor of pineal region (PTPR), **534–535**
Paraneoplastic syndromes (PS), **598–601**
Parasitic infections
- miscellaneous, **726–729**
  differential diagnosis, **727–728**
Parathyroid disorders, **874–875**
Parenchymal hypodensity, acute cerebral ischemia-infarction vs., **356**
Parkinson disease, **956–959**
- progressive supranuclear palsy vs., **969–970**
Parkinson-plus syndromes, multiple system atrophy vs., **962**
Parkinsonism-dementia-amyotrophic lateral sclerosis complex, Parkinson disease vs., **958**
Pearson marrow-pancreas syndrome, Kearns-Sayre syndrome vs., **791**
Pediatric human immunodeficiency virus-1 infection. *See* HIV infections, congenital.
Pelizaeus-Merzbacher disease
- Canavan disease vs., **831**
- hypomyelination vs., **779**
- metachromatic leukodystrophy vs., **801**
Penetrating injury, **144–147**
Perimesencephalic nonaneurysmal subarachnoid hemorrhage, **224–225**
Peritumoral cyst. *See* Nonneoplastic tumor-associated cysts.
Perivascular spaces
- enlarged, **632–635**
  nonneoplastic tumor-associated cyst vs., **653**
Periventricular cyst, **626–629**
Periventricular halo, normal, white matter injury of prematurity vs., **333–334**
Peroxisomal disorders, **816–819**
PHACES, Sturge-Weber syndrome vs., **102**
Pilomyxoid astrocytoma (PMA), **456–459**
- staging, grading, and classification, **457–458**
Pineal cyst, **636–639**
Pineal parenchymal tumor of intermediate differentiation (PPTID), **528–529**
Pineal region papillary tumor, **534–535**
Pineoblastoma, **530–533**
- differential diagnosis, **531–532**
Pineocytoma, **524–527**
Pituicytoma, **1052–1053**
Pituitary apoplexy, **1044–1047**
- differential diagnosis, **1045–1046**
Pituitary gland
- abscess, pituitary apoplexy vs., **1045–1046**
- anomalies, **1024–1027**
- overview, **1020–1023**
Pituitary hyperplasia, **1060–1061**
Pituitary macroadenoma, **1040–1043**
- differential diagnosis, **1041–1042**
Pituitary microadenoma, **1036–1039**
PKAN. *See* Pantothenate kinase-associated neurodegeneration (PKAN).
Pneumocephalus, **184–187**

https://CafePezeshki.IR

Polymicrogyria, **68–71**
- bilateral perisylvian syntelencephaly vs., **49–50**
- differential diagnosis, **69–70**
- Taylor-type, tuberous sclerosis complex vs., **97**

Porencephalic cyst, **646–649**
Posterior fossa arachnoid cyst, Dandy-Walker continuum vs., **27–28**
Pressure-related edema, post-traumatic brain swelling vs., **198**
Primary cholesteatoma. *See* Cerebellopontine angle-internal auditory canal, epidermoid cyst.
Primitive neuroectodermal tumor-medulloblastoma (PNET-MB). *See* Medulloblastoma.
Primitive neuroectodermal tumor (PNET)
- supratentorial, **540–543**

Progressive multifocal leukoencephalopathy (PML), **748–749**
Pseudo-TORCH infections
- metachromatic leukodystrophy vs., **801**
- Zellweger syndrome spectrum vs., **811**

Pseudo-TORCH syndromes
- congenital cytomegalovirus infection vs., **663**
- TORCH infections vs., **659**

Pseudoaneurysm, **236–237**
- non-ASVD fusiform aneurysm vs., **243**

Pseudoprogression, **920–921**
Pseudoresponse, **922–923**
Pseudotumor, inflammatory, idiopathic
- IgG4-related disease vs., **1137**
- intracranial, **1132–1135**
- meningioma, cerebellopontine angle-internal auditory canal vs., **1095**

R

Radiation-induced injury, **916–919**
- diagnostic checklist, **918**
- differential diagnosis, **917–918**
- staging, grading, and classification, **918**

Ramsay Hunt syndrome
- cerebellopontine angle-internal auditory canal, metastases vs., **1099**

