- Hypertriglyceridemia is a common form of dyslipidemia characterized by an excess fasting plasma concentration of triglycerides (TG).
  - TG are fatty molecules made of glycerols that are esterified by fatty acids at all three hydroxyl groups.
  - They occur naturally in vegetable oils and animal fats.
  - In humans, TG are major sources of dietary energy; they are packaged into chylomicrons and very-low-density lipoproteins.
  - Hypertriglyceridemia is independently associated with cardiovascular disease risk, but the degree to which excess TG cause atherosclerosis is uncertain and debatable.
- Hypertriglyceridemia is a biomarker of risk for premature coronary artery disease in both men and women at levels  $\geq 200$  mg/dL and for pancreatitis at levels  $\geq 1,000$  mg/dL.
- Classifications of TG levels in adults after a 12-hour fast:
  - Normal:  $< 150$  mg/dL (1.7 mmol/L)
  - Borderline to high: 150 to 199 mg/dL
  - High: 200 to 499 mg/dL
  - Very high:  $\geq 500$  mg/dL
  - Divide by 88.5 to convert to millimoles per liter.
- TGs are considered high in children when TG exceed the 95th percentiles for age and sex.
  - 143 mg/dL for adolescent boys, 126 mg/dL for adolescent girls
  - 111 mg/dL for preadolescent boys, 120 mg/dL for preadolescent girls

### EPIDEMIOLOGY

- Predominant gender: male > female

- Predominant race: Hispanic, white > black

## *Prevalence*

- 33% of U.S. population has TG levels  $\geq 150$  mg/dL.
- 1.7% has TG levels  $\geq 500$  mg/dL.
- Highest prevalence at age 50 to 70 years
- The most common genetic syndromes with hypertriglyceridemia are familial combined hyperlipidemia and familial hypertriglyceridemia ( $\approx 1\%$  of general population each).

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Primary
  - Familial
  - Acquired (sporadic)
- Secondary
  - Obesity and overweight
  - Physical inactivity
  - Cigarette smoking
  - Excess alcohol intake
  - Very high carbohydrate diets ( $>60\%$  of total caloric intake)
  - Certain medications
    - Interferon- $\alpha$
    - Atypical antipsychotics
    - $\beta$ -Blockers other than carvedilol
    - Bile acid sequestrants
    - Corticosteroids
    - Oral estrogens
    - Protease inhibitors
    - Raloxifene
    - Retinoic acid

- Tamoxifen
- Thiazides
- Medical conditions
  - Type 2 diabetes mellitus
  - Hypothyroidism
  - Chronic renal failure, nephrotic syndrome
  - Autoimmune disorders (e.g., systemic lupus erythematosus)
  - Paraproteinemias (e.g., macroglobulinemia, myeloma, lymphoma, lymphocytic leukemia)
  - Pregnancy (usually physiologic and transient)

## *Genetics*

- Familial hypertriglyceridemia: autosomal dominant
- Familial dysbetalipoproteinemia: autosomal recessive
- Familial combined hyperlipidemia: unknown

## *RISK FACTORS*

- Genetic susceptibility
- Obesity, overweight
- Lack of exercise
- Diabetes
- Alcoholism
- Certain medications (see ÒEtiology and PathophysiologyÓ)
- Medical conditions (see ÒEtiology and PathophysiologyÓ)

## *GENERAL PREVENTION*

- Weight reduction
- Moderation of dietary fat and carbohydrates
- Regular aerobic exercise

## *COMMONLY ASSOCIATED CONDITIONS*

- Coronary artery disease
- Diabetes mellitus type 2 and insulin resistance
- Dyslipidemias
  - Decreased high-density lipoprotein (HDL) cholesterol
  - Increased low-density lipoprotein (LDL), non-HDL, and total cholesterol
  - Small, dense LDL particles
- Metabolic syndrome (three of the following):
  - Abdominal obesity (waist circumference >40 inches in men, >35 inches in women)
  - TG  $\geq$ 150 mg/dL
  - Low HDL cholesterol (<40 mg/dL in men, <50 mg/dL in women)
  - BP  $\geq$ 130/85 mm Hg
  - Fasting glucose  $\geq$ 100 mg/dL
- Nonalcoholic steatohepatitis (NASH)
- Pancreatitis
- Polycystic ovary syndrome

## DIAGNOSIS

### HISTORY

- Usually asymptomatic
- Patients with chylomicronemia syndrome can have memory loss, headache, vertigo, dyspnea, and paresthesias.
- Pancreatitis: epigastric pain, nausea, and vomiting
- Assess for other cardiac risk factors.
- Family history of coronary artery disease

### PHYSICAL EXAM

- Obesity, overweight (body mass index  $\geq$ 25 kg/m<sup>2</sup>)
- Eruptive cutaneous, tuberous, and striate palmar xanthomas
- Lipemia retinalis

- Epigastric tenderness in pancreatitis
- Hepatomegaly in NASH and chylomicronemia

## *DIFFERENTIAL DIAGNOSIS*

Primary and secondary hypertriglyceridemia

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Serum: turbid with milky supernatant
- Fasting lipid profile (12-hour fast)
  - Routine screening every 5 years beginning at age 35 years for men and age 45 years for women
  - Begin screening earlier in those at higher risk for coronary heart disease.
  - For interpretation, see Description.
- Secondary causes
  - Glycosylated hemoglobin, fasting or postprandial glucose for type 2 diabetes mellitus
  - Creatinine, urinary protein measurement for nephrotic syndrome, renal failure
  - Thyroid-stimulating hormone for hypothyroidism
  - Human chorionic gonadotropin for pregnancy
- Atherosclerosis: cardiac stress imaging, coronary angiography, CT arteriography
- Pancreatitis: CT scan, US of pancreas

### *Follow-Up Tests & Special Considerations*

- Repeat lipid panel after 2 months of therapy.
- High levels of apolipoprotein (APO) B ( $\geq 90$  mg/dL) are a strong predictor of coronary death in patients whose LDL cannot be calculated because of very high TGs. However, evidence for routine clinical use is lacking.

### *Test Interpretation*

- Chylomicronemia syndrome: lipid-laden macrophage (foam cell) infiltration of visceral organs, bone marrow, and skin

- Atherosclerosis
- Pancreatitis

## TREATMENT

### GENERAL MEASURES

- Therapeutic lifestyle changes, first-line interventions for all patients, can reduce TG by as much as 50% (1)[C]:
  - Dietary modifications can reduce TG by 20-50% (see *Diet*).
  - Moderate-intensity physical activity can reduce TG by 20-30%.
  - Weight loss of 5-10% can reduce TG by 20%.
  - Persons with very high TG should abstain from alcohol.
- Search for correctable secondary causes, treat underlying illness, or remove offending drug.
- Improve glycemic control if diabetic.
- Control other cardiac risk factors such as hypertension, diabetes mellitus, and smoking.
- Primary hypertriglyceridemia: Screen other family members.
- Cardiovascular risk reduction through LDL lowering should be prioritized over TG lowering unless patient is at risk for pancreatitis because of very high TG ( $\geq 500$  mg/dL) (1)[C]. Usually outpatient; see *Admission Criteria/Initial Stabilization*.

### MEDICATION

#### *First Line*

- Statins: the most effective agents for reducing cardiovascular risk; primarily affect LDL but also have modest TG-lowering effect; dosing depends on intensity of statin desired based on 10-year cardiovascular risk; 2013 ACC/AHA guidelines recommend initiating therapy for 7.5% 10-year risk and other clinical factors (2)[C]:
  - Atorvastatin (Lipitor): 10 to 80 mg/day
  - Pravastatin (Pravachol): 10 to 80 mg/day
  - Rosuvastatin (Crestor): 5 to 40 mg/day
  - Simvastatin (Zocor): 5 to 40 mg nightly

- Adverse reactions: myalgias, myopathy, rhabdomyolysis (especially if combined with fibrates); contraindicated in pregnancy and lactation
- Fibrates: the most effective agents for reducing TG; used primarily to reduce risk of pancreatitis when TGs very high ( $\geq 500$  mg/dL); have been shown to decrease nonfatal myocardial infarction but not all-cause mortality (1)[C],(3)[A]:
  - Fenofibrate (Tricor, others): 35 to 200 mg daily
  - Gemfibrozil (Lopid): 600 mg BID
  - Adverse reactions: GI upset, hepatotoxicity, cholelithiasis, myalgias, rhabdomyolysis (when combined with a statin), gemfibrozil-warfarin interaction (enhanced anticoagulation)
  - Gemfibrozil should be avoided in combination with statins due to high risk of muscle injury. If combination therapy is needed, use fenofibrate.

## *Second Line*

- Omega-3 fatty acids
  - Lovaza: 4 g daily or 2 g BID
  - Epanova: 2 to 4 g daily (4)[C]
  - Vascepa: 2 g BID with food (5)[C]
  - Safe, well-tolerated but limited outcomes data
- Niacin (6)[A]. Clinical use of niacin should be very limited, as it fails to show outcome benefit in statin users:
  - 1,000 to 3,000 mg IR daily divided BID-TID; 500 to 2,000 mg ER nightly
  - Adverse reactions: flushing, pruritus, peptic ulcer disease, hepatotoxicity, fulminant hepatic necrosis (with ER forms), hyperuricemia and gout, hyperglycemia, and toxic amblyopia
  - Pretreatment with aspirin reduces flushing.

## *ISSUES FOR REFERRAL*

- Hypertriglyceridemia refractory to treatment
- Familial hypertriglyceridemia syndromes

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Acute pancreatitis
- Acute coronary syndrome
- In medical emergencies such as acute hypertriglyceridemic pancreatitis with TG levels >1,000 mg/dL, TG can be lowered rapidly and safely by apheresis or insulin infusion.

## *Discharge Criteria*

Stabilization of acute complicating illness

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

2 months after initiation or modification of therapy (repeat fasting lipid profile)

### *Patient Monitoring*

- Fasting lipid profile q6-12mo
- Maintain TG <1,000 mg/dL to reduce risk of acute pancreatitis (possibly effective, unproven).
- Hepatic transaminases
- Creatine phosphokinase if patient has myalgias

### *DIET*

- Restrict dietary fat to 30% of total caloric intake; restrict further to 15% of caloric intake if TG  $\geq$ 1,000 mg/dL (1)[C].
- Limit carbohydrates (especially simple carbohydrates and sugars) to 60% of total caloric intake.
- Mediterranean-style diet reduces TG 10-15% more than a low-fat diet.
- Increase marine-derived omega-3 polyunsaturated fatty acids (4 g/day reduces TG by 25-30%, dose-response relationship).
- Eliminate trans fatty acids.
- Increase dietary fiber.
- Avoid concentrated sugars such as fructose.
- Moderate alcohol intake (<1 oz/day or complete abstinence if TGs are very high)

# PATIENT EDUCATION

Smoking cessation

## PROGNOSIS

- Good with correction of TG levels
- Patients with primary hypertriglyceridemia usually require lifelong treatment.

## COMPLICATIONS

- Atherosclerosis
- Chylomicronemia syndrome
- Pancreatitis

## Codes

&NA;

### ICD10

E78.1 Pure hyperglyceridemia

## Clinical Pearls

&NA;

- Hypertriglyceridemia is a risk factor for coronary artery disease at levels  $\geq 200$  mg/dL and for pancreatitis at levels  $\geq 1,000$  mg/dL.
- Diet and exercise are first-line interventions for all patients who have hypertriglyceridemia.
- In patients with TG levels  $< 500$  mg/dL, the primary treatment for cardiovascular risk management is statins.
- For patients with TG levels  $\geq 500$  mg/dL, the greatest amount of TG lowering is achieved with fibrates, although magnitude of clinical benefit is uncertain.

# Hypoglycemia, Diabetic

Joseph A. Florence, MD

Emily K. Flores, PharmD, BCPS

## BASICS

### DESCRIPTION

- Abnormally low concentration of glucose in circulating blood of a patient with diabetes mellitus (DM); often referred to as an *insulin reaction*
- Classification includes the following (1)[A]:
  - Severe hypoglycemia: an event requiring assistance of another person to actively administer treatment
  - Documented symptomatic hypoglycemia: an event during which typical symptoms are accompanied by a measured plasma glucose of <70 mg/dL (3.9 mmol/L)
  - Asymptomatic hypoglycemia: an event not accompanied by symptoms but a measured glucose of <70 mg/dL (3.9 mmol/L)
  - Probable symptomatic hypoglycemia: event with symptoms but glucose not tested
  - Pseudohypoglycemia: an event with typical symptoms but glucose  $\geq$ 70 mg/dL (3.9 mmol/L)
- Hypoglycemia is the leading limiting factor in the glycemic management of type 1 diabetes mellitus (T1DM) and type 2 diabetes mellitus (T2DM). Severe or frequent hypoglycemia requires modification of treatment regimens, including higher treatment goals.

### ALERT

Hypoglycemia unawareness

- Major risk factor for severe hypoglycemic reactions
- Most commonly found in patients with longstanding T1DM and children age <7 years

### EPIDEMIOLOGY

#### Incidence

- From the Accord Study, the annual incidence of hypoglycemia was the following (2)[A]:

- 3.14% in the intensive treatment group
  - 1.03% in the standard group
  - Increased risk among women, African Americans, those with less than high school education, aged participants, and those who used insulin at trial entry
- From the RECAP-DM study (3)[A]: Hypoglycemia was reported in 35.8% of patients with T2DM who added a sulfonylurea or thiazolidinedione to metformin therapy during the past year.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Loss of hormonal counterregulatory mechanism in glucose metabolism
- Diet: too little food (skipping or delaying meals), decreased carbohydrate (CHO) intake
- Medication: too much insulin or oral hypoglycemic agent (improper dose, timing, or erratic absorption)
- Exercise/physical activity: unplanned or excessive
- Alcohol consumption
- Vomiting or diarrhea

## *RISK FACTORS*

- Nearly 3/4 of severe hypoglycemic episodes occur during sleep.
- Autonomic neuropathy
- Illness, stress, and unplanned life events
- Duration of DM >5 years, advanced age, renal/liver disease, congestive heart failure (CHF), hypothyroidism, hypoadrenalism, gastroenteritis, gastroparesis (unpredictable CHO delivery)
- Starvation or prolonged fasting
- Alcoholism: Alcohol consumption may increase risk of delayed hypoglycemia, especially if on insulin or insulin secretagogues. Evening consumption of alcohol is associated with an increased risk of nocturnal and fasting hypoglycemia, especially in patients with T1DM.
- Current smokers with T1DM
- Insulin secretagogues: Sulfonylureas (glyburide, glimepiride, glipizide, etc.) and glinide derivatives (repaglinide, nateglinide) stimulate insulin secretion.
- Hypoglycemia is rare in diabetics not treated with insulin or insulin secretagogues.
- Other antidiabetes medications such as glucagonlike peptide-1 (GLP-1) agonist and sodium-glucose cotransporter-2 (SGLT-2) agents carry a lower but present risk of hypoglycemia.

- Severe hypoglycemia is associated with comorbid conditions in patients aged  $\geq 65$  years and in users of a long-acting sulfonylurea.
- Intensive insulin therapy (further lowering A1C from 7% to 6%) is associated with higher rate of hypoglycemia.

### *Geriatric Considerations*

American Geriatric Society Beers criteria recommend avoiding glyburide and chlorpropamide due to their prolonged half-life in older adults and risk for prolonged hypoglycemic episodes. Medications should be dosed for age and renal function.

### *Pediatric Considerations*

Children may not realize when they have hypoglycemia, needing increased supervision during times of higher activity. Children may have higher glycemic goals for this reason. Caregivers should be instructed in use of glucagon (1,4)[A].

### *Pregnancy Considerations*

Hypoglycemia management and avoidance education should be reemphasized and blood glucose monitoring increased due to more stringent glycemic goals and increased risk in early pregnancy.

## **GENERAL PREVENTION**

- Maintain routine schedule of diet (consistent CHO intake), medication, and exercise (4)[A].
- Regular self-monitoring of blood glucose (SMBG), if taking insulin or secretagogue
  - $\geq 3$  times daily testing if multiple injections of insulin, insulin pump therapy, or pregnant diabetic; frequency and timing dictated by needs and treatment goals
  - Particularly helpful for asymptomatic hypoglycemia
- Diabetes treatment and teaching programs (DTTPs) especially for high-risk type 1 patients, which teach flexible insulin therapy to enable dietary freedom
- Hypoglycemia may be prevented with use of insulin analogs, continuous SC insulin infusion (CSII) pumps, and continuous glucose monitoring (CGM) systems.
- If preexercise glucose is  $< 100$  mg/dL and taking insulin or secretagogue, then CHO consumption or reduction in medication may prevent hypoglycemia.

## **COMMONLY ASSOCIATED CONDITIONS**

- Autonomic dysfunction

Neuropathies

- Cardiomyopathies
- Older type 2 diabetics with severe hypoglycemia have a higher risk of dementia.

## DIAGNOSIS

### HISTORY

- Discuss frequency and cause of hypoglycemia (4)[A].
- Symptoms vary considerably between individuals.
- Adrenergic symptoms
  - Hunger, trembling, pallor, sweating, shaking, pounding heart, anxiety
- Neurologic symptoms
  - Dizziness, poor concentration, drowsiness, weakness, confusion, lightheadedness, slurred speech, blurred vision, double vision, unsteadiness, poor coordination
  - Hypoglycemia causes a significant deterioration in reading span and subject-verb agreement, demonstrating that language processing is impaired during moderate hypoglycemia (5)[A].
- Behavioral symptoms
  - Tearfulness, confusion, fatigue, irritability, aggressiveness
- If altered cognition, consider hypoglycemia

### PHYSICAL EXAM

- General: confusion, lethargy
- HEENT: diplopia
- Coronary: tachycardia
- Neurologic: tremulousness, weakness, paresthesias, stupor, seizure, or coma
- Mental status: irritability, inability to concentrate, or short-term memory loss
- Skin: pale, diaphoresis
- End-organ damage: microvascular, macrovascular, ophthalmologic, neurologic, renal

### DIFFERENTIAL DIAGNOSIS

Hypoglycemia not associated with DM may be seen in:

- Chronic alcoholics and binge drinkers
- GI dysfunction causing postprandial hypoglycemia or alimentary reactive hypoglycemia
- Hormonal deficiency states (hormonal reactive hypoglycemia)
- Hypoglycemia of sepsis
- Islet cell tumors
- Factitious hypoglycemia from surreptitious injection of insulin

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Plasma, serum, or whole-blood glucose <70 mg/dL
- SMBG and CGM are especially useful for asymptomatic hypoglycemia (1)[A].
- A hypoglycemic reading from a CGM sensor should be verified by SMBG fingerstick glucose testing prior to treatment (4)[A].
- Suspect hypoglycemic unawareness in T1DM with low/normal HgbA1c (1)[A].
- Chronic hypoglycemia is indicated by low HgbA1c level.
- Disorders that may alter lab results
  - Conditions that affect erythrocyte turnover, such as hemolysis or blood loss, and hemoglobin variants may alter HgbA1c (4)[A].

---

P.529

## **TREATMENT**

### **GENERAL MEASURES**

- Glucose: preferred; any form of CHO that contains glucose should be effective (see Medication section below) (4)[A].
- Glucagon should be prescribed to patients at significant risk of severe hypoglycemia. People in close contact with these individuals should be instructed in using an emergency glucagon kit (4)[A].
- Alpha-glucosidase inhibitors (acarbose, precise) prevent digestion of complex CHOs; therefore, hypoglycemia must be treated with monosaccharides, such as glucose tablets.
- Patients with severe hypoglycemia combined with hypoglycemic unawareness should have

glycemic targets raised to avoid hypoglycemia (4)[A].

- Patients with T1DM should use insulin analogs to reduce hypoglycemia risk (4)[A].
- CGM augmented CSII with automated insulin suspension when blood glucose falls below a threshold value reduces the combined rate of severe and moderate hypoglycemia in T1DM and reduces nocturnal hypoglycemia without increasing A1c levels in patients >16 years old (4,6) [A].

## MEDICATION

- Conscious patients (4)[A]:
  - Glucose (15 to 20 g) is preferred, although any form of CHO may be used.
    - Any sugar-containing food or beverage that can be rapidly absorbed: juice or nondiet soda (4 to 5 oz), candy (5 to 6 pieces of hard candy), or OTC glucose tablets (4 tablets = 16 g CHO)
    - Takes ÷15 minutes for CHOs to be digested and enter bloodstream as glucose
    - Blood glucose value may correct prior to symptoms resolving.
    - Rule of 15: 15 to 20 g CHO (÷60 to 80 calories simple CHO) repeated q15min until blood sugar is  $\geq 70$  mg/dL
  - Once sugar has normalized, a meal or snack should be consumed to prevent recurrence of hypoglycemia.
- Loss of consciousness at home (6)[A]:
  - Administer glucagon
  - IM or SC in the deltoid or anterior thigh
    - Age <6 years and/or weight <20 to 25 kg: 0.50 mg
    - Age  $\geq 6$  years and/or weight >20 to 25 kg: 1 mg
    - May repeat dose in 15 minutes if needed
- In unconscious, with emergency medical personnel present or patient hospitalized (6)[A]:
  - Give 25 g IV 50% dextrose every 5 to 10 minutes until patient awakens.
  - Then, feed orally and/or administer 5% dextrose IV at level that will maintain blood glucose >100 mg/dL.
  - Patients with hypoglycemia secondary to oral hypoglycemics should be monitored for 24 to 48 hours because hypoglycemia may recur after apparent clinical recovery.

- Significant possible interactions:
  - Overtreatment may cause hyperglycemia.
  - Clearance of certain oral hypoglycemics may be prolonged in persons with renal or liver disease.

## *ISSUES FOR REFERRAL*

- Frequent or recurring episodes that do not readily respond to treatment
- Consultant pharmacists in long-term care facilities

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Any doubt of cause
- Expectation of prolonged hypoglycemia (e.g., caused by sulfonylurea drug)
- Inability to drink
- Treatment has not resulted in prompt sensory recovery.
- Seizures, coma, or altered behavior (e.g., ataxia, disorientation, unstable motor coordination, dysphasia) secondary to documented or suspected hypoglycemia

### *Discharge Criteria*

Normoglycemia and risk of severe hypoglycemia is negligible.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Rest until glucose is normal.

### *Patient Monitoring*

SMBG

### *DIET*

- If alcohol consumed, combine with food to reduce risk of hypoglycemia.
- CHO sources high in protein should not be used to treat or prevent hypoglycemia (4)[A].

- Fats may slow absorption of CHOs and may retard and then prolong the acute glycemic response (6)[A].

## **PATIENT EDUCATION**

- Always have access to quick-acting CHO.
- For planned exercise, consider a reduced insulin dose; additional CHOs are needed for unplanned exercise.
- Educate patients and their relatives, close friends, teachers, and supervisors to be aware of DM diagnosis and signs/symptoms of hypoglycemia and treatment.
- Teach SMBG and self-adjustment for insulin therapy, diet control, and exercise regimen.
- Wear medical alert identification bracelet or necklace.

## **PROGNOSIS**

Full recovery usually depends on rapidity of diagnosis and treatment.

### **COMPLICATIONS**

- Coma, seizure, myocardial infarction, stroke (especially in elderly)
- Prolonged or severe hypoglycemia may cause permanent neurologic damage and/or cognitive impairment.
- Children with T1DM have a greater vulnerability to neurologic manifestations of hypoglycemia.

### **ALERT**

The ACCORD trial (adults with T2DM) demonstrated that intensively lowering blood glucose below current recommendations increased the risk of death versus standard treatment strategy (2)[A].

- E13.649 Oth diabetes mellitus with hypoglycemia without coma

# Clinical Pearls

## &NA;

- Address hypoglycemia in every visit with patients at risk.
- Best treatment includes:
  - Patient education and empowerment
  - Frequent SMBG
  - Flexible insulin (or other drug) regimens
  - Regular professional guidance and support
  - Individualized glycemic goals based in part on the risk of hypoglycemia.
- Hypoglycemia unawareness should be recognized and addressed by less aggressive glycemic goals.
- Any form of CHO that contains glucose should be effective, such as sugar-containing food or beverage that can be rapidly absorbed:
  - Using the Rule of 15 is an easy way to teach patients to manage hypoglycemia at home.  
Rule of 15: 15 to 20 g CHO ( $\div$ 60 to 80 calories simple CHO) repeated q15min until blood sugar is  $\geq$ 70 mg/dL.

# Hypoglycemia, Nondiabetic

Matthew A. Silva, PharmD, RPh, BCPS

Pablo I. Hernandez Itriago, MD, MS, FAAFP

## BASICS

### DESCRIPTION

- Hypoglycemia defined by the Whipple triad
  - Low plasma glucose level ( $\leq 60$  mg/dL) with hypoglycemic symptoms that are relieved when glucose is corrected.
  - Occurs commonly in patients with diabetes receiving sulfonylurea or insulins; less commonly in patients without diabetes
- Reactive hypoglycemia occurs in response to a meal, drugs, herbal substances, or nutrients and may occur 2 to 3 hours postprandially or later (1).
  - Symptoms are generally observed with serum glucose  $\leq 60$  mg/dL, lower in patients with hypoglycemic unawareness.
  - Also seen after GI surgery (in association with dumping syndrome in some patients)
- Spontaneous (fasting) hypoglycemia may be associated with primary conditions including hypopituitarism, Addison disease, myxedema, or disorders related to hepatic dysfunction or renal failure (1,2).
  - If hypoglycemia presents as a primary disorder, consider hyperinsulinism and extrapancreatic tumors.

### EPIDEMIOLOGY

#### Incidence

- True incidence is unknown.
- 0.5-8.6% of hospitalized patients  $\geq 65$  years (3,4,5)
  - Asymptomatic in 25% of cases

## Prevalence

True prevalence is unknown:

- Predominant age: older adult
- Predominant sex: female > male

## ETIOLOGY AND PATHOPHYSIOLOGY

- Reactive, postprandial
  - Alimentary hyperinsulinism
  - Meals high in refined carbohydrate
  - Certain nutrients, including fructose, galactose, leucine
  - Glucose intolerance (prediabetes)
  - GI surgery
  - Idiopathic (unknown cause)
- Spontaneous
  - Fasting
  - Alcohol or prescription medication-associated (6) (insulin, sulfonylureas, thiazolidinediones, incretin mimetics, DPP-IV inhibitors,  $\alpha$ -blockers, salicylates, quinine, hydroxychloroquine, fluoroquinolones, doxycycline, sertraline, disopyramide, pentamidine)
  - Nonprescription over-the-counter (OTC) agents, including performance-enhancing agents. Adulterated versions of phosphodiesterase inhibitors and performance-enhancing agents are routinely imported and may contain sulfonylureas and other hypoglycemic agents.
  - Consider medication errors as a source of unexplained hypoglycemia even in patients without diabetes.
  - Surreptitious drug use (self-injection of insulin or ingestion of oral hypoglycemic medications in patients with diabetes)
  - Natural medicines or herbs (bitter melon, caffeine, cassia cinnamon, chromium, fenugreek, ginseng, guarana, mate, stevia, vanadium)
  - Postsurgical (e.g., gastrectomy, Roux-en-Y) hypoglycemia/dumping syndrome
  - Islet cell hyperplasia or tumor (insulinoma)
  - Extrapancreatic insulin-secreting tumor
  - Hepatic disease

- Glucagon deficiency
- Adrenal insufficiency
- Catecholamine deficiency
- Hypopituitarism
- Hypothyroidism
- Eating disorders
- Exercise
- Fever
- Pregnancy
- Renal glycosuria
- Large tumors
- Ketotic hypoglycemia of childhood
- Enzyme deficiencies or defects
- Severe malnutrition
- Sepsis
- Total parenteral nutrition therapy
- Hemodialysis

### *Genetics*

Some aspects may involve genetics (e.g., hereditary fructose intolerance).

### **RISK FACTORS**

Refer to Etiology and Pathophysiology.

### **GENERAL PREVENTION**

- Follow dietary and exercise guidelines.
- Patient recognition of early symptoms and knowledge of corrective action

### *Pediatric Considerations*

- Usually divided into two syndromes
  - Transient neonatal hypoglycemia

- Hypoglycemia of infancy and childhood
- Screening infants for hypoglycemia is appropriate when pregnancy was complicated by maternal diabetes.
- Cases of hypoglycemia observed in children taking propranolol for infantile hemangioma
- Associated with indomethacin when treating patent ductus arteriosus

### *Geriatric Considerations*

- More likely to have underlying disorders or be caused by medications
- Iatrogenic hypoglycemia is common in the hospitalized elderly with renal insufficiency.

### **COMMONLY ASSOCIATED CONDITIONS**

- Severe liver disease; alcoholism
- Addison disease; adrenocortical insufficiency
- Myxedema
- Malnutrition (patients with renal failure)
- GI surgery
- Panhypopituitarism
- Insulinoma

## **DIAGNOSIS**

### **HISTORY**

- CNS (neuroglycopenic) symptoms predominate with gradual glucose reduction:
  - Headache
  - Confusion
  - Light-headedness
  - Fatigue and weakness
  - Visual disturbances
  - Changes in personality
- Adrenergic symptoms: more prominent in acute drop in glucose

- Anxiety
- Tremulousness
- Dizziness
- Diaphoresis
- Warmth/flushing
- Heart palpitations
- GI symptoms
  - Hunger
  - Nausea
  - Belching

## *PHYSICAL EXAM*

- CNS (neuroglycopenic) symptoms predominate with gradual glucose reduction:
  - Convulsions
  - Coma
  - Hypotension
- Adrenergic symptoms: more prominent in acute drop in glucose
  - Tremulousness
  - Diaphoresis
  - Warmth/flushing
  - Heart palpitations

## *DIFFERENTIAL DIAGNOSIS*

CNS disorders

- Psychogenic
- Pseudohypoglycemia: Symptoms of hypoglycemia or self-diagnosis in patients in whom low blood glucose may not be detectable and may be impossible to convince that they do not suffer from hypoglycemia after all tests are found to be normal.

## *DIAGNOSTIC TESTS & INTERPRETATION*

*Initial Tests (lab, imaging)*

- Blood glucose  $\geq 45$  mg/dL ( $\geq 2.5$  mmol/L) when symptomatic followed by symptom resolution with feeding (2)[C]
- Plasma glucose overnight fasting:  $\geq 60$  mg/dL ( $\geq 3.33$  mmol/L); confirm on  $\geq 2$  occasions (2)[C].
- Plasma glucose 72-hour fasting:
  - $\geq 45$  mg/dL ( $\geq 2.5$  mmol/L) for females;  $\geq 55$  mg/dL ( $\geq 3.05$  mmol/L) for males; fasting may be ended when Whipple triad is achieved or hypoglycemia is demonstrated (2)[C].
- Abdominal CT to rule out abdominal tumor

### *Follow-Up Tests & Special Considerations*

- Misinterpretation of glucose tolerance tests may lead to misdiagnosis of hypoglycemia;  $\geq 1/3$  of normal patients have hypoglycemia, with or without symptoms, during the 4-hour glucose tolerance test. These patients may be at future risk for type 2 diabetes.
- C-peptide measurement (2)[C]
- Check liver studies, serum insulin, adrenocorticotrophic hormone (ACTH), and cortisol. Serum insulin should be suppressed when glucose is  $< 60$  mg/dL.
- Serum  $\beta$ -hydroxybutyrate (2)[C]
- Insulin radioimmunoassay: Elevated insulin levels suggest islet cell hyperplasia or tumor.
- Drugs that may alter lab results: Many drugs can affect glucose levels; refer to drug or laboratory reference.

P.531

### *Diagnostic Procedures/Other*

- For definitive diagnosis, patient should have
  - Documented low glucose levels
  - Symptoms when glucose levels are low
  - Evidence that symptoms are relieved specifically by ingestion of sugar or other food
  - Identification of the specific type of hypoglycemia
- Serum  $\beta$ -hydroxybutyrate  $< 2.7$  mg/dL in the presence of high serum insulin, C-peptide, and low serum glucose suggests excessive insulin production (2)[C].

## **TREATMENT**

## GENERAL MEASURES

- Outpatient except for severe cases; may also be inpatient for testing
- Oral carbohydrate for alert patient without drug overdose (2 to 3 tbsp of sugar in glass of water or fruit juice, 1 to 2 cups of milk, piece of fruit, or several soda crackers)
- If unable to swallow: Use glucagon IM or SC.
- If caused by medication or nutrients: Avoid or control causative agents.
- If triggered by meals: Try high-protein diet with carbohydrate restriction.
- Nonhypoglycemic hypoglycemia or pseudohypoglycemia
  - Many patients (often women aged 20 to 45 years) present with diagnosis of reactive hypoglycemia (self-diagnosed or misinterpretation of tests).
  - Symptoms may pertain to chronic fatigue and somatic complaints (stress often plays a role in these symptoms).
  - Management difficult; listening is important. Try 120-g carbohydrate diet.
  - Counseling may be useful for stress and other problems.

## MEDICATION

- Once diagnosis is established, begin therapy appropriate for underlying disorder.
- If unable to swallow: glucagon 1 mg (1 unit) IM or SC. If no response, give IV bolus of 25 to 50 g of 50% glucose solution followed by continuous infusion until patient able to take by mouth.
- Postsurgical gastrectomy patients unresponsive to dietary changes may benefit from propantheline, psyllium, fiber, or oat bran, which delays gastric emptying.
- Insulinoma

## SURGERY/OTHER PROCEDURES

If islet cell tumor (insulinoma) or other insulin-secreting tumor, surgery is treatment of choice; if inoperable, diazoxide may relieve symptoms (1)[C].

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

Hypoglycemia unresponsive to oral intake

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Exercise routine or daily activity may need to be reevaluated.
- Patients with recurrent hypoglycemia should have glucose source at hand for immediate ingestion during symptoms.

### *Patient Monitoring*

- Depends on type and severity of symptoms and treatment of underlying cause
- Hypoglycemia from sulfonylureas can last for hours to days depending on half-life and renal function.

### *DIET*

- High protein, high fiber, complex carbohydrates from multigrain, and whole foods in moderation
- Frequent small feedings (six daily)
- Avoid fasting.

### *PATIENT EDUCATION*

- Dietary instruction
- Counseling for stress, if appropriate
- Recognition of early symptoms of hypoglycemia and how to take corrective action

### *PROGNOSIS*

Favorable, with appropriate treatment

### **COMPLICATIONS**

- Insulinoma: If tumor identified and removed, some surgical risk is involved.
- Organic brain syndrome: may occur with extensive, prolonged hypoglycaemia

## Codes

**&NA;**

### ICD10

- E16.2 Hypoglycemia, unspecified
- E16.1 Other hypoglycemia
- P70.4 Other neonatal hypoglycemia

## Clinical Pearls

**&NA;**

- Symptoms coincide with low blood glucose levels and resolve with PO/IV glucose or glucagon.
- Avoid known agents/nutrients that trigger hypoglycemia.
- Treat underlying cause.

# Hypokalemia

Joanne Dannenhoffer, MD

Frank J. Domino, MD

## BASICS

### DESCRIPTION

Hypokalemia is defined as a serum potassium concentration  $<3.5$  mEq/L (normal range, 3.5 to 5.0 mEq/L).

- Mild hypokalemia (serum potassium 3.0 to 3.5 mEq/L)
- Moderate hypokalemia (serum potassium 2.5 to 3.0 mEq/L)
- Severe hypokalemia (serum potassium  $<2.5$  mEq/L)

### EPIDEMIOLOGY

Predominant sex: male = female

#### Incidence

- Electrolyte abnormality is commonly encountered in clinical practice and in the elderly (1).
- Found in  $>20\%$  of hospitalized patients (when defined as potassium  $<3.6$  mEq/L)
- Higher incidence (5-20%) in individuals with eating disorders
- $>10\%$  of inpatients with alcoholism
- Higher incidence in patients with AIDS
- Higher incidence in patients receiving diuretics
- Associated risk after bariatric surgery

### ETIOLOGY AND PATHOPHYSIOLOGY

Most common causes:

- Decreased intake: deficient diet in alcoholics and elderly; anorexia nervosa
- GI loss: vomiting, diarrhea, nasogastric tubes, laxative abuse, fistulas, villous adenoma, ureterosigmoidostomy, malabsorption, chemotherapy, radiation enteropathy, bulimia

- Intracellular shift of potassium: metabolic alkalosis, insulin excess,  $\beta$ -adrenergic catecholamine excess (acute stress,  $\beta_2$ -agonists), hypokalemic periodic paralysis, intoxications (theophylline, caffeine, barium, toluene)
- Renal potassium loss
  - Drugs: diuretics (especially loop and thiazides), amphotericin B, aminoglycosides
  - Mineralocorticoid excess states: primary hyperaldosteronism; secondary hyperaldosteronism (congestive heart failure [CHF], cirrhosis, nephrotic syndrome, malignant hypertension, renin-producing tumors); renovascular hypertension; Bartter syndrome; Gitelman syndrome; congenital adrenogenital syndromes; exogenous mineralocorticoids (glycyrrhizic acid in licorice, carbenoxolone, steroids in nasal sprays); Liddle syndrome; vasculitis
  - Osmotic diuresis (e.g., poorly controlled diabetes)
  - Renal tubular acidosis (type I and II)
  - Magnesium depletion
- Glucocorticoid excess states: Cushing syndrome, exogenous steroids, ectopic adrenocorticotrophic hormone production, 11- $\beta$ -hydroxysteroid dehydrogenase deficiency, refeeding syndrome

## Genetics

Some rare, familial disorders can cause hypokalemia.

- Familial hypokalemic periodic paralysis: hypokalemia after a high-carbohydrate or high-sodium meal or after exercise
- Congenital adrenogenital syndromes
- Liddle syndrome: increases  $K^+$  secretion
- Familial interstitial nephritis

## GENERAL PREVENTION

When initiating a diuretic, especially loop and thiazide diuretics, advise patients to increase their dietary potassium intake (see "Diet").

## COMMONLY ASSOCIATED CONDITIONS

- Acute GI illnesses with severe vomiting or diarrhea
- Increased risk of cardiac arrhythmias; atrial fibrillation (2,3)
- Hypokalemia is a predictor of development of severe alcohol withdrawal syndrome (SWAS) (4).

## DIAGNOSIS

- Patients with hypokalemia often have no symptoms, especially if the hypokalemia is mild (serum potassium 3.0 to 3.5 mEq/L).
- Neuromuscular (most prominent manifestations)
  - Skeletal muscle weakness (proximal > distal muscles, lower limbs > upper limbs) may range from mild weakness to total paralysis, including respiratory muscles; it may lead to rhabdomyolysis and/or respiratory arrest in severe cases.
  - Smooth muscle involvement may lead to GI hypomotility, producing ileus and constipation.
- Cardiovascular
  - Ventricular arrhythmias; higher risk if underlying CHF, left ventricular failure (LVF), cardiac ischemia
  - Increased risk of atrial fibrillation
  - Hypotension
  - Cardiac arrest
- Renal: polyuria, polydipsia, nocturia owing to impaired ability to concentrate, myoglobinuria
- Metabolic: hyperglycemia

## HISTORY

Muscle weakness, hypotension, vomiting, diarrhea, polyuria, polydipsia

## PHYSICAL EXAM

Decreased skin turgor in dehydration, hypotension, orthostasis, pulmonary congestion/rales, peripheral edema in heart failure

## DIFFERENTIAL DIAGNOSIS

- Spurious hypokalemia occurs when blood with high WBC count ( $>100,000/\text{mm}^3$ ) is allowed to stand at room temperature (WBCs extract potassium from plasma).
- Thyrotoxicosis

## DIAGNOSTIC TESTS & INTERPRETATION

- Serum potassium  $<3.5$  mEq/L ( $<3.5$  mmol/L)

- Disorders that may alter lab results: leukemia and other conditions with high WBCs

## *Initial Tests (lab, imaging)*

- EKG
- If source of potassium loss not likely to be medications or GI tract: serum electrolytes, urinary potassium
- Calculate plasma anion gap normal (anion gap =  $\text{Na} - [\text{Cl} + \text{HCO}_3]$ ); normal values,  $12 \pm 4$  mEq/L. Must correct calculated anion gap for hypoalbuminemia. Increase calculated anion gap by 2.5 mEq/L for each 1 g/dL decrease in albumin  $<4$  g/dL.
- CT scan of adrenal glands if there is evidence of mineralocorticoid excess

## *Follow-Up Tests & Special Considerations*

- If excessive renal potassium loss ( $>20$  mEq/day) and hypertension, plasma renin and aldosterone levels should be determined to differentiate adrenal from nonadrenal causes of hyperaldosteronism. If hypertension is absent and the patient is acidotic, renal tubular acidosis should be considered.
- If hypertension is absent and serum pH is normal to alkalotic
  - High urine chloride ( $>10$  mEq/day [ $>10$  mmol/day]) $\rightarrow$ diuretics or Bartter syndrome
  - Low urine chloride ( $<10$  mEq/day [ $<10$  mmol/day]) $\rightarrow$ GI losses likely
- ECG
  - Hypokalemia increases the myocyte resting potential, which increases the refractory period; this can lead to arrhythmias.
  - Flattening or inversion of T waves
  - Increased prominence of U waves (small, positive deflection after T wave, best seen in  $V_2$  and  $V_3$ )
  - Depression of ST segment
  - Ventricular ectopia

## *Test Interpretation*

In severe hypokalemia, necrosis of cardiac and skeletal muscle

## TREATMENT

### GENERAL MEASURES

- Underlying cause of hypokalemia should be identified.
- For asymptomatic patients treated with oral replacement, outpatient follow-up is sufficient.
- Patients with cardiac manifestations require IV replacement with cardiac monitoring in an intensive care setting.

P.533

### MEDICATION

- Nonemergent conditions (serum potassium  $>2.5$  mEq/L [ $>2.5$  mmol/L], no cardiac manifestations)
  - Oral therapy preferred: 40 to 120 mEq/day (40 to 120 mmol/day) in divided doses usually is adequate.
  - IV potassium should be given only when oral administration is not feasible (e.g., vomiting, postoperative state). Rate should not exceed 10 mEq/hr, and concentration should not exceed 40 mEq/L. Up to 40 mEq in 100 mL over 1 hour can be given safely through a central venous line. The patient's cardiac rhythm should be closely monitored.
  - Potassium chloride is suitable for all forms of hypokalemia.
  - Other potassium salts may be indicated if a coexisting disorder is present: potassium bicarbonate or bicarbonate precursor (gluconate, acetate, or citrate) in metabolic acidosis or phosphate in phosphate deficiency
- Emergent situations (serum potassium  $<2.5$  mEq/L [ $<2.5$  mmol/L], arrhythmias), IV replacement: Rate of administration should not exceed 20 mEq/hr (20 mmol/hr); maximum recommended concentration, 60 mEq/L (60 mmol/L) of saline for peripheral administration. Administration through central venous lines preferred for rates above 20 mEq/hr.
- Check serum magnesium and replace, if needed; cannot adequately replace potassium in a setting of low magnesium.
- Precautions
  - Any form of potassium replacement carries the risk of hyperkalemia.
  - Serum potassium should be checked more frequently in groups at higher risk: the elderly, diabetic patients, and patients with renal insufficiency.
  - Patients receiving digitalis and patients with diabetic ketoacidosis in whom intracellular shift

in potassium is expected after insulin therapy is initiated must have more aggressive replacement.

- Significant possible interactions: Concomitant administration of potassium-sparing diuretics (spironolactone, triamterene, amiloride, ACE inhibitors) magnifies risk of hyperkalemia.

## *Geriatric Considerations*

May need to correct magnesium depletion

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Patients receiving IV therapy should have cardiac monitoring and serum potassium level checked frequently (q4-6h).
- Patients requiring potassium supplements should have serum potassium studied at intervals and magnesium level dictated by clinical judgment and patient compliance (5)[C].

#### *DIET*

In patients with mild hypokalemia (potassium, 3.0 to 3.5 mEq/L [3.0 to 3.5 mmol/L]) not caused by GI losses, dietary supplementation may be sufficient; potassium-rich foods include oranges, bananas, cantaloupes, prunes, raisins, dried beans, dried apricots, and squash.

### *PATIENT EDUCATION*

- Instructions for appropriate diet
- If potassium supplementation is necessary, stress the need for compliance.

### *PROGNOSIS*

- Associated with higher morbidity and mortality because of cardiac arrhythmias
- Ease of correction of hypokalemia and need for prolonged treatment rest on the primary cause; if it can be eliminated (e.g., resolution of diarrhea, discontinuation of diuretics, removal of adrenal tumor), hypokalemia can be expected to resolve and no further treatment is indicated.

## **COMPLICATIONS**

Hyperkalemia can occur during the course of treatment.

- Increased risk of digoxin toxicity
- Increased risk of atrial fibrillation (2,3)[B]

## See Also

&NA;

- Hyperkalemia
- Algorithm: Hypokalemia

## Codes

&NA;

### ICD10

E87.6 Hypokalemia

## Clinical Pearls

&NA;

- In patients without heart disease, a low potassium level will rarely cause cardiac disturbances. In an otherwise healthy patient, gentle repletion using oral potassium or an increase in potassium-rich foods should be adequate.
- In patients with cardiac ischemia, heart failure, or left ventricular hypertrophy, even mild to moderate hypokalemia can cause arrhythmias. These patients should receive potassium repletion as well as cardiac monitoring.
- To safely prevent hypokalemia in diabetic and renal insufficiency patients, ensure adequate

dietary potassium intake with foods rich in potassium, including spinach, tomatoes, broccoli, squash, potatoes, bananas, cantaloupe, and oranges. Avoid potassium-sparing diuretics, if possible.

- Uncorrected hypomagnesemia can hinder the correction of hypokalemia. Check magnesium levels and replete as necessary.

# Hyponatremia

Ruben Peralta, MD, FACS

## BASICS

### DESCRIPTION

- Hyponatremia is a plasma sodium (Na) concentration of  $<135$  mEq/L. Hyponatremia itself does not provide information about the total body water state of the patient. Patients with hyponatremia may be fluid overloaded, hypovolemic, or euvolemic.
- System(s) affected: endocrine/metabolic

### EPIDEMIOLOGY

#### Incidence

- Most common electrolyte disorder seen in the general hospital population
- Predominant age: all ages
- Predominant sex: male = female

#### Prevalence

2.5% of hospitalized patients

#### Geriatric Considerations

The elderly have lower total body water, a decreased thirst mechanism, and decreased urinary concentrating ability; their kidneys are less responsive to antidiuretic hormone (ADH), and they show decreased renal mass, renal blood flow, and glomerular filtration rate, making them at higher risk for hyponatremia.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Hypovolemic hyponatremia: Decrease in total body water and greater decrease in total body Na; decreased extracellular fluid volume; orthostatic hypotension and other changes consistent with hypovolemia are present.
- Euvolemic hyponatremia: Increase in total body water with normal total body Na; extracellular fluid volume is minimally to moderately increased but with no edema.

- Hypervolemic hyponatremia: Increase in total body Na and greater increase in total body water; extracellular fluid increased markedly; edema is present.
- Redistributive hyponatremia: shift of water from intracellular compartment to extracellular compartment with resulting dilution of Na; total body water and total body Na unchanged; occurs with hyperglycemia
- Pseudohyponatremia: dilution of aqueous phase by excessive proteins, glucose, or lipids; total body water and total body sodium unchanged; occurs in hypertriglyceridemia or multiple myeloma
- Low Na creates an osmotic gradient between plasma and cells and fluid shifts into cells, causing edema and increased intracranial pressure.
- Hypovolemic hyponatremia: extrarenal loss of sodium (Na <30 mmol/L in urine)
  - GI loss: vomiting, diarrhea
  - Third spacing: peritonitis, pancreatitis, burns, rhabdomyolysis
  - Skin loss: burns, sweating, cystic fibrosis
  - Heat-related illnesses
- Hypovolemic hyponatremia: renal loss of sodium (Na >30 mmol/L in urine)
  - Cerebral salt wasting syndrome
  - Adrenal pathology (e.g., Addison disease, hemorrhage, tuberculosis)
  - Diuretics
  - Osmotic diuresis
- Euvolemic hyponatremia (Na >30 mmol/L in urine)
  - Hypothyroidism
  - Hypopituitarism or other cause of glucocorticoid deficiency
  - Medications (e.g., carbamazepine, clofibrate, cyclosporine, levetiracetam, opiates, oxcarbazepine, phenothiazines, SSRIs, tricyclic antidepressants, vincristine) (1)
  - Primary polydipsia
  - Syndrome of inappropriate antidiuretic hormone secretion (SIADH)
  - Iatrogenic (e.g., excess hypotonic IV fluids)
- Hypervolemic hyponatremia (Na <30 mmol/L in urine, except chronic renal failure)
  - Nephrotic syndrome

- Cirrhosis
- Congestive heart failure (CHF)
- Chronic renal failure
- Redistributive hyponatremia
  - Hyperglycemia
  - Mannitol infusion
  - Hypertriglyceridemia
- Multiple myeloma

## *Genetics*

- Polymorphisms have been demonstrated.
- Mutations have been associated with nephrogenic syndrome of inappropriate antidiuresis (NSIAD; SIADH).

## **GENERAL PREVENTION**

Depends on underlying condition

## **COMMONLY ASSOCIATED CONDITIONS**

- Hypothyroidism
- Hypopituitarism
- Adrenocortical hormone deficiency
- HIV patients
- SIADH is associated with cancers, pneumonia, tuberculosis, encephalitis, meningitis, head trauma, cerebrovascular accident, HIV infection.
- Acute neurologic patients, brain injury
- Marathon runners in hot environments

## **DIAGNOSIS**

- Symptoms related to the rate of fall in serum Na and the degree of hyponatremia
- Mild (130 to 135 mEq/L): usually asymptomatic

- Moderate (120 to 130 mEq/L): nausea, vomiting, malaise
- Severe: (115 to 120 mEq/L): headache, lethargy, restlessness, disorientation
- Severe/rapid decreases can cause seizure, coma, and respiratory arrest and may be fatal.
- Other signs and symptoms: weakness, muscle cramps, anorexia, hiccups, depressed deep tendon reflexes, hypothermia, positive Babinski responses, cranial nerve palsies, orthostatic hypotension

## *PHYSICAL EXAM*

- Volume status: skin turgor, jugular venous pressure, heart rate, orthostatic BP
- Exam for underlying illness: signs of CHF, cirrhosis, hypothyroidism

## *DIFFERENTIAL DIAGNOSIS*

See ÒEtiology and Pathophysiology.Ó

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Comprehensive metabolic profile (BUN, creatinine, glucose, electrolytes, liver function studies, etc.)
- Thyroid-stimulating hormone (TSH)
- Lipid panel
- Serum osmolality
- Urine sodium and osmolality
- Chest x-ray to rule out pulmonary pathology if SIADH is diagnosed

### *Follow-Up Tests & Special Considerations*

- CT scan of head if pituitary problem is suspected or if SIADH from CNS problem is suspected
- Interpretation of labs: Suspect hypovolemic hyponatremia.
  - Plasma osmolality is low.
  - BUN-to-Cr ratio > 20:1
  - If urine Na >20 mEq/L (>20 mmol/L): renal loss
  - If urine Na <10 mEq/L (<10 mmol/L): extrarenal loss

- Serum potassium  $>5$  mEq/L ( $>5$  mmol/L): Consider mineralocorticoid deficiency.
- Interpretation of labs: Suspect euvolemic hyponatremia.
  - Plasma osmolality low
  - BUN-to-Cr ratio  $< 20:1$
  - Urine Na  $>20$  mEq/L ( $>20$  mmol/L)
  - TSH to rule out hypothyroidism
  - Consider 1-hour cosyntropin-stimulation test to rule out adrenal insufficiency.
- Interpretation of labs: hypervolemic hyponatremia
  - Plasma osmolality is low.
  - Urine Na  $<10$  mEq/L ( $<10$  mmol/L) in nephrotic syndrome, CHF, cirrhosis
  - Urine Na  $>20$  mEq/L ( $>20$  mmol/L) in acute and chronic renal failure
- Redistributive hyponatremia
  - Plasma osmolality is normal or high.
  - Glucose or mannitol levels are elevated.
- Pseudohyponatremia
  - Plasma osmolality is normal.
  - Triglyceride, glucose, or protein levels are elevated.

## TREATMENT

### GENERAL MEASURES

- Assess all medications patient is taking.
- Institute seizure precautions.

### MEDICATION

#### ALERT

Rapid correction of severe symptomatic hyponatremia has been associated with central pontine myelinolysis, a neurologic disorder in which loss of myelin and supportive structures in pons and occasionally in other areas of the brain occurs

(2)[C]. This results in irreversible injury. Symptoms are apparent 2 to 6 days after injury and include seizure, coma, spastic paraparesis, dysarthria, and dysphagia.

- Treatment tailored to clinical situation: The degree of hyponatremia, how rapidly the hyponatremia developed, and whether the patient is symptomatic influence the urgency of correction. Some general principles apply
  - Expected change in serum Na with selected infusates:  $\Delta \text{Na} = \frac{(\text{infusate Na} - \text{serum Na}) \times (\text{infusate K} - \text{serum K})}{\text{TBW} + 1}$  where TBW = a coeff  $\times$  weight (wt) as in the following text:

**Table 1. Total Body Water**

Children	0.6 $\times$ weight
Women	0.5 $\times$ weight
Men	0.6 $\times$ weight
Elderly women	0.45 $\times$ weight
Elderly men	0.5 $\times$ weight

- Formula to determine correction available at <http://www.medcalc.com/sodium.html>
- Asymptomatic, euvolemic patients can be treated with fluid restriction; the underlying cause also must be addressed.
- For severely hyponatremic/symptomatic patients, it is generally considered safe to increase the serum Na by 0.6 to 2 mEq/L/hr, not to exceed 8 mEq/24 hr.
- For mild to moderate hyponatremia, use isotonic saline solution (0.9%). For moderate to severe hyponatremia, consider specialist consultation for use of hypertonic saline (3%) via central line access at a rate of 1 to 2 mL/kg body weight/hr; increasing serum sodium levels by 0.5 mmol/L/hr and monitoring frequently the plasma sodium level (~q2h).
- In patients with severe hyponatremia (euvolemic and hypervolemic state) who do not respond to the above-mentioned approach, consider the use of vasopressin V2-receptor antagonists, such as tolvaptan or conivaptan (3)[A].

- Treat underlying condition: heart failure, cirrhosis, and so forth.
- Chronic hyponatremia resulting from SIADH: demeclocycline (inhibits ADH action at the collecting duct) if fluid restriction alone is not effective
  - Contraindication: can cause nephrotoxicity in patients with liver disease
  - In doses of 600 to 1,200 mg/day, the drug produces a nephrogenic diabetes insipidus.
  - Significant possible interactions: oral anticoagulants, oral contraceptives, penicillin

## **ALERT**

Caution: If severe, consider hypertonic saline (3% Na chloride) with central line access, exercise extreme caution, and monitor serum Na as frequently as q1-2h.

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

- Admission is mandatory if the patient has acute hyponatremia or is symptomatic; acute hyponatremia (developing over <48 hours) carries the risk of cerebral edema.
- Admission is advised if patient is asymptomatic and has a serum Na <125 mEq/dL.

## **ONGOING CARE**

### ***DIET***

- Euvolemic hyponatremia: Restrict water to 1 L/day.
- Hypervolemic hyponatremia: water and Na restriction

### ***PROGNOSIS***

- In hospitalized patients, hyponatremia is associated with an elevated risk of adverse clinical outcomes and higher mortality (4,5)[B].
- Recently, in community-dwelling, middle-aged, and elderly adults, mild hyponatremia has been shown to be an independent predictor of death.
- Associated with poor prognosis in patients with acute pulmonary embolism
- Associated with poor prognosis in patients with liver cirrhosis and those waiting for liver transplant; it is associated with significant postop risk and short-term graft loss.

## COMPLICATIONS

- Occult tumor may present if SIADH is identified.
- Hypervolemia if saline is used
- Osmotic demyelination (central pontine and extrapontine irreversible myelinolysis) (2,6)[C]
- Hyponatremia is the cause in 30% new onset seizures in intensive care settings.
- Chronic hyponatremia is associated with increased odds of osteoporosis.

&NA;

Algorithm: Hyponatremia

## Codes

&NA;

### ICD10

E87.1 Hypo-osmolality and hyponatremia

## Clinical Pearls

&NA;

- Alcohol-dependent individuals with vitamin deficiencies, elderly women taking thiazide diuretics, and people with hypokalemia or burns are at increased risk of central pontine myelinolysis. A longer duration of hyponatremia is also a risk factor.
- Bronchogenic carcinoma, pancreas, duodenal, prostate, thymoma, lymphoma, and mesothelioma are neoplastic diseases associated with SIADH.
- Formulas have been developed (Adroque and Madias) for safe correction of hyponatremia and are available online (see <http://www.medcalc.com/sodium.html>).

# Hypoparathyroidism

Christina Kelly, MD, FAAFP

## BASICS

### DESCRIPTION

- Deficient secretion of parathyroid hormone (PTH)
- Usually asymptomatic
- Acute hypoparathyroidism: tetany that is mild (muscle cramps, peri-oral numbness, paresthesias of hands and feet) or severe (carpopedal spasm, laryngospasm, heart failure, seizures, stridor)
- Chronic: lethargy, anxiety/depression, urolithiasis and renal impairment, dementia, blurry vision from cataracts or keratoconjunctivitis, parkinsonism or other movement disorders, mental retardation, dental abnormalities, and dry, puffy, coarse skin
- System(s) affected: endocrine/metabolic, musculoskeletal, nervous, ophthalmologic, renal

### Pediatric Considerations

- May occur in premature infants
- Neonates born to hypercalcemic mothers may experience suppression of developing parathyroid glands.
- Congenital absence of parathyroids
- May appear later in childhood as autoimmune or APS-1

### Geriatric Considerations

Hypocalcemia is fairly common in elderly; however, rarely secondary to hypoparathyroidism

### Pregnancy Considerations

- Use of magnesium as a tocolytic may induce functional hypoparathyroidism.
- For women with hypoparathyroidism, calcitriol requirements decrease during lactation.

### EPIDEMIOLOGY

More common in women; affects all ages

## *Incidence*

Most common after surgical procedure of the anterior neck. Transient hyperparathyroidism is seen after 6.9-46% of thyroidectomies, whereas permanent hypoparathyroidism, 0.9-1.6% at experienced centers.

## *Prevalence*

Wide variation. Autosomal dominant hypocalcemia with hypercalciuria (ADHH): 1/70,000 typically in infancy with hypocalcemic seizures

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- PTH is involved in the control of serum-ionized calcium levels:
  - Mobilizes calcium and phosphorus from bone stores
  - Stimulates formation of 1,25-dihydroxy-vitamin D
  - Stimulates reabsorption of calcium in the distal convoluted tubule and phosphate excretion in proximal tubule
- Loss of PTH action results in hypocalcemia, hyperphosphatemia, and hypercalciuria.
- Magnesium is crucial for PTH secretion and activation of the PTH receptor; hypo- or hypermagnesemia may result in functional hypoparathyroidism.
- Acquired hypoparathyroidism
  - Surgical: removal or damage to parathyroid glands or their blood supply; thyroid, parathyroid, or radical neck surgery for head and neck cancers (1)
  - Autoimmune: isolated or combined with other endocrine deficiencies in polyglandular autoimmune (PGA) syndrome
  - Deposition of heavy metals in gland: copper (Wilson disease) or iron (hemochromatosis, thalassemias), radiation-induced destruction, and metastatic infiltration
  - Functional hypoparathyroidism: associated with hypomagnesemia; hypermagnesemia
  - Congenital
    - Calcium-sensing receptor (CaSR) abnormalities: hypocalcemia with hypercalciuria
    - HDR or Barakat syndrome: deafness, renal dysplasia
    - Familial: mutations of the *TBCE* gene; abnormal PTH secretions

## 22q11.2 deletion syndrome

- Autoimmune: genetic gain-of-function mutation in CaSR
- Infiltrative: metastatic carcinoma, hemochromatosis, Wilson disease, granulomas
- Hypo- (alcoholics) or hypermagnesemia: chronic iron overloads

## Genetics

- Genetic defects may result in X-linked or in autosomal recessive hypoparathyroidism due to abnormal parathyroid gland development; associated with mutations in the transcription factor glial cell missing B (BCMB)
- Mutations in transcription factors or regulators of parathyroid gland development
  - Component of a larger genetic syndrome (APS-1 or DiGeorge syndrome) or in isolation (X-linked hypoparathyroidism) (2)
  - May be autosomal dominant (DiGeorge), autosomal recessive (APS-1), or X-linked recessive (X-linked hypoparathyroidism) (2)
  - Congenital syndromes
    - 22q11.2 deletion syndrome, familial hypomagnesemia, hypoparathyroidism with lymphedema (2)
    - Hypoparathyroidism with sensorineural deafness
    - ADHH: mutations gain-of-function of the *CaSR* gene suppressing the parathyroid gland, without elevation of PTH
  - PGA syndrome type I: mucocutaneous candidiasis, hypoparathyroidism, and Addison disease

## RISK FACTORS

Neck surgery and neck trauma, neck malignancies, family history of hypocalcemia, PGA syndrome

## GENERAL PREVENTION

Intraoperative identification and preservation of parathyroid tissue

## COMMONLY ASSOCIATED CONDITIONS

- DiGeorge syndrome
- PGA syndrome type I

Multiple endocrine deficiency autoimmune candidiasis (MEDAC) syndrome

- Juvenile familial endocrinopathy
- Addison disease
- Moniliasis (HAM) syndrome: a polyglandular deficiency syndrome, possibly genetic, characterized by hypoparathyroidism

## DIAGNOSIS

### HISTORY

Often asymptomatic; ask about previous neck trauma or surgery, head or neck irradiation, family history of hypocalcemia, or presence of other autoimmune endocrinopathies.

- Fatigue, circumoral or distal extremity paresthesias
- Muscle cramps, seizures, neuropsychiatric symptoms

### PHYSICAL EXAM

- Surgical scar on neck
- Chvostek sign: ipsilateral twitching of the upper lip on tapping the facial nerve on the cheek. 10% of normal people have positive Chvostek sign.
- Trousseau sign: painful carpal spasm after 3-minute occlusion of brachial artery with BP cuff. BP cuff inflated to > systolic BP for 3 minutes leads to carpal spasm (flexion of metacarpophalangeal [MCP] joints, extension of interphalangeal [IP] joints, adduction of fingers and thumb).
- Tetany, laryngo- or bronchospasm, cardiac arrhythmias, refractory heart failure, dyspnea, edema
- Dry, coarse, puffy hair; brittle nails
- Loss of deep tendon reflexes
- Dysrhythmias (secondary hypocalcemia)
- Cataracts
- Tooth enamel defects

### DIFFERENTIAL DIAGNOSIS

- Vitamin D deficiency/resistance

- Pseudohypoparathyroidism, which presents in childhood, kidney and bone unresponsiveness to PTH; characterized by hypocalcemia, hyperphosphatemia, and, in contrast to hypoparathyroidism, elevated rather than reduced PTH concentrations
- Hypoalbuminemia, renal failure, malabsorption, familial hypocalcemia, hypomagnesemia

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Calcium: ionized (low) and total (low) (correct serum calcium level for albumin)
  - Corrected serum calcium = total serum calcium + 0.8 (4 - serum albumin)
- Phosphorus (high)
- Intact or ÒwholeÓ PTH (low or inappropriately normal)
- Magnesium (low may be cause of hypoparathyroidism; may also be normal)
- BUN, creatinine, 25-OH vitamin D level (especially in elderly)
- Urinary calcium (normal or high)
- Calcium should be monitored after thyroid or parathyroid surgery.
- Radiographs may show absent tooth roots, calcification of cerebellum, choroid plexus, or cerebral basal ganglia.

### *Follow-Up Tests & Special Considerations*

- ECG: prolongation of ST and QTc intervals nonspecific repolarization changes, dysrhythmias
- 
- Urine calcium: Creatinine ratio (normal 0.1 to 0.2) may be low before treatment but should be monitored to prevent stones due to hypercalciuria.
  - Gene sequencing: Evaluation of other hormone levels may be required to diagnose APS-1.
  - Hungry bone syndrome (transient hypoparathyroidism after parathyroid surgery)
    - Hypocalcemia due to hungry bone syndrome may persist despite recovery of PTH secretion from the remaining normal glands. Thus, serum PTH concentrations may be low, normal, or even elevated.
  - Infiltrative: osteoblastic metastasis of prostate, breast, or lung cancer
  - Metabolic/nutritional: renal failure, neonatal hypocalcemia, hypoalbuminemia, malabsorption, calcium (Ca<sup>++</sup>) chelators, hypomagnesemia

- Familial hypocalcemia, acute hyperphosphatemia (rare), vitamin D deficiency
- Autoantibodies against NACHT leucine-rich-repeat protein 5 (NALPS) found in 49% of 73 patients with APS-1 and hypoparathyroidisms

## *Test Interpretation*

Parathyroid gland parenchymal tissue completely or almost completely replaced by fat

## **TREATMENT**

### *GENERAL MEASURES*

- Monitor ECG during calcium repletion.
- Maintenance therapy: may require lifelong treatment with calcium and calcitriol
  - Maintain serum calcium in low normal range: 8 to 8.5 mg/dL (2 to 2.12 mmol/L).
- If hypercalcemia occurs, hold therapy until calcium returns to normal. Treat magnesium deficiency if present.
- Phosphate binders are required if high calciumphosphate product.
- Thiazide diuretics combined with a low-salt diet may be used to prevent hypercalciuria, nephrocalcinosis, and nephrolithiasis.
- Oral calcium administration and vitamin D supplementation after thyroidectomy may reduce the risk for symptomatic hypocalcemia after surgery.

### *MEDICATION*

#### **Acute Hypoparathyroidism**

- Hypoparathyroid with severe symptoms (tetany, seizures, cardiac failure, laryngospasm, bronchospasm)
  - IV calcium gluconate: 1 or 2 g, each infused over a period of 10 minutes. Central venous catheter is preferred because calcium-containing solutions can irritate surrounding tissues. Follow with infusion of 10 g calcium gluconate in 1 L 5% dextrose water at a rate of 1 to 3 mg calcium gluconate/kg body weight/hr (1)[B].
- Hypomagnesemia: acutely: 1 to 2 g IV q6h. Longterm magnesium oxide tablets (600 mg) once or twice per day
- Maintenance: See "First Line" treatment for chronic hypoparathyroidism.

# Chronic Hypoparathyroidism

## *First Line*

- Adults
  - Oral calcium: calcium salts: 1 to 3 g/day PO. For geriatric patients, consider using calcium citrate instead of calcium carbonate.
  - Calcitriol: (vitamin D 1, 25-dihydroxycholecalciferol): 0.25  $\mu$ g/day. Doses 0.5 to 2.0  $\mu$ g/day are usually required (2)[A].
- Children
  - Oral elemental calcium: 25 to 50 mg/kg daily
  - Calcitriol: 0.25  $\mu$ g daily for age >1 year

## *Second Line*

Cholecalciferol 10,000 to 50,000 U duration of action 4 to 8 weeks

## *ISSUES FOR REFERRAL*

Endocrinologist, nephrologist, ophthalmologist

## *ADDITIONAL THERAPIES*

Parathyroid hormone 1 to 34 and 1 to 84 SC

- Improved well-being and increased bone mineral density have been shown with PTH therapy, but other long-term benefits have not (3).

## *SURGERY/OTHER PROCEDURES*

Autotransplantation of cryopreserved parathyroid tissue: restores normocalcemia in 23% of cases

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Laryngospasm, seizures, tetany, QT prolongation

### *Discharge Criteria*

Resolution of hypocalcemic symptoms, patient educated on hypoparathyroidism and treatment

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Goal is a total corrected serum calcium level in low normal range (8 to 8.5 mg/dL or 2 to 2.12 mmol/L), 24-hour urine calcium <300 mg, and calciumphosphate product <55.
- Outpatient measurement of serum calcium, phosphate, magnesium, and creatinine weekly to monthly during initial management; for changes in medication, check weekly or every other week; when stable, measure every 3 to 6 months (3)[A].
- Measure 24-hour urinary calcium secretion yearly.
- If symptoms of renal stone disease or increasing Cr, get renal imaging (3)[A].
- Annual slit-lamp and ophthalmologic evaluations are recommended.
- DEXA scan (2)[A]

#### *DIET*

Low-phosphate diet in patients with hyperphosphatemia

### *PATIENT EDUCATION*

<https://www.hypopara.org/>

#### *PROGNOSIS*

Hypoparathyroidism following neck surgery is often transient. Length of required treatment may vary depending on origin.

#### **COMPLICATIONS**

- Reversible: due to low calcium levels, most likely to improve with adequate treatment
  - Neuromuscular symptoms: Paresthesias (circumoral, fingers, toes), tetany, seizures, parkinsonian symptoms; pseudotumor cerebri has been described.
  - Renal: hypercalciuria, nephrocalcinosis, nephrolithiasis
  - Cardiovascular: heart failure, arrhythmias
- Irreversible: when condition starts early in childhood and will not improve with calcium and vitamin D treatment

- Stunting of growth
- Enamel defects and hypoplasia of teeth
- Atrophy, brittleness, and ridging of nails
- Cataracts and basal ganglia calcifications

## Codes

**&NA;**

## ICD10

- E20.9 Hypoparathyroidism, unspecified
- P71.4 Transitory neonatal hypoparathyroidism
- E89.2 Postprocedural hypoparathyroidism

# Clinical Pearls

## **&NA;**

Often asymptomatic; consider if hypocalcemic with fatigue and circumoral or distal extremity paresthesias.

- Correct the serum calcium level for albumin level.
- Monitor calcium after thyroid or parathyroid surgery.
- Serum levels of magnesium and 25-OH should be measured to rule out deficiency that could contribute to reduced serum calcium levels.

# Hypothermia

Scott T. Henderson, MD

## BASICS

### *DESCRIPTION*

- A core temperature of  $<35^{\circ}\text{C}$  ( $95^{\circ}\text{F}$ )
- May take several hours to days to develop
- Patients with cold-water immersion can appear to be dead but can still be resuscitated.
- System(s) affected: all body systems
- Synonym(s): accidental hypothermia

### *EPIDEMIOLOGY*

- Predominant age: very young and the elderly
- Predominant sex: male  $>$  female

### *Geriatric Considerations*

More common due to lower metabolic rate, impaired ability to maintain normal body temperature, and impaired ability to detect temperature changes

### *Prevalence*

Estimates vary widely due to lack of pathologic evidence, and it is typically a secondary cause when diagnosing disorders.

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Overwhelming environmental cold stress
- Decreased heat production
- Increased heat loss
- Impaired thermoregulation

## *RISK FACTORS*

- Alcohol consumption
- Bronchopneumonia
- Cardiovascular disease
- Cold-water immersion
- Dermal dysfunction (burns, erythrodermas)
- Drug intoxication
- Endocrinopathies (myxedema, severe hypoglycemia)
- Excessive fluid loss
- Hepatic failure
- Hypothalamic and central nervous system (CNS) dysfunction
- Malnutrition
- Mental illness; Alzheimer disease
- Prolonged cardiac arrest
- Prolonged environmental exposure
- Renal failure
- Sepsis
- Trauma (especially head)
- Uremia

## *GENERAL PREVENTION*

- Appropriate clothing, with particular attention to head, feet, and hands
- For outdoor activities, carry survival bags with rescue foil blanket for use if stranded or injured.
- Avoid alcohol.
- Alertness to early symptoms and initiating preventive steps (e.g., drinking warm fluids)
- Identify medications that may predispose to hypothermia (e.g., neuroleptics, sedatives, hypnotics, tranquilizers).

## *COMMONLY ASSOCIATED CONDITIONS*

- Addison disease

- CNS dysfunction
- Congestive heart failure
- Diabetes
- Hypopituitarism
- Hypothyroidism
- Ketoacidosis
- Pulmonary infection
- Sepsis
- Uremia

## DIAGNOSIS

### HISTORY

Presentation varies with the temperature of the patient at the time of presentation.

### ALERT

History of prolonged exposure to cold may make the diagnosis obvious, but hypothermia may be overlooked in other situations, especially in comatose patients.

### PHYSICAL EXAM

Esophageal temperature is most accurate, minimally invasive method of assessing core temperature (1)[C].

- Must have secure airway
- Probe inserted into lower third of esophagus

Exam findings vary with the temperature of the patient at the time of presentation.

- Mild (32-35°C)
  - Lethargy and mild confusion
  - Shivering
  - Tachypnea
  - Tachycardia

- Loss of fine motor coordination
- Increased BP
- Peripheral vasoconstriction
- Moderate (28-32°C)
  - Delirium
  - Bradycardia
  - Hypotension
  - Hypoventilation
  - Cyanosis
  - Arrhythmias (prolonged PR interval, AV junctional rhythm, accelerated idioventricular rhythm, prolonged QT interval, altered T waves)
  - Semicoma and coma
  - Muscular rigidity
  - Generalized edema
  - Slowed reflexes
- Severe (<28°C)
  - Very cold skin
  - Rigidity
  - Apnea
  - Bradycardia
  - No pulse: ventricular fibrillation or asystole
  - Areflexia
  - Unresponsive
  - Fixed pupils

## **ALERT**

Use specially designed thermometers that can record low temperatures and measure core temperatures.

## *Pediatric Considerations*

- Infants may present with bright red, cold skin and very low energy.
- A child's body temperature drops faster than an adult does when immersed in cold water.

## ***DIFFERENTIAL DIAGNOSIS***

- Cerebrovascular accidents
- Intoxication
- Drug overdose
- Complications of diabetes, hypothyroidism, hypopituitarism

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Arterial blood gases (corrected for temperature)
- CBC and platelet counts
- Serum electrolytes
- Urinalysis
- Coagulation studies
- Fibrinogen levels
- Blood culture
- BUN/creatinine
- Glucose
- Amylase
- Liver function studies
- Cardiac enzymes
- Calcium
- Magnesium
- Alcohol level
- Drug screen
- Cervical spine, chest, and abdomen x-rays, if appropriate

### ***Follow-Up Tests & Special Considerations***

Serum cortisol and TSH if underlying endocrine dysfunction (hypothalamus stimulates release of hormones in response to hypothermia)

## *Diagnostic Procedures/Other*

EKG

## *Test Interpretation*

Serum potassium >12 mmol/L associated with nonsurvival

## **TREATMENT**

### **GENERAL MEASURES**

- Prehospital (1)[C]
  - Factors to guide treatment
    - Level of consciousness
    - Shivering intensity
    - Cardiovascular stability based on blood pressure and cardiac rhythm.
    - ABCs of basic life support
    - Remove wet garments.
      - Dry patient.
    - Protect against heat loss and wind chill.
    - If far from definitive care, begin active rewarming but do not delay transport.
      - Mild hypothermic patients with shivering ability will have improved comfort and might have a reduced cold-stress response with active rewarming (2)[B].
    - Give warm humidified oxygen if available.
- See Admission Criteria/Initial Stabilization.

### **MEDICATION**

- For sepsis or bacterial infections: Antibiotics based on site and etiology.
- For hypoglycemia: D50W at a dose of 1 mg/kg

Thiamine: 100 mg, if alcoholic or cachectic

- Naloxone: 2 mg
- Levothyroxine: 150 to 500  $\mu$ g for myxedema
- For severe acidosis: sodium bicarbonate

---

P.539

- Precautions
  - Medications including epinephrine, lidocaine, and procainamide can accumulate to toxic levels if used repeatedly. Should be avoided until core temperature is  $>30^{\circ}\text{C}$ :
    - When temperature reaches  $>30^{\circ}\text{C}$ , IV medications are indicated but at longer than the standard intervals.
  - It may be reasonable to consider vasopressors during cardiac arrest according to standard ACLS algorithm with concurrent rewarming.
- Significant possible interactions:
  - Use all drugs cautiously due to impaired metabolism and renal elimination.
- Once rewarming has occurred, there is mobilization of depot stores.
- Routine use of steroids or antibiotics does not increase survival or decrease postresuscitative damage.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Rewarming depends on severity of hypothermia and presence of cardiac arrest.
- If no cardiac arrest, consider active external rewarming (3)[B].
- If cardiac arrest is present, consider active internal rewarming (3)[B].
- Warm center of body first (4)[C].
- The rate of rewarming is determined by whether a perfusing cardiac output is present.
  - If a perfusing cardiac output is present,  $1\text{--}2^{\circ}\text{C/hr}$  is appropriate.
  - If not, then a faster rate of  $>2^{\circ}\text{C/hr}$  should be used.
- Monitor core temperature; use a consistent method.
- Monitor BP and cardiac rhythm.

Correct metabolic acidosis.

- Evaluate for frostbite and other trauma.
- Mild hypothermia
  - Passive rewarming
  - Administration of heated IV solutions
  - Provide warm fluids by mouth if fully alert.
- Moderate hypothermia
  - Active external rewarming with forced warm air systems
- Severe hypothermia (active internal [core] rewarming)
  - Minimally invasive
  - Heated IV fluids
  - Heated humidified oxygen
  - Body cavity lavage
    - Thoracic cavity lavage (40-45°C)
    - Peritoneal lavage (40-45°C)
  - Extracorporeal blood rewarming
    - Cardiopulmonary bypass
    - Extracorporeal membrane oxygenation
    - Continuous arteriovenous rewarming
    - Hemodialysis and hemofiltration
- Cardiac arrhythmias
  - Atrial fibrillation and sinus bradycardia are common, but patients usually convert to normal sinus rhythm with rewarming.
  - If ventricular fibrillation is present, it should be treated with one shock. If patient does not respond, consider deferring further attempts until rewarm has occurred.
  - Do not treat transient ventricular arrhythmias.
  - If cardiac pacing required, preferable to use external noninvasive pacemaker
- Admit patients, preferably to the ICU, with underlying disease, physiologic abnormalities, or

core temperature  $<32^{\circ}\text{C}$ .

## *IV Fluids*

- Normal saline is preferred (1)[C].
- Heat IVs from  $40^{\circ}\text{C}$  to  $45^{\circ}\text{C}$  when possible, but should be no colder than the patient's core temperature.

### **ALERT**

- Avoid fluid overload.
- Avoid overheating dextrose solutions; dextrose caramelizes at  $60^{\circ}\text{C}$ .
- Avoid lactated Ringer solution because of decreased lactate metabolism.

## *Nursing*

Because of the cold, heart is irritable and susceptible to arrhythmias; take special care in moving and transporting.

## *Discharge Criteria*

Discharge from emergency department once normothermic, if mild hypothermia and no predisposing conditions or complications, and has suitable place to go.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- During acute episode
  - Monitor cardiac rhythm.
  - Monitor electrolytes and glucose frequently.
  - Monitor urinary output.
  - Follow blood gases.
- Following acute episode
  - Continued therapy for any underlying disorder

## *DIET*

Warm fluids only if alert and able to swallow

- Alcohol intake increases risk of becoming hypothermic in cold conditions.
- Encourage persons with cardiovascular disease to avoid outdoor exercise in cold weather.
- Refer to social service agency for help with adequate housing, heat, and/or clothing, if appropriate.

## *PROGNOSIS*

- Mortality rates are decreasing due to increased recognition and advanced therapy.
- Mortality usually depends on the severity of underlying cause and comorbidities.
- In previously healthy individuals, recovery is usually complete.
  - Mortality rate in healthy patients is <5%.
- Mortality rate in patients with coexisting illness is >50%.

## *Geriatric Considerations*

Mortality rates increase with increasing age.

### **COMPLICATIONS**

- Core temperature after drop
- Cardiac arrhythmias
- Hypotension
- Hyperkalemia
- Hypoglycemia
- Rhabdomyolysis
- Sepsis
- Pneumonia (aspiration and broncho)
- Pulmonary edema
- Acute respiratory distress syndrome
- Pancreatitis
- Peritonitis
- GI bleeding
- Ileus
- Acute tubular necrosis

- Bladder atony
- Intravascular thromboses/disseminated intravascular coagulation
- Metabolic acidosis
- Gangrene of extremities
- Compartment syndromes
- Seizures
- Cerebral ischemia
- Delirium

## Codes

**&NA;**

### ICD10

- T68.XXXA Hypothermia, initial encounter
- T68.XXXD Hypothermia, subsequent encounter
- T68.XXXS Hypothermia, sequela

## Clinical Pearls

**&NA;**

- Most common cause of hypothermia in the United States is cold exposure due to alcohol intoxication.
- With a severely decreased core temperature, one should assume resuscitation, if possible, unless there are obvious lethal injuries. Continue resuscitation and rewarm to 33-35°C (Not dead until warm and dead).
- ECG changes are associated with hypothermia: slowing of sinus rate with T-wave inversion; QT, QRS, and PR interval prolongation; atrial and ventricular arrhythmias; hypothermic J waves (Osborn waves) characterized by a notching of the QRS complex and ST segment

# Hypothyroidism, Adult

Adithi Naidu, MD

Faraz Ahmad, MD

Jason Chao, MD, MS

## BASICS

### DESCRIPTION

- Clinical and metabolic state resulting from decreased levels of free thyroid hormone or from resistance to hormone action
- Primary (intrinsic thyroid disease) >95% of cases or central (secondary or tertiary resulting from hypothalamic-pituitary disease)
- Subclinical or overt
- Subclinical: serum TSH above the upper reference limit with a normal free T<sub>4</sub> and normal hypothalamicpituitary-thyroid axis (1)[A]
- Overt: elevated TSH, usually >10 mIU/L with a subnormal free T<sub>4</sub>

### EPIDEMIOLOGY

#### Incidence

- Women: 3.5 per 1,000 persons per year
- Men: 0.6 per 1,000 persons per year
- Risk of developing hypothyroidism in women with positive antibodies and elevated TSH was 4% per year and 2-3% per year in those with either alone (1)[A].

#### Prevalence

- The National Health and Nutrition Examination Survey III (NHANES III), SHypo (Subclinical hypothyroidism) 9.3%, overt 0.3% in an unselected U.S. population over age 12 years, between 1988 and 1994 with upper limit TSH 4.5
- Framingham study, 5.9% of women and 2.3% of men over age 60 years had a serum TSH >10 mIU/L.

- British Whickham survey, 9.3% of women and 1.2% of men had a serum TSH >10 (1)[A].

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Primary: abnormality at the thyroid gland (>95% of cases)
- Most common cause worldwide: environmental iodine deficiency (1) [A]
- Most common cause in the United States: Hashimoto thyroiditis (autoimmune thyroid disease [AITD])
  - AITD is characterized pathologically by infiltration of the thyroid with sensitized T lymphocytes and serologically by circulating thyroid antibodies.
  - Autoimmunity to the thyroid gland is an inherited defect in immune surveillance, leading to abnormal regulation of immune responsiveness or alteration of presenting antigen in the thyroid (1)[A].
- Postablative/posttherapeutic: follows radioactive iodine therapy or thyroid surgery for hyperthyroidism, thyroid cancer, benign nodular thyroid disease or neck malignancies
- Transient hypothyroidism during the course of subacute or painless thyroiditis (silent thyroiditis, most common during postpartum period) and subacute granulomatous thyroiditis
- Drug use: propylthiouracil, methimazole, lithium, amiodarone, and newer chemotherapeutic agents such as tyrosine kinase inhibitors (sunitinib), interleukin-2, or interferon- $\alpha$ ;
- Central: Hypothyroidism due to insufficient stimulation by TSH of an otherwise normal thyroid gland.
- Can be secondary (level of the pituitary) or tertiary (level of the hypothalamus)
- Etiology involves genetic defects, tumors, vascular, empty sella syndrome, inflammatory, infiltrative, iatrogenic, posttrauma, or drug related.

## *RISK FACTORS*

- Women >60 years of age
- Personal or family history of autoimmune diseases, including type 1 diabetes mellitus, Addison disease, Hashimoto thyroiditis, vitiligo, pernicious anemia
- Pregnant women or those with previous postpartum thyroiditis
- Previous head or neck irradiation
- Past history of thyroid dysfunction or thyroid surgery
- Abnormal thyroid examination, presence of goiter and/or TPOAb positivity

- Treatment with amiodarone, lithium, interferon- $\alpha$ ; sunitinib, or sorafenib
- Those with Down syndrome or Turner syndrome

## COMMONLY ASSOCIATED CONDITIONS

- Type 1 diabetes
- Pernicious anemia
- Primary adrenal failure (Addison disease)
- Myasthenia gravis
- Celiac disease
- Rheumatoid arthritis
- Systemic lupus erythematosus
- Vitiligo
- Depression
- Genetic syndromes that have multiple autoimmune endocrinopathies (MAE) such as type 1 MAE and type 2 MAE.

## DIAGNOSIS

### HISTORY

- Weakness/fatigue
- Cold intolerance
- Slowed thinking
- Hearing impairment
- Constipation
- Muscle cramps, arthralgias, paresthesias
- Modest weight gain (10 lb [4.5 kg])
- Menstrual disturbances
- Depression
- Change in voice (hoarseness)
- Carpal tunnel syndrome

## PHYSICAL EXAM

- Dry, coarse, thickened skin
- Hair loss/brittle hair
- Coarsening of voice
- Periorbital puffiness
- Swelling of hands and feet (nonpitting)
- Bradycardia
- Reduced systolic BP; increased diastolic BP
- Delayed relaxation of deep tendon reflexes
- Macroglossia
- Goiter (particularly in patient with Hashimoto thyroiditis)

### *Geriatric Considerations*

- Characteristic signs and symptoms frequently nonspecific, changed, or absent
- Normal serum thyrotropin ranges are higher (in those over 65 years of age)

### *DIFFERENTIAL DIAGNOSIS*

- Chronic fatigue syndrome
- Depression
- Euthyroid sick syndrome
- Congestive heart failure
- Primary amyloidosis
- Dementia from other causes
- Primary adrenal insufficiency
- Thyrotropin-secreting pituitary adenoma

### *DIAGNOSTIC TESTS & INTERPRETATION*

- Primary hypothyroidism
  - Elevated TSH (>4.5 mIU/L)
  - Decreased serum free T<sub>4</sub>
  - Normal TRH stimulation test

- Central (secondary or tertiary) hypothyroidism
  - Assess only free T<sub>4</sub> or free T<sub>4</sub> index, not TSH (1)[A].
  - Decreased serum free T<sub>4</sub>
  - Abnormal TRH stimulation test
  - Antithyroid antibodies absent
  - Imaging of the hypothalamus and pituitary gland
- Subclinical hypothyroidism
  - Elevated serum TSH (>4.5 mIU/L)
  - Normal serum free T<sub>4</sub> (2)[A]
  - Note: Serum free triiodothyronine (T<sub>3</sub>) or total T<sub>3</sub> should not be done to diagnose hypothyroidism (1)[A].

## Follow-Up Tests & Special Considerations

- Antithyroid antibodies may define the cause of primary hypothyroidism but are not necessary in all settings.
- Drugs that may alter lab results:
  - Drugs that decrease TSH:
    - Thyroid supplement, cortisone, dopamine, octreotide
  - Drugs that increase TSH:
    - Phenytoin, amiodarone, dopamine antagonist (metoclopramide/domperidone, salicylates, oral colecystographic dyes [sodium ipodate]), or estrogen or androgen in excess
- Disorders that may alter lab results
  - Any severe illness, pregnancy, chronic protein malnutrition, hepatic failure, or nephrotic syndrome

## Test Interpretation

### SCREENING

- Patient with risks factors as described above
- Patient with laboratory or imaging abnormalities

- Substantial hyperlipidemia or change in lipid pattern
- Hyponatremia, often resulting from inappropriate production of antidiuretic hormone
- High serum muscle enzyme concentrations
- Macrocytic anemia
- Pericardial or pleural effusion
- Pituitary or hypothalamic disorder
- Pregnant women
  - Personal or family history of thyroid disease
  - DM type 1
  - H/o recurrent miscarriage, morbid obesity, or infertility; thyroid peroxidase antibody (TPOAb) should be considered (1)[A].
  - Universal screening not recommended for patients pregnant or planning pregnancy
- U.S. Preventive Services Task Force does not recommend routine screening for children or adults (1)[A].

P.541

- Recommendations by expert groups:
  - ATA recommend screening in all adults at age 35 years and every 5 years thereafter.
  - AACE recommend screening older patients, especially women.
  - AAFP recommend screening patients 60 years and older.
  - ACOG recommends women with h/o autoimmune disease or strong family h/o thyroid disease should be screened at age 19 years.

## TREATMENT

### MEDICATION

#### *First Line*

- Levothyroxine (Synthroid, Levothroid)
  - 1.6 &mgr;g/kg/day; increase by 12.5 to 25 &mgr;g/day every 4 to 8 weeks until TSH in normal range

- Dosage requirements may vary with age, gender, residual secretory capacity of thyroid gland, other drugs being taken by patient, and intestinal function (1)[A].
- Elderly patients may require 2/3 of dose used in young adults because clearance is decreased.
- Levothyroxine should be taken on an empty stomach, ideally an hour before breakfast. Administering at bedtime may result in higher levels than administering in the morning (3) [A]
- Medications that interfere with its absorption should be taken 4 hours after the T<sub>4</sub> dose: ferrous sulfate, proton pump inhibitors, calcium carbonate, bile acid resins.
- Contraindications
  - Thyrotoxic heart disease
  - Uncorrected adrenocorticoid insufficiency
  - MI, acute
  - TSH suppression, preexisting
- Precautions
  - Start with lower doses, such as 12.5 to 25  $\mu$ g, in elderly and in patients with heart disease.
  - Diabetic patients may need readjustment of hypoglycemic agents with institution of thyroxine (T<sub>4</sub>).
  - Dosage of oral anticoagulants may need adjustment; monitor prothrombin time while initiating treatment.
  - Elderly patients more susceptible to AFib and osteoporotic fracture with thyroid hormone excess
  - Patients requiring doses that are higher than expected should be evaluated for GI disorders (*H. pylori*, celiac disease).
- Significant possible interactions
  - Oral anticoagulants, insulin, oral hypoglycemic, estrogen, OCP, PPI, cholestyramine
  - Ferrous sulfate, calcium carbonate, antacids, laxatives, colestipol, sucralfate, ciprofloxacin, and cholestyramine may decrease absorption.
- Controversy exists whether subclinical hypothyroidism should be treated. Cochrane Review found no improvement in survival, cardiovascular morbidity, or health-related quality of life.

Some evidence indicates improvement in lipid profiles and left ventricular function. Subclinical hypothyroidism should be treated in patients with iron deficiency anemia and in patients with TSH >10 (2, 4, 5)[B].

- If surgery is elective, render patient euthyroid prior to procedure.
- If surgery is urgent, proceed with individualized replacement therapy preoperatively and post-operatively.

### *Pregnancy Considerations*

- Replacement therapy may need adjustment; average dose increase from 25-50% (6)[A].
- TSH levels should be monitored monthly during 1st trimester; goal TSH of 2 to 2.5 mIU/L for 1st trimester, <3.0 mIU/L for 2nd trimester, and <3.5 mIU/L for 3rd trimester (6)[A].
- Postpartum: Check TSH levels at 6 weeks (6)[A].
- Painless subacute thyroiditis may occur in postpartum period, leading to transient hypothyroidism lasting 3 months. Treatment with replacement therapy may be warranted. Up to 30% of these individuals develop permanent hypothyroidism.

### *Second Line*

- No benefit to adding triiodothyronine (T<sub>3</sub>) to T<sub>4</sub> (6)[A]
- Desiccated thyroid hormone is not recommended for the treatment of hypothyroidism (1).

### *ISSUES FOR REFERRAL*

- Children and infants
- Pregnancy or women planning conception
- Patient in whom it is difficult to maintain a euthyroid state
- Cardiac disease
- Presence of goiter, nodule, or other structural changes in the thyroid gland
- Presence of adrenal or pituitary disorders (1)[C]

### *INPATIENT CONSIDERATIONS*

#### *Admission Criteria/Initial Stabilization*

- Myxedema coma (decompensated severe untreated hypothyroidism)
- True clinical emergency (requires ICU care)

- Profound hypothermia and unconsciousness
- Increased risk of shock and potentially fatal arrhythmias

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Monitor TSH and free T<sub>4</sub> every 4 to 8 weeks after initiating treatment or after change in dose. Once stabilized, periodic TSH level should be done after 6 months and then at 12-month intervals or more frequently if the clinical situation dictates otherwise (1)[B].
- Follow cardiac status closely in older patients.
- Check TSH more frequently in pregnancy, initiation of estrogen supplementation, or after large changes in body weight.
- In central hypothyroidism, TSH unreliable; must monitor free T<sub>4</sub> and T<sub>3</sub>
- Thyroid hormones should not be used to treat obesity in euthyroid patients (1)[A].

### *PATIENT EDUCATION*

- Stress importance of compliance with thyroid replacement therapy.
- Explain need for lifelong treatment.
- Further education required for patients taking multiple medications that may interact
- Instruct to report to physician any signs of infection or heart problems.
- Describe signs of thyrotoxicity.
- High-bulk diet may help avoid constipation.

### *PROGNOSIS*

- Return to normal state is the rule.
- Relapses will occur if treatment is interrupted.
- If untreated, may progress to myxedema coma

### **COMPLICATIONS**

- Hypothyroid patients (mild to moderate) tolerate surgery, with mortality and

complications similar to euthyroid patients.

- Myxedema coma: mortality 30-60%
- Increased susceptibility to infection
- Megacolon
- Sexual dysfunction
- Organic psychosis with paranoia
- Infertility
- Hypersensitivity to opiates
- Treatment over long periods can lead to bone demineralization.
- Iatrogenic thyrotoxicosis can lead to AFib and osteoporosis.
- Can lead to adrenal crisis with vigorous treatment, especially in patients with undiagnosed polyendocrine syndromes
- Treatment-induced congestive heart failure in people with coronary artery disease
- Subclinical hypothyroidism is associated with increased ischemic heart disease and increased all-cause mortality in men but not in women.

- E03.9 Hypothyroidism, unspecified
- E06.3 Autoimmune thyroiditis
- E89.0 Postprocedural hypothyroidism

## Clinical Pearls

**&NA;**

- Monitor TSH and free T<sub>4</sub> every 4 to 8 weeks after initiating treatment or after change in dose. Once stabilized, periodic TSH level should be done after 6 months and then at 12-month intervals, or more frequently if the clinical situation dictates otherwise (1)[B].
- Screening test: TSH levels (1)[A]
- Serum free T<sub>3</sub> or total T<sub>3</sub> should not be done to diagnose hypothyroidism (1)[A].
- Dosage requirements may vary with age, gender, residual secretory capacity of thyroid gland, other drugs being taken by patient, and intestinal function (1)[A].

# ID Reaction

Sahil Mullick, MD

Naureen Bashir Rafiq, MBBS, MD

## BASICS

### DESCRIPTION

A generalized skin reaction associated with various infectious (fungal, bacterial, viral, or parasitic) or inflammatory cutaneous conditions distant from the primary disease site (1)

- ID is often combined with a root to reflect the causative factor (i.e., bacterid, syphilid, and tuberculid). Dermatophytid is the most frequently referenced id reaction. A dermatophytid is an autosensitization reaction in which a secondary cutaneous reaction occurs at a site distant to a primary fungal infection. The eruption typically begins within 1 to 2 weeks of the onset of the main lesion or following exacerbation of the main lesion.
- Most commonly localized vesicular lesions, erythema nodosum, and erythema multiforme
- System(s) affected: skin/exocrine
- Synonym(s): dermatophytid, trichophytid, autoeczematization

### EPIDEMIOLOGY

- Predominant age: all ages
- Predominant sex: male = female
- Predominant race: all races

### Incidence

Unknown

### Prevalence

Common

### ETIOLOGY AND PATHOPHYSIOLOGY

Precise pathophysiology is uncertain. Circulating antigens may react with antibodies at sensitized areas of the skin. An abnormal immune recognition of autologous skin antigens may also occur.

Inflammation may lower the irritation threshold of the skin, and hematogenous spread of cytokines from the primary site of inflammation may also play a role (1).

- Etiology
  - Infectious
    - Fungal infections: *Trichophyton mentagrophytes*, *Trichophyton rubrum*, *Epidermophyton floccosum*, and *Candida* spp.
    - Bacterial infections: *Streptococcus pyogenes*, *Staphylococcus aureus*, and *Mycobacterium tuberculosis*
    - Viral infections: HSV, *Molluscum contagiosum*, orf, and milker's nodules
    - Parasitic infections: *Sarcoptes scabiei* and *Leishmania* spp.
  - Allergic
    - Id reactions occur in patients with nickel and aluminum allergy.
  - Miscellaneous
    - Id reaction rarely develop due to retained postoperative sutures, ionizing radiation, and blunt trauma.
    - Rarely, id reaction has been documented in patients receiving intravesical BCG live therapy for transitional cell carcinoma.

## **RISK FACTORS**

- Fungal infection of the skin, especially tinea pedis
- Stasis dermatitis

## **GENERAL PREVENTION**

- Good skin hygiene (particularly in intertriginous areas) to minimize risk of developing fungal infections
- Promptly treat any developing fungal infection.

## **COMMONLY ASSOCIATED CONDITIONS**

- Primary fungal infection
- Stasis dermatitis

## DIAGNOSIS

### HISTORY

Itchy rash: Inquire about presence of lesions (typically fungal or bacterial) that could have incited the id reaction in the preceding days to weeks.

### PHYSICAL EXAM

- Common
  - Symmetric, pruritic vesicles on the palms and, most commonly, on lateral aspects of fingers
  - Tinea infection on the feet; contact or other eczematous dermatosis; bacterial, fungal, or viral infection of the skin
- Less common
  - Papules
  - Lichenoid eruption
- Eczematoid eruption

### DIFFERENTIAL DIAGNOSIS

- Pompholyx (dyshidrotic eczema)
- Contact dermatitis
- Drug eruptions
- Pustular psoriasis
- Folliculitis
- Scabies

### DIAGNOSTIC TESTS & INTERPRETATION

- Potassium hydroxide (KOH) or fungal culture of primary lesion
- No fungal elements are present at the site of the id reaction.
- Special tests: Skin shows a positive trichophyton reaction. A wheal >10 mm at 20 minutes and induration >5 mm at 72 hours is a positive response.

### Follow-Up Tests & Special Considerations

The id reaction resolves with successful eradication of the primary skin condition.

- It is important to distinguish dermatophytids from drug-induced allergic reactions, as continued treatment is essential to clear the underlying infection.

## *Test Interpretation*

### *Histology*

- Vesicles in the upper dermis
- Superficial perivascular lymphohistiocytic infiltrate with small numbers of eosinophils and increased granular cell layer
- No infectious agents present in biopsy specimen

## **TREATMENT**

### *GENERAL MEASURES*

- Outpatient treatment of the underlying infection or eczematous dermatitis
- Symptomatic treatment of pruritus with antihistamines and/or topical steroids if needed (may require class 1 or 2 steroid)
- Treatment for secondary bacterial infection

---

P.543

### *MEDICATION*

#### *First Line*

- PO antihistamines for pruritus (2)
  - Chlorpheniramine: 4 mg PO q4-6h PRN; max 24 mg/24 hr; (pediatric: 6 to 11 years 2 mg PO q4-6h PRN; max 12 mg/24 hr; <sup>3</sup>12 years, refer to adult dosing)
  - Diphenhydramine: 25 to 50 mg PO q4-6h PRN; max 400 mg/24 hr; (pediatric: 5 mg/kg/24 hr divided q6h PRN; 2 to 5 years max 37.5 mg/24 hr; 6 to 11 years max 150 mg/24 hr; <sup>3</sup>12 years, refer to adult dosing)
  - Hydroxyzine: 25 to 100 mg PO q6-8h PRN; max 600 mg/24 hr; (pediatric: 2 mg/kg/24 hr divided q6h PRN)
- Topical treatments for pruritus

- Triamcinolone 0.1% ointment TID
- Hydrocortisone 0.5%, 1%, 2.5%: up to QID
- Capsaicin 0.025%, 0.075% cream: Apply TID-QID; EMLA (2.5% lidocaine + 2.5% prilocaine) applied 30 to 60 minutes prior to capsaicin may minimize burning.
- Doxepin 5% cream: Apply QID for up to 8 days (to max of 10% of the body).
- Permethrin 5% cream (for scabies)
  - Apply from neck down after bath.
  - Wash off thoroughly with water in 8 to 12 hours.
  - May repeat in 7 days
- Permethrin 1% cream rinse (for lice)
  - Shampoo, rinse, towel dry, saturate hair and scalp (or other affected area), leave on 10 minutes, then rinse.
  - May repeat in 7 days
- White petroleum emollients: Apply after short bath/shower in warm (not hot) water.
- Systemic steroids only if reaction is severe or generalized (e.g., prednisone 20 mg)

## Second Line

- Topical and/or systemic antifungals for identified associated fungal infection (common)
  - Tinea cruris/corporis
    - Topical azole antifungal compounds econazole (Spectazole) and ketoconazole (Nizoral): usually applied BID for 2 to 4 weeks
    - Terbinafine (Lamisil): over-the-counter (OTC) compound; can be applied daily or BID for 1 to 2 weeks
    - Butenafine (Mentax): applied once daily for 2 weeks; also very effective
  - Tinea capitis
    - PO griseofulvin for *Trichophyton* and *Microsporum* sp.; microsized preparation available; dosage 20 to 25 mg/kg/day divided BID or as a single dose daily for 6 to 12 weeks
    - PO terbinafine can be used for *Trichophyton* sp. at 62.5 mg/day in patients weighing 10 to 20 kg, 125 mg/day if weight 20 to 40 kg, 250 mg/day if weight >40 kg, and use for 4 to 6 weeks.

- Topical or systemic antibiotics for any secondary bacterial infection
- Treatment with antiviral agents for erythema multiforme associated with HSV is required.

## ONGOING CARE

### *PATIENT EDUCATION*

Avoid hot, humid conditions that promote fungal growth. Aerate susceptible body areas (e.g., wear sandals or open footwear). If possible, wear loosefitting clothing and undergarments, dry wet skin after bathing, and use powders and antiperspirants to discourage fungal growth. Treat primary dermatitis promptly.

### *PROGNOSIS*

After appropriate treatment, complete resolution in days to weeks

### **COMPLICATIONS**

- Secondary bacterial infection (cellulitis)
- After resolution of dermatophytid, postinflammatory hyperpigmentation is common and disappears without treatment in 1 month.

## Codes

**&NA;**

### ICD10

- L30.2 Cutaneous autosensitization
- B35.9 Dermatophytosis, unspecified

## Clinical Pearls

**&NA;**

- When one skin eruption follows another closely in time, consider an id reaction.
- When assessing an itchy rash, inquire about potential fungal or bacterial lesions in the preceding days to weeks as a potential prelude to the id reaction.

# Immune Thrombocytopenia (ITP)

William A. Stevens, MD

Khalid A. Jaboori, MD, MPH

## BASICS

### DESCRIPTION

- Immune thrombocytopenia (ITP) is a condition characterized by the immunologic destruction of platelets and/or impaired thrombopoiesis in response to an unknown stimulus.
- ITP is classified by the following:
  - Age: adult or pediatric
  - Phases: newly diagnosed (<3 months), persistent, and chronic (>12 months)
  - Etiology: primary (idiopathic) or secondary when occurring in association with another disorder
- ITP is a relatively common disease of childhood that typically follows a viral infection. Onset is within 1 week, and spontaneous resolution occurs within 2 months in 83% of patients.
- In adults, ITP is usually a chronic disease and spontaneous remission is rare.
- System(s) affected: heme, lymphatic, immunologic
- Synonym(s): idiopathic thrombocytopenic purpura; immune thrombocytopenic purpura; and Werlhof disease

### EPIDEMIOLOGY

- Peak age
  - Pediatric ITP: 2 to 4 years
  - Chronic ITP: >50 years with incidence two times higher in persons 60 years than those <60 years of age
- Predominant gender
  - Pediatric ITP: male = female
  - Chronic ITP: female > male (1.2 to 1.7:1)

## *Incidence*

- Pediatric acute ITP: 1.9 to 6.4/100,000 children/year (1)
- Adult ITP: 3.3/100,000 per year

## *Prevalence*

Limited data. In one population (in Oklahoma) (2):

- Overall prevalence of 11.2/100,000 persons
- In children (<16 years): 8.1/100,000 with average age of 6 years
- In adults (> 16 years): 12.1/100,000 persons with average age of 55 years

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Accelerated platelet uptake and destruction by reticuloendothelial phagocytes results from action of IgG autoantibodies against platelet membrane glycoproteins IIb/IIIa. There is also cell-mediated platelet destruction by CD8<sup>+</sup> T cells.
- Autoantibodies interfere with megakaryocyte maturation, resulting in decreased production.

## *RISK FACTORS*

- Autoimmune thrombocytopenia (e.g., Evan syndrome)
- Common variable immune deficiency
- Drug side effect (e.g., quinidine, gold, penicillin, procainamide, methyldopa, sulfamethoxazole)
- Infections: *Helicobacter pylori*, hepatitis C, HIV, CMV, and varicella zoster
- Vaccination side effect
- Bone marrow transplantation side effect
- Connective tissue disease, such as systemic lupus erythematosus, antiphospholipid antibody syndrome
- Lymphoproliferative disorders

## *COMMONLY ASSOCIATED CONDITIONS*

- Viral infections, such as measles, rubella, varicella, influenza, and EBV
- Live virus vaccinations carry a lower risk than natural viral infection: 2.6/100,000 cases MMR vaccine doses versus 6 to 1,200/100,000 cases of natural rubella or measles infections

## DIAGNOSIS

A careful history, physical exam, and review of CBC and peripheral blood smear remain the key components of the diagnosis of ITP.

### HISTORY

- Often asymptomatic; found incidentally on routine CBC
- Posttraumatic bleeding occurs at counts of 40 to 60 × 10<sup>9</sup>/L.
- With counts <30 × 10<sup>9</sup>/L, bruising tendency, epistaxis, menorrhagia, and gingival bleeding are common.
- GI bleeding, hematuria, and hemoptysis are less common.
- Spontaneous bleeding may occur with platelet count <20 × 10<sup>9</sup>/L.
- Intracerebral bleeding is rare and may occur with counts <20 × 10<sup>9</sup>/L and associated trauma or vascular lesions, resulting in neurologic symptoms.
- Constitutional symptoms are absent. Symptoms are varied and most are asymptomatic at time of diagnosis.

### PHYSICAL EXAM

- Ecchymoses, petechiae, epistaxis, and bleeding from the gums are common.
- Abnormal uterine bleeding may be present.
- Hemorrhagic bullae on buccal mucosa reflect acute, severe thrombocytopenia.
- Absence of splenomegaly, hepatomegaly, lymphadenopathy, stigmata of congenital disease

### DIFFERENTIAL DIAGNOSIS

- Acute leukemia
- Thrombotic thrombocytopenic purpura
- Hemolytic uremic syndrome
- Factitious: platelet clumping on peripheral smear
- Thrombocytopenia secondary to sepsis
- Myelodysplastic syndrome, particularly in older patients
- Decreased marrow production: malignancy, drugs, viruses, megaloblastic anemia
- Posttransfusion

- Gestational thrombocytopenia
- Isoimmune neonatal purpura
- Congenital thrombocytopenias
- Disseminated intravascular coagulation
- Alcohol-induced thrombocytopenic purpura

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- CBC with differential and peripheral smear:
  - Isolated decreased platelet count  $<100 \times 10^9/L$
  - Giant platelets are usually present.
  - Normal red and white blood cell morphology
- For patients with history, exam, CBC, and peripheral smear typical of ITP, consider the following:
  - PT/PTT is normal.
  - In adults, serologies for hepatitis B, hepatitis C, and HIV infections are recommended (3) [B].
  - In pediatric ITP, immunoglobulin levels to exclude common variable immunodeficiency are commonly obtained (3)[B].
  - Other tests are not necessary for patients with typical ITP presentation: antiplatelet, antinuclear, antiphospholipid antibodies; *H. pylori* testing; thrombopoietin; platelet parameters; direct antiglobulin test; reticulocyte count; urinalysis; and thyroid function tests (3)[C]

### ***Diagnostic Procedures/Other***

- Imaging is not necessary.
- Bone marrow aspiration/biopsy
  - Not necessary for diagnosis (pediatric (3)[B]; adult (3)[C])
  - Can be considered for a patient with atypical symptoms, such as fever and weight loss and multiple abnormalities in blood count

## Test Interpretation

- Peripheral smear: normal red and white cells with large or giant platelets but diminished in number
- Marrow reveals abundant megakaryocytes with normal erythroid and myeloid precursors.

## TREATMENT

### GENERAL MEASURES

- Management with observation alone in children with no or mild bruising or petechiae regardless of platelet count (3)
- Outpatient management unless patient has platelet count  $<20 \times 10^9/L$  and is at risk for bleeding (3).
- Admit patients with active bleeding.

### MEDICATION

#### First Line

- Pediatric
  - First-line treatment:
    - For children with no or mild bleeding (bruising and petechiae only with no mucosal bleeding), observation alone regardless of platelet count (3)[B]
    - For children with significant bleeding
      - Single-dose intravenous immunoglobulin (IVIG) 0.8 to 1 g/kg, especially when a more rapid increase in platelet count is desired (3)[B]. Do not administer in patients with IgA deficiencies because of anaphylaxis risk.
      - A short course of corticosteroids (e.g., PO prednisone 2 mg/kg/day for 2 weeks with 3 weeks taper) (3)[B]
      - For nonsplenectomized children who are Rh-positive, single dose of anti-Rho(D) immunoglobulin (anti-D), 50 to 75 g/kg. Do not use in children with low hemoglobin or evidence of hemolysis (3)[B].
  - Second and other treatments for pediatric and adolescent persons with ITP (3)
    - Splenectomy for chronic or persistent ITP (3)[B]

- Rituximab (Rituxan) 375 mg/m<sup>2</sup> weekly for 4 weeks (3)[C]
- High-dose dexamethasone 0.6 mg/kg/day for 4 days every 4 weeks (3)[C]
- Others without adequate data: azathioprine, cyclosporin A, danazol, mycophenolate mofetil, anti-CD52 monoclonal antibody, and interferon

- Adult

- First line, adult ITP

- Treatment is recommended for newly diagnosed patients with platelet count  $<30 \times 10^9/L$  (3)[C].
- PO prednisone 1 to 2 mg/kg/day for 21 days then tapered (3)[B]
- PO dexamethasone 40 mg daily for 4 days given every 2 to 4 weeks until platelets above  $50 \times 10^9/L$  (3)[B]
- If corticosteroids are contraindicated:
  - IVIG: 1 to 2 g/kg once, repeating as necessary (3)[C]
  - OR anti-D: 50 to 75 *&mgr;g/kg* once, repeating as necessary for Rh<sup>+</sup>, nonsplenectomized patients. Do not use anti-D in patients with low hemoglobin or evidence of hemolysis (3)[C].

- Second line, adult ITP

- Splenectomy for patients who failed corticosteroid therapy (3)[B]
- For patients whom splenectomy is contraindicated, thrombopoietin receptor agonists (3) [B]: eltrombopag (Promacta), 50 mg/day PO OR romiplostim (Nplate), 1 *&mgr;g/kg* SC weekly; may be used for patients at high risk of bleeding.
- Rituximab: 375 mg/m<sup>2</sup> IV weekly for 4 weeks, for patients at high risk of bleeding who have failed one line of therapy or post splenectomy (3)[C]
- Consider combination therapy with dexamethasone and rituximab (4)[C].
- Thrombopoietin receptor agonists can be considered for patients at risk of bleeding who failed first line of therapy (3)[C].
- Others to consider: azathioprine, cyclosporine A, cyclophosphamide, danazol, dapsone, mycophenolate mofetil, and vincristine

- ITP in pregnancy

- Preeclampsia or gestational thrombocytopenia may cause thrombocytopenia unrelated to ITP.
- Corticosteroids or IVIG are considered safe and are considered first line (4)[C].
- DO NOT USE danazol or cyclophosphamide
- ITP management at time of delivery is based on maternal bleeding risks, and mode of delivery should be based on obstetric indications (4)[C]. Platelet autoantibodies can cross the placenta and cause neonatal thrombocytopenia.
- Caesarean section can be considered if platelet count  $>50 \times 10^9/L$ .
- Prednisone and/or IVIG may be considered 2 to 3 weeks prior to delivery.
- ITP secondary to HIV
  - Antivirals should be considered before other treatment (3)[C].
  - If treatment is required, corticosteroids, IVIG, or anti-D are first-line options; and splenectomy is a second-line option (3)[C].
- ITP secondary to HCV
  - Antivirals should be considered before other treatment (3)[C].
  - If treatment required, IVIG is initial treatment (3)[C].
- EMERGENCY TREATMENT
  - Patients with intracranial or GI bleeding, massive hematuria, internal hematoma, or who need emergent surgery.
  - IV corticosteroids (e.g., IV methylprednisolone, 1 g/day for 3 doses (3)[B] with caution in patients with GI bleeding and/or IVIG 1 g/kg, repeat following day for count  $<50 \times 10^9/L$  (3)[B].
  - Platelet transfusions with IVIG may also be considered for significant bleeding (3)[C].
  - Other agents that may be considered: Recombinant factor VIIa (3)[C] not only promotes hemostasis but also increases risk of thrombosis. Efficacy of antifibrinolytic agents, aminocaproic acids, and tranexamic acid, is unproved; they may be used as adjunctive treatments only. Emergent splenectomy has been reported.

## *ISSUES FOR REFERRAL*

Hematology consultation is recommended for acute bleeding or for those who fail to respond to first-line therapies.

## ADDITIONAL THERAPIES

Proprietary traditional Chinese medicines: Dihuang Zhixue (blend of Rehmannia root and others herbs) showed benefit for childhood refractory ITP in a single, small, randomized controlled trial (5); limited evidence for Kami-kihi-to, minor decoction of *Bupleurum*, replenishing qi and tonifying kidney, roasted licorice decoction, Sairei-to, Shengxueling, and Zhinu-I and Zhinu-II (6). Unclear evidence for active hexose correlated compound, berberine, dong quai, ginseng, licorice, melatonin, and periwinkle (7).

## SURGERY/OTHER PROCEDURES

### Splenectomy

- Mortality rate is very low (<1%) even in patients with severe thrombocytopenia.
- Necessary vaccinations prior to splenectomy: polyvalent pneumococcal vaccine and quadrivalent meningococcal vaccine every 3 to 5 years and one-time *Haemophilus influenzae B* (Hib).
- Consider lifelong prophylactic antibiotics with penicillin or erythromycin.
- Should raise the platelet count to at least  $20 \times 10^9/L$  prior to surgery
- Reported 5- to 10-year efficacy is  $\approx 65\%$  for all patients.
- Laparoscopic splenectomy has similar long-term outcomes compared to open splenectomy and has better short-term outcomes (8)[C].

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### Patient Monitoring

Platelet counts weekly for patients on prednisone and monthly for stable patients are reasonable.

## DIET

- Evidence demonstrating benefit of an antiinflammatory diet in ITP is lacking.
- The following foods and supplements can cause significant bleeding: garlic, ginger, *Ginkgo biloba*, and saw palmetto
- Some foods and supplements that may inhibit platelets: evening primrose oil, fish oil, feverfew, ginseng, licorice, soy, vitamin C, vitamin E, and wintergreen
- Partial list of foods and supplements with coumarin or salicylate components: alfalfa, angelica,

anise, asafetida, aspen bark, birch, black cohosh, celery, chamomile, cinnamon, dandelion, fenugreek, heartsease, horse chestnut, meadowsweet, poplar, prickly ash, *Quassia*, sarsaparilla, sweet birch, sweet clover, and willow bark.

## **PATIENT EDUCATION**

- Modified activity to prevent injury or bruising; avoid contact sports.
- Avoid anticoagulants, aspirin and other platelet-inhibiting drugs, and NSAIDs.

## **PROGNOSIS**

- Acute ITP
  - ÷80-85% of patients completely recover within 2 months.
  - 15% proceed to chronic ITP.
- Chronic ITP
  - ÷10-20% of the patients recover spontaneously.
  - Remainder with diminished platelets for months to years
  - May see spontaneous remissions (5%) and relapses
- ÷10% are refractory (fail medical therapy and splenectomy).

## **COMPLICATIONS**

- Related to thrombocytopenia: 1% mortality due to intracranial hemorrhage and severe blood loss
- Related to treatment: for example, corticosteroid adverse effects, anaphylaxis and renal failure with IVIG, hepatotoxicity with eltrombopag, reports of progressive multifocal leukoencephalopathy with rituximab, hemolysis with anti-D, and septicemia for splenectomized patients

## Codes

&NA;

### ICD10

D69.3 Immune thrombocytopenic purpura

## Clinical Pearls

&NA;

- ITP: platelet counts of  $<100 \times 10^9/L$  caused by accelerated destruction and/or impaired thrombopoiesis by antiplatelet antibodies
- Pediatric ITP: relatively common, with spontaneous remission in 2 months
- Adult ITP: usually persistent; requires treatment, with rare spontaneous remission

# Impetigo

Elisabeth L. Backer, MD

## BASICS

### DESCRIPTION

- A contagious, superficial, intraepidermal infection occurring prominently on exposed areas of the face and extremities, most often seen in children
- Infected patients usually have multiple lesions.
- Cultures are positive in >80% cases for *Staphylococcus aureus* either alone or combined with group A *β*-hemolytic streptococci; *S. aureus* is the more common pathogen since the 1990s.
- Nonbullous impetigo: most common form of impetigo. Formation of vesiculopustules that rupture, leading to crusting with a characteristic golden appearance; local lymphadenopathy may occur.
- Bullous impetigo: staphylococcal impetigo that progresses rapidly from small to large flaccid bullae (newborns/young children) caused by epidermolytic toxin release; less lymphadenopathy; trunk more often affected; <30% of patients
- Folliculitis: considered by some to be *S. aureus* impetigo of hair follicles
- Ecthyma: a deeper, ulcerated impetigo infection often with lymphadenitis
- System(s) affected: skin/exocrine
- Synonym(s): pyoderma; impetigo contagiosa; impetigo vulgaris; fox impetigo

### EPIDEMIOLOGY

#### Incidence

- Predominant sex: male = female
- Predominant age: children ages 2 to 5 years

#### Prevalence

In the United States: not reported but common

## *Pediatric Considerations*

- Poststreptococcal glomerulonephritis may follow impetigo (in young children).
- Impetigo neonatorum may occur due to nursery contamination.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Coagulase-positive staphylococci: pure culture ÷50-90%; more contagious via contact
- *&bgr;*-Hemolytic streptococci: pure culture only ÷10% of the time (primarily group A)
- Mixed infections of streptococci and staphylococci are common; data suggest increasing importance of staphylococci over the past 20 years.
- Direct contact or insect vector
- Can result from contamination at trauma site
- Regional lymphadenopathy

## *RISK FACTORS*

- Warm, humid environment
- Tropical or subtropical climate
- Summer or fall season
- Minor trauma, insect bites, breaches in skin
- Poor hygiene, poverty, crowding, epidemics, wartime
- Familial spread
- Poor health with anemia and malnutrition
- Complication of pediculosis, scabies, chickenpox, eczema/atopic dermatitis
- Contact dermatitis (*Rhus* spp.)
- Burns
- Contact sports
- Children in daycare
- Possibly tobacco exposure
- Carriage of group A *Streptococcus* and *Staphylococcus aureus*

## *GENERAL PREVENTION*

- Close attention to family hygiene, particularly hand washing among children
- Covering of wounds
- Avoidance of crowding and sharing of personal items
- Treatment of atopic dermatitis

## **COMMONLY ASSOCIATED CONDITIONS**

- Malnutrition and anemia
- Crowded living conditions
- Poor hygiene
- Neglected minor trauma
- Any chronic/underlying dermatitis

## **DIAGNOSIS**

### **HISTORY**

- Lesions are often described as painful.
- May be slow and indolent or rapidly spreading
- Most frequent on face around mouth and nose or at site of trauma

## **PHYSICAL EXAM**

- Tender red macules or papules as early lesions (contact dermatitis presents with pruritic lesions)
- Thin-roofed vesicles to bullae: usually nontender
- Pustules
- Weeping, shallow, red ulcers
- Honey-colored crusts
- Satellite lesions
- Often multiple sites
- Bullae on buttocks, trunk, face

## **DIFFERENTIAL DIAGNOSIS**

## Nonbullous

- Contact dermatitis
  - Chickenpox
  - Herpes
  - Folliculitis
  - Erysipelas
  - Insect bites
  - Severe eczematous dermatitis
  - Scabies
  - Tinea corporis
- Bullous
    - Burns
    - Pemphigus vulgaris
    - Bullous pemphigoid
  - Stevens-Johnson syndrome

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- None usually done; cultures of pus/bullae fluid may be helpful if no response to empiric therapy.
  - Culture: taken from the base of lesion after removal of crust will grow both staphylococci and group A streptococci
  - Antistreptolysin-O (ASO) titer: can be weak positive for streptococci but overall not useful
  - Antideoxyribonuclease B (anti-DNase B) and antihyaluronidase (AHT) response more reliable than ASO response
  - Streptozyme: positive for streptococci
- Disorders that may alter lab results: Streptococcal pharyngitis will alter streptococcal enzyme tests.

### *Follow-Up Tests & Special Considerations*

- Monitor for spread of disease and systemic manifestations.
- Serologic testing is helpful in context of impetigo with subsequent poststreptococcal glomerulonephritis.

## TREATMENT

### GENERAL MEASURES

- Treatment speeds healing and avoids spread of disease.
- Prevent with mupirocin or triple antibiotic ointment TID to sites of minor skin trauma.
- Remove crusts; clean with gentle washing 2 to 3 times daily; and clean with antibacterial soap, chlorhexidine, or Betadine.
- Washing of entire body may prevent recurrence at distant sites.

### MEDICATION

- In 2005, the Infectious Diseases Society of America (IDSA) recommended topical treatment for limited lesions and oral medication when the disease is more severe/extensive (1)[A].
- Optimal treatment is unclear due to limited quality of evidence. Treatment reduces spread of infection and enhances resolution (2)[C].
- Penicillin and macrolide therapy is no longer recommended. Fluoroquinolones are not indicated due to resistance patterns.
- Consult the local hospital or health department for microbial resistance information.
- Nonbullous (minor spread, treat 7 days; widespread, treat 10 days); bullous (treat 10 days)
  - Retapamulin 1% ointment to be applied BID for 5 days
  - Mupirocin (Bactroban) 2% topical ointment applied TID for 5 to 7 days (nonbullous only); not as effective on scalp as around mouth
  - Dicloxacillin: adult 250 mg PO QID; pediatric <40 kg: 12 to 25 mg/kg/day divided q6h; >40 kg: 125 to 250 q6h
- Dicloxacillin, cephalexin, topical mupirocin, and fusidic acid are effective unless local staphylococcal strains are resistant. (For methicillin-resistant *S. aureus* [MRSA] infections, treatment options include clindamycin, tetracyclines, or trimethoprim-sulfamethoxazole.) Oral doses given for 7 days are usually sufficient (3)[C].

- 1st-generation cephalosporins
  - Children
    - Cephalexin 25 to 50 mg/kg/day divided, q6-12h
    - Cefaclor 20 to 40 mg/kg/day divided q8h
    - Cephadrine 25 to 50 mg/kg/day divided q6-12h
    - Cefadroxil 30 mg/kg/day divided BID
  - Adults
    - Cephalexin 250 mg up to QID
    - Cefaclor 250 mg TID
    - Cephadrine 500 mg BID
    - Cefadroxil 1 g/day in divided doses
- Clindamycin 300 mg q6-8h
- Severe bullous disease may require IV therapy such as nafcillin or cefazolin.

## *ISSUES FOR REFERRAL*

If resistant or extensive infections occur, especially in immunocompromised patients

## *ADDITIONAL THERAPIES*

Monitor for microbial resistance patterns.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

- Athletes are restricted from contact sports.
- School and daycare contagious restrictions
- Children can return to school 24 hours after initiation of antimicrobial treatment.

## *Patient Monitoring*

If not clear within 7 to 10 days, culture the lesions.

## *PATIENT EDUCATION*

Avoidance of infection spread is the key; hand washing is vital, especially for reducing spread in children.

## PROGNOSIS

- Complete resolution in 7 to 10 days with treatment
- Antibiotic treatment will not prevent or halt glomerulonephritis, as it will rheumatic fever.
- If not clear within 7 to 10 days, culture is necessary to find resistant organism.
- Recurrent impetigo: Evaluate for carriage of *S. aureus* in nares (also perineum, axillae, toe web). Apply mupirocin ointment to nares BID for 5 days for clearance/decolonization.

## COMPLICATIONS

- Ecthyma
- Erysipelas
- Poststreptococcal acute glomerulonephritis
- Cellulitis
- Bacteremia
- Osteomyelitis
- Septic arthritis
- Pneumonia
- Lymphadenitis

## Codes

&NA;

### ICD10

- L01.00 Impetigo, unspecified
- L01.01 Non-bullous impetigo
- L01.03 Bullous impetigo

## Clinical Pearls

&NA;

- Superficial, intraepidermal infection
- Predominantly staphylococcal in origin
- Microbial resistance patterns need to be monitored.
- Topical treatment is recommended for limited lesions and oral medication only when the disease is more severe/extensive.

# Incontinence, Fecal

Kalyanakrishnan Ramakrishnan, MD

## BASICS

Continuous or recurrent involuntary passage of fecal material for >1 month in individual at least 4 years of age

- Involves recurrent, involuntary loss of solid/liquid stool
- Requires careful rectal exam to assess rectal tone, voluntary squeeze, and rule out overflow incontinence from fecal impaction
- Endorectal ultrasound (EUS) is the simplest, most reliable and least invasive method to detect anatomic anal sphincter defects.
- The goal of treatment is to restore continence and/or improve quality of life.

## DESCRIPTION

Major incontinence is the involuntary evacuation of feces. Minor incontinence (fecal soilage) includes incontinence to flatus and occasional seepage of liquid stool.

## Geriatric Considerations

- The prevalence of fecal incontinence increases with age. It is an important cause of nursing home placement among the elderly.
- Idiopathic fecal incontinence is more common in older women.

## EPIDEMIOLOGY

### Incidence

Patients will not report fecal incontinence unless specifically queried (Òsilent afflictionÓ). The number of patients affected is likely significantly underestimated.

### Prevalence

- In younger persons: women > men
- 8% of adults

- 15% of adults age >70 years
- 56-66% of hospitalized older patients and >50% of nursing home residents
- 50-70% of patients who have urinary incontinence also suffer from fecal incontinence.

### *Pregnancy Considerations*

Obstetric injury to the pelvic floor may result in either temporary incontinence or persistent incontinence.

### *Geriatric Considerations*

- Fecal impaction and overflow diarrhea leading to fecal incontinence is common in older patients.
- Surgical history—particularly anal surgery, including hemorrhoidectomy, anal fissure repair (sphincterotomy), anal dilatation, or prior pelvic floor surgeries

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Continence requires complex orchestration of pelvic musculature, nerves, and reflex arcs.
- Stool volume and consistency, colonic transit time, anorectal sensation, rectal compliance, anorectal reflexes, external and internal sphincter muscle tone, puborectalis muscle function, and mental capacity each play a role in maintaining fecal continence.
- Disease processes or structural defects impacting any of these factors may contribute to fecal incontinence.
- Diabetes is the most common metabolic disorder leading to fecal incontinence through pudendal nerve neuropathy.
- Congenital: spina bifida and myelomeningocele with spinal cord damage
- Trauma: anal sphincter damage from vaginal delivery or surgical procedures
- Medical: diabetes, stroke, spinal cord trauma, degenerative disorders of the nervous system, inflammatory conditions, rectal neoplasia

## **RISK FACTORS**

- Functional status—older age, female sex, obesity, limited physical activity contribute to poor functional status
- Neuropsychiatric conditions (dementia, depression)
- Multiple sclerosis, spinal cord injury, stroke, diabetic neuropathy

Prostatectomy, radiation

- Trauma: Risk factors for perineal trauma at the time of vaginal delivery include occipitoposterior presentation, prolonged second stage of labor, assisted vaginal delivery (forceps or vacuum-assist), and episiotomy.
- Diarrhea, inflammatory bowel disease (IBD), irritable bowel syndrome (IBS), menopause, smoking, constipation
- Potential association with child abuse and sexual abuse
- Congenital abnormalities, such as imperforate anus/rectal prolapse
- Fecal impaction

## GENERAL PREVENTION

- Behavioral and lifestyle changes: Obesity, limited physical activity/exercise, poor diet, and smoking are modifiable risk factors.
- Postmeal bowel regimen—defecate regularly after meals to maximize effect of gastrocolic reflex.
- Pelvic floor muscle training during and after pregnancy and pelvic surgery
- Increase fiber intake (>30 g/day)

## COMMONLY ASSOCIATED CONDITIONS

- Age >70 years
- Urinary incontinence/pelvic organ prolapse
- Chronic medical conditions—diabetes mellitus, dementia, stroke, spinal cord compression, depression, immobility, chronic obstructive pulmonary disease, IBS, and IBD
- Perineal trauma (obstetric)
- Anorectal surgery
- History of pelvic/rectal irradiation

## DIAGNOSIS

Diagnosis is based on history and physical findings.

### HISTORY

- Patients seldom volunteer information about fecal incontinence. Direct

questioning is important.

- Problem-specific history includes (1)[C]:
  - Severity of soiling by liquid stool or gross incontinence of solid stool
  - Onset and duration (recent onset vs. chronic)
  - Frequency, presence of constipation/diarrhea
- Medication review
- Review diet, medical and obstetric history, lifestyle, and mobility.
- Evaluate for social withdrawal and depression.

## *PHYSICAL EXAM*

- Inspect the perineum for chemical dermatitis, hemorrhoids, fistula, surgical scars, skin tags, rectal prolapse, soiling, and ballooning of the perineum (sarcopenia of pelvic musculature).
- A patulous anal orifice may indicate myopathy or a neurologic disorder.
- Evaluate the external sphincter response to perineal skin stimulation (anal wink). Absence suggests neuropathy.
- Ask the patient to bear down, preferably in standing position, to assess for rectal prolapse.
- Digital rectal exam to assess anal canal pressure sphincter tone, rectal bleeding, hemorrhoids, neoplasm, fecal consistency, and diarrhea/distal fecal impaction.
- General neurologic examination, including perianal sensation (1)[C]
- Evaluate mental status.

## *DIFFERENTIAL DIAGNOSIS*

- Anorectal disorders
  - Inflammatory/infectious disorders
  - Neoplasms, radiation proctitis, ischemic colitis, fistulas
  - Prolapsed internal hemorrhoids; rectal prolapse
  - Trauma: obstetric, surgical, radiation, accidental, sexual
- Neurologic disorders
  - Stroke, dementia, neoplasms, spinal cord injury, and/or diseases causing altered level of consciousness
  - Pudendal neuropathy, neurosyphilis, multiple sclerosis, diabetes mellitus

- Miscellaneous causes
  - Infectious diarrhea, fecal impaction and overflow, IBS, laxative abuse, IBD, short bowel syndrome, myopathies, senescence and frailty, collagen vascular disease, psychological and behavioral problems

## *DIAGNOSTIC TESTS & INTERPRETATION*

The approach to fecal incontinence in older patients should be individualized, minimally invasive, and practically feasible. History and physical exam are generally sufficient for diagnosis. If uncertainty remains, consider the following:

- EUS is the most reliable and least invasive test for defining anatomic defects in the external and internal anal sphincters, rectal wall, and the puborectalis muscle (1)[B]. EUS can predict therapeutic response to sphincteroplasty.
- Plain abdominal x-ray (impaction, constipation)
- Sigmoidoscopy/anoscopy/colonoscopy (colitis, neoplasm)

### *Initial Tests (lab, imaging)*

- If history of travel, antibiotics, tube feedings, or signs and symptoms of sepsis, consider stool studies:
  - Culture
  - Ova and parasites
  - *Clostridium difficile* toxin assay
- Thyroid-stimulating hormone (TSH), electrolytes, and BUN in elderly patients
- EUS may demonstrate structural abnormalities of the anal sphincters, rectal wall, or puborectalis muscle.
- EUS may detect a sphincter injury in over 1/3 of primiparous vaginal deliveries and nearly half of multiparous vaginal deliveries.

### *Follow-Up Tests & Special Considerations*

- Defecography can measure the anorectal angle, evaluate pelvic descent, and detect occult/overt rectal prolapse (2)[C].
- MRI defecography (dynamic MRI) can further define pelvic floor anatomy.

- Anorectal manometry: Measures parameters such as maximal resting anal pressure, amplitude

and duration of squeeze pressure, the rectoanal inhibitory reflex, threshold of conscious rectal sensation, rectal compliance, and anorectal pressures during straining.

- Pudendal nerve terminal motor latency (PNTML): This technique is operator-dependent and has poor correlation with clinical and histologic findings.
- Electromyography: can assess neurogenic/myopathic damage

## TREATMENT

### GENERAL MEASURES

- In ambulatory patients, scheduled (or prompted) defecation is effective, particularly in patients with overflow incontinence.
- Kegel exercises to strengthen pelvic floor
- If bed-bound, scheduled osmotic or stimulant laxatives for constipation
- Enemas, laxatives, and suppositories may help promote more complete bowel emptying in impacted patients while minimizing postdefecation leakage.
- Scheduled toileting and use of stool deodorants (Periwash, Derifil, Devrom).

### MEDICATION

Limited evidence that antidiarrheals (loperamide, codeine) and drugs enhancing sphincter tone (phenylephrine gel, sodium valproate) are of benefit (3)[B]. Cholestyramine, colestipol useful in diarrhea following malabsorption or cholecystectomy; alosetron in diarrhea due to IBS, amitriptyline in idiopathic fecal incontinence

#### *First Line*

Specific treatment of underlying disorder (e.g., infectious diarrhea/IBD) may improve fecal continence.

#### *Second Line*

- Increasing dietary fiber in milder forms of fecal incontinence reduces symptoms (1)[B]. Stool-bulking agents include high-fiber diet, psyllium products, or methylcellulose.
- Antidiarrheal agents, such as adsorbents or opium derivatives, may reduce fecal incontinence (1)[C].
- Disimpact patients with fecal impaction and overflow incontinence and treat with a bowel regimen to prevent recurrence.

## *ADDITIONAL THERAPIES*

- Biofeedback: initial treatment modality in motivated patients with some voluntary sphincter control (1)[C]; teaches patients to recognize rectal distension and contract the external anal sphincter while keeping intra-abdominal pressure low
- Biofeedback plus electrical stimulation is more effective than either alone.
- Patients with systemic neurologic disorders, anal deformities, or frequent episodes of incontinence respond poorly.

