Scrapings for Gram and Giemsa stain may demonstrate bacteria, yeast, or intranuclear inclusions that may aid in the diagnosis.

## **TREATMENT**

### ***GENERAL MEASURES***

- Simple corneal abrasions can be managed by primary care physicians, but consider referral for lesions larger than 4 mm. See indications for referral in the following text.

- All patients with corneal ulceration should be referred immediately to an ophthalmologist. Corneal cultures should be obtained before starting antibiotics. If immediate referral is not possible, it is reasonable to start antibiotics without delay.
- Flash burns from welding or prolonged exposure to sunlight may be treated like corneal abrasions (3)[C].
- Topical ophthalmic steroids should be avoided: may delay healing of corneal abrasions (4)[C]. Use of topical anesthetics outside of clinical settings should be avoided: may develop corneal toxicity with prolonged use (5)[A]

## MEDICATION

### *First Line*

- Eye patching does not reduce pain or speed the healing process (6)[A].
- Topical NSAIDs have been proven to reduce eye pain (6)[A].
  - Ophthalmic NSAIDs: Diclofenac 0.1% QID helps relieve moderate pain:
    - Alternatives include ketorolac 0.5% and bromfenac 0.09%
    - Caution: Ophthalmic NSAIDs may rarely cause corneal melting and perforation.
- Ophthalmic antibiotics may help prevent further infection and ulceration of corneal abrasions (3)[C].
- Some ophthalmic antibiotics include ciprofloxacin 0.3%, ofloxacin 0.3%, gentamicin 0.3%, erythromycin 0.5%, polymyxin B/trimethoprim (Polytrim), and tobramycin 0.3%:
  - Ointment preparations may be more soothing to the eye than solutions.
  - Topical antibiotics should be continued until eye pain is resolved.
  - Chloramphenicol should be avoided due to high risk of toxicity and Stevens-Johnson syndrome.
- Large corneal abrasions (>4 mm) or very painful abrasions should be treated with a combination of topical antibiotic and topical NSAID.
- Reevaluate in 24 hours. If improving, no need for further follow-up (3)[C].
- Fungal keratitis is treated with a protracted course of topical antifungal agents (by ophthalmologist).
- A combination of cryotherapy and antifungal agents for treatment of fungal corneal ulcer could help facilitate the practice of fungal keratitis treatment in the future (7).

- Herpetic keratitis should be referred promptly to ophthalmologist and treated initially with trifluridine:
  - Vidarabine and acyclovir are alternatives.

## *Second Line*

- Oral analgesic medication (hydrocodone and other opioids) if topical analgesia not adequate
- Supplemental topical cycloplegics (i.e., homatropine 5% and cyclopentolate 1%) have not been found to be beneficial in relieving pain in corneal abrasion (8)[B].
- Topical 0.3% HA provided a promising treatment for superficial corneal abrasion caused by mechanical damage (9).
- Sodium hyaluronate reduces reepithelialization time when used after mechanical abrasions of the cornea (10).
- In the management of traumatic corneal abrasions, the administration of an eye gel containing sodium hyaluronate and xanthan gum is able to reduce the length of occlusive patching (11).

## *ISSUES FOR REFERRAL*

- Consultation with an ophthalmologist is recommended for all ulcers to help determine appropriate therapy. Moreover, ulcers need corneal cultures to be taken directly onto culture media.
- Also refer to ophthalmologist if there is history of the following:
  - Significant ocular trauma
  - Corneal infection is suspected (including viral keratitis).
  - Recurrent or nonhealing abrasion is encountered despite standard treatment.
  - Severe ocular pain not explained by apparent pathology (e.g., traumatic iritis)

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Contact lens wearer should be monitored daily with slit lamp for signs of secondary infection.
- Minor abrasion should be reevaluated only if it becomes more painful (3)[C].

- Large abrasion (>4 mm) should be reevaluated in 24 hours, and if improving, no need to follow further unless symptoms worsen again (3)[C].

## **PATIENT EDUCATION**

- Prevention of abrasions and proper handling of contact lenses can prevent recurrence of corneal ulcers.

## **PROGNOSIS**

- Corneal abrasions and ulcerations should improve daily and heal with appropriate therapy.
- If healing does not occur within 24 to 48 hours or the lesion extends, obtain an ophthalmology consultation.

## **COMPLICATIONS**

- Recurrence
- Scarring of the cornea
- Loss of vision
- Corneal perforation

## Clinical Pearls

### &NA;

- Contact lens use should be discontinued until corneal abrasion or ulcer is healed and pain is fully resolved.
- Eye patching is not recommended.
- Prescribe topical and/or oral analgesic medication for symptom relief and consider ophthalmic antibiotics.
- Prompt referral to an ophthalmologist should be made with suspicion of an ulcer, recurrence of abrasion, retained foreign body, viral keratitis, significant visual loss, or lack of improvement despite therapy.

# Corns and Calluses

Neil J. Feldman, DPM, FACFAS

## BASICS

### DESCRIPTION

- A callus (tyloma) is a diffuse area of hyperkeratosis, usually without a distinct border.
  - Typically, the result of exposure to repetitive forces, including friction and mechanical pressure; tend to occur on the palms of hands and soles of feet (1).
- A corn (heloma) is a circumscribed hyperkeratotic lesion with a central conical core of keratin that causes pain and inflammation. The conical core in a corn is a thickening of the stratum corneum.
- Hard corn or heloma durum (more common): more often on toe surfaces, especially 5th toe (proximal interphalangeal [PIP]) joint
- Soft corn (heloma molle): commonly in the interdigital space (1)
- Digital corns are also known as clavi.
- Intractable plantar keratosis is usually located under a metatarsal head (1st and 5th most common), is typically more difficult to resolve, and often is resistant to usual conservative treatments.

### EPIDEMIOLOGY

Corns and calluses have the largest prevalence of all foot disorders.

#### *Incidence*

Incidence of corns and calluses increases with age. Less common in pediatric patients. Women affected more often than men. Blacks report corns and calluses 30% more often than whites.

#### *Prevalence*

- 9.2 million Americans
- ÷38/1,000 people affected

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Increased activity of keratinocytes in superficial layer of skin leading to hyperkeratosis. This is a normal response to excess friction, pressure, or stress.

- Calluses typically arise from repetitive friction, motion, or pressure to skin.
- Soft corns arise from increased moisture from perspiration leading to skin maceration, along with mechanical irritation, especially between toes.
- Hard corns are an extreme form of callus with a keratin-based core. Often found on the digital surfaces and commonly linked to bony protrusions, causing skin to rub against shoe surfaces.

## *Genetics*

No true genetic basis was identified because most corns and calluses are due to mechanical stressors on the foot/hands.

## *RISK FACTORS*

- Extrinsic factors producing pressure, friction, and local stress
  - Ill-fitting shoes
  - Not using socks, gloves
  - Manual labor
  - Walking barefoot
  - Activities that increase stress applied to skin of hands or feet (running, walking, sports)
- Intrinsic factors
  - Bony prominences: bunions, hammertoes
- Enlarged bursa or abnormal foot function/structure: hammertoe, claw toe, or mallet toe deformity

## *GENERAL PREVENTION*

External irritation is by far the most common cause of calluses and corns. General measures to reduce friction on the skin are recommended to reduce incidence of callus formation. Examples include wearing shoes that fit well and using socks and gloves.

## *Geriatric Considerations*

In elderly patients, especially those with neurologic or vascular compromise, skin breakdown from calluses/corns may lead to increased risk of infection/ulceration. 30% of foot ulcers in the elderly

arise from eroded hyperkeratosis. Regular foot exams are emphasized for these patients as well as diabetic patients (2).

## **COMMONLY ASSOCIATED CONDITIONS**

- Foot ulcers, especially in diabetic patients or patients with neuropathy or vascular compromise
- Infection: look for warning signs of:
  - Increasing size or redness
  - Puslike drainage
  - Increased pain/swelling
  - Fever
  - Change in color of fingers or toes
- Signs of gangrene

## **DIAGNOSIS**

- Most commonly a clinical diagnosis based on visualization of the lesion
- Examination of footwear may also provide clues.

## **HISTORY**

- Careful history can usually pinpoint cause.
- Ask about neurologic and vascular history and diabetes. These may be risk factors for progression of corns/calluses to frank ulcerations and infection.

## **PHYSICAL EXAM**

- Calluses
  - Thickening of skin without distinct borders
  - Often on feet, hands; especially over palms of hands, soles of feet
  - Colors from white to gray-yellow, brown, red
  - May be painless or tender
  - May throb or burn
- Corns

Hard corns: commonly on dorsum of toes or dorsum of 5th PIP joint

- Varied texture: dry, waxy, and transparent to a hornlike mass
- Distinct borders
- More common on feet
- Often painful
- Soft corns
  - Often between toes, especially between 4th and 5th digits at the base of the webspace
  - Often yellowed, macerated appearance
  - Often extremely painful

---

P.233

## *DIFFERENTIAL DIAGNOSIS*

- Plantar warts (typically a loss of skin lines within the wart), which are viral in nature
- Porokeratoses (blocked sweat gland)
- Underlying ulceration of skin, with or without infection (rule out especially with diabetic patients)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Radiographs may be warranted if no external cause is found. Look for abnormalities in foot structure, bone spurs.
- Use of metallic radiographic marker and weight-bearing films often highlight the relationship between the callus and bony prominence.

### *Diagnostic Procedures/Other*

Biopsy with microscopic evaluation in rare cases

### *Test Interpretation*

Abnormal accumulation of keratin in epidermis, stratum corneum

## **TREATMENT**

## *GENERAL MEASURES*

- Debridement of affected tissue and use of protective padding
- Low-heeled shoes; soft upper with deep and wide toebox
- Extra-width shoes for 5th-toe corns
- Avoidance of activities that contribute to painful lesions
- Prefabricated or custom orthotics

## *MEDICATION*

- Most therapy for corns and calluses can be done as self-care in the home (1).
- Use bandages, soft foam padding, or silicone sleeve over the affected area to decrease friction on the skin and promote healing with digital clavi.
- Use socks or gloves regularly.
- Use lotion/moisturizers for dry calluses and corns.
- Keratolytic agents, such as urea or ammonium lactate, can be applied safely.
- Use sandpaper discs or pumice stones over hard, thickened areas of skin.

## *Geriatric Considerations*

Use of salicylic acid corn plasters can cause skin breakdown and ulceration in patients with thin, atrophic skin; diabetes; and those with vascular compromise. The skin surrounding the callus will often turn white and can become quite painful. Aggressive use of pumice stones can also lead to skin breakdown, especially surrounding the callus.

## *ISSUES FOR REFERRAL*

- May benefit from referral to podiatrist if use of topical agents and shoe changes are ineffective
- Abnormalities in foot structure may require surgical treatment.
- Diabetic, vascular, and neuropathic patients may benefit from referral to podiatrist for regular foot exams to prevent infection or ulceration.

## *SURGERY/OTHER PROCEDURES*

- Surgical treatment to areas of protruding bone where corns and calluses form
- Rebalancing of foot pressure through functional foot orthotics
- Shaving or cutting off hardened area of skin using a chisel or 15-blade scalpel. For corns,

remove keratin core and place pad over area during healing.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Many over-the-counter topical creams, ointments, and lotions are available for calluses (Kera brand, CalleX, Urea, Lac-Hydrin). Do not use on broken skin.
- Warm water/Epsom salt soaks.

## INPATIENT CONSIDERATIONS

### Admission Criteria/Initial Stabilization

- Admission usually not necessary, unless progression to ulcerated lesion with signs of severe infection, gangrene
- May require aggressive débridement in operating room should an abscess or deep space infection be suspected. Deep-space infections can develop where an abscess can penetrate into tendon sheaths and/or deep compartments within the foot or hand, potentially leading to rapid sepsis. Vascular status must be assessed and vascular referral considered.

### Nursing

Wound care, dressing changes for infected lesions

## ONGOING CARE

### PATIENT EDUCATION

- General information: <http://www.mayoclinic.org/diseases-conditions/corns-and-calluses/basics/definition/con-20014462>
- American Podiatric Medical Association: <http://www.apma.org>

### PROGNOSIS

Complete cure is possible once factors causing pressure or injury are eliminated.

### COMPLICATIONS

Ulceration, infection

## Codes

**&NA;**

### ICD10

L84 Corns and callosities

## Clinical Pearls

**&NA;**

Most therapy for corns and calluses can be done as self-care in the home using padding over the affected area to decrease friction or pressure. However, if simple home care is not helpful, then removal of the lesions is often immediately curative.

# Coronary Artery Disease and Stable Angina

Melody L. Strattan, DO

Merrill Krolick, DO, FACC, FACP, FSCAI

## BASICS

### DESCRIPTION

- Coronary artery disease (CAD) refers to the atherosclerotic narrowing of the epicardial coronary arteries. It may manifest insidiously as angina pectoris or as an acute coronary syndrome (ACS).
- Stable angina is a chest discomfort due to myocardial ischemia that occurs predictably at a certain level of exertion or emotional stress.
- The spectrum of ACS includes unstable angina (UA), non-ST segment elevation myocardial infarction (NSTEMI), and ST elevation myocardial infarction (STEMI). See separate chapters on these ACS.
- Definitions
  - Typical angina: exhibits three classical characteristics: (i) substernal chest tightness, pressure, or heaviness that frequently radiates to the jaw, back, or arms and generally lasts from 2 to 15 minutes; (ii) occurs in a consistent pattern at a certain level of myocardial oxygen demand from exertion, emotional stress, or increased sympathetic tone; and (iii) relieved with rest or sublingual nitroglycerin.
  - Atypical angina: exhibits two of the above typical characteristics
  - Noncardiac chest pain: exhibits <sup>2</sup>1 of the above typical characteristics
  - Anginal equivalent: Patients may present without chest discomfort but with nonspecific symptoms such as dyspnea, diaphoresis, fatigue, belching, nausea, light-headedness, or indigestion that occur with exertion or stress.
  - Unstable angina: anginal symptoms that are new or changed in character to become more frequent, more severe, or both; it is considered an ACS but does not present with cardiac biomarker elevation.
  - NSTEMI: Presents with cardiac biomarker elevation. Ischemic ECG changes may be present, but there is no ST segment elevation.

- STEMI: defined by ST elevations on ECG and elevated cardiac biomarkers; generally caused by acute plaque rupture and complete obstruction of the culprit vessel
- Canadian Cardiovascular Society grading scale:
  - Class I: Angina does not limit ordinary physical activity, occurring only with strenuous or prolonged exertion (7 to 8 METs).
  - Class II: Angina causes slight limitation of ordinary activity. It occurs when walking rapidly, uphill, or >2 blocks; climbing >1 flight of stairs; or with emotional stress (5 to 6 METs).
  - Class III: Angina causes marked limitation of ordinary physical activity. It occurs when walking one to two blocks or climbing one flight of stairs (3 to 4 METs).
  - Class IV: Angina occurs with any physical activity and may occur at rest (1 to 2 METs).

### *Geriatric Considerations*

- Elderly may present with atypical symptoms.
- Other physical limitations may delay recognition of angina until it occurs with minimal exertion or at rest.
- Maintain a high degree of suspicion during evaluation of dyspnea and other nonspecific complaints.
- Geriatric patients may be very sensitive to the side effects of medications used to treat angina.

### *EPIDEMIOLOGY*

- CAD is the leading cause of death for adults both in the United States and worldwide.
- CAD is responsible for about 30% of all deaths, averaging 1 death every 40 seconds in the United States alone.
- Global cost of CAD in 2010 \$863 billion
- ÷80% of CAD is preventable with healthy lifestyle.

### *Incidence*

In the United States, the lifetime risk of a 40-year-old developing CAD is 49% for men and 32% for women.

### *Prevalence*

In the United States, 17.6 million people carry a diagnosis of CAD, 10.2 million with angina pectoris (1).

## ETIOLOGY AND PATHOPHYSIOLOGY

- Anginal symptoms occur during times of myocardial ischemia caused by a mismatch between coronary perfusion and myocardial oxygen demand.
- Atherosclerotic narrowing of the coronary arteries is the most common etiology of angina, but it may also occur in those with significant aortic stenosis, pulmonary hypertension, hypertrophic cardiomyopathy, coronary spasm, or volume overload.
- Sensory nerves from the heart enter the spinal cord at levels C7-T4, causing diffuse referred pain/discomfort in the associated dermatomes.

## RISK FACTORS

- Traditional risk factors: hypertension, ↓HDL, smoking, diabetes, premature CAD in 1st-degree relatives (men <55 years old; women <65 years old), age (>45 for men, >55 for women)
- Nontraditional risk factors: obesity, sedentary lifestyle, abnormal ankle-brachial indices, renal disease

## GENERAL PREVENTION

- Smoking cessation
- Regular aerobic exercise program
- Weight loss for obese patients (goal BMI <25 kg/m<sup>2</sup>)
- BP control (goal <140/90 mm Hg; <150/90 mm Hg for those ≥60 years old) (2)
- Diabetes management
- Lipid-lowering therapy (statins) for those with diabetes, known CAD, and for 10-year risk ≥7.5%
- Low-dose aspirin may be considered in those with 10-year risk ≥10%.

## COMMONLY ASSOCIATED CONDITIONS

Hyperlipidemia, peripheral vascular disease, cerebrovascular disease, hypertension, obesity, diabetes

## DIAGNOSIS

### HISTORY

- Careful history is important to elicit symptoms.

Pain may be described with a clenched fist over the center of the chest (Levine sign).

- Discomfort is usually not affected by position or deep inspiration.
- Episodes of angina are generally of the same character and in the same location.
- Recent decrease in level of physical activity may be due to worsening anginal symptoms.
- Dyspnea on exertion may present as the only symptom. Atypical symptoms are more likely in women, the elderly, and diabetic patients.
- May present with symptoms similar to gastric reflux or GI upset (indigestion, nausea, diaphoresis)
- Ascertain whether symptoms are similar to those with previously diagnosed heart disease.

## ***PHYSICAL EXAM***

- Normal physical exam does not exclude the diagnosis of angina or CAD.
- Cardiac exam may reveal dysrhythmias, heart murmurs indicative of valvular disease, gallops, or signs of congestive heart failure.
- Evidence of peripheral vascular disease (diminished pulses, bruits, abdominal aortic aneurysm [AAA])

## ***DIFFERENTIAL DIAGNOSIS***

- Vascular: aortic dissection, pericarditis, myocarditis, myocardial infarction
- Pulmonary: pleuritis, pulmonary embolism, pneumothorax
- Gastroesophageal: gastric reflux, esophageal spasm, peptic ulcer
- Musculoskeletal: costochondritis, arthritis, muscle strain, rib fracture
- Other: anxiety, psychosomatic, cocaine abuse

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Serial cardiac troponin to rule out myocardial infarction (MI)
- CBC to evaluate for anemia, infectious cause (1)[C]
- Fasting lipid profile (1)[C]

- Fasting glucose or hemoglobin A1C (1)[C]
- Basic metabolic panel to rule out electrolyte abnormalities and assess renal function.
- ECG
  - Should be routinely obtained unless there is a noncardiac cause of the chest pain (1)[C]
  - Frequently unremarkable between angina episodes; may show signs of myocardial ischemia during symptomatic episodes, evidence of old MI
  - Left bundle branch block or ventricular pacing makes interpretation unreliable.
- Chest x-ray may exclude other causes of pain (1)[C].

### *Follow-Up Tests & Special Considerations*

- Goal is to detect possible high-risk coronary lesions, where intervention would improve long-term mortality or alleviate anginal symptoms.
- Stress testing is most helpful for patients at intermediate risk of heart disease.
  - Exercise testing for those who can physically exercise (<sup>3</sup>5 metabolic equivalents [METs]) (1)[A]
    - Standard exercise ECG for those with normal baseline ECG
    - Exercise stress testing with echo or perfusion imaging for those with abnormal baseline ECG or in premenopausal women
  - In patients who cannot tolerate exercise, consider pharmacologic stress testing (1)[A].
- Echocardiogram should be obtained in patients with a new or loud (<sup>3</sup>III/VI) murmur, evidence of myocardial infarction, symptoms of heart failure, concern for hypertrophic cardiomyopathy or pericardial effusion, and in those with new arrhythmias (1)[A].
- Echocardiogram can be considered in patients with hypertension or diabetes and abnormal ECG (1)[A].
- CT coronary angiography or MRI angiography can be alternative to stress testing in patients with continued symptoms despite negative or inconclusive stress testing for anatomic definition of disease.

### *Diagnostic Procedures/Other*

- Cardiac catheterization with coronary angiography is the gold standard for confirmation and delineation of coronary disease and direction of interventional therapy or surgery.

- Significant CAD is defined as  $\geq 50\%$  stenosis of the left main coronary artery or  $\geq 70\%$  stenosis of other major coronary arteries by angiography.
- Borderline lesions may be assessed with a pressure wire. Fractional flow reserve (FFR) of  $\leq 0.8$  demonstrates a hemodynamically significant lesion.

## TREATMENT

### GENERAL MEASURES

- BP control goal:  $< 140/90$  mm Hg for most, except in elderly (2)[A]
- Smoking cessation goal: complete cessation, no exposure to secondhand smoke or E-cigarettes
- Physical activity goal: 30 to 60 minutes of moderate aerobic activity, at least 5 (preferably 7) days/week
- Weight management goal: BMI 18.5 to 24.9  $\text{kg/m}^2$ ; waist circumference  $< 35$  inches (women) or  $< 40$  inches (men)
- Glycemic control in diabetics: Goal is strict glucose control while avoiding hypoglycemic episodes.

### MEDICATION

#### First Line

- $\beta$ -Blockers: decrease myocardial oxygen demand by lowering heart rate, BP, and contractility.
  - Improve mortality in patients with MI or heart failure; use as initial therapy (1)[A]
  - Can improve symptoms of angina
  - Metoprolol (25 to 400 mg daily [succinate] or divided BID [tartrate]) or carvedilol (3.125 to 25 mg BID). Adjust doses according to clinical response. Maintain resting heart rate 50 to 60 bpm.
  - Side effects bradycardia, fatigue, sexual dysfunction
- Calcium channel blockers (CCBs): cause arterial vasodilation, decreased myocardial oxygen demand, and improved coronary blood flow. Similar effectiveness to  $\beta$ -blockers; may be used instead of, or in addition to  $\beta$ -blockers (1)[A]. Only long-acting CCBs should be used:
  - Dihydropyridine CCBs: nifedipine (30 to 90 mg/day), amlodipine (5 to 10 mg/day), or felodipine (2.5 to 10 mg/day): vasodilators

- Nondihydropyridine CCBs such as diltiazem (120 to 480 mg/day) or verapamil (120 to 480 mg/day) also have negative inotropic effects; should not be used in those with EF <40%. Side effects include constipation and peripheral edema. The nondihydropyridine CCBs may also cause bradycardia or precipitate heart failure in those with severe systolic dysfunction (ejection fraction <40%).
- Nitrates: Dilate systemic veins and arteries (including coronary vessels) and cause decreased preload. At higher doses, they decrease BP and thus, after-load, increasing myocardial flow.
  - Sublingual nitroglycerin 0.4 mg every 5 minutes for 2 to 3 doses may be used for acute anginal episodes (1)[A].
  - Long-acting nitrates such as isosorbide mononitrate (30 to 240 mg daily [extended release]) can be used for angina prophylaxis.
  - Side effects include headache and hypotension, but tend to improve with continued usage.
- Lipid-lowering agents:
  - High-intensity statin therapy is indicated for all patients with CAD regardless of lipid levels (3)[A].
  - Statin therapy should also be encouraged for those with high CAD risk.
  - Atorvastatin (10 to 80 mg/day) and rosuvastatin (5 to 40 mg/day) are high-intensity statins.
  - Statins reduce risk of MI & revascularization need.
  - Side effects include myalgias, transaminitis, rhabdomyolysis (rare), impaired glucose tolerance.
- Aspirin: Decreases risk of thrombosis by inhibiting cyclo-oxygenase and thromboxane.
  - Aspirin (75 to 162 mg/day) decreases risk of first MI and reduces adverse cardiovascular events in those with stable angina (1)[A].
  - Clopidogrel (75 mg/day) may be used in patients with contraindications to aspirin (1)[A].
  - Dual antiplatelet therapy with aspirin + clopidogrel, prasugrel, or ticagrelor is indicated after percutaneous coronary intervention.
- Angiotensin-converting enzyme inhibitors (ACEIs): act on the renin-angiotensin-aldosterone system to reduce BP and afterload. They also have effects on cardiac remodeling after MI.
  - ACEIs such as lisinopril (5 to 40 mg/day) and enalapril (2.5 to 20 mg BID) have been shown to reduce both cardiovascular death and MI in patients with CAD and left ventricular systolic dysfunction (1)[A].
  - Angiotensin receptor blockers such as candesartan (4 to 32 mg daily) may be used in

patients intolerant to ACEIs.

- Side effects include cough (ACEIs only), hyperkalemia, and angioedema.

## *Second Line*

Ranolazine (500 to 1000 mg BID) decreases calcium overload in myocytes, acting as an antianginal/anti-ischemic agent.

- Does not affect heart rate or BP
- Use as adjunctive therapy when symptoms persist despite optimal doses of other antianginals
- Side effects can include nausea, constipation, dizziness, QT prolongation, and headache.

## *SURGERY/OTHER PROCEDURES*

- Revascularization should be considered when noninvasive testing suggests a high-risk lesion. It can also be performed if optimal medical therapy is inadequate to control symptoms.
- Percutaneous coronary intervention (PCI) with balloon angioplasty and/or stent placement (with drug-eluting or bare-metal stent) is performed for significant lesions. Additional techniques include laser therapy and atherectomy.
- PCI does not decrease mortality or risk of MI vs. with medical management with stable angina.
- Coronary artery bypass graft (CABG) is preferred over PCI for those with severe left main coronary stenosis, significant lesions in <sup>3</sup>3 major coronary arteries, and for lesions not amenable to PCI.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Relaxation/stress reduction therapy for angina

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Inpatient evaluation of patients with changes in anginal symptoms representing unstable angina (an ACS)

### *Discharge Criteria*

Without myonecrosis, discharge after appropriate risk stratification.

**ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

- Lifestyle modifications should be aggressively stressed at every visit.
- Patients should be followed clinically; routine stress testing is not necessary for asymptomatic patients.

### ***Patient Monitoring***

Frequent follow-up after initial event: every 4 to 6 months in 1st year, then 1 to 2 times per year

### ***DIET***

- Reduced intake of trans-fatty acids (1)[C]
- Adherence to dietary modification for comorbid conditions (diabetes, heart failure, hypertension)

### ***PROGNOSIS***

Variable; depends on severity of symptoms, extent of CAD, and left ventricular function

### **COMPLICATIONS**

ACS, arrhythmia, cardiac arrest, heart failure

## **REFERENCES**

### ICD10

- I25.119 Athscl heart disease of native cor art w unsp ang pctrs
- I25.118 Athscl heart disease of native cor art w oth ang pctrs
- I20.9 Angina pectoris, unspecified

## Clinical Pearls

&NA;

- Maximize antianginal therapy: Combine *&bgr*-blockers, CCBs, and nitrates as tolerated.
- Lifestyle changes and optimal medical therapy must be emphasized to prevent progression of atherosclerosis and to control contributing risk factors.

# Costochondritis

Smriti Ohri, MD

## BASICS

### DESCRIPTION

- Anterior chest wall pain associated with pain and tenderness of the costochondral and costosternal regions
- System(s) affected: musculoskeletal
- Synonym(s): costosternal syndrome; parasternal chondrodynia; anterior chest wall syndrome (1)

### EPIDEMIOLOGY

- Predominant age: 20 to 40 years
- Predominant gender: female

### Incidence

- 30% of chest pain visits in emergency room (2)
- 20% of chest pain visits in primary care office were due to musculoskeletal causes with 13% because of costochondritis (3).

### ETIOLOGY AND PATHOPHYSIOLOGY

Not fully understood

### RISK FACTORS

- Unusual physical activity or overuse that stresses the upper extremity
- Recent trauma (including motor vehicle accident, domestic violence) or new activity
- Recent upper respiratory infection (URI) with coughing

## DIAGNOSIS

- Pain is usually sharp, achy, or pressure-like
- Pain involves multiple and mostly unilateral 2nd to 5th costal cartilages.
- Exacerbated by upper body movements and exertional activities
- Reproduced by palpation of the affected cartilage segments
- Chest tightness is often associated with the pain.

## **HISTORY**

- A complete and thorough history is mandatory for the diagnosis, with special emphasis on cardiac risk factor evaluation.
- Social history: careful screening and evaluation for domestic violence and substance abuse

## **PHYSICAL EXAM**

- A physical exam to exclude more serious conditions that may present with chest pain is necessary for the diagnosis.
- Tenderness elicited over the costochondral junctions is necessary to establish the diagnosis but does not completely exclude other causes of chest pain.
- If swelling or redness of costal cartilage is present, this may be termed as Tietze syndrome.
- Movement of upper extremity of the same side may reproduce the pain (1).
- Palpation of epigastric region to evaluate for gastroesophageal reflux disease (GERD) and deep palpation in right upper quadrant of abdomen to evaluate gallbladder

## **Pediatric Considerations**

- Consider psychogenic chest pain in children who perceive family discord.
- Consider slipping rib syndrome in children with chronic chest and abdominal pain (4).

## **Geriatric Considerations**

- Presents with multiple problems capable of causing chest pain, making a thorough history and physical exam imperative
- Consider herpes zoster in elderly patients with nonspecific musculoskeletal chest pain.

## **DIFFERENTIAL DIAGNOSIS**

- Cardiac

- Coronary artery disease (CAD)
- Cardiac contusion from trauma
- Aortic aneurysm
- Pericarditis
- Myocarditis
- Gastrointestinal
  - Gastroesophageal reflux
  - Peptic esophagitis
  - Esophageal spasm
  - Cholecystitis
- Musculoskeletal (4)
  - Fibromyalgia
  - Slipping rib syndrome
  - Costovertebral arthritis
  - Painful xiphoid syndrome
  - Rib trauma
  - Ankylosing spondylitis
  - Precordial catch syndrome
- Psychogenic
  - Anxiety disorder
  - Panic attacks
  - Hyperventilation
- Respiratory
  - Asthma
  - Pulmonary embolism
  - Pneumonia
  - Chronic cough
  - Pneumothorax

- Other
  - Domestic violence and abuse
  - Herpes zoster
  - Spinal tumor
  - Metastatic cancer
  - Substance abuse (cocaine)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- The diagnosis of costochondritis is primarily based on a thorough history and physical exam.
- Laboratory exams should be used to exclude other differential diagnosis.
- ESR is inconsistently elevated.

### *Initial Tests (lab, imaging)*

No imaging is indicated for the diagnosis of costochondritis; chest x-ray and rib films are often normal.

### *Diagnostic Procedures/Other*

- None indicated for the diagnosis of costochondritis.
- Consider ECG in patients age >35 years, those with history or risk of CAD (5)[C].
- Consider chest x-ray in patients with cardiopulmonary symptoms (5)[C].
- Consider spiral CT for pulmonary embolism and D-dimer if history or risk factors are present.

### *Test Interpretation*

Costochondral joint inflammation

P.237

## **TREATMENT**

Reassurance of benign nature of condition and potential for long, slow recovery from pain

### *GENERAL MEASURES*

- Rest and heat (or ice massage, whichever makes the patient feel better) (6,7)[C]

Stretching exercises

- Minimizing activities that provoke the symptoms (e.g., reducing the frequency or intensity of exercise or work activities) (6,7)[C]

## **MEDICATION**

- Pain relief with NSAIDs (ibuprofen, naproxen, or diclofenac); acetaminophen or other analgesics may be considered in noninflammatory disorders (6,7)[C].
- Use of skeletal muscle relaxants may be beneficial if associated with muscle spasm.

## **ISSUES FOR REFERRAL**

Consider referral to physical therapy or osteopathy. Refractory cases of costochondritis can be treated with local injections of combined lidocaine (Xylocaine)/corticosteroid into costochondral areas if severe; however, this is rarely necessary (8)[C].

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Limited data on use of manipulation or ice massage but may be safely tried if patient is interested.

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

Only indicated if differential diagnosis is unclear and cardiac or other more serious etiology of chest pain is being considered

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Follow up within 1 week if diagnosis is unclear or symptoms do not abate with conservative treatment.

## **PATIENT EDUCATION**

- Educate the patient in regard to the self-limited (although potentially recurrent) nature of the illness.
- Instruct patient on proper physical activity regimens to avoid overuse syndromes.
- Stress importance of avoiding sudden, significant changes in activity.

## PROGNOSIS

- Self-limited illness lasts for weeks to months but usually abates by 1 year, although sometimes chronic especially in adolescents.
- Often recurs

## COMPLICATIONS

Incomplete attention to differential diagnosis or overly aggressive interventions to ensure a more life-threatening diagnosis is not missed.

## Codes

**&NA;**

### ICD10

M94.0 Chondrocostal junction syndrome [Tietze]

## Clinical Pearls

**&NA;**

- A very common disorder, accounting for perhaps 30% of all cases of chest pain
- Diagnosis is based primarily on history and physical with lab and other testing done to exclude various differentials based on thorough history and risk factors.
- Educate the patient in regard to the self-limited (although potentially recurrent) nature of the illness. Instruct patient on proper physical activity regimens to avoid overuse syndromes.

# Counseling Types

William T. Garrison, PhD

## BASICS

### DESCRIPTION

- Psychotherapeutic and counseling interventions play an important role in the management of chronic and acute-onset diseases and disorders. They are typically the primary initial mode of evaluation and/or treatment for most mild to moderate psychiatric disorders that reach criteria using the *DSM-5* (1) or *ICD-10* (2) diagnostic classification systems. It should be noted that the *DSM* system has recently been revised with significant changes in several disorder categories and their criteria. Treatment and successful control of either medical or psychological conditions require some form of professional counseling experience. Best outcomes occur when they are employed by a skilled practitioner. However, psychotherapy differs from generic counseling, which can take many forms and is delivered commonly in nonmedical settings, with mixed results.
- Counseling approaches are usually tailored to the specific presenting problem or issue and serve educational and emotional support functions. Typically, such counseling in medical settings will be time-limited and problem-focused and often not intended to lead to major medical symptom relief or major behavioral changes.
- The goals of psychotherapy range from increasing individual psychological insight and motivation for change to reduction of interpersonal conflict in the marriage or family, reduction of chronic or acute emotional suffering, and reversal of dysfunctional or habitual behaviors. There are several general types of psychotherapy, starting with individual, marital, or family approaches. In addition, a number of psychological theories guide various methods and treatment philosophies. The following is a brief overview of commonly used psychotherapeutic and counseling methods.
- Psychodynamic therapy: Unconscious conflict manifests as patient's symptoms/problem behaviors:
  - Short-term (4 to 6 months) and long-term (<sup>3</sup>1 year)
  - Focus is on increasing insight of underlying conflict or processes to initiate symptomatic change.
  - Therapist actively helps patient identify patterns of behavior stemming from existence of an

unconscious conflict or motivations that may not be accurately perceived.

- Cognitive-behavioral therapy (CBT): Patterns of thoughts and behaviors can lead to development and/or maintenance of symptoms. Thought patterns may not accurately reflect reality and may lead to psychological distress:
  - Therapy aims at modifying thought patterns by increasing cognitive flexibility and changing dysfunctional behavioral patterns.
  - Encourages patient self-monitoring of symptoms and the precursors or results of maladaptive behavior
  - Uses therapist-assisted challenges to patient's basic beliefs/assumptions
  - May use *exposure*, a procedure derived from basic learning theories, which encourages gradual steps toward change.
  - Can be offered in group or individual formats
  - Therapist's role is suggestive and supportive.
- Dialectical behavior therapy (DBT): Techniques such as social skills training, mindfulness, and problem solving are used to modulate impulse control and affect management:
  - Derivative of CBT
  - Originally used in treatment of patients with self-destructive behaviors (e.g., cutting, suicide attempts)
  - Seeks to change rigid patterns of cognitions and behaviors that have been maladaptive
  - Uses both individual and group treatment modalities
  - Therapist takes an active role in interpretation and support.
- Interpersonal psychotherapy: Interpersonal relationships in a patient's life are linked to symptoms. Therapy seeks to alleviate symptoms and improve social adjustment through exploration of patient's relationships and experiences. Focus is on one of four potential problem areas:
  - Grief
  - Interpersonal role disputes
  - Role transitions
  - Interpersonal deficits: Therapist works with the patient in resolving the problematic interpersonal issues to facilitate change in symptoms.
- Family therapy: focuses on the family as a unit of intervention

- Uses psychoeducation to increase patient's and family's insight
- Teaches communication and problem-solving skills
- Motivational interviewing: focuses on motivation as a key to successful change process
  - Short-term and problem-focused
  - Focuses on identifying discrepancies between goals and behavior
  - The 5 A's model is a brief counseling framework developed specifically for physicians to effect behavioral change in patients:
    - Assess for a problem.
    - Advise making a change.
    - Agree on action to be taken.
    - Assist with self-care support to make the change.
    - Arrange follow-up to support the change.
- Counseling (heterogeneous treatment)
  - Often focuses on situational factors maintaining symptoms
  - Often encourages the use of community resources
- Behavioral therapy: relatively nontheoretical approach to behavioral change or symptom reduction/eradication through application of principles of stimulus and response

### *Pediatric Considerations*

- Important distinctions are made between psychotherapy and counseling for children/teens compared to adults/couples.
- The focus of evaluation must include attention to parent and family processes and factors. Interventions typically include interactions and sessions with parents as well as collateral work with teachers and other school personnel.
- Younger children will often be evaluated and diagnosed through behavioral descriptions provided by parents and other adults who know them well as well as through direct observation and/or play techniques. Children of all ages should be screened using behavioral checklists that are norm-referenced for age.
- Any child or teenager who requests counseling should be interviewed initially by the primary care provider and referred appropriately. Most referrals will be in response to parental request, however.

Psychotherapeutic interventions with the strongest empirical basis with children include behavior therapy/modification, CBT, and family/parenting therapy. Play therapy has the least empirical support, and insight-oriented therapies appear to be more effective with older children (>11 years).

- There is controversy regarding the efficacy of psychopharmacologic treatment in preadolescents, although clear benefits have been demonstrated in some studies. Treatment guidelines for mild to moderate depressed mood and/or anxiety disorders typically recommend pediatric CBT initially, and studies have typically supported this approach in preteen and milder cases.

## **EPIDEMIOLOGY**

- ÷18.8 million adults suffer from clinical depression, and 20 million suffer from a diagnosable anxiety disorder.
- One in four Americans report seeking some form of mental health treatment in their adult life. This includes generic counseling in nonmedical settings such as work, clergy, or school settings and also includes visits to primary care providers. It is estimated that between 3.5% and 5% of adults in the United States actually participate in formal mental health psychotherapy annually.
- Public health experts report that the majority of those adults with diagnosable psychiatric disorders, however, do not receive professional mental health services. This is due to multiple factors, including failure to identify, noncompliance with psychiatric referral, regional shortages of providers, economic barriers, and excessive time duration from referral to available service.
- A large study conducted between 1987 and 1997 concluded that the percentage of adults in psychotherapy remained relatively stable over that decade, the use of psychopharmacology doubled, and older adults (aged 55 to 64 years) increasingly sought psychotherapy services. In that same study, it was found that psychotherapy duration (number of sessions) decreased substantially and about 1/3 of psychotherapy patients only attended one or two sessions.

---

P.239

## **RISK FACTORS**

The need for psychotherapy or counseling services is directly and indirectly associated with a host of socioeconomic and biogenetic factors, including the general effects of poverty, family or marital dysfunction; life stressors; medical diseases or conditions; and individual biologic predisposition to mental health disorders.

## **GENERAL PREVENTION**

It is generally assumed that early identification and intervention of child and adolescent

psychopathology increases the likelihood of reducing the risk for adult psychopathology, but this has not been sufficiently validated in all categories of psychological disorders. Data support such claims in disorders such as childhood ADHD, anxiety disorders, and habit disorders of childhood, however.

## TREATMENT

### *GENERAL MEASURES*

There is evidence of a Òdose effectÓ in psychotherapy outcomes research, with some investigators suggesting that 6 to 8 sessions are necessary to yield positive initial effects and upward of 15 to 20 sessions for longer term, sustainable therapeutic effects. This dose effect may not be applicable to counseling services with primarily informational or emotional/supportive functions. Also, long-term therapy should be evaluated at 6- to 12-month intervals to determine efficacy.

### *MEDICATION*

- Psychotherapy is most likely to be accompanied by use of pharmaceutical adjuncts in moderate to severe cases of psychological dysfunction that do not respond to other therapies or in cases of extremely poor quality of life or high risk. The most common examples are in cases of clinical depression or anxiety that clearly incapacitates the patient or significantly reduces his or her quality of life. Patients at risk for suicide or who represent a danger to others are also candidates for acute psychopharmacotherapy. Studies suggest that verbal and behaviorally oriented therapies can add efficacy to medication treatment in both depression and anxiety.
- There is controversy in the research field regarding the efficacy of medication alone versus psychotherapy alone versus combined treatments. The most recent consensus has been that combined treatments in moderate to severe psychological dysfunction are most likely to render positive short-term results and increase the likelihood that such effects can be sustained over time.

### *ADDITIONAL THERAPIES*

- Anxiety disorders
  - Panic disorder with and without agoraphobia: CBT, psychodynamic therapy
  - Generalized anxiety disorder: CBT
  - Obsessive-compulsive disorder: CBT
  - Posttraumatic stress disorder: CBT

- Specific phobia: CBT
- Social phobia: CBT
- Mood disorders
  - Unipolar depression: CBT, interpersonal therapy, psychodynamic therapy
  - Bipolar disorder: family therapy, interpersonal therapy, CBT
  - Schizophrenia: psychodynamic therapy, family therapy, CBT
- Eating disorders
  - Binge eating disorder: CBT, interpersonal therapy
  - Bulimia nervosa: CBT, interpersonal therapy
- Personality disorders
  - Borderline: DBT, CBT
- Substance-use disorders
  - Alcohol: counseling, CBT, motivational interviewing
  - Cocaine: CBT, counseling
  - Heroin: CBT, counseling
  - Smoking: 5 AÖs
- Somatoform disorders:
  - Hypochondriasis: CBT
  - Body dysmorphic disorder: CBT

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

A host of nonempirically based psychological and nutritional therapies can be found outside of mainstream medicine and psychological science. Very little or no evidence exists to support such experimental therapies, but all have the considerable power of the placebo effect fueling their anecdotal supports or claims. Placebo effects are also thought to be powerfully enhanced by the use of ingested or applied substances that create real physiologic, although not therapeutic, changes in the patient. If it makes them feel different, they are more likely to believe it helps.

**ONGOING CARE**

# FOLLOW-UP RECOMMENDATIONS

## Patient Monitoring

There is evidence of a dose effect in psychotherapy outcomes research, with some investigators suggesting that 6 to 8 sessions are necessary to yield positive initial effects and upward of 15 to 20 sessions for longer term, sustainable therapeutic effects. This dose effect may not be applicable to counseling services with primarily informational or emotional/supportive functions. Because many patients cease attendance to psychotherapy sessions after one or a few sessions, most interventions of this type cannot be accurately evaluated by the referring provider. Long-term therapy should also be evaluated for effectiveness at regular periods.

**Codes**

&NA;

## ICD10

- Z71.9 Counseling, unspecified
- Z71.89 Other specified counseling
- Z63.9 Problem related to primary support group, unspecified

## Clinical Pearls

### &NA;

- Combined medication and psychotherapeutic treatments in moderate to severe psychological dysfunction are most likely to render positive short-term results and increase the likelihood such effects can be sustained over time.
- Relapse is common over time and/or as treatments are discontinued.
- Children <10 years may benefit significantly from counseling or psychotherapy alone for symptom relief.
- Older children and those with more severe symptoms typically require psychopharmacologic options in concert with counseling or verbal therapy approaches.

# Crohn Disease

Eric Ji-Yuan Mao, MD

Samir A. Shah, MD, FACG, FASGE, AGAF

## BASICS

### DESCRIPTION

A chronic, relapsing inflammatory GI tract disorder, most commonly involving the terminal ileum (80%)

- Hallmark features
  - Transmural inflammation which can result in fibrosis, stricture formation, and fissures leading to sinus tracts, abscesses, or fistulas.
  - Noncaseating granulomas (30%), crypt abscesses
  - Skip lesions: patchy, segmental distribution of disease; lesions may affect multiple bowel segments, interspersed with areas of normal mucosa; disease can also be continuous, potentially mimicking ulcerative colitis (UC).
  - Diverse presentations: ileocolitis (50%); isolated colitis (20%) are most common. In cases of isolated colitis, 10% involve the rectum and 33% involve the anorectal area.
- Early disease
  - Ulcerations: focal lesions with surrounding edema, resembling aphthous ulcers
  - Perianal disease (pain, anal fissures, perirectal abscess) may precede intestinal disease.
  - May present as wasting illness or anorexia
- Developed disease
  - Mucosal cobblestoning; luminal stenosis; creeping fat; fissures between mucosal folds result in strictures/adhesions and/or fistulae

### EPIDEMIOLOGY

#### *Incidence*

- In North America, 8 to 15 cases/100,000 adults; incidence is rising in North America and

Western Europe.

- Bimodal age distribution: Predominant age is 15 to 25 years, with a second smaller peak at 50 to 70 years.
- Women slightly more affected than men; increased incidence in northern climates
- Increased risk in whites versus non-whites: 2 to 5 times
- Increased risk in Ashkenazi Jews: 3 to 5 times

## *Prevalence*

U.S. adults: 100 to 200 cases/100,000

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- General: Clinical manifestations result from activation of inflammatory cells, whose by-products produce nonspecific tissue injury.
- Mechanism of diarrhea: excess fluid secretion and impaired fluid absorption; bile salt malabsorption in inflamed ileum, with steatorrhea, bacterial overgrowth
- Multifactorial: Genetic, environmental triggers, and immunologic abnormalities result in inflammation and tissue injury in genetically predisposed individuals.

## *Genetics*

Of CD patients, 15% have a first-degree relative with inflammatory bowel disease (IBD); first-degree relative of an IBD patient has 3 to 30 times increased risk of developing IBD by age 28 years. At least 163 different genes associated with IBD.

- Mutations in susceptibility loci
  - Ileal CD: IBD1 gene (chromosome 16)
  - Early-onset CD (age  $\geq$ 15 years): mutations in 5q31-33 (IBD5), 21q22, and 20q13
  - North American white men with CD: 30% have HLA-DR7 and DQ4.
  - Extraintestinal manifestations of CD: mutations in HLA-A2, HLA-DR1, HLA-DQw5
  - Others: IL-10, IL-23 receptors; ATG16L1; IRGM
- Genetic syndromes associated with IBD: Turner and Hermansky-Pudlak syndromes, glycogen storage disease type 1b

## *RISK FACTORS*

- Environmental factors

- Cigarette smoking doubles the risk of developing CD; tobacco cessation may reduce frequency of flares and reduce relapses after surgery.
- Dietary factors: higher incidence if diet high in refined sugars, animal fat, protein (meat, fish)
- *Salmonella* or *Campylobacter* increase risk of developing IBD
- *Clostridium difficile* infection may trigger flare of IBD and make treatment more difficult.
- Immunologic abnormalities: an aggressive immune response against commensal enteric bacteria
  - Tumor necrosis factor (TNF): upregulation of inflammatory Th1 cytokines
  - Tissue inflammation may result from increased secretion of cytokine IL-17 by Th17 subset of CD4+ T cells.

## COMMONLY ASSOCIATED CONDITIONS

- Extraintestinal manifestations
  - Arthritis (20%): seronegative, primarily involving large joints; axial arthritis or ankylosing spondylitis (AS), and sacroiliitis (SI).
  - Skin disorders (10%): erythema nodosum, pyoderma gangrenosum, psoriasis
  - Ocular disease (5%): uveitis, iritis, episcleritis
  - Kidney stones: calcium oxalate stones (from steatorrhea and diarrhea) or uric acid stones (from dehydration and metabolic acidosis)
  - Fat-soluble vitamin deficiency (A, D, E, K), B<sub>12</sub>
  - Osteopenia and osteoporosis; hypocalcemia
  - Hypercoagulability: venous thromboembolism prophylaxis essential in hospitalized patients
  - Gallstones: cholesterol stones resulting from impaired bile acid reabsorption
  - Primary sclerosing cholangitis (5%): more common in men with UC; asymptomatic, elevated alkaline phosphatase as marker
  - Autoimmune hemolytic anemia
- Conditions correlated with increased disease activity
  - Peripheral arthropathy (but not SI and AS)
  - Episcleritis (but not uveitis)

- Oral aphthous ulcers and erythema nodosum
- SI, AS, and uveitis are associated with HLA-B27.
- Other significant complications: GI bleed, toxic megacolon, bowel perforation/peritonitis, malignancy, sclerosing cholangitis, rectovaginal fistula

## DIAGNOSIS

### HISTORY

Hallmarks: fatigue, fever, weight loss, prolonged diarrhea, perianal disease, crampy abdominal pain, with or without gross bleeding. Children may present with failure to thrive.

- Factors exacerbating CD: concurrent infection, smoking, NSAIDs, and possibly stress

### PHYSICAL EXAM

Presentation varies with location of disease.

- General: signs of sepsis/disease activity (fever, tachycardia, hypotension) or wasting/malnutrition
- Abdominal: focal or diffuse tenderness, distension, rebound/guarding; rectal bleeding
- Perianal: fistulae, fissures
- Skin: erythema nodosum; psoriasis

### DIFFERENTIAL DIAGNOSIS

- Acute, severe abdominal pain: perforated viscus, pancreatitis, appendicitis, diverticulitis, bowel obstruction, kidney stones, ovarian torsion
- Chronic diarrhea with crampy pain (colitis-like): UC, radiation colitis, infection, drugs, ischemia, microscopic colitis, IBD, celiac disease, malignancy (lymphoma, carcinoma), carcinoid
- Wasting illness: malabsorption, malignancy, psychiatric illness

### DIAGNOSTIC TESTS & INTERPRETATION

#### *Initial Tests (lab, imaging)*

- CBC, chem 10, LFTs, erythrocyte sedimentation rate, C-reactive protein, serum iron, vitamin B<sub>12</sub>, vitamin D-25 OH

- If diarrhea, stool specimen for routine culture, fecal leukocytes, *C. difficile*, and ova and parasites
- In hospitalized patients with severe flare-ups, KUB to rule out toxic megacolon
- Colonoscopy with ileoscopy provides the greatest diagnostic sensitivity and specificity for colonic disease.
- Small bowel: sensitivity of CT or magnetic resonance enterography (MRE) better than small bowel follow through. MRE has no radiation exposure (important in younger patients). Capsule endoscopy allows small bowel visualization but no biopsy (1)[A].
  - Signs of small bowel disease: narrowed lumen with nodularity and/or string sign; cobblestone appearance, fistula and abscess formation, bowel loop separation (transmural inflammation)
- Gastroduodenal: upper GI endoscopy
  - Signs of gastroduodenal disease: antral narrowing and segmental duodenal stricturing; inflammatory mucosal disease on endoscopy
- Perirectal complications: combination of endoscopic ultrasound (EUS) or MRI with exam under anesthesia
- Contraindications to endoscopy: perforated viscus, recent myocardial infarction, severe diverticulitis, toxic megacolon, or inability to undergo appropriate bowel preparation. In most cases, unprepared limited sigmoidoscopy allows adequate visualization to assess severity, extent, and aspirate stool for *C. difficile*, obtain biopsies to assess histologic severity, and exclude other disorders (e.g., cytomegalovirus).

## *Follow-Up Tests & Special Considerations*

### Evidence of complications

- Stricture: obstructive signs such as nausea, vomiting, pain, weight loss, diarrhea, or inability to pass gas/feces
- Abscess/phlegmon: localized abdominal peritonitis with fever and abdominal pain; diffuse peritonitis suggests intestinal perforation or abscess rupture (may be masked by steroids, opiates).
- Fistulae (33-50% of patients, after 10 to 20 years of disease, respectively)
  - Enteroenteric: asymptomatic or a palpable, commonly indolent abdominal mass
  - Enterovesical: pneumaturia, recurrent polymicrobial UTI
  - Retroperitoneal: psoas abscess, ureteral obstruction

- Enterovaginal: vaginal passage of gas or feces; clear, nonfeculent drainage from ileal fistula may be misdiagnosed as primary vaginal infection.

## Diagnostic Procedures/Other

How to distinguish CD from UC

- CD: small bowel disease, rectal sparing; skip lesions; granulomas, perianal disease, and/or fistulae; no gross bleeding; RLQ pain is common.
  - Commercially available antibody tests (overall 70% sensitive): anti-Saccharomyces cerevisiae antibody (ASCA), Cbir-1, OmpC, I2
- UC: diffuse, continuous involving the rectum; loss of vascularity, friable tissue; perinuclear antineutrophil cytoplasmic antibody (pANCA); LLQ pain; typically only affects colon; rectal bleeding common

### ALERT

CD can mimic UC with continuous bowel involvement; 10-15% of cases are difficult to differentiate; diagnosed as IBD unclassified (IBD-U).

## TREATMENT

- Disease severity: Crohn Disease Activity Index (CDAI)
  - Asymptomatic: spontaneously, after medical/surgical intervention, or while on steroids (CDAI <150)
  - Mild to moderate CD: ambulatory patients able to tolerate PO intake without dehydration, obstruction, or >10% weight loss. No abdominal tenderness, toxicity, or mass (CDAI 150 to 220)
  - Moderate to severe CD: Patients who have failed initial treatment or who continue to have mild symptoms such as fever, weight loss, and abdominal pain (CDAI 220 to 450).
  - Severe: persistent symptoms despite outpatient therapy with glucocorticoids and/or biologics, or fulminant disease (peritonitis, cachexia, intestinal obstruction, abscess) (CDAI >450)
- General strategies
  - Step-up approach: Begin treatment with milder therapy (5-ASA, antibiotics) followed by more aggressive agents (steroids, immunomodulators, anti-TNF agents), as needed.

- Top-down approach: Early management with immunomodulators and/or anti-TNF agents before patients receive steroids, become steroid-dependent, or require surgery.

## GENERAL MEASURES

Additional therapies depend on location of disease.

- Oral lesions: triamcinolone acetonide in benzocaine and carboxymethyl cellulose or topical sucralfate for aphthous ulcers, cheilitis, and/or granulomatous sialadenitis
- Gastroduodenal CD: no clinical trials, although slow-release mesalamine may be beneficial, as it is partially released in proximal small bowel. Case reports note success of anti-TNF therapies. Symptomatic relief possible from proton pump inhibitors, H<sub>2</sub>-receptor blockers, and/or sucralfate.
- Ileitis: supplementation of fat-soluble vitamins, iron, B<sub>12</sub>, folate, and calcium to prevent bone loss
- Treatment toxicity: pancreatitis, bone marrow toxicity, lymphoma, nonmelanoma skin cancer, infections (TB, histoplasmosis, others), malignancy

## MEDICATION

### First Line

- Asymptomatic patients: observation alone
- Mild CD
  - 5-Aminosalicylates have minimal role in CD management. They can be used for colonic CD without deep ulcerations or penetration/fibrosinosing disease (2)[C].
  - Antibiotics use is controversial. Controlled trials have not consistently demonstrated efficacy (2)[C].
  - Glucocorticoid therapy: controlled ileal release budesonide (9 mg/day for 8 to 16 weeks, then discontinued over 2- to 4-week taper) for distal ileum and/or right colon involvement (2,3)[A]
  - Consider adjunctive therapy: antidiarrheals (loperamide ); bile acid-binding resin (cholestyramine 4 to 12 g/day); probiotics (either alone or in combination may prevent recurrent inflammation and reduce symptoms in acute CD).
  - Induction/maintenance: 5-ASA is not recommended (3)[C]. Controlled ileal release budesonide, 9 mg/day, is effective for maintenance for up to 6 months (2)[A].
- Moderate to severe CD

- Induction: prednisone 40 to 60 mg/day (2)[A] or controlled-release budesonide (for isolated, moderate ileitis) or anti-TNF agents as initial induction agent or for lack of response to corticosteroid or immunomodulator (2,3)[A]
- Maintenance: no role for mesalamine. If steroids required for induction, use immunomodulator (2,3)[B] or biologic (anti-TNF agent) (2)[A],(3)[B] for maintenance.
- Except for budesonide, do not use steroids for maintenance (1)[A].
- Severe disease: immunomodulators, anti-TNF agents ± steroids
  - Azathioprine or 6-mercaptopurine: thiopurine methyltransferase (TPMT) and LFTs prior to initiation. Check CBC/LFTs q2-3mo.
  - Methotrexate: effective for steroid-dependent and steroid-refractory CD (2)[B]
    - Folic acid 1 mg/day; follow LFTs
  - Anti-TNF therapies: active disease, fistulae, steroid sparing, some extraintestinal disease. Infliximab, adalimumab, certolizumab pegol
    - Check for evidence of TB and HBV infection prior to initiation of anti-TNF therapy.
    - Avoid live vaccines.
    - Monitoring: Consider anti-drug Ab levels to assess for immunogenicity. Serum concentrations of anti-TNF agents may also correlate with disease activity.
- Combination therapy
  - Azathioprine + infliximab is more effective than either alone if no previously treatment with either.
  - Rare complication: hepatosplenic T-cell lymphoma (fatal, mostly seen in young males)
- Anti-adhesion molecules: prevent inflammatory cells from entering GI tract
  - Vedolizumab: gut-specific, can be used in anti-TNF failures or anti-TNF naive patients as induction and maintenance; given IV, no risk of progressive multifocal leukoencephalopathy (PML); FDA approved May 2014
  - Natalizumab: non-gut-specific, PML risk (1/1,000). Can minimize risk by testing for John Cunningham (JC) virus antibody. However, can avoid risk of PML now with vedolizumab.

## **ADDITIONAL THERAPIES**

### Complications

- Peritonitis: bowel rest and antibiotic therapy (7 to 10 days parenteral antibiotics, followed by 2-

to 4-week course of PO ciprofloxacin and metronidazole); surgery, as indicated

- Consider holding steroids which mask sepsis.
- Abscess: antibiotics, percutaneous drainage, or surgery with resection of affected segments
- Small bowel obstruction: IV hydration, nasogastric (NG) suction, total parenteral nutrition (TPN) for malnutrition, resolution typically in 24 to 48 hours. Surgery for nonresponders

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

Vaccinations in CD

- Check titers; avoid live vaccines (MMR, varicella, zoster) in patients on immunosuppressive therapy (steroids, 6MP, AZA, MTX, or anti-TNF).
- Regardless of immunosuppression: HPV, influenza, pneumococcal, meningococcal, hepatitis A, B; Tdap

### PATIENT EDUCATION

## Codes

**&NA;**

### ICD10

- K50.919 Crohn's disease, unspecified, with unspecified complications
- K50.00 Crohn's disease of small intestine without complications
- K50.10 Crohn's disease of large intestine without complications

## Clinical Pearls

**&NA;**

- The incidence of CD has risen over the past 4 decades.
- MRE allows assessment of luminal and extraluminal CD without radiation exposure.
- Assess for TB and HBV infection prior to initiating anti-TNF therapy.
- Cigarette smoking doubles the risk of developing CD; tobacco cessation may reduce frequency of flares and need for surgery.
- Test for *C. difficile* infection when evaluating diarrhea in all CD patients.
- Hospitalized CD patients require deep vein thrombosis prophylaxis.

# Croup (Laryngotracheobronchitis)

Garreth C. Debiegun, MD, FACEP, FAWM

## BASICS

### DESCRIPTION

- Croup is a subacute viral illness characterized by upper airway symptoms such as barking cough, stridor, and fever. "Croup" is used to refer to viral laryngotracheitis or laryngotracheobronchitis (LTB), although it is sometimes used for LTB with pneumonitis, bacterial tracheitis, or spasmodic croup.
- Most common cause of upper airway obstruction or stridor in children
- Spasmodic croup: noninfectious form with sudden resolution
  - No fever or radiographic changes
  - Initially treated as croup
  - Usually self-limiting and resolves with mist therapy at home
  - Often recurs on same night or in 2 to 3 nights
- System(s) affected: pulmonary, respiratory
- Synonym(s): infectious croup; viral croup

### EPIDEMIOLOGY

- Predominant age
  - Common among children 7 months to 3 years
  - Most common during the 2nd year of life
  - Rare among those >6 years
- Predominant sex: male > female (1.5:1)
- Timing
  - Possible during any time of year but is most common in autumn and winter (with parainfluenza 1 and respiratory syncytial virus [RSV])

## *Incidence*

- Six cases per year per 100 children <6 years old
- 1.5-6% of cases require hospitalization.
- 2-6% of those require intubation.
- Decreasing incidence in the United States and Canada

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Subglottic region/larynx is entirely encircled by the cricoid cartilage.
- Inflammatory edema and subglottic mucus production decrease airway radius.
- Small children have small airways with more compliant walls.
- Negative-pressure inspiration pulls airway walls closer together.
- Small decrease in airway radius causes significant increase in resistance (Poiseuille law: resistance proportional to  $1/\text{radius}^4$ ).
- Usually viruses that initially infect oropharyngeal mucosa and then migrate inferiorly
- Parainfluenza virus
  - Most common pathogen: 75% of cases
  - Type 1 is the most common, causing 18% of all cases of croup.
  - Types 2, 3, and 4 are also common.
  - Type 3 may cause a particularly severe illness.
- Other viruses: RSV, paramyxovirus, influenza virus type A or B, adenovirus, rhinovirus, enteroviruses (coxsackie and echo), reovirus, measles virus where vaccination not common, and metapneumovirus
- *Haemophilus influenzae* type B now rare with routine immunization
- May have bacterial cause: *Mycoplasma pneumoniae* has been reported.

## *RISK FACTORS*

- History of croup
- Recurrent upper respiratory infections
- Atopic disease increases the risk of spasmodic croup.

## COMMONLY ASSOCIATED CONDITIONS

- If recurrent (>2 episodes in a year) or during first 90 days of life, consider host factors.
- Underlying anatomic abnormality (e.g., subglottic stenosis)
  - In one study, found to be present in 59% children with recurrent croup
- Paradoxical vocal cord dysfunction
- Gastroesophageal reflux disease
- Neonatal intubation

## DIAGNOSIS

- Most children who present with acute onset of barking cough, stridor, and chest wall indrawing have croup.
- Croup is a clinical diagnosis; lab tests and imaging serve only ancillary purposes.
- Classic Òseal-likeÓ barking, spasmodic cough
- May have biphasic stridor
- Low- to moderate-grade fever
- Upper respiratory infection prodrome lasting 1 to 7 days
- Severity usually is determined by clinical observation for signs of respiratory effort: nasal flaring, retractions, tripodding, sniffing position, abdominal breathing, and tachypnea. Later symptoms: hypoxia/cyanosis or fatigue
- Westley croup score (<sup>2</sup>2 mild; 3 to 7 moderate; <sup>3</sup>8 severe), most useful for research purposes
  - Level of consciousness: normal, including sleep, 0; disoriented, 5
  - Cyanosis: none, 0; with agitation, 4; at rest, 5
  - Stridor: none, 0; with agitation, 1; at rest, 2
  - Air entry: normal, 0; decreased, 1; markedly decreased, 2
  - Retractions: none, 0; mild, 1; moderate, 2; severe, 2
- No change in stridor with positioning
- Nontender larynx
- Inflamed subglottic region with normal-appearing supraglottic region
- Differentiate from epiglottitis: non-toxic-appearing, normal voice, no drooling, is coughing (1).

## **HISTORY**

- 2 to 3 days of nonspecific prodromal syndrome with low-grade fever, coryza, and rhinorrhea
- Onset and recurrence at night when child is sleeping
- Symptoms often resolve en route to the hospital, as the child is exposed to cool night air.
- Lack of prodrome indicates spasmodic croup.

## **PHYSICAL EXAM**

- Pulse oximetry often is normal because there is no disturbance of alveolar gas exchange.
- Overall appearance: Is the child comfortable or struggling?
- Work of breathing: labored or comfortable?
- Sound of breathing and voice: hoarse, stridor, inspiratory wheezing, short sentences?
- Observed/subjective tidal volume: sufficient for child's size?

## **DIFFERENTIAL DIAGNOSIS**

- Epiglottitis: currently rare
- Foreign body aspiration
- Subglottic stenosis (congenital or acquired)
- Bacterial tracheitis
- Simple upper respiratory infection
- Retropharyngeal or peritonsillar abscess
- Trauma
- Allergic reaction (acute angioneurotic edema)
- Airway anomalies (e.g., tracheo-/laryngomalacia)
- Other anatomic obstructions: subglottic hemangioma, subglottic cyst

## **DIAGNOSTIC TESTS & INTERPRETATION**

- No laboratory abnormality is diagnostic.
- WBCs may be low, normal, or elevated.
- Lymphocytosis is expected but not required.

- Rapid antigen or viral culture tests are available in some centers.
  - Guide isolation precautions, not management.

### *Initial Tests (lab, imaging)*

- Posteroanterior and lateral neck films show funnel-shaped subglottic region with normal epiglottis: "steeples," "hourglass," or "pencil point" sign (present in 40-60% of children with LTB).
- CT may be more sensitive for defining obstruction in a confusing clinical picture.
- Patient should be monitored during imaging; airway obstruction may occur rapidly.

### *Test Interpretation*

- Inflammatory reaction of respiratory mucosa
- Loss of epithelial cells
- Thick mucoid secretions

## **TREATMENT**

### *GENERAL MEASURES*

- Minimize lab tests, imaging, and procedures that upset the child; agitation worsens tachypnea and can be more detrimental than accepting a clinical diagnosis.
- ECG monitoring and pulse oximetry
  - Frequent checks are more sensitive to worsening disease than is pulse oximetry.

### *MEDICATION*

#### *First Line*

- Well established in the literature; cornerstones of treatment are immediate nebulized epinephrine and dexamethasone.
- Racemic or L-epinephrine (Equal efficacy and side effect profiles; L-epinephrine is used for most other hospital purposes and is less expensive.) (2)[A]
  - Reserved for more severe cases with stridor at rest
  - Racemic epinephrine: 0.05 mL/kg/dose (max 0.5 mL) of 2.25% solution nebulized in normal

saline to total volume of 3 mL

- L-epinephrine: 0.5 mL/kg/dose (max 5 mL) of a 1:1,000 dilution nebulized

P.243

- Onset in 1 to 5 minutes, duration of 2 hours
- Repeat as necessary if side effects are tolerated.
- Observe child for 2 hours to ensure no recurrence after epinephrine wears off.
- Corticosteroids
  - Dexamethasone (least expensive, easiest), 0.15-0.6 mg/kg; higher doses have been traditional care, but studies have shown 0.15 mg/kg has equal efficacy (3)[B]. Single dose; IV/IM/PO has proven equal efficacy.
  - Randomized controlled trials show this begins to improve symptoms within 30 minutes (4) [A]; full effect by 4 hours
  - Other steroids (betamethasone, budesonide (5)[A], prednisolone) are beneficial; there may be minimal superiority of dexamethasone; also, dexamethasone carries benefit of single-dose administration (6,7)[A].
- Heliox: a helium-oxygen mixture
  - Smaller, lower mass helium molecule (compared with nitrogen) theoretically maintains laminar flow in narrower airways and serves as bridge therapy to steroids.
  - Minimum of 60% helium must be used; 70% is preferable; 79% if patient has no oxygen requirement.
  - Limited data; a Cochrane review found no benefit in mild cases but likely benefit in moderate to severe croup as a bridge to steroid effect (8)[A].
- Antibiotics are not indicated in this viral illness.
  - Antecedent or subsequent bacterial infection is possible but uncommon.
- Oxygen as needed
- Humidified air shows no clinical benefit.

## *Second Line*

Oseltamivir for influenza A

## *SURGERY*

- Intubation rarely is required; tube 0.5 to 1 mm smaller than normal.

- After trial of medical management, intubation is for fatigue caused by work of breathing or beginning total obstruction; not secondary to low oxygen saturation
- Extubate in 3 to 5 days when there is an appropriate air leak around the endotracheal tube.
- Tracheotomy: rarely; maintenance 3 to 7 days

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Although proven no benefit in hospital, may be helpful at home. Do not use high-temperature misters (e.g., teakettles) because of a risk of burns. A hot shower running in a bathroom is a good steam generator.
- Some children respond well to cold, dry air.
- Probiotics may decrease the incidence of upper respiratory tract infections (9)[A].

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

- Minor cases need no visit to a hospital or primary care physician (PCP).
- Outpatient care in mild cases
- Admit patients who do not respond to therapy or have recurrent stridor at rest after epinephrine wears off. Also admit those who have oxygen requirement, pneumonia, or congestive heart failure.
- In most cases, observation in the ED after medical management is sufficient.

### ***Discharge Criteria***

- >2 hours since last epinephrine
- No stridor at rest, no difficulty breathing
- Child able to tolerate liquids PO
- No underlying medical condition
- Caretakers able to assess changes to clinical picture and reaccess medical care

**ONGOING CARE**

## **FOLLOW-UP RECOMMENDATIONS**

## Patient Monitoring

Most patients will be seen in an ED or PCP office setting.

## DIET

- NPO and IV fluids for severe cases
- Frequent small feedings with increased fluids for mild cases

## PATIENT EDUCATION

- Must keep the patient quiet; crying may exacerbate symptoms.
- Educate parents about when to seek emergency care if mild cases progress.
- Provide emotional support and reassurance for the patient.

## PROGNOSIS

- Up to 1/3 of patients will have a recurrence.
- Recovery is usually full and without lasting effects.
- If multiple recurrences, consider referral to ENT specialist to evaluate for possible anatomic etiology.

## COMPLICATIONS

- Rare
- Subglottic stenosis in intubated patients
- Bacterial tracheitis
- Cardiopulmonary arrest
- Pneumonia

## Codes

**&NA;**

## **ICD10**

- J05.0 Acute obstructive laryngitis [croup]
- J20.9 Acute bronchitis, unspecified
- J38.5 Laryngeal spasm

## **Clinical Pearls**

**&NA;**

- Parainfluenza virus is the most common pathogen but caused by many viruses.
- Nebulized epinephrine only for stridor at rest
- Dexamethasone 0.6 mg/kg PO × 1
- Lateral neck films show funnel-shaped subglottic region with normal epiglottis: Òsteep, Ó Òhourglass, Ó or Òpencil point Ó sign (present in 40-60% of children with LTB).

# Cryptogenic Organizing Pneumonia

Roselyn Jan Wuthrich Clemente-Fuentes, MD

Merima Bucaj, DO

## BASICS

### DESCRIPTION

- Cryptogenic organizing pneumonia or COP (previously known as bronchiolitis obliterans organizing pneumonia or BOOP) is a primary (cryptogenic) or secondary process of the lungs characterized by granulation-like tissue involving the distal airways and alveoli.
- COP is a restrictive problem that is completely reversible.
- A specific reaction of lung tissue to a variety of injuries, but exact pathogenesis is unknown
- It may occur as patchy infiltrates, or it may be nodular or secondary to another lung disease.
- May also appear to be a migrating process
- May have a gradual or sudden onset.
- Lungs show a pattern of multiple patchy pneumonia, which are seen on the chest x-ray (CXR) as patchy alveolar or ground glass opacifications, with or without interstitial infiltrates; there may be air bronchograms as well.
- Most cases will respond to corticosteroids, which may have to be given for a year or more.
- Synonym(s): bronchiolitis obliterans organizing pneumonia; intraluminal fibrosis of distal airways; idiopathic BOOP; obliterative bronchiolitis

### *Geriatric Considerations*

More common than originally thought and may be sudden and very severe

### *Pediatric Considerations*

Rare but has been reported after viral pneumonia

### EPIDEMIOLOGY

- Incidence/prevalence in the United States: estimated at 0.01% but may be underdiagnosed
- Predominant age: reported cases range age 0 to 70 years; most commonly seen in age 40s to

## *Prevalence*

Unknown

## **ETIOLOGY AND PATHPHYSIOLOGY**

Idiopathic: a complex response to a variety of injuries such as toxic inhalation, postmycoplasma, viral and bacterial infection, aspiration, immunologic factors, drugs

## *Genetics*

No known genetic component

## **RISK FACTORS**

- Immunocompromised patients, including transplant recipients and AIDS patients
- Other autoimmune conditions
- Reported frequency of tobacco use in diagnosed cases 25-50%, making smoking unlikely to be a precipitating factor

## **GENERAL PREVENTION**

Except for prevention of relapse, none known

## **ASSOCIATED CONDITIONS**

- Drug-induced pneumonitis
  - Paraquat poisoning
  - Amiodarone toxicity
  - Acebutolol toxicity
  - Amphotericin B
- $\beta$ -Blockers
  - Bleomycin
  - Carbamazepine
  - Cephalosporins
  - Gold
  - Minocycline

- Nitrofurantoin
- Phenytoin
- Sulfamethoxypyridazine
- Sulfasalazine
- Ticlopidine
- Antineoplastic agents
  - Freebase cocaine pulmonary toxicity
  - Overdose of L-tryptophan
- Infections
  - Chronic infectious pneumonia
  - Malaria
  - Chlamydia
  - Legionella
  - Mycoplasma
  - Pneumocystis
  - Cryptococcus
- Immunocompromised (AIDS or bone marrow, lung, renal transplantation)
- Malignancy: colon, breast, lymphoma
- Bronchial obstruction (lack of mucociliary clearance), which is lung cancer
- Connective tissue diseases
  - COP itself is an autoimmune connective tissue disorder, so autoimmune connective tissue disorders confer a higher risk of acquiring the disease.
  - Rheumatoid arthritis
  - Sjögren syndrome
  - Polymyositis
  - Scleroderma
  - Essential mixed cryoglobulinemia
  - Wegener granulomatosis

- Miscellaneous
  - Cystic fibrosis
  - Bronchopulmonary dysplasia
  - Renal failure
  - Congestive heart failure (CHF)
  - Adult respiratory distress syndrome (ARDS)
- Idiopathic pulmonary fibrosis
  - Chronic eosinophilic pneumonia
  - Hypersensitivity pneumonitis
  - Histiocytosis X
  - Sarcoidosis
  - Pneumoconioses
- Radiation pneumonitis

## DIAGNOSIS

Consider differential in patients presenting with

- Flulike illness that lasts 4 to 10 weeks or longer. Most have been treated with empiric antibiotics without success.
- Fatigue, fever, and weight loss >10 lbs
- Persistent nonproductive cough
- Dyspnea may be severe.
- Bilateral crackles

## HISTORY

- Fatigue/malaise
- Fever/chills
- Weight loss
- Dry cough
- Dyspnea
- No improvement after multiple courses of antibiotics

- Other symptoms suggestive of connective tissue disease such as joint pain, dry eyes/mucus membranes, etc.
- A history of exposure to new medication, radiation, and other environmental exposures that may predispose

## *PHYSICAL EXAM*

- Hypoxia
- Cyanosis
- Respiratory distress
- Bilateral crackles
- Wheezing
- Dry cough
- Shortness of breath
- Rarely: hemoptysis, respiratory distress

## *DIFFERENTIAL DIAGNOSIS*

- Usual interstitial pneumonitis
- Noninfectious diseases
- Tuberculosis
- Sarcoidosis
- Histoplasmosis
- Berylliosis
- Goodpasture syndrome
- Neoplasm
- Polyarteritis nodosa
- Systemic lupus erythematosus
- Wegener granulomatosis
- Sjögren syndrome
- Chronic eosinophilic pneumonia
- Cryptogenic bronchiolitis

## DIAGNOSTIC TESTS & INTERPRETATION

- May have normal or nonspecific laboratory findings
  - Leukocytosis with a normal differential
  - Elevated ESR/CRP
  - Eosinophilia
  - If secondary to autoimmune process, it may have elevated levels of antinuclear antibodies (ANA), rheumatoid factor (RF), anti-SSA/Ro, anti-SSB/La, anti-Jo, etc.
  - Check HIV status.
  - Negative cultures
  - Negative serology for *Mycoplasma*, *Coxiella*, *Legionella*, psittacosis, and fungus
  - Negative viral studies
  - CXR: often appears more normal than the physical examination
    - CXR may show bilateral patchy alveolar opacities (typical pattern), often in the middle or upper lung area, a ground glass pattern that may have air bronchograms.
    - CXR can also reveal a solitary focal nodule or mass known as a focal pattern (1)[B].
  - Throughout the disease, new infiltrates may appear or may seem to migrate.
  - Effusions and cavitory lesions are rare on x-ray.
  - Patients with linear opacities at lung bases may have a poorer prognosis.
  - CT scans more accurately define the distribution and extent of the patchy alveolar opacities with areas of hyperlucency. Findings are commonly described as a reversed halo sign or a toll sign, a focal round area of ground glass attenuation; however, this is a nonspecific finding (2,3)[A].
  - Up to 90% of CT scans may show airspace consolidation with air bronchograms.
  - Pulmonary function shows a restrictive/obstructive pattern.
- 
- Flow-volume loop shows terminal airway obstruction.
  - The involved area may seem to migrate.
  - Ventilation-perfusion ratio scan: matched patchy defects

- In one study, open lung biopsy established the correct diagnosis in 1/3 of patients (4)[B].
- Transbronchial biopsy has yielded a correct diagnosis in 2/3 of cases (4,5)[B].
- Consider steroids for a diagnostic trial. If a diagnostic trial is successful, be prepared to treat the patient for at least 1 year. Relapses are common after stopping treatment.
- Bronchoalveolar lavage (BAL) fluid in patients with COP have shown larger amounts of natural killer cells, natural killer T-like cells, Fas and tumor necrosis factor receptor expression indicating cytotoxicity and local inflammation (5,6)[C]. In one specific study, the most frequent BAL profile was mixed alveolitis with lymphocytic predominance, a CD4/CD8 index of 0.4, and foamy macrophages, which was shown to be specific (88.8%) but not sensitive (4)[C].

## *Test Interpretation*

- Intraluminal fibrosis of distal airspaces is the major pathologic feature.
- Fibroblasts and plugs of inflammatory cells and loose connective tissue fill these distal airways, known as Masson bodies.
  - Characteristic butterfly pattern of intraluminal granulation tissue plugs extending from alveoli to bronchioles
- Inflammatory cells are mainly lymphocytes and plasma cells.
- Interstitial fibrosis is present.
- Plugs of edematous granulation tissue in the terminal and respiratory bronchioles and alveolar ducts do not cause permanent damage.

## **TREATMENT**

- Observation for patients with minimal symptoms and absent/mild PFT abnormalities as may spontaneously resolve. Reassess at 8 to 12 week intervals (8)[C].
- Inpatient care may be required for rapidly progressive disease or respiratory failure for high dose IV steroids and supportive care

## **GENERAL MEASURES**

- Monitor blood gases or pulse oximetry.
- Oxygen, as necessary

## **MEDICATION**

## *First Line*

### Prednisone

- 1 mg/kg (up to 60 mg/day) for 1 to 3 months, then 40 mg/day for 3 months, then 10 to 20 mg/day for up to 1 year (1)[A]
- May consider a 6-month-only taper or alternate day dosing for 1 year to limit steroid exposure
- Increase length of taper for patients on long-term therapy to avoid precipitating Addisonian crisis.
- Treatment may be needed for <sup>3</sup>1 year.
- In one study, the best response to corticosteroid therapy was seen in individuals <35 years of age, nonsmokers, and with morphologic features (large bronchial plugs, mild inflammatory reaction) and immunohistochemical markers (presence of collagen IV, absence of collagen III, CD-68-positive cells and positive VEGF) (7)[B].
- Precautions: Be aware of the patient's TB status and history of peptic ulcer disease. Long-term steroid treatment is associated with significant adverse effects, including adrenal suppression, infection, Cushing syndrome, fluid retention, osteoporosis, hyperkalemia, and poor wound healing.

## *Pediatric Considerations*

Prednisone: 1 mg/kg q24h for 1 month, followed by weaning over several months

## *Second Line*

- Steroids other than prednisone may be used.
- Prescribe antimicrobials if the original infection is persistent. The proper choice depends on the pathogen.
- Anecdotal use of inhaled triamcinolone and cyclophosphamide has been reported.
- Macrolide antibiotics have also been used for their anti-inflammatory properties; however, not employed in most cases (4)[C].
- If unresponsive to systemic glucocorticoids, can consider second immunosuppressive such as azathioprine or cyclophosphamide (9,10)[C]

## *ISSUES FOR REFERRAL*

Patients should be followed by a pulmonologist.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Frequent visits, weekly at first
- Prednisone must be continued because of the chance of relapse.
- Monitor the lung disease and the side effects of prednisone therapy.
  - Annual TB screening
  - Monthly CBC
  - Funduscopic examination every 3 to 6 months
  - Serial dual energy x-ray absorptiometry (DEXA) scans for osteoporosis

#### *DIET*

No special diet

### *PATIENT EDUCATION*

- Compliance: Emphasize the need to continue prednisone because of the chance of a relapse.
- Recurrence in up to 1/3 who do not complete full steroid treatment (1)

### *PROGNOSIS*

Typically complete recovery, but individual case management is mandatory.

#### **COMPLICATIONS**

- Bronchiectasis
- Most people recover completely without permanent sequelae if full course of steroids completed.
- Death occurs in up to 7% but usually in individuals who are elderly or have preexisting comorbid conditions.

## See-Also

&NA;

Sjšgren syndrome

**&NA;**

## **ICD10**

J84.116 Cryptogenic organizing pneumonia

## **Clinical Pearls**

**&NA;**

- COP is a restrictive problem that is completely reversible.
- Major risk factors for COP include immunosuppression. No known association with smoking.
- Consider COP in prolonged respiratory illness with fatigue, nonproductive cough, and weight loss unresponsive to multiple antibiotics.
- When diagnosing COP, one should perform an autoimmune workup.
- The classic CT finding of COP is the "reversed halo sign" also known as "atoll sign."
- The histopathology characteristic of excessive proliferation of granulation tissue that may extend into the "butterfly" pattern
- COP treatment is a prolonged course of corticosteroids.

# Cryptorchidism

Pamela Ellsworth, MD

## BASICS

### DESCRIPTION

- Incomplete or improper descent of one or both testicles; also called *undescended testes* (1)
- Normally, descent is in the 7th to 8th month of gestation. The cryptorchid testis may be palpable or nonpalpable.
- Types of cryptorchidism
  - Abdominal: located inside the internal ring
  - Canalicular: located between the internal and external rings
  - Ectopic: located outside the normal path of testicular descent from abdominal cavity to scrotum; may be ectopic to perineum, femoral canal, superficial inguinal pouch (most common), suprapubic area, or opposite hemiscrotum
  - Retractable: fully descended testis that moves freely between the scrotum and the groin
  - Iatrogenic: Previously descended testis becomes undescended secondary to scar tissue after inguinal surgery, such as an inguinal hernia repair or hydrocelectomy.
  - Also may be referred to as palpable versus nonpalpable (1)
- System(s) affected: reproductive
- Synonym(s): undescended testes (UDT)

### EPIDEMIOLOGY

#### Incidence

- Predominant age: premature newborns
- Predominant sex: male only

#### Prevalence

- In the United States, cryptorchidism occurs in 1-3% of full-term and 15-30% of premature

newborn males (2).

- Spontaneous testicular descent occurs by age 1 to 3 months in 50-70% of full-term males with cryptorchidism.
- Descent at 6 to 9 months of age is rare (3).

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

- Not fully known
- May involve alterations in
  - Mechanical factors (gubernaculum, length of vas deferens and testicular vessels, groin anatomy, epididymis, cremasteric muscles, and abdominal pressure), hormonal factors (gonadotropin, testosterone, dihydrotestosterone, and Müllerian-inhibiting substance [MIS]), and neural factors (ilioinguinal nerve and genitofemoral nerve)
  - Major regulators of testicular descent from intraabdominal location into the bottom of the scrotum are the Leydig cell-derived hormones, testosterone, and insulin-like growth factor 3 (IGF-3).
  - Mutations in the gene for IGF-3 and in the androgen receptor gene have been evaluated as possible causes of cryptorchidism as well as chromosomal alterations (1).
  - Environmental factors acting as endocrine disruptors of testicular descent also may contribute to the etiology of cryptorchidism (4).
- Risk of ascent may be as high as 32% in retractile testis (5).

## ***Genetics***

Occurrence of UDT in siblings, as well as fathers, suggests a genetic etiology.

## ***RISK FACTORS***

- Family history of cryptorchidism: highest risk if brother had UDT, followed by uncle, then father (6)
- Low birth weight, prematurity, and small for gestational age are associated with a substantial increase in incidence of cryptorchidism (1). Retractable testes are at increased risk for ascent (5).

## ***COMMONLY ASSOCIATED CONDITIONS***

- Inguinal hernia/hydrocele
- Abnormalities of vas deferens and epididymis

- Intersex abnormalities
- Hypogonadotropic hypogonadism
- Germinal cell aplasia
- Prune-belly syndrome
- Meningomyelocele
- Hypospadias
- Wilms' tumor
- Prader-Willi syndrome
- Kallmann syndrome
- Cystic fibrosis

## DIAGNOSIS

### HISTORY

- 1 testicles in a site other than the scrotum
- May be an isolated defect or associated with other congenital anomalies

### PHYSICAL EXAM

- Performed with warm hands, with child in sitting, standing, and squatting position
- A Valsalva maneuver and applied pressure to lower abdomen may help to identify the testes, especially a gliding testis.
- Failure to palpate a testis after repeated exams suggests an intra-abdominal or atrophic testis.
- An enlarged contralateral testis in the presence of a nonpalpable testis suggests testicular atrophy/absence.
- Testes should be palpated for quality and position at each recommended well-child visit (1)[B].

### DIFFERENTIAL DIAGNOSIS

- Retractable testis (hypermobile testis) a normally descended testis that ascends into the inguinal canal because of an active cremasteric reflex (more common in males 4 to 6 years of age)
- Atrophic testis: may occur as a result of neonatal torsion
- Vanished testis may be the result of a lack of development or in utero torsion.

# DIAGNOSTIC TESTS & INTERPRETATION

## *Initial Tests (lab, imaging)*

- In phenotypic male newborn with bilateral, nonpalpable UDTs, hormone levels are helpful to determine whether the testes are present and should be evaluated for possible disorder of sexual development (1)[A].
  - Luteinizing hormone (LH)
  - Follicle-stimulating hormone (FSH)
  - MIS
  - Testosterone
  - Serum electrolytes
  - Karyotype
- If bilateral nonpalpable testes and presenting >3 months of age, a human chorionic gonadotropin (hCG) stimulation test to determine presence or absence of testicular tissue (hCG 2,000 IU/day for 3 days, and check testosterone before and after stimulation) as well as gonadotropins to say testes are absent need negative stimulation test and elevated gonadotropins (7).
- Ultrasound or other imaging modalities should not be performed in the evaluation of boys with cryptorchidism prior to referral to a specialist, as they are rarely needed in decision making (1) [B].

## *Follow-Up Tests & Special Considerations*

- In newborns and children <6 months of age, periodic examination to determine if testis is palpable and descended prior to considering further intervention (1)
- In the absence of spontaneous testicular descent by 6 months of age (gestational age adjusted), infant should be referred to appropriate specialist and should perform surgery within 1 year (1,8)[B].
- In children with retractile testes, examination should be performed at least yearly to rule out subsequent ascent (1)[B].
- Best accuracy in predicting monorchism in boys 11 to 30 months of age with unilateral nonpalpable UDT if unilateral nonpalpable undescended testis and contralateral descended testis is 19 to 20 mm or greater in length measured by caliper (9)[B].

## *Diagnostic Procedures/Other*

Laparoscopy is useful in a child with nonpalpable cryptorchidism to confirm testicular absence or presence accurately and to determine the feasibility of performing a standard orchidopexy.

## *Test Interpretation*

- Higher incidence of carcinoma in UDT and alterations in spermatogenesis (10)
- Histologic changes occur by 1.5 years of age and include smaller seminiferous tubules, fewer spermatogonia, and more peritubular tissue (10,11).

## **TREATMENT**

### *GENERAL MEASURES*

- Rule out retractile testis.
- Appropriate health care: outpatient until surgery is performed
- Administration of chorionic gonadotropin may cause testicular descent in some boys. Reports of efficacy are inconsistent. American Urological Association (AUA) guidelines on cryptorchidism do not recommend use of hormonal therapy to induce testicular descent due to low response rate and lack of evidence for long-term efficacy (1).

### *MEDICATION*

Medical therapy is not indicated in the United States per the AUA guidelines on cryptorchidism 2014 (1).

### *ISSUES FOR REFERRAL*

- >1 testes not descended by 6 months age (1)[B]
- Bilateral nonpalpable UDTs (1)
- Newly diagnosed cryptorchidism after 6 months of age (1)[B]

---

P.247

### *SURGERY/OTHER PROCEDURES*

- Reasons to consider: avoids torsion, averts trauma, decreases but does not eliminate risk of malignancy, and prevents further alterations in spermatogenesis
- In the absence of spontaneous testicular descent by 6 months of age (gestational age-adjusted), surgery should be performed within 1 year (1)[B].
- Prepubertal orchidopexy decreases risk of testicular cancer and results in 2- to 6-fold reduction

in relative risk compared to postpubertal orchidopexy (1,12,13,14).

- Laparoscopy/abdominal exploration is performed first if testis is nonpalpable (15).
- If palpable, an inguinal approach is usually performed. If low-lying, a single incision scrotal approach can also be considered but may increase the risk of hernia (16,17).

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Initial follow-up within 1 month of surgery and periodically thereafter to assess testicular size/growth.
- Patients with retractile testes should be examined at least annually to monitor for secondary ascent until testis is no longer retractile (1)[B].

### *Patient Monitoring*

- Patients should be followed after surgery to evaluate testicular growth.
- Testicular tumors occur mainly during or after puberty; thus, these children should be taught self-examination when they are older.

### *DIET*

No restrictions

### *PATIENT EDUCATION*

Discuss with parents about causes, available treatments and possible effects on patient's reproductive potential and also increased risk for testicular cancer and need for regular self-examination.

### *PROGNOSIS*

- Disorder is usually corrected with medical or surgical therapy; however, there are possible lifelong consequences.
- If testicle is absent or orchiectomy is required, may consider placement of testicular prosthesis
- Early orchidopexy may decrease risk of testicular damage and risk of malignancy.

### **COMPLICATIONS**

- Progressive failure of spermatogenesis, if left untreated; even with orchidopexy, the fertility rate is still reduced, especially with bilateral UDTs.

- Spermatogenesis is related to the duration of cryptorchidism and the location of the testis (18).
- Formerly, bilaterally cryptorchid men have a greater decrease in fertility compared with unilateral cryptorchid male and the general male population (1,19,20,21,22,23).
- Abnormalities also have been identified in the contralateral descended testis, although less severe.

## Codes

&NA;

## ICD10

- Q53.9 Undescended testicle, unspecified
- Q53.10 Unspecified undescended testicle, unilateral
- Q53.20 Undescended testicle, unspecified, bilateral

## Clinical Pearls

### **&NA;**

- If testicular descent does not occur by 6 months of age, it is unlikely to occur. Therefore, refer patients to a specialist if a testis has not descended by 6 months of age.
- Children with bilateral, nonpalpable UDTs require laboratory evaluation to determine if viable testicular tissue is present and to rule out disorder of sexual differentiation.
- Radiologic imaging has no role in the initial evaluation of cryptorchidism.
- The risk of infertility is increased with bilateral UDTs.

# Cushing Disease and Cushing Syndrome

Linda Paniagua, MD

Geetha Gopalakrishnan, MD

## BASICS

### DESCRIPTION

- Clinical abnormalities associated with chronic exposure to excessive amounts of cortisol (the major adrenocorticoid)
- Cushing syndrome is defined as excessive corticosteroid exposure from exogenous sources (medications) or endogenous sources (pituitary, adrenal, pulmonary, etc.) or tumor. Exogenous intake of steroids is the primary cause of Cushing syndrome.
- Cushing disease is defined as glucocorticoid excess due to excessive adrenocorticotrophic hormone (ACTH) secretion from a pituitary tumor, the most common cause of primary Cushing syndrome.
- System(s) affected: endocrine/metabolic, musculoskeletal, skin/exocrine, cardiovascular; neuropsychiatric

### *Pediatric Considerations*

- Rare in infancy and childhood
- Cushing disease accounts for approximately 75% of all cases of Cushing syndrome in children >7 years.
- In children <7 years, adrenal causes of Cushing syndrome (adenoma, carcinoma, or bilateral hyperplasia) are more common.
- Most common presenting symptom is lack of growth consistent with the weight gain.

### *Pregnancy Considerations*

- Pregnancy may exacerbate disease.
- Cortisol levels increase in normal pregnancy states.

### EPIDEMIOLOGY

## *Incidence*

Uncommon: 0.7 to 2.4/1 million per year (1)

## *Prevalence*

2-5% prevalence reported in difficult-to-control diabetics with obesity and hypertension (HTN)

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Syndrome: excessive corticosteroid exposure from exogenous sources (medications) or endogenous sources (pituitary, adrenal, pulmonary, etc.) or tumor
- Disease: pituitary tumor causing excess ACTH (corticotropin)
- General population
  - Exogenous glucocorticoids
  - Endogenous ACTH-dependent hypercortisolism: 80-85%
    - ACTH-secreting pituitary tumor: 75%
    - Ectopic ACTH production (e.g., small cell carcinoma of lung, bronchial carcinoid): 20%
  - Endogenous ACTH-independent hypercortisolism: 15-20%
    - Adrenal adenoma
    - Adrenal carcinoma
    - Macronodular or micronodular hyperplasia
- Pediatric/adolescent (1)
  - Adrenal hyperplasia secondary to McCune-Albright: mean age 1.2 years
  - Adrenocortical tumors: mean age 4.5 years
  - Ectopic ACTH syndrome: mean age 10.1 years
  - Primary pigmented nodular adrenocortical disease: mean age 13.0 years
  - Cushing disease: mean age 14.1 years
- Pregnancy (2)
  - Pituitary-dependent Cushing syndrome: 33%
  - Adrenal causes: 40-50%
  - ACTH-independent adrenal hyperplasia: 3%

## Genetics

- Multiple endocrine neoplasia
- Carney complex (an inherited multiple neoplasia syndrome)
- McCune-Albright syndrome (mutation of *GNAS1* gene)
- Familial isolated pituitary adenomas (mutations in the aryl hydrocarbon receptor-interacting protein gene)

## RISK FACTORS

- Prevalent sex: female > male (3:1) (3)
- Most often occurs between the ages of 25 and 40 years
- Prolonged use of corticosteroids

## GENERAL PREVENTION

Avoid corticosteroid exposure, when possible.

## DIAGNOSIS

### HISTORY

- Weight gain: 95%
- Decreased libido: 90%
- Menstrual irregularity: 80%
- Depression/emotional lability: 50-80%
- Easy bruising: 65%
- Diabetes or glucose intolerance: 60%

## PHYSICAL EXAM

- Obesity (usually central): 95%
- Facial plethora: 90%
- Moon face (facial adiposity): 90%
- Thin skin: 85%
- Hypertension: 75%
- Skeletal growth retardation in children (epiphyseal plates remain open): 70-80%

- Hirsutism: 75%
- Proximal muscle weakness: 60%
- Purple striae on the skin
- Increased adipose tissue in neck and trunk
- Acne

## *DIFFERENTIAL DIAGNOSIS*

- Obesity
- Diabetes mellitus
- HTN
- Metabolic syndrome X
- Polycystic ovarian disease
- Pseudo-Cushing (e.g., alcoholism, physical stress, severe major depression)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Recent guidelines (4)[C]
  - The 2008 Endocrine Society guidelines recommend against widespread testing for Cushing syndrome except in patients with the following:
    - Adrenal incidentaloma
    - Multiple progressive features suggestive of Cushing syndrome
    - Unusual features for their age such as osteoporosis and HTN
    - Abnormal growth (children)
- Late-night salivary cortisol, 24-hour urinary free cortisol, or low-dose dexamethasone suppression testing
  - Elevated late-night salivary cortisol: Obtain at least two measurements. Cortisol secretion is highest in the morning and lowest between 11 PM and midnight. The nadir of serum cortisol is maintained in pseudo-Cushing (e.g., obesity, alcoholism, depression) but not in Cushing syndrome. Sensitivity and specificity are >90-95% (5,6)[B].
  - 24-hour urinary free cortisol level: Obtain <sup>3</sup>2 samples to rule out intermittent

hypercortisolism if results are normal and suspicion is high. Also measure 24-hour urinary creatinine excretion to verify adequacy of collection. Results may be falsely low if glomerular filtration rate  $<30$  mL/min. Overall sensitivity and specificity varies, 90-97% and 85-96%, respectively (5)[B]. Avoid drinking excessive amounts of water due to risk of false-positive values. False-positive values can be seen in the presence of pseudo-Cushing states.

- Low-dose dexamethasone suppression testing: Dexamethasone 1 mg is given between 11 PM and midnight, and fasting plasma cortisol is measured between 8 and 9 AM the following morning. A serum cortisol level below  $1.89 \mu\text{g/dL}$  excludes Cushing syndrome, but specificity is limited. The presence of pseudo-Cushing states (depression, obesity, etc.), hepatic or renal disease, or any drug that induces cytochrome P-450 enzymes may cause a false result.
- High-dose dexamethasone suppression test may be useful when baseline ACTH levels are indeterminate:
  - 8 mg overnight dexamethasone suppression test: 8 mg of oral dexamethasone is given at 11 PM, with measurement of an 8-AM cortisol level the next day. A baseline 8-AM cortisol measurement is also obtained the morning prior to ingesting dexamethasone. Suppression of serum cortisol level to  $<50\%$  of baseline is suggestive of a pituitary source of ACTH rather than ectopic ACTH or primary adrenal disease. Sensitivity and specificity are 95% and 100%, respectively (7)[B].
- If the initial results are positive or if clinical suspicion is high, perform additional studies to confirm diagnosis. Other tests to consider include the following:
  - Awake midnight plasma cortisol: Obtain samples on three consecutive nights. A late-evening serum cortisol  $>7.5 \mu\text{g/dL}$  has a sensitivity of 96% and specificity of 100% (8)[B]. Persistently elevated serum cortisol implies Cushing syndrome; nadir of serum cortisol is maintained in obese patients but not in Cushing.
  - Corticotropin-releasing hormone (CRH) after dexamethasone: used to distinguish Cushing syndrome from pseudo-Cushing syndrome. Dexamethasone 0.5 mg is given q6h for 48 hours starting at noon. CRH ( $1 \mu\text{g/kg}$ ) is given 2 hours after the last dose of dexamethasone. Plasma cortisol is  $>1.4 \mu\text{g/dL}$  15 minutes after CRH in patients with Cushing syndrome but not in those with pseudo-Cushing (9)[B].
- Pituitary MRI scan if pituitary tumor is suspected
- Abdominal CT scan if adrenal disease is suspected
- Chest CT scan if ectopic ACTH secretion is suspected
- Octreotide scintigraphy to look for occult ACTH-secreting tumor
- Dual energy x-ray absorptiometry to evaluate for osteoporosis

**ALERT**

- Antiepileptic drugs, progesterone, oral contraceptives (withdraw estrogen-containing drugs 6 weeks before testing), rifampin, and spironolactone may cause a false-positive dexamethasone suppression test.
- Pregnancy (4)[C]: Urine-free cortisol is recommended instead of dexamethasone testing in the initial evaluation of pregnant women. Only urine free cortisol in the 2nd or 3rd trimester >3 times the upper limit of normal can be taken to indicate Cushing syndrome.
- Epilepsy (4)[C]: best to use measured cortisol from saliva and urine instead of serum cortisol after dexamethasone. No data to guide length of time needed after withdrawal of such medication to allow dexamethasone metabolism to return to normal; such medication change may not be clinically possible.

*Follow-Up Tests & Special Considerations*

- Once the diagnosis of Cushing syndrome is confirmed, localization is the next step:
  - ACTH level: elevated in ACTH-dependent Cushing syndrome (e.g., pituitary and ectopic tumor) and low in ACTH-independent Cushing syndrome (e.g., adrenal tumors and exogenous glucocorticoids)
  - High-dose dexamethasone suppression testing: used to distinguish between an ACTH-secreting pituitary tumor and ectopic ACTH-secreting tumors. 0.5 mg dexamethasone is given q6h for 8 doses, with serum cortisol measured at 2 and 6 hours after last dose (sensitivity 79%, specificity 74%) (7)[B].
- Diagnosis of Cushing syndrome is complicated by the nonspecificity and high prevalence of clinical symptoms in patients without the disorder and involves a variety of tests of variable sensitivity and specificity. Efficient screening and confirmatory procedures are essential before considering therapy.

*Diagnostic Procedures/Other*

Diagnostic procedure depends on clinical judgment. Inferior petrosal sinus sampling with CRH stimulation can be considered if ACTH-dependent tumor is suspected but not localized.

*Test Interpretation*

- Thyroid function suppressed
- HTN

- Dyslipidemia
- Polycystic ovarian syndrome/hyperandrogenism
- Oligomenorrhea/hypogonadism
- Myopathy/cutaneous wasting
- Neuropsychiatric problems
- Ipsilateral adrenal gland hyperplasia and contralateral adrenal gland atrophy
- Hypercoagulable state
- Osteoporosis
- Nephrolithiasis
- Growth hormone reduced

## TREATMENT

### *MEDICATION*

- Drugs usually not effective for primary long-term treatment; used in preparation for surgery or as adjunctive treatment after surgery, pituitary radiotherapy, or both.
- Metyrapone, ketoconazole, and mitotane all lower cortisol by directly inhibiting synthesis and secretion in the adrenal gland. Replacement glucocorticoid therapy is often required. As initial treatment, remission rates up to 85% (10,11)[C].
- Mifepristone is a potent glucocorticoid receptor antagonist. It is FDA approved to control hyperglycemia in adults with endogenous Cushing syndrome who have type 2 diabetes or glucose intolerance secondary to hypercortisolism that has not responded to (or who are not candidates for) surgery.
- Pasireotide is a somatostatin receptor ligand with affinity for somatostatin receptor 5. It has been approved for adult Cushing disease treatment by the FDA.

### *SURGERY/OTHER PROCEDURES*

- Transsphenoidal surgery
  - Primary treatment for Cushing disease due to remission range of 65-90% (12)[C]
  - Resection of the ACTH-producing ectopic tumor
- Adrenal surgery

- For unilateral adrenal adenomas, laparoscopic surgery is the treatment of choice.
- For nodular hyperplasia, bilateral adrenalectomy is usually recommended.
- For patients with Cushing disease, bilateral laparoscopic adrenalectomy can be considered if the patient has persistent disease even after pituitary surgery and radiotherapy.
- RADIOTHERAPY and stereotactic radiosurgery (SRS) can be used to treat persistent hypercortisolism after transsphenoidal surgery in Cushing disease.
- Fractionated radiotherapy
  - Rates of remission range from 56% to 84% [B].
  - Its related complications of hypopituitarism has limited its usefulness [A].
- Stereotactic radiosurgery
- Rates of remission range from 17% to 83% [A].
- Can be used as primary treatment without resection in patients with cavernous sinus tumors

## **ONGOING CARE**

### *PATIENT EDUCATION*

- Teaching regarding diet and monitoring daily weight, early treatment of infections, emotional lability
- National Adrenal Disease Foundation. Great Neck, NY 11021; 516-407-4992

### *PROGNOSIS*

- Guardedly favorable prognosis with surgery for Cushing disease; generally chronic course with cyclic exacerbations and rare remissions
- Better prognosis following surgery for benign adrenal tumors; long-term recurrence rate is 20%.
- Poor with small cell carcinoma of the lung producing ectopic hormone; neuroendocrine tumors (bronchial carcinoid) have much better prognosis.

### **COMPLICATIONS**

- Osteoporosis
- Increased susceptibility to infections
- Metastases of malignant tumors

- Increased cardiovascular risk even after treatment
- Lifelong glucocorticoid dependence following treatment with bilateral adrenalectomy
- Nelson syndrome (pituitary tumor) after treatment with bilateral adrenalectomy (can occur in 8-38% of patients)

## See Also

&NA;

Algorithm: Cushing Syndrome

## Codes

&NA;

### ICD10

- E24.9 Cushing's syndrome, unspecified
- E24.0 Pituitary-dependent Cushing's disease
- E24.2 Drug-induced Cushing's syndrome

## Clinical Pearls

&NA;

- Cushing disease is due to excessive ACTH secretion from a pituitary tumor, resulting in corticosteroid excess.
- Cushing syndrome is due to excessive corticosteroid exposure from exogenous sources (medications) or endogenous sources (pituitary, adrenal, pulmonary, etc.) or tumor.
- Depression, alcoholism, medications, eating disorders, and other conditions can cause mild clinical and laboratory findings similar to those in Cushing syndrome (pseudo-Cushing

syndrome).

# Cutaneous Drug Reactions

Mary Iaculli, DO

Joanne Wilkinson, MD, MSc

## BASICS

### DESCRIPTION

- An adverse cutaneous reaction in response to administration of a drug. Rashes are the most common adverse drug reactions.
- Severity can range from mild eruptions that resolve within 48 hours after the removal of the inciting agent to severe skin damage with multiorgan involvement.
- Morbilliform/simple exanthem (75-95%) and urticarial (5-6%) eruptions are most common, but multiple morphologic types may occur.
- System(s) affected: skin/mucosa/exocrine, hematologic/lymphatic/immunologic

### EPIDEMIOLOGY

- All ages affected
- Predominant sex: female > male
- No correlation between development of adverse reaction and patient's age, diagnosis, or survival.
- Special consideration in the geriatric population who are on multiple medications: increased likelihood of severe cutaneous and systemic reactions; also consider in the pediatric group: difficult to distinguish from viral exanthems

### Incidence

In the United States, prevalence of 2-3% in hospitalized patients; estimated 1/1,000 hospitalized patients has had a severe cutaneous reaction.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Predictable adverse reactions are due to overdose, side effect, or drug interaction.
- Unpredictable reactions include intolerance, drug idiosyncrasy secondary to abnormality in

metabolism, or immune reaction. >700 drugs are known to cause a dermatologic reaction:

- Immunologically mediated reaction: immunoglobulin (Ig) E-mediated reaction (type I hypersensitivity), cytotoxic/IgG/IgM induced (type II), immune complex reactions (type III), and delayed-type hypersensitivity (type IV) with T cells, eosinophils, neutrophils, and monocytes
- Acneiform: OCPs, corticosteroids, iodinated compounds, hydantoins, lithium
- Erythema multiforme/Stevens-Johnson syndrome (SJS)/toxic epidermal necrolysis (TEN): >100 drugs reported. Most common include sulfonamides, cephalosporins NSAIDs, barbiturates, hydantoins, anticonvulsants tetracycline, terbinafine.
- Fixed drug eruptions: NSAIDs, sulfonamides, tetracycline, barbiturates, salicylates, OCPs
- Lichenoid: thiazides, NSAIDs, gold, ACE inhibitors, proton pump inhibitors, antimalarials, sildenafil
- Photosensitivity: doxycycline, thiazides, sulfonamides, quinolones, sulfonamides, NSAIDs
- Hypersensitivity vasculitis: hydralazine, penicillins, cephalosporins, thiazides, gold, sulfonamides, NSAIDs, propylthiouracil
- Drug rash with eosinophilia and systemic symptoms (DRESS) syndrome: anticonvulsants, sulfonamides, dapsone, minocycline, allopurinol
- Acute generalized exanthematous pustulosis (AGEP): penicillins, cephalosporins, macrolides, calcium channel blockers, antimalarials, carbamazepine, acetaminophen, terbinafine, nystatin, vancomycin
- Sweet syndrome (acute febrile neutrophilic dermatosis): sulfa drugs, granulocyte colony-stimulating factor (G-CSF), granulocyte-macrophage colony-stimulating factor (GM-CSF), diazepam, minocycline, nitrofurantoin, captopril, penicillamine
- Serum sickness-like reaction: cephalosporins, penicillins, TMP-SMX, propranolol, bupropion, minocycline
- Morbilliform/urticarial/exfoliative erythroderma: numerous medications, including penicillins, cephalosporins, sulfonamides, tetracyclines, ibuprofen, naproxen, allopurinol, acetylsalicylic acid, radiocontrast media (1)[A]

## Genetics

Genetics may play a role, as certain HLA antigens have been associated with increased predisposition to specific drug eruptions:

- HLA-B\*5801, HLA-B\*5701, and HLA-B\*1502 have been linked to allopurinol-induced and carbamazepine-induced SJS/TEN, respectively.

- HLA class I antigens, such as HLA-A2, HLA-B12, and HLA-B22, have been linked to TEN and fixed drug eruptions, respectively.

## **RISK FACTORS**

Previous drug reaction, multiple medications, concurrent infections, immunocompromised, disorders of metabolism, and certain genetic HLA haplotypes

## **GENERAL PREVENTION**

Always ask patients about prior adverse drug events. Be aware of medications with higher incidence of reactions as well as drug cross-reactions.

## **DIAGNOSIS**

### **HISTORY**

- New medications within the preceding 6 weeks, most commonly within preceding 2 weeks: all oral, parenteral, and topical agents, including over the counter drugs, vitamins, and herbal remedies
- Consider other etiologies: bacterial infections, viral exanthems, or underlying skin disease including cutaneous lymphoma

## **PHYSICAL EXAM**

May present as a number of different eruption types, including, but not limited to the following:

- Morbilliform eruptions (exanthems)
  - Most frequent cutaneous reaction (75-95%); difficult to distinguish from viral exanthem; often secondary to antibiotic
  - Starts on trunk as pruritic red macules and papules and extends to extremities in confluent fashion, sparing face, palms, soles, and mucous membranes
  - Onset 7 to 21 days after drug initiation (2)[C].
- Urticaria
  - Pruritic erythematous wheals distributed anywhere on the body, including mucous membranes; may progress to angioedema, appears as nonpitting edema without erythema or margins
  - Individual lesions fade within 24 hours, but new lesions may develop (2).
- Acneiform eruptions

- Folliculocentric, monomorphous pustules typically involving the face, chest, and back distinguished from acne vulgaris by absence of gross and/or microscopic comedones
  - Often may become secondarily infected (2)[C]
- Fixed drug eruptions
  - Single/multiple, round, sharply demarcated, violaceous plaques with gray center that may leave postinflammatory hyperpigmentation; occur on skin or mucous membrane
  - Appear shortly after drug exposure and recur in identical location after reexposure; some patients have a refractory period during which the drug fails to activate lesions.
  - Onset usually is 48 hours after ingestion of drug (2).
- AGEP
  - Multiple nonfollicular sterile pustules on erythematous background with desquamation after 7 to 10 days
  - Involves intertriginous areas but can be generalized and involve the face
  - Appears similar to pustular psoriasis, but AGEP has fever and marked leukocytosis with neutrophilia and/or eosinophilia (2)[C]
- DRESS syndrome
  - Classic triad of fever, exanthem, and internal organ involvement with possible pharyngitis and lymphadenopathy
  - Can lead to exfoliative dermatitis, often accompanied by facial edema
  - Internal organ involvement: 80% hepatic, 40% renal, 33% pulmonary, and cardiac lab tests show elevated liver transaminases and eosinophilia.
  - Onset 2 to 8 weeks after drug exposure; may develop 3 months or later into therapy (3)[B].
- Erythema multiforme
  - Relatively common, acute, often recurrent
  - Most commonly associated with herpes simplex virus and other viral/bacterial etiologies (i.e., mycoplasma); less likely secondary to drug exposure. 50% with unknown etiology
  - Three-zone target lesions and raised atypical two-zone targets with localized erythema
  - Lesions predominant on distal extremities including on acral surface with limited mucosal involvement; <10% epidermal detachment (4)[B]
- SJS/TEN

- Classification and distinction between SJS and TEN determined by affected body surface area (BSA)
    - SJS: <10% BSA; SJS-TEN overlap: 10-30% BSA; TEN: >30% BSA
  - Unlike erythema multiforme, strong association with preceding drug exposure as opposed to infection except in children where infection is more common (e.g., mycoplasma)
  - Onset is 1 to 3 weeks after starting offending agent: Flat atypical two-zone target lesions and erythematous macules that are truncal and generalized with mucosal involvement
  - May develop confluent areas of bullae, erosions, and necrosis; significant risk for infection and sepsis
  - SJS: 5-15% mortality; TEN: 30% mortality (5)[C],(6)[A]
  - Lichenoid eruptions
    - Flat-topped, violaceous, pruritic papules on extensor surfaces and involving oral mucosa
    - Reticular pattern: Lesions heal with hyperpigmentation.
    - Chronic lesions persist for weeks/months after the drug discontinued (2)
  - Photosensitivity reaction
    - Phototoxic reactions: occur within 24 hours of light exposure with exaggerated sunburn reaction; confined to sun-exposed areas
    - Photoallergic reactions: caused by UVA exposure; more pruritic than painful; can involve non-sun-exposed areas
- 
- P.251
- Hypersensitivity vasculitis
    - Petechiae/palpable purpura and/or maculopapular rash concentrated on lower extremities and dependent areas
    - Biopsy shows neutrophils around an arteriole or venule.
    - Possible renal, joint, and CNS involvement with fever, myalgias, arthritis, and abdominal pain (2)
  - Sweet syndrome
    - Fever, neutrophilia, tender edematous violaceous papules, plaques, or nodules, with or without pustules/vesicles that spontaneously resolve
    - May have oral ulcers or ocular manifestations, such as conjunctivitis

Classically seen in young women after a mild respiratory illness or GI infection, but 7-56% associated with malignancy and pregnancy

- Serum sickness-like reaction
  - Fever, nonspecific cutaneous eruption with possible bullous lesions, arthralgias
  - Onset 7 to 14 days
- Exfoliative dermatitis/erythroderma
  - Generalized erythema with exfoliation and/or fine desquamation over 90% of body surface
  - Difficult to distinguish between drug, primary cutaneous lymphoma, or inflammatory etiology
  - Lymphadenopathy, hepatosplenomegaly, leukocytosis, eosinophilia, or anemia may be present.
  - Increased risk of secondary infection and insensible fluid and temperature loss with hemodynamic instability

## *DIFFERENTIAL DIAGNOSIS*

- Viral exanthem: Presence of fever, lymphocytosis, and other systemic findings may help in narrowing differential.
- Primary dermatosis: Correlation of drug withdrawal to rash resolution may clarify diagnosis; skin biopsy is helpful.
- Bacterial infection: Cultures of pustules may distinguish primary infection from AGEP and acneiform eruptions.

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

A minimum number of tests are useful in evaluating for internal organ involvement. CBC with differential; significant eosinophilia may be seen in DRESS and other drug-induced allergic reactions. LFT, urinalysis, and serum creatinine; chest x-ray if suspected vasculitis

### *Diagnostic Procedures/Other*

- Special tests depend on suspected mechanism:
  - Type I: skin/intradermal testing, radioallergosorbent (RAST)
  - Type II: direct/indirect Coombs test

- Type III: ESR, C-reactive protein, ANA, antihistone antibody, tissue biopsy for immunofluorescence studies
- Type IV: patch testing, lymphocyte proliferation assay (investigational)
- Anaphylaxis/nonimmunologic mast and basophil cell reaction: serum tryptase levels
- Cultures useful in excluding infectious etiology; skin biopsy is nonspecific but useful in characterizing an eruption and excluding primary skin pathologies.
- Develop a timeline documenting the onset and duration of all drugs, dosages, and onset of cutaneous eruption (1)[A].

## *Test Interpretation*

- Nonspecific histologic findings are superficial epidermal and dermal infiltrates composed variably of lymphocytes, neutrophils, and eosinophils.
- SJS/TEN: partial or full-thickness necrosis of the epidermis necrotic keratinocytes, vacuolization leading to subepidermal blister at basal membrane zone

## **TREATMENT**

### *GENERAL MEASURES*

- Monitor for signs of impending cardiovascular collapse: Anaphylactic reactions, DRESS, SJS/TEN, extensive bullous reactions, and generalized erythroderma may require inpatient treatment.
- Do not rechallenge with drugs causing urticaria, bullae, angioedema, DRESS, anaphylaxis, or erythema multiforme.

### *MEDICATION*

- Withdrawal of offending drug. Depending on the type of eruption, symptomatic treatment may be useful, but most require no additional therapy except cessation of offending agent.
- Anaphylaxis or widespread urticaria: epinephrine 0.1 to 0.5 mg (1:1,000 [1 mg/mL] solution) SC every 5 to 15 min; prednisone may be given to prevent recurrence.
- Acute urticaria (<6 weeks) and chronic urticaria (>6 weeks): 2nd-generation antihistamines (preferred, less sedating): cetirizine 10 to 20 mg daily, loratadine 10 to 20 mg daily, fexofenadine 180 mg daily, levocetirizine 5 to 10 mg daily. 1st-generation antihistamines: diphenhydramine 10 to 25 mg QHS, hydroxyzine 10 to 25 mg TID, doxepin 10 to 50 mg QHS  
H<sub>2</sub> antagonists: cimetidine 400 mg BID, ranitidine 150 mg BID

- Anaphylaxis, severe urticaria: prednisone PO 1 mg/kg in tapering doses
- Erythema multiforme
  - Treatment is generally supportive with management of suspected underlying infection.
  - Herpes simplex virus (HSV)-associated: prophylaxis with acyclovir 400 mg BID, valacyclovir 500 to 1,000 mg/day, or famciclovir 250 mg BID
  - Magic mouthwash BID or TID is helpful for mucosal erosions. Consider ophthalmology consult for severe ocular involvement (4)[B].
- SJS/TEN: Treatment is supportive. Consult with a dermatologist and ophthalmologist. Systemic corticosteroid use remains controversial. Consider IVIG 2 to 3 g/kg for severe disease. In pediatric TEN patients, low-dose IVIG (0.05 to 0.1 g/kg/day) was effective. Varied success rates reported with use of anti-tumor necrosis factor- $\alpha$  agents, cyclosporine, cyclophosphamide, and plasmapheresis (5)[C],(6)[A].
- DRESS: prompt removal of offending drug and supportive measures; high-potency topical steroids for rash; systemic steroids with severe organ involvement; prednisone 0.5 to 2 mg/kg/day with prolonged taper 8 to 12 weeks (3)[B].

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- For urticarial, bullous, DRESS, or erythema multiforme spectrum lesions, close follow-up is needed.
- Patients with anaphylaxis/angioedema should be given EpiPen for secondary prevention and a Med-Alert bracelet; label the patient's medical record with the agent and reaction.
- If the patient needs to take the inciting drug (e.g., antibiotic) in the future, induction of drug tolerance or graded challenge procedures may be necessary.

### PROGNOSIS

- Eruptions generally begin fading within days after removing offending agent. With morbilliform eruptions, eruption may spread distally even when agent is removed, resolving over time.
- Anaphylaxis, angioedema, DRESS, SJS/TEN, and bullous reactions are potentially fatal.

### COMPLICATIONS

Anaphylaxis, bone marrow suppression, hepatitis (dapsone, hydantoin), renal failure, and pulmonary and thyroid toxicity

## Codes

&NA;

## ICD10

- L27.1 Loc skin eruption due to drugs and meds taken internally
- L50.0 Allergic urticaria
- R21 Rash and other nonspecific skin eruption

## Clinical Pearls

## **&NA;**

- Virtually, any drug can cause a rash; antibiotics are the most common culprits that cause cutaneous drug reactions.
- Focus on drug history with new suspicious skin eruptions.
- Usually self-limited after withdrawal of offending agent
- Symptoms such as tongue swelling/angioedema, skin necrosis, blisters, high fever, dyspnea, and mucous membrane erosions signify more severe drug reactions.
- Useful resources: Drug Eruption Reference Manual by Jerome Litt;  
[www.drugeruptiondata.com](http://www.drugeruptiondata.com); [www.druginteractions.com](http://www.druginteractions.com)

# Cystic Fibrosis

Brandon W. Bonds, MD

Tatiana P. Ivan, MD

## BASICS

### *DESCRIPTION*

- Cystic fibrosis (CF) is an autosomal recessive genetic mutation (CFTR gene) that most prominently affects the pulmonary and pancreatic systems.
- The GI, endocrine, and reproductive systems as well as the liver, sinuses, and skin can all be involved.
- Initially a pediatric disease, CF has become a chronic pediatric and adult medical condition as improvements in medical care have led to a dramatic increase in long-term survival.

### *EPIDEMIOLOGY*

CF is the most common lethal inherited disease in Caucasians and is found in every racial group.

#### *Incidence*

Number of infants born with CF in relation to the total number of live births in the United States

- 1 in 3,000 Caucasians
- 1 in 4,000 to 10,000 Latin Americans
- 1 in 15,000 to 20,000 African Americans
- 1 in 30,000 Asian Americans

#### *Prevalence*

- 30,000 patients with CF living in the United States
- ÷1,000 new diagnoses are made annually.

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Abnormal CFTR function leads to abnormally viscous secretions that alter organ function.

The lungs: obstruction, infection, and inflammation negatively affect lung growth, structure, and function

- Decreased mucociliary clearance
- Infection is accompanied by an intense neutrophilic response.
- Degradation of supporting tissues causes bronchiectasis and eventual failure.

## *Genetics*

*CFTR* gene (cystic fibrosis transmembrane conductance regulator): >1,500 mutations exist that can cause varying severity of phenotypic CF, all of which are recessively inherited. Most common is loss of the phenylalanine residue at 508th position ( $\Delta F508$ ), which accounts for 8.7% of affected alleles in the CF population in the United States. *G551D* mutation accounts for 4.3% of affected alleles.

## *RISK FACTORS*

CF is a single-gene disorder. The severity of the phenotype can be affected by the specific *CFTR* mutation (most predictive of pancreatic disease), other modifier genes (*CFTM1* for meconium ileus), gastroesophageal reflux disease (GERD), severe respiratory virus infection, and environmental factors such as tobacco smoke exposure.

## *GENERAL PREVENTION*

Preconception counseling

- American Congress of Obstetricians and Gynecologists (ACOG) recommends preconception or early (1st/2nd trimester) genetic analysis for all North American couples planning a pregnancy, with appropriate counseling to identified carriers and genetic analysis of siblings of known CF patients.
- Universal newborn screening (NBS) has been integral in early diagnosis (62% of new CF diagnosis in 2013 were found by NBS)
- Patients diagnosed prior to onset of symptoms have better lung function, nutritional outcomes, and should receive referral and early intervention services by an accredited regional CF center.

## *Pregnancy Considerations*

- Pulmonary disease may worsen during pregnancy.
- CF may cause increased incidence of preterm delivery, IUGR, and cesarean section (1)[A].
- Advances in fertility treatments now allow men with CF to father children (2)[A].

# DIAGNOSIS

## HISTORY

- Suspect with failure to thrive, steatorrhea, and recurrent respiratory problems
  - Chronic/recurrent respiratory symptoms, including airway obstruction and infections\*\*
  - Persistent infiltrates on chest x-rays (CXRs)
  - Hypochloremic metabolic acidosis
- Hx during neonatal period
  - Meconium ileus (20%) (generally considered pathognomonic for CF)
  - Prolonged jaundice
- Hx during infancy
  - Failure to thrive
  - Chronic diarrhea
  - Anasarca/hypoproteinemia
  - Pseudotumor cerebri (vitamin A deficiency)
  - Hemolytic anemia (vitamin E deficiency)
- Hx during childhood
  - Recurrent endobronchial infection
  - Bronchiectasis
  - Chronic pansinusitis
  - Steatorrhea
  - Poor growth
  - DIOS
  - Allergic bronchopulmonary aspergillosis
- Hx for adolescence and adulthood (7% diagnosed >18 years old) (3)[A]
  - Recurrent endobronchial infection
  - Bronchiectasis
  - Allergic bronchopulmonary aspergillosis
  - Chronic sinusitis
  - Hemoptysis
  - Pancreatitis

- Portal hypertension
- Azoospermia
- Delayed puberty

## *PHYSICAL EXAM*

- Respiratory
  - Rhonchi and/or crackles
  - Hyperresonance on percussion
  - Nasal polyps
- GI: Hepatosplenomegaly when cirrhosis is present.
- Other: digital clubbing, growth retardation, and pubertal delay

## *COMMONLY ASSOCIATED CONDITIONS*

- CF-related diabetes (CFRD)
  - May present as steady decline in weight, lung function, or increased frequency of exacerbation
  - Leading comorbid complication (20.3%)
  - Result of progressive insulin deficiency
  - Early screening and treatment may improve reduced survival found in CFRD (4)[A].
- Upper respiratory
  - Rhinosinusitis is seen in up to 100% of patients with CF.
  - Nasal polyps are seen in up to 86% of patients.
- The GI tract
  - Pancreatic exocrine insufficiency (85-90%) (1)[A]
  - Malabsorption of fat, protein, and fat-soluble vitamins (A, D, E, and K)
  - Hepatobiliary disease (10.8%)
  - Focal biliary cirrhosis
  - Cholelithiasis
  - Meconium ileus at birth (10-15%) (5)[A]

- Distal intestinal obstruction syndrome (DIOS): intestinal blockage that typically occurs in older children and adults (5.1%) (2)[A]
- GERD (31.3%) (2)[A]
- Endocrine
  - Bone mineral disease (14.8%) (2)[A]
  - Joint disease (2.9%) (2)[A]
  - Hypogonadism
  - Frequent low testosterone levels in men
  - Menstrual irregularities are common.
- Reproductive organs
  - Congenital bilateral absence of the vas deferens: obstructive azoospermia in 98% of males
- Depression (12%) (2)[A]

## *DIFFERENTIAL DIAGNOSIS*

- Immunologic
  - Severe Combined Immunodeficiency
- Pulmonary
  - Difficult-to-manage asthma
  - COPD
  - Recurrent pneumonia
  - Chronic/recurrent sinusitis
  - Primary ciliary dyskinesia
- Gastrointestinal
  - Celiac disease
  - Protein-losing enteropathy
  - Pancreatitis of unknown etiology
  - Shwachman-Diamond syndrome

## *DIAGNOSTIC TESTS & INTERPRETATION*

## *Initial Tests (lab, imaging)*

- NBS tests blood levels of immunoreactive trypsin (IRT) (2)[A].
- Patients must have clinical symptoms of CF involving at least one organ system
- Sweat test (gold standard)
  - Sweat chloride
    - >60 mmol/L (on 2 occasions) is (+) for CF.
    - <40 mmol/L is normal.
  - CFTR mutation analysis
  - Limited panel testing: Allele-specific polymerase chain reaction (PCR) identifies >90% of mutations; finite chance of false-negative finding. Full-sequence testing is more costly and time-consuming.
  - Nasal potential difference (when sweat test and DNA testing inconclusive)
  - CXR

## *Follow-Up Tests & Special Considerations*

To further investigate the presence of CF-related complications, these tests are generally ordered:

- Sputum culture (common CF organisms)
- Pulmonary function tests (PFTs)
- 72-hour fecal fat, stool elastase
- Oral glucose tolerance test (OGTT) annually after age 10 years

---

P.253

- Head CT: Abnormal sinus CT findings are nearly universal in CF and may include mucosal thickening, intraluminal sinus polyps, and sinus effusions.
- Chest CT (not routine): useful when unusual findings noted on CXR

## *Diagnostic Procedures/Other*

- Flexible bronchoscopy
- Bronchoalveolar lavage

## TREATMENT

### GENERAL MEASURES

- CF Foundation Guidelines call for yearly evaluation:
  - 4 office visits, 4 respiratory cultures, PFTs q6mo, and at least 1 evaluation by a multidisciplinary team including dietician, GI, and social worker
  - PFT goals: >75% predicted for adults, >100% predicted for children <18 years old
  - Annual screening for ABPA for patients >6 years old with total serum IgE concentration
  - Annual influenza vaccination for all CF patients age >6 months and all other age appropriate recommended vaccines
  - Screen all adults for osteoporosis with a DXA scan.
  - Annual measurement of fat soluble vitamins to rule out vitamin deficiencies
  - Annual LFTs
  - Decrease exposure to tobacco smoke
  - All patients should be followed in a CF center (accredited sites are listed at [www.cff.org](http://www.cff.org)).
- Infant care:
  - Monthly visits for first 6 months of life and then every 2 months until 1 year of life
  - Fecal elastase testing and salt supplementation after diagnosis
  - Consider palivizumab for RSV prophylaxis in infants with CF <2 years (6)[A].
  - Avoidance of smoke

### MEDICATION

- Pulmonary infections:
  - Antibiotics, oral
    - *Staphylococcus aureus*: Bactrim (MRSA), doxycycline (MRSA) or cephalexin
    - *Pseudomonas aeruginosa*: fluoroquinolones
  - Antibiotics, inhaled
    - TOBI (tobramycin): for *P. aeruginosa*, nebulizer twice daily for 28 days; stop for 28 days, then resume use (7)[A]

- Colistin (more commonly used in Europe)
- Cayston (aerosolized aztreonam) (7)[A]
- Antibiotics, IV
  - *S. aureus*: Cefazolin or nafcillin
  - Methicillin-resistant *S. aureus* (MRSA): vancomycin or linezolid
  - *P. aeruginosa*: Zosyn or ceftazidime plus aminoglycoside (tobramycin)
  - Dual therapy synergistic
- Medications recommended for chronic use in pulmonary disease:
  - Recombinant human DNase (Dornase alpha) (7)[A]
  - Hypertonic saline
  - High-dose ibuprofen in patients 6 to 17 years old with FEV<sub>1</sub> <sup>≥</sup>60 PPV
  - Inhaled tobramycin or aztreonam in *P. aeruginosa* positive patients
  - Azithromycin in *P. aeruginosa* positive patients
  - Ivacaftor (VX770): A small-molecule CFTR potentiator shown to improve lung function and improve risk of pulmonary exacerbations in patients 6 years and older with at least one copy of *G551D* mutation (7)[A].
- Inhaled steroids are not recommended for chronic use in the absence of asthma or ABPA.
- Insufficient evidence to recommend for or against chronic use: inhaled *β*<sub>2</sub>-agonist, inhaled anticholinergics, leukotriene modifiers, inhaled colistin
  - Pancreatic enzymes (87.3%) (2)[A]
    - Often combined with H<sub>2</sub> blocker or PPI to increase effectiveness
  - Fat-soluble vitamin supplementation (A, D, E, and K)
  - Liver disease (cholestasis)
    - Ursodeoxycholic acid has not been proven effective.

## ADDITIONAL THERAPIES

- High frequency chest wall oscillation vest is the most widely used airway clearance technique.
- Aerobic exercise is used as an adjunct therapy for airway clearance (8)[A].

- CF-related bone disease: Consider bisphosphonate therapy.

## ***SURGERY/OTHER PROCEDURES***

- Timing for lung transplantation (bilateral) is polyfactorial (9)[A].
- 5-year posttransplant survival is up to 62%.
- Liver transplantation is reserved for progressive liver failure ± portal hypertension with GI bleeding.
- Nasal polypectomy in 4.5% of CF patients (2)[A]

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- CF exacerbations should always be admitted on contact precautions and private rooms.
- Pulmonary exacerbation (most common reason for admission)
- Bowel obstruction (due to DIOS, previously known as meconium ileus equivalent [MIE])
- Pancreatitis (in pancreatic-sufficient patients)
- Nasal cannula oxygen when SaO<sub>2</sub> <90%

### ***IV Fluids***

- Increased salt loss increases risk of hyponatremic hypochloremic dehydration.
- Cautious use of IV fluids

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Upon discharge for a pulmonary exacerbation, follow-up with CF provider within 2 to 4 weeks
- Routine clinic visits every 3 months, with airway cultures and pulmonary function testing
- Annual comprehensive nutritional evaluation (5)[A]

### ***DIET***

High-calorie, high-fat diet titrated to specific BMI goals established by the CF Foundation nutrition guidelines. If not meeting nutritional goals, dietician, pancreatize enzyme, and oral or tube

supplemental feeding should be considered if indicated (8)[A].

## **PATIENT EDUCATION**

Cystic Fibrosis Foundation: [www.cff.org](http://www.cff.org)

## **PROGNOSIS**

- Median survival is 40.7 years.
- Progression of lung disease usually determines length of survival.

## Codes

&NA;

### ICD10

- E84.9 Cystic fibrosis, unspecified
- E84.11 Meconium ileus in cystic fibrosis
- E84.0 Cystic fibrosis with pulmonary manifestations

## Clinical Pearls

&NA;

- Meconium ileus is virtually pathognomonic for CF.
- When sweat test is equivocal, CFTR genetic testing is diagnostic.
- CF must be considered in *any* child with chronic diarrhea, especially if associated with poor growth or failure to thrive.
- All children with nasal polyps, digital clubbing, or bronchiectasis should be evaluated.
- A rapid decline in pulmonary function suggests the acquisition of resistant organisms (e.g., *Burkholderia cepacia*), CFRD, allergic bronchopulmonary aspergillosis (ABPA), or GERD.

# De Quervain Tenosynovitis

Jeff Wang, MD, MPH

J. Herbert Stevenson, MD

## BASICS

### DESCRIPTION

- First identified in 1895, de Quervain tenosynovitis is a painful condition due to stenosis of the tendon sheath in the first dorsal compartment of the radial aspect of the wrist.
- Caused by repetitive motion of the extensor pollicis brevis (EPB) and abductor pollicis longus (APL) over the radial styloid with resultant irritation of the surrounding tendon sheath

### EPIDEMIOLOGY

- The predominant age range is 30 to 50 years.
- Women are affected more commonly than men (1).

### Incidence

- The overall incidence of de Quervain tenosynovitis is 0.9/1,000 person-years (1).
- For patients age >40 years, the incidence is 1.4/1,000 person-years compared with 0.6/1,000 person-years for those younger than 20 years.
- Women have an incidence rate ratio of 2.8/1,000 person-years compared with 0.6/1,000 person-years in men.
- The incidence ratio rate of de Quervain tenosynovitis is 1.3/1,000 person-years in blacks and 0.8/1,000 person-years in whites.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Repetitive motions of the wrist and/or thumb result in microtrauma and thickening of the tendons (EPB, APL) and surrounding tendon sheath
- EPB and APL movement is resisted as they glide over the radial styloid causing pain with movements of the thumb and wrist.

## **RISK FACTORS**

- Women age 30 to 50 years
- Pregnancy (primarily 3rd trimester and postpartum)
- African American
- Systemic diseases (e.g., rheumatoid arthritis)
- Participation in activities that include repetitive motion or forceful grasping with thumb and wrist deviation such as golf, fly fishing, racquet sports, rowing, or bicycling
- Repetitive movements with the hand/thumb requiring forceful grasping with wrist involving ulnar/radial deviation; dental hygienists, musicians, carpenters, assembly workers, and machine operators

## **GENERAL PREVENTION**

Avoid overuse or repetitive movements of the wrist and/or thumb associated with forceful grasping and ulnar/radial deviation.

## **DIAGNOSIS**

### **HISTORY**

- Repetitive motion activity; overuse of wrist or thumb
- Gradually worsening pain along the radial aspect of the thumb and wrist with certain movements, particularly ulnar deviation of the wrist
- Pregnancy
- Sports, leisure, and occupational history
- Trauma (rare)

## **PHYSICAL EXAM**

- Pain over the radial styloid exacerbated when patients move the thumb or make a fist.
- Crepitus with movement of the thumb
- Swelling over the radial styloid and base of the thumb
- Decreased range of motion of the thumb
- Pain over the 1st dorsal compartment on resisted thumb abduction or extension
- Tenderness may extend proximally or distally along the tendons with palpation or stress.

Finkelstein test: The examiner grasps the affected thumb and deviates the hand sharply in the ulnar direction. A positive test occurs when there is pain along the distal radius.

- Eickhoff test: Patient grasps a flexed thumb and the examiner deviates the wrist in an ulnar direction.
- Finkelstein test is more sensitive for determining tenosynovitis of the APL and EPB tendons (2) [A].

## *DIFFERENTIAL DIAGNOSIS*

- Scaphoid fracture
- Scapholunate ligament tear
- Dorsal wrist ganglion
- Osteoarthritis of the 1st carpometacarpal joint
- Flexor carpi radialis tendonitis
- Infectious tenosynovitis
- Tendonitis of the wrist extensors
- Intersection syndrome
- Trigger thumb

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Primarily a clinical diagnosis. Radiographs of the wrist to rule out other pathology, such as carpometacarpal (CMC) arthritis, if the diagnosis is in question.
- MRI is the imaging test of choice to rule out coexisting soft tissue injury or wrist joint pathology.

### *Follow-Up Tests & Special Considerations*

Ultrasound can help to detect anatomic variations in the 1st dorsal extensor compartment of the wrist and target corticosteroid injections (3),(4)[C],(5)[B].

### *Test Interpretation*

Inflamed and thickened retinacular sheath of the tendon

## TREATMENT

- Most cases of de Quervain syndrome are self-limited.
- Rest and NSAIDs (2)[A]
- Ice (15 to 20 minutes 5 to 6 times a day)
- Immobilization with a thumb spica splint (2)[A]
- Occupational therapy (6)[A]
- Corticosteroid injection (ultrasound guided) (7)[A]
- Consider surgery if conservative measures fail >6 months.

## GENERAL MEASURES

- If full relief is not achieved, a corticosteroid injection of the tendon sheath can improve symptoms.
- Anatomic variation, including two tendon sheaths in the 1st compartment or the EPB tendon traveling in a separate compartment may complicate treatment. Ultrasound can distinguish these variants and improve anatomic accuracy of injections (3),(8)[B],(9,10).
- Surgical release may be indicated after 3 to 6 months of conservative treatment if symptoms persist. Surgery is highly effective and has a relatively low rate of complications.

## MEDICATION

### *First Line*

Splinting, rest, and NSAIDs

### *Second Line*

- Corticosteroid injection of the tendon sheath has shown significant cure rates. An 83% success rate after single injection has been reported. Additional injections are sometimes required (7) [A].
- Corticosteroid injection plus immobilization is more effective than immobilization alone (5)[B].
- Addition of hyaluronic acid to the corticosteroid injection improves outcome and reduces recurrence (11)[B].
- A 4-point injection technique may be preferred to 1- and 2-point injection techniques in high-resistance training athletes (12)[B].

- Percutaneous tenotomy and/or injection of platelet-rich plasma are newer techniques that show promise for treatment of de Quervain tenosynovitis.

## ***ISSUES FOR REFERRAL***

Referral to a hand surgeon is indicated if there is no improvement with conservative therapy.

## ***ADDITIONAL THERAPIES***

- Hand therapy, along with iontophoresis/phonophoresis, may help improve outcomes in persistent cases.
- Patients may use thumb-stretching exercises as part of their rehabilitation.

## ***SURGERY/OTHER PROCEDURES***

- Indicated for patients who have failed conservative treatment
- Endoscopic release may provide earlier relief, fewer superficial radial nerve complications, and greater patient satisfaction with resultant scar compared to open release (5)[B].

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Hospitalization for care associated with surgical treatment

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Additional corticosteroid injection may be performed at 4 to 6 weeks if symptoms persist. Caution with repeat steroid injections.
- Avoid repetitive motions and activities that cause pain.

### ***DIET***

As tolerated

### ***PATIENT EDUCATION***

Activity modification: Avoid repetitive movement of the wrist/thumb and forceful grasping.

## PROGNOSIS

Extremely good with conservative treatment. Complete resolution can take up to 1 year. 95% success rates have been shown with conservative therapy over 1 year. Up to 1/3 of patients will have recurrence (7)[A].

## COMPLICATIONS

- Most complications are secondary to treatment. This includes GI, renal, and hepatic injury secondary to NSAID use.
- Nerve damage may occur during surgery (13)[B].
- Hypopigmentation, fat atrophy, bleeding, infection, and tendon rupture have been reported as potential adverse events from corticosteroid injection. Ultrasound guidance reduces the rate of complications (14)[B].
- If not appropriately treated, thumb flexibility may be lost due to fibrosis.

&NA;

Algorithm: Pain in Upper Extremity

## Codes

&NA;

### ICD10

M65.4 Radial styloid tenosynovitis [de Quervain]

## Clinical Pearls

&NA;

- Repetitive movements of the wrist and thumb, and activities that require forceful grasping are the most common causes of de Quervain tenosynovitis.
- Initial treatment is typically conservative.
- Corticosteroid injections are helpful and have lower complication rates if done under ultrasound guidance.
- Surgery is helpful for recalcitrant cases.

# Deep Vein Thrombophlebitis

Denisse V. Tafur, MD

Alfonso Tafur, MD, MS, RPVI

## BASICS

### DESCRIPTION

- Development of blood clot within the deep veins, usually accompanied by inflammation of the vessel wall
- Major clinical consequences are embolization (usually to the lung) and postphlebitic syndrome.
- System(s) affected: cardiovascular

### EPIDEMIOLOGY

- Age and gender adjusted incidence of venous thromboembolism (VTE) is 100 times higher in the hospital than in the community. Almost half of all VTEs occur either during or soon after discharge from a hospital stay or surgery.
- Of patients with VTE, 1/3 die within 30 days, 20% will have sudden death due to pulmonary embolism (PE). The 28-day DVT fatality rate is 9%.

### Incidence

- In the United States, VTE occurs for the first time in 100/100,000 persons/year.
- $\div$ 2/3 of the new VTE cases are DVT alone.
- Higher incidence among Caucasians and African Americans relative to Hispanics and Asians
- Complicates  $\div$ 1/1,000 pregnancies

### Prevalence

Variable; depends on medical condition or procedure

- 22-52% of the patients with PE have DVT.
- 25% of patients with superficial venous thrombosis (1)[B]
- Present in 11% of patients with acquired brain injury entering to neurorehabilitation

## ETIOLOGY AND PATHOPHYSIOLOGY

Factors involved may include venous stasis, endothelial injury, and abnormalities of coagulation.

### Genetics

- Factor V Leiden is found in 5% of the population and in 20% of all VTE events. It is the most common thrombophilia. Homozygosity is found in 1/5,000 persons. It increases the risk of VTE 3- to 8-fold in heterozygous carriers and 50- to 80-fold in homozygous.
- Prothrombin 20210A is found in 3% of Caucasians. Increases the risk of thrombosis ÷ 3-fold.

## RISK FACTORS

- Acquired: age, previous thrombosis, immobilization, major surgery, orthopedic surgery, malignancy, oral contraceptives, hormonal replacement therapy, antiphospholipid syndrome, polycythemia vera, paroxysmal nocturnal hemoglobinuria, pregnancy/puerperium, diabetes who developed VTE
- Inherited: antithrombin deficiency, protein C deficiency, protein S deficiency, factor V Leiden R506Q, prothrombin G20210A, dysfibrinogenemia
- Mixed/unknown: hyperhomocysteinemia, high levels of factor VIII, high levels of thrombin activatable fibrinolysis inhibitor (TAFI), high levels of factor XI

## GENERAL PREVENTION

- Mechanical thromboprophylaxis is recommended in patients with high bleeding risk and as adjunct to anticoagulant-based thromboprophylaxis.
- Compression stockings have conflicting data on postthrombotic syndrome prevention (2)[B].
- Risk stratification of hospitalized patients using standardized scores is recommended (i.e., Caprini score).
- For acutely ill and for critically ill hospitalized patients at increased risk of thrombosis, low-molecular-weight heparin [LMWH], low-dose unfractionated heparin [LDUH], or fondaparinux are recommended (3)[C].
- Rivaroxaban and apixaban are approved in United States for surgical DVT prevention.
- For most patients, prolonged secondary prophylaxis is not recommended.

Modified Wells criteria

- Active cancer +1 point. Calf swelling >3 +1 point. Collateral superficial veins +1 point. Pitting edema +1 point. Previous documented DVT +1 point. Swelling of entire leg +1 point. Localized pain along distribution of deep venous system +1 point. Paralysis, paresis, or recent cast immobilization of lower extremities +1 point. Recently bedridden >3 days or major surgery requiring regional or general anesthetic in past 4 weeks +1 point. Alternative diagnosis at least as likely -2 points
- Interpretation: Score 0 to 1 DVT unlikely. Score <sup>3</sup>2: moderate to high probability.

## **HISTORY**

- Establish pretest probability based on Wells criteria.
- Classify as “provoked” or “idiopathic” based on underlying risk factors, that is, surgery, cancer, pregnancy, trauma.
- Clinical assessment of bleeding risk: bleeding with previous history of anticoagulation, history of liver disease, recent interventions, history of GI bleed

## **PHYSICAL EXAM**

- Physical exam is only 30% accurate for DVT.
- Resistance to dorsiflexion of the foot (Homan sign) is unreliable.
- Swelling of collateral veins. Massive edema with cyanosis is a medical emergency (phlegmasia cerulea dolens, rare).
- Thoracic outlet maneuvers in upper extremity DVT
- Attention to signs of possible malignancy

## **DIFFERENTIAL DIAGNOSIS**

Cellulitis, fracture, ruptured synovial cyst (Baker cyst), lymphedema, muscle strain/tear, extrinsic compression of vein (e.g., by tumor/enlarged lymph nodes), compartment syndrome, localized allergic reaction

## **DIAGNOSTIC TESTS & INTERPRETATION**

### *Initial Tests (lab, imaging)*

- D-dimer (sensitive but not specific; has a high negative predictive value [NPV])
- Patients with a prior DVT and those with malignancy have a high rate of VTE, which decreases the NPV of Wells prediction rule (4).

CBC, platelet count, activated partial thromboplastin time (aPTT), prothrombin time (PT)/INR

- In young patients with idiopathic/recurrent VTE, consider thrombophilia testing.
- Compression ultrasound (CUS): noninvasive; sensitive and specific for popliteal, femoral thrombi but has poor ability to detect calf vein thrombi
- Contrast venography: gold standard, is technically difficult, risk of morbidity
- Impedance plethysmography: as accurate as duplex US, less operator dependent but poor at detecting calf vein thrombi; not widely available
- MR venography: as accurate as contrast venography; may be useful for patients with contraindications to IV contrast
- <sup>125</sup>I-fibrinogen scan: detects only active clot formation; very good at detecting ongoing calf thrombi; takes 4 hours for results
- In patients with suspected DVT, the choice of diagnostic test process should be guided by the assessment of the pretest probability.
  - Low pretest probability: D-dimer, proximal CUS
  - Moderate pretest probability: D-dimer, proximal CUS, whole leg US
  - High pretest probability: proximal CUS, whole leg US
  - If negative, no further testing is recommended.
  - If positive
    - Low pretest probability, then CUS
    - Moderate pretest probability, then proximal CUS/whole leg US
    - CUS: if positive, treat DVT; if negative
  - Low pretest probability, no further testing
  - Moderate pretest probability, repeat proximal CUS in 1 week

### *Follow-Up Tests & Special Considerations*

Risk of an underlying malignancy is more likely if recurrent VTE, risk 3.2 (95% CI 2.0-4.8).

Unprovoked VTE, 4.6 times higher (vs. secondary); upper extremity DVT, not catheter associated; odds ratio (OR) 1.8, abdominal DVT; OR 2.2, (5) bilateral lower extremity DVT, OR 2.1 (5)

## **TREATMENT**

# MEDICATION

All proximal DVTs should receive treatment. Consider starting therapy even before confirmation in patients with high pretest probability.

## First Line

- Unfractionated heparin (UFH)
    - IV drip: initial dose of 80 U/kg or 5,000 U followed by continuous infusion of 18 U/kg/hr. Target an aPTT ratio >1.5. The aPTT prolongation should correspond to a 0.3 to 0.7 anti-Xa level.
    - SC UFH: monitored: 17,500 U or 250 U/kg BID with aPTT adjustment to an equivalent to 0.3 to 0.7 anti-Xa. Alternatively, fixed dose: 333 U/kg followed by BID dose 250 U/kg.
  - Enoxaparin (Lovenox): 1 mg/kg/dose SC q12h or 1.5 mg/kg/dose OD
  - Dalteparin (Fragmin): 200 U/kg SC q24h
  - Fondaparinux (Arixtra): 5 mg (body weight <50 kg), 7.5 mg (body weight = 50 to 100 kg), or 10 mg (body weight >100 kg) SC once daily
  - Rivaroxaban (Xarelto): 15 mg PO twice daily with food for the first 3 weeks.
  - Apixaban (Eliquis): 10 mg PO twice daily for 1 week followed by 2.5 to 5 mg PO twice daily
  - 2016 CHEST guidelines recommend using dabigatran, rivaroxaban, apixaban, or edoxaban instead of vitamin K antagonists for the first 3 months' treatment. Evidence to support these recommendations remains mixed. Because of cost and insurance coverage, implementation of these recommendations will be variable (<http://journal.publications.chestnet.org/article.aspx?articleid=2479255>).
- 
- P.257
- Maintenance therapy
    - Warfarin (Coumadin): 5 mg/day for 3 days, then adjust to a target INR of 2 to 3; overlap with injectable anticoagulant for minimum of 5 days and two consecutive therapeutic INRs
    - Rivaroxaban (Xarelto): 20 mg PO once daily with food after the first 3 weeks
    - Apixaban (Eliquis): 2.5 to 5 mg PO twice daily after the first 1 week
    - Dabigatran (Pradaxa): 150 mg PO twice daily (CrCl >30 mL/min) after 5 to 10 days of parenteral anticoagulant
    - Edoxaban (Savaysa): 60 mg PO once daily following 5 to 10 days of initial therapy with a parenteral anticoagulant (30 mg If CrCl 15 to 50 mL/min or <sup>2</sup>60 kg)
  - Adverse effects

- Heparin or LMWH: bleeding, edema, injection site irritation, skin eruptions, hematoma, thrombocytopenia
- Fondaparinux: bleeding, injection site irritation, rash, fever, anemia
- Warfarin: bleeding, skin necrosis, teratogenicity
- Rivaroxaban: bleeding, anemia, rash, increase in transaminases
- Dabigatran: bleeding, rash, edema
- Edoxaban: bleeding, rash, anemia
- Contraindications
  - Heparin or LMWH: bleeding, heparin hypersensitivity, heparin-induced thrombocytopenia (HIT), idiopathic thrombocytopenic purpura (ITP)
  - Fondaparinux: bleeding, thrombocytopenia
  - Warfarin: current bleeding, alcoholism, preeclampsia, pregnancy, surgery

## *Second Line*

Heparin can be given by intermittent SC self-injection.

## *Pregnancy Considerations*

- Warfarin (Coumadin) is a teratogen; treat with full-dose heparin initially, followed by SC heparin starting at 15,000 U q12h.
- Warfarin is safe with breastfeeding.
- LMWH, dalteparin, fondaparinux, apixaban are pregnancy Category B.
- Dabigatran, Edoxaban are pregnancy Category C.

## **ADDITIONAL THERAPIES**

Edoxaban (recently FDA approved) after initial treatment with heparin is as effective as warfarin in preventing recurrences in patients with acute VTE and has less bleeding complications (6)[B].

## **SURGERY/OTHER PROCEDURES**

- In selected patients with proximal DVT (iliofemoral DVT, <2 weeks of symptoms, good functional status, >1 year of life expectancy), consider catheter-directed thrombolysis/open thrombectomy.
- When anticoagulants have failed or are contraindicated, filtering devices are recommended in

the acute setting.

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

Admission for respiratory distress, proximal VTE, candidate for thrombolysis, active bleeding, renal failure, phlegmasia cerulea dolens, history of HIT

### ***Nursing***

Limb elevation and multilayered compression.

### ***Discharge Criteria***

Medically stable and properly anticoagulated; overlap of anticoagulation and warfarin monitoring may be done as an outpatient.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Gradual resumption of normal activity, with avoidance of prolonged immobility
- Duration of warfarin treatment after DVT
  - 3 months for treatment of a DVT secondary to a reversible risk factor
  - Patients with unprovoked DVT can be considered for prolonged secondary prophylaxis
    - In patients who have completed 3 months of anticoagulation after an unprovoked VTE, a positive D-dimer 1 month after discontinuation of therapy correlates with the risk of VTE recurrence (7)[A].

### ***Patient Monitoring***

- Monitor platelet count while on heparin, LMWH, fondaparinux.
- An anti-Xa activity level may help guide LMWH titration of therapy, but it is not usually needed.
- Investigate significant bleeding (e.g., hematuria or GI hemorrhage) because anticoagulant therapy may unmask a preexisting lesion (e.g., cancer, peptic ulcer disease, or arteriovenous malformation).

## **PATIENT EDUCATION**

- Patients should wear compression stockings post-DVT.
- Dietary habits should be discussed when warfarin is initiated to ensure that intake of vitamin K-rich foods is monitored.

## PROGNOSIS

- 20% of untreated proximal (e.g., above the calf) DVTs progress to pulmonary emboli, and 10-20% of those are fatal; with anticoagulant therapy, mortality is decreased 5- to 10-fold.
- DVT confined to the infrapopliteal veins has a small risk of embolization but can propagate into the proximal system.

## COMPLICATIONS

PE (fatal in 10-20%), arterial embolism (paradoxical embolization) with arteriovenous (AV) shunting, chronic venous insufficiency, postphlebotic syndrome (pain and swelling in affected limb without new clot formation), treatment-induced hemorrhage, soft tissue ischemia associated with massive clot and high venous pressures; phlegmasia cerulea dolens (rare but a surgical emergency)

- I80.299 Phlebitis and thombophlb of deep vessels of unsp low extrm
- I80.10 Phlebitis and thrombophlebitis of unspecified femoral vein

## Clinical Pearls

### &NA;

- Many cases are asymptomatic and are diagnosed after embolization.
- Of the patients with superficial thrombophlebitis, 25% will have DVT at presentation.
- Heparin and warfarin should overlap for a minimum of 5 days to achieve target INR.
- The current American Society of Clinical Oncology guidelines acknowledge the value of primary prophylaxis in selected patients with active cancer receiving outpatient chemotherapy.

# Dehydration

Jerin Mathew, MD

Mony Fraer, MD, FACP, FASN

## BASICS

### DESCRIPTION

- Dehydration is a state of negative fluid balance; strictly defined as free water deficiency
- The two types of dehydration:
  - Water loss
  - Salt and water loss (combination of dehydration and hypovolemia)

### EPIDEMIOLOGY

- Cause of 10% of all pediatric hospitalizations in the United States
- Gastroenteritis, one of its leading causes, accounts to 13/1,000 children <5 years of age annually in the United States.

### Incidence

- More than half a million hospital admissions annually in the United States for dehydration
- Of hospitalized older persons, 7.8% have the diagnosis of dehydration (1).
- Worldwide, ÷3 to 5 billion cases of acute gastroenteritis occur each year in children <5 years of age, resulting in nearly 2 million deaths.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Negative fluid balance occurs when ongoing fluid losses exceed fluid intake.
- Fluid losses can be insensible (sweat, respiration), obligate (urine, stool), or abnormal (diarrhea, vomiting, osmotic diuresis in diabetic ketoacidosis).
- Negative fluid balance can ultimately lead to severe intravascular volume depletion (hypovolemia) and ultimately end-organ damage from inadequate perfusion.
- The elderly are at increased risk as kidney function, urine concentration, thirst sensation,

aldosterone secretion, release of vasopressin, and renin activity are all significantly lowered with age.

- Decreased intake
- Increased output: vomiting, diarrheal illnesses, sweating, frequent urination
- Third spacing of fluids: effusions, ascites, capillary leaks from burns, or sepsis

## *Genetics*

Some underlying causes of dehydration have a genetic component (diabetes), whereas others do not (gastroenteritis).

## **RISK FACTORS**

- Children <5 years of age at highest risk
- Elderly
- Decreased cognition
- Lack of access to water such as in critically sick intubated patients

## **GENERAL PREVENTION**

- Patient/parent education on the early signs of dehydration
- Observing universal precautions (including hand hygiene)

## *Geriatric Considerations*

A systematic approach in assessing risk factors is necessary for early prevention and management of dehydration in the elderly, especially those in long-term care facilities.

## **COMMONLY ASSOCIATED CONDITIONS**

- Hypo-/hypernatremia
- Hypokalemia
- Hypovolemic shock
- Renal failure

## **DIAGNOSIS**

Calculate % dehydration = (preillness weight - illness weight)/preillness weight × 100.

Supplement this along with the ongoing fluid loss.

## Clinical Finding

(2)	Mild	Moderate	Severe
Dehydration: children	5-10%	10-15%	>15%
Dehydration: adults	3-5%	5-10%	>10%
General condition: infants	Thirsty, alert, restless	Lethargic/drowsy	Limp, cold, cyanotic extremities, may be comatose
General condition: older children	Thirsty, alert, restless	Alert, postural dizziness	Apprehensive, cold, cyanotic extremities, muscle cramps
Quality of radial pulse	Normal	Thready/weak	Feeble or impalpable
Quality of respiration	Normal	Deep	Deep and rapid/tachypnea
BP	Normal	Normal to low	Low (shock)
Skin turgor	Normal skin turgor	Reduced skin turgor, cool skin	Skin tenting, cool, mottled, acrocyanotic skin
Eyes	Normal	Sunken	Very Sunken
Tears	Present	Absent	Absent
Mucous membranes	Moist	Dry	Very dry
Urine output	Normal	Reduced	None passed in many hours
Anterior fontanelle	Normal	Sunken	Markedly sunken

## HISTORY

- Fever
- Intake (including description and amount)

- Diarrhea (including duration, frequency, consistency, ± mucus/blood)
- Vomiting (including duration, frequency, consistency, ± bilious/nonbilious)
- Urination pattern
- Sick contacts
- Medication history (e.g., diuretics, laxatives)

## *PHYSICAL EXAM*

- The most useful individual signs for identifying dehydration in children are prolonged capillary refill time, abnormal skin turgor, and abnormal respiratory pattern (3).
- Vitals: pulse, BP, temperature
- Orthostatic vital signs: Take BP and heart rate (HR) while supine, sitting, and standing.
  - Systolic BP decrease by 20, diastolic BP decrease by 10, or HR increase by 20 highly suggestive of hypovolemia (4)
- Weight loss: <5%, 10%, or >15%
- Mental status
- Head: sunken anterior fontanelle (for infants)
- Eyes: sunken, ± tear production
- Mucous membranes: tacky, dry, or parched
- Capillary refill: ranges from brisk to >3 seconds

## *DIFFERENTIAL DIAGNOSIS*

- Decreased intake: ineffective breastfeeding, inadequate thirst response, anorexia, malabsorption, metabolic disorder, obtunded state
- Excessive losses: gastroenteritis, diarrhea, febrile illness, diabetic ketoacidosis, hyperglycemia, hyperosmolar hyperglycemic state, diabetes insipidus, intestinal obstruction, sepsis

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- For mild dehydration: generally not necessary
- For moderate to severe dehydration
  - Blood work, including electrolytes, BUN, creatinine, and glucose

- Urinalysis (specific gravity, hematuria, glucosuria)
- Imaging does not play a role in the diagnosis of dehydration, unless diagnosis of the specific medical condition causing the dehydration requires imaging.
- In adults, there is evidence to support the use of inferior vena cava collapsibility as a surrogate marker for volume status.

### *Pediatric Considerations*

Infants and the elderly may not concentrate urine maximally, so a nonelevated specific gravity should not be reassuring.

P.259

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Oral rehydration is the first-line treatment in dehydrated children. If this is unsuccessful, use IV rehydration. If IV unobtainable, nasogastric (NG) rehydration can be considered (5).
- Oral rehydration is the first-line treatment in dehydrated adults as long as they can tolerate fluids. Have a lower threshold for IV rehydration if needed.
- If the patient is experiencing excessive vomiting, consider using an antiemetic.
- Ondansetron (PO/IV) may be effective in decreasing the rate of vomiting, improving the success rate of oral hydration, preventing the need for IV hydration, and preventing the need for hospital admission (6,7).
- Other antiemetics can be used.

#### *Second Line*

- Loperamide may reduce the duration of diarrhea compared with placebo in children with mild to moderate dehydration (two randomized controlled trials [RCTs] yes, one RCT no).
- In children ages 3 to 12 years with mild diarrhea and minimal dehydration, loperamide decreases diarrhea duration and frequency when used with oral rehydration.

### *Pediatric Considerations*

Given a higher risk for serious adverse events, loperamide is not indicated for children <3 years

of age with acute diarrhea.

## ***ISSUES FOR REFERRAL***

- For severe dehydration, critical care referral and ICU-level care may be warranted.
- Surgical consultation for acute abdominal issues

## ***SURGERY/OTHER PROCEDURES***

For specific underlying causes of dehydration, such as intestinal obstruction or appendicitis

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Intractable vomiting/diarrhea
- Electrolyte abnormalities
- Hemodynamic instability
- Inability to tolerate oral rehydration therapy (ORT)
- Stabilize ABCs.
- If mild dehydration, try ORT.
- If excessive vomiting/severe dehydration with shock, start IV access and IV fluids immediately.

### ***IV Fluids***

- Stage I
  - For moderate to severe dehydration in children: isotonic saline or Ringer lactate solution bolus of 10 to 20 mL/kg; may repeat up to 60 mL/kg; if still hemodynamically unstable, consider colloid replacement (blood, albumin, fresh frozen plasma) and address other causes for shock.
  - For moderate to severe hypovolemia in adults: isotonic saline or Ringer lactate 20 mL/kg/hr until normal state of consciousness returns/vital signs stabilize. Also consider colloid replacement if continued fluids required beyond 3 L.
- Stage II: Replace fluid deficit along with maintenance over 48 hours. Fluid deficit = preillness weight - illness weight.
- An alternative IV treatment option for moderate (10%) dehydration in children
  - Bolus with NS/LR at 20 mL/kg for 1 hour

- Replete fluid deficit with D5 1/2 NS + 20 mEq KCl/L at 10 mL/kg for 8 hours (hours 2 to 9).
- Replete 1.5 for maintenance fluids with D5 1/4 NS + 20 mEq/L of KCl for 16 hours (hours 10 to 24).
- An alternative to IV fluids is hypodermoclysis, the SC infusion of fluids into the body.
  - Indications: hydration of patients with mild to moderate dehydration who do not tolerate oral intake because of cognitive impairment, severe dysphagia, advanced terminal illness, or intractable vomiting. It is also indicated to prevent dehydration, especially in frail elderly residents living in long-term care settings who reject the oral route for any reason; useful technique for patients with difficult IV access
  - Contraindications: severe dehydration or shock, patients with coagulopathy or receiving full anticoagulation, patients with severe generalized edema (anasarca) or congestive heart failure, and those with fluid overload (8)

## *Nursing*

Strict inputs and outputs: oral and IV input and output of urine and stool, which may include weighing wet diapers

## *Discharge Criteria*

- Input > output
- Underlying etiology treated and improving

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

Activity as tolerated

- If mild to moderate dehydration, the patient may be mobile without restrictions, although watch for orthostasis/falls.
- If moderate to severe dehydration, bed rest.

## *Patient Monitoring*

Ongoing surveillance for recurrence

## *DIET*

- Bland food such as bananas, rice, apples, toast (BRAT) diet

- If diarrhea, avoid dairy for 48 hours after symptoms resolve. One review of weak RCTs and three of five subsequent RCTs found that lactose-free feeds reduced the duration of diarrhea in children with mild to severe dehydration, compared with lactose-containing feeds. However, two subsequent RCTs found no difference between lactose-free and lactose-containing feeds in duration of diarrhea.
- Small frequent sips of room temperature liquids
- For children, Pedialyte (liquid or popsicles)
- Continue breastfeeding ad lib.

## PATIENT EDUCATION

- Patients should go to the nearest emergency facility or call 911 if they or their child feels faint or dizzy when rising from a sitting or lying position, becomes lethargic and/or confused, or complains of a rapid heart rate.
- Patients should call their physician if they are unable to keep down any fluids, vomiting has been going on >24 hours in an adult or >12 hours in a child, diarrhea has lasted >2 days in an adult/child, or an infant/child is much less active than usual or is very irritable.
- Patient information on dehydration: <http://www.mayoclinic.org/diseases-conditions/dehydration/basics/definition/con-20030056>

## PROGNOSIS

Self-limited if treated early; potentially fatal

### COMPLICATIONS

- Seizures
- Renal failure
- Cardiovascular arrest

Oral Rehydration

## Codes

&NA;

## ICD10

- E86.0 Dehydration
- E87.1 Hypo-osmolality and hyponatremia
- E86.1 Hypovolemia

## Clinical Pearls

&NA;

- Dehydration is the result of a negative fluid balance and is a common cause of hospitalization in both children and the elderly.
- Begin by assessing the level of dehydration and determining the underlying cause.
- Treatment is directed at restoring fluid balance via oral rehydration (first-line) therapy or IV fluids and treating underlying causes.

# Delayed Sleep-Wake Phase Disorder (DSWPD)

Adam J. Sorscher, MD

## BASICS

### DESCRIPTION

- Circadian rhythm sleep disorders (CRSDs) are a family of conditions that occur when an individual's preferred timing of sleep is not synchronized to commitments to job, school, family, or social engagements. In CRSDs, intrinsic sleep is normal (i.e., there is no sleep fragmenting condition such as obstructive sleep apnea or periodic limb movement disorder). However, when forced by obligations to attempt sleep at nonpreferred times, individuals with CRSDs may complain of both sleep-initiation insomnia and excessive sleepiness in their wake time. These symptoms resolve entirely if the individual is allowed to sleep at his or her preferred time.
- Delayed sleep-wake phase disorder (DSWPD) is marked by a stable but persistent inability to initiate sleep at a desired time. Individuals are typically unable to initiate sleep until 2 to 6 hours later than societal norms (typically after 2 AM), and this frequently results in insufficient sleep/sleepiness in the day that follows.

### EPIDEMIOLOGY

DSWPD is the most common circadian rhythm disorder seen by referral in sleep medicine clinics.

#### *Prevalence*

DSWPD has an estimated prevalence of 0.1-0.2% in the general population. It is most common in adolescents, with a prevalence of 7-16%.

### ETIOLOGY AND PATHOPHYSIOLOGY

In all mammals, an oscillating signal from the suprachiasmatic nucleus (SCN) in the anterior hypothalamus establishes circadian rhythms, including the propensity to be awake or asleep. The average period of this signal in humans is 24.2 hours, slightly longer than the environmental day. Certain factors, most significantly morning light, shift the timing of the circadian rhythm and thereby synchronize it to the shorter environmental cycle day by day. DSWPD occurs when the circadian rhythm is not adequately synchronized to the shorter 24-hour environmental cycle, creating a mismatch between them. Some theories to account for inadequate synchronization are that it occurs in individuals who have an abnormally long circadian period (>25 hours) or whose

circadian clock does not properly respond to synchronizing agents such as light (1).

- Release of melatonin from the pineal gland in the evening initiates a cascade of events that usually triggers sleep behavior several hours later. Studies suggest that the timing of melatonin release within the circadian cycle is delayed by 40 to 120 minutes in late adolescence compared with prepuberty. This suggests that the tendency for teenagers to delay sleep onset is largely a genetically programmed developmental phenomenon.
- DSWPD is the result of biologic, behavioral, and psychosocial factors. The relative contributions of genetically predetermined endogenous factors (the shifting of the circadian phase just described) versus voluntary behaviors that delay bedtime are not fully delineated.

## *Genetics*

Emerging evidence indicates a genetic component to DSWPD. A positive family history is reported in approximately 40% of individuals. In one familial case report, DSWPD was shown to occur in an autosomal dominant inheritance pattern. Polymorphisms in circadian rhythm genes such as *hPer3* and *clock* among individuals with DSWPD constitute evidence of a genetic component to the disorder (2).

## **RISK FACTORS**

DSWPD primarily affects adolescents and young adults. A cohort who have a biologic tendency to delay the onset of sleep yet often need to be up early for school/work responsibilities. Children with autism spectrum disorders also frequently have disturbed circadian rhythm cycles.

## **GENERAL PREVENTION**

In DSWPD (and all CRSDs), careful attention to sleep hygiene is necessary to establish and maintain a desired sleep schedule. The most important behavioral practices needed to prevent an undesirably late fall-asleep time are as follows:

- Maintain a regular sleep/wake schedule 7 days/week.
- Avoid daytime napping.
- Minimize caffeine and stimulants.
- Avoid stimulating activities in the late evening, such as computer, TV, and social interactions. A 30-minute "wind-down" time prior to bedtime in which homework, socializing, and electronic devices are off-limits is helpful.
- If computer screens are to be used in the evening, consider "apps" that filter out blue and green wavelengths because these frequencies are especially potent at further delaying the onset of sleep.
- Attempt to arise at a similar time on weekends as on school/work mornings. Adolescents who

sleep *ad lib* on the weekends (sometimes into the afternoon) often find that they have especially great difficulty initiating sleep on Sunday night and, thus, get the week off to a bad start.

## DIAGNOSIS

### HISTORY

- People with DSWPD report both sleep initiation insomnia and excessive sleepiness in the daytime. They do not initiate sleep until 2 to 6 hours later than normative sleep times and they struggle to awaken for school/work in the morning.
- Careful questioning should explore for competing/comorbid causes of insomnia (poor sleep hygiene, significant mental health disorders, restless legs syndrome, medical conditions/medication side effects, and substance abuse disorders) and for competing/comorbid causes of hypersomnolence (symptoms of narcolepsy and obstructive sleep apnea, voluntary insufficient sleep, medical conditions/medication side effects, and substance abuse disorders).
- In contrast to DSWPD, individuals with psychophysiologic insomnia (psychologically conditioned arousal when attempting to initiate sleep) do not usually experience genuine hypersomnolence in the daytime despite short sleep times overnight, but instead complain of fatigue.
- People with DSWPD will have no complaint about sleep/wakefulness and their sleep will be of normal duration when they are able to sleep at their preferred time (e.g., their sleep/wakefulness complaints resolve when on summer vacation from school, when they can choose their own preferred sleep-wake schedule).

### PHYSICAL EXAM

Explore for features of sleep apnea, a competing cause of hypersomnolence: obesity/large neck circumference; hypertension; crowded oropharynx

### DIFFERENTIAL DIAGNOSIS

DSWPD and other CRSDs are unique in that they are often marked by the twin complaints of insomnia when attempting to sleep *and* hypersomnolence in the wake period. Other sleep disorders usually cause either insomnia or hypersomnolence but not both. DSWPD and other CRSDs resolve entirely if the individual is allowed to sleep at his or her preferred time.

## DIAGNOSTIC TESTS & INTERPRETATION

- Diagnosis of DSWPD is made primarily by thorough history taking.
- Sleep logs completed over 3 weeks time graphically reveal fall-asleep times that are consistently 2 to 6 hours later than societal norms and much later wake-up times (not infrequently in the afternoon) on days off from school/work (3)[B].
- Wrist actigraphy (using a wristwatch-like device with an accelerometer), undertaken for 3 weeks, also provides an accurate display of sleep and wake timing but is usually not reimbursable by insurance and is not needed if the individual can complete sleep logs (3)[B].
- Testing in the sleep lab is not indicated unless a suspicion exists of comorbid intrinsic disorders of sleep, such as sleep apnea, narcolepsy, or parasomnias (unusual behaviors arising out of sleep) (3)[A].

## TREATMENT

- The goal of treatment in DSWPD is to help the individual consistently initiate sleep at an earlier time. The principal therapies that advance sleep onset are light and melatonin (factors that shift the circadian rhythm are called zeitgebers). Comparatively, light is much more potent than melatonin in its phase-shifting ability. The phase-shifting effects of light and melatonin depend on the timing at which they are provided as depicted in the phase-response

P.261

curve (see online version). Key points: Light will advance sleep onset to an earlier time if provided after the body's temperature nadir that occurs  $\div 2/3$  through the habitual sleep phase and for several hours thereafter. Proper timing is critical because exposure to light in the evening or *before* the temperature nadir (i.e., in the initial  $2/3$  of the sleep period) will have the opposite effect—it will further delay sleep onset. For melatonin, the most potent phase-advancing effect occurs if it is provided in the evening, 4 to 6 hours before an individual's usual sleep onset time.

- Use the following rules to guide prescribing of light in order to advance sleep phase (3)[B]:
  - No single rule exists for intensity, duration, or wavelength for light therapy. Most protocols employ a 2,500 to 10,000 lux full-spectrum light box, set 2 to 3 feet from the individual for 30 to 120 minutes. A common prescription is 10,000 lux box for 30 minutes upon awakening in the morning. Retailers of full-spectrum light boxes abound on the Internet. Sunlight, when present in the morning in warm-weather seasons, is equally effective.
  - Prescribe exposure to full-spectrum light immediately upon awakening. (Note: Although the phase-advancing effect of light is actually greatest if it is provided *immediately* after the body temperature nadir that occurs  $\div 2/3$  through the sleep period, the strategy of waiting

until the habitual waking time is preferred for these reasons: [i] it acknowledges that it is onerous for the individual to wake up artificially early for light therapy and [ii] it minimizes the risk of unintentionally providing light *before* the temperature nadir, which further delays the sleep phase.)

- Light exposure in the evening has the effect of delaying sleep phase and worsening DSWPD. Instruct individuals to limit light exposure in the evening (consider using sunglasses or curtailing outdoor activities in warm-weather months).
- Contraindications to phototherapy include retinopathy, photosensitivity, and bipolar disorder.

## MEDICATION

- Prescribe melatonin to be taken 4 to 6 hours before the habitual (usual) fall-asleep time, *not* at bedtime. Melatonin in minute doses is as effective as higher doses in producing phase-shift; therefore, use the lowest dose available—usually 1 or 3 mg (3)[B].
- Once earlier sleep onset and wake-up occurs, adjust the timing of therapies every 3 to 5 days—continue to use light directly upon awakening; provide melatonin earlier and earlier in the evening corresponding to 4 to 6 hours before the newly observed fall-asleep time.

### ALERT

Melatonin has a weak sedating effect, and individuals should be counseled not to drive/operate dangerous machines after taking the medication. Other side effects include headache and unusual taste in mouth.

## ISSUES FOR REFERRAL

- Referral for evaluation and testing at a sleep clinic is not necessary in most cases of DSWPD. The chief indications for referral are suspicion of the following comorbid disorders:
  - Obstructive sleep apnea: indicated by loud snoring, obesity/large neck, witnessed apneas, and history of hypertension
  - Narcolepsy: indicated by severe levels of daytime sleepiness, despite adequate sleep quantity, and sometimes accompanied by cataplexy (bouts of sudden muscular weakness triggered by strong emotions)
  - Parasomnias: undesirable experiential/behavioral phenomena that arise out of sleep, such as dangerous sleepwalking or dream-enactment behavior
- In addition, many individuals with the complaint of insomnia/sleepiness have comorbid mental health disorders, primarily depression and possibly substance abuse. Referral for mental health disorders/substance abuse treatment is indicated if these are present.

## ADDITIONAL THERAPIES

- Chronotherapy is an older strategy in which the individual is instructed to delay sleep and wake times by 2 to 3 hours every 2 to 3 days, shifting the sleep cycle across the 24-hour day, until the individual reaches a desired bedtime. Carried out over several weeks, this protocol is extremely disruptive to daytime schedules and also has not been demonstrated to be effective. It is seldom used (4).
- Some early reports suggest that vitamin B<sub>12</sub> has circadian phase-shifting properties. This finding has not been confirmed in subsequent investigations, and presently, no evidence seen of benefit to the use of this supplement in CRSDs (3)[B].
- Use of sedative-hypnotic medications to treat the insomnia component and stimulant medications to treat daytime sleepiness has not been shown to be effective in the context of DSWPD (3)[C].

## ONGOING CARE

Remind patients to practice healthy sleep behaviors (see "General Prevention") if they wish to maintain an earlier sleep/wake pattern.

## Codes

### &NA;

## ICD10

G47.21 Circadian rhythm sleep disorder, delayed sleep phase type

## Clinical Pearls

### &NA;

- The tendency to become Ònight-owlishÓ with adolescence is, to a large extent, a biologically programmed phenomenon, not strictly a behavioral choice. Enlightened public policy would recognize this and allow for later start times for high schools.
- DSWPD can be diagnosed with careful history taking and sleep logs; referral for formal sleep studies is usually not indicated.
- Use of light and melatonin can shift habitual sleep onset and offset time by their action on the human circadian rhythm.
- To maintain a desirable sleep phase, individuals with DSWPD usually need to maintain meticulous attention to sleep hygiene, including a regular sleep/wake schedule 7 days/week, to avoid lapsing into a delayed phase pattern.

# Delirium

Whitney A. Gray, CRNP

Katrina A. Booth, MD

## BASICS

### *DESCRIPTION*

- A neurologic complication of illness and/or medication(s), especially common in older patients, manifested by new confusion and impaired attention
- A medical emergency requiring immediate evaluation to decrease morbidity and mortality
- System(s) affected: nervous
- Synonym(s): acute confusional state, altered mental status, organic brain syndrome, acute mental status change

### *EPIDEMIOLOGY*

- Predominant age: older persons
- Predominant sex: male = female

### *Incidence*

- >50% in older ICU patients
- 11-51% in postoperative patients
- 10-40% in hospitalized older patients

### *Prevalence*

- 8-17% in older ED patients
- 14% in older postacute care patients

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Multifactorial: believed to result from a decline in physiologic reserves with aging, resulting in a vulnerability to new stressors

- Neuropathophysiology is not clearly defined; cholinergic deficiency, dopamine excess, and neuroinflammation are the leading hypotheses.
- Often interaction between predisposing and precipitating risk factors
- With more predisposing factors (i.e., frail patients), fewer precipitating factors are needed to cause delirium.
- If few predisposing factors (e.g., very robust patients), more precipitating factors are needed to cause delirium.
- Multicomponent approach addressing contributing factors can reduce incidence and complications.

## *RISK FACTORS*

- Predisposing risk factors (1)
  - Advanced age, >70 years
  - Preexisting cognitive impairment
  - Functional impairment
  - Dehydration; high BUN:creatinine ratio
  - History of alcohol abuse
  - Malnutrition
  - Hearing or vision impairment
- Precipitating risk factors
  - Severe illness in any organ system(s)
  - Environmental irritants (urinary catheter, restraints)
  - Polypharmacy (<sup>35</sup> medications)
  - Specific medications, especially benzodiazepines, opioids (meperidine), and anticholinergics (diphenhydramine)
  - Pain
  - Any iatrogenic event
  - Surgery
  - Sleep deprivation

## GENERAL PREVENTION

Follow treatment approach.

## COMMONLY ASSOCIATED CONDITIONS

Multiple but most common are the following:

- New medicine or medicine changes
- Infections (especially lung, urine, and blood stream, but consider meningitis as well)
- Toxic-metabolic (especially low sodium, elevated calcium, renal failure, and hepatic failure)
- Heart attack or stroke
- Alcohol or drug withdrawal
- Preexisting cognitive impairment increases risk

## DIAGNOSIS

Diagnosis is made using a careful history, behavioral observation, and cognitive assessment.

- *DSM-5* is the current standard; diagnostic criteria include (2):
  - Disturbance in attention and awareness
  - Change in cognition not due to dementia
  - Onset over short (hours to days) period and fluctuates during course of day
  - Evidence from history, exam, or lab that disturbance is caused by physiologic consequence of medical condition, intoxicating substance, medication use, or more than one cause
- The confusion assessment method (CAM) is the most well-validated and tested clinical tool and has been adapted for ICU setting in adults (CAM-ICU) and children (pediatric CAM-ICU [pCAM-ICU]) (3)[B].

### ALERT

- Key diagnostic features of the CAM
  - Acute change in mental status that fluctuates
  - Abnormal attention and either disorganized thinking or altered level of consciousness
- Several nondiagnostic symptoms may be present:
  - Short- and long-term memory problems

- Sleep-wake cycle disturbances
- Hallucinations and/or delusions
- Emotional lability
- Tremors and asterixis
- Subtypes based on level of consciousness
  - Hyperactive delirium (15%): Patients are loud, agitated, and disruptive.
  - Hypoactive delirium (20%): quietly confused; sleepy, may sit and not eat, drink, or move
  - Mixed delirium (50%): features of both hyperactive and hypoactive delirium
  - Normal consciousness delirium (15%): still displays disorganized thinking, along with acute onset, inattention, and fluctuation

## **HISTORY**

- Time course of mental status changes
- Recent medication changes
- Symptoms of infection
- New neurologic signs
- Abrupt change in functional ability

## **PHYSICAL EXAM**

- Comprehensive cardiorespiratory exam is essential.
- Focal neurologic signs are usually absent.
- Mini-mental state exam (MMSE) is the most wellknown and studied cognitive screen, but it may not be the most appropriate in an acute care setting; shorter cognitive screens have been studied in delirious patients (i.e., short blessed test [SBT], Brief Alzheimer's Screen [BAS], and Ottawa 3DY) and may be helpful if performed serially over time. Most patients will perform poorly if delirium is present; dementia cannot be diagnosed during delirium.
- GI/GU exam for constipation/urinary retention

## **DIFFERENTIAL DIAGNOSIS**

- Depression (slow onset, disturbance of mood, normal level of consciousness, fluctuates weeks to months)
- Dementia (insidious onset, memory problems, normal level of consciousness, fluctuates days

to weeks)

- Psychosis (rarely sudden onset in older adults)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Guided by history and physical exam
  - CBC with differential
  - Comprehensive metabolic panel (CMP)
  - Urinalysis, urine culture, blood culture
  - Medication levels (digoxin, theophylline, antiepileptics where applicable)
- Chest radiograph for most
- ECG as necessary
- Others, if indicated by history and exam

### *Follow-Up Tests & Special Considerations*

- If lab tests listed above do not indicate a precipitator of delirium, consider
  - Arterial blood gases
  - Troponin
  - Toxicology screen
  - Ammonia
  - Thyroid-stimulating hormone
- Noncontrast-enhanced head CT scan if
  - Unclear diagnosis
  - Recent fall
  - Receiving anticoagulants
  - New focal neurologic signs
  - Need to rule out intracranial mass before lumbar puncture

### *Diagnostic Procedures/Other*

- Lumbar puncture (rarely necessary)
  - Perform if clinical suspicion of a CNS bleed or infection is high.
- EEG (rarely necessary)
  - Consider after above evaluation if cause remains unclear or suspicion of seizure activity.

## TREATMENT

- The best treatment is prevention (4)[A].
- Addressing six risk factors (i.e., cognitive impairment, sleep deprivation, dehydration, immobility, vision impairment, and hearing impairment) in at-risk hospitalized patients can reduce the incidence of delirium by 33%.
- Principles: Maintain safety, identify causes, and manage symptoms.
- Stabilize vital signs and ensure immediate evaluation.

## GENERAL MEASURES

- Postoperative patients should be monitored and treated for
  - Myocardial infarction/ischemia
  - Infection (i.e., pneumonia, UTI)
  - Pulmonary embolism
  - Urinary or stool retention (attempt catheter removal by postoperative day 2)
- Anesthesia route (general vs. epidural) does not affect the risk of delirium.
- ICU sedation-avoidance of benzodiazepines may reduce risk (5)[B].
- Multifactorial treatment: Identify contributing factors and provide preemptive care to avoid iatrogenic problems, with special attention to
  - CNS oxygen delivery (attempt to attain):
    - $\text{SaO}_2 > 90\%$  with goal of  $\text{SaO}_2 > 95\%$
    - Systolic BP  $< 2/3$  of baseline or  $> 90$  mm Hg
    - Hematocrit  $> 30\%$

- 
- Fluid/electrolyte balance

- Sodium, potassium, and glucose normal (glucose <300 mg/dL in diabetics)
- Treat fluid overload or dehydration.
- Treat pain
  - Schedule acetaminophen (650 mg QID) if daily pain
  - Opioids alone (morphine) or in combination (oxycodone, hydrocodone) may be used for breakthrough pain.

## **ALERT**

- Avoid meperidine (Demerol).
- Eliminate unnecessary medications.
  - Investigate new symptoms as potential medication side effects (i.e., Beers medications).
- Regulate bowel/bladder function.
  - Bowel movement at least every 48 hours
  - Screen for urinary retention.
  - Prevent major hospital-acquired problems.
  - 6-inch thick foam mattress overlay or a pressure-reducing mattress
  - Avoid urinary catheter.
  - Incentive spirometry
  - Venous thromboembolism (VTE) prophylaxis if bed-fast
  - Early mobilization
  - Environmental stimulation
    - Glasses and hearing aids
    - Clock and calendar
    - Soft lighting
    - Music and television, if desired
  - Sleep
    - Quiet environment
    - Soft music
    - Therapeutic massage
- Restraints increase risk of falls/injury
  - Use only in the most difficult-to-manage patients, as briefly as possible

---

## MEDICATION

- Nonpharmacologic approaches are preferred for initial treatment, but medication may be needed for agitation management, especially in the ICU setting (6)[C].
- Medications treat only the symptoms and do not address the underlying cause.
- No medication is FDA approved for delirium.
- Medications should not be used prophylactically.

### *First Line*

- Antipsychotics
  - Haloperidol (Haldol): initially, 0.25 to 0.5 mg PO/IM; reevaluate and potentially redose hourly. Critical care guidelines do not support use of antipsychotics for prevention of ICU delirium (5).
  - Quetiapine (Seroquel) 12.5 to 25 mg PO BID
  - Risperidone (Risperdal) 0.25 to 0.5 mg/day PO
- Benzodiazepines should be avoided except in alcohol withdrawal or if patient taking at baseline because delirium could be a sign of withdrawal.
- Lorazepam (Ativan): initially, 0.25 to 0.5 mg PO/IM/IV q6-8h; may need to adjust to effect (caution in patients with impaired liver function)
- Contraindications: Avoid typical antipsychotics in patients with Parkinsonism or Parkinson disease.
- Precautions: Typical antipsychotics may cause extrapyramidal effects; benzodiazepines may cause delirium. Both increase fall risk. Antipsychotics may prolong the QT interval.

### *Second Line*

- Olanzapine (Zyprexa) 2.5 to 5.0 mg/day PO
- Multiple trials demonstrate adverse events with cholinesterase inhibitors in the management of delirium; evidence does not support their use.

## ISSUES FOR REFERRAL

Geriatric, psychiatric, or neurologic consultation is helpful if delirium is not easily explainable or resolving after full evaluation. Interprofessional team approach is best.

## *ADDITIONAL THERAPIES*

Early mobilization critical

- Out of bed several hours daily starting on hospital day 2 (or postoperative day 1) if no contraindications
- Daily therapy if not ambulating or functioning independently

## *INPATIENT CONSIDERATIONS*

General measures described earlier are also applicable to delirium prevention.

### *Admission Criteria/Initial Stabilization*

New delirium is a medical emergency and requires admission, except in the setting of palliative home care.

### *IV Fluids*

As needed for dehydration

### *Nursing*

- Screen for development of delirium.
- Assessment of precipitants/contributing factors (pain, constipation, urinary retention)
- Reorient; maintain day/night orientation.
- Institute skin care program and turning regimen for immobile patients.
- Maintain and encourage mobility.
- Encourage family presence and participation.

### *Discharge Criteria*

- Resolution of precipitating factor(s)
- Safe discharge site if delirium is slow to resolve

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- If delirium at discharge, often needs postacute facility and ongoing assessment for resolution
- If no delirium at discharge and going home, follow-up with primary care physician in 1 to 2

weeks

## *Patient Monitoring*

- Evaluate and assess mental status daily.
- Continued evaluation for precipitating cause(s)

## *DIET*

- Liberalize diet to increase oral intake
- Nutritional supplements (1 to 3 cans/day) if intake poor
- Consider temporary nasogastric tube if unable to eat and bowels working.

## *PROGNOSIS*

- May take weeks/months to fully resolve
- Usually improves with treatment of underlying condition(s); can lead to chronic cognitive impairment
- Delirium significantly increases a person's chance of dying even up to 1 year later.

## **COMPLICATIONS**

- Falls
- Pressure ulcers
- Malnutrition
- Functional decline
- Future cognitive dysfunction
- Higher risk for institutionalization
- Death

## Codes

&NA;

### ICD10

- R41.0 Disorientation, unspecified

- F19.931 Oth psychoactive substance use, unsp w withdrawal delirium
- F10.231 Alcohol dependence with withdrawal delirium

## Clinical Pearls

### &NA;

- The CAM criteria for delirium are acute onset of fluctuating mental status, inattention, and either disorganized thinking or altered level of consciousness.
- Hypoactive subtype of delirium can easily be missed.
- Addressing six risk factors (i.e., cognitive impairment, sleep deprivation, dehydration, immobility, vision impairment, and hearing impairment) in hospitalized patients can reduce the incidence of delirium by 33%.
- Delirium may not resolve as soon as the treatable contributors resolve; may take weeks or months
- Avoid diphenhydramine and benzodiazepines in older patients. Nonpharmacologic measures are preferable as a sleep aid.

# Dementia

Umer Farooq, MD, MBBS

Wajiha Ilyas, MD

## BASICS

### DESCRIPTION

- *DSM-5* classifies dementias under neurocognitive disorders (major and mild).
- Evidence of cognitive decline from previous level of performance in one of cognitive domains (attention, executive function, learning, and memory). The cognitive deficits interfere significantly with ADLs (for major only) and do not occur exclusively in the context of delirium or any other mental disorder.
- *DSM-5* specifies the cause of neurocognitive decline secondary to the following:
  - Alzheimer dementia (AD)
    - Progressive cognitive decline; most common in age >65 years
  - Vascular dementia (VaD)
    - Usually correlated with a cerebrovascular event and/or cerebrovascular disease
    - Stepwise deterioration with periods of clinical plateaus
  - Lewy body dementia
    - Fluctuating cognition associated with parkinsonism, hallucinations and delusions, gait difficulties, and falls
  - Frontotemporal dementia
    - Language difficulties, personality changes, and behavioral disturbances
  - Creutzfeldt-Jakob disease (CJD)
    - Very rare; rapid onset
  - HIV dementia
  - Substance-/medication induced neurocognitive disorder

# EPIDEMIOLOGY

## Prevalence

- In patients age  $\geq 71$  years
  - AD: 5-10% up to 25% after 7th decade of life
  - VaD: 17%
  - Other: 13%
- Estimated 5.4 million Americans had AD in 2010.
  - 5 million  $>65$  years of age; 200,000  $<65$  years
  - Prevalence expected to double by 2030

## ETIOLOGY AND PATHOPHYSIOLOGY

- AD: involves  $\beta$ -amyloid protein accumulation and/or neurofibrillary tangles (NFTs), synaptic dysfunction, neurodegeneration, and eventual neuronal loss
- Age, genetics, systemic disease, smoking, and other host factors may influence the  $\beta$ -amyloid accumulation and/or the pace of progression toward the clinical manifestations of AD.
- VaD: cerebral atherosclerosis/emboli with clinical/subclinical infarcts

## Genetics

- AD: Positive family history in 50%, but 90% AD is sporadic: *APOE4* increases risk but full role unclear.
- Familial/autosomal dominant AD accounts for  $<5\%$  AD: amyloid precursor protein (APP), presenilin-1 (PSEN-1), and presenilin-2 (PSEN-2)

## RISK FACTORS

- Age; sex: female  $>$  male
- Genetic predisposition
- Hypertension: AD; VaD
- Hypercholesterolemia: AD; VaD
- Diabetes: VaD
- Cigarette smoking: VaD

- Endocrine/metabolic abnormalities: hypothyroidism, Cushing syndrome, thiamine and vitamin B<sub>12</sub> deficiency
- Chronic alcoholism, other drugs
- Lower educational status
- Head injury early in life
- Sedentary lifestyle

## **GENERAL PREVENTION**

- Treat reversible causes of dementia, such as drug-induced, alcohol-induced, and vitamin deficiencies.
- Treat hypertension, hypercholesterolemia, and diabetes.
- No evidence for statins (or any other specific medication) to prevent onset of dementia (1)[A]
- BP control and low-dose aspirin may prevent or lessen cognitive decline in VaD.

## **COMMONLY ASSOCIATED CONDITIONS**

- Anxiety and major depression
- Psychosis (delusions; delusions of persecution are common)
- Delirium
- Behavioral disturbances (agitation, aggression)
- Sleep disturbances

## **DIAGNOSIS**

### **HISTORY**

Probable diagnosis AD (2)[B]:

- Age between 40 and 90 years (usually >65 years)
- Progressive cognitive decline of insidious onset
- No disturbances of consciousness
- Deficits in areas of cognition
- No other explainable cause of symptoms
- Specifically rule out thyroid disease, vitamin (B<sub>12</sub>) deficiency, grief reaction, and depression

- Supportive factors: family history of dementia

## *PHYSICAL EXAM*

- Often normal physical
- No disturbances of consciousness
- Cognitive decline demonstrated by standardized instruments, including the following:
  - Mini-mental state exam
  - Montreal Cognitive Assessment (MoCA) Test
  - ADAS-Cog
  - Clock draw test
  - Use caution in relying solely on cognition scores, especially in those with learning difficulty, language barriers, or similar limitations.

## *DIFFERENTIAL DIAGNOSIS*

- Major depression
- Medication side effect
- Chronic alcohol use
- Delirium
- Subdural hematoma
- Normal pressure hydrocephalus
- Brain tumor
- Thyroid disease
- Parkinson disease
- Vitamin B<sub>12</sub> deficiency
- Toxins (aromatic hydrocarbons, solvents, heavy metals, marijuana, opiates, sedative-hypnotics)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Used to rule out causes

- CBC, CMP
- Thyroid-stimulating hormone
- Vitamin B<sub>12</sub> level
- Select patients
  - HIV, rapid plasma regain (RPR)
  - Erythrocyte sedimentation rate (ESR)
  - Folate
  - Heavy metal and toxicology screen
- Research studies with cerebrospinal fluid (CSF) biomarkers in patient with confirmed AD have shown decreased A $\beta$  (1 to 42) and increased tau and p-tau levels, which are specific features of AD, and CSF tau proteins are increased in CJD (3)[A].
- Neuroimaging (CT/MRI of brain): cerebral atrophy
  - Early age of onset (<65 years), rapid progression, focal neurologic deficits, cerebrovascular disease risk, or atypical symptoms: neuroimaging (MRI/CT) to rule out other causes
  - Important findings
    - AD: diffuse cerebral atrophy starting in association areas, hippocampus, amygdala
    - VaD: old infarcts, including lacunar

## *Diagnostic Procedures/Other*

PET scan is not routinely recommended; has been approved to differentiate between Alzheimer disease and frontotemporal dementia

## *Test Interpretation*

AD

- Neurofibrillary tangles: abnormally phosphorylated tau protein
- Senile plaques: amyloid precursor protein derivatives
- Microvascular amyloid

## **TREATMENT**

## GENERAL MEASURES

- Daily schedules and written directions
- Emphasis on nutrition, personal hygiene, accident-proofing the home, safety issues, sleep hygiene, and supervision
- Socialization (adult daycare)
- Sensory stimulation (display of clocks and calendars) in the early to middle stages
- Discussion with the family concerning support and advance directives

## MEDICATION

- Cognitive dysfunction
- Medications for AD show a small, statistically significant improvement in some cognitive measures, but it remains unclear if the improvement is clinically significant (4)[A].
- Cognitive dysfunction, mild
  - Cholinesterase inhibitors: donepezil (Aricept), 5 to 10 mg/day; rivastigmine (Exelon), 1.5 to 6 mg BID, transdermal system 4.6 mg/24 hr and 9.5 mg/24 hr; galantamine (Razadyne), 4 to 12 mg BID, extended release 8 to 24 mg/day
    - Adverse events: nausea, vomiting, diarrhea, anorexia, nightmares, bradycardia/syncope
  - Galantamine warning: associated with mortality in patients with mild cognitive impairment in clinical trial
  - Start drug with lowest acquisition cost; also consider adverse event profile, adherence, medical comorbidity, drug interactions, and dosing profiles.
- Cognitive dysfunction, moderate to severe
  - Cholinesterase inhibitors *OR*
  - Memantine (Namenda), 5 to 20 mg/day
    - Adverse events: dizziness, confusion, headache, constipation
    - *OR* combination cholinesterase inhibitor and memantine
- Commonly associated conditions
  - Psychosis and agitation/aggressive behavior
    - Look for precipitating factors (infection, pain, depression, medications).

- Nonpharmacologic therapies (behavioral interventions, music therapy, etc.) are preferred as first-line treatment.
- Mood stabilizers (valproic acid, carbamazepine) have been used, although evidence is lacking.
- For moderate/severe symptoms; antipsychotics: Initiate low doses, risperidone 0.25 to 1 mg/day; olanzapine 1.25 to 5 mg/day; quetiapine 12.5 to 50 mg/day; aripiprazole 5 mg/day; ziprasidone 20 mg/day
- Atypical antipsychotics associated with a better side effect profile: Quetiapine and aripiprazole are often first-line due to decreased extrapyramidal side effect.

## **ALERT**

Black box warning on antipsychotics due to increased mortality in elderly with dementia

- Depression and insomnia
  - Depression
    - Selective serotonin reuptake inhibitors (SSRIs): Initiate low doses, citalopram (Celexa) 10 mg/day, escitalopram (Lexapro) 5 mg/day, sertraline (Zoloft) 25 mg/day.
    - Adverse events: nausea, vomiting, agitation, parkinsonian effects, sexual dysfunction, hyponatremia
    - Venlafaxine, mirtazapine, and bupropion are also useful.
  - Sleep disturbances
    - Low-dose antidepressants (e.g., Remeron) have significant sedative properties at 7.5 or 15 mg.
    - Trazodone 25 to 100 mg is frequently used because of better side effect profile.
  - Psychosis and agitation/aggressive behavior
    - Some data for SSRIs
    - Benzodiazepines if agitation with anxiety; in elderly, use PRN.

## *Geriatric Considerations*

Initiate pharmacotherapy at low doses and titrate slowly up if necessary.

- Benzodiazepines are potentially inappropriate for older adults; yet, their use persists.

## **ALERT**

Benzodiazepine use is associated with increased fall risk (5)[B].

- Watch decreased renal function and hepatic metabolism.

## **ISSUES FOR REFERRAL**

Neuropsychiatric evaluation particularly helpful in early stages or mild cognitive impairment

## **ADDITIONAL THERAPIES**

Behavioral modification

- Socialization, such as adult daycare, to prevent isolation and depression
- Sleep hygiene program as alternative to pharmaceuticals for sleep disturbance
- Scheduled toileting to prevent incontinence

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Vitamin E is no longer recommended due to lack of evidence.
- Ginkgo biloba is not recommended due to lack of evidence.
- NSAIDs, selegiline, and estrogen lack efficacy and safety data.

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

- Worsening physical health issues
- Psychiatry admission may be required because of safety concerns (self-harm/harm to others), self-neglect, aggressive behaviors, or other behavioral issues.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Progression of cognitive impairment by use of standardized tool (e.g., MMSE, ADAS-Cog)
- Development of behavioral problems: sleep, depression, psychosis
- Adverse events of pharmacotherapy

- Nutritional status
- Caregiver evaluation of stress
- Evaluate issues that may affect quality of life.

## *PATIENT EDUCATION*

- Safety concerns
- Long-term issues: management of finances, medical decision making, possible placement when appropriate; legal guardianship, if necessary, to avoid capacity and competency issues
- Advance directives
- National Institute on Aging. About Alzheimer's disease: other dementias.  
<http://www.nia.nih.gov/alzheimers/topics/other-dementias>

## *PROGNOSIS*

- AD: usually steady progression leading to profound cognitive impairment
  - Average survival of AD is about 8 years.
- VaD: incrementally worsening dementia, but cognitive improvement is unlikely
- Secondary dementias: Treatment of the underlying condition may lead to improvement. Commonly seen with normal pressure hydrocephalus, hypothyroidism, and brain tumors.

## **COMPLICATIONS**

- Wandering
- Delirium
- Sundown syndrome: It is frequently common in older people (who are sedated) and also in people who have dementia (adverse reaction to small dose of psychoactive substances).
- Falls with injury
  - Hip fracture
  - Head trauma/hematomas
- Neglect and abuse
- Caregiver burnout

### &NA;

Algorithm: Dementia

## Codes

**&NA;**

## **ICD10**

- F03 Unspecified dementia
- G30.9 Alzheimer's disease, unspecified
- F01.50 Vascular dementia without behavioral disturbance

## **Clinical Pearls**

**&NA;**

- Medications for AD show a small, statistically significant improvement in some cognitive measures, but it remains unclear if the improvement is clinically significant.
- Do not forget the role of adult protective services in case of elderly abuse.
- A particular concern in nursing homes relates to the use of physical restraints and antipsychotic medication, which are regulated in the United States by the Omnibus Reconciliation Act of 1987.

# Dementia, Vascular

**Birju B. Patel, MD, FACP, AGSF**

**N. Wilson Holland, MD, FACP, AGSF**

## BASICS

Vascular dementia is a heterogeneous disorder caused by the sequel of cerebrovascular disease that manifests in cognitive impairment affecting memory, thinking, language, behavior, and judgment.

## DESCRIPTION

- Vascular dementia (previously known as multi-infarct dementia) was first mentioned by Thomas Willis in 1672. Later, it was further described in the late 19th century by Binswanger and Alzheimer as a separate entity from dementia paralytica caused by neurosyphilis. This concept has evolved tremendously since the advent of neuroimaging modalities.
- Synonym(s): vascular cognitive impairment (VCI); vascular cognitive disorder (VCD); arteriosclerotic dementia; poststroke dementia; senile dementia due to hardening of the arteries; Binswanger disease. *Diagnostic and Statistical Manual of Mental Disorders (DSM-5)* categorizes vascular dementia as mild or major VCD.

## EPIDEMIOLOGY

Second most common cause of dementia after Alzheimer dementia in the elderly

### *Incidence*

About 6 to 12 cases/1,000/person age >70 years

### *Prevalence*

- ÷1.2-4.2% in those age >65 years
- 14-32% prevalence of dementia after a stroke

## ETIOLOGY AND PATHOPHYSIOLOGY

Upon autopsy of those with dementia, many have significant vascular pathology are present, but this is not necessarily correlated clinically with vascular dementia. No set pathologic criteria exist for the diagnosis of vascular dementia such as those that exist for Alzheimer dementia. Pathology

includes the following:

- Large vessel disease: cognitive impairment that follows a stroke
- Small vessel disease: includes white matter changes (leukoaraiosis), subcortical infarcts, and incomplete infarction. This is usually the most common cause of multi-infarct dementia.
- Subcortical ischemic vascular disease: due to small vessel involvement within cerebral white matter, brain stem, and basal ganglia. Lacunar infarcts and deep white matter changes are typically included in this category.
- Noninfarct ischemic changes and atrophy
- Transient ischemic attack (TIA)/stroke
- Vascular, demographic, genetic factors
- Vascular disease (i.e., hypertension [HTN], peripheral vascular disease [PVD], atrial fibrillation, hyperlipidemia, diabetes)

## *Genetics*

- Cerebral autosomal dominant arteriopathy with subcortical infarcts (CADASIL) is caused by a mutation in the *NOTCH3* gene on chromosome 19 that results in leukoencephalopathy and subcortical infarcts. This is clinically manifested in recurrent strokes and associated cognitive decline.
- Apolipoprotein E gene type: Those with ApoE4 subtypes are at higher risk of developing both vascular and Alzheimer dementia.
- Amyloid precursor protein (APP) gene: leads to a form of vascular dementia called heritable cerebral hemorrhage with amyloidosis (1)

## *RISK FACTORS*

- Age
- Previous stroke
- Smoking
- Diabetes (especially with frequent hypoglycemia)
- HTN
- Atrial fibrillation
- PVD
- Hyperlipidemia

- Metabolic syndrome
- Coronary atherosclerotic heart disease (2)

## GENERAL PREVENTION

- Optimization and aggressive treatment of vascular risk factors, such as HTN, diabetes, and hyperlipidemia (3)[C]
- HTN is the single most modifiable risk factor and treatment for it must be optimized.
- Smoking is associated with white matter changes on imaging which may be associated with small vessel disease and vascular dementia progression (4)[B].
- Lifestyle modification: weight loss, physical activity, smoking cessation
- Medication management for vascular risk reduction: aspirin usage, statin therapy for hyperlipidemia, antihypertensive therapy (5)[B]

## COMMONLY ASSOCIATED CONDITIONS

- CADASIL
- Cerebral amyloid angiopathy (CAA): accumulation of amyloid in cerebral vasculature resulting in infarctions and hemorrhages

## DIAGNOSIS

Differentiation between Alzheimer dementia and vascular dementia can be difficult, and significant overlap is seen in the clinical presentation of these two dementias. The diagnosis of vascular dementia is a clinical diagnosis.

## HISTORY

- Gradual, stepwise progression is typical.
- Ask about onset and progression of cognitive impairment and the specific cognitive domains involved.
- Ask about vascular risk factors and previous attempts to control these risk factors.
- Ask about medication compliance.
- Ask about urinary incontinence and gait disturbances. Abnormal gait and falls are strong predictors of development of vascular dementia, particularly unsteady, frontal, and hemiparetic types of gait.
- Look for early symptoms, including difficulty performing cognitive tasks,

memory, mood, and assessment of instrumental activities of daily living (IADLs).

- Past history may include TIAs, cerebrovascular accidents (CVAs), coronary atherosclerotic heart disease, atrial fibrillation, hyperlipidemia, and/or PVD.

## *PHYSICAL EXAM*

- Screen for HTN. Average daily BP and not office BP is associated with progression of cerebrovascular disease and cognitive decline in the elderly.
- Focal neurologic deficits may be present.
- Gait assessment is important, especially looking at gait initiation, gait speed, and balance (6) [C].(7)[B].
- Check for carotid bruits as well as abdominal bruits and assess for presence of PVD.
- Check body mass index and waist circumference.
- Do a thorough cardiac evaluation that includes looking for arrhythmias (i.e., atrial fibrillation).

## *DIFFERENTIAL DIAGNOSIS*

- Alzheimer dementia
- Depression
- Drug intoxication
- CNS tumors
- Hypothyroidism
- Vitamin B<sub>12</sub> deficiency

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Cognitive testing, such as Mini-Mental Status Exam (MMSE), Saint Louis University Mental Status (SLUMS), and Montreal Cognitive Assessment (MOCA), provides more definitive information in terms of cognitive deficits, especially executive function, which may be lost earlier in vascular dementia.
- Neuropsychological testing may also be beneficial, especially in evaluating multiple cognitive domains and their specific involvements and deficits.

### *Initial Tests (lab, imaging)*

As appropriate, consider CBC, comprehensive metabolic profile, lipid panel, thyroid function,

hemoglobin A1C, and vitamin B<sub>12</sub>.

- Imaging is used in conjunction with history and physical examination to support a clinical diagnosis of vascular dementia.
- Cognitive deficits observed clinically do not always have to correlate with findings found on neuroimaging studies.
- MRI is best in terms of evaluation of subtle subcortical deficits.
- White matter changes and specific location of these changes can be associated with executive dysfunction and episodic memory impairment (8)[C].

## TREATMENT

Prevention is the real key to treatment:

- Control of risk factors, including HTN, hyperlipidemia, and diabetes
- Avoidance of tobacco and smoking cessation
- Healthy, low-cholesterol diet

---

P.267

## MEDICATION

- Acetylcholinesterase inhibitors may be used but are of limited benefit in vascular dementia (9) [A].
- Clinical evidence for use of memantine is limited with the clinical benefit likely modest.
- Controlling BP with any antihypertensive medications, treatment of dyslipidemia (e.g., statins), and treatment of diabetes are very important.
- Nicardipine has been studied and has been found to have some neuroprotective effects for vascular dementia (10)[B].
- Selective serotonin receptor inhibitors (SSRIs) may be of benefit for agitation and psychosis in vascular dementia (11)[A].