Rasmussen encephalitis, **706–709**
Rathke cleft cyst, **1032–1035**
Rendu-Osler syndrome. *See* Hemorrhagic telangiectasia, hereditary.
Rendu-Osler-Weber syndrome. *See* Hemorrhagic telangiectasia, hereditary.
Reversible cerebral vasoconstriction syndrome, **306–307**
Rhabdoid brain tumor. *See* Teratoid-rhabdoid tumor, atypical.
Rhombencephalosynapsis, **30–33**
Rickettsial diseases, **734–735**
Rosai-Dorfman disease, **1161**
Rosette-forming glioneuronal tumor (RGNT), **522–523**
- diagnostic checklist, **523**
- differential diagnosis, **523**
- staging, grading, and classification, **523**

S

Saccular aneurysm, **232–235**
- atypical, non-ASVD fusiform aneurysm vs., **243**
- blood blister-like aneurysm vs., **245**
- differential diagnosis, **233–234**

Sarcoidosis
- cerebellopontine angle-internal auditory canal meningioma vs., **1095**
  - metastases vs., **1099**

Sarcoma
- atypical teratoid-rhabdoid tumor vs., **545**
- gliosarcoma, **446–447**

Scalp
- overview, **1104–1107**
- sebaceous cyst, **1164–1165**

Scalp injuries, **140–143**
Schizencephaly, **76–79**
- "closed-lip," heterotopic gray matter vs., **65**
- severe bilateral open-lip, hydranencephaly vs., **331**

Schwannoma
- nonneoplastic tumor-associated cyst vs., **653**
- nonvestibular, **552–555**
- vestibular, **1090–1093**
  - cystic, arachnoid cyst of cerebellopontine angle-internal auditory canal vs., **1079**
  - meningioma, CPA-IAC vs., **1095**

Schwannomatosis, **130–131**
Sebaceous cyst, **1164–1165**
Second impact syndrome, **206–207**
Sella, empty, **1056–1059**
- differential diagnosis, **1057–1058**

Sella turcica, overview, **1020–1023**
Septooptic dysplasia, **52–55**
Septooptic-pituitary dysgenesis. *See* Septooptic dysplasia.
Shunts
- cerebrospinal fluid shunts and complications, **1014–1017**

Sickle cell disease of brain, **290–293**
Siderosis, superficial, **228–231**
Sigmoid sinus pseudolesion
- sinus-jugular foramen, dural arteriovenous fistula vs., **401**

Sinus pericranii, **416–419**
Skull
- craniostenoses, **1112–1115**
- extramedullary hematopoiesis, **1146–1149**
- fibrous dysplasia, **1138–1141**
  - staging, grading, and classification, **1139–1140**
- intracranial hypotension, **1128–1131**
  - differential diagnosis, **1129–1130**
- lacunar skull of newborn, congenital calvarial defects vs., **1109–1110**
- Langerhans cell histiocytosis, **1152–1155**
  - differential diagnosis, **1153–1154**
- leptomeningeal cyst ("growing fracture"), **1126–1127**
- metastases, **1194–1197**
- overview, **1104–1107**