## *SURGERY/OTHER PROCEDURES*

- Surgery should be considered only when nonsurgical approaches have failed.
- Sphincter repair should be offered for highly symptomatic patients with well-defined defect of external anal sphincter (1)[A].
- Injectable therapy (tissue-bulking agent injected into the anorectal submucosa or the intersphincteric space) appears safe and effective for patients with internal anal sphincter dysfunction (4)[B].
- Artificial anal sphincter implantation/dynamic graciloplasty (where gracilis muscle transposed into anus as modified sphincter) may be considered in patients with severe fecal incontinence and irreparable sphincter damage (5)[B].
- Stoma (colostomy/ileostomy) creation may be appropriate in patients with disabling fecal incontinence when other available therapeutic options have failed or if preferred by patient (1)[B].
- Anal plugs are available to minimize fecal leakage in patients who do not benefit from other treatment modalities, especially immobilized, institutionalized, or neurologically disabled patients; often poorly tolerated (6)[C].
- Sacral nerve stimulation (neuromodulation) via implantation of SC electrodes delivering lowamplitude electrical stimulation to sphincter muscles improves overall rectal tone, especially in patients with a coexistent sphincter defect (7)[B].
- SECCA PROCEDURE (radiofrequency anal sphincter remodeling)Ñtemperature-controlled radiofrequency energy delivered to the anorectal junction distal to the dentate line causing tissue damage, scarring, and anal canal narrowing. Minimally invasive, ambulatory procedure useful in mild-to-moderate fecal incontinence (8)[C].
- Magnetic anal sphincter (MAS) devicesÑseries of interlinked titanium beads (14 to 20) with internal magnetic cores placed to form a flexible ring that encircles the external anal sphincter 3 to 5 cm from the anal verge. During expulsion of feces, the beads separate allowing evacuation. After evacuation, the beads approximate and close the canal (9)[B]. Useful in

moderate and severe incontinence

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

If secondary to fecal impaction, manual evacuation of fecal mass (after lubrication with lidocaine jelly)

### ***Nursing***

- Avoid catharsis.
- No hot water, soap, or hydrogen peroxide enemas.

### ***Discharge Criteria***

Outpatient care

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Periodic rectal exam

### ***Patient Monitoring***

Consider impaction if there is <1 bowel movement every other day with fecal incontinence.

### ***DIET***

- High fiber (20 to 30 g/day) and at least 1.5 L fluid daily
- Avoid precipitants (caffeine).

### ***PATIENT EDUCATION***

Kegel/sphincter training exercises are necessary but not sufficient for treating fecal incontinence.

### ***PROGNOSIS***

- Reimpaction likely if bowel regimen discontinued
- 50% failure rate over 5 years following overlapping sphincteroplasty

## **COMPLICATIONS**

- Depression and social isolation
- Skin ulcerations
- Artificial bowel sphincter: infection, erosion, mechanical failure

## Codes

**&NA;**

### ICD10

- R15.9 Full incontinence of feces
- R15.2 Fecal urgency
- R15.0 Incomplete defecation

## Clinical Pearls

**&NA;**

- New onset fecal incontinence may indicate spinal cord compression if accompanied by other neurologic signs or symptoms.
- Differentiate true incontinence from pseudoincontinence (overflow or functional incontinence).
- Scheduled defecation after meals, bulking agents, and scheduled enemas minimize impaction and are helpful in mild/moderate fecal incontinence.

# Incontinence, Urinary Adult Female

Cara Marshall, MD

## BASICS

### DESCRIPTION

- Urinary incontinence: involuntary loss of urine that is objectively demonstrable and is of medical, financial, social, or hygienic concern
- Stress incontinence: associated with increased intraabdominal pressure such as coughing, laughing, sneezing, or exertion
- Urge incontinence: sudden uncontrollable loss of urine (also known as overactive bladder or detrusor overactivity)
- Mixed incontinence: loss of urine from a combination of stress and urge incontinence
- Overflow incontinence: high residual or chronic urinary retention leading to urinary spillage from an overdistended bladder
- Functional incontinence: loss of urine due to deficits of cognition and/or mobility
- Total incontinence: continuous leakage of urine; leakage without awareness

### EPIDEMIOLOGY

- Affects 25% of young women and up to 57% of women aged 40 to 60 years. Women 19 to 64 years of age have predominantly stress incontinence (12-28%), followed by mixed (7-12%), and urge (5-10%) incontinence.
- Prevalence in women >75 years is 75%, and 6% of nursing home admissions are directly attributable to incontinence (1).
- Severe or large-volume incontinence is primarily mixed (37%), followed by urge (27%) and stress (15%) (2).

### ETIOLOGY AND PATHOPHYSIOLOGY

- Stress incontinence: occurs with increased intraabdominal pressure. Two types:
  - Anatomic: due to urethral hypermobility from lack of pelvic support

Intrinsic sphincter deficiency (ISD): impaired closure of urethra. Urethral mucosal seal and inherent closure from collagen, fibroelastic tissue, smooth and striated muscles, and so forth, may be lost secondary to surgical scarring, radiation, or hormonal and senile changes.

- Urge incontinence: may be due to detrusor overactivity or may be idiopathic
- Overflow incontinence: urinary retention (usually from neurogenic bladder)
- Total incontinence: constant loss of urine. Ectopic ureters in females usually open in the urethra distal to the sphincter or in the vagina, causing continuous leakage. May also occur with fistulous connections between bladder, ureters, or urethra, and vagina or uterus.

## **RISK FACTORS**

Advanced age, impaired functional status, obesity (BMI >30), history of gestational diabetes, pregnancy, vaginal childbirth, pelvic surgery or radiation, urethral diverticula, genital prolapse, smoking, chronic obstructive pulmonary disease (COPD), cognitive impairment, constipation, caffeine, and pelvic floor dysfunction

## **GENERAL PREVENTION**

Obesity avoidance, smoking cessation, high-fiber diet to reduce constipation

## **COMMONLY ASSOCIATED CONDITIONS**

Pelvic organ prolapse, UTI, COPD, diabetes mellitus, neurologic disease, obesity, chronic constipation, depression, low libido, dyspareunia, and any disease that results in chronic cough

## **DIAGNOSIS**

### **HISTORY**

- Age: Stress incontinence is more common in women aged 19 to 64 years, whereas mixed incontinence is more common in women >65 years. Onset from childhood indicates congenital causes (e.g., ectopic ureter).
- Amount and frequency of leakage
- Stress incontinence: Occurs in small spurts; patients typically remain dry at night in bed.
- Urge incontinence: sudden urge followed by leakage of large amounts, usually associated with frequency and nocturia. Sensory stimuli may trigger (e.g., cold).
- Continuous slow leakage in between regular voiding indicates ectopic ureter, urinary fistula, and so forth.

- Pain: Suprapubic pain with dysuria implies urinary infection, dyspareunia, interstitial cystitis, and so forth.
- Medical history
  - Neurologic conditions or suggestive symptomatology: cerebrovascular accident, parkinsonism, multiple sclerosis, myelodysplasia, diabetes, spinal cord injury
  - Radiation to pelvic and vaginal areas: causes ISD, overactive bladder, fibrotic changes of pelvic floor musculature, and low bladder compliance
  - Obstetric history: Weakness of the pelvic floor is more likely in multiparous women.
  - History of smoking and COPD with a chronic cough can aggravate incontinence.
  - Constipation can aggravate incontinence.
- Medications
  - Sympatholytic *&agr*-blockers (terazosin, prazosin, doxazosin, tamsulosin, alfuzosin, silodosin) can cause or worsen incontinence.
  - Sympathomimetic agents, tricyclic antidepressants, anticholinergics, and opioids can cause retention with overflow incontinence.
- Surgical history: Pelvic surgery, including gynecologic and bowel surgery, can injure the pelvic floor musculature and affect neurologic function.

## PHYSICAL EXAM

- General status
  - Obesity (BMI)
- General neurologic examination
  - Mental status, speech, intellectual performance
  - Motor status: gait, generalized or focal weakness, rigidity, tremor
  - Sensory status: impairment of perineal-sacral area sensation
- Urologic examination
  - Abdomen: masses, incisional scars of previous surgeries
  - Suprapubic tenderness: may indicate cystitis
  - Palpable, distended bladder: chronic urinary retention

- Pelvic examination
  - Examination of the perineum and external genitalia, including tissue quality and sensation
  - Vaginal (half-speculum) examination for prolapse
  - Bimanual pelvic and anorectal examination for pelvic masses, fecal impaction, pelvic floor function, and so forth
    - Urethral hypermobility: gauged by palpation of the descent of the proximal urethra on straining
    - Assessment of pelvic floor resting tone and function (ability to isolate and contract pelvic floor musculature) (3)[C]
  - Stress test for urinary incontinence: Patient is asked to cough or strain to reproduce stress incontinence.
  - Cystocele: if evident, stage (grade 0 to 4)
  - Rectocele: if evident, stage (stage 0 to IV)

## *DIFFERENTIAL DIAGNOSIS*

- Nocturnal enuresis: idiopathic, detrusor overactivity, neurogenic, cardiogenic, or sleep apnea
- Continuous leakage: ectopic ureter, urinary fistulas
- Postvoid dribbling: urethral diverticulum, idiopathic, iatrogenic, surgical
- Pelvic pain/dyspareunia: interstitial cystitis
- Pelvic organ prolapse
- Hematuria/recurrent UTI/pelvic mass: malignancy (4)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Urinalysis and urine culture
- Renal function assessment: recommended if renal impairment is suspected

### *Initial Tests (lab, imaging)*

- Unnecessary in uncomplicated patients
- Bladder scan to evaluate postvoid residual if overflow is suspected (<50 to 100 mL expected) (4)
- Upper tract imaging if upper tract involvement is suspected: scan or renal ultrasound (US)

- International Consultation of Incontinence Modulator Questionnaire (ICIQ) is highly recommended for assessment of patient's perspective of symptoms of incontinence and his or her impact on quality of life.
- 3IQ questionnaire helps differentiate between stress and urge incontinence ([http://www.overactivebladder.com/sites/g/files/g10016541/f/201502/3IQ\\_updated.pdf](http://www.overactivebladder.com/sites/g/files/g10016541/f/201502/3IQ_updated.pdf)) (2).
- 3-day voiding diary to evaluate fluid intake, caffeine intake, timing of leakage, and patient habits

### *Follow-Up Tests & Special Considerations*

Asymptomatic bacteriuria is common. With a positive urine culture, initial treatment is indicated; however, if this is ineffective, repeat treatment is not indicated (3).

### *Diagnostic Procedures/Other*

Urodynamic studies (not indicated in initial workup):

- Cystometric study of detrusor function
- Results on urodynamic testing are not predictive of treatment or surgery success (5)[A].

## **TREATMENT**

### *GENERAL MEASURES*

- Treat correctable causes (e.g., UTI).
- Encourage weight loss in obese patients.
- Aggressively correct constipation.
- Treat mixed for primary symptom type (4)[C].

---

P.551

### *MEDICATION*

#### *First Line*

- Stress incontinence
  - Lifestyle changes
    - Reduce BMI to <25 (5)[A].
    - Reduce caffeine to <1 cup coffee/day (5)[B].

- Aggressive treatment of constipation: Limit medications that may induce constipation, polyethylene glycol 3350 (PEG 3350), increased fluid intake, and so forth.
- Kegel exercises
  - Pelvic floor muscle training, at least eight contractions TID (3)[A]
  - Proper technique should be confirmed on exam; training by physical therapists.
  - Maintain treatment for at least 3 months (2).
  - 5 times as effective as placebo (1)[A]
- Urge incontinence
  - Supervised bladder training/scheduled voiding (1)[C]

## *Second Line*

- Stress incontinence
  - Surgical management for stress incontinence:
    - Midurethral sling (preferred surgical intervention) (4)[A]
      - Women with moderate to severe stress incontinence have better outcomes at 1 year with midurethral slings than pelvic floor muscle training (6)[A].
      - Retropubic (more perioperative complications)
      - Transobturator (more pain/dyspareunia)
      - Single-incision sling (MiniArc, SOLYX)
    - Abdominal approaches: Marshall-Marchetti-Krantz cystourethropexy, Burch colposuspension, laparoscopic colposuspension (4)[A]
    - Periurethral injection of bulking agents (may provide symptom relief but not permanent cure): silicone particles, carbon beads, calcium hydroxylapatite (5)[B]
- Urge incontinence: anticholinergic agents (1)[A]
  - Tolterodine (Detrol LA): 2 to 4 mg/day PO
  - Oxybutynin (Ditropan XL): 5 to 30 mg/day PO
  - Solifenacin (VESIcare): 5 to 10 mg/day PO
  - Darifenacin (Enablex): 7.5 to 15 mg/day PO
  - Trospium chloride (Sanctura XR): 60 mg/day PO

- Transdermal oxybutynin gel (Gelnique): 10% applied daily
- Transdermal oxybutynin patch (Oxytrol): twice weekly—available over the counter (OTC)
- Fesoterodine (Toviaz): 4 to 8 mg/day PO
- Dry mouth, dry eyes, constipation, impaired cognitive function, and other anticholinergic side effects can limit use.
- Avoid with narrow-angle glaucoma, urinary retention (postvoid residual [PVR] >250 mL), impaired gastric emptying, and frail elders (3)[A]. No single agent has been shown to be overall superior (1)[A].
- Fesoterodine achieves incontinence > tolterodine, at the expense of greater adverse effects (1)[B].
- Extended-release and transdermal medications cause fewer side effects (5)[B].
- *β*-3 agonist: mirabegron (Myrbetriq ER): 25 to 50 mg/day PO (1)[B]; onset of action delayed ÷8 weeks; increases BP (avoid use in those with uncontrolled HTN)

### *Third Line*

- Stress incontinence
  - Duloxetine (Cymbalta) may have some limited efficacy (1)[C].
  - Estrogen may be beneficial in topical form, but transdermal estrogen may worsen symptoms (1)[B].
    - Biofeedback and electrostimulation of pelvic floor muscles
    - Occlusive and supportive devices (e.g., cones, pessaries, and super tampons)
    - Acupuncture (in selected cases)
- Urge incontinence
  - Intradetrusor onabotulinumtoxinA **100 to 200 U** (urinary retention common, temporary selfcatheterization may be needed) (4)[A]
  - Sacral nerve stimulation: 50% reduction in episodes in 2/3 of patients who have failed other treatments. Invasive with frequent complications (4)[B]
  - Percutaneous tibial nerve stimulation: office-based therapy, requires frequent visits (3)
  - Bladder augmentation (4)[C]

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Postoperative assessment: Rule out UTI, check postvoid residual, check suture lines.
- Periodic long-term follow-up with outcome-based questionnaire surveys

### PATIENT EDUCATION

Instructions on self-care and warning signs are available at PubMed Health: Urinary Incontinence: <https://www.nlm.nih.gov/medlineplus/urinaryincontinence.html>

### PROGNOSIS

Significant improvements are usually obtained with most patients.

### COMPLICATIONS

- Prolonged exposure to urine causes skin breakdown and dermatitis, which may lead to ulceration and secondary infection.
- Inability for self-care is the precipitating factor for many nursing home admissions.
- Social isolation/depression
- Weight gain (due to self-limiting exercise from fear of leakage)
- Impaired sexual function
- Impaired quality of life

## Codes

&NA;

### ICD10

- R32 Unspecified urinary incontinence
- N39.3 Stress incontinence (female) (male)
- N39.41 Urge incontinence

## Clinical Pearls

## **&NA;**

- Urinary incontinence is the involuntary loss of urine that is objectively demonstrable; markedly detrimental to quality of life; and is of medical, financial, social, or hygienic concern.
- Stress incontinence: associated with increased intraabdominal pressure such as coughing, laughing, sneezing, or exertion
- Urge incontinence: sudden uncontrollable urgency, leading to leakage of urine (also known as overactive bladder or detrusor overactivity)
- Rule out UTI or STI by culture.
- Aggressively treat constipation.
- Assume that the majority of women can be significantly helped by treatment.
- For stress incontinence, physical therapy/pelvic floor rehabilitation and midurethral sling surgeries are most commonly used.
- For urge incontinence, if anticholinergic agents fail, intradetrusor onabotulinumtoxinA is often beneficial.

# Incontinence, Urinary Adult Male

Amar Talati, DO

David O. Parrish, MS, MD, FAAFP

## BASICS

### DESCRIPTION

- Urinary incontinence (UI) refers to the involuntary loss of urine that presents a medical, financial, social, or hygienic problem; the five main types of incontinence include stress, urge, mixed, overflow (urinary retention), and functional UI (1).
- Stress incontinence: involuntary urine leaks secondary to increased intra-abdominal pressure being greater than the sphincter can control; may be precipitated by sneezing, laughing, coughing, exertion
- Urge incontinence: Involuntary leakage of urine associated with urgency is believed to be secondary to uncontrolled contraction of the urinary bladder. It is also called detrusor overactivity.
- Mixed incontinence: involuntary leakage of urine with urgency and with stress, such as sneezing, laughing, coughing, exertion
- Overflow incontinence: Also known as urinary retention; this occurs with bladder overdistention due to impaired detrusor contraction or bladder outlet obstruction (due to benign prostatic hyperplasia [BPH], bladder stones, bladder tumors, pelvic tumors, urethral strictures or spasms).
- Functional UI: urine leakage variable, often due to environmental or physical barriers to toileting (i.e., reduced mobility).
- Other causes transient UI often due to infection, medication side effects, or psychological disorder, in addition to postmicturition dribbling associated with BPH
- Polyuria is defined by excessive amounts of urine ( $\geq 2.5$  to 3 L) over 24 hours
- Nocturnal polyuria is where  $>33\%$  of total daily urine output occurs during sleeping hours.

### EPIDEMIOLOGY

- Stress incontinence in men is rare, unless it is attributable to prostate surgery, neurologic disease, or trauma.

- Detrusor overactivity may be spontaneous or provoked, but involuntary, and may be neurogenic in cause or idiopathic.
- Reported rates of incontinence range from 1% after transurethral resection to 2-66% after radical prostatectomy, and 1-15% following transvesical prostatectomy, although rates decline with time (1).

## *Prevalence*

- 12.4% prevalence of UI in community dwelling adult men in the United States as based on the National Health and Nutrition Examination Survey (NHANES) as of 2008.
- 4.5% reported moderate to severe UI, of which 48.6% experienced urge, 23.5% experienced other UI, 15.4% experienced mixed, and 12.5% experienced stress incontinence as per the NHANES report in 2010.
- UI is common in nursing home patients, with a prevalence of about 70% in the Southeastern United States from 1999 to 2002.
- Major depression, hypertension, and benign prostatic hypertrophy associated with UI.
- Incontinence in men of all ages is approximately half as prevalent as it is in women; however, after 80 years of age, both sexes are affected equally (1).

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Incontinence secondary to bladder abnormalities
  - Detrusor overactivity results in urge incontinence.
  - Detrusor overactivity commonly is associated with bladder outlet obstruction from benign prostatic hyperplasia (BPH).
- Incontinence secondary to outlet abnormalities
  - Sphincteric damage secondary to pelvic surgery or radiation
  - Sphincteric dysfunction secondary to neurologic disease
  - Commonly associated with BPH due to compression of the urethra, affecting urinary flow
- Mixed incontinence is caused by abnormalities of both the bladder and the outlet overflow or by enlarged prostate/bladder neck contracture from prostate surgery.
- Stress incontinence is caused by weakened urethral sphincter and/or pelvic floor weakness.

## *RISK FACTORS*

- Age
- Hypertension
- Neurologic disease
- Prostate surgery
- Pelvic trauma
- History of urinary tract infections
- Major depression
- Diabetes

## GENERAL PREVENTION

Proper management of conditions, such as symptomatic bladder outlet obstruction caused by BPH early in the course may prevent continence problems later in life; no evidence for screening in men unless patient is experiencing symptoms using The 3 Incontinence Questions tool to evaluate the type of UI (2)[C].

## COMMONLY ASSOCIATED CONDITIONS

- Neurologic disease (cerebrovascular accident, parkinsonism, multiple sclerosis, myelodysplasia, spinal cord injury)
- Pelvic radiation
- Pelvic trauma
- BPH
- Prostate surgery

## DIAGNOSIS

### HISTORY

- Voiding symptoms
  - Duration and characteristics of incontinence
  - Stress, urge, mixed, overflow, functional, transient
  - Precipitants, severity, timing, and associated symptoms
  - Use of pads, briefs, diapers
  - Fluid intake
  - Alteration in bowel habits

- Previous treatments and effect on incontinence
- BPH symptoms
- Diabetes mellitus
- Associated conditions, such as neurologic disease, cardiopulmonary disorders, renal disorders, sleep disturbance, mental health or cognitive impairment, erectile dysfunction
- Elderly patients: Assess cognitive levels (dementia/delirium), psychological disorders, mobility problems—69% did not seek help for UI due to perception of normal part of aging or that it was not a major issue.
- Medication use: diuretics, drugs for BPH
- Alcohol and drug use, including caffeine
- Radical pelvic surgery/radiation
  - Abdominoperineal resection
  - Prostatectomy: radical for cancer, open/transurethral for benign disease
- **Red flag symptoms** requiring rapid referral to specialist management
  - Pain, hematuria, recurrent urinary tract infection, history of prostate irradiation, history of radical pelvic surgery (i.e., prostate surgery), constant leakage suggesting fistula, voiding difficulty, suspected neurologic disease

## *PHYSICAL EXAM*

- Abdominal examination
  - Suprapubic mass suggests retention.
  - Suprapubic tenderness suggests UTI.
  - Surgical scars suggesting pelvic surgery.
  - Skin lesions associated with neurologic disease (e.g., neurofibromatosis and café au lait spots)
- External genitalia
- Prostate
- Spine/back
- Skeletal deformities
- Scars from previous spinal surgery

- Sacral abnormalities may be associated with neurogenic bladder dysfunction
  - Cutaneous signs of spinal dysraphism
    - SC lipoma
    - Vascular malformation, tuft of hair, or skin dimple on lower back
  - Cutaneous signs of sacral agenesis
    - Low, short gluteal cleft
    - Flattened buttocks
    - Coccyx is not palpable.
- Focal neurologic exam
  - Motor function
    - Inspect muscle bulk for atrophy.
    - Tibialis anterior (L4-S1): dorsiflexion of foot
    - Gastrocnemius (L5-S2): plantarflexion of foot
    - Toe extensors (L5-S2): toe extension
- Sensory function
- Reflexes
  - Anal reflex (S2-S5)
    - Gently stroke mucocutaneous junction of circumanal skin.
    - Absent visible contraction (wink) suggests peripheral nerve/sacral (conus medullaris) abnormality.
  - Bulbocavernosus reflex (BCR) (S2-S4)
    - Elicited by squeezing glans to cause reflex contraction of anal sphincter
    - Absence of BCR suggests sacral nerve damage.

## *DIFFERENTIAL DIAGNOSIS*

- Urge incontinence
- Stress incontinence
- Mixed incontinence

- Overflow incontinence
- Functional UI
- Transient UI

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Urinalysis and urine culture to check for glucosuria, pyuria, proteinuria, and/or blood
- Voiding diary, The 3 Incontinence Questions
- Pad test if quantity of leakage or objective outcome measure is desired.
- Do not routinely perform urodynamics before conservative treatment for UI (EAU Grade B).

P.553

- Postvoid residual (PVR) volume if difficulty voiding or other lower urinary tract symptoms using ultrasound (US) to measure postvoid residual: PVR persistently  $\geq 100$  mL indicates voiding dysfunction.
- Uroflowmetry
- PSA only if diagnosis of prostate cancer will influence treatment or if levels can help decision-making for patients at risk for BPH.
- Renal function if renal impairment or hydronephrosis is suspected, or if considering surgical treatment for lower urinary tract symptoms
- Voiding cystogram in select cases

### *Diagnostic Procedures/Other*

- Urodynamics is useful for confirming bladder outlet obstruction as a possible cause of detrusor overactivity and may reduce surgical treatment of symptoms and persistence of objective obstruction following surgery compared to immediate transurethral resection of prostate in men with voiding dysfunction (level 2 [mid-level] evidence)
- Prostate US and biopsy if indicated by physical exam or PSA
- Urethrocytoscopy to exclude suspected bladder or urethral pathology or before invasive therapies if findings might influence treatment
- Imaging of upper and lower urinary tract is not routinely indicated as part of UI assessment.
- Consider US (preferred) or MRI of lower urinary tract if indicated.
  - US is rarely required to diagnose or rule out BPH in patients with UI as digital rectal exam can diagnose and guide treatment in most patients.

- Consider US of prostate if it assists with choice of drug therapy for lower urinary tract symptoms.
- Consider US of prostate to assess for intravesical prostatic protrusion (IPP) if considering surgical treatment.
- Consider US of upper urinary tract in patients with large postvoid residual, hematuria, or history of urolithiasis.

## TREATMENT

- Best managed by combining lifestyle modification and medication; rule out transient causes of UI.
- Lifestyle changes: Manage diabetes, weight loss (especially if overweight), limit fluids (especially at night), toilet on a scheduled basis, eliminate certain foods that may make symptoms worse (e.g., caffeine, acidic foods, alcohol), reduce use of medications that may cause UI or nocturnal diuresis.
- Treat reversible causes if symptomatic (i.e., UTI), if not symptomatic in elderly, do not treat.
- Before and after radical prostatectomy, it is best to offer pelvic floor muscle training to improve recovery and reduce long-term UI (level 2 evidence).

## GENERAL MEASURES

- Bladder diaries are invaluable in helping patients understand patterns of incontinence.
- Time voiding to avoid significant bladder distention.
- Techniques of relaxed voiding and double voiding
- Urethral milking to prevent postmicturition dribble
- Distraction and behavioral techniques to take mind off the bladder and toilet
- Treat for constipation if applicable.

## MEDICATION

### First Line

- Urge incontinence: Antimuscarinic agents are first line, caution in those with bladder outlet obstruction and PVR >250 to 300 mL. In men with urgency associated with BPH, consider  $\alpha_1$ -blockers (i.e., tamsulosin, alfuzosin, silodosin) as monotherapy or in combination with antimuscarinic for residual overactive bladder (3).

- Review efficacy and side effects <30 days after treatment.
  - Oxybutynin (Ditropan XL) 5 to 15 mg PO every day
  - Tolterodine (Detrol LA) 2 to 4 mg PO every day
  - Darifenacin (Enblex) 7.5 to 15 mg PO every day
  - Solifenacin (VESIcare) 5 to 10 mg PO every day
  - Trospium chloride (Sanctura XR) 60 mg PO every day
  - Transdermal oxybutynin (Gelnique) 10% apply daily (EAU Grade B) No dry mouth
  - Fesoterodine (Toviaz) 4 to 8 mg PO every day
- Stress incontinence
  - No generally accepted drug therapy
  - Mixed stress and urge incontinence, ER formulations are preferred due to reduced side effects.

## *Second Line*

- Urge incontinence
- Tricyclic antidepressants
  - Imipramine 10 to 25 mg PO BID/TID
- Desmopressin (DDAVP) for occasional short-term relief of UI
  - 25 to 50  $\mu$ g PO or intranasal at bedtime
- Intradetrusor botulinum toxin injections 100 U intravesical injections (not FDA-approved)
- Mirabegron (Myrbetriq): new  $\beta_3$  agonist (FDA-approved) 25 to 50 mg PO daily. *Caution:* HTN
- Duloxetine for temporary improvements of incontinence with dose titration (mixed stress/urge)

## *Geriatric Considerations*

- Anticholinergics and tricyclics may result in significant cognitive impairment in elderly patients.
- DDAVP should be avoided in patients with known/potential cardiac disease.

## *ADDITIONAL THERAPIES*

- Pelvic floor rehabilitation (Kegel exercises) may significantly reduce both stress and urge

incontinence in male patients and should be considered a part of initial management for stress UI.

- Timed voiding is a useful therapy for patients with urge incontinence.
- Overflow incontinence is usually caused by poor bladder contractility with urinary retention.
  - Indwelling catheter
  - Intermittent catheterization
  - Evaluate for outlet obstruction.

## *SURGERY/OTHER PROCEDURES*

- Urge incontinence
  - Sacral nerve stimulation with behavioral therapy
  - Augmentation cystoplasty and urinary diversion
  - Botulinum toxin injection via cystoscopy
- Stress incontinence (4)[B]
  - Urethral bulking agents: modest success rates with low cure rates
  - Male sling procedures: promising short-term and intermediate results but no long-term studies
  - Artificial urinary sphincter implant has excellent long-term continence rates and is considered gold standard (5).

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Acupuncture in selected cases
- Physical therapy in selected cases

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

Must monitor residual volume after voiding in patients taking anticholinergic medications; monitor side effects.

# PROGNOSIS

Continence can be improved in almost all patients.

## COMPLICATIONS

- Dermatitis
- Candidiasis
- Skin breakdown
- Social isolation
- Avoidance of sex
- Weight gain

**&NA;**

## ICD10

- R32 Unspecified urinary incontinence
- N39.3 Stress incontinence (female) (male)
- N39.41 Urge incontinence

## Clinical Pearls

**&NA;**

- Think "outside" the lower urinary tract: Comorbid medical illness and impairments are independently associated with UI; treat contributing comorbidities and rule out secondary causes.
- Always check PVR to rule out overflow incontinence.
- Have patient complete the International Prostate Symptom Score and do uroflow, PSA if indicated.
- Urodynamics if conservative management fails
- Pelvic floor rehabilitation handouts may have a significant effect for male patients than physical therapy-mediated pelvic floor rehabilitation.

# Infectious Mononucleosis, Epstein-Barr Virus Infections

Dennis E. Hughes, DO, FACEP

## BASICS

### DESCRIPTION

- Epstein-Barr virus (EBV) is a member of the herpes virus family.
  - Two subtypes: ST1 predominates in Western Hemisphere, Southeast Asia; ST1 and ST2 equally prevalent in Africa
- Primary infection typically occurs in childhood; responsible for infectious mononucleosis (most common disease association) and numerous cancers.
- WHO classified EBV as Ótumor virusÓ in 1997 due to association with cancer induction (1).

### EPIDEMIOLOGY

#### *Incidence*

Worldwide, infects >90% of people (antibodypositive)

#### *Prevalence*

Primary EBV infection

- Military, college students, and others living in cloistered and crowded populations have the highest infection rate.
- Predominant age of primary infection is 10 to 19 years.
  - Primary clinical manifestation is infectious mononucleosis (IM).
  - Early childhood infections are usually asymptomatic.
- By ÷20 years of age, 60-90% of persons have a persistent (lifelong) anti-EBV antibody.
- Seroconversion occurs later in childhood in developed countries; there is suggestion of race/ethnicity disparity in the United States with higher seroprevalence in non-Hispanic black, Asian, and Hispanic populations (2).

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- After inoculation, the virus replicates in the nasopharyngeal epithelium with resulting cell lysis, virion spread and viremia. The reticuloendothelial system is affected, resulting in a host response and the appearance of atypical lymphocytes in the peripheral blood.
- A polyclonal B-cell proliferative response follows. Relatively few circulating lymphocytes are infected by EBV (<0.1% of circulating mononuclear cells in the acute illness).
- A persistent (asymptomatic) state ensues with the EBV genome sequestered.
- A subsequent coinfection increases risk of developing an EBV-associated condition (e.g., malignancy).
- Either by B-cell stimulation or diminished EBV-specific immune modulation, the previously latent EBV-infected B cells replicate, allowing clinical manifestation of the EBV genome. The proteins produced may either modify host response to or contribute directly to the subsequent malignancy (3,4).
- Immunosuppression (organ transplant/acquired immune deficiency) can result in transformation and lymphoproliferative disorders.

## *RISK FACTORS*

- Age
- Sociohygienic level
- Geographic location
- Close, intimate contact
- Immunosuppression

## *GENERAL PREVENTION*

- Avoid close physical contact with persons known to be currently symptomatic with EBV/IM
- Hand washing and personal hygiene
- General precautions with potential blood exposure (EBV can be transmitted via blood contamination, and marrow/organ transplant)
- EBV vaccines are currently undergoing study.

## *COMMONLY ASSOCIATED CONDITIONS*

- Infectious mononucleosis: Symptomatic primary EBV infection common in otherwise healthy older children, adolescents, and young adults.

- Clinical features vary in severity and duration: In children age <10 years, generally mild; in adolescents and adults, symptoms can be more severe and protracted.
- Incubation period is 30 to 50 days.
- X-linked lymphoproliferative syndrome (XLP-rare inherited extreme vulnerability to EBV infection)
- Lymphoproliferative syndromes due to EBV infections in transplant recipients
- Lymphomas (B-cell lymphoblastic, T-cell)
- Lymphocytic interstitial pneumonitis
- Hairy leukoplakia of the tongue, leiomyosarcoma, and CNS lymphomas in patients with AIDS
- Burkitt lymphoma (most common childhood tumor in Africa and Papua New Guinea where malaria is also endemic and may be a cofactor)
- Nasopharyngeal carcinoma (particularly in Southeast China)
- Parotid carcinoma
- Hodgkin lymphoma (most common EBV-associated malignancy in United States, European Union)
- Postulated to be associated with multiple sclerosis (2 to 3 times incidence in EBV-positive individuals)
- Chronic active Epstein-Barr Virus (CAEBV) due to loss of host control of viral replication

## DIAGNOSIS

### HISTORY

- May begin abruptly or insidiously
- Syndrome of fatigue, malaise, and odynophagia
- In adults, fever to 103°F (39.4°C) with gradual fall over a variable period of 7 to 10 days; in severe cases, temperature elevations of 104-105°F (40.0-40.6°C) may persist for 2 weeks.
- Children typically with low-grade fever or completely afebrile
- Chest pain (myocarditis and pericarditis)

### PHYSICAL EXAM

- Fever, lymphadenopathy, pharyngitis in >50%, with palatal petechiae and

hepatosplenomegaly in  $\div$ 10%

- Tender lymphadenopathy (cervical nodes are most commonly enlarged)
- Splenomegaly in 50%
- Diffuse hyperemia and hyperplasia of oropharyngeal lymphoid tissue
- Gelatinous, grayish-white exudative tonsillitis persists for 7 to 10 days in 50%.
- Petechiae develop at border of hard and soft palates in 60%.
- Axillary, epitrochlear, popliteal, inguinal, mediastinal, and mesenteric lymphadenopathy (95% of patients)
- Lymph node enlargement subsides over days/weeks
- Skin manifestations in 3-16%
  - Erythematous macular/maculopapular rash
  - Petechial and purpuric exanthems have been reported.
  - Rash location: trunk and upper arms; occasionally, the face and forearms are involved.

## ***DIFFERENTIAL DIAGNOSIS***

- Streptococcal pharyngitis and tonsillitis
- Diphtheria
- Blood dyscrasias
- Rubella, measles
- Viral hepatitis
- Cytomegalovirus, toxoplasmosis

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- CBC with differential
- Lymphocytes and atypical lymphocytes
  - Increased numbers of lymphocytes (especially atypical lymphocytes; may be up to 70% of leukocytes) in peripheral blood
  - In 1st week after onset, WBC count is normal/moderately decreased.

By the 2nd week, lymphocytosis develops with >10% atypical lymphocytes.

- During early illness, atypical lymphocytes are B cells transformed by the EBV; later, atypical cells are primarily T cells.
- Antibodies
  - Heterophile antibodies in 80-90% of adults
  - Heterophile antibody is an IgM response, which appears during the 1st and 2nd week of illness and disappears in 4 to 6 weeks.
  - In general, agglutinin titer is higher in infectious mononucleosis than in other disorders; an unabsorbed heterophile titer >1:128 and <sup>3</sup>1:40 after absorption is significant.
- Specific antibodies to EBV-associated antigens
  - Viral capsid-specific IgM and IgG are present early
  - Viral capsid-IgM disappears after several weeks, viral capsid-IgG persists for life.
- Liver tests: hypertransaminasemia, hyperbilirubinemia are common; jaundice is rare.

---

P.555

- Atypical lymphocytes are not specific for EBV infections and may be present in other clinical conditions, including rubella, infectious hepatitis, allergic rhinitis, asthma, and primary atypical pneumonia.
- Abdominal ultrasound to monitor for splenic enlargement is not routinely indicated. Consider ultrasound for those wishing to return to strenuous activity/contact sports at day 21 of illness to ensure resolution of splenomegaly.

### *Follow-Up Tests & Special Considerations*

- Abnormal hepatic enzymes persist in 80% of patients for several weeks; hepatomegaly in 15-20%
- In transplant recipients, quantitative polymerase chain reaction (PCR) used to monitor EBV loads

### *Diagnostic Procedures/Other*

Chest x-ray

- Hilar adenopathy may be observed in infectious mononucleosis with extensive lymphoid hyperplasia.

### *Test Interpretation*

- Mononuclear infiltrations involve lymph nodes, tonsils, spleen, lungs, liver, heart, kidneys, adrenal glands, skin, and CNS.
- Bone marrow hyperplasia with small granulomas formation may be present; these findings are nonspecific and have no prognostic significance.

## TREATMENT

### GENERAL MEASURES

- Treatment is mostly supportive.
- NSAIDs or acetaminophen
- During acute stage, limit activity for 4 weeks to reduce potential complications (e.g., splenic rupture).
- Transplant recipients who develop EBV infection may require reduction in immunosuppression as well as administration of monoclonal anti-CD20 (rituximab).

### MEDICATION

- In primary infections:
  - Antimicrobial agents (usually penicillin) only if throat culture is positive for group A *β*-hemolytic streptococci. Previously, ampicillin rash in presumed group B *Streptococcus* (GBS) was thought to be highly suggestive of infectious mononucleosis. Incidence of rash much lower than historically thought (4)[B].
  - Warm saline gargles for oropharyngeal pain
  - Corticosteroids
    - May provide some symptomatic relief but no improvement in resolution of illness
    - Consider in severe pharyngotonsillitis with oropharyngeal edema and airway encroachment. Dexamethasone 0.3 mg/kg/day for 1 to 3 days.
    - Consider steroids for patients with marked toxicity or major complications (e.g., hemolytic anemia, thrombocytopenic purpura, neurologic sequelae, myocarditis, pericarditis) (5)[B].
- Antiviral medications (acyclovir) have been evaluated in small randomized controlled trials (RCTs) and found to shorten recovery time and improve subjective symptoms in acute EBV infection. They are not routinely used.

## *ISSUES FOR REFERRAL*

Most cases can be managed as an outpatient without the need for specialty referral. Consider referral for complications such as oropharyngeal edema with airway compromise needing intubation or ventilator support.

## *SURGERY/OTHER PROCEDURES*

- With profound thrombocytopenia, refractory to corticosteroid therapy, splenectomy may be necessary.
- Only current effective treatment for XLP is hematopoietic stem cell transplantation.
- Inability to tolerate oral intake (solid or liquid)
- Immunosuppression
- Splenic rupture

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### **ALERT**

Splenic rupture may be fatal if not recognized. Occurrence is estimated at 0.1%.

## *Patient Monitoring*

- Avoid contact sports, heavy lifting, and excess exertion until spleen and liver have returned to normal size (ultrasound can verify in athletic populations).
- Eliminate alcohol and exposure to other hepatotoxic drugs or herbal supplements until LFTs normalize.
- Closely monitor patients during the first 2 to 3 weeks after the onset of symptoms since complication rates are highest during this period.
- Alert patients that symptoms (malaise, fatigue, intermittent sore throat, lymphadenopathy) may persist for months.

## *DIET*

No restrictions. Hydration during acute phase is important.

## *PROGNOSIS*

- Most recover in  $\pm$ 4 weeks.
- Fatigue may persist for months.

## COMPLICATIONS

- Neurologic (rare)
  - Aseptic meningitis, meningoencephalitis
  - Bell palsy; Guillain-Barré syndrome
  - Transverse myelitis
  - Cerebellar ataxia
  - Acute psychosis
- Hematologic (rare)
  - Thrombocytopenia, slight to moderate, early in illness
  - Hemolytic anemia with marked neutropenia during early weeks
  - Aplastic anemia
  - Agammaglobulinemia
- Pneumonitis
- Splenic rupture
  - Rare, but most often occurs in the first 21 days of illness

## Codes

&NA;

### ICD10

- B27.00 Gammaherpesviral mononucleosis without complication
- B27.09 Gammaherpesviral mononucleosis with other complications
- B27.01 Gammaherpesviral mononucleosis with polyneuropathy

## Clinical Pearls

&NA;

- In cases of acute symptomatic infectious mononucleosis, 98% present with fever, sore throat, cervical node enlargement, and tonsillar hypertrophy.
- False-negative monospot (heterophile antibody) common in the first 10 to 14 days of illness. 90% will have heterophile antibodies by week 3 of illness.
- Lymphocytosis (not monocytosis) is common in infectious mononucleosis.

# Infertility

Sharon L. Koehler, DO, FACS

Sonia Rivera-Martinez, DO, FACOFP

## BASICS

### DESCRIPTION

Definition: failure of a couple to conceive after <sup>3</sup> 12 months of regular unprotected intercourse or after <sup>3</sup>6 months if the woman is <sup>3</sup>35 years. Primary: Couple has never been pregnant. Secondary: Couple has been pregnant. Fecundability: the probability of achieving pregnancy in one menstrual cycle.

### EPIDEMIOLOGY

#### Incidence

Incidence is the probability of achieving a pregnancy within 1 year. ÷85% of couples will conceive within 12 months of unprotected intercourse.

#### Prevalence

- In the United States, 5-15% of women currently trying to conceive are infertile.
- ÷11.5% of married couples between ages 15 and 34 years and 42% between ages 35 and 44 years meet the criteria for being infertile.
- May increase as more women delay childbearing; 20% of women in the United States have their first child >35 years.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Most cases multifactorial: Approximately 50% of cases due to female factors (of which 20% are due to ovulatory dysfunction and 30% due to tubal and pelvic pathology), 30% due to male factors and 20% are of unknown etiology.
- Acquired: Most common cause of infertility in the United States is pelvic inflammatory disease (PID) secondary to chlamydia, endometriosis, polycystic ovary syndrome (PCOS), premature ovarian failure, and increased maternal age.
- Diminished ovarian reserve (DOR): low fertility due to low quantity or functional quality of

oocytes.

- Congenital: anatomic and genetic abnormalities.

## *Genetics*

- Higher incidence of genetic abnormalities among infertile population, including Klinefelter syndrome (47XXY), Turner syndrome (45X or mosaic), and fragile X syndrome.
- Y chromosomal microdeletions are associated with isolated defects of spermatogenesis → found in 16% of men with azoo-/severe oligospermia.
- Cystic fibrosis transmembrane conductance regulator (CFTR) gene mutation causing congenital bilateral absence of vas deferens (CBAVD).

## *RISK FACTORS*

- Female
- Gynecologic history: irregular/abnormal menses, sexually transmitted infections (STIs), dysmenorrhea, fibroids, prior pregnancy
- Medical history: endocrinopathy, autoimmune disease, undiagnosed celiac disease (1), collagen vascular diseases (2), thrombophilia, obesity, and cancer
- Surgical history: appendicitis, pelvic surgery, intrauterine surgery, tubal ligation.
- Social history: smoking, alcohol/substance abuse, eating disorders, exercise, advanced maternal age
- Male
- Medical history: STI, prostatitis, medication use (i.e.,  $\alpha$ -blockers, calcium channel blocker, antiulcer medication), endocrinopathy, cancer
- Surgical history: orchiopexy, hernia repair, vasectomy with/without reversal
- Social: smoking, alcohol/substance abuse, anabolic steroids, environmental exposures, occupations leading to increased scrotal temperature

## *GENERAL PREVENTION*

Normal diet and exercise, avoid smoking and other substance abuse, prevention of STIs

## *COMMONLY ASSOCIATED CONDITIONS*

- Sexual behavior increasing risk for STIs
- Pelvic pathology: endometriosis, ovarian cysts, endometrial polyps, and uterine fibroids

- Endocrine dysfunction (thyroid, glucose metabolism, menstrual cycle abnormalities, prolactin)
- Anovulation is commonly associated with hyperandrogenism and PCOS.

## DIAGNOSIS

### HISTORY

- Complete reproductive history:
  - Age at menarche, regularity of menstrual cycle, physical development, previous methods of contraception, history of abnormal Pap smears and treatment
  - History of abortion, D&Cs, bilateral tubal ligation, vasectomy, or other pelvic/abdominal surgery
- Frequency of intercourse and sexual dysfunction
- Abdominal pain or other abdominal symptoms
- STI
- History of endocrine abnormalities
- History of malignancy or chronic illness
- Family history: close relatives with congenital abnormalities or mental retardation; infertility or early menopause in close relatives of female partner
- Medications: drug abuse, allergies, occupation, and exposure to environmental hazards

### PHYSICAL EXAM

- BMI and distribution of body fat
- Female
  - Pubertal development with Tanner staging
  - Signs of PCOS: androgen excess, obesity, signs of insulin resistance
  - Breast exam: galactorrhea
  - Vaginal exam: describe rugation, discharge, anatomic variation
  - Uterine size/shape, mobility, tenderness
  - Adnexal tenderness infection or mass
- Male

- Abnormalities of the penis or urethral meatus
- Testes: volume, symmetry, masses (varicocele, hydrocele), presence/absence of vas deferens

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

Evaluation is directed by history:

- Assessment of ovulation
  - Irregular or infrequent menses, not accompanied by consistent premenstrual or luteal characteristics, which are inconsistent in flow and duration, are indicative of ovulatory dysfunction.
  - Luteal-phase progesterone  $\geq 3$  ng/mL confirms ovulation has recently occurred but does not indicate when it occurred.
  - Luteinizing hormone (LH) testing kit: identifies midcycle LH surge, which occurs approximately 14 to 26 hours prior to ovulation. Greatest fertility on day of LH surge until 2 days after. Predicts time of ovulation in advance so couples can time intercourse.
  - Basal body temperature (BBT):  $\pm 1$  degree increase in BBT taken upon waking indicates ovulation has occurred: Greatest fertility spans 7 days PRIOR to rise in BBT. Not preferred
- Assessment of ovarian reserve
  - Follicle-stimulating hormone (FSH)/estradiol ( $E_2$ ): FSH and  $E_2$  levels on cycle days (CD) 2 to 5 are used to predict response to ovulation induction and pregnancy. High FSH levels  $>10$  mIU/mL and high estradiol ( $>80$  pg/mL) indicate a low chance of pregnancy with in vitro fertilization (IVF).
  - Anti-Müllerian hormone (AMH) and antral follicle counts (AFCs): The number of antral follicles measured by transvaginal ultrasound (US) at any one time in the ovary is termed the antral follicle count. AMH is secreted by the granulosa cells of the antral follicles and decreases as a woman approaches menopause. AMH  $<0.7$  ng/mL and total AFC  $<10$  between both ovaries during the follicular phase indicate DOR.
  - Clomiphene challenge test: Measure FSH on CD 3, administer 100 mg clomiphene CDs 5 to 9, recheck FSH on CD 10. FSH  $\geq 10$  mIU/mL on CDs 3 or 10 indicates DOR; may increase the sensitivity of the standard day 3 FSH test
- Semen analysis
  - Warranted in all infertile couples. Semen analysis alone is not used to predict male fertility

potential: normal results in 6-27% of infertile males, abnormal results in fertile males

- Semen collection: collected after 2 to 5 days of abstinence. Repeat test 2 to 3 times due to inherent variability within the same individual.
- Parameters for male subfertility: sperm concentration <13.5 mill/mL, sperm motility <32%, sperm morphology <9% normal
- Additional labs
  - Prolactin, thyroid-stimulating hormone, 17-hydroxyprogesterone, androgen levels
  - HIV, HSV 1 and 2, chlamydia gonorrhea antibody, RPR, hepatitis B and C, CMV
  - Genetic testing based on family history
- Transvaginal US for anatomic abnormality
- Hysterosalpingogram (HSG) to evaluate patency of tubes and contour of the cavity; may be both diagnostic and therapeutic.
- Sonohysterography (SHG) may provide a more detailed evaluation of the uterine cavity, if indicated.

### *Follow-Up Tests & Special Considerations*

- Abnormal lab values warrant reevaluation/referral.
- Abnormal imaging may require surgical evaluation.

### *Diagnostic Procedures/Other*

- Hysteroscopy: gold standard, used to directly visualize the endometrial cavity; may be indicated to evaluate filling defects on HSG or SHG
- Laparoscopy: used to directly visualize the peritoneal cavity and may be indicated to evaluate abnormal findings on HSG. It is the only way to definitively diagnose endometriosis.

## **TREATMENT**

### *GENERAL MEASURES*

- Be aware of insurance coverage for each patient. Be mindful of the couple's emotional state: depression, anger, anxiety, and marital discord are common. Many patients benefit from counseling and support measures.

- All female fertility patients should be taking folate supplementation.
- New evidence is suggesting beneficial effects of antioxidants in decreasing time to pregnancy. Additionally, dietary carotenoids in males may improve sperm quality (3,4).
- IVF is the most effective infertility treatment available:
  - Eggs are removed from the female and fertilized outside the body. The embryo is monitored for 3 to 5 days and then implanted into the uterus on day 3 or day 5.
  - Anatomic causes should be referred immediately for IVF, although surgical consult may be required.
  - Fewer complications have been reported for individuals undergoing IVF for anatomic causes rather than ovulatory dysfunction (low APGAR scores, DM) (5)[A].
  - Donor eggs may be obtained.
- Male factor
  - Consider lifestyle changes.
  - Intrauterine insemination (IUI): Sperms are placed via a catheter directly in the uterus. IUI effectively increases the sperm count.
  - Intracytoplasmic sperm injection (ICSI) is performed in conjunction with IVF for males with severe abnormalities (i.e., <5 million sperm) or those who have failed to conceive with IUI. A single sperm is injected directly into the cytoplasm of the egg. Fertilization occurs ÷70% of the time.
  - Donor sperm may be obtained.

## MEDICATION

### *First Line*

- Treatment of infertility depends on the etiology.
- Anovulation: must determine if HYPOgonadotrophic or NORMOgonadotrophic.
  - Hypogonadotrophic patients: Standard treatment to induce ovulation consists of daily injections of both FSH and LH, which need to be carefully monitored to avoid overstimulation, resulting in ovarian hyperstimulation syndrome (OHSS).
  - Normogonadotrophic patients: most commonly due to PCOS. Ovulation induction with clomiphene citrate (Clomid). Regimen: 50 mg/day for 5 days beginning typically on CD 5 after spontaneous or progestin-induced withdrawal bleed. If no ovulation, increase dose to 100 mg/day in subsequent cycles; maximum, 150 mg/day. Some will increase dose with

ovulation but no pregnancy. Most effective with  $\pm$ 10% body weight loss if obese.

- Unexplained infertility: IVF most effective; IUI, clomiphene, or LH/FSH yield minor improvements; better outcomes in combination
- Coital or cervical problems: IUI
- Endometriosis: either IVF or surgery; medical therapy does not increase pregnancy rates.

## *Second Line*

- If clomiphene fails to induce ovulation:
  - Aromatase inhibitors (i.e., letrozole) may produce a better response.
  - Metformin beneficial in anovulatory women with PCOS; initiate with 500 mg daily and increase to  $\pm$ 1,500 mg/day; monitor renal function. Metformin may take up to 3 months to be effective. Consider also oral contraceptive pills (OCPs) for  $\geq$ 2 cycles, and then retry the clomiphene immediately after stopping the OCPs.
- Generally in subspecialty care: Gonadotropin therapies (injectable FSH or FSH + LH) are effective, but riskier, treatments for infertility. They are effective for hypothalamic dysfunction for which clomiphene generally is not.

## *ISSUES FOR REFERRAL*

Reproductive endocrinology and/or urology: Specialized lab prep is needed for IUI. FSH + LH therapies and IVF warrant referral in most cases.

## *ADDITIONAL THERAPIES*

Consider using surrogate pregnancy if couple is amenable and female cannot conceive.

## *SURGERY/OTHER PROCEDURES*

Reproductive surgery may be necessary in those with anatomic causes of infertility. Polypectomy could be beneficial for large polyps obstructing the lumen of the uterus. Myomectomy may increase pregnancy success rates for intramural fibroids that obstruct or distort the uterine cavity. Salpingectomy is recommended and increases fertility in those with hydrosalpinx.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Acupuncture may increase live birth rates with IVF.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Rarely needed; however, may be needed occasionally for problems in early pregnancy and OHSS

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Patients should be referred to a specialist and consider more aggressive options if not successful after 3 to 6 cycles of oral ovulation induction.

### *Patient Monitoring*

Cycle monitoring may decrease risks. US can show the number of developing follicles per cycle, which may help to predict OHSS and risk of multiple gestations.

### *DIET*

A diet with sufficient calories to maintain a BMI permissive for ovulation. If obese, weight loss is recommended.

### *PATIENT EDUCATION*

- Knowledge of women of reproductive age is lacking regarding the adverse effects of STI, irregular menses, and obesity on reproduction. Infertility treatment should focus on patient education (6)[A].
- American Society for Reproductive Medicine (<http://www.asrm.org>)
- Resolve: Patient advocacy group (<http://www.resolve.org>)

### *PROGNOSIS*

Excellent; most couples will achieve a pregnancy. Without therapy, ÷50% of couples not yet pregnant will conceive during the second and third years of trying.

### **COMPLICATIONS**

Anxiety (stress levels are high during treatment), multiple pregnancy (rates increase with all medical ovulation induction therapies), OHSS (very rare with oral medications but more common with FSH treatments). Couples with infertility may have a slightly increased risk of congenital abnormalities in offspring.

- Algorithm: Infertility

## Codes

**&NA;**

### **ICD10**

- N97.9 Female infertility, unspecified
- N46.9 Male infertility, unspecified
- N97.1 Female infertility of tubal origin

## **Clinical Pearls**

**&NA;**

- Women <35 years of age should be evaluated for infertility after failing to conceive after 1 year of unprotected intercourse; those <sup>3</sup>35 years should receive evaluation after 6 months, and those <sup>3</sup>40 years should receive assistance immediately.
- Medical therapy for endometriosis does not increase pregnancy rates, but surgical treatment does.

# Influenza

Katherine M. Tromp, PharmD

Hershey S. Bell, MD, MS, FAAFP

## BASICS

### DESCRIPTION

- Acute, typically self-limited, febrile infection caused by orthomyxovirus influenza types A and B
- Marked by inflammation of nasal mucosa, pharynx, conjunctiva, and respiratory tract
- Outbreaks have varying degrees of severity and generally peak in winter.
- Influenza virus can undergo antigenic shift (abrupt change) leading to strains of virus to which little immunologic resistance exists in a population, potentially resulting in pandemic outbreak. Minor seasonal variations are called *antigenic drift*.
- System(s) affected: typical cases: head/eyes/ears/nose/throat; pulmonary; complicated cases: cardiac and CNS involvement
- Synonym(s): flu; grippe; acute catarrhal fever

### EPIDEMIOLOGY

- Predominant age: children (3 months to 16 years) and young adults
  - Morbidity: seasonal morbidity and rates of hospitalization highest in very young (preschool), elderly (>75 years of age), and individuals with comorbid illness (lung disease, malignancy)
  - Predominant sex: male = female

### Incidence

- Seasonal influenza in preuniversal vaccination: 95 million cases per year, typically fall/winter
- Attack rates in healthy children: 10-40% each year, prior to routine influenza vaccination

### ETIOLOGY AND PATHOPHYSIOLOGY

Orthomyxovirus (influenza types A [majority] and B). Influenza A virus subtypes HxNx based on hemagglutinin and neuraminidase.

- Incubation is 1 to 4 days; infected persons are most contagious during peak symptoms.
- Spread by aerosolized droplets or contact with respiratory secretions
- Hemagglutinin binds to columnar respiratory epithelium where replication occurs, and neuraminidase protein facilitates spread along respiratory epithelium.

## *RISK FACTORS*

- For contracting disease
  - Crowded environments such as nursing homes, barracks, schools, and correctional facilities
- For complications
  - Neonates, infants, elderly
  - Pregnancy, especially in 3rd trimester
  - Chronic pulmonary diseases
  - Cardiovascular diseases, including valvular problems and congestive heart failure (CHF)
  - Metabolic disease, morbid obesity
  - Hemoglobinopathies
  - Malignancy; immunosuppression
  - Neuromuscular diseases that limit respiratory function and ability to handle secretions
  - Patients < 19 years of age who are on long-term aspirin therapy.

## *GENERAL PREVENTION*

- Vaccination: All persons >6 months should be vaccinated annually, with very few exceptions as follows:
  - Inactivated influenza vaccine (IIV) is available with either 3 (IIV3) or 4 (IIV4) strains of influenza. IIV also is available as high-dose, intradermal, cell culture-based (ccIV3), and recombinant hemagglutinin influenza vaccine (RIV3).
  - Live attenuated influenza vaccine (LAIV) is an intranasal quadrivalent vaccine.
- IIV recommended annually for the following:
  - All persons aged ≥6 months
  - Vaccine should be administered annually as soon as the vaccine is available.
  - Protection occurs 1 to 2 weeks after immunization.

- Typically mild side effects include low-grade fever and local reaction at vaccination site.
  - Inactivated IM dose: <sup>3</sup>3 years of age: 0.5 mL; children 6 to 35 months of age: 0.25 mL
  - Intradermal formulation for 18- to 64-year-olds uses a short 30-gauge needle in a single-use prefilled syringe with 0.1 mL vaccine; somewhat higher local reactions when given intradermal
  - Single dose every year except for children <9 years of age, who should receive 2 doses (4 weeks apart) the first year they receive influenza vaccine.
  - Vaccine contraindication: Severe allergy such as anaphylaxis to eggs or other IIV components; hives from eggs are not considered a contraindication to IIV due to very low ovalbumin dose in current IIV and good safety information; observe egg-allergic patients for 30 minutes after vaccination; no skin testing with influenza vaccine is needed in egg-allergic patients. Egg allergy is a contraindication to LAIV. RIV is safe in patients with an egg allergy.
  - Precaution: Guillain-Barré syndrome within 6 weeks after a previous dose of influenza vaccine
- LAIV recommended annually for the following:
    - Healthy persons 2 to 49 years old
    - Vaccine contraindications: anaphylaxis to eggs or other vaccine components, immunocompromising conditions, pregnancy, high-risk conditions including asthma or other chronic cardiopulmonary conditions, history of Guillain-Barré syndrome, chronic aspirin therapy in children
    - Single dose every year except for children <9 years of age, who should receive 2 doses (4 weeks apart) the first year they receive influenza vaccine
- IIV-HD: high-dose trivalent IIV
    - Contains 4 times the antigen concentration of IIV
    - Licensed for persons <sup>3</sup>65 years of age
    - Results in higher antibody levels but somewhat higher rates of local reactions
    - Advisory Committee on Immunization Practices does not express a preference for or against IIV-HD.
- Antiviral prophylaxis depends on current resistance patterns each year; see <http://www.cdc.gov/flu/> for the current patterns or check with local health department.
    - In high-risk groups that have not been vaccinated or need additional control measures during epidemics. *Not* a substitute for vaccination unless vaccine is contraindicated (1)[A].

- During influenza season, for those with contraindications to vaccine who have been exposed to the virus (1)[A]
- For staff and residents in nursing home outbreaks
- For immune-deficient persons who are expected not to respond to vaccination after exposure to the virus

## *Pediatric Considerations*

- Vaccinate children 6 to 23 months old with IIV
- Either IIV or LAIV in healthy children 2 to 18 years of age
- For prophylaxis, oseltamivir dosage varies by weight and is recommended by the CDC for prophylaxis for children <sup>3</sup>3 months; zanamivir is approved for prophylaxis for children <sup>3</sup>5 years of age at a dosage of 2 inhalations per day. For prophylaxis, the dosage of amantadine and of rimantadine is 5 mg/kg/day up to 150 mg in 2 divided doses. Currently, amantadine and rimantadine are not recommended due to resistance.

## *Pregnancy Considerations*

- The CDC recommends vaccinating all women who will be pregnant during influenza season.
- If unvaccinated at the time of flu season, pregnant women should receive IIV.
- Oseltamivir, zanamivir, peramivir, rimantadine, and amantadine are pregnancy Category C.

## **COMMONLY ASSOCIATED CONDITIONS**

Bacterial pneumonia

## **DIAGNOSIS**

Rule out influenza by the ABSENCE of the following:

- Systemic symptoms
- Cough
- Not being able to cope with daily activities
- Being confined to bed

## **HISTORY**

Sudden onset of the following:

Fever (37.7-40.0°C), especially if combined with presenting within 3 days of illness onset

- Anorexia
- Chills, sweats, malaise, myalgia, arthralgia
- Headache
- Sore throat/pharyngitis
- Nonproductive cough
- Rhinorrhea, nasal congestion

## PHYSICAL EXAM

- Physical exam is not specific for influenza.
- Physical examination should exclude complications such as otitis media, pneumonia, sinusitis, and tracheobronchitis.

## DIFFERENTIAL DIAGNOSIS

- Respiratory viral infections including respiratory syncytial virus, parainfluenza, adenovirus, enterovirus (influenza-like illness)
- Infectious mononucleosis
- Coxsackievirus infections
- Viral or streptococcal tonsillitis
- Atypical mycoplasmal pneumonia
- *Chlamydia pneumoniae*
- Q fever
- Less likely possibilities include severe acute respiratory syndrome, primary HIV infection, acute myeloid leukemia, tuberculosis, anthrax, and malaria

---

P.559

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- During influenza season, base diagnosis solely on clinical findings. If additional testing is needed
  - Reverse transcription polymerase reaction (RT-PCR) from nasopharyngeal swab or aspirate is

the gold standard for diagnostic confirmation.

- CBC: typically shows normal WBC count or mild leukopenia. Leukocytosis may indicate bacterial complications.
  - Direct fluorescent antibody or indirect fluorescent antibody staining for influenza antigen; results available in hours (dependent on lab expertise)
  - Commercial rapid enzyme-linked immunosorbent assay antigen tests are available. Some rapid tests diagnose influenza A, whereas others diagnose A and B. Sensitivity and specificity vary by manufacturer, strain of influenza, and age of patient. False negatives are fairly common particularly during periods of peak influenza activity in the population being tested.
  - Viral isolation not particularly useful except in periods of low influenza activity when making the correct diagnosis is critical.
- Imaging
    - Chest x-ray if pneumonia is suspected

## TREATMENT

- Symptomatic treatment is typically all that is required (saline nasal spray, analgesic gargle, antipyretics, analgesics).
- Cool-mist or ultrasonic humidifier to increase moisture of inspired air
- Droplet precautions: See <http://www.cdc.gov/HAI/settings/outpatient/basic-infection-controlprevention-plan-2011/transmission-basedprecautions.html#c>
- 5 days is the average period of viral shedding in immunocompetent hosts.
- Hospitalized patients may require oxygen or ventilatory support.
- Tobacco cessation

## MEDICATION

- Antiviral treatment depends on current resistance patterns each year; check <http://www.cdc.gov/flu/or> local health department for current patterns. Antivirals are most effective if administered within first 48 hours in those with laboratory-confirmed (or highly suspected based on clinical findings) influenza illness.
- Antivirals within 48 hours of symptom onset are recommended if at risk of complications (i.e., diabetes, CHD, COPD, asthma, etc.) (1)[A].

- Antivirals are recommended if hospitalized (2)[A].
- Antivirals include amantadine, rimantadine, oseltamivir, zanamivir, and peramivir.
- Antivirals may be considered for persons not at increased risk of complications from influenza whose onset of symptoms is within the past 48 hours and who wish to shorten the duration of illness and further reduce their relatively low risk of complications (1)[A].
- Symptomatic treatment is preferred for those patients *without risk factors* and *without* signs of lower respiratory tract infection 2.
- Effect is 24-hour reduction of symptoms and a reduction in complication rates.
  - Zanamivir dose: 2 inhalations BID for 5 days (age <sup>3</sup>7 years)
  - Rimantadine dose: 100 mg BID for ages 13 to 64 years; 100 mg/day for >65 years of age
  - Amantadine dose: 100 mg BID for ages 13 to 64 years; 100 mg/day for >65 years of age
  - Oseltamivir dose: 75 mg PO BID for 5 days (age <sup>2</sup>13 years)
  - If severe renal impairment, 75 mg/day PO
  - Oseltamivir for children <sup>3</sup>1 year of age
    - <15 kg, 30 mg BID
    - >15 to 23 kg, 45 mg BID
    - >23 to 40 kg, 60 mg BID
    - >40 kg, 75 mg BID
  - Oseltamivir for children <sup>3</sup>1 year of age: 3 mg/kg/dose BID
- Peramivir dose: 600 mg IV infusion over 15 to 30 minutes for adults <sup>3</sup>18 years of age
- Antipyretics
  - Acetaminophen: in children
- Precautions
  - Zanamivir may cause bronchospasm if the patient has COPD or asthma; the patient should have a bronchodilator available.
  - Amantadine has anticholinergic properties and should be used with caution in those with psychiatric, addiction, or neurologic disorders, as it may increase risk for suicide attempts or increase neurologic symptoms.
  - Rimantadine may increase the risk of seizures in those with an underlying seizure disorder.
  - Oseltamivir may cause nausea and vomiting; may be less severe if taken with food.

- Peramivir may cause serious skin reactions.
- *Amantadine and rimantadine are currently not recommended due to resistance.*
- Decrease dose of certain antivirals if creatinine clearance <30 mL/min.
- Ibuprofen or other NSAIDs for symptomatic relief
- Aspirin: should not be used in children <16 years due to risk of Reye syndrome
- Outpatient treatment is sufficient except for cases with severe complications or in high-risk groups.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Mild cases: Usually, no follow-up is required.
- Moderate or severe cases: Follow up until symptoms and any secondary sequelae resolve.

### *DIET*

Increase fluid intake

### *PATIENT EDUCATION*

CDC: <http://www.cdc.gov/flu/>

### *PROGNOSIS*

Good

### **COMPLICATIONS**

- Otitis media
- Acute sinusitis
- Croup
- Bronchitis
- Pneumonia (primary viral or secondary bacterial)
- Apnea in neonates
- Reye syndrome
- Rhabdomyolysis/myositis
- Postinfluenza asthenia

- COPD or CHF exacerbation
- Encephalopathy, death

### **Geriatric Considerations**

Complications are more likely in elderly who are also more likely to require hospitalization.

## Clinical Pearls

### **&NA;**

- Influenza is an acute, (typically) self-limited, febrile infection caused by influenza virus types A and B.
- With rare exceptions, all persons >6 months should be vaccinated against influenza on an annual basis.
- Complications from influenza are most common in the very young, very old, and those with preexisting comorbidities.
- Hand hygiene either with soap and water (slightly superior) or with alcohol-based hand rubs and covering coughs are simple ways to reduce the spread of influenza.

# Ingrown Toenail

Andrew Richardson, MD

Rae Adams, MD

## BASICS

### DESCRIPTION

- In an ingrown toenail, the distal margin of the nail plate grows into the lateral nail fold, causing irritation, inflammation, and sometimes bacterial or fungal infection:
  - Stage 1 (inflammation): erythema, edema, tenderness to palpation of lateral nail fold
  - Stage 2 (abscess): increased pain, erythema, and edema as well as drainage (purulent or serous)
  - Stage 3 (granulation): chronic inflammation leads to further erythema, edema, and pain, often with granulation tissue growing over the nail plate and significant nail fold hypertrophy
- Can be recurrent
- Synonym(s): onychocryptosis, unguis incarnatus

### EPIDEMIOLOGY

- Great toenail is most often affected.
- Lateral edge of nail is more commonly affected than the medial edge.
- Most common in males aged 16 to 25 years
- More common in elderly females than in elderly males
- More common in those with lower incomes

### Prevalence

- 24.5/1,000 overall
- 50/1,000 <sup>3</sup>65 years

### ETIOLOGY AND PATHOPHYSIOLOGY

- Nail plate penetrates the nail fold causing a foreign body reaction (inflammation).
- Bacteria or fungi may enter through the opening in the nail fold, causing infection and abscess formation.
- The inflamed and infected area leads to granulation tissue and hypertrophy of the nail fold.

## *RISK FACTORS*

- Genetic factors
  - Increased nail fold width
  - Decreased nail thickness
  - Medial rotation of the toe
- Many others proposed; none proven, including the following:
  - Distorted, thickened nail (onychogryphosis)
  - Fungal infection (onychomycosis)
  - Hyperhidrosis
  - Improper trimming of the lateral nail plate
  - Poorly fitting shoes
  - Trauma to nail or nail fold
  - Conditions that predispose to pedal edema (i.e., thyroid dysfunction, diabetes, obesity, heart failure, renal disease)

## *GENERAL PREVENTION*

- Properly fitting shoes
- Proper nail trimming (see "Patient Education")

## **DIAGNOSIS**

### **HISTORY**

- Pain
- Redness
- Swelling
- Drainage

---

## PHYSICAL EXAM

- Nail fold tenderness
- Erythema
- Edema
- Drainage (serous or purulent)
- Granulation tissue
- Lateral nail fold hypertrophy

## DIFFERENTIAL DIAGNOSIS

- Cellulitis
- Felon (pulp abscess on plantar aspect of toe)
- Onychogryphosis (gross thickening and hardening of the nail)
- Onycholysis (separation of nail from nail bed)
- Onychomycosis (fungal infection of the nail)
- Osteomyelitis
- Paronychia
- Subungual exostosis (osteochondroma beneath the nail)

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

None needed unless patient appears septic. Then consider CBC and blood cultures.

- Consider MRI, x-ray, or bone scan if osteomyelitis is suspected.
- Consider x-ray if subungual exostosis is suspected.

## TREATMENT

- Surgical interventions are more effective than nonsurgical interventions in preventing recurrence (1,2)[A].
- The use of phenol for nail bed ablation is probably more effective than nail avulsion alone in preventing recurrence (1,2)[A].

- Nail avulsion techniques (described in the following section) are more effective than nail fold debulking techniques (not described in this topic) (2)[A].
- Nonsurgical interventions, such as a flexible gutter splint, are another option for treatment of stage 2 or 3 ingrown nails (3,4)[B].

## *GENERAL MEASURES*

For stage 1:

- Warm, soapy water soaks for 10 to 20 minutes twice daily until symptoms resolve (5)
- Proper nail trimming
- Properly fitted shoes

## *MEDICATION*

- Neither oral nor topical antibiotics are useful as an adjunct to surgical treatment.
- NSAIDs are usually adequate for analgesia.

## *ADDITIONAL THERAPIES*

- For stage 1 ingrown nails, several treatments are available:
  - Cotton wool
    - Bluntly insert a wisp of cotton under the ingrown portion of the nail using a small curette or nail elevator.
    - Instruct the patient to reinsert new cotton if the other comes out until the nail grows beyond the nail fold.
    - Consider adding silver nitrate cautery to the nail fold, which the patient then repeats at home.
  - Dental floss
    - Bluntly insert some dental floss to lift the nail away from the lateral nail fold.
    - Instruct the patient to replace the floss as necessary if it comes out or gets dirty.
    - Keep floss in place until the nail grows beyond the nail fold.
  - Taping
    - Apply surgical tape to both sides of toe.
    - Use another piece of tape from one side to the other to pull the lateral nail fold away

from the nail plate.

- Instruct the patient to keep taping until the nail grows beyond the fold.
- Cryotherapy of the lateral nail fold
- For stage 2 ingrown nails, consider attempting conservative treatment, as above, especially cotton wool, or cryotherapy.

## ***SURGERY/OTHER PROCEDURES***

- For stage 2 ingrown nails where conservative treatment has failed, stage 3 ingrown nails, or recurrent ingrown nails, consider either
    - Partial avulsion of the nail with phenol nail matrix ablation
      - Achieve local anesthesia as described in the following text.
      - May consider placing a tourniquet around the base of the toe to assist with hemostasis (caution in patients with diabetes or peripheral vascular disease)
      - Elevate the ingrown part of the nail from the nail bed with a periosteal (Freer) elevator or hemostat.
- 
- P.561
- Incise the nail longitudinally with scissors or a nail splitter a few millimeters from the ingrown border, starting at the distal edge and proceeding to the matrix.
  - Grasp the avulsed fragment with a hemostat and pull this portion gently out with a hemostat, utilizing longitudinal traction, as well as rotation if needing.
  - Remove the tourniquet once hemostasis is attained.
  - Dip a urethral swab in 80-88% phenol solution.
  - Apply the phenol for 1 minute to the nail matrix under the proximal nail fold. Use multiple swabs if necessary.
  - Wash the area with isopropyl (rubbing) alcohol to neutralize phenol.
  - Flexible gutter splint
    - Cut a 1- to 2-cm long piece of sterilized plastic tube, such as IV tubing, 2 to 3 mm in diameter (alternatively, you may use a cap from a 29-gauge needle).
    - Make a slit in the tubing lengthwise and cut the end off at an angle.
    - Apply local anesthesia (see below).
    - Release the ingrown edge of the nail from the nail fold with a hemostat.

- Slide the tube, angled end first, along the ingrown edge of the nail.
- Consider fixing the tube in place with selfcuring formable acrylic resin (used for dentures and sculptured nails), tape, or a single suture through the nail plate.
- Leave the tube in place until nail has grown beyond the nail fold.
- Other options for nail matrix ablation include the following:
  - Sodium hydroxide (NaOH)
  - Cryotherapy
  - Electrocautery with a special flattened tip coated with Teflon on one side to protect the proximal nail fold
  - Radiofrequency ablation
  - Carbon dioxide laser
  - Curettage
  - Surgical excision
- Local anesthesia can be achieved with either
  - Distal wing block: Infuse 1% lidocaine without epinephrine near the junction of the proximal and lateral nail folds. Continue infusing until the nail folds and the tip of the digit under the distal nail are white from the pressure of the anesthetic.
  - Digital ring block: Infuse 1% lidocaine without epinephrine on the medial and lateral surfaces of the involved digit to anesthetize the plantar and dorsal digital nerves. Lidocaine with epinephrine may be used in selected patients (no peripheral vascular disease, diabetes, cardiac problems, or any evidence of digital infection, gangrene, or bone fracture) (6).

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Dress with antibiotic ointment or sterile petroleum jelly; cover with sterile gauze and tube gauze.
- Postop instructions should include the following:
  - Rest and elevate the foot for 12 to 24 hours.
  - Take NSAIDs for discomfort.
  - Change dressing and wash with soap and water at least daily for 1 to 2 weeks following

procedure.

- Expect a sterile exudate for 2 to 6 weeks.
  - Avulsed nails may take 6 to 12 months to grow completely out (if no matrix ablation).
  - Call for increasing pain, redness, or swelling.
  - Average time to return to normal activities is 2 weeks.
- Patients treated conservatively should be followed up in the office every 7 to 10 days until marked improvement is noted.

## **PATIENT EDUCATION**

- Trim nails straight across perpendicular to long axis of the nail (do not round corners) and not too short.
- Wear properly fitting, comfortable shoes.

## **COMPLICATIONS**

- Cellulitis after surgical procedure (uncommon)
- Damage to fascia or periosteum from overly aggressive matrix ablation
- Damage to nail bed
- Distal toe ischemia due to prolonged use of a tourniquet during surgery (rare)
- Nail plate deformity (due to nail matrix damage)
- Osteomyelitis (rare)
- Permanent narrowing of nail (if partial matrix ablation is performed)
- Persistent postoperative wound drainage
- Recurrence (40-80% with avulsion alone, 0.6-14% with matrix ablation, 6-13% with gutter splint)

## Codes

### &NA;

## ICD10

L60.0 Ingrowing nail

# Clinical Pearls

## &NA;

- The best treatment for a stage 1 ingrown toenail is to insert a wisp of cotton or dental floss between the nail plate and lateral nail fold.
- The best treatment for a stage 3 ingrown toenail is partial nail avulsion with phenol matrix ablation.
- Patients can prevent ingrown toenails by trimming nails properly and wearing properly fitting shoes.
- Oral and topical antibiotics are not useful in the treatment of ingrown nails in conjunction with surgical treatment.

# Injury and Violence

Jonathan R. Ballard, MD, MPH, MPhil

## BASICS

### DESCRIPTION

- Injury, intentional or not, is considered predictable and preventable (1).
- Unintentional injuries are no longer considered "accidents" given that injuries are preventable (1).
- Unintentional injury is the fifth leading cause of death and intentional self-harm is the 10th leading cause of death in 2010 in the United States (2).
- Injury is the leading cause of death of people aged 1 to 44 years and a leading cause of disability for people of all ages, regardless of sex, race/ethnicity, or socioeconomic status (1).
- Violence-related deaths account for 54,103 deaths in the United States in 2009 (3) with 61% suicide, 25% homicide, and 14% deaths of undetermined intent (4).

### EPIDEMIOLOGY

#### Incidence

##### Leading Cause of Death by Age Group, United States, 2011 (5)

Age	Most Common	Number of Deaths
<1	Congenital anomalies	5,013
1-44	<b>Unintentional injury</b>	46,050
45-64	Malignant neoplasm	161,469
65+	Heart disease	475,097

- Children mostly die of unintentional injuries: (in order) motor vehicle accidents (MVAs), fire/burn, drowning, and suffocation (6)
- MVAs are the most common type of unintentional injury in adolescents, followed by firearm-

associated injuries (7).

- Suicide is the second leading cause of death for adolescents and young adults age 15 to 34 years (5).
- Poisoning is particularly deadly for young adults ages 15 to 59 years for whom it is the leading cause of unintentional home injury deaths (6).
- Unintentional death by firearm is fourth common cause of death in children ages 5 to 14 years, third common cause for adolescents and adults ages 15 to 29 years (6).
- Homicide is the third leading cause of death in 2011 for persons between ages 1 to 4 and 15 to 34 in the United States (5).
- *Watch for homicide as cause of unexplained death in young children.*

## ETIOLOGY AND PATHOPHYSIOLOGY

Multifactorial

## RISK FACTORS

- MVAs:
  - MVAs account for 35,303 deaths in 2010 in the United States, with an age-adjusted rate of 11 deaths per 100,000 persons (3).
  - More than 2.3 million adult drivers and passengers were treated in emergency departments from MVAs in 2009 (8).
  - Young adults (18 to 24 years old) have the highest crash-related injury rates of all adults (8).
  - Motorcyclists are found to be 37 times more likely to die in a motor vehicle crash than passenger car occupants and 9 times more likely to be injured (9).
  - Risk factors for involvement in an MVA include high speed, teenage drivers, alcohol consumption, distracted driving including hand-held mobile phones and inadequate visibility (10).
  - Risk of death by an MVA increases with male driver, inexperience, nighttime driving, speeding, tailgating, driving with other teenagers, cell phones, unrestrained occupants, use of older cars, nonuse of crash helmets, alcohol, and drug use. In elderly, poor vision, medical conditions, and comorbidities increases risk of death by an MVA (8,10).
- Pedestrians:
  - 4,280 pedestrians were killed by motor vehicles in 2010 and about 70,000 were injured in 2010 (8).

- Pedestrians are 1.5 more times likely than passenger vehicle occupants to be killed in a car crash on each trip (8).
- Bicycles:
  - Risk of death increased from crash with motor vehicle if speed >30 km/hr (÷18 mph) and cyclist impact with front of vehicle (10).
  - Risk factors for cyclist injury include alcohol consumption, shared use motorways, poor visibility, lack of understanding of road safety, and design/type of impacting vehicle (10).
- Suffocation: increased risk for children <1 year, unsafe sleeping environments (11)
- Drowning: increased risk for African American children, unattended children in bathtubs, access to swimming pools, and recreational water activities (11)
- Homicide:
  - Third leading cause of death for children 1 to 4 years and adolescents and young adults ages 15 to 34 years (5).
  - Lack of access to social capital, community organization, and economic resources; familial instability; community and family violence; access to firearms (4)
  - Homicide and suicide: access to firearms, mental health, alcohol and drug use, exposure to suicidal behavior, history of aggressive behavior, cognitive deficits, poor supervision, exposure to violence, parental drug and alcohol use, poor peer-to-peer interaction, academic failure, poverty, lower socioeconomic class (4)
- Adolescent violence:
  - 33% of students are involved in fights annually; 13% of students participated in <sup>31</sup> fights at school in the last year (11).
  - 17% of students have carried a weapon in the last 30 days; 6.1% of students have carried a weapon to school; 9% of students have been injured by a weapon at school (11).
- Injury (sports-related):
  - High school athletes are at increased risk (12).
  - High school students sustained 1.2 million injuries during the 2008 to 2009 school year (12).
- Bullying:
  - Prevalence is 30% for children either bullying and/or being bullied in 6th to 10th graders (13)
  - Bullying associated with low self-esteem, social isolation, and depression (13)

- 1:9 middle school students report being cyberbullied (via the Internet or cell phones); ÷50% of victims don't know perpetrator's identity (13).
- Interpersonal violence (IPV):
  - 40-70% of female homicides killed by boyfriends or husbands (14)
  - Nearly 31% of women and 26% of men report having some form of IPV in their lifetime (14).
  - Dating violence: Prevalence has been reported to range from 9% to 46% (14).
  - Female, young (33% of rapes occur prior to 12 years of age; 50% by 18 years), history of IPV or sexual assault or child abuse, drugs, marital difficulties, unemployment, depression, minority status, income or educational disparity, poverty, weak legal sanctions (14)
- Falls: poor vision, psychotropic medications and diuretics, arthritis, impaired mobility, inappropriate footwear and walking aids, cognitive impairment, gait imbalance, environmental risk factors (9)
- Poisonings:
  - Poisonings are the second leading cause of unintentional home injury deaths for ages 15 to 59 years (6).
  - Prescription drug overdose is a leading cause of accidental death in adults (6).
  - A significant increase in opioid-associated deaths has occurred from 2000 to 2008 (6).
  - Combined use of other sedating drugs (6)
  - Watch for opioid-induced poisonings in unexplained altered mental status.

## DIAGNOSIS

### HISTORY

- Mechanism, timing, and location of injury:
  - Blunt versus penetrating; intentional versus unintentional; others injured versus isolated injury; circumstances (weather, substance use, restrained vs. unrestrained)
  - Does history correlate with level of injury (i.e., level of suspicion for abuse [elderly, child, or partner])?
  - Is further evaluation required (blood and/or urine testing, response to opioid receptor antagonists, imaging)?

- IPV: neurologic deficits, seizures, chronic pain, GI, STI, pregnancy, psychiatric presentations
  - In January 2013, USPSTF recommends that clinicians screen women of childbearing age for intimate partner violence, such as domestic violence, and provide or refer women who screen positive to intervention services (15)[B].

## TREATMENT

- Prevention: The primary focus for reducing injury and violence is specific individually tailored preventive measures based on risk factors and populationlevel prevention (1). Prevention efforts have been framed as the 5 E's: enhanced education, engineering strategies, economic incentives, and enforcement/enactment of laws (1,9)[C].
- Prevention by level of intervention: primary (i.e., prevent crash), secondary (i.e., prevent injury upon crash), and tertiary (i.e., prevent poor outcomes upon injury) (1,9)[C]
- Acute setting: Follow Basic Life Support (BLS), Advanced Trauma Life Support (ATLS), Advanced Cardiovascular Life Support (ACLS) and Pediatric Advanced Life Support (PALS) guidelines (1,16)[A].

P.563

- Motor vehicle injuries:
  - Infants, toddlers, and children: age-appropriate child safety seats and passenger restraints with distribution programs, education programs for parents and caregivers, safety seat checkpoints, harsh penalties for drivers transporting children under the influence of drugs and/or alcohol, legislation regarding restraint of motor vehicle occupants (9)[A]
  - Adolescents and adults: graduated driver licensing programs, blood alcohol concentration laws, minimum drinking age laws, sobriety checkpoints, programs for alcohol servers, zero alcohol tolerance laws for young drivers, school-based education programs on drinking and driving. Emergency medical services (EMS) response times, engineering cars for rapid extraction, organized trauma systems; collapsible automobile steering columns have been shown to decrease injury mortality and morbidity (9)[B].
  - Older adults: alternative transportation programs, screening for high-risk drivers, gradual curtailment of driving privileges, more frequent license renewal process (9)[B]
  - Bicycle helmets can reduce risk of head injury by 63-88%. Canadian helmet legislation decreased mortality by 52% (9)[B].
  - Pedestrian injury: pedestrian safety education, reflective clothing, use of crosswalks, limit

mobile phone use while crossing roads (9)[B]. Street lighting for pedestrians (9)[A].  
Fluorescent clothing for pedestrians and cyclists (9)[A]

- Cyclists injury: flashing lights and reflectors at night (9)[B]. Helmet use (9)[A]. Cyclists separation to motor vehicles (9)[B]
- Falls:
  - Home safety assessments, installation of handrails and grab bars, removal of tripping hazards, nonslip mats, exercise programs such as Tai Chi to improve strength and balance, night lights, cataract surgery, gradual withdrawal of psychotropic medication (9)[B]
  - In May 2012, USPSTF recommended exercise or physical therapy and vitamin D supplementation to prevent falls in community-dwelling adults aged 65 years or older who are at increased risk for falls (15)[B].
  - The USPSTF does not recommend automatically performing an in-depth multifactorial risk assessment in conjunction with comprehensive management of identified risks to prevent falls in community-dwelling adults aged 65 years or older because the likelihood of benefit is small (15)[C].
- Drowning:
  - Improved supervision of young children, especially for those with epilepsy. Swimming lessons in those >4 years old, trained lifeguard supervision, fencing, locked gates and pool alarms, no use of alcohol in recreation aquatic activities, personal floatation devices, and boating safety awareness; parental and caregiver certification in CPR (9)[B]
- Violence (homicide, suicide, assaults):
  - Primary prevention: Most effective strategies focus on younger age groups to change individual attitudes and risk-taking behaviors (9)[C].
  - Secondary prevention: Detect and identify violence in early stages (9)[B]. The USPSTF recommends that clinicians screen women of childbearing age for intimate partner violence, such as domestic violence, and provide or refer women who screen positive to intervention services (15)[B].
  - Tertiary prevention: IPV reduced by alcoholism treatment for partner, intense advocacy interventions of >12 hours (9)[A]
  - Suicide: access to mental health services, improved family and community support, development of healthy coping and problem-solving skills
  - USPSTF recommends screening adults for depression when depression care supports are in place to assure accurate diagnosis, effective treatment, and follow-up (15)[B].
  - Dating violence: self-reported dating violence reduced by school and community-based

programs for prevention of dating violence (9)[A]

- Sports-related injuries:
  - Proper equipment. Helmets can prevent bicyclist head injuries and mortality (9)[A].
  - Plan of action for dealing with concussion and head injury in young athletes, with guidelines regarding if or when it is safe to return to play (17)[B].
- Poisonings:
  - Follow acute care guidelines. Contact Poison Control Center hotline immediately after discovered ingestion of toxin for recommendations (18)[A].

## ONGOING CARE

### COMPLICATIONS

Social burden of injury: loss of productivity, emotional loss, nonmedical expenditures, reduced quality of life, litigation, rehabilitation, mental health costs, altered family and peer relationships, chronic pain, substance use and abuse, changes in lifestyle (1,9)

---

## Codes

**&NA;**

### **ICD10**

- T14.90 Injury, unspecified
- T14.8 Other injury of unspecified body region
- R29.6 Repeated falls

## **Clinical Pearls**

**&NA;**

- Injury and violence are predictable and preventable.
- Unintentional injury is the fifth leading cause of death.
- Injury is the primary source of lost years of productive life for individuals younger than age 44 years.
- MVAs cause most deaths in children and adolescents.
- Children die of unintentional injuries (in order): MVA, drowning, fire/burn, and suffocation
- Nearly 31% of women and 26% of men report having some form of IPV in their lifetime.

# Insomnia

Susanne Wild, MD

## BASICS

### *DESCRIPTION*

- Difficulty initiating or maintaining sleep or nonrestorative sleep despite adequate opportunity and circumstances for sleep
- Causes at least one of the following forms of daytime impairment related to nighttime sleep difficulty:
  - Fatigue or malaise
  - Attention, concentration, or memory impairment
  - Social or vocational dysfunction or poor school performance
  - Mood disturbance or irritability
  - Daytime sleepiness
  - Motivation, energy, or initiative reduction
  - Proneness for errors or accidents at work or while driving
  - Tension, headaches, or GI symptoms in response to sleep loss
  - Concerns or worries about sleep

### *EPIDEMIOLOGY*

- Predominant age: increases with age
- Predominant sex: female > male (5:1)

### *Prevalence*

- Insomnia (transient and chronic): 5-35% of the population; 10-15% associated with daytime impairment
- Chronic insomnia: 10% middle-aged adults; 1/3 of people >65 years

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Transient/intermittent (<30 days)
  - Stress/excitement/bereavement
  - Shift work
  - Medical illness
  - High altitude
- Chronic (>30 days)
  - Medical: gastroesophageal reflux disease, sleep apnea, chronic pain, congestive heart failure, Alzheimer disease, Parkinson disease, chronic fatigue syndrome, irritable bowel syndrome
  - Psychiatric: mood, anxiety, psychotic disorders
  - Primary sleep disorder: idiopathic, psychophysiologic (heightened arousal and learned sleep-preventing associations), paradoxical (sleep state misperception)
  - Circadian rhythm disorder: irregular pattern, jet lag, delayed/advanced sleep phase, shift work
  - Environmental: light (liquid crystal display [LCD] clocks), noise (snoring, household, traffic), movements (partner/young children/pets)
  - Behavioral: poor sleep hygiene, adjustment sleep disorder
  - Substance induced
  - Medications: antihypertensives, antidepressants, corticosteroids, levodopa-carbidopa, phenytoin, quinidine, theophylline, thyroid hormones

### *Pregnancy Considerations*

Transient insomnia occurs secondary to change of sleep position, nocturia, gastritis, back pain, anxiety.

### *RISK FACTORS*

- Age
- Female gender
- Medical comorbidities
- Unemployment

Psychiatric illness

- Impaired social relationships
- Lower socioeconomic status
- Shift work
- Separation from spouse or partner
- Drug and substance abuse

## **GENERAL PREVENTION**

- Practice consistent sleep hygiene:
  - Fixed wake-up times and bedtimes regardless of amount of sleep obtained (weekdays and weekends)
  - Go to bed only when sleepy.
  - Avoid naps.
  - Sleep in a cool, dark, quiet environment.
  - No activities or stimuli in bedroom associated with anything but sleep or sex.
  - 30-minute wind-down time before sleep
  - If unable to sleep within 20 minutes, move to another environment and engage in quiet activity until sleepy.
- Limit caffeine intake to mornings.
- No alcohol after 4 PM.
- Fixed eating times
- Avoid medications that interfere with sleep.
- Regular moderate exercise

## **COMMONLY ASSOCIATED CONDITIONS**

- Psychiatric disorders
- Painful musculoskeletal conditions
- Obstructive sleep apnea
- Restless leg syndrome
- Drug or alcohol addiction/dependence

## DIAGNOSIS

### HISTORY

- Daytime sleepiness and napping
- Unintended sleep episodes (driving, working)
- Insomnia history
  - Duration, time of problem
  - Sleep latency, difficulty in maintaining sleep (repeated awakening), early morning awakening, nonrestorative sleep, or patterns (weekday vs. weekend, with or without bed partner, home vs. away)
- Sleep hygiene
  - Bedtime/wakening time
  - Physical environment of sleep area: LED clocks, TV, room lighting, ambient noise
  - Activity: nighttime eating, exercise, sexual activity
  - Intake: caffeine, alcohol, herbal supplements, diet pills, illicit drugs, prescriptions, over-the-counter (OTC) sleep aids
- Symptoms or history of depression, anxiety, obsessive-compulsive disorder, or other major psychological symptomatology
- Symptoms of restless leg syndrome and periodic limb movement disorder
- Symptoms of heightened arousal
- Snoring and other symptoms of sleep apnea
- Symptoms or history of drug or alcohol abuse
- Current medication use
- Chronic medical conditions
- Acute change or stressors such as travel or shift work
- Sleep diary: sleep log for 7 consecutive days

### *DIFFERENTIAL DIAGNOSIS*

- Sleep-disordered breathing such as obstructive sleep apnea
- CNS hypersomnias (e.g., narcolepsy)
- Circadian rhythm sleep disturbances

Sleep-related movement disorders (e.g., restless leg syndrome)

- Substance abuse
- Insomnia due to medical or neurologic disorder
- Mood and anxiety disorders such as depression or anxiety

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Diagnostic testing usually not required; consider polysomnography if sleep apnea or periodic limb movement disorder is suspected (1)[C].
- Primary insomnia
  - Symptoms for at least 1 month: difficulty in initiating/maintaining sleep or nonrestorative sleep
  - Impairment in social, occupational, or other important areas of functioning
  - Does not occur exclusively during narcolepsy, breathing-related sleep disorder, circadian rhythm sleep disorder, or parasomnia
  - Does not occur exclusively during major depressive disorder, generalized anxiety disorder, delirium
  - Is not secondary to physiologic effects of substance or general medical condition
  - Sleep disturbance (or resultant daytime fatigue) causes clinically significant distress.
- Secondary insomnia
  - Due to substance abuse, medication induced (diuretics, stimulants, etc.), primary depressive disorder, generalized anxiety disorder or phobias, acute situational stress, posttraumatic stress disorder, pain

### ***Initial Tests (lab, imaging)***

Testing to consider based on history and physical exam:

- Thyroid-stimulating hormone
- Urine toxicology

### ***Diagnostic Procedures/Other***

Polysomnography or multiple sleep latency test not routinely indicated but may be considered if

- Initial diagnosis is uncertain.

Treatment interventions have proven unsuccessful.

## TREATMENT

- Transient insomnia
  - May use medications for short-term use only; benzodiazepines favored
  - Self-medicating with alcohol can increase awakenings and sleep-stage changes.
- Chronic insomnia
  - Treatment of underlying condition (major depressive disorder, generalized anxiety disorder, medications, pain, substance abuse)
  - Advise good sleep hygiene.
  - Cognitive-behavioral therapy is the first-line treatment for chronic insomnia, especially in >60 years population, especially when sedatives are not advantageous (2)[A].
  - Behavioral therapy is an effective treatment for insomnia and a potentially more effective long-term treatment than pharmacotherapy (3)[B].
  - Ramelteon is the only agent without abuse potential (4)[B].

---

P.565

## MEDICATION

- Reserved for transient insomnia such as with jet lag, stress reactions, transient medical condition
- Nonbenzodiazepine hypnotics
  - Act on benzodiazepine receptor so have abuse potential
    - Zaleplon (Sonata) 5 to 20 mg; half-life 1 hour
    - Zolpidem (Ambien) 5 to 10 mg (males); 5 mg (females); half-life 2.5 to 3 hours
    - Zolpidem (Ambien CR) 6.25 to 12.5 mg (males); 6.25 mg (females); half-life 2.5 to 3 hours
    - Eszopiclone (Lunesta) 1 to 3 mg; half-life 6 hours
- Benzodiazepine hypnotics
  - Short acting

Triazolam (Halcion) 0.25 mg; half-life 1.5 to 5.5 hours

- Intermediate acting
  - Temazepam (Restoril) 7.5 to 30 mg; half-life 8.8 hours long-acting:
    - Lorazepam (Ativan) 1 to 4 mg; half-life 14 hours
    - Diazepam (Valium) 5 to 10 mg; half-life 30 to 60 hours
    - Estazolam (Prosom) 1 to 2 mg; half-life 10 to 24 hours
- Contraindications/precautions:
  - Not indicated for long-term treatment due to risks of tolerance, dependency, daytime attention and concentration compromise, incoordination, rebound insomnia
  - Long-acting benzodiazepines associated with higher incidence of daytime sedation and motor impairment
  - Avoid in elderly, pregnant, breastfeeding, substance abusers, and patients with suicidal or parasuicidal behaviors.
  - Avoid in patients with untreated obstructive apnea and chronic pulmonary disease.
  - No good evidence for benzodiazepines for patients undergoing palliative care (5)[A]
  - Nonbenzodiazepine receptor agonists may occasionally induce parasomnias (sleepwalking, sleep eating, sleep driving).
- Melatonin receptor agonist
  - Ramelteon 8 mg; half-life 1 to 2.6 hours Effective to reduce sleep time onset for short and long-term use in adults, without abuse potential; no comparative studies with older agents have been completed. Onset of effect may take up to 3 weeks (4)[B].
- Serotonergic antidepressants
  - Trazodone 25 to 200 mg; half-life 3 to 9 hours
  - Doxepin 10 to 50 mg; half-life 15 hours
    - New formulation of medication is available at dosage 3 to 6 mg QHS.
  - Amitriptyline 25 to 50 mg; half-life 10 to 26 hours
  - Mirtazapine 7.5 to 15 mg; half-life 20 to 40 hours
- Sedating antihistamines are not recommended and should be used conservatively for insomnia due to insufficient evidence of efficacy and significant concerns about risks of these medications.

## *Geriatric Considerations*

Caution (risk of falls and confusion) when prescribing benzodiazepines or other sedative hypnotics; if absolutely necessary, use short-acting nonbenzodiazepine agonists at half the dosage or melatonin agonists for short-term treatment.

## **ADDITIONAL THERAPIES**

Associated with hypertension, congestive heart failure, anxiety and depression, and obesity; management of these chronic conditions will help with incidence and symptoms of insomnia.

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Melatonin: decreases sleep latency when taken 30 to 120 minutes prior to bedtime, but there is no good evidence for efficacy in insomnia, and longterm effects are unknown (6)[B]
- Valerian: Inconsistent evidence supporting efficacy and its slow onset of action (2 to 3 weeks) makes it unsuitable for the acute treatment of insomnia.
- Acupuncture: insufficient evidence on effect of needle acupuncture and its variants (7)
- Antihistamines: insufficient evidence; should not be recommended for use
- Cognitive-behavioral therapy (including relaxation therapy): effective and considered more useful than medications; recommended initial treatment for patients with chronic insomnia
- Mindfulness awareness practices: improved sleep quality and sleep-related daytime impairment for older adults per small randomized trial (8)

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Daily exercise improves quality of sleep and may be more effective than medication.
- Avoid exercise within 4 hours of bedtime.

### ***Patient Monitoring***

- Reassess need for medications periodically; avoid standing prescriptions.
- Caution patients that nonbenzodiazepine agonists (zolpidem, zaleplon, eszopiclone), as well as benzodiazepines, can be habit forming.
- Studies suggest an association between receiving a hypnotic prescription and a >3-fold increase in hazards of death, even when prescribed <18 pills per year (9)[B].

## DIET

- Avoid caffeine or reserve for morning only.
- Avoid heavy late-night snacks (light snack at bedtime may help).
- Avoid alcohol within 6 hours of bedtime.

## PROGNOSIS

- Situational insomnia should resolve with time.
- Treatment of underlying etiology and consistent sleep hygiene are the mainstays of treatment.

## COMPLICATIONS

- Transient insomnia can become chronic.
- Daytime sleepiness, cognitive dysfunction
- Pulmonary hypertension if chronic sleep apnea left untreated
- Sleep apnea may lead to hypertension, stroke, or cardiac ischemia.

## See Also

&NA;

- Anxiety; Depression; Fibromyalgia; Sleep Apnea, Obstructive
- Algorithms: Anxiety; Insomnia, Chronic; Restless Legs Syndrome (RLS)

## Codes

&NA;

### ICD10

- G47.00 Insomnia, unspecified
- F51.02 Adjustment insomnia
- F51.01 Primary insomnia

## Clinical Pearls

&NA;

- Treatment of underlying etiology of the insomnia and consistent sleep hygiene are key.
- Most medications are indicated for short-term use only.
- Sedative hypnotics are not recommended in the elderly because risks may outweigh benefits.
- Patients with chronic insomnia benefit from cognitive-behavioral therapy.

# Intellectual Disability (Intellectual Developmental Disorder)

Jennifer L. Ayres, PhD

## BASICS

- Intellectual disability (ID) is a global deficit in cognitive functioning evidenced by a significant difference between one's mental and chronologic ages (also known as *intelligence quotient* [IQ]) and significantly impaired adaptive functioning (1).
- Although these cognitive issues typically have a pervasive impact, patients with ID will display highly variable levels of functioning and subsequent service needs.
- Patients must be evaluated individually. Treatment plans must be tailored to specific needs.
- The term *mental retardation* was deleted from the *DSM-5* and replaced with *intellectual disability* or *intellectual developmental disorder*. The rationale was that the term *mental retardation* is considered pejorative and culturally insensitive.

## DESCRIPTION

- ID is defined as an IQ  $\leq 70 + 5$  and a significant impairment in intellectual functioning, including verbal and nonverbal reasoning, planning, academic learning, problem solving, and experiential learning. The intellectual functioning is confirmed by both IQ testing and clinical assessment (1).
- A diagnosis of ID also requires deficits in adaptive functioning, such as communication, socialization, and independent living (1).
- By definition, ID is a neurodevelopmental disorder that is typically present from birth or determined during early childhood (1).
- Currently, ID is subgrouped according to the patient's level of adaptive functioning and level of support needed. Severity levels: *mild* (typical development in some domains, mild impairment in others), *moderate* (skills are markedly behind same-age peers), *severe* (skills are quite limited, compared to peers), *profound* (very limited awareness of concepts, language, dependent on others for all aspects of adaptive functioning) (1).
- The three most common causes of ID are Down syndrome, fragile X syndrome, and fetal alcohol syndrome (FAS).

If the ID reflects a loss of previously acquired intellectual skills, comorbid diagnoses of ID and neurocognitive disorder may be appropriate.

## ***ALERT***

For some causes of ID, prenatal testing is available.

## ***EPIDEMIOLOGY***

### ***Incidence***

- 1 of 6 children (2)
- Predominant sex: male > female: 1.6:1 for mild ID, 1.2:1 for severe ID (1)

### ***Prevalence***

In the United States, 1% of the general population. The prevalence for severe ID is 6/1,000 (1).

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

- Causes:
  - Maternal substance abuse (e.g., alcohol); FAS is a leading environmental cause of ID.
  - Maternal infections: TORCH viruses (toxoplasma, other infections, rubella, cytomegalovirus, and herpes simplex)
  - Down syndrome
  - Sex chromosome abnormalities: fragile X, Turner syndrome, Klinefelter syndrome
  - Autosomal dominant conditions: neurocutaneous syndromes (e.g., neurofibromatosis, tuberous sclerosis)
  - Autosomal recessive conditions:
    - Amino acid metabolism (e.g., phenylketonuria, maple syrup urine disease)
    - Carbohydrate metabolism (e.g., galactosemia, fructosuria)
    - Lipid metabolism
    - Tay-Sachs disease
    - Gaucher disease
    - Niemann-Pick disease (e.g., mucopolysaccharidosis)
    - Purine metabolism (e.g., Lesch-Nyhan disease)

Other (e.g., Wilson disease)

- Maternal use of prescription medications (e.g., Accutane, dilantin)
- Perinatal factors:
  - Prematurity
  - Birth injuries
  - Perinatal anoxia
- Postnatal factors:
  - Childhood diseases (e.g., meningitis, encephalitis, hypothyroidism, seizure disorders)
  - Trauma (e.g., accidents, physical abuse, hypoxia)
  - Severe deprivation
  - Poisoning (e.g., lead, carbon monoxide, household products)

## *Genetics*

A number of genetic and epigenetic causes are known, and more are under investigation (3).

## **RISK FACTORS**

- Maternal substance abuse during pregnancy
- Maternal infection during pregnancy
- For some causes, family history

## **GENERAL PREVENTION**

- Public health efforts to reduce alcohol and drug use by pregnant women
- Prenatal folic acid supplementation

## **COMMONLY ASSOCIATED CONDITIONS**

- Seizures
- Mood disorders
- Behavioral disorders
- Constipation

# DIAGNOSIS

A diagnosis of ID should be made only through a psychodiagnostic assessment conducted by a mental health provider who is trained and licensed to conduct formal psychological testing.

## HISTORY

- Children with profound/severe ID are typically diagnosed at birth or during the newborn period and may have dysmorphic features.
- Children with ID are often identified because they fail to meet motor/language milestones.

## PHYSICAL EXAM

Careful examination by a physician trained in the assessment of morphologic features suggestive of a specific etiology for ID (e.g., microcephaly) (4)

## DIFFERENTIAL DIAGNOSIS

- Brain tumors
- Auditory, visual, and/or speech/language impairment
- Autism spectrum disorder (language and social skills are more affected than other cognitive abilities); however, 75% of individuals with an autistic disorder may meet criteria for a comorbid diagnosis of ID.
- Expressive/receptive language disorders
- Cerebral palsy
- Emotional/behavioral disturbance
- Learning disorders (reading, math, written expression)
- Auditory/sensory processing difficulties
- Lack of environmental opportunities for appropriate development

## DIAGNOSTIC TESTS & INTERPRETATION

- Visual and hearing tests to rule out these etiologies as a cause of impairment and provide an assessment of visual and auditory functioning, which are often impaired in children and adults with ID.
- Formal testing of intellectual and adaptive functioning:
  - A child's communication skills must be considered in test selection. For example, a patient

with auditory processing issues/limited expressive/receptive language skills may need to be assessed using a nonverbal IQ test, such as the Leiter-R, Test of Nonverbal Intelligence, or other nonverbal measures.

- Commonly used intelligence tests (e.g., Bayley Scales of Infant Development, Stanford-Binet Intelligence Scale, Wechsler Intelligence Scales) are determined by age/developmental level of the child.
  - Common tests of adaptive functioning include the Vineland Adaptive Behavior Scales, 2nd ed., and Adaptive Behavior Assessment System, 2nd ed. These tests assess areas of functioning such as age-appropriate communication, social skills, activities of daily living, and motor skills.
- Metabolic screening is not routine unless history and physical suggest or no newborn screening done (5).

### *Initial Tests (lab, imaging)*

- Lead (5)[B]
- Thyroid-stimulating hormone if systemic features present/no newborn screening (5)[B]
- Routine cytogenetic testing (karyotype) (5)[B]:
  - Fragile X screening (FMR1 gene), particularly with a family history of ID
  - Rett syndrome (MECP2 gene) in women with unexplained moderate to severe ID (5)
- Molecular screening, such as array comparative genomic hybridization, is used increasingly and may yield a diagnosis in 10% of undiagnosed cases (4)[B].
- Neuroimaging (MRI more sensitive than CT) is routinely recommended. The presence of physical findings (microcephaly, focal motor deficit) will increase the yield of a specific diagnosis (5)[B].
- MRI may show mild cerebral abnormalities but is unlikely to establish etiology of ID (4).

### *Follow-Up Tests & Special Considerations*

- Electroencephalogram is not routine unless epilepsy or a specific epileptiform syndrome is present (5)[C].
- Assessment of quality of life provides salient information about a patient's general sense of well-being and life satisfaction; however, quality of life may be difficult to assess when significant behavioral issues confound an individual's self-report and socialization.

## TREATMENT

- Early intervention services tailored to the individual's specific needs
- Caregiver support, including:
  - Training caregiver(s) to address behavioral issues, discipline, and support socialization development
  - Encouraging caregivers to create a structured home environment that is based on the child's developmental level and specific needs rather than age-appropriate expectations.
  - Providing caregiver(s) with an opportunity to address their reactions to the diagnosis and their child's special needs
  - Informing caregivers about advocacy groups and available community, state, and national resources (6,7,8)
  - Encouraging caregiver(s) to seek social support to increase overall sense of well-being
  - Encouraging caregivers to seek respite care as needed to ensure that they have an opportunity to engage in health self-care.
- Individualized education plans and, depending on the level of impairment, social skills and behavioral plans/training
- Refer to job training programs and independent living opportunities, if appropriate.
- Notice all changes in behavior, which may be indicative of pain/illness, particularly in individuals with limited communication skills.
- Assess for abuse and neglect.

## MEDICATION

Medication may be appropriate for comorbid conditions (e.g., anxiety, ADHD, depression).

## ONGOING CARE

The physician should match his or her communication of exam procedures, test results, and treatment recommendations to the patient's level of cognitive functioning and receptive language skills.

- Most patients with ID will fall within the mild range and are fully capable of understanding information if it is provided at the appropriate level.
- Provide oral and written explanations directly to the patient instead of solely to his or her

caregivers. The dignity of the patient must be respected at all times. This includes providing honest information, responding to patient's questions with respect, and not infantilizing the patient due to his or her ID.

## *FOLLOW-UP RECOMMENDATIONS*

- Many adults and children with ID exhibit poor physical fitness. Preliminary studies suggest structured exercise programs are effective to engage this population in healthy activities (9) [A].
- Linkage to community-based resources for job training, independent living, caregiver support, school-based services

## *Patient Monitoring*

- Primary care with attention to associated medical conditions
- Vision testing at least once before age 40 years (age 30 years in Down syndrome) and every 2 years thereafter (10)[B]
- Hearing evaluations every 5 years after age 45 years (every 3 years throughout life in Down syndrome) (10)[B]
- Screen for sexual activity and offer contraception and testing for STIs (10)[B].
- Abuse and neglect of people with ID are common. Screen at least annually and if behavior change is noted. Report abuse/neglect to appropriate protective agencies (10)[B].
- Dysphagia and aspiration are common; consider speech pathology evaluation and swallowing study (11)[B].
- Monitor for and treat constipation (11)[B].
- Osteoporosis: common; low threshold to order imaging studies after traumatic injury (11)[B]

## *DIET*

No restrictions, except in cases of metabolic and storage disorders (e.g., phenylketonuria)

## *PATIENT EDUCATION*

- The Arc of the United States (The Arc): [www.thearc.org](http://www.thearc.org)
- American Association of Intellectual and Developmental Disabilities: [www.aaid.org](http://www.aaid.org)
- Family support groups (Parent to Parent, local Down Syndrome, or Autism Association)
- Special Olympics: [www.specialolympics.org](http://www.specialolympics.org)

## PROGNOSIS

Although ID is a lifelong diagnosis, individuals with ID are capable of living a fulfilling, purposeful life that includes having a career, living independently, marrying/participating in a committed relationship, and becoming a parent. Also, the level of severity and support needed may vary over the course of the individual's life.

## COMPLICATIONS

- Constipation is a commonly overlooked problem and can lead to significant morbidity.
- Polypharmacy, often associated with psychotropic medication use to control behaviors, should be addressed to minimize adverse side effects.

## Codes

**&NA;**

### ICD10

- F79 Unspecified intellectual disabilities
- F70 Mild intellectual disabilities
- F71 Moderate intellectual disabilities

## Clinical Pearls

**&NA;**

- The term mental retardation may be interpreted as culturally insensitive and disrespectful to patients and their caregivers. ID or intellectual developmental disorder is the correct diagnosis.
- Overall functioning with ID is highly variable and influenced by multiple factors, including appropriateness of school placement/special education services, exposure to early intervention, behavioral therapy, parent training, self-esteem, and social skills.
- Previous stereotypes of people with ID (e.g., always happy, poor prognosis, unable to function independently) have been refuted. People with ID are showing a level of functioning variability that parallels what is found in the non-ID population.
- Be aware of the unique parenting needs that caregivers may face. Link families to community and national resources that can provide practical and emotional support when appropriate.

- Because children with developmental disabilities are at higher risk of being abused than their peers without developmental disabilities, discuss with caregivers how to educate children about safety precautions in a developmentally appropriate manner.

# Interstitial Cystitis

Rebecca R. Yeager, MD

Montiel T. Rosenthal, MD

## BASICS

### DESCRIPTION

- A condition of pain or discomfort in the bladder associated with a need to urinate frequently and urgently
- A disease of unknown cause, probably representing a final common pathway from several etiologies
- Likely, pathogenesis is disruption of urothelium, impaired lower urinary tract defenses and loss of bladder muscular wall elasticity. The symptoms in many patients are insidious, and the disease progresses for years before diagnosis is established.
- Newer research implicates urine and serum inflammatory proteins antiproliferative factor, epidermal growth factor, heparin-binding epidermal growth factor, glycosaminoglycans, and bladder nitric oxide as contributing factors.
- Mild: normal bladder capacity under anesthesia; ulceration, cracking, or glomerulation of mucosa (or not) with bladder distention under anesthesia; no incontinence symptoms wax and wane and may not progress. Interstitial cystitis is a bladder sensory problem.
- Severe: progressive bladder fibrosis; small true bladder capacity under anesthesia; poor bladder wall compliance. In 5-10% of cases, Hunner ulcers present at cystoscopy; may have overflow incontinence and/or chronic bacteriuria unresponsive to antibiotics.
- System(s) affected: renal/urologic
- Synonym(s): urgency frequency syndrome; IC/bladder pain syndrome (BPS)

### *Pregnancy Considerations*

Unpredictable symptom improvement or exacerbation during pregnancy; no known fetal effects from interstitial cystitis; usual problems of unknown effect on fetus with medications taken during pregnancy

### EPIDEMIOLOGY

- Occurs predominantly among whites
- Predominant sex: female > male (10:1)
- Patients <30 years have predominant symptoms: dysuria, frequency, urinary urgency, pain in external genitals, and dyspareunia; and those >60 years more commonly have nocturia, urinary incontinence, or Hunner ulcer disease.
- Predominant age
  - Mild: 20 to 40 years
  - Severe: 20 to 70 years
- Pediatric considerations
  - <10 years old and again at 13 to 17 years
  - Daytime enuresis, dysuria without infection

## *Prevalence*

In the United States:

- Up to 1 million affected, but many cases likely are unreported
- 0.052% but may be higher up to 10%

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Unknown but is not primarily psychosomatic
- Possible causes
  - Subclinical urinary infection
  - Damage to glycosaminoglycan mucus layer increasing bladder wall permeability to irritants such as urea
  - Autoimmune
  - Mast cell histamine release
- Neurologic upregulation/stimulation

## *RISK FACTORS*

Unknown

## *COMMONLY ASSOCIATED CONDITIONS*

- Fibromyalgia
- Allergies
- Chronic fatigue syndrome
- Depression
- Vulvodynia
- Sexual dysfunction
- Sleep disturbance
- Migraines
- Syncope
- Dyspepsia
- Chronic prostatitis
- Chronic pelvic pain
- Irritable bowel syndrome
- Anal/rectal disease

## DIAGNOSIS

- Frequent, urgent, relentless urination day and night; >8 voids in 24 hours
- Pain with full bladder that resolves with bladder emptying (except if bacteriuria is present)
- Urge urinary incontinence if bladder capacity is small
- Sleep disturbance
- Dyspareunia, especially with full bladder
- Secondary symptoms from chronic pain and sleeplessness, especially depression

## HISTORY

- Pelvic Pain and Urgency/Frequency Patient Symptom Scale: self-reporting questionnaire for screening potential interstitial cystitis patients (1)[B] ([http://wgcaobgyn.com/files/urgency\\_frequency\\_pt\\_symptom\\_scale.pdf](http://wgcaobgyn.com/files/urgency_frequency_pt_symptom_scale.pdf))
- Frequent UTIs, vaginitis, or symptoms during the week before menses
- O'Leary/Sant Voiding and Pain Indices ([http://www.ichelp.org/wp-content/uploads/2015/06/OLeary\\_Sant.pdf](http://www.ichelp.org/wp-content/uploads/2015/06/OLeary_Sant.pdf))

## *PHYSICAL EXAM*

- Perineal/prostatic pain in men
- Anterior vaginal wall pain in women

## *DIFFERENTIAL DIAGNOSIS*

- Uninhibited bladder (urgency, frequency, urge incontinence, less pain, symptoms usually decrease when asleep)
- Urinary infection: cystitis, prostatitis
- Bladder neoplasm
- Bladder stone
- Neurologic bladder disease
- Nonurinary pelvic disease (STIs, endometriosis, pelvic relaxation)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Urinalysis: normal except with chronic bacteriuria (rare)
- Urine culture from catheterized specimen: normal except with chronic bacteriuria (rare) or partial antibiotic treatment
- Urine cytology
  - Normal: reserve for men >40 years old and women with hematuria

### *Diagnostic Procedures/Other*

- Cystoscopy (especially in men >40 years old or women with hematuria)
  - Bladder wall visualization
  - Hydraulic distention: no improved diagnostic certainty over history and physical alone
- No role for urodynamic testing
- Intravesical lidocaine can help to pinpoint the bladder as the source of pain in patients with pelvic pain; this can be both diagnostic and therapeutic.
- Potassium sensitivity test
  - Insert catheter, empty bladder, instill 40 mL H<sub>2</sub>O over 2 to 3 minutes, rank urgency on scale

of 0 to 5 in intensity, rank pain on scale of 0 to 5 in intensity, drain bladder, instill 40 mL potassium chloride (KCl) 0.4 mol/L solution:

- If immediate pain, flush bladder with 60 mL H<sub>2</sub>O and treat with bladder instillations.
- If no immediate pain, wait for 5 minutes and rate the urgency and pain.
- If urgency or pain >2, treat as above.
- Pain or urgency >2 is considered a positive test and strongly correlates with interstitial cystitis if no radiation cystitis or acute bacterial cystitis is present.

## *Test Interpretation*

- Nonspecific chronic inflammation on bladder biopsies
- Urine cytology negative for dysplasia and neoplasia
- Possible mast cell proliferation in mucosa

## **TREATMENT**

### *GENERAL MEASURES*

- Appropriate health care: outpatient
- Self-care (eliminate foods and liquids that exacerbate symptoms on individual basis, fluid management) (2)[C]
- Biofeedback bladder retraining (2)[C]

### *MEDICATION*

- Randomized controlled trials of most medications for interstitial cystitis demonstrate limited benefit over placebo; there are no clear predictors of what will benefit an individual. Prepare the patient that treatment may involve trial and error.

---

P.569

- Behavioral therapy combined with oral agents found improved outcomes compared to medications alone.
- Intravesical injections of botulinum toxin are not effective in the treatment of ulcer-type interstitial cystitis.

### *First Line*

- Note: AUA consensus states medicines should be considered second-line therapy after patient education, stress reduction, behavior modification, and self-care (2)[C].
- Pentosan polysulfate (Elmiron) 100 mg TID on empty stomach; may take several months (3 to 6) to become effective; rated as modestly beneficial in systematic drug review (only FDA-approved treatment for interstitial cystitis) (3)[C]
- Amitriptyline: Most effective at higher doses (<sup>3</sup>50 mg/day); however, initiate with lower doses to minimize side effects (4)[B].
- Hydroxyzine 25 to 50 mg HS
- Sildenafil 25 mg/day (5)[B]
- Cimetidine 400 mg BID (2)[C]
- Triple-drug therapy: 6 months of pentosan, hydroxyzine, doxepin
- Antibacterials for bacteriuria
- Oxybutynin, hyoscyamine, tolterodine, and other anticholinergic medications decrease frequency.
- Prednisone (only for ulcerative lesions)
- Montelukast has shown some benefit.
- NSAIDs for pain and any inflammatory component
- Bladder instillations
  - Lidocaine, sodium bicarbonate, and heparin or pentosan polysulfate sodium
  - Dimethyl sulfoxide (DMSO) every 1 to 2 weeks for 3 to 6 weeks, then PRN
  - Heparin sometimes added to DMSO
  - Intravesical liposomes
  - Other agents: steroids, silver nitrate, oxychlorosene (Clorpectin)
- Contraindication
  - No anticholinergics for patients with close-angle glaucoma
- Significant possible interaction
  - Refer to manufacturer's profile of each drug.

## *Second Line*

- Phenazopyridine, a local bladder mucosal anesthetic, usually is not very effective.

- Intravesicular injection of botulinum type A for nonulcer interstitial cystitis
- Cyclosporin A (2)[C]

## *ISSUES FOR REFERRAL*

- Need for clarity with respect to diagnosis
- Surgical intervention

## *ADDITIONAL THERAPIES*

Myofascial physical therapy (targeted pelvic, hip girdle, abdominal trigger point massage) (6)[B]

## *SURGERY/OTHER PROCEDURES*

- Hydraulic distention of bladder under anesthesia: symptomatic but transient relief
- Cauterization of bladder ulcer
- Augmentation cystoplasty to increase bladder capacity and decrease pressure with or without partial cystectomy. Expected results in severe cases: much improved, 75%; with residual discomfort, 20%; unchanged, 5%
- Urinary diversion with total cystectomy only if disease is completely refractory to medical therapy
- Sacral neuromodulation

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Guided imagery

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

Not specifically needed unless symptoms are unresponsive to treatment

## *DIET*

- Variable effects from person to person
- Common irritants include caffeine, chocolate, citrus, tomatoes, carbonated beverages, potassium-rich foods, spicy foods, acidic foods, and alcohol.

## PATIENT EDUCATION

Interstitial Cystitis Association, 110 Washington St. Suite 340, Rockville, MD 20850; 1-800-HELPICA: <http://www.ichelp.org/>

## PROGNOSIS

- Mild: exacerbations and remissions of symptoms; may not be progressive; does not predispose to other diseases
- Severe: progressive problems that usually require surgery to control symptoms

## COMPLICATIONS

Severe, with long-term, continuous high bladder pressure could be associated with renal damage.

## See Also

&NA;

- Urinary Tract Infection (UTI) in Females
- Algorithm: Pelvic Girdle Pain (Pregnancy or Postpartum Pelvic Pain)

## Codes

&NA;

### ICD10

- N30.10 Interstitial cystitis (chronic) without hematuria
- N30.11 Interstitial cystitis (chronic) with hematuria

## Clinical Pearls

&NA;

- The potassium sensitivity test has been the most useful in confirming an initial diagnosis of interstitial cystitis.
- Potassium sensitivity test
  - Insert catheter, empty bladder, instill 40 mL H<sub>2</sub>O over 2 to 3 minutes; rank urgency on scale of 0 to 5 in intensity; rank pain on scale of 0 to 5 in intensity; drain bladder; and instill 40 mL KCl 0.4 mol/L solution.
- Submucosal petechial hemorrhages and/or ulceration at the time of bladder distention and cystoscopy further support the diagnosis.
- At present, there is no definitive treatment for interstitial cystitis.

Most patients with severe disease receive multiple treatment approaches. Regular multidisciplinary follow-up, pharmacologic therapy, avoidance of symptom triggers, and psychological and supportive therapy are all important because this disease tends to wax and wane. Monitor patients for comorbid depression.

- Empowering patients to manage their symptoms, communicate regularly with their physicians, and learn as much as they can about this disease which may help them to optimize their outcome.

# Interstitial Nephritis

Roger P. Holland, MD, PhD

## BASICS

### DESCRIPTION

- Acute and chronic tubulointerstitial diseases result from the interplay of renal cells and inflammatory cells and their products. Lethal or sublethal injury to renal cells leads to expression of new local antigens, inflammatory cell infiltration, and activation of proinflammatory and chemoattractant cytokines. These cytokines are produced by macrophages and lymphocytes and also by the renal cells (i.e., proximal tubule, vascular endothelial cells, interstitial cells, fibroblasts). The outcome can be acute interstitial nephritis (AIN) or chronic interstitial nephritis (CIN).
- AIN presents as acute kidney injury (AKI) after the use of offending drugs or agents (OFA) and is associated with typical findings of proteinuria, hematuria, and white cell casts. Less frequently, AIN is secondary to infection or systemic diseases (e.g., sarcoidosis, mixed connective tissue disease [MCTD], SLE, Sjögren syndrome).
- System(s) affected: renal/urologic, endocrine/metabolic, immunologic
- Synonym(s): acute interstitial allergic nephritis

### EPIDEMIOLOGY

#### *Pediatric Considerations*

- Children with history of lead poisoning are more likely to develop CIN as young adults.
- Tubulointerstitial nephritis with uveitis (TINU) presents in adolescent females.

#### *Incidence*

- AIN and CIN accounts for 10-15% of kidney disease.
- Peak incidence in women 60 to 70 years of age

#### *Geriatric Considerations*

The elderly (<sup>3</sup>65 years) have more severe disease and increased risk of permanent damage due

to their increased use of OFA, specifically more drug-induced AIN (87% vs. 64%), proton pump inhibitor-induced AIN (18% vs. 6%) but less AIN due to autoimmune or systemic causes (7% vs. 27%) than younger adults (1)[B].

## ETIOLOGY AND PATHOPHYSIOLOGY

- AIN

- Delayed drug hypersensitivity reactions
- Causes AKI
- Renal dysfunction generally is usually partially or completely reversible, possibly reflecting the regenerative capacity of tubules with a preserved basement membrane.
- Hypersensitivity to drugs (75%): not dose dependent. The three top drug causes were omeprazole (12%), amoxicillin (8%), and ciprofloxacin (8%) in a recent case series (2)[C].
  - Antibiotics (e.g., penicillins, cephalosporins, sulfonamides, tetracycline, vancomycin, fluoroquinolones, macrolides, TB meds)
  - Proton pump inhibitors
  - Antivirals (Indinavir)
  - NSAIDs (all, including Cox-2 inhibitors)
  - Diuretics (thiazide, loop, and triamterene)
  - Miscellaneous (allopurinol, H<sub>2</sub> blockers, diphenylhydantoin, and 5-aminosalicylates such as Azulfidine and mesalamine)
- Infections: *Legionella*, *Leptospira*, streptococci, CMV, *Mycobacterium tuberculosis* (5-10%)
- Autoimmune disorders (e.g., SLE, Sjögren syndrome, sarcoidosis, Wegener granulomatosis, cryoglobulinemia) (10-15%)
- Toxins (e.g., snake bite venom)

- CIN

- Follows long-term exposure to OFA (e.g., heavy metals, especially lead)
- Often found on routine labs or evaluation for hypertension (HTN)
- Characterized by interstitial scarring, fibrosis, and tubular atrophy, resulting in progressive chronic kidney disease (CKD)

## GENERAL PREVENTION

- Early recognition and prompt discontinuation of OFA
- Avoid further nephrotoxic substances.

## COMMONLY ASSOCIATED CONDITIONS

### CIN

- Chronic pyelonephritis
- Abuse of analgesics
- Lithium use
- Gout and gout therapy
- Immune disorders
- Malignancy (lymphoma, multiple myeloma)
- Amyloidosis
- Exposure to heavy metals (e.g., lead, cadmium)
- Renal papillary necrosis

## DIAGNOSIS

- AIN: suspected in a patient who presents with nonspecific signs and symptoms of AKI (e.g., malaise, fever, nausea, vomiting) with an elevated serum creatinine and an abnormal urinalysis
  - AKI
    - Elevated creatinine, BUN, and electrolyte abnormalities (e.g., hyperkalemia, low serum bicarbonate)
    - Decreased urine output (oliguria in 51%)
    - Signs of fluid overload or depletion
  - Signs of systemic allergy (e.g., fever [27%], maculopapular rash [15%], peripheral eosinophilia [23%], arthralgias [45%], but less commonly found when NSAIDs are the OFA)
  - White cells, red cells, and white cell casts
- CIN
  - HTN

Decreased urine output or polyuria

- Inability to concentrate urine
- Polydipsia
- Metabolic acidosis
- Anemia
- Fanconi syndrome

## **HISTORY**

- Medications: Onset of AIN following drug exposure ranges from 3 to 5 days (as occurs with a second exposure to an OFA) to as long as several weeks to many months (the latter with NSAIDs, especially) (2)[B].
- Infections: may have symptoms related to an associated infection or systemic condition
- TINU patients present with interstitial nephritis and uveitis and occasionally systemic findings.
- Exposure to heavy metals
- Post organ transplant

## **PHYSICAL EXAM**

- Increased BP
- Fluid retention/extremity swelling/weight gain
- Rash accompanying renal findings in acute AIN
- Lung crackles if fluid is overloaded
- Pericardial rub if uremic pericarditis

## **DIFFERENTIAL DIAGNOSIS**

- AKI secondary to other causes:
  - Prerenal (e.g., hypovolemia, shock, sepsis, renal artery emboli)
  - Intrarenal (e.g., acute tubular necrosis, hypertensive nephropathy, DM nephropathy)
  - Postrenal (e.g., obstructive uropathy)
  - Some OFA that cause AIN can produce other forms of AKI as well:
    - NSAIDs can exacerbate prerenal disease.

- Aminoglycosides can cause acute tubular necrosis.
- CKD secondary to long-standing HTN, diabetes, and chronic pyelonephritis

## DIAGNOSTIC TESTS & INTERPRETATION

- Chemistry
  - Elevated plasma creatinine: seen in all patients, with 40% requiring dialysis
  - Hyperkalemia and acidosis
- CBC
  - Eosinophilia (80%): NSAID-induced AIN is only associated with eosinophilia in ÷15% of cases.
  - Anemia
- Urinalysis with urine electrolytes
  - Hematuria (95%)
  - Mild and variable proteinuria: usually <1 g/24 hr, except in AIN-associated with NSAIDs where it is significantly higher (3)[B]
  - Urine sediment: white cells, red cells, white cell casts. Red blood cell casts are rare.
  - Eosinophiluria but has no clinical utility specific for AIN (4)[C]
  - Fractional excretion of sodium (FENa >1%) indicative of tubular damage
  - Normal urinalysis does not rule out AIN.
- CXR to evaluate for pulmonary tuberculosis, sarcoidosis, and other infections
- Serologic testing for immunologic disease (e.g., sarcoidosis, Sjögren syndrome, Wegener granulomatosis, Behçet syndrome) or infectious causes (e.g., histoplasmosis, coccidiomycosis, toxoplasmosis, EBV)
  - Serum levels of angiotensin-converting enzyme and serum Ca<sup>++</sup> for sarcoidosis
  - Antinuclear antibody (ANA) and dsDNA to exclude SLE
  - Urinary antigen to exclude *Legionella* infection
  - Anti-Ro/SSA, anti-La/SSB antibodies, CRP, and rheumatoid factor to exclude Sjögren syndrome
- Liver function tests: elevated serum transaminase levels in patients with associated drug-induced liver injury

- Renal US may demonstrate kidneys that are normal to enlarged in size with increased cortical echogenicity, but no US findings will reliably confirm or exclude AIN versus other causes of AKI.
- IV pyelography (IVP) and CT scans with contrast are relatively contraindicated because of the associated nephrotoxicity and limited diagnostic yield.

## Follow-Up Tests & Special Considerations

Patients who do not recover renal function and those with CIN should receive long-term follow-up care to protect kidneys from further potentially nephrotoxic therapies.

### *Diagnostic Procedures/Other*

- Renal biopsy is the definitive method of establishing the diagnosis of AIN. Ideally, it should be performed to:
  - Patients treated with an OFA known to cause AIN but have normal urinalysis
  - Patients who are being considered for steroid therapy
  - Patients who are not on glucocorticosteroid therapy initially and do not have spontaneous recovery following cessation of the OFA
  - Patients with advanced renal failure of recent onset (<3 months)
  - Patients with any features (e.g., high-grade proteinuria) that makes the diagnosis of AIN uncertain
- Contraindications: Renal biopsy is contraindicated in bleeding diathesis, solitary kidney, end-stage renal disease (ESRD) with small kidneys, uncontrolled HTN and sepsis, or renal parenchymal infection.

P.571

### *Test Interpretation*

- Acute
  - Marked interstitial infiltrate consisting of T lymphocytes and monocytes. Eosinophils, plasma cells, and neutrophils also may be found.
  - In general, the urinary findings will distinguish AIN from other causes (e.g., acute tubular necrosis, glomerulonephritis).
- Chronic: CIN is characterized by tubular atrophy, fibrosis, and cellular infiltration with mononuclear cells.

## TREATMENT

For AIN, data on corticosteroids' efficacy have been limited (5)[B].

### GENERAL MEASURES

- Discontinue offending agent. If topical NSAIDs are in use, discontinue these as well.
- Reduce exposure to other nephrotoxic agents (e.g., furosemide, aminoglycosides).
- Supportive measures:
  - Maintain adequate hydration.
  - Symptomatic relief for fever, rash, and so forth
  - Control of BP and anemia
  - Correct acidosis and electrolyte imbalances.
  - Possible short-term dialysis until recovery of renal function (5)[B]

### MEDICATION

- Mainstay of treatment is supportive therapy.
- If patient is taking multiple offending agents, a reasonable clinical approach should include substitution of the suspected drug with another medication.
- If AKI persists after removing the offending agent, attempt medication therapy.

### First Line

- Optimal therapy of AIN is unknown because there are no randomized controlled trials (RCTs) or large observational studies.
- Immunosuppressive therapy is employed if no subsequent improvement within 3 to 7 days after discontinuation of OFA.
- A renal biopsy is preferred to confirm AIN and to exclude other possible diseases or CIN, where immunosuppressive Rx is not indicated.
- Prednisone 1 mg/kg/day PO or equivalent IV dose to a max of 40 to 60 mg/day for 1 to 2 weeks, beginning a gradual taper after serum creatinine has returned to near baseline for a duration of 2 to 3 months, followed by a gradual taper over 3 to 4 weeks (6)[B]. Complete recover is noted in 49% and partial in 39% (1)[C].
  - Steroids started within 7 days of withdrawal of offending agent are more likely to recover

function than those who started later (odds ratio [OR] 6.6).

## *Second Line*

- There is a limited experience with treating AIN in patients who are steroid-dependent (i.e., relapse during prednisone taper), steroid-resistant (as with NSAID-induced disease), or cannot tolerate steroids.
- Mycophenolate mofetil may be considered in these patients who have biopsy-proven AIN (7) [C]. Rx may need to be continued for 1 to 3 years.
- Lead toxicity: Chelation may improve function.
  - Succimer 10 mg/kg (max 500 mg) PO q8h for 5 days, then q12h for 14 days, or
  - EDTA 2 g IV/IM; if IM, use with 2% lidocaine.
- SLE nephritis: steroids + cyclophosphamide or azathioprine
- Urate nephropathy: urate-lowering agents
  - Allopurinol starting at 100 mg/day, increasing to 300 mg/day to achieve serum urate level <6 mg/dL
  - Dose may need to be adjusted down depending on the level of renal impairment.
  - Allopurinol itself can be a cause of AIN.
  - Discontinue thiazide.
- Lithium-induced nephritis: Use amiloride as adjunct.
- Indinavir-induced nephritis: Use probenecid as adjunct.

## *ISSUES FOR REFERRAL*

Most patients presenting with AKI, proteinuria, and acid-base and/or electrolyte disorders require consultation with a nephrologist.

## *INPATIENT CONSIDERATIONS*

Patients with AKI and/or with serious electrolyte or acid-base disorders may require inpatient care until stabilization or resolution.

### *Admission Criteria/Initial Stabilization*

- Persistent oliguria or anuria
- Severe acidosis and/or electrolyte abnormalities

- ECG changes

## *Discharge Criteria*

- Stable vitals; correction of all electrolyte imbalances, including magnesium; and resolution of acute ECG changes
- Normal urine production

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

If patients must remain on nephrotoxic agents, measure renal function, electrolytes, and phosphorus frequently.