## ADDITIONAL THERAPIES

- Limit alcohol drink intake to <sup>2</sup>1/day in women and 2/day in men.
- Heavy sustained alcohol use contributes to HTN.
- Aspirin and/or clopidogrel may be useful in some cases.

## ***SURGERY***

Carotid endarterectomy/stenting should be considered if evidence of significant internal carotid artery stenosis (i.e., >70-80%).

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Ginkgo biloba should be avoided due to increased risk of bleeding, especially in CAA.

## ***INPATIENT CONSIDERATIONS***

- Remain sensitive to functional assessment and avoidance of pressure ulcers after CVAs.
- Avoid Foley catheter usage unless absolutely necessary due to increased risk of infection.

## ***Nursing***

- Nonpharmacologic approaches to behavior management should be attempted prior to medication usage.
- Providing optimal sensory input to patients with cognitive impairment is important during hospitalizations to avoid delirium and confusion. Patients should be given frequent cues to keep them oriented to place and time. They should be informed of any changes in the daily schedule of activities and evaluations. Family and caregivers should be encouraged to be with patients with dementia as much as possible to further help them from becoming confused during hospitalization. Recreational, physical, occupational, and music therapy can be beneficial during hospitalization in avoiding delirium and preventing functional decline.
- Particular emphasis has to be placed on screening for, and optimizing, the mood of the patient. Depression is very common in older patients, especially those who have had strokes and have become hospitalized. Depression in itself can present as "pseudodementia" with worsening confusion during hospitalization and is a treatable condition.

## **ONGOING CARE**

Vascular dementia is a condition that should be followed with multiple visits in the office setting with goals of optimizing cardiovascular risk profiles for patients. Future planning and advanced directives should be addressed early. Family and caregiver evaluation and burden should also be evaluated.

## ***FOLLOW-UP RECOMMENDATIONS***

Perform regular follow-up with a primary care provider or geriatrician for risk factor modification and education on importance of regular physical and mental exercises as tolerated.

## *Patient Monitoring*

Appropriate evaluation and diagnosis of this condition, need for future planning, optimizing vascular risk factors, lifestyle modification counseling, therapeutic interventions

## *DIET*

- The American Heart Association diet and dietary approaches to stop hypertension (DASH) diet is recommended for optimal BP and cardiovascular risk factor control.
- Low-fat, decreased concentrated sweets and carbohydrates, especially in those with metabolic syndrome

## *PATIENT EDUCATION*

- Lifestyle modification is important in vascular risk reduction (smoking cessation, exercise counseling, dietary counseling, weight-loss counseling).
- Optimizing vascular risk factors via medications (i.e., HTN, diabetes, atrial fibrillation, PVD, heart disease)
- Avoiding smoking, including secondhand smoke
- Home BP monitoring and glucometer testing of blood sugars if HTN, impaired glucose tolerance and/or diabetes is present.

## *PROGNOSIS*

- Lost cognitive abilities that persist after initial recovery of deficits from stroke do not usually return. Some individuals can have intermittent periods of self-reported improvement in cognitive function.
- Risk factors for progression of cognitive and functional impairment poststroke include age, prestroke cognitive abilities, depression, polypharmacy, and decreased cerebral perfusion during acute stroke.

## **COMPLICATIONS**

- Physical disability from stroke
- Severe cognitive impairment
- Death

&NA;

## Codes

**&NA;**

### ICD10

- F01.50 Vascular dementia without behavioral disturbance
- F01.51 Vascular dementia with behavioral disturbance

## Clinical Pearls

**&NA;**

- Executive dysfunction and gait abnormalities are often seen early and are more pronounced in vascular dementia as opposed to Alzheimer dementia.
- Memory is relatively preserved in vascular dementia when compared with Alzheimer dementia in the early stages of this disease.
- Stepwise progression, as opposed to progressive decline in Alzheimer dementia, is typical.
- Considerable overlap exists between vascular dementia and Alzheimer dementia in clinical practice and classification into one of these categories is often difficult.

# Dental Infection

Hugh Silk, MD, MPH, FAAFP

Sheila O. Stille, DMD

Nina E. Suresh, MD, MS

## BASICS

### DESCRIPTION

- Very painful area ± swelling in the head and neck region arising from the teeth and supporting structures; if left untreated, can lead to serious and potentially life-threatening illnesses
- Assume any head and neck infection or swelling to be odontogenic in origin until proven otherwise.

### EPIDEMIOLOGY

#### *Incidence*

- Caries (a.k.a. tooth decay or cavity) is a contagious bacterial infection that causes demineralization and destruction of the hard tissues of the teeth (enamel, dentin, and cementum).
- Transmitted vertically from caregivers
- Completely preventable disease with good oral hygiene and diet
- The introduction of fluoride has dramatically decreased dental caries.

#### *Prevalence*

- 23% of 2- to 5-year-olds have caries (1)[A].
- Rates are higher in Hispanic and black children (1)[A].
- Percentage of children 6 to 19 years with untreated dental caries: 19.1% (2011 to 2012) (2) [A]
- 92% of adults 20 to 64 years have had dental caries; 23% have untreated dental caries (2005 to 2008) (2)[A]
- 25% of children 5 to 17 years account for 80% of caries in the United States.

- 5% of adults age 20 to 64 years has no teeth.

## ETIOLOGY AND PATHOPHYSIOLOGY

Caries or trauma can lead to pulpal death, which in turn leads to infection of pulp and/or abscess of adjacent tissues via direct or hematogenous bacterial colonization.

- *Streptococcus mutans* vertically transmitted to newly dentate infants from caregivers
- Acidic secretions from *S. mutans* are implicated in early caries.
- Often polymicrobial mix of strict anaerobes and facultative anaerobes in dental abscess
- Anaerobes, including *peptostreptococci*, *Bacteroides*, *Prevotella*, and *Fusobacterium*, have been implicated. *Lactobacilli* not seen in healthy subjects but seen in those with rampant caries (3) [B].

## RISK FACTORS

- Low socioeconomic status
- Parent and/or sibling with history of caries or existing untreated dental caries
- Previous caries
- Poor access to dental and health care
- Fear of dentist
- Poor oral hygiene
- Poor nutrition, including diet containing high level of sugary foods and drinks
- Trauma to the teeth or jaws
- Inadequate access to and use of fluoride
- Gingival recession (increased risk of root caries)
- Physical and mental disabilities
- Decreased salivary flow (e.g., use of anticholinergic medications, immunologic diseases, radiation therapy to head and neck)

## GENERAL PREVENTION

- Prevent caries and contagious bacterial infection (*S. mutans*).
- Majority of dental problems can be avoided through flossing; brushing with fluoride toothpaste, systemic fluoride (fluoridated bottled water; fluoride supplements for high-risk patients in nonfluoridated areas), and fluoride varnish for moderate- to high-risk pediatric patients; and

regular dental cleanings (4)[B].

- Consider prevention of transmission of *S. mutans* from mother to infant by improving mother's dentition and decreasing mother's bacterial load through proper dental care, chlorhexidine gluconate rinses, and use of xylitol products. Avoid smoking, which is linked to severe periodontal disease (5)[A].
- Good control of systemic diseases (e.g., diabetes)
- Fluoride varnish provided by dental or medical primary care providers twice per year (4)[B]

## COMMONLY ASSOCIATED CONDITIONS

- Rampant caries throughout dentition, faulty restorations, extractions, crowding, and multiple missing teeth
- Periapical abscesses associated with necrotic teeth
- Periodontal abscesses
- Soft tissue cellulitis
- Periodontitis (deep inflammation ± infection of gingiva, alveolar bone support, and ligaments)

## DIAGNOSIS

### HISTORY

- Pain at infected site or referred pain to ears, jaw, cheek, neck, or sinuses. Unexplained headaches.
- Sensitivity to hot or cold stimuli
- Unprovoked, intermittent, or constant throb along nerve pathway
- Pain on biting or chewing
- Trismus (inability to open mouth)
- Bleeding or purulent drainage from gingival tissues
- When severe infection (systemic)
  - Fever
  - Difficulty breathing or swallowing
  - Mental status changes
- Children <4 years with stiff neck, sore throat, and dysphagia should be worked up for retropharyngeal abscess secondary to primary molar infection.

## *PHYSICAL EXAM*

- Gingival edema and erythema
- Cheek (extraoral swelling) or intraoral swelling
- Presence of fluctuant mass
- Suppuration of gingival margin or from tooth
- Submandibular or cervical lymphadenopathy on side of complaint
- Severe (systemic) infection may present with dysphagia, fever, and signs of airway compromise.

## *DIFFERENTIAL DIAGNOSIS*

- Bacterial or viral throat infection
- Pericoronitis (inflammation ± infection of gum flap over mandibular last molar, typically third molars)
- Otitis media
- Sinusitis
- Viral (HSV1, herpangina, hand-foot-mouth disease) or aphthous stomatitis
- Temporomandibular joint (TMJ) dysfunction (myofascial pain, +/- internal derangement of TMJ)
- Parotitis
- Cyst
- Jaw pain can be angular equivalent, especially in women, and especially lower left side of the jaw.

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- No initial labs needed, unless patient looks acutely ill
- If acutely ill
  - Consider CBC with differential.
  - Culture and sensitivity; if abscess present, aspirate pus and culture for aerobes and anaerobes (3)[A].
  - Polymicrobial infections, most likely anaerobic gram-negative rods and anaerobic gram-

positive cocci (4)[B]

- Individual dental films of suspected teeth, including root apices; test with palpation, percussion, and cold sensitivity to diagnose correct tooth
- Panoramic film of the teeth and jaw for evaluation of the extent of infection

### *Follow-Up Tests & Special Considerations*

- Panoramic radiograph on patients with trismus
- In large facial swellings extending below inferior border of mandible or into infraorbital space (eye closing), CT scan can be used to determine the extent and density of the swelling, locating the abscess within the soft tissue and bone, and airway involvement. This aids in determining treatment course and planning need for and location of external drainage by oral and maxillofacial surgeon or ENT.

## **TREATMENT**

- Place patient on appropriate antibiotic, if indicated (if systemic). Pain without swelling or systemic signs of infection does not warrant antibiotic use.
- If localized infection, incision and drainage may be warranted.
- Appropriate pain control: Anti-inflammatory agents are 1st line; short-course opioids in some cases (6)[A].
- Refer to dentist as soon as possible for definitive treatment: root canal or extraction or gum therapy (7)[B]
- If infection is severe (systemic symptoms), consider hospitalization with IV antibiotics until stabilized. Patient may need intraoral or extraoral incision and drainage of abscess as well. Definitive treatment necessary to prevent progression or recurrence.

---

P.269

## **GENERAL MEASURES**

- Ibuprofen 600 to 800 mg (peds: 10 mg/kg) q6h or acetaminophen 650 to 1,000 mg (peds: 10 to 15 mg/kg) q4-6h PRN for pain
- For more severe pain, consider acetaminophen or ibuprofen + short course of opioids.
- Can consider local anesthetic nerve block with long-acting anesthetic (bupivacaine) as adjunct; avoid penetrating infection with needle to avoid tracking infection.

# MEDICATION

## *First Line*

- Amoxicillin: 500 mg TID for 7 to 10 days; in children, 40 to 60 mg/kg/day divided TID
- If penicillin-allergic, use clindamycin 300 mg PO TID for 7 days.

## *Second Line*

If long-standing infection or previously antibiotic-treated infection that does not respond to 1st-line treatment

- Clindamycin: 300 mg PO TID for 7 to 10 days
- Amoxicillin/clavulanic acid (500 mg/125 mg), 1 tablet PO TID for 7 days
- If severe infection, consider IV antibiotics (ampicillin-sulbactam, cefoxitin, cefotetan)
- Consider double coverage with metronidazole 500 mg PO TID for 7 days for better bone penetration and good anaerobic coverage. Do not use metronidazole alone. Will increase development of resistant strains; can be used with amoxicillin or clindamycin

## ISSUES FOR REFERRAL

A dentist should be consulted and follow-up definitive care appointment should be secured prior to discharge from medical office, emergency room, or hospital unit.

## SURGERY/OTHER PROCEDURES

- Incision and drainage of abscess should be performed if abscess is large and fluctuant.
- Root canal or extraction should be performed as definitive treatment.

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

Criteria for hospital admission include swelling involving deep spaces of the neck, floor of the mouth, or infraorbital region; deviation of the airway; unstable vital signs; fever; chills; raspy voice; confusion or delirium; or evidence of invasive infection or cellulitis.

- Secure airway, if compromised, with either endotracheal intubation or tracheotomy.
- IV fluid resuscitation with normal saline may be indicated in acutely ill patients.

## *Nursing*

Ensure good oral hygiene.

- Rinse or swab mouth with chlorhexidine gluconate BID.
- Use warm saltwater rinses several times per day to encourage drainage, especially after incision and drainage. In conjunction, use ice packs on outside of face to decrease swelling and help encourage drainage into mouth.

## *Discharge Criteria*

Discharge patient if

- Airway not compromised
- Abscess and sepsis eliminated
- Able to take PO intake and ambulate.

## **ONGOING CARE**

Educate patient in need for proper oral hygiene, need for follow-up dental care, and need for routine dental care and stress medical complications that can and have occurred due to lack of dental care.

## *FOLLOW-UP RECOMMENDATIONS*

- Follow up with dentist within 24 hours.
- Ensure adequate PO intake, including protein.

## *DIET*

- Maintain a healthful diet; bacteria thrive on refined sugar and starch.
- Avoid sugary foods that stick between the teeth.
- Avoid continuous sugary/carbonated drinks throughout day; encourage water as beverage of choice between meals.

## *Pediatric Considerations*

In children, limit the frequency of sugary drinks and advise against sleeping with a bottle to decrease the chance of dental caries.

## *PATIENT EDUCATION*

- Manage dental disease, comprehensively. Caries and periodontal disease need to be controlled.

- Minimally, biannual dental visits after disease control
- Nutritional education
  - Limit the frequency of sugar/carbonated drinks and sugary or sticky foods.
- In young children, avoid sleeping with a bottle to decrease the chance of dental caries.
- Brush twice daily and floss daily
- Caretakers should tend to their personal oral hygiene ± chlorhexidine gluconate rinses in first 3 years of the child's life to decrease the risk of transmission of the caries-causing microorganisms.

## PROGNOSIS

Prognosis is excellent with proper treatment.

## COMPLICATIONS

- Ludwig angina
- Retropharyngeal and mediastinal infection
- Osteomyelitis
- Endocarditis
- Submental infection
- Submandibular infection
- Can cause unstable diabetes in diabetics/worsen preexisting heart disease
- Brain abscess/death

Codes

**&NA;**

## **ICD10**

- K02.9 Dental caries, unspecified
- K04.7 Periapical abscess without sinus
- K12.2 Cellulitis and abscess of mouth

## **Clinical Pearls**

**&NA;**

- Do not ignore toothache pain.
- Treat patients with facial swelling aggressively, as infections can spread quickly, leading to significant morbidity or death.
- Promote prevention (oral hygiene, fluoride, dental visits) to avoid infections.

# Depression

Rachel Bramson, MD

Michael L. Brown, MD

Suzanne Shurtz, MLIS, AHIP

## BASICS

### DESCRIPTION

- A primary mood disorder characterized by a sustained depressed mood and/or decreased interest in things that used to give pleasure (anhedonia), which represents a change from previous functioning.
- Variants: (1) major depressive disorder (MDD), (2) dysthymic disorder, and (3) depressive disorder not otherwise specified (NOS). (Last two disorders have slightly different diagnostic criteria but are still treated as below.)

### EPIDEMIOLOGY

#### *Incidence*

In United States, 6.9% of 18 years of age or older in the past year

#### *Prevalence*

- 16.2% lifetime risk of having MDD
- Patients can relapse; risk decreases with longer remission period but increases in patients with severe episodes, episodes at a younger age, and multiple episodes.
- Predominant age
  - Low risk before early teens but highest prevalence in teens and young adults
- Predominant gender
  - Females > males (2:1)

### ETIOLOGY AND PATHOPHYSIOLOGY

Complex etiology with two major models in the literature

- *Monoamine-deficiency hypothesis*: symptoms related to decreased levels of norepinephrine (dullness and lethargy) and serotonin (irritability, hostility, and suicidal ideation) in multiple regions of the brain; other neurotransmitters involved include dopamine, acetylcholine, &ggr;-aminobutyric acid (GABA), glutamate
- *Stress/hypothalamic-pituitary-adrenal axis*: Abnormalities in cortisol response lead to depression; elevated cortisol levels can be associated with depression, but cortisol tests are not indicated for diagnosis.
- Other areas of research interest: inflammatory processes and abnormal circadian rhythms; impaired synthesis/metabolism of neurotransmitters
- Environmental factors and learned behavior may affect neurotransmitters and/or have an independent influence on depression.

## *Genetics*

Multiple gene loci place a person at increased risk when faced with environmental stressor; twin studies suggest 37% concordance (1).

## **RISK FACTORS**

- Female > male (2:1)
- Severity of 1st episode
- Persistent sleep disturbances
- Presence of chronic disease(s), recent myocardial infarction (MI), cardiovascular accident (CVA)
- Strong family history (depression, bipolar, suicide, substance abuse), spouse with depression
- Substance abuse and dependence, domestic abuse/violence
- Losses, stressors, unemployment
- Single, divorced, or unhappily married

## **COMMONLY ASSOCIATED CONDITIONS**

- Bipolar disorder, cyclothymic disorder, grief reaction, anxiety disorders, somatoform disorders, schizophrenia/schizoaffective disorders
- Medical comorbidity
- Substance abuse

# DIAGNOSIS

## HISTORY

DSM-5 requires all of the following criteria for MDD:

- Criterion A: 5 of the following symptoms present nearly every day during the same 2-week period, with at least one of the five being either depressed mood or loss of interest or pleasure:
  - Depressed mood most of the day by subjective report or observation from other people
  - Diminished interest or pleasure in all activities most of the day by subjective report or observation from other people
  - Decreased or increased appetite or significant weight loss without dieting
  - Insomnia or hypersomnia
  - Fatigue or energy loss
  - Restlessness, irritability, or withdrawal observable by others
  - Worthlessness, excessive/inappropriate guilty feelings
  - Diminished thinking/concentration, poor memory, indecisiveness
  - Recurrent thoughts of death, suicidal ideations, and may or may not have a specific plan
- Criterion B: symptoms cause significant social, occupational, or functional distress or impairment
- Criterion C: symptoms not attributable to substance effects or other medical conditions

### ***Geriatric Considerations***

- Difficult to diagnose due to medical comorbidity
- Can present with memory difficulties as chief complaint; treatment reverses memory difficulty
- Can be the initial presentation of irreversible dementia
- Geriatric Depression Scale (GDS 15) improves rate of diagnosis in primary care setting (2,3)[A].

### ***Pediatric Considerations***

- Can present as irritable or angry rather than sad or dejected
- Failure to make expected weight gains can substitute weight loss symptom above

A sudden and remarkable drop in grades can indicate difficulty concentrating.

- Can present with separation anxiety

## *PHYSICAL EXAM*

Complete physical with focus on endocrine, cardiac, neurologic, and psychiatric (affect, attention, cognition, memory); look for evidence of contributing medical or neurologic disorder

## *DIFFERENTIAL DIAGNOSIS*

- Psychiatric: depressed phase of bipolar disorder— inquire if prior mania, family or personal history of bipolar disorder, prior agitation or excitement with antidepressant medication. If positive, monitor carefully for mood elevation or destabilization, adjustment disorder, and bereavement.
- Neurologic or degenerative CNS diseases, dementias
- Medical comorbidity: adrenal disease, thyroid disorders, diabetes, metabolic abnormalities (hypercalcemia), liver/renal failure, malignancy, chronic fatigue syndrome, fibromyalgia, lupus
- Nutritional: pernicious anemia, pellagra
- Medications/substances: abuse, side effects, overdose, intoxication, dependence, withdrawal

## *DIAGNOSTIC TESTS & INTERPRETATION*

- A clinical diagnosis made by eliciting personal, family, social, and psychosocial factors
- The Patient Health Questionnaire-9 (PHQ-9) is a brief screening test valid for diagnosis of MDD in primary care settings (3)[A].
- Other validated standard rating scales include the following: Beck Depression Inventory, Zung, GDS 15, and so forth. Rating scales are also useful to track response to treatment over time (3)[A].
- Rule out hypothyroidism, anemia, and metabolic disorders with TSH, CBC, and comprehensive metabolic panel (CMP)
- Order urine drug screen if symptoms suggest intoxication.

## **TREATMENT**

American Psychiatric Association (APA) 2010 guidelines recommend phasic approach: acute phase (first 3 months), continuation phase (4 to 9 months), and maintenance (9 months until discontinuation) (4)[A].

- Acute phase
  - Full evaluation, including risk to self and others, with selection of appropriate treatment setting (hospitalization for those at risk of harm to self or others, or so incapacitated as to be unable to take care of themselves and/or who have no support system to assist with treatment)
  - Goal should be symptom remission, with intervention based on clinical picture, including patient's preference, availability of services
  - For mild to moderate depression, psychotherapies (individual, interpersonal, or cognitive-behavioral therapy [CBT]) and/or medication are recommended.
  - For refractory/severe depression, medication is indicated.
  - For patients not responding to medication alone, CBT should be initiated.
  - Continue to increase dosage q3-4wk until symptoms in remission. Full medication effect is complete in 4 to 6 weeks. Augmentation with 2nd medication may be necessary.
  - See within 2 to 4 weeks of starting medication and q2wk until improvement, then monthly to monitor medication changes.
  - 36 visits recommended for monitoring (younger patients; those at high suicide risk, see within 1st week, and follow frequently)
- Continuation/maintenance phase
  - Regular visits to monitor for signs of relapse, q3-6mo if stable; depression rating scales should be used.
  - Once remission achieved, dosage should be continued for at least 6 to 9 months to reduce relapse; CBT is also effective in reducing relapse (visits typically q2wk).
  - If/when drug discontinuation is considered, medications should be tapered gradually (weeks to months).

## **ISSUES FOR REFERRAL**

- Refer immediately for active suicidal ideations, psychosis, severe agitation, severe self-neglect, and significant risk of self-harm.
- Refer to psychiatry for failed response to medication trials, suspected bipolar disorder, more persistent suicidal thoughts, and self-neglect.

## **MEDICATION**

- Effectiveness of medications is comparable between/within classes; selection should be based on provider familiarity and patient characteristics/preferences (5)[A].
- Selective serotonin reuptake inhibitors (SSRIs) and tricyclic antidepressants (TCAs) are effective, but TCAs are second line due to side effects and lethality in overdose. Tolerability is much poorer than newer antidepressants.
- First-line SSRIs\* (starting dose; usual dose)
  - Fluoxetine (Prozac): 20 mg/day; 20 to 60 mg/day
  - Sertraline (Zoloft): 50 mg/day; 50 to 200 mg/day
  - Paroxetine (Paxil): 10 mg/day; 20 to 50 mg/day
  - Paroxetine CR (Paxil CR): 12.5 mg/day; 25 to 62.5 mg/day
  - Citalopram (Celexa): 20 mg/day; 20 to 40 mg/day (higher doses not advised; EKG monitoring for doses >40 mg/day due to increased risk of QTc prolongation)
  - Escitalopram (Lexapro): 10 mg/day; 10 to 20 mg/day
  - Precautions: abrupt discontinuation may result in withdrawal symptoms (i.e., dizziness, nausea, headache, paresthesia)
  - Fluoxetine, paroxetine may raise serum levels of other drugs; escitalopram, sertraline have minimal to no drug interactions.
  - Common side effects: sexual dysfunction (20%), nausea, GI upset, dizziness, insomnia, headache; typically resolve in the 1st week
  - Less common side effects: drowsiness, weight gain, emotional blunting, dry mouth
  - \*Lower starting doses for elderly, adolescents, those with comorbid conditions, panic disorder, significant anxiety, or hepatic conditions
- Others (starting dose; usual dose)
  - Venlafaxine (Effexor, Effexor XR): 37.5 mg/day; 300 mg/day
  - Bupropion XL (Wellbutrin XL): 150 mg/day; 300 to 450 mg/day (precautions: lowers seizure threshold at doses >450 mg/day)
  - Duloxetine (Cymbalta): 30 mg/day; 60 to 120 mg/day
  - Desvenlafaxine (Pristiq): 50 to 100 mg/day
  - Vilazodone: start 10 mg/day; usual target 40 mg/day
  - Vortioxetine: start 5 mg/day; target dose 20 mg/day
  - Levomilnacipran: start 20 mg/day; target dose 40 to 120 mg/day

## Second Line

- TCAs (starting dose; usual dose)
  - Amitriptyline (Elavil): 25 to 50 mg/day; 100 to 300 mg/day
  - Nortriptyline (Pamelor): 25 mg/day; 50 to 150 mg/day
  - Doxepin (Sinequan): 25 to 50 mg/day; 100 to 300 mg/day
  - Imipramine (Tofranil, Tofranil-PM): 25 to 50 mg/day; 100 to 300 mg/day
  - Desipramine (Norpramin): 25 to 50 mg/day; 100 to 300 mg/day
  - Precautions: advanced age, glaucoma, benign prostate hyperplasia, hyperthyroidism, cardiovascular disease, liver disease, monamine oxidase inhibitor (MAOI) treatment, potential for fatal overdose, arrhythmia, worsening glycemic control; \*SSRIs recommended for patients with diabetes (4)[A]
  - Common side effects: dry mouth, blurred vision, constipation, urinary retention, tachycardia, confusion/delirium; elderly particularly susceptible
- $\alpha_2$ -Antagonists (sedating) (starting dose; usual dose)
  - Mirtazapine (Remeron): 15 mg/day; 15 to 45 mg/day
- Atypical antipsychotics
  - Adjunctive treatment: aripiprazole or quetiapine
  - Treatment-resistant depression (TRD): olanzapine
  - Significant side effects: dyslipidemia, hypertriglyceridemia, glucose dysregulation, diabetes mellitus, hyperprolactinemia, tardive dyskinesia, neuroleptic malignant syndrome, QTc prolongation (6)[A]
  - Recommended for depression with psychotic features; consult with psychiatry and consider carefully before starting (4)[A].
- Significant potential interactions
  - TCAs: amphetamines, barbiturates, clonidine, epinephrine, ethanol, norepinephrine
  - ALL ANTIDEPRESSANTS: allow 14-day washout period before starting MAOIs
  - MAOIs: not recommended in primary care. Significant drug and food interactions limit use.

### **ALERT**

- Black box warning: increased risk of suicidality in children, adolescents, and

young adults up to age 25 years who are treated with antidepressants. Although this has not been extended to adults, suicide risk assessments are warranted for all patients.

- Serotonin syndrome—a rare but potentially lethal complication from rapid increase in dose or new addition of medication with serotonergic effects
- Caution with personal or family history of bipolar disorder: Antidepressants can precipitate mania.

## *Pregnancy Considerations*

SSRIs: Fluoxetine, sertraline, and bupropion considered safe in pregnancy (paroxetine, Category D; other SSRIs, Category C).

## **ADDITIONAL THERAPIES**

- Electroconvulsive therapy (ECT) for refractory cases
- Repetitive transcranial magnetic stimulation (rTMS) may be helpful for TRD (6)[A].

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Used in mild depression but *not* regulated by FDA nor recommended by APA

- Hypericum perforatum (St. John's wort): multiple drug interactions; not safe in pregnancy
- Data do not support S-adenosyl methionine (SAM-e) or acupuncture.

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

Inpatient care is indicated for severe depression, patients at risk of suicide/homicide, and for comorbid conditions.

### *Discharge Criteria*

Depressive symptoms abating, no longer suicidal, appropriate outpatient follow-up in place

## **ONGOING CARE**

### **PATIENT EDUCATION**

- Depression is a common medical illness, not a character defect.
- Emphasize the need for long-term treatment and follow-up, which includes lifestyle changes.

- Exercise, good sleep hygiene, good nutrition, and decreased use of tobacco and alcohol are recommended. The optimal regimen is one the patient prefers and will adhere to.

## PROGNOSIS

- 70% show significant improvement
- Of patients with a single depressive episode, 50% will relapse over their lifetime.

## COMPLICATIONS

- Suicide
- Lower quality of life

## BASICS

### DESCRIPTION

- *DSM-5* depressive disorders include disruptive mood dysregulations disorder (DMDD), major depressive disorder (MDD), dysthymia, premenstrual dysphoric disorder, substance-/medication-induced depressive disorder, and other nonspecific depression. This chapter focuses on MDD.
- MDD is a primary mood disorder characterized by sadness and/or irritable mood with impairment of functioning; abnormal psychological development; and a loss of self-worth, energy, and interest in typically pleasurable activities.
- DMDD is characterized by a chronic, severe persistent irritability with frequent temper outbursts in response to frustration.
- Dysthymic disorder is differentiated from major depression by less intense symptoms that are more persistent, lasting at least 1 year.
- Adolescents with depression are likely to suffer broad functional impairment across social, academic, family, and occupational domains, along with a high incidence of relapse and a high risk for substance abuse and other psychiatric comorbidity.

### EPIDEMIOLOGY

#### *Incidence*

During adolescence, the cumulative probability of depression ranges from 5% to 20% (1,2).

#### *Prevalence*

- MDD: 6-12% of adolescents; twice as common in females (1)
- DMDD: 2-5%; more prominent in males (3)

### ETIOLOGY AND PATHOPHYSIOLOGY

Unclear; low levels of neurotransmitters (serotonin, norepinephrine) may produce symptoms; decreased functioning of the dopamine system also contributes.

- External factors may affect neurotransmitters independently.

## *Genetics*

- Offspring of parents with depression have three to four times increased rates of depression compared with offspring of parents without mood disorder (2).
- Family studies indicate that anxiety in childhood tends to precede adolescent depression (2).

## *RISK FACTORS*

- Increased three to six times if first-degree relative has a major affective disorder; three to four times in offspring of parents with depression
- Prior depressive episodes
- History of low self-esteem, anxiety disorders, attention deficit hyperactivity disorder (ADHD), and/or learning disabilities
- Hormonal changes during puberty
- Female gender
- Low socioeconomic status
- General stressors: adverse life events, difficulties with peers, loss of a loved one, academic difficulties, abuse, chronic illness, and tobacco abuse

## *GENERAL PREVENTION*

Insufficient evidence for universal depression prevention programs (psychological and social) (4) [B]

- Some evidence indicates that child and adolescent mental health can be improved by successfully treating maternal depression (2,4)[A].
- Agency for Healthcare Research and Quality (AHRQ) recommends the screening of adolescents (12 to 18 years of age) for major depressive disorder when systems are in place to ensure accurate diagnosis, psychotherapy (cognitive-behavioral or interpersonal), and follow-up (5) [C].

## *COMMONLY ASSOCIATED CONDITIONS*

- 2/3 of adolescents with depression have at least one comorbid psychiatric disorder.
- 20% meet the criteria for generalized anxiety disorder.

- Also associated with behavioral disorders, substance abuse, eating disorders

## DIAGNOSIS

### HISTORY

- Adolescents may present with medically unexplained somatic complaints (fatigue, irritability, headache).
- Based on *DSM-5* criteria, 5 of the following symptoms have been present during the same 2-week period and represent a change from previous functioning: At least one of the symptoms is either depressed mood or loss of interest or pleasure (3):
  - Criterion A
    - Depressed mood most of the day, nearly every day by either subjective report or observation by others (feelings of sadness, emptiness, hopelessness; in children, can be irritability)
    - Markedly diminished interest or pleasure in all activities most of the day, nearly every day
    - Significant weight loss when not dieting or weight gain (>5% body weight in 1 month)
    - Insomnia or hypersomnia
    - Psychomotor agitation or retardation nearly every day
    - Fatigue or loss of energy
    - Feelings of worthlessness or excessive or inappropriate feelings of guilt nearly every day
    - Diminished ability to think or concentrate, or indecisiveness, nearly every day
    - Recurrent thoughts of death, recurrent suicidal ideation, or attempt
  - Criterion B. Symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.
  - Criterion C. Episode is not attributable to substances' effects or other medical conditions.
  - Criterion D. Episode is not better explained by a schizoaffective, schizophreniform, or delusional disorder.
  - Criterion E. There has never been a manic or hypomanic episode.

## *PHYSICAL EXAM*

- Psychomotor retardation/agitation may be present.
- Clinicians should carefully assess patients for signs of self-injury (wrist lacerations) or abuse.

## *DIFFERENTIAL DIAGNOSIS*

- Normal bereavement
- Substance-induced mood disorder
- Bipolar disorder
- Mood disorder secondary to a medical condition (thyroid, anemia, vitamin deficiency, diabetes)
- Organic CNS diseases
- Malignancy
- Infectious mononucleosis or other viral diseases
- ADHD, posttraumatic stress disorder (PTSD), eating disorders, and anxiety disorders
- Sleep disorder

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

May be used to rule out other diagnoses (i.e., CBC, TSH, glucose, mono spot, and urine drug)

### *Follow-Up Tests & Special Considerations*

None with sufficient sensitivity/specificity for diagnosis

### *Diagnostic Procedures/Other*

- Depression is primarily diagnosed after a formal interview, with supporting information from caregivers and teachers.
- Standardized tests are useful as screening tools and to monitor response to treatment but should not be used as the sole basis for diagnosis:
  - Beck Depression Inventory (BDI): ages 12 to 18 years (2)[A]
  - Child Depression Inventory (CDI): ages 7 to 17 years
  - Reynolds Adolescent Depression Scale (RADS): teenagers in grades 7 to 12
  - Mood and Feelings Questionnaire (MFQ) (6)[A]

- Patient Health Questionnaire-9 (PHQ-9): ages 13 to 17 years with ideal cut point of 11 or higher (instead of 10 used for adults) (7)[B]
- The USPSTF concludes that the current evidence is insufficient to assess the balance of benefits and harms of screening for suicide risk in adolescents in a primary care setting (8)[C].

## TREATMENT

### GENERAL MEASURES

- Active support and monitoring with short validated scales should be used in mild cases for 6 to 8 weeks.
- Psychotherapy and/or medication should be considered if active support and monitoring do to improve symptoms (9)[A].
- Treatment should include psychoeducation, supportive management, and family and school involvement (10)[C].
- Initial management should include treatment planning and ensuring that the patient and family is comfortable with the plan (11)[C].
- A Cochrane review showed that there was no significant difference between remission rates for adolescents treated with cognitive behavioral therapy (CBT) versus medication or combination therapy immediately postintervention (12)[A].
- A multitreatment meta-analysis showed that combined fluoxetine/CBT had higher efficacy than monotherapies, but other SSRIs such as sertraline and escitalopram were better tolerated (9) [A].

P.273

### MEDICATION

#### *First Line*

- Fluoxetine: for depression in age >8 years. Starting dose of 10 mg/day; effective dose of 10 to 60 mg/day The most studied SSRI and with the most favorable effectiveness and safety data has the longest half-life of the SSRIs and is not generally associated with withdrawal symptoms between doses or upon discontinuation (13)[A].
- Escitalopram: for depression in age >12 years. Starting dose of 5 mg/day; effective dose of 10 to 20 mg/day (13)[A]
- Citalopram: for depression in age >12 years. Starting dose of 10 mg/day; effective dose of 10 to 40 mg/day (13)[A]

- Sertraline: for depression in age >12 years. Starting dose of 25 mg/day; effective dose of 50 to 200 mg/day (13)[A]
- Can titrate dose every 1 to 2 weeks if no significant adverse effects emerge (headaches, GI upset, insomnia, agitation, behavior activation, suicidal thoughts) (13)[A]
- SSRI black box warning to monitor for worsening condition, behavior changes, and suicidal thoughts (13)[A]
- Antidepressant treatment should be continued for 6 to 12 months after the resolution of symptoms at the same dosage (10)[C].
- Given their rates of increased drug metabolism, adolescents may be at higher risk for withdrawal symptoms from SSRIs than adults; if these are present, twice-daily dosing may be considered (9)[A].
- All other SSRIs except fluoxetine should be slowly tapered when discontinued (9)[A].

### *Pediatric Considerations*

- Tricyclic antidepressants (TCAs) have not been proven to be effective in adolescents and should not be used (9)[A].
- Paroxetine (SSRI): Avoid use due to short half-life, associated withdrawal symptoms, and higher association with suicidal ideation.

### *ISSUES FOR REFERRAL*

- Collaborative care interventions between mental health and primary care have a greater improvement in depressive symptoms after 12 months (14)[B].
- Primary care providers should provide initial treatment of pediatric depression. Refer to a child psychiatrist for severe, recurrent, or treatment-resistant depression or if the patient has comorbidities (13)[A].

### *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Physical exercise and light therapy may have a mild to moderate effect (15)[B].
- St. John's wort, acupuncture, S-adenosylmethionine, and 5-hydroxytryptophan have not been shown to have an effect or have inadequate studies to support use in adolescent depression (15)[B].

### *INPATIENT CONSIDERATIONS*

#### *Admission Criteria/Initial Stabilization*

If severely depressed, psychotic, suicidal, or homicidal, one-on-one supervision may be needed.

## ONGOING CARE

### *Patient Monitoring*

- Systematic and regular tracking of goals and outcomes from treatment should be performed, including assessment of depressive symptoms and functioning in home, school, and peer settings (13)[A].
- Diagnosis and initial treatment should be reassessed if no improvement is noted after 6 to 8 weeks of treatment (13)[A].
- The goal of treatment should be no symptoms or a significant reduction of depressive symptoms for 2 weeks (10)[C].
- Educate patients and family members about the causes, symptoms, course and treatments of depression, risks of treatments, and risk of no treatment.

### *PROGNOSIS*

- 60-90% of episodes remit within 1 year.
- 50-70% of remissions develop subsequent depressive episodes within 5 years.
- Depression in adolescence predicts mental health disorders in adult life, psychosocial difficulties, and ill health (2)[A].
- Baseline symptom severity and comorbid anxiety may impact treatment response (16)[A].
- Parental depression at baseline significantly affects intervention effects (4)[A].

### **COMPLICATIONS**

- Treatment-induced mania, aggression, or lack of improvement in symptoms
- School failure/refusal
- Suicide

## Codes

&NA;

### ICD10

- F32.9 Major depressive disorder, single episode, unspecified
- F33.9 Major depressive disorder, recurrent, unspecified
- F33.8 Other recurrent depressive disorders

## Clinical Pearls

## **&NA;**

- Adolescent depression is underdiagnosed and often presents with irritability and anhedonia.
- Fluoxetine is the most studied FDA approved for treatment of adolescent depression.
- Escitalopram, citalopram, and sertraline are also FDA-approved antidepressants.
- CBT combined with fluoxetine is efficacious for adolescents with major depression.
- Paroxetine and TCAs should not be used to treat adolescent depression.
- Referral to a child psychiatrist is appropriate for complex cases or treatment-resistant depression.
- Monitor all adolescents with depression for suicidality, especially during the 1st month of treatment with an antidepressant.

# Depression, Geriatric

Jennifer M. Slowik, DO, MS

Rachel M. Jones, DO

Jeffrey B. Lanier, MD, FAAFP

## BASICS

### DESCRIPTION

- Depression is a primary mood disorder characterized by a depressed mood and/or a markedly decreased interest or pleasure in normally enjoyable activities most of the day, almost every day for at least 2 weeks, and causing significant distress or impairment in daily functioning with at least four other symptoms of depression.
- It is not considered a part of normal aging.

### EPIDEMIOLOGY

Prevalence rates among the elderly vary largely depending on the specific diagnostic instruments used and their current health and/or home environment:

- 5% of community-dwelling elderly
- 5-10% seen in primary care clinics
- 10-37% of hospitalized elderly patients
- 12-27% of nursing home residents

### ETIOLOGY AND PATHOPHYSIOLOGY

- Significant gaps exist in the understanding of the underlying pathophysiology
- Ongoing research has identified several possible mechanisms, including the following:
  - Monoamine transmission and associated transcriptional and translational activity
- Epigenetic mechanisms and resilience factors
- Neurotrophins, neurogenesis, neuroimmune systems, and neuroendocrine systems
- Depression appears to be a complex interaction between heritable and environmental factors.

# RISK FACTORS

- General
  - Female sex
  - Lower socioeconomic status
  - Chronic physical health condition(s)
  - History of mental health problems
  - Family history of depression
  - Death of a loved one
  - Caregiving
  - Social isolation
  - Lack/loss of social support
  - Significant loss of independence
  - Uncontrolled or chronic pain
  - Insomnia/sleep disturbance
- Prevalence of depression in medical illness
  - Stroke (22-50%)
  - Cancer (18-50%)
  - Myocardial infarction (15-45%)
  - Parkinson disease (10-39%)
  - Rheumatoid arthritis (13%)
  - Diabetes mellitus (5-11%)
  - Alzheimer dementia (5-15%)
- Suicide
  - Suicide is the 11th leading cause of death in the United States for all ages.
  - Suicide rates are higher for Americans age >65 years compared with the general population (÷ 15/100,000 people)
  - Suicide rates are highest for males aged >75 years (rate 38.5/100,000).

# DIAGNOSIS

## HISTORY

- Depressed mood most of the day, nearly every day, and/or loss of interest/pleasure in life for at least 2 weeks
- Other common symptoms include the following:
  - Feeling hopeless, helpless, or worthless
  - Insomnia and loss of appetite/weight (alternatively, hypersomnia with increased appetite/weight in atypical depression)
  - Fatigue and loss of energy
  - Somatic symptoms (headaches, chronic pain)
  - Neglect of personal responsibility or care
  - Psychomotor retardation or agitation
  - Diminished concentration, indecisiveness
  - Thoughts of death or suicide
- Screening with "SIGECAPS"
  - **Sleep:** changes in sleep habits from baseline, including excessive sleep, early waking, or inability to fall asleep
  - **Interest:** loss of interest in previously enjoyable activities (anhedonia)
  - **Guilt:** excessive or inappropriate guilt that may or may not focus on a specific problem or circumstance
  - **Energy:** perceived lack of energy
  - **Concentration:** inability to concentrate on specific tasks
  - **Appetite:** increase/decrease in appetite
  - **Psychomotor:** restlessness and agitation or the perception that everyday activities are too strenuous to manage
  - **Suicidality:** desire to end life or hurt oneself, harmful thoughts directed internally, recurrent thoughts of death or thoughts of homicidality

## PHYSICAL EXAM

Mental status exam, thorough neurologic exam, and general physical exam to rule out other conditions

## DIFFERENTIAL DIAGNOSIS

Concurrent medical conditions, cognitive disorders, and medications may cause symptoms that mimic depression:

- Medical conditions: hypothyroidism, vitamin B<sub>12</sub> or folate deficiency, liver or renal failure, cancers, stroke, sleep disorders, electrolyte imbalances, Cushing disease, chronic fatigue syndrome
- Dementia and neurodegenerative disorders
- Delirium
- Medication-induced: interferon- $\alpha$ ,  $\beta_2$ -blockers, isotretinoin, benzodiazepines, glucocorticoids, levodopa, clonidine, H<sub>2</sub> blockers, baclofen, varenicline, metoclopramide, reserpine
- Psychiatric disorders: adjustment disorder with depressed mood, grief reaction, bipolar disorder, dysthymic disorder, anxiety disorders, substance abuse-related mood disorders, psychotic disorders

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

Initial laboratory evaluation is done primarily to rule out potential medical factors that could be causing symptoms.

- Thyroid-stimulating hormone (hypothyroidism)
- CBC with differential (anemia, infection)
- Vitamin B<sub>12</sub>, folic acid (deficiencies)
- Urinalysis (urinary tract infection, glucosuria)
- Comprehensive metabolic panel (uremia, hypo- or hyperglycemia, hypo- or hypernatremia, hypercalcemia, liver failure)
- Urine drug screen
- 24-hour urine free cortisol (Cushing disease)

### ***Follow-Up Tests & Special Considerations***

Additional testing for possible confounding medical and cognitive disorders, as warranted. May consider a sleep study for patients with decreased energy, sleep disturbances, changes in concentration or psychomotor activity.

## *Diagnostic Procedures/Other*

Validated screening tools and rating scales:

- Geriatric Depression Scale: 15- or 30-point scales
- Patient Health Questionnaire (PHQ-2 or PHQ-9)
- Hamilton Depression Rating Scale
- Beck Depression Inventory
- Cornell Scale for Depression in Dementia (1)[A]

## **TREATMENT**

Although response alone, usually interpreted as a 50% reduction in symptoms, can be clinically meaningful, the goal is to treat patients to the point of remission (i.e., essentially the absence of depressive symptoms).

## **GENERAL MEASURES**

- Lifestyle modifications:
  - Increase physical activity
  - Improve nutrition
  - Encourage social interactions
  - Exercise: may be beneficial for depression in the elderly population (2)[A]
- Psychotherapy: Studies do show some benefit in depressed elderly patients (3)[B]:
  - Cognitive-behavioral therapy
  - Problem-solving therapy
  - Interpersonal therapy
  - Psychodynamic psychotherapy

## **MEDICATION**

- Typically more conservative initial dosing and titration of antidepressants in the elderly, starting with 1/2 of the usual initiation dose and increasing within 2 to 4 weeks, as tolerated
- Continue titrating dose every 2 to 4 weeks, as appropriate to reach an adequate treatment dose.

## First Line

- SSRIs have been found to be effective in treating depression in the elderly (4)[A].
- No single SSRI clearly outperforms others in the class; choice of medication often reflects side effect profile or practitioner familiarity (5)[A]:
  - Citalopram: Start at 10 mg/day. Treatment range 10 to 20 mg/day.
  - Sertraline: Start at 25 to 50 mg/day. Treatment range 50 to 200 mg/day.
  - Escitalopram: Start at 10 mg/day. Treatment range 10 to 20 mg/day.
  - Fluoxetine: Start at 10 mg/day. Treatment range 20 to 60 mg/day
  - Paroxetine: Start at 10 mg/day. Treatment range 20 to 40 mg/day.
- SSRIs should not be used concomitantly with monoamine oxidase inhibitors (MAOIs)
- Common side effects—increased risk of falls, nausea, diarrhea, sexual dysfunction

## Second Line

- Atypical antidepressants: more effective than placebo in treatment of depression in the elderly, although additional studies are needed to better delineate patient factors that determine response:
  - Bupropion (sustained/twice a day and extended/once daily available): start at 150 mg/day. Increase dose in 3 to 4 days. Treatment range 300 to 450 mg/day. Avoid in patients with elevated seizure risk, tremors, or anxiety (5)[B].

---

- Venlafaxine (immediate- and extended-release available): start at 37.5 mg/day extended-release and titrate weekly. Treatment range 150 to 225 mg/day. May be associated with elevated BP at higher doses (5)[C].
- Duloxetine: start at 20 to 30 mg/day. Treatment range 60 to 120 mg/day. Also may be associated with elevated BP (5)[A].
- Mirtazapine: start at 7.5 to 15 mg nightly. Treatment range 30 to 45 mg/day; can produce problems with dry mouth, weight gain, sedation, and cognitive dysfunction (5)[B]
- Desvenlafaxine: 50 mg/day in AM; higher doses do not confer additional benefit; 50 mg every other day if CrCl <30 mL/min (6)[A]

P.275

## ISSUES FOR REFERRAL

Depression with suicidal ideation, psychotic depression, bipolar disorder, comorbid substance

abuse issues, polypharmacy, severe or refractory illness

## *ADDITIONAL THERAPIES*

- For patients who have not responded to initial SSRI trial:
  - Switch to a different SSRI medication, switch to an atypical antidepressant, or augment initial antidepressant with bupropion (7)[A]
- Second generation antipsychotic agents (5)[C]:
  - Aripiprazole: 2 to 5 mg/day. Treatment range 5 to 15 mg/day; can produce sedation, weight gain, increased cholesterol levels
  - Should only be used for augmentation in conjunction with other antidepressant medications
- Tricyclic antidepressants (TCAs):
  - Nortriptyline: 25 to 50 mg nightly. Treatment range 75 to 150 mg nightly; can produce anticholinergic effects, weight gain, increase risk of falls (5)[C]
  - TCAs have been shown to be effective in treating depression in the elderly. However, they are difficult for elderly patients to tolerate due to side effect profile and are potentially lethal in overdose, limiting their use as initial treatment agents (4)[A].
- MAOIs also appear more effective than placebo in the treatment of depression in the elderly. They are not used frequently in clinical practice due to potential side effects and necessary dietary restrictions (4)[A].
- Although not FDA approved, buspirone, lithium, or triiodothyronine are sometimes used off-label to augment a primary antidepressant (7)[B].
- Evidence for benefit of antidepressants in the treatment of depression in patients with dementia is equivocal. Consideration should be made for a limited trial with close monitoring for symptom improvement or side effects and used only in patients with severe symptoms (8)[A].
- Electroconvulsive therapy (ECT): has been shown to produce remission of depressive symptoms in the elderly. It should be considered as an initial option for patients with severe or psychotic depression (9)[B].

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Acupuncture: equally beneficial as counseling (10)[B]
- St. John's wort may have minimal benefit and has numerous drug interactions (11)[A].
- Tryptophan and hydroxytryptophan: 150 to 300 mg/day; possible efficacy, additional

investigation required (12)[B]

## *INPATIENT CONSIDERATIONS*

Inpatient care is indicated in cases of imminent safety risk (e.g., acutely suicidal patients) or for those patients unable to care adequately for themselves due to depression.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Due to the delay of benefit following initiation of antidepressant therapy, it is necessary to ensure open communication with the patient to prevent premature discontinuation of therapy. An adequate explanation of potential side effects with instructions to call the office before discontinuing therapy is imperative.

### *Patient Monitoring*

- A patient with severe depression who exhibits suicidality may require admission to an appropriate facility.
- Monitor for worsening anxiety symptoms or increase in suicidality especially in the week following initiation of antidepressants.

### *DIET*

No dietary restrictions are necessary, except for patients taking MAOIs, which necessitates dietary restriction of foods high in tyramine.

### *PATIENT EDUCATION*

- Depression is a treatable illness.
- Medications may need to be taken for at least 2 to 4 weeks before any beneficial effect is noted and may take 6 to 8 weeks to reach maximum efficacy.
- Depression is often a recurring illness.
- National Suicide Prevention Lifeline at 1-800-273-TALK (8255) is a free, 24-hour hotline available to anyone in suicidal crisis or emotional distress. Calls will be routed to the nearest crisis center.

### *PROGNOSIS*

- Treatment outcomes in the elderly may be worse than in the general population, possibly

mediated by physical comorbidities and other factors.

- Depending on the population studied and specific clinical measures used, estimates vary for initial clinical response and remission (between 30% and 70%).

## COMPLICATIONS

- Impairment in social, occupational, or interpersonal functioning
- Difficulty performing activities of daily living and self-care
- Increase in medical services utilization and increased costs of care
- Suicide

## See Also

&NA;

Algorithms: Depressed Mood Associated with Medical Illness; Depressive Episode, Major

## Codes

&NA;

### ICD10

- F32.9 Major depressive disorder, single episode, unspecified
- F03 Unspecified dementia
- F43.21 Adjustment disorder with depressed mood

## Clinical Pearls

&NA;

- Depression is not a normal part of aging.
- Depression in the elderly may be difficult to diagnose precisely due to medical and cognitive

comorbidities.

- Depression may present primarily with cognitive dysfunction and this may improve with treatment of the depression.
- A multidisciplinary approach to the treatment of depression is often the most efficacious.
- SSRIs are considered 1st-line therapy for safety and tolerability. A full remission may take upward of 12 weeks of treatment. Long-term treatment may be needed to prevent recurrence.

# Depression, Postpartum

Kathryn Myer, MD

Nancy Byatt, DO, MBA, FAPM

## BASICS

### DESCRIPTION

- Major depressive disorder (MDD) that recurs or has its onset in the postpartum period
- May also occur in mothers adopting a baby or in fathers
- Postpartum depression (PPD) is similar to nonpregnancy depression (sleep disorders, anhedonia, psychomotor changes, etc.); it most often has its onset within the first 12 weeks postpartum yet can occur within 1 year after delivery.
- Different than postpartum blues (sadness and emotional lability), which is experienced by 30-70% of women and has an onset and resolution within first 10 days postpartum.

### EPIDEMIOLOGY

#### *Incidence*

**14.5%** of women have a new episode of major or minor depression during postpartum period (1).

#### *Prevalence*

- More than 50% of women with postpartum depression enter pregnancy depressed or have an onset during pregnancy (2).
- As many as 19.2% women suffer from depression within 3 months in the postpartum period (3).

### ETIOLOGY AND PATHOPHYSIOLOGY

- May be related to sensitivity in hormonal fluctuations, including estrogen; progesterone; and other gonadal hormones as well as neuroactive steroids; cytokines; hypothalamic-pituitary-adrenal (HPA) axis hormones; altered fatty acid, oxytocin, and arginine vasopressin levels; and genetic and epigenetic factors

Multifactorial including biologic-genetic predisposition in terms of neurobiologic deficit, destabilizing effects of hormone withdrawal at birth, inflammation, and psychosocial stressors

## *RISK FACTORS*

- Previous episodes of PPD
- History of MDD
- MDD during pregnancy
- Anxiety during pregnancy
- History of premenstrual dysphoria
- Family history of depression
- Unwanted pregnancy
- Socioeconomic stress
- Low self-esteem
- Young maternal age
- Alcohol abuse
- Marital conflict
- Multiple births
- African Americans and Hispanics may have higher rates of PPD.
- Preterm and low birth weight baby
- Postpartum pain, sleep disturbance, and fatigue
- Recent immigrant status
- Increased stressful life events
- History of childhood sexual abuse
- Decision to decrease antidepressants during pregnancy
- Intimate partner violence (4)

## *GENERAL PREVENTION*

- Universal screening during pregnancy to allow for detection and treatment
- Screen using Edinburgh Postnatal Depression Scale during pregnancy and the postpartum year: <http://www.testandcalc.com/etc/tests/edin.asp>

- Postnatal visits, psychotherapy, and/or psychoeducation for high-risk women
- For women with depression during pregnancy, psychotherapy or treatment with antidepressants during pregnancy may prevent PPD.
- Depression care manager who provides education, routine telephone contact, and follow-up to engage women in treatment

## COMMONLY ASSOCIATED CONDITIONS

- Bipolar mood disorder
- Depressive disorder not otherwise specified
- Dysthymic disorder
- Cyclothymic disorder
- MDD

## DIAGNOSIS

### HISTORY

- Increased/decreased sleep
- Decreased interest in formerly compelling or pleasurable activities
- Guilt, low self-esteem
- Decreased energy
- Decreased concentration
- Increased/decreased appetite
- Psychomotor agitation or retardation
- Suicidal ideation

## DIFFERENTIAL DIAGNOSIS

- Baby blues: not a psychiatric disorder; mood lability resolves within days
- Postpartum psychosis: a psychiatric emergency
- Postpartum anxiety/panic disorder
- Postpartum obsessive-compulsive disorder
- Hypothyroidism
- Postpartum thyroiditis: can occur in up to 5.7% of patients in the United States and can

present as depression (5)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

Thyroid-stimulating hormone (TSH), B<sub>12</sub>, folate and Vitamin D

### *Diagnostic Procedures/Other*

- Edinburgh Postnatal Depression Scale is a validated screening tool.
- The Patient Health Questionnaire-9 (PHQ-9) is a validated commonly used screening tool.
- Edinburgh Postnatal Depression Scale (Partner Version): to be completed by mother's partner to obtain his or her view of mother's depression

## **TREATMENT**

### *GENERAL MEASURES*

- Outpatient individual psychotherapy in combination with pharmacotherapy
- Interpersonal psychotherapy and cognitive behavioral therapy
- Strongly consider pharmacotherapy when symptoms are moderate or severe.
- Assess suicidal ideation.
- Assess homicidal ideation and thoughts of harming the baby.
- Thoughts of harming the baby require immediate hospitalization.
- Visiting nurse services can provide direct observations of the mother regarding safety concerns and mother-child bonding.

### *MEDICATION*

#### *First Line*

- For nonbreastfeeding women, selection of antidepressants is similar to nonpostpartum patients.
- Selective serotonin reuptake inhibitors (SSRIs) are generally effective and safe:
  - Fluoxetine (Prozac): 20 to 80 mg/day PO (most activating of all SSRIs)
  - Sertraline (Zoloft): 50 to 200 mg/day PO (mildly sedating)

- Paroxetine (Paxil): 20 to 60 mg/day PO (sedating)
- Citalopram (Celexa): 20 to 40 mg/day PO (FDA recommendation)
- Escitalopram (Lexapro): 10 to 20 mg/day PO
- Tricyclic antidepressants (TCAs) are effective and less expensive yet also are lethal in overdose and have unfavorable side effects:
  - Avoid TCAs in mothers with a history of suicidal ideation.
- Bupropion (Wellbutrin): 150 to 450 mg/day PO in patients with depression plus psychomotor retardation and hypersomnia and with weight gain. Bupropion is less likely to cause weight gain or sexual dysfunction and is highly activating.
- Mirtazapine (Remeron): 15 to 45 mg/day PO at bedtime; may assist with sleep restoration and weight gain; no sexual dysfunction
- Serotonin-norepinephrine reuptake inhibitors (SNRIs)
  - Venlafaxine (Effexor XR): a dual-action antidepressant that blocks the reuptake of serotonin in doses of up to 150 mg/day and then blocks the reuptake of norepinephrine in doses of 150 to 450 mg/day PO
  - Duloxetine (Cymbalta): more balanced serotonin/norepinephrine reuptake throughout dosing; 40 to 60 mg/day PO (doses >60 mg have not been demonstrated to be more effective)
  - Desvenlafaxine (Pristiq): 50 mg/day PO
- Bipolar disorder requires treatment with mood stabilizer.
- Among breastfeeding mothers
  - Breastfeeding should generally not preclude treatment with antidepressants.
  - SSRIs and some other antidepressants are considered a reasonable option during breastfeeding.
  - All antidepressants are excreted in breast milk but are generally compatible with lactation.
  - Paroxetine and sertraline have lower translactal passage.
  - SSRIs and nortriptyline have a better safety profile.
  - Translactal passage is greater with fluoxetine and citalopram (4)[B].
  - Start with low doses and increase slowly. Monitor infant for adverse side effects.
  - Continuing an efficacious medication is preferred over switching antidepressants to avoid exposing the mother and infant to the risks of untreated PPD (4)[B].

- Breastfeeding women need additional education and support regarding the risks and benefits of use of antidepressants during breastfeeding.
- Consider negative effects of untreated PPD on infant and child development.
- Discussions of the treatment options with the patient and her partner when possible. Take into account the patient's personal psychiatric history and previous response to treatment, the risks of no treatment or undertreatment, available data about the safety of medications during breastfeeding, and her individual expectations and treatment preferences (6)[B].
- For further information: <http://toxnet.nlm.nih.gov/>

## *Second Line*

Consider switching to a different antidepressant or augmentation if patient has a lack of response. Electroconvulsive therapy (ECT) is an option for depressed postpartum women who do not respond to antidepressant medications, have severe or psychotic symptoms, cannot tolerate antidepressant medications, are actively engaged in suicidal self-destructive behaviors, or have a previous history of response to ECT (7)[B].

## *ISSUES FOR REFERRAL*

- Obtain psychiatric consultation for patients with psychotic symptoms.
- Strongly consider immediate hospitalization if delusions or hallucinations are present.
- Hospitalization is indicated if mother's ability to care for self and/or infant is significantly compromised.

## *ADDITIONAL THERAPIES*

- Psychoeducation, including providing reading material for the patient and family
- Psychotherapy: Interpersonal psychotherapy, cognitive behavioral therapy, and psychodynamic psychotherapy have shown to be effective (5)[B].

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Breastfeeding has been associated with reduced stress and improved maternal mood.
- Infant massage, infant sleep intervention, exercise, and bright light therapy may be beneficial (7)[B].

## *INPATIENT CONSIDERATIONS*

## **ALERT**

Obtain psychiatric consultation for patients with psychotic symptoms. If delusions or hallucinations are present, strongly consider immediate hospitalization. The psychotic mother should *not* be left alone with the baby.

### *Admission Criteria/Initial Stabilization*

Presence of suicidal or homicidal ideation and/or psychotic symptoms and/or thoughts of harming baby and/or inability to care for self or infant, severe weight loss

### *Discharge Criteria*

- Absence of suicidal or homicidal ideation and/or psychotic symptoms and/or thoughts of harming the baby
- Mother must be able to care for self and infant.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Collaborative care approach, including primary care visits and case manager follow-ups
- Consultation with the infant's doctor, particularly if the mother is breastfeeding while taking psychotropic medications

### *DIET*

- Good nutrition and hydration, especially when breastfeeding
- Mixed evidence to support the addition of multivitamin with minerals and omega-3 fatty acids

### *PATIENT EDUCATION*

- *This Isn't What I Expected: Overcoming Postpartum Depression*, by Karen R. Kleinman and Valerie Davis Raskin
- *Down Came the Rain: My Journey Through Postpartum Depression*, by Brooke Shields, 2005
- *Behind the Smile: My Journey Out of Postpartum Depression*, by Marie Osmond, Marcia Wilkie, and Judith Moore, 2001

- <http://www.womensmentalhealth.org/>
- <http://www.motherrisk.org/>
- <http://www.step-ppd.com/>

## PROGNOSIS

- Treatment of maternal depression to remission has been shown to have a positive impact on children's mental health.
- Some patients, particularly those with undertreated or undiagnosed depression, may develop chronic depression requiring long-term treatment.
- Untreated maternal depression is linked to impaired mother-infant bonding and cognitive and language development delay in infants and children (8).
- Postpartum psychosis is associated with tragic outcomes such as maternal suicide and infanticide.

## COMPLICATIONS

- Suicide
- Self-injurious behavior
- Psychosis
- Neglect of baby
- Harm to the baby

## Codes

**&NA;**

### ICD10

- F53 Puerperal psychosis
- O90.6 Postpartum mood disturbance

## Clinical Pearls

**&NA;**

- PPD is a common, debilitating medical condition that impairs a mother's ability to function and interact with her infant and family.
- Universal screening for depression is recommended during the 1st and 3rd trimester and at regular intervals during the postpartum period.
- Early diagnosis and treatment are vital, as untreated PPD can lead to developmental difficulties for the infant and prolonged disability and suffering for the mother.
- Breastfeeding is recommended for maternal and child health. Several medication options for treating depression in mothers are safe for breastfeeding infants.
- Treatment with antidepressants should be individualized for breastfeeding mothers (4)[B].

# Depression, Treatment Resistant

Michelle Magid, MD

Roger L. McRoberts III, MD

## BASICS

### DESCRIPTION

- Major depressive disorder (MDD) that has failed to respond to <sup>3</sup>2 adequate trials of antidepressant therapy in <sup>3</sup>2 different classes (1).
- Antidepressant therapy must be given for 6 weeks at standard doses before being considered a failure.

### EPIDEMIOLOGY

- Depression affects >18 million people in the United States and >340 million people worldwide.
- 16% lifetime risk of MDD (2,3)
- Approximately 1/3 of patients with MDD will develop treatment-resistant depression (3,4).

### ETIOLOGY AND PATHOPHYSIOLOGY

- Unclear. Low levels of neurotransmitters (serotonin, norepinephrine, dopamine) have been indicated.
- Serotonin has been linked to irritability, hostility, and suicidal ideation.
- Norepinephrine has been linked to low energy.
- Dopamine may play a role in low motivation and depression with psychotic features.
- Environmental stressors such as abuse and neglect may affect neurotransmission.
- Inflammation and oxidative stress in the brain can contribute to treatment-resistant depression (5).

### Genetics

A genetic abnormality in the serotonin transporter gene (5-HTTLPR) may increase risk for treatment-resistant depression.

## *RISK FACTORS*

- Severity of disease
- Mislabeling patients with depression who are bipolar
- Comorbid medical disease (including chronic pain)
- Comorbid personality disorder
- Comorbid anxiety disorder
- Comorbid substance abuse
- Familial predisposition to poor response to antidepressants

## *GENERAL PREVENTION*

- Medication adherence in combination with psychotherapy
- Maintenance electroconvulsive therapy (ECT) may prevent relapse.

## *COMMONLY ASSOCIATED CONDITIONS*

- Suicide
- Bipolar disorder
- Substance use disorders
- Anxiety disorders
- Dysthymia
- Eating disorders
- Somatic symptom disorders

## **DIAGNOSIS**

### **HISTORY**

- Symptoms are the same as in MDD. However, patients do not respond to standard form of treatment. Severity and duration are extreme.
- Especially important to screen for suicidality in treatment-resistant depression
- Screening with SIGECAPS
  - Sleep: too much or too little
  - Interest: failure to enjoy activities

- Guilt: excessive and uncontrollable
- Energy: poor energy
- Concentration: inability to focus on tasks
- Appetite: too much or too little
- Psychomotor changes: restlessness/agitation or slowing/lethargy
- Suicidality: desire to end life

## *PHYSICAL EXAM*

Mental status exam may reveal poor hygiene, poor eye contact, blunted affect, tearfulness, weight loss or gain, psychomotor retardation, or agitation.

## *DIFFERENTIAL DIAGNOSIS*

- Bipolar disorder
- Dysthymia
- Dementia
- Early-stage Parkinson disease
- Personality disorder
- Medical illness such as malignancy, thyroid disease, HIV
- Substance use disorders

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Used to rule out medical factors that could be causing/contributing to treatment resistance
  - CBC
  - Complete metabolic profile, including liver tests, calcium, and glucose
  - Urine drug screen
  - Thyroid-stimulating hormone (TSH)
  - Vitamin D level (25-OH vitamin D)
  - Testosterone, if applicable
- CT or MRI of the brain if neurologic disease, tumor, or dementia is suspected.

## Follow-Up Tests & Special Considerations

Delirium and dementia may often look like depression.

## Diagnostic Procedures/Other

- Depression is a clinical diagnosis.
- Validated depression rating scales to assist
  - Beck Depression Inventory
  - Hamilton Rating Scale for Depression
  - Patient Health Questionnaire 9 (PHQ-9)

## TREATMENT

### MEDICATION

#### First Line

- Please see "Depression" topic. When those fail, augmentation and combination strategies are as follows:
  - Antidepressants in combination
    - Citalopram (Start 20 mg/day. Max dose 40 mg/day) + bupropion (start 100 mg BID; max dose 450 mg total) (4,6)[B]
    - Tricyclic antidepressants (TCAs) and selective serotonin reuptake inhibitors (SSRIs) may be used in combination. Proceed with caution due to risk of serotonin syndrome. Citalopram (start 20 mg/day; max dose 40 mg/day) + nortriptyline (start 50 mg at bedtime; max dose 150 mg at bedtime)
  - Antidepressants + antipsychotics
    - Citalopram (start 20 mg/day; max dose 40 mg/day) + aripiprazole (2 to 5 mg/day, different mechanism of action at higher doses) OR + risperidone (start 0.5 to 1 mg at bedtime; max dose 6 mg/day) OR + quetiapine (start 25 mg at bedtime; titrate to 100 to 300 mg at bedtime. Max dose 600 mg/day) (7,8)[A]
  - Antidepressant + lithium
    - TCA: nortriptyline (start 50 mg at bedtime; max dose 150 mg at bedtime) + lithium (start 300 mg at bedtime; max dose 900 mg BID) (1,7,9)[A]

- SSRI: citalopram (start 20 mg/day; max dose 40 mg QD) + lithium (start 300 mg at bedtime; max dose 900 mg BID) (1,4,7)[B]
- Antidepressant + thyroid supplementation
  - Citalopram (start 20 mg/day; max dose 40 mg/day) + triiodothyronine (T3) (12.5 to 50 &mgr;g/day) (4,10)[B]
- In all above combinations, citalopram (Celexa) can be replaced with other SSRIs such as fluoxetine (Prozac) 20 to 80 mg/day, sertraline (Zoloft) 50 to 200 mg/day, and escitalopram (Lexapro) 10 to 20 mg/day or with serotonin-norepinephrine reuptake inhibitors (SNRIs) duloxetine (Cymbalta) 30 to 120 mg/day, venlafaxine XR (Effexor XR) 75 to 225 mg/day, or desvenlafaxine (Pristiq) 50 to 100 mg/day.
- Maximum doses for medication in treatment-resistant cases may be higher than in treatment-responsive cases.

## Second Line

Monamine oxidase inhibitor (MAOI)

- Tranylcypromine (Parnate): start 10 mg BID, increase 10 mg/day every 1 to 3 weeks; max dose 60 mg/day
- Selegiline transdermal (Emsam patch): Apply 6-mg patch daily, increase 3 mg/day; max dose 12 mg/day

P.279

- Side-effect profile (e.g., hypertensive crisis), drug-drug interactions, and dietary restrictions make MAOIs less appealing. Patch version does not require dietary restrictions at lower doses.
- High risk of serotonin syndrome, if combined with another antidepressant; 2-week washout period is advised.

## ISSUES FOR REFERRAL

Treatment-resistant depression should be managed in consultation with a psychiatrist.

## ADDITIONAL THERAPIES

- First line
  - ECT: safe and effective treatment for treatment-resistant and life-threatening depression, with a 60-90% success rate (11,12)[A]:
    - Known to rapidly relieve suicidality, psychotic depression, and catatonia

Controversy due to cognitive side effects during the treatment

- 3 types of lead placements
  - Bitemporal: rapid and effective. Usually need 6 to 10 treatments at 1.5× seizure threshold
  - Right unilateral: may be slightly less rapid but fewer cognitive side effects. Usually need 8 to 12 treatments at 6× seizure threshold
  - Bifrontal: newer technique that may offer similar speed to bitemporal, with slightly improved side-effect profile
- Second line
  - Deep brain stimulation (DBS): Surgical implantation of intracranial electrodes, connected to an impulse generator implanted in the chest wall (13,14)[C]:
    - Reserved for those who have failed medications, psychotherapy, and ECT
    - Preliminary data are promising, showing 40-70% response rate and 35% remission rate, but further trials are warranted.
  - Transcranial magnetic stimulation (TCMS): Noninvasive brain stimulation technique that is generally safe. A few case reports on efficacy in treatment-resistant depression but thus far is only FDA approved for less severe forms of the illness (9,14)[C].
  - Vagus nerve stimulation (VNS): Surgical implantation of electrodes onto left vagus nerve. Its use in treatment-resistant depression has become limited in recent years (13)[C].
  - Ketamine—Not FDA approved, but evidence of rapid improvement in mood and suicidal thinking, although the literature is limited. In addition, the effects of ketamine appear temporary, disappearing after days to weeks (9,15)[C].

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Inpatient care is indicated for severely depressed, psychotic, catatonic, or suicidal patients.

### ***Discharge Criteria***

Symptoms improving, no longer suicidal, psychosocial stressors addressed

**ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

- Frequent visits (i.e., every month)
- During follow-up, evaluate side effects, dosage, and effectiveness of medication as well as need for referral to ECT.
- Patients who have responded to ECT may need maintenance treatments (q3-12wk) to prevent relapse.
- Combination of lithium/nortriptyline after ECT appears to be as effective as maintenance ECT in reducing relapse.

## ***DIET***

Patients on MAOIs need dietary restriction.

## ***PATIENT EDUCATION***

Educate patients that depression is a medical illness, not a character defect.

- Review signs and symptoms of worsening depression and when patient needs to come in for further evaluation.
- Discuss safety plan to address suicidal thoughts.

## ***PROGNOSIS***

With medication adherence, close follow-up, improved social support, and psychotherapy, prognosis improves.

## **COMPLICATIONS**

- Suicide
- Disability
- Poor quality of life

## Codes

&NA;

### ICD10

- F32.9 Major depressive disorder, single episode, unspecified
- F33.9 Major depressive disorder, recurrent, unspecified

## Clinical Pearls

&NA;

- Treatment-resistant depression is common, affecting 1/3 of those with MDD.
- Combination and augmentation strategies with antidepressants, antipsychotics, and mood stabilizers can be helpful.
- ECT should be considered in severe and life-threatening cases.

# Dermatitis Herpetiformis

Geoffrey Strider Farnsworth, MD

## BASICS

### DESCRIPTION

- Dermatitis herpetiformis (DH) presents as a chronic, relapsing, polymorphous, intensely pruritic, erythematous papulovesicular eruption with symmetrical distribution primarily involving extensor skin surfaces of the elbows, knees, buttocks, back, and scalp.
- DH is an autoimmune disease associated with gluten sensitivity with genetic, environmental, and immunologic influences.
- DH is distinguished from other bullous diseases by characteristic histologic and immunologic findings, as well as associated gluten-sensitive enteropathy (GSE).
- System(s) affected: skin
- Synonym(s): Duhring disease, Duhring-Brocq disease

### EPIDEMIOLOGY

- Occurs most frequently in those of Northern European origin
- Rare in persons of Asian or African American origin
- Predominant age: most common in 4th and 5th decades but may present at any age
- Childhood DH is rare in most countries, although an Italian study showed 27% of patients were younger than the age of 10 and 36% younger than the age of 20.
- Predominant gender: Adults: male > female (1.5:1 in the United States, 2:1 worldwide)  
Children: female > male

### Incidence

1/100,000 persons per year in the United States

### Prevalence

11/100,000 persons in the U.S. population; as high as 39/100,000 persons worldwide

## ETIOLOGY AND PATHOPHYSIOLOGY

- Evidence suggests that epidermal transglutaminase (eTG) 3, a keratinocyte enzyme involved in cell envelope formation and maintenance, is the autoantigen in DH.
- eTG is highly homologous with tissue transglutaminase (tTG), which is the antigenic target in celiac disease and GSE.
- The initiating event for DH is presumed to be the interaction of wheat peptides with tTGs, which results in the formation of an autoantigen with high affinity for particular class II major histocompatibility complex (MHC) molecules.
- Presentation of the autoantigen leads to activation of T cells and the humoral immune system.
- IgA antibodies against tTG cross-react with eTG and result in IgA-eTG immune complexes that are deposited in the papillary dermis. Subsequent activation of complement and recruitment of neutrophils to the area result in inflammation and microabscesses.
- Skin eruption may be delayed up to 5 to 6 weeks after exposure to gluten.
- Gluten applied directly to the skin does not result in the eruption, whereas gluten taken by mouth or rectum does. This implies necessary processing by the GI system.
- Thought to be immune complex-mediated disease

## Genetics

- High association with human leukocyte antigen DQ2 (95%), with remaining patients being positive for DQ8, DR4, or DR3
- Strong association with combination of alleles DQA1\*0501 and DQB1\*0201/0202, DRB1\*03 and DRB1\*05/07, or DQA1\*0301 and DQB1\*0302

## RISK FACTORS

- GSE: >90% of those with DH will have GSE, which may be asymptomatic.
- Family history of DH or celiac disease

## GENERAL PREVENTION

Gluten-free diet (GFD) results in improvement of DH and reduces dependence on medical therapy. GFD also may reduce the risk of lymphomas associated with DH.

## COMMONLY ASSOCIATED CONDITIONS

- Hypothyroidism is the most common autoimmune condition associated with DH.
- GSE, gluten ataxia

- Gastric atrophy, hypochlorhydria, pernicious anemia
- GI lymphoma, non-Hodgkin lymphoma
- Hyperthyroidism, thyroid nodules, thyroid cancer
- IgA nephropathy
- Autoimmune disorders, including systemic lupus erythematosus, dermatomyositis, Sjögren syndrome, rheumatoid arthritis, sarcoidosis, Raynaud phenomenon, insulin-dependent diabetes mellitus, myasthenia gravis, Addison disease, vitiligo, alopecia areata, primary biliary cirrhosis, and psoriasis

## DIAGNOSIS

Diagnosis of DH involves a clinicopathologic correlation among clinical presentation, histologic and direct immunofluorescence evaluation, serology, and response to therapy or dietary restriction.

### HISTORY

- Waxing and waning, intensely pruritic eruption with papules and tiny vesicles
- Eruption may worsen with gluten intake.
- GI symptoms may be absent or may not be reported until prompted.

### PHYSICAL EXAM

- Classic lesions described as symmetric, grouped, erythematous papules and vesicles
- More commonly presents with erosions, excoriations, lichenification, hypopigmentation, and/or hyperpigmentation secondary to scratching and healing of old lesions
- Areas involved include extensor surfaces of elbows (90%), knees (30%), shoulders, buttocks, and sacrum. The scalp is also frequently affected. Oral lesions are rare.
- In children, purpura may be visible on digits and palmoplantar surfaces.
- Adults with associated enteropathy are most often asymptomatic, with about 20% experiencing steatorrhea and <10% with findings of bloating, diarrhea, or malabsorption.
- Children with associated enteropathy may present with abdominal pain, diarrhea, iron deficiency, and reduced growth rate.

### DIFFERENTIAL DIAGNOSIS

- In adults

Bullous pemphigoid: linear deposition of C3 and IgG at the basement membrane zone

- Linear IgA disease: homogeneous and linear deposition of IgA at the basement membrane zone, absence of GSE
- Prurigo nodularis
- Urticaria: wheals, angioedema, dermal edema
- Erythema multiforme
- In children
  - Atopic dermatitis: face and flexural areas
  - Scabies: interdigital areas, axillae, genital region
  - Papular urticaria: dermal edema
  - Impetigo

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Serum IgA tTG antibodies: Detection of tTG antibodies was noted to be up to 95% sensitive and >90% specific for DH in patients on unrestricted diets (1,2)[A].
- Serum IgA eTG antibodies: Antibodies to eTG, the primary autoantigen in DH, were shown to be more sensitive than antibodies to tTG in the diagnosis of patients with DH on unrestricted diets (95% vs. 79%) but is not widely available in all labs (1,2)[A].
- Serum IgA endomysial antibodies: have a sensitivity between 50% and 100% and a specificity close to 100% in patients on unrestricted diets but is more expensive, time-consuming, and operator-dependent than tTG (2)

### ***Follow-Up Tests & Special Considerations***

Serologic assessment of anti-tTG and anti-eTG correlate with intestinal involvement of disease and in conjunction with antiendomysial antibodies (EMA) may be useful in monitoring major deviations from GFD (1,2).

### ***Diagnostic Procedures/Other***

The Ògold standardÓ for diagnosing DH is a skin biopsy of perilesional skin evaluated via direct immunofluorescence, which demonstrates granular IgA deposited in dermal papillae and/or basement membrane (1,2)[A],(3)[C].

## Test Interpretation

- Direct immunofluorescence of perilesional skin reveals a granular pattern of IgA deposition in the dermal papillae (1,2).
- Histopathology of lesion with routine staining reveals neutrophilic microabscesses in the tips of the dermal papillae and may show subepidermal blistering (1,2).

## TREATMENT

### GENERAL MEASURES

- GFD is the mainstay of treatment and can lead to complete resolution of symptoms (1,2)[A].
- Typically requires 18 to 24 months of strict adherence to GFD prior to resolution of skin lesions without other treatment.
- Lesions can recur within 12 weeks of reintroduction of gluten.

### MEDICATION

Medication is useful for immediate symptom management but should be used as an adjunct to dietary modification (2).

#### First Line

- Dapsone is approved by the FDA for use in DH and is the most widely used medication (2,4) [A]. Initial dosing of 50 mg/day typically results in improvement of symptoms within 24 to 48 hours; can increase dose to 200 mg to obtain control (1)[C]. Use minimum effective dose with slow titration based on patient response and tolerability. Average maintenance dose is 1 mg/kg/day (50 to 150 mg/day). Minor outbreaks on the face and scalp are common even with treatment. Not ideal for long-term use in DH.

---

P.281

- Dapsone works by inhibiting neutrophil recruitment and IL-8 release, inhibiting the respiratory burst of neutrophils, and protecting cells from neutrophil-mediated injury, thereby suppressing the skin reaction. It has no role in preventing IgA deposition or mitigating the immune reaction in the gut (2,4).
- Precautions
  - Common side effects include nausea, vomiting, headache, dizziness, weakness, and hemolysis.
  - A drop in hemoglobin of 1 to 2 g is characteristic with dapsone 100 mg/day.

- G6PD deficiency increases severity of hemolytic stress. Dapsone should be avoided, if possible, in those who are G6PD-deficient.
- Dose-related methemoglobinemia may occur with doses >100 mg/day. Cimetidine may reduce the severity of this side effect.
- Risk of distal motor neuropathy

## **ALERT**

- Monitor for potentially fatal dapsone-induced sulfone syndrome: fever, jaundice and hepatic necrosis, exfoliative dermatitis, lymphadenopathy, methemoglobinemia, and hemolytic anemia.
- Can occur 48 hours or 6 months after treatment, most often 5 weeks after initiation

## *Pediatric Considerations*

- <2 years: Dosing is not established.
- >2 years: 0.5 to 1.0 mg/kg/day

## *Pregnancy Considerations*

- Category C: Safety during pregnancy is not established.
- Secreted in breast milk and will produce hemolytic anemia in infants
- Adherence to a strict GFD 6 to 12 months before conception should be considered with the hope of eliminating need for dapsone during pregnancy.

## *Second Line*

- High-potency topical steroids can be used acutely to control symptoms until dapsone becomes effective (1)[C].
- Sulfapyridine (1 to 2 g/day) is FDA approved for use in DH and is thought to be the active metabolite in sulfasalazine (2 to 4 g/day) (2,5)[B]. Common side effects include nausea, vomiting, and anorexia. Enteric-coated form may reduce side effects. Other side effects include agranulocytosis, hypersensitivity reactions, hemolytic anemia, proteinuria, and crystalluria (2,5).

## *ISSUES FOR REFERRAL*

Over time, interdisciplinary treatment may involve a dermatologist, gastroenterologist, and registered dietician. Genetic counseling and testing should be considered on diagnosis (1,2).

## ADDITIONAL THERAPIES

A single case report describes topical dapsone therapy as potential alternative treatment or as an adjunct to oral dapsone to decrease systemic exposure and risk of severe side effects. However, it has not been studied extensively (6)[C].

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Every 6 to 12 months by physician and dietician to evaluate GFD adherence and recurrence of symptoms
- Adherence to GFD can be monitored with serologic levels of anti-tTG, anti eTG, and EMA levels (1).
- Patients on dapsone require lab monitoring weekly for the 1st month, biweekly for 2 months, then every 3 months for the duration of medication use (1,4).

## DIET

### GFD

- Grains that should be avoided: wheat (includes spelt, kamut, semolina, and triticale), rye, and barley (including malt)
- Safe grains (gluten-free): rice, amaranth, buckwheat, corn, millet, quinoa, sorghum, teff (an Ethiopian cereal grain), and oats
- Care should be taken to avoid gluten-free grains that are contaminated with sources of gluten during processing such as oats.
- Sources of gluten-free starches that can be used as flour alternatives
  - Cereal grains: amaranth, buckwheat, corn, millet, quinoa, sorghum, teff, rice (white, brown, wild, basmati, jasmine), and montina
  - Tubers: arrowroot, jicama, taro, potato, and tapioca
  - Legumes: chickpeas, lentils, kidney beans, navy beans, pea beans, peanuts, and soybeans
  - Nuts: almonds, walnuts, chestnuts, hazelnuts, and cashews
  - Seeds: sunflower, flax, and pumpkin

## PATIENT EDUCATION

- Patients on dapsone should be made aware of potential hemolytic anemia and the signs associated with methemoglobinemia.
- American Academy of Dermatology, 930 N. Meacham Road, P.O. Box 4014, Schaumburg, IL 60168-4014; (708)330-0230
- The University of Chicago Celiac Disease Center, 5841 S. Maryland Ave., Mail Code 4069, Chicago, IL 60637; (773) 702-7593; [www.celiacdisease.net](http://www.celiacdisease.net) or <http://www.cureceliacdisease.org/>
- Gluten Intolerance Group of North America, 31214-124 Ave. SE, Auburn, WA 98092; (206) 246-6652; fax (206) 246-6531; <https://www.gluten.org/>
- The Celiac Disease Foundation, 13251 Ventura Blvd., #1, Studio City, CA 9160; (818) 990-2354; fax (818) 990-2379

## PROGNOSIS

- Lifelong disease with favorable prognosis
- 10- to 15-year survival rates do not seem to differ from general population.
- Remission in 10-15%
- Skin disease responds readily to dapsone. Occasional new lesions (2 to 3 per week) are to be expected and are not an indication for altering daily dosage.
- Strict adherence to a GFD improves clinical symptoms and decreases dapsone requirement. GFD is the only sustainable method of eliminating cutaneous and GI disease.
- Risk of lymphoma may be decreased in those who maintain a GFD.

## COMPLICATIONS

- Majority of complications are associated with GSE.
- Malnutrition, weight loss, nutritional deficiencies (folate, B<sub>12</sub>, iron)
- Abdominal pain, dyspepsia
- Osteoporosis, dental abnormalities
- Autoimmune diseases
- Lymphomas

**&NA;**

- Celiac Disease
- Algorithm: Rash, Focal

## Codes

**&NA;**

### ICD10

L13.0 Dermatitis herpetiformis

## Clinical Pearls

**&NA;**

- DH is a chronic, relapsing, intensely pruritic rash that often presents with erosions, excoriations, lichenification, and pigmentary changes secondary to scratching and healing of old papulovesicular lesions.
- Strong association with gluten-sensitive enteropathy
- Diagnosis established with perilesional skin biopsy showing direct immunofluorescence demonstrating granular IgA deposits in the dermal papillae.
- Serologic levels of IgA transglutaminase aid in diagnosis and monitoring of deviations from GFD.
- Mainstay of treatment is a GFD with dapsone used primarily for short-term symptom relief.

# Dermatitis, Atopic

Dennis E. Hughes, DO, FACEP

## BASICS

### DESCRIPTION

- A chronic, relapsing, pruritic eczematous condition affecting characteristic sites
- Early onset cases have coexisting allergen sensitization more often than late onset.
- Clinical phenotypical presentation is highly variable, suggesting multifactorial pathophysiology.
- May have significant effect on quality of life for patient and family

### EPIDEMIOLOGY

- 45% of all cases begin in the first 6 months of life with 95% onset prior to age 5 years.
- 70% of affected children will have a spontaneous remission before adolescence.
- Incidence on the rise for the past 3 decades in industrialized countries; overall, affects ÷15% of children at some time (United States)
- Also, may have late-onset dermatitis in adults or relapse of childhood condition—primarily hand eczema
- Asians and blacks are affected more often than whites.
- 60% if one parent is affected; rises to 80% if both parents are affected

### ETIOLOGY

- Two main hypothesis: immunologic with unbalanced immune response and/or skin barrier dysfunction (1)
- Alteration in stratum corneum results in transepidermal water loss and defect in barrier function.
- Epidermal adhesion is reduced either as a result of (i) genetic mutation resulting in altered epidermal proteins or (ii) defect in immune regulation causing an altered inflammatory response.
- Interleukin-31 (IL-31) upregulation is thought to be a major factor in pruritus mediated by

cytokines and neuropeptides rather than histamine excess.

## *Genetics*

- Recent discovery of association between atopic dermatitis (AD) and mutation in the filaggrin gene (on chromosome 1), which codes for a skin barrier protein (2)
- Both epidermal and immune coding likely involved

## *RISK FACTORS*

- Itch-scratch cycle (stimulates histamine release)
- Skin infections
- Emotional stress
- Irritating clothes and chemicals
- Excessively hot or cold climate
- Food allergy in children (in some cases)
- Exposure to tobacco smoke
- Family history of atopy
  - Asthma
  - Allergic rhinitis

## *COMMONLY ASSOCIATED CONDITIONS*

- Food sensitivity/allergy in many cases
- Asthma
- Allergic rhinitis
- Hyper-IgE syndrome (Job syndrome)
  - AD
  - Elevated IgE
  - Recurrent pyodermas
  - Decreased chemotaxis of mononuclear cells

# DIAGNOSIS

## HISTORY

Presence of major symptoms, including relapsing of condition, family history, typical distribution, and morphology necessary to make diagnosis of AD

## PHYSICAL EXAM

Primarily skin manifestations

- Distribution of lesions
  - Infants: trunk, face, and flexural surfaces; diaper-sparing
  - Children: antecubital and popliteal fossae
  - Adults: hands, feet, face, neck, upper chest, and genital areas
- Morphology of lesions
  - Infants: erythema and papules; may develop oozing, crusting vesicles
  - Children and adults: Lichenification and scaling are typical with chronic eczema as a result of persistent scratching and rubbing (lichenification rare in infants).
- Associated signs
  - Facial erythema, mild to moderate
  - Perioral pallor
  - Infraorbital fold (Dennie sign/Morgan line)-atopic pleat
  - Dry skin progressing to ichthyosis
  - Increased palmar linear markings
  - Pityriasis alba (hypopigmented asymptomatic areas on face and shoulders)
  - Keratosis pilaris

## DIFFERENTIAL DIAGNOSIS

- Photosensitivity rashes
- Contact dermatitis (especially if only the face is involved)
- Scabies
- Seborrheic dermatitis (especially in infants)
- Psoriasis or lichen simplex chronicus if only localized disease is present in adults

- Rare conditions of infancy
  - Histiocytosis X
  - Wiskott-Aldrich syndrome
  - Ataxia-telangiectasia syndrome
- Ichthyosis vulgaris

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- No test is diagnostic.
- Serum IgE levels are elevated in as many as 80% of affected individuals, but test is not routinely ordered.
- Eosinophilia tends to correlate with disease severity.
- Scoring atopic dermatitis (SCORAD) is scoring system for AD comprising scores for area, intensity, and subjective symptoms.

## **TREATMENT**

### *GENERAL MEASURES*

- Minimize flare-ups and control the duration and intensity of flare-up.
- Avoid agents that may cause irritation (e.g., wool, perfumes).
- Minimize sweating.
- Lukewarm (not hot) bathing
- Minimize use of soap (superfatted soaps best).
- Sun exposure may be helpful.
- Humidify the house.
- Avoid excessive contact with water.
- Avoid lotions that contain alcohol.
- If very resistant to treatment, search for a coexisting contact dermatitis.

### *Pediatric Considerations*

Chronic potent fluorinated corticosteroid use may cause striae, hypopigmentation, or atrophy, especially in children.

## MEDICATION

### *First Line*

- Frequent systemic lubrication with thick emollient creams (e.g., Eucerin, Vaseline) over moist skin is the mainstay of treatment before any other intervention is considered (1)[A].
- Infants and children: 0.5-1% topical hydrocortisone creams or ointments (use the Öfingertip unit [FTU]Ó dosing) (1)[C]

P.283

- Adults: higher potency topical corticosteroids in areas other than face and skin folds
- Short-course, higher potency corticosteroids for flares; then return to the lowest potency (creams preferred) that will control dermatitis.
- Antihistamines for pruritus (e.g., hydroxyzine 10 to 25 mg at bedtime and as needed)

### *Second Line*

- Topical immunomodulators (tacrolimus or pimecrolimus) for episodic use for children >2 years. There is a black box warning from the FDA regarding potential cancer risk.
- Plastic occlusion in combination with topical medication to promote absorption
- For severe AD, consider systemic steroids for 1 to 2 weeks (e.g., prednisone 2 mg/kg/day PO [max 80 mg/day] initially, tapered over 7 to 14 days).
- Topical tricyclic doxepin, as a 5% cream, may decrease pruritus.
- Modified Goeckerman regimen (tar and ultraviolet light)
- Low-dose methotrexate was established as effective treatment in adults, and recent review suggests it is safe for children and adolescents (3)[B].

## ISSUES FOR REFERRAL

- Ophthalmology evaluation for persistent vernal conjunctivitis
- If using topical steroids around eyes for extended periods, ophthalmology follow-up for cataract evaluation

## ADDITIONAL THERAPIES

- Methods to reduce house mite allergens (micropore filters on heating, ventilation, and air-

conditioning systems; impermeable mattress covers)

- Behavioral relaxation therapy to reduce scratching
- Bleach baths may reduce staph colonization, but definitive evidence for benefit in the condition is lacking. Recommend 1/2 cup of standard 6% household bleach for a full tub of water and soak for 5 to 10 minutes, blotting skin dry upon leaving the bath.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Evening primrose oil (includes high content of fatty acids)
  - May decrease prostaglandin synthesis
  - May promote conversion of linoleic acid to omega-6 fatty acid
- Probiotics may reduce the severity of the condition, thus reducing medication use.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

Evaluate to ensure that secondary bacterial or fungal infection does not develop as a result of disruption of the skin barrier. Most patients with AD are colonized by *Staphylococcus*. There is a little evidence for the routine use of antimicrobial interventions to reduce skin bacteria, but treatment of clinical infection with coverage for *Staphylococcus* is recommended.

#### DIET

- Trials of elimination may find certain triggers in some patients.
- Breastfeeding in conjunction with maternal hypoallergenic diets may decrease the severity in some infants.

### PATIENT EDUCATION

- <http://www.aad.org/skin-conditions/dermatology-a-to-z/atopic-dermatitis>
- National Eczema Association: [www.nationaleczema.org](http://www.nationaleczema.org)

### PROGNOSIS

- Chronic disease

Declines with increasing age

- 90% of patients have spontaneous resolution by puberty.
- Localized eczema (e.g., chronic hand or foot dermatitis, eyelid dermatitis, or lichen simplex chronicus) may continue in some adults.

## COMPLICATIONS

- Cataracts are more common in patients with AD.
- Skin infections (usually *Staphylococcus aureus*); sometimes subclinical
- Eczema herpeticum
  - Generalized vesiculopustular eruption caused by infection with herpes simplex or vaccinia virus
  - Causes acute illness requiring hospitalization
- Atrophy and/or striae if fluorinated corticosteroids are used on face or skin folds
- Systemic absorption may occur if large areas of skin are treated, particularly if high-potency medications and occlusion are combined.

Algorithm: Rash, Focal

## Codes

&NA;

### ICD10

- L20.9 Atopic dermatitis, unspecified
- L20.89 Other atopic dermatitis
- L20.83 Infantile (acute) (chronic) eczema

## Clinical Pearls

&NA;

- Institute early and proactive treatment to reduce inflammation. Use the lowest potency topical steroid that controls symptoms.
- Monitor for secondary bacterial infection.
- Frequent systemic lubrication with thick emollient creams (e.g., Eucerin, Vaseline) over moist skin is the mainstay of treatment before any other intervention is considered.

# Dermatitis, Contact

Aamir Siddiqi, MD

## BASICS

### *DESCRIPTION*

- A cutaneous reaction to an external substance
- Primary irritant dermatitis is due to direct injury of the skin. It affects individuals exposed to specific irritants and generally produces discomfort immediately after exposure (1).
- Allergic contact dermatitis (ACD) affects only individuals previously sensitized to a substance. It represents a delayed hypersensitivity reaction, requiring several hours for the cascade of cellular immunity to be completed to manifest itself (2).
- System(s) affected: skin/exocrine
- Synonym(s): dermatitis venenata

### *EPIDEMIOLOGY*

Common

#### *Incidence*

Occupational contact dermatitis: 20.5/100,000 workers/year in one Australian study

#### *Prevalence*

- Contact dermatitis represents >90% of all occupational skin disorders.
- Predominant sex: male = female
  - Variations due to differences in exposure to offending agents, as well as normal cutaneous variations between males and females (eccrine and sebaceous gland function and hair distribution)

#### *Geriatric Considerations*

Increased incidence of irritant dermatitis secondary to skin dryness

## *Pediatric Considerations*

Increased incidence of positive patch testing due to better delayed hypersensitivity reactions (3)

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Hypersensitivity reaction to a substance generating cellular immunity response (4)

- Plants
  - Urushiol (allergen): poison ivy, poison oak, poison sumac
  - Primary contact: plant (roots/stems/leaves)
  - Secondary contact: clothes/fingernails (not blister fluid)
- Chemicals
  - Nickel: jewelry, zippers, hooks, and watches (5)
  - Potassium dichromate: tanning agent in leather
  - Paraphenylenediamine: hair dyes, fur dyes, and industrial chemicals
  - Turpentine: cleaning agents, polishes, and waxes
  - Soaps and detergents
- Topical medicines
  - Neomycin: topical antibiotics
  - Thimerosal (Merthiolate): preservative in topical medications
  - Anesthetics: benzocaine
  - Parabens: preservative in topical medications
  - Formalin: cosmetics, shampoos, and nail enamel

## *Genetics*

Increased frequency of ACD in families with allergies

## **RISK FACTORS**

- Occupation
- Hobbies
- Travel
- Cosmetics

- Jewelry

## GENERAL PREVENTION

- Avoid causative agents.
- Use of protective gloves (with cotton lining) may be helpful.

## DIAGNOSIS

### HISTORY

- Itchy rash
- Assess for prior exposure to irritating substance.

### PHYSICAL EXAM

- Acute
  - Papules, vesicles, bullae with surrounding erythema
  - Crusting and oozing
  - Pruritus
- Chronic
  - Erythematous base
  - Thickening with lichenification
  - Scaling
  - Fissuring
- Distribution
  - Where epidermis is thinner (eyelids, genitalia)
  - Areas of contact with offending agent (e.g., nail polish)
  - Palms and soles relatively more resistant, although hand dermatitis is common.
  - Deeper skin folds spared
  - Linear arrays of lesions
  - Lesions with sharp borders and sharp angles are pathognomonic.
- Well-demarcated area with a papulovesicular rash

## *DIFFERENTIAL DIAGNOSIS*

- Based on clinical impression
  - Appearance, periodicity, and localization
- Groups of vesicles
  - Herpes simplex
- Diffuse bullous or vesicular lesions
  - Bullous pemphigoid
- Photodistribution
  - Phototoxic/allergic reaction to systemic allergen
- Eyelids
  - Seborrheic dermatitis
- Scaly eczematous lesions
  - Atopic dermatitis
  - Nummular eczema
  - Lichen simplex chronicus
  - Stasis dermatitis
  - Xerosis

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Diagnostic Procedures/Other*

Consider patch tests for suspected allergic trigger (systemic corticosteroids or recent, aggressive use of topical steroids may alter results).

### *Test Interpretation*

- Intercellular edema
- Bullae

## TREATMENT

### GENERAL MEASURES

- Remove offending agent:
  - Avoidance
  - Work modification
  - Protective clothing
  - Barrier creams, especially high-lipid content moisturizing creams (e.g., Keri lotion, petrolatum, coconut oil)
- Topical soaks with cool tap water, Burow solution (1:40 dilution), saline (1 tsp/pt water), or silver nitrate solution
- Lukewarm water baths
- Aveeno oatmeal baths
- Emollients (white petrolatum, Eucerin)

---

P.285

### MEDICATION

#### *First Line*

- Topical medications (6)[A]
  - Lotion of zinc oxide, talc, menthol 0.15% (Gold Bond), phenol 0.5%
  - Corticosteroids for ACD as well as irritant dermatitis
    - High-potency steroids: fluocinonide (Lidex) 0.05% gel, cream, or ointment TID-QID
    - Use high-potency steroids only for a short time, then switch to low- or medium-potency steroid cream or ointment
    - Caution regarding face/skin folds: use lower potency steroids, and avoid prolonged usage. Switch to lower potency topical steroid once the acute phase is resolved.
- Calamine lotion for symptomatic relief
- Topical antibiotics for secondary infection (bacitracin, erythromycin)
- Systemic

- Antihistamine
  - Hydroxyzine: 25 to 50 mg PO QID, especially useful for itching
  - Diphenhydramine: 25 to 50 mg PO QID
  - Cetirizine 10 mg PO BID-TID
- Corticosteroids
  - Prednisone: taper starting at 60 to 80 mg/day PO, over 10 to 14 days
  - Used for moderate to severe cases
  - May use burst dose of steroids for up to 5 days
- Antibiotics for secondary skin infections
  - Dicloxacillin: 250 to 500 mg PO QID for 7 to 10 days
  - Amoxicillin-clavulanate (Augmentin): 500 mg PO BID for 7 to 10 days
  - Erythromycin: 250 mg PO QID in penicillin-allergic patients
  - Trimethoprim-sulfamethoxazole (Bactrim DS): 160 mg/800 mg (1 tablet) PO BID for 7 to 10 days (suspected resistant *Staphylococcus aureus*)
- Precautions
  - Antihistamines may cause drowsiness.
  - Prolonged use of potent topical steroids may cause local skin effects (atrophy, stria, telangiectasia).
  - Use tapering dose of oral steroids if using >5 days.

## *Second Line*

Other topical or systemic antibiotics, depending on organisms and sensitivity

## *Pregnancy Considerations*

Usual caution with medications.

## *ISSUES FOR REFERRAL*

May need referral to a dermatologist or allergist if refractory to conventional treatment

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

The use of complementary and alternative treatment is a supplement and not an alternative to

conventional treatment.

## *Admission Criteria/Initial Stabilization*

Rarely needs hospital admission

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Stay active, but avoid overheating.

### *Patient Monitoring*

- As necessary for recurrence
- Patch testing for etiology after resolved

### *DIET*

No special diet

### *PATIENT EDUCATION*

- Avoidance of irritating substance
- Cleaning of secondary sources (nails, clothes)
- Fallacy of blister fluid spreading disease

### *PROGNOSIS*

- Self-limited
- Benign

### **COMPLICATIONS**

- Generalized eruption secondary to autosensitization
- Secondary bacterial infection

## See Also

&NA;

Algorithm: Rash, Focal

## Codes

&NA;

## ICD10

- L25.9 Unspecified contact dermatitis, unspecified cause
- L23.9 Allergic contact dermatitis, unspecified cause
- L25.5 Unspecified contact dermatitis due to plants, except food

## Clinical Pearls

&NA;

- Anyone exposed to irritants or allergic substances is predisposed to contact dermatitis, especially in occupations that have high exposure to chemicals.
- The most common allergens causing contact dermatitis are plants of the *Toxicodendron* genus

(poison ivy, poison oak, poison sumac).

- Poison-ivy dermatitis typically requires 10 to 14 days of topical or oral steroid therapy to prevent recurrent eruption.
- The usual treatment for contact dermatitis is avoidance of the allergen or irritating substance and temporary use of topical steroids.
- A contact dermatitis eruption presents in a nondermatomal geographic fashion due to the skin being in contact with an external source.

# Dermatitis, Diaper

Dennis E. Hughes, DO, FACEP

## BASICS

### DESCRIPTION

- Diaper dermatitis is a rash occurring under the covered area of a diaper. It is usually initially a contact dermatitis.
- System(s) affected: skin/exocrine
- Synonym(s): diaper rash; nappy rash; napkin dermatitis

### Geriatric Considerations

Incontinence is a significant cofactor.

### EPIDEMIOLOGY

#### Incidence

- The most common dermatitis found in infancy
- Peak incidence: 7 to 12 months of age, then decreases
- Lower incidence reported in breastfed babies due to lower pH, urease, protease, and lipase activity.

#### Prevalence

Prevalence has been variably reported from 4-35% in the first 2 years of life.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Immature infant skin with histologic, biochemical, functional differences compared to mature skin (1)
- Wet skin is central in the development of diaper dermatitis, as prolonged contact with urine or feces results in susceptibility to chemical, enzymatic, and physical injury; wet skin is also penetrated more easily.
- Fecal proteases and lipases are irritants.

- Superhydrase urease enzyme found in the stratum corneum liberates ammonia from cutaneous bacteria.
- Fecal lipase and protease activity is increased by acceleration of GI transit; thus, a higher incidence of irritant diaper dermatitis is observed in babies who have had diarrhea in the previous 48 hours.
- Once the skin is compromised, secondary infection by *Candida albicans* is common. 40-75% of diaper rashes that last >3 days are colonized with *C. albicans*.
- Bacteria may play a role in diaper dermatitis through reduction of fecal pH and resulting activation of enzymes.
- Allergy is exceedingly rare as a cause in infants.

## ***RISK FACTORS***

- Infrequent diaper changes
- Improper laundering (cloth diapers)
- Family history of dermatitis
- Hot, humid weather
- Recent treatment with oral antibiotics
- Diarrhea (>3 stools per day increases risk)
- Dye allergy
- Eczema may increase risk.

## ***GENERAL PREVENTION***

Attention to hygiene during bouts of diarrhea

## ***COMMONLY ASSOCIATED CONDITIONS***

- Contact (allergic or irritant) dermatitis
- Seborrheic dermatitis
- Psoriasis
- Candidiasis
- Atopic dermatitis

## DIAGNOSIS

### HISTORY

- Onset, duration, and change in the nature of the rash
- Presence of rashes outside the diaper area
- Associated scratching or crying
- Contact with infants with a similar rash
- Recent illness, diarrhea, or antibiotic use
- Fever
- Pustular drainage
- Lymphangitis

### PHYSICAL EXAM

- Mild forms consist of shiny erythema  $\pm$  scale.
- Margins are not always evident.
- Moderate cases have areas of papules, vesicles, and small superficial erosions.
- It can progress to well-demarcated ulcerated nodules that measure  $\approx 1$  cm in diameter.
- It is found on the prominent parts of the buttocks, medial thighs, mons pubis, and scrotum.
- Skin folds are spared or involved last.
- *Tidemark dermatitis* refers to the bandlike form of erythema of irritated diaper margins.
- Diaper dermatitis can cause an id reaction (autoeczematous) outside the diaper area.

### DIFFERENTIAL DIAGNOSIS

- Contact dermatitis
- Seborrheic dermatitis
- Candidiasis
- Atopic dermatitis
- Scabies
- Acrodermatitis enteropathica
- Letterer-Siwe disease
- Congenital syphilis

- Child abuse
- Streptococcal infection
- Kawasaki disease
- Biotin deficiency
- Psoriasis
- HIV infection

## **DIAGNOSTIC TESTS & INTERPRETATION**

### *Initial Tests (lab, imaging)*

Rarely needed

### *Follow-Up Tests & Special Considerations*

- Consider a culture of lesions or a potassium hydroxide (KOH) preparation.
- The finding of anemia in association with hepatosplenomegaly and the appropriate rash may suggest a diagnosis of Langerhans cell histiocytosis or congenital syphilis.
- Finding mites, ova, or feces on a mineral oil preparation of a burrow scraping can confirm the diagnosis of scabies.

### *Test Interpretation*

- Biopsy is rare.
- Histology may reveal acute, subacute, or chronic spongiotic dermatitis.

---

P.287

## **TREATMENT**

Prevention is the key to treatment of this condition.

### **GENERAL MEASURES**

- Expose the buttocks to air as much as possible.
- Use mild, slightly acidic cleanser with water; no rubbing and pat dry.
- Avoid impermeable waterproof pants during treatment (day or night); they keep the skin wet and subject to rash or infection.

- Change diapers frequently, even at night, if the rash is extensive.
- Superabsorbable diapers are beneficial, as they wick urine away from skin and still allow air to permeate (2)[C].
- Discontinue using baby lotion, powder, ointment, or baby oil (except zinc oxide).
- Use of appropriately formulated baby wipes (fragrance-free) is safe and as effective as water (3)[B].
- Apply zinc oxide ointment or other barrier cream to the rash at the earliest sign and BID or TID (e.g., Desitin or Balmex). Thereafter, apply to clean, thoroughly dried skin (4)[C].
- Cornstarch can reduce friction. Talc powders that do not enhance the growth of yeast can provide protection against frictional injury in diaper dermatitis, but do not form a continuous lipid barrier layer over the skin and obstruct the skin pores. These treatments are not recommended.

## MEDICATION

### *First Line*

- For a pure contact dermatitis, a low-potency topical steroid (hydrocortisone 0.5-1% TID for 3 to 5 days) and removal of the offending agent (urine, feces) should suffice.
- If candidiasis is suspected or diaper rash persists, use an antifungal such as miconazole nitrate 2% cream, miconazole powder, econazole (Spectazole), clotrimazole (Lotrimin), or ketoconazole (Nizoral) cream at each diaper change.
- If inflammation is prominent, consider a very low-potency steroid cream such as hydrocortisone 0.5-1% TID along with an antifungal cream ± a combination product such as clioquinol-hydrocortisone (Vioform-Hydrocortisone) cream.
- If a secondary bacterial infection is suspected, use an antistaphylococcal oral antibiotic or mupirocin (Bactroban) ointment topically.
- Precautions: Avoid high- or moderate-potency steroids often found in combination of steroid antifungal mixtures—these should never be used in the diaper area.

### *Second Line*

Sucralfate paste for resistant cases

## ISSUES FOR REFERRAL

Consider if a systemic disease such as Langerhans cell histiocytosis, acrodermatitis enteropathica, or HIV infection is suspected

# INPATIENT CONSIDERATIONS

## Admission Criteria/Initial Stabilization

- Febrile neonates
- Recalcitrant rash suggestive of immunodeficiency
- Toxic-appearing infants

## Nursing

Assist first-time parents with hygiene education.

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### Patient Monitoring

Recheck weekly until clear; then at times of recurrence.

## PATIENT EDUCATION

Patient education is vital to the treatment and prevention of recurrent cases.

## PROGNOSIS

- Quick, complete clearing with appropriate treatment
- Secondary candidal infections may last a few weeks after treatment has begun.

## COMPLICATIONS

- Secondary bacterial infection (consider community-acquired methicillin-resistant *Staphylococcus aureus* [MRSA] in pustular dermatitis that does not respond to normal therapy)
- Rare complication is inoculation with group A  $\beta$ -hemolytic *Streptococcus* resulting in necrotizing fasciitis.
- Secondary yeast infection

&NA;

Algorithm: Rash, Focal

## Codes

&NA;

## ICD10

- L22 Diaper dermatitis
- B37.2 Candidiasis of skin and nail

## Clinical Pearls

&NA;

- Hygiene is the main preventative measure.

Look for secondary infection in persistent cases.

# Dermatitis, Seborrheic

Juan Qiu, MD, PhD

## BASICS

### DESCRIPTION

Chronic, superficial, recurrent inflammatory rash affecting sebum-rich, hairy regions of the body, especially the scalp, eyebrows, and face

### EPIDEMIOLOGY

#### Incidence

- Predominant age: infancy, adolescence, and adulthood
- Predominant sex: male > female

#### Prevalence

Seborrheic dermatitis: 3-5%

### ETIOLOGY AND PATHOPHYSIOLOGY

- Skin surface yeasts *Malassezia* (formerly *Plasmodium ovale*) may be a contributing factor (1,2).
- The mite *Demodex folliculorum* may have a direct/indirect role (3).
- Genetic and environmental factors: Flares are common with stress/illness.
- Parallels increased sebaceous gland activity in infancy and adolescence or as a result of some acneogenic drugs.
- Seborrheic dermatitis is more common in immunosuppressed patients, suggesting that immune mechanisms are implicated in the pathogenesis of the disease, although the mechanisms are not well defined (1).

#### Genetics

Positive family history; no genetic marker is identified to date.

### RISK FACTORS

- Parkinson disease
- AIDS (disease severity correlated with progression of immune deficiency)
- Emotional stress
- Medications may flare/induce seborrheic dermatitis: auranofin, aurothioglucose, buspirone, chlorpromazine, cimetidine, ethionamide, gold, griseofulvin, haloperidol, interferon- $\alpha$ , lithium, methoxsalen, methyldopa, phenothiazine, psoralen, stanozolol, thiothixene, trioxsalen (2)

## GENERAL PREVENTION

Seborrheic skin should be washed more often than usual.

## COMMONLY ASSOCIATED CONDITIONS

- Parkinson disease
- AIDS

## DIAGNOSIS

Diagnosis of seborrheic dermatitis usually can be made by history and physical exam.

### HISTORY

- Intermittent active phases manifest with burning, scaling, and itching, alternating with inactive periods; activity is increased in winter and early spring, with remissions commonly occurring in summer.
- Infants
  - Cradle cap: greasy scaling of scalp, sometimes with associated mild erythema
  - Diaper and/or axillary rash
  - Age at onset typically ~ 1 month
  - Usually resolves by 8 to 12 months
- Adults
  - Red, greasy, scaling rash in most locations consisting of patches and plaques with indistinct margins
  - Red, smooth, glazed appearance in skin folds
  - Minimal pruritus
  - Chronic waxing and waning course

- Bilateral and symmetric
- Most commonly located in hairy skin areas: scalp and scalp margins, eyebrows and eyelid margins, nasolabial folds, ears and retroauricular folds, presternal area, middle to upper back, buttock crease, inguinal area, genitals, and armpits

## *PHYSICAL EXAM*

- Scalp appearance varies from mild, patchy scaling to widespread, thick, adherent crusts. Plaques are rare.
- Seborrheic dermatitis can spread onto the forehead, the posterior part of the neck, and the postauricular skin, as in psoriasis.
- Skin lesions manifest as brawny or greasy scaling over red, inflamed skin.
- Hypopigmentation is seen in African Americans.
- Infectious eczematoid dermatitis, with oozing and crusting, suggests secondary infection.
- Seborrheic blepharitis may occur independently.

## *DIFFERENTIAL DIAGNOSIS*

- Atopic dermatitis: Distinction may be difficult in infants.
- Psoriasis
  - Usually knees, elbows, and nails are involved.
  - Scalp psoriasis will be more sharply demarcated than seborrhea, with crusted, infiltrated plaques rather than mild scaling and erythema.
- Candida
- Tinea cruris/capitis: Suspect these when usual medications fail/hair loss occurs.
- Eczema of auricle/otitis externa
- Rosacea
- Discoid lupus erythematosus: Skin biopsy will be beneficial.
- Histiocytosis X: may appear as seborrheic-type eruption
- Dandruff: scalp only, noninflammatory

## *DIAGNOSTIC TESTS & INTERPRETATION*

## *Diagnostic Procedures/Other*

Consider biopsy if

- Usual therapies fail
- Petechiae is noted.
- Histiocytosis X is suspected.
- Fungal cultures in refractory cases or when pustules and alopecia are present.

## *Test Interpretation*

Nonspecific changes

- Hyperkeratosis, acanthosis, accentuated rete ridges, focal spongiosis, and parakeratosis are characteristic.
- Parakeratotic scale around hair follicles and mild superficial inflammatory lymphocytic infiltrate

## **TREATMENT**

### *GENERAL MEASURES*

- Increase frequency of shampooing.
- Sunlight in moderate doses may be helpful.
- Cradle cap
  - Frequent shampooing with a mild, nonmedicated shampoo
  - Remove thick scale by applying warm mineral oil, then wash off 1 hour later with a mild soap and a soft-bristle toothbrush or terrycloth washcloth.
- Adults: Wash all affected areas with antiseborrheic shampoos. Start with over-the-counter products (selenium sulfide) and increase to more potent preparations (containing coal tar, sulfur, or salicylic acid) if no improvement is noted.
- For dense scalp scaling, 10% liquor carbonic detergens in Nivea oil may be used at bedtime, covering the head with a shower cap. This should be done nightly for 1 to 3 weeks.

### *MEDICATION*

#### *First Line*

- Cradle cap: Use a coal tar shampoo or ketoconazole (Nizoral) shampoo if the nonmedicated shampoo is ineffective.
- Adults
  - Topical antifungal agents
    - Ketoconazole or miconazole 2% shampoo twice a week for clearance, then once a week or every other week for maintenance (1,4,5,6)[A] Ketoconazole (Nizoral) and sertaconazole 2% cream may be used to clear scales in other areas (1,4,5,6)[A].
    - Ciclopirox 1% shampoo twice weekly (1)[A]
  - Topical corticosteroids
    - Begin with 1% hydrocortisone and advance to more potent (fluorinated) steroid preparations, as needed (1,4,5,6)[A].
      - Avoid continuous use of the more potent steroids to reduce the risk of skin atrophy, hypopigmentation, or systemic absorption (especially in infants and children).
      - Precautions: Fluorinated corticosteroids and higher concentrations of hydrocortisone (e.g., 2.5%) may cause atrophy or striae if used on the face or on skin folds.
  - Other topical agents
    - Coal tar 1% shampoo twice a week Selenium sulfide 2.5% shampoo twice a week (1,4,5,6)[A]
    - Zinc pyrithione shampoo twice a week
    - Lithium succinate ointment twice a week
- Once controlled, washing with zinc soaps or selenium lotion with periodic use of steroid cream may help to maintain remission.

## *Second Line*

- Calcineurin inhibitors
  - Pimecrolimus 1% cream BID (7)[B]
  - Tacrolimus 0.1% ointment BID (1,4,5,6)[A]
- Systemic antifungal therapy
  - Data are limited.
  - For moderate to severe seborrheic dermatitis

- Ketoconazole: 200 mg/day (8)[A]
- Itraconazole: 200 mg/day (8)[A]
- Daily regimen for 1 to 2 months followed by twice-weekly dosing for chronic treatment
- Monitor potential hepatotoxic effects.
- Low-molecular-weight hyaluronic acid
  - Hyaluronic acid sodium salt gel 0.2% BID (9)[B]

## *ISSUES FOR REFERRAL*

No response to first-line therapy and concerns regarding systemic illness (e.g., HIV)

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Every 2 to 12 weeks, as necessary, depending on disease severity and degree of patient sophistication

### *PATIENT EDUCATION*

<http://familydoctor.org/familydoctor/en/diseases-conditions/seborrheic-dermatitis.html>

### *PROGNOSIS*

- In infants, seborrheic dermatitis usually remits after 6 to 8 months.
- In adults, seborrheic dermatitis is usually chronic and unpredictable, with exacerbations and remissions. Disease is usually easily controlled with shampoos and topical steroids.

### **COMPLICATIONS**

- Skin atrophy/striae is possible from fluorinated corticosteroids, especially if used on the face.
- Glaucoma can result from use of fluorinated steroids around the eyes.
- Photosensitivity is caused occasionally by tars.
- Herpes keratitis is a rare complication of herpes simplex: Instruct patient to stop eyelid steroids if herpes simplex develops.

Algorithm: Rash, Focal

## Codes

&NA;

### ICD10

- L21.9 Seborrheic dermatitis, unspecified
- L21.1 Seborrheic infantile dermatitis
- L21.0 Seborrhea capitis

## Clinical Pearls

&NA;

- Search for an underlying systemic disease in a patient who is unresponsive to usual therapy.
- In adults, seborrheic dermatitis is usually chronic and unpredictable, with exacerbations and remissions. Disease is usually easily controlled with shampoos and topical steroids.

# Dermatitis, Stasis

Joseph A. Florence, MD

Fereshteh Gerayli, MD, FAAFP

## BASICS

### DESCRIPTION

- Chronic, eczematous, erythema, scaling, and noninflammatory edema of the lower extremities accompanied by cycle of scratching, excoriations, weeping, crusting, and inflammation in patients with chronic venous insufficiency, due to impaired circulation and other factors (nutritional edema)
- Clinical skin manifestation of chronic venous insufficiency usually appears late in the disease.
- May present as a solitary lesion
- System(s) affected: skin/exocrine
- Synonym(s): gravitational eczema; varicose eczema; venous dermatitis

### EPIDEMIOLOGY

#### *Incidence*

In the United States: common in patients age >50 years; annual incidence of varicose vein 2-2.6%

#### *Prevalence*

- Prevalence of varicose vein is 7% (5-30%) and symptomatic chronic venous insufficiency is 0.86%
- Predominant age: adult, geriatric
- Predominant sex: female > male

#### *Geriatric Considerations*

Prevalence

- Common in this age group:

- Estimated to affect 15 to 20 million patients age >50 years in the United States

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Incompetence of perforating veins causing blood to backflow to the superficial venous system leading to venous hypertension (HTN) and cutaneous inflammation
- Deposition of fibrin around capillaries
- Microvascular abnormalities
- Ischemia
- Continuous presence of edema in ankles, usually present because of venous valve incompetency (varicose veins)
- Weakness of venous walls in lower extremities
- Trauma to edematous, ischemic skin
- Itch may be caused by inflammatory mediators (from mast cells, monocytes, macrophages, or neutrophils) liberated in the microcirculation and endothelium.
- Abnormal leukocyte-endothelium interaction is proposed to be a major factor.
- A cascade of biochemical events leads to ulceration.

## *Genetics*

Familial link probable

## *RISK FACTORS*

- Previous deep venous thrombosis
- Chronic edema (due to CHF, pulmonary HTN, obstructive sleep apnea; cirrhosis, nephrotic syndrome, or medication)
- Previous pregnancy
- Obesity
- Atopy
- Superimposed itch scratch cycle
- Trauma
- Genetic propensity
- Prolonged medical illness

Secondary infection

- Low-protein diet
- Old age
- Tight garments that constrict the thigh
- Vein stripping
- Vein harvesting for coronary artery bypass graft surgery
- Previous cellulitis

## **GENERAL PREVENTION**

- Use compression stockings to avoid recurrence of edema and to mobilize the interstitial lymphatic fluid from the region of stasis dermatitis and also following DVT.
- Topical lubricants twice a day to prevent fissuring and itching

## **COMMONLY ASSOCIATED CONDITIONS**

- Varicose veins
- Venous insufficiency
- Other eczematous disease
- Hyperhomocysteinemia
- Venous HTN
- Most diseases that worsen peripheral edema (e.g. CHF, diastolic dysfunction)

## **DIAGNOSIS**

### **HISTORY**

- Older than 50 years with exception of acquired venous insufficiency due to surgery, trauma, or thrombosis (1)
- Pruritus, pain, and burning may precede skin signs, which are aggravated during evening hours.
- Insidious onset (2)
- Usually bilateral (3)
- Reddish-brown skin discoloration (3)
- Edema—initially develops around the ankle (3)

- Trauma is more indicative of cellulitis (3).

## *PHYSICAL EXAM*

- Evaluation of the lower extremities characteristically reveals:
  - Bilateral, pitting edema (4,5)
  - Typically with erythema, hyperpigmentation— more common in the lower 1/3 of the extremity and medially (4,5)
- Violaceous (sometimes brown), erythematous-colored lesions due to deoxygenation of venous blood (postinflammatory hyperpigmentation and hemosiderin deposition within the cutaneous tissue)
  - Serous drainage, weeping, crusting, inflammation of the skin
  - Superficial desquamation (4)
  - May present as a solitary lesion mimicking a neoplasm (6)

## *DIFFERENTIAL DIAGNOSIS*

- Cellulitis or erysipelas
- Trauma-related inflammation
- Deep vein thrombosis
- Nonspecific dermatitis
- Thrombophlebitis
- Contact dermatitis
- Vasculitis
- Basal cell or squamous cell carcinoma
- Lipodermatosclerosis
- Lymphedema
- Eosinophilic cellulitis
- Other eczematous diseases

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Blood tests usually not indicated unless cellulitis and/or sepsis are suspected. Leukocytosis is more likely with true cellulitis (3).
- If stasis dermatitis is secondary to venous thrombosis, a thorough hematologic workup may be indicated to rule out hypercoagulability states.
- Duplex ultrasound imaging may diagnose deep venous thrombosis or severe valve damage secondary to past thrombosis.
- Potentially more accurate gold standards (e.g., skin biopsy) would introduce considerable risk to study patients and would not be acceptable from an ethical standpoint (3)

### *Diagnostic Procedures/Other*

- Rule out arterial insufficiency (check peripheral pulses); ankle brachial pressure index (ABPI or ABI).
- Check for diabetes.

### *Test Interpretation*

- ABPI <0.8 is suggestive of arterial insufficiency.
- ABPI can be falsely elevated in diabetic patients and others with distal small vessel calcifications.
- Arterial duplex ultrasound and angiography are the gold standards.

## **TREATMENT**

### *GENERAL MEASURES*

- Primary role of treatment is to reverse effects of venous HTN.
- Typically outpatient:
  - Reduce edema:
    - Leg elevation: heels higher than knees; knees higher than hips
    - Compression therapy: elastic bandage wraps: ace bandages or Unna paste boot (zinc gelatin) or compression stockings (Jobst or nonfitted type) (7)[A]
    - Graduated elastic compression of 30 to 40 mm Hg at the ankle improves ulcer healing rate and may prevent ulcer recurrence (7)[A].
    - No specific type of topical dressing (hydrocolloid versus simple nonadherent dressing)

superior to another when used with compression therapy to maintain moist wound environment. Multilayer or bilayer compression bandages are more effective than nonelastic or short stretch bandages for severe cases (7)[A].

- High compression is contraindicated in arterial insufficiency; pneumatic compression devices (7)[A].
- Treat infection: Debride the ulcer base of necrotic tissue.
- Activity:
  - Avoid standing still.
  - Stay active and exercise regularly.
  - Elevate foot of bed unless contraindicated.
- Inpatient, for endovascular radiofrequency ablation, vein stripping, sclerotherapy, or skin grafts; treatment of advanced cellulitis or venous ulcers
  - Venous ulcer treatment includes autolytic, biologic, chemical, mechanical, and surgical.

## MEDICATION

### *First Line*

- Topical moisturizers, emollients, and barrier creams (e.g., white petroleum, lanolin, etc.) aid with
- 
- P.291
- antipruritic treatment via reducing transepidermal water loss (8)[B].
- No evidence for routine use of systemic or topical antibiotics unless clear evidence of infection (9)[A]
  - Uncomplicated stasis dermatitis can be treated with short courses of topical steroids (8,10)[B]. (Topical triamcinolone 0.1% cream/ointment TID or betamethasone valerate 0.1% cream/ointment/solution TID) (10)[B].
  - Topical antipruritic: pramoxine, camphor, menthol, and doxepin 5% cream (8)[B]
  - Antipruritic medications (e.g., diphenhydramine, cetirizine hydrochloride, desloratadine) (8)[B]
  - Pentoxifylline (400 mg TID) is effective in treating venous leg ulcer and may be effective in the absence of compression (11)[A].
  - Enteric-coated aspirin (at least 300 mg) daily improves venous ulcer healing (12)[B].
  - In light of increasing bacterial resistance to antibiotics, current guidelines recommend the use of antibacterial preparations only for clinical infection (cellulitis, increased pain, warmth,

malodorous exudate) not for bacterial colonization (9)[A].

- Current evidence does not support the routine use of honey or silver-based products (9)[A].
- There is no reliable evidence in the effectiveness of topical preparations such as povidone-iodine, peroxide based preparations, mupirocin, chlorhexidine (9)[A].
- Insufficient evidence exists to either support or refute the routine use of silver sulfadiazine (SSD) for ambulatory patients with either partial-thickness burns or stasis dermatitis ulcers to decrease mortality, prevent infection, or augment wound healing (9)[A].
- If secondary infection, treat with PO antibiotics for *Staphylococcus* or *Streptococcus* organisms (e.g., dicloxacillin 250 mg QID, levofloxacin 500 mg QID, clindamycin 300 mg QID, or trimethoprim-sulfamethoxazole DS BID (3)[B].

## *Second Line*

Consider antibiotics on basis of culture results of exudate from infected ulcer craters.

## **ISSUES FOR REFERRAL**

- Consider referral for nonhealing ulcer.
- Arterial insufficiency
- Uncertain diagnosis
- Rheumatoid arthritis
- Patch testing to evaluate for contact dermatitis
- Associated disease (e.g., symptomatic varicose veins)

## **ADDITIONAL THERAPIES**

If the patient is on amlodipine therapy, consider discontinuing amlodipine (13)[B].

## **SURGERY/OTHER PROCEDURES**

Sclerotherapy and surgery may be required for associated disease.

## **ONGOING CARE**

## **FOLLOW-UP RECOMMENDATIONS**

### *Patient Monitoring*

- If Unna boot compression is used: Cut off and reapply boot once a week. Unna boots reduce

edema by compression and prevent scratching.

- Regular use of high compression stockings reduces chance of recurrent venous ulcer (14)[A].

## *DIET*

lose weight, if overweight.

## *PATIENT EDUCATION*

- Encourage staying active to keep circulation and leg muscles in good condition. Walking is ideal.
- Keep legs elevated while sitting or lying.
- Do not wear girdles, garters, or pantyhose with tight elastic tops.
- Do not scratch.
- Avoid leg injury.
- Elevate foot of bed with 2- to 4-inch blocks.
- Apply compression stockings prior to getting out of bed when less edema is present. Regular use of high compression stockings may prevent recurrence of venous ulcers.

## *PROGNOSIS*

- Chronic course with intermittent exacerbations and remissions
- The healing process for ulceration is often prolonged and may take months.

## **COMPLICATIONS**

- Sensations of itching, pain, and burning have negative impact on the quality of life (2)[B].
- Secondary bacterial infection
- DVT
- Bleeding at dermatitis sites
- Squamous cell carcinoma in edges of long-standing stasis ulcers
- Scarring, which in turn leads to further compromise to blood flow and increased likelihood of minor trauma

## See Also

&NA;

- Varicose Veins
- Algorithm: Rash, Focal

## Codes

&NA;

### ICD10

- I83.10 Varicose veins of unsp lower extremity with inflammation
- I83.11 Varicose veins of right lower extremity with inflammation
- I83.12 Varicose veins of left lower extremity with inflammation

## Clinical Pearls

## **&NA;**

- Treatment of edema associated with stasis dermatitis via elevation and/or compression stockings is essential for optimal results.
- Pentoxifylline 1,200 mg daily and aspirin 300 mg daily improve venous ulcer healing.
- No difference in healing rate of venous stasis ulcers by use of hydrocolloid dressing versus simple nonadherent dressing when used beneath compression. Decision about the dressing should be based on local cost and patient or physician's preferences (7)[A].
- Mild topical corticosteroids reduce inflammation and itching; however, these may potentiate infection; high-potency topical corticosteroids should be avoided due to increased risk of atrophy and ulceration.

# Diabetes Mellitus, Type 1

Matthew C. Brown, MD

Courtney Dawley, DO

## BASICS

### DESCRIPTION

- Type 1 diabetes mellitus (T1DM) is a chronic disease caused by pancreatic insufficiency (deficiency) of insulin production.
- Results in hyperglycemia and end-organ complications (e.g., accelerated atherosclerosis, neuropathy, nephropathy, and retinopathy)
- Features include the following:
  - Patients are insulinopenic and require insulin.
  - Polyphagia, polydipsia, and polyuria
  - Ketosis
  - Usually rapid onset
  - Body habitus: normal or thin physique
- System(s) affected: endocrine/metabolic

### Pregnancy Considerations

- Hyperglycemia increases the incidence of congenital malformations. Tight control of blood sugar prior to conception (goal A1C <7%) is important (1).
- Women with microalbuminuria during the 1st trimester are at increased risk for preeclampsia and preterm delivery.
- A safe pregnancy is possible with vaginal delivery of a term baby. Close monitoring of blood sugar during labor is important.
- Many drugs used to treat diabetic complications are relatively/absolutely contraindicated in pregnancy.

### EPIDEMIOLOGY

- Age of onset peaks between 5 and 7 years of age and again around puberty; rapid decline in incidence after adolescence.
- Slightly more common in males than females
- Overall incidence is increasing worldwide.
- More cases are diagnosed in the autumn and winter than in spring and summer.

### *Incidence*

- 18/100,000 per year in the United States (0 to 60/100,000 worldwide) (2)
- Average lifetime prevalence risk of T1DM in the general population is 0.4%.
- Racial predilection for whites
- African Americans have lowest overall incidence.

### *Pediatric Considerations*

- Although onset is usually before the age of 19 years, T1DM can occur for the first time in patients who are well into their 30s.
- Young children are more likely to present in diabetic ketoacidosis (DKA) due to atypical presentation and because they may not express thirst or obtain fluids as readily as older children or adults.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Genetic predisposition is thought to exist.
- Alteration in immunologic integrity, placing the  $\beta$ -cell at special risk for inflammatory damage
- Autoantibodies present in >90% of patients at presentation: glutamic acid decarboxylase (GAD), insulinoma-associated autoantigen 2 (IA2A), zinc transporter 8 (ZnT8A), and insulin (IAA) (2)
- Associated environmental triggers (none have been verified):
  - Vitamin D deficiency
  - Infant feeding practices (short-term breastfeeding, early exposure to complex proteins)
  - Viruses (e.g., enteroviruses, retroviruses)
  - Environmental toxins
- Various epigenetic modifications of gene expression (DNA methylation, histone modifications,

and micro-RNA dysregulation) have been noted, further suggesting a role between genetics and environment in the development of T1DM (3).

## *Genetics*

- T1DM is a polygenic disorder with 40+ loci known to affect susceptibility to the disease (2).
- Genes located on major histocompatibility complex (MHC) on chromosome 6 provide about half of the genetic susceptibility leading to T1DM risk (2).
- HLA class II shows the strongest association with T1DM risk, but class I MHCs also affect risk (2).

## *RISK FACTORS*

- Certain human leukocyte antigen (HLA) types, MHC classes, and autoantibodies (2)
- Increased susceptibility to T1DM is inheritable (3):
  - Only 10-15% of newly diagnosed T1DM patients have a positive family history of T1DM.
  - Among autoimmune conditions, T1DM has the highest concordance rates in monozygotic twins.
  - Average prevalence risk of T1DM in children of patients with T1DM is  $\div$  6%.
  - Relative risk for siblings of patients with T1DM is about 15%.
- See environmental triggers above (2).

## *COMMONLY ASSOCIATED CONDITIONS*

- Autoimmune diseases, such as celiac disease, vitamin B<sub>12</sub> deficiency, and hypothyroidism
- T1DM can also be seen as part of autoimmune polyendocrine syndromes.

## **DIAGNOSIS**

### *DIFFERENTIAL DIAGNOSIS*

- Benign renal glycosuria
- Glucose intolerance
- Type 2 diabetes
- Consider monogenic diabetes if

- Diabetes is diagnosed before 6 months of age.
- Strong family history of diabetes without classic features of type 2 diabetes
- Mild fasting hyperglycemia
- Nonobese diabetic child with negative autoantibodies
- Secondary diabetes
  - Pancreatic disease (chronic pancreatitis, cystic fibrosis, hereditary hemochromatosis)
  - Endocrine-associated diabetes: acromegaly, Cushing syndrome, pheochromocytoma, glucagonoma, neuroendocrine tumors
  - Drug- or chemical-induced glucose intolerance: glucocorticosteroids, HIV protease inhibitors, atypical antipsychotics, tacrolimus, cyclosporine
- Acute poisonings (salicylate poisoning can cause hyperglycemia and glycosuria and may mimic DKA)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- \*Criteria for the diagnosis of diabetes (1)[C]:
  - Fasting glucose  $\geq 126$  mg/dL (7.0 mmol/L)
  - Random of  $\geq 200$  mg/dL (11.1 mmol/L) in a patient with classic symptoms of hyperglycemia
  - Oral glucose tolerance test; plasma glucose  $\geq 200$  mg/dL 2 hours after a glucose load of 1.75 g/kg (max dose 75 g)
  - Glycated hemoglobin (HbA1c) level  $\geq 6.5\%$  -\*In the absence of unequivocal hyperglycemia, results should be confirmed by repeat testing.
- Other tests to consider:
  - Serum electrolytes, especially in sicker patients who may have ketoacidosis
  - Urinalysis for glucose, ketones, and microalbuminuria
  - Pancreatic autoantibodies
    - Islet cell, IAA, GAD, IA2A, and ZnT8A
  - CBC (WBC count and hemoglobin may be elevated)
- C-peptide insulin level if needed to differentiate from type 2 diabetes

## Test Interpretation

Inflammatory changes, lymphocytic infiltration around the islets of Langerhans, or islet cell loss

### HISTORY

- Polyuria and polydipsia (4)[C]
  - Polyuria may present as nocturia, bedwetting, or incontinence in a previously continent child.
  - Polyuria may be difficult to appreciate in diaper-clad children.
- Weight loss 10-30%
  - Often almost devoid of body fat at diagnosis due to hypovolemia and increased catabolism
- Prolonged or recurrent candidal infection, usually in the diaper area
- Increased fatigue, lethargy, muscle cramps
- Abdominal discomfort, nausea
- Vision changes, such as blurriness
- Altered school or work performance

### TREATMENT

#### GENERAL MEASURES

- Overall control of carbohydrate metabolism for all pediatric age ranges (1)[C]
  - Before meals, strive for blood glucose levels in range of 90 to 1,300 mg/dL (5.0 to 7.2 mmol/L)
  - Bedtime/overnight: 90 to 150 mg/dL (5.0 to 8.3 mmol/L)
  - A1c goal: <7.5% across all pediatric age groups
  - A1c <7.0% is reasonable if achieved without excessive hypoglycemia.
- Very tight control might be dangerous in young children due to risk of repeated hypoglycemia.
- Adult A1c goal: <7.0% (1)[B]
  - A1c <6.5% is reasonable in select individuals (1)[C].
  - Less stringent A1c goals (such as <8%) may be appropriate for others (1)[B].

Normal growth and development and overall good health (asymptomatic) (4)[C]:

- Reach optimal height for genetic potential.
  - Appropriate and timely pubertal maturation
  - Coping psychosocial development: normal school or work attendance and performance; normal goals/career plans. Screen children <sup>3</sup>10 years of age annually for depression.
- Prevent acute complications, including the following:
    - Hypoglycemic insulin reactions
    - Ketoacidosis
  - Delay or prevent chronic end-organ complications

## **MEDICATION**

- Most type 1 diabetes patients will require some form of insulin supplementation, either multiple-dose insulin injections or continuous subcutaneous insulin infusion (1)[A].
- Types of insulin (1)[C]:
  - Long-acting insulin analogues: insulin glargine (Lantus) and insulin detemir (Levemir). These should not be mixed with other insulins in the same syringe.
  - Intermediate-acting insulin (NPH) Humulin N or Novolin N can be mixed with other insulins
  - Short-acting (regular) insulin: Novolin R or Humulin R
  - Very rapid-acting insulin analogues: insulin lispro (Humalog), insulin aspart (Novolog), and insulin glulisine (Apidra)

## **First Line**

- Flexible intensive insulin therapy is the gold standard.
- Multiple dose insulin (MDI) or continuous subcutaneous insulin infusion (CSII) have equal efficacy (1)[B].
- Total initial dose is 0.2 to 0.4 U/kg/day for insulin-na•ve patients (will often need 0.6 to 0.7 U/kg/day).
- 40-60% of total dose given as basal insulin, with the rest as bolus insulin
- MDI regimen (1)[A],(5)[C]:
  - Basal, long-acting insulin once or twice a day
  - Prandial, short-acting insulin based on number of carbohydrate portions (e.g., 1:10,

meaning 1 U of insulin for every 10 g of carbohydrate to be eaten)

- Correctional short-acting mealtime insulin based on premeal blood glucose level (subtract target blood glucose level and divided by sensitivity factor)
  - Administration of the mealtime insulin before a meal may be more efficacious than during or after the meal.
- CSII regimen:
    - May use regular insulin or rapid-acting insulin analogues
    - Basal insulin is infused continuously at a preset rate, and bolus doses are given with meals as above.

## *Second Line*

- Twice-daily injections with NPH along with regular or rapid-acting insulin
- Not physiologic, but lower cost and fewer injections may improve adherence in the less-motivated patient.
- Premixed insulin available as NPH/regular (Novolin or Humulin 70/30) or NPH/rapid-acting insulin (e.g., Novolog 75/25 Mix or Humulin 75/25 Mix) (5)[C]
- Pancreatic transplantation is usually reserved for patients with end-stage renal failure, who may receive kidney-pancreatic transplants at the same time.
- Oral hypoglycemics not indicated in type 1 diabetes (except in obese patients, who may have a combination of type 1 and type 2): Metformin (Glucophage)

## *INPATIENT CONSIDERATIONS*

Newly diagnosed type 1 diabetics may require hospitalization during initiation of insulin therapy.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Normal; full participation in sports activities
- Regular aerobic exercise is recommended.

### *Patient Monitoring*

- BP monitoring at every office visit. If elevated, consider an ACE inhibitor or an angiotensin receptor blocker; avoid in pregnancy (1)[C].

- Monitor height, weight, and sexual maturation (in children) (5)[C].
- Daily home blood glucose monitoring with home blood glucose meter: Blood tests should be done at least 4 to 6 times daily (more frequently in pump patients) for optimal monitoring.
- Quarterly measurement of HbA1c
- Annual screenings (1)[C]:
  - Microalbuminuria for earliest signs of possible nephropathy
  - Ophthalmology exam (after 3 to 5 years of diabetes, also depending on glycemic control); annually thereafter
  - Annual lipid profile, thyroid levels, blood chemistries, CBC
  - Annual influenza vaccine in patients  $\geq 6$  months of age
  - Pneumococcal polysaccharide vaccine to all patients  $\geq 2$  years
  - Hepatitis B vaccination to unvaccinated adults aged 19 to 59 years

## *DIET*

- American Diabetic Association diet: <http://www.diabetes.org/food-and-fitness/food/>
- Carbohydrate counting using insulin-to-carbohydrate ratio with all meals and snacks; allows patient flexibility in eating and ability to eat almost anything

## *PROGNOSIS*

- Initial remission or honeymoon phase with decreased insulin needs and easier control, usually 3 to 6 months
- Current prognosis for reduced life expectancy:
  - Increasing longevity and quality of life with careful blood glucose monitoring, improvement in insulin delivery regimens, and appropriate glycemic control

## **COMPLICATIONS**

- Microvascular disease (retinopathy, nephropathy, neuropathy)
- Hyperlipidemia
- Macrovascular disease (coronary and cerebral artery disease)
- Chronic foot ulcers/amputations
- Hypoglycemia
- DKA

- Excessive weight gain
- Increased risk for preeclampsia and preterm delivery
- Driving mishaps
- Psychological problems of chronic disease

## Codes

**&NA;**

### ICD10

- E10.9 Type 1 diabetes mellitus without complications
- E10.8 Type 1 diabetes mellitus with unspecified complications
- E10.69 Type 1 diabetes mellitus with other specified complication

## Clinical Pearls

**&NA;**

- Polyuria may present as nocturia, bedwetting, or incontinence in a previously continent child.
- Young children are more likely to present in DKA because they may not express thirst or obtain fluids as readily as older children or adults.
- Onset usually before the age of 19 years, but type 1 diabetes can present in patients who are well into their 30s.

# Diabetes Mellitus, Type 2

Swathi A.N. Rao, MD

Sathya S. Krishnasamy, MD

## BASICS

### DESCRIPTION

- Can manifest as nonketotic hyperglycemia and is due to a progressive insulin secretory defect in the setting of insulin resistance
- Significant contributing factor to blindness, renal failure, and lower limb amputations

### *Geriatric Considerations*

Monitor elderly for hypoglycemia; adjust doses for renal/hepatic dysfunction and cognitive function.

### *Pediatric Considerations*

Incidence is increasing and parallels weight gain.

### *Pregnancy Considerations*

First-line drug is insulin (class B), but metformin and glyburide are alternatives that do not cause adverse effects in some females (1,2)[A].

## EPIDEMIOLOGY

### *Incidence*

1.7 million new diagnoses/year in 2012

### *Prevalence*

- In 2012, 29.1 million Americans or 9.3% of the population had DM; men and women equally affected
- 7.6% of non-Hispanic Caucasians, 12.8% of Hispanics, 13.2% of non-Hispanic African Americans, 9% of Asian Americans, and 15.9% of Native Americans

## ETIOLOGY AND PATHOPHYSIOLOGY

- Peripheral insulin resistance, defective insulin secretion, increased gluconeogenesis, altered gut microbiome. Genetic factors: monogenic (e.g., *PPAR $\alpha$* ; and insulin gene mutations) and polygenic
- Obesity, hemochromatosis
- Drug- or chemical-induced (e.g., glucocorticoids, highly active antiretroviral therapy [HAART], atypical antipsychotics, posttransplant immunosuppressants)

### Genetics

50% concordance in monozygotic twins

## RISK FACTORS

- Family hx of DM in first-degree relative, genetic factors, ethnicity (African American, Latino, Native American, Asian, and Pacific Islander)
- Gestational diabetes or history of baby with birth weight  $\geq 4$  kg (9 lb), PCOS, obesity (BMI  $\geq 30$  kg/m<sup>2</sup>) and visceral adiposity, hypertriglyceridemia or low high-density lipoprotein, sedentary lifestyle, impaired fasting glucose (IFG)/impaired glucose tolerance (IGT)/metabolic syndrome (1)[A]

## GENERAL PREVENTION

Weight loss of 5-10% body weight, exercise 150 minutes/week, decrease in fat and caloric intake. Follow USDA dietary recommendation of 14 g fiber/1,000 kcal; metformin, acarbose, or TZDs in high-risk prediabetics with cardiovascular risk factors (1)[A]

## COMMONLY ASSOCIATED CONDITIONS

Hypertension, hyperlipidemia, metabolic syndrome, fatty liver disease, infertility, PCOS, acanthosis nigricans (1)[A]

## DIAGNOSIS

### HISTORY

Polyuria, polydipsia, polyphagia, weight loss, weakness, fatigue, blurry vision, and frequent infections

## PHYSICAL EXAM

BMI, funduscopic exam, oral exam, cardiopulmonary exam, abdominal exam for hepatomegaly,

focused neurologic exam, and diabetic foot exam

## ***DIFFERENTIAL DIAGNOSIS***

- Type 1 DM
- Cushing syndrome, acromegaly, and glucagonoma

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

Criteria for diagnosis

- HbA1c  $\geq 6.5\%$  is diagnostic.
- Hyperglycemic crisis + random plasma glucose  $\geq 200$  mg/dL (11.1 mmol/L) *or*
- Fasting plasma glucose (FPG)  $\geq 126$  mg/dL (7.0 mmol/L) *or*
- 2-hour postprandial plasma glucose  $\geq 200$  mg/dL (11.1 mmol/L) after a 75-g glucose load after overnight fast of at least 8 hours
- If equivocal, repeat testing (1,3)[A].

### ***Follow-Up Tests & Special Considerations***

Screen patients with history of gestational diabetes for persistent diabetes/prediabetes 6 to 12 weeks postpartum with OGTT, 1 year postpartum, and at least every 3 years thereafter (2,3)[A].

## **TREATMENT**

- Use an individualized, patient-centered approach with attention to cost, comorbidities, and compliance.
- A1C targets
  - A1C  $\geq 6.5\%$ : for nonpregnant adults with long life expectancy, no cardiovascular disease, DM for a short duration, and no hx of hypoglycemia. If not achievable safely,  $<7.0\%$  (1,3)[A].
  - For those with a limited life expectancy, advanced micro- or macrovascular complications, extensive comorbidities, and history of hypoglycemia or long-standing DM goal A1C of 7-8% per AACE,  $<8\%$  per ADA (1,3)[A]
  - Individualized goals for high glycators/variation in hemoglobin glycation index (4)[A]
- FPG goal is  $<110$  mg/dL (5.5 mmol/L) and 2-hour postprandial goal is  $<140$  mg/dL (1)[A]. Per ADA, recommended 2-hour postprandial goal: 80 to 130 mg/dL and peak postprandial glucose

<180 mg/dL (1)[A]

- General approach
  - Individualized medical nutrition therapy by certified nutritionist and individualized exercise regimen with at least 150 minutes of moderate-intensity exercise per week
  - If A1C is <7.5%, oral monotherapy in the form of biguanides, GLP-1 receptor agonist, DPP-4 inhibitor, SGLT2 inhibitor, or  $\alpha$ -glucosidase inhibitor. Consider TZD, glinide, or sulfonylureas but with caution due to side effects.
  - If 7.5% < A1C <9.0%, metformin plus second medication, ideally weight-neutral or weight loss-promoting with low risk of hypoglycemia
  - If A1C  $\geq$ 9.0%, initiate insulin alone or in combination with oral agents (1)[A].

## GENERAL MEASURES

- Comprehensive diabetic foot exam annually (3)[A].
- Nephropathy: annual urine microalbumin to creatinine ratio and eGFR or albumin excretion rate (1,3)[A]
- Retinopathy: dilated fundoscopic exam by ophthalmologist at diagnosis and every 2 years if normal, otherwise annually (3)[A]
- If 40 to 75 years old, begin a statin—moderate intensity for low-risk and high-intensity statin if  $\geq$ 7.5% ASCVD risk (3,5)[A].
- Low-dose aspirin for all adults with CVD risk unless contraindicated.
- Hypertension: goal BP <130/80 mm Hg (SBP <120 mm Hg preferred if tolerated). ACE inhibitor/ARB first-line antihypertensives (3)[A]
- Vaccination: Follow CDC recommendations (1,3)[A]. Limit protein intake to 0.8 to 1 g/kg body weight/day for diabetics with early stages of CKD and to 1 g/kg body weight/day for those with advanced CKD (1,3)[A].

## PATIENT EDUCATION

Diabetes self-management education and support by certified diabetes educator (1,3)[A].

## MEDICATIONS

### First Line

- Biguanides
  - Metformin (Glucophage, Fortamet, Riomet, Glumetza): preferred first medication. Promotes

weight loss and improves insulin resistance. Dosage: 500 to 2,000 mg in divided doses or ER 1,000 to 2,000 mg every evening. Maximum effective dose 2,000 mg/day

- Avoid metformin and combination drugs containing metformin in renal insufficiency, prior to radiocontrast agent use, surgery, and severe acute illnesses (e.g., liver disease, cardiogenic shock, pancreatitis, hypoxia) due to increased risk of lactic acidosis.
  - Caution with acute heart failure, alcohol abuse, elderly (can merge with previous bullet)
  - Associated with GI side effects, vitamin B<sub>12</sub> deficiency (3)[A].
- Dipeptidyl peptidase-4 inhibitors
    - Weight neutral with minimal risk for hypoglycemia; dose adjustments in renal function decline with exception of linagliptin
    - Sitagliptin (Januvia): 100 mg/day
    - Saxagliptin (Onglyza): 2.5 mg/day, maximum 5 mg/day
    - Linagliptin (Tradjenta): 5 mg/day
    - Alogliptin (Nesina) 25 mg/day. Significant interactions with metformin (3)[A]
    - Linagliptin/metformin (Jentadueto): 2.5/500 mg PO BID, maximum 2.5/1,000 mg PO BID (3)[A]
  - Sulfonylureas
    - Caution with renal or liver disease, sulfa allergy, creatinine clearance <50 mL/min, elderly, pregnancy
    - Glipizide (Glucotrol): 2.5 to 40 mg/day. Dosage >10 mg/day given BID 30 minutes before meals
    - Glipizide extended-release: 5 to 20 mg/day
    - Glyburide (DiaBeta, Glynase, Micronase): 1.25 to 20 mg/day, Glynase 0.75 to 12 mg/day
    - Glimepiride (Amaryl): 1 to 8 mg/day (3)[A]
    - Drugs that may potentiate effects of sulfonylureas: salicylates, clofibrate, warfarin (Coumadin), ethanol, and ACE inhibitors
  - Thiazolidinediones
    - Obtain baseline liver function tests: if abnormal, use with caution. Contraindicated in patients with NYHA Class III or IV heart failure.
    - Pioglitazone (Actos): 15 to 45 mg/day

- Cumulative use of pioglitazone or rosiglitazone was not associated with the incidence of bladder cancer in a large, pooled multipopulation analysis (6)[A].
- Duetact (pioglitazone hydrochloride and glimepiride): 30/2 mg PO daily with meal
- Rosiglitazone (Avandia): 4 to 8 mg/day

## Second Line

- Insulin: rapid (aspart, lispro, glulisine); short (regular insulin); intermediate (neutral protamine hagedorn); long-acting (glargine, detemir); premixed (several types)
  - May be used in combination with certain oral agents. Combination basal/bolus insulin may be used (0.5 to 2 U/kg/day) after failure of oral agents.
  - Long-acting insulins have lower risk of hypoglycemia than short-acting insulin.
  - Insulin detemir (Levemir) or insulin glargine (Lantus): 10 units (or 0.1 to 0.2 units/kg) once daily in the evening or 2 divided doses (already mentioned). Onset of action 1 hour. No peak. Duration of action is 16 to 23 hours.
  - Human insulin inhalation powder (Afrezza): given as a single inhalation before a meal, in combination with long-acting insulin; contraindicated in chronic lung disease; can cause edema when given with TZDs (3)[B]
  - Concentrated human regular insulin (U-500) Eli Lilly: used for extreme insulin resistance (7) [B]
  - Toujeo Solostar pen (glargine U300) Sanofi-Aventis: used for insulin resistant patients. Improvement in nocturnal hypoglycemia compared to U100 glargine (8)[A]. Consider insulin pump therapy and V-Go in select patients (3)[A].
- Amylinomimetic
  - Pramlintide (Symlin): 60 to 120 &mgr;g SC before every major meal
  - Prandial insulins (short-acting/rapid-acting) should be reduced by 50% if pramlintide is initiated to avoid hypoglycemia.
  - Avoid anticholinergics that slow intestinal absorption of nutrients (3)[A].
- GLP-1 (glucagonlike peptide-1) receptor agonist (incretins)
  - Exenatide (Byetta): 5 to 10 &mgr;g SC BID within 60 minutes before meals and at least 6 hours apart. Extended-release formulation (Bydureon): 2 mg SC weekly
  - Liraglutide (Victoza): 0.6 mg/day SC for 1 week, then increase to 1.2, maximum 1.8 mg/day. Less expensive and better tolerated than exenatide; contraindicated in patients

with personal or family history of medullary thyroid cancer or (MEN) type 2 (black box warning).

- Liraglutide (Saxenda): 3 mg SC daily approved for treatment of obesity.
- Albiglutide (Tanzeum): 30 to 50 mg SC qwk in a single-dose pen
- Dulaglutide (Trulicity) 0.75 to 1.5 mg weekly: 2 mg/wk Associated increased risk of acute pancreatitis with GLP-1 agonists and DPP4 inhibitors and caution with use in CKD <sup>3</sup> stage 4. GLP-1 analogs and Symlin require insulin adjustment and may exacerbate gastroparesis (3,9)[A].
- $\alpha$ -Glucosidase inhibitors
  - Acarbose (Precose): 25 to 100 mg TID
  - Miglitol (Glyset): 25 to 100 mg TID
  - Take at beginning of meals to decrease postprandial hyperglycemia.
  - Avoid in renal insufficiency and bowel diseases.
  - Drug binders, such as cholestyramine resin, should be taken at least 2 hours apart from  $\alpha$ -glucosidase inhibitors (3)[A].
- Meglitinides
  - Repaglinide (Prandin): 0.5 to 4 mg before meals; may be useful in patients with sulfa allergy or renal impairment
- Diphenylalanine derivatives
  - Nateglinide (Starlix): 60 to 120 mg before meals TID (3)[A]
- Bile acid sequestrants
  - Colesevelam: 3.75 g/day or 1.875 g BID (3)[A]
- Dopamine-2 agonists
  - Bromocriptine mesylate immediate release (Cycloset): 0.8 to 1.6 mg/day within 2 hours of awakening
  - Alters hypothalamic regulation of metabolism and reduces hepatic gluconeogenesis (10)[A].
  - May cause dizziness, nausea, fatigue, rhinitis (3)[A]
- SGLT2 inhibitors
  - Inhibits glucose reabsorption by sodium glucose cotransporter-2 inhibition

- Canagliflozin (Invokana): 100 to 300 mg single dose before breakfast; adjust dose with renal function decline
  - Dapagliflozin (Farxiga): 5 to 10 mg daily; avoid use if eGFR <60
  - Empagliflozin (Jardiance): 10 to 25 mg daily; avoid use if eGFR <45
  - Xigduo (dapagliflozin-metformin): 5/100, 10/1,000 mg PO daily
  - May cause hypotension, genital mycotic infections, UTI, impairment of renal function, electrolyte abnormalities, elevated LDL, and DKA and increased fracture risk (canagliflozin) (3)[A]
- Drug interactions: Thiazides cause IGT and fluoroquinolones can cause hyper- and hypoglycemia.

## ***SURGERY/OTHER PROCEDURES***

For patients with BMI >35 m<sup>2</sup>/kg, consider bariatric surgery (11)[B].

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Cinnamon may improve glycemic control, with improvements in A1C and FBG (12)[B].

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Office visit frequency per physician discretion, use telemedicine/mobile communications and home BG monitoring.
- Monitor glucose, HbA1c, BP, body weight, lipid profile, and renal and liver function.
- A1c twice a year for patients with well-controlled blood glucose and quarterly for patients with hyperglycemia or recent changes in therapy
- Consider CGM as clinically indicated.

## ***PROGNOSIS***

There is evidence that intensive glycemic control in newly diagnosed diabetics may reduce long-term CVD rates.

## **COMPLICATIONS**

- Emergencies: hyperosmolar coma, DKA, hypoglycemia

- CVD: CAD, PVD, stroke; microvascular: peripheral neuropathy, proliferative retinopathy, nephropathy, erectile dysfunction, and CKD; ophthalmic: blindness, cataracts, glaucoma, retinopathy; GI: NAFLD, gastroparesis, diarrhea; neurologic: autonomic dysfunction; foot ulcers and soft tissue infections

Individualized, patient-centered approach to management.

# Diabetic Ketoacidosis

Melanie J. Lippmann, MD

## BASICS

### DESCRIPTION

- A life-threatening medical emergency in diabetics secondary to severe insulin deficiency and characterized by hyperglycemia, ketosis, and metabolic acidosis
- System(s) affected: endocrine/metabolic

### EPIDEMIOLOGY

#### Incidence

- In the United States: 46 episodes/10,000 diabetics; 2/100 patient-years of type 1 diabetes mellitus (DM) (1)
- Predominant age: 19 to 44 years (56%) and 45 to 65 years (24%); only 18% are <20 years.

### ETIOLOGY AND PATHOPHYSIOLOGY

A deficiency of insulin, exacerbated by an increase in counterregulatory hormones (e.g., catecholamines, cortisol, glucagon, and growth hormone) leading to a hyperglycemic crisis, osmotic diuresis, ketosis with metabolic acidosis, and frequently accompanied by electrolyte disturbances

- Noncompliance/insufficient insulin: 25%
- Infection: 30-40%
- First presentation of DM: 10-25%
- Myocardial infarction (MI): 5-7%
- No cause identified: 10-30%
- Cerebrovascular accident (CVA)
- Medications (corticosteroids, sympathomimetics, atypical antipsychotics)
- Illicit drugs (cocaine)

- Trauma
- Surgery
- Emotional stress
- Pregnancy

## ***RISK FACTORS***

- Type 1 > type 2 DM
- Younger patients at higher risk

## ***GENERAL PREVENTION***

- Close monitoring of glucose during periods of stress, infection, and trauma
- Careful insulin control and regular monitoring of blood glucose levels
- "Sick day" management instructions

## ***COMMONLY ASSOCIATED CONDITIONS***

Complications of chronic (and poorly controlled) DM such as nephropathy, neuropathy, and retinopathy

## **DIAGNOSIS**

### **HISTORY**

- Recent illness, injury, or surgery
- Changes in diet or medications
- Missed insulin doses/noncompliance or failure of insulin pump
- Weight loss in patients recently diagnosed with type 1 DM
- Polyuria, nocturia
- Polydipsia, polyphagia
- Generalized weakness
- Malaise, fatigue, lethargy
- Anorexia or increased appetite
- Nausea, vomiting
- Abdominal pain
- Decreased perspiration

- Fever

## *PHYSICAL EXAM*

- Hypotension
- Tachycardia
- Hypothermia or fever
- Tachypnea, Kussmaul respirations
- Fruity odor of ketotic breath (acetone smell)
- Decreased reflexes
- Abdominal tenderness, decreased bowel sounds
- Dry mucous membranes, poor skin turgor
- Decreased perspiration
- Altered mental status
- Coma

## *DIFFERENTIAL DIAGNOSIS*

- Hyperosmolar hyperglycemic crisis
- Alcoholic ketoacidosis
- Starvation ketosis
- Toxic ingestions (e.g., salicylates, methanol)
- Lactic acidosis
- Uremia/chronic renal failure
- Sepsis
- Acute pancreatitis

## *DIAGNOSTIC TESTS & INTERPRETATION*

- ECG
  - Usually shows sinus tachycardia
  - Changes consistent with electrolyte abnormalities
  - Ischemia/MI as a precipitating factor

- Urine and blood cultures
- Consider lumbar puncture (meningitis).
- Chest x-ray to rule out possible infectious etiology

## *Initial Tests (lab, imaging)*

### **ALERT**

- Diagnostic criteria (1)[C]:
  - Hyperglycemia (glucose usually 250 to 800 mg/dL)
  - Low  $\text{HCO}_3^-$  (usually  $< 18$  mEq/L)
  - Metabolic acidosis on arterial blood gases (pH  $< 7.3$ )
  - Anion gap = serum sodium – (serum chloride + bicarbonate),  $> 10$  mmol
- Other important labs:
  - Serum ketosis: Check  $\beta$ -hydroxybutyrate ( $\beta$ -HB) instead of ketones to evaluate ketosis (2)[B].  $\beta$ -HB is the predominant ketone produced and is preferred over serum ketones.  $\beta$ -HB  $> 3$  mg/dL is abnormal and should be decreased to  $< 1.5$  mg/dL within 12 to 24 hours (3)[B].
  - Urine ketosis (urinalysis [UA]) may only identify acetoacetate and not  $\beta$ -HB.
  - Glycosuria
  - Hyperamylasemia, hyperlipasemia
  - Hypertriglyceridemia/hypercholesterolemia
  - Increased creatinine and BUN: Markedly increased serum ketones may cross-react and cause a falsely high serum creatinine.
  - Pseudohyponatremia: Hyperglycemia or hypertriglyceridemia may cause an artificially low sodium concentration. The measured sodium is suppressed by 1.6 mg/dL for every 100 mg/dL of glucose over 100 mg/dL.
  - Decreased calculated total body  $\text{K}^+$ : Severe acidosis gives an artificially high  $\text{K}^+$  level.
  - Increased serum osmolality (mOsm/kg) =  $[2 \times \text{serum Na (mEq/L)} + \text{glucose (mg/dL)}/18 + \text{BUN (mg/dL)}/2.8]$ ; if calculated osmolality  $< 320$  mOsm/kg, consider etiologies other than diabetic ketoacidosis (DKA)
  - Elevated base deficit
  - A1C helps determine history of diabetic control.

- CBC, electrolytes, BUN, creatinine
- Serum & -HB or ketones
- Arterial blood gases (ABGs); venous blood gases (VBGs) may also be used (VBG pH correlates with 0.03 lower than ABG pH).
- Chest x-ray to rule out pulmonary infection
- Head CT scan if suspected CVA or cerebral edema
- If necessary, cardiac enzymes and blood cultures

## *Diagnostic Procedures/Other*

Only if surgical problem is the underlying precipitant (e.g., appendicitis, cholecystitis)

## **TREATMENT**

- Oxygen and airway management, as needed
- Establish IV access.
- Cardiac monitoring
- Start isotonic crystalloid solution (0.9% saline).
- Fingerstick glucose testing

## **GENERAL MEASURES**

- All but mild cases require inpatient management.
- Severe DKA requires an ICU setting.
- Goals
  - Fluid resuscitation
  - Insulin therapy to normalize serum glucose
  - Resolution of anion gap acidosis
  - Correction of electrolytes
- Identify and treat the precipitating cause (e.g., infection, MI)
- Laboratory testing during management:
  - Serum glucose q1-2h until stable
  - Electrolytes, phosphorus, and venous pH q2-6h as needed

# MEDICATION

## First Line

- Insulin (1)[C]
  - Bolus 0.1 U/kg IV then continuous infusion at 0.1 U/kg/hr (do not use initial insulin bolus in children)
  - If without bolus, 0.14 U/kg/hr continuous infusion (4)
  - Aim for rate of serum glucose decline of 100 mg/dL/hr
  - When glucose 200 mg/dL, reduce infusion to 0.02 to 0.05 U/kg/hr IV or give rapid-acting insulin at 0.1 U/kg SC q2h; goal glucose is 150 to 200 mg/dL.
  - Overlap and continue IV insulin infusion for 1 to 2 hours after SC insulin is initiated.
- IV fluids to correct dehydration: Start with 0.9% NaCl bolus, calculate corrected sodium; if serum Na<sup>+</sup> is high, consider 0.45% NaCl to replace free fluid loss or when adding potassium replacement.
  - When glucose is 200 mg/dL, change to 5% dextrose with 0.45% NaCl at 150 to 250 mL/hr.
- Potassium: falsely elevated due to acidosis; when K<sup>+</sup>  $\geq$ 5.2 mg/dL and if urine output is adequate, start replacement with 20 to 30 mEq/L of K<sup>+</sup> in 1 L IV fluids (1).
  - Hold insulin if K<sup>+</sup>  $\geq$ 3.3 mg/dL; give IV potassium 20 to 30 mEq/hr with fluids until  $>$ 3.3 mg/dL to prevent cardiac arrhythmia (class III).
  - For each 0.1 unit of pH, serum K<sup>+</sup> will change by  $\div$ 0.6 mEq in opposite direction.

---

P.297

- Phosphorus: Routine replacement may lead to hypocalcemia; if very low ( $<$ 1.0), give 20 to 30 mEq/L of K-Phos in fluids.
- Sodium bicarbonate: no demonstrable benefit with a pH  $>$ 7.0 (2,5)[B]; rehydration usually leads to resolution of acidosis. Guidelines recommend its use with pH  $<$ 6.9 or in patients with life-threatening hyperkalemia; however, there is evidence that it may increase cerebral edema, especially in children (6)[A].
- Magnesium: If Mg  $\geq$ 1.8 mg/dL and the patient is symptomatic, consider replacement.
- Precautions
  - If the patient is on an insulin pump, it should be stopped.

- If glucose does not fall by 10% in 1st hour, give regular insulin 0.14 U/kg IV bolus, then continuous infusion at previous rate.
- If using bicarbonate, add 100 mmol or 2 ampules of sodium bicarbonate to 400 mL isotonic solution with 20 mEq KCL over 200 mL/hr for 2 hours until venous pH is >7.0, then stop infusion (1).

## *Second Line*

Insulin, SC or IM: Load with 0.3 U/kg SC, followed by 0.1 U/kg/hr; space dosing to q2h once glucose <250 mg/dL; in uncomplicated DKA, may be safe and cost effective (7)[B]

## *Pediatric Considerations*

- Children with moderate to severe DKA should be transferred to the nearest pediatric critical care hospital.
- Cerebral edema is a rare complication ( $\div$ 1%) but has a mortality of 20-50%:
  - Diagnostic criteria exist for diagnosis; CT may rule out alternative diagnoses (8).
  - Treat with IV bolus of mannitol 1 g/kg in 20% solution, reduce IV fluid rate, and consider hypertonic 3% saline (9).

## *Geriatric Considerations*

Must be careful with impaired renal function or congestive heart failure when correcting fluid and electrolyte abnormalities

## *Pregnancy Considerations*

- Pregnancy itself is diabetogenic and also results in a compensated respiratory alkalosis ( $\text{HCO}_3^-$  19 to 20 mEq/L) with theoretically reduced buffering capacity
- Pregnant women are more susceptible to DKA.
- Euglycemic DKA
- Increased risk of preeclampsia and fetal death
- $\beta$ -Tocolytics and corticosteroids can trigger DKA.
- Perinatal death: 9-35%

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

ADA admission guidelines: blood glucose >250 mg/dL; pH <7.3; HCO<sub>3</sub><sup>2</sup>15 mEq/L; ketones in urine; ICU setting for severe DKA (10)

## *IV Fluids*

- 1 to 1.5 L over the 1st hour, then, if serum corrected Na is high or normal, give 0.45% NaCl at 250 to 500 mL/hr depending on hydration state.
- Switch to 5% dextrose in 0.45% saline at maintenance rate when serum glucose <200 mg/dL; maintain blood glucose between 150 and 250 mg/dL.
- Overly rapid correction of fluid balance may precipitate cerebral edema (2)[C]; if the blood glucose level is falling too rapidly, consider using a 10% dextrose solution instead.

## *Pediatric Considerations*

Bolus 10 to 20 mL/kg initially; 4-hour fluid total should be <50 mL/kg to reduce chance of cerebral edema.

## *Discharge Criteria*

- Discharge when DKA has resolved: anion gap <12, glucose <200 mg/dL; pH >7.3; bicarbonate >18 mEq/L; additionally, patients must be tolerating PO intake and able to resume home medication regimen.
- Underlying precipitant (e.g., infection) must be identified and treated.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Monitor mental status, vital signs, and urine output q30-60min until improved, then q2-4h.
- Monitor blood sugar q1h until <200 mg/dL, then q2-6h.
- Monitor electrolytes, BUN, venous pH, and creatinine q2-4h.

#### *DIET*

- NPO initially
- Advance to preketotic diet when nausea and vomiting are controlled.
- Avoid foods with high glycemic index (e.g., soft drinks, fruit juice, white bread, etc.).

## PROGNOSIS

- 16% of all diabetes-related fatalities
- Overall DKA mortality of 0.5-2%.
- In children <10 years of age, DKA causes 70% of diabetes-related fatalities.

## COMPLICATIONS

- Cerebral edema (most common cause of death in children with DKA)
- Pulmonary edema
- Vascular thrombosis
- Hypokalemia
- Hypophosphatemia
- Cardiac dysrhythmia (secondary to hypokalemia or acidosis)
- MI, myocardial injury
- Acute gastric dilatation
- Late hypoglycemia (secondary to treatment)
- Erosive gastritis
- Infection, mucormycosis
- Respiratory distress

- E10.11 Type 1 diabetes mellitus with ketoacidosis with coma

## Clinical Pearls

### &NA;

- Admit if blood glucose  $>250$  mg/dL, pH  $<7.3$ ,  $\text{HCO}_3^- \geq 15$  mEq/L, and ketones in urine.
- Potassium is falsely elevated due to acidosis; start replacement when  $\text{K}^+ \geq 5.2$  mg/dL and urine output is adequate.

# Diabetic Polyneuropathy

Samir Malkani, MD, MRCP(UK)

## BASICS

### DESCRIPTION

Peripheral nerve dysfunction seen in diabetes; several patterns described (1):

- Symmetric polyneuropathy
  - Distal sensory or sensorimotor
  - Proximal lower extremity polyneuropathy
- Focal and multifocal neuropathy
  - Cranial neuropathy
  - Focal limb or truncal neuropathy
  - Radiculoplexus neuropathy (diabetic amyotrophy)
- Acute painful small fiber neuropathy
- Autonomic neuropathies
- Chronic inflammatory demyelinating polyneuropathy (CIDP)

### EPIDEMIOLOGY

#### Prevalence

- Generalized polyneuropathy
  - 10% at diabetes diagnosis
  - 50% at 25 years
  - Cross-sectional prevalence: 15% by symptoms; 50% by nerve conduction
- Autonomic neuropathy: 16.7% in a United Kingdom study

### ETIOLOGY AND PATHOPHYSIOLOGY

- Metabolic derangement due to hyperglycemia
  - Aldose reductase converts excess glucose to sorbitol, which causes nerve damage.
  - Nonenzymatic glycation of neural proteins and lipids forms damaging advanced glycosylation end products.
  - Protein kinase C activation causes vascular endothelial changes.
  - Oxidative stress from excessive production of reactive oxygen species
  - Cyclo-oxygenase 2 and poly (ADP ribose) polymerase activation
- Vasculopathy causing nerve ischemia: predominant factor in mononeuropathies

## **RISK FACTORS**

- Poor glycemic control
- Duration of diabetes
- Hypertension
- Hyperlipidemia
- Alcohol consumption

## **GENERAL PREVENTION**

Maintenance of normal blood sugar

## **DIAGNOSIS**

### **HISTORY**

- Most common form (typical): symmetric distal sensory or sensorimotor polyneuropathy
  - Distressing numbness, tingling, pain of legs/feet, usually worse at night; allodynia; hyperalgesia
  - Sometimes silent sensory loss, patient unaware
  - Ataxia due to proprioceptive loss
  - Neuropathic foot ulcers due to analgesia and repetitive injury
  - Neuropathic degeneration of foot joints
  - Hands involved late
  - Distal muscle involvement, usually mild

- Symmetric proximal polyneuropathy
  - Proximal leg weakness and wasting
  - Muscles of shoulder girdle rarely involved
  - Pain and sensory changes less prominent
- Focal cranial or limb mononeuropathy
  - May involve 3rd, 4th, 6th, or 7th cranial nerve
  - Femoral, sciatic, or peroneal neuropathy: weakness or pain in nerve distribution
  - Any major peripheral nerve can be involved.
- Truncal neuropathies: painful radiculopathy over dermatomes
- Lumbar radiculoplexus neuropathy (diabetic amyotrophy)
  - Unilateral hip, thigh pain
  - Pelvic girdle and thigh weakness with atrophy
  - Recovery over months
- Diabetic autonomic neuropathy
  - GI: nocturnal diarrhea, sometimes alternating with constipation; gastroparesis with postprandial fullness; nausea and vomiting
  - Cardiovascular: postural dizziness, exercise intolerance
  - Urogenital: urinary hesitancy, overflow incontinence; erectile dysfunction; vaginal dryness; sexual dysfunction
  - Sudomotor: anhidrosis or hyperhidrosis; gustatory sweating of head and upper body
- CIDP: progressive, severe motor loss
- Diabetic cachexia: painful small fiber neuropathy with prominent weight loss and depression

## *PHYSICAL EXAM*

- Symmetric distal polyneuropathy
  - Stacking-and-glove distal sensory loss
  - Large-fiber neuropathy: loss of perception of vibration and light touch (10-G monofilament)
  - Small-fiber involvement: loss of temperature and pinprick
  - Absent ankle reflexes

- Wasting, weakness of small muscles in foot; changes to arch of foot or clawing of toes
- With small-fiber involvement, there may be lack of objective sensory deficit despite pain.
- Symmetric proximal polyneuropathy
  - Proximal leg, arm wasting, and weakness
  - Loss of patellar reflexes
- Focal cranial or limb mononeuropathy
  - 3rd cranial nerve palsy: painful ophthalmoplegia and ptosis; preserved pupillary reflexes (in contrast to compressive palsies)
  - 6th cranial nerve: lateral gaze palsy
  - Femoral neuropathy: weakness of lower leg extension, hip flexion, quadriceps wasting, absent patellar reflex, sensory loss in anterior thigh
  - Sciatic neuropathy: pain or sensory loss in back of thigh and leg; weakness of hamstrings, lower leg muscles
  - Peroneal neuropathy: foot drop
- Truncal neuropathies: sensory loss along dermatome
- Lumbar radiculoplexopathy (amyotrophy)
  - Weakness and wasting pelvic girdle and thigh
  - Sensory loss in L2-L3
  - Absent patellar reflex
- Autonomic neuropathy
  - Cardiovascular: resting tachycardia; orthostatic hypotension
  - Gastroparesis: postprandial distension; gastric splash
- CIDP: motor weakness

## *DIFFERENTIAL DIAGNOSIS*

- Uremic polyneuropathy
- Drug induced
  - Antineoplastic drugs: cisplatin, vincristine
  - Isoniazid

- Amiodarone
- Toxic
  - Chronic arsenic poisoning
  - *n*-Hexane, methyl-*n*-butyl ketone
- Nutritional deficiency
  - Usually associated with alcoholism
- Paraneoplastic polyneuropathy
- Hypothyroidism

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Fasting plasma glucose, 2-hour glucose tolerance test or hemoglobin A1c for diagnosis and to assess glycemic control
- Serum B<sub>12</sub>
- Thyroid function
- Creatinine and BUN
- Syphilis testing
- Serum protein electrophoresis
- Vitamin D
- In mononeuropathy/mononeuritis multiplex, test for vasculitis, paraproteinemia, and sarcoid.
- In radiculopathy or mononeuropathy, imaging studies to exclude compressive lesions

### *Diagnostic Procedures/Other*

- Bedside testing of vibration perception with 128-Hz tuning fork, monofilament perception of 10G filament
- Quantitative sensory testing for vibratory and thermal thresholds
  - Standardized measures for assessing severity and risk of foot ulceration
- Electromyogram nerve conduction velocity
  - Useful to confirm mononeuropathy and entrapment syndromes

- Sensitive but nonspecific index of presence and severity of diabetic polyneuropathy
- In small unmyelinated fiber painful neuropathy, test may be normal.
- Lumbar puncture
  - In CIDP, elevation of spinal fluid protein
- Skin biopsy with epidermal nerve fiber density
  - Enables direct study of small nerve fibers that are difficult to assess electrophysiologically
- Corneal confocal microscopy
  - Noninvasive approach based on examination of corneal innervation

### *Test Interpretation*

- In nerve biopsy of peripheral nerve, Wallerian degeneration, focal axonal swellings containing neurofilaments, axonal atrophy, and demyelination are seen.
- Thick neural capillary basement membrane and endothelial proliferation
- Obliterative microvascular lesions and perivascular inflammation

P.299

## **TREATMENT**

### *GENERAL MEASURES*

- Maintain blood glucose close to normal.
- Provide appropriate footwear to prevent pressure damage to insensate feet.

### *MEDICATION*

#### *First Line*

- Management of pain and sensory neuropathy
  - Tricyclic antidepressants (TCA) (2),(3)[A] (off-label)
- Analgesia may be related to effects on sodium channels. NNT ÷ 1.5 to 5.5, NNH ÷ 3 to 16
- Amitriptyline 25 to 150 mg at bedtime
- Nortriptyline (25 to 150 mg); desipramine (25 to 200 mg) is less sedating than amitriptyline

but limited trial data.

- Anticholinergic side effects may occur.
  - Calcium channel modulators: gabapentin (2),(3)[A] (off-label)
- Binds  $\text{Ca}^{2+}$  channel-associated protein  $\alpha_2\text{-}\delta$ , inhibits neurotransmitter release
- Dose range from 300 to 1,200 mg TID, NNT  $\div$  4 to 12
- Reduce dose in renal insufficiency.
- Adverse effects: dizziness, fatigue, edema
- Fewer side effects than TCA
  - Calcium channel modulators: pregabalin (2),(3)[A]
- Binds same calcium channel as gabapentin
- Linear pharmacokinetics, unlike gabapentin
- Usual dose: 150 to 300 mg/day, NNT  $\div$  3 to 6
- Adverse effects are dizziness and edema.
  - Duloxetine (2),(3)[A]
- Selective serotonin and norepinephrine reuptake inhibitor
- Usual dose is 60 mg/day. NNT  $\div$  3 to 6
- Adverse effects are nausea and dizziness.
- Management of autonomic neuropathy
  - Orthostatic hypotension
    - Fludrocortisone (off-label)
    - Midodrine (off-label)
  - Gastroparesis
    - Metoclopramide or domperidone
    - Erythromycin (off-label)
  - Diabetic diarrhea
    - Loperamide
    - Clonidine (off-label)

- Octreotide (off-label)
- Antibiotics for bacterial overgrowth
- Hyperhidrosis
  - Propantheline (off-label)

## *Geriatric Considerations*

Anticholinergic effects of TCAs may cause urinary retention and arrhythmias.

## *Second Line*

- Antidepressants
  - Venlafaxine (2),(3)[B] (75 to 225 mg daily) (off-label)
    - Serotonin-norepinephrine reuptake inhibitor
- Anticonvulsants
  - Carbamazepine (3)[C] (off-label)
    - Blocks sodium channels
    - Dose 100 to 800 mg/day
- Topical therapies
  - Capsaicin 0.075% cream applied TID
    - Depletes C fibers in skin of substance P
  - Lidocaine 5% (700 mg) patches applied daily to feet (off-label):
    - Causes sodium channel blockade
- Opiate analgesia
  - Tramadol (3)[B] (off-label): 100 to 400 mg/day, NNT 3 to 8
    - Binds opiate receptors; also inhibits reuptake of norepinephrine and serotonin; fewer opiate side effects
  - Tapentadol (3)[B]
    - Binds to  $\mu$ -opiate receptor and inhibits norepinephrine uptake
- $\alpha$ -lipoic acid (3)[C]

- Antioxidant properties may limit free radical-mediated damage.
- 600 mg/day PO dose showed benefit in small studies; intravenous more effective.

## *ISSUES FOR REFERRAL*

If CIDP is suspected, refer to neurologist for investigation and treatment.

## *ADDITIONAL THERAPIES*

- Transcutaneous electrical nerve stimulation
- Percutaneous nerve stimulation
- Electrical spinal cord stimulation
- Actovegin, dextromethorphan with quinidine
- C-peptide

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Acupuncture, Reiki, electromagnetic field treatment: no convincing trial data

## *SURGERY/OTHER PROCEDURES*

Electrical spinal cord stimulation

## **ONGOING CARE**

## *PROGNOSIS*

- Generalized symmetric polyneuropathies
  - Usually slow, chronic progression
  - Insensitive but painless foot as pain lessens
- Focal neuropathies
  - Recovery over months to years

## **COMPLICATIONS**

- Claw foot deformity
- Neurotropic ulceration
  - Painless ulcers on weight-bearing area

- Callus formation is a precursor to ulceration.
- Neuropathic arthropathy
  - Results in complete disorganization of joint structure in foot, Charcot joint

**&NA;**

Diabetes Mellitus, Type 1; Diabetes Mellitus, Type 2

**&NA;**

## **ICD10**

- E10.42 Type 1 diabetes mellitus with diabetic polyneuropathy
- E11.42 Type 2 diabetes mellitus with diabetic polyneuropathy
- E13.42 Oth diabetes mellitus with diabetic polyneuropathy

## **Clinical Pearls**

**&NA;**

- Occasionally, when glycemic control improves dramatically, as can occur when treatment for diabetes is initiated, there may be a worsening of neuropathy symptoms. Symptoms usually stabilize and gradually improve as glycemic control is maintained.
- It is common to combine agents with different mechanisms of action in the management of neuropathic pain. Topical therapies can be combined with systemic therapies. There is limited evidence-based data to support combination therapy.

# Diarrhea, Acute

Pia Prakash, MD

Bedoor Alabbas, MD

Marie L. Borum, MD, EdD, MPH

## BASICS

### DESCRIPTION

- Acute diarrhea is an abnormal increase in stool water content, volume, or frequency ( $\geq 3$  in 24 hours) for <14 days duration.
- Acute viral diarrhea (50-70%)
  - Most common; usually occurs for 1 to 3 days and is typically self-limited
- Bacterial diarrhea (15-20%)
  - Develops 6 to 24 hours after ingestion of contaminated food
  - Suspect when concurrent illness in others who have shared potentially contaminated food
  - Suspect *Clostridium difficile* in patients with recent antibiotic use or hospitalization.
- Protozoal infections (10-15%)
  - Prolonged, watery diarrhea in areas with contaminated water supply
  - Consider if diarrhea lasts >7 days.
- Traveler's diarrhea typically begins 3 to 7 days after arrival in foreign location; rapid onset

### EPIDEMIOLOGY

- In developing countries, acute diarrhea is more common in children. No age predilection in developed countries
- Acute diarrhea accounts for >128,000 U.S. hospital admissions and approximately 1.5 million worldwide deaths annually (1).

### Prevalence

- 7th leading cause of death worldwide (1)

- Affects 11% of the general population
- In developing countries, acute diarrhea is most common in children aged >5 years.
- Rotavirus and adenovirus common in children >2 years
- In developing world, acute diarrhea is largely due to contaminated food and water.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Bacterial
  - *Escherichia coli*
  - *Salmonella*
  - *Shigella*
  - *Campylobacter jejuni*
  - *Vibrio parahaemolyticus*
  - *Vibrio cholerae*
  - *Yersinia enterocolitica*
  - *C. difficile*
  - *Staphylococcus aureus*
  - *Bacillus cereus*
  - *Clostridium perfringens*
  - *Listeria monocytogenes*
- Viral
  - Rotavirus and norovirus (most common)
  - Adenovirus
  - Astrovirus
  - Cytomegalovirus (in immunocompromised)
- Protozoal
  - *Giardia lamblia*
  - *Entamoeba histolytica*
  - *Cryptosporidium*

- *Isospora belli*
- *Cyclospora*
- *Microspora*
- Pathophysiology (2)
  - Noninflammatory: increased intestinal secretions without disruption of intestinal mucosa
  - Inflammatory: disrupts intestinal mucosal integrity, with subsequent tissue invasion/damage
- Viral diarrhea: changes in small intestine cell morphology that include villous shortening, increased number of crypt cells, and increased cellularity of the lamina propria
- Bacterial diarrhea: Bacterial invasion of colonic wall leads to mucosal hyperemia, edema, and leukocytic infiltration.

## **RISK FACTORS**

- Travel to developing countries
- Failure to observe food/water precautions
- Immunocompromised host
- Antibiotic use
- Proton pump inhibitor (PPI) use (3)
- Daycare attendance
- Nursing home residence
- Pregnancy (12-fold increase for listeriosis) (2)

## **GENERAL PREVENTION**

- Frequent hand washing
- Proper food and water precautions, particularly during foreign travel
  - boil it, peel it, cook it, or forget it
- Avoid undercooked meats, raw fish, unpasteurized milk.
- Rotavirus vaccine (for infants) (4)
- Typhoid fever and cholera vaccine (for travel to endemic areas) (5,6)
- Probiotics have not been shown to prevent traveler's diarrhea (7).

## **COMMONLY ASSOCIATED CONDITIONS**

- Inflammatory bowel disease
- Immunocompromise (HIV, malignancy, chemotherapy)

## DIAGNOSIS

### HISTORY

- Duration of symptoms <14 days
- Historical clues for dehydration: orthostatic hypotension, dizziness, increased thirst, decreased urinary output, or altered mental status
- Description of stool—characteristics and output
  - Frequency
  - Quantity
  - Character: presence of mucus, blood, or fat
  - Consistency
  - Floating (8)[A]
  - *Giardia* associated with pale, greasy stools
- Weight loss
- Associated symptoms: change in appetite, abdominal pain or bloating, nausea/vomiting, or fever
- Recent hospitalization or antibiotic use
- Travel history
- Ingestion of raw or undercooked meat; raw seafood; unpasteurized milk
- Sick contacts (8)[A]
- Immunocompromised state
- Pregnancy
- Daycare attendance
- Nursing home residence

### PHYSICAL EXAM

- General: fever, volume status, pulse; blood pressure
- Cardiovascular: tachycardia, orthostatic hypotension
- Abdominal: bowel sounds, abdominal distention, abdominal tenderness, masses, hepatomegaly
- Rectal: stool with blood or mucus, tenderness

- Skin: turgor and capillary refill

## *Geriatric Considerations*

Watery diarrhea with chronic constipation may be caused by fecal impaction or obstructing neoplasm.

## ***DIFFERENTIAL DIAGNOSIS***

- Inflammatory bowel disease
- Malabsorption
- Medications (cholinergic agents, magnesium-containing antacids, chemotherapy, antibiotics)
- *C. difficile* colitis secondary to antibiotic use
- Diverticulitis; ischemic colitis
- Spastic (irritable) colon
- Fecal impaction
- Endocrinopathies: thyroid disease
- Neoplasia

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### *Initial Tests (lab, imaging)*

- CBC
  - Leukocytosis, anemia from blood loss, eosinophilia (parasite infection)
- Serum electrolytes
- BUN and creatinine may elevate with volume depletion.
- Nonanion gap metabolic acidosis
- Stool sample
  - Occult blood present in inflammatory bowel disease, bowel ischemia, and certain bacterial infections
  - Fecal leukocytes
  - Stool ova and parasites
  - Stool culture

- For bloody diarrhea, consider *Salmonella*, *Shigella*, *Campylobacter*, *E. coli* 0157:H7, *Y. enterocolitica*, *E. histolytica*.
- *C. difficile* toxin (especially with recent hospitalization or antibiotic use) (8)[B]
- *Giardia* ELISA >90% sensitive in at-risk population
- Abdominal radiographs (flat plate and upright) if severe abdominal pain or concern for obstruction
- Abdominal CT scan is preferred to evaluate intraabdominal and intestinal disease.

## Diagnostic Procedures/Other

- Consider sigmoidoscopy or colonoscopy in patients with persistent diarrhea, when there is no clear diagnosis after routine blood and stool tests, and if empiric or supportive therapy is ineffective.
- Consider colonoscopy in immunocompromised patients to evaluate for CMV colitis.
- Colonoscopy helps to distinguish infectious diarrhea from inflammatory bowel disease.

P.301

## TREATMENT

### GENERAL MEASURES

- Oral rehydration and electrolyte management are key elements in successful treatment (9)[A].
- Diet, as tolerated—If the gut works, use it!
- IV fluids if patient cannot tolerate oral rehydration or presents with severe dehydration

### MEDICATION

#### First Line

- Consider empiric antibiotics (fluoroquinolones or macrolides) in patients with signs and symptoms of systemic infection and severe cases of traveler's diarrhea (10).
  - Fever
  - Bloody diarrhea
  - Presence of fecal leukocytes
  - Immunocompromised host

- Signs of volume depletion
- Symptoms >1 week
- Tailor antibiotics to stool culture results (11)
  - *Giardia*: metronidazole, tinidazole
  - *E. histolytica*: metronidazole
  - *Shigella*: ciprofloxacin or azithromycin
  - *Campylobacter*: azithromycin or erythromycin
  - *C. difficile*: metronidazole, PO vancomycin, or fidaxomicin
  - Traveler's diarrhea: patients without fever or dysentery: rifaximin 200 mg PO TID or ciprofloxacin 500 mg PO BID. Patients with fever or dysentery: azithromycin 500 mg PO × 1 on day 1 followed by 250 mg PO for 4 days
- General considerations
  - Antibiotics are not recommended in *Salmonella* infections unless caused by *Salmonella typhosa*, or if the patient is febrile or immunocompromised.
  - Avoid antibiotics in patients with *E. coli* 0157:H7 due to risk for hemolytic-uremic syndrome.
  - Antibiotics are not indicated for foodborne toxigenic diarrhea.
  - Avoid antimotility agents (e.g., loperamide) when possible in patients suspected of having infectious diarrhea (especially, *E. coli* 0157:H7) or antibiotic-associated colitis.
  - Antimotility agents, when used in combination with antibiotics, may speed recovery from traveler's diarrhea (12)[A].
- Significant medication interactions
  - Salicylate absorption from bismuth subsalicylate can cause toxicity in patients already taking aspirin-containing compounds and may alter anticoagulation control in patients taking warfarin.
  - Avoid alcoholic beverages with metronidazole due to the possibility of a disulfiram reaction.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Probiotic use above  $10^{10}$ /g may help in patients with antibiotic-associated diarrhea (3)[A].
- The use of probiotics is controversial in the treatment of acute diarrhea. Probiotics should be avoided in immunocompromised patients (3,13)[A].

Probiotics shorten the duration of symptoms in pediatric (14).

- Zinc supplementation can decrease diarrhea-related morbidity and mortality (15)[A].

## INPATIENT CONSIDERATIONS

### Admission Criteria/Initial Stabilization

Outpatient management, except for patients who are severely ill with signs of volume depletion

## ONGOING CARE

### DIET

- Early refeeding is encouraged. Regular diets are as effective as restricted diets.
- The traditional bananas, rice, applesauce, toast (BRAT) diet has little evidence-based support, despite heavy clinical use, and may result in suboptimal nutrition.
- During periods of active diarrhea, coffee, alcohol, dairy products, fruits, vegetables, red meats, and heavily seasoned foods may exacerbate symptoms.

### PATIENT EDUCATION

See guidelines in "General Prevention" section.

### PROGNOSIS

Acute diarrhea is rarely life-threatening if adequate hydration is maintained.

### COMPLICATIONS

- Volume depletion, shock
- Sepsis
- Anemia
- Hemolytic uremic syndrome with *E. coli* 0157:H7
- Guillain-Barré syndrome with *C. jejuni*
- Reactive arthritis with *Salmonella*, *Shigella*, and *Yersinia*
- Functional bowel disorders (e.g., postinfectious irritable bowel syndrome [PI-IBS]) (16)

## Codes

**&NA;**

## ICD10

- R19.7 Diarrhea, unspecified
- A09 Infectious gastroenteritis and colitis, unspecified
- A08.4 Viral intestinal infection, unspecified

## Clinical Pearls

### &NA;

- Viruses are the most common causes of acute diarrheal illness in the United States.
- Oral rehydration is the most important step in treating acute diarrhea.
- Routine stool culture is not recommended, unless the patient presents with bloody diarrhea, fever  $>38.5^{\circ}\text{C}$ , severe dehydration, signs of inflammatory disease, persistent symptoms  $>3$  to 7 days, or immunosuppression.
- Start empiric antibiotics in patients who are severely ill or immunocompromised.

# Diarrhea, Chronic

Aung S. Myint, DO

Matthew Chandler, MD

Marie L. Borum, MD, EdD, MPH

## BASICS

### DESCRIPTION

- An increase in frequency of defecation or decrease in stool consistency (typically >3 loose stools per day) for >4 weeks (1,2,3):
  - Etiologies include osmotic, secretory, malabsorptive, inflammatory, and hypermotility.
  - Infectious etiologies are less common in chronic diarrhea.
- System(s) affected: gastrointestinal (GI)

### EPIDEMIOLOGY

#### Prevalence

Variable depending on etiology, but overall  $\div$  3-5% of the U.S. population is affected (3)

### ETIOLOGY AND PATHOPHYSIOLOGY

In most cases, chronic diarrhea is the result of disturbances in the intestinal luminal water and electrolyte balance. This varies depending on etiology.

- Osmotic (fecal osmotic gap >125 mOsm/kg) (2,3)
  - Carbohydrate malabsorption
    - Disaccharides including lactose
    - Monosaccharides including fructose
    - Polyols including sorbitol, xylitol, sucralose, and saccharin (common sugar substitutes)
    - These substances cannot be metabolized, thus creating an osmotic gradient.
  - Substances including magnesium, phosphate, and sulfate

- Secretory (fecal osmotic gap  $<50$  mOsm/kg) (2,3)
  - Stimulant laxative ingestion
  - Postcholecystectomy
    - Excessive bile salts in intestinal lumen cause choleraic diarrhea; often resolves in 6 to 12 months
  - Ileal bile acid malabsorption
    - Ileal resection of  $<100$  cm leads to choleraic diarrhea due to excessive colonic bile salts.
  - Disordered motility
    - Postvagotomy
    - Diabetic autonomic neuropathy
    - Hyperthyroidism
  - Neuroendocrine tumors
    - VIPoma
    - Gastrinoma
    - Somatostatinoma
    - Carcinoid syndrome
  - Metastatic medullary carcinoma of the thyroid
  - Systemic mastocytosis
  - Protein-losing enteropathy
- Malabsorption (2,3)
  - Whipple disease
  - Giardiasis
  - Celiac disease
  - Short bowel syndrome
    - Ileal resection of  $>100$  cm leads to insufficient bile salt concentrations in the duodenum for optimal fat absorption, leading to fat and fat-soluble vitamin malabsorption.
  - Small intestinal bacterial overgrowth
  - Pancreatic exocrine insufficiency (CF, chronic pancreatitis)

- Inadequate bile acid production/secretion
- Inflammatory (2,3)
  - Ulcerative colitis
  - Crohn disease
  - Microscopic colitis (lymphocytic or collagenous)
  - Vasculitis
  - Radiation enterocolitis
  - Eosinophilic enterocolitis
- Hypermotility (normal fecal osmotic gap) (1,2,3)
  - Irritable bowel syndrome (IBS)
  - Functional diarrhea
- Drugs: NSAIDs, colchicine, metformin, digoxin, SSRIs (3)
- Herbal products: St. John's wort, echinacea, garlic, saw palmetto, ginseng, cranberry extract, *aloe vera*
- Infectious (2,3)
  - Bacterial: *Clostridium difficile*, *Mycobacterium avium intracellulare*
  - Viral: cytomegalovirus
  - Parasitic: *Giardia lamblia*, *Cryptosporidium*, *Isospora*
  - Helminthic: *Strongyloides*

## Genetics

- Celiac disease is associated with HLA-DQ2 and HLA-DQ8 haplotypes on major histocompatibility complex (MHC) class II antigen-presenting cells (4).
- IBD is polygenic (5).
- Cystic fibrosis (CF) is caused by a mutation in the CF transmembrane conductance regulator (CFTR), resulting in abnormal exocrine gland secretions.
- Familial diarrhea syndrome is linked to a missense mutation in GUCY2C resulting in hyperactivation of CFTR (6).

## RISK FACTORS

- Osmotic
  - Excessive ingestion of nonabsorbable carbohydrates
  - Lactose intolerance
  - Celiac disease
- Secretory
  - Extensive small bowel resection/ileal surgery
  - History of neuroendocrine disease
  - History of stimulant laxative abuse
  - Dysmotility syndromes
- Malabsorptive
  - CF
  - Chronic alcohol abuse
  - Chronic pancreatitis/pancreatic insufficiency
  - Celiac disease
  - Medications (e.g., orlistat, acarbose)
- Inflammatory
  - Inflammatory bowel disease (IBD)
  - NSAID use
  - Thoracoabdominal radiation
  - HIV/AIDS
  - Antibiotic use
  - Immunosuppressant therapy
- Hypermotility
  - Psychosocial stress
  - Preceding infection
- Genetic predisposition

## **ALERT**

Diabetes mellitus and/or prior cholecystectomy both cause secretory and

osmotic diarrhea.

## GENERAL PREVENTION

- Variable depending on etiology of the diarrhea
- Treat the underlying disorder.

## COMMONLY ASSOCIATED CONDITIONS

- Extraintestinal manifestations of IBD include arthralgias, aphthous stomatitis, uveitis/episcleritis, erythema nodosum, pyoderma gangrenosum, perianal fistulas, rectal fissures, ankylosing spondylitis, and primary sclerosing cholangitis.
- Celiac disease is associated with dermatitis herpetiformis.
- A significant number of patients with IBS have psychiatric comorbidities.

## DIAGNOSIS

### HISTORY

- Detailed history of symptoms, including the following (1,2,3):
  - Onset, pattern, and frequency
  - Stool volume and quality (including presence of blood or mucus)
  - Presence of nocturnal symptoms
  - Travel history
  - Antibiotic exposure
  - Dietary habits
  - Current medications
  - Family history
- Determine aggravating or alleviating factors, including changes with oral intake or improvement with selective food avoidance (e.g., dairy products).
- Evaluate for recent unintentional weight loss.
- Complete review of systems, including rashes, arthritis, ocular problems, heat intolerance, polyuria/polydipsia, headache, fever, flushing, alcohol intake
- IBS or functional diarrhea by Rome III criteria (3):
  - IBS: recurrent abdominal pain or discomfort at least 3 days/month in last 3 months. 2 of the following criteria must be met:

- Improvement with defecation
- Onset associated with change in frequency of stool
- Onset associated with change in form of stool
- Functional diarrhea: loose or watery stools 75% of the time without pain for >3 months (symptoms >6 months)

## PHYSICAL EXAM

- General: Assess for volume depletion, nutritional status, recent weight loss (2,3).
- Skin: flushing (carcinoid), erythema nodosum (IBD), pyoderma gangrenosum (IBD), ecchymoses (vitamin K deficiency), dermatitis herpetiformis (celiac disease) (1,2,3)
- HEENT: iritis/uveitis (IBD)
- Neck: goiter (hyperthyroid), lymphadenopathy (Whipple disease)
- Cardiovascular: tachycardia (hyperthyroid)
- Pulmonary: wheezing (carcinoid)
- Abdomen: hyperactive bowel sounds (IBD), abdominal distention (IBD/IBS), diffuse tenderness (IBD/IBS)
- Anorectal: anorectal fistulas (IBD), anal fissures (IBD)
- Extremities: arthritis (IBD)
- Neurologic: tremor (hyperthyroid)

## DIFFERENTIAL DIAGNOSIS

See above.

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Blood: CBC with differential, electrolytes (Mg, P, Ca), total protein, albumin, thyroid-stimulating hormone (TSH), free T4, erythrocyte sedimentation rate, iron studies (2,3)
- Stool: WBCs, culture, ova and parasites, *Giardia* stool antigen, *C. difficile* toxin, stool electrolytes (fecal osmotic gap), fecal occult blood, qualitative fecal fat (Sudan stain) (2,3).
- Plain film of the abdomen to evaluate for obstruction, toxic megacolon, bowel ischemia (1)
- CT to rule out chronic pancreatitis if abnormal pancreatic enzymes or evidence of malabsorption (1,2)

## Follow-Up Tests & Special Considerations

- Celiac disease: antiendomysial antibody IgA, antitissue transglutaminase (TTG) IgA, antigliadin (AGA) IgA, serum IgA (10% of celiac patients have IgA deficiency that may result in false-negative results) (4)[A]
- Chronic pancreatic insufficiency: fecal elastase (2)[A]
- Protein-losing enteropathy: fecal  $\alpha_1$  antitrypsin (2)[A]
- Carbohydrate malabsorption: fecal pH (3)[A]
- Small bowel overgrowth: hydrogen breath test
- Prior history of hospitalization or antibiotics: *C. difficile* toxin (3)[A]
- HIV ELISA, special stains for *Isospora* and *Cryptosporidium* (2)[A]
- Allergy testing (2)[C]
- Neuroendocrine tumor
  - Serum: chromogranin A, VIP, gastrin (1,3)
  - Urine: 5-HIAA, histamine (1,3)

## Diagnostic Procedures/Other

- Ileocolonoscopy with biopsies: to diagnose IBD, microscopic colitis, CMV colitis, and colorectal neoplasia (7)[A]
- Flexible sigmoidoscopy: especially if pregnant, with comorbidities, or if left-sided symptoms predominate (tenesmus and urgency) (7)[A]
- Esophagogastroduodenoscopy (EGD) with small bowel biopsies if malabsorption is suspected:
  - Celiac, *Giardia* infection, Crohn disease, eosinophilic gastroenteropathy, Whipple disease, intestinal amyloid, pancreatic insufficiency (7)[A]
- Capsule endoscopy if further evaluation of small bowel is needed (7)[C]
- Upper GI series with small bowel follow-through
- CT or magnetic resonance (MR) enterography (1,2)

## Test Interpretation

- Celiac disease: Marsh classification:

- Intraepithelial lymphocytosis, crypt hyperplasia, villous atrophy (4)
- Crohn disease: cobblestoning, linear ulcerations, skip lesions, noncaseating granulomas
- Ulcerative colitis: crypt abscesses, superficial inflammation
- Lymphocytic colitis: increased intraepithelial infiltration of lymphocytes, increased inflammatory cells within the lamina propria, normal mucosal architecture (8)
- Melanosis coli suggests laxative abuse (2).

## TREATMENT

### GENERAL MEASURES

- Volume resuscitation if necessary (2)[A]
- Electrolyte replacement if indicated (2)[A]
- If stable, treatment is generally outpatient.

### MEDICATION

#### First Line

- Based on underlying cause:
  - Lactose intolerance: lactose-free diet (9)[A]
  - Cholecystectomy or ileal resection: cholestyramine or colestipol 2 to 16 g/day PO divided (10)[A]
  - Diabetes: aggressive diabetes management and glucose control
  - Hyperthyroidism: methimazole 5 to 20 mg/day PO, propylthiouracil (PTU) 100 to 150 mg/day PO divided; thyroid ablation
  - *C. difficile*: vancomycin 125 mg PO q6h or metronidazole (Flagyl) 500 mg PO q8h or fidaxomicin 200 mg PO BID
  - *G. lamblia*: metronidazole 250 mg PO Q8H, nitazoxanide 500 mg PO q12h (2)[A]
  - Whipple disease: ceftriaxone 2 g IV for 14 days then Bactrim DS 160/800 mg PO BID for 1 to 2 years (11)[A]
  - Small intestinal bacterial overgrowth: rifaximin 550 mg PO BID, fluoroquinolones 250 to 750 mg PO BID, metronidazole 500 mg PO q6-8h, penicillins (12)[A]
  - Pancreatic insufficiency: pancreatic enzyme replacement (1)[A]

- HIV/AIDS: antiretroviral therapy
- Microscopic colitis: budesonide 9 mg/day PO, mesalamine 800 mg PO TID, Pepto-Bismol 786 mg PO TID (8)[A]
- IBD: 5-aminosalicylic acid (5-ASA), corticosteroids (short-term only), antibiotics (short-term only), immunomodulators (6-mercaptopurine [6-MP], azathioprine, methotrexate), anti-TNF therapy (infliximab, adalimumab, certolizumab) (5)[A]
- Neuroendocrine tumor: octreotide 100 to 600 &mgr;g/day SC (2,13)[A]
- Celiac disease: gluten-free diet (wheat/barley/rye avoidance) (4)[A]
- IBS diarrhea predominant: rifaximin 550 mg PO BID, alosetron 0.5 to 1 mg PO BID, peppermint oil (14)[A]
- Symptom relief:
  - Loperamide (Imodium) 4 to 8 mg/day PO divided
  - Diphenoxylate-atropine (Lomotil) 1 to 2 tabs PO BID-QID (2)[A]

## ***SURGERY/OTHER PROCEDURES***

- Resection of neuroendocrine tumors (13)[A]
- Intestinal resection for medically refractory IBD
- Fecal transplant for recurrent *C. difficile* infection (14)[A]

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Many homeopathic and naturopathic formulations are available; most have not been evaluated by the FDA.

## **ONGOING CARE**

### ***DIET***

Abstain from gluten-containing foods, nonabsorbable carbohydrates, lactose-containing products, and food allergens depending of etiology of diarrhea.

### ***PATIENT EDUCATION***

- Reassure patient of wide variation in what is accepted as "normal" bowel habits.
- Restrict colon stimulants.

- Specific education and dietary changes based on underlying etiology.

## PROGNOSIS

Depends on etiology

## COMPLICATIONS

- Fluid and electrolyte abnormalities (1,3)
- Malnutrition (1); anemia (1,3)
- Malignancy (colon cancer in IBD, small bowel cancer in celiac disease and Crohn disease, lymphoma with IBD therapies) (5)
- Infection with immunomodulator, biologic, and corticosteroid therapies for IBD (5)

Algorithm: Diarrhea, Chronic

## Codes

&NA;

### ICD10

K52.9 Noninfective gastroenteritis and colitis, unspecified

## Clinical Pearls

&NA;

- Consider IBS, IBD, malabsorption syndromes (such as lactose intolerance), celiac disease, over-the-counter medications, and herbal products and chronic infections (particularly in patients who are immunocompromised).
- The appropriate workup is based on a comprehensive medical history.

# Diffuse Interstitial Lung Disease

Jacqueline L. Olin, MS, PharmD, BCPS, FASHP, FCCP

J. Andrew Woods, PharmD, BCPS

Brian Hertz, MD

## BASICS

### DESCRIPTION

- Interstitial lung diseases (ILDs) represent a diverse group of chronic progressive lung diseases associated with alveolar inflammation and/or potentially irreversible pulmonary fibrosis.
- >200 individual diseases may present with similar characteristics, making ILD difficult to classify.
- A classification scheme proposed by the American Thoracic Society and European Respiratory Society includes these subtypes:
  - Known causes (environmental, occupational, or drug-associated disease)
  - Systemic disorders (e.g., sarcoidosis, Wegener granulomatosis, collagen vascular disease)
  - Rare lung diseases (e.g., pulmonary histiocytosis, lymphangioleiomyomatosis)
  - Idiopathic interstitial pneumonias (IIPs)
- Based on clinical, radiologic, and histologic features, IIPs are further subclassified into the following diagnoses (1):
  - Major IIPs, including idiopathic pulmonary fibrosis (IPF), nonspecific interstitial pneumonia (NSIP), respiratory bronchiolitis-associated ILD (cryptogenic organizing pneumonia [COP], etc.)
  - Rare IIPs
  - Unclassifiable IIPs
- Classification of IIPs and relationships between the subtypes are difficult to classify due to mixed patterns of injury (1).

### *Pediatric Considerations*

ILD in infants and children represents a heterogeneous group of respiratory disorders. Diseases

result from a variety of processes involving genetic factors and inflammatory or fibrotic responses, and processes are distinct from those that cause ILD in adults (2). Some diseases result from developmental disorders and growth abnormalities in infancy (2,3). After common causes are excluded, referral of infants to a subspecialist is recommended (2).