https://CafePezeshki.IR

- Paget disease, **1142–1145**
  differential diagnosis, **1143–1144**
- thick, **1150–1151**
Skull base
- pseudotumor, inflammatory, intracranial idiopathic, **1132–1135**
Skull injuries, **140–143**
Spine and cord trauma, **135–136**
Status epilepticus, **928–931**
- differential diagnosis, **929–930**
- human herpes virus 6 (HHV-6) encephalitis vs., **703**
- low-grade diffuse astrocytoma vs., **436**
Steele-Richardson-Olszewski syndrome. *See* Supranuclear palsy, progressive.
Steroid-responsive encephalopathy associated with autoimmune thyroiditis (SREAT). *See* Thyroid disorders.
Streptococcal meningitis, group B, **670–673**
Stroke, **248–253**
- aberrant internal carotid artery, **284–287**
  differential diagnosis, **285–286**
- antiphospholipid antibody syndrome
  non-SLE, systemic lupus erythematosus vs., **313**
- Behçet disease, **324–325**
- cerebellar hemorrhage, remote, **266–267**
- cerebral hemiatrophy, **352–353**
- cerebral hyperperfusion syndrome, **372–375**
  differential diagnosis, **373–374**
- cerebral ischemia-infarction. *See* Cerebral ischemia-infarction, acute.
- childhood, **348–351**
- cortical venous thrombosis, **380–383**
- deep cerebral venous thrombosis, **384–387**
  differential diagnosis, **385–386**
- dural sinus and aberrant arachnoid granulations, **388–391**
- fibromuscular dysplasia, **328–329**
- germinal matrix hemorrhage, **268–271**
- hydranencephaly, **330–331**
- imaging, approach to, **248–249**
- lacunar infarction, **368–371**
- moyamoya, **294–297**
- persistent carotid basilar anastomoses, **288–289**
- reversible cerebral vasoconstriction, **306–307**
- sickle cell disease of brain, **290–293**
- systemic lupus erythematosus, **312–315**
  differential diagnosis, **313–314**
- traumatic. *See* Cerebral ischemia-infarction, traumatic.
- white matter injury of prematurity, **332–335**
  differential diagnosis, **333–334**
Sturge-Weber-Dimitri syndrome. *See* Sturge-Weber syndrome.
Sturge-Weber syndrome, **100–103**
- cerebral hemiatrophy vs., **353**
- choroid plexus cyst vs., **641**
- developmental venous anomaly vs., **411–412**
- diagnostic checklist, **102**
- differential diagnosis, **101–102**
- encephalocraniocutaneous lipomatosis vs., **115**
- meningioangiomatosis vs., **105**
- Rasmussen encephalitis vs., **707**
- staging, grading, and classification, **102**
Subarachnoid hemorrhage, **218–219**
- aneurysmal, **220–223**
  differential diagnosis, **221–222**
- convexal, **226–227**
- perimesencephalic nonaneurysmal, **224–225**
- "pseudo-SAH," aneurysmal subarachnoid hemorrhage vs., **222**
- traumatic, **168–171**
Subarachnoid spaces
- enlarged, **996–999**
Subcortical arteriosclerotic encephalopathy, normal pressure hydrocephalus vs., **1011–1012**
Subcortical injury, **180–183**
Subdural hematoma
- acute, **156–159**
  differential diagnosis, **157–158**
- chronic, **164–167**
  differential diagnosis, **165–166**
- subacute, **160–163**
  differential diagnosis, **161–162**
Subependymal giant cell astrocytoma, **464–467**
Subependymal heterotopia, X-linked, tuberous sclerosis complex vs., **97**
Subependymoma, **490–493**
Supranuclear palsy, progressive, **968–971**
- differential diagnosis, **969–970**
Susac syndrome, **326–327**
Syntelencephaly (middle interhemispheric variant), **48–51**
- differential diagnosis, **49–50**
Systemic lupus erythematosus, **312–315**
- differential diagnosis, **313–314**

T

Tay-Sachs (TS) disease. *See* Gangliosidosis.
Telangiectasia
- capillary, **424–427**
  differential diagnosis, **425–426**
- hereditary hemorrhagic, **110–113**
Temporal bone (T-bone) fractures, **135**
Teratoid-rhabdoid tumor, atypical, **544–547**
- astroblastoma vs., **477**
- choroid plexus carcinoma vs., **499–500**
- diagnostic checklist, **546**
- differential diagnosis, **545**
- infratentorial ependymoma vs., **483**
- medulloblastoma vs., **537**
- staging, grading, and classification, **546**
- supratentorial ependymoma vs., **487**
- supratentorial PNET vs., **541**
- teratoma vs., **583**
Teratoma, **582–585**
- atypical teratoid-rhabdoid tumor vs., **545**
- lipoma vs., **23–24**
Thick skull, **1150–1151**
Thyroid disorders, **870–873**
Tolosa-Hunt syndrome. *See* Inflammatory pseudotumor, intracranial idiopathic.
TORCH infections, **658–661**

https://CafePezeshki.IR

Toxic disorders
- acquired
  overview, **858–861**
- alcoholic encephalopathy, **880–883**
  differential diagnosis, **881–882**
- cyanide poisoning, **910–911**
- methanol poisoning, **908–909**

Toxoplasmosis
- acquired, **742–743**

Transient global amnesia (TGA), **932–933**
Transient seizure-related MR changes. *See* Status epilepticus.
Transverse-sigmoid sinus pseudolesion, dural sinus and aberrant arachnoid granulations vs., **389**
Trauma, **134–139**
- brain death, **204–205**
- cerebral contusion, **172–175**
- cerebral ischemia/infarction, traumatic, **200–203**
- chronic encephalopathy, **214–215**
- diffuse axonal injury, **176–179**
- epidural hematoma, classic, **148–151**
  differential diagnosis, **149–150**
- epidural hematoma, variant, **152–155**
- intracranial arterial dissection, **208–211**
- intracranial herniation syndromes, **192–195**
- missile and penetrating injury, **144–147**
- second impact syndrome, **206–207**