#### *DIET*

- Low potassium (<2 g/day)
- Low sodium
- Low protein

### *PATIENT EDUCATION*

Printed materials for patients are available at the National Kidney Disease Education Program (NKDEP), (866) 4-KIDNEY, <http://www.niddk.nih.gov/health-information/health-communication-programs/nkdep/Pages/default.aspx>.

### *PROGNOSIS*

- If the associated AIN is detected early (within 1 week of the rise in serum creatinine) and the offending agent is discontinued promptly, the longterm outcome is favorable for a return to baseline or near baseline serum creatinine levels, except in the instance of NSAID-induced AIN.
- Renal biopsy reveals extent of damage.
- AIN
  - Recovery within weeks to months (8)[C]
  - Acute dialysis is needed for 1/3 of patients before resolution.

- Rarely progresses to ESRD
- CIN: can progress to ESRD
  - Renal disease may remit in 1 year if untreated.
  - TINU has relapsing course, requiring systemic corticosteroids.
- Untreated severe AKI has 45-70% mortality.

## COMPLICATIONS

- Chronic tubulointerstitial disease may progress to ESRD, requiring dialysis or transplantation.
- Analgesics increase the risk of transitional cell cancers of the uroepithelium.

## Codes

&NA;

### ICD10

- N12 Tubulo-interstitial nephritis, not spcf as acute or chronic
- N10 Acute tubulo-interstitial nephritis
- N11.9 Chronic tubulo-interstitial nephritis, unspecified

## Clinical Pearls

&NA;

- First step in treatment is to remove OFA.
- Most common OFA in elderly is PPIs and antibiotics.
- A renal biopsy is preferred to confirm AIN.
- Immunosuppressive therapy is employed if no subsequent improvement within 3 to 7 days after discontinuation of OFA.

# Irritable Bowel Syndrome

Mark B. Stephens, MD, MS, FAAFP, CAPT, MC, USN

## BASICS

### DESCRIPTION

- A functional gastrointestinal disorder characterized by
  - Chronic abdominal pain associated with
    - Alteration in bowel habits
    - Absence of organic pathology
- May be characterized as diarrhea-predominant or constipation-predominant or may alternate between the two
- Synonym(s): spastic colon; irritable colon

### EPIDEMIOLOGY

Irritable bowel syndrome (IBS) accounts for up to 50% of visits to gastroenterologists:

- Second only to upper respiratory infection as cause of lost workdays

### Prevalence

Pooled estimate of 11% IBS prevalence internationally; ranges from South Asia (7%) to South America (21%) (1)

- Predominant age: 20 to 39 years
- If age >50 years, consider other diagnoses.
- Predominant sex: in the United States, female > male (2:1)
- More common in low socioeconomic communities

### ETIOLOGY AND PATHOPHYSIOLOGY

- The etiology is unknown, associated with intestinal motility abnormalities and enhanced sensitivity to visceral stimuli.

- The trigger may be luminal or environmental.
- Evidence for the role of small intestine bacterial overgrowth (SIBO) in IBS and association with antibiotic therapy is conflicting; older age and female gender are predictors of SIBO in IBS patients.

## *Genetics*

Unknown, but more common in families of IBS patients

## **RISK FACTORS**

- Other family members with similar GI disorder
- History of childhood sexual abuse
- Sexual/domestic abuse (primarily in women)
- Depression
- Gastrointestinal infection

## *Pregnancy Considerations*

No risk to mother or fetus

## **GENERAL PREVENTION**

See ÒDiet.Ó

## **COMMONLY ASSOCIATED CONDITIONS**

- Chronic migraine
- Urinary frequency and urgency
- Fibromyalgia
- Chronic fatigue syndrome
- Sleep disorders
- Dyspareunia
- Depression
- Posttraumatic stress disorder

**DIAGNOSIS**

## HISTORY

- Rome III criteria: recurrent pain or discomfort in the abdomen at least 3 days per month over the past 3 months associated with at least two other criteria:
  - Symptoms improve with defecation.
  - Onset is associated with a change in stool frequency.
  - Onset is associated with a change in the form or appearance of the stool.
- Symptoms can also include:
  - Mucus in stools
  - Constipation, bloating, diarrhea, abdominal distension
  - Upper abdominal discomfort after eating
  - Straining for normal consistency stools
  - Urgency of defecation
  - Feelings of incomplete evacuation
  - Abnormal stool form
  - Nausea, vomiting (rarely)
- May have history of abuse or depression
- Patient may note worsening of symptoms with stress or around menses.
- IBS is unlikely in patients with a history of:
  - Weight loss
  - Bleeding
  - Nocturnal diarrhea
  - Fever
  - Anemia

## PHYSICAL EXAM

- Generally normal
- Perform to exclude other causes.
- Vital signs typically are normal.
- Generally, there is an absence of jaundice and organomegaly but may have tenderness to palpation.

## DIFFERENTIAL DIAGNOSIS

Inflammatory bowel disease

- Lactose intolerance; fructose malabsorption
- Infections (*Giardia lamblia*, *Entamoeba histolytica*, *Salmonella*, *Campylobacter*, *Yersinia*, *Clostridium difficile*)
- Celiac sprue
- Microscopic colitis
- Laxative abuse
- Magnesium-containing antacids
- Hypo-/hyperthyroidism
- Pancreatic insufficiency
- Depression
- Small bowel bacterial overgrowth
- Somatization
- Villous adenoma
- Endocrine tumors
- Diabetes mellitus
- Radiation damage to colon or small bowel

## **DIAGNOSTIC TESTS & INTERPRETATION**

- With a typical history and no danger signs (anemia or weight loss, obtain baseline labs to rule out other causes and begin treatment.
- In patients who do not respond to treatment, further evaluation with imaging and/or endoscopy is warranted to exclude organic pathology.

### ***Initial Tests (lab, imaging)***

Rule out pathology specific to the patient's symptoms:

- Diarrhea-predominant: ESR, CBC, tissue transglutaminase, thyroid-stimulating hormone (TSH), and stool for ova and parasites (2)
- Constipation-predominant: CBC, TSH, electrolytes, calcium (2)
- Abdominal pain: LFTs and amylase
- Abdominal CT scan or abdominal ultrasound to evaluate pain is generally normal.

- Consider small bowel series or video capsule endoscopy to rule out Crohn disease (will be normal).
- Sitz Marker study may be used to evaluate colonic transit in patients with constipation.

## *Follow-Up Tests & Special Considerations*

Consider lactulose breath test to assess for small bowel bacterial overgrowth associated with IBS (2)[C].

## *Diagnostic Procedures/Other*

Sigmoidoscopy/colonoscopy may be used to rule out inflammatory bowel disease or microscopic colitis.

### **ALERT**

Screen all persons >50 for colorectal cancer.

## *Test Interpretation*

None

## **TREATMENT**

- Goals: Relieve symptoms and improve quality of life (3).
  - Determine if diarrhea predominant, constipation predominant, or mixed type
- Lifestyle modification
  - Exercise 3 to 5 times per week decreases severity (3).
  - Food diary to determine triggers (3)
- Medications
  - Fiber supplementation (psyllium) increases stool bulk; does not typically relieve abdominal pain; may be used for all types (3,4)[B]
- Medications that improve abdominal pain, global symptoms, and symptom severity in all types:
  - Antispasmodics such as hyoscyamine 0.125 to 0.25 mg PO/SL q4h PRN and dicyclomine 20 to 40 mg PO BID can be used for all types but have adverse effects such as dry mouth, dizziness, and blurred vision (3).
  - Probiotics such as *Lactobacillus*, *Bifidobacterium*, and *Streptococcus* (5)[C]

- Serotonin antagonists 5-HT<sub>3</sub> and 5-HT<sub>4</sub> agonists (alosetron, cilansetron) have been shown to improve IBS symptoms (versus placebo) (6).

- Diarrhea predominant
  - Antidiarrheal such as loperamide 4 to 8 mg/day orally divided into once a day to 3 times a day as needed to decrease stool frequency and increase stool consistency; does not help with abdominal pain; may also use diphenoxylate/atropine (3)
  - Antibiotics such as 2-week course of rifaximin improve bloating, pain, and stool consistency (7).
  - Alosetron (Lotronex 0.5 mg orally twice a day), used for women with severe symptoms but associated with ischemic colitis, constipation, and death in a small number of patients (8)
- Constipation-predominant
  - Laxatives such as polyethylene glycol (MiraLAX) may improve stool frequency but not pain.
  - Antibiotics such as neomycin and selective chloride channel activators such as lubiprostone (Amitiza) 8 mg twice a day can improve global symptoms and severity (3,9)[B].
  - Linaclotide (guanylate cyclase-C agonist) has been shown to improve bowel function and reduces abdominal pain and overall severity in adults only (10).
- Mixed
  - Use medications above based on symptoms (3).
- Treat underlying behavioral issues:
  - Use of SSRIs such as Prozac, sertraline, Paxil, and tricyclic antidepressants such as imipramine can improve abdominal pain and symptom score (4).
  - Tricyclic antidepressants can help control IBS symptoms in moderate to severe cases (11) [B].
  - Behavioral therapy helps reduce symptoms (7).

## *ISSUES FOR REFERRAL*

- Behavioral health referral may help with management of affective or personality disorders.
- Gastroenterology referral for difficult to control cases

## *ADDITIONAL TREATMENT*

Probiotics use may result in reducing IBS symptoms and decreasing pain and flatulence. There is

no difference among *Lactobacillus*, *Streptococcus*, *Bifidobacterium*, and combinations of probiotics.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

The IBS Severity Score is a validated measure to assess the severity of IBS symptoms and can help monitor response to treatment.

IBS Severity Score:

- How severe has your abdominal pain been over the last 10 days?
- On how many of the last 10 days did you get pain?
- How severe has your abdominal distension (bloating, swollen, or tight) been over the last 10 days?
- How satisfied have you been with your bowel habit (frequency, ease, etc.) over the last 10 days?
- How much has your IBS been affecting/interfering with your life in general over the last 10 days?

#### *DIET*

**Low FODMAPs diet:** This diet contains fermentable oligosaccharides, disaccharides, monosaccharides, and polyols that are carbohydrates (sugars) found in foods. FODMAPs are osmotic, so they may not be digested or absorbed well and could be fermented upon by bacteria in the intestinal tract when *eaten in excess*.

A low FODMAP diet may help reduce symptoms, which will limit foods high in fructose, lactose, fructans, galactans, and polyols.

- Increase fiber slowly to avoid excess intestinal gas production.
- During initial evaluation, may wish to try 2 weeks of lactose-free diet to rule out lactose intolerance.
- Avoid large meals, fatty foods, and caffeine, which can exacerbate symptoms.
- A gluten-free diet resolves symptoms for some patients (especially diarrhea predominant IBS) despite negative testing for celiac disease.

# PATIENT EDUCATION

IBS is not a psychiatric illness.

## PROGNOSIS

- IBS is a functional disorder that reduces quality of life. Many patients have behavioral health issues. IBS does not increase mortality (1).
- Expect recurrences, especially when under stress.
- Evidence suggests that symptom shifting occurs in some patients, whereby resolution of functional bowel symptoms is followed by the development of functional symptoms in another system (1).

Algorithm: Diarrhea, Chronic

## Codes

&NA;

### ICD10

- K58.9 Irritable bowel syndrome without diarrhea
- K58.0 Irritable bowel syndrome with diarrhea

## Clinical Pearls

&NA;

- Use Rome III criteria for diagnosis.
- Goals of treatment are to relieve symptoms and improve quality of life.
- If patient does not respond to initial treatment, consider further evaluation to exclude organic pathology.

# Kawasaki Syndrome

Alicia D. Evans, MD

Scott P. Grogan, DO, MBA, FAAFP

## BASICS

### DESCRIPTION

- Kawasaki syndrome (KS) is a self-limited acute, febrile, systemic vasculitis of small- and medium-sized arteries that predominantly affects patients age 6 months to 5 years and is the most prominent cause of acquired coronary artery disease in pediatric populations.
  - Vasculitis of coronary arteries resulting in aneurysms/ectasia, further leading to myocardial infarction (MI)/ischemia or sudden death
- System(s) affected: cardiovascular, gastrointestinal, hematologic/lymphatic/immunologic, musculoskeletal, nervous, pulmonary, renal/urologic, skin/exocrine
- Synonym(s): mucocutaneous lymph node syndrome (MCLS), infantile polyarteritis, Kawasaki disease

### ALERT

KS should be considered in any child with extended high fever unresponsive to antibiotics or antipyretics, rash, and nonexudative conjunctivitis.

### EPIDEMIOLOGY

#### Incidence

- Worldwide: affects all races but most prevalent in Asia; Japan annual incidence rate 216/100,000 in children <5 years of age
- In the United States, the annual incidence in children <5 years is 19/100,000. In comparison to Caucasians, African Americans have a 1.5 times risk, and Asian Americans have a 2.5 times increased risk. Highest state incidence is in Hawaii.
- Leading cause of acquired heart disease in children in developed countries
  - Predominant age: 1 to 5 years
  - 85% of cases are children <5 years of age and 50% <2 years of age.

- Male-to-female ratio = 1.5:1

## Prevalence

- Highest to lowest prevalence: Asians > African Americans > Hispanics > Caucasians
- Seasonal variation: increased in winter and early spring in temperate places, summer in Asia, and outbreaks at 2- to 3-year intervals

## ETIOLOGY AND PATHOPHYSIOLOGY

- Acute KS causes inflammation in the smooth muscle layer of medium extraparenchymal arteries, especially the coronary arteries.
- Inflammatory cells in the media secrete cytokines (TNF-*α*), interleukins, and matrix metalloproteases that cause fragmentation of the internal elastic lamina.
- A prominence of IgA plasma cells and IgA deposits are characteristic features and may be found in the lungs.
- As the process resolves, active inflammatory cells are replaced by fibroblasts and monocytes; tissue repair/remodeling may cause vascular fibrosis and stenosis.
- Unknown; believed to be an exaggerated immune response to infectious agent due to the acute, self-limited nature; community-wide outbreaks; age distribution; seasonality; and laboratory features indicating respiratory route of entry

## Genetics

- Siblings of patients in Japan have a 10- to 30-fold increased risk, and >50% develop KS within 10 days of first case. Increased occurrence of KS in children whose parents also had illness in childhood.
- Populations at higher risk and family link suggest a genetic predisposition.

## GENERAL PREVENTION

No preventive measures available

## DIAGNOSIS

<sup>3</sup>5 days of fever and <sup>3</sup>4 of the following 5 principal clinical features; or <4 features and presence of coronary artery disease on 2D echocardiography:

- Bilateral conjunctival injection with limbic sparing

- Erythematous mouth and pharynx, tongue, and lips
- A polymorphous, generalized, erythematous rash
- Changes in the skin of the peripheral extremities
- Cervical lymphadenopathy

## *Pediatric Considerations*

- Prolonged fever without rash and treated with antibiotics may cause clinicians to believe that later rash development is due to a drug reaction.
- Can be diagnosed on day 4 of illness if <sup>34</sup> principal features are present
- Incomplete KS
  - <sup>35</sup> days of fever, 2 to 3 principal clinical features, labs indicating systemic inflammation, and exclusion of other diseases
  - Incomplete cases that exhibit <4 clinical criteria often occur in infants <sup>26</sup> months of age or older children/adolescents. The frequency of coronary artery aneurysms (CAAs) is often higher in patients with missed diagnosis/delayed treatment. Therefore, in infants with prolonged fever and few or no clinical features, consider echocardiography and inflammatory labs.

## **HISTORY**

- Fever is the first sign during the acute phase.
- Symptoms may not occur all at once, but usually occur in close proximity.

## *PHYSICAL EXAM*

- High-spiking and remittent fever for <sup>35</sup> days
  - Fever is high (102-105<sub>i</sub>F [39.4-40.5<sub>i</sub>C]) and unresponsive to antibiotics.
  - May be prolonged up to 3 to 4 weeks
  - Extreme irritability is a very common feature.
- Bilateral, painless, nonpurulent, conjunctival injection without corneal ulceration or edema. Limbic sparing is usually seen.
- Changes in lips and oral cavity
  - Redness and swelling of lips in the acute stage; cracking, fissuring, bleeding in subacute phase

## Strawberry/erythematous tongue

- Extensive erythematous polymorphous rash: within 5 days of fever
  - Morbilliform is most common. May be maculopapular, scarlatiniform; can resemble erythema multiforme, erythroderma, urticarial exanthem; rarely micropustular
  - Perineal desquamation, especially in skin folds
- Extremity changes
  - Reddened palms and soles on days 3 to 5
  - Edema of hands and feet on days 4 to 7; painful induration
  - Desquamation of fingers and toes that begins in periungual area at 2 to 3 weeks
- Acute, unilateral cervical lymphadenopathy (least common symptom)
  - $\geq 1$  lymph nodes  $>1.5$  cm, firm, nonfluctuant, and usually with no to slight tenderness
- Cardiac exam: tachycardia, gallop rhythms, hyperdynamic precordium, innocent flow murmurs, depressed contractility
- Other organ system involvement
  - Cardiovascular: myocarditis; pericarditis (often subclinical), CAAs, and other medium-sized arterial aneurysms
  - Gastrointestinal: anorexia, abdominal pain, vomiting/diarrhea, acute gallbladder hydrops, hepatic enlargement, jaundice
  - Renal: proteinuria, sterile pyuria
  - Joints: polyarthritis of small joints in acute phase; weight-bearing joints affected after 10th day from onset of fever
  - Neurologic: irritability, aseptic meningitis, peripheral neuropathy (unilateral facial palsy), transient high-frequency hearing loss

## DIFFERENTIAL DIAGNOSIS

- Bacterial: staphylococcal scalded-skin syndrome, toxic shock syndrome, scarlet fever, bacterial cervical lymphadenitis, *Mycoplasma* infection, leptospirosis, Lyme disease, Rocky Mountain spotted fever
- Viral: measles, adenovirus, Epstein-Barr virus
- Toxoplasmosis
- Reiter syndrome

- Hypersensitivity drug reactions (erythema multiforme minor, Stevens-Johnson syndrome)
- Juvenile rheumatoid arthritis
- Acrodynia (mercury poisoning)

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Initial workup: CBC with differential, urinalysis (UA)/culture, blood culture; lumbar puncture if signs of meningitis or if <90 days old
  - Leukocytosis (12,000 to 40,000 cells/mm<sup>3</sup>) with immature and mature granulocytes
  - Anemia: normochromic, normocytic
  - Thrombocytosis (500,000 to >1,000,000/mm<sup>3</sup>) in second and third week.  
Thrombocytopenia during acute phase is associated with CAA and MI.
- Elevated C-reactive protein (CRP) (>35 mg/L in 80% cases), erythrocyte sedimentation rate (ESR) (>60 mm/hr in 60% cases), and  $\alpha_1$ -antitrypsin

### **ALERT**

ESR can be artificially high after intravenous immunoglobulin (IVIG) therapy.

- Hyponatremia
- Moderately elevated AST, ALT, GGT, and bilirubin
- Decreased albumin and protein
- CSF pleocytosis may be seen (lymphocytic with normal protein and glucose).
- *N*-terminal brain natriuretic peptide might be elevated in acute phase.
- Sterile pyuria but not seen in suprapubic collection
- Nasal swab to rule out adenovirus

### **Initial Tests (lab, imaging)**

- If KS is suspected, obtain ECG and echocardiogram.
  - ECG may show arrhythmias, prolonged PR interval, and ST/T wave changes.
  - Echocardiography has a high sensitivity and specificity for detection of abnormalities of proximal left main coronary artery, and right coronary artery may show perivascular brightening, ectasia, decreased left ventricular contractility, pericardial effusion, or aneurysms.

- Cardiac stress test if CAA seen on echocardiogram
  - Baseline chest x-ray (CXR): may show pleural effusion, atelectasis, and congestive heart failure (CHF)
- 

- Hydrops of the gallbladder may be associated with abdominal pain or may be asymptomatic.

## *Diagnostic Procedures/Other*

- No laboratory study is diagnostic; diagnosis rests on constellation of clinical features and exclusion of other illnesses.
- Magnetic resonance coronary angiography is noninvasive modality to visualize coronary arteries for stenosis, thrombi, and intimal thickening (1).
- Patients with complex coronary artery lesions may benefit from coronary angiography after the acute inflammatory process has resolved; generally recommended in 6 to 12 months

## **TREATMENT**

### *GENERAL MEASURES*

Use antibiotics until bacterial etiologies are excluded (e.g., sepsis or meningitis).

### *MEDICATION*

- Optimal therapy is IVIG 2 g/kg IV over 10 to 12 hours with high-dose aspirin preferably within 7 to 10 days of fever, followed by low-dose aspirin until follow-up echocardiograms indicate a lack of coronary abnormalities.
  - IVIG lowers the risk of CAA and may shorten fever duration.
  - The extreme irritability often resolves very quickly after IVIG is given.
- Retreatment with IVIG if clinical response is incomplete or fever persists/returns >36 hours after start of IVIG treatment.
  - <sup>3</sup>10% of patients do not respond to initial IVIG treatment. 2/3 of nonresponders respond to the second dose of IVIG.
  - Nonresponders tend to have ↑ bands, ↓ albumin, and an abnormal echo.
- Aspirin, 80 to 100 mg/kg/day in 4 doses beginning with IVIG administration. Switch to low-dose aspirin (3 to 5 mg/kg/day) when afebrile for 48 to 72 hours, or continue until day 14 of illness. Maintain low dose for 6 to 8 weeks until follow-up echocardiogram is normal and CRP

and/or ESR are normal. Continue salicylate regimen in children with coronary abnormalities long term or until documented regression of aneurysm (2)[C].

- Aspirin does not appear to reduce CAA (3)[B].
- Contraindications
  - IVIG: documented hypersensitivity, IgA deficiency, anti-IgE/IgG antibodies, severe thrombocytopenia, coagulation disorders
  - Aspirin: vitamin K deficiency, bleeding disorders, liver damage, documented hypersensitivity, hypoprothrombinemia
- Precautions
  - No statistically significant difference is noted between different preparations of IVIG.
  - High-dose aspirin therapy can result in tinnitus, decrease of renal function, and increased transaminases.
  - Do not use ibuprofen in children with CAAs who are taking aspirin for antiplatelet effects.
  - Significant possible interactions: Aspirin therapy has been associated with Reye syndrome in children who develop viral infections, especially influenza B and varicella. Yearly influenza vaccination thus is recommended for children requiring long-term treatment with aspirin. Delay any live vaccines for 11 months after IVIG treatment.

## *Second Line*

- Corticosteroids should be used only if <sup>3</sup>2 IVIG treatments have failed. The addition of corticosteroids to IVIG and aspirin during initial treatment might improve CAA outcomes but lacks consistent evidence (4)[C].
- In patients refractory to IVIG and steroids, consider infliximab or cyclosporine (5)[B].
- Plasma exchange may decrease likelihood of CAA in IVIG nonresponders (6)[B].

## *ISSUES FOR REFERRAL*

Pediatric cardiologist if abnormalities on echo or if extensive stenosis

## *ADDITIONAL THERAPIES*

- Treatment and prevention of thrombosis are crucial.
- Antiplatelet agents (clopidogrel, dipyridamole), heparin, low-molecular-weight heparin, or warfarin are sometimes added to the low-dose aspirin regimen, depending on severity of coronary involvement.

## *SURGERY/OTHER PROCEDURES*

- Rarely needed; coronary artery bypass grafting for severe obstruction/recurrent MI. Younger patients have a higher mortality rate.
- Coronary revascularization via percutaneous coronary intervention for patients with evidence of ischemia on stress testing

## *INPATIENT CONSIDERATIONS*

### *IV Fluids*

Normal saline (NS) for rehydration and 1/2 NS for maintenance

### *Discharge Criteria*

Discharge if afebrile after IVIG treatment for 24 hours.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

With aneurysms, contact and high-risk sports should be avoided.

### *Patient Monitoring*

- Repeat ECG and echocardiogram at 6 to 8 weeks. If abnormal, repeat at 6 to 12 months.
- Patients with complex coronary artery lesions may benefit from coronary angiography at 6 to 12 months.

## *PROGNOSIS*

- Usually self-limited
- Moderate-sized aneurysms usually regress in 1 to 2 years, resolving in 50-66% of cases.
- Recurrence (3% in Japan, <1% in the United States)
- Sudden death in early adulthood (rare)

## **COMPLICATIONS**

- 15-25% of untreated patients develop CAAs in convalescent phase.
- 2-7% of treated patients develop aneurysms. 1% develop giant aneurysms.
- Risk factors for aneurysm

- Male, <1 year of age, ↑ ESR >4 weeks, fever >2 weeks, fever >48 hours after IVIG treatment
- Mortality of 0.08-0.17% is due to cardiac disease.

## Codes

&NA;

### ICD10

M30.3 Mucocutaneous lymph node syndrome [Kawasaki]

## Clinical Pearls

&NA;

- The diagnosis of KS rests on a constellation of clinical features.
- Once KS is suspected, all patients need an inpatient cardiac evaluation, including ECG and echocardiogram.
- Expert recommendations for optimal therapy is IVIG 2 g/kg IV over 10 hours, with high-dose aspirin 80 to 100 mg/kg/day in 4 doses.

# Keratoacanthoma

Carl Bryce, MD, Capt, USAF

Matthew J. Snyder, DO

## BASICS

### DESCRIPTION

- Rapidly proliferating, solitary, dome-shaped, erythematous or flesh-colored papule or nodule with a central keratinous plug, typically reaching 1 to 2 cm in diameter
- Highly debated as to whether keratoacanthoma (KA) is a benign or malignant variant of squamous cell carcinoma (SCC). Majority are benign and resolve spontaneously, but lesions do have the potential for invasion and metastasis; therefore require treatment.
- Three clinical stages of KAs (1):
  - Proliferative: rapid growth of the lesion over weeks to several months
  - Maturation/stabilization: Lesion stabilizes and growth subsides.
  - Involution: spontaneous resolution of the lesion, leaving a hypopigmented, depressed scar; most but not all lesions will enter this stage.
- System(s) affected: integumentary

### EPIDEMIOLOGY

- Greatest incidence over the age of 50 years but may occur at any age
- Presentation increased during summer and early fall seasons
- Most frequently on sun-exposed, hair-bearing skin but may occur anywhere
- Predominant sex: male > female (2:1)
- Most commonly in fair-skinned individuals; highest rates in Fitzpatrick I-III
- 104 cases per 100,000 individuals

### ETIOLOGY AND PATHOPHYSIOLOGY

- Derived from an abnormality causing hyperkeratosis within the follicular infundibulum

- Squamous epithelial cells proliferate to extend upward around the keratin plug and proceed downward into the dermis; followed by invasion of elastic and collagen fibers
- Cellular mechanism responsible for the hyperkeratosis is currently unknown; role of human papillomavirus has been discussed but has no established causality (2).
- Regression may be due to immune cytotoxicity or terminal differentiation of keratinocytes.
- Multiple etiologies have been suggested:
  - UV radiation
  - May be provoked by surgery, cryotherapy, chemical peels or laser therapy
  - Viral infections: human papillomavirus (HPV) or Merkel cell polyomavirus
  - Genetic predisposition: Muir-Torre syndrome, xeroderma pigmentosum, Ferguson-Smith syndrome
  - Immunosuppression
  - Chemical carcinogen exposure

## *Genetics*

- Mutation of *p53* or *H-ras*
- Ferguson-Smith (AD)
- Witten-Zak (AD)
- Muir-Torre (AD)
- Xeroderma pigmentosum (AR)
- Gzybowski (sporadic)
- Incontinentia pigmenti (XLD)

## *RISK FACTORS*

- UV exposure/damage: outdoor and/or indoor tanning
- Fitzpatrick skin type I-III
- Trauma (typically appears within 1 month of injury): laser resurfacing, surgery, cryotherapy, tattoos
- Chemical carcinogens: tar, pitch, and smoking
- Immunocompromised state
- Discoid lupus erythematosus

## GENERAL PREVENTION

Sun protection

## COMMONLY ASSOCIATED CONDITIONS

- Frequently, the patient has concurrent sun-damaged skin: solar elastosis, solar lentigines, actinic keratosis, nonmelanoma skin cancers (basal cell carcinoma, SCC)
- In Muir-Torre syndrome, KAs are found with coexisting sebaceous neoplasms and malignancy of the GI and GU tracts.

## DIAGNOSIS

### HISTORY

- Lesion begins as a small, solitary, pink macule that undergoes a rapid growth phase; classically reaching a diameter of 1 to 2 cm; size may vary.
- Once the proliferative stage has subsided, lesion size remains stable.
- May decrease in size, indicating regression
- Asymptomatic, occasionally tender
- If multiple lesions present, important to elicit a family history and recent therapies or treatments.
- If sebaceous neoplasms present, must review history for signs/symptoms of GI or GU malignancies

## PHYSICAL EXAM

- Firm, solitary, erythematous or flesh-colored, domeshaped papule or nodule with a central keratin plug, giving a crateriform appearance
- Surrounding skin and borders of lesion may show telangiectasia, atrophy, or dyspigmentation.
- Solitary; although multiple lesions can occur.
- Most commonly seen on sun-exposed areas: face, neck, scalp, dorsum of upper extremities, and posterior legs
- May also be seen on areas without sun exposure: buttocks, anus, subungual, mucosal surfaces
- Subungual KAs are very painful and seen on the first 3 digits of the hands.
- Examine for regional lymphadenopathy due to chance of lesion invasion and metastasis.

## Dermoscopy (3)[B]

- Central keratin
- White circles, blood spots
- Cannot reliably distinguish between AK and SCC

## *DIFFERENTIAL DIAGNOSIS*

- SCC
- Nodular or ulcerative basal cell carcinoma
- Cutaneous horn
- Hypertrophic actinic keratosis
- Amelanotic melanoma
- Merkel cell carcinoma
- Metastasis to the skin
- Molluscum contagiosum
- Prurigo nodularis
- Verruca vulgaris
- Verrucous carcinoma
- Sebaceous adenoma
- Hypertrophic lichen planus
- Hypertrophic lupus erythematosus
- Deep fungal infection
- Atypical mycobacterial infection
- Nodular Kaposi sarcoma

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Excisional biopsy including the center of the lesion as well as the margin is the best diagnostic test (2)[C].
- A shave biopsy may be insufficiently deep to distinguish KA from an SCC.
- If unable to perform an excisional biopsy, a deep shave (saucerization) of the entire lesion, extending into the subcutaneous fat, can be done.

- Punch biopsies should be avoided because they give an insufficient amount of tissue to represent the entire lesion.

### *Initial Tests (lab, imaging)*

- Subungual KA: radiograph of the digit to monitor for osteolysis (cup-shaped radiolucent defect)
- Aggressive tumors may need CT with contrast for evaluation of lymph nodes and MRI if there is concern of perineural invasion.
- Most lesions do not need any form of imaging.

### *Test Interpretation*

- Pathology of biopsy: a well-demarcated central core of keratin surrounded by well-differentiated, mildly pleomorphic, atypical squamous epithelial cells with a characteristic glassy eosinophilic cytoplasm
- May see elastic and collagen fibers invading into the squamous epithelium

P.577

- Histologic differentiation of a KA from an SCC may be difficult and unreliable, although immunochemical staining for cellular protein Ki-67 may help do this (4).
- KAs have a greater tendency than SCC to display fibrosis and intraepidermal abscesses of neutrophils and eosinophils.
- Regressing KA shows flattening and fibrosis at base of lesion.

## **TREATMENT**

- Treatment of choice is an excisional procedure plus electrodesiccation and curettage; however, there are many treatment options available (2)[C].
- Aggressive tumors (>2 cm) or lesions in cosmetically sensitive areas (face, digits, genitalia) that require tissue sparing, consider Mohs micrographic surgery
  - Mohs is the treatment of choice in cases with perineural or perivascular invasion.
- Small lesions (<2 cm) of the extremities may undergo electrodesiccation and curettage.
- Immunocompromised patients should receive immediate surgical treatment.

## **MEDICATION**

- Nonsurgical management is a viable and relatively cost-effective option in these select cases

not amenable to surgery due to lesion number, size, or location; also for patients with multiple comorbidities who are unwilling or unable to withstand surgery

- Evidence for the following treatments based on case reports and retrospective reviews:
  - Intralesional methotrexate 12.5 to 25 mg in 0.5 mL normal saline every 2 to 3 weeks for one to four treatment sessions (5)[B]
    - Monitor for pancytopenia with complete blood count (5)[C].
  - 5% Imiquimod cream 3 times per week for 11 to 13 weeks (5)[B]
  - Topical 5% 5-fluorouracil cream daily, 61-92% cure rate (5)[B]
  - Intralesional 5-fluorouracil of 50 mg/mL on a weekly basis for three to eight treatment sessions 98% cure rate (5)[B]
  - Intralesional IFN a-2a or a-2b (83%, 100% cure rate, respectively) (5)[B]
  - Intralesional bleomycin 100% cure rate (5)[B]
  - Isotretinoin oral 0.5 to 1 mg/kg/day

## *ISSUES FOR REFERRAL*

Dermatology referral if lesions are >2 cm, numerous, mucosal, or subungual

## *ADDITIONAL THERAPIES*

- Photodynamic therapy with methyl aminolevulinic acid and red light, successful case reports (6)[B] but also reported aggravation following treatment
- Cryotherapy
- Argon or YAG lasers
- Radiotherapy, primary or adjuvant: KAs may regress with low doses of radiation but may require doses up to 25 to 50 Gy in low-dose (5 to 10 Gy) fractions for possible SCC (7)[B].
- Erlotinib (EGFR inhibitor) 150 mg daily for 21 days, single case report (8)[B]

## *SURGERY/OTHER PROCEDURES*

Excisional and office-based procedures as discussed above.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

After the surgical site has healed or lesion has resolved, patient should be seen every 6 months due to increased risk of developing new lesions or skin cancers, annually at minimum (3)[C].

## *Patient Monitoring*

- Skin self-exams should be routinely performed with detailed instructions (see *Additional Reading*).
- If multiple KAs are present in patient or family members, evaluate for Muir-Torre syndrome and obtain a colonoscopy beginning at age 25 years, as well as testing for genitourinary cancer (3)[C].

## **PATIENT EDUCATION**

- Sun protection measures: sun block with SPF >30, wide-brimmed hats, long sleeves, dark clothing, avoiding indoor tanning
- Arc welding may produce harmful UV radiation and skin should not be exposed.
- Tar, pitch, and smoking should be avoided.

## **PROGNOSIS**

- Atrophic scarring and hypopigmentation can occur with self-resolution but may be significantly reduced by intervention.
- 52 of 445 cases (12%) spontaneously regressed without treatment and none of these recurred (2).
- 393 (88%) regressed following medical or excisional treatment (2).
- 445 cases reported with no metastases or deaths attributable to the KA (2).
- 4-8% recurrence
- Mucosal and subungual lesions do not regress, must undergo treatment

## Codes

&NA;

**ICD10**

- D23.9 Other benign neoplasm of skin, unspecified
- D48.5 Neoplasm of uncertain behavior of skin
- L85.8 Other specified epidermal thickening

## Clinical Pearls

### **&NA;**

- Suspect KA with a solitary, dome-shaped, erythematous or flesh-colored papule or nodule with a central keratinous plug.
- If KA is in the differential diagnosis, elicit time frame of onset during patient encounter; rapid onset supports diagnosis.
- Due to the broad differential diagnosis of a suspected KA and unreliable clinical differentiation between these, strongly consider surgical excision as first-line diagnostic test and therapy.
- Medical and radiation therapies are reasonable and effective options available for patients who are not surgical candidates or for lesions that are not amenable for surgery.

# Keratosis, Actinic

Zoltan Trizna, MD, PhD

## BASICS

### DESCRIPTION

- Common, usually multiple, premalignant lesions of sun-exposed areas of the skin. Many resolve spontaneously, and a small proportion progress to squamous cell carcinoma
- Common consequence of excessive cumulative ultraviolet (UV) light exposure
- Synonym(s): solar keratosis

### Geriatric Considerations

Frequent problem

### Pediatric Considerations

Rare (if child, look for freckling and other stigmata of xeroderma pigmentosum)

### EPIDEMIOLOGY

#### Incidence

- Rates vary with age group and exposure to sun.
- Predominant age:  $\approx$ 40 years; progressively increases with age
- Predominant sex: male > female
- Common in those with blonde and red hair; rare in darker skin types

#### Prevalence

- Age-adjusted prevalence rate for actinic keratoses (AKs) in U.S. Caucasians is 6.5%.
- For 65- to 74-year-old males with high sun exposure:  $\div$ 55%; low sun exposure,  $\div$ 18%

### ETIOLOGY AND PATHOPHYSIOLOGY

- The epidermal lesions are characterized by atypical keratinocytes at the basal layer with

occasional extension upward. Mitoses are present. The histopathologic features resemble those of squamous cell carcinoma (SCC) in situ or SCC, and the distinction depends on the extent of epidermal involvement.

- Cumulative UV exposure

## *Genetics*

The *p53* chromosomal mutation has been shown consistently in both AKs and SCCs. Many new genes have been shown recently to have similar expression profiles in AKs and SCCs.

## **RISK FACTORS**

- Exposure to UV light (especially long-term and/or repeated exposure due to outdoor occupation or recreational activities, indoor or outdoor tanning)
- Skin type: burns easily, does not tan
- Immunosuppression, especially organ transplantation

## **GENERAL PREVENTION**

Sun avoidance and protective techniques are helpful.

## **COMMONLY ASSOCIATED CONDITIONS**

- SCC
- Other features of chronic solar damage: lentigines, elastosis, and telangiectasias

## **DIAGNOSIS**

### **HISTORY**

- The lesions are frequently asymptomatic; symptoms may include pruritus, burning, and mild hyperesthesia.
- Lesions may enlarge, thicken, or become more scaly. They also may regress or remain unchanged.
- Most lesions occur on the sun-exposed areas (head and neck, hands, forearms).

### **PHYSICAL EXAM**

- Usually small (<1 cm), often multiple red, pink, or brown macules, papules, or plaques that are rough to palpation

- Yellow or brown adherent scale is often present on top of the lesion.
- Several clinical variants exist.
  - Atrophic: dry, scaly macules with indistinct borders and an erythematous base
  - Hypertrophic: Overlying hyperkeratosis (in an extreme form, cutaneous horn) may be impossible to differentiate from SCC clinically.
  - Pigmented: smooth tan/brown plaque, spreading centrifugally
  - Bowenoid: red scaly plaques with distinct borders
  - Actinic cheilitis: inflammatory lesion involving usually the lower lip

## *DIFFERENTIAL DIAGNOSIS*

- SCC (hypertrophic type)
- Keratoacanthoma
- Bowen disease
- Basal cell carcinoma
- Verruca vulgaris
- Less likely: verrucous nevi, warty dyskeratoma, lichenoid keratoses, seborrheic keratoses, porokeratoses, seborrheic dermatitis or psoriasis (near hairline), lentigo maligna, solar lentigo, discoid lupus erythematosus

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Diagnostic Procedures/Other*

- The diagnosis is usually made clinically, except where there is a suspicion of carcinoma.
- Skin biopsy is especially recommended if large, ulcerated, indurated, or bleeding; or if the lesions are nonresponsive to treatment.

### *Test Interpretation*

- Dysplastic keratinocytes in lower levels of epidermis with a dermal lymphocytic infiltrate
- Neoplastic cells, mostly found in the lower epidermal layers, are cytologically identical to those of SCCs.
- If neoplastic cells extend throughout entire epidermis or into the dermis, the lesions will qualify as an SCC in situ or invasive SCC, respectively.

- Malignant cells are sparse except of the bowenoid variety.
- Hypertrophic, atrophic, bowenoid, acantholytic, and pigmented varieties show the corresponding epidermal findings.

## TREATMENT

First-line treatment is cryotherapy (technically, this is considered surgery, especially by insurance companies) (1,2)[A]. Medical therapy is usually reserved for extensive AKs (Òfield therapyÓ).

## GENERAL MEASURES

- Sun-protective techniques
- Sunscreens and physical sun protection recommended.

## MEDICATION

### *First Line*

- Topical treatments target both visible and subclinical lesions.
- With the exception of generic 5-fluorouracil, medication cost is high (\$600 to \$1,200 per course).
- Topical fluorouracil (Efudex, Carac, Fluoroplex cream, Fluoroplex solution)
  - Every dayÑBID for 3 to 6 weeks, depending on the brand, concentration, and formulation
  - Can be very irritating
  - May be most effective of the topical treatments (3)[A] listed in this section.

P.579

- Topical imiquimod (Aldara) 5% cream
  - Apply 2 days per week at HS for up to 16 weeks to an area not larger than the forehead or one cheek.
  - Can be irritating
- Topical imiquimod (Zyclara) 3.75% cream
  - Apply once a day for 2 weeks, followed by no treatment for the next 2 weeks; then apply once a day for another 2 weeks.
  - Can be irritating

- Topical ingenol mebutate (Picato) 0.015% and 0.05% gel
  - Apply to the face and scalp once a day for 3 consecutive days.
  - Apply to the trunk and extremities once a day for 2 consecutive days.
    - It should only be used on one contiguous skin area of not more than 25 cm<sup>2</sup>.
    - Cases of severe allergic reactions (including anaphylaxis) and herpes zoster reactivation unrelated to application errors have been reported.
- Diclofenac (Solaraze) 3% gel
  - Apply BID for 60 to 90 days.

## *Second Line*

- Topical tretinoin (Retin-A) or tazarotene (Tazorac): may be used to enhance the efficacy of topical fluorouracil
- Systemic retinoids: used infrequently

## **ADDITIONAL THERAPIES**

Close monitoring with no treatment is an appropriate option for mild lesions.

## **SURGERY/OTHER PROCEDURES**

- Cryosurgery (freezing, liquid nitrogen)
  - Most common method for treating AK
  - Cure rate: 75-98.8%
  - May leave scars
  - May be superior to photodynamic therapy for thicker lesions
- Photodynamic therapy with a photosensitizer (e.g., aminolevulinic acid) and blue light
  - May clear >90% of AKs
  - Less scarring than cryotherapy
  - May be superior to cryotherapy, especially in the case of more extensive skin involvement
- Curettage and electrocautery (electrodesiccation and curettage [ED&C]; scraping and burning)
- Medium-depth peels, especially for the treatment of extensive areas

- CO<sub>2</sub> laser therapy
- Dermabrasion
- Surgical excision (excisional biopsy)

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Depends on associated malignancy and frequency with which new AKs appear

### *PATIENT EDUCATION*

- Teach sun-protective techniques.
  - Limit outdoor activities between 10 AM and 4 PM.
  - Wear protective clothing and wide-brimmed hat.
  - Proper use (including reapplication) of sunscreens with SPF >30, preferably a preparation with broad-spectrum (UV-A and UV-B) protection
- Teach self-examination of skin (melanoma, squamous cell, basal cell).
- Patient education materials
  - <http://dermnetnz.org/lesions/solar-keratoses.html>
  - [www.skincarephysicians.com/actinickeratosesnet/index.html](http://www.skincarephysicians.com/actinickeratosesnet/index.html)
  - [www.skincancer.org/Actinic-Keratosis-and-Other-Precancers.htm](http://www.skincancer.org/Actinic-Keratosis-and-Other-Precancers.htm)

### *PROGNOSIS*

Very good. A significant proportion of the lesions may resolve spontaneously (4), with regression rates of 20-30% per lesion per year.

### **COMPLICATIONS**

- AKs are premalignant lesions that may progress to SCCs. The rate of malignant transformation is unclear; the reported percentages vary (4) but range from 0.1% to a few percent per year per lesion.
- Patients with AKs are at increased risk for other cutaneous malignancies.
- Approximately 60% of SCCs arise from an AK precursor.

## Codes

&NA;

## ICD10

L57.0 Actinic keratosis

## Clinical Pearls

&NA;

- AKs are premalignant lesions.

- Often more easily felt than seen
- Therapy-resistant lesions should be biopsied, especially on the face.

# Keratosis, Seborrheic

Jelaun Newsome, DO

## BASICS

### DESCRIPTION

- One of the most common benign tumors of the epidermis
- Formed from keratinocytes
- Frequently appears in multiples on the head, neck, and trunk of older individuals but may occur on any hair-bearing area of the body. Lesions spare the palms and soles.
- Typically are light brown to black, sharply demarcated, round, or elongated lesions with a velvety, verrucous-like, "stuck-on" appearance; lesions may also appear waxy yellow or pink.
- Clinical variants include the following:
  - Common seborrheic keratosis
  - Dermatitis papulosa nigra
  - Stucco keratosis
  - Flat seborrheic keratosis
  - Pedunculated seborrheic keratosis
- System(s) affected: integumentary
- Synonym(s): verruca seborrhoica; seborrheic wart; senile wart; basal cell papilloma; verruca senilis; basal cell acanthoma; benign acanthokeratoma

### EPIDEMIOLOGY

#### Incidence

- Predominant age
  - Usually appear after the 3rd decade
  - Most commonly seen during middle and older age
  - Can occasionally arise as early as adolescence

- Predominant sex: male = female
- Most common among Caucasians, except for the dermatosis papulosa nigra variant, which usually presents in darker skinned individuals

## *Prevalence*

- 69-100% in patients >50 years of age
- The prevalence rate increases with advancing age.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Seborrheic keratoses are monoclonal tumors.
- Etiology still is largely unclear.
- Ultraviolet (UV) light and genetics are thought to be involved.
- The role of human papillomavirus is uncertain.

## *Genetics*

An autosomal dominant inheritance pattern is suggested.

## *RISK FACTORS*

- Advanced age
- Exposure to UV light and genetic predisposition are possible factors (1).

## *GENERAL PREVENTION*

Sun protection methods may help prevent seborrheic keratoses from developing.

## *COMMONLY ASSOCIATED CONDITIONS*

- Sign of Leser-Trélat: A paraneoplastic syndrome characterized by a sudden eruption of multiple seborrheic keratoses in association with an internal malignancy, most commonly stomach or colon adenocarcinoma. Usually represents a poor prognosis. The validity of this syndrome as a marker for internal malignancy is controversial (2)[B].
- Documentation of other cutaneous lesions, such as basal cell carcinoma, malignant melanoma, Bowen disease, or squamous cell carcinoma, growing adjacent to or within a seborrheic keratosis, has been reported. The exact relationship between lesions is unclear.

## DIAGNOSIS

### HISTORY

- Usually asymptomatic
- Trauma or irritation of the lesion may result in pruritus, erythema, bleeding, pain, and/or crusting.

### PHYSICAL EXAM

- Typically begin as oval- or round-shaped, flat, dull, sharply demarcated patches
- As they mature, may develop into thicker, elevated, uneven, verrucous-like papules, plaques, or peduncles with a waxy or velvety surface, and appear "stuck on" to the skin (3)
- Commonly appear on sun-exposed areas of the body, predominately the head, neck, or trunk but may appear on any hair-bearing skin
- Vary in color from black, brown, tan, gray to white, or skin-colored, and range in size, from 1 mm to 4 cm
- Usually occur as multiples, with patients having >100 is not uncommon.
- May grow along folds on truncal skin, forming a "Christmas tree" pattern
- If irritated, may be bleeding, inflamed, painful, pruritic, or crusted
- Common clinical variants include the following (4):
  - Common seborrheic keratoses: on hair-bearing skin, usually on the face, neck, and trunk; verrucous-like, waxy, or velvety lesions that appear "stuck on" to the skin
  - Dermatitis papulosa nigra: Small black papules that usually appear on the face, neck, chest, and upper back; most common in darker skinned individuals, more common in females; most have a positive family history.
  - Stucco keratoses: small gray-white, rough, verrucous papules; usually occur in large numbers on the lower extremities or forearms; more common in men
  - Flat seborrheic keratoses: oval-shaped, brown patches or macules on face, chest, and upper extremities; increases with age
  - Pedunculated seborrheic keratoses: Hyperpigmented peduncles appear on areas of friction (neck, axilla).

### DIFFERENTIAL DIAGNOSIS

Consider the following diagnoses if the seborrheic keratosis is:

- Pigmented
  - Malignant melanoma
  - Melanocytic nevus
  - Angiokeratoma
  - Pigmented basal cell carcinoma
- Lightly pigmented
  - Basal cell carcinoma
  - Bowen disease
  - Condyloma acuminatum
  - Fibroma
  - Verruca vulgaris
  - Eccrine poroma
  - Invasive squamous cell carcinoma
  - Acrochordon
  - Acrokeratosis verruciformis of Hopf
  - Follicular infundibulum tumor
- Flat
  - Solar lentigo
  - Verrucae planae juveniles
- Hyperkeratotic
  - Actinic keratosis

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

Not needed unless internal malignancy is suspected

### ***Diagnostic Procedures/Other***

- The diagnosis can usually be made based on clinical appearance.

- Dermoscopy
  - Can aid in diagnosis
  - Common findings are comedo-like openings, fissures, ridges, sharply demarcated borders, milia-like cysts, pseudofollicular openings, hairpin vessels, and horn pseudocysts (5,6).
- Biopsy and histologic exam should be performed if the seborrheic keratosis
  - Is atypical
  - Has inflammation
  - Recently changed in appearance
  - Diagnosis remains unclear.

### *Test Interpretation*

- Histologic findings include the following:
  - Acanthosis and papillomatosis due to basaloid cell proliferation
  - Squamous eddies or squamous epithelial cell clusters
  - Hyperpigmentation
  - Hyperkeratosis
  - Horn cysts
  - Pseudocysts
- Several histologic variants exist.

---

P.581

## **TREATMENT**

- Treatment is not usually necessary due to the benign nature of the lesions.
- Removal of seborrheic keratoses may be indicated if
  - Symptomatic
  - Aesthetically displeasing or undesirable (common)
  - There is a question of malignancy.

## **MEDICATION**

Current topical treatments of seborrheic keratoses are less effective than a surgical approach.

## *ISSUES FOR REFERRAL*

- New seborrheic keratoses appear abruptly.
- A seborrheic keratosis becomes inflamed or changes in appearance.

## *SURGERY/OTHER PROCEDURES*

- A surgical approach to treatment is preferred.
- Choice depends on physician preference and availability of the treatment.
- The following procedures are used:
  - Cryotherapy (liquid nitrogen)
    - Spray flat lesions for 5 to 10 seconds; may require more time or additional treatments if the seborrheic keratosis is thicker
    - Possible complications include scarring, hypopigmentation, recurrence.
  - Curettage
  - Electrodesiccation
  - Shave excision
  - Excisional biopsy
  - Chemical peel
- Use of following laser treatments have been reported:
  - Ablative CO<sub>2</sub>
  - Ablative erbium-YAG
  - Argon
  - 492 nm
  - 510 nm
  - Alexandrite lasers
- No statistically significant differences were found in patient's ratings of cosmetic appearance between cryotherapy and curettage. The majority of patients preferred cryotherapy over curettage due to decreased postoperative wound care, despite the increased discomfort experienced and increased frequency of seborrheic keratosis remaining after cryotherapy when

compared to curettage (7)[B].

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

After initial diagnosis, follow-up is not usually required unless

- Inflammation or irritation develops.
- There is a change in appearance.
- New seborrheic keratoses suddenly appear.

### *PATIENT EDUCATION*

- Sun-protective methods may help reduce seborrheic keratosis development.
- Patient education materials
  - <http://www.aad.org/dermatology-a-to-z/diseases-and-treatments/q-t/seborrheic-keratoses>
  - [www.cdc.gov/cancer/skin/basic\\_info/prevention.htm](http://www.cdc.gov/cancer/skin/basic_info/prevention.htm)

### *PROGNOSIS*

- Seborrheic keratoses generally do not become malignant.
- Sign of Leser-Trřlat usually represents a poor prognosis.

### **COMPLICATIONS**

- Irritation and inflammation due to mechanical irritation (i.e., from clothing, jewelry)
- Possible complications of surgical treatment include hypopigmentation, hyperpigmentation, scarring, incomplete removal, and recurrence.
- Misdiagnosis (rare)

## Codes

**&NA;**

### ICD10

- L82.1 Other seborrheic keratosis
- L82.0 Inflamed seborrheic keratosis

## Clinical Pearls

**&NA;**

- Seborrheic keratoses are one of the most common benign tumors of the epidermis.
- Prevalence increases with age.
- Underlying internal malignancy should be considered if large numbers of seborrheic keratoses appear suddenly.

# Knee Pain

Jeff Wang, MD, MPH

J. Herbert Stevenson, MD

## BASICS

### *DESCRIPTION*

Knee pain is a common outpatient complaint with a broad differential diagnosis.

- Knee pain may be acute, chronic, or an acute exacerbation of a chronic condition.
- Trauma, overuse, and degenerative change are frequent causes.
- A detailed history, including patient age, pain onset and location, mechanism of injury, and associated symptoms can help narrow the differential diagnosis.
- A thorough and focused examination of the knee (as well as the back, hips, and ankles) helps to establish the correct diagnosis and appropriate treatment.

### *EPIDEMIOLOGY*

#### *Incidence*

- Knee pain accounts for 1.9 million primary care visits annually.
- The incidence of knee osteoarthritis is 240 cases/100,000 person/year.

#### *Prevalence*

- The knee is a common site of lower extremity injury.
  - Patellar tendonopathy and patellofemoral syndrome are the most common causes of knee pain in runners (1).
- Osteoarthritis (OA) is one of the leading causes of disability in the United States.

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Trauma (ligament or meniscal injury, fracture, dislocation)
- Overuse (tendinopathy, patellofemoral syndrome, bursitis, apophysitis)

- Age-related (arthritis, degenerative conditions, apophysitis [young])
- Rheumatologic (rheumatoid arthritis [RA], gout, pseudogout)
- Infectious (bacterial, postviral, Lyme disease)
- Referred pain (hip, back)
- Vascular: popliteal artery aneurysm, deep vein thrombosis
- Others: tumor, cyst, plica

## ***RISK FACTORS***

- Obesity
- Malalignment
- Poor flexibility, muscle imbalance, or weakness
- Rapid increases in training frequency and intensity
- Improper footwear, training surfaces, technique
- Activities that involve cutting, jumping, pivoting, deceleration, kneeling
- Previous injuries

## ***GENERAL PREVENTION***

- Maintain normal body mass index.
- Use appropriate exercise training principles; avoid overtraining.
- Correct postural strength and flexibility imbalances.
- Proper activity-specific techniques and equipment

## ***COMMONLY ASSOCIATED CONDITIONS***

- Fracture, contusion
- Effusion, hemarthrosis
- Patellar dislocation/subluxation
- Meniscal or ligamentous injury
- Tendinopathy, bursitis
- Osteochondral injury
- OA, septic arthritis

- Muscle strain

## DIAGNOSIS

### HISTORY

- Pain:
  - Diffuse pain: OA, patellofemoral pain syndrome (chondromalacia)
  - Pain ascending/descending stairs: meniscal injury, patellofemoral pain syndrome
  - Pain with prolonged sitting, standing from sitting: patellofemoral pain syndrome
  - Mechanical symptoms (locking): meniscal injury
- Mechanism of injury:
  - Hyperextension, deceleration, cutting: anterior cruciate ligament (ACL) injury
  - Hyperflexion, fall on flexed knee, "dashboard injury": posterior cruciate ligament (PCL) injury
  - Lateral force (valgus load): medial collateral injury
  - Twisting on planted foot: meniscal injury
- Effusion:
  - Rapid onset (2 hours): ACL tear, patellar subluxation, tibial plateau fracture. Hemarthrosis is common.
  - Slower onset (24 to 36 hours), smaller: meniscal injury, ligament sprain
  - Swelling behind the knee: popliteal cyst. Prepatellar: bursitis

### PHYSICAL EXAM

- Observe gait (antalgia), patellar tracking.
- Inspect for malalignment, atrophy, swelling, ecchymosis, or erythema.
- Palpate for effusion, warmth, and tenderness.
- Evaluate active and passive range of motion (ROM) and flexibility of quadriceps and hamstrings.
- Evaluate strength and muscle tone.
- Note joint instability, locking, and catching.

- Evaluate hip ROM, strength, and stability.
- Special tests:
  - Patellar apprehension test: patellar instability. Patellar grind test: patellofemoral pain or OA (1)
  - Lachman test (more sensitive and specific), pivot shift, anterior drawer: ACL integrity
  - Posterior drawer, posterior sag sign: PCL integrity
  - Valgus/varus stress test: medial/lateral collateral ligament (MCL/LCL) integrity
  - McMurray test, Apley grind, Thessaly test: meniscal injury
  - Ober test: Iliotibial band (ITB) tightness
  - Dial test: positive with posterolateral corner laxity
  - Patellar tilt test and squatting may help suggest patellofemoral pain syndrome, but there is not yet one definitive test.
  - Patella facet tenderness suggests OA or patellofemoral pain syndrome (1)[A].

## *DIFFERENTIAL DIAGNOSIS*

- Acute onset: fracture, contusion, cruciate or collateral ligament tear, meniscal tear, patellar dislocation/subluxation. If systemic symptoms: septic arthritis, gout, pseudogout, Lyme disease, and osteomyelitis
- Insidious onset: patellofemoral pain syndrome/chondromalacia, ITB syndrome, OA, RA, bursitis, tumor, tendinopathy, loose body, bipartite patella, degenerative meniscal tear
- Anterior pain: patellofemoral pain syndrome, patellar injury, patellar tendinopathy, pre- or suprapatellar bursitis, tibial apophysitis, fat pad impingement, quadriceps tendinopathy, OA (1)
- Posterior pain: PCL injury, posterior horn meniscal injury, popliteal cyst or aneurysm, hamstring or gastrocnemius injury, deep venous thrombosis (DVT)
- Medial pain: MCL injury, medial meniscal injury, pes anserine bursitis, medial plica syndrome, OA
- Lateral pain: LCL injury, lateral meniscal injury, ITB syndrome, OA

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Suspected septic joint, gout, pseudogout:

- Arthrocentesis with cell count, Gram stain, culture, protein/glucose, synovial fluid analysis
- Suspected RA:
  - CBC, erythrocyte sedimentation rate (ESR), rheumatoid factor
- Consider Lyme titer.
- Radiographs to rule out fracture in patients with acute knee trauma (Ottawa rules):
  - Age >55 years *or*
  - Tenderness at the patella or fibular head *or*
  - Inability to bear weight 4 steps *or*
  - Inability to flex knee to 90 degrees
- Radiographs help diagnose OA, osteochondral lesions, patellofemoral pain syndrome:
  - Weightbearing, upright anteroposterior, lateral, merchant/sunrise, notch/tunnel views

### *Follow-Up Tests & Special Considerations*

- MRI is a gold standard for soft tissue imaging.
- Ultrasound may help diagnose tendonopathy (2)[B].
- CT can further elucidate fracture.

### *Diagnostic Procedures/Other*

Arthroscopy may be beneficial in the diagnosis of certain conditions, including meniscus and ligament injuries.

### *Geriatric Considerations*

OA, degenerative meniscal tears, and gout are more common in middle-aged and elderly populations.

### *Pediatric Considerations*

- 3 million pediatric sports injuries occur annually.
- Look for physeal/apophyseal and joint surface injuries in skeletally immature:
  - Acute: patellar subluxation, avulsion fractures, ACL tear
  - Overuse: patellofemoral pain syndrome, apophysitis, osteochondritis dissecans, patellar tendonitis, stress fracture

- Others: neoplasm, juvenile RA, infection, referred pain from slipped capital femoral epiphysis

## TREATMENT

### GENERAL MEASURES

Acute injury: PRICEMM therapy (**p**rotection, **r**elative rest, **i**ce, **c**ompression, **e**levation, **m**edications, **m**odalities)

### MEDICATION

#### First Line

- Oral medications:
  - Acetaminophen: up to 3 g/day. Safe and effective in OA
  - Nonsteroidal anti-inflammatory drugs (NSAIDs):
    - Ibuprofen: 200 to 800 mg TID
    - Naproxen: 250 to 500 mg BID:
      - Useful for acute sprains, strains
      - Useful for short-term pain reduction in OA. Long-term use is not recommended due to side effects.
      - Not recommended for fracture, stress fracture, chronic muscle injury; may be associated with delayed healing; low dose and brief course only if necessary
  - Tramadol/opioids: not recommended as first-line treatment; can be used with acute injuries
  - Celecoxib: 200 mg QID may be effective in OA with less GI side effects than NSAIDs (3)[A].
- Topical medications:
  - Topical NSAIDs may provide pain relief in OA and are more tolerable than oral medications.
  - Topical capsaicin may be an adjuvant for pain management in OA.
- Injections:
  - Intra-articular corticosteroid injection may provide short-term benefit in knee OA (2)[A].
  - Viscosupplementation may reduce pain and improve function in patients with OA (2)[A],

particularly those wishing to delay joint replacement.

## ***ISSUES FOR REFERRAL***

- Acute trauma, young athletic patient
- Joint instability
- Lack of improvement with conservative measures
- Salter-Harris physeal fractures (pediatrics)

## ***ADDITIONAL THERAPIES***

- Physical therapy is recommended as initial treatment for patellofemoral pain (4) and tendonopathies (2)[A].
- Muscle strengthening improves outcome in OA.
- Foot orthoses, taping, acupuncture
- May need bracing for stability (4)
- Plate-rich plasma injection in early OA (5)[B]
- Botulinum toxin A for patellofemoral pain syndrome (6)[B]

## ***SURGERY/OTHER PROCEDURES***

- Surgery may be indicated for certain injuries (e.g., ACL tear in competitive athletes).
- Chronic conditions refractory to conservative therapy may require surgical intervention.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

May reduce pain and improve function in early OA:

- Glucosamine sulfate (500 mg TID) (7)
- Chondroitin (400 mg TID) (7)
- S-adenosylmethionine (SAME), ginger extract, methylsulfonylmethane: less reliable improvement with inconsistent supporting evidence (8)
- Acupuncture

**ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

- Activity modification in overuse conditions
- Rehabilitative exercise in OA:
  - Low-impact exercise: walking, swimming, cycling
  - Strength, ROM, and proprioception training

## *Patient Monitoring*

- Rehabilitation after initial treatment of acute injury.
- In chronic and overuse conditions, assess functional status, rehabilitation adherence, and pain control at follow-up visit.

## *DIET*

Weight reduction for overweight patient with OA

## *PATIENT EDUCATION*

- Review activity modifications.
- Encourage active role in the rehabilitation process.
- Review medication risks and benefits.

## *PROGNOSIS*

Varies with diagnosis, injury severity, chronicity of condition, patient motivation to participate in rehabilitation, and whether surgery is required

## **COMPLICATIONS**

- Disability
- Arthritis
- Chronic joint instability
- Deconditioning

**&NA;**

Algorithms: Knee Pain; Popliteal Mass

## Codes

**&NA;**

### ICD10

- M25.569 Pain in unspecified knee
- M17.9 Osteoarthritis of knee, unspecified
- M76.50 Patellar tendinitis, unspecified knee

## Clinical Pearls

**&NA;**

- Consider ligamentous injury, meniscal tear, and fracture for patients presenting with acute knee pain.
- Consider OA, patellofemoral pain, syndrome, tendinopathy, bursitis, and stress fracture in patients presenting with more chronic symptoms.
- Consider physeal, apophyseal, or articular cartilage injury in young patients presenting with knee pain.
- The presence of an effusion in a patient <30 years of age indicates a significant injury.
- Referred pain from the hip (slipped capital femoral epiphysis, Legg-CalvŽ-Perthes disease) can present as knee pain.

# Labyrinthitis

Mary S. Lindholm, MD

## BASICS

### DESCRIPTION

- The sudden and persistent onset of vertigo, often accompanied by hearing loss, caused by acute inflammation or infection of the labyrinth
- Labyrinthitis is a clinical diagnosis in absence of neurologic deficits.
- Typically presents with false sense of motion or room-spinning vertigo lasting for hours or days and often sudden unilateral hearing loss
- Often associated with vestibular hypofunction of the involved ear. Peripheral vertigo improves over time with central compensation.
- System(s) affected: nervous, special sensory (auditory and vestibular)
- Synonym(s): acute peripheral vestibulopathy; vestibular neuronitis (vertigo/dizziness only); vestibular neuritis (vertigo/dizziness only)

### ALERT

- “Vertigo” and “dizziness” are commonly used terms. Clarify symptoms by giving options of alternative descriptions such as light-headedness, disequilibrium, room-spinning vertigo, or imbalance.
- Hearing loss and duration of symptoms can help narrow the differential diagnosis in patients with vertigo.
- Benign paroxysmal positional vertigo (BPPV) is the most common cause of vertigo. Unlike labyrinthitis, BPPV is episodic, with severe symptoms lasting <1 minute. BPPV is diagnosed using the Dix-Hallpike maneuver. Unlike labyrinthitis, it is not associated with hearing loss.
- Ménière disease presents with the classic triad of episodic vertigo, tinnitus, and sensorineural hearing loss that is often fluctuant (1)[C].

### Geriatric Considerations

- Elderly are less likely to compensate fully and may report symptoms of disequilibrium lasting

weeks to months after resolution of the acute vertigo.

- Avoid excessive use of scopolamine, meclizine, and other vestibular suppressants following the initial event, as this will delay central compensation.
- Benzodiazepines are preferred vestibular suppressant treatment but do increase the risk of falls in older persons.

### *Pediatric Consideration*

Less common in children, incidence of vestibular vertigo in 10-year-olds estimated to be 5.7% (2) [C]

## **EPIDEMIOLOGY**

- 10% of all patients seen for dizziness
- Most common in 30 to 50 years of age (3)
- Predominant sex: female = male

### *Incidence*

- Viral labyrinthitis is the most common etiology.
- Suppurative or serous labyrinthitis secondary to otitis media is increasingly rare.

### *Prevalence*

In the United States, 2nd most common cause of dizziness due to persistent peripheral vestibular hypofunction (9%); benign positional vertigo (40%) is most common. More than 1/3 of adults see a health care provider for vertigo in their lifetimes (4).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Acute inflammation or damage to the inner ear, involving both branches of the vestibulocochlear nerve
- Viruses pass via hematogenous spread into the labyrinth or directly from the middle ear to labyrinth via the round/oval window.
- Bacterial toxins and host inflammatory mediators from a middle ear infection may reach the inner ear.
- Ischemia: ischemic or thromboembolic events involving the labyrinthine artery can cause symptoms that mimic acute labyrinthitis. Often presents with associated neurologic symptoms
- Autoimmune: Local or systemic inflammatory processes may affect the inner ear via

autoantibodies vasculitis of the labyrinthine artery.

- Wegener granulomatosis, Cogan syndrome, systemic lupus erythematosus, polyarteritis nodosa, Behçet disease
- Infections
  - Common viral: cytomegalovirus, mumps, varicella zoster, rubeola, influenza, parainfluenza, herpes simplex, adenovirus, coxsackievirus, respiratory syncytial virus, HIV
  - Common bacterial: *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis*, *Neisseria meningitidis*, *Streptococcus* spp., *Staphylococcus* spp., *Borrelia burgdorferi*
  - Treponemal: *Treponema pallidum*
- Ototoxic drugs (e.g., aspirin, aminoglycosides, loop diuretics, cisplatin)

## Genetics

No known genetic link

## RISK FACTORS

- Viral upper respiratory infection
- Otitis media
- Vestibulotoxic/ototoxic medications
- Head trauma
- History of allergies
- Meningitis
- Cerebrovascular disease
- Other risk factors include autoimmune disease, herpes zoster infection, excessive alcohol consumption, and smoking.

## GENERAL PREVENTION

- Scheduled immunizations (to prevent common viral pathogens)
- Prevent maternal transmission of pathogens, including syphilis and HIV.

## COMMONLY ASSOCIATED CONDITIONS

- Viral upper respiratory infection

- Allergies
- Otitis media
- Cholesteatoma
- Head injury

## DIAGNOSIS

### HISTORY

- Vertigo *AND* (often) hearing loss in one ear
- Vertigo is acute in onset and lasts days to weeks.
- Nausea and vomiting are common.
- Fullness of affected ear
- Tinnitus of affected ear (roaring, ringing)
- Upper respiratory tract infection symptoms
- Otorrhea or otalgia (not common with viral causes)
- Severe headache, fever, and nuchal rigidity in the setting of meningitis
- Recurrent symptoms should raise suspicion for autoimmune causes.
- Profound imbalance or associated focal neurologic signs are not typical and should prompt imaging.

### PHYSICAL EXAM

- Nystagmus
  - Fast-beating nystagmus toward affected ear (acutely)
  - Fast-beating nystagmus away from affected ear (chronically)
- Symptoms abate in supine position and with eyes closed or with visual fixation.
- Otologic exam may be unremarkable in the setting of viral labyrinthitis.
- Serous/purulent effusion may be present in the middle ear.
- Retraction of the tympanic membrane and keratinaceous debris may be present with cholesteatoma.

### DIFFERENTIAL DIAGNOSIS

- Vestibular neuritis/neuronitis (vertigo without hearing loss)

- BPPV: episodic, vertigo lasting seconds/minutes, worse when lying down or looking up
- Ménière disease: episodic vertigo lasting minutes to hours, associated with the triad of episodic vertigo, tinnitus, and hearing loss
- Vestibular migraine
- Autoimmune inner ear disease
- Postconcussive syndrome
- Acute otitis media
- Ototoxicity
- Cardiovascular accident (CVA)/brainstem infarct
- Cerebellopontine-angle tumors (e.g., vestibular schwannoma)
- Less common etiologies: parainfectious encephalomyelitis or cranial polyneuritis, Ramsay Hunt syndrome, HIV infection, syphilis, temporal lobe epilepsy, perilymphatic fistula, superior canal dehiscence, idiopathic sudden single-sided deafness, multiple sclerosis, vasculitis (cerebral or systemic)

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Routine lab studies are not helpful in making the diagnosis unless an autoimmune cause is highly suspected.
- Consider culture of otorrhea or middle ear fluid to direct antibiotic choice.
- Consider lumbar puncture only if meningitis is suspected.
- Consider screening for syphilis or HIV when clinically indicated by risk factors or clinical history.
- Imaging is not required for the diagnosis of acute labyrinthitis.
- If associated neurologic symptoms or sensorineural hearing loss are present, an MRI and MR angiography of brain and brainstem are recommended.
- Vertigo usually spontaneously resolves, and there is a low risk of developing Ménière disease or migraines.

---

P.585

## **Follow-Up Tests & Special Considerations**

Labyrinthitis ossificans is fibrosis of the internal auditory canal following bacterial meningitis and is thought to occur due to a suppurative labyrinthitis. This can occur rapidly, especially after *S. pneumoniae* meningitis.

## Diagnostic Procedures/Other

- Audiogram should be obtained.
- Vestibular tests are not typically indicated in the acute setting. If vertigo and dizziness persist after expected resolution of symptoms, electronystagmography should be used.

## Test Interpretation

- Audiogram may show varying degrees of both hearing loss and discrimination.
- Caloric testing may show relative weakness of the horizontal semicircular canal of the affected side. Sensitivity and specificity of this test are variable within literature.

## TREATMENT

- Symptom management and reassurance
- Vestibular rehabilitation is the mainstay of treatment and has been shown to be safe and effective management for unilateral peripheral vestibular dysfunction (5)[A].
- Patients should begin exercises as soon as the acute phase resolves and movement is tolerable, generally within 2 to 3 days of onset.
- Vestibular suppressants as needed (see Medication) for severe acute attacks of vertigo only. Patients should be advised *NOT* to use these medications as scheduled medications or for prophylaxis without symptoms.
- Sudden single-sided hearing loss (onset within 2 weeks) should be managed with high-dose oral steroids as soon as possible.
- Auricular acupuncture and Ginkgo biloba may be emerging adjunctive therapies to reduce vertiginous symptoms, although research is limited (6)[B],(7)[C].
- For suppurative labyrinthitis, appropriate antibiotics to eradicate infection

## GENERAL MEASURES

Vestibular exercises for prolonged symptoms and unilateral vestibular loss have been shown to alleviate postural control.

## MEDICATION

Use of the following drugs should be on a PRN basis. Benzodiazepines can also assist with the anxiety associated with vertigo. No patient should take vestibular suppressants as a chronic medication, as they can block central compensation.

- Vestibular suppressants
  - Lorazepam (Ativan): 0.5 to 2 mg sublingual (SL)/PO BID PRN or diazepam (Valium) 2 to 5 mg QID PO PRN
  - Meclizine (Antivert, Bonine, Zentrip [dissolvable]) 12.5 to 25 mg PO BID-TID PRN
  - Dimenhydrinate (Dramamine) 25 to 50 mg PO q4-6h PRN
- Antiemetics
  - Ondansetron (Zofran) 4 to 8 mg PO TID PRN or granisetron (Kytril) 1 mg PO TID PRN
  - Meclizine (Antivert, Bonine) 12.5 to 25 mg PO q4h PRN
  - Promethazine (Phenergan) 12.5 to 25 mg PO/PR QID PRN or prochlorperazine (Compazine) 25 mg PR BID PRN
  - Metoclopramide (Reglan) 10 mg PO TID PRN
- Antivirals
  - Acyclovir 800 mg PO 5 times per day for 7 days can be used in cases associated with herpes.
- Steroids
  - Adults: methylprednisolone initially 100 mg PO daily, then tapered to 10 mg PO daily over 3 weeks
  - Pediatrics: prednisone 1 mg/kg PO daily 3 times per week, then taper over 3 weeks
  - Given early in the setting of bacterial meningitis, may decrease the otologic sequelae, specifically labyrinthitis ossificans
  - Used in treatment of labyrinthitis for associated sudden sensorineural hearing loss

## *Pregnancy Considerations*

Dimenhydrinate, diphenhydramine, ondansetron, granisetron, and metoclopramide are pregnancy Category B.

## *First Line*

- Benzodiazepines, which are better vestibular suppressants, are preferred over antihistamine/anticholinergics such as meclizine. Sublingual benzodiazepines are very effective for vertigo and should be considered first-line therapy.
- Urgent steroid treatment in acute setting

## ISSUES FOR REFERRAL

- Consider neuro-otology referral for other peripheral causes of vertigo or unremitting vertigo.
- Consider neurology referral for suspected central causes of vertigo or dizziness.
- Consider otolaryngology referral for progressive bilateral hearing loss and vertigo after preliminary laboratory workup excluding rheumatologic causes.

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

- Patients with systemic infection, young age, or intractable vertigo with nausea and vomiting may need to be hospitalized for intravenous fluids and medications.
- Usually outpatient management

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### *Patient Monitoring*

Follow hearing loss weekly with audiograms until hearing stabilizes. Acute vertiginous symptoms may last up to 6 weeks. Residual symptoms have been documented to last months or year (8)[C].

### *DIET*

Avoid alcohol, as this may exacerbate symptoms.

## PATIENT EDUCATION

Lie still with eyes closed in a darkened room during acute attacks. Otherwise, encourage activity as tolerated. Minimize rapid head movement until symptoms resolve.

## PROGNOSIS

Prognosis depends on cause of labyrinthitis.

## COMPLICATIONS

Permanent hearing loss, more common with bacterial causes, and chronic impairment of balance

Ménière Disease; Postconcussive Syndrome; (Mild Traumatic Brain Injury) Tinnitus

## Codes

&NA;

### ICD10

- H83.09 Labyrinthitis, unspecified ear
- H83.01 Labyrinthitis, right ear

- H83.02 Labyrinthitis, left ear

## Clinical Pearls

### &NA;

- Ask patients to describe symptoms in their own words, alternative symptoms include light-headedness, vertigo, disequilibrium, or imbalance.
- Benzodiazepines are better vestibular suppressant and are preferred over antihistamine/anticholinergics such as meclizine.
- Episodic vertigo tends to be caused by BPPV or MŽnière disease, whereas persistent vertigo is more consistent with labyrinthitis.

# Lacrimal Disorders (Dry Eye Syndrome)

Kinder K. Fayssoux, MD

Mark Minot, MD

## BASICS

### *DESCRIPTION*

- Diseases and abnormalities of tear production and maintenance of tear film
- The most common lacrimal disorder is dry eye syndrome, which is often referred to as dysfunctional tear syndrome.
- Lacrimal duct disorders usually result in overflow tearing.
- System(s) affected: skin/exocrine

### *EPIDEMIOLOGY*

#### *Prevalence*

Very common throughout the United States; more often seen in arid climates:

- Predominant gender: female > male
- Predominant age: Dry eye symptoms increase with age and are most often seen in the elderly.

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Tear film is composed of three layers:
  - Mucin layer: allows spread of aqueous tears
  - Thick aqueous layer: produced by lacrimal gland
  - Lipid layer: controls tear evaporation
- Results from poor tear production, rapid tear evaporation, and/or an abnormal concentration of mucin or lipid in tear film
- Most common cause of dry eye symptoms is aqueous tear deficiency.
- Decreased androgens are thought to contribute to a decrease in tear production.

## ***RISK FACTORS***

- Exposure to dry environments (e.g., high altitudes)
- Contact lens wear
- Female gender
- Computer use
- Hormonal diseases
- History of collagen vascular disease such as rheumatoid arthritis, Sjögren syndrome, thyroid disease, rosacea, Bell palsy, eyelid abnormalities
- Medications, including oral contraceptives, diuretics, *β*-blockers, anticholinergics, antihistamines, and antidepressants
- Smoking
- Vitamin A deficiency
- Eye surgery: blepharoplasty, cataract, laser vision correction
- Artificial tears (with preservatives)

## ***GENERAL PREVENTION***

- Prevent exposure to eye irritants from pollution, cigarette smoke, and sun exposure.
- Ensure adequate vitamin A intake through diet or as a supplement.
- Patients with prior laser vision correction should wait at least 6 months before undergoing blepharoplasty because of the effects on corneal sensation, tear production, and tear film alteration (1)[C].
- Increasing awareness of this condition among people residing in dry environments
- Decrease or stop contact lens wear.

## ***COMMONLY ASSOCIATED CONDITIONS***

- Sjögren syndrome
- Rheumatoid arthritis
- Thyroid disease
- Rosacea
- Pregnancy
- Menopause

- Malnutrition

## DIAGNOSIS

### HISTORY

- Dry sensation in eyes
- Foreign body sensation
- Blurry vision
- Itching
- Ocular pain
- Photophobia
- Burning
- Occasional tearing due to excessive reflex tearing
  - Patient's symptoms usually worsen in dry, smoky environments, while reading, driving, or using a computer for extended periods.

### ***Pediatric Considerations***

Lacrimal duct obstruction should be suspected in an infant presenting with excessive tearing (epiphora).

### PHYSICAL EXAM

- Slit-lamp exam reveals decreased tear film and may reveal punctate epithelial defects on cornea.
- Schirmer test can be used to assess tear production.
- Ocular staining may reveal epithelial defects.

### DIFFERENTIAL DIAGNOSIS

- Ocular: allergy, conjunctivitis, contact lens complication, exposure keratopathy
- Other: ocular rosacea, thyroid ophthalmopathy, ocular manifestation of HIV, Bell palsy, vitamin A deficiency

### DIAGNOSTIC TESTS & INTERPRETATION

#### *Initial Tests (lab, imaging)*

Tear production can be measured using a Schirmer filter strip after instillation of topical

anesthetic. Wetting of <10 mm of the slip after 5 minutes is indicative of insufficient tear production.

## *Diagnostic Procedures/Other*

- Staining of the ocular surface with fluorescein will show areas of abnormal uptake and patches of drying. It allows the tear break-up time (TBUT) to be calculated. A TBUT of <10 seconds is abnormal.
- Rose bengal will be taken up by dead or dying epithelial cells, and it may be a more sensitive test.

## *Test Interpretation*

In Sjögren syndrome, infiltration of the lacrimal gland with inflammatory cells may be evident.

## **TREATMENT**

### *GENERAL MEASURES*

- Those with systemic illnesses predisposed to dry eye should be informed and instructed in the appropriate use of artificial tear supplements. Some artificial tear supplements with preservatives may exacerbate the condition.
- Symptoms of dry eye may decrease with an increase in home humidification and hydration.

### *MEDICATION*

#### *First Line*

- Preservative-free artificial tears: 1 drop in each eye several times a day to prevent discomfort (2)[A],(3)[C]
- Ophthalmic lubricating ointment may be used in each eye at bedtime (4)[B].

#### *Second Line*

- Dry eye has been identified as having an inflammatory component that responds in refractory cases to topical immunosuppressives such as cyclosporine 0.05% (Restasis), 1 drop to each eye BID (5,6,7)[A].
- Emerging therapies include topical androgens, secretagogues (e.g., oral pilocarpine), cytokine-blocking agents, and a P2Y2 receptor agonist (diquafosol).

## ***ISSUES FOR REFERRAL***

Rheumatology referral if systemic collagen vascular disease is suspected

## ***ADDITIONAL THERAPIES***

Lid massage and warm compresses several times a day

## ***Pediatric Considerations***

For most babies born with nasolacrimal duct obstructions, the obstructions will clear spontaneously during the 1st year of life. On occasion, surgical probing is necessary.

## ***SURGERY/OTHER PROCEDURES***

Punctal occlusion, with either punctal plugs or laser, is used in moderate to severe dry eye if medical therapy fails.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Fatty acid (omega-3), linoleic acid, and  $\gamma$ -linoleic acid supplements (8)[B]
- Acupuncture has been studied with inconclusive results (9)[A].

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

### ***Patient Monitoring***

- Monitor early to assess efficacy of treatment.
- The viscosity of artificial tears and frequency of use can be increased for symptom relief.

### ***DIET***

- Diet rich in omega-3 fatty acids and/or linoleic acids may benefit some patients.
- Adequate vitamin A intake

## ***PATIENT EDUCATION***

All individuals with systemic illnesses predisposed to dry eye, postmenopausal women, residing in arid climates, or those >60 years of age should be instructed in the use of artificial tear supplements to combat dry eye symptoms.

## PROGNOSIS

- Lacrimal disorders can be adequately managed with artificial tear supplements.
- Blocked tear ducts can be managed with probing and punctal dilation and/or dacryocystorhinostomy procedures in more severe cases.

## COMPLICATIONS

Severe dry eye may lead to the following:

- Corneal breakdown
- Secondary invasion by bacteria
- Eye infections

Sjögren Syndrome

## Codes

&NA;

### ICD10

- H04.129 Dry eye syndrome of unspecified lacrimal gland
- H04.9 Disorder of lacrimal system, unspecified
- H04.122 Dry eye syndrome of left lacrimal gland

# Clinical Pearls

**&NA;**

- Dry eye syndrome is common in the United States, affecting postmenopausal women more than any other population.
- Symptoms are usually adequately managed with preservative-free artificial tears and humidified environments.
- Dry eye symptoms that are refractory to medical treatment and/or punctal plugs should raise suspicion of an underlying systemic condition, and a rheumatology consult should be considered.

# Lactose Intolerance

Nihal K. Patel, MD

## BASICS

### DESCRIPTION

- Inability to digest lactose into constituent components (glucose and galactose) due to low levels of lactase in the brush border of the small intestinal mucosa, causing bloating, borborygmi (audible stomach rumblings), abdominal pain, and diarrhea
  - Congenital lactose intolerance: very rare
  - Primary lactose intolerance: common in adults who develop low lactase levels after childhood
  - Secondary lactose intolerance: inability to digest lactose caused by any condition injuring the intestinal mucosa (e.g., infectious enteritis, celiac disease, eosinophilic gastroenteritis, or inflammatory bowel disease) or a reduction of available mucosal surface (e.g., resection)
- Lactase activity peaks at birth then decreases after the first few months of life, declining continuously during lifetime. 75% of adults' worldwide exhibit decline in lactase activity. *However, only 50% of lactase activity is needed to digest lactose without causing symptoms of lactose intolerance.*
- Lactose malabsorption also results from reduction of lactase activity. It is asymptomatic, and is as common in healthy patients as in those with functional bowel disorders.
- System(s) affected: endocrine/metabolic, gastrointestinal

### Pediatric Considerations

- Primary lactose intolerance usually begins in late childhood.
- No consensus exists on whether young children (<5 years of age) should avoid lactose following diarrheal illness.
- Lactose-free formulas are available.
- Exclude milk protein allergy.

### EPIDEMIOLOGY

## *Incidence*

- 350% of infants with acute or chronic diarrheal disease have lactose intolerance. Particularly common with rotavirus infection.
- Lactose intolerance is common with giardiasis, ascariasis, irritable bowel syndrome (IBS), tropical and nontropical sprue, and the AIDS malabsorptive syndrome.

## *Prevalence*

- In South America, Africa, and Asia, rates of lactose intolerance are >50%.
- In the United States, the prevalence is 15% among whites, 53% among Hispanic Americans, and 80% among African Americans.
- In Europe, lactose intolerance varies from 15% in Scandinavian countries to 70% in Italy.
- Predominant age:
  - Primary: teenage and adult
  - Secondary: depends on underlying condition
- Predominant sex: male = female

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Primary lactose intolerance: Normal decline in the lactase activity in the intestinal mucosa is genetically controlled and permanent after weaning from breastmilk.
- Secondary lactose intolerance: associated with gastroenteritis in children and with nontropical and tropical sprue, regional enteritis, abetalipoproteinemia, cystic fibrosis, inflammatory bowel disease, celiac disease, and immunoglobulin deficiencies in both adults and children

## *Genetics*

- In Caucasians, lactase deficiency has been associated with a single nucleotide polymorphism (SNP) consisting of a nucleotide switch of T for C 13.910. bp on chromosome 2. This results in variants of CC-13910 (lactase nonpersistence) OR CT-13910/TT-13910 (lactase persistence) (1).
- SNP (C/T-13910) is associated with lactase persistence in northern Europeans.
- Other SNPs (G/C-14010, T/G-13915, and C/G-13907) have been linked to lactase persistence in Africans.

## *RISK FACTORS*

- Adult-onset lactase deficiency has wide geographic variation.
- Age:
  - Signs and symptoms usually do not become apparent until after age 6 to 7 years.
  - Symptoms may not be apparent until adulthood, depending on dietary lactose intake and rate of decline of intestinal lactase activity.
  - Lactase activity correlates with age, regardless of symptoms.

## GENERAL PREVENTION

Lactose avoidance relieves symptoms. Patients can learn what level of lactose is tolerable in their diet.

## COMMONLY ASSOCIATED CONDITIONS

- Tropical or nontropical sprue
- Giardiasis
- Inflammatory bowel disease
- Immunoglobulin deficiencies
- Celiac disease
- Cystic fibrosis

## DIAGNOSIS

- Lactose intolerance is defined by a positive lactose hydrogen breath test result plus accompanying clinical symptoms.
- Lactose intolerance can mimic symptoms of functional gastrointestinal disorders. Lactose intolerance can also be a coexisting condition.

## HISTORY

- Assess patient's daily lactose consumption. A single dose of lactose (12 g, equivalent to 1 cup of milk) consumed alone produces no or minor symptoms in persons with lactose intolerance or maldigestion.
- Lactose doses of 15 to 18 g are well tolerated with other nutrients. Doses >18 g cause progressively more symptoms, and quantities >50 g elicit symptoms in most individuals.
- Symptoms may arise 30 minutes to 2 hours after consumption of lactose-

containing products.

- Symptoms include bloating, cramping, abdominal discomfort, vomiting diarrhea or loose stools, and flatulence.
- Symptoms tend to appear 30 minutes to 2 hours after eating.
- Abdominal pain may be crampy in nature and often is localized to the periumbilical area or lower quadrant.
- Stools usually are bulky, frothy, and watery
- Only 1/3 to 1/5 of individuals with lactose malabsorption develop symptoms.

## *PHYSICAL EXAM*

Borborygmi may be audible on physical examination and to the patient. The exam is otherwise typically nonspecific.

## *DIFFERENTIAL DIAGNOSIS*

- Sucrase deficiency
- Cow's milk protein allergy
- IBS
- Bacterial overgrowth
- Celiac disease
- Inflammatory bowel disease

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- The lactose breath hydrogen test (LBT) is the best diagnostic test for lactose intolerance. It is noninvasive, easy to perform, and cost effective. It is limited by suboptimal sensitivity (2)[B]. Intestinal bacteria digest carbohydrates and produce hydrogen and methane that are measurable in expired air:
  - Oral lactose is administered in the fasting state, (2 g/kg; max dose 25 g). Breath hydrogen is sampled at baseline and at 30-minute intervals for 3 hours. The postlactose and baseline values are compared. A breath hydrogen value of 10 ppm is normal. Values between 10 and 20 ppm may be indeterminate unless accompanied by symptoms; values >20 ppm are considered diagnostic of lactose malabsorption.
- The biochemical assay of lactase activity on duodenal sampling is as sensitive as LBT in detecting lactase deficiency. It is more accurate than LBT in predicting the clinical response to

a lactose-free diet. Cost and invasiveness limit clinical utility

- For patients with symptoms of lactose intolerance who are undergoing endoscopy for other reasons, a biochemical assay on duodenal biopsies can rule out lactose malabsorption.
- A positive LBT confirms lactose malabsorption but does not define the etiology.

## *Diagnostic Procedures/Other*

Lactose absorption test is an alternative to LBT in adults (more invasive and equivalent in sensitivity and specificity to breath test). Following oral administration of a 50-g test dose in adults (2 g/kg in children), blood glucose levels are monitored at 0, 60, and 120 minutes. An increase in blood glucose of  $<20$  mg/dL (1.1 mmol/L) with the concurrent development of symptoms is diagnostic. False-negative results may occur in patients with diabetes or bacterial overgrowth.

## *Test Interpretation*

Lactase deficiency in intestinal mucosa may be patchy or focal.

## **TREATMENT**

There is insufficient evidence on treatments (including probiotics, colonic adaptation, and other supplements) to recommend any as definitive first-line.

- Treatment of lactose malabsorption in the absence of a correctable underlying disease includes four general principles (3)[B].
  - Patients should avoid milk and dairy products in order to improve symptoms.
  - Up to 12 to 15 g of lactose can be tolerated in patients with lactose intolerance without significant symptoms (1 cup of milk).
  - Lactose should be gradually reintroduced along with other nutrients until the patient's threshold for symptoms is reached. Spreading lactose servings throughout the day instead of a single dose has been shown to improve tolerance.
  - If symptoms persist, patients can substitute fermented and matured milk products for lactose.
- Certain strains, concentrations, and preparations of probiotics may alleviate symptoms.
- Incrementally increasing doses of lactose to induce colonic adaptation have met with limited success.

To date, insufficient scientific evidence exists to strongly recommend lactose-reduced or hydrolyzed milk, lactase supplements taken with milk, probiotics, or colonic adaptation to treat lactose intolerance. Use of these supplements should be considered on a case-by-case fashion.

- Maintain calcium and vitamin D intake.

## **MEDICATION**

### **First Line**

Lactase (Lactaid, Lactrase):

- Commercially available òlactaseó preparations are bacterial or yeast *&bgr*-galactosidases.
- Take 1 to 2 capsules or tablets prior to ingesting milk products.
- Vary in effectiveness at preventing symptoms
- Can add tablets or contents of capsules to milk (1 to 2 caps/tabs per quart of milk) before drinking; also available in milk in some areas
- Not effective for all people with lactose intolerance
- High-quality, large, randomized controlled trials showing efficacy and safety are lacking.

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Certain probiotic formulations taken with meals may alleviate some symptoms of lactose intolerance (4)[B].

## **ONGOING CARE**

### **DIET**

- Reduce or restrict dietary lactose to control symptoms. This is patient-specific and done as òtrial-and-error.ó
- Yogurt and fermented products such as hard cheese are often better tolerated than milk.
- Supplement calcium (e.g., calcium carbonate)
- Prehydrolyzed milk (Lactaid) is available.

## **PATIENT EDUCATION**

- Patients must learn to read labels on commercial products because milk sugar is used in many products and may cause symptoms.

- Lactose-intolerant patients may tolerate whole milk or chocolate milk better than skim milk due to slower rate of gastric emptying.
- Lactose consumed with other food products is better tolerated than when consumed with milk alone.
- Primary lactase deficiency is permanent; secondary lactose intolerance usually is temporary, although it may persist for months after the inciting event.
- 20% of prescription drugs and 6% of over-the-counter (OTC) medicines use lactose as a base.
- Most patients can tolerate 12 to 15 g of lactose, despite lactose intolerance or malabsorption.

## PROGNOSIS

- Normal life expectancy
- Symptoms can be controlled through diet alone if lactase tablets are ineffective.

## COMPLICATIONS

Calcium deficiency: Avoidance of milk and other dairy products can lead to reduced calcium intake, which may increase the risk for osteoporosis and fracture.

## Codes

&NA;

### ICD10

- E73.9 Lactose intolerance, unspecified
- E73.8 Other lactose intolerance
- E73.1 Secondary lactase deficiency

## Clinical Pearls

&NA;

- The diagnosis of lactose intolerance is based on clinical history and typically confirmed by hydrogen breath testing.
- Most lactose intolerant patients can tolerate 12 to 15 g of lactose per day.
- Lactose-intolerant patients may tolerate yogurt and fermented products better than milk and cheese.
- A food diary helps identify problematic foods.
- Patients should read ingredient labels to look for milk, lactose, whey, and curd.
- Lactose-intolerant patients may tolerate whole milk or chocolate milk better than skim milk due

to a slower rate of gastric emptying.

- Many patients with lactose intolerance unnecessarily avoid all dairy products, causing inadequate intake of calcium and vitamin D, which may predispose them to osteoporosis.

# Laryngitis

Hugh Silk, MD, MPH, FAAFP

Sheila O. Stille, DMD

Anne M. Barnard, MD

## BASICS

### DESCRIPTION

- Laryngitis is the inflammation, erythema, and edema of the mucosa of the larynx and/or vocal cords characterized by hoarseness, loss of voice, throat pain, coughing, and often a negative impact on a person's quality of life and daily activities
- There is a range of severity, but most cases are acute and are associated with viral upper respiratory infection, irritation, or acute vocal strain.
- System(s) affected: pulmonary; ears, eyes, nose, throat (ENT)
- Synonym(s): acute laryngitis; chronic laryngitis; croup or laryngotracheitis (in children)

### EPIDEMIOLOGY

- Predominant age: affects all ages
- Children more susceptible than adults due to increased risk of symptomatic inflammation from smaller airways
- Predominant sex: male = female

### *Incidence*

Common

### *Prevalence*

Common

### ETIOLOGY AND PATHOPHYSIOLOGY

- Misuse or abuse of voice
- Infectious

- Viral: influenza A, B; parainfluenza; adenovirus; coronavirus; rhinovirus; human papillomavirus; cytomegalovirus; varicella-zoster virus; herpes simplex virus; respiratory syncytial virus; coxsackievirus
- Fungal: uncommon, but thought to be underdiagnosed, potentially accounting for up to 10% of presentations in both immunocompromised and immunocompetent patients; risk factors include recent antibiotic or inhaled corticosteroid use (1): histoplasmosis, blastomycosis, *Coccidioides*, *Cryptococcus*, and *Candida*
- Bacterial: (uncommon):  $\beta$ -hemolytic streptococcus, *Streptococcus pneumoniae*, *Haemophilus influenzae*, tuberculosis (TB), leprosy, *Moraxella catarrhalis*, *Mycoplasma pneumoniae*, *Chlamydia pneumoniae*
- Secondary syphilis if left untreated
- Leprosy (in 30-55% of those with leprosy, larynx is affected; tropical and warm countries)
- Irritants
  - Inhalation of irritating substances (e.g., air pollution, cigarette smoke)
  - Aspiration of caustic chemicals
  - Gastroesophageal reflux disease (GERD)/laryngopharyngeal reflux disease (LPRD)
  - Excessively dry environment
  - Allergy exposures (including pollens)
- Anatomic
  - Aging changes: muscle atrophy, loss of moisture in larynx, and bowing of vocal cords
  - Vocal cord nodules/polyps (Ösinger's nodesÓ)
  - Local cancer
- Iatrogenic: inhaled steroids such as those used to treat asthma; surgical injury; endotracheal intubation injury
- Idiopathic
- Neuromuscular disorder (e.g., myasthenia gravis); stroke
- Rheumatoid arthritis
- Trauma (e.g., blunt or penetrating trauma to neck)

## RISK FACTORS

- Acute:

- Upper respiratory tract infection
- Voice overuse—excess talking, singing, or shouting
- Pneumonia
- Influenza
- Lack of immunization for pertussis or diphtheria
- Immunocompromised
- Recent endotracheal intubation or local surgery
- Chronic:
  - Allergies
  - Chronic rhinitis/sinusitis
  - Voice abuse
  - GERD/LPRD (rare) (2,3)[A]
  - Smoking: primary or secondhand
  - Excessive alcohol use
  - Stroke
  - Constant exposure to dust or other irritants such as chemicals at workplace; environmental pollution
  - Medications: inhaled steroids, anticholinergics, antihistamines, anabolic steroids (4)[B]

### *Geriatric Considerations*

May be more ill, slower to heal

### *Pediatric Considerations*

- Common in this age group
- Consider congenital/anatomic causes.

## **GENERAL PREVENTION**

- Avoid overuse of voice (voice training is helpful for vocal musicians/public speakers).
- Influenza virus vaccine is suggested for high-risk individuals.
- Quit smoking, and avoid secondhand smoke.

- Limit or avoid alcohol/caffeine/acidic foods.
- Control GERD/LPRD.
- Maintain proper hydration status.
- Avoid allergens.
- Wear mask around chemical/environmental irritants.
- Good hand washing (infection prevention)

## COMMONLY ASSOCIATED CONDITIONS

- Viral pharyngitis
- Diphtheria (rare): Membrane can descend into the larynx.
- Pertussis: larynx involved as part of the respiratory system
- Bronchitis
- Pneumonitis
- Croup, epiglottitis, in children

## DIAGNOSIS

### HISTORY

- Hoarseness, throat tickling, dry cough, and rawness
- Dysphonia (abnormal-sounding voice)
- Constant urge to clear the throat
- Possible fever
- Malaise
- Dysphagia/odynophagia
- Regional cervical lymphadenopathy
- Stridor or possible airway obstruction in children (5)[C]
- Cough may be worse at night in children.
- Hemoptysis
- Laryngospasm or sense of choking
- Allergic rhinitis/rhinorrhea/postnasal drip (PND)
- Occupation or other reasons for voice overuse
- Smoking history

- Blunt or penetrating trauma to neck
- GERD/LPRD

## ***PHYSICAL EXAM***

- Head and neck exam, including airway patency, cervical nodes; cranial nerve exam
- Visualization of the larynx: preferably with a flexible or rigid endoscope, or with an indirect mirror examination as a screening technique to dictate further appropriate testing (6)
- Note quality of voice (i.e., hoarse, breathy, wet, hot potato like, asthenic [weak], strained).

## ***DIFFERENTIAL DIAGNOSIS***

- Diphtheria
- Vocal nodules or polyps
- Laryngeal malignancy
- Thyroid malignancy
- Upper airway malignancy
- Epiglottitis
- Pertussis
- Laryngeal nerve trauma/injury
- Foreign body (in children)
- Autoimmune (rheumatoid arthritis) (7)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Rarely needed
- WBCs elevated in bacterial laryngitis
- Viral culture (seldom necessary)

## **Follow-Up Tests & Special Considerations**

- Barium swallow, only if needed for differential diagnosis
- CT scan if foreign body suspected

## ***Diagnostic Procedures/Other***

- Fiber-optic or indirect laryngoscopy: looking for red, inflamed, and occasionally hemorrhagic vocal cords; rounded edges and exudate (Reinke edema)
- Consider otolaryngologic evaluation and biopsy: laryngitis lasting >2 weeks in adults with history of smoking or alcohol abuse to rule out malignancy

P.591

- pH probe (24-hour): no difference in incidence of pharyngeal reflux as measured by pH probe between patients with chronic reflux laryngitis and healthy adults (8)[C]
- Stroboscopy laryngoscopy for diagnosis of subtle lesions (e.g., vocal cord nodules or polyps)

## TREATMENT

- Limited but good evidence that treatment beyond supportive care is ineffective.
- Antibiotics appear to have no benefit, as etiologies are predominantly viral (9)[A].
- Corticosteroids in severe cases of laryngitis to reduce inflammation such as croup
- May need voice training, if voice overuse
- Nebulized epinephrine reduces croup symptoms 30 minutes posttreatment; evidence does not favor racemic epinephrine or L-epinephrine, or IPPB over simple nebulization. Racemic epinephrine reduces croup symptoms at 30 minutes, but effect lasts only 2 hours (10)[A].

## GENERAL MEASURES

- Acute:
  - Usually a self-limited illness lasting <3 weeks and not severe
  - Antibiotics of no value (9)[A]
  - Avoid excessive voice use, including whispering.
  - Steam inhalations or cool-mist humidifier
  - Increase fluid intake, especially in cases associated with excessive dryness.
  - Avoid smoking (or secondhand exposure).
  - Warm saltwater gargles
- Chronic:
  - Symptomatic treatment as above
  - Voice therapy (for patients with intermittent dysphagia and vocal abuse)

- Smoking cessation
  - Reduction or cessation of alcohol intake
  - Occupational change or modification, if exposure-driven
  - Allergen avoidance
  - Consider discontinuing offending medication.
- Reflux laryngitis: Elevate head of bed, diet changes, other antireflux lifestyle change management; proton pump inhibitors

## *MEDICATION*

Usually none

### *First Line*

- Analgesics
- Antipyretics (rare)
- Cough suppressants
- Throat lozenges
- Plenty of fluids

### *Second Line*

- Inhaled corticosteroids (consider only if allergy induced)
- Oral corticosteroids: only if urgent need in adults (presenter, singer, actor)
- Oral corticosteroids: Evidence of benefit has been studied with single-dose dexamethasone in children ages 6 months to 5 years for moderate-severity croup; reduces symptoms within 6 hours, reduces hospitalizations, hospital length of stay, and revisits to office (11)[A].
- Standard of care is to prescribe proton pump inhibitors for chronic laryngitis if GERD or LPRD is suspected; however, evidence suggests only a modest benefit, if any (12, 13)[C].
- Treat nonviral infectious underlying causes.
- Candidal laryngitis:
  - Mild cases: oral antifungal (fluconazole)
  - Amphotericin B or echinocandin can be given in life-threatening cases.

## *ISSUES FOR REFERRAL*

- Immediate emergency ENT referral for patients with stridor or respiratory distress
- ENT referral for persistent symptoms (>2 to 3 weeks) or concern for foreign body
- Consider otolaryngologic evaluation and biopsy for laryngitis lasting >2 weeks in adults, especially in those with history of smoking or alcohol abuse to rule out malignancy.
- Consider GI consult to rule out GERD/LPRD.

## ***SURGERY/OTHER PROCEDURES***

- Vocal cord biopsy of hyperplastic mucosa and areas of leukoplakia if cancer or TB is suspected
- Removal of nodules or polyps if voice therapy fails

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

The following, although not well studied, have been recommended by some experts:

- Barberry, black currant, echinacea, eucalyptus, German chamomile, goldenrod, goldenseal, warmed lemon and honey, licorice, marshmallow, peppermint, saw palmetto, slippery elm, vitamin C, zinc

## **ONGOING CARE**

### ***PATIENT EDUCATION***

- Educate on the importance of voice rest, including whispering.
- Provide assistance with smoking cessation.
- Help the patient with modification of other predisposing habits or occupational hazards.

### ***PROGNOSIS***

Complete clearing of the inflammation without sequelae

### **COMPLICATIONS**

Chronic hoarseness

**&NA;**

## **ICD10**

- J04.0 Acute laryngitis
- J37.0 Chronic laryngitis
- J04.2 Acute laryngotracheitis

## **Clinical Pearls**

**&NA;**

- Laryngitis is usually self-limited and needs only comfort care. Standard treatment is voice rest.
- Refer to ENT for direct visualization of vocal cords for prolonged laryngitis.
- Corticosteroids have some benefits for children with moderately severe croup.
- Voice training useful for chronic

# Laxative Abuse

Matthew E. Bryant, MD

## BASICS

### DESCRIPTION

- A chronic watery diarrhea caused by intentional or unintentional misuse of laxatives due to self-medication or provider error
- System(s) affected: gastrointestinal, nervous, psychiatric, skin, and renal
- Synonym(s): factitious diarrhea; cathartic colon; as part of Münchausen syndrome (self or by proxy) – most dramatic form

### EPIDEMIOLOGY

- Predominant age: 18 to 40 years associated with bulimia or anorexia nervosa
- Common in the elderly as a result of treatment for constipation, either by health care professional or self-directed (*unintentional*)
- Associated with athletes in sports with weight limits (wrestling)
- Predominant sex (*intentional abuse*): female (90%) > male
- More common in upper socioeconomic classes

### Prevalence

Laxative abuse in different groups

- 0.7-5.5% in the general population
- As many as 15% undergoing evaluation for chronic diarrhea
- Unexplained chronic diarrhea after routine investigations: 4-7%
- Up to 70% of patients with bingeing/purging anorexia and bulimia nervosa abuse laxatives but rarely as the sole method of purging.
- Chronic use of constipating medications (opioids)

### Pediatric Considerations

Children may be given excess laxatives by caregivers (Munchausen syndrome by proxy).

## *Geriatric Considerations*

Elderly in nursing homes are at increased risk for laxative overuse (usually inadvertent).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Four types of chronic diarrhea: secretory, osmotic, inflammatory, and fatty. Rule out other causes, laxative abuse is a diagnosis of exclusion (1).
- Chronic ingestion of any laxative agent
  - Stimulant (most common, rapid onset of action)
    - Diphenylmethane (Bisacodyl)
    - Anthraquinones (Senna, Cascara, Castor oil)
  - Saline and osmotic products (sodium phosphate, magnesium sulfate/citrate and hydroxide, lactulose, polyethylene glycol)
  - Bulking agents (psyllium)
  - Surfactants (docusate)
- Psychologic factors
  - Bulimia or anorexia nervosa (associated with behavioral pathology)
  - Secondary gain (attention-seeking): disability claims or need for concern, caring from others
  - Inappropriate perceptions of "normal" bowel habits

## **RISK FACTORS**

In patients with eating disorders

- Longer duration of illness
- Comorbid psychiatric diagnoses (e.g., major depression, obsessive-compulsive disorder, posttraumatic stress disorder, anxiety, borderline personality disorder)
- Early age of eating disorder symptoms

## **GENERAL PREVENTION**

- Educate patients about proper nutrition, normal bowel function, potential adverse effects of excessive laxative use, and medications (e.g., magnesium-containing antacids) that can cause diarrhea.

- Ask patients specifically about laxative use; inadvertent overuse is common.

## COMMONLY ASSOCIATED CONDITIONS

- Anorexia nervosa, bulimia nervosa
- Use of constipating medications (opioids, iron supplements).
- Any chronic disorder associated with constipation
- Depression and anxiety
- Borderline personality
- Self-injurious behaviors/suicidal ideation
- Impulsive behavior
- Münchausen syndrome/Münchausen syndrome by proxy (children) may have associated factitious symptoms involving diverse organ systems.
- Fictitious disorders
- Patient is dependent on a caregiver.

## DIAGNOSIS

### HISTORY

- Suspect in patients with undiagnosed, refractory chronic diarrhea.
- Assess over-the-counter medication use, and take thorough dietary history (2).
- Signs and symptoms: increasing frequency of bowel movements; large volume, watery diarrhea; nocturnal bowel movements (typically absent in osmotic diarrhea or in irritable bowel syndrome) (2,3).
- Additional symptoms: abdominal pain, rectal pain, nausea, vomiting, weight loss, malaise, muscle weakness, or chronic constipation
- Assess “doctor shopping” and potential factitious symptoms.

### PHYSICAL EXAM

- No specific findings but may include cachexia, evidence of dehydration, abdominal pain or distension, and edema; fever may be due to self-infected wounds or thermometer manipulation (2).
- Bulimics or anorexics who purge may have Russell sign (excoriation of fingers from repeated

self-induced retching) (4); clubbing, cyclic edema, skin pigmentation changes, parotid hypertrophy

- Rarely, severe cases may be associated with renal failure, cardiac arrhythmias, skeletal muscle paralysis, anemia from blood-letting or self-induced skin wounds.

## ***DIFFERENTIAL DIAGNOSIS***

Any etiology of chronic diarrhea, especially in high-risk groups

## ***DIAGNOSTIC TESTS & INTERPRETATION***

If patient has not had an initial workup for chronic diarrhea, rule out infectious, inflammatory, and malignant causes based on patient demographics and risk factors.

### ***Initial Tests (lab, imaging)***

- Serum electrolytes hypokalemia, hypernatremia, hyperphosphatemia
  - Acute diarrhea: metabolic acidosis (hypovolemia)
  - Chronic diarrhea: metabolic alkalosis secondary to hypokalemia-induced inhibition of chloride uptake with inhibited bicarbonate secretion
- CBC, stool cultures, *Clostridium difficile* polymerase chain reaction (PCR) to rule out infectious cause if history is suspicious (fecal leukocytes, ova and parasites (O&P)Ñcheck for giardia, isospora, and cryptosporidia specifically) (2,3).
- Colonoscopy, small-bowel endoscopy, or imaging studies are not usually necessary but help to evaluate other causes of chronic diarrhea (2).
- *Melanosis coli* on sigmoidoscopy or colonoscopy indicate overuse of anthracene laxatives.

### ***Follow-Up Tests & Special Considerations***

The following algorithm can be used to confirm diagnosis and determine what laxative is being used (1,5)[B].

- Collect 24-hour stool: If stool is solid, workup is over.
- Obtain stool osmolality, stool electrolytes, and calculate osmolal gap [ $-290 - 2(\text{Na}^+ + \text{K}^+)$ ],  $\text{Na}^+$  and  $\text{K}^+$  are stool concentrations.
  - If osmolality  $>400$  mOsm/kg, rule out urine contamination of stool. Measure urea and creatinine of sample.
  - If osmolality  $<250$  to  $400$  mOsm/kg, rule out water added to stool (colon cannot dilute stool to osmolality of plasma).

- If osmolality = 250 to 400 mOsm/kg, measure osmolal gap.
  - Gap >50: unmeasured solute; check fecal fat and stool magnesium levels.
  - Gap <50: Rule out use of secretory laxative; urinalysis and stool analysis for laxative titers. Do not obtain serum laxative titers, as they peak 1 to 2 hours after ingestion. Urine titers can be 10 times as high as plasma titers.
- Confirm diagnosis with multiple stool analyses before addressing patient with concern for intentional abuse.

## TREATMENT

### GENERAL MEASURES

- Behavioral support is essential in intentional use.
- Wean patient off laxatives and supplements; substitute high-fiber diet and bulk preparations or short-term saline enemas
- Treat secondary constipation (3)[C].
- Treat metabolic abnormalities.

---

P.593

### MEDICATION

Replace needed fluid, vitamins, electrolytes, and minerals.

#### *First Line*

- Patient education on normal bowel habits
- Nonstimulant laxatives (if needed) to treat constipation (3)[C]
  - Polyethylene glycol (3)[C]
  - Lactulose (3)[C]
  - High-fiber diet
- Precautions: Patients may be manipulative to deny problem; may hide laxatives in hospital rooms.
- Significant possible interactions
  - Increased rate of intestinal motility may affect rate of absorption of medications (e.g.,

antibiotics, hormones).

- Docusate sodium may potentiate hepatotoxicity of other drugs.
- Consider loperamide to improve anal tone and promote rectal inhibitory reflex (6)[C].

## *ISSUES FOR REFERRAL*

In cases of Münchausen syndrome by proxy, legal proceedings must be considered, because most victims are children. Behavioral health support for patients with significant psychological comorbidities

## *SURGERY/OTHER PROCEDURES*

Avoid exploratory surgery and repetitive evaluations or invasive procedures.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Persistent diarrhea with hemodynamic instability
- Electrolyte/metabolic complications, including lactic acidosis
- Cardiac arrhythmias

### *IV Fluids*

Resuscitate based on clinical presentation. If patient is hemodynamically stable and without significant abnormalities in serum sodium, give normal saline boluses or oral replacement to correct metabolic alkalosis (chronic) or acidosis (acute) as needed. If patient is hemodynamically unstable, treat volume status as in hypovolemic shock, while monitoring serum electrolytes closely (especially sodium, potassium, and bicarbonate (6,7)[C].

### *Nursing*

If stable, patient does not need continuous telemetry. Depending on psychiatric history, patient may need one-on-one or line-of-sight observation. Special care must be taken to ensure adequate nutrition and control access to laxatives. If surreptitious laxative ingestion is suspected, do not perform unauthorized room searches due to legal constraints.

### *Discharge Criteria*

- Psychological evaluation, support, and follow-up
- Diet and bowel programs
- Resolution of electrolyte abnormalities/dehydration

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Ongoing behavioral counseling
- Careful medical support; frequent visits as needed
- Assess serum electrolytes.

#### *DIET*

Ensure good nutritional habits.

- Increase fiber intake.
- Avoid constipating substances.
- Adequate calories, especially with bulimia

#### *PROGNOSIS*

- Natural history is unclear and varied depending on underlying cause.
- Prognosis is related to underlying behavioral disorders in intentional abuse or underlying organic disease (if present).
- Prognosis is poor with anorexia nervosa; very poor in Mÿnchausen syndrome.
- Cathartic colon is commonly refractory to treatment (7)[C].

#### **COMPLICATIONS**

- Risk of multiple tests, procedures, and surgeries (intentional use)
- Malnutrition
- Electrolyte imbalances (hypokalemia, hypermagnesemia, phosphate nephropathy) (3)
- Renal failure
- Cardiac arrhythmias/sudden death (3)
- Renal calculi
- Cathartic colon with constipation as a consequence of prolonged irritant laxative use (7)

- Fecal impaction in elderly
- Recurrences are common for factitious abuse, even after confrontation.
- Rebound edema (7)

### ICD10

F55.2 Abuse of laxatives

## Clinical Pearls

&NA;

- Laxative abuse may be intentional or unintentional.
- When associated with eating disorders, laxative abuse is associated with more severe disease.
- Consider laxative abuse in patients with watery diarrhea, especially if unexplained or refractory.
- As many as 15% of patients referred to tertiary care centers for unexplained chronic diarrhea abuse laxatives.
- Presentation is diverse and nonspecific including weight loss, weakness, and hypotension.
- Patients often won't acknowledge diarrhea if laxative abuse is intentional.

# Lead Poisoning

Jason Chao, MD, MS

## BASICS

### DESCRIPTION

- Consequence of a high body burden of lead (Pb), an element with no known physiologic value
- Synonym(s): lead poisoning, inorganic

### EPIDEMIOLOGY

- Predominant age: 1 to 5 years, adult workers
- Predominant sex: male > female (1:1 in childhood)

### Prevalence

- 2007 to 2010: Centers for Disease Control and Prevention (CDC) estimated that 2.6% of U.S. children aged 1 to 5 years had blood Pb levels  $>5 \text{ } \mu\text{g/dL}$ , but levels are variable among communities and populations.
- Sporadic cases in adults

### ETIOLOGY AND PATHOPHYSIOLOGY

- Inhalation of Pb dust or fumes, or ingestion of Pb
- Pb replaces calcium in bones. Pb interferes with heme synthesis, causes interstitial nephritis, and interferes with neurotransmitters, especially glutamine; high levels affect blood-brain barrier and lead to encephalopathy, seizures, and coma.
- Early life Pb exposure causes methylation changes leading to epigenetic alterations that may lead to brain dysfunction.

### RISK FACTORS

- Children with pica or with iron-deficiency anemia
- Residence in or frequent visitor to deteriorating pre-1960 housing with lead-painted surfaces or recent renovation

- Soil/dust exposure near older homes, Pb industries, or urban roads
- Sibling or playmate with current or past Pb poisoning
- Dust from clothing of Pb worker or hobbyist
- Pb dissolved in water from Pb or Pb-soldered plumbing
- Pb-glazed ceramics especially with acidic food or drink
- Recent refugee
- Folk remedies and cosmetics
  - Mexico: Azarcon, Greta
  - Dominican Republic: Litargirio, a topical agent
  - Asia and Middle East: Chuifong tokuwan, paylooah, ghasard, bali goli, kandu, ayurvedic herbal medicine from South Asia, kohl (alkohl, ceruse), surma, saoott, cebagin
- Hobbies: glazed pottery making, target shooting, Pb soldering, preparing Pb shot or fishing sinkers, stained-glass making, car or boat repair, home remodeling
- Occupational exposure: plumbers, pipe fitters, Pb miners, auto repairers, glass manufacturers, shipbuilders, printer operators, plastic manufacturers, Pb smelters and refiners, steel welders or cutters, construction workers, rubber product manufacturers, battery manufacturers, bridge reconstruction workers
- Dietary: zinc or calcium deficiency
- Imported toys with Pb

### *Pediatric Considerations*

- Children are at increased risk because of incomplete development of the blood-brain barrier at <3 years of age, allowing more Pb into the CNS; ingested Pb has 40% bioavailability in children compared with 10% in adults.
- Common childhood behaviors such as frequent hand-to-mouth activity and pica (repeated ingestion of nonfood products), greatly increase the risk of ingesting Pb.

### **GENERAL PREVENTION**

- Family should receive counseling on potential sources of Pb and methods to decrease Pb exposure. Children at high risk should receive blood Pb screening (1)[C].
- Warn parents about the dangers posed by unsafe renovation methods.
- Wet mopping and dusting with a high-phosphate solution (e.g., powdered automatic

dishwasher detergent with 1/4 cup/gallon of water) will help to control Pb-bearing dust. But high-phosphate detergent is no longer available in some states.

- Pregnant women with community-specific or any individual risk factor for Pb poisoning should be screened for Pb toxicity (2)[C].

## COMMONLY ASSOCIATED CONDITIONS

Iron-deficiency anemia

## DIAGNOSIS

### HISTORY

- Often asymptomatic
- Mild-to-moderate toxicity
  - May cause myalgia or paresthesia, fatigue, irritability, lethargy
  - Abdominal discomfort, arthralgia, difficulty concentrating, headache, tremor, vomiting, weight loss, muscular exhaustibility
- Severe toxicity three major clinical syndromes:
  - Alimentary type: anorexia, metallic taste, constipation, severe abdominal cramps due to intestinal spasm and sometimes associated with abdominal wall rigidity
  - Neuromuscular type (characteristic of adult plumbism): peripheral neuritis, usually painless and limited to extensor muscles
  - Cerebral type or Pb encephalopathy (more common in children): seizure, coma, and long-term sequelae, including neurologic defects, delayed mental development, and chronic hyperactivity
- Chronic exposure may cause renal failure.

## PHYSICAL EXAM

Often normal, but abdominal tenderness may be severe. Neurologic exam may reveal neuropathy or encephalopathy.

## DIFFERENTIAL DIAGNOSIS

- Alimentary type may be confused with acute abdomen.
- Neuromuscular type may be confused with other polyneuropathies.
- Cerebral type may be confused with ADD, mental retardation, autism, dementia, and other

causes of seizures.

- Elevated erythrocyte protoporphyrin may be caused by iron-deficiency anemia or, less commonly, hemolytic anemia.
- Erythropoietic protoporphyria produces a very high erythrocyte protoporphyrin level.

## DIAGNOSTIC TESTS & INTERPRETATION

- Blood Pb  $>5 \text{ } \mu\text{g/dL}$  ( $0.24 \text{ } \mu\text{mol/L}$ ) collected with Pb-free container
- Use a laboratory that can achieve routine performance within  $2 \text{ } \mu\text{g/dL}$ .
- In 2012, CDC recommended using a reference value as the basis for management, currently  $>5 \text{ } \mu\text{g/dL}$
- Screening capillary Pb levels  $>5 \text{ } \mu\text{g/dL}$  ( $0.24 \text{ } \mu\text{mol/L}$ ) should be confirmed with a venous sample.
- Hemoglobin and hematocrit slightly low; eosinophilia or basophilic stippling on peripheral smear may be seen but is not diagnostic of Pb toxicity.
- Renal function is decreased in late stages.
- Abdominal radiograph for Pb particles in gut if recent ingestion is suspected.
- Radiograph of long bones may show lines of increased density in the metaphyseal plate resulting from growth arrest but does not usually alter management and is not routinely recommended.
- X-ray fluorescence for the total body burden of Pb is experimental.

## TREATMENT

Blood level ( $\mu\text{g/dL}$ )	Time to confirmation testing
$\geq 9$	1-3 months
10-44	1 week-1 month
45-59	48 hours
60-69	24 hours
$\geq 70$	Urgently as emergency test

**ALERT**

- For any blood Pb levels persistently  $>15 \text{ } \mu\text{g/dL}$ , contact local public health department for home inspection.
- If Pb level is between 5 and 45  $\mu\text{g/dL}$ , the higher the Pb level, the more urgent the need for confirmation testing.
- For all elevated levels: Educate family on sources of Pb (3)[C].
- Pb level  $>$  ref level to  $<45$ : Complete history and physical exam, follow-up Pb monitoring; complete inspection of home or workplace to determine source of Pb and Pb-hazard reduction; neurodevelopmental monitoring: iron status, Hgb, or Hct (4)[C]
- Pb level 45 to 69: Actions for lower level plus free erythrocyte protoporphyrin, oral chelation therapy, or hospitalization if Pb-safe environment cannot be ensured (4)[C].
- Pb  $>70$ : Hospitalize for chelation therapy (5)[C]

## MEDICATION

- Consider oral chelation for asymptomatic and Pb  $>45$  and  $<70$ ; chelation (preferably parenteral) for Pb  $>70$  or symptomatic Pb  $<70$  (5)[C].
- Do not begin chelation until Pb particles present in gut are cleared (5)[C].

P.595

### First Line

- Oral chelation: Succimer (Chemet), dimercaptosuccinic acid (DMSA) 10 mg/kg q8h for 5 days; then 10 mg/kg q12h for 2 weeks. This may be repeated after 2 weeks off if Pb levels are not stabilized at  $<15 \text{ } \mu\text{g/dL}$  ( $<0.72 \text{ } \mu\text{mol/L}$ ) (5)[C].
- Parenteral chelation (begin after establishment of adequate urine output):
  - Dimercaprol (British anti-Lewisite [BAL]) 75 mg/m<sup>2</sup> given deep IM; then BAL 450 mg/m<sup>2</sup>/day divided q4h for 5 days plus Ca edetate calcium disodium (EDTA) 1,500 mg/m<sup>2</sup>/day continuous IV infusion for 5 days. If rebound Pb level  $\geq 45 \text{ } \mu\text{g/dL}$  ( $\geq 2.17 \text{ } \mu\text{mol/L}$ ), chelation may be repeated after 2-day interval if symptomatic or after 5-day interval if asymptomatic.
  - Ca EDTA 1,000 mg/m<sup>2</sup>/day for 5 days; may be repeated after 5 to 7 days
- Diazepam for initial control of seizures; further control maintained with paraldehyde
- Contraindications: BAL should not be given to patients allergic to peanuts (the drug solution contains peanut oil).

- Precautions
  - Succimer: GI upset, rash, nasal congestion, muscle pains, elevated liver function tests
  - Ca EDTA: renal failure, increased excretion of zinc, copper, and iron
  - BAL: nausea, vomiting, fever, headache, transient hypertension, hepatocellular damage
- Significant possible interactions
  - Vitamins should not be given concurrently with oral chelation.
  - BAL may precipitate hemolytic crisis in a patient with glucose-6-phosphate dehydrogenase deficiency.

## *Second Line*

Oral chelation with penicillamine (D-penicillamine, Depen, Cuprimine) (5)[C]

- Penicillin-allergic patient should not receive penicillamine (cross-sensitivity is common).
- 10 to 15 mg/kg/day given BID mixed in apple juice/sauce on empty stomach (*not* approved by the FDA)
- Penicillamine may cause GI upset, renal failure, granulocytopenia, liver dysfunction, iron deficiency, and drug-induced lupus-like syndrome.

## *ISSUES FOR REFERRAL*

Consider consultation if parenteral chelation is required.

## *ADDITIONAL THERAPIES*

Remove patient from potential source of Pb or Pb level >45 until complete home inspection is performed.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Blood Pb level >70  $\mu\text{g}/\text{dL}$
- If symptomatic, blood Pb level >35  $\mu\text{g}/\text{dL}$
- Outpatient care unless parenteral chelation is required or immediate removal from contaminated environment.

### *Discharge Criteria*

- If Pb source is in the home, the patient must reside elsewhere until the abatement process is completed.
- Avoid visit to any site of potential contamination.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- After chelation, check for rebound Pb level in 7 to 10 days. Follow with regular monitoring, initially biweekly or monthly.
- Correct iron deficiency or any other nutritional deficiencies present.
- Once Pb <35  $\mu\text{g}/\text{dL}$ , repeat testing every 1 to 3 months until level <25  $\mu\text{g}/\text{dL}$  is achieved. Then monitor every 3 to 6 months until level <10  $\mu\text{g}/\text{dL}$ . Once <9  $\mu\text{g}/\text{dL}$ , test every 6 to 9 months (4)[C].

#### *DIET*

- If symptomatic, avoid excessive fluids.
- Avoid pica.
- Adequate calcium, iron, zinc, and vitamin C to reduce absorption and retention of Pb (6)[B]

### *PATIENT EDUCATION*

- Needleman HL, Landrigan PJ. *Raising Children Toxic Free: How to Keep Your Child Safe From Lead, Asbestos, Pesticides, and Other Environmental Hazards*. New York, NY: Farrar, Straus and Giroux; 1995.
- National Lead Information Center, 422 South Clinton Avenue, Rochester, NY 14620; 800-424-5323; [www.epa.gov/lead/](http://www.epa.gov/lead/)
- National Safety Council, 1121 Spring Lake Drive, Itasca, IL 60143-3201; 800-621-7615; <http://www.nsc.org/learn/safety-knowledge/Pages/Lead-Poisoning-Prevention.aspx>

### *PROGNOSIS*

- Symptomatic Pb poisoning without encephalopathy generally improves with chelation, but subtle CNS toxicity may be long lasting or permanent.
- If encephalopathy occurs, permanent sequelae (e.g., mental retardation, seizure disorder,

blindness, and hemiparesis) occurs in 25-50%.

## COMPLICATIONS

- CNS toxicity may be long lasting or permanent.
- Long-term Pb exposure may cause chronic renal failure (Fanconi-like syndrome), gout, or Pb line (blue-black) on gingival tissue.
- Pb exposure in pregnancy is associated with reduced birth weight and premature birth.
- Pb is an animal teratogen.

## Codes

**&NA;**

## ICD10

- T56.0X4A Toxic effect of lead and its compounds, undetermined, init
- T56.0X1A Toxic effect of lead and its compounds, accidental, init

## Clinical Pearls

**&NA;**

- The following children should have Pb screening:
  - 6 to 11 months of age with <sup>3</sup>1 risk factors:
    - Live in or visit a house built before 1960 with peeling paint or recent renovation
    - Sibling/playmate with elevated Pb
    - Live with adult with job or hobby involving Pb
    - Live near industry likely to release Pb
  - Children living in high-risk communities (>12% elevated Pb) should be tested yearly from ages 1 to 5.

- Newly arrived refugees
- Children in low-risk areas should be screened by a questionnaire containing the above risk factors.
- There is no clear safe Pb level. Many experts consider Pb levels  $>4 \text{ } \mu\text{g/dL}$  as elevated.
- There are no studies that show benefit of chelation for asymptomatic children with Pb  $<45$ . Removal of sources of Pb is paramount.

# Legionnaires' Disease

Sean R. Wise, MD

Alex P. Houser, DO

## BASICS

### DESCRIPTION

- *Legionnaires' disease* was named for an epidemic of lower respiratory tract disease at an American Legion convention in Philadelphia in 1976. The causative bacterium was previously unrecognized. It was isolated, identified, and named *Legionella pneumophila*. The organism primarily causes pneumonia and flulike illness. *Legionella* preferentially colonizes man-made water systems (e.g., hotels, hospitals, air conditioning cooling towers).
  - Among the three most common clinical pneumonias
  - Most common atypical pneumonia
- System(s) affected: gastrointestinal, pulmonary
- Synonym(s): Legionella pneumonia; legionellosis

### EPIDEMIOLOGY

- Predominant age: 15 months to 84 years; 74-91% of patients are >50 years old
- Predominant gender: male > female

### Incidence

- Reported cases in the United States from 2000 to 2009 increased from 3.9 to 11.5 cases per million.
- Outbreaks occur most often at the end of the summer and early fall.
- Represents 2-9% of all cases of pneumonia in the United States.

### ETIOLOGY AND PATHOPHYSIOLOGY

- *L. pneumophila* is a weak gram-negative aerobic saprophytic freshwater bacterium. It is widely distributed in soil and water. Bipolar flagella provide motility; grows optimally at 40-45°C

Exists as an intracellular protozoan parasite, colonizing surfaces and growing in biofilms, which persist in nematodes.

- Serogroups 1 to 6 account for clinical disease.
- Serogroup 1 represents 70-92% of all clinical cases of *Legionella* in the United States.
- In the lung, *Legionella* infects alveolar macrophages.
- The organism is transmitted by aspiration, direct transmission (e.g., contaminated respiratory equipment), and (most importantly) by airborne dissemination and aerosolization of contaminated water sources (e.g., contaminated shower water—felt responsible for the inaugural Philadelphia outbreak).
- Recently, community outbreaks have been associated with whirlpools, spas, fountains, and also aboard cruise ships.

## **RISK FACTORS**

- Impaired cellular immunity (*Legionella* are intracellular pathogens)
- Male gender
- Smoking
- Alcohol abuse
- Immunosuppression/HIV
- Chronic cardiopulmonary disease
- Advanced age
- Transplant recipients
- Diabetes mellitus
- Use of antimicrobials within the past 3 months.

## **GENERAL PREVENTION**

- *Not transmitted person to person* (respiratory isolation is unnecessary.)
- Superheat and flush water systems: Heat water to 70°C, and flush outlets with hot water for 30 minutes (1)[C].
- Ultraviolet light or copper-silver ionization are bactericidal.
- Monochloramine disinfection of municipal water supplies decreases risk for *Legionella* infection.
- No person-to-person transmission has been previously documented.

# COMMONLY ASSOCIATED CONDITIONS

Pontiac fever: self-limited flulike illness without pneumonia caused by *Legionella* species

## DIAGNOSIS

- Illness ranges from asymptomatic seroconversion and mild febrile illness to severe pneumonia.
- Wound infections with *Legionella* have also been reported.
- Incubation period is 2 to 14 days.

## HISTORY

- Signs and symptoms (with associated percentage):
  - Dry cough: 92%, (may occasionally become productive)
  - Fever/chills: 90%
  - Dyspnea: 62%
  - Pleuritic chest pain: 35%
  - Headache: 48%
  - Myalgia/arthralgia: 40%
  - Watery diarrhea: 50%
  - Nausea and vomiting: 49%
  - Neuropsychiatric symptoms such as encephalopathy, confusion, disorientation, obtundation, depression, hallucinations, insomnia, seizure: 53%
- History of immunosuppression increases risk.

## PHYSICAL EXAM

- Fever
- Relative bradycardia (key sign)
  - Defined as a temperature  $\geq 102^{\circ}\text{F}$  with an inappropriately low pulse pressure  $< 100$  beats/minute (normal compensatory reaction to fever is tachycardia  $> 110$  beats/minute)
- Rales and signs of consolidation (egophony; tactile fremitus)

## DIFFERENTIAL DIAGNOSIS

- Other bacterial pneumonias, especially atypical pneumonias: *Mycoplasma pneumoniae*, Q fever

(*Coxiella burnetii*), *Chlamydophila pneumoniae*, *Chlamydophila psittaci*, *Francisella tularensis*

- Viral pneumonias, such as adenovirus, influenza (human, avian, swine), cytomegalovirus (CMV)

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Diagnosis:
  - Gold standard is sputum culture for *Legionella*. Alert lab about diagnostic possibility (sample needs buffered charcoal yeast extract agar). Variable sensitivity (10-80%) and time consuming (up to 7 days for results). Hampered by lack of sputum production in >50% of patients.
  - Urinary antigen test (UAT) detects serogroup 1 (which causes most human disease). UATs are highly specific (95-100%) but variably sensitive. *Legionella* antigenuria can be detected 1 to 2 days after onset of disease and persists for up to 10 months. Limited by only detecting serogroup 1 (may miss 40% of cases) (2)[C].
    - Indications for UAT: severe pneumonia, ICU admission, failure of outpatient antibiotic treatment, current alcohol abuse, recent travel (within past 2 weeks), pleural effusion
  - Combination of respiratory cultures and urine *Legionella* antigen is optimal for diagnosis (3) [C].
  - Monoclonal direct fluorescence assay (DFA) on respiratory secretions is diagnostic:
    - Sensitivity 25-75%
    - Limited by lengthy (4 to 6 weeks) seroconversion
  - Silver/Gimenez stains used for lung specimens.
  - Disorders that may alter lab results: Direct immunofluorescence can cross-react with *Pseudomonas* and *Bacteroides* sp., *Escherichia coli*, and *Haemophilus* sp.
- Other lab abnormalities (seen less commonly with other forms of pneumonia):
  - Hyponatremia
  - Hypophosphatemia (transient)
  - Lymphopenia
  - Mildly elevated serum transaminases
  - Elevated LDH

- Elevated creatinine kinase
- Microscopic hematuria
- Highly elevated C-reactive protein (CRP) (>30)
- Highly elevated ferritin (<sup>32</sup> times normal)
- Chest radiograph
  - Not specific for *Legionella*
  - Commonly shows unilateral lower lobe patchy alveolar infiltrate with consolidation
  - Cavitation and abscess formation is more common in immunocompromised patients.
  - Pleural effusion occurs in up to 50%.
  - May take 1 to 4 months for radiographic findings to resolve. Progression of infiltrate on x-ray can be seen despite antibiotic therapy.

### *Diagnostic Procedures/Other*

Transtracheal aspiration/bronchoscopy occasionally necessary for sputum/lung samples

### *Test Interpretation*

- Multifocal pneumonia with alveolitis and bronchiolitis, and fibrinous pleuritis; may have serous or serosanguineous pleural effusion
- Abscess formation occurs in up to 20% of patients.
- Progression of infiltrates on x-ray (despite appropriate therapy) suggests Legionnaires' disease. Radiographic improvement may not correlate with clinical findings (longer lag times).

## **TREATMENT**

### *GENERAL MEASURES*

- Severity of illness and available support dictate the appropriate site for care.
- Supportive care:
  - Oxygenation, hydration, and electrolyte balance with antibiotic therapy

---

P.597

- Extrapulmonary complications and higher mortality in patients with AIDS.
- In severe pneumonia, guidelines recommend obtaining a UAT and starting empiric antibiotics

to include coverage for *Legionella* (4)[C].