## **EPIDEMIOLOGY**

### *Incidence*

- Exact incidence and prevalence are difficult to determine because of differences in case definitions and procedures used in diagnosis.
- Cited incidence of IPF in the United States: 16.3 to 17.4/100,000 (4) and pediatric ILD of 1.32/1,000,000 (3)

### *Prevalence*

Cited prevalence of IPF in the United States: 42.7 to 63 cases/100,000 in the general population (4) and pediatric ILD of 3.6/1 million (3)

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Alveolar inflammation may progress into irreversible fibrosis.
- Varying degrees of ventilatory dysfunction occur among the ILD subtypes.
- ILD associated with collagen vascular disease and systemic connective disorders can manifest involvement of skin, joints, muscular, and ocular systems.
- Some types of ILD are associated with specific exposures:
  - Medications (amiodarone, antibiotics [especially nitrofurantoin], chemotherapy agents, gold, illicit drugs)
  - Inorganic dusts (silicates, asbestos, talc, mica, coal dust, graphite)
  - Organic dusts (moldy hay, inhalation of fungi, bacteria, animal proteins)
  - Metals (tin, aluminum, cobalt, iron, barium)
  - Gases, fumes, vapors, aerosols

### *Genetics*

Some subtypes of ILD may be associated with specific predisposing genes and environmental exposures; however, the role of genetic factors is unknown.

## **RISK FACTORS**

- Environmental or occupational exposure to inorganic or organic dusts
- 66-75% of patients with ILD have a history of smoking.
- Due to diversity of diseases, age is not a reliable predictor of pathology:
  - Most patients with connective tissue disease-related pathology and inherited subtypes present between ages 20 and 40 years.
  - Median age of patients with IPF is 66 years. Studies of clinical predictors of survival including age, ethnicity, and smoking status have been inconsistent (5).

## GENERAL PREVENTION

Avoiding environmental/occupational exposure to organic or inorganic dust and smoking cessation may reduce incidence or improve clinical course in patients with established ILD.

## COMMONLY ASSOCIATED CONDITIONS

Many systemic disorders and primary diseases are associated with ILD. A partial list includes the following:

- Collagen vascular disease
- Sarcoidosis
- Amyloidosis
- Goodpasture syndrome
- Churg-Strauss syndrome
- Wegener granulomatosis

## DIAGNOSIS

- Accurate diagnosis is imperative, as treatment choices and prognosis can vary with pathogenesis.
- Diagnosis of IPF requires exclusion of other known ILD causes, the presence of a UIP pattern on high-resolution computed tomography (HRCT), and/or surgical lung biopsy pattern (6).

## HISTORY

- Symptoms may include progressive exertional dyspnea and nonproductive cough.
- Patients may also present with hemoptysis or fatigue.

Obtaining a history of illness duration (acute vs. chronic), potential environmental/occupational exposures, travel, medical conditions (including systemic diseases), and medication reconciliation is important in assessing the cause of the ILD.

- Some cases of lung disease may occur weeks to years after discontinuation of an offending agent (e.g., carmustine).

## *PHYSICAL EXAM*

Physical findings are usually nonspecific. Some common features includes the following:

- Crackles (typically present on auscultation of lung bases on posterior axillary line)
- Rales
- Inspiratory 0squeaks0
- Clubbing of the digits and cyanosis in advanced disease

## *DIFFERENTIAL DIAGNOSIS*

- Acute pulmonary edema
- Diffuse hemorrhage
- Atypical pneumonia
- Diffuse bronchoalveolar cell carcinoma or lymphatic spread of tumor

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- O<sub>2</sub> saturation
- Peak expiratory flow rate
- CBC with differential, comprehensive metabolic profile
- CRP or sedimentation rate
- Chest x-ray (CXR): most commonly reticular pattern, less commonly nodular or mixed patterns

### *Follow-Up Tests & Special Considerations*

HRCT of the chest is the most useful tool for distinguishing among ILD subclasses, especially if normal CXRs:

- If indicated, arterial blood gas (ABG), hypersensitivity pneumonitis panel, plasma ACE inhibitor

concentration (sarcoidosis)

- If a systemic disorder is suspected, consider antinuclear antibody (ANA), rheumatoid factor (RF), erythrocyte sedimentation rate (ESR), and antineutrophil cytoplasmic antibodies (ANCA).

## *Diagnostic Procedures/Other*

- Pulmonary function testing (PFT; spirometry, lung volumes, carbon monoxide diffusing capacity)
  - Commonly demonstrates a restrictive defect (decreased vital capacity and total lung capacity)
  - Forced vital capacity (FVC) has been shown to decline 100 to 200 mL/year in the placebo arm of IPF patients in clinical trials (5).
- Bronchoscopy
  - Bronchoalveolar lavage (BAL) cellular analysis studies may be useful in distinguishing subtypes (including sarcoidosis, hypersensitivity pneumonitis, cancer). If performed, the BAL target site should be chosen based on the HRCT finding (7).
  - Bronchoscopic transbronchial lung biopsy may help diagnose sarcoidosis and, on occasion, is sufficiently supportive of other ILD diagnoses.
- Thoracoscopic surgery for lung biopsy has the greatest diagnostic specificity for ILDs but is less frequently used given improved specificity of HRCT. May be indicated if a diagnosis cannot be determined from transbronchial biopsy or HRCT

## *Test Interpretation*

- Diagnostic classifications of IIPs are based on histopathologic patterns seen on lung biopsy.
- Major histologies include an inflammation and fibrotic and granulomatous patterns.
- Characteristic changes on HRCT may help to distinguish between the following subtypes:
  - Reticulonodular, ground glass opacities, and, in later stages, honeycombing may be seen.
  - Associated hilar and mediastinal adenopathy are characteristic of stage I and II sarcoidosis.
- No specific test is the gold standard, which emphasizes the importance of a multidisciplinary consensus for diagnosis with clinical, radiologic, and pathologic findings.

## TREATMENT

- Evidence does not support the routine use of any specific therapy for ILD in general, and especially IPF (6).
- No survival benefit of home oxygen use in ILD (8)[A].
- Corticosteroids have a role in some ILD subtypes (9)[A].
- Current evidence does not clearly support routine use of noncorticosteroid anti-inflammatory agents for IPF, including cyclosporine, azathioprine, colchicines, cyclophosphamide, cytokines, bosentan, etanercept, methotrexate, N-acetylcysteine, or interferon.
- Clinical trials have indicated that anticoagulation (warfarin) and endothelin receptor antagonists (ambrisentan, bosentan) are ineffective, potentially harmful, and therefore not recommended in the treatment of IPF.
- Lung transplant among selected IPF patients has demonstrated median survival of 4.5 years (10)[A].

## GENERAL MEASURES

- Avoid/minimize offending environmental/occupational exposures/medications.
- Smoking cessation
- Supplemental oxygen, if indicated

## MEDICATION

### *First Line*

- Corticosteroids are most effective for certain ILDs, especially exacerbations of sarcoidosis, NSIP, COP, and hypersensitivity pneumonitis. However, response rates have been variable across and within subtypes. The optimal dose and duration of therapy are unknown.
- Common starting dose of prednisone is 0.5 to 1 mg/kg/day for 4 to 12 weeks, with potential up-titration to 0.5 mg/kg based on patient response.

### *Second Line*

- Two antifibrotic agents were approved in 2014 for IPF, which have demonstrated modest slowing of FVC decline over 52 weeks compared to placebo. Both medications decreased all-cause mortality rates. Longer term studies are not yet available. It is not clear if FVC is the most conclusive meaningful efficacy variable for IPF.
  - Pirfenidone (Esbriet), an orally active antifibroblast agent has demonstrated a favorable risk-

to-benefit profile in three randomized, placebo-controlled trials of IPF patients with mild-to-moderate impairment of lung function. The ASCEND trial demonstrated that pirfenidone led to a significant reduction in rate of decline in FVC compared with placebo. Notable secondary endpoints include the following: significant improvement in progression-free survival; in pooled analysis that included patients from other phase 3 trials, there was a significant reduction in all-cause death as well as death from IPF. Adverse effects from the ASCEND trial were GI related (nausea, vomiting, anorexia, weight loss, GERD, and dyspepsia), rash, insomnia, dizziness, fatigue, and aminotransferase elevation. Most were mild to moderate in nature and did not result in pirfenidone discontinuation. Pirfenidone is not recommended for patients with severe liver impairment or ESRD (requiring dialysis) (11) [A].

- Pirfenidone is titrated over 2 weeks to 801 mg orally 3 times daily with food.
- Nintedanib (Ofev), a tyrosine kinase inhibitor, reduced the annual rate of decline in FVC and fewer acute exacerbations occurred compared to placebo. The most common adverse effects are GI upset (nausea, vomiting, diarrhea, abdominal pain), anorexia, aminotransferase elevation, and hypertension. It is not recommended in moderate to severe liver impairment and can cause birth defects (12)[A].
- Nintedanib is given at 150 mg orally twice daily with food.
- The addition of tacrolimus to corticosteroids (with cyclosporine, cyclophosphamide, or no additional therapy) demonstrated improved event-free survival in patients with ILD complicated with polymyositis or dermatomyositis (13)[A].
- Several second-line agents have been used in Wegener granulomatosis:
  - Cyclophosphamide is commonly used in treatment of Wegener granulomatosis. It is given 1.5 to 2 mg/kg/day PO for 3 to 6 months.
  - Methotrexate has been used in treatment of mild Wegener granulomatosis in combination with corticosteroids. A studied dosing regimen consisted of an initial methotrexate dose of 0.3 mg/kg (maximum dose of 15 mg) once weekly, with 2.5 mg titration each week (maximum dose of 25 mg/week).
  - Other second-line agents that have been studied include mycophenolate, mofetil, and rituximab.

## ***SURGERY/OTHER PROCEDURES***

Single- or double-lung transplantation may be a treatment of last resort. Some ILDs associated with systemic disease may recur in the recipient lung.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Follow-up testing should include PFTs, cardiopulmonary stress test, pulse oximetry, and CXR.

### *PATIENT EDUCATION*

National Heart, Lung, and Blood Institute: <http://www.nhlbi.nih.gov/health/health-topics/topics/ipf/>

### *PROGNOSIS*

IPF confers the worst prognosis (median survival of 2.5 to 3 years) (5). A clinical prediction model to estimate the risk of death from ILD has been described (14). Other subtypes, including hypersensitivity pneumonitis, nonspecific interstitial pneumonia, and cryptogenic organizing pneumonia, have a good prognosis.

### **COMPLICATIONS**

- Cor pulmonale
- Pneumothorax
- Progressive respiratory failure

## Codes

**&NA;**

### ICD10

- J84.9 Interstitial pulmonary disease, unspecified
- J84.10 Pulmonary fibrosis, unspecified
- J84.111 Idiopathic interstitial pneumonia, not otherwise specified

## Clinical Pearls

**&NA;**

- ILD differs from chronic obstructive pulmonary disease (COPD); anatomically, ILD involves the lung parenchyma (i.e., alveoli) and COPD involves both airways and alveoli.
- In some cases, avoiding or minimizing offending environmental/occupational exposures, medications, and smoking may alter disease severity.

# Diverticular Disease

Jin Sol Oh, MD

David Hardy, MD, RPVI

Steven B. Holsten Jr., MD, FACS

## BASICS

### DESCRIPTION

Diverticular disease includes asymptomatic diverticulosis, symptomatic uncomplicated diverticular disease, uncomplicated diverticulitis, complicated diverticulitis, and diverticular bleeding.

- Diverticulum (single) or diverticula (multiple) are outpouchings of colonic mucosa and submucosa through weakened muscle layers in the colonic wall.
  - Less common in vegetarians and more common in cultures with low-fiber diets
  - Most diverticula occur on the left side of the colon; Asian populations have more right-sided diverticula.
  - Prevalence of diverticulosis and the number of diverticula increase with age.
- Symptomatic uncomplicated diverticular disease: recurrent abdominal pain attributed to diverticula in the absence of macroscopically overt colitis or diverticulitis (1)
- Uncomplicated diverticulitis: diverticular inflammation and/or infection without systemic sequelae
- Complicated diverticulitis inflammation/infection with secondary abscess formation, bowel obstruction or perforation, peritonitis, fistula, or stricture formation
- Diverticular bleeding occurs in 3-5% of patients with diverticular disease.
  - Accounts for >40% of lower GI bleeds and 30% of cases of hematochezia in general
  - Bleeding more common with right-sided diverticula
- System(s) affected: entire GI tract except the rectum

### EPIDEMIOLOGY

#### *Incidence*

- Diverticulosis affects 60% of the population above the age of 60, and 70% by age of 80.
- 1-2% of the general population is affected by diverticulitis over the course of a lifetime (1).
- Traditionally, 15-25% of patients with diverticulosis were thought to develop diverticulitis in their lifetime. The true incidence of diverticulitis is likely <5%.
- Yearly mortality rate: 2.5/100,000

## *Prevalence*

- Increased from 62 to 75/100,000 persons from 1998 to 2005; large increase in incidence for patients <45 years of age due to changes in diet
- Male = female overall. More common in men <65 years of age and more common in women >65 years

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Diverticula form where intestinal blood flow (vasa recta) penetrates the colonic mucosa. This results in decreased resistance to intraluminal pressure. Diverticulitis occurs when there is diverticular inflammation, infection, and/or perforation.

- Age-related degeneration of mucosal wall, increased intraluminal pressure from dense, fiber-depleted stools, and abnormal colonic motility contribute to diverticular disease.
- Thinning of the vasa recta over the neck of the diverticula increases susceptibility to bleeding.
- Diverticulitis occurs when local inflammation and infection contribute to tissue necrosis with risk for mucosal micro- or macroperforation.
- Most right-sided diverticula are true diverticula (all layers of the colonic wall).
- Most left-sided diverticula are pseudodiverticula (outpouchings of the mucosa and submucosa only).
- Surgical and autopsy studies show mycosis, a constellation of thickened circular muscle (pseudohypertrophy due to increased elastin in the taeniae), short taeniae, and luminal narrowing.
- Diverticulitis: inflammation with lymphocytic infiltrate, ulceration, mucin depletion necrosis, Paneth cell metaplasia, and cryptitis
- Alterations in intestinal microbiota contribute to chronic inflammation (1,2).
- Diverticular disease and irritable bowel syndrome (IBS) may be on the same disease continuum.

## Genetics

- No known genetic pattern
- Asian and African populations have lower overall prevalence but develop diverticular disease with adoption of a Western lifestyle.

## RISK FACTORS

- Age >40 years
- Low-fiber diet
- Sedentary lifestyle, obesity
- Previous diverticulitis. Risk rises with the number of diverticula
- Smoking increases the risk of perforation (1).
- NSAIDs, steroids, and opiate analgesics increase risk for diverticular bleeding. Calcium channel blockers and statins appear to protect against diverticular bleeding.

## GENERAL PREVENTION

High-fiber diet or nonabsorbable fiber (psyllium) (>30 g/day of fiber)

## COMMONLY ASSOCIATED CONDITIONS

Connective tissue diseases, colon cancer, and inflammatory bowel disease

## DIAGNOSIS

### HISTORY

- Diverticulosis
  - 80-85% of patients are asymptomatic. Of the 15-20% with symptoms, 1-2% will need hospitalization and 0.5% will need surgery.
  - Abdominal pain is most common symptom: dull, colicky, primarily left lower quadrant (LLQ). Pain can be exacerbated by eating and by bowel movement or passage of flatus.
  - Diarrhea or constipation
- Diverticulitis: uncomplicated (75%) and complicated (25%)
  - Abdominal pain: acute onset, typically in LLQ
  - Fever and/or chills

- Anorexia, nausea (20-62%), or vomiting
- Constipation (50%) or diarrhea (25-35%)
- Dysuria and urinary frequency suggest bladder or ureteral irritation.
- Pneumaturia and fecaluria can occur if colovesical fistula develops.
- Diverticular bleeding
  - Melena, hematochezia
  - Painless rectal bleeding
- Immunocompromised patients may not present with fever or leukocytosis but are at higher risk for perforation and abscess formation (2).

## *PHYSICAL EXAM*

- Diverticulosis
  - Exam may be completely normal.
  - May have intermittent distension or tympany
  - No signs of peritoneal inflammation
  - May have heme + stools
- Diverticulitis
  - Abdominal tenderness usually localized to the LLQ.
  - Rebound tenderness, involuntary guarding, or rigidity (suggests peritoneal inflammation or potential bowel perforation)
  - Palpable mass in LLQ (20%) that is tender, firm, or fixed.
  - Abdominal distension and tympany
  - Bowel sounds hypoactive or could be high-pitched and intermittent if obstruction ensues
  - Rectal exam may reveal tenderness or mass.
  - Colovaginal, colovesical, and perirectal fistulae may be the initial manifestation (rarely).

## *DIFFERENTIAL DIAGNOSIS*

IBS, lactose intolerance, carcinoma, inflammatory bowel disease, fecal impaction, incarcerated hernia, gallbladder disease, angiodysplasia, colitis, acute appendicitis, ectopic pregnancy

## *DIAGNOSTIC TESTS & INTERPRETATION*

## *Initial Tests (lab, imaging)*

- WBC is normal in diverticulosis and up to 45% of cases of diverticulitis. As diverticulitis worsens, WBC typically elevated with left shift.
- Hemoglobin normal (unless bleeding)
- ESR elevated in diverticulitis
- Urinalysis (UA) may show microscopic pyuria or hematuria.
- Urine culture: usually normal. Persistent infection suspicious for colovesical fistula
- Blood cultures positive in systemic cases of diverticulitis
- Diverticulosis
  - Asymptomatic diverticulosis is a common incidental finding on routine colonoscopy.
- Diverticulitis
  - Plain films of the abdomen (acute abdominal series—supine and upright) to assess for air under the diaphragm (bowel perforation) and signs of bowel obstruction (dilated loops of bowel)
  - CT scan with IV, oral, and rectal contrast to stage disease and map treatment plan (3)[A]
  - Ultrasound and magnetic resonance imaging are useful alternative.
  - Barium enema is not recommended due to risk of peritoneal extravasation.
- Diverticular bleeding/hematochezia
  - Endoscopy is the test of choice to evaluate GI bleeding (4,5).
  - Angiography if bleeding obscures endoscopy or when endoscopy cannot visualize a source (4,5)

## *Diagnostic Procedures/Other*

- For evaluation of suspected diverticular bleeding
  - Place NG tube for lavage to exclude upper GI bleeding (4).
  - <sup>99m</sup>Tc-pertechnetate-labeled RBC scan (more sensitive) with follow-up angiography to localize bleeding (not studied in a comparison trial) (4,5)
- For diverticulitis, gallium- or indium-labeled leukocytes to localize abscess (rarely used)

## TREATMENT

### GENERAL MEASURES

- Diverticulosis: Outpatient therapy with fiber supplementation and/or bulking agents (psyllium) is recommended (preferably >20 to 30 g/day) (3)[A].

- Uncomplicated diverticulitis: pain, tenderness, leukocytosis, but no toxicity or peritoneal signs;

P.307

use oral antibiotics. 1-2% of subjects require hospitalization for toxicity, septicemia, peritonitis, or failure of symptoms to resolve. Up to 30% of patients may require surgery at first episode of diverticulitis. Recurrent bouts of diverticulitis increase need for surgical intervention.

- Complicated diverticulitis: Hinchey classification to describe severity:
  - Stage I: diverticulitis + confined paracolic abscess or phlegmon
  - Stage II: diverticulitis + distant abscess
  - Stage III: diverticulitis + purulent peritonitis
  - Stage IV: diverticulitis + fecal peritonitis
- Patients who are septic or hemodynamically unstable require hospitalization, bowel rest, and broad-spectrum antibiotic therapy until symptoms improve.
- Symptomatic improvement is expected within 2 to 3 days. Antibiotics should be continued for 7 to 10 days.
- 80% of diverticular bleeding resolves spontaneously (4).

### MEDICATION

#### First Line

- Symptomatic uncomplicated diverticular disease: cyclical rifaximin 400 mg PO BID for 7 days every month or continuous mesalamine 800 mg PO BID (3)[B]
- Diverticulitis
  - Outpatient: PO antibiotics: cover for anaerobes and gram-negatives with:
    - A fluoroquinolone (ciprofloxacin 750 mg BID or levofloxacin 750 QD) *plus* metronidazole 500 mg TID (may use clindamycin if metronidazole intolerant) or
    - Trimethoprim/sulfamethoxazole DS BID *plus* metronidazole 500 TID
    - Treat for 7 to 10 days

- The routine use of antibiotics in uncomplicated diverticulitis is controversial (6)[A].
- Inpatient: Use IV antibiotics.
  - Monotherapy with a  $\beta$ -lactam/ $\beta$ -lactamase inhibitor: piperacillin/tazobactam (3,375 g IV QID) or ampicillin/sulbactam 3 g IV q6h or ertapenem (1 g IV QD)
  - Penicillin-allergic patient: quinolone (levofloxacin 750 mg IV QD plus metronidazole 500 mg IV TID)
  - Unresponsive or severe disease: imipenem or meropenem
- Recurrences of acute diverticulitis may be decreased by using mesalamine  $\pm$  rifaximin (7) [A] or probiotics.
- Diverticular bleeding
  - Consider vasopressin 0.2 to 0.3 units/min through selective intra-arterial catheter.
- Precautions
  - Avoid morphine and other opiates that may increase intraluminal pressure or promote ileus.
  - Increased fiber intake is not recommended in the acute management of diverticulitis.

## *Second Line*

- Outpatient: amoxicillin/clavulanate monotherapy (875/125 mg BID) (contraindicated in patients with clearance  $<30$  mL/min) or moxifloxacin (400 mg PO QD) *plus* metronidazole (500 mg PO TID)
- Severely ill inpatients: ampicillin (500 mg IV q6h) + metronidazole (500 mg IV TID) + a quinolone *or* ampicillin + metronidazole + an aminoglycoside

## *ISSUES FOR REFERRAL*

- After resolution of diverticulitis, (typically 6 to 8 weeks), perform colonoscopy to exclude malignancy, fistula, strictures, or inflammatory bowel disease (3).
- Patients with complicated diverticulitis (hemodynamic instability or failure to respond to initial IV antibiotic therapy) should have appropriate surgical and critical care/infectious disease consultations.

## *SURGERY/OTHER PROCEDURES*

- Indication for emergent surgery: peritonitis, uncontrolled sepsis, perforated viscus, colonic obstruction, or acute deterioration

- Elective resection in nonemergent or recurrent cases of diverticulitis is a case-by-case decision (3)[B]:
  - After first episode of diverticulitis, there is a 33% chance of recurrence. After a second episode, there is a 66% chance of further recurrence.
  - Most complications occur during first bout of diverticulitis.
  - Emergent surgery carries a much higher risk of morbidity/mortality.
  - Recommendations for elective surgery are based on severity of complications (not solely on number of recurrences).
  - Elective resection is typically advised after recovery from a complicated diverticulitis treated nonoperatively (3)[B].
  - Younger patients are more likely to have recurrence.
  - Immunocompromised patients are more likely to present with acute complicated diverticulitis, fail medical management, and have complications from elective surgery.
- Large abscesses (>4 cm) can be drained using radiographic guidance and managed nonoperatively (3).
- Diverticular bleeding
  - Endoscopy and hemostasis by epinephrine injection, electrocautery, or clipping can be achieved (5).
  - Angiography can identify bleeding source and embolize the feeding artery (5).
  - Patient with massive bleeding and recurrent bleeding requires limited or subtotal colonic resection.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

Probiotics such as *Lactobacillus casei* and *Escherichia coli* Nissle 1917 have been used with mixed success to prevent recurrence.

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

- Admit for toxicity, sepsis, and/or peritonitis.
- Admit patients who cannot tolerate oral intake or who need IV fluids, analgesics, antibiotics, bowel rest, and NG suction.

## ONGOING CARE

### DIET

- NPO during acute diverticulitis; advance diet as tolerated as bowel function returns
- Patients with known diverticulosis or a history of diverticulitis should consume a high-fiber diet (>30 g/day) to prevent recurrence (8).

### PROGNOSIS

- Typically good with early detection and prompt treatment
- Risk for recurrence increases with each subsequent bout of diverticulitis.
- Rebleeding occurs in up to 6%.
- Diverticulitis recurs more often in younger patients, but severity is similar to elderly.

### COMPLICATIONS

Hemorrhage, perforation, peritonitis, obstruction, abscess, or fistula

## Codes

&NA;

### ICD10

- K57.90 Dvrtclos of intest, part unsp, w/o perf or abscess w/o bleed
- K57.30 Dvrtclos of lg int w/o perforation or abscess w/o bleeding
- K57.92 Diverticulitis of intestine, part unspecified, without perforation or abscess without bleeding

## Clinical Pearls

&NA;

- Diverticular disease is age-related and more common in Western cultures due to diet and lifestyle.

- Patients with known diverticular disease should consume a high-fiber diet (>30g/day).
- Decision for elective surgery in diverticulitis is made on a case-by-case basis.

# Domestic Violence

Rhonda A. Faulkner, PhD

Luis T. Garcia, MD

## BASICS

### DESCRIPTION

- Domestic violence (DV) is the behavior in any relationship that is used to gain or maintain power and control over an intimate partner.
- May include physical, sexual, and/or emotional abuse; economic or psychological actions; or threats of actions that influence another person
- Although women are at greater risk of experiencing DV, it occurs among patients of any race, age, sexual orientation, religion, gender, socioeconomic background, and education level.
- Synonym(s): intimate partner violence (IPV); spousal abuse; family violence

### EPIDEMIOLOGY

#### *Incidence*

8% in the United States; women are more likely to report partner violence than men.

#### *Prevalence*

- DV occurs in 1 of 4 American families. Nearly 5.3 million incidents of DV occur each year among U.S. women aged <sup>3</sup>18 and 3.2 million incidents among men.
- DV results in nearly 2 million injuries and up to 4,000 deaths annually in the United States.
- 30% of women and 22% of men have experienced physical, sexual, or psychological IPV during their lifetime in the United States.
- 14-35% of adult female patients in emergency departments report experiencing DV within the past year.
- Costs of DV are estimated to exceed \$5.8 billion annually, of which \$4.1 billion are for direct medical and mental health services.
- DV survivors have a 1.6- to 2.3-fold increase in health care use compared with the nonabused population.

## *Geriatric Considerations*

- 4-6% of elderly are abused, with ÷2 million elderly persons experiencing abuse and/or neglect each year. In 90% of cases, the perpetrator is a family member.
- Elder abuse is any form of mistreatment that results in harm or loss to an older person; may include physical, sexual, emotional, financial abuse, and/or neglect.

## *Pediatric Considerations*

- >3 million children aged 3 to 17 years are at risk of witnessing acts of DV.
- ÷1 million abused children are identified in the United States each year.
- Children living in violent homes are at increased risk of physical, sexual, and/or emotional abuse; anxiety and depression; decreased self-esteem; emotional, behavioral, social, and/or physical disturbances; and lifelong poor health.

## *Pregnancy Considerations*

DV occurs during 7-20% of pregnancies. Women with unintended pregnancy are at 3 times greater risk of DV. 25% of abused women report exacerbation of abuse during pregnancy. There is a positive correlation between DV and postpartum depression.

## **RISK FACTORS**

- Patient/victim risk factors
  - Substance abuse
  - Poverty/financial stressors/unemployment
  - Recent loss of social support
  - Family disruption and life cycle changes
  - History of abusive relationships or witness to abuse as child
  - Mental or physical disability in family
  - Social isolation
  - Pregnancy
  - Attempting to leave the relationship
- Abuser risk factors
  - Substance abuse (e.g., PCP, cocaine, amphetamines, alcohol)

- Young age
- Unemployment
- Low academic achievement
- Witnessing or experiencing violence as child
- Depression
- Personality disorders
- Threatening to self or others
- Violence to children or violence outside the home
- Relational risk factors
  - Marital conflict
  - Marital instability
  - Economic stress
  - Traditional gender role norms
  - Poor family functioning
  - Obsessive, controlling relationship

### *Geriatric Considerations*

Factors associated with the abuse of older adults include increasing age, nonwhite race, low-income status, functional impairment, cognitive disability, substance use, poor emotional state, low self-esteem, cohabitation, and lack of social support.

### *Pediatric Considerations*

Factors associated with child abuse or neglect include low-income status, low maternal education, nonwhite race, large family size, young maternal age, single-parent household, parental psychiatric disturbances, and presence of a stepfather.

## **DIAGNOSIS**

- DV is often underdiagnosed, with only 10-12% of physicians conducting routine screening.
- Although prevalence of DV in primary care settings is 7-50%, <15% are screened.
- Pregnancy increases risk.

Barriers to screening: time constraints, discomfort with the subject, fear of offending the patient, and lack of perceived skills and resources to manage DV

- Abused patients may refuse to disclose abuse for many reasons, which includes the following:
  - Not feeling emotionally ready to admit the reality of the situation
  - Shame and self-blame
  - Feelings of failure if abuse is admitted
  - Fear of rejection by the physician
  - Fear of retribution from abuser
  - Belief that abuse will not happen again
  - Belief that no alternatives or available resources exist

## HISTORY

- Physicians should introduce the subject of DV in a general way (i.e., "I routinely ask all patients about domestic violence. Have you ever been in a relationship where you were afraid?").
- How to screen
  - Screen patient alone, without partner or others present.
  - Ask screening questions in patient's primary language; do not use children or other family members as interpreters.
- Partner violence screen (sensitivity 35-71%; specificity 80-94%)
  - "Have you ever been hit, kicked, punched, or otherwise, hurt by someone within the past year? If so, by whom?"
  - "Do you feel safe in your current relationship?"
  - "Is there a partner from a previous relationship who is making you feel unsafe now?"
- CDC-recommended RADAR system
  - **R**: Routinely screen every patient; make screening a part of everyday practice in prenatal, postnatal, routine gynecologic visits, and annual health screenings.
  - **A**: Ask questions directly, kindly, and be nonjudgmental.
  - **D**: Document findings in the patient's chart using the patient's own words, with details. Use body maps and photographs as necessary.
  - **A**: Assess the patient's safety and see if the patient has a safety plan.

**R:** Review options for dealing with DV with the patient and provide referrals.

- SAFE questions
  - **Stress/safety:** “Do you feel safe in your relationship?”
  - **Afraid/abused:** “Have you ever been in a relationship where you were threatened, hurt, or afraid?”
  - **Friends/family:** “Are your friends or family aware that you have been hurt? Could you tell them, and would they be able to give you support?”
  - **Emergency plan:** “Do you have a safe place to go and the resources you need in an emergency?”
- “How often does your partner: physically hurt you? insult or talk down to you? threaten you with harm? scream or curse at you?”
- Assess pregnancy difficulties such as poor/late prenatal care, low-birth-weight babies, and perinatal deaths.
- Pelvic and abdominal pain, chronic without demonstrable pathology
- Headaches, back pain
- Gynecologic disorders
- Sexually transmitted infections (STIs) including HIV/AIDS
- Depression, suicidal ideation, anxiety, fatigue
- Substance abuse
- Eating disorders
- Overuse of health services/frequent emergency room visits
- Noncompliance

## *PHYSICAL EXAM*

- Clinical presentation/psychological signs and symptoms
  - Delay in seeking treatment
  - Inconsistent explanation of injuries
  - Reluctance to undress
  - Signs of battered woman syndrome and/or posttraumatic stress disorder (PTSD) (flat affect/avoidance of eye contact, evasiveness, heightened startle response, sleep disturbance, traumatic flashbacks)
  - Depression, anxiety, chronic fatigue, substance abuse

- Suspicious partner accompaniment at appointment; overly solicitous partner and/or refusal to leave exam room
- Physical signs and symptoms
  - Tympanic membrane rupture
  - Rectal or genital injury (centrally located injuries with bathing-suit pattern of distributionÑ concealable by clothing)

P.309

- 
- Head and neck injuries (site of 50% of abusive injuries)
  - Facial scrapes, loose or broken tooth, bruises, cuts, or fractures to face or body
  - Knife wounds, cigarette burns, bite marks, welts with outline of weapon (such as belt buckle)
  - Broken bones
  - Defensive posture injuries
  - Injuries inconsistent with the explanation given
  - Injuries in various stages of healing

## *DIAGNOSTIC TESTS & INTERPRETATION*

- The U.S. Preventive Services Task Force (USPSTF) in 2013 issued guidelines recommending that clinicians screen all women of childbearing age (14 to 46 years old) for DV and provide or refer women to intervention services when appropriate (1)[B].
- Other recommendations
  - American College of Physicians (ACP) recommends routine screening for DV for all women in primary care settings at periodic intervals and when women present for emergency care with traumatic injuries.
  - The American Medical Association (AMA) recommends that all patients be routinely screened for DV with inquiry into history of family violence.
  - The World Health Organization (WHO) recommends against DV screening or routine inquiry about exposure to DV; however, they recommend asking about exposure to DV when assessing conditions that may be caused or complicated by abuse (2)[B].
  - U.S. Surgeon General and American Association of Family Practitioners recommend that physicians consider the possibility of DV as a cause of illness and injury.
  - The Partner Violence Screen is a 3-question screening tool with a high specificity.

- There is no evidence of harm in screening for DV.

## *Pediatric Considerations*

American Academy of Pediatrics (AAP) and AMA recommend that physicians remain alert for signs and symptoms of child physical and sexual abuse in the routine exam.

## *Pregnancy Considerations*

American Congress of Obstetrics and Gynecologists (ACOG) and AMA guidelines on DV recommend that physicians routinely assess all pregnant women for DV. ACOG recommends periodic screening throughout obstetric care (at the first prenatal visit, at least once per trimester, at the postpartum checkup).

## *Initial Tests (lab, imaging)*

Liver function tests (LFTs), amylase, lipase if abdominal trauma is suspected

## **TREATMENT**

- Treatment includes initial diagnosis; ongoing medical care; emotional support, counseling, and patient education regarding the DV cycle; referrals to community and supportive services as needed.
- On diagnosis, use the SOS-DoC intervention:
- **S:** Offer Support and assess Safety
  - Support: "You are not to blame. I am sorry this is happening to you. There is no excuse for DV."
  - Remind patient of your commitment to confidential communication.
  - Safety: Listen and respond to safety issues for the patient: "Do you feel safe going home?"; "Are your children safe?"
- **O:** Discuss Options, including safety planning and follow-up.
  - Provide information about DV and help when needed. Make referrals to local resources:
    - "Do you need or want to access a safety shelter or DV service agency?"
    - "Do you want police intervention and if so, would you like me to call the police so they can make a report with you?"
    - Offer numbers to local resources and National DV Hotline: 1-800-799-SAFE (open 24/7; can provide physicians in every state with information on local resources).

- **S:** Validate patient's Strengths:
  - ÒIt took courage for you to talk with me today. You have shown great strength in very difficult circumstances.Ó
- **Do:** Document observations, assessment, and plans:
  - Use patient's own words regarding injury and abuse.
  - Legibly document injuries: Use a body map.
  - If possible, take instant photographs of patient's injuries if given patient consent.
  - Make patient safety plan. Prepare patient to get away in an emergency:
    - Encourage patient to keep the following items in a safe place: keys (house and car); important papers (Social Security card, birth certificates, photo ID/driver's license, passport, green card); cash, food stamps, credit cards; medication for self and children; children's immunization records; important phone numbers/addresses (friends, family, local shelters); personal care items (e.g., extra glasses)
    - Encourage patient to arrange a signal with someone to let that person know when she or he needs help.
- **C:** Offer Continuity:
  - Offer a follow-up appointment and assess barriers to access.

## GENERAL MEASURES

- Reporting child and elder abuse to protective services is mandatory in most states. Several states have laws requiring mandatory reporting of IPV.
- Contact the local DV program to find out about laws and community resources before they are needed.
- Display resource materials (National DV Hotline: 1-800-799-SAFE) in the office, all exam rooms, and restrooms.

## ADDITIONAL THERAPIES

- National DV Hotline: 1-800-799-SAFE (7233)
- Post in all exam rooms posters in both English and Spanish; available at <http://www.thehotline.org/resources/download-materials/>

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Schedule prompt follow-up appointment.
- Inquire about what has happened since last visit.
- Review medical records and ask about past episodes to convey concern for the patient and a willingness to address this health issue openly.
- DV often requires multiple interventions over time before it is resolved.

### *PATIENT EDUCATION*

- Counsel patients about nonviolent ways to resolve conflict.
- Educate patients about the cycle of violence.
- Counsel parents about developmentally appropriate ways to discipline their children.
- Educate parents about the negative consequences of arguments on children and each other.
- National Coalition Against Domestic Violence: <http://www.ncadv.org/>
- CDC: <http://www.cdc.gov/violenceprevention/>

### *PROGNOSIS*

Most DV perpetrators do not voluntarily seek therapy unless pressured by partners or upon legal mandate. Current evidence is insufficient on effectiveness of therapy for perpetrators.

## Codes

**&NA;**

### ICD10

- T74.91XA Unspecified adult maltreatment, confirmed, initial encounter
- T74.11XA Adult physical abuse, confirmed, initial encounter
- T74.31XA Adult psychological abuse, confirmed, initial encounter

## Clinical Pearls

**&NA;**

- Display resource materials in the office (e.g., posting abuse awareness posters/National DV Hotline, 1-800-799-SAFE, in both English and Spanish, in all exam rooms and restrooms).
- Given the high prevalence of DV and the lack of harm and potential benefits of screening, routine screening is recommended.
- For those who screened positive, offer resources, reassure confidentiality, and provide close follow-up.

# Down Syndrome

Michele Roberts, MD, PhD

Brian G. Skotko, MD, MPP

## BASICS

### DESCRIPTION

- Down syndrome (DS) is a congenital condition associated with intellectual disability and an increased risk of multisystem medical problems.
- System(s) affected: neurologic (100%), cardiac (40-50%), GI (8-12%)
- Synonym(s): trisomy 21

### *Pediatric Considerations*

Murmur may not be present at birth. Delay in recognition of heart condition may lead to irreversible pulmonary hypertension.

### *Geriatric Considerations*

- Life expectancy has increased to  $\pm$ 60 years
- Age-related health issues occur at earlier age than in the general population.
- Communication difficulties may interfere with prompt recognition of some medical issues.

### *Pregnancy Considerations*

- American Congress of Obstetricians and Gynecologists (ACOG) recommends all pregnant women be offered traditional prenatal screening and diagnostic testing for DS.
  - Maternal prenatal screening may be performed in the 1st or 2nd trimester.
  - Prenatal diagnostic tests include chorionic villus sampling or amniocentesis.
- ACOG and the Society for Maternal-Fetal Medicine (SMFM) acknowledge that any women may choose noninvasive prenatal screening (NIPS), although conventional screening tests remain most appropriate for most women. American College of Medical Genetics and Genomics (ACMG) recommends all women be offered NIPS.
- Most, but not all, men with DS are believed to be infertile.

- Most women with DS are subfertile but can conceive children with and without DS.

## *EPIDEMIOLOGY*

### *Incidence*

In the United States, 1 per 792 live births, ÷5,300 births/year (1)

### *Prevalence*

÷250,000 persons in the United States (2)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Etiology: presence of all or part of an extra chromosome 21
- Trisomy 21: 95% of DS, an extra chromosome 21 is found in all cells due to nondisjunction, usually in maternal meiosis.
- Translocation DS: 3-4% of DS, extra chromosome 21q material is translocated to another chromosome (usually 13, 14, or 21); ÷25% have parental origin.
- Mosaic trisomy 21: 1-2% of DS, manifestations may be milder.

### *Genetics*

- Online Mendelian Inheritance in Man (OMIM) 190685
- Inheritance: most commonly sporadic nondisjunction resulting in trisomy 21
- Chance of having another child with DS is
  - 1% (or age risk, whichever is greater) after conceiving a pregnancy with nondisjunction trisomy 21
  - 10-15% for mothers/sisters and 3-5% for fathers/brothers who carry balanced translocation with chromosome 21
  - 100% if the parental balanced translocation is 21:21 (45,t[21:21])
  - Unclear after child with mosaic DS but ÷1%

## *RISK FACTORS*

- DS believed to occur in all races with equal frequency.
- Chance of having an infant with DS increases with mother's age.
- Relatively more infants with DS are born to younger mothers because younger women are

more likely to become pregnant.

- Prenatal diagnosis of DS is more common in older women, and a high percentage of such pregnancies are electively terminated.

## *GENERAL PREVENTION*

- No prevention for nondisjunction trisomy 21
- Preimplantation diagnosis with in vitro fertilization (IVF), prenatal diagnosis and termination, and adoption are current options for expectant parents who do not wish to raise a child with DS.

## *COMMONLY ASSOCIATED CONDITIONS*

- Cardiac
  - Congenital heart defects (40-50%)
- GI/growth
  - Feeding problems are common in infancy.
  - Structural defects (÷12%)
  - Gastroesophageal reflux
  - Constipation
  - Celiac disease (÷5%)
- Pulmonary
  - Tracheal stenosis/tracheoesophageal fistula
  - Pulmonary hypertension
  - Obstructive sleep apnea (50-75%)
- Genitourinary
  - Cryptorchidism, hypospadias
- Hematologic/neoplastic
  - Transient myeloproliferative disorder (÷10%): generally resolves spontaneously; can be preleukemic (acute megakaryoblastic leukemia [AMKL]) in 20-30%
  - Leukemia (AMKL or acute lymphoblastic leukemia [ALL]) in 0.5-1%
  - Decreased risk of most solid tumors; increased risk of germ cell tumors

- Endocrine
  - Hypothyroidism: congenital or acquired (13-63%) (3)
  - Diabetes
- Skeletal
  - Atlantoaxial instability (15%): ÷2% symptomatic
  - Short stature is common.
  - Scoliosis (some cases have adult onset)
  - Hip problems (1-4%)
- Immune/rheumatologic
  - Abnormal immune function with increased rate of respiratory infections
  - Increased risk of autoimmune disorders, including Hashimoto thyroiditis, celiac disease, and alopecia
- Neurologic
  - Intellectual ability ranging from mild to severe disability. Average is moderate intellectual disability.
  - Autism spectrum disorder (<18%); autism (<6%)
  - Seizures: (8%), typically occurring <1 year of age or >30 years of age
  - Alzheimer disease: at least 40% at age 40 years develop signs of dementia; percentage increases with age
- Psychiatric
  - Attention deficit hyperactivity disorder (ADHD), obsessive-compulsive disorder (OCD), oppositional-defiant disorder (ODD), and autism spectrum disorder increased frequency in children.
  - Generalized depression and anxiety with increased frequency in young adults/adults
- Sensory
  - Hearing loss (75%): mostly conductive due to high frequency of asymptomatic middle ear effusion; otitis media (50-70%)
  - Visual impairment (60%): mostly strabismus (refractive errors, 15%), nystagmus, cataracts (15%)

- Dermatologic
  - Xerosis, eczema, palmoplantar hyperkeratosis, atopic or seborrheic dermatitis, onychomycosis, syringomas, furunculosis/folliculitis

## DIAGNOSIS

### HISTORY

~85% of mothers of infants with DS learn of the diagnosis postnatally, although this is changing with the availability of NIPS.

### PHYSICAL EXAM

- Typical growth curves should be used (4).
- Infants and children
  - Brachycephaly (100%)
  - Hypotonia (80%)
  - Small ears, often low set and simplified
  - Upslanting palpebral fissure (90%)
  - Epicanthic folds (90%)
  - Brushfield spots
  - Depressed nasal bridge
  - Short neck, often with increased nuchal folds
  - Single palmar crease, single flexion crease on fifth finger
  - Increased space between toes 1 and 2, fifth finger clinodactyly, brachydactyly

### DIAGNOSTIC TESTS & INTERPRETATION

#### *Initial Tests (lab, imaging)*

- Maternal prenatal screening includes the following:
  - 1st trimester: combined screen (maternal age, &agr;-human chorionic gonadotropin [&agr;-hCG], pregnancy-associated plasma protein A [PAPP-A], and nuchal translucency)
  - 2nd trimester: quad screen (&agr;-fetoprotein, &agr;-hCG, estriol, inhibin-A)
  - Sequential screen (combined screen in 1st trimester, if abnormal, obtain amniocentesis or

await 2nd trimester quad screening)

- Integrated screen (combined screening in 1st trimester plus quad screen in 2nd trimester)
- NIPS with cell-free DNA (beginning at 10 weeks' gestation)

---

P.311

- Prenatal diagnosis includes the following:
  - Chorionic villus sampling: 1st trimester, ÷99% accurate, ÷1% miscarriage
  - Amniocentesis: 2nd trimester, ÷99% accurate, ÷0.25% miscarriage rate
- Postnatal diagnosis
  - Fluorescence in situ hybridization (FISH) can be performed at time of clinical suspicion, but karyotype should always be done to differentiate type of DS.
  - Parental (and adult-aged sibling) karyotype is indicated only if translocation DS found in child.
- Labs for newborns
  - Echo, with or without murmur (4)
  - CBC with differential (to look for transient myeloproliferative disorder) (4)
  - Thyroid-stimulating hormone (TSH) (4)
  - Audiogram (4)
  - Ophthalmologic exam (look for red reflex) (4)
  - Swallowing study for those with feeding difficulties (4)

### *Follow-Up Tests & Special Considerations*

- After delivering a prenatal diagnosis, the physician should offer "Understanding a Down Syndrome Diagnosis" ([www.lettercase.org](http://www.lettercase.org)) (5).
- If the diagnosis is postnatal, the mother and her partner should be informed of the diagnosis promptly by a physician (preferably the obstetrician and pediatrician or family physician), on the basis of clinical observations and before the karyotype is available, but with consideration of extenuating circumstances (e.g., mother's medical condition). The spouse/partner and infant should be present unless this would cause undue delay. The meeting should be private. Refer to the baby by name (6).
- In the postnatal setting, the physician should be knowledgeable on the subject of DS and should conduct a discussion with content that is current, respectful, balanced, informative, and

realistic, but not overly pessimistic, concentrating on what is relevant to the first year of life (6,7).

- Cardiac follow-up, as indicated (4).

## TREATMENT

### *GENERAL MEASURES*

Genetic evaluation and counseling

### *ISSUES FOR REFERRAL*

- Infant stimulation programs (early intervention) (8)[A]
- Lactation consultant
- Physical/occupational/speech therapy (8)[A]
- Educational inclusion often successful.
- Pediatric cardiologist, if indicated.
- DS specialty clinics can improve medical outcomes (9)[B].

### *SURGERY/OTHER PROCEDURES*

Repair of congenital anomalies is appropriate. Plastic surgery for facial features is not recommended.

### *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- There is no evidence to support the use of antioxidant or folic acid supplements in children with DS.
- Craniosacral manipulation is dangerous due to potential atlantoaxial instability.
- Sicca is illegal in United States, potentially dangerous, and without any evidence of benefit.
- Piracetam is much publicized, without scientific evidence of benefit.

### *INPATIENT CONSIDERATIONS*

#### *Admission Criteria/Initial Stabilization*

If the social situation indicates adoption, consider the National Down Syndrome Adoption Network (NDSAN) ([www.ndsan.org](http://www.ndsan.org)), national registry of families seeking to adopt a child with DS.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

The American Academy of Pediatrics recommends ongoing assessment and review, at least annually, the following surveillance (4)[C]:

- Vision: Assess for strabismus, cataracts, and nystagmus by ophthalmologist by 6 months, annually between ages 1 and 5 years; every 2 years ages 5 to 13 years; every 3 years ages 13 to 21 years.
- Hearing: neonatal screen with auditory brainstem response (ABR) or otoacoustic emissions (OAE), then audiogram every 6 months until age 3 years, then annually
- Thyroid: initial newborn screen. Repeat TSH at 6 months, 12 months, and then annually (4)[C]
- Screening for celiac disease (total IgA and tissue transglutaminase [TTG]-IgA) annually, if symptomatic
- Three-view cervical spine films if patient symptomatic, beginning at 3 to 5 years of age
- Hemoglobin annually to screen for iron deficiency anemia
- Repeat echocardiogram in teens if with murmur or fatigue.

#### *DIET*

- No special diet, but caloric needs are lower in adolescents/adults with DS than their peers.
- Obesity is prevalent at all ages.
- No scientific evidence supports megavitamin therapy or dietary supplements.

#### *PATIENT EDUCATION*

- National Down Syndrome Congress 800-232-NDSC; [www.ndsccenter.org](http://www.ndsccenter.org)
- National Down Syndrome Society 800-221-4602; [www.ndss.org](http://www.ndss.org)
- The LuMind Down Syndrome Research Foundation provides information on the latest research for people with DS: [www.lumindfoundation.org](http://www.lumindfoundation.org)
- [www.lettercase.org](http://www.lettercase.org) provides peer-reviewed booklet for parents who have received a prenatal diagnosis of DS and have not yet made a decision about their pregnancy.
- [downsyndromepregnancy.org](http://downsyndromepregnancy.org) provides a free downloadable book for expectant mothers who

have decided to continue their pregnancies after a prenatal diagnosis of DS.

- [www.downsyndromediagnosis.org](http://www.downsyndromediagnosis.org)

## PROGNOSIS

- Associated congenital anomalies are the immediate concern during the newborn period.
- 99% of young adults/adults with DS report being happy with their lives (10).
- Life expectancy ÷ 60 years

### ICD10

- Q90.9 Down syndrome, unspecified
- Q90.1 Trisomy 21, mosaicism (mitotic nondisjunction)
- Q90.0 Trisomy 21, nonmosaicism (meiotic nondisjunction)

## Clinical Pearls

**&NA;**

- 99% of young adults/adults with DS report being happy with their lives.
- DS specialty clinics can improve medical outcomes.

# Drug Abuse, Prescription

Carolyn Cammarano, PharmD, RPh

Matthew A. Silva, PharmD, RPh, BCPS

Jeffrey Baxter, MD

## BASICS

### DESCRIPTION

- Prescription drug abuse behaviors exist on a continuum and may include the following:
  - Use of medication for nonmedical reasons such as to get high or enhance performance
  - Use of medication for medical reasons other than what the prescriber intended
  - Use of medication for any reason by someone other than the person for whom the medication was originally prescribed
- Commonly abused prescription medications include opioid analgesics (morphine, oxycodone, hydrocodone, oxymorphone, hydromorphone, fentanyl, methadone, buprenorphine), stimulants (amphetamine, methylphenidate), benzodiazepines (alprazolam, clonazepam), and barbiturates (secobarbital, amobarbital).
- *Diversion* is a term used to describe the rerouting of medications from prescriptions or other legitimate supplies for recreational use or criminal activity, such as selling prescription medication for personal profit.

### EPIDEMIOLOGY

- In 2011, 56% of the 2.5 million drug-related ED visits attributed to drug misuse and abuse were due to pharmaceuticals (1.4 million) (1).
- Prescription opioids are the second most commonly used class to initiate illicit drug use (1.9 million) (2).

### Incidence

- Predominant sex: males > females (2)
- Predominant age: highest among adults 18 to 25 years, then adolescents and teens 12 to 17 years, followed by adults <sup>3</sup>26 years (2)

- >20% of the 3.1 million persons who were first-time substance abusers in 2011 used prescription medications nonmedically (2).
- The average age of persons with the first reported instance of nonmedical prescription drug use is 22.4 years (2).

## *Prevalence*

- The number of persons with nonmedical opioid dependence increased from 936,000 in 2002 to 1.4 million in 2011 (2).
- Lifetime prevalence of prescription drug abuse is highest for opioids, benzodiazepines, and stimulants.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Prescription medications are now perceived by young adults to be more socially acceptable than other illicit drugs.
- Pharmacokinetics, compound purity, government approval, and extensive media advertising, along with personal or family experiences with prescription medication, contribute to perceived advantages of prescription drug misuse over street drugs and other illicit substances.

## *Genetics*

Variant alleles affecting the expression and function of opioid, dopamine, acetylcholine, serotonin, and GABA may explain susceptibility to all forms of prescription and nonprescription drug abuse behaviors.

## *RISK FACTORS*

- Sociodemographic, psychosocial, pain- and drug-related factors
- Genetics and environment; family history

## *GENERAL PREVENTION*

- Educate and raise awareness about the dangers of misuse and abuse of prescription drugs. Focus on individuals, then families, then communities.
- Educate and reinforce safe practices in evaluating patients and prescribing medications. Use office-based peer-to-peer education and follow-up with pharmacies when abuse behaviors are suspected.
- Develop or adopt a standard practice agreement for prescribing and monitoring controlled substances with abuse potential (3,4,5)

- Prescription monitoring programs (PMP) show fair evidence in reducing doctor shopping but have not reliably shown reductions in ED visits for drug overdose and prescription drug abuse-related deaths (3).
- Avoid prescribing benzodiazepines and hypnotics to elderly (6).
- Avoid using benzodiazepines >2 to 4 weeks.
- Minimize controlled substances when patients have a personal or family history of substance abuse or psychiatric disorders (7).
- Limit or avoid prescribing controlled medications on first visit and until a relationship can be established.
- Take a thorough history, contact family members and past prescribers, and perform observed urine drug screens. Stop prescribing prescription analgesics for chronic pain when they are not working, if a patient is unable to take medications as prescribed or if there are problems related to opioid and nonopioid analgesics. Identify and treat underlying substance abuse problems, and involve behavioral health providers when possible.
- Effective intranasal naloxone education and distribution to opioid users, family, friends, and social service agency staff contacts in communities with >1 enrollment/100,000 people and 5 or more opioid-related overdose fatalities reduce new opioid overdose deaths (8)[B].
- Consider providing spouse/family members and/or caretakers access to and education on intranasal naloxone use in the event of a suspected opioid overdose (8)[B].

## COMMONLY ASSOCIATED CONDITIONS

- Benzodiazepines: withdrawal syndromes/delirium, psychosis, anxiety, sleep driving, blackout states, cognitive impairment, impaired driving while awake; increased fall risk and mortality in elderly patients
- Amphetamines: hypertension, tachyarrhythmias, myocardial ischemia, seizures, hypothermia, psychosis, hallucinations, paranoia, anxiety
- Opioids: respiratory depression and death with overdose, low testosterone, and sexual dysfunction with chronic abuse. Methadone is associated with QT prolongation, which increases risk for torsades de pointes.

## DIAGNOSIS

Screening: ◊How many times in the past year have you used an illegal drug or used a prescription medication for nonmedical reasons?◊; primary care setting sensitivity of 100% and specificity of ÷75% (9)[C]

## *HISTORY*

Consider aberrant behaviors found when taking a history. Patient may ask for dose escalations and early refills (Òspilled the bottle Ó, Òpharmacist shorted me Ó, etc.), has strong preference for one drug, targets appointments at end of day and after hours, and shows hostile/threatening behavior or overly flattering behavior.

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Urine drug screens are recommended to identify patients who are noncompliant or abusing prescription drugs despite limited evidence of reliability and accuracy (3,10)[C].
- Urine drug screen (UDS): Order an expanded panel to detect commonly used opioids (ask specifically for semisynthetics [hydrocodone, hydromorphone, oxycodone] and synthetics [methadone, fentanyl, propoxyphene, meperidine]) along with tramadol and buprenorphine.
- Clonazepam and lorazepam rarely show up as benzodiazepines in routine UDS and should be ordered specifically.

### *Initial Tests (lab, imaging)*

- Interpretation: Results are positive if drugs that are not prescribed are present; positive in presence of illicit drugs (marijuana, cocaine); suspect diversion if negative for prescribed drug.
- Be suspicious if patient refuses test.
- OxyContin will only be positive for oxycodone.
- Hydrocodone will be positive for hydrocodone and hydromorphone.
- Codeine will be positive for codeine plus morphine.
- Heroin will be positive for morphine.
- Thus, if UDS is positive for morphine, it could mean that a patient took morphine, codeine, heroin, or hydrocodone.

### *Diagnostic Procedures/Other*

Cut down, Anger at being questioned about use, Guilt about prior use, Eye-opener use early in day (CAGE) or Alcohol use disorders identification test (AUDIT) to assess current alcohol use. Drug abuse screening test (DAST) helps determine patient's involvement with drugs over the past year. Details: <http://counsellingresource.com/lib/quizzes/drug-testing/drug-abuse/>. Screener and Opioid Assessment for Patients with Pain (SOAPP); Opioid Risk Tool (ORT); and Diagnosis, Intractability, Risk, Efficacy (DIRE) are tools used to assess risk of opioid misuse (11)[C].

### *Test Interpretation*

## TREATMENT

- Whenever there is evidence of prescription opioid abuse, the controlled substance should be tapered to begin discontinuing drug therapy (3)[C].
- Benzodiazepines cannot be stopped abruptly for risk of seizures and death. A Cochrane Review supported a gradual benzodiazepine withdrawal over 10 weeks (12)[A].
- Amphetamines can be stopped abruptly without risk of severe withdrawal or death.
- The general approach to treatment includes inpatient, residential, or outpatient detoxification as required; counseling and intensive counseling as needed; and ongoing medication-assisted treatment.

## GENERAL MEASURES

Alcoholics Anonymous/Narcotics Anonymous is helpful, as are Al-Anon/Alateen for family members. Nonjudgmental interactions and cognitive-behavioral therapy focused on motivational interviewing, goal-setting, and brief interventions help manage anxiety, insomnia, and denial and improve willingness to change.

## MEDICATION

- Opioid detoxification programs use clonidine (13)[A], buprenorphine (13,14)[A], or methadone (15)[A] under the direction of an addiction specialist. Buprenorphine is as effective as methadone but safer (16)[A]. Both buprenorphine and methadone are more effective than clonidine for detoxification.
- Buprenorphine and methadone have been found to be similarly effective when used in long-term opioid maintenance therapy. Long-term therapy supervised by an addiction specialist is preferable to short-term detoxification.
- Subutex (buprenorphine) lacks naloxone and is prone to diversion and abuse because patients can crush, snort, or shoot to get high. Suboxone (buprenorphine and naloxone) discourages abuse and diversion because naloxone displaces buprenorphine binding to opioid receptors. Newer Suboxone sublingual film is preferred as the dosage form is difficult to adulterate.
- There is neither support for using or converting to long half-life benzodiazepines before beginning a slow, gradual 10-week benzodiazepine taper, although diazepam is often preferred, nor are there any benefits shown using propranolol, buspirone, progesterone, hydroxyzine, or dothiepin to manage withdrawal symptoms. Carbamazepine may be useful in

patients who were dependent on 30 mg diazepam equivalents daily, and antidepressants may be helpful for depression and anxiety linked to benzodiazepine withdrawal.

- Atomoxetine and bupropion SR can also be helpful in managing ADHD symptoms in select patients.

## ***ISSUES FOR REFERRAL***

Refer to chemical dependency groups/addiction specialists/pain management and psychiatry/psychology when patients have polysubstance abuse and to treat underlying mood and anxiety disorders, PTSD, and ADHD.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Acupuncture, yoga, meditation, or martial arts may aid in anxiety management and stress reduction.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Indications for inpatient detoxification are concomitant alcohol and benzodiazepine dependence (increased risk of seizures), mental confusion/delirium, history of seizures, psychosis, active suicidal ideation, serious comorbid medical issues, and absence of social support.

## **ONGOING CARE**

### ***PATIENT EDUCATION***

- Advise patients receiving controlled medication to keep them hidden and inaccessible to others. Inform patients that giving their medication to others may result in legal charges. Warn about potential addiction when starting controlled substances and about withdrawal symptoms when a medication is stopped abruptly. Warn of the dangers of respiratory depression and death when opioids are mixed with benzodiazepines. Advise patients on controlled substances; avoid all alcohol and any illicit drugs.
- Tell patient to come to you if he or she begins to need medication in increasing amounts, uses it to feel high or overcome stress, or spends a lot of time craving it and thinking about the next dose. Emphasize that you will create a mutual plan to stop the medication and try something new. Inform spouse/family members when family dynamics are an important behavioral component.

## Codes

**&NA;**

### **ICD10**

- F19.10 Other psychoactive substance abuse, uncomplicated
- F11.10 Opioid abuse, uncomplicated
- F15.10 Other stimulant abuse, uncomplicated

## **Clinical Pearls**

## **&NA;**

- Education and prescription monitoring programs are important for preventing prescription drug abuse.
- Use a standardized office practice agreement when prescribing controlled substances.
- Screening: ÓHow many times in the past year have you used an illegal drug or prescription medication for nonmedical reasons?Ó
- Avoid prescribing controlled substances and nonbenzodiazepine hypnotics to patients at risk for substance abuse or with an Axis 1 or Axis 2 diagnosis.
- Discontinue prescription opioid analgesics if pain or functionality does not improve and if there's evidence of prescription or illicit drug abuse (i.e., positive UDS, driving while intoxicated [DWI], accidental or intentional overdose, early refills).
- Limit benzodiazepine use to 2 to 4 weeks.
- Conduct frequent, observed Urine screen.
- Addiction is a potentially fatal disease.

# Ductal Carcinoma in Situ

Bradley M. Turner, MD, MPH, MHA

David G. Hicks, MD

## BASICS

### DESCRIPTION

- Ductal carcinoma in situ (DCIS) is a heterogeneous group of lesions that have in common the presence of a clonal proliferation of neoplastic epithelial cells confined to ducts and lobules.
- Considered a premalignant lesion—the neoplastic cells are not invasive (pure DCIS).
- Classified as low, intermediate, or high-grade
- Mortality from DCIS with subsequent progression to invasive breast carcinoma (IBC) is low, regardless of histologic type or type of treatment.

### EPIDEMIOLOGY

#### *Incidence*

- Estimated 58,168 new diagnoses of DCIS in 2014.
- DCIS accounts for approximately 80-85% of in situ breast carcinomas (lobular carcinoma in situ [LCIS] accounts for approximately 15-20%).
- Stable incidence in women <sup>≥</sup>50 years of age over the last several years.
- Increasing incidence in women <50 years of age over the last several years.
- Represents ÷26% of all new IBC—An estimated 60,290 new cases in 2015.
- Incidence rate of DCIS is comparable among women of different ethnicities.

### ETIOLOGY AND PATHOPHYSIOLOGY

- A non-obligate precursor to IBC
- Presumed to be the final step prior to invasive breast cancer, part of a poorly understood spectrum of polyclonal and clonal epithelial proliferative lesions.
- Either low- or high-grade DCIS has the potential for subsequent invasion into the surrounding

stroma; however, the changes necessary for transition to IBC are poorly understood.

- Molecular evidence suggests that low- and high-grade DCIS are genetically distinct lesions, with high-grade DCIS associated with more aggressive disease.

## Genetics

- Low-grade DCIS typically shows diffuse and strong expression of estrogen receptor (ER) and progesterone receptor (PR), without HER2 protein overexpression or amplification.
- High-grade DCIS not consistently ER+ or PR+; frequent HER2 protein overexpression and amplification; commonly associated with p53 gene mutations.
- HER2 overexpression is even more frequent in high-grade DCIS compared to IBC.
- *BRCA1* and *BRCA2* associations observed
- If patients are high risk, consider genetic counseling after diagnosis of DCIS.

## RISK FACTORS

- Similar to IBC, although not as strongly associated
- Female gender, older age, nulliparity, late age at first birth, late age at menopause, family history of a first-degree relative with breast cancer, prior breast biopsies, long-term use of postmenopausal hormone replacement therapy, elevated body mass index in postmenopausal women not taking hormone replacement, high mammographic breast density
- Association with smoking, lactation, early menarche, increased alcohol consumption, and oral contraceptive use are less clear.

## GENERAL PREVENTION

- Screening may result in overdiagnosis with little or no reduction in the incidence of advanced cancers.
- General screening guidelines have been suggested for asymptomatic women with an average risk of breast carcinoma.
- Women with increased risk should have more aggressive screening (risk assessment tool available at <http://www.cancer.gov/bcrisktool/Default.aspx>).
- General screening guidelinesÑU.S. Preventive Services Task Force (USPSTF)
  - Biennial mammography for women aged 50 to 74 years.
  - Avoid routine screening mammography in women aged 40 to 49 years of age. The decision to start biennial mammographic screening before age 50 years should be individualized based on the patient's values regarding specific benefits or harms.

- Discourage teaching of breast self-exam (BSE).
- Insufficient evidence to assess the value of clinical breast exam (CBE) in women after age 40 years. If this service is offered, the patient should understand this uncertainty.
- Insufficient evidence to assess the benefit or harm of digital mammography or MRI over film mammography. If this service is offered, the patient should understand this uncertainty.
- General screening guidelinesÑNational Comprehensive Cancer Network (NCCN)
  - NCCN recommends that women should be familiar with their breast, promptly report changes to their health care provider, and that periodic, consistent BSE may facilitate breast self-awareness.
  - Ages 25 to 39 years: breast awareness, CBE every 1 to 3 years
  - Age 40 years and older: breast awareness, annual CBE, annual screening mammography
- Clinicians should use judgment when applying screening guidelines.
- Mammography screening should be individualized.
- If no intervention would occur based on screening findings, patient should not undergo screening.
- Risk reduction
  - Assess for familial/genetic and other elements that contribute to an increased risk of breast cancer.
  - Lifestyle modifications: Limit alcohol intake to <1 drink/day, exercise, maintain healthy diet, and weight control.
  - Risk reduction surgery supported for carefully selected women at high risk of breast cancer who desire this intervention.
  - Risk reduction agents (i.e., tamoxifen) are recommended in certain high-risk women <sup>335</sup> years of age.

## DIAGNOSIS

### HISTORY

- Most DCIS is now diagnosed by screening mammography (presence of microcalcifications in approximately 72%); patients may be asymptomatic with nonpalpable mass (12%) (1,2)[A].

- More advanced lesions may present with a palpable mass, spontaneous nipple discharge, or Paget disease (1,3)[A].

## PHYSICAL EXAM

- CBE with inspection of breasts with patient in upright and supine position, evaluating for asymmetry, spontaneous discharge, skin changes (peau d'orange, erythema, scaling), nipple retraction/excoriation (Paget disease).
- Palpation of all breast quadrants with patient in upright and supine position, including lymph node examination (axillary, supraclavicular, and internal mammary nodes).
- Positive clinical findings: Refer for consideration of diagnostic imaging and/or surgical evaluation, unless <30 years of age with a low clinical suspicion (observe 1 to 2 menstrual cycles; if positive clinical findings persist, refer for imaging) (3)[A].

## DIFFERENTIAL DIAGNOSIS

Usual ductal hyperplasia, flat epithelial atypia, atypical ductal hyperplasia (ADH), LCIS, microinvasive carcinoma (1)[A]

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Mammography Breast Imaging Reporting and Data System (BI-RADS) developed by the American College of Radiology is used for uniform reporting of mammography results.
- BI-RADS interpretation: **Categories (0 to 6)** **0:** incomplete and needs additional imaging; **1:** negative; **2:** benign finding; **3:** probably benign finding; **4:** suspicious abnormality; **5:** highly suggestive of malignancy; **6:** known biopsy-proven malignancy
- Similar BI-RADS interpretations for diagnostic ultrasound (US).
- Screening BI-RADS category 0: diagnostic workup with consideration for diagnostic imaging
- Screening BI-RADS categories 1 and 2: screening recommendations.
- Screening BI-RADS category 3: diagnostic imaging at 6 months, then every 6 to 12 months for 2 to 3 years; consider biopsy if patient anxious or follow-up uncertain.
- Screening BI-RADS categories 4 and 5: diagnostic imaging with follow-up
- Screening BI-RADS category 6: technically not a "screening" category other than to assess a known cancer that might need additional evaluation. NCCN guidelines for breast cancer should be followed.
- DCIS is commonly seen on imaging as clustered microcalcifications (2)[A].

- Diagnostic imaging will result in consideration for tissue biopsy.

## *Follow-Up Tests & Special Considerations*

- US is not recommended for screening (3)[A].
- The sensitivity of breast MRI screening is higher than mammography but has lower specificity resulting in a greater number of false positives (2,3)[A].
- Screening with MRI is only recommended in certain women: *BRCA* mutation, first-degree relative of *BRCA* carrier, <sup>3</sup>20% lifetime risk of breast cancer, radiation to chest between the ages of 10 and 30 years, presence of Li-Fraumeni, Cowden, or Bannayan-Riley-Ruvalcaba syndrome in patient or first-degree relative (3)[A].
- Screening with MRI is not recommended in women with <15% lifetime risk of breast cancer.

---

P.315

- MRI can also complement mammography in the diagnostic setting, particularly in patients with skin changes (3)[A].
- Although MRI and US are complementary diagnostic methods to mammography, US is less sensitive in detecting most microcalcifications and MRI does not typically detect microcalcifications at all (2,3)[A].
- Pathology
  - Tissue is necessary for diagnosis: typically core needle (CN) or vacuum-assisted (VA) biopsy (mammographic/stereotactic, US, or MRI guided). Open surgical biopsy can be performed in patients not amenable to CN or VA biopsy.
  - Fine-needle aspiration (FNA) is not adequate for specific diagnosis of DCIS; however, it can suggest the presence of neoplastic cells.
  - Histologic classification
    - Classification is subjective; however, traditionally classified as either low, intermediate, or high-grade based on architectural patterns (comedo, solid, cribriform, clinging, papillary, and micropapillary), nuclear grade (I, II, or III), and the absence or presence of necrosis (1,2).
    - Ductal intraepithelial neoplasia (DIN) is an alternative histologic classification incorporating size as a discriminating factor (2,4)[C].
    - Grade is more important for prognosis, risk for progression, and local recurrence.
    - Comedo-type necrosis (necrosis filling central portion of involved duct), is typically seen in high-grade DCIS, with varying degrees of necrosis in other types of DCIS.

- Determination of ER and PR status (1)[A].
- Studies show unclear or weak evidence of HER2 status as a prognostic indicator in DCIS (5) [A].

## TREATMENT

### *SURGERY/OTHER PROCEDURES*

- Surgery is the primary treatment option. Options for surgery are based on risk of recurrence, anatomic location, extent of disease, and the ability to achieve "negative" margins (5)[A].
- Positive margins are considered "ink on tumor" (6)[A].
- Negative margins controversial with DCIS (5)[C]
- Margins <1 mm considered inadequate (1,5)[A]
- Totality of evidence may not support distinguishing between margins of "no ink on tumor" and margins of <1 mm (6)[C].
- Margins <1 mm at the breast fibroglandular boundary (chest wall or skin) do not mandate surgical excision but may be an indication for higher boost dose radiation in patients opting for breast conservation (5)[A].
- Surgical options include the following:
  - **Breast conservation (lumpectomy) without lymph node procedure, with or without whole breast radiation therapy** (5)[A]
  - A sentinel lymph node biopsy should strongly be considered if the lumpectomy is in an anatomic location compromising the performance of a future sentinel lymph node procedure (5)[C].
  - Radiation decreases recurrence rates by about 50% (2,7,8)[A].
  - ÷50% of recurrences are pure DCIS; ÷50% are IBC (1,5)[A].
  - Recurrence generally requires mastectomy with consideration for systemic treatment (2)[C].
  - Patients not amenable to margin-free lumpectomy should have total mastectomy (5)[C].
  - **Mastectomy with or without sentinel node biopsy ± breast reconstruction** (5)[A]
  - Mastectomy provides maximum local control.
  - Rates of recurrence for DCIS and IBC are similar to lumpectomy.
  - Recurrence should be treated with wide local excision, chest wall radiation, and

consideration for systemic treatment (5)[A].

- Long-term cause-specific survival seems to be equivalent to lumpectomy with whole breast radiation (5)[A].
- Secondary chemoprevention following breast-conserving surgery for ER + DCIS
  - Tamoxifen for 5 years (5)[A]
  - Considered in lumpectomy patients with or without whole breast radiation (5)[A]
  - Benefit of tamoxifen and trastuzumab in patients with ER-negative/HER2-positive disease is unclear (1,9,10)[C].

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- History and physical exam every 6 months for first 5 years, then annually
- Mammography 6 to 12 months after whole breast radiation, then every 12 months
- If treated with tamoxifen, monitor per NCCN guidelines for breast cancer risk reduction (5,10).

### *PROGNOSIS*

- Good prognosis: 10-year breast cancer-specific survival rates of >95%; overall mortality after diagnosis of treated pure DCIS generally >98%
- Risk of local recurrence after mastectomy generally reported as 1-2% (higher in some studies).
- Higher risk of local recurrences after breast-conserving therapy in younger age (particularly before age 40 years), larger tumor size, high nuclear grade, comedo-type necrosis, and close/positive margin status (related to DCIS volume)
- ER+ tumors are associated with lower risk for recurrence.
- The Oncotype Dx DCIS score, a multigene assay including seven DCIS related genes, offers hope for quantifying the risk of local recurrence of DCIS or the development of IBC in certain patient populations (tumors  $\leq 2.5$  cm, negative margins) (11,12)[B].

## See Also

&NA;

Breast Cancer

## Codes

&NA;

### ICD10

- D05.10 Intraductal carcinoma in situ of unspecified breast
- D05.11 Intraductal carcinoma in situ of right breast
- D05.12 Intraductal carcinoma in situ of left breast

## Clinical Pearls

&NA;

- DCIS is a heterogeneous group of noninvasive neoplastic lesions arising from the breast ductal epithelial cells.
- The incidence of DCIS has continued to increase in women <50 years of age, with a more stable incidence in women <sup>3</sup>50 years of age.
- The goal of DCIS treatment is to prevent recurrence and progression to IBC.
- The Oncotype DX DCIS score may be useful in identifying patients at higher risk for recurrence or progression to IBC.
- Current standard of care is breast-conserving therapy with consideration for postoperative whole breast radiation therapy and/or postsurgical tamoxifen therapy, unless otherwise contraindicated.
- With appropriate therapy, the overall prognosis of pure DCIS is good.

# Dupuytren Contracture

Joshua L. Eaton, MD, FAWM

Alex Nguyen, MD

## BASICS

### DESCRIPTION

- Palmar fibromatosis; caused by progressive fibrous proliferation and tightening of the fascia of the palms, resulting in flexion deformities and loss of function
- Not the same as Òtrigger finger,Ó which is caused by thickening of the distal flexor tendon
- Similar change rarely occurs in plantar fascia, usually appearing simultaneously.
- System(s) affected: musculoskeletal
- Synonyms: morbus Dupuytren; Dupuytren disease; ÒCeltic handÓ

### EPIDEMIOLOGY

#### Prevalence

- Increases with age; mean prevalence in western countries: 12%, 21%, and 29% at ages 55, 65, and 75 years, respectively. Norway: 30% of males >60 years; Spain: 19% of males >60 years
- More common in Caucasians of Scandinavian or Northern European ancestry

### ETIOLOGY AND PATHOPHYSIOLOGY

Unknown; possibly a T-cell-mediated autoimmune disorder. Occurs in three stages:

- Proliferative phase: proliferation of myofibroblasts with nodule development on palmar surface
- Involutional stage: spread along palmar fascia to fingers with cord development
- Residual phase: spread into fingers with cord tightening and contracture formation

#### Genetics

- Autosomal dominant with incomplete penetrance:

Siblings with 3-fold risk

- 68% of male relatives of affected patients develop disease at some time.

## **RISK FACTORS**

- Smoking (mean: 16 pack-years; odds ratio: 2.8)
- Increasing age
- Male/Caucasian; male > female (1.7:1)
- Workers exposed to vibration—risk doubles if regular (weekly) exposure
- Diabetes mellitus (increases with duration of DM, usually mild; middle and ring finger involved)
- Epilepsy
- Chronic illness (e.g., pulmonary tuberculosis, liver disease, HIV)
- Hypercholesterolemia
- Alcohol consumption

## **GENERAL PREVENTION**

Avoid risk factors, especially if a strong family history.

## **COMMONLY ASSOCIATED CONDITIONS**

- Alcoholism
- Epilepsy
- Diabetes mellitus
- Chronic lung disease
- Occupational hand trauma (vibration)
- Hypercholesterolemia
- Carpal tunnel syndrome
- Peyronie disease

## **DIAGNOSIS**

### **HISTORY**

- Caucasian male aged 50 to 60 years

- Family history
- Mild pain early:
  - Begins in palm and spreads to digits
- Unilateral or bilateral (50%)
- Right hand more frequent
- Ring finger more frequent
- Ulnar digits are more affected than radial digits
- Flexion contracture of metacarpophalangeal (MCP) before proximal interphalangeal (PIP) joint

## *PHYSICAL EXAM*

- Painless plaques or nodules in palmar fascia
- Cordlike band in the palmar fascia
- Skin adheres to fascia and becomes puckered.
- Palpable subcutaneous nodules
- Reduced flexibility of MCP and PIP joints
- No sign of inflammation
- Web space contractures
- Ectopic Dupuytren can involve plantar (Ledderhose~10%) and penile (Peyronie~2%) fascia.
  - Knuckle pads over PIP:
    - Garrod nodes associated with severe disease
  - Disease stages:
    - Early: skin pits (can also be seen in nevoid basal cell cancer and palmar keratosis)
    - Intermediate: nodules and cords. Nerves and vessels can be entwined in cords.
    - Late: contractures

## *DIFFERENTIAL DIAGNOSIS*

- Tendon abnormalities
- Camptodactyly: early teens; tight fascial bands on ulnar side of small finger
- Diabetic cheiroarthropathy: all four fingers

- Volkmann ischemic contracture

## **DIAGNOSTIC TESTS & INTERPRETATION**

### *Diagnostic Procedures/Other*

MRI can assess cellularity of lesions that correlate with recurrence after surgery.

### *Test Interpretation*

- Myofibroblasts predominate
- Nodules: lumps fixed to skin hypercellular masses
- Cords: organized collagen type III arranged parallel and hypocellular
- First stage (proliferative): increased myofibroblasts
- Second stage (residual): dense fibroblast network
- Third stage (involutional): Myofibroblasts disappear.

## **TREATMENT**

### **GENERAL MEASURES**

- Physiotherapy alone is ineffective:
  - Intermittent splinting is unlikely to be effective.
  - Continuous splinting may help pre- and postop.
- Follow isolated involvement of palmar fascia conservatively.
- MCP joint involvement can be followed conservatively if flexion contracture is <30 degrees.

### **MEDICATION**

#### *First Line*

- Clostridial collagenase injections (FDA-approved in 2010):
  - Degrades collagen to allow manual rupture of diseased cord
  - Best for isolated cord of MCP joint
  - 5-year recurrence rate of 47%; comparable with surgical recurrence rates (1)[B]
  - More rapid recovery of hand function compared to limited fasciectomy with fewer serious

adverse events (2)[B]

- Complications: injection site reaction, skin tear
- Can do two cords concurrently
- Can be effective for postsurgical recurrence
- Steroid injection:
  - Can treat acute nodules or painful knuckle pads
  - Serial triamcinolone injections improved long-term outcomes when combined with needle aponeurotomy (3)[B].

## *Second Line*

Surgery for contracture >30%

---

P.317

## *ISSUES-FOR-REFERRAL*

- Any involvement of PIP joints
- MCP joints contracted >30 degrees
- Positive Hueston tabletop test: When the palm is placed on a flat surface, the digits cannot be simultaneously placed fully on the same surface as the palm because of flexion contractures.

## *ADDITIONAL THERAPIES*

- Percutaneous and needle fasciotomy:
  - Best for MCP joint; improvement of 93% versus 57% for PIP joint (4)[B]
  - Recurrence common; 50%
  - Shown to be effective for recurrent disease (4)[B]
  - Better for MCP joints in patients with comorbid conditions; lower complication rate, but higher recurrence (5)[C]
- Continuous elongation (atraumatic elongation using an external device, typically on 4th and 5th digits prepares a severely contracted joint for surgery (6)[B].

## *SURGERY/OTHER PROCEDURES*

- Dermofasciectomy/limited fasciectomy/segmental aponeurectomy:
  - Greater initial correction over nonincisional treatment; higher complication rates (5)[C]

- Night extension orthosis in combination with standard hand therapy no different maintaining finger extension than hand therapy alone in the 3 months following surgical release (6)[B].
- Indications:
  - Any involvement of the PIP joints
  - MCP joints contracted at least 30 degrees
  - Positive Hueston tabletop test
- May require skin grafts for wound closure with severe cutaneous shrinkage
- 80% have full range of movement with early surgery.
- Amputation of 5th digit if severe and deforming
- MCP joints respond better to surgery than PIP joints, especially if contracted >45 degrees.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Regular follow-up every 6 months to 1 year

### *PATIENT EDUCATION*

- Avoid risk factors (alcohol, vibratory exposure, etc.), especially if strong family history.
- Mild disease: Passively stretch digits twice a day and avoid recurrent gripping of tools.

### *PROGNOSIS*

- Unpredictable but usually slowly progressive
- 10% may regress spontaneously.
- Dupuytren diathesis predicts aggressive course. Features include ethnicity (Nordic), family history, bilateral lesions outside of palm, age <50 years— all factors with 71% risk of recurrence compared to baseline 23% without any risk factors.
- Prognosis is better for MCP versus PIP joint after surgery and collagenase injection.

### **COMPLICATIONS**

- Reflex sympathetic dystrophy postsurgery

- Operative nerve injury
- Postoperative recurrence in 46-80%
- Postoperative hand edema and skin necrosis
- Digital infarction

## Codes

**&NA;**

### ICD10

M72.0 Palmar fascial fibromatosis [Dupuytren]

## Clinical Pearls

**&NA;**

- Dupuytren contracture is a fixed flexion deformity of (most commonly) the 4th and 5th digits due to palmar fibrosis. 90% of cases are progressive.
- Refer patients with involvement of the PIP joints or MCP involvement with contractures of >30 degrees.
- Both surgical and enzymatic fasciotomy have high rate of recurrence.

# Dyshidrosis

Cara Marshall, MD

## BASICS

### DESCRIPTION

- A skin rash (dermatitis) within the Dyshidrosis family. Literature supports the presence of several different classes within the family dyshidrosis but no general agreement about a strict definition of these classes.
- Dyshidrotic eczema
  - Common, chronic, or recurrent; nonerythematous; symmetric vesicular eruption primarily of the palms, soles, and interdigital areas
  - Associated with burning, itching, and pain
- Pompholyx (from Greek *ō*bubble*ō*)
  - Rare condition characterized by abrupt onset of large bullae.
  - Sometimes used interchangeably with dyshidrotic eczema (small vesicles). Some believe these to be discrete entities.
- Lamellar dyshidrosis
  - Fine, spreading exfoliation of the superficial epidermis in the same distribution as described above.
- System(s) affected: dermatologic, exocrine, immunologic
- Synonym(s): cheiropompholyx, keratolysis exfoliativa, vesicular palmoplantar eczema, desquamation of interdigital spaces, palmar pompholyx reaction, acute and recurrent hand dermatitis (1)

### EPIDEMIOLOGY

#### *Incidence*

- Mean age of onset is 40 years and younger
- Male = female

- Comprises 5-20% of hand eczema cases

## *Prevalence*

20 cases/100,000 populations

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Exact mechanism unknown; thought to be multifactorial
- Dermatopathology: spongiosis with intraepidermal vesicles
- Despite the name, sweat glands are not altered/affected (2)
- Vesicles remain intact due to thickness of stratum corneum of palmar/plantar skin (1).
- Exact cause not known.
- Aggravating factors (debated)
  - Hyperhidrosis (in 40% of patients with the condition)
  - Climate: hot/cold weather; humidity
  - Contact sensitivity (in 30-67% of patients with the condition) (2)
  - Nickel, cobalt, and chromate sensitivity (may include implanted orthopedic or orthodontic metals) (1)
  - Irritating compounds and solutions
  - Stress
  - Dermatophyte infection (present in 10% of patients with the condition) (2)
  - Prolonged wear of occlusive gloves
  - IV immunoglobulin therapy
  - Smoking

## *Genetics*

- Atopy: 50% of patients with dyshidrotic eczema have atopic dermatitis (1)
- Rare autosomal dominant form of pompholyx found in Chinese population maps to chromosome 18q22.1-18q22.3 (2).

## **RISK FACTORS**

- Many risk factors are disputed in the literature, with none being consistently associated.

- Atopy
- Other dermatologic conditions
  - Atopic dermatitis (early in life)
  - Contact dermatitis (later in life)
  - Dermatophytosis
- Sensitivity to
  - Foods
  - Drugs: neomycin, quinolones, acetaminophen, and oral contraceptives
  - Contact and dietary: nickel (more common in young women), chromate (more common in men), and cobalt (1)
  - Smoking in males

## *GENERAL PREVENTION*

- Control emotional stress.
- Avoid excessive sweating.
- Avoid exposure to irritants.
- Avoid diet high in metal salts (chromium, cobalt, nickel).
- Avoid smoking.

## *COMMONLY ASSOCIATED CONDITIONS*

- Atopic dermatitis
- Allergic contact dermatitis
- Parkinson disease
- HIV (2)

## **DIAGNOSIS**

### **HISTORY**

- Episodes of pruritic rash
- Recent emotional stress
- Familial or personal history of atopy

- Exposure to allergens or irritants (3)
  - Occupational, dietary, or household
  - Cosmetic and personal hygiene products
  - Vesicular eruption typically occurs 24 hours after allergen challenge (1).
- Costume jewelry use
- IV immunoglobulin therapy
- HIV
- Smoking

## *PHYSICAL EXAM*

- Symmetric distribution on the palms and soles; also may affect the dorsal aspects of hands and feet
- Lesions may not heal completely between flares (1).
- Early findings
  - 1 to 2 mm, clear, nonerythematous, deep-seated vesicles
- Late findings
  - Unroofed vesicles with inflamed bases
  - Desquamation
  - Peeling, rings of scale, or lichenification common

## *DIFFERENTIAL DIAGNOSIS*

- Vesicular tinea pedis/manuum
- Vesicular id reaction
- Contact dermatitis (allergic or irritant)
- Scabies
- Chronic vesicular hand dermatitis
- Drug reaction
- Dermatophytid
- Bullous disorders: dyshydrosiform bullous pemphigoid, pemphigus, bullous impetigo, epidermolysis bullosa

- Pustular psoriasis
- Acrodermatitis continua
- Erythema multiforme
- Herpes infection
- Pityriasis rubra pilaris
- Vesicular mycosis fungoides

## *DIAGNOSTIC TESTS & INTERPRETATION*

### **Follow-Up Tests & Special Considerations**

- Skin culture in suspected secondary infection (most commonly, *Staphylococcus aureus*) (4)
- Consider antibiotics based on culture results and severity of symptoms.

### *Diagnostic Procedures/Other*

- Diagnosis is based on clinical exam.
- Potassium hydroxide (KOH) wet mount (if concerned about dermatophyte infection)
- Patch test (if suspecting allergic cause)

### *Test Interpretation*

- Fine, 1- to 2-mm spongiotic intraepidermal vesicles with little to no inflammatory change
- No eccrine glandular involvement
- Thickened stratum corneum

## **TREATMENT**

### *GENERAL MEASURES*

- Avoid possible causative factors: stress, direct skin contact with irritants, nickel, occlusive gloves, household cleaning products, smoking, sweating
- Use moisturizers/emollients for symptomatic relief and to maintain effective skin barrier.
- Skin care
  - Wear shoes with leather rather than rubber soles (e.g., sneakers).

- Wear socks and gloves made of cotton and change frequently.
- Wash infrequently, carefully dry, then apply emollient.
- Avoid direct contact with fresh fruit (5)[C].

## MEDICATION

### First Line

- Mild cases: topical steroids (high potency) (2)[B]
  - Considered cornerstone of therapy but limited published evidence
- Moderate to severe cases
  - Ultrahigh-potency topical steroids with occlusion over treated area (4)[B]
  - Prednisone 40 to 100 mg/day tapered after blister formation ceases (2)[B]
  - Psoralens plus ultraviolet (UV)-A therapy (PUVA), either systemic/topical *or* immersion in psoralens (2)[B]
- Recurrent cases (4)[B]
  - Systemic steroids at onset of itching prodrome
  - Prednisone 60 mg PO for 3 to 4 days

### Second Line

- Topical calcineurin inhibitors (mitigate the long-term risks of topical steroid use)
  - Topical tacrolimus (6)[B]
  - Topical pimecrolimus (6)[B]
  - May not be as effective on plantar surface
- Other therapies (typically with dermatology consultation)
  - Oral cyclosporine (4)[B]
  - Injections of botulinum toxin type A (BTXA) (6)[B]
    - Newer topical forms of BTXA currently being developed show promise
    - Painful, requires nerve block
  - Systemic alitretinoin (teratogenic) (5)[B]

- Topical bexarotene (a teratogenic retinoid X receptor agonist approved for use in cutaneous T-cell lymphoma) (6)[B]
- Methotrexate (6)[C]
- Azathioprine (1)[C]
- Disulfiram or sodium cromoglycate in nickel-allergic patients (1)[C]
- Mycophenolate mofetil (2)[C]
- Tap water iontophoresis (2)[C]

## *ISSUES FOR REFERRAL*

- Allergist (if allergen testing required)
- Psychologist (if stress modification needed)

## *ADDITIONAL TREATMENT*

- Radiation therapy (1)[C]
- UV-free phototherapy (5)[C]
- Treat underlying dermatophytosis (1).

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Topical treatments to minimize pruritus (not curative) (4)[C]: Burow solution (aluminum acetate) or vinegar compresses
- Exposure to sunlight as maintenance therapy, 12 minutes every other day, 10 to 15 exposures (5)[C]
- Dandelion juice (avoid in atopic patients) (6)[C]

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Dyshidrotic Eczema Area and Severity Index (DASI) (1)
- Parameters used in the DASI score

Number of vesicles per square centimeter

- Erythema
  - Desquamation
  - Severity of itching
  - Surface area affected
- Grading: mild (0 to 15), moderate (16 to 30), severe (31 to 60)
  - Monitor BP and glucose in patients receiving systemic corticosteroids.
  - Monitor for adverse effects of medications.

## *DIET*

- Consider diet low in metal salts if there is history of nickel sensitivity (4)[B].
- Updated recommendations for low-cobalt diet are available (1).

## *PATIENT EDUCATION*

- Instructions on self-care, complications, and avoidance of triggers/aggravating factors
- PubMed Health: Dyshidrotic Eczema at:  
<http://www.ncbi.nlm.nih.gov/pubmedhealth/PMH0001835/>

## *PROGNOSIS*

- Condition is benign.
- Usually heals without scarring.
- Lesions may spontaneously resolve.
- Recurrence is common.

## **COMPLICATIONS**

- Secondary bacterial infections (*S. aureus* most common)
- Dystrophic nail changes
- Fissures
- Skin tightening/discomfort
- Psychological distress

## See Also

**&NA;**

Algorithm: Rash, Focal

## Codes

**&NA;**

### ICD10

L30.1 Dyshidrosis [pompholyx]

## Clinical Pearls

**&NA;**

- Dyshidrosis is a transient, recurrent vesicular eruption most commonly of the palms, soles, and interdigital areas.
- Etiology and pathophysiology are unknown but are most likely related to a combination of genetic and environmental factors.
- Best prevention is effective skin care and limiting exposure to irritating agents.
- Treatments are based on disease severity; preferred treatments include topical steroids, oral steroids, and calcineurin inhibitors.
- Condition is benign and usually heals spontaneously and without scarring. Medical treatment decreases healing time and risk for progression to secondary bacterial infection.

# Dysmenorrhea

Taiwona Elliott, DO

## BASICS

### DESCRIPTION

- Pelvic pain occurring at/around time of menses; a leading cause of absenteeism for women <30 years old
- Primary dysmenorrhea: pelvic pain without pathologic physical findings
- Secondary dysmenorrhea: often more severe, results from specific pelvic pathology. Severity based on activity impairment
  - Mild: painful, rarely limits daily function, or requires analgesics
  - Moderate: daily activity affected, rare absenteeism, and requires analgesics
  - Severe: daily activity affected, likelihood absenteeism, limited benefit from analgesics
- System affected: reproductive
- Synonym(s): menstrual cramps

### EPIDEMIOLOGY

- Predominant age
  - Primary: onset 6 to 12 months after the start of menarche, teens to early 20s
  - Secondary: 20s to 30s
- Predominant sex: women only

### Prevalence

- Up to 90% of menstruating females have experienced primary dysmenorrhea.
- Up to 42% lose days of school/work monthly due to dysmenorrhea.
- Up to 20% reported impairment in daily activities.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Primary: Elevated prostaglandin (PGF<sub>2</sub>α;) production through indirect hormonal control (stimulation of production by estrogen) causes nonrhythmic hypercontractility and increased uterine muscle tone with vasoconstriction and resultant uterine ischemia. Ischemia results in hypersensitization of type C pain nerve fibers. Intensity of cramps directly proportional to amount of PGF<sub>2</sub>α; released.
- Secondary
  - Endometriosis (most common cause)
  - Congenital abnormalities of uterine/vaginal anatomy
  - Cervical stenosis
  - Pelvic inflammatory disease
  - Adenomyosis
  - Ovarian cysts
  - Pelvic tumors, especially leiomyomata (fibroids) and uterine polyps

## *Genetics*

Not well studied

## **RISK FACTORS**

- Primary (1)
  - Cigarette smoking
  - Alcohol use
  - Early menarche (age <12 years)
  - Age <30 years
  - Irregular/heavy menstrual flow
  - Nonuse of oral contraceptives
  - Sexual abuse
  - Psychological symptoms (depression, anxiety, increased stress, etc.)
  - Nulliparity
- Secondary (10%)
  - Pelvic infection

- Use of intrauterine device (IUD)
- Structural pelvic malformations
- Family history of endometriosis in first-degree relative

## GENERAL PREVENTION

- Primary: Choose a diet low in animal fats.
- Secondary: Reduce risk of sexually transmitted infections (STIs).

## *Pediatric Considerations*

Onset with first menses raises probability of genital tract anatomic abnormality (i.e., transverse vaginal septum, imperforate or minimally perforated hymen, uterine anomalies).

## COMMONLY ASSOCIATED CONDITIONS

- Irregular/heavy menstrual periods
- Longer menstrual cycle length/duration of bleeding
- Endometriosis

## DIAGNOSIS

Based on characteristic history of suprapubic/low back cramping/pain occurring at or near menstrual flow onset lasting for 8 to 72 hours (2).

### HISTORY

- Primary: Onset once ovulatory cycles are established in adolescents; 6 to 12 months after menarche on average
- Patients may have associated nausea, vomiting, diarrhea, headache, fatigue, or pain radiating into the inner thighs.
- Recurrence at or just before the onset of the menstrual flow
  - Pelvic pain occurring between menstrual periods is not likely to be dysmenorrhea.
  - Present with most menstrual periods (cyclic)
- Relief associated with the following:
  - Continued bleeding for the usual duration
  - Use of analgesics, especially NSAIDs

## Orgasm

- Local heat application
- Response to NSAIDs helps confirm diagnosis.
- Secondary: associated with chronic pelvic pain, midcycle pain, dyspareunia, and abnormal uterine bleeding

## PHYSICAL EXAM

- Primary: Physical exam typically is normal. Examine to rule out secondary dysmenorrhea. Pelvic exam is recommended if sexually active to rule out infection.
- Secondary: Evaluate for cervical discharge, uterine enlargement, tenderness, irregularity, or fixation.

## DIFFERENTIAL DIAGNOSIS

- Primary: History is characteristic.
- Secondary
  - Pelvic/genital infection
  - Complication of pregnancy
  - Missed/incomplete abortion
  - Ectopic pregnancy
  - Uterine/ovarian neoplasm
  - Endometriosis
  - UTI
  - Complication with IUD use

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Pregnancy test
- Urine testing for infection
- Gonorrhea/chlamydia cervical testing, especially in women age <25 years and in high-prevalence areas.
- Primary: Consider pelvic ultrasound to rule out secondary abnormalities if history is not

characteristic or suspected abnormality on exam.

- Secondary: Ultrasound/laparoscopy to define anatomy for severe/refractory cases. MRI may be useful as second-line noninvasive imaging if ultrasound is nondiagnostic and torsion, deep endometriosis, or adenomyosis suspected.

## *Follow-Up Tests & Special Considerations*

Counsel regarding appropriate preventive measures for STI and pregnancy.

## *Diagnostic Procedures/Other*

Laparoscopy is rarely needed.

## *Test Interpretation*

- Primary: none
- Secondary: Specific anatomic abnormalities may be noted (see "Differential Diagnosis").

## *Pregnancy Considerations*

Consider ectopic pregnancy when pelvic pain occurs with vaginal bleeding.

## **TREATMENT**

- Reassure the patient that treatment success is very likely with adherence to recommendations.
- Relief may require the use of several treatment modalities at the same time.

## **GENERAL MEASURES**

- Exercise and local heat are noninvasive general measures to relieve pain.
- High-frequency transcutaneous electrical nerve stimulation (TENS) has been found to be beneficial. There is conflicting evidence for low-frequency TENS.
- Secondary dysmenorrhea: Treatment of infections; suppression of endometrium if endometriosis suspected; remove IUD if contributing factor.

## **MEDICATION**

### *First Line*

- NSAIDs: No NSAID has been found to be superior to others. Medication should be taken on scheduled dosing 1 to 2 days *prior* to onset of menses and continued for 2 to 3 days (2,3)[A].

If one NSAID preparation does not work, another NSAID preparation should be tried.

- Ibuprofen 400 mg q8h
- Naproxen sodium 500 mg BID
- Celecoxib 400 mg × 1, then 200 mg q12h
- Mefenamic acid 500 mg × 1, then 250 mg q6h
- Hormonal contraceptives: recommended for primary dysmenorrhea in women desiring contraception (2)[B]. Directly limits endometrial growth resulting in reduced prostaglandin production and intrauterine pressure. Continuous rather than cyclic dosing may initially be more effective at reducing pain, however, may have similar benefit after 6 months (4)[B]. Estrogen-containing contraceptives are recommended as first-line for secondary dysmenorrhea due to endometriosis, although progestin-only methods have also been shown to be beneficial (2)[B].
- Levonorgestrel IUDs can decrease primary dysmenorrhea (5)[B].
- Potential contraindications to NSAIDs and combined oral contraceptives (COCs)
  - Platelet disorders
  - Gastric ulceration or gastritis

---

- Thromboembolic disorders
- Vascular disease
- Migraine with aura
- Precautions
  - GI irritation
  - Lactation
  - Coagulation disorders
  - Impaired renal function
  - Heart failure
  - Liver dysfunction
- Significant possible interactions
  - Coumadin-type anticoagulants
  - Aspirin with other NSAIDs

## *Second Line*

- Local heat can help relieve pain and may be as effective as NSAIDs (2)[B].
- Exercise may have beneficial effects in relieving pain (6)[B].
- $\beta_2$ -adrenoceptor agonists have not definitively been shown to relieve pain in dysmenorrhea (7)[B].
- Behavioral interventions, such as relaxation exercises, may help alleviate pain in primary dysmenorrhea.

## *SURGERY/OTHER PROCEDURES*

Laparoscopic uterosacral nerve ablation has been shown to relieve pain at >12 months postoperatively.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Spinal manipulation has not been shown to be effective in treating pain (8)[A].
- Chinese herbal medicine shows promising evidence of decreasing pain, but more evidence is needed.
- Acupuncture treatments have been shown to decrease pain in dysmenorrhea, but further randomized, well-designed studies are needed (2,9)[B].
- Acupoint stimulation, particularly noninvasive stimulation (acupressure), can relieve pain (10) [B].
- Aromatherapy abdominal massage performed daily for 10 minutes, 7 days prior to onset of menses can decrease primary dysmenorrhea (11)[B].
- Further research needed to determine benefit and safety for use of oral fennel, extracorporeal magnetic innervation, vitamin K<sub>1</sub> injection into the spleen-6 acupuncture point, use of high-frequency vibratory stimulation tampon, and vaginal sildenafil.

## *INPATIENT CONSIDERATIONS*

Both primary and secondary dysmenorrhea are usually managed in the outpatient setting.

### *Admission Criteria/Initial Stabilization*

- Primary: outpatient care
- Secondary: usually outpatient care

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

Normal

### DIET

- Vitamin B<sub>1</sub> 100 mg daily, omega-3 fatty acid, and fish oil supplementation may be beneficial (12)[B].
- Magnesium has been shown to be useful, but the correct dosage has not been determined.
- Insufficient evidence to show usefulness of zinc and vitamin E at this time
- Low-fat vegetarian diet can be helpful in some patients (12).

### PATIENT EDUCATION

Reassure the patient that primary dysmenorrhea is treatable with the use of NSAIDs, COCs, IUD, or local heat; and that it will usually abate with age and parity.

### PROGNOSIS

- Primary: reduced with age and parity
- Secondary: likely to require therapy based on underlying cause

### COMPLICATIONS

- Primary: anxiety and/or depression
- Secondary: infertility from underlying pathology

## Codes

**&NA;**

### ICD10

- N94.6 Dysmenorrhea, unspecified
- N94.4 Primary dysmenorrhea
- N94.5 Secondary dysmenorrhea

## Clinical Pearls

**&NA;**

- Dysmenorrhea is a leading cause of absenteeism for women age <30 years.
- In women who desire contraception, hormonal contraceptives are the preferred treatment.
- All NSAIDs studied have been found to be equally effective in the relief of dysmenorrhea and should be initiated 1 to 2 days prior to onset of menses with scheduled dosing.

# Dyspareunia

Scott T. Henderson, MD

## BASICS

### DESCRIPTION

- Recurrent and persistent genital pain associated with sexual activity, which is not exclusively due to lack of lubrication or vaginismus.
- May be the result of organic, emotional, or psychogenic causes
  - Primary: present throughout one's sexual history
  - Secondary: arising from some specific event or condition (e.g., menopause, drugs)
  - Superficial: pain at, or near, the introitus or vaginal barrel associated with penetration
  - Deep: pain after penetration located at the cervix or lower abdominal area
  - Complete: present under all circumstances
  - Situational: occurring selectively with specific situations
- System(s) affected: reproductive

### EPIDEMIOLOGY

- Predominant age: all ages
- Predominant sex: female > male

### Incidence

>50% of all sexually active women will report dyspareunia at some time.

### Geriatric Considerations

Incidence increases dramatically in postmenopausal women primarily because of vaginal atrophy.

### Prevalence

- Most sexually active women will experience dyspareunia at some time in their lives.
  - ÷15% (4-40%) of adult women will have dyspareunia on a few occasions during a year.

- ÷1-2% of women will have painful intercourse on a more-than-occasional basis.
- Male prevalence is ÷1%.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Disorders of vaginal outlet
  - Adhesions
  - Condyloma
  - Clitoral irritation
  - Episiotomy scars
  - Fissures
  - Hymeneal ring abnormalities
  - Inadequate lubrication
  - Infections
  - Lichen planus
  - Lichen sclerosus
  - Postmenopausal atrophy
  - Psoriasis
  - Trauma
  - Vulvar papillomatosis
  - Vulvar vestibulitis/vulvodynia
- Disorders of vagina
  - Abnormality of vault owing to surgery or radiation
  - Congenital malformations
  - Inadequate lubrication
  - Infections
  - Inflammatory or allergic response to foreign substance
  - Masses or tumors
  - Pelvic relaxation resulting in rectocele, uterine prolapse, or cystocele

- Disorders of pelvic structures
  - Endometriosis
  - Levator ani myalgia/spasm
  - Malignant or benign tumors of the uterus
  - Ovarian pathology
  - Pelvic adhesions
  - Pelvic inflammatory disease (PID)
  - Pelvic venous congestion
  - Prior pelvic fracture
  - Uterine fibroids
- Disorders of the GI tract
  - Constipation
  - Crohn disease
  - Diverticular disease
  - Fistulas
  - Hemorrhoids
  - Inflammatory bowel disease
- Disorders of the urinary tract
  - Interstitial cystitis
  - Ureteral or vesical lesions
  - Urethritis
- Chronic disease
  - Behçet syndrome
  - Diabetes
  - Sjögren syndrome
- Male
  - Cancer of penis
  - Genital muscle spasm

- Infection or irritation of penile skin
- Infection of seminal vesicles
- Lichen sclerosus
- Musculoskeletal disorders of pelvis and lower back
- Penile anatomy disorders
- Phimosis
- Prostate infections and enlargement
- Testicular disease
- Torsion of spermatic cord
- Urethritis
- Psychological disorders
  - Anxiety
  - Conversion reactions
  - Depression
  - Fear
  - Hostility toward partner
  - Phobic reactions
  - Psychological trauma

## *RISK FACTORS*

- Fatigue
- Stress
- Depression
- Diabetes
- Estrogen deficiency
  - Menopause
  - Lactation
- Previous PID

- Vaginal surgery
- Alcohol/marijuana consumption
- Medication side effects (antihistamines, tamoxifen, bromocriptine, low-estrogen oral contraceptives, SSRIs, depo-medroxyprogesterone, desipramine)

### *Pregnancy Considerations*

Pregnancy is a potent influence on sexuality; dyspareunia is common. Women who experience delivery interventions including episiotomy are at greater risk than women who deliver over an intact perineum or have an unsutured tear.

## **COMMONLY ASSOCIATED CONDITIONS**

Vaginismus

### *Pregnancy Considerations*

Episiotomies do not have a protective effect (1)[A].

## **DIAGNOSIS**

### **HISTORY**

- Identify pain characteristics
  - Onset
  - Duration
  - Location: entry versus deep, single versus multiple sites; positional
  - Intensity/quality: varying degrees of pelvic/genital pressure, aching, tearing, and/or burning
  - Pattern (precipitating or aggravating factors): when pain occurs (at entry, during, or after intercourse)
  - Relief measures: Avoid intercourse, change positions, and have intercourse only at certain times of the month.
- Include menstrual, obstetric, reproductive, sexual, domestic violence, and rape histories with medical, surgical, and psychosocial history

### **PHYSICAL EXAM**

- A complete exam, including a focused pelvic exam, to identify pathology and provide patient education.

- Because examination often reproduces the pain, examiner should be cautious and sensitive to patient's anxiety. Exam must include inspection and palpation of vulva and vaginal areas, palpation of the uterine and adnexal structures, and a rectovaginal exam. Sensory mapping with a cotton-tipped applicator to identify sensitive and painful areas.
- Inspect and palpate urethra and base of the bladder.

## *DIFFERENTIAL DIAGNOSIS*

Vaginismus

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

Based on history and exam findings

- Wet mount
- Gonorrhea and chlamydia cultures
- Herpes culture
- Urinalysis and urine culture
- Pap smear

### *Follow-Up Tests & Special Considerations*

- Serum estradiol if vulvodynia or atrophic vaginitis
- Voiding cystourethrogram if urinary tract involvement
- GI contrast studies if GI symptoms
- Ultrasound and CT scan are of limited value; perform if clinically indicated.

---

P.323

### *Diagnostic Procedures/Other*

Based on history and exam findings

- Colposcopy and biopsy if vaginal/vulvar lesions
- Laparoscopy if complex deep-penetration pain
- Cystoscopy if urinary tract involvement
- Endoscopy if GI involvement

## *Test Interpretation*

Depends on etiology

## **TREATMENT**

- Potential relationships exist between primary dyspareunia and vaginismus, low libido, and arousal disorders.
- Endocrine factors, such as primary amenorrhea, might reduce the biologic basis of sexual response.
- If pain prevents penetration, severe vaginismus may be present.

## **GENERAL MEASURES**

- Educate the patient and partner regarding the nature of the problem. Reassure both that there are solutions to the problem.
- Initiate specific treatment when initial evaluation identifies an organic cause.
- Once organic causes are ruled out, treatment is a multidimensional and multidisciplinary approach (2)[C].
  - Individual behavioral therapy
    - Indicated to help the patient deal with intrapersonal issues and assess the role of the partner
  - Couple behavioral therapy
    - Indicated to help resolve interpersonal problems
    - May involve short-term structured intervention or sexual counseling
    - Designed to desensitize systemically uncomfortable sexual responses and intercourse through a series of interventions over a period of weeks
    - Interventions range from muscle relaxation and mutual body massage to sexual fantasies and erotic massage.

## **MEDICATION**

### *First Line*

Depends on the etiology

Antibiotics, antifungals, or antivirals, as indicated, for infection

- Vaginal moisturizers and lubricants for dryness
- Analgesics and topical anesthetics for pain
- Topical estrogen for vaginal and vulvar atrophy
- Neuropathic pain associated with vulvar vestibulitis/vulvodynia may respond to tricyclic antidepressants (amitriptyline or nortriptyline) or gabapentin.

## *Second Line*

Ospemifene for moderate to severe symptoms due to menopause-related vulvar and vaginal atrophy (3)[B]

## **ISSUES FOR REFERRAL**

Referral for long-term therapy may be necessary.

## **ADDITIONAL THERAPIES**

Physical therapy for pelvic floor muscle pain

## **SURGERY/OTHER PROCEDURES**

- Laparoscopic excision of endometriotic lesions has shown benefit (4)[C].
- Surgical vestibulectomy can be considered if medical measures fail with vulvar vestibulitis (5) [B].

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Sitz baths may relieve painful inflammation.
- Perineal massage
- Antioxidants may improve symptoms associated with endometriosis.

## **ONGOING CARE**

## **FOLLOW-UP RECOMMENDATIONS**

### *Patient Monitoring*

- Outpatient follow-up depends on therapy.
- Every 6 to 12 months once resolved

## DIET

A high-fiber diet may help if constipation is a contributing cause.

## PATIENT EDUCATION

- Boston Women's Health Book Collective. *Our Bodies, Ourselves: A New Edition for a New Era*. New York, NY: Simon & Schuster; 2005.
- Kegel exercise information
- Provide couples with information about sexual arousal techniques.

## PROGNOSIS

Depends on underlying cause but most patients will respond to treatment.

**&NA;**

- Balanitis; Endometriosis; Pelvic Inflammatory Disease (PID); Sexual Dysfunction in Women; Genito-Pelvic Pain/Penetration Disorder (Vaginismus); Vulvovaginitis, Estrogen Deficient; Vulvovaginitis, Prepubescent
- Algorithms: Dyspareunia; Discharge, Vaginal

## Codes

**&NA;**

### ICD10

- N94.1 Dyspareunia
- F52.6 Dyspareunia not due to a substance or known physiol cond

## Clinical Pearls

**&NA;**

- Careful history to determine if patient feels pain before, during, or after intercourse will help identify cause.
  - Pain before intercourse suggests a phobic attitude toward penetration and/or the presence of vestibulitis.
  - Pain during intercourse combined with the location of the pain is most predictive of the causes of pain.
  - Introital pain after intercourse suggests vestibulitis in women of childbearing age, hypertonic pelvic floor, or vulvovaginal dystrophia.
- Potential relationship exists between primary dyspareunia and vaginismus, low libido, and

arousal disorders.

- Episiotomy does not offer any benefit in the prevention of dyspareunia; an episiotomy in fact may cause more future discomfort.

# Dyspepsia, Functional

Kristina Burgers, MD, FAAFP

Matthew W. Short, MD, FAAFP

## BASICS

### DESCRIPTION

- The presence of bothersome postprandial fullness, early satiety, or epigastric pain/burning in the absence of causative structural disease (to include normal upper endoscopy) for the preceding 3 months with initial symptom onset at least 6 months prior to diagnosis (Rome III criteria)
- Rome III criteria divide patients into two subtypes:
  - Postprandial distress syndrome
  - Epigastric pain syndrome
- System(s) affected: GI
- Synonym(s): idiopathic dyspepsia; nonulcer dyspepsia; nonorganic dyspepsia; postprandial distress syndrome; and epigastric pain syndrome

### EPIDEMIOLOGY

#### *Incidence*

Unknown, accounts for 70% of patients with dyspepsia, and ÷5% of primary care visits

#### *Prevalence*

- 15-30% prevalence in developed countries (3-10% when strict Rome III criteria are used)
- Predominant age: adults but can be seen in children
- Predominant gender: female > male

### ETIOLOGY AND PATHOPHYSIOLOGY

Unknown, but proposed mechanisms or associations include gastric motility disorders, visceral pain hypersensitivity, *Helicobacter pylori* infection, alteration in upper GI microbiome,

medications, anxiety, and depression

## *Genetics*

Possible link to G-protein  $\beta$ -3 subunit 825 CC genotype and serotonin transport genes

## *Pediatric Considerations*

Be alert for family system dysfunction.

## *Pregnancy Considerations*

Pregnancy may exacerbate symptoms.

## *Geriatric Considerations*

Patients >50 years with new-onset dyspepsia should have an upper endoscopy.

## **RISK FACTORS**

- Other functional disorders
- Anxiety/depression psychosocial factors: divorce, unemployment
- Smoking

## **GENERAL PREVENTION**

Avoid foods and habits known to exacerbate symptoms.

## **COMMONLY ASSOCIATED CONDITIONS**

Other functional bowel disorders

## **DIAGNOSIS**

### **HISTORY**

- Postprandial fullness (1)[B]
- Early satiety (1)[B]
- Epigastric pain (1)[B]
- Epigastric burning (1)[B]
- Symptoms for 3 months (1)[C]
- Warning signs that necessitate endoscopy include (2,3)[C]:
  - Unintended weight loss

- Progressive dysphagia
- Persistent vomiting
- GI bleeding
- Family history of cancer
- Age >55 years

## *PHYSICAL EXAM*

- Document weight status and vital signs.
- Examine for signs of systemic illness.
  - Murphy sign for cholelithiasis
  - Rebound and guarding for ulcer perforation
  - Palpation during muscle contraction for abdominal wall pain
  - Jaundice
  - Thyromegaly

## *DIFFERENTIAL DIAGNOSIS*

- Peptic ulcer disease; gastroesophageal reflux disease
- Cholecystitis
- Gastric or esophageal cancer; esophageal spasm
- Malabsorption syndromes; celiac disease
- Pancreatic cancer; pancreatitis
- Inflammatory bowel disease; carbohydrate malabsorption; gastroparesis
- Ischemic bowel disease
- Intestinal parasites
- Irritable bowel syndrome
- Ischemic heart disease
- Diabetes mellitus; thyroid disease
- Connective tissue disorders
- Conversion disorder
- Medication effects

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- Functional dyspepsia is a diagnosis of exclusion. Order labs are based on clinical suspicion (3) [C].
- CBC (if anemia or infection are suspected)
- LFT (if hepatobiliary disease is suspected)
- Test for *H. pylori* (stool antigen or urea breath test) in areas of high *H. pylori* prevalence (3,4) [A].
- Upper endoscopy for patients >55 years or those with alarm symptoms (weight loss, signs of blood loss, dysphagia, concern for cancer) (3)[C]
- Perform upper endoscopy if patient does not respond to gastric acid suppression trial (3)[C].
- A self-report questionnaire can help assess and track symptoms (3)[C].

## Diagnostic Procedures/Other

Esophageal manometry or gastric accommodation studies are rarely needed (3)[C].

## Test Interpretation

None (by definition this a functional disorder)

## TREATMENT

### GENERAL MEASURES

- Few effective treatment options are available (5).
- Reassurance and physician support are helpful (3)[C].
- Treatment is based on presumed etiologies.
- Discontinue offending medications (3)[C].

---

P.325

## MEDICATION

### First Line

- Treat *H. pylori* if confirmed on testing (3,4)[A].

- Trial of once daily proton pump inhibitor (PPI) medication (e.g., omeprazole 20 mg PO QD) or H2RA (e.g., ranitidine 150 mg BID) for up to 8 weeks in patients without alarm symptoms (3,5)[A]

## *Second Line*

- Trial of low-dose tricyclic antidepressant (TCA) medication is helpful in epigastric pain syndrome but not postprandial distress syndrome (amitriptyline 10 mg at bedtime); consider doubling dose after a few days (2,5)[A],(6)[B]; caution in elderly.
- Trazodone 25 mg at bedtime is an alternative (2,5) [A]. Consider a 1-month trial of prokinetic medication (metoclopramide) or buspirone if no response to TCA (2,5)[B]. Caution with metoclopramide in elderly due to side effects of tardive dyskinesia and parkinsonian symptoms.

## *ADDITIONAL THERAPIES*

- Stress reduction (2,5)[A]
  - Relaxation techniques
  - Physical exercise
  - Reflux precautions where applicable
- Psychotherapy effective in some patients (2)[A],(3)[B]

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Alternative approaches need further study.

- Peppermint oil +/- caraway oil
- Probiotics have theoretical benefit but few controlled trials (5)[B].
- Hypnotherapy may help (3)[B].
- Transcutaneous electroacupuncture may help (3)[B].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Provide ongoing support and reassurance.

- Upper endoscopy if persistent symptoms
- Change medications if no change after 4 weeks (3)[C].
- Discontinue drug therapy after symptom resolution (3)[C].

## DIET

- Limited data to support dietary modification
- Consider limiting fatty foods (2,5)[C].
- Avoid foods that exacerbate symptoms: wheat and cow milk proteins, peppers or spices, coffee, tea, and alcohol (2,5)[C].

## PATIENT EDUCATION

Reassurance and stress reduction techniques

## PROGNOSIS

Long-term/chronic symptoms with symptom-free periods

## COMPLICATIONS

Iatrogenic, from evaluation to rule out serious pathology

**See Also**

**&NA;**

- Irritable Bowel Syndrome
- Algorithms: Dyspepsia

## Codes

**&NA;**

### ICD10

K30 Functional dyspepsia

## Clinical Pearls

**&NA;**

- Dyspepsia without underlying organic disease is termed functional or idiopathic.
- Consider empiric treatment with acid suppression as first-line therapy for functional dyspepsia.
- Extensive diagnostic testing is not recommended unless alarm symptoms are present.

# Dysphagia

Felix B. Chang, MD, DABMA, FAAMA

## BASICS

Difficulty transmitting the alimentary bolus from the mouth to stomach

## DESCRIPTION

- Oropharyngeal dysphagia: difficulty transferring food bolus from oropharynx to proximal esophagus
- Esophageal dysphagia: difficulty moving food bolus through the body of the esophagus to the pylorus

## EPIDEMIOLOGY

10% of individuals >50 years of age

## Prevalence

- Common primary care complaint
- Rates of impaired swallowing in nursing home residents range from 29% to 32%.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Oropharyngeal (transfer dysphagia):
  - Mechanical causes: pharyngeal and laryngeal cancer, acute epiglottitis, carotid body tumor, pharyngitis, tonsillitis, strep throat, lymphoid hyperplasia of lingual tonsil, lateral pharyngeal pouch, hypopharyngeal diverticulum
- Esophageal:
  - Esophageal mechanical lesions: carcinomas, esophageal diverticula, esophageal webs, Schatzki ring, structures (peptic, chemical, trauma, radiation), foreign body
  - Extrinsic mechanical lesions: peritonsillar abscess, thyroid disorders, tumors, mediastinal compression, vascular compression (enlarged left atrium, aberrant subclavius, aortic aneurysm), osteoarthritis cervical spine, adenopathy, esophageal duplication cyst
- Neuromuscular: achalasia, diffuse esophageal spasm, hypertonic lower esophageal sphincter,

scleroderma, nutcracker esophagus, CVA, Alzheimer disease, Huntington chorea, Parkinson disease, multiple sclerosis, skeletal muscle disease (polymyositis, dermatomyositis), neuromuscular junction disease (myasthenia gravis, Lambert-Eaton syndrome, botulism), hyper- and hypothyroidism, Guillain-Barré syndrome, systemic lupus erythematosus, acute lymphoblastic leukemia, amyloidosis, diabetic neuropathy, brainstem tumors, Chagas disease

- Infection: diphtheria, chronic meningitis, tertiary syphilis, Lyme disease, rabies, poliomyelitis, CMV, esophagitis (*Candida*, herpetic)
- Globus phenomenon

## **RISK FACTORS**

- Children: hereditary and/or congenital malformations
- Adults: age >50 years. Elderly: GERD, stroke, COPD, chronic pain
- Smoking, excess alcohol intake, obesity
- Medications: quinine, potassium chloride, vitamin C, tetracycline, Bactrim, clindamycin, NSAIDs, procainamide, anticholinergics, bisphosphates
- Neurologic events or diseases: CVA, myasthenia gravis, multiple sclerosis, Parkinson disease, amyotrophic lateral sclerosis (ALS), Huntington chorea
- HIV patients with CD4 cell count <100 cells/mm<sup>3</sup>
- Trauma or irradiation of head, neck, and chest; mechanical lesions
- Extrinsic mechanical lesions: lung, thyroid tumors, lymphoma, metastasis
- Iron deficiency
- Anterior cervical spine surgery (up to 71% in the first 2 weeks postop; 12-14% at 1 year postop)
- Dysphagia lusoria (vascular abnormalities causing dysphagia): complete vascular ring, double aortic arch, right aortic arch with retroesophageal left subclavian artery and left ligamentum arteriosum, and right aortic arch with mirror-image branching and left ligamentum arteriosum

## **GENERAL PREVENTION**

- Correct poorly fitting dentures in older patients.
- Educate patients on prolonged chewing and drinking large volumes of water to accompany meals.
- Liquid and soft food diet in appropriate patients

- Avoid alcohol with meals.
- Prophylactic swallowing exercises in patients with head and neck cancer undergoing chemoradiation

## COMMONLY ASSOCIATED CONDITIONS

Peptic stricture, esophageal webs and rings, carcinoma; history of stroke, dementia, pneumonia

## DIAGNOSIS

### HISTORY

- Dysphagia to both solids and liquids from the onset of deglutition is likely an esophageal motility disorder.
- Oropharyngeal dysphagia presents as difficulty in initiating the swallowing process.
- Dysphagia for solids that later progresses to involve liquids more likely reflects mechanical obstruction.
- Progressive dysphagia is usually caused by cancer or a peptic stricture. Intermittent dysphagia is most often related to a lower esophageal ring.
- Inquire about heartburn, weight loss, hematemesis, coffee ground emesis, anemia, regurgitation of undigested food particles, and respiratory symptoms.
- Inquire about regurgitation, aspiration, or drooling immediately after swallowing.
  - May represent oropharyngeal dysphagia
- Does the food bolus feel stuck?
  - Upper sternum or back of throat may represent oropharyngeal dysphagia, whereas sensation over the lower sternum is typical of esophageal dysphagia.
- Is odynophagia present?
  - May represent inflammation, achalasia, diffuse esophageal spasm, esophagitis, pharyngitis, pill-induced esophagitis, cancer
- Globus sensation ("lump in the throat")?
  - Indicates cricopharyngeal or laryngeal disorders.
- History of sour taste in the back of the throat or history of chronic heartburn suggests GERD.

Inquire about alcohol and/or tobacco use.

- Are there associated symptoms such as weight loss or chest pain?
  - Double aortic arch, right aortic arch with retroesophageal left subclavian artery and left ligamentum arteriosum
  - Anticholinergics, antihistamines, and some antihypertensives can decrease salivary production.
- Halitosis: Rule out diverticulitis.
- Prior history of a connective tissue disorder
- Changes in speech, hoarseness, weak cough, dysphonia? Rule out neuromuscular dysfunction.

## *PHYSICAL EXAM*

- General: vital signs
- Skin:
  - Telangiectasia, sclerodactyly, calcinosis (r/o autoimmune disease); Reynaud phenomenon, sclerodactyly may be found in CREST syndrome or systemic scleroderma; stigmata of alcohol abuse (palmar erythema; telangiectasia)
- Head, eye, ear, nose, throat (HEENT):
  - Oropharyngeal:
    - Pharyngeal erythema/edema, tonsillitis, pharyngeal ulcers or thrush, odynophagia (bacterial, viral, fungal infections)
    - Tongue fasciculations (ALS)
  - Neck:
    - Neck masses, lymphadenopathy, neck tenderness, goiter
    - Neck tenderness: acute thyroiditis
- Neurologic:
  - Cranial nerve exam:
    - Sensory: cranial nerves V, IX, and X
    - Motor: cranial nerves V, VII, X, XI, and XII
  - CNS, mental status exam, strength testing, Horner syndrome, ataxia, cogwheel rigidity

(CVA, dementia, Parkinson disease, Alzheimer disease)

- Eye position, extraocular motility
- Informal bedside swallowing evaluation:
  - Observe level of consciousness, postural control-upright position, oral hygiene, mobilization of oral secretions.

## *DIFFERENTIAL DIAGNOSIS*

See Etiology and Pathophysiology.

## *DIAGNOSTIC TESTS & INTERPRETATION*

Adults: (1)[C]

- Barium swallow
- Fiberoptic endoscopic examination of swallowing (FEES)
- Gastroesophageal endoscopy
- Barium cine/video esophagogram
- Ambulatory 24-hour pH testing
- Esophageal manometry
- Videofluoroscopic swallowing study (VFSS): oropharyngeal dysphagia

### *Initial Tests (lab, imaging)*

- Guided by diagnostic considerations (2)[C]
  - CBC (infection and inflammation)
  - Serum protein and albumin levels for nutritional assessment
  - Thyroid function studies to detect dysphagia associated with hypothyroidism or hyperthyroidism, cobalamin levels
  - Antiacetylcholine antibodies (myasthenia)
- Barium swallow: detects strictures or stenosis

### *Follow-Up Tests & Special Considerations*

- CT scan of chest
- MRI of brain and cervical spine

- Videofluoroscopic swallowing function study (VSFS) (lips, tongue, palate, pharynx, larynx, proximal esophagus)
- Fiberoptic endoscopy and videofluoroscopy are similar in terms of diagnostic sensitivity (3)[C].

## *Diagnostic Procedures/Other*

Endoscopy with biopsy; esophageal manometry; esophageal pH monitoring

## *Test Interpretation*

- Squamous cell or adenocarcinoma
- Barrett metaplasia
- Fibrous tissue of a ring, web, or stricture
- Loss of smooth muscle (scleroderma)

## **TREATMENT**

### *GENERAL MEASURES*

Exclude cardiac disease. Ensure airway patency and adequate pulmonary function. Assess nutritional status. Speech therapy evaluation is helpful.

### *MEDICATION*

#### *First Line*

- For esophageal spasms: calcium channel blockers: nifedipine 10 to 30 mg TID; imipramine 50 mg at bedtime; sildenafil 50 mg/day PRN
- For esophagitis:
  - Antacids: Tums, Mylanta, Maalox
  - H<sub>2</sub> blockers:
    - Cimetidine: up to 1,600 mg orally per day in 2 or 4 divided doses for 12 weeks
    - Ranitidine: initial 150 mg orally 4 times daily and maintenance 150 mg orally twice daily
    - Nizatidine: 150 mg orally twice daily for 12 weeks
    - Famotidine: 20 to 40 mg orally twice daily for 12 weeks

- Proton pump inhibitors:
  - Omeprazole: 20 mg once daily for 4 to 8 weeks
  - Lansoprazole: 30 mg once daily for up to 8 weeks
  - Rabeprazole: 20 mg orally once daily for 4 to 8 weeks
  - Esomeprazole: 20 to 40 mg orally once daily for 4 to 8 weeks
  - Pantoprazole: 40 mg orally once daily for up to 8 weeks
- Prokinetic agents: rarely used
- Precautions: may need to use liquid forms of medications because patients might have difficulty swallowing pills

## *ISSUES FOR REFERRAL*

- Gastroenterology: endoscopy, refractory symptoms
- Surgery: dilation, esophageal myotomy, biopsy

## *ADDITIONAL THERAPIES*

Speech therapy to assess swallowing; nutritional evaluation for dietary and positioning recommendations; physical therapy for muscle-strengthening exercise; no eating at bedtime; remaining upright after eating

- Self-expanded metal stent is safe, effective, and quicker in palliating dysphagia compared to other modalities.

## *SURGERY/OTHER PROCEDURES*

- Esophageal dilatation (pneumatic or bougie)
- Esophageal stent; laser for cancer palliation (4)[A]
- Treatment for underlying problem (e.g., thyroid goiter, vascular ring, esophageal atresia)
- Nd:YAG laser incision of lower esophageal rings refractory to dilation
- Photodynamic therapy (cancer) (4)[C]
- Cricopharyngeal myotomy (oropharyngeal dysphagia)
- Surgery for Zenker diverticulum, refractory strictures, or myotomy (for achalasia)
- Percutaneous endoscopic gastrostomy (PEG) decreases risk of dysphagia when compared with nasogastric tube.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture has been used for neurogenic dysphagia.
- Electroacupuncture combined with dilating granule has been used in the treatment of GERD.
- Insufficient evidence for routine use of botulinum toxin

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

- Complete or partial esophageal obstruction with malnutrition or hypovolemia/dehydration
- Comorbid conditions complicating dysphagia
- Need for enteral feeding
- Outpatient for conditions where patient is able to maintain nutrition and has little risk of complications.
- Hospitalization may be required for adults when dysphagia is associated with total or near-total obstruction of esophageal lumen.
- Hospitalization may be needed for endoscopy and/or esophageal dilation and is generally indicated for diagnostic or therapeutic surgical procedures.

### *IV Fluids*

For dehydrated, hypovolemic patients, and patients with impaired consciousness

### *Discharge Criteria*

Tolerating adequate diet without nausea/pain

## ONGOING CARE

### *DIET*

See òGeneral Prevention.ó

### *PATIENT EDUCATION*

Dietary modification; no eating at bedtime; remaining upright after eating; smoking cessation

### *PROGNOSIS*

Vary with specific diagnosis.

## COMPLICATIONS

- Oropharyngeal: pneumonia, lung abscess, aspiration, airway obstruction
- Malnutrition and dehydration

Codes

**&NA;**

## **ICD10**

- R13.10 Dysphagia, unspecified
- R13.12 Dysphagia, oropharyngeal phase
- R13.14 Dysphagia, pharyngoesophageal phase

## **Clinical Pearls**

**&NA;**

- Preventing aspiration is a priority.
- Swallow therapy is recommended in patients with oropharyngeal dysphagia following a stroke, head or neck trauma, surgery, or degenerative neurologic diseases.
- Patients with oropharyngeal dysphagia usually report feeling an obstruction in the neck and point to this area when asked to identify the site of their symptoms.
- Weight loss is usually associated with malignancy or achalasia.
- Most patients with Sjögren syndrome have associated dysphagia.

# Ectopic Pregnancy

Ryan J. Callery, MD

## BASICS

### DESCRIPTION

Ectopic: pregnancy implanted outside the confines of the uterine cavity. Subtypes include:

- Tubal: pregnancy implanted in any portion of the fallopian tube
- Abdominal: pregnancy implanted intra-abdominally, most commonly after tubal abortion or rupture of tubal ectopic pregnancy
- Heterotopic: pregnancy implanted intrauterine and a separate pregnancy implanted outside uterine cavity
- Ovarian: implantation of pregnancy in ovarian tissue
- Cervical: implantation of pregnancy in cervix
- Intraligamentary: implantation of pregnancy within the broad ligament

### EPIDEMIOLOGY

#### *Incidence*

- 108,800 cases in 1992 in the United States, according to CDC census (most recent data available) meaning that 1.5-2.0% of all pregnancies were ectopic. The true incidence is difficult to estimate because many patients are treated in the outpatient setting.
- In the United States, ectopic pregnancy is the leading cause of 1st-trimester maternal deaths and accounts for 6% of all pregnancy-related deaths.
- Heterotopic pregnancy, although rare (1:30,000), occurs with greater frequency in women undergoing in vitro fertilization (IVF) (1/1,000).

#### *Prevalence*

÷33% recurrence rate if prior ectopic pregnancy

### ETIOLOGY AND PATHOPHYSIOLOGY

- 97% of ectopic pregnancies occur in the fallopian tube, of which, 55% in the ampullary portion of the tube, 25% in the isthmus, and 17% in the fimbria.
- Of the remaining 3%, most are ovarian, cervical, abdominal pregnancies, or heterotopic.
- For a tubal pregnancy, impaired movement of the fertilized ovum to the uterine cavity due to dysfunction of the tubal cilia, scarring, or narrowing of the tubal lumen
- Other locations are rare but may occur from reimplantation of an aborted tubal pregnancy or from uterine structural abnormalities (mainly cervical pregnancy).

## **RISK FACTORS**

- History of pelvic inflammatory disease (PID), endometritis, or current gonorrhea/chlamydia infection
- Previous ectopic pregnancy
- History of tubal surgery (≈33% of pregnancies after tubal ligation will be ectopic)
- Pelvic adhesive disease (infection or prior surgery)
- Use of an intrauterine device (IUD): Overall chance of pregnancy of any type with an IUD is low; however, there is an increased likelihood of ectopic location if pregnancy occurs. IUDs reduce absolute risk of ectopic pregnancy.
- Use of assisted reproductive technologies
- Diethylstilbestrol exposure in utero (DES was last used in 1972)
- Tobacco use
- Patients with disorders that affect ciliary motility may be at increased risk (e.g., endometriosis, Kartagener).

## **GENERAL PREVENTION**

- Reliable contraception or abstinence
- Screening and treatment of STIs (i.e., gonorrhea, chlamydia) that can cause PID and tubal scarring

## **DIAGNOSIS**

### **HISTORY**

In >50% of presenting cases, patients have sudden-onset abdominal pain coupled with cessation of/or irregular menses. Other common symptoms include

nausea and/or vomiting, vaginal bleeding, and pain referred to the shoulder (from hemoperitoneum).

## **PHYSICAL EXAM**

- Abdominal tenderness ± rebound tenderness
- Vaginal bleeding
- Palpable mass on pelvic exam (adnexal or cul-de-sac fullness)
- Cervical motion tenderness
- In cervical cases, an hourglass-shaped cervix might be noted.
- In cases of rupture and significant intraperitoneal bleeding, signs of shock such as pallor, tachycardia, and hypotension may be present.

## **DIFFERENTIAL DIAGNOSIS**

- Missed, threatened, inevitable, or completed abortion
- Gestational trophoblastic neoplasia (Molar pregnancy)
- Appendicitis
- Salpingitis, PID
- Ruptured corpus luteum or hemorrhagic cyst
- Ovarian tumor, benign or malignant
- Ovarian torsion
- Cervical polyp, cancer, trauma, or cervicitis

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- Human chorionic gonadotropin (hCG): Serial quantitative serum levels normally increase by at least 53% every 48 hours: Abnormal rise should prompt workup for gestational abnormalities. Clinical impression of acute abdomen/intraperitoneal bleeding concurrent with a positive hCG level is indicative of ectopic pregnancy until proven otherwise (1).
- CBC and ABO type and antibody screen
- Serum progesterone level (>20 mg/mL associated with lower risk of ectopic pregnancy). In women with pain and/or bleeding who have an inconclusive US, serum progesterone level <3.2 ng/mL ruled out a viable pregnancy in 99.2% of women (2).

- Under investigation: evaluation of serum progesterone levels in conjunction with vascular endothelial growth factor, inhibin A, and activin A using an algorithm. This diagnosed patients with ectopic pregnancy with 99% accuracy (3).
- Transvaginal US (TVUS) is the gold standard for diagnosis:
  - Failure to visualize a normal intrauterine gestational sac when serum hCG is above the discriminatory level (>1,500 to 2,000 IU/L) suggests an abnormal pregnancy (4).
  - Recent studies show an hCG level of 3,500 IU/L to be associated with a 99% probability of detecting a normal intrauterine gestational sac in clinical practice (5).
  - These values are not valid for multiple gestations
- MRI is also useful but costly and rarely used if TVUS is available.

### *Diagnostic Procedures/Other*

- In the setting of an undesired pregnancy, sampling of the uterine cavity with endometrial biopsy or D&C can identify the presence/absence of intrauterine chorionic villi. When an intrauterine pregnancy (IUP) has been evacuated by curettage, hCG levels should drop by 15% the next day (6).
- Historically, culdocentesis was performed to confirm suspected hemoperitoneum prior to surgical management. Currently, TVUS quantification of pelvic fluid is sufficient.

### *Test Interpretation*

Products of conception (POC; especially chorionic villi) outside the uterine cavity

## **TREATMENT**

### *MEDICATION*

- Methotrexate (MTX): treatment for unruptured tubal pregnancy or for remaining POCs after laparoscopic salpingostomy. MTX inhibits DNA synthesis via folic acid antagonism by inactivating dihydrofolate reductase. Most effective when pregnancy is <3 cm diameter, hCG <5,000 mIU/mL, and no fetal heart movement is seen. Success rate is 88% if hCG <1,000 mIU/mL, 71% if hCG <2,000 mIU/mL:
  - Dosage:
    - Single: IM methotrexate: 50 mg/m<sup>2</sup> of body surface area; may repeat once (preferred method) if <15% decline in hCG by day 7

- Double dose: methotrexate 50 mg/m<sup>2</sup> of body surface area once and then repeated on day 4; if <15% decline in hCG on day 7, may repeat dose on days 7 and 11
- Multidose: methotrexate 1 mg/kg IM/IV every other day, with leucovorin 0.1 mg/kg IM in between. Maximum 4 doses; course may be repeated 7 days after last dose if necessary.
- Contraindications
  - Hemodynamic instability or any evidence of rupture
  - Moderate to severe anemia
  - Severe hepatic or renal dysfunction
  - Immunodeficiency
- Relative contraindications
  - Fetal heart rate seen
  - Large gestational sac
  - Noncompliance or limited access to hospital or transportation
  - High hCG count >5,000 mIU/mL
- Precautions: immunologic, hematologic, renal, GI, hepatic, and pulmonary disease, or interacting medications
- Pretreatment testing: serum hCG, CBC, liver and renal function tests, blood type, and screen
- Patient counseling: During therapy, refrain from use of alcohol, aspirin, NSAIDs, and folate supplements (decreases efficacy of MTX); avoid excessive sun exposure.
  - Adherence to scheduled follow-up appointments is critical.
  - Increased abdominal pain may occur during treatment; however, severe pain, nausea, vomiting, bleeding, dizziness, or light-headedness may indicate treatment failure and require urgent evaluation.
- Rupture of ectopic pregnancy during MTX treatment ranges from 7% to 14%.
- Side effects include stomatitis, conjunctivitis, abdominal cramping, and rarely neutropenia, pneumonitis, or alopecia (7,8,9).

## ***ISSUES FOR REFERRAL***

- Consider gynecologic consultation if not experienced in medical management.
- Refer to a gynecologist for surgical care.

## ***ADDITIONAL THERAPIES***

- Physician or patient may elect for surgical treatment as primary method, then postop hCG should guide need for MTX.
- After evidence of medical failure or tubal rupture, surgery is necessary.
- Surgery may either be salpingostomy (with preservation of tube) or salpingectomy (tubal removal). Abdominal entry is typically laparoscopic.
- Treatment of cervical, ovarian, abdominal, or other ectopic pregnancy is complicated and requires immediate specialist referral.
- Follow all patients treated medically to an hCG of 0 to ensure that there is no need for surgical intervention.
- Offer anti-D Rh prophylaxis at a dose of 50 µg to all Rh-negative women who have a surgical procedure to manage an ectopic pregnancy.
- Expectant management to allow for spontaneous resolution of ectopic pregnancy is acceptable in asymptomatic patients with no evidence of rupture or hemodynamic instability coupled with an appropriately low hCG (<200 mIU/mL) and no extrauterine mass suggestive of ectopic. Ruptured tubal pregnancies may occur even with extremely low hCG levels (<100 mIU/mL) (10).

## ***SURGERY/OTHER PROCEDURES***

- Indications include ruptured ectopic pregnancy, inability to comply with medical follow-up, previous tubal ligation, known tubal disease, current heterotopic pregnancy, desire for permanent sterilization at time of diagnosis.
- Laparoscopy is the first-line surgical management.
- Salpingostomy is preferred in patients who wish to maintain fertility particularly if contralateral tube is damaged/absent:
  - No difference in recurrence rate compared to salpingectomy (11).
  - Persistent trophoblastic tissue with salpingostomy remains in the fallopian tube in 4-15% of cases.
- Salpingectomy is indicated for uncontrolled bleeding, recurrent ectopic pregnancy, severely damaged tube, large gestational sac, or patient desire for sterilization.

## ***INPATIENT CONSIDERATIONS***

## *Admission Criteria/Initial Stabilization*

- Fails criteria for methotrexate management, suspicion of rupture, orthostatic, shock, and severe abdominal pain requiring IV narcotics
- Inpatient observation in the setting of an uncertain diagnosis, particularly with an unreliable patient, may be appropriate.
- Surgical emergency
  - Two IV access lines should be placed immediately if suspicion of rupture; aggressive resuscitation as needed
  - Blood product transfusion if necessary en route to OR
  - In cases of shock, pressors and cardiac support may be necessary.

## *IV Fluids*

- Unnecessary for a stable ectopic pregnancy being medically treated
- Critical for a surgical patient who is bleeding

## *Nursing*

Strict input/output, hourly vitals, orthostatics if mobile, frequent abdominal exams, serial hematocrit, pad counts if heavy vaginal bleeding

## *Discharge Criteria*

Afebrile, abdominal pain resolving or resolved, diagnosis established, surgical treatment, and recovery is complete

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Serial serum quantitative hCG until level drops to zero:
  - After methotrexate administration, a strict monitoring protocol should be followed (8).
  - Following salpingostomy, weekly levels are appropriate.
  - Following salpingectomy, further follow-up may be unnecessary.
- Pelvic US for persistent or recurrent masses

- Pain control: brief course of narcotics usually necessary
- Liver and renal function tests following methotrexate administration if repeat dosing is required
- Delay of subsequent pregnancy for at least 3 months after treatment with methotrexate due to teratogenicity (folate deficiency)

## **DIET**

- During treatment, avoid foods and vitamins high in folate (leafy greens, liver, edamame) due to interaction with methotrexate efficacy.
- Maintain excellent hydration.

## **PATIENT EDUCATION**

- Signs and symptoms of ectopic pregnancy should be reviewed.
- Patients should be encouraged to plan subsequent pregnancies and seek early medical care on discovery of future pregnancies.

## **PROGNOSIS**

- Chronic ectopic pregnancies are rare and treated with surgical removal of the fallopian tube.
- Future fertility depends on fertility prior to ectopic pregnancy and degree of tubal compromise.
- ÷66% of women with a history of ectopic pregnancy will have a future IUP if they are able to conceive.
- If infertility persists beyond 12 months, the fallopian tubes should be evaluated.

## **COMPLICATIONS**

- Hemorrhage and hypovolemic shock
- Persistent trophoblastic tissue after medical or surgical management
- Infection
- Infertility
- Blood transfusions with associated infections/transfusion reaction
- Disseminated intravascular coagulation in the setting of massive hemorrhage

## Codes

**&NA;**

### ICD10

- O00.9 Ectopic pregnancy, unspecified
- O00.1 Tubal pregnancy
- O00.0 Abdominal pregnancy

## Clinical Pearls

**&NA;**

- Ectopic pregnancy is the leading cause of 1st-trimester maternal death and accounts for 6% of U.S. pregnancy deaths.
- 97% of ectopic pregnancies occur in the fallopian tube.
- Diagnosis requires high clinical suspicion in the setting of abdominal pain and a positive pregnancy test.

# Ejaculatory Disorders

Payam Sazegar, MD, CCFP

## BASICS

### DESCRIPTION

- Premature ejaculation (PE): inability to control ejaculatory reflex resulting in ejaculation sooner than desired; most common type of sexual dysfunction affecting all age groups:
  - Defined (ISSM 2007) as an ejaculation that always or nearly always occurs prior to or within 1 minute of penetration; an inability to ejaculate on all or nearly all penetrations and with negative personal consequences (1,2).
  - Natural biologic response is to ejaculate within 2 to 5 minutes after vaginal penetration.
  - Ejaculatory control is an acquired behavior that increases with experience.
- Delayed ejaculation (DE): prolonged time to ejaculate (>30 minutes) despite desire, stimulation, and erection
- Aspermia (lack of sperm in the ejaculate):
  - Anejaculation (AE): lack of emission or contractions of bulbospongiosus muscle
  - Retrograde ejaculation (RE): partial or complete ejaculation of semen into the bladder
  - Obstruction: ejaculatory duct obstruction or urethral obstruction
- Painful ejaculation: genital or perineal pain during or after ejaculation
- Ejaculatory anhedonia: normal ejaculation lacking orgasm or pleasure
- Hematospermia: presence of blood in the ejaculate
- Ejaculatory duct obstruction
- Synonym(s): rapid ejaculation; retarded ejaculation; inhibited orgasm in males; ejaculatory dysfunction

### EPIDEMIOLOGY

#### Prevalence

PE is common. Reported prevalence in U.S. males ranges from 20-30% depending definition.

- DE is reported in 5-8% of men age 18 to 59 years, but <3% experience the problem for >6 months.
- Predominant age: all sexually mature age groups
- Predominant sex: male only

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Male sexual response:

- Erection mediated by parasympathetic nervous system
- Normal ejaculation consists of three phases:
  - Emission phase: Semen is deposited into urethra by contraction of prostate, seminal vesicles, and vas deferens; under autonomic sympathetic control.
  - Ejaculation phase: Semen is forcibly propelled out of urethra by rhythmic contractions of bulbospongiosus and ischiocavernosus muscles. This is mediated by the somatic nervous system on the motor branches of the pudendal nerve. Bladder neck contracture induced by  $\alpha$ -adrenergic receptors ensures anterograde ejaculation.
  - Orgasm: the pleasurable sensation associated with ejaculation (cerebral cortex); smooth muscle contraction of accessory sexual organs; release of pressure in posterior urethra
- PE has many theoretical causes:
  - Penile hypersensitivity
  - 5-hydroxytryptamine (5-HT) receptor sensitivity
  - Sexual inexperience
  - High level of sexual arousal and/or long interval since last ejaculation
  - Fear of sexual transmitted infections (STIs)
  - Anxiety or guilty feelings about sex
  - Lack of privacy
  - Interpersonal maladaptation (e.g., marital problems, unresponsiveness of partner)
- DE:
  - Rarely due to underlying painful disorder (e.g., prostatitis, seminal vesiculitis)
  - Psychogenic

- Sexual performance anxiety and other psychosocial factors
- Medications may impair ejaculation (e.g., MAOIs, SSRIs,  $\alpha$ - and  $\beta$ -blockers, thiazides, antipsychotics, tricyclic and tetracyclic antidepressants, NSAIDs, opiates, alcohol).
- Never any ejaculate:
  - Congenital structural disorder (Müllerian duct cyst, Wolffian abnormality)
  - Acquired (radical prostatectomy, postinfectious, posttraumatic, T10-T12 neuropathy)
- AE:
  - Retroperitoneal lymph node (LN) dissection
  - Spinal cord injury or other (traumatic) sympathetic nerve injury
  - Medications ( $\alpha$ - and  $\beta$ -blockers, benzodiazepines, SSRIs, MAOIs, TCAs, antipsychotics, aminocaproic acid)
  - Diabetes mellitus (DM) (neuropathy)
  - Radical prostatectomy
- RE:
  - Transurethral resection of the prostate (25%) or other prostate resection procedures
  - Surgery on the neck of the bladder
  - Extensive pelvic surgery
  - Retroperitoneal LN dissection for testicular cancer (also may produce failure of emission)
  - Neurologic disorders (MS, DM)
  - Medications ( $\alpha$ -blockers, in particular tamsulosin, ganglion blockers, antipsychotics)
  - Urethral stricture (may be posttraumatic)
- Painful ejaculation:
  - Infection or inflammation (orchitis, epididymitis, prostatitis, urethritis)
  - Ejaculatory duct obstruction
  - Seminal vesicle calculi
  - Obstruction of the vas deferens
  - Psychological/functional
- Ejaculatory anhedonia:

- Medications
- Psychological
- Hormonal imbalances
- Decreased libido
- Hematospermia (often unable to find cause):
  - Inflammation/infection
  - Calculi: bladder, seminal vesicle, prostate, urethra
  - Trauma to genital area (cycling, constipation)
  - Obstruction
  - Cyst
  - Tumor (prostate cancer [1-3% present with hematospermia])
  - Arteriovenous malformations
  - Iatrogenic
  - Hypertension

## **COMMONLY ASSOCIATED CONDITIONS**

- Neurologic disorders (e.g., multiple sclerosis [MS])
- DM
- Prostatitis
- Ejaculatory duct obstruction
- Urethral stricture
- Psychological disorders
- Endocrinopathies
- Relationship/interpersonal difficulties

## **DIAGNOSIS**

- Ejaculation occurs before individual wishes (PE).
- Ejaculation does not occur following normal stimulation (including masturbation).

## **HISTORY**

- Detailed sexual history, including:
  - Time frame of the problem
  - Quality of patient's sexual response
  - Sense of ejaculatory control and sexual distress
  - Overall assessment of the relationship
  - Ask specific questions as patients often reluctant to discuss openly
- Detailed history of recent and current medications
- History of past trauma or recent infections
- Past surgical history with particular attention to genitourinary (GU) surgeries
- Supplements and alternative therapies tried
- Many men do not distinguish initially between problems related to erection and ejaculation.
- Some men have unrealistic expectations of ejaculatory response and frequency.
- Include the sexual partner in the interview, especially if the patient expresses a belief that he is not meeting his partner's needs.
- In review of systems, elicit any evidence of testosterone deficiency or prolactin excess especially if anhedonia present.

## **PHYSICAL EXAM**

- Check vitals. Look for focal neurologic signs (MS, spinal cord injury) and psychiatric disorders.
- Thorough GU exam, including:
  - Size and texture of testes and epididymis
  - Verification of the presence of the vas deferens
  - Location and patency of urethral meatus
  - Digital rectal examination to evaluate prostate consistency and size and possible midline lesions

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Laboratory test results may be normal.
- Fasting glucose or HgbA1c to rule out diabetes

- Postorgasmic urinalysis will confirm RE. Semen fructose level, sperm count, and viscosity can be measured. Patient may complain of cloudy urine.
- AE will have fructose negative, sperm negative, nonviscous postorgasmic urinalysis
- In painful ejaculation, urinalysis and urine culture
- If prostate cancer is considered, check prostate-specific antigen (PSA).
- In anhedonia, consider checking testosterone, prolactin, glucose, and thyroid levels.
- In hematospermia, painful ejaculation, or if ejaculatory duct obstruction is considered, transrectal ultrasound (TRUS) may be helpful.
- TRUS-guided seminal vesicle aspiration; if ejaculatory duct obstruction is present, then the aspirate will contain sperm.
- If suspicious of anatomic abnormality, can get scrotal US and/or MRI

## TREATMENT

### GENERAL MEASURES

- Identifying any medical cause (even if not reversible) helps patient accept condition.
  - Improve partner communication.
  - Psychological counseling for patient and partner
- 
- Reduce performance pressure through reassurance
  - Use of a variety of resources may be necessary (e.g., psychiatrist, psychologist, sex therapist, vascular surgeon, urologist, endocrinologist, neurologist).
  - PE:
    - Use sensate focus therapy (gradual progression of nonsexual contact to sexual contact).
    - Quiet vagina: female partner stops moving just prior to ejaculation
    - Techniques to learn ejaculatory control (e.g., coronal squeeze technique [squeezing the glans penis until ejaculatory urge ceases] or start-and-stop technique [cessation of penile stimulation when ejaculation approaches and resumption of stimulation when ejaculatory feeling ends]) (3)[B]
  - DE:
    - Change to antidepressant less likely to cause DE (citalopram, fluvoxamine, nefazodone).

- AE/RE:
  - Discontinue offending medication(s).
  - Diabetic control
  - If urethral obstruction present, refer to urologist
  - RE may be helped if intercourse occurs when bladder is full.
  - Consider penile vibratory stimulation (effective in spinal cord injuries >T10) or electroejaculation (place on monitor if lesions above T6 because autonomic dysreflexia may result) to collect sperm in AE cases.
- Painful ejaculation:
  - Counseling may be beneficial.
  - If seminal vesicle stones are possible, refer to urologist
- Hematospermia:
  - Often resolves spontaneously, without known cause
  - May try empiric antibiotic, but little evidence to support
  - If persistent or high degree of suspicion for abnormality, refer to urologist.

## *MEDICATION*

- PE:
  - Treating underlying erectile dysfunction (if identified) with PDE5 inhibitors
- First line:
  - Topical anesthetic gel applied (2.5% prilocaine ± 2.5% lidocaine [EMLA]) 2.5 g under a condom for 30 minutes prior to intercourse (4,5)[A]
  - Daily dosing of clomipramine 20 to 50 mg, sertraline 25 to 200 mg, fluoxetine 5 to 20 mg, or paroxetine 10 to 40 mg can delay ejaculation within 1 to 3 weeks of starting medication (4)[A].
  - Dapoxetine, a short-acting SSRI, used on demand 30 to 60 mg 1 to 2 hours prior to sex (2,4)[A].
  - Tramadol 5 to 50 mg used on demand 2 hours before sex. Effective in many studies (6) [A].
  - Some other on-demand options include: clomipramine 20 to 40 mg 4 to 24 hours

before intercourse, sertraline 50 mg 4 to 8 hours before intercourse, and paroxetine 20 mg 3 to 4 hours before intercourse (2)[A]

- Consider switching antidepressants to bupropion, nefazodone, or mirtazapine.
- Second line: behavioral/sex therapy, pelvic floor muscle therapy (3)[B]
- DE (limited options):
  - Patients who must continue SSRIs may respond to bupropion, buspirone (1)[B], or yohimbine (1)[C] before intercourse.
  - Sex therapy, self-stimulation therapies (1)[B]
  - Some evidence that amantadine or cyproheptadine may be helpful (2)[B]
- AE/RE:
  - $\alpha$ -Agonists and antihistamines can be helpful but are not approved by the FDA.
  - First line:
    - Pseudoephedrine 60 mg po daily to QID (7)[A]
    - Imipramine 25 to 75 mg po BID (7)[A]
  - Second line: For RE, can try postejaculation bladder harvest of sperm (if fertility desired). For AE, can try midodrine, penile vibratory stimulation, or electroejaculation (7)[B].
- Painful ejaculation:
  - Treat underlying infection/inflammatory process
  - $\alpha$ -Blockers may have some benefit.

## ***ISSUES FOR REFERRAL***

The following conditions, when suspected, should be referred to a urologist:

- Ejaculatory duct obstruction
- Seminal vesicle or prostatic stones
- Urethral obstruction
- Vas deferens obstruction
- Calculi
- Persistent or severe hematospermia

## SURGERY/OTHER PROCEDURES

Surgical treatment of ejaculatory duct obstruction:

- Transurethral resection of the ejaculatory ducts

## ONGOING CARE

## PATIENT EDUCATION

See òGeneral Measures.ó

## PROGNOSIS

Often improves with therapy and counseling

## COMPLICATIONS

Psychological impact on some males: signs of severe inadequacy, self-doubt, additional anxiety, and guilt

## Codes

**&NA;**

### ICD10

- F52.4 Premature ejaculation
- N53.11 Retarded ejaculation
- N53.14 Retrograde ejaculation

## Clinical Pearls

**&NA;**

- If erectile dysfunction is contributing to ejaculatory difficulty, management of erectile dysfunction should precede attempted management of ejaculatory disorders.
- Medications should always be thoroughly reviewed because they may be the primary cause of ejaculatory disorders.
- PE and DE generally have both psychogenic and physical causes, whereas AE and RE are due to organic neurogenic/autonomic dysfunction.
- A multidisciplinary approach, including the primary care physician, urologists, psychologists, and other appropriate health care professionals, is essential to the proper treatment of ejaculatory disorders.

# Elder Abuse

Nitin Budhwar, MD

Kimberly Kone, MD

## BASICS

### DESCRIPTION

- The National Center of Elder Abuse divides abuse into three categories (older than age 60) (1) [A]:
  - **Domestic:** Abuse from someone who has a special relationship with the elderly individual (spouse, child, friend, or in-home caregiver) that occurs in the home of the elderly or caregiver.
  - **Institutional:** Occurs in the setting of a facility that is responsible for caring for the elderly, such as a nursing home or long-term care facility.
  - **Self-neglect:** The behavior of the elderly individual leads to harm.
- Types of abuse in estimated order of occurrence:
  - Self-neglect (estimated 50%). The most common form of abuse (2)[C].
  - Financial
  - Neglect
  - Emotional
  - Physical
  - Sexual
  - Taken advantage of: Misinformation and unregulated online pharmaceutical, financial companies, and so forth, that specifically target the elderly leading to deleterious outcomes (3)[C].

### EPIDEMIOLOGY

#### *Incidence*

Estimate is that as many as 1:10 have been victims of abuse, placing a conservative number at

50,000 cases per year. Majority of whom are believed to be women (4)[A].

## *Prevalence*

A recent national survey measuring prevalence of abuse in individuals of at least 60 years and older found that 11.9% of the surveyed population suffered some form of abuse:

- 5.2% encountered financial mistreatment by family members
- 5.1% suffered potential neglect
- 4.6% encountered emotional mistreatment, mostly by humiliation or verbal abuse
- 1.6% encountered physical mistreatment, mostly through battery
- 0.6% sexually mistreated, mostly through forced intercourse

## *ETIOLOGY AND PATHOPHYSIOLOGY*

The etiology of elder abuse is a complex biopsychosocial combination of increased dependence on the caregiver by the victim in a suboptimal environment with poor behavioral coping methods, which is compounded by increased stress.

## *Genetics*

Not contributory

## *RISK FACTORS*

- The victim:
  - Advanced age
  - Exploitable resources
  - Prior history of abuse in life
  - Dementia or other cognitive impairment
  - Female gender
  - Disability in caring for him/herself
  - Depression
  - Social isolation
  - Stress: health, financial, or situational
- The abuser:
  - Mental illness

- Financial dependency
- Substance abuse
- History of violence
- Other antisocial behavior (5)[C]

## GENERAL PREVENTION

- Improve patient social contact and support.
- Identify and correct potential risk factors for elder abuse:
  - Home visit to identify for potential risks of fall hazards and barriers to ambulation that could lead to fractures and functional decline that could leave the individual vulnerable to abuse
  - Evaluate for assistive devices that help the patient independently complete his/her ADLs and prevent caregiver dependence.
  - Screen for depression using validated tools like the Geriatric Depression Scale.
  - Early identification and treatment of cognitive impairment
- Identify caregiver stress and burden; refer to community programs that aid with emotional assistance.
- Advance life directives planning, including identifying possible caregivers, choosing a medical power of attorney (MPOA), estate, and will planning, and so forth.

## COMMONLY ASSOCIATED CONDITIONS

Most common associated conditions with elder abuse are also identified as risk factors: social isolation, increased dependence for ADL/IADLs, depression, cognitive impairment, and aggressive behavior (5) [C],(6)[B].

## DIAGNOSIS

A high index of suspicion when risk factors are present is important; types of abuse should be kept in mind as some types might not be obvious. It can be difficult to diagnose elder abuse in a single clinic visit, so it is important to get social services involved and to consider doing home visits, when abuse is suspected (5)[C].

## HISTORY

It is important to take a detailed history with focus on the living arrangements, degree of functionality, who the caregivers are, and other risk factors listed

above. Pay attention to clues such as withdrawal from normal activities or a sudden change in finances or abrupt changes to a will.

## *PHYSICAL EXAM*

- It is important objectively to document positive and negative findings in your physical exam and to be very detailed because it can be admissible in court if abuse is suspected.
- Vital signs: Check weight and assess for progressive loss in weight; BP and pulse rate can be an indicator of dehydration that could be secondary to neglect.
- General overall appearance:
  - Wasting or cachexia
  - Poor hygiene, unkempt clothing
  - If the patient is bedbound, it is important to assess the integrity of the mattress and sheets. Look for excessive skin flakes, hair, or urine-soiled mattresses.
- Oral exam:
  - Assess for poor dentition, oral ulcers, or abscesses.
- Skin exam:
  - Most bruises from elder abuse are large (>5 cm) and located on the face, lateral arm, or back.
  - Bite or burn marks
  - It is important to check for pressure ulcers on the bony prominences of the patient: elbows, sacrum, heels, and scapula
- Mental/psychiatric:
  - Withdrawn, anxious, fearful, blunted
- Genital/rectal exam if sexual abuse is suspected (4)[A].

## *DIFFERENTIAL DIAGNOSIS*

- Advanced dementia can present with individuals appearing withdrawn and they are often malnourished.
- Elderly with advanced dementia of Alzheimer type or Lewy body dementia can present with delusions of persecution and aggression that can be confused for elder abuse.
- Patients with Parkinson disease often fall and may exhibit fractures and bruises on a frequent

basis that may mimic recurrent physical abuse.

- Coagulopathy seen in patients in advanced malignancy with bone marrow suppression or invasion, and those on chronic antiplatelet therapy can appear with bruising that can be easily confused with elder abuse.
- Wasting from malignancy, infections, chronic disease
- Thyroid disorder can present with altered mental status (AMS), depression, or anxiety.
- Chronic lung disease can present with decreased weight.
- Delirium from acute electrolyte disturbances, infectious etiology, or cardiovascular compromise can all present similar to elder abuse.
- Impaired financial status can also be confused with self-neglect.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

The following workup is recommended:

- Nutritional assessment: iron, vitamin B<sub>12</sub>, folate, thiamine, albumin, prealbumin, CBC, LFTs, electrolytes
- Malignancy workup, as per current guidelines
- If bruising is noted, check for coagulopathies (e.g., platelets, bleeding times, PT/INR, and PTT)
- If cognitive impairment is observed, check thyroid-stimulating hormone, vitamin B<sub>12</sub> level; consider syphilis and HIV testing if indicated.
- Assessment of infection: may include urinalysis and culture, chest radiograph, blood count, and cultures
- Radiographic imaging of areas below soft tissue injury is indicated if there is evidence of infection (osteomyelitis) at a pressure ulcer site or bruising of a limb (fracture).
- If physical abuse is suspected and cognitive impairment present, then cranial imaging to look for hemorrhage (e.g., subdural) is indicated using CT scan or MRI.

### ***Diagnostic Procedures/Other***

- Pulse test: Check BP and pulse in presence and absence of suspected abuser. Elevation of either in the presence of the suspected abuser should raise suspicion. Useful in patients with dementia or other condition that makes history-taking difficult.
- Folstein Mini-Mental State Examination (MMSE), Montreal Cognitive Assessment (MOCA), or other validated tools to assess for cognitive impairment if suspected

- Geriatric Depression Scale if suspected
- Documentation: Practitioners may make statements of suspected mistreatment, but should avoid making definitive diagnosis of abuse in their initial assessment, unless it is very obvious.

## TREATMENT

Most states require all health care providers to report suspected elder abuse to a local agency such as the Adult Protective Services ([http://www.nccafv.org/state\\_elder\\_abuse\\_hotlines.htm](http://www.nccafv.org/state_elder_abuse_hotlines.htm)).

## MEDICATION

None

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

- Victims of elder abuse should be admitted to the hospital if there are no safe discharge alternatives.
- Management of uncontrolled chronic conditions due to neglect (i.e., wound care from ulcers or infections)
- Cases of suspected abuse *must be reported* to the state's Adult Protective Services agency or a designated alternative (e.g., if patient resides in nursing home, then report to that state's regulatory entity). Social services may help. If physical harm has occurred, consider reporting to local law enforcement for investigation.
- Hospital security may need to be notified if restricted visitor access to a patient is required, and the patient's name may be hidden from the public hospital census.
- If the patient is a victim of elder abuse, he/she must be relocated to a safer alternative and may need admission for sequelae caused by the abuse.

### *Discharge Criteria*

Victims should not be discharged to a potentially abusive environment. Alternatives to discharge to the unsafe environment may include:

- Friend or family member
- Nursing home
- Personal care home
- Assisted living facility

- Local victims' rescue or sheltering program if available

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Victims of abuse should not be discharged without adequate follow-up, including:

- Primary care physician visit within 1 week
- Follow-up with Adult Protective Services or other agency; a home visit should be scheduled prior to discharge if the patient is going back home.
- Home Health Agency for assessment of safety (physical therapy)
- Follow-up with appropriate mental health care

### *Patient Monitoring*

The patient should have frequent visits and be followed through the appropriate agencies to reduce continuation of abuse and to identify recurring abuse.

### *PATIENT EDUCATION*

- For Elder Abuse Resources in your state, you can go to the National Center of Elder Abuse at [www.ncea.aoa.gov](http://www.ncea.aoa.gov)
- Or your local representative by calling 1-800-677-1166

### *PROGNOSIS*

Elder abuse and self-neglect are associated with an overall increased risk in mortality (7)[B].

### **COMPLICATIONS**

Complications of elder abuse can lead to worsening depression, increased mortality, and overall poor quality of life.

# Codes

**&NA;**

## ICD10

- T74.11XA Adult physical abuse, confirmed, initial encounter
- T74.21XA Adult sexual abuse, confirmed, initial encounter
- T74.01XA Adult neglect or abandonment, confirmed, initial encounter

## Clinical Pearls

**&NA;**

- Elder abuse, or elder mistreatment, is a condition in which the physical, psychological, or financial wellbeing of an older adult is infringed upon through intentional acts or lack of action, even if harm is not intended.
- It is important to identify vulnerable individuals through proper evaluation of potential risk factors for abuse (social isolation, depression, cognitive impairment, disability requiring assistance, and financial dependence by the caregiver).
- Correction of risk factors is important to reduce the incidence of elder abuse (strengthen the patients' social support, treat depression, provide the patient with assistive devices, screen for cognitive impairment with a trial of medication if possible, and identify caregiver burn out).
- Clearly document your physical exam with only specific objective findings.
- Contact APS or your local resources if elder abuse is suspected; it is unlawful not to report suspected elder abuse.

# Encopresis

Jay Fong, MD

William T. Garrison, PhD

## BASICS

### DESCRIPTION

- Voluntary or involuntary fecal soilage in a (typically) previously toilet-trained child
  - Age may be chronologic or developmental.
  - No underlying organic disease
  - At least one event per month for 3 months
  - Classified into functional constipation (retentive encopresis) and functional nonretentive fecal incontinence (FNRFI); both cause fecal incontinence. There is no constipation in FNRFI. *Functional constipation is more common.*
- System(s) affected: GI; psychological
- Synonyms(s): fecal incontinence, soiling

### EPIDEMIOLOGY

#### *Incidence*

Predominant sex: male > female (4 to 6:1). Constipation accounts for 3% of general pediatric referrals; up to 84% of constipated children have fecal incontinence at some point.

#### *Prevalence*

Occurs in 1-3% of children 4 years of age

### ETIOLOGY AND PATHOPHYSIOLOGY

- In 90% of cases, encopresis develops as a consequence of chronic constipation, with resulting overflow incontinence (*retentive encopresis*). The other 10% are caused by specific organic etiologies.
- Chronic constipation with irregular and incomplete evacuation results in progressive rectal

distension and stretching of the internal/external anal sphincters.

- As a child habituates to chronic rectal distension, they may no longer sense the normal urge to defecate. Eventually, soft or liquid stool leaks around the retained fecal mass.
- Many children voluntarily withhold stool in response to the urge to defecate for fear of pain or a preoccupation with not interrupting social activities.
- Psychological
  - Stool withholding, fear, anxiety
  - Difficulty with toilet training, including unusual anxiety or conflict with parent
  - Resistance to using public toilet facilities, such as school bathrooms or outdoor toilets
  - Known association with sexual abuse in boys; likely similar association in girls
  - Developmental delay
- Anatomic
  - Rectal distension and desensitization
  - Anal fissure or painful defecation
  - Muscle hypotonia
  - Slow intestinal motility
  - Hirschsprung disease
  - Cystic fibrosis
  - Spinal cord defects (e.g., spina bifida)
  - Congenital anorectal malformations
  - Anal stenosis
  - Anterior displacement of the anus
  - Postoperative stricture of anus or rectum
  - Pelvic mass
  - Neurofibromatosis
- Dietary or metabolic
  - Inadequate dietary fiber
  - Excessive protein or milk intake
  - Inadequate water intake

- Hypothyroidism
- Hypercalcemia
- Hypokalemia
- Diabetes insipidus; diabetes mellitus
- Food allergy
- Gluten enteropathy
- Medication side effects

## *Genetics*

None known; although incidence may be higher in children with family history of constipation.

## *RISK FACTORS*

- Male gender
- Constipation
- Very low birth weight
- Painful defecation
- Difficulty with bowel training, including social pressure related to early daycare placement
- Organic/anatomic causes
- Anxiety and depression
- Insufficient fluid or fiber intake
- Refusal to use public restrooms
- Attention deficit

## *GENERAL PREVENTION*

Family education: toilet training when ready, optimize fluid and fiber intake

## *COMMONLY ASSOCIATED CONDITIONS*

- Constipation, Hirschsprung disease
- Cerebral palsy, cystic fibrosis
- Developmental and behavioral diagnoses, urinary incontinence

# DIAGNOSIS

## HISTORY

- Signs/symptoms of constipation:
  - Hard, large-caliber stools
  - <3 defecations/week
  - Pain or discomfort with stool passage, withholding of stool
  - Blood on stool or in diaper/toilet bowl
  - Decreased appetite
  - Abdominal pain that improves with stool passage.
  - Hiding while defecating before child is toilet-trained; avoiding use of the toilet
  - Diet low in fiber or fluids, high in dairy products
  - No stool passage in the first 48 hours of life
  - Pasty stool on underclothes
  - Recurrent UTIs
- Abrupt onset after age 5 years more likely to be associated with psychological trauma.
- Overlap with attention deficit disorder (ADD) common in children >5 years
- Medication use: opiates, phenobarbital, and tricyclic antidepressants (TCAs)
- Family history of constipation

## PHYSICAL EXAM

- Neurologic exam of lower extremities and perineal area, with attention to S1-S4 distribution, perineal sensation, cremasteric reflex, and anal sphincter tone
- Genital examination and digital rectal exam: Assess for anal fissures, sphincter tone, rectal distension/impaction, occult or visible blood.
- Abdominal exam: bowel sounds, percussion note (tympany), abdominal distension; palpate for stool (most common in left lower quadrant).

## DIAGNOSTIC TESTS & INTERPRETATION

Most cases of encopresis can be diagnosed by history and physical.

### *Initial Tests (lab, imaging)*

- Only to rule out organic causes
- UA/urine culture: UTI/glucosuria
- Thyroid function tests: hypothyroidism
- Electrolyte panel, including calcium: hypokalemia, hypercalcemia, or hyperglycemia
- Abdominal plain films if impaction is suspected and not detected by abdominal or rectal exam.

### *Follow-Up Tests & Special Considerations*

- Failure to pass meconium within 48 hours of birth, failure to thrive, bloody diarrhea, or bilious vomiting in a neonate should be promptly evaluated to exclude aganglionic megacolon.
- Constipation and diarrhea, rash, failure to thrive, or recurrent pneumonia should prompt evaluation for cystic fibrosis. Patients with abdominal distension or ileus should be evaluated for possible obstruction.

### *Diagnostic Procedures/Other*

Manometric studies may be useful in patients who have constipation that does not respond to treatment.

## **TREATMENT**

### *GENERAL MEASURES*

- Anticipatory guidance relative to toilet training including advice about when children should reduce reliance on diapers or use pull-ups during the daytime hours (average age for toilet training in girls is 29 months; 31 months for boys).
- Eliminate impaction prior to maintenance therapy.
- Avoid frequent and repeated rectal exams, enemas, and suppositories, especially in infants.
- Once stools are regular in frequency, child should sit on toilet BID at the same time each day for 10 to 15 minutes and for 10 to 15 minutes after meals. Incorporate positive reinforcement for successful bowel movements.

### *MEDICATION*

- Remove impaction and start maintenance treatment.
- No randomized, controlled studies have compared methods of disimpaction: can use oral agents, enemas, and rectal suppositories; oral agents are least traumatic. Glycerin

## *First Line*

- Disimpaction with polyethylene glycol (PEG)
  - Give 17 g (240 mL) water or juice: 1 to 1.5 g/kg/day for 3 days for disimpaction
  - 0.4 to 0.8 g/kg/day for maintenance
- Disimpaction with mineral oil for child >1 year; give 15 to 30 mL/year of age to max 240 mL.
  - Maintenance: 1 to 3 mL/kg/day or divided BID
  - May mix with orange juice to make palatable; avoid in infants to avoid aspiration pneumonia.
- Other maintenance regimens include the following:
  - Milk of magnesia (MOM) 400 mg (5 mL): 1 to 2 mL/kg/day BID
  - Lactulose 10 g (15 mL): 1 to 3 mL/kg/day divided BID
  - Senna syrup 8.8 g sennoside (5 mL): age 2 to 6 years: 2.5 to 7.5 mL/day divided BID; age 6 to 12 years: 5 to 15 mL/day divided BID
  - Bisacodyl suppository 10 mg: 0.5 to 1 suppository once or twice per day

## *ISSUES FOR REFERRAL*

If symptoms do not improve after 6 months of good compliance with a multifactorial treatment model, refer to pediatric gastroenterologist for recommendations and further evaluation.

## *ADDITIONAL THERAPIES*

Behavioral treatment and counseling

## *SURGERY/OTHER PROCEDURES*

If ongoing constipation is refractory to a combination of medical and behavioral therapy, consider anorectal manometry to evaluate for internal anal sphincter achalasia (or ultrashort-segment Hirschsprung disease). If present, this condition can be treated successfully in most patients with an internal sphincter myectomy.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Children with volitional stool holding who receive behavioral treatment in addition to

medications are more likely to have resolution of encopresis at 3 and 6 months than children receiving medication alone (1)[A].

- No evidence that biofeedback training adds benefit to conventional treatment for functional fecal incontinence in children (2)[A]
- Behavioral interventions combined with laxative therapy (rather than laxative therapy alone) improve continence in children with functional fecal incontinence associated with constipation (1)[B].

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Continued soiling and recurrent impaction on outpatient medical therapy, whether from lack of medication efficacy or patient nonadherence
- Decreased intake leading to malnutrition or dehydration
- Recalcitrant vomiting or concern for obstruction
- Involve appropriate agencies if concern for abuse
- Hospital admission and abdominal films may be necessary to ensure complete removal of impaction. This may include direct gastric administration of balanced electrolyte-PEG solutions if the patient cannot tolerate by mouth. Serial abdominal films and observation of the rectal effluent can help to determine treatment adequacy.

### ***IV Fluids***

IV fluids if the patient is dehydrated and having difficulty tolerating oral hydration

### ***Nursing***

Nursing to document stool output and character

### ***Discharge Criteria***

- Stools that are looser in consistency and clearer in appearance are a successful inpatient end point.
- Abdominal radiographs showing less fecal loading (compared with a pretreatment radiograph) with improving serial abdominal exams

**ONGOING CARE**

# *FOLLOW-UP RECOMMENDATIONS*

## *Patient Monitoring*

- Continue maintenance treatment for 6 months to 2 years with visits every 4 to 10 weeks for support and to ensure compliance; more frequent visits with oppositional or anxious children
- Telephone or virtual visits can be used to adjust doses and to provide ongoing encouragement.
- Treat recurrences of impaction promptly.
- Emphasize compliance with medication and self-initiation of regular bathroom visits.
- Children who do not progress using a well-designed behavior plan should be referred for more in-depth mental health evaluation and counseling.

## *DIET*

Adequate fluid and fiber intake (2)[A]. Reduce cow's milk products. Avoid excessive consumption of bananas, rice, apples, and gelatin.

## *PATIENT EDUCATION*

- Demystify defecation.
- Carefully explain the treatment plan including medications and dietary changes.
- Avoid punishment for inadvertent soiling.
- In children >4 years of age, explain to parents how overreliance on diapers and pull-ups (while convenient) can prolong the problem.
- Always attempt to use positive reinforcement for successful toilet sits and medication compliance.
- If positive approach is unsuccessful, consider removing desired privileges (e.g., TV, video games) for noncompliance with behavioral plan. Some children respond well to a token economy (earned privileges) to promote desired behavior.

## *PROGNOSIS*

- Many children exhibit a good response and relapse due to noncompliance by parents and/or child.
- From 30% to 50% of children may still have encopresis after 5 years of treatment.
- Children with psychosocial or emotional problems preceding the encopresis are more recalcitrant to treatment.

## COMPLICATIONS

- Colitis due to excessive enema/suppository
- Perianal dermatitis
- Anal fissure

- Loening-Baucke V, Pashankar DS. A randomized, prospective, comparison study of polyethylene glycol 3350 without electrolytes and milk of magnesia for children with constipation and fecal incontinence. *Pediatrics.* 2006;118(2):528-535.

## Codes

&NA;

## ICD10

- R15.9 Full incontinence of feces

- R15.1 Fecal smearing
- F98.1 Encopresis not due to a substance or known physiologic condition

## Clinical Pearls

### &NA;

- 90% of encopresis results from chronic constipation.
- Address toddler constipation early by decreasing excessive milk intake, increasing fruits/vegetables intake, and ensuring adequate fluid and fiber intake.
- Eliminate fecal impaction before initiating maintenance therapy.

# Endocarditis, Infective

Danielle DeFoe, MS, DO

Theodore B. Flaum, DO, FACOFP

## BASICS

### DESCRIPTION

- An infection of the valvular (primarily) and mural (rarely) endocardium
- System(s) affected: cardiovascular, endocrine/metabolic, hematologic/lymphatic, immunologic, pulmonary, renal/urologic, skin/exocrine, neurologic
- Synonym(s): bacterial endocarditis; subacute bacterial endocarditis (SBE); acute bacterial endocarditis (ABE)

### EPIDEMIOLOGY

#### Incidence

- Increase in incidence in United States from 11 per 100,000 to 15 per 100,00 between 2000 and 2011
- 1.5-3.0% incidence 1 year after prosthetic valve replacement; at 5 years, the incidence is 3-6%.
- Increasing incidence of cardiovascular device-related infections, due to higher frequency of implantable devices, especially in the elderly

### ETIOLOGY AND PATHOPHYSIOLOGY

- ABE: *Staphylococcus aureus*; *Streptococcus* groups A, B, C, G; *Streptococcus pneumoniae*; *Staphylococcus lugdunensis*; *Enterococcus* spp. (gram-positive); *Haemophilus influenzae* or *parainfluenzae*; *Neisseria gonorrhoeae* (gram-negative)
- SBE:  $\alpha$ -Hemolytic streptococci (viridans group strep), *Streptococcus bovis*, *Enterococcus* spp., *Staphylococcus aureus*, *Staphylococcus epidermidis* (gram-positive); HACEK organisms: *Haemophilus aphrophilus* or *paraphrophilus*, *Actinobacillus (Aggregatibacter) actinomycetemcomitans*, *Cardiobacterium hominis*, *Eikenella corrodens*, *Kingella kingae*
- Endocarditis in IV drug abusers (tricuspid valve): *Staphylococcus aureus*, *Enterococcus* spp.

(gram-positive); *Pseudomonas aeruginosa*, *Burkholderia cepacia*, other bacilli (gram-negative); *Candida* spp.

- Early prosthetic-valve endocarditis (<60 days after valve implantation): *Staphylococcus aureus*, *Staphylococcus epidermidis* (gram-positive); gram-negative bacilli; fungi: *Candida* spp., *Aspergillus* spp.
- Late prosthetic valve endocarditis (>60 days after valve implantation):  $\alpha$ -Hemolytic streptococci, *Enterococcus* spp., *S. epidermidis* (gram-positive); *Candida* spp., *Aspergillus* spp.
- Culture-negative endocarditis: 10% of cases; *Bartonella quintana* (homeless); *Brucella* spp., fungi, *Coxiella burnetii* (Q fever), *Chlamydia trachomatis*, *Chlamydophila psittaci*, HACEK organisms; Abiotrophia (formerly B<sub>6</sub>-deficient streptococci); use of antibiotics prior to blood cultures
- Device-related endocarditis: coagulase-negative staphylococci or *S. aureus*

## RISK FACTORS

- Injection drug use, IV catheterization, certain malignancies (colon cancer), poor dentition, chronic hemodialysis
- High-risk conditions
  - Prosthetic cardiac valve, implantable devices (pacemaker, automatic implantable cardioverter defibrillator [AICD]), total parenteral nutrition
  - Previous infective endocarditis (IE)
  - Congenital heart disease (CHD): unrepaired cyanotic CHD, including palliative shunts and conduits; repaired CHD with prosthetic device during the first 6 months; repaired CHD with residual defects at or near prosthetic site; cardiac transplant with valvulopathy (1)[B]

## GENERAL PREVENTION

- Maintain good oral hygiene.
- Antibiotic prophylaxis is only recommended for high-risk cardiac conditions (1)[B]Ñprosthetic heart valve, history of endocarditis, transplant with abnormal valvular function, CHD (see ÒRisk FactorsÓ).
- *Procedures requiring prophylaxis*
  - Oral/upper respiratory tract: any manipulation of gingival tissue or periapical region of teeth or perforation of the oral mucosa (1)[B], invasive respiratory procedures involving incision, or biopsy of the respiratory mucosa merit prophylaxis; amoxicillin 2 g PO (if penicillin allergic, clindamycin 600 mg PO) 30 to 60 minutes before procedure or ampicillin 2 g IV/IM

are first-line prophylactic choices. For penicillin-allergic patients, use clindamycin 600 mg IV, or cephalexin 2 g PO, or azithromycin/clarithromycin 500 mg PO, or cefazolin/ceftriaxone 1 g IV/IM 30 minutes before procedure. Pediatric doses are amoxicillin 50 mg/kg PO (max 2 g), cephalexin 50 mg/kg PO (max 2 g), clindamycin 20 mg/kg PO (max 600 mg), and ampicillin or ceftriaxone 50 mg/kg (maximum 1 g) IM/IV.

- GI/GU: Only consider coverage for enterococcus (with penicillin, ampicillin, piperacillin, or vancomycin ) for patients with an established infection undergoing procedures (1)[B].
- Cardiac valvular surgery or placement of prosthetic intracardiac/intravascular materials: perioperative cefazolin 1 to 2 g IV 30 minutes preop, or vancomycin 15 mg/kg (maximum 1 g) (penicillinallergic patients) 60 minutes preop (1)[B]
- Skin: incision and drainage of infected tissue; use agents active against skin pathogens (e.g., cefazolin 1 to 2 g IV q8h or vancomycin 15 mg/kg q12h; max 1 g) if penicillin-allergic or if methicillin-resistant *Staphylococcus aureus* (MRSA) suspected.

## DIAGNOSIS

- Modified Duke Criteria for Diagnosis of IE (2)[B] (definite: 2 major criteria, or 1 major and 3 minor criteria, or 5 minor criteria; possible: 1 major and 1 minor criteria, or 3 minor criteria)
- Major clinical criteria
  - Positive blood culture: isolation of typical microorganism for IE from two separate blood cultures or persistently positive blood culture
  - Single positive blood culture for *C. burnetii* or anti-phase-1 IgG antibody titer >1:800
  - Positive echocardiogram: presence of vegetation, abscess, or new partial dehiscence of prosthetic valve; must be performed rapidly if IE is suspected
  - New valvular regurgitation (change in preexisting murmur not sufficient)
- Minor criteria
  - Predisposing heart condition or IV drug use
  - Fever  $\geq 38.0^{\circ}\text{C}$  ( $100.4^{\circ}\text{F}$ )
  - Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysm, intracranial hemorrhage, conjunctival hemorrhage, Janeway lesions
  - Immunologic phenomena: glomerulonephritis, Osler nodes, Roth spots, rheumatoid factor (RF)
  - Microbiologic evidence: positive blood culture but not a major criterion (excluding single

positive cultures for coagulase-negative staphylococci and organisms that do not cause endocarditis) or serologic evidence of infection likely to cause IE

## HISTORY

- Fever ( $>38^{\circ}\text{C}$ ), chills, cough, dyspnea, orthopnea; especially in subacute endocarditis: night sweats, weight loss, fatigue
- Predisposition to IE (see "Risk Factors")
- Symptoms of transient ischemic attack, cerebrovascular accident (CVA), or myocardial infarction (MI) on presentation

## PHYSICAL EXAM

- Most patients with IE have new murmur or change in existing murmur. Signs of heart failure (rales, edema) if valve function is compromised.
- Peripheral stigmata of IE: splinter hemorrhages in fingernail beds, Osler nodes on fleshy portions of extremities, Roth spots retinal hemorrhages, Janeway lesions (cutaneous evidence of septic emboli), palatal or conjunctival petechiae, splenomegaly, hematuria (due to emboli or glomerulonephritis)
- Neurologic findings consistent with CVA, such as visual loss, motor weakness, and aphasia

## DIFFERENTIAL DIAGNOSIS

Fever of unknown origin, infected central venous catheter, marantic endocarditis, connective tissue diseases, intra-abdominal infections, rheumatic fever, salmonellosis, brucellosis, malignancy, tuberculosis, atrial myxoma, septic thrombophlebitis

## DIAGNOSTIC TESTS & INTERPRETATION

- When patient is not critically ill; three sets of blood cultures drawn  $>2$  hours apart from different sites *before administration of antibiotics*.
- In acutely ill patients, draw three sets of blood cultures over a 1-hour period *prior to empiric antibiotic therapy*.
- Leukocytosis common in acute endocarditis
- Anemia, decreased C3, C4, CH50, and RF in subacute endocarditis
- ESR, C-reactive protein (CRP)
- Hematuria, microscopic or macroscopic
- Consider serologies for *Chlamydia*, Q fever, *Legionella*, and *Bartonella* in culture-negative endocarditis.

- Transthoracic or transesophageal echocardiogram (TTE/TEE) should be performed as soon as IE is suspected.
- Baseline ECG may provide clues to extension of infection.
- CT scan may help locate embolic abscesses (e.g., splenic abscess).
- Vegetations are composed of platelets, fibrin, and colonies of microorganisms. Destruction of valvular endocardium, perforation of valve leaflets, rupture of chordae tendineae, abscesses of myocardium, rupture of sinus of Valsalva, and pericarditis may occur.
- Emboli, abscesses, and/or infarction may occur in any organ system.
- Immune-complex glomerulonephritis

## TREATMENT

### MEDICATION

#### First Line

- Initial empirical treatment should be started after three sets of blood cultures have been drawn while waiting for a causative organism to be identified.
    - Native valves: Ampicillin-sulbactam 12 g/day IV divided into 4 doses with gentamicin 3 mg/kg/day
- 
- P.337
- IV/IM in 2 or 3 doses. If penicillin allergic, use vancomycin 30 mg/kg/day IV in 2 doses with gentamicin 3 mg/kg/day IV/IM in 2 or 3 doses and with ciprofloxacin 1,000 mg/day PO or 800 mg/day IV, both in 2 doses (3)[A].
- Prosthetic valves: Vancomycin 30 mg/kg/day IV in 2 doses with gentamicin 3 mg/kg/day IV/IM in 2 doses and rifampin 1,200 mg/day PO in 2 doses, if <12 months postsurgery. If >12 months, use native valve regimen (3)[A].
- Penicillin-susceptible viridans group streptococci or *S. bovis*
    - Native valve: penicillin G 12 to 18 million U/day IV continuously or in 4 to 6 doses or ceftriaxone 2 g/day IV/IM in 1 dose, both for 4 weeks (2)[B]
    - Prosthetic valve: penicillin G 24 million U/day IV continuously or 4 to 6 doses for 6 weeks or ceftriaxone 2 g/day IV/IM in 1 dose ± gentamicin 3 mg/kg IV/IM q24h for 2 weeks (peak gentamicin level 3 &mgr;g/mL and trough <1 &mgr;g/mL) (2)[B]
  - Penicillin-resistant viridans group streptococci or *S. bovis*

- Native valve: penicillin G 24 million U/day IV, either continuously or in 6 equally divided doses or ceftriaxone 2 g/day IV/IM in 1 dose for 4 weeks + gentamicin 3 mg/kg IV/IM q24h for 2 weeks (peak gentamicin level 3 &mgr;g/mL and trough <1 &mgr;g/mL) (2)[B]
  - Prosthetic valve: Regimen is equivalent, but length of therapy is 6 weeks for all antibiotics.
- *Staphylococcus*
    - Native valve: oxacillin or nafcillin 12 g IV every day for 4 to 6 weeks. The use of gentamicin is optional (e.g., patients with severe sepsis) and at most limited to 3 days. According to BSAC and IDSA guidelines, for MRSA bacteremia, the use of gentamicin is no longer recommended for staphylococcal native valve IE. For oxacillin-resistant strains, use vancomycin 15 mg/kg/day IV q12h for 6 weeks for goal trough of 15 to 20 &mgr;g/mL (2) [B].
    - Prosthetic valve: oxacillin or nafcillin 12 g/day IV in 4 to 6 doses + rifampin 300 mg IV/PO q8h, for 6 weeks, + gentamicin 3 mg/kg/day IV for first 2 weeks (peak gentamicin level 3 &mgr;g/mL and trough <1 &mgr;g/mL). For oxacillin-resistant strains, use vancomycin 15 mg/kg IV q12h, + rifampin 300 mg IV/PO q8h, both for 6 weeks, + gentamicin 3 mg/kg/day IV/IM in 2 to 3 doses for the first 2 weeks (peak gentamicin level 3 &mgr;g/mL and trough <1 &mgr;g/mL) (2)[B].
  - Penicillin-sensitive *Enterococcus*, native or prosthetic valve: ampicillin 12 g IV divided q4h or penicillin G 18 to 30 million U/day IV continuously or in 6 doses plus gentamicin 3 mg/kg IV q8h for 4 to 6 weeks (peak gentamicin level 3 &mgr;g/mL and trough <1 &mgr;g/mL) (2)[B]. Consider expert consultation for penicillin-resistant enterococci.
  - *HACEK* organisms: ceftriaxone 2 g IM or IV q24h for 4 weeks (2)[B] or ampicillin-sulbactam 12 g IV divided q4h for 4 weeks or ciprofloxacin 1 g/day PO or 800 mg/day IV in 2 equally divided doses for 4 weeks
    - Cardiac device-related endocarditis: Whole device removal is recommended for all patients with lead infection, followed by antibiotic therapy based on organism susceptibility (4)[B].
  - Precautions: In patients with renal impairment, dosage adjustment should be made for penicillin G, gentamicin, cefazolin, ampicillin, ampicillin/sulbactam, ciprofloxacin, and vancomycin. Rapid infusion of vancomycin <1 hour may cause "red man syndrome" due to histamine release, not an allergic reaction. Treat with antihistamines and decrease infusion rate.
  - Interactions: Vancomycin + gentamicin increases renal toxicity. Rifampin increases the requirement for Coumadin and oral hypoglycemic agents.

## Second Line

For patients allergic to penicillin:

- Penicillin-susceptible or resistant viridans group streptococci or *S. bovis*: vancomycin 30 mg/kg (not to exceed 2 g/day) IV for 4 weeks (6 weeks for prosthetic valve endocarditis) for goal trough of 15 to 20 &mgr;g/mL (2)[B]
- *Enterococcus*, native or prosthetic valve: Desensitization to penicillin should be considered. Vancomycin 15 mg/kg (usual dose, 1 g) IV q12h, + gentamicin or streptomycin (peak gentamicin level 3 &mgr;g/mL and trough <1 &mgr;g/mL) for 4 to 6 weeks (6 weeks for prosthetic valve endocarditis) (2)[B]
- *Staphylococcus* of native valve: cefazolin 2 g IV q8h (not to be used in patients with immediate-type hypersensitivity to penicillin) for 4 to 6 weeks *or* vancomycin 30 mg/kg (usual dose, 1 g) IV q12h for a goal trough of 15 to 20 &mgr;g/mL, for 6 weeks (2)[B]

## ***SURGERY/OTHER PROCEDURES***

Surgery is required in 50% of IE cases. Indications include (3)[A]:

- Heart failure due to of aortic or mitral valve disease
- Prevention of embolism: aortic or mitral valve vegetations >10 mm with prior embolic episodes; isolated very large vegetation >15 mm; in patients with major ischemic stroke, surgery is delayed for at least 4 weeks, if possible (5)[C].
- Uncontrolled infection: persistent fever and positive cultures >7 to 10 days; infection caused by fungi or resistant organism; presence of abscess, fistula, false aneurysm, or enlarging vegetations
- Early prosthetic valve IE

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Check gentamicin peak ( $\div 3$  &mgr;g/mL) and trough (<1 &mgr;g/mL) levels if used for >5 days and with renal dysfunction. Perform twice-weekly BUN and serum creatinine while on gentamicin. Consider audiometry baseline and follow-up during long-term aminoglycoside therapy.
- Check vancomycin trough (15 to 20 &mgr;g/mL) levels in all patients (typically prior to 4th dose) (3)[B].
- Baseline ECG; monitor ECG for conduction disturbances/MI in initial weeks of therapy.

- TTE at the conclusion of therapy
- Blood cultures q48h until negative

## PROGNOSIS

Late complications contribute to the poor prognosis of IE. The main complications are heart failure, reinfection, and cerebral emboli. 10-year survival is 60-90% (6)[A].

## COMPLICATIONS

- Cerebral complications are the most frequent and severe, occurring in 15-20% of patients (1)[A].
- Emboli: arterial (e.g., MI, mesenteric, splenic, cerebral infarction), infectious (e.g., abscesses of heart, lung, brain, meninges, bone, pericardium)
  - Neurologic events are the most frequent complications in patients with IE requiring ICU admission. Ischemic stroke is the presenting symptom of IE in 20% of cases (6)[A].
- Inflammatory/immune disorders (e.g., arthritis, myositis, glomerulonephritis)
- Other complications: congestive heart failure (CHF), ruptured valve cusp, sinus of Valsalva aneurysm, arrhythmia, and mycotic aneurysms

## Codes

&NA;

### ICD10

- I33.0 Acute and subacute infective endocarditis
- I39 Endocarditis and heart valve disord in dis classd elswhr
- A54.83 Gonococcal heart infection

## Clinical Pearls

&NA;

- Antibiotic prophylaxis is recommended for patients with artificial heart valves, history of IE, CHDs, and cardiac transplants with valvulopathy.
- TEE/TTE and blood cultures are the mainstays for the diagnosis of IE.
- Most common organisms involved in IE are viridians *Streptococcus* spp. and *Staphylococcus*.

# Endometrial Cancer and Uterine Sarcoma

Jay R. Patibandla, MD

Michael P. Hopkins, MD, MEd

## BASICS

### DESCRIPTION

- Endometrial cancer: malignancy of the endometrial lining of the uterus
  - Two types
    - Type I: estrogen dependent, grade 1 or grade 2, better prognosis, endometrioid histology
    - Type II: estrogen independent, higher grade, more aggressive, include grade 3 endometrioid and nonendometrioid: serous, clear cell, mucinous, poor prognosis (1)[A]
- Cell types: adenocarcinoma, adenosquamous (malignant squamous elements), clear cell, and papillary serous
- Sarcomas: malignancy of the uterine mesenchyme and mixed tumors
  - Mixed müllerian sarcoma (carcinosarcoma): Heterologous sarcoma elements are not native to the müllerian system (e.g., cartilage or bone); homologous sarcoma elements are native to the müllerian system (40-50% prevalence of all sarcomas).
  - Leiomyosarcoma develops in the myometrium, characterized by cellular atypic mitoses and coagulative necrosis (30% prevalence of all sarcomas).
  - Endometrial stromal sarcoma develops from the stromal component of the endometrium (15% prevalence of all sarcomas).
  - Poorer prognosis (2)[C]
- Predominant age
  - Endometrial cancer: Most patients are postmenopausal:
    - Average age of diagnosis: 63 years old
  - Sarcomas: occurs in both pre- and postmenopausal:

- Average age of diagnosis: 40 to 69 years old (2)[C]
- 70% of endometrial cancer is stage I at the time of diagnosis.
- System(s) affected: reproductive
- Synonym(s): uterine cancer; endometrial cancer; corpus cancer

### *Pregnancy Considerations*

This malignancy is not associated with pregnancy.

## **EPIDEMIOLOGY**

### *Incidence*

- Endometrial cancer is the most common gynecologic malignancy; fourth most common cancer in women and eighth leading cause of cancer-related death in women worldwide.
- In the United States, it is estimated that endometrial cancer will account for 54,870 new cases and 10,170 deaths in 2015 (2)[C].

### *Prevalence*

500,000 women in the United States

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Continuous estrogen stimulation unopposed by progesterone

- Endometrial: unopposed estrogen
  - Estrogen replacement therapy without concomitant progesterone increases the risk. Addition of progesterone decreases risk to that of general population.
- Sarcomas: etiology unknown

### *Genetics*

- Endometrial: Lynch syndrome (hereditary nonpolyposis colorectal cancer)
- Sarcoma: African American, higher incidence of leiomyosarcoma, childhood retinoblastoma survivors

## **RISK FACTORS**

- Early menarche/late menopause
- Nulliparity

- Personal or family history of colon or reproductive system cancer
- Obesity
- Diabetes mellitus
- Hypertension
- Polycystic ovarian syndrome
- Estrogen-secreting tumor
- Endometrial hyperplasia
- Unopposed estrogens
- Tamoxifen use
- Increasing age

## *GENERAL PREVENTION*

- In young women who are obese or anovulatory, the risk of endometrial cancer can be reduced by taking oral contraceptive pills, permanently losing weight, or taking cyclic progesterone to prevent unopposed estrogen's effects on the uterus (3)[A].
- Estrogen replacement therapy should always include progesterone unless the woman has had a hysterectomy (3)[A].
- Cigarette smoking has been associated with a lower risk of type I endometrial cancer; however, it is not recommended secondary to its many health risks and increase risk of type II endometrial cancer.

## *COMMONLY ASSOCIATED CONDITIONS*

- Endometrial hyperplasia: 1-25% will progress to endometrial adenocarcinoma:
  - Simple without atypia
  - Complex without atypia
  - Simple with atypia
  - Complex with atypia
    - 43% with complex hyperplasia with atypia have concurrent endometrial cancer.
- Endometrial cancer patients should be screened regularly for breast and colon cancer because of an increased risk of these cancers.

Patients who have breast or colon cancer are at increased risk for endometrial cancer.

- Granulosa cell tumors of the ovary produce estrogen; these patients will have an increased risk of endometrial cancer.

## DIAGNOSIS

### HISTORY

- Endometrial cancer
  - Postmenopausal bleeding is the most frequent sign. Any spotting or abnormal discharge mandates evaluation.
  - Premenopausal patients with history of anovulation and heavy, irregular, or prolonged periods that fail multiple medical managements mandate evaluation.
- Sarcoma
  - Mixed müllerian sarcoma: bleeding and prolapsing tissue, pain (2)[C]
  - Leiomyosarcoma: pelvic pain, pressure, uterine mass, abnormal bleeding

### PHYSICAL EXAM

Pelvic exam: enlarged, fixed

### DIFFERENTIAL DIAGNOSIS

- Atypical complex hyperplasia: a premalignant lesion of the endometrium
- Cervical cancer
- Ovarian cancer invading the uterus
- Endometriosis
- Adenomyosis
- Leiomyoma

### DIAGNOSTIC TESTS & INTERPRETATION

#### *Initial Tests (lab, imaging)*

- Liver and renal function tests
- Transvaginal ultrasound usually shows increased endometrial thickness (>4 mm in

postmenopausal patients or in patients with irregular or heavy periods if >35 years of age) (1) [A].

- Levels of cancer antigen 125 (CA-125) may be elevated when intra-abdominal disease is present (1)[A].
- Chest x-ray (CXR): Most common site of metastases is the lungs.
- Mammogram and colonoscopy: Endometrial cancer is associated with breast and colon cancer.

### *Follow-Up Tests & Special Considerations*

- Endometrial cancer is mostly localized to the uterus, therefore preop evaluation for metastasis is not needed unless metastasis is already suspected (2)[A].
- CT scan, PET/CT, MRI, CA-125: not part of the routine evaluation but may be needed if metastasis is suspected; patient is a poor operative candidate or pathology returns high grade (G3 endometrioid, papillary serous, clear cell, carcinosarcoma) (2)
- MRI has been reported to show the depth of myometrial penetration accurately but is not always cost-effective (4)[A].

### *Diagnostic Procedures/Other*

- Office endometrial biopsy (90% accurate): If negative with high suspicion for cancer or patient continues to have bleeding, a dilation and curettage (D&C) is necessary (2)[B]. Endometrial stromal sarcoma and leiomyosarcoma rarely are diagnosed preoperatively. Any patient with history of irregular, heavy, or prolonged periods should undergo endometrial biopsy prior to endometrial ablation procedures.
- Fractional D&C is 99% accurate except in cases of sarcoma.
- If surgical approach is favored, D&C with hysteroscopic guidance is recommended over D&C alone, due to its ability to pick up discrete lesions (2)[A].

### *Test Interpretation*

- Federation of Gynecology and Obstetrics Staging System: revised 2009
  - Stage I (confined to corpus uteri)
    - A: no or <1/2 myometrial invasion
    - B: invasion  $\geq$  1/2 the myometrium
  - Stage II: Tumor invades cervical stroma but does not extend beyond the uterus.
  - Stage III: local and/or regional spread

- A: uterine serosal and/or adnexal invasion
- B: vaginal and/or parametrial involvement
- C: metastases to pelvic and/or para-aortic lymph nodes

P.339

- IIIC1: + pelvic nodes
- IIIC2: + para-aortic lymph nodes positive pelvic lymph nodes
- Stage IV: Tumor invades bladder and/or bowel mucosa and/or distant metastases:
  - A: Tumor invades bladder and/or bowel mucosa. B: distant metastases, including intra-abdominal metastases and/or inguinal lymph nodes (1)[A]
  - Uterine sarcoma criteria for diagnosis: mitotic index, cellular atypia, and areas of coagulative necrosis separated from tumor (5)[C]

## TREATMENT

### GENERAL MEASURES

- Main treatment for uterine cancer is surgery.
- Radiation is used to prevent tumor recurrence at the vaginal cuff.

### MEDICATION

#### First Line

- Endometrial
  - Chemotherapy for advanced or recurrent disease incurable with surgery and radiation
    - Paclitaxel + carboplatin (2)[B]
    - Doxorubicin + cisplatin + paclitaxel
- Hormonal therapy
  - Medroxyprogesterone acetate: for recurrence or metastases
  - Megestrol (Megace) 160 mg/day for at least 2 months for women with premalignant lesions, atypical complex hyperplasia, or well-differentiated endometrial cancer in patients desiring fertility. Follow with D&C to determine cancer resolution.
  - Levonorgestrel-containing intrauterine device: as mentioned earlier for patients who desire

future fertility (3,6,7)[A]

- Sarcoma
  - Chemotherapy
    - Doxorubicin as single agent or in combination (5)[A]
- Hormonal
  - Tamoxifen or aromatase inhibitors; not fully studied
- Progesterones (3)[A]

## ***ADDITIONAL THERAPIES***

Radiation therapy

- Nonoperative candidates: radiation therapy alone
- Low risk: no adjuvant radiation therapy
- Intermediate risk: Consider adjuvant vaginal brachytherapy; reduces local recurrences but has no effect on overall survival
- High risk: chemotherapy and radiation therapy in some cases (4,8)[A]

## ***SURGERY/OTHER PROCEDURES***

Surgical staging

- Extrafascial hysterectomy and bilateral salpingo-oophorectomy
- Cytologic washings
- Pelvic and para-aortic lymph node dissection
- Omental sampling, as indicated
- Optimal tumor debulking (1)[A]

### ***Geriatric Considerations***

Older (and obese) patients may be at high risk for surgery. Alternative radiation therapy can be considered.

## ***INPATIENT CONSIDERATIONS***

***Admission-Criteria/Initial Stabilization***

- Excessive vaginal bleeding
- Preoperative stabilization

## *Nursing*

Routine; ensure postoperative pain is controlled.

## *Discharge Criteria*

Postsurgical criteria: pain controlled, tolerating diet, ambulating, and voiding

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Follow-up visit for speculum and rectovaginal exam every 3 to 6 months for 2 years, then every 6 months for 3 years, and then annually for life (2)[C]

### *PATIENT MONITORING*

- Annual CXR is no longer recommended.
- CT scan or PET/CT scan of the chest, abdomen, and pelvis should be used only to investigate suspicion of recurrent disease, not routinely

### *DIET*

As tolerated and according to comorbidities

### *PATIENT EDUCATION*

After surgery:

- No intercourse for  $\pm$ 6 weeks
- No lifting >10 to 15 lb
- No driving until pain-free
- Do not expect resumption of full activity for 6 weeks.

### *PROGNOSIS*

5-year survival rates

- Uterine adenocarcinoma

Stage	Survival (%)
-------	--------------

I	70
---	----

II	45
----	----

III	30
-----	----

IV	15
----	----

(3,4)[A]

## COMPLICATIONS

- Surgical: excessive bleeding, wound infection, lymphedema, deep vein thrombosis (DVT), and damage to the urinary or intestinal systems
- Radiation: diarrhea, ileus, bowel obstruction or fistula, radiation cystitis, proctitis, vaginal stenosis, DVT
- Chemotherapy: per the drug given

- Cervical Malignancy
- Algorithm: Pelvic Pain

## Codes

&NA;

## ICD10

- C54.1 Malignant neoplasm of endometrium
- C55 Malignant neoplasm of uterus, part unspecified
- C54.2 Malignant neoplasm of myometrium

## Clinical Pearls

### &NA;

- Most common presenting symptom is abnormal uterine bleeding.
- Any patient with history of irregular, heavy, or prolonged periods should undergo endometrial biopsy.
- Primary cause is unopposed estrogen.
- Endometrial thickness on transvaginal ultrasound of <5 mm makes endometrial cancer very unlikely.
- Primary treatment is with surgery, with possible chemotherapy  $\pm$  radiation.

# Endometriosis

Andrew G. Alexander, MD

Maegen Dupper, MD

Heidi S. Millard, MD

## BASICS

### DESCRIPTION

- Endometriosis is a common but potentially painful and debilitating estrogen-dependent gynecologic condition affecting women of predominately reproductive age (1)[A].
- Symptoms and signs generally consists of pelvic pain and decreased fertility.
- Due to estrogen-dependent implants of endometrial tissue found outside the uterus. Although endometriomas have been recorded in liver, bowel, umbilicus, lung, and other tissue, the most common pathologic sites are:
  - Peritoneum(bladder, cul-de-sac, pelvic walls, ligaments, and fallopian tubes)
  - Ovaries
  - Rectovaginal septum
- Ectopic endometrial implants proliferate and slough with the menstrual cycle
- Stage I (minimal) to IV (severe). Staging is useful in therapeutic planning but does not correlate with pain severity.

### EPIDEMIOLOGY

#### Prevalence

- Female only
- Affects 11% of fertile women (2)
- Found in 30-50% of infertile women
- Found in 50-60% of women and adolescent women with pelvic pain

#### Pediatric Considerations

Endometriosis may begin with puberty as endometrial implants are dependent on ovarian hormones. This can lead to debilitating pelvic pain and severe dysmenorrhea associated with missed school, social, and family activities.

### *Pregnancy Considerations*

The presence of endometriosis decreases fecundability from 15-20% per month to 2-10% per month. 25-50% of infertile women have endometriosis. However, pelvic endometriosis generally improves during pregnancy.

### *Geriatric Considerations*

Although menopause often results in a resolution of symptoms, pelvic endometriosis may extend into menopause and is exacerbated by hormone replacement therapy (HRT).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Not fully understood, several factors are believed to play a role, including immunologic changes and genetic predisposition in the presence of abnormal proliferating endometrial tissue implants causing chronic peritoneal inflammation.
- Theories include:
  - **Sampson theory:** Retrograde menstruation results in peritoneal implantation and disease
  - **Halban theory:** Distant disease is probably caused by hematogenous/lymphatic dissemination or metaplastic transformation.
  - **Coelomic metaplasia:** Coelomic epithelium remains undifferentiated in the peritoneal cavity and differentiates to form functioning endometrium.
- Endometrial-associated infertility is multifactorial:
  - Pelvic inflammation
  - Anatomic disruption of pelvic structures (involvement of the fallopian tube may cause isthmic tubal obstruction)
  - Proliferation and activation of peritoneal macrophages (may predispose to gamete phagocytosis)
  - Alteration in eutopic endometrium

### *Genetics*

Odds ratio of symptomatic endometriosis with a first degree affected relative is 7.2. Those with affected first-degree relatives have a 26% chance of severe manifestations, versus 12% if no first degree affected relatives.

## **RISK FACTORS**

- Family history
- Menstruation and ovulation
- Delayed childbirth

## **GENERAL PREVENTION**

- Suppression of heavy menstruation and ovulation with oral contraceptives during adolescence may delay sequelae.
- Some factors are considered protective:
  - Fruits, green vegetables, n-3 long-chain fatty acids
  - Aerobic exercise may decrease pelvic pain.
- Early diagnosis and treatment might help prevent sequelae.