Trigeminal neuralgia, **1086–1087**
Tuber cinereum hamartoma, **1028–1031**
Tuberculosis, **712–715**
- differential diagnosis, **713–714**

Tuberous sclerosis complex, **96–99**
- Lhermitte-Duclos disease vs., **119**
- Li-Fraumeni syndrome vs., **129**

Tumor-associated arachnoid cyst. *See* Nonneoplastic tumor-associated cysts.
Tumor-associated enlarged perivascular spaces. *See* Nonneoplastic tumor-associated cysts.
Tumors, low-attenuation, chronic cerebral infarction vs., **363**
Turcot syndrome, Li-Fraumeni syndrome vs., **129**

U

Urea cycle disorders, **824–825**

V

Vascular dementia, **942–945**
- differential diagnosis, **943–944**
- multi-infarct, traumatic cerebral ischemia/infarction vs., **201**

Vascular malformations
- capillary telangiectasia, **424–427**
  differential diagnosis, **425–426**
- overview, **394–395**
- sinus pericranii, **416–419**
- vein of Galen aneurysmal malformation, **406–409**

Vascular metastasis, von Hippel-Lindau syndrome vs., **93**
Vascular neurocutaneous syndromes
- multiple AVMs in, von Hippel-Lindau syndrome vs., **93**

Vasculitis
- autoimmune-mediated
  acute disseminated encephalomyelitis vs., **765**
  multiple sclerosis vs., **757**
- Lhermitte-Duclos disease vs., **119**
- miscellaneous, **302–305**

Vasogenic edema. *See* Brain swelling, post-traumatic.
Vasospasm, **308–311**
- blood blister-like aneurysm vs., **245**
- subarachnoid hemorrhage-induced, traumatic cerebral ischemia/infarction vs., **201**

Vein of Galen aneurysmal malformation, **406–409**
Venous thrombosis
- deep cerebral, **384–387**
  differential diagnosis, **385–386**

Ventricles
- aqueductal stenosis, **1006–1009**
- chordoid glioma of third ventricle, **478–479**
- isolated 4th, Dandy-Walker continuum vs., **28**
- overview, **988–993**
- subarachnoid spaces
  enlarged, **996–999**

Ventriculitis, **686–687**
Vertebrobasilar dolichoectasia, **238–239**
- non-ASVD fusiform aneurysm vs., **243**

Vessel infundibulum
- blood blister-like aneurysm vs., **245**

Vestibular schwannoma, **1090–1093**
- cystic, arachnoid cyst of cerebellopontine angle-internal auditory canal vs., **1079**
- meningioma, CPA-IAC vs., **1095**

Vestigial carotid-basilar anastomoses. *See* Carotid basilar anastomoses, persistent.
Virchow-Robin spaces. *See* Perivascular spaces, enlarged.
von Hippel-Lindau syndrome, **92–95**
- diagnostic checklist, **94**
- differential diagnosis, **93**
- Li-Fraumeni syndrome vs., **129**
- staging, grading, and classification, **94**

W

Wallerian degeneration, **976–979**
- differential diagnosis, **977–978**

West Nile virus encephalitis, **700–701**
White matter
- age-related changes, arteriolosclerosis vs., **281**

White matter disease
- with lactate, X-linked adrenoleukodystrophy vs., **814**

White matter injury of prematurity, **332–335**
- differential diagnosis, **333–334**

Wilson disease, **852–855**
- Creutzfeldt-Jakob disease vs., **953**
- differential diagnosis, **853–854**

Wyburn-Mason syndrome
- hemangioblastoma vs., **559**
- Sturge-Weber syndrome vs., **102**

https://CafePezeshki.IR

X

Xanthoastrocytoma, pleomorphic, **460–463**
X-linked adrenoleukodystrophy, **812–815**
- diagnostic checklist, **814**
- differential diagnosis, **813**
- megalencephaly with leukoencephalopathy and cysts vs., **839**
- staging, grading, and classification, **814**
- Wallerian degeneration vs., **978**

X-linked dominant chondrodysplasia punctata, peroxisomal disorders vs., **817**
X-linked lissencephaly. *See* Lissencephaly.
X-linked subependymal heterotopia, tuberous sclerosis complex vs., **97**

Z

Zellweger syndrome spectrum, **810–811**