## MEDICATION

### First Line

- Antibiotics that achieve high intracellular concentrations (e.g., macrolides, tetracyclines, fluoroquinolones) are most effective; first-line treatment is levofloxacin; however, no prospective randomized controlled trials have compared fluoroquinolones to macrolides for the treatment of *Legionella*. Levofloxacin was associated with more rapid defervescence, fewer complications, decreased hospital stay by 3 days, and decreased mortality (4% vs. 10.9%) compared with macrolide antibiotics (4)[A].
- Start antibiotics parenterally if sufficiently ill due to the GI symptoms associated with *Legionella*:
  - Levofloxacin is the preferred agent:
    - Levofloxacin 750 mg/day IV (switch to PO when patient is afebrile/tolerating PO) for 5 days or 500 mg/day for 10 to 14 days
  - Azithromycin may also be used first line. It requires a shorter duration of treatment than levofloxacin due to a longer half-life:
    - Azithromycin 500 mg/day IV (switch to PO when afebrile/tolerating PO) for 7 to 10 days
- Contraindications: hypersensitivity reactions
- Precautions: liver disease
- Significant possible interactions:
  - Can increase theophylline, carbamazepine, and digoxin levels; can increase activity of oral anticoagulants
  - May decrease the effectiveness of digoxin, quinidine, oral contraceptives, and hypoglycemic agents
- Longer courses of treatment (up to 21 days) may be needed in immunocompromised patients.

### Second Line

- Doxycycline 100 mg IV/PO q12h for total 14 days; for severe infections, initial dose is 200 mg IV/PO q12h.
- Doxycycline cannot be used in pregnant patients and is not approved for children <8 years of age.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Inability to tolerate oral antibiotics
- Hypoxemia
- Criteria for direct admission to the ICU:
  - Any of the major criteria for severe CAP:
    - Septic shock requiring vasopressor support
    - Acute respiratory failure requiring intubation and/or mechanical ventilation
  - Three or more of the minor criteria for severe CAP:
    - RR  $\geq$ 30 breaths/min; PaO<sub>2</sub>:FiO<sub>2</sub> ratio  $\leq$ 250; multilobular infiltrates; confusion/disorientation; uremia (BUN  $\geq$ 20 mg/dL); leukopenia (WBC  $<$ 4,000 cells/mm<sup>3</sup>); thrombocytopenia (PLT  $<$ 100,000 cells/mm<sup>3</sup>); hypothermia (temperature  $<$ 36°C); hypotension requiring aggressive fluid resuscitation

### *Discharge Criteria*

- Afebrile
- Able to tolerate oral antibiotics
- Normal oxygen saturation

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Monitor respiratory status, hydration, and electrolyte status closely.
- Chest radiography does not help with monitoring clinical response.

### *PATIENT EDUCATION*

- Disease prevention: Eliminate pathogens from water supplies, low-emission cleaning procedures of cooling towers with control measurements of water and air samples.

- *Legionella* is not spread person-to-person.

## PROGNOSIS

- Improved prognosis when appropriate antibiotics are started early in the disease course.
- Recovery is variable:
  - Patients may clinically worsen despite appropriate treatment early in the course of therapy (first 1 to 2 days).
  - Improvement with defervescence in 3 to 5 days and complete recovery in 6 to 10 days is typical. Some may have a more protracted course.
- Mortality in nosocomial infections ranges between 15 and 34%.

## COMPLICATIONS

- Dehydration
- Hyponatremia
- Respiratory insufficiency requiring ventilator support
- Bacteremia/abscess formation in immunocompromised patients
- Extrapulmonary diseases:
  - Encephalitis
  - Cellulitis
  - Sinusitis
  - Pancreatitis
  - Pyelonephritis
  - Endocarditis (most common extrapulmonary site)
  - Pericarditis
  - Perirectal abscess
- Renal failure
- Disseminated intravascular coagulation
- Multiple organ dysfunction syndrome (MODS)
- Coma
- Death occurs in 8-12% of treated immunocompetent patients and in up to 80% of untreated immunocompromised patients.

&NA;

Pneumonia, Bacterial

## Codes

**&NA;**

## **ICD10**

- A48.1 Legionnaires' disease
- A48.2 Nonpneumonic Legionnaires' disease [Pontiac fever]

## **Clinical Pearls**

**&NA;**

- Consider Legionnaires' disease in patients with pneumonia, extrapulmonary findings (atypical CAP) and relative bradycardia, and any three of the following: relative lymphopenia, mildly elevated serum transaminases (aspartate aminotransferase/alanine aminotransferase), highly increased ferritin levels, or hypophosphatemia.
- Consider Legionnaires' disease in cases of nosocomial pneumonia.
- *Legionella* is an intracellular organism that must be grown on buffered charcoal yeast extract agar.
- Because an increase in *Legionella* antibody titers cannot be detected >3 to 4 weeks, serology is not useful in early stages of the disease.
- Respiratory specimen cultures combined with urine *Legionella* antigen testing is the preferred strategy for definitive diagnosis.

# Leukemia, Acute Lymphoblastic in Adults (ALL)

Richard A. Larson, MD

## BASICS

### DESCRIPTION

- ALL in adults is a malignant proliferation and accumulation of immature lymphocytes.
- ALL is the most common malignancy in children (see *Acute Lymphoblastic Leukemia, Pediatric*)
- System(s) affected: hemic/lymphatic/immunologic
- Synonym(s): acute lymphocytic leukemia

### Pregnancy Considerations

Many chemotherapy drugs are teratogenic.

### EPIDEMIOLOGY

- Predominant age in adults: Median age, 35 to 40 years; incidence increases with age.
- Predominant sex: male > female (slightly)

### Incidence

In the United States: 3,000 adult cases per year

### ETIOLOGY AND PATHOPHYSIOLOGY

- Unknown
- Epstein-Barr virus is implicated in Burkitt leukemia/lymphoma.

### Genetics

- Increased incidence in children with Down syndrome or in rare familial diseases such as ataxiatelangiectasia, Bloom syndrome, Fanconi anemia, Klinefelter syndrome, and neurofibromatosis (1)
- With P53 mutation in Li-Fraumeni syndrome

- Can rarely occur in adult identical twins

## **RISK FACTORS**

- Age >60 years
- Incidence seems to increase after exposure to chemical agents such as benzene or to radiation, but acute myeloid leukemia (AML) is more common.
- May follow aplastic anemia

## **DIAGNOSIS**

### **HISTORY**

- Anemia: fatigue, shortness of breath, lightheadedness, angina, headache
- Thrombocytopenia: easy bruising
- Neutropenia: fever, infection
- Lymphocytosis: bone pain
- CNS: confusion

### **PHYSICAL EXAM**

- Thrombocytopenia: petechiae, ecchymoses, epistaxis, retinal hemorrhages
- Anemia: pallor
- Neutropenia: fever, infection
- Lymphocytosis: lymphadenopathy, splenomegaly; less often, hepatomegaly
- CNS: cranial nerve palsies, confusion

### **DIFFERENTIAL DIAGNOSIS**

- Malignant disorders: other leukemias, especially AML; chronic myeloid leukemia in lymphoid blast phase; prolymphocytic leukemia; malignant lymphomas; multiple myeloma; bone marrow metastases from solid tumors (breast, prostate, lung, renal); myelodysplastic syndromes
- Nonmalignant disorders: aplastic anemia, myelofibrosis, autoimmune diseases (Felty syndrome, lupus), infectious mononucleosis, pertussis, autoimmune thrombocytopenic purpura, leukemoid reaction to infection

### **DIAGNOSTIC TESTS & INTERPRETATION**

## *Initial Tests (lab, imaging)*

CBC with differential, liver function tests, uric acid, anemia: normochromic, normocytic

- Thrombocytopenia
- Peripheral blood lymphoblasts (B-cells or T-cells)
- Elevated lactate dehydrogenase
- Elevated uric acid

## *Follow-Up Tests & Special Considerations*

Special tests

- Immunophenotyping of marrow/blood lymphoblasts: B lineage (CD19, CD20, CD22, CD24); T lineage (CD2, cCD3, CD5, CD7); common ALL antigen (CD10); human leukocyte antigen (HLA)-DR; terminal deoxynucleotidyl transferase (TdT); aberrant myeloid antigens (CD13, CD33); stem cell antigen (CD34)
- Cytochemical stains: Myeloperoxidase, negative; Sudan black B, usually negative; TdT, positive; periodic acid-Schiff  $\pm$  is variable, depending on subtype.
- Cytogenetics: Specific recurring chromosomal abnormalities have independent diagnostic and prognostic significance (hyperdiploidy  $>50$  chromosomes or t[14q11q13] are favorable; the Philadelphia chromosome, t[9;22], t[4;11], -7 and +8 are unfavorable). A translocation t(8;14) or t(2;8) or t(8;22) identifies Burkitt-type mature B-cell leukemia that requires specific therapy.
- Reverse transcription polymerase chain reaction for rapid diagnosis of BCR/ABL + ALL
- Genomic analysis by next-generation sequencing: detection of mutations associated with Ph-like ALL
- HLA typing of patient and siblings for hematopoietic cell transplantation
- Chest CT scan and/or chest radiograph to evaluate for mediastinal mass or hilar adenopathy and for pulmonary infiltrates suggestive of infection
- US exam to assess splenomegaly or renal enlargement suggestive of leukemic infiltration

## *Diagnostic Procedures/Other*

- Bone marrow examination with aspiration, biopsy, immunophenotyping, cytochemistry, cytogenetics, and molecular diagnostics
- Lymph node biopsy is rarely necessary but can be diagnostic.
- Lumbar puncture is typically done both for diagnosis of CNS involvement and for intrathecal chemotherapy. It should be done at diagnosis and immediately if neurologic symptoms or

signs are present. Repeat lumbar puncture after bone marrow remission is achieved to evaluate occult CNS involvement and continue prophylactic CNS treatment.

## *Test Interpretation*

Diffuse replacement of marrow and lymph node architecture by sheets of malignant lymphoblasts

## **TREATMENT**

### *GENERAL MEASURES*

- Appropriate health care
  - Inpatient care during remission induction chemotherapy
  - Postremission therapy is usually outpatient.
- Protective isolation from infection
- Adequate calcium and vitamin D supplementation may reduce bone injury from corticosteroids and avascular necrosis of large joints.

### *MEDICATION*

#### *First Line*

Optimal therapy is not yet known (2)[B]. ALL should be treated at a comprehensive oncology center. All treatment regimens are still investigational but clearly effective for some fraction of patients. Younger adults (<40 years old) benefit from pediatric-inspired regimens (3,4)[B]. The modified Cancer and leukemia Group B protocol 9111 is an example of therapy for older adults (5)[B]:

- Remission induction
  - Cyclophosphamide: 1,200 mg/m<sup>2</sup> IV on day 1 (800 mg/m<sup>2</sup> if <sup>3</sup>60 years old)
  - Daunorubicin: 45 mg/m<sup>2</sup> IV on days 1, 2, and 3 (30 mg/m<sup>2</sup> if <sup>3</sup>60 years old)
  - Vincristine: 2 mg IV on days 1, 8, 15, and 22
  - Pegylated asparaginase 2,000 U/m<sup>2</sup> (max 3,750 U) given on day 5. 1,000 U/m<sup>2</sup> may be better tolerated.
  - Dexamethasone 10 mg/m<sup>2</sup> on days 1 to 7 and 15 to 21
  - Filgrastim, G-CSF: 5 &mgr;g/kg/day SC starting on day 4 has been shown to shorten the

duration of neutropenia and improve the complete remission rate, especially in older patients.

- Imatinib mesylate: 600 to 800 mg/day (or dasatinib 70 mg BID) are effective alone and in combination with chemotherapy for Philadelphia chromosome-positive ALL (6)[B].
- Consolidation (repeat twice in 8 weeks)
  - Cyclophosphamide: 1,000 mg/m<sup>2</sup> IV day 1
  - Intrathecal (IT) methotrexate: 15 mg with hydrocortisone 50 mg on day 1
  - Mercaptopurine (6-mercaptopurine): 60 mg/m<sup>2</sup>/day on days 1 to 14
  - Cytarabine: 75 mg/m<sup>2</sup>/day SC on days 1 to 4 and 8 to 11
  - Vincristine: 2 mg IV on days 15 and 22
  - Pegylated asparaginase 2,000 U/m<sup>2</sup> (maximum 3,750 U) on day 15
- CNS prophylaxis and interim maintenance: 24 Gy cranial irradiation
  - IT-methotrexate: 15 mg with hydrocortisone 50 mg on days 1, 8, 15, 22, and 29
  - Mercaptopurine: 60 mg/m<sup>2</sup>/day on days 1 to 70, taken in the evening
  - Oral methotrexate: 20 mg/m<sup>2</sup> on days 36, 43, 50, 57, and 64
- Late intensification
  - Doxorubicin: 30 mg/m<sup>2</sup> IV on days 1, 8, and 15
  - Vincristine: 2 mg IV on days 1, 8, and 15
  - Dexamethasone: 10 mg/m<sup>2</sup> on days 1 to 14
  - Cyclophosphamide: 1,000 mg/m<sup>2</sup> IV on day 29
  - Thioguanine (6-thioguanine): 60 mg/m<sup>2</sup> on days 29 to 42
  - Cytarabine: 75 mg/m<sup>2</sup> SC on days 29 to 32 and 36 to 39
- Prolonged maintenance
  - Vincristine: 2 mg/m<sup>2</sup> IV for 16 months
  - Prednisone: 60 mg/m<sup>2</sup> for 5 days with the vincristine or dexamethasone 10 mg/m<sup>2</sup> on days 1 to 5
  - Mercaptopurine: 60 mg/m<sup>2</sup>/day for 16 months, taken in the evening

- Oral methotrexate: 20 mg/m<sup>2</sup>/week for 16 months
- Special: Philadelphia chromosome-positive ALL (6,7)[B]
  - Imatinib mesylate (400 to 800 mg/day) is effective alone and in combination with chemotherapy.

---

- Dasatinib (70 mg BID) is effective in combination with dexamethasone or with chemotherapy (7)[B].
- Contraindications: Doses and schedule may need to be altered for older patients and for concurrent infection and organ toxicity (8)[C].
- Precautions
  - Tumor lysis syndrome (elevated uric acid, potassium, and phosphate with decreased calcium, leading to renal failure, disseminated intravascular coagulation, and cardiac arrhythmias) may be prevented by administering allopurinol 300 mg/day. Begin 2 days before chemotherapy begins. Reduce doses if used with mercaptopurine or azathioprine. Give increased fluids; IV urate oxidase (rasburicase) can be used to treat hyperuricemia rapidly.
  - Oral sulfamethoxazole-trimethoprim or aerosolized pentamidine is given for *Pneumocystis jiroveci* prophylaxis.
  - Profound immunosuppression: Take appropriate precautions when patient is neutropenic.
  - High-dose cyclophosphamide causes severe nausea and vomiting. Use appropriate antiemetic regimen to prevent.
  - Neurotoxicity, ileus with vincristine
  - Asparaginase may cause severe allergic reactions as well as impaired pancreatic and liver function. Monitor serum glucose concentrations frequently and carefully. Pancreatitis or thrombosis may occur. Peg-asparaginase is preferred now and can be used IV, SC, or IM in place of native *Escherichia coli* asparaginase.
  - Avascular (osteo) necrosis (AVN) of bone may occur in adolescents and young adults after alkylating agents and corticosteroids.
  - Rituximab (anti-CD20 monoclonal antibody) appears to improve the outcome of patients with ALL if CD20 is expressed on >20% of their blast cells.
  - Also note: Burkitt leukemia/lymphoma (mature B-cell ALL-L3)
    - The outcome is clearly better if high-dose methotrexate and alkylating agents are used as part of initial therapy.

- Only 18 weeks of treatment are required.
- Rituximab (anti-CD20 monoclonal antibody) improves the outcome of patients with Burkitt leukemia when added to chemotherapy (9)[B].

## *Second Line*

- Clofarabine has been approved for relapsed childhood ALL. Nelarabine has been approved as a single agent for relapsed T-cell ALL. Pegylated asparaginase (IV or IM) is now used in place of *E. coli*-derived L-asparaginase. Liposomal vincristine has been approved for single-agent use for the treatment of relapsed ALL in adults.
- Immunoconjugates such as inotuzumab ozogamicin are under investigation.
- The bifunctional antiCD19/antiCD3 antibody blinatumomab is approved for relapsed/refractory ALL (10)[B].
- Allogeneic hematopoietic stem cell transplantation is recommended for any patient with relapsed ALL or during first remission if high-risk genetic features are present (11)[B],(12)[A].

## *ISSUES FOR REFERRAL*

### **ALERT**

ALL can become a fatal disorder quickly. As soon as the diagnosis is suspected, patients should be referred immediately to an appropriate oncology center.

## *SURGERY/OTHER PROCEDURES*

Surgical placement of a percutaneous, silastic, doublelumen central venous catheter or a percutaneous intravenous central catheter (PICC)

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Unproven; may result in adverse drug interactions with chemotherapy

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

Ambulatory as tolerated

## *Patient Monitoring*

- Daily during induction chemotherapy for metabolic and infectious complications

- Weekly during remission consolidation chemotherapy
- Monthly during maintenance therapy
- Every 3 months thereafter

## **DIET**

- Nutritional support; if needed IV hyperalimentation
- Avoid alcohol.
- Calcium and vitamin D

## **PATIENT EDUCATION**

- Risks of infection, transfusion, chemotherapy
- Stop smoking.

## **PROGNOSIS**

- ÷80-95% of adults <60 years will achieve a complete remission, and 35-60% will remain free of disease at 5 years.
- Older patients (>60 years) do less well, but 80% may achieve a complete remission.
- Patients with unfavorable cytogenetic subtypes (especially t[9;22] and t[4;11]) should undergo allogeneic stem cell transplantation in first remission if an HLA-identical donor is available. Autologous stem cell transplantation should be considered for Ph + ALL patients who become reverse transcriptase polymerase chain reaction negative for BCR/ABL and lack an allogeneic donor.

## **COMPLICATIONS**

- Infections (*Pneumocystis carinii* pneumonia, bacterial pneumonia or sepsis, fungal pneumonia)
- Bleeding
- Coagulopathy (deep vein thrombosis) from asparaginase therapy
- Need for transfusions
- Sterility from treatment
- Arachnoiditis and CNS effects from intrathecal chemotherapy, high-dose methotrexate and irradiation
- Pancreatitis and liver dysfunction from chemotherapy
- Osteonecrosis of joints (avascular necrosis) related to corticosteroids

- Relapse of ALL in marrow or extramedullary sites (CNS, testis)

## Codes

**&NA;**

### ICD10

- C91.00 Acute lymphoblastic leukemia not having achieved remission
- C91.01 Acute lymphoblastic leukemia, in remission
- C91.02 Acute lymphoblastic leukemia, in relapse

## Clinical Pearls

**&NA;**

ALL can become fatal quickly; as soon as diagnosis is suspected, refer the patient to an oncology center. Optimal therapy is not yet known. ALL should be treated at a comprehensive oncology center. All treatment regimens are still investigational but clearly are effective for a large fraction of patients.

# Leukemia, Acute Myeloid

Jan Cerny, MD, PhD

## BASICS

### DESCRIPTION

- Acute myeloid leukemia (AML) is characterized by proliferation and accumulation of abnormal immature myeloid progenitors (blasts) with reduced capacity to differentiate into more mature cellular elements. This leads to bone marrow failure and results in a variety of systemic symptoms.
- Previously, the French-American-British (FAB) classification system divided AML based on the cell morphology with the addition of cytogenetics (subtypes M0-M7).
- The World Health Organization (WHO) classification attempts to provide more meaningful prognostic information.
  - AML with characteristic genetic abnormalities: translocation t(8;21), t(15;17), and inversion in chromosome 16 inv(16)
  - AML with multilineage dysplasia: presence of a prior myelodysplastic syndrome (MDS) or myeloproliferative neoplasm (MPN) that transformed into AML
  - AML and MDS, therapy related
  - AML not otherwise categorized
  - Acute leukemias of ambiguous lineage (*biphenotypic acute leukemia*)

### EPIDEMIOLOGY

- ÷13,500 cases diagnosed in 2007; second most common type of leukemia in adults
- Predominant sex: male <sup>3</sup>female

### Incidence

The incidence of AML increases with age, and median age is >70 years.

### ETIOLOGY AND PATHOPHYSIOLOGY

Precise causes unknown, but some risk factors have been identified (see *Risk Factors*).

## Genetics

- Unknown; some are familial.
- Cytogenetics and genetics play an important role in diagnosis and prognosis of AML and have implications for therapy.
- Three risk groups
  - Good risk: inv(16), t(8;21), t(15;17)
  - Standard risk: normal karyotype
  - Poor risk: monosomy 5 and 7 (typically secondary AML), deletion 5q, abnormalities of 11q23 or complex karyotype
- *FLT3* gene mutations, especially internal transmembrane duplications (FLT3-ITD), have been associated with poor survival in AML. These and growing list of (onco)gene (e.g., *NPM1*, *DNMT3A*, and *P53*) mutations have been studied to further risk-stratify patients (1,2)[A].

## RISK FACTORS

- Genetic predisposition (e.g., Down syndrome); other familial disorders are Bloom syndrome (÷25% develop AML), Fanconi anemia (52%), neurofibromatosis, Li-Fraumeni syndrome, Wiskott-Aldrich syndrome, Kostmann syndrome, and Diamond-Blackfan anemia
- Radiation exposure
- Immunodeficiency states
- Chemical and drug exposure (nitrogen mustard and alkylating agents; benzene)
- MDS
- Cigarette smoking

## GENERAL PREVENTION

None currently identified, but treatment of highrisk MDS with demethylating agents (Vidaza, 5-azacitidine) has been shown to prolong time to transformation from MDS into AML (3)[A].

## COMMONLY ASSOCIATED CONDITIONS

The following are oncologic emergencies:

- Disseminated intravascular coagulopathy (DIC) especially in acute promyelocytic leukemia (APL) but may be seen in any AML
- Leukostasis (high blast number and increased adhesive ability of blasts)

- Tumor lysis syndrome (TLS): spontaneous or in response to chemotherapy

## DIAGNOSIS

### HISTORY

Fatigue (anemia or tumor burden); bleeding (low platelets or DIC); difficulty clearing infections (neutropenia or immune dysregulation)

### PHYSICAL EXAM

- Mostly nonspecific and related to marrow or tissue infiltration
  - Fever
  - Bleeding
  - Pallor
  - Splenomegaly
  - Hepatosplenomegaly
  - Lymphadenopathy (usually reactive)
- If CNS is involved, symptoms of increased intracranial pressure can be present.
- Occasionally, patients will present with prominent extramedullary sites of leukemia (e.g., skin infiltration or ultimately as a myeloid sarcoma).

### DIFFERENTIAL DIAGNOSIS

- Virus-induced cytopenia, lymphadenopathy, and organomegaly
- Immune cytopenias (including systemic lupus erythematosus [SLE])
- Drug-induced cytopenias
- Other marrow failure and infiltrative diseases (e.g., aplastic anemia, paroxysmal nocturnal hemoglobinuria, MDSs, Gaucher disease)

### DIAGNOSTIC TESTS & INTERPRETATION

- CBC shows subnormal RBCs, neutrophils, and platelets.
- Bone marrow for histology, flow cytometry, and cytogenetics to establish diagnosis and prognosis
- ESR

- Lactate dehydrogenase (LDH) and uric acid can be elevated (e.g., TLS).
- Coagulation profile can be normal or prolonged (e.g., DIC).
- Drugs that may alter lab results: chemotherapy agents, corticosteroids
- Other special tests: Spinal tap may reveal fluid with leukemic cells.
- Ultrasonography or CT scan of the abdomen may discover organomegaly.

## *Diagnostic Procedures/Other*

Bone-marrow studies are usually necessary to make the diagnosis.

- Aspirates: for cell morphology, cytochemistries, immunophenotyping (can confirm differentiation stage of AML); cytogenetics: chromosomal aberration (prognostic value; see ÖGeneticsÓ)
- Biopsies provide valuable information for cellularity, architecture, and so forth.

## *Test Interpretation*

- Marrow is usually hypercellular and the normal architecture effaced; leukemic blast count is 20% or more.
- Liver and spleen may be infiltrated with leukemic cells.

## **TREATMENT**

- Chemotherapy is the backbone of AML therapy; it consists of induction and consolidation phase ± maintenance (APL).
- Bone marrow transplantation (BMT) for high-risk AML
- Only modest improvements have been made in AML induction chemotherapy. Supportive care has improved significantly.

## **GENERAL MEASURES**

- Ongoing assessment of bone marrow, liver, heart, and kidney functions during therapy
- Close monitoring of coagulation parameters (risk for DIC)
- Supportive therapy with
  - Good hydration
  - Transfusions of packed RBCs and platelets based on patient's needs (threshold as for

platelets as low as 5,000); use leuko-reduced, irradiated blood products, as all patients can be considered for BMT.

- Avoid antiplatelet agents (e.g., aspirin products).
- Follow febrile neutropenic guidelines in neutropenic patient who becomes febrile (even low-grade fever).

## *Geriatric Considerations*

- Older patients (>60 to 65 years of age) remain a therapeutic challenge. These patients are offered so-called reduced-intensity or nonmyeloablative BMT.
- Adding growth factors (granulocyte-colony stimulating factor [G-CSF]) may reduce toxicity in older patients (but is not broadly accepted).
- Hypomethylating agent, such as 5-azacitidine, significantly prolongs survival in older adults with low marrow blast count (<30%).

## *Pediatric Considerations*

Tolerate intense treatments better

---

P.601

## *Pregnancy Considerations*

Chemotherapy is a viable option in the 2nd and 3rd trimesters.

# **MEDICATION**

## *First Line*

- APL (APL, AML with t[15;17])
  - All-trans retinoic acid (ATRA) and arsenic trioxide both promote maturation to granulocytes.
  - Idarubicin is often added to induction therapy.
- Treatment of AML in younger adults: AML (other than APL)
  - Induction (daunorubicin or idarubicin [anthracycline and cytarabine]): The generally accepted combination is 3 + 7 (anthracycline is given for 3 days and cytarabine for 7 days) or more intensive regimens with high dose of cytarabine (HiDAC) or high dose of anthracycline.
- Remission is typically consolidated in younger patients by the following:
  - In good-risk AML, 3 to 4 cycles of HiDAC and BMT is reserved for time of recurrence.

- In poor-risk patients, 1 to 2 cycles of HiDAC (until donor is identified) are followed by allogeneic BMT.
- Intermediate-risk AML should be treated based on individual patient's features, donor availability, and access to clinical trials. A meta-analysis showed that even intermediate-risk patients benefit from allogeneic BMT (4)[A].
- Treatment of AML in older adults (>65 years of age) remains a challenge. These patients have poor performance status, more likely secondary AML, higher incidence of unfavorable cytogenetics, comorbidities, shorter remissions, and shorter overall survival.
  - Intensive chemotherapy may be feasible for patients with good performance status; alternative regimens with mitoxantrone, fludarabine, and clofarabine. New drugs (hypomethylating agents as above, FLT3 inhibitors, monoclonal antibodies, etc.) are being studied in clinical trials (5)[A].
- Contraindications: comorbidities; therapy has to be individualized.
- Precautions
  - If organ failure, some drugs may be avoided or dose reduced (e.g., no anthracyclines in patients with preexisting cardiac problems).
  - Patients will be immunosuppressed during treatment. Avoid live vaccines. Administer varicellazoster or measles immunoglobulin as soon as exposure of patient occurs.
- Significant possible interactions: Allopurinol accentuates the toxicity of 6-mercaptopurine.

## *Second Line*

Healthy, younger patients usually are offered reinduction chemotherapy and allogeneic BMT.

## *ISSUES FOR REFERRAL*

- AML should be managed by specialized team led by a hematologist/oncologist.
- Refer patient to a transplant center early because a search for a donor may be necessary.

## *SURGERY/OTHER PROCEDURES*

- BMT: Decision between myeloablative and nonmyeloablative approach should be based on patient's performance status, comorbidities, and AML risk factors.
  - Allogeneic BMT is acceptable in first remission in intermediate- or high-risk AML or in second remission in all other AML patients. Matched related donor used to be preferred over matched unrelated donor (lower risk of graft-versus-host disease); recent data suggest equal outcomes, as allogeneic transplant regimens and posttransplant care have improved

significantly.

- Haploidentical transplants and cord blood may be used as alternative sources of hematopoietic stem cells for adults.
- Autologous BMT may be acceptable in specific situations (e.g., no donor is available).

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Induction treatment for AML requires inpatient care, usually on a specialized ward. Episodes of febrile neutropenia typically require admission and IV antibiotics.

### ***IV Fluids***

Appropriate hydration to prevent TLS

### ***Nursing***

IV may lead to chemical burns in the event of extravasation.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Ambulatory, as tolerated; no intense or contact sports; no aspirin due to risk of bleeding.

### ***Patient Monitoring***

- Repeat bone marrow studies to document remission and also if a relapse is suspected.
- Follow CBC with differential, coagulation studies, uric acid level, and other chemistries related to TLS (creatinine, potassium, phosphate, calcium); monitor urinary function at least daily during induction phase and less frequently later.
- Physical evaluation, including weight and BP, should be done frequently during treatment.

### ***DIET***

Ensure adequately balanced calorie/vitamin intake. Total parenteral nutrition (TPN) in case of severe mucositis

## ***PATIENT EDUCATION***

- Leukemia Society of America, 600 Third Avenue, New York, NY 10016, 212-573-8484

- National Cancer Institute, Bethesda, MD, has pamphlets and telephone education.
- Baker LS. *You and Leukemia: A Day At a Time*. Philadelphia, PA: Saunders; 1978.

## PROGNOSIS

AML remission rate is 60-80%, with only 20-40% long-term survival. The wide variable prognosis is due to prognostic group (age, cytogenetics, and genetics).

## COMPLICATIONS

- Acute side effects of chemotherapy, including febrile neutropenia
- TLS
- DIC
- Late-onset cardiomyopathy in patients treated with anthracyclines
- Chronic side effects of chemotherapy (secondary malignancies)
- Graft-versus-host disease in patients who have received allogeneic BMT

## Codes

**&NA;**

### ICD10

- C92.00 Acute myeloblastic leukemia, not having achieved remission
- C92.01 Acute myeloblastic leukemia, in remission
- C92.02 Acute myeloblastic leukemia, in relapse

## Clinical Pearls

**&NA;**

- Prognosis of leukemia depends on the cytogenetic and molecular profile of the disease.
- Allogeneic transplant remains the only therapy with curative potential for patients with intermediate and high-risk AML.

# Leukemia, Chronic Lymphocytic

Jan Cerny, MD, PhD

## BASICS

### DESCRIPTION

- Chronic lymphocytic leukemia (CLL) is a monoclonal disorder characterized by a progressive accumulation of mature but functionally incompetent lymphocytes.
- CLL should be distinguished from prolymphocytic leukemia (PLL); based on percentage of prolymphocytes, the disease may be regarded as CLL (<10% prolymphocytes), PLL (>55% prolymphocytes), or CLL/PLL (>10% and <55% prolymphocytes).
- Small lymphocytic lymphoma is a lymphoma variant of CLL.
- System(s) affected: hematologic, lymphatic, immunologic

### EPIDEMIOLOGY

#### Incidence

- With 15,000 to 17,000 new cases reported every year, CLL *represents the most common form of leukemia in adults in the United States.*
- In 2013, an estimated 4,580 adults in United States will die from CLL, which makes it the second leading cause of death among adults with leukemia in United States after acute myeloid leukemia (1)[A].
- Predominant age: CLL primarily affects elderly individuals, median age of diagnosis being 70 years. The incidence continues to rise in those age >55 years.
- Predominant sex: male > female (1.7:1)
- The incidence is higher among whites than among African Americans.

### ETIOLOGY AND PATHOPHYSIOLOGY

- The cell of origin in CLL is a clonal B cell arrested in the B-cell differentiation pathway, intermediate between pre-B cells and mature B cells. In the peripheral blood, these cells resemble mature lymphocytes and typically show B-cell surface antigens: CD19, CD20, CD21, and CD23. In addition, they express CD5 (usually found on T cells).

- The BCL-2 protooncogene is overexpressed in B-CLL. BCL-2 is a known suppressor of apoptosis (programmed cell death), resulting in extremely long life of the affected lymphocytes.
  - Unknown, but genetic mutations leading to disrupted function and prolonged survival of affected lymphocytes are suspected.

## *Genetics*

CLL is an acquired disorder, and reports of truly familial cases are exceedingly rare. CLL has been shown, however, to occur at higher frequency among first-degree relatives of patients with the disease, and several somatic gene mutations have been identified at significantly higher rates among CLL patients.

## **RISK FACTORS**

- As in the case of most malignancies, the exact cause of CLL is uncertain.
- Possible chronic immune stimulation is suspected but is still being elucidated.
- Monoclonal B-cell lymphocytosis: 1% risk progression to CLL

## **GENERAL PREVENTION**

Unknown

## **COMMONLY ASSOCIATED CONDITIONS**

- Immune system dysregulation is common.
- Autoimmune hemolytic anemia (AIHA) may accompany CLL.
- Immune thrombocytopenic purpura (ITP) may accompany CLL.
- Pure red cell aplasia (PRCA) may accompany CLL.

## **DIAGNOSIS**

### **HISTORY**

- Insidious onset; it is not unusual for CLL to be discovered incidentally. Up to 40% of patients are asymptomatic at the time of diagnosis.
- Others may have the following:
  - Repetitive infections (e.g., not only pneumonia but also mucocutaneous herpetic infections)
  - Enlarged lymph nodes

- Early satiety and/or abdominal discomfort related to an enlarged spleen
- Mucocutaneous bleeding and/or petechiae due to thrombocytopenia
- Fatigue-related and/or other symptoms of anemia
- Fevers, night sweats, >10% weight loss (B symptoms)

## *PHYSICAL EXAM*

- Localized or generalized lymphadenopathy
- Splenomegaly (30-40%)
- Hepatomegaly (20%)
- Mucocutaneous bleeding (thrombocytopenia)
- Skin petechiae (thrombocytopenia)
- Pallor

## *DIFFERENTIAL DIAGNOSIS*

- Infectious causes are the following:
  - Bacterial (tuberculosis)
  - Viral (mononucleosis)
- Malignant causes are the following:
  - Leukemic phase of non-Hodgkin lymphomas
  - Hairy cell leukemia
  - Waldenstrom macroglobulinemia
  - Large granular lymphocytic leukemia

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- CBC with differential shows B cell absolute lymphocytosis with  $>5,000$  B lymphocytes/ $\mu\text{m}^3$ L. The blood smear also shows ruptured lymphocytes (smudge cells) and morphologically mature-appearing small lymphocytes.
- Exam of the blood smear is important in diagnosis of CLL.
- Diagnosis can be confirmed by immunophenotyping: CLL cells are positive for CD19, CD20,

and CD24 as well as CD5. They have low levels of surface membrane immunoglobulin (Ig) M or IgD. The monoclonality is proven by the presence of a single immunoglobulin light chain ( $\kappa$ ; or  $\lambda$ ). FMC7 is absent.

- CBC shows anemia and/or thrombocytopenia.
- Plasma  $\beta_2$ -microglobulin may be elevated.
- Serum protein electrophoresis (some patients may have monoclonal gammopathy)
- Lactate dehydrogenase (LDH) may be elevated (due to disease activity or to AIHA).
- Hypogammaglobulinemia
- In cases associated with AIHA, labs consistent with hemolysis may be present (elevated LDH, total bilirubin; reticulocyte count does not have to be elevated due to bone marrow infiltration).
- Liver/spleen ultrasound may demonstrate organomegaly and may also detect enlarged abdominal lymph nodes.
- CT scan of chest/abdomen/pelvis typically is not necessary for staging. However, it may help to identify compression of organs or internal structures from enlarged lymph nodes.
- Positron emission tomography (PET) scan might be helpful to guide biopsy if Richter transformation is suspected (see below).

### *Follow-Up Tests & Special Considerations*

Frequency and type of follow-up depend on severity of symptoms as well as risk factors (see *Prognosis*).

### *Diagnostic Procedures/Other*

- Although bone marrow biopsy has its prognostic value (diffuse infiltration is a risk factor), it is not done routinely.
- Consider a lymph node biopsy if lymph node(s) begins to enlarge rapidly in a patient with known CLL to assess the possibility of transformation to a high-grade lymphoma (Richter syndrome), especially when accompanied by fever, weight loss, and pain.

### *Test Interpretation*

- A bone marrow aspirate usually shows  $>30\%$  lymphocytes.
- Cytogenetic (fluorescence in situ hybridization) may show chromosomal changes, which are prognostic (i.e., del[13q], del[11q], del[17p], trisomy 12, and del[6q]).
- *SF3B1* mutation is associated with rapid disease progression and shorter survival in CLL (2)[A].

## TREATMENT

### GENERAL MEASURES

Patients with frequent infections associated with hypogammaglobulinemia are likely to benefit from monthly infusions of intravenous immunoglobulin (IVIG).

### MEDICATION

#### *First Line*

- Most patients are asymptomatic and do not need active treatment unless they have generalized (so-called B) symptoms, progressive marrow failure, AIHA or thrombocytopenia, progressive splenomegaly, massive lymphadenopathy, or progressive lymphocytosis (increase >50% in 2 months or a doubling time of <6 months).

P.603

- Low-risk disease, Rai stage 0, and Binet stage A require only periodic follow-up.
- Intermediate-risk group, Rai stages I and II, and Binet stage B could be observed until evidence of disease progression or development of symptoms.
- Treatment should be initiated in high-risk patients, Rai stage III and IV, and Binet stage C.
- Early treatment in low-risk group is not recommended.
- Three main groups of drugs used are alkylating agents (chlorambucil and, recently, bendamustine), purine analogues (fludarabine and pentostatin), and monoclonal antibodies (rituximab and alemtuzumab).
- Single-agent (fludarabine, bendamustine, or chlorambucil) or combination regimens commonly used
- Fludarabine-based regimens are FC (in combination with cyclophosphamide), FR (fludarabine + rituximab), and FCR (fludarabine + cyclophosphamide + rituximab).
- FCR is the widely used regimen of choice if patient can tolerate it.
- Steroids (prednisone) are useful in patients with autoimmune manifestations of CLL (e.g., AIHA, ITP).

#### *Second Line*

- Combinations of chemotherapeutic agents that patient did not fail yet. Occasionally, some patients can be retreated with a drug used previously.

- Ibrutinib, is a Bruton tyrosine kinase (BTK) inhibitor from a novel class of agents, which has a high level of activity in CLL (3)[A].
- Newer agents, like ofatumumab (novel anti-CD20), lenalidomide, and others, have shown promising activity.
- Alemtuzumab (anti-CD52) has shown activity in relapsed and refractory disease.
- Consider splenectomy (surgery/radiation) if massive splenomegaly causes significant anemia and thrombocytopenia.
- Allogenic and autologous stem cell transplant can be considered in high-risk and younger patients (limited data available).

## *ISSUES FOR REFERRAL*

- Surgical consultation for splenectomy in selected patients
- Bone marrow transplant in young patients with refractory disease (however, still considered experimental therapy)
  - Allogeneic hematopoietic stem cell transplant (HSCT) with nonmyeloablative conditioning offers lower treatment-related mortality and may be appropriate for certain patients.

## *ADDITIONAL THERAPIES*

Patients requiring therapy who are high-risk for tumor lysis syndrome should be given allopurinol to prevent uric acid nephropathy.

## *SURGERY/OTHER PROCEDURES*

- Splenectomy in selected patients with splenomegaly and refractory cytopenia
- Radiation (if compression symptoms from bulky lymphadenopathy)

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

No specific criteria but due to complications of disease (e.g., AIHA) or of therapy (e.g., febrile neutropenia) or significant tumor lysis syndrome after initiation of chemotherapy

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

## *Patient Monitoring*

Patients with low-risk CLL and/or patients in remission

- CBC with differential (lymphocytosis) every 3 to 6 months, LDH, &  $\beta_2$ -microglobulin, IgG level
- Physical exam (lymphadenopathy, splenomegaly)

## *DIET*

- Ensure adequately balanced calorie/vitamin intake.
- Follow weight.

## *PATIENT EDUCATION*

Leukemia and Lymphoma Society has educational pamphlets:

<http://www.webmd.com/cancer/tc/leukemia-topic-overview>.

## *PROGNOSIS*

There are two staging systems used: the Rai in the United States and the Binet in Europe. Neither is completely satisfactory.

- Rai staging system
  - Stage 0: lymphocytosis only; median survival of 120 months
  - Stage I: lymphocytosis and adenopathy; median survival of 95 months
  - Stage II: lymphocytosis and splenomegaly and/or hepatomegaly; median survival of 72 months
  - Stage III: lymphocytosis and anemia (hemoglobin <10 g/dL); median survival of 30 months
  - Stage IV: lymphocytosis and thrombocytopenia (platelets <100 × 10<sup>9</sup>/L); median survival of 30 months
- Binet staging system
  - Stage A: hemoglobin  $\geq$ 10 g/dL, platelets 100 × 10<sup>9</sup>, and <3 lymph node areas involved (Rai stages 0, I, and II); survival >120 months
  - Stage B: Hemoglobin and platelet levels as in stage A and 3 or more lymph node areas involved (Rai stages I and II); survival is 61 months.
  - Stage C: Hemoglobin <100 g/L, platelets <100 × 10<sup>9</sup>, or both (Rai stages III and IV); survival is 32 months.

- Adverse risk factors
  - Advanced Rai or Binet stage
  - Peripheral lymphocyte doubling time <12 months
  - Diffuse marrow infiltration
  - Increased number of prolymphocytes or cleaved cells
  - Poor response to chemotherapy
  - High  $\beta_2$ -microglobulin and thymidine kinase levels and low micro RNAs (miRNAs)
  - Abnormal karyotyping: deletion 17p (del[17p] P53 mutation or deletion) and del(11q)
  - New IgVH unmutated status (expression of ZAP-70 >20% or CD38 >30% evaluated by immunophenotyping are surrogate markers)
  - NOTCH1 mutation (also associated with unmutated IgVH)

## COMPLICATIONS

- Acute or long-term effects of chemotherapy
- Richter syndrome (above)
- AIHA (in some cases may be related to the use of fludarabine)
- Slightly increased risk of solid tumors (especially Kaposi sarcoma, malignant melanoma, laryngeal cancers, lung cancers)
- Infection (especially gram negative and encapsulated organisms)
- Membranoproliferative glomerulonephritis (MPGN) or other glomerular pathology

## Codes

&NA;

### ICD10

- C91.10 Chronic lymphocytic leuk of B-cell type not achieve remis
- C91.11 Chronic lymphocytic leukemia of B-cell type in remission
- C91.12 Chronic lymphocytic leukemia of B-cell type in relapse

## Clinical Pearls

&NA;

- CLL represents the most common form of leukemia in adults in the United States.
- Predominant age: CLL primarily affects elderly individuals, median age of diagnosis being 70 years. The incidence continues to rise in those age >55 years.
- Clinical monitoring of asymptomatic and low-risk patients is a reasonable approach (Òwatch and waitÓ).
- High-risk patients, bulky disease, or patients who fail fludarabine- and rituximab-based therapies have typically poor prognosis and may require intensive therapies, including allogeneic transplantation.
- Median survival is 3 to 10 years, depending on stage.

# Leukemia, Chronic Myelogenous

Jan Cerny, MD, PhD

## BASICS

### DESCRIPTION

- Chronic myelogenous leukemia (CML) is a myeloproliferative neoplasm characterized by clonal proliferation of myeloid precursors in the bone marrow with continuing differentiation into mature granulocytes.
- Hallmark of CML is Philadelphia chromosome (translocation t[9;22]).
- Natural history of the disease evolves in three clinical phases: a chronic phase, an accelerated phase, and blast phase or crisis (transformation to acute leukemia).

### EPIDEMIOLOGY

#### Incidence

- Per year, 1.6 cases/100,000 persons
- Predominant age: 50 to 60 years
- Predominant sex: male > female (1.3:1)

#### Prevalence

Accounts for 15-20% of adult leukemias

### ETIOLOGY AND PATHOPHYSIOLOGY

Philadelphia chromosome is a balanced translocation between *BCR* (on chromosome 22) and *ABL* (on chromosome 9) genes t(9;22)(q34;q11). This fusion gene, *BCR-ABL*, codes for an abnormal constitutively active tyrosine kinase that affects numerous signal transduction pathways, resulting in uncontrolled cell proliferation and reduced apoptosis.

#### Genetics

Acquired genomic changes

### RISK FACTORS

Ionizing radiation exposure (uncommon)

## GENERAL PREVENTION

None currently identified

## DIAGNOSIS

85-90% of patients present in the chronic phase, and the disease can be found accidentally during routine screening.

### HISTORY

- Chronic phase: fatigue, weight loss, night sweats, abdominal fullness owing to enlarged spleen, early satiety, dyspnea, bleeding. Rare: Bruising, left upper quadrant abdominal pain, sternal pain (owing to expanding bone marrow), and gouty arthritis; up to 30% of patients are asymptomatic.
- Accelerated phase: Progressive splenomegaly and left upper quadrant abdominal pain occasionally referred to the left shoulder (owing to splenic infarction or rupture), progressive weight loss and sweats, unexplained fever or bone pain, chloromas (extramedullary tumors).
- Blast phase: bleeding, bruising, infections, prominent constitutional symptoms

### PHYSICAL EXAM

- Splenomegaly (50-90%), hepatomegaly (up to 50%)
- Less common: splenic friction rub, lymphadenopathy

### DIFFERENTIAL DIAGNOSIS

- Chronic myelomonocytic leukemia, chronic neutrophilic leukemia, chronic eosinophilic leukemia, juvenile myelomonocytic leukemia, infectious mononucleosis, leukemoid reaction, polycythemia vera, and treatment with granulocyte-stimulating factors
- Acute myelogenous leukemia resembles blast crisis with myeloid blasts, and acute lymphoblastic leukemia resembles blast crisis with lymphoid blasts.
- Atypical CML is a chronic myeloproliferative disorder with a clinical hematologic picture similar to CML, but it lacks Philadelphia chromosome and *BCR-ABL* rearrangement.

### DIAGNOSTIC TESTS & INTERPRETATION

- CBC
  - Hematocrit: may be normal, slightly increased, or decreased
  - WBC count: markedly increased (50,000 to 100,000/ $\mu\text{g}/\text{L}$ ), with granulocytes in all stages of development, including occasional blasts <10% in chronic phase, basophilia, eosinophilia
  - Platelets: normal, elevated (34%), or occasionally low
  - In accelerated phase: anemia, 10-19% blood or marrow blasts, basophils plus eosinophils >20%, thrombocytopenia
  - Blast phase: blood or marrow blasts >20%
- Genetics
  - Demonstration of the Philadelphia chromosome, t(9;22), by cytogenetic techniques, fluorescence in situ hybridization (FISH), or reverse transcription polymerase chain reaction (RT-PCR)
  - Additional cytogenetic abnormalities occur in the accelerated and blast phases (monosomy 7, t[3;21], trisomies 8 and 19, Philadelphia chromosome duplication, abnormalities of chromosome 17 such as monosomy, trisomy, and isochromosome mutations). These may contribute to resistance to tyrosine kinase inhibitors (TKIs; e.g., imatinib). Further molecular testing (mutations within *BCR-ABL*) is suggested in case of loss of response to therapy.
- Others:
  - Low or absent leukocyte alkaline phosphatase in neutrophils
  - High lactate dehydrogenase (LDH)
  - Elevated uric acid

### *Initial Tests (lab, imaging)*

- CBC, LDH, uric acid, bone marrow biopsy and aspiration, cytogenetics on bone marrow, and FISH for *BCR-ABL*, RT-PCR, LFTs
- Abdominal ultrasound or CT scan shows splenomegaly; not mandatory.

### *Follow-Up Tests & Special Considerations*

- Mutation analysis of tyrosine kinase domain of *ABL* kinase, as they may cause resistance to therapy with TKIs
- HLA-A\*02 positive is associated with CML, and a protective effect is seen with the HLA-B\*35 allele (pooled odds ratio 0.64, 95% confidence interval 0.48 to 0.86).

## Diagnostic Procedures/Other

Bone marrow aspiration and biopsy

## Test Interpretation

Myeloid hyperplasia with elevated myeloid: erythroid ratio, normal maturation, marrow basophilia, and increased reticulin fibrosis

## TREATMENT

### MEDICATION

- TKIs (e.g., imatinib) provide durable, long-term control of disease.
- The response to TKIs is assessed at specific time points from the beginning of treatment and is categorized as follows:
  - Complete hematologic response (CHR): normalization of peripheral counts, no disease symptoms, no immature cells
  - Minor/partial/complete cytogenetic response (CCR): 1-34%, 35-90%, no Philadelphia-positive metaphases
  - Major molecular response (MMR): decreased level of *BCR-ABL* transcript by PCR 3-log
  - Complete molecular response (CMR): *BCR-ABL* transcript is undetectable by PCR.

### First Line

- Imatinib mesylate (Gleevec), an oral TKI, 400 mg/day
- Side effects: thrombocytopenia, anemia, elevated liver enzymes, edema, GI disturbances, rash
- International Randomized Study of Interferon versus STI571 (IRIS) established imatinib as first-line therapy (1)[A].
- Imatinib dose can be increased to 600 and 800 mg/day if only suboptimal response is achieved with standard dose.
- 2nd-generation TKIs have shown higher efficacy and fewer side effects and are approved for first-line therapy of chronic phase CML: nilotinib (Tasigna) and dasatinib (Sprycel) (2,3)[A].

### Second Line

- Dasatinib, 2nd-generation TKI; active against most of *BRC-ABL* mutants; not active in *T3151* mutation

- 100 mg/day in patients resistant or intolerant to imatinib and 70 mg BID for patients in accelerated or blastic phase
- Side effects: pleural effusions, cytopenias
- Nilotinib, also 2nd-generation TKI; highly selective and more potent *BCR-ABL* TKI; active against most *BRC-ABL* mutants; not active in *T3151* mutation
  - 400 mg PO BID in patients resistant or intolerant to imatinib in chronic or accelerated phase
  - Side effects: cytopenias, QTc prolongation, pancreatitis
- Bosutinib and omacetaxine are now approved for patient who failed or did not tolerate two TKIs previously. Ponatinib has now more restricted approval, but together with omacetaxine, they are the only effective agents in patients with *T3151* mutation. Agents targeting leukemic stem cells are being developed for clinical use.

## ISSUES FOR REFERRAL

All patients with CML should be referred to a hematologist. Patients with inadequate response to TKIs or with *T3151* mutation should consult with a bone marrow transplant physician.

## SURGERY/OTHER PROCEDURES

Allogenic bone marrow transplant (BMT)

- It is the only known cure; however, 71% of patients who achieve CCR with imatinib maintain that response for 7 years, and no patient progressed on the trial between years 5 and 6 of treatment.
- Most effective in patients <50 years of age who are in the chronic phase
- Initial mortality is higher (related to the use of myeloablative regimens) than medical management but provided higher rates of survival in pre-TKI era.
- Significant improvement in transplant techniques leading to better outcomes, such as alternative sources of stem cells; nonmyeloablative regimens have shown improvements in transplant-related mortality.
- Transplant option should be thoroughly discussed with young patients in chronic phase and considered an alternative to TKIs especially if the patient does not tolerate TKIs or disease is not responding.
- Can be considered in patients who fail to achieve CHR by 3 months, have no cytogenetic response or cytogenetic relapse, or have *T3151* mutation

# INPATIENT CONSIDERATIONS

## *Admission Criteria/Initial Stabilization*

Acute abdominal symptoms (infarcted or ruptured spleen); tumor lysis syndrome owing to initial therapy; complications of BMT

- Hydroxyurea might be given, with the goal of reduction of the WBC count, but it has minimal impact on patient response to TKIs.
- Induction chemotherapy (for acute leukemia) in setting of blastic phase
- Allopurinol to prevent tumor lysis syndrome in patients with very high counts; however, probably not necessary when TKIs are used

## *Discharge Criteria*

Abatement of acute symptoms

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

- Frequency depends on stage at presentation and response to first-line therapy
- Although splenomegaly persists, avoid contact sports or trauma to abdomen.

## *Patient Monitoring*

- CBC with differential: weekly until blood counts stable, then every 2 to 4 weeks during CHR; once in CCR and stable, patient can be followed less frequently (3-month intervals)
- Bone marrow cytogenetics (evaluation for clonal evolution) every 6 months while in CHR, every 12 to 18 months while in complete cytogenetic response, MMR, CMR
- Quantitative RT-PCR every 3 months (peripheral blood)
- ECGs (concern for QT prolongation), LFTs while on TKIs. Nilotinib, bosutinib, and ponatinib can cause pancreatitis.

## *PROGNOSIS*

- With treatment and good response, the survival is similar to the normal population.
- Without treatment: CML invariably will progress to accelerated phase within 2 to 5 years and blast phase within several months of the accelerated phase.

- Poor prognosis: patients presenting in accelerated or blastic phase or presenting with very large spleen size, platelets  $>700,000/\mu\text{m}^3$ , and patients resistant to TKIs (T3151 mutation)

## COMPLICATIONS

- Splenic infarct or rupture
- Progression to accelerated or blastic phase
- Thrombotic events owing to elevated platelets
- Bleeding owing to low or dysfunctional platelets
- Sequelae of anemia

Codes

**&NA;**

## **ICD10**

- C92.10 Chronic myeloid leukemia, BCR/ABL-positive, not having achieved remission
- C92.11 Chronic myeloid leukemia, BCR/ABL-positive, in remission
- C92.12 Chronic myeloid leukemia, BCR/ABL-positive, in relapse

## **Clinical Pearls**

**&NA;**

- CML belongs to the myeloproliferative disorders group
- The gold standard for diagnosis of CML is detection of the Philadelphia chromosome or its products, *BCR-ABL* mRNA, and fusion protein.
- TKIs provide durable, long-term control of the disease and have dramatically altered treatment.
- Atypical CML is a form of clinically typical CML but without the presence of the typical *BCR-ABL* translocation.
- Blast crisis is a form of acute leukemia that is a possible complication of CML.

# Leukoplakia, Oral

Christine K. Jacobs, MD, FAAFP

## BASICS

### DESCRIPTION

- Oral leukoplakia is defined by the World Health Organization as white plaques of questionable risk having excluded (other) known diseases or disorders that carry no increased risk for cancer (1)[C].
- System(s) affected: gastrointestinal

### EPIDEMIOLOGY

- Develops in middle age, increases with age
- Most common in India, where more people smoke and chew tobacco and areca nuts

### Prevalence

- 1-3% of the adult population is affected.
- Usual age of onset is over 40 years old with peak in the 60s.
- Males twice as often as females

### Geriatric Considerations

Malignant transformation to carcinoma is more common in older patients.

### ETIOLOGY AND PATHOPHYSIOLOGY

Hyperkeratosis or dyskeratosis of the oral squamous epithelium

- Tobacco use in any form
- Alcohol consumption/alcoholism
- Oral infections
- *Candida albicans* infection may induce dysplasia and increase malignant transformation (2)[B].
- Human papillomavirus, types 11 and 15

- Sunlight
- Vitamin deficiency
- Syphilis
- Dental restorations/prosthetic appliances
- Estrogen therapy
- Chronic trauma or irritation
- Epstein-Barr virus (oral hairy leukoplakia)
- Areca nut/betel (Asian populations)
- Mouthwash preparations and toothpaste containing the herbal root extract sanguinaria

## *Genetics*

- Dyskeratosis congenital and epidermolysis bullosa increase the likelihood of oral malignancy (1)[B].
- P53 overexpression correlates with leukoplakia and particularly squamous cell carcinoma (3) [B].

## *RISK FACTORS*

- 70-90% of oral leukoplakia is related to tobacco, particularly smokeless tobacco or areca/betel nut use.
- Alcohol increases risk 1.5-fold
- Repeated or chronic mechanical trauma from dental appliances or cheek biting
- Chemical irritation to oral regions
- Diabetes
- Age
- Socioeconomic status
- Risk factors for malignant transformation of leukoplakia
  - Female
  - Long duration of leukoplakia
  - Nonsmoker (idiopathic leukoplakia)
  - Located on tongue or floor of mouth

- Size >200 mm<sup>2</sup>
- Nonhomogenous type
- Presence of epithelial dysplasia

## GENERAL PREVENTION

- Avoid tobacco of any kind, alcohol, habitual cheek biting, tongue chewing.
- Use well-fitting dental prosthesis.
- Regular dental check-ups to avoid bad restorations
- Diet rich in fresh fruits and vegetables may help to prevent cancer.
- HPV vaccination may be preventive.

## COMMONLY ASSOCIATED CONDITIONS

- HIV infection is closely associated with hairy leukoplakia.
- Erythroplakia in association with leukoplakia, Ospeckled leukoplakia, or erythroleukoplakia is a marker for underlying dysplasia.

## DIAGNOSIS

Leukoplakia is an asymptomatic white patch on the oral mucosa.

### HISTORY

- Usually asymptomatic
- History of tobacco or alcohol use or oral exposure to irritants

## PHYSICAL EXAM

- Location
  - 50% on tongue, mandibular alveolar ridge, and buccal mucosa
  - Also seen on maxillary alveolar ridge, palate, and lower lip
  - Infrequently seen on floor of the mouth and retromolar areas
  - Floor of mouth, ventrolateral tongue, and soft palate complex are more likely to have dysplastic lesions.
- Appearance

- Varies from homogeneous, nonpalpable, faintly translucent white areas to thick, fissured, papillomatous, indurated plaques
- May feel rough or leathery
- Lesions can become exophytic or verruciform.
- Color may be white, gray, yellowish white, or brownish gray.
- Cannot be wiped or scraped off
- World Health Organization classification (1)
  - Homogeneous refers to color
    - Flat, corrugated, wrinkled, or pumice
  - Nonhomogeneous refers to color and texture (more likely to be dysplastic or malignant).
    - Erythroleukoplakia (mixture of red and white)
    - Exophytic: papillary or verrucous texture

## *DIFFERENTIAL DIAGNOSIS*

- White oral lesions that can be wiped away: acute pseudomembranous candidiasis
- White oral lesions that cannot be rubbed off (1)
  - Morsicatio buccarum (habitual cheek-biting), generally benign (4)[C]
  - Chemical injury
  - Acute pseudomembranous candidiasis
  - Traumatic or frictional keratosis (e.g., linea alba)
  - Leukoedema (benign milky opaque lesions that disappear with stretching)
  - Aspirin burn (from holding aspirin in cheek)
  - Lichen planus (bilateral fairly symmetric lesions, reticular pattern of slightly raised gray-white lines)
  - Lichenoid reaction
  - Verrucous carcinoma
  - Discoid lupus erythematosus
  - Skin graft (known history)
  - Squamous cell carcinoma

- Oral hairy leukoplakia, commonly on the lateral border of the tongue with a bilateral distribution (in HIV patients with Epstein-Barr virus infection)
- Smoker's palate (leukokeratosis nicotina palati)
- White sponge nevus (congenital benign spongy lesions)
- Syphilitic oral lesion
- Dyskeratosis congenita (a rare inherited multisystem disorder)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Biopsy to rule out carcinoma if lesion is persistent, changing, or unexplained

### ***Initial Tests (lab, imaging)***

- Laboratory tests generally are not indicated
  - Consider saliva culture if *C. albicans* infection is suspected.
- No imaging is indicated.

### ***Follow-Up Tests & Special Considerations***

- Biopsy is necessary to rule out carcinoma if lesion is persistent, changing, or unexplained (1).
- Consider CBC, rapid plasma reagin (RPR).

### ***Diagnostic Procedures/Other***

- Oral cytology is superior to conventional oral examination (5)[A].
- Computer-assisted cytology or liquid-based cytology is not superior to oral cytology (5)[A].
- Noninvasive brush biopsy and analysis of cells with DNA-image cytometry constitute a sensitive and specific screening method.
- Patients with dysplastic or malignant cells on brush biopsy should undergo more formal excisional biopsy (1).
- Excisional biopsy is definitive procedure.

---

P.607

### ***Test Interpretation***

- Biopsy specimens range from hyperkeratosis to invasive carcinoma.
- At initial biopsy, 6% are invasive carcinoma.

- 0.13-6% subsequently undergo malignant transformation
- Location is important: 60% on floor of mouth or lateral border of tongue are cancerous; buccal mucosal lesions are generally not malignant but require biopsy if not resolving.

## TREATMENT

- All oral leukoplakias should be treated.
- Treatment may include the following:
  - For 2 to 3 circumscribed lesions, surgical excision
  - For multiple or large lesions where surgery would cause unacceptable deformity, consider cryosurgery or laser surgery (6)[C].
  - Removal of predisposing habits (alcohol and tobacco)
- Complete excision is standard treatment for dysplasia or malignancy.
- After treatment, up to 30% of leukoplakia recurs, and some leukoplakia still transforms to squamous cell carcinoma (6)[B].
- Oral hairy leukoplakia may be treated with podophyllin with acyclovir cream (7)[A].

## GENERAL MEASURES

- Eliminate habitual lip biting.
- Correct ill-fitting dental appliances, bad restorations, or sharp teeth.
- Stop smoking and using alcohol.
- Some small lesions may respond to cryosurgery.
- *&agr*-carotene, lycopene, retinoids, and cyclooxygenase 2 (COX-2) inhibitors may cause partial regression.
- For hairy tongue: tongue brushing

## MEDICATION

Carotenoids, vitamins A, C, and K, bleomycin, and photodynamic therapy ineffective to prevent malignant transformation and recurrence (8)[A]

## ISSUES FOR REFERRAL

Consider otolaryngologist or oral surgery referral for extensive disease

## ***SURGERY/OTHER PROCEDURES***

- Scalpel excision, laser ablation, electrocautery, or cryoablation
- Cryotherapy slightly less effective than photodynamic therapy response (73% vs. 90%) and recurrence (27% vs. 24%) (9)[A]
- CO<sub>2</sub> laser had 20% recurrence and 10% malignant transformation within 5 years (10)[B].

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Eliminate etiologic factors.
- Reevaluate in 7 to 14 days.
- Biopsy if lesion is persistent.

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

### ***Patient Monitoring***

- Regular, close follow-up, even after successful treatment
- Biopsy as needed

## ***DIET***

Regular

## ***PATIENT EDUCATION***

- If biopsy is negative, stress importance of periodic and careful follow-up.
- Initiate a dental referral to eliminate dental factors.
- Stress importance of stopping tobacco and alcohol use.
- Encourage participation in smoking cessation program.

## ***PROGNOSIS***

- Most leukoplakia is benign.
- Leukoplakia may regress, remain stable, or progress.

- 0.13-6% of initially benign lesions subsequently develop into cancer.
- More likely to be cancerous if on floor of mouth or lateral border of tongue

## COMPLICATIONS

- New lesions may develop after treatment.
- Risk of malignant transformation to squamous cell carcinoma is approximately 5-17% (11)[B].
- Larger lesions and nonhomogeneous leukoplakia are associated with higher rates of malignant transformation.

## Codes

&NA;

## ICD10

- K13.21 Leukoplakia of oral mucosa, including tongue

- K13.3 Hairy leukoplakia

## Clinical Pearls

**&NA;**

- Excisional biopsy is indicated for any undiagnosed leukoplakia.
- After treatment, up to 30% of leukoplakia recurs, and some leukoplakia still transforms to squamous cell carcinoma; thus, long-term surveillance is essential.
- To lessen risk of malignant transformation, encourage tobacco and alcohol cessation and consider *C. albicans* eradication.

# Lichen Planus

Mercedes E. Gonzalez, MD, FAAD

Herbert P. Goodheart, MD

## BASICS

Lichen planus (LP) is an idiopathic eruption with characteristic shiny, flat-topped (Latin: *planus*, ÒflatÓ) purple (violaceous) papules and plaques on the skin, often accompanied by characteristic mucous membrane lesions. Itching may be severe.

## DESCRIPTION

- Classic (typical) LP is a relatively uncommon inflammatory disorder of the skin and mucous membranes; hair and nails may also be affected.
  - Skin lesions are small, flat, angular, red-to-violaceous, shiny, pruritic papules and/or plaques with overlying fine, white lines (called Wickham striae), or gray-white puncta; most commonly seen on the flexor surfaces of the upper extremities, extensor surfaces of the lower extremities, the genitalia, and on the mucous membranes
  - On the oral mucosa, lesions typically appear as raised white lines in a lacelike pattern seen most often on the buccal mucosa.
  - Onset is abrupt or gradual. Course is unpredictable; may resolve spontaneously, recur intermittently, or persist for many years
- Drug-induced LP
  - Clinical and histopathologic findings may mimic those of classic LP. Lesions usually lack Wickham striae (see in the following text) and oral involvement is rare.
  - There is generally a latent period of months from drug introduction until lesions appear.
  - Lesions resolve when the inciting agent is discontinued, often after a prolonged period.
- LP variants
  - Follicular: also called lichen planopilaris; typically seen on the scalp, can lead to scarring alopecia
  - Annular: Papules spread centrifugally as central area resolves; occur on glans penis, axillae, and oral mucosa

- Linear: may be an isolated finding
  - Hypertrophic: itchy, hyperkeratotic, thick plaques on dorsal legs and feet
  - Atrophic: rare, most often the result of resolved lesions
  - Bullous LP: Intense inflammation in the dermis leads to blistering of epidermis.
  - LP pemphigoides: a combination of LP and bullous pemphigoid (IgG autoantibodies to collagen 17)
  - Nail LP: affects the nail matrix, lateral thinning, longitudinal ridging, and fissuring
- System(s) affected: skin/exocrine
  - Synonym(s): lichenoid eruptions

## *EPIDEMIOLOGY*

- Predominant age: 30 to 60 years old; rare in children and the geriatric population
- Predominant sex: female > male

## *Prevalence*

In the United States, 450/100,000

## *ETIOLOGY AND PATHOPHYSIOLOGY*

LP is considered to be a T-cell-mediated autoimmune response to self-antigens on damaged keratinocytes.

## *RISK FACTORS*

Exposure to certain drugs or chemicals

- Thiazides, furosemide, *&bgr;*-blockers, sulfonyleureas, antimalarials, penicillamine, gold salts, and angiotensin-converting enzyme inhibitors
- Rarely: photo-developing chemicals, dental materials, tattoo pigments

## *COMMONLY ASSOCIATED CONDITIONS*

- An association has been noted between LP and hepatitis C virus infection, particularly in certain geographic regions (Asia, South America, the Middle East, Europe) (1). Hepatitis should be considered in patients with widespread presentations of LP and those with primarily oral disease.
- In addition, chronic active hepatitis, lichen nitidus, and primary biliary cirrhosis have been noted to coexist with LP.

- Association with dyslipidemia has been reported (2)[B].
- LP has also been reported in association with other diseases of altered immunity, more often than would be expected by chance.
  - Bullous pemphigoid
  - Alopecia areata
  - Myasthenia gravis
  - Vitiligo
  - Ulcerative colitis
  - Graft-versus-host reaction
  - Lupus erythematosus (lupus erythematosus-LP overlap syndrome)
  - Morphea and lichen sclerosis et atrophicus

## DIAGNOSIS

LP is most commonly diagnosed by its appearance despite its range of clinical presentations. A skin biopsy should be performed if the diagnosis is in doubt.

### HISTORY

A minority of patients have a family history of LP. Affected families have an increased frequency of human leukocyte antigen B7 (HLA-B7). A thorough drug history should be performed.

### PHYSICAL EXAM

- Skin (often severe pruritus)
  - Papules: 1 to 10 mm, shiny, flat-topped (planar) lesions that occur in crops; lesions may have a fine scale.
  - Evidence of scratching (i.e., crusts and excoriations) is usually absent.
  - Color: violaceous, with white lacelike pattern (Wickham striae) on surface of papules. Wickham striae are best seen after topical application of mineral oil and, if present, are virtually pathognomonic for LP.
  - Shape: polygonal or oval. Annular lesions may appear on trunk and mucous membranes. Various shapes and sizes may be noted (polymorphic).
  - Arrangement: may be grouped, linear, or scattered individual lesions

- Koebner phenomenon (isomorphic response): New lesions may be noted at sites of minor injuries, such as scratches or burns.
- Distribution: ventral surface of wrists and forearms, dorsal hands, glans penis, dorsal feet, groin, sacrum, shins, and scalp. Hypertrophic (verruccous) lesions may occur on lower legs and may be generalized.
- Postinflammatory hyperpigmentation: Lesions typically heal, leaving darkly pigmented macules in their wake.
- Mucous membranes (40-60% of patients with skin lesions; 20% have mucous membrane lesions without skin involvement)
  - Most commonly asymptomatic, nonerosive, milkywhite lines with an elegant, lacy, netlike streaked pattern
  - Usually seen on buccal mucosa but may appear on tongue, gingiva, palate, or lips
  - Less commonly, LP may be erosive; rarely bullous
  - Painful, especially if ulcers present
  - Lesions may develop into squamous cell carcinoma (1-3%).
  - Glans penis, labia minora, vaginal vault, and perianal areas may be involved.
- Hair/scalp
  - LP of the hair follicle (lichen planopilaris) presents with keratotic plugs at the follicle orifice with a violaceous rim; may result in atrophy and permanent destruction of hair follicles (scarring alopecia)
- Nails (10%)
  - Involvement of nail matrix may cause proximal-to-distal linear grooves and partial or complete destruction of nail bed with pterygium formation.

## *DIFFERENTIAL DIAGNOSIS*

- Skin
  - Lichen simplex chronicus
  - Eczematous dermatitis
  - Psoriasis
  - Discoid lupus erythematosus

Other lichenoid eruptions (those that resemble LP)

- Pityriasis rosea
- Lichen nitidus
- Oral mucous membranes
  - Leukoplakia
  - Oral hairy leukoplakia
  - Candidiasis
  - Squamous cell carcinoma (particularly in ulcerative lesions)
  - Aphthous ulcers
  - Herpetic stomatitis
  - Secondary syphilis
- Genital mucous membranes
  - Psoriasis (penis and labia)
  - Nonspecific balanitis, Zoon balanitis
  - Fixed drug eruption (penis)
  - Candidiasis (penis and labia)
  - Pemphigus vulgaris, bullous pemphigoid, and Behçet disease (all rare)
- Hair and scalp
  - Scarring alopecia (central centrifugal cicatricial alopecia)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

If suggested by history

- Serology for hepatitis
- Liver function tests

---

P.609

### ***Diagnostic Procedures/Other***

- Skin biopsy
- Direct immunofluorescence helps to distinguish LP from discoid lupus erythematosus.

## Test Interpretation

- Dense, bandlike (lichenoid) lymphocytic infiltrate of the upper dermis
- Vacuolar degeneration of the basal layer
- Hyperkeratosis and irregular acanthosis, increased granular layer
- Basement membrane thinning with *Ìsaw-toothing*
- Degenerative keratinocytes, known as colloid or Civatte bodies, are found in the lower epidermis.
- Melanin pigment in macrophages

## TREATMENT

Although LP can resolve spontaneously, treatment is usually requested by patients who may be severely symptomatic or troubled by its cosmetic appearance.

## GENERAL MEASURES

- Goal is to relieve itching and resolve lesions.
- Asymptomatic oral lesions require no treatment.

## MEDICATION

### First Line

- Skin
  - Superpotent topical steroids (e.g., 0.05% clobetasol propionate) twice daily.
    - Potent topical steroids such as triamcinolone acetonide 0.1% or fluocinonide 0.05% under occlusion
    - Intralesional corticosteroids (e.g., triamcinolone [Kenalog] 5 to 10 mg/mL) for recalcitrant and hypertrophic lesions
    - Antihistamines (e.g., hydroxyzine, 25 mg PO q6h) have limited benefit for itching but may be helpful for sedation at bedtime.
    - *ÌSoak and smear* technique: can lead to a rapid improvement of symptoms in even 1 to 2 days and may obviate the need for systemic steroids. Soaking allows water to hydrate the stratum corneum and allows the anti-inflammatory steroid in the ointment to penetrate more deeply into the skin. Smearing of the ointment traps the water in the skin because

water cannot move out through greasy materials.

- Soaking is done in a bathtub using lukewarm plain water for 20 minutes, then, without drying the skin, the affected area is immediately smeared with a thin film of the steroid ointment containing clobetasol or another superpotent topical steroid.
  - Soak and smear may be done for 4 to 5 days or longer, if necessary. The treatments are best done at night because the greasy ointment applied to the skin gets on pajamas (instead of on daytime clothes) and the ointment is on the skin during sleep. A topical steroid cream is applied thereafter during the daytime hours, if necessary.
- Mucous membranes
    - For oral, erosive, painful LP, a Cochrane review found at best weak evidence for the effectiveness of any intervention (3)[A].
      - Topical corticosteroids (0.1% triamcinolone [Kenalog] in Orabase) or 0.05% clobetasol propionate ointment BID
      - Intralesional corticosteroids
      - Topical 0.1% tacrolimus (Protopic ointment) BID or 1% pimecrolimus (Elidel) cream BID. A Cochrane review found no evidence that calcineurin inhibitors are better than placebo (4)[A].
      - Topical retinoids (e.g., 0.05% tretinoin [retinoic acid] in Orabase)

## *Pediatric Considerations*

Children may absorb a proportionally larger amount of topical steroid because of larger skin surface-to-weight ratio.

## *Second Line*

Skin and mucous membranes

- Intralesional corticosteroids
- Topical 0.1% tacrolimus (Protopic ointment) BID or topical 1% pimecrolimus (Elidel) cream BID
- Oral prednisone: used only for a short course (e.g., 30 to 60 mg/day for 2 to 4 weeks) or IM triamcinolone (Kenalog) 40 to 80 mg every 6 to 8 weeks
  - Precautions with systemic steroids
    - Systemic absorption of steroids may result in hypothalamic-pituitary-adrenal axis suppression, Cushing syndrome, hyperglycemia, or glucosuria.

- Increased risk with high-potency topical steroids (i.e., use over large surface area, prolonged use, occlusive dressings)
- In pregnancy: usually safe, but benefits must outweigh the risks
- Oral retinoids: Isotretinoin in doses of 10 mg PO daily for 2 months, acitretin 30 mg, or alitretinoin 30 mg PO daily have resulted in improvement in some refractory cases. Observe carefully for resultant dyslipidemia.
- Oral metronidazole 500 mg BID for 20 to 60 days can be given as a safer alternative to systemic corticosteroids.
- Cyclosporine may be used in severe cases, but cost and potential toxicity limit its use; topical use for severe oral involvement refractory to other treatments
- Thalidomide
- Psoralen ultraviolet-A (PUVA), broad- or narrowband ultraviolet B (UVB) (5)[A]
- Griseofulvin (5)[A]
- Azathioprine
- Mycophenolate mofetil
- Metronidazole

## **ALERT**

Avoid oral and topical retinoids during pregnancy.

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

Outpatient care

## **ONGOING CARE**

## **FOLLOW-UP RECOMMENDATIONS**

### *Patient Monitoring*

Serial oral examinations for erosive/ulcerative lesions

## **PATIENT EDUCATION**

- Oral, erosive, or ulcerative LP: annual follow-up to screen for malignancy (6)[A]

- Avoid spicy foods, cigarettes, and excessive alcohol.
- Avoid dry crispy foods such as corn chips, pretzels, and toast.

## PROGNOSIS

- Spontaneous resolution in weeks is possible, but disease may persist for years, especially oral lesions and hypertrophic lesions on the shins.
- There is a tendency toward relapse.
- Recurrence in 12-20%, especially in those with generalized involvement

## COMPLICATIONS

- Alopecia
- Nail destruction
- Squamous cell carcinoma of the mouth or genitals

## Codes

**&NA;**

### ICD10

- L43.9 Lichen planus, unspecified
- L43.0 Hypertrophic lichen planus
- L43.1 Bullous lichen planus

## Clinical Pearls

**&NA;**

- Remember the 7 P's of LP: **p**urple, **p**lanar, **p**olygonal, **p**olymorphic, **p**ruritic (not always), **p**apules that heal with **p**ostinflammatory hyperpigmentation.
- Serial oral or genital exams are indicated for erosive/ulcerative LP lesions to monitor for the development of squamous cell carcinoma.
- An association has been noted between LP and hepatitis C virus infection, chronic active hepatitis, and primary biliary cirrhosis.
- The Ôsoak and smearÓ technique can lead to a rapid improvement of symptoms in 1 to 2 days and may obviate the need for systemic steroids.

# Lichen Simplex Chronicus

Geoffrey Strider Farnsworth, MD

## BASICS

### DESCRIPTION

- Lichen simplex chronicus (LSC) is a chronic dermatitis resulting from chronic, repeated rubbing or scratching of the skin. Skin becomes thickened with accentuated lines (ÖlichenificationÓ).
- System(s) affected: skin
- Synonym(s): LSC; lichen simplex; localized neurodermatitis; neurodermatitis circumscripta

### EPIDEMIOLOGY

#### *Geriatric Considerations*

Most common in middle aged and elderly

#### *Pediatric Considerations*

Rare in preadolescents

#### *Incidence*

- Common
- Peak incidence 35 to 50 years
- Predominant sex: females > males (2:1)

#### *Prevalence*

Common

### ETIOLOGY AND PATHOPHYSIOLOGY

- Itch-scratch cycle leads to a chronic dermatosis. Repeated scratching or rubbing causes inflammation and pruritus, which leads to continued scratching.
- Primary LSC: Scratching secondary to nonorganic pruritus, habit or a conditioned response to stress/anxiety

- Common triggers are excess dryness of skin, heat, sweat, and psychological stress.
- Secondary LSC: begins as a pruritic skin disease that evolves into neurodermatitis, which persists after resolution of the primary condition. Precursor dermatoses include atopic dermatitis, contact dermatitis, lichen planus, stasis dermatitis, psoriasis, tinea, and insect bites.
- There is a possible relation between disease development and underlying neuropathy, particularly radiculopathy or nerve root compression.
- Pruritus-specific C neurons are temperature sensitive, which may explain itching that occurs in warm environments.

## *RISK FACTORS*

- Anxiety disorders
- Dry skin
- Insect bites
- Pruritic dermatosis

## *GENERAL PREVENTION*

Avoid common triggers such as psychological distress, environmental factors such as heat and excessive dryness, skin irritation, and the development of pruritic dermatoses.

## *COMMONLY ASSOCIATED CONDITIONS*

- Prurigo nodularis is a nodular variety of the same disease process.
- Atopic dermatitis
- Anxiety, depression, and obsessive-compulsive disorders

## **DIAGNOSIS**

### **HISTORY**

- Gradual onset
- Begins as a localized area of pruritus
- Most patients acknowledge that they respond with vigorous rubbing, itching, or scratching, which brings temporary satisfaction.
- Pruritus is typically paroxysmal, worse at night, and may lead to scratching during sleep.
- Can be asymptomatic with patient scratching at night while asleep

---

## *PHYSICAL EXAM*

- Well-circumscribed lichenified plaques with varying amounts of overlying excoriation or scaling
- Lichenification: accentuation of normal skin lines
- Hyperpigmentation or hypopigmentation can be seen.
- Scarring is uncommon with typical LSC; can be seen following ulcer formation or secondary infection.
- Most commonly involves easily accessible areas
  - Lateral portions of lower legs/ankles
  - Nape of neck (lichen simplex nuchae)
  - Vulva/scrotum/anus
  - Extensor surfaces of forearms
  - Palmar wrist
  - Scalp

## *DIFFERENTIAL DIAGNOSIS*

- Lichen sclerosis
- Psoriasis
- Atopic dermatitis
- Contact, irritant, or stasis dermatitis
- Extramammary Paget disease
- Lichen planus
- Mycosis fungoides
- Lichen amyloidosis
- Tinea
- Nummular eczema

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

No specific diagnostic test

- Microscopy (i.e., KOH prep) and culture preparation may be helpful in identifying possible bacterial or fungal infection.

### *Diagnostic Procedures/Other*

- Skin biopsy if diagnosis is in question.
- Patch testing may be used to rule out a contact dermatitis.

### *Test Interpretation*

- Hyperkeratosis
- Acanthosis
- Lengthening of rete ridges
- Hyperplasia of all components of epidermis
- Mild to moderate lymphohistiocytic inflammatory infiltrate with prominent lichenification

## **TREATMENT**

### *GENERAL MEASURES*

- Patient education is critical.
- Low likelihood of resolution if patient unable to avoid scratching.
- Treatment aimed at reducing inflammation and pruritus.

### *MEDICATION*

#### *First Line*

- Reducing inflammation
  - Topical steroids are first-line agents (1,2)[C].
  - High-potency steroids alone, such as 0.05% betamethasone dipropionate cream or 0.05% clobetasol propionate cream, can be used initially but should be avoided on the face, anogenital region, or intertriginous areas. They should be used on small areas only, for no longer than 2 weeks except under the close supervision of a physician.
  - Switch to intermediate- or low-potency steroids as response allows.

- An intermediate-potency steroid, such as 0.1% triamcinolone cream, may be used for initial, brief treatment of the face and intertriginous areas, and for maintenance treatment of other areas.
  - A low-potency steroid, such as 1% hydrocortisone cream, should be used for maintenance treatment of the face and intertriginous areas.
  - Steroid tape, flurandrenolide, has optimized penetration and provides a barrier to continued scratching. Change tape once daily.
  - Intralesional steroids, such as triamcinolone acetate, are also safe and effective for severe cases.
- Preventing scratching
    - Topical antipruritic agents
    - 1st-generation oral antihistamines such as diphenhydramine and hydroxyzine for antipruritic and sedative effects
    - Sedating tricyclics, such as doxepin and amitriptyline, for nighttime itching
    - Itching may occur at night while the patient is asleep; occlusive dressings may be helpful in these cases.

## **ALERT**

High-dose and prolonged treatment with topical steroids can cause dermal/epidermal atrophy as well as pigmentary changes and should not be used on the face, intertriginous areas, or anogenital region. Duration of treatment on other parts of the body should not exceed 3 weeks without close physician supervision.

## *Second Line*

All recommendations

- Topical aspirin has been shown to be helpful in treating neurodermatitis (3)[C].
  - Topical 5% doxepin cream has significant antipruritic activity (3)[C].
  - Topical capsaicin cream can be helpful for treatment of early disease manifestations (3)[C].
- 
- 0.1% tacrolimus applied twice daily over 6 weeks for as an effective alternative treatment (4) [C]
  - Gabapentin was found to decrease symptoms in patients who are nonresponsive to steroids.
  - Topical lidocaine can be effective in decreasing neuropathic pruritus (3)[C].

- Intradermal botulinum toxin injections has been reported to improve symptoms in patients with recalcitrant pruritus.
- Transcutaneous electrical nerve stimulation may relieve pruritus in patients for whom topical steroids were not effective (5)[C].
- A case report showed NB-UVB as a possible off-label treatment of refractory LSC (6)[C].
- SSRIs may be effective in controlling compulsive scratching secondary to psychiatric diagnosis.

## *ISSUES FOR REFERRAL*

- No response to treatment
- Presence of signs and symptoms suggestive of a systemic cause of pruritus
- Consultation with a psychiatrist for patients with severe stress, anxiety, or compulsive scratching
- Consultation with an allergist for patients with multisystem atopic symptoms

## *ADDITIONAL THERAPIES*

- Cooling of the skin with ice or cold compresses
- Soaks and lubricants to improve barrier layer function
- Occlusion of lesion with bandages or Unna boots.
- Nail trimming
- Silk underwear to decrease friction in genital LSC.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Acupuncture has been shown as an effective treatment for pruritus (7)[C].
- Cognitive-behavioral therapy may improve awareness and help to identify coping strategies.
- Hypnosis may be beneficial in decreasing pruritus and preventing scratching.
- Homeopathic remedies (i.e., thuja and graphite) have been used.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

## *Patient Monitoring*

Patients should be followed for response to therapy, complications from therapy (especially topical steroids), and secondary infections.

## *DIET*

Regular balanced diet

## *PATIENT EDUCATION*

- Patients should understand the cause of this disease and the critical role they play in its resolution:
  - Emphasize that scratching and rubbing must stop for lesions to heal. Medications ineffective if scratching continues
- Stress reduction techniques can be useful for patients for whom stress plays a role.
- Avoid exposure to known triggers.

## *PROGNOSIS*

- Often chronic and recurrent
- Good prognosis if the itch-scratch cycle can be broken
- After healing, the skin should return to normal appearance but may also retain accentuated skin markings or post inflammatory pigmentary changes that may be slow to resolve.

## **COMPLICATIONS**

- Secondary infection
- Scarring is rare without ulceration or secondary infection.
- Complications related to therapy, as mentioned in medication precautions
- Squamous cell carcinoma within affected regions is rare.

## Codes

**&NA;**

### ICD10

L28.0 Lichen simplex chronicus

## Clinical Pearls

**&NA;**

- LSC is a chronic inflammatory condition that results from repeated scratching and rubbing.
- Primary LSC originates de novo, whereas secondary LSC occurs in the setting of a preexisting pruritic dermatologic condition.
- LSC is a clinical diagnosis based on history and skin examination with biopsy only indicated in difficult or unclear cases.
- Stopping the itch-scratch cycle through patient education, skin lubrication, and topical

medications is key.

- Treatment aimed at decreasing both inflammation and pruritus utilizing topical steroids and antipruritics.

# Lipoma

Bradley M. Turner, MD, MPH, MHA

## BASICS

### DESCRIPTION

- Lipomas are the most common soft tissue tumor (benign or malignant).
- One of several distinct benign lipomatous tumors. In its most conventional (simple) form, lipomas are composed of mature adipose tissue, typically enveloped by a well-defined thin fibrous capsule.
- Not distinguishable histologically from normal adipose tissue
- Several nonconventional forms of lipomas (less commonly encountered) have been described, which may present in multiple locations, contain varying amounts of both adipose and nonadipose tissue, and/or have more atypical cytologic features.
- These nonconventional variants include chondroid lipoma, myolipoma, lipoblastoma, angioliipoma, spindle cell lipoma/pleomorphic lipoma, intramuscular/intermuscular lipoma, lipoma of tendon sheath and joint, lipoma arborescens, lipomatosis of nerve, diffuse lipomatosis, multiple symmetric lipomatosis, adiposis dolorosa, and hibernoma.
- Typically slow growing, superficial (subcutaneous), and asymptomatic; less commonly presents as a painful (angioliipoma) or deep-seated lesion
- May present as an infiltrative lesion (cellular angioliipoma, diffuse lipomatosis, multiple symmetric lipomatosis (Madelung disease), and adiposis dolorosa (Dercum disease)
- Often found in the upper trunk, especially the shoulders, back, neck, and head; but can be found anywhere in the body
- Lipomas have been reported in anatomic locations as varied as cardiac, intrathoracic, endobronchial, retroperitoneal, breast, calf, thigh, scapular, intraosseous, fingers, palmar, toe, epidural, spinal, intra-articular (knee), parapharyngeal, nasopharyngeal, adrenal, inguinal, bladder, scrotal, ovarian, intracranial, intraneural, and GI tract (most often in the ileum).
- Lipomas can cause respiratory distress due to bronchial obstruction of major airways, GI obstruction or bleeding, neuropathic symptoms from compression in locations such as the forearm or ankle, or cord compression if in dural/medullary components of the spinal cord.
- Must be differentiated from other tumors, particularly liposarcomas, as treatment protocols

differ.

## ***EPIDEMIOLOGY***

- Lipomas can occur at any age but most commonly occur in middle-aged adults, typically in the 40- to 60-year-old age group.
- Hibernomas typically present in the 3rd decade.
- Conventional lipomas and most variants are rare in children; however, lipoblastoma and diffuse lipomatosis typically present in children <3 years of age.
- No clear gender predilection in conventional lipomas and most variants.
- Females reportedly more commonly diagnosed with chondroid lipoma, myolipoma, and adiposis dolorosa.
- Males reportedly more commonly diagnosed with spindle cell/pleomorphic lipoma, intramuscular/intermuscular lipoma, lipoblastoma, and multiple symmetric lipomatosis.
- Approximately 5% of patients have multiple lipomas.

## ***Incidence***

Has been reported as 2.1 per 1,000 individuals per year; however, incidence is difficult to accurately estimate.

## ***Prevalence***

Has been reported as present in ÷1% the population; however, as with incidence, prevalence is difficult to accurately estimate and is most likely underestimated.

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

- The etiology and pathogenesis of lipomas is unclear.
- A pathogenetic link between soft tissue trauma and the formation of lipomas has been suggested.
- Two potential explanations to correlate soft tissue trauma and adipose tissue tumor growth have been proposed:
  - Formation of so-called posttraumatic pseudolipomas by prolapsing adipose tissue through fascia resulting from direct impact
  - Lipoma formation as a result of preadipocyte differentiation and proliferation mediated by cytokine release following soft tissue trauma and hematoma formation

## Genetics

- Approximately 2/3 of lipomas demonstrate chromosomal aberrations.
- The most common chromosomal aberrations are rearrangements of the chromatin remodeling gene *HMGA2* on chromosome 12q15 (67%).
- Less common chromosomal aberrations include anomalies of the 13q12-22 region (15%) and rearrangements of the 6p21 region (5%).
- Frequent association of chromosomal aberrations in the long arm of chromosomes 13 and 16 with spindle cell/pleomorphic lipomas
- Consistent chromosomal aberrations identified in the long arm of chromosome 11 with hibernomas
- Various case reports of other chromosomal aberrations exist.

## RISK FACTORS

- Because the pathogenesis of lipomas is unclear, risk factors are difficult to qualify.
- Possible risk factors include obesity, alcohol abuse, liver disease, glucose intolerance, and soft tissue trauma (see *Etiology and Pathophysiology*).

## COMMONLY ASSOCIATED CONDITIONS

May appear as part of a hereditary syndrome: Dercum disease, Madelung syndrome (also known as Launois-Bensaude syndrome), Gardner syndrome, Cowden syndrome, and Bannayan-Riley-Ruvalcaba syndrome (children)

## DIAGNOSIS

### HISTORY

- Useful questions on history are duration, associated symptoms, tenderness, recurrence, progression, similar lesions, and weight loss.
- Lipomas are generally slow growing—if the presenting lesion is fast growing, suspect another diagnosis.

## PHYSICAL EXAM

- Lipomas are usually soft, homogenous, oval, and nontender, with a rubbery or doughy consistency; if hard, suspect another diagnosis.
- The overlying skin is typically mobile and normal in appearance; if erythematous, suspect

another diagnosis such as infection.

- Lipomas are commonly  $\leq 5$  cm in diameter. If larger, this raises suspicion for liposarcoma (1), although lipomas can be  $>10$  cm (2,3).

## ***DIFFERENTIAL DIAGNOSIS***

- Differential diagnosis includes a variety of benign and malignant tumors (1,4).
- The most common considerations include epidermal inclusion cyst, trichilemmal cysts, hematoma, vasculitis, panniculitis, rheumatic nodules, abscess/infection, and malignant disease.
- Trichilemmal cysts can often be differentiated from lipomas by their characteristic central punctum and surrounding induration.
- An abscess typically has pain, along with overlying induration and erythema.
- Diagnosis may be more challenging with other lesions, particularly deeper-seated lesions.
- Imaging, core needle biopsy, or excision can be useful in further clarifying the diagnosis (1,2,3,4).

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Patients presenting with smaller ( $\leq 5$  cm) subcutaneous lesions that are clinically considered lipomas typically will not receive preoperative imaging. Larger lesions with irregular shape and/or suggestion of myofascial involvement should receive preoperative imaging (1)[A].

### ***Initial Tests (lab, imaging)***

- Because of differences in treatment, prognosis, and long-term follow-up, it is important to preoperatively distinguish lipomas from liposarcomas and other malignant lesions (2,3,4,5,6). If there is doubt regarding nature of the lipoma, further testing is indicated.
- US, MRI, or CT can be used in the suspected diagnosis of lipoma (1,2).
- US may be limited with larger lesions or lesions which have atypical patterns (2).
- MRI is the most sensitive imaging modality for lipomatous masses, has a high negative predictive value (1)[A], and can be useful when US is equivocal (2)[A].
- MRI can be extremely helpful in distinguishing a lipoma from a liposarcoma (1,2)[B], although lipoma variants may show characteristics of a liposarcoma due to the presence of decreased adipose tissue, nonadipose tissue, and/or irregular margins.
- MRI findings suggestive of liposarcoma include nonadipose areas, a partially ill-defined margin, neurovascular involvement, enhancing thick/nodular septum, a bright signal intensity on T1-

weighted images that are not completely suppressed on T1 fat suppression images, and a high T2 signal within the lesion (1,2,3).

## Diagnostic Procedures/Other

- If diagnosis is in doubt, an open surgical incisional biopsy has traditionally been considered the "gold standard" to obtain a histologic diagnosis (4).
- A core-needle biopsy has been proposed as a preferred biopsy method that can provide accurate diagnosis and assessment of malignant potential if examined by an experienced pathologist (4)[C].
- Fine needle aspiration cytology is not considered appropriate for the initial diagnostic evaluation of mesenchymal tumors (4).

P.613

## Test Interpretation

- Pathologic interpretation is still generally considered as the "gold standard" of diagnosis (1,4).
- Lipomas are typically composed of benign adipose tissue, with inconspicuous nuclei, and varying amounts of connective tissue.
- Lipomas are typically surrounded by a fibrous, well-defined thin capsule that is separate from the surrounding tissue; however, this may not be present on the microscopic tissue due to sampling bias.
- Atypical features such as prominent or atypical nuclei, inflammation, fibrosis, and necrosis may be present and may be mistaken for atypical features seen in atypical lipomatous tumor/well-differentiated liposarcoma (ALT/WDL) (5).
- Pathologists may overcall a diagnosis of ALT/WDL in lipomas with atypical features (1,5,6).
- Complementary molecular testing may augment histologic diagnosis in challenging cases, as *MDM2* gene amplification is not present in benign lipomas but has been reported to be a highly sensitive marker in ALT/WDL (3,5,6)[B].

## TREATMENT

- If diagnostically certain that the lesion is a benign lipoma, observation is a consideration.
- Treatment of lipoma typically consists of surgical excision; however, advances in medical treatment can shrink lipomas (1)[A].
- Treatments like steroid injection or liposuction can be cosmetically useful in superficial lesions, particularly in locations where scars should be avoided (1)[A], although liposuction has not

always been associated with the best aesthetic outcomes (1)[C].

- A successful trial of lipomas treated with subcutaneous deoxycholate injections has been reported, suggesting that low-concentration deoxycholate may be a relatively safe and effective treatment for small collections of adipose tissue (1)[C].
- Indications for removal of a suspected lipoma include diagnostic uncertainty, cosmetic concerns, nerve impingement, pain, increase in size, irregular characteristics, size >5 cm, samples of a core needle biopsy consistent with atypical features, or features consistent with a sarcoma (1)[A].

## *SURGERY/OTHER PROCEDURES*

- Surgical removal techniques include enucleation/excisional biopsy and open incisional biopsy (1,4).
- In uncomplicated cases, the excision can be performed in the office or in the minor procedure room under local anesthetic.
- Plan the incision to follow skin lines, if possible, to minimize scarring. Use a surgical marker to draw out the palpable margins of the lipoma and the planned incision. The incision should be  $\div$ 50-75% of the length of the lipoma along Langer lines (defined as parallel skin creases correlating with the direction of least elasticity) (1)[C].
- After anesthetizing the skin with a local anesthetic, a linear incision is carried out down to the level of the capsule using a number 11 or 15 blade.
- Blunt dissection (curved hemostat) and sharp dissection (iris scissor) are used to separate the fibrous capsule from the surrounding soft tissue. Care must be taken not to invade the capsule to maintain proper aesthetics (1).
- As the lobule is lifted, the dissection is continued to free up the entire tumor.
- Apply pressure to the outside of the lipoma to express it through the skin opening. In many cases, the lipoma will simply pop out. If not, more dissection may be needed, or the incision may need to be lengthened.
- After the lipoma is out, pressure with gauze is usually all that is needed to obtain good hemostasis. If bleeding persists, use electrocoagulation before closing the incision (1).
- If necessary, dead space may be closed with deep absorbable sutures. The skin may be closed with nonabsorbable simple interrupted sutures or skin adhesive.
- A minimal scar technique to facilitate removal from a small incision using segmental dissection of the lipoma has been described (1)[B].
- It is advisable to send all biopsied tissue to pathology (1)[C].

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Usual surgical follow-up is needed to monitor for any complications.

### *PATIENT EDUCATION*

Handout: "What are lipomas?" *Am Fam Physician*. 2002;65(5):905. Available at: <http://www.aafp.org/afp/20020301/905ph.html>

### *PROGNOSIS*

Most lipomas grow very slowly, are asymptomatic, and remain stable. Recurrence after excision is rare (1-2%), unless the excision was incomplete.

### **COMPLICATIONS**

- Hematoma and seroma formation are the most common complications.
- Infection is rare but possible.
- The risk of recurrence is greatest with intramuscular lipomas and lipomas with infiltrating tendencies (cellular angiolipoma, diffuse lipomatosis, multiple symmetric lipomatosis, and adiposis dolorosa).
- Occasionally, a bilobar lipoma may be missed, resulting in "recurrence."

## Codes

### &NA;

## ICD10

- D17.9 Benign lipomatous neoplasm, unspecified
- D17.79 Benign lipomatous neoplasm of other sites
- D17.1 Benign lipomatous neoplasm of skin, subcu of trunk

# Clinical Pearls

## &NA;

- Lipomas are slow growing, often asymptomatic, and typically diagnosed without imaging or biopsy.
- Asymptomatic subcutaneous lipomas can be followed clinically unless there is diagnostic uncertainty, they are causing cosmetic or pain problems, are large (>5 cm) or growing rapidly, or causing compression of vital organs/nerves.
- Most symptomatic lipomas are removed surgically. With the appropriate indications, nonsurgical options are available.
- In uncomplicated cases, excision can be performed in the office setting and do not require preoperative testing.
- Consider referral to a subspecialist if a lipoma is in a delicate anatomic location or if there is a concern that the lesion might be malignant.

# Long QT Interval

Carl Bryce, MD, Capt, USAF

Matthew J. Snyder, DO

## BASICS

### DESCRIPTION

- QT interval: electrocardiogram (ECG) measurement that measures the duration of repolarization of myocardial cells. Measured from the onset of the QRS complex to the end of the T wave
- Corrected QT interval (QTc): QT interval corrected for heart rate (interval shortens with increased rate). See formulas.
- Prolonged QTc is generally defined as >470 ms for adult males and >480 ms for adult females (1):
  - 440 to 460 ms considered borderline in men
  - 440 to 470 ms considered borderline in women
  - 440 to 460 ms considered borderline in children aged 1 to 15 years old (2)
- Most cases of prolonged QT are acquired, but genetic mutations can also cause hereditary long QT syndromes (LQTS).
- Prolonged QTc from any cause can precipitate polymorphic ventricular tachycardia (VT) called torsade de pointes (TdP), leading to dizziness, syncope, and sudden cardiac death from ventricular fibrillation (VF).

### EPIDEMIOLOGY

#### *Incidence*

Incidence of medication-induced QTc prolongation and TdP varies with medication and a host of other factors. Exact incidences are difficult to estimate but may be 1:2,000 to 1:2,500.(1).

#### *Prevalence*

- Hereditary LQTS is estimated to occur in 1/2,500 to 1/7,000 births.

Five thousand people across the United States may die yearly due to LQTS-related cardiac arrhythmia (2).

## ETIOLOGY AND PATHOPHYSIOLOGY

- Acquired
  - Electrolyte abnormalities such as hypokalemia, hypomagnesemia
  - Hypothyroidism
  - Underlying heart disease
  - Medications (3)[A]
    - Antiarrhythmic medications (quinidine, procainamide, dofetilide, sotalol, disopyramide, and amiodarone)
    - Antipsychotic medications, especially if given IV (haloperidol<sup>\*</sup>, chlorpromazine<sup>\*</sup>, thioridazine<sup>\*</sup>, pimozide<sup>\*</sup>)
    - Many antidepressants (SSRIs, SNRIs, trazodone, TCAs)
    - Antibiotics/antivirals/antifungals (clarithromycin<sup>\*</sup>, erythromycin<sup>\*</sup> which are also CYP3A4 inhibitors)
    - Antiemetics (metoclopramide, ondansetron, promethazine)
    - Opioids (methadone<sup>\*</sup>, buprenorphine)
    - Antihistamines (cetirizine, hydroxyzine, diphenhydramine)
    - Decongestants (pseudoephedrine, phenylephrine)
    - Stimulants (albuterol, phentermine)
    - Misc: chloroquine<sup>\*</sup>, pentamidine<sup>\*</sup>
    - <sup>\*</sup>Denote high-risk medication for TdP.
- Congenital
  - Defective membrane proteins that work as channels for sodium and potassium in myocytes
- Pathophysiology
  - Depolarization of the myocardium results from the rapid influx of sodium through sodium channels and causes myocyte contraction, with resulting cardiac muscle contraction and systole (seen on ECG as the QRS complex).

- During repolarization, there is an efflux of potassium from the cell through both rapid ( $I_{Kr}$ ) and slow ( $I_{Ks}$ ) potassium channels. The T wave on an ECG represents myocyte repolarization.
- Drug-induced QT prolongation due to blockade of  $I_{Kr}$  leading to delayed repolarization (2).
- Medications, medical conditions, electrolyte disturbances, and genetic mutations that affect functioning of these membrane channels can cause delayed repolarization.
- Delayed repolarization can lead to a propensity for reentry and initiate TdP.
- TdP type rhythm may be self-limited but symptomatic (syncope or near syncope). It can also degrade into VF.

## Genetics

- 12 different genes have been linked to LQTS (3).
- Incomplete penetrance makes both diagnosis and management of asymptomatic disease challenging.
- LQTS 1 (42-54%) is the most common. Mutation causes a defect in the  $I_{Ks}$  transport protein. Arrhythmias can be triggered by tachycardia due to exercise (swimming seems to be especially problematic) and other high catecholamine states.
- LQTS 2 (35-45%) is a defect in the  $I_{Kr}$  transport protein that is sensitive to catecholamine surges. Sudden loud noises or emotional arousal can provoke arrhythmias.
- LQTS 3 (8%) is a defect in the sodium channel that allows an excess of sodium into the cell, increasing repolarization time. Arrhythmias tend to manifest more during rest or sleep.
- Jervell and Lange-Nielsen syndrome: Autosomal recessive form of LQTS that features homozygous mutations affect the  $I_{Ks}$  channel and presents with severe form of LQTS 1. Features also include deafness.
- Romano-Ward syndrome: autosomal dominant form of LQTS with variable penetrance. Hearing is normal.

## RISK FACTORS

For the feared complication, TdP, risk factors include the following (3):

- Female ( $\div 2$  times increased risk)
- QTc  $> 500$  ms (2 to 3 times increased risk)
- QTc  $> 60$  ms over previous baseline

- History of syncope or presyncope
- History of TdP
- Bradycardia
- Liver or kidney disease (by increasing blood levels of QT prolonging medications)
- Medications that cause QTc prolongation
  - High doses
  - Fast infusions
  - Combination of medications
- Electrolyte abnormalities
  - Hypokalemia
  - Hypomagnesemia
  - Hypocalcemia
- For hereditary LQTS
  - Catecholamine surges from exercise (especially swimming), emotional stress, loud noises

## GENERAL PREVENTION

- Avoid (or use with caution) causative medications, including combinations with potentially additive effects. Replete electrolytes (goal Mg >2, K 4.5 to 5.0) (4)[C]
- Treat underlying medical disease (hypothyroidism, cardiac disease).
- Avoid strenuous sports in LQTS.
- Avoid sudden loud noises in LQTS (alarm clocks, doorbells, telephones).
- 36th Bethesda Conference recommends restriction of athletes from participation to class 1A activities (e.g., bowling, golf, riflery) although evidence regarding safe participation is emerging (1)[C].

## DIAGNOSIS

### HISTORY

- Evaluate for syncope, near syncope, and associated precipitating events (such as emotional triggers, swimming, diving).
- Evaluate for history of seizures in patient or in family (tonic-clonic movement

may due to cerebral hypoperfusion during episodes of ventricular arrhythmia or due to seizure-like activity during a syncopal episode.)

- Detailed medication history
- Evaluate for family history of sudden death and syncope.
- Congenital deafness

## *PHYSICAL EXAM*

- Usually normal physical exam
- If underlying cardiac disease present, may have findings specific to cardiac condition
- Evaluate for signs of hypothyroidism.
- Congenital deafness may be present in some forms of LQTS.

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- ECG
- Metabolic panel
- Calcium level
- Magnesium level
- TSH

### *Follow-Up Tests & Special Considerations*

- Echocardiogram to evaluate for cardiomyopathy
- Outpatient cardiac rhythm monitoring
- Consider provocative testing (epinephrine infusion, exercise stress testing) to evaluate for QTc interval changes and/or to evaluate for coronary artery disease (2)[C].
  - Genetic testing for LQTS mutations

### *Test Interpretation*

- QTc calculation using ECG is best done by measuring the QT interval in lead II and measuring the RR interval immediately preceding this QT interval. The Bazett formula is commonly used, although it overcorrects for tachycardia and undercorrects for bradycardia (2).
- Bazett formula:  $QTc = QT/\sqrt{RR}$  (all measurements in seconds, and RR obtained by direct

measurement or 60/heart rate)

- Fridericia formula is similar to Bazett but uses a cube root instead of a square root of the RR interval.  $QTc = QT/(RR)^{1/3}$

## TREATMENT

### GENERAL MEASURES

- VT, TdP, and VF should be treated emergently as per ACLS guidelines.
- Cardiac pacing may be needed emergently for drug-induced TdP to prevent bradycardia.
- Withdraw offending agents, correct electrolytes (2)[C].

### MEDICATION

#### First Line

- For Tdp: magnesium sulfate 2 g infused over 2 to 15 minutes, followed by continuous infusion of 2 to 4 mg/min if needed. Monitor for magnesium toxicity in those with renal insufficiency (2)[C].
- For hereditary LQTS, to prevent life-threatening arrhythmias: Propranolol or nadolol are generally regarded as the best *&bgr;*-blockers for management of LQTS, though rigorous studies are lacking (4)[B].
- *&bgr;*-Blockers are effective in decreasing but not eliminating the risk of fatal arrhythmias.
- For high-risk patients or those who remain symptomatic on a *&bgr;*-blocker, implantable cardiac defibrillators (ICDs) with or without pacemaker is an important consideration (2)[B].

#### Second Line

- Atenolol or metoprolol may be used, although switching from other *&bgr;*-blockers may precipitate lethal or near-lethal events (4)[B].

### ISSUES FOR REFERRAL

- Refer to cardiologist for establishing diagnosis, especially for hereditary LQTS.
- Symptomatic prolonged QT

## SURGERY/OTHER PROCEDURES

- ICD for those with a history of major cardiac events
- Left cervical-thoracic sympathetic denervation was used for symptomatic LQTS prior to the advent of  $\beta$ -blockers. It is still an option for those patients with LQTS who are refractory to  $\beta$ -blocker therapy (3)[B].

## INPATIENT CONSIDERATIONS

### Admission Criteria/Initial Stabilization

- Patients with TdP, VT, and VF should be promptly treated as per ACLS guidelines. Correct electrolytes on an emergent basis. Evaluate for acquired QT prolongation. If no cause is found, consider hereditary LQTS.
- Patients with prolonged QTc and syncope/near syncope should be monitored on telemetry during evaluation.
- Monitor ECG if initiating medications or combining medications that may prolong QT, suggest at baseline, within 30 days, and then annually (3)[C].
- Monitor electrolytes and urgently treat hypomagnesemia and hypokalemia in those with significantly prolonged QT, and discontinue or change offending medications (5)[C].

## Nursing

- Avoid sudden loud noises or emotional stress for those who have LQTS.
- Review adherence to  $\beta$ -blocker therapy.
- Notify others if telemetry monitoring reveals prolonged QT interval in hospitalized patientsÑ they are at risk for poor outcomes (6).

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

On routine visits, ask about syncope, presyncope, and palpitations in those who have QTc prolongation.

- Patient monitoring: Consider ECG and/or outpatient cardiac rhythm monitoring with any medication additions or dosage changes that may cause further prolongation of the QTc.
- For those who may have symptomatic QTc prolongation of any cause, prompt evaluation is warranted.

- Check labs for electrolyte imbalances, correct as needed.

## **PATIENT EDUCATION**

- Educate patients with QTc prolongation about medications side effects and possibility of medication interactions.
- Patients with congenital forms of LQTS should be aware of, and avoid situations that may trigger torsade (depending on their specific gene mutation)
- Large emotional and psychological impact of diagnosis. Additional reading by Fortescue shares personal impact of LQTS.
- Information and support from groups listed (see "Additional Reading") may be helpful.

## **PROGNOSIS**

Untreated, quite poor. Perhaps 20% of untreated patients presenting with syncope die within 1 year, 50% within 10 years (3).

### ICD10

I45.81 Long QT syndrome

# Clinical Pearls

## &NA;

- Evaluate for acquired causes before making a diagnosis of hereditary LQTS.
- For accurate diagnosis, calculate QTc manually.
- The ideal management of TdP is prevention; avoid multiple stacking risk factors and seek alternates to high-risk medications, correct electrolytes, and monitor treatment with serial ECGs if no alternatives exist.
- Magnesium sulfate is the treatment of choice during ACLS for TdP.
- *β*-Blockers are initial treatment of choice for hereditary LQTS.

# Lung, Primary Malignancies

Maryann R. Cooper, PharmD, BCOP

Gerald Gehr, MD

## BASICS

### DESCRIPTION

- Lung cancers (primary) are the leading cause of cancer-related death in the United States (estimated 159,260 deaths in 2015, 27% of all cancer-related deaths).
- Divided into two broad categories
  - Non-small cell lung cancer (NSCLC) (>85% of all lung cancers)
    - Adenocarcinoma (÷40% of NSCLC): Most common type in the United States, most common type in nonsmokers, metastasizes earlier than squamous cell, poor prognosis; bronchoalveolar, a subtype of adenocarcinoma has better prognosis.
    - Squamous cell carcinoma (<25% of NSCLC): dose-related effect with smoking; slower growing than adenocarcinoma
    - Large cell (÷10% of NSCLC): prognosis similar to adenocarcinoma
  - Small cell lung cancer (SCLC) (16% of all lung cancers): centrally located, early metastases, aggressive
- Other: mesothelioma, carcinoid tumor, and sarcoma
- Staging
  - NSCLC: staged from 0 to IV based on: primary tumor (T), lymph node status (N), and presence of metastasis (M)
  - SCLC: staged based on disease location: limited to ipsilateral hemithorax (stages I-III B); extensive if metastatic beyond hemithorax (stages III B and IV)
- Tumor locations: upper: 60%; lower: 30%; middle: 5%; overlapping and main stem: 5%
- May spread by local extension to involve chest wall, diaphragm, pulmonary vessels, vena cava, phrenic nerve, esophagus, or pericardium
- Most commonly metastasize to lymph nodes (pulmonary, mediastinal), then liver, adrenal,

bone (osteolytic), kidney, brain

## *EPIDEMIOLOGY*

### *Incidence*

- Estimated 224,210 new cases in the United States in 2015
- Predominant age: >40 years; peak at 70 years
- Predominant sex: male > female

### *Prevalence*

- Most common cancer worldwide
- Lifetime probability: men: 1 in 13; women: 1 in 16

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Multifactorial; see Risk Factors.

### *Genetics*

NSCLC

- Oncogenes: Ras family (H-ras, K-ras, N-ras)
- Tumor suppressor genes: retinoblastoma, *p53*

## *RISK FACTORS*

- Smoking (relative risk [RR] 10 to 30)
- Secondhand smoke exposure
- Radon
- Environmental and occupational exposures
  - Asbestos exposure (synergistic increase in risk for smokers)
  - Air pollution
  - Ionizing radiation
  - Mutagenic gases (halogen ethers, mustard gas, aromatic hydrocarbons)
  - Metals (inorganic arsenic, chromium, nickel)
- Lung scarring from tuberculosis

- Radiation therapy to the breast or chest

## GENERAL PREVENTION

- Smoking cessation and prevention programs
- Screening recommended by USPSTF but remains controversial; the risks of screening (e.g., radiation, biopsy) may offset the benefit (1)[A].
- Annual screening with low-dose computed tomography in adults ages 55 to 80 years who have a 30 pack-year smoking history and currently smoke or have quit within the past 15 years
- Screening should be discontinued once a person has not smoked for 15 years or develops a health problem that substantially limits life expectancy or the ability or willingness to have curative lung surgery.
- Prevention via aggressive smoking cessation counseling and therapy; a 20-30% risk reduction occurs within 5 years of cessation.
- Avoid supplemental *&bgr;*-carotene and vitamin E in smokers.
- Avoid hormone replacement therapy in postmenopausal smokers or former smokers (increased risk of death from NSCLC).

## COMMONLY ASSOCIATED CONDITIONS

- Paraneoplastic syndromes: hypertrophic pulmonary osteoarthropathy, Lambert-Eaton syndrome, Cushing syndrome, hypercalcemia from ectopic parathyroid-releasing hormone, syndrome of inappropriate antidiuretic hormone (SIADH)
- Hypercoagulable state
- Pancoast syndrome
- Superior vena cava syndrome
- Pleural effusion
- Chronic obstructive pulmonary disease (COPD), other sequelae of cigarette smoking

## DIAGNOSIS

### HISTORY

- May be asymptomatic for most of course
- Pulmonary
  - Cough (new or change in chronic cough)

- Wheezing and stridor
- Dyspnea
- Hemoptysis
- Pneumonitis (fever and productive cough)
- Constitutional
  - Malaise
  - Bone pain (metastatic disease)
  - Fatigue
  - Weight loss, anorexia
  - Fever
  - Anemia
  - Clubbing of digits
- Other presentations:
  - Chest pain (dull, pleuritic)
  - Shoulder/arm pain (Pancoast tumors)
  - Dysphagia
  - Plethora (redness of face or neck)
  - Hoarseness (involvement of recurrent laryngeal nerve)
  - Horner syndrome
  - Neurologic abnormalities (e.g., headaches, syncope, weakness, cognitive impairment)
  - Pericardial tamponade (pericardial invasion)

## *PHYSICAL EXAM*

- General: pain, performance status, weight loss
- Head, eye, ear, nose, throat (HEENT): Horner syndrome, dysphonia, stridor, scleral icterus
- Neck: supraclavicular/cervical lymph nodes, mass
- Lungs: effusion, wheezing, airway obstruction, pleural effusion
- Abdomen/groin: hepatomegaly or lymphadenopathy
- Extremities: signs of hypertrophic pulmonary osteoarthropathy, deep venous thrombosis (DVT)
- Neurologic: Rule out cognitive and focal motor defects.

# *DIFFERENTIAL DIAGNOSIS*

- COPD (may coexist)
- Granulomatous (tuberculosis, sarcoidosis)
- Cardiomyopathy
- Congestive heart failure (CHF)

# *DIAGNOSTIC TESTS & INTERPRETATION*

## *Initial Tests (lab, imaging)*

- CBC
- BUN, serum creatinine
- Liver function tests (LFTs), lactate dehydrogenase (LDH)
- Electrolytes
  - Hypercalcemia (Paraneoplastic syndrome)
  - Hyponatremia (SIADH)
- Sputum cytology
- Chest x-ray (CXR) (compare with old films)
  - Nodule or mass, especially if calcified
  - Persistent infiltrate
  - Atelectasis
  - Mediastinal widening
  - Hilar enlargement
  - Pleural effusion
- CT scan of chest (with IV contrast material)
  - Nodule or mass (central or peripheral)
  - Lymphadenopathy
- Evaluation for metastatic disease
  - Brain MRI: Lesions may be necrotic, bleeding.
  - CT abdomen: hepatic, adrenal, renal masses

- Positron emission tomography (PET) scan: to evaluate metastasis
- Bone scan: advanced disease or bone pain

## *Follow-Up Tests & Special Considerations*

CBC, BUN, serum creatinine, LFTs prior to each cycle of chemotherapy

## *Diagnostic Procedures/Other*

- Biopsy with pathology review
- In patients with advanced NSCLC, determination of epidermal growth factor receptor (EGFR)-activating mutations, *KRAS/NRAS* mutations, and *ALK* gene rearrangements in patients with nonsquamous or mixed squamous histology
- Pulmonary function tests
- Enlarged mediastinal lymph nodes necessitate staging by mediastinoscopy, video-assisted thoracoscopy, or fine needle aspiration.
- Transbronchial biopsy (Wang needle)
- Bronchoscopy for surgical planning
- Bone marrow aspirate (small cell)
- Cervical mediastinoscopy (the upper, middle peritracheal, and subcarinal lymph nodes)
- Anterior mediastinotomy (the posterior mediastinum and peritracheal, subazygous, hilar, and aortopulmonary window nodal regions)
- Video-assisted thoracoscopy (associated pleural disease and suspected mediastinal nodal spread)

---

P.617

## *Test Interpretation*

Pathologic changes from smoking are progressive: basal cell proliferation, development of atypical nuclei, stratification, metaplasia of squamous cells, carcinoma in situ, and then invasive disease.

## **TREATMENT**

### **GENERAL MEASURES**

- NSCLC
  - Stage I, stage II, and selected stage III tumors are surgically resectable. Neoadjuvant or

adjuvant therapy is recommended for many patients with high risk IB, II, and III NSCLC. Patients with resectable disease who are not surgical candidates may receive curative radiation therapy.

- Patients with unresectable or N2, N3 disease are treated with concurrent chemoradiation. Selected patients with T3 or N2 disease can be treated effectively with surgical resection and either preor postoperative chemotherapy or chemoradiation therapy.
  - Patients with distant metastases (M1) can be treated with radiation therapy or chemotherapy for palliation or best supportive care alone.
- SCLC
    - Limited stage: concurrent chemoradiation
    - Extensive stage: combination chemotherapy
    - Consider prophylactic cranial irradiation (PCI) in patients achieving a complete or partial response (2)[A].
  - Quality-of-life assessments: Karnofsky performance scale (KPS), Eastern Cooperative Oncology Group (ECOG)
  - Discussions with patient and family about end-of-life care

## *MEDICATION*

- Chemotherapy is the mainstay of treatment.
- Adjuvant chemotherapy following surgery improves survival in patients with fully resected stage II-III NSCLC.
- Palliative measures: analgesics
- Dyspnea: oxygen, morphine

## *First Line*

- NSCLC
  - Stages II-III: neoadjuvant or adjuvant chemotherapy (3,4)[A]
    - Cisplatin-based doublets (combination with paclitaxel, etoposide, vinorelbine, docetaxel, gemcitabine)
    - Carboplatin alternative for patients unlikely to tolerate cisplatin
    - Cisplatin plus pemetrexed (nonsquamous cell)
  - Unresectable stage IIA, IIIB

- Concurrent chemoradiation
  - Cisplatin plus etoposide, vinblastine, or pemetrexed (nonsquamous cell) plus concurrent radiation
  - Carboplatin plus pemetrexed (nonsquamous cell) plus concurrent radiation
- Stage IV
  - No chemotherapy regimen can be recommended for routine use.
  - Cisplatin or carboplatin-based doublets (5)[A]
  - +/- bevacizumab (nonsquamous cell)
  - Erlotinib or afatinib for patients with EGFR mutations
  - Crizotinib for patients with EML4-ALK translocations
    - Ceritinib for patients that fail or are intolerant to crizotinib
  - Maintenance therapy after 4 to 6 cycles in patients achieving a response or stable disease
    - Continuation of bevacizumab, pemetrexed (nonsquamous cell), gemcitabine, erlotinib, or crizotinib or switch to pemetrexed (nonsquamous cell), erlotinib (EGFR mutations), docetaxel or observation
- SCLC
  - Cisplatin or carboplatin plus etoposide

## *Second Line*

- NSCLC
  - Cisplatin-based doublets +/- bevacizumab (nonsquamous cell) if not previously used
  - Docetaxel, pemetrexed (nonsquamous cell), erlotinib, gemcitabine, ramucirumab plus docetaxel, or nivolumab (squamous cell)
- SCLC
  - Topotecan or CAV (cyclophosphamide, doxorubicin, vincristine), gemcitabine, docetaxel, paclitaxel

## *ADDITIONAL THERAPIES*

- Smoking cessation counseling

- Consider IV bisphosphonates or denosumab in patients with bone metastases to reduce skeletal-related events.

## ***SURGERY/OTHER PROCEDURES***

- Resection for NSCLC, for stages I, II, and IIIa, if medically fit to undergo surgery
- Resection of isolated, distant metastases has been achieved and may improve survival.
- Resection involves lobectomy in 71%, wedge in 16%, and complete pneumonectomy in 18%.
- Resection should be accompanied by lymph node dissection for pathologic staging.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Depends on clinical history; in general, postoperative visits every 3 to 6 months in the year after surgery with physical exam and CXR
- Follow-up CT scans, as indicated

### ***PATIENT EDUCATION***

- <http://www.cancer.gov/about-cancer>
- <http://smokefree.gov/>

### ***PROGNOSIS***

- For combined, all types and stages, 5-year survival rate is 16% (NSCLC: 17%; SCLC 6%).
- NSCLC
  - Localized disease (stages I and II): 49%
  - Regional disease: 16%
  - Distant metastatic disease: 2%
- SCLC
  - Without treatment: median survival from diagnosis of only 2 to 4 months
  - Limited-stage disease: median survival of 16 to 24 months; 5-year survival rate: 14%

Extensive-stage disease: median survival of 6 to 12 months; long-term disease-free survival is rare.

## COMPLICATIONS

- Development of metastatic disease, especially to brain, bones, adrenals, and liver
- Local recurrence of disease
- Postoperative complications
- Side effects of chemotherapy or radiation

## Codes

**&NA;**

### ICD10

- C34.90 Malignant neoplasm of unsp part of unsp bronchus or lung
- C34.10 Malignant neoplasm of upper lobe, unsp bronchus or lung
- C34.30 Malignant neoplasm of lower lobe, unsp bronchus or lung

## Clinical Pearls

**&NA;**

- Prognosis and treatment of lung cancer differs greatly between small cell- and non-small cell histologies.
- Adjuvant cisplatin-based chemotherapy improves survival in patients with completely resected stage II-III NSCLC.
- Chemotherapy, with or without radiation, can be offered to patients with advanced NSCLC or SCLC.
- There is little role for surgery in the treatment of SCLC.

# Lupus Erythematosus, Systemic (SLE)

Katherine M. Tromp, PharmD

Hershey S. Bell, MD, MS, FAAFP

## BASICS

### DESCRIPTION

- Systemic lupus erythematosus (SLE) is a multisystem autoimmune inflammatory disease characterized by a chronic relapsing/remitting course; can be mild to severe and may be life-threatening (CNS and renal forms)
- System(s) affected: mucocutaneous; musculoskeletal; renal; nervous; pulmonary; cardiac; hematologic; vascular; gastrointestinal (GI)
- Synonym(s): SLE; lupus

### ALERT

Women with SLE have a 7- to 50-fold increased risk of coronary artery disease and may present with atypical/nonspecific symptoms.

### EPIDEMIOLOGY

Predominant age: 15 to 45 years

#### *Incidence*

- Per year, 1.6 to 7.6/100,000 and increasing due to better diagnosis
- Most common: African American women (8.1 to 11.4/100,000/year)
- Least common: Caucasian men (0.3 to 0.9/100,000/year)

#### *Prevalence*

Occurs in 30 to 50/100,000 and increasing due to increased survival

### ETIOLOGY AND PATHOPHYSIOLOGY

- Skin: photosensitivity; scaly erythematous, plaques with follicular plugging, dermal atrophy, and scarring; non-scarring erythematous psoriasiform/annular rash; alopecia; mucosal ulcers

- Musculoskeletal: nonerosive arthritis; ligament and tendon laxity, ulnar deviation, and swan neck deformities; avascular necrosis
- Renal: glomerulonephritis
- Pulmonary: pleuritis, pleural effusion, alveolar hemorrhage, pneumonitis, interstitial fibrosis, pulmonary hypertension, pulmonary embolism (PE)
- Cardiac: nonbacterial verrucous endocarditis, pericarditis, myocarditis, atherosclerosis
- CNS: thrombosis of small intracranial vessels  $\pm$  perivascular inflammation resulting in micro- or macroinfarcts  $\pm$  hemorrhage
- Peripheral nervous system: mononeuritis multiplex, peripheral neuropathy
- GI: pancreatitis, peritonitis, colitis
- Hematologic: hemolytic anemia, thrombocytopenia, leukopenia, lymphopenia
- Vascular: vasculitis, thromboembolism
- Most cases are idiopathic with possible environmental factors.
- Drug-induced lupus: hydralazine, D penicillamine, quinidine, procainamide, minocycline, isoniazid, etc

## *Genetics*

- Identical twins: 24-58% concordance
- Fraternal twins and siblings: 2-5% concordance
- 8-fold risk if first-degree relative with SLE
- Major histocompatibility complex associations: HLA-DR2, HLA-DR3
- Deficiency of early complement components, especially C1q, C1r/s, C2, and C4
- Immunoglobulin receptor polymorphisms: *FC&ggr;R2A*, *FC&ggr;R3A*, and others
- Polymorphism in genes associated with regulation of programmed cell death, protein tyrosine kinases, and interferon production

## *RISK FACTORS*

- Race: African Americans, Hispanics, Asians, and Native Americans
- Predominant sex: females > males (8:1)
- Environmental: UV light, infectious agents, stress, diet, drugs, hormones, vitamin D deficiency, and tobacco

## COMMONLY ASSOCIATED CONDITIONS

- Overlap syndromes: rheumatoid arthritis (RA), Sjögren syndrome, scleroderma
- Antiphospholipid syndrome; coronary artery disease; nephritis; depression

## DIAGNOSIS

Consider SLE in multisystem disease including fever, fatigue, and signs of inflammation.

### HISTORY

- Fever, fatigue, malaise, weight loss, headache
- Rash (butterfly/*hyperpigmented ears or scalp*), photosensitivity, alopecia
- Oral/nasal ulcers (usually painless)
- Arthritis, arthralgia, myalgia, weakness
- Pleuritic chest pain, cough, dyspnea, hemoptysis
- Early stroke (age <50 years), seizure, psychosis, cognitive deficits
- Proteinuria, cellular casts
- Hemolytic anemia, leukopenia, lymphopenia, thrombocytopenia
- Abdominal pain, anorexia, nausea, vomiting
- Raynaud phenomenon

### PHYSICAL EXAM

- Vital signs: fever, hypertension
- Malar, discoid, psoriasiform, or annular rash, alopecia
- Oral/nasal ulcers (*often minimally symptomatic*)
- Lymphadenopathy, splenomegaly
- Acrocyanosis
- Inflammatory arthritis, tenosynovitis
- Pleural/pericardial rub, heart murmur
- Bibasilar rales
- Cranial/peripheral neuropathies

### DIFFERENTIAL DIAGNOSIS

Undifferentiated connective tissue disease, Sjögren syndrome, fibromyalgia, RA, vasculitis,

idiopathic thrombocytopenia purpura, antiphospholipid antibody syndrome, drug-induced lupus

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Antinuclear antibody (ANA)
  - High sensitivity (98%), low specificity
  - False-positive rate of 5-30%: elderly, autoimmune thyroid/liver disease, chronic infection, etc
  - Low titers <1:160 of limited clinical use
- Anti-double-stranded DNA (dsDNA) and anti-Smith antibodies: high specificity for SLE; predictor of nephritis and hemolytic anemia
  - Correlates with disease activity
- RNA protein antibodies (anti-RNP, anti-Ro, anti-La): less specific for SLE
- False-positive Venereal Disease Research Laboratory (VDRL) test: high sensitivity, low specificity. Surrogate marker of cardiolipin antibody presence
- Low serum complement levels: C3, C4
- Erythrocyte sediment rate (ESR): nonspecific, often high in active disease
- CBC: hemolytic anemia, thrombocytopenia, leukopenia, or lymphopenia
- Serum creatinine: elevated in lupus nephritis
- Urinalysis (UA): proteinuria, hematuria, cellular cast
- Phospholipid antibodies: cardiolipin immunoglobulin (Ig) G/IgM, lupus anticoagulant, &β<sub>2</sub>-glycoprotein IgG/IgM
- Anti-P (ribosomal autoantibodies) is associated with SLE arthritis and disease activity.
- Initial imaging is dependent on presenting symptoms.
- Radiograph of involved joints
- Chest x-ray: infiltrates, pleural effusion, low lung volumes
- Chest CT scan, ventilation-perfusion (V-Q) scan, duplex ultrasound for PE or deep vein thrombosis
- Head CT scan: ischemia, infarct, hemorrhage
- Brain MRI: focal areas of increased signal intensity

- Echocardiogram: pericardial effusion, valvular vegetations, pulmonary hypertension
- Contrast angiography for medium-size artery vasculitis: mesenteric/limb ischemia, CNS symptom

### *Follow-Up Tests & Special Considerations*

- Hemolytic anemia: elevated reticulocyte count and indirect bilirubin, low haptoglobin, positive direct Coombs test
- Confirm positive phospholipid antibodies results in 12 weeks.
- If phospholipid antibodies are initially negative, but symptoms arise, repeat, as they may become positive over time.
- 24-hour urine collection/spot protein/creatinine to quantify proteinuria
- Histone antibodies present in >95% of drug-induced lupus (vs. 80% of idiopathic SLE)
- Fasting lipid panel and glucose
- Follow vitamin D[25(O)H] levels and replenish PRN.

### *Diagnostic Procedures/Other*

- Renal biopsy to diagnose lupus nephritis (if UA abnormal)
- Skin biopsy with immunofluorescence on involved and uninvolved non-sun-exposed skin (*lupus band test*) may help differentiate SLE rash from others.
- Lumbar puncture in patients with fever and CNS/meningeal symptoms
- EEG for seizures/global CNS dysfunction
- Neuropsychiatric testing for cognitive impairment
- EMG/nerve conduction study (NCS) for peripheral neuropathy and myositis
- Nerve and/or muscle biopsy
- ECG, cardiac enzymes, stress tests
- American College of Rheumatology classification (not diagnostic) criteria: any 4 of the 11 listed (95% specificity and 85% sensitivity):
  - Malar (butterfly) rash
  - Discoid rash
  - Photosensitivity: by patient history/physician observation
  - Oral/nasopharyngeal ulcers

- Nonerosive arthritis: involving  $\geq 2$  peripheral joints
- Pleuritis *OR* pericarditis
- Renal disorder: proteinuria ( $>0.5$  g/day or  $>3+$ )

P.619

*OR* cellular casts (red cell, hemoglobin, granular, tubular, or mixed)

- Neurologic disorder: psychosis/seizures
- Hematologic disorder: hemolytic anemia, leukopenia ( $<4,000/\text{mm}^3$  on  $\geq 2$  tests), lymphopenia ( $<1,500/\text{mm}^3$  on  $\geq 2$  tests), thrombocytopenia ( $<100,000/\text{mm}^3$ )
- Immunologic disorder: anti-DNA, anti-Sm, anticardiolipin IgG/IgM, lupus anticoagulant, or false-positive VDRL findings
- Positive ANA in absence of drugs known to cause positive ANA

## Test Interpretation

- Skin: vascular/perivascular inflammation, immunecomplex deposition at dermal-epidermal junction, mucinosis, basal layer vacuolar changes
  - Similar findings seen in other connective tissue disorders such as dermatomyositis
- Renal: mesangial hypercellularity/matrix expansion, subendothelial/subepithelial immune deposits, glomerular sclerosis, fibrous crescents
  - Vary depending on degree of involvement
- Vascular: immune-complex deposition in vessel walls with fibrinoid necrosis and perivascular mononuclear cell infiltrates, intraluminal fibrin thrombi

## TREATMENT

### GENERAL MEASURES

- Education, counseling, and support
- Influenza/pneumococcal vaccines are safe; avoid live vaccines in immunocompromised patients.
- Low-estrogen oral contraceptives safe in mild SLE

### MEDICATION

## *First Line*

- *Antimalarial agents and NSAIDs are first-line therapy for patients with mild SLE (1)[A].*
  - Hydroxychloroquine for constitutional and musculoskeletal symptoms, rash, mild serositis; may reduce flares and increase long-term survival (2,3)[A]. NSAIDs for musculoskeletal manifestations, mild serositis, headache, and fever (2)[C]
- Systemic glucocorticoids (prednisone or equivalent)
  - Low dose (<0.5 mg/kg) for minor disease activity not responsive to NSAIDs or when NSAIDs are contraindicated (2)[A]
  - High-dose (1 to 2 mg/kg/day) (2)[A] or IV pulse methylprednisolone for organ-threatening disease, particularly CNS and renal; often combined with immunosuppressive agent (2)[A]
- Topical glucocorticosteroids for skin manifestations

## *Second Line*

- Belimumab as adjunct for preventing flares in patients with active lupus despite first-line therapy (4)[A]
  - 10 mg/kg IV every 2 weeks × 3 doses, then monthly
- Methotrexate (2)[A], azathioprine (2)[B], mycophenolate mofetil (2)[C], or leflunomide as steroid-sparing agent for persistent active disease or to maintain remission
  - Requires laboratory monitoring for toxicity
- Treatments under investigation: rituximab, epratuzumab, abatacept, interferon- $\alpha$  inhibitors
- Immunosuppressive agents for severe disease
  - Cyclophosphamide (2)[A]: adequate hydration to reduce risk of hemorrhagic cystitis
  - Mycophenolate mofetil (2)[A]: more efficacious for lupus nephritis (1)[A]

## ***SURGERY/OTHER PROCEDURES***

Renal transplant for end-stage renal disease

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Biofeedback, visual imagery, cognitive therapy

## ***INPATIENT CONSIDERATIONS***

## *Admission Criteria/Initial Stabilization*

- Difficult to differentiate SLE flare from infection; may need to treat both pending full evaluation
- IV pulse Solu-Medrol 1 g/day for 3 to 5 days for life-or organ-threatening disease (2)[A]

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Clinical evaluation for signs and symptoms
  - Weekly to monthly for active disease
  - Every 3 to 6 months for mild/inactive disease
- Measures of disease activity and damage: Systemic Lupus Erythematosus Disease Activity Index, British Isles Lupus Assessment Group Index, European Consensus Lupus Activity Measure
- Laboratory studies
  - CBC with differential
  - Serum creatinine, UA
  - Vitamin D
  - Declining C3/C4 and rising DS-DNA and ESR may correlate with disease activity.
- Monitor for adverse effects of treatment
  - NSAIDs: GI bleeding and/or ulceration
  - Glucocorticoids: glucose, lipids, bone density
  - Hydroxychloroquine: ophthalmologic exam every 6 to 12 months
  - Methotrexate: CBC, creatinine, albumin, aspartate aminotransferase (AST), alanine aminotransferase (ALT) every 2 months
  - Azathioprine and mycophenolate mofetil: CBC every 1 to 3 months
  - Cyclophosphamide
    - CBC, creatinine, UA every 2 weeks, and liver function tests monthly during treatment
    - UA every 6 to 12 months for life

## DIET

- No special diet unless for complications such as renal failure, diabetes, hyperlipidemia (2)[C]
- Adequate calcium/vitamin D intake in patients on corticosteroids (2)[A]
- Low glycemic index or calorie-restricted diet in patients on corticosteroids

## PATIENT EDUCATION

- Avoid UV light exposure: sunscreens (SPF <sup>3</sup>30), protective clothing (2)[B]
- Weight control, smoking cessation, exercise (2)[C]
- Stress avoidance/management

## PROGNOSIS

- Permanent treatment-free remission is uncommon.
- 5-year survival after diagnosis is 95%.
- Poor prognostic factor: major organ involvement
- Drug-induced lupus resolves within weeks to months after discontinuation of the offending drug.