## **COMMONLY ASSOCIATED CONDITIONS**

Associated with increased risks for cancer of the ovary, breast, endometrium; increased risk for cutaneous melanoma, non-Hodgkin lymphoma, autoimmune diseases, asthma, and cardiovascular disease

## **DIAGNOSIS**

- History: dysmenorrhea (50-90% of cases) due to deep infiltrating endometrial implants
- Dyspareunia due to lesions of the cul-de-sac, uterosacral ligaments, and posterior vaginal fornix
- Dyschezia due to involvement of the rectosigmoid colon and rectovaginal regions
- Chronic pelvic pain (<sup>3</sup>6 months) that worsens with time and begins 1 to 2 days prior to menstrual cycles
- Hematochezia
- Cyclic nausea, abdominal distention
- Infertility (late finding)
- History of pelvic pain, infertility, and hysterectomy in first- or second-degree relative

## *PHYSICAL EXAM*

- Focal pain/tenderness on pelvic exam is associated with endometriosis in 66% of patients.
- Pelvic mass may be present.
- Immobile pelvic organs (frozen pelvis)
- Rectovaginal exam revealing uterosacral nodules, beading, or tenderness
- An exquisitely tender ÖbarbÖ stabbing pain in the region of the uterosacral ligament is found in severe cases.

## *DIFFERENTIAL DIAGNOSIS*

Differential diagnosis of pelvic pain includes all causes of acute abdomen and

- Complications of intrauterine/ectopic pregnancy
- Pelvic adhesions
- Acute salpingitis/pelvic inflammatory disease
- Ruptured ovarian cyst
- Uterine leiomyomas
- Adenomyosis
- Irritable bowel syndrome
- Inflammatory bowel disease
- Pelvic malignancy
- Cystitis
- Depression
- History of sexual abuse
- Chronic pain syndrome

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Labs are only useful to rule out other diagnoses; there are no useful labs to rule in endometriosis.
- CA-125 levels are not recommended (3)[C] due to low sensitivity.
- If history and physical exam reveal adnexal pain or tenderness with/without fullness on pelvic

exam

- Transvaginal ultrasound (US) and MRI are equally effective in detecting ovarian endometriomas: sensitivity, 80-90%; specificity, 60-98% for both
- US is preferred (less costly).
- Both modalities are poor in detecting peritoneal implants and adhesions.

## *Diagnostic Procedures/Other*

Definitive diagnosis is made by the gross and microscopic characteristics of tissue visualized and biopsied during laparoscopy or laparotomy.

## *Test Interpretation*

- Laparoscopically visualized red and blue-black lesions described as "powder-burns," adhesions, and "chocolate cysts" on the ovarian and peritoneal surfaces.
- Histologically described endometrial glands and stroma on analysis of biopsied lesions

## **TREATMENT**

### **GENERAL MEASURES**

Management is dependent on multiple factors:

- Age and reproductive desires of the patient
- The certainty of the diagnosis
- The degree of degradation on quality of life due to pain and infertility
- The threat to other organ systems: GI tract, bladder

### **MEDICATION**

Medications are used to improve the patient's quality of life through symptom relief, and to prevent progression of the disease and its potential to cause organ dysfunction.

---

P.341

### **First Line**

Women found to have endometriomas during incidental surgery or studies may not need any treatment. Others with minimal symptoms may find sufficient relief with NSAID medications. Increased exercise, especially aerobic, may help others.

- NSAIDs initiated at the beginning or just before menses. Evidence is inconclusive on effectiveness (4)[B].
- Cyclic combined oral contraceptive pills (OCPs) suppress ovulation.

## *Second Line*

- Low-dose OCPs or low-dose progestins with recommendations to switch from cyclic to continuous contraception for 3 to 6 months if symptoms persist or if there is chronic, noncyclic pelvic pain
  - Levonorgestrel intrauterine device (IUD) (Mirena) found to decrease recurrence of painful menstruation (although not FDA approved for this indication).
- Medroxyprogesterone acetate 150 mg IM 3 months. Prolonged use may lead to loss of bone mineral density of uncertain clinical significance. Gonadotropin-releasing hormone (GnRH) agonists: Inhibit pituitary gonadotropin synthesis and induce a hypoestrogenic state.
- Norethindrone acetate 5 mg PO once daily plus conjugated equine estrogen 0.625 mg PO once daily

## *Third Line*

If symptoms and signs continue, physicians should be experienced in the use and side effects of gonadotropin-releasing hormone analogues prior to their use (symptoms return in as many as 70% of treated patients):

- Leuprolide acetate (Depo-Lupron) 3.75 mg IM each month or 11.25 mg IM every 3 months (gluteal)
- Nafarelin (Synarel) intranasal one spray (200 &mgr;g) in one nostril each morning and the other nostril each evening (start between days 2 and 4 of menstrual cycle)
- Goserelin (Zoladex) implant 3.6 mg SC in upper abdominal wall every 28 days
- Danazol: also effective, with side effects similar to GnRH analogs
- Aromatase inhibitors (anastrozole and letrozole) prolong the remission induced by gonadotropin-releasing hormone medications.

### **ALERT**

Calcium (1,000 to 1,500 mg/day) with vitamin D 1,000 to 2,000 IU daily or low-dose estrogen with progestogen (5)[B] is recommended when using GnRH agonists to prevent calcium loss.

## *ISSUES FOR REFERRAL*

- Refer early to a physician with expertise in medical and surgical treatment of endometriosis, especially if the patient desires to conceive in the future.
- Indications for referral to a properly experienced gynecologist include the following:
  - Need for definitive diagnosis
  - Failure to respond to a conservative or first-line therapy
  - Chronic pelvic pain
  - Delayed fertility

## ***ADDITIONAL THERAPIES***

Regular exercise and counseling for pain-management strategies. Narcotics are contraindicated for chronic pain.

## ***SURGERY/OTHER PROCEDURES***

Surgery (laparoscopy or laparotomy) is both diagnostic and therapeutic (first line or when conservative measures fail):

- Peritoneal endometriosis: laser ablation/excision/fulguration
- Ovarian endometriosis (endometriomas) >3 to 4 cm: ablation, excision, drainage
- Lysis of adhesions (LOA)
- Hysterectomy with bilateral salpingo-oophorectomy for debilitating symptoms refractory to other medical or surgical treatments:
  - Relieves pain in 80-90%, but pain recurs in 10% within 1 to 2 years after surgery
  - Postoperative HRT should include estrogen and progestogen or progesterone
- Interruption of nerve pathways: laparoscopic ablations and presacral neurectomy improve dysmenorrhea
- Fertility procedures: Ablation or excision of lesions with LOA is recommended to treat infertility in stages I-II disease:
  - Spontaneous conception should be attempted for 1 year prior to assisted reproduction techniques.
  - Disease does not endanger in vitro fertilization (IVF) pregnancies.

### **ALERT**

Surgery for endometriomas may decrease ovarian reserve in advanced disease

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Osteopathic manipulative therapy found to improve quality of life (3)[C].
- Postsurgical use of Chinese herbal medicine has been found to be effective.
- Acupuncture may be more effective than Danazol to decrease pain, irregular menstruation, and perineal swelling (6)[B].
- Osteopathic manipulation

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

Routine gynecologic care

#### *Patient Monitoring*

Symptomatic and asymptomatic pelvic masses <http://www.acog.org/>

### PROGNOSIS

- Excellent, especially if diagnosis and treatment plans are initiated early in disease course
- Poor for recovery of fertility if the disease has progressed to stage III/IV
- Symptoms and signs improve after bilateral oophorectomy.

### COMPLICATIONS

Sequelae include chronic pelvic pain, reduced quality of life, repetitive surgical intervention, depression, infertility, medication side effects and costs, and infertility.

## Codes

### &NA;

## ICD10

- N80.9 Endometriosis, unspecified

N80.3 Endometriosis of pelvic peritoneum

- N80.2 Endometriosis of fallopian tube

## Clinical Pearls

**&NA;**

- Severe dysmenorrhea and dyspareunia are never normal. Failure to respond to NSAIDs and/or OCPs warrants further investigation.
- A rectovaginal exam can be useful in patients suspected of having endometriosis.

# Endometritis and Other Postpartum Infections

Justin P. Lavin Jr., MD, FACOG

Ayesha Hasan, MD

Danielle Taylor, DO, MS

## BASICS

### DESCRIPTION

- Endometritis (infection of the endometrium) is the most common postpartum infection.
- Bacterial infection of genital tract, usually within the 1st week after delivery, can occur as late as 1 to 6 weeks postpartum.
- Less common are postpartum infections of the myometrium and parametrial tissues. Vaginal and cervical infections, perineal cellulitis, pelvic cellulitis, septic pelvic vein thrombophlebitis, and parametrial phlegmon are other less-common postpartum infections of the pelvic region.
- System(s) affected: reproductive
- Synonym(s): postpartum infection; endometritis; endoparametritis; endomyometritis; myometritis; endomyoparametritis; metritis; metritis with pelvic cellulitis

### EPIDEMIOLOGY

#### *Incidence*

Predominant age and gender: women of childbearing years

#### *Prevalence*

- Occurs after 1-3% of all births
- Infection is 10 times more likely after cesarean section
  - 2-15% of infections occur prior to labor
  - 30-35% occur after labor in absence of appropriate antibiotic prophylaxis; 2-15% occur after labor with appropriate prophylaxis
  - Fifth leading cause of maternal mortality, accounting for 11% of maternal deaths

## ETIOLOGY AND PATHOPHYSIOLOGY

- Endometritis is more common in labors complicated by chorioamnionitis.
- Other infections follow trauma to the perineum, vagina, cervix, and uterus.
- Postpartum infections are typically polymicrobial, involving organisms ascending from the lower genital tract:
  - Aerobic isolates (70%): *Streptococcus faecalis*, *Streptococcus agalactiae*, *Streptococcus viridans*, *Staphylococcus aureus*, *Escherichia coli*
  - Anaerobic isolates (80%): *Peptococcus* sp., *Peptostreptococcus* sp., *Clostridium* sp., *Bacteroides bivius*, *Bacteroides fragilis*, *Fusobacterium* sp.
- Other genital mycoplasmata
- Consider herpes simplex virus and cytomegalovirus, particularly in immunocompromised patients failing to improve on appropriate antibiotics.
- Thrombosis of any pelvic vein, including vena cava
- Phlegmon on leaves of the broad ligament

## RISK FACTORS

- Cesarean delivery is the primary risk factor.
- Chorioamnionitis
- Bacterial vaginosis
- Group B streptococcal colonization of genital tract
- HIV infection
- Prolonged labor
- Prolonged rupture of membranes
- Multiple vaginal examinations
- Internal fetal monitoring during labor
- Operative vaginal delivery
- Manual extraction of the placenta
- Low socioeconomic status
- Obesity
- Anemia

- Care in a teaching hospital

## GENERAL PREVENTION

- Vaginal delivery
  - Avoid unnecessary vaginal examinations.
  - Treat chorioamnionitis during labor.
  - Avoid manual placental extraction and retained placental products.
  - Consider antibiotic prophylaxis for third- and fourth-degree laceration (1)[B].
  - Use aseptic technique for operative vaginal delivery.
  - Antibiotic prophylaxis for operative vaginal delivery is not necessary (2)[A].
- Cesarean delivery
  - Preoperative preparation using a paint and scrub technique with a 10% povidone iodine scrub and topical solution decreases puerperal infection by up to 38% (3)[B].
  - Prophylactic antibiotics before both emergency and scheduled cesarean deliveries prior to skin incision reduces the prevalence of postpartum infection (4)[A],(5,6)[B].
    - Antibiotics should be administered within 1 hour of the surgery start time (6)[B].
    - Appropriate administration of antibiotics results in a 40% reduction in postpartum maternal infections without any increase in neonatal infectious outcomes (6)[B].
  - Extending the spectrum of coverage to include both a cephalosporin and a macrolide may further decrease infection risk (7)[A],(8)[B].
  - Vaginal preparation with povidone iodine solution immediately before cesarean delivery reduces the risk of postoperative endometritis (9)[A].
  - Weight-based antibiotic dosage helps ensure appropriate tissue concentrations prior to skin incision (10).

## COMMONLY ASSOCIATED CONDITIONS

- Chorioamnionitis
- Wound infection

**DIAGNOSIS**

## HISTORY

- History of cesarean delivery or chorioamnionitis
- Fever and chills
- Malaise
- Headache
- Anorexia
- Abdominal pain
- Heavy vaginal bleeding or foul smelling lochia

## PHYSICAL EXAM

- Oral temperature  $>38.3^{\circ}\text{C}$  ( $100.9^{\circ}\text{F}$ )
- Tachycardia
- Uterine tenderness on exam
- Other localized abdominopelvic tenderness on exam
- Purulent or malodorous lochia
- Heavy vaginal bleeding
- Ileus
- Group A or B streptococcal bacteremia may have no localizing signs.

## DIFFERENTIAL DIAGNOSIS

- $\text{Mnemonic: Wind (pneumonia); Water (UTI); Wound infection; Wow (mastitis); Wonder drug (medication-related fever)}$
- Viral syndrome; dehydration
- Thrombophlebitis
- Thyroid storm
- Appendicitis

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- CBC: Interpret with care (*Physiologic leukocytosis may be as high as 20,000 WBCs.*)
- Two sets of blood cultures (especially with suspected sepsis)

- Note: Diagnosis often made on clinical grounds. Potential testing includes:
  - Genital tract cultures and rapid test for group B streptococci (may be done during labor)
  - Amniotic fluid Gram stain: usually polymicrobial
  - Uterine tissue cultures: Prep the cervix with Betadine and use a shielded specimen collector or Pipelle; difficult to obtain without contamination
- If patient is not responsive to antibiotics in 24 to 48 hours:
  - Ultrasound for retained products of conception, pelvic abscess, or mass
  - CT or MRI looking for pelvic vein thrombophlebitis, abscess, or deep-seated wound infection

## *Diagnostic Procedures/Other*

Paracentesis/culdocentesis with culture rarely necessary

## *Test Interpretation*

- Superficial layer of infected necrotic tissue in microscopic sections of uterine lining
- >5 NEUTROPHILS per high-power field in superficial endometrium; <sup>31</sup> plasma cell in endometrial stroma

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Clindamycin 900 mg IV q8h + gentamicin 5 mg/kg IV q24h (11)[A]
- Potential side effects include nephrotoxicity, ototoxicity, pseudomembranous colitis, or diarrhea (in up to 6%).

#### *Second Line*

- Ampicillin-sulbactam 3 g IV q6h
- Metronidazole 500 mg q8-12h + penicillin 5,000,000 U q6h, *or*
- Ampicillin 2 g q6h + gentamicin 5 mg/kg q24h (11)[A]
- Cefoxitin 2 g IV q6h. Add ampicillin 2 g IV q6h, if clinical failure after 48 hours
- Cefotetan 2 g IV q12h. Add ampicillin 2 g IV q6h, if clinical failure after 48 hours (11)[A]

- Note: Base therapy on cultures, sensitivities, and clinical response.
- Contraindications
  - Drug allergy
  - Renal failure (aminoglycosides)
  - Avoid sulfa, tetracyclines, and fluoroquinolones before delivery and if breastfeeding. Metronidazole is relatively contraindicated if breastfeeding.
- Precautions:
  - Clindamycin and other antibiotics occasionally cause pseudomembranous colitis.
  - Antibiotic-associated diarrhea (*Clostridium difficile*)
- Note: Consider adding a macrolide antibiotic (for chlamydia coverage) for infections occurring after 48 hours.
- Note: Heparin typically indicated for septic pelvic vein thrombophlebitis; requires 10 days of full anticoagulation

## ***SURGERY/OTHER PROCEDURES***

- Curettage for retained products of conception
- Surgery to drain abscess
- Surgery to decompress the bowel
- Surgical drainage of a phlegmon is not advised unless it is suppurative. Surgical removal of other inflamed tissue is usually not required.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Inpatient care is recommended for postpartum infections.
- Many infections occur after hospital discharge.
- IV antibiotics and close observation for severe infections
- Open and drain infected wounds.
- Optimize fluid status.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Individualize according to severity
- IV antibiotics can be stopped when the patient is afebrile for 24 to 48 hours.
- Oral antibiotics on discharge are not necessary, unless patient was bacteremic; then continue oral antibiotics to complete a 7-day course.

#### *DIET*

As tolerated, although may be limited by ileus

### *PATIENT EDUCATION*

- Advise patient to contact physician with fever  $>38.3^{\circ}\text{C}$  ( $100.9^{\circ}\text{F}$ ) postpartum, heavy vaginal bleeding, foul-smelling lochia, or other symptoms of infection.
- Information available at <http://www.healthline.com/health/pregnancy/complications-postpartum-endometritis>

### *PROGNOSIS*

With supportive therapy and appropriate antibiotics, most patients improve quickly and recover without complication.

### **COMPLICATIONS**

- Resistant organisms; peritonitis; pelvic abscess
- Septic pelvic thrombophlebitis
- Ovarian vein thrombosis
- Sepsis; death

Algorithm: Pelvic Pain

## Codes

&NA;

### ICD10

- O86.12 Endometritis following delivery
- O86.4 Pyrexia of unknown origin following delivery
- O86.13 Vaginitis following delivery

## Clinical Pearls

&NA;

- Postpartum endometritis follows 1-3% of all births.
- Infections are typically polymicrobial and involve organisms ascending from the lower genital tract.
- Evidence supports antibiotic prophylaxis prior to skin incision for all cesarean deliveries but not for operative vaginal deliveries.

clindamycin 900 mg IV q8h and gentamicin 5 mg/kg q24h are recommended as first-line therapy for endometritis. Treat until the patient is afebrile for 24 to 48 hours, at which point antibiotics can be stopped completely (except in cases of documented bacteremia, which require a 7-day course of therapy).

- If no improvement occurs on antibiotics, consider retained placental products, abscess, wound infection, hematoma, cellulitis, phlegmon, or septic pelvic vein thrombosis.

# Enuresis

Cody B. Godfrey, DO

Swati Avashia, MD, FAAP

## BASICS

### DESCRIPTION

- Classification
  - Primary nocturnal enuresis (NE): 80% of all cases; child/adult who has never established urinary continence on consecutive nights for a period of  $\geq 6$  months
  - Secondary NE: 20% of cases; resumption of enuresis after at least 6 months of urinary continence
- NE: intermittent nocturnal incontinence after the anticipated age of bladder control (age 5 years)
  - Primary monosymptomatic NE (PMNE): bed wetting with no history of bladder dysfunction or other lower urinary tract (LUT) symptoms
  - Nonmonosymptomatic NE (NMNE): bed wetting with LUT symptoms such as frequency, urgency, daytime wetting, hesitancy, straining, weak or intermittent stream, posturination dribbling, lower abdominal or genital discomfort, or sensation of incomplete emptying

### ALERT

Adult-onset NE with absent daytime incontinence is a serious symptom; complete urologic evaluation and therapy are warranted.

- System(s) affected: nervous, renal/urologic
- Synonym(s): bed wetting; sleep enuresis; nocturnal incontinence; primary NE

### EPIDEMIOLOGY

#### Incidence

- Depends on family history
- Spontaneous resolution: 15% per year, 99% of children are dry by age 15 years.

## *Prevalence*

- Very common. 5 to 7 million children in the U.S.
- 40% of 3-year-olds; 10% of 6-year-olds; 3% of 12-year-olds; 1% of adults
- Male > female (3:1)
- Nocturnal > day (3:1)

## *Geriatric Considerations*

Infrequent; often associated with daytime incontinence (formerly referred to as diurnal enuresis)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- A disorder of sleep arousal, a low nocturnal bladder capacity, and nocturnal polyuria are the three factors that interrelate to cause NE.
- Both functional and organic causes (below); many theories, none absolutely confirmed
- Detrusor instability
- Deficiency of arginine vasopressin (AVP); decreased nocturnal AVP or decreased AVP stimulation secondary to an empty bladder (bladder distension stimulates AVP)
- Maturational delay of CNS
- Severe NE with some evidence of interaction between bladder overactivity and brain arousability: association with children with severe NE and frequent cortical arousals in sleep
- Organic urologic causes in 1-4% of enuresis in children: UTI, occult spina bifida, ectopic ureter, lazy bladder syndrome, irritable bladder with wide bladder neck, posterior urethral valves, neurologic bladder dysfunction
- Organic nonurologic causes: epilepsy, diabetes mellitus, food allergies, obstructive sleep apnea, chronic renal failure, hyperthyroidism, pinworm infection, sickle cell disease
- NE occurs in all stages of sleep.

## *Genetics*

Most commonly, NE is an autosomal-dominant inheritance pattern with high penetrance (90%).

- 1/3 of all cases are sporadic.
- 75% of children with enuresis have a first-degree relative with the condition.
- Higher rates in monozygotic versus dizygotic twins (68% vs. 36%)
- If both parents had NE, risk in child is 77%; 44% if one parent is affected. Parental age of

resolution often predicts when child's enuresis should resolve.

## ***RISK FACTORS***

- Family history
- Stressors (emotional, environmental) common in secondary enuresis (e.g., divorce, death)
- Constipation
- Encopresis
- Organic disease: 1% of monosymptomatic NE (e.g., urologic and nonurologic causes)
- Psychological disorders
  - Comorbid disorders are highest with secondary NE: depression, anxiety, social phobias, conduct disorder, hyperkinetic syndrome, internalizing disorders
  - Association with ADHD; more pronounced in ages 9 to 12 years
- Altered mental status or impaired mobility

## ***GENERAL PREVENTION***

No known measures

## ***COMMONLY ASSOCIATED CONDITIONS***

- Obstructive sleep apnea syndrome: atrial natriuretic factor inhibits renin-angiotensin-aldosterone pathway leading to diuresis
- Constipation (1/3 of patients with NE)
- Behavioral problems (specifically ADHD)

## **DIAGNOSIS**

### **HISTORY**

- Age of onset, duration, severity
- LUT tract symptoms
- Constipation and encopresis (15% with comorbid encopresis)
- Daily intake patterns
- Voiding and elimination patterns (voiding diary)
- Psychosocial history

- Family history of enuresis
- Investigation and previous treatment history

## *PHYSICAL EXAM*

- ENT: evaluation for adenotonsillar hypertrophy
- Abdomen: enlarged bladder, kidneys, fecal masses, or impaction
- Back: Look for dimpling or tufts of hair on sacrum.
- Genital urinary exam
  - Males: meatal stenosis, hypospadias, epispadias, phimosis
  - Females: vulvitis, vaginitis, labial adhesions, ureterocele at introitus; evidence of abuse
- Rectal exam: tone and constipation
- Neurologic exam, especially lower extremities

## *DIFFERENTIAL DIAGNOSIS*

- Primary NE
  - Delayed physiologic urinary control
  - UTI (both)
  - Spina bifida occulta
  - Obstructive sleep apnea (both)
  - Idiopathic detrusor instability
  - Previously unrecognized myelopathy or neuropathy (e.g., multiple sclerosis, tethered cord, epilepsy)
  - Anatomic urinary tract abnormality (e.g., ectopic ureter)
- Secondary NE
  - Bladder outlet obstruction
  - Neurologic disease, neurogenic bladder (e.g., spinal cord injury)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

Only obligatory test in children is urinalysis.

- Urinalysis and urine culture: UTI, pyuria, hematuria, proteinuria, glycosuria, and poor concentrating ability (low specific gravity) may suggest organic etiology, especially in adults.
- Urinary tract imaging is usually not necessary.
- If abnormal clinical findings or adult onset: renal and bladder US
- IV pyelogram, voiding cystourethrogram (VCUG), or retrograde pyelogram as indicated
- Spine radiographs for spina bifida occulta

### *Follow-Up Tests & Special Considerations*

- Secondary enuresis: serum glucose, BUN, creatinine, thyroid-stimulating hormone (TSH), urine culture
- In children, imaging and urodynamic studies are helpful for significant daytime symptoms, history of UTIs, suspected structural abnormalities, and in refractory cases.

### *Diagnostic Procedures/Other*

Urodynamic studies may be beneficial in adults and nonmonosymptomatic NE.

### *Test Interpretation*

- Dysfunctional voiding
- Detrusor instability and/or reduced bladder capacity most common findings

## **TREATMENT**

### *GENERAL MEASURES*

- Use nonpharmacologic approaches as first line before prescribing medications (1)[A].
- Simple behavioral interventions (e.g., scheduled waking, positive reinforcement, bladder training, diet changes) are effective though less so than alarms or medications (2)[B].
  - Explain the three pathophysiologic factors.
  - Encourage normal drinking patterns during daytime hours and reduction of intake in the hours prior to sleep.
  - Emphasize regular bedtime with full night's sleep.
  - Scheduled voiding before bed

- Nightlights to light the way to the bathroom
- Reward system for dry nights
- Use pull up over regular underwear or cloth underwear with built in waterproof barrier.
- Do not shame or punish bedwetting but have the child participate in removing and laundering soiled bedding and garments.
- If behavioral interventions alone have no success, combined therapy (e.g., enuresis alarm, bladder training, motivational therapy, and pelvic floor muscle training) is more effective than each component alone or than pharmacotherapy (1)[A].

P.345

- Enuresis alarms (bells or buzzers)
  - 66-70% success rate; must be used nightly for 3 to 4 months; offers cure; significant parental involvement; disruption of sleep for entire family
  - In children, number needed to treat (NNT) = 2 (3)[A].
  - If successful, it should be used until 14 consecutive dry nights achieved (4)[B].
- See "Patient Education" for options.

## MEDICATION

### First Line

- Desmopressin (DDAVP): synthetic analogue of vasopressin that decreases nocturnal urine output (5)[A]
  - Adults only: 20 mg (2 sprays) intranasally at bedtime
  - FDA recommends against use in children due to reports of severe hyponatremia resulting in seizures and deaths in children using intranasal formulations of desmopressin.
  - Oral DDAVP: dose-dependent: begin at 0.2 mg tablet taken at bedtime on empty stomach; may titrate to 0.6 mg
    - Maximally effective in 1 hour; cleared within 9 hours
    - Trial nightly for 6 months, then stop for 2 weeks for test of dryness
    - Suspend dose in children who experience acute condition affecting fluid/electrolyte balances (fever, vomiting, diarrhea, vigorous exercise).
  - 10-70% success; safe even when used for >12 months; high relapse rate after discontinuation without a structured withdrawal program

- In children, NNT = 6 (6)[A].
- Anticholinergics
  - Oxybutynin (Ditropan, Ditropan XL, Oxytrol patch): anticholinergic; smooth muscle relaxant, antispasmodic; may increase functional bladder capacity and aids in timed voiding (6)[B]
    - Ditropan: adults and children >5 years of age: 5 mg PO TID to QID; children 1 to 5 years of age: 0.02 mg/kg/dose BID to QID (syrup 5 mg/5 mL)
    - Ditropan XL: adults: 5 mg/day PO; increase to 30 mg/day PO (5-, 10-mg tabs)
    - Oxytrol patch: 1 patch every 3 to 4 days (3.9 mg/patch) (periodic trials off the medication, that is, weekends or weeks at a time, will help determine efficacy and resolution of primary disturbance)
    - Ditropan: 5 to 10 mg at night; 30-50% success; 50% relapse after stopped
  - Tolterodine (Detrol, Detrol LA): anticholinergic; fewer side effects than Ditropan (7)[B]
    - Detrol: 1 to 2 mg PO BID
    - Detrol LA: 2 to 4 mg/day

## *Pediatric Considerations*

FDA recommends against using intranasal formulations of desmopressin in children due to reports of severe hyponatremia resulting in seizures and deaths (8)[A].

## *Second Line*

- Imipramine (Tofranil): tricyclic antidepressant, anticholinergic effects; increases bladder capacity, antispasmodic properties
  - Primarily in adults; use in children is reserved for resistant cases.
  - Dose: adults, 25 to 75 mg and children >6 years, 10 to 25 mg PO at bedtime; increase by 10 to 25 mg at 1- to 2-week intervals; treat for 2 to 3 months; then taper
  - 25-30% success when used <3 months.
  - Pretreatment ECG recommended identifying underlying rhythm disorders.
- Precautions
  - Oxybutynin: glaucoma, myasthenia gravis, GI or genitourinary obstruction, ulcerative colitis, megacolon; use a decreased dose in the elderly.
  - Tolterodine: urinary retention, gastric retention, or uncontrolled narrow-angle glaucoma;

significant drug interactions with CYP2D6, CYP3A3/4 substrates

- DDAVP: Avoid in patients at risk for electrolyte changes or fluid retention (congestive heart failure [CHF], renal insufficiency). Stop during gastroenteritis or other acute illness with risk of dehydration.
- Imipramine: Do not use with monoamine oxidase inhibitors (MAOIs), hypotension, and arrhythmias; low-toxic therapeutic ratio
- Combination therapy with DDAVP and oxybutynin has better results than individual use (7)[B].
- Prostaglandin inhibitors (e.g., indomethacin) have been studied; may increase bladder capacity, not as effective as DDAVP, and increase adverse effects (7)[B]

## **ALERT**

Imipramine: cardiotoxicity and death with overdose

## **ISSUES FOR REFERRAL**

- Primary NE: persistent enuresis despite nonpharmacologic and pharmacologic therapies
- Diurnal incontinence or nonmonosymptomatic enuresis with voiding dysfunction or underlying medical condition

## **ADDITIONAL THERAPIES**

Individual and family psychotherapy, crisis intervention

## **SURGERY/OTHER PROCEDURES**

Only for surgically correctable causes (e.g., tethered cord, ectopic ureter, benign prostatic hypertrophy, obstructive sleep apnea)

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Acupuncture and hypnosis are other treatments offered; small amounts of supportive data (9,10) [B]

## **ONGOING CARE**

### **FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*

*DIET*

- Limit fluid and caffeine intake 2 hours before sleep.
- Limit dairy products 4 hours before sleep (decrease osmotic diuresis).

## **PATIENT EDUCATION**

Web resources for hypnosis scripts, alarms, and supplies

- [www.bedwettingstore.com/index.htm](http://www.bedwettingstore.com/index.htm); [www.drissleeper.com](http://www.drissleeper.com); [www.enurad.com](http://www.enurad.com); [www.nitetrain-r.com](http://www.nitetrain-r.com); [www.sleepydryalarm.com](http://www.sleepydryalarm.com); [www.wetstop.com](http://www.wetstop.com); [www.pottypager.com/](http://www.pottypager.com/)

## **PROGNOSIS**

In children, NE is usually self-limiting; 1% will persist as adult; evaluate for organic causes.

## **COMPLICATIONS**

UTI, perineal excoriation, psychological disturbance (especially in children)

- Incontinence, Urinary Adult Female; Incontinence, Urinary Adult Male
- Algorithm: Enuresis

## Codes

&NA;

### ICD10

- N39.44 Nocturnal enuresis
- R32 Unspecified urinary incontinence
- F98.0 Enuresis not due to a substance or known physiol condition

## Clinical Pearls

&NA;

- Initial evaluation is history, exam, and urinalysis.
- For PMNE in children, if the condition is not distressing to child and caretakers, treatment is unnecessary.
- Behavioral and lifestyle interventions are the first-line treatment for PMNE, alarms and desmopressin are the most effective treatments.
- Dryness is possible for most children.

# Eosinophilic Esophagitis

Peter I. Chung, MD

Benjamin Hyatt, MD

## BASICS

Eosinophilic esophagitis (EoE) is a chronic, immune-mediated, inflammatory esophageal disease characterized clinically in adults by dysphagia, food impaction, and heartburn and in children with nonspecific abdominal complaints, abdominal pain, and failure to thrive. Histologically, EoE is characterized by eosinophilic predominate inflammation (1)[A].

## EPIDEMIOLOGY

All ages, most common in 20s to 30s; male > female, 3:1

### *Incidence*

Incidence in general population is approximately 1 case in 10,000 persons per year (2)[A].

### *Prevalence*

Gradually increasing, perhaps due to better case finding, understanding of EoE in multiple clinical guises; 45 to 55/100,000

- Increased prevalence in those with celiac disease.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Believed to be an atopic inflammatory disease, whose pathogenesis is an aberrant immune response to antigenic stimulation
- Like eczema and asthma, T-helper 2 (T<sub>H</sub>2) lymphocytes play a role, as do mixed IgE and non-IgE-mediated allergic responses to food and environmental allergens.
- Although not well-understood, the pathophysiology of EoE is postulated to be due to increased recruitment and activation of eosinophils in the esophagus. Eosinophil chemoattractants include eotaxin-3, IL-5, and IL-13.

### *Genetics*

- EoE susceptibility may be caused by polymorphisms in thymic stromal lymphopoietin protein

(TSLP) (3)[A].

- Potential new subphenotype of EoE (may also overlap with GERD): proton pump inhibitor (PPI)-responsive esophageal eosinophilia, where PPIs may act to decrease the inflammatory response in EoE (3)[A]

## **RISK FACTORS**

- EoE is commonly associated with atopy/allergic disorders, such as asthma, hay fever, or eczema (1,4)[A].
- High rate of associated food antigen allergies/anaphylaxis

## **DIAGNOSIS**

There are no pathognomonic findings for EoE. A definitive diagnosis is made by esophageal endoscopy and biopsy.

### **HISTORY**

- Solid food dysphagia and food impaction are the most common symptoms and are usually present for 3 to 4 years prior to the diagnosis.
- Patients may also have reflux symptoms. Often, the diagnosis is entertained after patients fail a trial of antireflux medications. Other common complaints include nausea or vomiting, regurgitation, chest pain, upper abdominal pain, or decreased appetite.
- Patients may also have a history of food or environmental allergies, as well as asthma or atopic conditions (e.g., dermatitis).

## **PHYSICAL EXAM**

No specific physical exam findings are associated with the diagnosis. However, signs and symptoms of allergies or asthma with symptoms of ongoing dysphagia or GERD-like symptoms should raise suspicion; some patients will have signs indicating weight loss or malnutrition.

## **DIFFERENTIAL DIAGNOSIS**

- GERD
  - Associated with EoE; diseases may coexist in individual patients.
- PPI-responsive esophageal eosinophilia (PPI-REE)
  - Characteristics of PPI-REE

- Shows classic EoE symptoms
  - Diagnosis of GERD has been excluded.
  - Responds to PPIs clinically and histologically
- Secondary causes of esophageal eosinophilia including celiac disease, Crohn esophagitis, infection, vasculitis, PPIs, achalasia, connective tissue disease, eosinophilic gastrointestinal diseases
  - Functional dyspepsia
  - Congenital rings
  - Esophageal carcinoma
  - Esophageal motility disorders

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- To exclude PPI-REE, patients with suspected EoE should be given a 2-month course of PPI followed by endoscopy with biopsies.
- Solid food dysphagia is an indication for esophagogastroduodenoscopy (EGD), as are other concerning or red-flag symptoms, many of which occur in patients with EoE; they include the following:
  - Odynophagia
  - Weight loss
  - Early satiety or vomiting
  - Aspiration/wheezing or cough
  - GI bleeding
  - Unexplained iron deficiency anemia
  - Male >45 years with long-standing symptoms
- GERD patients who show no symptomatic improvement after 8 to 12 weeks of a PPI should also be considered for EGD and biopsy.
- Serum IgE levels are elevated in 70% of patients.
- Peripheral eosinophilia occurs in 10-50% of patients.

## **Follow-Up Tests & Special Considerations**

Testing for asthma and IgE-mediated food/inhalant allergies, if clinically relevant, can help

manage coexisting atopic conditions:

- Serum IgE, skin prick test, or atopy patch test

## *Diagnostic Procedures/Other*

EGD: 17% of biopsy-proven cases of EoE had an endoscopically normal exam (5)[A].

- Endoscopic findings: esophageal rings (trachealization), strictures, white plaques or exudates, linear furrows, narrow-caliber esophagus, and pallor or decreased vasculature
  - Esophageal biopsies are required for diagnosis; two to four biopsies from both proximal and distal esophagus. At initial diagnosis, biopsies should be obtained from antrum and/or duodenum to rule out other causes of esophageal eosinophilia in all children and adults with gastric or small intestinal symptoms or endoscopic abnormalities (1)[A].
    - Biopsy specimen: Pathologic findings may include surface layering of eosinophils, eosinophilic microabscesses, subepithelial lamina propria fibrosis, or basal cell hyperplasia.
- Barium contrast radiography
  - Can help to identify anatomic abnormalities in EoE but has a low sensitivity for diagnosis
  - May be an alternative to repeated endoscopies in previously treated patients who have changing symptoms
- pH monitoring: may be helpful in differentiating EoE from GERD
- Consensus American Gastroenterological Association guidelines for diagnosis of EoE (1)[A]
  - Clinical symptoms of esophageal dysfunction
  - $\geq 15$  eosinophils in one high-power field on biopsy
  - Mucosal eosinophilia is isolated to esophagus and persists after PPI use.
  - Secondary causes of esophageal eosinophilia are excluded.

## **TREATMENT**

End points of therapy of EoE include improvements in clinical symptoms and reducing esophageal eosinophilic inflammation. Defining evidence-based end points in EoE is still an area of active research (1)[A].

## **MEDICATION**

## First Line

- Corticosteroids
  - Topical steroids (swallowed, not inhaled) are the first-line pharmacologic treatment.
    - Initial dosing for treatment of EoE: Swallowed fluticasone dose in adults is 880 to 1,760  $\mu\text{g}/\text{day}$  in a divided dose and in children is determined based on age or weight.

P.347

Swallowed budesonide dose in adults is 2 mg/day, typically in divided doses; in children determined based on age or weight. Initial duration of treatment is 8 weeks. Medication should be discontinued if patient develops side effects or other intolerances. Patients have relapsed after withdrawal of the medication. Inhaled topical steroid trials are ongoing.

- Systemic steroids: Prednisone can be helpful if topical steroids are not effective or for patients who require a more rapid improvement to symptoms, such as those with refractory dysphagia and in patients who are hospitalized. Long-term toxicity limits use (1)[A].
- Diet
  - Dietary elimination is considered initial therapy in both children and adults.
  - Three dietary regimens have been shown to be effective in treatment of EoE: (i) elemental amino acid-based diet; (ii) elimination diet based on various food allergy tests; and (iii) six-food elimination diet of the most common food groups known to trigger EoE: wheat, soy, cow's milk, eggs, nuts, and seafood. All three methods have been shown to be effective in children for both clinical and histologic improvement, with the elemental diet being most effective:
    - In children, success rates of 77-98% have been reported for clinical and histologic remission using an elemental amino acid formula. A retrospective chart review comparing the three diets showed that the elemental diet was superior, with 96% remission (6)[B]. Yet, this treatment has not gained popularity because of its high cost, impaired quality of life, and overall practicality.
  - In adults, food allergy plays an important role in EoE, and six-food elimination diet (SFED) is an effective therapy (7)[B]:
    - Gonsalves et al. evaluated SFED in adult patients with EoE and demonstrated clinical, endoscopic, and histologic improvement. Symptoms improved in 94% of patients. Reintroduction of eliminated food caused reactivation of EoE with wheat (60%) and cow's milk (50%) as the leading causative agents. Skin-prick allergy testing was only 13% predictive in identifying food triggers.

## Second Line

- Endoscopic esophageal dilation
  - May be used effectively in symptomatic patients with strictures that are resistant to medical or dietary treatments and initially in patients with severe and symptomatic esophageal stenosis (1)[A]
  - A systematic review showed that 92% of patients treated with dilation had improvement in dysphagia symptoms for up to 1 to 2 years.
  - Patients should be informed of the risks of esophageal dilation. The most common risk is postprocedure chest pain, which occurs in 75% of patients. The perforation rate for dilation is 0.3%, contrary to early reports which showed higher rates of perforation. Bleeding requiring endoscopic intervention or blood products is very rare, with only one occurrence reported to date (1,4)[A].

## ISSUES FOR REFERRAL

Refer to an allergist and/or nutritionist to help identify/manage allergic disorders and diet regimens.

## ADDITIONAL THERAPIES

Other pharmacologic therapies

- Montelukast, mepolizumab (IL-5 monoclonal antibody), acid suppression therapy, purine analogues, anti-TNF therapy. Biologic agents have been well-tolerated with low adverse effects (AEs); yet, no studies have shown prolonged symptomatic relief (1)[A].
- Antihistamines: Case studies showed no benefit.

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

- EoE is a chronic disease with symptom recurrence after discontinuing treatment the rule rather than the exception. Prevention of progression of esophageal dysfunction is primary. Maintenance therapy with swallowed topical corticosteroid therapy and/or dietary restriction should be considered in all patients after clinicopathologic remission indefinitely or PRN (1)[A]. This is not yet standardized; only one RCT maintenance study has been done using low-dose budesonide (0.25 mg BID) versus placebo after remission for 50 weeks. Those maintained on budesonide had modest reduction in eosinophilia and fewer symptom recurrences, but there was still significant recurrence (8)[A]. As such, ongoing therapy needs to be tailored to

individual patient cases.

- Patient should be counseled on the high likelihood of symptom recurrence after discontinuing treatment.

## *Patient Monitoring*

- No guidelines yet established. It is reasonable to order periodic endoscopy based on symptoms or after completing a recent therapeutic regimen.
- There is no evidence to date of esophageal malignancy or hypereosinophilic syndromes associated with EoE.
- Esophageal candidiasis is a common side effect of chronic corticosteroid therapy.

## *PROGNOSIS*

EoE does not seem to affect life expectancy. Quality of life is affected to some extent due to the chronic nature of the disease, difficulty in adhering to a restrictive diet, and so forth. Nutritional status can be maintained with appropriate care and diligence.

## **COMPLICATIONS**

- Food impaction
- Esophageal stricture/ring/narrowing
- Nutritional deficiencies
- Subglottic stenosis or laryngeal edema is very rare.

## Codes

&NA;

### ICD10

K20.0 Eosinophilic esophagitis

## Clinical Pearls

&NA;

- Food impaction or recurrent solid food dysphagia in a young, adult male: Think EoE.

- EoE commonly mimics disorders like GERD and PPI-REE.
- A PPI trial is now required prior to the diagnosis of EoE.
- Remember "red flags" in patients with GERD: dysphagia, odynophagia, weight loss, early satiety or vomiting, aspiration/wheezing/cough, GI bleeding, unexplained iron deficiency anemia, age >50 years. Each "red flag" justifies EGD.

# Epicondylitis

Kevin Heaton, DO

## BASICS

### DESCRIPTION

- Tendinopathy of the elbow characterized by pain and tenderness at the origins of the wrist flexors/extensors at the humeral epicondyles
- May be acute (traumatic) or chronic (overuse)
- Two types
  - Medial epicondylitis (Ògolfer's elbowÓ)
    - Involves the wrist flexors and pronators, which originate at the medial epicondyle
  - Lateral epicondylitis (Òtennis elbowÓ)
    - Involves the wrist extensors and supinators, which originate at the lateral epicondyle
- May be caused by many different athletic or occupational activities
- Common in carpenters, plumbers, gardeners, and athletes
- Usually involves the dominant arm
- Lateral epicondylitis is more common.

### EPIDEMIOLOGY

- Predominant age: >40 years
- Predominant sex: male = female

### Incidence

- Common overuse injury
- Lateral > medial
- Estimated between 1% and 3%

## *Prevalence*

- Lateral epicondylitis: 1.3%
- Medial epicondylitis: 0.4%

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Acute (tendonitis)
  - Inflammatory response to injury
- Chronic (tendinosis)
  - Overuse injury
  - Tendon degeneration, fibroblast proliferation, microvascular proliferation, lack of inflammatory response
- Repetitive wrist flexion or extension places strain across enthesis of flexor/extensor group
- Tool/racquet gripping
- Shaking hands
- Sudden maximal muscle contraction
- Direct blow

## *RISK FACTORS*

- Repetitive wrist motions
  - Flexion/pronation: medial
  - Extension/supination: lateral
- Smoking
- Obesity
- Upper extremity forceful activities

## *GENERAL PREVENTION*

- Limit overuse of the wrist flexors, extensors, pronators, and supinators.
- Use proper techniques when working with hand tools or playing racquet sports.
- Use lighter tools and smaller grips.

# DIAGNOSIS

## HISTORY

- Pain typically localized to lateral or medial elbow.
- Occupational activities
- Sports participation
- Direct trauma
- Duration and location of symptoms
- Prior treatments or medication use
- Pain with gripping
- Sensation of mild forearm weakness

## PHYSICAL EXAM

- Localized pain just distal to the affected epicondyle
- Increased pain with wrist flexion/pronation (medial)
- Increased pain with wrist extension/supination (lateral)
- Medial epicondylitis
  - Tenderness at origin of wrist flexor tendons
  - Increased pain with resisted wrist flexion and pronation
  - Normal elbow range of motion
  - Increased pain with gripping
- Lateral epicondylitis
  - Tenderness at origin of wrist extensors
  - Increased pain with resisted wrist extension/supination
  - Normal elbow range of motion
  - Increased pain with gripping

## DIFFERENTIAL DIAGNOSIS

- Elbow osteoarthritis
- Epicondylar fractures

- Posterior interosseous nerve entrapment (lateral)
- Ulnar neuropathy (medial)
- Synovitis
- Medial collateral ligament injury
- Referred pain from shoulder or neck

## **DIAGNOSTIC TESTS & INTERPRETATION**

### *Initial Tests (lab, imaging)*

No imaging is required for initial evaluation and treatment of a classic overuse injury.

### *Follow-Up Tests & Special Considerations*

- Anterior-posterior/lateral radiographs if decreased range of motion, trauma, or no improvement with initial conservative therapy. Assess for fractures or signs of arthritis.
- For recalcitrant cases
  - Musculoskeletal ultrasound (US) reveals abnormal tendon appearance (e.g., tendon thickening, partial tear at tendon origin, calcifications). US can also guide injections of steroid and/or anesthetic.
  - MRI can show intermediate or high T2 signal intensity within the common flexor or extensor tendon or the presence of peritendinous soft tissue edema.

### *Diagnostic Procedures/Other*

Infiltration of local anesthetic with subsequent resolution of symptoms supports the diagnosis if clinically in doubt.

## **TREATMENT**

### **GENERAL MEASURES**

Initial treatment consists of activity modification, counterforce bracing, oral or topical NSAIDs, ice, and physical therapy:

- Observation: If left untreated, symptoms typically last between 6 months and 2 years. For patients with good function and minimal pain, consider conservative management using a "wait and see" approach based on patient preference.
- Modify activity, encourage relative rest, and correct faulty biomechanics

- Counterforce bracing with a forearm strap is easy and inexpensive. Systematic reviews are inconclusive about overall efficacy, but initial bracing may improve the ability to perform daily activities in the first 6 weeks.
- Consider nighttime wrist splinting for repetitive daily activities if counterforce bracing fails.
- Ice frequently after activities
- Physical therapy
  - Begin once acute pain is resolved. Infiltration of local anesthetic can reduce pain and allow for physical therapy
  - Eccentric strength training and stretching program
  - US therapy
  - Corticosteroid iontophoresis
  - Dry needling

## MEDICATION

### *First Line*

- Topical NSAIDs: Low-quality evidence suggests topical NSAIDs are significantly more effective than placebo with respect to pain and number needed to treat to benefit (NNT = 7) in the short term (up to 4 weeks) with minimal adverse effects (1)[A].
- Oral NSAIDs: Unclear efficacy with respect to pain and function, but may offer short-term pain relief. Associated with adverse GI effects (1)[A].

### *Second Line*

Corticosteroid injections: Short-term (28 weeks) reduction in pain. No benefits found for intermediate or long-term outcomes (2)[A].

## ISSUES FOR REFERRAL

Failure of conservative therapy

## ADDITIONAL THERAPIES

- Platelet-rich plasma (PRP) injections
  - Injection of concentrated autologous PRP leads to a local inflammatory response. Platelets degranulate, release growth factors, and stimulate the physiologic healing cascade

- PRP treatment of chronic lateral epicondylitis significantly reduces pain and increases function. The benefit exceeds that of corticosteroid injection even after a follow-up of 2 years (3)[B].
- Autologous blood injections
  - Stimulates the inflammatory cascade within the degenerated tendon by providing cellular and humoral mediators for regeneration.
  - More effective at 3 months than corticosteroid injection for improving pain, function and grip strength (4)[B]
- US-guided percutaneous needle tenotomy
  - Injection of a local anesthetic followed by US-guided tendon fenestration, aspiration, and abrasion of the underlying bone. Thought to break apart scar tissue and stimulate inflammation and healing.
- Prolotherapy
  - Injection of a dextrose solution into and around the tendon attachment stimulates a localized inflammatory response, leading to increased blood flow to stimulate healing.
- Glyceryl trinitrate (GTN) transdermal patch
  - Nitric oxide (NO) is a small free radical generated by nitric oxide synthases. NO is expressed by fibroblasts and is postulated to aid in collagen synthesis. Topical application of GTN theoretically improves healing by this mechanism. 1/4 of a 5-mg/24-hour GTN transdermal patch is applied once daily for up to 24 weeks.
  - Significant decrease in pain are seen at 3 weeks and 6 months compared to placebo patch (5)[B].
- Botulinum toxin A for chronic lateral epicondylitis
  - Injections into the forearm extensor muscles (60 units) can be performed in the outpatient setting.

## *SURGERY/OTHER PROCEDURES*

- Elbow surgery may be indicated in refractory cases:
  - Fair evidence for treatment (6)[B]
  - Involves debridement and tendon release
  - Can be performed open or arthroscopically

- Denervation of the lateral humeral epicondyle
  - Transection of the posterior cutaneous nerve of the forearm with implantation into the triceps may help with chronic symptoms and pain.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture: effective for short-term pain relief for lateral epicondyle pain

### ONGOING CARE

#### PROGNOSIS

Good: Majority resolve with conservative care.

## See Also

**&NA;**

Algorithm: Pain in Upper Extremity

## Codes

**&NA;**

### ICD10

- M77.00 Medial epicondylitis, unspecified elbow
- M77.10 Lateral epicondylitis, unspecified elbow
- M77.01 Medial epicondylitis, right elbow

## Clinical Pearls

**&NA;**

- Medial epicondylitis (golfer's elbow) is characterized by pain and tenderness at the tendinous origins of the wrist flexors at the medial epicondyle.
- Lateral epicondylitis (tennis elbow) is characterized by pain and tenderness at the tendinous origins of the wrist extensors at the lateral epicondyle.
- Left untreated, symptoms typically last between 6 months and 2 years.
- Most patients improve using conservative treatment with bracing, activity modification, and physical therapy.

# Epididymitis

Thomas M. Savage, MD

Holly L. Baab, MD

## BASICS

- Acute epididymitis: pain for <6 weeks
- Chronic epididymitis: pain for ≥3 months

## DESCRIPTION

- Inflammation (infectious or noninfectious) of epididymis resulting in scrotal pain and swelling, induration of the posterior epididymis, and eventual scrotal wall edema, involvement of the adjacent testicle, and hydrocele formation.
- Epididymitis with involvement of testis is named epididymo-orchitis
- Classification: infectious (bacterial, viral, fungal, parasitic) versus sterile (chemical, traumatic, autoimmune, idiopathic, industrial, noninfectious, vasoepididymal reflux syndrome, vasal reflux syndrome); chronic versus acute
- System(s) affected: reproductive

## EPIDEMIOLOGY

- Predominant age: usually younger, sexually active men or older men with UTIs; in older men, usually secondary to bladder outlet obstruction
- Predominant sex: male only

## Pediatric Considerations

In prepubertal boys: Epididymitis is found to be the most common cause of acute scrotum—more common than testicular torsion.

## Incidence

- Common (600,000 cases annually in the United States) (1)
- 1 in 1,000 males per year

## Prevalence

Common

## ETIOLOGY AND PATHOPHYSIOLOGY

- Infectious epididymitis
  - Retrograde passage of urine or urinary bacteria from the prostate or urethra to the epididymis via the ejaculatory ducts and the vas deferens; rarely, hematogenous spread
  - Causative organism is identified in 80% of patients and varies according to patient age.
- Sterile epididymitis
  - Chemical epididymitis occurs when sterile urine flows backward from the urethra to the epididymis
  - Can develop as a sequelae of strenuous exercise with a full bladder when urine is pushed through internal urethral sphincter (located at proximal end of prostatic urethra)
  - Reflux of urine through orifice of ejaculatory ducts at verumontanum may occur with history of urethritis/prostatitis, as inflammation may produce rigidity in musculature surrounding orifice to ejaculatory ducts, holding them open.
  - Exposure of epididymis to foreign fluid may produce inflammatory reaction within 24 hours.
- <35 years and sexually active
  - Usually *Chlamydia trachomatis* or *Neisseria gonorrhoeae*
  - Look for serous urethral discharge (chlamydia) or purulent discharge (gonorrhea)
  - With anal intercourse, likely *Escherichia coli* or *Haemophilus influenzae*
- >35 years
  - Coliform bacteria usually, but sometimes *Staphylococcus aureus* or *Staphylococcus epidermidis*
  - In elderly men, often with distal urinary tract obstruction, benign prostatic hyperplasia (BPH), UTI, or catheterization
  - Tuberculosis (TB), if sterile pyuria, nodularity of vas deferens (hematogenous spread), and recent infection. TB is the most common granulomatous disease affecting the epididymitis (2).
  - Sterile urine reflux after transurethral prostatectomy
  - Granulomatous reaction following BCG intravesical therapy for bladder cancer

- Prepubertal boys
  - Usually coliform bacteria
  - Evaluate for underlying congenital abnormalities, such as vesicoureteral reflux, ectopic ureter, or anorectal malformation (rectourethral fistula).
- Amiodarone may cause noninfectious epididymitis; resolves with decreasing drug dosage.
- Syphilis, blastomycosis, coccidioidomycosis, and cryptococcosis are rare causes, but brucellosis can be a common cause in endemic areas.

## *RISK FACTORS*

- UTI
- Prostatitis
- Indwelling urethral catheter
- Urethral instrumentation or transurethral surgery
- Urethral or meatal stricture
- Transrectal prostate biopsy
- Prostate brachytherapy (seeds) for prostate cancer
- Anal intercourse
- High-risk sexual activity
- Strenuous physical activity
- Prolonged sedentary periods
- Bladder obstruction (benign prostatic hyperplasia, prostate cancer)
- HIV-immunosuppressed patient
- Severe Behçet disease
- Presence of foreskin
- Constipation
- Sterile epididymitis
  - Increased intra-abdominal pressure (due to frequent physical strain)
    - Military recruits, especially who begin physically unprepared.
    - Laborers; restaurant kitchen workers

- Full bladder during intense physical exertion

## **GENERAL PREVENTION**

- Vasectomy or vasoligation during transurethral surgery
- Safer sexual practices
- Mumps vaccination
- Antibiotic prophylaxis for urethral manipulation
- Early treatment of prostatitis/BPH
- Avoid vigorous rectal exam with acute prostatitis.
- Emptying the bladder prior to physical exertion
- Physically conditioning the body prior to engaging in regular intense physical exertion
- Treat constipation.

## **COMMONLY ASSOCIATED CONDITIONS**

- Prostatitis/urethritis/orchitis
- Hemospermia
- Constipation
- UTI

## **DIAGNOSIS**

- Scrotal pain, sometimes radiating to the groin region, may begin acutely over several hours.
- Urethral discharge or symptoms of UTI, such as frequency of urination, dysuria, cloudy urine, or hematuria
- Initially, only the posterior-lying epididymis, usually the lowermost tail section, is very tender and indurated; will eventually progress to involvement of body and head of epididymis
- Elevation of the testes/epididymis reduces the discomfort (Prehn sign).
- Entire hemiscrotum becomes swollen and red; the testis becomes indistinguishable from the epididymis; the scrotal wall becomes thick and indurated; and reactive hydrocele may occur.
- Sterile epididymitis
  - Unilateral scrotal pain and swelling preceded by several hours of intense physical exertion.

Patient may recall full bladder prior to exertion.

- No symptoms of infection

## *Pediatric Considerations*

- In prepubertal patients, may be postinfectious inflammatory condition; treat with anti-inflammatories, analgesics.
- Antibiotic therapy can be reserved for young infants and those with pyuria or positive urine cultures (3).
- Bacteremia from *H. influenzae* infection may produce acute epididymitis.
- In adolescent males, particularly age >13 years, must rule out testicular torsion.
- History not helpful in distinguishing epididymitis from testicular torsion

## *Geriatric Considerations*

Diabetics with sensory neuropathy may have no pain despite severe infection/abscess.

## *PHYSICAL EXAM*

- The tail of the epididymis is larger in comparison with the contralateral side.
- Epididymis is markedly tender to palpation.
- Absence of a cremasteric reflex should raise suspicion for testicular torsion.

## *DIFFERENTIAL DIAGNOSIS*

- Epididymal congestion following vasectomy
- Testicular torsion
- Torsion of testicular appendages
- Orchitis
- Testicular malignancy
- Testicular trauma
- Epididymal cyst
- Inguinal hernia
- Urethritis
- Spermatocele

- Hydrocele
- Hematocele
- Varicocele
- Epididymal adenomatoid tumor
- Epididymal rhabdomyosarcoma
- Vasculitis (Henoch-Schönlein purpura)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- All suspected cases should be evaluated for objective evidence of inflammation by one of the following:
  - Urinalysis preferably on first-void urine to evaluate for positive leukocyte esterase
  - Gram stain urethral discharge.  $\geq 2$  WBC per oil immersion field. Also for evaluation of presence or absence of gonococcal infection
  - Microscopic examination of sediment from a spun first-void urine with  $\geq 10$  WBC per high power field.

---

P.351

- Urine culture, preferably first-void
- Urine GC/chlamydia testing by NAAT for all suspected cases (2)[A].
- CRP  $>24$  mg/L suggestive of epididymitis (4)[C]
- Urinalysis clear and culture-negative suggest sterile epididymitis.
- If testicular torsion cannot be excluded (especially in children), Doppler ultrasound is test of choice (1).
- In adult men, Doppler ultrasound: sensitivity and specificity of 100% in evaluation of acute scrotum (5)

### *Pediatric Considerations*

Further radiographic imaging in children should be done to rule out anatomic abnormalities.

### *Diagnostic Procedures/Other*

This is a clinical diagnosis.

## TREATMENT

### GENERAL MEASURES

- Bed rest or restriction on activity
- Athletic scrotal supporter
- Scrotal elevation
- Ice pack wrapped in towel
- Avoid constipation.
- Spermatic cord block with local anesthesia in severe cases
- If chemical epididymitis
  - No strenuous physical activity and avoidance of any Valsalva maneuvers for several weeks.
  - Empty bladder prior to strenuous exercises

### MEDICATION

#### First Line

- <35 years, or suspected STD etiology: doxycycline 100 mg PO BID for 10 days (*C. trachomatis* coverage) **PLUS** ceftriaxone 250 mg IM for 1 (*N. gonorrhoeae* coverage). Refer sexual partner(s) for evaluation and treatment if contact within 60 days of the onset of symptoms (2) [A].
- ≥35 years, not suspecting STD etiology with suspected enteric organism (i.e., bacteriuria due to bladder outlet obstruction, prostate biopsy, urinary instrumentation, systemic disease, and/or immunosuppression)
  - Levofloxacin (Levaquin) 500 mg/day PO for 10 days OR
  - Ofloxacin 300 mg PO BID for 10 days (2)[A]
- Men who are at risk for both STD and enteric organism (i.e., men who have sex with men who report insertive anal intercourse): ceftriaxone 250 mg IM for 1 plus fluoroquinolone as above (2)[A].
- Analgesia (infectious and chemical epididymitis)
  - NSAIDs (e.g., naproxen or ibuprofen) for mild to moderate pain
  - Consider corticosteroid if patient cannot tolerate NSAID.

- Acetaminophen-codeine or acetaminophenoxycodone for moderate to severe pain
- Septic or toxic patient
  - 3rd-generation cephalosporin or aminoglycoside
- For Behçet, sarcoid, Henoch-Schönlein purpura
  - Corticosteroids, such as methylprednisolone, 40 mg/day recommended

## *Second Line*

- Trimethoprim-sulfamethoxazole (Bactrim, Septra) double-strength PO BID for 10 to 14 days; increasing bacterial resistance may limit effectiveness.
- Add rifampin (rifampicin) or vancomycin, as required.

## *ISSUES FOR REFERRAL*

- If suspicion is high for testicular torsion or cancer, consult a urologist.
- Epididymitis in prepubertal boys requires a urology referral due to high incidence of associated urogenital abnormalities.
- If medical management fails, should be referred to urologist to rule out anatomic abnormality or chemical epididymitis.

## *SURGERY/OTHER PROCEDURES*

- Vasostomy to drain infected material if severe or refractory case
- Scrotal exploration if unable clinically to distinguish between epididymitis and testicular torsion
- Drainage of abscesses, epididymectomy (acute suppurative), or epididymo-orchietomy in severe cases refractory to antibiotics
- Surgery to correct underlying anatomic abnormality or obstruction

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Intractable pain
- Sepsis
- Abscess
- Persistent vomiting

- Scheduled surgery
- Purulent drainage
- Most cases can be managed with outpatient care

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Return to office if symptoms fail to improve within 72 hours of treatment for reevaluation of diagnosis and therapy (2).
- In chemical epididymitis, follow up in 4 weeks to assess efficacy of NSAIDs and lifestyle changes.

#### *DIET*

If constipation is contributing to pain or chemical epididymitis, then consider constipation prevention and/or treatment.

### *PATIENT EDUCATION*

- Stress completing course of antibiotics, even when asymptomatic
- Early recognition and treatment of UTI or prostatitis
- Safer sexual practices
- If chemical epididymitis, then educate on noninfectious etiology and proper lifestyle changes.

### *PROGNOSIS*

- Pain improves within 1 to 3 days, but induration may take several weeks/months to completely resolve.
- If bilateral involvement, sterility may result.
- In chemical epididymitis, symptoms usually resolve in <1 week.

### **COMPLICATIONS**

- Recurrent epididymitis
- Infertility
- Oligospermia

- Testicular necrosis or atrophy
- Secondary abscess formation
- Fournier gangrene (necrotizing synergistic infection)

**&NA;**

## **ICD10**

- N45.1 Epididymitis
- N45.3 Epididymo-orchitis
- N45.4 Abscess of epididymis or testis

## **Clinical Pearls**

**&NA;**

- With epididymitis, the pain is gradual in onset and the tenderness is mostly posterior to the testis. With testicular torsion, the symptoms are quite rapid in onset, the testis will be higher in the scrotum and may have a transverse lie, and the cremasteric reflex will be absent. The absence of leukocytes on urine analysis and decreased blood flow on scrotal ultrasound with Doppler will suggest torsion.
- Prostatic massage is contraindicated in epididymitis because of the risk for worsening local infection and the potential for sepsis are increased with acute prostatitis.
- Chemical epididymitis is a clinical diagnosis of exclusion, and infectious causes are much more common; but certain occupations, such as soldiers and laborers, must be considered.

# Episcleritis

Sean M. Oser, MD, MPH

Tamara K. Oser, MD

## BASICS

- Episcleritis is the localized inflammation of the vascular connective tissue superficial to the sclera.
- Usually a self-limited condition, typically resolving within 3 weeks
- Most cases resolve without treatment.
- Topical lubricants and/or topical corticosteroid treatment may relieve symptoms while awaiting spontaneous resolution.

## DESCRIPTION

- Edema and injection confined to the episcleral tissue
- Two types
  - Simple (diffuse scleral involvement) more common
  - Nodular (focal area[s] of involvement) less common

## EPIDEMIOLOGY

Slight female predominance (÷ 60-65%)

### *Incidence*

- May occur at any age
- Peak incidence in 40s to 50s
- Community incidence not well-known (÷ 20 to 50 cases/100,000 person-years)

### *Prevalence*

Not historically well-known; a recent community study found a prevalence of 53 cases/100,000 persons.

## ETIOLOGY AND PATHOPHYSIOLOGY

Etiology: Usually idiopathic, but other causes may be found (either nonimmune or immune).

### Pathophysiology

- Nonimmune (e.g., dry eye syndrome, with histology showing widespread vasodilation, edema, lymphocytic infiltration)
- Immune (systemic vasculitis or rheumatologic disease)

## COMMONLY ASSOCIATED CONDITIONS

- Usually not associated with another condition
- Less commonly associated conditions include the following:
  - Rheumatoid arthritis
  - Vasculitis
  - Inflammatory bowel disease
  - Ankylosing spondylitis
  - Systemic lupus erythematosus
  - Gout
  - Herpes zoster
  - Hypersensitivity disorders
    - Rosacea
    - Contact dermatitis
    - Penicillin sensitivity
    - Erythema multiforme

## DIAGNOSIS

Episcleritis is a clinical diagnosis (1,2)[C].

## HISTORY

- History should elicit potential causative factors, recurrence, or associated systemic disease (2)[C].
- Pain is often absent; when present, it is usually mild and localized to the eye

(1,2,3)[C].

- Mild tearing may be present (2)[C].

## **PHYSICAL EXAM**

- Check visual acuity; decreased vision is very unusual with episcleritis, and its presence should raise suspicion for another condition such as scleritis (1,2,3)[C].
- Focal hyperemia (2,4)[C]
- Pupils equal and reactive (2)[C]
- Superficial episcleral vascular dilation (1,2)[C]
- Episcleral edema (1,2)[C]
  - Diffuse in simple episcleritis
  - Focal in nodular episcleritis
- Tenderness over involved area may be present (2)[C] but is usually absent (3,4)[C].
- Superficial episcleral vascular hyperemia blanches with topical phenylephrine (1,4)[C].

## **ALERT**

Recurrent episodes, difficulty confirming the diagnosis, or worsening symptoms require prompt ophthalmology referral (2)[C].

## **DIFFERENTIAL DIAGNOSIS**

- Scleritis
- Bacterial conjunctivitis
- Viral conjunctivitis
- Herpes (ulcerative) keratitis
- Superficial keratitis
- Increased intraocular pressure (ocular hypertension)

## **DIAGNOSTIC TESTS & INTERPRETATION**

Most patients with episcleritis do not require any further lab work or diagnostic studies (5)[C].

## **TREATMENT**

## **MEDICATION**

Treatment for episcleritis typically consist of symptomatic relief. The goal is to suppress the inflammation, which will, in turn, relieve the discomfort or pain. In most cases, treatment is not needed.

### **First Line**

Topical lubricants such as artificial tears are typically used for initial management of symptomatic episcleritis (2)[C].

### **Second Line**

- Topical corticosteroids are useful when discomfort is not sufficiently controlled by conservative measures (2,5,6)[C].
  - Fluorometholone 0.1% drops 4 times daily; if not effective, may increase frequency
  - Prednisolone 0.5-1% eye drops
- Refractory episcleritis may be treated with oral NSAIDs, typically indomethacin 25 mg 3 or 4 times daily (5)[C].

---

P.353

## **ISSUES FOR REFERRAL**

Recurrent episodes, uncertain diagnosis, and/or worsening symptoms should prompt ophthalmology referral. Rarely, episcleritis may progress to scleritis in which case ophthalmology referral is also recommended.

## **ADDITIONAL THERAPIES**

- Topical NSAIDs have not been shown to have a significant benefit over artificial tears (7)[B].
- When episcleritis results from viral infection, appropriate antiviral therapy is indicated (6)[C].

## **ONGOING CARE**

### **FOLLOW-UP RECOMMENDATIONS**

Episcleritis is usually self-limited (up to 21 days) and does not typically require follow-up.

### **PROGNOSIS**

- Most patients have no ocular complications.

- Prognosis for episcleritis is excellent, with most patients making a full recovery.

## COMPLICATIONS

Associated complications are rare, even at tertiary care referral centers, where referral bias likely overestimates their community incidence. When complications do occur, they tend not to be severe.

- Anterior uveitis may occur in 4-16% of cases (1,5,6)[C].
- Decreased vision may occur in 0-4% of cases (1,5,6)[C].
- Ocular hypertension has been reported in 0-3.5% of cases (1,5,6)[C].

## Codes

**&NA;**

### ICD10

- H15.109 Unspecified episcleritis, unspecified eye
- H15.129 Nodular episcleritis, unspecified eye
- H15.102 Unspecified episcleritis, left eye

## Clinical Pearls

**&NA;**

- Episcleritis typically is a benign, self-limited disorder.
- Is often not painful and presents without decrease in visual acuity
- Although treatment is often not needed, when employed, the goal is symptomatic relief while awaiting spontaneous resolution.
- Topical lubricants and/or topical corticosteroid treatment may relieve symptoms.
- Associated complications are uncommon and not severe but may include anterior uveitis, decreased vision, and ocular hypertension.
- Episcleritis can be an early presentation of scleritis, which is more severe. Accurate diagnosis of episcleritis is important.

# Epistaxis

Brian E. Neubauer, MD

## BASICS

### DESCRIPTION

- Hemorrhage from the nose involving either the anterior or posterior mucosal surfaces
- Synonym(s): nosebleed
- Intractable or refractory epistaxis: recurrent or persistent despite appropriate packing or multiple episodes during a short period, each requiring medical attention

### EPIDEMIOLOGY

#### Incidence

- In the United States: common
- Estimated lifetime prevalence: ÷60%
- Bimodal, with peaks in children up to 15 years and in adults >50 years, particularly ages 70 to 79 years
- Most common in males <49 years.
- Rare in children <2 years.
- ÷6% of patients require medical or surgical intervention; accounts for ÷1 in 200 ER visits

### ETIOLOGY AND PATHOPHYSIOLOGY

- Local versus systemic disease. Most are due to local causes.
- Anterior: 90-95% of all cases (Kiesselbach plexus)
- Posterior: 5-10% of cases. Usually branches of sphenopalatine arteries: may be asymptomatic or may present with other symptoms (hematemesis, hemoptysis)
- Idiopathic
- Local inflammation/irritation
  - Infection (viral URI, sinusitis, TB, syphilis)

- Irritant inhalation (smoking, rhinitis)
- Topical steroid or antihistamine use
- Septal deviation (more air movement on one side)
- Low humidity, nasal oxygen use, CPAP
- Tumors: benign, malignant
- Vascular malformations
- Trauma
  - Epistaxis digitorum (nose picking)
  - Foreign bodies
  - Septal perforation
  - Nasal fracture
  - Nasal surgery
- Systemic
  - Thrombocytopenia
  - Congenital or acquired coagulopathies
  - Liver or renal disease
  - Chronic alcohol abuse
  - Leukemia
  - Anticoagulant drug use
  - CHF
  - Hereditary hemorrhagic telangiectasia (HHT)
  - Collagen abnormalities
  - Mitral valve stenosis
  - Multiple myeloma
  - Polycythemia vera

## *RISK FACTORS*

- Local irritation from multiple causes (see Etiology and Pathophysiology)

- Medications/supplements including aspirin, clopidogrel, ginseng, garlic, ginkgo biloba, warfarin, and other anticoagulants

## **GENERAL PREVENTION**

- Humidification at night
- Cut fingernails to minimize picking.
- For topical-nasal medication users, direct spray laterally away from septum. Use opposite hand to spray (i.e., right hand to spray in left nostril).
- Petroleum jelly to prevent anterior mucosal drying

## **COMMONLY ASSOCIATED CONDITIONS**

- Vascular malformation/telangiectasia (HHT)
- Neoplasm (rare, but consider in persistent unilateral cases)
- Systemic
  - Coagulopathy: primary or iatrogenic
  - Thrombocytopenia
  - Cirrhosis
  - Renal failure
  - Alcoholism
- No proven association with hypertension (HTN) but may make control of bleeding more difficult.

## **DIAGNOSIS**

### **HISTORY**

- Assess patency of airway and cardiovascular stability first.
- Initial presentation, including detail on which side bleeding began, anterior or posterior, duration.
- Trauma includes nose picking, other precipitating events.
- Previous episodes
- Comorbid conditions (cardiovascular compromise symptoms)
- Current medications including over-the-counter and supplements

## *PHYSICAL EXAM*

- Blood loss through one or both nostrils in most cases is due to anterior nasal septal bleeding and can often be directly visualized.
- Focus on localizing site of bleeding to anterior versus posterior nasal cavity.
- Patient is seated, head forward, to avoid blood going down the posterior pharynx.
- Use of nasal speculum improves visualization.

## *DIFFERENTIAL DIAGNOSIS*

- Diagnosis usually apparent; the differential for the etiology is key.
- Posterior bleeding must be included in the differential for any chronic blood loss.

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Indicated only in complicated cases and/or profuse blood loss
- Lab testing is not indicated in most uncomplicated cases in which bleeding is reasonably easily controlled and is not truly hemorrhagic.

### *Initial Tests (lab, imaging)*

- Mild cases, responsive to pressure: no labs
- For recurrent or intractable cases
- CBC, PT/PTT, BMP
- PT/PTT if on warfarin or other medications affecting coagulation.
- Cross-match when appropriate.
- Toxicology screen when nasal use of illicit drugs is suspected
- For most cases, imaging is not indicated.

### *Follow-Up Tests & Special Considerations*

If recurrent unilateral epistaxis, especially if not responding to treatment measures, consider evaluation for neoplasm.

### *Diagnostic Procedures/Other*

Nasal endoscopy

## *Pediatric Considerations*

More likely anterior, idiopathic, and recurrent

## *Geriatric Considerations*

More likely to be posterior bleed

## **TREATMENT**

- Most cases are managed as outpatient (1)[B].
- Home useÑNosebleed QR: a nonprescription powder of hydrophilic polymer with potassium salt; induces scab formation
- Patient applies direct pressure by pinching the lower part of the nose (nasal ala) for 5 to 20 minutes without a break. This will stop active bleeding in most patients.
- An ice pack placed over the dorsum of the nose may help with hemostasis.
- Inspect the nasal septum for the bleeding site.

## *GENERAL MEASURES*

Resuscitation, as indicated. Use universal ÒABCÓ approach.

---

P.355

## *MEDICATION*

### *First Line*

- If general measures fail, affected naris may be sprayed with topical vasoconstrictor, such as:
  - Phenylephrine: 0.5-1%
  - Oxymetazoline: 0.05%
  - Epinephrine: 1:1,000
  - Cocaine: 4%

### *Second Line*

- Chemical (silver nitrate) or electrical cautery
- Nasal packing: ribbon gauze, nasal tampons, nasal balloon catheter
- For intractable/refractory: Consider surgical ligation, endoscopic ligation/cautery, endovascular

embolization.

## *ISSUES FOR REFERRAL*

- Posterior bleeding frequently requires an otolaryngology consultation.
- Anterior bleeding that fails conservative measures, packing, and cauterization
- Recurrent episodes
- Patients with HHT should establish care with ENT early.

## *ADDITIONAL THERAPIES*

- Nasal packing: either with ribbon gauze or preformed nasal tampons. Systemic prophylactic antibiotics are unnecessary in the majority of patients with nasal packs; topical antibiotics may be as effective and cheaper (2)[B].
- FloSeal: A biodegradable hemostatic sealant (a thrombin-type gel) in one study is more effective and better tolerated than packing (3)[B].
- If an actively bleeding anterior septal site is visualized, this may be treated with gentle and specific silver nitrate cautery for  $\div$ 10 seconds for definitive treatment. 75% silver nitrate is preferred. Apply in a spiral fashion, starting around the bleeding vessel, moving inward.
- Limit cautery (silver nitrate) to one side of septum, or wait 4 to 6 weeks in between treatments to reduce risk of perforation.
- Posterior: posterior packing or tamponade with balloon devices (Foley catheter has been used). Inpatient monitoring is generally required.
- Recurrent epistaxis: Cochrane review in children shows no difference in effectiveness between antiseptic nasal cream, petroleum jelly, silver nitrate cautery, or no treatment (4)[A].
  - Silver nitrate cautery followed by 4 weeks of antiseptic cream may be better than antiseptic cream alone (5)[B].

## *SURGERY/OTHER PROCEDURES*

- Packing
  - Layering of Vaseline ribbon gauze (1/2 inch)
    - For gauze packing, be certain that both ends of the ribbon gauze protrude from the nostril.
    - Packing is layered from the floor upward.
    - Secure packing with gauze across the outside of the nostril.

- Nasal tampon may be used after lubricating the tip with KY Jelly or antibiotic cream or ointment.
  - Additional saline may be needed to expand the tampon if the bleeding has slowed.
  - Merocel and Rapid Rhino packs are easier to use than gauze packing and are usually well tolerated.
- Posterior bleed
    - In the emergent setting, this may be attempted utilizing a Foley catheter or a specific posterior packing balloon.
    - With both methods, the tubing is introduced through the nose similar to the passage of a nasogastric tube. Once it reaches the posterior oral pharynx, the balloon is inflated and the tubing is pulled back outward to tamponade the posterior bleeding source.
      - If using a Foley catheter (10 to 14F catheter), the balloon can be inflated with 10 mL of saline.
      - Traction is maintained with an umbilical cord clamp with adequate padding between the clip and the nose to avoid injury.

## *INPATIENT CONSIDERATIONS*

Consider hospitalization for elderly or for patients with posterior bleeding or coagulopathy. May also consider if significant comorbidities

### *Admission Criteria/Initial Stabilization*

- Posterior bleed
- Hemodynamic changes
- Clotting dysfunction
- Universal Airway/breathing/circulation (ABC) approach. Stop blood loss.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- When significant blood loss, hemodynamic monitoring

- 24-Hour minimum of packing in place; some authors recommend 3 to 5 days. The latter recommendation carries the risk of mucosal injury and toxic shock syndrome. The former has the risk of rebleed, which usually occurs between 24 and 48 hours.

## **PATIENT EDUCATION**

- Demonstrate proper pinching pressure techniques.
- Avoidance of trauma or irritants is key.
- Management of systemic illness and proper use of medication

## **PROGNOSIS**

- Most are self-limited.
- Good results with proper treatment

## **COMPLICATIONS**

- Septal perforation
- Pressure-induced tissue necrosis of the nasal mucosa
- Toxic shock syndrome with packing
- Arrhythmias triggered by packing (particularly posterior)

## Codes

**&NA;**

### ICD10

R04.0 Epistaxis

## Clinical Pearls

**&NA;**

- Most episodes are anterior in etiology and respond to timed pressure over the anterior nares for 5 to 20 minutes.
- Most are idiopathic or as a result of nose picking.
- Posterior nosebleeds can be asymptomatic or present with nausea, hematemesis, or heme-positive stool.
- Consider evaluation for neoplasm if recurrent unilateral episodes.

# Erectile Dysfunction

Michael C. Barros, PharmD, BCPS, BCACP

Neela Bhajandas, PharmD

Paul N. Williams, MD, FACP

## BASICS

### DESCRIPTION

- Erectile dysfunction (ED): the consistent or recurrent inability to acquire or sustain an erection of sufficient rigidity and duration for sexual intercourse
- In the past, ED was assumed to be a symptom of the aging process in men, but it can result from concurrent medical conditions of the patient or from medications that patients may be taking to treat those conditions.
- Sexual problems are frequent among older men and have a detrimental effect on their quality of life but are infrequently discussed with their physicians (1).
- Synonym(s): impotence

### ALERT

When ED occurs in a younger man, it is associated with a significantly increased risk of future cardiac events (2).

### EPIDEMIOLOGY

#### *Incidence*

It is estimated that >600,000 new cases of ED will be diagnosed annually in the United States, although this may be an underestimation of the true incidence, as ED is vastly underreported.

#### *Prevalence*

Overall prevalence for ED:

- 52% in men age 40 to 70 years
- Age-related increase ranging from 12.4% in men age 40 to 49 years up to 46.6% in men age 50 to 69 years

# ETIOLOGY AND PATHOPHYSIOLOGY

- ED is a neurovascular event.
  - With stimulation, there is release of nitrous oxide, which increases production of guanosine 3',5'-cyclic monophosphate (cGMP).
  - This leads to relaxation of cavernous smooth muscle, leading to increased blood flow to penis.
  - As cavernosal sinusoids distend with blood, there is passive compression of subtunical veins, which decreases venous outflow, and this leads to an erection.
- Alterations in any of these events leads to ED.
- ED may result from problems with systems required for normal penile erection.
  - Vascular: diseases that compromise blood flow
    - Peripheral vascular disease, arteriosclerosis, essential hypertension
  - Neurologic: diseases that impair nerve conduction to brain or penile vasculature
    - Spinal cord injury, stroke, diabetes
  - Endocrine: diseases associated with changes in testosterone, luteinizing hormone, prolactin levels
  - Structural: phimosis, lichen sclerosis, congenital curvature
  - Psychological: patients suffering from malaise, depression, performance anxiety
- Social habits such as smoking or excessive alcohol intake
- Medications may cause ED.
- Structural injury or trauma (bicycling accident)

## Genetics

Rarely related to chromosomal disorders

## RISK FACTORS

- Advancing age
- Cardiovascular disease
- Diabetes mellitus
- Metabolic syndrome

- Sedentary lifestyle
- Cigarette smoking
- Urologic surgery, radiation, trauma/injury to pelvic area or spinal cord
- Medications that induce ED
  - SSRIs, &agr;-blockers, clonidine, digoxin, spironolactone, antiandrogens, corticosteroids, H<sub>2</sub> blockers
- Central neurologic and endocrinologic conditions
- Substance abuse
- Psychological conditions: stress, anxiety, or depression

## GENERAL PREVENTION

The two best ways to prevent ED are by the following:

- Making healthy lifestyle choices by exercising regularly, eating well-balanced meals, limiting alcohol, and avoiding smoking
- Treating existing health problems and working with your patients to manage diabetes, heart disease, and other chronic problems

### ALERT

Aging alone is not a cause.

## COMMONLY ASSOCIATED CONDITIONS

- Cardiovascular disease:
  - Men with ED have a greater likelihood of having angina, myocardial infarction, stroke, transient ischemic attack, congestive heart failure, or cardiac arrhythmia compared to men without ED (3).
- Diabetes
- Psychiatric disorders

## DIAGNOSIS

Inability to achieve or maintain erection satisfactory for intercourse

## HISTORY

- Identify concurrent medical illnesses or surgical procedures, history of trauma, and a list of current medications (e.g., antihypertensive meds).
- Psychosocial history: smoking, ethanol intake, recreational drug use, anxiety and depression, satisfaction with current relationship
- Presence or absence of morning erections
- Speed of onset and duration of symptoms
- Relationship of symptoms to libido
- Detailed sexual history important to rule out premature ejaculation, as this is frequently confused with ED

## *PHYSICAL EXAM*

- Signs and symptoms of hypogonadism: gynecomastia, small testicles, decreased body hair
- Penile plaques (Peyronie disease)
- Detailed examination of the cardiovascular, neurologic, and genitourinary systems
  - Blood pressure
  - Check femoral and lower extremity pulses to assess vascular supply to genitals.
  - Check anal sphincter tone and genital reflexes, including cremasterics and bulbocavernosus.

## *DIFFERENTIAL DIAGNOSIS*

- Premature ejaculation
- Decreased libido
- Anorgasmia
- Sudden versus chronic ED

## *DIAGNOSTIC TESTS & INTERPRETATION*

Vascular and/or neurologic assessment, and monitoring of nocturnal erections may be indicated in selected patients but not for routine workup (4)[C].

### *Initial Tests (lab, imaging)*

- Hgb A1c, lipid panel, TSH, and morning total testosterone level (3)[C]
- Doppler, angiogram, and cavernosogram are available radiologic modalities but not recommended in routine practice for the diagnosis of ED (4)[C].

## Follow-Up Tests & Special Considerations

Other hormonal tests, such as prolactin, should only be ordered when there is suspicion for a specific endocrinopathy.

## Diagnostic Procedures/Other

Questionnaires can be offered to assess the severity of ED, including the International Index of Erectile Function (IEFF) and its validated and more easily administered abridged version, the Sexual Health Inventory for Men (SHIM) (4)[C].

## TREATMENT

- Lifestyle modifications and managing medications contributing to ED is first-line therapy for ED (5)[C]. Use least invasive therapy first; reserve more invasive therapies for nonresponders.
- Phosphodiesterase type 5 (PDE-5) inhibitor choice should be based on patient's preference (cost, ease of use, and adverse effects).

## GENERAL MEASURES

- Psychotherapy alone or in combination with psychoactive drugs may be helpful in men whose ED is related to depression or anxiety.
- Weight loss and increased physical activity for obese men with ED

## MEDICATION

### First Line

PDE-5 inhibitors are effective in the treatment of ED in many men, including those with diabetes mellitus and spinal cord injury and sexual dysfunction associated with antidepressants (3)[A].

There is insufficient evidence to support the superiority of one agent over the others (5)[A]:

- Sildenafil (Viagra): usual daily dose: 50 to 100 mg within at least 60 minutes of sexual intercourse
- Vardenafil (Levitra): usual daily dose 5 to 20 mg within at least 60 minutes of sexual intercourse

---

P.357

- Vardenafil (Staxyn): ODT: usual dose 10 mg within 60 minutes of sexual intercourse
- Tadalafil (Cialis): usual daily dose 5 to 20 mg within at least 30 minutes of sexual intercourse or 2.5 mg once daily without regard to sexual activity

- Avanafil (Stendra): usual daily dose: 50 to 200 mg within at least 15 to 30 minutes of sexual intercourse
  - Adverse effects of PDE-5 inhibitors: headache, facial flushing, dyspepsia, nasal congestion, dizziness, hypotension, increased sensitivity to light (sildenafil and vardenafil), vision changes, lower back pain (tadalafil), and priapism (with excessive doses)
  - Sildenafil and vardenafil should be taken on an empty stomach for maximum effectiveness.

## *Geriatric Considerations*

Use doses at the lower end of the dosing range for elderly patients.

- Sildenafil 25 mg daily
- Vardenafil 5 mg daily

## *Second Line*

Intraurethral and intracavernosal injectables are second-line therapies shown to be effective and should be administered based on patient preference (3)[B]. Intraurethral suppositories are a less invasive treatment option than intracavernosal injections; however, they are not as effective (5) [C]. Alprostadil, also known as prostaglandin E1, causes smooth muscle relaxation of the arterial blood vessels and sinusoidal tissues in the corpora:

- Intraurethral alprostadil (Muse):
  - Urethral suppository: 125-, 250-, 500-, and 1,000- $\mu$ g pellets. Administer 5 to 50 minutes before intercourse. No more than 2 doses in 24 hours are recommended.
- Intracavernosal alprostadil (available in 2 formulations):
  - Alprostadil (Caverject): usual dose: 10 to 20  $\mu$ g, with max dose of 60  $\mu$ g. Injection should be made at right angles into one of the lateral surfaces of the proximal third of the penis using a 0.5-inch, 27- or 30-gauge needle. Do not use >3 times a week or more than once in 24 hours.
  - Alprostadil may also be combined with papaverine (Bimix) plus phentolamine (Tri-Mix).

### **ALERT**

- Initial trial dose of second-line agents should be administered under supervision of a specialist or primary care physician with expertise in these therapies.
- Patient should notify physician if erection lasts >4 hours for immediate attention.

- Vacuum pump devices are a noninvasive second-line option and are available over the counter. Do not use vacuum devices in men with sickle cell anemia or blood dyscrasias.
- Testosterone supplementation in men with hypogonadism improves ED and libido (3)[B]. Available formulations include injectable depots, transdermal patches and gels, SC pellets, and oral therapy.
- Contraindications:
  - Nitroglycerin (or other nitrates) and phosphodiesterase inhibitors: potential for severe, fatal hypotension
  - Precautions/side effects:
    - Testosterone: *precautions*: Exogenous testosterone reduces sperm count and thus do not use in patients wishing to keep fertility; *side effects*: acne, sodium retention
    - Intraurethral suppository: local penile pain, urethral bleeding, dizziness, and dysuria
    - Intracavernosal injection: penile pain, edema and hematoma, palpable nodules or plaques, and priapism
    - Sildenafil: hypotension (caution for patients on nitrates)
    - PDE-5 inhibitors: Use caution with congenital prolonged QT syndrome, class Ia or II antiarrhythmics, nitroglycerin, &agr;-blockers (e.g., terazosin, tamsulosin), retinal disease, unstable cardiac disease, liver and renal failure.
    - Significant possible interactions
    - PDE-5 inhibitor concentration is affected by CYP3A4 inhibitors (e.g., erythromycin, indinavir, ketoconazole, ritonavir, amiodarone, cimetidine, clarithromycin, delavirdine, diltiazem, fluoxetine, fluvoxamine, grapefruit juice, itraconazole, nefazodone, nevirapine, saquinavir, and verapamil). Serum concentrations and/or toxicity may be increased. Lower starting doses should be used in these patients.
    - PDE-5 inhibitor concentration may be reduced by rifampin and phenytoin.

## ADDITIONAL THERAPIES

Behavioral therapy: Couples therapy aimed at improving relationship difficulties found that men who received this therapy plus sildenafil had more successful intercourse than those who received only sildenafil (6)[A].

## ***SURGERY/OTHER PROCEDURES***

Penile prosthesis should be reserved for patients who have failed or are ineligible first- or second-line therapies.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Trazodone, yohimbine, and herbal therapies are not recommended for the treatment of ED, as they have not proven to be efficacious.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

Treatment should be assessed at baseline and after the patient has completed at least 1 to 3 weeks of a specific treatment: Monitor the quality and quantity of penile erections, and monitor the level of satisfaction patient achieves.

#### ***DIET***

Diet and exercise recommended to achieve a normal body mass index; limit alcohol

### ***PROGNOSIS***

- All commercially available PDE-5 inhibitors are equally effective. In the presence of sexual stimulation, they are 55-80% effective.
  - Lower success rates with diabetes mellitus and radical prostatectomy patients who suffer from ED.
- Overall effectiveness is 70-90% for intracavernosal alprostadil and 43-60% for intraurethral alprostadil (4)[B].
- Penile prostheses are associated with an 85-90% patient satisfaction rate (4)[C].

## Codes

**&NA;**

### ICD10

- N52.9 Male erectile dysfunction, unspecified
- N52.1 Erectile dysfunction due to diseases classified elsewhere
- F52.21 Male erectile disorder

## Clinical Pearls

**&NA;**

- Nitrates should be withheld for 24 hours after sildenafil or vardenafil administration and for 48 hours after use of tadalafil. PDE-5 inhibitors are contraindicated in patients taking concurrent nitrates of any form (regular or intermittent nitrate therapy), as it can lead to severe hypotension and syncope.
- Reserve surgical treatment for patients who do not respond to drug treatment.
- The use of PDE-5 inhibitors with  $\alpha$ -adrenergic antagonists may increase the risk of hypotension. Tamsulosin is the least likely to cause orthostatic hypotension.
- Avanafil should not be used with strong CYP3A4 inhibitors and max dose should be 50 mg with moderate CYP3A4 inhibitors.
- ED serves as a predictor for future cardiovascular events; thus, these patients should be

followed vigilantly.

# Erysipelas

Fozia Akhtar Ali, MD

Mary Anne de la Cruz Estacio, DO

## BASICS

### DESCRIPTION

- Distinct form of cellulitis notable for acute, well-demarcated, superficial bacterial skin infection with lymphatic involvement almost always caused by *Streptococcus pyogenes*
- Usually acute, but a chronic recurrent form also exists (1)
- Nonpurulent
- System(s) affected: skin, exocrine
- Synonym(s): St. Anthony's Fire

### EPIDEMIOLOGY

- Predominant age: infants, children, and adults >40 years
- Greatest in elderly (>75 years)
- No gender/racial predilection
- Affects all races

### Incidence

- Erysipelas occurs in  $\div 1/1,000$  persons/year (2).
- Incidence on the rise since the 1980s (3)

### Prevalence

Unknown

### ETIOLOGY AND PATHOPHYSIOLOGY

- Group A streptococci induce inflammation and activation of the contact system, a proinflammatory pathway with antithrombotic activity, releasing proteinases and

proinflammatory cytokines.

- The generation of antibacterial peptides and the release of bradykinin, a proinflammatory peptide, increase vascular permeability and induce fever and pain.
- The M proteins from the group A streptococcal cell wall interact with neutrophils, leading to the secretion of heparin-binding protein, an inflammatory mediator that also induces vascular leakage.
- This cascade of reactions leads to the symptoms seen in erysipelas: fever, pain, erythema, and edema.
- Group A  $\beta$ -hemolytic streptococci primarily; commonly *S. pyogenes*, occasionally, other *Streptococcus* groups C/G
- Rarely, group B streptococci/*Staphylococcus aureus* may be involved.

## RISK FACTORS

- Disruption in the skin barrier (surgical incisions, insect bites, eczematous lesions, local trauma, abrasions, dermatophytic infections, intravenous drug user [IVDU])
- Chronic diseases (diabetes, malnutrition, nephrotic syndrome, heart failure)
- Immunocompromised (HIV)/debilitated
- Fissured skin (especially at the nose and ears)
- Toe-web intertrigo and lymphedema (2)
- Leg ulcers/stasis dermatitis
- Venous/Lymphatic insufficiency (saphenectomy, varicose veins of leg, phlebitis, radiotherapy, mastectomy, lymphadenectomy)
- Alcohol abuse
- Morbid obesity
- Recent streptococcal pharyngitis
- Varicella

## GENERAL PREVENTION

- Good skin hygiene
- It is recommended that predisposing medical conditions, such as tinea pedis and stasis dermatitis, be appropriately managed first.
- Men who shave within 5 days of facial erysipelas are more likely to have a recurrence.

- With recurrences, search for other possible sources of streptococcal infection (e.g., tonsils, sinuses).
- Compression stockings should be encouraged for patients with lower extremity edema.
- Consider suppressive prophylactic antibiotic therapy, such as penicillin, in patients with >2 episodes in a 12-month period.

## *Pediatric Considerations*

Group B *Streptococcus* may be a cause of erysipelas in neonates/infants.

## **DIAGNOSIS**

Prodromal symptoms before the skin eruption of erysipelas may include:

- Moderate- to high-grade fever
- Chills
- Headache
- Malaise
- Anorexia, usually in the first 48 hours (4)[B]
- Vomiting
- Arthralgias

### **ALERT**

It is important to differentiate erysipelas from a methicillin-resistant *S. aureus* (MRSA) infection, which usually presents with an indurated center, significant pain, and later evidence of abscess formation.

## *PHYSICAL EXAM*

- Vital signs: moderate- to high-grade fever with resultant tachycardia. Hypotension may occur.
- The presence of a fever in erysipelas can be considered a differentiating factor from other skin infections.
- Headache and vomiting may be prominent.
- Acute onset of intense erythema; well-demarcated painful plaque (5)
- Peau d'orange appearance
- Milian's ear sign (erythema involves skin of ear as well as face implies erysipelas)

- Vesicles and bullae may form but are not uniformly present.
- Desquamation may occur later.
- Lymphangitis
- Location
  - Lower extremity 70-80% of cases
  - Face involvement is less common (5-20%), especially nose and ears.
  - Chronic form usually recurs at site of the previous infection and may recur years after initial episode.
- Patients on systemic steroids may be more difficult to diagnose because signs and symptoms of the infection may be masked by anti-inflammatory action of the steroids.
- Systemic toxicity resolves rapidly with treatment; skin lesions desquamate on days 5 to 10 but usually heal without scarring.
- In geriatric patients, facial involvement presents in a butterfly pattern. Pustules characteristically absent and regional lymphadenopathy with lymphangitic streaking is seen.

### *Pediatric Considerations*

- Abdominal involvement is more common in infants, especially around umbilical stump.
- Face, scalp, and leg involvement are common in older children due to the excoriations of anterior rhinitis sicca allowing an easy port of entry.

### *Geriatric Considerations*

- Fever may not be as prominent.
- Face and lower extremity are the most common areas.
- High-output cardiac failure may occur in debilitated patients with underlying cardiac disease.
- More susceptible to complications

## ***DIFFERENTIAL DIAGNOSIS***

- Cellulitis (margins are less clear and does not involve ear)
- Necrotizing fasciitis (systemic illness and more pain)
- Skin abscess (feel for area of fluctuance)
- DVT (need to rule out if clinically suspected)

- Acute gout (check patient history)
- Insect bite (check patient history)
- Dermatophytes
- Impetigo (blistered/crusted appearance; superficial)
- Ecthyma (ulcerative impetigo)
- Herpes zoster (dermatomal distribution)
- Erythema annulare centrifugum (raised pink-red ring/bull's-eye marks)
- Contact dermatitis (no fever, pruritic, not painful)
- Giant cell urticaria (transient, wheal-appearance, severe itching)
- Angioneurotic edema (no fever)
- Scarlet fever (widespread rash with indistinct borders and without edema; rash is most common early in skin folds; develops generalized "sandpaper" feeling as it progresses)
- Toxic shock syndrome (diffuse erythema with evidence of multiorgan involvement)
- Lupus (of the face; less fever, positive antinuclear antibodies)
- Polychondritis (common site is the ear)
- Other bacterial infections to consider:
  - Meat, shellfish, fish, and poultry workers: *Erysipelothrix rhusiopathiae* (known as erysipeloid)
  - Human bite: *Eikenella corrodens*
  - Cat/dog bite: *Pasteurella multocida*/*Capnocytophaga canimorsus*
  - Salt water exposure: *Vibrio vulnificus*
  - Fresh/brackish water exposure: *Aeromonas hydrophilia*

## DIAGNOSTIC TESTS & INTERPRETATION

Reserve diagnostic tests for severely ill, toxic patients, or those who are immunosuppressed.

### *Initial Tests (lab, imaging)*

- Leukocytosis
- Blood culture (<5% positive)
- Elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)

- Streptococci may be cultured from exudate/noninvolved sites.

## *Test Interpretation*

Biopsy is not needed. However, skin findings would show

- Dermal and epidermal edema, extending into the SC tissues
- Peau d'orange appearance caused by edema in the superficial tissue surrounding the hair follicles
- Vasodilation and enlarged lymphatics
- Mixed interstitial infiltrate mainly consisting of neutrophils and mononuclear cells
- Endothelial cell swelling
- Gram-positive cocci in lymphatics and tissue with rare invasion of local blood vessels
- Fibrotic thickening of lymphatic vessel walls with possible luminal occlusion may be seen in recurrent erysipelas.

## **TREATMENT**

### *GENERAL MEASURES*

- Symptomatic treatment of myalgias and fever
- Adequate fluid intake
- Local treatment with cold compresses
- Elevation of affected extremity
- Appropriate therapy for any underlying predisposing condition

### *MEDICATION*

- Antibiotics cure 50-100% of infections, but which regimen is most successful is unclear
- Antibiotics may be as effective when given orally versus intravenously.
- A 5-day course of antibiotics may be as effective as a 10-day course at curing (6)[A].

### *First Line*

- Adults

- Extremities, nondiabetic
  - Primary
    - Penicillin G: 1 to 2 million U IV q6h *or* cefazolin 1 g IV q8h
  - Alternative (if penicillin-allergic)
    - Vancomycin 15 mg/kg IV q12h
    - When afebrile **Pen VK** 500 mg PO QID AC and HS
- Total 10 days, diabetics
  - Early-mild:
    - Trimethoprim-sulfamethoxazole (TMP-SMX)-DS: 1 to 2 tabs PO BID and penicillin VK 500 mg PO QID *or* cephalexin 500 mg PO QID
- Severe disease
  - IMP or MER or ERTA IV and linezolid 600 mg IV/PO BID. *or* vancomycin IV or daptomycin 4 mg/kg IV q24h
- Facial
  - Primary
    - Vancomycin: 15 mg/kg (actual weight) IV q8-12h with target trough 15 to 20
  - Alternative
    - Daptomycin 4 mg/kg IV q24h *or* linezolid: 600 mg IV q12h
- Children
  - Penicillin G
    - 0 to 7 days, <2,000 g: 50,000 U/kg q12h
    - 8 to 28 days, <2,000 g: 75,000 U/kg q8h
    - 0 to 7 days, >2,000 g = 50,000 U/kg q8h
    - 8 to 28 day, >2,000 g = 50,000 U/kg q6h
    - >28 days to 50,000 U/kg per day
  - Cefazolin
    - 0 to 7 days, <2,000 g: 25 mg/kg q12h

- 8 to 28 days, <2,000 g: 25 mg/kg q12h
  - 0 to 7 days, >2,000 g = 25 mg/kg q12h
  - 8 to 28 day, >2,000 g = 25 mg/kg q8h
  - >28 days to 25 mg/kg q8h
- No reported group A streptococci resistance to  $\beta$ -lactam antibiotics
  - In chronic recurrent infections, prophylactic treatment after the acute infection resolves:
    - Penicillin G benzathine: 1.2 million U IM q4wks *or* penicillin VK 500 mg PO BID *or* azithromycin 250 mg PO QD
  - If staphylococcal infection is suspected or if patient is acutely ill, consider a  $\beta$ -lactamase-stable antibiotic.
  - Consider community-acquired MRSA, and depending on regional sensitivity, may treat MRSA with TMP-SMX DS 1 tab PO BID *or* vancomycin 1 g IV q12h *or* doxycycline 100 mg PO BID

## ***ISSUES FOR REFERRAL***

Recurrent infection, treatment failure

## ***ADDITIONAL THERAPIES***

Some patients may notice a deepening of erythema after initiating antimicrobial therapy. This may be due to the destruction of pathogens that release enzymes, increasing local inflammation. In this case, treatment with corticosteroids, in addition to antimicrobials, can mildly reduce healing time and antibiotic duration in patients with erysipelas. Consider prednisolone 30 mg/day with taper over 8 days (7).

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Patient with systemic toxicity
- Patient with high-risk factors (e.g., elderly, lymphedema, postsplenectomy, diabetes)
- Failed outpatient care

### ***IV Fluids***

IV therapy if systemic toxicity/unable to tolerate PO

### ***Discharge Criteria***

No evidence of systemic toxicity with resolution of erythema and swelling

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Bed rest with elevation of extremity during acute infection, then activity as tolerated

### *Patient Monitoring*

Patients should be treated until all symptoms and skin manifestations have resolved.

### *PATIENT EDUCATION*

Stress importance of completing prescribed medication regimen

### *PROGNOSIS*

- Patients should recover fully if adequately treated.
- May experience deepening of erythema after initiation of antibiotics
- Most respond to therapy after 24 to 48 hours.
- Mortality is <1% in patients receiving appropriate treatment.
- Bullae formation suggests longer disease course, and often indicates a concomitant *S. aureus* infection that may require antibiotic coverage for MRSA.
- Chronic edema/scarring may result from chronic recurrent cases.
- Rarely, obstructive lymphadenitis may result from chronic recurrent cases.

### **COMPLICATIONS**

- Recurrent infection
- Abscess (suggests staphylococcal infection)
- Necrotizing fasciitis
- Lymphedema (most prominent risk factor for recurrence) (8)
- Bacteremia, which may lead to sepsis
- Pneumonia (due to sepsis/toxin-producing organism)
- Meningitis (due to sepsis/toxin-producing organism)
- Embolism
- Gangrene
- Bursitis, septic arthritis, tendinitis, or osteitis

---

**Codes**

&NA;

# ICD10

A46 Erysipelas

## Clinical Pearls

**&NA;**

- Athlete's foot is the most common portal of entry.
- Erysipelas is distinguished from cellulitis by its sharp, shiny, fiery-red, raised border.
- In recurrent cases, search for other possible source of streptococcal infection (e.g., tonsils, sinuses, intertrigo).
- Most erysipelas infections now occur on the legs, rather than the face.

# Erythema Multiforme

Tyler S. Rogers, MD

John Scott Earwood, MD

## BASICS

- Erythema multiforme (EM) is relatively common, acute, recurrent, self-limiting inflammatory disease.
  - Mostly (÷90% of cases) triggered by infectious agents (up to 50% by herpes simplex virus [HSV]-1 or -2), or less commonly, by drugs and vaccinations (1,2)
  - Skin lesions include acraly distributed, distinct targetoid lesions with concentric color variation, sometimes accompanied by oral, genital, or ocular mucosal lesions (1,3).
  - Flat, atypical lesions and macules with or without blisters are more suggestive of Stevens-Johnson syndrome (SJS) or toxic epidermal necrolysis (TEN) (4,5,6).
- There is no universal diagnostic criteria, but clinical history, clinical examination, skin biopsy, laboratory studies, and special consideration of persistent EM are all included in making a diagnosis.

## DESCRIPTION

- Two subtypes, erythema multiforme minor (EMm) and erythema multiforme major (EMM), with the former involving none or one mucous membrane, and the latter involving at least two mucous membrane sites. EMM is now separate from SJS and TEN (4).
- Recurrent EM is defined as >3 attacks but has a mean number of 6 attacks (range 2 to 24) per year and a mean duration of 6 to 9.5 years (range 2 to 36) (1).

## EPIDEMIOLOGY

### *Incidence*

Annual U.S. incidence is estimated at 0.01-1% (1).

### *Prevalence*

- Peak incidence in 20s and 40s; rare <3 years and >50 years of age (4)

Male > female (3:2 to 2:1)

## ETIOLOGY AND PATHOPHYSIOLOGY

- The exact pathophysiology of EM is incompletely understood but appears to be the result of a TH1-mediated immune response to an inciting event such as infection or drug exposure.
- Genetic susceptibility can be a predisposing factor in some patients with EM. Different HLA alleles have been found to be consistent in patients with EM.
- HSV containing a certain *HSV pol*, a polymerase associated with the HSV-triggered EM seems to involve autoimmune activation (1)
- With electron microscopy, there is evidence of lichenoid inflammatory infiltrate and epidermal necrosis including circulating immune complexes, deposition of C3, IgM, and fibrin around the upper dermal blood vessels.
- SJS and TEN have an increased granulysin and perforin expression within T cells than in EM (5,6).
- Previous viral infections, particularly; also Epstein-Barr, coxsackie, echovirus, varicella, mumps, polio-virus, hepatitis C, cytomegalovirus, HIV, molluscum contagiosum virus (1)
- Bacterial infections, particularly *M. pneumoniae*; other reported bacterial infections include *Treponema pallidum* and *Gardnerella vaginalis* (1)
- Medications, including NSAIDs, antibiotics, sulfonamides, and antiepileptics (1,3)
- Vaccines: stronger association with HPV, MMR, and small pox vaccines, but also associated with hepatitis B, meningococcal, pneumococcal, varicella, influenza, diphtheria-pertussis-tetanus, and *H. influenzae* (2,7)
- Occupational exposures: herbicides (alachlor and butachlor), iodoacetonitrile
- Radiation therapy
- Premenstrual hormone changes (3)
- Malignancy (3)

### Genetics

Strong association with HLA-DQB10301, particularly in herpes-related cases (1); possible association in recurrent cases with HLA-B35, -B62, -DR53

## RISK FACTORS

Previous history of EM

## GENERAL PREVENTION

- Known or suspected etiologic agents should be avoided.
- Acyclovir or valacyclovir may help prevent herpes-related recurrent EM.

## COMMONLY ASSOCIATED CONDITIONS

See "Etiology and Pathophysiology" earlier.

## DIAGNOSIS

Clinical

### HISTORY

- Absent or mild prodromal symptoms
- Acute, self-limiting, episodic course
- History of new medication
- Preceding HSV infection 10 to 15 days before the skin eruptions
- Rash involving the skin and sometimes the mucous membrane, most commonly the mouth.
- Symptoms of any of the infections associated with EM, most commonly HSV and *Mycoplasma pneumoniae*

## PHYSICAL EXAM

- Acral extremities
- Symmetric cutaneous eruptions composed of targetoid lesions with concentric color variation.
- Mucosal involvement
  - Oral involvement manifest as erythema, erosions, bullae, and ulcerations on both nonkeratinized and keratinized mucosal surfaces and on the vermilion of the lips. Minimal involvement in EMM, if present, most commonly involves the mouth.
  - Can include any mucosal tissue including genital, ocular, oral, and so forth
  - At least two mucosal sites involved in EMM, including eyes (conjunctivitis, keratitis); mouth (stomatitis, cheilitis, characteristic blood-stained crusted erosions on lips); and probable trachea, bronchi, GI tract, or genital tract (balanitis and vulvitis) (6)

## DIFFERENTIAL DIAGNOSIS

- SJS
  - Generalized distribution of lesions; concentrated on the trunk
  - Macular atypical targetoid lesions
  - Flat target lesions or macules with coalescence of lesions
  - Blisters and skin detachment <10% of the total body surface area (6)
  - 1-5% mortality (4)
  - Presence of constitutional symptoms with presence of high fever (>38.5°C) more likely with SJS than EM
  - More likely to have mucosal involvement at <sup>3</sup>2 sites, lymphadenopathy, high C-reactive protein levels (>10 mg/dL), and hepatic dysfunction, and >90% have severe mucosal involvement at least at one site (1)
- TEN
  - Similar to SJS but has full-thickness skin necrosis and skin detachment >30% of the total body surface area (6,8)
  - 34-40% mortality rate (4)
- Urticaria
- Fixed drug eruption
- Bullous pemphigoid
- Paraneoplastic pemphigoid
- Sweet syndrome
- Rowell syndrome
- Polymorphus light eruption
- Cutaneous small-vessel vasculitis
- Mucocutaneous lymph node syndrome
- Erythema annulare centrifugum
- Acute hemorrhagic edema of infancy
- Subacute cutaneous lupus erythematosus
- Contact dermatitis
- Pityriasis rosea

HSV

- Secondary syphilis
- Tinea corporis
- Dermatitis herpetiformis
- Herpes gestationis
- Septicemia
- Serum sickness
- Viral exanthem
- Rocky Mountain spotted fever
- Meningococemia
- Lichen planus
- Behçet syndrome
- Recurrent aphthous ulcers
- Herpetic gingivostomatitis
- Granuloma annulare

---

P.361

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- No lab test is indicated to make the diagnosis of EM (1,4,9).
- Skin biopsy of lesional and perilesional tissue in equivocal conditions
- Direct and indirect immunofluorescence (DIF and IIF) to differentiate EM from other vesiculobullous diseases. DIF is detected on a biopsy of perilesional skin, and IIF is detected from a blood sample (1).
- HSV tests in recurrent EM (serologic tests, swab culture, or tests using skin biopsy sample to check HSV antigens or DNA in keratinocytes by DIF or direct fluorescent antibody [DFA] or polymerase chain reaction [PCR])
- Antibody staining to IFN- $\gamma$ ; and TNF- $\alpha$ ; to differentiate HSV from drug-associated EM
- As the second most common cause of EM, *M. pneumoniae* should be worked up with CXR, swabs, and serologic test.
- In persistent EM, check complement levels (1).

## Initial Tests (lab, imaging)

No imaging studies are indicated in most cases unless there is suspicion for *M. pneumoniae*.

## Follow-Up Tests & Special Considerations

Chest x-ray may be necessary if an underlying pulmonary infection (*M. pneumoniae*) is suspected.

## Test Interpretation

- Vacuolar interface dermatitis with CD4<sup>+</sup> T lymphocytes and histiocytes in papillary dermis and the dermal-epidermal junction
- Superficial perivascular lymphocytic inflammation
- Satellite cell necrosis
- Necrotic keratinocytes mainly in the basal layer
- Papillary dermal edema

## TREATMENT

### GENERAL MEASURES

- Step 1 DISCONTINUE OR TREAT INCITING FACTOR (1,4,9)
- Wound care for severe cases with epidermal detachment.
- Oral lesions should be addressed to insure maintenance of PO intake. This can include oral anesthetic solutions and antiseptic rinses.

### MEDICATION

- Acute EM
  - Discontinuation of inciting factors and treatment of underlying disease (1,4,9)[B]
  - Symptomatic treatment with oral antihistamines and topical (1)[B]
  - HSV-induced EM: Most recent sources report no proven effect on the course of EM using antivirals with acute mild EM (1,9)[B]
  - *M. pneumoniae*-associated EM may require antibiotics.
- Mucosal membrane EM
  - Consider high-potency topical corticosteroid gel, oral antiseptic, and oral anesthetic

solutions if mild.

- If more severe, consider prednisone 40 to 60 mg/day with dosage tapered over 2 to 4 weeks (1)[B].
- Ophthalmology consultation is imperative for ocular involvement (4)[A].
- Recurrent EM
  - First-line treatment for HSV-associated and idiopathic recurrent EM is antiviral prophylaxis; 12 to 24 months of prophylaxis is most effective (1,10)[B].
  - Therapy includes acyclovir 400 mg BID, valacyclovir 500 mg BID, famciclovir 250 mg BID (1)[B]
  - Second-line therapy includes dapsone (100 to 150 mg/day), azathioprine (Imuran, 100 to 150 mg/day), thalidomide (100 to 200 mg/day), tacrolimus (0.1% ointment daily), mycophenolate mofetil (CellCept 1,000 to 1,500 mg BID), hydroxychloroquine (400 mg/day) (1)[B]

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

- Care at home
- Hospitalization needed for fluid and electrolyte management in patient with severe mucous membrane involvement, impaired oral intake, and dehydration
- IV antibiotics if secondary infection develops

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- The disease is self-limiting.
- Complications are rare, with no mortality.

#### ***DIET***

As tolerated, with increased fluid intake

### ***PATIENT EDUCATION***

- The disease is self-limiting. However, the recurrence risk may be 30%.
- Avoid any identified etiologic agents.

## PROGNOSIS

- Rash evolves over 1 to 2 weeks and subsequently resolves within 2 to 6 weeks, generally without scarring or sequelae.
- Following resolution, there may be some postinflammatory hyper- or hypopigmentation.

## COMPLICATIONS

Secondary infection

## Codes

**&NA;**

### ICD10

- L51.9 Erythema multiforme, unspecified
- L51.8 Other erythema multiforme
- L51.0 Nonbullous erythema multiforme

## Clinical Pearls

**&NA;**

- EM is diagnosed clinically by careful review of the history, thorough detailed physical exam, and by excluding other similar disorders. No lab tests are required for the diagnosis.
- Typical lesions are characteristic targetoid or ØirisÓ lesions but can include raised targetoids.
- Lesions are symmetrically distributed on palms, soles, dorsum of the hands, and extensor surfaces of extremities and face. The oral mucosa is the most affected mucosal region in EM.
- Management of EM involves determining the etiology when possible. The first step is to treat the suspected infection or discontinue the causative drug.
- Complications are rare. Most cases are self-limited. However, the recurrence risk may be as

high as 30%.

- Recurrent cases often are secondary to HSV infection. Antiviral therapy may be beneficial.

# Erythema Nodosum

Faruq Pradhan, MBBCh

Fredric D. Gordon, MD, AGAF

## BASICS

### DESCRIPTION

- A delayed-type hypersensitivity reaction to various antigens, or an autoimmune reaction presenting as a panniculitis that affects subcutaneous fat
- Clinical pattern of multiple, bilateral, erythematous, tender nodules in a typically pretibial distribution that undergo a characteristic pattern of color changes, similar to that seen in bruises. Unlike erythema induratum, the lesions of erythema nodosum (EN) do not typically ulcerate.
- Occurs most commonly on the shins; less commonly on the thighs, forearms, trunk, head, or neck
- Often associated with nonspecific prodrome including fever, weight loss, and arthralgia
- Often idiopathic but may be associated with a number of clinical entities
- Usually remits spontaneously in weeks to months without scarring, atrophy, or ulceration
- Uncommon to have recurrences after initial presentation

### *Pregnancy Considerations*

May have repeat outbreaks during pregnancy

### *Pediatric Considerations*

Rare pediatric variant has lesions only on palms or soles, often unilateral. Typically has a shorter duration in children than adults.

## EPIDEMIOLOGY

### *Incidence*

- 1 to 5/100,000/year
- Predominant age: 20 to 30 years

- Predominant sex: female > male (6:1) in adults

## Prevalence

Varies geographically depending on the prevalence of disorders associated with EN

## ETIOLOGY AND PATHOPHYSIOLOGY

- Idiopathic: up to 55%
- Infectious: 44%. Streptococcal pharyngitis (most common), mycobacteria, mycoplasma, chlamydia, mycoplasma, coccidioidomycosis, rarely can be caused by *Campylobacter* spp., rickettsiae, *Salmonella* spp., psittacosis, syphilis
- Sarcoidosis: 11-25%
- Drugs: 3-10%. Sulfonamides, amoxicillin, oral contraceptives, bromides, azathioprine, vemurafenib
- Pregnancy: 2-5%,
- Enteropathies: 1-4%. Ulcerative colitis, Crohn disease, Behçet disease, celiac disease, diverticulitis
- Rare causes: <1% (1)
  - Fungal: dermatophytes, coccidioidomycosis, histoplasmosis, blastomycosis
  - Viral/chlamydial: infectious mononucleosis, lymphogranuloma venereum, paravaccinia, HIV
  - Malignancies: lymphoma/leukemia, sarcoma, myelodysplastic syndrome
  - Sweet syndrome

## RISK FACTORS

See òEtiology and Pathophysiology.ó

## COMMONLY ASSOCIATED CONDITIONS

See òEtiology and Pathophysiology.ó

## DIAGNOSIS

### HISTORY

- Often a prodrome 1 to 3 weeks prior to onset of lesions; can consist of malaise, fever, weight loss, cough, and arthralgia

- Increasingly tender nodules on the legs, usually over the shins
- Fever, malaise, chills, fatigue
- Headache
- Can precede systemic process by weeks

## PHYSICAL EXAM

- Lesions initially present as warm, tender, erythematous firm nodules and become fluctuant, gradually fading to resemble a bruise over 1 to 2 months (erythema contusififormis).
- Typically pretibial, although can extend proximally to involve thighs or trunk (atypically can involve extensor surface of forearms)
- Diameter varies from 1 to 10 cm with poor demarcation.

## DIFFERENTIAL DIAGNOSIS

- Nodular vasculitis or erythema induratum (warm ulcerating calf nodules)
- Superficial thrombophlebitis
- Cellulitis
- Weber-Christian disease (violaceous, scarring nodules)
- Lupus panniculitis
- Cutaneous polyarteritis nodosa
- Sarcoidal granulomas
- Cutaneous T-cell lymphoma
- EN leprosum (clinically similar to EN but shows vasculitis on histopathology)
- Subcutaneous infection (including staphylococcus, *Sporothrix schenckii*, *Nocardia brasiliensis*, *Mycobacterium marinum*, *Leishmania braziliensis*)

## DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis is made clinically, with support of testing

- ESR or C-reactive protein (CRP): often elevated, but can be normal in up to 40% (2)[C]
- CBC: mild leukocytosis (2)[C]
- Urine pregnancy test (2)[C]
- Throat culture, antistreptolysin O titer (2)[C]

- Blood and/or stool culture, stool ova and parasites (O&P)
- Tuberculin skin testing (2)[C]
- Seronegative rheumatoid factor

### *Initial Tests (lab, imaging)*

CXR for hilar adenopathy or infiltrates related to sarcoidosis or tuberculosis (2)[C]

### *Diagnostic Procedures/Other*

Deep-incisional or excisional skin biopsy including subcutaneous tissue; rarely necessary except in atypical cases with ulceration, duration >12 weeks, or absence of nodules overlying lower limbs (3)[C]

### *Test Interpretation*

- Septal panniculitis without vasculitis
- Neutrophilic infiltrate in septa of fat tissue early in course
- Actinic radial (Miescher) granulomas, consisting of collections of histocytes around a central stellate cleft, may be seen.
- Fibrosis, paraseptal granulation tissue, lymphocytes, and multinucleated giant cells predominate late in course (4).

## **TREATMENT**

- Condition usually self-limited within 1 to 2 months
- All medications listed as treatment for EN are offlabel uses of the medications. There are no specific FDA-approved medications.

---

P.363

## **GENERAL MEASURES**

- Mild compression bandages and leg elevation may reduce pain. (Wet dressings, hot soaks, and topical medications are not useful.)
- Discontinue potentially causative drugs.
- Treat underlying disease.
- Indication for treatment is poorly defined in literature; hence, therapy specifically for EN is directed towards symptom management.

# MEDICATION

## First Line

- NSAIDs:
  - Ibuprofen 400 mg PO q4-6h (not to exceed 3,200 mg/day)
  - Indomethacin 25 to 50 mg PO TID
  - Naproxen 250 to 500 mg PO BID
- Precautions
  - GI upset/bleeding (avoid in Crohn or ulcerative colitis)
  - Fluid retention
  - Renal insufficiency
  - Dose reduction in elderly, especially those with renal disease, diabetes, or heart failure
  - May mask fever
  - NSAIDs can increase cardiovascular (CV) risk.
- Significant possible interactions
  - May blunt antihypertensive effects of diuretics and  $\beta$ -blockers
  - NSAIDs can elevate plasma lithium levels.
  - NSAIDs can cause significant elevation and prolongation of methotrexate levels.

## Second Line

- Potassium iodide 400 to 900 mg/day divided BID or TID for 3 to 4 weeks (for persistent lesions); need to monitor for hyperthyroidism with prolonged use; pregnancy class D (5)[B]
- Corticosteroids for severe, refractory, or recurrent cases in which an infectious workup is negative. Prednisone 1 mg/kg/day for 1 to 2 weeks is the recommended dose/duration. Potential side effects include hyperglycemia, hypertension, weight gain, worsening gastroesophageal reflux disease, mood changes, bone loss, osteonecrosis, and proximal myopathy (1)
- For EN related to Behçet disease, one can also consider colchicine 0.6 to 1.2 mg BID. Potential side effects include GI upset and diarrhea (6)[B].

# INPATIENT CONSIDERATIONS

## *Admission Criteria/Initial Stabilization*

Occasionally, admission may be needed for the antecedent illness (e.g., tuberculosis).

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Keep legs elevated
- Elastic wraps or support stockings may be helpful when patients are ambulating.

### *Patient Monitoring*

Monthly follow-up or as dictated by underlying disorder

### *DIET*

No restrictions

### *PATIENT EDUCATION*

- Lesions will resolve over a few weeks to months
- Scarring is unlikely.
- Joint aches and pains may persist.
- <20% recur

### *PROGNOSIS*

- Individual lesions resolve generally within 2 weeks.
- Total time course of 6 to 12 weeks but may vary with underlying disease.
- Joint aches and pains may persist for years.
- Lesions do not scar.
- Recurrences: occurs over variable periods, averaging several years; seen most often in sarcoid, streptococcal infection, pregnancy, and oral contraceptive use. If medication induced, avoid recurrent exposure.

### **COMPLICATIONS**

- Vary according to underlying disease
- None expected from lesions of EN

**&NA;**

## **ICD10**

- L52 Erythema nodosum
- A18.4 Tuberculosis of skin and subcutaneous tissue

## **Clinical Pearls**

**&NA;**

- Lesions of EN appear to be erythematous patches, but when palpated, their underlying nodularity is appreciated.
- Evaluation for a concerning underlying etiology is necessary in EN, but most cases are idiopathic.
- EN in the setting of hilar adenopathy may be seen with multiple etiologies and does not exclusively indicate sarcoidosis.
- In patients with a history of Hodgkin lymphoma, EN may be an early sign of recurrence.

# Esophageal Varices

Edward Feller, MD, FACP, FACG

## BASICS

### DESCRIPTION

- Dilated distal esophageal veins connecting the portal and systemic circulations
- Results from portal hypertension (most commonly due to liver cirrhosis), resistance to portal blood flow, and increased portal venous blood inflow
- Superficial location of distal esophageal veins makes them susceptible to rupture.
- Esophageal variceal rupture: Most common fatal complication of cirrhosis; severity of liver disease correlates with presence of varices and risk of bleeding.

### EPIDEMIOLOGY

#### *Incidence*

- At diagnosis, 30% of cirrhotic patients have varices; increases to 90% at 10 years (1).
- 1-year rate of first variceal bleeding is 5% for small varices, 15% for large varices.

#### *Pediatric Considerations*

Portal hypertension is common in chronic liver disease in children. No clear guidelines for screening; pharmacologic or endoscopic treatment are equivalent (2)[A].

#### *Prevalence*

- 50% of patients with esophageal varices will experience bleeding at some point.
- Variceal bleeding: 15-20% mortality in the following 6 weeks after the episode
- Gender: male > female

### ETIOLOGY AND PATHOPHYSIOLOGY

- Fibrous tissue and regenerative nodules in cirrhosis lead to splanchnic arteriolar vasodilatation, increased portal inflow, and increased resistance to outflow resulting in portal hypertension. Increased production of endothelin-1 and decreased production of nitrous oxide causes

intrahepatic vasoconstriction, with further reduction in flow (1).

- Portal hypertension: pressure gradient  $>10$  mm Hg between the portal vein and inferior vena cava. Collateral vessels (varices) form to decompress portal circulation.
- Cirrhotic portal hypertension
  - $>90\%$  of cases due to alcohol and HCV
  - Less common: hemochromatosis, hepatitis B, nonalcoholic fatty liver disease, primary biliary cirrhosis and autoimmune cirrhosis
- Noncirrhotic portal hypertension
  - Extrahepatic portal or splenic vein thrombosis, trauma, chronic pancreatitis, thrombotic disease, polycythemia
  - Metastasis to liver sinusoids/portal vein: lymphoma, leukemia, hepatoma, or other carcinomas
  - Metabolic disease altering liver sinusoids: amyloidosis, Gaucher disease, Budd-Chiari syndrome, veno-occlusive disease

## *Genetics*

Cirrhosis is rarely hereditary.

## **RISK FACTORS**

- Cirrhosis due to any cause
- In cirrhotic patients, thrombocytopenia and splenomegaly, correlated with portal hypertension, are independent predictors of esophageal varices.
- Noncirrhotic portal hypertension
- Increased bleeding risk in known varices include varix size and endoscopic signs (red wale marks, cherry-red spots); vessel wall thickness; abrupt increase in variceal pressure (i.e., Valsalva maneuver)
- MELD/Child-Pugh score; presence of portal vein thrombosis; high hepatic venous pressure gradient [HVPG])

## **GENERAL PREVENTION**

- Prevent underlying causes: alcoholism, hepatitis B vaccine, needle hygiene, detox in IV drug use (IVDU) to avoid HCV exposure; specific screening and therapy for hepatitis B and C, hemochromatosis (1)

- See "Treatment" for prevention of first and second bleeds.

## COMMONLY ASSOCIATED CONDITIONS

- Portal hypertensive gastropathy; varices in stomach, duodenum, colon, rectum (causes massive bleeding, unlike hemorrhoids); rarely at umbilicus (caput medusa) or ostomy sites
- Isolated gastric varices can occur due to splenic vein thrombosis/stenosis from hypercoagulability/contiguous inflammation (most commonly, chronic pancreatitis). Tumors can compress/infiltrate the splenic vein leading to pressure increase in short gastric veins. Signs of portal hypertension or esophageal varices may be absent (3).
- Other complications of cirrhosis: hepatic encephalopathy, ascites, hepatorenal syndrome, spontaneous bacterial peritonitis, hepatocellular carcinoma

## DIAGNOSIS

- First indication of varices often associated with GI bleeding episode: painless hematemesis, hematochezia, and/or melena
- Occult bleeding (anemia): uncommon

## HISTORY

- Underlying history of cirrhosis/liver disease. Variceal bleed can be initial presentation of previously undiagnosed cirrhosis.
- Alcoholism, exposure to blood-borne viruses
- Hematemesis, melena, or hematochezia
- Rapid upper GI bleed can present as rectal bleeding.

## PHYSICAL EXAM

- Assess hemodynamic stability: hypotension, tachycardia (active bleeding).
- Assess airway integrity.
- Abdominal exam—liver palpation/percussion (often small and firm with cirrhosis)
- Splenomegaly, ascites (shifting dullness; puddle splash)
- Visible abdominal periumbilical collateral circulation (caput medusae)
- Peripheral stigmata of alcoholism: spider angiomas on chest/back, palmar erythema, testicular atrophy, gynecomastia
- Anal varices (which collapse with digital pressure, whereas hemorrhoids do not)

- Hepatic encephalopathy; asterixis
- Blood on rectal exam

## ***DIFFERENTIAL DIAGNOSIS***

- Upper GI bleeding: 10-30% are due to varices.
  - In patients with known varices, as many as 50% bleed from nonvariceal sources.
  - Peptic ulcer; gastritis
  - Gastric/esophageal malignancy
  - Congestive gastropathy of portal hypertension
  - Arteriovenous malformation
  - Mallory-Weiss tears
  - Aortoenteric fistula
  - Hemoptysis; nosebleed
- Lower GI bleeding
  - Rectal varices; hemorrhoids
  - Colonic neoplasia
  - Diverticulosis/arteriovenous malformation
  - Rapidly bleeding upper GI site
- Continued/recurrent bleeding risk: actively bleeding/large varix, high Childs-Pugh severity score, infection, renal failure

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Anemia: Hemoglobin may be normal in active bleeding; may require 6 to 24 hours to equilibrate; other causes of anemia are common in cirrhotics.
- Thrombocytopenia: most sensitive and specific lab parameter, correlates with portal hypertension, large esophageal varices
- Abnormal aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, bilirubin; prolonged PT, low albumin suggest cirrhosis (4).
- BUN, creatinine (BUN often elevated in GI bleed)

- Esophagogastroduodenoscopy (3)[A]
  - Can identify actively bleeding varices as well as large varices and stigmata of recent bleeding
  - Can treat bleeding with esophageal band ligation (preferred to sclerotherapy); prevent rebleeding; detect gastric varices, portal hypertensive gastropathy; diagnose alternative bleeding sites
  - Can identify and treat nonbleeding varices appearing as protruding submucosal veins in the distal third of the esophagus

## *Diagnostic Procedures/Other*

- HVP  $>10$  mm Hg: significant portal hypertension (normal: 1 to 5 mm Hg) (3)[A]
- Video capsule endoscopy screening: may be an alternative for those unwilling to undergo screening endoscopy
- Doppler sonography (second line): demonstrates patency, diameter, and flow in portal and splenic veins, and collaterals; very sensitive for gastric varices; documents patency after ligation or transjugular intrahepatic portosystemic shunt (TIPS).
- MRI (second line, not routine): demonstrates large vascular channels in abdomen, mediastinum; demonstrates patency of intrahepatic portal and splenic vein
  - Venous-phase celiac arteriography: demonstrates portal vein and collaterals; diagnoses hepatic vein occlusion
  - Portal pressure measurement using retrograde catheter in hepatic vein

## **TREATMENT**

### *GENERAL MEASURES*

- Treat underlying comorbidities related to cirrhosis.
- Variceal bleeding is often complicated by hepatic encephalopathy and infection.
- Active bleeding (5)[A]
  - IV access, hemodynamic resuscitation
  - Type and crossmatch packed RBCs. Overtransfusion increases portal pressure and increases rebleeding risk.

- Treat coagulopathy as necessary. Fresh frozen plasma may increase blood volume and increase rebleeding risk.
- Avoid sedation, monitor mental status, and avoid nephrotoxic drugs and  $\beta$ -blockers acutely.
- Thiamine replacement as indicated, monitor blood glucose, risk for alcohol withdrawal, and delirium tremens
- IV octreotide to lower portal venous pressure as adjuvant to endoscopic management. IV bolus of 50  $\mu$ g followed by drip of 50  $\mu$ g/hr.
- Terlipressin (alternative): 2 mg q4h IV for 24 to 48 hours, then 1 mg q4h
- Urgent upper GI endoscopy for diagnosis and treatment
  - Variceal band ligation preferred to sclerotherapy for bleeding varices. Also for nonbleeding medium-to-large varices to decrease bleeding risk
  - Ligation: lower rates of rebleeding, fewer complications, more rapid cessation of bleeding, higher rate of variceal eradication.
- Repeat ligation/sclerosant for rebleeding.
- If endoscopic treatment fails to stop bleeding, consider per oral placement of Sengstaken-Blakemore-type tube to stabilize patient for TIPS.
- As many as 2/3 of patients with variceal bleeding develop an infection, most commonly spontaneous bacterial peritonitis, UTI, or pneumonia. Antibiotic prophylaxis with oral norfloxacin 400 mg or IV ceftriaxone 1 g q12h for up to a week.
- In active bleeding, avoid  $\beta$ -blockers, which decrease BP and blunt the physiologic increase in heart rate during acute hemorrhage.
- Prevent recurrence of acute bleeding
  - Vasoconstrictors: terlipressin, octreotide (reduce portal pressure)
  - Endoscopic band ligation (EBL): if bleeding recurs/portal pressure measurement shows portal pressure remains  $>12$  mm Hg
  - TIPS: Second-line therapy if above methods fail; TIPS decreases portal pressure by creating communication between hepatic vein and an intrahepatic portal vein branch.

## MEDICATION

Primary prevention of variceal bleeding (6)[A]

- Endoscopy: assesses variceal size, presence of red wale sign (longitudinal variceal reddish

streak that suggests either a recent bleed or a pending bleed) to determine risk stratification

- Endoscopy every 2 to 3 years if cirrhosis but no varices; every 1 to 2 years if small varices and not receiving  $\beta$ -blockers

### *First Line*

- (Not actively bleeding). Nonselective  $\beta$ -blockers reduce portal pressure and decrease risk of first bleed from 25% to 15% in primary prophylaxis. Used in cirrhosis with small varices and increased hemorrhage risk, as well as cirrhosis + medium-to-large varices (6)[A]
  - Propranolol: 20 mg BID increase until heart rate decreased by 25% from baseline
  - Nadolol 80 mg daily; increase as above
  - Contraindications: severe asthma
- Chronic prevention of rebleeding (secondary prevention): Nonselective  $\beta$ -blockers and EBL reduce rate of rebleeding to a similar extent, but  $\beta$ -blockers reduce mortality, whereas ligation does not (7)[A].

### *Second Line*

Obliteration of varices with esophageal banding for those intolerant of medication prophylaxis

- During ligation: proton pump inhibitors, such as lansoprazole 30 mg/day, until varices obliterated

## *ISSUES FOR REFERRAL*

Referral considerations include endoscopy, liver transplantation, and interventional radiology for TIPS.

## *ADDITIONAL THERAPIES*

Patients should receive pneumococcal vaccine and hepatitis A/B virus (HAV/HBV) vaccine.

## *SURGERY/OTHER PROCEDURES*

- Esophageal transection: in rare cases of uncontrollable, exsanguinating bleeding
- Liver transplantation

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Inpatient for acute bleeding and hemodynamic stabilization, therapeutic endoscopy. ICU care is the most appropriate initially.

## *Discharge Criteria*

Bleeding cessation; hemodynamic stability and appropriate treatment plan for comorbidities

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Close monitoring of vital signs.
- Endoscopic variceal ligation, repeated every 1 to 4 weeks until varices eradicated
- If TIPS, repeat endoscopy for rebleeding.
- Endoscopic screening in patients with known cirrhosis every 2 to 3 years; yearly in patients with decompensated cirrhosis

### *PATIENT EDUCATION*

National Digestive Information Clearinghouse, (<http://www.niddk.nih.gov/health-information/health-topics/digestive-diseases/Pages/default.aspx>) or American Liver Foundation, (<http://www.liverfoundation.org/>)

### *PROGNOSIS*

- Depends on underlying comorbidities
- In cirrhosis, 1-year survival is 50% for those surviving 2 weeks following a variceal bleed.
- In-hospital mortality remains high related to severity of underlying cirrhosis, ranging from 0% in Child A to 32% in Child C disease (5).
- Prognosis in noncirrhotic portal fibrosis is better than for cirrhotics.

### **COMPLICATIONS**

- Formation of gastric varices or varices in other uncommon locations may occur after eradication of esophageal varices.
- Esophageal varices can recur.
- Hepatic encephalopathy, renal dysfunction, hepatorenal syndrome
- Infections are common after banding/ligation of varices.

&NA;

## Codes

**&NA;**

### ICD10

- I85.00 Esophageal varices without bleeding
- I85.01 Esophageal varices with bleeding
- I85.10 Secondary esophageal varices without bleeding

## Clinical Pearls

**&NA;**

- Cirrhosis is the most common underlying cause of esophageal variceal bleeding.
- In acute bleeding, avoid  $\beta$ -blockers, which decrease BP and blunt the physiologic increase in heart rate.
- In acute bleeding, overtransfusion can elevate portal pressure and increases bleeding risk.
- Thrombocytopenia is the most sensitive marker of increased portal pressure, large esophageal varices.
- During bleeding, consider antibiotic prophylaxis for spontaneous peritonitis and other infections with IV ciprofloxacin or oral norfloxacin for 7 to 10 days.

# Essential Tremor Syndrome

Jonathon M. Firnhaber, MD

## BASICS

### DESCRIPTION

- A postural (occurring with voluntary maintenance of a position against gravity) or kinetic (occurring during voluntary movement) flexion-extension tremor that is slow and rhythmic and primarily affects the hands and forearms, head, and voice with a frequency of 4 to 12 Hz
- Older patients tend to have lower frequency tremors, whereas younger patients exhibit frequencies in the higher range.
- May be familial, sporadic, or associated with other movement disorders
- Can begin at any age but the incidence and prevalence increase with age
- The tremor can be exacerbated by emotional or physical stresses, fatigue, and caffeine.
- System(s) affected: neurologic, musculoskeletal, ear/nose/throat (ENT) (voice)

### EPIDEMIOLOGY

Essential tremor is the most common pathologic tremor in humans.

#### *Incidence*

- Can occur at any age but bimodal peaks exist in the 2nd and 6th decades
- Incidence rises significantly after age 49 years.

#### *Prevalence*

The overall prevalence for essential tremor has been estimated between 0.4% and 0.9% but is increased in older (65 years) patients to 4.6% and in advanced age (95 years) up to 22% (1)[B].

### ETIOLOGY AND PATHOPHYSIOLOGY

- Suspected to originate from an abnormal oscillation within thalamocortical and cerebello-olivary loops, as lesions in these areas tend to reduce essential tremor
- Essential tremor is not a homogenous disorder; many patients have other motor

manifestations and nonmotor features, including cognitive and psychiatric symptoms.

## Genetics

- Positive family history in 50-70% of patients; autosomal dominant inheritance is demonstrated in many families, but twin studies suggest that environmental factors are also involved.
- A link to genetic loci exists on chromosomes 2p22-2p25, 3q13, and 6p23. In addition, a Ser9Gly variant in the dopamine D<sub>3</sub> receptor gene on 3q13 has been suggested as a risk factor.

## COMMONLY ASSOCIATED CONDITIONS

- Can be present in 10% of patients with Parkinson disease (PD); characteristics of PD that distinguish it from essential tremor include 3- to 5-Hz resting tremor; accompanying rigidity, bradykinesia, or postural instability; and no change with alcohol consumption.
- Patients with essential tremor have a 4% risk of developing PD. Although action tremors may precede PD, they will be diagnosed as essential tremor as long as the bradykinesia and rigidity of PD are not yet present (1)[B].
- Resting tremor, typically of the arm, may be seen in up to 20-30% of patients with essential tremor. Although action tremor is the hallmark feature of essential tremor, it is commonly found in patients with PD as well.

## DIAGNOSIS

### HISTORY

- Core criteria for diagnosis
  - Bilateral (less likely unilateral) action (postural or kinetic) tremor of the hands and forearms that is most commonly asymmetric
  - Absence of other neurologic signs, with the exception of cogwheel phenomenon
  - May have isolated head tremor with no signs of dystonia
- Secondary criteria include long duration (>3 years), positive family history, and beneficial response to alcohol (2)[C].

## PHYSICAL EXAM

- Tremor can affect upper limbs (÷95% of patients).
- Less commonly, the tremor affects head (÷34%), lower limbs (÷30%), voice (÷12%), tongue

(÷7%), face (÷5%), and trunk (÷5%).

## ***DIFFERENTIAL DIAGNOSIS***

- PD
- Wilson disease
- Hyperthyroidism
- Multiple sclerosis
- Dystonic tremor
- Cerebellar tremor
- Asterixis
- Psychogenic tremor
- Orthostatic tremor
- Drug-induced or enhanced physiologic tremor (amiodarone, cimetidine, lamotrigine, itraconazole, valproic acid, SSRIs, steroids, lithium, cyclosporine, & bgr;-adrenergic agonists, ephedrine, theophylline, tricyclic antidepressants [TCAs], antipsychotics) (3)[B].

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- No specific biologic marker or diagnostic test is available.
- Ceruloplasmin and serum copper to rule out Wilson disease
- Thyroid-stimulating hormone to rule out thyroid dysfunction
- Serum electrolytes, BUN, creatinine
- Brain MRI usually is not necessary or indicated unless Wilson disease is found or exam findings imply central lesion.

### ***Diagnostic Procedures/Other***

- Accelerometry evaluates tremor frequency and amplitude; >95% of PD cases exhibit frequencies in the 4- to 6-Hz range, and 95% of essential tremor cases exhibit frequencies in the 5- to 8-Hz range.
- Surface electromyography is less helpful in distinguishing essential tremor from PD.

# Test Interpretation

## Posture-related tremor

## TREATMENT

### MEDICATION

Pharmacologic treatment should be considered when tremor interferes with activities of daily living (ADLs) or causes psychological distress.

#### First Line

- Propranolol 60 to 320 mg/day in divided doses or in long-acting formulation reduces limb tremor magnitude by  $\div$ 50%, and almost 70% of patients experience improvement in clinical rating scales. There is insufficient evidence to recommend propranolol for vocal tremor. Single doses of propranolol, taken before social situations that are likely to exacerbate tremor, are useful for some patients.
- Primidone 25 mg at bedtime, gradually titrated to 150 to 300 mg at bedtime, improves tremor amplitude by 40-50%. Maximum dose is 750 mg/day, with doses  $>$ 250 mg/day typically divided to BID or TID. Low-dose therapy ( $<$ 250 mg/day) is just as effective as high-dose (750 mg/day) therapy.
- Propranolol and primidone have similar efficacy when used as initial therapy for limb tremor; both carry a level A recommendation (4)[A].
- 30-50% of patients will not respond to either propranolol or primidone.

P.367

#### Second Line

- Topiramate at a mean dose of 292 mg/day demonstrated significantly greater reduction in tremor rating scale (TRS) compared with placebo (7.70 vs. 0.08;  $p < .005$ ; baseline TRS = 37.0) in a small study combining results of three double-blind, randomized, controlled trials following a common protocol. Use is limited by dropout rates as high as 40% due to appetite suppression, weight loss, paresthesias, and concentration difficulties (5)[B].
- Gabapentin up to 400 mg TID
- Sotalol, nadolol, and atenolol are alternative  $\beta$ -blockers; each has less evidence than propranolol to support use.
- Clonazepam and alprazolam should be used with caution because of abuse potential.
- Clozapine has shown efficacy at doses of 6 to 75 mg/day but is recommended only for

refractory cases of limb tremor because of a 1% risk of agranulocytosis. The American Academy of Neurology (AAN) indicates that insufficient evidence exists to support or refute the efficacy of clozapine for chronic use (4)[A].

- Memantine, in a pilot study using doses up to 40 mg/day, showed significant benefit in a small subset of the study group. Adverse events at this dose included dizziness, somnolence, and poor energy (6)[B].
- Pramipexole, at a dose of 2.1 mg/day, demonstrated moderate efficacy in reducing severity of tremor in a pilot study of 29 patients. Immediate- and extended-release formulations were equally effective (7)[B].
- Levetiracetam and 3,4-diaminopyridine are probably ineffective at reducing limb tremor and should not be considered according to the AAN (4)[A].
- Other medications that have been evaluated for treatment of essential tremor, with limited data to support their use, include acetazolamide, clonidine, flunarizine, methazolamide, nimodipine, olanzapine, phenobarbital, pregabalin, quetiapine, sodium oxybate, and zonisamide (4)[A].
- Alcohol may provide transient improvement in symptoms, but its brief duration of action, subsequent rebound, and associated risk of developing alcohol addiction make it a less attractive option for longer term treatment. Alcohol may be an appropriate option for short-term, situation-specific improvement in symptoms.
- Botulinum toxin A injections should be offered as a treatment option for cervical dystonia (level A recommendation from AAN) and may be offered for blepharospasm, focal upper extremity dystonia, adductor laryngeal dystonia, and upper extremity essential tremor. Limited data support its use for head and voice tremor (8)[B].

## *ISSUES FOR REFERRAL*

Referral to a neurologist can help to differentiate those with dystonia, neuropathic tremor, PD, or drug-induced tremor.

## *SURGERY/OTHER PROCEDURES*

- Deep brain stimulation provides a magnitude of benefit that is superior to all available medications and may be used to treat medically refractory limb tremor; it has fewer adverse effects than thalamotomy (9)[B].
- Bilateral thalamic stimulation is effective in reducing tremor and functional disability; however, dysarthria is a possible complication.
- Unilateral thalamotomy may be used to treat limb tremor that is refractory to medical management.

- Bilateral thalamotomy is not recommended because of adverse side effects.

## ONGOING CARE

### DIET

Avoid caffeine.

### PROGNOSIS

Tremor tends to worsen with age, increasing in amplitude.

## Codes

**&NA;**

### ICD10

G25.0 Essential tremor

## Clinical Pearls

**&NA;**

- Core criteria for diagnosis of essential tremor include bilateral action (intention) tremor of the hands, forearm, and/or head without resting component.
- Beneficial response to alcohol and positive family history help to differentiate essential tremor from PD (PD is characterized by tremor at rest, bradykinesia, and rigidity, and it does not improve with alcohol use).
- 10% of patients with PD will have both resting tremors of PD and essential (intention) tremors.
- Wilson disease, thyroid disease, and medication effect should be ruled out.
- Brain MRI is usually not necessary or indicated.

First-line treatments include propranolol and primidone.

# Eustachian Tube Dysfunction

Adam W. Kowalski, MD

Vernon Wheeler, MD, FAAFP

## BASICS

### DESCRIPTION

- Eustachian tube dysfunction (ETD) represents a spectrum of disorders involving an impairment in the functional valve of the eustachian tube of the middle ear.
- ETD can be classified as *patulous dysfunction*, in which the eustachian tube is excessively open, or *dilatatory dysfunction*, in which there is failure of the tubes to dilate (i.e., open) appropriately.
- Pathophysiology is thought to be related to pressure dysregulation, impaired protection secondary to reflux of irritating material into the middle ear, or impaired clearance by the mucociliary system.
- May occur in the setting of pressure changes (e.g., scuba diving or air travel) or acute upper airway inflammation (e.g., allergic or infectious rhinosinusitis, acute otitis media)
- Chronic ETD may lead to a retracted tympanic membrane, recurrent serous effusion, recurrent otitis media (OM), adhesive OM, chronic mastoiditis, or cholesteatoma.
- System(s) affected: auditory
- Synonym(s): auditory tube dysfunction; eustachian tube disorder; blocked eustachian tube; patulous eustachian tube

### ALERT

- Sudden sensorineural hearing loss (SSNHL) can be misdiagnosed as ETD.
- A simple 512-Hz tuning fork test lateralizes to the opposite ear in SSNHL and to the affected ear in ETD with conductive hearing loss.
- Any SSNHL is a medical emergency and should be referred to an otolaryngologist immediately.

### EPIDEMIOLOGY

- Limited quality studies on epidemiology of ETD

- Most common in children <5 years of age, thought to be related to anatomical differences (see *Etymology and Pathophysiology* section)
- Usually decreases with age

## *Incidence*

70% of children by age 7 years have experienced ETD.

## *Prevalence*

- 1% of the adult population
- Males > females
- Highest prevalence among Native Americans, Inuits, Australian Aborigines, Hispanics, Africans

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Under normal circumstances, the eustachian tube (ET) is closed but can open to release a small amount of air to equalize pressure between the middle ear and the surrounding atmosphere.
- ETD is failure of the ET, palate, nasal cavities, and nasopharynx to regulate middle ear and mastoid pressure.
- ET functions
  - Ventilation/regulation of middle ear pressure
  - Protection from nasopharyngeal secretions
  - Drainage of middle ear fluid
  - ET is closed at rest and opens with yawning, swallowing, and chewing.
- Cycle of dysfunction: Structural or functional obstruction of the ET compromises three functions
  - Negative pressure develops in middle ear.
  - Serous exudate is drawn from the middle ear by negative pressure or refluxed into the middle ear if the ET opens momentarily.
  - Infection of static fluid causes edema and release of inflammatory mediators, which exacerbates cycle of inflammation and obstruction.
- In children, a horizontal and shorter ET predisposes to difficulties with ventilation and drainage.

- Adenoid hypertrophy can block the torus tubarius (proximal opening of the ET).
- In adults, paradoxical closing with swallowing has been noted in a majority of affected patients.
- Tumors that impair/occlude the ET proximally or distally, or that invade the tensor veli palatini and impair normal swallow regulation, can also lead to dysfunction.

## *Genetics*

Twin studies show a genetic component. Specific genetic cause is still undefined.

## *RISK FACTORS*

- Adult and pediatric
  - Allergic rhinitis, tobacco exposure, GERD, chronic sinusitis, adenoid hypertrophy or nasopharyngeal mass, neuromuscular disease, altered immunity
- Pediatric
  - In addition to the earlier mentioned, prematurity and low birth weight, young age, daycare, crowded living conditions, low socioeconomic status, prone sleeping position, prolonged bottle use, craniofacial abnormalities (e.g., cleft palate, Down syndrome)

## *Pregnancy Considerations*

ETD may be exacerbated by rhinitis of pregnancy; symptoms resolve postpartum.

## *GENERAL PREVENTION*

- Control sources of upper airway inflammation: allergies, infectious rhinosinusitis, GERD
- Autoinsufflation of middle ear (i.e., blow gently against pinched nostril and closed mouth)
- Avoid atmospheric pressure changes (e.g., plane flight, scuba diving) in the setting of acute allergy exacerbation or URI.
- Avoid exposure to environmental irritants: tobacco smoke and pollutants.

## *COMMONLY ASSOCIATED CONDITIONS*

- Hearing loss
- OM: acute, chronic, and serous
- Chronic mastoiditis
- Cholesteatoma

- Allergic rhinitis
- Chronic sinusitis/URI
- Adenoid hypertrophy
- GERD
- Cleft palate
- Down syndrome
- Obesity
- Nasopharyngeal carcinoma or other tumor

## DIAGNOSIS

### HISTORY

- Symptoms of ear pain, fullness, “plugging,” hearing loss, tinnitus, popping or snapping noises, and vertigo are commonly seen with ETD.
- Other historical elements
  - Unilateral or bilateral. Adults presenting with persistent unilateral symptoms should be evaluated for nasopharyngeal process (tumor).
  - History of previous ear infections, surgeries, head trauma, recent flying or diving
  - Voice change (hypo- or hypernasal voice, consider NP mass or palatal dysfunction)
  - Differentiate patulous dysfunction, in which patient's own voice and breath sounds are amplified (autophony), from dilatory dysfunction, in which patient complains more of ear pain, “plugged” ear, hearing loss, and tinnitus.
- ETDQ-7 is a new questionnaire to attempt to quantify ETD in adult patients. Based on presence and intensity of symptoms in past 1 month, severity is rated on 1 to 7 scale, with 1 indicating no problem and 7 indicating severe problems. A total score cutoff >14.5 categorizes patient as having diagnosis of ETD (1,2)[B]. Data is limited but promising. Questions:
  - Pressure in ears in past 1 month?
  - Pain in ears in past 1 month?
  - A feeling that ears are clogged or “under water”?
  - Ear symptoms when you have cold or sinusitis?

- Crackling or popping sounds in the ears?
- Ringing in ears?
- A feeling that your hearing is muffled?

## PHYSICAL EXAM

- Pneumatic otoscopy: retracted tympanic membrane, effusion, decreased drum movement
- Toynbee maneuver: view changes of the drum while patient autoinsufflates against closed lips and pinched nostrils; may show various degrees of retraction
  - Entire drum may be retracted and lateralize with insufflation.
  - Posterosuperior quadrant (pars flaccida) may form a retraction pocket.
- Tuning fork tests: 512-Hz fork placed on the forehead lateralizes to affected ear (Weber test); the fork will be louder behind the ear on the mastoid than in front of the ear (bone conduction > air conduction, Rinne test) in conductive hearing loss.
- Nasopharyngoscopy: adenoid hypertrophy or nasopharyngeal mass
- Anterior rhinoscopy: deviated nasal septum, polyps, mucosal hypertrophy, turbinate hypertrophy

## DIFFERENTIAL DIAGNOSIS

- SSNHL (a medical emergency)
- Tympanic membrane perforation
- Barotrauma
- Temporomandibular joint disorder
- Ménière disease
- Superior semicircular canal dehiscence

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Radiologic studies are not performed routinely if clinical signs/symptoms suggest ETD.
- CT scan (not necessary) may show changes related to OM or middle ear/mastoid opacification.
- Functional MRI might determine cause of ETD (in recalcitrant cases), as the ET opening can be visualized during Valsalva.

## Diagnostic Procedures/Other

- Audiogram may show conductive hearing loss.
- Tympanometry: type B or C tympanograms indicate fluid or retraction, respectively. Negative middle ear peak pressures seen even with normal (type A) tympanograms.

P.369

## TREATMENT

- Due to limited high-quality evidence, it is difficult to recommend any one treatment option/intervention as superior (3)[C].
- Use of a Nasal balloon<sup>Ó</sup> shown effective for clearing OM with effusion; unclear of benefit for ETD
- Generally, principle of treatment is to remove or fix the underlying cause (e.g., infection, tumor, perforation of TM, restore tensor palitini muscle, etc.) and hopefully end or at least reduce cycle of infection/inflammation.
- Although no evidence exists, some consider antibiotics for AOM; decongestants, nasal steroids, antihistamines (if allergic rhinitis is present), and surgery/procedures for recalcitrant cases
- Tympanostomy tubes ± adenoidectomy when indicated for recurrent ear infections or severe progressive retractions

## MEDICATION

- Only when infection such as AOM is suspected as driving cause of ETD should antibiotics be given; large study giving antibiotics to children with OM with effusion showed no benefit (4) [A].
- Few data support pharmacologic treatments such as decongestants, nasal steroids, or antihistamines for ETD.
- Medication options are for treatment of comorbid conditions.
- Decongestants, topical, oral
  - Avoid prolonged use (>3 days); can cause rhinitis medicamentosa.
  - Decongestants are most useful for acute ETD related to a resolving URI.
  - Decongestants are not typically used for relief of chronic ETD in children.
    - Phenylephrine: adults and children <sup>3</sup>12 years of age, 1 tablet (10 mg) q4h PRN; children

- 6 to 11 years of age, 5 mg q4h PRN; children 4 to 5 years of age, 2.5 mg q4h PRN
- Pseudoephedrine: adults, 60 mg q4-6h PRN; children 6 to 12 years of age, 30 mg q4-6h PRN; children 4 to 5 years of age, 15 mg q4-6h PRN
  - Oxymetazoline: adults and children <sup>3</sup>6 years of age, 1 to 2 sprays each nostril q12h PRN. Limit use to <sup>2</sup>3 days.
  - Phenylephrine: adults, 1 to 2 sprays each nostril q4h PRN. Limit use to <sup>2</sup>3 days.
- Nasal steroids (may be beneficial for those with allergic rhinitis) (5)[A]
    - Beclomethasone (Beconase, Vancenase): adults and children <sup>3</sup>12 years of age, 1 to 2 sprays each nostril BID; children 6 to 11 years of age, 1 spray each nostril BID. Not recommended for children <6 years of age
    - Budesonide (Rhinocort): adults and children <sup>3</sup>6 years of age, 1 spray each nostril daily
    - Ciclesonide (Omnaris) (a prodrug activated on nasal mucosa): adults and children <sup>3</sup>6 years of age, 2 sprays each nostril daily
    - Flunisolide (Nasarel, Nasalide): adults and children <sup>3</sup>6 years of age, 2 sprays each nostril BID
    - Fluticasone furoate (Veramyst): adults and children <sup>3</sup>12 years of age, 2 sprays each nostril daily; children 2 to 11 years of age, 1 spray each nostril daily
    - Fluticasone propionate (Flonase): adults 1 to 2 sprays each nostril daily; children <sup>3</sup>4 years of age, 1 spray each nostril daily
    - Mometasone (Nasonex): adults and children <sup>3</sup>12 years of age, 2 sprays each nostril daily; children 2 to 12 years of age, 1 spray each nostril daily
    - Triamcinolone (Nasacort): adults and children <sup>3</sup>6 years of age, 1 to 2 sprays each nostril daily; children 2 to 5 years of age, 1 spray each nostril daily
  - 2nd-generation H<sub>1</sub> antihistamines (may be beneficial for those with ETD and chronic rhinitis)
    - Cetirizine (Zyrtec) (tablets, chewable tablets, liquid): adults and children <sup>3</sup>6 years of age, 5 to 10 mg/day PO; children 12 months to 5 years of age: 2.5 mg/day PO, may increase to BID; children 6 to <12 months of age: 2.5 mg/day PO
    - Desloratadine (Clarinet) (tablets, Reditabs, liquid): adults and children <sup>3</sup>12 years of age, 5 mg/day PO; children 6 to 11 years of age, 2.5 mg/day PO; children 12 months to 5 years of age, 1.25 mg/day PO; children 6 to 11 months of age, 1 mg/day PO
    - Fexofenadine (Allegra) (tablets, Reditabs, liquid): adults and children <sup>3</sup>12 years of age, 60 mg PO BID or 180 mg/day PO; children 2 to 11 years of age, 30 mg PO BID

Levocetirizine (Xyzal) (tablets, liquid): adults and children <sup>3</sup>12 years of age, 2.5 to 5 mg PO every evening; children 6 to 11 years of age, 2.5 mg PO every evening; children 6 months to 5 years of age, 1.25 mg PO every evening

- Antihistamine nasal sprays (may be beneficial for those with ETD and chronic rhinitis)
  - Azelastine (Astepro or Astelin): adults and children <sup>3</sup>12 years of age, 1 to 2 sprays each nostril BID; children 6 to 11 years of age, 1 spray each nostril BID
  - Olopatadine (Patanase): adults and children <sup>3</sup>12 years of age, 2 sprays each nostril BID; children 6 to 11 years of age, 1 spray each nostril BID

## ***SURGERY/OTHER PROCEDURES***

- Myringotomy and pressure equalization tube placement to ventilate middle ear, relieve pressure, and prevent sequelae of chronically retracted drum
- Patients with ETD during pressure changes may benefit from minimally invasive laser eustachian tuboplasty.
- New studies are emerging regarding balloon tuboplasty, but to date are very limited in terms of efficacy, safety, and long-term outcomes (6)[B].
- Adenoidectomy if hypertrophied tissue is present.
  - In children, first set of tubes are typically placed alone. Adenoidectomy is performed with second set of tubes if problems recur.
  - Some advocate adenoidectomy even in absence of excess tissue; reduces frequency and number of subsequent tubes

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Monitor pressure equalization tubes every 6 to 8 months in children and every 6 to 12 months in adults.
- Monitor tympanic membrane retraction pocket for progression every 6 to 12 months to allow for early intervention for progression in hearing loss, obvious ossicular erosion, or cholesteatoma.

### ***DIET***

Breastfeeding is associated with lower incidence of ETD and OM.

## PROGNOSIS

If symptoms of ETD persist beyond age 7 years, patient is more likely to have long-term problems and require regular monitoring.

## COMPLICATIONS

Morbidity related to hearing compromise or associated sequela of chronic ear infections

## Codes

&NA;

### ICD10

- H69.90 Unspecified Eustachian tube disorder, unspecified ear
- H69.00 Patulous Eustachian tube, unspecified ear
- H68.109 Unspecified obstruction of Eustachian tube, unspecified ear

## Clinical Pearls

&NA;

- ETD can be acute or chronic. Treatment is based on the underlying etiology.
- Weber test: 512-Hz fork placed on the forehead lateralizes to affected ear in ETD and opposite ear in SSNHL
- SSNHL (medical emergency) can be misdiagnosed as ETD and should always be ruled out, especially in patients with unilateral symptoms.

# Factor V Leiden

Marina Rasnow-Hill, MD

## BASICS

### DESCRIPTION

- Factor V Leiden is a genetic mutation at the activated protein C (APC) cleavage site on the factor V and Va molecule leading to the most common form of inherited thrombophilia.
- System(s) affected: cardiovascular, gastrointestinal, hemo-/lymphatic/immunologic, nervous, pulmonary, reproductive
- Synonym(s): factor V Leiden thrombophilia; factor V Leiden mutation; hereditary APC resistance

### *Pediatric Considerations*

Potential for increased thrombosis risk in patients with factor V Leiden and concomitant risks

### *Pregnancy Considerations*

- Recurrent late pregnancy loss is a possible complication.
- Increased thrombotic risk in pregnancy and postpartum (additive) especially in homozygous state
- Possible increased risk of IUGR, preeclampsia, placental abruption, evidence mixed (1)

### EPIDEMIOLOGY

#### *Prevalence*

Studies estimate  $\div$ 5-8% occurrence of heterozygosity in Caucasians, Hispanic Americans  $\div$ 2%, African Americans  $\div$ 1%, and Asian Americans  $\div$ 0.45%.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Factor V circulates in the plasma. When exposed to tissue factor from endothelial activation, factor V amplifies the production of thrombin which in turn further promotes clotting by activating factor V into procoagulant factor Va.

- For balance, thrombin also promotes APC production which will cleave and inactivate factor V, Va, and VIII, thereby keeping the clotting cascade in check (negative feedback loop).
- In factor V Leiden, a point mutation at the binding site of APC (Arg506Glu) renders it less able to cleave factor V or Va. This, in turn, reduces the anticoagulant role of factor V as a cofactor to APC, and increases the *procoagulant* role of activated factor V, as there is now 20-fold slower degradation of factor Va Leiden.

## RISK FACTORS

- Risk for venous thromboembolism (VTE) is  $\div$ 7-fold in heterozygous and  $\div$ 80-fold in homozygous factor V Leiden individuals, compared with individuals without the mutation (2). This risk is compounded/increased by the presence of the following:
  - Having non-O blood type (A, B, or AB) (increased risk 2- to 4-fold)
  - Oral contraceptives: homozygotes up to 100-fold; heterozygotes, 35-fold. The increased risk is halved when the patient uses desogestrel-containing oral contraceptives.
  - Hormone replacement therapy (HRT) and selective estrogen receptor modulators (SERMs) both increase the risk of thrombosis; in patients with factor V Leiden, that risk is compounded.
  - Pregnancy and *homozygous* factor V Leiden increase the risk of thrombosis 7- to 16-fold during pregnancy and the puerperium.
- Data are conflicting with regard to risk for recurrent VTE for patients with factor V Leiden but trend toward an increased risk (1,3).

## GENERAL PREVENTION

### ALERT

Patients with factor V Leiden without thrombosis do not require prophylactic anticoagulation.

## COMMONLY ASSOCIATED CONDITIONS

Venous thrombosis

## DIAGNOSIS

### HISTORY

- Previous thrombosis
- Family history of thrombosis

---

## PHYSICAL EXAM

- Family history of factor V Leiden mutation
- Findings suggestive of VTE in any form (DVT, PE, cerebral vein thrombosis); 10-26% of patients with VTE are carriers of the factor V Leiden mutation.
- Thrombosis in unusual locations, such as the sagittal sinus, or mesentery and portal systems, although these are less common in patients with factor V Leiden than in patients with deficiency of protein C or S.
- There is a weak, however significant, association between procoagulant states (including factor V Leiden) and coronary events in younger patients (4).

## DIFFERENTIAL DIAGNOSIS

- Protein C deficiency
- Protein S deficiency
- Antithrombin deficiency
- Other causes of APC resistance (e.g., antiphospholipid antibodies)
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocystinemia
- Prothrombin 20210 mutation
- Elevated factor VIII levels

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- For evaluation of a new clot in patient at risk: CBC with peripheral smear, PT/INR, aPTT, thrombin time, lupus anticoagulant, antiphospholipid antibodies, factor VIII, anticardiolipin antibody, anti-β<sub>2</sub>GP-I antibodies, APC resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A
- Genetic test: DNA-based test for factor V mutation; will be unaffected by anticoagulation and other drugs
- Functional test: plasma-based coagulation assay using factor V-deficient plasma to which patient plasma is added along with purified APC. The relative prolongation of the activated

partial thromboplastin time (aPTT) is used to assay for the defect. Heparin, direct thrombin inhibitors, and factor Xa inhibitor may cause false-negative results. In the absence of exposure to anticoagulants, functional testing is preferred to genomic for cost and time to diagnosis (5) [A].

- Extremity US for DVT
- V/Q scan or spiral CT for PE

### *Follow-Up Tests & Special Considerations*

- US may not show DVT acutely; repeat in 5 to 7 days if strong suspicion.
- V/Q scan for evaluation of PE may be difficult to interpret in smokers or those with underlying lung disease.

### *Diagnostic Procedures/Other*

Magnetic resonance angiography (MRA), venography, or arteriography to detect thrombosis

## **TREATMENT**

Only indicated if thrombotic event

### **GENERAL MEASURES**

- Like general VTE treatment, patients with factor V Leiden and a first thrombosis should be anticoagulated initially with heparin or LMWH and warfarin for at least 3 months.
- Treatment with low-molecular-weight heparin (LMWH) is recommended over unfractionated heparin, unless the patient has severe renal failure (6)[A].
- Treat as outpatient, if possible (6)[A]
- Initiate warfarin with LMWH on the first treatment day and discontinue LMWH after minimum of 5 days and when INR >2 for two consecutive days (6)[A].
- Patients should be maintained on warfarin with an INR of 2 to 3 for at least 3 months (6)[A].
- For those patients with recurrence, the risks and benefits of indefinite anticoagulation need to be assessed.

### **MEDICATION**

#### *First Line*

- LMWH:

- Enoxaparin (Lovenox): 1 mg/kg SC BID, start warfarin simultaneously, continue enoxaparin for minimum of 5 days and until INR is >2 for two consecutive days, at which time enoxaparin can be stopped.
  - Fondaparinux (Arixtra): 5 mg (body weight <50 kg), 7.5 mg (body weight 50 to 100 kg), or 10 mg (body weight >100 kg) SC daily
- 
- Tinzaparin (Innohep): 175 anti-Xa IU/kg SC daily for minimum of 5 days and patient is adequately anticoagulated with warfarin (INR of at least 2 for two consecutive days)
  - Dalteparin (Fragmin): 200 IU/kg SC daily
- Oral anticoagulant
    - Warfarin (Coumadin) PO with dose adjusted to an INR of 2 to 3 (3)[A].
  - Contraindications
    - Active bleeding precludes anticoagulation
    - Risk of bleeding is a relative contraindication to long-term anticoagulation.
    - Warfarin is contraindicated in patients with history of warfarin skin necrosis (6)[A].
    - Warfarin is contraindicated in pregnancy.
  - Precautions
    - Observe patient for signs of embolization, further thrombosis, or bleeding
    - Avoid IM injections. Periodically check stool and urine for occult blood; monitor CBCs, including platelets.
    - Heparin: thrombocytopenia and/or paradoxical thrombosis with thrombocytopenia
    - Warfarin: necrotic skin lesions (typically breasts, thighs, or buttocks)
    - LMWH: adjust dosage in renal insufficiency. May also need dose adjustment in pregnancy
  - Significant possible interactions
    - Agents that intensify the response to oral anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfapyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
    - Agents that diminish the response to anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

## *Second Line*

- Heparin 80 mg/kg IV bolus followed by 18 g/kg/hr continuous infusion
- Adjust dose depending on aPTT.
- In patients requiring large daily doses of heparin, measure an anti-Xa level for dose guidance.
- Alternatively, for outpatients, weight-adjusted subcutaneous unfractionated heparin with 333 U/kg first, then 250 U/kg, without monitoring (6)[A]
- Consider deficiency of antithrombin as a comutation in patients with significant elevated heparin requirements.

## *ISSUES FOR REFERRAL*

- Recurrent thrombosis on anticoagulation
- Difficulty anticoagulating
- Genetic counseling
- Homozygous state in pregnancy

## *SURGERY/OTHER PROCEDURES*

- Anticoagulation must be held for surgical interventions.
- For most patients with DVT, recommendations are against routine use of vena cava filter in addition to anticoagulation except when there is contraindication for anticoagulation (6)[A].
- Thrombectomy may be necessary in some cases.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Complicated thrombosis, such as PE

### *Nursing*

- Teach LMWH and warfarin use.
- See above for drug interactions.

### *Discharge Criteria*

Stable on anticoagulation

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Warfarin use requires periodic ( $\pm$ monthly after initial stabilization) INR measurements, with a goal of 2 to 3 (6)[A].

#### *DIET*

- No restrictions
- Large amounts of foods rich in vitamin K may interfere with anticoagulation with warfarin.

### *PATIENT EDUCATION*

- Patients should be educated about the following:
  - Use of oral anticoagulant therapy
  - Avoidance of NSAIDs while on warfarin
- The role of family screening is unclear, as most patients with this mutation do not have thrombosis. In a patient with a family history of factor V Leiden, consider screening during pregnancy or if considering oral contraceptive use.

### *PROGNOSIS*

- Most patients heterozygous for factor V Leiden do not have thrombosis.
- Homozygotes have about a 50% lifetime incidence of thrombosis.
- Recurrence rates after a first thrombosis are not clear, with some investigators finding rates as high as 5% and others finding rates similar to the general population.
- Despite the increased risk for thrombosis, factor V Leiden does not increase overall mortality.

### **COMPLICATIONS**

- Recurrent thrombosis
- Bleeding on anticoagulation

## Codes

&NA;

# ICD10

D68.51 Activated protein C resistance

## Clinical Pearls

**&NA;**

- Extremely rare in Asian and African populations
- Asymptomatic patients with factor V Leiden do not need anticoagulation.
- For pregnant women homozygous for factor V Leiden but no prior history of VTE, postpartum prophylaxis with prophylactic or intermediate-dose LMWH or vitamin K antagonists with target INR 2 to 3 for 6 weeks is recommended. Antepartum prophylaxis is added if there is positive family of VTE.

# Failure to Thrive

Durr-e-Shahwaar Sayed, DO

## BASICS

### DESCRIPTION

- Failure to thrive (FTT) is not a diagnosis but a sign of inadequate nutrition in young children manifested by a failure of physical growth, usually affecting weight. In severe cases, decreased length and/or head circumference may develop.
- Various parameters are used to define FTT, but in clinical practice, it is commonly defined as either weight for age that falls below the 5th percentile on more than one occasion or weight that drops two or more major percentile lines on standard growth charts.
- A combination of anthropometric criteria rather than one criterion should be used to identify children at risk of FTT (1)[C].

### Pediatric Considerations

- Children with genetic syndromes, intrauterine growth restriction (IUGR), or prematurity follow different growth curves.
- 25% of children will decrease their weight or height crossing <sup>3</sup>2 major percentile lines in the first 2 years of life. These children are failing to reach their genetic potential or demonstrating constitutional growth delay (slow growth with a bone age < chronologic age). After shifting down, these infants grow at a normal rate along their new percentile and do not have FTT.

### EPIDEMIOLOGY

#### Incidence

- Predominant age: 6 to 12 months; 80% <18 months
- Predominant sex: male = female

#### Prevalence

- As many as 10% of children seen in primary care have signs of growth failure.
- 1-5% of pediatric inpatient admissions are for FTT.

- Occurs more frequently in children living in poverty (1)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Mismatch between caloric intake and caloric expenditure
- Often grouped into four major categories:
  - Inadequate caloric intake (most frequent)
  - Inadequate caloric absorption
  - Excessive caloric expenditure
  - Defective utilization
- Traditionally, FTT was classified as organic or nonorganic, but most cases are multifactorial.
- FTT often begins with a specific event and may lead to persistent difficulties.
- Causes of FTT can be grouped by pathophysiology (including examples):
  - Inadequate intake: breastfeeding difficulty, incorrect formula preparation, poor transition to food (6 to 12 months), poor feeding habits (e.g., excessive juice, restrictive diets), mechanical problems (e.g., oromotor dysfunction, congenital anomalies, GERD, CNS or PNS anomalies), oral aversion, poverty, neglect, poor parent-child interaction
  - Inadequate absorption: necrotizing enterocolitis, short gut syndrome, biliary atresia, liver disease, cystic fibrosis, celiac disease, milk protein allergy, vitamin/mineral deficiency
  - Increased expenditure: hyperthyroidism, congenital/chronic cardiopulmonary disease, HIV, immunodeficiencies, malignancy, renal disease
  - Defective utilization: metabolic disorders, congenital infections (TORCH: toxoplasmosis, other agents, rubella, cytomegalovirus, herpes simplex)

### *Genetics*

Multiple genetic disorders can cause FTT.

## *RISK FACTORS*

- Psychosocial risks
  - Poverty, parent(s) with mental health disorder or cognitive impairment, poor parenting skills or hypervigilant parents, families with unique health/nutritional beliefs, physical or emotional abuse, substance abuse, and social isolation
- Medical risks

- Intrauterine exposures, history of IUGR (symmetric or asymmetric), congenital abnormalities, oromotor dysfunction, premature or sick newborn, infant with physical deformity, acute or chronic medical conditions, developmental delay, lead poisoning, anemia

## *Pregnancy Considerations*

FTT is linked to intrauterine exposures, IUGR, and prematurity.

## **GENERAL PREVENTION**

- Educate parents on normal feeding and parenting skills.
- Access to supplemental feeding programs (women, infants, and children [WIC])

## **DIAGNOSIS**

### **HISTORY**

- Prenatal and developmental history
- Past medical history: acute/chronic disease affecting caloric intake, digestion, absorption, or causing increased energy need or defective utilization
- Medication history, including complementary and alternative medications
- Family history: stature of parents and growth trajectories of siblings, chronic diseases, genetic disorders, developmental delay
- Diet history from birth: breastfeeding or formula feeding; timing and introduction of solids; who feeds the child, when, and how often; placement of child during feeds; amounts consumed/caloric intake; beverages consumed; snacking; vomiting or stooling associated with feeds; oral aversions or unusual behaviors during feeding
- Social history: family composition, socioeconomic status, child-rearing beliefs, stressors, parental depression, parental substance abuse, caretaker personal history of abuse/neglect
- Review of systems: anorexia, activity level, mental status, fevers, dysphagia, vomiting, gastroesophageal reflux, stooling pattern/consistency, dysuria, urinary frequency

## **PHYSICAL EXAM**

- A combination of anthropometric criteria, rather than one criterion should be used (1)[C].
- Accurate measurement of height, weight, and head circumference on National Center for Health Statistics (NCHS) growth charts ([www.cdc.gov/growthcharts](http://www.cdc.gov/growthcharts)) (2).

- The World Health Organization (WHO) growth charts may be more appropriate for breastfed infants ([www.who.int/childgrowth/standards/en/](http://www.who.int/childgrowth/standards/en/)).
- Growth charts exist for many other syndromes/conditions such as Down syndrome, Turner syndrome, and the premature infant.
- Exam should assess for the following:
  - Signs of dehydration or severe malnutrition are as follows:
    - Severity of malnutrition estimated via Gomez classification: Compare current weight for age with expected weight for age (50th percentile): severe, <60% of expected; moderate, 61-75%; mild, 76-90%.
  - Underlying medical disease
  - Dysmorphic features
  - Mental status (alert, responsive to stimuli)
  - Any signs of physical abuse and/or neglect
- Observe interaction with caregivers and feeding techniques, specifically bonding and social/psychological cues.

## ***DIFFERENTIAL DIAGNOSIS***

Differentiate based on growth patterns

- FTT classically presents as low weight for age, normal linear growth, normocephalic *or* low weight for age, followed by decreased linear growth *or* low weight for age, leading to decreased linear growth and decreased head circumference (without neurologic signs).
  - In this situation, consider differential diagnosis as outlined in Etiology and Pathophysiology.
- If low linear growth with normal weight for length *or* low linear growth and proportionately low weight and decreased head circumference:
  - Consider genetic potential (constitutional short stature or growth delay), genetic syndromes, teratogens, endocrine disorders
- If microcephaly with prominent neurologic signs, with poor growth secondary to presumed neurologic disorder:
  - Consider TORCH infections, genetic syndromes, teratogens, brain injury (i.e., hypoxic/ischemic)

## DIAGNOSTIC TESTS & INTERPRETATION

- Labs useful only in  $\div$ 1% of cases and are generally not recommended (1)[C].
- A period of addressing nutritional causes is preferable prior to extensive labs and other workup.

### *Initial Tests (lab, imaging)*

Labs should be ordered based on history and physical exam findings and the age of the patient.

- Tests often considered in initial evaluation:
  - CBC, ESR
  - Electrolytes, BUN/creatinine, liver function tests
  - Urinalysis and urine culture
  - Lead level
- Other tests as dictated by the history and exam:
  - TSH, amylase/lipase, serum zinc level, iron studies, karyotype, genetic testing, sweat chloride test, stool for ova and parasite or fat/reducing substances, guaiac,  $\alpha$ -1-antitrypsin and elastase, radioallergosorbent test for IgE food allergies, tissue transglutaminase and total IgA (celiac sprue), P-ANCA and anti-*Saccharomyces cerevisiae* antibodies (for inflammatory bowel disease [IBD]), TB test, HIV, ELISA, hepatitis A and B, other infections

### *Follow-Up Tests & Special Considerations*

- Prospective 3-day food diary for accurate record of caloric intake should be obtained.
- Home visit by a clinician to observe infant feeding, interaction of caretakers, and home environment (3)
- Observe breastfeeding and/or formula preparation to ensure adequacy and offer instruction.

---

P.373

- Additional indicated evaluations may be performed by dietitians, occupational, physical and speech therapists, social workers, developmental specialists, psychiatrists, psychologists, visiting nurses, lactation consultants, and/or child protection services.
- Can consider
  - Skeletal survey if suspicion of physical abuse
  - Bone age if possible endocrine disorder

- Swallowing studies, small bowel follow-through if possible oromotor dysfunction, GERD, structural abnormalities
- Brain imaging if microcephalic and/or neurologic findings on examination

## TREATMENT

### GENERAL MEASURES

- Treat underlying conditions.
- Caregiver and infant interaction should be evaluated in infants and children with FTT.
- Age appropriate nutritional counseling should be provided (1)[C].
  - The goal is to improve nutrition to allow catch-up growth (weight gain 2 to 3 times > average for age).
- Calculate energy needs based on recommended energy intake for age, increased by 50%.
  - Recommended energy intake (use expected, not actual weight, to calculate needs)
    - 0 to 1 month: 120 kcal/kg/day
    - 1 to 2 months: 115 kcal/kg/day
    - 2 to 3 months: 105 kcal/kg/day
    - 3 to 6 months: 95 kcal/kg/day
    - 6 months to 3 years: 90 kcal/kg/day (4)[C]
- Alternatively, may calculate caloric requirements for infants to achieve catch-up growth
  - $\text{kcal/kg/day required} = \text{RDA for age (kcal/kg)} \times \text{ideal weight for height/actual weight}$ , where ideal weight for height is the median weight for the patient's height
- Try various strategies to increase caloric intake, such as the following:
  - Optimize breastfeeding support, consider supplementation.
  - Higher calorie formulas
  - Addition of rice cereal or fats to current foods
  - Limit intake of milk to 24 to 32 oz/day.
  - Avoid juice and soda.

Vitamin and/or nutritional supplements

- Assist with social and family problems (WIC, food stamps, and other transitional assistance).
- Rapid high-calorie intake can cause diarrhea, malabsorption, hypokalemia, and hypophosphatemia. Therefore, increasing formulas more than 24 kcal/oz is not recommended.
- The target energy intake should be slowly increased to goal over 5 to 7 days.
- Catch-up growth should be seen in 2 to 7 days.
- Accelerated growth should be continued for 4 to 9 months to restore weight and height.

## *MEDICATION*

Use only for identified underlying conditions.

## *ISSUES FOR REFERRAL*

- Refer as indicated for underlying conditions.
- Multidisciplinary care is beneficial (1)[A]. Specialized multidisciplinary clinics may be of benefit for children with complicated situations, failure to respond to initial treatment, or when the PCP does not have access to specialized services such as nutrition, psychology, PT/OT, and speech therapy (2).

## *ADDITIONAL THERAPIES*

In severe cases, nasogastric tube feedings or gastrostomy may be considered.

## *INPATIENT CONSIDERATIONS*

Most cases of FTT can be managed as outpatients.

### *Admission Criteria/Initial Stabilization*

Hospitalization should be considered if (1)[C]:

- Outpatient management fails.
- There is evidence of severe dehydration or malnutrition.
- There are signs of abuse or neglect.
- There are concerns that the psychosocial situation presents harm to child.
- During catch-up growth, some children will develop nutritional recovery syndrome:
  - Symptoms include sweating, increased body temperature, hepatomegaly (increased glycogen deposits), widening of cranial sutures (brain growth > bone growth), increased

periods of sleep, fidgetiness, and mild hyperactivity.

- There may also be an initial period of malabsorption with resultant diarrhea.

## *Discharge Criteria*

Catch-up growth should be seen in 2 to 7 days. If this is not seen, reevaluation of causes is needed.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- If specific disease is identified, follow-up as indicated.
- Close long-term follow-up with frequent visits is important to create and maintain a healthy, supportive environment (3).
- Children with history of FTT are at increased risk of recurrent FTT, and growth should be monitored closely (1,4).
- If the family fails to comply, child protection authorities must be notified.

## *DIET*

Nutritional requirements for a normal child:

- Infant
  - 120 kcal/kg/day, decreased to 95 kcal/kg/day at 6 months; if breastfed, ensure appropriate frequency and duration of feeding.
  - Between 6 and 12 months, continue breast milk and/or formula, but pureed foods should be consumed several times a day during this period.
- Toddler
  - Three meals plus two nutritional snacks, 16 to 32 oz of milk/day; avoid juice and soda, and feed in a social environment.
  - Do not restrict fat and cholesterol in children <2 years.
- Rate of weight gain expected for age:
  - 0 to 3 months: 26 to 31 g/day
  - 3 to 6 months: 17 to 18 g/day

- 6 to 9 months: 12 to 13 g/day
- 9 to 12 months: 9 g/day
- 1 to 3 years: 7 to 9 g/day

## PATIENT EDUCATION

- Counsel parents regarding the need to avoid "food battles," which worsen the problem.
- Educate parents regarding infant social and physiologic cues, formula/food preparation, proper feeding techniques, and importance of relaxed and social mealtimes.
- When environmental deprivation is identified, educating in a nonpunitive way is essential.
- "Failure to thrive: What this means for your child," available from AAFP at: [www.aafp.org/afp/2011/0401/p837.html](http://www.aafp.org/afp/2011/0401/p837.html)
- WIC provides grants to states for supplemental foods, health care referrals, and nutrition education for low-income pregnant, breastfeeding, and nonbreastfeeding postpartum women and to infants and children up to age 5 years at nutritional risk: [www.fns.usda.gov/wic/](http://www.fns.usda.gov/wic/)

## PROGNOSIS

- Many children with FTT show adequate improvement in dietary intake with intervention.
- Some studies looking at children with FTT have demonstrated an association with later problems with cognitive development, behavioral issues, and growth, but there is no consensus on these long-term outcomes or their clinical significance (1).
- Children with FTT are at increased risk for future undernutrition, overnutrition, and eating disorders.

## Codes

&NA;

### ICD10

- R62.51 Failure to thrive (child)
- P92.6 Failure to thrive in newborn

## Clinical Pearls

&NA;

- FTT is a sign of inadequate nutrition.
- Underlying medical and/or social issues are generally suggested by history and physical exam, and extensive laboratory or imaging tests are rarely needed.
- A multidisciplinary team approach to diagnosis and treatment is critical to help children with FTT and their families.
- Prompt diagnosis and intervention is important to decrease the risk of adverse effects.

# Female Athlete Triad

Andrew J. McBride, MD

Rahul Kapur, MD, CAQSM

## BASICS

Syndrome of three interrelated clinical entities: low energy availability (EA) (with or without disordered eating [DE]), menstrual dysfunction (MD), and low bone mineral density (BMD) (1).

## DESCRIPTION

- Female athlete triad was first described in 1992: Patients may meet criteria for only one or two parts of the triad.
- Prevention and early intervention are essential to prevent progression to serious clinical endpoints of eating disorders, amenorrhea, and osteoporosis.
- 2014 Female Athlete Triad Coalition Consensus Statement and the 2007 American College of Sports Medicine (ACSM) Position Stand suggest (1):
  - Each component of the triad represents a spectrum ranging from health to dysfunction.
  - Energy availability is fundamental to the propagation of the triad.
  - Full recovery is not possible without correction of low energy availability.
- Energy availability (EA)
  - Dietary energy intake minus exercise energy expenditure. The core element of the triad.
  - Represents the amount of dietary energy remaining for bodily functions after correcting for exercise training
  - Low EA results in reduced capacity for cellular maintenance, thermoregulation, and growth.
  - Low EA serves a causal role in the induction of exercise-associated menstrual disturbances.
  - Low EA occurs either intentionally or inadvertently. Examples include increasing training disproportionately to energy intake; DE; and reducing energy intake by restricting, fasting, binging, and purging or use of diet pills, laxatives, diuretics, or enemas. Not all athletes meet diagnostic criteria from *Diagnostic and Statistical Manual of Mental Disorders* 5th edition (*DSM-5*) for eating disorders.
- Menstrual dysfunction (MD)

- Low EA alters the hypothalamic-pituitary axis, resulting in decreased estrogen levels.
  - MD ranges from eumenorrhea to amenorrhea.
  - MD includes athletes who have low estrogen levels but still experience menstruation.
  - Energy deficit results in menstrual dysfunction at  $\pm 30$  kcal/kg lean body mass per day.
  - MD includes luteal suppression (shortened luteal phase, prolonged follicular phase, and decreased estradiol level), anovulation, oligomenorrhea (menstrual cycle  $>35$  days), and primary and secondary hypothalamic amenorrhea.
  - Primary amenorrhea, although less common, can occur in young athletes. Secondary amenorrhea is defined as the absence of menstrual cycles for  $>3$  months after menarche established.
  - Although hypothalamic suppression is the most common cause of secondary amenorrhea in these athletes, other causes must be ruled out.
- BMD
    - Ranges from optimal bone health to osteoporosis
    - Bone health encompasses bone strength as well as bone quality. The current practice standard (dual-energy x-ray absorptiometry) measures bone density not bone quality. However, newer research using peripheral quantitative CT scans have shown that amenorrheic female athletes have a lower proportion of cortical bone, which is thought to be related to deficient mineralization and may be responsible for the increased fracture risk (2). This research may help providers better understand why two athletes with the same BMD may have very different bone fracture histories.
      - ACSM Position Stand recommends using the International Society of Clinical Densitometry (ISCD) guidelines for BMD Z-scores  $<-2.0$ .
      - Because most athletes have a higher BMD than nonathletes, ACSM recommends further workup for any athlete with a Z-score  $<-1$ , even in the absence of fracture.
    - Endothelial dysfunction
      - Emerging evidence suggests that the female athlete triad is associated with endothelial dysfunction. Reduced levels of estrogen alter vasodilation. Athletic amenorrhea is associated with reduced brachial artery flow-mediated dilation, which has a 95% positive predictive value for coronary endothelial dysfunction. Consequences include decreased blood flow to muscles during exercise and accelerated atherosclerosis. In the future, this clinical syndrome may be considered a tetrad (3).

# EPIDEMIOLOGY

## Prevalence

- Overall prevalence: 0-16% of female athletes (4). Prevalence of two criteria varies: MD + BMD 0-8% ( $n = 460$ ), MD + LE 18% ( $n = 80$ ), and BMD + LE 4% ( $n = 80$ ) (4)
- DE higher than general population (4)
- Menstrual dysfunction: Prevalence of secondary amenorrhea is as high as 60% in female athletes compared to 2-5% in the general population (4).
- Bone health: Using the World Health Organization (WHO) criteria for low BMD, prevalence of osteopenia (T-score between  $-1$  and  $-2$ ) ranges from 0% to 40% in female athletes, as compared to  $\div 12\%$  in the general population (4).

## ETIOLOGY AND PATHOPHYSIOLOGY

- Low EA disrupts the hypothalamic-pituitary-ovarian axis, decreasing pulsatile gonadotropin-releasing hormone (GnRH) release (5).
- Low GnRH levels decrease luteinizing hormone (LH) and follicle-stimulating hormone (FSH) levels, decreasing estrogen production with resultant menstrual dysfunction.
- Estrogen deficiency negatively affects bone density. A chronic state of malnutrition reduces the rate of bone formation and increases the rate of bone resorption. Changes in bone metabolism occur within 5 days of reductions in EA.

## RISK FACTORS

- History of menstrual irregularities and amenorrhea; history of stress fractures and recurrent or nonhealing injuries; history of critical comments about eating or weight from parent or coach; history of depression; history of dieting; personality factors including perfectionism and/or obsessiveness, overtraining, and inappropriate coaching behaviors (1)
- Lean physique, sports with an aesthetic component (ballet, figure skating, gymnastics, distance running, diving, and swimming), or sports with weight classifications (martial arts and wrestling). Frequent weigh-ins, consequences for weight gain, and win-at-all-cost attitude all increase risk (6).
- A lack of family or social support; intense training hours; social isolation or entering a new environment (boarding school or college); an athlete with comorbid psychological conditions (anxiety, depression, and/or obsessive-compulsive disorder)

## GENERAL PREVENTION

Education of athletes (middle school through college), coaches, trainers, parents, and physicians. Young athletes are extremely impressionable and may turn negative comments and unhealthy advice into maladaptive eating and exercising habits.

- General screening during preparticipation exam (PPE) and annual physicals is endorsed by AAP, AAFP, ACSM, AAOSM, and AMSSM (6).
- Female Athlete Triad Coalition has 11-question screening to use during PPE (1).
- Screen athletes presenting with red flag conditions such as fractures, weight changes, fatigue, amenorrhea, bradycardia, orthostatic hypotension, syncope, arrhythmias, electrolyte abnormalities, or depression.

## COMMONLY ASSOCIATED CONDITIONS

- Anorexia nervosa, bulimia nervosa, avoidant or restrictive food intake disorder, and other psychological disorders, including low self-esteem, depression, and anxiety (5)
- Low BMD predisposes athletes to stress fractures and may not be fully reversible. This may lead to a higher rate of fractures after menopause.

## DIAGNOSIS

The female athlete triad is a clinical diagnosis based primarily on patient history. Screening for the female athlete triad at annual sports physicals or during routine exams and acute visits if there are concerns (1,5)[A]. There are several screening tools that have been validated for use in female athletes, including Athletic Milieu Direct Questionnaire (AMDQ), Brief Eating Disorders in Athletes Questionnaire (BEDA-Q), and Female Athlete Screening Tool (FAST) (7). However, there is no current consensus on which tool to use in practice (7).

## HISTORY

Assess menstrual history (including oral contraceptive use), fracture history, and symptoms of depression. Assess dietary practices, eating behaviors, and history of weight changes. Dietary intake logs and a nutritional assessment by a sports dietitian can help. Assess body image; fear of weight gain; fluctuations in weight; history of DE; and use of laxatives, diet pills, or enemas.

## PHYSICAL EXAM

- Height, weight, body mass index (BMI)  $<17.5\% \text{ kg/m}^2$  or  $<85\%$  of expected body weight in adolescents (1)[A]
- Common findings include bradycardia, orthostatic hypotension, hypothermia, cold or cyanotic extremities, lanugo, parotid gland enlargement or tenderness, epigastric tenderness, eroded

tooth enamel, and knuckle or hand calluses (Russell sign).

- Patients with amenorrhea should undergo a pelvic exam to verify the presence of a uterus and evaluate for outflow tract abnormalities. Vaginal atrophy may be present if the patient is hypoestrogenic.

## ***DIFFERENTIAL DIAGNOSIS***

Screen for anorexia nervosa, bulimia nervosa, avoidant/restrictive food intake disorder, and

P.375

rumination disorder using the *DSM-5* criteria. Rule out the following in amenorrheic patients:

- Pregnancy
- Endocrine abnormalities: thyroid dysfunction, Cushing syndrome
- Hypothalamic dysfunction: psychological stress-induced amenorrhea, medication-induced amenorrhea, Kallmann syndrome
- Pituitary dysfunction: prolactinoma, Sheehan syndrome, sarcoidosis, empty sella syndrome
- Ovarian dysfunction: polycystic ovarian syndrome, premature ovarian failure, menopause, gonadal dysgenesis, Turner syndrome, ovarian neoplasm, autoimmune disease
- Uterine dysfunction: Asherman syndrome, absence of uterus

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Basic metabolic panel, magnesium, phosphorus, albumin, CBC with differential, ESR, thyroid-stimulating hormone (TSH), calcium, 25-OH vitamin D, and urinalysis (1,6)
- Evaluation for secondary amenorrhea includes urine hCG, FSH, LH, prolactin, and TSH.
- Pelvic ultrasound in patients with hyperandrogenism to exclude polycystic ovaries or virilizing ovarian tumors
- ECG to rule out prolonged QT interval

### ***Follow-Up Tests & Special Considerations***

- BMD testing by dual-energy x-ray absorptiometry (DEXA) is based on a risk stratification model (1). Risk factors include DE, eating disorders >6 months, hypoestrogenism, amenorrhea, oligomenorrhea, and/or in patients with a history of stress fractures or fractures from minimal impact.
- If components of the triad persist, ISCD 2013 guidelines suggest reevaluation by the same

DEXA machine every 1 to 2 years.

## TREATMENT

- The goal is to optimize nutritional status and treat maladaptive behavioral disorders (1,4)[A].
- A multidisciplinary team includes a physician, registered dietitian, and behavioral health provider. Build open lines of communication with coaches, trainers, and family.
- A positive EA of  $>30$  kcal/kg of fat-free muscle mass/day is sufficient to restore menses (5)[A].
- Physically active females should strive for an EA of  $>45$  kcal/kg of fat-free muscle mass/day (1)[A].

## MEDICATION

### *First Line*

- Increasing EA through appropriate nutrition is the best strategy for normalizing gonadotropin pulsatility and release. The use of combination oral contraceptive pills (cOCPs), hormone replacement therapy (HRT), and/or bisphosphonates has not been clearly shown to increase BMD or aid in the restoration of normal menstrual cycling. cOCPs or transdermal estradiol with cyclic progesterone can be considered in patients with particularly low BMD Z-scores and fracture histories who do not respond to 1 year of nonpharmacologic management.
- cOCP or transdermal estradiol can also be given to minimize further bone loss in patients  $>16$  years and  $<21$  years who, despite adequate nutrition and body weight gain, continue to have decreasing BMD and functional hypothalamic amenorrhea.
- Provide calcium and vitamin D supplementation to maintain serum levels within 32 to 50 mg/mL (1)[A].

## INPATIENT CONSIDERATIONS

Evaluate patients with eating disorders for potentially life-threatening conditions requiring hospital admission, including bradycardia, severe orthostatic hypotension, significant electrolyte imbalances, hypothermia, arrhythmias, or prolonged QT interval.

## ONGOING CARE

- Patients should have regular follow-up with a multidisciplinary treatment team (6)[A].
- Cognitive-behavioral therapy (CBT) is effective for exercising women with ED and may be more beneficial than nutritional counseling alone in women with DE behavior.

- Clearance and Return to Play (RTP) Guidelines by Medical Risk Stratification help determine when to allow an athlete to return to competition. More research is needed to validate this model (1)[A].
- To continue training and competing, athletes with eating disorders must agree to the following stipulations as part of a behavioral contract: to comply with all treatment strategies; to be closely monitored by health care providers; to place treatment goals over training goals; and to modify the type, duration, and intensity of training or competition as necessary.

## PATIENT EDUCATION

All young female patients should be counseled on the importance of proper nutrition, calcium, and vitamin D intake and the benefits of regular weight-bearing exercise. Patients presenting with <sup>3</sup>1 components of the triad should be educated about the short- and long-term effects of low BMD (1,4)[A].

## PROGNOSIS

- The short- and long-term prognosis for patients with female athlete triad depends on time to diagnosis and response to treatment.
- It is estimated that amenorrheic women will lose 2-3% of bone mass per year without intervention.
- With early diagnosis and treatment using a multidisciplinary team, the prognosis for patients with the female athlete triad is good. Patients regain normal menstrual cycling and increase BMD.
- Because the triad often occurs within the age window of optimal bone strengthening, patients with a prolonged disease course may suffer from complications of decreased BMD throughout their adolescent and adult life.
- Patients with DE behaviors often require long-term therapy to manage their disease.

## Codes

**&NA;**

### ICD10

- F50.9 Eating disorder, unspecified
- N91.2 Amenorrhea, unspecified
- R53.83 Other fatigue

# Clinical Pearls

## &NA;

- The female athlete triad consists of: low EA (with or without DE), MD, and low BMD. Athletes may exhibit varying degrees of dysfunction in any of these three areas.
- Screen at-risk women to allow for early diagnosis and intervention.
- Early intervention by a multidisciplinary team, including physicians, registered dietitians, mental health professionals, coaches, trainers, and parents, is the most successful strategy to minimize further bone loss, recover BMD, and regain normal menstrual function.
- Current guidelines recommend screening for abnormal BMD using DEXA studies for patients with DE, eating disorders >6 months, hypoestrogenism, amenorrhea, oligomenorrhea, and/or in patients with a history of stress fractures or fractures from minimal impact.

# Fever of Unknown Origin (FUO)

Scott T. Henderson, MD

## BASICS

### *DESCRIPTION*

- Classic definition
  - Repeated fever  $>38.3^{\circ}\text{C}$
  - Fever duration at least 3 weeks
  - Uncertain diagnosis after 1 week of study in the hospital
- The FUO definition has evolved over time and should be based on characteristics and patient subtypes. In-hospital evaluation has been eliminated in previously healthy people.
- Some expand the definition to include nosocomial, neutropenic, and shorter duration HIV-associated fevers.

### *EPIDEMIOLOGY*

#### *Incidence*

Incidence unclear

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- $>200$  causes; each with prevalence of  $\approx 25\%$
- Most commonly, FUO is an atypical presentation of a common condition.
- Spectrum of causes varies by geography
- Infection
  - Abdominal or pelvic abscesses
  - Amebic hepatitis
  - Catheter infections
  - Cytomegalovirus

- Dental abscesses
- Endocarditis/pericarditis
- HIV (advanced stage)
- Mycobacterial infection (often with advanced HIV)
- Osteomyelitis
- Renal
- Sinusitis
- Wound infections
- Other miscellaneous infections
- Neoplasms
  - Atrial myxoma
  - Colorectal cancer
  - Hepatoma
  - Lymphoma
  - Leukemia
  - Solid tumors (renal cell carcinoma)
- Noninfectious inflammatory disease
  - Connective tissue diseases
    - Adult Still disease
    - Rheumatoid arthritis
    - Systemic lupus erythematosus
  - Granulomatous disease
    - Crohn disease
    - Sarcoidosis
  - Vasculitis syndromes
    - Giant cell arteritis
    - Polymyalgia rheumatica

## Other causes

- Alcoholic hepatitis
  - Cerebrovascular accident
  - Cirrhosis
  - Medications
    - Allopurinol, captopril, carbamazepine, cephalosporins, cimetidine, clofibrate, erythromycin, heparin, hydralazine, hydrochlorothiazide, isoniazid, meperidine, methyldopa, nifedipine, nitrofurantoin, penicillin, phenytoin, procainamide, quinidine, sulfonamides
  - Endocrine disease
  - Factitious/fraudulent fever
  - Occupational causes
  - Periodic fever
  - Pulmonary emboli/deep vein thrombosis
  - Thermoregulatory disorders
- In up to 20-30% of cases, the cause of the fever will not be identified despite thorough workup.

## *RISK FACTORS*

- Recent travel
- Exposure to biologic or chemical agents
- HIV-infection (particularly in advanced stages)
- Elderly
- Drug abuse
- Immigrants
- Young female health care workers (consider factitious fever)

## *Geriatric Considerations*

Noninfectious inflammatory diseases are the most frequent causes in high-income countries. This most commonly includes temporal arteritis, polymyalgia rheumatica, or rheumatoid arthritis. In elderly patients with infections, common causes include intra-abdominal abscess, complicated

urinary tract infection, tuberculosis, and endocarditis. Other common causes of FUO in patients >65 years include malignancies, particularly hematologic malignancies and drug-induced fever.

## *Pediatric Considerations*

- ≈50% of FUO in published pediatric case series are infectious. Collagen vascular disease, malignancy are also common (1)[A].
- Inflammatory bowel is a common cause in older children and adolescents.

## **DIAGNOSIS**

### **HISTORY**

- Common constitutional symptoms
  - Chills, night sweats, myalgias, weight loss with an intact appetite (infectious)
  - Arthralgias, myalgias, fatigue (inflammatory)
  - Fatigue, night sweats, weight loss with loss of appetite (neoplasms)
- Past medical history: chronic infections, abdominal diseases, transfusion history, malignancy, psychiatric illness, and recent hospitalization
- Past surgical history: type of surgery performed, postoperative complications, and any indwelling foreign material
- Obtain a comprehensive list of all medications, including over-the-counter and herbal remedies.
- Family history, such as periodic fever syndromes and recent febrile illnesses in family members to which the patient may have been exposed

### **ALERT**

Obtain a thorough travel, psychosocial, occupational, sexual, and drug use history.

## *PHYSICAL EXAM*

- Physical findings with high diagnostic yield
  - Funduscopic exam for choroid tubercles or Roth spots
  - Temporal artery tenderness
  - Oral-mucosal lesions

Auscultation for bruits and murmurs

- Abdominal palpation for organomegaly
- Rectal examination
- Testicular examination
- Lymph node examination
- Skin and nail bed exam for clubbing, nodules, lesions, and erosions
- Focal neurologic signs
- Bony tenderness or joint effusion
- Serial exams are often helpful for evolving physical signs associated with FUO (e.g., lesions associated with endocarditis).

## *DIFFERENTIAL DIAGNOSIS*

See Etiology and Pathophysiology.

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- CBC
- Peripheral blood smear
- Electrolytes, BUN and creatinine
- Lactate dehydrogenase
- Calcium
- LFTs
- C-reactive protein, ESR
- HIV testing
- Blood cultures (not to exceed six sets)
- Urinalysis and urine culture
- Chest x-ray
- CT or MRI of abdomen and pelvis (with directed biopsy, if indicated) (2)[C]

### *Follow-Up Tests & Special Considerations*

- Rheumatoid factor and antinuclear antibody test
- Serologic tests: Epstein-Barr, hepatitis, syphilis, Lyme disease, Q fever, cytomegalovirus, amebiasis, coccidioidomycosis
- Serum ferritin
- Serum protein electrophoresis
- Sputum and urine cultures for TB
- Thyroid function tests
- Tuberculin skin test
  - May not be helpful if anergic or acute infection
  - If test negative, repeat in 2 weeks
  - If indicated, consider an interferon gamma release assay (IGRA) test.
- Technetium-based scan, if infectious process or tumor suspected (2)[B]
- FDG-PET/CT scan if infectious process, inflammatory process, or tumor suspected; PET scans have a high negative predictive value and good sensitivity (but may have false positives) (3) [A].

P.377

- Ultrasound of abdomen and pelvis (plus directed biopsy, if indicated) if renal obstruction or gallbladder/biliary tree pathology suspected
- Echocardiogram if cardiac valve lesions (endocarditis), atrial myxomas, or pericardial effusion is suspected
- Lower-extremity Doppler if deep vein thrombosis/pulmonary embolism suspected
- CT scan of chest if pulmonary emboli suspected
- Indium-labeled leukocyte scanning if inflammatory process or occult abscess suspected
- Bone scan if osteomyelitis or metastatic disease suspected

### *Diagnostic Procedures/Other*

- Liver biopsy if granulomatous disease suspected (2)[C]
- Temporal artery biopsy, particularly in the elderly
- Lymph node, muscle, or skin biopsy, if clinically indicated
- Bone marrow aspiration biopsy with smear, culture, histologic examination, and flow cytometry
- Spinal tap, if clinically indicated

## Test Interpretation

Depends on etiology

## TREATMENT

### GENERAL MEASURES

- Treatment depends on the specific etiology.
- Therapeutic trials are a last resort and should be as specific as possible based on available clinical evidence. Such "shotgun" approaches are discouraged because they obscure the clinical picture, have untoward effects, and do not provide a diagnostic solution (2)[C].

### MEDICATION

#### First Line

- First-line drugs depend on the diagnosis.
- Evidence does not support isolated treatment of fever (4)[C].

#### Second Line

Only if the patient has localizing symptoms associated with the fever or continues to decline, consider a therapeutic trial—consultation with appropriate specialists (infectious disease, rheumatology) is recommended in this case.

- Antibiotic trial based on patient's history and suspected culture negative endocarditis
- Antituberculous therapy if there is a high risk for TB pending definitive culture results
- Corticosteroid trial based on patient's history (once occult malignancy is ruled out) if temporal arteritis is suspected

#### ALERT

If a steroid trial is initiated, patient may have a relapse after treatment or if certain conditions (e.g., TB) have been undiagnosed.

### ADDITIONAL THERAPIES

Febrile patients have increased caloric and fluid demands.

### SURGERY/OTHER PROCEDURES

The need for exploratory laparotomy has been largely eliminated with the advent of more sophisticated tests and imaging modalities.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Reserved for the ill and debilitated
- Consider if factitious fever has been ruled out or an invasive procedure is indicated

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

If the etiology of the fever remains unknown, repeat the history, physical exam, and screening lab studies.

#### ***DIET***

No specific dietary recommendations have been shown to ameliorate undiagnosed fever.

### ***PATIENT EDUCATION***

Maintain an open line of communication between physician and patient/family as the workup progresses:

- The extended time required in establishing a diagnosis can be frustrating.

### ***PROGNOSIS***

- Depends on etiology and age
- Patients with HIV have the highest mortality.
- 1-year survival rates (reflecting deaths due to all causes)

<b>Age</b>	<b>Survival</b>
<35 years	91%
35-64 years	82%

>64 years 67%

## COMPLICATIONS

Depends on etiology

### ***Pregnancy Considerations***

Fever increases the risk of neural tube defects in pregnancy and can also trigger preterm labor.

## Codes

**&NA;**

### ICD10

R50.9 Fever, unspecified

## Clinical Pearls

**&NA;**

- A sequential approach to FUO based on a careful history, physical examination, and targeted testing/imaging typically leads to a rational diagnosis in most cases.
- Use empiric therapy only in carefully defined circumstances.
- FUO cases that defy precise diagnosis after intensive investigation and prolonged observation generally carry a favorable prognosis.
- FUO in older persons may represent atypical presentations of a common disease.
- The most common causes of FUO in high-income countries are noninfectious inflammatory diseases and cases that remain idiopathic.

# Fibrocystic Changes of the Breast

Alain Michael P. Abellada, MD

## BASICS

### DESCRIPTION

- Fibrocystic changes (FCC) is not a disease but refers to a constellation of benign histologic findings. It is the most frequent female benign clinical breast finding.
- The most common symptoms are cyclic pain and tenderness, swelling, and fullness.
- The breast tissue may feel dense with areas of thicker tissue having an irregular, nodular, or ridge-like surface.
- Women may experience sensitivity to touch with a burning sensation. For some women, the pain is so severe that it limits exercise or the ability to lie prone.
- Usually affects both breasts, most often in the upper outer quadrant where most of the milk-producing glands are located.
- Histologically, in addition to macrocysts and microcysts, FCC may contain solid elements including adenosis, sclerosis, apocrine metaplasia, stromal fibrosis, and epithelial metaplasia and hyperplasia.
  - Depending on the presence of epithelial hyperplasia, fibrocystic change is classified as nonproliferative, proliferative without atypia, or proliferative with atypia.
- System(s) affected: endocrine/metabolic, reproductive
- Synonym(s): diffuse cystic mastopathy; fibrocystic disease; chronic cystic mastitis; or mammary dysplasia

### EPIDEMIOLOGY

FCC occurs with great frequency in the general population. It affects women between the ages of 25 and 50 years and it is rare below the age of 20.

### Incidence

Unknown but very frequent

## Prevalence

Up to 1/3 of women aged 30 to 50 years have cysts in their breasts. It most commonly presents in the 3rd decade, peaks in the 4th decade when hormonal function is at its peak, and sharply diminishes after menopause.

- With hormone replacement therapy, FCC may extend into menopause
- Less common in East Asian races

## ETIOLOGY AND PATHOPHYSIOLOGY

- FCC originates from an exaggerated response of breast stroma and epithelium to a variety of circulating and locally produced hormones (mainly estrogen and progesterone) and growth factors.
- Cysts may form due to dilatation of the lobular acini possibly due to imbalance of fluid secretion and resorption, or due to obstruction of the duct leading to the lobule.

## RISK FACTORS

- In many women, methylxanthine-containing substances (e.g., coffee, tea, cola, and chocolate) can potentiate symptoms of FCC, though a direct causality has not been established.
- Diet high in saturated fats may increase risk of FCC.

## COMMONLY ASSOCIATED CONDITIONS

FCC categorized as proliferative with atypia confers a higher risk of breast cancer.

## DIAGNOSIS

### HISTORY

- Obtain personal history of breast biopsy and family history of breast disease (benign or malignant). It is important to ascertain if the patient has a known family history of *BRCA1* or *BRCA2*-related cancer.
- Inquire regarding pertinent signs/symptoms, such as breast pain, engorgement, nipple discharge, palpable lumps, tenderness.
  - Symptomatically, the condition is manifested as premenstrual cyclic mastalgia, with pain and tenderness to touch.

## PHYSICAL EXAM

The patient should be examined in the following positions while disrobed down to the waist (1):

- With the patient standing with arms at sides, observe for elevation of the level of a nipple, dimpling, bulging, and peau d'orange.
  - With the patient's arms raised above her head, observe for dimpling and elevation of the nipple (may accentuate a mass fixed to the pectoral fascia). If so, have the patient push her hands down against her hips to flex and tense the pectoralis major muscles, move the mass to determine fixation to the underlying fascia.
  - If the patient has large and pendulous breasts, ask her to lean forward, so that her breasts hang free from the chest wall (retraction and masses may become more evident).
  - With the patient lying supine, palpate with the pads of the three middle fingers (with varying pressures from light, to medium, to deep), rotating the fingers in small circular motions and moving in vertical overlapping passes from rostral to caudal and then back caudal to rostral in the next pass. The lateral half of the breast is best palpated with the patient rolled onto the contralateral hip and the medial half with the patient supine, both with the ipsilateral hand behind the head. The entire breast from the second to sixth rib and from the left sternal border to the midaxillary line must be palpated against the chest wall.
- Be certain to examine the creases under and between the breasts. If the patient has noted a lump, ask her to point it out; always palpate the opposite breast first.
  - Patients with fibrocystic changes have clinical breast findings that range from mild alterations in texture to dense, firm breast tissue with palpable masses.

## *DIFFERENTIAL DIAGNOSIS*

- Pain
  - Mastitis
  - Costochondritis
  - Pectoralis muscle strain
  - Neuralgia
  - Breast cancer
  - Angina pectoris
  - Gastroesophageal reflux (GERD)
  - Superficial phlebitis of the thoracoepigastric vein (Mondor disease)
- Masses

- Breast cancer
- Sebaceous cyst
- Fibroadenoma
- Lipoma
- Fat necrosis
- Skin changes
  - Breast cancer (peau d'orange: thickened skin similar to peel of an orange)
  - Eczema

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Evaluation should focus on excluding breast cancer.
- Testing may be conducted based on a level of clinical suspicion.
- FCC can be evaluated with mammogram, though dense breast tissue may appear normal in women <35 years of age.
- Ultrasound is the most important method in assessing a cyst.

### *Initial Tests (lab, imaging)*

- On mammogram, FCC appears as nodular densities of breast tissue; solitary cysts can appear as round or ovoid or well-circumscribed masses, usually with low to intermediate density. FCC may also contain calcifications.
- On ultrasound, if a simple cyst is demonstrated as an anechoic structure with imperceptible wall and posterior acoustic enhancement, benign diagnosis is confirmed and no further imaging or intervention is indicated. However, if the cyst appears to be thickwalled and/or contains internal echoes, differential diagnosis should include a complicated cyst, an abscess, a galactocele, or a focal duct ectasia in the appropriate clinical contexts.
- MRI is indicated in patients with *BRCA1* or *BRCA2* mutation or in any woman with <sup>3</sup>25% lifetime risk for breast cancer.
- On MRI, cystic changes are well-circumscribed lesions of high-signal intensity on T2-weighted sequences and of low-signal intensity on T1-weighted images.

### *Diagnostic Procedures/Other*

- Fine-needle aspiration (FNA) and biopsy:

- Allows differentiation of cystic and solid lesions
  - Aspirate may be straw-colored, dark brown, or green.
  - Cells sent for cytology can reveal cancer with high accuracy.
  - Low morbidity
- If mass disappears, no further evaluation is necessary (including cytologic evaluation of aspirated fluid).

P.379

- On the basis of the presence and degree of epithelial hyperplasia, FCC is comprised of nonproliferative, (approximately 65% of the total), proliferative without, (approximately 30% of the total), and proliferative with atypia, (approximately 5% to 8% of the total) (2).

## *Test Interpretation*

Certain histologic changes in the setting of fibrocystic change confer an increased risk for breast cancer:

- Nonproliferative changes: relative risk of 1.2 to 1.4
- Proliferative disease (PD) without atypia: relative risk of 1.7 to 2.1
- PD with atypia: relative risk <sup>34</sup> (3)[B]

## **TREATMENT**

- After ruling out malignancy by means of examination and/or imaging and diagnostic procedures, FCC may not require treatment and often resolves with time.
- Cool compresses, avoiding trauma, and around-the-clock wearing of a well-fitting, supportive brassiere may be useful for symptom relief.

## *MEDICATION*

### *First Line*

For cyclic pain and swelling: NSAIDs:

- Ibuprofen 400 mg QID/PRN
- Naproxen 500 mg BID/PRN

### *Second Line*

- Oral contraceptives may be useful in modulating symptoms or in preventing the development of new changes.
- For severe pain, consider the following (4,5)[B]:
  - Danazol (Danocrine) 100 to 400 mg/day divided in 2 doses for 4 to 6 months
  - Bromocriptine 1.25 to 2.5 mg BID for 3 months
  - Tamoxifen 10 mg/day for 3 to 6 months
  - These medications are not without serious side effects and thorough counseling is required. Consultation with a breast specialist may be considered.
- Bromocriptine, danazol, and tamoxifen all significantly reduced pain. Tamoxifen was found to have the fewest adverse effects (4)[A].

## *ISSUES FOR REFERRAL*

- If discrete palpable lesion in a woman <sup>3</sup>35 years: US, then refer to a surgeon.
- If discrete palpable lesion in a woman >35 years: Diagnostic mammography ± US, then refer to surgeon.

## *SURGERY*

- Breast cyst aspiration can be both diagnostic and therapeutic.
- Core-needle biopsies performed under stereotactic guidance with vacuum assistance has similar accuracy in distinguishing between malignant and benign lesions compared to open surgical biopsy (6)[A].

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- The use of vitamin E has shown effectiveness in treating breast pain due to FCC (3)[B].
- Evening primrose oil and pyridoxine have not been shown to reduce mastalgia (4)[A],(7)[B].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Condition is benign, chronic, and recurrent.

### *Patient Monitoring*

- Follow-up times are variable, depending on the clinical situation and pertinent family history.

- US is useful to differentiate cysts from solid lesions and in evaluating women <35 years of age for FCC but is not useful for screening.
- Screening mammograms should be obtained after age 40 to 50 years. Refer to the USPSTF, ACOG, or ACS recommendations for screening schedules.

## DIET

The role of caffeine consumption in the development and treatment of FCC has never been proven; however, some patients report relief of symptoms after abstinence from coffee, tea, and chocolate.

### Codes

### &NA;

## ICD10

- N60.19 Diffuse cystic mastopathy of unspecified breast

- N60.09 Solitary cyst of unspecified breast
- N60.29 Fibroadenosis of unspecified breast

## Clinical Pearls

### &NA;

- FCC of the breast comprise a spectrum of histopathologic changes are a common finding in reproductive-aged women. The former term of fibrocystic disease is a misnomer.
- Atypia, as demonstrated histopathologically, confers an increased cancer risk.
- NSAIDs are the first-line treatment. OCPs, Danazol, Bromocriptine, and Tamoxifen are second-line treatments, though not without considerable adverse effects. Caution should be used and consultation with a breast specialist is recommended.

# Fibromyalgia

F. Stuart Leeds, MD, MS

## BASICS

### DESCRIPTION

- Chronic, widespread noninflammatory musculoskeletal pain syndrome with multisystem manifestations. Although the specific pathophysiology has not been elucidated, it is generally thought to be a disorder of altered central pain regulation.
- Synonym(s): FMS; fibrositis, fibromyositis (misnomers); Òpsychogenic rheumatismÓ (archaic and inaccurate)

### EPIDEMIOLOGY

#### *Incidence*

- Predominant sex: female > male (70-90% are females) (1)
- Predominant age range: 20 to 65 years

#### *Prevalence*

2-5% of adult U.S. population (2); 8% of primary care patients

### ETIOLOGY AND PATHOPHYSIOLOGY

- Idiopathic, but appears to be a primary disorder of central pain processing, termed central sensitization (3). Afferent augmentation of peripheral nociceptive stimuli
- Alterations in neuroendocrine, neuromodulation, neurotransmitter, neurotransporter, biochemical, and neuroreceptor function/physiology
- Sleep abnormalitiesÑ&agr;-wave intrusion (4)
- Inflammation is not a feature of fibromyalgia.

#### *Genetics*

- Genetics

High familial aggregation

- Inheritance is unknown but likely polygenic.
- Odds ratio may be as high as 8.5 for a first-degree relative of a familial proband (5).
- Environmental—several triggers have been described:
  - Physical trauma or severe illness
  - Stressors (e.g., work, family, life events, and physical/sexual abuse)
  - Viral and bacterial infections

## **RISK FACTORS**

- Female gender
- Poor functional status
- Negative/stressful life events
- Low socioeconomic status

## **GENERAL PREVENTION**

No known strategies for prevention.

## **COMMONLY ASSOCIATED CONDITIONS**

- Often a comorbid condition with other rheumatologic or neurologic disorders
- Obesity is frequently present and is associated with increased severity of symptoms (6).

## **DIAGNOSIS**

- Original 1990 ACR criteria, still widely used: (i) pain in all four quadrants, (ii) axial (neck/spine) involvement, (iii) tender points (TPs) <sup>3</sup>11, (iv) no other explanation for symptoms (2)
- Per the 2010 revised ACR criteria (2)
  - Based on Widespread Pain Index (WPI) and Symptom Score (SS)
    - Must have (WPI <sup>3</sup>7 + SS <sup>3</sup>5) or (WPI <sup>3</sup>3 and SS <sup>3</sup>9); *and*
    - Symptoms for >3 months; *and*
    - No other explanation for these symptoms
- A questionnaire tool to facilitate WPI/SS patient scoring and diagnosis may be found at:

- This tool assesses the following:
  - WPI counts the number of sites of regional pain occurring over past week (**score 0 to 19 sites**)
  - The SS scale score is the sum of two parts.
    - Part 1 grades the three key symptoms: **fatigue, waking unrefreshed, and cognitive symptoms**
    - Part 2 counts 40 + associated symptoms, ranking them from 0none0 to 0many0
    - The parts are added together to give a total SS of **0 to 12**.
- The Visual Analogue Scale Fibromyalgia Impact Questionnaire (VASFIQ) (7) is recommended for initial and serial assessment of patient's functional status. It may be found at:  
<http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3383533/figure/fig1-1759720X11416863/>
- Enhancements to the 2010 criteria, termed **2011modCr** and **2013altCr** (8) have been proposed, but are not yet widely accepted.

## HISTORY

- Universal symptoms include
  - Chronic widespread pain 3 months: bilateral limbs and in the axial skeleton
  - Fatigue and sleep disturbances
- Often present:
  - Mood disorders, including depression, anxiety, and panic symptoms
  - Cognitive impairment: qualitatively different from that seen in isolated mood disorders ("fibro fog") (9)
  - Headaches: typically, tension and migraine types
  - Other regional pain syndromes, such as irritable bowel syndrome, chronic pelvic pain, vulvodynia, and interstitial cystitis
  - Paresthesias, often "nonanatomic"
  - Exercise intolerance, dyspnea, and palpitations
  - Sexual dysfunction
  - Ocular dryness
  - "Multiple chemical sensitivity" and an increased tendency to report drug reactions

- Impaired social/occupational functioning
- Symptoms can wax and wane on a day-to-day basis, varying in quality, intensity, and location.

## *PHYSICAL EXAM*

- Classic fibromyalgia TPs: 9 symmetric pairs (5 anterior, 4 posterior) located at anterior sternocleidomastoids, upper mid-trapezius, medial 2nd intercostal spaces, lateral epicondyles, medial fat pad of knees, and posteriorly, at occipital insertions, upper medial scapular insertions, upper outer quadrants of gluteals, and posterior greater trochanters. The presence of 311 TPs carries a sensitivity of 88.4% and specificity 81.1% for the disease (2). These are distinct from the "trigger points" found in myofascial pain syndrome.
- Joints examined for swelling, tenderness, erythema, decreased range of motion, crepitus, and cystic or mass lesions—all typically absent in isolated fibromyalgia.
- Document absence of inflammatory musculoskeletal disease features (e.g., no synovitis, enthesopathy, dermatologic/ocular findings)
- Neurologic exam: may demonstrate generalized or "nonanatomic" dysesthesia, hyper- or hypesthesia

## *DIFFERENTIAL DIAGNOSIS*

- RA, SLE, sarcoidosis, and other inflammatory connective tissue disorders
- Diffuse/advanced OA
- Seronegative spondyloarthropathies (AS, psoriatic arthritis, etc.)
- Polymyalgia rheumatica
- Inherited myopathies
- Drug-induced and endocrine myopathies
- Viral/postviral polyarthralgia
- Anemia and iron deficiency
- Electrolyte disturbances: Mg, Na, K, Ca
- Obstructive sleep apnea
- Osteomalacia/vitamin D deficiency
- Opioid-induced hyperalgesia
- Hypothyroidism

- Multiple sclerosis
- Lyme disease
- Hepatitis B and C (chronic)
- Inclusion-body myositis
- Spinal stenosis/neuropathies
- Peripheral vascular disease
- Somatoform disorder
- Overlap syndromes
  - Chronic fatigue syndrome/chronic fatigue immune dysfunction syndrome (CFIDS)
  - Myofascial pain syndrome (more anatomically localized than fibromyalgia, but they may co-occur)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- CBC with differential, ESR or CRP, CPK, TSH, comprehensive metabolic profile; consider 25-OH vitamin D, Mg, B<sub>12</sub>, folate, and urine drug screen
- ANA, RF, and other rheumatologic labs unnecessary, unless there is evidence of an inflammatory connective tissue disorder.
- Imaging is not indicated, except to exclude other diagnoses.

### *Diagnostic Procedures/Other*

- Sleep studies may be indicated to rule out obstructive sleep apnea or narcolepsy.
- Consider psychiatric or neuropsychiatric evaluation for mood disorders and cognitive disturbances.

## **TREATMENT**

According to the HHS National Guideline Summary (10) and other sources, evidence-based interventions include the following:

- Nonpharmacologic treatment critical to successful outcomes
- Nonpharmacologic

- Educate the patient about the diagnosis, signs, symptoms, and treatment options (10)[A].
- Provide Internet education resources.
  - www.fmaware.org
  - www.nfra.net
  - www.fmnetnews.com
- Use the VASFIQ for initial assessment and interval evaluation during treatment (10)[A].
- Cognitive-behavioral therapy improves mood, energy, pain, and functional status (10)[A].
- Aerobic exercise: moderately intense, with gradual progression to avoid symptom exacerbation (11)[A]
- Weight loss may augment the benefits of exercise.
- Strength/resistance training—mild to moderate (11)[A]
- Aquatic exercise training (12)[A]
- Sleep hygiene

---

P.381

- Pharmacologic

- The three FDA-approved drugs are duloxetine, milnacipran, and pregabalin; others are used off-label.

## MEDICATION

### *First Line*

- Amitriptyline: 10 to 50 mg PO at bedtime to treat pain, fatigue, and sleep disturbances (13)[A]
- Duloxetine: initially 30 mg/day for 1 week, then increase to 60 mg/day as tolerated. Taper if discontinued (13)[A].
- Milnacipran: day 1: 12.5 mg/day; days 2 to 3, begin dividing doses: 12.5 mg BID; days 4 to 7: 25 mg BID; after day 7: 50 mg BID; max dose 100 to 200 mg BID. Taper if discontinued (13)[A].
- Pregabalin: Start with 75 mg BID, titrate over 1 week to 150 mg BID; max dose 450 mg/day divided BID-TID (14)[A].
- Cyclobenzaprine 5 mg HS; titrate up to 10 mg BID-TID (10)[B].

### *Second Line*

- Gabapentin start at 300 mg HS, titrate to 1,200 to 2,400 mg/day divided BID-TID (10)[B].
- Fluoxetine 10 to 80 mg/day PO (higher doses may be more effective). Taper if discontinued (10)[B].
- Paroxetine CR 12.5 to 62.5 mg/day. Taper if discontinued (10)[B].
- Tramadol 50 to 100 mg q6h; likely more effective in combination with acetaminophen (10)[C]
- Several investigational agents show some promise of benefit, including pramipexole (15), naltrexone, quetiapine, sodium oxybate (4), nabilone, and pirlindole (16)
- Cholecalciferol may be beneficial in patients with low 25-OH vitamin D levels (17).
- Medications likely to be ineffective (10)[C] include NSAIDs, opioids, benzodiazepines, magnesium, guaifenesin, thyroxine, corticosteroids, DHEA, melatonin, calcitonin; also antiepileptic agents (other than pregabalin and gabapentin) (18)[A].
- *Note that, given the frequent co-presentation of fibromyalgia with other pain syndromes, it may be reasonable to treat the latter with NSAIDs, corticosteroids, opioids, and other such agents in conjunction with evidence-based fibromyalgia therapies.*

## ISSUES FOR REFERRAL

In the case of unclear diagnosis or poor response to therapy, may refer to rheumatology, neurology, and/or pain management.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture (especially electroacupuncture), biofeedback, hypnotherapy (10,19)[B]
- Balneotherapy (mineral-rich baths) (10)[B]
- Yoga, tai chi, and qi gong improve sleep, fatigue, and quality of life but may not decrease pain (20).
- Limited double-blind trials have shown effectiveness of supplementation with S-adenosyl methionine, and acetyl-L-carnitine.
- Transcranial direct current or magnetic stimulation and repetitive transcranial magnetic stimulation (21,22)
- Likely to be ineffective: chiropractic treatment, massage, electrotherapy, ultrasound, trigger point injections (10)[A]

**ONGOING CARE**

# FOLLOW-UP RECOMMENDATIONS

## Patient Monitoring

- For efficacy of therapy at 2- to 4-week intervals
- Advance exercise gradually to maintain tolerability

## DIET

No proven efficacy of any specific diet. Caloric or carbohydrate restriction may be helpful in obese patients.

## PROGNOSIS

- 50% partial remission after 2 to 3 years of therapy (23)
- Typically has fluctuating, chronic course
- Poorer outcome tied to greater duration/severity of symptoms, depression, advanced age, lack of social support

## Codes

&NA;

### ICD10

M79.7 Fibromyalgia

## Clinical Pearls

&NA;

- Use rigorous ACR criteria to make the diagnosis.
- Fibromyalgia is not a somatoform disorder and is not merely a manifestation of depression or anxiety, although as with all chronic pain syndromes, it is frequently associated with mood disturbances.
- Best outcomes occur in patients who understand their illness and are willing to actively engage in a multimodal treatment plan, including exercise, medication, CBT, and lifestyle modifications.

# Folliculitis

David L. Anderson, MD

Thomas P. Garigan, MD, MA

## BASICS

### DESCRIPTION

- Superficial inflammation of a follicle, usually a hair follicle, caused by infection, local trauma, or chemical irritation (1)
- Can occur anywhere on the body that hair is found
- Most frequent symptom is pruritus.
- Painless or tender pustules, vesicles, or pink/red papulopustules up to 5 mm in size.
- Most commonly infectious in etiology:
  - *Staphylococcus aureus* bacteria (most common)
  - *Pseudomonas aeruginosa* infects areas of the body exposed to poorly chlorinated hot tubs, pools, or contaminated water.
  - *Aeromonas hydrophila* with recreational water exposure
  - Fungal (dermatophytic, *Pityrosporum*, *Candida*)
  - Viral (VZV, herpes simplex virus [HSV])
  - Parasitic (*Demodex* spp. mites, schistosomes)
- Noninfectious types
  - Acneiform folliculitis
  - Actinic superficial folliculitis
  - Acne vulgaris
  - Keloidal folliculitis
  - Folliculitis decalvans
  - Perioral dermatitis
  - Rosacea

- Fox-Fordyce disease
- Pruritus folliculitis of pregnancy
- Eosinophilic pustular folliculitis (three variants: Ofuji disease in patients of Asian descent, HIV-positive/immunocompromised, infantile)
- Toxic erythema of the newborn
- Eosinophilic folliculitis (seen in HIV-positive/immunocompromised)
- Follicular mucinosis
- Skin disorders may produce a follicular eruption that includes the following:
  - Pseudofolliculitis: similar in appearance; occurs after shaving; affects the face, scalp, pubis, and legs. Pseudofolliculitis barbae, or razor bumps, occurs frequently in black men.
  - Atopic dermatitis
  - Follicular psoriasis

## EPIDEMIOLOGY

Affects persons of all ages, gender, and race

## ETIOLOGY AND PATHOPHYSIOLOGY

Predisposing factors to folliculitis

- Chronic staphylococcal carrier
- Diabetes mellitus
- Malnutrition
- Pruritic skin disease (e.g., scabies, eczema, etc.)
- Exposure to poorly chlorinated swimming pools/hot tubs or water contaminated with *P. aeruginosa*, *A. hydrophila*, or schistosomes
- Occlusive corticosteroid use (for multiple hours)
- Bacteria
  - Superficial or deep
  - Most frequently due to *S. aureus* (increasing number of MRSA cases)
  - Also due to *Streptococcus* species, *Pseudomonas* (following exposure to water contaminated with the species), or *Proteus*.

- May progress to furunculosis (painful pustular nodule with central necrosis that leaves a permanent scar after healing)
- Fungal
  - Dermatophytic (tinea capitis, corporis, pedis)
  - Pityrosporum (*Pityrosporum orbiculare*) commonly affecting teenagers and men, predominantly on upper chest and back
  - *Candida albicans*, although rare, has been reported with broad spectrum antibiotic use, glucocorticoid use, immunosuppression, and in those who abuse heroin, resulting in candidemia that leads to pustules and nodules in hair-bearing areas.
- Viral
  - HSV
  - May be due to molluscum contagiosum, usually a sign of immunosuppression
- Parasitic
  - *Demodex* spp. mites (most commonly *Demodex folliculorum*)
  - Schistosomes (swimmer's itch)
- Acneiform type commonly drug-induced (systemic and topical corticosteroids, lithium, isoniazid, rifampin), EGFR inhibitors
- Severe vitamin C deficiency
- Actinic superficial type occurs within 24 to 48 hours of exposure to the sun, resulting in multiple follicular pustules on the shoulders, trunk, and arms.
- Acne vulgaris
- Keloidal folliculitis is a chronic condition affecting mostly black patients; involves the neck and occipital scalp, resulting in hypertrophic scars and hair loss; usually secondary to folliculitis barbae from shaving
- Folliculitis decalvans is a chronic folliculitis that leads to progressive scarring and alopecia of the scalp.
- Rosacea consists of papules, pustules, and/or telangiectasias of the face; individuals are genetically predisposed. *Helicobacter pylori* and *D. folliculorum* have also been implicated.
- Perioral dermatitis seen most commonly in children and young women; restricted to the perioral region as well as the lower eyelids. May be due to cosmetics, hyperandrogenemia, or use of fluorinated topical corticosteroids

- Typically spares vermillion border
- Fox-Fordyce disease affects the skin containing apocrine sweat glands (i.e., axillae), resulting in chronic pruritic, annular, follicular papules.
- Eosinophilic pustular folliculitis (EPF) has three variants: classic (Ofuji disease), associated with HIV infection, and infantile
- Toxic erythema of the newborn is a self-limiting pustular eruption usually appearing during the first 3 to 4 days of life and subsequently fading in the following 2 weeks.
- Malassezia infections in adult males with lesions on trunk (2)

## **RISK FACTORS**

- Hair removal (shaving, plucking, waxing, epilating agents)
- Other pruritic skin conditions: eczema, scabies
- Occlusive dressing or clothing
- Personal carrier or contact with methicillin-resistant *S. aureus* (MRSA)-infected persons
- Diabetes mellitus
- Immunosuppression (medications, chemotherapy, HIV)
- Use of hot tubs or saunas
- Use of EGFR inhibitors
- Chronic antibiotic use (gram-negative folliculitis)

## **GENERAL PREVENTION**

- Good hygiene practices
  - Wash hands frequently.
  - Antimicrobial soap
  - Wash towels, clothes, and linens frequently with hot water to avoid reinfection.
- Good hair removal practices
  - Exfoliate beforehand.
  - Use witch hazel, alcohol, or Tend Skin afterward.
  - Shave in direction of hair growth; use moisturizer/warm water.
  - Decrease frequency of shaving

- Use clippers primarily or single-blade razors if straight shaving is desired.

## *COMMONLY ASSOCIATED CONDITIONS*

- Impetigo
- Furunculosis
- Scabies
- Acne
- Follicular psoriasis
- Eczema

## **DIAGNOSIS**

### **HISTORY**

- Recent use of hot tubs, swimming pools, topical corticosteroids, certain hair styling and shaving practices, antibiotics or systemic steroids
- HIV status
- History of STDs (specifically syphilis)
- MRSA exposures/carrier status
- Ask about home and work environment (risk/exposure potential).
- Pityrosporum folliculitis occurs more often in warm, moist climates.
- Inquire about the timeline in which the lesions have occurred, including previous similar episodes.

### *PHYSICAL EXAM*

- Characteristic lesions are 1- to 5-mm-wide vesicles, pustules, or papulopustules with surrounding erythema.
- Rash occurs on hair-bearing skin, especially the face (beard), proximal limbs, scalp, and pubis.
- Pseudomonas folliculitis appears as a widespread rash, mainly on the trunk and limbs.
- In pseudofolliculitis, the growing hair curls around and penetrates the skin at shaved areas.

### *DIFFERENTIAL DIAGNOSIS*

- Acne vulgaris/acneiform eruptions

Arthropod bite

- Contact dermatitis
- Cutaneous candidiasis
- Milia
- Atopic dermatitis
- Follicular psoriasis
- Hidradenitis suppurativa

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Diagnosis is usually made clinically, taking risk factors, history, and location of lesion into account.
- Culture and Gram stain of the pustule by scraping the pustule with a no. 15 blade and not directly swabbing the skin to identify infectious agent and sensitivities to antibiotics

---

P.383

- KOH preparation as well as Wood lamp fluorescence to identify *Candida* or yeast
- Tzanck smear where suspicion of herpetic simplex viral folliculitis is high

### *Follow-Up Tests & Special Considerations*

- If risk factors or clinical suspicion exist, consider serologies for HIV or syphilis.
- If recurrent, consider HIV testing and A1C/fasting blood sugar testing to evaluate for diabetes.
- Punch biopsy may be considered if lesions persist despite treatment (3)[C].

### *Test Interpretation*

- Treat positive bacterial culture according to sensitivities.
- Positive HIV serology: Follow up with CD4 count and punch biopsy to rule out eosinophilic folliculitis.
- Eosinophilic folliculitis: Collect eosinophils within superficial follicle (4).

## TREATMENT

## GENERAL MEASURES

- Lesions usually resolve spontaneously.
- Avoid shaving and waxing affected areas (5)[C].
- Warm compresses may be applied TID.
- Systemic antibiotics are typically unnecessary.
- Topical mupirocin may be used in presumed *S. aureus* infection.
- Topical antifungals for fungal folliculitis (2)[B]
- Preventive measures are keys to avoidance of recurrence:
  - Antibacterial soaps (Dial soap, chlorhexidine, or benzyl peroxide wash when showering/bathing)
  - Bleach baths (1/2 cup of 6% bleach per standard bathtub, and soak for 5 to 15 minutes followed by water rinse 1 to 2 times a week)
  - Keep skin intact; daily skin care with noncomedogenic moisturizers; avoid scratching.
  - Clean shaving instruments daily or use disposable razor, disposing after 1 use.
  - Change washcloths, towels, and sheets daily.

## MEDICATION

Antiseptic and supportive care is usually enough. Systemic antibiotics may be used with questionable efficacy.

### First Line

- Staphylococcal folliculitis
  - Mupirocin ointment applied TID for 10 days
  - Cephalosporin (cephalexin): 250 to 500 mg PO QID for 7 to 10 days
  - Dicloxacillin: 250 to 500 mg PO QID for 7 to 10 days
- For MRSA
  - Bactrim DS: 1 to 2 tablets (160 mg/800 mg) BID PO for 5 to 10 days
  - Clindamycin: 300 mg PO TID for 10 to 14 days
  - Minocycline: 200 mg PO initially then 100 mg BID for 5 to 10 days
  - Doxycycline: 50 to 100 mg PO BID for 5 to 10 days

- Pseudomonal folliculitis
  - Topical dilute acetic acid baths
  - Ciprofloxacin: 500 to 750 mg PO BID for 7 to 14 days only if patient is immunocompromised or lesions are persistent
- Eosinophilic folliculitis/eosinophilic pustular folliculitis
  - HAART treatment for HIV-positive-related causes
  - Topical corticosteroids: betamethasone 0.1% BID for 3 to 24 weeks *or*
  - Antihistamines (hydroxyzine, cetirizine) *or*
  - Tacrolimus topically BID for 3 to 24 weeks *or*
  - Isotretinoin 0.5 mg/kg/day PO for 4 to 8 weeks *or*
  - Itraconazole or metronidazole
- Fungal folliculitis
  - Topical antifungals: ketoconazole 2% cream or shampoo or selenium sulfide shampoo daily *or*
  - Econazole cream applied to affected area BID for 2 to 3 weeks
    - Systemic antifungals for relapses fluconazole (100 to 200 mg/day for 3 weeks) *or* itraconazole (200 mg/day for 1 to 3 weeks)
    - Griseofulvin (tinea capitis in children; 10 to 20 mg/kg/day for 6 weeks minimum)
- Parasitic folliculitis
  - 5% permethrin: Apply to affected area, leave on for 8 hours, and wash off.
  - Ivermectin: 200 &mgr;g/kg × 1 followed by topical permethrin
- Herpetic folliculitis
  - Valacyclovir: 500 mg PO TID for 5 to 10 days *or*
  - Famciclovir: 500 mg PO TID for 5 to 10 days *or*
  - Acyclovir: 200 mg PO 5 times daily for 5 to 10 days

## ISSUES FOR REFERRAL

Unusual or persistent cases should be biopsied and then referred to dermatology.

## ADDITIONAL THERAPIES

### Public Health Measures

- Outbreaks of culture-positive *Pseudomonas* hot tub folliculitis should be reported so that source identification can be determined and superchlorination (14 parts/million) can occur.

## SURGERY/OTHER PROCEDURES

Incision and drainage is unlikely to be necessary and typically not preferred due to potential for scar formation.

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### Patient Monitoring

- Resistant cases should be followed every 2 weeks until cleared.
- One return visit in 2 weeks if symptoms abate

## DIET

For obese patients, weight reduction will decrease skin-on-skin friction.

## PATIENT EDUCATION

Avoid shaving in involved areas.

## PROGNOSIS

- Usually resolves with treatment; however, *S. aureus* carriers may experience recurrences.
- Mupirocin nasal treatment for carrier status and for family/household members might be helpful.
- Resistant or severe cases may warrant testing for diabetes mellitus or immunodeficiency (HIV) (3)[C].

## COMPLICATIONS

- Primary complication is recurrent folliculitis.
- Extensive scarring with hyperpigmentation
- Progression to furunculosis or abscesses

## See Also

**&NA;**

Algorithm: Rash, Focal

## Codes

**&NA;**

### ICD10

- L73.9 Follicular disorder, unspecified
- L66.2 Folliculitis decalvans
- L73.8 Other specified follicular disorders

## Clinical Pearls

**&NA;**

- Folliculitis lesions are typically 1 to 5 mm clusters of pruritic erythematous papules and pustules.
- Most commonly due to *S. aureus*. If community has increased incidence of MRSA, consider anti-MRSA treatment.
- It is extremely important to educate patients on proper hygiene and skin care techniques in order to prevent chronic or recurrent cases.

# Food Allergy

Stanley Fineman, MD

## BASICS

### DESCRIPTION

- Hypersensitivity reaction caused by certain foods
- System(s) affected: gastrointestinal, hemic/lymphatic/immunologic, pulmonary, skin/exocrine
- Synonym(s): allergic bowel disease; dietary protein sensitivity syndrome

### EPIDEMIOLOGY

- Predominant age: all ages but more common in infants and children
- Predominant sex: male > female (2:1)

### Incidence

Prospective studies indicate  $\pm$ 2.5% of infants experience hypersensitivity reactions to cow's milk in their 1st year of life (1)[B].

### Prevalence

- The true prevalence of IgE-mediated food allergy when assessed by double-blind, placebo-controlled food challenge is 3% (2)[B].
- The self-reported prevalence of food allergy is 12% in children and 13% in adults (2)[B].
- In young children, the most common food allergies are cow's milk (2.5%), egg (1.3%), peanut (0.8%), and wheat (0.4%) (3)[B].
- Adults tend to have allergies to shellfish (2%), peanut (0.6%), tree nuts (0.5%), and fish (0.4%).
- In general, only 3-4% of children >4 years of age have persisting food allergy; food allergy is frequently a transient phenomenon (4)[B].
- 20% of children with peanut protein allergy may outgrow their sensitivity by school age.

### ETIOLOGY AND PATHOPHYSIOLOGY

Allergic response triggered by immunologic mechanisms, such as the classic IgE-allergic response or nonimmunologic-mediated mechanisms

- Any food or ingested substance can cause allergic reactions:
  - Most commonly implicated foods include cow's milk, egg whites, wheat, soy, peanuts, fish, tree nuts (walnut and pecan), and shellfish.
- Several food dyes and additives may elicit non-IgE-mediated allergic-like reactions.

## *Genetics*

In family members with a history of food hypersensitivity, the probability of food allergy in subsequent siblings may be as high as 50%.

## **RISK FACTORS**

- Persons with allergic or atopic predisposition have increased risk of hypersensitivity reaction to food.
- Family history of food hypersensitivity

## **GENERAL PREVENTION**

- Avoidance of offending food
- In patients at risk for anaphylaxis, epinephrine autoinjectors should be readily available.

## **DIAGNOSIS**

### **PHYSICAL EXAM**

- GI (system usually affected)
  - More common: nausea, vomiting, diarrhea, abdominal pain, occult bleeding, flatulence, and bloating
  - Less common: malabsorption, protein-losing enteropathy, eosinophilic-enteritis, colitis
- Dermatologic
  - More common: urticaria/angioedema, atopic dermatitis, pallor, or flushing
  - Less common: contact rashes
- Respiratory

- More common: allergic rhinitis, asthma and bronchospasm, cough, serous otitis media
- Less common: pulmonary infiltrates (Heiner syndrome), pulmonary hemosiderosis
- Neurologic
  - Less common: migraine headaches
- Other symptoms
  - Systemic anaphylaxis, vasculitis

## ***DIFFERENTIAL DIAGNOSIS***

- A careful history is necessary to document a temporal relationship with the manifestations of suspected food hypersensitivity.
- True food allergy or hypersensitivity should be differentiated from food intolerance which may present with similar symptoms.
- GI (irritable bowel syndrome, celiac sprue, dumping syndrome, inflammatory bowel diseases, etc.), dermatologic, respiratory, neurologic, psychiatric (generalized anxiety disorder, personality disorders, etc.), or other systemic manifestations may mimic a variety of clinical entities.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- CBC with differential: Eosinophilia in blood or tissue suggests atopy.
- Serum IgA antitissue transglutaminase (IgA-anti-TTG)
- Epicutaneous (prick or puncture) allergy skin tests are used to document IgE-mediated immunologic hypersensitivity and can be done using commercially available extracts (variable sensitivities) or freshfood skin testing.
- Skin testing using the suspect food is helpful. If positive on skin test, an oral challenge may aid in diagnosis. The overall correlation between commercially available allergy skin testing and oral food challenge is 60% but increases to 90% when fresh food skin testing is done (i.e., a positive skin test correlates with a positive challenge to a particular food)
  - Skin testing has a high sensitivity (low false-negative rate) *but* a low specificity (high false-positive rate) so *only* skin test against antigens found on history (5)[C].
- Food-specific IgE assays (radioallergosorbent [RAST] and fluorescent enzyme immunoassay [FEI]) detect specific IgE antibodies to offending foods and are less sensitive to skin testing.

- In certain laboratories, the ImmunoCap food-specific IgE was almost as accurate as a skin test in predicting positive oral challenges.
- Using a serum assay alone to diagnose food allergy has been shown to result in misdiagnosis of true clinical food allergic sensitivity, particularly in children with atopic dermatitis. Do not test using a panel but rather for specific IgE to foods based on patient history.
- Periodic monitoring of the peanut-specific IgE levels every 2 years may be helpful. If the level of peanut-specific IgE falls to <0.5 kU/L, then a cautious oral challenge under the supervision of an allergist may be considered. A fresh food skin test with peanut protein should be considered prior to the oral challenge (6)[B].
- Patch testing for foods for determining delayed-sensitivity immunologic reactions, in patients with eosinophilic esophagitis and atopic dermatitis, is considered of marginal benefit (7)[B].
- Widespread allergy skin testing or serum IgE tests are *not* recommended because of their poor predictive value without a clinical correlating history (3)[B].
- Leukocyte histamine release and assays for circulating immune complexes are predominantly research procedures and are of limited use in clinical practices:
  - Assays for IgG and IgG 4 subclass antibodies are commercially available.
  - No convincing data suggest that these tests are reliable for the diagnosis of food allergy (4) [B].
- The provocative injection and sublingual provocative tests are highly controversial and have been proven useless for diagnosis of food allergy.
- The leukocytotoxic assay is an unproven diagnostic procedure and is not useful for the diagnosis of allergy (7)[B].
- Other unproven diagnostic procedures that are not recommended include provocative neutralization, lymphocyte stimulation, hair analysis, and applied kinesiology (3)[B].

### *Diagnostic Procedures/Other*

Elimination and challenge test is the best procedure for confirming food allergy:

- The suspected food is eliminated from the diet for 1 to 2 weeks.
- The patient's symptoms are monitored. If they disappear or substantially improve, an oral challenge with the suspected food should be performed under medical supervision.
- Optimally, this challenge should be performed in a double-blind, placebo-controlled manner.
- Patients with history of anaphylaxis should not have an oral challenge unless lack of IgE sensitivity can be documented.

- Most allergic reactions will occur within 30 minutes to 2 hours after challenge, although late reactions have also been described that may occur from 12 to 24 hours.
- Consider referral to gastroenterology for endoscopy and/or psychiatry if history and testing are inconclusive.

## *Test Interpretation*

Pathologic findings are not common in food allergies; however, inflammatory changes can sometimes be seen in the GI tract. The diagnosis of eosinophilic esophagitis is defined by the finding of >15 to 20 eosinophils per high-power field on esophageal biopsy (8)[C].

## **TREATMENT**

### *GENERAL MEASURES*

- Avoiding the offending food is the most effective mode of treatment for patients with food allergies.
- Those patients with exquisite and severe allergy hypersensitivity to a food should be more cautious in their avoidance of that food. They should carry epinephrine for self-administration in the event that the offending food is ingested unknowingly and a subsequent immediate reaction develops.
- Immunotherapy or hyposensitization with food extracts by various routes, including SC immunotherapy or sublingual neutralization, are not recommended. Research studies are in progress, but immunotherapy is considered experimental at this time.

### *MEDICATION*

- Patients with significant type 1, IgE-mediated hypersensitivity should have epinephrine for autoinjection available in case of accidental ingestion and resulting severe anaphylactic reaction.
- After receiving epinephrine for a systemic anaphylactic reaction to a food, the patient should be monitored in a medical facility because 15-25% of patients may require >1 dose of epinephrine.
- Symptomatic treatment for milder reactions (e.g., antihistamine)
- The use of cromolyn has been suggested but is not recommended for use in most patients with food allergy.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

There are reports of benefit using various Chinese herbal medicines in laboratory animals with induced food allergy. Benefits have not been reported in humans at this time.

### ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### *Patient Monitoring*

As needed

### *DIET*

- As determined by tests and clinical evaluation
- Strict avoidance of offending food

## PATIENT EDUCATION

- Patients should be counseled by a dietitian to maintain a nutritionally sound diet despite avoiding those foods to which the patient is sensitive.
- Patient support: Food Allergy Research & Education, Inc.: 7925 Jones Branch Drive Suite 1100 McLean, VA 22102 Toll-Free: 800-929-4040; Web site [www.foodallergy.org](http://www.foodallergy.org)
- Other information available at: [www.allergyasthmanetwork.org](http://www.allergyasthmanetwork.org), [www.acaai.org](http://www.acaai.org), and [www.aaaai.org](http://www.aaaai.org)

## PROGNOSIS

- Most infants will outgrow their food hypersensitivity by 2 to 4 years:
  - It may be possible to reintroduce the offending food cautiously into the diet (particularly helpful when the food is one that is difficult to avoid). It is critical that a specific IgE to the offending food is checked, optimally by fresh food allergy skin test, and is negative prior to an oral challenge.
  - 20% of young children with peanut allergy experience resolution by the age of 5 years.
  - 42% of children with egg allergy and 48% of children with milk allergy develop clinical tolerance and lose their sensitivity over time (1)[C].
- Adults with food hypersensitivity (particularly to milk, fish, shellfish, or nuts) tend to maintain their allergy for many years (3)[B].

## COMPLICATIONS

- Anaphylaxis
- Angioedema
- Bronchial asthma
- Enterocolitis
- Eosinophilic esophagitis
- Eczematoid lesions

# Clinical Pearls

## &NA;

- Recent studies suggest that up to 20% of children with peanut allergy may outgrow their sensitivity:
  - Periodic monitoring of the peanut-specific IgE levels every 2 years may be helpful. If the level of peanut-specific IgE falls to  $<0.5$  kU/L, then a cautious oral challenge under the supervision of an allergist may be considered. A FRESH FOOD skin test with peanut protein should be considered prior to the oral challenge (1)[B].
- Oral itching following ingestion of fresh fruit may be a warning of risk for anaphylaxis but may also represent oral allergy syndrome.
  - This syndrome is the result of cross-reacting proteins in pollens (e.g., patients sensitive to birch tree pollen frequently have cross-reactivity to fresh apples and pears. Cooked fruits are usually tolerated) (1)[B].
- Current evidence does not support a major role for maternal dietary restrictions during pregnancy or lactation in the prevention of atopic disease in infants. It is generally recommended to exclusively breastfeed for the first 6 months of life, particularly when there is a family history of atopy and food allergy. Although solid foods should not be introduced before 4 to 6 months of age, there is no convincing evidence that delaying their introduction beyond this period has a significant protective effect on the development of allergies (9)[C].
- There is a recent evidence suggesting that children 4 to 11 months of age who have eczema or other food allergy may benefit from early introduction of peanut protein. Allergy skin testing should be a consideration prior to introducing peanut protein (10).

# Food Poisoning, Bacterial

Jewell P. Carr, MD

Daniel J. Fisher, MD

## BASICS

### DESCRIPTION

- Food poisoning (also known as foodborne illness) is a state resulting from the consumption of contaminated food (1).
- The illness may be caused by bacterial, parasitic, or viral infection or by toxins produced by bacteria (2).

### EPIDEMIOLOGY

#### Incidence

- The Centers for Disease Control and Prevention (CDC) estimates that roughly 1 in 6 Americans (48 million people) get sick, 128,000 are hospitalized, and 3,000 die of foodborne diseases annually (3).
- Contaminated produce is the most common source of diarrhea due to foodborne infection (1).
- No pathogen is identified in 80% of cases of foodborne illness (3).
- Noroviruses are responsible for >50% of cases of foodborne illness (1).
- According to CDC data, the bacterial pathogens most commonly contributing to foodborne illness are *Salmonella* (nontyphoidal) *Campylobacter*, *Clostridium perfringens*, and *Staphylococcus aureus* (3).

### ETIOLOGY AND PATHOPHYSIOLOGY

- Short incubation period (1 to 6 hours): likely preformed toxin-induced
  - *Bacillus cereus*
    - Food sources: improperly cooked rice/fried rice and red meats
    - Causes sudden onset of severe nausea and vomiting. Diarrhea may be present.

## *S. aureus*

- Food sources: nonrefrigerated or improperly refrigerated meats and potato and egg salads
  - Causes sudden onset of severe nausea and vomiting. Abdominal cramps and fever may be present.
- Medium incubation period (8 to 16 hours)
    - *Bacillus cereus* (toxin)
      - Food sources: meat, stew gravy, vanilla sauce
      - Causes watery diarrhea, abdominal cramps, nausea
    - *C. perfringens*
      - Food sources: dry/precooked meats and poultry
      - Causes watery diarrhea, nausea, abdominal cramps
  - Long incubation period (>16 hours)
    - Toxin-producing organisms:
      - *Clostridium botulinum*: Source is commercially canned or improperly home-canned foods. Causes vomiting, diarrhea, slurred speech, diplopia, dysphagia, and descending muscle weakness/flaccid paralysis
      - Enterohemorrhagic *Escherichia coli* (e.g., O157:H7): Food sources are undercooked beef, especially hamburger, unpasteurized milk, raw fruits and vegetables, and contaminated water. Causes severe diarrhea that often becomes bloody, abdominal pain, vomiting. More common in children <4 years of age
      - Enterotoxigenic *E. coli*: Food sources are foods or water contaminated by human feces. Causes watery diarrhea, abdominal cramps, and vomiting
      - *Vibrio cholerae*: Food sources are contaminated water, fish, and shellfish, especially food sold by street vendors. Causes profuse watery diarrhea and vomiting, which can lead to severe dehydration and death within hours
    - Invasive organisms: often bloody stool and fever
      - *Salmonella*: Food sources are contaminated eggs, poultry, unpasteurized milk or juice, cheese, contaminated raw fruits and vegetables, and contaminated peanut butter. Causes watery diarrhea, fever, abdominal cramps, vomiting
      - *Campylobacter jejuni*: Food sources are raw and undercooked poultry, unpasteurized

milk, and contaminated meats. Causes diarrhea (may be bloody), cramps, vomiting, fever

- *Shigella*: Food sources are food or water contaminated by human fecal material. Causes abdominal cramps, fever, diarrhea
- *Vibrio parahaemolyticus*: Food source is raw shellfish. Causes nausea, vomiting, diarrhea, abdominal pain
- *Vibrio vulnificus*: Food source is undercooked and raw seafood; wounds exposed to sea water. Causes vomiting, diarrhea, abdominal pain, bacteremia, wound infections; can be fatal in patients with liver disease or those who are immunocompromised
- *Yersinia enterocolitica* and *Y. pseudotuberculosis*: Food sources are undercooked pork, unpasteurized milk, tofu, contaminated water. Causes appendicitis-like symptoms: abdominal pain, fever, diarrhea, vomiting; occurs primarily in older children and younger adults
- *Listeria*: Sources include unpasteurized/contaminated milk, soft cheese, and processed/delicatessen meats. Causes nausea, vomiting, fever, watery diarrhea

## RISK FACTORS

- Recent travel to a developing country (1)
- Food handlers, daycare attendees, nursing home residents, and recently hospitalized patients (2)
- Altered immunity due to underlying disease or medications (1); patients taking antacids, H<sub>2</sub> blockers, and proton pump inhibitors (1)
- Cross-contamination and subsequent ingestion of improperly prepared and stored foods

## GENERAL PREVENTION

- When preparing food at home:
  - Wash hands, cutting boards, and surfaces before food preparation and after preparing each food item.
  - Wash fresh produce thoroughly before eating.
  - Keep raw meat, poultry, fish, and their juices away from other food that will not be cooked (e.g., salad).
  - Do not put cooked protein or washed produce back into containers or on surfaces where unwashed or raw food was stored.
  - Thoroughly cook meat to the following internal temperature:

- Fresh beef, veal, pork, and lamb: 145°F
- Ground meats and egg dishes: 160°F
- Poultry: 165°F
- Cook chicken eggs thoroughly until the yolk is firm.
- Refrigerate leftovers within 2 to 3 hours in clean, shallow, and covered containers. If the temperature is >90°F, refrigerate within 1 hour.
- When traveling to underdeveloped countries:
  - Eat only freshly prepared foods.
  - Avoid beverages and foods prepared with nonpotable water.
  - Other risky foods include raw or undercooked meat and seafood, unpeeled raw fruits, and vegetables.
  - Bottled, carbonated, and boiled beverages are generally safe to drink.
- Concerning prevention, improved hygiene and sanitation reduces the risk of traveler's diarrhea, but the prevention strategy "Boil it, Cook it, Peel it, or Forget it" has inconsistent and limited evidence (4,5)[C].
- Chemoprophylaxis for traveler's diarrhea (trips <14 days):
  - Bismuth subsalicylate 525 mg QID (4)[A]
  - Ciprofloxacin 500 mg daily or BID (4)[A]
  - Rifaximin 200 mg daily or BID (4)[A]

## DIAGNOSIS

### HISTORY

- Onset, duration, frequency, severity, and character (i.e., watery, bloody, mucus-filled, etc.) of diarrhea should be noted (2).
- The definition of diarrhea is >3 or more unformed stools daily or the passage of >250 g of unformed stool per day (1).
- Suspect bacterial food poisoning when multiple persons have rapid onset of symptoms after eating the same meal; have high fever, blood, or mucus in stool; severe abdominal pain; signs of dehydration; or recent travel to a foreign country (1,2).
- Any of the following should prompt further evaluation and possible supportive

treatment: high fever ( $101.3^{\circ}\text{F}$ ), 6 stools/day, blood in the stools, elevated white blood cell count, signs of dehydration, and diarrheal illness that lasts  $>2$  to 3 days (1).

- Suspect *Clostridium difficile* colitis if with recent prolonged antibiotic use or recurrent *C. difficile* infection in repeated episodes (1,6).

## PHYSICAL EXAM

- Focus on signs of dehydration: delayed capillary refills, increased skin turgor, dry mucous membranes, and orthostatic changes (2).
- Fever may be suggestive of a more invasive or toxin producing bacteria (2).
- Abdominal exam: important to assess for pain and to differentiate between other acute abdominal processes (2)
- Rectal exam may be useful to assess for blood, rectal pain or consistency of stool (2).

## DIFFERENTIAL DIAGNOSIS

- Infectious gastrointestinal illness of any kind (i.e., viral or parasitic)
- *C. difficile* colitis
- Inflammatory bowel disease
- Appendicitis and other acute abdominal surgical processes
- Hepatitis
- Malabsorption

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Culture of stool and sensitivity, fecal leukocytes, and Hemocult testing; consider ova and parasites if dehydration, history of foreign travel, or symptoms lasting  $>2$  weeks (1)[C].
- CBC, BMP for severe cases with dehydration, inpatient, and nursing home exposure (1)[C]

P.387

- Flexible sigmoidoscopy and colonoscopy are reserved for severe cases or when pathogen is suspected in setting of negative stool cultures (1).
- Abdominal CT may be helpful when intra-abdominal pathology or bowel disease are in the differential (1).

## Follow-Up Tests & Special Considerations

Epidemiologic investigation may be warranted.

## TREATMENT

Most cases of food poisoning are self-limiting and do not require medication.

## MEDICATION

### First Line

- Children, the elderly, and pregnant patients with signs of mild diarrhea should be started on oral rehydration solution to prevent dehydration (2)[C].
- Oral rehydration options can be purchased or mixed simply from common home ingredients: 6 tsp sugar and 1/2 tsp salt in 1 L of clean, potable water (2)[B].
- Travelers may consider empiric treatment for diarrhea with a single dose of ciprofloxacin 750 mg together with loperamide (2)[A].
- Empiric antibiotic therapy for traveler's diarrhea should be considered in cases of moderate to severe disease (4)[A].

### Second Line

For severe cases of food poisoning (up to 8% have bacteremia) or if the patient has a prosthetic valve, the following medications are recommended.

- *B. cereus* (2)
  - Supportive care only
- *Campylobacter jejuni* (1,2,5)
  - Mild: supportive care only-antibiotics may induce resistance (5)
  - Severe: azithromycin 500 mg/day for 3 to 5 days or ciprofloxacin 500mg BID to QID for 5 to 7 days
- *C. botulinum*
  - Supportive care. Antitoxin can be helpful if administered early in the course of the illness.
- *C. perfringens*
  - Supportive care only

- *C. difficile* (1,2,6)
  - Mild disease: metronidazole 500 mg TID for 10 days (6)[A]
  - Moderate disease: vancomycin 125 mg PO QID for 14 days (6)[A]
  - Severe disease: vancomycin 500 mg PO QID plus metronidazole 500 mg IV every 8 hours (6)[A]; or fidaxomicin 200 mg BID for 10 days
  - Discontinue offending antibiotic if applicable.
- Enterohemorrhagic *E. coli* (e.g., O157:H7) (1)
  - Supportive care only. Closely monitor renal function, hemoglobin, and platelets. Infection associated with hemolytic uremic syndrome (HUS). Antibiotics may increase this risk.
- Enterotoxigenic *E. coli* (common cause of traveler's diarrhea) (1,2,4,5)
  - Generally self-limited. Antibiotics shorten course of illness (4,5)[A]
  - Ciprofloxacin 500 mg BID or 750 mg daily for 1 to 3 days; azithromycin 1 g × single dose or daily for 3 days; or rifaximin 200 mg TID for 3 days
- *Salmonella, nontyphoidal* (1,2,4,5)
  - No therapy in mild disease-increases duration of shedding without reducing disease duration (5)
  - Moderate: ciprofloxacin 500 mg BID for 5 to 7 days, levofloxacin 500 mg daily for 7 to 10 days or TMP/SMX DS 160/800 mg twice per day for 5 to 7 days
  - Severe diarrhea, immunocompromised, systemic signs, positive blood cultures: IV ceftriaxone 1 to 2 g daily for 7 to 10 days
- *Shigella* (1,2)
  - Ciprofloxacin 500 mg BID or 750 mg daily for 3 days, or 2-g single dose; alternative options: azithromycin 500 mg twice per day for 3 days, TMP/SMX DS 160/800 mg twice per day for 5 days, or ceftriaxone 2 to 4 g single dose
- *S. aureus* (1)
  - Supportive care only
- Noncholeraic *Vibrio* (1)
  - Ciprofloxacin 750 mg daily for 3 days or azithromycin 500 mg daily for 3 days
- *Vibrio cholerae* (1)

Doxycycline 300 mg 1-time dose in most cases or tetracycline 500 mg QID for 3 days or erythromycin 250 mg TID for 3 days or azithromycin 500 mg/day for 3 days

- *Yersinia* (2)
  - Usually supportive care only
  - Severe: doxycycline combine with aminoglycoside; TMP/SMX DS 160/800 mg BID for 5 days; or ciprofloxacin 500 mg BID for 7 to 10 days

## ADDITIONAL THERAPIES

- For severe nausea and vomiting, promethazine is effective in adults. Ondansetron is effective in children (4).
- Loperamide 4 mg initially, then 2 mg after each loose stool to a maximum of 8 mg in a 24-hour period may be used *unless* high fever, bloody diarrhea, and/or severe abdominal pain present (signs of enteroinvasion) (4)[A]
- Bismuth subsalicylate (Pepto-Bismol) 525 mg QID is moderately effective in traveler's diarrhea (4)[A].
- Probiotics (i.e., *Lactobacillus* sp.) have been shown to reduce severity and sometimes duration by 24 hours. May also decrease likelihood of antibiotic-associated diarrhea (1,2). However, the evidence for their use is inconsistent (4)[C].
- Diligent hand washing during course will decrease spread (2)[A].

## ONGOING CARE

### DIET

- Avoid food while nausea is present, but drink plenty of fluids in frequent sips.
- As the nausea subsides, drink adequate fluids; add in bland, low-fat meals; and rest. Avoid alcohol, coffee, nicotine, and spicy foods.
- Nursing infants should continue to be breastfed on demand, and infants and older children should be offered their usual food.
- For diarrhea, consider a bland diet (BRAT: Bananas, Rice, Apples, Toast-dry).
- Limiting dairy till 24 hours after last diarrhea episode may assist in symptom reduction.

### PROGNOSIS

Most infections are self-limited and will resolve over the course of 4 to 5 days. If antibiotics are

given in moderate to severe traveler's diarrhea, the duration may shorten to a day and a half (Steffen).

## COMPLICATIONS

- Dehydration (2)
- Hemolytic uremic syndrome (HUS following *E. coli* 0157:H7 infection) (5)
- Guillain-Barré syndrome after *Campylobacter* enteritis (1)
- Reactive arthritis after salmonella, shigella, or yersinia infections (1)
- *Clostridium difficile* colitis after antibiotic use (6)
- Postinfectious irritable bowel (1)

## Codes

**&NA;**

### ICD10

- A05.9 Bacterial foodborne intoxication, unspecified
- A02.0 Salmonella enteritis
- A04.5 Campylobacter enteritis

## Clinical Pearls

**&NA;**

- Consider bacterial food poisoning when multiple people present after ingesting the same food with fevers and blood/mucus in stool or have recently returned from a developing nation.
- Consider culture and antibiotics in a prolonged febrile state with blood/mucus in stool, septicemic states, and traveler's diarrhea.
- With signs of enteroinvasion (high prolonged fever, bloody diarrhea, severe pain, septicemia), consider withholding antispasmodics (e.g., loperamide).

# Frostbite

Donald Morando, DO

Lina N. Qazi, DO

Courtney Maiden, DO

## BASICS

### DESCRIPTION

- A localized complication of exposure to cold, causing tissue to freeze, resulting in diminished blood flow to the affected part (especially hands, face, or feet).
- System(s) affected: endocrine/metabolic, skin/exocrine
- Synonym(s): dermatitis congelationis; frostnip; environmental injuries

### EPIDEMIOLOGY

- Predominant age: all ages
- Predominant sex: male = female

### ETIOLOGY AND PATHOPHYSIOLOGY

- Prolonged exposure to cold
- Refreezing thawed extremities
- Ice crystals form intracellularly, damaging capillaries
- Vasoconstriction reduces blood flow and microclotting leads to ischemia.
- Cellular dehydration, abnormal electrolyte concentrations due to the above and ultimately cell death
- In severe cases, deep tissue freezing may occur with damage to underlying blood vessels, muscles, and nerve tissue.
- With rewarming, the ice crystals melt and injured endothelium promotes edema resulting in the formation of epidermal blisters.
- Inflammatory mediators, prostaglandins, and thromboxane A2 induce vasoconstriction and platelet aggregation, worsening ischemia.

## *RISK FACTORS*

- Environmental: lack of proper clothing or shelter resulting in prolonged exposure to below freezing temperatures
- Substance abuse, especially alcohol
- Age: infants and elderly
- Previous cold-related injury
- Decreased caloric intake (<1,500 calories/day)
- Dehydration or hypovolemia
- Underlying psychiatric disturbance
- Smoker
- Lean body mass
- Raynaud phenomenon
- Peripheral vascular disease
- Diabetes

## *GENERAL PREVENTION*

- Dress in layers with appropriate cold weather gear, avoid clothing that is too constricting.
- Cover exposed areas and extremities appropriately.
- Prepare properly for trips to cold climates.
- Minimize wind exposure.
- Stay dry.
- Avoid alcohol.
- Ensure adequate hydration and caloric intake.
- Supplemental oxygen at very high altitudes (>7,500 meters)

## *COMMONLY ASSOCIATED CONDITIONS*

- Alcohol and/or drug abuse
- Hypothermia

# DIAGNOSIS

## HISTORY

- Throbbing pain
- Paresthesia
- Excessive sweating
- Joint pain
- Determine duration and severity of cold exposure.

## PHYSICAL EXAM

- Feet, hands, and face are the most commonly affected.
- Classified as superficial or deep injuries
- Superficial: Only the skin and subcutaneous tissues are involved. Tissue is pliable. White mottled appearance with minimal capillary refill. Erythematous and edematous on rewarming, blisters are usually clear and neurovascular compromise is reversible.
- Deep: Injury extends into the bone. Tissue remains mottled and pulseless after rewarming, loss of sensation persists. Infrequent hemorrhagic blister formation. Tissue loss is common. High risk of infection

## DIFFERENTIAL DIAGNOSIS

- Frostnip: a superficial cold injury that does not cause permanent damage
- Chilblains (pernio): an inflammatory reaction to short-term cold, wet exposure without tissue freezing
- Immersion syndrome (trench foot): inflammatory reaction to prolonged cold, wet exposure, typically socks or footwear

## DIAGNOSTIC TESTS & INTERPRETATION

ECG in hypothermia may show bradycardia, atrial fibrillation, atrial flutter, ventricular fibrillation, diffuse T-wave inversion, Osborn waves (upward-going hump following S wave in the RST segment).

### *Initial Tests (lab, imaging)*

- Baseline labs: CBC, CMP, UA for myoglobinuria, culture wound if suspected infection
- Triple-phase bone scan can identify tissue viability at early stage and facilitate early

dŽbridement.

- Other imaging techniques sometimes used include MRI/MRA, infrared thermography, angiography, digital plethysmography, and laser Doppler studies.

## *Test Interpretation*

- Ice crystallization in the intravascular extracellular space
- Atrophy
- Fibroblastic proliferation
- Skin necrosis

## **TREATMENT**

### *Geriatric Considerations*

- Associated disease states increase mortality.
- Periarticular osteoporosis complicates
- More prone to hypothermia

### *Pediatric Considerations*

Loss of epithelial growth centers

#### **ALERT**

Acidosis

## **GENERAL MEASURES**

- Admit patient to a burn center for deep injuries.
- Increase patient's body temperature to 34°C.
- Only warm areas of injury if possibility of refreezing can be excluded. Warm affected parts of body in 37-39°C water with antiseptics (iodine, polyhexanide) for 15 to 60 minutes or until skin color changes to red/violet (1)[C].
- Apply topical aloe vera gel before dressing.
- DŽbride open blisters only, dŽbridement of tense, cloudy, or clear blisters at discretion of provider
- Splint and elevate affected extremity.

- Tetanus prophylaxis
- Analgesia and hydration, oral hydration if patient is alert and has no GI symptoms, otherwise IV hydration with warm normal saline in small boluses.
- Ibuprofen 400 mg BID
- Daily bathing in warm water containing antiseptics with active and passive mobilization
- Dry, loose bulky dressings, including in between fingers/toes (2)[C]
- Prohibit smoking
- Regular monitoring for reperfusion, consider experimental vasodilatation, thrombolytics, or sympathectomy for failed reperfusion (1)[C].

## *MEDICATION*

### *First Line*

- tPA administered within 24 hours of injury may prevent damage from thrombosis and may reduce amputation rate (3),(4)[B].
- Low-molecular-weight dextran to decrease blood viscosity should be considered in patients not given other systemic treatments (e.g., thrombolysis) (2)[C].
- Aspirin 250 mg plus buflomedil 400 mg IV followed by 8 days of iloprost 0.5 to 2 mg/kg/min for 6 hr/day may prevent amputation in patients with frostbite extending to the proximal phalanx (5)[B].
- Tetanus toxoid
- Ibuprofen 400 mg q12h to inhibit prostaglandins (6)[C]
- NSAIDs for mild to moderate pain; for severe pain, narcotic analgesia
- Systemic antibiotics should be used for proven infection, trauma, or cellulitis. Prophylactic antibiotics are not recommended (7)[C].
- **Precautions:** tPA should not be used with history of recent bleeding, stroke, ulcer, and so forth.

---

P.389

### *Second Line*

Pentoxifylline has been tried with some success (6)[C].

## *ADDITIONAL THERAPIES*

Heated oxygen

- Warm IV fluids via central venous pressure line
- Avoid rubbing the affected area, as this can lead to further tissue destruction and worse outcomes.

## ***SURGERY/OTHER PROCEDURES***

- Urgent surgery is rarely needed, except fasciotomy for compartment syndrome.
- Suspect compartment syndrome if tissue swollen and compartment pressures >37 to 40 mm Hg.
- Fasciotomy is indicated if elevated compartment pressures (2)[B]
- Surgical débridement, as needed, to remove necrotic tissue
- Amputation should not be considered until tissues are definitively dead: may take ÷3 weeks to know whether the tissue is permanently injured.
- Imaging with 99 mTc bone scan and/or MRA should be considered in severe cases to help determine extent of injury and assess viability of surrounding tissue. Imaging can help determine need for surgery (8).

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Hospitalization is generally recommended unless no blisters are present after rewarming (4,8).

- Institute emergency measures for hypothermic patient without pulse or respiration. Such measures may include CPR and internal warming with warm IV fluids and warm oxygen (see topic "Hypothermia").
- Prevent refreezing.
- It may be necessary to keep the frostbitten part frozen until the patient can be transported to a care facility. Prolonged freezing is preferable to warming and refreezing (9)[C].
- Remove nonadherent wet clothing and shoes.
- Treat for hypothermia.
- Treat for pain.
- NSAIDs and/or narcotics, if needed.
- Do not rub areas to warm them; increased tissue damage may occur (3)[C].
- Avoid pressure on frostbitten body parts except when the life of the patient or rescuer is in

danger (10)[C].

## *IV Fluids*

If patient cannot tolerate oral fluids or has altered mental status, give warmed normal saline in small boluses (2)[C].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Outpatient or inpatient, depending on severity

- As tolerated; protect injured body parts.
- Initiate physical therapy once healing progresses sufficiently.
- Avoid nicotine.
- Avoid recurrent cold exposure.
- Properly fitting attire; consider custom footwear if feet were affected (7).

### *Patient Monitoring*

- Preferably, electronic probe for temperature monitoring (rectal or vascular)
- Follow-up for physical therapy progress, infection, other complications

### *DIET*

- As tolerated
- Warm oral fluids

### *PATIENT EDUCATION*

- Refer to local library for information.
- Provide education on
  - Exposure protection
  - Risk factors for frostbite injuries
  - Early signs and symptoms of frostbite

### *PROGNOSIS*

- Anesthesia and bullae may occur.
- The affected areas will heal or mummify without surgery; the process may take 6 to 12 months for healing.
- Patient may be sensitive to cold and experience burning and tingling.
- Cyanotic nonblanching skin and blisters with dark fluid suggest worse prognosis (9)[C].
- Loss of sensation after rewarming indicates poor prognosis.

## COMPLICATIONS

- Hyperglycemia
- Acidosis
- Refractory arrhythmias
- Tissue loss: Distal parts of an extremity may undergo spontaneous amputation.
- Gangrene
- Hyperhidrosis due to nerve injury
- Decreased hair and nail growth
- Raynaud phenomenon
- Chronic regional pain
- Localized osteoporosis
- Death

- T34.90XA Frostbite with tissue necrosis of unsp sites, init encntr
- T33.829A Superficial frostbite of unspecified foot, initial encounter

## **Clinical Pearls**

**&NA;**

- Frostbite is considered a tetanus-prone injury. Treat as any injury involving tissue destruction.
- Avoid rewarming en route to the hospital if there is a chance of refreezing. Avoid burns to affected areas, which may be numb and insensitive to heat.
- It is difficult to assess degree of tissue involvement early on. Delay surgery until definite tissue destruction is present.

# Furunculosis

Zoltan Trizna, MD, PhD

## BASICS

### DESCRIPTION

- Acute bacterial abscess of a hair follicle (often *Staphylococcus aureus*)
- System(s) affected: skin/exocrine
- Synonym(s): boils

### EPIDEMIOLOGY

#### Incidence

- Predominant age
  - Adolescents and young adults
  - Clusters have been reported in teenagers living in crowded quarters, within families, or in high school athletes.
- Predominant sex: male = female

#### Prevalence

Exact data are not available.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Infection spreads away from hair follicle into surrounding dermis.
- Pathogenic strain of *S. aureus* (usually); most cases in United States are now due to community-acquired methicillin-resistant *S. aureus* (CA-MRSA) whereas methicillin-sensitive *S. aureus* (MSSA) is most common elsewhere (1).

#### Genetics

Unknown

## RISK FACTORS

- Carriage of pathogenic strain of *Staphylococcus* sp. in nares, skin, axilla, and perineum
- Rarely, polymorphonuclear leukocyte defect or hyperimmunoglobulin E-*Staphylococcus* sp. abscess syndrome
- Diabetes mellitus, malnutrition, alcoholism, obesity, atopic dermatitis
- Primary immunodeficiency disease and AIDS (common variable immunodeficiency, chronic granulomatous disease, Chediak-Higashi syndrome, C3 deficiency, C3 hypercatabolism, transient hypogammaglobulinemia of infancy, immunodeficiency with thymoma, Wiskott-Aldrich syndrome)
- Secondary immunodeficiency (e.g., leukemia, leukopenia, neutropenia, therapeutic immunosuppression)
- Medication impairing neutrophil function (e.g., omeprazole)
- The most important independent predictor of recurrence is a positive family history.

## GENERAL PREVENTION

Patient education regarding self-care (see "General Measures"); treatment and prevention are interrelated.

## COMMONLY ASSOCIATED CONDITIONS

- Usually normal immune system
- Diabetes mellitus
- Polymorphonuclear leukocyte defect (rare)
- Hyperimmunoglobulin E-*Staphylococcus* sp. abscess syndrome (rare)
- See "Risk Factors."

## DIAGNOSIS

### HISTORY

- Located on hair-bearing sites, especially areas prone to friction or repeated minor traumas (e.g., underneath belt, anterior aspects of thighs, nape, buttocks)
- No initial fever or systemic symptoms
- The folliculocentric nodule may enlarge, become painful, and develop into an

abscess (frequently with spontaneous drainage).

## **PHYSICAL EXAM**

- Painful erythematous papules/nodules (1 to 5 cm) with central pustules
- Tender, red, perifollicular swelling, terminating in discharge of pus and necrotic plug
- Lesions may be solitary or clustered.

## **DIFFERENTIAL DIAGNOSIS**

- Folliculitis
- Pseudofolliculitis
- Carbuncles
- Ruptured epidermal cyst
- Myiasis (larva of botfly/tumbu fly)
- Hidradenitis suppurativa
- Atypical bacterial or fungal infections

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

Obtain culture if with multiple abscesses marked by surrounding inflammation, cellulitis, systemic symptoms such as fever, or if immunocompromised.

### ***Follow-Up Tests & Special Considerations***

- Immunoglobulin levels in rare (e.g., recurrent or otherwise inexplicable) cases
- If culture grows gram-negative bacteria or fungus, consider polymorphonuclear neutrophil leukocyte functional defect.

### ***Test Interpretation***

Histopathology (although a biopsy is rarely needed)

- Perifollicular necrosis containing fibrinoid material and neutrophils
- At deep end of necrotic plug, in SC tissue, is a large abscess with a Gram stain positive for small collections of *S. aureus*.

## TREATMENT

### GENERAL MEASURES

- Moist, warm compresses (provide comfort, encourage localization/pointing/drainage) 30 minutes QID
- If pointing or large, incise and drain: consider packing if large or incompletely drained.
- Routine culture is not necessary for localized abscess in nondiabetic patients with normal immune system.
- Sanitary practices: Change towels, washcloths, and sheets daily; clean shaving instruments; avoid nose picking; change wound dressings frequently; do not share items of personal hygiene (2)[B].

### MEDICATION

#### First Line

- Systemic antibiotics usually *unnecessary*, unless extensive surrounding cellulitis or fever
- If suspecting MRSA, see *Second Line*.

P.391

- If multiple abscesses, lesions with marked surrounding inflammation, cellulitis, systemic symptoms such as fever, or if immunocompromised: place on antibiotics therapy directed at *S. aureus* for 10 to 14 days.
  - Dicloxacillin (Dynapen, Pathocil) 500 mg PO QID *or* cephalexin 500 mg PO QID *or* clindamycin 300 mg TID, if penicillin-allergic

#### Second Line

- Resistant strains of *S. aureus* (MRSA): clindamycin 300 mg q6h *or* doxycycline 100 mg q12h *or* trimethoprim-sulfamethoxazole (TMP-SMX DS) 1 tab q8-12h *or* minocycline 100 mg q12h
- If known or suspected impaired neutrophil function (e.g., impaired chemotaxis, phagocytosis, superoxide generation), add vitamin C 1,000 mg/day for 4 to 6 weeks (prevents oxidation of neutrophils).
- If antibiotic regimens fail:
  - May try PO pentoxifylline 400 mg TID for 2 to 6 months
  - Contraindications: recent cerebral and/or retinal hemorrhage; intolerance to

methylxanthines (e.g., caffeine, theophylline); allergy to the particular drug selected

- Precautions: prolonged prothrombin time (PT) and/or bleeding; if on warfarin, frequent monitoring of PT

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Instruct patient to see physician if compresses are unsuccessful.

#### *DIET*

Unrestricted

### *PROGNOSIS*

- Self-limited: usually drains pus spontaneously and will heal with or without scarring within several days.
- Recurrent/chronic: may last for months or years
- If recurrent, usually related to chronic skin carriage of staphylococci (nares or on skin). Treatment goals are to decrease or eliminate pathogenic strain *or* suppress pathogenic strain.
  - Culture nares, skin, axilla, and perineum (culture nares of family members).
  - Mupirocin 2%: Apply to both nares BID for 5 days each month.
  - Culture anterior nares every 3 months; if failure, retreat with mupirocin or consider clindamycin 150 mg/day for 3 months.
- Especially in recurrent cases, wash entire body and fingernails (with nailbrush) daily for 1 to 3 weeks with povidone-iodine (Betadine), chlorhexidine (Hibiclens), or hexachlorophene (pHisoHex soap), although all can cause dry skin.

### **COMPLICATIONS**

- Scarring
- Bacteremia
- Seeding (e.g., septal/valve defect, arthritic joint)

## See Also

&NA;

Folliculitis; Hidradenitis Suppurativa

## Codes

&NA;

## ICD10

- L02.92 Furuncle, unspecified

- L02.12 Furuncle of neck
- L02.429 Furuncle of limb, unspecified

## Clinical Pearls

### &NA;

- Pathogens may be different in different localities. Keep up-to-date with the locality-specific epidemiology.
- If few, furuncles/furunculosis do not need antibiotic treatment. If systemic symptoms (e.g., fever), cellulitis, or multiple lesions occur, oral antibiotic therapy is used.
- Other treatments for MRSA include linezolid PO or IV and IV vancomycin.
- Folliculitis, furunculosis, and carbuncles are parts of a spectrum of pyodermas.
- Other causative organisms include aerobic (e.g., *Escherichia coli*, *Pseudomonas aeruginosa*, and *Streptococcus faecalis*), anaerobic (e.g., *Bacteroides*, *Lactobacillus*, *Peptobacillus*, and *Peptostreptococcus*), and *Mycobacteria*.
- Decolonization (treatment of the nares with topical antibiotic) is only recommended if the colonization was confirmed by cultures because resistance is common and treatment is of uncertain efficacy.

# Galactorrhea

Nicole Nelson, DO

David Bode, MD

## BASICS

### DESCRIPTION

- Milky nipple discharge not associated with gestation or present >1 year after weaning. Galactorrhea does not include serous, purulent, or bloody nipple discharge.
- System(s) affected: endocrine/metabolic, nervous, reproductive
- Synonym(s): disordered lactation; nipple discharge

### *Pregnancy Considerations*

Most cases of galactorrhea during pregnancy are physiologic.

### EPIDEMIOLOGY

- Predominant age: 15 to 50 years (reproductive age)
- Predominant sex: female > male (rare, e.g., in patients with multiple endocrine neoplasia type 1 [MEN1], the most common anterior pituitary tumors are prolactinomas)

### *Incidence*

Common

### *Prevalence*

6.8% of women referred to physicians with a breast complaint have nipple discharge.

### ETIOLOGY AND PATHOPHYSIOLOGY

Disorders of lactation are associated with elevated prolactin levels, either from overproduction or loss of inhibitory regulation by dopamine.

- Nipple stimulation
- Pituitary gland overproduction

- Prolactinoma
- Loss of dopamine via hypothalamic dysregulation
  - Craniopharyngiomas
  - Meningiomas or other tumors
  - Sarcoid
  - Irradiation
  - Vascular insult
  - Stalk disruption
  - Traumatic injury
- Medications that suppress dopamine (1):
  - Typical and atypical antipsychotics
  - SSRIs
  - Tricyclic antidepressants
  - Cimetidine
  - Ranitidine
  - Reserpine
  - α-Methyldopa
  - Verapamil
  - Estrogens
  - Isoniazid
  - Opioids
  - Stimulants
  - Neuroleptics
  - Metoclopramide
  - Domperidone
  - Protease inhibitors
- Chest wall injury
  - Zoster, surgical, or other trauma

- Postoperative condition, especially oophorectomy
- Renal failure
- Other causes
  - Primary hypothyroidism
  - Cirrhosis
  - Cushing disease
  - Ectopic prolactin secretion
  - Renal failure
  - Sarcoid
  - Lupus
  - Multiple sclerosis
  - Polycystic ovary syndrome
- Idiopathic
  - Normal prolactin levels

## ***GENERAL PREVENTION***

- Frequent nipple stimulation can cause galactorrhea.
- Avoid medications that can suppress dopamine.

## ***COMMONLY ASSOCIATED CONDITIONS***

See ÒEtiology and Pathophysiology.Ó

## **DIAGNOSIS**

- Findings vary with causes
- Look for signs/symptoms of associated conditions:
  - Adrenal insufficiency
  - Acromegaly
  - Hypothyroidism
  - Chest wall conditions

## **HISTORY**

- Usually bilateral milky nipple discharge; may be spontaneous or induced by stimulation
- Determine possibility of pregnancy or recent discontinuation of lactation
- Signs of hypogonadism from hyperprolactinemia
  - Oligomenorrhea, amenorrhea
  - Inadequate luteal phase, anovulation, infertility
  - Decreased libido (especially in affected males)
- Mass effects from pituitary enlargement
  - Headache, cranial neuropathies
  - Bitemporal hemianopsia, amaurosis, scotomata

## **PHYSICAL EXAM**

Breast examination should be performed with attention to the presence of spontaneous or induced nipple discharge.

## **DIFFERENTIAL DIAGNOSIS**

- Pregnancy-induced lactation or recent weaning
- Nonmilky nipple discharge
  - Intraductal papilloma
  - Fibrocystic disease
- Purulent breast discharge
  - Mastitis
  - Breast abscess
  - Impetigo
  - Eczema
- Bloody breast discharge: Consider malignancy (Paget disease, breast cancer).

## **DIAGNOSTIC TESTS & INTERPRETATION**

Perform formal visual field testing if pituitary adenoma suspected.

## *Initial Tests (lab, imaging)*

- Prolactin level, thyroid-stimulating hormone, pregnancy test, liver, and renal functions
- Drugs that may alter lab results: medications that can cause hyperprolactinemia
- Situations that may alter lab results:
  - Lab evaluation of prolactin may be falsely elevated by a recent breast examination.
  - Vigorous exercise
  - Sexual activity
  - High-carbohydrate diet
  - Consider repeating the test under different circumstances if the value is borderline (30 to 40) elevated.
- Prolactin levels may fluctuate. Elevated prolactin levels should be confirmed with at least one additional level drawn in a fasting, nonexercised state, with no breast stimulation (2)[C].
- Prolactin levels >250 ng/mL are highly suggestive of a pituitary adenoma (3)[C].
- If a breast mass is palpated in the setting of nipple discharge, evaluation of that mass is indicated with mammogram and/or ultrasound.
- Pituitary MRI with gadolinium enhancement if the serum prolactin level is significantly elevated (>200 ng/mL) or if a pituitary tumor is otherwise suspected.

## *Follow-Up Tests & Special Considerations*

- Consider evaluation of follicle-stimulating hormone and luteinizing hormone if amenorrheic.
- Consider evaluation of growth hormone levels if acromegaly suspected.
- Measure adrenal steroids if signs of Cushing disease present.

## *Diagnostic Procedures/Other*

If diagnosis is in question, confirm by microscopic evaluation that nipple secretions are lipid.

## *Test Interpretation*

None, unless pituitary resection required

## **TREATMENT**

- Avoid excess nipple stimulation.
- Idiopathic galactorrhea (normal prolactin levels) does not require treatment.
- Discontinue causative medications, if possible.
- Treat to manage symptoms, reduce patient anxiety, and restore fertility.
- Treat tumors >10 mm (even if asymptomatic) to reduce pituitary tumor size or prevent progression to avoid neurologic sequelae.
- If microadenoma, watchful waiting can be appropriate because 95% do not enlarge.

## **MEDICATION**

- Dopamine agonists work to reduce prolactin levels and shrink tumor size. Therapy is suppressive, not curative (4)[C].
- Treatment is discontinued when tumor size has reduced or regressed completely or after pregnancy has been achieved.
- Cabergoline (Dostinex)
  - Start at 0.25 mg PO twice weekly and increase by 0.25 mg monthly until prolactin levels normalize. Usual dose ranges from 0.25 to 1 mg PO once or twice weekly.
  - More effective and better tolerated than bromocriptine (5)[A]
  - Convenient dosing
- Although cabergoline has been associated with valvular heart disease in patients treated for Parkinson disease, the lower doses used in treatment of prolactinomas have not been adequately studied (6)[C].
- Bromocriptine
  - Start at 1.25 mg/day PO with food and increase weekly by 1.25 mg/day until therapeutic response achieved (usually 2.5 to 15 mg/day, divided once daily/TID).
  - More expensive and more frequent dosing; however, most providers have experience with this effective drug.
  - Long-term treatment can cause woody fibrosis of the pituitary gland.
- Contraindications are similar for all and include the following:
  - Uncontrolled hypertension
  - Sensitivity to ergot alkaloids
- Precautions

- Nausea, vomiting, and drowsiness are common.
- Orthostasis, light-headedness, or syncope
- Hypertension, seizures, acute psychosis, and digital vasospasm are rare.
- Significant possible interactions
  - Phenothiazines, butyrophenones; other drugs listed under ÒEtiology and PathophysiologyÓ

## ***SURGERY/OTHER PROCEDURES***

- Surgery
  - Macroadenomas need surgery if (a) medical management does not halt growth, (b) neurologic symptoms persist, (c) size >10 mm, or (d) patient cannot tolerate medications. Also considered in young patients with microadenomas to avoid long-term medical therapy.
  - Transsphenoidal pituitary resection
  - 50% recurrence after surgery
- Radiotherapy
  - Radiation is an alternative tumor therapy for macroprolactinomas not responsive to other modes of treatment:
    - 20-30% success rate
    - 50% risk of panhypopituitarism after radiation
    - Risk of optic nerve damage, hypopituitarism, neurologic dysfunction, and increased risk for stroke and secondary brain tumors

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Outpatient care unless pituitary resection required
- Bromocriptine patients need adequate hydration
- Dopamine agonist therapy should be discontinued in pregnancy.

### ***Patient Monitoring***

- Varies with cause

- Check prolactin levels every 6 weeks until normalized, then every 6 to 12 months.
- Monitor visual fields and/or MRI at least yearly until stable.

## **DIET**

No restrictions

## **PATIENT EDUCATION**

- Warn about symptoms of mass enlargement in pituitary.
- Discuss treatment rationale, risks of treating, and expectant management.
- Patient education material available from American Family Physician:  
[www.aafp.org/afp/20040801/553ph.html](http://www.aafp.org/afp/20040801/553ph.html)

## **PROGNOSIS**

- Depends on underlying cause
- Symptoms can recur after discontinuation of a dopamine agonist.
- Surgery can have 50% recurrence.
- Prolactinomas <10 mm can resolve spontaneously.

## **COMPLICATIONS**

- If enlarging pituitary adenoma, risk of permanent visual field loss
- Panhypopituitarism can complicate radiation or surgical therapy.
- Osteoporosis if amenorrhea persists without estrogen replacement.

## Clinical Pearls

&NA;

- Galactorrhea is a common disorder, affecting up to 50% of reproductive-age women.
- Common causes include idiopathic, from excess nipple stimulation, dopamine-suppressing

medications, or pituitary prolactinoma

- Most cases may be adequately evaluated by thyroid-stimulating hormone, prolactin, and human chorionic gonadotropin measurement, with additional testing as suggested by the presence of other symptoms or signs.
- Lab evaluation of prolactin may be falsely elevated due to recent sexual activity, breast examination, exercise, or a high-carbohydrate diet. Repeat any borderline elevation before continuing evaluation or initiating treatment.
- Evaluate prolactin  $>200$  ng/mL (or suspicion of pituitary macroadenoma) with a gadolinium-enhanced MRI.

# Gambling Addiction

Rebecca Collins, DO, MPH, FAAFP

## BASICS

### DESCRIPTION

Gambling is the act of placing something of value at risk in the hopes of gaining something of greater value. Pathologic gambling (PG) and problem gambling affect up to 15 million Americans with the number of those affected increasing, especially in young people. The essential feature of gambling disorder is persistent and recurrent maladaptive gambling behavior that disrupts personal, family, and/or vocational pursuits. Individuals with gambling disorder have high rates of comorbidity with other mental disorders (substance use, depression, anxiety, and personality disorders). There is a debate as to whether gambling addiction is an impulse-control disorder or a non-substance abuse-related disorder.

### EPIDEMIOLOGY

- Predominant sex: male > female, though gap narrowing
- Rates of pathologic and problem gambling are higher in adolescents and middle-age persons than older adults.
- The younger a person starts gambling, the more likely he or she is to become a pathologic gambler.
- Economics: \$0.5 trillion wagered in United States annually.

### Prevalence

- Lifetime gambling disorder prevalence is 0.4-1% in the U.S. adults.
  - Males 0.6%, females 0.2%
  - African American 0.9%, Caucasian 0.4%, Hispanic 0.3%
- Living in closer proximity to a casino increases prevalence.

### GENERAL PREVENTION

- Focus on treatment; patient education; awareness of risk factors, associated conditions, and warning signs of pathologic or problematic gambling behaviors.

- Primary prevention using educational programs that target at-risk youth and adults
- Public health interventions: Decrease available gambling locations and lottery venues, ban advertising for gambling activities, keep lottery tickets out of sight, add warning label of risk of problem gambling to packaging of gambling products, enforce legal age of gambling, moratorium on building new casinos (1).

## ETIOLOGY AND PATHOPHYSIOLOGY

- *DSM-5* characterizes gambling disorder as a nonsubstance related and addictive disorder; however, there is a debate whether it is an impulse-control disorder or possibly both.
- Impulse control: changes in serotonin metabolites in pathologic gamblers and patients with impulse-control disorders
- Substance abuse: similarities found between PG and substance use (tolerance, withdrawal, anticipatory craving, relapses)
- The brains of pathologic gamblers may have some predisposition to illness. Functional MRI studies indicate that the ventromedial prefrontal cortex is less activated when gambling stimuli are presented to pathologic gamblers.
- Abnormalities in the neurotransmitters serotonin, norepinephrine, dopamine, and glutamate may be implicated in PG.
  - Norepinephrine: Low levels seem to help a patient avoid gambling, whereas high levels may lead to poor decision making.
  - Serotonin: involved in impulse control by helping a patient weigh the risks of gambling
  - Dopamine: High levels in the nucleus accumbens while gambling lead to a pleasurable rush may induce reversible PG in Parkinson patients who take dopamine agonists.
- Medicine classes for each category have been used to treat.

## Genetics

- *SLC6A4* serotonin transporter gene has been associated with PG in males but not in females.
- Dopamine receptor genes *DRD1*, *DRD2*, *DRD3*, and *DRD4* have been correlated with PG.
- More prevalent among first-degree relatives of alcoholics than among general population.

## RISK FACTORS

- Some types of gambling present a greater risk to cause PG than other types: pull tabs, casino gambling, bingo, and card games outside a casino

- Being involved with several gaming modalities is related to PG and suggests that the gambler is very captivated with risking money for excitement as opposed to risking money for social pleasure or for an interest in sports.
- Lower socioeconomic status
- Adults in mental health treatment
- Substance abuse (nicotine, alcohol, inhalants, marijuana)
- Positive family history
- Antisocial personality disorder, depressive and bipolar disorders, other substance abuse disorders (especially alcohol)

## COMMONLY ASSOCIATED CONDITIONS

- Poor nutrition
- Stress-related medical conditions (e.g., peptic ulcer disease [PUD], hypertension, migraine, palpitations)
- Suicidal ideation and attempts
- Substance abuse disorder (especially alcohol)
- Attention deficit hyperactivity disorder
- Bipolar disorder and other mood disorders
- Impulse-control disorders
- Personality disorders
- Incarceration
- Financial problems (e.g., previous bankruptcy)

## DIAGNOSIS

DSM-5 criteria for gambling disorder (2):

- Persistent and recurrent gambling behavior leading to significant impairment or distress as indicated by <sup>24</sup> of the following in a 12-month period, AND gambling behavior is not better explained by a manic episode:
  - Often preoccupied with gambling
  - Need to gamble with increasing amounts of money to achieve the desired excitement

Repeated unsuccessful efforts to control, cut back, or stop gambling

- Restless or irritable when attempting to cut down or stop gambling
  - Often gambles when feeling distressed (e.g., helpless, guilty, anxious, depressed)
  - After losing money gambling, often returns another day to get even (‘chasing’ one's loses)
  - Lies to conceal the extent of involvement with gambling
  - Has jeopardized or lost a significant relationship, job, or educational or career opportunity because of gambling
  - Relies on others to provide money to relieve a desperate financial situation caused by gambling (‘bailout’ behavior)
- Specifiers:
    - Episodic: meets diagnostic criteria at >1 time point with symptoms subsiding for at least several months
    - Persistent: continuous symptoms for multiple years
    - Early remission: After criteria met previously, none met for <sup>3</sup>3 months but <12 months.
    - Sustained remission: After criteria met previously, no criteria met for <sup>3</sup>12 months.
    - Current severity: mild (4 to 5 criteria), moderate (6 to 7 criteria), or severe (8 to 9 criteria)

## HISTORY

- Preoccupation with gambling and chasing losses are most frequently endorsed criteria.
- Those with moderate to severe forms of disorder are usually the individuals who present for treatment.
- May have distortions in thinking (e.g., denial, superstitions, sense of power and control over outcome of chance events)
- Preoccupation with money; belief that money is the cause and solution to their problems
- Personality characteristics: impulsivity, competitive, energetic, restless OR depressed, lonely, helpless, guilty
- 50% of patients in treatment for PG have suicidal ideation, 17% have suicide attempts.
- Symptoms can develop anytime from adolescence through older adulthood.
- Amounts of money wagered is not in themselves indicative of gambling disorder (some individuals can wager thousands of dollars per month and not

have a problem, some may wager much smaller amounts but experience substantial gambling-related difficulties).

- Loss of important relationships with family or friends
- Absenteeism or poor work/school performance
- Poor general health; high use of medical services
- Unexplained new financial problems
- New participation in illegal or dishonest money-making endeavors or activities
- Disruptions in personal life or career
- Patient may ask his or her family and friends to pay off his or her debts (“bailing them out”).

P.395

## *DIFFERENTIAL DIAGNOSIS*

- Social gambling
- Professional gambling
- Bipolar disorder, manic episode
- Personality disorder
- Other medical conditions (patients on dopaminergic medications, e.g., Parkinson)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- South Oaks Gambling Screen (SOGS):
  - Most extensively used and validated screening tool
  - 20-question screen for PG
  - Score of 3 to 4 suggests problem gambling.
  - Score of  $\geq 5$  indicates probable PG.
  - Criticized as having high false-positive rate and being too lengthy to administer
- Gamblers Anonymous 20 questions:
  - Easily obtainable from Gamblers Anonymous Web site
  - Scores of  $>7$  are indicative of problem/PG.
- Lie/Bet method: ÒHave you ever had to lie to people important to you about how much you gambled?Ó ÒHave you ever felt a need to bet more money?Ó:

- A patient who answers at least one question with a "Yes" suggests further investigation needed to see if criteria are met for PG.
- This test has been shown to have >85% specificity and >95% sensitivity.

## *Initial Tests (lab, imaging)*

None usually indicated

## **TREATMENT**

To treat PG, treat comorbidities first. The usual comorbid disorders are substance abuse, bipolar disorder, ADHD, and other impulse-control disorders. Nonpharmacologic therapies are more effective than pharmacologic therapies. Some data suggest that gambling abstinence is not necessary for treatment; patients can still exhibit controlled gambling.

## **GENERAL MEASURES**

- Get a sense of the patient's readiness for change.
- Provide intervention/patient education. Although there are no FDA-approved drug treatments for PG, make clinically based medication recommendations.
- Screen for and treat comorbid conditions.
- Provide referrals:
  - Addiction psychiatrist/counselor
  - Gamblers Anonymous
  - Consumer credit organizations
  - Bankruptcy lawyers
  - Gam-Anon for family members

## **MEDICATION**

- There are no FDA-approved medicines for gambling addiction; pharmacotherapy is most effective when directed toward patient's comorbid psychiatric condition (3)[A].
- SSRIs:
  - Currently seen as beneficial for treating comorbid impulse-control disorders, although their efficacy has been under question for PG
  - All studies with SSRIs limited due to small size, short follow-up, conflicting outcomes, and in

some cases study design; confirmation for some positive findings need larger randomized controlled trials with extended follow-up before recommendations for use can be made

- Opiate antagonists have the ability to decrease dopamine release in the dopamine reward pathway. Naltrexone and nalmefene have been reported to cause improvements on gambling symptom assessment scores (4,5)[B].

## *ADDITIONAL THERAPIES*

- Cognitive-behavioral therapy (CBT):
  - The main effective interventions for PG are psychoeducation, cognitive restructuring, problem solving, social skills training, and relapse prevention. Studies indicated that CBT resulted in significant improvement as short-term therapy.
  - CBT may be done in several formats: individual, group, brief group, and dual diagnosis. All these formats have been shown to be effective. Group therapy is favored because patients are often extroverted. Couple or family therapy also may be used.
- Gamblers Anonymous:
  - A 12-step program similar to Alcoholics Anonymous for a person suffering from a gambling addiction.
  - Dropout rate is high if this is the only means of therapy.
  - Patients may deny need to attend in the first place, and for that reason, Gamblers Anonymous may not be appropriate for patients who are in the precontemplation stage.
- Motivational enhancement therapy (MET):
  - Provides nonargumentative exploration of patient's stage of change
  - Patient receives positive reinforcement from clinician.
  - Motivational enhancement strategies support self-efficacy.
  - Improves patient rapport; aids in removing barriers to treatment
  - In one study, MET alone did not show any improvement, but MET and CBT together improved outcome measures.
- Because of increased suicide rates, patients may need to be hospitalized acutely for safety and to prevent gambling.
- Because patients are at increased risk from mental and physical illness, they benefit from relaxation exercises to reduce stress, identify triggers, substitute gambling with other activities and a complete physical and lab work with nutrition evaluation.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

Patients seeking treatment for gambling addiction should be followed routinely to monitor the response to treatment, tolerance to medications, and relapse.

### PATIENT EDUCATION

- Gamblers Anonymous:
  - <http://www.gamblersanonymous.org/ga/>
  - National hotline 1-888-GA-HELPS (888-424-3577)
- Gam-Anon: support group for spouses, family, or close friends: <http://www.gam-anon.org/>
- Responsible Gambling Council: <http://www.responsiblegambling.org/>
- Humphrey H. *This Must Be Hell: A Look at Pathological Gambling*. Bloomington, IN: iUniverse; 2000.
- Lee B. *Born To Lose: Memoirs of a Compulsive Gambler*. Center City, MN: Hazelden; 2005.
- **PROGNOSIS**
- Patients with gambling addiction can be treated but many relapse.
- 36-39% of patients did not experience any gambling-related problems according to one study, and only 7-12% sought formal treatment or Gamblers Anonymous meetings.
- Roughly 1/3 of patients who have a gambling addiction recover without any intervention.

## Codes

&NA;

### ICD10

- F63.0 Pathological gambling
- Z72.6 Gambling and betting

## Clinical Pearls

&NA;

- Several brief screening strategies can be used to identify PG, including the SOGS, the Gamblers Anonymous 20 questions, and the Lie/Bet method.
- To treat PG, first treat comorbidities such as substance abuse, bipolar disorder, ADHD, and other mental health/substance abuse disorders.
- Nonpharmacologic therapies are more effective than pharmacologic therapies. There is no

FDA-approved therapy for PG.

- Patients seeking treatment for gambling addiction should be followed routinely by physicians and counselors to monitor the response to treatment, tolerance to medications, and possibility of relapse.

# Ganglion Cyst

**Matthew W. Thompson, MD**

**William Fiden, MD**

## BASICS

- Ganglion cysts are common benign tumors that are not related to nerve tissue (as implied incorrectly by the name).
- Can be located anywhere throughout the body but usually adjacent to or within joints and tendons, with the most common locations being the wrist, foot, and ankle
- Not a true cyst as microscopic examination does not show an epithelial lining
- Most are asymptomatic except for changing size. Local nerve compression can result in pain or activity limitation.
- Synonym(s): synovial cyst; myxoid cyst; Gideon disease; Bible bump.

## EPIDEMIOLOGY

- Can affect all age groups. Unusual in children
- Most common in ages 20 to 40 years and twice as common in women
- Common in dorsal wrist, radial wrist, and dorsum of the distal interphalangeal (DIP) joint (referred to as a mucous cyst)
- Mucous cysts are usually seen in older patients.
- 60-70% of hand and wrist ganglion cysts are on the dorsal wrist; 15-20% are on the volar wrist.

## Prevalence

- Prevalence of wrist ganglia in patients presenting with wrist pain is as high as 19%.
- Prevalence of ganglia in patients with a palpable mass in the wrist is as high as 27%.
- Reported prevalence in ankles is 5.6%.

## ETIOLOGY AND PATHOPHYSIOLOGY

Pathogenesis is unclear. Cysts are filled with mucin and communicate with the adjacent joint

space, tendon and/or tendon sheath via a stalk. Several theories about their origin include:

- Herniation of synovial lining creates a one-way valve. Although this is supported by dye studies, the lack of a synovial (epithelial) lining in the cyst wall makes this less likely.
- Muroid degeneration of connective tissue results in formation of hyaluronic acid, leading to cystic space formation. Studies haven't confirmed this hypothesis.
- Joint stress leads to a tear in the joint capsule or tendon sheath allowing synovial fluid to leak into surrounding tissues. Local irritation leads to production of fluid and a pseudocapsule forms (explaining the lack of an epithelial lining).
- Recurrent stress may stimulate mucin production by nearby mesenchymal cells (seen on electron microscopy) resulting in cyst formation.

## *Genetics*

No specific genetic links have been found.

## *RISK FACTORS*

- Female > male
- Osteoarthritis for muroid cysts
- Joint trauma (possible but not proven)

## *COMMONLY ASSOCIATED CONDITIONS*

Mucous cysts are usually associated with osteoarthritis at the DIP joint.

## **DIAGNOSIS**

Usually made on basis of history and physical examination

### **HISTORY**

- Patients presents with an asymptomatic mass that has been present for months or years (most common) or when the cyst become painful, causes weakness, increases in size or interferes with activities.
- Pain is typically annoying as opposed to debilitating.
- Variable in size and location
- May increase in size and pain with activity and recede with rest

## *PHYSICAL EXAM*

- Mass
  - Rubbery
  - Subcutaneous
  - May transilluminate
  - Fixed to the tendon sheath and only slightly mobile
  - No overlying skin changes
- Palpation may cause pain due to nerve compression.
- Small ganglions may only be palpable in full wrist flexion or extension.
- Occult ganglions are not palpable but can be quite painful.

## *DIFFERENTIAL DIAGNOSIS*

- Carpal bossing: a small, immovable mass of bone on the back of the wrist
- Giant cell tumor, lipoma, sarcoma, hamartoma, interosseous neuroma
- Epidermal inclusion cyst
- True synovial cyst
- Anomalous musculature
- Tenosynovitis

## *DIAGNOSTIC TESTS & INTERPRETATION*

Unless diagnosis is unclear, imaging is not necessary.

### *Initial Tests (lab, imaging)*

- Most are apparent clinically and do not need imaging
- Plain films can exclude bony pathology but rarely alter the course of treatment.
- Other options to exclude occult ganglions:
  - Ultrasound; MRI
  - Arthroscopy
- US and MRI have similar rates of sensitivity and specificity. US is less expensive than MRI but more operator-dependent.
- Arthroscopy is used for both diagnostic and therapeutic purposes and can be considered when

initial workup is nondiagnostic and conservative treatment is not effective.

## Test Interpretation

- Gross pathologic evaluation shows that cysts are often multilobulated.
- Microscopic exam reveals a relatively acellular outer wall with several layers of randomly oriented collagen fibers and mesenchymal cells in the collagen fibers.
- Cyst fluid is highly viscous and contains glucosamine, albumin, globulin, and hyaluronic acid.
- Histopathologically identical regardless of anatomic location

P.397

## TREATMENT

Four primary treatment options include:

- Reassurance and observation: Ganglia are not likely to be malignant or to cause damage. May treat with splinting and NSAIDs if desired for comfort
  - Multiple studies suggest spontaneous cyst resolution in half of patients over 5 years (1,2) [A].
- Closed rupture: historically done by hitting cyst with a book (ÖKing James Bible treatmentÓ)
  - Results in initial treatment decreased clinical symptoms by 22-66%, recurrence is common.
  - Typically a home remedy.
- Aspiration: can be done in the office under local anesthesia with a 16-gauge needle at base of the cyst. Studies demonstrate mixed results on aspirations with 30-85% success with multiple aspirations (1,2)[A]. Volar wrist ganglia should not be aspirated without US guidance due to risk of damage to neurovascular structures. Mucous cysts can be aspirated, but recurrence is >50% and pain may not resolve if due to underlying osteoarthritis.
  - Concurrent injection of steroids or hyaluronidase have mixed results and are not clearly more effective than aspiration alone. Steroids have the additional risk of fat atrophy and skin depigmentation.
  - Multiple cyst punctures are not more effective than simple aspiration.
  - Sclerotherapy or injections that increase inflammation and cause fibrosis to reduce recurrence are less common due to concerns for joint damage.
- Surgical excision

## MEDICATION

### *First Line*

- NSAIDs for pain relief
- No other medications have been shown to be effective.

## SURGERY/OTHER PROCEDURES

- Recurrence rates vary among studies but have been as low as 0-28%. Results better at high-volume centers and actual recurrence rates are likely higher.
  - Arthroscopic excision is as good as open excision with better cosmetic outcomes and a faster return to normal function (3)[A].
- A 6-year study comparing blind aspiration, surgery, and watchful waiting showed:
  - Recurrence rates of 58% after aspiration, 39% after surgery, and 58% in untreated patients.
  - Patient satisfaction was 81% with aspiration, 83% with surgery, and 53% with reassurance.
  - There was no significant difference in pain, weakness, or stiffness between groups.
  - Pain was reduced significantly in all groups.
  - Time away from work is greater with excision compared to aspiration and reassurance.
  - Neither aspiration nor surgical excision provides a clear long-term benefit over simple observation. The primary benefit of surgery is early cosmetic resolution (4)[B].
- Bottom line
  - Surgery appears to provide the lowest rates of cyst recurrence but does not provide significantly higher pain reduction or patient satisfaction.
  - Determine the patient's reasons for seeking medical attention. Education alone can provide adequate treatment.

## ONGOING CARE

May require supervised hand therapy after surgical repair to improve stiffness and function

## FOLLOW-UP RECOMMENDATIONS

- Hand/occupational therapy may be helpful if ganglion symptoms persist despite rest.

- Manage expectations about recurrence.

## PROGNOSIS

- Generally very good
- Up to 50% will resolve with watchful waiting.
- Higher rate of resolution in children

## COMPLICATIONS

- Risk of recurrence is present regardless of treatment; no specific recommendations to minimize this risk.
- Risks of surgical excision include the following:
  - Residual pain
  - Poor cosmesis
  - Neuropathy
  - Stiffness and instability of the wrist, especially scapholunate ligament instability
  - Open excision if arthroscopic treatment fails to resolve symptoms

## Additional Reading

&NA;

## See Also

&NA;

Algorithm: Pain in Upper Extremity

## Codes

&NA;

### ICD10

- M67.40 Ganglion, unspecified site
- M67.48 Ganglion, other site
- M67.439 Ganglion, unspecified wrist

## Clinical Pearls

&NA;

- Ganglion cysts (technically not true cysts) are the most common wrist masses.
- Diagnosis is based on history and physical examination.
- Treatment options include observation, aspiration, and excision. Long-term outcomes are generally similar with all three approaches.
- Volar wrist ganglia should not be aspirated without ultrasound guidance due to the risk of damage to neurovascular structures from blind aspiration.

# Gastritis

Miles C. Layton, DO

Matthew W. Short, MD, FAAFP

## BASICS

### DESCRIPTION

- Inflammation of the gastric mucosa with a spectrum of clinical findings
- Patchy erythema of gastric mucosa
  - Common on endoscopy; usually insignificant
- Erosive gastritis or reactive gastropathy
  - A reaction to mucosal injury by a noxious agent (especially NSAIDs or alcohol)
- Reflux gastritis
  - A reaction to protracted reflux exposure to biliary and pancreatic fluid, usually associated with a pyloric defect
  - Typically limited to the prepyloric antrum
- Hemorrhagic gastritis (stress ulceration)
  - A reaction to hemodynamic disorder (e.g., hypovolemia or hypoxia [as in shock])
  - Common in ICU patients, particularly after severe burns and trauma
  - Seen rarely with dabigatran (oral thrombin inhibitor)
- Infectious gastritis
  - Commonly associated with *Helicobacter pylori*, colonizing organism in much of world's population
  - Viral infection, usually as a component of systemic infection, is common.
  - Significant infection by other microbes is rare.
- Atrophic gastritis
  - Frequent in the elderly

- Primarily from long-standing *H. pylori* infections
  - May be caused by prolonged PPI use
  - Major risk factor for gastric cancer
  - Associated with primary (pernicious) anemia
  - Autoimmune disease
- Synonym(s): erosive gastritis; reflux gastritis; hemorrhagic gastritis; acute gastritis

### *Geriatric Considerations*

Persons age >60 years often harbor *H. pylori* infection.

### *Pediatric Considerations*

Gastritis rarely occurs in infants or children.

## **EPIDEMIOLOGY**

- Predominant age: all ages
- Predominant sex: male = female

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Noxious agents cause a breakdown in the gastric mucosal barrier, leaving the epithelial cells unprotected.
- Infection: *H. pylori* (most common cause), *Staphylococcus aureus* exotoxins, and viral infection
- Alcohol
- Aspirin and other NSAIDs
- Bile reflux
- Pancreatic enzyme reflux
- Portal hypertensive (HTN) gastropathy
- Emotional stress

### *Genetics*

Unknown, but observational studies show that 10% of a given population is never colonized with *H. pylori*, regardless of exposure. Genetic variations in *TLR1* may help explain some of this observed variation in individual risk for *H. pylori* infection.

## RISK FACTORS

- Age >60 years
- Exposure to potentially noxious drugs or chemicals (e.g., alcohol or NSAIDs)
- Hypovolemia, hypoxia (shock), burns, head injury, complicated postoperative course
- Autoimmune diseases (thyroid disease and diabetes)
- Family history of *H. pylori* and/or gastric cancer
- Stress (hypovolemia or hypoxia)
- Tobacco use
- Radiation
- Ischemia
- Pernicious anemia
- Gastric mucosal atrophy

## GENERAL PREVENTION

- Avoid injurious drugs or chemical agents.
- Patients with hypovolemia or hypoxia (especially patients confined to an intensive care ward) should receive prophylactic antacid therapy.
- In ICU patients (particularly burn and trauma), H<sub>2</sub> receptor antagonists, prostaglandins, or sucralfate commonly used for gastric mucosal protection
- Consider testing for *H. pylori* (and eradicating if present) in patients on long-term NSAID therapy.

## COMMONLY ASSOCIATED CONDITIONS

- Gastric or duodenal peptic ulcer
- Primary (pernicious) anemia  
Atrophic gastritis
- Portal HTN, hepatic failure
- Gastric lymphoma linked to lymphoid follicles

## DIAGNOSIS

## HISTORY

- Nondescript epigastric distress, often aggravated by eating and often severe.
- Burning epigastric pain
- Anorexia
- Nausea, with or without vomiting
- Significant bleeding is unusual except in hemorrhagic gastritis.
- Hiccups
- Bloating or abdominal fullness

## ***PHYSICAL EXAM***

- Assess vital signs. Abdominal exam often normal
- Mild epigastric tenderness
- May have heme-positive stool
- Stool may be black in color.
- Examine for stigmata of chronic alcohol abuse.

## ***DIFFERENTIAL DIAGNOSIS***

- Functional abdominal pain (dyspepsia)
- Peptic ulcer disease
- Viral gastroenteritis
- Pancreatic disease
- Gastric cancer (elderly)
- Cholecystitis
- Pancreatic disease (inflammation vs. tumor)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Usually normal
- CBC to evaluate for blood loss/anemia
- <sup>13</sup>C-urea breath test for *H. pylori*
  - 95% specificity and sensitivity

- *H. pylori*, serology serum IgG
  - Inexpensive
  - 85% sensitivity, 79% specificity
  - Positive in history of colonization or prior infections, therefore, cannot be used to assess eradication
- Stool analysis for fecal *H. pylori* antigen
  - 95% specificity and sensitivity
- Gastric acid analysis may be abnormal but is not a reliable indicator of gastritis.
- Low serum pepsinogen I (PG I) relative to PG II is associated with fundal intestinal metaplasia.
- Drugs that may alter lab results: Antibiotics or PPIs may affect urea breath test for *H. pylori*.
  - Hold PPIs for 2 weeks, H<sub>2</sub> receptor antagonists for 24 hours, and antibiotics for 4 weeks prior to stool or breath tests (1,2)[C].

## *Follow-Up Tests & Special Considerations*

### Endoscopy for *H. pylori*

- Culture; polymerase chain reaction (PCR); histology; rapid urease testing

## *Diagnostic Procedures/Other*

- Gastroscopy with biopsy allows for a precise diagnosis and is a first-line diagnostic tool in:
  - Age >55 years with new-onset signs and symptoms
  - Weight loss, persistent vomiting, or GI bleed (1)[C]
- Biopsies (multiple) in both body and antrum recommended if there is a poor response to the initial treatment (3)[C],(4)[B]. *Patient must discontinue PPIs for 2 weeks prior to endoscopy to improve accuracy of result.*

## *Test Interpretation*

Acute or chronic inflammatory infiltrate in gastric mucosa, often with distortion or erosion of adjacent epithelium. Presence of *H. pylori* often confirmed

## **TREATMENT**

## GENERAL MEASURES

- Treatment of *H. pylori* is required to relieve symptoms.
- Parenteral fluid and electrolyte supplements if oral intake is compromised.
- Consider discontinuing NSAIDs.
- Encourage alcohol and smoking cessation.
- Endoscopy indicated for patients not responsive to treatment

## MEDICATION

### First Line

- Antacids: best given in liquid form, 30 mL 1 hour after meals and at bedtime; useful mainly as an emollient
- H<sub>2</sub> receptor antagonists (e.g., cimetidine [Tagamet]): oral cimetidine 300 mg q6h (or ranitidine [Zantac] 150 mg BID or famotidine [Pepcid] 20 mg BID or nizatidine [Axid])150 mg BID not shown to be clearly superior to antacids
- Sucralfate (Carafate): 1 g q4-6h on an empty stomach; rationale uncertain but empirically helpful
- Prostaglandins (misoprostol [Cytotec]): can help allay gastric mucosal injury; suggested dosage 100 to 200 &mgr;g QID

---

P.399

- PPIs can be used if there is no response to antacids or H<sub>2</sub> receptor blockers (e.g. omeprazole 20 mg daily or BID or esomeprazole 20 mg daily or BID)
- *H. pylori* eradication
  - Clarithromycin triple therapy (CTT)
    - A short-course therapy (10 to 14 days) of amoxicillin 1 g BID, standard dose PPI BID (omeprazole 20 mg BID, etc.), and clarithromycin 500 mg BID (1,2,5)[A]
    - 70-85% eradication
    - Optimal treatment still undefined.
    - IF PCN ALLERGIC: Substitute amoxicillin with metronidazole 500 mg BID.
  - Bismuth quadruple therapy (BQT)
    - PPI (omeprazole 20 mg) BID plus bismuth (Pepto-Bismol) 30 mL liquid or 2 tablets QID plus metronidazole 250 mg QID plus tetracycline 500 mg QID for 10 to 14 days (1,2,5,6)

[A]

- 75-90% eradication
  - Use as initial therapy in areas of high clarithromycin resistance (>15%).
  - Consider in penicillin-allergic patients.
- *H. pylori* alternative treatment: Consider sequential antibiotic therapy with standard dose PPI (i.e., omeprazole 20 mg) and amoxicillin 1 g BID for 5 days followed by clarithromycin 500 mg and tinidazole 500 mg BID with standard dose PPI (omeprazole 20 mg) BID for 5 days. Some studies show it works just as well or better than triple therapy (1,2)[B],(5)[A].
  - *H. pylori* treatment failure: use a different regimen, avoiding clarithromycin (unless resistance testing confirms susceptibility):
    - BQT for 7 to 14 days (1,2,5)[A]
    - Consider levofloxacin 250 mg BID, amoxicillin 1 g BID, and standard dose PPI BID for 14 days in those who fail two attempts (1,2,5)[A].
  - Consider probiotics in known symptomatic *H. pylori*, to decrease the density of *H. pylori* in the gastric antrum and body, decrease severity of gastritis, peptic ulcers, and possibly slow the progression toward atrophic gastritis and gastric adenocarcinoma (7)[A],(8)[C],(9)[A].
    - Probiotics alone likely do not eradicate *H. pylori*.
  - Contraindications: hypersensitivity
  - Precautions:
    - If bismuth is prescribed, warn the patient about the side effect of stool becoming black.
    - Refer to the manufacturer's profile of each drug.
  - Significant possible interactions: Refer to the manufacturer's profile of each drug.

## INPATIENT CONSIDERATIONS

Gastritis may occur in ICU patients.

### Admission Criteria/Initial Stabilization

Outpatient, except for severe hemorrhagic gastritis

**ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

Usually no restrictions

- Confirm *H. pylori* eradication in patients with:
  - Gastric ulcer
  - Persistent dyspepsia despite treatment
  - *H. pylori* associated mucosa-associated lymphoid tissue (MALT) lymphoma
  - History of resection of gastric cancer

## ***Patient Monitoring***

- Repeat gastroscopy after 6 weeks if gastritis was severe or if patient has a poor treatment response.
- Surveillance gastroscopy every 3 to 5 years in patients with atrophic gastritis in both the antrum and body; within 1 year for patients with low-grade dysplasia, (with extensive biopsy sampling); 6 and 12 months in patients with high-grade dysplasia (4)[B]

## ***DIET***

Restrictions, if any, depend on symptom severity (e.g., bland, light, soft foods); avoid caffeine and spicy foods and alcohol.

## ***PATIENT EDUCATION***

- Smoking cessation; limit alcohol
- Dietary changes
- Relaxation therapy
- Avoid NSAIDs as possible

## ***PROGNOSIS***

- Most cases clear spontaneously when the cause has been identified and treated.
- Recurrence of *H. pylori* infection requires a repeated course of treatment.

## ***COMPLICATIONS***

- Bleeding from extensive mucosal erosion or ulceration
- Clearing *H. pylori* before chronic gastritis develops may prevent development of gastric cancer.

## Codes

**&NA;**

### ICD10

- K29.70 Gastritis, unspecified, without bleeding
- K29.71 Gastritis, unspecified, with bleeding
- K29.00 Acute gastritis without bleeding

## Clinical Pearls

**&NA;**

- *H. pylori* is the most common cause of gastritis.
- >50% of adult patients are colonized with *H. pylori*.
- *H. pylori* antibodies decline in the year after treatment and should not be used to determine eradication. *H. pylori* antibody titers rise significantly with reinfection.
- *H. pylori* stool antigen tests can be used before and after therapy to assess for eradication and reinfection.
- Several courses of rescue therapy may be necessary to eradicate *H. pylori*.
- Discontinue PPIs 2 weeks prior to endoscopy to improve diagnostic accuracy in cases of suspected gastritis.

- Consider probiotics as adjunct treatment in symptomatic *H. pylori* gastritis.

# Gastroesophageal Reflux Disease

Anna Cecilia S. Tenorio, MD

Fozia Akhtar Ali, MD

## BASICS

### DESCRIPTION

Backward flow of stomach acid or contents into the mouth or esophagus that occurs for twice a week for several weeks, causing symptoms of discomfort often described as heartburn, acid indigestion, and acid reflux

### EPIDEMIOLOGY

#### *Incidence*

Incidence: 5 per 1,000 person-years

#### *Prevalence*

- Prevalence of gastroesophageal reflux disease (GERD) is about 10-20% in the United States and United Kingdom, and in Asia is about 5%.
- 40% of adults in the United States have symptoms of reflux.
- 50-85% of GERD patients have nonerosive reflux disease
- Chronic GERD is a risk factor for Barrett esophagus.
- 10% of patients with chronic GERD have Barrett esophagus.
- Risk of adenocarcinoma without Barrett esophagus and no dysplasia: 0.1-0.5% per patient year
- Risk of adenocarcinoma with Barrett esophagus and high-grade dysplasia: 6-19% per patient-year
- Pediatric population: Regurgitation occurs at least once a day in 67% of 4-month-old infants. Prevalence decreased to 21% at age 6 to 7 months, and down to 5% at age 10 to 12 months.

### ETIOLOGY AND PATHOPHYSIOLOGY

- The pattern and mechanism of reflux varies depends on the severity of disease.

- GERD begins with contact of acidic stomach contents with the squamous mucosal lining of the esophagus, at the esophagogastric junction (EGJ).
- Usually affected by inappropriate transient lower esophageal sphincter relaxation. Foods that are spicy, acidic and high in fat, caffeine, alcohol, tobacco, anticholinergic medications, nitrates, smooth muscle relaxants affect LES relaxation.
- Most people with severe GERD have some evidence of hiatal hernia, which affects GERD by (1):
  - Trapping acid in the hernia sac
  - Impaired acid emptying
  - Increasing retrograde acid flow rate
  - Reducing the EGJ sphincter pressure
  - Increased frequency of transient lower esophageal sphincter relaxations

## *Genetics*

Genetic heterogeneity has been associated with GERD.

## **RISK FACTORS**

- Obesity
- Hiatal hernia
- Scleroderma
- Alcohol use
- Tobacco use
- Pregnancy

## **GENERAL PREVENTION**

- Decrease consumption of food and beverage triggers such as spicy, fatty foods, alcohol and caffeine
- Weight loss
- Avoid lying down soon after eating a meal.
- Tobacco and alcohol cessation
- Elevated head of bed when sleeping at night

- Avoid having meals close to bedtime.
- Infants: Use car seat for 2 to 3 hours after meals; thickened feedings

## COMMONLY ASSOCIATED CONDITIONS

- Nonerosive esophagitis
- Erosive esophagitis
- Irritable bowel syndrome
- Peptic ulcer disease
- Extraesophageal reflux: aspiration, chronic cough, laryngitis, vocal cord granuloma, sinusitis, otitis media
- Halitosis
- Hiatal hernia: acid pocket (zone of high acidity in the proximal stomach after a meal) above the diaphragm in patients with hiatal hernia is a risk factor (2)[B]
- Peptic stricture: 10% of patients with GERD
- Barrett esophagus
- Esophageal adenocarcinoma

## DIAGNOSIS

- Typical symptoms: acid regurgitation, heartburn, dysphagia (mostly post prandial)
- Atypical symptoms: epigastric fullness/pressure/pain, dyspepsia, nausea, bloating, belching, chest pain, lump in throat
- Extraesophageal signs and symptoms: chronic cough, bronchospasm, wheezing, hoarseness, sore throat, asthma, laryngitis, dental erosions

## HISTORY

- Heartburn: retrosternal burning sensation
- Regurgitation; sour or acid taste in mouth (“water brash”)
- Symptoms worse with bending or recumbency
- Extraesophageal symptoms (cough; wheezing; hoarseness)
- Diet, alcohol and tobacco use
- Diagnosis often solely based on history and clinical symptoms

## **PHYSICAL EXAM**

Typically unremarkable

- BMI
- Rare epigastric tenderness or palpable epigastric mass
- Look for stigmata of chronic systemic disease or alcohol use.

## **DIFFERENTIAL DIAGNOSIS**

- Infectious esophagitis (*Candida*, herpes, HIV, cytomegalovirus)
- Chemical esophagitis
- Pill-induced esophagitis
- Eosinophilic esophagitis
- Nonulcer dyspepsia
- Biliary tract disease
- Radiation injury
- Crohn disease
- Angina/coronary artery disease
- Esophageal stricture or anatomic defect (ring, sling)
- Esophageal adenocarcinoma
- Achalasia
- Scleroderma
- Peptic ulcer disease

## **DIAGNOSTIC TESTS & INTERPRETATION**

Patients with typical symptoms of GERD and without alarm symptoms (dysphagia odynophagia, weight loss, early satiety, anemia, new onset, male >50 years) should be initially treated empirically with antisecretory agents without any further diagnostic testing.

### ***Initial Tests (lab, imaging)***

- Indication for blood work depends on clinical presentation. Check for anemia (history of bleeding; or possible poor B<sub>12</sub> absorption due to chronic proton pump inhibitor [PPI] use).
- Patients with GERD presenting with noncardiac chest pain should undergo evaluation first

before the onset of treatment.

## *Diagnostic Procedures/Other*

- Upper endoscopy
  - First-line diagnostic test for those with alarm signs and uncontrolled symptoms (2)[B]
  - Indications for UGI endoscopy
    - Alarm symptoms such as dysphagia, bleeding, anemia, weight loss, recurrent vomiting
    - Persistent typical GERD symptoms despite empiric treatment of twice-daily PPI for 4 to 8 weeks
    - Men >50 years old with chronic GERD (>5 years) and other risk factors: hiatal hernia, high BMI, tobacco use, high abdominal fat distribution
    - History of severe erosive esophagitis to assess healing and check for Barrett esophagus and other UGI pathology
    - Surveillance in patients with history of Barrett's esophagus
  - ~50-70% of patients with heartburn have negative endoscopy findings
- Savary-Miller classification
  - Grades esophagitis based on endoscopy
    - Grade I:  $\geq 1$  nonconfluent reddish spots, with or without exudate
    - Grade II: erosive and exudative lesions in the distal esophagus; may be confluent but not circumferential
    - Grade III: circumferential erosions in the distal esophagus
    - Grade IV: chronic complications such as deep ulcers, stenosis, or scarring with Barrett metaplasia
- Esophageal manometry
  - Not recommended for primary GERD diagnosis; a second option for those with GERD and normal endoscopy (2)[B]
  - Diagnose motility disorders: functional heartburn, achalasia, and distal esophageal spasm.
  - Used to evaluate peristaltic function preoperatively and to record LES pressure
- Ambulatory reflux (ph) monitoring
  - Used to evaluate possible excessive esophageal acid exposure to those with GERD, normal

endoscopy and no PPI response (2)[B]

- Used also to document frequency of reflux
- Need to discontinue PPI use for 7 days prior to procedure
- Barium swallow: not used for GERD diagnosis. Used to evaluate complaints of dysphagia to outline anatomic abnormalities (hiatal hernia)

## *Test Interpretation*

- Acute inflammation (especially eosinophils)
- Epithelial basal zone hyperplasia seen in 85%
- Barrett epithelial change: Gastric columnar epithelium replaces squamous epithelium in distal esophagus (metaplasia).

---

P.401

## **TREATMENT**

### **GENERAL MEASURES**

Lifestyle changes are first-line intervention:

- Elevate head of bed (2)[B].
- Avoid meals 2 to 3 hours before bedtime (2)[B].
- Avoid stooping, bending and tight-fitting garments.
- Avoid medications that relax LES (anticholinergic drugs; calcium channel blockers).
- Weight loss (2)[B]
- Tobacco cessation and alcohol avoidance
- Limit consumption of patient-specific food triggers (global elimination of all reflux-causing foods is not necessary or beneficial).
- Stepped therapy
  - Phase I: lifestyle and diet modifications, antacids plus H<sub>2</sub> blockers or PPIs
  - Phase II: If symptoms persist, consider endoscopic evaluation.
  - Phase III: If symptoms still persist, consider surgical options.

# MEDICATION

## First Line

- H<sub>2</sub> blockers in equipotent oral doses (e.g., cimetidine 800 mg BID or 400 mg QID, ranitidine 150 mg BID, famotidine 20 mg BID, or nizatidine 150 mg BID)
  - Renally dosed
- PPIs: Irreversibly bind proton pump (H<sup>+</sup>/K<sup>+</sup> ATPase), effective onset within 4 days. Omeprazole 20 to 40 mg/day, lansoprazole 15 to 30 mg/day, dexlansoprazole 30 mg/day, pantoprazole 40 mg/day, rabeprazole 20 mg/day, esomeprazole 40 mg/day
  - No major differences in efficacy among PPIs (3)[A]
  - Dose 30 to 60 minutes before meals with the exception of dexlansoprazole (2)[A].
  - PPIs may increase risk of hypomagnesemia, hip fracture, *Clostridium difficile* infection, vitamin B<sub>12</sub> deficiency, and community acquired pneumonia.
- PPI is more effective than H<sub>2</sub> blocker and prokinetics for healing erosive esophagitis and nonerosive esophagitis (4)[A].
- Erosive esophagitis: 8 weeks of PPI effective in 90%

## Pediatric Considerations

Antacids or liquid H<sub>2</sub> blockers and PPIs are available. Prokinetics have a minimal role due to safety concerns and limited efficacy.

## Second Line

- Antacids or barrier agents (sucralfate 1 g PO QID 1 hour before meals and at bedtime for 4 to 8 weeks) may relieve breakthrough symptoms.
- Prokinetics: metoclopramide 5 to 10 mg before meals
- Baclofen as add-on therapy with a PPI
- Precautions
  - Blood dyscrasias and anemia with PPIs and H<sub>2</sub> blockers
  - Metoclopramide is a dopamine blocker; risk of dystonia and tardive dyskinesia
  - Tachyphylaxis may occur with H<sub>2</sub> blockers.
- Significant possible interactions

- PPIs and H<sub>2</sub> blockers: multiple cytochrome P450 drug interactions; that is, warfarin, phenytoin, antifungals, digoxin

## ***SURGERY/OTHER PROCEDURES***

- Laparoscopic fundoplication (wrapping gastric fundus around distal esophagus) increases pressure gradient between stomach and esophagus.
- Bariatric surgery
  - Surgery indicated if: Patient desires to discontinue medical therapy, has side effects with medical therapy, large hiatal hernia, esophagitis refractory to medical therapy, or refractory symptoms (4)[A].
  - Pre-op ambulatory pH monitor is mandatory in patients without evidence of erosive esophagitis (4)[A].
  - Rule out esophageal dysmotility prior to surgery by manometry to rule out achalasia or scleroderma like esophagus (4)[A].
  - Best surgical response is seen in patients with typical symptoms who respond well to PPI therapy.
  - If it is estimated that a patient will require >10 years of PPI treatment, surgery may be more cost-effective.
  - Bariatric surgery can be considered for patients with comorbid obesity. Gastric bypass is preferred (4)[A].

### ***Pediatric Considerations***

Surgery for severe symptoms (apnea, choking, persistent vomiting)

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Monitor and follow symptoms over time.
- Repeat endoscopy at 4 to 8 weeks if there is a poor symptomatic response to medical therapy, especially in older patients.
- Endoscopic surveillance every 2 to 3 years in patients with Barrett esophagus to screen for

malignant transformation (in patients who would opt for treatment if cancer is detected)

## *DIET*

Avoid foods that can trigger or make symptoms worse.

## *PATIENT EDUCATION*

Lifestyle and dietary modifications: Eat small meals; avoid lying down soon after meals; elevate head of bed; weight loss; smoking cessation; avoid alcohol and caffeine.

## *PROGNOSIS*

- Symptoms and esophageal inflammation often return promptly when treatment is withdrawn. To prevent relapse of symptoms, continue antisecretory therapy (in addition to lifestyle and dietary modifications).
  - PPI maintenance therapy likely improves quality of life better than H<sub>2</sub> blocker maintenance.
  - Full-dose PPIs are more effective than half-dose for maintenance (4)[A].
  - In erosive esophagitis, daily maintenance therapy with PPI prevents relapse; intermittent PPI therapy not as effective (2)[A]
- Medical and surgical therapy are equally effective for symptom reduction (4)[A].
- Antireflux surgery
  - 90-94% symptom response. Patients with persistent symptoms should have repeat anatomic evaluation (endoscopy or esophagram).
  - Some surgically treated patients eventually require medical therapy.
- Regression of Barrett epithelium does not routinely occur despite aggressive medical or surgical therapy.

## **COMPLICATIONS**

- Peptic stricture: 10-15%
- Barrett esophagus: 10%
  - Adenocarcinoma cancer develops at an annual rate of 0.5%.
  - Primary treatment for Barrett esophagus with high-grade dysplasia is endoscopic radiofrequency ablation.
- Extraesophageal symptoms: hoarseness, aspiration (including pneumonia)
- Bleeding due to mucosal injury
- Noncardiac chest pain

## Geriatric Considerations

Complications more likely (e.g., aspiration pneumonia)

## See Also

&NA;

Algorithms: Abdominal Pain, Upper; Dyspepsia

**&NA;**

## ICD10

- K21.9 Gastroesophageal reflux disease without esophagitis
- K21.0 Gastro-esophageal reflux disease with esophagitis

## Clinical Pearls

**&NA;**

- GERD is primarily diagnosed by history.
- GERD should be considered in nonsmokers who have chronic cough (>3 weeks).
- PPI treatment does not appear to inhibit neoplastic progression in Barrett esophagus.
- No evidence to support that patients with GERD should routinely be tested for *Helicobacter pylori*.
- Empiric treatment with H<sub>2</sub> blockers or PPI leads to symptomatic relief in most cases. Persistent symptoms should be evaluated with endoscopy.

# Genito-Pelvic Pain/Penetration Disorder (Vaginismus)

Jeffrey D. Quinlan, MD, FAAFP

## BASICS

Genito-pelvic pain/penetration disorder is the name of the conditions formally known as vaginismus and dyspareunia. Vaginismus results from involuntary contraction of the vaginal musculature. Primary vaginismus occurs in women who have never been able to have penetrative intercourse. Women with secondary vaginismus were previously able to have penetrative intercourse but are no longer able to do so.

## DESCRIPTION

- Persistent or recurrent difficulties for 6 months or more with at least one of the following:
  - Inability to have vaginal intercourse/penetration on at least 50% of attempts
  - Marked genito-pelvic pain during at least 50% of vaginal intercourse/penetration attempts
  - Marked fear of vaginal intercourse/penetration or of genito-pelvic pain during intercourse/penetration on at least 50% of vaginal intercourse/penetration attempts
  - Marked tensing or tightening of the pelvic floor muscles during attempted vaginal intercourse/penetration on at least 50% of occasions
- The disturbance causes marked distress or interpersonal difficulty.
- Dysfunction is not as a result of:
  - Nonsexual mental disorder
  - Severe relationship stress
  - Other significant stress
  - Substance or medication effect
- Specify if with a general medical condition (e.g., lichen sclerosis, endometriosis) (1).

## Pregnancy Considerations

- May first present during evaluation for infertility

- Pregnancy can occur in patients with genito-pelvic pain/penetration disorder when ejaculation occurs on the perineum.
- Vaginismus may be an independent risk factor for cesarean delivery.

## *EPIDEMIOLOGY*

### *Incidence*

The incidence of vaginismus is thought to be about 1-17% per year worldwide. In North America, 12-21% of women have genito-pelvic pain of varying etiologies (2).

### *Prevalence*

- True prevalence is unknown due to limited data/reporting.
- Population-based studies report prevalence rates of 0.5-30%.
- Affects women in all age groups.
- Approximately 15% of women in North America report recurrent pain during intercourse.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Most often multifactorial in both primary and secondary vaginismus

- Primary
  - Psychological and psychosocial issues
    - Negative messages about sex and sexual relations in upbringing may cause phobic reaction.
    - Poor body image and limited understanding of genital area
    - History of sexual trauma
  - Abnormalities of the hymen
  - History of difficult gynecologic examination
- Secondary
  - Often situational
  - Often associated with dyspareunia secondary to:
    - Vaginal infection
    - Inflammatory dermatitis

- Surgical or postdelivery scarring
- Endometriosis
- Inadequate vaginal lubrication
- Pelvic radiation
- Estrogen deficiency
- Conditioned response to pain from physical issues previously listed

## **RISK FACTORS**

- Most often idiopathic
- Although the exact role in the condition is unclear, many women report a history of abuse or sexual trauma.
- Often associated with other sexual dysfunctions

## **COMMONLY ASSOCIATED CONDITIONS**

- Marital stress, family dysfunction
- Anxiety
- Vulvodynia/vestibulodynia

## **DIAGNOSIS**

*DSM-5* has combined vaginismus and dyspareunia in a condition called genito-pelvic pain/penetration disorder.

## **HISTORY**

- Complete medical history
- Full psychosocial and sexual history, including the following:
  - Onset of symptoms (primary or secondary)
  - If secondary, precipitating events, if any
  - Relationship difficulty/partner violence
  - Inability to allow vaginal entry for different purposes
    - Sexual (penis, digit, object)
    - Hygiene (tampon use)
    - Health care (pelvic examination)

- Infertility
- Traumatic experiences (exam, sexual, etc.)
- Religious beliefs
- Views on sexuality

## *PHYSICAL EXAM*

- Pelvic examination is necessary to exclude structural abnormalities or organic pathology.
- Educating the patient about the examination and giving her control over the progression of the examination is essential, as genital/pelvic examination may induce varying degrees of anxiety in patients.
- Referral to a gynecologist, family physician, or other provider specializing in the treatment of sexual disorders may be appropriate.
- Contraction of pelvic floor musculature in anticipation of examination may be seen.
- Lamont classification system aids in the assessment of severity
  - First degree: Perineal and levator spasm relieved with reassurance.
  - Second degree: Perineal spasm maintained throughout the pelvic exam.
  - Third degree: levator spasm and elevation of buttocks
  - Fourth degree: levator and perineal spasm and elevation with adduction and retreat

## *DIFFERENTIAL DIAGNOSIS*

- Vaginal infection
- Vulvodynia/vestibulodynia
- Vulvovaginal atrophy
- Urogenital structural abnormalities
- Interstitial cystitis
- Endometriosis

## *DIAGNOSTIC TESTS & INTERPRETATION*

No laboratory tests indicated unless signs of vaginal infection are noted on examination. When diagnosing of this disorder has been conducted, five factors should be considered.

- Partner factors

- Relationship factors
- Individual vulnerability factors
- Cultural/religious factors
- Medical factors

## *Test Interpretation*

Not available; may be needed to check for secondary causes

## **TREATMENT**

- Genito-pelvic pain penetration disorder may be successfully treated (2)[B].
- Outpatient care is appropriate.
- Treatment of physical conditions, if present, is first line (see "Secondary" under "Etiology and Pathophysiology").
- Role for pelvic floor physical therapy and myofascial release

P.403

- Some evidence suggests that cognitive-behavioral therapy may be effective, including desensitization techniques, such as gradual exposure, aimed at decreasing avoidance behavior and fear of vaginal penetration (3)[A].
- Based on a Cochrane review, a clinically relevant effect of systematic desensitization cannot be ruled out (4)[A].
- Evidence suggests that Masters and Johnson sex therapy may be effective (5)[B].
  - Involves Kegel exercises to increase control over perineal muscles
  - Stepwise vaginal desensitization exercises
    - With vaginal dilators that the patient inserts and controls
    - With woman's own finger(s) to promote sexual self-awareness
    - Advancement to partner's fingers with patient's control
    - Coitus after achieving largest vaginal dilator or three fingers; important to begin with sensate-focused exercises/sensual caressing without necessarily a demand for coitus
    - Female superior at first; passive (nonthrusting); female-directed
    - Later, thrusting may be allowed.

- Topical anesthetic or anxiolytic with desensitization exercises may be considered.
- Patient education is an essential component of treatment (see "Patient Education" section).

## **MEDICATION**

- Antidepressants and anticonvulsants have been used with limited success. Low-dose tricyclic antidepressant (amitriptyline 10 mg) may be initiated and titrated as tolerated (6)[B].
- Topical anesthetics or anxiolytics may be utilized in combination with either cognitive-behavioral therapy or desensitization exercises as noted above (4)[B].
- Botulinum neurotoxin type A injections may improve vaginismus in patients who do not respond to standard cognitive-behavioral and medical treatment for vaginismus.
  - Dosage: 20, 50, and 100 to 400 U of botulinum toxin type A injected in the levator ani muscle have been shown to improve vaginismus (4)[B].
- Intravaginal botulinum neurotoxin type A injection (100 to 150 U) followed by bupivacaine 0.25% with epinephrine 1:400,000 intravaginal injection (20 to 30 mL) while the patient is anesthetized may facilitate progressive placement of dilators and ultimately resolution of symptoms (7)[B].

## **ISSUES FOR REFERRAL**

For diagnosis and treatment recommendations, the following resources may be consulted:

- Obstetrics/gynecology
- Pelvic floor physical therapy
- Psychiatry
- Sex therapy
- Hypnotherapy

## **SURGERY/OTHER PROCEDURES**

Contraindicated

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Biofeedback
- Functional electrical stimulation

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Desensitization techniques of gentle, progressive, patient-controlled vaginal dilation

#### *Patient Monitoring*

General preventive health care

#### *DIET*

No special diet

### *PATIENT EDUCATION*

- Education about pelvic anatomy, nature of vaginal spasms, normal adult sexual function
- Handheld mirror can help the woman to learn visually to tighten and loosen perineal muscles.
- Important to teach the partner that spasms are not under conscious control and are not a reflection on the relationship or a woman's feelings about her partner
- Instruction in techniques for vaginal dilation
- Resources

Dyspareunia; Sexual Dysfunction in Women

## Codes

**&NA;**

### ICD10

- N94.2 Vaginismus
- N94.1 Dyspareunia

## Clinical Pearls

**&NA;**

- In a patient with suspected genito-pelvic pain penetration disorder, a complete medical history, including a comprehensive psychosocial and sexual history and a patient-centric, patient-controlled educational pelvic exam should be conducted.
- This condition can be treated effectively.
- Cognitive-behavioral therapy may be effective for the treatment of this condition.
- Botox injection therapy is in the experimental stages but looks promising for the treatment of vaginismus. Bupivacaine and dilation under general anesthesia has also been tried as a treatment for vaginismus.

# Giardiasis

Iryna Matkovska, DO

Deborah Pierce, DO

Merle A. Carter, MD, FACEP

## BASICS

### DESCRIPTION

- Intestinal infection caused by the protozoan parasite *Giardia lamblia*:
  - *G. lamblia* is also called *Giardia duodenalis* and *Giardia intestinalis*.
- Infection results from ingestion of cysts, which transform into trophozoites:
  - Trophozoites colonize the small intestine and cause symptoms.
  - Cycle is continued when the trophozoites encyst in the small intestine and are subsequently transmitted through water, food, or hands contaminated by feces of infected person.
- Most infections result from fecal-oral transmission or ingestion of contaminated water (e.g., swimming).
- Less commonly, giardiasis is the result of contaminated food.

### EPIDEMIOLOGY

- Predominant age:
  - All ages but most common in early childhood ages 1 to 9 years and adults 35 to 44 years
- Predominant gender:
  - Male > female (slightly)
- Minimal seasonal variability; slight increase in summer

### Pediatric Considerations

Most common in early childhood

### Prevalence

- 5% of patients with stools submitted for ova and parasite exams
- > 19,000 cases/year in reportable U.S. states:
  - *Giardia* is not reportable in Indiana, Kentucky, Mississippi, North Carolina, and Texas.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

*Giardia* trophozoites colonize the surface of the proximal small intestine: The mechanism of diarrhea is unknown.

### **Genetics**

No known genetic risk factors

## **RISK FACTORS**

- Daycare centers
- Anal intercourse
- Wilderness camping
- Travel to developing countries
- Children adopted from developing countries
- Public swimming pools
- Pets with *Giardia* infection/diarrhea

## **GENERAL PREVENTION**

- Hand hygiene
- Water purification when camping and when traveling to developing countries
- Properly cook all foods.

## **COMMONLY ASSOCIATED CONDITIONS**

Hypogammaglobulinemia and possibly IgA deficiency: diarrhea more severe and prolonged in these patients

## **DIAGNOSIS**

### **HISTORY**

- 25-50% of infected persons are symptomatic.

- Symptoms usually appear 1 to 2 weeks after exposure.
- Chronic diarrhea (can last for weeks)
- Abdominal bloating
- Flatulence
- Loose, greasy, foul-smelling stools that tend to float
- Weight loss
- Nausea
- Lactose intolerance

## *PHYSICAL EXAM*

- Typically normal vital signs
- Nonspecific; abdominal exam; may have bloating tenderness or increased bowel sounds

## *DIFFERENTIAL DIAGNOSIS*

- Cryptosporidiosis, isosporiasis, cyclosporiasis
- Other causes of malabsorption include celiac sprue, tropical sprue, bacterial overgrowth syndromes, and Crohn ileitis.
- Irritable bowel (diarrhea without weight loss)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Stool for ova and parasites:
  - Repeat 3 times on separate days
  - Cysts in fixed or fresh stools, and occasionally, trophozoites are found in fresh diarrheal stools.
- Limitations: experienced operator, intermittent shedding of ova may not be present in stool sample, labor intensive
  - ELISA: sensitivity and specificity of 100% and 91.5% respectively (compared to 50-70% sensitivity using microscopy) (1)[B].
- Polymerase chain reaction (PCR) techniques are more sensitive than microscopy but have not been widely adopted due to high cost.
- Rapid detection tests have been studied showing high detection rates not widely available (2)

[B].

## *Follow-Up Tests & Special Considerations*

String test (Entero-test):

- A gelatin capsule on a string is swallowed and left in the duodenum for several hours or overnight. The string is removed and visualized microscopically.

## *Diagnostic Procedures/Other*

Esophagogastroduodenoscopy (EGD) with biopsy and sample of small intestinal fluid

## *Test Interpretation*

Intestinal biopsy shows flattened, mild lymphocytic infiltration and trophozoites on the surface.

## **TREATMENT**

Outpatient for mild cases; inpatient if symptoms are severe enough to cause dehydration warranting parenteral fluid replacement

## **GENERAL MEASURES**

- Medical therapy for all infected individuals
- Fluid replacement if dehydrated

## **MEDICATION**

### *First Line*

- Metronidazole (Flagyl): 250 mg PO TID for 5 to 7 days (2)[B]
- Tinidazole: 2 g PO single dose (50 mg/kg up to 2 g for children)
- Albendazole: 400 mg/day PO for 5 days:
  - Albendazole has comparable effectiveness to metronidazole with fewer side effects and lower cost.
- Precautions:
  - Theoretical risk of carcinogenesis with metronidazole
- Significant possible interactions: occasional disulfiram reaction with metronidazole or tinidazole

## Pregnancy Considerations

Medications to treat giardiasis are relatively contraindicated during pregnancy; consider appropriate consultation with infectious disease or maternal-fetal medicine specialist.

## Pediatric Considerations

In one study, administration of vitamin A reduced prevalence of *G. lamblia* (3)[A].

P.405

## Second Line

- Furazolidone: 8 mg/kg/day TID for 10 days (slightly less effective but commonly used in pediatrics because it is well tolerated); not available in United States
- Paromomycin (Humatin): a nonabsorbable aminoglycoside that is probably less effective but commonly recommended in pregnancy because of lower risk of teratogenicity
- Quinacrine: 100 mg TID for 5 to 7 days; withdrawn from the U.S. market
- Nitazoxanide suspension was approved by the FDA in 2003 for treatment of giardiasis in children 1 to 11 years. Children aged 1 to 4 years receive 100 mg BID and age 5 to 11 years receive 200 mg BID for 3 days.
- Two other nitroimidazole antibiotics, ornidazole and secnidazole, are effective against *Giardia* but are not available in the United States.

## ADDITIONAL THERAPIES

- There have been anecdotal reports of herbal products containing *Mentha crispera* being effective in the treatment of *Giardia*. When studied, it was much less effective than secnidazole (a metronidazole analog).
- A recent study showed tetrahydrolipstatin (Orlistat) had activity against *Giardia* (may be a potential treatment option in the future for patients who are resistant to metronidazole) (4)[C].
- In mouse studies, auranofin, miltefosine, disulfiram, and omeprazole have all shown effective activity against *G. lamblia*. Research is still needed in humans (5,6,7,8)[C].

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### Patient Monitoring

Symptoms, weight, stool exams if patients fail to improve

## DIET

Low lactose, low fat, monitor for dehydration

## PATIENT EDUCATION

- Hand washing may be more important than water purification to prevent transmission in outdoor enthusiasts.
- Lactose intolerance may follow *Giardia* infection and cause of persistent diarrhea posttreatment. Consider low-lactose diet.
- CDC Facts about *Giardia* and Swimming Pools:  
<http://www.cdc.gov/healthywater/pdf/swimming/resources/giardia-factsheet.pdf>
  - Don't swim if you have diarrhea.
  - Wash hands with soap after changing diapers before returning to the pool.
  - Do not ingest pool, lake, or river water.
  - Use chlorine to kill *Gardia* in water used for recreational activities.

## PROGNOSIS

- Untreated giardiasis lasts for weeks.
- Most (90%) patients respond to treatment within a few days:
  - Most nonresponders or relapses respond to a second course with the same or a different agent.

## COMPLICATIONS

Malabsorption, reactive arthritis, and weight loss, lactose intolerance

## ALERT

Notifiable disease

## See Also

&NA;

Algorithm: Diarrhea, Chronic

## Codes

&NA;

### ICD10

A07.1 Giardiasis [lambliaosis]

## Clinical Pearls

&NA;

- Daycare facilities and public swimming pools are common sources of *Giardia* (don't assume camping or travel is required).
- Metronidazole has high cure rates (but is often poorly tolerated).
- Most treatment failures respond to a second course of antibiotics (with same or other drugs).
- A single FA or ELISA is as sensitive as three stool samples for ova and parasites for detecting *Giardia*.

# Gilbert Disease

Robert A. Marlow, MD, MA

## BASICS

### *DESCRIPTION*

Mild, chronic, or intermittent unconjugated hyperbilirubinemia (not due to hemolysis) with otherwise normal liver function (1)

### *Pediatric Considerations*

Rare for the disorder to be diagnosed before puberty (2)

### *Pregnancy Considerations*

The relative fasting that may occur with morning sickness can elevate bilirubin level.

### *EPIDEMIOLOGY*

- Predominant age: present from birth but most often presents in the 2nd or 3rd decade of life; heterozygous for single abnormal gene (3)
- Predominant sex: male > female (2 to 7:1)

### *Prevalence*

Prevalence in the United States:  $\div 7\%$  of the population (4);  $\div 1$  in 3 of those affected are not aware that they have the disorder.

### *ETIOLOGY AND PATHOPHYSIOLOGY*

The hyperbilirubinemia results from impaired hepatic bilirubin clearance ( $\div 30\%$  of normal). Hepatic bilirubin conjugation (glucuronidation) is reduced, although this is likely not the only defect (3).

### *Genetics*

A gene defect resulting in reduced bilirubin uridine diphosphate-glucuronosyltransferase-1 appears to be necessary but not sufficient for Gilbert syndrome (5).

## RISK FACTORS

Male gender

## COMMONLY ASSOCIATED CONDITIONS

Gilbert disease may be part of a spectrum of hereditary disorders that includes types I and II Crigler-Najjar syndrome.

## DIAGNOSIS

### HISTORY

No significant symptoms, although a variety of nonspecific symptoms have been described. An episode of nonpruritic jaundice can be triggered by stressors such as fasting, dehydration, infections, physical exertion, lack of sleep, and surgery. Some medications may also trigger episodes of jaundice, such as drugs that inhibit glucuronyl transferase, such as gemfibrozil and the protease inhibitors atazanavir and indinavir. Any symptoms present during an episode of jaundice, including fatigue, are caused by the triggering factor and are not directly a result of the Gilbert disease (6).

### PHYSICAL EXAM

No abnormal physical findings other than occasional mild jaundice that can be precipitated by the above-mentioned triggers (fasting, dehydration, infections, physical exertion, lack of sleep, and surgery).

### DIFFERENTIAL DIAGNOSIS

- Hemolysis
- Ineffective erythropoiesis (megaloblastic anemias, certain porphyrias, thalassemia major, sideroblastic anemia, severe lead poisoning, congenital dyserythropoietic anemias)
- Cirrhosis
- Chronic persistent hepatitis
- Pancreatitis
- Biliary tract disease

### DIAGNOSTIC TESTS & INTERPRETATION

*Initial Tests (lab, imaging)*

- Bilirubin: Elevated but <6 mg/dL (103 &mgr;mol/L) and usually <3 mg/dL (51 &mgr;mol/L), virtually all unconjugated (indirect), with conjugated bilirubin within the normal range and/or <20% of the total bilirubin (6).
- CBC with peripheral smear is normal.
- Reticulocyte count is normal.
- Liver function tests (LFTs) (aspartate aminotransferase [AST], alanine transaminase [ALT], alkaline phosphatase, and gamma-glutamyl transpeptidase [GGT]) are normal.
- Fasting and postprandial serum bile acids are normal.
- Up to 60% of patients have clinically insignificant mild hemolysis that frequently can only be detected with sophisticated red cell survival studies.
- Drugs that may alter lab results: Bilirubin level may be raised by nicotinic acid and lowered by phenobarbital.
- Disorders that may alter lab results: Bilirubin levels increase during fasting and may increase during a febrile illness.

### *Follow-Up Tests & Special Considerations*

If history, physical exam, and laboratory tests are normal, see the patient on two to three further occasions during the ensuing 12 to 18 months. If the patient develops no symptoms, reticulocytosis, or new liver function abnormalities, make the diagnosis of Gilbert disease.

### *Diagnostic Procedures/Other*

#### **ALERT**

A liver biopsy is not usually needed to exclude other diagnoses (4).

- Some clinicians recommend confirming the diagnosis by reducing daily caloric intake to 400 kcal for 48 hours, which results in a 2- to 3-fold increase in unconjugated bilirubin, but other clinicians consider this impractical and nonspecific for Gilbert disease.
- After 12 hours of fasting, an increase of total bilirubin to >1.9 mg/dL 2 hours after an oral dose of rifampin 900 mg distinguishes patients with Gilbert disease with a sensitivity of 100% and a specificity of 100% (7).

## **TREATMENT**

- Outpatient

- The most important treatment is to make a positive diagnosis of Gilbert disease to reassure the patient and prevent further unnecessary procedures.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

If history, physical exam, and laboratory tests are normal, see the patient on two to three further occasions during the ensuing 12 to 18 months. If the patient develops no symptoms, reticulocytosis, or new liver function abnormalities, make the diagnosis of Gilbert disease.

### *PATIENT EDUCATION*

Reassure the patient that the condition is benign with no known sequelae.

### *PROGNOSIS*

- The disorder is benign with an excellent prognosis.
- There is some preliminary evidence that patients with Gilbert disease may have a lower incidence of cardiovascular disease (8,9). Elevated levels of bilirubin may exert an antioxidation effect (9).
- Patients with Gilbert syndrome are able to serve as donors for right lobe of liver for transplantation (10).

### **COMPLICATIONS**

No known complications

## Codes

**&NA;**

### ICD10

- E80.4 Gilbert syndrome
- E80.6 Other disorders of bilirubin metabolism

## Clinical Pearls

**&NA;**

- Gilbert disease: a mild chronic or intermittent unconjugated hyperbilirubinemia (not due to hemolysis) with otherwise normal liver function
- The hyperbilirubinemia results from impaired hepatic bilirubin clearance (30% of normal). Hepatic bilirubin conjugation (glucuronidation) is reduced, although this is likely not the only

defect.

- The most important reason to make the diagnosis of Gilbert disease is to reassure the patient that this is a benign condition with no known sequelae and to prevent unnecessary procedures.
- To diagnose Gilbert disease: History, physical exam, and laboratory tests (LFTs, reticulocytosis, etc.) are normal on visits every 6 months over 18 months.
- A liver biopsy is not usually needed to rule out other liver diseases. The diagnosis can be confirmed by otherwise normal LFTs, no evidence of hemolysis, and the response to fasting or a dose of rifampin.
- The etiology of Gilbert disease can result when the patient has a gene defect resulting in reduced conjugation of bilirubin. The gene defect is necessary but not sufficient to produce Gilbert disease.

# Gingivitis

**Hugh Silk, MD, MPH, FAAFP**

**Sheila O. Stille, DMD**

**Nerissa P. Duchin, MD**

## **BASICS**

### *DESCRIPTION*

Gingivitis is a reversible form of inflammation of the gingiva. It is a mild form of periodontal disease. Classification includes the following:

- Plaque-induced
- Not plaque-induced (bacterial, viral, or fungal; e.g., acute necrotizing gingivitis, Vincent disease [Òtrench mouthÓ], denture-related)
- Modified by systemic factors (e.g., pregnancy, puberty, HIV, diabetes, smoking, leukemia)
- Modified by medications (calcium channel blockers, antipsychotics, antiepileptics, antirejection medications, hormones)
- Modified by malnutrition (vitamin deficiencies)
- System(s) affected: gastrointestinal; ears, nose, throat; dental
- Synonym(s): mild periodontal disease; gum disease

### *Geriatric Considerations*

More frequent in this age group (due more to additive effects than to increased susceptibility)

### *Pediatric Considerations*

Mild cases common in children (most common form of pediatric periodontal disease) and usually require no specific interventions other than improved oral hygiene

### *Pregnancy Considerations*

- Very common in pregnant women; hormonal effect
- Self-limited

## EPIDEMIOLOGY

- Predominant age: children, teenagers, and young adults. Predominant sex: slightly more males than female
- Prevalence ÷50% of children
- ÷90% of adolescents and adult population
- ÷30-75% of pregnant women

## ETIOLOGY AND PATHOPHYSIOLOGY

Inflammation of gingiva. This can progress to deeper, destructive inflammation. If involving supporting bone, will be classified as periodontitis, not gingivitis.

- Usually noncontagious
- Inadequate plaque removal
- Blood dyscrasias (pregnancy)
- Oral contraceptives
- Allergic reactions
- Nutritional deficiencies
- Vasoconstriction (nicotine, methamphetamine)
- Endocrine/hormonal variations
  - Pregnancy
  - Menses
  - Menarche
- Chronic debilitating disease
- Vincent disease
  - Synergistic infection with fusiform bacillus (*Fusobacterium* spp.) and spirochete (*Borrelia vincentii*)
- Pathology
  - Acute or chronic inflammation
  - Hyperemic capillaries
  - Polymorphonuclear infiltration

Papillary projections in subepithelial tissue

- Fibroblasts

## *Genetics*

Possible genetic link (up to 30% of population); rare condition called hereditary gingival fibromatosis associated with hirsutism

## **RISK FACTORS**

- Poor dental hygiene/plaque formation
- Pregnancy
- Uncontrolled diabetes mellitus
- Malocclusion or dental crowding
- Smoking
- Mouth breathing
- Xerostomia
- Faulty dental restoration
- HIV-positive; AIDS
- Stress
- Hospitalization (1)[A]
- Vitamin C deficiency; coenzyme Q10 deficiency
- Dental appliances (dentures, braces)
- Eruption of primary or secondary teeth
- Necrotizing ulcerative gingivitis
  - Stress
  - Lack of sleep
  - Malnutrition
  - Viral illness
  - Typically teens and young adults
- Bronchial asthma and other respiratory diseases (2,3)[B]
- Rheumatoid arthritis (4)[B]

## GENERAL PREVENTION

- Good oral hygiene
  - Adults
    - Regular twice-daily brushing with fluoride toothpaste and increased benefit of using circular oscillating electric brush rather than regular brush or sonic/vibration (5,6)[A]
    - Daily "high-quality" flossing (studies show that flossing only helps when it is done correctly) (7)[A]
    - Chlorhexidine with oral hygiene better than other oral rinse agents (8,9)[A]
      - Use in acute phase sparingly (10)[B]
  - Pediatrics
    - Regular twice-daily brushing with fluoride toothpaste under parental supervision until full manual dexterity ( $\approx$ 8 years of age)
    - Regular flossing if no spaces between teeth
- Cleaning by a dentist or hygienist every 6 months or more frequently, if indicated
- Mouth rinse with essential oils (menthol, thymol, eucalyptol; e.g., Listerine) combined with brushing (11)[B]
  - Caution: Long-term use of alcohol-based mouth rinse may be associated with an increased risk of oral cancer (12)[B].

## COMMONLY ASSOCIATED CONDITIONS

- Periodontitis
- Glossitis
- Pedunculated growths (pyogenic granulomata)

## DIAGNOSIS

### HISTORY

- Gum erythema, swelling, and edema
- Gums are tender when touched but otherwise painless.
- Bleeding of gums when brushing, flossing, or eating

- Inquire about HIV risk, pregnancy, nutritional deficiencies, diabetes, and other risk factors as indicated (see “Risk Factors”).
- Smoking history
- Oral hygiene, dental visit history

## *PHYSICAL EXAM*

- Normal gums should appear pink, firm, stippled, and scalloped.
- Gingivitis—marginal gum swelling and edema (usually painless, except to touch)
- Gum erythema: bright red or red-purple appearance
- Bleeding with manipulation of gums
- Change of normal gum contours
- Plaque (soft) and calculus (not easily removed)
- Edema of interdental papillae
- HIV gingivitis
  - Also called linear gingival erythema
  - Narrow band of bright red inflamed gum surrounding neck of tooth
  - Painful
  - Bleeds easily
  - Rapid destruction of gingival tissue and can progress to periodontitis with destruction of underlying support tissues (periodontal ligament, supporting alveolar bone)
- Vincent disease
  - Ulcers
  - Fever
  - Malaise
  - Regional lymphadenopathy
  - Pain
  - Mouth odor

## *DIFFERENTIAL DIAGNOSIS*

- Periodontitis (deeper inflammation, causing destruction to connective tissue, ligaments, and

alveolar bone)

- Glossitis
- Desquamative gingivitis (painful, persistent, usually middle-aged women)
- Pericoronitis (gum flap traps food and plaque over partially erupted third molar), common in adolescence
- Gingival ulcers (aphthous, herpetic, malignancy, TB, syphilis)
- Specific forms of gingivitis: See "Description," including acute necrotizing ulcerative gingivitis (Vincent disease) and HIV gingivitis (linear gingival erythema).

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- No tests usually needed
- Possible smear or culture to identify causative agent (HIV gingivitis includes gram-negative anaerobes, enteric strains, and *Candida*)
- Labs for contributing conditions (HIV, pregnancy, diabetes, nutritional deficiencies)

---

P.409

## TREATMENT

### GENERAL MEASURES

- Stop any contributing medications.
- Remove irritating factors (plaque, calculus, faulty dental restorations, or partial dentures).
- Good oral hygiene (see "General Prevention")
- Regular dental checkups (for scaling and polishing if plaque and/or tartar are present)
- Smoking cessation
- Warm saline rinses BID
- Special care needs patients: use of tray-applied 10% carbamide peroxide gels (13)[C]

### MEDICATION

#### First Line

Chlorhexidine rinses or varnishes may be used (14)[B].

- Mouth rinses with essential oils (EOMW) may be equally effective to chlorhexidine for reduction of gingival inflammation (while EOMW is not as effective for plaque control) (15)[A].
- Both chlorhexidine and EOMW rinses are as clinically effective as oral prophylaxis and oral hygiene instruction at 6-month recall (16)[B].
- Antibiotics indicated only for acute necrotizing ulcerative gingivitis (Vincent disease)
- Antibiotics
  - Penicillin V: pediatric dose, 25 to 50 mg/kg/day divided q6h; adult dose, 250 to 500 mg q6h, *OR*
  - Metronidazole: pediatric dose, 30 mg/kg/day PO/IV divided q6h; maximum 4 g/day; adult dose, 500 mg BID or TID for 10 days *OR*
  - Amoxicillin/clavulanic acid: pediatric dose, 30 mg/kg/day PO divided q12h; info: use 125 mg/31.25 mg/5 mL susp; adult dose, 875 mg/125 mg PO BID for 10 days
  - Erythromycin: pediatric dose 30 to 40 mg/kg/day divided q6h; adult dose, 250 mg q6h
  - Doxycycline: adult dose, 100 mg BID 1st day, then QD for 10 days
- Topical corticosteroids
  - Triamcinolone 0.1% in Orabase (spray or ointment), applied locally TID, QID
    - Contraindications
      - Allergy to specific medication
- Precautions
  - Erythromycin frequently causes GI issues.

## *Second Line*

- Acetaminophen or ibuprofen for any pain (rare)
- Other antibiotics or antifungal rinses or systemic according to culture or smear
- Decapinol oral rinse (surfactant that acts as a physical barrier, making it harder for bacteria to stick to tooth and mucosal surfaces) to reduce bacteria (not recommended for pregnant women or children <12 years); should be used in conjunction with other oral hygiene practices when those practices alone are not enough

## *ISSUES FOR REFERRAL*

- Dental referral for cleanings and further treatment, as needed
- If gingivitis becomes periodontitis, deep root scaling, planing, and antibiotics may be indicated.

## ***SURGERY/OTHER PROCEDURES***

- Debridement for acute necrotizing gingivitis
- Minor surgery may be necessary to correct tissue overgrowth for gingivitis caused by medicines.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Bilberry: potentially helpful in reducing inflammation and stabilizing collagen tissue
- Coenzyme Q10: topically, to restore coenzyme Q10 deficiency
- Replace any other deficiencies (e.g., vitamin C).

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Outpatient
- No restrictions

### ***Patient Monitoring***

Until clear; dental follow-up for continued cleanings and secondary prevention

### ***DIET***

- Well-balanced diet that includes fruits, vegetables, vitamin C; avoid sugary snacks and drinks, which contribute to plaque formation.
- Soft foods during flare, if significant inflammation/bleeding

### ***PATIENT EDUCATION***

- Good oral hygiene, including twice-daily brushing with circular oscillating electric brush, fluoridated toothpaste, and daily flossing; regular dental visits
- Printable and viewable patient information available under "Gum diseases" from the American Dental Association at <http://www.mouthhealthy.org/en/> and the American Academy of Periodontology under "Patient resources" at <http://www.perio.org/>

## PROGNOSIS

- Usual course: acute, relapsing, intermittent; chronic
- Prognosis: generally favorable, responds well to appropriate treatment
- Left untreated, may progress to periodontitis (controversial), which is a major cause of tooth loss

## COMPLICATIONS

Severe periodontal disease (which is associated with heart disease, diabetes, and preterm birth)

- Dental Infection; Glossitis

- Algorithm: Bleeding Gums

## Codes

**&NA;**

### ICD10

- K05.10 Chronic gingivitis, plaque induced
- K05.11 Chronic gingivitis, non-plaque induced
- K05.00 Acute gingivitis, plaque induced

## Clinical Pearls

**&NA;**

- Gingivitis may be prevented and treated with regular dental cleanings, good oral hygiene, and use of certain mouth rinses including chlorhexidine.
- Untreated, gingivitis may progress to periodontitis, a possible contributor to systemic inflammation and its consequences (e.g., coronary artery disease and uncontrolled diabetes).
- New-onset or difficult-to-treat gingivitis, consider differential of etiology: pregnancy, HIV, diabetes, medications, and vitamin deficiencies.

# Glaucoma, Primary Closed-Angle

H. Anh Hinshaw, MD

David S. Pfoff, MD

## BASICS

### DESCRIPTION

- Primary angle closure suspect (PACS): eye has narrow or occludable anterior chamber angle, but no other abnormalities (1)
- Primary angle closure (PAC): signs of trabecular meshwork obstruction appear, such as increased intraocular pressure (IOP) or synechiae formation (1)
  - Acute angle closure: sudden block of meshwork by iris (2)
  - Subacute (intermittent) angle closure: periodic acute episodes with normal IOP between (2)
  - Chronic angle closure: most common, refers to an eye with permanent closure of areas of the anterior chamber angle by peripheral anterior synechiae (1)[C]
- Primary angle closure glaucoma (PACG): glaucomatous optic neuropathy and visual field loss are present (1)[C].

### Geriatric Considerations

Increased risk with age and prior history of cataract, hyperopia, and/or uveitis

### Pregnancy Considerations

Medications used may cross the placenta and be excreted into breast milk.

### EPIDEMIOLOGY

- Age >40 years
- Female > male
- Inuit and Asian > African and European

### Prevalence

- Estimated that over 23 million (in 2020) and 32 million (in 2040) people worldwide will have

PACG with the majority in Asia (3)

- PACG is not as common in the United States, accounts for 10% of all glaucoma (2).

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

- Iridotrabecular contact (ITC): instigating factor; peripheral iris apposition to the posterior trabecular meshwork (1)
- ITC causes obstruction of aqueous humor outflow through the trabecular meshwork, which causes elevation in IOP. Prolonged ITC can cause scarring to form, degradation of trabecular meshwork, and loss of vision (1).
- Most common underlying mechanism of PAC is anterior lens displacement, leading to pupillary block in which aqueous humor egress through the pupil is limited. This causes pressure to build posterior in the peripheral iris, leading to anterior bowing of the iris and closing of the angle (1,2).
- Other mechanisms include predisposing ocular anatomy, such as plateau iris (2)

## ***Genetics***

First-degree relatives have a 1-12% increased risk in whites, 6 times greater risk in Chinese patients with positive family history.

## ***RISK FACTORS***

- Hyperopia
- Age >40 years
- Shallow anterior chamber
- Female gender
- Family history of angle closure
- Asian or Inuit descent
- Short axial length
- Thick crystalline lens
- Anterior positioned lens
- Plateau iris
- Drugs that can induce angle-closure:
  - Adrenergic agonists (albuterol, phenylephrine), anticholinergics (oxybutynin, atropine, botulinum toxin A), antihistamines, antidepressants including selective serotonin reuptake

inhibitors (SSRIs) and tricyclic antidepressants (TCAs), cholinergic agents, sulfa-based drugs, topiramate, cocaine, ecstasy (4)[A]

## GENERAL PREVENTION

- Routine eye exam with gonioscopy for high-risk populations
- U.S. Preventive Services Task Force: insufficient evidence to recommend for or against screening adults for open-angle glaucoma (5)[A]
- Prophylactic laser iridotomy for PACS patients has been found to be effective in preventing PACG.
- Prophylactic laser iridotomy in contralateral eye of patients that have had unilateral acute PAC has been effective in preventing acute attacks in the contralateral eye (2)[C].

## COMMONLY ASSOCIATED CONDITIONS

- Cataract
- Hyperopia
- Microphthalmos
- Systemic hypertension

## DIAGNOSIS

### HISTORY

- Patient's previous medical and ophthalmologic history
- Family history of glaucoma
- Obtain history of prescription, over-the-counter, and herbal medications
- Precipitating factors (dim light, medicines)
- Review of symptoms
- Acute (6)[C]
  - Severe eye pain
  - Blurred vision
  - Eye redness
  - Halos around lights/objects
  - Frontal headache
  - Nausea and vomiting, which may lead to erroneous abdominal exploration

- Chronic (2)[C]
  - May have subacute symptoms (intermittent subacute attacks)
  - Compromised peripheral, then central vision
  - Usually asymptomatic until advanced vision loss has occurred.

## *PHYSICAL EXAM*

- Includes, but is not limited to, the following in the undilated eye (1)[C]
  - Visual acuity
  - Visual field testing and ocular motility
  - Pupil size and reactivity (mid-dilated, minimally reactive)
  - External examination
  - Undilated fundus exam (congestion, cupping, atrophy of optic nerve)
  - Slit-lamp exam (anterior segments)
  - Tonometry (determination of IOP)
  - Gonioscopy (visualization of the angle)
- Acute (6)[C]
  - Elevated IOP (>21 mm Hg)
  - Corneal microcystic edema (haze)
  - Hyperemic conjunctiva
  - Mid-dilated, nonreactive, or irregular pupil
  - Shallow anterior chamber, often with inflammatory reaction (cell and flare in anterior chamber)
  - Pain with eye movement
  - Closed angle by gonioscopy or anterior segment optical coherence tomography (AS-OCT)
- Chronic (6)[C]
  - Multiple peripheral anterior synechiae
  - Normal or elevated IOP
  - Increased cup-to-disc ratio or excavation of disc
  - Glaucoma flecks (lens) and iris atrophy (previous acute attacks)

## ***DIFFERENTIAL DIAGNOSIS***

- Acute orbital compartment syndrome
- Traumatic hyphema
- Conjunctivitis, episcleritis
- Corneal abrasion
- Glaucoma, malignant or neovascular
- Herpes zoster ophthalmicus
- Iritis and uveitis
- Orbital/periorbital infection
- Vitreous or subconjunctival hemorrhage
- Tight necktie, causing increased IOP
- Lens-induced angle closure

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

Ultrasound (US) biomicroscopy AS-OCT (1)[C]

### ***Diagnostic Procedures/Other***

Careful ophthalmic examination, including gonioscopy and tonometry (1)[C]

### ***Test Interpretation***

- Narrow or closed anterior angle
- Corneal stromal and epithelial edema
- Endothelial cell loss (guttata)
- Iris stromal necrosis
- Anterior subcapsular cataract (*glaukomflecken*)
- Optic disc congestion, cupping, excavation
- Optic nerve atrophy

## TREATMENT

Goals of treatment (1)[C]:

- Reverse or prevent angle-closure process
- Control IOP
- Prevent damage to the optic nerve

## GENERAL MEASURES

- For acute attack: ocular emergency
  - Manage nausea and pain
  - Immediate ophthalmology consultation
  - Goals of therapy through medical and surgical treatment: reduce IOP to <35 mm Hg or by >25% of presenting IOP (7)[B]

## MEDICATION

- During acute attack, therapy can be initiated with 2% pilocarpine, 0.5% timolol maleate, and 1% apraclonidine drops 1 minute apart, and acetazolamide 500 mg PO, glycerin (Osmoglen) (50%) 6 oz PO, and IV mannitol 20% 1.5 to 2g/kg infused over 30 to 60 minutes for a rapid decrease in IOP; after the cornea clears, a peripheral iridotomy is done (8)[C].

P.411

- Additionally, medical therapy to decrease IOP and clear the cornea prior to surgery can also be accomplished using some or all of the following (1,9)[C]:
  - Carbonic anhydrase inhibitors (CAIs):
    - Contraindications/precautions: sulfa allergy, hepatic insufficiency
    - Systemic:
      - Acetazolamide (Diamox): 500 mg IV/PO; may repeat with 250 mg in 4 hours to a maximum of 1 g/day
      - Methazolamide (Neptazane): 50 to 100 mg PO BID-TID
    - Topical:
      - Dorzolamide (Trusopt) 2% eyedrops: 1 drop in affected eye(s) TID
      - Brinzolamide (Azopt) 1% suspension: 1 drop in affected eye(s) TID

- $\beta_1$ -Blockers:
  - Contraindications/precautions: decompensated heart failure, sinus bradycardia, heart block, severe COPD/asthma
    - Timolol (Timoptic) 0.25-0.5% solution: 1 drop in affected eye(s) BID
    - Timolol (Timolol GFS, Timoptic-XE) 0.25-0.5% gel-forming solution: 1 drop daily
    - Levobunolol (Betagan) 0.5% solution: 1 drop in affected eye(s) 1 to 2 times daily
    - Betaxolol (Betoptic) 0.5% solution: 1 to 2 drops in affected eye(s) BID
    - Carteolol (Ocupress) 1% solution: 1 drop in affected eye(s) BID
    - Metipranolol (Optipranolol) 0.3% solution: 1 drop in affected eye(s) BID
- $\alpha_2$ -Agonists: (used as adjunct therapy)
  - Contraindications/precautions: MAO inhibitor therapy
    - Brimonidine (Alphagan P) 0.15%, 0.2% solution: 1 drop in affected eye(s) TID
    - Apraclonidine (Iopidine) 0.5% solution: 1 to 2 drops in affected eye(s) TID
- Prostaglandin analogs:
  - Precautions: changes to iris, eyelid, and eyelash pigmentation, eyelash growth, irritation, redness; can cause corneal epithelium herpes to recur
    - Latanoprost (Xalatan) 0.005% solution: 1 drop in affected eye(s) daily
    - Travoprost (Travatan Z) 0.004% solution: 1 drop in affected eye(s) daily
    - Bimatoprost (Lumigan) 0.01% solution: 1 drop in affected eye(s) daily
    - Tafluprost (Zioptan) 0.0015% solution: 1 drop in affected eye(s) nightly
    - Unoprostone (Rescula) 0.15% solution: 1 drop in affected eye(s) BID
- Direct cholinergic agonists:
  - Precautions: may worsen the condition due to anterior rotation of the lens-iris diaphragm, impaired night vision, color vision changes
    - Pilocarpine (Isopto Carpine) (1%, 2%, 4% solution): 1 drop up to 6 times daily to reduce IOP; for acute attack, 1 drop of 1-2% in affected eye(s) every 10 minutes up to 3 doses
- Cholinesterase inhibitor:

- Precautions: may worsen the condition due to anterior rotation of the lens-iris diaphragm, impaired night vision
  - Echothiophate iodide (Phospholine Iodide) 0.125% solution: 1 drop BID
- Combination products:
  - Timolol-Dorzolamide (Cosopt) 0.5%/2% solution: 1 drop in affected eye(s) BID
  - Timolol-Brimonidine (Combigan) 0.5%/0.2% solution: 1 drop in affected eye(s) BID
  - Brinzolamide-Brimonidine (Simbrinza) 1%/0.2% solution: 1 drop in affected eye(s) TID

## *ADDITIONAL THERAPIES*

Keep patient supine.

## *SURGERY/OTHER PROCEDURES*

- Acute (1)[C],(6)[B]
  - Laser peripheral iridotomy is preferred surgical treatment, but surgical iridectomy can be used if laser is not available.
- Subacute and chronic (1,5,10)[B]
  - Laser iridectomy for pupillary block
  - Goniosynechialysis to separate synechiae
  - Phacoemulsification to remove cataract

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Patient requires metabolic ± electrolyte and volume status monitoring (with osmotic agents).
- Facilitate close ophthalmology monitoring.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Schedule an immediate ophthalmologic follow-up.

## *Patient Monitoring*

- Postsurgical follow-up
- Evaluation of the contralateral eye
- Routine monitoring after acute attack per ophthalmologist recommendations

## *PATIENT EDUCATION*

- Advise patient to seek emergency medical attention if experiencing a change in visual acuity, blurred vision, eye pain, or headache.
- If narrow angles, but no peripheral iridotomy performed: Avoid decongestants, motion sickness medications, adrenergic agents, antipsychotics, antidepressants, and anticholinergic agents.
- Correct eyedrop administration technique, including the following:
  - Remove contact lenses before administration and wait 15 minutes before reinserting.
  - Allow at least 5 minutes between administration of multiple ophthalmic products.
- Patients with significant visual impairment should be referred to vision rehab and social services.
- Patient education materials:
  - Glaucoma Research Foundation: <http://www.glaucoma.org>
  - National Eye Institute: <http://www.nei.nih.gov>

## *PROGNOSIS*

- With timely treatment, most patients do not have permanent vision loss.
- Prognosis depends on ethnicity, underlying eye disease, and time-to-treatment.

## **COMPLICATIONS**

- Chronic corneal edema
- Corneal fibrosis and vascularization
- Iris atrophy
- Cataract
- Optic atrophy
- Malignant glaucoma
- Central retinal artery/vein occlusion

- Permanent decrease in visual acuity
- Repeat episode
- Fellow (contralateral) eye attack

Glaucoma, Primary Open-Angle

## Codes

**&NA;**

### ICD10

- H40.20X0 Unsp primary angle-closure glaucoma, stage unspecified
- H40.219 Acute angle-closure glaucoma, unspecified eye
- H40.2290 Chronic angle-closure glaucoma, unsp eye, stage unspecified

## Clinical Pearls

**&NA;**

- Examiner can determine if patient is hyperopic by observing the magnification of the patient's face through his or her glasses (myopic lenses minify).
- A careful history may reveal similar episodes of angle closure that resolved spontaneously.
- Miotics, such as pilocarpine, can be effective during mild attacks, but in the setting of high IOP (due to iris sphincter ischemia), other agents such as CAIs, prostaglandin analogs,  $\alpha_2$ -agonists, and  $\beta$ -blockers are necessary.

# Glaucoma, Primary Open-Angle

Richard W. Allinson, MD

## BASICS

### DESCRIPTION

- Primary open-angle glaucoma (POAG) is an optic neuropathy resulting in visual field loss frequently associated with increased intraocular pressure (IOP).
- Normal IOP is 10 to 22 mm Hg. However, glaucomatous optic nerve damage also can occur with normal IOP and as a secondary manifestation of other disorders such as corticosteroid-induced glaucoma.
- System(s) affected: nervous
- Synonym(s): chronic open-angle glaucoma

### Pregnancy Considerations

Prostaglandins should be avoided during pregnancy in the treatment of POAG.

### EPIDEMIOLOGY

#### Incidence

- Predominant age: usually >40 years
- Increases with age
- Predominant gender: male = female

#### Prevalence

Prevalence in persons >40 years of age is  $\div$ 1.8%.

#### Geriatric Considerations

Increasing prevalence with increasing age

### ETIOLOGY AND PATHOPHYSIOLOGY

- Abnormal aqueous outflow resulting in increased IOP

- Normally, aqueous is produced by the ciliary epithelium of the ciliary body and is secreted into the posterior chamber of the eye.
- Aqueous then flows through the pupil and enters the anterior chamber to be drained by the trabecular meshwork in the iridocorneal angle of the eye into the Schlemm canal and into the venous system of the episclera.
- 5-10% of the total aqueous outflow leaves via the uveoscleral pathway.
- Impaired aqueous outflow through the trabecular meshwork
  - Increased resistance within the aqueous drainage system

## *Genetics*

A family history of glaucoma increases the risk for developing glaucoma.

## **RISK FACTORS**

- Increased IOP
- Myopia
- Diabetes mellitus (DM)
- African American
- Elderly
- Hypothyroidism
- Positive family history
- Central corneal thickness  $< 550 \mu\text{m}$
- Larger vertical cup-to-disc ratio (CDR)
- Larger horizontal CDR
- CDR asymmetry
- Disc hemorrhage
- Prolonged use of topical, periocular, inhaled, or systemic corticosteroids
- Obstructive sleep apnea
- Hypertension (1)[B]
- Corneal hysteresis (CH) (2)[B]
  - A measure of the viscoelastic damping of the cornea

- Lower CH associated with faster rates of visual field loss

## GENERAL PREVENTION

Possible reduced risk of open-angle glaucoma with long-term use of oral statins among persons with hyperlipidemia

## COMMONLY ASSOCIATED CONDITIONS

DM

## DIAGNOSIS

### HISTORY

Painless, slowly progressive visual loss; patients are generally unaware of the visual loss until late in the disease. Central visual acuity remains unaffected until late in the disease.

## PHYSICAL EXAM

- Visual acuity and visual field assessment
- Ophthalmoscopy to assess optic nerve for glaucomatous damage
- Increased IOP
- CDR >0.5: Normal eyes show a characteristic configuration for disc rim thickness of inferior <sup>3</sup> superior <sup>3</sup> nasal <sup>3</sup> temporal (ISNT rule).
- Earliest visual field defects are paracentral scotomas and peripheral nasal steps.

## DIFFERENTIAL DIAGNOSIS

- Normal-tension glaucoma
- Optic nerve pits
- Anterior ischemic optic neuropathy
- Compressive lesions of the optic nerve or chiasm
- Posthemorrhagic (shock optic neuropathy)

## DIAGNOSTIC TESTS & INTERPRETATION

*Initial Tests (lab, imaging)*

Optical coherence tomography can be useful in the detection of glaucoma by measuring the thickness of the retinal nerve fiber layer (RNFL).

- RNFL is thinner in patients with glaucoma.
- RNFL tends to be thinner with older age, in Caucasians, greater axial length, and smaller optic disc area.

### *Diagnostic Procedures/Other*

- Visual field testing: perimetry
  - A multifocal intraocular lens may reduce visual sensitivity on standard automated perimetry.
- Tonometry to measure IOP

### *Test Interpretation*

- Atrophy and cupping of optic nerve
- Loss of retinal ganglion cells (RGCs) and their axons produces defects and thinning in the RNFL.
- Significant RGC loss may occur at specific location before corresponding visual field loss is detected (3)[B].

## **TREATMENT**

### *GENERAL MEASURES*

- Early Manifest Glaucoma Trial
  - Early treatment delays progression.
  - The magnitude of initial IOP reduction influences disease progression (4)[A].
- Ocular Hypertension Treatment Study
  - Patients who only had increased IOP in the range of 24 to 32 mm Hg were treated with topical ocular hypotensive medication.
  - Treatment produced  $\approx$ 20% reduction in IOP
  - At 5 years, treatment reduced the incidence of POAG by  $>$ 50%: 9.5% in the observation group versus 4.4% in the medication-treated group (5)[A].
- The Advanced Glaucoma Intervention Study

- Eyes were randomized to laser trabeculoplasty or filtering surgery when medical therapy failed.
- In follow-up, if IOP was always <18 mm Hg, visual fields tended to stabilize. When IOP was >17 mm Hg, >1/2 the time, patients tended to have worsening of visual fields (6)[A].
- Whites did better with trabeculectomy first whereas African Americans did better with argon laser trabeculoplasty as the initial procedure.
- Collaborative Initial Glaucoma Treatment Study
  - Both initial medical and surgical (trabeculectomy) treatment achieved significant IOP reduction, and both had little visual field loss over time (7)[A].
  - There was a 5-year risk of endophthalmitis of 1.1% after trabeculectomy (8)[A].

## MEDICATION

- >1 medication, with different mechanisms of action, may be needed.
- When 3-5 medications are required, compliance is difficult, and surgery may be needed. Ocular hypotensive agent categories
  - $\beta$ -Adrenergic antagonists (nonselective and selective): decrease aqueous formation; best when used as an add-on therapy: timolol 0.25% (initial) to 0.5% one drop in affected eye q12h; gel-forming solution (0.35% or 0.5%) one drop in affected eye once daily; betaxolol 0.5% one drop in affected eye twice daily
  - Parasympathomimetics (miotic), including cholinergic (direct-acting) and anticholinesterase agents (indirect-acting parasympathomimetic): increase aqueous outflow
    - Pilocarpine 1-4%: one drop in affected eye BID to QID (cholinergic)
- Carbonic anhydrase inhibitors (oral, topical): decrease aqueous formation
  - Acetazolamide: 250 mg PO 1 to 4 times per day
  - Dorzolamide 2%: one drop TID
  - Brinzolamide 1%: one drop TID
- Adrenergic agonists (nonselective and selective  $\alpha_2$ -adrenergic agonists)
  - Epinephrine 0.5-2%: One drop BID and Propine (dipivefrin) 0.1% one drop BID are both nonselective agents that increase aqueous outflow through the trabecular meshwork and increase uveoscleral outflow.
  - Brimonidine tartrate 0.1%: One drop TID ( $\alpha_2$ -adrenergic agonist) decreases aqueous

formation and increases uveoscleral outflow.

- Prostaglandin analogues: enhance uveoscleral outflow and increase aqueous outflow through the trabecular meshwork: latanoprost 0.005% one drop at bedtime; travoprost 0.004% one drop at bedtime
- Hyperosmotic agents: increase blood osmolality, drawing water from the vitreous cavity
  - Mannitol 20% solution: administered IV at 2 g/kg of body weight
  - Glycerin 50% solution: administered PO; dosage is usually 4 to 7 oz.
- Contraindications/precautions
  - Nonselective  $\beta$ -adrenergic antagonists: Avoid in asthma, chronic obstructive pulmonary disease (COPD), 2nd- and 3rd-degree atrioventricular (A-V) block, and decompensated heart failure.

---

P.413

Betaxolol is a selective  $\beta$ -adrenergic antagonist and is safer in pulmonary disease.

- Parasympathomimetics (miotic): Indirect-acting parasympathomimetic agents increase risk of ocular and systemic side effects and are used rarely.
- Carbonic anhydrase inhibitors
  - Do not use with sulfa drug allergies.
  - Do not use with cirrhosis because of the risk of hepatic encephalopathy.
- Adrenergic agonists: Caution is recommended when using brimonidine and monoamine oxidase (MAO) inhibitor or tricyclic antidepressant (TCA) and in patients with vascular insufficiency. Brimonidine can cause excessive sleepiness and lethargy in children.
- Prostaglandin analogues: caution with uveitis and avoided during pregnancy
- Hyperosmotic agents
  - Glycerin can produce hyperglycemia or ketoacidosis in diabetic patients.
  - Can cause congestive heart failure
  - Do not use in patients with anuria.
- Precautions
  - $\beta$ -Adrenergic antagonists: caution with obstructive pulmonary disease, heart failure, and DM
  - Parasympathomimetics (miotic): cause pupillary constriction and may cause decreased vision in patients with a cataract; may cause eye pain or myopia due to increased

accommodation. All miotics break down the blood-aqueous barrier and may induce chronic iridocyclitis.

- Adrenergic agonists (e.g., brimonidine): caution with vascular insufficiency
- Contact lens wearers: Many products contain benzalkonium chloride; remove contact lens prior to administration and wait 15 minutes before reinsertion.
- Prostaglandin analogues may cause increased pigmentation of the iris and periorbital tissue (eyelid).
  - Increased pigmentation and growth of eyelashes
  - Should be used with caution in active intraocular inflammation (iritis/uveitis)
  - Caution is also advised in eyes with risk factors for herpes simplex, iritis, and cystoid macular edema.
  - Macular edema may be a complication associated with treatment.
- Hyperosmotic agents: caution in diabetics; dehydrated patients; and those with cardiac, renal, and hepatic disease
- Significant possible interactions: &agr;-adrenergic antagonists: caution in patients taking calcium antagonists because of possible A-V conduction disturbances, left ventricular failure, or hypotension
- Parasympathomimetics (miotic): Indirect-acting parasympathomimetic agents, anticholinesterase eye drops, can reduce serum pseudocholinesterase levels. If succinylcholine is used for induction of general anesthesia, prolonged apnea may result.

## ***SURGERY/OTHER PROCEDURES***

- Argon laser trabeculoplasty (ALT)
  - Can be applied up to 180 degrees of the trabecular meshwork
  - Improves aqueous outflow
  - The Glaucoma Laser Trial Research Group showed in newly diagnosed, previously untreated patients with POAG that ALT was as effective as topical glaucoma medication within the first 2 years of follow-up.
  - Usually reserved for patients needing better IOP control while taking topical glaucoma drops
- Selective laser trabeculoplasty (SLT)
  - 532-nm Nd:YAG laser
  - Appears to be as effective as ALT in lowering IOP

- Trabeculectomy (glaucoma filtering surgery)
  - Usually reserved for patients needing better IOP control after maximal medical therapy and who may have previously undergone an ALT
  - Mitomycin C can be applied at the time of surgery to increase the chances of a surgical success.
  - Subconjunctival bevacizumab may be a beneficial adjunctive therapy for reducing late surgical failure after trabeculectomy.
- Shunt (tube) surgery
  - For example, Molteno and Ahmed devices
  - Generally reserved for difficult glaucoma cases in which conventional filtering surgery has failed or is likely to fail
- Tube Versus Trabeculectomy (TVT) Study
  - After 5 years of follow-up, both procedures were associated with similar IOP reduction and the number of glaucoma medications needed (9)[A].
- Ciliary body ablation: indicated to lower IOP in patients with poor visual potential or those who are poor candidates for filtering or shunt procedures
- Canaloplasty can control IOP in patients with POAG. Canaloplasty involves the placement of a microcatheter circumferentially through Schlemm canal, vasodilation of the canal, and placement of a nylon tensioning suture.
- Cataract extraction can decrease IOP in patients with ocular hypertension (10)[A].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Monitor vision and IOP every 3 to 6 months.
- Visual field testing every 6 to 18 months
- Optic nerve evaluation every 3 to 18 months, depending on POAG control
- A worsening of the mean deviation by 2 dB on the Humphrey field analyzer and confirmed by a single test after 6 months had a 72% probability of progression.

- The IOP response to ocular hypotensive agents tends to be reduced in persons with thicker corneas.

## PATIENT EDUCATION

POAG is a silent robber of vision, and patients may not appreciate the significance of their disease until much of their visual field is lost.

## PROGNOSIS

- With standard glaucoma therapy, the rate of visual field loss in POAG is slow.
- Patients still may lose vision and develop blindness, even when treated appropriately.
- The rate of legal blindness from POAG over a follow-up of 22 years is 19%.
- The rate of progression of visual field loss increases with older age.

## COMPLICATIONS

Blindness

## Codes

&NA;

### ICD10

- H40.11X0 Primary open-angle glaucoma, stage unspecified
- H40.11X1 Primary open-angle glaucoma, mild stage
- H40.11X2 Primary open-angle glaucoma, moderate stage

# Clinical Pearls

**&NA;**

- Topical or systemic steroids can cause the IOP to increase.
- Pain is not a frequent symptom of POAG.
- Painless, slowly progressive visual loss; patients generally are unaware of the visual loss until late in the disease. Central visual acuity remains unaffected until late in the disease.
- Patients still may lose vision and develop blindness, even when treated appropriately.

# Glomerulonephritis, Acute

Jonathan T. Lin, MD

Michael J. Ross, MD

## BASICS

### DESCRIPTION

- Acute glomerulonephritis (GN) is an inflammatory process involving the glomerulus of the kidney, resulting in a clinical syndrome consisting of hematuria, proteinuria, and renal insufficiency, often in association with hypertension and edema.
- Acute GN may be caused by primary glomerular disease or secondary to systemic disease:
  - Postinfectious GN
  - IgA nephropathy/Henoch-Schönlein purpura (HSP)
  - Antiglomerular basement membrane disease (anti-GBM disease)
  - Antineutrophil cytoplasmic antibody (ANCA)-associated GN
  - Membranoproliferative GN (MPGN)
  - Lupus nephritis
  - Cryoglobulin-associated GN
- Clinical severity ranges from asymptomatic microscopic or gross hematuria to a rapid loss of kidney function over days to weeks, termed rapidly progressive GN (RPGN).

### ALERT

Urgent investigation and treatment are required to avoid irreversible loss of kidney function.

### EPIDEMIOLOGY

- Postinfectious GN
  - Most commonly follows group A  $\beta$ -hemolytic *Streptococcus* infection but can occur as a result of other bacterial infections or less commonly in the setting of viral or parasitic infections

- Accounts for 80% of acute GN in children
  - May also occur in the setting of infective endocarditis
- IgA nephropathy
  - Most common form of primary acute GN
  - Occurs mainly in the 2nd and 3rd decades
  - Male > female (2:1)
  - Incidence differs geographically: Asia > United States
  - HSP typically childhood illness, usually <10 years old
- Anti-GBM disease
  - A notable cause of the pulmonary-renal syndrome known as Goodpasture disease
  - Peak distribution in 3rd and 6th decades
- ANCA-associated GN
  - Often has a relapsing and remitting course
  - Four disease presentations:
    - Granulomatosis with polyangiitis (GPA) formerly Wegener granulomatosis
    - Microscopic polyangiitis (MPA)
    - Isolated Pauci-immune GN when isolated to kidneys
    - Eosinophilic granulomatosis with polyangiitis (EGPA), formerly Churg-Strauss disease GN relatively common but renal involvement rarely severe
  - Older patients are more commonly affected, although this GN can affect any age group.
- MPGN
  - May be primary or secondary
  - May present in the setting of a systemic viral (hepatitis B or hepatitis C) or rheumatologic illness
  - Classification by immunofluorescence: immune complex mediated or complement mediated (dense deposit disease [DDD] and C3 glomerulonephritis [C3GN])
  - Classification by electron microscopy: MPGN types I-III
- Lupus nephritis

- 30-70% of systemic lupus patients will have renal involvement.
- Several histologic variants but diffuse proliferative GN most severe and requires urgent treatment
- Cryoglobulin-associated vasculitis
  - 80% of cases are associated with hepatitis C infection.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- In general, an immunologic mechanism triggers inflammation and proliferation of glomerular tissue.
- Postinfectious GN: immune complex disease with host immune reaction to nephritogenic strains of streptococci as a trigger
- IgA nephropathy: relates to an abnormal glycosylation of IgA
- Anti-GBM disease: caused by autoantibodies that target type IV collagen of basement membranes
- ANCA-associated GN: Autoantibodies against neutrophil granules are involved in the pathogenesis.
- MPGN: An immune or genetic etiology is presumed, which triggers glomerular deposits and inflammation.
- Lupus nephritis: an immune complex-mediated glomerular disease
- Cryoglobulin-associated GN: An immune etiology is presumed but not clearly defined.

## *Genetics*

Genetic factors are likely to play a role in susceptibility to many of the acute GNs, although these have not been sufficiently defined to be clinically useful in most circumstances.

## *RISK FACTORS*

- Epidemics of nephritogenic strains of streptococci are triggers for postinfectious GN.
- Hepatic cirrhosis, celiac disease, and HIV infection place patients at risk for IgA nephropathy.
- Anti-GBM disease has been associated with influenza A infection and inhaled hydrocarbon solvent exposure.
- ANCA-associated GN is increased in settings where there is increased silica exposure (i.e., earthquakes and farming).
- Infection with hepatitis B or C is known to be associated with MPGN.

- Infection with hepatitis C is a risk factor for developing cryoglobulinemic GN.
- Mutations in alternate complement pathway genes are associated with complement-mediated MPGN.

## GENERAL PREVENTION

Early detection is paramount.

## DIAGNOSIS

### HISTORY

- Patients may report cola- or tea-colored urine and decreased urine volume.
- Edema occurs in many patients, typically in face and lower extremities.
- Shortness of breath may occur with significant fluid overload.
- Generalized malaise
- Timing
  - Postinfectious GN typically occurs 1 to 3 weeks after pharyngitis or 2 to 6 weeks after skin infection.
  - IgA nephropathy may present within several days after an acute infection.
- Patients may also present with complaints more specific to the associated disease:
  - Joint pain or rash in lupus nephritis
  - Hemoptysis in pulmonary-renal syndromes (see “Physical Exam”)
  - Sinusitis, pulmonary infiltrates, arthralgias in ANCA-associated GN
  - Abdominal or joint pain and purpura in IgA-HSP
  - Purpura and skin vasculitis in cryoglobulinemia-associated GN

## PHYSICAL EXAM

- A complete physical exam may discover clues to systemic disease as a potential cause.
- Sinus disease: ANCA-associated GN, most commonly GPA
- Pharyngitis or impetigo: postinfectious GN or IgA nephropathy
- Pulmonary hemorrhage (pulmonary-renal syndrome): anti-GBM disease/Goodpasture, ANCA-associated GN, or lupus nephritis
- Hepatomegaly or liver tenderness could point to cryoglobulinemia-associated GN or IgA

nephropathy.

- Purpura may point to ANCA-associated GN or HSP/IgA nephropathy.

## *DIFFERENTIAL DIAGNOSIS*

Nonglomerular hematuria: trauma, prostate diseases, urologic cancer, cystitis, nephrolithiasis, renal cysts

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Urinalysis with examination of sediment
  - Dysmorphic RBCs or RBC casts on urine microscopy indicate glomerular hematuria and strongly suggest the diagnosis of an acute GN.
  - Pyuria and white blood cell casts may also be present.
- Electrolytes, BUN, creatinine, CBC
- Antistreptolysin O titer, streptozyme: often positive in poststreptococcal GN
- Complement levels (C3, C4)
  - C3 complement levels are low in postinfectious GN.
  - C3 and C4 are abnormal in lupus nephritis and MPGN.
  - C4 can be low in cryoglobulinemia.
- Proteinuria: 24-hour collection or random urine protein/creatinine ratio
  - Typically mild to moderate proteinuria, sometimes nephrotic range
- Antinuclear antibody (ANA) to rule out lupus nephritis
- ANCA antibody screen: MPO and PR3 antibodies
- Anti-GBM antibody
- Hepatitis B surface antigen and antibody
- Hepatitis C antibody
- HIV testing
- A chest x-ray may be useful in the setting of hemoptysis or a suspected infiltrate on exam.

## Test Interpretation

- Renal biopsy
- If clinical picture is consistent with postinfectious GN in a child, a biopsy may not be required.
- If there is clinical suspicion for other causes of acute GN, renal biopsy should be done.
- Light microscopy
  - Diffuse hypercellularity suggests a proliferative disease such as IgA nephropathy, lupus nephritis, or postinfectious GN.
  - Presence of glomerular crescents correlates with RPGN and disease severity.
- Immunofluorescence
  - Isolated mesangial IgA staining is pathognomonic for IgA nephropathy, with the absence of immune complex staining suggesting ANCA-associated GN.
  - Pattern of IgG, IgM, C3, and C4 staining may also aid in characterizing the GN.
  - Lupus nephritis typically positive for all immunoglobulins and complements (‘‘full house’’)
- Electron microscopy: The location of immunoglobulin deposits is useful in pointing to a particular diagnosis.

## TREATMENT

Supportive in postinfectious GN

## MEDICATION

### First Line

- Hypertension
  - Diuretics are useful for management of salt retention and edema.
  - Calcium channel blockers
  - Avoid angiotensin-converting enzyme inhibitors (ACE-I) or angiotensin receptor blockers (ARBs) if acute renal dysfunction is present.
- Peripheral edema: Loop diuretics are often required due to the degree of edema.
- Pulmonary edema: oxygen and diuretics

## *Second Line*

- Each of the glomerular diseases often requires a specific treatment plan based on renal biopsy results; therefore, a nephrologist is often the guiding care at this point.
- Empiric pulse methylprednisolone prior to kidney biopsy may be indicated in cases of RPGN (1) [C].
- Crescents on renal biopsy may be an indication for steroids in postinfectious GN and in other cases, are often an indication for potent immunosuppressive medications in addition to steroids (2)[C].
- Steroids plus either cyclophosphamide, rituximab, or mycophenolate may be used to treat ANCA-associated renal disease and proliferative forms of lupus nephritis (2,3,4,5,6)[A].
- Plasmapheresis may also be considered in some cases for RPGN or anti-GBM disease or ANCA-associated renal disease with diffuse pulmonary hemorrhage (2)[C],(4,7)[A].
- Dialysis may be needed for uremia, hyperkalemia refractory to medical management, intractable acidosis, and diuretic-resistant pulmonary edema.
- IgA nephropathy: ACE-Is or ARBs recommended for patients with proteinuria (1,2)[C], selected patients may benefit from immunosuppression.

## *ISSUES FOR REFERRAL*

Consultation with a nephrologist is usually required to assist with renal biopsy to confirm diagnosis and assist with management.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Consider admission for patients with no urine output, rapidly deteriorating renal function, significant hypertension, and suspicion of pulmonary hemorrhage or fluid overload that is compromising heart or respiratory function.

### *Discharge Criteria*

Hemodynamically stable patients without complications may be managed as outpatients.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

## *Patient Monitoring*

- Depends on type of GN
- Regular BP checks and urinalysis to detect recurrence, assessment of renal function to detect acute or follow chronic renal disease as a result of the primary event, and regular clinical assessment to detect suspicious symptoms that may herald a recurrence (i.e., rash, joint complaint, hemoptysis)
- Periodic reassessment of serology tests to detect asymptomatic individuals

## *DIET*

- No-added-salt diet and fluid restriction until edema and hypertension clear
- Avoid high-potassium foods if significant renal dysfunction is present.

## *PATIENT EDUCATION*

- National Kidney Foundation, <https://www.kidney.org/atoz/content/glomerul>

## *PROGNOSIS*

- In general, the prognosis depends on the cause of the GN.
- The GN may be self-limited (as often is the case in postinfectious GN) or part of a chronic disease that makes the possibility of recurrence of acute disease likely, with the potential for progressive loss of renal function over time.
- Some forms of acute GN (including ANCA associated and severe lupus) require long-term immunosuppression to prevent recurrence.

## **COMPLICATIONS**

- Hypertensive retinopathy and encephalopathy
- RPGN
- Microscopic hematuria may persist for years.
- Chronic kidney disease
- Nephrotic syndrome (~10%)

# Clinical Pearls

**&NA;**

- Dysmorphic RBCs and RBC casts are a key component of the urinalysis in GN.
- Postinfectious GN in children is typically a self-limited disease.
- Searching for other organ involvement is useful in establishing a definitive diagnosis.
- With the discovery of a GN, monitor the initial renal function labs frequently to identify a RPGN.

# Glomerulonephritis, Postinfectious

Rebecca S. Domalski, DO

Theodore B. Flaum, DO, FACOFP

## BASICS

### DESCRIPTION

Postinfectious glomerulonephritis (PIGN) is an immune complex disease preceded by nonrenal infection with certain strains of bacteria, most commonly *Streptococcus* and *Staphylococcus*. The most common form of PIGN, poststreptococcal glomerulonephritis (PSGN), predominantly affects children. The clinical presentation varies from asymptomatic to the acute nephritic syndrome, characterized by gross hematuria, proteinuria, edema, hypertension (HTN), and acute kidney injury.

### EPIDEMIOLOGY

A global decline in incidence, especially in developed countries is attributed to better hygiene and a decreased incidence of streptococcal skin infections. Of cases, 97% occur in developing countries. PSGN is primarily a pediatric disease, but a recent increase has been seen in nonstreptococcal GN in adults.

### Incidence

- Pediatrics: 24.3 cases/100,000 persons per year in developing countries; 6 cases/100,000 persons per year in developed countries
- Adults: 2 cases/100,000 persons per year in developing countries; 0.3 cases/100,000 persons per year in developed countries
- Worldwide, 34% of cases are now seen in adults with a global burden of 68,000 cases per year.
- Male > female (2:1) (1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Glomerular immune complex disease induced by specific nephritogenic strains of bacteria:
  - Group A  $\beta$ -hemolytic *Streptococcus* (GAS)

- Staphylococcus (predominantly *Staphylococcus aureus*; more commonly methicillin-resistant *S. aureus* [MRSA], occasionally coagulase-negative *Staphylococcus*)
- Gram-negative bacteria including *Escherichia coli*, *Yersinia*, *Pseudomonas*, and *Haemophilus* (1)
- Proposed mechanisms for the glomerular injury (2):
  - Deposition of circulating immune complexes with streptococcal or staphylococcal antigens  
these complexes can be detected in patients with streptococcal- or staphylococcal-related GN but do not correlate to disease activity (3).
  - In situ immune complex formation from deposition of antigens within the glomerular basement membrane (GBM) and subsequent antibody binding
  - In situ glomerular immune complex formation promoted by antibodies to streptococcal or staphylococcal antigens
  - Alteration of normal renal antigen leading to molecular mimicry that elicits an autoimmune response
- Glomerular immune complex causing complement activation and inflammation:
  - Nephritis-associated plasmin receptor (NAP1r): activates plasmin, contributes to activation of the alternative complement pathway
  - Streptococcal pyrogenic exotoxin B (SPE B): binds plasmin and acts as a protease; promotes the release of inflammatory mediators
- Activation of the alternative complement pathway causes initial glomerular injury as evidenced by C3 deposition and decreased levels of serum C3. The lectin pathway of complement activation has also been recently implicated in glomerular injury (4).

## RISK FACTORS

- Children 5 to 12 years of age
- Older patients (>65 years of age) (1):
  - Patients with immunocompromising comorbid conditions
  - Diabetes
  - Alcohol abuse

## GENERAL PREVENTION

- Early antibiotic treatment for streptococcal and staphylococcal infections, when indicated,

although efficacy in preventing GN is uncertain

- Improved hygiene
- Prophylactic penicillin treatment to be used in closed communities and household contacts of index cases in areas where PIGN is prevalent

## COMMONLY ASSOCIATED CONDITIONS

Streptococcal infection, staphylococcal infection

## DIAGNOSIS

### HISTORY

- Patients present with acute nephritic syndrome, characterized by sudden onset of hematuria associated with edema and HTN 1 to 2 weeks after an infection
- A triad of edema, hematuria, and HTN is classic.
- Urine described as “tea-colored” or “cola-colored.”
- PIGN in children usually follows GAS skin/throat infection.
- The latent period between GAS infection and PIGN depends on the site of infection: 1 to 3 weeks following GAS pharyngitis and 3 to 6 weeks following GAS skin infection.
- Adult PIGN most commonly follows staphylococcal infections (3 times more common than streptococcal infections) of the upper respiratory tract, skin, heart, lung, bone, or urinary tract. Studies show 7-16% of cases of adult PIGN have no preceding evidence of infection and, in 24-59% the offending microorganism cannot be identified (5)[A].

### PHYSICAL EXAM

- Edema: present in ÷2 of 3 adult patients due to sodium and water retention; less common in pediatric patients
- Gross hematuria: present in 25-60% of patients
- HTN: present in 80-90% of patients and varies from mild to severe; secondary to fluid retention Hypertensive encephalopathy is an uncommon but serious complication
- Microscopic hematuria: subclinical cases of PIGN
- Respiratory distress: due to pulmonary edema (rare)

## DIFFERENTIAL DIAGNOSIS

The diagnosis of PIGN is generally by history once the diagnosis of acute nephritis is made, with documentation of a recent infection and nephritis beginning to resolve 1 to 2 weeks after presentation. However, with progressive disease >2 weeks, persistent hematuria/HTN >4 to 6 weeks, or no adequate documentation of a GAS or other infection, the differential diagnosis of GN needs to be considered and renal biopsy ordered:

- Membranoproliferative glomerulonephritis (MPGN): The presentation of MPGN may be indistinguishable initially with hematuria, HTN, proteinuria, and hypocomplementemia after an upper respiratory infection. However, patients with MPGN continue to have persistent nephritis and hypocomplementemia beyond 4 to 6 weeks and possibly also have a further elevation in serum creatinine. Patients with PIGN tend to have resolution of their disease and a return of normal C3 and CH50 levels within 2 to 4 weeks.
- Secondary causes of GN: Lupus nephritis and Henoch-Schönlein purpura nephritis have features similar to PIGN. Extrarenal manifestations and laboratory tests for these underlying systemic diseases help differentiate them from PIGN. Hypocomplementemia is not characteristic of Henoch-Schönlein purpura and the hypocomplementemia that occurs in lupus nephritis is with reductions in both C3 and C4, whereas C4 levels are normal in PIGN.
- IgA nephropathy often presents after an upper respiratory infection. It can be distinguished from PIGN based on a shorter time frame between the upper respiratory illness and hematuria, as well as history of gross hematuria, as PIGN recurrence is rare. IgA nephropathy is a chronic illness and will recur. Patients with IgA nephropathy have normal C3/C4 levels.
  - Note: IgA-dominant PIGN is a newly recognized form of PIGN occurring in poststaphylococcal GN. This differs from primary IgA nephropathy in that these patients do not have a history of renal disease (1)[A].
- Pauci-immune crescentic GN: In elderly patients with severe renal failure and active urine sediment, this is much more common, so antineutrophil cytoplasmic antibody (ANCA) testing should be done (1)[A].