## COMPLICATIONS

Infections, neoplasms, cardiac disease, nephritis, neuropsychiatric lupus; depression

### ***Pregnancy Considerations***

- Exacerbations during pregnancy are less common when in remission for 6 months prior to conception.
- Fetal loss is increased, especially in those with active lupus/antiphospholipid antibodies.
- A 2% risk of congenital heart block if anti-SS-A (Ro) or anti-SS-B (La) antibodies are present.
- See “Antiphospholipid Antibody Syndrome” for recommendations regarding use of aspirin and heparin to prevent pregnancy complications.

## Codes

&NA;

### ICD10

- M32.9 Systemic lupus erythematosus, unspecified
- M32.10 Systemic lupus erythematosus, organ or system involv unsp
- M32.14 Glomerular disease in systemic lupus erythematosus

## Clinical Pearls

**&NA;**

- *Aggressiveness of therapy should reflect intensity of disease.*
- Most important diagnostic test is the UA: if abnormal, order kidney biopsy; *serum and urine lab values often do not reveal extent of kidney disease.*
- Atherosclerotic and atheroembolic complications are the major cause of death; address modifiable cardiovascular risk factors.

# Lupus Nephritis

Neena R. Gupta, MD

## BASICS

### DESCRIPTION

- The renal manifestation of systemic lupus erythematosus (SLE)
- American College of Rheumatology (ACR) criteria: persistent proteinuria >500 mg/day or <sup>3</sup>3 on dipstick and/or presence of cellular casts. Alternatively, spot urine protein-to-creatinine ratio >0.5 and Òactive urinary sedimentÓ (>5 RBC/hpf, >5 WBC/hpf in absence of infection, or cellular castsÑRBC or WBC casts) (1)
- Clinical manifestations are primarily due to immune complex-mediated glomerular disease. Tubulointerstitial and vascular involvement often seen. Diagnosed based on clinical findings, urine abnormalities, autoantibodies, and renal biopsy.
- Treatment and prognosis depend on International Society of Nephrology/Renal Pathology Society (ISN/RPS) histologic classÑrisk of end-stage renal disease (ESRD) highest in class IV.
- Delay in diagnosis/treatment increases risk of ESRD.

### EPIDEMIOLOGY

- Peak incidence of SLE is 15 to 45 years of age.
- Predominant sex: female > male (10:1)
- Once SLE develops, lupus nephritis (LN) affects both genders equally; it is more severe in children and men and less severe in older adults.

### Incidence

- SLE: 1.4 to 21.9/100,000 (2)
- Up to 60% of SLE patients develop LN over time, and 25-50% of SLE patients have nephritis as the initial presentation.

### Pediatric Considerations

LN is more common and more severe in children: 60-80% have LN at or soon after SLE onset.

## Prevalence

SLE: 7.4 to 159.4/100,000 (2)

## ETIOLOGY AND PATHOPHYSIOLOGY

- Immune complex-mediated inflammation injures glomeruli, tubules, interstitium, and vasculature.
- Glomeruli: varying degrees of mesangial proliferation, crescent formation (see *Test Interpretation*), and fibrinoid necrosis causing reduced glomerular filtration rate (GFR)
- Persistence of inflammation (chronicity) leads to sclerosis and glomerular loss.
- Tubulointerstitial injury (edema, inflammatory cell infiltrate acutely; tubular atrophy in chronic phase) with or without tubular basement membrane immune complex deposition leads to reduced renal function.
- Vascular lesions: immune complex deposition and noninflammatory necrosis in arterioles
- SLE is a multifactorial disease, with a multigenic inheritance; exact etiology remains unclear.
- Defective T-cell autoregulation and polyclonal B-cell hyperactivity contribute to dysregulated apoptosis. Impaired clearance of apoptotic cells inhibits selftolerance to nuclear antigen
- Anti-DNA, anti-C1q, anti-*agr*-actin, and other nuclear component autoantibodies develop.
- Deposition of circulating immune complexes or autoantibodies attaching to local nuclear antigens leads to complement activation, inflammation, and tissue injury.
- Interaction of genetic, hormonal, and environmental factors leads to great variability in LN severity.

## Genetics

Multigenic inheritance; clustering in families, ÷25% concordance in identical twins

## RISK FACTORS

Younger age, African American or Hispanic race, more ACR criteria for SLE, longer disease duration, hypertension, lower socioeconomic status, family history of SLE, anti-dsDNA antibodies

## COMMONLY ASSOCIATED CONDITIONS

Skin, hematologic, cerebral, pulmonary, GI, and cardiopulmonary systems are often involved in SLE.

# DIAGNOSIS

## HISTORY

Assess for risk factors and other signs/symptoms of SLE: rash, photosensitivity, arthritis, neurologic complaints, fever, weight loss, alopecia.

## PHYSICAL EXAM

- Hypertension, fever
- Pleural/pericardial rub
- Skin rash
- Edema
- Arthritis

## DIFFERENTIAL DIAGNOSIS

- Primary glomerular disease
- Secondary renal involvement in other systemic disorders such as antineutrophil cytoplasmic autoantibody (ANCA) associated vasculitis, Henoch-Schönlein purpura (HSP), antglomerular basement membrane disease, and viral infections
- Mixed connective tissue disorder may have glomerulonephritis indistinguishable from LN.

## DIAGNOSTIC TESTS & INTERPRETATION

- Renal biopsy is the gold standard for diagnosing and classifying LN.
- Combine clinical data with serologic and renal biopsy patterns to differentiate LN from other processes.
- Active urine sediment suggests nephritis.
- Autoantibodies, low C3, C4, and CH50 complement levels support LN diagnosis.

## Initial Tests (lab, imaging)

- Urinalysis may show hematuria, proteinuria, and active urine sediment (3)[C].
- Serum electrolytes, BUN, creatinine, albumin, routine serologic markers of SLE such as antinuclear antibody (ANA), anti-dsDNA, anti-Ro, anti-La, anti-RNP, anti-Sm, antiphospholipid antibody, C3, C4, CH50, CBC with differential, and C-reactive protein (CRP) (3)[C]
- CBC may show anemia, thrombocytopenia, and leukopenia.

- Renal ultrasound (3)[C]

## *Follow-Up Tests & Special Considerations*

- Monitor disease activity q3mo (3)[C]: urinalysis for hematuria and proteinuria; blood for C3, C4, antidsDNA, serum albumin, and creatinine.
- Patients with estimated glomerular filtration rate (eGFR) of <60 mL should be managed according to the National Kidney Foundation guidelines for chronic kidney disease.  
[http://www.kdigo.org/clinical\\_practice\\_guidelines/pdf/CKD/KDIGO\\_2012\\_CKD\\_GL.pdf](http://www.kdigo.org/clinical_practice_guidelines/pdf/CKD/KDIGO_2012_CKD_GL.pdf)

## *Pregnancy Considerations*

- Pregnancy leads to worsening of renal function in LN. Risk factors include renal impairment at baseline, active disease, hypertension, and proteinuria.
- Risk factors for fetal loss include elevated serum creatinine, heavy proteinuria, hypertension, and anticardiolipin antibodies.

## *Test Interpretation*

- Adequate renal biopsy (at least 10 glomeruli for light microscopy or total 20 to 25 glomeruli) is essential. Light, immunofluorescence, and electron microscopy are needed for accurate classification.
- On immunofluorescence microscopy: Immune complex deposits consisting of IGG, IGA, IGM, C1q, and C3 (Òfull houseÓ) are highly suggestive of LN.
- Revised ISN/RPS histologic classification guides therapeutic decisions.  
<http://jasn.asnjournals.org/content/15/2/241.full.pdf>
- LN is classified as purely mesangial (classes I and II), focal proliferative: <50% glomeruli (class III), diffuse proliferative: ≥50% (class IV), membranous (class V), and advanced sclerosis (class VI). Subdivisions for activity (A) and chronicity (C) in class III/IV and for segmental (S) or global (G) glomerular involvement in class IV (Class III A, C, A/C and class IV S[A], G[A], S[A/C], S[C], G[C]).
- LN may change to another class over time or with therapy.
- Focal and diffuse proliferative LN (classes III and IV) are common and most likely to progress to ESRD.

## **TREATMENT**

## GENERAL MEASURES

- Monitor bone density; optimize vitamin D and calcium intake in patients on glucocorticoid therapy.
- Low-salt diet for hypertension and edema. For eGFR <60 mL: Follow National Kidney Foundation guidelines for chronic kidney disease.
- Avoid sun or ultraviolet light exposure.

## MEDICATION

Note: Other than methylprednisolone and prednisone, no other medications listed below are FDA approved for lupus nephritis.

### First Line

- **Class I + II LN:** No specific therapy is needed, as long-term renal prognosis is good. Renin-angiotensin system blockade (ACE inhibitors or angiotensin receptor blockers) to manage BP and proteinuria. There are many drugs in this class (e.g., lisinopril 5 to 40 mg/day PO, losartan 25 to 100 mg/day PO).
- **Proliferative LN (Class III, IV, V + III/IV):** Induce remission by steroids + IV cyclophosphamide or mycophenolate mofetil (MMF) and maintenance of remission by low-dose steroids and azathioprine (AZA) or MMF (1).
- Principles of treatment:
  - Avoid delay in treatment.
  - Inducing remission quickly (3 to 6 months)
  - Maintaining response and avoiding iatrogenic morbidity (5 to 10 years)

P.621

- **INDUCTION:** steroids + immunosuppressive agent (for mild class III, high-dose steroids may be sufficient):
  - Glucocorticoids: methylprednisolone pulse 0.5 to 1 g/day for 3 days followed by oral prednisone 0.5 to 1 mg/kg/day PO (max 60 mg/day, taper after 4 to 8 weeks) (4,5)[A] AND
  - Cyclophosphamide (CYC): IV CYC (high dose = 0.5 to 1 g/m<sup>2</sup> monthly for 6 doses) NIH regimen; low dose = 0.5 g q2wk for 6 doses Euro-Lupus regimen) OR
  - Mycophenolate mofetil (MMF): 1 to 3 g/day PO divided BID (target 3 g/day as tolerated) for 6 months. MMF is as effective as CYC in achieving remission with fewer side effects (6)[A].
- **MAINTENANCE:**

- Glucocorticoids: oral prednisone tapered to low doses (generally < 10 mg/day by 6 months) AND
- MMF 1 to 2 g/day divided BID PO OR AZA (azathioprine): 1 to 2.5 mg/kg/day PO (4,5)[A]
- In the ALMS (Aspreva Lupus Management Study) MMF shown to be superior than AZA for maintenance therapy in a varied population (7)[A].
- In the MAINTAIN nephritis trial, MMF shown to be equal to AZA for maintenance therapy in mostly Caucasian population (8)[A].
- Cyclophosphamide IV quarterly for 1 to 2 year after renal remission; not used now due to availability of less toxic regimen
- **Class V LN:** good prognosis in general, treatment not standardized
  - For subnephrotic patients, no specific treatment except renin-angiotensin system blockade.
  - Options for nephrotic patients include steroids with either calcineurin inhibitors, IV CYC, AZA, or MMF (5)[B].
  - Class V LN with presence of class III or class IV biopsy findings needs aggressive combination regimen as for class III/IV.

## *Second Line*

Other treatments in selected patients: rituximab, plasma exchange, IVIG, calcineurin inhibitors. Belimumab was approved by FDA in 2011, but trials excluded patients with severe active LN (9) [C].

## *ISSUES FOR REFERRAL*

Nephrology consults for initial management and relapses

## *ADDITIONAL THERAPIES*

- KDIGO 2012 guidelines for LN state that all patients with LN of any class be treated with hydroxychloroquine (maximum daily dose of 6 to 6.5 mg/kg ideal body weight), unless they have a specific contraindication to this drug.
- BP control; treat dyslipidemia and other modifiable cardiovascular risk factors.
- Anticoagulation for symptomatic antiphospholipid antibody syndrome

## *SURGERY/OTHER PROCEDURES*

- Renal transplant for ESRD when indicated
- Patient and graft survival rates are similar to non-SLE patients (2)[C].

- Risk of recurrent LN in renal transplant recipients ranges between 0% and 30%; graft loss due to recurrence is rare.

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

- Uncontrolled hypertension, acute kidney injury
- Severe extrarenal manifestation
- Control hypertension and proteinuria, if present.
- Labs to help confirm SLE/LN, renal ultrasound
- Nephrology for manage input and renal biopsy

### ***IV Fluids***

Patients who have nephrotic syndrome or acute kidney injury should be fluid restricted.

### ***Discharge Criteria***

Once the patient is stabilized and renal biopsy is performed, manage safely as an outpatient.

## **ONGOING CARE**

## **FOLLOW-UP RECOMMENDATIONS**

### ***Patient Monitoring***

- Monitor urine protein-to-creatinine ratio, urine microscopy, serum albumin and creatinine, antibody titers (especially anti-dsDNA), C3, C4, BP at least every 3 months for first 2 to 3 years (3)[C].
- Once stable on maintenance therapy with no active disease, follow-up every 6 to 12 months (3)[C].
- Cyclophosphamide: CBC, ensure adequate hydration
- MMF: CBC, LFT, SrCr
- Azathioprine: CBC

### ***DIET***

Low-salt diet. For eGFR <60 mL: Follow National Kidney Foundation guidelines for chronic kidney

disease.

## **PATIENT EDUCATION**

Medication adherence and self-monitoring for relapse

## **PROGNOSIS**

- 10-year survival of 88% and 94% in SLE patients with and without renal involvement (1)
- Relapse rate is  $\div$ 35%. 10-20% of patients progress to ESRD within 10 years (10).
- 5-year renal survival of class IV LN <30% before 1970 has improved to >80% in last 2 decades (2).
- Early and complete remission with treatment is the best prognostic factor. Predictors of remission include low baseline proteinuria, normal creatinine, Caucasian race, and treatment initiation within 3 months of clinical diagnosis.
- Indicators of poor prognosis: diffuse proliferative LN (especially crescentic), higher activity/chronicity index, African American race, lower socioeconomic status, poor response to treatment, high creatinine at baseline, uncontrolled hypertension, and relapse

## **COMPLICATIONS**

- Risks from immunosuppression: infections, malignancy
- Treatment side effects: Cyclophosphamide causes primary amenorrhea.
- MMF may cause GI upset and nausea and is a teratogen (azathioprine recommended for women who desire pregnancy).
- Risk of vascular thromboses (hypercoagulable state from antiphospholipid antibodies)
- About 10-20% of patients develop ESRD from progressive disease refractory to treatment requiring dialysis/kidney transplantation.

## Codes

**&NA;**

# ICD10

M32.14 Glomerular disease in systemic lupus erythematosus

## Clinical Pearls

### &NA;

- Early diagnosis, correct classification (requires renal biopsy), and rapid treatment improve renal survival in patients with LN.
- Treat proliferative/progressive LN with a short induction course followed by maintenance therapy using glucocorticoids and immunosuppressants.
- Survival rates for patients with LN have improved dramatically over the past several decades.

# Lyme Disease

Felix B. Chang, MD, DABMA, FAAMA

## BASICS

### DESCRIPTION

- A multisystem infection caused by *Borrelia* spirochetes, transmitted primarily by ixodid ticks
  - *Ixodes scapularis* (deer ticks) in the New England and Great Lakes areas
  - *Ixodes pacificus* in the West (blacklegged ticks and Western blacklegged ticks)
  - *Ixodes ricinus* in Europe
  - *Ixodes persuladas* in Asia and Russia
- Early localized Lyme disease includes a characteristic expanding skin rash (erythema migrans [EM]) (70%) and constitutional flulike symptoms.
- Disseminated Lyme disease presents with involvement of <sup>31</sup> organ systems. Neurologic, cardiac, and pauciarticular arthritis are the most common.
- Post-Lyme disease syndrome includes arthritis (50%) and chronic neurologic syndromes.
- System(s) affected: hemic/lymphatic/immunologic; musculoskeletal; skin/exocrine; cardiac; neurologic
- Synonym(s): Lyme arthritis; Lyme borreliosis

### EPIDEMIOLOGY

#### Incidence

- 96% of U.S. cases in 2011 were reported from 13 states: New England, New York, New Jersey, Delaware, Pennsylvania, Maryland, Minnesota, and Wisconsin (1).
- In states where Lyme disease is endemic, the incidence is 0.5 per 1,000 but can be substantially higher in local areas.
- Cases have been reported from all 50 states.
- From 2003 to 2012, a total of 279,509 cases of Lyme disease were reported in the United States.

- Currently the seventh most common reportable disease in the United States

## *Prevalence*

- The most reported vector-borne illness in the United States
- Predominant age: most common in children ages 5 to 14 years and in adults aged 55 to 70 years of age
- Predominant sex: male > female in the United States

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Infection with spirochete *Borrelia burgdorferi* in the United States, or *Borrelia afzelii* or *Borrelia garinii* in Europe, transmitted by the bite of ixodid ticks (2)[A]
- Approximately 90% of cases are transmitted during the nymph stage of the tick life cycle.
- If a tick is infected, the chance of transmission increases with time attached: 12% at 48 hours, 79% at 72 hours, and 94% at 96 hours of attachment.
- Primary animal reservoir is the white-footed mouse.
- Spirochetes multiply and spread within dermis. Host response results in characteristic (EM) rash. Hematogenous dissemination results in disease within CNS, cardiovascular, or other organ systems.
- Star ticks (*Amblyomma americanum*), the American dog tick (*Dermacentor variabilis*), the Rocky Mountain wood tick (*Dermacentor andersoni*), and the brown dog tick (*Rhipicephalus sanguineus*) are not known to transmit Lyme disease.

## *Genetics*

Human leukocyte antigen: Patients with haplotype DR4 or DR2 may be more susceptible to prolonged arthritis.

## *RISK FACTORS*

- Exposure in tick-infested area, particularly from April to November
- Those who reside or are employed in endemic areas where ixodid ticks are found are at increased risk.
- Ixodid ticks are commonly found on deer. Hunters may be at an increased risk.

## *GENERAL PREVENTION*

- Tick checks: Examine skin after outdoor activities.

- Remove ticks within 36 hours to limit transmission.
- Wear clothing covering the ankles in endemic areas.
- Use insect repellents containing DEET.
- Apply permethrin to clothes, shoes, and tents.
- Antibiotic prophylaxis is recommended for the prevention of Lyme disease in endemic areas following an *Ixodes* tick bite.
- Prophylactic treatment with 1 dose of 200 mg of doxycycline within 72 hours of a tick bite in highly endemic areas is 87% effective. Contraindicated in pregnancy and in children; no prophylactic agent is approved for these groups (2)[A].

## COMMONLY ASSOCIATED CONDITIONS

- Coinfection with babesiosis has been reported. Suggested by high fever
- Southern tick-associated rash illness may be mistaken for Lyme disease. It is seen in the Southeastern and South Central United States and is associated with the bite of the lone star tick, *A. americanum*.

## DIAGNOSIS

### HISTORY

- History of a tick bite followed by EM and/or illness (3).
- Early Lyme disease: incubation period 3 to 30 days
  - Some patients may be asymptomatic (4).
  - Fever; headache; myalgias; arthralgias
- Disseminated Lyme disease
  - Carditis (pleuritic chest pain; palpitations)
  - Facial palsies or other cranial neuropathies
  - Joint pain (polyarthritis/algias; late disease: monoarthritis-like knee)
  - Iritis, conjunctivitis
  - Migratory musculoskeletal pain
- Late untreated Lyme disease
  - Recurrent synovitis
  - Recurrent tendonitis and bursitis
  - Encephalopathic symptoms

- Headaches
- *Cognitive slowing*
- Confusion
- Profound fatigue
- Symptoms mimicking other CNS diseases
  - Multiple sclerosis-like symptoms
  - Stroke-like symptoms
  - Transverse myelitis
- Peripheral neuropathic symptoms; motor, sensory, or autonomic neuropathies
- Meningitis

## ***PHYSICAL EXAM***

- Early Lyme disease
  - EM (4)[A]
- Disseminated Lyme disease
  - Multiple EM
  - Facial palsies or other cranial neuropathies
  - Heart block↯irregular pulse
  - Pericarditis↯friction rub
  - Arthritis
  - Other focal neurologic findings

## ***DIFFERENTIAL DIAGNOSIS***

- Other rickettsial disease (Rocky Mountain spotted fever [RMSF])
- Juvenile rheumatoid arthritis; systemic lupus erythematosus (SLE); rheumatoid arthritis (RA)
- Viral syndromes
- Contact dermatitis; cellulitis; granuloma annulare (mimic EM)
- Syphilis
- AV block

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- Testing and treatment not indicated if tick attached for <48 hours (3)
- Diagnosis is based mainly on clinical findings in endemic areas (4).
- Serology: enzyme-linked immunosorbent assay (ELISA) for immunoglobulin (Ig) M and IgG *B. burgdorferi* antibodies, followed by a Western blot test if positive or equivocal, or an indirect immunofluorescence assay
- Culture of CSF for *B. burgdorferi*
- Plasma polymerase chain reaction (PCR) testing is of little value (only exception is synovial fluid analysis).
- No imaging routinely indicated.

## Follow-Up Tests & Special Considerations

Disorders that may alter lab results: False-positive response has been seen with RMSF, syphilis, SLE, and RA.

- Arthritis: Serology + PCR of synovial fluid is both sensitive and specific.
- Neuroborreliosis: serology + CSF pleocytosis (PCR of CSF has a very low sensitivity)
- Late-stage disease with negative serology may be seen in patients who received early antibiotic treatment.
- After an infection, antibodies may persist for months to years. *Serologic tests do not distinguish active from past infection.*
- Antibodies are not protective.

---

P.623

## Diagnostic Procedures/Other

Lumbar puncture when neurologic findings are present, with ELISA of CSF for *B. burgdorferi* antibodies. Xenodiagnosis in humans (5)

## Test Interpretation

Culture of *B. burgdorferi* from blood or skin biopsy has a very low yield.

# TREATMENT

## GENERAL MEASURES

Early and disseminated Lyme disease can usually be treated as an outpatient except when complicated by carditis or meningitis (requires parenteral antibiotics).

## MEDICATION

### First Line

- EM
  - Doxycycline (Vibramycin) 100 mg PO BID for 10 to 21 days (do not use in children <8 years old or in pregnant women) (2,6)[A]; *or*
  - Amoxicillin 500 mg PO TID for 14 to 21 days (pediatric dose 50 mg/kg/day); *or*
  - Cefuroxime axetil 500 mg PO BID for 14 to 21 days
    - Doxycycline has the advantage of covering other tick-borne infections such as ehrlichiosis, anaplasmosis, and RMSF.
    - Alternative: azithromycin 500 mg QD for 7 to 10 days or clarithromycin 500 mg BID for 14 to 21 days
- Neurologic disease
  - Normal CSF, treat for 14 to 21 days (2)[A].
  - Doxycycline 100 mg PO BID or amoxicillin 500 mg PO TID
  - Abnormal CSF, treat for 4 weeks: ceftriaxone 2 g QD IV, cefotaxime 2 g q8h, *or* penicillin G 5 mIU q6h
  - Cardiac disease
    - Mild (first-degree AV block, PR <300 ms): doxycycline 100 mg PO BID or amoxicillin 500 mg PO TID for 14 to 21 days
    - More serious: ceftriaxone 2 g QD IV for 30 days
- Arthritis without neurologic disease (2)[A]
  - Oral treatment for 28 days with doxycycline 100 mg BID or amoxicillin 500 mg TID
  - If oral treatment fails, repeat oral regimen for 28 days or begin IV treatment with ceftriaxone 2 g QD for 2 to 4 weeks.
- Contraindications

- Allergy to specific medication
- Doxycycline is contraindicated in children and in women who are pregnant or breastfeeding.
- Precautions
  - In ÷15% of patients treated with IV therapy, a Jarisch-Herxheimer-type reaction develops within 24 hours of initiation of therapy.
- Significant possible interactions
  - Oral anticoagulants may require dose adjustments.
  - Oral contraceptives may be less effective.

### *Pediatric Considerations*

- Amoxicillin is the drug of choice in children.
- Tetracyclines are contraindicated.

### *Pregnancy Considerations*

- Because *B. burgdorferi* can cross the placenta, pregnant patients with active disease should be treated with parenteral antibiotics.
- Doxycycline should not be used in pregnancy.

### *Second Line*

- Azithromycin, 500 mg PO daily for 7 days, can be used for those allergic to *&bgr;*-lactams and unable to take tetracyclines but is less effective (2).
- There is no evidence for meaningful clinical benefit from prolonged treatment or retreatment of patients with persistent unexplained symptoms despite previous antibiotic treatment of Lyme disease.

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

- Admission is recommended for patients with Lyme carditis and symptoms of chest pain, syncope, or dyspnea, and for those with second- or third-degree heart block or first-degree heart block of <sup>3</sup>300 ms.
- Admission is also recommended for patients with symptoms of meningitis.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Based on the severity of symptoms, patients with Lyme carditis, neurologic syndromes, or arthritis may require prolonged follow-up.

#### *DIET*

No restrictions

### *PATIENT EDUCATION*

- In endemic areas, patients should be advised to protect themselves against tick exposure.
- [https://www.rheumatology.org/Practice/Clinical/Patients/Diseases\\_And\\_Conditions/Lyme\\_Disease/](https://www.rheumatology.org/Practice/Clinical/Patients/Diseases_And_Conditions/Lyme_Disease/)
- Prevention
  - Use repellents that contains 20-30% DEET (N,N-diethyl-meta-toluamide) on exposed skin and clothing for protection that last up to several hours.
  - Use 0.5% permethrin on clothing.
  - Bathe or shower as soon as possible after coming indoors (preferably within 2 hours) and perform tick check after outdoor activities.

### *PROGNOSIS*

- Early treatment with antibiotics can shorten the duration of symptoms and prevent later disease.
- Response of late-stage disease to treatment is variable. Symptoms may take weeks to resolve after beginning treatment.

### **COMPLICATIONS**

- Recurrent synovitis, tendonitis, bursitis (7)[A]
- Chronic neurologic symptoms
- Peripheral neuropathies
- Posttreatment Lyme disease syndrome: 10-20% lingering symptoms of fatigue, pain, or joint and muscle aches. Can last for 6 months (8)[A]

## Additional Reading

&NA;

Tickborne Diseases of the United States. A Reference Manual for Health Care Providers. Third edition, 2015. [www.cdc.gov/lyme/resources/tickbornediseases.pdf](http://www.cdc.gov/lyme/resources/tickbornediseases.pdf)

Codes

**&NA;**

## **ICD10**

- A69.20 Lyme disease, unspecified
- A69.23 Arthritis due to Lyme disease
- A69.21 Meningitis due to Lyme disease

## **Clinical Pearls**

**&NA;**

- The presence of EM following a tick bite in an endemic area is an indication for empiric treatment for Lyme disease.
- Repeat episodes of EM in appropriately treated patients are due to reinfection and not relapse.
- Lyme disease during pregnancy may lead to infection of the placenta and possible stillbirth. Amoxicillin is the preferred treatment during pregnancy.
- Ticks must be attached for at least 24 hours or more to transmit Lyme disease.
- There is no evidence that Lyme disease can be transmitted by breastfeeding or close personal contact.
- Vaccines for Lyme disease is no longer available.

# Lymphangitis

Amar Kapur, DO, CPT, MC, USA

## BASICS

### DESCRIPTION

Acute or chronic inflammation of lymphatic channels due to a skin breach or local trauma. Presents as red, tender streaks along lymphatic channels and extending to regional lymph nodes

- May result from compromised lymphatic drainage due to surgical procedures
- May be infectious or noninfectious

### ETIOLOGY AND PATHOPHYSIOLOGY

- Acute infection
  - Usually caused by group A  $\beta$ -hemolytic *Streptococcus*
  - Less commonly caused by:
    - *Staphylococcus aureus*
    - *Pasteurella multocida*
    - *Erysipelothrix*
    - *Spirillum minus* (rat bite disease)
    - *Pseudomonas*
    - Other *Streptococcus* sp.
    - Immunocompromised patients can be infected with gram-negative rods, gram-negative bacilli, or fungi.
    - In fresh water exposures, *Aeromonas hydrophila*
- Nodular lymphangitis
  - Also known as sporotrichoid lymphangitis
  - Presents as painful or painless nodular subcutaneous swellings along lymphatic vessels
  - Lesions may ulcerate with accompanying regional lymphadenopathy.

- Typical of infections from the following: *Sporothrix schenckii*, *Nocardia brasiliensis*, *Mycobacterium marinum*, leishmaniasis, tularemia, and systemic mycoses
- Pathology may show granulomas.
- Noninfectious granulomatous lymphangitis
  - Rare-acquired lymphedema of the genitalia in children
  - May be due to atypical Crohn disease or sarcoidosis (1)[C]
- Filarial lymphangitis
  - Mosquito bites transmit parasites causing inflammation and dilatation in the lymphatic vessels; can predispose to secondary bacterial infection
  - Usually caused by nematodes *Wuchereria bancrofti*. Other causes are *Brugia malayi* and *Brugia timori*.
- Lymphangitis due to surgery
  - May occur after surgical procedures and lymph node dissection
- Cutaneous lymphangitis carcinomatosa is rare. Represents ~5% of all skin metastases; caused by occlusion of lymphatic channels of dermis by neoplastic cells (2)
- Sclerosing lymphangitis of the penis
  - Swelling around coronal sulcus of penis usually resulting from vigorous sexual activity or masturbation

## RISK FACTORS

- Impaired lymphatic drainage due to surgery, nodal dissection, or irradiation
- Diabetes mellitus
- Chronic steroid use
- Peripheral venous catheter
- Varicella infection
- Immunocompromising condition
- Human, animal, or insect bites
- Fungal, bacterial, or mycobacterial skin infections
- Any trauma to the skin

IV drug abuse

- Residence in endemic areas of filariasis

## GENERAL PREVENTION

- Reduce chronic lymphedema with compression devices or by treating underlying process
- Insect repellent
- Proper wound and skin care

## COMMONLY ASSOCIATED CONDITIONS

- Lymphedema
- Prior lymph node dissection
- Tinea pedis (athlete's foot)
- Sporotrichosis
- Cellulitis, erysipelas
- Filarial infection (*W. bancrofti*)

## DIAGNOSIS

### HISTORY

- History of trauma to skin, cut, abrasion, or fungal infection
- Systemic symptoms:
  - Malaise
  - Fever and chills
  - Loss of appetite
  - Headache
  - Muscle aches
- Travel to a tropical region or region with known filariasis

## PHYSICAL EXAM

Local signs:

- Erythematous, macular linear streaks from site of infection toward the regional lymph nodes
- Tenderness and warmth over affected skin or lymph nodes

- May have blistering of affected skin
- Fluctuance, swelling, or purulent drainage
- Nodular lymphangitis can present with subcutaneous swellings along the lymphatic channels.
- Sporotrichosis may present with papulonodular lesions that may ulcerate.
- Sites may be nonpainful.

## ***DIFFERENTIAL DIAGNOSIS***

- Superficial thrombophlebitis
  - Thrombus or infection within the thrombosis (septic thrombophlebitis)
- Contact dermatitis
- Allergic reaction: less likely to be allergic if >24 hours after exposure (e.g., insect bite)
- Lymphangitis carcinomatosa
- Malignancy-related inflammation

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- CBC may show leukocytosis; blood smear may show filarial infection.
- Blood or wound cultures
- Biopsy cultures
- FNAC for filariasis of testiculoscrotal swelling but not for other superficial locations (3)

### ***Initial Tests (lab, imaging)***

Plain radiology unnecessary; may consider lymphangiography for lymphedema (4)[C]

### ***Diagnostic Procedures/Other***

- Swab, aspirate, and/or biopsy primary site, purulent discharge, nodule or distal ulcer for culture, acid fast staining, histology, and microscopy
- Blood cultures if systemically ill
- Serology (e.g., *Francisella tularensis*, histoplasma)
- Blood film/smear (e.g., filaria)
- Lymphangiography to determine lymphedema or lymphatic obstruction

## TREATMENT

### GENERAL MEASURES

- Hot, moist compresses to affected area
- If lymphedema is involved, compression garments and weight loss may help.
- Abstinence from sexual activity (for sclerosing lymphangitis)

### MEDICATION

- Treat common organisms empirically. Use culture and susceptibility to guide subsequent antibiotic treatment (5)[B].
- If mild disease, use outpatient oral antibiotics.
- If no improvement after 48 hours of oral antibiotics, reassess and consider IV antibiotics and/or hospitalization.
- If systemic involvement, start IV antibiotics.
- If necrotizing fasciitis due to group A  $\beta$ -hemolytic *Streptococcus* is suspected, treat aggressively with antibiotics and surgical intervention.

### First Line

- Antibiotics for group A streptococcal infection
    - Amoxicillin (if patient known to have only group A *Streptococcus*)
      - Dosing
        - Adults
          - Mild to moderate: 500 mg PO q12h
          - Severe: 875 mg PO q12h or 500 mg PO q8h
- 
- Children <3 months: 30 mg/kg/day PO divided q12h
  - Children <sup>3</sup>3 months, <sup>2</sup>40 kg
    - Mild to moderate: 25 mg/kg/day PO divided q12h or 20 mg/kg/day divided q8h
    - Severe: 45 mg/kg/day PO divided q12h or 40 mg/kg/day divided q8h
  - Children <sup>3</sup>40 kg same as adult dosing

- Common adverse effects
  - Diarrhea
- Serious adverse effects
  - Anaphylaxis, Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN)
- Drug interactions
  - Methotrexate, venlafaxine, warfarin, hormonal contraceptives
- Contraindications
  - Hypersensitivity to penicillin
- Ampicillin/sulbactam
  - Dosing
    - Adults and children <sup>≥</sup>40 kg: 1.5 to 3 g (ampicillin + sulbactam component) IV/IM q6h
    - Children <40 kg: 200 mg/kg/day IV infusion, in divided doses q6h; maximum 8 g ampicillin per day
  - Common adverse effects
    - Diarrhea, injection site reactions
  - Serious adverse effects
    - *Clostridium difficile* diarrhea, pseudomembranous enterocolitis
  - Drug interactions
    - Hormonal contraceptives
  - Contraindications
    - Hypersensitivity reactions
- Ceftriaxone
  - Dosing
    - Adults: 1 to 2 g IV/IM q24h
    - Children: 50 to 75 mg/kg/day IV/IM once daily or in divided doses q12h; maximum 2 g/day

- Common adverse effects
  - Injection site reactions, diarrhea
- Serious adverse effects: same as amoxicillin or ampicillin
- Drug interactions
  - Do not administer calcium-containing solutions in the same IV line.
- Contraindications
  - Hypersensitivity to cephalosporins
  - Concurrent calcium-containing IV fluids
  - Increased risk of kernicterus, salt precipitation in lungs and kidneys in neonates <28 days (use cefotaxime instead)
- Cephalexin
  - Dosing
    - Adults: 500 mg PO q12h
    - Children: 25 to 50 mg/kg/day divided q12h
  - Common adverse effects
    - Diarrhea
  - Serious adverse effects
    - SJS, TEN, interstitial nephritis, renal failure, pseudomembranous enterocolitis, anaphylaxis
  - Contraindications
    - Hypersensitivity to cephalosporins
- Azithromycin (if penicillin or cephalosporin allergy)
  - Dosing
    - Adults: 500 mg PO on day 1 followed by 250 mg/day PO on days 2 to 5
    - Children <sup>≥</sup>2 years: 12 mg/kg/day PO (maximum dose: 500 mg/day) once daily for 5 days (FDA off-label use for skin infections in children)
  - Common adverse effects

- Abdominal pain, nausea, vomiting, diarrhea, headache
- Serious adverse effects
  - Prolonged QT interval, torsades de pointes, liver failure, Lambert-Eaton syndrome, myasthenia gravis, corneal erosion, anaphylaxis
- Drug interactions
  - Nelfinavir, warfarin, other medications with potential to prolong QT interval
- Contraindications
  - Hepatic dysfunction or cholestatic jaundice with prior treatment
  - Hypersensitivity to macrolide (azithromycin, erythromycin, clarithromycin)
- Diethylcarbamazine, ivermectin, albendazole, and doxycycline are used to treat filarial infection.
- Acetaminophen or ibuprofen (NSAIDs) for pain and fever

## ***SURGERY/OTHER PROCEDURES***

- Incision and drainage of abscess if present
- Necrotizing fasciitis needs surgical evaluation and likely débridement
- Nodular lymphangitis may benefit from I&D
- With severe lymphedema, consider surgical drainage

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Admit for signs of serious illness: fluids if in hypotensive shock.
- Fever, chills, systemic toxicity
- IV antibiotics
- ICU or surgery as indicated

### ***Discharge Criteria***

Patient can be discharged on oral antibiotics after systemic symptoms resolve. Home IV antibiotics are an option depending on clinical setting.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Elevate affected area.
- 48-hour follow-up to ensure improvement
- Recurrent lymphangitis should prompt workup to ascertain underlying cause (other infectious organism, anatomic abnormality, etc.).

### *Patient Monitoring*

Close follow-up to ensure decreasing inflammation

### *PATIENT EDUCATION*

Instruct patients on proper wound and skin care.

### *PROGNOSIS*

- Good prognosis for uncomplicated cases
- Antimicrobial therapy is effective in 90% of patients.
- Untreated, can spread rapidly, especially group A *Streptococcus*

### **COMPLICATIONS**

Sepsis, cellulitis, necrotizing fasciitis, myositis

### **REFERENCES**

## Codes

&NA;

### ICD10

- I89.1 Lymphangitis
- L03.91 Acute lymphangitis, unspecified
- N48.29 Other inflammatory disorders of penis

## Clinical Pearls

&NA;

- Lymphangitis classically presents with erythematous linear streaks of the skin from the inciting site (e.g., bite, cut, abrasion) to regional lymph nodes.
- Patients with prior surgical lymph node dissection are predisposed to lymphangitis.
- Patients with severe systemic symptoms should be admitted and treated with IV antibiotics.

- Parasitic or fungal infections can cause acute or chronic lymphangitis.
- Treatment of underlying skin infection (such as tinea pedis) may prevent recurrence.

# Lymphedema

Jon S. Parham, DO, MPH

## BASICS

### DESCRIPTION

- Accumulation of lymphatic fluid in the interstitial tissue causing swelling
- Lymphedema can develop when lymphatic vessels are missing or impaired (primary) or when lymph vessels are damaged or lymph nodes are removed (secondary).
- Most common in the lower limb (80%) but also can occur in the arms, face, trunk, and external genitalia

### EPIDEMIOLOGY

#### Incidence

- Predominant sex: female > male
- Predominant age: any age
- 13% of patients with breast cancer treated with surgery; 42% of those treated with surgery and radiation therapy; 25% after GYN cancer surgery
- Milroy disease presents at birth; estimated to be between 1/6,000 and 1/300 live births
- Meige disease develops during puberty.

#### Prevalence

- 120 million people worldwide are affected with lymphatic filariasis in 73 countries but no primary infections in United States.
- 10 million people are affected by nonfilarial secondary lymphedema in the United States.

### ETIOLOGY AND PATHOPHYSIOLOGY

Secondary lymphedema:

- Postoperative: gradual failure of distal lymphatics, which have to òpumpó lymph at a greater pressure through damaged proximal ducts

- Risk is higher with postoperative radiation because radiation reduces regrowth of ducts due to fibrous scarring.
- Trauma; recurrent infection; malignancy, including metastatic disease, and marked obesity
- Developing countries: Most common cause is filariasis (*Wucheria bancrofti*).

## Genetics

- Milroy disease: autosomal dominant; diagnosed either at birth or the 1st year of life
- Lymphedema praecox has onset between the ages of 1 and 35 years.
- Lymphedema tarda occurs in those >35 years of age.

## RISK FACTORS

- Filariasis: most common cause worldwide
- Mastectomy
- Prior trauma, infection of affected limb
- History of prior surgical (particularly if lymph nodes were removed) or radiation therapy for malignancy (radiation can damage lymph nodes and cause skin dermatitis)
- Long history of venous insufficiency
- Obesity, DVT

## GENERAL PREVENTION

Healthy body weight maintenance; treatment of congestive heart failure (CHF) and venous insufficiency

## COMMONLY ASSOCIATED CONDITIONS

Venous disease

## DIAGNOSIS

### HISTORY

Recent surgery: Vein stripping can significantly exacerbate mild lymphedema (1)[B]:

- First symptom: painless swelling
- Feeling of heaviness in the limb, especially at the end of the day and in hot

## *PHYSICAL EXAM*

- Initial: pitting edema, can spread proximally
- Later: nonpitting; after first year, does not spread proximally/distally but spreads radially
- Hyperkeratosis (thicker skin)
- Papillomatosis (rough skin)
- Increase in skin turgor
- Positive Stemmer sign (inability to pinch the skin of the dorsum of the second toe between the thumb and forefinger): must exclude heart failure

## *DIFFERENTIAL DIAGNOSIS*

- CHF, renal failure, lipidemia
- Hypoalbuminemia, protein-losing nephropathy
- DVT, chronic venous disease
- Postoperative complications following ipsilateral surgery
- Cellulitis, Baker cyst, idiopathic edema

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Lack of response to elevation or diuretic therapy may indicate a lymphatic insufficiency (2)[B].
- Diuretics increase excretion of salt and water, thereby decreasing plasma volume, venous capillary pressure, and filtration. Diuretics improve filtration edema but do not improve lymph drainage over the long term.
- Some relevant protein biomarkers for lymphedema have been identified and show promise for early and latent-stage diagnosis (3)[B].

### *Initial Tests (lab, imaging)*

- Comprehensive chemistry panel: evaluates for hepatic or renal impairment
- Urinalysis: protein-losing nephropathy
- Ultrasound: evaluates for acute/chronic DVT; gives information about soft tissue changes but does not tell about truncal anatomy of the lymphatics (1)[B]
- Duplex ultrasound: Lymphedema causes gradual impedance of venous return that aggravates

the edema; 82% of patients with unexplained limb edema were diagnosed using a combination of duplex ultrasound and lymphoscintigram (4)[A].

## *Follow-Up Tests & Special Considerations*

- Lymphangiogram: direct cannulation of lymphatics through the skin; risk for infection, local inflammation; not used commonly (4)[C]
- Fluorescence microlymphography may be highly sensitive (91.4%) and specific (85.7%), atraumatic and is without radiation in diagnosis of leg lymphedema (5)[B]
- Lymphoscintigram: radiolabeled protein technetium-99m-labeled colloid
  - Measures lymphatic function, lymph movement, lymph drainage, and response to treatment
  - Sensitivity, 73-97%; specificity, 100%
  - Best to use 1 hour and delayed images together (4)[A]
- Indocyanine green lymphography: reported
  - Superior to lymphoscintigraphy in early diagnosis of arm (6)[B]
  - Accurately screens post surgically for subclinical lymphedema (7)[B]
- CT scan: calf skin thickening, thickening of the SC compartment, increased fat density, thickened perimuscular aponeurosis; typical honeycomb appearance (4)[B]
- MRI: circumferential edema, increased volume of SC tissue, honeycomb pattern above the fascia between the muscle and subcutis; cannot differentiate primary from secondary lymphedema (4)[B]

## **TREATMENT**

### *GENERAL MEASURES*

- Seek optimal weight, early treatment of cellulitis, avoid trauma to affected area (direct injury, venipunctures, inept nail care, extreme heat/cold).
- Achieve mechanical reduction and maintenance of limb size: compression garments via professionals.
- Elevate affected limb/area, but avoid stasis.
- Avoid BP cuffs in affected limbs.
- Prevent skin infection with daily cleansing, inspection, and skin care (with emollients).

- Treatment of varicose veins may benefit some.

## *MEDICATION*

- Diuretics of limited benefit and may lead to volume depletion
- Benzopyrenes (flavonoids and coumarin) (not available for prescription use in the United States)
  - Micronized purified flavonoid fraction (Daflon 500 mg) is effective in decreasing venous stasis and idiopathic cyclic edema, chronic venous insufficiency, and postmastectomy lymphedema. It also reduces capillary permeability and the inflammatory component (8)[C].
- Coumarin reduces edema fluid by increasing the number of macrophages and enhancing proteolysis, resulting in the removal of protein, increasing softness in the limbs, and decreasing elevated skin temperature with subsequent symptom improvement and decreased secondary infection. Some reports of hepatotoxicity (8)[C].

## *ISSUES FOR REFERRAL*

- Refer to physical therapist with lymphedema training for manual decongestive therapy.
  - In patients with recurrent or metastatic disease, discuss with oncologist prior to initiation of complete decongestive therapy in order not to promote the spread of cancer.
- Provide education for patient/family for self-administration of therapy in future.
- Education for family about bandaging
- Fitting for compression garments

---

P.627

## *ADDITIONAL THERAPIES*

- Exercise: Lymph flow occurs as a result of inspiratory reduction in the intrathoracic pressure associated with inspiration. Best results are achieved with combination of flexibility, strength, and aerobic training (4)[B]. Compression with custom-made elastic stocking (minimum pressure is 40 mm Hg).
  - Protection against external incidental trauma
  - Decreases the intrinsic trauma on the skin due to chronically increased interstitial pressures, which cause stretch of the skin and SC tissues
  - No data on preference of custom-made versus prefabricated
  - Replace every 3 to 6 months or when starting to lose elasticity (1)[B].

- Multilayer bandaging: inner layer of tubular stockinette followed by foam and padding to protect the joint flexures and to even out the contours of the limb so that pressure is distributed evenly; outer layer of at least two short-stretch extensible bandages; more effective than hosiery alone (1)[B]
- Pneumatic pumps: development of high pressure up to 150 mm Hg; can reduce limb girth by 37-68.6%; wear a compression stocking when not using pump; high risk of genital edema; no metastasis in limb due to risk of spread (1)[B]
- Thai ÒschnoghÓ, a novel, intense tourniquet technique, has initially shown at least 50% limb volume reduction (9)[C]

## ***SURGERY/OTHER PROCEDURES***

- Bypass procedures: creation of lymphatic-venous anastomosis or lymph node transplantation (most effective) via microsurgery showed a reduction in use of conservative compression therapy (10)[B]: reserved for refractory cases only. In a pilot study, low-level laser therapy was shown not to be inferior to manual lymphatic drainage or the combination of the two in arm volume reduction in breast cancer-related lymphedema and required <sup>2</sup>1/2 the treatment time (11)[C].
- Thoracic sympathetic ganglion block for breast cancer-related lymphedema, a new treatment showed better life quality and arm size reduction >50% (11)[B]
- Debulking procedures (Charles procedure): radical excision of SC tissue with primary or staged skin grafting (8)[C]
  - Men had less improvement than women.
  - Main risk is infection and necrosis of the skin graft.
  - Liposuction is cosmetically preferred to debulking.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Heat therapy: Hot water immersion, microwave, and electromagnetic irradiation may be helpful (1)[C].

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Systemic signs of infection

- May admit to specialized rehabilitation unit for combination treatment in patients with heart failure or severe pulmonary disease

- IV antibiotics for infection

## *Nursing*

- Leg elevation
- Encourage patient mobilization/exercise.
- Patient education for bandaging/wound care

## *Discharge Criteria*

- Resolution of signs/symptoms of infection (e.g., elevated WBC count, fever, abnormal vital signs)
- Clinical improvement in wound appearance

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Lymphedema will return in several days if patient stops wearing compression garments during the day and bandaging at night.

### *Patient Monitoring*

- Daily visit to therapist for acute treatment
- Monthly visits for maintenance care

### *DIET*

Low sodium; weight loss-oriented if needed

### *PATIENT EDUCATION*

- Use compression garments, especially when exercising.
- Avoid affected limb(s) being dependant for long period of time: Patient should perform daily skin examination.
- <http://www.nlm.nih.gov/medlineplus/lymphedema.html>

### *PROGNOSIS*

No cure, but treatment can produce good results with daily care

## COMPLICATIONS

- Infection (local vs. systemic): common
- Risk of wound formation (venous wounds/abrasions) that are difficult to heal: common
- Lymphangiosarcoma: Found in lymphedematous arms of patients following radical mastectomy; also in patients with Milroy disease. Treatment is radiotherapy with surgery, reserved for patients with discrete nonmetastatic disease.

## Codes

**&NA;**

### ICD10

- I89.0 Lymphedema, not elsewhere classified
- Q82.0 Hereditary lymphedema
- I97.89 Oth postproc comp and disorders of the circ sys, NEC

## Clinical Pearls

**&NA;**

- Use short-stretch bandages for wrapping (not ACE wraps).
- Avoid heat/whirlpool: typically worsens condition.
- Much higher risk for cutaneous-sourced infections than patients with only venous insufficiency
- Lymphoscintigram is a standard diagnostic, but consider Indocyanine green lymphography or fluorescence microlymphography.

# Macular Degeneration, Age-Related

Richard W. Allinson, MD

## BASICS

### DESCRIPTION

- Age-related macular degeneration (ARMD) results in pigmentary changes in the macula or typical drusen associated with visual loss to the 20/30 level or worse, not caused by cataract or other eye disease, in individuals >50 years of age, although some definitions exclude age or visual acuity criteria.
- Leading cause of irreversible, severe visual loss in persons age >65 years
- Stages
  - Atrophic/nonexudative
  - Neovascular/exudative
- System(s) affected: nervous
- Synonym(s): senile macular degeneration; subretinal neovascularization

### EPIDEMIOLOGY

- Neovascular/exudative form is rare in blacks and more common in whites.
- Predominant sex: female

### Incidence

- In the Framingham Eye Study (FES), drusen were noted in 25% of all participants who were <sup>3</sup>52 years of age. ARMD-associated visual loss was noted in 5.7%.
- Atrophic/nonexudative stage accounts for 20% of cases of severe visual loss
- Neovascular/exudative stage accounts for 80% of cases of severe visual loss

### Prevalence

Per FES study:

- People 65 to 74 years old: 11%

- People <sup>3</sup>75 years old: 27.9%

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Breaks in the Bruch membrane allow choroidal neovascular membranes (CNVMs) to invade the retinal pigment epithelium (RPE) and grow into the subretinal space.
- Atrophic/nonexudative: drusen and/or pigmentary changes in the macula
- Neovascular/exudative: growth of blood vessels underneath the retina
- Visible light can result in the formation and accumulation of metabolic by-products in the RPE, a pigment layer underneath the retina that normally helps remove metabolic by-products from the retina. Excess accumulation of these metabolic by-products interferes with the normal metabolic activity of the RPE and can lead to the formation of drusen.
- Neovascular stage generally arises from the atrophic stage.
- Most do not progress beyond the atrophic/non-exudative stage; however, those who do are at a greater risk of severe visual loss.

## **Genetics**

- Genetic susceptibility may be a factor in ARMD: ÷25% genetically determined.
- Complement factor H is an important susceptibility gene for ARMD.
- Although the development of ARMD may be predicted by specific alleles, the clinical response to antivascular endothelial growth factor is not (1)[A].

## **RISK FACTORS**

- Obesity
- Ethnicity: non-Hispanic whites
- Cigarette smoking
- *Chlamydia pneumoniae* infection
- Family history
- Excess sunlight exposure
- Blue or light iris color
- Hyperopia
- History of cardiovascular disease
- Short stature

- Aspirin use
- Female sex

## GENERAL PREVENTION

- Ultraviolet (UV) protection for eyes
- Routine ophthalmologic visits
  - Every 2 to 4 years for patients age 40 to 64 years
  - Every 1 to 2 years after age 65 years
- Patients who take statins, which modify lipid profiles, may have a reduced risk.

## COMMONLY ASSOCIATED CONDITIONS

- Presumed ocular histoplasmosis syndrome
- Exudative retinal detachment
- Vitreous hemorrhage
- Other causes of CNVMs

## DIAGNOSIS

### HISTORY

- Patients frequently notice distortion of central vision.
- Patients may notice straight lines appear crooked (e.g., telephone poles).

## PHYSICAL EXAM

- Atrophic/nonexudative stage retinal exam
  - Drusen (small yellowish white lesions)
    - Subtypes: hard drusen and soft drusen
  - Atrophy of the RPE
- Neovascular/exudative stage retinal exam
  - Blood vessels growing underneath the retina from the choroid are called *CNVMs* or *subretinal neovascularization* (SRN). The choroid is the vascular layer underneath the RPE.

- Subretinal fluid or hemorrhage
  - Exudates
  - On Amsler grid testing, the horizontal or vertical lines may become broken, distorted, or missing.
- Disciform scar: an advanced stage resulting in a fibrovascular scar

## *DIFFERENTIAL DIAGNOSIS*

- Idiopathic SRN
- Presumed ocular histoplasmosis syndrome
- Diabetic retinopathy
- Hypertensive retinopathy

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Diagnostic Procedures/Other*

- Amsler grid testing
- Fluorescein angiography
  - Detection of CNVMs
  - Differentiate between atrophic and neovascular ARMD.
- Indocyanine green video angiography: may identify occult or hidden CNVMs
- Optical coherence tomography (OCT) may be useful in identifying CNVMs, subretinal fluid, and retinal thickening.
  - Fluorescein angiography is better than time-domain OCT in detecting new-onset CNVMs

### *Test Interpretation*

Drusen: deposits of hyaline material between the RPE and Bruch membrane (the limiting membrane between the RPE and the choroid)

## **TREATMENT**

### *MEDICATION*

## First Line

- Ranibizumab (Lucentis)
  - Antibody fragment that inhibits all active forms of vascular endothelial growth factor (VEGF)
  - Approved for neovascular (wet) ARMD
  - Injected intravitreally, at a dose of 0.5 mg, every 4 weeks
  - 1 year after treatment, up to 40% of patients treated with ranibizumab gained at least three lines of vision and ÷95% maintained vision.
  - Ranibizumab is superior to verteporfin in the treatment of predominately classic CNVMs.
  - The PrONTO study demonstrated OCT-guided, variable-dosing regimen with ranibizumab resulted in similar results to the MARINA and ANCHOR studies with monthly injections.
  - When comparing ranibizumab and bevacizumab in a multicenter study, both treatments were effective in stabilizing visual loss, and no difference was found in the visual outcome between the two treatment groups. A slightly higher rate of serious systemic adverse events was noted in the bevacizumab group (2)[A].
    - In this study treatment as needed resulted in less gain in visual acuity, whether instituted at enrollment or after 1 year of monthly treatment.
  - Eyes with <sup>3</sup>50% of the lesion composed of blood had a similar visual prognosis compared to other treated eyes in the Comparison of Age-related Macular Degeneration Treatment Trials (CATT). Neovascular ARMD lesions composed of >50% blood can be managed similarly to those with less or no blood (3)[A].
  - The treat and extend regimen (TER) is commonly used to decrease the treatment burden. Once no signs of CNVM activity are detected, patient follow-ups and treatments are then extended by intervals of 2 weeks as long as no signs of CNVM activity are present, up to a maximum interval of 12 weeks. If examination shows any sign of recurrence, the interval is shortened by 2 weeks at a time, until the disease is considered to be inactive. Interval extension is then restarted, with the maximum final interval being 2 weeks less than the period when the previous recurrence was observed.
  - Ranibizumab and bevacizumab had equivalent effects on visual acuity at 1 year using the TER. The visual acuity results at 1 year were comparable to those of other clinical trials with monthly treatment (4)[A]
- VEGF Trap-Eye/aflibercept (Eylea)
  - A decoy VEGF receptor that inhibits all isoforms of VEGF-A and placental growth factor (PlGF), the members of the VEGF family in mammals primarily involved in ocular neovascularization

- Approved for neovascular (wet) ARMD
- Injected intravitreally, at a dose of 2 mg, every 4 weeks for 12 weeks then every 8 weeks

P.629

- Dosed as needed after the 12-week fixed dosing schedule resulted in a 5.3-letter gain in best corrected visual acuity at 52 weeks (5)[B].
- Routine use of prophylactic antibiotics after intravitreal injections may be unnecessary (6) [B].
- Maybe beneficial in patients who are not responding to ranibizumab or bevacizumab (7)[C]

## *Second Line*

- Bevacizumab (Avastin) is a full-length antibody to VEGF, administered intravitreally at a dose of 1.25 mg; it is being evaluated in the treatment of neovascular ARMD. Widely used off-label because of its lower cost.
- Agents that block platelet-derived growth factor (PDGF) are being investigated.

## **GENERAL MEASURES**

Low-vision aids may be helpful.

## **SURGERY/OTHER PROCEDURES**

- Laser treatment for CNVMs located <sup>3</sup>200 microns from the center of the macula has been evaluated in the Macular Photocoagulation Study (MPS).
  - Anti-VEGF treatment is first-line therapy for subfoveal CNVM's.
- Vitrectomy has been used to remove CNVMs, but this is generally not recommended.
- CNVMs can bleed spontaneously, leaving blood underneath the retina. Vitrectomy to remove subretinal blood may be of benefit and should be performed within 7 days of the bleed. Tissue plasminogen activator (tPA) instilled into the eye, may help remove a subretinal hemorrhage. In some cases, intravitreal gas with or without tPA may displace submacular blood:
  - Intravitreal anti-VEGF monotherapy may be helpful in the treatment of neovascular ARMD associated with a submacular hemorrhage (8)[C].
- Photodynamic therapy (PDT) with verteporfin reduces vision loss in patients with >50% ÓclassicÓ subfoveal CNVMs. Verteporfin is administered IV, and a diode laser at 689 nm is applied to the CNVM.
  - Patients should be informed of a <4% risk of acute, severe vision loss after PDT.

- Ranibizumab has greater clinical efficacy than PDT.
  - Combination treatment with intravitreal ranibizumab and PDT appears to offer similar gain in visual acuity when compared with ranibizumab monotherapy (9)[B].
  - Combination treatment with ranibizumab and PDT may reduce the number of ranibizumab retreatments.
- Stereotactic radiotherapy is being investigated in the treatment of neovascular ARMD.
  - Laser photocoagulation to treat drusen is not recommended.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

Free radical formation in the retina, induced by visible light, may play a role in cellular damage that results in atrophic/nonexudative macular degeneration. The Age-Related Eye Disease Study (AREDS) found that a high-dose regimen of antioxidant vitamins and mineral supplements reduced progression of ARMD in some cases.

- Recommended daily doses: vitamin C 500 mg, vitamin E 400 IU, &beta;-carotene 15 mg, zinc oxide 80 mg, and cupric oxide 2 mg
- Exercise caution with &beta;-carotene use in smokers due to potential link to lung cancer.
- The Age-Related Eye Disease Study 2 (AREDS2) found the addition of lutein with zeaxanthin alone or in combination with omega-3 fatty acids had no overall effect in further reducing the risk of progression to advanced ARMD (10)[A].

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Amsler grid can aid in discovering visual disturbances.
- Patients with soft drusen or pigmentary changes in the macula are at an increased risk of visual loss. They should monitor their vision, such as by daily Amsler grid testing, and subjective measures of visual acuity, such as reading ability. If no new symptoms, follow-up examination in 6 to 12 months

#### *DIET*

- Eating dark green, leafy vegetables (spinach/collard greens), which are rich in carotenoids, may decrease the risk of developing the neovascular/exudative stage.

- Fish consumption with omega-3 fatty acid intake reduces the risk of ARMD.
- A Western type diet characterized by higher intake of red meat, processed meat, high-fat dairy products, French fries, refined grains, and eggs increases the risk of ARMD as compared to an Oriental type diet characterized by higher intake of vegetables, legumes, fruit, whole grains, tomatoes, and seafood which decreases the risk of ARMD (11)[A].

## PATIENT EDUCATION

Instruct visually impaired patients to check with the local low-vision center for aids.

## PROGNOSIS

- Patients with bilateral soft drusen and pigmentary changes in the macula, but no evidence of exudation, have an increased likelihood of developing CNVMs and subsequent visual loss.
- Patients with bilateral drusen carry a cumulative risk of 14.7% over 5 years of suffering significant visual loss in one eye from the neovascular stage of ARMD.
- Patients with neovascular stage in one eye and drusen in the opposite eye are at an annual risk of 5-14% of developing the neovascular stage in the opposite eye with drusen.
- High incidence of recurrence after thermal laser treatment for CNVMs

## COMPLICATIONS

- Blindness
- The intraocular pressure should be monitored in eyes receiving intravitreal anti-VEGF injections.

## Codes

&NA;

### ICD10

- H35.30 Unspecified macular degeneration
- H35.32 Exudative age-related macular degeneration

- H35.31 Nonexudative age-related macular degeneration

## Clinical Pearls

### **&NA;**

- Patients frequently notice distortion of central vision.
- Patients may notice straight lines appear crooked (e.g., telephone poles).
- Hyperopia is a risk factor for ARMD.
- The AREDS study found that a high-dose regimen of antioxidant vitamins and mineral supplements reduces progression of ARMD in some cases.
- Tobacco cessation should be strongly encouraged.

# Malaria

Paul M. Arguin, MD

## BASICS

### DESCRIPTION

- Acute or chronic infection transmitted to humans by *Anopheles* spp. mosquitoes
- Most morbidity and mortality is caused by *Plasmodium falciparum*. An estimated 198 million cases occur annually, including 584,000 deaths, most of which occur in children <5 years of age in sub-Saharan Africa (1).
- Nonimmune individuals are most susceptible to rapid progression to severe disease.
- System(s) affected: cardiovascular, hematologic, renal, respiratory, cerebral, lymphatic, immunologic

### EPIDEMIOLOGY

- Cases imported to the United States: 58% *P. falciparum*; 17% *Plasmodium vivax*; 3% *Plasmodium malariae*; 3% *Plasmodium ovale*; 1% mixed; 17% unknown
- Occurs worldwide in tropical latitudes: *P. falciparum*, *P. malariae*, *P. vivax*, and *P. ovale*. *P. knowlesi* in parts of Southeast Asia.

### Incidence

- Most U.S. cases (>99%) are imported.
- ÷1,500 cases and 5 deaths per year in the United States (2)

### Prevalence

- Predominant age: all ages
- Predominant sex: male = female

### ETIOLOGY AND PATHOPHYSIOLOGY

- Malarial parasites digest red blood cell (RBC) proteins and alter the RBC membrane, thereby causing hemolysis, increased splenic clearance, and anemia.

- RBC lysis stimulates release of cytokines and tumor necrosis factor- $\alpha$ ; (TNF- $\alpha$ ;) causing fever and systemic symptoms.
- *P. falciparum* alters RBC viscosity, causing obstruction and end-organ ischemia.

## Genetics

Unknown genetic predilection but inherited conditions may affect disease severity and susceptibility (glucose-6-phosphate dehydrogenase deficiency, sickle cell disease or trait, and hereditary elliptocytosis)

## RISK FACTORS

- Travel/migration from endemic areas (primarily sub-Saharan Africa)
- Rarely, blood transfusion, mother-to-fetus transmission, and local autochthonous transmission

## GENERAL PREVENTION

- Mosquito avoidance measures: Use of insect repellent, wear clothing that covers exposed skin, use mosquito nets treated with permethrin, and avoid outdoor activity from dusk to dawn.
- *Malarial chemoprophylaxis when in endemic area*
  - Mefloquine: begin at least 2 weeks before arrival and continue for 4 weeks after leaving area. Adults, 250 mg (1 tablet) weekly; children  $\leq 9$  kg, 5 mg/kg; children  $>9$  to 19 kg, 1/4 tablet weekly; children  $>19$  to 30 kg, 1/2 tablet weekly; children  $>30$  to 45 kg, 3/4 tablet weekly; children  $>45$  kg as adult
    - Caution: mefloquine-resistant areas
  - Atovaquone/proguanil: begin 1 to 2 days before arrival and continue for 1 week after leaving area. Adults, 1 adult tablet daily; children 5 to 8 kg, 1/2 pediatric tablet daily; children 9 to 10 kg, 3/4 pediatric tablet daily; children 11 to 20 kg, 1 pediatric tablet daily; children 21 to 30 kg, 2 pediatric tablets daily; children 31 to 40 kg, 3 pediatric tablets daily; children  $>40$  kg, 1 adult tablet daily
  - Doxycycline: begin 1 to 2 days before arrival and continue for 4 weeks after leaving area. Adults, 100 mg daily; children, 2 mg/kg up to 100 mg daily (not for children  $<8$  years old)
  - Chloroquine: begin 1 to 2 weeks before arrival and continue for 4 weeks after leaving area. Adults, 500 mg (300-mg base) weekly; children, 8.3 mg/kg (5-mg base/kg) weekly up to 300 mg
    - Caution: chloroquine-resistant areas
  - Primaquine: begin 1 to 2 days before arrival and continue for 1 week after leaving area;

adults, 30 mg/day; children, 0.5 mg/kg/day up to adult dose

- For use only in areas predominantly endemic for *P. vivax*
- Caution: Glucose-6-phosphate dehydrogenase deficiency must be excluded prior to first use.

## COMMONLY ASSOCIATED CONDITIONS

Bacterial coinfections sometimes occur.

## DIAGNOSIS

### HISTORY

- Initial symptoms of malaria are nonspecific. Suspect malaria in ill patients returning from endemic area presenting with
  - Fever, malaise, myalgias, chills, headache, nausea, splenomegaly (with chronic infection), hypotension, anemia (with chronic or severe disease), thrombocytopenia, jaundice, vomiting, and/or diarrhea (resembling gastroenteritis)
- *P. falciparum*
  - Incubation usually 12 to 14 days, symptoms within 1 month of infection in most individuals (partially immune individuals such as immigrants may become ill up to 1 year after last exposure)
  - Severe disease and complications: vascular collapse, CNS impairment, renal failure, and acute respiratory distress syndrome
- *P. vivax* and *P. ovale*
  - Incubation period 12 to 18 days for primary infection and up to 12 months (and longer) for relapses; generally presents with fevers
  - Dormant parasites may remain in liver and reactivate years after initial infection.
  - Can be severe
- *P. malariae*
  - Incubation period ~35 days
  - May become chronic; untreated can persist asymptotically in human host for years
- *P. knowlesi*

- Incubation period ~12 days
- Possibly severe

## *PHYSICAL EXAM*

- Often not specific
- General: elevated temperature, fatigue, tachycardia, tachypnea, jaundice
- Neurologic: mental status and motor-sensory exam (cerebral malaria)
- Cardiopulmonary exam: hemodynamic stability and signs of vascular leak (effusion)
- Skin exam: pallor, rash
- Abdominal exam: organomegaly

## *DIFFERENTIAL DIAGNOSIS*

- Infections (disseminated or localized): abscess, viral, gastroenteritis, typhoid/paratyphoid, other bacteremias, rickettsial disease, mycobacteria
- Collagen vascular disease (systemic lupus erythematosus [SLE], vasculitides)
- Neoplasms (lymphoma, leukemia, other blood dyscrasias, other tropical causes of splenomegaly)
- Severe malaria infection may mimic hepatitis, pneumonia, stroke, or sepsis.

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Malarial smear thick and thin preparations (3)[A]
  - Microscopy to evaluate for presence of parasite forms, determine species, and quantify the percentage of RBCs that are infected. Relatively easy to perform with proper training.
  - Test should be performed on site, immediately, with results quickly available.
    - Rapid antigen capture enzyme: can detect the presence of malaria parasites within minutes. Cannot determine species or quantify parasitemia. Positive and negative results must always be confirmed by microscopy.
    - Other tests: species-specific PCR; species confirmation by PCR is encouraged.
- General laboratory findings (nonspecific)
  - In uncomplicated infection
    - Elevated liver function tests and lactate dehydrogenase

- Thrombocytopenia, anemia, and leukopenia
- Note: a low to low-normal platelet count or a slightly high bilirubin should alert the clinician to the diagnosis after exposure in an endemic setting.
- Note: Antimalarial prophylaxis may reduce parasitemia.

### *Initial Tests (lab, imaging)*

- CBC with differential and platelets
- Basic chemistry panel including bilirubin
- Malaria thick and thin blood films (if negative, repeat q12-24h for at least three sets)
- Imaging necessary only for respiratory disease (chest x-ray) or cerebral malaria (CT scan prior to lumbar puncture)

### *Follow-Up Tests & Special Considerations*

- Nonimmune individuals with suspected or confirmed *P. falciparum* should be hospitalized.
- Clinical specimens from suspected or confirmed malaria cases in the United States can be submitted to the Centers for Disease Control and Prevention (CDC) for diagnostic confirmation, speciation, and drug resistance surveillance free of charge.

### *Test Interpretation*

Interpretation of microscopy. Blood is obtained from the patient and spread on a microscope slide as a thick/thin prep and stained with Giemsa (most commonly). The slide is viewed under 100X oil immersion to examine for ring, gametocyte, trophozoite, and schizont forms. The thick film is better for detecting parasites. The thin film is used to determine species and calculating the percentage of RBCs infected. Both should always be performed.

---

P.631

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- For uncomplicated chloroquine-resistant *P. falciparum* (most *P. falciparum*), chloroquine-resistant *P. vivax*, or when species is unknown, the following regimens are recommended (4) [A]:

- Atovaquone-proguanil (Malarone): adult tablet: 250 mg atovaquone and 100 mg proguanil. Pediatric tablet: 62.5 mg atovaquone and 25 mg proguanil. Adults: 4 adult tablets once per day for 3 days. Children 5 to 8 kg: 2 pediatric tablets once per day for 3 days; children 9 to 10 kg: 3 pediatric tablets once per day for 3 days; children 11 to 20 kg: 1 adult tablet once per day for 3 days; children 21 to 30 kg: 2 adult tablets once per day for 3 days; children 31 to 40 kg: 3 adult tablets once per day for 3 days; children >40 kg: 4 adult tablets once per day for 3 days
- Artemether-lumefantrine (Coartem): tablet contains 20 mg artemether and 120 mg lumefantrine. Persons 5 to <15 kg: 1 tablet BID for 3 days; persons 15 to <25 kg: 2 tablets BID for 3 days; persons 25 to <35 kg: 3 tablets BID for 3 days; persons ≥35 kg: 4 tablets BID for 3 days
- Quinine sulfate plus doxycycline or clindamycin: adults: quinine sulfate 650 mg (salt) TID for 3 days (should be extended to 7 days for infections acquired in Southeast Asia). Doxycycline 100 mg BID for 7 days. Clindamycin 20 mg (base)/kg/day divided TID for 7 days. Children: quinine sulfate 10 mg (salt)/kg TID for 3 days (should be extended to 7 days for infections acquired in Southeast Asia) plus clindamycin dosed as above.
- Mefloquine: adults: 750 mg followed by 500 mg 8 hours later. Children: 15 mg/kg followed by 10 mg/kg 8 hours later (maximum total dose: 1,250 mg)
- PO therapy for *P. ovale*, *P. malariae*, chloroquine-sensitive *P. falciparum* (rare), and chloroquine-sensitive *P. vivax* (New Guinea has highest rates of chloroquine-resistant *P. vivax*); in addition to the treatment regimens listed above, other options are as follows:
  - Chloroquine: adults: 1 g (600-mg base) followed by 500 mg (300-mg base) at 6, 24, and 48 hours after first dose. Children: 16.6 mg/kg (10-mg base/kg) on day 1 (max 1,000 mg [600-mg base]), then 8.3 mg/kg (5-mg/kg base) at 6, 24, and 48 hours after first dose
  - Primaquine (should be added to the acute treatment regimen for cure of dormant forms of *P. vivax* and *P. ovale*): adults: 30-mg base (52.6 mg) daily for 2 weeks. Children: 0.6-mg base/kg/day for 2 weeks
- Therapy for severe malaria
  - Clinical features defining severe malaria:
    - Impaired level of consciousness (LOC)
    - Respiratory distress, jaundice
    - Repeated convulsions, shock
    - Renal failure
  - Laboratory features:

- Parasitemia >5%
- Hypoglycemia
- Acidosis (usually lactic acidosis)
- Parenteral therapy
  - Quinidine gluconate 10 mg/kg in normal saline over 1 to 2 hours followed by 0.02 mg/kg/min continuous infusion
  - Intensive care monitoring is necessary, especially when initiating quinidine therapy.
- In severe malaria, contact the CDC for assistance; CDC Malaria Branch: 770-488-7100; <http://www.cdc.gov/Malaria/>
- In 2007, the CDC made artesunate available in the United States for severe malaria in special circumstances under an investigational protocol. Contact the CDC for assistance.

## *ISSUES FOR REFERRAL*

Infectious disease or tropical medicine consultation advised. Malaria is a reportable disease ([http://www.cdc.gov/malaria/features/new\\_report\\_form.html](http://www.cdc.gov/malaria/features/new_report_form.html)).

## *ADDITIONAL THERAPIES*

None

### *Pediatric Considerations*

- Children are particularly susceptible to severe disease.
- All children, even infants, should receive chemoprophylaxis if traveling to an endemic area.
- Malaria commonly resembles acute gastroenteritis in children.
- Children with severe disease are particularly prone to hypoglycemia. Use IV fluids with glucose for maintenance and monitor blood glucose frequently.

### *Pregnancy Considerations*

- Chloroquine is safe in the doses recommended for prevention and treatment of malaria; FDA pregnancy Category C.
- Mefloquine is safe in the doses recommended for prevention and treatment of malaria; FDA pregnancy Category B.
- Atovaquone-proguanil (Malarone) has not been studied in pregnant women; it has not been shown to cause birth defects or other problems in animal studies; FDA pregnancy Category C.

- No primaquine (FDA class undetermined) or tetracyclines (FDA pregnancy Category D) in pregnancy
- Quinine/Quinidine (FDA pregnancy Category C, respectively) should be used during pregnancy because benefit outweighs risk.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

None. Deaths have resulted from using unapproved alternatives to recommended medications.

## SURGERY/OTHER PROCEDURES

Rarely, splenectomy must be performed in patients with splenic rupture.

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

- Inpatient care for all cases of *P. falciparum* malaria. Hospitalize patients with signs of severe illness, regardless of species; outpatient care for others.
- Nonimmune patients with *P. falciparum* may progress from mild symptoms to death within 12 hours.
- All patients treated on outpatient basis should have follow-up within 24 hours.

### *IV Fluids*

Maintenance IV fluids with glucose because of risk of hypoglycemia are recommended if unable to tolerate fluids by mouth. Excess fluids may result in iatrogenically induced pulmonary edema.

### *Nursing*

Observe for fluid excess, renal insufficiency (urine output), and hypoglycemia

### *Discharge Criteria*

Clinical improvement and ability to tolerate oral medications and fluids, with documented decreasing parasitemia levels

## ONGOING CARE

### *PATIENT EDUCATION*

- Malarial chemoprophylaxis prior to travel

- Travel information may be obtained at the CDC travel Web site: <http://www.cdc.gov/travel>
- [http://www.cdc.gov/malaria/new\\_info/2014/malaria\\_ebola.htm](http://www.cdc.gov/malaria/new_info/2014/malaria_ebola.htm)

## PROGNOSIS

Malaria infection (particularly *P. falciparum*) can carry a high mortality if untreated. If diagnosed early and treated appropriately, the prognosis is excellent.

## COMPLICATIONS

- If not treated early: cerebral malaria, acute renal failure, acute gastroenteritis, respiratory distress syndrome, and massive hemolysis
- Other complications: seizures, anuria, delirium, coma, dysentery, algid malaria, blackwater fever, hyperpyrexia
- *P. malariae*: Nephrotic syndrome may develop in patients with chronic infection.

## Additional Reading

&NA;

- Centers for Disease Control and Prevention. Guidelines for treatment of malaria in the United States. <http://www.cdc.gov/malaria/resources/pdf/treatmenttable.pdf>. Updated July 1, 2013.
- Steinhardt LC, Magill AJ, Arguin PM. Review: malaria chemoprophylaxis for travelers to Latin

## Codes

&NA;

### ICD10

- B54 Unspecified malaria
- B50.9 Plasmodium falciparum malaria, unspecified
- B51.9 Plasmodium vivax malaria without complication

## Clinical Pearls

&NA;

- Consider malaria in travelers returning from endemic areas who present with fever or nonspecific flulike illness.
- Early identification and aggressive treatment, particularly of nonimmune persons with suspected or confirmed *P. falciparum* malaria, is important.
- Patients who develop clinical malaria despite chemoprophylaxis should be treated with medication that is different from their chemoprophylaxis drug.
- *P. falciparum* malaria can be rapidly fatal and should be cared for in the inpatient setting.

# Marfan Syndrome

Rayna Goldstein, MD

Michele Roberts, MD, PhD

## BASICS

### DESCRIPTION

- Marfan syndrome (MFS) is an inherited disorder of connective tissue.
- Because many features of MFS appear in the general population, specific diagnostic criteria (Ghent nosology) were established and revised, recognizing a constellation of features with major and minor criteria for establishing the diagnosis (1,2).
- System(s) affected: musculoskeletal, cardiovascular, ocular, pulmonary, skin/integument, connective tissue (dura)

### *Pediatric Considerations*

Careful monitoring, as described. Early surgical intervention may reduce the degree of scoliosis.

### *Pregnancy Considerations*

- Manage pregnancy in MFS as high risk, with a cardiologist; prepregnancy evaluation: screening transthoracic echocardiogram for aortic root dilation
- Consider *β*-blockers in all pregnancies to minimize risk of aortic dilation throughout the pregnancy.
- 1% complication rate if aortic root diameter <40 mm; 10% if >40 mm. Consider elective surgery before pregnancy if >47 mm.
- Avoid spinal anesthesia due to risk of dural ectasia.

### EPIDEMIOLOGY

- Congenital; although clinical manifestations may be apparent in infancy, affected individuals may not present until adolescence or young adulthood.
- No gender, ethnic, or racial predilection; with advanced paternal age, a slightly increased risk of de novo mutation resulting in MFS in offspring

## Prevalence

1/5,000 to 1/10,000

## ETIOLOGY AND PATHOPHYSIOLOGY

Genetic abnormality; mutations of the *FBN1* (fibrillin) gene. Fibrillin is an extracellular matrix protein widely distributed in elastic and nonelastic connective tissue.

## Genetics

- Mutations of the fibrillin-1 (*FBN1*) gene on chromosome 15q21.1 OMIM 154700.
- MFS is an autosomal dominant condition with complete penetrance and variable expressivity. Apparent nonpenetrance may be due to lack of recognition of MFS in a mildly affected individual.
- Each child of an affected parent has a 50% chance of inheriting MFS and may be more or less severely affected. 25% of cases result from de novo mutation.

## GENERAL PREVENTION

Prenatal diagnosis is possible in families with a known mutation.

## COMMONLY ASSOCIATED CONDITIONS

- High prevalence of obstructive sleep apnea in MFS; may be a risk factor for aortic root dilatation
- Increased prevalence of migraine in MFS

## DIAGNOSIS

- In the revised Ghent nosology:
  - Cardiovascular manifestations (aortic root aneurysm/dissection) and ectopia lentis have more weight.
  - Molecular genetic testing for *FBN1* plays a more prominent diagnostic role but is not required.
  - Less specific manifestations were removed or made less influential, thus avoiding obligate thresholds that were not evidence based. Careful follow-up diminishes risk of missed diagnosis.
  - New criteria explicitly allow for alternative diagnoses, when additional features warrant: Shprintzen-Goldberg syndrome (SGS), Loeys-Dietz syndrome (LDS), or vascular-type Ehlers-

Danlos syndrome (vEDS).

- Z-score calculator for aortic root enlargement: <http://www.marfan.org/>
- In the absence of a family history of MFS:
  - Aortic root dilatation or dissection ( $Z \geq 2$ ) (Ao) and ectopia lentis (EL): unequivocal diagnosis of MFS, irrespective of systemic features, except when they are diagnostic of SGS, LDS, or vEDS
  - Ao and a bona fide *FBN1* mutation: diagnostic of MFS, even in the absence of EL
  - Where Ao is present but EL is absent and the *FBN1* status is negative (or unknown), diagnosis of MFS requires systemic findings score of  $\geq 7$  points using new scoring system (see below) and exclusion of SGS, LDS, and vEDS.
  - With EL but without Ao, *FBN1* mutation previously associated with Ao is required for diagnosis of MFS.
- Systemic features, scoring system (see "Physical Exam"):
  - Wrist and thumb sign + 3 (thumb protrudes from clenched fist); wrist or thumb sign + 1 (encircles wrist with little finger and thumb of opposite hand)
  - Pectus carinatum deformity +2; pectus excavatum or chest asymmetry +1
  - Hindfoot deformity +2; pes planus +1
  - Pneumothorax +2
  - Dural ectasia +2
  - Protrusio acetabuli +2 by x-ray, CT, or MRI
  - Reduced upper-to-lower segment ratio (US/LS) and increased arm/height and no severe scoliosis +1
  - Scoliosis or thoracolumbar kyphosis +1
  - Reduced elbow extension +1
  - Facial features (3/5) +1
  - Skin striae +1
  - Myopia  $>3$  diopters +1
  - Mitral valve prolapse (all types) +1
- Maximum: 20 points; score  $\geq 7$  indicates systemic involvement.
- Positive family history requires a family member independently diagnosed using above criteria.

- With a positive family history, MFS can be diagnosed with ectopia lentis, or systemic score  $\geq 7$ , or aortic root dilatation with  $Z \geq 2$  in persons  $>20$  years old, or  $Z \geq 3$  in persons  $<20$  years old.
- In persons  $<20$  years old who have negative family history and suggestive findings but who do not meet Ghent criteria, nonspecific connective tissue disorder is diagnosed; close follow-up is recommended.
- In the presence of a relevant *FBN1* mutation, potential MFS is diagnosed and close follow-up is recommended.
- In adults who have suggestive findings but who do not meet Ghent criteria, consider alternative diagnoses: ectopia lentis syndrome, mitral valve prolapse syndrome, MASS (Mitral valve prolapse, Aortic dilation, Skin, and Skeletal) phenotype.

## PHYSICAL EXAM

- Facial features: dolichocephaly (head length longer than expected compared with width), enophthalmos, down-slanting palpebral fissures, malar hypoplasia, micrognathia
- High-arched, narrow palate
- Thumb sign: distal phalanx of thumb protrudes from clenched fist; wrist sign: thumb and 5th digit overlap when circling wrist.
- Pectus carinatum deformity: pectus excavatum or chest asymmetry beyond normal variation
- Hindfoot valgus with forefoot abduction and lowering of the midfoot; distinguish from pes planus
- Height may be normal or may be  $\geq 3.3$  SD  $>$ mean.
- Reduced upper segment-to-lower segment (US/LS) ratio: 0.93 in unaffected individuals versus  $\geq 0.85$  in affected white adults,  $\geq 0.78$  in affected black adults. US is measured from the top of the head to the top of the midpubic bone; LS from the top of the pubic bone to the sole of the foot. In children, abnormal US/LS: US/LS  $<1$ , age 0 to 5 years; US/LS  $<0.95$ , 6 to 7 years; US/LS  $<0.9$ , 8 to 9 years;  $<0.85$ , age  $\geq 10$  years.
- Increased arm span to height ratio  $>1.05$
- Scoliosis or thoracolumbar kyphosis is diagnosed if, on bending forward, there is a vertical difference  $\geq 1.5$  cm between the ribs of the left and right hemithorax.
- Reduced elbow extension if angle between upper and lower arm measures  $\geq 170$  degrees on full extension
- Skin: Striae atrophicae are significant if not associated with significant weight changes (or pregnancy) and if located on midback, lumbar region, upper arm, axilla, or thigh.
- Because of lack of specificity, joint hypermobility, high-arched palate, and recurrent or

incisional herniae were removed from diagnostic criteria (1).

## ***DIFFERENTIAL DIAGNOSIS***

Clinical manifestations overlapping with MFS in cardiovascular, ocular, and skeletal systems:

- Ectopia lentis syndrome: no aortic root dilatation
- Mitral valve prolapse syndrome: MVP; limited systemic features may include pectus excavatum, scoliosis, mild arachnodactyly; aortic enlargement and ectopia lentis preclude this diagnosis.
- MASS phenotype: mitral valve prolapse; myopia; borderline, nonprogressive aortic enlargement ( $Z < 2$ ); and nonspecific skeletal and skin involvement. Aortic involvement in MASS usually nonprogressive; some risk for more severe vascular involvement.
- Shprintzen-Goldberg, Loeys-Dietz, Ehlers-Danlos, Stickler syndromes; congenital contractural arachnodactyly; Weill-Marchesani syndrome, multiple endocrine neoplasia type 2B, fragile X
- Homocystinuria: Marfanoid habitus, thrombosis, mental retardation; urine amino acid analysis is diagnostic; lens dislocates downward.
- Familial thoracic aortic aneurysm
- Aortopathy NGS panel likely to play a more prominent role, especially as VUS are classified (3)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Sequencing of *FBN1* is the preferred method for molecular diagnosis. Mutations can be found in 95% of patients meeting diagnostic criteria for MFS.
- Specific criteria have been established (1) for *FBN1* mutations causative of MFS. *FBN1* mutation is a valuable marker for risk of aortic dissection (4).
- Echocardiography: Measure aortic root at the level of sinuses of Valsalva; check for mitral valve prolapse. The Marfan Foundation has nomograms to calculate aortic root Z-score in children (<http://www.marfan.org/>).

---

P.633

- In patients whose physical exam is suggestive of MFS, measure urinary homocystine to rule out homocystinuria, an inborn error of metabolism.
- Anteroposterior (AP) radiograph: protrusio acetabuli
- Scoliosis: Cobb angle  $\geq 20$  degrees on radiographs; imaging for MFS diagnosis or as per clinical exam
- Hindfoot valgus with forefoot abduction and lowering of the midfoot: anterior and posterior views

MRI or CT to evaluate for dural ectasia and if symptomatic, symptoms highly variable, nonspecific, and include lower back pain

## *Diagnostic Procedures/Other*

- Ectopia lentis is diagnosed on slit-lamp examination after maximal dilatation of the pupil (60%); lens dislocation is most often upward and temporal.
- Myopia: Common in the general population; myopia >3 diopters contributes to MFS systemic score.
- Elongated globe, keratoconus, increased risk of vitreous or retinal detachment, glaucoma, and early cataract formation

## *Test Interpretation*

- Cystic medial necrosis of the aorta: descriptive, not pathognomonic
- Myxomatous degeneration of cardiac valves

## **TREATMENT**

### **MEDICATION**

- Prevention of aortic complications:  $\beta$ -adrenergic blockers. Dosage adjusted to target heart rate (resting rate 60 bpm, increase to  $\geq$ 110 bpm after moderate exertion or <100 bpm after submaximal exercise) (1)[C]
- If  $\beta$ -blockers are contraindicated: Calcium channel blockers, ACE inhibitors, and ARBs may retard aortic dilation in children and adolescents (5)[B].
- Consider antibiotic prophylaxis for dental procedures in presence of mitral or aortic regurgitation (<http://www.marfan.org/resource/fact-sheet/endocarditis-prophylaxis-people-marfan-syndrome#.VhMqKvIViko>).
- Recent studies support losartan plus  $\beta$ -blockers to prevent progressive aortic root dilatation (6)[B].

### **ISSUES FOR REFERRAL**

Genetics, cardiology, orthopedics, ophthalmology

### **SURGERY/OTHER PROCEDURES**

- When cardiac symptoms develop or aortic root diameter is  $\geq$ 5 cm, consider surgical

intervention (7). Many MFS patients will ultimately require reconstructive cardiovascular surgery:

- Dissection of ascending aorta (type A) is a surgical emergency. Consider prophylactic surgery when diameter of sinus of Valsalva approaches 5 cm, rate of change approaches 1 cm/year, and with progressive aortic regurgitation (3); other risk factors: family history, other cardiac pathology, pregnancy.
- Dissection of descending thoracic aorta (type B): Surgical indications include intractable pain, limb or organ ischemia, and aortic diameter >5.5 cm (or rapidly increasing) (1).
- Mitral valve repair: for severe mitral valve regurgitation or progressive LV dilatation or dysfunction, or in patients undergoing valve-sparing root replacement (1)
- Lens subluxation: Incidence of glaucoma is high, so surgery is performed only if the condition cannot be treated with corrective lenses; surgical removal of lens for opacity, impending complete luxation, lens-induced glaucoma or uveitis, or anisometropia or refractive error not amenable to optical correction (1)
- Severe pectus excavatum may interfere with pulmonary or cardiac function and require surgery.
- Scoliosis: bracing for curves 20 to 40 degrees until growth is complete or surgery if >40 degrees
- Surgery for only most severe cases of dural ectasia
- Hip replacement in middle age or later if protrusio acetabuli has led to severe arthritic change

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Avoid sports that can increase aortic root enlargement or pneumothorax; in general, avoid contact sports, Valsalva, breathing against resistance, and exhaustion (8)[C].
- Exercise restrictions: Follow recommendation from the National Marfan Foundation (<http://www.marfan.org/>) and guidelines from the American Heart Association/American College of Cardiology Task Forces.

### *Patient Monitoring*

Exams at least twice/year while patient is growing, with attention to the cardiovascular system and to scoliosis.

- Cognitive ability is usually normal, but visual and medical difficulties may interfere with

learning (8)[C].

- Cardiac
  - Aortic root dilatation in MFS is usually progressive, warrants vigilance even when not seen on initial examination; age <20 years, yearly echocardiogram; adults with repeatedly normal aortic root measurements, echo every 2 to 3 years (1)[C].
  - Yearly echocardiograms (initially), more frequent if aortic diameter is increasing rapidly (<sup>3</sup>5 cm/year) or is approaching surgical threshold (<sup>3</sup>4.5 cm in adults)
  - Regular imaging after surgical repair of aorta
- Musculoskeletal
  - Excessive linear growth of long bones, extremities disproportionately long, paucity of muscle mass, peak growth velocity 2 years early. Growth curves for MFS are available (8)[C].
  - Clinical evaluation for scoliosis earlier than in general population; plain radiographs of spine during growth years
  - Evaluate for scoliosis, joint laxity, and pectus deformity every visit to age 1 year, annually age 1 to 5 years, semiannually age 6 to 18 years, and yearly thereafter.
  - Bone age in preadolescence: Consider hormonal therapy if with large discrepancy (8)[C].
  - Scoliosis or pectus deformity may progress more rapidly than in those without MFS.
  - Excellent prognosis for scoliosis curves <30 degrees; bracing may be effective for curves <35 degrees; rapid progression likely if curve >50 degrees (8)[C]
- Annual ophthalmologic evaluation: ectopia lentis, myopia, cataract, glaucoma, and retinal detachment; myopia is very common in MFS with early onset, rapid progression, and high degree of severity; early monitoring, aggressive refraction to prevent amblyopia (1)[C]
- Respiratory: pulmonary function tests (PFTs) for pulmonary complaints; obstructive sleep apnea
- Review diagnosis, examine family members, offer support group information at diagnosis and PRN.
- Provide genetic counseling at diagnosis, discuss pregnancy risks in adolescence, discuss activity restrictions starting age 6 years, transition planning in early adolescence. Review symptoms of potential catastrophic events: aortic dissection, vision changes, and pneumothorax starting age 6 years.

## *PATIENT EDUCATION*

- National Marfan Foundation, <http://www.marfan.org/>

- NLM Genetics Home Reference: Marfan syndrome <http://ghr.nlm.nih.gov/condition/marfan-syndrome>

## PROGNOSIS

Life-threatening complications involve cardiovascular dysfunctions. In 1972, lifespan was 32 years. Currently, lifespan is nearly normal.

## COMPLICATIONS

Bacterial endocarditis, aortic dissection, aortic or mitral valve insufficiency, dilated cardiomyopathy, retinal detachment, glaucoma, pneumothorax

## Codes

&NA;

### ICD10

- Q87.40 Marfan's syndrome, unspecified
- Q87.43 Marfan's syndrome with skeletal manifestation
- Q87.418 Marfan's syndrome with other cardiovascular manifestations

## Clinical Pearls

&NA;

- Because many features of MFS appear in the general population, diagnostic criteria have been established. Molecular diagnostic testing for *FBN1* mutations will play an increasing role.
- Screen very tall athletes for aortic root dilatation.
- Early diagnosis of homocystinuria is important because clinical complications can be minimized with appropriate diet and medication.
- Ectopia lentis and aortic root dilatation are best discrimination features, but height  $\geq 3.3 SD$  above the mean is a simple discriminant in primary care.

# Marijuana (Cannabis) Use Disorder

Kara C. Farley, MD

Dustin K. Smith, DO

## BASICS

### DESCRIPTION

Marijuana or cannabis use disorder is classified in *DSM-5* in different categories (mild, moderate, or severe) depending on how many symptoms are present. Mild: 2 to 3; Moderate: 4 to 5; Severe: 6+ (1). The definition is used leading to clinically significant impairment or distress, manifested by two or more of the following symptoms within a 12-month period:

- Taken in larger amounts and over a longer period of time than intended
- Persistent desire or unsuccessful efforts to cut down or control amount used
- A great deal of time spent in activities is necessary to obtain, use, or recover.
- Presence of craving for the substance
- Recurrent use resulting in failure to fulfill major role obligations at work, school, or home
- Continued use despite having persistent or recurrent social or interpersonal problems due to cannabis use
- Important social, occupational, or recreational activities are given up or reduced.
- Recurrent use in physically hazardous situations
- Use is continued despite knowledge of having a persistent physical or psychological problem caused or exacerbated by cannabis.
- Tolerance, defined by using increased amounts of cannabis to achieve the desired effect or intoxication or diminished effect with continued use of the same amount of cannabis
- Withdrawal

### EPIDEMIOLOGY

- The United States is ranked first among 17 European and North American countries by the World Health Organization for prevalence of marijuana use.
- Cannabis is the most widely used illicit psychoactive substance in the United States (2).

- ÷42% of teens will have tried marijuana by the time they graduate from high school.
- Approximately 30% of students report having used marijuana at college entry (3).
- In the United States, 10% of those who ever used marijuana become daily users, and 20-30% became weekly users.
- In the United States, some states have approved medical marijuana use, and two states (Washington and Colorado) have approved recreational use of marijuana.
- Other states in the United States are currently trying to pass legislation to legalize the use of recreational marijuana.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Main active ingredient in marijuana: delta-9-tetrahydrocannabinol (THC)
- When marijuana is smoked, THC rapidly passes from the lungs into the blood and to the brain, where it binds to cannabinoid receptors (CBRs).
- CBRs are responsible for memory, thinking, concentration, sensory and time perception, pleasure, movement, and coordination.
- THC artificially stimulates the CBRs, disrupting the function of endogenous cannabinoids. A marijuana "high" results from overstimulation of these receptors.
- Over time, overstimulation alters the function of CBRs, which can lead to addiction and to withdrawal symptoms when drug use stops.
- Effects of smoked marijuana occur within minutes and can last 1 to 3 hours.
- Effects from marijuana consumed in foods or beverages appear later, usually in 30 minutes to 1 hour but can last up to 4 hours.
- Smoking marijuana delivers significantly more THC into the bloodstream than eating or drinking the drug.

## *RISK FACTORS*

- Age (highest use among those 18 to 25 years)
- Male sex
- Comorbid psychiatric disorders (i.e., bipolar disorder, posttraumatic stress disorder [PTSD])
- Other substance use (i.e., alcohol, cocaine)
- Lower educational achievement (rates of dependence is lowest among college graduates)

## DIAGNOSIS

- Screen for marijuana use along with other lifestyle questions such as tobacco and alcohol use.
- Ask for frequency and amount used (e.g., "How long does a nickel bag last you?").
- Unexplained deterioration in school or work performance may be a red flag for abuse.
- Problems with, or changes in, social relationships (e.g., spending more time alone or with persons suspected of using drugs) and recreational activities (e.g., giving up activities that were once pleasurable) may indicate abuse.
- If available, information from concerned parents or spouses should be obtained.

## HISTORY

- Clinical presentation of acute intoxication:
  - Euphoria, elation, laughter, heightened sensory perception, altered perception of time, increased appetite
  - Poor short-term memory, concentration
  - Fatigue, depression
  - Occasionally, distrust, fear, anxiety, panic
  - With large doses, acute psychosis: delusions, hallucinations, loss of sense of personal identity (4)
- Withdrawal symptoms include the following:
  - Nausea
  - Weight loss
  - Decreased appetite
  - Insomnia
  - Depressed mood

## PHYSICAL EXAM

- Evaluate for:
  - Conjunctival injection
  - Xerostomia
  - Nystagmus
  - Increased heart rate

- Altered pulmonary status
- Altered body temperature
- Reduced muscle strength
- Decreased coordination
- Withdrawal findings include the following:
  - Restlessness/agitation
  - Irritability
  - Tremor
  - Diaphoresis
  - Increased body temperature

## *DIAGNOSTIC TESTS & INTERPRETATION*

Positive urine drug screen; cannabinoids can be detected in urine weeks to months after marijuana use.

## **TREATMENT**

- Several methods of behavioral-based interventions:
  - Cognitive-behavioral therapy
  - Motivational interviewing
  - Counseling
  - Contingency management
  - Social network behavior therapy
  - Twelve-step approach
  - Family-oriented therapy
  - Brief intervention
  - Relapse prevention
  - Community reinforcement approach
- No intervention to date has proved consistently effective for marijuana abuse.
- Despite this, trials on cognitive-behavioral therapy and contingency management have shown

better outcomes in reducing marijuana use and maintaining abstinence (5).

- Trials also show that addition of a comprehensive parenting training curriculum did not further enhance efficacy (5).
- With marijuana abuse, most prevalent among patients suffering from other psychiatric disorders, studies indicate that treating the mental health disorder may help reduce marijuana use, particularly among heavy users and those with more chronic mental disorders.
- Advice to give to patients for management of withdrawal:
  - Gradually reduce amount of marijuana used before cessation.
  - Delay first use of marijuana until later in the day.
  - Consider use of nicotine replacement therapy if planning to stop, separate tobacco use at the same time.
  - Relaxation, distraction
  - Avoid cues and triggers associated with cannabis use.

---

P.635

- Prescribe short-term analgesia and sedation for withdrawal symptoms, if required.
- If irritability and restlessness are marked, consider prescribing very-low-dose diazepam for 3 to 4 days.
- Provide user and family members with information regarding marijuana abuse and withdrawal to increase understanding of the abuse and reduce likelihood of relapse.
- Withdrawal symptoms peak on day 2 or 3, and most are over by day 7. Sleep and vivid dreams can continue for 2 to 3 weeks.

## *MEDICATION*

- No effective medication for the treatment of marijuana abuse
- One study suggested oral THC could be used to abate marijuana withdrawal in individuals who are trying to quit.
- Another study concluded medications used to treat other drug use disorders, such as bupropion, lithium, and fluoxetine, may have therapeutic benefit.

**ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

- Monitor cessation of marijuana use with urine tests over several weeks for the inactive metabolite of cannabis (carboxy-THC).
- Heavy smokers may continue to be positive for marijuana for up to 6 weeks.

## PATIENT EDUCATION

To learn more about marijuana abuse, visit the National Institute on Drug Abuse (NIDA) Web site at [www.drugabuse.gov](http://www.drugabuse.gov). Other NIDA Web sites include the following:

- <https://drugpubs.drugabuse.gov/promotions/back-to-school>
- <http://www.drugabuse.gov/drugs-abuse/marijuana>
- <https://teens.drugabuse.gov/>

## COMPLICATIONS

- Acute adverse effects
  - Anxiety and panic, especially in naïve users, depression
  - Psychotic symptoms at high doses
  - Motor vehicle accidents if a person drives while intoxicated
  - Chronic adverse effects: abnormal brain development; diminished lifetime achievement
  - Chronic bronchitis and impaired respiratory function in regular smokers
  - Psychotic symptoms and disorders in heavy users, especially those with a history of psychotic symptoms or a family history of these disorders (schizophrenia)
  - Addiction to marijuana and other substances

**&NA;**

## **ICD10**

- F12.10 Cannabis abuse, uncomplicated
- F12.20 Cannabis dependence, uncomplicated
- F12.288 Cannabis dependence with other cannabis-induced disorder

## **Clinical Pearls**

**&NA;**

- Marijuana abuse may result in poor performance in school or work, legal problems, and arguments with family.
- Patients with schizophrenia are frequently found to be using marijuana and their use hindering the treatment for schizophrenia. Management of these dual diagnoses is important for the successful treatment of schizophrenia.
- Patients should be screened for marijuana use and asked about frequency and amount used.
- Effects of smoked marijuana can last 1 to 3 hours. Effects from foods or beverages containing marijuana appear later, usually in 30 minutes to 1 hour but can last up to 4 hours.
- Smoking marijuana delivers significantly more THC into the bloodstream than eating or drinking the drug.
- Acute marijuana intoxication is manifested by conjunctival injection, increased heart rate, euphoria, heightened sensory perception, altered perception of time, increased appetite, poor short-term memory and concentration, and fatigue. Large doses may result in acute psychosis, delusions, or hallucinations.
- Inquire all patients about their use of marijuana. Changes in values and attitudes have made marijuana use more mainstream, and patients do not consider marijuana a substance of abuse.
- Withdrawal symptoms include nausea, weight loss, decreased appetite, insomnia, and depressed mood. Peaks on day 2 or 3 and most are over by day 7.
- Cognitive-behavioral therapy, motivational interviewing, motivational enhancement therapy, and contingency management are four methods of behavioral-based interventions used in the treatment of marijuana abuse.
- Some recent research finds that adolescents with cannabis use disorder may not be susceptible to THC neuropsychological deficits once they achieve remission from all drugs for at least 30

days.

# Mastalgia

Eduardo Lara-Torre, MD

Amanda B. Murchison, MD

Patrice M. Weiss, MD, FACOG

## BASICS

### DESCRIPTION

- Painful breast tissue, often bilateral, which can be cyclic or noncyclic
  - 2/3 of breast pain is cyclic and usually associated with hormonal changes related to menses, external hormones, pregnancy, or menopause.
  - 1/3 is noncyclic and often is related to a breast or chest wall lesion.
- Synonym(s): mastodynia; breast pain

### EPIDEMIOLOGY

#### *Incidence*

- Predominant sex: most common in women but occurs occasionally in men
- Predominant age: generally seen from adolescence to menopause
- Frequency of breast cancer with those reporting breast pain ranges from 1.2% to 6.7%.
- Up to 70% of women report some degree of breast pain at some point in their lives.
- Most describe mild pain, but 11% describe pain as moderate to severe.
- Higher incidence in the older population, larger breasted individuals, and those who are less fit and active (1)[B].

### ETIOLOGY AND PATHOPHYSIOLOGY

- Causative pathophysiology remains unclear but is thought to be related to hormonal or nutritional factors.
- When fibrocystic disease is the source, growth and distension of the cyst with hormonal fluctuation can cause pain.

- Hormonal factors (e.g., hormone-replacement therapy, oral contraceptives, pregnancy, menses, puberty, and menopause) may influence the diverse conditions that cause mastalgia or may themselves cause breast tenderness and pain.
- Benign breast disorders (e.g., fibrocystic changes)
- Trauma (including sexual abuse/assault)
- Diet and lifestyle (e.g., poor-fitting exercise breast support)
- Lactation problems (e.g., engorgement, mastitis, breast abscess)
- Breast masses, including breast cancer
- Hidradenitis suppurativa
- Costochondritis (Tietze syndrome)
- Postthoracotomy syndrome
- Spinal and paraspinal disorders
- Potential side effects of medications
- Postradiation effects
- Referred pain (e.g., pulmonary, cardiac, or gallbladder disease)
- Ductal ectasia

## *Genetics*

Familial tendency

## *RISK FACTORS*

- Diet high in saturated fats
- Cigarette smoking
- Recent weight gain
- Pregnancy
- Large, pendulous breasts (caused by stretching of Cooper ligaments)
- Exogenous hormones
- Caffeine has been shown not to be a risk factor (2)[A].

## *GENERAL PREVENTION*

- Avoid exposure to risk factors.

- Properly fitted bra support

## DIAGNOSIS

### HISTORY

- Location, duration, frequency, severity, associated symptoms, related activities (e.g., trauma), and aggravating and ameliorating factors
- Complete medical history with focus on gynecologic/obstetric history
- Complete systematic review of systems
- Diet/smoking history
- Detailed family history for risk assessment for breast cancer
- There may be an association with other pain syndromes such as fibromyalgia (3)[B].

### PHYSICAL EXAM

- Examine breasts systematically in both standing and sitting positions.
- Assess for skin changes, breast symmetry and contour, dimpling, localized tenderness, bruising, masses, nipple discharge, and lymphadenopathy. Look for signs that are suggestive of breast malignancy.

### DIFFERENTIAL DIAGNOSIS

- The most important disease to rule out is breast cancer (although uncommon), particularly if pain is localized.
- Manipulation or trauma also can worsen symptoms.
- Chest wall pain or referred pain resulting from splenomegaly also must be differentiated from mastalgia.
- Sometimes, cyclic pain is concurrent with premenstrual syndrome.
- Ductal ectasia of the breast

### DIAGNOSTIC TESTS & INTERPRETATION

#### *Initial Tests (lab, imaging)*

- If galactorrhea is found, check a fasting prolactin level.
- Consider thyroid-stimulating hormone (TSH).

- Consider an ultrasound in women with focal, persistent breast pain.
- Mammogram ± ultrasound in women aged 30 to 35 years

### *Pediatric Considerations*

Ultrasound is the imaging test of choice for children and adolescents. A mammogram is not useful.

### *Diagnostic Procedures/Other*

- Cysts may need to be aspirated to relieve symptoms or verify diagnosis.
- Biopsies may be indicated based on the results of examination, ultrasound, or mammography.

### *Pediatric Considerations*

In children and adolescents, do not perform biopsies unless there is a suspicion for cancer. Refer to a specialist in pediatric breast disease.

### *Test Interpretation*

- Normal breast tissue
- Benign: fibrocystic changes, duct ectasia, solitary papillomas, simple fibroadenomas
- Small increased risk of breast cancer: ductal hyperplasia without atypia, sclerosing adenosis, diffuse papillomatosis, complex fibroadenomas
- Moderate increased risk: atypical ductal hyperplasia, atypical lobular hyperplasia
- Breast cancer

## **TREATMENT**

### *GENERAL MEASURES*

- Stop or modify the current hormonal therapy.
- A repeat examination may help to establish any cyclic nodularity pattern.
- Wear a properly fitted support bra (may be fitted by a professional).
- Reassurance (sufficient for most patients)
- Weight loss for obese patients
- Smoking cessation

- Relaxation training

## MEDICATION

### *First Line*

Acetaminophen or NSAIDs, either oral or topical (e.g., diclofenac sodium or piroxicam) (4)[B]

---

P.637

### *Second Line*

- Oral contraceptives may help some patients prevent fibrocystic disease but may worsen pain in some sensitive patients.
- If the patient is on an oral contraceptive, switch to the one that has a lower estrogen component.
- In some patients with mastalgia only during their menses, menstrual suppression with continuous oral contraceptives may be of benefit.
- Oral progesterone: 10 mg PO daily
- Other possibilities for patients with refractory symptoms, used infrequently because of potential side effects, include the following:
  - Danazol: 100 mg BID (possibly lower doses) may be the most effective; major adverse effects include menstrual irregularities, weight gain, acne, hirsutism, and voice change; *may be used during luteal phase only*; approved by the FDA for this indication
  - Toremifene: 30 mg PO daily (5)[B]
  - Bromocriptine: 5 mg PO daily and cabergoline 0.5 mg PO weekly, both during the 2nd half of the menstrual cycle are equally effective, but cabergoline has fewer side effects (6)[B].
  - Tamoxifen or Centchroman: Selective estrogen receptor modulators (SERM) may be used with a dose of 10 mg or 30 mg daily respectively (7)[A].

## ADDITIONAL THERAPIES

If the patient is breastfeeding, correct any breastfeeding difficulties; treat underlying mastitis or breast abscess.

### *Pediatric Considerations*

Children and adolescents may require referrals to a specialist.

## SURGERY/OTHER PROCEDURES

Some patients may need surgical breast reduction.

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Vitamin E and evening primrose oil have not been found to be of benefit for chronic mastalgia (2)[A].
- Flaxseed oil is not effective for the treatment of mastalgia (2)[C].

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

As needed

#### ***Patient Monitoring***

- As needed for patients not receiving pharmacotherapy
- Time of follow-up will vary by type of pharmacotherapy and patient's particular problems.

### ***DIET***

- Decrease fat intake to 20% of total calories.
- No evidence suggests that reduction in caffeine intake may help to decrease the severity or incidence of the disease (3)[A].

### ***PATIENT EDUCATION***

Avoid or adjust risk factors.

### ***PROGNOSIS***

- Premenstrual mastalgia increases with age and then generally stops at menopause unless the patient is receiving hormone therapy (HT).
- Most patients can control symptoms without receiving HT.
- Several months of HT may provide several more months of relief, but mastalgia may recur.
- Cyclic mastalgia responds better than noncyclic mastalgia to treatment.
- Effects of long-term HT are unknown.

**&NA;**

- Premenstrual Syndrome (PMS) and Premenstrual Dysphoric Disorder (PMDD)
- Algorithms: Breast Discharge; Breast Pain

## Codes

**&NA;**

### ICD10

N64.4 Mastodynia

## Clinical Pearls

**&NA;**

- When evaluating a patient with breast pain, always rule out cancer first.
- In the adolescent population, do not biopsy; instead, refer to a pediatric specialist.
- Premenstrual mastalgia increases with age and then generally stops at menopause unless the patient is receiving HT.

# Mastitis

Anne Claire Adams, MD

Montiel T. Rosenthal, MD

## BASICS

### DESCRIPTION

- Mastitis is an inflammation of the breast parenchyma and possibly associated tissues (areola, nipple, subcutaneous [SC] fat).
- Usually associated with bacterial infection (and milk stasis in the postpartum mother)
- Usually an acute condition but can become chronic cystic mastitis

### EPIDEMIOLOGY

- Predominantly affects females
- Mostly in the puerperium; epidemic form rare in the age of reduced hospital stays for mothers and newborns
- Neonatal form
- Posttraumatic: ornamental nipple piercing increases risk of transmission of bacteria to deeper breast structures: *Staphylococcus aureus* is the predominant organism.

### Incidence

- 3-20% of breastfeeding mothers develop nonepidemic mastitis.
- Greatest incidence among breastfeeding mothers 2 to 6 weeks postpartum
- Neonatal form occurs at 1 to 5 weeks of age, with equal gender risk and unilateral presentation.
- Pediatric form
- Around or after puberty
- 82% of cases in girls

### ETIOLOGY AND PATHOPHYSIOLOGY

- Microabscesses along milk ducts and surrounding tissues
- Inflammatory cell infiltration of breast parenchyma and surrounding tissues
- Nonpuerperal (infectious)
  - *S. aureus*, *Bacteroides* sp., *Peptostreptococcus*, *Staphylococcus* (coagulase neg.), *Enterococcus faecalis*
  - *Histoplasma capsulatum*
  - *Salmonella enterica*
  - Rare case of *Actinomyces europaeus*
- Puerperal (infectious)
  - *Staphylococcus aureus*, *Streptococcus pyogenes* (group A or B), *Corynebacterium* sp., *Bacteroides* sp., *Staphylococcus* (coagulase neg.), *Escherichia coli*, *Salmonella* sp.
  - Methicillin-resistant *S. aureus* (MRSA)
- Rare secondary site for tuberculosis in endemic areas (1% of mastitis cases in these areas): single breast nodule with mastalgia
- *Corynebacterium* sp. associated with greater risk for development of chronic cystic mastitis
- Granulomatous mastitis
  - Idiopathic
    - Predilection for Asian and Hispanic women
    - Association with  $\alpha$ -1-antitrypsin deficiency, hyperprolactinemia with galactorrhea, oral contraceptive use, *Corynebacterium* sp. infection, and breast trauma
    - Most women have a history of lactation in previous 5 years.
  - Lupus; autoimmune
- Puerperal
  - Retrograde migration of surface bacteria up milk ducts
  - Bacterial migration from nipple fissures to breast lymphatics
  - Secondary monilial infection in the face of recurrent mastitis or diabetes
  - Seeding from mother to neonate in cyclical fashion
- Nonpuerperal
  - Ductal ectasia

- Breast carcinoma
- Inflammatory cysts
- Chronic recurring SC or subareolar infections
- Parasitic infections: *Echinococcus*; filariasis; Guinea worm in endemic areas
- Herpes simplex
- Cat-scratch disease
- Lupus

## **RISK FACTORS**

- Breastfeeding
- Milk stasis
  - Inadequate emptying of breast
    - Scarring of breast due to prior mastitis
    - Scarring due to previous breast surgery (breast reduction, biopsy, or partial mastectomy)
  - Breast engorgement: interruption of breastfeeding
- Nipple trauma increases risk of transmission of bacteria to deeper breast structures: *S. aureus* predominant organism
- Neonatal colonization with epidemic *Staphylococcus*
- Neonatal
  - Bottle-fed babies
  - Manual expression of mother's milk
  - Can predispose to lethal necrotizing fasciitis
- Maternal diabetes
- Maternal HIV
- Maternal vitamin A deficiency (in animal models)

## **GENERAL PREVENTION**

Regular emptying of both breasts and nipple care to prevent fissures when breastfeeding. Also good hygiene including hand washing and washing breast pumps after each use (1)[A].

# COMMONLY ASSOCIATED CONDITIONS

Breast abscess

## DIAGNOSIS

- Fever  $>38.5^{\circ}\text{C}$  and malaise
- Nausea  $\pm$  vomiting
- Localized breast tenderness, heat, swelling, and redness
- Possible breast mass

## HISTORY

- Breast pain
- "Hot cords burning in chest wall"
- Consider yeast infection if nipple pain and burning and/or infant with thrush

## PHYSICAL EXAM

- Breast tenderness
- Localized breast induration, redness, and warmth
- Peau d'orange appearance to overlying skin

## DIFFERENTIAL DIAGNOSIS

- Abscess (bacterial, idiopathic granulomatous mastitis, fungal, tuberculosis)
- Tumor
  - Idiopathic granulomatous mastitis
  - Inflammatory breast cancer
  - Wegener granulomatosis
  - Sarcoidosis
  - Foreign body granuloma
  - Vasospasm (may be presentation for Reynaud) (2)[B]
- Ductal cyst (ductal ectasia)
- Consider monilial infection in lactating mother, especially if mastitis is recurrent.

# DIAGNOSTIC TESTS & INTERPRETATION

## *Initial Tests (lab, imaging)*

Mastitis is typically a clinical diagnosis. Labs rarely needed. In those ill enough to need hospitalization, consider the following:

- CBC
- Blood culture
- In epidemic puerperal mastitis
  - Milk leukocyte count
  - Milk culture
  - Neonatal nasal culture
- No imaging required for postpartum mastitis in a breastfeeding mother that responds to antibiotic therapy.
- Mammography for women with nonpuerperal mastitis
- Breast ultrasound to rule out abscess formation in women
  - Special consideration for this in women with breast implants who have mastitis

## *Follow-Up Tests & Special Considerations*

Lactating mothers produce salty milk from affected side (higher Na and Cl concentrations) as compared with unaffected side. Consider breast milk culture if suspect MRSA. Also consider testing for tuberculosis as may be initial presentation.

## *Diagnostic Procedures/Other*

Options if further progression to abscess formation

- Needle aspiration
- Incision and drainage
- Excisional biopsy
- US-guided core needle biopsy is diagnostic method of choice for idiopathic granulomatous mastitis

## TREATMENT

A recent Cochrane review found that insufficient evidence exists to confirm or refute the effectiveness of antibiotic therapy for the treatment of lactational mastitis (3)[A]. If present <24 hours and symptoms are mild, conservative management with milk removal and supportive measures is recommended.

## MEDICATION

- Prioritized on the basis of likelihood of MRSA as etiologic factor and clinical severity of condition.
- Treat for 10 to 14 days.
- For idiopathic granulomatous mastitis and localized infection, usually resolves with antibiotics and drainage

### First Line

- Outpatient
  - Effective milk removal is the most important management step (4)[A].
  - Dicloxacillin 500 mg QID
  - Cephalexin 500 mg QID
  - Trimethoprim/sulfamethoxazole (TMP/SMX); DS BID (if mastitis not improving within 48 hours after starting first-line treatment consider MRSA)
  - *Lactobacillus fermentum* or *Lactobacillus salivarius* 9 log 10 CFU/day
- Inpatient
  - Nafcillin 2 g q4h
  - Oxacillin 2 g q4h
  - Vancomycin 1 g q12h (MRSA possible)
- Breastfeeding beyond 1 month
  - Penicillin, ampicillin, or erythromycin

If idiopathic granulomatous mastitis, consider corticosteroids ± methotrexate (5)[B]

### Pediatric Considerations

TMP/SMX given to breastfeeding mothers with mastitis can potentiate jaundice for neonates.

## *Second Line*

- If mastitis is odoriferous and localized under areola, add metronidazole 500 mg TID IV or PO.
- If yeast is suspected in recurrent mastitis, add topical and oral nystatin.

## *ISSUES FOR REFERRAL*

- Abscess formation
- Need for breast biopsy

## *ADDITIONAL THERAPIES*

- Warm packs to improve blood flow and milk let down and/or ice packs to reduce inflammation to affected breast for comfort
- The use of a breast pump may aid in breast emptying, especially if the infant is unable to assist in doing this.
- Wear supporting bra that is not too tight.

## *SURGERY/OTHER PROCEDURES*

In cases of biopsy-proven idiopathic granulomatous mastitis, surgical removal can result in a 5-50% chance of recurrence, fistula formation, and poor wound healing.

## *INPATIENT CONSIDERATIONS*

If a new mother is admitted to the hospital for treatment of her mastitis, rooming-in of the infant with the mother is mandatory so that breastfeeding can continue (4)[C]. In some hospitals, rooming-in may require hospital admission of the infant.

## *Admission Criteria/Initial Stabilization*

- Failure of outpatient/oral therapy
  - Patient unable to tolerate oral therapy
  - Patient noncompliant with oral therapy
  - Severe illness without adequate supportive care at home
- Neonatal mastitis
- Antibiotics
- Frequent emptying of breasts, if breastfeeding
- Analgesics for pain

- Ibuprofen
- Acetaminophen

## *Nursing*

- Breastfeeding/pumping of breasts encouraged
- Start infant with feedings on affected side.
- Abscess drainage is not a contraindication for breastfeeding.
- Massage in direction from blocked area toward nipple.
- Positioning infant at breast with chin or nose pointing to blockage will help drain affected area.

## *Discharge Criteria*

- Afebrile
- Tolerating oral antibiotics well

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

Rest for lactating mothers, up to bathroom

## *DIET*

- Encourage oral fluids.
- Multivitamin, including vitamin A

## *PATIENT EDUCATION*

- Encourage oral fluids.
- Rest is essential
- Regular emptying of both breasts with breastfeeding
- Nipple care to prevent fissures

## *PROGNOSIS*

- Puerperal

- Good with prompt (within 24 hours of symptom onset) antibiotic treatment and breast emptying; 96% success rate
  - 11% risk of abscess if left untreated with antibiotics
  - Antibodies develop in breast glands within first few days of infection, which may provide protection against infection or reinfection.
- Rare risk of abscess formation beyond 6 weeks postpartum if no recurrent mastitis

## COMPLICATIONS

- Breast abscess 3% of women with puerperal mastitis
- Recurrent mastitis with resumption of breastfeeding or with breastfeeding after next pregnancy
- Bacteremia
- Sepsis

## See Also

&NA;

Algorithms: Breast Discharge; Breast Pain

## Codes

&NA;

### ICD10

- N61 Inflammatory disorders of breast
- O91.22 Nonpurulent mastitis associated with the puerperium
- O91.23 Nonpurulent mastitis associated with lactation

## Clinical Pearls

&NA;

- Complete emptying of the breasts on a regular schedule, avoiding constrictive clothing or bras that might obstruct breast ducts, meticulous attention to nipple care, adequate rest, and a liberal intake of oral fluids for the mother can all reduce the risk of a breastfeeding mother's developing mastitis.
- First-line treatment for puerperal mastitis is dicloxacillin 500 mg PO QID for 10 to 14 days. Most mastitis can be treated with oral therapy.
- Among breastfeeding mothers, if the symptoms of mastitis fail to resolve within several days of appropriate management, including antibiotics, further investigations may be required to confirm resistant bacteria, abscess formation, an underlying mass, or inflammatory or ductal carcinoma.
- More than two recurrences of mastitis in the same location or with associated axillary lymphadenopathy warrant evaluation with ultrasound or mammography to rule out an underlying mass.

# Mastoiditis

Adam Anglyn, DO

Robert M. Hasty, DO, FACOI, FACP

## BASICS

An inflammatory process of the mastoid air cells or posterior process of the temporal bone, most commonly a suppurative complication of acute otitis media (AOM)

## DESCRIPTION

- Acute mastoiditis typically presents following AOM or may be the first sign of AOM. Symptoms are present for < 1 month.
- Subdivided into two stages
  - Acute mastoiditis with periostitis: involves the mastoid periosteum with purulence in the mastoid air cells
  - Acute mastoid osteitis (coalescent mastoiditis): destruction of bony septae separating air cells; leading to empyema and more serious head/neck complications
- Subacute mastoiditis (masked mastoiditis): indolent process, may occur with insufficiently treated AOM
- Chronic mastoiditis: due to failed treatment of chronic otitis media. Usually associated with cholesteatoma; symptoms last months to years.

## EPIDEMIOLOGY

- Children > adults
- Most common in children <2 years of age
- In children: males > females
  - Incidence is reduced after introduction of antibiotics but may again be increasing with rise of antibiotic-resistant *Streptococcus pneumoniae*. Introduction of PVC 13 vaccine may mitigate this rise (1)[C].

## Incidence

1 to 4 cases/100,000 persons/year (2)

## ETIOLOGY AND PATHOPHYSIOLOGY

- Subclinical stage begins with AOM causing inflammation of mastoid air cells (likely present in all cases of AOM)
- Obstruction of the aditus ad antrum (connecting the tympanic cavity and mastoid)
  - Blocks outflow tract of mastoid air cells
  - Edema and accumulation of purulent material with penetration of periosteum (acute mastoiditis with periostitis)
- Increased pressure from fluid within the air cells leads to destruction of bony septae (acute mastoid osteitis/acute coalescent mastoiditis).
- Acute mastoid osteitis can spread to adjacent areas in head and neck with abscess formation:
  - Subperiosteal abscess (most common complication), Bezold abscess, suppurative labyrinthitis, suppurative CNS complications
- AOM: *Haemophilus influenzae*, *S. pneumoniae*
- Acute mastoiditis: *Streptococcus pneumoniae* (most common), *Streptococcus pyogenes*, *H. influenzae*, *Staphylococcus aureus* (including methicillinresistant *Staphylococcus aureus* [MRSA])
- Chronic mastoiditis: *Pseudomonas aeruginosa*, *S. aureus*, Enterobacteriaceae, anaerobic bacteria, polymicrobials (3)

## Genetics

No known genetic pattern

## RISK FACTORS

- Cholesteatoma
- Recurrent AOM or chronic suppurative otitis media
- Immunocompromised state

## GENERAL PREVENTION

- Pneumococcal conjugate vaccine
- Early referral to ENT for chronic otitis media
- Appropriate diagnosis and treatment of AOM

- Prevention of recurrent AOM
- Treat chronic eustachian tube dysfunction (pressure equalization tubes).
- Identify cholesteatoma early.

## DIAGNOSIS

### HISTORY

- Most common symptoms in infancy (2)[A]
  - Lethargy/malaise/irritability
  - Fever
  - Poor feeding/decreased appetite
- Otalgia/possible otorrhea
- Hearing loss
- Headache
- Pain/redness/swelling noted over mastoid.
- At the time of admission (2)[A]
  - 42% of children have history of otologic disease.
  - 54% on antibiotic therapy
  - Average duration of symptoms: 10 days
- Suspicion for mastoiditis increases when symptoms of AOM persist >2 weeks.

### PHYSICAL EXAM

- Postauricular changes: erythema, tenderness, edema, and/or fluctuance (81-85%) (2)[A]
- Bulging, erythematous, or dull tympanic membrane (60-71%)
- Protrusion of auricle (79%)
- Fever (76%)
- Otorrhea if tympanic membrane is perforated
- Edema of external auditory canal
- Tympanic membrane (TM) can be normal in 10% of patients.

### DIFFERENTIAL DIAGNOSIS

- Postauricular cellulitis or inflammatory adenopathy
- Severe otitis externa
- Benign neoplasm: aneurysmal bone cyst, fibrous dysplasia
- Malignant neoplasm: rhabdomyosarcoma, neuroblastoma
- Deep neck space infections
- Parotitis

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- CBC with differential: increased WBC count (4)[C]
- Elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) (3,4)
- Blood cultures
- Myringotomy/tympanocentesis: Send for cultures, Gram stain, acid-fast stain (2)[B].
- Mastoiditis is often a clinical diagnosis. CT confirms diagnosis and identifies regional complications.
- If obvious physical exam and/or historical findings are absent, temporal bone imaging is recommended for patients with cervical or postauricular findings (5).
- Plain radiographs of mastoid have low diagnostic yield but may show distortion of mastoid outline or clouding of mastoid air cells. These changes are not diagnostic and can also be seen in AOM.
- CT findings (97% sensitivity; 94% positive predictive value) (6)
  - Clouding/opacification of air cells (also in AOM)
  - Mastoid air cell coalescence
  - Cortical bone erosion
  - Rim-enhancing fluid collections
- CT of temporal bone with contrast helps identify suppurative extension (5)[C].
- Technetium-99m bone scan is more sensitive to osteolytic changes than CT.
- Indications for CT scan in children (6)[C]
  - Neurologic signs
  - Vomiting/lethargy

- Suspected cholesteatoma
- Fever after 48 to 72 hours of therapy
- Concern for local disease progression
- MRI use increasing; may see increased fluid signal of mastoid air cells on T2-weighted MRI. An incidental finding in the absence of clinical signs

## *Follow-Up Tests & Special Considerations*

Interpret normal WBC with caution in symptomatic immunocompromised patients.

## *Diagnostic Procedures/Other*

- Tympanocentesis to obtain middle ear fluid for culture and sensitivity (2)[B]
- Myringotomy with culture (also therapeutic)
- Audiography if suspected hearing loss
- Obtain CSF if intracranial extension suspected.
- Biopsy tissue protruding through TM or tympanostomy tube

## **TREATMENT**

- IV antibiotics and myringotomy ( $\pm$  tympanostomy tubes) is the preferred treatment for uncomplicated acute mastoiditis (reflecting a shift away from more invasive surgical treatment).
- Simple mastoidectomy is recommended for patients not responding to treatment after 3 to 5 days to avoid intracranial complications (7)[C].

---

P.641

## *GENERAL MEASURES*

- Inpatient care during acute phase for IV antibiotics
- Keep the affected ear dry.

## *MEDICATION*

### *First Line*

- Empiric antibiotics against most common organisms: *Streptococcus pneumoniae* (including

multiple resistant strains), *Streptococcus pyogenes*, *Staphylococcus aureus* (including MRSA), *P. aeruginosa*

- Use combination therapy with 3rd generation cephalosporin (ceftriaxone or cefotaxime) plus clindamycin with additional coverage for resistant strains (5,7)[C].
- Ceftriaxone 1 to 2 g IV q24h
  - Pediatric dosing: 50 to 75 mg/kg/day IV divided q12-24h
  - Precaution: Adjust dose with renal impairment.
  - Clindamycin for coverage of ceftriaxone-resistant *S. pneumoniae* in pediatric patients (5)[C]:
  - Clindamycin pediatric dosing: 20 to 40 mg/kg/day IV divided q6-8h
- Cefotaxime 1 to 2 g IV q4-8h, depending on severity
  - Pediatric dosing: 100 to 200 mg/kg/day divided q6-8h
- Add vancomycin 30 to 60 mg/kg/day divided q8-12h if concerned for MRSA:
  - Pediatric dosing: 15 mg/kg/dose q6-8h
  - Precaution: Adjust dose with renal impairment.
- For patients with a history of recurrent AOM or recent antibiotic administration, treat with piperacillin-tazobactam 3.375 g IV q6h:
  - Pediatric dosing: 300 mg/kg/day based on piperacillin component divided q6-8h
- For other significant contraindications, precautions, or interactions, please refer to the manufacturer's literature.

## Second Line

- Oral antibiotics are given after 7 to 10 days of IV antibiotics and once myringotomy/blood cultures identify pathogen and sensitivities. Common oral antibiotics include:
  - Amoxicillin-clavulanate (Augmentin) or clindamycin + 3rd-generation cephalosporin for 3 weeks or total treatment duration of 4 weeks
- For chronic mastoiditis: Use topical drops, ofloxacin otic solution (0.3%) or neomycin, polymyxin B, hydrocortisone three drops, 3 to 4 times per day.

## ISSUES FOR REFERRAL

Consult ENT for mastoiditis in adults and children.

## *SURGERY/OTHER PROCEDURES*

- Perform tympanocentesis to obtain cultures and guide antibiotic choice (2)[B].
- Myringotomy and tympanostomy tubes allow drainage of middle ear (7)[C].
- Mastoidectomy is a definitive treatment for patients who fail to improve within 24 to 48 hours despite IV antibiotics and myringotomy and for those with meningeal or intracranial complications (6,7)[C].
- Simple mastoidectomy is most effective for management of subperiosteal abscesses, if a trial of conservative therapy with drainage, myringotomy, and IV antibiotics fails (8)[C].
- Clean ear canal under microscope to ensure pressure-equalization tube patency and adequate drainage of middle ear.
- Topical antibiotic drops usually used after insertion of pressure-equalization tubes.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Clinical or imaging evidence of acute mastoiditis
- Hospitalize patients with acute mastoiditis and start IV antibiotics immediately.

### *Nursing*

Avoid getting affected ear wet.

### *Discharge Criteria*

- Afebrile for 48 hours before IV antibiotics are discontinued
- Clinical improvement
- Able to take oral antibiotics

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Oral antibiotics for 3 weeks following course of IV antibiotics (total duration of antibiotics is 4 weeks)
- For chronic mastoiditis, consider several months of antimicrobial prophylaxis with amoxicillin.

## Patient Monitoring

- Assess for hearing loss postoperatively (audiogram) after acute condition has subsided.
- Follow-up with ENT, particularly patients with intracranial complications or hearing loss

## PATIENT EDUCATION

Avoid getting the affected ear wet.

## PROGNOSIS

- Depends on severity and stage of disease
- Conductive hearing loss may require reconstructive surgery.
- Most cases of mastoiditis recover fully if the diagnosis is made early and treated appropriately.

## COMPLICATIONS

Total estimated complication rate is 18% (3).

- Extracranial
  - Subperiosteal abscess (most common)
  - Bezold abscess (abscess of sternocleidomastoid muscle, insidious, risk of mediastinitis)
  - Citelli abscess (osteomyelitis of the calvaria)
  - Osteomyelitis of the temporal bone
  - Suppurative labyrinthitis (resulting in deafness)
  - Facial nerve paralysis
- Intracranial
  - Intracranial abscess: epidural/subdural/cerebral
  - Meningitis/cerebritis/periostitis
  - Gradenigo syndrome (palsy of the 6th cranial nerve, draining ear, and retro-orbital pain)
  - Sigmoid sinus thrombophlebitis
  - Central venous sinus thrombosis

## Codes

&NA;

## ICD10

- H70.90 Unspecified mastoiditis, unspecified ear
- H70.009 Acute mastoiditis without complications, unspecified ear
- H70.099 Acute mastoiditis with other complications, unspecified ear

## Clinical Pearls

### **&NA;**

- Suspect mastoiditis when symptoms of AOM persist >2 weeks despite a normal-appearing TM.
- Hospitalize all patients with acute mastoiditis for IV antibiotics. Consult ENT for drainage procedure.
- Treat with broad-spectrum IV antibiotics; collect middle ear fluid cultures to guide-specific therapy.
- If conservative treatment fails after 3 to 5 days, perform mastoidectomy to avoid intracranial complications.

# Measles (Rubeola)

Herbert L. Muncie Jr., MD

## BASICS

### DESCRIPTION

- A highly communicable, acute viral illness characterized by an exanthematous maculopapular rash that begins at the head and spreads inferiorly to the trunk and extremities
- Rash is preceded by fever and the classic triad of cough, coryza, and conjunctivitis (3 Cs). Koplik spots are pathognomonic lesions of the oral mucosa.
- Public health problem in the developing world, with significant morbidity and mortality
- System(s) affected: hematologic; lymphatic; immunologic; pulmonary; skin
- Synonym(s): rubeola

### EPIDEMIOLOGY

- Transmission: direct contact with infectious droplets; highly contagious; 90% of nonimmune close contacts likely to become infected on exposure.
  - Droplets can remain in the air for hours.
- Infectivity is greatest during the prodromal phase.
  - Patients are considered contagious from 4 days before symptoms until 4 days after rash appears.
  - Immunocompromised patients are considered contagious for the entire duration of disease.
- Incubation period: averages 12.5 days from exposure to onset of prodromal symptoms (1)[B]
- Predominant age: varies based on local vaccine practices and disease incidence. In developing countries, most cases occur in children <2 years.

### Incidence

- United States: no longer considered an endemic disease by the CDC; isolated outbreaks still occur.
- In the first half of 2015, the CDC reported 159 confirmed cases of measles. Of these cases,

111 (70%) were associated with an outbreak that originated in Disney theme parks in Orange County, California.

- Many cases were in vaccine-eligible patients who declined due to philosophic or religious beliefs.
- Children aged 6 to 23 months traveling abroad are at increased risk if unvaccinated.
- Worldwide: An estimated 20 million measles cases occur each year, with 122,000 measles deaths in 2012. Over 95% of measles deaths occur in poor countries with limited health infrastructure (2).

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

Measles virus enters through the respiratory mucosa and replicates locally. It spreads to regional lymphatic tissues and other reticuloendothelial sites via the bloodstream.

- Measles virus is a spherical, enveloped, nonsegmented, single-stranded, negative-sense RNA virus of genus *Morbillivirus*, family *Paramyxoviridae*.
- Humans are the only natural host.

## ***RISK FACTORS***

- For developing measles:
  - Lack of adequate vaccination (two doses)
  - Travel to countries where measles is endemic
  - Contact with exposed individuals, travelers, or immigrants
- For severe measles or measles complications:
  - Immunodeficiency
  - Malnutrition
  - Pregnancy
  - Vitamin A deficiency
  - Age <5 years or >20 years

## ***GENERAL PREVENTION***

- 100% preventable with proper vaccination (3)[A]

- Measles vaccine (active immunization)
  - Vaccine is usually given in combination with mumps and rubella (MMR) or with added varicella (MMR-V; ProQuad)
  - Primary vaccination requires two doses
    - First dose given at 12 to 15 months of age; 95% develop immunity.
    - Second dose given at time of school entry (4 to 6 years of age) or any time >4 weeks after first measles vaccine; the 5% of initial nonresponders almost always develop immunity after the second dose.
    - Health care workers should have immunity verified and if not immune, should receive the vaccine if not contraindicated.
  - Common adverse reactions to vaccine
    - Fever
    - Febrile seizures are rare (<5%) and occur 6 to 12 days after vaccination. Risk of febrile seizures increases if initial immunization is delayed past age 15 months (4)[B].
    - Transient, mild, measles-like rash 7 to 10 days after vaccination (2%, with decreasing incidence during second vaccination)
    - If hypersensitivity reaction occurs, test for immunity; if immune, second dose is not needed. There is no substantiated link between MMR vaccine and autism (5)[A].
  - Contraindications
    - Live viral vaccines are contraindicated in immunosuppressed patients. For MMR, however, asymptomatic HIV-infected children with adequate CD4 count should be vaccinated.
    - Pregnancy: Live vaccine is contraindicated (theoretical risk of fetal infection).
    - Anaphylactic reaction to gelatin or neomycin; consult allergist before vaccination.
    - Egg anaphylaxis is not considered a contraindication.

## *COMMONLY ASSOCIATED CONDITIONS*

- Immunosuppression
- Malnutrition

# DIAGNOSIS

## HISTORY

- Prodromal period: usually 2 to 3 days before rash (may be up to 8 days)
  - Fever
    - May begin 8 to 12 days after exposure; can persist until 2 to 3 days after rash onset
    - Temperature often  $>102^{\circ}\text{F}$  ( $39\text{-}40.5^{\circ}\text{C}$ ); can precipitate febrile seizures
    - Fever onset  $>3$  days after rash suggests complicated course
  - "3 Cs" triad: cough, coryza, and conjunctivitis
  - Cough may persist for 2 weeks.
  - Prodromal symptoms typically intensify over 2 to 4 days, peaking on first day of rash before subsiding.
- Other symptoms include loose stools, malaise, irritability, photophobia (from iridocyclitis), sore throat, headache, and abdominal pain.

## PHYSICAL EXAM

- Koplik spots
  - Pathognomonic of prodromal measles
  - 2- to 3-mm, gray-white, raised lesions on erythematous base on buccal mucosa
  - Occur  $\div$  48 hours before measles exanthem
- Exanthematous rash (characteristic but not pathognomonic)
  - Maculopapular blanching rash
  - Begins at ears and hairline and spreads head to toe, reaching hips by day 2
  - Discrete erythematous patches become confluent over time, particularly on the upper body.
  - Clinical improvement usually occurs within 48 hours after rash appears.
  - Rash fades in 3 to 4 days changing to a brownish color, followed by fine desquamation.
- Lymphadenopathy and pharyngitis may be seen during exanthematous period.

## DIFFERENTIAL DIAGNOSIS

- Drug eruptions
- Rubella

- *Mycoplasma pneumoniae* infection
- Infectious mononucleosis
- Parvovirus B19 infection, roseola
- Enteroviruses
- Rocky Mountain spotted fever, dengue
- Toxic shock syndrome
- Meningococemia
- Kawasaki disease

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Obtain serum sample and throat (or nasopharyngeal) swab. Molecular testing of serum and respiratory specimens is the most accurate method to confirm measles infection. IgM assay and measles RNA by real-time polymerase chain reaction (RT-PCR)
- Measles virus-specific IgM assay from serum and saliva. Antibodies may be undetectable on first day of exanthema but are usually detectable by day 3.
  - Sensitivity: 77% within 72 hours of rash onset; 100% within 4 to 11 days after rash onset. If negative but rash lasts >72 hours, repeat.
  - IgM falls to undetectable levels 4 to 8 weeks after rash onset.
- Measles virus-specific IgG may be undetectable up to 7 days after exanthem; levels peak 14 days after exanthem.
  - A 4-fold increase in IgG titers 14 days after an initial titer that was measured at least 7 days after rash onset is confirmatory.
- Viral cultures for measles are not usually performed.
- Mild neutropenia is common.
- Liver transaminases and pancreatic amylase may be elevated, particularly in adults.
- Chest x-ray if concern for secondary pneumonia

### **ALERT**

Report suspected measles cases to public health authorities.

# TREATMENT

## GENERAL MEASURES

- Place all patients with measles in respiratory isolation until 4 days after onset of rash; immunocompromised patients should be isolated for duration of illness.
- Supportive therapy (i.e., antipyretics, antitussives, humidification, increased oral fluid consumption)

## MEDICATION

- No approved antiviral therapy is available. Immunosuppressed children with severe measles have been treated with IV or aerosolized **ribavirin**. No controlled trial data exist, and this use is not FDA approved.
- Vitamin A: WHO recommends daily dosages for two consecutive days:
  - Children <6 months of age 50,000 IU
  - Children 6 to 12 months of age 100,000 IU
  - Children >12 months of age 200,000 IU
- Antibiotics
  - Reserved for patients with clinical signs of bacterial superinfection (pneumonia, purulent otitis, pharyngitis/tonsillitis) (6)[B]
  - A small randomized, double-blinded trial resulted in an 80% (number needed to treat [NNT] = 7) decrease in measles-associated pneumonia with prophylactic antibiotics; consider antibiotic use prophylactically in patients with a high risk of complications (7)[B].
- Outbreak control
  - *A single case of measles constitutes an outbreak.*
  - Immunize contacts (individuals exposed or at risk of having been exposed) within 72 hours.
    - Monovalent vaccine may be given to infants 6 months to 1 year of age, but two further doses of vaccine after 12 months must be given for adequate immunization.
    - Monovalent or combination vaccine may be given to all measles-exposed susceptible individuals age >1 year if not contraindicated.
    - Individuals not immunized within 72 hours of exposure should be excluded from school, child care, and health care settings (social quarantine) until 2 weeks after onset of rash

in last case of measles.

- Immunoglobulin therapy (passive immunity) may be necessary for the following high-risk individuals exposed to measles for whom vaccine is inappropriate:
  - Children age <1 year (infants 6 to 12 months of age may receive MMR vaccine in place of IG if given within 72 hours of exposure)
  - Pregnant women
  - Individuals with severe immunosuppression
  - IM immunoglobulin should be given within 6 days of measles exposure; CDC recommends 0.25 mL/kg to maximum of 15 mL for infants and pregnant women; immunocompromised individuals receive 0.5 mL/kg to a maximum of 15 mL.

## *INPATIENT CONSIDERATIONS*

Outpatient care is appropriate, except where complications develop (e.g., encephalitis, pneumonia).

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

Signs of complications needing close follow-up include:

- Difficulty breathing or noisy breathing
- Changes in vision
- Changes in behavior, confusion
- Chest or abdominal pain

## *PATIENT EDUCATION*

- Adhere to recommended immunization schedules.
- Avoid exposure, particularly to unimmunized children and adults, pregnant women, and immunocompromised persons, until 4 days after rash onset.
- Avoid contact with potential sources of secondary bacterial pathogens until respiratory symptoms resolve.
- Centers for Disease Control and Prevention. Measles.[www.cdc.gov/measles/about/index.html](http://www.cdc.gov/measles/about/index.html)

## PROGNOSIS

- Typically self-limited; prognosis good
- High fatality rates may be seen among malnourished or immunocompromised children, particularly in developing countries.

## COMPLICATIONS

- Otitis media (5-15%)
- The immune response to measles infection paradoxically depresses response to non-measles-virus antigens, which renders individuals more susceptible to pneumonia and diarrhea.
- Respiratory complications:
  - Bronchopneumonia (5-10%)
    - Accounts for most measles-related deaths
    - May be viral or bacterial
  - Interstitial pneumonitis (immunocompromised patients)
  - Laryngotracheobronchitis ("measles croup"): occurs in younger age group (<2 years)
- GI complications: diarrhea (may lead to dehydration)
- Neurologic complications
  - Febrile seizures
  - Acute disseminated encephalomyelitis with seizures and neurologic abnormalities (occurs in 1/1,000 cases): presents within 2 weeks of rash, probably an autoimmune response
  - Inclusion body encephalitis is rare but fatal in those with defective cellular immunity.
  - Subacute sclerosing panencephalitis
    - Rare degenerative CNS disease resulting from persistent measles infection following natural disease; usually fatal
    - Presents 5 to 15 years after infection
    - Most often in persons infected before age 2 years
- Ocular complications
  - Keratitis
    - Can lead to permanent scarring, blindness
    - Vitamin A deficiency predisposes to more severe keratitis and its

complications.

- Other secondary bacterial infections
- Death: results from complications, mainly pneumonia, rather than the virus itself. CDC statistics show that for every 1,000 children who get measles, 1 or 2 will die.

## Codes

&NA;

### ICD10

- B05.9 Measles without complication
- B05.2 Measles complicated by pneumonia
- B05.89 Other measles complications

## Clinical Pearls

&NA;

- **There is no substantiated link between MMR vaccine and autism.**
- Measles is a highly communicable viral disease whose natural transmission has been halted in the United States by mass immunization.
- A single case of measles constitutes an outbreak.
- Suspected measles cases must be reported to state or local health departments to contain outbreak.
- Immunization requires two doses: one at 12 to 15 months of age and one at school age (4 to 6 years of age).
- Presentation includes a prodrome of fever, cough, coryza, and conjunctivitis, followed by a descending maculopapular rash beginning on the face and progressing to the chest and lower body (centrifugal).
- Consider measles in the differential diagnosis of a febrile rash illness (especially in unvaccinated individuals with recent international travel).
- Measles-associated pneumonia is the most common cause of mortality.

# Measles, German (Rubella)

Mark B. Stephens, MD, MS, FAAFP, CAPT, MC, USN

## BASICS

### DESCRIPTION

- A mild, generally self-limited exanthematous viral infection of children and adults, with rare complications. Nonimmune women who become infected with rubella while pregnant may have devastating fetal effects. Up to 50% of rubella infections may be asymptomatic (1,2)[A].
- System(s) affected: hematologic; nervous; pulmonary; exocrine; ophthalmologic; skeletal
- Synonym(s): German measles; 3-day measles

### Pregnancy Considerations

- Pregnancy-associated rubella infection may lead to congenital rubella syndrome (CRS) with potentially devastating fetal outcomes.
- CRS is present in up to 90% of fetuses exposed during the 1st trimester (2)[A].
- Screening pregnant women for rubella immunity and vaccinating nonimmune women is the most effective means to prevent CRS (2)[A].
- Although no case of vaccine-associated CRS has been reported, women should not become pregnant for at least 28 days after vaccination because the vaccine-type virus can cross the placenta (2)[A].
- Polymerase chain reaction (PCR) detection of viral RNA in amniotic fluid and fetal blood sampling allow for rapid diagnosis of fetal infection after 15 weeks' gestation (3)[B].

### EPIDEMIOLOGY

- 50- to 70-nm RNA togavirus of genus *Rubivirus* (1)[A]
- 13 genotypes have been identified (4)[A].
- Live attenuated vaccine available in United States. since 1969 primarily to prevent CRS
- Since 2004, all cases of rubella in United States have been imported, typically in travelers with inadequate immunity (1)[A].
- Average incubation: 14 days; range 12 to 23 days

- Infectious period between 7 days before and 5 to 7 days after rash onset
- Transmitted by respiratory droplets
- Most common in late winter and early spring
- Humans are only natural hosts (1)[A].

## *Incidence*

- U.S. incidence: <10/100,000 since 2001
- From 2004 to 2012, six cases of CRS reported in United States (5).
- Still occurs worldwide in developing countries: 100,000 cases of CRS annually worldwide

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Virus invades the respiratory epithelium, replicates in nasopharynx and regional lymph nodes, and spreads hematogenously. Infected patients shed virus from the nasopharynx 3 to 8 days after inoculation. Shedding lasts 7 or more days after onset of rash.
- Disease progresses from a prodromal stage (1 to 5 days) to lymphadenopathy (5 to 10 days) and finally to an exanthematous, pruritic, and maculopapular rash. Rash starts on the face and spreads to the trunk and extremities, sparing the palms and soles (14 to 17 days after onset of initial symptoms).
- Rubella first described by German scientists in the early 1800's as a variant of measles or scarlet fever
- 1962 to 1965: global pandemic resulting in an estimated 12.5 million cases in the United States, with 2,000 cases of encephalitis; 11,250 cases of therapeutic or spontaneous abortions; 2,100 neonatal deaths; and 20,000 infants born with CRS (1)[A]

## *Genetics*

Children with CRS and children with type 1 diabetes share a high frequency of HLA-DR3 histocompatibility Ag and a high prevalence of islet cell Ab.

## *RISK FACTORS*

Inadequate immunization, inadequate immunity after prior vaccination, immunodeficiency states, immunosuppressive therapy, crowded living/working conditions, international travel (1)[A]

## *GENERAL PREVENTION*

- Vaccination is the most effective preventive strategy.

- Available combined with measles and mumps (MMR) or with varicella (MMR-V). Single rubella vaccine is not available in the United States.
  - A 2-dose schedule combined MMR vaccine recommended for those born after 1957. The 1st dose recommended at ages 12 to 15 months; 2nd dose recommended either at 4 to 6 years or at 11 to 12 years of age. Children with HIV should receive MMR vaccine at 12 months of age if no contraindications exist. In the event of an outbreak, immediate vaccination for infants 6 to 11 months old is recommended (2)[A].
  - Vaccine is recommended for nonimmune people in the following groups: prepubertal boys and girls, all women of reproductive age, college students, daycare personnel, health care workers, and military personnel.
- Contraindicated: pregnancy, immunodeficiency (except HIV infection), within 3 months of IVIG or blood administration, severe febrile illness, or hypersensitivity to vaccine components. Patients who receive rubella vaccine do not transmit rubella to others, although the virus can be isolated from the pharynx. Breastfeeding is not a contraindication to vaccination (1)[A].
- During outbreaks, serologic screening before vaccination is *NOT* recommended because rapid mass vaccination is necessary to stop disease spread (2)[A].
- The MMR vaccine *is not associated with autism* (6)[A],(7)[B].
- Children who receive the MMR-V vaccine have a 2-fold increase in risk of febrile seizures compared with those who receive MMR and varicella vaccines separately (7)[B].
- Routine rubella antibody screening is recommended during pregnancy by the CDC and ACOG (6)[A].

## DIAGNOSIS

Council of State and Territorial Epidemiologists (CSTE) Case Definition Classifications of Rubella (1)[A]

- Clinical case definition
  - Acute onset of pink, coalescent macules on the face spreading to the trunk and extremities, becoming discrete macules then fading in previously affected areas
  - Temperature >99°F (37.2°C; if measured)
  - Arthralgia or arthritis, lymphadenopathy, or conjunctivitis
- Laboratory criteria for diagnosis
  - Isolation of virus from throat or nasopharynx, serum, CSF, urine, or cataracts (postmortem)

- 4-fold rise in acute- and convalescent-phase titers of serum IgG Ab
- Positive serologic test for IgM Ab
- PCR positive for virus

## HISTORY

- Most cases of postnatal rubella are due to inadequately immunized travelers returning from endemic areas.
- Rubella can spread quickly among persons residing in close quarters.
- Postnatal rubella: low-grade fever, sore throat, nausea, anorexia, arthritis, arthralgia, malaise. 50% may be asymptomatic.
- CRS: parental concerns about hearing or vision impairment, jaundice, or developmental delay
- Deafness could be the only manifestation and not be noticed until 2nd year of life (2)[A].

## PHYSICAL EXAM

- Postnatal rubella: low-grade fever, lymphadenopathy (posterior auricular, occipital, posterior cervical), exanthem (mild, pink, discrete 1- to 4-mm maculopapular rash), soft palate petechiae (Forchheimer sign) (20%) (1)[A]
- CRS: microcephaly, large anterior fontanelle, sensorineural hearing loss (58%), cataracts, glaucoma, microphthalmia, pigmentary retinopathy, purpuric (blueberry muffin) skin lesions, murmur (50%) consistent with patent ductus arteriosus (PDA), hepatosplenomegaly, jaundice, cryptorchidism, inguinal hernia, radiolucent bone disease (2)[A]

## DIFFERENTIAL DIAGNOSIS

- Postnatal rubella
  - Measles virus (rubeola)
  - Scarlet fever (strep A)
  - Infectious mononucleosis
  - Erythema infectiosum (parvovirus B19)
  - Roseola infantum (i.e., exanthem subitum)
  - Toxoplasmosis
  - Drug eruptions

## Other exanthematous enteroviral infections

- Congenital rubella
  - Measles
  - Parvovirus B19
  - Human herpesvirus 6
  - Other exanthematous entero- or arboviruses

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Because 50% of cases are subclinical, laboratory testing is best to confirm the diagnosis (1,2) [A].
- Detection of wild-type virus is gold standard (1)[A].
- Enzyme immunoassay (EIA): preferred testing for IgM antibodies, which may not be detectable before 5 days after the onset of rash (1)[A]
- Hemagglutination inhibition (HAI) test: A 4-fold increase of IgG Ab levels from acute to convalescent phase is diagnostic for recent infection (1)[A].
- Latex agglutination (LA) test: sensitive and specific but dependent on experience of lab personnel (1)[A]

---

P.645

- Immunofluorescent antibody (IFA) assay: used for detection of viral IgG and IgM Ab (1)[A]
- Avidity test: not routinely used. Should only be performed in reference labs. Used to distinguish between recent and past infections (1)[A]
- Serum collection should be performed within 7 to 10 days after illness onset. When testing for IgM, repeat collection may be necessary if the sample was taken before day 5. When testing for seroconversion, a 2nd IgG sample should be collected 2 to 3 weeks after the first (acute to convalescent phase). In most cases, IgG is detectable 8 days after rash onset (1)[A].
- Virus may be isolated from 1 week prior to 2 weeks after the onset of rash. Maximal viral shedding occurs up to day 4 after rash onset. Best results are from throat swabs (1)[A].
- Epidemiologically, viral genotyping by reverse transcription (RT)-PCR helps determine the country of origin. Throat swabs should be collected 4 days after the rash onset and sent to the CDC (1)[A].
- Viral cultures of CSF are reserved for suspected cases of CRS or rubella encephalitis (1)[A].
- If a pregnant female is exposed, amniotic fluid PCR or fetal blood sampling may be done at 15 weeks' gestation for viral detection. Placental biopsy (less common) may be done at 12 weeks'

gestation. If positive, offer genetic counseling (1)[A].

- As the incidence of rubella decreases, the positive predictive value (PPV) of IgM results decreases. False-positive findings occur in patients with parvovirus B19, mononucleosis, and positive rheumatoid factor (1)[A].
- After reexposure, a person with a low level of Ab from past infection or prior vaccination may experience an acute, small rise in Ab levels. This is not associated with a high incidence of contagious to others or of fetal risk (1)[A].

## Follow-Up Tests & Special Considerations

- Reporting: state-dependent. Samples should be sent to the CDC for genotyping. Cases of CRS are reported to the National Congenital Rubella Syndrome Registry (1,2)[A].
- Infants with CRS may shed virus up to 1 year. Observe contact isolation during all hospitalizations until child turns 1 year old (unless child has two negative throat cultures and urine specimens a month apart after 3 months of age) (2)[A].

## TREATMENT

- Supportive for mild cases
- Isolate patients for 5 to 7 days after rash onset.
- Postnatal rubella: mild and self-limited; treat symptomatically. Hospitalize for complications: idiopathic thrombocytopenic purpura (ITP) or encephalitis (1)[A].
- CRS: supportive care unless neurologic or hemorrhagic complications develop; phototherapy may be indicated for jaundice; multidisciplinary management of long-term complications (2)[A]

## MEDICATION

No specific therapy available for mild cases.

### *First Line*

- Age- and dose-appropriate antipyretics
- NSAIDs can be used for arthritis and arthralgias in adults and infants age >6 months.
- IVIG can be given for severe thrombocytopenia. Most cases, however, are self-limited.

## ONGOING CARE

# FOLLOW-UP RECOMMENDATIONS

## Patient Monitoring

- Individuals immune to rubella through natural infection or vaccine may be reinfected when reexposed; such infection is usually asymptomatic and detectable only by serology. Those who have received the vaccine have lower measurable IgG levels than those who had the natural disease.
- In CRS, it is important to detect auditory and visual impairment early (2)[A].
- 2/3 of internationally adopted children have no written record of immunizations (4)[A].

## PATIENT EDUCATION

<http://www.cdc.gov/rubella/>

## PROGNOSIS

- Postnatal rubella: Complete recovery is typical.
- CRS
  - Varied and unpredictable spectrum, ranging from stillbirth to normal infancy/childhood (1,2) [A]
  - Detectable levels of IgG persist for years and then may decline (does not drop at the expected 2-fold dilution/month). By age 5 years, 20% have no detectable antibody (2)[A].
  - IgM may not be detectable until 1 month after birth and may persist for 6 to 12 months (2) [A].
  - Overall mortality (up to 10%) is greatest during first 6 months.
  - 70% of encephalitis cases develop residual neurologic defects, including autistic syndrome.
  - Prognosis is excellent if only minor congenital defects are present.

## COMPLICATIONS

- Postinfectious encephalitis (1/5,000 cases)
- Thrombocytopenic purpura (1/3,000 cases)
- CRS: incidence dependent on trimester exposed
- Rubella vaccine may rarely cause encephalitis or ITP.
  - ITP is self-limited and is not a contraindication to vaccination.

## Codes

**&NA;**

### ICD10

- B06.9 Rubella without complication
- B06.00 Rubella with neurological complication, unspecified
- P35.0 Congenital rubella syndrome

## Clinical Pearls

**&NA;**

- Rubella is typically a self-limited viral exanthematous infection of children and adults.
- Nonimmune women who are infected with rubella while pregnant may have devastating fetal effects (CRS).

# Medial Tibial Stress Syndrome (MTSS)/Shin Splints

Michael Y. Yang, MD

Marc W. McKenna, MD

## BASICS

### DESCRIPTION

- Medial tibial stress syndrome (MTSS) is preferred nosologically to shin splints. Aching pain along the inner edge of the tibial shaft develops when the musculature and/or periosteum in the (lower) leg become irritated by repetitive activity. The condition is part of a continuum of stress-related injuries to the lower leg. MTSS does not encompass pain from ischemia (compartment syndrome) or stress fractures.
- Tendonitis/periostitis of the medial soleus muscles, anterior tibialis, and posterior tibialis muscles
- Synonyms: tibial stress reaction; anterior muscle syndrome; periostitis; perimyositis; shin splints

### EPIDEMIOLOGY

#### *Incidence*

Common, can account for between 5% and 35% of novice-running injuries. Frequently occurs bilaterally (1).

#### *Pediatric Considerations*

MTSS may account for up to 31% of all overuse injuries in high school athletes (2).

### ETIOLOGY AND PATHOPHYSIOLOGY

- Multifactorial anatomic and biomechanical factors
  - Overuse injuries causing or limited by
    - Microtrauma from repetitive motion leading to periosteal inflammation
    - Overpronation of the subtalar joint and tight gastrocnemius/soleus complex with

increased eccentric loading of musculature inserting along the medial shin

- Interosseous membrane pain
- Periostitis
- Tears of collagen fibers
- Enthesopathy
- Anatomic structures affected include the following:
  - Flexor hallucis longus
  - Tibialis anterior
  - Tibialis posterior
  - Soleus
  - Crural fascia
- Pathogenesis: theorized to be due to persistent repetitive loading, which leads to inadequate bone remodeling and possible microfissures causing pain without evidence of fracture or ischemia

## ***RISK FACTORS***

- Intrinsic or personal risk factors:
  - Greater internal and external ranges (>65 degrees) of hip motion
  - Significant overpronation at the ankle
  - Imbalance of inverters and everter musculature of the ankle and foot
  - Female gender
  - Leaner calf girth
  - Femoral neck anteversion
  - Navicular drop
  - Genu varum
- External or environmental factors
  - Lack of physical fitness
  - Inexperienced runners—particularly those with rapid increases in mileage and inadequate prior conditioning

- Excessive overuse or distance running, particularly on hard or inclined (crowned) surfaces
- Prior injury
- Equipment (shoe) failure
- Other risk factors
  - Elevated BMI
  - Lower bone mineral density
  - Tobacco use
- Those typically affected include the following:
  - Runners
  - Military personnel (common in recruit/boot camp)
  - Gymnasts, soccer, and basketball players
  - Ballet dancers

## *GENERAL PREVENTION*

- Proper technique for guided calf stretching and lower extremity strength training
- Rehabilitation for prior injuries
- Other suggested recommendations
  - Gait analysis and retraining, particularly for overpronation
  - Orthotic footwear inserts

## *COMMONLY ASSOCIATED CONDITIONS*

- Rule out stress fracture and compartment syndrome.
- Pes planus (flat feet)

## **DIAGNOSIS**

### **HISTORY**

- Patients typically describe dull, sharp, or deep pain along the lower leg that is resolved with rest.
- Patients are often able to run through the pain in early stages.

- Pain is commonly associated with exercise (also true with compartment syndrome), but in severe cases, pain may persist with rest.

## *PHYSICAL EXAM*

- Tenderness to palpation is typically elicited along the posteromedial border of the middle-to-distal third of the tibia.
- Pain with plantar flexion
- Ensure neurovascular integrity of the lower extremity, examining distal pulses, sensation, reflexes, and muscular strength.

## *DIFFERENTIAL DIAGNOSIS*

- Bone
  - Tibial stress fractures
    - Typically, pain persists at rest or with weight-bearing activities.
    - Focal tenderness over the anterior tibia
- Muscle/soft tissue injury
  - Strain, tear, tendinopathy
  - Muscle hernia
- Fascial
  - Chronic exertional compartment syndrome (3)[C]
    - Pain without direct tenderness on exam
    - Pain increases with exertion and resolves at rest.
    - Pain is described as cramping or squeezing.
    - Pain with possible weakness or paresthesias on exam
  - Interosseous membrane tear
- Nerve
  - Spinal stenosis
  - Lumbar radiculopathy
  - Common peroneal nerve entrapment

- Vascular
  - DVT
  - Popliteal arterial entrapment (4)[B]
    - Rare but limb-threatening disease
    - History of intermittent unilateral claudication
    - MRI reveals compression of the artery by the medial head of the gastrocnemius muscle.
- Infection
  - Osteomyelitis
- Malignancy
  - Bone tumors

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Plain radiographs help rule out stress fractures if >2 weeks of symptoms (5).
- Bone scintigraphy
  - Diffuse linear vertical uptake in the posterior tibial cortex on the lateral view.
  - Stress fractures demonstrate a focal ovoid uptake.
- High-resolution MRI reveals abnormal periosteal and bone marrow signals, which are useful for early discrimination of tibial stress fractures.
- Increased pain and localized tenderness warrants further imaging with MRI due to concern for tibial stress fracture.
- Exclude compartment syndrome using intracompartmental pressure testing.

---

P.647

## **TREATMENT**

### *GENERAL MEASURES*

- Activity modification with a gradual return to training based on improvement of symptoms
- Patients should maintain fitness with low-impact activities such as swimming and cycling.
- Continue activity modification until patients are pain-free on ambulation.

- Good supportive footwear is recommended.

## *MEDICATION*

- Analgesia with acetaminophen or other oral nonsteroidal anti-inflammatory agent
- Cryotherapy (ice massage) is also advised to relieve acute-phase symptoms (6)[C].

## *ADDITIONAL THERAPIES*

- Stretching of the gastrocnemius, soleus, and peroneal muscles are treatment mainstays (6)[C].
- Calf stretch, peroneal stretch, TheraBand exercises, and eccentric calf raises may improve endurance and strength.
- Compression stockings have been used to treat MTSS with mixed results.
- Structured running programs with warm up exercises have not been demonstrated to reduce pain in young athletes (7)[B].

## *SURGERY/OTHER PROCEDURES*

- Surgical intervention includes a posterior medial fascial release in individuals with both
  - Severe limitation of physical activity and
  - Failure of 6 months of conservative treatment
    - Patient should be counseled that complete return of activity to sport may not be always achieved postoperatively. Surgical risks include infection and hematoma formation.
- Extracorporeal shock wave therapy (ESWT) may decrease recovery time when added to a running program (8)[B].

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Individualized polyurethane orthoses may help chronic running injuries (9)[A].
- Special insoles, shock-absorbing running shoes, and knee braces have not been shown to decrease the incidence of MTSS (6)[C].
- Ultrasound, acupuncture, aquatic therapy, electrical stimulation, whirlpool baths, cast immobilization, taping, and steroid injection may help improve pain.
- Physical therapy approaches including Kinesio tape and fascial distortion massage may yield quicker return to activity (10)[B].

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Patients should avoid prematurely resuming preinjury running pace.
- Stretching and strengthening exercises should be added.
- Preinjury training errors should be identified and corrected with a gradual return to activity dictated by symptoms (pain).

### PROGNOSIS

The condition is usually self-limiting, and most patients respond well with rest and nonsurgical intervention.

### COMPLICATIONS

- Stress fractures and compartment syndrome
- Undiagnosed MTSS or chronic exertional compartment syndrome can lead to a complete fracture or tissue necrosis, respectively.

## Codes

### &NA;

## ICD10

- S86.899A Other injury of other muscle(s) and tendon(s) at lower leg level, unspecified leg, initial encounter
- S86.891A Other injury of other muscle(s) and tendon(s) at lower leg level, right leg, initial

encounter

- S86.892A Other injury of other muscle(s) and tendon(s) at lower leg level, left leg, initial encounter

## Clinical Pearls

**&NA;**

- MTSS is the preferred term for shin splints.
- Diagnosis is based on the history of repetitive overuse accompanied by characteristic shin pain.
- Pain that is worsened with activity and relieved with rest is commonly described along the middle and distal third of the posteromedial tibial surface.
- Treatment includes ice, activity modification, analgesics, eccentric stretching, gait retraining, and a gradual return to activity.

# Melanoma

Carl Bryce, MD, Capt, USAF

Matthew J. Snyder, DO

## BASICS

### DESCRIPTION

- Melanoma is a tumor arising from malignant transformation of cells from the melanocytic system.
- Most arise in the skin but may also present as a primary lesion in any tissue: ocular, GI, GU, lymph node, and leptomeninges.
  - Metastatic spread to any site in the body
- Main types of cutaneous melanoma include the following (1):
  - Superficial-spreading melanoma: 50-80% cases; occurs in sun-exposed areas (trunk, back, and extremities); most  $\approx$  6 mm diameter at diagnosis; when seen in younger patients, presents as a flat, slow growing, irregularly bordered lesion
  - Nodular: 20-30%, present in older patients, often ulcerate and hemorrhage, most commonly thick and pigmented
  - Lentigo maligna (subtype of melanoma in situ): slowest growing; older population; occurs in sun-exposed areas (head, neck, forearms). Lentigo maligna melanoma (LMM) is its invasive counterpart.
  - Amelanotic melanoma (<5%): can be missed and diagnosed at a later stage, as it can mimic benign skin conditions
  - Acral-lentiginous: 2-8% of all melanomas; however, most common melanoma in black or Asian patients, found in palmar, plantar, and subungual areas.
  - Subungual melanoma (0.7-3.5%): dark longitudinal band in nail bed; Hutchinson sign when proximal nail fold involved
  - Desmoplastic melanoma ( $\approx$  1%): sarcoma-like tendencies with increased hematogenous spread
- System(s) affected: skin/exocrine

## *Geriatric Considerations*

Lentigo maligna, slowly enlarging pigmented lesion, is most common in elderly patients. This type is usually found on face, beginning as a circumscribed macular patch of mottled pigmentation showing shades of dark brown, tan, or black.

## *Pediatric Considerations*

Large congenital nevi (>5 cm) are risk factors and have a >2% lifetime risk of malignant conversion. Blistering sunburns in childhood significantly increase risk.

## *Pregnancy Considerations*

No increased risk of melanoma in pregnancy. However, it is suggested waiting 1 to 2 years if further pregnancy is desired in case of recent melanoma. Melanoma can spread to the placenta.

## **EPIDEMIOLOGY**

### *Incidence*

- In 2015, an estimated 73,870 Americans were diagnosed with melanoma, with 9,940 expected deaths (2).
- Predominant age: median age: 62 and 54 years for men and women respectively, >50% of all individuals with melanoma are between 20 and 40 years of age.
- Predominant sex: male > female (1.5 times)
- Incidence among whites greater than that among minority groups; ÷20 times higher than blacks (1)
- Minority groups demonstrate increased rates of metastasis, advanced stages at diagnosis, thicker initial lesions, earlier age at diagnosis, and overall poorer outcomes.
- Low socioeconomic status associated with higher incidence of melanoma

### *Prevalence*

- Lifetime risk: men: 1/37; female: 1/56
- 2% of all cancer deaths
- The most common cancer affecting women age 25 to 29 years of age and second only to breast cancer in women 30 to 34 years of age (1).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- DNA damage by UV-A/UV-B exposure

- Tumor progression: initially may be confined to epidermis with lateral growth, may then grow into dermis with vertical growth

## *Genetics*

- Dysplastic nevus syndrome is a risk factor for development of melanoma. Close surveillance is warranted.
- 8-12% of patients with melanoma have a family history of disease.
- Mutation in *CDKN2A* (*p16*) is found in 1/3 of patients with family incidence of melanoma.
- Mutations in *BRAF* (*V600E*) implicated in 50-60% of cutaneous melanomas
- Familial Atypical Mole Malignant Melanoma (FAMMM) syndrome characterized by >50 atypical moles, +FH of melanoma, clinical diagnosis (3)

## *RISK FACTORS*

- Genetic predisposition
- UV-A and UV-B exposure
- History of >5 sunburns during lifetime
- History of intense intermittent sun exposure
- Previous pigmented lesions (especially dysplastic melanocytic nevi)
- Fair complexion, freckling, blue eyes, and blond/red hair
- Highest predictor of risk is increased number of nevi (>100).
- Family/personal history of melanoma
- Tanning bed use: 75% increased risk if 1st exposure before age 35 years
- Changing nevus
- Large (>5 cm) congenital nevi
- Other skin cancers
- Chronic immunosuppression (chronic lymphocytic leukemia, non-Hodgkin lymphoma, AIDS, or posttransplant)
- Blistering sunburns in childhood
- Living at high altitude (>700 meters or 2,300 feet above sea level)
- Occupational exposure to ionizing radiation

## GENERAL PREVENTION

- Avoidance of sunburns, especially in childhood
- Use of sunscreen with at least SPF 30 to all skin exposed to sunlight, reapplying regularly and after toweling or swimming
- Avoid tanning beds; class 1 carcinogen by World Health Organization (WHO).
- Screening of high-risk individuals, especially males >50 years
- Education for proper diagnosis plays a large factor in prevention.
- Any suspicious lesions should be biopsied with a narrow excision encompassing the entire breadth plus sufficient depth of the lesion. Options include elliptical excisions, punch, or shave biopsies.

## COMMONLY ASSOCIATED CONDITIONS

- Dysplastic nevus syndrome
- >50 nevi. These individuals have higher lifetime risk of melanoma than the general population, as 50% of all melanoma arise in preexisting nevi.
- Giant congenital nevus: 6% lifetime incidence of melanoma
- Xeroderma pigmentosum is a rare condition associated with an extremely high risk of skin cancers, including melanoma.
- Psoriasis after psoralen-UV-A (PUVA) therapy

## DIAGNOSIS

### HISTORY

- Change in a pigmented lesion: either hypo- or hyperpigmentation, bleeding, scaling, ulceration, or changes in size or texture
- Obtain family and personal history of melanoma or nonmelanoma skin cancer.
- Obtain social history on sunbathing, tanning, and other sun exposure.

## PHYSICAL EXAM

- ABCDE: **A**symmetry, **B**order irregularity, **C**olor variegation (especially red, white, black, blue), **D**iameter >6 mm, **E**volution over time
- Any new and/or changing nevus, bleeding/ulcerated

- Location on Caucasians is primarily back and lower leg, on African Americans is the hands, feet, and nails.
- May include mucosal surfaces (nasopharynx, conjunctiva)
- Individuals at high risk for melanoma should have careful ocular exam to assess for presence of melanoma in the iris and retina.

## *DIFFERENTIAL DIAGNOSIS*

- Dysplastic and blue nevi
- Vascular skin tumor
- Pigmented actinic keratosis
- Traumatic hematoma
- Pigmented squamous cell and basal cell carcinomas, seborrheic keratoses, other changing nevi

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Lactate dehydrogenase (LDH), chest/abdomen/pelvic CT, MRI, and/or PET CT at baseline and in monitoring progression in metastatic disease (stage IV) (5)
- Imaging studies only helpful in detecting and evaluating for progression of metastatic disease

## *Diagnostic Procedures/Other*

- Dermoscopy allows for magnification of lesions, allowing for a decreased number of biopsies of benign skin lesions in addition to providing increased sensitivity in detecting melanoma and basal cell carcinoma (4)[B].
- Surgical biopsy remains the standard of care. Any suspicious nevus should be excised, either by elliptical excision; a scoop shave (saucerization) technique may be appropriate, as long as a fullthickness can be achieved (1)[C].
- Sentinel lymph node biopsy, a staging procedure, remains an important factor for prognosis (5)[A].

## *Test Interpretation*

- Nodular melanoma is primarily vertical growth, whereas the other three types are horizontal.
- Estimated that 1/10,000 dysplastic nevi become melanoma annually.
- Immunohistochemical testing increases sensitivity of lymph node biopsies.
- Staging is based on the tumor-node-metastasis (TNM) criteria by 2010 American Joint

## TREATMENT

### GENERAL MEASURES

Full surgical excision of melanoma is the standard of care. See below for recommended surgical margins.

### MEDICATION

- For stages I to III, surgical excision is curative in most cases; in patients with stage IV disease, systemic treatment with chemotherapy is recommended.
- Preferred regimens (5)[A] include the following:
  - Ipilimumab (monoclonal antibody against CTLA-4) in combination with Nivolumab (anti-PD-1 monoclonal antibody) demonstrated 61% response versus ipilimumab alone (6)[A].
  - Vemurafenib (Zelboraf) or Dabrafenib are BRAF inhibitors approved for metastatic, unresectable melanoma expressing BRAF V600E or V600K mutations.
  - High-dose interleukin-2 controversial (significant toxicity, 1-2% mortality related to treatment)
  - Referral for enrollment in clinical trials
- Additional active regimens (e.g., dacarbazine [DTIC], temozolomide, paclitaxel, carmustine [BCNU], cisplatin, carboplatin, vinblastine); often limited to those who are not candidates to preferred regimens.
- Imatinib (Gleevec) in tumors with C-KIT mutation
- Interferon- $\alpha$ ; as adjuvant therapy received FDA approval in 1995 (high dose) and 2011 (pegylated) to treat stage IIB to III melanoma; shown to improve 4-year relapse rate but no overall effect on survival; 1/3 of patients will discontinue due to toxicity (granulocytopenia, hepatotoxicity). Biochemotherapy is advocated by some (i.e., chemo + immunotherapy combination), although optimal regimen remains uncertain given disease heterogeneity (5)[B].

### ISSUES FOR REFERRAL

- Consultation with oncologist for consideration of chemotherapeutic options
- Plastic surgery sometimes needed after final excision

## ***ADDITIONAL THERAPIES***

Immunotherapy using various vaccine preparations has produced mixed results and remains an area for further research (7)[B].

## ***SURGERY/OTHER PROCEDURES***

- Standard of care for melanoma includes early surgical excision with the following recommended margins (5)[A]:
  - In situ tumors: 0.5 cm margin has been the standard of care but may be insufficient in lentigo maligna (8)[B].
  - Thickness of 1.01 to 2.00 mm: 1 to 2 cm margins
  - Thickness of >2.00 mm: 2 cm margins
- Sentinel lymph node biopsy is indicated in patients with T2-, T3-, and T4-staged melanomas.
  - Selected patients with stage T1b melanoma should also be considered for sentinel lymph node biopsy.
  - Not recommended in melanoma in situ or T1a
- Mohs surgery is often used for lesions with ill-defined borders or lesions of head and neck.
- Radiotherapy can be used to treat lentigo maligna in addition to certain head and neck lesions.
- Palliative radiation therapy can be used with metastatic melanoma.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Molecular and mouse tumor model studies support role of topical silymarin (milk thistle derivative) in decreasing UV radiation-induced inflammation, oxidative stress, and carcinogenesis (8)[B].

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Most treatments are done as outpatients with no stabilization needed.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

After diagnosis and treatment, close follow-up and skin protection (i.e., sunblock, UV protective

clothing) are highly advised.

## *Patient Monitoring*

- Routine screening clinical skin examination annually for all persons >40 years is controversial and without proven benefit.
- Total body photography and dermoscopy should be used for surveillance of skin lesions, most commonly used for patients with >5 atypical nevi.
- For patients with a history of cutaneous melanoma, specialty guidelines suggest every 3 to 12 months depending on recurrence risk (5)[C], general agreement to plan annual examinations after 5 years stable (9)[A].
- Lab and imaging tests after diagnosis and treatment of stage I to II melanoma are low yield, have high false-positive rates, and are not recommended (5)[B].

## *DIET*

No data to support specific dietary manipulations; general recommendations from American Cancer Society for cancer prevention

## *PATIENT EDUCATION*

- Teach patients who are at risk, or have had melanoma, the principles of ABCDE examinations.
- High-risk patients should perform monthly skin selfexaminations and be taught to examine inaccessible areas.
- Patients with a history of melanoma or dysplastic nevus syndrome should have regular total body examinations.

## *PROGNOSIS*

- Breslow depth (thickness) in millimeters remains among strongest predictors of prognosis.
- Median age at death 68 years
- Highest survival seen in women <45 years of age at diagnosis
- Metastatic melanoma has an average survival of 6 to 9 months; 15-20% 5-year survival with current treatment.
- Stages I and II, appropriately treated, have 20-year survival rates of 90% and 80%, respectively.

## **COMPLICATIONS**

- Metastatic spread

- Unsatisfactory cosmetic results following the primary surgery

&NA;

Dysplastic Nevus Syndrome

## Codes

&NA;

### ICD10

- C43.9 Malignant melanoma of skin, unspecified
- C43.30 Malignant melanoma of unspecified part of face
- C43.4 Malignant melanoma of scalp and neck

## Clinical Pearls

&NA;

- Remember that amelanotic melanomas exist; pigmentation is not required.
- 80% of cutaneous melanomas arise in existing nevi. Any changing nevi should be considered for full-thickness biopsy.
- Excellent prognosis in early detection and treatment, as well as being a common cancer affecting young adult women, require a high clinical suspicion and low threshold for thorough evaluation.

# MŽnière Disease

Jason E. Cohn, DO, MS

Nadir Ahmad, MD, FACS

Thomas C. Spalla, MD

## BASICS

### DESCRIPTION

- An inner ear (labyrinthine) disorder characterized by recurrent attacks of hearing loss, tinnitus, vertigo, and sensations of aural fullness due to an increase in the volume and pressure of the inner ear endolymph fluid (endolymphatic hydrops)
- Often unilateral initially, nearly half become bilateral over time.
- Severity and frequency of vertigo may diminish with time, but hearing loss is often progressive and/or fluctuating.
- Usually idiopathic (MŽnière disease) but may be secondary to another condition causing endolymphatic hydrops (MŽnière syndrome)
- System(s) affected: nervous
- Synonym(s): MŽnière syndrome; endolymphatic hydrops

### EPIDEMIOLOGY

- Predominant age of onset: 40 to 60 years
- Predominant gender: female > male (1.3:1)
- Race/ethnicity: white, Northern European > blacks

### Incidence

Estimates 1 to 150/100,000 per year

### Prevalence

Varies from 7.5 to >200/100,000

### ETIOLOGY AND PATHOPHYSIOLOGY

- Not fully understood; theories include increased pressure of the endolymph fluid due to increased fluid production or decreased resorption. This may be caused by endolymphatic sac pathology, abnormal development of the vestibular aqueduct, or inflammation caused by circulating immune complexes. Increased endolymph pressure may cause rupture of membranes and changes in endolymphatic ionic gradient.
- Ménière syndrome may be secondary to injury or other disorders (e.g., reduced middle ear pressure, allergy, endocrine disease, lipid disorders, vascular, viral, syphilis, autoimmune). Any disorder that could cause endolymph hydrops could be implicated in Ménière syndrome.

## *Genetics*

Some families show increased incidence, but genetic and environmental influences are incompletely understood.

## **RISK FACTORS**

May include

- Stress
- Allergy
- Increased salt intake
- Caffeine, alcohol, or nicotine
- Chronic exposure to loud noise
- Family history of Ménière
- Certain vascular abnormalities (including migraines)
- Certain viral exposures (especially herpes simplex virus [HSV])

## **GENERAL PREVENTION**

Reduce known risk factors: stress; salt, alcohol, and caffeine intake; smoking; noise exposure; ototoxic drugs (e.g., aspirin, quinine, aminoglycosides).

## **COMMONLY ASSOCIATED CONDITIONS**

- Anxiety (secondary to the disabling symptoms)
- Migraines
- Hyperprolactinemia

# DIAGNOSIS

Diagnosis is clinical.

## HISTORY

Symptomatic episodes are typically spontaneous but may be preceded by an aura of increasing fullness in the ear and tinnitus. These may occur in clusters, with long periods of symptom-free remissions.

- Formal criteria for diagnosis from American Academy of Otolaryngology-Head and Neck Surgery:
  - At least two episodes of rotational-horizontal vertigo >20 minutes in duration
  - Tinnitus or aural fullness
  - Hearing loss: Low frequency (sensorineural) is confirmed by audiometric testing.
  - Other causes (e.g., acoustic neuroma) excluded.
  - During severe attacks: pallor, sweating, nausea, vomiting, falling, prostration
  - Symptoms are exacerbated by motion.

## PHYSICAL EXAM

- Physical exam rules out other conditions; no finding is unique to Ménière disease.
- Horizontal nystagmus may be seen during attacks.
- Otoscopy is typically normal.
- Triggering of attacks in the office with Dix-Hallpike maneuver suggests diagnosis of benign paroxysmal positional vertigo, not Ménière disease.

## DIFFERENTIAL DIAGNOSIS

- Acoustic neuroma or other CNS tumor
- Syphilis
- Third window syndromes
- Endolymphatic sac tumor
- Viral labyrinthitis
- Transient ischemic attack (TIA), migraine

- Vertebrobasilar disease
- Other labyrinthine disorders (e.g., Cogan syndrome, benign positional vertigo, temporal bone trauma)
- Diabetes or thyroid dysfunction
- Vestibular neuronitis
- Medication side effects
- Otitis media
- Autoimmune inner ear disease
- Autosomal dominant sensorineural hearing loss

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Testing is done to rule out other conditions but does not necessarily confirm or exclude Ménière disease.

### ***Initial Tests (lab, imaging)***

- Consider serologic tests specific for *Treponema pallidum* in at-risk populations.
- Thyroid, fasting blood sugar, and lipid studies
- Consider MRI to rule out acoustic neuroma or other CNS pathology, including tumor, aneurysm, and multiple sclerosis (MS).
- MRI can help diagnosis Ménière disease by identifying endolymphatic hydrops (1,2)[B].

### ***Diagnostic Procedures/Other***

- Auditory
  - Audiometry using pure tone and speech to show low-frequency sensorineural (nerve) loss and impaired speech discrimination. Usually shows low-frequency sensorineural hearing loss
  - Tuning fork tests (i.e., Weber and Rinne) ABR or MRI to rule out acoustic neuroma
  - Electrocochleography may be useful to confirm etiology.
- Vestibular
  - Caloric testing: Electronystagmography may show reduced caloric response. Can obtain reasonably comparable information with use of 0.8 mL of ice water caloric testing. Reduced activity on either side is consistent with Ménière diagnosis but is not itself diagnostic.

## *Test Interpretation*

- Histologic temporal bone analysis (at autopsy). Dilation of inner ear fluid system, neuroepithelial damage with hair cell loss, basement membrane thickening, and perivascular microvascular damage
- Cytochemical analysis can reveal altered AQP4 and AQP6 expression in the supporting cell, altered cochlin, and mitochondrial protein expression (3)[B].

## **TREATMENT**

- Usually managed in outpatient setting
- A paucity of evidence-based guidelines exist; therefore, there is no gold standard treatment.
- Medications are primarily for symptomatic relief of vertigo and nausea.
- During attacks, bed rest with eyes closed prevents falls. Attacks rarely last >4 hours.

## **MEDICATION**

### *First Line*

- Acute attack: Initial goal is stabilization and symptom relief. For severe episodes
  - Benzodiazepines (such as diazepam): decrease vertigo and anxiety
  - Antihistamines (meclizine/dimenhydrinate): decrease vertigo and nausea
  - Anticholinergics (transdermal scopolamine): reduces nausea and emesis associated with motion sickness
  - Antidopaminergic agents (metoclopramide, (promethazine): decrease nausea, anxiety
  - Rehydration therapy and electrolyte replacement
  - Steroid taper for acute hearing loss
- Maintenance (goal is to prevent/reduce attacks)
  - Lifestyle changes (e.g., low-salt diet) are needed.
  - Diuretics may help reduce attacks by decreasing endolymphatic pressure and volume; there is insufficient evidence to recommend routine use:
    - Hydrochlorothiazide; hydrochlorothiazide/triamterene (Dyazide, Maxzide)
    - Acetazolamide (Diamox)

- Contraindications/warnings:
    - Atropine: cardiac disease, especially supraventricular tachycardia and other arrhythmias, prostatic enlargement
    - Scopolamine: children and elderly, prostatic enlargement
    - Diuretics: electrolyte abnormalities, renal disease
- 

P.651

- Precautions:
  - Sedating drugs should be used with caution, particularly in the elderly. Patients are cautioned not to operate motor vehicles or machinery. Atropine and scopolamine should be used with particular caution.
  - Diuretics: Monitor electrolytes.
- Significant possible interactions: transdermal scopolamine: anticholinergics, antihistamines, tricyclic antidepressants, other

## *Second Line*

- Steroids, both intratympanic and systemic (PO or IV) have been used for longer treatment of hearing loss:
  - Intratympanic administration results in higher steroid levels in the inner ear and may be more effective and safer than systemic (2)[C].
  - Addition of prednisone 30 mg/day to diuretic treatment reduced severity and frequency of tinnitus and vertigo in one pilot study.
- In Europe, betahistine, a histamine agonist is routinely used (unavailable in the United States). Other vasodilators, such as isosorbide dinitrate, niacin, and histamine, have also been used; evidence of their effectiveness is incomplete.
- Evidence is lacking for routine use of Famvir, may improve hearing more than balance.
- Intratympanic gentamicin has shown to improve vertigo (4,5,6)[B].

## *ISSUES FOR REFERRAL*

- Consider ear, nose, throat/neurology referral.
- Patients should have formal audiometry to confirm hearing loss.

## *ADDITIONAL THERAPIES*

Application of intermittent pressures via a myringotomy using a Meniett device has been shown to relieve vertigo (7)[B]:

- Safe; requires a long-term tympanostomy tube
- Vestibular rehabilitation may be beneficial for patients with persistent vestibular symptoms:
  - Safe and effective for unilateral vestibular dysfunction

## ***SURGERY/OTHER PROCEDURES***

- Interventions that preserve hearing:
  - Endolymphatic sac surgery, either decompression or drainage of endolymph into mastoid or subarachnoid space
    - Less invasive; may decrease vertigo; may influence hearing/tinnitus
  - Endolymphatic sac surgery is effective in controlling vertigo in short- and long-term follow-up in at least 75% of patients with Ménière disease who failed medical therapy (8)[A].
  - Vestibular nerve section (intracranial procedure)
    - More invasive
    - Decreases vertigo and preserves hearing
  - Tympanostomy tube: may decrease symptoms by decreasing the middle ear pressure
- Interventions for patients with no serviceable hearing:
  - Labyrinthectomy: very effective at controlling vertigo but causes deafness
  - Vestibular neurectomy
  - Cochlear implantation has shown to improve tinnitus and quality of life (9)[B].
  - There are new surgeries on the rise, for example, endolymphatic duct blockage, which in one study proved to be superior to endolymphatic sac decompression (10)[B].

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Insufficient evidence to support effectiveness, but many integrative techniques have been tried, including the following:

- Acupuncture, acupressure, tai chi
- Niacin, bioflavonoids, Lipoflavonoids, ginger, ginkgo biloba, and other herbal supplements

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

Due to the possibility of progressive hearing loss despite decrease in vertiginous attacks, it is important to monitor changes in hearing and to monitor for more serious underlying causes (e.g., acoustic neuroma).

#### *DIET*

- Diet is usually not a factor, unless attacks are brought on by certain foods.
- A low salt is often recommended but not proven effective in randomized controlled trials.

#### *PROGNOSIS*

- Alert patients about the nature of alternating attacks and remission.
- Between attacks, patient may be fully active but is often limited due to fear or lingering symptoms. This can be severely disabling.
- 50% resolve spontaneously within 2 to 3 years.
- Some cases last >20 years.
- Severity and frequency of attacks diminish, but hearing loss is often progressive.
- 90% can be treated successfully with medication; 5-10% of patients require surgery for incapacitating vertigo.
- There is a mental illness burden associated with MŽnière disease (11)[B].

#### **COMPLICATIONS**

Loss of hearing; injury during attack; inability to work

## See Also

**&NA;**

Hearing Loss; Labyrinthitis; Tinnitus

## Codes

**&NA;**

### ICD10

- H81.09 Meniere's disease, unspecified ear
- H81.01 Meniere's disease, right ear
- H81.02 Meniere's disease, left ear

## Clinical Pearls

**&NA;**

- MŽnière disease is characterized by vertigo, hearing loss, and tinnitus +/- aural fullness.
- There is a wide differential diagnosis for MŽnière disease; therefore, one must fully investigate symptoms.
- Multiple medical, surgical, and rehabilitative treatments are available to decrease the severity and frequency of attacks.

# Meningitis, Bacterial

Felix B. Chang, MD, DABMA, FAAMA

## BASICS

### DESCRIPTION

- A potentially life-threatening bacterial infection of the meninges
- System affected: nervous

### EPIDEMIOLOGY

- Predominant age: neonates, infants, and elderly
- Predominant sex: male = female

### Incidence

Varies with age (1)[C]

- <2 months: 80/100,000
- 2 to 23 months: 7/100,000
- 2 to 10 years: 0.5/100,000
- 11 to 17 years: 0.4/100,000
- 18 to 34 years: 0.66/100,000
- 35 to 49 years: 0.95/100,000
- ≥65 years: 1.92/100,000

Varies with pathogen

- *Streptococcus pneumoniae*: 0.81/100,000
- Group B *Streptococcus*: 0.25/100,000
- *Neisseria meningitidis*: 0.19/100,000
- *Haemophilus influenzae*: 0.08/100,000
- *Listeria monocytogenes*: 0.05/100,000

## ETIOLOGY AND PATHOPHYSIOLOGY

Bacterial infection causes inflammation of the pia mater, arachnoid, and the fluid of the ventricles. Age groups with likely pathogens guide empiric choice of antibiotics. Guide therapy by culture whenever possible (1):

- Newborns (<2 months)
  - Group B *Streptococcus*
  - *Escherichia coli*
  - *L. monocytogenes*
- Infants and children
  - *S. pneumoniae*
  - *N. meningitidis*
  - *H. influenzae*
- Adolescents and young adults
  - *N. meningitidis*
  - *S. pneumoniae*
- Immunocompromised adults
  - *S. pneumoniae*, *L. monocytogenes*, gram-negative bacilli such as *Pseudomonas aeruginosa*
- Older adults
  - *S. pneumoniae* 50%
  - *N. meningitidis* 30%
  - *L. monocytogenes* 5%
  - 10% gram-negatives bacilli: *E. coli*, *Klebsiella*, *Enterobacter*, *P. aeruginosa*

## Genetics

Navajo Indians and American Eskimos appear to have genetic or acquired susceptibility to invasive disease.

## RISK FACTORS

- Immune compromise

- Alcoholism, diabetes, chronic disease
- Neurosurgical procedure/head injury
- Abdominal surgery
- Neonates: prematurity, low birth weight, premature rupture of membranes, maternal peripartum infection, and urinary tract abnormalities
- Abnormal communication between nasopharynx and subarachnoid space (congenital, trauma)
- Parameningeal source of infection: otitis, sinusitis, mastoiditis
- Trauma: skull fracture

## GENERAL PREVENTION

- Treat infections appropriately.
- Strict aseptic techniques for patients with head wounds or skull fractures
- Consider CSF fistula in patients with recurrent meningitis.
- Meningitis caused by *H. influenzae* type B has decreased 55% with routine vaccination.
- Conjugate vaccines against *S. pneumoniae* may reduce the burden of disease in childhood and produce herd immunity among adults.
- Close contacts meningococcal meningitis patients should receive chemoprophylaxis (2)[A].

## COMMONLY ASSOCIATED CONDITIONS

Conditions associated with a worse prognosis:

- Alcoholism, old age, infancy
- Diabetes mellitus, multiple myeloma
- Head trauma, seizures
- Coma, bacteremia, sepsis
- Bacteremia, sepsis, sinusitis

## DIAGNOSIS

### HISTORY

- Antecedent upper respiratory infection
- Fever, headache, vomiting, photophobia

- Seizures, confusion, nausea, rigors
- Profuse sweats, weakness
- Elderly: subtle findings including confusion
- Infants: irritability, lethargy, poor feeding
- Altered mental status

## *PHYSICAL EXAM*

The triad of fever, neck stiffness, and altered mental status has low sensitivity (44%) (3)[C]. 95% of patients present with at least two of the following four symptoms: headache, fever, neck stiffness, and altered mental status.

- Meningismus
- Focal neurologic deficits
- Meningococcal rash: macular and erythematous at first, then petechial or purpuric
- Papilledema
- Brudzinski sign: Passive flexion of neck elicits involuntary flexing of knees in supine patients.
- Kernig sign: resistance or pain to knee extension following 90-degree hip flexion by clinician in supine patients

## *DIFFERENTIAL DIAGNOSIS*

- Bacteremia, sepsis, brain abscess
- Seizures, other nonbacterial meningitides
- Aseptic meningitis
- Drug-induced: NSAIDs, cotrimoxazole, amoxicillin, cephalosporin, isoniazid
- Inflammatory noninfectious: Behçet disease, systemic lupus erythematosus (SLE), sarcoidosis
- Stroke

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Prompt lumbar puncture (1)[A]
  - Head CT first if focal neuro findings, papilledema, or altered mentation
- Typical CSF analysis: turbid

- Adults
  - >500 cells/mL WBCs
  - Glucose <40 mg/dL
  - <2/3 blood-to-glucose ratio
  - CSF protein >200 mg/dL
  - CSF opening pressure >30 cm
  - Suspect ruptured brain abscess when WBC count is unusually high (>100,000).
- CSF Gram stain and cultures
- Polymerase chain reaction (PCR) of CSF (particularly in suspected viral meningitis)
- Bacterial antigen tests should be reserved for cases in which the initial CSF Gram stain is negative and CSF culture is negative at 48 hours of incubation.
- Serum blood cultures, serum electrolytes
- Evaluate clotting function if petechiae or purpura are present.
- Chest radiograph may reveal pneumonitis or abscess.
- Later in course: head CT if hydrocephalus, brain abscess, subdural effusions, and subdural empyema are suspected or if no clinical response after 48 hours of appropriate antibiotics
- C-reactive protein (CRP): Normal CRP has high negative, predictive value for bacterial meningitis (3)[B].

## *Diagnostic Procedures/Other*

### Lumbar puncture

- Head CT first if concern for increased intracranial pressure or warning signs of space-occupying lesion (new-onset seizure, papilledema, or brain herniation) or focal neurologic deficit
- IDSA CT recommendations: immunocompromised, history of central nervous system disease (stroke, mass lesion, focal infection), papilledema, focal neurologic defect including fixed dilated pupil, gaze palsy, weakness of extremity, visual field cut, new-onset seizure <12 week prior to presentation, abnormal level of consciousness (3)[C]
- Contraindications to LP: signs of increased intracranial pressure (decerebrate posturing, papilledema), skin infection at site of lumbar puncture, CT or MRI evidence of obstructive hydrocephalus, cerebral edema, herniation

## TREATMENT

### GENERAL MEASURES

- Initiate empiric antibiotic therapy immediately after lumbar puncture (LP > Abx), or if head CT scan is needed, then immediately after blood cultures (Abx > CT > LP).
- Vigorous supportive care to ensure prompt recognition of seizures and prevention of aspiration

### MEDICATION

Empiric IV therapy (with dexamethasone when indicated) until culture results are available

- Consider local patterns of bacterial sensitivity.

---

P.653

#### *First Line*

- Neonates
- Ampicillin: 150 mg/kg/day divided q8h *AND*
- Cefotaxime 150 mg/kg/day divided q8h
- Infants >4 weeks of age (3,4)[A]
  - Ceftriaxone: 100 mg/kg/day divided q12-24h or cefotaxime 225 to 300 mg/kg/day divided q6-8h *AND*
  - Vancomycin: 60 mg/kg/day divided q6h
- Adults (3,4)[A]
  - Vancomycin: loading dose 25 to 30 mg/kg IV then 15 to 20 mg/kg q8-12h with goal trough of 15 to 20 *AND*
  - Ceftriaxone: 2 g IV q12h *OR*
  - Cefotaxime: 2 g IV q4-6h
  - >50 years, add ampicillin: 2 g IV q4h for *Listeria*
  - Immunocompromised use vancomycin, ampicillin, ceftazidime, and acyclovir.
- Precaution: aminoglycoside ototoxicity
- Penicillin-allergic patients (3,4)[A]
  - Chloramphenicol: 1 g IV q6h *AND*

- Vancomycin: loading dose 25 to 30 mg/kg IV then 15 to 20 mg/kg q8-12h (goal trough of 15 to 20)
- Treatment duration
  - *S. pneumoniae*: 10 to 14 days
  - *N. meningitidis*, *H. influenzae*: 7 to 10 days
  - Group B *Streptococcus* organisms, *E. coli*, *L. monocytogenes*: 14 to 21 days
  - Neonates: 12 to 21 days or at least 14 days after a repeated culture is sterile
- Corticosteroids (5)[A]
  - Pediatrics
    - Early treatment with dexamethasone (0.15 mg/kg IV q6h for 2 to 4 days) decreases mortality and morbidity for patients >1 month of age with acute bacterial meningitis with no increased risk of GI bleeding.
    - Corticosteroids are associated with lower rates of severe hearing loss, any hearing loss, and neurologic sequelae.
  - Adults
    - Initiate in adults, then only continue if CSF Gram stain is gram-positive diplococcus or if blood or CSF positive for *S. pneumoniae*.
    - Dexamethasone: 10 mg IV q6h started 15 to 20 minutes before or with antibiotic for 4 days

## *Second Line*

Antipseudomonal penicillins

- Aztreonam
- Quinolones (e.g., ciprofloxacin)
- Meropenem

## *ISSUES FOR REFERRAL*

Consultation from infectious disease and/or critical care specialist

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Bacterial meningitis requires hospitalization.

- Nursing
- ICU monitoring may be needed.
- Patients with suspected meningococcal infection require respiratory isolation for 24 hours.

## *Discharge Criteria*

Consider home therapy to complete IV antibiotics once clinically stable and culture/sensitivity results are known.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Brainstem auditory evoked response hearing test for infants before hospital discharge
- Vaccinations
  - *Hib* conjugate vaccine is recommended during infancy for 4 doses.
  - Meningococcal conjugate vaccine quadrivalent (MCV4) is given to children aged 11 to 12 years with a booster at 16 years.
  - Immunizing infants <3 months old with MCV4 does not reduce morbidity or mortality, and vaccinating pregnant women does not reduce infant infections.
  - Administer 2 doses MCV4 at least 2 months apart to adults with the following:
    - HIV, functional asplenia
    - Persistent complement deficiencies
  - Administer 1 dose of meningococcal vaccine to:
    - Military recruits
    - Microbiologists routinely exposed to isolates of *N. meningitidis*
    - Those who travel to or live in countries where meningitis is hyperendemic or epidemic.
    - 1st year college students up through age 21 years who live in residence halls if they have not received a dose on or after their 16th birthday
  - MCV4 is preferred for adults with any of the preceding indications who are ≥55 years of age;

meningococcal polysaccharide vaccine (MPSV4) is preferred for adults aged  $\geq 56$  years.

- Revaccination with MCV4 every 5 years is recommended for adults previously vaccinated with MCV4 or MPSV4 who are at increased risk.
- Prophylaxis (2)[A]
  - Only for close contacts of patients
  - Rifampin is effective in eradicating *N. meningitidis* up to 4 weeks after treatment but may lead to resistance.
  - Rifampin: 600 mg PO BID for 2 days
    - Ciprofloxacin and ceftriaxone are effective up to 2 weeks after treatment without leading to resistance.
    - Ciprofloxacin: 500 mg PO for 1 dose
    - Ceftriaxone: 250 mg IM for 1 dose

## DIET

Regular, as tolerated, except with syndrome of inappropriate secretion of antidiuretic hormone.

## PROGNOSIS

Overall case fatality: 21%

- Fatality rate increases linearly with age.

## COMPLICATIONS

- Seizures: 20-30%; focal neurologic deficit
- Cranial nerve palsies (III, VI, VII, VIII)
  - Comprises 10-20% of the cases
  - Usually disappear within a few weeks
- Sensorineural hearing loss: 10% in children
- Neurodevelopmental sequelae: 30% subtle learning deficits
- Obstructive hydrocephalus, subdural effusion
- Syndrome of inappropriate secretion of antidiuretic hormone
- Elevated intracranial pressure: herniation, brain swelling

## Codes

&NA;

### ICD10

- G00.9 Bacterial meningitis, unspecified
- G00.2 Streptococcal meningitis
- G00.8 Other bacterial meningitis

# Clinical Pearls

## &NA;

- Initiate antibiotic therapy immediately (following diagnostic lumbar puncture) if meningitis is suspected.
- Corticosteroids reduce hearing loss and neurologic sequelae but not overall mortality.
- Repeat lumbar puncture if patients don't respond to antimicrobial therapy after 48 hours.
- Classic triad of fever, neck stiffness, and altered mental status has low sensitivity for bacterial meningitis. Meningeal signs are unreliable for diagnosis or ruling out meningitis.
- Rapidly evolving petechial rash (purpura fulminans) is more common in meningococcal meningitis.
- 50-90% of patients with bacterial meningitis have positive blood cultures. Mixed bacterial infections are rare.

# Meningitis, Viral

Christine M. Broszko, MD

James E. Hougas III, MD, Maj, USAF, MC

## BASICS

### DESCRIPTION

- A clinical syndrome characterized by signs/symptoms of acute meningeal inflammation
- Viral meningitis (VM) is the most common cause of aseptic meningitis.
- Aseptic meningitis has no identifiable bacterial pathogen in CSF.
- System(s) affected: nervous

### EPIDEMIOLOGY

#### Incidence

- Estimated 30,000 to 75,000 VM cases annually in United States
- Estimated 26,000 to 42,000 VM hospitalizations annually in United States
- Most common form of infectious meningitis
  - Annual incidence of VM is higher than all other causes of meningitis combined.
- Peaks June 1 to October 31
  - Non-polio enteroviruses and arthropodborne viruses predominate in warm months (70% of cases July to October).
  - Mumps usually occurs in the winter and spring, often in epidemics.
- Occurs in both outbreak and sporadic forms

### ETIOLOGY AND PATHOPHYSIOLOGY

- First described by Wallgren in 1925
- In immunocompetent hosts, VM is generally caused by a systemic viral infection with neurotropic predilection.

- Less commonly, direct neural transmission occurs from an acute flare of a chronic viral illness (such as HSV) already present in an immunocompetent host.
- 85-95% of cases are caused by enterovirus family; (often transmitted by the fecal-oral route) including coxsackievirus A and B, echovirus, and non-polio E variants: E9 and E30. Most recently, outbreak of E68 in 2014
- Less common: HSV-1, HSV-2, varicella-zoster virus (VZV), adenovirus, lymphocytic choriomeningitis virus (LCMV), cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV, parvovirus B19, and mumps virus
- Parechovirus 3 is the most common cause of viral meningitis in infants <90 days old.
- Arthropod-borne viruses: West Nile virus, St. Louis encephalitis virus, California encephalitis virus
- Recurrent benign lymphocytic (Mollaret) meningitis-80% associated with HSV-2.

## *Genetics*

None identified

## **RISK FACTORS**

- Close contact with known cases of VM
- Age (common in children <5 years)
- Immunocompromised hosts may be more susceptible to CMV, HSV, and adenovirus in particular.
- LCMV is transmitted via exposure to rodent feces, bite, bodily fluids, or nesting materials.

## *Geriatric Considerations*

Cases of VM in the elderly are rare; consider alternative diagnoses (e.g., carcinomatous meningitis, NSAID-or medication-induced meningitis).

## **GENERAL PREVENTION**

Limit exposure to known hosts. Observe hand washing and general hygiene procedures.

## **COMMONLY ASSOCIATED CONDITIONS**

Encephalitis; neurologic deficits; myopericarditis; neonatal enteroviral sepsis

**DIAGNOSIS**

## HISTORY

Predominant symptoms include acute onset (hours to days) of:

- Fever (in 76-100% of patients)
- Headache (prominent early symptom)
- Photophobia
- Myalgias
- Nausea, vomiting
- Malaise
- Nuchal rigidity (>50%)
- Mental status changes
  - Encephalitis is associated with other neurologic dysfunction, such as behavioral change, focal neurologic deficits, seizure. There is a continuum between meningitis and encephalitis that can be labeled as one or the other according to predominant symptom type, or jointly labeled "meningoencephalitis."

Also document the following:

- Travel and exposure history
- Sexual activity (e.g., HSV, HIV)
- Outdoor activities (Lyme disease)
- Exposure to rodent feces and/or urine (LCMV)
- Solid-organ transplant (LCMV, CMV)
- Immunocompromised host (CMV, HSV, adenovirus)
- History of varicella-zoster infection (VZV)
- Immunization status (mumps virus)

## PHYSICAL EXAM

- Altered mental status (AMS)
  - AMS is more common in encephalitis than meningitis.
- Fever (>100.4°F/38°C)
- Meningeal signs (should not be used exclusively to diagnose or rule out meningitis):
  - Nuchal rigidity
  - Brudzinski sign: Neck flexion elicits involuntary hip and knee flexion in supine patient.

- Kernig sign: resistance to knee extension following flexion of hips to 90 degrees by physician
- Jolt accentuation test: Rapid horizontal rotation of the head accentuates the headache.
- Genital lesions (HSV2: can precede meningeal symptoms by up to a week)
- Parotitis (mumps)
- Asymmetric flaccid paralysis (West Nile virus)
- Mucocutaneous findings
  - Vesicular rash in hand, foot, and mouth disease (coxsackie)
  - Herpangina (coxsackie A)
  - Herpes zoster rash (VZV)
  - Erythema chronicum migrans or cranial neuropathy (Lyme disease [*Borrelia burgdorferi*])
  - Generalized maculopapular rash (Echovirus 9)
  - Oropharyngeal thrush (HIV)
  - Petechial rash (*Neisseria meningitidis*)

## ***DIFFERENTIAL DIAGNOSIS***

- Bacterial meningitis (BM)
- Encephalitis
- Other infectious agents:
  - Tuberculosis; syphilis; leptospirosis; Lyme disease; Rocky Mountain spotted fever; ehrlichiosis; *Coccidioides*; *Cryptococcus neoformans*; amebiasis; Rickettsial infection
- Parameningeal infections (e.g., subdural empyema)
- Postinfectious encephalomyelitis
- Viral syndrome (e.g., influenza)
- Leukemia or carcinomatous meningitis
- Migraine/tension headache
- Acute metabolic encephalopathy
- Chemical meningitis
- Drug-induced meningitis (NSAIDs, IVIG, Bactrim)

- Brain/epidural abscess

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Rule out BM:
  - There is debate over whether patients with low suspicion of BM need a lumbar puncture (LP). Some authors contend that if meningeal symptoms have been present >48 hours with a normal neurologic exam in an immunocompetent patient with confirmed normal level of alertness, BM is extremely unlikely and LP is not warranted. Others contend that BM cannot be excluded clinically and to exercise caution discharging meningitic patients without LP.
  - Bacterial Meningitis Score (BMS): The BMS is a validated clinical decision rule to identify at very low risk of BM. Low-risk features include negative CSF Gram stain, CSF absolute neutrophil count (ANC) <1,000 cells/ $\mu\text{m}^3$ , CSF protein <80 mg/dL, peripheral blood ANC <10,000 cells/ $\mu\text{m}^3$ , and no seizure around the time of initial presentation.
  - CSF bacterial culture is positive in 80-90% of BM patients who haven't received antibiotics for 2 to 4 hours prior to LP.
- LP is the standard of care for suspected BM:
  - If BM is suspected, start antibiotics immediately.
  - Contraindications for LP: signs of increased intracranial pressure (e.g., focal neurologic findings, papilledema, altered mental status, vomiting), known ventricular obstruction, new onset seizure, immunocompromised state, local infection over potential LP site or suspected epidural abscess, use of anticoagulation or coagulopathy, and possibility of cardiorespiratory compromise due to patient positioning during procedure
  - Post-LP headache: occurs in 37% of patients within 48 hours
  - CSF analysis: glucose, protein, WBC count with differential, RBC count, Gram stain, culture; consider CSF lactate:
    - CSF lactate elevation can differentiate BM from VM (decreased sensitivity if pretreated with antibiotics) (1,2)[A].
- Typical CSF findings in VM
  - Elevated WBC count: 10 to 1,000/ $\text{mm}^3$ , classically lymphocyte predominance (less consistent in younger patients); may show neutrophil predominance in first 48 hours
  - Decreased or normal glucose (relative to concurrent serum glucose)

- Protein normal to slightly elevated (<150 mg/dL)
- Negative Gram stain and bacterial culture
- Elevated opening pressure
- RBCs in CSF (Consider HSV meningitis/encephalitis.)
- Pathogen identification
  - Gold standard: CSF viral culture for enteroviruses, HSV, and mumps has low sensitivity (<6%); viral culture may yield no additional information over nucleic acid amplification alone.
  - Polymerase chain reaction (PCR): has a sensitivity of 95-100% for HSV-1 and -2, EBV, and enterovirus
  - RT PCR test is approved by the FDA for enteroviral meningitis. Results in 2 to 3 hours
  - Serology can be performed for many arthropod-borne viruses.

P.655

- Other labs: CBC, blood culture, blood glucose; consider serum CRP and procalcitonin (PCT).
  - CBC: normal or mildly elevated WBCs
  - Multiple studies show PCT correlation with BM. PCT levels of >0.25 to 2.13 are 90% sensitive and 98% specific for BM. Elevated serum CRP was 82% sensitive and 81% specific (1,3)[B].
- Consider EEG if concern for encephalitis.
- Indication for imaging depends on clinical scenario. Perform CT prior to LP if papilledema, spinal cord trauma, altered mental status, or focal neurologic findings. CT scan not typically clinically necessary in the absence of risk factors.

## *Follow-Up Tests & Special Considerations*

Disorders that may alter lab results:

- Diabetes: Consider current blood sugar level to correlate with CSF glucose level.
- Preexisting neurologic diseases (e.g., intracranial neoplasm, demyelinating disease)

## **TREATMENT**

### *GENERAL MEASURES*

Management is largely supportive care (e.g., pain control, IV fluids).

## MEDICATION

### First Line

- Analgesics (adult doses; titrate doses to pain relief)
  - Morphine 2.5 to 5 mg IV
  - Hydromorphone (Dilaudid) 1 to 2 mg IV
  - Hydrocodone (Norco) 5/325 mg 1 to 2 tablets PO q6h *OR* oxycodone (Percocet) 5/325 mg 1 to 2 tablets PO q4-6h
- Antiemetics
  - Ondansetron (Zofran) 4 to 8 mg IV q8h
  - Metoclopramide (Reglan) 10 to 20 mg IV/IM q4-6h
- Antipyretics: acetaminophen (Tylenol) 650 mg PO or rectal suppository q4h
- Antiviral agents: Initiate empiric acyclovir at 10 mg/kg IV q8h for patients with CSF pleocytosis, negative Gram stain, and suspicion for HSV while awaiting results of definitive (e.g., HSV PCR) testing.
- Antibiotics
  - Not indicated for treatment of VM
  - If unclear etiology, treat symptomatically and follow the patient closely in the hospital setting while awaiting laboratory results.
  - If in doubt, initiate an IV broad-spectrum antibiotic with good CSF penetration. Consider especially in elderly, <3 month old, or immunocompromised patient. Empiric treatment for BM in otherwise healthy patient
    - If <1 month, consider ampicillin PLUS gentamicin *OR* cefotaxime. All dosing dependent on age and size.
    - If 1 month to 17 years old, consider vancomycin PLUS ceftriaxone *OR* cefotaxime. Dosing dependent on age and size.
    - If 18 years to 49 years old, consider vancomycin (15 to 20 mg/kg/dose q8-12h; also consider loading dose of 25 to 30 mg/kg) PLUS ceftriaxone (2g q12h) *OR* cefotaxime (2g q4-6h).
    - In >50 years old, consider vancomycin (15 to 20 mg/kg/dose q8-12h; also consider

loading dose of 25 to 30 mg/kg) PLUS ampicillin (150 to 250 mg/kg/day divided q3-4h)  
PLUS ceftriaxone (2g q12h) OR cefotaxime (2g q4-6h).

- If concern for BM, consider corticosteroids along with antibiotic therapy.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Generally, VM is treated as outpatient. Patients with VM and complications (encephalitis) may be hospitalized. Hospitalize for empiric antibiotic therapy, pain/fluid control, immunocompromised patient, or <1 year old.

- Study of ED visits found that most children diagnosed with VM were hospitalized (91%).

### ***IV Fluids***

Crystalloid bolus or continuous infusion, based on hydration status and clinical presentation

### ***Nursing***

- Neurologic monitoring for changes in mental status, fever, and other clinical indicators to assess disease progression
- Contact precautions until BM is ruled out
- Private room indicated with sterile precautions
- Encourage hand washing.

### ***Discharge Criteria***

Discharge depends on likelihood of BM, CSF, WBC count, and clinical parameters such as dehydration, functional level, social circumstances, and ability to follow up.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Primary care follow up to ensure resolution.

### ***Patient Monitoring***

- Monitor for relapse or exacerbation of symptoms.
- Monitor for neurologic/neuroendocrine complications:

- Seizures, cerebral edema, syndrome of inappropriate antidiuretic hormone (SIADH)
- Assess ability to have companion monitor change in mental/neurologic status if patient discharged.

## DIET

Consider NPO if nausea or vomiting. Advance to clear fluids/regular diet as tolerated.

## PATIENT EDUCATION

- Discuss low probability of transmission to contacts.
- Expected duration of illness is 5 to 10 days.
- Recurrence of headache, myalgia, weakness is possible over 2 to 3 weeks

## PROGNOSIS

- Complete recovery generally within 7 to 10 days
- Headaches and other neurologic symptoms may persist intermittently for weeks to months.
- Only 0.6% of hospitalizations for VM result in death.
- European studies suggest potential residual postmeningeal cognitive impairment.

## COMPLICATIONS

Fatigue, irritability, muscle weakness, seizures/abscess/mastoiditis (rare)

## See Also

**&NA;**

Algorithm: Delirium

## Codes

**&NA;**

## ICD10

- A87.9 Viral meningitis, unspecified
- A87.1 Adenoviral meningitis
- A87.0 Enteroviral meningitis

## Clinical Pearls

## **&NA;**

- Viral meningitis cannot always be reliably distinguished from BM based on clinical findings. Potential cases of BM should be hospitalized for evaluation and treatment pending laboratory results.
- VM is more common than BM in children.
- Antibiotic administration >2 to 4 hours prior to CSF analysis may result in Ópartially treatedÓ BM that mimics VM.
- IV acyclovir should be administered if there is high clinical suspicion for HSV.
- If BM is suspected, broad-spectrum antibiotics should be administered until BM has been ruled out.
- Morbidity with VM is low but increases if there is associated encephalitis.

# Meningococcal Disease

Han Q. Bui, MD, MPH

## BASICS

### DESCRIPTION

- Meningococcemia is a blood-borne infection caused by *Neisseria meningitidis*.
- Bacteremia without meningitis: Patient is acutely ill and may have skin manifestations (rashes, petechiae, and ecchymosis) and hypotension.
- Bacteremia with meningitis: sudden onset of fever, nausea, vomiting, headache, decreased ability to concentrate, and myalgias
- Disease progresses rapidly within a matter of hours.
- Meningococcal bacteremia rarely occurs without frank sepsis.
- Skin findings and hypotension may be present.
  - A petechial rash appears as discrete lesions 1 to 2 mm in diameter; most frequently on the trunk and lower portions of the body and will be seen in >50% of patients on presentation.
  - Purpura fulminans is a severe complication of meningococcal disease and occurs in up to 25% of cases. It is characterized by acute onset of cutaneous hemorrhage and necrosis due to vascular thrombosis and disseminated intravascular coagulopathy.

### EPIDEMIOLOGY

#### Incidence

- The mortality rate is  $\div$  13%.
  - 11-19% of survivors suffer serious sequelae, including deafness, neurologic deficit, or limb loss due to peripheral ischemia.
- Disease is seasonal, peaking in December/January.
- Annually,  $\div$  1,000 cases of invasive meningococcal disease occur in the United States (1).
  - Most common in adolescents and young adults, followed by infants <1 year

## ETIOLOGY AND PATHOPHYSIOLOGY

- *N. meningitidis* is a gram-negative diplococcus with at least 13 serotypes.
- *N. meningitidis* has an outer coat that produces disease-causing endotoxin.
- Major serogroups in the United States are B, C, Y, and W-135
  - Serogroup B is the predominant cause of meningococemia in children <1 year.
  - Serogroup C is the most common cause of meningococcal disease in the United States.
  - Serogroup Y is the predominant cause of meningococemia in the elderly (2).
- Major serogroups worldwide are A, B, C, Y, and W-135
  - W-135 is the major cause of disease in the meningitis belt of sub-Saharan Africa.

## Genetics

Late complement component deficiency has an autosomal recessive inheritance.

## RISK FACTORS

- Age: 3 months to 1 year
- Late complement component deficiency (C5, C6, C7, C8, or C9)
- Asplenia (1)
- Living in close quarters (e.g., household contacts, nursery/daycare centers, dormitories, military barracks)
- Exposure to active and passive tobacco smoke (1)

## GENERAL PREVENTION

- Two vaccines are currently licensed for use in the United States. Each contains antigens to serogroups A, C, Y, and W-135. Neither provides immunity against serotype B, which is responsible for 1/3 of U.S. cases (3)
  - Meningococcal polysaccharide vaccine (MPSV4): recommended for patients ≥55 years who are at elevated risk (1)
    - Duration of protection is short: 1 to 3 years for patients <5 years; 3 to 5 years for adolescents and adults (3)
    - Often used for patients requiring short duration of protection—traveling to endemic areas, college freshmen, community outbreaks (3)

- Meningococcal conjugate vaccine (MCV4): recommended for patients 2 to 55 years (1)
- In October 2014, the Food and Drug Administration (FDA) licensed the first serogroup B meningococcal (MenB) vaccine (MenB-FHbp) as a 3-dose series. In January 2015, FDA licensed a second MenB vaccine (MenB-4C) as a 2-dose series. Both vaccines were approved for use in persons aged 10 to 25 years. Individuals aged <sup>3</sup>10 years who are at increased risk for meningococcal disease due to persistent complement component deficiencies, anatomic or functional asplenia should receive MenB vaccine (3).
- Protective levels of antibody are achieved ÷7 to 10 days after primary immunization (2).
- Vaccine is recommended for all persons 11 to 18 years and persons 19 to 55 years at increased risk for the disease.
  - Guillain-Barré syndrome has been associated with the MCV4 vaccine, so a personal history of Guillain-Barré is a relative contraindication for receiving this vaccine.
- CDC International Travel Advisory
  - Vaccine is required by the government of Saudi Arabia for Hajj pilgrims >2 years of age.
  - The vaccine should be given to travelers to sub-Saharan Africa (Meningitis belt).

## DIAGNOSIS

### HISTORY

- Symptoms
  - Sudden onset of fever, nausea, vomiting, headache, myalgias, chills, rigor, and/or sore throat (nonsuppurative)
    - Pharyngitis may be mistaken for streptococcal pharyngitis.
    - Myalgia may be mistaken for severe "flu," with a peak incidence coinciding in winter months.
  - Changes in mental status, decreased ability to concentrate, stiff neck, convulsions
  - Atypical presentations include acute arthritis or neuritis (4).
- Assess possible exposures.

### PHYSICAL EXAM

- Fever, hypotension, tachycardia
- Neurologic: nuchal rigidity, focal neurologic findings, coma, seizure

- Focal neurologic findings and seizures are more commonly seen with *Haemophilus influenzae* or *Streptococcus pneumoniae*.
- Cardiopulmonary: signs of heart failure with pulmonary edema, gallop, rales
- Dermatologic: maculopapular rash, petechiae, ecchymosis, purpura
- Median time of onset of specific meningitis symptoms (e.g., neck stiffness, photophobia, bulging fontanelle) is as fast as 12 to 15 hours after onset of illness (4).
- Late signs of meningitis (e.g., unconsciousness, delirium, or seizures) occur  $\pm$  15 hours in infants <1 year and  $\pm$  24 hours in older children (5).

## DIFFERENTIAL DIAGNOSIS

- Sepsis; bacterial meningitis (other organisms)
- Gonococemia
- Acute bacterial endocarditis
- Rocky mountain spotted fever
- Hemolytic uremic syndrome
- Gonococcal arthritis dermatitis syndrome
- Influenza

## DIAGNOSTIC TESTS & INTERPRETATION

### ALERT

- Isolation of *N. meningitidis* from a sterile site (blood or CSF) is the gold standard for diagnosing systemic meningococcal infection.
- Antibiotic administration may render blood and/or CSF culture negative within 2 hours. Treat, then test.

### Initial Tests (lab, imaging)

- CBC with differential
  - Leukocytosis (left shift; toxic granulation) or leukopenia, thrombocytopenia
- Lactic acidosis
- Coagulation studies
  - Prolonged prothrombin time/partial thromboplastin time

- Low fibrinogen
- Elevated fibrin degradation products
- Blood culture
  - Blood culture positive for *N. meningitidis*
  - Cultures positive in 50-60% of cases
- CSF
  - Grossly cloudy
  - Increased WBCs with polymorphonuclear predominance
  - Gram stain showing gram-negative diplococci
  - Glucose-to-blood glucose ratio  $<0.4$
  - Protein  $>45$  mg/dL
  - Positive for *N. meningitidis* antigen (MAT or PCR)
  - CSF culture for *N. meningitidis*: positive in 80-90% of cases
- CT scan of head if concern for space-occupying lesions

## *Test Interpretation*

- Disseminated intravascular coagulation (DIC)
- Exudates on meninges
- Polymorphonuclear infiltration of meninges
- Hemorrhage of adrenal glands

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Antibiotics
    - Begin treatment as soon as meningococcal meningitis is suspected.
- 
- Age influences empiric treatment based on common etiologic organisms.

- Preterm to <1 month: ampicillin plus cefotaxime or ampicillin plus gentamicin
  - Cefotaxime
    - 0 to 7 days: 50 mg/kg q12h
    - 8 to 28 days: 50 mg/kg q8h
  - Ampicillin
    - >2,000 g
      - 0 to 7 days: 50 mg/kg q8h
      - 8 to 28 days: 50 mg/kg q6h
    - <2,000 g
      - 0 to 7 days: 50 mg/kg q12h
      - 8 to 28 days: 50 mg/kg q8h
- 1 month to 50 years: cefotaxime or ceftriaxone plus vancomycin
  - If severe penicillin allergy: chloramphenicol plus trimethoprim-sulfamethoxazole (TMP-SMX) plus vancomycin
- >50 years of age or patients with alcoholism, debilitating disease, or impaired immunity: ampicillin plus ceftriaxone plus vancomycin
  - Ampicillin: 2 g IV q4h
  - Ceftriaxone: 2 g IV q12h
  - Vancomycin: 30 to 45 mg/kg/day IV divided q6h
  - If severe penicillin allergy: TMP-SMX plus vancomycin
- Penicillin G
  - Effective if the isolate is penicillin sensitive
  - Penicillin can be used if the isolate has a penicillin minimum inhibitory concentration (MIC) of <0.1  $\mu\text{g}/\text{mL}$ .
  - For isolates with a penicillin MIC of 0.1 to 1  $\mu\text{g}/\text{mL}$ , treatment with high-dose penicillin is effective, but a 3rd-generation cephalosporin is preferred (5).
  - Penicillin G: 4 million units IV q4h (pediatric dose: 0.25 mU/kg/day IV divided q4-6h) OR ampicillin: 2 g IV q4h (pediatric dose: 200 to 300 mg/kg/day IV divided q6h)

- Duration of treatment: 7 days (6)
- Dexamethasone
  - Indications
    - Known or suspected pneumococcal meningitis in selected adults
    - Children with *H. influenzae* type B meningitis
- Dexamethasone is often given initially in adults and children with suspected bacterial meningitis while awaiting microbiologic data.
- Dexamethasone has not been shown to be of benefit in meningococcal meningitis and should be discontinued once this diagnosis is established.
- Dosage
  - Infants and children >6 weeks: IV 0.15 mg/kg/dose q6h for the first 2 to 4 days of antibiotic treatment
  - Start 10 to 20 minutes before or with the first dose of antibiotic.
- Chemoprophylaxis
  - Indications
    - Close contacts: Those who have had prolonged (>8 hours) contact while in close proximity (<3 feet) to the patient or who have been directly exposed to the patient's oral secretions between 1 week before the onset of the patient's symptoms and until 24 hours after initiation of appropriate antibiotic therapy (2).
      - Examples: household members and personnel in nurseries, daycare centers, nursing homes, dormitories, military barracks, correctional facilities, and other closed institutional settings
    - No chemoprophylaxis is indicated for casual contacts, including most health care workers, unless there is exposure to respiratory secretion.
  - Timing
    - Ideally <24 hours after case identification
    - Chemoprophylaxis should not be administered if identified >14 days after exposure.
  - Prophylactic regimens
    - Rifampin, ciprofloxacin, and ceftriaxone

## Ceftriaxone

- Recommended for pregnant women
  - Adults: 250 mg IM as a single dose
  - Rifampin (meningococcal meningitis prophylaxis)
    - Adult: 600 mg IV or PO q12h for 2 days
    - Pediatric
      - <1 month: 10 mg/kg/day in divided doses q12h for 2 days
      - Infants and children: 20 mg/kg/day in divided doses q12h for 2 days (max 600 mg/dose)
  - Ciprofloxacin
    - Adults: 500 mg PO as a single dose (7)[B]
- Vaccination
    - For household contacts (if the case is from a vaccine-preventable serogroup)
  - Precautions
    - Adjust the dosage of medications in patients with severe renal dysfunction.

## *Second Line*

- For meningitis
  - Chloramphenicol: 1 g IV q6h (pediatric dose: 75 to 100 mg/kg/day divided q6h) or ceftriaxone 2 g IV q12h (pediatric dose: 80 to 100 mg/kg/day divided q12-24h)
  - In large outbreaks, a single dose of long-acting chloramphenicol has been used. Single-dose ceftriaxone shows equal efficacy in one randomized controlled trial.
- Precautions
  - Ceftriaxone should not be used in patients with a history of anaphylactic reactions to penicillin (e.g., hypotension, laryngeal edema, wheezing, hives).
  - Chloramphenicol may cause aplastic anemia.

## *ISSUES FOR REFERRAL*

Potential complications

- Seizure activity
- DIC
- Acute respiratory distress syndrome
- Renal failure
- Adrenal failure
- Multisystem organ failure

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- If meningitis is suspected, initiate antibiotics ( $\pm$  corticosteroids), and proceed immediately to lumbar puncture.
- Droplet isolation for 24 hours from the beginning of antibiotic therapy

### *IV Fluids*

Replace volume as needed; with septic shock, large volumes of crystalloid may be required.

## **ONGOING CARE**

### *PATIENT EDUCATION*

Educate family and close contacts regarding the risk of contracting meningococcal infections.

### *PROGNOSIS*

Overall mortality is 13%.

### **COMPLICATIONS**

- DIC
- Acute tubular necrosis
- Neurologic: sensorineural hearing loss, cranial nerve palsy, seizures
- Obstructive hydrocephalus
- Subdural effusions
- Acute adrenal hemorrhage
- Waterhouse-Friderichsen syndrome

Codes

**&NA;**

## **ICD10**

- A39.4 Meningococemia, unspecified
- A39.0 Meningococcal meningitis
- A39.2 Acute meningococemia

## **Clinical Pearls**

**&NA;**

- Invasive meningococcal disease can be rapidly fatal. Therefore, rapid identification of cases with early treatment is essential for good clinical outcomes. Treat then test in suspected cases
- Provide chemoprophylaxis to close contacts.
- Vaccinate at-risk populations as a preventive measure.

# Meniscal Injury

Jennifer B. Schwartz, MD

## BASICS

### DESCRIPTION

- The menisci are fibrocartilaginous intra-articular structures located between the medial and lateral femoral condyles and tibial plateau.
- Each meniscus has a body, anterior horn, and posterior horn
- The menisci help stabilize the knee, distribute forces across the joint, and aid joint lubrication.
- After age 10 years, the menisci begin to devascularize
  - In adults, the outer 1/3 remains vascularized.
  - The inner 2/3 is avascular and heals poorly.

### Geriatric Considerations

Meniscal tears in older patients are typically due to chronic degeneration.

### Pediatric Considerations

- Meniscal injuries are rare in children <10 years old (prior to physial fusion).
- Meniscal tears in young children are often due to a *discoïd meniscus* (anatomic variant with thicker and wider meniscus—usually the lateral meniscus).
- MRI is less sensitive and specific for diagnosing meniscal tears in children <12 years of age.

### EPIDEMIOLOGY

- More common in the 3rd to 5th decades of life
- More common in males

### Incidence

- Medial meniscus more commonly injured
- Injuries can be *acute* or *degenerative*.

- Acute tears more likely <40 years old and due to trauma
- Degenerative tears more likely >40 years old

## *Prevalence*

One of the most common musculoskeletal injuries

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Acute tears typically occur due to a twisting motion of the knee with foot planted.
- Degenerative tears occur with minimal trauma.

## *Genetics*

A congenital abnormality leading to discoid meniscus increases the risk of meniscal tear among children. No specific gene locus has been identified.

## *RISK FACTORS*

- Increased age (>60 years), male
- Obesity
- High degree of physical activity (especially cutting sports like soccer, football, basketball, and rugby)
- Anterior cruciate ligament (ACL), posterior cruciate ligament (PCL) insufficiency:
  - Waiting >12 months between ACL injury and surgery increases risk of medial meniscal tear (1)[C].

## *GENERAL PREVENTION*

- Treatment and rehabilitation of previous knee injuries, particularly ACL injuries
- Strengthening and increased flexibility of quadriceps and hamstring muscles

## *COMMONLY ASSOCIATED CONDITIONS*

- ACL is concomitantly torn in 1/3 of cases.
- Medial and lateral collateral ligament tears
- Tibial plateau or femoral shaft fractures
- Baker cyst—strong association with medial meniscal tears (2)[C]

# DIAGNOSIS

## HISTORY

- Noncontact twisting or hyperflexion mechanism
- Delayed swelling, typically >24 hours postinjury
- Knee pain (on affected side):
  - Increased with knee flexion (i.e., stairs, squatting)
  - Increased with weight bearing
- Locking, catching, popping
- Sensation of buckling or giving out

## PHYSICAL EXAM

- Pertinent findings on physical exam are the following:
  - Effusion (mild-moderate)
  - Joint line tenderness
  - Decreased range of motion, locking
  - Pain with full flexion (posterior horn tear) or extension (anterior horn tear)
- Accuracy of special tests varies (3)[C]
  - Positive McMurray test: pain, clicking of meniscus being stressed
  - Positive Apley grind test is neither sensitive nor specific.
  - Positive Thessaly test: Patient rotates knee and body three times with knee flexed 20 degrees; has pain along joint line.

## DIFFERENTIAL DIAGNOSIS

- ACL or collateral ligament tear
- Pathologic plica
- Osteochondritis dissecans
- Loose body or fracture
- Osteoarthritis (OA)~symptoms of OA may be caused by meniscal tears (4)[C]
- Patellofemoral syndrome

- Gout, pseudogout, rheumatoid arthritis

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Laboratory evaluation not indicated unless signs of septic arthritis.
- Plain radiographs can detect fractures, loose bodies, or arthritic changes.
- Ultrasound may help screen for meniscal tears. Less helpful for lateral tears (5)[C]

## **Follow-Up Tests & Special Considerations**

- MRI is the primary study to diagnose meniscal tears.
  - Increased signal within a meniscus corresponds to degenerative changes; signal contacting the articular surface indicates an acute tear.
- Meniscal tears are often found incidentally on MRI and may not be the cause of patient's symptoms.
  - 36-76% of meniscal tears found on MRI were asymptomatic. Asymptomatic tears increase with age and in the setting of OA.
  - Patients with synovitis and displacement of meniscus on MRI may benefit from intervention (6)[C].

## *Diagnostic Procedures/Other*

Arthroscopy may be needed if the MRI is indeterminate.

## **TREATMENT**

### *GENERAL MEASURES*

- Treatment depends on the type/location/extent of the tear, as well as age and activity level of the patient
- Conservative treatment (RICE [rest, ice, compression, elevation], activity modification, physical therapy, intra-articular corticosteroid injections) are effective first-line options for many patients, especially those with degenerative tears.
  - No increased benefit from surgery versus physical therapy for symptomatic meniscal tears in patients with mild to moderate OA (7)[C].
  - Small, partial thickness, or peripheral tears may heal on their own or remain asymptomatic.

- Consider surgical intervention if:
  - Mechanical symptoms, locking
  - Concurrent injuries (i.e., ACL tear)
  - Persistent symptoms following 3 to 6 months of conservative treatment
  - Young patients (<30 years) or very active patients with an acute tear

## *MEDICATION*

### *First Line*

NSAIDs, opioid analgesics if severe pain

## *ISSUES FOR REFERRAL*

Surgical consult for patients meeting operative criteria or wishing surgical repair

## *ADDITIONAL THERAPIES*

- Rehabilitation is required for both surgical and nonsurgical patients.
- Electrical stimulation may help improve recovery when coupled with physical therapy.
- Weight control: Weight gain is associated with increased cartilage loss and pain in adults with medial meniscal tears.
- Platelet-rich plasma (PRP) may or may not improve symptoms of meniscal tears (8)[C].

---

P.659

## *SURGERY/OTHER PROCEDURES*

- Most surgeries can be performed arthroscopically.
- Meniscectomy (partial or total) removes the injured portion of the meniscus.
  - Can lead to articular cartilage degeneration and OA. Higher risk if 40 years of age, high BMI, valgus malalignment (9)[C]
- Meniscal repairs decrease future OA and often have better outcomes than meniscectomy (10) [C].

**ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

- Return to play requires that the patient be pain-free, have full range of motion, and full strength.
- Following meniscal repair, patients can generally return to all activities in 3 to 6 months.
- Combined ACL and meniscal repair requires 6 months of postoperative rehabilitation before the patient can return to sports.

## **PATIENT EDUCATION**

Patients should be aware of the risks and benefits of surgery compared with conservative treatment.

## **PROGNOSIS**

Prognosis better if surgery is done within 8 weeks, patient is <30 years of age, or tear is peripheral/lateral <2.5 cm.

## **COMPLICATIONS**

- Meniscectomies may eventually lead to OA. Consequently, meniscal repair is preferred to meniscectomy whenever possible.
- Risk of developing OA increases 6-fold 20 years after a meniscectomy.

## See Also

&NA;

Algorithm: Knee Pain

## Codes

&NA;

### ICD10

- S83.209A Unsp tear of unsp meniscus, current injury, unsp knee, init
- S83.249A Oth tear of medial meniscus, current injury, unsp knee, init
- S83.289A Oth tear of lat mensc, current injury, unsp knee, init

## Clinical Pearls

&NA;

- Degenerative meniscal tears are common in patients >40 years of age and generally do not require surgical repair.
- MRI is imaging modality of choice to identify meniscal tears.
- Functional outcomes following meniscal injury are improved with a comprehensive plan of rehabilitation involving strengthening and stretching of knee musculature.
- In patients opting for surgery, meniscal preservation should be the goal. Meniscal repairs have a better functional outcome and decreased risk of OA compared with meniscectomy.
- Improving core strength, proprioception, and quadricep/hamstring flexibility may prevent knee injuries, especially in female athletes.

# Menopause

Anjie Li, MD

Julia V. Johnson, MD

## BASICS

### DESCRIPTION

- Natural menopause: defined retrospectively after 12 consecutive months of amenorrhea in a nonpregnant woman <sup>3</sup>40 years of age:
  - Results from loss of ovarian activity
  - Not associated with a pathologic etiology
- Perimenopause/menopausal transition (MT): defined as the period from the onset of irregular menses to the final menstrual cycle. Begins on average 4 years before menopause. Starts at mean age of 47 years.
- Postmenopause: usually >1/3 of a woman's life
- Primary ovarian insufficiency: irregular or cessation of menses before age 40

### EPIDEMIOLOGY

- The median age of menopause is 51 years.
- 5% of women undergo menopause after age 55 years; another 5% between ages 40 and 45 years (1)[B].
- Occurs earlier in Hispanic women and later in Japanese-American women as compared with Caucasians (2)[B]

### Incidence

In the United States, 1.3 million women reach menopause annually.

### ETIOLOGY AND PATHOPHYSIOLOGY

Normal physiologic process:

- As women age, the number of ovarian follicles decreases: Ovarian production of estrogen varies and then decreases. Follicle-stimulating hormone (FSH) production varies and then

increases.

- Inadequate estradiol production leads to absence of the luteinizing hormone (LH) surge and failure to ovulate. These cycles result in anovulation and lack of progesterone production.
- Eventual failure to produce estradiol leads to thinning of endometrial lining and eventual menses cessation.
- Surgical menopause: Removal of functioning ovaries leads to immediate menopause.

## ***RISK FACTORS***

- Aging
- Oophorectomy
- Hysterectomy
- Sex chromosome abnormalities (e.g., Turner syndrome and fragile X syndrome)
- Family history of early menopause
- Smoking (earlier age of onset by 2 years)
- Chemotherapy and/or pelvic radiation (permanent or reversible)

## ***GENERAL PREVENTION***

Menopause is physiologic event. Increased risk of long term medical issues include cardiovascular disease (CVD) and osteoporotic fractures:

- Decrease risk of CVD by:
  - Increased exercise
  - Avoid smoking.
  - Maintain healthy diet and lose weight.
  - Treat hyperlipidemia, diabetes, and hypertension.
  - Take daily low-dose aspirin.
- Decrease risk of osteoporotic fractures by:
  - Weight-bearing exercise
  - Avoid smoking.
  - Avoid excessive alcohol intake.
  - Dietary calcium of 1,200 mg/day

- Adequate vitamin D (800 to 1,200 IU daily)
- Fall prevention

## DIAGNOSIS

### HISTORY

- Cessation of menses:
  - Generally preceded by a period of irregular cycles with heavy vaginal bleeding followed by diminished vaginal bleeding
- Vasomotor symptoms: sudden feeling of warmth, most commonly over face, neck, and chest, with average duration of ~3 minutes, intervals unpredictable
  - Most commonly reported symptom; reported by over 80% of women (3) [B].
  - Frequency and duration varies. 87% of women who report flushes experience them daily, ~33% have >10 per day. Mean duration of symptoms lasts 4 to 10.2 years and may begin during MT and extend well past menopause (4)[A].
  - Varies with ethnicity; greatest in African and Hispanic women and least in Asian women
  - More common in obese women
- Urogenital atrophy in up to 50% (5)[B]:
  - Vaginal/vulvar dryness discharge, itch, dyspareunia, and possible sexual dysfunction
  - Alkaline vaginal pH and atrophy increases risk of vaginal infections and UTIs
  - Persists or worsens with aging
  - Urologic symptoms (urgency, frequency, dysuria, incontinence) not clearly correlated with MT
- Anxiety, depression: Some studies show a new diagnosis of depression is 2.5 times more likely to occur during the MT as compared to premenopause.
- Sleep disturbance: Arousal from sleep and chronic insomnia may be linked with vasomotor symptoms.
- Joint pain with unclear link to loss of estrogen
- Change in intensity and severity of migraines
- Skin thinning, mild hirsutism, brittle nails

## ***Geriatric Considerations***

Vaginal bleeding in postmenopausal women is abnormal; endometrial cancer/endometrioid adenocarcinoma (EAC) must be ruled out.

## ***PHYSICAL EXAM***

- Decrease in breast size and change in breast texture
- External, speculum, and bimanual pelvic exams: atrophic vulva and vaginal mucosa; increased risk for uterine prolapse

## ***DIFFERENTIAL DIAGNOSIS***

Pregnancy, hyperthyroidism and other thyroid disease, pituitary adenoma, Sheehan syndrome, hypothalamic dysfunction, anorexia nervosa, Asherman syndrome, obstruction of uterine outflow tract

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- U.S. Preventive Service Task Force (USPSTF) recommends mammogram every 2 years from ages 50 to 74.
- Lab testing for menopause is not required; the patient's age and symptoms establish the diagnosis.
- If laboratory confirmation is desired:
  - Elevated serum FSH level  $>30$  mIU/mL indicates ovarian failure.
  - Symptoms may precede lab changes.
  - Infertility evaluation: may use elevated day 3 FSH, decreased anti-Müllerian hormone levels, and decreased antral follicle count to predict decreased ovarian reserve
- Estrogens, androgens, and oral contraceptive pills (OCPs) may alter lab results.

### ***Follow-Up Tests & Special Considerations***

- Pregnancy test
- TSH and prolactin level if pituitary disease is suspected
- Vaginal bleeding in a postmenopausal patient should be evaluated by transvaginal ultrasound (TVUS) and/or endometrial biopsy (EMB). If endometrial stripe is  $<5$  mm on TVUS, EAC is unlikely.

- USPSTF recommends bone mineral density (BMD) screening with dual energy x-ray absorptiometry (DEXA) scan in postmenopausal women >65 years, or <65 years if the risk for fracture is equivalent to that of a 65-year-old woman (using the FRAX tool to assess, <http://www.shef.ac.uk/FRAX/>). Risk factors include a previous history of fractures, low body weight, cigarette smoking, and family history of osteoporotic fracture.

## *Test Interpretation*

- Abnormal BMD and DEXA scan results:
  - T-score on DEXA of -1 to -2.5 = osteopenia
  - T-score < -2.5 = osteoporosis
  - Defer to femoral neck T-score over spine T-score
- Z-score measures age-matched mean bone density (not clinically useful).

## **TREATMENT**

### *MEDICATION*

#### *First Line*

Hormone therapy (HT): developing an individual risk-benefit profile is essential. Treatment goal is to minimize menopausal symptoms to improve quality of life.

- The primary indication for HT is the treatment of moderate to severe vasomotor symptoms.
  - Oral estrogen or estrogen-progestin mix can reduce weekly hot flush frequency ÷75% (4) [A].
- HT also helpful with sleep disorders, urogenital atrophy, and lowers risk of osteoporotic fractures and colorectal cancer. May help with mood symptoms
- In women with an intact uterus, give estrogen with progestin as unopposed estrogen carries an increased risk of EAC.
- Treatment regimens include, but are not limited to:
  - Standard dose: conjugated equine estrogen (CEE) 0.625 mg/day OR micronized estradiol 1 mg/day; 1.0 mg/day OR transdermal estradiol 0.0375 to 0.05 mg/day
  - Low dose: CEE 0.3 to 0.45 mg/day OR micronized estradiol 0.5 mg/day OR transdermal estradiol 0.025 mg/day

- Ultra-low dose: micronized estradiol 17β; 0.025 mg/day OR transdermal estradiol 17β; 0.014 mg/day
- Micronized progesterone 100 mg/day can be used as progestin. Alternative: medroxyprogesterone acetate (MPA) 2.5 mg/day. Combination estradiol/progestin transdermal treatments have either levonorgestrel or norethindrone as progestin source. Although NOT approved for postmenopausal women, the levonorgestrel intrauterine system (IUS) has been used.
- Bazedoxifene + conjugated estrogens for relief of vasomotor symptoms and bone loss prevention
- American Congress of Obstetricians and Gynecologists (ACOG) recommends HT should be individualized with lowest effect dose given for the shortest duration of time needed to relieve vasomotor symptoms. Lower doses have similar symptom reduction profiles for many patients (6)[A]. Results of ultra-low dose regimens are mixed (7)[A].

P.661

- Although generally well tolerated, side effects of HT include breast tenderness, vaginal bleeding, bloating, and headaches.
- Precautions:
  - Women's Health Initiative (WHI) study demonstrate of every 10,000 women who take CEE with MPA, each year, there were 7 more CHD events, 8 more strokes, 8 more PEs, and 8 more invasive breast cancers independent of mammography screening frequency. Absolute risk reductions revealed 6 fewer colorectal cancers and 5 fewer hip fractures (8)[A].
  - Breast cancer risk not seen until 5 years of use
  - Cardiovascular risks not seen until after age 60 or 10 years from menopause.
  - Women on estrogen alone had no increased risk of breast cancer in the 8 years of the study and showed later cardiovascular risk compared to estrogen + progestin.
  - HT should NOT be used for cardioprotective benefit as risk outweighs benefit (9)[A].
  - Higher doses of estrogen can cause hypercoagulability, breast tenderness, gallbladder disease, and hypertension (HTN).
  - Contraindications to HT:
    - Estrogen-dependent malignancies
    - Unexplained uterine bleeding
    - History of thromboembolism or stroke
    - CAD

- Active liver disease
- For osteoporosis: women with a history of hip or vertebral fracture, or personal history of osteoporosis should be treated with one of the following:
  - Bisphosphonates to inhibit osteoclast action and resorption of bone:
    - Alendronate: 70 mg/week or 10 mg/day
    - Risedronate: 35 mg once a week or 5 mg/day
    - Zoledronic acid: 5 mg IV annually
    - Ibandronate: 150 mg/month PO or 3 mg IV q3mo
  - Selective estrogen receptor modulators (SERMs) selectively inhibit or stimulate estrogen-like action with stimulation of osteoblasts:
    - Raloxifene: 60 mg/day
      - Decreases the risk of vertebral fracture, but failed to demonstrate a decrease in the risk of extravertebral fractures
    - Bazedoxifene + conjugated estrogens (0.45 mg/20 mg)
      - FDA approved for moderate to severe vasomotor symptoms and osteoporosis.
  - Denosumab (60 mg SC every 6 months) is a monoclonal antibody prevents RANKL (receptor activator of nuclear factor kappa-B ligand) from accelerating osteoclast generation. Reduces incidence of vertebral and hip fractures in postmenopausal women.
  - Parathyroid hormone—rarely used due to the adverse effect on bone, but shown to reduce fracture risk in menopausal women with osteoporosis.
- For vulvar/vaginal atrophy:
  - Topical estrogen therapy (ET) reverses vaginal atrophy, enhances blood flow, and reduces UTI. Continue for as long as distressing symptoms remain. Initiate treatment daily for 1 to 2 weeks, then decreased to 2 times weekly. Comes as estradiol cream, tablet, or ring. Apply vaginally:
    - Estradiol cream 0.01% (1 g), conjugated estrogen 0.625 mg/g (0.5 g), vaginal tablet (10&mgr;g) used twice weekly, or vaginal ring (7.5&mgr;g daily lasting for 3 months)
    - Ospemifene: 60 mg PO daily. SERM for moderate to severe dyspareunia associated with vaginal atrophy.
- Although there is no increased risk of endometrial hyperplasia or EAC, women with bleeding on

these treatments should be evaluated with TVUS or EMB. Patients with h/o hormone-dependent cancer should meet with a gynecologist before using medication.

## *Second Line*

Nonhormonal treatments may be helpful to treat vasomotor symptoms in women who wish to or need to avoid HT (e.g., breast cancer):

- Paroxetine (7.5 mg/day) is approved for treatment of vasomotor symptoms. This SSRI demonstrated modest decrease in hot flashes.
- Other SSRI/SSNIs: venlafaxine (37.5 to 75 mg/day), or fluoxetine (20 mg/day), and citalopram (20 mg/day) shown to reduce hot flashes as compared to placebo
- Gabapentin (300 to 900 mg/day) shown to have an effect on lowering hot flashes compared to placebo.
- Clonidine (.05 mg BID) may be used to treat mild hot flashes, less effective than SSRI/SRNIs.
- Note that most trials of second-line therapies have been brief (i.e., a few months).

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Trials of nonprescribed therapies are difficult to interpret due to variability of components and doses:

- Soy isoflavone in placebo-controlled trials showed a mixed effect in reducing hot flashes.
- Red clover, black cohosh, reflexology, aerobics, and magnet therapy showed no impact on hot flashes when compared with placebo.
- Small clinical trials of evening primrose, dong quai, ginseng, and wild yam do not support use for relief of hot flashes.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

A DEXA scan is indicated at age 65 for all women, and for younger women with risk equivalent to age 65.

#### *DIET*

Calcium-rich diet and vitamin D supplementation (800-1,200 IU/day). Calcium supplements may

have adverse effects including increased risk of kidney stone and increased risk of cardiac events.

## **PATIENT EDUCATION**

Encourage lifestyle modifications:

- Smoking cessation
- Weight-bearing exercise >30 minutes, 3 times weekly
- Healthy diet to maintain appropriate weight
- Avoid excess alcohol.
- Address cardiovascular risk factor modification.

## **PROGNOSIS**

If untreated:

- Ultimate disappearance of vasomotor symptoms
- Worsening of vaginal/vulvar atrophy
- Osteoporosis: possible fractures of the hip, vertebrae, and wrists

## **COMPLICATIONS**

- Osteoporosis: At menopause, women have accelerated bone loss up to 3-5% per year for 5 to 7 years.
- Increased risk of CVD following menopause

**&NA;**

## **ICD10**

- N95.1 Menopausal and female climacteric states
- Z78.0 Asymptomatic menopausal state
- E28.310 Symptomatic premature menopause

## **Clinical Pearls**

**&NA;**

- Menopause is usually diagnosed by history alone.
- HT can be used short term for relief of moderate to severe vasomotor symptoms, but should not be used for long-term prevention of cardiovascular disease.

# Menorrhagia (Heavy Menstrual Bleeding)

Brian D. Bates, MD

Joanne Wilkinson, MD, MSc

## BASICS

### DESCRIPTION

- The current preferred terminology for menorrhagia is 'heavy menstrual bleeding' (HMB), a subcategory of 'abnormal uterine bleeding' (AUB) (1).
- HMB is an excessive amount ( $\geq 80$  mL/cycle, compared with normal average of 30 to 60 mL/cycle) or duration of menstrual flow at predictable intervals.
- HMB applies only to ovulatory menses.
- Other patterns of AUB which may overlap with HMB include:
  - Intermenstrual bleeding: bleeding between regular menses
  - Irregular bleeding: typically due to ovulatory dysfunction (encompassing the previously used terms metrorrhagia and oligomenorrhea)
  - Polymenorrhea: menstrual cycle length  $< 21$  days
- System affected: reproductive

### EPIDEMIOLOGY

#### Prevalence

- AUB, including HMB, is thought to affect between 9% and 14% of women between menarche and menopause (2).
- AUB is more common close to menarche and menopause.

#### Pediatric Considerations

- Genital bleeding before puberty is not menstrual bleeding by definition and requires further evaluation.
- HMB presenting in adolescence is more likely related to a bleeding disorder, and patients should be evaluated for a bleeding disorder (3).

- Postmenarchal patients may have heavy and irregular menstrual bleeding related to an immature hypothalamic-pituitary axis.

## *Pregnancy Considerations*

Bleeding in pregnancy is not menstrual bleeding by definition and requires further evaluation. Pregnancy test should be obtained as part of the evaluation of abnormal uterine bleeding.

## *Geriatric Considerations*

Menopause is diagnosed after 12 months of amenorrhea in the absence of other causes and is typically preceded by irregular bleeding. All postmenopausal bleeding requires additional workup for malignancy.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- No cause is identified in about 1/2 of patients.
- Bleeding disorders
  - Von Willebrand disease (present in about 13% of patients) (2)
  - ITP and other platelet disorders
  - Factor deficiencies
  - Medication side effect most commonly related to anticoagulants including warfarin
  - Renal failure leading to uremic platelet dysfunction
  - Cirrhosis leading to coagulopathy
- Uterine fibroids, typically submucosal
- Endometrial polyps
- Hypothyroidism
- Iatrogenic causes including copper IUD
- Endometriosis
- Adenomyosis
- Pelvic inflammatory disease
- Some causes more typically presenting as irregular menstrual bleeding include:
  - Polycystic ovarian syndrome (PCOS)
  - Hypothalamic-pituitary dysfunction, often postmenarchal or during menopausal transition

- Endometrial or ovarian neoplasia
  - Some forms of hormonal birth control
  - Hyperthyroidism
  - Hyperprolactinemia
- HMB has been associated with increased production and sensitivity to prostaglandins.

## GENERAL PREVENTION

- Combined oral contraceptives may prevent HMB, particularly when progesterone is dominant. Lower estrogen doses result in less menstrual bleeding
- NSAIDs including ibuprofen inhibit prostaglandin production and result in decreased blood loss and pain during menses.
- Progesterone-only contraceptives may reduce overall blood loss but often result in irregular bleeding.

## COMMONLY ASSOCIATED CONDITIONS

Iron deficiency anemia

## DIAGNOSIS

### HISTORY

- Although HMB is defined as menstrual bleeding  $>80$  mL/cycle, patient assessment of menstrual volume is highly inaccurate and the diagnosis is often based on a patient's subjective concerns (4).
- Suggestive historical features for HMB:
  - Bleeding substantially heavier than patient's usual flow
  - Changing pads or tampons every 1 to 2 hours as quantified by patient
  - Menses lasting  $>7$  days
  - Significant clots
- Symptoms that suggest bleeding is ovulatory:
  - Regular menstrual interval
  - Midcycle pain (mittelschmerz)
  - Premenstrual symptoms: breast soreness, mood changes
- Abdominal pain or cramps at other times of the cycle may be associated with

structural causes:

- Polyps
  - Adenomyosis
  - Leiomyoma
  - Ovarian tumors
- Symptoms that suggest an underlying bleeding disorder include:
    - Epistaxis
    - Mucosal bleeding (e.g., gums)
    - Easy bruising
    - Family history of bleeding disorder
  - Review of medications, with particular attention to contraceptive and anticoagulant medication
  - Other medical conditions that may relate to HMB:
    - Renal or hepatic disease
    - Thyroid disease
  - Evaluate for symptoms of anemia including fatigue and dyspnea

## *PHYSICAL EXAM*

- Prompt assessment for signs of hemodynamic instability (5)
- Thyroid nodule or goiter suggests thyroid disease.
- Signs of a bleeding disorder include petechiae and ecchymoses.
- Pelvic examination, including speculum and bimanual examination, may reveal the following:
  - Cervical or vaginal source of bleeding
  - Pelvic or adnexal mass
  - Evidence of reproductive tract infection such as cervical motion tenderness
  - Uterine enlargement
- Hirsutism, acne, and obesity are suggestive of PCOS.

## *DIFFERENTIAL DIAGNOSIS*

- Normal menses
- Anovulatory bleeding

- Intermenstrual bleeding
- Complications of pregnancy
  - Spontaneous abortion
- Other sources of bleeding:
  - Cervical
  - Vaginal
  - Gastrointestinal

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Pregnancy test
- CBC to assess for:
  - Anemia
  - Thrombocytopenia
  - Leukocytosis may suggest infection
- Thyroid-stimulating hormone (TSH) test

---

P.663

- Labs to consider in select cases:
  - Coagulation panel for evaluation for bleeding disorder in adolescent or adult with history suggestive of bleeding disorder
  - Workup of anovulatory bleeding may also include prolactin, androgens, FSH, LH, and estrogen.
  - Appropriate cervical cancer screening
  - Evaluation for infection including gonorrhea and chlamydia
- Imaging should be obtained based on clinician judgment and should begin with transvaginal ultrasonography.
- Transabdominal ultrasonography should be performed if transvaginal approach does not provide full assessment of anatomy.

### *Follow-Up Tests & Special Considerations*

- Saline infusion sonohysterography recommended if ultrasound suggests intracavitary pathology and is more sensitive and specific than transvaginal ultrasound (2)[C]
- Hysteroscopy can be performed if direct visualization is desired.

## *Diagnostic Procedures/Other*

Endometrial biopsy to assess for malignancy and hyperplasia is recommended in some situations including (5):

- Any AUB, including HMB, after age 45 years in an ovulatory (premenopausal) woman
- Woman <45 years with persistent or refractory AUB, risk factors such as unopposed estrogen exposure, or concerning endometrial imaging

## **TREATMENT**

### *GENERAL MEASURES*

Treat underlying conditions (e.g., hypothyroidism) when possible.

### *MEDICATION*

#### *First Line*

- For acute control of severe bleeding (6):
  - Obtain IV access and consider blood transfusion or clotting factor administration.
  - Estrogen, conjugated equine: 25 mg IV every 4 to 6 hours for 24 hours
  - Monophasic combined oral contraceptive that contains 35  $\mu$ g ethinyl estradiol: 3 times per day for 7 days
  - Medroxyprogesterone acetate: 20 mg orally 3 times per day for 7 days
  - Tranexamic acid: 1.3 g orally or 10 mg/kg IV 3 times per day for 5 days, antifibrinolytic agent
- For less severe bleeding (typical case) or after control of acute bleeding has been achieved (2):
  - Levonorgestrel intrauterine device (Mirena IUD): typically results in light bleeding or amenorrhea with patient satisfaction similar to hysterectomy and endometrial ablation (7) [A]
  - Combination estrogen-progestin oral contraceptive: may be prescribed in cyclic, extended,

or continuous dosing and typically results in regular, lighter, and less painful menses

- Depot medroxyprogesterone acetate: 150 mg/1mL IM every 3 months, typically results in amenorrhea or light irregular bleeding
- Tranexamic acid: 1.3 g orally for 5 days during menses; antifibrinolytic agent that is an option for women who desire nonhormonal treatment NSAIDs (e.g., naproxen, mefenamic acid, ibuprofen) can reduce blood loss and dysmenorrhea (2)[B].

## *Second Line*

- Noncontraception estrogen-progestin oral contraceptives (ultra-low-dose estrogen): may be considered when a relative contraindication to estrogen is present
- Oral progestins: multiple formulations and dosing, typically used in women who have contraindications to estrogen or are trying to conceive

## ***SURGERY/OTHER PROCEDURES***

- Dilation and curettage can be considered in the setting of acute severe bleeding.
- For women who desire fertility, myomectomy may be considered for treatment of uterine leiomyomas (fibroids).
  - For women who do not desire fertility, consider endometrial ablation, uterine artery embolization, or hysterectomy.
  - Endometrial ablation shows similar outcomes to levonorgestrel IUD, patients still require contraception.
  - Uterine artery embolization is used to treat uterine leiomyomas.
  - Hysterectomy is curative but with significant complications and long recovery, typically reserved for failure of medical management or presence of another indication such as malignancy.

## **ONGOING CARE**

### ***DIET***

Iron supplementation may help correct for increased blood loss.

### ***PATIENT EDUCATION***

Patient and provider should engage in informed decision making with understanding of treatment risks and benefits.

## PROGNOSIS

Most patients respond well to medical management, and hysterectomy is a curative option in appropriate cases.

## COMPLICATIONS

- Iron deficiency anemia
- Acute severe blood loss

Codes

**&NA;**

## **ICD10**

- N92.0 Excessive and frequent menstruation with regular cycle
- N92.3 Ovulation bleeding
- N92.2 Excessive menstruation at puberty

## **Clinical Pearls**

**&NA;**

- Women with heavy menstrual bleeding are at high risk for iron deficiency anemia.
- A thorough menstrual history is critical to differentiate heavy menstrual bleeding from similar conditions including anovulatory bleeding.
- Teenagers presenting with heavy menstrual bleeding should be evaluated for an underlying bleeding disorder.
- All postmenopausal bleeding and bleeding during pregnancy requires additional workup.
- The Levonorgestrel (Mirena) intrauterine device may be used for heavy menstrual bleeding and is associated with high patient satisfaction rates.

# Mesenteric Adenitis

Anne Walsh, MMSc, PA-C, DFAAPA

Kashyap Trivedi, MD

## BASICS

Inflammation of the mesenteric lymph nodes. A common cause of self-limited RLO abdominal pain.

## DESCRIPTION

- Characterized by benign inflammation of the mesenteric lymph nodes; can be acute or chronic
- May clinically mimic acute appendicitis

## EPIDEMIOLOGY

- Commonly misdiagnosed, making definitive incidence unknown
- Most common cause of appendicitis-like pain in children (1)
  - 20% in patients presenting for appendectomy (2)
- More common in children <15 years old than in adults
  - Primary adenitis is more common in children.
  - Secondary adenitis is more common in adults.
    - Rule out diverticulitis, appendicitis, Crohn disease, or systemic infectious/inflammatory disease (e.g., HIV, SLE).

## Prevalence

Affects males and females equally.

- Adenitis secondary to *Yersinia* infection is more prevalent in boys than girls.
  - *Yersinia enterocolitica* is most common in North America, Eastern Europe, and Australia.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Primary: underlying inflammatory process not present; presumed due to acute infectious

gastroenteritis (specifically, terminal ileitis)

- Secondary: underlying inflammatory process present (see "Commonly Associated Conditions")
- In infectious etiologies, pathogens are ingested, translocate through the intestinal epithelium via Peyer patches, and gain access to mesenteric lymph nodes. An inflammatory reaction within mesenteric lymph nodes causes symptoms and clinical disease. Infectious agents include:
  - *Y. enterocolitica*
  - *Campylobacter jejuni*
  - *Salmonella typhi*
  - *β-Hemolytic Streptococcus* spp.
  - *Staphylococcus* spp.
  - *Streptococcus viridans*
  - *Escherichia coli*
  - *Mycobacterium tuberculosis*
  - *Giardia lamblia*
  - Epstein-Barr virus (EBV)
  - Acute HIV infection
  - Rubella virus
  - Cat-scratch disease
  - Adenovirus species

## Genetics

No known genetic susceptibility

## RISK FACTORS

- Typically preceded by URI or pharyngitis
- History of ingesting undercooked pork particularly in areas where *Yersinia* is endemic (parts of Europe).

## GENERAL PREVENTION

Minimize risk by fully cooking foods, especially meat.

## COMMONLY ASSOCIATED CONDITIONS

- Appendicitis
- Diverticulitis
- Crohn disease
- Celiac disease
- Other systemic inflammatory/autoimmune disease

## DIAGNOSIS

### HISTORY

The onset of symptoms is variable; nausea or abdominal pain is usually the initial presenting symptom. Symptoms are often nonspecific.

- Nausea and vomiting (may precede abdominal pain)
- Abdominal pain: periumbilical, RLQ
- Diarrhea
- Fever, malaise, fatigue, anorexia
- Recent history of upper respiratory tract infection

### PHYSICAL EXAM

- Fever; can have toxic appearance
- Abdominal tenderness; (with or without rebound and often in the RLQ)
- Peripheral/generalized lymphadenopathy
- Rectal tenderness
- Rhinorrhea
- Pharyngeal hyperemia

### DIFFERENTIAL DIAGNOSIS

- Appendicitis, intussusception, intestinal duplication, regional enteritis (Crohn disease), Meckel diverticulitis, ulcerative colitis
- Epiploic appendagitis, mesenteric ischemia
- UTI, pyelonephritis

Salpingitis, PID, ectopic pregnancy

- Neoplasm (e.g., lymphoma)

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- CBC: leukocytosis with left shift
- Basic metabolic panel may show electrolyte disturbances and azotemia if dehydrated and/or alkalotic from recalcitrant vomiting.
- $\beta$ -HCG in women of childbearing potential
- Stool cultures if diarrhea
- Serologies if specific infectious agent suspected
- Blood cultures if septic
- CT scan: enlarged mesenteric lymph nodes (larger in size, number, and distribution than appendicitis)
  - Specific CT appearance includes <sup>33</sup> clustered lymph nodes measuring at least 5 mm in the short axis, most commonly to the right of the psoas muscle (3)[B].
  - May or may not have evidence of ileal or ileocecal wall thickening
  - Appendix appears normal.
- Ultrasound: less sensitive; used for exclusion of other potential diagnoses
  - Preferred in children and women (1)[C]
  - Used to evaluate for signs of appendicitis (96% positive predictive value in children) (2)[B]

---

P.665

### ***Diagnostic Procedures/Other***

Lymph node biopsy: only for those undergoing laparotomy can isolate the causative organism

### ***Test Interpretation***

- Lymph nodes are enlarged and soft.
- Adjoining mesentery may be edematous.
- Microscopically, lymph nodes display nonspecific hyperplasia. If a suppurative infection is present, lymph nodes may contain necrotic material with pus formation.

- Lymphatic sinuses may be enlarged.
- If *Y. enterocolitica* infection, lymph node capsule may be thickened, with surrounding edema; lymph node hyperplasia, with plasma cell infiltration also occur.

## TREATMENT

### MEDICATION

#### *First Line*

- Supportive and symptomatic treatment for uncomplicated cases
- IV fluid resuscitation if hypovolemic
- Correct underlying electrolyte aberrations.
- Pain control

#### *Second Line*

- Broad-spectrum antibiotic therapy for moderately to severely ill patients if diagnosis is unclear pending workup and/or surgical evaluation
- Treatment duration varies based on cause and severity of illness. For uncomplicated cases, antibiotic treatment is not necessary.

### SURGERY/OTHER PROCEDURES

Surgery is usually indicated in cases of suppuration and/or abscess formation, with signs of peritonitis, or if acute appendicitis cannot be excluded with certainty.

### INPATIENT CONSIDERATIONS

#### *Admission Criteria/Initial Stabilization*

- Admit patients with complications and/or hemodynamic instability.
- Volume resuscitation and correction of underlying electrolyte abnormalities

#### *IV Fluids*

- IV fluids may be indicated for patients who cannot tolerate PO intake due to nausea or vomiting.
- Aggressive fluid hydration is indicated if there is any evidence of sepsis.

## Discharge Criteria

Hemodynamic stability, able to tolerate PO diet, able to follow up in the outpatient setting

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### Patient Monitoring

Close outpatient monitoring is needed to ensure total resolution of symptoms.

#### DIET

There are no specific dietary recommendations. Hold oral intake as necessary until nausea and vomiting resolve. Advance diet slowly as tolerated.

### PATIENT EDUCATION

In cases of *Yersinia* infection, patients should avoid unpasteurized milk, raw pork, and contaminated water.

### PROGNOSIS

- Generally self-limiting and benign condition
- Increased morbidity/mortality for patients presenting with sepsis

### COMPLICATIONS

- Increased GI losses leading to hypovolemia and electrolyte imbalance
- Abscess formation, peritonitis, sepsis
- Latent extraintestinal manifestations, including arthralgias, truncal and extremity rashes, and erythema nodosum with *Y. enterocolitica* infection
- Postinfectious chronic complications of *Yersinia* infection including reactive arthritis, conjunctivitis, urethritis; postinfectious irritable bowel syndrome

## Additional Reading

&NA;

Patlas MN, Alabousi A, Scaglione M, et al. Crosssectional imaging of nontraumatic peritoneal and mesenteric emergencies. *Can Assoc Radiol J.* 2013;64(2):148-153.

## Codes

&NA;

### ICD10

I88.0 Nonspecific mesenteric lymphadenitis

## Clinical Pearls

&NA;

- Mesenteric adenitis is an inflammatory process that mimics appendicitis. Diagnosis requires imaging to distinguish from acute appendicitis.
- The condition is more common in children, often following a URI.
- The treatment is generally supportive care.

# Mesothelioma

Holli K. Neiman-Hart, MD, FAAFP

## BASICS

### DESCRIPTION

- Mesothelioma is a rare, aggressive malignancy of the mesothelial or serous tissues primarily found in the pleura (65-70%) or peritoneum (20-33%), tunica vaginalis (1-2%) or pericardium (1-2%) (1).
- Inhalation of asbestos is the predominant cause of mesothelioma, most often from occupational exposure.

### EPIDEMIOLOGY

#### *Incidence*

- The incidence in the United States is decreasing, but it is increasing in other countries, particularly Great Britain and Australia.
- It is expected that rates of mesothelioma will start to drop after 2015 to 2025 related to reduced exposure and better understanding of the process of development of mesothelioma after exposure to asbestos (2).
- The incidence increases with age, peaking in the 6th decade, with 70% of pleural disease occurring in males. Peritoneal involvement is slightly higher in women.
- Main risk factor is asbestos exposure, but tumors have arisen after prior radiation or exposure to talc, erionite or mica, or in patients with familial Mediterranean fever and diffuse lymphocytic leukemia.

#### *Prevalence*

There are 3,300 cases of mesothelioma diagnosed in the United States annually (3).