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (labs, imaging)*

Urinalysis shows hematuria; can be with/without RBC casts and pyuria. Proteinuria is present, but nephrotic range proteinuria is uncommon in children (more likely in adults).

### *Follow-Up Tests & Special Considerations*

- Culture: PSGN usually presents weeks after a GAS infection; only ÷25% of patients will have either a positive throat or skin culture.

- Complement: 90% of pediatric patients (slightly fewer adult patients) will have depressed C3 and CH50 levels in the first 2 weeks of the disease, whereas C2 and C4 levels remain normal. C3 and CH50 levels return to normal within 4 to 8 weeks after presentation.

- Creatinine: elevated to the point of renal insufficiency in 25-83% of cases, more commonly in adults (83%) (4)[A].
- Serology: Elevated titers of antibodies support evidence of a recent GAS infection. Streptozyme test measuring antistreptolysin O (ASO), antihyaluronidase (AHase), antistreptokinase (ASKase), anti-nicotinamide-adenine dinucleotidase (anti-NAD), and anti-DNAse B antibodies: positive in >95% of patients with PSGN due to pharyngitis and 80% with skin infections. In pharyngeal infection, ASO, anti-DNAse B, anti-NAD, and AHase titers are elevated. In skin infections, only the anti-DNAse and AHase titers are typically elevated.

### *Diagnostic Procedures/Other*

Renal biopsy is rarely done in children; recommended in most adults to confirm the diagnosis and rule out other glomerulopathies with similar clinical presentations that require immunosuppressive treatment.

### *Test Interpretation*

- Light microscopy: diffuse proliferative glomerulonephritis with prominent endocapillary proliferation and numerous neutrophils within the capillary lumen. Deposits may also be found in the mesangium (Ostarry skyO). Severity of involvement varies and correlates with clinical findings. Crescent formation is uncommon and is associated with a poor prognosis.
- Immunofluorescence microscopy: Deposits of C3 and IgG distributed in a diffuse granular pattern.
- Electron microscopy: dome-shaped subepithelial electron-dense deposits that are referred to as Ohumps.O These deposits are immune complexes, and they correspond to the deposits of IgG and C3 found on immunofluorescence. Rate of clearance of these deposits affects recovery time.
- Renal biopsy: usually not performed in most patients to confirm the diagnosis of PIGN as clinical history is highly suggestive and resolution of PIGN typically begins within 1 week of presentation. A biopsy is done when other glomerular disorders are being considered, such as in the case of persistently low C3 levels beyond 6 weeks for possible diagnosis of MPGN, recurrent episodes of hematuria suggestive of IgA nephropathy, or a progressive increase in serum creatinine not characteristic of PIGN.

## TREATMENT

### MEDICATION

- No specific therapy exists for PIGN, and no randomized controlled trials indicate that aggressive immunosuppressive therapy has a beneficial effect in patients with rapidly progressive crescentic disease. Despite this, patients with >30% crescents on renal biopsy are often treated with steroids (4)[A].
- Older patients often require hospitalization to prevent and treat complications of heart failure (HF) from volume overload (1).
- Management is supportive, with focus on treating the clinical manifestations of PIGN. These include HTN and pulmonary edema:
  - General measures include salt and water restriction and loop diuretics.
  - Calcium channel blockers/angiotensin-converting enzyme (ACE) inhibitors may be used in cases of severe HTN (4)[A].
- Patients with evidence of persistent bacterial infection should be given a course of antibiotic therapy.

### SURGERY/OTHER PROCEDURES

Acute dialysis is required in approximately 50% of elderly patients (1).

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Repeat urinalysis to check for clearance of hematuria and/or proteinuria.
- Consider other diagnosis if no improvement within 2 weeks.
- Recurrence is rare.

### DIET

Renal diet if requiring instances of dialysis

### PROGNOSIS

- Most children with PIGN have an excellent outcome, with >90% of cases achieving full recovery of renal function.
- Elderly patients, especially adults, develop HTN, recurrent proteinuria, and renal insufficiency long after the initial illness. Adults with multiple comorbid factors have the worst prognosis and highest incidence of chronic renal injury following PIGN (1).
- Complete remission in adult PIGN is only 26-56%. This has declined since the 1990s, suggesting prognosis is worsening (5).
- The presence of diabetes, higher creatinine levels, and more severe glomerular disease (e.g., crescents) on biopsy are all risk factors for developing endstage renal disease (1).

## Codes

&NA;

### ICD10

- N05.9 Unsp nephritic syndrome with unspecified morphologic changes
- N00.9 Acute nephritic syndrome with unsp morphologic changes

## Clinical Pearls

&NA;

- PIGN is an immune complex disease occurring after infection with certain strains of bacteria, most commonly group A *Streptococcus pyogenes*.
- The clinical presentation varies from asymptomatic to the acute nephritic syndrome, characterized by gross hematuria, proteinuria, edema, HTN, and acute kidney injury.
- Treatment is primarily supportive and includes treating HTN and edema, along with antibiotics for any ongoing bacterial infection.
- Persistent nephritis and low C3 levels for >2 weeks should prompt evaluation for other causes of GN, such as MPGN or systemic lupus erythematosus nephritis.

# Glucose Intolerance

Kristina McGraw, DO

Jennifer Lee, DO

Robert A. Baldor, MD, FAAFP

## BASICS

### DESCRIPTION

- Glucose intolerance is a chronic condition defined as blood glucose higher than considered normal, yet does not meet criteria levels for diabetes.
- Individuals with impaired fasting glucose (IFG) and/or impaired glucose intolerance (IGT) have been referred to as having prediabetes:
  - IFG: 100 to 125 mg/dL
  - IGT: 140 to 199 mg/dL 2 hours after ingestion of 75 g oral glucose load
  - Hemoglobin A1c as a screening test 5.7-6.4% (1)

### EPIDEMIOLOGY

- As of 2010, it is estimated that one of every three U.S. adults <sup>3</sup>20 years of age have prediabetes (2).
- An estimated 86 million people in the United States are living with prediabetes.
- Only 11% of people with prediabetes are aware of their condition (3).
- Prediabetes has a 37% prevalence among adults >20 years old and 51% of adults <sup>2</sup>65 years in the United States (4).

### Incidence

- 15-30% of people with prediabetes will develop type 2 diabetes within 5 years.
- Prospective studies indicate that A1c range of 5.5-6.0% have a 5-year cumulative incidence from 9% to 25% for developing diabetes (2).
- Highest incidence in American Indians/Alaska Natives, non-Hispanic blacks, and Hispanics (2)

# ETIOLOGY AND PATHOPHYSIOLOGY

Insulin resistance and progressive insulin secretory defect (5)

## RISK FACTORS

- Body mass index (BMI)  $\geq 25$ : overweight
- Obesity and metabolic syndrome
- 10-fold risk increase for future diabetes in A1c ranges 5.7-6.4%
- History of gestational diabetes (GDM)
- Sedentary lifestyle
- Glucocorticoids and antipsychotic use

## GENERAL PREVENTION

- Lifestyle modification with weight reduction and increased physical activity
- A decrease in excess body fat provides the greatest risk reduction.
- Medical therapy: weight loss medications
  - Phentermine
  - Orlistat
  - Lorcaserin
  - Phentermine topiramate ER
- Surgical therapy (BMI  $\geq 35$ )
  - Lap band
  - Gastric sleeve
  - Gastric bypass
- Patients with other cardiovascular risk factors (e.g., dyslipidemia, hypertension, obesity, tobacco use) should receive appropriate counseling to modify diet and exercise.

## Pregnancy Considerations

- Screening for diabetes in pregnancy is based on risk factor analysis:
  - High risk: first prenatal visit
  - Average risk: 24 to 28 weeks' gestation

- Women with GDM should be screened for diabetes 6 to 12 weeks' postpartum (6).

## COMMONLY ASSOCIATED CONDITIONS

- Obesity (abdominal and visceral obesity)
- Dyslipidemia with high triglycerides (TG)
- Metabolic syndrome
- PCOS
- GDM
- Low HDL
- HTN
- Congenital diseases (Down, Turner, Klinefelter, and Wolfram syndromes)

## DIAGNOSIS

Who to screen

- BMI  $\geq 25$
- Age  $>45$  years
- First-degree relative with diabetes
- Low HDL  $<35$  mg/dL
- High TG  $>250$  mg/dL
- HTN: BP  $>140/90$  mm Hg or on treatment
- Hx of GDM
- Physical inactivity
- Hx of cardiovascular disease
- Ethnic group at increased risk (non-Hispanic black, Native American, Hispanics, Asian American, Pacific Islander)
- HgbA1c  $\geq 5.7\%$ , IGT, or IFG on previous testing
- PCOS
- Conditions associated with insulin resistance such as severe obesity or acanthosis nigricans

## HISTORY

- No clear symptoms
- Polyuria
- Polydipsia
- Weight loss
- Blurred vision
- Polyphagia

## *PHYSICAL EXAM*

- General physical exam
- BMI assessment

## *DIFFERENTIAL DIAGNOSIS*

- Type A insulin resistance
- Leprechaunism
- Rabson-Mendenhall syndrome
- Lipotrophic diabetes
- Pancreatitis
- Cystic fibrosis
- Hemochromatosis
- Acromegaly
- Cushing syndrome
- Glucagonoma
- Pheochromocytoma
- Hyperthyroidism
- Somatostatinoma
- Aldosteronoma
- Drug-induced hyperglycemia
  - Thiazide diuretics (high doses)
  - $\beta$ -blockers
  - Corticosteroids (including inhaled corticosteroids)

- Thyroid hormone
- &agr;-Interferon
- Pentamidine
- Protease inhibitors
- Atypical antipsychotics

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Fasting glucose
- 2-Hour OGTT
- HbA1c
- Repeat screen at least at 3-year intervals with normal results or sooner depending on risk status (5).

### *Follow-Up Tests & Special Considerations*

- Fasting lipid profile
- Creatinine and GFR
- Urinalysis
- Microalbumin-to-creatinine ratio
- Thyroid-stimulating hormone with free T<sub>4</sub>

## **TREATMENT**

- Lifestyle aimed at increasing physical activity and weight loss prevents or delays the development of diabetes in people with IGT and IFG (6)[C].
- Exercise and lifestyle:
  - At least 150 minute/week of moderate-intensity aerobic exercise and/or at least 90 minute/week of vigorous aerobic exercise
  - Resistance exercise improves insulin sensitivity to the same extent as aerobic exercise; resistance training 3 times per week is recommended for those with type 2 diabetes
  - Smoking cessation

- Follow-up counseling (6)[B]
- Diabetes prevention programs are cost effective (6)[B].
  - Diabetes prevention program (participants <60 years of age, BMI  $\geq 35$  kg/m<sup>2</sup>, women with a history of gestational diabetes) showed that loss of weight through diet and exercise reduces risk of developing diabetes by 58% and demonstrated that lifestyle modification decreases risk of diabetes more than metformin.
- Because of its effectiveness, low cost, and long-term safety, the ADA recommends consideration of metformin for prevention of diabetes in individuals with IGT [A], IFG [C], or an A1c 5.7-6.4% [C], especially for those with BMI  $>35$ kg/m<sup>2</sup>, aged <60 years, and women with history of GDM [A].

P.419

- Dietary recommendations:
  - Either low-carbohydrate, low-fat calorie-restricted, or Mediterranean diets may be effective.
  - Diets high in fiber-rich foods, such as vegetables, fruits, whole grains, seeds, and nuts plus white meat sources are protective against type 2 diabetes (7).
  - Restrict beverages containing simple sugars, as they increase risk of diabetes (7).
  - Intake of polyunsaturated fatty acid (PUFA) may improve glycemic control; however, data is inconsistent regarding PUFA and other types of fatty acids (7).
  - Individuals who have prediabetes or diabetes should receive individualized medical nutrition therapy (MNT) as needed to achieve treatment goals, preferably provided by a registered dietitian familiar with the components of diabetes MNT (6).

## MEDICATION

### *First Line*

Metformin (drug of choice) 500 mg BID or 850 mg daily may reduce incidence of new-onset diabetes and BMI (level 2); contraindicated with Cr  $>1.5$  in males and  $>1.4$  in females increases risk of lactic acidosis (6).

### *Second Line*

Acarbose: started as 50 mg PO once daily and titrated to 100 mg PO TID, may reduce incidence of diabetes; GI upset is common (7).

## ISSUES FOR REFERRAL

- Nutritionist
- Diabetes educator/registered dietitian upon diagnosis
- Exercise physiologist
- Lifestyle coaching

## ***ADDITIONAL THERAPIES***

- Weight loss of 5-10% improves glycemic control, increases insulin sensitivity, improves lipids, and lowers BP.
- Alternative/botanical therapy:
  - Fenugreek, bitter melon, and cinnamon have reduced hyperglycemia and improved insulin sensitivity in studies by Deng (8) and Graf et al. (9).

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Consider self-monitoring of blood glucose.
- At least annual monitoring for development of diabetes with HbA1c, 2-hour OGTT, or fasting glucose
- BP should be routinely measured.
- Annual testing for lipid abnormalities and microalbuminuria (for detection and therapy modification of incipient diabetic nephropathy)

#### ***DIET***

- Monitor carbohydrate intake.
- Macronutrient distribution should be based on individual assessment of eating patterns, preferences, and metabolic goals.
- Consider Mediterranean diet.
- Maximize low glycemic index foods.
- Low-fat (<25%) intake: Saturated fat intake should be <7% of total calories.
- Minimize *trans* fat intake.

- Low-sodium intake <2,300 mg/day
- High-fiber ( $\approx$ 50 g/day; 14 g/1,000 kcal) and wholegrain intake
- Drink ample quantities of water, minimum of 64 oz of water daily, and strictly avoid sugar-sweetened beverages.
- Moderate alcohol intake: 1 drink/day for women; 2 drinks/day for men

## PROGNOSIS

- Individuals with IFG and/or IGT have high risk for the future development of diabetes.
- Prediabetes increases the risk of developing type 2 diabetes, heart disease, and stroke.
- The potential impact of interventions to reduce mortality or the incidence of cardiovascular disease has not been demonstrated to date.
- 20-70% of individuals with prediabetes who do not lose weight, change their dietary habits, and/or engage in moderate physical activity will progress to type 2 diabetes within 3 to 6 years (7).
- HbA1c >6.5% at age 12 to 39 years associated with increased risk of death before age 55 years compared with HbA1c <5.7%

## COMPLICATIONS

- Cardiovascular disease
- PAD
- Stroke: 2 to 4 times higher risk
- Ketoacidosis
- Sexual dysfunction
- Gastroparesis
- Nephropathy and potential for renal failure
- Retinopathy and potential for loss of vision
- Peripheral and autonomic neuropathy

&NA;

## ICD10

- E74.39 Other disorders of intestinal carbohydrate absorption
- R73.09 Other abnormal glucose
- R73.01 Impaired fasting glucose

## Clinical Pearls

### &NA;

- Lifestyle optimization is essential for all patients with prediabetes.
- Research shows that you can lower your risk for type 2 diabetes by 58% by losing 7% of your body weight (or 15 lb if you weigh 200 lb).
- Exercising moderately (such as brisk walking) 30 minutes/day, 5 days a week
- Consider concurrent cardiovascular risks and further workup as indicated clinically.
- Patient education and lifestyle reinforcement should be emphasized in all clinical encounters.

# Gonococcal Infections

Paul Lyons, MD

## BASICS

### DESCRIPTION

A sexually or vertically transmitted bacterial infection caused by *Neisseria gonorrhoeae*:

- *N. gonorrhoeae* is a fastidious gram-negative intracellular diplococcus (1)[A].
- Presents as conjunctival, pharyngeal, urogenital or anorectal infections. Urogenital infections are most common (1)[A].
- Hematogenous dissemination also occurs leading to fever, skin lesions, arthralgias, purulent or sterile arthritis, tenosynovitis, endocarditis, or (rarely) meningitis (1)[A].
- Asymptomatic carrier state can occur in both sexes.
- In newborns, gonococcal ophthalmia neonatorum, a purulent conjunctivitis, may occur after vaginal delivery by an infected mother, potentially leading to blindness if not treated promptly (1,2)[A].
- System(s) affected: cardiovascular, musculoskeletal, nervous, reproductive, skin/exocrine
- Synonym(s): gonococcal infection (GC); clap

### EPIDEMIOLOGY

- Predominant age: 15 to 24 years (1,2)[A]
- Predominant sex: women 105/100,000; men 92/100,000 (2)[A]

### Incidence

CDC 2012:334,826 reported cases (107.5/100,000 U.S. population) (2)[A]

### Prevalence

Incidence and prevalence of are approximately equal. The true prevalence is higher due to the asymptomatic nature of the disease (2)[A]:

- Rates peaked in mid-1970s and fell 74% over the next 20 years with national control program (2)[A].

- Highest rate: women aged 20 to 24 years (578/100,000) followed by women aged 15 to 19 years (521/100,000) (2)[A]
- Blacks (462/100,000) have higher reported rates of infections than whites (31/100,000) (2)[A].
- The southern regions of the United States have higher reported rates. Highest reported state rate is Mississippi (231/100,000) (2)[A].

## ETIOLOGY AND PATHOPHYSIOLOGY

Infection requires four steps: (i) mucosal attachment. Bacterial proteins bind to receptors on host cells; (ii) local penetration/invasion; (iii) local proliferation; (iv) inflammatory response or dissemination *N. gonorrhoeae* (gonococcus). *N. gonorrhoeae* spreads most commonly during sexual relations.

### Genetics

Congenital deficiency of late components of complement cascade (C7 to C9) are prone to develop dissemination of local gonococcal infections.

## RISK FACTORS

- History of previous gonorrhoea infection or other STIs
- Sexual exposure to an infected individual without barrier protection (condom)
- New/multiple sexual partners
- Inconsistent condom use
- Commercial sex work or drug use
- Infants: infected mother
- Children: sexual abuse by infected individual
- Autoinoculation (finger to eye)

## GENERAL PREVENTION

- Condoms offer partial protection. They must be used appropriately for protection during oral, anal, and vaginal intercourse.
- Treat sexual contacts; consider expedited partner therapy (EPT) (2,3)[A].

## COMMONLY ASSOCIATED CONDITIONS

Other STIs: *Chlamydia*, syphilis, HIV, hepatitis B, herpes (2,3,4)[A]

# DIAGNOSIS

## HISTORY

- Sexual history
  - Number of partners and age of onset of sexual activity; STI history
  - New/recent change in sexual partner
  - Contact with commercial sex workers
  - Condom use
  - Menses and possibility of pregnancy
- *10% males and 20-40% of women are asymptomatic (2)[A].*
- If symptomatic, explore the onset, context, duration, timing, severity, and associated symptoms:
  - Symptoms typically appear within 1 to 14 days after exposure (when present) (1)[A].
- Ocular symptoms: discharge, itch, redness (1)[A]
- Pharyngeal symptoms: asymptomatic infection (98%), sore throat (1)[A]
- GI symptoms: acute diarrhea (1)[A]
- Urinary symptoms: urinary frequency, urgency, dysuria (1)[A]
- Urethral symptoms: copious urethral discharge (1,2)[A]
  - Males: scant to copious purulent urethral discharge (82%), dysuria (53%), testicular pain (1%), asymptomatic infection (10%), proctitis
  - Females: asymptomatic cervical infection (20%), endocervical discharge (96%), vaginal discharge, Bartholin gland swelling, dysmenorrhea, menometrorrhagia, abdominal pain/tenderness, dyspareunia, cervical motion tenderness, rebound, infertility, chronic pelvic pain
- Either sex, for receptive anal intercourse: rectal discharge, tenesmus, rectal burning; can be asymptomatic.
- Disseminated syndromes (1,2)[A]
  - Fever, chills, malaise, skin rash, arthralgia
  - Endocarditis: high fevers
  - Meningitis: meningeal signs, headache, skin lesions, fever, altered mental status

## PHYSICAL EXAM

- General: fever, chills (1)[A]
- Ocular: purulent discharge, conjunctivitis, chemosis, eyelid edema, corneal ulceration (1)[A]
- Pharyngeal infection: exudative pharyngitis (<1%) (1)[A]
- GI: acute diarrhea, hyperactive bowel sounds (1)[A]
- Genitourinary (GU) (1)[A]
  - Males: urethral discharge, testicular tenderness (1%)
  - Females: endocervical discharge, Bartholin gland abscess, abdominal pain/tenderness, cervical motion tenderness, rebound tenderness
- Either sex, for receptive anal intercourse: Rectal discharge; rectal exam may be normal (1)[A].
- Disseminated syndromes (1)[A]:
  - Fever, chills, malaise, tenosynovitis, maculopapular pustular rash, polyarthralgia (typically large joints (knee, wrist, ankle), purulent arthritis
  - Endocarditis: rapid cardiac valve destruction, heart murmurs, high fevers
  - Meningitis: meningeal signs, headache, skin lesions, fever, altered mental status

## DIFFERENTIAL DIAGNOSIS

*Chlamydia trachomatis*, UTIs, other vaginitis, or urethritis (bacterial, viral, or parasitic)

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Nucleic acid amplification (NAAT) is the most sensitive and specific test for *N. gonorrhoeae* (2) [A]. Other options include:
  - Genital culture
  - Add pharyngeal culture in adolescents
  - Gram stain (recommended for urethritis)
  - Urethral smear, sensitivity in symptomatic male: 395%; sensitivity of endocervical smear in infected woman: 40-60%; specificity: 100%
- DNA probes and polymerase chain reaction (PCR) sensitivity: 92-99% dependent on population; specificity: >97%; can replace culture
- Blood culture is 50% sensitive in disseminated disease. Joint fluid culture is 50% sensitive in

septic arthritis. Screen for additional STIs, especially chlamydia, syphilis, and HIV.

- Imaging is not generally recommended.

### *Follow-Up Tests & Special Considerations*

- Test of cure is not generally recommended (1,2,3)[A].
- Follow-up testing may be considered in cases of recurrent infection, when oral cephalosporin treatment is used and/or in areas where significant antibiotic resistance exists (2,3)[A].
- Pelvic ultrasound or CT scan may demonstrate thick, dilated fallopian tubes or abscess formation.

### *Diagnostic Procedures/Other*

Culdocentesis may demonstrate free purulent exudate and provide material for Gram staining and culture. Gram-staining material from unroofed skin lesions may show typical organisms.

### *Test Interpretation*

- Gram-negative intracellular diplococci
- Nonpathologic gram-negative diplococci may be found in extragenital locations. For this reason, Gram stain of pharyngeal or rectal swabs is not recommended.

## **TREATMENT**

### *GENERAL MEASURES*

- STI counseling and condom use
- In children and adolescents, suspect sexual abuse.

### *MEDICATION*

- *N. gonorrhoeae* multidrug antimicrobial resistance continues to increase: *CDC recommends dual therapy for all uncomplicated GC infections in U.S. adults and adolescents (both to treat for concomitant chlamydia and to increase efficacy against drug-resistant strains) (2,3,4)[A].*

---

P.421

- Quinolones are not recommended (2,3,4)[A].
- *If treatment fails, check culture and sensitivities, and report to CDC through local health authorities (2,3,4)[A].*

Treat with regimen that is also effective against uncomplicated genital chlamydial infection (2,3,4)[A].

## First Line

- Uncomplicated urogenital, anorectal, and pharyngeal gonorrhoeal infection (2,3)[A]
  - Ceftriaxone 250 mg IM in a single dose
  - *PLUS* treatment for chlamydia (azithromycin 1 g PO single dose or doxycycline 100 mg PO BID for 7 days)
- Pharyngitis: ceftriaxone 250 mg IM once *PLUS* treatment for chlamydia (azithromycin 1 g PO single dose or doxycycline 100 mg PO BID for 7 days) (1,2,3)[A]
- Conjunctivitis: ceftriaxone, 1 g IM single dose (1,2,3)[A]
- Pelvic inflammatory disease (PID): Parenteral and oral treatments are equivalent for mild to moderate severity PID. If using IV therapy, switch to PO within 24 to 48 hours of clinical improvement (1,2,3)[A].
  - Cefotetan 2 g IV q12 OR cefoxitin 2 g IV q6h + doxycycline 100 mg PO or IV q12h
  - Clindamycin 900 mg IV q8h + gentamicin loading dose IV or IM (2 mg/kg of body weight), followed by a maintenance dose (1.5 mg/kg) q8h. Daily dosing (3 to 5 mg/kg) can be substituted.
  - Preferred Oral regimen includes the following:
    - Ceftriaxone 250 mg IM once + doxycycline, 100 mg PO BID for 14 days
    - With or without metronidazole, 500 mg PO BID for 14 days
- Disseminated infection in adults (1,2,3)[A]
  - Ceftriaxone 1 g IM or IV q24h until 24 to 48 hours after improvement begins, then switch to cefixime 400 mg PO BID to complete at least 1 week of antibiotic treatment. *Also treat for chlamydial infection.*
- Meningitis and endocarditis (1,2,3)[A]
  - Ceftriaxone 1 to 2 g IV q12h 10 to 14 days for meningitis; 4 weeks for endocarditis
- *Contraindications:* Doxycycline is *contraindicated in pregnancy and young children.*

## Pediatric Considerations

- Children >45 kg same dosing as adults (1,2,3)[A]

- Children <45 kg: uncomplicated urethral, cervical, rectal or pharyngeal gonococcal infections (1,2,3)[A]
  - Ceftriaxone 125 mg IM in single dose
  - Disseminated infections: ceftriaxone 50 mg/kg IV or IM daily (max dose 1 g) in single dose; bacteremia: 7 days; meningitis: 10 to 14 days; endocarditis: 4 weeks
- Ophthalmic neonatorum prophylaxis: single application of erythromycin 0.5% ophthalmic ointment to each eye immediately after delivery (1,2,3)[A]
- Neonatal conjunctivitis: ceftriaxone 25 to 50 mg/kg IV or IM in a single dose (not to exceed 125 mg) (1,2,3)[A]
- *Conjunctival exudates should be cultured for definitive diagnosis* (1,2,3)[A].
- Scalp abscesses (from scalp electrodes) (1,2,3)[A]
  - Ceftriaxone 25 to 50 mg/kg/day IV or IM in a single daily dose for 7 days, with duration of 10 to 14 days if meningitis is documented.
- Asymptomatic infants born to mothers with untreated gonorrhea (1,2,3)[A]
  - Ceftriaxone 25 to 50 mg/kg IV or IM, not to exceed 125 mg in a single dose

## *Pregnancy Considerations*

Pregnant women should be treated with cephalosporin or recommended alternative (1,2,3,4)[A].

- Azithromycin 2 g orally in single dose for women intolerant to cephalosporin
- Treat concurrently with azithromycin or amoxicillin for presumed *C. trachomatis* coinfection.
- Women with 1st-trimester gonococcal infection should be retested within 3 to 6 months.
- High-risk uninfected pregnant women should be retested during the 3rd trimester.

## *Second Line*

- Due to antimicrobial resistance, combination therapy using two agents with different mechanisms of action improves treatment efficacy and decreases resistance to cephalosporins (1,2,3)[A].
  - Use of a second antimicrobial (azithromycin as a single 1-g oral dose or doxycycline 100 mg orally twice daily for 7 days) is recommended for use with ceftriaxone (1,2,3)[A].
  - Azithromycin as the second antimicrobial is preferred to doxycycline because of convenience and compliance of single-dose therapy as well as higher resistance with tetracyclines (1,2,3) [A].

- For additional treatment options, see CDC STD treatment guidelines:  
<http://www.cdc.gov/std/tg2015/>

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

- Hematogenously disseminated infection
- Pneumonia or eye infection in infants
- PID: if unable to take oral medications, significant tubo-ovarian abscess, or patient is pregnant

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

U.S. Preventive Services Task Force (USPSTF) (4)[A]

- Screen all sexually active women, including those who are pregnant if they are at increased risk of infection (*young or have other individual/population risk factor*): **Grade B recommendation**
- Insufficient evidence to recommend for or against screening men at increased risk of infection: **Grade I recommendation**
- No routine screening in men and women who are low risk for infection: **Grade D recommendation**
- Insufficient evidence to recommend for or against screening in pregnant women who are not at increased risk for infection: **Grade I recommendation**
- Prophylactic ocular topical medication for *all* newborns: **Grade A recommendation**
- Report cases of gonorrhea to public health authorities (3,4)[A]

### *PATIENT EDUCATION*

- Counseling concerning risk reduction, condom use, future fertility, and full STI testing
- Encourage patient to notify partners (from past 60 days); consider EPT.

### *PROGNOSIS*

Complete cure with return to normal function with adequate and timely treatment

## COMPLICATIONS

- Infertility
- Urethral stricture
- Corneal scarring
- Destruction of joint articular surfaces
- Cardiac valvular damage

### ***Pediatric Considerations***

Vertical transmission to newborn infants is a significant risk among patients with gonococcal infection at the time of delivery (1,2)[A].

## Codes

**&NA;**

## **ICD10**

- A54.9 Gonococcal infection, unspecified
- A54.31 Gonococcal conjunctivitis
- A54.03 Gonococcal cervicitis, unspecified

## **Clinical Pearls**

**&NA;**

- Due to frequent coinfection, treatment for uncomplicated gonorrhea should include two drugs, one of which is effective against chlamydia.
- Screen patients with gonorrhea for chlamydia, syphilis, HIV, and hepatitis.

# Gout

Ryan B. Feeney, PharmD

Michael C. Barros, PharmD, BCPS, BCACP

Paul N. Williams, MD, FACP

## BASICS

### DESCRIPTION

- Gout is an inflammatory arthritis related to a hyperuricemia (serum uric acid [SUA] level >6.8 mg/dL) (1).
- Acute gouty arthritis can affect <sup>3</sup>1 joints; the first metatarsophalangeal joint is most commonly involved at presentation (podagra).
- Although hyperuricemia is necessary for the development of gout, it is not the only determining factor.
- Characterized by deposition of monosodium urate (MSU) crystals that accumulate in joints and soft tissues, resulting in acute and chronic arthritis, soft-tissue masses called tophi, urate nephropathy, and uric acid nephrolithiasis
- After an initial flare, a second flare occurs in  $\pm$ 60% of patients within 1 year and 78% within 2 years of the initial attack (2).
- Management involves treating acute attacks and preventing recurrent disease by long-term reduction of SUA levels through pharmacology and lifestyle adjustments

### EPIDEMIOLOGY

#### *Incidence*

Annual incidence of gout (3):

- Uric acid 7 to 8.9 mg/dL is 0.5%.
- Uric acid >9 mg/dL is 4.5%.

#### *Prevalence*

- Increasing prevalence over the past decades (3)

- 2007 to 2008 prevalence of gout in the United States (3)
  - Men 5.8% (6.1 million)
  - Women 2.0% (2.2 million)
- 2008 prevalence of hyperuricemia in the United States (3)
  - Men 21.2% (SUA >7.0 mg/dL)
  - Women 21.6% (SUA >5.7 mg/dL)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Hyperuricemia results from urate overproduction, underexcretion, or often a combination of the two.
- Gout occurs when MSU, a product of purine metabolism, precipitates out of solution and accumulates in joints and soft tissues.
- Transient changes in urate solubility caused by local temperature decrease, trauma, or acidosis may lead to an acute gouty attack.
- Urate crystals that precipitate trigger an immune response.
- Left untreated, this crystal deposition leads to permanent joint damage and tophus formation.

## *Genetics*

- Phosphoribosyl pyrophosphate (PRPP) deficiency and hypoxanthine-guanine-phosphoribosyltransferase (HGPRT) deficiency (Lesch-Nyhan syndrome) are inherited enzyme defects associated with overproduction of uric acid.
- Polymorphisms in the URAT1 and SLC 2A9 (GLUT9) renal transporters are hereditary enzyme defects resulting in primary underexcretion of uric acid.

## *RISK FACTORS*

- Age >40 years
- Male gender
- Increased purine uptake (meats and seafood)
- Alcohol intake (especially beer)
- High fructose intake
- Obesity

## Hyperuricemia

- Congestive heart failure
- Coronary artery disease
- Dyslipidemia
- Renal disease
- Organ transplant
- Hypertension
- Hyperinsulinemia
- Metabolic syndrome
- Diabetes mellitus
- Urate-elevating medications:
  - Thiazide diuretics: ethambutol
  - Loop diuretics (less of a risk vs. thiazides)
  - Niacin
  - Calcineurin inhibitors (cyclosporine and tacrolimus)
  - Acetylsalicylic acid (*not* recommended in high doses)

## **GENERAL PREVENTION**

- Maintain optimal weight.
- Regular exercise
- Diet modification (purine-rich foods)
- Reduce alcohol consumption (beer and liquor).
- Maintain fluid intake and avoid dehydration.

## **COMMONLY ASSOCIATED CONDITIONS**

- Hypertension
- Dyslipidemia
- Nontraumatic joint disorders
- Heart disease

Urinary tract disease

- Diabetes mellitus
- Metabolic syndrome
- Obesity
- Renal disease

## DIAGNOSIS

### HISTORY

- Classic presentation of acute gouty arthritis:
  - Intense pain and tenderness in the first metatarsophalangeal joint (podagra)
  - Can occur in the midtarsal, ankle, or knee joints
  - Joint may be swollen, warm, and red
  - Often awakes patients from sleep due to an intolerance to contact with clothing or bed sheets
  - There is a rapid onset of intense pain, often beginning in the early morning and progressing rapidly over 12 to 24 hours.
  - In the absence of treatment, flares can last up to 10 days.
- Fever can be seen.
- SC or intraosseous nodules, referred to as tophi
- Pain with urination secondary to uric acid renal stones

### PHYSICAL EXAM

- Examine suspected joint(s) for tenderness, swelling, and range of motion (ROM).
- Assess for presence of firm nodules known as tophi.
- In patients with chronic gout, tophi can frequently be found in the helix of the ear, over the olacrenon process, or on the Achilles tendon.
- Patients with untreated chronic gout can have evidence of joint inflammation and deformity.

### DIFFERENTIAL DIAGNOSIS

Acute bursitis, tendonitis, septic arthritis, pseudogout (calcium pyrophosphate deposition disease), cellulitis, osteoarthritis

## DIAGNOSTIC TESTS & INTERPRETATION

- SUA (may be normal during an acute flare)
- CBC (can see elevation of WBC during an acute gout flare)
- Synovial fluid analysis: urate crystals (negatively birefringent under polarizing microscopy), cell count (WBC usually 2,000 to 5,000 cells/mm<sup>3</sup>); culture to rule out infection. Some guidelines suggest that gout can be diagnosed clinically without synovial fluid analysis.
- Screen for uric acid overproduction—24-hour urinary uric acid in those patients with gout onset before the age of 25 years or had a history of urolithiasis (1)[C].
- Radiograph is normal early in disease but can reveal
  - Swelling in acute gout
  - Periarticular erosions with periosteum overgrowth in chronic gout
- Urate kidney stones are radiolucent and thus invisible on radiograph.

## TREATMENT

### GENERAL MEASURES

Topical ice as needed (4)[B]

### MEDICATION

- Acute treatment
  - General principles:
    - Acute gouty arthritis attacks should be treated with pharmacologic therapy (4)[C].
    - Pharmacologic treatment should be initiated within 24 hours of acute gout attack onset (4)[C].
    - Ongoing pharmacologic urate-lowering therapy should not be interrupted during an acute gout attack (4)[C].
    - Choice of agent is based on severity of pain and the number of joints involved (4).
  - Mild/moderate gout severity (≥6 of 10 on visual analog pain scale, particularly for an attack involving only one or a few small joints or one to two large joints)
    - NSAIDs:

- Naproxen (Naprosyn, Anaprox, Aleve): 750 mg followed by 250 mg q8h for 5 to 8 days (4)[A]
  - Indomethacin (Indocin): 50 to 150 mg/day for 2 to 7 days (4)[A]
  - Sulindac (Clinoril): 200 mg BID for 7 to 10 days (4)[A]
  - Celecoxib (Celebrex)
  - Not FDA approved but can be considered in selected patients with contraindications or intolerance to NSAIDs (4)[B].
    - Dose at 800 mg once followed by 400 mg on day 1, then 400 mg BID for 1 week (4)[B]
- Corticosteroids
- Those with an acute flare involving one to two large joints can consider intra-articular corticosteroids; can consider using PO corticosteroids in combination.
  - For other acute flares, use PO corticosteroids:
    - Prednisone (Sterapred): 0.5 mg/kg/day for 5 to 10 days followed by discontinuation (4)[A] or alternately 2 to 5 days at full dose followed by tapering for 7 to 10 days and then discontinuing (4)[C]
    - Methylprednisolone (Medrol) dose pack (4)[C]
    - Triamcinolone acetonide (Trivaris): 60 mg IM single dose followed by oral corticosteroids (4)[C]

---

P.423

- Colchicine (Colcrys)
- Used for gout attacks where the onset was <36 hours prior to treatment initiation (4) [A]
  - Begin a loading dose of 1.2 mg followed by 0.6 mg 1 hour later, followed by 0.6 mg once or twice daily 12 hours later, until the gout attack resolves (4)[C].
  - Dose reduction recommended in moderate to severe kidney disease and in those on inhibitors of cytochrome P450 3A4 and P-glycoprotein (clarithromycin, erythromycin, cyclosporine, and disulfiram) (4).
- Severe gout (<sup>3</sup>7 of 10 on visual analog pain scale, involving <sup>3</sup>4 joints with arthritis involving >1 region, or involving three separate large joints)
    - Initial combination therapy is an option and includes the use of full doses of the following (4)[C]:

- Colchicine and NSAIDs
  - PO corticosteroids and colchicine
  - Intra-articular steroids with all other modalities
- For patients not responding to initial pharmacologic monotherapy, add a second agent (4) [C].
- Chronic treatment
  - Indications for pharmacologic urate-lowering therapy include any patient with
    - Tophus or tophi by clinical exam or imaging study (1)[A]
    - Frequent attacks of acute gouty arthritis ( $\geq 2$  attacks/year) (1)[A]
    - Chronic kidney disease (CKD) stage 2 or worse (1)[C]
    - Past urolithiasis (1)[C]
  - Treat to the serum urate:
    - Minimum serum urate target is  $<6$  mg/dL (1)[A].
    - Serum urate target may need to be  $<5$  mg/dL to improve gout signs and symptoms (1) [B].
  - Urate-lowering agents can be prescribed during an acute attack provided that effective anti-inflammatory prophylaxis has been initiated prior to urate-lowering therapy (1)[C].
  - Anti-inflammatory prophylaxis required when initiating urate-lowering therapy include the following:
    - First line
      - Low-dose colchicine: 0.6 mg once or twice daily (4)[A]
      - Low-dose NSAIDs with proton pump inhibitor if indicated: naproxen 250 mg PO BID (4)[C]
    - Second line: Use of colchicine and NSAIDs both are not tolerated, contraindicated, or ineffective:
      - Low-dose prednisone or prednisolone at  $\geq 10$  mg/day (4)[C]
    - Treatment duration for the greater of
      - At least 6 months (4)[A] *or*

3 months after achieving serum urate appropriate for the patient with no tophi on exam (4)[B], or for 6 months after achieving serum urate appropriate for the patient with <sup>3</sup>1 tophi on exam (4)[C]

- Pharmacologic urate-lowering agents:
  - Allopurinol (Zyloprim): xanthine oxidase inhibitor (1)[A]
    - Starting dose should be no higher than 100 mg/day (1)[B]
    - Starting dose should be 50 mg/day in stage 4 CKD or worse
    - Gradually titrate the dose upward q2-5wk to appropriate maximum dose (1)[C]
    - Dose can be >300 mg/day, even with renal impairment, as long as accompanied by patient education and monitoring of drug toxicity; maximum FDA-approved dosage is 800 mg/day (1)[B].
    - Regularly monitor for allopurinol hypersensitivity syndrome (AHS), pruritus, rash, elevated hepatic transaminases, and eosinophilia.
    - Screening for the HLA-B\*5801 allele for AHS should be performed in those of Korean descent with stage 3 CKD or worse and Han Chinese or Thai descent irrespective of renal function (1)[A].
  - Febuxostat (Uloric): selective xanthine oxidase inhibitor (1)[A]
    - No renal or hepatic adjustments needed for mild-to-moderate hepatic or renal impairment
    - Starting dose 40 mg/day; may be titrated to 80 mg/day
    - In select instances, may dose up to 120 mg/day (not FDA approved) (1)[A]
  - Probenecid: uricosuric agent (1)[B]
    - Alternative first line urate-lowering therapy; use if at least one xanthine oxidase inhibitor is contraindicated or not tolerated (1)[B].
    - May be used in addition to allopurinol or febuxostat if serum urate target not achieved
    - Multiple drug interactions exist, as well as risk of urolithiasis with this agent.
    - Not recommended if creatinine clearance (CrCl) is <50 or with patient history of urolithiasis (1)[C].
    - Starting dose is 250 mg BID; gradually titrate to 2,000 mg/day
- Other treatment

- Acute treatment: adrenocorticotrophic hormone (ACTH): 25 to 40 IU SC (4)[A]; especially in those NPO
- Pegloticase in select severe instances (1)

## ***SURGERY/OTHER PROCEDURES***

Large tophi that are infected or interfering with joint motion may need to be surgically removed.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- SUA q2-5wk while titrating urate-lowering treatment to goal (1)[C]
- Regularly monitor CBC, renal function, liver function test, and urinalysis.

#### ***DIET***

- General lack of evidence regarding specific recommendations, although the American College of Rheumatology has outlined the following (1)[C]:
- General measures:
  - Weight loss for obese patients
  - Healthy overall diet
  - Exercise
  - Smoking cessation
  - Stay well hydrated
- Avoid
  - Organ meats high in purine content (sweetbreads, liver, kidney) (1)[A]
  - High-fructose corn syrup-sweetened sodas, other beverages, or foods
  - Alcohol overuse (>2 servings per day for men and >1 serving per day for women) (1)[A]
  - Any alcohol use in gout during periods of frequent gout attacks or advanced gout under poor control
- Limit

- Serving sizes of beef, lamb, pork, and seafood with high purine content such as sardines and shellfish (1)[B]
- Servings of naturally sweetened fruit juices
- Table sugar and sweetened beverages and desserts
- Table salt, including in sauces and gravies
- Alcohol (particularly beer) in all gout patients (1)[B]
- Encourage
  - Low-fat or nonfat dairy products
  - Vegetables

## PATIENT EDUCATION

- Dietary and lifestyle modifications (1)[B]
- Patient instructions on initiating treatment on signs and symptoms of an acute gout attack without the need to consult health care provider for each attack (1)[B]
- Discussion that gout is caused by excess uric acid and that effective urate-lowering therapy is essential treatment (1)[B]

## PROGNOSIS

Gout can usually be successfully managed with proper treatment.

## COMPLICATIONS

- AHS
- Increased susceptibility to infection
- Urate nephropathy
- Renal stones

---

## Codes

**&NA;**

### ICD10

- M10.9 Gout, unspecified
- M10.00 Idiopathic gout, unspecified site
- M10.30 Gout due to renal impairment, unspecified site

## Clinical Pearls

**&NA;**

- MSU crystals found in synovial fluid aspirate are pathognomonic for gout.
- Acute gout and sepsis can coexist.
- Asymptomatic hyperuricemia does not require treatment.
- Losartan possesses uricosuric properties, therefore it may be an excellent agent if patient is hypertensive.

# Granuloma Annulare

Mary Iaculli, DO

Joanne Wilkinson, MD, MSc

## BASICS

### DESCRIPTION

A benign skin condition characterized by grouped, flesh-colored, or erythematous papules, which typically occur in an annular (ring-like) pattern. Five variants have been described; the most common of which is localized granuloma annulare (GA). The other types are generalized, patch type, subcutaneous (SC) (deep dermal), and perforating.

### EPIDEMIOLOGY

#### *Incidence*

- GA is not common, although exact prevalence in the general population is unknown.
- Predominant sex: female > male (2.5:1)
- Most lesions resolve in 2 to 24 months but may last up to 5 to 10 years. 2/3 of patients are <30 years, and the age distribution varies by type, as follows:
  - Localized: children and adults <30 years
  - Generalized: bimodal: children <10 years and adults 30 to 60 years
  - Patch type: adults >30 years
  - SC: children 2 to 10 years
  - Perforating: typically children but also young adults

#### *Prevalence*

Among cases of GA, the approximate distribution is as follows:

- Localized: 75%
- Generalized: 10-15%
- Patch type: <5%

- Subcutaneous: <5%
- Perforating: <5% (perhaps higher in Hawaii)

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

The cause of GA remains unknown, although it is hypothesized to be a delayed-type hypersensitivity to an unknown antigen. Lymphohistiocytic infiltrates, degeneration of collagen, and mucin deposition are characteristic histopathologic features of GA.

### ***Genetics***

There is some evidence for a possible hereditary component. Increased frequency of HLA-B35 in patients with generalized GA were reported in two studies (1,2).

## ***RISK FACTORS***

No definite risk factors have been identified. There is some evidence for possible associations with diabetes mellitus; TB; HIV, EBV, and other viral infections (including HSV); interferon- $\alpha$ ; therapy; trauma; insect bites; borreliosis; and malignancies (most commonly lymphoma).

## ***GENERAL PREVENTION***

There are no established strategies for preventing GA.

## ***COMMONLY ASSOCIATED CONDITIONS***

- Diabetes mellitus: There are conflicting reports about the association of GA with diabetes mellitus, and methodological design for these studies is weak. One retrospective study of 557 aged-matched patients found a higher incidence in localized GA with insulin-dependent diabetes mellitus (3). Another retrospective study reported higher incidence of diabetes mellitus in generalized GA versus localized GA (4). In contrast, two small studies, one is a case control and one is a prospective study, did not reveal an association between these disorders (5,6).
- Malignancy: There is a possible association with GA and malignancy; however, data is severely lacking. Cases linked with malignancy most commonly had an atypical presentation of GA with lymphoma (7).
- Dyslipidemia: Dyslipidemia may be associated with GA. A case-control study of 140 adults showed a statistically significant increase in elevated lipids in patients with GA, most commonly generalized GA (8).
- HIV: There are many case reports suggesting an association between GA and HIV. Generalized GA is most common pattern with HIV.
- For all associations, weak evidence exists through poorly designed, underpowered studies.

More investigations are necessary.

## DIAGNOSIS

### HISTORY

Cutaneous lesions of GA are generally asymptomatic. They may persist for months or years; longer duration is more often seen in the generalized subtype. They typically resolve spontaneously and may recur.

### PHYSICAL EXAM

- Localized: asymptomatic, flesh-colored, or erythematous annular or arciform plaque with a moderately firm, rope-like border and central clearing, ranging from 5-mm to 5-cm in diameter. Small 1- to 2-mm papules may be noted in periphery, often not in continuous border. The most common locations are the dorsal aspects of the distal extremities. Involvement of palms is rare. 50% will have multiple lesions.
- Generalized: similar to localized but a higher number of lesions (>10), which are more diffuse distribution, often larger, and typically persist longer
- Patch type: erythematous macules and patches distributed symmetrically on the extremities and trunk. The typical annular configuration may or may not be present; often involves proximal extremities.
- SC: firm, nontender, SC nodule, which tends to grow rapidly; usually solitary but may occur in groups. Most common location is scalp or lower extremities, especially pretibial; other sites include upper extremities and buttocks.
- Perforating: Damaged collagen from dermis is extruded onto skin surface. Papules may be up to 4 mm and display yellowish umbilication, crusting, or scale. Lesions are often generalized and may occur anywhere. Lesions often heal with scar.

### DIFFERENTIAL DIAGNOSIS

- Localized: tinea corporis, annular lichen planus, necrobiosis lipoidica, pityriasis rosea, erythema migrans of Lyme disease, leprosy
- Generalized: sarcoidosis, lichen planus, cutaneous metastases, mycosis fungoides
- Patch type: erythema migrans
- SC: rheumatoid nodule
- Perforating: molluscum contagiosum, sarcoidosis, insect bites

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- Diagnosis is typically established by history and physical, so lab investigations are rarely needed. Skin scraping/KOH test may be useful for excluding a fungal process.
- May consider work up for dyslipidemia, DM, HIV, and malignancy if clinically indicated

## Diagnostic Procedures/Other

Skin punch biopsy is useful to confirm the diagnosis and designate subtype.

Immunohistochemical streptavidin-biotin-horseradish peroxidase (HRP) analysis for CD68/KP-1, which is a marker for histiocytic differentiation, may aid in the diagnosis.

## Test Interpretation

Dermal granulomatous infiltrate demonstrating foci of degenerative collagen associated with palisading around an anuclear dermis with mucin deposition. Histologic variants include interstitial (histiocytic infiltrate between collagen fibers), classic (palisading dermal granulomas), and epithelioid (tuberculoid and sarcoidal granulomas).

## TREATMENT

### GENERAL MEASURES

GA is a self-limited, asymptomatic condition that is likely to regress spontaneously. The clinician's primary role after diagnosis is to educate the patient regarding the anticipated natural history and to provide reassurance.

P.425

### MEDICATION

- No strong evidence supports therapeutic intervention for GA. Reassurance with observation may be an adequate treatment for localized, asymptomatic disease.
- The trauma induced by biopsy alone can cause involution of the lesions through an unknown mechanism.
- The following therapies have been tried with variable success, and the possible benefit of treatment must be weighed against the significant toxicities of these treatments.

### First Line

Corticosteroids (9)

- High-potency topical, with or without occlusion
- Intralesional triamcinolone: 2.5 to 5 mg/mL

## *Second Line*

- Methotrexate: 15 mg IM weekly (10)
- Rifampin: 600 mg, ofloxacin 400 mg, with minocycline 100 mg once daily (11)
- Pimecrolimus 1% cream BID
- Isotretinoin: 0.5 to 0.75 mg/kg/day
- Dapsone: 100 mg/day
- Chloroquine: 3 mg/kg/day
- Hydroxychloroquine: 3 to 6 mg/kg/day
- Cyclosporine: 3 to 4 mg/kg/day
- Niacinamide: 500 mg TID
- TNF- $\alpha$  inhibitors, such as infliximab 5 mg/kg IV weeks 0, 2, and 6 and monthly thereafter for 10 months or adalimumab 80 mg SC  $\times$  1 for the 1st week then 40 SC  $\times$  1 for weeks 2 to 4

## **ADDITIONAL THERAPIES**

- Fractional thermolysis (Er:YAG fractionated laser)
- Psoralen ultraviolet A (PUVA)
- Cryotherapy
- Surgical excision for SC GA

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Routine follow-up is not required unless treatment is initiated. Then follow-up may be important to monitor for possible adverse effects associated with treatment. Referral to a dermatologist is prudent in cases of generalized GA and in those cases that persist despite conservative therapy.

### ***PATIENT EDUCATION***

The patient should be educated that GA is a benign, self-limited condition that may persist a long time, resolve, and/or recur.

## PROGNOSIS

>50% of cases resolve spontaneously within 2 months to 2 years; although recurrence, typically at the original site, is common (>40%). Patients <39 years have been shown to have a shorter duration of illness.

## COMPLICATIONS

Complications of treatment are much more likely than complications from GA.

&NA;

# ICD10

L92.0 Granuloma annulare

## Clinical Pearls

**&NA;**

- This condition is benign and often self resolves. Consider risk-benefit with patient when discussing treatment.
- In cases of suspected tinea that lack scaling, consider GA.
- Consider lipid testing, especially in those with generalized subtype.

# Granuloma, Pyogenic

Eddie Needham, MD, FAAFP

## BASICS

### DESCRIPTION

- Pyogenic granulomas (PG) are benign, acquired, and solitary vascular proliferations that occur most often on the head and neck, the lips and oral cavity, the trunk, and the extremities (1).
- They are friable and tend to bleed easily due to the vascular nature of the lesion.
- Smooth, red to purple, sessile or pedunculated, grow rapidly over several weeks
- Synonym(s): Given that PG are neither pyogenic nor granulomatous, another term is lobular capillary hemangioma.

### EPIDEMIOLOGY

The peak incidence of PG are the 2nd and 3rd decades of life (2).

#### *Incidence*

- In children, PG accounts for <1% of all skin lesions.
- 42% of all cases occur by age 5 years (2).
- 2% of pregnant women in the United States develop a PG by 5 months' pregnancy (3).

#### *Prevalence*

Relatively common condition

### ETIOLOGY AND PATHOPHYSIOLOGY

- Thought to be an aberrant healing response to minor trauma in many cases
- May be related to hormonal changes in pregnancy
- Not caused by bacterial infection but associated with capillary proliferation
- Not considered as a hemangioma or neoplasm
- Associated with acute and chronic trauma, peripheral nerve injury, inflammatory systemic

diseases, infection, drugs (systemic steroids, protease inhibitors, retinoids, epidermal growth factor receptor inhibitors)

## **RISK FACTORS**

- Pregnancy
- Trauma
- Intraoral trauma or surgery
- Inflammatory systemic diseases

## **GENERAL PREVENTION**

Good oral hygiene may be helpful.

## **DIAGNOSIS**

### **HISTORY**

- Solitary lesion that develops rapidly from days to weeks after minor trauma
- Tends to bleed easily
- Grows early in pregnancy and partially regresses postpartum

## **PHYSICAL EXAM**

- Most commonly located at the head, neck, and upper extremities, especially in children
- Among oral lesions, gingiva is the most common location.
- Usually a bright red, friable papule; can also be purple, yellow, or brown
- Moist and sometimes scaly-appearing surface
- Usually <1 cm but ranges from a few millimeters to 2 to 3 cm in diameter
- Giant lesions may occur on areas such as the foot (rare).
- Soft; pedunculated or sessile
- Solitary red papule, grows rapidly, forming a stalk, may bleed, and ulcerate.
- On diascopy, red structureless areas surrounded by a white collarette intersected by white lines
- Erythematous, soft compressible papule with serosanguineous crusting and sharp demarcation

# DIFFERENTIAL DIAGNOSIS

- Benign lesions
  - Cherry/infantile hemangioma (4)
  - Fibrous papule (1,4)
  - Bacillary angiomatosis, from by *Bartonella* (1)
- Malignant lesions
  - Basal cell carcinoma (1)
  - Squamous cell carcinoma (1)
  - Amelanotic melanoma (1)
  - Kaposi sarcoma (1)
  - Cutaneous metastases (1)

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

No labs are necessary for the diagnosis.

### *Diagnostic Procedures/Other*

- Excisional/shave biopsy
- Send for pathology.

### *Test Interpretation*

Microscopic examination reveals

- Small, endothelial-lined vascular spaces
- Loose/dense connective tissue stroma
- Acute and chronic inflammatory cells

- 
- *No true granuloma formation*
  - Abundant mitotic activity
  - Resembles granulation tissue in an edematous matrix, showing immature capillaries with interspersed tissue

## TREATMENT

When feasible, surgical excision is best to yield material for histopathologic analysis (1,5).

### MEDICATION

- Cryotherapy with liquid nitrogen (recur 2%) (6)[B]
- Laser (recur 5%) (6)[B]
- Topical imiquimod (recur 0%) (6)[B]
- Silver nitrate (recur 15%) (6)[A]
- Topical 1.5% phenol solution may be used for periungual lesion (6)[B].
- Perform excision for bx if recurrent.

### SURGERY/OTHER PROCEDURES

- Excisional biopsy should be tried in all situations, if possible, to ensure a proper diagnosis (i.e., not missing malignancies such as amelanotic melanoma or basal cell carcinoma) (recur 2-3%) (6)[B]. For smaller lesions in noncosmetically sensitive areas, surgical excision with simple closure gives the best result with least recurrence (6)[B].
- Liquid nitrogen may be nonsurgical option with the lowest recurrence rate (recur 2%) (6)[B].
- Shave excision with cautery may be optimal treatment for a lesion on fingertips (recur 7-9%) (6)[B].
- Electrosurgery: electrodesiccation and curettage (recur 7-9%) (6)[B]
- Excision must be adequate to avoid recurrence. Even a small fragment of tissue left behind may lead to recurrence.

## ONGOING CARE

### PATIENT EDUCATION

Patient should avoid trauma to area following excision.

### PROGNOSIS

- Some lesions spontaneously resolve on their own (usually within 6 months).
- Complete resolution is expected with adequate excision.

## COMPLICATIONS

Recurrence: After removal or destruction of solitary lesion, multiple satellite lesions can form around original treatment site.

**&NA;**

## **ICD10**

- L98.0 Pyogenic granuloma
- K06.8 Oth disrd of gingiva and edentulous alveolar ridge
- K13.4 Granuloma and granuloma-like lesions of oral mucosa

## **Clinical Pearls**

**&NA;**

- Benign, acquired, usually rapidly growing, solitary vascular proliferation that involves exposed areas, such as distal extremities and face, as well as in the oral cavity
- Excision must be adequate to avoid recurrence.
- Excisional biopsy recommended to ensure proper diagnosis (and to not miss a malignant lesion)
- Excision with primary closure or excision with cautery should be the first choice for treatment in most lesions.

# Graves Disease

Jasmine S. Beria, DO, MPH

Oksana Davydov, MD

## BASICS

### DESCRIPTION

Autoimmune disease in which thyroid-stimulating antibodies cause increased thyroid function; most common cause of hyperthyroidism. Classic findings are goiter, ophthalmopathy (orbitopathy), and occasionally dermopathy (pretibial or localized myxedema).

### EPIDEMIOLOGY

#### Prevalence

- Overall prevalence of hyperthyroidism in United States:  $\div$ 2% for women and 0.2% for men
- More common in white and Hispanic populations in comparison to the black population
- Graves disease accounts for 60-80% of all cases of hyperthyroidism.
- Hyperthyroidism occurs in 0.2% of pregnancies, of which 95% is due to Graves disease.
- Predominant age: 30 to 40 years
- Synonym(s): Basedow disease

### ETIOLOGY AND PATHOPHYSIOLOGY

- Excessive production of thyroid-stimulating hormone (TSH) receptor antibodies from B cells primarily within the thyroid, likely due to genetic clonal lack of suppressor T cells
- Binding of these antibodies to TSH receptors in the thyroid activates the receptor, stimulating thyroid hormone synthesis and secretion as well as thyroid growth (leading to goiter).
- Binding to similar antigen in retro-orbital connective tissue causes ocular symptoms.

#### Genetics

Higher risk with personal or family history of any autoimmune disease, especially Hashimoto thyroiditis

## **RISK FACTORS**

- Female gender
- Postpartum period
- Stressful life events
- Medications: iodine, amiodarone, lithium, highly active antiretroviral (HAART); rarely, immunomodulating medications (e.g., interferon therapy)
- Smoking (higher risk of developing ophthalmopathy)

## **GENERAL PREVENTION**

Screening TSH in asymptomatic patients is not recommended. No data conclusively show that treatment of subclinical thyroid dysfunction improves quality of life or clinical outcome measures.

## **COMMONLY ASSOCIATED CONDITIONS**

- Mitral valve prolapse
- Type 1 diabetes mellitus
- Addison disease, hypokalemic periodic paralysis
- Vitiligo, alopecia areata
- Other autoimmune disorders (myasthenia gravis, celiac disease)

## **DIAGNOSIS**

Hyperthyroid patients appear hypermetabolic with increased adrenergic tone.

### **HISTORY**

- Tachycardia, palpitations
- Tremor, restlessness
- Hyperactivity, anxiety, emotional lability, insomnia
- Sweating, heat intolerance
- Pruritus, skin changes
- Weight loss with increased appetite
- Fatigue, dyspnea (due to muscle weakness)
- Oligo-/amenorrhea (women), loss of libido, erectile dysfunction (men), gynecomastia
- Loose, frequent stools

- Blurred vision or diplopia, lacrimation, photophobia, gritty sensation in eyes (ocular dryness), retro-orbital discomfort, painful eye movement, loss of color vision or visual acuity
- Worsening of chronic medical conditions (anxiety, bipolar disorder, glucose intolerance, heart failure, or angina)

### ***Geriatric Considerations***

Elderly patients may not display classic symptoms; may present with atrial fibrillation, weight loss, or shortness of breath (1)[B].

## ***PHYSICAL EXAM***

- Ophthalmologic (present in 50% of cases): Grittiness/discomfort in the eyes, retrobulbar pressure/pain, lid lag/retraction, proptosis, ophthalmoplegia, papilledema, and loss of color vision may signify optic neuropathy.
- Thyroid: enlarged (goiter), nontender, and without nodules; possible bruit (increased blood flow)
- Integumentary: fine hair, warm skin, onycholysis, palmar erythema, possible pretibial myxedema (orange peel appearance), possible hyperpigmented plaques (dermopathy)
- Cardiac: resting tachycardia, hyperdynamic circulation, possible atrial fibrillation
- Extremities: fine tremor, hyperreflexia, proximal myopathy; rarely, soft tissue edema of extremities and clubbing of digits (acropachy)

## ***DIFFERENTIAL DIAGNOSIS***

- Toxic multinodular goiter (multiple hormone-producing nodules)
- Toxic adenoma (single hormone-producing nodule)
- Thyroiditis (hormone leakage)
  - Subacute, usually postviral (thyroid will be tender)
  - Lymphocytic, including postpartum
  - Hashimoto thyroiditis (antithyropoxidase [TPO] antibodies may stimulate TSH receptors)
- Iatrogenic (treatment-induced)
  - Iodine-induced (dietary, radiographic contrast, or medications)
  - Amiodarone
  - Thyroid hormone overreplacement (accidental or intentional)

- Tumor
  - Pituitary adenoma producing TSH
  - Human chorionic gonadotropin (hCG)-producing tumors (stimulate TSH receptors)
  - Extraglandular thyroid hormone production (e.g., struma ovarii or metastatic thyroid cancer)

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- TSH is initial test: Suppressed (low or undetectable) TSH confirms hyperthyroidism.
- Free T<sub>4</sub> level will be high in Graves disease.
- After confirming suppressed TSH and high T<sub>4</sub>, perform radioactive iodine uptake (RAIU) and scan. Patients with Graves disease will have diffuse, elevated RAIU (vs. localized/nodular elevated uptake in adenoma and multinodular goiter and decreased uptake in thyroiditis or exogenous thyroid hormone).

### *Pregnancy Considerations*

Increase in serum T<sub>4</sub>-binding globulin concentration and initial stimulation of TSH by hCG results in a total T<sub>4</sub> and T<sub>3</sub> rise during first half of pregnancy. The TSH level is decreased throughout pregnancy and should be compared to the trimester-specific ranges for pregnancy. Measurement of thyrotropin receptor antibody (TRAb) is positive in 95% of patients with Graves and should be used if diagnosis is unclear in pregnancy (2)[B].

## TREATMENT

### *MEDICATION*

Goal is to correct hypermetabolic state with the fewest side effects and lowest incidence of posttreatment hypothyroidism.

### *First Line*

- β-blockers provide prompt control of adrenergic symptoms; start while workup is in progress. Long-acting propranolol is used most commonly and titrated to symptom control (40 to 320 mg/day). Calcium channel blockers are an alternative in patients who cannot take β-blockers (3)[C].
- Radioactive iodine (RAI)

- Concentrates in the thyroid gland and destroys thyroid tissue
- Radioiodine plus prednisone therapy might have the least probability of leading to an exacerbation or new appearance of ophthalmopathy, and radioiodine therapy might have the least probability of causing a recurrence (4)[A].
- Treatment of choice for definitive therapy of hyperthyroidism, in the absence of moderate or severe orbitopathy (4)[A]
- High cure rate with single treatment, especially with high-dose regimen
- Risks: side effects (neck soreness, flushing, decreased taste); worsening ophthalmopathy (15% incidence, higher in smokers); posttreatment hypothyroidism (80% incidence, not dosage-dependent); radiation thyroiditis (1% incidence); need to adhere to safety precautions until radiation is eliminated from the body
- May worsen Graves orbitopathy (GO): Symptoms are usually mild and transient in those patients with no or mild ophthalmopathy; however, treatment for patients with moderate to severe GO is still guided by expert opinion pending further study (5)[C].
- Pretreatment with antithyroid medication should be considered in patients with severe disease and the elderly, to reduce risk of posttreatment transient hyperthyroidism and posttreatment radiation thyroiditis as well as quicker return to normal thyroid function. Controversy remains regarding whether pretreatment results in treatment failure, and no definitive data support use (6)[C].
- May be repeated in as soon as 3 months but usually after 6 months if not euthyroid

## *Pregnancy Considerations*

RAI is contraindicated in pregnancy and during breastfeeding.

- Antithyroid drugs: methimazole (MMI) and propylthiouracil (PTU)
  - Compete with the thyroid for iodine, thereby decreasing the synthesis of thyroid hormone; PTU blocks peripheral conversion of  $T_4$  to  $T_3$ .

---

P.429

- Treatment of choice for children and for adults who refuse RAI
- May use as pretreatment for older or cardiac patients before RAI or surgery
- MMI is now almost exclusively used because of its longer duration of action, allowing for once daily dosing, more rapid efficacy, and lower incidence of side effects (2)[A].
- No improvement in remission rates were noted with higher dose MMI; lowest effective dose should be used (7)[B].

- Minor side effects (<5% incidence): controlled by switching from one agent to another: rash, fever, arthralgias, GI side effects
- Major side effects necessitating change in treatment: polyarthritis (1-2%), agranulocytosis (<0.5%), and cholestasis/jaundice (rare)
- Discontinue treatment after 1 year if patient is euthyroid.
- 60% remission rate with 2 years of treatment (standard regimen); newer studies suggest no increased benefit to treatment beyond 18 months (8)[B].
- Relapse rates up to 50% in patients who respond initially; higher rates if smoker, large goiter, or positive thyroid-stimulating antibodies at end of treatment.

### *Pregnancy Considerations*

PTU is preferred in 1st trimester of pregnancy due to teratogenic effects of MMI. Switch to MMI in 2nd and 3rd trimesters due to risk of PTU-induced hepatotoxicity (9)[A].

### *ISSUES FOR REFERRAL*

- Endocrinologist for RAI therapy; if patient is pregnant or breastfeeding
- Graves ophthalmopathy
- Surgery if failed drug therapy or refusing RAI; obstruction or cosmesis

### *ADDITIONAL THERAPIES*

- Symptom control may be achieved with iodides, which block conversion of T<sub>4</sub> to T<sub>3</sub> and inhibit TSH release. Use for pregnant patients who do not tolerate antithyroid medication or in conjunction with antithyroid medications; should not be used long term (may cause paradoxical increase in TSH release) or in combination with radioactive iodine.
- For corneal protection: tinted glasses when outdoors, artificial tears, patching/taping the lids at night
- For orbitopathy: Mild cases can be treated with lubricants, nocturnal ointments, botulinum toxin injection for upper lid retraction, and smoking cessation (10)[C]. Moderate to severe cases should be treated with pulse-dose IV glucocorticoid if no contraindications (11)[C]. Alternative is PO steroid (prednisone 60 to 80 mg/day for 2 to 4 weeks, then taper off).
- For dermopathy, medium- to high-potency topical corticosteroid

### *SURGERY/OTHER PROCEDURES*

With regard to ophthalmopathy progression, postoperative bleeding, permanent hypoparathyroidism, temporary and permanent recurrent laryngeal nerve palsy

thyroidectomy (TT) is consistent with subtotal thyroidectomy (ST) in patients with Graves disease. However, TT is associated with a reduced incidence of recurrent hyperthyroidism and results in an increase in temporary hypoparathyroidism (12)[A].

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Nutritional supplementation with L-carnitine may act as an antagonist of thyroid hormone and reduce hyperthyroid symptoms as well as decrease bone demineralization.

## **INPATIENT CONSIDERATIONS**

Indications for hospital admission:

- Thyroid storm (rare but a life-threatening complication): Admit to ICU.
- Ophthalmopathy with visual impairment: severe cardiac symptoms (heart failure, rapid atrial fibrillation, angina)

## **ONGOING CARE**

## **FOLLOW-UP RECOMMENDATIONS**

### ***Patient Monitoring***

- Monitoring is for the resolution of hyperthyroidism and for the development of hypothyroidism.
- Check TSH and T<sub>4</sub> levels every 1 to 2 months for the first 6 months after treatment, then every 3 months for a year, then every 6 to 12 months thereafter. For patients on treatment with PTU and MMI, check CBC yearly. Also, check anti-TSH receptor antibodies at 12 months of treatment to determine possibility of discontinuing medication.

### ***Pregnancy Considerations***

Postpartum exacerbation of hyperthyroidism is common for women not currently under treatment, so TSH and symptoms should be monitored.

## **PATIENT EDUCATION**

Adherence to both follow-up surveillance and medication regimens is the most important way to achieve a good outcome and promote lifelong health.

## **PROGNOSIS**

- Generally good with treatment

- May have irreversible ocular, cardiac, and psychiatric consequences
- Increased morbidity and mortality due to osteoporosis, atherosclerotic disease, insulin resistance and obesity, and endothelial cell dysfunction (thromboembolic risk)

## COMPLICATIONS

Hypothyroidism is the most common consequence of treatment (25-80%, depending on treatment modality). Patients should be monitored annually, even if asymptomatic.

- E05.20 Thyrotxcosis w toxic multinod goiter w/o thyrotoxic crisis

## Clinical Pearls

&NA;

Thyroid hormone controls metabolic rate and affects many organ systems. Hyperthyroid patients appear hypermetabolic, with symptoms and signs of increased adrenergic tone.

# Guillain-Barré Syndrome

Simon B. Griesbach, MD

Grant M. Reed, DO

## BASICS

### DESCRIPTION

- A group of acquired autoimmune disorders causing acute peripheral neuropathy and ascending paralysis that progressively worsens for up to 4 weeks followed by a slow spontaneous recovery of function.
- Subtypes classified by pattern of neural injury:
  - *Acute inflammatory demyelinating polyradiculoneuropathy (AIDP)*: progressive limb weakness with areflexia (÷95% of GBS cases in Europe and North America)
  - Axonal subtypes:
    - *Acute motor axonal neuropathy (AMAN)*: Pure motor neuropathy strongly associated with *Campylobacter jejuni* and a higher rate of respiratory failure. (÷5% of cases in Europe and North America but 30-47% of cases in China, Japan, and Central and South America.)
    - *Acute motor-sensory axonal neuropathy (AMSAN)*: combined motor-sensory neuropathy; poor prognosis with prolonged course
  - Regional subtypes:
    - *Miller Fisher syndrome (MFS)*: triad with ophthalmoplegia, ataxia, and areflexia; antibodies to GQ1b present in 90% of patients with MFS.
    - *Bickerstaff encephalitis*: possible variant of MFS with encephalopathy, ophthalmoplegia, ataxia, and hyperreflexia
    - *Pharyngeal-cervical-brachial GBS*: Parasympathetic and cholinergic dysfunction leads to neck, arm, and oropharyngeal weakness along with upper extremity areflexia.
  - Sensory subtypes:
    - *Acute pandysautonomia*: orthostatic hypotension, gastroparesis, ileus, constipation/diarrhea, sudomotor/pupillary abnormalities, and neuropathic pain

- *Acute sensory ataxic neuropathy (ASAN)*: controversial variant with sensory loss and ataxia
- *Polyneuritis cranialis*: Bilateral cranial nerve involvement and severe peripheral sensory loss associated with CMV infections.
- Synonym(s): GBS, acute inflammatory demyelinating polyneuropathy; Landry-Guillain-Barré-Strohl syndrome, acute inflammatory idiopathic polyneuritis; acute autoimmune neuropathy; Landry ascending paralysis

### **ALERT**

Rapidly progressing paralysis and respiratory failure occurs in 25-30% of patients. Some require mechanical ventilation within 48 hours.

### **ALERT**

Areflexia is a red flag for GBS in patients with rapidly progressive limb weakness.

### **ALERT**

A history of weakness preceded by respiratory or GI infection suggests GBS.

## **EPIDEMIOLOGY**

### *Incidence*

- Most common acute paralytic disease in Western countries at 0.6 to 4.0/100,000 worldwide
- U.S. incidence: 1.6 to 1.8/100,000, with 4,954 new cases reported from 2000 to 2004.
- Increases with age: 0.8/100,000 in children <18 years of age; 3.2/100,000 in adults >60 years of age
- 1.8 times higher incidence in males compared to females.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Autoimmune targeting of Schwann cell surface membrane, myelin, and/or gangliosides causing destruction and demyelination of peripheral nerves.
- Pathogenesis thought to involve molecular mimicry (i.e., an immune response to antigenic targets that are coincidentally shared by infectious organisms and host peripheral nerve tissue).

### *Genetics*

Host factors appear to play a role in GBS, but no clear genetic risk has been identified.

## RISK FACTORS

- Influenza vaccinations
  - Inactivated seasonal flu vaccines associated with a small increase in GBS risk equivalent to 1 case/million vaccines above background incidence. This compares to 17 cases of GBS per million people infected with influenza virus.
  - Incidence of GBS associated with influenza vaccine has steadily decreased over time.
  - *Of historical note:* Increased incidence during 1976 U.S. National H1N1 Immunization Program had vaccine-attributable risk of 8.8 per million recipients compared to 1.6 per million recipients in the 2009 H1N1 vaccination campaign.

## COMMONLY ASSOCIATED CONDITIONS

- Infection of the respiratory (22-53%) or GI tract (6-26%) in preceding 6 weeks
  - *C. jejuni*: most common precipitant of GBS, (21-32% of cases):
    - Associated with axonal degeneration, slower recovery, more severe residual disability
  - Cytomegalovirus (CMV): Primary CMV infection precedes 10-22% of cases.
  - Rarely associated with *Mycoplasma pneumoniae*, influenza infection, Epstein-Barr virus, varicellazoster virus, and HIV infection

## DIAGNOSIS

### HISTORY

- AIDP presents with onset of progressive limb weakness that reaches its worst within 4 weeks (73% reach a functional nadir in 1 week).
- Preceding respiratory or gastrointestinal infection
- Earliest symptoms include pain, numbness, paresthesias, or limb weakness. These typically affect distal extremities and spread proximally.
- Neuropathic pain, sometimes severe, occurs in 40-50%, commonly in the back and lower extremities.
- Purely sensory symptoms effectively excludes GBS.

## PHYSICAL EXAM

Diagnostic criteria for typical GBS:

- Required for diagnosis:
  - Progressive weakness reaching nadir between 12 hours and 28 days
  - Affects >1 limb
  - Areflexia/hyporeflexia
- Strongly supportive:
  - Paresthesias with only mild changes in objective sensory function (e.g., pinprick, light touch)
  - Relative symmetry
  - Cranial nerve involvement, especially bilateral/symmetric weakness of facial muscles
  - Recovery beginning within 4 weeks after progression ceases
  - Autonomic dysfunction
  - Absence of fever at onset

## *DIFFERENTIAL DIAGNOSIS*

Differential diagnosis of acute flaccid paralysis:

- Brain: basilar artery stroke, brainstem encephalitis
- Spinal cord: transverse myelitis, cord compression
- Motor neuron: poliomyelitis
- Peripheral neuropathy other than GBS: vasculitis, critical illness polyneuropathy, infectious (e.g., diphtheria, Lyme disease), CIDP, acute intermittent porphyria
- Neuromuscular junction: myasthenia gravis, Eaton-Lambert, botulism, toxins (e.g., heavy metals, inhalant abuse, organophosphates)
- Muscle: electrolyte disturbance (hypokalemia, hypophosphatemia), inflammatory myopathy, critical illness myopathy, acute rhabdomyolysis, trichonosis, periodic paralysis
- Psychological causes of weakness

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Studies to establish the diagnosis:
  - Lumbar puncture (LP): Increased CSF protein (>0.55 g/L) without pleocytosis is present in

÷80% of cases (CSF protein is often normal within the first 48 hours of symptom onset).

- Nerve conduction study (NCS): *Most useful confirmatory test*; conduction velocities abnormal in 85% of patients with demyelination, even early in the disease. If nondiagnostic, repeat after 1 to 2 weeks.
- Imaging generally not required. MRI demonstrates spinal nerve root and/or cauda equina enhancement.
- Studies to find underlying cause:
  - Stool culture and serology for *C. jejuni*
  - Acute and convalescent serology for CMV, EBV, HIV, and *M. pneumoniae*
  - Anti-GQ1b antibodies in MFS variant

### *Follow-Up Tests & Special Considerations*

- Analyze CSF prior to treatment with intravenous immunoglobulin (IVIg), which can cause aseptic meningitis.
- A repeat NCS 3 to 8 weeks after onset can classify the subtype of GBS (1)[B].

### *Diagnostic Procedures/Other*

Sural nerve biopsy not indicated except to rule out vasculitis or amyloidosis

## **TREATMENT**

### *GENERAL MEASURES*

- Pain treatment: NSAIDs helpful but often insufficient. Gabapentin and carbamazepine decrease opiate requirements in patients with GBS. One is not superior to the other (2)[A].
- DVT prophylaxis recommended in nonambulatory patients (3)[C].
- Neostigmine or erythromycin may be effective for ileus, if present (3)[C].

---

P.431

### *MEDICATION*

#### *First Line*

- IVIg 0.4 g/kg/day for 5 days
  - In severe disease, IVIg started within 2 weeks of onset hastens recovery as much as

plasma exchange (PE) (4)[A].

- In children, IVIG likely hastens recovery compared with supportive care alone (4)[A].
- Treatment with IVIG after PE confers no clinically significant extra benefit (4)[A].
- Plasma exchange (PE):
  - Compared with supportive treatment alone, those treated with PE have a quicker to recover walking (NNT 7), less requirement and shorter duration for mechanical ventilation (NNT 8), recover full muscle strength more quickly (NNT 8), and have fewer severe sequelae at 1 year (NNT 17) (5)[A].
  - Higher risks of relapse found with PE versus supportive care with no difference in severe infection or mortality (5)[A].
  - In mild GBS, two sessions of PE are superior to none. In moderate GBS, four sessions are superior to two. In severe GBS, six sessions are not significantly better than four (5)[A].
  - PE is most beneficial if started within 7 days of disease onset. It is still helpful until up to 30 days (5)[A].
  - The value of PE in children <12 years old is unknown.

## *Second Line*

- Corticosteroids: not beneficial as monotherapy; do not significantly hasten recovery or affect long-term outcome. Low-quality evidence suggests they delay recovery (6)[A].
- CSF filtration is no different than PE in one small RCT (7)[B].
- Interferon  $\gamma$  and brain-derived neurotrophic factor no different than placebo (7)[B]

## *ADDITIONAL THERAPIES*

- Physical and occupational therapy improve fatigue and functional abilities (3)[C].
- Speech and language therapy improve swallowing function, if affected (3)[C].

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Tripterygium polyglycoside hastened recovery significantly more than corticosteroids (NNT 4), in one small trial (7)[A].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Admit all patients suspected of having GBS.

- Closely monitor respiratory status with serial measurement of vital capacity (VC) and static inspiratory/expiratory pressures ( $PI_{max}$  and  $PE_{max}$ ).
- Predictors of respiratory failure:
  - Rapid progression: <sup>3</sup>3 days between onset of weakness and hospital admission
  - Facial and/or bulbar weakness
  - VC decrease >30%
  - Medical Research Council (MRC) sum score indicating muscle weakness: 0 to 5/5 muscle strength grading for bilateral upper arm abductors, elbow flexors, wrist extensors, hip flexors, knee extensors, and foot dorsal flexors totaling 60 points.
- Indications for intubation:
  - VC <20 mL/kg
  - $PI_{max}$  <30 cm H<sub>2</sub>O
  - $PE_{max}$  <40 cm H<sub>2</sub>O

## *Nursing*

- Prevent complications of immobilization with DVT prophylaxis and frequent turning.
- Respiratory care, aspiration precautions, pulmonary toilet
- Monitor bowel and bladder function for ileus and urinary retention.

## *Discharge Criteria*

Mildly affected patients who can walk unaided and are stable for >2 weeks are unlikely to experience disease progression and may be managed as outpatients. Monitor bowel and bladder function for ileus and urinary retention.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Patients require close monitoring of respiratory, cardiac, and hemodynamic function, typically in the ICU setting.

- Pulmonary function testing (VC, respiratory frequency) q2-6h in the progressive phase and q6-12h in the plateau phase
- Monitor bulbar weakness and ability to handle airway secretions.
- Telemetry in patients with severe disease

## ***PATIENT EDUCATION***

Emphasize expectation for significant recovery and explain phases of illness.

## ***PROGNOSIS***

- If untreated, three phases of illness:
  - Initial progressive phase up to 4 weeks with highest risk of death and complication
  - Variable plateau phase
  - Recovery phase (weeks to months): return of proximal then distal strength
- 80% recover within 6 to 12 months with maximum 18 months past onset
- 20% with residual disability after 1 year:
  - Bilateral footdrop, intrinsic hand muscle wasting, sensory ataxia, dysesthesia
  - Half with severe disability
- Factors associated with poor functional outcome:
  - Age >60 years, rapid progression, severe disease indicated by GBS disability score or MRC sum score, preceding diarrhea, positive *C. jejuni* or CMV serology, axonal degeneration, need for mechanical ventilation

## **COMPLICATIONS**

- 3% mortality at 6 months and 4% at 1 year. Older patients, those with severe disease have highest risk.
- 25-30% require mechanical ventilation.
- 70% develop autonomic dysfunction with hemodynamic instability, urinary retention, ileus, and anhidrosis.
- 10% have relapse
- ~2% develop relapsing chronic inflammatory demyelinating polyradiculoneuropathy (CIDP).

# Codes

&NA;

## ICD10

G61.0 Guillain-Barré syndrome

## Clinical Pearls

&NA;

- Suspect GBS in cases of ascending flaccid paralysis with areflexia and antecedent history of viral respiratory illness or gastroenteritis.
- When GBS is suspected, evaluate VC and inspiratory force for signs of respiratory compromise.
- Uncomplicated GBS has a slow spontaneous recovery. Treatment with IVIG or PE speeds rate of recovery and reduces disability.
- Most useful diagnostic tests are nerve conduction studies and LP.
- GBS risk following influenza infection is 40 to 70 times greater than after seasonal influenza vaccination.

# Gynecomastia

Christine C. Zacharia, MD

Geetha Gopalakrishnan, MD

## BASICS

### DESCRIPTION

- Benign glandular proliferation of male breast tissue
- Increase in estrogens relative to androgens leads to the development of gynecomastia.
- Gynecomastia can be transient and represent the normal physiologic changes that occur in utero or in adolescence. However, gynecomastia presenting or persisting in adulthood is typically pathologic in nature.

### EPIDEMIOLOGY

- 60-90% of infants have transient gynecomastia (1).
- 48-64% of pubertal males have mild transient gynecomastia (onset at 10 to 12 years of age and resolution by age 18 years in most individuals) (1).
- 24-65% of men between 50 and 80 years of age report gynecomastia (2).

### ETIOLOGY AND PATHOPHYSIOLOGY

Increase in estrogen activity relative to androgen activity leads to the development of gynecomastia (3). Estrogen stimulates ductal cell hyperplasia, facilitates ductal branching and lengthening, increases vascularity, and results in the proliferation of periductal fibroblasts. These changes occur within 12 months and are followed by fibrosis in the later stages of gynecomastia. Multiple factors can alter the estrogen to androgen ratio and precipitate gynecomastia:

- Decrease in androgen production
- Increase in estrogen production
- Increase in peripheral conversion to estrogen
- Inhibition of the androgen receptor
- Increase in the level of sex hormone-binding globulin (SHBG) or the affinity of androgens to SHBG (decreases free or bioavailable testosterone)

- Displacement of estrogen relative to testosterone from SHBG due to medications

## **RISK FACTORS**

Gynecomastia can be physiologic or pathologic in nature.

- Physiologic gynecomastia presents in infants and adolescent boys and resolves spontaneously.
  - Neonatal gynecomastia: The placenta converts dehydroepiandrosterone (DHEA) and dehydroepiandrosterone sulfate (DHEA-S) to estrone and estradiol resulting in transient gynecomastia.
  - Adolescent gynecomastia: Transient increases in estradiol levels at the onset of puberty leads to gynecomastia.
- Pathologic gynecomastia refers to persistent or adult-onset gynecomastia. Multiple medications and medical conditions can alter the estrogen to androgen ratio and precipitate gynecomastia. However, 25% of cases are idiopathic in nature.
  - Medications: spironolactone, calcium channel blockers, proton pump inhibitors, cimetidine, efavirenz, ketoconazole, phenytoin, cytotoxic drugs, antidepressants, antiandrogen, estrogen, gonadotropin-releasing hormone (GnRH) agonists, 5-alpha reductase inhibitors, growth hormone (4,5)

### **ALERT**

Illicit drugs (most common cause): marijuana, heroin, methadone, alcohol, amphetamines, over the counter body building supplements

- Primary or secondary hypogonadism
- Testicular tumor: germ cell (secrete human chorionic gonadotropin or hCG), Leydig cell (secrete estrogen), Sertoli cell (excessive aromatization to estrogens)
- Adrenal tumors (secrete DHEA-S and estrogens)
- Ectopic hCG tumors (hepatoblastoma, gastric tumors, renal cell carcinomas)
- Prolactinemia: leads to secondary hypogonadism and gynecomastia. Prolactin can stimulate milk production in breast tissue.
- Hyperthyroidism
- Cirrhosis
- Renal disease or dialysis
- Malnutrition/starvation

Androgen insensitivity syndromes (defect in the androgen receptor)

- True hermaphroditism (both testicular and ovarian tissue present)
- Aromatase excess syndrome (increased peripheral conversion of androgens to estrogen)
- Idiopathic: most likely secondary to age-associated decline in free testosterone and adipose tissue-mediated aromatase activity

### *Pediatric Considerations*

Transient gynecomastia is seen in neonates or pubertal boys. Typically resolves within 6 to 24 months.

### *Geriatric Considerations*

Age-associated decline in testosterone production and increase in SHBG production leads to low free testosterone levels in the elderly population. Furthermore, the increased ratio of fat mass to lean mass noted with aging leads to adipose tissue-mediated peripheral conversion of androgens to estrogen. Both factors contribute to the development of idiopathic gynecomastia in the elderly. Medications also play a significant role in the development of gynecomastia in this population.

## **COMMONLY ASSOCIATED CONDITIONS**

- Peutz-Jeghers syndrome—autosomal dominant disorder associated with Sertoli cell tumors, benign hamartomatous polyps, and mucocutaneous hyperpigmentation
- Carney complex—autosomal dominant disorder associated with Sertoli cell tumors, myxoma, hyperpigmentation of the skin (lentiginosis), and endocrine disorders like Cushing syndrome
- Prostate carcinoma—treatment with estrogen and antiandrogen leads to gynecomastia in 50% of patients
- Klinefelter syndrome—congenital abnormality leads to primary hypogonadism and gynecomastia. These patients are at risk for breast cancer and need regular breast exams.

## **DIAGNOSIS**

### **HISTORY**

- Inquire about duration of breast growth, increase in breast tissue size, and associated breast pain and discharge.
- If suspicious of hypogonadism, ask about erectile dysfunction, muscle mass, and decreased shaving frequency and libido.
- Obtain a complete medical history including headache, loss of vision, loss of

appetite, weight loss, malignancy, thyroid disorders, liver disease, renal disease, and genetic abnormalities.

- Obtain a family history including Carney complex and Peutz-Jeghers syndrome.
- Review medication list extensively and inquire about the use of illicit substances.

## *PHYSICAL EXAM*

- Careful breast exam to evaluate characteristics:
  - Firm, concentric glandular tissue beneath the nipple and areola palpable by pinching the thumb and forefinger together from either side of the breast toward the nipple
  - May involve one or both breasts
  - Usually asymptomatic but may be painful or tender if it is of recent onset
  - Off center, hard, fixed mass is concerning for malignancy while palpation of subareolar fat is more consistent with pseudogynecomastia.
  - Breast discharge should raise concern for malignancy or prolactinemia. In the latter, the discharge is typically clear or milky.
- Thyroid exam (evaluate for diffuse enlargement and palpable nodules and check extremities for tremor and brisk reflexes)
- Abdominal exam (evaluate for masses and liver size)
- Genitourinary exam (evaluate for testicular size, hair pattern, and presence of ovary or uterus)
- Visual field exam (evaluate for peripheral field defect)

## *DIFFERENTIAL DIAGNOSIS*

- Pseudogynecomastia—fat deposition without glandular proliferation often seen in obesity
- Breast cancer—Non exam the lesion is typically unilateral, firm, eccentric to the nipple, and associated with skin dimpling, nipple retraction/discharge, and lymphadenopathy
- Lipomas
- Sebaceous cyst
- Dermoid cyst
- Mastitis
- Hematoma

- Hamartoma

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Laboratory and radiologic investigations should be tailored to fit history and physical exam findings.
- Idiopathic gynecomastia is a diagnosis of exclusion and therefore, laboratory tests to rule out medical conditions associated with gynecomastia is recommended.

### **Initial Tests (lab, imaging)**

- Luteinizing hormone (LH)Ñelevated in primary hypogonadism and decreased in secondary hypogonadism (6)[C]
- Morning total and free testosteroneÑdecreased testosterone level in hypogonadism (6)[C]
- Human chorionic gonadotropin (hCG)Ñelevated in germ cell tumors and ectopic hCG tumors (6)[C]
- EstradiolÑelevated in Leydig cell tumors, Sertoli cell tumors, adrenal tumors, and with increased aromatase activity (6)[C]
- Urine for drugs of abuse (UDA)
- Other tests to consider include creatinine, liver function test, thyroid function tests, and prolactin.

### **Follow-Up Tests & Special Considerations**

Consider imaging studies based on laboratory findings.

- Testicular ultrasound (testicular tumor)
- Chest x-ray (CXR) and abdominal CT/MRI (extragonadal germ cell tumor, ectopic hCG tumor, and adrenal tumor)
- MRI of pituitary (pituitary tumor)

### **Diagnostic Procedures/Other**

Based on physical exam findings, consider biopsy of breast mass to rule out malignancy (i.e., off center, hard, fixed, discharge).

### **Test Interpretation**

- **Elevated hCG:** Check testicular ultrasound. If positive for a mass, likely a testicular germ cell

tumor. If the ultrasound is negative, consider extragonadal germ cell tumor or hCG-secreting neoplasm and order a CXR and CT abdomen (6)[C].

- **Elevated LH:** if in relation to low testosterone, likely primary hypogonadism. If elevated in relation to high testosterone, check thyroid-stimulating hormone (TSH) and free thyroxine (FT4). If FT4 elevated and TSH is suppressed, likely hyperthyroidism; if TSH and FT4 are normal, likely androgen resistance (6)[C]
- **Normal or decreased LH in relation to low testosterone:** Check prolactin level. If prolactin is elevated, likely due to a prolactin-secreting pituitary tumor; if normal, likely due to secondary hypogonadism (6)[C]
- **Normal or decreased LH in relation to increased estradiol:** Check testicular ultrasound. If positive for a mass, likely Leydig or Sertoli cell tumor. If negative for mass, check CT abdomen to evaluate the adrenals. If mass is present, possible adrenal neoplasm versus adenoma; if no mass is detected, then likely due to increased aromatase activity in extraglandular tissue (6)[C]
- **hCG, LH, testosterone, and estradiol are normal:** likely idiopathic or medication/drug-induced gynecomastia (6)[C]

## TREATMENT

### GENERAL MEASURES

- Gynecomastia usually regresses spontaneously within 6 months of onset. This is true even for adult males. Therefore, patients can be monitored for the first 6 months and treatment considered if gynecomastia persists.
- The histologic changes early in the disease process can be reversed with medical therapy. However, with the development of fibrotic tissue, surgery is typically required. Typically, 1 to 2 years after the onset of gynecomastia, fibrotic changes can be seen and medical intervention is less effective (7)[C].
- Neonatal and pubertal gynecomastia spontaneously resolves within 6 to 24 months. Persistent pubertal gynecomastia (>24 months) occurs in 8% of pubertal boys. In adult males, 75% of gynecomastia is secondary to persistent pubertal gynecomastia, medications, and idiopathic conditions. Only 25% is related to an underlying medical condition.
- All illicit drug use and offending medications should be stopped if appropriate, and patients monitored for clinical improvement.
- Underlying medical conditions need to be treated (i.e., testosterone replacement for hypogonadal men, dopamine agonist for prolactinoma, appropriate treatment for

thyrotoxicosis, and tumor resection).

- Medical and surgical therapy to reduce gynecomastia should be considered in patients with significant physical or psychological discomfort.

## **MEDICATION**

- There are no FDA-approved medications for the treatment of gynecomastia but clinical trials involving selective estrogen receptor modulators and aromatase inhibitors demonstrate partial regression and symptom relief (i.e., breast tenderness).
  - Selective estrogen receptor modulators (SERMs): Clinical trials of both tamoxifen (10 to 20 mg/day) and raloxifene (60 mg/day) showed partial reduction in pubertal gynecomastia in 90% of study participants after 3 to 9 months but 40% of patients in both treatment groups were not satisfied with the final results and underwent surgical removal (7)[B]. Tamoxifen has also been shown to reduce breast tenderness and prevent the development of gynecomastia in prostate cancer patients on androgen deprivation therapy. Therefore, SERMs (particularly tamoxifen) can be considered in men with 6 to 12 months of severe, painful gynecomastia symptoms.
  - Aromatase inhibitors block peripheral conversion of androgens to estrogens. In clinical trials, anastrozole (1 mg daily) has shown mixed results with one study reporting reduced breast volume in pubertal males and others not reporting a benefit. In prostate cancer patients, anastrozole prevented the development of gynecomastia in patients undergoing androgen deprivation therapy (8,9)[B].

## **ISSUES FOR REFERRAL**

- Refer patients to an endocrinologist if abnormally elevated hormone levels are confirmed.
- If patients have refractory gynecomastia despite medical therapy and have prolonged gynecomastia characterized by the late fibrotic stage or symptoms concerning for breast cancer, referral to a surgeon would be appropriate.

## **ADDITIONAL THERAPIES**

In clinical trials, prophylactic radiotherapy (10 to 15 Gy in one fraction over 3 days) prevented the development of gynecomastia in prostate cancer patients on androgen deprivation therapy. Higher doses (20 Gy in five fractions) improved pain symptoms in the same population. More studies are needed to evaluate the use of radiation therapy in other populations.

## **SURGERY/OTHER PROCEDURES**

Surgery to remove breast tissue is recommended if:

- Gynecomastia does not regress within 12 months either spontaneously or after medical therapy
- Significant discomfort (i.e., pain, tenderness)
- Causes embarrassment or anxiety
- Biopsy suspicious for malignancy

## ***FOLLOW-UP RECOMMENDATIONS***

### ***Patient Monitoring***

- Every 3 to 6 months for 24 months; consider medical therapy (i.e., tamoxifen) if severe, painful symptoms persist after 6 to 12 months and surgery after 12 to 24 months. In individuals with asymptomatic or mild disease, routine yearly breast and physical exam is recommended.
- Patients with Klinefelter syndrome are at increased risk of breast cancer and should have routine breast exams done.

## ***PATIENT EDUCATION***

Patients should be encouraged to do periodic breast examination and to alert their clinical provider if a nodule is palpated in the breast or axilla, skin discoloration occurs, or nipple discharge develops.

## ***PROGNOSIS***

- Good in physiologic cases, as they often regress spontaneously within 3 to 6 months (6)
- Majority of patients experience regression once underlying disorder is treated or offending agents are eliminated (6).
- In patients who undergo surgery, majority are satisfied with the postop cosmetic appearance (10).

&NA;

Algorithm: Gynecomastia

**&NA;**

## **ICD10**

N62 Hypertrophy of breast

## **Clinical Pearls**

**&NA;**

- Gynecomastia can be transient and represents the normal physiologic changes in neonates or adolescents. However, gynecomastia presenting or persisting in adulthood is typically pathologic in nature.
- Thorough history and physical exam should be performed on all patients and offending medications eliminated.
- Lab and radiologic studies should be conducted to rule out medical conditions associated with gynecomastia including thyrotoxicosis, prolactinemia, hypogonadism, testicular tumors, adrenal tumors, and ectopic hCG tumors. Treatment should be tailored to exam findings.
- ÷25% of gynecomastia is idiopathic in nature and treatment should focus on symptom control.
- Clinical trials of SERMs, aromatase inhibitors, and radiation therapy seem promising. Surgery is the treatment of choice for refractory gynecomastia.

# Hammer Toes

**Nicole Nelson, DO**

**David Bode, MD**

## **BASICS**

Deformities of digits 2 to 5 (ØlesserØ digits) of the foot.

### *DESCRIPTION*

- Plantar flexion deformity of the proximal interphalangeal (PIP) joint with varying degrees of hyperextension of the metatarsophalangeal (MTP) and distal interphalangeal (DIP) joint; primarily in sagittal plane (1)
- Can be flexible, semirigid, or fixed
  - Flexible: passively correctable to neutral position
  - Semirigid: partially correctable to neutral position
  - Fixed: not correctable to neutral position without intervention

### *EPIDEMIOLOGY*

Most common deformity of lesser digits, typically affecting only one or two toes:

- Second toe is the most commonly involved.

### *Incidence*

- Undefined
- Increases with age, duration of deformity (from flexible to rigid)

### *Prevalence*

- Predominant sex: female > male (2)
  - Female predominance from 2.5:1 to 9:1, depending on age group
- Can range from 1% to 20% of population studied
- Blacks are more often affected than whites (2).

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Can be congenital or acquired
- Biomechanical dysfunction results in loss of function of extensor digitorum longus (EDL) tendon at the PIP joint and the flexor digitorum longus (FDL) tendon at the MTP joint; the intrinsic muscles sublux dorsally as the MTP hyperextends. This results in plantar flexion of the PIP joint and hyperextension of the MTP joint (2).
- Specific pathomechanics vary by etiology:
  - Toe length discrepancy or narrow footwear toe box induces PIP joint flexion by forcing digit to accommodate shoe.
    - May also lead to MTP joint synovitis secondary to overuse, with elongation of plantar plate and MTP joint hyperextension
  - Rheumatoid arthritis (RA) causes MTP joint destruction and resultant subluxation.
  - Any condition that compromises intra-articular and periarticular tissues, such as second ray longer than first, inflammatory joint disease, neuromuscular conditions, improper-fitting shoes, and trauma (3)
  - Damage to joint capsule, collateral ligaments, or synovia leads to unstable PIP joint or MTP joint.

### *Genetics*

- Significant heritability rates of 49-90% (4)
- Specific genetic markers are not identified.

## *RISK FACTORS*

- Pes cavus, pes planus
- Hallux valgus
- Metatarsus adductus
- Ankle equinus
- Neuromuscular disease (rare)
- Trauma; improperly fitted shoes (narrow toe box) and/or tight hosiery
- Abnormal metatarsal and/or digit length
- Inflammatory joint disease (e.g., RA)

- Connective tissue disease
- Diabetes mellitus

## **GENERAL PREVENTION**

- Proper fitting of shoes. Use of pressure-dispersive footwear helps reduce pain.
- Foot orthoses modulate biomechanical dysfunction and muscular imbalance, preventing progression (2).
- Control of predisposing factors (e.g., inflammatory joint disease) may also slow progression.

## **COMMONLY ASSOCIATED CONDITIONS**

- Hallux valgus
- Cavus foot
- Metatarsus adductus
- Dorsal callus

## **DIAGNOSIS**

History and physical exam are typically sufficient for diagnosis of hammer toes. Additional tests are available to exclude other conditions.

### **HISTORY**

- Location, duration, severity, and rate of progression of foot deformity
- Type, location, duration of pain
  - Patients often relate sensation of lump on plantar aspect of MTP joint.
- Degree of functional impairment
- Improving/exacerbating factors
- Type of footwear and hosiery worn
- Peripheral neurologic symptoms
- Any prior treatment rendered

### **PHYSICAL EXAM**

- Note MTP joint hyperextension, PIP joint flexion, and DIP joint extension.
- Observe any adjacent toe deformities (e.g., hallux valgus, flexion contractures).

- Assess degree of flexibility and reducibility of deformity in both weight-bearing and non-weightbearing positions (2)[C].
- Note any hyperkeratosis over the joint, ulcers, clavi (dorsal PIP joint, metatarsal head), adventitious bursa, erythema, or skin breakdown (2)[C].
- Palpate for pain over dorsal aspect of PIP joint or MTP joint.
- Drawer test of MTP joint
- Palpate web spaces to exclude interdigital neuroma.
- Neurovascular evaluation (e.g., pulses, sensation, muscle bulk)

## *DIFFERENTIAL DIAGNOSIS*

- Hammer toe: hyperextension of the MTP and DIP joints and plantar flexion of the PIP joint
- Claw toe: dorsiflexion of MTP joint and plantar flexion of the DIP joint
- Mallet toe: fixed or flexible deformity of the DIP joint of the toe
- Overlapping fifth toe
- Interdigital neuroma
- Plantar plate rupture
- Nonspecific synovitis of MTP joint
- Fracture; exostosis
- Arthritis (e.g., rheumatoid, psoriatic)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Not required unless clinically indicated to rule out suspected metabolic or inflammatory arthropathies (2)[C]: rheumatoid factor, antinuclear antibodies (ANA), HLA-B27 serologies for inflammatory disease
- Weight-bearing x-rays of affected foot in anteroposterior (AP), lateral, and oblique views (2)[C]:
  - AP view superior for assessing MTP subluxation or dislocation
  - Lateral view is best for the evaluation of hammer toe.

### *Follow-Up Tests & Special Considerations*

MRI or bone scan if osteomyelitis is suspected

## *Diagnostic Procedures/Other*

- Nerve conduction studies or EMG if neurologic disorder is suspected
- Doppler or plethysmography if impaired circulation and surgery is considered
- Computerized weight-bearing pressure testing is indicated only in setting of neuromuscular deficiencies.

## *Test Interpretation*

Histologic evaluation is not necessary before treatment.

## **TREATMENT**

- Goal of treatment is to relieve symptoms and help patients return to their normal activity level.
- Surgical and nonsurgical interventions are available.
- Mild cases may not require treatment.

## **GENERAL MEASURES**

Nonsurgical (conservative) treatments include

- Shoe modifications (wider and/or deeper toe box) to accommodate the deformity and decrease the pressure over osseous prominences. Avoid high-heeled shoes (2)[C].
- Toe sleeve or orthodigital padding of the hammer toe prominence (5)[C]
- Hammer toe-straightening orthotics or taping to reduce flexible deformities

P.435

- Debridement of hyperkeratotic lesions can reduce symptoms. Topical keratolytics may be helpful (2)[C].
- Shoe orthotics mitigate abnormal biomechanics.
- Physical therapy for stretching and strengthening of the toes helps preserve flexibility.

## **MEDICATION**

For pain relief

### *First Line*

NSAIDs may be helpful in managing symptoms of pain as well as soft tissue and joint inflammation.

## ***ISSUES FOR REFERRAL***

If nonsurgical (conservative) treatment is unsuccessful and/or impractical or patient has combined deformity of MTP joint, PIP joint, and/or DIP joint, then patient may be referred to an orthopedic surgeon or surgical podiatrist.

## ***SURGERY/OTHER PROCEDURES***

- Surgical procedures for the correction of hammer toes depend on the degree and flexibility of the contracture(s) and related abnormalities.
- Surgical interventions for *flexible* hammer toes include (1, 3, 5, 6)[C]
  - PIP joint arthroplasty (most common)
  - Flexor tendon lengthening/flexor tenotomy
  - Extensor tendon lengthening/tenotomy/MTP joint capsulotomy
  - Flexor to extensor tendon transfer
  - Exostosectomy
  - Implant arthroplasty
- Surgical interventions for semirigid/rigid hammer toes include (1,3,5)[C]
  - PIP joint resection arthroplasty or arthrodesis
  - Girdlestone-Taylor flexor-to-extensor transfer
  - Metatarsal shortening (Weil osteotomy)
  - Exostosectomy
  - Diaphysectomy of the proximal phalanx (less common)
  - Middle phalangectomy (less common)
  - Soft tissue releases/lengthening
- Procedures may be performed as isolated operations or in conjunction with other procedures.
- Contraindications for surgery: active infection, inadequate vascular supply, and desire for cosmesis alone

# ONGOING CARE

## *FOLLOW-UP RECOMMENDATIONS*

- Obtain radiographs immediately following surgery or at the first postoperative visit; subsequent x-rays as needed.
- Full weight-bearing in a postoperative (surgical) shoe or other device based on the procedure(s) performed and the individual patient
- Elevate the foot to minimize swelling.
- Return to regular shoe wear after pain is controlled, swelling has subsided, and wounds have healed.
- Role and efficacy of postoperative physical therapy (3 times a week for 2 to 3 weeks) unclear

## *Patient Monitoring*

In the absence of complications, the patient should be seen initially within the 1st week following the procedure(s). Frequency of subsequent visits is determined based on the procedure(s) performed and the postoperative course.

## *PATIENT EDUCATION*

- Patients should be aware of mild to moderate swelling and plantar foot discomfort that may persist for many (1 to 6) months after surgery and may limit footwear options until resolved.
- MTP joint and PIP joint may remain stiff for extended periods of time.
- Molding of the operative toe (assuming the contours of adjacent toes) is common.
- Encourage patients to wear shoes of adequate size with roomy (rounded or squared) toe box.

## *PROGNOSIS*

- Nonoperative (conservative) treatment usually alleviates pain; however, the deformity may progress.
- Surgical treatment of flexible hammer toe deformity reliably corrects the deformity and alleviates pain. Recurrence and progression are common, especially if the patient continues to wear ill-fitting shoes.
- Surgical treatment of fixed hammer toe deformity provides reliable deformity correction and pain relief. Recurrence is uncommon.

## **COMPLICATIONS**

- Common complications specific to digital surgery include but are not limited to
  - Persistent edema
  - Recurrence of deformity
  - Residual pain
  - Excessive stiffness
  - Metatarsalgia
- Less common complications include
  - Numbness (e.g., digital nerve palsy)
  - Flail toe
  - Symptomatic osseous regrowth
  - Malposition of toe
  - Malunion/nonunion
  - Infection
  - Vascular impairment (e.g., toe ischemia, gangrene)

## See Also

&NA;

Algorithm: Foot Pain

## Codes

&NA;

### ICD10

- M20.40 Other hammer toe(s) (acquired), unspecified foot
- M20.41 Other hammer toe(s) (acquired), right foot
- M20.42 Other hammer toe(s) (acquired), left foot

## Clinical Pearls

&NA;

- Hammer toe is a plantar flexion deformity of the PIP joint.
- Initial management of hammer toe deformity is conservative. Consider surgery if pain persists or the deformity worsens.
- Properly fitting footwear helps minimize recurrence. Patients should be aware of mild to moderate swelling and plantar foot discomfort that may persist for months after surgery and may limit footwear options until resolved.

# Hand-Foot-and-Mouth Disease

Lee J. Herskowitz, DO, MBA

## BASICS

### *DESCRIPTION*

- Common acute viral illness affecting mostly children
- Characterized by vesicles on the buccal mucosa and tongue and peripherally distributed small, tender cutaneous lesions on the hands, feet, buttocks, and (less commonly) genitalia
- Group A coxsackieviruses are the most common causative agent (1).
- Synonym(s): herpangina (when affecting oral mucosa and posterior pharynx)

### *EPIDEMIOLOGY*

- Self-limiting illness resolves in 7 to 10 days.
- Moderately contagious
- Infection is spread by direct contact with nasal discharge, saliva, blister fluid, or stool.
- Infected individuals are most contagious during the 1st week of the illness. Some exposed individuals (especially adults) may be asymptomatic but still contagious.
- The viruses that cause hand-foot-and-mouth disease (HFMD) can persist for weeks after symptoms have resolved, most commonly in stool, allowing transmission following resolution of symptoms.
- The incubation period is 3 to 7 days (1).

### *Incidence*

- Children <5 years of age are most commonly affected, especially in day care facilities (1,2).
- Can occur as isolated cases, outbreaks, or epidemics
- Occurs worldwide
- Mother-to-fetus transmission is possible.
- Most large outbreaks occur in Southeast Asia.

## ETIOLOGY AND PATHOPHYSIOLOGY

- HFMS is not the same as foot (hoof) and mouth found in cattle, and there is no cross species infectious concern (3).
- Transmission by the fecal-oral route or contact with skin lesions or oral secretions; caused by viruses that belong to the Enterovirus genus and replicated in the GI tract (3)
- Most commonly coxsackievirus A16
- Also coxsackieviruses A5, A7, A9, A10, B2, B5, and Enterovirus 71

## GENERAL PREVENTION

- Hand washing, especially around food handling or diaper changes
- Exclusion of children from group settings during the first few days of the illness in the presence of open lesions in the mouth or on the skin may reduce the spread of infection.
- Hand hygiene measures are effective in reducing transmission.
- Pregnant woman should avoid contact with infected individuals.

## DIAGNOSIS

### HISTORY

- 1- to 2-day prodrome of fever, anorexia, malaise, abdominal pain, upper respiratory symptoms
- Fever may last 3 to 4 days
- Sore throat (follows fever)
- Painful mouth lesions (often preceding skin lesions)
- Rash on hands and feet
- Often history of sick contacts

## PHYSICAL EXAM

- Tender vesicles or ulcers on buccal mucosa, sides of tongue, and palate
- Begin as small red papules and evolve into vesicles and then ulcerations
- May persist for up to 1 week
- Cutaneous vesicles 3 to 5 mm in diameter start as painful maculopapular eruptions, occur typically on dorsal aspect of fingers and toes.

- May also occur on the palms, soles, buttocks, and groin
- Adults are less likely to have cutaneous findings.

## ***DIFFERENTIAL DIAGNOSIS***

- Herpes simplex
- Herpes zoster
- Scarlet fever
- Roseola infantum
- Fifth disease
- Other enteroviral infections
- Kawasaki disease
- Viral pharyngitis
- Varicella
- Rickettsial infection (RFSF)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Typically clinically diagnosed

### ***Initial Tests (lab, imaging)***

Culture for responsible virus (virus isolation) can be obtained from oral lesions, cutaneous vesicles, nasopharyngeal swabs, stool, and CSF, although not typically performed. PCR of throat swabs and vesicle fluid is the most efficient test if enterovirus 71 is suspected (3).

---

P.437

## **TREATMENT**

- Symptomatic
- Avoid spicy or acidic foods to limit oral pain.
- Numbing sprays or cautious use of viscous lidocaine can be used for oral pain, especially for pharyngitis (use oral topical analgesics)
- IV fluids may be required in more severe cases of dehydration.

## ***MEDICATION***

- Symptomatic care using ibuprofen or acetaminophen for pain from oral ulcers or fever
- Soothing mouthwashes (ÒMAGIC MOUTHWASHÓ) can be compounded by the parents or pharmacy containing equal amounts of viscous lidocaine, diphenhydramine, and Maalox. Instruct to swish and spit (caution in young children due to risk of lidocaine toxicity).

### *Pediatric Considerations*

Avoid aspirin use in treating febrile illness in children.

## **INPATIENT CONSIDERATIONS**

- Patients with CNS manifestations or autonomic dysregulation should require hospitalization.
- Admit those with dehydration unable to maintain adequate oral hydration.

## **ONGOING CARE**

### *DIET*

- Encourage cold liquids (e.g., ice cream, popsicles) to prevent dehydration.
- Avoid acidic, salty, and spicy foods, as they will increase pain.

## **COMPLICATIONS**

- Dehydration most common due to painful oral ulcerations
- Rarely, aseptic meningitis or other neurologic complications
- Fever >3 days and lethargy are associated with CSF pleocytosis.
- Concomitant CNS disease may occur when HFM syndrome is caused by Enterovirus 71. In Southeast Asia, this results in a mortality rate of 3 deaths per 10,000 cases.
- Cardiopulmonary complications include myocarditis, pneumonitis, and pulmonary edema.
- Temporary loss of fingernails or toenails may occur rarely.

## Codes

**&NA;**

### ICD10

- B08.4 Enteroviral vesicular stomatitis with exanthem
- B34.1 Enterovirus infection, unspecified
- B08.5 Enteroviral vesicular pharyngitis

## Clinical Pearls

**&NA;**

- Most common: May to October
- Children <5 years of age tend to have worse symptoms than older children.
- Hand-foot-and-mouth disease is the most common cause of mouth sores in pediatric patients.
- Usually self-limiting, resolving in 7 to 10 days
- Careful handwashing to limit dissemination.

# Headache, Cluster

Jeffrey Phillips, MD

## BASICS

### DESCRIPTION

- Primary headache disorder
- Multiple attacks of unilateral, excruciating, sharp, searing, or piercing pain. Typically localized in the periorbital area and temple accompanied by signs of ipsilateral autonomic features
- Autonomic symptoms: parasympathetic hyperactivity signs (ipsilateral lacrimation, eye redness, nasal congestion) and sympathetic hypoactivity (ipsilateral ptosis and miosis)
- Patients often pace, rubbing their heads to try to alleviate the pain.
- Symptoms usually remain on the same side during a single cluster attack.
- Individual attacks last 15 to 180 minutes if untreated and occur from once every other day to 8 times per day.
- Attacks usually occur in series (cluster periods) lasting for weeks or months separated by remission periods usually lasting months or years. However, about 10-15% of patients have chronic symptoms without remissions.

### EPIDEMIOLOGY

#### *Incidence*

1-year incidence: 53/100,000

#### *Prevalence*

- Lifetime prevalence 124/100,000 ( $\pm$ 0.1%)
- Predominant sex: male > female (4.3:1)
- Mean age of onset: between 29.6 and 35.7 years
- Episodic/chronic ratio 6:1

### ETIOLOGY AND PATHOPHYSIOLOGY

- Complex and incompletely understood
- Proposed mechanisms include the following:
  - Activation of posterior hypothalamus may trigger an attack, causing activation of the trigeminal nerve, leading to intense pain symptoms.
  - Autonomic symptoms: activation of craniofacial parasympathetic nerve fibers secondary to pathologic activation of trigemino-autonomic brainstem reflex

## *Genetics*

- Usually sporadic: autosomal dominant in 5% of cases; autosomal recessive or multifactorial in other families
- Evidence varies: first-degree relatives carry 5- to 8-fold; second degree, 1- to 3-fold increased relative risk of disease

## *RISK FACTORS*

- Male gender
- Age (70% onset before age 30 years)
- Cigarette smoking
- Family history of cluster headache (CH)
- Head trauma
- Alcohol induces attacks during a cluster but not during remission.
- Small amounts of vasodilators (e.g., alcohol, nitroglycerin, sildenafil)
- Strong odors

## *COMMONLY ASSOCIATED CONDITIONS*

- Depression (24%)
- Increased risk of suicide secondary to the extreme nature of the pain
- Medication-overuse headache
- Asthma (9%)
- History of migraine, frequently in female patients
- Sleep apnea (14%)
- Increased prevalence of cardiac right-to-left shunt and patent foramen ovale (relationship

unclear)

## DIAGNOSIS

- Diagnosis is clinical.
- *International Classification of Headache Disorders* (2nd edition) criteria: at least five attacks of severe or very severe unilateral orbital, supraorbital, or temporal pain lasting 15 to 180 minutes if untreated
- At least one of the following:
  - Ipsilateral
    - Conjunctival injection and/or lacrimation
    - Nasal congestion and/or rhinorrhea
    - Eyelid edema
    - Forehead and facial sweating
    - Miosis and/or ptosis
  - Sense of restlessness or agitation
- Attack frequency: one every other day to eight per day
- Episodic CH: at least two cluster periods lasting 7 days to 1 year, separated by a pain-free interval of >1 month (80-90% of cases)
- Chronic CH: cluster-free interval of <1 month in a <sup>3</sup>12-month period

## HISTORY

- Episodic periods of headache described as excruciating, unilateral, sharp, searing, or piercing pain, typically localized in the periorbital area.
- Eye redness, tearing, nasal discharge, sweating
- Timing of headaches often circadian in nature

## PHYSICAL EXAM

- Usually patients seen between attacks
- Acute distress, crying, screaming, restless, and/or agitated during attacks
- Ipsilateral lacrimation, injected conjunctivae, ptosis, and miosis
- Nasal stuffiness or rhinorrhea

- Bradycardia or tachycardia

## *DIFFERENTIAL DIAGNOSIS*

- Paroxysmal hemicrania, short-lasting unilateral neuralgiform headache attacks with conjunctival injection and tearing (SUNCT)
- Hemicrania continua, hypnic headaches, trigeminal and other facial neuralgias, migraine, temporal arteritis, herpes zoster
- Secondary CH:
  - Vertebral or carotid artery dissection, brain arteriovenous malformations, intracranial artery aneurysms
  - Pituitary tumors
  - Nasopharyngeal carcinoma
  - Maxillary sinus with foreign body/sinusitis
  - Cavernous hemangioma
  - Meningiomas/carcinomas/metastases

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Diagnosis is primarily clinical.
- Diagnosis is often delayed (>40% report 5-year delay in diagnosis).
- Consider neuroimaging (MRI/CT head and vascular imaging of brain):
  - Abnormal neurologic exam
  - Suspect secondary CH

## **TREATMENT**

Many of the medications discussed in the following section are used off-label in the treatment of CH.

## *GENERAL MEASURES*

- Avoid major changes in sleep habits.
- Stop smoking.

- Avoid use of alcohol during cluster period.
- Avoid extreme changes in altitude due to changes in oxygen levels.
- Avoid exposure to chemical agents/solvents.

## **MEDICATION**

- Avoid pain therapy, especially narcotic analgesics, for acute attacks.
- Goal is abortion of acute attack and prophylaxis for expected duration of the cluster.
- Assess cardiovascular risk before instituting a vasoactive drug, such as triptans or ergot derivatives.

### **First Line**

For acute attacks:

- Oxygen
  - 100% at 6 to 12 L/min for 15 minutes via nonrebreathing mask provides relief within 15 minutes (1)[A].
  - Avoid in severe chronic obstructive pulmonary disease (COPD) as might affect hypoxic respiratory drive.
- Sumatriptan (Imitrex)
  - 6 mg SC, max 12 mg/24 hr with at least 1 hour between injections is most effective medication for acute attacks. NNT (needed to treat) 2.4 for headache relief in 15 minutes. Sumatriptan nasal spray: 20 mg. May repeat in 2 hours, max dose 40 mg/24 hr NNT 3.2 for headache relief at 30 minutes (2)[A].
- Zolmitriptan
  - Nasal spray: 5- and 10-mg dosage both effective. May repeat in 2 hours, max 10 mg/24 hr. NNT 12 and 4.9 for headache relief in 15 minutes for 5 and 10 mg, respectively. Zolmitriptan tablet: 5- and 10-mg dosage both effective. May repeat in 2 hours, max dose 10 mg/24 hr. NNT 6.7 and 4.5 for headache relief in 30 minutes for 5 and 10 mg, respectively (2)[A].

### **ALERT**

Triptans are contraindicated in ischemic cardiac disease, stroke, uncontrolled hypertension, Prinzmetal angina, basilar migraine, hemiplegic migraine, ischemic bowel disease, and peripheral vascular disease.

- Prophylaxis: used at start of cluster period to prevent and shorten further attacks. Start as soon as possible:
  - Verapamil
    - Can start at 240 mg/day and increase by 40 to 80 mg every 10 to 14 days. Short- or long-acting equivalent. Most patients respond to daily dose of 200 to 480 mg but up to 960 mg/day may be needed. NNT = 1.2 (3)[A]
    - ECG monitoring for doses/increments >480 mg/day required because of risk of bradycardia (q3mo used as a guideline)
    - Similar efficacy to lithium, but fewer adverse effects and faster onset make it the preferred choice.
    - Often used in conjunction with another agent

---

P.439

## Second Line

- Acute attack
  - Lidocaine/**cocaine**: 10 mg (1 mL) of lidocaine or 40 to 50 mg of 10% cocaine intranasal. No well-controlled randomized controlled trials (RCTs) done. Most common side effects are nasal congestion, unpleasant taste (4)[B].
  - Octreotide: SC 100 *&mgr*;g. Can be considered in patients when triptans are contraindicated. Main side effect is GI upset (5)[A].
  - Ergotamine/dihydroergotamine (DHE): original treatments for CH. Now rarely used because of significant side effects. No controlled trials done. Still used for transitional prophylaxis (see below)
- Prophylaxis
  - Lithium: Start 300 mg BID, titrate to therapeutic range of 0.8 to 1.1 mEq/L. Most patients benefit from 600 to 1,200 mg/day. Widely used without formal evidence of efficacy. Retrospective case series show that lithium led to >50% reduction in attack frequency within 2 weeks in 77% of the patients with episodic CH. Must monitor levels of liver, renal, and thyroid function. Caution with nephrotoxic drugs, diuretics. Inferior to verapamil (6)[B]
  - Melatonin: 10 mg in the evening showed reduction in headache frequency versus placebo in small RCT. No side effects were reported.
  - Antiepileptics: topiramate, sodium valproate, gabapentin: Open studies showed reduction of cluster duration and frequency of headache, but RCT did not show superiority to placebo. Significant adverse effects

- Civamide: 100  $\mu$ g/L of 0.025% into each nostril daily. Only studied in episodic CH in one trial of 28 patients. Not available in the United States. Most common side effects were nasal burning, lacrimation, pharyngitis, and rhinorrhea.
- Capsaicin: 0.025% ipsilateral nostril for 7 days, shows benefit in small RCT.
- Methysergide: No studies available to confirm efficacy. Has serious adverse effects, including pulmonary and retroperitoneal fibrosis. Cannot be given with triptans and ergots
- Pizotifen: Modest benefit limited by fatigue and weight gain

## ADDITIONAL THERAPIES

Transitional preventive treatment are as follows:

- Used until longer-term preventive treatment becomes effective. Longer term maintenance agents are started concurrently:
  - Steroids: Several open studies suggested benefit, but no rigorous trials to prove efficacy. Studies support at least 40 mg/day (up to 80 mg/day) prednisone with a 10- to 30-day taper provides benefit to 60-90% patients. Adverse effects for short-term use: insomnia, psychosis, hyponatremia, edema, hyperglycemia, peptic ulcer

### ALERT

Ergots are contraindicated in patients with cardiovascular disease and cannot be used with triptans.

## Pregnancy Considerations

Collaboration between headache specialist, obstetrician, and pediatrician strongly encouraged. Patient should be informed of treatment benefits and risks as well as drug's potential teratogenic effect. For abortive treatment, oxygen is most appropriate first-line therapy. Nasal lidocaine (pregnancy Category B) can be used as second-line therapy. As preventive therapy, verapamil (pregnancy Category C) and steroids (pregnancy Category C) remain the preferred options. Use of SC or intranasal sumatriptan (pregnancy Category C) should be limited as much as possible. Avoid ergotamines (pregnancy Category X).

## ISSUES FOR REFERRAL

Consider a neurology or headache center referral for refractory or complicated patients.

## SURGERY/OTHER PROCEDURES

- Surgery may be considered only for patients who are refractory to, or have contraindications to, medical therapy.

- Various techniques focus on stimulation or ablation of segments of trigeminal nerve root and sphenopalatine ganglion. Other techniques are aimed at decreasing pain and inflammation surrounding the greater occipital nerve.
- Greater occipital nerve steroid injection: A retrospective analysis showed ÷80% of patients with partial or complete response. Effect lasted 3.5 weeks; 21 mg of betamethasone and 2 mL of 2% lidocaine were used. One class I RCT showed benefit within 72 hours in 85% of lidocaine/betamethasone group compared with none in lidocaine/saline group. Cortivazol injection reduced severity and frequency of headache compared with placebo in an RCT (7)[A].
- No evidence for Botox or hyperbaric oxygen treatment
- Neurostimulation
  - Occipital nerve stimulation (ONS) was shown to reduce severity and attack frequency in chronic CH patients.
  - Deep brain stimulation (DBS) of the posterior inferior hypothalamus shows moderate therapeutic effect.
  - Currently investigating sphenopalatine ganglion stimulation

## *INPATIENT CONSIDERATIONS*

Suicidal ideation, unwilling to contract for safety

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Anticipate cluster bouts and initiate early prophylaxis.
- Monitor for depression.
- Watch for adverse medication response and side effects, such as unmasking of underlying cardiovascular disorder when using medications to treat CH.

## *PROGNOSIS*

- Unpredictable course. With aging, attack frequency often decreases.
- Poor prognosis associated with older age of onset, male gender, disease duration of >20 years for episodic form

Possibility of transformation of episodic cluster to chronic cluster and occasionally chronic cluster to episodic cluster

## COMPLICATIONS

- Depression and suicide
- Side effects of medication, including unmasking of coronary artery disease
- Potential for drug abuse/misuse

## See Also

&NA;

Algorithm: Headache, Chronic

## Codes

&NA;

## ICD10

- G44.009 Cluster headache syndrome, unspecified, not intractable
- G44.019 Episodic cluster headache, not intractable
- G44.029 Chronic cluster headache, not intractable

## Clinical Pearls

&NA;

- CHs are rare but disabling. Patients are often agitated and restless during the attack.
- Oxygen and triptans, not narcotics, are first-line therapy for acute attacks.
- Abortive, transitional, and prophylactic treatment must all be considered.

# Headache, Migraine

Benjamin N. Schneider, MD

## BASICS

### DESCRIPTION

Recurrent headache disorder manifesting in attacks lasting 4 to 72 hours. Typical characteristics are unilateral location, pulsating quality, moderate or severe intensity, aggravation by physical activity, and association with nausea and/or photophobia and phonophobia (1).

- Most frequent subtypes of migraine (1):
  - Without aura (common migraine): defining >80% of attacks, often associated with nausea, vomiting, photophobia, and/or phonophobia
  - With aura (classic migraine): visual or other types of fully reversible neurologic phenomenon lasting 5 to 60 minutes
  - Chronic (transformed) migraine: chronic headache pattern evolving from episodic migraine. Migraine-like attacks are superimposed on a daily or near-daily headache pattern (e.g., tension headaches), >15 headache days/month for at least 3 months.
  - Menstrual-related (mofiminal) migraine: associated with onset of menstrual period
- Rare but important subtypes (1):
  - Status migrainosus: debilitating migraine lasting >72 hours
  - With brainstem aura (basilar migraine): brainstem symptoms—dysarthria, vertigo, tinnitus, or ataxia, which are fully reversible and lasting 5 to 60 minutes.
  - Hemiplegic migraine: aura consisting of fully reversible hemiplegia and/or hemiparesis
  - Recurrent painful ophthalmoplegic neuropathy (ophthalmoplegic migraine): neuralgia accompanied by paresis of an ocular cranial nerve with ipsilateral headache
  - Retinal: repeated attacks of monocular visual disturbance, including scintillations, scotomata, or blindness, associated with migraine headache

### EPIDEMIOLOGY

Female > male (3:1)

## *Prevalence*

- Affects >28 million Americans
- Adults: women 18%; men 6%

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- No longer believed to be primarily vascular in etiology; rather, cortical spreading depolarization/depression
- Trigeminovascular hypothesis: hyperexcitable trigeminal sensory neurons in brainstem are stimulated and release neuropeptides, such as substance P and calcitonin gene-related peptide (CGRP), leading to vasodilation and neurogenic inflammation.

## *Genetics*

- >80% of patients have a positive family history.
- Familial hemiplegic migraine has been shown to be linked to chromosomes 1, 2, and 19 (1).

## *RISK FACTORS*

- Family history of migraine
- Female gender
- Stress
- Menstrual cycle, hormones
- Sleep pattern disruption
- Diet: skipped meals (40-56%), alcohol (29-35%), chocolate (19-22%), cheese (9-18%), caffeine overuse (14%), monosodium glutamate (MSG) (12%), and artificial sweeteners (e.g., aspartame, sucralose)
- Medications: estrogens, vasodilators

## *GENERAL PREVENTION*

- Avoid precipitants of attacks.
- Biofeedback, education, and psychological intervention
- Lifestyle modifications are the cornerstone of prevention: sleep hygiene, stress management, healthy diet, and regular exercise.
- Prophylactic medication if attacks are frequent, severely debilitating, or not controlled by acute

## COMMONLY ASSOCIATED CONDITIONS

- Depression, psychiatric disorders
- Sleep disturbance (e.g., sleep apnea)
- Cerebral vascular disease
- Peripheral vascular disease
- Seizure disorders
- Irritable bowel syndrome
- Obesity
- Patent foramen ovale (PFO)
- Medication overuse headache (MOH)

## DIAGNOSIS

Migraine is a clinical diagnosis; thorough history and neuro examination are usually all that are necessary.

### HISTORY

- Screening mnemonic “**P**OUND”: **P**ulsating, duration of 4 to 72 h**O**urs, **U**nilateral, **N**ausea, **D**isabling
  - + Likelihood ratio (LR) = 24 for migraine diagnosis if 4 of 5 criteria are present
  - + LR = 0.41 for migraine diagnosis if 2 criteria are present (2)
    - Headache usually begins with mild pain escalating into unilateral (30-40% bilateral) throbbing (40% nonthrobbing) pain lasting 4 to 72 hours.
    - Intensified by movement and associated with systemic manifestations: nausea (87%), vomiting (56%), diarrhea (16%), photophobia (82%), phonophobia (78%), muscle tenderness (65%), lightheadedness (72%), and vertigo (33%)
    - May be preceded by aura
  - Visual disruptions are most common—scotoma, hemianopsia, fortification spectra, geometric visual patterns, and occasionally hallucinations.
  - Somatosensory disruption in face or arms

- Speech difficulties
  - Obtain headache profile: number of headaches per month; number of days per month headaches limit daily activities; and frequency and amount of all headache medications used.
  - Migraine disability assessment (MiDAS) is a useful tool to assess level of disability and correlates well with headache diaries.
  - Identify possible triggers (e.g., stress, sleep disturbance, food, caffeine, alcohol).

## *PHYSICAL EXAM*

Neurologic exam should be performed including fundoscopy; abnormalities consistent with other causes to severe headaches MIGHT include the following:

- Gait abnormalities and other new cerebellar findings
- Loss of gross and/or fine motor function
- Altered mental status including possible hallucinations (visual, auditory, olfactory)
- Short-term memory loss

## *DIFFERENTIAL DIAGNOSIS*

- Other primary headache syndromes
- If focal neurologic signs/symptoms are present, consider transient ischemic attack (TIA) or stroke.
- Secondary headaches: tumor, infection, vascular pathology, prescription or illicit drug use (MOH)
- Psychiatric disease
- Rarely, atypical forms of epilepsy

## *DIAGNOSTIC TESTS & INTERPRETATION*

Neuroimaging is appropriate ONLY with suspicious symptomatology and/or an abnormality on physical examination (3). Other red flags include the following:

- New onset in patient >50 years of age
- Change in established headache pattern
- Atypical pattern or unremitting/progressive neurologic symptoms

Prolonged or bizarre aura

- Type of imaging: Data are insufficient to make evidence-based recommendations regarding relative sensitivity of MRI compared with CT in the evaluation of migraine or other nonacute headache
- EEG is NOT indicated unless evaluating loss of consciousness or altered mental status.

## *Pregnancy Considerations*

- Frequency may decrease in 2nd and 3rd trimesters.
- Nonpharmacologic methods are mainstay of treatment.
- No treatment drug has an FDA approval during pregnancy.
  - Acetaminophen (Category C) triptans, antiemetics, and short-acting opioids can be considered for acute headaches during pregnancy.
  - Ergotamines are contraindicated (Category X).
  - Avoid herbal remedies.
  - Sumatriptan, naratriptan and opiates are pregnancy Category C risk cannot be rule out but early data suggest no increase in birth defects.
  - Sumatriptan by injection is ideal for breastfeeding women with disabling migraines.
  - Propranolol (Category C) is effective for prophylaxis during pregnancy and lactation.

## **TREATMENT**

### *GENERAL MEASURES*

- Most patients manage attacks with self-care.
- Cold compresses to area of pain
- Withdrawal from stressful surroundings
- Sleep is desirable.
- See also "General Prevention."

### *MEDICATION*

- **First-line abortive treatments**
  - Mild to moderate attacks:

- NSAIDs, such as ibuprofen, naproxen, and diclofenac are inexpensive and effective in up to 60% of cases.
- Aspirin 500 mg-acetaminophen 500 mg-caffeine 130 mg (AAC) combination (e.g., Excedrin Migraine) is an inexpensive, nonprescription, and FDA-approved treatment.

- Moderate to severe attacks:

- Triptans are preferred when OTC agents fail for mild/moderate attacks OR as initial treatment for moderate to severe attacks:
- All triptans have similar efficacy and tolerability, but some patients may respond better to one triptan over another.

P.441

- Early intervention with triptans during the aura, prior to onset of pain, prevent headache 89% of the time.

- Common adverse drug reactions include chest pressure, flushing, weakness, dizziness, feeling of warmth, and paresthesia.

- Suggested initial doses (refer to individual labeling for more detailed dosing instructions)

- Sumatriptan 100 mg PO; 6 mg SQ; 20 mg intranasal

- SQ route quickest onset but most side effects

- Eletriptan 40 mg PO

- Rizatriptan 10 mg PO

- Zolmitriptan 2.5 mg PO; 5 mg intranasal

- Naratriptan 2.5 mg PO

- Frovatriptan 2.5 mg PO

- 44-77% of patients taking triptans report complete pain relief within 2 hours.

- Frovatriptan and naratriptan have slow onset but long half-lives.

- Combination triptan and NSAID: sumatriptan 85 mg/naproxen 500 mg PO at onset of HA show improved efficacy over either alone.

- Antiemetics: Consider anti-nausea medications that antagonize dopamine receptors:

- Metoclopramide, prochlorperazine

- Emergency therapy; 10 to 25 mg single dose (4)[A]

- **Contraindications to treatments**

- Avoid 5-HT-1 agonists (triptans) and ergots in coronary artery disease, peripheral vascular disease, uncontrolled hypertension, and complicated migraine (e.g., brainstem or hemiplegic migraine).
  - Triptans should not be used with ergots, MAOI, or other triptans.
  - Avoid opioids or butalbital in patients with frequent migraines.
- **Precautions**
    - Frequent use of acute-treatment drugs may lead to increase in migraine patterns and medication overuse headache.
- **Second-line abortive treatment**
    - Acetaminophen 1,000 mg or aspirin 975 mg plus the addition of a dopamine antagonist (e.g., metoclopramide 10 mg) may be as effective as PO sumatriptan 100 mg for acute migraine.
    - Ergotamines (e.g., dihydroergotamine SC, Migranal intranasal): drug of choice in status migrainosus and nonpregnant patients but limited use due to side effects and replaced by triptans
    - Opiate use is controversial and can contribute to medication overuse or chronic daily headache with use as few as 8 days per month (5).
      - IV dexamethasone: Use as adjunctive
- **First-line preventative treatment**
    - Prevention should not be limited to pharmacologic agents. Trigger reduction, biofeedback, relaxation techniques, and cognitive behavioral therapy have evidence of efficacy.
    - Lifestyle modifications should be recommended for all migraine sufferers.
    - ÷38% of migraineurs need preventative therapy, but only 3-13% use it (6). Trial and error is needed to determine optimal therapy.
  - The American Migraine Prevalence and Prevention Study recommendations suggest prophylactic treatment when:
    - Quality of life is severely impaired.
    - <sup>3</sup>6 headache days/month of any severity, <sup>3</sup>4 headache days/month of moderate severity, or <sup>3</sup>2 headache days/month of severe impairment.
    - Migraine unresponsive to abortive treatment.
    - Frequent, very long, or uncomfortable auras occur.

- For prevention of *episodic migraine*, divalproex, valproate, topiramate, metoprolol, and timolol are effective for migraine prevention and should be offered to patients to reduce attack frequency and severity (6)[A].
  - NSAIDs are probably effective for migraine prevention, especially for people with predictable triggers (menses, etc.) but pose a risk for MOH.
- For treatment/prevention of *chronic migraine*, the FDA has approved botulinum toxin A (Botox), as it significantly reduced the frequency of headache days in chronic migraineurs.

## ISSUES FOR REFERRAL

- Obscure diagnosis, concomitant medical conditions, significant psychopathology
- Unresponsive to usual treatment
- Analgesic-dependent headache patterns

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Butterbur (*Petasites hybridus*; Petadolex): 50 to 75 mg BID
  - Use caution with CYP3A4 meds.
- Riboflavin (vitamin B<sub>2</sub>): 400 mg/day
- Magnesium: 400 mg/day
- MIG-99 (feverfew): 6.25 mg TID
- Histamine SC: 1 to 10 ng twice weekly
- Acupuncture is at least as effective as, or possibly more effective than prophylactic drug treatment and has fewer adverse effects.

## INPATIENT CONSIDERATIONS

### Admission Criteria/Initial Stabilization

Consider if diagnosis not clear; status migrainosus; may need to exclude intracranial bleeds, TIA, stroke; monitor vital signs and patient comfort.

### IV Fluids

Fluids are a necessary part of inpatient management.

### Discharge Criteria

Judgment based on patient's overall clinical status and patient's ability to tolerate PO medications

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Early intervention is key at the onset of an attack.
- Preventative treatment should aim to decrease frequency and severity of acute attacks, make acute treatments more efficacious, and minimize adverse drug reactions.

### *Patient Monitoring*

- Monitor frequency of attacks, pain behaviors, and medication usage via headache diary.
- Encourage lifestyle modifications. Counsel patients and manage expectations.

### *PATIENT EDUCATION*

Educate patients about migraine triggers.

### *PROGNOSIS*

- With increasing age, there may be a reduction in severity, frequency, and disability of attacks.
- Most attacks subside within 72 hours.

### **COMPLICATIONS**

- Status migrainosus (>72 hours)
- Cerebral ischemic events (rare)
- Medication overuse headache (MOH): Headache occurring 10 or more days/month for >3 months as a consequence of regular overuse of an acute or symptomatic headache medication. Likelihood with butalbital > opiates > triptans > NSAIDs.

## See Also

&NA;

Algorithm: Headache, Chronic

## Codes

&NA;

## ICD10

- G43.909 Migraine, unsp, not intractable, without status migrainosus
- G43.109 Migraine with aura, not intractable, w/o status migrainosus
- G43.409 Hemiplegic migraine, not intractable, w/o status migrainosus

## Clinical Pearls

&NA;

- Migraine is a chronic headache disorder of unclear etiology often characterized by unilateral,

throbbing headaches that may be associated with additional neurologic symptoms.

- Accurate diagnosis of migraine is crucial.
- Consider nonspecific analgesics for milder attacks; migraine-specific treatments (triptans) for more severe attacks.
- Avoid opiates and barbiturates as well as frequent (>8/month) use of triptans or NSAIDs to avoid creating an MOH.
- All patients should be counseled on lifestyle modifications and trigger identification.
- Those with frequent or highly debilitating migraines prophylactic treatment should be encouraged.

# Headache, Tension

Kaelen C. Dunican, PharmD

Brandi Hoag, DO

## BASICS

### DESCRIPTION

- Typically characterized by bilateral mild to moderate pain and pressure; may be associated with pericranial tenderness at the base of the occiput
- Two types
  - Episodic tension-type headache (ETTH) divided into
    - Infrequent: <1 day per month
    - Frequent:  $\geq 1$  but <15 days per month
  - Chronic tension-type headache (CTTH):  $\geq 15$  days per month for  $\geq 3$  months
- Synonym(s): muscle contraction headache; stress headache

### EPIDEMIOLOGY

Most common type of primary headache

#### Prevalence

- Global prevalence in adults is 42% (1).
- Lifetime prevalence is 79%.
- More prevalent among women
- Prevalence of CTTH is 3%.
- Prevalence of ETTH decreases with age, whereas the prevalence of CTTH increases with age.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Debatable: peripheral and/or central mechanisms
- Activation of peripheral nociceptors leads to muscle tenderness in ETTH.

- Central sensitization is associated with CTTH:
  - Nitric oxide may play an important role in central sensitization.
  - Debatable: low-platelet serotonin
- Peripheral: may provoke the central mechanism leading from ETTH to CTTH
- Stress is the most frequently reported precipitating factor.

## *Genetics*

An increased genetic risk has been suggested by studies, particularly for CTTH.

## **RISK FACTORS**

Associated with triggers/precipitating factors

- Stress (mental or physical)
- Change in sleep regimen
- Skipping meals
- Certain foods (caffeine, alcohol, chocolate)
- Dehydration
- Physical exertion
- Environmental factors (sun glare, odors, smoke, noise, lighting)
- Poor or sustained posture
- Female hormonal changes
- Medications (e.g., nitrates, SSRIs, antihypertensives)
- Overuse of abortive headache medication

## **GENERAL PREVENTION**

- Identify and avoid triggers/precipitating factors.
- Minimize emotional stress.
- Encourage relaxation techniques:
  - Biofeedback, relaxation therapy, and physical therapy
  - Consider counseling/psychotherapy.

## COMMONLY ASSOCIATED CONDITIONS

- 83% of patients with migraine headaches also suffer from tension-type headaches.
- Debatable: increased prevalence of comorbid anxiety and depression

## DIAGNOSIS

### HISTORY

Obtain a thorough headache history to rule out other headache disorders, including severity, symptoms, onset, location, and radiation of pain; quality of pain; concurrent medical conditions and medications; and recent trauma or other procedures.

Diagnosis is based on clinical symptoms.

- Diagnostic criteria provided by the International Headache Society:
  - Headache lasting 30 minutes to 7 days
  - At least two of the following:
    - Bilateral location
    - Pressing/tightening (nonpulsating) quality
    - Mild or moderate intensity
    - Not aggravated by routine physical activity
  - Not associated with nausea or vomiting (chronic type may be associated with nausea)
  - No more than one of the following: photophobia or phonophobia
- Headache not due to another disorder
- Fronto-occipital or generalized pain (dull, pressing, or bandlike)
- Associated symptoms:
  - Fatigue
  - Irritability
  - Difficulty concentrating
  - Muscular tightness, tenderness, or stiffness in neck, occipital, and frontal regions

### PHYSICAL EXAM

- General physical exam: vital signs, fundoscopic and cardiovascular assessment, palpation of

the head and neck

- Neurologic exam: mental status, pupillary responses, motor-strength testing, deep tendon reflexes, sensation, cerebellar function, gait testing, signs of meningeal irritation

## *DIFFERENTIAL DIAGNOSIS*

- Migraine headache
- Cluster headache
- Head trauma
- Subarachnoid hemorrhage
- Subdural hematoma
- Unruptured vascular malformation
- Ischemic cerebrovascular disease
- Temporal arteritis
- Arterial hypertension (HTN)
- Cerebral venous thrombosis
- Benign intracranial HTN
- Intracranial neoplasm, infection, or meningitis
- Low CSF pressure
- Medication (nonprescription analgesic dependency, nitrates)
- Caffeine dependency
- Metabolic disorders (hypoxia, hypercapnia, hypoglycemia)
- Toxic effects from drugs or fumes
- Temporomandibular joint syndrome
- Eyes: glaucoma, refractive errors
- Sinusitis or middle ear infection
- Cervical spondylosis
- Severe anemia or polycythemia
- Uremia and hepatic disorders
- Paget disease of bone

## DIAGNOSTIC TESTS & INTERPRETATION

Labs and neuroimaging (CT or MRI) are only necessary when a secondary cause is suspected:

- Atypical pattern of headache (does not fit specific category such as migraine, cluster, or tension)
- Rapid increase in frequency (2)[C]
- Focal neurologic findings
- New onset after age 40 years
- Sudden onset or worsening with exertion CT scan, with and without contrast, is as sensitive as MRI and is the test of choice.
- Use MRI when lesions of the posterior fossa or an aneurysm is suspected.

## TREATMENT

- NSAIDs, acetaminophen (APAP), and aspirin (ASA) are effective for short-term pain relief of ETTH (3,4)[B].
- Amitriptyline should be considered first line for prophylaxis of CTTH (3,4)[B].

## GENERAL MEASURES

Relief measures: relaxation routines; rest in quiet, dark room; hot bath or shower; massage of back of neck and temples

## MEDICATION

Choice of simple analgesic is based on patient-specific parameters:

- NSAIDs may be more effective than APAP for ETTH (3)[C]:
  - Ibuprofen and naproxen may be preferred due to better GI tolerability.
- APAP should be considered for patients taking warfarin, unable to tolerate NSAIDs, or allergic to ASA or NSAIDs.

## First Line

- For acute attack (ETTH): NSAIDs, APAP, or ASA:
  - NSAIDs:
    - Ibuprofen (Motrin, Advil): 400 to 800 mg; may repeat q8h PRN (max 3.2 g/day)

- Naproxen (Naprosyn): 375 to 500 mg or naproxen sodium (Aleve, Anaprox) 440 to 550 mg; may repeat q8-12h PRN (max 1,250 mg base/day)
- Ketoprofen (Orudis): 12.5 to 50 mg; may repeat q6-8h PRN (max 300 mg/day)
- Diclofenac (Voltaren, Cataflam): 50 to 100 mg; may repeat q8h PRN (max 150 mg/day)
- Contraindications: ASA or NSAID allergy or bronchospasm, renal disease, bleeding disorders, increased risk of cardiovascular events (myocardial infarction [MI], stroke, new onset, or worsening of HTN)
- Drug interactions: antihypertensives, anticoagulants, antiplatelet drugs, ASA, lithium, methotrexate
- Adverse effects: epigastric distress, peptic ulcer

P.443

- APAP (Tylenol): 1,000 mg; may repeat q6h PRN (max 4 g/day):
  - Adverse effects (rare): rash, pancytopenia, liver damage
  - Precaution: hepatic impairment, consumption of <sup>33</sup>/day alcoholic beverages
- Aspirin: 500 to 1,000 mg; may repeat q6h PRN (max 4 g/day):
  - Contraindication: ASA or NSAID allergy or bronchospasm, bleeding disorders
  - Drug interactions: anticoagulants, antiplatelet drugs, ACE inhibitors, *&agr*-blockers, corticosteroids, NSAIDs, sulfonylureas
  - Adverse effects: GI irritation/bleeding, thrombocytopenia
- Prophylaxis for CTTH: tricyclic antidepressants (TCAs) (amitriptyline [Elavil]) 10 to 75 mg/day:
  - Not FDA approved for CTTH
  - Contraindications: acute recovery phase of MI, use of monamine oxidase inhibitors (MAOIs) within 14 days
  - Drug interactions: clonidine, MAOIs, quinolone antibiotics, SSRIs, sympathomimetics,azole antifungals, valproic acid
  - Adverse effects: drowsiness, dry mouth, tachycardia, heart block, blurred vision, urinary retention, seizure

## Second Line

- For acute attack (ETTH):
  - Caffeine combinations: 130 mg caffeine with 500 mg APAP and/or 500 mg ASA q6h PRN (3)

[C]

- Narcotic analgesics (rarely indicated; consider secondary causes of headache or secondary gain such as drug-seeking behavior for personal use or diversion/sale)
- Ketorolac: 60 mg IM, single dose
- For CTTH prophylaxis:
  - Mirtazapine: 15 to 30 mg/day (not FDA approved for CTTH) (3,4)[B]
  - Venlafaxine XR (Effexor XR): 37.5 to 300 mg/day (not FDA approved for CTTH) (3,4)[B]

## **ALERT**

Use of abortive agents >2 days/week may lead to *medication-overuse headaches*; must withdraw acute treatment to diagnose.

## *Pediatric Considerations*

ASA and antidepressants are contraindicated.

## **ADDITIONAL THERAPIES**

- The combination of stress management therapy and a TCA (amitriptyline) may be most effective for CTTH.
- Maprotiline: 75 mg/day (not FDA approved for CTTH) (3)[C]
- Topiramate: 100 mg/day (limited clinical evidence for prevention of CTTH; not FDA approved for CTTH)
- Alternative TCAs (although limited evidence of benefit, all are widely used for prophylaxis) (5) [B]
  - Desipramine (Norpramin): 50 to 100 mg/day
  - Imipramine (Tofranil): 50 to 100 mg/day
  - Nortriptyline (Pamelor): 25 to 50 mg/day
  - Protriptyline (Vivactil): 25 mg/day
- Drugs with conflicting clinical evidence for CTTH (not FDA approved for CTTH):
  - Tizanidine: 2 to 6 mg TID
  - Memantine: 20 to 40 mg/day
- Botulinum toxin type A is not likely to be effective for ETTH or CTTH (6)[A].

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Electromyographic (EMG) biofeedback may be effective and is enhanced when combined with relaxation therapy (3,7)[C].
- Cognitive-behavioral therapy may be helpful (3,7)[C].
- Physical therapy, including positioning, ergonomic instruction, massage, transcutaneous electrical nerve stimulation, and application of heat/cold may help.
- Alternative agents (not FDA approved for TTH)
  - Tiger Balm or peppermint oil applied topically to the forehead may be effective for ETTH.
  - Limited evidence for use of acupuncture and physical therapy (7)[B]
- Chiropractic spinal manipulation cannot be recommended for the management of ETTH; recommendations cannot be made for CTTH (8)[B].

## **INPATIENT CONSIDERATIONS**

### **Admission Criteria/Initial Stabilization**

Outpatient treatment

## **ONGOING CARE**

### **FOLLOW-UP RECOMMENDATIONS**

- Regulate sleep schedule.
- Regular exercise

### **DIET**

- Identify and avoid dietary triggers.
- Regulate meal schedule.

### **PATIENT EDUCATION**

For additional information, contact:

- National Headache Foundation: <http://www.headaches.org>
- American Council for Headache Education: <http://www.achenet.org>

## PROGNOSIS

- Usually follows a chronic course when life stressors are not changed
- Most cases are intermittent.

## COMPLICATIONS

- Lost days of work and productivity (more with CTTH)
- Cost to health system
- Dependence/addiction to narcotic analgesics
- GI bleeding from NSAID use

## See Also

&NA;

Algorithm: Headache, Chronic

## Codes

&NA;

### ICD10

- G44.209 Tension-type headache, unspecified, not intractable
- G44.219 Episodic tension-type headache, not intractable
- G44.229 Chronic tension-type headache, not intractable

## Clinical Pearls

&NA;

- Tension-type headache may be difficult to distinguish from migraine without aura. A tension-type headache is typically described as bilateral, mild to moderate, and dull pain, whereas a migraine is typically pulsating, unilateral, and associated with nausea, vomiting, and photophobia or phonophobia.
- Evidence suggests that NSAIDs may be more effective than APAP for ETTH. Consider APAP for patients who cannot tolerate, or have a contraindication, to NSAIDs. Initial dose of APAP should be 1,000 mg (500 mg may not be as effective).
- CTTH is difficult to treat, and these patients are more likely to develop medication-overuse headache. Clinical evidence supports the use of amitriptyline + stress-management therapy for CTTH.
- Medication-overuse headaches must be avoided by limiting use of abortive agents to no more than 2 days/week.
- A headache diary may be useful to identify triggers, response to treatment, and medication-overuse headaches.

# Hearing Loss

Scott A. Wiltz, MD, MPH, FAAFP

## BASICS

### *DESCRIPTION*

- Decrease in the ability to comprehend sound. It can be partial, complete, unilateral, or bilateral.
- Types of hearing loss include conductive hearing loss (CHL or air-bone gap), sensorineural hearing loss (SNHL), or mixed hearing loss.
- System(s) affected: auditory; external and middle ear (CHL) or inner ear (SNHL)

### *EPIDEMIOLOGY*

- All ages affected; common in children (CHL) and elderly (SNHL)
- Usually more severe at an earlier age in men

### *Incidence*

- 37% of people >60 years of age
- At least 1.4 million children (≥18 years of age)
- Sudden sensorineural hearing loss (SSHL) occurs in 5 to 20 per 100,000 persons.

### *Prevalence*

Hearing loss has increased in individuals aged ≥3 years from 13.2 million in 1971 to 37.5 million in 2004.

### *Geriatric Considerations*

- ÷80% of people aged >85 years have hearing loss.
- Hearing aids are underused.
- Loss of communication is a source of emotional stress and a physical risk for the elderly.

### *Pediatric Considerations*

- Congenital hearing loss
  - 1 to 6/1,000 infants have hearing loss.
  - Mandatory screening in >97% of newborns with otoacoustic emission (OAE) and auditory brainstem response (BR) testing
- Audiologic testing after major intracranial infection (meningitis)

## *Pregnancy Considerations*

- Otosclerosis can worsen during pregnancy.
- Maternal infections cause permanent pediatric hearing loss.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- CHL: Hearing loss can result from middle ear effusion, obstruction of canal (cerumen/foreign body, osteomas/exostoses, cholesteatoma, tumor), loss of continuity (ossicular discontinuity), stiffening of the components (myringosclerosis, tympanosclerosis, and otosclerosis), and loss of the pressure differential across the tympanic membrane (TM) (perforation).
- SNHL: damage along the pathway from oval window, cochlea, auditory nerve, and brainstem. Examples include vascular/metabolic insult, mass effect, infection and inflammation, and acoustic trauma.
  - Noise-induced hearing loss is caused by acoustic insult that affects outer hair cells in the organ of Corti, causing them to be less stiff. Over time, severe damage occurs with fusion and loss of stereocilia; eventually may progress to inner hair cells and auditory nerve as well.
- Large vestibular aqueduct or superior canal dehiscence: Third mobile window shunts acoustic energy away from cochlea.

## *Genetics*

- Connexin 26 (13q11-13q12): most common cause of nonsyndromic genetic hearing loss
- Mitochondrial disorders (may predispose to aminoglycoside ototoxicity)
- Otosclerosis: familial
- Most common congenital syndromes
  - Hemifacial microsomia
  - Stickler syndrome

- Congenital cytomegalovirus
- Usher syndrome
- Branchio-oto-renal syndrome
- Pendred syndrome
- CHARGE association
- Neurofibromatosis type 2
- Waardenburg syndrome

## *RISK FACTORS*

- Conductive
  - Chronic sinusitis; allergy
  - Cigarette smoking
  - Sleep apnea with continuous positive airway pressure (CPAP) use
  - Adenoid hypertrophy; nasopharyngeal mass
  - Eustachian tube dysfunction
  - Neuromuscular disease
  - Family history/heredity
  - Prematurity and low birth weight
  - Craniofacial abnormalities (e.g., cleft palate, Down syndrome)
  - Third mobile window (superior canal dehiscence or large vestibular aqueduct)
- Sensorineural
  - Aging/older age
  - Loud noise/acoustic trauma
  - Dizziness/vertigo: especially Ménière disease or history of labyrinthitis
  - Medications (aminoglycosides, loop diuretics, quinine, aspirin, chemotherapeutic agents)
  - Bacterial meningitis
  - Head trauma
  - Atherosclerosis
  - Vestibular schwannoma/skull base neoplasm

- Previous ear surgery
- Sensorineural, pediatric specific
  - Postnatal asphyxia
  - Mechanical ventilation lasting <sup>3</sup>5 days
  - In utero infections (toxoplasmosis, other agents, rubella, cytomegalovirus, herpes simplex [TORCH] syndrome)
  - Toxemia of pregnancy
  - Maternal diabetes
  - Rh incompatibility
  - Prematurity or birth weight < 1,500 g
  - Hyperbilirubinemia; exchange transfusions
  - Anomalous temporal bone (Mondini or large vestibular aqueduct)
  - Infectious diseases: chickenpox, measles, encephalitis, influenza, mumps

## GENERAL PREVENTION

- Limit noise exposure; use hearing protection.
- Avoid ear canal instrumentation (e.g., cotton swabs).
- Limit ototoxic medications.

## DIAGNOSIS

### HISTORY

- There is an indeterminate evidence per the U.S. Preventive Services Task Force for universal screening of hearing loss in adults.
- Social problems and comments from friends and family members are often the first presentation of presbycusis, as patients are often not aware of the degree of hearing loss they experience and how it affects their life. Onset is gradual.
- Difficulty hearing
  - Rapid versus gradual decline: Rapid loss (<3 days) is a medical emergency. Urgent ENT referral and steroid therapy is recommended.
  - Difficulty with discrimination of sounds, hearing in crowds, or turning up

the volume of television sets

- Frequently having to ask speakers to repeat
- Friends/family complain of hearing loss
- Tinnitus, bilateral or unilateral
- Otagia
- Otorrhea, clear or purulent
- Dizziness or vertigo
- Ear fullness
- Autophony (hearing own voice louder or echoing)
- Depression or anxiety
- History of ear infections or ear surgeries
- History of trauma or noise exposure
- Family history of hearing loss
- History of recent viral infection
- Nasal obstruction
- Frequent epistaxis

## *PHYSICAL EXAM*

- A simple 512-Hz tuning fork test lateralizes to unaffected ear in sudden SNHL (emergency) and lateralizes to the affected ear in CHL (not an emergency).
- Whispering screen: A whisper heard from  $\pm 2$  feet away is a good screen for intact hearing. Patients with SNHL have difficulty with this because their hearing loss is usually in the high frequency range.
- 512-Hz tuning fork tests:
  - Sensorineural loss
    - Placed on the forehead: lateralizes to nonaffected ear (Weber test)
    - Base of tuning fork placed on the mastoid and then fork end placed next to ear; heard louder next to ear (Rinne test)
  - Conductive loss
    - Placed on the forehead or teeth lateralizes to affected or symptomatic ear
    - Placed on the mastoid and then next to ear; heard louder behind the ear on the side of conductive deficit

- Otoscopy: Assess for deformity, canal patency, and otorrhea; TM integrity/retraction/mobility with insufflation, canal, or middle ear mass.
- Facial symmetry
- Cranial nerve exam
- Nasopharyngoscopy: adenoid hypertrophy or nasopharyngeal mass (mandatory in adult patient with new unilateral serous effusion)
- Pediatric: Survey for syndromic anomalies.

## *DIFFERENTIAL DIAGNOSIS*

- Conductive
  - Cerumen impaction/foreign body
  - Perforation of TM
  - Middle ear fluid (serous otitis media)
  - Acute otitis media/adhesive otitis media
  - Ossicular erosion (infection, cholesteatoma)
  - Myringosclerosis/tympanosclerosis
  - Temporal bone fracture
  - Otosclerosis
  - Glomus tumor
- Sensorineural
  - Presbycusis (hearing loss related to aging)
  - Noise-induced (recreational, occupational)
  - MŽnière disease
  - Ototoxicity (aspirin, aminoglycosides)
  - Viral labyrinthitis
  - Cerebellopontine angle tumor
  - Large vestibular aqueduct syndrome
  - Syndromic hearing loss

Congenital cochlear malformation

- Syphilis
- Cytomegalovirus; rubella
- Temporal bone fracture
- Metabolic (hyper-/hypothyroidism)
- Paget disease
- Perilymphatic (inner ear) fistula

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Often, labs are not needed. If indicated

- MRI of the brain and brainstem with gadolinium to evaluate SNHL in congenital, early onset, and asymmetric hearing loss
- Fine-cut CT temporal bones without contrast may help in the evaluation of CHL.
- Any pediatric patient with SNHL: Consider genetic testing for connexin 26, mitochondrial studies.
- TORCH screening (congenital infection)
- Rapid plasma reagin (RPR) or Venereal Disease Research Laboratory (VDRL) confirmed by fluorescent treponemal antibody absorption (FTA-ABS)
- Lyme titer in endemic areas
- Antinuclear antibodies and sedimentation rate as a screen for autoimmune disease
- Pendred syndrome (goiter, mental retardation + SNHL): perchlorate test, thyroid function tests
- Alport syndrome (nephritis + SNHL): urinalysis, renal function tests
- Jervell and Lange-Nielsen syndrome (syncope, family history of sudden death + profound SNHL): ECG

## ***Diagnostic Procedures/Other***

- Audiometry: pure tone (air and bone), speech testing, and impedance (middle ear pressure) testing
- Tympanometry: Type B or C tympanograms indicate fluid or retraction, respectively. Negative middle ear peak pressures were seen even with normal (type A) tympanograms.
- Other tests

- Auditory brainstem response
- OAEs: Echo of the cochlea
- Behavioral (visual reinforcement) audiometry; used in children 6 months to 5 years old
- Myringotomy and tubes can be considered for persistent fluid with hearing loss.

## *Test Interpretation*

Varies depending on etiology

## **TREATMENT**

Hearing rehabilitation:

- Personal amplifiers, situation-specific amplification (e.g., amplified phone), or personal hearing aids can be considered for any individual who has significant communication difficulties due to hearing loss.
- Cochlear implants for patients with bilateral severe to profound hearing loss who no longer derive benefit from hearing aids

## *MEDICATION*

- Depends on cause
- Any sudden SNHL (usually unilateral) is a medical emergency; obtain a hearing testing and start steroid therapy.
- Treatment should begin ASAP, ideally within 1 to 2 weeks of onset with high-dose oral steroids: 1 mg/kg or 60 to 100 mg/day prednisone or 12 to 16 mg/day dexamethasone for 7 to 14 days, followed by a taper: For patients who cannot tolerate systematic steroids, intratympanic steroids are equally effective (1)[A].
  - Clinical practical guidelines for sudden hearing loss include the following (2)[C]:
    - Distinguishing SNHL from CHL; testing for bilateral sudden hearing loss in patients with unilateral sudden hearing loss; obtaining an MRI, auditory brainstem response, or audiometric follow-up to evaluate for retrocochlear pathology; offer intratympanic steroid perfusion for refractory cases after initial management fails to treat idiopathic sudden SNHL (ISSNHL) and follow-up within 6 months of diagnosis.
    - May offer corticosteroids as initial therapy to patients with ISSNHL and hyperbaric oxygen within 3 months of ISSNHL diagnosis
    - Recommended against prescribing antivirals, thrombolytics, vasodilators, vasoactive

substances, or antioxidants to patients with ISSNHL

- Also recommended against routine laboratory tests in patients with ISSNHL

## ***ISSUES FOR REFERRAL***

- Audiology: If hearing loss is suspected, refer to audiology for formal evaluation. Audiologists also provide hearing aid options and maintenance.
- Genetics: if congenital syndrome or familial hearing loss is suspected
- Speech therapist: if speech delay or speech impediment is present
- Endocrinology: Pendred syndrome, other associated endocrine disorder (hypo-/hyperthyroidism)
- Cardiology: Jervell and Lange-Nielsen syndrome
- Ophthalmology: Usher syndrome
- Neurology and neurosurgery: cerebellopontine angle (CPA) lesion, intracranial complication of middle ear disease

## ***SURGERY/OTHER PROCEDURES***

- CHL often has surgical options for repair.
  - Tympanostomy and tube placement
  - Tympanoplasty
  - Mastoidectomy
  - Ossicular chain reconstruction
  - Stapedectomy/stapedotomy
  - Canaloplasty
- Those with profound bilateral SNHL may qualify for cochlear implantation.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

Audiogram and clinical exam are the primary means of monitoring patient. Patients with hearing

assistive devices benefit from audiology involvement.

## DIET

Salt restriction to 2 g/day is helpful for patients with Ménière disease.

## PATIENT EDUCATION

National Institute on Deafness and Other Communication Disorders (NIDCD):

<http://www.nidcd.nih.gov/health/hearing/Pages/Default.aspx>

## PROGNOSIS

- SNHL is usually permanent and may be progressive. However, amplification devices (e.g., hearing aids) may help improve functionality.
- ISSNHL may recover spontaneously in 32-70% of cases, but urgent referral and treatment is recommended to maximize recovery. No factors have been proven to predict recovery (3).

## COMPLICATIONS

Acute middle ear problems may become chronic (perforations, cholesteatoma).

## Codes

&NA;

## ICD10

- H91.90 Unspecified hearing loss, unspecified ear
- H90.2 Conductive hearing loss, unspecified
- H90.5 Unspecified sensorineural hearing loss

# Clinical Pearls

**&NA;**

- In sudden hearing loss, if a 512-Hz tuning fork test (Weber test) lateralizes to the *unaffected ear*, suspect sensorineural causes (emergent evaluation needed), but if it lateralizes to the *affected ear*, the diagnosis is CHL (not an emergency).
- ~80% of people aged >85 years have hearing loss, encourage screening and treatment, especially in patients with early dementia.

# Heart Failure, Acutely Decompensated

Bruce L. Lovins, MD

Jennifer M. Slowik, DO, MS

Christopher J. Snyder, MD

## BASICS

### DESCRIPTION

Acute decompensated heart failure (ADHF) is a heterogeneous syndrome of acute impairment in cardiac pump function resulting in inefficient perfusion to bodily tissues. This may be due to structural or functional cardiac disorders and may represent a new diagnosis or worsening of preexisting chronic HF.

### EPIDEMIOLOGY

#### Incidence

- Medicare spends more to diagnose and treat HF than any other medical condition. In 2012, the total cost of HF approached \$30.7 billion. In the United States, there are 870,000 new cases annually. HF is the primary cause of >55,000 deaths each year and a contributing factor in >280,000 deaths.
- 1 million hospital discharges/year and about half of people who have HF die within 5 years of diagnosis.

#### Prevalence

- ~5.7 million people over the age of 20 in the United States carry an HF diagnosis; prevalence is expected to increase 46% from 2012 to 2030 resulting in more than 8 million cases.
- Primarily a disease of the elderly; 75% of hospital admissions for HF are in persons >65 years of age.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Two physiologic components explain most of the clinical findings of ADHF.
  - Systolic dysfunction: an *inotropic* abnormality, often due to myocardial infarction (MI) or dilated or ischemic cardiomyopathy, resulting in diminished systolic emptying (ejection

fraction <45%)

- Diastolic dysfunction: a *compliance* abnormality, often due to hypertensive cardiomyopathy, in which the ventricular relaxation is impaired (ejection fraction >45%).
- Common causes of ADHF
  - Exacerbation of chronic HF caused by dietary or medication nonadherence, infection, or any of the following as cause of new HF or exacerbation
  - Coronary artery disease (CAD), MI (especially new-onset ADHF)
  - Arrhythmia: atrial fibrillation, tachyarrhythmias, high-grade heart block
  - Valvular and vascular abnormalities: aortic stenosis or regurgitation, rheumatic heart disease (mitral and aortic valvular disease)
  - Uncontrolled hypertension (HTN), pulmonary HTN
  - High-output states: hyperthyroidism, anemia
  - Medications: cardiac depressants (*&bgr*;-blocker overdose), chemotherapeutic agents
  - Others: infiltrative disease, Chagas disease, pericardial disease, postpartum cardiomyopathy, wet beriberi, sepsis, COPD, pulmonary embolism

## Genetics

Familial cardiomyopathy predisposes to development of HF (rare).

## RISK FACTORS

- History of chronic HF
- CAD and MI
- HTN, systemic or pulmonary
- Valvular heart disease
- Diabetes mellitus
- Cardiotoxic medications
- Chronic kidney disease and acute kidney injury (AKI)
- Arrhythmia
- Infection

## GENERAL PREVENTION

Control BP and other risk factors. Thiazide diuretics and ACE inhibitors are superior to other agents in preventing development of HF. Treat cardiovascular disease.

## COMMONLY ASSOCIATED CONDITIONS

- Dysrhythmia followed by pump failure is the leading cause of death in ADHF. Most patients have >5 comorbidities (especially CAD, chronic kidney disease, and diabetes) and take >5 medications.
- Cardiogenic shock
- Hyponatremia and altered mental status, especially in the elderly

## DIAGNOSIS

Clinical diagnosis, no gold standard: ED diagnosis of ADHF is incorrect 10-20% of the time.

### HISTORY

- History of HF, prior MI, uncontrolled HTN
- Dyspnea on exertion, deteriorating exercise capacity, fatigue, general weakness, chest pain/discomfort if acute coronary syndrome (ACS) is present.
- Paroxysmal nocturnal dyspnea, orthopnea, nocturnal nonproductive cough, sometimes frothy or pink sputum, wheezing (especially nocturnal) in absence of history of asthma or infection (cardiac asthma)
- Edema, abdominal bloating (ascites), anasarca, cyanosis, weight gain (>2 kg/week)

### PHYSICAL EXAM

- S<sub>3</sub> and/or jugular venous distension most useful positive finding, although no vital sign/PE finding has sensitivity >70%
- Peripheral edema, cool extremities, cyanosis, hepatomegaly, hepatojugular reflux, cardiac murmur, hypotension, laterally displaced apical impulse
- Lung exam: rales (crackles) and sometimes wheezing, Cheyne-Stokes respirations

### DIFFERENTIAL DIAGNOSIS

Pulmonary embolism, exertional asthma, acute MI, cardiac ischemia with angina, chronic obstructive pulmonary disease (COPD), pneumonia, constrictive pericarditis, tamponade, tension pneumothorax, high-output states (anemia, sepsis, hyperthyroidism, ARDS)

## DIAGNOSTIC TESTS & INTERPRETATION

Laboratory data are adjunctive and indicative of complications.

### *Initial Tests (lab, imaging)*

- Cardiac troponins, EKG to evaluate for ACS (1)[C]
- Echocardiogram: Determining ejection fraction (EF) is critical to proper diagnosis and management of heart failure, but may not be necessary in the acute setting if performed recently. Formal echocardiographic study is most useful single test to determine EF and valvular abnormalities; may be repeated if change suspected in underlying cardiac status. Echocardiogram: EF <45% is HF with reduced EF, EF >45% is HF with preserved EF, valvular abnormalities, tamponade (1)[C].
- B-type natriuretic peptide (BNP) and/or N-type pro-BNP (BT-BNP) may be helpful to differentiate the cause of dyspnea if diagnosis is not certain, but is not indicated in routine care of ADHF. Both tests have been shown to have similar specificities and sensitivities in identifying ADHF (2)[A].
- BNP < 100 essentially rules out HF as a cause of dyspnea with negative predictive value of ÷99%. Most dyspneic patients with ADHF have BNP >400.
- BNP values of 100 to 400 are more problematic, as they may indicate HF or may be due to conditions such as pulmonary embolism, AKI, ACS, atrial fibrillation, and pulmonary HTN.
- BNP may be higher in the elderly, lower in the obese
- NT-proBNP values >450 pg/mL for people below age 50, >900 pg/mL ages 50 to 75 years, and >1,800 pg/mL for people older than 75 years are highly suggestive of HF (sensitivity 90%, specificity of 84%) (3)[B].
- Chest x-ray (changes lag clinical symptoms by up to 6 hours): increased heart size (cardiothoracic ratio >50%), vascular redistribution (cephalization) with butterfly pattern of pulmonary edema, interstitial and alveolar edema, Kerley B lines, pleural effusions
- Other labs that may help identify the cause of the decompensation: TSH (hypothyroidism), CBC (anemia), serum creatinine (renal disease) (1)[C]
- Respiratory alkalosis and dilutional hyponatremia (poor prognosis) may also be present.

### *Follow-Up Tests & Special Considerations*

Please see Heart Failure, Chronic topic.

### *Diagnostic Procedures/Other*

Cardiac catheterization may be considered when CAD is suspected. Pulmonary artery catheterization may be performed to guide therapy in severe cases with cardiogenic shock.

## Test Interpretation

Cardiac pathology depends on the etiology of HF. Please refer to Heart Failure, Chronic topic.

## TREATMENT

Approach is to improve symptoms, hemodynamics, and renal function, to minimize myocardial damage and hospital length of stay, and to identify the etiology or precipitating factors. See Heart Failure, Chronic chapter as well.

## MEDICATION

### ALERT

Many medications have been shown to improve hemodynamics and symptoms in ADHF but do not decrease mortality. Diuretics are used initially in fluid overload ADHF, with nitrates added if needed. Nitrates have been used historically to treat ischemic ADHF, but there is no solid evidence-based for this practice, although evidence is sparse (4)[A]. Once ADHF is stabilized, an ACE inhibitor and  $\beta$ -blocker should be started in those with reduced systolic function (5)[A]. Avoid NSAIDs. Avoid use of diltiazem and verapamil in patients with systolic dysfunction.

### First Line

- Loop diuretics initially for fluid-overloaded ADHF in hemodynamically stable patients (contraindicated if SBP <90 mm Hg, severe hyponatremia, acidosis) (6)[A]; be cautious of electrolyte abnormalities if kidney disease is present. Avoid if possible diagnosis of pneumonia. Continuous infusion is not better than bolus, and high dose is not significantly better than low dose (5)[B].
  - Furosemide (Lasix): 40 mg IV
  - If on Lasix chronically, initial IV dose should be equal or exceed chronic oral daily dose (max 180 mg). Monitor for appropriate urine output.
  - Metolazone (Zaroxolyn): 2.5 to 20 mg/day PO, more useful if reduced creatinine clearance
- Thiazides in combination with loop diuretics may be useful if resistant to diuresis (HCTZ 25 mg PO).

Thiazides and spironolactone or eplerenone (25 to 50 mg PO) may be used in combination with loop diuretics if excessive volume overload

- Vasodilators: no change in outcomes but may reduce dyspnea in patients with severe HTN, mitral regurgitation, or acute pulmonary edema; don't use if SBP <90 mm Hg, history of aortic stenosis, or phosphodiesterase inhibitor use (5)[A]
  - IV nitroglycerin may be of short-term benefit to decrease preload, afterload, and systemic resistance (IV 10 to 20  $\mu\text{g}/\text{min}$ ).
  - IV nitroprusside: Administer with caution, infusion rate 5 to 10  $\mu\text{g}/\text{min}$ . Consider an arterial line.
- Morphine: IV boluses 2.5 to 5 mg IV helps with chest pain and restlessness. Monitor respirations.

## Second Line

- Tolvaptan (an oral vasopressin antagonist), for treatment of cognitive symptoms of severe hypovolemic hyponatremia refractory to water restriction and maximum medical therapy (5) [B]
- Inotropes: consider adding if reduced systolic function and signs of hypoperfusion. Withdraw as soon as hemodynamic parameters improve, as these may increase short- and medium-term mortality.
  - Phosphodiesterase inhibitors (milrinone, enoximone) decrease pulmonary resistance; may be used for patients on  $\beta$ -blockers but may increase medium-term mortality in CAD patients
  - Dobutamine infusion requires close BP monitoring; avoid in cardiogenic shock or with tachyarrhythmias.
  - Low-dose dopamine infusion may be considered.
  - Levosimendan (calcium sensitizer) improves hemodynamic parameters but not survival compared to placebo while improving hemodynamic parameters and survival compared to dobutamine
- Nesiritide, a BNP analog, is not recommended for most hospitalized patients with ADHF; higher rates of hypotension, no benefit on death, or rehospitalization rates

## ADDITIONAL THERAPIES

- Oxygen: begin treatment early; ideally, arterial oxygen saturation >92% (90% if COPD). For acute cardiogenic pulmonary edema, noninvasive positive pressure ventilation decreases early

mortality compared to standard therapy (7)[A].

- No significant difference between continuous positive airway pressure (CPAP) and noninvasive positive pressure ventilation (NIPPV). If possible, avoid mechanical ventilation for patients with right HF (7)[A].
- Treat anemia with transfusion: conservative trigger Hgb <8; target Hgb 10.
- For patients with new-onset arrhythmias, consider pacing and/or antiarrhythmics.
- For patients with HF with preserved EF, achieve BP control; no mortality benefit demonstrated with any specific class of medications
- For severe cardiogenic shock, consider intra-aortic balloon pump or percutaneous or surgically implanted ventricular assist devices (VADs).
- Please refer to *Heart Failure, Chronic* for maintenance treatments.

## ***SURGERY/OTHER PROCEDURES***

- Heart valve surgery if defective heart valve is responsible
- PCI/CABG for patients with CAD/MI if applicable
- Cardiac transplantation considered in patients <55 years of age and without other disqualifying medical problems who are developing chronic decompensated HF unresponsive to other therapeutic maneuvers and who are considered to have a life expectancy of >1 year.

## ***INPATIENT CONSIDERATIONS***

Postdischarge appointment, left ventricular EF assessment, and start on ACE inhibitor (or ARB) and *beta*-blocker if left ventricular systolic dysfunction present

### ***Admission Criteria/Initial Stabilization***

See earlier discussion.

- Acute change in HF, with pulmonary edema accompanied by decreased oxygenation, change in mental status, AKI, or significant hyponatremia
- Consider observation unit stay for hemodynamically stable patients with preexisting HF and the following:
  - No acute interventions needed for comorbid condition
  - SBP > 120 mm Hg, BUN <40, creatinine <3.0, absence of elevated troponins/ischemic EKG changes
  - Respiratory rate <32 breaths/min without needing noninvasive ventilation

- No actively titrated vasoactive IV infusions
- Partial improvement in vital signs and/or increased urine output with initial treatment
- Clinical impression that patient could be discharged in the next 24 hours and rapid outpatient follow-up is available.

## *IV Fluids*

1.5 to 2 L/day fluid restriction may be useful to reduce congestive symptoms, especially in the case of hyponatremia (5)[C].

## *Discharge Criteria*

Subjective improvement, resting heart rate (HR) <100 bpm, systolic BP >80 mm Hg, HF outpatient education

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Patient education performed at all outpatient and inpatient visits. Please see *Heart Failure, Chronic* topic.

### *Patient Monitoring*

Rapid office follow-up after hospitalization and home health monitoring by specially trained nurses have both been shown to decrease frequency of hospitalizations.

### *DIET*

Reduce sodium (2 g); maintain cardiac or diabetic diet if these comorbidities are present.

### *PATIENT EDUCATION*

- Definition and etiology: Understand the cause of HF and why symptoms occur.
- Prognosis: Understand important prognostic factors and make realistic decisions.
- Symptom monitoring and self-care: recognize signs/symptoms, record daily weight, know how and when to contact a health care provider; may increase diuretic dose with >1 kg in a day, >2 kg weight gain in 5 days or dyspnea/contact health care provider
- Pharmacologic treatment: Understand indications, dosing, effects, and side effects of drugs.
- Adherence: Understand the importance of maintaining the treatment plan.

Alcohol, smoking, and drugs: Abstinence is recommended in patients with alcohol-induced cardiomyopathy. Otherwise, normal alcohol guidelines apply. Smoking and illicit drug cessation.

- Exercise: Understand the benefits of exercise.

## PROGNOSIS

- The ADHERE risk tree stratifies ADHF patients for inpatient mortality using systolic blood pressure, BUN, and creatinine.
- S<sub>3</sub> on physical exam correlates with poor prognosis.
- After diagnosis, 1-year survival ÷75%, 5-year survival <50%, 10-year survival <25%

## COMPLICATIONS

Arrhythmia, pulmonary edema, hyponatremia, death

## Codes

**&NA;**

### ICD10

- I50.9 Heart failure, unspecified
- I50.21 Acute systolic (congestive) heart failure
- I50.31 Acute diastolic (congestive) heart failure

## Clinical Pearls

**&NA;**

- BNP is overused diagnostically and is best reserved for situations in which diagnosis of ADHF is unclear.
- Look for underlying cause of each episode of ADHF.
- IV diuretics are used initially in fluid-overload acute HF, with nitrates added if needed.
- Using early noninvasive ventilation for the treatment of pulmonary edema can bridge care while awaiting the effects of diuretics, and can decrease morbidity and mortality associated with intubation.

# Heart Failure, Chronic

Jeffrey Shih, MD

David DeNofrio, MD

## BASICS

### DESCRIPTION

- Heart failure (HF) is the condition resulting from inability of the heart to fill and/or pump blood sufficiently to meet tissue metabolic needs. Alternatively, HF may occur when adequate cardiac output can be achieved only at the expense of elevated filling pressures. It is the principal complication of heart disease.
- HF is the preferred term over congestive heart failure because patients are not always congested (fluid overloaded).
- HF may involve the left heart, the right heart, or be biventricular. The New York Heart Association (NYHA) classification is a subjective grading scale used for classifying patients with HF: NYHA I: asymptomatic; NYHA II: symptomatic with moderate exertion; NYHA III: symptomatic with mild exertion and may limit activities of daily living; NYHA IV: symptomatic at rest. For acute HF, see [Heart Failure, Acutely Decompensated](#).

### EPIDEMIOLOGY

The annual direct and indirect cost of HF in the United States is ~\$34.4 billion.

#### *Incidence*

In the United States, 550,000 new cases diagnosed annually with >250,000 deaths per year.

#### *Prevalence*

- ~5.7 million people in the United States have HF; <1% in those age <50 years, increasing to 10% of those age >80 years
- Primarily a disease of the elderly; 75% of hospital admissions for HF are for persons >65 years of age.

### ETIOLOGY AND PATHOPHYSIOLOGY

Two physiologic components explain most of the clinical findings of HF and result in classifications

of patients in four general categories:

- HF with reduced ejection fraction (HFrEF) or systolic HF: an *inotropic* abnormality, often due to myocardial infarction (MI) or dilated cardiomyopathy, resulting in diminished systolic emptying (ejection fraction [EF]  $\approx$ 40%)
- HF with preserved ejection fraction (HFpEF) or diastolic HF: a *compliance* abnormality, often due to hypertensive cardiomyopathy, in which the ventricular relaxation is impaired (EF  $\approx$ 50%)
- Borderline HFpEF (EF 41-49%): mild systolic dysfunction but clinically behaves like HFpEF
- Improved HFpEF (EF  $>$ 40%): previously HFrEF but with improvement in systolic function
- Patients with systolic dysfunction may also have diastolic dysfunction.
- Most common etiologies: coronary artery disease (CAD)/MI and hypertension (HTN)
- Myocarditis and cardiomyopathy (CM): alcoholic, viral, long-standing HTN, drugs (e.g., chemotherapeutic agents), muscular dystrophy, infiltrative (e.g., amyloidosis, sarcoidosis), postpartum state, infectious (e.g., Chagas disease, HIV), hypertrophic CM (HCM), inherited familial dilated CM, left ventricular noncompaction
- Valvular and vascular abnormalities: any valvular stenosis or regurgitation, rheumatic heart; renal artery stenosis, usually bilateral, may cause recurrent flash pulmonary edema, especially in setting of severe chronic HTN
- Chronic lung disease and pulmonary HTN (cor pulmonale)
- Iatrogenic volume overload (requires extreme overload in patients with normal hearts and kidneys)
- Arrhythmias (atrial fibrillation and other tachyarrhythmias, high-grade heart block)
- Miscellaneous: high-output states: hyperthyroidism, anemia; cardiac depressants (e.g., -blocker overdose), stress-induced
- Idiopathic: 20-50% of idiopathic dilated cardiomyopathies are familial.
- HF is progressive—manifested by the remodeling (altered heart geometry) process.

## Genetics

Multiple genetic abnormalities responsible for a variety of phenotypes have been identified (HCM, arrhythmogenic right ventricular [RV] dysplasia, left ventricular [LV] noncompaction, dilated CM). Consider genetic screening for first-degree relatives of HCM and arrhythmogenic RV dysplasia.

## RISK FACTORS

For development of HF: CAD/MI, HTN (80% of cases of HF in the United States caused by either CAD or HTN), valvular heart disease, diabetes mellitus, cardiotoxic medications (e.g.,

anthracyclines, tyrosine-kinase inhibitors, TNF-*α* inhibitors), obesity, older age

## GENERAL PREVENTION

Control HTN and other risk factors. Thiazide diuretics and angiotensin-converting enzyme inhibitors (ACE-I) are superior to other agents in preventing development of HF.

## COMMONLY ASSOCIATED CONDITIONS

Sudden cardiac death and progressive pump failure are the leading causes of death. Most patients have >5 comorbid medical conditions and take >5 medications.

## DIAGNOSIS

### HISTORY

- Dyspnea on exertion: *cardinal sign of left-sided HF*. Deteriorating exercise capacity: easily fatigued, general weakness
- Nocturnal nonproductive cough, orthopnea, and paroxysmal nocturnal dyspnea; sometimes frothy or pink sputum. Wheezing, especially nocturnal, in absence of history of asthma or infection (cardiac asthma); Cheyne-Stokes respirations
- Anorexia and/or fullness or dull pain in right upper quadrant (hepatic congestion). Nausea and poor appetite may indicate advanced HF.

## PHYSICAL EXAM

- Increased filling pressures: rales (crackles) and sometimes wheezing, peripheral edema, S<sub>3</sub> gallop, hepatomegaly, jugular venous distension, hepatojugular reflux, ascites
- Remodeling: enlarged or displaced point of maximal impulse
- Poor cardiac output: hypotension, pulsus alternans, tachycardia, narrow pulse pressure, cool extremities, cyanosis

## DIFFERENTIAL DIAGNOSIS

Simple dependent edema, pulmonary embolism, exertional asthma, cardiac ischemia, asthma/COPD, constrictive pericarditis, nephrotic syndrome, cirrhosis, venous occlusive disease with subsequent peripheral edema, high-output states: anemia, sepsis, hyperthyroidism, lymphedema, tamponade

## DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis should be primarily clinical, with laboratory data as adjunctive and indicative of complications.

### *Initial Tests (lab, imaging)*

- *b*-type natriuretic peptide (BNP) and N-type pro-BNP (NT-BNP) helpful in the acute setting to differentiate the cause of dyspnea (BNP <100 essentially rules out HF; most dyspneic patients with HF have a BNP >400) (1)[A]. Other, non-HF conditions, such as pulmonary embolism, renal failure, and acute coronary syndromes, may cause elevated BNP. Obesity may lower BNP levels. The use of BNP-guided therapy in chronic HF and acutely decompensated HF is not well-established.
- Lab findings include respiratory alkalosis, mild azotemia, decreased ESR, proteinuria (usually < 1 g/day), elevated creatinine (cardiorenal syndrome), dilutional hyponatremia (poor prognosis), hyperuricemia, and hyperbilirubinemia.
- Chest x-ray (changes lag clinical symptoms by up to 6 hours): increased heart size, vascular redistribution (cephalization) with "butterfly" pattern of pulmonary edema, interstitial and alveolar edema, Kerley B lines, and pleural effusions. Findings of pulmonary edema may be absent in long-standing HF.

### *Diagnostic Procedures/Other*

Determination of left ventricular ejection fraction (LVEF) is critical to proper diagnosis and management:

- Echocardiogram is the most useful test to determine LVEF, RV function, diastolic dysfunction, ventricular size, wall thickness, and valvular abnormalities. May be repeated if change suspected in underlying cardiac status
- Nuclear imaging to estimate ventricular sizes, assess for ischemia or infarction and systolic function
- Cardiac MRI can be considered in select circumstances: suspicion of cardiac sarcoidosis, arrhythmogenic RV CM, acute myocarditis, amyloidosis, and hemochromatosis. It is also useful for differentiating restrictive CM and constrictive pericarditis.
- Cardiac catheterization is important for excluding CAD as an etiology in the setting of risk factors.
- Endomyocardial biopsy should not be performed routinely, only in special circumstances (e.g., suspected giant cell myocarditis) that may change therapy (1)[C].

### *Test Interpretation*

Cardiac pathology depends on underlying etiology.

## TREATMENT

### GENERAL MEASURES

Correct and treat risk factors for HF. The treatment of chronic HF is focused on improving hemodynamics, relieving symptoms, and blocking the neurohormonal response to hopefully improve survival.

### MEDICATION

Diuretics are used initially in fluid overload acute HF. The addition of ACE-I and aldosterone antagonists can be added at any time. Once acute HF is stabilized, a  $\beta$ -blocker should be started. Avoid nonsteroidal anti-inflammatory drugs (NSAIDs), which markedly worsen HF. Avoid use of diltiazem and verapamil in patients with systolic dysfunction as they may increase mortality and have negative inotropic effects.

#### First Line

- ACE-I: used to decrease afterload. Shown to increase survival, improve symptoms and overall

P.449

exercise capacity in patients in all NYHA classifications; benefit greatest for patients with systolic dysfunction and post-MI. Number needed to treat (NNT)  $\div$  25 per year for mortality. All ACE-I considered equally effective. Initiate at low doses and titrate as tolerated to target doses.

- Angiotensin receptor blockers (ARBs) are indicated for those who are intolerant to ACE-I. They are probably slightly less effective than ACE-I. Avoid combination of ACE-I and ARB.
- $\beta$ -Blockers: used in systolic or diastolic HF (Note: initiate in hemodynamically stable/compensated patients at low dose and titrate upward slowly); NNT = 25 for mortality. Mortality decreased in systolic HF. Evidence for titration to heart rate rather than specific dose (1)[A].
  - Carvedilol: 3.125 mg PO BID to a target of 25 mg PO BID; metoprolol succinate extended release: 12.5 mg/day PO to a target of 200 mg/day PO or bisoprolol 1.25 to 10 mg once daily (currently not FDA approved for the treatment of HF)
- Diuretics are helpful to manage volume overload/reduce preload.
  - Furosemide (Lasix): 20 to 320 mg/day IV/IM/PO divided dose; bumetanide (Bumex): 0.5 mg to 10 mg/day IV/PO divided dose; torsemide (Demadex): 10 to 200 mg/day PO divided dose (1)[C]
  - Metolazone (Zaroxolyn): 2.5 to 20 mg/day PO divided dose; hydrochlorothiazide: 12.5 to

100 mg/day PO divided dose; chlorothiazide (Diuril): 250 to 2,000 mg/day IV/PO divided dose

- Spironolactone, eplerenone (improve mortality when added to standard therapy in NYHA class II-IV + EF <35%): spironolactone 12.5 to 25 mg/day PO; maximum 50 mg/day PO; eplerenone 25 to 50 mg/day. Caution regarding hyperkalemia and chronic kidney disease (CKD) (1)[A]
- Digoxin reduces symptoms but has not clearly shown any positive effect on mortality: In patients with preserved renal function (creatinine clearance >50 mL/min), the recommended dose is 0.125 mg/day. Levels lower than used for atrial fibrillation are effective and safer (1) [B].
- The combination of hydralazine (75 mg/day divided BID or TID) and isosorbide dinitrate (40 mg QID) is effective for African Americans (1)[A] or if unable to take ACE-I or an ARB (1)[B].
- Ivabradine (Corlanor) is FDA approved to reduce hospitalization from worsening HF based on the SHIFT trial (2). Ivabradine is contraindicated in ADHF, hypotension (<90/50 mm Hg), severe hepatic impairment, pacemaker-dependence, bradyarrhythmias, or strong CYP3A4 inhibitors. It should not be administered to patients that are currently in atrial fibrillation and should be discontinued if atrial fibrillation develops (2)[A].
- Sacubitril/valsartan (Entresto) was approved by the FDA in July of 2015. It is indicated to reduce the risk of CV death and HF hospitalizations in patients with NYHA class II-IV symptoms due to HFrEF based on the PARADIGM HF trial. This medication is used in place of an ACE inhibitor or ARB and in conjunction with other HF therapies (3)[A].
- Anticoagulation is not recommended in patients with HFrEF unless there are other indications such as atrial fibrillation, cardioembolism, or intracardiac thrombus (4)[A].
- In diastolic HF, no medical therapy has improved survival (1,5)[A]. ARBs and spironolactone can be used to potentially reduce hospitalizations (1)[A], (6)[B].

## **ADDITIONAL THERAPIES**

Device therapy including implantable cardioverter defibrillators (ICD) and cardiac resynchronization therapy (CRT) shown to improve outcomes

- CRT is recommended for patients in sinus rhythm with a QRS width  $\geq 150$  ms due to left bundle branch block (LBBB) and LVEF  $\leq 35\%$  and persistent mild to moderate HF (NYHA II-III) despite optimal medical therapy. CRT may be considered for ambulatory NYHA class IV patients in sinus rhythm with a QRS width  $\geq 150$  ms, LBBB, and LVEF  $\leq 35\%$  (1)[A].
- CRT may be considered for patients with LVEF  $\leq 35\%$ , sinus rhythm, QRS width  $\geq 150$  ms, non-LBBB pattern, and NYHA III or ambulatory NYHA IV symptoms (1)[A].

- CRT may also be considered for patients with a QRS width between 120 and 150 ms, LBBB, LVEF  $\geq 35\%$ , and persistent mild to severe HF (NYHA II-IV) despite optimal medical therapy (1) [B].
- ICDs are recommended for primary prevention in patients with *nonischemic* CM and *ischemic* CM who are at least 40 days post-MI; LVEF  $\geq 35\%$ , NYHA class II or III HF (1)[A], or LVEF  $\geq 30\%$ , NYHA I HF (1)[B]; and on optimal medical therapy and  $>1$  year estimated survival. Generally not indicated in American Heart Association (AHA) stage D (end-stage) HF
- CRT is recommended in patients with reduced LVEF and chronic RV pacing or with bradyarrhythmias and an anticipated need for a pacemaker (7)[A].

## ***SURGERY/OTHER PROCEDURES***

- Heart valve surgery if defective heart valve is responsible; mitral valve repair especially helpful if mitral regurgitation is the primary issue and not functional.
- Advanced therapies such as cardiac transplantation and LV assist device (LVAD) implantation can be considered in patients with HF refractory to conventional medical/device therapies without other disqualifying medical and psychosocial conditions. Cardiac transplantation is generally considered for patients  $\geq 70$  years old with a predicted 1-year survival worse than that afforded by transplantation. Indications for LVAD implantation are generally similar to cardiac transplantation but are evolving.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- See Heart Failure, Acutely Decompensated.
- Admit patients with hemodynamic/respiratory compromise, hypoxia/hypoxemia, change in mental status, acute renal insufficiency, significant volume overload, and significant electrolyte abnormalities (e.g., hyponatremia).

### ***Discharge Criteria***

Subjective improvement, euvolemia on clinical assessment, resting heart rate (HR)  $< 100$  bpm, systolic BP  $>80$  mm Hg, HF outpatient education performed

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Critical patient education performed at all outpatient and inpatient physician visits

- Rapid office follow-up (1 to 2 weeks) after hospitalization.

## *Patient Monitoring*

Home health monitoring by specially trained nurses have both been shown to decrease frequency of hospitalizations. Readmissions remain problematic.

## *DIET*

Reduce sodium load (<1.5 to 2 g/day). Optimal level is unknown.

## *PATIENT EDUCATION*

AHA: [www.americanheart.org](http://www.americanheart.org)

## *PROGNOSIS*

After diagnosis: 1-year survival  $\div$ 75%, 5-year survival <50%, and 10-year survival <25%

## **COMPLICATIONS**

Sudden death (arrhythmic), acute pulmonary edema, death, progressive pump failure

Algorithms: Congestive Heart Failure: Differential Diagnosis

## Codes

**&NA;**

### ICD10

- I50.9 Heart failure, unspecified
- I50.1 Left ventricular failure
- I50.22 Chronic systolic (congestive) heart failure

## Clinical Pearls

**&NA;**

- Have patients weigh themselves daily and report weight gains of >2 lb in a day or 5 lb above dry weight.
- *&bgr;*-Blockers, ACE-I, and aldosterone antagonists are the core medications for management of chronic HF.
- Consider referral for biventricular pacing in patients with LBBB and ICD in those with low EF.
- Refer to an HF specialist if frequently hospitalized.

# Heat Exhaustion and Heat Stroke

Sean C. Robinson, MD

Brian Frank, MD

## BASICS

### DESCRIPTION

- A continuum of increasingly severe heat illnesses caused by dehydration, electrolyte losses, and failure of the body's thermoregulatory mechanisms when exposed to elevated environmental temperatures.
  - Heat exhaustion is a mild to moderate form of heat illness displaying dehydration type symptoms with a normal to elevated temperature  $< 104^{\circ}\text{F}$  (1).
  - Heat stroke is characterized by an elevated core temperature  $>104^{\circ}\text{F}$  with central nervous system abnormalities (1,2).
- System(s) affected: endocrine/metabolic, nervous, hepatic, hematologic
- Synonym(s): heat illness; heat injury; hyperthermia; heat collapse; heat prostration

### *Geriatric Considerations*

Elderly persons are more susceptible.

### *Pediatric Considerations*

Children are more susceptible.

### *Pregnancy Considerations*

Pregnant women may be more susceptible to volume depletion with heat stress.

### EPIDEMIOLOGY

- Predominant age: more likely in children or elderly
- Predominant sex: male = female

### *Incidence*

Depends on intensity of heat; estimate of 20/100,000 persons per season (3)

- Concern for increasing incidence of disease if ambient environmental temperatures continue to rise

## *Prevalence*

- Depends on predisposing conditions in combination with environmental factors
- Roughly 600 deaths/year in the United States

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Direct cellular toxicity of heat, imbalance between inflammatory and anti-inflammatory cytokines, and vascular endothelial damage causing end-organ dysfunction
- Interplay between failure of heat-dissipating mechanisms, an overwhelming heat stress, and an exaggerated acute-phase inflammatory response

## *RISK FACTORS*

- Poor acclimatization to heat or poor physical conditioning
- Salt or water depletion
- Obesity
- Acute febrile or GI illnesses
- Chronic illnesses: uncontrolled diabetes mellitus or hypertension, cardiac disease
- Alcohol and other substance abuse
- High heat and humidity, poor air circulation in environment
- Heavy, restrictive clothing
- Nutritional supplementation that includes ephedra (2)
- Medications (*&agr*;-adrenergics, anticholinergics, antihistamines, antipsychotics, benzodiazepines, *&bgr*;-blockers, calcium channel blockers, clopidogrel, diuretics, laxatives, neuroleptics, phenothiazines, thyroid agonists, tricyclic antidepressants) (1)

## *GENERAL PREVENTION*

- The most important factor in preventing heat stress is adequate fluid replacement.
- Allow acclimatization to hot weather through proper conditioning and activity modification.
- Dress appropriately with loose-fitting, open-weaved, light-colored clothing.

- Avoid dehydration by consuming a proper amount of fluids during activity or exercise.
- Never leave children unattended in cars during hot weather.
- Try to gain access to air-conditioned environments during hot weather.

## **PROGNOSIS**

- The prognosis is good when mental function is not altered and when serum enzymes are not elevated; recovery is within 24 to 48 hours in most cases.
- The mortality rate for heat stroke (10-80%) is directly related to the duration and intensity of hyperthermia, as well as to the speed and effectiveness of diagnosis and treatment (3).

## **COMPLICATIONS**

- May involve failure of any major organ system
- Cardiac arrhythmias or infarction
- Pulmonary edema, acute respiratory distress syndrome
- Coma, seizures
- Acute renal failure
- Rhabdomyolysis
- Disseminated intravascular coagulopathy (DIC)
- Hepatocellular necrosis

## **DIAGNOSIS**

- Heat exhaustion: Symptoms are milder than in heat stroke, with no severe CNS derangements:
  - Fatigue and lethargy
  - Weakness
  - Dizziness
  - Nausea, vomiting
  - Myalgias
  - Headache
  - Profuse sweating
  - Tachycardia
  - Hypotension

- Lack of coordination
- Agitation
- Intense thirst
- Hyperventilation
- Paresthesias
- Core temperature usually elevated but can be normal, if elevated < 104°F (40°C)
- Heat stroke: divided into two categories, classic and exertional:
  - Classic: caused by environmental exposure, primarily in elderly or chronically ill patients, and may develop gradually over days
    - Delirium
    - Confusion
    - Coma
    - Core temperature >104°F (>40°C)
    - Hot, flushed, dry skin
  - Exertional: typically younger, very active patients; rapid onset
    - Exhaustion
    - Confusion, disorientation
    - Delirium
    - Coma
    - Hot, flushed skin, typically with sweating
    - Core temperature >104°F (>40°C) (1,2)

## *DIFFERENTIAL DIAGNOSIS*

- Other causes of elevated temperature, dehydration, or circulatory collapse
- Febrile illnesses, sepsis
- Drug-induced fluid loss
- Cardiac arrhythmia or infarction
- Acute cocaine intoxication
- Neuroleptic malignant syndrome

- Malignant hyperthermia (an autosomally inherited disorder of skeletal and cardiac muscle in which patients have abnormal muscle metabolism on exposure to halothane or skeletal muscle reactants)

## **DIAGNOSTIC TESTS & INTERPRETATION**

Used primarily to detect end-organ damage

### ***Initial Tests (lab, imaging)***

- Electrolytes, urinalysis
- Creatinine, BUN
- Liver enzymes, muscle enzymes (creatine phosphokinase)
- CBC
- Increased urine-specific gravity
- Results of these studies may indicate hypernatremia, hyperchloremia, and hemoconcentration.
- Drugs that may alter lab results: diuretics

### ***Diagnostic Procedures/Other***

Rectal temperature monitoring (do not rely on oral temperature) (1,2)[A]

## **TREATMENT**

### **GENERAL MEASURES**

- Fluid and electrolyte replacement with normal saline gradually; avoid hypotonic fluids (1,2)[C].
- Consider CVP monitoring.
- Body immersion in ice water, careful consideration of airway protection (1,3)[C]
- Evaporative cooling: spraying water over the patient and facilitating evaporation and convection with the use of fans (1,3)[C]
- Immersing the hands and forearms in cold water (3)[C]
- Use of ice or cold packs on the neck, groin, and axillae (1,2)[C]
- No clear superiority of any one method (1).

# MEDICATION

## *First Line*

No medications are required in the initial management. Use isotonic saline solution to rehydrate (1,3)[C].

## *Second Line*

- Consider immunomodulators such as corticosteroids.
- Iced gastric, bladder, or peritoneal lavage (3)[C]
- In DIC, consider appropriate replacement therapy.

# INPATIENT CONSIDERATIONS

## *Admission Criteria/Initial Stabilization*

- Important to cool patient before transport if you suspect heat stroke
- Rapid cooling: Remove clothing, wet patient down, and apply ice packs.
- Emergency treatment; best in a hospital setting

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

Rest with legs elevated (3)[C].

## *Patient Monitoring*

- Rectal temperature monitoring: Cooling may be discontinued when the core temperature drops to 102°F (38.9°C) and stabilizes.
- Heat stroke patients may require airway management, hemodynamic monitoring, and careful fluid and electrolyte administration and monitoring.
- Consider CVP monitoring.

## *DIET*

- Cool or cold clear liquids only (noncarbonated)
- Avoid caffeine.
- Unrestricted sodium

## PATIENT EDUCATION

- The key to prevention is proper hydration.
- Stress the importance of proper conditioning and acclimatization.
- Instruct patients to recognize heat stress signs and symptoms.
- Maintain as much skin exposure as possible in hot, humid conditions while using proper sunblock protection.

## Codes

&NA;

## ICD10

- T67.5XXA Heat exhaustion, unspecified, initial encounter
- T67.0XXA Heatstroke and sunstroke, initial encounter
- T67.3XXA Heat exhaustion, anhydrotic, initial encounter

## Clinical Pearls

### **&NA;**

- The diagnosis of heat stroke relies on both hyperthermia and CNS dysfunction (e.g., irritability, ataxia, confusion, seizures, or coma).
- Start the cooling process immediately when heat exhaustion or heat stroke is recognized, beginning with wetting the skin with a cool mist and giving oral rehydration solutions containing saline, if the patient is alert and oriented.
- If in the field (e.g., sporting events, wilderness), cooling should be priority prior to transport
- Do not rely on oral temperature.

# Hematuria

Tracy O. Middleton, DO

## BASICS

### *DESCRIPTION*

- Gross (visible) or microscopic (nonvisible) blood in the urine
- Symptomatic or asymptomatic

### *EPIDEMIOLOGY*

#### *Prevalence*

- Microscopic hematuria in school-aged children: 0.4-4%
- Microscopic hematuria in asymptomatic adults varies from 0.19% to 31%, depending on population (1).

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Trauma
  - Exercise-induced (resolves with rest)
  - Abdominal trauma or pelvic fracture with renal, bladder, or ureteral injury
  - Iatrogenic from abdominal or pelvic surgery; chronic indwelling catheters
  - Foreign body, physical/sexual abuse
- Neoplasms
  - Urologic malignancies
  - Benign tumors
  - Endometriosis of the urinary tract (suspect in females with cyclic hematuria)
- Inflammatory causes
  - UTI: most common cause of hematuria in adults
  - Renal diseases: radiation nephritis and cystitis, acute/chronic tubulointerstitial nephritis (due

to drugs, infections, systemic disease)

- Glomerular disease
  - Goodpasture syndrome (antiglomerular basement membrane disease; autoimmune; associated pulmonary hemorrhage)
  - IgA nephropathy
  - Lupus nephritis
  - Henoch-Schönlein purpura
  - Membranoproliferative, poststreptococcal, or rapidly progressive glomerulonephritis (GN)
  - Wegener granulomatosis
- Endocarditis/visceral abscesses
- Other infections: schistosomiasis, TB, syphilis
- Metabolic causes
  - Stones (85% have hematuria)
    - Hypercalciuria: a common cause of both gross and microscopic hematuria in children
    - Hyperuricosuria
- Congenital/familial causes
  - Cystic disease: polycystic, solitary renal cyst
  - Benign familial hematuria or thin basement membrane nephropathy (autosomal dominant)
  - Alport syndrome (X-linked in 85%; hematuria, proteinuria, hearing loss, corneal abnormalities)
  - Fabry disease (X-linked recessive inborn error of metabolism; vascular kidney disease)
  - Nail-patella syndrome (autosomal dominant; nail and patella hypoplasia; hematuria in 33%)
  - Renal tubular acidosis type 1 (autosomal dominant or autoimmune)
- Hematologic causes
  - Bleeding dyscrasias (e.g., hemophilia)
  - Sickle cell anemia/trait (renal papillary necrosis)
- Vascular causes
  - Hemangioma

- Arteriovenous malformations (rare)
- Nutcracker syndrome: compression of left renal vein and subsequent renal parenchymal congestion
- Renal artery/vein thrombosis
- Arterial emboli to kidney
- Chemical causes
  - Aminoglycosides, cyclosporine, analgesics, oral contraceptives, Chinese herbs
- Obstruction
  - Strictures or posterior urethral valves
  - Hydronephrosis from any cause
  - Benign prostatic hyperplasia: Rule out other causes of hematuria.
- Other causes: loin pain hematuria (most often in young women on oral contraceptives)

## *RISK FACTORS*

- Smoking
- Occupational exposures (dyes, rubber, or tire manufacturing)
- Analgesic abuse (e.g., phenacetin)
- Medications (e.g., cyclophosphamide)
- Pelvic irradiation
- Chronic infection, especially with calculi
- Recent upper respiratory tract infection
- Positive family history of renal diseases (stones, GN)
- Underlying primary renal disorder
- Chronic indwelling foreign body

## **DIAGNOSIS**

### **HISTORY**

#### Considerations

- Burning, urgency, frequency: UTI

- Dark cola-colored urine: glomerular origin
- Clots: extraglomerular bleeding
- Arthritis/arthralgias/rash: lupus, vasculitis, Henoch-Schönlein purpura
- Flank pain: stones, infarction, pyelonephritis
- Recent upper respiratory infection (URI): poststreptococcal GN, membranoproliferative GN
- Concurrent URI: IgA nephropathy
- Excessive vitamin use: stones
- Marathon runner: traumatic, rhabdomyolysis
- Travel: schistosomiasis, TB
- Painless hematuria and/or weight loss: malignancy
- Family history: Alport disease (hereditary nephritis), sickle cell, polycystic, IgA nephropathy, thin basement membrane disease, von Willebrand

## *PHYSICAL EXAM*

### Considerations

- Elevated BP, edema, and weight gain: glomerular disease
- Fever: infection
- Palpable kidney: neoplasm, polycystic
- Genitalia: Look for meatal erosion, lesions

## *DIAGNOSTIC TESTS & INTERPRETATION*

- A hematuria risk index may assist in stratifying patients at risk for urothelial malignancies who require more intensive testing. High-risk indicators are gross hematuria, age >50 years, male gender, and smoking (2)[B].
- Studies are ongoing using urinary biomarkers + clinical factors to predict the likelihood of bladder cancer (3)[B].
- American Urological Association (AUA) suggests upper urinary tract imaging in all adults with unexplained hematuria (4)[C].

### *Initial Tests (lab, imaging)*

- Urine dipstick (sensitivity 91-100%; specificity 65-99%)
  - False negatives are rare but can be caused by high-dose vitamin C.