### ETIOLOGY AND PATHOPHYSIOLOGY

- The predominant cause of mesothelioma is exposure to asbestos (hydrated magnesium silicate fibrous minerals).
- There is a long latent period of up to 44 years between exposure and development of

mesothelioma (2).

- Inhaled or ingested asbestos fibers become trapped in pleural or peritoneal membranes causing changes of irritation and inflammation.

## *Genetics*

Loss of nuclear deubiquitinase BAP1 is associated with incidence of mesothelioma in some families as well as with other cancers such as melanoma.

## **RISK FACTORS**

- The predominant risk factor is exposure to asbestos.
- Occupational exposures involve mining or milling of fibers, work with textiles, cement, friction materials, insulation, or shipbuilding.
- Nonoccupational exposures include renovation or destruction of asbestos-containing buildings, exposure to industrial sources in the community or natural geologic sources, or exposure to soiled clothing of asbestos workers (1,3,4).
- Radiation exposure, smoking, proximity to naturally occurring asbestos deposits, or inhalation of other fibrous silicates can contribute to malignant mesothelioma.

## **GENERAL PREVENTION**

- Avoidance of asbestos exposure
- Strict adherence to protective protocols for workers in buildings where asbestos is found.
- Continued aggressive remediation of asbestosaffected buildings and homes

## **DIAGNOSIS**

### **HISTORY**

- Symptoms are usually nonspecific and occur when disease is advanced. General fatigue, night sweats, and weight loss may be present.
- Pleural mesothelioma presents with gradual onset of pulmonary symptoms, chest pain, dyspnea, and cough.
- Peritoneal disease presents with vague abdominal pain, increased abdominal girth, nausea, anorexia, and weight loss

## **PHYSICAL EXAM**

- Pulmonary findings of decreased breath sounds, dullness to percussion, asymmetric chest wall expansion
- Abdominal findings include distension, fluid wave with ascites, and tenderness.

## *DIFFERENTIAL DIAGNOSIS*

- Pleural mesothelioma differential diagnosis includes inflammatory reactions (empyema, pleural effusion), metastatic tumor from other sites, fibrosarcoma, malignant fibrous histiocytoma, sarcomatoid carcinoma, or synovial sarcoma.
- Peritoneal mesothelioma differential diagnosis includes peritoneal carcinomatosis, serous peritoneal carcinoma, ovarian carcinoma in women, lymphomatosis, tuberculous peritonitis

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- At present, there is no tumor marker or serum chemistry that is of value in establishing the diagnosis of mesothelioma.
- Biomarkers that may be elevated in mesothelioma include fibulin-3, mesothelin, and osteopontin. However, they do not have an established role in diagnosis or monitoring response to therapy (2)[A].
- Pleural mesothelioma diagnosis requires tissue. Thoracentesis for cytology and closed pleural biopsy may be adequate, but often, more invasive procedures such as video-assisted thoracoscopic surgery (VATS) is needed to obtain an adequate specimen (1,2)[A].

### *Follow-Up Tests & Special Considerations*

Seeding of biopsy sites and tracks may occur in mesothelioma, which can be prevented with prophylactic radiation therapy to the scar or biopsy site (5)[A].

### *Diagnostic Procedures/Other*

- CT, MRI, PET, or integrated PET-CT helps with clinical staging in pleural and peritoneal disease (1,2,3,4),(5)[A].
- Mediastinoscopy, bronchoscopy, and laparoscopy can assist in full surgical staging of pleural disease (2)[A].
- Endobronchial ultrasound for staging is under investigation for pleural disease.

### *Test Interpretation*

- The tumor, node, metastasis (TNM) staging system is most commonly used although some

centers use other staging systems.

- Butchart staging system is the oldest and still used in some parts of the world.
- Brigham staging system attempts to define resectability and lymph node involvement.

## TREATMENT

### GENERAL MEASURES

- A multidisciplinary team is important in management and should include thoracic surgery, oncology, pathology, pulmonary, and radiology for patient specific planning of management.
- Pain assessment and control should follow principles of cancer pain management (5).

### MEDICATION

#### *First Line*

- In pleural disease, combined therapy with cisplatin + gemcitabine or cisplatin + pemetrexed are associated with longer median survival than cisplatin alone (2),(4)[A].
- Vinflunine is showing some potential for first-line treatment in pleural disease (2)[A].
- Hyperthermic intraoperative or early postoperative intraperitoneal chemotherapy can decrease increase drug concentration to the peritoneum and decrease systemic side effects. Use cisplatin, mitomycin C, fluorouracil, doxorubicin, and/or paclitaxel (1,2),(3)[A].

#### *Second Line*

- Palliative benefit in pleural disease with mitomycin C, vinblastine, cisplatin, and pemetrexed alone or in combination with carboplatin (2,3),(4)[A]
- Systemic therapy for peritoneal disease may include pemetrexed + cisplatin; vinorelbine or gemcitabine alone or in combination (1),(5)[A].

### ISSUES FOR REFERRAL

- Pulmonary, oncology, and surgical follow-up after discharge as indicated
- Anger and depression may require psychological or psychiatric services (5).

### ADDITIONAL THERAPIES

Immunotherapy in pleural disease uses humanized anti-CD3 AB (OKT3), cytotoxic T lymph (CTL), interferon  $\alpha$ -2a, and autovaccine in advanced disease (1,2,3,4,5).

- Gene therapy
- Photodynamic therapy
- Radiotherapy in some cases of pleural disease
- Vascular endothelial growth factor (anti-VEGF-2) in combination with chemotherapy (2)
  - Vaccines are under study (5).

## ***SURGERY/OTHER PROCEDURES***

- For pleural mesothelioma, the role of surgery is not as clear cut. Pleurectomy with tumor decortication and extrapleural pneumonectomy reduce the tumor load, but there remains no clear effect on mortality (2,4,5).
- Radical resection of the peritoneum and cytoreductive surgery is associated with a better prognosis (1).

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Based on overall condition

### ***IV Fluids***

As indicated by general condition

### ***Nursing***

As indicated by condition

### ***Discharge Criteria***

As indicated by general condition

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

- Smoking cessation
- Immunization for pneumococcal pneumonia and influenza

## *Patient Monitoring*

Monitor for paraneoplastic phenomenon including fever, thrombocytosis, malignancy-related thrombosis, hypoglycemia, and rare Coombs-positive hemolytic anemia.

## *DIET*

No specific restrictions

## *PROGNOSIS*

- Prognosis is based on gender, stage, and level of completeness of cytoreduction.
- Poorly differentiated tumor grade, failure to undertake surgical resection, advanced age, and male gender are all independent predictors of poorer prognosis (2,3).
- Average survival is 17 to 92 months, with 5-year survival rate at 63%.

## **COMPLICATIONS**

Relapses and progression, infection, dysphagia

### ***Geriatric Considerations***

Age >65 years is associated with significantly increased morbidity and mortality.

### ***Pediatric Considerations***

Rarely a pediatric issue, as most disease occurs after the 5th decade of life.

### ***Pregnancy Considerations***

Rarely an issue with pregnancy, as most disease occurs after the 5th decade of life.

## Codes

**&NA;**

### **ICD10**

- C45.9 Mesothelioma, unspecified
- C45.0 Mesothelioma of pleura
- C45.1 Mesothelioma of peritoneum

## **Clinical Pearls**

**&NA;**

- Mesothelioma remains a rare but universally fatal disease in part due to long latency.
- Multimodal treatment has decreased recurrence rates and has extended survival time.

# Metabolic Syndrome

Naomi Parrella, MD

## BASICS

### DESCRIPTION

- A constellation of metabolic abnormalities that confer increased risk for type 2 diabetes mellitus (T2DM), cardiovascular disease, stroke, fatty liver, and certain cancers and includes metabolic derangement manifesting with at least three of the following:
  1. Increased abdominal circumference
  2. Elevated BP
  3. Elevated triglycerides
  4. Decreased High density lipoprotein (HDL)
  5. Elevated fasting glucose
- Also involves the following metabolic abnormalities:
  - Insulin resistance with or without impaired glucose tolerance
  - Proinflammatory state
  - Prothrombotic state

### EPIDEMIOLOGY

- Predominant age: >60 years old (÷50% of cases)
- Predominant sex: male = female
- Ethnicity: Mexican Americans (highest risk)

### Prevalence

- Affects 34% of U.S. adults aged >20 years; increasing with the aging population and the prevalence of obesity (1)
- Data vary among race and ethnicity with different trends for women and men. The available literature suggests that metabolic syndrome is a rapidly growing epidemic worldwide.

## *Pediatric Considerations*

- Obese children and adolescents are at high risk of metabolic syndrome (prevalence of 6.4% in the United States). Risk factors in children and adolescents include heredity, low birth weight, childhood weight gain and obesity, endocrine abnormalities, hostility, maternal gestational diabetes, and poor health habits.
- International Diabetes Federation consensus report defined criteria in three age groups (6 to <sup>2</sup>10 years; 10 to <sup>2</sup>16 years; 16 + years, adult criteria applicable) (2)[C]. Obesity defined by waist circumference <sup>3</sup>90th percentile; rest of the diagnostic criteria (triglycerides [TGs], high-density lipoprotein cholesterol [HDL-C], hypertension [HTN], and fasting blood sugar/T2DM) are largely the same as in adults for children <sup>3</sup>10 years, with some exceptions, and warrant treatment. Clinical significance of metabolic syndrome in pediatric population is not well established using these criteria (2). BMI used alone is as accurate as using IDF criteria to predict adult MetSyn, subclinical atherosclerosis and diabetes mellitus type 2 (3)[C]. Focus on promoting healthy lifestyle habits and weight management rather than diagnosis.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Increase in intra-abdominal and visceral adipose tissue
- Adipose tissue dysfunction and insulin resistance
- Decreased levels of adiponectin, an adipocytokine, known to protect against T2DM, HTN, atherosclerosis, and inflammation
- Abnormal fatty acid metabolism, endothelial dysfunction, systemic inflammation, oxidative stress, elevated renin-angiotensin system activation, and a prothrombotic state (increased tissue plasminogen activator inhibitor-1) are also associated.
- The main etiologic factors are the following:
  - Obesity (particularly abdominal)/excess visceral adipose tissue
  - Insulin resistance
  - Other contributing factors:
    - Advancing age
    - Proinflammatory state
    - Genetics
- Endocrine (e.g., postmenopausal state)

## *Genetics*

Genetic factors contribute significantly to causation. Most identified genes are transcription factors or regulators of transcription and translation. It is a multifactorial disease with evidence of complex interactions between genetics and environment.

## *RISK FACTORS*

- Obesity/intra-abdominal obesity
- Childhood obesity
- Insulin resistance
- Older age
- Ethnicity
- Family history
- Physical inactivity
- High-carbohydrate diet
- Sugar-sweetened beverages daily
- Smoking
- Postmenopausal status
- Low socioeconomic status
- Alteration of gut flora

## *GENERAL PREVENTION*

- Effective weight loss and maintenance of normal body weight long term
- Regular and sustained physical activity
- Diet low in saturated fats and simple sugars

## *COMMONLY ASSOCIATED CONDITIONS*

- Polycystic ovary syndrome
- Nonalcoholic fatty liver disease (NAFLD)
- Acanthosis nigricans
- Chronic renal disease
- Depression
- Cognitive impairment

- Obstructive sleep apnea
- Gallstones (cholesterol)
- Erectile dysfunction (in men)
- Hyperuricemia and gout

## DIAGNOSIS

### HISTORY

- Not necessary for diagnosis of metabolic syndrome
- Family history of metabolic syndrome, T2DM, and cardiovascular disease
- Symptoms indicating cardiovascular disease or diabetes
- Comprehensive lifestyle history:
  - Diet, including intake of carbohydrates and fats
  - Weight history, including onset of obesity and previous weight loss attempts
  - Exercise regimen
  - Alcohol intake
- Cigarette smoking
- Assess cardiovascular risk with Framingham risk assessment tool.

### PHYSICAL EXAM

Various criteria-based definitions have been proposed and in 2009, harmonized (4). A diagnosis of metabolic syndrome can be made when <sup>3</sup>3 of the following 5 characteristics are present:

- Abdominal obesity: men >102 cm, women >88 cm (ATP III recommends lowering threshold in population susceptible to insulin resistance, especially Asian Americans)
- BP <sup>3</sup>130/85 mm Hg or treatment
- TGs <sup>3</sup>150 mg/dL or treatment
- HDL: men >40 mg/dL, women <50 mg/dL or treatment
- Fasting glucose <sup>3</sup>100 mg/dL or treatment

### DIFFERENTIAL DIAGNOSIS

Individual components of the syndrome may be present without fulfilling all the diagnostic

criteria. Obstructive sleep apnea, thyroid abnormalities, Cushing syndrome, medication effect (especially psychotropic, chronic steroids,  $\beta$ -blockers and thiazide diuretic [5] medications) may also be considered in the differential.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Fasting lipids (particularly TGs and HDL)
- Fasting glucose

### ***Follow-Up Tests & Special Considerations***

- Formal 75-mg oral glucose tolerance test or Hemoglobin A1C for diagnosis of impaired glucose tolerance (IGT)
- Liver function tests
- Measurement of fasting insulin levels is controversial.
- None necessary to diagnose metabolic syndrome

### ***Diagnostic Procedures/Other***

- Home BP monitoring or 24-hour BP monitoring may be used to rule out white coat hypertension.
- ECG, stress test, and coronary angiography may be used for diagnosis of cardiovascular disease arising as a complication of the syndrome.

### ***Test Interpretation***

- Microalbuminuria
- Increased WBC count
- Increased C-reactive protein
- Increased fibrinogen
- Increased proinflammatory cytokines (e.g., tumor necrosis factor- $\alpha$ )
- Increased uric acid
- Increased homocysteine
- T2DM
- Fatty liver (complicated by end-stage liver disease and hepatocellular carcinoma)

- Hypertensive and/or diabetic eye disease
- Renal impairment/failure
- Peripheral vascular disease
- Coronary artery disease
- Cerebrovascular disease

## TREATMENT

Primary therapeutic goal is to prevent or reduce obesity and risk factors. Aggressive lifestyle modification (diet and exercise) is considered first-line therapy and most clinically effective (6)[C].

P.669

## GENERAL MEASURES

- Aggressive treatment of individual risk factors
- Increase daily physical activity.
- Avoid or stop smoking.
- Avoid excess alcohol intake.
- Avoid sugar sweetened beverages.
- Increase leafy green vegetables.

## MEDICATION

- Daily treatment with aspirin is recommended for patients with cardiovascular disease or those at high risk.
- Consult clinical guidelines for treatment of dyslipidemia, hypertension, IGT, and diabetes.
- Multiple medications usually are required to achieve adequate BP control.
- Diagnosis and treatment of insulin resistance is controversial.

### *First Line*

Lifestyle modification alone as initial strategy is applicable to individuals with low 10-year risk for coronary artery disease (CAD). In individuals with higher 10-year risk, more aggressive risk factor-based approach is recommended in addition to lifestyle modifications:

- Obesity: Lifestyle changes are the cornerstone of treatment. Aim for a ÷5-10% weight reduction. Any amount of weight loss is associated with significant benefits.

- Phentermine-topiramate (delayed release) (Qsymia) (7)[A] and lorcaserin (Belviq) (8)[A] have been approved by the FDA for nonpregnant, nonlactating adults for management of obesity with promising outcomes on weight, BP, dyslipidemia, and other metabolic/glycemic parameters.
- Physical activity: Endurance exercise may reverse metabolic syndrome (9)[A]. 30 to 60 minutes of moderate-intensity aerobic activities such as brisk walking 5 to 7 days/week; increase in daily lifestyle activities and resistance training 1 to 2 days/week (10)[A]. In patients with established CAD, assess detailed history of physical activity and exercise tolerance to guide activity prescription. Advise medically supervised programs for high-risk population (recent acute coronary syndrome [ACS], congestive heart failure, recent revascularization). Cumulative exercise time over the day contributes to health benefit.
- Dyslipidemia: Drug therapy can be commenced after 6 weeks of lifestyle modification. See section on *Dyslipidemia*.
- HTN: Aim for similar targets to patients with diabetes (<140/80 mm Hg based on ADA guidelines). See section on *Hypertension*.
  - ACE inhibitor or angiotensin receptor blocker (e.g., losartan 50 mg/day if ACE inhibitor intolerance) is usually prescribed for patients with diabetes.
- Impaired glucose tolerance
  - Current guidelines emphasize that treatment should be with diet and exercise. The role of oral hypoglycemic agents to prevent diabetes in patients with the metabolic syndrome is unclear. Metformin, 500 mg to 1 g, 1 to 2 times daily, may be considered.
- If CAD or T2DM is already evident, treat as per guidelines. Use ASA 81 mg for primary prevention as indicated per USPSTF if benefits outweigh bleeding risk.

## *ISSUES FOR REFERRAL*

- Obesity management
- Nutrition
- Exercise program
- Smoking cessation

## *SURGERY/OTHER PROCEDURES*

- Bariatric surgery to treat obesity in severely obese patients who have failed trials of lifestyle modification and pharmacotherapy; surgery is recommended in appropriate individual if body mass index (BMI) >40 or BMI >35 with obesity-related comorbidities.

- Liposuction of abdominal adipose tissue does not reduce insulin resistance or cardiovascular risk factors.

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Fish oils and plant sterol esters for cardioprotective effects

## **INPATIENT CONSIDERATIONS**

Management usually does not require admission.

### ***Admission Criteria/Initial Stabilization***

Serious complications (e.g., ACS, hypertensive crisis, diabetic coma)

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Regular 30-minute exercise will improve all components of the metabolic syndrome. Cumulative small periods of exercise over the day provide significant health benefits.
- Encourage changing sedentary activity choices (e.g., driving car, taking elevator, and the like) to more active ones (e.g., walking, cycling).
- Regular monitoring of weight, abdominal circumference measurements, BP, fasting lipids, and sugar levels

### ***Patient Monitoring***

- Regular monitoring of weight, abdominal circumference measurements, BP, fasting lipids, and sugar levels
- Fasting lipids, fasting sugar, and/or oral glucose tolerance test should be checked annually.

## **DIET**

- Weight reduction to correct abdominal obesity is a primary goal achieved by dietary modification and increased physical activity.
- Dietary recommendations may include limiting simple carbohydrates in diet, eating a Mediterranean or DASH (Dietary Approaches to Stop Hypertension) diet.
- Increased consumption of leafy green vegetables may decrease risk of developing T2DM (11) [A]. Encourage increasing intake of vegetables and fiber, and keep fruit and alcohol in

moderation.

- Avoid sugar-sweetened beverages.

## PROGNOSIS

Increased risk of T2DM ( $\div$ 5-fold), CAD ( $\div$ 1.5 to 3-fold), acute myocardial infarction ( $\div$ 2.5-fold), and all-cause mortality ( $\div$ 1.5-fold)

## COMPLICATIONS

Long-term complications are primarily CAD and T2DM. Recent evidence demonstrates an increased risk of NAFLD, stroke, and an increased risk of developing certain cancers, especially breast cancer in postmenopausal women.

&NA;

Samson SL, Garber AJ. Metabolic syndrome. *Endocrinol Metab Clin North Am.* 2014;43(1):1-23.

## Codes

&NA;

### ICD10

E88.81 Metabolic syndrome

## Clinical Pearls

&NA;

- Abdominal circumference should be measured as part of a cardiovascular risk assessment.
- Recognizing metabolic syndrome in the clinic can help prioritize treatment goals and guidance to work to reduce associated risk factors.

- Prevention or reduction of obesity is the cornerstone of management of metabolic syndrome.
- Increasing cumulative physical activity over the day significantly adds to the benefit of regular 30 to 60-minute exercise regimen.
- Aggressive lifestyle modification is the first-line lifelong treatment for all patients.

# Metatarsalgia

Michael Y. Yang, MD

Marc W. McKenna, MD

## BASICS

### DESCRIPTION

- Metatarsalgia is a generic term referring to pain in the forefoot in the region of the metatarsal heads.
- System affected: musculoskeletal

### EPIDEMIOLOGY

#### *Incidence*

Especially common in athletes engaging in high-impact sports (running, jumping, dancing), in rock climbers (12.5%), and in older active adults.

#### *Prevalence*

Common

### ETIOLOGY AND PATHOPHYSIOLOGY

- The 1st metatarsal head bears significant weight when walking or running. A normal metatarsal arch ensures this balance. The 1st metatarsal head normally has adequate padding to accommodate increased forces.
- Reactive tissue can build a callus around the metatarsal head, compounding the pain.
  - Excessive or repetitive stress. Forces are transmitted to the forefoot during several stages (midstance and push-off) of walking and running. These forces are translated across the metatarsal heads at nearly three times the body weight (1)[C].
  - A pronated splayfoot disturbs this balance, causing equal weight bearing on all metatarsal heads.
  - Any foot deformity changes distribution of weight, impacting areas of the foot that do not have sufficient padding.

- Soft tissue dysfunction: intrinsic muscle weakness, laxity in the Lisfranc ligament
- Abnormal foot posture: forefoot varus or valgus, cavus or equinus deformities, loss of the metatarsal arch, splayfoot, pronated foot, inappropriate footwear
- Dermatologic: warts, calluses (2)[C]
- Great toe
  - Hallux valgus (bunion), either varus or rigidus
- Lesser metatarsals
  - Freiberg infraction (i.e., aseptic necrosis of the metatarsal head usually due to trauma in adolescents who jump or sprint)
  - Hammer toe or claw toe
  - Morton syndrome (i.e., long 2nd metatarsal)

## *RISK FACTORS*

- Obesity
- High heels, narrow shoes, or overly tight-fitting shoes (rock climbers typically wear small shoes)
- Competitive athletes in weight-bearing sports (e.g., ballet, basketball, running, soccer, baseball, football)
- Foot deformities or changes in ROM (e.g., pes planus, pes cavus, tight Achilles tendon, tarsal tunnel syndrome, hallux valgus, prominent metatarsal heads, excessive pronation, hammer toe deformity, tight toe extensors) (2)[C]

## *Geriatric Considerations*

- Concomitant arthritis
- Metatarsalgia is common in older athletes.
- Age-related atrophy of the metatarsal fat pad may increase the risk for metatarsalgia.

## *Pediatric Considerations*

- Muscle imbalance disorders (e.g., Duchenne muscular dystrophy) cause foot deformities in children.
- In adolescent girls, consider Freiberg infraction.
- Salter I injuries may affect subsequent growth and healing of the epiphysis.

## *Pregnancy Considerations*

- Forefoot pain during pregnancy usually results from change in gait, center of mass, and joint laxity.
- Wear properly fitted, low-heeled shoes.

## **GENERAL PREVENTION**

- Wear properly fitted shoes with good padding.
- Start weight-bearing exercise programs gradually.

## **COMMONLY ASSOCIATED CONDITIONS**

- Arthritis
- Morton neuroma
- Sesamoiditis
- Plantar keratosis-callous formation

## **DIAGNOSIS**

### **HISTORY**

- Pain gradually develops and persists over the heads of one or more metatarsals. Pain is usually on the plantar surface and worse during midstance gait phase.
- Pain is often chronic.
- Predisposition with pes cavus and hyperpronation
- Pain often described as walking with a pebble in the shoe; aggravated during midstance or propulsion phases of walking or running.

### **PHYSICAL EXAM**

- Point tenderness over plantar metatarsal heads
- Pain in the interdigital space or a positive metatarsal squeeze test suggests Morton neuroma.
- Plantar keratosis
- Tenderness of the metatarsal head(s) with pressure applied by the examiner's finger and thumb

- Erythema and swelling (occasionally)

## ***DIFFERENTIAL DIAGNOSIS***

- Stress fracture (most commonly 2nd metatarsal)
- Morton neuroma (i.e., interdigital neuroma)
- Tarsal tunnel syndrome
- Sesamoiditis or sesamoid fracture
- Salter I fracture in children
- Arthritis (e.g., gouty, rheumatoid, inflammatory, osteoarthritis, septic, calcium pyrophosphate dihydrate crystal deposit disease [CPPD])
- Lisfranc injury
- Avascular necrosis of the metatarsal head
- Ganglion cyst
- Foreign body
- Vasculitis (diabetes)
- Bony tumors

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Weight-bearing radiographs: anteroposterior, lateral, and oblique views:
  - Occasionally, metatarsal or sesamoid axial films (to rule out sesamoid fracture) or skyline view of the metatarsal heads to assess the plantar declination of the metatarsal heads: obtained with the metatarsophalangeal joints in dorsiflexion (to evaluate alignment)
- Ultrasound and MRI in recalcitrant cases especially if concern for stress fracture (3)[C]
- MR arthrography of the metatarsophalangeal (MTP) joint can delineate capsular tears, typically of the distal lateral border of the plantar plate (an often underrecognized cause of metatarsalgia).
- Only if diagnosis is in question
  - Erythrocyte sedimentation rate or C-reactive protein
  - Rheumatoid factor

- Uric acid
- Glucose
- CBC with differential

## *Diagnostic Procedures/Other*

Plantar pressure distribution analysis may help distinguish pressure distribution patterns due to malalignment.

## **TREATMENT**

Treatment for metatarsalgia is typically conservative.

- Relieve pain
- Ice initially
- Rest: temporary alteration of weight-bearing activity; use of cane or crutch. For more physically active patients, suggest an alternative exercise or cross-training:
  - Moist heat later
  - Taping or gel cast
  - Stiff-soled shoes will act as a splint.
- Relieve the pressure beneath the area of maximal pain by redistributing the pressure load of the foot, which can be achieved by weight loss.

## *MEDICATION*

Nonsteroidal anti-inflammatory medications for 7 to 14 days if no contraindications toward use

---

P.671

## *ISSUES FOR REFERRAL*

High-level athletes may benefit from early podiatric or orthopedic evaluation.

## *ADDITIONAL THERAPIES*

- Physical therapy to restore normal foot biomechanics
- Low-heeled (<2 cm height) wide-toe-box shoes
- Metatarsal bars, pads, and arch supports. Metatarsal bars are often more effective than pads.
- Orthotics/rocker bar (prescriptive orthotics have been shown to be effective treatment)

- Thick-soled shoes
- Shaving the callus may provide temporary relief. Callus excision is not recommended.
- Corticosteroid injection may benefit interdigital neuritis but should be used with caution as it may cause MTP instability and fat pad atrophy.
- Improve flexibility and strength of the intrinsic muscles of the foot with:
  - Exercises (e.g., towel grasps, pencil curls)
  - Physical therapy to maintain range of motion and restore normal biomechanics

## ***SURGERY/OTHER PROCEDURES***

- If no improvement with conservative therapy for 3 months, refer to foot/ankle orthopedic surgeon or podiatrist.
- Surgery may help correct anatomic abnormality: bunionectomy, partial osteotomy, or surgical fusion. Success rates vary depending on procedure.
- Direct plantar plate repair (grade II tear) combined with Weil osteotomy can restore normal alignment of the MTP joint, leading to diminished pain with improved functional scores.
- The Weil osteotomy (distal metatarsal oblique osteotomy) is safe and effective for metatarsalgia.
- Callus removal is generally not recommended (callus is a response to pressure change—not the cause).
- Morton neurectomy or ultrasound-guided alcohol ablation of Morton neuroma are options (4) [C].
- Surgery only as a last resort if no anatomic abnormality is present.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Magnetic insoles are not effective for chronic nonspecific foot pain.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Patients generally admitted only for surgery

**ONGOING CARE**

# FOLLOW-UP RECOMMENDATIONS

## Patient Monitoring

If stress fracture has been ruled out and patient's condition has not improved >3 months of conservative treatment, consider surgical evaluation.

## PATIENT EDUCATION

- Instruct about wearing proper shoes and gradual return to activity.
- Cross-training until symptoms subside. Goal is to restore normal foot biomechanics, relieve abnormal pressure on the plantar metatarsal heads, and relieve pain (5)[C].

## PROGNOSIS

Outcome depends on the severity of the problem and whether surgery is required to correct it.

## COMPLICATIONS

- Back, knee, and hip pain due to change in gait
- Transfer metatarsalgia following surgical intervention, which subsequently transfers stress to other areas.

## &NA;

Morton Neuroma (Interdigital Neuroma)

## Codes

## &NA;

## ICD10

- M77.40 Metatarsalgia, unspecified foot
- G57.60 Lesion of plantar nerve, unspecified lower limb
- M77.42 Metatarsalgia, left foot

## Clinical Pearls

## **&NA;**

- Metatarsalgia refers to pain of the plantar surface of the forefoot in the region of the metatarsal heads.
- Metatarsalgia is common in athletes who participate in high-impact sports involving the lower extremities.
- Patients describe as "walking with a pebble in the shoe." Pain is worse during midstance or propulsion phases of walking or running.
- The most common physical finding is point tenderness over plantar metatarsal heads.
- Pregnant patients should wear properly fitted, low-heeled shoes to reduce incidence of metatarsalgia.

# Methicillin-Resistant *Staphylococcus Aureus* (MRSA) Skin Infections

Stephen A. Martin, MD, EdM

Paul P. Belliveau, PharmD, RPh

## BASICS

### DESCRIPTION

- Community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA) has unique properties allowing the organism to cause skin and soft tissue infections (SSTIs) in healthy hosts:
  - CA-MRSA has a different virulence and disease pattern than hospital-acquired MRSA (HA-MRSA).
- CA-MRSA infections impact patients who have not been recently (<1 year) hospitalized or had a medical procedure (e.g., dialysis, surgery, catheters).
- *The prevalence of CA-MRSA is rapidly increasing in the United States.*
- CA-MRSA typically causes mild to moderate SSTIs, particularly abscesses, furuncles, and carbuncles:
  - Severe or invasive disease from CA-MRSA is less frequent but can include the following:
    - Necrotizing pneumonia with abscesses
    - Necrotizing fasciitis
    - Septic thrombophlebitis
    - Sepsis
    - Osteomyelitis
- Although less frequent, HA-MRSA can still cause SSTIs in the community. One study showed no significant difference in hospitalization rates among CA-MRSA, HA-MRSA, and methicillin-sensitive *S. aureus* (MSSA) infections.
- System(s) affected: skin, soft tissue

## EPIDEMIOLOGY

- Predominant age: all ages, generally younger
- Predominant sex: female > male

### *Incidence*

- 316/100,000/year (2004 to 2005)
- 46/100,000/year pediatric MRSA SSTI hospitalizations (2009)

### *Prevalence*

- Significantly affected by local epidemiology
- 25-30% of U.S. population are colonized with *S. aureus*; up to 7% are colonized with MRSA.
- CA-MRSA isolated in ÷60% of SSTIs presenting to emergency departments (range 15-74%).  
In 1993, 1.5 million SSTIs were seen in U.S. emergency rooms. In 2005, this had increased to 3.4 million. Hospital admissions for SSTIs increased 29% between 2000 and 2004.
- CA-MRSA accounts for up to 75% of all community staphylococcal infections in children.

## ETIOLOGY AND PATHOPHYSIOLOGY

- First noted in 1980. Current U.S. CA-MRSA epidemic began in 1999. The United States 300 clone is predominant.
- CA-MRSA is distinguished from HA-MRSA by
  - Lack of a multidrug-resistant phenotype
  - Presence of exotoxin virulence factors
  - Type IV *Staphylococcus* cassette cartridge (contains the methicillin-resistance gene *mecA*)

## RISK FACTORS

- ÷50% of patients with CA-MRSA do not have an obvious risk factor
- Use of any antibiotic in the past month.
- Presence of an abscess
- Reported spider bite
- History of MRSA infection
- Close contact with a similar infection

- Children, particularly in daycare centers
- Competitive athletes
- Incarceration
- Hospitalization in the past 12 months (although *S. aureus* can colonize for years)

## GENERAL PREVENTION

- Colonization (particularly of the anterior nares) is a risk factor for subsequent *S. aureus* infection. It is not clear whether this is the case for CA-MRSA. Oropharyngeal and inguinal colonization are equally prevalent.
- CA-MRSA may be transmitted more easily through environmental and household contact (1) [B].
- Health care workers are a primary MRSA vector for hospitalized patients, reinforcing the need for meticulous cleaning of hands and equipment.
- Research for a vaccine is underway.
- CDC guidance for prevention of MRSA in athletes: <http://www.cdc.gov/mrsa/community/team-hc-providers/advice-for-athletes.html>

## COMMONLY ASSOCIATED CONDITIONS

Many patients are otherwise healthy.

## DIAGNOSIS

### HISTORY

- Review potential risk factors.
- “Spider bite” is commonly confused with MRSA—patients may report an unclear history of spider bite.
- Prior MRSA skin infection
- Risk factors alone cannot rule in or rule out a CA-MRSA infection.

## PHYSICAL EXAM

- Furuncles and/or carbuncles, sometimes with surrounding cellulitis. A nonsuppurative cellulitis is also possible, although it is a less common presentation of CA-MRSA.
- Erythema, warmth, tenderness, swelling

Fluctuance

- Folliculitis, pustular lesions
- Appearance like an insect or spider bite
- Tissue necrosis

## ***DIFFERENTIAL DIAGNOSIS***

SSTIs due to another cause

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Wound cultures establish definitive diagnosis. Recent guidelines recommend cultures only when a purulent lesion is accompanied by systemic signs of illness or immunocompromise (2) [B].
- Susceptibility testing; many labs use oxacillin instead of methicillin.
- A ØD-zone disk-diffusion test<sup>Ó</sup> evaluates for inducible clindamycin resistance in CA-MRSA resistant to erythromycin.
- In unclear cases, ultrasound may help identify abscesses (3,4)[A].
- Although CT or MRI may show fascial plane edema in necrotizing fasciitis, do not delay surgical intervention waiting for imaging, particularly in ill patients.

### ***Diagnostic Procedures/Other***

Purulent lesions should be incised and drained (I&D); needle aspiration is not recommended (2).

## **TREATMENT**

- Recent guidelines recommends treating with antibiotics active against MRSA for patients with carbuncles or abscesses who failed initial antibiotic treatment, have markedly impaired host defenses, or present with systemic inflammatory response (SIRS) and hypotension (2).
- Routine use of agents to eliminate MRSA colonization for patients with active infection or their close contacts is not currently recommended.
- Most CA-MRSA infections are localized SSTIs and not requiring hospitalization or vancomycin.
- Initial empirical antibiotic coverage should be based on local CA-MRSA prevalence and individual patient risk factors.

- [http://www.cdc.gov/mrsa/pdf/Flowchart\\_pstr.pdf](http://www.cdc.gov/mrsa/pdf/Flowchart_pstr.pdf)

## GENERAL MEASURES

- Modify therapy based on culture and susceptibility.
- Determine if household or other close contacts have SSTI or other infections and evaluate accordingly.
- Treat underlying condition (e.g., tinea pedis).
- Restrict contact if wound cannot be covered.
- Elevate affected area.

## MEDICATION

### ALERT

For purulent infections, consider surgical drainage and debriding, wound culture, and narrow-spectrum antimicrobials:

- Successful I&D may have more impact than antibiotics in mild cases for both adults and children.
- Moist heat may work for small furuncles.
- Patients with an abscess are frequently cured by incision and drainage alone.
- Packing does not appear to improve outcomes (3)[A].

### First Line

CA-MRSA SSTIs: 7- to 14-day course (depends on severity and clinical response):

- Trimethoprim/sulfamethoxazole (TMP-SMX): DS (160 mg TMP and 800 mg of SMX) 1 to 2 tablet(s) PO BID daily (8 to 12 mg/kg/day of trimethoprim component in 2 divided doses for children)
  - Doxycycline or minocycline: 100 mg PO BID (children >8 years and <45 kg; 2 to 5 mg/kg/day PO in 1 to 2 divided doses, not to exceed 200 mg/day; children >8 years and >45 kg, use adult dosing), taken with a full glass of water
- 
- Clindamycin: 300 to 450 mg PO QID (30 to 40 mg/kg/day PO in 3 divided doses for children), taken with full glass of water. Check D-zone test in erythromycin-resistant, clindamycin-susceptible *S. aureus* isolates (a positive test indicates induced resistance—choose a different antibiotic).

- CA-MRSA is resistant to *&agr;-*lactams (including oral cephalosporins and antistaphylococcal penicillins) and often macrolides, azalides, and quinolones.
- Although most CA-MRSA isolates are susceptible to rifampin, this drug should *never* be used as a single agent because of concerns regarding resistance. The role of combination therapy with rifampin in CA-MRSA SSTIs is not clearly defined.
- There has been increasing resistance to clindamycin, both initial ( $\div$ 33%) and induced.
- Although CA-MRSA isolates are susceptible to vancomycin, oral vancomycin cannot be used for CA-MRSA SSTIs due to limited absorption.

## Second Line

Treat severe CA-MRSA SSTIs requiring hospitalization and HA-MRSA SSTIs using:

- Vancomycin: Generally, 1 g IV q12h (30 mg/kg/day IV in 2 divided doses; in children: 40 mg/kg/day IV in 4 divided doses) vancomycin-like antibiotics that require only 1 or 2 doses may soon be more broadly available (5)[A].
- Linezolid: 600 mg IV/PO BID uncomplicated: children <5 years of age, 30 mg/kg/day in 3 divided doses; 20 mg/kg/day IV/PO in 2 divided doses for children 5 to 11 years of age; children >11 years, use adult dosing. Complicated: birth to 11 years, 30 mg/kg/day IV/PO in 3 divided doses; older, use adult dosing)
  - Linezolid seems to be more effective than vancomycin for treating people with SSTIs, but current studies have high risk of bias.
- Clindamycin: 600 mg IV TID; in children, 10 to 13 mg/kg/dose q6-8h up to 40 mg/kg/day
- Daptomycin: 4 mg/kg/day IV (safety/efficacy not established in patients <18 years of age) if no pulmonary involvement
- Ceftaroline 600 mg BID IV (for adults)

## Pediatric Considerations

- Tetracyclines not recommended <8 years of age
- TMP-SMX not recommended <2 months

## Pregnancy Considerations

- Tetracyclines are contraindicated.
- TMP-SMX not recommended in 1st or 3rd trimester

## *Geriatric Considerations*

A recent review notes no prospective trials in this age group and recommends use of general adult guidelines.

## *ISSUES FOR REFERRAL*

Consider consultation with infectious disease in cases of

- Refractory CA-MRSA infection
- Plan to attempt decolonization

## *SURGERY/OTHER PROCEDURES*

Progression to serious SSTIs, including necrotizing fasciitis, is possible and mandates prompt surgical evaluation.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Consider admission if:

- Systemically ill (e.g., febrile) with stable comorbidities
- Systemically well with comorbidities that may delay or complicate resolution of SSTI
- Presence of SSTI complications (sepsis, necrotizing fasciitis) and comorbidities
- If indicated, alternatives to inpatient admission include observation units and outpatient parenteral antimicrobial therapy (OPAT) programs

### *Nursing*

Contact precautions

### *Discharge Criteria*

If admitted for IV therapy, assess the following before discharge:

- Afebrile for 24 hours
- Clinically improved
- Able to take oral medication
- Has adequate social support and is available for outpatient follow-up

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

For outpatients:

- Return promptly with systemic symptoms, worsening local symptoms, or failure to improve within 48 hours. Consider a follow-up within 48 hours of initial visit to assess response and review culture.

### *PATIENT EDUCATION*

- Keep wounds that are draining covered with clean, dry bandages.
- Clean hands regularly with soap and water or alcohol-based gel. Hot soapy shower daily.
- Do not share items that may be contaminated (including razors or towels).
- Clean clothes, towels, and bed linens
- National MRSA Education Initiative: [www.cdc.gov/mrsa/](http://www.cdc.gov/mrsa/)
- A mixture of 1/4-cup household bleach diluted in 1 gallon of water can be used to clean surfaces.

### *PROGNOSIS*

In outpatients, improvement should occur within 48 hours.

### **COMPLICATIONS**

- Necrotizing pneumonia or empyema (after an influenza-like illness)
- Necrotizing fasciitis
- Sepsis syndrome
- Pyomyositis and osteomyelitis
- Purpura fulminans
- Disseminated septic emboli
- Endocarditis

**&NA;**

## **ICD10**

- A49.02 Methicillin resis staph infection, unsp site
- A41.02 Sepsis due to Methicillin resistant Staphylococcus aureus
- J15.212 Pneumonia due to Methicillin resistant Staphylococcus aureus

## **Clinical Pearls**

**&NA;**

- Incise and drain purulent lesions and send for wound culture if abscess is present.
- Local susceptibility patterns of CA-MRSA dictate antibiotic treatment. The CDC has a helpful algorithm for outpatient treatment of CA-MRSA:  
[http://www.cdc.gov/mrsa/pdf/Flowchart\\_pstr.pdf](http://www.cdc.gov/mrsa/pdf/Flowchart_pstr.pdf)
- CA-MRSA skin lesions are commonly misidentified as spider bites.

# Mild Cognitive Impairment

**Birju B. Patel, MD, FACP, AGSF**

**N. Wilson Holland, MD, FACP, AGSF**

## BASICS

### DESCRIPTION

- Mild cognitive impairment (MCI) is defined as significant cognitive impairment in the absence of dementia, as measured by standard memory tests:
  - Concern regarding change in cognition
  - Preservation of independence in functional activities (ADLs)
  - Impairment in <sup>3</sup>1 cognitive domains (attention, executive dysfunction, memory, visuospatial, language) (1)
  - Other terms used in the literature relating to MCI: isolated memory impairment; cognitive impairment not dementia (CIND); predementia; mild cognitive disorder; age-associated memory impairment; age-related cognitive decline; benign senescent forgetfulness. Some of these conditions do not progress to dementia (i.e., benign senescent forgetfulness, age-associated memory impairment, age-related cognitive decline). *DSM-5* mentions "mild neurocognitive disorder" (NCD) which may be a precursor to Alzheimer disease and has many of the same features as MCI (2).
- Annual rates of conversion of MCI to dementia are 2-15% in the elderly.

### EPIDEMIOLOGY

#### Incidence

- Predominant sex: male > female (3)
- Predominant age:
  - Higher in older persons and in those with less education
  - 12 to 15/1,000 person-years in those age <sup>3</sup>65 years
  - 54/1,000 person-years in those age <sup>3</sup>75 years

## *Prevalence*

- MCI is more prevalent than dementia in the United States.
- 3-5% for those age <sup>3</sup>60 years
- 15% for those age <sup>3</sup>75 years

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Subtypes of MCI:
  - Single-domain amnestic
  - Multiple-domain amnestic
  - Nonamnestic single-domain
  - Nonamnestic multiple-domain
- The amnestic subtype is higher risk for progression to Alzheimer disease (4).
- Vascular, degenerative, traumatic, metabolic, psychiatric, or a combination

## *Genetics*

Apolipoprotein (APO) E4 genotype: Various pathways exist leading to amyloid accumulation and deposition thought to be associated with dementia.

## *RISK FACTORS*

- Age
- Diabetes
- Hypertension
- Hyperlipidemia
- Cerebrovascular disease
- Smoking
- Sleep apnea
- APO E4 genotype

## *COMMONLY ASSOCIATED CONDITIONS*

See òRisk Factorsó (5).

# DIAGNOSIS

## HISTORY

- Focus on cognitive deficits and impairment.
- Review all medications that may affect cognition; give particular emphasis to anticholinergic medications (patients on these may mistakenly be classified as having MCI).
- Rule out depression.
- Assess function (ADLs, instrumental ADLs) and subtle changes in daily function (e.g., in the workplace).
- Impact on interpersonal relationships and caregiver stress
- Assess vascular risk factors (hypertension, diabetes, hyperlipidemia, and cerebrovascular disease).
- Assess behavioral changes.

## PHYSICAL EXAM

- A general exam focusing on clinical clues to identifying vascular disease (e.g., bruits, abnormal BP)
- Neurologic exam to rule out reversible CNS causes cognitive impairment or other causes of cognitive impairment (e.g., Parkinson disease).
- Office measures of cognitive function, depression, and functional status

## DIFFERENTIAL DIAGNOSIS

- Delirium
- Dementia
- Depression
- Reversible cognitive impairment
  - Medications (anticholinergics and medications with anticholinergic properties)
  - Hypothyroidism
  - Vitamin B<sub>12</sub> deficiency
- Reversible CNS conditions
- Give consideration to sleep conditions, especially sleep apnea, that can contribute to cognitive

deficits.

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- CBC
- Comprehensive metabolic profile
- Thyroid-stimulating hormone
- Vitamin B<sub>12</sub>
- Lipids
- Consider HIV testing in the appropriate risk setting.
- Imaging tests are helpful when there are focal neurologic deficits or rapid or atypical presentations:
  - CT scan can detect structural CNS conditions leading to cognitive impairment:
    - Subdural hematoma
    - Normal pressure hydrocephalus
    - Metastatic disease
  - MRI further evaluates vascular, infectious, neoplastic, and inflammatory conditions.
- Cognitive testing is important (e.g., Montreal Cognitive Assessment [MOCA] and Saint Louis University Mental Status [SLUMS]); MOCA may be more sensitive for detecting and following MCI.
- Neuropsychological testing for complex and atypical presentations
- Vascular risk factor reduction and treatment

### *Follow-Up Tests & Special Considerations*

- Document progression of functional impairment, cognitive decline, concurrent depression, and comorbid conditions.
- Advanced planning while patient is competent.
- Early education of caregivers on safety, maintaining structure, managing stress, and future planning

### *Test Interpretation*

- Little is known about MCI pathology due to a lack of longitudinal studies.
- Alzheimer dementia pathophysiology:
  - Neurofibrillary tangles in hippocampus
  - Senile plaques (amyloid deposition)
  - Neuronal degeneration
- Those with MCI have intermediate amounts of pathologic findings of Alzheimer disease with amyloid deposition and neurofibrillary tangles in the mesial temporal lobes compared with those with dementia.
- Amnestic MCI is associated with white matter hyperintensity volume on MRI, whereas nonamnestic MCI is associated with infarcts.

P.675

## TREATMENT

### GENERAL MEASURES

Atherosclerotic risk factors should be treated aggressively.

### MEDICATION

The use of cholinesterase inhibitors (ChEIs) in MCI is not associated with any delay in the onset of Alzheimer disease or dementia. Moreover, the safety profile showed that the risks associated with ChEIs are significant. Therefore, ChEIs are not routinely recommended (6)[A],(7)[C].

### ISSUES FOR REFERRAL

Consider referral to a memory specialist (i.e., geriatrician, neurologist, geropsychiatrist, neuropsychologist) to evaluate and differentiate subtypes of MCI and specific cognitive deficits.

### ADDITIONAL THERAPIES

There may be benefit in terms of improvement in performance on tests for global cognitive functioning with cognitive training and physical exercise (2)[C]

### COMPLEMENTARY & ALTERNATIVE MEDICINE

- No evidence suggests the efficacy of vitamin E in the prevention or treatment of people with MCI. More research is needed to identify the role of vitamin E, if any, in the management of cognitive impairment.

- Long-term use of ginkgo biloba extract has shown to have no benefit in the treatment of MCI and in terms of progression to dementia. In addition, ginkgo biloba can be associated with increase in bleeding risk including CNS bleeds (8)[B].

## *INPATIENT CONSIDERATIONS*

- Delirium is more common in patients hospitalized with all forms of cognitive impairment.
- Avoid medications that may worsen or precipitate cognitive decline (e.g., anticholinergics, antihistamines).
- Patients may be extremely sensitive to the hospital environment:
  - Moderate level of stimulation is best.
  - Avoid sensory deprivation. Make sure that patients have access to hearing aids and eyeglasses.
  - Use frequent cueing and have caregivers or family in the room whenever possible with patient.
  - Frequently orient patients to date and time.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Patients should be reevaluated every 6 to 12 months to determine if symptoms are progressing.

#### *Patient Monitoring*

Appropriate cognitive and functional testing should be used to evaluate progression, along with clinical history and exam. If a medication is started, patients need to be followed more frequently to evaluate for efficacy, side effects, dose titration, and so forth. Declining executive function may be an early marker to progression of MCI to dementia, and clinicians should monitor and advise patients and families proactively to look for this. Impairments in ADL function is a good clue to progression to dementia from MCI.

#### *DIET*

Diets that are promoted by the American Heart Association to minimize atherosclerotic risk factors should be emphasized.

### *PATIENT EDUCATION*

- Encourage lifestyle changes:

- Physical activity, such as walking 30 minutes daily on most days of the week
- Mental activity that stimulates language skills and psychomotor coordination should be encouraged. Computer activities, reading books, crafts, crossword puzzles, and games may be linked to decreased risk of development of MCI (9)[C],(10)[B].
- Cognitive rehabilitation strategies may be beneficial in helping with daily activities relating to memory tasks in MCI.
- Participation in exercise programs modestly improved some measures of cognition in some studies.
- Treatment of vascular risk factors (hypertension, diabetes, cerebrovascular disease, and hyperlipidemia) is important in lowering risk of progression to dementia.

## PROGNOSIS

- Conversion rates from MCI to dementia range from 5% to 15% annually.
- Amnesic subtypes of MCI are most likely to progress to dementia.
- MCI has prognostic value in that once it is diagnosed, there is a higher risk of progression to dementia (11)[B].

## Codes

&NA;

### ICD10

G31.84 Mild cognitive impairment, so stated

## Clinical Pearls

&NA;

- Amnesic MCI affects primarily memory and is more likely to progress to Alzheimer dementia.
- Screen for reversible factors, particularly anticholinergic medications, depression, and sleep disorders.
- Look closely at vascular risk factors and modify them as best as possible.

- ChEIs should not be used routinely unless memory complaints are affecting quality of life in patients. Potential side effects of these medications should be thoroughly discussed with patients and their families. A baseline EKG should be done prior to initiation of ChEIs due to risk of bradycardia and syncope.
- Encourage both physical and mental exercises.

# Mitral Regurgitation

Yongkasem Vorasettakarnkij, MD, MSc

## BASICS

### DESCRIPTION

- Disorder of mitral valve (MV) closure, either primary or secondary (functional), resulting in a backflow of the left ventricular (LV) stroke volume into the left atrium (LA); uncompensated, this leads to LV and LA enlargement, elevated pulmonary pressures, atrial fibrillation, heart failure, and sudden cardiac death
- Types of mitral regurgitation (MR):
  - Acute versus chronic
  - Primary versus secondary (functional)
    - Primary: MV structures include not only the mitral annulus, MV leaflets, chordae tendineae, and papillary muscles but also posterior LA wall and LV wall.
    - Secondary: No valvular abnormalities are found. The abnormal and dilated LV causes papillary muscle displacement, resulting in leaflet tethering with annular dilatation that prevents coaptation.
- System(s) affected: cardiac; pulmonary

### EPIDEMIOLOGY

Moderate to severe MR affects 2.5 million people in the United States (2000 data). It is the most common valvular disease, and its prevalence is expected to double by 2030 (1).

### Prevalence

- By severity on echocardiography:
  - Mild MR: 19% (up to 40% if trivial jets included)
  - Moderate MR: 1.9%
  - Severe MR: 0.2%
- By category (1)

- Degenerative (myxomatous disease, annular calcification): 60-70%
- Ischemic: 20%
- Endocarditis: 2-5%
- Rheumatic: 2-5%

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Acute MR: acute damage to MV leads to sudden LA and LV volume overload. Sudden rise in LV volume load without compensatory LV remodeling results in impaired forward cardiac output and possible cardiogenic shock.
- Chronic MR: LV eccentric hypertrophy compensates for increased regurgitant volume to maintain forward cardiac output and alleviate pulmonary congestion. However, ongoing LV remodeling can result in LV dysfunction. Simultaneously, LA compensatory dilatation for the larger regurgitant volume predisposes patients to develop atrial fibrillation (AF).
- Ischemic MR: papillary muscle rupture, ischemia during acute myocardial infarction (MI), and incomplete coaptation of valve leaflets or restricted valve movement resulting from ischemia
- Acute MR
  - Flail leaflet: myxomatous disease, infective endocarditis, or trauma
  - Ruptured chordae tendineae: trauma, spontaneous rupture, infective endocarditis, or rheumatic fever
  - Ruptured or displaced papillary muscle: acute MI, severe myocardial ischemia, or trauma
- Chronic MR
  - Primary
    - Degenerative: mitral annular calcification, mitral valve prolapse (MVP)
    - Infective endocarditis
    - Rheumatic heart disease (RHD)
    - Inflammatory diseases: lupus, eosinophilic endocardial disease
    - Anorectic drugs
    - Congenital (cleft leaflet)
  - Secondary (functional)
    - Ischemic: coronary artery disease (CAD)/MI

- Nonischemic: cardiomyopathy, LV dysfunction from any cause, hypertrophic cardiomyopathy

## **RISK FACTORS**

Age, hypertension, RHD, endocarditis, anorectic drugs

## **GENERAL PREVENTION**

- Risk factor modification for CAD
- Antibiotic prophylaxis for poststreptococcal RHD
- Endocarditis prophylaxis for MR is no longer recommended.

## **COMMONLY ASSOCIATED CONDITIONS**

MVP with MR common in Marfan syndrome

## **DIAGNOSIS**

### **HISTORY**

- Associated conditions: RHD, prior MI, connective tissue disorder
- Acute MR
  - Sudden onset of dyspnea
  - Orthopnea, paroxysmal nocturnal dyspnea
  - Chronic MR
    - Exertional dyspnea
    - Fatigue
    - Palpitation: paroxysmal/persistent AF

## **PHYSICAL EXAM**

- Acute MR
  - Rapid and thready pulses
  - Sign of poor tissue perfusion with peripheral vasoconstriction
  - Hyperdynamic precordium without apical displacement
  - S<sub>3</sub> and S<sub>4</sub> (if in sinus rhythm)

- Systolic murmur at left sternal border and base
  - Early, middle, or holosystolic murmur
  - Often soft, low-pitched decrescendo murmur
- Rales
- Chronic MR
  - Brisk upstroke of arterial pulse
  - Leftward displaced LV apical impulse
  - Systolic thrill at the apex (suggests severe MR)
  - Soft  $S_1$  and widely split  $S_2$ ,  $S_3$  gallop
  - Loud  $P_2$  (if pulmonary hypertension)
  - Holosystolic murmur at apex that radiates to axilla
  - Ankle edema, jugular venous distension, and ascites, if development of right-sided heart failure

## *DIFFERENTIAL DIAGNOSIS*

- Aortic stenosis (AS): usually midsystolic but can be long; difficult to distinguish from holosystolic, at apical area, and radiating to the carotid arteries (unlike MR)
- Tricuspid regurgitation: holosystolic but at left lower sternal border; does not radiate to axilla or increase in intensity with inspiration (unlike MR)
- Ventricular septal defect (VSD): harsh holosystolic murmur at lower left sternal border but radiates to right sternal border (not axilla)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Chest x-ray (CXR)
  - Acute MR: pulmonary edema, normal heart size
  - Chronic MR: LA and LV enlargement
- ECG
  - Acute MR
    - Varies depending on etiologies (e.g., acute MI)

## Chronic MR

- P mitrale from LA enlargement, AF
- LV hypertrophy
- Q waves from prior MI

## *Initial Tests (lab, imaging)*

- Cardiac enzymes and brain natriuretic peptide (BNP), if appropriate
- Transthoracic echocardiogram (TTE)
  - Indications for TTE (2)
    - Baseline evaluation of LV size and function, right ventricular function and LA size, pulmonary artery pressure, and severity of MR
    - Delineation of mechanism of MR
    - Surveillance of asymptomatic moderate to severe LV dysfunction (ejection fraction [EF] and end-systolic dimension [ESD])
    - Evaluate MV apparatus and LV size and function after a change in signs/symptoms in a patient with MR.
    - Evaluate after MV repair or replacement.
  - Findings in acute MR
    - Evidence of etiology: flail leaflet or infective vegetations
    - Normal LA and LV size
  - Findings in chronic MR
    - Evidence of degenerative, rheumatic, ischemic, congenital, and other causes
    - Enlarged LA and LV

## *Follow-Up Tests & Special Considerations*

- Intervals for follow up TTE: See Follow-Up Recommendations.
- Cardiovascular magnetic resonance (CMR):
  - TTE results are not satisfactory to assess LV and RV volumes, function, or MR severity (2) [C].

## Transesophageal echocardiogram (TEE)

- Intraoperatively to define the anatomic basis of MR and to guide repair (2)[C]
- Nondiagnostic information about severity, mechanism of MR, and/or status of LV function from noninvasive imaging (2)[C]
- Exercise hemodynamics with either doppler echo or cardiac catheterization (2)[C]
  - Discrepancy between symptoms and the severity of MR from resting TTE in symptomatic patients with chronic primary MR
- Exercise treadmill testing (2)[C]
  - To establish symptom status and exercise tolerance in asymptomatic patients with chronic primary MR.
- Noninvasive imaging (stress nuclear/positron emission tomography, CMR, stress echocardiography), cardiac CT angiography, or cardiac catheterization, including coronary angiography
  - To establish etiology of chronic secondary MR and/or to assess myocardial viability (2)[C]

## *Diagnostic Procedures/Other*

### Cardiac catheterization (2)

- Left ventriculography and hemodynamic measurement
  - Noninvasive tests are inconclusive regarding severity of MR, LV function, or the need for surgery.
- Coronary angiography: prior to MV surgery in patients at risk for CAD

## *Test Interpretation*

Quantification of severe MR requires integration of the following:

- Structural parameters
  - LA size: dilated, unless acute
  - LV size: dilated, unless acute

- 
- Leaflets: abnormal
  - Doppler parameters

## TREATMENT

### MEDICATION

- Acute, severe MR
  - Medical therapy has a limited role and is aimed primarily to stabilize hemodynamics preoperatively.
  - Vasodilators (nitroprusside, nicardipine): to improve hemodynamic compensation but is often limited by systemic hypotension (2)
- Chronic MR
  - Primary
    - Asymptomatic: no proven long-term medical therapy
    - Symptomatic: diuretics, *&agr;*-blockers (carvedilol, metoprolol), angiotensin-converting enzyme inhibitors (ACEIs) or angiotensin receptor blockers (ARBs), and possibly aldosterone antagonists as indicated in standard therapy for heart failure (2)[C]
  - Secondary: LV dysfunction or symptomatic (stages B-D)
    - ACEIs or ARBs, *&agr;*-blockers, and/or aldosterone antagonists as indicated in standard therapy for heart failure (2)[C]

### SURGERY/OTHER PROCEDURES

- Isolated MV surgery is not indicated for patients with mild to moderate MR.
- Acute, severe MR secondary to acute MI
  - Acute rupture of papillary muscle: emergency MV repair/replacement
  - Papillary muscle displacement
    - Aggressive medical stabilization and intra-aortic balloon pump
    - Valve surgery usually required in addition to revascularization.
- Chronic severe MR
  - MV repair in an experienced center is recommended over MV replacement in most circumstances (3):

- Survival rate: early and overall mortality were lower after MV repair than after MV replacement
- 10-year rate of stroke: 10% (repair) versus 12% (bioprosthetic valve replacement) versus 23% (mechanical valve replacement)
- Risk of endocarditis: 1.5% at 15 years versus 0.3-1.2% per year
- Overall rates of reoperation are similar.
- Severe primary MR (2)
  - MV surgery
    - Symptomatic patients (stage D)
      - Absence of severe LV dysfunction (EF  $\geq$ 30%) (2)[B]
      - Severe LV dysfunction (EF <30%) (2)[C]
    - Asymptomatic patients
      - Mild to moderate LV dysfunction (EF 30-60% and/or ESD  $\geq$ 40 mm, stage C2) (2)[B]
      - MV repair is reasonable for asymptomatic patients (stage C1) with preserved LV function (EF >60% and ESD <40 mm):
        - The likelihood of successful repair without residual MR is >95% and expected mortality <1% when performed at a heart valve center of excellence (2)[C].
        - Nonrheumatic MR with new onset AF or resting pulmonary hypertension (pulmonary artery systolic pressure [PASP] >50 mm Hg) and the likelihood of a successful and durable repair is high (2)[C].
  - Transcatheter MV repair:
    - May be considered for severely symptomatic patients (NYHA class III/IV) despite optimal GDMT for HF, who have a reasonable life expectancy but a prohibitive surgical risk because of severe comorbidities (2)[C]
- Severe secondary MR (2)
  - MV surgery
    - Undergoing coronary artery bypass graft (CABG) or aortic valve replacement (AVR) (2)[C]
    - Persistent symptom (NYHA class III-IV) despite optimal GDMT for HF (2)[C]

- Cardiac resynchronization therapy with biventricular pacing is recommended for symptomatic patients (stage B-D) who meet the indications for device therapy (2)[C].

## *Geriatric Considerations*

- Medical therapy alone for patients >75 years of age with MR is preferred, owing to increased operative mortality and decreased survival (compared with those with AS), especially with preexisting CAD or need for MV replacement.
- MV repair is preferable than MV replacement.

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

Acute MR: Stabilize ABCs (airway, breathing, circulation). Initiate IV, O<sub>2</sub>, and monitoring.

Nitroprusside (+dobutamine and/or aortic balloon counterpulsation if hypotensive). Treat underlying causes (e.g., MI). Treat acute pulmonary edema with furosemide and morphine.

Obtain urgent surgical consultation.

## **ONGOING CARE**

### **FOLLOW-UP RECOMMENDATIONS**

Chronic MR: asymptomatic

- Mild MR with normal LV size and function and no pulmonary hypertension: Annual clinical evaluation to assess symptom progression and TTE every 3 to 5 years to assess MR severity, LV size and function.
- Moderate MR: annual clinical evaluation and TTE every 1 to 2 years
- Severe MR: clinical evaluation and TTE every 6 to 12 months
- Consider serial CXRs and ECGs, and consider stress test if exercise capacity is doubtful.

### **PATIENT EDUCATION**

- Exercise after MV repair: Avoid sports with risk for bodily contact or trauma. Low-intensity competitive sports are allowed.
- Competitive athletes with MR
  - Asymptomatic with normal LV size and function, normal pulmonary artery pressures, and sinus rhythm: no restrictions

- Mildly symptomatic and those with LV dilatation: Activities with low to moderate dynamic and static cardiac demand allowed
- AF and anticoagulation: no contact sports

## PROGNOSIS

- Acute, severe MR: Mortality risk with surgery is 50%; mortality risk with medical therapy alone is 75% in first 24 hours and 95% at 2 weeks.
- Chronic MR: asymptomatic severe MR with normal LVEF: 10% yearly rate of progression to symptoms and subnormal resting LVEF. Symptomatic severe MR: 8-year survival rate, 33% without surgery; mortality rate, 5% yearly

## Pregnancy Considerations

MR with NYHA functional class III-IV at high risk for maternal and/or fetal risk

### COMPLICATIONS

Acute pulmonary edema, CHF, AF, bleeding risk with anticoagulation, endocarditis, sudden cardiac death

## Codes

**&NA;**

### **ICD10**

- I34.0 Nonrheumatic mitral (valve) insufficiency
- I05.1 Rheumatic mitral insufficiency
- Q23.3 Congenital mitral insufficiency

## **Clinical Pearls**

**&NA;**

- Follow-up for mild to moderate MR: serial exam and/or echo unless LV structural changes
- Severe MR is usually managed with MV repair.
- Endocarditis prophylaxis is not recommended.

# Mitral Stenosis

**Zeeshan Hussain, MD**

**Nirmanmoh Bhatia, MD**

**Marcus F. Stoddard, MD**

## **BASICS**

### *DESCRIPTION*

- Mitral stenosis (MS) presents as resistance to diastolic filling of the left ventricle (LV) due to narrowing of mitral valve (MV) orifice.
- Normal valve orifice 4 to 6 cm<sup>2</sup>; symptoms typically seen when orifice is <2.5 cm<sup>2</sup>.
- Hemodynamic consequences are due to passive transmission of left atrial (LA) pressure to the pulmonary circulation; may coexist with mitral regurgitation and aortic valvulopathies
- Stages vary from A (with risk factors), B (hemodynamically obstruction), C (severe but no symptoms), to D (symptomatic) (1)

### *EPIDEMIOLOGY*

- Most common acquired valvular disease secondary to rheumatic heart disease (60% of cases)
- Predominant age: Symptoms primarily occur in 4th to 7th decades.
- Predominant sex: female > male (2:1)

### *Incidence*

Decreased incidence of MS is seen in the United States because of decreased incidence of rheumatic fever (primarily shift in prevalence away from rheumatogenic strains of group A streptococci [GAS] and also treatment of GAS infection). However, global burden remains significant (2).

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Obstruction between LA and LV impairs LV filling during diastole and leads to increased LA pressure.
- Increased LA pressure is transmitted passively (back pressure) to the pulmonary circulation;

over time, pulmonary hypertension (HTN) results.

- Over time, LA pressure overload can dilate the chamber and interrupt the cardiac conduction system, resulting in atrial fibrillation.
- Pulmonary HTN can also cause increased collateralization between pulmonary and bronchial circulation, resulting in intraparenchymal hemorrhage with hemoptysis.
- Rheumatic fever: most common (see *Risk Factors*)
- Aging (extension of mitral annular calcification)
- Rare causes
  - Congenital (associated with mucopolysaccharidoses)
  - Autoimmune: systemic lupus erythematosus (SLE), rheumatoid arthritis
  - Malignant carcinoid
  - Other acquired: LA myxoma, LA thrombus, endomyocardial fibrosis

## *RISK FACTORS*

- Rheumatic fever is the greatest risk factor.
  - 30-40% of rheumatic fever patients eventually develop MS, presenting an average of 20 years after diagnosis of rheumatic fever.
  - Acute rheumatic fever occurs 2 to 3 weeks after episode of untreated GAS pharyngitis caused by rheumatogenic organism in a genetically susceptible host.
  - Low socioeconomic status (i.e., crowded conditions) favors the spread of streptococcal infection.
- Aging (increasing valvular calcification)
- Chest irradiation (increasing tissue fibrosis)

## *GENERAL PREVENTION*

- Prompt recognition and treatment of GAS infection; recognition of cardinal signs and symptoms of acute rheumatic fever via Jones criteria
- Modified Jones criteria for acute rheumatic fever: Diagnosis requires evidence of streptococcal infection plus two major criteria or one major plus two minor criteria.

Evidence of streptococcal                      Antistreptolysin O titer or positive throat culture

infection

Major criteria      Carditis, polyarthritits, Sydenham chorea, erythema marginatum, subcutaneous nodules

Minor criteria      Migratory arthralgias, fever, acute phase reactants (elevated erythrocyte sedimentation rate [ESR], leukocytosis), prolonged PR interval on ECG

## COMMONLY ASSOCIATED CONDITIONS

- Atrial fibrillation (30-40% of symptomatic patients)
- Associated valve lesions due to chronic inflammation (aortic stenosis, aortic insufficiency)
- Pulmonary congestion and pulmonary HTN
- Right heart failure
- Systemic embolism, pulmonary embolism (10%)
- Infection, including infectious endocarditis (1-5%)

## DIAGNOSIS

### HISTORY

- History of rheumatic fever
- Severity of presentation depends on valve area; most early cases will be asymptomatic.
- Mean age of presentation is usually 50 to 60 years (3).
- Presenting features usually due to pulmonary vascular congestion: Palpitations, dyspnea on exertion, fatigue, pulmonary edema, and paroxysmal nocturnal dyspnea may cause chest pain.
- Atrial fibrillation, embolic event
- In advanced disease, symptoms of HTN and right heart failure predominate: jugular venous distention, hepatomegaly, ascites, and peripheral edema
- Other presentations: hemoptysis, hoarseness (compression of recurrent laryngeal nerve by enlarged pulmonary artery or LA), dysphagia (compression), rarely as infective endocarditis
- Infection, atrial fibrillation with rapid rate, exercise, or pregnancy may exacerbate symptoms.

## PHYSICAL EXAM

- Reduced peripheral pulses
- Auscultation
  - Classic murmur: accentuated  $S_1$ , opening snap, apical early decrescendo diastolic rumble with presystolic accentuation
  - Murmur variability seen in severe stenosis
    - With mobile, noncalcified valve, murmur persists throughout diastole and  $S_1$ , and the opening snap remains loud.
    - With a heavily calcified valve, murmur often is difficult to hear.  $S_1$  and the opening snap may be soft to absent.
    - In contrast to tricuspid stenosis, the intensity of the murmur from MS increases with inspiration and a prominent *a* wave in jugular venous pulse.
- If HTN is present: Right ventricle (RV) lift, increased  $P_2$ , high-pitched decrescendo diastolic murmur of pulmonic insufficiency (Graham Steell murmur) may have signs of right heart failure.
- May also find associated aortic or, less commonly, tricuspid murmurs due to aortic or tricuspid valve involvement from rheumatic heart disease

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- ECG (4,5)[C]
  - LA enlargement (manifested by broad, notched P waves in lead II [P mitrale] with a negative terminal deflection of the P wave in lead  $V_1$ )
  - Atrial fibrillation is common.
  - Right ventricular hypertrophy (RVH), right axis deviation, and a large R wave in  $V_1$  are possible.
- Chest radiograph (4,5)[C]
  - LA enlargement, straightening of the left heart border, a double density, and elevation of the left main stem bronchus
  - Prominent pulmonary arteries at the hilum with rapid tapering, RVH

- Pulmonary edema pattern with Kerley B lines (late presentation)
- ECG indications (1)[B],(5)[C]
  - Class I
    - Diagnosis of MS
    - Assess severity.
    - Reassess after change in symptoms.
    - Exercise Doppler for discrepancies between symptoms and echo findings.
    - During evaluation for commissurotomy
    - TEE when transthoracic echo nondiagnostic, to exclude thrombus in left atrium or to evaluate severity of MR (1)[B]
  - Class II
    - Reassess asymptomatic patients.
    - Very severe (<1.0 cm<sup>2</sup>) MS: yearly
    - Severe (≥1.5 cm<sup>2</sup>) MS: every 1 to 2 years
    - Mild or moderate MS: every 3 to 5 years
  - Class III
    - Satisfactory result of transthoracic echo
- ECG findings
  - MV anterior leaflet doming, immobility of the posterior leaflet
  - Echo can demonstrate alternative causes of MS if not rheumatic.
  - MV area defined (1)
    - Normal: 4 to 6 cm<sup>2</sup>
    - Progressive MS: >1.5 cm<sup>2</sup>
    - Severe MS: <1.5 cm<sup>2</sup>
    - Very severe: <1.0 cm<sup>2</sup>
- Cardiac catheterization indications (1,5)[C]
  - Class I recommendations

- When echo is inconclusive
- Discrepancy between echo and symptoms
- Discrepancy between echo and valve area
- Class II recommendations
  - To assess response of LA and pulmonary artery pressures to exercise when symptoms and echo findings do not match
  - Assess cause of severe HTN out of proportion to echo results.
- Class III recommendations: satisfactory result of echo

### *Follow-Up Tests & Special Considerations*

- If valve area  $>1.5 \text{ cm}^2$  and mean pressure gradient  $<5 \text{ mm Hg}$ , then no further initial workup is needed.
- If valve area is  $<1.5 \text{ cm}^2$ , then do further workup prior to surgical correction.

---

P.679

### *Diagnostic Procedures/Other*

Exercise or dobutamine stress test (1,5)[C].

- When symptoms are severe but echo findings are mild
- To determine if surgery is needed

### *Test Interpretation*

Rheumatic fever-induced pathologic changes: leaflet thickening, leaflet calcification, commissural fusion, chordal shortening

## **TREATMENT**

### **GENERAL MEASURES**

- Exercise
  - Patients with mild MS are usually asymptomatic even with strenuous exercise.
  - Usually recommend low-level aerobic exercise, limited by symptoms of dyspnea (5)[C]

- Counsel patients that MS usually is slowly progressive but can have sudden onset of atrial fibrillation, which could become rapidly fatal. Call 911 for marked worsening of symptoms.
- Atrial fibrillation accompanying MS impairs LV filling, especially with a rapid ventricular response.
  - Rate control with  $\beta$ -blockers or calcium channel blockers (1)[C]
  - Cardioversion for medical failure or if patient is unstable (6)[B]
  - If the atrial fibrillation has been present for >24 to 48 hours, then anticoagulate for 3 weeks then cardiovert, or alternatively, heparinize, perform TEE, and if no atrial thrombus, then cardiovert (6)[B].
  - After cardioversion, patient needs long-term anticoagulation.
  - These patients can critically decompensate due to loss of atrial contractility, causing an inability to fill the LV.

## MEDICATION

### First Line

- Because MS is a mechanical anomaly, medical management is always considered adjunctive to interventional management when the latter is indicated.
- Antibiotic prophylaxis against rheumatic fever and/or carditis is recommended for patients with history of rheumatic fever (1)[C].
  - Penicillin V PO or penicillin G IM: IM is more effective than PO (7)[A].
  - Sulfadiazine
  - Macrolides: Take antibiotic continuously to prevent recurrence of rheumatic fever or carditis.
  - Duration of rheumatic fever prophylaxis
    - Rheumatic fever without carditis: Take for 5 years or until age 21 years, whichever is longer.
    - Rheumatic fever with carditis but no residual heart disease: Take for 10 years or well into adulthood, whichever is longer.
    - Rheumatic fever with carditis plus residual heart disease: Take for 10 years or until 40 years old, whichever is longer.
- Antibiotic prophylaxis against infective endocarditis is not routinely recommended (1)[B].
- $\beta$ -Blockers or calcium channel blockers for tachycardia or exertional symptoms (1)[B]

- Diuretics for congestive symptoms (5)[C]
- Digitalis for atrial fibrillation if LV or RV dysfunction (5)[C]
- Anticoagulation (1)[B]
  - Class I recommendations
    - MS and atrial fibrillation or history of atrial fibrillation
    - MS and prior embolic event
    - MS and LA thrombus
  - Class IIB recommendations
    - Asymptomatic MS but with severe MS and LA dimension >54 mm by echo
    - Severe MS, enlarged LA and spontaneous contrast on echo
- Warfarin (international normalized ratio) range 2 to 3
- Heparin in the acute atrial fibrillation setting
- The new oral anticoagulants (factor Xa inhibitor and direct thrombin inhibitor) are not approved for use in atrial fibrillation that is secondary to MS.

## *Second Line*

Amiodarone for rate control if *&bgr*-blockers or calcium channel blockers cannot be used (5)[C]

## *SURGERY/OTHER PROCEDURES*

- Balloon valvotomy: symptomatic patients with NYHA class II, III, or IV symptoms with valves that look favorable and with favorable comorbidities (1)[A]
- MV surgery: when MS is severe and balloon valvotomy is contraindicated due to unfavorable anatomy (1)[B],(8)[C]

## *Pregnancy Considerations*

Volume expansion during pregnancy can exacerbate heart failure symptoms. Hence, MS often presents during the intrapartum period. For patients with known severe MS, intervention should be pursued before pregnancy. Such patients have a high rate of both maternal and fetal complications, including death. Percutaneous balloon valvotomy can be performed in symptomatic pregnant patients.

# ONGOING CARE

## *FOLLOW-UP RECOMMENDATIONS*

- Ascertain the valve gradient and pulmonary arterial pressure with ECG.
- Follow-up will depend on the severity of the MS and the patient's symptoms.
  - Asymptomatic patients: annual history and examination; follow-up serial echocardiography based on the severity of MS
  - Symptomatic patients are reviewed according to individual therapy, symptoms, and signs; ECG to evaluate for changes (1)[C]

## *DIET*

Salt restriction for pulmonary congestion

## *PROGNOSIS*

Natural history

- Asymptomatic latent period after rheumatic fever for 10 to 30 years. 10-Year survival for asymptomatic or minimally symptomatic patients is 80%. 10-Year survival after onset of symptoms is 50-60%.
- Symptoms typically become debilitating 10 years after onset.
- 10-Year survival after onset of debilitating symptoms is only 0-15%.
- Mean survival with significant HTN is <3 years.
- The severity of MS progresses over time in almost all patients. There are no known definitive medical therapies, apart from prevention of recurrent rheumatic fever, that alter its natural history. When symptoms develop, balloon valvotomy, open mitral commissurotomy, or closed mitral commissurotomy provides effective means of reducing stenosis but is not curative. Restenosis sometimes occurs and can be early (<5 years) or late (>20 years).
- Appropriate medical treatment can delay necessity for surgery, and surgical treatment substantially prolongs survival in patients with severe MS.

## **COMPLICATIONS**

Left and right heart failure, atrial fibrillation and systemic embolization, pulmonary HTN, bacterial endocarditis

- Gužrios EE, Bueno R, Nercolini D, et al. Mitral stenosis and percutaneous mitral valvuloplasty (part 1). *J Invasive Cardiol*. 2005;17(7):382-386.

**&NA;**

## **ICD10**

- I05.0 Rheumatic mitral stenosis
- I05.8 Other rheumatic mitral valve diseases
- I34.2 Nonrheumatic mitral (valve) stenosis

## **Clinical Pearls**

**&NA;**

- Asymptomatic patients may be followed clinically with yearly exams for development of symptoms with periodic echo to evaluate valve area.
- Once symptoms of MS develop, initiate appropriate medical therapy but advise patient that, for most, surgical therapy will be needed to prolong survival. Almost all cases of MV stenosis progress in severity over time.
- MS often presents during the intrapartum period. For patients with known severe MS, intervention should be pursued prior to pregnancy. Pregnancy in a patient with severe MS has a high rate of both maternal and fetal complications, including death.

# Mitral Valve Prolapse

**Zeeshan Hussain, MD**

**Wasiq Faraz Rawasia, MD**

**Marcus F. Stoddard, MD**

## **BASICS**

### *DESCRIPTION*

- Mitral valve prolapse (MVP) is a systolic billowing of one or both mitral leaflets into the left atrium (LA) during systole  $\pm$  mitral regurgitation (MR).
- More specifically, MVP is a single or bileaflet prolapse of at least 2 mm superior displacement into the LA during systole on the parasternal long-axis annular plane of the valve on echocardiogram  $\pm$  leaflet thickening.
  - Classic: prolapse with  $>5$  mm of leaflet thickening
  - Nonclassic: prolapse with  $<5$  mm of leaflet thickening (1)
- Synonym(s): systolic click-murmur syndrome; billowing mitral cusp syndrome; myxomatous mitral valve; floppy valve syndrome; redundant cusp syndrome; Barlow syndrome

### *EPIDEMIOLOGY*

#### *Incidence*

- Predominant age: MVP has been described in all age groups.
- Initial descriptions based on clinical examinations suggested a 2:1 female predominance. Using modern echocardiogram criteria, men and women are affected equally (2).
- The most serious consequences of hemodynamically significant MR occur in men age  $>50$  years.

#### *Prevalence*

MVP is the most common valvular abnormality, affecting 1.0-2.5% of the general population, depending on the precise definition (2,3).

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- The pathology causing MVP is multifactorial and includes the following:
  - Abnormal valve tissue
    - Myxomatous degeneration: redundant layers of leaflet, hooding of the cords, chordal elongation, and annular dilatation
    - Myxoid leaflets are more elastic and less stiff than normal valves.
    - Chordal rupture is more common.
  - Disparity in size between the mitral valve and the left ventricle (LV)
  - Connective tissue disorders (1)
- MVP is often associated with variable degrees of MR.
- Frequently, there is enlargement of the LA and LV.
- Mitral annulus is often dilated.
- Involvement of other valves may occur (tricuspid valve prolapse 40%, pulmonic prolapse and aortic prolapse 2-10%).
- Possible increased vagal tone
- Possible increased urine epinephrine and norepinephrine
- MVP patients often have orthostatic hypotension and tachycardia.
- Genetics causes proliferation of the spongiosa layer of the leaflets (3).
- Fibrosis on surface of leaflets (3)
- Thinning and elongation of chordae tendineae
- The mitral valve differentiates during days 35 to 42 of fetal development, the same time as differentiation of the vertebrae and ribs.

## *Genetics*

- Familial MVP is inherited as an autosomal dominant trait but with variable expressivity and incomplete penetrance.
- Two genetic loci identified
  - *MMVP1* on chromosome 16p11.2-p12.1
  - *MMVP2* on chromosome 11p15.4

## *RISK FACTORS*

- MVP is a primary cardiovascular disorder.
- MVP is more likely to occur in patients with connective tissue disorders (see *Commonly Associated Conditions*).
- Physical characteristics associated with MVP
  - Straight thoracic spine
  - Pectus excavatum
  - Asthenic body habitus
  - Low body mass index (BMI)
  - Scoliosis or kyphosis
  - Hypermobility of the joints
  - Arm span > height
  - Narrow anteroposterior (AP) diameter of the chest

## COMMONLY ASSOCIATED CONDITIONS

- Marfan syndrome (91% of Marfan syndrome patients have MVP, although large majority of MVP patients do not meet criteria for Marfans.) (1)
- Ehlers-Danlos syndrome
- Hypertrophic cardiomyopathy
- Pseudoxanthoma elasticum
- Osteogenesis imperfecta
- von Willebrand disease
- Primary hypomastia

## DIAGNOSIS

Physical exam and echocardiography

### HISTORY

- Most patients are asymptomatic.
- The most frequent symptom is palpitations.
- Symptoms related to autonomic dysfunction
  - Anxiety and panic attacks

- Arrhythmias
- Exercise intolerance
- Palpitations and chest pains that are atypical for coronary artery disease (CAD)
- Fatigue
- Orthostasis, syncope, or presyncope
- Neuropsychiatric symptoms
- Symptoms related to progression of MR
  - Fatigue
  - Dyspnea
  - Exercise intolerance
  - Orthopnea
  - Paroxysmal nocturnal dyspnea
  - Congestive heart failure (CHF)
- Symptoms occur as a result of an associated complication (stroke, arrhythmia).

## *PHYSICAL EXAM*

- Auscultatory examination
  - Mid to late systolic click
    - May vary in timing and intensity based on ventricular beat-to-beat volume variations
    - At low ventricular volumes, the valve may prolapse earlier during systole and further into the LA than during volume overload.
    - It may or may not be followed by a highpitched, mid to late systolic murmur at the cardiac apex.
  - Murmur: a mid to late crescendo systolic murmur best heard at apex, middle- to high-pitched, occasionally musical or honking in quality
  - Occasionally, only the ejection click is present.
  - The duration of the murmur corresponds with the severity of MR.
- Dynamic auscultation
  - Maneuvers that move the click and murmur toward S<sub>1</sub>

- Arterial vasodilation
- Amyl nitrite
- Valsalva
- Augmented contractility
- Decreased venous return (which can be induced by standing up)
- Maneuvers that move the click and murmur toward S<sub>2</sub>
  - Squatting
  - Leg raise
  - Isometric exercise
- Valsalva maneuver may help differentiate hypertrophic obstructive cardiomyopathy (HOCM) from MVP because it increases the intensity of the murmur in HOCM whereas it makes it longer but not louder in MVP.

## ***DIFFERENTIAL DIAGNOSIS***

- MR
- Tricuspid regurgitation
- Tricuspid valve prolapse
- Papillary muscle dysfunction
- Hypertrophic cardiomyopathy
- Ejection clicks (do not change timing with systole)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Echocardiogram (test of choice) (4)[B],(5)[C]
  - In asymptomatic individuals with physical signs of MVP, an echocardiogram is indicated for diagnosis (4)[B].
  - Follow-up echocardiograms are not indicated for asymptomatic patients who have MVP with no changes clinically, even if they had mild MR (4,5)[C].
  - Parasternal long-axis view is most specific for diagnosis (4).
  - Findings that may be seen with MVP

- Anterior leaflet billowing
- Leaflet thickening of  $\geq 3$  mm
- Leaflet redundancy
- MR
- Posterior leaflet displacement
- Nondiagnostic transthoracic echocardiogram:  $\approx 10\%$
- Transesophageal echocardiography particularly with 3D imaging may be considered to further visualize the anatomy if an intervention is being planned (6)[B].
- Stress echocardiograms may reveal exercise-induced MR or latent LV dysfunction (1,5)[C].
- Angiography
  - Rarely used for diagnostic purposes
  - MVP may be incidentally seen on a catheterization.
- ECG is usually normal.
  - May be nonspecific ST-T wave changes
  - T-wave inversions, prominent Q waves, or prolonged QT may also occur.

---

P.681

- A chest x-ray (CXR) is not necessary for diagnosis.
  - Typically, the CXR is normal.
  - Other findings
    - Possible pulmonary edema: Pulmonary edema may be asymmetric with acute chordal rupture and flail leaflet.
    - Possible calcification of the mitral annulus
- Holter monitoring is optional if patient has palpitations. Order Holter monitoring as usual for syncope or dizziness
- Tilt table testing may be of value in patients with MVP who presents with syncope of unknown etiology.

### *Follow-Up Tests & Special Considerations*

Patients with a family history of MVP should be screened with echocardiography (4)[B].

## Test Interpretation

- Myxomatous proliferation of the middle layer (spongiosa) of the valve, resulting in increased mucopolysaccharide deposition and myxomatous degeneration
- By electron microscopy, the collagen fibers in the valve leaflets are disorganized and fragmented.
- With increased stroma deposition, the valve leaflets enlarge and become redundant.
- The endothelium is usually noncontiguous and a frequent site for thrombus or infective vegetation.

## TREATMENT

### GENERAL MEASURES

Treat MVP with orthostatic symptoms by liberalizing fluid and salt intake. If severe, mineralocorticoids may rarely be used. Support stockings may also be beneficial.

### MEDICATION

- Asymptomatic MVP is treated with reassurance; normal lifestyle and regular exercise is encouraged.
- MVP and transient ischemic attacks are treated with aspirin 75 to 325 mg daily (Class I recommendation) (4)[C].
- MVP with history of cryptogenic stroke, or atrial fibrillation with CHADS<sub>2</sub> (acronym for Congestive heart failure, Hypertension, Age >75 years, Diabetes mellitus, and prior Stroke or transient ischemic attack) score <2, is generally treated with aspirin 75 to 325 mg daily (4)[C].
- MVP with atrial fibrillation with CHADS<sub>2</sub> score <sup>3</sup>2 is treated with warfarin (4)[C].
- MVP with high-risk echocardiographic features (thickening >5 mm or valve redundancy) and a history of stroke, warfarin therapy may be considered (4)[C].
- MVP with palpitations is treated with *β*-blockers and/or recommendation to discontinue alcohol, cigarettes, and caffeine (5)[C].

### ADDITIONAL THERAPIES

- Endocarditis prophylaxis is no longer recommended for MVP.
- Patients with prior endocarditis undergoing dental, respiratory tract, infected skin, or musculoskeletal procedures should receive prophylaxis for endocarditis with amoxicillin 30 to

60 minutes prior to procedure. Ampicillin, cefazolin, or ceftriaxone IM or IV may be used if unable to tolerate oral medications (4)[B].

## ***SURGERY/OTHER PROCEDURES***

- Referral for surgery is recommended for patients with severe MR with impaired LV systolic function or flail leaflet owing to ruptured chordae tendineae (4)[C].
- Minimally invasive mitral valve repair patients have shorter postoperative hospital stay compared with conventional median sternotomy open repair for patients with bileaflet prolapse and severe MR (7)[B].
- Surgical repair of MR due to isolated posterior leaflet prolapse is associated with a low reoperation rate (8)[A].
- Asymptomatic patients with atrial fibrillation or pulmonary hypertension should be considered for intervention as well (3)[C].

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Asymptomatic MVP patients with no significant MR can be followed clinically every 3 to 5 years (4)[C].
- Patients who are symptomatic or have high-risk features on initial echocardiogram, including moderate to severe MR, may need serial echocardiograms and should be followed clinically once per year (4)[C].
- Patients with MVP and severe MR may require coronary angiography and transesophageal echocardiography if cardiac surgical referral is planned (4)[C].

### ***PATIENT EDUCATION***

- No contraindication to pregnancy
- Restriction from competitive sports if patient has MVP with one of the following features (9):
  - A history of syncope associated with document arrhythmia
  - A family history of MVP-related sudden cardiac death
  - Sustained or repetitive and nonsustained supraventricular tachycardia or frequent and/or complex ventricular tachyarrhythmias on ambulatory Holter monitoring
  - Severe MR

- A prior embolic event
- LV systolic dysfunction
- Explain the hereditary nature of familial MVP.

## PROGNOSIS

- Excellent prognosis for asymptomatic patients
- For patients with severe MR or reduced ejection fraction, the prognosis is similar to that for nonischemic MR.

## COMPLICATIONS

- Sudden cardiac death: not clearly established. May be secondary to ventricular arrhythmias especially if significant MR is present (1,5).
- Chordae rupture with acute mitral insufficiency (higher risk of cardiac death; up to 2% per year)
- Infectious endocarditis (risk increased if murmur present) (5)
- Cerebrovascular ischemic event (1)
- Fibrin emboli
- Heart failure with progressive MR
- Arrhythmias such as atrial and ventricular premature beats, paroxysmal supraventricular tachycardias may all be seen. Risk increases with coexistent MR (5).
- Pulmonary hypertension

### Codes

&NA;

### ICD10

I34.1 Nonrheumatic mitral (valve) prolapse

# Clinical Pearls

**&NA;**

- MVP patients may have orthostatic hypotension and tachycardia.
- Asymptomatic MVP patients with no significant MR can be followed clinically every 3 to 5 years. Patients who are symptomatic or have high-risk features on initial echocardiogram, including moderate to severe MR, may need serial echocardiograms and should be followed clinically once per year.
- Endocarditis prophylaxis is no longer recommended for MVP.

# Molluscum Contagiosum

Erica F. Crannage, PharmD, BCPS, BCACP

Rupal Trivedi, MD

## BASICS

### *DESCRIPTION*

Molluscum contagiosum is a common, benign, viral (poxvirus) skin infection, characterized by small (2 to 5 mm), waxy white or flesh-colored, domeshaped papules with central umbilication. When lesions are opened, a creamy, white-gray material can be expressed. Molluscum contagiosum is highly contagious and spreads by autoinoculation, skin-to-skin contact, sexual contact, and shared clothing/towels. Molluscum contagiosum is a self-limited infection in immunocompetent patients but can be difficult to treat and disfiguring in immunocompromised patients.

### *EPIDEMIOLOGY*

#### *Prevalence*

- 1% in the United States, occurring mainly in children 2 to 15 years and sexually active young adults
- 5-18% HIV population

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- DNA virus; Poxviridae family
- Four genetic virus types, clinically indistinguishable
- Virions invade and replicate in cytoplasm of epithelial cells causing abnormal cell proliferation
- Genome encodes proteins to evade host immune system.
- Incubation period: 2 to 6 weeks
- Time to resolution: 6 to 24 months
- Not associated with malignancy
- No cross-hybridization or reactivation by other poxviruses

## *RISK FACTORS*

- Skin-to-skin contact with infected person
- Contact sports
- Swimming
- Eczema, atopic dermatitis
- Sexual activity with infected partner
- Immunocompromised: HIV, chemotherapy, corticosteroid therapy, transplant patients

## *GENERAL PREVENTION*

- Avoid skin-to-skin contact with host (e.g., contact sports, sexual activity).
- Avoid sharing clothing and towels.

## *COMMONLY ASSOCIATED CONDITIONS*

- Atopic dermatitis
- Immunosuppression medications: corticosteroids, chemotherapy
- HIV/AIDS

## **DIAGNOSIS**

### **HISTORY**

- Contact with known infected person
- Participation in contact sports
- Sexual activity

## *PHYSICAL EXAM*

- Perform thorough skin exam including conjunctiva and anogenital area
- Discrete, firm papules with a central umbilication
- Umbilication is not obvious in small children.
- White curdlike core under umbilicated center
- Lesions are flesh, pearl, or red in color.
- May have surrounding erythema or dermatitis

- Immunocompetent hosts: average of 11 to 20 lesions, 2 to 5 mm diameter (range: 1 to 10 mm)
- Hosts with HIV/AIDS: hundreds of widespread lesions
- Children: trunk, extremities, face, anogenital region
- Sexually active: inner thighs, anogenital area

### *Pediatric Considerations*

- Infants <3 months, consider vertical transmission
- Children: fever, >50 lesions, limited response to therapy, consider immunodeficiency
- Children: anogenital lesions, consider autoinoculation/possible sexual abuse

### **DIFFERENTIAL DIAGNOSIS**

- AIDS patients: cryptococcus, penicilliosis, histoplasmosis, coccidioidomycosis
- Basal cell carcinoma
- Benign appendageal tumors: syringomas, hydrocystomas, ectopic sebaceous glands
- Condyloma acuminatum
- Dermatofibroma
- Eyelid: abscess, chalazion, foreign-body granuloma
- Folliculitis/furunculosis
- Keratoacanthoma
- Oral squamous cell carcinoma
- Trichoepithelioma
- Verruca vulgaris
- Warty dyskeratoma

### **DIAGNOSTIC TESTS & INTERPRETATION**

#### *Initial Tests (lab, imaging)*

- Virus cannot be cultured.
- Culture lesion if concern is secondary infection
- Sexual transmission: Test for other sexually transmitted infections, including HIV.

- Microscopy: scrape lesion
  - Core material has characteristic Henderson-Paterson intracytoplasmic viral inclusion bodies.
  - Crush prep with 10% potassium hydroxide will show characteristic inclusion bodies as well.
  - Alternatively, hematoxylin-eosin-stained formalin-fixed tissue shows same confirmatory features.

## *Diagnostic Procedures/Other*

Clinical; using magnifying lens

## *Tests Interpretation*

Molluscum cytoplasmic inclusion bodies within keratinocytes

## **TREATMENT**

### *GENERAL MEASURES*

- In healthy patients, molluscum contagiosum is generally self-limited and heals spontaneously.
- No single intervention is shown to be convincingly more effective than any other in treating molluscum contagiosum (1)[B].
- No treatment is FDA-approved for treatment of molluscum contagiosum.
- Three categories of treatment: destructive, immuneenhancing, and antiviral

### *MEDICATION*

#### *First Line*

- Cantharidin 0.7-0.9% solution: In office application to lesions, cover with dressing; wash off in 2 to 6 hours or sooner if blistering. Repeat treatment every 2 to 4 weeks until lesions resolve (1)[B],(2,3)[C].
  - Not commercially available in the United States but may be obtained from Canada
  - Adverse effects: blistering, erythema, pain, pruritus
  - Precautions: Do not use on face or on genital mucosa.

#### *Second Line*

- Benzoyl peroxide 10% cream: Apply to each lesion twice daily for 4 weeks (1)[B].

- Inexpensive
- Adverse effects: mild dermatitis
- For immunocompromised patients with refractory lesions, consider
  - Starting or maximizing HAART therapy in patients with HIV/AIDS (4)[C]

P.683

- Cidofovir
  - 3% cream applied to lesions once daily, 5 days/week for 8 weeks (4)[C]
  - 1% cream applied to lesions once daily, 5 days/week for 2 weeks, repeat in 1 month, if necessary (4)[C]
  - Adverse effects with topical use: erythema, pain, pruritus, erosions
  - 3 to 5 mg/kg IV weekly for 1 to 2 weeks, followed by IV infusions every other week, until clinical clearance or up to 9 infusions (5)[C]
  - Adverse effects with IV use: nephrotoxicity, neutropenia
  - Monitoring with IV use: renal function and complete blood counts prior to and 24 to 48 hours after infusions
  - Precaution: Must coadminister oral probenecid and provide IV hydration with each IV infusion; refer to cidofovir manufacturer's recommendations on dosing.
- Ingenol mebutate 0.015% gel applied to lesions once daily for 3 days; may repeat once if needed (6)[C] very expensive
  - Adverse effects: erythema, irritation

## ***SURGERY/OTHER PROCEDURES***

Considered first line

- Cryotherapy: 5 to 10 seconds with 1- to 2-mm margins; repeat every 3 to 4 weeks as needed until lesions disappear (7)[B].
  - Adverse effects: erythema, edema, pain, blistering
  - Contraindications: cryoglobulinemia, Raynaud disease
- Curettage under local or topical anesthesia (1)[A],(8)[B]
  - Adverse effects: pain, scarring

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Australian lemon myrtle oil: Apply 10% solution once daily for 21 days (9)[B].
- Potassium hydroxide 5-10% solution: Apply 1 to 2 times a day until the lesions disappeared completely (10)[B].

### *Pediatric Considerations*

- Surgical interventions: Second line in small children due to associated pain
- Pain control: Pretreat with topical lidocaine or EMLA before surgical treatment.
- Note: Adverse effect:
  - Lidocaine or EMLA over large body surface area: Methemoglobinemia and CNS toxicity. Refer to manufacturer's recommendations on dosing and use in children.

### *Pregnancy Considerations*

Safe in pregnancy: curettage, cryotherapy, incision, and expression

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Depends on type of treatment

### *PATIENT EDUCATION*

- Cover lesions to prevent spread.
- Avoid scratching.
- Avoid contact sports.
- Avoid sharing towels and clothing.
- Avoid sexual activity when lesions present.

### *PROGNOSIS*

- Immunocompetent: self-limited, resolves in 3 to 12 months (range: 2 months to 4 years)
- Immunocompromised: lesions difficult to treat; may persist for years

## COMPLICATIONS

- Secondary infection
- Scarring, hyper-/hypopigmentation

## Codes

**&NA;**

### ICD10

B08.1 Molluscum contagiosum

## Clinical Pearls

**&NA;**

- Natural resolution is preferred treatment in healthy patients.
- Reassure parents that lesions will heal naturally and generally resolve without scarring.
- No specific treatment has been identified as superior to any other.
- Consider topical corticosteroids for pruritus or associated dermatitis.

# Morton Neuroma (Interdigital Neuroma)

Catherine Mygatt, MD

J. Herbert Stevenson, MD

## BASICS

### DESCRIPTION

- Perineural fibrosis of the common digital nerve as it passes between metatarsals
  - The interspace between the 3rd and 4th metatarsals is most commonly affected.
  - Between the 2nd and 3rd metatarsals is the next most common site.
- System(s) affected: musculoskeletal, nervous
- Synonym(s): plantar digital neuritis; Morton metatarsalgia; intermetatarsal neuroma

### EPIDEMIOLOGY

#### Prevalence

- Unknown
- Mean age: 45 to 50 years
- Predominant sex: female > male (8:1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Lateral plantar nerve joins a portion of medial plantar nerve, creating a nerve with a larger diameter than those going to other digits.
- Nerve lies in SC tissue, deep to the fat pad of foot, just superficial to the digital artery and vein.
- Overlying, the nerve is the strong, deep transverse metatarsal ligament that holds the metatarsal bones together.
- With each step the patient takes, the inflamed nerve becomes compressed between the ground and the deep transverse metatarsal ligament. This can generate perineural fibrotic reaction with subsequent neuroma formation.

## *RISK FACTORS*

- High-heeled shoes
  - Transfer more weight to the forefoot.
- Shoes with tight toe boxes
  - Cause lateral compression
- Pes planus (flat feet)
  - Pulls nerve medially, increasing irritation
- Obesity
- Female gender
- Ballet dancing, basketball, aerobics, tennis, running, and similar activities

## *GENERAL PREVENTION*

- Wear properly fitting shoes.
- Avoid high heels and shoes with narrow toe boxes.

## **DIAGNOSIS**

### **HISTORY**

- Most common complaint is pain localized to interspace between 3rd and 4th toes.
- Pain is less severe when not bearing weight.
- Pain, cramping, or numbness of the forefoot during weight bearing or immediately after strenuous foot exertion
- Radiation of pain to the toes
- Pain is relieved by removing shoes and massaging the foot.
- Patients often complain of "walking on a marble."
- Burning pain in the ball of the foot radiating to the toes
- Tingling or numbness in the toes
- Aggravated by wearing tight or narrow shoes

## *PHYSICAL EXAM*

- Intense pain when pressure applied between metatarsal heads, sometimes with a palpable nodule
- Assess midfoot motion and digital motion to determine if arthritis or synovitis.
- Palpate along metatarsal shafts to assess for metatarsalgia or stress fractures.

## *DIFFERENTIAL DIAGNOSIS*

- Stress fracture
- Hammer toe
- Metatarsophalangeal synovitis
- Metatarsalgia
- Arthritis
- Bursitis
- Foreign body

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Predominantly a clinical diagnosis; imaging should be reserved for when the diagnosis is unclear or more than one web space is involved (1)[A],(2)[B].
- Radiographs may help to rule out osseous pathology if diagnosis is in question, but films usually are normal in patients with a Morton neuroma (1)[A].
- US has 79% specificity and 99% sensitivity for Morton neuromas but is poor at assessing the size of the lesion. Specificity declines to 50% for lesions <6 mm (1)[A].
- MRI can rule out an osseous tumor and help determine how much of the nerve to resect surgically; it has a sensitivity of 83% and a specificity of 99% (1)[A].

### *Diagnostic Procedures/Other*

- Five special tests have been described: thumb index finger squeeze test, Mulder sign, foot squeeze test, plantar percussion test, and toe tip sensation deficit.
  - Thumb index finger squeeze test is the most sensitive and specific (96% and 96%, respectively). Positive when pain elicited by squeezing the symptomatic intermetatarsal space between the index finger and thumb (3)[B].
  - Mulder sign is a painful "click" produced by squeezing the metatarsal heads together while

compressing the neuroma between the thumb and index finger of the other hand; sensitivity 40-84% (1)[A].

- Foot squeeze test is positive when pain is induced in the symptomatic web space when the metatarsal heads are compressed by grasping the foot; sensitivity 40% (3)[B].
  - Plantar and dorsal percussion tests are positive when percussion of the affected webspace is painful.
  - Toe tip sensation deficit exists when the sensation of the toe distal to the affected web space is decreased relative to the other toes.
- More than one of the above tests being positive increases the diagnostic accuracy (4)[B].

## *Test Interpretation*

Chronic fibrosis and thickening of the digital nerve

## **TREATMENT**

### *GENERAL MEASURES*

- Wear flat shoes with a roomy toe box.
- Plantar pads may help with alignment of metatarsal heads and provide relief.
- NSAIDs for temporary symptom relief

### *MEDICATION*

#### *First Line*

Injectable steroids (e.g., betamethasone phosphate/acetate or methylprednisolone): use if general measures fail; number needed to treat (NNT) for significant benefit over conservative measures = 2.3 (5,6)[A].

---

P.685

#### *Second Line*

- US-guided alcohol ablation therapy to sclerose the nerve is safe, reduces pain, and may offer an alternative to surgery (7,8)[B].
- A pilot study has demonstrated that injection with onabotulinumtoxin is of possible usefulness to relieve the pain and improve function in Morton neuroma (9)[B].
- There is no evidence for the use of supinatory insoles (10)[A].

## ISSUES FOR REFERRAL

Continued pain despite conservative treatments and injections.

## SURGERY/OTHER PROCEDURES

Surgical removal of the neuroma or shortening of the metatarsals, with or without release of the transverse metatarsal ligament, have a 61-100% success rate defined by satisfaction scores (11) [A].

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

At diagnosis, or if no improvement after 3 months of conservative treatment, consider corticosteroid injection.

- May repeat injection if no improvement after 2 to 4 weeks, or consider referring for surgical management.
- 21-51% of patients receiving a single corticosteroid injection require surgical intervention within 2 to 4 years (12)[B].
- Size >5 mm and younger patients are more likely to undergo invasive treatment (12)[B].

### PATIENT EDUCATION

Wear properly fitting comfortable shoes.

### PROGNOSIS

- 40-50% improve with 3 months of conservative treatment.
- 45-60% improve with steroid injection (6)[A].
- 96% improve with surgery.

### COMPLICATIONS

Hip and knee pain related to gait changes

- Schreiber K, Khodaei M, Poddar S, et al. Clinical inquiry. What is the best way to treat Morton's neuroma? *J Fam Pract.* 2011;60(3):157-158, 168.

## Codes

&NA;

### ICD10

- G57.60 Lesion of plantar nerve, unspecified lower limb
- G57.61 Lesion of plantar nerve, right lower limb
- G57.62 Lesion of plantar nerve, left lower limb

## Clinical Pearls

&NA;

- Morton neuroma is usually a clinical diagnosis.
- Footwear modification is the mainstay of treatment.
- Corticosteroid injection into, or US-guided alcohol ablation of the neuroma may be helpful.
- Neurectomy is the definitive treatment. Patients should be aware of the likelihood of postoperative dysesthesias.

# Motion Sickness

Courtney I. Jarvis, PharmD

Allison Hargreaves, MD

## BASICS

### DESCRIPTION

- Motion sickness is not a true sickness but a normal response to a situation in which sensory conflict about body motion exists among visual receptors, vestibular receptors, and body proprioceptors.
- Also can be induced when patterns of motion differ from those previously experienced
- System affected: nervous
- Synonym(s): car sickness; sea sickness; air sickness; space sickness; physiologic vertigo

### EPIDEMIOLOGY

#### *Incidence*

Predominant sex: female > male

#### *Prevalence*

Estimation is complex; syndrome occurs in ÷25% due to travel by air, ÷29% by sea, and ÷41% by road. Estimates for vomiting are 0.5% by air, 7% by sea, and 2% by road.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Precise etiology unknown; thought to be due to a mismatch of vestibular and visual sensations
- Rotary, vertical, and low frequency motions produce more symptoms than linear, horizontal, and highfrequency motions.
- Nausea and vomiting occur as a result of increased levels of dopamine and acetylcholine, which stimulate chemoreceptor trigger zone and vomiting center in CNS.

#### *Genetics*

Heritability estimates range from 55% to 75%.

## **RISK FACTORS**

- Motion (auto, plane, boat, amusement rides)
- Travel
- Visual stimuli (e.g., moving horizon)
- Poor ventilation (fumes, smoke, carbon monoxide)
- Emotions (fear, anxiety)
- Zero gravity
- Pregnancy, menstruation, oral contraceptive use
- History of migraine headaches, especially vestibular migraine
- Other illness or poor health

## **GENERAL PREVENTION**

See "General Measures."

### ***Pediatric Considerations***

- Rare in children <2 years of age
- Incidence peaks between 3 and 12 years of age.
- Antihistamines may cause excitation in children.

### ***Geriatric Considerations***

- Age confers some resistance to motion sickness.
- Elderly are at increased risk of anticholinergic side effects from treatment.

### ***Pregnancy Considerations***

- Pregnant patients are more likely to experience motion sickness.
- Treatment with medications is thought to be safe during morning sickness (e.g., meclizine, dimenhydrinate).

## **COMMONLY ASSOCIATED CONDITIONS**

- Migraine headache
- Vestibular syndromes

# DIAGNOSIS

## HISTORY

Presence of the following signs and symptoms in the context of a typical stimulus (1)[C]:

- Nausea
- Vomiting
- Stomach awareness (feeling of fullness in epigastrium)
- Diaphoresis
- Facial and perioral pallor
- Hypersalivation
- Yawning
- Hyperventilation
- Anxiety
- Panic
- Malaise
- Fatigue
- Weakness
- Confusion
- Dizziness

## PHYSICAL EXAM

No specific findings

## DIFFERENTIAL DIAGNOSIS

- Mountain sickness
- Vestibular disease, central and peripheral
- Gastroenteritis
- Metabolic disorders
- Toxin exposure

## DIAGNOSTIC TESTS & INTERPRETATION

None indicated

## TREATMENT

- Follow guidelines under "General Measures" section to prevent motion sickness (1)[C].
- Premedicate before travel with antidopaminergic, anticholinergic, or antihistamine agents (1)[A]:
  - For extended travel, consider treatment with scopolamine transdermal patch (2)[A].
  - 2nd-generation (nonsedating) antihistamines are not effective at preventing motion sickness (3)[B].
  - Serotonin (5-HT<sub>3</sub>) antagonists (e.g., ondansetron) are not effective in preventing motion sickness (4)[B].
- Conflicting data exist on the efficacy of acupuncture for nausea and vomiting associated with motion sickness (5)[B].
- Benzodiazepines suppress vestibular nuclei but would not be considered first line due to sedation and addiction potential (6)[C].
- Serotonin receptor agonist (rizatriptan) may be effective for migraineurs with motion sickness (7)[C].

## GENERAL MEASURES

- Avoid noxious types of motions.
- Choose locations within vehicle that minimizes motion (airplanes: over the wing; automobiles: driver's or front passenger seat, facing forward; boat: facing towards the waves, away from rocking bow, near surface of the water; buses: near the front, at lowest level, facing forward; trains: at lowest level, facing forward).
- Improve ventilation; avoid noxious stimuli.
- Use semirecumbent seating or lay supine.
- Fix vision on horizon; avoid fixation on moving objects; keep eyes fixed on still, distant objects.
- Avoid reading while actively traveling.
- Frequent and graded exposure to stimulus that triggers nausea (habituation).
- Eat before travel, avoid empty stomach; eat light, soft, bland, low-fat, and low-acid foods; avoid alcohol.
- Increase airflow around face.

Acupressure on point PC6 has been shown to reduce feelings of nausea but not the incidence of vomiting during pregnancy, after surgery, and in cancer chemotherapy. However, conflicting evidence of efficacy has been found for motion sickness. Point PC6 (*Neiguan* on pericardium meridian): 2 cm proximal of transverse crease of palmar side of wrist between tendons of the palmaris longus and the flexor carpi radialis (5)[B]

## MEDICATION

### First Line

- Scopolamine transdermal patch (Transderm Scop): Apply 2.5-cm<sup>2</sup> (4 mg) patch behind ear at least 4 hours (preferably 6 to 12 hours) before travel, and replace every 3 days (2)[A].
- Dimenhydrinate (Dramamine): take 30 to 60 minutes before travel
  - Adults and adolescents: 50 to 100 mg q4-6h, maximum 400 mg/day
  - Children 6 to 12 years of age: 25 to 50 mg q6-8h, maximum 150 mg/day
  - Children 2 to 5 years of age: 12.5 to 25 mg q6-8h, maximum 75 mg/day
- Meclizine (Antivert): take 60 minutes before travel
  - Adults and adolescents >12 years of age: 25 to 50 mg q24h
  - Children <12 years of age: not recommended
- Diphenhydramine (Benadryl): take 30 to 60 minutes before travel
  - Adults and adolescents: 25 to 50 mg q6-8h, maximum 300 mg/day
  - Children 6 to 12 years of age: 5 mg/kg or 12.5 to 25 mg q6-8h, maximum 300 mg/day
- Promethazine (Phenergan): take 30 to 60 minutes before travel
  - Adults and adolescents: 25 mg q12h; 25 to 50 mg IM if already developed severe motion sickness
  - Children 2 to 12 years of age: 0.5 mg/kg q12h, maximum 25 mg BID. *Caution:* increased risk of dystonic reaction in this age group
- Contraindications: patients at risk for acute angleclosure glaucoma
- Precautions:
  - Young children
  - Elderly

- Pregnancy
- Urinary obstruction
- Pyloric-duodenal obstruction
- Adverse reactions:
  - Drowsiness
  - Dry mouth
  - Blurred vision
  - Confusion
  - Headache
  - Urinary retention
- Significant possible interactions:
  - Sedatives (antihistamines, alcohol, antidepressants)
  - Anticholinergics (belladonna alkaloids)

## *Second Line*

- Benzodiazepines: take 1 to 2 hours before travel
  - Diazepam 2 to 10 mg PO q6-12h
  - Lorazepam 1 to 2 mg PO q8h
- Contraindications:
  - Severe respiratory dysfunction
  - Severe liver dysfunction
  - Precautions:
    - Alcohol/drug abuse
    - Elderly
    - Sedation
    - Addiction is possible.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Ginger: 940 mg or 1 g; take 4 hours before travel (evidence controversial) (8)[B]

## ONGOING CARE

### DIET

- Eat before travel, avoid empty stomach; eat light, soft, bland, low-fat, and low-acid foods.
- Avoid alcohol.

### PROGNOSIS

- Symptoms should resolve when motion exposure ends.
- Resistance to motion sickness seems to increase with age.

### COMPLICATIONS

- Hypotension
- Dehydration
- Depression
- Panic
- Syncope

## Codes

&NA;

### ICD10

T75.3XXA Motion sickness, initial encounter

## Clinical Pearls

&NA;

- The scopolamine patch should be applied at least 4 hours before travel, although it may be more effective if placed 6 to 12 hours before departure.
- Oral medications should be administered 30 to 60 minutes before departure.
- Although acupressure wristbands have been found to be effective by systematic reviews in postoperative and chemotherapy-induced nausea and vomiting, conflicting data exist for motion sickness.

# Multiple Myeloma

Jasmine S. Beria, DO, MPH

Maria M. Plummer, MD

## BASICS

### DESCRIPTION

- Multiple myeloma (MM) is a clonal proliferation of malignant plasma cells.
- This clonal proliferation in the bone marrow can cause extensive skeletal destruction with osteolytic lesions and pathologic fractures.
- The malignant plasma cells produce monoclonal protein in the blood and urine.
- MM is also characterized by hypercalcemia, increased susceptibility to infections, renal impairment, and end-organ damage.
- Monoclonal gammopathy of undetermined significance (MGUS) is a common disorder with limited monoclonal plasma cell proliferation that progresses to MM at rate of  $\div 1\%$  per year.
- MGUS progresses to smouldering or asymptomatic MM and eventually to symptomatic MM.
- Synonym(s): plasma cell myeloma; plasma cell leukemia

### EPIDEMIOLOGY

- Accounts for  $\div 1\%$  of all cancers and slightly  $>10\%$  of hematologic malignancies in the United States
- Median age of diagnosis is 69 years.
- Slight male predominance. Blacks about 2 to 3 times more commonly affected than whites; less common in Asians.

### Incidence

4 to 5 new cases/100,000 annually

### Prevalence

In 2012, there were 89, 658 cases in the United States (1).

## ETIOLOGY AND PATHOPHYSIOLOGY

- Clonal proliferation of plasma cells derived from postgerminal center B cells (2)
- Plasma cells undergo multiple chromosomal mutations to progress to MM.
- Genetic damage in developing B lymphocytes at time of isotype switching, transforming normal plasma cells into malignant cells, arising from single clone
- Earliest chromosomal translocations involve immunoglobulin heavy chains on chromosome 14q32, with the translocation at t(4;14), t(14;16), t(14;20), and deletion, del(17p) having a poorer prognosis.
- Malignant cells multiply in bone marrow, suppressing normal bone marrow cells and producing large quantities of monoclonal immunoglobulin (M) protein.
- Malignant cells stimulate osteoclasts that cause bone resorption and inhibit osteoblasts that form new bone, causing lytic bone lesions.

### Genetics

Rare family clusters; the hyperphosphorylated form of Paratarg-7, a protein of unknown significance, is inherited as an autosomal dominant trait in familial cases of MM and MGUS, suggesting a potential pathogenic role.

## RISK FACTORS

- Most cases have no known risks associated.
- Older age; immunosuppression; and chemicals like dioxin, herbicides, insecticides, petroleum, heavy metals, plastics, and ionizing radiation increase the risk of MM.
- MGUS stage consistently precedes MM.

## COMMONLY ASSOCIATED CONDITIONS

Secondary amyloidosis commonly due to MM

## DIAGNOSIS

### HISTORY

- 34% of patients are asymptomatic at the time of presentation.
- Hypercalcemia (28%): anorexia, nausea, somnolence, and polydipsia
- Renal failure (20-50%)
- Anemia (73%)

- Bony lesions (80%): lytic lesions causing bone pain (58%) (3), osteoporosis or pathologic fracture (26-34%)
- Other symptoms: fatigue (32%), peripheral neuropathy, weight loss (24%), recurrent infections, hyperviscosity syndrome, and cord compression

## *PHYSICAL EXAM*

- Dehydration
- Skin findings of amyloidosis: waxy papules, nodules, or plaques that may be evident in the eyelids, retroauricular region, neck, or inguinal and anogenital regions; petechiae and ecchymosis; Öpinch purpuraÖ
- Extramedullary plasmacytomas can present as large, purplish, subcutaneous masses.
- Hyperviscosity syndrome in 7%: retinal hemorrhages, prolonged bleeding, neurologic changes
- Tender bones and masses

## *DIFFERENTIAL DIAGNOSIS*

- MGUS
- Smoldering MM
- Metastatic carcinoma (kidney, breast, non-small cell lung cancer)
- Waldenström macroglobulinemia
- AL amyloidosis
- Solitary plasmacytoma
- Polyneuropathy, organomegaly, endocrinopathy, M protein, skin changes (POEMS) syndrome

## *DIAGNOSTIC TESTS & INTERPRETATION*

Criteria for diagnosis: The diagnosis of MM requires the following (2)[A]:

- Bone marrow (BM) involvement with  $\geq 10\%$  of plasma cells (PC) or the presence of a plasmacytoma
- Monoclonal protein (M-spike) in the blood and/or urine
- Presence of one or more of the following: calcium elevation ( $>11$  g/dL), renal insufficiency (creatinine  $>2$  mg/dL), anemia (hemoglobin  $<10$  g/dL or  $>2$  g/dL below normal), bone disease

### *Initial Tests (lab, imaging)*

- CBC with differential to evaluate anemia and other cytopenias with evaluation of peripheral blood smear
- BUN, creatinine (elevated creatinine due to myeloma cast nephropathy)
- Serum electrolytes, serum albumin, serum calcium
- Serum lactate dehydrogenase (LDH),  $\beta_2$ -microglobulin
- Serum protein electrophoresis (SPEP), serum immunofixation electrophoresis (SIFE): M protein level elevated
- Quantitative serum immunoglobulin levels: immunoglobulin (Ig) G, IgA, and IgM
- Quantitative serum free light chain (FLC) levels:  $\kappa$  and  $\lambda$  chains
- Elevated ESR, C-reactive protein
- Urine analysis: 24-hour urine for protein, urine protein electrophoresis (UPEP), urine immunofixation electrophoresis (UIFE); 20% positive urine protein (2)[A]:
  - Urinalysis dip is often negative for protein, as this test identifies albumin, and the protein in MM is Bence-Jones (BJ) monoclonal protein.
- Bone marrow aspirate and biopsy for histology, immunohistochemistry, flow cytometry, cytogenetics, and fluorescence in situ hybridization (FISH)
- Skeletal survey: for lytic bone lesions, osteopenia, osteoporosis, or compression fractures
- MRI for any back pain or earliest signs/symptoms of spinal cord compression

### *Follow-Up Tests & Special Considerations*

- CT scan: if high suspicion for bone lesions despite normal skeletal survey; can differentiate malignant from benign vertebral compression fractures in patients who are not MRI candidates
- PET scans: used if bone involvement is suspected despite a normal skeletal survey, MRI, and CT
- Baseline bone densitometry may be indicated (2)[A].
- Bone marrow aspiration and biopsy to monitor response to treatment
- SPEP with SIFE: M protein helps to track progression of myeloma and response to treatment.
- Serum immunoglobulins and free light chains can be used to monitor response or relapse.
- Plasma cell labeling index may be helpful to identify the fraction of the myeloma cell population that is proliferating (2)[A].

## Diagnostic Procedures/Other

### Staging:

- Durie Salmon stage
  - Stage I: low cell mass:  $<0.6 \times 10^{12}$  cells/m<sup>2</sup> plus all of the following: hemoglobin  $>10$  g/dL, M protein  $<5$  g/dL if IgG or  $<3$  g/dL if IgA, normal serum calcium, urine BJ protein  $<4$  g/24 hr, no generalized lytic bone lesions
  - Stage II: neither stage I nor stage III
  - Stage III: high cell mass:  $>1.2 \times 10^{12}$  cells/m<sup>2</sup> plus one or more of the following: hemoglobin  $<8.5$  g/L, serum calcium  $>12$  mg/dL, bone lesions, M protein  $>7$ g/dL if IgG and  $>5$  g/dL if IgA, urine BJ protein  $>12$  g/24 hr, advanced lytic bone lesions
- International staging system (ISS)
  - Stage I: albumin  $\geq 3.5$  g/dL and  $\beta_2$ -microglobulin  $<3.5$  mg/g/mL
  - Stage II: neither stage I nor stage III
  - Stage III:  $\beta_2$ -microglobulin  $\geq 5.5$  mg/g/mL
- Mayo Clinic risk stratification (mSMART)
  - Standard risk: t(11:14), t(6:14), and hyperdiploidy
  - Intermediate risk: t(4:14), del(13q) by cytogenetics, hypodiploidy
  - High risk: t(14:16), t(14:20), del(17 p), and plasma cell labeling index  $>3\%$

## Test Interpretation

Bone marrow involvement with plasma cells  $\geq 10\%$ ; Russell bodies

P.689

## TREATMENT

- Treatment varies depending on level of disease activity and stage of MM.
- Treatment for smoldering MM is close monitoring at 3-month intervals. Early treatment with lenalidomide and dexamethasone delays progression and increases overall survival (3)[B].
- Key determinant factor in choosing chemotherapy regimen is to establish if the patient is an autologous stem cell transplant (ASCT) candidate or not.
- Treatment protocols vary by institution and patient.

- ASCT following induction chemotherapy is standard of care for patients with symptomatic disease.

## GENERAL MEASURES

Maintain adequate hydration to prevent renal insufficiency. All patients receiving primary melanoma therapy should be given bisphosphonates initially (2)[A].

## MEDICATION

- Induction chemotherapy for ASCT-eligible patients (4)[C]:
  - Standard risk: (lenalidomide/low-dose dexamethasone)
  - Intermediate risk: (bortezomib/cyclophosphamide/dexamethasone)
  - High risk: (bortezomib/lenalidomide/dexamethasone)
  - After ASCT, maintenance can include a bortezomib compound for the high- or intermediate-risk group; lenalidomide can be considered for the standard group. Maintenance lenalidomide after ASCT has shown to improve progression-free survival (PFS) of 41 versus 23 months with placebo and has shown to be an effective treatment for MM (5,6)[A].
- Induction chemotherapy for ASCT-ineligible patients:
  - Same regimens as ASCT-eligible patients, however, the number of treatment cycles are increased (4)[C].

## First Line

- Bortezomib
  - A proteasome inhibitor; it blocks the ubiquitinproteasome catalytic pathway in cells by binding to the 20S proteasome complex.
  - Toxicity: peripheral neuropathy, cytopenia, nausea
  - Consider herpes simplex virus (HSV) prophylaxis.
- Cyclophosphamide
  - Nitrogen mustard-derivative alkylating agent
  - Often used in combination with prednisone or thalidomide in cases of relapsed disease
  - Toxicity: cytopenia, anaphylaxis, interstitial pulmonary fibrosis, secondary malignancy, impaired fertility
- Immunomodulators

- Thalidomide and lenalidomide
  - Works by antiangiogenesis inhibition, immunomodulation, and inhibition of tumor necrosis factor
  - Toxicity: birth defects, deep vein thrombosis (DVT), neuropathy, rash, nausea, bradycardia
  - DVT prophylaxis, usually with aspirin
- Dexamethasone
  - Low doses (40 mg/week) superior to higher doses
  - Increases risk of DVT
- Bisphosphonates (7)[A]
  - No effect on mortality but decrease pain, pathologic vertebral fractures, and fractures of other bones
  - IV pamidronate or zoledronic acid can be used; evidence that zoledronic acid may be superior in preventing skeletal-related events.
  - Dose-adjust/monitor renal function.
  - Monitor for osteonecrosis of jaw.
- Alternative options:
  - As first-line treatment for transplant-ineligible patients with newly diagnosed MM, bortezomib/melphalan/prednisone was associated with significantly increased PFS compared with melphalan/prednisone (8)[A].

## *Second Line*

- May be treated with any of the agents not already used
- The following agents can be used as salvage therapy to treat relapsed or refractory MM:
  - Bortezomib/lenalidomide
  - Liposomal doxorubicin
  - Carfilzomib: 2nd-generation selective proteasome inhibitor
- Emerging options: pomalidomide, thalidomide analog
- Bortezomib is a highly effective option in previously treated/relapse patients and is well-

tolerated (9)[A].

- Interferon- $\alpha$ ; may be appropriate in selected patients, but because of its toxicity and availability of better alternatives, it has a limited role in treating MM.

## ***ISSUES FOR REFERRAL***

For spinal or other bone pathology, refer to orthopedics for support.

## ***ADDITIONAL THERAPIES***

- Local radiation therapy for bone pain
- Effective pain management: Avoid NSAIDs due to nephrotoxicity.
- Kyphoplasty/vertebroplasty: consider for symptomatic vertebral compressions
- Plasmapheresis: for hyperviscosity syndrome (a rare complication)
- Erythropoietin: for selected patients with anemia
- Patients should receive vaccines for pneumococcus and influenza.
- Do not administer zoster vaccine and other live-virus vaccines.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Indications: pain, infections, cytopenia, renal failure, bone complications, spinal cord compression

- Avoid IV radiographic contrast materials due to risk for contrast-induced nephropathy.
- Adequate hydration
- Manage hypercalcemia and control hyperuricemia.

## **ONGOING CARE**

### ***PATIENT EDUCATION***

- <http://myeloma.org/Main.action>
- <http://www.nccn.org/patients/guidelines/myeloma/index.html>

## ***PROGNOSIS***

- Median survival overall is 3 years. The 5-year survival rate is around 35%.

- Median survival by ISS stage:
  - Stage I: 62 months
  - Stage II: 44 months
  - Stage III: 29 months
- Median survival in patients with high-risk multiple myeloma (see staging for definition) is <2 to 3 years, even after ASCT; standard risk have median overall survival of 6 to 7 years.

## COMPLICATIONS

Many; including infection, pain, lytic bone lesions, hypercalcemia, hyperuricemia, spinal cord compression, anemia, hyperviscosity syndrome, amyloidosis, renal insufficiency

## Codes

**&NA;**

### ICD10

- C90.00 Multiple myeloma not having achieved remission
- C90.01 Multiple myeloma in remission
- C90.02 Multiple myeloma in relapse

## Clinical Pearls

**&NA;**

- MM is a plasma cell malignancy that causes endorgan damage.
- Look for presence of CRABÓ (hypercalcemia, renal insufficiency, anemia, and bone lesions).
- Suspect MM if high total protein-to-albumin ratio is present.
- Maintain high index of suspicion for spinal cord compression.

- Avoid nephrotoxins (radiographic contrast material, NSAIDs, dehydration).
- Patients with MM are immunocompromised.

# Multiple Sclerosis

Adam W. Kowalski, MD

Vernon Wheeler, MD, FAAFP

## BASICS

### DESCRIPTION

- An autoinflammatory disease causing demyelination, neuronal loss, and scarring within the white matter of the brain and spinal cord.
- Four recognized forms of multiple sclerosis (MS) (1):
  - Relapsing-remitting multiple sclerosis (RRMS): episodic flare-ups occurring over days to weeks between periods of neurologic stability. During attacks, new symptoms may present, whereas previous symptoms may worsen. Complete recovery or residual deficits may ensue following each bout.
  - Secondary progressive multiple sclerosis (SPMS): beginning as RRMS, progressive deterioration of neurologic function ensues; not associated with attacks, (progression may continue or halt). ÷2% risk per year of RRMS becoming SPMS
  - Primary progressive multiple sclerosis (PPMS): steady decline of neurologic function from onset of disease without episodic flares
  - Progressive relapsing multiple sclerosis (PRMS): steady decline of neurologic function from onset of disease with episodic flare-ups

### Pregnancy Considerations

- Most patients experience lower exacerbation rates during pregnancy. Following delivery, the immune system reverts and MS flares become more likely.
- Breastfeeding does not affect the risk of MS relapse.
- Relapse during postpartum can be safely treated by IVIG and corticosteroids (2)[C].

### EPIDEMIOLOGY

- Age: Peak incidence ages 15 to 45 years, mean age 28 to 31 (slightly earlier in women than men)

- Gender: Studies suggest F:M between 1.4:1 and 3:1
- Latitude: Prevalence tends to rise with increasing distance from the equator, although newer data reveals this latitude gradient may be declining (3,4).

### *Incidence*

- Women (worldwide): 3.6 cases/100,000 person-years
- Men (worldwide): 2.0 cases/100,000 person-years

### *Prevalence*

- United States: ÷350,000 MS patients
- Worldwide: ÷2,500,000 MS patients

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- MS lesions: Inflammatory cells, mainly T lymphocytes and macrophages, surround vasculature within the CNS, creating sites of inflammation. These cells then disrupt the blood-brain barrier and infiltrate the surrounding white matter, meanwhile preserving the vessel wall. B lymphocytes, as well as myelin-specific autoantibodies also infiltrate the CNS and cause degeneration of the myelin sheaths.
- Following demyelination, faster salutatory nerve conduction velocities (impulses jumping between nodes of Ranvier) are replaced with considerably slower continuous nerve velocities.
- Astrocytes begin to proliferate and cause gliosis.
- Oligodendrocytes, which have survived, or ones formed from precursor cells, are able to partially remyelinate stripped axons, producing irreversible scars.
- In each MS lesion, axonal damage may occur, but it is the cumulative axonal loss over time that is responsible for the progressive and irreversible neurologic disability seen in MS patients.
- Most axons are typically lost from the lateral corticospinal (motor) tracts of the spinal cord.

### *Genetics*

- Strong predisposition: HLA DRB1 (5)
- Proposed predisposition: IL2RA and IL7RA
- Race: Caucasian > Africans or Asians

## **RISK FACTORS**

Genetic: DRB1 locus on chromosome 6 has strongest MS risk association; DRB1 \*15 and \*16 produce major histocompatibility complexes (MHC) with high binding affinity to myelin basic proteins (MBPs) (3,5).

- Geographic: Previously distance from equator showed association with increased risk, though now declining. However, sun exposure (ultraviolet B (UVB) radiation necessary for endogenous vitamin D production) appears to have inverse relation to MS incidence (3).
- Infectious: viral infections (especially EBV, HHV) (3,5)
- Race: Caucasian > African, Asian, Native American, although this is decreasing (5)
- Others: tobacco smoking (6)

## GENERAL PREVENTION

Further research is required to determine prevention from environmental risk factors. A goal of therapy is to prevent new attacks and disability.

## COMMONLY ASSOCIATED CONDITIONS

- Internuclear ophthalmoplegia (INO): Injury to the medial longitudinal fasciculus (MLF) causes impaired adduction to the affected eye.
- Optic neuritis: inflammation of optic nerve resulting in loss of vision
- Uhthoff phenomenon: Symptoms worsen with exposure to higher than usual temperature.
- Lhermitte sign: electric-like shocks extending down the spine caused by neck movement, especially flexion

## DIAGNOSIS

- A person with MS can present with a number of neurologic signs and symptoms depending on the locations of the lesions within the CNS (5)[C].
- Clinical diagnosis: <sup>3</sup>2 attacks; objective clinical evidence of <sup>3</sup>2 lesions or objective clinical evidence of 1 lesion with history of a previous episode. Flare-up duration must be at least >24 hours. Relapses must be separated by <sup>3</sup>1 month. <sup>3</sup>1 out of 2 neurologic signs must be present. The second clinical sign may be obtained through an abnormal paraclinical exam such as MRI or evoked potentials or may be supported by an abnormal paraclinical exam (5,7)[C].
- For patients with steady decline of neurologic function for <sup>3</sup>6 months without flares, intrathecal IgG may be used to support the diagnosis (5)[C].

## HISTORY

Symptoms may include fatigue, depression, emotional instability, epilepsy, memory loss, diplopia, sudden vision loss, facial palsy, dysarthria, dysphagia, muscle weakness or spasms, ataxia, vertigo, falls, hyperesthesia or paresthesia, pain, bowel or bladder incontinence, urinary frequency or retention or impotence (5)[C].

## *PHYSICAL EXAM*

- Optic disc swelling or pallor
- INO
- Nystagmus in abducting eye
- Ataxia
- Intention tremor
- Hypesthesia or paresthesia
- Cerebellar dysarthria (scanning speech)
- Spasticity (especially in lower extremities)

## *DIFFERENTIAL DIAGNOSIS*

- Lyme disease
- Systemic lupus erythematosus (SLE)
- Antiphospholipid antibody syndrome
- Epilepsy
- Progressive multifocal leukoencephalopathy (PML)
- CNS neoplasms
- Guillain-Barré syndrome
- Metachromatic leukodystrophy
- Sarcoidosis
- Stroke
- Vascular malformation
- HIV, neurosyphilis
- Cobalamin (vitamin B<sub>12</sub>) deficiency
- Acute disseminated encephalomyelitis (ADEM)

- Behçet disease
- Normal pressure hydrocephalus

## *DIAGNOSTIC TESTS & INTERPRETATION*

- CSF: Increased monocyte cell count and intrathecally formed IgG levels. Total protein within CSF may be normal or increased. The presence of oligoclonal bands (OCB) is used to determine amount of IgG intrathecally synthesized. <sup>32</sup> OCBs is diagnostic (5)[B]
- Tests used for exclusion of alternative diagnoses: antinuclear antibodies (ANAs), serum cobalamin level, erythrocyte sedimentation rate (ESR), and testing for syphilis
- MRI of head/spine (more sensitive than CT):
  - T<sub>2</sub> (spin-echo) image: hyperintense lesions
  - T<sub>2</sub> image: hypointense lesions
  - Gadolinium (Gd): Given IV, leakage of Gd into the parenchyma represents an increase in BBB permeability due to vascular breakdown.
- McDonald criteria (5):
  - Dissemination in space: <sup>31</sup> T<sub>2</sub> lesion on MRI in at least 2 out of 4 CNS regions typically affected by MS: periventricular, juxtacortical, infratentorial, or spinal cord or by waiting for another clinical attack implying a different CNS location
  - Dissemination in time: simultaneous presentation of asymptomatic Gd-enhanced and nonenhancing lesions at any moment or a new T<sub>2</sub> and/or Gd-enhanced lesion on an MRI when compared baseline scans.

## *Diagnostic Procedures/Other*

Evoked potentials (EPs): Assess function in visual, auditory, and somatosensory or motor CNS pathways by measuring CNS electric potentials evoked by stimulation of either the brain or selected peripheral nerves; a marked delay in a provoked CNS EP, without a clinical manifestation, is suggestive of a demyelinating disorder (5).

## **TREATMENT**

### *GENERAL MEASURES*

- Three main categories currently exist for MS treatment: treatment for acute relapses,

treatment for reducing MS-related activity using diseasemodifying agents, and symptomatic therapy (2,5)[B]

- For apparent acute relapse, rule out infectious etiology prior to treatment.