- False positives: oxidizers (povidone, bacterial peroxidases, bleach), myoglobin, alkaline urine (>9), semen, food coloring, food (beets, blackberries) (1)
  - Phenazopyridine may discolor the dipstick, making interpretation difficult.
- Microscopic urinalysis should always be done to confirm dipstick findings and quantify RBCs.
  - AUA defines clinically significant microscopic hematuria as  $\geq 3$  RBCs/HPF on a properly collected urinary specimen when there is not an obvious benign cause (4)[C].
  - Positive dipstick but a negative microscopic exam should be followed by 3 repeat tests. If any 1 is positive, proceed with a workup (4)[C].
  - Exclude factitious or nonurinary causes, such as menstruation, mild trauma, exercise, poor collection technique, or chemical/drug causes, through cessation of activity/cause and a repeat urinalysis in 48 hours (1)[C].
  - RBC casts are pathognomonic for glomerular origin; dysmorphic cells are also suggestive.
- Voided urine cytology
  - No longer recommended by AUA for routine evaluation of hematuria (4)[C]
  - Some still consider cytology in those with risk factors for urinary malignancy (1)[C].
- Renal function tests (eGFR, BUN, creatinine) to differentiate intrinsic renal disease and to evaluate for risks for imaging contrast dye or certain medications
  - Indicators of renal disease are: significant (>500 mg/day) proteinuria, red cell casts, dysmorphic RBCs, increased creatinine, and albumin:creatinine ratio  $\geq 30$  mg/mmol (4)[C], (5)[A].
- Urine culture if suspected infection/pyuria (1)[C]
- PT/INR for patients on warfarin or suspected of abusing warfarin
- Multidetector CT urography (MDCTU); sensitivity 91-100%, specificity 94-97% (1)[C]
  - The initial imaging of choice in nonpregnant adults with unexplained hematuria (1,6)[C]
  - Highly specific and relatively sensitive for the diagnosis of upper urinary tract neoplasms, especially when >1 cm (6)[C]
  - Higher radiation dose; weigh risk of disease versus risk of radiation exposure.
  - Does not obviate the need for cystoscopy, particularly in high-risk patients (6)[C]
  - Presence of calculi on noncontrast does not exclude another diagnosis or need for contrast phase.
  - Visualization of ureters is discontinuous.

- Less cost-efficient
- CT
  - Perform unenhanced helical CT for suspected stone disease in children if US is negative (7) [C].
  - Perform CT abdomen and pelvis with contrast in children with traumatic hematuria (7)[C].
- Renal ultrasound
  - Best for differentiating cystic from solid masses
  - Sensitive for hydronephrosis
  - No radiation or iodinated contrast exposure
  - Cost-efficient
  - Poor sensitivity for renal masses <3 cm

---

- Point of care US in the emergency room may help patients with suspected stones avoid CT (8)[B].
- US can be used first line in patients with contraindications to CTU or at low risk of malignancy (6)[C].
- Main disadvantage is inability to thoroughly evaluate the urothelium for transitional cell cancer.
- Magnetic resonance urography (MRU)
  - High sensitivity/specificity for renal parenchyma; less useful for collecting system or stones
  - Can be used in patients with contraindications to MDCTU (4,6)[C]
- IV urography (IVU)
  - Limited sensitivity for small renal masses and for differentiating cystic from solid masses
  - Addition of US or CT often necessary to evaluate renal parenchyma, so IVU is rarely used.
  - Potential reactions to IV iodine contrast media
- MRI
  - Similar to CT in sensitivity for renal masses
  - No radiation exposure
  - Least cost-efficient

- Limited ability to reliably detect urinary tract calcifications (6)[C]
- Can be combined with retrograde pyelogram (RPG) for patients who cannot tolerate MDCTU or MRU (4)[C]

## *Diagnostic Procedures/Other*

- Flexible cystoscopy
  - Best for evaluation of bladder pathology, especially small urothelial lesions; negative predictive value for bladder tumors is 99% (1)[C].
  - AUA recommends all patients with hematuria who are  $\geq 35$  years of age and all patients with risk factors for bladder cancer regardless of age to receive cystoscopy in addition to imaging (4)[C].
- Renal biopsy
  - Not routine but may be necessary to diagnose GN or in the face of increasing renal insufficiency
- RPG
  - Reserved for patients in which findings on MDCTU are equivocal or in addition to US or noncontrast studies in patients who are contraindicated for contrast or MRI (4,6)[C]
  - Sensitive for small lesions of supraventricular collecting system
  - Requires cystoscopy
- Ureteroscopy/pyeloscopy
  - For visualization of suspected supraventricular collecting system lesions
  - Biopsy, excision, fulguration, or extraction of lesions/stones possible
  - Requires anesthesia
  - Requires cystoscopy
  - Risk of injury to collecting system

## *Follow-Up Tests & Special Considerations*

- Other tests depend on suspected etiology: STD testing, antineutrophil cytoplasmic antibody (ANCA), C3, C4, antistreptolysin O (ASO) titer, hemoglobin electrophoresis (9)[C].
- Consider genetic testing in patients suspected of having familial hematuria (10)[C].
- Insufficient evidence to recommend routine use of urinary tumor markers

- Malignancies are detected in up to 5% of patients with microscopic hematuria and up to 40% of patients with gross hematuria (1)[C].

## *Pregnancy Considerations*

Renal US is initial imaging choice for pregnant patients (6)[C]. MRU or RPG combined with either MRI or US are alternatives (4)[C].

## *Pediatric Considerations*

- Consider GN, Wilms tumor, child abuse, and hypercalciuria.
- Isolated asymptomatic microscopic hematuria may not need full workup; these patients rarely need cystoscopy; observe for development of hypertension, gross hematuria, or proteinuria (9) [C].
- Gross or symptomatic hematuria needs a full workup.
  - If eumorphic RBCs, consider US (rule out stones, congenital abnormalities) and urinary Ca:Cr ratio. Urine Ca:Cr ratio >0.2 is suggestive of hypercalciuria in children >6 years of age (9)[C].
- If dysmorphic RBCs, consider renal consult.
- Renal US identifies most congenital and malignant conditions; CT is reserved for cases of suspected trauma (with contrast) or stones (without contrast) (7,9)[C].

## **TREATMENT**

### *MEDICATION*

None indicated for undiagnosed hematuria

### *ISSUES FOR REFERRAL*

Prompt nephrology referral for proteinuria, red cell casts, elevated serum creatinine, and albumin:creatinine ratio  $\geq 30$  mg/mmol (4,5)[A].

### *SURGERY/OTHER PROCEDURES*

Gross hematuria: Clots may require continuous bladder irrigation with a large-bore Foley catheter (2- or 3-way catheter may be helpful) to prevent clot retention.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

Some experts still recommend periodic urinalysis; recent literature suggests that, after thorough initial negative investigations (imaging, cystoscopy), no follow-up is indicated for the asymptomatic patient with microscopic hematuria unless symptoms or frank hematuria develop. AUA recommends annual urinalyses in these patients, until two consecutive are negative and the consideration for a repeat workup at 3 to 5 years if hematuria is persistent (1,4)[C].

#### *DIET*

Increased fluids for stones or clots

### PROGNOSIS

- Generally excellent for common causes of hematuria
- Poorer for malignant tumors and certain types of nephritis
- Persistent asymptomatic microscopic hematuria is associated with an increased risk of end-stage renal disease in patients aged 16 to 25 years.

&NA;

Algorithm: Hematuria

## Codes

&NA;

### ICD10

- R31.9 Hematuria, unspecified
- R31.1 Benign essential microscopic hematuria
- R31.0 Gross hematuria

## Clinical Pearls

&NA;

- Screening asymptomatic patients for microscopic hematuria is an **Ø** recommendation from the USPSTF (1)[B].

- Asymptomatic hematuria and hematuria persisting after treatment of UTIs must be evaluated.
- Patients with bladder cancer can have intermittent microscopic hematuria; a thorough evaluation in high-risk patients is needed after just one episode.
- Routine use of anticoagulants should not cause hematuria unless there is an underlying urologic abnormality (1)[C].
- Signs of underlying renal disease indicate the need for a nephrologic workup, but a urologic evaluation is still needed in the presence of persistent hematuria (4)[C].

# Hemochromatosis

Robert A. Marlow, MD, MA

## BASICS

### *DESCRIPTION*

Hemochromatosis is a hereditary disorder in which the small intestine absorbs excessive iron (1,2).

- Early clinical features include arthralgia, fatigue, and decreased libido.
- Late effects include cirrhosis of the liver, diabetes, hypermelanotic pigmentation of the skin, and heart failure.
- Because there is no mechanism to excrete excess iron, the excess is stored in muscle and in organs, including the liver, pancreas, and heart, eventually resulting in severe damage to the affected organs.
- Liver damage ultimately may result in hepatocellular carcinoma.
- System(s) affected: endocrine/metabolic
- Synonym(s): bronze diabetes; Troisier-Hanot-Chauffard syndrome

### *EPIDEMIOLOGY*

#### *Incidence*

- Predominant age: Metabolic abnormality is congenital, but symptoms usually present in the 5th and 6th decades.
- Predominant sex: gene frequency: male = female, although clinical signs are more frequent in men (3)

#### *Prevalence*

- 3/1,000 people (heterozygote frequency, 1/10) (4)
- The most common genetic abnormality in the United States

#### *Pediatric Considerations*

Rarely, iron overload may occur as early as 2 years of age. The disorder can be diagnosed before iron overload is clinically apparent.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Type 1 hemochromatosis is caused by mutations in the *HFE* gene, type 2 by mutations in either the *HFE2* gene or *HAMP* gene, type 3 by mutations in the *TFR2* gene, and type 4 by mutations in the *SLC40A1* gene. The cause of neonatal hemochromatosis is unknown.
- The mechanism for increased iron absorption in the face of excessive iron stores is not clear. Iron metabolism appears normal in this disease except for a higher level of circulating iron.
- Iron overload may be caused by thalassemia, sideroblastic anemia, liver disease, excess iron intake, or chronic transfusion.

## **Genetics**

- Genetically heterogeneous disorder of iron overload; types 1, 2, and 3 are autosomal recessive; type 4 is autosomal dominant. Neonatal hemochromatosis is rare.
- Penetrance is incomplete; expressivity is variable.
- Factors contributing to variable expressivity include different mutations in the same gene, mitigating or exacerbating genes, and environmental factors.

## **RISK FACTORS**

- The disease is a genetic disorder.
- Affected individuals should not ingest iron supplements, eat raw shellfish, or eat large quantities of iron-rich food, such as red meat.
- Alcohol increases the absorption of iron. (As many as 41% of patients with symptomatic disease are alcoholic.)
- Loss of blood, such as that which occurs during menstruation and pregnancy, delays the onset of symptoms.

## **GENERAL PREVENTION**

- Family members of affected individuals should be screened.
- Pregnant women with the disorder should avoid iron supplements.

### **ALERT**

Screening of population is *not* recommended because the vast majority of those with homozygous hemochromatosis will remain asymptomatic and have a

normal life span (5,6)[A].

## COMMONLY ASSOCIATED CONDITIONS

See ÒComplications.Ó

## DIAGNOSIS

### HISTORY

- Weakness (83%)
- Abdominal pain (58%)
- Arthralgia (43%)
- Loss of libido or potency (38%)
- Amenorrhea (22%)
- Dyspnea on exertion (15%)
- Neurologic symptoms (6%)
- Symptoms of diabetes

### PHYSICAL EXAM

- Hepatomegaly (83%)
- Increased skin pigmentation (75%)
- Loss of body hair (20%)
- Splenomegaly (13%)
- Peripheral edema (12%)
- Jaundice (10%)
- Gynecomastia (8%)
- Ascites (6%)
- Testicular atrophy
- Hepatic tenderness

### DIFFERENTIAL DIAGNOSIS

- Repeated transfusions
- Hereditary anemias with ineffective erythropoiesis

- Alcoholic cirrhosis
- Porphyria cutanea tarda
- Atransferrinemia
- Excessive ingestion of iron (rare)

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Transferrin saturation (serum iron concentration ÷ total iron-binding capacity × 100): >70% is virtually diagnostic of iron overload; 345% warrants further evaluation. Iron supplements and transfusions may elevate serum iron.
- Serum ferritin: >300 *&mgr;*g/L for men and postmenopausal women and 200 *&mgr;*g/L for premenopausal women (7); may be elevated by inflammatory reactions, other forms of liver disease, certain tumors (e.g., acute granulocytic leukemia), and rheumatoid arthritis
- After the diagnosis is established
  - Obtain an oral glucose tolerance test or hemoglobin A1C to rule out diabetes and an echocardiogram to rule out cardiomyopathy.
  - Consider abdominal US to assess for cirrhosis.
  - Decreased FSH
  - Decreased LH
  - Decreased testosterone
  - Increased serum glutamic-oxaloacetic transaminase
  - Hypoalbuminemia
- If the diagnosis is uncertain after laboratory testing, MRI may be helpful to assess hepatic iron (1).

## **Diagnostic Procedures/Other**

- Liver biopsy for stainable iron is the standard for diagnosis. Presence or absence of cirrhosis also can be ascertained. However, with the availability of genetic testing, liver biopsy is not frequently necessary to confirm the diagnosis (7)[C].
- DNA PCR testing for *HFE* gene mutations C282Y and H63D: present in 85-90% of patients
- Homozygosity for the C282Y mutation or compound heterozygosity for C282Y and H63D with biochemical evidence for iron overload can confirm the diagnosis (8).

## Test Interpretation

- Increased hepatic parenchymal iron stores
- Hepatic fibrosis and cirrhosis with hepatomegaly
- Pancreatic enlargement
- Excess hemosiderin in liver, pancreas, myocardium, thyroid, parathyroid, joints, skin
- Cardiomegaly
- Joint deposition of iron

## TREATMENT

### MEDICATION

- None. Only when phlebotomy is not feasible or in the presence of severe heart disease should the iron-chelating agent deferoxamine (Desferal) be considered.
- Hepatitis A and hepatitis B immunizations should be done if there is no evidence of previous exposure (9).

---

P.455

### GENERAL MEASURES

- Remove excess iron by repeated phlebotomy once or twice weekly to establish and maintain a mild anemia (hematocrit of 35-39%) (7)[C].
- When the patient finally becomes iron-deficient, a lifelong maintenance program of 2 to 6 phlebotomies a year to keep storage iron normal; maintain serum ferritin 50 to 100  $\mu\text{g/L}$ .

### INPATIENT CONSIDERATIONS

#### Admission Criteria/Initial Stabilization

Outpatient treatment

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

Full activity unless there is significant heart disease

## *Patient Monitoring*

- Measure hematocrit before each phlebotomy; skip phlebotomy if hematocrit is <36%.
- Schedule an additional phlebotomy when hematocrit is >40%.
- When anemia becomes refractory, repeat transferrin saturation and serum ferritin to confirm depletion of iron stores.
- When iron stores are depleted, 2 to 6 phlebotomies a year should keep iron stores normal; maintain serum ferritin 50 to 100  $\mu\text{g/L}$ .
- During maintenance therapy, measure transferrin saturation and serum ferritin yearly.

## *DIET*

- An iron-poor diet is not of significant benefit.
- Avoid alcohol, iron-fortified foods, iron-containing supplements, and uncooked shellfish (increased susceptibility to *Vibrio* sp.).
- Restrict vitamin C to small doses between meals.
- Tea chelates iron and may be drunk with meals.

## *PATIENT EDUCATION*

- Iron Disorders Institute, PO Box 675, Taylors, SC 29687
- American Hemochromatosis Society, Inc., PO Box 950871, Lake Mary, FL 32795-0871

## *PROGNOSIS*

- Patients diagnosed before cirrhosis develops and treated with phlebotomy have a normal life expectancy.
- Life expectancy is reduced in patients with cirrhosis and DM and in those who require >18 months of phlebotomy therapy to return iron stores to normal.
- Patients with ferritin levels <1,000  $\mu\text{g/L}$  are unlikely to have cirrhosis (3,10).

## *COMPLICATIONS*

- Cirrhosis
- Hepatoma (only in patients with cirrhosis)
- DM
- Cardiomyopathy

- Arthritis
- Hypogonadism

## Codes

&NA;

### ICD10

- E83.110 Hereditary hemochromatosis
- E83.118 Other hemochromatosis
- E83.111 Hemochromatosis due to repeated red blood cell transfusions

## Clinical Pearls

&NA;

- The best laboratory tests available to screen a patient initially for hemochromatosis are serum ferritin and transferrin saturation. An elevated transferrin saturation is the earliest abnormality in hemochromatosis. Ferritin is a sensitive measure of iron overload but can be elevated in a variety of infectious and inflammatory conditions without iron overload being present.
- Liver biopsy need not be done to confirm the diagnosis or to check for cirrhosis if the patient is homozygous for C282Y or is heterozygous for C282Y/H63D. If the patient's serum ferritin is  $<1,000$   $\mu\text{g/L}$ , LFTs are normal, and hepatomegaly is not present, cirrhosis is very unlikely, so liver biopsy is not needed.
- Initially, a patient with hemochromatosis should have a phlebotomy weekly until the serum

ferritin is 50 to 100  $\mu\text{g/L}$ , and the transferrin saturation falls to  $<30\%$ . Then, lifelong maintenance therapy of 2 to 6 phlebotomies a year is mandatory to keep the ferritin 50 to 100  $\mu\text{g/L}$  and the transferrin saturation  $<50\%$ .

- Most patients with hemochromatosis go undiagnosed. Because treatment with phlebotomy will prevent all complications when begun early, physicians should consider the diagnosis of hemochromatosis much more frequently. However, the U.S. Preventive Services Task Force recommends against routine screening of asymptomatic average-risk populations.

# Hemophilia

Katie L. Westerfield, DO

Bryan Malave, MD

## BASICS

### DESCRIPTION

- Deficiency of factor VIII (hemophilia A) or factor IX (hemophilia B) coagulation proteins leading to bleeding tendencies in affected individuals. The majority of cases are due to inherited genetic mutations in factor VIII or factor IX coagulation proteins. However, an estimated 30% of all hemophilia cases result from spontaneous mutations.
- Hemophilia A and B are clinically indistinguishable, but can be differentiated by assays that detect levels of factors VIII and IX, respectively.
- Disease severity correlates with the relative levels of coagulation factors present in serum analysis:
  - Severe: frequent spontaneous bleeding (factor activity <1%)
  - Moderate: bleeding with mild to moderate trauma (factor activity 1-5%)
  - Mild: bleeding with major trauma, tooth extraction, or surgery (factor activity 5-40%)
- Frequency of bleeding is similar when levels of severity are comparable in hemophilia A and B.
- Synonym(s): Christmas disease (hemophilia B)

### EPIDEMIOLOGY

- Worldwide, an estimated 400,000 people are affected with hemophilia. Estimated frequency of 1 in 10,000 births (1).
- Hemophilia A represents 80-85% of the total hemophilia population; hemophilia B comprises the remaining 15-20%.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Damage to vascular endothelium leads to exposure of subendothelial tissue factors, which interact with platelets, plasma proteins, and coagulation factors to produce a localized platelet plug contributing to hemostasis. Complexes involving factors VIII and IX participate in the

intrinsic coagulation pathway to activate factor X, FXa. Downstream interactions involving FXa culminate in the conversion of prothrombin to thrombin, mediating platelet activation and fibrin deposition necessary for stabilization of the platelet plug.

- Deficiencies of factor VIII or factor IX result in decreased production of FXa, leading to an unstable platelet plug and impaired hemostasis.

## *Genetics*

- Exhibits an X-chromosome linked inheritance pattern. Males are almost exclusively affected; females are asymptomatic carriers, unless their factor activity is <40% of normal.
- Carriers with symptomatically low clotting factor levels are treated similarly to patients with the trait:
  - May bleed at the time of surgery
- Males within the same family share similar deficiencies and level of severity owing to the same genetic defect.

## **GENERAL PREVENTION**

- Patients should carry medical ID tags listing their bleeding disorder or factor deficiency, inhibitor status, type of treatment products used, and initial treatment doses for mild, moderate, or severe bleeding.
- Immediate family members of affected patients should have factor VIII and IX levels checked prior to invasive procedures, childbirth, and if bleeding tendencies occur.
- Genetic testing should be offered to at-risk female family members to facilitate genetic counseling.

## **DIAGNOSIS**

- History and initial presentation
  - 2/3 of presenting hemophilic patients have a positive family history. All male infants born to known carriers should have factor level testing.
  - Prolonged bleeding with circumcision, dental work, surgery, or injury
  - Excessive or easy bruising in early childhood
  - Spontaneous bleeding, especially in joints, muscle, or soft tissue
  - Typical presentation times: mild (36 months), moderate (8 months), severe (1 month)

- *Pregnancy Considerations*: Treat all males born to a carrier as if they have hemophilia. Test at birth. Avoid vacuum/forceps deliveries (2)[B].
  - Cord blood can be used for testing (3)[A].
- Life-threatening bleeds
  - Intracranial hemorrhage: generally resulting from trauma; incidence of 1:10; fatal in 30% of cases
  - Hematomas of bowel wall can cause obstruction or intussusception as well as pain mimicking appendicitis.
  - Neck or throat bleeds: can lead to airway obstruction
- Serious bleeds
  - Hemarthrosis, most commonly of ankles, elbows, and knees
    - Infants may present with irritability or decreased use of limb.
    - Adults may have prodromal stiffness, acute pain, and swelling of joint.
    - Arthropathy results from repeated bleeding into joints, damaging cartilage, and subchondral bone:
      - Can result in fixed joints, muscle wasting, and significantly impaired mobility
  - Muscular hematomas most commonly occur in quadriceps, iliopsoas, and forearm:
    - May result in compartment syndrome and ischemic nerve damage, such as femoral nerve neuropathy due to undetected retroperitoneal hemorrhage
  - Mucous membrane bleeding, such as in the genitourinary tract, leading to hematuria
  - Pseudotumor syndrome: untreated hemorrhage causing a hematoma, which calcifies (named because it can be mistaken for cancer)

## ***DIFFERENTIAL DIAGNOSIS***

- Von Willebrand disease
- Vitamin K deficiency, anticoagulant (warfarin, rivaroxaban, argatroban, heparin, enoxaparin) therapy (factor IX is vitamin K-dependent)
- Other factor deficiencies: afibrinogenemia, dysfibrinogenemia, fibrinolytic defects, platelet disorders
- Child abuse

# DIAGNOSTIC TESTS & INTERPRETATION

## *Initial Tests (lab, imaging)*

- CBC with platelet count, PT, aPTT, platelet function (preferred) or bleed time, vWF, factor VIII:C assay, factor IX assay. Prolonged aPTT: corrected when mixed with pooled normal plasma in absence of inhibitors
- PT, platelet count, and platelet function are normal.
- Diagnosis based on factor VIII:C or IX activity
  - Normal factor levels: 50 to 150 IU/dL
  - Mild: 5 to 40 IU/dL
  - Moderate: 1 to 5 IU/dL
  - Severe: <1 IU/DI

## *Follow-Up Tests & Special Considerations*

Inhibitors to factor VIII and IX (see "Complications"):

- Should be periodically measured using the Nijmegen or Bethesda assay, which quantifies the alloantibody titer
- Screen before invasive procedures and at regular intervals.

## *Diagnostic Procedures/Other*

Prenatal diagnosis: genetic testing of a sample of chorionic villus or fluid obtained at amniocentesis. Not recommended (2)[B]

## *Test Interpretation*

In affected joints: synovial hemosiderosis, articular cartilage degeneration, thickening of periarticular tissues, bony hypertrophy

## TREATMENT

### GENERAL MEASURES

- Avoid aspirin or other NSAIDs.
- Treat early; symptoms may occur before bleeding is clinically apparent. Acute bleeds should be treated as quickly as possible, preferable within 2 hours (1)[A].

- For surgical prophylaxis
  - If major surgery is undertaken, factor levels should be maintained at >50% for at least 2 to 3 weeks after the procedure:
    - Fibrin glue products may be beneficial for oozing.
  - Dental extractions: Antifibrinolytics (Amicar, tranexamic acid) may be used.
  - Minor procedures: may use desmopressin (DDAVP)
- Hepatitis A and B vaccinations are recommended.
- Encourage physical activity for normal neuromuscular development: Patients should avoid high-impact contact sports; restrict activities in proportion to degree of factor deficiency. Organized sports should be encouraged as opposed to unstructured activities (1)[B].

## MEDICATION

### *First Line*

- Principles of therapy
  - Primary prophylaxis: administration of specific factor replacement therapy in the absence of bleeding to maintain adequate baseline plasma levels sufficient for hemostasis in all categories of severity (1)[A]
    - Lower frequency of acute bleeds and episodes of life-threatening hemorrhage compared to on-demand therapy
    - Standard of care for children with severe hemophilia A to prevent joint bleeds and joint degeneration
    - Dosing, frequency, duration of therapeutic regimens tailored to individual patient needs in clinical practice
  - On-demand therapy: treatment administered in response to occurrence of bleeding
    - Amount and duration of factor replacement depends on location and severity of bleeding:
      - Mild bleeds correct to a factor level of >30% major hemorrhages and large muscle bleeds require correction to levels between 50% and 100%.
      - Life-threatening bleeds require levels between 80% and 100%, sustained with bolus dosing or continuous infusion.

- 
- Specific agents:

- Hemophilia A: Replacement with factor VIII concentrates is the treatment of choice:
  - Two sources for the factor available:
    - Purified plasma-derived factor VIII: Donor pool is screened and the plasma-derived factor is treated to inactivate viruses (HIV, hepatitis B, and hepatitis C). Theoretical risks still exist.
    - Recombinant factor VIII
      - Dosing: 1 IU of factor VIII (the amount in 1 mL of plasma)/kg body weight administered will raise the plasma level of the recipient by 2%.
      - Most FVIII products have short half-lives, requiring frequent injections novel recombinant factor VIII, rFVIII-Fc, dosed prophylactically 1 to 2 times per week (4) [B].
- Hemophilia B: Replacement with factor IX concentrates is the treatment of choice:
  - Plasma-derived factor IX and recombinant factor IX (preferred) are commercially available.
    - Dosing: 1 IU/kg body weight administered will raise plasma factor IX levels 1%.
- Hemophilia patients with inhibitors (neutralizing alloantibodies to factors VIII or IX)
  - Inhibitor formation should be suspected when replacement with the deficient factor fails to correct coagulopathy.
  - Low-titer (<5 BU/mL) patients: Replace with high doses of the deficient factor to overcome the circulating inhibitor concentration.
  - High-titer patients: Treat using products that *bypass* the factor neutralized by the alloantibody, or emergently with high doses of the specific deficient factor:
    - Two bypassing agents are available; both are efficacious at providing 80% of bleeding episodes:
      - Anti-inhibitor coagulation complex (AICC)
      - Recombinant activated factor VII (rFVIIa)
- Immune tolerance induction (ITI): protocols to promote immune tolerance through repeated exposure to high-dose factor VIII therapy over 12 to 18 months, with or without immunosuppressive therapy (corticosteroids, cyclophosphamide, rituximab). Success rates are 60-80%.

- Home therapy allows immediate access to clotting factor, resulting in decreased pain, dysfunction, and long term disability (2)[B].

## Second Line

- Cryoprecipitate and fresh frozen plasma (FFP) can be used in instances where the specific factor concentrate is unavailable for *emergent hemostasis*.
  - FFP: contains all coagulation factors but generally difficult to attain high levels of factors VIII or IX
    - Starting dose: 15 to 20 mL/kg
  - Cryoprecipitate: derived from precipitates of cooled FFP; contains significant levels of factor VIII (up to 100 IU/bag) but *not* factor IX:
    - Dosing: 1 mL cryoprecipitate has  $\div$ 3 to 5 IU factor VIII.
- Desmopressin (DDAVP): synthetic vasopressin; stimulates endogenous release of factor VIII (and *vWF*) from endothelial stores; used in mild to moderate hemophilia
  - IV or SC: 0.3 &mgr;g/kg infused 30 minutes prior to procedure; may repeat if needed
  - Intranasal (150 &mgr;g/spray): adult dose, 1 spray to each nostril (300 &mgr;g total). Alternate dose if <50 kg: 150 &mgr;g once.
  - Adverse effect: hyponatremic seizures, especially in children; restrict fluids and watch sodium levels and urine output.
- Antifibrinolytic agents: inhibit plasminogen activation, thereby stabilizing the clot
  - Effective in controlling mucosal bleeding, such as bleeding in oral cavity, epistaxis, and menorrhagia; can also be used prophylactically (e.g., prior to tooth extractions)
    - Tranexamic acid (25 mg/kg PO q6-8h or 10 mg/kg IV q6-8h)
    - Aminocaproic acid (Amicar) is less frequently used.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### Patient Monitoring

Regular evaluations every 6 to 12 months, including a musculoskeletal evaluation, an inhibitor screen, liver tests, and tests for antibodies to hepatitis viruses and HIV

## PATIENT EDUCATION

- National Hemophilia Foundation: <http://www.hemophilia.org/>
- World Federation of Hemophilia: <http://www.wfh.org/>

## PROGNOSIS

- Survival is normal for those with mild disease; mortality is increased 2- to 6-fold in those with moderate to severe disease.
- Intracranial hemorrhage is a leading cause of death in hemophilia.
- Hemophilic arthropathy is the main cause of morbidity in patients with severe hemophilia.

## COMPLICATIONS

- Hemophilic arthropathy: Symptoms include pain, limitation of motion, and contractures.
- Theoretical transmission of bloodborne infections, such as hepatitis A, B, C, and D and HIV; this risk has been greatly reduced with current testing of blood products.
- Development of inhibitor autoantibodies
  - More common in hemophilia A (20-30% of patients compared to 5% in hemophilia B) and in patients with severe disease requiring multiple transfusions
  - Risk factors for inhibitor development:
    - Specific genetic defect (family history); null mutations have higher inhibitor incidence.
    - Very low or no circulating factor, therefore requiring multiple transfusions
    - Age of first exogenous factor exposure; previous studies report a higher incidence of developing antibodies in those exposed to exogenous factor at <6 months of age, but new studies show this may be due to severity of disease.
    - Concurrent inflammation/infection when administering factor (e.g., surgical prophylaxis)
    - Duration of factor exposure
  - No increased risk of bleeding, but when bleeding occurs, it is more difficult to achieve hemostasis due to decreased response to factor replacement.

&NA;

### ICD10

- D66 Hereditary factor VIII deficiency
- D67 Hereditary factor IX deficiency
- Z14.01 Asymptomatic hemophilia A carrier

# Hemorrhoids

Juan Qiu, MD, PhD

## BASICS

### DESCRIPTION

- Varicosities of the hemorrhoidal venous plexus
- External hemorrhoids
  - Located below the dentate line (painful)
  - Covered by squamous epithelium
- Internal hemorrhoids
  - Located above the dentate line (painless)
- Both types of hemorrhoids often coexist.
- Classification of internal hemorrhoids (1,2,3)
  - 1st-degree: Hemorrhoids do not prolapse.
  - 2nd-degree: prolapse through the anus on straining but reduce spontaneously
  - 3rd-degree: protrude and require digital reduction
  - 4th-degree: cannot be reduced
- Hemorrhoids often progress from itching, bleeding stage to protrusion with easy reduction; then difficult reduction; and finally, rectal prolapse. Thrombosis may occur at any protrusion stage. External hemorrhoids cause pain; internal hemorrhoids generally do not (2,3).

### *Geriatric Considerations*

Hemorrhoids are more common in elderly, as is rectal prolapse.

### *Pediatric Considerations*

- Uncommon in infants and children; when discovered, look for underlying cause (e.g., vena caval or mesenteric obstruction, cirrhosis, portal hypertension [HTN]).
- Occasionally, as in adults, hemorrhoids may result from chronic constipation, fecal impaction,

and straining at stool. Surgery is rarely required in children.

## *Pregnancy Considerations*

- Common in pregnancy
- Usually resolves after pregnancy
- No treatment required, unless extremely painful.

## *EPIDEMIOLOGY*

- Predominant age: adults; peak from 45 to 65 years
- Predominant sex: male = female

## *Incidence*

Common

## *Prevalence*

÷4-5% in general population in the United States

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- There are three primary hemorrhoidal cushions typically located in left lateral, right anterior, and right posterior positions. Hemorrhoidal cushions augment anal closure pressure and protect the anal sphincter during stool passage. During Valsalva, intra-abdominal pressure increases raising pressure within the hemorrhoidal cushions helping to preserve anal closure. Mechanisms implicated in symptomatic hemorrhoidal disease include the following:
  - Dilated veins of hemorrhoidal plexus
  - Tight internal anal sphincter
  - Abnormal distention of the arteriovenous anastomosis
  - Prolapse of the cushions and the surrounding connective tissues

## *Genetics*

No known genetic pattern

## *RISK FACTORS*

- Pregnancy
- Pelvic space-occupying lesions

- Liver disease; portal HTN
- Constipation
- Occupations that require prolonged sitting
- Loss of perianal muscle tone due to old age, rectal surgery, birth trauma/episiotomy, anal intercourse
- Obesity
- Chronic diarrhea

## **GENERAL PREVENTION**

- Avoid constipation by consuming high-fiber diet (>30 g/day) and ensuring proper hydration.
- Maintain appropriate weight.
- Avoid prolonged sitting or straining on the toilet.

## **COMMONLY ASSOCIATED CONDITIONS**

- Liver disease; portal HTN
- Pregnancy
- Constipation

## **DIAGNOSIS**

Diagnosis is typically straightforward through history and inspection of the perineum, rectal exam, and anoscopy.

### **HISTORY**

- Internal/external hemorrhoids
  - Classically, bright red blood per rectum
    - May range from scant blood on toilet paper to copious blood in the toilet bowl
  - Constipation or diarrhea
  - Straining with defecation
- Small or minimal external hemorrhoids
  - Episodic bleeding on stool or toilet paper, pruritus and pain

More extensive internal hemorrhoids

- Feeling of incomplete evacuation
- Thrombosed hemorrhoids present as an acute painful mass (2,3).

## *PHYSICAL EXAM*

- Anorectal exam including anoscopy (2,3)
- Inspection following straining at stool
- For protruding hemorrhoids: mass, more prominent bleeding. If not reducible, increased risk of strangulation and/or thrombosis with acute pain
- Abdominal exam to exclude mass
- Peripheral stigmata of cirrhosis and portal hypertension (caput, telangiectasias, palmar erythema)

## *DIFFERENTIAL DIAGNOSIS*

- Rectal or anal neoplasia
- Condyloma
- Skin tag
- Inflammatory bowel disease
- Anal fistula, fissure, or abscess

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Diagnostic Procedures/Other*

Sigmoidoscopy or colonoscopy depending on risk factors for malignancy in patients with rectal bleeding (3)[A]

## **TREATMENT**

### *Prevention*

- Fiber supplements
- Stool softeners

## GENERAL MEASURES

- Hemorrhoids are a recurrent disease, even after surgical excision. Preventive measures should be continued indefinitely.
- For mild symptoms or prevention (3)[A]
  - Avoid prolonged sitting during bowel movements.
  - Avoid straining.
  - Avoid constipation by eating a high-fiber diet or by taking fiber supplements; if necessary, take regular stool softeners.
  - Regular exercise
- For pain, Sitz baths warm water or hypertonic Epsom salts (1 cup per 2 quarts of water)
- Pruritus or mild discomfort after stooling responds well to topical hydrocortisone ointment, anesthetic ointments or sprays, and warm Sitz baths.
- Constipation relief, anal hygiene, local ointments, and Sitz baths are effective through the stage of easy reduction (stage 2). More severe stages often require ligation or surgery (3)[A].

## MEDICATION

### *First Line*

- Dietary modification with adequate fluid (generally <sup>3</sup>2 L water/day) and fiber (<sup>3</sup>30 g/day) is the primary first-line, nonoperative therapy for symptomatic hemorrhoids (3)[A].
- Pain
  - Hydrocortisone ointment (0.5-1%)
  - Analgesic sprays or ointments: benzocaine and dibucaine (Nupercainal). Use sprays with caution, as they may contain alcohol that can cause burning sensation when applied.
- Pruritus: hydrocortisone (Anusol-HC, Cortifoam) ointment
- Bleeding
  - Astringent suppositories (Preparation H)
  - Hydrocortisone (Anusol-HC, Cortifoam) ointment

### *Second Line*

Treatment for special cases

Thrombosed external hemorrhoids: common complication of hemorrhoidal disease. With conservative treatment, the thrombus will be absorbed over the course of weeks, and pain improves within 2 to 3 days (1,2,3)[A].

- With severe acute pain, prompt excision should be performed under local anesthetics and the wound left open without packing. Use Sitz baths, topical anesthetics, and mild pain relievers for the first 7 to 10 days after excision (1,2,3)[A].
- Strangulated hemorrhoid: from irreducible 3rd- or 4th-degree hemorrhoid. If untreated, it can progress to ulceration and thrombosis. Treatment requires urgent or emergent hemorrhoidectomy.
- Acute hemorrhoidal bleeding associated with portal HTN can be life-threatening. Treatment should be suture of the bleeding site with incorporation of the mucosa, submucosa, and internal sphincter. Coagulopathy should be corrected.

---

P.459

## ***SURGERY/OTHER PROCEDURES***

- Indications: failure of medical and nonoperative therapy, symptomatic stage 3 or stage 4 symptoms in presence of a concomitant anorectal condition requiring surgery, or patient preference (1,2,3)[A]
- Incision of thrombosed hemorrhoid: for severe pain
- Severe protruding hemorrhoids
  - Rubber band ligation (internal hemorrhoids only) (1,2,3)[A]
  - Sclerotherapy: for symptomatic prolapsed stage I or II hemorrhoids; care must be taken not to inject near periprostatic parasympathetic nerves. Not for advanced disease or if evidence of infection, inflammation, and ulceration is present
    - Cryotherapy is no longer recommended due to high rate of complications.
  - Prolapsed rectum
    - Requires surgical correction
  - Surgical resection
    - Gold standard: Conventional hemorrhoidectomy should be considered for grade III hemorrhoids not responding to banding, mixed internal and external, grade IV hemorrhoids, or when complicated by fissures, fistula, or extensive skin tags (1,2,3)[A].
- Newer techniques reduce surgical time, early postoperative pain, urinary retention, and time to return to normal activity.

- Transanal hemorrhoidal dearterialization (THD): fewer complications and can be used in cases of recurrent diseases (2,3)[A],(4)[B]
- Stapled hemorrhoidopexy: less painful than traditional surgery but higher incidence of skin tags and recurrent prolapse (2)[A],(4)[B]
- LigaSure hemorrhoidectomy: reduces operating time, is superior in patient tolerance, and is equally effective as conventional hemorrhoidectomy in long-term symptom control (5,6)[B], (7,8)[A]

## COMPLEMENTARY & ALTERNATIVE MEDICINE

Aloe vera cream on the surgical site after hemorrhoidectomy reduces postoperative pain and decreases healing time and analgesic requirements.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

- Encourage physical fitness, weight management, and dietary compliance.
- Avoid prolonged sitting and straining on the toilet.

### Patient Monitoring

As needed, depending on treatment

### DIET

High-fiber with a target of 30 g of insoluble fiber/day through sources such as wheat bran cereals, oatmeal, peanuts, artichokes, beans, corn, peas, spinach, potatoes, apples, apricots, blackberries, raspberries, prunes, pears, bananas; adequate fluids (6 to 8 glasses of water/day); avoid excessive caffeine.

### PATIENT EDUCATION

High-fiber diet: Today's Dietitian Top Fiber-Rich Foods List.

<http://www.todaysdietitian.com/newarchives/063008p28.shtml>

### PROGNOSIS

- Spontaneous resolution
- Recurrence

## COMPLICATIONS

- Thrombosis
- Ulceration
- Anemia (rare)
- Incontinence
- Pelvic sepsis following hemorrhoidectomy

## Codes

**&NA;**

### ICD10

- K64.9 Unspecified hemorrhoids
- K64.0 First degree hemorrhoids
- K64.1 Second degree hemorrhoids

## Clinical Pearls

**&NA;**

- Hemorrhoids are a very common clinical condition. Internal hemorrhoids are painless. External hemorrhoids are typically painful.
- Anal hygiene and symptomatic pain relief are the treatments of choice for stage 1 and 2 hemorrhoids. Sitz baths with warm water or hypertonic Epsom salts (1 cup per 2 quarts of water) are effective for pain relief.
- All patients should be encouraged to eat a high-fiber diet with 30 g of insoluble fiber per day.
- More advanced hemorrhoidal disease requires intervention with ligation or surgery.

# Henoch-Schönlein Purpura

Shani I. Muhammad, MD

## BASICS

### DESCRIPTION

- Henoch-Schönlein purpura (HSP) is a nonthrombocytopenic, predominantly IgA-mediated, small vessel vasculitis that affects multiple organ systems and occurs in both children and adults.
- HSP is often self-limited, with the greatest morbidity and mortality attributable to long-term renal damage.
- Characterized by a tetrad of purpuric skin lesions, arthralgia, abdominal pain, and nephropathies

### EPIDEMIOLOGY

#### Incidence

- Annual incidence: 135/1 million children and 3.4 to 14.3/1 million adults
- Mean age of patients affected is 6 years; 90% <10 years of age but has been reported in patients age 6 months to 75 years old
- Gender: Male-to-female ratio is 1.2:1.
- Race/ethnicity: most common in Caucasians and Asians, less common among African Americans

#### Prevalence

- Annual prevalence: 10 to 22/100,000 persons
- Year-round occurrence; more common in late fall to early spring

### ETIOLOGY AND PATHOPHYSIOLOGY

- Autoimmune disorder in which IgA production is increased in response to trigger(s), IgA1 immune complexes then activate the complement pathway, leading to production of inflammatory cytokines and chemokines.

- Immune complex deposition results in small vessel inflammation; fibrosis; and necrosis within skin, intestinal mucosa, joints, and kidneys.
- No single etiologic agent has been identified.
- Known triggers include infection, drugs, vaccinations, and insect bites.
- Infectious antigens include (but are not limited to) group A *Streptococcus* (may be present in up to 30% of HSP-associated nephritis), parvovirus B19, *Bartonella henselae*, *Helicobacter pylori*, *Haemophilus parainfluenzae*, coxsackievirus, adenovirus, hepatitis A and B viruses, *Mycoplasma*, Epstein-Barr virus, varicella, *Campylobacter*, methicillin-resistant *Staphylococcus aureus*.
- Drugs: acetaminophen, quinolones, etanercept, codeine, clarithromycin
- Vaccinations: MMR (measles, mumps, rubella), pneumococcal, meningococcal, influenza, hepatitis B

## Genetics

Associated with  $\alpha_1$ -antitrypsin deficiency, familial Mediterranean fever, *HLA-DRB1\*01*, *HLA-B35*

## COMMONLY ASSOCIATED CONDITIONS

- Malignancy (rare): Greatest association is with solid tumors, including lymphoma, prostate cancer, and non-small cell lung cancer, but also associated with multiple myeloma.
- Studies suggest a possible relationship with *H. pylori* infection (1)[A].

## DIAGNOSIS

Palpable purpura and *at least one* of the following:

- Diffuse abdominal pain
- Biopsy with predominant IgA deposition
- Arthralgia or arthritis
- Renal involvement (hematuria or proteinuria)
- Direct immunofluorescence showing IgA deposition (2)[A]

## HISTORY

- History of exposure to known trigger, including recent infection (particularly upper respiratory infection), vaccination, or offending drug

- Rash (most common presenting symptom): purpuric, palpable; distribution often symmetric on lower extremities and buttocks; may present on upper extremities, trunk, and face; typical duration 3 to 10 days; no definitive temporal association with other symptoms
- Fatigue
- Low-grade fever
- Nausea/vomiting
- Abdominal pain (diffuse, colicky, may be transient or constant)
- Hematochezia/melena
- Polyarthrititis (often symmetric involvement of knees and ankles)
- Gross hematuria
- Rare symptoms: periorbital or scrotal swelling, headache, neuropathy, hemoptysis

## *PHYSICAL EXAM*

- Rash (96% of cases, 74% primary presenting symptom):
  - May start as urticaria, develops into nonblanching purpura, with or without petechiae and ecchymoses, may also be bullous
  - Distribution usually symmetric, most commonly involving the lower extremities but may involve the face and trunk
- Abdominal tenderness (66% of cases, 12% primary presenting symptom):
  - Evidence of GI hemorrhage (28% of cases)
- Joint tenderness (64% of cases, 15% primary presenting symptom):
  - Mainly affects knees or ankles; may have associated warmth and limited range of motion, less commonly effusion; erythema is absent.
  - Mostly nonmigratory, transient, and nondeforming
- Orchitis (5%):
  - Presents as scrotal swelling and tenderness, may have associated torsion
- Renal disease (<1% primary presenting symptom):
  - Hypertension may be present.
- Rarely, patients present with CNS or pulmonary involvement, which may manifest as signs of

cerebral hemorrhage or diffuse interstitial pneumonia, respectively.

## *DIFFERENTIAL DIAGNOSIS*

- Infection:
  - Meningococemia
  - Rocky Mountain spotted fever
  - Bacterial endocarditis
  - Rheumatic fever
- Immune-mediated:
  - Polyarteritis nodosa
  - Wegener granulomatosis
  - Systemic lupus erythematosus
  - Kawasaki disease
- Other:
  - Inflammatory bowel disease
  - Idiopathic thrombocytopenic purpura
  - Juvenile rheumatoid arthritis
  - Leukemia
  - Acute surgical abdomen
  - Child abuse

## *DIAGNOSTIC TESTS & INTERPRETATION*

- No single lab test confirms the diagnosis of HSP.
- Labs directed toward excluding other illnesses and assessing degree of renal involvement

### *Initial Tests (lab, imaging)*

The following are generally accepted as initial labs for HSP:

- CBC:
  - Leukocytosis and thrombocytosis may occur. Thrombocytopenia indicates an alternative cause of purpura.

- Hemoglobin is variable, depending on whether GI hemorrhage occurs.
- Basic serum chemistry panel (electrolytes, BUN, creatinine):
  - Electrolyte imbalances or elevated creatinine indicate renal dysfunction.
- Urinalysis:
  - Gross or microscopic hematuria, proteinuria, and red cell casts indicate renal dysfunction.
- PT and PTT:
  - Normal in HSP
- Imaging is not part of the routine workup for HSP but may be performed to rule out alternative etiologies or for evaluation of suspected complications, particularly in cases of GI and renal involvement. Initial imaging modalities to consider include the following:
  - Abdominal radiographs, with or without barium enema: evaluate for free abdominal air suggestive of bowel perforation
  - Abdominal ultrasound: sensitive for the detection of intramural bleeding in HSP and may also show thickened bowel wall, reduced peristalsis, intussusception
- Renal ultrasound: evaluates for hydronephrosis in cases of renal failure

### *Follow-Up Tests & Special Considerations*

The following labs are also useful in diagnosing HSP:

- Blood culture:
  - To rule out sepsis/bacteremia when diagnosis is unclear
- Acute phase reactants:
  - Expect mild elevation.
- IgA level:
  - Often elevated, although nonspecific, nonsensitive
- Visfatin levels (3)
- Degree of elevation correlates with disease severity and likelihood of renal involvement (3).
- Complement levels:
  - Normal; sometimes decreased

- Antinuclear antibody/antineutrophil cytoplasmic antibody:
  - Negative
- Antistreptolysin-O titer:
  - Evaluates for preceding streptococcal infection
- Stool guaiac if suspected GI hemorrhage
- CT arteriography may be necessary to identify the location of bleeding in patients with GI hemorrhage.

### *Diagnostic Procedures/Other*

- Renal biopsy: Obtain if diagnosis is uncertain or if nephrotic range proteinuria shows mesangial IgA deposition, mesangial proliferation, or, in severe cases, crescentic glomerulonephritis.
- Skin biopsy of purpura: IgA deposition in the dermis on immunofluorescence (2)[A]

P.461

- Endoscopy may be considered in cases of GI hemorrhage given symptomatic overlap of HSP with inflammatory bowel disease.
- Barium enema may be therapeutic in some instances of intussusception, although surgical correction is commonly needed.

## **TREATMENT**

### *GENERAL MEASURES*

Rest and elevation of affected areas may limit purpura.

### *MEDICATION*

- In the absence of renal dysfunction or complication, HSP is usually self-limited and best managed with supportive care.
- NSAIDs are effective for symptomatic treatment of joint pain. Caution is advised in cases of GI hemorrhage; avoid use in cases of renal involvement and consider acetaminophen as an alternative.
- Steroids given early in disease course using oral prednisone 1 to 2 mg/kg/day for 1 to 2 weeks decrease both duration of abdominal pain and severity of joint pain and may have benefit in preventing GI bleeding and causes of surgical abdomen, including intussusception.
- Steroids have benefit in treatment of severe and/or bullous purpura.

- Steroids given early in disease are effective for the acute treatment of crescentic nephritis and may prevent chronic renal disease in such patients.
- Early intervention with steroids has no effect on the prevention or development of renal involvement after 1 year.
- High-dose IV pulse steroids (500 mg to 1 g) may be considered in cases of mesenteric vasculitis and severe renal impairment. Evidence is very limited to support use of cyclophosphamide, plasmapheresis, and intravenous immunoglobulin (IVIG) for severe renal and GI involvement, as well as colchicine for severe skin lesions.
- Mycophenolate mofetil (MMF) could be valuable in the treatment of complicated HSP (3,4)[A].

## *ISSUES FOR REFERRAL*

- Consider nephrology referral for renal biopsy if nephrotic range proteinuria at any time or proteinuria >100 mg/mmol for 3 months after diagnosis.
- Dermatology referral for skin biopsy

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Insufficient oral intake
- Renal insufficiency
- Severe abdominal pain
- Severe GI bleeding
- Altered mental status
- Mobility restriction due to arthritis
- HTN
- Nephrotic syndrome

### *IV Fluids*

Hydration should be maintained.

**ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

## *Patient Monitoring*

- Patients should be seen weekly during the acute illness. Visits should include history and physical exam to include BP measurement and urinalysis.
- Because  $\div$ 100% of patients who develop renal involvement will do so within 6 months of HSP diagnosis, all patients should be followed at least monthly with BP and urinalysis for a duration of no  $<$ 6 months.
- Women with a history of HSP should be monitored for proteinuria and HTN during pregnancy.
- Consider workup for occult malignancy in patients with adult-onset HSP.

## **PATIENT EDUCATION**

- American Family Physician handout on HSP available at:  
<http://www.aafp.org/afp/1998/0801/p411.html>
- National Kidney and Urologic Diseases Information Clearinghouse (NKUDIC):  
<http://www.niddk.nih.gov/health-information/health-topics/kidneydisease/henoch-sch%C3%B6nlein-purpura-hsp/Pages/facts.aspx>

## **PROGNOSIS**

- Long-term prognosis heavily dependent on presence and severity of nephritis
- HSP is self-limited in 94% of children and 89% of adults.
- Most cases of HSP resolve within 4 weeks of diagnosis. Recurrence rate within 6 months of diagnosis is 33%.
- Factors associated with poorer prognosis include age  $>$ 8 years, fever at presentation, purpura above the waist, elevated ESR or IgA concentration, and increasing severity of renal histology grade.
- Chronic renal disease occurs in up to 20% of children with nephritic and nephrotic syndrome compared with 50% of adults who had any renal involvement. Risk of long-term renal failure is 25%.
- Risk factors that may result in renal failure include old age, HTN, elevated serum creatinine, and nephrotic and mixed nephritic-nephrotic syndrome at the onset of disease (3)[A].

## **COMPLICATIONS**

- Nephrotic/nephritic syndrome and renal failure
- HTN
- Hemorrhagic cystitis

- Ureteral obstruction
- Intestinal infarction, perforation, obstruction, stricture
- GI hemorrhage
- Intussusception
- Alveolar hemorrhage
- CNS complications, including cerebral hemorrhage and seizure
- Anterior uveitis
- Myocarditis
- Orchitis
- Testicular torsion

## Codes

&NA;

### ICD10

D69.0 Allergic purpura

## Clinical Pearls

&NA;

- HSP is a systemic small vessel vasculitis characterized by clinical tetrad of palpable purpura,

abdominal pain, arthralgia, and renal dysfunction.

- The main form of treatment is supportive care, but oral corticosteroids are beneficial in certain circumstances.
- In all patients with HSP, regardless of renal involvement at presentation, it is reasonable to check BP and urinalysis at weekly to monthly intervals for no <6 months after diagnosis to monitor for developing renal dysfunction.

# Heparin-Induced Thrombocytopenia

Tipsuda Junsanto-Bahri, MD

Maria A. Pino, PhD, MS, RpH

## BASICS

### DESCRIPTION

- Unexplained decrease in platelet count in a patient treated with heparin
  - Minimum platelet count falls between 30 and 50% from baseline.
- Antibody-mediated prothrombotic disorder initiated by heparin administration
- Unlike other thrombocytopenias, heparin-induced thrombocytopenia (HIT) is an idiosyncratic reaction that produces thrombosis rather than bleeding.
- Two types: nonimmune heparin-associated thrombocytopenia (previously called HIT type I) and HIT (immune induced; previously called HIT type II)
  - Nonimmune heparin-associated thrombocytopenia: more common, onset 1 to 4 days after starting heparin, mild thrombocytopenia ( $>100,000$ ), few complications
  - HIT: less common, onset 5 to 14 days after primary exposure to heparin, thrombocytopenia often  $<100,000$  but usually  $>20,000$ ; high risk of thrombosis
    - Presentation of thrombocytopenia can be immediate with recent heparin exposure (within past 100 days).

### EPIDEMIOLOGY

#### Incidence

- 10-15% of heparin-treated patients will experience decrease in platelet count.
- 0.3-3% will develop HIT.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Nonimmune heparin-associated thrombocytopenia: potentially a result of direct platelet membrane binding with heparin

- HIT: Heparin can cause an increase in the blood concentration of platelet factor 4 (PF4), a chemokine. PF4 will form a complex with heparin.
- Heparin/PF4 complex can, in turn, stimulate the production of specific antiheparin/PF4 complex antibodies. These antibodies cause platelet activation and a prothrombotic state. Ultimately, this hypercoagulable state leads to thromboembolic complications in many patients.

## *RISK FACTORS*

- Postsurgical > medical > obstetric
  - Postcardiopulmonary bypass is the most significant risk factor.
- Bovine unfractionated heparin (UFH) > porcine UFH > low-molecular-weight heparin (LMWH)
- Female > male
- Heparin duration >4 days

## *GENERAL PREVENTION*

- Inquire about recent heparin exposure and any history of HIT.
- Use of LMWH (vs. unfractionated), for a shorter duration, reduce the risk of developing HIT.
- Properly document past HIT reactions in patient's medical record. Develop a HIT recognition and treatment protocol (1)[A].
- No form of heparin should be administered once the diagnosis of HIT is confirmed.

## *COMMONLY ASSOCIATED CONDITIONS*

- Venous thrombosis: deep venous thrombosis (DVT), pulmonary embolism (PE), adrenal vein thrombosis with hemorrhagic infarction
- Arterial thrombosis
- Skin lesions (skin necrosis at site of injection)
- Acute systemic reactions

## **DIAGNOSIS**

- Nonimmune heparin-associated thrombocytopenia: asymptomatic drop in platelet count
- HIT: thrombocytopenia or thrombosis with the presence of heparin-dependent antibodies
  - The foundation for diagnosis is based on both clinical and serologic findings.

## HISTORY

- Duration of current heparin therapy
- Previous exposure to heparin, including heparin flushes and heparin-coated catheters
- In patients being treated with heparin for thrombosis, in which thrombosis recurs during therapy, consider HIT as a potential cause.
- Pretest probability for HIT can be calculated using the “4 Ts” methodology:
  - Thrombocytopenia of new onset
  - Timing of thrombocytopenia (5 to 10 days after exposure)
  - Thrombosis of new onset
  - Thrombocytopenia by other causes is ruled out.
- The HIT Expert Probability score is an effective pretest probability tool (2)[B].

## PHYSICAL EXAM

- Signs of venous or arterial thrombosis
- Skin necrosis (begins with erythema, progresses to ecchymosis and necrosis)
- Ischemic changes (signs of limb, renal, splenic, mesenteric ischemia)
- Bleeding (less common)
- Acute systemic reactions after IV bolus of heparin (e.g., signs of anaphylaxis)

## DIFFERENTIAL DIAGNOSIS

Other potential causes of thrombocytopenia include (list is not all-inclusive)

- Sepsis and other infections
- Drug reactions
- Autoimmune
- Transfusion reactions
- Physical destruction (e.g., during cardiopulmonary bypass)

## DIAGNOSTIC TESTS & INTERPRETATION

- Serial platelet counts in patients receiving heparin who have a possible risk of HIT >1%: Check platelets at baseline and then every 2 to 3 days from days 4 to 14 of heparin therapy (3)[B]:

Withhold platelet monitoring for patients receiving heparin with risk of HIT <1%

- Confirmatory lab tests needed for a clinical diagnosis can be divided into two major categories:
  - Antigen assay to detect presence of HIT antibodies:
    - ELISA: up to 99% sensitive, poor specificity; thus, has an excellent negative predictive value for HIT
  - Functional assay to detect evidence of platelet activation in the presence of heparin:
    - Serotonin release assay (SRA), gold standard for diagnosis: high specificity and high sensitivity
    - Heparin-induced platelet activation (HIPA): high specificity and low sensitivity
- Antigenic assay should be the initial test.
  - Either a functional assay or an antigenic assay alone may not be adequate for clinical diagnosis; their use in combination is usually recommended.
- The diagnostic interpretation of these laboratory tests must be made in the context of the clinical estimation of the pretest probability because HIT is a clinicopathologic syndrome. Patients may form heparin-dependent antibodies and still not develop HIT.

## TREATMENT

Treatment is by prompt withdrawal of heparin and replacement with a suitable alternative anticoagulant.

## GENERAL MEASURES

- Discontinue all heparin products, including flushes and heparin-coated catheters.
- All patients with a diagnosis of HIT should receive alternative anticoagulation as they are of high thrombotic risk.
- Nonimmune heparin-associated thrombocytopenia generally resolves when heparin is stopped:
  - Consider a nonheparin alternative such as fondaparinux if pharmacologic DVT prophylaxis is warranted (3)[C].
- Platelet transfusions can increase thrombosis. Give platelet transfusions only if bleeding or during an invasive procedure with a high risk of bleeding.
- Warfarin should not be administered until platelet recovery. If warfarin has been administered, vitamin K should be given (reference, Warkentin TE).

- Adverse reaction to heparin should be clearly documented in the medical record with instruction to avoid all heparin products.
- For patients with a documented history of HIT, under special circumstances only (such as the need for cardiopulmonary bypass), the use of heparin for a short duration may be acceptable if the absence of heparin/PF4 complex antibodies can be documented. Patients who develop antibodies to the heparin/PF4 complex have a significantly higher rate of postoperative thrombotic events than patients who lack these antibodies (4)[B].

## MEDICATION

- Most patients require anticoagulation because of
  - Preexisting thrombosis *or*
  - Risk of thrombosis during 30 days after HIT diagnosis (consider anticoagulation for 30 days)
- Dosing of anticoagulant depends on indication (prophylaxis vs. treatment):
  - In cases with a clinically low suspicion/pretest probability of HIT and laboratory confirmation is pending, it may be appropriate to continue antithrombotic prophylaxis using nonheparin anticoagulants.
  - In cases with high suspicion/pretest probability of HIT and laboratory confirmation is pending, it is appropriate to begin anticoagulation treatment with a nonheparin product (5) [B].

---

P.463

- Direct thrombin inhibitors (DTIs) (argatroban and bivalirudin)
  - Reduce relative risk of thrombosis by 30% and are associated with a 5-10% risk of important bleeding.
  - Can produce misleading elevation in international normalized ratio (INR) (most likely an in vitro reaction)
    - Argatroban > bivalirudin (3)[B]
  - Argatroban
    - Initial dose, 2 &mgr;g/kg/min by continuous IV infusion; decrease dose with reduced hepatic function or with critical illness.
    - Dose adjustments based to achieve activated partial thromboplastin time (aPTT) 1.5 to 3 times the baseline.
  - Bivalirudin

- Favorable pharmacologic profile; however, evidence for use is insufficient compared to argatroban (limited to case series).
- Reduced risk of bleeding in patients undergoing percutaneous artery interventions (PCIs) and other cardiac procedures
- Initial dose of 0.15 mg/kg/hr followed by adjustments to keep aPTT 1.5 to 2.5 times the baseline. Reduced dose with renal insufficiency (creatinine clearance [CrCl] <30 mL/min)
- Dose adjustments based on aPTT
- Factor Xa inhibitor (fondaparinux)
  - Reports of its use are theorized to be useful; however, minimal data support its efficacy for HIT, and an ideal dose has yet to be determined.
  - Association with the development of HIT has been reported.
  - Optional agent for thromboembolic prophylaxis when practitioner wants to avoid heparin
  - Contraindicated in patients with renal dysfunction (CrCl <30 mL/min) (5)[C]
- Warfarin
  - Must anticoagulate with an immediate-acting agent before starting warfarin
  - Use of warfarin without other anticoagulants should be avoided because it can cause thrombosis.
  - Begin warfarin after platelet count is >150,000.
  - Discontinue other anticoagulant and continue only warfarin after INR is therapeutic (2 to 3) for at least 5 days. This management differs from the normal heparin-to-warfarin transition in other conditions requiring anticoagulation (5,6)[C].
- LMWH
  - Although LMWH has a lower risk of initiating a HIT reaction, it should *not* be used when antibodies are already present. These antibodies can cross-react with LMWH and induce thrombosis and thrombocytopenia.

## INPATIENT CONSIDERATIONS

### *Nursing*

- Avoid heparin flushes.
- Avoid platelet transfusion.
- Clearly document reaction in all medical records to control the future use of heparin.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- The transition period of anticoagulation with a DTI and warfarin in patients with HIT can be problematic.
- The INR while administering both a DTI and warfarin should be therapeutic (2 to 3) for at least 5 days before discontinuing the DTI.
- Warfarin therapy should not be commenced until the platelet count has stabilized within a normal range.
- Warfarin therapy should continue for a minimum of 3 months.
- DTIs can prolong INR; therefore, if INR is  $<4$  while on both warfarin and a DTI, temporarily hold the DTI for 4 to 6 hours and recheck INR; this second INR will represent only the anticoagulant effect of warfarin.
- Monitor use of concurrent drugs with warfarin.

### *Patient Monitoring*

- Serial platelet counts
- Monitor PTT or INR as determined by the anticoagulation agent.

### *PATIENT EDUCATION*

- Patient should inform all health care providers of any previous adverse reaction to heparin.
- HIT information available at: [http://medlibrary.org/medwiki/Heparin-induced\\_thrombocytopenia](http://medlibrary.org/medwiki/Heparin-induced_thrombocytopenia)

### *PROGNOSIS*

- Thrombosis in HIT has 20-30% mortality, with additional morbidity from stroke and limb ischemia.
- Platelet counts normalize within weeks after stopping heparin.
- Risk of delayed thrombosis, especially in the first 30 days

## Codes

**&NA;**

### **ICD10**

D75.82 Heparin induced thrombocytopenia (HIT)

## **Clinical Pearls**

**&NA;**

- Heparin exposure through virtually any preparation (including LMWH), any dose, or any route can cause HIT, a life-threatening condition which is associated with severe and extensive thromboembolism.
- LMWH is contraindicated in HIT; although LMWH is less likely to cause HIT. Once HIT is present, the antibodies will cross-react and continue to cause a HIT reaction.
- If a patient is suspected of HIT (with or without confirmatory testing), immediately discontinue all forms of heparin.
- Patients will require anticoagulation either because of preexisting thrombosis or the risk of thrombosis in first 30 days after HIT.
- A direct thrombin inhibitor (DTI) should be used until a patient's INR is therapeutic (2 to 3) on warfarin for at least 5 days.
- The key to avoiding sequelae from HIT is awareness, vigilance, and a high degree of suspicion.

# Hepatic Encephalopathy

Walter M. Kim, MD, PhD

Jyoti Ramakrishna, MD

## BASICS

### DESCRIPTION

- Reversible altered mental and neuromotor functioning occurring in association with acute or chronic liver disease and/or portal systemic shunting
- The prominent features are confusion, impaired arousability, and a Øflapping tremorÓ (asterixis).
- System(s) affected: gastrointestinal; nervous
- Synonym(s): portosystemic encephalopathy; hepatic coma; liver coma

### EPIDEMIOLOGY

Predominant sex: male = female (reflecting underlying liver disease)

### Prevalence

- Overt HE occurs in 30-45% of cirrhotic patients.
- Occurs in all cases of fulminant hepatic failure
- Present in nearly 1/2 of patients who require liver transplantation.
- Parallels the age predominance of fulminant liver disease: peaks in the 40s; cirrhosis peaks in the late 50s; may occur at any age

### ETIOLOGY AND PATHOPHYSIOLOGY

- There is no defined pathophysiology for the development of HE. Three classifications have been proposed (1):
  - Type A: resulting from acute liver failure
  - Type B: resulting from portosystemic bypass or shunting
  - Type C: resulting from cirrhosis

- Several metabolic factors have been implicated in HE based on the failure of the liver to detoxify agents noxious to the CNS (e.g., ammonia, mercaptan, fatty acids).
- Increased aromatic and reduced branched chain amino acids in blood may act as false neurotransmitters, possibly interacting with the  $\gamma$ -aminobutyric acid (GABA) receptor and causing clinical symptoms.
- HE presents most commonly in long-standing cirrhosis with spontaneous shunting of intestinal blood through collateral vessels or surgically constructed portacaval shunts.
- Transjugular intrahepatic portosystemic shunt (TIPS), a widely used radiologically inserted shunt to lower portal pressure, is associated with HE in some cases.
- Asterixis is the inability to maintain a particular posture due to metabolic encephalopathy. Abnormal diencephalic function leads to the characteristic liver flap noted when the arms and wrists are held in extension. Asterixis is also present in patients with uremia, barbiturate toxicity, and some cases of pulmonary disease. As such, asterixis is not pathognomonic for HE.

## Genetics

- Unknown
- Conditions such as cystic fibrosis,  $\alpha$ -1-antitrypsin deficiency, and Wilson disease can contribute to HE.

## RISK FACTORS

In patients with underlying liver disease, precipitating factors include the following:

- Infection (overt or occult, including spontaneous bacterial peritonitis)
- GI hemorrhage
- Use of sedative or opiate drugs.
- Fluid or electrolyte disturbance ( $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Mg}^{2+}$ , or other electrolyte depletion)
- TIPS
- Constipation

## GENERAL PREVENTION

- Recognize early signs and seek prompt treatment.
- Avoid nonessential medications, particularly opiates, benzodiazepines, and sedatives.

## COMMONLY ASSOCIATED CONDITIONS

- May occur as a complication of acute fatty liver of pregnancy
- Occurs rarely in patients with a portacaval shunt but normal liver function

## DIAGNOSIS

### HISTORY

- Preexisting liver disease
- Confusion; altered mental status
- Impaired arousability

### PHYSICAL EXAM

- Age 10 to 60 years
  - Prominent signs of underlying liver disease (50%); jaundice most common, ascites second most common
  - GI hemorrhage with hematemesis or melena (20%)
  - Systemic infection, urinary tract infection, or pulmonary infection (20%)
  - Five grades (West Haven classification) of confusion and degree of obtundation (1):
    - Minimal: psychometric or neuropsychological alterations without mental status changes
    - Grade I: lack of awareness, anxiety, shortened attention span, impairment of arithmetic, altered sleep rhythm
    - Grade II: asterixis, lethargy, disorientation to time, personality change, inappropriate behavior
    - Grade III: somnolence, confusion, gross disorientation, bizarre behavior
    - Grade IV: coma
- Age >60 years
  - Signs of underlying liver disease diminish (25%)
  - Confusion more prominent
  - Precipitating GI hemorrhage or infection is less often identified.
  - Progression is slower.
- Age <10 years

- Signs of underlying liver disease prominent; usually fulminant hepatic failure or advanced cirrhosis
- Progression is very rapid, often 6 to 12 hours.
- Wilson disease can imitate HE.
- Vital signs:
  - Bradycardia
  - Increased blood pressure suggestive of increased intracranial pressure
- Jaundice, ascites, and other correlates of liver disease
- CNS exam pertaining to stage of HE: Assess short-term memory and presence of asterixis (Oliver flap—flapping of the wrist when arms are held in extension with the wrist fully extended)

## *DIFFERENTIAL DIAGNOSIS*

- Metabolic encephalopathy related to anoxia, hypoglycemia, hypokalemia, hypo- or hypercalcemia, or uremia
- Head trauma, concussion, subdural hematoma
- Transient ischemic attack (TIA), ischemic stroke
- Alcohol intoxication
- Alcohol withdrawal syndrome
- Confusion due to medications or illicit drugs
- Meningitis, encephalitis
- Wilson disease
- Reye syndrome

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Clinical findings yield diagnosis in 80% of cases.
- Response to treatment often confirms the diagnosis.
- EEG: symmetric slowing of basic (*&agr;*) rhythm (common with other metabolic encephalopathies-limited utility) (2)
- Visual evoked potential: specific in grades II to IV
- Number connection test, line drawing test, clicker flicker frequency (CFF) test, continuous

reaction time (CRT) test, inhibitory control test (ICT), and other psychometric tests may be used to assess for minimal HE.

### *Initial Tests (lab, imaging)*

- Liver tests, including aspartate aminotransferase (AST), alanine aminotransferase (ALT), and serum albumin to evaluate severity of liver disease
- Prothrombin time (PT) and international normalized ratio (INR) are elevated in liver failure due to impaired hepatic synthesis of coagulation factors.
- Serum ammonia level is elevated in 90% of patients with HE; levels affected by infusion of amino acid solutions, opiate administration (constipation), uremia, tissue breakdown, burns, trauma, or infection
- CBC-anemia and leukocytosis
- Complete metabolic profile to identify hypokalemia, hyperbilirubinemia, altered calcium concentration, hypomagnesemia, and hypoglycemia
- BUN: Creatinine >20 suggests dehydration or GI bleeding.
- Blood, urine, and ascitic fluid cultures to identify infection, if clinically indicated
- Consider arterial blood gas measurement.
- Toxicology screen for illicit drugs.
- Head CT to identify frontal cortical atrophy and mild general edema.
- MRI may demonstrate increased T1 signal in globus pallidus.

### *Tests Interpretation*

- Brain edema in 100% of fatal cases
- Glial hypertrophy in chronic encephalopathy

## **TREATMENT**

### *GENERAL MEASURES*

- Identify and treat precipitating causes: GI bleeding, infection, electrolyte imbalance. Eliminate offending medications.
- Grade I or higher: Ensure adequate fluid intake and at least 1,000 kcal (4.19 MJ) daily; avoid hypoglycemia.

- Administer initial enema to all patients who don't have diarrhea.
  - If clumsiness and poor judgment are prominent, avoid falls and other accidents.
  - Avoid sedatives, opiates, diphenoxylate, and atropine.
- 

## MEDICATION

### *First Line*

- Lactulose syrup (nonabsorbable disaccharide whose laxative action decreases colonic transit time while bacterial digestion acidifies the colon, thereby promoting excretion of ammonia): 30 to 45 mL PO up to every hour for goal of 3 to 6 bowel movements per day. Diminish to 15 to 30 mL BID when <sup>3</sup>3 bowel movements occur daily (3)[A].
- Lactulose enema (for patients who cannot tolerate oral lactulose or have suspected ileus): 300 mL lactulose plus 700 mL tap water, retained for 1 hour
- If worsening occurs acutely or there is no improvement in 2 days, add antibiotics:
  - Rifaximin: 400 mg PO TID or 550 mg PO BID (nonabsorbable antibiotic); highly effective in reversing minimal HE and preventing HE recurrence (4)[B]
- Contraindications:
  - Total ileus
  - Hypersensitivity reaction
- Precautions:
  - Hypokalemia
  - Electrolyte imbalance
  - Renal failure

### *Second Line*

- Neomycin: 1 to 2 g/day PO divided q6-8h, if renal function is within normal limits
- Polyethylene glycol has recently been studied for acute hepatic encephalopathy and appears to be effective.
- Metronidazole is an alternative antibiotic.
- Flumazenil may be of benefit in select patients.

## *ISSUES FOR REFERRAL*

Refer early to a transplant center.

## *SURGERY/OTHER PROCEDURES*

- Artificial liver perfusion devices are useful in fulminant hepatic failure as a bridge until a donor liver is available for transplantation.
- Consider liver transplant in grade II to IV patients.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Probiotics and prebiotics have been associated with improvement of HE through modulation of gut flora (5)[C].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Monitor clinical status closely in grades I and II when diagnosis is clear, and watch for progression.
- Evaluate patients with grade II to IV HE in fulminant hepatic failure for liver transplantation

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Activity as tolerated once resolved

### *Patient Monitoring*

- Trail-making test (a pencil/paper connect-the-dots according to numbers) can help monitor HE patients. Period evaluation helps determine how much maintenance treatment is needed and what diet is appropriate. The test should be run daily at first and then at each visit when changes in drugs and diet are made.
- Patients with changed findings on the trail-making test should be seen twice weekly.
- Stable patients should be seen monthly.
- Number connection test or line drawing test at each office visit also help with patient monitoring.
- In cirrhosis, evaluate for transplantation and periodically monitor Model for End-stage Liver Disease (MELD) score.

## DIET

- Integrate with underlying disease.
- Regular protein diet (1.2 to 1.5 g/kg/day) (6)[C]; vegetable protein diets are better tolerated than animal protein diets in patients with advanced cirrhosis; special IV/enteral formulations with increased branched chain amino acids are available.
- Grades III to IV patients need parenteral nutrition or jejunal feeds.

## PATIENT EDUCATION

American Association for the Study of Liver Diseases, 1729 King Street, Suite 200, Alexandria, VA 22314; 703-299-9766; www.aasld.org

## PROGNOSIS

- With adequate aggressive treatment, HE resolves without residue or recurrence
- Chronic disease
  - Coma returns.
  - With each recurrence, HE is more difficult to treat—the degree of improvement with treatment is less and the mortality rate approaches 80%.

## COMPLICATIONS

- Recurrence
- With many recurrences, permanent basal ganglion injury (non-Wilsonian hepatolenticular degeneration)
- Hepatorenal syndrome

Algorithm: Delirium

## Codes

&NA;

### ICD10

- K72.90 Hepatic failure, unspecified without coma
- K72.91 Hepatic failure, unspecified with coma

## Clinical Pearls

&NA;

- HE includes a spectrum of neuropsychiatric findings that occur in patients with significant alterations in hepatic function.
- Lactulose is a cornerstone of therapy for HE.
- Asterixis (Oliver flap) is the classic physical finding associated with HE.

# Hepatitis A

Daniel J. Stein, MD, MPH

Stephen K. Lane, MD, FAAFP

## BASICS

### *DESCRIPTION*

One of the world's most common diseases, hepatitis A is an infection with the hepatitis A virus (HAV) primarily involving the liver (1).

### *EPIDEMIOLOGY*

#### *Pediatric Considerations*

- Disease is often milder or asymptomatic in children; severity increases with age.
- Infections are asymptomatic in 70% of children age <6 years.
- In 2009, <50% of 13- to 17-year-olds in the United States had been vaccinated.

#### *Pregnancy Considerations*

- Pregnant women with HAV have increased risk of complications including preterm labor (2).
- Vertical transmission has been reported; fecal-oral transmission during birth is possible.
- Breastfeeding is not contraindicated.

#### *Incidence*

- HAV is cause of roughly 50% of reported cases of viral hepatitis in the United States (3).
- 1.4 million cases globally each year
- Since the hepatitis A vaccine has been in routine use (1995), the incidence of HAV has decreased by 95%.
- Approximately 3,000 HAV infections in 2009, lowest ever recorded in the United States (1)
- Incidence in the United States: 0.5/100,000 (1)
- No difference based on sex

- As many as 1/2 of current HAV infections in the United States are acquired from travel to endemic countries.

## *Prevalence*

Serologic evidence of prior HAV infection: 1/3 of United States population. Anti-HAV prevalence related to age, ranging from 9% in children ages 6 to 11 years to 75% of those >70 years.

Related inversely to income

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- HAV is a single-stranded linear RNA enterovirus of the *Picornaviridae* family.
- Infection is limited to liver hepatocytes and macrophages.
- HAV is excreted into the bile and then stool, providing major route of spread.
- Primary transmission is fecal-oral.
- Humans are the only natural host.
- Incubation is 2 to 6 weeks (mean 4 weeks).
- Greatest infectivity is during 2 weeks before and one week after the onset of clinical illness.
- Infection occurs primarily after consuming food or water contaminated with HAV, or via direct contact with HAV-infected person with poor hygiene.
- Outbreaks can occur related to a common food or water source with multiple individuals exposed
- Virus is stable in water and on surfaces, but is easily killed with high heat or cleaning agents.
- Shellfish (clams and oysters) may be contaminated if harvested from waters contaminated with HAV.
- Blood-borne transmission is rare.
- HAV is not a chronic disease, but can last for months.

## *Genetics*

Autoimmune hepatitis is rarely associated with human leukocyte antigen class II; DR3 and DR4 after active infection with HAV.

## **RISK FACTORS**

- Travel to developing countries accounts for >50% of cases in North America and Europe.
- Employment in health care

- Household exposure
- Intimate exposure, especially men who have sex with men
- Injection of illicit drugs
- Child care centers, schools
- Institutionalized individuals
- Clotting factor disorders, such as hemophilia
- Blood exposure/transfusion (rare)
- No identifiable risk factor in 50%

## **GENERAL PREVENTION**

- Proper sanitation and personal hygiene (including hand washing), especially for food handlers, health care, and daycare workers
- Active immunization: HAV vaccines: Havrix and Vaqta; Twinrix-combination HAV and HBV
- Vaccine is recommended for (1)[C],(4)[A]:
  - All children aged 12 to 23 months, with catch-up administration until 18 years old
  - All travelers to countries with a high endemic rate of hepatitis A
  - Men who have sex with men
  - Illicit IV drug users
  - Anyone with chronic liver disease (including pre and post liver transplant)
  - Individuals with a clotting factor disorder
  - Household members and close contacts of children adopted from countries with a high HAV prevalence (prior to arrival)
  - Anyone exposed during an outbreak
- Per the CDC, routine vaccination is no longer routinely recommended for food service, child care, or health care workers (1)[C].
- HIV-infected patients who are negative for HAV IgG should receive HAV vaccine series, preferably early in course of HIV infection
  - If CD4 count is  $<200$  cells/mm<sup>3</sup> or the patient has symptomatic HIV disease, defer vaccination until several months after initiation of antiretroviral (ARV) therapy to maximize the antibody response to the vaccine.

- HAV is *not* killed by freezing.
- HAV is killed by
  - Heating to 185°F for 60 seconds
  - Chlorine
  - Iodine

## DIAGNOSIS

### HISTORY

- Onset is often abrupt. Common symptoms include nausea, emesis and diarrhea, and headache
- Symptom severity increases with age
- Pediatric cases (under 6) frequently asymptomatic
- Other symptoms:
  - Fever, malaise, fatigue, myalgias, anorexia
  - Dark urine (bilirubinuria)
  - Right upper abdominal pain
  - Pruritus (can suggest cholestasis)

### PHYSICAL EXAM

- Fever (variable)
- Jaundice and icterus present in >70% of adults and older children
- Hepatomegaly is also common; splenomegaly is less common.
- Right upper quadrant abdominal tenderness
- Rarely can have lymphadenopathy (cervical), arthritis, or rash
- Asterixis can indicate acute hepatic failure.

### DIFFERENTIAL DIAGNOSIS

- Hepatitis B, C, D, E. Not clinically distinguishable from other forms of viral hepatitis; diagnosis may be suspected with typical symptoms during an outbreak.
- Drug-induced hepatitis; toxin-induced hepatitis

Alcoholic hepatitis

- Hemochromatosis (adults) or Wilson disease
- Autoimmune hepatitis
- Malaria
- Infectious mononucleosis, cytomegalovirus (CMV)
- Primary or secondary hepatic malignancy
- Ischemic hepatitis or Budd-Chiari syndrome
- Nonhepatobiliary disease (elevated AST/ALT): celiac disease, congestive heart failure, thyroid disease
- Bacterial infections (Q fever, leptospirosis, syphilis, Rocky Mountain spotted fever)
- Parasites (liver flukes or toxocariasis)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Anti-HAV IgM: positive at time of onset of symptoms sensitivity and specificity >95%. Primary test used to diagnose acute infection.
- Anti-HAV IgG: appears soon after IgM and generally persists from years to lifetime
- AST and ALT elevated  $\div$ 500 to 5,000: ALT usually > AST (3)
- Alkaline phosphatase: mildly elevated
- Bilirubin: conjugated and unconjugated fractions usually increased. Usually follows rises in ALT/AST, consistent with hepatocellular injury pattern
- Prothrombin time and partial thromboplastin time usually remain normal or near normal.
  - Significant rises should raise concern of possible acute hepatic failure or coexistent chronic liver disease
- CBC: mild leukocytosis; aplasia and pancytopenia are rare.
  - Thrombocytopenia may predict illness severity.
  - Autoimmune hemolytic anemia (rare)
- Albumin, electrolytes, and glucose to evaluate for hepatic and renal function (rare renal failure)
- Urinalysis (not clinically necessary): bilirubinuria
- Consider ultrasound (US) to rule out biliary obstruction only if lab pattern is cholestatic.

## *Follow-Up Tests & Special Considerations*

Illness usually resolves within 4 weeks from onset of symptoms. Repeat labs are not generally indicated unless symptoms persist or new ones develop.

## *Diagnostic Procedures/Other*

Liver biopsy is usually not necessary. US can evaluate other causes (e.g., thrombosis or concurrent cirrhosis)

---

P.467

## *Tests Interpretation*

- Positive serum markers in hepatitis A
  - Acute disease: anti-HAV IgM only
  - Recent disease (last 6 months): anti-HAV IgM and IgG positive
  - Previous disease: anti-HAV IgM negative and IgG positive
- If liver biopsy obtained, shows portal inflammation; immunofluorescent stains for HAV antigen positive

## **TREATMENT**

### *GENERAL MEASURES*

- Maintain appropriate nutrition/hydration.
- Avoid alcohol.
- Attend to personal hygiene to prevent spread.
- Monitor coagulation defects, fluid and electrolytes, acid-base imbalance, hypoglycemia, and impairment of renal function.
- Report to local public health department.
- Laboratory evaluation including coagulation factors is important to rule out fulminant hepatic failure.
- Referral to liver transplant center for fulminant failure (rare)

### *MEDICATION*

Preexposure vaccination should be given according to recommended guidelines.

- Give postexposure prophylaxis to persons within 2 weeks of exposure to HAV who have not previously received HAV vaccine (5)[A],(6)[C].
  - Administer hepatitis A vaccine to healthy persons between the ages of 1 and 40 years at age-appropriate dose (7)[A].
  - Administer immunoglobulin (0.02 mL/kg) to persons <1 or >40 years of age, or to patients with significant comorbidities (immunosuppression, liver disease) who are at risk for poor immune response (5)[A],(6)[C].
- Use immunoglobulin for passive preexposure prophylaxis in those not eligible for the vaccine (5)[A],(6)[C].
  - 0.02 mL/kg provides 1 to 2 months of coverage; 0.06 mL/kg provides 3 to 5 months of coverage
  - Long-term prophylaxis should be with 0.06 mL/kg every 5 months for sustained risk (e.g., travelers)
  - Use immunoglobulin with the vaccine in cases where travelers need immediate protection and are older than 40 years.
  - Use immunoglobulin alone in children under 1 year old and unvaccinated pregnant women who will be traveling.
  - Do not give immunoglobulin with the MMR or varicella vaccines.

### *First Line*

- No antiviral medications indicated; spontaneous resolution occurs in almost all patients.
- Limit acetaminophen use to 2 g/day or less.
- Avoid hepatotoxic agents.

### *Second Line*

- Antiemetics (e.g., ondansetron)
- IV fluids
- Pruritus: diphenhydramine 50 mg PO IM q6h, consider cholestyramine 4 g BID if cholestasis

### *ISSUES FOR REFERRAL*

- Dictated by severity of illness

- Hepatic failure, refer to a high-volume liver transplant program

## ***SURGERY/OTHER PROCEDURES***

Liver transplant in fulminant hepatic failureÑrare

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Avoid botanicals with potential hepatotoxicity, including barberry, comfrey, golden ragwort, groundsel, huang qin, kava kava, pennyroyal, sassafras, senna, valerian, wall germander, and wood sage.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Treatment is usually outpatient unless signs of liver failure; dictated by severity of illness

### ***IV Fluids***

Treat dehydration and any noted electrolyte imbalances.

### ***Nursing***

Enteric isolation. Private rooms, gowns, and masks are not necessary. Frequent hand washing. Use gloves when handling material potentially contaminated with feces.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Return to work/school 10 to 14 days after onset of symptoms with diligence to hygiene (patients remain infectious for up to 4 weeks from symptom onset).

### ***Patient Monitoring***

Monitor coagulation defects, fluid and electrolytes, acid-base imbalance, hypoglycemia, and renal function.

### ***DIET***

- Adequate balanced nutrition
- Avoid alcohol.

## PATIENT EDUCATION

- Segregate food handlers with HAV.
- HAV immunity persists after infection
- CDC Hepatitis A FAQs Link: <http://www.cdc.gov/hepatitis/hav/afaq.htm>

## PROGNOSIS

- Excellent; mortality is 0.3% (1)
- Risk increased with underlying chronic liver disease and in the elderly (1.8% mortality age >50) (1)

## COMPLICATIONS

- Coagulopathy, encephalopathy, and renal failure
- Relapsing HAV: usually milder than the initial case
- Positive anti-HAV IgM. Total duration is usually <9 months.
- Prolonged cholestasis: characterized by protracted periods of jaundice and pruritus (>3 months), resolves without intervention (supportive care only)
- Autoimmune hepatitis: can be seen after HAV infection; good response to steroids
- Hepatic failure: rare (1-2%)
- Postviral encephalitis, Guillain-Barré syndrome, pancreatitis, aplastic or hemolytic anemia, agranulocytosis, thrombocytopenic purpura, pancytopenia, arthritis, vasculitis, and cryoglobulinemia (all rare)

- Hepatitis B; Hepatitis C
- Algorithm: Hyperbilirubinemia, Cirrhosis, and Jaundice

## Codes

&NA;

### ICD10

B15.9 Hepatitis A without hepatic coma

## Clinical Pearls

&NA;

- HAV disease severity directly correlates with age; children are often asymptomatic.
- HAV vaccine is indicated for all children, travelers, those at elevated risk of disease, and anyone with liver impairment.
- Check HAV IgG in all HIV-positive patients; provide HAV vaccine to those who are negative.
- Treatment of acute disease is supportive
- Give postexposure prophylaxis to eligible patients within 14 days of exposure

# Hepatitis B

Jason Chao, MD, MS

## BASICS

### *DESCRIPTION*

Systemic viral infection associated with acute and chronic liver disease and hepatocellular carcinoma (HCC)

### *EPIDEMIOLOGY*

#### *Incidence*

- Predominant age: can infect patients of all ages
- Predominant sex: fulminant hepatitis B virus (HBV): male > female (2:1)
- In the United States, estimated 38,000 new infections in 2009, 70% due to IV drug use
- African Americans have the highest rate of acute HBV infection in the United States.
- Overall rate of new infections is down 82% since 1991 (due to national immunization strategy).
- U.S. vaccine coverage for the birth dose of HBV increased from 68.6% in 2011 to 71.6% in 2012.

#### *Prevalence*

- In the United States, 800,000 to 1.4 million people have chronic HBV.
- Asia and the Pacific Islands have the largest populations at risk for HBV.
- Chronic HBV worldwide: 350 to 400 million persons
  - 1 million deaths annually
    - Second most important carcinogen (behind tobacco)
    - Of chronic carriers with active disease, 25% die due to complications of cirrhosis or HCC.
    - Of chronic carriers, 75% are Asian.

# ETIOLOGY AND PATHOPHYSIOLOGY

HBV is a DNA virus of the *Hepadnaviridae* family. Highly infectious via blood and secretions for at least a week outside the body.

## Genetics

Family history of HBV and/or HCC

## RISK FACTORS

- Screen the following high-risk groups for HBV with HBsAg/sAb. Vaccinate if seronegative (1) [A]:
  - Persons born in endemic areas (45% of world)
  - Hemodialysis patients
  - IV drug users (IVDUs), past or present
  - Men who have sex with men (MSM)
  - HIV- and HCV-positive patients
  - Household members of HBsAg carriers
  - Sexual contacts of HBsAg carriers
  - Inmates of correctional facilities
  - Patients with chronically elevated aspartate aminotransferase/alanine aminotransferase (AST/ALT)
- Additional risk factors:
  - Needle stick/occupational exposure
  - Recipients of blood/products; transplanted organ recipients
  - Intranasal drug users
  - Body piercing/tattoos
  - Survivors of sexual assault

## Pediatric Considerations

- Shorter acute course; fewer complications
- 90% of vertical/perinatal infections become chronic.

## Pregnancy Considerations

- Screen all prenatal patients for HBsAg (1)[A].
- Consider treating patients with high viral load at 28 weeks with oral nucleos(t)ide medicines beginning at 32 weeks to reduce perinatal transmission (2)[C].

Marker	Acute Infection	Chronic Infection	Inactive Carrier	Resolved Infection	Susceptible to Infection	Vaccinated
HBsAg	+	+	+	-	-	-
HBsAb	-	-	-	+	-	+
HBcAb	+ IgM	- IgM; +total/IgG	+	+	-	-
HBeAg	+	±	-	-	-	-
HBeAb	-	±	+	±	-	-
HBV DNA	Present	Present	Low-negative	-	-	-
ALT	Marked elevation	Normal to mildly elevated	Normal	Normal	Normal	Normal

- Infants born to HBV-infected mothers require HB immune globulin (HBIG) (0.5 mL) and HBV vaccine within 12 hours of birth.
- Breastfeeding is safe if HBIG and HBV vaccine are administered and the areolar complex is without fissures or open sores. Oral nucleos(t)ide medications are not recommended during lactation.
- HIV coinfection significantly increases risk of vertical transmission.
- Continue medications if pregnancy occurs while on an oral antiviral therapy to prevent acute flare.

## GENERAL PREVENTION

Most effective: HBV vaccination series (three doses)

- Vaccinate
  - All infants at birth and during well-child care visits

- All at-risk patients (see `Risk Factors`)
- Health care and public safety workers
- Sexual contacts of HBsAg carriers
- Household contacts of HBsAg carriers
- Proper hygiene/sanitation by health care workers, IVDU, and tattoo/piercing artists
  - Barrier precautions, needle disposal, sterilize equipment, cover open cuts
- Do not share personal items exposed to blood (e.g., nail clipper, razor, toothbrush).
- Safe sexual practices (condoms)
- HBsAg carriers cannot donate blood or tissue.
- Postexposure (e.g., needle stick): HBIg 0.06 mL/kg in <24 hours in addition to vaccination

## COMMONLY ASSOCIATED CONDITIONS

HIV coinfection, hepatitis C coinfection

## DIAGNOSIS

### HISTORY

- Exposure: detailed family and social history
- Acute HBV
  - Fever, malaise, fatigue, arthralgias, myalgias
  - Anorexia, nausea, vomiting
  - Jaundice, scleral icterus
  - Dark urine, pale stools
  - Right upper quadrant (RUQ) abdominal pain
- Chronic HBV: typically asymptomatic

## PHYSICAL EXAM

Acute: ill; jaundice/scleral icterus; RUQ tenderness; hepatomegaly

## DIFFERENTIAL DIAGNOSIS

- Epstein-Barr virus (EBV); cytomegalovirus (CMV); hepatitis A, C, or E

- Drug-induced, alcoholic, or autoimmune hepatitis
- Wilson disease or rheumatologic/immunologic disorders

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- AST/ALT: markedly elevated in acute HBV (particularly ALT), with levels in the hundreds to several thousand IU/mL. Transaminases may be normal or mildly elevated in chronic HBV:
  - Transaminases elevate before bilirubin
- Bilirubin (conjugated/unconjugated): normal to markedly elevated in acute HBV
  - Last test to normalize as acute infection resolves
- Alkaline phosphatase: mild elevation
- HBcAb IgM may be the only early finding (window period, before HBsAg turns positive)
- For acute hepatitis:
  - Monitor PT, albumin, electrolytes, glucose, and CBC.
  - If severe acute HBV, check for superinfection with hepatitis D (HDV Ag and HDV Ab)
  - Hepatitis B serologic markers
- Hepatitis B e-antigen (HBeAg+) indicates high replication/infectivity; confirmed with high HBV DNA ( $\geq 10^5$  copies/mL); these patients benefit from medical therapy.
- HBV precore mutants have undetectable HBeAg despite active viral replication (confirm with HBV DNA level) as well as antibody to e-antigen (HBeAb+).
- Screen for HDV, HIV, HCV, and immunity to hepatitis A virus (HAV Ab total/IgG).
- Ultrasound to document ascites, organomegaly, signs of portal hypertension, hepatic or portal obstruction, and to screen for HCC
- Contrast CT or MRI if ultrasound is abnormal or if  $\alpha$ -fetoprotein (AFP) is elevated.

### ***Follow-Up Tests & Special Considerations***

HBsAg+ persistence >6 months defines chronic HBV:

- Measure HBV DNA level and ALT every 3 to 6 months.
- If age >40 years and ALT borderline or mildly elevated, consider liver biopsy.
- Measure baseline AFP.

- Follow HBeAg for elimination (every 6 to 12 months)
- Lifetime monitoring for progression, need for treatment, and screening for HCC

### *Diagnostic Procedures/Other*

- Liver biopsy
- Noninvasive tests (Hepascore, Fibrotest) or measurement of elastography (Fibroscan) to assess for hepatic fibrosis.

### *Test Interpretation*

Liver biopsy in chronic HBV may show interface hepatitis and inflammation, necrosis, cholestasis, fibrosis, cirrhosis, or chronic active hepatitis.

## **TREATMENT**

### *GENERAL MEASURES*

- Vaccinate for HAV if seronegative
- Monitor CBC, coagulation, electrolytes, glucose, renal function, and phosphate.
- Monitor ALT and HBV DNA; increased ALT and reduced DNA implies response to therapy.
- Screen for HCC if HBsAg+.

### *MEDICATION*

#### *First Line*

- Acute HBV
  - Supportive care; spontaneously resolves in 95% of immunocompetent adults
  - Antiviral therapy not indicated except for fulminant liver failure or immunosuppressed.

#### **Chronic Hepatitis B Therapy**

<b>HBeAg</b>	<b>HBV DNA viral load</b>	<b>ALT*</b>	<b>Recommend</b>
(+)	<sup>3</sup> 20,000	Elevated	Treat with antiviral or interferon.

	IU/mL		
(-)	$\geq 2,000$ IU/mL	Elevated	Consider biopsy or serum fibrosis marker and treatment.
(+)	$\geq 20,000$ IU/mL	Any	Monitor q6-12mo
(-)	$\geq 2,000$ IU/mL	Normal	Biopsy; treat if disease
(+)	$\geq 20,000$ IU/mL	Normal	Observe, consider treatment if ALT elevated. Biopsy if age >40 years or ALT is high normal to mild elevation.
(-)	$\geq 2,000$ IU/mL	Any	Monitor q6-12mo
Cirrhosis	Any	Any	Treat with mono or combination treatment.
Liver failure	Any	Any	Treat + refer for transplant

\* ALT elevated if  $>2 \times$  ULN; ULN for male = 30 IU/mL and for female = 19 IU/mL.

- Chronic HBV: Treatment is based on HBeAg status:
  - FDA-approved drugs: lamivudine 100 mg, adefovir 10 mg, entecavir 0.5 to 1 mg, telbivudine 600 mg, or tenofovir 300 mg, all given PO every day (dose based on renal function); pegylated interferon (peg-IFN)  $\&agr;$ 2a,  $\&agr;$ 2b SC weekly (3)[A]
- Entecavir, tenofovir, and peg-IFN are preferred first-line agents (3)[A].
- Extended oral agents regimens indicated (3)[A]:
  - If HBeAg+, treat 6 to 12 months post loss of HBeAg and gain of HBeAb, and monitor after cessation.
  - If HBeAg-, treat indefinitely or until HBsAg clearance and HBsAb development.
- Change/add drug based on resistance:
  - Confirm patient adherence with medications before assuming resistance.
  - Adherence to therapy lowers rate of resistance.
- Adjust dosing for renal function

- Peg-IFN preferred to standard interferon:
  - Weekly peg-IFN (Pegasys) injections for 48 weeks
  - Most efficacious for genotype A
  - Contraindicated if decompensated cirrhosis
- Goals of therapy: undetectable HBV DNA, normal ALT, loss of HBeAg, gain of HBeAb; loss of HBsAg and gain of HBsAb
- Precautions:
  - Oral drugs: renal insufficiency
  - Peg-IFN: coagulopathy, myelosuppression, depression/suicidal ideation

## *Second Line*

Emtricitabine suppresses viral load; not FDA approved.

## *ISSUES FOR REFERRAL*

- Refer all persistent HBsAg+ patients to have them evaluated for antiviral therapy.
- Refer immediately to liver transplant program if fulminant acute hepatitis, end-stage liver disease, or HCC

## *SURGERY/OTHER PROCEDURES*

Liver transplantation, operative resection, radiofrequency ablation for HCC

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Worsening course (marked increase in bilirubin, transaminases, or symptoms)
- Hepatic failure (high PT, encephalopathy)

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Monitor serial ALT and HBV DNA:

- High ALT + low HBV DNA associated with favorable response to therapy
- Serologic markers: See table.
- CBC to monitor WBC and platelets for patients on interferon therapy
- Monitor HBV DNA q3-6mo during therapy:
  - Undetectable DNA at week 24 of oral drug therapy associated with low resistance at year 2
- Monitor for complications (ascites, encephalopathy, variceal bleed) in cirrhosis.
- Recommend vaccination for all household contacts and sexual partners.
- Ultrasound q6-12mo to screen for HCC starting at age 40 years in men and age 50 in women (3)[B].

## *DIET*

Avoid alcohol.

## *PATIENT EDUCATION*

- Acute HBV
  - Review transmission precautions.
- Chronic HBV
  - Alcohol and tobacco use accelerate progression
  - Strict medication compliance to prevent flare
- Patient education materials in English and others, including many Asian languages, available at <http://www.cdc.gov/hepatitis/Resources/PatientEdMaterials.htm>

## *PROGNOSIS*

- Acute infection: 95% of adults recover
- Severity of encephalopathy predicts survival in fulminant hepatic failure
- Acute HBV: mortality 1%
- Acute HBV + HDV: mortality 2-20%
- Chronic HBV
  - Spontaneous resolution: 0.5% per year
  - Premature death from cirrhosis or HCC: 25%

- Risk of HCC rises with rate of viral replication, even if no cirrhosis

## COMPLICATIONS

- Acute or subacute hepatic necrosis; cirrhosis; hepatic failure
- HCC (all chronic HBV patients are at risk)
- Severe flare of chronic HBV with corticosteroids and other immunosuppressants: Avoid if possible.
- Reactivation of resolved infection if immunosuppressed (e.g., chemotherapy): premedicate prophylactically if HBsAg+ or if HBcAb+ and receiving systemic chemotherapy (1)[A]

## **ICD10**

- B19.10 Unspecified viral hepatitis B without hepatic coma
- B16.9 Acute hepatitis B w/o delta-agent and without hepatic coma
- B18.1 Chronic viral hepatitis B without delta-agent

## **Clinical Pearls**

**&NA;**

- All patients born in endemic countries should be screened for HBV infection with HBsAg.
- Patients with chronic HBV need lifetime monitoring for disease progression and HCC.
- HBV is the second most common worldwide carcinogen (behind tobacco).

# Hepatitis C

Christopher Lin-Brandt, MD

Amy M. Davis, MD

Krunal Patel, MD

## BASICS

### *DESCRIPTION*

Systemic viral infection (acute and chronic) primarily involving liver

### *EPIDEMIOLOGY*

- Highest incidence ages 20 to 39; highest prevalence ages 40 to 59
- Males and non-Hispanic blacks more likely to be infected (1).

### *Geriatric Considerations*

Age >60 years less likely to respond to therapy; treat earlier if able.

### *Pregnancy Considerations*

- Routine HCV testing is not indicated.
- Vertical transmission occurs in 6 of every 100 births in HCV-positive mothers; risk increases 2 to 3 times if HIV coinfection.
- Breastfeeding is safe if no fissures.

### *Pediatric Considerations*

- Prevalence: 0.3%
- Test children born to HCV-positive mothers with HCV Ab after 18 months or HCV RNA at 1 to 2 months for early diagnosis.
- Fewer symptoms; fewer abnormal liver tests; more likely to clear spontaneously; slower rate of progression

### *Incidence*

In 2013, CDC estimated there were 29,718 total new cases of hepatitis C. 2,138 of these were new acute cases.

## *Prevalence*

- ÷3.6 million in the United States (1.3%) are HCV Ab-positive.
- Prevalence is highest in persons born between 1945 and 1965 (2.6%) (1).
- 2.7 million have chronic HCV (HCV RNA-positive).
- HCV-related deaths are more common than HIV-related deaths.
- Most common cause of chronic liver disease and transplantation in the United States
- Six genotypes (GT) were known. GT 1 is predominant form in the United States (75%). GT does not change during infection and predicts response to treatment.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Single-stranded RNA virus of *Flaviviridae* family

## *RISK FACTORS*

- Exposure risks
  - Chronic hemodialysis
  - Blood/blood product transfusion or organ transplantation before July 1992
  - Hemophilia treatment before 1987
  - Household or health care-related exposure to HCV-infected body fluids (1.8% risk)
  - Children born to HCV-positive mothers
  - Adults born between 1945 and 1965
- Risk behaviors and/or medical conditions
  - Prior history of injection drug use
  - Intranasal illicit drug use
  - History of incarceration
  - Tattooing in unregulated settings
  - Current sexual partners of HCV-positive persons
  - HIV and hepatitis B infection

## GENERAL PREVENTION

- *Primary prevention*
  - Do not share razors/toothbrushes/nail clippers.
  - Use and dispose needles properly through harmreduction programs.
  - Practice safer sex.
  - Cover cuts and sores.
- *Secondary prevention*
  - No vaccine or postexposure prophylaxis available
  - Substance abuse treatment
  - Reinforce use of barrier contraception for HIV-seropositive coinfecting with HCV.
  - Assess for degree of liver fibrosis/cirrhosis.

## COMMONLY ASSOCIATED CONDITIONS

Diabetes, metabolic syndrome, iron overload, depression, substance abuse/recovery, autoimmune and hematologic disease, HIV, and hepatitis B coinfection

## DIAGNOSIS

### HISTORY

- Determine exposure risk: *detailed* social history including alcohol and IV drug use, psychiatric and medical comorbidities, coinfections
- Chronic HCV: Most cases are mildly symptomatic (nonspecific fatigue) or asymptomatic elevated ALT/aspartate aminotransferase (AST).
- Acute HCV: *If* symptoms develop (rare)
  - Onset typically 4 to 12 weeks postexposure
  - Jaundice, dark urine, steatorrhea, nausea, abdominal pain (right upper quadrant), fatigue, low-grade fevers, myalgias, arthralgias
  - 15-40% resolve; rest progress to chronic hepatitis C

## PHYSICAL EXAM

- Typically normal unless advanced fibrosis/cirrhosis
- May have right upper quadrant (RUQ) tenderness/hepatomegaly

- General signs of chronic liver disease: spider angioma, caput medusa, palmar erythema, jaundice, gynecomastia, Terry nails, ascites
- Extrahepatic manifestations: arthralgias/myalgias, neuropathy, glomerulonephritis, livedo reticularis, lichen planus, pruritus, sicca syndrome, cold agglutinin disease

## ***DIFFERENTIAL DIAGNOSIS***

Hepatitis A or B; Epstein-Barr virus (EBV), cytomegalovirus (CMV); alcoholic hepatitis; nonalcoholic steatohepatitis (NASH); hemochromatosis; Wilson disease, &agr;1-antitrypsin deficiency; ischemic, drug-induced, or autoimmune hepatitis

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Screening is recommended for adults born between 1945 and 1965, anyone with exposure risks, current and former IV drug users, HIV-positive individuals, especially men who have sex with men (MSM) and patients with persistently elevated ALT.
- CDC algorithm
  - HCV Ab
    - If nonreactive, no further action unless recent exposure is suspected (HCV RNA).
    - If reactive, test HCV RNA and genotype.
  - HCV RNA
    - If not detected, no current HCV infection. No further action in most cases but can repeat either test if recent exposure suspected
    - If detected, that there is current HCV infection, counsel and treat.
- HCV Ab can be detected 4 to 10 weeks after infection.
- HCV RNA can be detected 2 to 3 weeks after infection.
- RNA detectability precedes ALT elevation.
- AST/ALT: often normal but may be persistently elevated in chronic HCV; ALT usually is 1 to 2 times upper limit of normal; AST may be normal/elevated, but typically less so than ALT.
  - Acute hepatitis C can cause elevation of transaminases and bilirubin (direct and indirect).
- AST/ALT ratio <sup>3</sup>1 associated with cirrhosis
  - If AST/ALT ratio >2, rule out alcohol abuse.

- Persistent HCV RNA >6 months = chronic HCV

## *Follow-Up Tests & Special Considerations*

- Platelets, creatinine, TSH, vitamin D (may predict treatment response)
- Liver function panel, coagulation factors
- HCV GT
- IL28B testing: C/C homozygote more likely to clear
- HBV (hepatitis panel) and HIV coinfection
- Vaccinate if seronegative for hepatitis A/B.
- Pneumococcal polysaccharide vaccine (PPSV23)

## *Diagnostic Procedures/Other*

Evaluate for advanced hepatic fibrosis.

- Indirect markers: AST-to-platelet ratio index (APRI), FIB-4, FibroIndex, Forns index, HepaScore/FibroScore, FibroSure
  - Factors such as age, gender, AST, ALT, platelets, bilirubin, estimate fibrosis.
- Direct markers: FIBROSpect II
- Liver imaging: US, CT scan, MRI, transient ultrasound elastography, MR elastography
- Liver biopsy (gold standard)
  - Indications: discordant indirect marker results, concurrent non-HCV liver disease, elastography not available
  - Not necessary to diagnose hepatocellular carcinoma if diagnosis is clear based on imaging

## *Test Interpretation*

- Biopsy measures grade (degree of inflammation) and stage (amount of existing fibrosis)
- Scoring systems: Batts and Ludwig, METAVIR, International Association for the Study of the Liver (IASL)

## **TREATMENT**

## GENERAL MEASURES

- Report acute cases of HCV to health department.
- Consider treating all patients with virologic evidence of HCV.
- Pretreatment counseling should include thorough behavioral health and substance abuse history.
- Optimize medical therapy for comorbid conditions prior to treatment.
- Discuss treatment plan and likelihood of success based on individual factors such as BMI, genotype, race, stage of fibrosis, and viral load.
- Treatment evolution of HCV (2)
  - Pegylated-interferon (PEG) plus ribavirin (RBV) regimens in the 1990s: ÷50% cure (may still be used for directly-acting antiviral agent [DAA] nonresponders)
  - Combination PEG/RBV plus DAA in early 2000s: ÷75% cure
  - All-oral DAAs in the last 4 years: >95% cure
- New therapies increasingly all-oral, including DAAs and host-targeting antiviral agents (HTAs)
- Goal is sustained virologic response (SVR): undetectable HCV RNA after 12 to 24 weeks of treatment.
- HCV cascade: Of those with chronic HCV, only 50% are diagnosed, 25% are HCV RNA confirmed, 15% are prescribed treatment, and 10% achieve SVR (3).

---

P.471

## MEDICATION

### First Line

Acute HCV: Treatment may be delayed 12 to 16 weeks after suspected inoculation to allow chance for spontaneous clearance. Regimen is same as for chronic HCV.

#### Genotype Drug Regimen

1a <sup>a</sup>	Ledipasvir/sofosbuvir (Harvoni) for 12 weeks Ombitasvir/paritaprevir/ritonavir plus dasabuvir (Viekira Pak) and weight-based RBV (Rebetol) for 12 weeks (no cirrhosis) or 24 weeks (cirrhosis) Sofosbuvir (Sovaldi) plus simeprevir (Olysio) with or without weight-based RBV for 12 weeks (no cirrhosis) or 24 weeks (cirrhosis)
1b <sup>a</sup>	Ledipasvir/sofosbuvir for 12 weeks

- Ombitasvir/paritaprevir/ritonavir plus dasabuvir for 12 weeks (no cirrhosis) or with the addition of weight-based RBV for 24 weeks (cirrhosis)  
Sofosbuvir plus simeprevir for 12 weeks (no cirrhosis) or 24 weeks (cirrhosis)
- 2 Sofosbuvir plus weight-based RBV for 12 weeks (no cirrhosis) or for 16 weeks (cirrhosis)
- 3 Sofosbuvir plus weight-based RBV for 24 weeks
- 4<sup>a</sup> Ledipasvir/sofosbuvir for 12 weeks  
Ombitasvir/paritaprevir/ritonavir plus dasabuvir and weight-based RBV for 12 weeks  
Sofosbuvir plus weight-based RBV for 24 weeks
- 5 Sofosbuvir plus pegylated interferon plus weight-based RBV for 12 weeks
- 6 Ledipasvir/sofosbuvir for 12 weeks

AASLD, American Association for the Study of Liver Diseases; RBV, ribavirin.

<sup>a</sup> Three options with similar effectiveness.

## *ISSUES FOR REFERRAL*

- Involve a physician experienced with HCV therapy in all cases.
- Refer to liver transplant program if fulminant acute hepatitis, at first complication of end-stage disease, MELD score <sup>3</sup>12 or at diagnosis of HCC.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

No evidence for effective complementary therapy in HCV/cirrhosis/HCC. Milk thistle (silymarin) safe; may reduce ALT, does not eradicate virus or improve outcomes; avoid on IFN.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Treat early to prevent fibrosis. If cirrhosis is already present, treatment may not prevent decompensation.
- If treatment is deferred, screen patients with annual LFTs, monitor for disease progression, and maintain sobriety (if alcohol dependence involved).

- Monitor serial viral load only if on antiviral therapy.
- Abdominal ultrasound every 6 to 12 months to monitor for hepatocellular carcinoma (expert opinion). AFP is no longer in AASLD guidelines.

## *Patient Monitoring*

- Serial ALT/AST; fasting glucose and CBCs
- Follow electrolytes, thyroid-stimulating hormone (TSH), renal function, PT.
- For 12-week course, follow-up 4 weeks after starting therapy and 12 weeks after completing therapy
  - 4-week HCV RNA: If detectable, recheck at week 6. If RNA has increased >10 times, stop therapy.
  - SVR12: Undetectable HCV RNA 12 weeks after completing therapy generally translates to long-term cure (goal of therapy).
- SVR decreases risk of portal hypertension, hepatic decompensation, and hepatocellular carcinoma (HCC). Monitor for decompensation (low albumin, ascites, encephalopathy, GI bleed).

## *DIET*

- Low-fat, high-fiber diet and exercise to treat obesity/fatty liver
- Extra protein and fluids while on IFN therapy

## *PATIENT EDUCATION*

- Avoid alcohol, tobacco, and illicit drugs (including marijuana); refer to rehabilitation/12-step program and monitor for relapse as appropriate.
- Warn against claims of false cures.
- Caution with nutritional supplements and hepatotoxic medications (may contain hepatotoxins)
- <http://www.cdc.gov/knowmorehepatitis/>

## *PROGNOSIS*

- For every 100 persons infected with HCV
  - 75 to 85 will develop chronic infection.
  - 60 to 70 will develop chronic liver disease.

- 10 to 20 will develop cirrhosis over 20 to 30 years (more rapid if older age at infection, male gender, alcohol/substance abuse, HIV/HBV coinfection, or diabetes/insulin resistance).
  - 1-5% annual risk of HCC
  - 3-6% annual risk of hepatic decompensation
- Chronic HCV is *curable* in ÷70% of cases; in noncirrhotic genotype 2 or 3, cure rate is ÷90%.

## COMPLICATIONS

- Fibrosis and cirrhosis typically develop within the first 5 to 10 years of infection.
- Acute/subacute hepatic necrosis, liver failure, hepatocellular carcinoma, transplant and complications, death
- Risk factors for cirrhosis: age, white race, hypertension, alcohol use, anemia. Risk for decompensation: diabetes, hypertension, anemia

## Codes

&NA;

### ICD10

- B19.20 Unspecified viral hepatitis C without hepatic coma
- B17.10 Acute hepatitis C without hepatic coma
- B18.2 Chronic viral hepatitis C

## Clinical Pearls

&NA;

- 1 of every 10 patients with hepatitis C has no identifiable risk factors.
- 15-25% of HCV-infected persons spontaneously resolve infection without specific treatment.
- Look for coinfections (HBV/HIV) and comorbid substance abuse in patients infected with HCV.

# Hernia

Margaret Fairhurst, DO

## BASICS

### DESCRIPTION

Hernias are areas of weakness or frank disruption of the fibromuscular tissues of the body wall through which intracavity structures pass.

- Types
  - Inguinal
    - Direct inguinal: acquired; herniation through defect in transversalis fascia of abdominal wall medial to inferior epigastric vessels; increased frequency with age as fascia weakens
    - Indirect inguinal: congenital; herniation lateral to the inferior epigastric vessels through internal inguinal ring into inguinal canal. A "complete hernia" is one that descends into the scrotum, whereas an "incomplete hernia" remains within the inguinal canal.
  - Pantaloon: combination of direct and indirect inguinal hernia with protrusion of abdominal wall on both sides of the epigastric vessels
  - Femoral: herniation that descends through the femoral canal deep to the inguinal ligament. Because of the narrow neck of a femoral hernia, this type of hernia is especially prone to incarceration and strangulation.
  - Incisional or ventral: herniation through a defect in the anterior abdominal wall at the site of a prior surgical incision
  - Congenital: herniation through fascial defect in abdominal wall, secondary to collagen deficiency disease
  - Umbilical: Defect occurs at umbilical ring tissue.
  - Epigastric: protrusion through the linea alba above the level of the umbilicus. These may develop at exit points of small paramidline nerves and vessels, or through an area of congenital weakness in the linea alba.
  - Interparietal (e.g., Spigelian hernia): Hernia sac insinuates itself between layers of the abdominal wall; strangulation common, often mistaken for tumor or abscess.

Other: obturator, sciatic, perineal

- Definitions
  - Reducible: Extruded sac and its contents can be returned to original intra-abdominal position, either spontaneously or with gentle manual manipulation.
  - Irreducible/incarcerated: Extruded sac and its contents cannot be returned to original intraabdominal position.
  - Strangulated: Blood supply to hernia sac contents is compromised.
  - Richter: Partial circumference of the bowel is incarcerated or strangulated. Partial wall damage may occur, increasing potential for bowel rupture and peritonitis.
  - Sliding: wall of a viscus forms part of the wall of the inguinal hernia sac (i.e., R-cecum, L-sigmoid colon)

### *Geriatric Considerations*

Abdominal wall hernias increase with advancing age, with significant increase in risk during surgical repair.

### *Pregnancy Considerations*

- Increased intra-abdominal pressure and hormone imbalances with pregnancy may contribute to increased risk of abdominal wall hernias.
- Umbilical hernias are associated with multiple, prolonged deliveries.

## **EPIDEMIOLOGY**

### *Incidence*

- 75-80% groin hernias: inguinal and femoral
- 2-20% incisional/ventral, depending on whether a prior surgery was associated with infection or contamination
- 3-10% umbilical, considered congenital
- 1-3% other
- Groin
  - 6-27% lifetime risk in adult men
  - Two-peak theory: most inguinal hernias present before 1 year of age or after 55 years of age

- ÷50% of children <2 years of age will have a patent processus vaginalis, decreasing to 40% after age 2 years. Only between 25% and 50% will become clinically significant.
- Inguinal hernia found in <5% of newborns but male-to-female ratio is 10:1.
- Increased incidence in premature infants
- Increased incidence in patients with abdominal aortic aneurysms
- Femoral <10% of all groin hernias, 40% present as a surgical emergency
- Incisional/ventral: ÷10-23% of abdominal surgeries complicated by an incisional hernia, most common in upper midline incisions.
- Incidence ratio: male = female
- Umbilical: 10-20% of newborns; most close by 5 years of age

## *Prevalence*

- Groin and inguinal hernias are more prevalent in men.
- Femoral and umbilical hernias are more prevalent in women.
- Most inguinal hernias are indirect in both genders.
- Incisional/ventral hernias are more prevalent in obese persons, as well as in smokers. The opposite may be true for inguinal hernias.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Loss of tissue strength and elasticity, especially with aging or congenital defect in abdominal fascia resulting in a defect in the fascia of the abdominal wall. Most pediatric hernias are congenital defects (e.g., patent processus vaginalis), whereas most adult hernias are a result of acquired weakness in the tissues of the anterior abdominal wall.

## *Genetics*

No known genetic pattern

## *RISK FACTORS*

- Increased abdominal pressure, coughing, heavy lifting, constipation, pregnancy, ascites, prostatism, obesity, advancing age (loss of tissue turgor), smoking, steroid use, low birth weight, prematurity
- Age: Femoral and scrotal hernias, along with recurrent groin hernias, are associated with increased risk for acute hernia surgery.

## COMMONLY ASSOCIATED CONDITIONS

Obesity, chronic obstructive pulmonary disease, multiple abdominal surgeries, pregnancy, advanced age, Ehlers-Danlos syndrome, Marfan syndrome, polycystic kidney disease (PKD), osteogenesis imperfecta, Down syndrome, abdominal aortic aneurysm

## DIAGNOSIS

### HISTORY

- Pain, nausea, vomiting, bloating; relieved with reclining; many are asymptomatic.
- May observe protrusion through abdominal wall during increased intra-abdominal pressure (Valsalva maneuver or cough)

### PHYSICAL EXAM

- Exam should initially occur with patient standing. During palpation, the patient should be instructed to cough, strain, or perform Valsalva maneuver so the extent of intracavitary content movement can be appreciated. Exam should also be performed with patient in supine position.
- Inguinal (superior to inguinal ligament)
  - Direct inguinal hernia: Finger in inguinal canal finds defect of the transversalis fascia as a deep (posterior to anterior) bulge palpated by pad of finger with increased intra-abdominal pressure.
  - Indirect inguinal hernia: Finger in inguinal canal finds a persistent process vaginalis as a bulge (lateral to medial) palpated by fingertip; it may extend down into scrotum.
- Femoral (inferior to inguinal ligament): bulge in upper middle thigh; neck of the sac will protrude lateral to and below a finger placed on the pubic tubercle.
- Umbilical: palpable protrusion at umbilicus
- Incisional/ventral: palpable protrusion at site of prior abdominal incision or midline superior to the umbilicus
- Epigastric: palpable protrusion that occurs off midline above umbilicus

### DIFFERENTIAL DIAGNOSIS

Lymphadenopathy, hydrocele, lipoma, varices, cryptorchidism, abscess, tumor, sports hernia (athletic pubalgia), pelvic fractures, adductor tears, omphalomesenteric duct, urachal cyst

## DIAGNOSTIC TESTS & INTERPRETATION

Hernia evaluation rarely requires imaging; reserve for suspected abdominal hernia or unclear diagnosis. Plain radiographs to rule out obstruction

- Ultrasound (US) can be used to assess inguinal hernias.
- CT or tangential radiography for incisional and abdominal wall hernias and postsurgical patients with complaints of abdominal pain
- Herniography is no longer recommended.

### *Pediatric Considerations*

There is insufficient evidence for contralateral exploration in pediatric patients, except using US.

### *Follow-Up Tests & Special Considerations*

For occult hernias not well appreciated on exam or with imaging, diagnostic laparoscopy may be beneficial.

## TREATMENT

- Elective setting
    - Elective surgical repair is associated with significantly lower morbidity and mortality.
  - Acute setting
    - Pain management is recommended for symptomatic hernias.
    - Strangulated hernias should be surgically repaired as early as possible to prevent complications such as necrosis and viscus perforation.
- 
- Manual reduction of incarcerated hernia improves outcomes by allowing for elective repair after reduction of acute swelling and inflammation.
  - Complication rate is nearly 20 times greater in emergent repair of pediatric inguinal hernias than elective procedure.
  - Acute hernia repair carries a higher morbidity and lower survival rate.
  - Laparoscopic repair of incisional/ventral hernia (IVH) is safe, with fewer complications and shorter hospital stays and possibly a shorter surgical time. However, postoperative pain and recurrence rates are similar for both techniques.
  - For patients undergoing repair, operative times are shorter for laparoscopic totally

P.473

extraperitoneal repair then with open mesh repair and without any difference in complication rates (1)[B].

## **MEDICATION**

- Antibiotics: Antibiotic prophylaxis did not reduce wound infections after groin hernia repairs.
- Pain: Local anesthetic during surgical repair results in significant reduction of postoperative pain. Tension-free procedures, such as Lichtenstein, may be performed under local anesthesia.

## **ADDITIONAL THERAPIES**

### ***Geriatric Considerations***

Use of a truss (external supportive device) for direct inguinal hernias is common; no data exist regarding efficacy.

## **ISSUES FOR REFERRAL**

Warn patients of symptoms or signs of incarceration or strangulation (acute abdominal pain, fever, bloody bowel movements), which mandate immediate selfreferral to emergency room.

## **SURGERY/OTHER PROCEDURES**

All inguinal hernias should be surgically repaired, but watchful waiting in the asymptomatic patient is a safe option if significant comorbidities may compromise emergent repair.

- Incarceration and strangulation are absolute indications for hernia repair.
- Contraindications: patients who are not surgical candidates based on cardiovascular risk factors
  - Elective repair should be avoided in pregnant patients or those with active infections.
- Special considerations
  - Umbilical hernias <0.5 cm usually obliterate and can be managed by observation.
  - Umbilical hernias in children age 2 to 4 years may be observed, as there is a high rate of spontaneous closure.
  - Operative times and complication rates are similar when comparing single-incision laparoscopic inguinal hernia repair versus traditional multiport laparoscopic repair (2)[B].
  - Watchful waiting is recommended in pregnancy. Elective postpartum hernia repair provided similar results to the nonpregnant population without increased risk of incarceration or strangulation before or during delivery.

- Women had lower recurrence rates with laparoscopic methods than with Lichtenstein open method.
- Ascites is not a strict contraindication for surgical repair. There is a greater risk of strangulation and complication without repair than the increased risks associated with repair in the presence of ascites.
- The more emergent hernia operations can be performed using the same methods for nonacute situations. However, incarceration with strangulation may require laparotomy with partial bowel resection.
- Gold standard
  - Inguinal hernia
    - Open: Lichtenstein with mesh (37%) or mesh plug (34%): decreased recurrence rates
    - Laparoscopic (14%) with mesh: decreased hospital stay and postoperative pain
      - Requires general anesthesia
      - Transabdominal preperitoneal (TAPP) versus total extraperitoneal (TEP)
    - Pediatric: Laparoscopic percutaneous repair is an efficient, safe, and effective alternative to open repair. It is associated with reduced operative times without an increase in complication or recurrence rates (3)[B].
  - Incisional/ventral
    - Laparoscopic repair is effective for most patients with primary or recurrent ventral hernias; it is associated with a <10% recurrence rate.
  - Umbilical
    - Pediatric: open excision and closure with suture
    - Adult: Open repair with mesh or plug may reduce hernia recurrence.
- Newer techniques
  - Prolene hernia system
  - Biologic wound closure system: reduced recurrence in contaminated procedures
- Complications
  - Recurrence
  - Seromas
  - Postoperative pain, temporary or chronic: improved in laparoscopic approach versus open

- Wound infection
- Injury to cord structures in inguinal herniorrhaphy; with nerve injury, most symptoms will resolve.

## ONGOING CARE

### PATIENT EDUCATION

- Cleveland Clinic: [http://my.clevelandclinic.org/disorders/hernia/hic\\_hernia.aspx](http://my.clevelandclinic.org/disorders/hernia/hic_hernia.aspx)
- Umbilical hernias: Boston Children's Hospital: <http://www.childrenshospital.org/az/Site1018/mainpageS1018P0.html>

### PROGNOSIS

- Groin (pediatric): low recurrence rates (<3%) with surgical treatment; may spontaneously resolve in infants
- Groin (adult): 31% per year risk of bowel strangulation without surgical treatment; 0-10% postoperative recurrence rates, depending on surgeon's experience level and method
- Incisional/ventral: 3-5% postoperative occurrence: 2-17% postrepair recurrence, increased to 20-46% in larger hernias
- Umbilical (pediatric)
  - High rate of spontaneous resolution
  - Hernia less likely to close further in older children and in children with larger defects
- Umbilical (adult): up to 11% postoperative recurrence rate
- Epigastric: most will ultimately become incarcerated and/or strangulated without surgical treatment. Recurrence is high due to frequency of missed defects during repair.

- K40.90 Unil inguinal hernia, w/o obst or gangr, not spcf as recur
- K41.90 Unil femoral hernia, w/o obst or gangrene, not spcf as recur

## Clinical Pearls

### &NA;

- Inguinal
  - Direct inguinal: acquired; herniation through defect in transversalis fascia of abdominal wall medial to inferior epigastric vessels
  - Indirect inguinal: congenital; herniation lateral to the inferior epigastric vessels; a "complete hernia" descends into the scrotum; an "incomplete hernia" remains within the inguinal canal.
- Pantaloon: combination of direct and indirect inguinal hernia
- Femoral: descends through the femoral canal deep to the inguinal ligament
- Incisional or ventral: iatrogenic, herniation through a defect at site of a prior surgical incision
- Umbilical: Defect occurs at umbilical ring tissue.

# Herpes Eye Infections

Rachel Marinch Carpenter, MD

William Fosmire, MD

## BASICS

### DESCRIPTION

- Eye infection (blepharitis, conjunctivitis, keratitis, stromal keratitis, uveitis, retinitis, glaucoma, or optic neuritis) caused by herpes simplex virus (HSV) types 1 or 2 or varicella-zoster virus (VZV, also known as human herpes virus type 3 [HHV3])
- Categories
  - HSV: can affect many parts of the eye but most often affects the cornea (herpes keratoconjunctivitis); HSV1 > HSV2; can be further divided into primary and recurrent
  - VZV: when VZV is reactivated and affects the ophthalmic division of the 5th cranial nerve, this is known as herpes zoster ophthalmicus (HZO), a type of shingles
- System(s) affected: eye, skin, CNS (neonatal)

### EPIDEMIOLOGY

- Predominant age: HSV-mean age of onset 37.4 years but can occur at any age, including primary infection in newborns; VZV usually advancing age (>50 years)
- Predominant sex: HSV—male = female; HZO—female > male

### Incidence

- HSV keratitis: In the United States, approximated at 18.2 per 100,000 person-years. Incidence is 1.5 million per year worldwide (1).
- VZV: 1 million new cases of shingles per year in the United States; 25-40% develop ophthalmic complications. Temporary keratitis is most common.

### Prevalence

- Ocular HSV prevalence estimated at 500,000 in the United States (1)
- VZV: Prevalence of herpes zoster infection is 20-30%. Ocular involvement in 50% if not

treated with antivirals (2). Overall lifetime prevalence of HZO: 1%

## ETIOLOGY AND PATHOPHYSIOLOGY

- HSV and VZV are *Herpesviridae* dsDNA viruses
- HSV: primary infection from direct contact with infected person via saliva, genital contact, or birth canal exposure (neonates)
  - Primary infection may lead to severe disease in neonates, including eye, skin, CNS, and disseminated disease.
  - Recurrent infection is more common overall cause of herpetic eye infections.
- VZV: Primary infection from direct contact with infected person may cause varicella (ÒchickenpoxÓ) and/or lead to a latent state within trigeminal ganglia.
  - Reactivation of the virus may affect any dermatome (resulting in herpes zoster or ÒshinglesÓ), including the ophthalmic branch (HZO).

## RISK FACTORS

- HSV: personal history of HSV or close contact with HSV-infected person
  - General risk factors for reactivation: stress, trauma, fever, UV light exposure, other viral infections
  - Risk factors for HSV keratitis: UV laser eye treatment, some topical ocular medications such as prostaglandin analogues and primary/secondary immunosuppression
- HZO
  - History of varicella infection, advancing age (>50 years), sex (female > male), acute/painful prodrome, trauma, stress, immunosuppression (1,3)

### **ALERT**

Consider primary/secondary immunodeficiency disorders in all zoster patients <40 years of age (e.g., AIDS, malignancy).

## GENERAL PREVENTION

- Contact precautions with active lesions (HSV and VZV)
- VZV can be spread to those who have not had chickenpox and are not immunized.
- Varicella vaccination (Zostavax) (VZV only): single 0.65 mL SC dose; no booster. Recommended by the CDC for all persons age  $\geq$ 60 years. Reduces incidence of herpes zoster

by 51% and HZO for 49%; also significantly decreases rates of post-herpetic neuralgia (PHN) (4)

- Acyclovir can be used prophylactically to prevent recurrence of ocular HSV.
- HSV immunization currently being researched (1)

## **ALERT**

Zoster vaccination is contraindicated if HIV-positive or other immunocompromised state, pregnancy, or in active untreated tuberculosis (TB).

## *Pregnancy Considerations*

- Pregnant women without history of chickenpox should avoid contact with persons with active zoster.
- Pregnancy increases risk of recurrence of HSV/VZV.
- Live vaccine (Zostavax) is contraindicated during pregnancy.

## *COMMONLY ASSOCIATED CONDITIONS*

Primary and secondary immunocompromised states

## **DIAGNOSIS**

### **HISTORY**

- Varies according to the virus and the ocular structures involved
- History of varicella or herpes simplex infection
- Acute onset, eye pain, headache, photophobia, tearing, ocular redness, decreased or blurry vision (3)[A]
- May present with a prodromal period of fever, malaise, headache, and eye pain before skin eruptions and eye lesions (HZO) (3)[A]

## *PHYSICAL EXAM*

- Varies according to the virus and ocular structures involved
  - HSV most commonly affects the corneal epithelium (1)[A].
  - VZV most commonly affects corneal stroma and uvea (3)[A].
- Typically unilateral in presentation
  - HZO presents as early as 1 to 2 days after unilateral vesicular eruption in a dermatomal

pattern (3)[A].

- Decreased visual acuity
- Conjunctival injection near the limbus
- Decreased corneal sensation
- Slit-lamp exam
  - Fluorescein and rose bengal stain: Dendritic corneal lesions most often seen in HSV, followed by stromal keratitis, corneal edema, or infiltrate (2)[C].
  - Stromal keratitis often seen in HZO, although dendritic lesions may form (2)[A].

## **ALERT**

Unilateral dermatomal vesicular rash most commonly in ophthalmic branch ( $V_1$ ) of trigeminal nerve (VZV):

- Hutchinson sign: vesicular lesion on nose from VZV indicates an increased risk of HZO due to involvement of nasociliary branch of trigeminal nerve, which also innervates the eye (3)[A].

## **DIFFERENTIAL DIAGNOSIS**

- Any other cause of red, painful eye
  - Bacterial, fungal, allergic, or other viral conjunctivitis
  - Acute angle-closure glaucoma
- Corneal abrasion, recurrent corneal erosion, toxic conjunctivitis
- Temporal arteritis
- Trigeminal neuralgia

## **DIAGNOSTIC TESTS & INTERPRETATION**

### **Initial Tests (lab, imaging)**

- Typically none needed, as diagnosis is primarily based on history and physical exam (3)[A]
- Other
  - Corneal swab for HSV DNA by polymerase chain reaction (PCR) (PPV = 96%)
  - If vesicle present, can perform a Tzanck smear for VZV or HSV (multinucleated giant cells)
  - Antibody titers to assess exposure only; DFA (direct fluorescent antibody); tissue culture

## ALERT

Urgent ophthalmology referral necessary for slit-lamp exam, dilated fundus exam, and intraocular pressure measurement

## TREATMENT

### GENERAL MEASURES

- Avoid contact with nonimmune people.
- No contact lenses should be worn during treatment period.
- Cool compresses
- Artificial tears
- Oral pain medications

### MEDICATION

#### *First Line*

- HSV corneal epithelial disease
  - Trifluridine 1%: apply 1 drop q2h while awake to a max of 9 drops daily until reepithelialization occurs, then 1 drop q4h for another 7 days
  - Acyclovir: 400 mg PO 5 times per day for 10 days
  - Ganciclovir 0.15% gel: apply 1 drop in eye q3h while awake, ~5 times daily, until reepithelialization occurs, then 1 drop q8h for 7 days
  - Vidarabine 3% ointment (Vira-A): apply 0.5 inch into lower conjunctival sac 5 times daily q3h, until reepithelialization occurs.
  - Trifluridine and acyclovir cure about 90% of treated eyes within 2 weeks with no significant differences in effectiveness (5)[A].
  - Evidence conflicting as to whether ganciclovir is as good as or better than acyclovir (5)[A].
  - Epithelial debridement by an ophthalmologist: may accelerate healing in combination with treatment as above (5)[A]
  - Avoid topical steroids.

Utility of PO antivirals unclear HSV stromal keratitis or uveitis (without epithelial disease): combination of antiviral and steroid treatment; requires ophthalmology evaluation

- Prednisolone acetate: 1% drops QID with slow taper (6)[A]
- Consider systemic steroids in severe uveitis (6)[A].
- Trifluorothymidine: 1% drops QID for prophylaxis while on topical steroids
- HZO
  - Valacyclovir (Valtrex) 1 g PO TID for 7 to 10 days *or* famciclovir (Famvir) 500 mg PO TID for 7 to 10 days *or* acyclovir 800 mg PO 5 times a day for 7 to 10 days
  - Valacyclovir and famciclovir result in significant reduction in PHN compared to acyclovir (number needed to treat [NNT] = 3) with equivalent efficacy (7)[A]
  - Topical antibiotic ophthalmic ointment to protect ocular surfaces (e.g., Bacitracin, Polymyxin): 0.5-inch ribbon BID to TID for 7 to 10 days (8)[C]
  - If immunocompromised: acyclovir 10 to 15 mg/kg IV q8h for 10 days
  - Prednisolone acetate: 1% drops QID with slow taper with an ophthalmologist (8)[C]
- Cycloplegic agent if anterior uveitis present; intraocular pressure-lowering agent if necessary

## *Second Line*

- HSV: acyclovir 2 g/day PO in divided doses over 10 days in patients intolerant of topical antivirals
- Topical idoxuridine, acyclovir, brivudine, although approved internationally, are not approved for use in the United States.
- Concomitant treatment with interferon may also improve outcomes but is not currently available.

## **ALERT**

- HZO: Antiviral therapy is most effective within the first 72 hours of rash onset but should still be initiated >72 hours after onset because of the possible complications of HZO (2)[C].
- Topical antiviral agents
  - Toxic to corneal epithelium, especially after 10 to 14 days of continuous use
- Acyclovir: reduce dosage in renal insufficiency
- Topical steroids

- Should only be prescribed by an ophthalmologist
- Contraindicated with active corneal epithelial disease, which is best monitored with a slit lamp
- Can increase intraocular pressure, cause corneal thinning, and, with long-term use, cause cataracts
- Prednisone: caution in immunocompromised patients

## *ISSUES FOR REFERRAL*

Emergent or urgent ophthalmology referral, depending on severity of disease

## *ADDITIONAL THERAPIES*

- Recurrent HSV requires suppressive therapy:
  - Acyclovir 400 mg PO every day or BID or valacyclovir 500 mg PO daily (9)[C]
- HZO leading to PHN is very common and can be treated with gabapentin or pregabalin, TCAs, opioids, and/or lidocaine gel.

## *SURGERY/OTHER PROCEDURES*

Corneal transplantation for severe scarring or perforation

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Severe systemic VZV disease
- Systemic HSV in neonates Ñsee ÒHerpes Simplex Virus, PediatricÓ

### *Discharge Criteria*

Resolution of systemic disease

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Monitor with slit-lamp exam q1-2d until improvement, then q3-4d until epithelial defect resolves.

- Weekly after epithelial disease resolves until off topical antivirals

## *PATIENT EDUCATION*

Educate patients about the importance of early recognition of recurrent symptoms and need for prompt evaluation and treatment.

## *PROGNOSIS*

- Many cases are self-limited but, depending on the ocular structure involved, can lead to permanent blindness, especially in the setting of recurrent disease.
- Ocular HSV is the number one cause of infectious blindness worldwide (1).
- Recurrent ocular HSV
  - HSV epithelial disease without treatment
  - Without sequelae, 40% resolve.
  - With treatment, 90-95% resolve without complication.

## *Pediatric Considerations*

- Neonatal primary HSV often disseminated, with high mortality rate; 37% develop vision worse than 20/200
- Pediatric cases more likely to be bilateral (26%); recurrent (48% in 15 months); and may cause amblyopia

## **COMPLICATIONS**

- Recurrence
- Corneal neovascularization and scarring resulting in poor vision
- Neurotrophic ulcer with perforation
- Secondary bacterial or fungal infection
- Secondary glaucoma in 10%
- Post-herpetic neuralgia in 20-40% with VZV, typically longer lasting in older patients
- Vision loss from optic neuritis or chorioretinitis

## Codes

**&NA;**

### ICD10

- B00.50 Herpesviral ocular disease, unspecified
- B02.30 Zoster ocular disease, unspecified
- B00.52 Herpesviral keratitis

## Clinical Pearls

**&NA;**

- HSV and VZV can lead to a wide array of ocular manifestations, ranging from self-limited disease to potentially vision-threatening disease and complications.
- A slit-lamp exam with fluorescein stain should be performed on all patients with possible HSV keratitis or HZO.
- Topical antiviral treatment is appropriate for HSV, but systemic PO antiviral treatment is necessary for HZO.
- An ophthalmologist should be consulted before prescribing topical steroids. All HZO patients should be referred to an ophthalmologist.
- Hutchinson sign (vesicular lesion on nose from VZV) is a strong indicator of HZO.
- Zostavax is effective at preventing zoster and HZO as well as decreasing the duration of PHN.

# Herpes Simplex

Sonia Rivera-Martinez, DO, FACOFP

Sharon L. Koehler, DO, FACS

## BASICS

### DESCRIPTION

- Characteristic vesicular rash primarily located in oral and genital regions as the result of infection with
  - Herpes simplex virus (HSV)-1 is primarily associated with blisters on lips, in mouth, face, eyes.
  - HSV-2 is the primary source of genital herpes, although cross-reactivity is common (HSV-1 can cause genital sores through oral-genital contact).
- Associated with a wide range of sequelae. Complexity and variation of presentation depends on the age and immune status of host, whether the infection is primary or recurrent and the degree of dissemination.
- Viral shedding is typically greatest in the first (primary) infection and lessens with recurrences.
- Meningitis/encephalitis and pneumonia are serious systemic manifestations associated with HSV infection.

### EPIDEMIOLOGY

- Predominant age: Affects all ages; however, most HSV-1 is acquired in childhood, and most HSV-2 is acquired in young-middle adulthood.
- Predominant sex: male = female

### Incidence

- Over 1,000,000 new cases of HSV per year
- HSV can reactivate, causing recurrent disease.

### Prevalence

- Widespread; 0.65-25% of adults may shed HSV-1 or HSV-2 at any given time. Many are

unaware of their infection status.

- Prevalence of antibodies to HSV-1 is 90% by adulthood in the general population. 30% of adults have antibodies to HSV-2.

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

HSV-1 and 2 are double-stranded DNA viruses from the family *Herpesviridae*. HSV-1 and 2 are transmitted by contact with infected skin during periods of viral shedding. Transmission also occurs vertically during childbirth. Most often, HSV-1 is associated with oral lesions and HSV-2 with genital lesions.

## ***RISK FACTORS***

- Immunocompromised state
  - Chemotherapy, malignancy/chronic disease states such as diabetes or AIDS, old age
- Atopic eczema, especially in children
- Prior HSV infection
- Sexual intercourse with infected person (condoms help minimize HSV transmission, but lesions outside condom-protected areas can spread virus)
- Occupational exposure
  - Dental professionals at higher risk for HSV-1 and resulting herpetic whitlow
- Neonatal herpes simplex: Primary infection is lifethreatening and usually acquired by vaginal birth to an infected mother; fetal and neonatal risk are greatest in mothers with primary genital herpes infection; incubation is usually from 5 to 7 days (rarely 4 weeks); cutaneous, mucous membrane, or ocular signs seen in only 70%.

## ***GENERAL PREVENTION***

- If active lesions are present, avoid direct contact with immunocompromised people, elderly, and newborns.
- Hand hygiene
- Kissing, sharing beverages, and sharing utensils/toothbrushes can transmit HSV.
- Genital herpes: Avoid sexual contact if active lesions (herpes simplex is also transmitted when disease appears to be inactive), discuss condom benefits and limits, consider antiviral therapy to reduce viral shedding, encourage safe sex.
- Topical microbicides (not yet commercially available) may prevent transmission of HSV-2.

## COMMONLY ASSOCIATED CONDITIONS

- Erythema multiforme: 50% of associated cases are caused by HSV-1 or -2.
- Screen all severe, unusual locations, or treatment-resistant HSV cases for HIV.

## DIAGNOSIS

### HISTORY

- Many patients are unaware of a known exposure.
- Prodrome of fatigue, low-grade fever, itching, tingling, or hot skin for several days immediately prior to outbreak of characteristic vesicular rash
- Herpes labialis is precipitated by sunlight, fever, trauma, menses, and stress; prodrome of pain, burning, and itching commonly occur 6 to 48 hours before vesicles appear.

### PHYSICAL EXAM

- Vesicles are often clustered and become painful ulcerated lesions, often with erythematous base.
- Primary genital herpes: See Herpes, Genital.
- Primary herpetic gingivostomatitis and pharyngitis: usually in early childhood; incubation from 2 to 12 days, followed by fever, sore throat, pharyngeal edema, and erythema
  - Small vesicles develop on pharyngeal and oral mucosa, rapidly ulcerate, and increase in number to involve soft palate, buccal mucosa, tongue, floor of mouth, lips, and cheeks; tender, bleeding gums; cervical adenopathy; fever, general toxicity, poor oral intake, and excess salivation contribute to dehydration; autoinoculation of other sites may occur; resolves in 10 to 14 days
- Primary herpes keratoconjunctivitis: unilateral conjunctivitis with regional adenopathy, blepharitis with vesicles on lid marginal keratitis with dendritic lesions, or with punctate opacities; lasts 2 to 3 weeks; systemic involvement prolongs process
- Eczema herpeticum: diffuse pox-like eruption complicating atopic dermatitis; sudden appearance of lesions in typical atopic areas (upper trunk, neck, head); high fever, localized edema, adenopathy
- Herpetic whitlow: localized infection of affected finger with intense itching and pain, followed by vesicles that may coalesce with swelling and erythema. Mimics pyogenic paronychia; neuralgia and axillary adenopathy are possible; heals in 2 to 3 weeks

- Congenital infection through transplacental transfer may present with jaundice, hepatosplenomegaly, disseminated intravascular coagulation (DIC), encephalitis, seizures, temperature instability, chorioretinitis, and conjunctivitis with or without vesicles.
- Recurrent diseases from endogenous reactivation
  - Herpes labialis: recurrent lesions with HSV-1; usually <1 recurrence/6 months, but 5-25% may have >1 attack/month; vesicles often at vermilion border, then ulcerate and crust within 48 hours; heal within 8 to 10 days; may have local adenopathy
  - Ocular herpes: May recur as keratitis, blepharitis, or keratoconjunctivitis; dendritic ulcers, decreased corneal sensation, decreased visual acuity; uveitis may cause permanent visual loss.

## *DIFFERENTIAL DIAGNOSIS*

- Impetigo: honey-crusted vesicles
- Aphthous stomatitis: grayish, shallow erosions with ring of hyperemia of anterior in mouth and lips
- Herpes zoster: unilateral dermatome distribution
- Syphilitic chancre: painless ulcer
- Folliculitis: may mimic "shave bumps" in genital area
- Herpangina: Vesicles predominate on anterior tonsillar pillars, soft palate, uvula, and oropharynx but not more anteriorly on lips/gums (usually caused by group A coxsackievirus).
- Stevens-Johnson syndrome

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Screen for other sexually transmitted infections (STIs) in patients with primary genital herpes.
- Viral: HIV, hepatitis B and C, and human papillomavirus (HPV) have crossover
- Bacterial: Screen for concurrent gonorrhea, chlamydia in new primary genital outbreaks.

### *Initial Tests (lab, imaging)*

- Tzanck smear shows multinucleated giant cells often with eosinophilic intranuclear inclusions (scrape material from lesion to slide, fix with ethanol/methanol, stain with Giemsa or Wright stain); varicella (herpes zoster) has identical findings.
- HSV culture: Swab and plate on viral-specific media. Sample may need to be refrigerated; can take up to 6 days to be positive. Highly specific, hence, reliable if positive but has 20% false-

negative rate.

- HSV type-specific antibody tests distinguish between HSV-1 and HSV-2.
  - Polymerase chain reaction (PCR), direct fluorescent antibody (DFA), ELISA, and Western blot
  - 3 weeks after infection, 50% of those infected test positive; 70%, 6 weeks after infection; by 16 weeks nearly all infected test positive

## *Diagnostic Procedures/Other*

Biopsy is occasionally needed to confirm diagnosis.

## *Test Interpretation*

- Intraepithelial edema (ballooning degeneration) and intracellular edema
- Brain biopsy (in encephalitis) shows hemorrhagic necrosis of gray and white matter with acute and chronic inflammation, thrombosis, and fibrinoid necrosis of parenchymal vessels; intranuclear inclusions in astrocytes, oligodendroglia, and neurons

---

P.477

## **TREATMENT**

### **GENERAL MEASURES**

- Cool dressings moistened with aluminum acetate solution
- Painful urination and inability to void due to painful genital lesions is helped by pouring a cup of warm water over genitals while urinating or by sitting in a warm bath while urinating (sitz baths).
- Children with gingivostomatitis who resist oral intake due to pain or extensive skin disease (eczema herpeticum) may require IV hydration.

### **MEDICATION**

#### *First Line*

- Begin treatment promptly, preferably in prodromal phase.
- Acyclovir (generic)
  - Mucocutaneous (or genital) HSV

- Primary/first infection: 400 mg TID or 200 mg 5 times per day for 7 to 10 days
- If severe, start with IV q8h dosing for the first few days, then complete 10-day course PO route.
- Recurrence: 400 mg PO TID for 5 days *or* 800 mg BID for 5 days *or* 800 mg TID for 2 days
- Suppression: 400 mg BID daily (1)[B]
- Keratitis HSV: 400 mg PO 5 times per day; however, topical treatment is preferred as first line.
- Pediatric dosing: neonatal herpes simplex or encephalitis: 60 mg/kg/day IV divided q8h for 14 to 21 days (2)[B]
  - Older (>3 months of age) immunocompetent is weight-based dosing (40 to 80 mg/kg/day [max 1,000 mg/day] divided q8h for 5 to 7 days).
- Safe in pregnancy and lactationÑCategory B
- Recurrent herpes labialis: 800 to 1,600 mg/day for prevention (3,4,5)[B]
- Penciclovir (Denavir): 1% cream. Apply to oral lesions q2h during waking hours for 4 days (6) [B].
- Valacyclovir (Valtrex)
  - Primary genital herpes: 1 g PO BID for 7 to 10 days. Recurrent genital herpes: 500 mg PO BID for 3 days; suppression: 500 to 1,000 mg PO daily (depending on frequency of outbreaks); labialis HSV (cold sores/oral lesions): 2,000 mg PO q12h for 1 day (3,4,5)[B]
  - 500-mg daily dose if suppression is needed/desired
  - Recurrent herpes labialis: 500 mg/day for 4 months for prevention (3,4)[B]
- Famciclovir (Famvir)
  - Primary genital herpes: 250 mg PO TID for 7 to 10 days
  - Recurrence: 125 mg PO BID for 5 days or 1,000 mg PO BID for 1 day
  - Suppression: 250 mg PO BID
- Precautions
  - Renal dosing for all oral antivirals
  - Significant possible interactions: Probenecid with IV acyclovir and possibly probenecid with valacyclovir may reduce renal clearance and elevate antiviral drug levels.

## *Second Line*

- Foscarnet
  - Drug of choice for acyclovir resistance in immunocompromised persons with systemic HSV
  - 40 mg/kg IV q8h (assume valacyclovir and famciclovir resistance also if acyclovir resistance occurs)
- Other topicals
  - Ophthalmic preparations for herpes keratoconjunctivitis; acyclovir, vidarabine (Vira-A), ganciclovir, trifluridine
  - Topical acyclovir and penciclovir improve recurrent herpes labialis healing times by  $\div$ 10% (3)[B].
  - Topical analgesics: Lidocaine 2% or 5% helps reduce pain associated with vulvar and penile outbreaks.
- Over-the-counter topical antivirals: docosanol

## *ISSUES FOR REFERRAL*

Refer recurrent cases of herpes keratoconjunctivitis to an ophthalmologist.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Pregnancy considerations
  - Caesarean section and/or acyclovir are indicated if any active genital lesions (or prodrome) present at time of delivery; consider cesarean delivery if primary genital herpes is suspected within previous 4 weeks (6)[B].
  - Daily oral antivirals from 36 weeks onward in women with history of recurrent genital herpes to prevent outbreak near to/at time of delivery
  - Avoid fetal scalp electrodes, forceps, vacuum extractor, and artificial rupture of membranes if mother has history of genital HSV.
  - Risk of viral shedding at delivery from asymptomatic recurrent genital HSV is low ( $\div$ 1.6%).
- Pediatric considerations
  - Neonates with likely exposure (high index of suspicion) to HSV at birth or those who exhibit signs of HSV infection should have all body fluids cultured and immediately start treatment

with IV acyclovir.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- For most cases, follow-up is not necessary. Lesions and symptoms resolve rapidly within 10 days. Extensive cases should be rechecked in 1 week; monitor for secondary bacterial infections.
- Consider long-term suppression.

### *DIET*

If oral lesions are present, avoid salty, acidic, or sharp foods (e.g., snack chips, orange juice).

### *PATIENT EDUCATION*

- Explain the natural history that timing of exposure is difficult to determine and that the virus will remain in the body indefinitely. Minimize psychological impact of the diagnosis to reduce stigma.
- Emphasize personal hygiene to avoid self-spreading to other body areas (autoinoculation) or exposing others. Frequent hand washing; avoid scratching; cover active, moist lesions.
- Reinforce safe sexual practices.

### *PROGNOSIS*

- Usual duration of primary disease is 5 days to 2 weeks.
- Antiviral treatment shortens duration, reduces complications, and mitigates recurrences (if used for suppression).
- Viral shedding during recurrence is briefer than with primary disease; frequency of recurrence is variable and depends on individual host factors.
- Newborns/immunocompromised individuals are at highest risk for major morbidity/mortality.
- HSV is never eliminated from the body but stays dormant in dorsal root ganglia and can reactivate, causing recurrent symptoms and lesions.

### **COMPLICATIONS**

- Herpes encephalitis: Brain biopsy may be needed for diagnosis.
- Herpes pneumonia

- Herpes, Genital
- Algorithm: Genital Ulcers

## Codes

**&NA;**

## **ICD10**

- B00.9 Herpesviral infection, unspecified
- A60.00 Herpesviral infection of urogenital system, unspecified
- B00.1 Herpesviral vesicular dermatitis

## **Clinical Pearls**

**&NA;**

- 25-30% of the U.S. population has evidence of genital herpes (HSV-2), and >80% is seropositive for HSV-1.
- Most individuals are unaware they are infected. This allows for asymptomatic passage of the virus.
- Viral suppression therapy for patients with frequent recurrences reduces transmission and decreases outbreak frequency.

# Herpes Zoster (Shingles)

Robert J. Hyde, MD, MA, NRP, FACEP

## BASICS

### DESCRIPTION

- Results from reactivation of latent varicella-zoster virus (human herpesvirus type 3) infection
- Postherpetic neuralgia (PHN) is defined as pain persisting at least 1 month after rash has healed. The term *zoster-associated pain* is more clinically useful.
- Usually presents as a painful unilateral vesicular eruption with a dermatomal distribution
- System(s) affected: nervous; integumentary; exocrine
- Synonym(s): shingles

### EPIDEMIOLOGY

Predominant sex: male = female

#### *Incidence*

- Incidence increases with age. 2/3 of cases occur in adults age <sup>3</sup>50 years. Incidence is increasing overall as the U.S. population ages.
- Herpes zoster: 4/1,000 person-years (1)
- PHN: 18% in adult patients with herpes zoster; 33% in patients <sup>3</sup>79 years of age

#### *Prevalence*

Nearly 1 million new cases of herpes zoster annually

#### *Pregnancy Considerations*

May occur during pregnancy

#### *Geriatric Considerations*

- Increased incidence of zoster outbreaks
- Increased incidence of PHN

## *Pediatric Considerations*

- Occurs less frequently in children
- Has been reported in newborns infected in utero

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Reactivation of varicella-zoster virus from dorsal root/cranial nerve ganglia. Upon reactivation, the virus replicates within neuronal cell bodies, and virions are carried along axons to dermatomal skin zones, causing local inflammation and vesicle formation.

## **RISK FACTORS**

- Increasing age
- Immunosuppression (malignancy or chemotherapy)
- HIV infection
- Use of immunosuppressant drugs (e.g., following organ transplant surgery)
- Spinal surgery

## **GENERAL PREVENTION**

- Herpes zoster vaccination (Zostavax) is recommended by Advisory Committee on Immunization Practices (ACIP) for patients <sup>≥</sup>60 years (FDA-approved for patients >50 years) (2,3,4):
  - Vaccine reduces cases of zoster and the incidence of PHN (5,6).
- Patients with active zoster may transmit disease-causing varicella virus (chickenpox) to susceptible persons.

## **COMMONLY ASSOCIATED CONDITIONS**

Immunocompromised individuals, HIV infection, posttransplantation, immunosuppressive drugs, and malignancy

## **DIAGNOSIS**

### **HISTORY**

- Prodromal phase (sensations over involved dermatome prior to rash)
  - Tingling, paresthesias
  - Itching

- Boring “knifelike” pain
- Acute phase
  - Constitutional symptoms (e.g., fatigue, malaise, headache, low-grade fever) are variable.
  - Dermatomal rash

## PHYSICAL EXAM

- Acute phase
  - Rash: initially erythematous and maculopapular; evolves rapidly to grouped vesicles
  - Vesicles become pustular and/or hemorrhagic in 3 to 4 days.
  - Weakness (1% have weakness in distribution of rash)
  - Resolution of rash, with crusts separating by 14 to 21 days
- Possible sine herpette (zoster without rash) and other chronic disorders associated with varicellazoster virus without the typical rash
  - Herpes zoster ophthalmicus (HZO). Vesicles on tip of the nose (Hutchinson sign) indicate involvement of the external branch of cranial nerve V; associated with increased incidence of ocular zoster.
- Chronic phase
  - PHN (15% overall; increases with age)
  - A small percentage (1-5%) may affect the motor nerves, causing weakness (*zoster motorius*); facial nerve (e.g., Ramsay Hunt syndrome); spinal motor radiculopathies.

## DIFFERENTIAL DIAGNOSIS

- Rash
  - Herpes simplex virus
  - Coxsackievirus
  - Contact dermatitis
  - Superficial pyoderma
- Pain
  - Cholecystitis

- Appendicitis
- Nephrolithiasis
- Pleuritis
- Myocardial infarction
- Diabetic neuropathy

## **DIAGNOSTIC TESTS & INTERPRETATION**

### *Initial Tests (lab, imaging)*

Rarely necessary because clinical appearance is sufficiently distinctive

### *Follow-Up Tests & Special Considerations*

- Viral culture
- Tzanck smear (does not distinguish from herpes simplex, and false-negative results occur)
- Polymerase chain reaction
- Immunofluorescent antigen staining
- Varicella-zoster-specific IgM

### *Test Interpretation*

- Multinucleated giant cells with intralesional inclusion
- Lymphatic infiltration of sensory ganglia with focal hemorrhage and nerve cell destruction

## **TREATMENT**

### **GENERAL MEASURES**

- Treatment is directed to control symptoms and prevent complications.
- Antiviral therapy decreases viral replication, lessens inflammation and nerve damage, and reduces the severity and duration of long-term pain.
- Prompt analgesic control may shorten the duration of zoster-associated pain.
- Lotions, such as calamine and colloidal oatmeal, may help reduce itching and burning sensation.

# MEDICATION

## First Line

- Acute treatment
  - Antiviral agents initiated within 72 hours of skin lesions help relieve symptoms, speed resolution, and prevent or mitigate PHN (7)[A].
  - Valacyclovir: 1,000 mg PO TID for 7 days
  - Famciclovir: 500 mg PO TID for 7 days
  - Acyclovir: 800 mg q4h (5 doses daily) for 7 days
- Analgesics (acetaminophen, NSAIDs)
- Corticosteroids given acutely during zoster infection do not prevent PHN (8).
  - Tricyclic antidepressants (TCAs; amitriptyline 25 mg at bedtime and other low-dose TCAs) relieve pain acutely and may reduce pain duration; dose may be titrated up to 75 to 150 mg/day as tolerated.
  - Lidocaine patch 5% (Lidoderm) applied over painful areas (limit 3 patches simultaneously or trim a single patch) for up to 12 hours may be effective.
  - Gabapentin: 100 to 600 mg TID for pain and other quality-of-life indicators; limited by adverse effects

---

- Capsaicin cream and other analgesics may be useful adjuncts. Use opioids sparingly.
- Pregabalin: 50 to 100 mg TID reduces pain, but usefulness is limited by side effects.
- Prevention of PHN and zoster-associated pain: No treatment has been shown to prevent PHN completely, but treatment may shorten duration and/or reduce severity of symptoms (9)[A].
  - Antiviral therapy with valacyclovir, famciclovir, or acyclovir given during acute skin eruption may decrease the duration of pain.
  - Low-dose amitriptyline (25 mg at bedtime) started within 72 hours of rash onset and continued for 90 days may reduce PHN incidence/duration.
  - Insufficient evidence to suggest that corticosteroids reduce incidence, severity, or duration of PHN (8)
- Precautions
  - Assess renal function prior to using valacyclovir, famciclovir, or acyclovir.

Valacyclovir, famciclovir, and acyclovir are pregnancy Category B.

## *Second Line*

Numerous therapies have been advocated, but supporting evidence to routinely recommend is lacking.

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Studies on cupping therapy (traditional Chinese medicine) show potential benefit, but evidence is conflicting (10)[A].

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

Outpatient treatment, unless disseminated or occurring as complication of serious underlying disease requiring hospitalization

## **ONGOING CARE**

### **FOLLOW-UP RECOMMENDATIONS**

Referral to ophthalmology if concern for involvement of ophthalmic branch of the trigeminal nerve

### *Patient Monitoring*

Follow duration of symptoms—particularly PHN. Consider hospitalization if symptoms are severe; patients are immunocompromised; >2 dermatomes are involved; serious bacterial superinfection, disseminated zoster, or meningoencephalitis develops.

### **DIET**

No special diet

### **PATIENT EDUCATION**

- The duration of rash is typically 2 to 3 weeks.
- Encourage good hygiene and proper skin care.
- Warn of potential for dissemination (dissemination must be suspected with constitutional illness signs and/or spreading rash).
- Warn of potential PHN.
- Warn of potential risk of transmitting illness (chickenpox) to susceptible persons.

- Seek medical attention if any eye involvement.

## PROGNOSIS

- Immunocompetent individuals should experience spontaneous and complete recovery within a few weeks.
- Acute rash typically resolves within 14 to 21 days.
- PHN may occur in patients despite antiviral treatment.

## COMPLICATIONS

- PHN
- Herpes zoster ophthalmicus: 10-20%
- Superinfection of skin lesions
- Meningoencephalitis
- Disseminated zoster
- Hepatitis; pneumonitis; myelitis
- Cranial and peripheral nerve palsies
- Acute retinal necrosis

&NA;

- Bell Palsy; Chickenpox (Varicella Zoster); Herpes Eye Infections; Herpes Simplex
- Algorithm: Genital Ulcers

## Codes

&NA;

### ICD10

- B02.9 Zoster without complications
- B02.29 Other postherpetic nervous system involvement

## Clinical Pearls

&NA;

- Zoster vaccine is recommended for patients <sup>3</sup>60 years of age and is approved for patients >50 years.
- Patients with herpes zoster should begin antiviral therapy within 72 hours of the onset of rash to be most effective.
- Patients with active herpes zoster can transmit clinically active disease (chickenpox) to susceptible individuals.

# Herpes, Genital

Cecilia M. Kipnis, MD

## BASICS

### *DESCRIPTION*

- Chronic, recurrent infection of any area innervated by the sacral ganglia
- Due to herpes simplex virus (HSV) type 1 or 2
- HSV-1 causes anogenital and orolabial lesions.
- HSV-2 causes anogenital lesions.
- Primary episode: occurs in the absence of preexisting antibodies to HSV-1 or HSV-2 (may be asymptomatic)
- 1st episode nonprimary: initial genital eruption (likely due to HSV-2); preexisting antibodies to HSV-1 are present.
- Reactivation: recurrent episodes
- Synonym(s): herpes genitalis

### *EPIDEMIOLOGY*

- Predominant age: 15 to 65 years; cases increase with age due to cumulative effect
- Predominant sex: female > male
- Predominant race: non-Hispanic blacks

### *Incidence*

>700,000 new cases per year

### *Prevalence*

- 50-70% in developed countries, approaches 100% in developing countries (1)
- Overall prevalence of HSV-2 is 10-40% in the general population and up to 60-95% in the HIV-positive population (1).
- Up to 90% of seropositive persons do not have formal diagnosis.

- >50 million are infected with HSV-2 in the United States.

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

- HSV is a double-stranded DNA virus of the Herpetoviridae family (1).
- Spread via genital-to-genital contact, oral-to-genital contact, and via maternal-fetal transmission. Viral shedding continues in the absence of lesions (2).
- Incubation is 2 to 12 days after exposure.

## ***RISK FACTORS***

- Risk increases with age, number of lifetime partners, history of sexually transmitted infections (STIs), sexual encounters before the age of 17 years, and partner with HSV-1 or HSV-2.
- Infection with HSV-1 increases the risk of being infected with HSV-2 by 3-fold.
- Immunosuppression, fever, stress, and trauma increases risk of reactivation.

## ***COMMONLY ASSOCIATED CONDITIONS***

Syphilis, HIV, chlamydia, gonorrhea, and other STIs

## **DIAGNOSIS**

### **HISTORY**

- Many patients are asymptomatic (74% of HSV-1 and 63% of HSV-2) or do not recognize clinical manifestations of disease (2).
- Symptoms often more severe, associated with constitutional symptoms and longer in duration with primary episode.
- Common presenting symptoms (primary episode): multiple genital ulcers, dysuria, pruritus, fever, tender inguinal lymphadenopathy, headache, malaise, myalgias, cervicitis/dyspareunia, urethritis (watery discharge)
- 1st episode, nonprimary: less severe symptoms than a primary episode due to preexisting antibodies to HSV-1 which have some activity against HSV-2
- Common presenting symptoms for recurrent episodes: prodrome of tingling, burning, or shooting pain (2 to 24 hours before lesion appears); single ulcer; dysuria; pruritus (last 4 to 6 days on average)
- Less common presentations: constipation (from anal involvement causing tenesmus), proctitis, stomatitis, pharyngitis, sacral paresthesias

## *PHYSICAL EXAM*

- Impossible to differentiate primary, 1st episode nonprimary, recurrent disease, or type of virus (HSV-1 or HSV-2) based on symptoms or exam
- Lesions occur in Öboxer shortÓ distribution and within anus, vagina, and on cervix.
- Lesion may appear as papular, vesicular, pustular, ulcerated, or crusted; can be in various stages.
- Inguinal lymphadenopathy
- Extragenital manifestations include meningitis, recurrent meningitis (Mollaret syndrome), sacral radiculitis/paresthesias, encephalitis, transverse myelitis, and hepatitis

## *Pediatric Considerations*

- Neonatal infection occurs in 20 to 50/100,000 live births; 80% of infections result from asymptomatic maternal viral shedding during an undiagnosed primary infection in the 3rd trimester.
- Transmission ranges from 30-50% if the primary episode is near time of delivery. High morbidity and mortality
- Suspect sexual abuse with genital lesions in children

## *DIFFERENTIAL DIAGNOSIS*

- Primary syphilis
- Chancroid
- Herpes zoster
- Ulcerative balanitis
- Granuloma inguinale
- Lymphogranuloma venereum
- HIV
- Cytomegalovirus; Epstein-Barr virus
- Drug eruption
- Trauma
- Behçet syndrome
- Neoplasia

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- Viral isolation from lesion (swab or scraping)
  - Culture and PCR are preferred (3)[A].
  - Use Dacron or polyester-tipped swabs with plastic shafts (cotton tips/wood shafts inhibit viral growth and/or replication) (1).
  - Culture by unroofing vesicle to obtain fluid sample. Specificity >99%, sensitivity depends on sample: 52-93% for vesicle, 41-72% for ulcer, 19-30% for crusted lesion (1,3)
  - Culture requires timely transport of live virus to the laboratory in appropriate medium at 4°C.
  - PCR has the greatest sensitivity (98%) and specificity (>99%) but is also expensive and not readily available. It can increase detection rates by up to 70% (4). Used primarily for CSF (1)
- Type-specific serologic assays
  - Western blot (gold standard) and type-specific IgG antibody (glycoprotein G) enzyme-linked immunosorbent assay (ELISA) are used to discriminate between HSV-1 and HSV-2 (3)[B].
  - Western blot is >97-99% sensitive and specific but labor intensive and not readily available (1,3).
  - ELISA is 81-100% sensitive and 93-100% specific (1).
  - Seroconversion occurs 10 days to 4 months after infection (3). *Antibody testing is not necessary if a positive culture or PCR has been obtained.*
  - IgM antibody testing is not useful because HSV IgM is often present with recurrent disease and does not distinguish new from old infection.
  - Screening with type-specific antibody in the general population is not recommended (3) but may be considered in
    - Asymptomatic patients with HIV infection
    - Discordant couples (one partner with known HSV, the other without)

## TREATMENT

## GENERAL MEASURES

- Cool compresses with aluminum acetate (Domeboro)
- Ice packs to perineum, sitz baths, topical anesthetics
- Analgesics, NSAIDs

## **MEDICATION**

Antiviral medications should be started within 72 hours of onset of symptoms (including prodrome). If presentation is >72 hours, antivirals may be helpful if new lesions continue to form or patient is experiencing significant pain.

---

P.481

### ***First Line***

- Acyclovir (4)[A]: the most studied antiviral in genital herpes. Decreases pain, duration of viral shedding, and time to full resolution
  - Primary episode
    - 400 mg PO TID for 7 to 10 days
    - 200 mg PO 5 times a day for 7 to 10 days
    - Longer if needed for incomplete healing
  - Episodic therapy
    - 200 mg 5 times per day for 5 days
    - 400 mg TID for 5 days
    - 800 mg BID for 5 days
    - 800 mg TID for 2 days
  - Daily suppression
    - 400 mg BID
  - Severe, complicated infections requiring IV therapy
    - 5 to 10 mg/kg/dose q8h until clinical improvement; switch to PO therapy to complete a 10-day course.
  - HIV infection: 400 mg PO 3 to 5 times per day until clinical resolution is attained
  - Precautions
    - Modify dose in renal insufficiency.

- Valacyclovir (Valtrex) (4)[A]: prodrug of acyclovir, improved bioavailability, less frequent dosing
  - Primary episode
    - 1 g PO BID for 7 to 10 days
  - Episodic therapy
    - 500 mg PO BID for 3 to 5 days
    - 1 g PO daily for 5 days
  - Daily suppression
    - 500 mg PO daily
    - 1 g PO daily
- Famciclovir (Famvir) (4)[A]
  - Primary episode
    - 250 mg PO TID for 7 to 10 days
  - Episodic therapy
    - 125 mg PO BID for 5 days
    - 1 g PO BID for 1 day
  - Daily suppression: 250 mg PO BID

## *Second Line*

- Used for acyclovir-resistant HSV
- Foscarnet: 40 mg/kg/dose IV q8h in severe disease
  - Associated with significant toxicity
- Cidofovir topical: 0.1-0.3% gel for 5 days

## *Pregnancy Considerations*

ACOG Clinical Management Guidelines (4)[A],(5)[C]:

- SCREENING: Pregnant women who test antibody negative for HSV-1 and HSV-2 should avoid sexual contact in the 3rd trimester if their partner is antibody positive.

- **SUPPRESSIVE THERAPY:** Pregnant women with a history of genital herpes should be offered suppression treatment starting at 36 gestational weeks until delivery to decrease reactivation rate. Goal is to reduce the risk of neonatal infection and C-section. Recommended regimens to continue until delivery:
  - Acyclovir 400 mg PO TID
  - Valacyclovir 500 mg PO BID
- Monitor for outbreaks during pregnancy and examine for any lesions at the onset of labor. C-section is recommended if prodromal symptoms or lesions are present at onset of labor to reduce neonatal transmission.

### *Pediatric Considerations*

- High-risk infants include those with active symptoms or lesions, those delivered vaginally with maternal lesions present, and those born during a primary maternal episode. Monitor closely, obtain diagnostic laboratory specimens (HSV PCR and ocular, nasal, anal, and oral cultures), and treat with acyclovir 20 mg/kg IV q8h for 10 to 14 days (4)[A].
- Low-risk infants who are asymptomatic can be observed while obtaining serum HSV PCR and ocular, nasal, anal, and oral cultures.
- Infants with possible HSV infection should be isolated from other neonates; maternal separation is not necessary and breastfeeding is not contraindicated.

## **ONGOING CARE**

### *GENERAL PREVENTION*

- Use barrier contraception, daily suppressive antiviral therapy, and avoid sexual contact when symptoms are present to decrease transmission.
- Abstinence is the only means of complete protection.

### *FOLLOW-UP RECOMMENDATIONS*

- Avoid sexual contact when symptoms or lesions are present.
- Alert partners of herpes status prior to sexual activity.
- Concordant couples (i.e., both partners with the same type of herpes [HSV-1 or HSV-2]) may have sex without worry of triggering outbreaks.

### *Patient Monitoring*

Test for other STIs if initial HSV infection

## **PATIENT EDUCATION**

- Herpes Resource Center: <http://www.ashasexualhealth.org/stdsstis/herpes/>
- Warren T. *The Good News About the Bad News: Herpes: Everything You Need to Know*. Oakland, CA: New Harbinger Publications; 2009.
- Centers for Disease Control and Prevention: <http://www.cdc.gov/>

## **PROGNOSIS**

- Resolution of signs/symptoms: 3 to 21 days
- Average recurrence rate is one to four episodes per year (2).
- Antivirals do not eliminate virus from body but can reduce transmission, shedding, and outbreaks.

## **Pediatric Considerations**

Neonatal infection survival rates: localized >95%, CNS 85%, systemic 30%

## **COMPLICATIONS**

Behavioral issues include lowered self-esteem, guilt, anger, depression, fear of rejection, and fear of transmission to partner.

## Codes

&NA;

## ICD10

- A60.00 Herpesviral infection of urogenital system, unspecified
- A60.04 Herpesviral vulvovaginitis
- A60.09 Herpesviral infection of other urogenital tract

## Clinical Pearls

&NA;

- Genital herpes infections can be caused by HSV-1 and HSV-2.
- Many seropositive individuals are unaware that they are infected.

- Most primary episodes are asymptomatic.
- Viral shedding occurs in the absence of lesions.

# Hiccups

Vanessa W. McNair, MD, MPH

Jeannette M. McIntyre, MD

Steven B. Sapida, DO

## BASICS

### DESCRIPTION

- Hiccups are caused by a repetitive sudden involuntary contraction of the inspiratory muscles (predominantly the diaphragm) terminated by abrupt closure of the glottis, which stops the inflow of air and produces a characteristic sound.
- Hiccups are classified based on their duration: Acute hiccups last <48 hours; persistent hiccups last >48 hours but <1 month; intractable hiccups last for >1 month.
- System(s) affected: nervous, pulmonary
- Synonym(s): hiccoughs; singultus

### Geriatric Considerations

Can be a serious problem, particularly among the elderly

### Pregnancy Considerations

- Fetal hiccups are noted as rhythmic fetal movements (confirmed sonographically) that can be confused with contractions.
- Fetal hiccups are a sign of normal neurologic development (1).

### EPIDEMIOLOGY

- Predominant age: all ages (including fetus)
- Predominant sex: male > female (4:1)

### Prevalence

Self-limited hiccups are extremely common, as are intra- and postoperative hiccups.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Results from stimulation of 31 limbs of the hiccup reflex arc (vagus and phrenic nerves) with a hiccup center located in the upper spinal cord and brain (2)
- In men, >90% have an organic basis; whereas in women, a psychogenic cause is more common.
- Specific underlying causes include the following:
  - Alcohol abuse
  - CNS lesions (brain stem tumors, vascular lesions, Parkinson disease, multiple sclerosis, syringomyelia, hydrocephalus)
  - CNS infections (encephalitis, meningitis)
  - Seizure disorder
  - Diaphragmatic irritation (tumors, pericarditis, eventration, splenomegaly, hepatomegaly, peritonitis)
  - Irritation of the tympanic membrane
  - Pharyngitis, laryngitis
  - Mediastinal and other thoracic lesions (pneumonia, aortic aneurysm, tuberculosis [TB], myocardial infarction [MI], lung cancer, rib exostoses)
  - Esophageal lesions (reflux esophagitis, achalasia, *Candida* esophagitis, carcinoma, obstruction)
  - Gastric lesions (ulcer, distention, cancer)
  - Hepatic lesions (hepatitis, hepatoma)
  - Pancreatic lesions (pancreatitis, pseudocysts, cancer)
  - Inflammatory bowel disease
  - Cholelithiasis, cholecystitis
  - Prostatic disorders
  - Appendicitis
  - Postoperative, abdominal procedures
  - Toxic metabolic causes (uremia, hyponatremia, gout, diabetes)
  - Drug-induced (dexamethasone, methylprednisolone, anabolic steroids, benzodiazepines, &agr;-methyldopa, propofol)

Psychogenic causes (hysterical neurosis, grief, malingering)

- Idiopathic

## ***RISK FACTORS***

- General anesthesia; conscious sedation
- Postoperative state
- Genitourinary disorders
- Irritation of the vagus and phrenic nerve (or branches)
- Gastroesophageal reflux
- Structural, vascular, infectious, neoplastic, or traumatic CNS lesions

## ***GENERAL PREVENTION***

- Identify and correct the underlying cause if possible.
- Avoid gastric distention.
- Acupuncture shows promise in comparison to chronic drug therapy to control hiccups (3).

## ***COMMONLY ASSOCIATED CONDITIONS***

See ÒEtiology.Ó

## **DIAGNOSIS**

- Hiccup attacks usually occur at brief intervals and last only a few seconds or minutes. Persistent bouts lasting >48 hours often imply an underlying physical or metabolic disorder.
- Intractable hiccups may occur continuously for months or years (4).
- Hiccups usually occur with a frequency of 4 to 60 per minute (4).
- Persistent and intractable hiccups warrant further evaluation.

## **HISTORY**

- Recent surgery (especially genitourinary)
- General anesthesia
- Behavioral health history
- Medications
- Alcohol use/illicit drug use

- GI, cardiac, neurologic, or pulmonary disorders (see “Etiology”)

## **PHYSICAL EXAM**

- Correlate exam with potential etiologies (e.g., rales with pneumonia; organomegaly with splenic or hepatic disease).
- Examine the ear canal for foreign bodies.
- Head and neck exam to look for neck masses and lymphadenopathy
- Complete neurologic exam

## **DIFFERENTIAL DIAGNOSIS**

Hiccups may rarely be confused with burping (eructation).

## **DIAGNOSTIC TESTS & INTERPRETATION**

- If history suggests an underlying etiology, consider condition-specific testing as appropriate (e.g., CBC, metabolic panel, chest x-ray).
- Fluoroscopy is useful to determine whether one hemidiaphragm is dominant.

## **Diagnostic Procedures/Other**

- Upper endoscopy; colonoscopy; CT scan (or other imaging) of brain, thorax, abdomen, and pelvis looking for underlying causes
- The extent of the workup is often in proportion to the duration and severity of the hiccups (2,5).

## **TREATMENT**

- Outpatient (usually)
- Inpatient (if elderly, debilitated, or intractable hiccups)
- Many hiccup treatments are purely anecdotal.

## **GENERAL MEASURES**

- Seek medical attention for frequent bouts or persistent hiccups.
- Treat any specific underlying cause when identified (2, 4, 5)[C]
  - Dilate esophageal stricture or obstruction.

- Treat ulcers or reflux disease.
- Remove hair or foreign body from ear canal.
- Angostura bitters for alcohol-induced hiccups
- Catheter stimulation of pharynx for operative and postoperative hiccups
- Antifungal treatment for *Candida* esophagitis
- Correct electrolyte imbalance.
- Medical measures
  - Relief of gastric distention (gastric lavage, nasogastric aspiration, induced vomiting)
  - Counterirritation of the vagus nerve (supraorbital pressure, carotid sinus massage, digital rectal massage)Ñuse with caution
  - Respiratory center stimulants (breathing 5% CO<sub>2</sub>)
  - Behavioral health modification (hypnosis, meditation, paced respirations)
  - Phrenic nerve block or electrical stimulation (or pacing) of the dominant hemidiaphragm
  - Acupuncture
  - Miscellaneous (cardioversion)

## MEDICATION

### *First Line*

Possible drug remedies (5,6,7)[B]

- Baclofen, a GABA analog: 5 to 10 mg PO TID (2, 4, 5, 8)[B]
  - Chlorpromazine (FDA approved for hiccups): 25 to 50 mg PO/IV TID
  - Haloperidol: 2 to 5 mg PO/IM followed by 1 to 2 mg PO TID
  - Phenytoin: 200 to 300 mg PO HS
- 
- Metoclopramide: 5 to 10 mg PO QID
  - Nifedipine: 10 to 20 mg PO daily to TID
  - Amitriptyline: 10 mg PO TID
  - Viscous lidocaine 2%: 5 mL PO daily to TID
  - Gabapentin (Neurontin): 300 mg PO HS; may increase up to 1,800 mg/day PO in divided doses

(4)[B]; 1,200 mg/day PO for 3 days, then 400 mg/day PO for 3 days in patients undergoing stroke rehabilitation or in the palliative care setting where chlorpromazine adverse effects are undesirable (4)[B].

- Combination of lansoprazole 15 mg PO daily, clonazepam 0.5 mg PO BID, and dimenhydrinate 25 mg PO BID (6)[B].
- Contraindications: Refer to manufacturer's literature.
  - Baclofen is not recommended in patients with stroke or other cerebral lesions or in severe renal impairment.
- Precautions: Refer to manufacturer's literature.
  - Abrupt withdrawal of baclofen should be avoided.

## *Second Line*

Possible drug therapies (2, 6, 8,9,10)[C]

- Amantadine, carbidopa-levodopa in Parkinson disease
- Steroid replacement in Addison disease
- Antifungal agent in *Candida* esophagitis
- Ondansetron in carcinomatosis with vomiting
- Nefopam (a nonopioid analgesic with antishivering properties related to antihistamines and antiparkinsonian drugs) is available outside the United States in both IV and oral formulations.
- Olanzapine 10 mg QHS
- Pregabalin 375 mg/day

## *ISSUES FOR REFERRAL*

For acupuncture or phrenic nerve crush, block, or electrostimulation; cardioversion

## *SURGERY/OTHER PROCEDURES*

- Phrenic nerve crush or transaction or electrostimulation of the dominant diaphragmatic leaflet
- Resection of rib exostoses

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Acupuncture is increasingly used to manage persistent or intractable hiccups, especially in cancer patients (3,4)[A].

- Simple home remedies (2,7)[C]
  - Swallowing a spoonful of sugar
  - Sucking on hard candy or swallowing peanut butter
  - Holding breath and increasing pressure on diaphragm (Valsalva maneuver)
  - Tongue traction
  - Lifting the uvula with a cold spoon
  - Inducing fright
  - Smelling salts
  - Rebreathing into a paper (not plastic) bag
  - Sipping ice water
  - Rubbing a wet cotton-tipped applicator between hard and soft palate for 1 minute

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Most patients can be managed as outpatients; those with severe intractable hiccups may require rehydration, pain control, IV medications, or surgery.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

Until hiccups cease

#### ***DIET***

Avoid gastric distension from overeating, carbonated beverages, and aerophagia.

### ***PATIENT EDUCATION***

See "General Measures."

### ***PROGNOSIS***

- Hiccups often cease during sleep.

- Most acute benign hiccups resolve spontaneously or with home remedies.
- Intractable hiccups may last for years or decades.
- Hiccups have persisted despite bilateral phrenic nerve transection.

## COMPLICATIONS

- Inability to eat
- Weight loss
- Exhaustion, debility
- Insomnia
- Cardiac arrhythmias
- Wound dehiscence
- Death (rare)

## Codes

&NA;

### ICD10

- R06.6 Hiccough
- F45.8 Other somatoform disorders

## Clinical Pearls

**&NA;**

- Most hiccups resolve spontaneously.
- An organic cause for persistent hiccups is more likely to be found in men and individuals with intractable hiccups.
- Rule out a foreign body in the ear canal as hiccup trigger.
- Baclofen and gabapentin are the only pharmacologic agents proven effective in a clinical trial.
- Acupuncture may be effective for persistent hiccups.

# Hidradenitis Suppurativa

Travis C. Geraci, MD

Siva Vithanathan, MD, FACS

## BASICS

### DESCRIPTION

- Chronic follicular occlusive disease manifested as recurrent inflammatory nodules, abscesses, sinus tracts, and complex scar formation
- Lesions are tender, malodorous, often with exudative drainage.
- Common in intertriginous skin regions: axillae, groin, perianal, perineal, inframammary skin
- System affected: skin
- Synonym(s): acne inversa; Verneuil disease; apocrinitis; hidradenitis axillaris

### Geriatric Considerations

Rare after menopause

### Pediatric Considerations

Rarely occurs before puberty; occurrence in children is associated with premature adrenarche.

### Pregnancy Considerations

No Accutane (isotretinoin) or tetracycline treatment during pregnancy. Disease may ease during pregnancy and rebound after parturition.

## EPIDEMIOLOGY

Predominant sex: female > male (3:1)

### Incidence

Peak onset during 2nd and 3rd decades of life

### Prevalence

0.3-4%

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Not fully understood; previously considered a disorder of apocrine glands
- Inflammatory disorder of the hair follicle triggered by follicular plugging within apocrine gland-bearing skin.
- Hormonally induced ductal keratinocyte proliferation leads to a failure of follicular epithelial shedding, causing follicular occlusion.
- Mechanical stress on skin (intertriginous regions) precipitates follicular rupture and immune response.
- Bacterial involvement is a secondary event.
- Rupture and reepithelialization cause sinus tracts to form.
- Obesity and smoking are major risk factors in disease onset and severity.

## *Genetics*

- Familiar occurrences suggest single gene transmission (autosomal dominant), but the condition may also be polygenic.
- Estimated 40% of patients have an affected family member.

## *RISK FACTORS*

- Obesity
- Smoking
- Hyperandrogenism, oral contraceptive pills (OCPs)
- Lithium may trigger onset of or exacerbate this condition.

## *GENERAL PREVENTION*

- Lose weight if overweight or obese.
- Smoking cessation
- Avoid constrictive clothing/synthetic fabrics, frictional trauma, heat exposure, excessive sweating, shaving, depilation, and deodorants.
- Use of antiseptic soaps.

## *COMMONLY ASSOCIATED CONDITIONS*

- Acne vulgaris, acne conglobate

- Perifolliculitis capitis abscedens et suffodiens (dissecting cellulitis of scalp)
- Pilonidal disease
- Arthritis and spondyloarthritis (seronegative)
- Obesity (with diabetes, atopy, acanthosis)
- Irritable bowel disease (Crohn disease)
- Squamous cell carcinoma
- PAPASH syndrome (pyogenic arthritis, pyoderma gangrenosum, acne, suppurative hydradenitis)

## DIAGNOSIS

### HISTORY

- Diagnostic criteria adopted by the 2nd International Conference on Hidradenitis Suppurativa, 2009 (1)[C]
- All three criteria must be present for diagnosis:
  - Typical lesions: painful nodules, abscesses, draining sinus, bridged scars, and “tombstone” doubleended pseudocomedones in secondary lesions
  - Typical topography: axillae, groins, perineal and perianal region, buttocks, infra- and intermammary folds
  - Chronicity and recurrences, commonly refractory to initial treatments.

### PHYSICAL EXAM

- Tender nodules (dome-shaped) 0.5 to 3 cm in size are present.
  - Location corresponds with the distribution of apocrine-related mammary tissue and terminal hair follicles dependent on low androgen concentrations.
  - Sites ordered by frequency of occurrence: axillary, inguinal, perianal and perineal, mammary and inframammary, buttock, pubic region, chest, scalp, retroauricular, eyelid
  - Large lesions are often fluctuant; comedones may be present.
  - Possible malodorous discharge
- Hurley clinical staging system
  - Stage I: abscess formation (singular or multiple) without sinus tracts or scarring

- Stage II: widely separated, recurrent abscesses with tract formation and scarring
- Stage III: diffuse, multiple interconnected tracts and abscesses
- Sartorius clinical staging system (points attributed)
  - Anatomic region
  - Quantity and quality of lesions
  - Distance between lesions
  - Presence or absence of normal skin between lesions

## ***DIFFERENTIAL DIAGNOSIS***

- Acne vulgaris, conglobate
- Furunculosis/carbuncles
- Infected Bartholin or sebaceous cysts
- Lymphadenopathy/lymphadenitis
- Cutaneous Langerhans cell histiocytosis
- Actinomycosis
- Granuloma inguinale
- Lymphogranuloma venereum
- Apocrine nevus
- Crohn disease with anogenital fistula(s) (may coexist with hidradenitis suppurativa)
- Cutaneous tuberculosis
- Fox-Fordyce disease

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Cultures of skin or aspirates of boils are most commonly negative. When positive, cultures are often polymicrobial and commonly grow *Staphylococcus aureus* and *Staphylococcus epidermidis*.
- Lesion biopsy usually unnecessary. Useful to rule out other disorders such as squamous cell carcinoma.
- May note increased erythrocyte sedimentation rate (ESR), leukocytosis, decreased serum iron,

normocytic anemia, or changes in serum electrophoresis pattern.

## *Follow-Up Tests & Special Considerations*

- Consider biopsy of concerning lesions due to increased risk of squamous cell carcinoma.
- If the patient is female, overweight, and/or hirsute, consider evaluating the following:
  - Dehydroepiandrosterone sulfate
  - Testosterone: total and free
  - Sex hormone-binding globulin
  - Progesterone

## *Diagnostic Procedures/Other*

- Incision and drainage, culture and biopsy
- Ultrasound may be useful in planning an excision to identify the full extent of sinus tracts.

## *Test Interpretation*

- Dermis shows granulomatous inflammation and inflammatory cells, giant cells, sinus tracts, subcutaneous abscesses, and extensive fibrosis.
- Hair follicular dilatation and occlusion by keratinized stratified squamous epithelium

## **TREATMENT**

Despite the prevalence of this condition, few largescale randomized controlled trials have explored the safety and efficacy of treatment. Evidence is generally of poor quality (2)[A]. Treatment goals: Reduce extent of disease, prevent new lesions, remove chronic disease, and limit scar formation.

- Conservative treatment includes all items under general prevention, plus use of warm compresses, sitz baths, topical antiseptics for inflamed lesions, and nonopioid analgesics.
- Weight loss and smoking cessation result in marked improvement.
- For stage I-II, attempt medical treatment.
- Short medical trial may be appropriate in stage III prior to moving on to surgical therapies.
- No medications are curative; relapse is almost inevitable, but the disease may be controlled.

## GENERAL MEASURES

- Education and psychosocial support
- Appropriate hygiene including avoidance of shearing stress to skin (light clothing), daily cleansing with antibacterial soap
- Diet: Avoid dairy and high glycemic loads.
- Symptomatic treatment for acute lesions
- Improve environmental factors that cause follicular blockage (see "General Prevention").
- Smoking cessation and weight loss

---

P.485

## MEDICATION

### First Line

- Stage I disease: Consider either systemic or topical antibiotics.
  - Topical antibiotics (clindamycin has the most evidence) (3)[B]
    - Clindamycin 1% solution BID for 12 weeks with or without Benzoyl peroxide 5-10% solution
    - Chlorhexidine 4% solution
  - Systemic antibiotics (initial 7- to 10-day course)
    - Tetracycline 500 mg BID
    - Doxycycline 100 mg q12h
    - Augmentin 875 mg q8-12h
    - Clindamycin 300 mg BID (4)[B]
- Stage II-III disease
  - Address overlying bacterial infection with broadspectrum coverage. Base antibiotic selection on disease location, characteristics; longer durations (3 to 6 months) may be required.
  - Tetracycline 500 mg BID
  - Minocycline 100 mg BID
  - Doxycycline 100 mg BID
  - Minor surgical procedures (punch debridement, local unroofing) to treat individual lesions or

sinus tracts

- Other modalities (rarely used)
  - Hormonal therapy: antiandrogenic therapy such as cyproterone acetate (may not be available in the United States), estrogen/norgestrel oral contraceptive, finasteride (5 mg daily) (5)[B]
- Intralesional corticosteroids: accelerates healing, although efficacy not formally evaluated (triamcinolone acetonide 5 to 10 mg/mL)

## *Second Line*

- Combination of antibiotic regimens
  - Clindamycin and rifampin
  - Rifampin, moxifloxacin, and metronidazole
- Dapsone 50 to 150 mg daily (6)[C]
- Metformin: significant reduction in Sartorius score (7)[B]
- Oral retinoids (Isotretinoin): poor efficacy, limited therapeutic effect (8)[B]
- TNF- $\alpha$  inhibitors:
  - Infliximab: a majority of patients in the treatment group had a 50% or greater decrease in disease (9)[B]
  - Etanercept: no difference versus placebo (10)[A]
  - Adalimumab: limited efficacy

## *ISSUES FOR REFERRAL*

- Lack of response to treatment, stage II-III disease, or concern for malignancy (squamous cell carcinoma) is a reason to refer for surgical excision or radiation/laser treatment (stage II).
- If significant psychosocial stress exists secondary to disease, refer for stress management or psychiatric evaluation.
- Suspicion of hyperandrogenic states (e.g., polycystic ovary syndrome [PCOS]) should prompt investigation or referral.
- Severe perianal/perivulvar disease or otherwise very extensive disease may prompt referral to plastic surgeon or reconstructive urologist.

## *SURGERY/OTHER PROCEDURES*

- Important mode of treatment
- Could be used in conjunction with antibiotics or if first-line therapy fails
- Various surgical approaches have been used for stage II-III disease (11,12)[B]:
  - Incision and drainage: may be necessary to treat as a temporizing method for acute flare-ups
  - Deroofing and marsupialization of the sinus tracts is often beneficial primarily for Hurley stage I-II disease, as healing time is reduced. Recurrences remain common but usually are smaller than original lesions (13)[B].
  - Wide full-thickness excision with healing by granulation or flap placement is the most definitive treatment and rarely has local recurrence if all sinus tracts are excised. Rates of local recurrence (within 3 to 72 months): axillary (3%), perianal (0%), inguinoperineal (37%), submammary (50%)
- Laser therapy for Hurley stage I-II disease (rarely used)
  - Consider monthly treatments with neodymiumdoped yttrium aluminum garnet (Nd:YAG) laser for 3 to 4 months.
  - CO<sub>2</sub> laser ablation with healing by secondary intention
- Cryotherapy and photodynamic therapy have shown variable results, they are not routinely recommended.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Follow up monthly or sooner to evaluate progress and to assist with symptom management.

### *DIET*

- Avoid dairy, high glycemic loads.
- Healthy diet that promotes weight loss.
- May benefit from zinc supplementation

### *PATIENT EDUCATION*

- Severity can range from only 2 to 3 papules per year to extensive draining sinus tracts.
- Medications are temporizing measures, rarely curative. Attempts at local surgical cures do

not affect recurrence at other sites.

- Smoking cessation and weight loss can improve symptoms significantly. Hidradenitis Suppurativa Foundation: [www.hs-foundation.org](http://www.hs-foundation.org)

## PROGNOSIS

- Individual lesions heal slowly in 10 to 30 days.
- Recurrences may last for several years.
- Relentlessly progressive scarring and sinus tracts are likely with severe disease.
- Radical wide-area excision, with removal of all hair-bearing skin in the affected area, shows the greatest chance for cure.

## COMPLICATIONS

- Contracture and stricturing of the skin after extensive abscess rupture, scarring, and healing; or at sites of surgical excisions
- Lymphatic obstruction, lymphedema
- Psychosocial: anxiety, malaise, depression, self-injury
- Anemia, amyloidosis, and hypoproteinemia (due to chronic suppuration)
- Lumbosacral epidural abscess, sacral bacterial osteomyelitis
- Squamous cell carcinoma may develop in indolent sinus tracts.
- Disseminated infection or septicemia (rare)
- Urethral, rectal, or bladder fistula (rare)

## Codes

&NA;

### ICD10

L73.2 Hidradenitis suppurativa

## Clinical Pearls

&NA;

- Chronic inflammatory disease of the skin, often difficult to control with behavior changes and medication alone
- First-line treatment for mild disease is topical and/or systemic antibiotics.
- For patients with refractory or severe disease, wide local excision provides the only chance at a cure. Success rates depend on the location and extent of excision.

# Hirsutism

Laura Novak, MD

Imola K. Osapay, MD

## BASICS

### DESCRIPTION

- Presence of excessive terminal (coarse, pigmented) hair of body and face, in a male pattern, in women of reproductive age
- May be present in normal adults as an ethnic characteristic or may develop as a result of androgen excess
- Often seen in polycystic ovarian syndrome (PCOS) which is characterized by hirsutism, acne, menstrual irregularities, and obesity
- System(s) affected: dermatologic, endocrine/metabolic, reproductive

### Pregnancy Considerations

- May have related infertility. Offer intervention, if desired.
- As hormone balance improves, fertility may increase; provide contraception, as needed.
- Several medications used for treatment are contraindicated in pregnancy.

### EPIDEMIOLOGY

#### Prevalence

5-10% of adult women

### ETIOLOGY AND PATHOPHYSIOLOGY

- Hirsutism is due to increased androgenic (male) hormones, either from increased peripheral binding (idiopathic) or increased production from the ovaries, adrenals, or fat.
- Exogenous medications can also cause hirsutism.

#### Genetics

Multifactorial

## RISK FACTORS

- Family history
- Ethnicity—increased in Ashkenazi Jews and Mediterranean backgrounds
- Anovulation

## GENERAL PREVENTION

- Women with late-onset congenital adrenal hyperplasia (CAH) should be counseled that they may be carriers for the severe early-onset childhood disease.
- Avoid quackery.

## COMMONLY ASSOCIATED CONDITIONS

- PCOS: most common cause of hirsutism. Variable presentation but commonly presents with a combination of excess androgen, abnormal menses, and insulin resistance. It is estimated that 75% of hirsute women have PCOS (1).
- Associated insulin resistance or PCOS can increase the risk of heart disease.
- Prolonged amenorrhea and anovulation:
  - Prolonged amenorrhea may, over time, put the patient at risk for endometrial hyperplasia or carcinoma.
- Hypothyroidism or hyperprolactinemia
- Late-onset CAH (21-hydroxylase deficiency): a genetic enzyme deficiency associated with more severe and earlier onset hirsutism; present in <2% of hirsute, amenorrheic patients
- Tumor: rare (<0.2%); ovarian or adrenal; especially if associated with virilization (rapid onset, clitoromegaly, balding, deepening voice) (2)
- Cushing syndrome: rare; characterized by central obesity, moon facies, striae, hypertension

## DIAGNOSIS

### HISTORY

- Severity, duration, and age of onset of hirsutism
- Psychosocial impact on patient
- Menstrual and fertility history
- Medication history: Look for use of valproic acid, testosterone, danazol,

glucocorticoids, and athletic performance drugs.

- The presence of galactorrhea

## *PHYSICAL EXAM*

- Increased hair growth on face, chest, and groin
- Check skin for acne, striae, acanthosis nigricans (velvety black skin in the axilla or neck).
- Virilization: Deep voice, male pattern balding, and clitoromegaly indicate risk of tumor.
- The Ferriman-Gallwey scale (an instrument that rates hair growth in nine areas on a scale of 0 to 4, with >8 being positive) may be used for diagnosis but underrates patient's perception of hirsutism and altered by previous cosmetic treatment (1).

## *DIFFERENTIAL DIAGNOSIS*

- Idiopathic hirsutism—hirsutism with normal androgen levels
- PCOS—irregular menses, elevated androgens, polycystic ovaries on US, infertility, insulin resistance
- Late-onset CAH presents in adolescence with severe hirsutism and irregular menses.
- Androgen-secreting tumor—rapid onset, virilization, resistance to treatment
- Thyroid dysfunction
- Hyperprolactinemia if accompanied by galactorrhea or amenorrhea
- Rare endocrine disorders—Cushing (central obesity, stria, and hypertension), acromegaly (enlarging extremities and facial deformity)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Diagnosis is clinical. Empiric treatment without lab workup is an acceptable option in mild-moderate hirsutism (2)[C].
- PCOS is diagnosed by having two out of three signs: menstrual dysfunction, clinical or biochemical hyperandrogenemia, polycystic ovaries on US (2)[C].
- Lab testing is performed to rule out underlying tumor and pituitary diseases, which are rare.

### *Initial Tests (lab, imaging)*

- Basic workup of mild-moderate hirsutism is a total testosterone level +/- a thyroid screen (1,2,3)[C]. Testosterone: random total testosterone level is usually sufficient. A morning free testosterone is slightly more sensitive, but the difference is not clinically relevant (1,4).

- If testosterone is  $>150$  (some use 200) ng/dL, consider ovarian or adrenal tumor (2,3).
- Testosterone is made by both the ovaries and adrenals, so both areas should be imaged. US is best for the ovaries, and CT is best for the adrenals.
- If testosterone is not in the tumor range, treat clinically TSH-elevation indicates hypothyroidism.
- The workup of PCOS recommended by ACOG (the American Congress of Obstetricians and Gynecologists) includes the above plus:
  - Screening for metabolic syndrome with a fasting and 2-hour glucose after 75-g glucose load, lipid panel, waist circumference, and blood pressure (3)[C]
- Ovarian US
- If the patient is amenorrheic, check prolactin, FSH, LH, and a pregnancy test.

### *Follow-Up Tests & Special Considerations*

- 17-hydroxyprogesterone (17-OHP)
  - Elevations of 17-OHP ( $>300$ ) can indicate late-onset CAH; rare ( $<2\%$ )
  - Consider in patients with onset in early adolescence or high-risk group (Ashkenazi Jews) (2) [C].
  - If elevated, do corticotropin stimulation test.
- If prolactin level is high, MRI the pituitary
- If PCOS is diagnosed, ACOG recommends screening for dyslipidemia and DM type 2 (3)[C].
- Dehydroepiandrosterone sulfate (DHEA-S) is no longer recommended routinely but should be checked in virilization (4)[C].
  - Levels  $>700$  may indicate adrenal tumor.

## **TREATMENT**

### *GENERAL MEASURES*

- Treatment in mild hirsutism depends on patient preference and psychosocial effect.
- If patient desires pregnancy, induction of ovulation may be necessary.
- Provide contraception, as needed.

Encourage patient to maintain ideal weight with lifestyle modification.

- Treat accompanying acne.

## MEDICATION

### First Line

- Treatment goal is to decrease new hair growth and improve metabolic disorders.
- Oral contraceptives are first line to manage menstrual abnormalities and hirsutism/acne (5)[B]; it will decrease androgens, improve metabolic syndrome, and slow but not reverse hair growth. It take 6 months to show effect and are continued for years; any preparation is effective; however, those containing the progestins, norgestimate, desogestrel, or drospirenone may have more androgen-blocking effects, but also are associated with more DVTs (3)[C].
- Progesterone (depot or intermittent oral) can be used if estrogens are contraindicated (3)[C].
- Eflornithine (Vaniqa) HCl cream: apply BID at least 8 hours apart; reduces facial hair in 40% of women (must be used indefinitely to prevent regrowth). Only FDA-approved hirsutism treatment.

### Second Line

- Antiandrogenic drugs will further reduce hirsutism to 15-25%. Usually begun 6 months after first-line therapy if results are suboptimal. Must be used in combination with oral contraceptives to prevent menorrhagia and potential fetal toxicity. All should be avoided in pregnancy (2,4)[C].
  - Spironolactone, 50 to 200 mg/day: onset of action is slow; use with oral contraceptives to prevent menorrhagia. Watch for hyperkalemia, especially with drospirenone-containing OCP (Yasmin); avoid use in pregnancy.
  - Finasteride: 5 mg/day decreases androgen binding; not approved by FDA. Use with contraception (pregnancy Category X).
  - Cyproterone, not available in the United States: 12.5 to 100 mg/day for days 5 to 15 of cycle combined with ethinyl estradiol 20 to 50  $\mu$ g days 5 to 25 of cycle
  - Flutamide is not recommended (2).
- Insulin sensitizers (metformin, thiazolidinediones): mildly effective but less so than oral contraceptives. May be used in diabetes or if oral contraceptives are contraindicated. Metformin is more effective than thiazolidinediones (2)[A].
- Steroids: used in late-onset CAH

- Dexamethasone: 2 mg/day
- Cosmetic treatment: includes many methods of hair removal
  - Temporary: shaving, chemical depilation, plucking, waxing
  - Permanent: Laser epilation and photoepilation are preferred to electrolysis (3)[C].

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Several herbals including spearmint tea, saw palmetto, licorice, fennel, and soy have been shown in small (<50 people) and short (<12 weeks) studies to decrease hair size or lower androgen levels (5)[C].

## **ONGOING CARE**

### **FOLLOW-UP RECOMMENDATIONS**

No special activity

### **Patient Monitoring**

Monitor for known side effects of medications.

### **DIET**

No special diet

### **PATIENT EDUCATION**

- Hormonal treatment stops further hair growth and will improve but not reverse present hair.
  - Treatment takes 6 months to effect and may need to be lifelong.
- Cosmetic measures may be needed for the present hair (see above).

### **PROGNOSIS**

- Good (with long-term therapy) for halting further hair growth
- Moderate to poor for reversing current hair growth

### **COMPLICATIONS**

- If PCOS is present, dysfunctional uterine bleeding may lead to anemia.
- If PCOS is present, anovulation may increase uterine cancer risk.

- Androgenic excess may adversely affect lipid status, cardiac risk, and bone density.
- Poor self-image

### ICD10

- L68.0 Hirsutism
- E28.2 Polycystic ovarian syndrome

## Clinical Pearls

&NA;

- PCOS is the most common cause of hirsutism (two out of three: menstrual dysfunction, clinical or biochemical hyperandrogenemia, polycystic ovaries on US)
- Treatment is long term and often lifelong.
- Associated insulin resistance and DM is common and need to be treated.

# HIV/Aids

Meera Shah, MD, MS, AAHIVS

## BASICS

### DESCRIPTION

HIV is a retrovirus (subgroup lentivirus) that integrates into CD4 T-lymphocytes, altering cell-mediated immunity and causing cell death, severe immunodeficiency, opportunistic infections, and malignancies if untreated.

- Because of treatment advances, HIV is now classified as a chronic disease.
- The natural history of untreated HIV infection includes viral transmission, acute retroviral syndrome, recovery and seroconversion, asymptomatic chronic HIV infection, and symptomatic HIV infection or AIDS.
- Without treatment, the average patient progresses to AIDS about 10 years after acquiring the virus.
- All HIV-infected persons with CD4  $<200$  cells/mm<sup>3</sup> or with AIDS-defining illnesses are categorized as living with AIDS.

### EPIDEMIOLOGY

#### *Incidence*

In the United States, HIV incidence has remained relatively stable at about 50,000 infections per year since the mid-1990s.

#### *Prevalence*

- Estimated 1.2 million persons in the United States are living with HIV/AIDS as of 2012; 12.8% are unaware of their status (1).
- HIV/AIDS cases are disproportionately high among racial/ethnic minority populations.
- Transmission of drug-resistant HIV is rising.

### ETIOLOGY AND PATHOPHYSIOLOGY

- HIV primarily infects CD4+ cells. HIV is a singlestranded, positive-sense, enveloped RNA virus.

After entering target cells, through the process of reverse transcription, viral RNA is transcribed to DNA and imported to the host cell nucleus and encoded into the cellular DNA. The virus can become latent or produce new viral RNA and proteins that are released to infect other CD4+ cells. Host CD8+ cells are activated to produce the seroconversion response.

- There are two types of HIV. HIV-1 is the virus that was first described and is more virulent. It causes the majority of HIV infections worldwide. HIV-2 is less infective and seen primarily in West Africa or countries with economic ties to West Africa.

## *Genetics*

People who have a mutation in CCR5, a cell-surface chemokine coreceptor, are resistant to HIV infection.

## *RISK FACTORS*

- Sexual activity (70% of transmission): Ulcerative urogenital lesions promote transmission (2).
- Male-to-male sexual contact accounts for most (63%) newly diagnosed HIV/AIDS cases (1).
- Injection drug abuse (IDA)
- Children of HIV-infected women
  - Maternal HIV-1 RNA level predicts transmission.
  - HIV testing and treatment in pregnancy: With ARV prophylaxis, scheduled C-section and avoiding breastfeeding, HIV transmission rates have declined to <2% in the US and Europe (3)[B].
  - HIV can also be transmitted in breastmilk. HIV+ women should not breastfeed their infants.
- Recipients of blood products prior to 1985
- Occupational exposure (health care workers)

## *GENERAL PREVENTION*

- Avoid unprotected, high-risk sexual intercourse and intravenous drug use, particularly with shared needles.
- Preexposure prophylaxis (PrEP) is recommended for individuals at high risk for transmission (4) [A].

## *COMMONLY ASSOCIATED CONDITIONS*

- Syphilis may be more aggressive in HIV-infected.
- Tuberculosis (TB) is coepidemic with HIV; test all persons with HIV for TB (and vice versa).

Dually infected patients have 100 times greater risk of developing active TB.

- Patients coinfecting with hepatitis C or hepatitis B have a more rapid progression to cirrhosis.

## DIAGNOSIS

- Acute retroviral syndrome: CD4 lymphocyte count declines with increase in viral load 1 to 4 weeks after transmission; confirmed by demonstrating a high-HIV RNA in the absence of HIV antibody
- Acute retroviral syndrome presents as a mononucleosislike syndrome including:
  - Fever (97%)
  - Adenopathy
  - Pharyngitis (73%)
  - Rash (77%)
  - Myalgias/arthralgia (58%)
  - Less common symptoms include headache, diarrhea, nausea, vomiting, weight loss, thrush, and neurologic symptoms (12%).
  - Seroconversion: Positive HIV antibody test occurs 4 weeks to 6 months after exposure.
- Clinical latency (asymptomatic): variable duration (average is 8 to 10 years) accompanied by a gradual decline in CD4 cell counts and relatively stable HIV RNA levels (the viral set point). Patients often develop persistent generalized lymphadenopathy (>1 cm in <sup>3</sup>2 extrainguinal sites) and may develop fever, weight loss, myalgias, and gastrointestinal problems if the diagnosis is unrecognized.
- Symptomatic conditions:
  - Fever or diarrhea >1 month, bacillary angiomatosis, thrush, persistent candidal vulvovaginitis, cervical dysplasia or carcinoma in situ, oral hairy leukoplakia, herpes zoster, idiopathic thrombocytopenic purpura, pelvic inflammatory disease, peripheral neuropathy or myelopathy
- AIDS: defined by a CD4 cell count <200, a CD4 cell percentage of total lymphocytes <14%, or one of several AIDS-related opportunistic infections: *Pneumocystis jirovecii* (carinii) pneumonia, cryptococcal meningitis, recurrent bacterial pneumonia, candida esophagitis, CNS toxoplasmosis, TB and non-Hodgkin lymphoma (NHL), progressive multifocal encephalopathy, HIV nephropathy, Kaposi sarcoma, NHL, Hodgkin lymphoma, invasive cervical cancer
- Advanced HIV disease: CD4 cell count <50. Most AIDS-related deaths occur at this time.

Common late opportunistic infections: cytomegalovirus (CMV) disease (retinitis, colitis) or disseminated *Mycobacterium avium* complex as well as HIV wasting syndrome (>10% weight loss) and HIV encephalopathy/dementia/cognitive-motor disorder.

## HISTORY

- Complete medical history, including risk exposures and social/occupational history
- Review of systems: fever, chills, night sweats, diarrhea, weight loss, fatigue, adenopathy, oral sores, odynophagia (esophageal candidiasis), cough, shortness of breath and dyspnea on exertion (early *P. jiroveci* pneumonia), visual changes (CMV retinitis), skin rash, neurologic symptoms (CNS infection, malignancy, or dementia), sinusitis
- Review immunization record.

## PHYSICAL EXAM

Focus on weight, skin, retinal exam, oropharynx, lymph nodes, liver, spleen, mental status, sensation, genital, and rectal examinations.

## DIFFERENTIAL DIAGNOSIS

Burkitt lymphoma; candidiasis; coccidioidomycosis; cryptococcus; CMV; herpes simplex; lymphoma; toxoplasmosis, influenza

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Screening: Rapid oral test available and FDA approved. Two FDA-approved home testing kits are also available.
- Obtain HIV RNA if acute HIV infection is suspected.
- 4th-generation HIV testing combines antibody/antigen immunoassay for HIV-1, HIV-2 (5)
  - Can be positive within 2 to 3 weeks of exposure
  - Is considered a confirmatory test
- CD4 cell count and percentage (5)[A]
- HIV RNA viral load (5)[A]
- CBC with differential
- Serum chemistry

- Serologies: hepatitis A, B, and C; syphilis
- Urine screen for STIs (*Neisseria gonorrhoeae*, *Chlamydia trachomatis*)
- Oral and anal screen for STIs (*N. gonorrhoeae*, *C. trachomatis*)
- Cervical cytology at diagnosis, after 6 months and then annually in women with a cervix
- Anal cytology in HIV-positive men who have sex with men and women with abnormal cervical cytology
- Purified protein derivative (PPD) or QuantiFERON-TB Gold to screen for latent TB infection, chest x-ray if pulmonary symptoms or positive PPD
- Glucose-6-phosphate levels
- HLAB\*5701 testing if abacavir is considered for treatment.
- Lipids at baseline and during highly active antiretroviral therapy (HAART)
- Genotypic tests for resistance to antiretrovirals for patients with pretreatment HIV RNA >1,000 copies/mL. Transmitted resistance to at least one drug can be seen in 6-16% of individuals (5) [A].
- Tropism assay if considering CCR5 antagonist therapy

## TREATMENT

- Initiate antiretroviral therapy in all patients with HIV to reduce risk of disease progression (AI to BIII) and to prevent the risk of transmission (AI to AIII) (5).
- 
- P.489
- Several conditions increase the urgency for therapy including pregnancy (AI), AIDS-defining conditions (AI), acute opportunistic infections, CD4 <200 (AI), HIV-associated nephropathy (AII), acute/early infection (BII), HIV/HBV coinfection (AII), HIV/HCV coinfection (BII), rapidly declining CD4 counts (>100 cells/mm<sup>3</sup> per year) (AIII), and high viral loads (> 100,000 copies/mL) (BII) (5)
  - Genotypic testing is recommended to guide therapy in patients who are na•ve to antiretroviral therapy.
  - Tenofovir/emtricitabine or Truvada (300 mg/200 mg PO daily) FDA-approved for PrEP in adults at high risk (4)

## GENERAL MEASURES

- The main goal of HAART is to reduce viral load (ideally below limits of assay detection) and

delay immune suppression. Viral load is the most important indicator of response to HAART.

- Check for transmitted drug resistance before starting HAART (5)[A].
- Prevent HIV-associated complications, short- and long-term adverse drug reactions, HIV transmission and drug resistance, and preservation of HIV treatment options.
- Assess substance abuse, economic factors (unstable housing, food insecurity), social support, mental illness, comorbidities, high-risk behaviors, and factors known to impair adherence and promote transmission.
- Prophylactic antimicrobial agents and vaccines:
  - *P. jiroveci* prophylaxis: trimethoprim/sulfamethoxazole (TMP-SMX) 1 DS (160 mg/800 mg) tab PO daily indicated if CD4 <200 cells/mm<sup>3</sup>, prior *P. jiroveci*, thrush, or unexplained fever for >2 weeks
  - *Mycobacterium tuberculosis*: Treat for latent TB if positive PPD or QuantiFERON-Gold without prior prophylaxis or treatment, with negative CXR, recent TB contact, or history of inadequately treated TB that healed.
  - *Toxoplasma gondii* prophylaxis: 33% per year risk of infection in untreated patients with CD4 <100 cells/mm<sup>3</sup>; prophylaxis: TMP-SMX 1 DS tab daily
  - *M. avium* complex prophylaxis: 20-40% risk with CD4 <50 and no HAART. Preferred prophylaxis is azithromycin 1,200 mg PO weekly.
  - *Streptococcus pneumoniae*: 50 to 100 times increased risk of invasive infection compared with general population; Prevnar and Pneumovax at least 8 weeks apart, every 5 years
  - Influenza vaccine annually
  - Hepatitis A and B vaccines
  - Tdap vaccination every 10 years. Substitute onetime dose of Tdap vaccine at time of next booster.

## MEDICATION

- Recommended regimens for ARV-na•ve (5):
  - Integrase strand transfer inhibitor-based regimens:
    - Dolutegravir/abacavir/lamivudine (50 mg/600 mg/300 mg PO daily) Nonly for patients who are HLA-B\*5701 negative (AI)
    - Dolutegravir (50mg PO daily) plus tenofovir disoproxil fumarate/emtricitabine (300 mg/200 mg PO daily) (AI)

- Elvitegravir/cobicistat/tenofovir/emtricitabine (150 mg/150 mg/300 mg/200 mg PO daily) Not for patients with preantiretroviral therapy CrCl >70 mL/min (AI)
- Raltegravir (400 mg PO BID) plus tenofovir/emtricitabine (300 mg/200 mg PO daily) (AI)
- Protease inhibitor-based regimen:
  - Darunavir and ritonavir (800 mg PO daily and 100 mg PO daily) plus tenofovir/emtricitabine (300 mg/200 mg PO daily) (AI)
- Alternative regimens
  - Based on a patient's individual needs and genotype, an alternative regimen may be chosen, which have been outlined in the DHHS guidelines.
- Drug failure: Before selecting regimen, review clinical symptoms, history of HAART, and adherence. Perform resistance testing.
- Protease inhibitors (PI) can cause metabolic syndrome.
- HAART, especially the protease inhibitors, have interactions with other medications, such as antacids, steroids, contraceptives

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- If HIV RNA is detectable at 2 to 8 weeks, repeat every 4 to 8 weeks until suppressed to less than level of detection, then follow every 3 to 6 months (5).
- Monitor HIV RNA, CD4, CBC every 3 to 4 months (5). CD4 monitoring may be spaced out after long-term virologic control.
- Test fasting lipids and fasting glucose annually; basic chemistry, aspartate aminotransferase, alanine aminotransferase, T/D bilirubin every 6 to 12 months (5)
- HLA-B 5701 if considering abacavir (5)
- Pregnancy test women of childbearing age (5)
- Urinalysis every 6 to 12 months or as clinically indicated (5)
- Hepatitis C as clinically indicated (5)

#### *DIET*

- Encourage good nutrition.
- Discuss unknown and potentially harmful effects of supplement use including drug-drug interactions.
- Avoid raw eggs and unpasteurized milk. Severely immunocompromised patients should boil tap water to prevent *Cryptosporidium*.

## PATIENT EDUCATION

- Provide nonjudgmental, sex-positive prevention counseling, reviewing high-risk behaviors and viral transmission.
- Emphasize importance of adherence to HAART to prevent resistance.
- National AIDS Hotline: 800-342-2437 [Spanish 800-342-7432]
- National Institute of Health AIDS Clinical Trials Group: 800-874-2572
- American Foundation for AIDS Research: 212-719-0033 (new treatments and research)  
www.aidsinfo.nih.gov

## PROGNOSIS

- Untreated HIV infection leading to the diagnosis of AIDS has an associated life expectancy of about 3 years, and if the patient has an OI, the life expectancy is about 1 year.
- AIDS-defining opportunistic infections usually do not develop until CD4 <200.
- Adherence failure—not drug resistance—is the most common cause of treatment failure (1)[B].

## COMPLICATIONS

- Immunodeficiency
- Opportunistic infections
- Malignancy, including cervical or anal cancer

&NA;

Aberg JA, Gallant JE, Ghanem KG, et al. Primary care guidelines for the management of persons infected with HIV: 2013 update by the HIV medicine association of the Infectious Diseases Society of America. *Clin Infect Dis*. 2014;58(1):e1-e34.

## Codes

&NA;

### ICD10

- Z21 Asymptomatic human immunodeficiency virus infection status
- B20 Human immunodeficiency virus [HIV] disease
- R75 Inconclusive laboratory evidence of human immunodef virus

## Clinical Pearls

&NA;

- Acute HIV seroconversion illness mimics mononucleosis and is characterized by fever, sore throat, adenopathy, myalgias, and rash.
- Transmitted drug resistance is increasing. Evaluate patients for resistance before initiating

HAART.

- Appropriate vaccination and prophylactic antibiotics should be administered to HIV+ patients based on clinical history and CD4 count.
- Discuss prevention strategies, including PrEP, with individuals who are at high risk of HIV infection.

# Hodgkin Lymphoma

Jennifer J. Gao, MD

Fred J. Schiffman, MD

## BASICS

### DESCRIPTION

Historical background:

- Described in 1832 by Thomas Hodgkin in "On some morbid appearance of the absorbent glands and spleen"
- First neoplasm to be (i) defined by cytologic grounds based on presence of Reed-Sternberg (RS) cells, (ii) clinically staged neoplastic disease, and (iii) treated with chemotherapy and/or radiotherapy
- Neoplastic RS cells of monoclonal lymphoid B-cell origin within inflammatory background of lymphocytes (T-helper type 2 and regulatory T cells), eosinophils, histiocytes, and plasma cells (1,2)
- Two subtypes: classic Hodgkin lymphoma (CHL, 95% of cases) and nodular lymphocyte predominant Hodgkin lymphoma (NLPHL, 3-8% of cases) (1)
  - NLPHL: B cells, neoplastic lymphoid cells with multilobulated nuclei, small nucleoli, and popcorn-like appearance
  - CHL histologic subdivisions: nodular sclerosing (60%), mixed cellularity (30%), lymphocyte depleted (<10%), lymphocyte rich (<10%)
  - Frequency of lymph node involvement: cervical > mediastinal > axillary > paraaortic

### EPIDEMIOLOGY

- Incidence: 2.8/100,000/year
- Predominance: 8% of lymphoid malignancies (1)

### Geriatric Considerations

Poorer prognosis if present at <sup>3</sup> 60 years:

Less likely to tolerate intensive chemotherapy

- Less likely to be included in clinical trial

### *Pediatric Considerations*

Young females (<30 years of age) treated with thoracic radiation are at high risk for breast cancer, and early breast cancer screening is recommended.

### *Pregnancy Considerations*

- Abdominal ultrasonography to detect subdiaphragmatic disease
- Treatment:
  - Delay until after delivery if asymptomatic and early-stage
  - ABVD safely used in 2nd and 3rd trimesters
  - Vinblastine monotherapy to control symptoms
  - 1st trimester: ABVD may or may not cause fetal malformations.

### *Incidence*

- ~9,000 new cases in the United States annually
- Mean age at diagnosis: 38 years
- Hodgkin is most common in early adulthood (15 to 40) and then again after age 55 years.

### *Prevalence*

÷190,000 living with Hodgkin lymphoma in the United States in 2012

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- RS cells likely derived from germinal center B cells with mutations in immunoglobulin variable chain
- Seasonal features and higher frequencies with Epstein-Barr virus (EBV) suggest environmental factors.
- T-lymphocyte defects persist even after successful treatment.
- Human leukocyte antigen (HLA) is strongly associated with increased risk (2).
- EBV positivity associated with increased risk (2)
- Genome-wide association studies identified 19p13.3 at intron 2 of *TCF3*.

## *Genetics*

- First-degree relative: 3 to 9 times risk
- Siblings of younger patients: 7 times risk
- Weak correlation between familial HL and HLA class I regions containing HLA A1, B5, B8, B18 alleles

## *RISK FACTORS*

- Immunodeficiency (inherited or acquired)
- Autoimmune disorders
- EBV (2)
- Seasonal factors

## *COMMONLY ASSOCIATED CONDITIONS*

In HIV:

- AIDS-defining illness
- Predominantly mixed-cellularity or lymphocytedepleted histologic subtypes
- At diagnosis: widespread disease, extranodal involvement, systemic symptoms

## **DIAGNOSIS**

### **HISTORY**

- Asymptomatic lymphadenopathy (cervical/supraclavicular)
- Pel-Ebstein fever
- Constitutional symptoms: night sweats, weight loss, fatigue, anorexia
- Alcohol-induced pain
- Pruritus

## *PHYSICAL EXAM*

Focus on lymph nodes, spleen, and liver.

## *DIFFERENTIAL DIAGNOSIS*

Non-Hodgkin lymphoma, infectious lymphadenopathy, solid tumor metastases, sarcoidosis,

autoimmune disease, AIDS/HIV, drug reaction

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- CBC and electrolytes
- LFT, including hepatitis serologies
- HIV
- Pregnancy test
- Pulmonary function tests (diffusion capacity of the lung for carbon monoxide for ABVD or BEACOPP)
- Chest x-ray
- CT of chest, abdomen, and pelvis
- PET: for initial staging, midtreatment decision making, and end-of-treatment evaluation
- Bone scan, gallium scan, abdominal ultrasound
- EBV (2)

### ***Follow-Up Tests & Special Considerations***

- Fertility considerations:
  - Semen cryopreservation if chemotherapy or pelvic radiation therapy
  - In vitro fertilization or ovarian tissue/oocyte cryopreservation
- Radiation therapy (RT) considerations:
  - Splenic RT: pneumococcal, *Haemophilus influenzae*, meningococcal vaccine

### ***Diagnostic Procedures/Other***

- Excisional lymph node biopsy
- Immunohistochemistry
- Bone marrow biopsy
- Liver biopsy (in selected cases)

### ***Test Interpretation***

RS cell characteristics include the following:

- Diameter: 20 to 50  $\mu\text{m}$
- Abundant acidophilic cytoplasm
- Bi- or polylobulated nucleus
- Acidophilic nucleoli
- CD30+, CD15+, CD45-, CD3-, CD20+ in 40% of cases
- RS cells necessary but not sufficient for diagnosis (needs inflammatory background)

## TREATMENT

- Ann Arbor staging with Cotswold modification
  - Stage I: single lymph node or of a single extralymphatic organ or site
  - Stage II:  $\geq 2$  lymph node regions on the same side of diaphragm alone or with involvement of extralymphatic organ or tissue
  - Stage III: node groups on both sides of the diaphragm
  - Stage IV: dissemination involving extranodal organs (except the spleen, which is considered lymphoid tissue)
  - Subclasses: A = no systemic symptoms; B = systemic symptoms (fever, night sweats, weight loss  $>10\%$  body weight); X = bulky disease (widened mediastinum,  $>$  intrathoracic diameter, or  $>10\text{-cm}$  nodal mass)
  - Pathologic stage at given site denoted by: M = bone marrow, H = liver, L = lung, O = bone, P = pleura, D = skin:
    - Splenectomy, liver biopsy, lymph node biopsy, bone marrow biopsy mandatory for pathologic staging
- Goal: Aim for cure.
- All subsequent treatment and follow-up care recommendations based on National Comprehensive Cancer Network (NCCN) consensus. Please refer to NCCN Practice Guidelines in Oncology for Hodgkin lymphoma.

## MEDICATION

### *First Line*

- ABVD: doxorubicin, bleomycin, vinblastine, dacarbazine:
  - Highly emetic, severe phlebitis
  - Monitor cardiac function on doxorubicin.
  - Dacarbazine cannot be omitted without loss of efficacy (3).
- BEACOPP: bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, prednisone:
  - Bleomycin: risk of pulmonary toxicity, death; test dose may be administered prior to first cycle
- Stage I/II with no risk factors: two cycles ABVD followed by 20 Gy involved field radiotherapy (IFRT)
- Stage I/II with risk factors (large mediastinal mass, unfavorable histology, age, extranodal disease, erythrocyte sedimentation rate (ESR), B symptoms, number of nodal areas): four cycles chemotherapy (BEACOPP and/or ABVD) followed by 30 Gy IFRT
- Stage III/IV: four to six cycles chemotherapy (BEACOPP and/or ABVD) and consider autologous stem cell transplant (SCT) or radiotherapy

P.491

- Relapsed and refractory: high-dose conditioning therapy (HDCT) followed by autologous SCT:
  - Maintenance therapy: trials with brentuximab vedotin (anti-CD30) and lenalidomide under way
  - Brentuximab vedotin: anti-CD30, use in relapsed HL after two prior lines of treatment have been tried, side effects include peripheral neuropathy, nausea, fatigue, neutropenia, diarrhea (4)
  - Allogeneic SCT to be considered if failed autologous SCT (used in trials only)
  - Consolidation with brentuximab vedotin after autologous SCT improves progression free survival in those at risk for relapse or progression after transplantation (5).

## Second Line

- Median survival <3 years if fail second-line therapy, including SCT
- SCT in progressive disease or relapse:
  - High-dose chemotherapy and autologous stem cell transplant (HDCT/autoSCT): improved eventfree and progression-free survival compared with conventional chemotherapy but not overall survival; can achieve disease-free survival in 30-40% of patients after alloSCT (6,7)

- Reduced intensity conditioning (RIC) with bischloroethylnitrosourea (BCNU), etoposide, cytarabine, melphalan (BEAM) followed by allogeneic transplant (alloSCT) to induce graft-versus-tumor (GVT) effect in patients who have relapsed after autoSCT, complete response seen in 81%, nonrelapse mortality of 13% at 1 year, 1-year relapse rate of 36% (6,8)
- Rituximab: excellent activity against lymphocytedominant variant due to CD20+ lymphocytes
- Brentuximab vedotin: anti-CD30 chimeric antibody conjugated to synthetic antimicrotubule agent monomethyl auristatin E:
  - Approved by the U.S. Food and Drug Administration (FDA) in 2011 for patients who failed/not candidate for SCT or failure of two prior multiagent chemotherapy regimens
- Nivolumab: anti-PD1 therapy with response in 20 out of 23 patients (9)
- Novel agents undergoing studies: NF- $\kappa$ B inhibitors (bortezomib), mammalian target of rapamycin (mTOR) inhibitors (everolimus), immunomodulators (lenalidomide), cell signaling targets histone deacetylase (HDAC) inhibitors (vorinostat, panobinostat, mocetinostat)

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- During therapy: CBC, nutrition, and hydration
- Restage with PET after two to four cycles of chemotherapy: sensitive prognostic indicator
- Posttreatment monitoring:
  - History and physical (H&P): q2-4mo for first 2 years, then q3-6mo for next 3 to 5 years
  - Laboratory studies
    - CBC, platelets, ESR, chemistry profile q2-4mo for 1 to 2 years, then q3-6mo for next 3 to 5 years
    - Thyroid-stimulating hormone (TSH) annually if radiation to neck
  - Imaging:
    - Chest: chest x-ray or CT q6-12mo during first 2 to 5 years
    - Abdominal/pelvic: CT q6-12mo during first 2 to 3 years
    - Annual breast mammogram or MRI beginning 8 to 10 years after therapy or at age 40

years if chest or axillary irradiation

- Surveillance PET should not be done routinely due to risk of false-positive findings.
- Splenic irradiation or splenectomy as part of Hodgkin treatment increases risk of secondary cancers (leukemia, myelodysplastic syndrome, non-Hodgkin lymphoma, solid cancers) (10).

## *PATIENT EDUCATION*

- Reproductive impact
- Risks of secondary malignancy
- Oral and dental care during therapy
- Leukemia & Lymphoma Society (<http://www.lls.org/>)

## *PROGNOSIS*

- Cure rate for classic Hodgkin lymphoma: 80%
- Relapse or progression of disease rate: 5-20%
- Overall survival rates:
  - 1-year survival: 92%
  - 5-year survival: 85%
  - 10-year survival: 81%
- International prognostic score for advanced disease:
  - Age  $\geq$ 45 years
  - Male gender
  - Albumin  $<$ 4 g/dL
  - Hemoglobin  $<$ 10.5 g/dL
  - Lymphocytopenia:  $<$ 600 lymphocyte cells/dL or lymphocytes  $<$ 8% of WBC
  - WBC  $\geq$ 15,000 cells/dL
  - Stage IV disease
- Main cause of death
  - Initial 5 years: Hodgkin lymphoma
  - After 5 to 10 years: leukemia, myelodysplastic syndrome

- After 20 years: second primary malignancy, cardiovascular disease

## Codes

&NA;

### ICD10

- C81.90 Hodgkin lymphoma, unspecified, unspecified site
- C81.91 Hodgkin lymphoma, unsp, lymph nodes of head, face, and neck
- C81.92 Hodgkin lymphoma, unspecified, intrathoracic lymph nodes

## Clinical Pearls

&NA;

## Neoplastic disease of lymphatics

- RS cells of monoclonal lymphoid B-cell origin within inflammatory background of lymphocytes
- Two subtypes: CHL, 95% of cases and NLPHL, 5% of cases
- Cure rate for CHL: 80%
- 5-year survival: ÷86%
- Relapse or progression of disease rate: 5-20%
- Immunotherapy with PD1 blockade currently underway and promising

# Homelessness

Dana Sprute, MD, MPH, FAAFP

Lauren Engelmann, MD

## BASICS

### DESCRIPTION

ÒHomelessÓ or Òhomeless individual or homeless personÓ includes the following: (i) an individual who lacks a fixed, regular, and adequate nighttime residence; and (ii) an individual who has a primary nighttime residence that is (a) a supervised publicly or privately operated shelter designed to provide temporary living accommodations (including welfare hotels, congregate shelters, and transitional housing for the mentally ill); (b) an institution that provides a temporary residence for individuals intended to be institutionalized; and (c) a public or private place not designed for, or ordinarily used as, a regular sleeping accommodation for human beings.

### EPIDEMIOLOGY

#### Prevalence

As of January 2014, on any given night there are 578,424 homeless individuals in the United States: 37% are homeless families; 15% are chronically homeless individuals; 48% are not chronically homeless individuals; and 33% are children (1)[A].

- From 2013 to 2014, overall homelessness decreased by 2.3%; targeted federal assistance has increased. Risk for becoming homeless remains high (1)[A].
- Although many homeless individuals reside in temporary housing or shelters, 42% live on the streets (1,2)[A].
- Homelessness continues to decrease due to increases in targeted federal funding for rapid rehousing/permanent housing; 2015 fiscal year \$4.5 billion (highest in history to date) (2)[A].

### RISK FACTORS

- Economic factors
  - Poverty
    - 2015 federal poverty definition: \$24,250 annual income for 4-person household in the lower 48 states and District of Columbia, slightly higher in Alaska and Hawaii (3)[A].

- In 2013, 15% of the U.S. population fell below federal poverty definition (4)[A].
- Unemployment: U.S. rate 5.3% in July 2015 (U.S. Bureau of Labor Statistics, accessed August 4, 2015)
- Lack of affordable health care: In 2015, 13.2% of people in United States are without health insurance (4)[A].
  - Young adults (ages 19 to 34 years) are disproportionately uninsured (27%) compared with the average for all ages (13%); the uninsured rate for ages 19 to 25 years decreased by 7.4% since between 2009 and 2013, following Affordable Care Act provision allowing individuals in this age group to stay on their parents' insurance plans (4)[A].
  - Access to insurance has markedly improved because of the introduction of the Affordable Care Act; the number of uninsured Americans has dropped 35% since October 2013 (4) [A].
- Lack of affordable housing: housing is considered affordable if <sup>2</sup>30% of household income
  - Over 6.5 million households are defined by HUD as <sup>0</sup>severely housing cost burdened<sup>0</sup> (<sup>3</sup>50% of income is spent on housing) (5)[A].
- At-risk populations: intimate partner violence, victims of violence; youth (particularly those aging out of foster care); veterans; rural; addiction; psychiatric illness; disabled due to chronic medical disease, psychiatric illness, or substance use disorder; reentry after incarceration/prison
  - Intimate partner violence (IPV): 63% of homeless women experience IPV; in many cases, IPV leads directly to homelessness (6)[A].
  - Youth: Each year, 550,000 unaccompanied youths (up to age 24 years) experience an episode of homelessness lasting longer than a week (6)[A].
  - Veterans: 11% of homeless adults; homelessness rate decreased between 2009 and 2014 (1) [A].
  - Addiction disorders: 46% of homeless individuals report alcohol and/or drug use as a major factor contributing to homelessness (6)[A].
  - Psychiatric illness: 45% of homeless report indicators of a mental health issue in the past year; 25% of homeless adults suffer from chronic mental illness (6)[A].
  - Reentry after incarceration: 30-50% of parolees are homeless at any given time (6)[A].
- Fundamental issues in homelessness and health care that require ongoing consideration (7) [C]:

- Unstable housing, limited access to nutritious food and water, lack of transportation
- Higher risk for abuse and violence
- Physical/cognitive impairments, behavioral health problems
- Developmental discrepancies for children: speech delay, chronic ear infection, insufficient opportunity to practice gross and fine motor skills
- Higher risk for communicable disease
- Lack of health insurance/resources, discontinuous/inaccessible health care, lack of a medical home, barriers to disability assistance
- Cultural/linguistic barriers: racial and ethnic groups overrepresented in homeless population
- Limited education/literacy
- Lack of social supports: Alienation from family and friends precipitates homelessness.
- Criminalization of homelessness: frequent arrests for loitering, sleeping in public places

## *GENERAL PREVENTION*

- Policy and funding for community programs that provide emergency/rapid housing, housing stabilization, and case management services to address risk factors.
- Affordable Care Act (ACA): In 2010, increased Medicaid eligibility for homeless and expanded home- and community-based services and case management for the homeless population (8) [A].
- Department of Housing and Urban Development (HUD): increasing permanent supportive housing units, increasing services for veterans and those with disabilities (8)[A]
- Social Justice Policy Recommendations: permanent affordable housing, foreclosure and homelessness prevention, increased funds for HUD McKinney-Vento programs (emergency, transitional, and permanent housing), rural homeless assistance, universal health care, universal livable income, employment/workforce services, prevention of hate crimes against the homeless, decriminalization of homelessness

## *COMMONLY ASSOCIATED CONDITIONS*

- Hunger
- Medical conditions
  - Worsening of chronic conditions: lack of healthy food, places to store medications, or medical equipment; inability to get restful sleep; decreased health literacy (7)[C]

- Infectious diseases
  - Tuberculosis (TB), HIV/AIDS, STI (7)[C]
  - Skin/nail infections and infestation (lice and scabies)
  - Liver disease (e.g., hepatitis B or C, or alcohol-related)
- Cognitive impairment: traumatic brain injury (TBI), cerebrovascular accident (CVA), substance use
- Dental problems
- Exposure-related conditions (frostbite, heatstroke)
- Psychiatric illness (7)[C]
- Trauma: increased risk of assault, victims of hate crimes

## DIAGNOSIS

### HISTORY

- Living conditions: location, access to food, restrooms, place to store medicines, safety
- Prior homelessness: what precipitated it, first time, chronic
- Individual/family history of reactive airway disease (RAD), chronic otitis media, anemia, diabetes, cardiovascular disease (CVD), TB, HIV/STIs, hospitalizations
- Family members, especially dependent children
- Medications: include OTC medication, dietary supplements, medication “borrowed” from others
- Prior providers: oral health, primary care, current medical home
- Mental health: stress, anxiety, appetite, sleep, concentration, mood, speech, memory, thought process and content, suicidal/homicidal ideation, insight, judgment, impulse control, social interactions; symptoms of brain injury (headaches, seizures, memory loss, lability, irritability, dizziness, insomnia, poor organizational/decision-making skills)
- Alcohol/nicotine/drug use: amount, frequency, duration
- Gender identity/orientation, behaviors, rape, pregnancies, hepatitis, HIV, other STIs
- History or current abuse: emotional, physical, sexual; patient safety
- Legal problems/violence: history of incarceration

- Regular/strenuous activities: routines (treatment feasibility); level of strenuous activity
- Work: previous types of jobs, length held, veteran status, occupational injuries/toxic exposures; vocational skills, interest
- Education: highest level; ever in special education; assess ability to read/language skills/English fluency.
- Nutrition/hydration: diet, food resources, preparation skills, liquid intake
- Cultural heritage/affiliations: family, friends, faith community, other sources of support
- Strengths: coping skills, resourcefulness, abilities, interests

## *PHYSICAL EXAM*

- Comprehensive exam: height/weight, BMI, especially: liver, dermatologic, oral, feet, neurologic, mental status

P.493

- Focused exams: for patients uncomfortable with full-body, unclothed exam at first visit
- Dental assessment: age-appropriate teeth, obvious caries, dental/referred pain, diabetes, CVD

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Mental health: Patient Health Questionnaire (PHQ-9, PHQ-2), MHS-III, MDQ
- Cognitive assessment: Mini-Mental Status Exam (MMSE), Traumatic Brain Injury Questionnaire (TBIQ), Repeatable Battery for the Assessment of Neuropsychological Status (RBANS)
- Developmental assessment: Ages & Stages Questionnaires, Parents' Evaluation of Developmental Status (PEDS), Denver II, or other standard screening tool
- Interpersonal violence: IPV, sexual assault, TBI
- Forensic evaluation: if indicated by history
- Baseline labs: as needed to address suspected medical concerns
- TB screening: PPD
- STI screening: HIV, chlamydia, gonorrhea, syphilis, hepatitis B, hepatitis C, trichomonas, bacterial vaginosis, monilia
- Substance abuse: SSI-AOD (Simple Screening Instrument for Alcohol and Other Drugs), urine drug screen

## Follow-Up Tests & Special Considerations

- **Reproductive health care and STIs:** Obtain detailed sexual history (sexual identity, orientation, behaviors/sexual practices, number of partners). Consider possible exploitation of patient, especially if mental illness/developmental disability suspected. Communicate willingness to initiate contraception first visit without exam. Genital exam recommended, but be sensitive to patient needs, if possible sexual abuse history. If pelvic exam is refused, consider empiric treatment for STI (and possibility of multiple orifice infection). Dispense medications on site; ask if partner needs treatment.
- **Pediatric care:** complete exam every visit, use each visit to identify/address problems and provide vaccinations as homeless families may not see a medical provider unless child is sick. Vision and hearing screening at every visit and refer for abnormalities.

## TREATMENT

- Establish rapport: sensitivity to prior negative health care experiences
- Enlist resources: mental health and substance abuse programs, free clinics, case management
- Health care maintenance: vaccinations (hepatitis A and B, Pneumovax, Tdap, influenza) cancer and chronic disease screening for adults; Early Periodic Screening, Diagnosis, and Treatment Program (EPSDT) screening and vaccinations for children
- Care plan
  - Basic needs: Food, clothing and housing may be higher priorities than health care.
  - Patient goals and priorities: immediate/long-term health needs. Address patient wants first.
  - Action plan: simple language, portable pocket card
  - After hours: extended clinic hours
  - Safety plan: for violence and abuse suspected; mandatory reporting requirements
  - Emergency plan: location of nearest emergency department (ED), preparation for evacuation
  - Adherence plan: Use of interpreter; identification of potential barriers.

## MEDICATION

- Simple regimen: low pill count, once-daily dosing
- Dispensing: small amounts on-site to promote follow-up, decrease loss/theft/misuse risk. Determine resources for written prescriptions.

- Storage of medications: If no access to refrigeration, avoid medications requiring it.
- Patient assistance: free/low-cost drugs if readily available for continuous use; seek local options for assistance
- Aids to adherence: harm reduction, outreach/case management, directly observed therapy
- Side effects: primary reason for nonadherence (diarrhea, polyuria, nausea, disorientation)
- Analgesia/symptomatic treatment: Consider pain contract, single provider for pain medication refills.
- Dietary supplements: multivitamins with minerals, nutritional supplements
- Managed care: generics, if possible; assistance getting prescription filled
- Lab monitoring: Monitor patients on antipsychotic medications for metabolic disorders.

## *ADDITIONAL THERAPIES*

- Associated problems/complications
  - Fragmented care: multiple providers. Use electronic medical record (EMR); list prescribed medication on wallet-sized card.
  - Masked symptoms/misdiagnosis: for example, weight loss, dementia, edema, lactic acidosis
  - Focus on immediate concerns, not possible future consequences
  - Integrated treatment for concurrent mental illness/substance use disorders
  - Support for parent of child abused by others and for abused parent
- Follow-up
  - Reliable phone/e-mail contact for patient/friend/family/case manager
  - Frequent follow-up, incentives, nonjudgmental care regardless of adherence
  - Anticipate/accommodate unscheduled clinic visits.
  - Provide car fare, tokens, and help with transportation services.
  - Monitor school attendance and address health/developmental problems with family/school.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Homeless likely to benefit from admission if living conditions are suboptimal to treat medical, psychiatric, and substance use disorders.

## *Discharge Criteria*

- Bed rest, extended periods of elevation, rest, or icing are not feasible in most instances.
- Plans requiring multiple return visits likely to fail if no transportation.
- Admission to inpatient rehabilitation if appropriate and possible

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Patients with a history of nonadherence need additional support (e.g., case manager, outreach) to succeed in ongoing care after hospital discharge.
- Limited access to telephones to schedule appointments; may be unable to receive telephone messages with test results or rescheduled appointment times.
- Arrange appointments prior to discharge.
- Document the best way to contact the individual.
- Refer to health care agency designed to address needs of people who are homeless with integrated physical/mental health services and substance use treatment.

## *PROGNOSIS*

Mortality rates for homeless adults are 3 to 4 times higher compared with general U.S. population (9)[C].

## Codes

&NA;

### ICD10

- Z59.0 Homelessness
- Z59.1 Inadequate housing
- Z59.8 Other problems related to housing and economic circumstances

## Clinical Pearls

&NA;

- Ending homelessness requires permanent housing, supportive services, and implementing policies to prevent chronic homelessness.

- Assistance in gaining access to benefits or meeting basic needs may decrease stress, improve therapeutic relationship, and allow individuals to direct attention to physical health.

# Hordeolum (Stye)

Konstantinos E. Deligiannidis, MD, MPH, FAAFP

## BASICS

### DESCRIPTION

- An acute inflammation or infection of the eyelid margin involving the sebaceous gland of an eyelash (external hordeolum) or a meibomian gland (internal hordeolum)
- System(s) affected: skin/exocrine
- Synonym(s): internal hordeolum; external hordeolum; Zeisian stye; meibomian stye; stye

### EPIDEMIOLOGY

- Predominant age: none
- Predominant sex: male = female

### Incidence

Unknown: Although external hordeolum is common, internal hordeolum is rare.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Bacterial infection of sebaceous or meibomian glands, causing an acute inflammatory reaction
- In an internal hordeolum, the meibomian gland may become obstructed, leading to a pustule on the conjunctival surface as opposed to the margin of the eyelid.
- Most commonly caused by *Staphylococcus aureus* (÷90-95% of all cases) or by *Staphylococcus epidermidis*
- Seborrhea can predispose to infections of the eyelid.

### Genetics

No known genetic pattern

### RISK FACTORS

- Poor eyelid hygiene

- Previous hordeolum
- Contact lens wearers
- Application of makeup
- Predisposing blepharitis (low-grade infections of the eyelid margin)
- Ocular rosacea

## **GENERAL PREVENTION**

Eyelid hygiene

## **COMMONLY ASSOCIATED CONDITIONS**

- Acne
- Seborrhea
- An association may exist between hordeolum during childhood and developing rosacea in adulthood.

## **DIAGNOSIS**

### **HISTORY**

- Localized inflammation (vs. involvement of the entire eyelid or surrounding skin)
- Foreign body sensation in the eye
- Prior episodes are common.

## **PHYSICAL EXAM**

- Localized inflammation of the eyelashes or a small pustule at the margin of the eyelid
- Localized swelling and tenderness on the internal or external aspect of the eyelid with an opening to either side
- To determine if an internal hordeolum is obstructed, the eyelid should be gently everted to examine for a pustule on the tarsal conjunctiva.
- Itching or scaling of the eyelids; collection of discharge, redness, and irritation leading to localized tenderness and pain
- The size of the swelling usually correlates to the severity of the hordeolum.

## *DIFFERENTIAL DIAGNOSIS*

- Chalazion
- Blepharitis
- Eyelid neoplasms
- Periorbital cellulitis
- Dacryocystitis

## *DIAGNOSTIC TESTS & INTERPRETATION*

Culture of the eyelid margins usually is not necessary.

### *Diagnostic Procedures/Other*

History and eye exam

### *Test Interpretation*

Bacterial contamination and white cells in eyelid discharge

## **TREATMENT**

### *GENERAL MEASURES*

- The hordeolum should not be expressed.
- Warm compresses to the area of inflammation can help increase blood supply and encourage spontaneous drainage.
- Good personal hygiene with attention to cleansing the eyelids on a daily basis helps to prevent recurrent infections.

### *MEDICATION*

#### *First Line*

- A Cochrane review found no evidence for or against nonsurgical treatment of internal hordeolum. External hordeola were not considered (1)[A].
- Usually, a hordeolum spontaneously drains, aided by warm compresses to the area.
- Also, lid scrubs, digital massage, and alternative medicine have been used to reduce healing time and relieving symptoms.

- Application of an antibiotic ointment (e.g., erythromycin) to the margin of the eyelid after proper cleansing (except in children age <12 years, in whom there is a risk of blurred vision and amblyopia) helps reduce bacterial proliferation. There is little evidence that any topical therapy is effective. Erythromycin ophthalmic ointment may be applied up to 6 times per day for 7 to 10 days or an antibiotic ointment containing bacitracin (2,3)[C].
- Treat underlying dry eye with artificial tears.

## *Second Line*

- Occasionally, the use of an aminoglycoside ophthalmic ointment, such as gentamicin or tobramycin, may be necessary if condition is refractory to simpler treatment (case reports).
- Oral dicloxacillin or cephalexin for 2 weeks if refractory to topical antibiotics

P.495

## *ISSUES FOR REFERRAL*

Consider referral if unresponsive to oral antibiotics.

## *SURGERY/OTHER PROCEDURES*

- If the infection becomes localized to a single gland, incision, drainage, or curettage sometimes is necessary. This is an in-office procedure with a local anesthetic: Exercise caution because ocular perforation has been reported with the injection of an anesthetic to an infected lid.
- Use of combined antibiotic ointment (neomycin sulfate, polymyxin B sulfate, and gramicidin) after surgery was not shown to have any statistically significant benefit compared with artificial tears.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Broncasma berna is a polyvalent antigen vaccine that may be useful in the treatment of recurrent hordeolum.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Outpatient

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

No restrictions

## *Patient Monitoring*

The patient should be seen within several weeks to assess the effectiveness of therapy or should at least call the physician's office with a progress report.

## *DIET*

No special diet

## *PATIENT EDUCATION*

- The patient should be instructed in proper cleansing of the eyelids using a solution of tap water and baby shampoo or a commercially prepared hypoallergenic cleanser.
- The styte should not be squeezed or incised.

## *PROGNOSIS*

- Usually responds well to good hygiene and warm compresses
- Inflammation usually improves within a week.
- Hordeolum tends to recur in some patients, usually due to incomplete elimination of bacteria.

## **COMPLICATIONS**

An internal hordeolum, if untreated, may lead to chalazion, infections of adjacent glands, or generalized cellulitis of the lid.

## Codes

**&NA;**

### ICD10

- H00.019 Hordeolum externum unspecified eye, unspecified eyelid
- H00.029 Hordeolum internum unspecified eye, unspecified eyelid
- H00.039 Abscess of eyelid unspecified eye, unspecified eyelid

## Clinical Pearls

**&NA;**

- A hordeolum should not be expressed.
- Warm compresses to the area of inflammation can encourage spontaneous drainage.
- Application of an antibiotic ointment (e.g., erythromycin) to the margin of the eyelid after proper cleansing helps reduce bacterial proliferation but may have no effect on the healing of the stye.
- Good personal hygiene with attention to cleansing the eyelids on a daily basis can prevent recurrent infections.

# Horner Syndrome

Deborah A. Lardner, DO, DTM&H

Michael Passafaro, DO, DTM&H, FACEP, FACOEP

## BASICS

### DESCRIPTION

- Horner syndrome presents as a classic triad of ipsilateral miosis, eyelid ptosis, and/or anhidrosis of the face and neck (with iris heterochromia in children).
- It is caused by the interruption of sympathetic nerve supply to the head, neck, and eye.
  - Central or preganglionic lesion (complete syndrome): 1st- or 2nd-order neuron
  - Peripheral postganglionic lesion (incomplete syndrome, no anhidrosis): 3rd-order neuron
- System(s) affected: nervous, skin/exocrine
- Synonym(s): Bernard-Horner syndrome; Bernard syndrome; Horner's syndrome; cervical sympathetic syndrome; oculosympathetic syndrome; oculosympathetic paralysis; oculosympathetic deficiency; oculosympathetic paresis

### EPIDEMIOLOGY

- Predominant age: none
- Predominant sex: male = female

### Incidence

Unknown

### Prevalence

Unknown

### ETIOLOGY AND PATHOPHYSIOLOGY

- Constellation of signs produced when sympathetic innervation to the head, neck, and eye is interrupted somewhere along the three-neuron arc
  - Absence of innervation of iris dilator and M ller muscles leads to miosis and slight ptosis,

respectively.

- Sympathetic innervation also controls sweat glands; interruption causes anhidrosis.
- Oculosympathetic pathway
  - 1st-order neuron: Sympathetic nerve fibers originate in the hypothalamus, descend through the brainstem, and synapse at the ciliospinal center (of Budge) located at approximately the C8-T2 levels of the spinal cord.
  - 2nd-order neuron: exits the spinal column at the T1 level primarily, arches over the apex of the lung and under the subclavian artery, ascending to the superior cervical ganglion at the level of the carotid bifurcation and angle of the jaw
  - 3rd-order neuron: ascends along the adventitia of the internal carotid artery, through the cavernous sinus in proximity to cranial nerve [CN] VI, and joins CN VI to innervate the iris dilator muscle and Müller muscle in the eye
- Sympathetic fibers innervating sweat glands and vasodilatory muscles branch off before the cervical sympathetic ganglion traveling along the external carotid artery, so distal lesions will not result in anhidrosis.
- Lesions anywhere along this pathway will lead to ipsilateral Horner syndrome.
- Idiopathic (40%), congenital, or acquired
- Best classified by which order neuron is affected and by age (pediatric vs. adult)
- 1st-order neuron (13%)
  - Arnold-Chiari malformation
  - Basal meningitis (e.g., syphilis)
  - Basal skull tumors
  - Cerebral vascular accident: lateral medullary (Wallenberg) syndrome
  - Cervical cord trauma
  - Demyelinating disease (multiple sclerosis)
  - Intrapontine hemorrhage
  - Neck trauma
  - Pituitary tumor
  - Syringomyelia
  - Unintended subdural placement of lumbar epidural catheter

- 2nd-order neuron (44%)
  - Aneurysm/dissection of aorta
  - Central venous catheterization
  - Chest tubes
  - First rib fracture
  - Lymphadenopathy (Hodgkin, leukemia, tuberculosis, mediastinal tumors, sarcoid)
  - Mandibular tooth abscess
  - Neurofibromatosis types I and II
  - Pancoast tumor or infection of lung apex
  - Proximal common carotid artery dissection
  - Trauma/surgical injury
- 3rd-order neuron lesions (43%)
  - Carotid cavernous fistula or other pathology
  - Carotid endarterectomy or carotid artery stenting
  - Cluster headaches
  - Internal carotid artery dissection
  - Herpes zoster
  - Lesions of the middle ear (acute otitis media)
  - Lyme disease
  - Nasopharyngeal cancer
  - Tonsillectomy
  - Raeder paratrigeminal syndrome
- Drugs: acetophenazine, alseroxylon, bupivacaine, butaperazine, carphenazine, chlorprocaine, deserpidine, diacetylmorphine, diethazine, ethopropazine, etidocaine, guanethidine, influenza virus vaccine, levodopa, lidocaine, mepivacaine, mesoridazine, methdilazine, methotrimeprazine, oral contraceptives, perazine, prilocaine, procaine, prochlorperazine, promazine, propoxycaine, reserpine, thioproperazine, thioridazine, trifluoperazine

## *Genetics*

Rare autosomal dominant inheritance

## RISK FACTORS

- Most common: apical bronchogenic carcinoma (Pancoast tumor) in smokers
- Aneurysm of the carotid or subclavian artery
- Injuries to the carotid artery high in the neck
- Dissection of the carotid arteries
- Carotid artery occlusion
  - 15% of patients with carotid artery occlusion develop ipsilateral Horner syndrome.
  - May occur without evidence of cerebral ischemia, neck injuries, or operative procedures
- Cluster headaches
  - 20% have an ipsilateral Horner syndrome.

## *Pediatric Considerations*

2nd-order neuron lesion is the most common etiology: birth trauma to neck and shoulder, chest surgery, neuroblastoma (paraspinal), and vascular anomalies of the carotid arteries.

## COMMONLY ASSOCIATED CONDITIONS

- Wallenberg syndrome
- Pancoast tumor
- C8 radiculopathy

## DIAGNOSIS

### HISTORY

- Ptosis (typically mild; 1 to 2 mm)
- Miosis (with an associated dilation lag)
- Anhidrosis or hypohidrosis (often not appreciated by patients or clinicians):
  - Ipsilateral side of the body: central (1st-order neuron)
  - Ipsilateral face: preganglionic (2nd-order neuron)
  - Medial portion of forehead and side of nose: postganglionic (3rd-order neuron after vasomotor and sudomotor fiber have branched off)

### *Pediatric Considerations*

In infants and children, loss of facial flushing is appreciated more than anhidrosis (harlequin sign).

## **ALERT**

Horner syndrome in the presence of pain merits special consideration:

- Axial, shoulder, scapula, arm, or hand pain may be related to Pancoast tumor.
- Acute-onset, ipsilateral facial or neck pain: Consider carotid artery dissection until proven otherwise.
- Paratrigeminal syndromes:
  - Raeder paratrigeminal syndrome type I: orbital pain, miosis, ptosis, with associated ipsilateral lesions of CN III-VI; suspect middle cranial fossa mass lesion.
  - Raeder paratrigeminal syndrome type II: episodic retrobulbar or orbital pain, miosis, ptosis with no CN lesions; suspect migraine variant, syphilis, herpes zoster, hypertension.

## **PHYSICAL EXAM**

- Measure pupillary diameter in dim and bright light and reactivity to light and accommodative response:
  - Anisocoria is greatest in dark, with affected pupil failing to dilate.
  - Redilation (after light is removed) may lag 15 to 20 seconds on the affected side.
- Examine the upper lids for ptosis (<2 mm).
- Examination of the lower lids for Upside-down ptosis: elevation of lower lid due to Müller muscle weakness
  - Illusion of enophthalmos secondary to narrowing of palpebral fissure
- Ipsilateral impaired flushing may be found.
- Loss of ciliospinal reflex. Pinching the skin on back of the neck normally produces ipsilateral pupil dilation (unreliable).
- Biomicroscopic exam of the papillary margin and iris structure and color
  - In congenital Horner syndrome, long-standing Horner syndrome, or Horner syndrome that occurs in children <2 years: Iris shows reduced pigmentation, blue-gray, and mottling of the affected eye (heterochromia iridis) because formation of iris pigment early in life is under sympathetic control.

- Observe for the presence of nystagmus, facial swelling, lymphadenopathy, or vesicular eruptions.
- Ophthalmoparesis, specifically CN VI palsy with Horner syndrome, is suggestive of cavernous sinus lesion.
- Neurologic and chest exams for associated physical findings

---

P.497

## ***DIFFERENTIAL DIAGNOSIS***

- Neurologic diseases
- 3rd nerve palsy
- Unilateral use of miotics
- Unilateral use of mydriatics
- Adie tonic pupil
- Iris sphincter muscle damage

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

CBC, fluorescent treponemal antibody absorption test, venereal disease research laboratory, purified protein derivative; vanillylmandelic acid, homovanillic acid to rule out neuroblastoma in pediatric patients

- Chest x-ray if patient is a smoker (apical bronchogenic carcinoma)
- CT/MRI/MRA of the brain, chest, and spinal cord
  - If painful, order MRI/MRA to evaluate for carotid artery dissection emergently.
- Ultrasound may be considered for evaluation of internal carotid artery

### ***Pediatric Considerations***

In a child of any age without contributory history, MRI brain, neck, and chest to exclude a mass lesion (1)[B]

## ***DIAGNOSTIC PROCEDURES/OTHER***

- Confirmation of Horner syndrome

Topical 0.5% apraclonidine (2)[A],(3,4)[B]

- 4-10% topical cocaine
  - Used to confirm diagnosis of Horner syndrome but will not identify location of lesion
  - If the diagnosis is clear clinically, this test is not required.
  - A normal pupil will dilate. The miotic pupil in Horner syndrome (regardless of location of lesion) will not dilate or will dilate poorly after 45 minutes because of the absence of norepinephrine at the nerve endings of the 3rd-order neuron (2)[A].
  - Positive test is anisocoria of  $\geq 1$  mm.
  - Cocaine blocks the reuptake of norepinephrine by the neuron.
- Distinguishing a 3rd-order neuron disorder from a 1st- or 2nd-order neuron disorder:
  - Topical 1% hydroxyamphetamine (2)[A]
    - If there is a 1st- or 2nd-order neuron lesion, dilation will take place.
    - Failure of the pupil to dilate, or poor dilation, indicates a 3rd-order neuron lesion (positive when anisocoria increases by  $\geq 1$  mm).
    - No pharmacologic test exists to differentiate between a 1st- and 2nd-order neuron lesion.
    - Hydroxyamphetamine causes release of endogenous norepinephrine stored in the postganglionic neuron.
    - Alternative test: 1% topical pholedrine
- Must wait >24 hours between the cocaine and hydroxyamphetamine tests.

## *Pediatric Considerations*

Due to transsynaptic degeneration in children, the hydroxyamphetamine test is not reliable.

## *Test Interpretation*

- Brainstem lesion
- Massive hemisphere lesion
- Cervical cord lesion
- Root lesion
- Sympathetic chain lesion

## TREATMENT

### GENERAL MEASURES

- Horner syndrome in itself does not produce any disability or necessarily require treatment.
- Treat the underlying etiology.
- Search for a tumor or other compressive lesion.

### MEDICATION

Carotid artery dissection: Pharmacologic treatment options include thrombolysis, antithrombotic therapy with anticoagulation, or antiplatelet therapy. No randomized control trials have compared these treatment options (5)[C].

### ISSUES FOR REFERRAL

- Neurologic, neuro-ophthalmic, oculoplastic
- Neurologic or vascular surgery: interventional in cases of suspected carotid artery dissection or aneurysm
- Neurosurgery, surgical oncology, oncology, or radiotherapy consultation depends on the particular etiology.

### SURGERY/OTHER PROCEDURES

- Surgical care depends on etiology.
- Consider ptosis repair surgery (oculoplastics).

## ONGOING CARE

### PROGNOSIS

- Postganglionic: usually benign
- Central and preganglionic: poorer prognosis

### COMPLICATIONS

- Chronic pupillary constriction
- Cosmesis

## Codes

**&NA;**

### ICD10

- G90.2 Horner's syndrome
- S14.5XXA Injury of cervical sympathetic nerves, initial encounter

## Clinical Pearls

**&NA;**

- Horner syndrome triad: ipsilateral miosis, eyelid ptosis, and anhidrosis caused by a lesion of the oculosympathetic pathway
- Ptosis is mild, usually <2 mm.
- Red flags: If associated with pain, suspect central or preganglionic lesion.
- Confirm the diagnosis clinically with topical cocaine to the affected eye.
- Use hydroxyamphetamine to differentiate which order neuron is affected.
- Order imaging studies based on history and physical and hydroxyamphetamine testing.
- Horner syndrome in the presence of acute-onset, ipsilateral facial or neck pain: Consider carotid artery dissection until proven otherwise.

# Hydrocele

Jared M. Patton, MD, MS

John E. Laird, MD, FAAFP

## BASICS

### DESCRIPTION

A collection of fluid between the parietal and visceral layers of the tunical vaginalis within the scrotum

- Communicating hydrocele (patent processus vaginalis)
  - Direct communication with the peritoneal cavity
  - Contains peritoneal fluid
  - Almost always with associated indirect inguinal hernia
  - Decreases in size with recumbent position
- Noncommunicating hydrocele (the processus vaginalis is not patent)
  - No direct connection to the peritoneal cavity
  - Fluid contained is from the mesothelial lining.
  - Can be isolated to the cord with the distal and proximal portions of the processus vaginalis closed
- Acute hydrocele: fluid collection resulting from an acute process within the tunica vaginalis, typically involving only the scrotum
- System(s) affected: Urogenital

### *Pediatric Considerations*

In a communicating hydrocele, consider contralateral inguinal exploration to rule out an occult indirect hernia.

### EPIDEMIOLOGY

Predominant age: childhood (1)

## *Incidence*

Estimated at 0.7-4.7% of male infants

## *Prevalence*

- 1,000/100,000
- Estimated at 1% of adult men

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Incomplete closure of the processus vaginalis trapping peritoneal fluid anywhere along the length of the tunica vaginalis
- Failure of closure of the processus vaginalis maintaining a communication to the peritoneal cavity
- Imbalance of the secretion and reabsorption of fluid from the lining of the tunica vaginalis
- Infection
- Tumors
- Trauma
- Ipsilateral renal transplantation

## *RISK FACTORS*

- Ventriculoperitoneal shunt
- Exstrophy of the bladder
- Cloacal exstrophy
- Ehlers-Danlos syndrome
- Peritoneal dialysis

## *COMMONLY ASSOCIATED CONDITIONS*

- Testicular tumors
- Scrotal trauma
- Ventriculoperitoneal shunt
- Nephrotic syndrome
- Renal failure with peritoneal dialysis

# DIAGNOSIS

## HISTORY

- Acute, subacute, or chronic swelling of the scrotum or inguinal canal
- Frequent changes in size of the hydrocele with position change or activity (indicative of communicating)
- Usually painless unless acute onset
- Sensation of heaviness or pressure in the scrotum
- Pain radiating to the flank/back

## PHYSICAL EXAM

- Swelling in the scrotum or inguinal canal
- Scrotal mass, usually fluctuant
- Fluctuation in size with change of position (communicating hydrocele)
- Scrotal mass that transilluminates

## DIFFERENTIAL DIAGNOSIS

- Indirect inguinal hernia
- Orchitis
- Epididymitis
- Varicocele
- Traumatic testicular injury
- Testicular torsion or torsion of appendix testes
- Testicular neoplasm

## DIAGNOSTIC TESTS & INTERPRETATION

- Inguinoscrotal ultrasound (US): can demonstrate the presence of bowel (e.g., distinguish incarcerated hernia from a hydrocele of the cord) as well as the presence of testicular torsion
- Testicular MRI when US is unable to distinguish etiology
- Doppler US or testicular nuclear scan can distinguish testicular torsion.

## Diagnostic Procedures/Other

## **ALERT**

Aspiration of a hydrocele for diagnosis is not indicated and may lead to severe complications if herniated bowel is present.

## *Test Interpretation*

Patent processus vaginalis on imaging in communicating hydroceles

## **TREATMENT**

### *ISSUES FOR REFERRAL*

- Urology referral for symptomatic adults or if underlying diagnosis is unclear
- Pediatric urology/surgery referral for children with symptomatic noncommunicating hydrocele
- Children with communicating hydroceles can be expectantly managed until at least 2 years of age to allow time for spontaneous resolution unless there is a concern for inguinal hernia (1) [C].
- New-onset hydrocele in late childhood and preadolescent patients typically resembles the adult type hydrocele pathology (2)[B].

### *SURGERY/OTHER PROCEDURES*

- Children: Surgical treatment is generally deferred until 2 years of age as many hydroceles will spontaneously resolve. Some evidence shows that delaying longer than 2 years may be appropriate and decrease unnecessary surgery (1)[C].
  - When surgery is indicated, children with communicating hydroceles may undergo either open or laparoscopic approach.
    - Open inguinal approach involves ligation of the processus vaginalis and excision, distal splitting, or drainage of hydrocele sac (in a hydrocele of cord, the sac can be completely removed) (3)[B]
    - Open scrotal approach involves ligation and removal of the processus vaginalis. The benefit of this approach is improved cosmesis and decreased operative time (4)[B].
    - Laparoscopic repair offers the benefit of contralateral exploration and repair with low long-term recurrence rates and similar operative times as open procedures (5)[B].

- 
- Adults: No therapy is needed unless the hydrocele causes discomfort or unless there is a significant underlying cause such as a tumor (6).

- If resection is indicated, a scrotal approach with resection of hydrocele sac has the highest complication rate but lowest recurrence rate (7)[C].
- Jaboulay-Winkelmann procedure (for a thick hydrocele sac): The hydrocele sac is wrapped posteriorly around cord structures (7)[C],(8)[A].
- Lord procedure (for a thin hydrocele sac): Radial sutures are used to gather the hydrocele sac posterior to testis and epididymis (7)[C],(8)[A].
- Aspiration of the hydrocele with instillation of a sclerosing agent has been successfully used in adults.
  - Aspiration with instillation of 1 to 4 mg of polidocanol has demonstrated a cure rate of 56% after the first treatment and 89% after the second treatment (9)[A].
  - The benefit of aspiration versus surgery is a decrease in cost and operative complications. (9)[A].
- Hydrocelectomy may be performed endoscopically via a transscrotal approach; it involves cauterization of the entire parietal surface of the tunical vaginalis (10)[A].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Open inguinal or scrotal approach is typically performed as an outpatient.
- Laparoscopic approach may require 24-hour admission for postoperative monitoring.
- Sclerotherapy is a same-day office procedure.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Depending on method of treatment, initial follow-up is generally in the first 4 to 6 weeks.
- With sclerotherapy follow-up for confirmation of resolution or to proceed with retreatment
- Postoperative follow-up at 2 to 4 weeks and subsequent 2- to 3-month intervals until resolution of any postoperative complications

## **COMPLICATIONS**

- Complication rate for a scrotal approach may reach 30% (6)[C].
- Postoperative traumatic hydrocele is common and usually resolves spontaneously.
- Injury to vas deferens or spermatic vessels
- Suture granuloma
- Hematoma
- Wound infection
- Recurrence

## Codes

**&NA;**

### ICD10

- N43.3 Hydrocele, unspecified
- N43.2 Other hydrocele
- P83.5 Congenital hydrocele

## Clinical Pearls

**&NA;**

- A hydrocele can usually be diagnosed by physical exam and transillumination. If there is any concern for other underlying process, a formal US is recommended.
- Aspirating a hydrocele is not indicated as the primary treatment due to high recurrence rate.
- Attempted aspiration of an unconfirmed hydrocele could lead to bowel injury in an undiagnosed inguinal hernia.
- Laparoscopic repair in children offers the benefit of contralateral exploration and repair.
- Expectant management of children with hydrocele until >2 years of age is acceptable to allow sufficient time for spontaneous resolution.

# Hydrocephalus, Normal Pressure

Dennis E. Hughes, DO, FACEP

## BASICS

### DESCRIPTION

- Normal pressure hydrocephalus (NPH) is a clinical triad of gait instability, incontinence, and dementia (mnemonic: *wet, wobbly, wacky*). Originally described by Hakim in 1957, it occurs rarely but is potentially treatable.
- Two forms of the disorder: idiopathic and secondary (to trauma)
- Absence of papilledema on clinical exam and normal CSF pressures at lumbar puncture

### ALERT

Idiopathic NPH primarily affects persons >60 years; extremely rare before 40 years

### EPIDEMIOLOGY

#### Incidence

- No formal epidemiologic data exist regarding NPH because of the lack of consensus-derived diagnostic criteria. The natural history of untreated NPH has not been studied.
- Idiopathic (iNPH) form primarily affects elderly, at least >40 years of age.
- Secondary form can occur at any age.
- Male = female

#### Prevalence

- 3.3/100,000 age 50 to 59 years to 11.7/100,000 age 70 to 79 years for iNPH and increases to upwards of 5.9% in those <sup>3</sup>80 years
- Estimated to be a contributing factor in 6% of all cases of dementia

### ETIOLOGY AND PATHOPHYSIOLOGY

- Idiopathic form is a communicating hydrocephalus, a disorder of decreased CSF absorption (not over-production). In iNPH, the leading theory suggests that poor venous compliance impairs

the subarachnoid granulations' ability to maintain baseline removal of CSF. In secondary NPH, scarring is likely.

- The result is a pressure gradient between the subarachnoid space and ventricular system.
- CSF production decreases in the face of an increased pressure set-point (but still in excess of the amount of CSF absorbed).
- Elevated pressure distends ventricles and compresses the brain parenchyma.
- As a result of compression, ischemic changes occur in the parenchymal vasculature with subsequent tissue damage and loss.
- Some believe that the idiopathic form is a result of persistently insufficient removal of CSF by immature subarachnoid granulations from childhood.
- Secondary NPH may result from the following:
  - Head trauma (most common)
  - Subarachnoid hemorrhage
  - Resolved acute meningitis
  - Chronic meningitis (tuberculosis, syphilis)
  - Paget disease of the skull

## RISK FACTORS

- Idiopathic risk is unknown (case reports suggest a possible genetic link but unsubstantiated).
- Secondary form is due to head trauma, subarachnoid hemorrhage, meningitis, or encephalitis.

## DIAGNOSIS

Detailed history and careful examination is the key to early diagnosis.

### HISTORY

- Insidious and usually progressive gait instability usually manifests initially, followed by changes in mentation, and eventually, urinary incontinence.
- Behavioral changes noted in many cases: Depression, mania, and psychotic features in many cases precede the physical findings and respond poorly to usual treatment (1)[B].
- Difficulty with initiation of movement: Feet appear "glued to the floor." Gait is wide-based, shuffling, and turning appears "en bloc."
- Inattention, forgetfulness, and lack of spontaneity often are seen with the

subcortical dementia of NPH.

- Urinary urgency initially, followed by lack of inhibition and then frank incontinence.
- A minimum duration of at least 3 to 6 months of symptoms and progression over time
- A remote trauma or infection suggests secondary versus the idiopathic form.
- A lack of psychiatric, neurologic, or other medical conditions to explain the symptoms (including structural reasons for CSF flow restriction) (2)
- Because memory impairment may be present, it is important to include a knowledgeable informant who is familiar with the patient's premorbid state.
- Frontal lobe function is affected disproportionately to the memory impairment (objective testing may lead to an early diagnosis).

## *PHYSICAL EXAM*

- Decreased step height and length
- Reduced speed of walking (cadence)
- Widened standing base
- Swaying of trunk during walking
- Decreased fine motor speed and accuracy
- Recall impaired for recent events
- Impaired ability to do multistep tasks or interpret abstractions

## *DIFFERENTIAL DIAGNOSIS*

- Alzheimer disease (may be a comorbid condition in as many as 75%)
- Parkinson disease
- Chronic alcoholism
- Intracranial infection
- Multi-infarct dementia
- Subdural hematoma
- Carcinomatous meningitis
- Collagen vascular disorders
- Depression

- Syphilis
- B<sub>12</sub> deficiency
- Urologic disorders
- Other hydrocephalus disorders

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- Thyroid-stimulating hormone (TSH)
- Syphilis serology
- CBC
- Serum B<sub>12</sub>, folate
- Metabolic profile
- Blood alcohol, analysis for drugs of abuse
- Urinalysis
- CSF analysis, including an opening pressure <245 mm H<sub>2</sub>O (a value greater than this rules out iNPH by definition)
- Imaging is essential.
  - Either CT or MRI shows the ventriculomegaly (particularly lateral and 3rd ventricles) with preservation of the cerebral parenchyma (as opposed to ventricular enlargement seen in other forms of dementia where brain atrophy is present). A narrow subarachnoid space (tight convexity) was recently shown to correlate to probable or definite iNPH (3)[A].
  - MRI can allow detection of other features, such as signs of altered brain water content and callosal angles. However, these supportive findings are not independently diagnostic of NPH.

---

P.501

### ***Diagnostic Procedures/Other***

CSF removal aids in the definitive diagnosis as well as predicting response to surgical treatment.

- High-volume (30 to 70 mL) CSF removal via spinal tap on 3 successive days or continuous spinal drainage (150 to 200 mL/day) for 3 days
- Comparison of gait analysis before and after CSF removal (a <sup>3</sup>20% improvement indicates a positive test) especially when combined with coexisting executive function improvement (4)[B]

## TREATMENT

### *MEDICATION*

- No medication is significantly helpful.
- Use of carbonic anhydrase inhibitors (acetazolamide) with repeat lumbar punctures has provided mild and transient relief but is only supported by anecdotal evidence.
- Use of levodopa to rule out Parkinson disease may be helpful (NPH will display little, if any, significant improvement to dopamine agonist).

### *ISSUES FOR REFERRAL*

- Neurology or neurosurgical consultation is helpful in suspected cases when other reversible medical conditions are ruled out.
- Recent cohort studies have demonstrated clinical improvement after surgical shunts. Perimeters of urinary continence, gait stability, and cognitive scores all improved at 1-year post shunt.

### *ADDITIONAL THERAPIES*

Gait training and use of ambulation assist devices, as indicated, but limited efficacy

### *SURGERY/OTHER PROCEDURES*

- Current therapy is limited to placement of ventriculoperitoneal or ventriculoatrial shunt from a lateral ventricle tunneled SC and drained into the peritoneal cavity (or right atrium). There is no compelling evidence (no randomized controlled trial [RCT]) that this therapy is effective.
- Patients whose symptoms have been present for a shorter period (<2 years) have a greater chance of improvement with shunting. Also, patients with a known cause of NPH tend to respond more favorably. However, improvement has been seen in patients with symptoms present for a long time (5)[B].

### *INPATIENT CONSIDERATIONS*

#### *Admission Criteria/Initial Stabilization*

Usually only for planned surgical treatment

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

- Assessment and modification of environment for fall risks
- Evaluation for ability to operate a motor vehicle safely (if driving)

## Patient Monitoring

- Repeat neuropsychological testing to evaluate the status of the dementia after treatment.
- Improvement in the incontinence and walking speed can also be objectively measured.

## PATIENT EDUCATION

Information at:

[http://www.ninds.nih.gov/disorders/normal\\_pressure\\_hydrocephalus/normal\\_pressure\\_hydrocephalus.htm](http://www.ninds.nih.gov/disorders/normal_pressure_hydrocephalus/normal_pressure_hydrocephalus.htm)

## PROGNOSIS

Natural history is progressive deterioration. Patient's axial skeletal stability worsens with inability to walk, stand, sit, or turn over in bed.

## COMPLICATIONS

- In patients treated surgically, cerebral infarcts, hemorrhage, infection, and seizures (in addition to the usual surgical risks): all usual age-related illnesses (as NPH is a condition affecting those age >65 years)
- Shunt malfunction (especially when symptoms recur after successful shunt placement)
- Falls due to gait instability
- UTIs
- Skin breakdown, pressure ulcers, infections as movement dysfunction progresses

## Clinical Pearls

**&NA;**

- Consider in unexplained dementia or behavioral change
- Poor prognosis without therapy

# Hydronephrosis

Pang-Yen Fan, MD

## BASICS

### DESCRIPTION

- Hydronephrosis refers to a structural finding—dilatation of the renal calyces and pelvis.
  - May occur with urinary tract infection (UTI), vesicoureteric reflux (VUR), high urine output, or physiologic changes in pregnancy
  - Sometimes accompanied with hydroureter
  - Presentation varies from incidental finding to discovery during workup for UTI or for flank or abdominal pain.
- Hydronephrosis should not be used interchangeably with obstructive uropathy, which refers to the damage to renal parenchyma resulting from urinary tract obstruction (UTO).

### EPIDEMIOLOGY

- UTO is more common in men than women and in children than adults (congenital anomalies).
- Acute unilateral obstruction is more common than bilateral.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Hydronephrosis develops with increased pressure in the urinary collecting system.
- Increased pressure within the renal collecting system can cause calyceal fornix rupture and urinary extravasation.
- Over time, pressures return to normal, but kidney function declines from intense renal vasoconstriction.
- With concomitant urinary infection, bacteria can enter the renal vasculature, resulting in sepsis.
- UTO: may be acute/chronic, partial/complete, uni-/bilateral
  - Intraluminal obstruction: calculi, sloughed renal papillae, blood clot, fungal ball
  - Intrinsic abnormality of the urinary collecting system: transitional cell carcinomas, benign

prostatic hypertrophy, prostate cancer, congenital ureteropelvic junction (UPJ) obstruction, ureterocele, neurogenic bladder (functional obstruction), urethral stricture or tuberculosis (TB) (can cause ureteral narrowing)

- Extrinsic compression of the urinary collecting system: extraurinary malignancy (lymphoma, colon, cervix), aortic/iliac aneurysm, retroperitoneal fibrosis, uterine prolapse (15% affected), endometriosis, ovarian vein syndrome, IgG4-related disease
- Transplant hydronephrosis: Consider BK virus.
- UTO in transplanted kidneys is commonly due to ureteral strictures, lymphoceles (ureteral compression and bladder dysfunction).
- VUR resulting in varying degrees of hydroureteronephrosis
- Physiologic hydronephrosis of pregnancy
- Hydronephrosis due to high urine output (e.g., diabetes insipidus, psychogenic polydipsia)
- Hydronephrosis of infection: due to bacterial toxins inhibiting smooth muscle contraction of the renal pelvis and ureter

### *Pediatric Considerations*

- Antenatal hydronephrosis is diagnosed in 1-5% of pregnancies, usually by US, as early as the 12th to 14th week of gestation.
- Children with antenatal hydronephrosis are at greater risk of postnatal pathology.
- Postnatal evaluation begins with US exam; further studies, such as voiding cystourethrogram (VCUG), based on the severity of postnatal hydronephrosis
- In neonates, it is the most common cause of abdominal mass.
- Common etiologies in children are VUR, congenital UPJ obstruction, neurogenic bladder, and posterior urethral valves.
- Pediatric diagnostic algorithm differs from adult due to different differential diagnosis necessitating age-appropriate testing.

### *Pregnancy Considerations*

- Physiologic hydronephrosis in pregnancy is more prominent on the right than left and can be seen in up to 80% of pregnant women.
- Dilatation is caused by hormonal effects, external compression from expanding uterus, and intrinsic changes in the ureteral wall.
- Despite high incidence, most cases are asymptomatic.

- If symptomatic and refractory to medical management, ureteric calculus should be considered and urinary infection must be excluded.

## DIAGNOSIS

Symptoms vary according to cause, chronicity, location, and degree of obstruction.

### HISTORY

- Although often asymptomatic, hydronephrosis can be associated with pain ranging from vague, intermittent discomfort to severe renal colic.
- Nausea and vomiting may be associated with severe pain or infection.
- Fever, chills with coexisting infection
- Polyuria may occur due to impaired urinary concentration in partial obstruction, postobstructive diuresis.
- Anuria, if complete bilateral obstruction or complete obstruction of a solitary kidney
- Symptoms of chronic kidney disease (CKD): anorexia, malaise, weight gain, edema, shortness of breath, mental state changes, tremors from long-standing bilateral obstruction
- Dietl crisis: sudden attack of flank pain due to distension of renal pelvis caused by rapid ingestion of large amount of liquid or kinking of a ureter, producing temporary occlusion of urine flow
- Symptoms of bladder outlet obstruction: weak urine stream, nocturia, straining to void, overflow incontinence, urgency, and frequency
- General medical and surgical history: malignancy (extrinsic compression), radiotherapy (ureteric stricture/fibrosis), surgery (iatrogenic obstruction), trauma (hematoma or fibrosis), gynecologic disease (endometriosis, ovarian masses, uterine prolapse), smoking (urothelial cancer), drugs (methysergide-induced retroperitoneal fibrosis)

### PHYSICAL EXAM

- General signs
  - Volume overload (edema, rales, hypertension [HTN]) from renal failure
  - Diaphoresis, tachycardia, tachypnea with pain
  - High-grade fever, if infection
- Abdominal exam: CVA tenderness, palpable bladder, rarely palpable abdominal mass (may be

visible, particularly in thin children)

- Pelvic exam: pelvic mass, uterine prolapse, palpable enlarged prostate (cancer or benign), urethral meatal stenosis, phimosis

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Urinalysis with microscopy: hematuria, proteinuria, crystalluria, pyuria
- Midstream urine culture and sensitivity: Exclude UTI.
- Basic metabolic panel: Elevated urea and creatinine may indicate obstructive uropathy. Hyperkalemic nonanion gap metabolic acidosis may indicate type 4 distal RTA due to obstruction.
- CBC: Anemia of CKD, leukocytosis; if infection, check platelet count prior to considering ureteral instrumentation.
- Prostate-specific antigen (PSA): adult males age >50 years or with abnormal digital rectal exam or bladder outlet obstruction signs or symptoms
- Urine cytology: for malignant cells in urothelial malignancies
- US and noncontrast CT scan are effective in diagnosing presence and cause of obstruction in most cases.
- US: screening test of choice for hydronephrosis
  - Sensitivity 90%, specificity 84.5% compared with IVU. Does not assess function and rarely detects cause and level of obstruction. Degree of hydronephrosis does not correlate with duration or severity of the obstruction.
  - Advantages: detects renal parenchymal disease (decreased renal size, increased cortical echogenicity, cortical thinning, cysts); no exposure to radiation or contrast; safe in pregnancy, contrast allergy, and renal dysfunction
  - False-positive findings 15.5% (for UTO): normal extrarenal pelvis, parapelvic cysts, VUR, excessive diuresis
  - False-negative findings 10%: dehydration, acute obstruction, calyceal dilatation misinterpreted as renal cortical cysts, and retroperitoneal fibrosis
- Noncontrast helical CT (NHCT): test of choice for suspected nephrolithiasis
  - Reported sensitivity 94-96%, specificity 94-100%. Stone is most commonly found at levels of ureteric luminal narrowing: UPJ, pelvic brim, and the vesicoureteric junction.
  - Typical findings in acute obstruction are hydronephrosis with hydroureter proximal to the level of obstruction, perinephric stranding, and renal swelling. If chronic, renal atrophy may

be noted.

- Advantages: no contrast exposure, time-saving, cost-effective, identifies extraurinary pathology
- Disadvantages: does not assess function or degree of obstruction; higher radiation exposure, although low radiation dose protocols have shown comparable accuracy

---

P.503

- DTPA or MAG-3 radionuclide renal scan (diuretic renal scintigraphy)
  - Indicated only for evaluation of hydronephrosis without apparent obstruction
  - Determines presence of true obstruction as well as total and split (right vs. left) renal function
  - Furosemide is given 20 minutes after the tracer and the T1/2 for the tracer's washout is measured. T1/2; <10 minutes is unobstructed, >20 minutes is obstructed, and 10 to 20 minutes is equivocal; some experts consider <15 minutes normal.
  - Advantages: no contrast exposure, safe in contrast allergy and renal dysfunction
  - False-positive findings: delayed excretion due to renal failure, massive dilatation causing a water-reservoir effect of delayed excretion without obstruction
  - False-negative findings: dehydration or inadequate diuretic challenge
- Multiphase contrast-enhanced CT
  - Nonenhanced phase detects stones and swelling.
  - Parenchymal phase demonstrates decreased enhancement of renal parenchyma with acute obstruction; can identify extraurinary causes of obstruction and determine the relative glomerular filtration rate (GFR) of each kidney with accuracy equal to radionuclide renal scan
  - Delayed phase allows visualization of the collecting system and soft tissue filling defects (e.g., urothelial cancer).
- Magnetic resonance urography (MRU): indicated when US and NHCT are nondiagnostic
  - Provides anatomic, functional, and prognostic information. Sensitivity not superior to US or NHCT for nephrolithiasis (70%) but superior for soft tissue causes including strictures.
  - Advantages: no radiation exposure, safe in young children and pregnant women
  - Disadvantages: more expensive and time-consuming (35 vs. 5 minutes) and less available compared with CT. Gadolinium is contraindicated in renal failure due to risk of nephrogenic systemic fibrosis.

## Diagnostic Procedures/Other

Cystoscopy, retrograde pyelogram ± ureteroscopy, and biopsy are occasionally used to determine the cause of obstruction (e.g., small urothelial cancer missed on imaging) or to confirm a normal distal ureter prior to pyeloplasty. In addition, such procedures are often needed to establish a definitive pathologic diagnosis for mass lesions.

## TREATMENT

### GENERAL MEASURES

- Medical treatment: correction of fluid and electrolyte abnormalities, pain control, antibiotics as an adjunct to drainage if infection present
- Relief of obstruction: prompt drainage indicated in the presence of UTI, compromised renal function, or uncontrollable/persistent pain
  - Bladder outlet obstruction: urethral or suprapubic catheter
  - Ureteric obstruction: retrograde (cystoscopic) or antegrade (percutaneous) stenting
- VUR is often managed conservatively with antibiotics; surgical management required in severe cases in children or women of childbearing age
- Medical expulsive therapy (MET) with  $\alpha$ -blockers or calcium channel blockers indicated for urethral stones <10 mm in patients with controlled pain, no signs of sepsis, with good renal function

### SURGERY/OTHER PROCEDURES

- Hydronephrosis due to obstruction
  - Congenital UPJ obstruction: Pyeloplasty (open or laparoscopic) and minimally invasive stricture incision (endopyelotomy) are used with comparable results.
  - Nephrolithiasis: Extracorporeal shock wave lithotripsy (ESWL) is the initial treatment of choice for management of impacted upper urethral stones  $\geq 2$  cm. Ureteroscopy with or without intracorporeal lithotripsy has lower retreatment but higher complication rates and longer hospital stay. Ureteral stenting pre-ESWL or post-ureteroscopy associated with no additional benefit and more discomfort and morbidity (1)[A]
  - Transitional cell cancer: nephroureterectomy
  - Idiopathic retroperitoneal fibrosis: ureterolysis (frees ureters from inflammatory mass)
  - Prostate disorders: various treatment modalities, including transurethral resection of the

prostate (TURP) and radical prostatectomy

- Nonobstructed hydronephrosis
  - VUR: ureteric reimplantation, endoscopic suburethral injection

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Obstruction coexisting with infection (pyonephrosis) is a true urologic emergency requiring urgent drainage. Typically, this requires placement of percutaneous nephrostomy tube(s), as retrograde (cystoscopic) stenting is often difficult, but both are equally effective.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Serial monitoring of kidney function (electrolytes, BUN, and creatinine) and BP until renal function stabilizes. Frequency of monitoring depends on severity of renal dysfunction.
- Follow-up US after stabilization of renal function to assess for resolution of hydronephrosis. If hydronephrosis persists, consider diuretic radionuclide study to rule out persistent obstruction.

### *PROGNOSIS*

- Recovery of renal function depends on etiology, presence or absence of UTI, and degree and duration of obstruction.
- Significant recovery can occur despite days of complete obstruction, although some irreversible injury may develop within 24 hours. Delays in therapy can lead to irreversible renal damage (2).
- Diagnostic testing is of poor predictive value. Course of incomplete obstruction is highly unpredictable.

### **COMPLICATIONS**

- Urine stasis: increased risk of infection and stones formation
- Obstruction causes progressive atrophy of kidney with irreversible loss of function.
- Spontaneous rupture of a calyx may occur with urine extravasation in the perinephric space.
- Postobstructive diuresis: marked polyuria after relief of obstruction:

- Caused mostly by fluid and solute overload but may be exacerbated by impaired renal tubular concentrating ability. Urine output may be >500 mL/hr.
- Replace urine losses with hypotonic fluid (usually with 0.45% NaCl) and only enough to avoid volume depletion. Replacement of urine output with equal amounts of saline will perpetuate the diuresis.

## Codes

&NA;

## ICD10

- N13.30 Unspecified hydronephrosis

- N13.39 Other hydronephrosis
- Q62.0 Congenital hydronephrosis

## Clinical Pearls

**&NA;**

- US and noncontrast CT identify most causes of hydronephrosis.
- Relief of obstruction, when present, is the primary treatment.

# Hypercholesterolemia

Sebastian T. Tong, MD, MPH

Wendy Brooks Barr, MD, MPH, MSCE

## BASICS

### DESCRIPTION

- Serum total cholesterol >240 mg/dL
- Lipoprotein subtypes:
  - Low-density lipoproteins (LDL): primary target of therapy, atherogenic
  - High-density lipoproteins (HDL): atheroprotective
  - Triglycerides (TG)
- High cholesterol is a significant risk factor for atherosclerotic cardiovascular disease (ASCVD).
- System(s) affected: cardiovascular (CV)

### EPIDEMIOLOGY

Age: increases with age

### Prevalence

27.9% of men and 27.5% of women in the United States with total cholesterol >240 mg/dL

### ETIOLOGY AND PATHOPHYSIOLOGY

- Pathophysiology
  - Deposition of cholesterol in vascular walls creating fatty streaks that become fibrous plaques
  - Inflammation causes plaque instability, leading to plaque rupture.
- Etiology
  - Primary: diet, lack of physical activity, obesity
  - Secondary: excessive alcohol intake, hypothyroidism, diabetes, nephrotic syndrome, liver disease, chronic renal failure, medications (thiazide diuretics, carbamazepine, cyclosporine,

progestins, anabolic steroids, corticosteroids, protease inhibitors)

## Genetics

- Familial hypercholesterolemia (FH)
  - Elevated LDL levels from birth
  - Prevalence = 1/500 in the United States
  - Predisposed to atherosclerotic disease in early adulthood and high coronary heart disease (CHD) risk in 40s to 50s
  - Tendon xanthomas on Achilles and extensor tendons of hands are common.
  - Early lipid-lowering drug therapy is shown to reduce ASCVD risk.
- Early cholesterol testing of first-degree relatives is beneficial.

## RISK FACTORS

Obesity (BMI >30 kg/m<sup>2</sup>), physical inactivity, heredity. Traditionally, diet rich in saturated fat and cholesterol is considered to be risk factors for hypercholesterolemia and vascular disease. This has become somewhat controversial, with emphasis now on trans-fats as more atherogenic. Relationship of diet to disease is very complex.

## GENERAL PREVENTION

- Reduced intakes of saturated fat and cholesterol
- Regular physical activity
- Weight control (see "Ongoing Care")

## COMMONLY ASSOCIATED CONDITIONS

Hypertension, diabetes mellitus (DM), obesity

## DIAGNOSIS

Screening recommendations:

- U.S. Preventive Services Task Force (USPSTF): total cholesterol and HDL cholesterol (HDL-C) every 5 years
  - All men age ≥35 years
  - Women ≥45 years if at increased risk for ASCVD

- Men aged 20 to 35 years and women aged 20 to 45 years if at increased risk for ASCVD (1) [A]
- American Diabetic Association: yearly dyslipidemia screening for diabetics

## *Pediatric Considerations*

National Heart, Lung, and Blood Institute (NHLBI): recommended lipid screening on all children between 9 and 11 years. However, these recommendations are highly controversial and not supported by most other organizations (2)[C].

### **HISTORY**

- Review possible secondary etiologies.
- Review medications that may change lipid levels.
- Assess other ASCVD risk factors.

## *PHYSICAL EXAM*

Nonspecific findings

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Fasting lipid panel: total cholesterol (TC), LDL, HDL, TG: LDL is usually a calculated value and is accurate if TG <350 mg/dL.
- If elevated LDL or other form of hyperlipidemia, clinical/laboratory assessment before initiating lipid-lowering therapy: ALT, diabetes screening
- Consider genetic etiology in very high LDL (>190 mg/dL).

## **TREATMENT**

### **ALERT**

2013 American College of Cardiology/American Heart Association (ACC/AHA) cholesterol guidelines no longer recommend treatment to an LDL goal. Review of evidence suggests there was never a strong evidence to support specific LDL targets.

*United States: ACC/AHA cholesterol guidelines (3)[C]*

Four groups benefit from statin therapy:

- Clinical ASCVD
  - <75 years old: high-intensity statin
  - >75 years old or not candidate for high-intensity statin: moderate-intensity statin
- Primary elevation of LDL-C >190 mg/dL: high-intensity statin
- Diabetes (type 1 or 2) ages 40 to 75 years with LDL-C 70 to 189 mg/dL:
  - 10-year ASCVD risk <7.5%: moderate-intensity statin
  - 10-year ASCVD risk >7.5%: high-intensity statin
- Without above but estimated 10-year ASCVD risk >7.5% based on Pooled Cohort Equations ([http://my.americanheart.org/professional/StatementsGuidelines/PreventionGuidelines/Prevention-Guidelines\\_UCM\\_457698\\_SubHomePage.jsp](http://my.americanheart.org/professional/StatementsGuidelines/PreventionGuidelines/Prevention-Guidelines_UCM_457698_SubHomePage.jsp)): Consider moderate- to high-intensity statin.
- Definition of clinical ASCVD:
  - Acute coronary syndrome or history of MI
  - Stable or unstable angina
  - Coronary or other arterial revascularization
  - Stroke or TIA
  - Peripheral arterial disease
- Significant controversy over recommendation to treat patients with >7.5% 10-year ASCVD risk:
  - Concern that Pooled Cohort Equations significantly overestimate ASCVD risk.
  - Concern for significant overtreatment: one study showing 96% of men and 66% of women >55 years of age on statins based on recommendations
- Many more patients treated and medications used in the United States than elsewhere in the world without substantial evidence for improved outcomes

### *United Kingdom: National Institute for Health and Care Excellence (NICE) cholesterol guidelines (4)[C]*

- No history of CV disease: if 10-year risk of CVD >10%, start atorvastatin 20 mg
- If eGFR <60 or type I diabetes, start atorvastatin 20 mg regardless of risk.
- History of CV disease: Start atorvastatin 80 mg.

- 10-year risk to be calculated using QRISK2: <http://www.qrisk.org/>
- Nonfasting lipid panel before treatment initiation and at 3 months of treatment: goal reduction of 40% in non-HDL cholesterol

## *European: European Society of Cardiology/European Atherosclerosis Society (ESC/EAS) cholesterol guidelines (5)[C]*

- Risk stratification to low, moderate, high, and very high risk based on SCORE charts
- High- and very high-risk patients should be offered drug therapy.

### **ALERT**

Elevated serum TG

- If >500, TG lowering becomes primary target until TG <500 to prevent acute pancreatitis.
  - Therapeutic life changes + statin + fibrate

## **MEDICATION**

- Therapeutic lifestyle changes are cornerstone therapies to be attempted before drug therapy (diet and regular exercise; see *Ongoing Care*).
- Check fasting lipoprotein profile 4 to 12 weeks after starting medication to evaluate response/compliance.
  - High-intensity statin: should lower LDL-C >50%
  - Moderate-intensity statin: should lower LDL-C 30-50%

## *First Line*

HMG-CoA reductase inhibitors (statins)

- Categorized based on intensity
  - High intensity
    - Atorvastatin 40 to 80 mg/day
    - Rosuvastatin 20 to 40 mg/day
  - Moderate intensity
    - Atorvastatin 10 to 20 mg/day
    - Rosuvastatin 5 to 10 mg/day

- Simvastatin 20 to 40 mg/day
  - Pravastatin 40 to 80 mg/day
  - Lovastatin 40 mg/day
- 
- Fluvastatin XL 80 mg/day
  - Fluvastatin 40 mg BID
  - Pitavastatin 2 to 4 mg/day
- Low intensity
    - Simvastatin 10 mg/day
    - Pravastatin 10 to 20 mg/day
    - Lovastatin 20 mg/day
    - Fluvastatin 20 to 40 mg/day
    - Pitavastatin 1 mg/day
- To be taken in the evening or at bedtime for best effect (exception: atorvastatin, rosuvastatin)
  - Effect is greatest in lowering LDL-C; shown to decrease CHD incidence and all-cause mortality, although number needed to treat may be high in primary prevention.
  - Contraindications: pregnancy, lactation, or active liver disease
  - Drug interactions: cyclosporine, macrolide antibiotics, various antifungal agents, HIV protease inhibitors, fibrates/nicotinic acid (to be used with caution)
  - Adverse reactions:
    - Mild myalgia is common.
    - Liver transaminase elevations: ALT before therapy to establish baseline; if ALT >3 times upper limit of normal, do not start statin; routine monitoring is not recommended; reasonable to measure hepatic function if symptoms suggesting hepatotoxicity occur.
    - Association with increased cases of diabetes: 0.1 excess cases of diabetes per 100 persons on moderate-intensity statin and 0.3 excess cases per 100 persons on high-intensity statin
    - Myopathies (considered rare but not well studied):
      - Creatine kinase (CK) baseline reasonable for those at increased risk for adverse muscle events; routine monitoring not needed unless muscle symptoms occur
      - Instruct patients to report immediately any muscle pain, muscle weakness, or brown

urine.

- If myopathy or rhabdomyolysis is suspected, discontinue statin use and draw serum CK, creatinine, urine analysis.
- Can rechallenge statin at lower dose or different type after resolution of symptoms

## **ALERT**

FDA alert: Simvastatin should no longer be prescribed at 80 mg/day doses due to increased risk of myopathy. Patients who have been at this drug dosage for >1 year can continue if no signs of myopathy. Dose restrictions to reduce myopathy risk include the following:

- Do not exceed simvastatin 10 mg/day with amiodarone, verapamil, and diltiazem.
- Do not exceed simvastatin 20 mg/day with amlodipine and ranolazine.

## **ALERT**

Avoid grapefruit juice with statins.

## *Pregnancy Considerations*

- Statins contraindicated during pregnancy: class X
- Lactation: possibly unsafe

## *Second Line*

- Second-line drugs are no longer recommended in any guidelines.
- Ezetimibe
  - Can be taken by itself or in combination with a statin: monotherapy (Zetia 10 mg/day) or ezetimibe/simvastatin (Vytorin 10/10, 10/20, 10/40)
  - Effect: Lowers LDL-C; one recent RCT shows combination therapy with statin has small benefit in reducing CV events and CV-related mortality after acute coronary syndromes (6).
  - Adverse reactions: generally well tolerated
- Fibrates
  - Types: Gemfibrozil (Lopid) 600 mg BID, fenofibrate (Antara, Lofibra, Tricor, Triglide)
  - Effect: most effective in lowering TG with moderate effect in lowering LDL and raising HDL. More recent studies fail to show benefit in most patients.
  - Contraindications: severe hepatic or renal insufficiency

- Possible interactions: potentiates effects of warfarin and oral hypoglycemic agents
- Adverse reactions: GI complaints; increased likelihood of gallstones
- Nicotinic acid: raises HDL but no evidence for improved outcomes in recent trials and significant potential harms; should no longer be used in routine practice
- Bile acid sequestrant: causes significant GI side effects, no evidence for improved outcomes, rarely used
- Proprotein Convertase Subtilisin/Kexin Type 9 (PCSK9) inhibitors (7):
  - Drug currently in approval process showing significant reduction in all-cause mortality, CV mortality and CV events
  - Requires SC injections every 2 to 4 weeks to administer and will be very expensive

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Omega-3 fatty acids and fish oil intake: Sources are fish oil (salmon), plant sources (flaxseed, canola oil, soybean oil, nuts); mainly lower TG level but has some benefit in lowering LDL and raising HDL although overall CV benefit and mortality reduction is uncertain. Supplements do not reduce overall or cardiovascular mortality. Patients should be advised to eat a variety of oily fish twice a week.
- *&bgr;*-Sitosterols and red yeast rice (contains natural lovastatin-analogue) can reduce total cholesterol and LDL.
- Garlic: appears to have some lipid-lowering effect, but more studies are needed; effective dose not established but generally 1 to 2 cloves of raw garlic/day, 300 mg dried garlic powder tablet BID or TID, or 7.2 g of aged garlic extract/day

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

Exercise: sustained exercise for 30 minutes, 3 to 4 times per week: increases HDL, lowers total cholesterol, and helps control weight

### Patient Monitoring

- Initially, lipid panel in 4 to 12 weeks after starting therapy, routine monitoring of LDL levels in patients on statin is not necessary.
- Routine monitoring of LFTs is no longer recommended if initial ALT is within normal range.

Taylor F, Huffman MD, Macedo AF, et al. Statins for the primary prevention of cardiovascular

## See Also

**&NA;**

- Hypothyroidism, Adult
- Algorithm: Hypercholesterolemia

## Codes

**&NA;**

### ICD10

E78.0 Pure hypercholesterolemia

## Clinical Pearls

**&NA;**

- Hypercholesterolemia is a significant risk factor for ASCVD, but ASCVD is a multifactorial disease with many different risk factors.
- Diet and exercise should be tried before pharmaceutical interventions.
- Statins are considered first-line medications for hypercholesterolemia. Other medications show little evidence of benefit.

# Hyperemesis Gravidarum

Emma Brooks, MD

## BASICS

### DESCRIPTION

- Hyperemesis gravidarum is persistent vomiting in a pregnant woman that interferes with fluid and electrolyte balance as well as nutrition:
  - Usually associated with the first 8 to 20 weeks of pregnancy
  - Believed to have biomedical and behavioral aspects
  - Associated with high estrogen and human chorionic gonadotropin (hCG) levels
  - Symptoms usually begin ~2 weeks after first missed period.
- System(s) affected: endocrine/metabolic; gastrointestinal; reproductive
- Synonym(s): morning sickness

### *Pregnancy Considerations*

Common condition during pregnancy, typically in the 1st and 2nd trimesters but may persist into the 3rd trimester.

### EPIDEMIOLOGY

#### *Incidence*

Hyperemesis gravidarum occurs in 1-2% of pregnancies.

#### *Prevalence*

Hyperemesis gravidarum is the most common cause of hospitalization in the first half of pregnancy and the second most common cause of hospitalization of pregnant women.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Unknown
- Possible psychologic factors

- Hyperthyroidism
- Hyperparathyroidism
- Gestational hormones
- Liver dysfunction
- Autonomic nervous system dysfunction
- CNS neoplasm
- Addison disease

## ***RISK FACTORS***

- Obesity
- Nulliparity
- Multiple gestations
- Gestational trophoblastic disease
- Gonadotropin production stimulated
- Altered GI function
- Hyperthyroidism
- Hyperparathyroidism
- Liver dysfunction
- Female fetus
- *Helicobacter pylori* infection (1)

## ***GENERAL PREVENTION***

Anticipatory guidance in 1st and 2nd trimesters regarding dietary habits in hopes of avoiding dehydration and nutritional depletion.

### ***Pregnancy Considerations***

- 2% of pregnancies have electrolyte disturbances.
- 50% of pregnancies have at least some GI disturbance.

## ***COMMONLY ASSOCIATED CONDITIONS***

Hyperthyroidism

# DIAGNOSIS

## HISTORY

- Hypersensitivity to smell
- Alteration in taste
- Excessive salivation
- Poor appetite
- Nausea
- Vomiting with retching
- Decreased urine output
- Fatigue
- Dizziness with standing

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Urinalysis: may see glucosuria, albuminuria, granular casts, and hematuria (rare); ketosis more common
- Thyroid-stimulating hormone (TSH), T4
- Electrolytes, BUN, creatinine:
  - Electrolyte abnormalities due to nausea and vomiting and subsequent dehydration
  - Acidosis
- Calcium
- Uric acid
- Hypoalbuminemia
- No imaging is indicated for the diagnosis of hyperemesis gravidarum unless there is concern for hydatidiform mole or multiple gestation, in which case ultrasound may be obtained.

### *Follow-Up Tests & Special Considerations*

- If hypercalcemia, consider checking parathyroid hormone (PTH) for hyperparathyroidism.
- Drugs are unlikely to alter lab results.

## *Diagnostic Procedures/Other*

Indicated only if it is necessary to rule out other diagnoses, as listed in the following section

## **DIFFERENTIAL DIAGNOSIS**

Other common causes of vomiting must be considered:

- Gastroenteritis
- Gastritis
- Reflux esophagitis
- Peptic ulcer disease
- Cholelithiasis
- Cholecystitis
- Pyelonephritis
- Anxiety
- Hyperparathyroidism
- *H. pylori* infection

## **TREATMENT**

Pyridoxine and doxylamine (pregnancy Category A) are first-line treatments for hyperemesis gravidarum (2)[C]. This is followed by metoclopramide or ondansetron (pregnancy Category B), then prochlorperazine (pregnancy Category C), methylprednisolone (pregnancy Category C), or promethazine (pregnancy Category C).

## **GENERAL MEASURES**

- Patient reassurance
- Bed rest
- If dehydrated, IV fluids, either normal saline or 5% dextrose normal saline (with consideration for potential thiamine deficiency). Repeat if there is a recurrence of symptoms following initial improvement.
- For severe cases, consider PO thiamine 25 to 50 mg TID or IV 100 mg in 100 mL of normal saline over 30 minutes once weekly and potential parental nutrition if needed.
- Ondansetron carries an FDA warning regarding concerns for QT prolongation, but this is in the setting of high-dose IV administration and in patients with heart disease. It has unclear risk in

the setting of pregnancy. The majority of the current studies appear to show no increased risk of fetal malformation with the use of ondansetron, but this is still an area of controversy (3) [C],(4)[B].

## **MEDICATION**

- Pyridoxine (vitamin B<sub>6</sub>) 25 mg PO or IV every 8 hours
- Antihistamines (e.g., diphenhydramine [25 to 50 mg q4-6h] or doxylamine [12.5 mg PO BID]) (5)[C]
- Combination product Diclegis (sustained-release pyridoxine 10 mg and doxylamine 10 mg) dosed (start 2 tabs PO q hs; if sx persist, increase to 1 tab in AM & 2 hs; if sx still persist, take 1 tab q AM, 1 mid day, and 2 hs; max 4 tablets/day)

---

P.507

- Phenothiazines (e.g., promethazine or prochlorperazine):
  - Precautions: Phenothiazines are associated with prolonged jaundice, extrapyramidal effects, and hyper- or hyporeflexia in newborns.
- Meclizine 25 mg PO q6h
- Metoclopramide 10 mg PO q6 to 8h
- Methylprednisolone 16 mg PO/IV q8h for 2 to 3 days, then taper over 2 weeks if initial 3-day treatment is effective.
- Ondansetron 4 to 8 mg PO q8h

## **Pregnancy Considerations**

All medications taken during pregnancy should balance the risks and benefits both to the mother and the fetus.

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Ginger 350 mg PO TID may help (6)[A].
- Motion sickness wristbands are another nonpharmacologic intervention that may improve symptoms. Evidence is mixed regarding the impact of acupressure and acupuncture in treating hyperemesis gravidarum (7)[C].
- Medical hypnosis may be a helpful adjunct to the typical medical treatment regimen, but further study is needed (8)[C].

## **INPATIENT CONSIDERATIONS**

## *Admission Criteria/Initial Stabilization*

- Typically outpatient therapy
- In some severe cases, parenteral therapy in the hospital or at home may be required.
- Enteral volume and nutrition repletion may be indicated.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Activity as tolerated after improvement

### *Patient Monitoring*

- In severe cases, follow-up on a daily basis for weight monitoring.
- Special attention should be given to monitor for ketosis, hypokalemia, or acid-base disturbances due to hyperemesis.

### *DIET*

- NPO for first 24 hours if patient is ill enough to require hospitalization.
- For outpatient: a diet rich in carbohydrates and protein, such as fruit, cheese, cottage cheese, eggs, beef, poultry, vegetables, toast, crackers, rice. Limit intake of butter. Patients should avoid spicy meals and high-fat foods. Consider cold foods. Encourage small amounts at a time every 1 to 2 hours.

### *PATIENT EDUCATION*

- Attention should be given to psychosocial issues, such as possible ambivalence about the pregnancy.
- Patients should be instructed to take small amounts of fluid frequently to avoid volume depletion.
- Avoid individual foods known to be irritating to the patient.
- Wet-to-dry nutrients (sherbet, broth, gelatin to dry crackers, toast)

### *PROGNOSIS*

- Self-limited illness with good prognosis if patient's weight is maintained at >95% of prepregnancy weight.

- With complication of hemorrhagic retinitis, mortality rate of pregnant patient is 50%.

## COMPLICATIONS

- Patients with >5% weight loss are associated with intrauterine growth retardation and fetal anomalies.
- Poor weight gain is associated with slightly increased risk for small gestational age infant <2,500 g and premature birth <37 weeks (9)[A].
- Hemorrhagic retinitis
- Liver damage
- CNS deterioration, Wernicke encephalopathy secondary to thiamine deficiency, coma

## Codes

&NA;

### ICD10

- O21.9 Vomiting of pregnancy, unspecified
- O21.0 Mild hyperemesis gravidarum
- O21.1 Hyperemesis gravidarum with metabolic disturbance

## Clinical Pearls

**&NA;**

- Do not allow patients to become volume depleted. Once this occurs, it is more difficult to interrupt the process.
- Do not be hesitant to use medications to assist the patient, as this may help avoid volume depletion.
- Consider secondary causes of hyperemesis if it develops after 12 weeks of gestation.

# Hyperkalemia

Merima Bucaj, DO

Roselyn Jan Wuthrich Clemente-Fuentes, MD

## BASICS

### DESCRIPTION

- Hyperkalemia is a common electrolyte disorder that may be defined as a plasma potassium (K) concentration  $>5.5$  mEq/L ( $>5$  mmol/L).
- Hyperkalemia depresses cardiac conduction and can lead to fatal arrhythmias.
- Normal K regulation
  - Ingested K enters portal circulation; pancreas releases insulin in response. Insulin facilitates K entry into cells.
  - K in renal circulation causes renin release from juxtaglomerular cells, leading to activation of angiotensin I, which is converted to angiotensin II in lungs. Angiotensin II acts in adrenal zona glomerulosa to stimulate aldosterone secretion. Aldosterone, at the renal collecting ducts, causes K to be excreted and sodium to be retained.
- Four major causes
  - Increased load: either endogenous from tissue release or exogenous from a high intake, usually in association with impaired excretion
  - Decreased excretion: due to decreased glomerular filtration rate
  - Cellular redistribution: shifts from intracellular space (majority of K is intracellular) to extracellular space
  - Pseudohyperkalemia: related to red cell lysis during collection or transport of blood sample, thrombocytosis, or leukocytosis

### Geriatric Considerations

Increased risk for hyperkalemia because of decreases in renin and aldosterone as well as comorbid conditions

### EPIDEMIOLOGY

## *Prevalence*

- 1-10% of hospitalized patients
- 2-3% in general population but as high as 50% in patients with chronic kidney disease (1)
- Predominant sex: male = female
- No age-related predilection

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Pseudohyperkalemia
  - Hemolysis of red cells in phlebotomy tube (spurious result is most common)
  - Thrombolysis
  - Leukocytosis
  - Thrombocytosis
  - Hereditary spherocytosis
  - Infectious mononucleosis
  - Traumatic venipuncture or fist clenching during phlebotomy (spurious result)
- Transcellular shift (redistribution)
  - Metabolic acidosis
  - Insulin deficiency
  - Hyperglycemia (diabetic ketoacidosis or hyperosmolar hyperglycemic state)
  - Tissue damage (rhabdomyolysis, burns, trauma) (2)
  - Tumor lysis syndrome (3)
  - Cocaine abuse
  - Exercise with heavy sweating
  - Mannitol
- Impaired K excretion
  - Renal insufficiency/failure
  - Addison disease
  - Mineralocorticoid deficiency

- Primary hyporeninemia, primary hypoaldosteronism
- Type IV renal tubular acidosis (hyporeninemic hypoaldosteronism)
- Medication-induced
  - Excess K supplementation
  - Statins
  - ACE inhibitors
  - Angiotensin receptor blockers
  - $\beta$ -Blockers
  - Cyclosporine
  - Digoxin toxicity
  - Ethinyl estradiol/drospirenone
  - Heparin
  - NSAIDs
  - Penicillin G potassium
  - Pentamidine
  - Spironolactone
  - Succinylcholine
  - Tacrolimus
  - Trimethoprim, particularly with other medications associated with hyperkalemia (4,5)

## *Genetics*

Associated with some inherited diseases and conditions

- Familial hyperkalemic periodic paralysis
- Congenital adrenal hyperplasia

## *RISK FACTORS*

- Impaired renal excretion of K
- Acidemia
- Massive cell breakdown (rhabdomyolysis, burns, trauma)

- Use of K-sparing diuretics.
- Excess K supplementation

## **GENERAL PREVENTION**

Diet and oral supplement compliance in those at risk

## **DIAGNOSIS**

### **HISTORY**

- Neuromuscular cramps
- Diarrhea
- Abdominal pain
- Myalgias
- Numbness
- Muscle weakness or paralysis

### **PHYSICAL EXAM**

- Decreased deep tendon reflexes
- Flaccid paralysis of extremities

### **DIAGNOSTIC TESTS & INTERPRETATION**

- Serum electrolytes
- Renal function: BUN, creatinine
- Urinalysis: K, creatinine, osmoles (to calculate fractional excretion of K and transtubular K gradient; both assess renal handling of K)
- Disorders that may alter lab results
  - Acidemia: K shifts from the intracellular to extracellular space
  - Insulin deficiency
  - Hemolysis of sample
- Cortisol and aldosterone levels to check for mineralocorticoid deficiency when other causes are ruled out

## Diagnostic Procedures/Other

EKG abnormalities usually occur when  $K \geq 7$  mEq/L

- Peaked T wave with shortened QT interval in precordial leads (most common, usually earliest EKG change) (6)
- Lengthening of PR interval
- Loss of P wave
- Widened QRS
- Sine wave at very high K
- Can eventually lead to arrhythmias including ventricular fibrillation and asystole

## TREATMENT

### MEDICATION

- Stabilize myocardial membranes. Initial treatment with calcium gluconate IV 1,000 mg (10 mL of 10% solution) over 2 to 3 minutes
  - With constant cardiac monitoring
  - Can repeat after 5 minutes if needed
  - Effect begins within minutes, but only lasts 30 to 60 minutes and should be used in conjunction with definitive therapies
  - Can also use calcium chloride (3 times as concentrated; however, it needs central or deep vein to avoid tissue necrosis)
- Drive extracellular potassium into cells
  - Nebulized albuterol (at 10 to 20 mg/4 mL saline over 10 minutes—4 to 8 times bronchodilation dose) and other  $\beta_2$ -agonists have an additive effect with insulin and glucose
  - Dextrose 50% 1 amp (if plasma glucose  $< 250$  mg/dL) and insulin 10 U IV may drive K intracellularly but does not decrease total body K and may result in hypoglycemia (close monitoring advised, especially 1 to 2 hours postinjection).
  - Sodium bicarbonate not routinely recommended but some possible benefits in severe metabolic acidosis (7)[C]

- Remove excess potassium from body.
  - Cation exchange resins definitive treatment but require several doses and best used with rapidly acting transient therapies above and when dialysis not readily available (8)[A]
  - Sodium polystyrene sulfonate (Kayexalate): 15 g PO or 30 g rectally
    - This requires 1 to 4 hours to lower K. This may be repeated q6h, if necessary.
    - Enema has faster effect than PO.
  - Hemodialysis is the definitive therapy when other measures are not effective. This may be required particularly when conditions such as digitalis toxicity, rhabdomyolysis, end-stage renal disease, severe chronic kidney disease, or acute kidney injury, are present. Should watch for postdialysis rebound
  - Little clinical evidence for the use of diuretics (loop and thiazides), however, can consider for control of chronic hyperkalemia (2)[B].
  - Zirconium cyclosilicate and patiromer calcium are promising therapies in development which bind potassium in intestinal tract (9)[C].

## ALERT

- Sodium polystyrene sulfonate provides a sodium load that may exacerbate fluid overload in patients with cardiac or renal failure.
- Avoid sodium polystyrene sulfonate use in patients who are postoperative or with a bowel obstruction or ileus due to high risk of intestinal necrosis.
- Rapid administration of calcium in patients with suspected digitalis toxicity may result in a fatal dysrhythmia. Calcium should be administered slowly over 20 to 30 minutes in 5% dextrose with extreme caution.

## INPATIENT CONSIDERATIONS

### Admission Criteria/Initial Stabilization

- If hyperkalemia is severe, treat first, and then do diagnostic investigations.
- IV calcium to stabilize myocardium (caution in setting of digoxin toxicity, when calcium may worsen effects of toxicity)
- Insulin (usually 10 U IV, given with 50 mL of 50% glucose (if serum glucose <250 mg/dL) to avoid hypoglycemia; consider repeating if elevation persists.
- Inhaled  $\beta_2$ -agonist (nebulized albuterol)
- Discontinue any medications that may increase K (e.g., K-sparing diuretics, exogenous K).

- Admit for cardiac monitoring if EKG changes are present or if K is  $>6$  mEq/L (6 mmol/L).

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Reduction of plasma K should begin within the first hour of treatment initiation.
- Serum K levels should be rechecked every 2 to 4 hours until the patient has stabilized, and recurrent hyperkalemia is no longer a threat.
- Identification and elimination of possible causes and risk factors for hyperkalemia are essential.

#### *DIET*

$\approx 80$  mEq ( $\approx 80$  mmol) of K/24 hours. Many foods contain K. Those that are particularly high in K ( $>6.4$  mEq/serving) include bananas, orange juice, other citrus fruits and their juices, tomatoes, tomato juice, cantaloupe, honeydew melon, peaches, potatoes, and salt substitutes. Multiple herbal medications can also increase K levels, including alfalfa, dandelion, horsetail nettle, milkweed, hawthorn berries, toad skin, oleander, foxglove, and ginseng.

#### *PATIENT EDUCATION*

Consult with a dietitian about a low-K diet.

#### *PROGNOSIS*

- Associated with poor prognosis in patients with heart failure and chronic kidney disease
- Associated with poor prognosis in disaster medicine, with trauma, tissue necrosis,  $K^+$  supplementation, metabolic acidosis, if calcium gluconate administered for treatment of hyperkalemia, if AKI, or if prolonged duration of hyperkalemia (2,7)

#### **COMPLICATIONS**

- Life-threatening cardiac arrhythmias
- Hypokalemia
- Potential complications of the use of ion-exchange resins for the treatment of hyperkalemia include volume overload and intestinal necrosis (8)[C].

## Codes

**&NA;**

### ICD10

E87.5 Hyperkalemia

## Clinical Pearls

**&NA;**

- Emergency and urgent management of hyperkalemia takes precedent to a thorough diagnostic workup. Urgent treatment includes stabilization of the myocardium with calcium gluconate to protect against arrhythmias and pharmacologic strategies to move K from the extracellular (vascular) space into cells.
- Calcium and dextrose/insulin are only temporizing measures and do not actually lower total body K levels. Definitive treatment with either dialysis or cation exchange resin (sodium polystyrene sulfonate) necessary.
- To lower a patient's risk of developing hyperkalemia, have the patient follow a low-K diet, use selective  $\beta_1$ -blockers, such as metoprolol or atenolol, instead of nonselective  $\beta$ -

blockers such as carvedilol. Avoid NSAIDs. Concomitant use of kaliuretic loop diuretics may be useful.

# Hypernatremia

Nilgun Ozturk, MD

Pang-Yen Fan, MD

## BASICS

### DESCRIPTION

- Serum sodium (Na) concentration  $>145$  mEq/L (1)
- Usually represents a state of hyperosmolality (1)
- Na concentration reflects balance between total body water (TBW) and total body Na. Hypernatremia occurs from deficit of water relative to Na.
- Hypernatremia results from net water loss or, more rarely, from primary Na gain (1).
- May exist with hypo-, hyper-, or euvoemia, although hypovolemia is by far most common type
  - Hypovolemic: occurs with a decrease in TBW and a proportionately smaller decrease in total body Na
  - Euvoemic: no change in TBW with a proportionate increase in total body Na
  - Hypervolemic: increase in TBW and a proportionately greater increase in total body Na
- It has been shown to be an indicator for higher mortality in critically ill patients and patients with chronic kidney disease (CKD) (2)[B].

### EPIDEMIOLOGY

#### Incidence

- More common in elderly and young
- Occurs in 1% of hospitalized elderly patients (3)
- Seen in about 9% of ICU patients (3). Gastroenteritis with diarrhea is the most common cause of hypernatremia in infants.
- Women are at an increased risk due to decreased TBW, as compared with men.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Pure water loss (total body Na normal) resulting from the following:
  - Adipsia/hypodipsia (e.g., impaired thirst regulation, decreased access to water) (4)
  - Nephrogenic diabetes insipidus (DI) (congenital or due to renal dysfunction, hypercalcemia, hypokalemia, medication-related, particularly lithium)
  - Central DI (due to head trauma, stroke, meningitis) (3)
  - Increased insensible water loss (e.g., fever, hyperventilation, hypermetabolic state, heat exposure, newborns under radiant warmers)
- Hypotonic fluid loss (total body Na decreased) resulting from the following:
  - Loss of fluid containing relatively more water than Na (e.g., excessive sweating, severe burns)
  - Urinary loss
    - Osmotic diuresis: hyperglycemia, mannitol
    - Diuretics, especially loop diuretics
    - Diabetes mellitus, particularly new presentation/decompensated
    - Post acute tubular necrosis (ATN) or post obstructive diuresis
    - Intrinsic renal disease
  - Gastrointestinal loss
    - Diarrhea, especially in children
    - Vomiting, nasogastric (NG) lavage
    - Enterocutaneous fistula
- Excess Na (increase in total body Na) resulting from the following:
  - IV NaCl or NaHCO<sub>3</sub> during cardiopulmonary resuscitation, metabolic acidosis, or hyperkalemia (3)
  - Sea water ingestion
  - Excessive use of NaHCO<sub>3</sub> antacid.
  - Incorrect infant formula preparation
  - Intrauterine NaCl for abortion
  - Excessive Na in dialysate solutions
  - Disorders of the adrenal axis (Cushing syndrome, Conn syndrome, congenital adrenal

hyperplasia)

- Tube feeding

With acute hypernatremia, the rapid decrease in brain volume can cause rupture of the cerebral veins, leading to focal intracerebral and subarachnoid hemorrhages and possibly irreversible neurologic damage (5).

## *Genetics*

Some forms of DI may be hereditary.

## *RISK FACTORS*

- Patients at increased risk include those with an impaired thirst mechanism or restricted access to water, as well as those with increased water loss
- Infants/children
- Elderly patients (may also have a diminished thirst response to osmotic stimulation via an unknown mechanism)
- Patients who are intubated/have altered mental status.
- Diabetes mellitus
- Prior brain injury
- Surgery
- Diuretic therapy, especially loop diuretics
- Lithium treatment

## *GENERAL PREVENTION*

- Treatment/prevention of underlying cause
- Properly prepare infant formula and never add salt to any commercial infant formula.
- Keep patients well hydrated.

## *COMMONLY ASSOCIATED CONDITIONS*

- Gastroenteritis
- Altered mental status
- Burns
- Hypermetabolic conditions

- Head injury
- Renal dysfunction

## DIAGNOSIS

### HISTORY

- Excessive thirst, nausea, vomiting, diarrhea, oliguria, polyuria
- Fever, myalgia, muscle weakness
- Neurologic symptoms common: altered mental status, seizure (especially if rapid development of hypernatremia), twitching, lethargy, irritability, coma, anophthalmos
- Severe symptoms are likely to occur with acute increases in plasma Na levels or at concentrations  $>160$  mEq/L.
- Obtain list of current and recent medications.
- Review recent illnesses and activities.

### PHYSICAL EXAM

- Sinus tachycardia, hypotension, orthostatic hypotension, poor  $O_2$  saturation
- Dry mucous membranes, cool/gray skin
- Neurologic abnormalities: lethargy, weakness, focal deficits (in cases of intracerebral bleeding/lesion), confusion, coma, seizures

### DIFFERENTIAL DIAGNOSIS

- DI
- Hyperosmotic coma
- Salt ingestion
- Hypertonic dehydration
- Hypothyroidism
- Cushing syndrome

### DIAGNOSTIC TESTS & INTERPRETATION

#### *Initial Tests (lab, imaging)*

- Serum Na, potassium, BUN, creatinine, calcium, and osmolality (serum lithium if appropriate)
- Urine Na and osmolality
  - DI: urine osmolality (usually  $<300$  mosmol/kg)  $<$  serum osmolality, and urine Na usually low normal/slightly low (due to dilution) (4)
  - Osmotic diuresis: urine osmolality intermediate, urine Na low/low-normal, total daily osmole excretion high
  - Salt ingestion: increased urine osmolality (above 600 mosmol/kg) and high urine Na
  - Hypertonic dehydration: increased urine osmolality and decreased urine Na
- Serum glucose
- Special tests for DI
  - Water deprivation test: In DI, urine osmolality does not increase as it normally should when hypernatremic.
  - Antidiuretic hormone (ADH) stimulation: distinguishes central versus nephrogenic DI
    - Urine osmolality does not increase after ADH or desmopressin (DDAVP) in nephrogenic DI.
- Head CT/MRI in DI to rule out craniopharyngioma, other brain tumor or masses, or median cleft syndrome

## *Diagnostic Procedures/Other*

History, physical, laboratory studies, family history for central DI

## **TREATMENT**

### **GENERAL MEASURES**

- The treatment of hypernatremia involves treating the underlying cause and correcting the water deficit.
- Goal for corrected Na is 145 mEq/L (1).
- Speed of correction depends on symptom severity/rate of development of hypernatremia. Avoid rapid correction to prevent development of cerebral edema if chronic hypernatremia ( $>24$  hours):
  - Maximum of 0.5 mEq/L/hr or 10 mEq/L/day (6)[C]

- May correct at up to 1 mEq/L/hr if acute hypernatremia (<24 hours) (1)
  - Treat volume depletion first, then hypernatremia:
    - Restore intravascular volume with IV fluids to normalize serum Na levels.
  - Replace water orally if patient is conscious.
  - Important formulas in determining rate of fluid administration
    - $TBW = \text{coefficient} \times \text{wt (kg)}$ , where coefficient = 0.6 for children, 0.5 for nonelderly women and elderly men, 0.45 for elderly women
- 
- P.511
- $\text{Calculated free water deficit (liters)} = TBW \times [1 - (\text{Na}_t/\text{Na}_m)]$ , where  $\text{Na}_t$  = target  $\text{Na}^+$ , and  $\text{Na}_m$  = measured  $\text{Na}^+$ . Note: wt = weight in kilograms.
  - $\text{Change in serum Na per 1 L infusate} = [(\text{infusate Na} + \text{infusate K}) - \text{serum Na}]/[\text{TBW} + 1]$
  - Account for ongoing fluid losses during calculation of rate of fluid administration.
  - Dialysis can be considered if acute kidney injury is present concomitantly and if conventional treatment has failed (7)[B].

## MEDICATION

### First Line

- See "General Measures" for overall approach.
- Volume depletion: Use isotonic fluids initially if signs of hemodynamic compromise, then change to hypotonic fluids when stable:
  - Hypotonic fluids (0.45% NaCl or dextrose 5% in water)
    - Important not to decrease serum Na by >10 mEq/L/day to prevent cerebral edema (4) [C]
- Hypervolemia: Give furosemide along with hypotonic fluids. Dose varies depending on desired urine output. Loop diuretics with fluid restriction worsen hypernatremia (4)[C].
- Central DI
  - DDAVP acetate: Use parenteral form for acute symptomatic patients, and use intranasal or oral form for chronic therapy (4).
  - Free water replacement: may use 2.5% dextrose in water if giving large volumes of water in DI to avoid glycosuria

May consider sulfonylureas/thiazide diuretics for chronic, but not acute, treatment

- Nephrogenic DI
  - Treat with diuretics and NSAIDs.
  - Lithium-induced nephrogenic DI: hydrochlorothiazide 25 mg PO BID or indomethacin 50 mg PO TID, or amiloride hydrochloride 5 to 10 mg PO BID (8)
- Precautions
  - Rapid correction of hypernatremia can cause cerebral edema, central pontine myelinosis, seizures, or death (9).
  - Hypocalcemia and more rarely acidosis can occur during correction.
  - DI: High rates of dextrose 5% in water can cause hyperglycemia and glucose-induced diuresis.

## *Second Line*

- Consider NSAIDs in nephrogenic DI.
- Modalities requiring further investigations
- Continuous renal replacement therapy (CRRT): Multiple case reports and case series have shown success and safety in using CRRT to treat hypernatremia in critically ill patients with CHF and severe burns (7,10).

## *ISSUES FOR REFERRAL*

Underlying renal involvement associated with hypernatremia would benefit from a nephrology referral.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Symptomatic patient with serum Na >155 mEq/L requires IV fluid therapy.

### *IV Fluids*

Refer to "Medication" section.

### *Nursing*

Bed rest until stable or underlying condition resolved/controlled

## *Discharge Criteria*

Stabilization of serum Na level and symptoms are minimal.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Frequent reexams in an acute setting
- Frequent electrolytes and blood glucose: initially q4-6h
- Urine osmolality and urine output in DI
- Ensure adequate ingestion of calories because patients may ingest so much water that they feel full and do not eat.
- Measure ongoing losses of water and solute and replace as needed.
- Daily weights

#### *DIET*

- Ensure proper nutrition during acute phase.
- After resolution of acute phase, may want to consider Na-restricted diet for patient
- Low-salt, low-protein diet in nephrogenic DI

### *PATIENT EDUCATION*

Patients with nephrogenic DI must avoid salt and drink large amounts of water.

### *PROGNOSIS*

Most recover but neurologic impairment can occur.

### **COMPLICATIONS**

- CNS thrombosis/hemorrhage
- Seizures
- Mental retardation
- Hyperactivity
- Chronic hypernatremia: >2 days duration has higher mortality
- Serum Na >180 mEq/L (>180 mmol/L): often results in residual CNS damage

- More common if rapid development of hypernatremia

&NA;

- Diabetes Insipidus
- Algorithm: Hypernatremia

## Codes

&NA;

### ICD10

E87.0 Hyperosmolality and hypernatremia

## Clinical Pearls

&NA;

- Occurs from water deficit in comparison to total body Na stores
- Common causes include dehydration, DI, impaired access to fluids
- Determine if the patient has hypervolemic, euvolemic, or hypovolemic hypernatremia in the differential diagnosis of etiology; most commonly hypovolemic; other entities rare
- Avoid rapid correction of hypernatremia to prevent development of cerebral edema when hypernatremia is chronic (goal rate is 10 meq/L in 24 hours).
- Use hypotonic fluids unless patient has hemodynamic compromise, which necessitates use of isotonic fluids.
- Use oral replacement in conscious patients if possible.
- Use the estimated water deficit, desired rate of correction, and estimation of ongoing free water losses to calculate a fluid repletion regimen.

# Hyperparathyroidism

Aleta Paschal, MD

Cassandra White, MD

## BASICS

### DESCRIPTION

A dysfunction of the body's normal regulatory feedback mechanisms resulting in excess production of parathyroid hormone (PTH)

- Primary hyperparathyroidism (HPT): intrinsic parathyroid gland dysfunction resulting in excessive secretions of PTH with a lack of response to feedback inhibition by elevated calcium
- Secondary HPT: excessive secretion of PTH in response to hypocalcemia, which can be caused by vitamin D deficiency or renal failure
- Tertiary HPT: autonomous hyperfunction of the parathyroid gland in the setting of long-standing secondary HPT

### EPIDEMIOLOGY

#### *Incidence*

Predominant sex: female > male (2:1)

#### *Prevalence*

Primary HPT: 1/1,000 in the United States

### ETIOLOGY AND PATHOPHYSIOLOGY

- PTH is synthesized by the four parathyroid glands, which are located behind the four poles of the thyroid gland (locations can vary).
- Ectopic (abnormal locations and most common is the thymus) or supernumerary glands (more than four glands) (1)
- Blood supply: inferior thyroid artery
- PTH releases calcium from bone by osteoclastic stimulation (bone resorption).
- PTH increases reabsorption of calcium in the distal tubules of the kidneys.

- PTH stimulates conversion of 25-hydroxycholecalciferol (25[OH]D) to 1,25-dihydroxycholecalciferol (1,25[OH]<sub>2</sub>D or active vitamin D) in the kidneys.
  - 1,25(OH)<sub>2</sub>D increases calcium absorption from the GI tract, increases calcium and phosphate reabsorption in the kidneys, and stimulates osteoclastic activity and bone resorption.
- Primary HPT: unregulated PTH production and release, causing increase in serum calcium
  - Solitary adenoma (89%)
  - Double adenomas (5%)
  - Diffuse hyperplasia (6%) caused by multiple adenomas, multiple endocrine neoplasia (MEN) types 1 and 2a, and familial hypocalciuric hypercalcemia
  - Parathyroid carcinoma (<2%)
- Secondary HPT: adaptive parathyroid gland hyperplasia and hyperfunction
  - Dietary: vitamin D or calcium deficiency
  - Chronic renal disease resulting in the following:
    - Renal parenchymal loss causing hyperphosphatemia
    - Impaired calcitriol production causing hypocalcemia
    - General skeletal and renal resistance to PTH
- Tertiary HPT: autonomous oversecretion of PTH following prolonged parathyroid stimulation

## *Genetics*

- MEN types 1 and 2a: Patients with multiple gland hyperplasia in the absence of renal disease should be screened for MEN-1 gene mutation.
- Neonatal severe primary HPT
- HPT~jaw tumor syndrome
- Familial hypocalciuric hypercalcemia (FHH): autosomal dominant
- Familial isolated HPT

## *RISK FACTORS*

Chronic kidney disease, increasing age, poor nutrition, radiation, and/or family history

## GENERAL PREVENTION

Adequate intake of calcium and vitamin D may help prevent secondary HPT.

## COMMONLY ASSOCIATED CONDITIONS

- MEN syndromes types 1 and 2a
- Chronic renal failure

## DIAGNOSIS

### HISTORY

- History of present illness
  - 50% of patients are asymptomatic.
  - Bone, abdominal, and flank pain as well as psychosis, which are all classic complaints of hypercalcemia
- Past medical history
  - The following conditions may be associated with HPT:
    - MEN syndrome (MEN-associated conditions include pancreatic cancer, pituitary adenomas, medullary thyroid cancer, and pheochromocytoma), nephrolithiasis (in 20-30%), nephrocalcinosis, pancreatitis, gastroduodenal ulcer, hypertension, short QT interval, left ventricular hypertrophy, osteitis fibrosa cystica, cystic bone lesions, spontaneous fracture, vertebral collapse, osteoporosis, gout, pseudogout, anxiety, depression, psychosis, coma, conjunctivitis, band keratopathy, conjunctival calcium deposits, radiation to the neck
- Medications: thiazides or lithium
- Review of systems
  - Possible symptoms include polydipsia, polyuria, flank pain, abdominal pain, constipation, vomiting, anorexia, weight loss, muscle fatigue, pain, weakness, hypotonia, arthralgia, bone pain, fatigue, apathy, and somnolence.

## PHYSICAL EXAM

Limited usefulness; 70-80% of patients have no obvious symptoms or signs of disease.

- Physical findings may found related to underlying cause of HPT.

## *DIFFERENTIAL DIAGNOSIS*

- Increased PTH: ectopic PTH production
- Nonparathyroid causes
  - Malignancy: lung (squamous cell) carcinoma, breast carcinoma, multiple myeloma, lymphoma, leukemia, prostate cancer, Paget disease
  - Granulomatous disease: sarcoidosis, tuberculosis, berylliosis, histoplasmosis, coccidioidomycosis
  - Drugs: thiazide diuretics, vitamin D intoxication, vitamin A excess, lithium, milk-alkali syndrome, exogenous calcium intake
  - Endocrine: hyperthyroidism, acute adrenal insufficiency
  - Familial: hypocalciuric hypercalcemia

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Disease is often detected by an incidental finding of hypercalcemia.
- Order serum calcium level and albumin
  - Calculate serum calcium on 2 occasions using:  $(0.8 \times [\text{Normal Albumin} - \text{Pt's Albumin}]) + \text{Serum Ca}$ . If corrected calcium is above your lab's normal range (normally  $>2.65$  mmol/L), consider this true hypercalcemia which is consistent with hyperparathyroidism.
- If hypercalcemia is confirmed, follow with intact PTH level (2)[B].
  - High PTH ( $>3.0$  pmol/L) suggests primary HPT.
  - Low PTH ( $<3.0$  pmol/L) suggests non-PTH-mediated hypercalcemia.
- If elevated calcium is inconsistent, elevated ionized serum calcium in the setting of high PTH confirms diagnosis. Other findings may include low serum phosphate, elevated serum chloride, decreased serum  $\text{CO}_2$ , and abnormal 24-hour urine calcium excretion.
- Normocalcemic primary HPT found in 2009; consistent with normal calcium, low bone mineral density, and elevated PTH (must r/o secondary HPT) (3)
- In secondary HPT, an elevated phosphorus suggests chronic renal failure; a low phosphorus suggests another cause, most commonly vitamin D deficiency.

### *Follow-Up Tests & Special Considerations*

- A 24-hour urine calcium concentration to creatinine clearance ratio  $>0.02$  suggests primary HPT; a ratio  $<0.01$  may be normal or indicate FHH; important because FHH does not require surgery (2)[C]
- Routine measurement of 25(OH)D levels is recommended in all patients with primary HPT. In case of vitamin D deficiency ( $<20$  ng/mL or  $<50$  nmol/L), defer management decisions until levels are maintained  $>20$  ng/mL (50 nmol/L) (4)[C].
- Intraoperative measurement of intact PTH and/or *gggr*-probe localization of abnormal glands with technetium-99m sestamibi scan has aided focused resections for patients with single-gland etiology (5)[C].
- Screening for kidney stones is not recommended in patients without a history of nephrolithiasis (5)[B].

### *Diagnostic Procedures/Other*

- Consider EKG to assess for short QT interval.
  - Imaging is not required for diagnosis. It is required for surgical planning, especially for minimally invasive parathyroidectomy (MIP) (6)[C].
    - Imaging is also indicated to localize hyperplasia or an ectopic parathyroid gland in repeat surgery.
  - Imaging options for presurgical localization
    - Technetium-99m sestamibi with single-photon emission computed tomography (SPECT)
      - Has had the greatest reported success in localizing single parathyroid adenomas (7)[B]
    - US
      - Painless, noninvasive, inexpensive, and does not expose the patient to radiation; however, its accuracy is very operator-dependent (8)[C].
- 
- Positron emission tomography (PET) using C-methionine (MET-PET) is comparable to US and technetium-99m sestamibi with SPECT in terms of diagnostic use (6)[B].
  - Four-dimensional CT (4D-CT) may be more effective for primary localization than both US and sestamibi-SPECT (9)[B].
  - CT and MRI are mostly used to localize ectopic mediastinal glands.
  - Comprehensive cervical US (CCU) used for further localization following a negative sestamibi scan often reveals a single adenoma (10)[C].

- A negative sestamibi scan likely indicates parathyroid hyperplasia/multiglandular disease and thus requires open neck exploratory surgery.
- CCU after negative sestamibi result allows more patients who were previously excluded to be candidates for MIP.

## TREATMENT

### *MEDICATION*

- Primary HPT: Operative management is curative. For those awaiting or unable to have surgery
  - Bisphosphonates (alendronate): reduces bone turnover and helps to maintain bone density; avoid in kidney disease.
  - Calcimimetics (cinacalcet): Further studies needed to establish long-term benefit in primary HPT.
  - Selective estrogen receptor modulator therapy (raloxifene)
  - Hormone replacement therapy with estrogens is not recommended as first-line treatment; must weigh benefit with risks of known systemic effects
    - Can be used in postmenopausal women who do not undergo or refuse surgery
- Secondary HPT
  - Calcium replacement
  - Vitamin D analogues (paricalcitol and calcitriol)
  - Phosphorus-binding agents (sevelamer)
  - Calcimimetic (cinacalcet) (2,11)[A]: activates calcium-sensing receptor in parathyroid gland thereby inhibiting PTH secretion
- Tertiary HPT
  - Medical treatment is not curative and generally not indicated.

### *SURGERY/OTHER PROCEDURES*

- Operative management is curative for patients with primary HPT in 95-98% of patients.
- Indications for parathyroidectomy
  - Symptomatic primary HPT

- Nephrolithiasis
- Nephrocalcinosis
- Osteitis fibrosa cystica
- Asymptomatic primary HPT
  - Serum Ca<sup>+</sup> level >1 mg/dL above normal
  - Age <50 years
  - GFR <60 mL/min/1.73 m<sup>2</sup> or creatinine clearance reduced to <60 mL/min
  - Bone density loss with a *T* score <sup>2</sup> -2.5 at the lumbar spine, femoral neck, total hip, or 33% radius
- Tertiary HPT
- Surgical removal of diseased gland or tissue is only proven curative therapy for HPT.
- Surgical options include the following:
  - Bilateral open neck exploratory surgery
  - MIP using preoperative sestamibi scan with SPECT/US and intraoperative PTH levels (high sensitivity 79-95% to predict location of single parathyroid adenoma) (11) which result in decreased pain, smaller incisions, improved cosmetic results, lower morbidity, and decreased length of hospital stay when compared with open neck exploratory surgery.
- Follow postoperative serum calcium level (hypocalcemia in Hungry bone syndrome); patients also at risk for bleeding and airway compromise; keep injectable calcium and seizure medications at bedside.
- Monitor renal function closely.

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

Critical hypercalcemia requires IV fluid rehydration, IV bisphosphonate therapy, and SC calcitonin (4 U/kg q12h) for severe symptoms.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Asymptomatic patients with primary HPT require serial monitoring of calcium and PTH.

## Patient Monitoring

In patients with primary HPT who are asymptomatic, measurements of serum calcium and creatinine annually and bone density scan every 1 to 2 years is sufficient.

## DIET

- In the presence of hypercalciuria or elevated  $1,25(\text{OH})_2\text{D}$  levels, dietary calcium restriction is recommended. Otherwise, daily calcium intake should be maintained at up to 1,000 mg.
- Restrict dietary phosphate in secondary HPT.

## PATIENT EDUCATION

- Importance of periodic lab testing
- Signs of severe hypercalcemia

## PROGNOSIS

Prognosis after surgery is excellent in primary HPT, with resolution of many of the preoperative symptoms.

## COMPLICATIONS

Related to high levels of PTH and/or elevated calcium

## Codes

&NA;

### ICD10

- E21.3 Hyperparathyroidism, unspecified
- E21.0 Primary hyperparathyroidism
- E21.1 Secondary hyperparathyroidism, not elsewhere classified

## Clinical Pearls

## **&NA;**

- 50% of patients with primary HPT are asymptomatic.
- HPT is often detected by an incidental finding of hypercalcemia on a routine serum chemistry analysis.
- Classic symptoms of hypercalcemia include painful bones, renal stones, abdominal pains, and behavioral changes (Óstones, bones, moans, and groansÓ).
- Repeat calcium (elevated), correct for serum albumin, and obtain intact PTH levels to make an initial diagnosis.
- The two most commonly used imaging modalities in HPT are technetium-99m sestamibi scan and US.
- Surgery is curative for most cases of primary HPT.

# Hyperprolactinemia

D'Ann Somerall, DNP, FNP-BC

William E. Somerall Jr., MD, MEd

## BASICS

### *DESCRIPTION*

Hyperprolactinemia is an abnormal elevation in the serum prolactin level with multiple possible etiologies.

### *EPIDEMIOLOGY*

#### *Prevalence*

- Predominant age: reproductive age
- Predominant sex: female > male
- More readily detected in females because a slight elevation in prolactin causes changes in menstruation and galactorrhea

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Prolactin, which is produced by lactotrophs in the anterior pituitary, is regulated by:
  - Inhibitory factors, primarily dopamine, produced in the hypothalamus and delivered via the hypothalamic-pituitary vessels in the pituitary stalk
  - Stimulatory factors, primarily thyrotropin-releasing hormone (TRH)
- Causes of hyperprolactinemia include the following:
  - Physiologic
    - Pregnancy due to increased estrogen
    - Breastfeeding
    - Nipple stimulation
    - Stress, including postoperative state
  - Medications

- Dopamine (D<sub>2</sub>) blockers: prochlorperazine, metoclopramide
- Dopamine depleters: *α*-methyldopa, reserpine
- Antidepressants: selective serotonin reuptake inhibitors (SSRIs), tricyclic antidepressants (SSRIs do not appear to cause clinically significant hyperprolactinemia)
- Verapamil (but no other calcium channel blockers; thought to decrease hypothalamic synthesis of dopamine)
- Antipsychotics: haloperidol, fluphenazine, risperidone
- Hypothyroidism (due to elevated TRH)
- Chest wall conditions:
  - Herpes zoster
  - After thoracotomy
  - Trauma
- Prolactin-secreting adenoma (anterior pituitary), categorized:
  - Microadenoma: <1 cm
  - Macroadenoma: >1 cm
- Pituitary stalk compression/disruption:
  - Craniopharyngioma
  - Rathke cleft cyst
  - Meningioma
  - Astrocytoma
  - Metastases
  - Head trauma
  - Infiltrative/inflammatory disorders
- Diminished prolactin clearance:
  - Chronic renal failure
  - Cirrhosis
- Cocaine

# DIAGNOSIS

## HISTORY

- Galactorrhea
- Amenorrhea
- Oligomenorrhea
- Infertility
- Osteoporosis/osteopenia
- Decreased libido, impotence
- Weight gain
- Also may have signs and symptoms of pituitary enlargement:
  - Headache
  - Visual field impairment (bitemporal hemianopsia)
  - Hypopituitarism (secondary to tumor pressure on surrounding structures)
- Also may have signs and symptoms of associated conditions:
  - Hypothyroidism
  - Cushing disease
  - Acromegaly
  - Multiple endocrine neoplasia (MEN)-1 syndrome

## PHYSICAL EXAM

- Visual field testing
- Cranial nerve exam

## DIFFERENTIAL DIAGNOSIS

Macroprolactinemia: Macroprolactin, a polymer of several units of prolactin, is detected by immunologically based lab tests but is not biologically active. If patient is asymptomatic but found to have elevated prolactin (PRL), consider this diagnosis and notify the lab. No treatment is required.

## DIAGNOSTIC TESTS & INTERPRETATION

- Serum prolactin (most accurate results if checked fasting, in morning) <25  $\mu\text{g/L}$  normal; >25  $\mu\text{g/L}$  abnormal; >250  $\mu\text{g/L}$  often indicates a prolactinoma (1)[A].

Pregnancy test

- Thyroid-stimulating hormone (TSH)
- Luteinizing hormone (LH)/follicle-stimulating hormone (FSH) if amenorrheic
- Chemistry, renal function
- LFTs

### *Initial Tests (lab, imaging)*

A single measurement of serum prolactin; a level above the upper limit of normal confirms the diagnosis.

- Pituitary MRI: single best imaging
- CT scan if MRI is contraindicated
- Levels should be drawn prior to breast exam.

### *Follow-Up Tests & Special Considerations*

Formal visual field testing if pituitary adenoma is suspected

## **TREATMENT**

### *GENERAL MEASURES*

- Discontinue offending medications, if any (1)[A].
- Treat underlying causes (1)[A].
- For asymptomatic patients with mild PRL elevations, observation alone may be considered (1,2)[A]
- Medications indicated for (1)[A]:
  - Symptoms of hypogonadism, such as decreased libido
  - Galactorrhea (if bothersome to patient)
  - Restoration of fertility
  - Pituitary adenoma
  - Prevention of osteoporosis

### *MEDICATION*

Dopamine agonists: decrease serum prolactin concentrations and decrease the size of most lactotroph adenomas

- Cabergoline (Dostinex): This is now a first-line choice due to efficacy and favorable side effect profile (1,3)[A]: dosed twice weekly. Cabergoline was more effective than bromocriptine in reducing persistent hyperprolactinemia, galactorrhea, and amenorrhea/oligomenorrhea (2)[A]. Has recently been reported to be associated with significant improvements in the body mass index, total HDL and LDL cholesterol levels, and insulin sensitivity; decrease in proinflammatory markers; and carotid intima media thickness, indicated with bromocriptine failure or resistance; has been shown to reduce erectile dysfunction in hyperprolactinemic men (1)[A]
  - Adverse effects (better tolerated if start with low dose, slow titration, given at night with food):
    - Nausea/vomiting
    - Headache
    - Dizziness
    - Fatigue
    - Light-headedness
    - Postural hypotension (2)[A]
- Bromocriptine (Parlodel): This has the longest clinical history: dosed BID; preferred by some clinicians when infertility is an indication for treatment (2,4)[A].
- Both are effective for reducing tumor size and improving symptoms (2)[A].
- SE less with cabergoline than bromocriptine (2)[A]. Pergolide (Permax) is no longer used in the United States. If patient is still on med, do not withdraw abruptly.

---

P.515

## ***ADDITIONAL THERAPIES***

Patients with medically and surgically refractory prolactinomas; radiotherapy produced a reduction in prolactin levels in nearly all patients and normalization in over a quarter of patients with low complication rates (2)[A].

## ***SURGERY/OTHER PROCEDURES***

- For adenomas, medical treatment will be successful in 80-90% of patients. In some cases, surgery is indicated (1).
- Indications

- Intolerance or resistance to medical treatment
- Headache
- Visual field loss
- CSF leak due to tumor apoplexy or shrinkage
- Cranial nerve deficit
- Risks
  - High recurrence rate (up to 40%)
  - CSF leakage
  - Meningitis
  - Transient diabetes insipidus (5)
- Pituitary insufficiency

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Depends on etiology
- After at least 2 years of treatment, no tumor and prolactin levels normal may consider decreasing and stopping medication. Must be followed closely, as tumor may grow back (1).
- Consider:
  - Formal visual field testing yearly (4)[A]
  - Serial MRIs if clinically indicated (4)[A]

#### *Pregnancy Considerations*

- If pregnancy is desired in a woman with hyperprolactinemia, dopamine agonists are not approved during pregnancy and should be discontinued once pregnancy is confirmed, but their use is recommended if neurologic findings are present (1)[A].
- With microprolactinoma: Treat with bromocriptine if symptomatic; monthly pregnancy tests; discontinue bromocriptine when pregnancy is confirmed.

With macroprolactinomas: a definitive, individualized plan is made. Options include discontinuation of bromocriptine at conception and careful monitoring of PRL levels and VS, with or without MRI scan evidence of tumor enlargement; prepregnancy transsphenoidal surgery with debulking of tumor; continuation of bromocriptine throughout gestation, with a risk to the fetus.

- Careful monitoring of visual fields in each trimester. No need to monitor prolactin levels, as they are normally high due to pregnancy (1)[A].

## **PATIENT EDUCATION**

- Discuss risks of untreated hyperprolactinemia:
  - Headache
  - Visual field loss
  - Decreased bone density
  - Infertility
- Patient guide to hyperprolactinemia diagnosis and treatment

## **PROGNOSIS**

- Tends to recur after discontinuation of medical therapy (1)
- Over 10 years, 7% chance of progression of prolactin-secreting microadenoma (4)

## **COMPLICATIONS**

- Depends on underlying cause
- If pituitary adenoma, risk of permanent visual field loss

## Codes

&NA;

### ICD10

E22.1 Hyperprolactinemia

## Clinical Pearls

&NA;

- If a cause for hyperprolactinemia cannot be found by history, examination, and routine laboratory testing, an intracranial lesion might be the cause and brain MRI with specific pituitary cuts and intravenous contrast media should be performed.
- Treatment of hyperprolactinemia should be targeted at correcting the cause (hypothyroidism, discontinuation of offending medications, etc.).
- There is a difference among antipsychotics in influencing prolactin levels. In general, those with the highest potency D<sub>2</sub> antagonism are most likely to elevate prolactin levels. Among the newer atypical antipsychotics, risperidone has been identified as more likely to elevate prolactin.
- Chronic nipple piercing has not been shown to cause hyperprolactinemia (6).
- High prolactin levels decrease testosterone by inhibiting gonadotropin-releasing hormone (GnRH), LH, and FSH secretion and by decreasing central dopamine activity, both of which are important in mediating sexual arousal.

# Hypersensitivity Pneumonitis

Han Q. Bui, MD, MPH

## BASICS

- Hypersensitivity pneumonitis (HP) is also called extrinsic allergic alveolitis (EAA).
- HP is a diffuse inflammatory disease of the lung parenchyma caused by an immunologic reaction to aerosolized antigenic particles found in a variety of environments. Classification depends on time frame involved:
  - Acute: fever, chills, diaphoresis, myalgias, nausea; cough and dyspnea common but not necessarily present. Occurs 4 to 12 hours after heavy exposure to an inciting agent. Symptoms subside within 12 hours to several days after removal from exposure. Complete resolution occurs within weeks.
  - Subacute: mainly caused by continual low-level antigen exposure, could have a low-grade fever in first week; cough, dyspnea, fatigue, anorexia, weight loss—develops over days to weeks
  - Chronic: from recurrent exposure either acute or subacute cases, prolonged and progressive cough, dyspnea, fatigue, weight loss, could lead to fibrosis and respiratory failure
- Farmer's lung is an old term of this disease, a type of HP, particular to the farmer population; causative agent is a bacterium found in moldy hay or straw. Farmer's lung now has new and different etiologies due to modernization of farming practices (1,2).

## EPIDEMIOLOGY

- Not well defined. Tends to occur in adults as a result of occupation-related exposure, but some home environmental exposures are also seen.
- HP is increasingly recognized as an important cause of fibrotic interstitial lung disease (3).

### *Incidence*

0.9 per 100,000

### *Prevalence*

- Farmers: 1-19% exposed farmers

- Bird fanciers: 6-20% exposed individuals
- Others: 1-8% exposed

## ETIOLOGY AND PATHOPHYSIOLOGY

- Hypersensitivity reaction involving immune complexes: inhaled antigens bind to IgG, triggering complement cascade (types III and IV immunologic reactions) (4)
- Cellular-mediated reaction: T cell-mediated immune inflammatory response
- Farming, vegetable, or dairy cattle workers (1,2)
  - Moldy hay, grain, silage: thermophilic actinomycetes, such as *Faenia rectivirgula*
  - Mold on pressed sugar cane: *Thermoactinomyces sacchari*, *Thymus vulgaris*
  - Tobacco plants: *Aspergillus* sp., *Scopulariopsis brevicaulis*
  - Mushroom worker's lung: *Saccharopolyspora rectivirgula*, *T. vulgaris*, *Aspergillus* spp.
  - Potato riddler's lung: Thermophilic actinomycetes, *T. vulgaris*, *Faenia rectivirgula*, *Aspergillus* sp.
  - Wine maker's lung: *Mucor stolonifer*
  - Cheese washer's lung: *Penicillium casei*, *Aspergillus clavatus*
  - Coffee worker's lung: coffee bean dust
  - Tea grower's lung: tea plants
- Ventilation and water-related contamination (1,2)
  - Contaminated humidifiers and air conditioners: amoebae, nematodes, yeasts, bacteria
  - Unventilated shower: *Epicoccum nigrum*
  - Hot-tub lung: *Cladosporium* sp., *Mycobacterium avium* complex
  - Sauna taker's lung: *Aureobasidium* sp.
  - Summer-type pneumonitis: *Trichosporon cutaneum*
  - Swimming pool lung (lifeguard) lung: aerosolized endotoxin and *M. avium* complex
  - Contaminated basement pneumonitis: *Cephalosporium* and *Penicillium* spp.
- Bird and poultry handling (1)
  - Bird fancier's lung: droppings, feathers, serum proteins
  - Poultry worker's lung: serum proteins

- Turkey-handling disease: serum proteins
- Canary fancier's lung: serum proteins
- Duck fever: feathers, serum proteins
- Veterinary work and animal handling (1,2)
  - Laboratory worker's lung: urine, serum, pelts, proteins
  - Pituitary snuff taker's disease: dried, powdered neurohypophysis
  - Furrier's lung: animal pelts
  - Bat lung: bat serum protein
  - Fish meal worker's lung: fish meal
  - Coptic lung: cloth wrapping of mummies
  - Mollusc shell HP: sea-snail shell
  - Pearl oyster shell pneumonitis: oyster shells
- Grain and flour (1,2)
  - Grain measurer's lung: cereal grain, grain dust
  - Miller's lung: *Sitophilus granarius*
  - Malt worker's disease: *A. fumigatus*, *A. clavatus*
- Lumber milling, construction, wood stripping, paper, wallboard manufacture (1,2)
  - Wood dust pneumonitis: *Alternaria* sp., *Bacillus subtilis*
  - Sequoiosis: *Graphium*, *Pullularia*, *Trichoderma* sp., *Aureobasidium pullulans*
  - Maple bark disease: *Cryptostroma corticale*
  - Wood trimmer's disease: *Rhizopus* sp., *Mucor* sp.
  - Wood pulp worker's disease: *Penicillium* sp.
  - Suberosis: *T. viridis*, *P. glabrum*
- Plastic manufacturing, painting, electronics, chemicals (1)
  - Chemical HP: diphenyl diisocyanate, toluene diisocyanate
  - Detergent worker's lung: *B. subtilis* enzymes
  - Pauli reagent alveolitis: sodium diazobenzene sulfate
  - Vineyard sprayer's lung: copper sulfate

- Pyrethrum: *Pyrethrum*
- Epoxy resin lung: phthalic anhydride
- Bible printer's lung: moldy typesetting water
- Machine operator's lung: *Pseudomonas fluorescens*, aerosolized metal working fluid
- Textile workers
  - Byssinosis: cotton mill dust
  - Velvet worker's lung: nylon, tannic acid, potato starch
  - Upholstery fabric: aflatoxin-producing fungus, *Fusarium* sp.
  - Lycoperdonosis: puffball spores

## Genetics

No evidence of clear genetic susceptibility. Possible genetic predisposition involving tumor necrosis factor alpha (TNF- $\alpha$ ) and major histocompatibility complex (MHC) class II genes (1,4)[B]

## RISK FACTORS

- Contact with organic antigens increases the risk of developing HP. Viral infection at time of exposure could also increase risk (5).
- Nonsmokers have an increased incidence of HP compared with smokers (nicotine could have a protective effect) (5).
  - Smokers have a diminished antibody response to inhaled antigens.
  - However, smokers that develop disease tend to have the chronic form, and mortality is higher.

## GENERAL PREVENTION

Avoidance of offending antigen and/or use of protective equipment

## COMMONLY ASSOCIATED CONDITIONS

Constrictive bronchiolitis

## DIAGNOSIS

- Diagnosis criteria most widely used but not validated: (i) history and physical and pulmonary

function tests (PFTs) indicating restriction or diffusion disease, (ii) radiologic imaging consistent with interstitial lung disease, (iii) exposure to a recognized cause, (iv) proof of sensitization in BAL fluids (serum precipitins and/or lymphocytosis) (2)

- Six significant predictors: exposure to a known antigen, positive precipitating antibodies, recurrent episodes of symptoms, inspiratory crackles, symptoms 4 to 8 hours after exposure, weight loss (6)
- Acute form: develops 4 to 12 hours following exposure. Cough, dyspnea without wheezing, fever, chills, diaphoresis, headache, nausea, malaise, chest tightness. Symptoms last hours to days.
- Sequela (prior subacute, chronic): gradual or progressive productive cough, dyspnea, fatigue, anorexia, weight loss can lead to respiratory failure; develops over days, weeks to months.
- Symptomatic improvement when away from work or home

## PHYSICAL EXAM

- Acute: fever, tachypnea, diffuse fine rales
- Sequela or chronic: inspiratory crackles, progressive hypoxia, weight loss, diffuse rales, clubbing, rarely wheezing

---

P.517

## DIAGNOSTIC TESTS & INTERPRETATION

- Testing for antibodies (Ab) is NOT diagnostic as up to 40% may have positive AB without disease. Antigens that cover most cases: pigeon and parakeet sera, dove feather, *Aspergillus sp.*, *Penicillium*, *S. rectivirgula*, and *T. viridans*.
- PFTs: Typical profile is a restrictive pattern with low diffusing capacity, could also have an obstructive pattern (6).
- Bronchoalveolar lavage (BAL) with serum precipitins and lymphocytosis: usually with low CD4-to-CD8 ratio. Findings not unique to HP (1,6)
- Positive antigen-specific inhalation challenge testing: reexposure to the environment, inhalation challenge to the suspected antigen in a hospital setting but it lacks standardization (7)
- Chest x-ray (CXR): used to rule out other diseases
  - Acute: ground-glass infiltrates, nodular or striated patchy opacities, interstitial pattern in a variety of distributions in lung field. Up to 20% could be normal.
  - Sequela/chronic: upper lobe fibrosis, nodular or ground-glass opacities, volume loss,

emphysematous changes

- CT scan of chest. Patterns not specific to HP:
  - Acute: ground-glass opacities, poorly defined centrilobular nodules and ground-glass opacities and air trapping on expiratory images (7,8)
  - Chronic: fibrosis, ground-glass attenuation, irregular opacities, bronchiectasis, loss of lung volume, honeycombing, emphysematous changes (7,8)
- High-resolution CT (HRCT) mid-to-upper zone predominance of centrilobular ground glass or nodular opacities with signs of air trapping (7).
- Usually start with CXR; may progress to HRCT based on findings (1,7)

## *Diagnostic Procedures/Other*

Lung biopsy:

- Transbronchial: reveals small, poorly formed noncaseating granulomas near respiratory or terminal bronchioles, large foam cells, peribronchial fibrosis
- Open lung biopsy: highest yield in advanced disease. Reveals varying patterns of organizing pneumonia, centrilobular and perilobular fibrosis, multinucleated giant cells with clefts

## **DIFFERENTIAL DIAGNOSIS**

- Acute: acute infectious pneumonia: influenza (or other viral pneumonia), mycoplasma, *Pneumocystis jiroveci* pneumonia, asthma, aspiration (4)
- Chronic: sarcoidosis, chronic bronchitis, chronic obstructive pulmonary disease, tuberculosis, collagen vascular disease, idiopathic pulmonary fibrosis, lymphoma, fungal infections, *P. jiroveci* pneumonia (4)

### **ALERT**

HP in farmers must be distinguished from febrile, toxic reactions to inhaled dusts (organic dust toxic syndrome [ODTS]). Nonimmunologic reactions occur 30-50% more commonly than HP in farmers. ODTS is associated with intense exposure occurring on a single day.

## **TREATMENT**

### **GENERAL MEASURES**

Outpatient, except for acute pneumonitis cases and admission for workup (BAL, lung biopsy)

## *First Line*

- Avoidance of offending antigen is primary therapy and results in disease regression (1,2).
- Corticosteroids: help control the symptoms of exacerbations but do not improve long-term outcomes
  - Prednisone: 20 to 50 mg daily (6)
  - For severe symptomatic patients, initial course of 1 to 2 weeks with taper (6)

## *Second Line*

- Bronchodilators and inhaled corticosteroids may symptomatically improve patients with wheeze and chest tightness (5,6)[B].
- Oxygen may be needed in advanced cases.
- Lung transplantation may be the last resort in severe cases unresponsive to therapy.

## *ISSUES FOR REFERRAL*

Referral to pulmonologist/immunologist

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Supportive management, as needed, to maintain oxygenation and ventilation:

- Unstable ventilation, oxygen requirement, mental status changes
- Need for invasive evaluation (lung biopsy)

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Initial follow-up should be weekly to monthly, depending on severity and course
- Follow treatments with serial CXR, PFTs, and circulating antibody levels

## *DIET*

No dietary restrictions

## PATIENT EDUCATION

Note that chronic exposure may lead to a loss of acute symptoms with exposure (i.e., the patient may lose awareness of exposure-symptom relationship).

## PROGNOSIS

- Presence of fibrosis is a poor prognosis factor (1,2).
- Acute: good prognosis with reversal of pathologic findings if elimination of offending antigen early in disease (2,5)
- Sequela/chronic: Corticosteroids have been found to improve lung function acutely but offer no significant difference in long-term outcome (5,6)[C].

## COMPLICATIONS

- Progressive interstitial fibrosis with eventual respiratory failure
- Cor pulmonale and right-sided heart failure

## Codes

&NA;

### ICD10

- J67.9 Hypersensitivity pneumonitis due to unspecified organic dust
- J67.0 Farmer's lung
- J67.2 Bird fancier's lung

## Clinical Pearls

&NA;

- Skin testing is not useful for the diagnosis of HP.
- Diagnosis should be suspected in every patient with unexplained cough and dyspnea on exertion, functional impairment (restriction or diffusion defect), and unclear fever, especially if exposure to potential antigens is known (workplace, domestic bird keeping, moldy walls in the home) (2).
- Once the disease is established, smoking does not appear to attenuate its severity, and it may predispose to more chronic and severe course.
- Use of protective gear on individual with high-risk exposure occupations can prevent HP.
- Chronic hypersensitivity pneumonitis is increasingly recognized as an important mimic of other fibrotic lung diseases (3).

# Hypersplenism

Shadi Hamdeh, MD

Adil Abdalla, MD

## BASICS

### DESCRIPTION

- Hypersplenism is defined as overactivity of the spleen and presents as the following:
  - Splenomegaly (commonly but not always)
  - Cytopenias with respective bone marrow hyperplasia of precursors
  - Resolution of cytopenias with splenectomy
- Splenomegaly is not synonymous with hypersplenism. Overactivity of the spleen can occur without enlargement, as is seen in immune thrombocytopenic purpura (ITP) and autoimmune hemolytic anemia. Similarly, splenomegaly is not always associated with hypersplenism.

### EPIDEMIOLOGY

May be as common as 30-70% in patients with cirrhosis and portal hypertension (HTN)

### ETIOLOGY AND PATHOPHYSIOLOGY

Enlargement of the spleen results in sequestration of formed blood elements, leading to peripheral cytopenias and concomitant bone marrow precursor hyperplasia.

Many of the common etiologies are listed below. Almost any process involving the spleen or the hematologic system can result in hypersplenism:

- Infectious
  - Tuberculosis
  - Brucellosis
  - Malaria
  - Leishmaniasis
  - Ehrlichiosis

Schistosomiasis

- Histoplasmosis
- Candidiasis
- Viral
- Syphilis
- Infective endocarditis
- Hematologic
  - Myeloproliferative disorders
  - Polycythemia vera
  - Primary hypersplenism
  - ITP
  - Hemolytic anemias
- Neoplastic
  - Hematologic malignancies
  - Melanoma
  - Various carcinomas
  - Metastatic cancers
- Storage diseases
  - Gaucher disease
  - Niemann-Pick disease
  - Amyloidosis
  - Glycogen storage disease
- Inflammatory
  - Sarcoidosis
  - Systemic lupus erythematosus
  - Felty syndrome
- Congestive
  - Cirrhosis

- Heart failure
- Portal or splenic vein thrombosis
- Congenital malformations of the portal vein

## DIAGNOSIS

### HISTORY

- Patients may complain of abdominal fullness or protrusion of the spleen through the abdominal wall; may complain of early satiety if the spleen is compressing stomach
- Patients may complain of tenderness in the left upper quadrant, especially with viral infections. In lymphoproliferative disorders, spleen may be enlarged but asymptomatic unless there is splenic infarction. Given location of the spleen next to the diaphragm, a sense of fullness may be referred through the phrenic nerve to the C3-C5 dermatomes in the left shoulder.
- Symptoms related to the underlying cause of hypersplenism may be present.

### PHYSICAL EXAM

#### Splenomegaly

- The normal spleen is not palpable. A palpable spleen always indicates underlying abnormality such as splenomegaly and, in turn, hypersplenism in the appropriate clinical context or may indicate a wandering spleen. Also, spleen can be palpated in chronic obstructive pulmonary disease and acute asthma exacerbation, without coexisting splenomegaly.
- Begin by percussing Traube semilunar space, demarcated laterally by left anterior axillary line, inferiorly by the left costal margin, and superiorly by the left 6th rib. This space is usually hollow. Splenic enlargement may cause dullness to percussion in this area. Other processes that may cause dullness include pleural or pericardial effusions. Additionally, if the patient recently ate a large meal, this area may be dull to percussion.
- With patient supine, rest hand gently on the abdomen to prevent sudden tensing of the abdominal musculature, which may obscure palpation. Better abdominal relaxation can be obtained by flexing the knees toward the abdomen. As the spleen enlarges, it moves caudally and medially. Start by palpating in the right lower quadrant and moving toward the umbilicus, toward the left upper quadrant. If there is doubt about whether the spleen has moved beyond the costal margin, ask patient to take a large breath, which will push the diaphragm, and, in turn, the spleen toward the examiner's hands.

- Jaundice: if hemolytic anemia is present or in advanced cirrhosis
- Petechiae, purpura, or ecchymosis: if thrombocytopenia is present
- Lymphadenopathy: in hematologic or solid organ malignancies. It also can be seen in infectious etiologies.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

On CBC, any and all cell lines may be decreased, resulting in the following:

- Anemia
- Leukopenia
- Thrombocytopenia

### ***Initial Tests (lab, imaging)***

- CBC
- Reticulocyte count if anemia
- If there is hemolysis, there should be an elevated reticulocyte count, elevated LDH, decreased haptoglobin, along with evidence of hyperbilirubinemia (unconjugated).
- US
- CT
- Tc-99m sulfur colloid scintigraphy
- PET
- MRI

### ***Follow-Up Tests & Special Considerations***

Based on other historical and exam findings, testing for specific infectious etiologies may be warranted:

- Blood parasite smear for malaria and other parasitic infections
- EBV serologies
- HIV ELISA with Western blot
- JAK2 mutation in polycythemia vera
- PPD for tuberculosis
- Hgb electrophoresis in hereditary hemoglobinopathies

## Diagnostic Procedures/Other

- Bone marrow biopsy
- Liver biopsy for cirrhosis and storage diseases

## Test Interpretation

Hyperplasia of bone marrow precursors, especially those correlating with the patient's individual cytopenias

## TREATMENT

### MEDICATION

- No specific medication can be recommended for patients with hypersplenism. The most important intervention is to treat the underlying disorder.
- If ITP is the cause, the patient may benefit from the following:
  - Prednisone or methylprednisolone
  - IVIG
  - Rituximab
- If an infectious cause is discovered, treatment with appropriate antibiotic therapy may help to improve the cytopenias.

### SURGERY/OTHER PROCEDURES

- Many patients with severe uncontrolled cytopenias undergo splenectomy.
- Laparoscopic splenectomy is preferred over open splenectomy (1)[A].

P.519

#### ALERT

- Splenectomized patients should receive immunization to pneumococcus, meningococcus, *Haemophilus influenzae*, and influenza at least 14 days prior to splenectomy (2)[A].
- If this cannot be done (i.e., in cases of emergent splenectomy), wait at least 14 days postsplenectomy to immunize.
  - Pneumococcal vaccine

- Pneumococcal polyvalent-23 vaccine (PPSV23) for use in adults and fully immunized children <sup>≥</sup>2 years of age
- Pneumococcal polyvalent-13 vaccine (PCV13) for infants and young children <sup>≥</sup>2 months of age as part of routine immunization schedule (3)[A]
- PCV13 for children >2 years of age, adolescents and adults in addition to PPSV23; refer to CDC for timing of administration
- Current guidelines recommend single revaccination of PPSV23 5 years after the initial dose and again at age of <sup>≥</sup>65 years, at least 5 years after the previous dose.
- *H. influenzae* vaccine
  - All unvaccinated individuals <sup>≥</sup>5 years of age should be given 1 dose of *H. influenzae* type B (Hib) conjugate vaccine.
  - Children <5 years old should also be vaccinated. Refer to CDC for timing.
  - Vaccinated individuals can also be given additional dose of vaccine (4)[A].
- Meningococcal vaccine (5)[A]
  - Meningococcal conjugate vaccine (MCV4) for use in patients between 2 and 55 years
  - Meningococcal polysaccharide vaccine (MPSV4) for use in patients >55 years of age
  - Revaccination is recommended every 5 years.
- Influenza vaccine should be administered yearly based on prevalent circulating strains. Although patients are not at higher risk from influenza itself, infection with influenza may place patients at higher risk for secondary bacterial infections.
- Radiofrequency ablation (RFA) is becoming more available and can be successful at preventing recurrence of hypersplenism. It is not currently known whether there are differences between RFA and splenectomy in terms of postprocedure infectious risks. Other alternatives to splenectomy include total and partial splenic embolization and shunting, although these techniques are evolving and additional studies are needed to evaluate efficacy and morbidity as compared to splenectomy.

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

- Hypersplenism alone generally does not warrant admission. However, all patients should be monitored closely for complications of the resulting cytopenias, including bleeding and infection, as well as complications of splenomegaly, including increased risk of splenic rupture.

In some patients, the large spleen compresses the stomach and prevents adequate oral intake.

- Splenectomized patients are at increased risk of infection and postsplenectomy sepsis, especially with *Streptococcus pneumoniae*. Fevers, chills, or pain concerning for underlying infection warrant immediate attention as clinical decompensation can occur within hours. Empiric broad-spectrum antibiotics should not be delayed while evaluation is ongoing. Common empiric regimens include the following:
  - Ceftriaxone: 2g IV q24h and vancomycin 1 g IV q12h
  - Levofloxacin: 750 mg IV q24h and vancomycin 1 g IV q12h in *&bgr;-*lactam-allergic patients

## ONGOING CARE

- Adult patients who are splenectomized should be advised to monitor closely for fever or rigors at home, which may be an early sign of bacteremia. They should be instructed to begin antibiotics immediately prior to proceeding to a medical facility for evaluation. Early antibiotics have been shown to reduce the mortality from overwhelming postsplenectomy sepsis.
- Controlled trials have not been performed, but some regimens include the following:
  - Amoxicillin-clavulanate: 875 mg PO twice daily
  - Cefuroxime axetil: 500 mg PO twice daily
- Patients allergic to *&bgr;-*lactam antibiotics can be given an extended-spectrum fluoroquinolone such as levofloxacin 750 mg PO *or* moxifloxacin 400 mg PO daily.
- In children with splenectomy, daily antibiotic prophylaxis for overwhelming postsplenectomy sepsis with penicillin VK or amoxicillin is recommended until age 5 or at least 3 years after splenectomy:
  - Age 2 months to 5 years: 125 mg PO BID
  - >5 years old: 250 mg PO BID

## PATIENT EDUCATION

Patients who are splenectomized should be counseled extensively about the risk of overwhelming postsplenectomy sepsis and the need to obtain prompt medical evaluation in the event of fevers, chills, or any other concerning symptoms.

**&NA;**

Anemia, Autoimmune Hemolytic; Malaria; Polycythemia Vera; Tuberculosis

## Codes

**&NA;**

### ICD10

D73.1 Hypersplenism

## Clinical Pearls

**&NA;**

- Splenectomy is not necessary to make the diagnosis.
- Avoid splenectomy in patients unless absolutely necessary. Splenectomized patients are at lifelong risk for overwhelming postsplenectomy infection and sepsis.
- If splenectomy is to be performed, give immunization for pneumococcus, meningococcus, *Haemophilus*, and influenza at least 14 days prior to surgery. Otherwise, wait until the 14th postop day to immunize.

# Hypertension, Essential

Lisa M. Schroeder, MD

Luma Dababneh, MD

## BASICS

### DESCRIPTION

- Hypertension (HTN) is defined (JNC VIII) as <sup>3</sup>2 elevated BPs
  - Age 60 years or older: systolic BP (SBP) <sup>3</sup>150 mm Hg and/or diastolic BP (DBP) <sup>3</sup>90 mm Hg at <sup>3</sup>2 visits (1)
  - Age <60 years with chronic kidney disease (CKD) or diabetes: SBP <sup>3</sup>140 mm Hg and/or DBP <sup>3</sup>90 mm Hg at <sup>3</sup>2 visits (1)
- HTN is a strong risk factor for cardiovascular disease and strokes.
- Synonym(s): benign, chronic, idiopathic, familial, or genetic HTN; high BP

### Geriatric Considerations

- Isolated systolic HTN is common.
- Therapy has been shown to be effective and beneficial at preventing stroke, although target SBP is higher than in younger patients ( $\pm$  150 mm Hg systolic), and adverse reactions to medications are more frequent. The benefit of therapy has been conclusively demonstrated in older patients for SBP <sup>3</sup>160 mm Hg.

### Pediatric Considerations

- Measure BP during routine exams for >3 years of age.
- Defined as SBP or DBP <sup>3</sup>95th percentile on repeated measurements (2)
- Pre-HTN: SBP or DBP between 90th and 95th percentile (2)

### Pregnancy Considerations

- Elevated BP during pregnancy may be either chronic HTN or pregnancy-induced preeclampsia. ACE inhibitors and angiotensin II receptor blockers (ARBs) are contraindicated.

Maternal and fetal mortality benefit from treatment of severe HTN. Evidence is not clear for mild HTN (see topic "Preeclampsia").

## EPIDEMIOLOGY

### *Incidence*

- Lifetime risk for men and women aged 55 to 65 years by age 80 to 85 years is >90%.
- Predominant age: essential (primary, benign, idiopathic) onset usually in the 20s to 30s
- Predominant sex: male > female; males tend to run higher than females and have a significantly higher risk of cardiovascular disease at any given pressure.

### *Prevalence*

In 2009 to 2010, prevalence in adults was 28.6% (2009-2010 National Health and Nutrition Examination Survey [NHANES])

## ETIOLOGY AND PATHOPHYSIOLOGY

- >90% of HTN has no identified cause.
- Secondary causes of HTN (see "Hypertension, Secondary and Resistant"): renal parenchymal: glomerulonephritis, pyelonephritis, polycystic kidneys; endocrine: primary hyperaldosteronism, pheochromocytoma, hyperthyroidism, Cushing syndrome; vascular: coarctation of aorta, renal artery stenosis; chemical: commonly, oral contraceptives, NSAIDs, decongestants, corticosteroids; sleep apnea, black licorice, caffeine

### *Genetics*

BP levels are strongly familial, but no clear genetic pattern exists. Familial risk for cardiovascular diseases should be considered.

## RISK FACTORS

Family history, obesity, alcohol use, excess dietary sodium, stress, physical inactivity, tobacco abuse, insulin resistance

## DIAGNOSIS

### HISTORY

- HTN is asymptomatic except in extreme cases or after related cardiovascular complications develop.

- Headache can be seen with higher BP, often present on awakening and occipital in nature.

## *PHYSICAL EXAM*

- Retinopathy: narrowed arteries, arteriovenous (AV) nicking, copper or silver wiring of retinal arterioles
- Increased/louder S<sub>2</sub> (aortic component heart sound)
- Synchronous radial and femoral pulse can help to rule out coarctation of the aorta.

## *DIFFERENTIAL DIAGNOSIS*

- Secondary HTN: Because of the low incidence of reversible secondary HTN, special tests should be considered only if the history, physical exam, or basic laboratory evaluation indicate the possibility. (See *Hypertension, Secondary and Resistant*.)
- White coat hypertension: elevation of BP in office setting and normal BP outside office

## *DIAGNOSTIC TESTS & INTERPRETATION*

### MEASURING BP:

- Caffeine, exercise and smoking avoided >30 minutes before measurement.
- Patient seated quietly for 5 minutes with feet on floor.
- Patient's arm supported at heart level.
- Correct cuff size
- Average of two or more measurements

### *Initial Tests (lab, imaging)*

- Hemoglobin and hematocrit or CBC
- Complete urinalysis (may reveal proteinuria)
- Potassium, calcium, creatinine, and uric acid
- Lipid panel (total, HDL, LDL, triglyceride [TG])
- Fasting blood glucose, hemoglobin A1c
- ECG to evaluate possible presence of left ventricular hypertrophy (LVH) or rhythm abnormalities affecting therapy

## *Follow-Up Tests & Special Considerations*

- Special tests (only if history, physical, or labs indicates) (See "Hypertension, Secondary and Resistant.")
- Ambulatory (24-hour) BP monitoring if "white coat" HTN is suspected, episodic HTN or autonomic dysfunction
- Home BP monitoring is effective, especially if white coat HTN is a consideration; elevated home BPs correlate with adverse outcomes, possibly more so than office BPs, and normal readings are reassuring.

## *Diagnostic Procedures/Other*

- Age 60 years or older: SBP (SBP)  $\geq 150$  mm Hg and/or DBP  $\geq 90$  mm Hg) at  $\geq 2$  visits
- Age <60 years with CKD or diabetes: SBP  $\geq 140$  mm Hg and/or DBP  $\geq 90$  mm Hg at  $\geq 2$  visits
- The Joint National Committee (JNC) 8 recommends emphasis on
  - Family or personal history of HTN; cardiovascular, cerebrovascular, renal disease, and diabetes
  - Previous elevated BPs
  - Previous treatment for HTN
  - History of weight gain, exercise activities, sodium and fat intake, and alcohol use
  - Symptoms suggesting secondary HTN
  - Psychosocial and environmental factors affecting BP and risk for cardiovascular disease
  - Other cardiovascular risk factors, such as obesity, smoking, hyperlipidemia, and diabetes, OSA
  - Funduscopic exam for arteriolar narrowing, AV compression, hemorrhages, exudates, and papilledema
  - Body mass index (BMI)
  - Waist circumference
  - BP in both arms
  - Complete cardiac and peripheral pulse exam: Compare radial and femoral pulse for differences in volume and timing, auscultation for carotid and femoral bruits.
  - Abdominal exam for masses and bruits: Listen high in the flanks over the kidneys.
  - Neurologic assessment

## TREATMENT

### GENERAL MEASURES

- Benefit of pharmacologic treatment of low-risk patients with Class I hypertension (SBP 140 to 150 mm Hg, DBP 90 to 99 mm Hg) remains uncertain (3)[A].
- Treating patients age <60 years or with CKD or diabetes to lower-than-standard BP targets,  $\approx$ 140/90 mm Hg, does not further reduce mortality or morbidity. Individualize goal pressures based on risk factors.
- Target SBP at or just below 150 mm Hg in patients >60 years of age is acceptable in the general population (1).
- Although primary focus is SBP goal, treatment should accommodate patient preferences (1). Majority of treatment benefit is attained with initial 2 to 3 medications. Striving for small additional drops in BP to achieve a "target" is less clinically beneficial and more likely to cause side effects.
- Lower DBP targets were not associated with decreased morbidity/mortality (4).
- Aerobic exercise (30 minutes of aerobics 4 to 5 days per week), weight reduction for obese patients
- Smoking cessation
- Reduce salt intake <2.4 g/day.
- Risk stratification from JNC 7 no longer addressed in JNC 8 (1)
  - Age 60 years or older: SBP  $\approx$ 150 mm Hg and/or DBP  $\approx$ 90 mm Hg at  $\approx$ 2 visits
  - Age <60 years with CKD or diabetes: SBP  $\approx$ 140 mm Hg and/or DBP  $\approx$ 90 mm Hg at  $\approx$ 2 visits
  - Assess overall risk and individualize decision to treat.
- Choose from one of four classes of medications: (1)[A] ACE inhibitors, ARBs, calcium channel blockers (CCBs), or diuretics.

### MEDICATION

- Multiple drugs at submaximal dose may achieve target BP with fewer side effects. In patients on >1 medication, divide between morning and nighttime for better 24-hour antihypertensive effect.
- Sequential monotherapy attempts might be tried with different classes because individual responses vary.

- Many patients will require multiple medications.

- First-line agents for uncomplicated essential HTN include thiazide diuretics, ACE inhibitors, ARBs, and long-acting CCBs (amlodipine, felodipine) (1,5)[A].
- If concomitant conditions, choose first-line agent based on comorbidity.
- Combination first-line agents: Benazepril combined with amlodipine may be superior to combination with HCTZ in high-risk patients. Some suggest that ACE/ARB + dihydropyridine CCB is the first choice after monotherapy.
- *&bgr;*-Blockers had been strongly recommended until recent meta-analyses. Atenolol may be particularly *ineffective* in reducing adverse outcomes of HTN (except in patients with left ventricle hypertrophy undergoing dialysis).
- *&bgr;*-Blockers might benefit patients with ischemic heart disease, CHF, or migraine post ST segment elevation myocardial infarction (STEMI). ACE inhibitors should be used in patients with diabetes, proteinuria, atrial fibrillation, or heart failure with reduced ejection fraction (HFrEF) but *not in pregnancy*.
- *&agr;*-Adrenergic blockers are not the first choice for monotherapy but remain as second line after combination therapy of first-line agents; might benefit males with benign prostatic hypertrophy (BPH).
- CCB could be considered in patients with isolated systolic HTN, atherosclerosis, angina, migraine, or asthma; well-documented to reduce risk of stroke
- Thiazide diuretics or CCB preferred as first line in the general black population.

## First Line

- Thiazide diuretics (4)[A]
  - Chlorthalidone: 12.5 to 25 mg/day (more potent than hydrochlorothiazide but causes more hyponatremia and hypokalemia)
  - Hydrochlorothiazide: 12.5 to 50 mg/day
  - Indapamide: 1.25 to 2.5 mg/day
- ACE inhibitors
  - Lisinopril: 10 to 40 mg/day
  - Enalapril: 5 to 40 mg/day
  - Ramipril: 2.5 to 20 mg/day
  - Benazepril: 10 to 40 mg/day

- CCB
  - Diltiazem CD: 180 to 360 mg/day
  - Nifedipine (sustained release): 30 to 90 mg/day
  - Verapamil (sustained release): 120 to 480 mg/day
  - Amlodipine: 2.5 to 10 mg/day
- ARBs
  - Losartan: 25 to 100 mg in 1 or 2 doses; has unique but modest uricosuric effect
  - Valsartan: 80 to 320 mg daily
  - Irbesartan: 75 to 300 mg daily
  - Candesartan: 4 to 32 mg daily
  - Renin inhibitor: aliskiren 150 to 300 mg daily
- Contraindications
  - Diuretics may worsen gout.
  - $\beta$ -Blockers (relative) in reactive airway disease, heart block, diabetes, and peripheral vascular disease; probably should be avoided in patients with metabolic syndrome or insulin-requiring diabetes
  - Diltiazem or verapamil: Do not use with systolic dysfunction or heart block.
  - ACE inhibitors can worsen bilateral renovascular disease and are pregnancy Category D.

## Second Line

- Many may be combined. Choose additional medications with complementary effects (i.e., ACE inhibitors/ARBs with diuretic or a vasodilator with a diuretic or  $\beta$ -blocker).
- Medication-refractory HTN or suspected aldosteronism: spironolactone: 25 to 100 mg/day
- Centrally acting  $\alpha_2$  agonists: clonidine: 0.1 to 1.2 mg BID or weekly patch 0.1 to 0.3 mg/day; guanfacine: 1 to 3 mg daily; or methyldopa: 250 to 2,000 mg BID
- $\alpha_1$ -Adrenergic antagonists: prazosin: 1 to 10 mg BID; terazosin: 1 to 20 mg/day; or doxazosin: 1 to 16 mg/day
- Peripherally acting adrenergic inhibitors: rarely used: reserpine: 0.1 to 0.25 mg/day
- Vasodilators

- Hydralazine: 10 to 25 mg QID; risk of tachycardia, so generally combined with *&bgr*;-blocker; also drug-induced systemic lupus erythematosus (SLE)
- Minoxidil: rarely used due to adverse effects. May be more effective than other medications in renal failure and refractory HTN
- Loop diuretics (for volume overload): furosemide: 20 to 320 mg/day or bumetanide: 0.5 to 2 mg/day
- K<sup>+</sup>-sparing diuretics in patients with hypokalemia while taking thiazides: amiloride: 5 to 10 mg/day or triamterene: 50 to 150 mg/day

## COMPLEMENTARY & ALTERNATIVE MEDICINE

Biofeedback and relaxation exercise

### ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### *Patient Monitoring*

- Reevaluate patients q3-6mo until stable, then q6-12mo. Consider use of home self-BP monitoring; quality-of-life issues including sexual function should be considered.
- Poor medication adherence is a leading cause of apparent medication failure.
- Annual urinalysis, creatinine, and potassium

### DIET

- ÷20% of patients will respond to reduced-salt diet (<100 mmol/day; <6 g NaCl or <2.4 g Na).
- Consider Dietary Approaches to Stop Hypertension (DASH) diet: [http://www.nhlbi.nih.gov/files/docs/public/heart/hbp\\_low.pdf](http://www.nhlbi.nih.gov/files/docs/public/heart/hbp_low.pdf)
- Limit alcohol consumption to <1 oz/day.
- Dietary supplements such as garlic, cocoa, vitamin C, coenzyme Q10, omega 3, and magnesium have been suggested for lowering BP but evidence is lacking.

## PATIENT EDUCATION

- Emphasize the asymptomatic nature of HTN and importance of lifetime treatment.
- Printed aids for high BP education available: <http://www.nhlbi.nih.gov/health/resources/heart>

## COMPLICATIONS

Heart failure, renal failure, LVH, myocardial infarction, retinal hemorrhage, stroke, hypertensive heart disease, drug side effects

## Codes

&NA;

### ICD10

I10 Essential (primary) hypertension

## Clinical Pearls

&NA;

- Treatment of HTN reduces risk of many serious medical conditions with numbers needed to treat to prevent one serious event (e.g., stroke or myocardial infarction) ranging from  $\div 20$  patients per year for severe HTN to more than several hundred per year for mild HTN.
- Multiple submaximal doses are likely to have fewer side effects and more effectiveness than fewer maximum-dosed drugs.
- In older patients, measure BP standing to avoid overtreatment and syncope.

# Hypertension, Secondary and Resistant

George H. Maxted, MD

## BASICS

### DESCRIPTION

Uncontrolled hypertension (HTN) comprises the following entities (see *Alert* below):

- Resistant HTN: defined as blood pressure that remains above goal in spite of the concurrent use of three antihypertensive agents of different classes. Ideally, one of the three agents should be a diuretic, and all agents should be prescribed at optimal dose amounts (1,2,3)[C].
- Secondary HTN: elevated BP that results from an identifiable underlying mechanism (1,2,3)
- Both the recent Eighth Joint National Committee (JNC 8) and AHA/ACC/CDC guidelines recommend a goal BP of <140/90 mm Hg, although JNC 8 allows for a goal of <150/90 mm Hg for patients older than age 60 years (4,5)[C].

### Geriatric Considerations

- Onset of HTN in adults >60 years of age is a strong indicator of secondary HTN.
- In patients >80 years of age, consider a higher target systolic blood pressure (SBP) of <sup>3</sup>150 mm Hg. Be cautious to avoid excessive diastolic lowering.
- Elderly may be particularly responsive to diuretics and dihydropyridine calcium channel blockers.
- Systolic HTN is particularly problematic in the elderly.
- Secondary causes more common in the elderly include sleep apnea, renal disease, renal artery stenosis, and primary aldosteronism.

### ALERT

#### Pseudoresistance

- Inaccurate measurement of BP
  - Cuff too small
  - Patient not at rest; sitting quietly for 5 minutes

- Poor adherence: In primary care settings, this has been estimated to occur in 40-60% of patients with HTN.
- White coat effect: prevalence 20-40%. Do not make clinical decisions about HTN based solely on measurement in the clinic setting. Home BP monitoring and/or ambulatory BP monitoring is more reliable.
- Inadequate treatment

## *EPIDEMIOLOGY*

- Predominant age: In general, HTN has its onset between ages 30 and 50 years. Patients with resistant HTN are more likely to experience the combined outcomes of death, myocardial infarction, congestive heart failure (CHF), stroke, or chronic kidney disease.
- Depending on etiology, age of onset can vary. Age of onset <20 or >50 years increases likelihood of a secondary cause for HTN.
- The strongest predictors for resistant HTN are age (>75 years), presence of left ventricular hypertrophy (LVH), obesity (body mass index [BMI] >30), and high baseline systolic BP. Other predictors include chronic kidney disease, diabetes, living in the southeastern United States, African American race (especially women), and excessive salt intake.

## *Prevalence*

- Prevalence of resistant HTN is unknown. NHANES analysis indicates only 53% of adults are controlled to a BP of <140/90 mm Hg.
- Secondary HTN occurs in about 5-10% of adults with chronic HTN.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Obstructive sleep apnea (OSA): one study diagnosed OSA in 83% of treatment-resistant hypertensives.
- Primary hyperaldosteronism (17-22% of resistant HTN cases)
- Chronic renal disease (2-5% of hypertensives)
- Renovascular disease (0.2-0.7%, up to 35% of elderly, 20% of patients undergoing cardiac catheterization)
- Cushing syndrome (0.1-0.6%)
- Pheochromocytoma (0.04-0.1% of hypertensives)
- Other rare causes: hyperthyroidism, hyperparathyroidism, aortic coarctation, intracranial tumor
- Drug-related causes

- Medications, especially NSAIDs (may also blunt effectiveness of ACE inhibitors), decongestants, stimulants (e.g., amphetamines, attention deficient hyperactivity disorder [ADHD] medications), anorectic agents (e.g., modafinil, ephedra, guarana, ma huang, bitter orange), erythropoietin, natural licorice (in some chewing tobacco), yohimbine, glucocorticoids
  - Oral contraceptives: unclear association; mainly epidemiologic and with higher estrogen pills
  - Cocaine, amphetamines, other illicit drugs; drug and alcohol withdrawal syndromes
- Lifestyle factors: Obesity and dietary salt may negate the beneficial effect of diuretics. Excessive alcohol may cause or exacerbate HTN. Physical inactivity also contributes.

## RISK FACTORS

A recent large cohort study revealed that those with resistant HTN (16.2%) were more likely to be male, Caucasian, older, and diabetic. They were also more likely to be taking  $\beta$ -blockers, calcium channel blockers, and  $\alpha$ -adrenergic blockers compared with other drug classes. Factors predictive of resistant or secondary HTN: female sex, African American race, obesity, diabetes, worsening of control in previously stable hypertensive patient, onset in patients age <20 years or >50 years, lack of family history of HTN, significant target end-organ damage, stage 2 HTN (systolic BP >160 mm Hg or diastolic BP >100 mm Hg), renal disease, and alcohol or drug use (3)[A]

## GENERAL PREVENTION

The prevention of resistant and secondary HTN is thought to be the same as for primary or essential HTN: Adopting a Dietary Approaches to Stop Hypertension (DASH) diet, a low-sodium diet, weight loss in obese patients, exercise, limitation of alcohol intake, and smoking cessation may all be of benefit. Relaxation techniques may be of help, but data are limited.

## DIAGNOSIS

### HISTORY

- Ask or review at every visit: "The Big Four" SANS mnemonic: (i) Salt intake, (ii) Alcohol intake, (iii) NSAID use, (iv) Sleep (author's suggestion, based on reference listed).
- Review home BP readings; consider ambulatory BP monitoring.
- History will vary with etiology of HTN
  - Pheochromocytoma: episodes of headache, palpitations, sweating
  - Cushing syndrome: weight gain, fatigue, weakness, easy bruising,

amenorrhea

- OSA: loud snoring while asleep, daytime somnolence
- Increased intravascular volume: swelling

## PHYSICAL EXAM

- Ensure that the BP is measured correctly. The patient should be sitting quietly with back supported for 5 minutes before measurement. Proper cuff size: bladder encircling at least 80% of the arm. Support arm at heart level. Minimum of two readings at least 1 minute apart. Check BP in both arms. Also check standing BP for orthostasis.
- Attention to findings related to possible etiologies: renovascular HTN: systolic/diastolic abdominal bruit. Pheochromocytoma: diaphoresis, tachycardia. Cushing syndrome: hirsutism, moon facies, dorsal hump, purple striae, truncal obesity. Thyroid disease: enlarged thyroid, tremor, exophthalmos, tachycardia. Coarctation of the aorta: upper limb HTN with decreased or delayed femoral pulses
- Funduscopic exam

## DIAGNOSTIC TESTS & INTERPRETATION

- ECG performed as part of the initial workup; LVH is an important marker of resistant HTN.
- Sleep study if history and physical indicate. The Epworth Sleepiness Scale is recommended.
- Home-based polysomnography has been shown to be accurate in screening for OSA. Overnight oximetry is not helpful.

### *Initial Tests (lab, imaging)*

Initial limited diagnostic testing should include urinalysis, CBC, potassium, sodium, glucose, creatinine, lipids, thyroid-stimulating hormone (TSH), and calcium. 50% of patients with hyperaldosteronism may have normal potassium levels.

- Imaging tests listed are necessary only if history, physical, or lab data indicate.
- Abdominal US: if renal disease is suspected
- MR angiography (MRA) of renal vasculature: Preferred test for renovascular HTN. Sensitive but low specificity. Conventional angiography or CT angiography second line after MRA to look at distal renal artery. Renal arteriography remains the gold standard for renovascular disease.
- Adrenal incidentaloma frequently arises in this era of multiple CT studies. If present in the setting of resistant HTN, consider hyperaldosterone or hyperadrenocorticoid states.

## Follow-Up Tests & Special Considerations

Further testing for primary aldosteronism (PA) may be considered.

- Empiric treatment with an aldosterone inhibitor may be preferable and more clinically relevant: Spironolactone or eplerenone. Amiloride may be more effective in African Americans.
- Plasma aldosterone-to-renin ratio (ARR) is the preferred lab test, *but* the test is difficult to perform and interpret properly. Consult your reference lab and interpret results with caution.
  - Further testing for pheochromocytoma: plasma
  - Other tests to consider for resistant or secondary HTN: 24-hour urine for free cortisol, calcium, parathyroid hormone (PTH), overnight 1-mg dexamethasone suppression test, urine toxicology screen

P.523

## Diagnostic Procedures/Other

Consider 24-hour ambulatory BP monitoring, especially if white coat effect is suspected. Home BP monitor results predict mortality, stroke, and other target organ damage better than office BP. Optimal protocol involves two paired measurements: morning and evening (four measurements) over 4 to 7 days.

- Oscillometric, electronic, upper arm, fully automatic device with memory; average multiple readings over several days
- See <http://www.dableducational.org/> for validated monitors.

## TREATMENT

- Treatment modality depends on etiology of HTN. Please see each etiology listed for information on proper treatment.
- Emphasize Adherence to JNC 8 and/or AHA/ACC guidelines, with emphasis on lifestyle modification. (4,5)[C]
  - Obese patients, African Americans, and elderly may be particularly responsive to diuretics.
  - Tolerance to diuretics may occur: long-term adaptation to thiazides or the òbraking effect. Ó Consider increasing the dose of thiazide or adding an aldosterone inhibitor.
- Treatment specific to certain secondary etiologies
  - Primary aldosteronism: aldosterone receptor antagonist: spironolactone or eplerenone
  - Cushing syndrome: aldosterone receptor antagonist

- OSA: continuous positive airway pressure (CPAP) ± oxygen, surgery, weight loss.
  - Mandibular advancement devices may be equally effective in some patients.
- Nocturnal hypoxia: oxygen supplementation
- Earlier studies had suggested benefit from renal sympathetic denervation, but a recent sham study, SYMPPLICITY HTN-3, was not supportive (6)[B].

## MEDICATION

- Follow treatment guidelines and algorithms by JNC8 and AHA/ACC/CDC, understanding the differences between them (4,5)[C].
- Aldosterone antagonists may offer significant benefit (7,8)[B].
- Central-acting agents (e.g., clonidine) are effective at reducing BP, but outcome data are lacking.

### ALERT

- Agents specific for treatment of HTN emergencies should be initiated under a situation in which immediate BP reduction will prevent or limit end-organ damage (see “Hypertensive Emergencies”).
- Renovascular HTN: Angioplasty is the treatment of choice for fibromuscular dysplasia of a renal artery.
- The recent CORAL study concluded that in patients with atherosclerotic renovascular disease and HTN, renal artery stenting did not improve outcomes over medical therapy alone (9).
- Referral to an HTN specialist or clinic: Retrospective studies indicate improved control rates for patients with resistant HTN referred to special HTN clinics.

### *First Line*

See òHypertension.ó

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

Hospitalization may be necessary for hypertensive urgency or emergency general measures.

**ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

Encourage aerobic activity of 30 min/day, depending on patient condition.

## ***DIET***

- Reduced salt may lower BP.
- Recommend the Mediterranean diet or DASH.

## ***PATIENT EDUCATION***

Home BP monitoring is recommended.

## Codes

**&NA;**

### ICD10

- I15.9 Secondary hypertension, unspecified
- I15.8 Other secondary hypertension
- I15.0 Renovascular hypertension

## Clinical Pearls

**&NA;**

- Onset of HTN in adults >60 years of age is a strong indicator of secondary HTN.
- Common causes of resistant HTN: obstructive sleep apnea, excessive salt intake, medication nonadherence
- Common secondary causes include sleep apnea, renal disease, renal artery stenosis, and primary aldosteronism.
- Home BP monitoring predicts outcomes better than office monitoring of BP.

# Hyperthyroidism

Anup K. Sabharwal, MD, MBA, FACE, CCD

Atil Y. Kargi, MD

## BASICS

Hyperthyroidism or thyrotoxicosis is composed of a spectrum of clinical findings consistent with thyroid hormone excess. The former describes excess from the thyroid gland, whereas the latter can be produced from another source.

## DESCRIPTION

- Graves disease (GD): the most common form; diffuse goiter and thyrotoxicosis are common characteristics. Infiltrative orbitopathy is seen in up to 50% of patients. Infiltrative dermopathy is rare. Autoantibodies are directed at the thyrotropin-stimulating hormone (TSH) receptors.
- Toxic multinodular goiter (TMNG): second most common; most common cause of hyperthyroidism in patients > age 65; patients >40 years, insidious onset, frequent in iodine-deficient areas
- Toxic adenoma (Plummer disease): younger patients, autonomously functioning nodules
- Iodine-induced hyperthyroidism
- Thyroiditis: transient autoimmune process:
  - Subacute thyroiditis/De Quervain: granulomatous giant cell thyroiditis, benign course; viral infections have been involved.
  - Postpartum thyroiditis
  - Drug-induced thyroiditis: amiodarone, interferon- $\alpha$ , interleukin-2, lithium
  - Miscellaneous: thyrotoxicosis factitia, TSH-secreting pituitary tumors, and functioning trophoblastic tumors (1)[B]
- Subclinical hyperthyroidism: suppressed TSH with normal thyroxine ( $T_4$ ); may be associated with osteoporosis and atrial fibrillation
- Thyroid storm: rare hyperthyroidism; fever, tachycardia, gastrointestinal symptoms, CNS dysfunction (e.g., coma); up to 50% mortality

## *Geriatric Considerations*

- Characteristic symptoms and signs may be absent.
- Atrial fibrillation is common when TSH  $<0.1$  mIU/L (2)[A].

## *Pediatric Considerations*

- Neonates and children are treated with antithyroids for 12 to 24 months.
- Radioactive iodine treatment is controversial in patients  $<15$  to 18 years.

## *Pregnancy Considerations*

Propylthiouracil (PTU) is currently the drug of choice during 1st trimester of pregnancy and methimazole (MMI) is preferred in the 2nd and 3rd trimester. Treat with lowest effective dose. Avoid treatment-induced hypothyroidism. Radioiodine therapy is contraindicated.

## **EPIDEMIOLOGY**

- 1.3% of population
- Predominant sex: female  $>$  male (7 to 10:1)
- Predominant age: autoimmune thyroid disease (GD) in 2nd and 3rd decades. TMNG more common in patients  $>40$  years.

## *Incidence*

- Female: 1/1,000
- Male: 1/3,000

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- GD: autoimmune disease
- TMNG: 60% TSH receptor gene abnormality; 40% unknown
- Toxic adenoma: point mutation in TSH receptor gene with increased hormone production
- Thyroiditis:
  - Hashitoxicosis: autoimmune destruction of the thyroid; antimicrosomal antibodies present
  - Subacute/de Quervain thyroiditis: granulomatous reaction; genetic predisposition in specific human leukocyte antigens; viruses, such as coxsackievirus, adenovirus, echovirus, and influenza virus, have been implicated; self-limited course, 6 to 12 months
  - Suppurative: infectious

- Drug-induced thyroiditis: Amiodarone produces an autoimmune reaction and a destructive process. Lithium, interferon- $\alpha$ , and interleukin-2 cause an autoimmune thyroiditis.
- Postpartum thyroiditis: autoimmune thyroiditis that lasts up to 8 weeks and, in 60% of patients, hypothyroidism manifests in the future

## Genetics

Concordance rate for GD among monozygotic twins is 35%.

## RISK FACTORS

- Positive family history, especially in maternal relatives
- Female
- Other autoimmune disorders
- Iodide repletion after iodide deprivation, especially in TMNG

## COMMONLY ASSOCIATED CONDITIONS

- Autoimmune diseases
- Down syndrome
- Iodine deficiency

## DIAGNOSIS

### HISTORY

- Thyrotoxicosis is a hypermetabolic state in which energy production exceeds needs, causing increased heat production, diaphoresis, and even fever.
- Thyrotoxicosis affects several different systems:
  - Constitutional: fatigue, weakness, increased appetite, weight loss
  - Neuropsychiatric: agitation, anxiety, emotional lability, psychosis, coma and poor concentration and memory
  - GI: increased appetite, hyperdefecation
  - Gynecologic: oligomenorrhea, amenorrhea
  - Cardiovascular: tachycardia (most common) and chest discomfort that mimics angina

### Geriatric Considerations

## *PHYSICAL EXAM*

- Adults:
  - Skin: warm, moist, pretibial myxedema (GD only)
  - Head, eye, ear, nose, throat (HEENT): exophthalmos, lid lag
  - Endocrine: hyperhidrosis, heat intolerance, goiter, gynecomastia, low libido, and spider angiomas (males)
  - Cardiovascular: tachycardia, atrial fibrillation, cardiomegaly
  - Musculoskeletal: skeletal demineralization, osteopenia, osteoporosis, fractures
  - Neurologic: tremor, proximal muscle weakness, anxiety and lability, brisk deep tendon reflexes
  - Rarely: thyroid acropathy (clubbing), localized dermopathy
- Children:
  - Linear growth acceleration
  - Ophthalmic abnormalities more common

## *DIFFERENTIAL DIAGNOSIS*

- Anxiety
- Malignancy
- Diabetes mellitus
- Pregnancy
- Menopause
- Pheochromocytoma
- Depression
- Carcinoid syndrome

## *DIAGNOSTIC TESTS & INTERPRETATION*

- 95% have suppressed TSH and elevated free T<sub>4</sub>. Total T<sub>4</sub> and triiodothyronine (T<sub>3</sub>) represent the bound hormone and can be affected by pregnancy and hepatitis (1)[A].

- $T_3$ : elevated, especially in  $T_3$  toxicosis or amiodarone-induced thyrotoxicosis: presence of TSH receptor antibody or thyroid-stimulating immunoglobulin is diagnostic of GD
- Free thyroxine index (FTI): calculated from  $T_4$  and thyroid hormone-binding ratio; corrects for misleading results caused by pregnancy and estrogens
- Inappropriately normal or elevated TSH with high  $T_4$  suspicious for pituitary tumor or thyroid hormone resistance
- Drugs may alter lab results: estrogens, heparin, iodine-containing compounds (including amiodarone and contrast agents), phenytoin, salicylates, steroids (e.g., androgens, corticosteroids)
- Drug precautions: Amiodarone and lithium may induce hyperthyroidism; MMI may cause warfarin resistance.
- Other findings that can occur: anemia, granulocytosis, lymphocytosis, hypercalcemia, transaminase, and alkaline phosphate elevations

### *Initial Tests (lab, imaging)*

- TSH, free  $T_4$ ,  $T_4$ ,  $T_3$ , thyroid-stimulating immunoglobulin (TSI)
- TSH receptor antibodies (TSH-R Abs): The routine assay is the TSH-binding inhibitor immunoglobulin assay (TBII). TSH-R Abs are useful in the prediction of postpartum Graves thyrotoxicosis and neonatal thyrotoxicosis.
- Thyroxine/triiodothyronine ratio: The  $T_4$ -to- $T_3$  ratio may be a useful tool when the iodine uptake testing is not available/contraindicated.  $\div 2\%$  of thyrotoxic patients have  $\text{OT}_3$  toxicosis.
- Nuclear medicine uptake and scanning ( $^{123}\text{I}$  or  $^{131}\text{I}$ ): The reference-range values for 24-hour radioiodine uptake is between 5% and 25%.
- Increased thyroid iodine uptake is seen with TMNG, toxic solitary nodule, and GD.
- GD shows a diffuse uptake and can have a paradoxical finding of high uptake at 4 to 6 hours but normal uptake at 24 hours because of the rapid clearance.
- TMNG will show a heterogeneous uptake, whereas solitary toxic nodule will show a warm or hot nodule.
- In iodine-deficient areas, an increased uptake is associated with low urine iodine levels.

- 
- Causes of thyrotoxicosis with low iodine uptake:

- Acute thyroiditis, thyrotoxicosis factitia, and iodine intoxication with amiodarone or contrast material can cause low-uptake transient thyrotoxicosis. After thyroiditis resolves, the patient can become euthyroid or hypothyroid.
- Iodine loading can cause iodine trapping and decreased iodine uptake (Wolff-Chaikoff effect).
- Thyrotoxicosis factitia: Thyroglobulin levels are low in exogenous intake and high in endogenous production.
- Other extrathyroidal causes include struma ovarii and metastatic thyroid carcinoma.
- Technetium-99m scintigraphy: controversial because it has a 33% discordance rate with radioactive iodine scanning

### *Follow-Up Tests & Special Considerations*

In severe cases, such as thyroid storm, hospitalize until stable, especially if >60 years of age, because of the risk of atrial fibrillation.

### *Diagnostic Procedures/Other*

Neck US will show increased diffuse vascularity in GD.

### *Test Interpretation*

- GD: hyperplasia
- Toxic nodule: nodule formation

## **TREATMENT**

- Decision of which patients to treat and how to treat should be individualized.
- Observation may be appropriate for patients with mild hyperthyroidism (TSH >0.1 or with no symptoms) especially those who are young and with low risk of complications (Afib, osteoporosis).
- Antithyroid medication is contraindicated in patients with thyroiditis. Treatment for subacute thyroiditis is supportive with NSAIDs and  $\beta$ -blockers. Steroids can be used for 2 to 3 weeks (3). GD or TMNG can be managed by either antithyroid medication, RAIT, or thyroidectomy.
- Radioactive iodine therapy (RAIT): most common definitive treatment used in United States for GD and TMNG
- Pretreatment with antithyroid drugs is preferred to avoid worsening thyrotoxicosis after RAIT. MMI is preferred over PTU as pretreatment because of decreased relapse, but it is held 3 to 5

days before therapy (3)[A].

- Usually patients become hypothyroid 2 to 3 months after RAIT; therefore, antithyroid medications are continued after ablation.
- Glucocorticoids: reduce the conversion of active  $T_4$  to the more active  $T_3$ . In Graves ophthalmopathy, the use of prednisone before and after RAIT prevents worsening ophthalmopathy (3)[B].
- Smoking in GD patients is a risk factor for ophthalmopathy, especially after RAIT.
- For GD, due to the chance of remission, 12- to 18-month trial of antithyroid medications may be considered prior to offering RAIT.
- For TMNG, the treatment of choice is RAIT. Medical therapy with antithyroid medications has shown a high recurrence rate. Surgery is considered only in special cases (3)[B].
- For amiodarone-induced thyrotoxicosis (AIT) type I, the treatment is antithyroid drugs and  $\beta$ -blockers. Thyroidectomy is the last option. AIT type II is self-limited but may use glucocorticoids.

## MEDICATION

### First Line

- Antithyroid drugs: MMI and PTU are thionamides that inhibit iodine oxidation, organification, and iodotyrosine coupling. PTU can block peripheral conversion of  $T_4$  to active  $T_3$ . Both can be used as primary treatment for GD and prior to RAIT or surgery (1)[A].
- Duration of treatment: 12 to 18 months; 50-60% relapse after stopping; treatment beyond 18 months did not show any further benefit on remission rate. The most serious side effects are hepatitis (0.1-0.2%), vasculitis, and agranulocytosis; baseline CBC recommended:
  - MMI (preferred): adults: 10 to 15 mg q12-24h; children aged 6 to 10 years: 0.4 mg/kg/day PO once daily
  - PTU: adults (preferred in thyroid storm and 1st trimester of pregnancy): 100 to 150 mg PO q8h, not to exceed 200 mg/day during pregnancy
- $\beta$ -Adrenergic blocker: Propranolol in high doses ( $>160$  mg/day) inhibits  $T_3$  activation by up to 30%. Atenolol, metoprolol, and nadolol can be used.
- Glucocorticoids: reduce the conversion of active  $T_4$  to the more active  $T_3$
- Cholestyramine: anion exchange resin that decreases thyroid hormone reabsorption in the enterohepatic circulation; dose: 4 g QID (1)[B]

- Other agents:
  - Lithium: inhibits thyroid hormone secretion and iodotyrosine coupling; use is limited by toxicity
  - Lugol solution or saturated solution of potassium iodide (SSKI); blocks release of hormone from the gland but should be administered at least 1 hour after thionamide was given; otherwise, acts as a substrate for hormone production (Jod-Basedow effect)
  - RAIT: See "Treatment" section.

## ISSUES FOR REFERRAL

Patients with Graves ophthalmopathy should be referred to an experienced ophthalmologist.

## SURGERY/OTHER PROCEDURES

Thyroidectomy for compressive symptoms, masses, and thyroid malignancy may be performed in the 2nd trimester of pregnancy only.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### Patient Monitoring

- Repeat thyroid tests q3mo, CBC and LFTs on thionamide therapy; continue therapy with thionamides for 12 to 18 months.
- After RAIT, thyroid function tests at 6 weeks, 12 weeks, 6 months, and annually thereafter if euthyroid; TSH may remain undetectable for months even after patient is euthyroid; follow T<sub>3</sub> and T<sub>4</sub>.

#### DIET

Sufficient calories to prevent weight loss

#### PROGNOSIS

Good (with early diagnosis and treatment)

#### COMPLICATIONS

- Surgery: hypoparathyroidism, recurrent laryngeal nerve damage, and hypothyroidism

RAIT: postablation hypothyroidism

- GD: high relapse rate with antithyroid drug as primary therapy
- Graves ophthalmopathy, worsening heart failure if cardiac condition, atrial fibrillation, muscle wasting, proximal muscle weakness, increased risk of cerebrovascular accident (CVA) and cardiovascular mortality

## Codes

&NA;

### ICD10

- E05.90 Thyrotoxicosis, unspecified without thyrotoxic crisis or storm
- E05.20 Thyrotoxicosis w toxic multinod goiter w/o thyrotoxic crisis
- E06.1 Subacute thyroiditis

## Clinical Pearls

&NA;

- Not all thyrotoxicoses are secondary to hyperthyroidism.
- GD presents with hyperthyroidism, ophthalmopathy, and goiter.
- Medical treatment for GD has a high relapse rate after stopping medications.
- Thyroid storm is a medical emergency that needs hospitalization and aggressive treatment.

Serum TSH level may be misleading and remain low in the early period after initiating treatment, even when  $T_4$  and  $T_3$  levels have decreased.