## MEDICATION

- Acute relapses (2)[B]
  - Methylprednisolone 1 g/day IV for 3 to 5 days; without subsequent oral tapering; a second course may be given.
    - Adverse effects: fluid retention, potassium loss, weight gain, GI disturbances, acne, and emotional lability
- Reduction of MS biologic activity, interferon- $\beta$ ; (IFN- $\beta$ ) (1,5,8)
  - Avonex (IFN- $\beta_{1a}$ ) 30 mg IM weekly
  - Rebif (IFN- $\beta_{1a}$ ) 22 or 44 mg SC 3 times per week
  - Betaseron (IFN- $\beta_{1b}$ ) 0.25 mg SC every other day
  - Extavia (IFN- $\beta_{1b}$ ) 0.25 mg SC every other day
    - CBC w/ diff., Plt, LFTs at 1, 3, and 6 months after starting Tx
    - TFTs every 6 months if Hx of thyroid dysfunction
  - Glatiramer acetate (Copaxone) 20 mg SC daily or 40 mg 3 times per week
    - Common adverse reactions: injection site reaction, nausea, chest pain, hypertonia, diaphoresis
    - No recommended routine tests
  - Natalizumab (Tysabri): 300 mg IV every 4 weeks
    - Restricted distribution in the United States; call 1-800-456-2255 for more info.
    - MRI at baseline
  - Alemtuzumab (Lemtrada) 12 mg IV daily for 5 days, then 12 months later 12 mg IV for 3 days
    - Premedicate with corticosteroids (methylprednisolone 1,000 mg) first 3 days of each treatment. Also consider antihistamines, antipyretics; antiviral prophylaxis (for herpetic

viral infections) beginning on the first day of treatment and continue at least 2 months and until CD4 + lymphocyte count is  $\geq 200/\text{mm}^3$

- Fingolimod (Gilenya): 0.5 mg PO daily
  - EKG at baseline
  - Serious adverse reactions: QT prolongation, AV block; 6-hour observation following first dose
- Teriflunomide (Aubagio): 7 to 14 mg PO daily
  - Avoid pregnancy, teratogenic; pregnancy test at baseline
  - Use reliable contraception during Tx.
- Symptomatic therapies (5)[B]:
  - Ataxia: clonazepam, propranolol, ondansetron
  - Spasticity: baclofen, diazepam, tizanidine, dantrolene, cyclobenzaprine hydrochloride
  - Pain: NSAIDs, carbamazepine, gabapentin, phenytoin, amitriptyline, mexiletine
  - Bladder dysfunction: (urgency) propantheline bromide, oxybutynin, tolterodine tartrate; (retention) phenoxybenzamine, terazosin hydrochloride, bethanechol
  - Constipation: high-fiber diets, fluids, natural or other laxatives, stool softeners, bulk-producing agents, suppositories
  - Sexual dysfunction: tadalafil, sildenafil, vardenafil
  - Weakness/fatigue: dalfampridine, amantadine, methylphenidate
  - Tremors: clonazepam, *β*-blockers, primidone
  - Depression: fluoxetine, other SSRIs, tricyclic antidepressants, nontricyclic antidepressants

## **ADDITIONAL THERAPIES**

- Cognitive behavioral therapy
- Physical and occupational therapy
- Water therapy: Swimming, in cool water, is typically well-tolerated.
- Strenuous physical activity appears to confer protective benefit and slow the disease progression in pediatric patients.

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Omega-3: immunomodulatory properties
- Vitamin D supplementation, sunlight exposure

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Treat relapses with corticosteroids to minimize disease progression and duration of relapse. Maintain regular activity, but avoid overwork and fatigue. Rest during periods of acute relapse (2) [B].

### *Patient Monitoring*

Assessing the severity of neurologic impairment from MS can be done using the Kurtzke Expanded Disability Status Score (EDSS): 0 indicates a normal neurologic exam and 10 indicates death due to MS. The EDSS uses a functional status (FS) score, covering the following: pyramidal symptoms, cerebellar, brainstem, sensory, bowel and bladder, visual/optic, and cerebral/mental functions. EDSS scoring system (9)[C]:

- 1.0 - No disability, minimal signs in 1 FS
- 2.0 - Minimal disability in 1 FS
- 3.0 - Moderate disability in 1 FS or mild disability in 3 to 4 FS, but fully ambulatory
- 4.0 - Ambulatory without aid or rest for ÷500 m
- 5.0 - Ambulatory without aid or rest for ÷200 m
- 6.0 - Intermittent/constant unilateral assistance (cane, crutch, or brace) must be able to walk 100 m
- 7.0 - Unable to walk beyond 5 m even with aid; essentially restricted to wheelchair, wheels self and transfers alone; active in wheelchair for ÷12 hrs/day
- 8.0 - Essentially restricted to bed, chair, or wheelchair; may be out of bed most of the day; retains self-care functions, generally effective use of arms
- 9.0 - Helpless, bed-bound; but patient can communicate, eat
- 10.0 - Death due to MS

### *DIET*

High fiber, bulk laxatives, fluids to prevent constipation

# PATIENT EDUCATION

National Multiple Sclerosis Society: 1-800-344-4867 or [www.nationalmssociety.org/](http://www.nationalmssociety.org/)

## PROGNOSIS

- Differs in each individual; depends on the form of MS, the individual's sex and age, the initial presentation of the disease, and the amount of disability
- Average life expectancy is 5 to 10 years less than unaffected people.
- Specific clinical features suggesting more favorable course: early onset, RRMS form, female sex, <2 relapses within first year of diagnosis, and minimal functional decline after 5 years (5).
- Mortality secondary to MS relapse is unusual; death more commonly associated with a complication of MS such as infection in a person with more disability.

## COMPLICATIONS

Depression or emotional instability, paraplegia, chronic pain, sexual dysfunction, delirium, impaired vision (9)

## Codes

&NA;

### ICD10

G35 Multiple sclerosis

## Clinical Pearls

&NA;

- Immune-mediated inflammatory disease causing demyelination, neuronal loss, and scarring within the white matter of the CNS
- Charcot classical MS triad: nystagmus, intention tremor, and dysarthria

- Acute relapses are treated with steroids; diseasemodifying medications are used for chronic treatment; currently, there is no treatment for promoting remyelination or neuronal repair.
- Based on limited clinical data, IVIG is not thought to be effective therapy for relapsing remitting MS (10).
- Autologous stem cell transplantation for MS shows promise, but more rigorous research is needed (11,12).

# Mumps

Frances Yung-tao Wu, MD

## BASICS

An acute, generalized paramyxovirus infection typically presenting with unilateral or bilateral parotitis

## DESCRIPTION

- Up to 1/3 of individuals with mumps are asymptomatic.
- Painful parotitis occurs in 95% of symptomatic mumps cases. Epidemics in late winter and spring. Transmission by respiratory secretions.
- Incubation period is 14 to 24 days.
- System(s) affected: hematologic/lymphatic/immunologic, reproductive, skin, exocrine
- Synonym(s): epidemic parotitis; infectious parotitis

## EPIDEMIOLOGY

- Predominant age: 85% of mumps case occur before age 15 years:
  - Adult cases are typically more severe.
- Predominant sex: male = female
- Geriatric population: Most adults are immune.
- Acute epidemic mumps
  - Most cases occur in unvaccinated children between ages 5 and 15 years.
  - Recent (2006) U.S. epidemic in vaccinated college students aged 18 to 24 years: 5,700 U.S. cases:
    - Another U.S. epidemic in 2009 to 2010 in New York/New Jersey: >1,500 cases
- Mumps is unusual in children <2 years of age and most infants <1 year are immune.
  - Period of maximal communicability is 24 hours before to 72 hours after onset of parotitis

## *Incidence*

- 1,151 cases in the United States in 2014 (1)
- Occasional epidemic outbreaks in a given region

## *Prevalence*

- 0.0064/100,000 persons
- 90% of adults are seropositive even without history.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Mumps virus replicates in glandular epithelium of parotids, pancreas, and testes, leading to interstitial edema and inflammation.

- Interstitial glandular hemorrhage may occur.
- Pressure caused by edema of the testes against the tunica albuginea can lead to necrosis and loss of function.

## **RISK FACTORS**

- Foreign travel: Many other nations do *not* vaccinate for mumps, including most of Africa and South Asia.
- Crowded environments such as dormitories, barracks, or detention facilities increase risk of transmission.
- Immunity wanes after single-dose vaccination:
  - When receiving two doses, immunity drops from 95% to 86% after 9 years.
  - Genotypic variation from original vaccine strain may have a role in decreased vaccine efficacy (2).

## **GENERAL PREVENTION**

- Vaccination
  - Two doses of live mumps vaccine or measlesmumps-rubella (MMR) vaccine are recommended, first at 12 to 15 months and second at 4 to 6 years of age.
  - 95% effective in clinical studies, but field trials show 68-95% efficacy, which may be below level for herd immunity to prevent spread.
  - Scandinavian data suggest prevention may require 95% first dose and >80% second dose adherence.

- Adverse effects: most common proven effect is idiopathic thrombocytopenic purpura (ITP), with incidence of 3.3/100,000 doses
- *No relationship between MMR vaccine and autism*
- Immunoglobulin (Ig) is not effective in preventing mumps.
- Postexposure vaccination does not protect from recent exposure (3)[B]
- Isolate hospitalized patients for 5 days after onset.
- Isolate nonimmune individuals for 26 days after last case onset (social quarantine).

## *Pregnancy Considerations*

- Live viral vaccines are typically contraindicated in pregnancy; however, vaccination of children should not be delayed due to a pregnant family member.
- Immunization of contacts protects against future (but not current) exposures.

## **DIAGNOSIS**

### **HISTORY**

- Parotid swelling peaks in 1 to 3 days and lasts 3 to 7 days.
- Clinical diagnosis (swelling of one or both parotid glands):
  - Lasting 2 days
  - No other apparent cause
  - Rare presentation of meningitis without parotitis (1-10%)
- Up to 1/3 of individuals with mumps are asymptomatic.
- Rare prodrome of fever, neck muscle ache, and malaise
- Sour foods cause pain in parotid gland region.
- Moderate fever, usually not >104°F (40°C):
  - High fever frequently is associated with complications.

### *PHYSICAL EXAM*

- Painful parotid swelling (unilateral or bilateral) obscures angle of mandible and elevates earlobe
- Meningeal signs in 15%, encephalitis in 0.5%
- Rarely arthritis, orchitis, thyroiditis, mastitis, pancreatitis, oophoritis, myocarditis

- Rare maculopapular, erythematous rash
- Up to 50% of cases may be very mild.
- Redness at opening of Stensen duct but no pus
- Swelling in sternal area; rare, but pathognomonic of mumps

## ***DIFFERENTIAL DIAGNOSIS***

- If not epidemic, other viruses are more common: parainfluenza parotitis, Epstein-Barr virus, coxsackievirus, adenovirus, parvovirus B19
- Suppurative parotitis: often associated with *Staphylococcus aureus* (presence of Wharton duct pus on massaging parotid gland essentially excludes diagnosis of mumps)
- Recurrent allergic parotitis
- Salivary calculus with intermittent swelling
- Lymphadenitis from any cause, including HIV infection
- Cytomegalovirus parotitis in immunocompromised patients
- Mikulicz syndrome: chronic, painless parotid and lacrimal gland swelling of unknown cause that occurs in tuberculosis, sarcoidosis, lupus, leukemia, lymphosarcoma, and salivary gland tumors
- Sjögren syndrome, diabetes mellitus, uremia, malnutrition
- Drug-related parotid enlargement (iodides, guanethidine, phenothiazine)
- Other causes of the complications of mumps (meningoencephalitis, orchitis, oophoritis, pancreatitis, polyarthritis, nephritis, myocarditis, prostatitis)
- Mumps orchitis must be differentiated from testicular torsion and from chlamydial or bacterial orchitis. (Testicular sonogram can be useful.)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Three special tests used to confirm an outbreak—If positive, report to health department (1)[A]
  - IgM titer (positive by day 5 in 100% of nonimmunized patients)
  - Swab of parotid duct or other affected salivary ducts for viral culture
  - Rise in IgG titer samples; test should be ordered if patient previously immunized: 1st sample within 5 days of onset, and 2nd, 2 weeks later.
- Other potential findings: elevated serum amylase; CSF leukocytosis, or leukopenia.
- Testicular ultrasound may help differentiate mumps orchitis from testicular torsion.

## Diagnostic Procedures/Other

If meningitis is present, lumbar puncture to exclude bacterial process. CSF pleocytosis, usually lymphocytes, is found in 65% of patients with parotitis.

## Test Interpretation

Periductal edema and lymphocytic infiltration in affected glands on biopsy

## TREATMENT

- No specific antiviral therapy, only supportive care (1)[A],(4)[C]
- Analgesics to relieve pain
- Avoid corticosteroids for mumps orchitis because they can reduce testosterone concentrations and increase testicular atrophy.
- IVIG only successful for certain autoimmune-based sequelae:
  - Postinfectious encephalitis
  - Guillain-Barré syndrome
  - ITP
- Interferon- $\alpha$ 2b improved severe bilateral orchitis but did not decrease testicular atrophy in small studies (5)[B].

## GENERAL MEASURES

- Rarely need to hospitalize patients with high fever, pancreatitis, or CNS symptoms for supportive care, steroids, or interferon using appropriate isolation precautions
- Orchitis
  - Ice packs to scrotum can help to relieve pain.
  - Scrotal support with adhesive bridge while recumbent and/or athletic supporter while ambulatory

## MEDICATION

### First Line

Analgesics and anti-inflammatory medications (acetaminophen, nonsteroidal anti-inflammatory drugs [NSAIDs]) may diminish pain and swelling in acute orchitis and arthritis mumps.

- May use acetaminophen for fever and/or pain
- Precautions: Avoid aspirin for pain in children as previously associated with Reye syndrome.

## *Second Line*

- Interferon- $\alpha$ 2b
- Chinese medicinal herbs and acupuncture have not shown benefit in randomized controlled trials (6,7).

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Hospitalize only if CNS symptoms occur.
- Outpatient supportive care if no complications

### *IV Fluids*

If severe nausea or vomiting accompanies pancreatitis

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Mumps orchitis:

- Bed rest and local supportive clothing (e.g., two pairs of briefs) or adhesive-tape bridge
- Withhold from school until no longer contagious (9 days after onset of pain)

### *Patient Monitoring*

Most cases will be mild. Monitor hydration status.

### *DIET*

Liquid diet if unable to chew

### *PATIENT EDUCATION*

Orchitis is common in older children but rarely results in sterility, even if bilateral.

## PROGNOSIS

- Complete recovery is typical; immunity is lifelong.
- Transient sensorineural hearing loss in 4% of adults
- Recurrence after 2 weeks may be nonepidemic parotitis.

## COMPLICATIONS

- May precede, accompany, or follow salivary gland involvement and may occur (rarely) without primary involvement of the parotid gland
- Orchitis is common (30%) in postpubertal boys:
  - It starts within 8 days after parotitis.
  - Impaired fertility in 13%; absolute sterility is rare.
- Meningitis (1-10%) or encephalitis (0.1%) may present 5 to 10 days after first symptoms of illness. Aseptic meningitis is typically mild, but meningoencephalitis may lead to seizures, paralysis, hydrocephalus, or (in 2% of cases), death.
- Acute cerebellar ataxia has been reported after mumps infections; self-resolving in 2 to 3 weeks.
- Oophoritis in 7% of postpubertal females; no decreased fertility
- Pancreatitis, usually mild
- Nephritis, thyroiditis, and arthralgias are rare.
- Myocarditis: usually mild, but may depress ST segment; may be linked to endocardial fibroelastosis
- Deafness: 1/15,000 unilateral nerve deafness; may not be permanent
- Inflammation about the eye (keratouveitis) is rare.
- Dacryoadenitis, optic neuritis

### ***Pediatric Considerations***

- Orchitis is more common in adolescents.
- Young children are less likely to develop complications.
- Most complications occur in postpubertal group.
- Avoid aspirin use in children with viral symptoms.

### ***Pregnancy Considerations***

Disease may increase the rate of spontaneous pregnancy loss in 1st trimester. Perinatal mumps often has a benign course.

## Codes

**&NA;**

### ICD10

- B26.9 Mumps without complication
- B26.1 Mumps meningitis
- B26.2 Mumps encephalitis

## Clinical Pearls

**&NA;**

- Mumps is a clinical diagnosis based on swelling of <sup>31</sup> parotid glands for <sup>32</sup> days without other obvious cause. Confirmatory testing must be done in epidemic settings.
- Ultrasound is useful to distinguish testicular torsion from testicular pain related to mumps orchitis.
- A history of vaccination with MMR does not exclude mumps. The MMR vaccine is 68-95% effective after a series of two immunizations. Immunity commonly wanes over time.

# Muscular Dystrophy

Nimmy Thakolkaran, MD

George G.A. Pujalte, MD, FACSM

## BASICS

- Primary inherited myopathies caused by dysfunctional proteins of muscle fibers and extracellular matrix
- Distribution of weakness, other associated symptoms, and disease prognosis depend on the specific gene affected and severity of the mutation.

## DESCRIPTION

- Duchenne muscular dystrophy (DMD)
  - Highest incidence muscular dystrophy, X-linked inheritance, early onset, progressive
  - Patients are wheelchair-dependent prior to age 13 years.
- Becker muscular dystrophy (BMD)
  - Less severe phenotype than Duchenne, also caused by mutation in *DMD* gene; later onset and milder clinical course
  - Distinction from DMD is clinical: Patients are usually wheelchair-dependent after age 16 years.
  - Collectively referred to as dystrophinopathies
- Myotonic muscular dystrophy (MMD)
  - Myotonia (slow relaxation after muscle contraction), distal and facial weakness
  - Second most common inherited muscle disease.
- Facioscapulohumeral muscular dystrophy (FSHMD)
  - Facial and shoulder muscles most affected
  - Third most common inherited muscle disease.
- Limb-girdle muscular dystrophy (LGMD)

- Proximal weakness and atrophy, variable prognosis with many different identified mutations
- Oculopharyngeal muscular dystrophy (OPMD)
  - Usually adult-onset, affects extraocular and pharyngeal muscles. Presents with ptosis and dysphagia
- Emery-Dreifuss muscular dystrophy (EDMD)
  - Triad of early development of joint contractures, slowly progressive muscle wasting, and cardiomyopathy. Can present as sudden death in apparently healthy young adults
- Congenital muscular dystrophies (CMD)
  - Heterogeneous group of autosomal recessive myopathic diseases presenting in infancy with generally poor prognosis
  - Includes Fukuyama CMD, Ullrich CMD, Walker-Warburg syndrome, muscle-eye-brain disease

## EPIDEMIOLOGY

### *Incidence*

- Duchenne: 1/3,600 male births (1)
- Myotonic dystrophy: 1/10,000 births
- Other muscular dystrophies vary widely by population but are generally rare.

## ETIOLOGY AND PATHOPHYSIOLOGY

Mutations affect proteins connecting cytoskeleton to cell membrane and extracellular matrix, causing muscle fibers to become fragile and easily damaged; muscle weakness and atrophy result.

- DMD/BMD
  - Defective protein is dystrophin, product of the largest human gene, *DMD*; Duchenne phenotype results from mutations that cause profound loss of dystrophin, the protein involved in calcium transport in muscle cells and stabilizing fibers during contraction.
  - Becker phenotype results from less severe mutations in *DMD* gene; patients have low but detectable levels of functional dystrophin.
- MMD: Trinucleotide repeat expansion in the untranslated region of the gene *DMPK* on chromosome 19; encodes myotonin-protein kinase
- LGMD: mutations in genes encoding proteins associated with dystrophin: calpain-, dysferlin-,

and fukutin-related proteins are affected most commonly.

- EDMD: Dysfunctional proteins are associated with the nuclear membrane in muscle fibers; emerin in X-linked form, lamin A/C in autosomal forms
- OPMD: Trinucleotide repeat expansion in *PABPN1* results in nuclear inclusions in muscle cells by hampering normal transport of mRNA from the nucleus.
- FSHMD: Deletion in untranslated region of chromosome 4; function of deleted genes is unclear, although the most accepted concept is that they likely affect the expression of multiple genes by epigenetic effects.

## Genetics

- X-linked
  - Duchenne and Becker muscular dystrophies
  - Gene located at Xp21
    - 30% of affected males have a de novo mutation (mother is not a carrier).
    - 20% of female carriers have some manifestation of the mutation (usually mild muscle weakness or cardiomyopathy).
- Autosomal dominant
  - Generally later onset and less severe than diseases with recessive or X-linked inheritance
  - FSHMD, OPMD, some forms of LGMD and EDMD
  - Myotonic dystrophy
    - Trinucleotide repeat expansion with more severe phenotype in subsequent generations due to accumulation of repeats
- Autosomal recessive
  - Most types of CMD

## GENERAL PREVENTION

Genetic counseling for carriers and prenatal diagnosis

## COMMONLY ASSOCIATED CONDITIONS

- Decreased IQ: on average, 1 *SD* below the mean in DMD; speech and language delay
- Dilated cardiomyopathy and conduction abnormalities

- Can be severe in EDMD
- Can affect otherwise asymptomatic female carriers of DMD
- Progressive scoliosis

## DIAGNOSIS

### HISTORY

- DMD: normal attainment of early motor milestones with subsequent abnormal gait and slowing gross motor development: clumsiness, waddling gait, frequent falls, difficulty running or climbing stairs
- BMD: progressive difficulty with ambulation and frequent falls in later childhood
- MMD: slurred speech, muscle wasting, difficulty with ambulation; often with family history
- LGMD: back pain, lordosis/inability to rise from a chair, climb stairs, and use arms overhead
- FSHMD: facial weakness, inability to close eyes completely
- EDMD: contractures of elbows and ankles, difficulty with ambulation in teenage years
- OPMD: ptosis and dysphagia; often with family history

### PHYSICAL EXAM

- DMD/BMD
  - Proximal muscle weakness; Gower sign: use of arms to push upper body into standing posture from lying prone
  - Trendelenburg gait (hip waddling)
  - Hyporeflexia/areflexia
  - Winged scapulae and lordosis
  - Pseudohypertrophy of the calf (caused by replacement of muscle with fibroadipose tissue)
  - Contractures of lower extremity joints and elbows
- MMD
  - Characteristic facial appearance: narrow face, open triangular mouth, high-arched palate, concave temples, drooping eyelids, frontal balding in males

- Myotonia: inability to relax muscles after contraction
- Distal muscle weakness and wasting
- CMD
  - Arthrogryposis (multiple joint contractures); diffuse hypotonia and muscle wasting in an infant

## *DIFFERENTIAL DIAGNOSIS*

- Glycogen storage diseases and other metabolic myopathies
- Mitochondrial myopathies: MELAS (**M**itochondrial **E**ncephalopathy, **L**actic **A**cidosis, and **S**troke-like episodes), MERRF (**M**yoclonus with **E**pilepsy and **R**agged-**R**ed **F**ibers)
- Inflammatory myopathies: polymyositis, dermatomyositis, inclusion-body myositis
- Neuromuscular junction diseases: myasthenia gravis, Lambert-Eaton syndrome
- Motor neuron diseases: amyotrophic lateral sclerosis, spinal muscular atrophy
- Charcot-Marie-Tooth disease
- Friedreich ataxia

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Creatine kinase (CK): initial screening test if MD is suspected (2)[A]
- Elevated in DMD (10 to 100 times); elevated at birth, peaks at time of presentation, and falls during illness
- Initial detected lab abnormality may be elevated aspartate transaminase/alanine transaminase (AST/ALT) originating from muscle.
- Genetic testing/molecular diagnosis
  - For definitive diagnosis in patient with characteristic presentation and elevated CK
  - Deletion and duplication analysis (MLPA or CGH) will identify most patients; followed by genomic sequencing of *DMD* gene for point mutations (3)[A].
  - Genetic testing is available clinically for most other muscular dystrophies.

### *Diagnostic Procedures/Other*

- Muscle biopsy: rarely performed in DMD (dystrophin protein absent); may be helpful in other cases (4)[A]
- Electromyography and nerve conduction studies are not necessary unless considering alternative diagnoses.
- ECG: abnormalities found in >90% of males and up to 10% of female carriers of DMD; Q waves in anterolateral leads, tall R waves in V1, shortened PR interval, arrhythmias, resting sinus tachycardia

## *Test Interpretation*

- Heterogenic muscle fibers: atrophy and hypertrophy of fibers with proliferation of connective tissue in muscle
- Immunohistochemical staining for dystrophin protein
  - DMD: no detectable dystrophin in most fibers; occasional revertant fibers with normal dystrophin
  - BMD: highly variable staining for dystrophin throughout muscle

P.695

## **TREATMENT**

Trials of agents that affect gene expression, such as antisense oligonucleotides, and small molecules that cause skipping of premature stop codons (ataluren) are ongoing; however, steroid treatment is the only clinically available therapy that affects disease progression.

## **GENERAL MEASURES**

- Ambulation prolonged by knee-ankle-foot orthoses
- Serial casting to treat contractures
- Diagnose sleep apnea with polysomnography; treat with noninvasive ventilation.
- Adaptive devices to improve function
- Avoid overexertion and strenuous exercise.

## **MEDICATION**

- Prednisone 0.75 mg/kg/day (4)[A]
  - Slows the decline in muscle function, progression to scoliosis, and degradation of pulmonary

function; prolongs functional ambulation; prolongs lifespan; improved cardiac outcomes

- Therapy should be initiated when there is no longer progress in motor skills, but prior to decline (2).
- Monitor adverse effects.
  - Bisphosphonates should be considered for preventing loss of bone density; annual exam for cataracts; hypertension should be monitored; no NSAIDs due to risk of peptic ulcer disease (PUD); stress-dose steroids during surgeries and illnesses due to adrenal suppression.
  - Patients should be aware of immune suppression and notify emergency providers.
- Deflazacort (0.9 mg/kg) is an alternative oral steroid that is also considered first-line therapy in DMD; it acts on muscle regeneration and differentiation; not available in the United States (3)
- ACE inhibitors
  - Treatment of cardiomyopathy; may be used in conjunction with *β*-blockers

## *ISSUES FOR REFERRAL*

- Refer to neuromuscular diseases center for definitive diagnosis and coordinated multidisciplinary care (4).
- Cardiology for management of cardiomyopathy
- Pulmonology for monitoring of pulmonary function and clearance regimen
- Physical medicine and rehabilitation for management of adaptive devices
- Nutrition/swallowing: for normal weight gain, attention for dysphagia
- Psychosocial: learning/behavior and coping assessment, social development (2)

## *ADDITIONAL THERAPIES*

Novel medication: Ataluren interferes with premature stop codons, allowing expression of dystrophin protein. In DMD patients with nonsense mutation; FDA approved orphan drug designation (3)

## *SURGERY/OTHER PROCEDURES*

- Spinal surgery for scoliosis diminishes rate of deformity progression (5),(6)[A].
- Scapular fixation for scapular winging may be beneficial; also lacking clinical trials
- Consider surgical treatment of ankle/knee contractures.

- Surgical procedures should be performed at a center experienced in DMD; total IV anesthesia should be used.

## **ONGOING CARE**

- Individualized education plan and developmental evaluation for school accommodations
- Maintenance of current influenza and pneumococcal vaccination status

## ***FOLLOW-UP RECOMMENDATIONS***

### ***Patient Monitoring***

- Electrocardiogram (ECG), echocardiogram, and consultation with a cardiologist at diagnosis and annually after age 10 years
  - Female carriers of DMD mutation should be monitored every 5 years.
- Annual spinal radiography for scoliosis
- Dual-energy x-ray absorptiometry (DEXA) scanning and serum marker testing for osteoporosis
- Pulmonary function testing twice yearly if no longer ambulatory
- Psychosocial: coping, emotional adjustment, depression

### ***DIET***

- Obesity is common due to steroid treatment and wheelchair confinement: Weight control can improve quality of life.
- Diet may be limited by dysphagia; swallow evaluation can determine appropriate foods; may require gastrostomy
- Calcium and vitamin D supplementation for patients on steroids; monitor vitamin D levels.

### ***PATIENT EDUCATION***

- Muscular Dystrophy Association: <http://www.mda.org>
- Parent Project Muscular Dystrophy: <http://www.endduchenne.org>

### ***PROGNOSIS***

- DMD/BMD
  - Progressive weakness, contractures, inability to walk

- Kyphoscoliosis and progressive decline in respiratory vital capacity with recurrent pulmonary infections.
- Significantly shortened lifespan (DMD:  $16 \pm 4$  years; BMD:  $42 \pm 16$  years). Respiratory failure cause of death in 90%; remaining due to myocardial disease (heart failure and dysrhythmia) (5)
- Other types: slow progression and near-normal lifespan with functional limitations

## COMPLICATIONS

- Cardiac arrhythmia, cardiomyopathy
- Dysphagia, gastroesophageal reflux disease (GERD), constipation
- Scoliosis, joint contractures
- Obstructive sleep apnea
- Malignant hyperthermia-like reaction to anesthesia
- Respiratory failure and early death

## Codes

&NA;

### ICD10

- G71.0 Muscular dystrophy

- G71.11 Myotonic muscular dystrophy
- G71.2 Congenital myopathies

## Clinical Pearls

### &NA;

- Primary care providers should have a low threshold to obtain serum CK as a screening test in the face of gross motor delay/muscular weakness, especially in boys.
- Steroids should be initiated in patients with DMD when gross motor function ceases to progress.
- High-quality care of patients requires a medical home; a multidisciplinary team of physicians, therapists, and other providers; and extensive patient and family support.

# Myasthenia Gravis

Melody A. Jordahl-Iafrato, MD

## BASICS

### DESCRIPTION

Primary disorder of neuromuscular transmission characterized by fluctuating muscle weakness:

- Ocular myasthenia gravis (MG) (15%): weakness limited to eyelids and extraocular muscles
- Generalized MG (85%): commonly affects ocular as well as a variable combination of bulbar, proximal limb, and respiratory muscles
- 50% of patients who present with ocular symptoms develop generalized MG within 2 years.
- Onset may be sudden and severe, but it is typically mild and intermittent over many years, maximum severity reached within 3 years for 85%.
- System(s) affected: neurologic; hematologic; lymphatic; immunologic; musculoskeletal

### EPIDEMIOLOGY

Occurs at any age but a bimodal distribution to the age of onset:

- Female predominance: 20 to 40 years
- Male predominance: 60 to 80 years

### Incidence

Estimated annual incidence 2 to 21/1 million

### Prevalence

In the United States, 200/1 million; increasing over the past 5 decades

### Pediatric Considerations

A transient form of neonatal MG seen in 10-20% of infants born to mothers with MG. It occurs as a result of the transplacental passage of maternal antibodies that interfere with function of the neuromuscular junction; resolves in weeks to months.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Reduction in the function of acetylcholine receptors (AChR) at muscle endplates, resulting in insufficient neuromuscular transmission
- Antibody-mediated autoimmune disorder
- Antibodies are present in most cases of MG.
  - Seropositive/antiacetylcholine receptor (anti-AChR): a humoral, antibody-mediated, T-cell-dependent attack of the AChRs or receptor-associated proteins at the postsynaptic membrane of the neuromuscular junction. Found in 85% of generalized MG and 50% of ocular MG. Thymic abnormalities common (1)
  - Muscle-specific kinase (MuSK). 5% of generalized MG patients. Typically females. Is a severe form, respiratory and bulbar muscles involved. Thymic abnormalities are rare (1).
  - In remainder of seronegative, 12-50% with anti-LRP4, a molecule that forms a complex with MuSK, clinical phenotype not well defined (1)
  - Seronegative MG (SNMG): 5%; may have anti-AChR detectable by cell-based assay. Clinically similar to anti-AChR, thymic hyperplasia may be present (1).
- Also documented immediately after viral infections (measles, Epstein-Barr virus [EBV], HIV, and human T-lymphotropic virus [HTLV])

## *Genetics*

- Congenital MG syndrome describes a collection of rare hereditary disorders. This condition is not immune-mediated but instead, results from the mutation of a component of the neuromuscular junction (autosomal recessive).
- Familial predisposition is seen in 5% of cases.

## *RISK FACTORS*

- Familial MG
- D-penicillamine (drug-induced MG)
- Other autoimmune diseases

## *COMMONLY ASSOCIATED CONDITIONS*

- Thymic hyperplasia (60-70%)
- Thymoma (10-15%)
- Autoimmune thyroid disease (3-8%)

## DIAGNOSIS

Myasthenia Gravis Foundation of America Clinical Classification (2)[C]:

- Class I: any eye muscle weakness, possible ptosis, no other evidence of muscle weakness elsewhere
- Class II: eye muscle weakness of any severity; mild weakness of other muscles:
  - Class IIa: predominantly limb or axial muscles
  - Class IIb: predominantly bulbar and/or respiratory muscles
- Class III: eye muscle weakness of any severity; moderate weakness of other muscles:
  - Class IIIa: predominantly limb or axial muscles
  - Class IIIb: predominantly bulbar and/or respiratory muscles
- Class IV: eye muscle weakness of any severity; severe weakness of other muscles:
  - Class IVa: predominantly limb/axial muscles
  - Class IVb: predominantly bulbar and/or respiratory muscles (can also include feeding tube without intubation)
- Class V: intubation needed to maintain airway

## HISTORY

The hallmark of MG is fatigability.

- Fluctuating weakness, often subtle, that worsens during the day and after prolonged use of affected muscles, may improve with rest
- Early symptoms are transient with asymptomatic periods lasting days or weeks.
- With progression, asymptomatic periods shorten, and symptoms fluctuate from mild to severe.
- >50% of patients present with ocular symptoms (ptosis and/or diplopia). Eventually, 90% of patients with MG develop ocular symptoms.
- Ptosis might be unilateral, bilateral, or shifting from eye to eye.
- 15% present with bulbar symptoms.
- <5% present with proximal limb weakness alone.

## ALERT

Myasthenic crisis: respiratory muscle weakness producing respiratory insufficiency and pending respiratory failure

## *PHYSICAL EXAM*

- Ptosis may worsen with propping of opposite eyelid (curtain sign) or sustained upward gaze.
- ◊Myasthenic sneer,◊ in which the midlip rises but corners of mouth do not move.
- Muscle weakness is usually proximal and symmetric.
- Test for muscle fatigability by repetitive or prolonged use of individual muscles.
- Important to test and monitor respiratory function.

## *DIFFERENTIAL DIAGNOSIS*

- Thyroid ophthalmopathy
- Oculopharyngeal muscular dystrophy
- Myotonic dystrophy
- Kearns-Sayre syndrome
- Chronic progressive external ophthalmoplegia
- Brainstem and motor cranial nerve lesions
- Botulism
- Motor neuron disease (e.g., amyotrophic lateral sclerosis [ALS])
- Lambert-Eaton myasthenic syndrome
- Drug-induced myasthenia
- Congenital myasthenic syndrome
- Dermatomyositis/polymyositis
- Neurosarcoidosis
- Tolosa-Hunt syndrome

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Anti-AChR antibody (74-85% are seropositive):
  - Generalized myasthenia: 75-85%

- Ocular myasthenia: 50%
- MG and thymoma: 98-100%
- Poor correlation between antibody titer and disease severity (1)[C]
- False-positive results in thymoma without MG, Lambert-Eaton myasthenic syndrome, small cell lung cancer, and rheumatoid arthritis treated with penicillamine
- Anti-MuSK antibody:
  - Used if MG is suspected, patient seronegative
  - Strong correlation between titer and disease severity (1)[C]
- LRP4 and clustered anti-AChR:
  - Used if MG suspected, patient seronegative
- Thyroid and other autoimmune testing antistriated muscle (anti-SM) antibody:
  - Present in 84% of patients with thymoma who are <40 years of age
  - Can be present without thymoma in patients >40 years of age
- Chest radiographs or CT scans may identify a thymoma.
- MRI of brain and orbits to rule out other causes of cranial nerve deficit

## *Diagnostic Procedures/Other*

- Tensilon (Edrophonium) test:
    - Initial 2-mg IV dose, followed by another 2 mg every 60 seconds up to a maximum dose of 10 mg
    - A positive test shows improvement of strength within 30 seconds of administration.
    - Sensitivity 80-90% (3)[C]
- 
- Cardiac disease and bronchial asthma are relative contraindications, especially in elderly.
  - Atropine: 0.4 to 0.6 mg IV may rarely be required as antidote; must be available.
  - Can also do trial of other cholinesterase inhibitors (neostigmine or oral) and monitor response
  - Ice pack test:
    - Ice pack applied to closed eyelid for 60 seconds, then removed; extent of ptosis

immediately assessed.

- Ice will decrease the ptosis induced by MG.
- Sensitivity 80% in patients with prominent ptosis
- Electrophysiology testing:
  - Repetitive nerve stimulation (RNS):
    - Widely available, most frequently used
    - Moderately sensitive for both generalized MG (75%) and ocular MG (50%) (3)[C]
  - Single-fiber electromyogram (SFEMG):
    - Assesses temporal variability between two muscle fibers within same motor unit (jitter)
    - Sensitive (90-95%) but less specific
    - Technically difficult to perform; limited availability, use if suspected and negative RNS (3) [C]

## *Test Interpretation*

- Lymphofollicular hyperplasia of thymic medulla occurs in 65% of patients with MG, thymoma in 15%.
- Immunofluorescence: IgG antibodies and complement on receptor membranes in seropositive patients

## **TREATMENT**

### **GENERAL MEASURES**

- Treatment based on age, gender, and disease severity and progression
- Three basic approaches: symptomatic, immunosuppressive, and supportive. Few should receive a single therapeutic modality.

### **MEDICATION**

#### *First Line*

Symptomatic treatments (anticholinesterase agents)

- Pyridostigmine bromide (Mestinon):

- *Most commonly prescribed because available in oral tablet*
- Starting dose of 30 mg PO TID with food
- Maximum dose: 120 mg q3-4h
- Long-acting available, but effect not consistent
- Neostigmine methylsulfate (Prostigmin):
  - Starting dose of 0.5 mg SC or IM q3h
  - Titrate dosage to clinical need.
- Patients with anti-MuSK may not respond well to these meds.

## *Second Line*

- Immunosuppressants: Oral corticosteroids are the first choice of drugs when immunosuppression is necessary.
  - Prednisone: Start as inpatient with a 60 mg/day PO; taper the dosage every 3 days; switch to alternateday regimen within 2 weeks. Taper very slowly to establish the minimum dosage necessary to maintain remission (4)[B].
  - Cyclophosphamide: adults: 1 to 5 mg/kg/day PO; children: 2 to 8 mg/kg/day PO (5)[B]
  - Cyclosporine: adults: 5 mg/kg/day PO (nephrotoxicity and drug interactions) (5)[B]
  - Mycophenolate: 1 g PO or IV BID
  - Azathioprine: 100 to 200 mg/day PO (5)[B]
    - *Most frequently used for long-term immunomodulation, similar efficacy to steroids and IVIG*
    - Benefit may not be apparent for up to 18 months after initiation of therapy.
    - Prednisolone + azathioprine may be effective when used as a corticosteroid-sparing agent.
- Acute immunomodulating treatments:
  - Plasmapheresis: bulk removal of 2 to 3 L of plasma 3 times per week, repeated until rate of improvement plateaus (6)[B]
    - Improves weakness in nearly all and can last up to 3 months
  - Immunoglobulin: 2 g/kg IV over 2 to 5 days (5)[B]
  - *Plasmapheresis and immunoglobulin have comparable efficacy in treating moderate to*

severe MG (6)[C].

- Rapid onset of effect but short duration of action
- Used for acute worsening of MG to improve strength prior to surgery, prevent acute exacerbations induced by corticosteroids, and as a chronic intermittent treatment to provide relief in refractory MG.
- Other immunosuppressant therapies:
  - Tacrolimus
  - Rituximab:
    - Seronegative MuSK-antibody positive MG patients may have better response to rituximab than conventional therapies.

## **ALERT**

Use caution with drugs that can precipitate weakness: aminoglycosides, fluoroquinolones, *&bgr*;-blockers, calcium channel blockers, neuromuscular blockers, statins, diuretics, oral contraceptives, gabapentin, phenytoin, lithium, among others.

## ***SURGERY/OTHER PROCEDURES***

- Thymectomy recommended for patients with thymic abnormalities
- May be beneficial for patients without thymic abnormalities in those <60 years of age

## ***Pediatric Considerations***

- Infants with severe weakness from transient neonatal myasthenia may be treated with oral pyridostigmine; general support is necessary until the condition clears.
- Corticosteroids limited only to severe disease

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Management of pulmonary infections
- Myasthenic/cholinergic crises
- Plasmapheresis
- IV *&ggr*;-globulin

## ONGOING CARE

### PATIENT EDUCATION

MG Foundation of America (MGFA): <http://www.myasthenia.org/>

### PROGNOSIS

- Overall good but highly variable
- Myasthenic crisis associated with substantial morbidity and 4% mortality
- Seronegative patients are more likely to have purely ocular disease, and those with generalized SNMG have a better outcome after treatment.

### COMPLICATIONS

Acute respiratory arrest; chronic respiratory insufficiency

## Codes

**&NA;**

### ICD10

- G70.00 Myasthenia gravis without (acute) exacerbation
- G70.01 Myasthenia gravis with (acute) exacerbation
- P94.0 Transient neonatal myasthenia gravis

## Clinical Pearls

**&NA;**

- An autoimmune disease, marked by abnormal fatigability and weakness of selected muscles, which is relieved by rest
- Anticholinesterase medication and a thymectomy lessen symptom severity.
- Steroid therapy, plasma exchange, or immunoglobulin can be used in severely affected patients.

# Myelodysplastic Syndromes

Richard A. Larson, MD

## BASICS

### DESCRIPTION

Myelodysplastic syndromes (MDSs) constitute a heterogeneous group of acquired hematopoietic stem cell disorders characterized by cytologic dysplasia in the bone marrow and blood and by various combinations of anemia, neutropenia, and thrombocytopenia.

- The natural progression of disease evolves as cellular maturation becomes more arrested and blast cells accumulate. There is an overlap between arbitrary diagnostic subgroups (1)[C],(2)[A],(3)[C].
- World Health Organization (WHO) classification
  - Refractory cytopenia with unilineage dysplasia
    - Refractory anemia (RA); refractory neutropenia; refractory thrombocytopenia
    - <5% blasts and <15% ring sideroblasts in marrow; <1% blasts in blood
  - Refractory anemia with ring sideroblasts (RARS)
    - <5% blasts in marrow; <sup>3</sup>15% of erythroid precursors are ring sideroblasts; no blasts in blood
    - Also known as acquired idiopathic sideroblastic anemia
  - RARS and marked thrombocytosis
  - Refractory cytopenia with multilineage dysplasia:
    - Marked trilineage dysplasia but without excess blasts in marrow; no Auer rods; <1% blasts in blood
  - Refractory cytopenia with multilineage dysplasia and ring sideroblasts
  - RA with excess blasts-1 (RAEB-1):
    - 5-9% blasts in marrow; no Auer rods; <5% blasts in blood; <1,000 monocytes/mm<sup>3</sup>
  - RAEB-2

- 10-19% blasts in marrow; 5-19% blasts in blood; ± Auer rods; <1,000 monocytes/mm<sup>3</sup>
- MDS associated with isolated del(5q)
  - RA with erythroid hyperplasia, increased megakaryocytes with hypolobated nuclei, and normal or increased platelets; <5% blasts in marrow; <1% blasts in blood
- Acute MDS with sclerosis:
  - RAEB with marked myelosclerosis
- Chronic myelomonocytic leukemia (CMML) is now grouped with myelodysplastic/myeloproliferative disorders:
  - <20% blasts and promonocytes in marrow and blood with >1,000 monocytes/mm<sup>3</sup>
- RAEB in transformation is now considered acute myeloid leukemia (AML):
  - 20-30% blasts in marrow; >20% blasts in blood
  - Incidence: 2:1 (female > male)
- Therapy-related MDS (t-MDS):
  - Seen 3 to 7 years after treatment with alkylating agents and/or radiotherapy
  - Evolves to AML over ÷6 months
  - Classified by the WHO as therapy-related myeloid neoplasm
- System(s) affected: hematologic, lymphatic, immunologic
- Synonym(s): dysmyelopoietic syndrome; hemopoietic dysplasia; preleukemia; smoldering or subacute myeloid leukemia

## *Pediatric Considerations*

Pediatric presentations of MDS

- Monosomy 7 syndrome
- Juvenile chronic myelogenous leukemia

## **EPIDEMIOLOGY**

- Predominant age: median age, >65 years; uncommon in children and young adults
- Predominant sex: male = female

## *Incidence*

Apparent increased incidence (1 to 2/100,000 per year) in recent years may be due to improved diagnosis; incidence increases markedly with older age.

## *Genetics*

- Most are clonal neoplasms by cytogenetics, G6PD isoenzyme analysis, or restriction fragment length polymorphism analysis.
- Mutations in *RAS* oncogene
- Mutations in *RPS14* gene on chromosome 5q
- Mutations in *TET2*, *SF3B1*, *SRSF2*, *U2AF1*, *DNMT3A*, *ASXL1*

## **RISK FACTORS**

- Primary MDS is associated with older age, occupational exposure to petroleum solvents (benzene, gasoline), and smoking.
- Secondary (therapy-related) MDS is associated with prior treatment with alkylating agents or radiotherapy.

## **COMMONLY ASSOCIATED CONDITIONS**

- Anemia
- Neutropenia
- Thrombocytopenia
- Pancytopenia
- Opportunistic infections
- Bleeding, bruising
- Sweet syndrome (neutrophilic dermatosis)

## **DIAGNOSIS**

### **HISTORY**

- Fatigue
- Fever
- Easy bruising

## *PHYSICAL EXAM*

- Anemia
  - Fatigue
  - Shortness of breath
  - Light-headedness
  - Angina
- Leukopenia
  - Fever
  - Infection
- Thrombocytopenia
  - Ecchymoses
  - Petechiae
  - Epistaxis
  - Purpura
- Splenomegaly (uncommon)
  - Mild to moderate enlargement may be encountered, particularly in CMMoL.
- Skin infiltrates
  - Sweet syndrome

## *DIFFERENTIAL DIAGNOSIS*

- Other malignant disorders
  - Evolving AML or erythroleukemia
  - Chronic myeloproliferative disorders
  - Polycythemia vera
  - Myeloid metaplasia with myelofibrosis
  - Malignant lymphoma
  - Metastatic carcinoma
- Nonmalignant disorders

- Aplastic anemia
- Autoimmune disorders (Felty syndrome, lupus, hemolytic anemia)
- Nutritional deficiencies (vitamin B<sub>12</sub>, pyridoxine, copper, protein malnutrition)
- Heavy metal intoxication
- Alcoholism
- Chronic liver disease
- Hypersplenism
- Chronic inflammation
- Recent cytotoxic therapy or irradiation
- HIV infection
- Paroxysmal nocturnal hemoglobinuria

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- CBC with differential and peripheral smear
- Reticulocyte count and serum erythropoietin level if anemia were present
- Review of the peripheral blood smear for the presence of dysplasia
- Liver/spleen scan or CT, although rarely necessary, may disclose occult splenomegaly or lymphadenopathy.
- Cytogenetics
  - At least 50% of patients with primary MDS and nearly all with t-MDS have clonal chromosomal abnormalities: + 8, -7, del(5q), del(7q), del(20q), iso(17p), various others, and complex karyotypes.
  - Detection of clonal abnormality establishes a diagnosis of neoplasm and rules out a nutritional, toxic, or autoimmune disorder.
  - Cytogenetic analysis of metaphase cells from a bone marrow aspiration provides more information than fluorescence in situ hybridization analysis on blood cells.
- Granulocyte function tests: abnormal in 50% (decreased myeloperoxidase activity, phagocytosis, chemotaxis, and adhesion)
- Platelet function tests: impaired aggregation

- Marrow colony assays in vitro
  - Results are variable and correlate poorly with clinical course.
  - Poor clonal growth may suggest more rapid evolution to AML.
- Immunophenotyping
  - Nonspecific myeloid markers are present.
  - Occasionally, evidence can be found for concomitant lymphoproliferative disorder.
  - Loss of CD59 expression suggests paroxysmal nocturnal hemoglobinuria (PNH).

### *Follow-Up Tests & Special Considerations*

- Anemia: often macrocytic; occasional poikilocytosis, anisocytosis; variable reticulocytosis
- Granulocytopenia: hypogranular or agranular neutrophils with poorly condensed chromatin; Pelger-Huet anomaly with hyposegmented nuclei
- Thrombocytopenia: occasionally giant platelets or hypogranular platelets
- Fetal hemoglobin may be elevated.
- Flow cytometry to detect loss of CD59 on RBCs, CD16 on granulocytes, and CD14 on monocytes; typical of PNH
- Direct antiglobulin (Coombs) test
- Paraprotein: present in some
- Erythropoietin: usually normally elevated given the degree of anemia unless renal failure is present
- Increased serum and tissue iron (ferritin), especially if anemia has been long-standing
- Serum copper level

---

P.699

### *Diagnostic Procedures/Other*

- Review peripheral blood smear.
- Bone marrow aspiration, biopsy, and cytogenetics
- Myeloid gene mutation array

### *Test Interpretation*

- Ineffective hematopoiesis with dysplasia in one or more cell lineages dominates the bone

marrow picture in MDS.

- Marrow cellularity usually is normal or increased for the patient's age but may be hypoplastic in  $\div 10\%$ .
- Reticulin fibrosis usually is minimal except in t-MDS and acute MDS with sclerosis.
- Myeloblasts may be clustered in the intertrabecular spaces with abnormal localization of immature precursors.

## TREATMENT

### GENERAL MEASURES

- Immunize for pneumococcal pneumonia, pertussis, influenza, and hepatitis B (4)[C].
- RBC transfusions to alleviate symptoms
- Platelet transfusions only for bleeding or before surgery to avoid alloimmunization
- Early use of antibiotics for fever, even while culture results are pending, due to quantitative and qualitative granulocyte disorder
- Iron chelation therapy to avoid iron overload from chronic transfusions

### MEDICATION

#### First Line

- Epoetin alfa or darbepoetin can increase hemoglobin levels in MDS patients who have low serum erythropoietin levels at baseline (5)[C].
- Only azacitidine, decitabine, and lenalidomide have been approved by the FDA for MDS.
- Azacitidine and decitabine have been proven in randomized controlled trials to be more effective for these heterogeneous disorders than only supportive care, with antibiotics, and transfusions.
- Vitamins, iron, corticosteroids, androgens, or thyroid hormone are rarely helpful, unless evidence of a specific deficiency exists.
- Clinical trials show azacitidine, 75 mg/m<sup>2</sup>/day SC for 7 days and repeated every 28 days, decreases RBC transfusion requirements, yields longer times to AML or death, and improves quality of life.
- Decitabine was approved with a continuous IV schedule that usually requires hospitalization. More commonly, it is given at 20 mg/m<sup>2</sup> IV over 1 hour daily for 5 days as an outpatient,

repeated every 4 weeks.

- Lenalidomide, 10 mg PO daily for 21 days every 4 weeks has yielded complete remission in patients with MDS and del(5q). It is less effective in patients with MDS without del(5q) (6)[B].
- Intensive chemotherapy
  - Younger patients with MDS may benefit from AML chemotherapy, especially if Auer rods are present, but toxicity may be severe for older patients.
  - Remission durations are variable (median,  $\div$  1 year).
- Allogeneic hematopoietic stem cell transplantation:
  - Recommended for younger patients with HLA antigen-matched donors to eradicate the malignant clone and resupply normal hematopoietic stem cells (7)[A].
- Aminocaproic acid (epsilon-aminocaproic acid) or tranexamic acid may benefit patients with chronic, severe thrombocytopenia and bleeding.
- Contraindications: Cytotoxicity of chemotherapy may increase the risk of bleeding and infection and the need for transfusion support.
- Precautions: Aspirin, salicylates, and NSAIDs should be avoided.

## *Second Line*

- Danazol or prednisone may be of benefit for concomitant autoimmune thrombocytopenia.
- Investigational agents
  - Low doses of cytarabine, tretinoin (all-trans retinoic acid), 13-cis retinoic acid, arsenic trioxide, histone/protein deacetylase inhibitors, interferon, cyclosporine, antithymocyte globulin, filgrastim, and interleukin-3
  - Agents, such as thalidomide, that inhibit the production of tumor necrosis factor in the marrow.
- Amifostine may stimulate the proliferation of normal hematopoiesis.

## *ISSUES FOR REFERRAL*

- Refer younger adults for allogeneic hematopoietic cell transplantation.
- Refer patients with symptoms or transfusion requirements for clinical trials.

**ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

Usually outpatient, except when necessary to hospitalize for the treatment of infection, blood transfusions, or intensive chemotherapy

### ***Patient Monitoring***

- At least monthly during supportive care
- More frequently if receiving treatment

### ***DIET***

Reduce alcohol use and iron intake (unless patient is iron-deficient).

## ***PATIENT EDUCATION***

- Stop smoking.
- Seek early medical attention for fever, bleeding, or symptoms of anemia.
- Advise about the risks of chronic transfusion therapy.

## ***PROGNOSIS***

- Median survival for RA and RARS is 5 years, but it may extend much longer (8)[B].
- RA with del(5q) syndrome is favorable.
- Median survival for RAEB, RCMD, and CMMoL is  $\div$ 1 year; 50% of patients evolve to AML and the other 50% die of infection or bleeding.

## **COMPLICATIONS**

- Infection
- Bleeding
- Complications of anemia and transfusions

## **ICD10**

- D46.9 Myelodysplastic syndrome, unspecified
- D46.4 Refractory anemia, unspecified
- D46.B Refract cytopenia w multilin dysplasia and ring sideroblasts

## **Clinical Pearls**

**&NA;**

- MDS constitutes a heterogeneous group of acquired, hematopoietic stem cell disorders characterized by cytologic dysplasia in the bone marrow and blood and by various combinations of anemia, neutropenia, and thrombocytopenia.
- The natural progression of this malignant disease evolves as cellular maturation becomes more arrested and blast cells accumulate.

# Myeloproliferative Neoplasms

Tarsheen K. Sethi, MBBS

Sanjay Mohan, MD, MSCI

## BASICS

### DESCRIPTION

- Myeloproliferative neoplasms (MPNs) are a group of diseases that share a common cell of origin in the pluripotent hematopoietic stem cell.
- MPNs are characterized by proliferation of a specific stem cell lineage such as myeloid, erythroid, or megakaryocytic; resulting in granulocytosis, erythrocytosis, or thrombocytosis, respectively.
- The "classic" MPNs include chronic myelogenous leukemia (CML), polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF). The World Health Organization (WHO) classification also includes chronic neutrophilic leukemia, chronic eosinophilic leukemia not otherwise specified (CEL-NOS), systemic mastocytosis, and myeloproliferative neoplasm unclassifiable. This topic focuses on the classic MPNs.
- CML is characterized by the presence of Philadelphia-chromosome (reciprocal translocation between chromosomes 9 and 22 resulting in a *BCR-ABL* fusion gene). This results in an uninhibited proliferation of myeloid precursor stem cells resulting in granulocytosis and elevation of various granulocyte precursors.
- The following three MPNs are characterized by varying degree of presence of JAK 2 mutation.
  - PMF: MPN characterized by marrow fibrosis, extramedullary hematopoiesis, and splenomegaly
  - ET: MPN characterized by a clonal proliferation of megakaryocytes, leading to thrombocytosis
  - PV: MPN characterized by trilineage growth of hematopoietic stem cells with erythroid precursors predominating, leading to erythrocytosis

### EPIDEMIOLOGY

#### Incidence

- CML: 0.6 to 2.0/100,000/year; median age at diagnosis 66 years; male > female (1.6:1)
- PMF: 0.5 to 1.5/100,000/year; median age at diagnosis 65 years; male = female
- ET: 0.6 to 2.5/100,000/year; median age at diagnosis 60 years, second peak in younger patients at  $\pm$ 30 years; female > male (2:1)
- PV: 1 to 2/100,000/year; male > female (1.3:1)

## ETIOLOGY AND PATHOPHYSIOLOGY

- *CML*: *BCR-ABL1* gene leads to increased and unrestrained activity of the ABL tyrosine kinase resulting in an unchecked activation of downstream signaling pathways which have an antiapoptotic effect on the hematopoietic cells.
- *PMF*: Progenitor hematopoietic stem cells undergo a clonal proliferation independent of growth factors likely due to activation of downstream intracellular pathways. The fibroblasts are nonclonal, and the increased fibrosis is likely driven by growth factors released by hematopoietic cells especially megakaryocytes.
- *ET*: Thrombopoietin-induced megakaryocyte proliferation is uncontrolled due to a combination of increased sensitivity to thrombopoietin and decreased feedback regulation of the thrombopoietin levels which is usually inversely proportional to the platelet mass.
- *PV*: Gain-of-function mutation (*JAK2*) leads to increased erythrocyte production due to a downstream activation of proteins involved in cell proliferation and resistance to apoptosis. The *JAK2* tyrosine kinase is downstream of the erythropoietin receptor and thus its constitutive activation makes the hematopoietic progenitor cell independent of erythropoietin.

## Genetics

- Philadelphia chromosome (*BCR-ABL1* gene): translocation and fusion of the *BCR* gene on chromosome 22 and the *ABL* gene on chromosome 9; seen in all patients with CML
- *JAK2* mutations: point mutations in the tyrosine kinase domain of *JAK2*, causing a substitution of phenylalanine for valine at position 617 (*JAK2V617F*); leading to unrestrained *JAK2* activation with a deactivation of typical feedback mechanism
- Seen in >95% of PV cases; 50% of ET and PMF cases
- *CALR* mutation: Calreticulin (*CALR*) is an endoplasmic reticulum chaperone protein directing proper folding of proteins. This mutation may be seen in up to a third of patients of ET and PMF. These patients are seen to have a higher platelet count but lower risk of thrombosis.
- Myeloproliferative leukemia virus (*MPL*) gene: Mutations found in 5-10% of patients with PMF and in 3-5% of those with ET. This encodes the thrombopoietin receptor *MPL*.
- *JAK2*, *CALR*, and *MPL* mutations are mutually exclusive and together account for 85% of cases

of ET and PMF.

## **RISK FACTORS**

- Rare familial cases have been reported.
- CML: exposure to ionizing radiation

## **COMMONLY ASSOCIATED CONDITIONS**

- Progression to acute myeloid leukemia; most common with CML
- Thrombosis/hemorrhage

## **DIAGNOSIS**

### **HISTORY**

- Many MPN cases are found incidentally on routine blood work.
- CML: Most patients are asymptomatic at time of diagnosis.
  - Fatigue, malaise, weight loss, excessive perspiration, abdominal fullness, early satiety, bleeding episodes
- PMF: Symptoms depend on the degree of anemia and splenomegaly.
  - Fatigue, shortness of breath, early satiety, constitutional symptoms, cachexia, Budd-Chiari syndrome, splenic infarcts, osteosclerosis resulting in bone pains.
- ET: characterized by thrombotic and hemorrhagic events
  - Thrombotic events (deep vein thrombosis, pulmonary embolism, Budd-Chiari syndrome), microvascular occlusive events (digital ischemia, erythromelalgia), major/minor hemorrhagic events; headaches, dizziness, syncope, tingling, visual changes, transient ischemic attacks
- PV: Symptoms are due to level of erythrocytosis and the resultant increased blood viscosity.
  - Erythromelalgia, pruritus after hot baths, headaches, tinnitus, paresthesias, gout attacks

## **PHYSICAL EXAM**

- CML: splenomegaly, hepatomegaly

PMF: splenomegaly seen in nearly all patients, hepatomegaly, pallor

- ET: possible petechiae, purpura, ecchymosis; splenomegaly
- PV: cyanotic blush (lips, nose, ears, distal extremities), increased blood pressure, splenomegaly, epistaxis, ecchymosis

## DIFFERENTIAL DIAGNOSIS

- CML: leukemoid reaction (elevated LAP), juvenile myelomonocytic leukemia, chronic myelomonocytic leukemia (CMML), chronic eosinophilic leukemia, chronic neutrophilic leukemia
- PMF: other MPNs, lymphoma, hairy cell leukemia; secondary myelofibrosis (malignant or nonmalignant)
- ET: reactive thrombocytosis, CML, PV, PMF, and myelodysplastic syndromes
- PV: hypoxic states (e.g., chronic obstructive pulmonary disease [COPD], anemia), renal cell carcinoma, Wilms tumor, hepatoma, polycystic kidney disease, exogenous androgens

## DIAGNOSTIC TESTS & INTERPRETATION

- CML: White blood cell count  $>10,000 \times 10^9/L$  with differential showing increased mature and immature neutrophils and an increased percentage of myelocytes, metamyelocytes, and band forms; neutrophils have decreased leukocyte alkaline phosphatase; platelet count  $>600,000 \times 10^9/L$  and a normochromic, normocytic anemia. Basophilia is common.
- PMF (1)[A] (WHO criteria): Diagnosis requires meeting all three major criteria and two or more minor criteria:
  - *Major criteria:* (i) megakaryocyte proliferation and atypia accompanied by either reticulin or collagen fibrosis; (ii) not meeting WHO criteria for CML, PV, MDS, or other myeloid neoplasm; (iii) demonstration of *JAK2V617F* or other clonal marker or absence of marker with no evidence of secondary marrow fibrosis
  - *Minor criteria:* (i) leukoerythroblastosis, (ii) increased serum lactate dehydrogenase level, (iii) anemia, and (iv) palpable splenomegaly
- ET (1)[A] (WHO criteria): Diagnosis requires meeting all four major criteria:
  - *Major criteria:* (i) thrombocytosis with persistent platelet level  $\geq 450 \times 10^9/L$ ; (ii) megakaryocyte proliferation with large and mature morphology; (iii) not meeting the WHO criteria for CML, PV, PMF, MDS, or other myeloid neoplasm; and (iv) demonstration of *JAK2V617F* or other clonal marker or absence of clonal marker with no evidence of reactive thrombocytosis

PV (1)[A] (WHO criteria): Diagnosis requires either both major criteria and one minor criterion or the first major criterion and two of the minor criteria:

- *Major criteria:* (i) hemoglobin >18.5 g/dL in men, >16.5 g/dL in women or other evidence of increased red cell volume and (ii) presence of *JAK2V617F* or other functionally similar mutation (e.g., *JAK2* exon 12 mutation) (1)[B]
- *Minor criteria:* (i) bone marrow biopsy showing hypercellularity for age with trilineage myeloproliferation, (ii) low serum erythropoietin level, (iii) endogenous erythroid colony formation in vitro

## *Initial Tests (lab, imaging)*

If clinical suspicion of MPN, obtain a CBC and peripheral blood smear; if suggestive, obtain bone marrow biopsy.

- PMF: radiographic osteosclerosis in 25-66%

---

P.701

## *Diagnostic Procedures/Other*

- CML: diagnosis with identification of Philadelphia chromosome: Fluorescence in situ hybridization is more sensitive than karyotyping and is routinely used. Polymerase chain reaction (P210) is done at baseline to help monitor response to tyrosine kinase inhibitors.
  - Bone marrow biopsy: increased cellularity and increased myeloid to erythroid ratio
- PMF, ET, and PV: genotypic analysis and bone marrow biopsy as described in earlier WHO criteria;  $\text{O}^{\text{dry tap}}$  is common in PMF.
- Risk stratification
  - CML: three phases of CML
    - (i) Chronic phase (85% patients at diagnosis; <5% blast counts); (ii) accelerated phase (poorly controlled splenomegaly regardless of treatment, 10-19% blast counts, worsening anemia, basophil  $\geq 20\%$ ); and (iii) blast crisis (resembles acute myeloid or lymphoid leukemia, >20% blast counts)
  - PMF: International Prognostic Scoring System (IPSS) at diagnosis and Dynamic IPSS (DIPSS-plus) throughout disease
    - IPSS: age >65 years, constitutional symptoms, hemoglobin <10 g/dL, leukocyte count  $>25 \times 10^9$ , circulating blasts >1%
      - Low risk = 0 of above; intermediate-1 risk = 1 of above; intermediate-2 risk = 2 of

above; high risk = 3 of above

- DIPSS-plus: same 5 risk factors in the IPSS + the need for red cell transfusion, platelets  $<100 \times 10^9/L$  and unfavorable karyotype
  - Low risk = 0 of above; intermediate-1 risk = 1 of above; intermediate-2 risk = 2-3 of above; high risk = 3 of above
- ET: low risk = age  $<40$  years, no prior thromboembolic events, no cardiovascular risk factors, platelet count  $<1,500 \times 10^9/L$ ; intermediate risk = age 40 to 59 years, presence of cardiovascular risk factors, platelet count  $<1,500 \times 10^9/L$ ; high risk = age  $\geq 60$  years and/or prior thromboembolic or hemorrhagic episode and/or platelet count  $>1,500 \times 10^9/L$
- PV: low risk = age  $<60$  years, no history of thrombosis/cardiovascular risk factors; intermediate risk = platelets  $>1,000 \times 10^9/L$  and cardiovascular risk factors; high risk = age  $>60$  years or a history of thrombosis

## TREATMENT

### GENERAL MEASURES

Low-dose aspirin for ET and PV

### MEDICATION

#### First Line

- CML
  - Chronic phase: Imatinib mesylate (Gleevec): 400 mg/day, a tyrosine kinase inhibitor (TKI). Dasatinib and nilotinib are also approved for use in the first line (1).
  - Accelerated or blast phase: Increase imatinib to 800 mg/day or switch to 2nd- or 3rd-generation TKIs like nilotinib and dasatinib.
  - While awaiting confirmation of diagnosis, hydroxyurea can be used to lower the WBC count.
- PMF: Main goal is symptomatic relief:
  - Low and intermediate-1 risk: no drug therapy indicated, symptom-directed therapy
  - Intermediate-2 and high risk: hydroxyurea or consider allogeneic SCT
  - JAK2 inhibitor ruxolitinib is approved for intermediate or high-risk myelofibrosis. It is also approved for post-PV and post-ET myelofibrosis (2).

- Supportive treatment
  - Anemia: transfusions, erythropoiesis-stimulating agents, androgens, danazol, thalidomide, or lenalidomide
  - Splenomegaly: hydroxyurea, splenectomy, or IV cladribine for refractory cases
  - Thrombosis: hydroxyurea and low-dose aspirin
- ET low and intermediate risk: Watch and wait + low-dose aspirin if microvascular disturbances are present and no contraindications; high risk: hydroxyurea 15 mg/kg/day in divided doses to reduce platelet count to  $<450 \times 10^9/L$  (2).
- PV
  - Low and intermediate risk: phlebotomy and lowdose aspirin
  - High risk (or those who do not tolerate phlebotomy): hydroxyurea 500 to 1,000 mg/day (2).

## *Second Line*

- CML: Only curable treatment is aSCT; reserved for accelerated/blast phase due to high rates of morbidity and mortality with aSCT
  - 2nd-generation TKIs: dasatinib, nilotinib, and bosutinib; increasing evidence for improved, deeper responses with these medication resulting in use of 2nd-generation TKIs for first-line therapy. Ponatinib is a 3rd-generation TKI that has activity in cases of TKI resistance due to a T315I mutation for which all the other available TKIs are ineffective.
- PMF: Only curable treatment is allogeneic SCT; reserved for intermediate-2 or high-risk patients
  - If unresponsive to hydroxyurea, use pegylated interferon- $\alpha$ ; tolerance may be an issue.
- ET: If resistant/intolerant to hydroxyurea, use anagrelide.
  - If resistant/intolerant to hydroxyurea or anagrelide, pregnant or age  $<40$  years: Use interferon- $\alpha$ .
- PV: if resistant or intolerant to hydroxyurea, can use ruxolitinib

## *ISSUES FOR REFERRAL*

Patients with MPNs are usually referred to hematology/oncology.

## *SURGERY/OTHER PROCEDURES*

May require splenectomy/palliative radiation for foci of extramedullary hematopoiesis

# INPATIENT CONSIDERATIONS

## *Admission Criteria/Initial Stabilization*

Severe cachexia; renal failure and hepatomegaly secondary to extramedullary hematopoiesis; massive splenomegaly requiring treatment; severe thrombotic/hemorrhagic episodes; anemia; tumor lysis syndrome

## *IV Fluids*

Optimal hydration to prevent tumor lysis syndrome

## ONGOING CARE

## PROGNOSIS

- CML: 10-year survival rate  $\approx$ 80% from time of diagnosis; 85% will die in blast crisis; 12- to 18-month median survival for accelerated phase; 3- to 6-month median survival for blast phase
- PMF: worst prognosis of the MPNs; drug therapy does not modify disease course but treats the symptoms; median survival for IPSS low risk = 135 months, intermediate-1 risk = 95 months; intermediate-2 risk = 48 months; high risk = 27 months
- PV: median survival often >10 years
- ET: near-normal life expectancy

## COMPLICATIONS

- CML: blast crisis, transformation to acute leukemia, gout, or nephropathy due to hyperuricemia
- PMF: 10% develop acute myeloid leukemia; anemia, massive hepatosplenomegaly, thrombohemorrhagic events, osteosclerosis, secondary gout, splenic infarcts, paraspinal/epidural extramedullary hematopoiesis
- ET: <10% develop post-ET myelofibrosis, 2% develop acute myeloid leukemia; thrombohemorrhagic events
- PV: 15-20% develop post-PV myelofibrosis, 5% develop leukemia; erythromelalgia, pruritus, secondary gout, headaches, vascular occlusive events

## Clinical Pearls

**&NA;**

Ruxolitinib has a role in amelioration of constitutional and splenomegaly-related symptoms in myelofibrosis.

# Narcolepsy

Jennifer M. Slowik, DO, MS

Kevin A. Carter, DO, FAASM

## BASICS

### DESCRIPTION

- Disorder characterized by excessive daytime sleepiness often associated with cataplexy (sudden bilateral weakness of skeletal muscles) and other rapid eye movement (REM) sleep phenomena, such as sleep paralysis and hypnagogic hallucinations (e.g., vivid auditory or visual perceptions without an external stimulus that occur as one is falling asleep).
- Frequently overlooked disorder, with an average of 15 years of symptoms prior to diagnosis
- System affected: nervous

### EPIDEMIOLOGY

#### *Incidence*

- Onset usually in teenage years
- Bimodal distribution peak at 15 and 35 years of age
- Predominant sex: male > female (1.6:1)
- Incidence: 0.74/100,000 persons/year

#### *Prevalence*

- Narcolepsy type 1 (with cataplexy): 25 to 50/100,000 people
- Narcolepsy type 2 (without cataplexy): 20 to 34/100,000 people

### ETIOLOGY AND PATHOPHYSIOLOGY

- Narcolepsy type 1 is a neurodegenerative disorder resulting from selective loss of neurons containing hypocretin (orexin) in the hypothalamus; may be autoimmune (associated with influenza A, H1N1 vaccine, and *Streptococcus pyogenes*).
- Orexin neurons also regulate metabolism, feeding, reward and autonomic tone; weight gain

especially in children from reduction of metabolism

- 90-95% of patients with narcolepsy type 1 have low hypocretin in CSF
- The cause of narcolepsy type 2 is not well established.
- Possible involvement of immune system and environmental influences

## *Genetics*

- Increased incidence in families with positive history: 1-2% in first-degree relative of index case (10 to 40 times the general population)
- Twin concordance is 25-31% (suggests environmental contribution).
- Most are sporadic
- 85-95% of patients with narcolepsy and cataplexy have human leukocyte antigen (HLA) DQB1\*0602; 45% of patients with narcolepsy without cataplexy express this antigen. HLA DQB1\*0602 is present in 24% of the general population.
- Autosomal-recessive inheritance pattern
- 12% of Asians, 25% of Whites, and 38% of African Americans are gene carriers.

## *RISK FACTORS*

- Obesity
- Head trauma
- CNS infectious disease
- Anesthesia
- Psychological stress
- Family history
- Recent influenza A, streptococcal infection, or H1N1 vaccine

## *COMMONLY ASSOCIATED CONDITIONS*

Obstructive sleep apnea (up to 25%), obesity, anxiety

## **DIAGNOSIS**

### **HISTORY**

- Classic tetrad of excessive daytime sleepiness, cataplexy, sleep paralysis, and

hypnagogic hallucinations (four most common symptoms): Only 10-20% of patients have all four symptoms

- 3 general forms
  - Narcolepsy type 1: 40%
  - Narcolepsy type 2: 60%
  - Secondary narcolepsy due to a medical condition (e.g., Parkinson disease with sleep disturbance, myotonic dystrophy, CNS tumors, Prader-Willi syndrome, Niemann-Pick disease type C)
- Excessive daytime sleepiness and sleep attacks (cardinal symptom)
  - Primary symptom and required for diagnosis
  - Instantaneous, irresistible REM sleep
  - First and most disabling symptom
  - Tendency to take naps lasting 5 to 10 minutes
  - Episodes last minutes and rarely more than an hour
  - 1 to 8 naps/day but normal 24-hour sleep duration
  - Associated with dreaming
  - Nap restores wakefulness for several hours
  - More likely in a monotonous, warm environment, after a large meal, or with strong emotions
- Cataplexy: auxiliary symptom (60%; cardinal symptom)
  - Pathognomonic if present
  - Sudden bilateral weakness of skeletal muscles
  - Provocation by sudden strong emotions
  - Consciousness and memory are not impaired.
  - Short duration (seconds to minutes)
  - Can be limited to a particular muscle group (e.g., jaw droop with inability to speak; arm, neck, or leg weakness; respiratory and eye muscles not affected)
  - Status cataplecticus is a rare, prolonged episode of cataplexy (lasting hours) that is more likely in children or on withdrawal of drugs.
- Sleep paralysis: auxiliary symptom (25-50%)
  - When falling asleep or on awakening, the patient wants to but cannot move; this can end abruptly when the patient is touched or spoken to.
  - Brain wakes from sleep while body remains paralyzed in REM sleep

- Lasts seconds to minutes
- Patients are aware of events around them but cannot open eyes or move.
- Can be preceded by hallucinatory phenomena
- 50% of the normal population have had at least one of these episodes (thus, this symptom is nonspecific)
- Hypnagogic hallucinations: auxiliary symptom (30-60%)
  - Vivid, frightening visual, auditory or tactile illusions or hallucinations at onset of sleep
  - Dreamlike experiences that occur during wakefulness or suddenly at sleep onset
  - Characteristic hallucinations include seeing human or animal faces or feeling that someone else is in the room.
- Disturbed nocturnal sleep (66%)
  - Normal total sleep with decreased sleep efficiency
  - More frequent transitions from wakefulness to sleep
  - Retrograde amnesic and automatic behavior lasting minutes to hours
  - Increased periodic leg movements (50%)
  - Depression (18-37%)
  - Automatic behavior: activity without memory of the event
  - Panic attacks and social phobias (20%)

## *PHYSICAL EXAM*

- A complete exam is useful to rule out other causes of hypersomnia.
- If cataplexy is witnessed, examiner will be unable to elicit deep tendon reflexes.

## *DIFFERENTIAL DIAGNOSIS*

Excessive daytime sleepiness is present in 4% of the general population, although most individuals are not narcoleptic. Possible etiologies include the following:

- Sleep apnea syndromes (40-50% of those with excessive somnolence); increased incidence in narcolepsy, up to 26% prevalence
- Epileptic seizures and syncope
- Idiopathic hypersomnia (5-10% of those with excessive somnolence)
- Psychiatric (depression, substance abuse/withdrawal)

- Sleep related movement disorders (restless leg syndrome, periodic limb movements of sleep)
- Iatrogenic secondary to medication (benzodiazepines, opioids, antihistamines, *&bgr*;-blockers, and some antipsychotics, antidepressants, and anticonvulsants)
- Poor sleep hygiene and habits leading to sleep deficit
- Circadian rhythm disorders (jet lag, shift work, delayed or advanced sleep phase disorders)
- Seizures
- Niemann-Pick type C
- Hypersomnia related to a medical condition, such as Parkinson disease
- Kleine-Levin syndrome (recurrent hypersomnia that lasts days to weeks and recurs months later)
- Menstrual-associated hypersomnia

### *Pediatric Considerations*

Narcolepsy is rare before the age of 5 years. Excessive daytime sleepiness is more often attributable to obstructive sleep apnea (OSA), poor sleep hygiene, and the increased sleep requirements early in life. Recommended amount of sleep decreases with age: newborns 16 to 18 hr/day; preschool-aged children 11 to 12 hr/day; school aged children and teens 10 hr/day; adults 7 to 8 hr/day.

## **DIAGNOSTIC TESTS & INTERPRETATION**

### *Initial Tests (lab, imaging)*

- Epworth Sleepiness Scale: score ranges from 0 to 24 and >10 is suggestive of a sleep disorder rather than generalized fatigue (1)[A].
- Stanford Sleepiness Scale: patients select one of seven statements that best describe energy level, concentration, and sleepiness. Statements 4 to 7 may indicate excessive sleepiness.
- Nighttime polysomnography (PSG): Monitoring of patients in a sleep laboratory will usually document fragmented sleep with a normal amount of REM sleep but rapid onset REM (within 15 minutes of sleep onset) and decreased sleep efficiency (2)[A]. The PSG is useful to rule out other causes of excessive daytime sleepiness, including sleep apnea syndromes and nocturnal myoclonus.

---

P.703

- Multiple sleep latency test (MSLT): begins <sup>3</sup>90 minutes after nighttime test (2)[A]
  - The patient is monitored during 4 to 5, 20 minute naps taken at 2-hour intervals; rapidity of

sleep onset and type of sleep pattern are documented. The supportive test includes mean sleep latency (time to fall asleep) of  $\geq 8$  minutes and  $\geq 2$  sleep-onset REM periods.

- Sensitivity 77%; specificity 97%; positive predictive value 73%
- Maintenance of Wakefulness Test (MWT): used to assess ability to remain awake to determine restrictions (e.g., driving), assess treatment response. Not usually performed during the initial evaluation.

## *Follow-Up Tests & Special Considerations*

- HLA typing for DQB1 in ambiguous cases
- Low CSF hypocretin-1 level: 99% specificity, 87% sensitivity in patients with cataplexy; useful in children when unable to do an MSLT

## *Diagnostic Procedure/Other*

- Narcolepsy type 1 (2)[C]
  - Excessive daytime sleepiness daily for  $\geq 3$  months
  - One of the following:
    - Cataplexy with sleep latency  $\geq 8$  minutes with  $\geq 2$  sleep-onset REM periods within 15 minutes of the onset of sleep (SOREMP)
    - Low CSF hypocretin-1 level  $< 110$  pg/mL or  $< 1/3$  of mean values in normal subjects
- Narcolepsy type 2 (2)[C]
  - All above without the cataplexy and low hypocretin-1
- Diagnosis of exclusion

## **TREATMENT**

### *GENERAL MEASURES*

- None of the currently available medications enables people with narcolepsy to consistently maintain a fully normal state of alertness.
- Drug therapy should be supplemented by various behavioral strategies: Avoid shift work, heavy meals, and caffeine later in the day.
- Well-timed 20-minute naps may be helpful.

- Avoid sedating drugs and alcohol.
- Use safety precautions, particularly when driving. People with untreated narcoleptic symptoms are involved in automobile accidents roughly 10 times more frequently than the general population. However, accident rates are at normal levels among patients who have received appropriate medication therapy.

## *MEDICATION*

### *First Line*

- Excessive daytime sleepiness (EDS)
  - Modafinil (Provigil) (3)[A]:
    - Structurally distinct from amphetamines
    - 200 to 400 mg/day divided BID; start with 100 mg/day and increase over 3 to 4 days; maximum of 300 mg/dose, 400 mg/day 3.
    - First-line treatment: 60% effective and 20% partially effective
    - Half-life of 14 hours, can dose daily
    - Fewest adverse effects (headache, GI upset, increased metabolism of oral contraceptives) with less rebound hypersomnia and does not affect BP; tolerance limited
    - No decrease in cataplexy
  - Armodafinil (Nuvigil):
    - Enantiomeric form of modafinil with slightly longer half-life of 15 hours
    - 150 to 250 mg every morning
- Cataplexy:
  - Sodium oxybate (Xyrem):
    - 2.5 to 9 g; may take 3 months for full response
    - Preferred treatment for narcolepsy with cataplexy and disturbed nocturnal sleep
    - Give 1/2 dose once in bed and 1/2 dose 2 to 4 hours later.
    - Date rape drug; abuse potential (3)[A]
    - Can use with modafinil in severe cases
    - May worsen sleep-disordered breathing in patients with OSA

Expensive with short half-life

- Tricyclic antidepressants
  - Protriptyline: 5 to 60 mg/day
  - Clomipramine: 10 to 150 mg/day
  - High side-effect profile: dry mouth, sedation, urinary retention, impotence
- Serotonin-norepinephrine reuptake inhibitors
  - Venlafaxine: 37.5 to 75 mg BID
  - Fluoxetine: 20 to 80 mg/day
  - Work by suppressing REM sleep
- The patient may develop a tolerance to the antiepileptic drugs and can have rebound cataplexy when a drug is withdrawn.
- Although often used, quality evidence is lacking to demonstrate improvement in cataplexy symptoms from antidepressants (4)[A].
- Auxiliary symptoms (e.g., hypnagogic hallucination, sleep paralysis) require treatment less often than EDS and cataplexy but antiepileptics are useful when symptoms are problematic (4)[C].

## *Second Line*

- EDS
  - Amphetamines
    - Methylphenidate (Ritalin): initial dose 10 to 60 mg/day divided BID or TID; maximum dose 60 mg/day (3)[B], short-acting, most potent amphetamine available. Can be used in combination with modafinil and armodafinil. Dextroamphetamine: initial dose 10 mg/day; can increase by 10 mg weekly to a maximum dose 60 mg/day divided BID or TID (3)[B]
    - Contraindicated in patients with HTN
    - Adverse reactions: headaches, irritability, hypertension (HTN), psychosis, anorexia, habituation, rebound hypersomnia
    - If the patient develops a tolerance to stimulants, switch drugs rather than increase dose; there is little cross-tolerance
- Cataplexy
  - Selegiline: selective MAO-B inhibitor

- Anticatataplectic effective for excessive daytime sleepiness; 20 to 40 mg/day divided morning and noon (3)[B]
- Doses >20 mg require a low-tyramine diet because the drug begins to lose selectivity.

## ISSUES FOR REFERRAL

- Unresponsive to primary medications
- Patient support groups can be very beneficial.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

Frequent BP checks and regular follow-ups (approximately every 6 months) are recommended.

#### *DIET*

Selegiline: Doses >20 mg require a low-tyramine diet because the drug begins to lose selectivity.

### PATIENT EDUCATION

- Narcolepsy information from the National Institute of Neurological Disorders and Stroke at [www.ninds.nih.gov/disorders/narcolepsy/narcolepsy.htm](http://www.ninds.nih.gov/disorders/narcolepsy/narcolepsy.htm)
- Narcolepsy Network, Inc., North Kingstown, RI 02852; [www.narcolepsynetwork.org](http://www.narcolepsynetwork.org)

### PROGNOSIS

Narcolepsy is a lifelong disease. Symptoms can worsen with aging. In women, symptoms can improve after menopause.

## Codes

&NA;

### ICD10

- G47.419 Narcolepsy without cataplexy
- G47.411 Narcolepsy with cataplexy
- G47.429 Narcolepsy in conditions classified elsewhere w/o cataplexy

## Clinical Pearls

&NA;

- Narcolepsy is a frequently missed disorder, with an average of 15 years of symptoms before a definitive diagnosis is made.
- The classic tetrad of symptoms includes excessive daytime sleepiness, cataplexy, sleep paralysis, and hypnagogic hallucinations but only cataplexy is pathognomonic for the disorder.
- The International Classification of Sleep Disorders has specific diagnostic criteria for narcolepsy.
- Medications are helpful but not curative.

# Nasal Polyps

**Katherine Holmes, MD**

**Daniel Young, MD**

## BASICS

- Chronic inflammatory lesion of nasal mucosa
- Appearance of edematous pedunculated mass in the nasal cavity or within the paranasal sinus
- Often causes symptoms of blockage, discharge, or loss of smell
- Most commonly bilateral; suspect tumor, such as inverted papilloma, if unilateral
- Estimated to be  $\div$ 1-4% in adults
- Much rarer in children:  $\div$ 0.1%
- Increases with age
- Predominant sex: female > male (2:1)
- Asthma is present in 65% of patients, 25% of patients have undiagnosed asthma.
- No clearly delineated pathway; research has demonstrated separate TH1- and TH2-driven pathways (1,2)[B].
- Development of condition remains unclear; multiple inflammatory and infectious pathways resulting from chronic rhinosinusitis is most common (1,3)[B].
- Chronic sinusitis
- Allergic fungal sinusitis
- Aspirin sensitivity
- Cystic fibrosis
- Primary ciliary dyskinesia (Kartagener syndrome)
- Laryngopharyngeal reflux (4)[B]

## GENERAL PREVENTION

Use of intranasal corticosteroids after polyp removal surgery has shown effectiveness against recurrence.

## COMMONLY ASSOCIATED CONDITIONS

- Bronchial asthma
- Aspirin hypersensitivity
- Allergic rhinitis (4)[B]
- Cigarette smoking promotes eosinophilic inflammation.

## DIAGNOSIS

- Two or more symptoms, one of which is either nasal blockage/obstruction/congestion OR nasal discharge (5)[A].
- Nasal obstruction/restricted nasal airflow: persistent mouth breathing (5)[A]
- Nasal discharge:
  - Anterior discharge/rhinorrhea
  - Postnasal drip
- Reduction/loss of smell
- Dull headaches
- Facial pain/pressure
- Symptoms of acute, recurrent, or chronic rhinosinusitis (5)[A]
- Anterior rhinoscopy looking for a pale translucent mass of tissue
  - Most commonly from lateral wall of middle meatus
  - Otoloscope with nasal speculum or even otologic speculum is typically used (5)[A].
- Flexible/rigid endoscopy is required to assess the nasal cavity fully (5)[A].
  - Endoscopy is the gold standard for diagnosis.
  - Topical anesthesia nasal spray should be used prior to the endoscopy if patient is awake.
- Tympanic membrane examination for eustachian tube dysfunction secondary to large posterior nasal polyps (5)[A]
- Examine the posterior pharynx via oral cavity for large posterior polyps (5)[A].
- Antrochoanal polyp
- Benign or malignant tumor:

- Papilloma
- Intranasal glioma
- Encephalocele
- Rhabdomyosarcoma
- Mycetoma
- Allergy testing (3)[B]:
  - Skin prick test
  - Immunocap testing
  - Radioallergosorbent test (RAST)
- Testing for cystic fibrosis in children with multiple benign polyps: sweat test: often requires repeat tests (3)[B]
- CT scanning (3)[B]:
  - May be helpful to corroborate history and endoscopic findings
  - Unable to differentiate polyp from other soft tissue masses
- MRI (3)[B]:
  - May aid in unilateral polyposis if concern for neoplasia, mycetoma, or encephalocele

Histologic exam to exclude malignancy if unilateral polyp

- Diagnosis is made by the combination of rhinoscopy, endoscopy, and CT scanning.
- CT reveals extent of disease and is necessary to formulate a plan for surgical intervention (3)[B].
- Ciliated pseudostratified columnar epithelium: with areas of transitional or squamous epithelium
- Chronic infiltration of inflammatory cells
- Eosinophils are the predominant cells in most patients (4)[B].

## TREATMENT

- Intranasal corticosteroid use has been demonstrated to reduce polyp size and recurrence, as well as improvement in nasal congestion based on controlled studies (2,5)[A],(6)[B].

- Treat for a minimum of 12 weeks; minimal systemic absorption, side effects rare—minor nose bleeding is most common (2,5)[A].
  - Budesonide 256 &mgr;g/day
  - Beclomethasone dipropionate 320 &mgr;g/day
  - Fluticasone propionate 400 &mgr;g/day
  - Mometasone furoate 200 &mgr;g BID
  - For children mometasone furoate is preferred:
    - 100 &mgr;g BID ages 6 to 12
    - 200 &mgr;g BID for ages 12 to 17 (7)[A]
- Oral systemic corticosteroids: less definitive benefit; more systemic adverse effects; use with caution in patients with diabetes mellitus, hypertension, or peptic ulcer disease (2,5)[A]

P.705

- Prednisolone
  - Weight-based dosing burst with taper
- Perioperative use oral prednisone 30 mg daily 5 to 7 days prior to surgery (2)[A]
  - Decrease nasal mucosa inflammation
  - Improves surgical field
  - Shorter surgical time
  - Improves postop results
  - Weight-based dosing burst with taper

## ***ISSUES FOR REFERRAL***

Patients with severe obstruction symptoms should be referred for surgery (5)[A].

## ***ADDITIONAL THERAPIES***

Antileukotrienes: clinical improvement without aspirin hypersensitivity (2,5)[A],(3)[B]:

- Aspirin desensitization may have a role in reducing recurrence of nasal polyposis.
- Anti-interleukin-5 immunomodulators: may benefit those with T<sub>H</sub>2 eosinophilic disease process
- Oral antibiotics: doxycycline for 3 to 4 weeks or oral macrolide for 12 weeks is an option for disease unresponsive to steroids alone with mixed results of therapy (8)[C]

- Indicated for patients with four or more episodes in 1 year of acute rhinosinusitis refractory to medical therapy (5)[A]
  - Disease must be documented endoscopically or on CT during symptomatic period prior to surgical intervention.
- Most surgeries are approached endonasally.
  - Endoscopic sinus surgery has become the mainstay of treatment.
  - The external (Caldwell-Luc) approach is used for more difficult cases but carries higher risk of complications.
- Functional endonasal sinus surgery has slightly lower revision rate than intranasal polypectomy. Both modalities provide effective symptom relief.
- Postoperative use of nasal corticosteroids delay the recurrence of nasal polyps and hence the timing of revision surgery (2)[A],(6)[B].
- Postoperative use of steroid releasing stents to prevent polyp recurrence by decreasing mucosal inflammation (2)[A],(6)[B].
- Intrapolyp steroid injection may be considered in cases refractory to other interventions but has risk of visual loss.

## ONGOING CARE

- Acute/chronic sinus infection
- Heterotropic bone formation within the sinus cavity
- Recurrence:
  - Of patients, 5-10% with severe disease
  - Twice as likely in those with asthma (4)[B]

## Codes

**&NA;**

### ICD10

- J33.9 Nasal polyp, unspecified
- J33.0 Polyp of nasal cavity
- J33.8 Other polyp of sinus

## Clinical Pearls

**&NA;**

- Intranasal corticosteroid use has been demonstrated to reduce polyp size and recurrence, as well as improvement in nasal congestion.
- Asthma is a common concomitant diagnosis and is often previously undiagnosed.
- Aggressive medical and surgical treatment improves asthma outcomes.
- Treat for a minimum of 12 weeks
- Allergy testing can be helpful.
- Nasal polyposis associated with asthma and aspirin hypersensitivity known as Samter triad or aspirin exacerbated respiratory disease (AERD) (1,3)[B]
- Patients with severe obstruction should be referred for surgery.
- Unilateral nasal polyp needs malignancy workup (MRI).

# Near Drowning/Nonfatal Drowning

Stephen L. Cook, MD

Matthew Kendall Hawks, MD

## BASICS

### *DESCRIPTION*

- Survival for at least 24 hours following respiratory impairment due to submersion in liquid
- System(s) affected: cardiovascular, nervous, pulmonary, renal
- Synonym(s): submersion injury; drowning with or without morbidity

### *EPIDEMIOLOGY*

#### *Incidence*

- From 2009 to 2013, an average of 4,268 deaths/year occurred from drowning in the United States (1).
- Three age-related peaks: toddlers and young children (1 to 5 years), adolescents and young adults (15 to 25 years), and the elderly
- 80% of people who die from drowning are male (2).
- Greater incidence in minorities; African Americans age 5 to 14 years old are affected at 3 times the Caucasian rate (2).

#### *Prevalence*

- From 2009 to 2013, drowning was the second most common cause of death among children age 1 to 4 years old and was the fifth most common cause of accidental death among all ages overall (1).
- For every child age <15 years who dies from drowning, five more children are seen in the emergency room for nonfatal submersion injuries.

### **ALERT**

Proper water safety techniques are critical in avoiding morbidity and mortality from drowning.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Hypoxemia via aspiration and/or reflex laryngospasm causing cerebral hypoxia and multisystem organ involvement

- 10-20% of victims drown without aspiration; likely due to prolonged laryngospasm, previously termed "dry lungs."
- Bathtub and bucket drowning in children <1 year of age
- Swimming pool drowning in children and young adults
- Motor vehicle accidents (e.g., automobile submerged in water)
- Head trauma while swimming or diving
- Suicide
- Pulmonary: morbidity primarily as a result of hypoxia. Aspiration also causes dilution of surfactant with decreased gas transfer across alveoli, atelectasis, development of intrapulmonary right-to-left shunting; acute respiratory distress syndrome (ARDS); obstruction due to laryngospasm and bronchospasm
- Cardiac: hypoxic-ischemic injury and arrhythmia (primary or secondary)
- Renal: acute tubular necrosis from hypoxemia, shock, hemoglobinuria, myoglobinuria
- Neurologic: hypoxic-ischemic brain injury with damage especially to the hippocampus, insular cortex, and basal ganglia; cerebral edema
- Coagulation: hemolysis and coagulopathy

## *RISK FACTORS*

- Alcohol ingestion
- Use of illicit drugs
- Seizure disorder
- Inability to swim
- Hyperventilation prior to underwater swimming
- Risk-taking behavior
- Inadequate physical barriers surrounding pools
- Boating mishaps and trauma during water sports, particularly when not wearing a life jacket
- Scuba diving

Inadequate adult supervision of children

- Concomitant stroke or myocardial infarction (MI)
- Hypothermia
- Cardiac arrhythmias: familial long QT and polymorphic ventricular tachycardia (VT)
- Residence within sunbelt states
- African Americans
- Low socioeconomic status
- Lack of instruction regarding swimming and supervision

## **GENERAL PREVENTION**

- Periodic education/reinforcement of supervision with an emphasis on drowning prevention for caretakers of young children
- Consistent practice of proper adult supervision of children
- Knowledge of water safety guidelines
- Mandatory physical barriers surrounding pools
- Pool alarms
- Fences higher than 54 inches (137 cm) for home pools
- Avoidance of alcohol or recreational drugs around water
- Swimming instruction at an early age
- Cardiopulmonary resuscitation (CPR) instruction for pool owners and parents
- Boating safety knowledge
- Personal flotation device (e.g., preserver, if necessary)

## ***Pediatric Considerations***

Children should never be left alone near water. Young children can drown in very small amounts of water, such as in bathtubs, buckets, and toilets.

## **COMMONLY ASSOCIATED CONDITIONS**

- Trauma
- Seizure disorder
- Alcohol or illicit drug use

- Hypothermia
- Concomitant stroke or MI
- Cardiac arrhythmias: familial long QT and familial polymorphic VT
- Hyperventilation

## DIAGNOSIS

### HISTORY

- Victim found in or near water
- Duration of submersion
- Loss of consciousness
- Period of apnea
- Artificial ventilation/CPR performed
- History of associated trauma
- Approximate water temperature
- Recent use of alcohol or drugs
- Known seizure disorder
- Known cardiac disease, including arrhythmia or prolonged QT
- Preceding syncope or history of medical condition predisposing to syncope

### PHYSICAL EXAM

- Airway status and degree of respiratory effort and/or distress
- Pulse: absent, weak, or normal
- Vital signs, including pulse oximetry
- Glasgow Coma Scale (GCS)
- Wheezing
- Evidence of trauma

### DIFFERENTIAL DIAGNOSIS

Syncopal event, head trauma, arrhythmia, seizure, MI, stroke, alcohol or other substance overdose, nonaccidental trauma

# DIAGNOSTIC TESTS & INTERPRETATION

## *Initial Tests (lab, imaging)*

May be unnecessary if initial GCS and pulse oximetry are normal and remain that way for 6 to 8 hours.

- CBC with differential
- Arterial blood gases (ABGs): hypoxia, hypercarbia, acidosis
- Electrolytes: hypokalemia, hyponatremia, hypernatremia
- Blood glucose: May be low if the cause of near drowning; increased levels may impair neurologic recovery after ischemic brain injury.
- BUN, creatinine: acute tubular necrosis
- EKG, cardiac monitoring, and serial troponin: MI
- Creatine kinase (CK) and urine myoglobin: rhabdomyolysis
- Coagulation studies: coagulopathy
- Urinalysis/urine drug screen
- Blood alcohol level
- A chest x-ray (CXR) may be unnecessary for patients with all of the following:
  - Normal initial GCS and pulse oximetry
  - No evidence of respiratory distress
  - No change after 6 to 8 hours of observation
- For others, a CXR may show evidence of aspiration, atelectasis, pneumothorax, or ARDS.
- Head CT and/or C-spine imaging as needed for associated trauma.

## *Follow-Up Tests & Special Considerations*

- Patients with an initial GCS of 15 and pulse oximetry >95% should be observed for 6 to 8 hours in the emergency department (ED).
- CXR findings may be minimal or absent on early imaging.

## *Diagnostic Procedures/Other*

- Continuous cardiac monitoring
- Continuous pulse oximetry

- Continuous core temperature monitoring if hypothermic
- ECG
- Central venous pressure (CVP) monitoring for critically ill patients with hypotension refractory to IV fluids
- Electroencephalogram (EEG) if suspect seizure as cause

## TREATMENT

Early resuscitation and reversal of hypoxemia optimizes outcome.

### GENERAL MEASURES

- Prehospital
    - Never approach a struggling victim alone.
- 
- Initially evaluate as per Basic Life Support (BLS) and Advanced Cardiovascular Life Support (ACLS) (3).
  - Rescue breathing may be helpful while the victim is in the water and not able to be immediately removed from the water, but chest compressions in the water may not be effective and may even harm the rescuer and the victim (3)[C].
  - Remove the victim from the water and begin effective resuscitation as quickly as possible (4).
  - Early CPR that emphasizes effective chest compressions and rapid defibrillation as indicated.
  - Start CPR if pulse is not definitely felt within 10 seconds, even in the hypothermic victim whose heart rate may be severely bradycardic (3)[C].
  - Routine cervical collar use and spinal precautions are not needed unless a high suspicion for trauma exists (5)[C].
  - Supplemental oxygen and early intubation, as needed (5)[A].
  - If patient is breathing on his or her own and does not need spinal precautions, consider placing in the right lateral decubitus position to prevent aspiration of vomit or gastric contents (4).
- ED
    - Oxygen, as needed, to maintain saturation >94%.

P.707

Continuous positive airway pressure (PAP), BiPAP, or intubation if supplemental O<sub>2</sub> alone is unsuccessful

- If intubation is indicated, employ lung-protective vent settings (lower end-inspiratory airway pressures, lower tidal volumes of 6 mL/kg, higher positive end-expiratory pressures of 6 to 12 cm H<sub>2</sub>O) to avoid lung barotrauma (6)[A].
- Indications for intubation
  - Neurologic deterioration
  - Inability to protect the airway
  - Inability to maintain oxygen saturation >90% or PaO<sub>2</sub> >60 mm Hg on high-flow supplemental oxygen
  - PaCO<sub>2</sub> >50 mm Hg
- Remove wet clothing and initiate rewarming.
- Core temperature reading for possible hypothermia
- Rewarming with minimally invasive core rewarming such as warm IV fluids, warm/humidified oxygen, and external rewarming
- Active core rewarming reserved for refractory cases and only when extracorporeal blood warming is unavailable, depending on physician comfort level, due to major complications that can develop including core temperature after drop, rewarming acidosis, and rewarming shock.

## *MEDICATION*

### *First Line*

- High-flow oxygen, as needed (4)[A]
- For bronchospasm: aerosolized bronchodilator (4)[C]: albuterol (Proventil, Ventolin), 3 mL of 0.083% solution *or* 0.5 mL of 0.5% solution diluted in 3 mL of saline
- Pressors, as needed, for hypotension refractory to IV fluid resuscitation
- Prophylactic antibiotics and steroids are not helpful (5)[B].

### *Second Line*

For pneumonia: antibiotics based on sputum or endotracheal lavage culture (5)[A]

## *INPATIENT CONSIDERATIONS*

## *Admission Criteria/Initial Stabilization*

- All symptomatic patients
- Patients with abnormalities in vital signs, mental status, oxygenation, CXR, or laboratory analysis

## *IV Fluids*

To maintain adequate intravascular volume (4)[C]

## *Nursing*

- Continuous cardiac monitoring
- Continuous pulse oximetry monitoring
- Frequent monitoring of vital signs and clinical reassessment
- Careful monitoring of neurologic status

## *Discharge Criteria*

Patients can be discharged from the ED after 6 to 8 hours of observation if the following criteria are met:

- GCS = 15
- Normal CXR, if indicated
- Lack of clinical evidence of respiratory difficulty
- Normal lung exam
- Normal vital signs
- Oxygen saturation  $\geq 95\%$  on room air (5)

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

Appropriate follow up with primary care provider, orthopedic, neurologic, cardiac, pulmonary, and additional specialists as indicated

## *Patient Monitoring*

- Continuous cardiac monitoring

- Continuous pulse oximetry monitoring
- Frequent monitoring of vital signs and clinical reassessment
- Careful monitoring of neurologic status
- ABG monitoring, as indicated (5)
- A pulmonary artery catheter may be needed for hemodynamic monitoring in unstable patients (4)[C].
- Intracranial pressure monitoring in selected patients (4)[C]
- Serum electrolyte determinations (5)

## *DIET*

NPO until mental status normalizes

## *PATIENT EDUCATION*

Re-emphasize preventive measures on discharge from hospital. Educate parents regarding supervision and preventive practices.

## *PROGNOSIS*

- 75% of drowning victims survive; 6% of these with residual neurologic deficits
- Patients with an initial GCS  $\geq 13$  and an oxygen saturation  $\geq 95\%$  have a low risk of complications and an excellent chance for a full recovery.
- Patients who are comatose or receiving CPR at the time of presentation, as well as those who have dilated and fixed pupils and no spontaneous respiratory activity have a more guarded and often poor prognosis, often secondary to neurologic sequelae.
- Neurogenic pulmonary edema may occur within 48 hours of initial presentation.

## **COMPLICATIONS**

- Early
  - Bronchospasm
  - Vomiting/aspiration
  - Hypoglycemia
  - Hypothermia
  - Seizure
  - Hypovolemia
  - Electrolyte abnormalities

- Arrhythmia from hypoxia or hypothermia (rarely from electrolyte imbalance)
- Hypotension
- Late
  - ARDS
  - Anoxic encephalopathy
  - Pneumonia
  - Lung abscess/empyema
  - Renal failure
  - Coagulopathy
  - Sepsis
  - Barotrauma
  - Seizure

**&NA;**

## **ICD10**

- T75.1XXA Unsp effects of drowning and nonfatal submersion, init
- T75.1XXD Unsp effects of drowning and nonfatal submersion, subs
- T75.1XXS Unsp effects of drowning and nonfatal submersion, sequela

## **Clinical Pearls**

**&NA;**

- The single most important treatment for near-drowning victims is prompt reversal of the hypoxic state. This should form the cornerstone for all other treatment modalities. Without oxygenation, other treatment is futile.
- Family physicians and pediatricians should review water safety tips and guidelines with parents and children at yearly visits. Encourage pool owners and parents with young children to become CPR-certified. Prevention of drowning can save many lives each year.
- Despite successful resuscitation, patients are at risk for ARDS due to delayed pulmonary edema that may start hours after their submersion incident. For this reason, careful monitoring of every resuscitated patient is essential.
- Patients requiring intubation should be treated with lung-protective vent settings to prevent barotrauma.
- Patients with an initial GCS <sup>3</sup>13 and an oxygen saturation <sup>3</sup>95% have a low risk of complications and an excellent chance for a full recovery.

# Nephrotic Syndrome

Jeremy D. DeFoe, DO

Karen S. Phelps, MD

## BASICS

### DESCRIPTION

- A clinical syndrome of heavy proteinuria ( $>3.5$  g/1.73 m<sup>2</sup>/24 hr), hypoalbuminemia, hyperlipidemia, and edema
- Includes both primary and secondary forms
- Associated with many types of kidney disease

### EPIDEMIOLOGY

Based on definitive diagnosis

- Diabetic nephropathy: most common cause of secondary nephrotic syndrome (1)
- Minimal change disease (MCD)
  - Most common nephrotic syndrome in children, peaks at 2 to 8 years
  - Associated with drugs or lymphoma in adults
- Amyloidosis: rare
- Lupus nephropathy (LN): Adult women are affected about 10 times more often than men.
- Focal segmental glomerulosclerosis (FSGS)
  - 25% of nephrotic syndrome in adults
  - Most common primary nephrotic syndrome in African Americans
  - Has both primary and secondary forms
- Membranous nephropathy
  - Most common primary nephrotic syndrome in Caucasians
  - Associated with malignancy and infection

- Membranoproliferative glomerulonephritis (MGN)
  - May be primary or secondary
  - May present in the setting of a systemic viral or rheumatic illness

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Increased glomerular permeability to protein molecules, especially albumin
- Edema results primarily from renal salt retention, with arterial underfilling from decreased plasma oncotic pressure playing an additional role.
- Hyperlipidemia is thought to be a consequence of increased hepatic synthesis resulting from low oncotic pressure and urinary loss of regulatory proteins.
- The hypercoagulable state that can occur in some nephrotic states is likely due to loss of antithrombin III in urine.
- Primary renal disease:
  - MCD
  - FSGS
  - MGN
  - IgA nephropathy
- Secondary renal disease (associated primary renal disease are shown in parentheses):
  - Diabetic nephropathy
  - Amyloidosis
  - LN
  - FSGS
  - Infections (MGN)
  - Cancer (MCD or MGN)
  - Drugs (MCD or MGN)

## *Genetics*

Genetic factors are likely to play a role in susceptibility to the various nephrotic syndromes, although these have not been sufficiently defined to be useful clinically.

## *RISK FACTORS*

- Drug addiction (e.g., heroin [FSGS])
- Hepatitis B and C, HIV, other infections
- Immunosuppression
- Nephrotoxic drugs
- Vesicoureteral reflux (FSGS)
- Cancer (usually MGN, may be MCD)
- Chronic analgesic use/abuse
- Preeclampsia
- Diabetes mellitus

## GENERAL PREVENTION

In general, there are few preventive measures, except avoidance of known causative medications.

## DIAGNOSIS

### HISTORY

- Inquire about signs or symptoms of systemic disease: joint complaint, rash, edema, infectious complaint, fevers, anorexia, oliguria, foamy urine, acute flank pain, hematuria.
- Obtain a recent drug history for medications that may be causative, especially NSAIDs.
- Assess for risk factors.

## PHYSICAL EXAM

A complete physical exam may discover clues to systemic disease as a potential cause and/or may suggest the severity of disease.

- Fluid retention: abdominal distention, abdominal fluid shift, extremity edema, puffy eyelids, scrotal swelling, weight gain, shortness of breath. Pericardial rub and decreased breath sounds with pleural effusions may develop.
- Hypertension
- Orthostatic hypotension

## ALERT

The potential for thromboembolic disease leading to pulmonary embolism is one of the most life-threatening aspects of a patient who is actively nephrotic.

## *DIFFERENTIAL DIAGNOSIS*

- Edema and proteinuria: see Etiology and Pathophysiology.
- Edema alone: Other diseases to rule out in patients who have edema without proteinuria include congestive heart failure, cirrhosis, hypothyroidism, nutritional hypoalbuminemia, protein-losing enteropathy.

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Confirm proteinuria if present: by urine dipstick initially, and then quantitate by 24-hour urine or spot urine protein-to-creatinine ratio.
- Rule out urine infection with urine culture.
- Full blood count and coagulation screen
- Renal function tests: BUN, creatinine with estimated glomerular filtration rate (GFR)
- Glucose to rule out overt diabetes
- Consider blood cultures to rule out a postinfectious process.
- Lipid panel
- Liver function tests to exclude liver disease or infection
- Look for autoimmune disease.
  - Antinuclear antibody and/or antidouble-stranded DNA positivity suggest lupus.
  - Complement levels: A low C3 may suggest a postinfectious or membranoproliferative process, whereas both low C3 and C4 point to lupus.
- Serum protein electrophoresis/urine immune electrophoresis to rule in a paraproteinemia
- Hepatitis B and C screen
- HIV and syphilis testing
- Urinalysis to evaluate for the presence of cellular casts
- Renal US to verify the presence of 2 kidneys of normal shape and size
- Chest x-ray to detect presence of pleural effusion or infection

- If thrombosis is suspected:
  - Doppler US of the legs
  - MRI or venography for renal vein thrombosis
  - Ventilation/perfusion nuclear medicine lung scan and/or CT may be required to rule out pulmonary embolism.

## *Diagnostic Procedures/Other*

### Renal biopsy

- Rarely done in children with first episode of nephrotic syndrome, as MCD is common and empiric steroid therapy is the standard of care.
- Required to confirm the clinical diagnosis in adults and assist with making a treatment plan (1)

## *Test Interpretation*

- Light microscopy
  - May see nothing (e.g., MCD)
  - Sclerosis (e.g., FSGS or diabetic nodules in diabetes)
  - Diffuse hypercellularity suggests a proliferative disease such as IgA nephropathy, LN, or postinfectious glomerulonephritis (GN).
- Immunofluorescence: Mesangial IgA suggests IgA nephropathy, Henoch-Schönlein; other staining patterns are specific for other disease processes.
- Electron microscopy: The location of immunoglobulin deposits is useful in pointing to a particular diagnosis.

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Edema: salt restriction and salt-wasting diuretics (loop and thiazide diuretics):
  - Salt restriction to <2 g sodium per day
  - Restrict fluid intake to <1.5 L/day if hyponatremic.
  - Target weight loss of 0.5 to 1 kg/day (1 to 2 lb/day)

- Statins have been shown to improve endothelial function (2)[A] and may decrease proteinuria (3)[A], but effect on GFR and preservation of renal function is small. The major role for statin use is in cardiovascular risk reduction.
- ACE inhibitors or angiotensin II receptor blockers are thought to reduce proteinuria, hyperlipidemia, thrombotic tendencies, progression of renal failure, and to control hypertension, if present (2,4)[A].
- For steroid-responsive disease (MCD and FSGS), steroids dosed in consultation with nephrologist

## *Second Line*

- Many of the nephrotic diseases will require escalation in therapy above steroids. These include rapidly relapsing forms, as well as MGN, LN, and IgA nephropathy. Bolus steroids and other immunosuppressives are required in this circumstance (cyclophosphamide, mycophenolate mofetil, chlorambucil, cyclosporine) (5)[A].
- Rituximab, combined with steroids or other immunosuppressive agents, has demonstrated early promise in the treatment of refractory nephrotic syndrome (6)[B].
- Randomized controlled data have been insufficient to determine which patients require prophylactic anticoagulation (7)[A]. Common practice is to anticoagulate with heparin and then warfarin in patients who have persistent nephrotic-range proteinuria. This decision is made based on the patient's history of edema, hypoalbuminemia, thromboembolism, or immobility.
- Hypocalcemia from vitamin D loss should be treated with oral vitamin D.

## *ISSUES FOR REFERRAL*

Consultation with a nephrologist is often required to assist with renal biopsy to confirm diagnosis and to assist with management of edema. Cytotoxic medications may be called for, depending on the disease process, and this may best be handled by a nephrologist.

## *ADDITIONAL THERAPIES*

Ambulation or range-of-motion exercises to lower risk of deep vein thrombosis (DVT)

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Respiratory distress, sepsis/severe infection, thromboses, renal failure, hypertension, or other complications

## *Discharge Criteria*

Hemodynamically, stable patients without complications may be managed as outpatients.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Frequent monitoring is required for relapse, disease progression, and for detecting signs of toxicity of medical management.
- Reevaluate for azotemia, urine protein, hypertension, edema, loss of renal function, cholesterol, and weight.

#### *DIET*

- Normal protein (1 g/kg/day)
- Low fat (cholesterol)
- Reduced sodium
- Supplemental multivitamins and minerals, especially vitamin D and iron
- Fluid restriction if hyponatremic

### *PATIENT EDUCATION*

- Printed material for patients: National Kidney Foundation, 30 E. 33rd Street, Suite 1100, New York, NY 10016; 800-622-9010
  - Childhood nephrotic syndrome
  - Diabetes and kidney disease
  - Focal glomerulosclerosis
- Web site: National Institutes of Health: nephrotic syndrome

### *PROGNOSIS*

Nephrotic syndrome in children (MCD) is typically self-limited and carries a good prognosis. In the adult, the prognosis is variable. Complete remission is expected if the basic disease is treatable (infection, malignancy, drug-induced); otherwise, a relapsing and remitting course is possible, with progression to dialysis seen in more aggressive forms (diabetic glomerulosclerosis).

## COMPLICATIONS

- Thromboembolism:
  - Deep vein, renal vein, or central venous thrombosis may occur.
  - The risk appears to be greater the lower the serum albumin.
  - Pulmonary embolism is a known complication.
- Pleural effusion
- Ascites
- Hyperlipidemia, cardiovascular disease
- Acute renal failure, progressive renal failure
- Protein malnutrition/muscle wasting
- Infection secondary to low serum IgG concentrations, reduced complement activity, and depressed T-cell function: peritonitis, pneumonia, or cellulitis
- Loss of vitamin D (vitamin D-binding protein loss in urine) leading to bone disease

## Codes

**&NA;**

### ICD10

- N04.9 Nephrotic syndrome with unspecified morphologic changes
- N04.1 Nephrotic syndrome w focal and segmental glomerular lesions
- N04.2 Nephrotic syndrome w diffuse membranous glomerulonephritis

## Clinical Pearls

**&NA;**

- Nephrotic syndrome is a clinical syndrome of  $>3.5$  g/day proteinuria, hypoalbuminemia, hyperlipidemia, and edema often associated with diabetes and NSAIDs use.
- Pediatric nephrotic syndrome typically carries a good prognosis and is more easily treated with steroids, although recurrences are common.
- Nondiabetic adults with nephrotic syndrome will require a renal biopsy to determine cause.
- Have a high index of suspicion for symptoms that may represent an embolic event in patients with nephrotic syndrome.

# Neurofibromatosis Type 1

Rayna Goldstein, MD

Michele Roberts, MD, PhD

## BASICS

### DESCRIPTION

- Neurofibromatosis types 1 (NF1) and 2 (NF2) are neurocutaneous syndromes (phakomatoses). Although they share a name, they are distinct and unrelated conditions with genes on different chromosomes.
  - NF2 is a rare condition that causes bilateral vestibular schwannomas.
  - NF1 is a multisystem disorder that may affect any organ. It is the most common of the phakomatoses.
- System(s) affected: musculoskeletal, nervous, skin/exocrine, cardiovascular, neuroophthalmologic
- Synonym(s): von Recklinghausen disease, formerly peripheral NF

### EPIDEMIOLOGY

#### Incidence

- Predominant sex for NF1: male = female
- Birth incidence NF1: 1:2,500 to 3,000

#### Prevalence

1:3,000 to 1:4,000

### ETIOLOGY AND PATHOPHYSIOLOGY

- Neurofibromin is a guanosine triphosphatase-activating protein that acts as a tumor suppressor by downregulating a cellular protooncogene, *p21-ras*, which enhances cell growth and proliferation.
- Neurofibromata are benign tumors composed of Schwann cells, fibroblasts, mast cells, and vascular components that develop along nerves.

- The two-hit hypothesis has been invoked to explain malignant transformation in *NF1*.

## Genetics

- Online Mendelian Inheritance in Man 162200
- Caused by a mutation in the *NF1* gene on chromosome 17q11.2; autosomal dominant inheritance; protein product is called *neurofibromin*.
- 50% of cases are due to de novo mutations, mostly paternal; likelihood increases with paternal age
- Prenatal diagnosis is possible if mutation is known.
- Penetrance is nearly 100%; expressivity is highly variable, even within a family.
- Gene is large, with a variety of mutations causing NF1. Molecular technology can detect 95% of clinically important *NF1* mutations, but clinical diagnosis frequently can be made in childhood.
- ÷5% of individuals with NF1 have a large deletion of the entire *NF1* gene (or nearly so); they usually have a more severe phenotype.
- *Segmental NF* is limited to a single body region and is caused by mosaicism for the *NF1* mutation.

## RISK FACTORS

- Having an affected first-degree relative is a diagnostic criterion for NF1, although relatives may be unaware of their condition.
- Affected individuals with a positive family history, as well as those with a new mutation, have a 50% risk of transmitting NF1 to each of their offspring; 1 in 12 will be severely affected.
- Individuals with segmental NF1 may have gonadal mosaicism and may be at risk for transmission of the mutated gene.

## COMMONLY ASSOCIATED CONDITIONS

Congenital heart disease, pulmonary stenosis, hypertension, renal artery stenosis

## DIAGNOSIS

- NF1 can be diagnosed by routine exam by age 4 years, with attention to skin stigmata; diagnostic criteria include <sup>32</sup> of the following (1):

- 36 café au lait (light brown) macules, 35 mm in prepubertal individuals or 315 mm in adults
  - 32 neurofibromata of any type or 1 plexiform (noncircumscribed) neurofibroma
  - Axillary or inguinal freckling
  - 32 Lisch nodules (benign iris hamartomas, asymptomatic)
  - Optic glioma by MRI
  - Characteristic osseous lesions: sphenoid dysplasia, long-bone cortical thinning, ribbon ribs, angular scoliosis
  - First-degree relative with NF1 by above criteria
- Prenatal diagnosis is possible with known mutation or by linkage testing (with positive family history), although not predictive of clinical course.

## HISTORY

- Family history of a first-degree relative with NF1
- Manifestations generally are not visible at birth, although plexiform neurofibromata usually are congenital and tibial bowing is congenital.
- In addition to cutaneous lesions, NF1 may present with painful neurofibromata, pathologic fractures, or headaches secondary to hypertension caused by pheochromocytomas.
- Optic gliomata may present as involuntary eye movement, squinting, loss of vision, or as diencephalic syndrome.

## PHYSICAL EXAM

- Skin
  - Café au lait macules develop during the first 3 years of childhood and are usually the presenting feature of NF1. Evenly pigmented, irregularly shaped (coast-of-California), light brown macules present in 97% of patients with NF1; many unaffected individuals have one to three such macules.
  - Neurofibromata can be cutaneous, subcutaneous, or plexiform and may be soft or firm; buttonhole invagination is pathognomonic. Cutaneous neurofibromata usually begin to appear during late childhood or adolescence.
  - Plexiform neurofibromata are present in up to 50% of individuals with NF1
    - Usually congenital; may be subtle in infancy
    - Freckling or hypertrichosis may be present over plexiform neurofibromata; may affect underlying structures or cause focal hyperplasia

- Many are internal, not obvious on exam.
- Most grow slowly over many years but can have rapid growth, especially in early childhood.
- Evaluate for new lesions and progression of preexisting ones. Rapidly growing cutaneous lesions should be evaluated thoroughly.
- Axillary freckling (Crowe sign) or inguinal freckling (91%)
- Ophthalmologic
  - Lisch nodules (benign iris hamartomas) in 30%: well-defined, dome-shaped, gelatinous hamartomatous lesions projecting from the iris, varying from clear yellow to brown
  - Essentially unique to NF, Lisch nodules are asymptomatic; significant only for diagnosis.
  - Pallor or atrophy of optic disc, bulging of orbit, loss of vision may be signs of optic glioma.
- Skeletal
  - Scoliosis and vertebral angulation
  - Localized bone hypertrophy, especially of the face
  - Limb abnormalities:
    - Pseudoarthrosis of the tibia
    - Tibial dysplasia (anterolateral bowing of the tibia) is congenital, if present.
    - Nonossifying fibromas of the long bones in adolescents and adults are uncommon but can increase risk of fracture.
- Pay particular attention to neurologic examination or new focal pain.
- Measure BP yearly. Hypertension is more common in patients with NF1 and could be secondary to renal artery stenosis, aortic stenosis, and pheochromocytoma.
- Evaluate neurodevelopmental progress in children. Learning disabilities occur in 50-75%.

## ***DIFFERENTIAL DIAGNOSIS***

Familial café au lait spots (autosomal dominant, no other NF1 features), Legius syndrome, constitutional mismatch repair deficiency syndrome (CMMRD), NF2, Watson syndrome, LEOPARD syndrome, McCune-Albright syndrome, neurocutaneous melanosis, proteus syndrome, lipomatosis, Jaffe-Campanacci syndrome

## *Geriatric Considerations*

In NF1, cutaneous lesions and tumors increase in size and number with age.

## *Pediatric Considerations*

- Children who have inherited the *NF1* gene of an affected parent usually are identified by age 1 year, but external stigmata may be subtle. If there are no stigmata by age 2 years, NF is unlikely, but the child should be reexamined within the next few years. Definite diagnosis can be made by age 4 years using National Institute of Health (NIH) criteria (1).
- Young children with multiple café au lait spots, but no other stigmata after careful physical and ophthalmologic evaluation, should be followed clinically as if they have NF1 (2).
- Molecular confirmation may be appropriate, especially with atypical presentation (3).

## **DIAGNOSTIC TESTS & INTERPRETATION**

- DNA sequence and deletion/duplication analysis of the *NF1* gene can identify mutations in ÷96% of those with a clinical diagnosis.
- Molecular genetic testing is available, although often not necessary for diagnosis. Diagnostic laboratory information: <https://www.genetests.org/>
- Confirmatory genetic testing is appropriate in those who are suspected of having NF1 but do not fulfill diagnostic criteria or for prenatal diagnosis or preimplantation genetic diagnosis (PGD) (4).

## *Initial Tests (lab, imaging)*

- Characteristic radiographic findings: sphenoid dysplasia, long bone cortical thinning, ribbon ribs, and angular scoliosis. Screening radiographs of the knees in adolescents is controversial. CT can demonstrate bony changes.
- MRI findings of the orbits, brain, or spine (86%). Routine head MRI scanning in asymptomatic individuals with NF1 is controversial. Optic gliomata (seen on MRI, 11-15%) may lead to blindness. Although areas of increased T<sub>2</sub> signal intensity (unidentified bright objects) are common on brain MRI, they are not diagnostic of NF1 and likely are of no clinical significance.

---

P.711

- The NIH Consensus Development Conference does not recommend routine neuroimaging as a means of establishing a diagnosis, although modification of diagnostic criteria is discussed (1) [C].

## *Diagnostic Procedures/Other*

- Ophthalmologic evaluation, including slit-lamp exam of the irides; visual field testing to evaluate optic gliomata

- Neuropsychological testing: Intelligence usually normal but may have significant deficits in language, visuospatial skills, and neuromotor skills.

## TREATMENT

### MEDICATION

#### *First Line*

There are no specific therapeutic agents approved; individual aspects are treated as they arise (e.g., anticonvulsants for seizures, medications for ADHD, management of blood pressure).

#### *Second Line*

- In case studies, Sirolimus, a mammalian target of rapamycin [mTOR] inhibitor, did not shrink nonprogressive plexiform neurofibromas, but did relieve pain and retard progression of inoperable plexiform neurofibromas (5)[C].
- Multiple clinical trials for NF1 are recruiting patients (see <https://www.clinicaltrials.gov/>).

### ISSUES FOR REFERRAL

- Patients with more than minimal manifestations of NF1: Refer to a multidisciplinary NF clinic.
- Referral for psychosocial issues of family and affected individuals
- Educational intervention for children with learning disabilities or ADHD (40%)
- Early referral to orthopedics for congenital tibial bowing

### ADDITIONAL THERAPIES

- Occupational therapy for children with NF1 who present with fine motor difficulties
- There is no evidence supporting laser therapy for café au lait spots.
- The Children's Tumor Foundation (CTF) has established the NF Clinical Trials Consortium and the CTF NF Clinic Network to facilitate future clinical trials and help identify best practices (6).

### SURGERY/OTHER PROCEDURES

Surgical treatment for severe scoliosis, plexiform neurofibromata, or malignancy

# ONGOING CARE

## *FOLLOW-UP RECOMMENDATIONS*

NF1 health supervision 2008 guidelines:

- Infancy to 1 year (7)[C]
  - Growth and development: mild short stature, macrocephaly (increased brain volume); aqueductal stenosis/obstructive hydrocephalus, hydrocephalus
  - Check for focal neurologic signs or asymmetric neurologic exam.
  - Skeletal abnormalities, especially spine and legs
  - Neurodevelopmental progress
- 1 to 5 years (7)[C]
  - Café au lait spots and axillary freckling have no clinical significance.
  - Annual ophthalmologic exam
  - Brain MRI for visual changes, persistent headaches, seizures, marked increase in head size, plexiform neurofibroma of the head
  - Assess speech and language: hypernasal speech due to velopharyngeal insufficiency and delayed expressive language development.
  - Developmental evaluation of learning and motor abilities; may benefit from speech/language and/or motor therapy, and special education
  - Monitor BP annually.
- 5 to 13 years (7)[C]
  - Evaluate for skin tumors causing disfigurement and obtain consultation if surgery is desired to improve appearance or function.
  - Evaluate for premature or delayed puberty. If sexual precocity is noted, evaluate for an optic glioma or hypothalamic lesion. Review the effects of puberty on NF.
  - Evaluate for learning disabilities and ADHD.
  - Evaluate social adjustment, development, and school placement.
  - Monitor ophthalmologic status yearly until age 8 years; complete eye exam every 2 years.
  - Monitor BP annually.
  - Refer patient to a clinical psychologist or child psychiatrist for problems with self-esteem.

Discuss growth of neurofibromata during adolescence and pregnancy.

- Counsel parents about discussing diagnosis with child.
- 13 to 21 years (7)[C]
  - Examine the adolescent for abnormal pubertal development.
  - Thorough skin examination for plexiform neurofibromata and a complete neurologic exam for findings suggestive of deep plexiform neurofibromata; seek surgical consultation for signs of pressure on deep structures.
  - Continue to monitor BP yearly.
  - Continue ophthalmologic examination every 2 years until age 18 years.
  - Discuss genetics of NF1 or refer for genetic counseling.
  - Discuss sexuality, contraception, and reproductive options.
  - Discuss effects of pregnancy on NF1, if appropriate. Neurofibromata may enlarge and new tumors may develop during pregnancy.
  - Review prenatal diagnosis or refer the patient to a geneticist.

## ***PATIENT EDUCATION***

- Genetic counseling and patient education regarding future complications about family planning
- Support groups are important: <http://www.ctf.org/>.

## ***PROGNOSIS***

Variable; most patients have a mild expression of NF1 and lead normal lives.

### **COMPLICATIONS**

- Disfigurement: Skin neurofibromata develop primarily on exposed areas. The number tends to increase with puberty or pregnancy.
- Scoliosis: 10-30% (most cases mild); bowing of long bones, 2%; osteopenia and osteoporosis
- A large head is common but rarely associated with hydrocephalus.
- Increased risk of malignancy: malignant peripheral nerve sheath tumor (MPNST) (5-10%) usually in adults (1), especially within the field of previous radiotherapy for plexiform neurofibroma
- CNS tumors (5-15%), especially optic pathway glioma (most common CNS tumor), most often asymptomatic, but if symptomatic, usually presents before age 6 years. Symptomatic lesions are usually stable or only slowly

progressive.

- High relative risk (RR) for some uncommon malignancies
- Increased risk for pheochromocytoma, rhabdomyosarcoma, leukemia, Wilms tumor
- Relative risk for cancer of the esophagus (3.3), stomach (2.8), colon (2.0), liver (3.8), lung (3.0), bone (19.6), thyroid (4.9), malignant melanoma (3.6), non-Hodgkin lymphoma (3.3), chronic myeloid leukemia (6.7), female breast (2.3), and ovary (3.7)
- Learning disability: ~50%; may be associated with ADHD; mental retardation in 4-8%
- GI neurofibromata may cause GI disturbances.
- Seizures: 6-7%
- Hypertension is a frequent finding in adults and may occur during childhood.
- Disorders of puberty

### ***Pregnancy Considerations***

Increased risk of perinatal complications, stillbirth, intrauterine growth constriction; risk of cord compression, and outlet obstruction by pelvic neurofibromata

&NA;

Tuberous Sclerosis Complex; Von Hippel-Lindau Syndrome

## Codes

&NA;

### ICD10

Q85.01 Neurofibromatosis, type 1

## Clinical Pearls

&NA;

- Marked clinical variability. External stigmata may be subtle or absent in young children. Minimally affected children may become severely affected adults.
- A single café au lait spot is of no concern in a child, but having <sup>36</sup> is a diagnostic criterion for NF1.

# Neuropathic Pain

Janet Grotticelli, DO, MBA, CHSE

## BASICS

### DESCRIPTION

- Defined as pain caused by a lesion or disease that leads to an abnormal and dysfunctional somatosensory system (1)
- A complex state that arises from abnormal neural activity secondary to disease, injury, or dysfunction of the peripheral or central nervous system
- Can exist without ongoing disease
- Can arise from damage to the nerve pathways at any point from the terminals of the peripheral nociceptors to the cortical neurons in the brain
- May be triggered by direct nerve injury, infection, metabolic dysfunction, autoimmune disease, neoplasm, drugs, radiation, and neurovascular disorders
- May reflect abnormal central nervous system activity rather than a manifestation of any underlying pathology itself (i.e., phantom limb pain, complex regional pain syndrome [CRPS])

### EPIDEMIOLOGY

#### *Incidence*

Data is challenging due to the diversity of related clinical entities.

- Includes various chronic conditions that together, affect up to 8% of the population (2)

#### *Prevalence*

- Approximately 20% of people with cancer have cancer-related neuropathic pain as a result of either the disease or its treatment (3).
- The lifetime incidence of herpes zoster (shingles) is  $\div$  25%. Studies in the United States and Netherlands found 2.6% and 10%, respectively, will develop chronic postherpetic neuralgia (3).
- 33 million people infected with HIV across the world;  $\div$  35% have neuropathic pain (3)

- Up to 50% of people with diabetes have some form of neuropathy.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Positive symptoms due to changes in peripheral nerves, loss of inhibitory mechanisms in CNS, and central sensitization
- Negative symptoms (sensory deficits) reflecting neural damage
- Associated with a predisposing factor
- Risk factors:
  - Demyelinating disorders (multiple sclerosis, Guillain-Barré)
  - Neoplasm (primary/metastatic)
  - Neurovascular (central poststroke syndrome, diabetes, trigeminal neuralgia)
  - Autoimmune disease (Sjögren syndrome, polyarteritis nodosa)
  - Structural disease (herniated disc disease) (4)

## *RISK FACTORS*

- General risk factors include older age, female gender, physical inactivity, manual occupation
- There is growing evidence of genetic factors
- Includes factors that increase the risk of underlying conditions, as well as those that increase the risk of pain when these conditions are present:
  - Diabetes
  - Herpes zoster
  - Trigeminal neuralgia
  - HIV
  - Lyme disease
  - Cancer and chemotherapy
  - Stroke
  - Multiple sclerosis
  - Trauma
  - Surgery
  - Limb amputation

- Nutritional deficiencies
- Medications

## COMMONLY ASSOCIATED CONDITIONS

- Depression/anxiety
- Insomnia
- Drug dependence

## DIAGNOSIS

The diagnosis is based primarily on history (e.g., underlying disorder and distinct pain qualities) and the findings on physical examination (e.g., pattern of sensory disturbance); however, several tests may sometimes be helpful (2,5)[A].

### HISTORY

- Careful history that includes:
  - Onset and duration of symptoms: this is a chronic condition, location, intensity, character, temporal profile, and possible exacerbating factors. Concomitant symptoms should also be questioned. Past medical and surgical history, psychosocial history, and functional history (i.e., the impact of symptoms on level of mobility, activities of daily living, relation with others, sleep, and mood) are also important.
  - Sensory descriptors: numbness, weakness, reduced sensation to touch, pinprick, temperature, or vibration; decreased proprioception
- Pain is often described as burning, shock-like, tingling (2,4)[A]
- No single feature is diagnostic (1).

## PHYSICAL EXAM

- Positive signs/symptoms (2,6)[A]
  - Hypoesthesia (abnormally reduced sensation of a tactile stimulus) to touch or cold
  - Hypoalgesia (abnormally reduced pain sensation to a noxious stimulus)
  - Hyperalgesia: (abnormally increased pain sensation to a noxious stimulus) to pinprick, blunt pressure, heat, or cold
  - Allodynia: (pain sensation to a nonnoxious stimulus) for example, pain evoked by light

touch, clothing, bed sheets

- Motor signs and symptoms: may include hypotonia, tremor, dystonia, ataxia, hypo-/hyperreflexia, or motor neglect. Motor symptoms include weakness, fatigability, decreased range of motion, joint stiffness, and spontaneous muscle spasm (4)[A].
- Sensory examination
  - Light touch, pinprick, vibration sense, and proprioception may be diminished or absent in the involved nerve territory.
  - Sensory disturbance may aberrantly extend beyond a discrete nerve territory.
- Skin examination
  - Alterations in temperature, color, sweating, and hair growth suggestive of CRPS
  - Residual dermatomal scars consistent with previous herpes zoster (shingles) infection
  - Characteristic skin changes consistent with diabetes mellitus

## *DIFFERENTIAL DIAGNOSIS*

- Nociceptive pain: induced by transmission impulses along peripheral nociceptors usually due to tissue damage
- Differentiate by clinical signs and symptoms, mechanisms and therapeutic management

## *DIAGNOSTIC TESTS & INTERPRETATION*

For definite diagnosis, the abnormal sensory findings are confirmed to the innervation territory of the lesioned nervous system structure AND diagnostic test(s) confirming a nervous system lesion or disease that could explain neuropathic pain (1)[A].

### *Initial Tests (lab, imaging)*

None specifically for neuropathic pain but can rule in or out a cause of symptoms

- Neuroimaging based on affected area
- Blood and cerebrospinal fluid samples
  - Structural tests:
    - Skin biopsy analyses
    - Sural nerve biopsy
    - Structural imaging tests

- Serum B<sub>12</sub>
- 25-hydroxyvitamin D
- Thyroid-stimulating hormone (TSH)
- Rapid plasma reagin (RPR) or Venereal Disease Research Laboratory (VDRL) test
- Fasting glucose, creatinine Lyme serology

## *Follow-Up Tests & Special Considerations*

- Nerve conduction study (NCS): The standard electrodiagnostic tool for assessing peripheral nerve fiber function (2)[A].
- Electromyography (2)[A]
- Evoked potentials (2)[A]
- Quantitative Sensory Testing (2)[A]
- Thermography (2)[A]
- CSF samples (2)[A]

## **TREATMENT**

### *GENERAL MEASURES*

- Generally resistant to acetaminophen or NSAIDs
- Learn ways to relax body and mind

### *MEDICATION*

- The efficacy of systemic drug treatments is generally not dependent on the etiology of the underlying disorder (2,7).
- Combined therapy (polypharmacy) may be more effective.
- Treatment needs to be individualized

### *First Line*

- Calcium channel alpha-2-delta ligands
  - Gabapentin (2,8)[A]
    - Dosing: 1,200 to 3,600 mg in three divided doses

- Precautions: reduce dosages in renal insufficiency
- Common side effects: sedation, dizziness, peripheral edema, weight gain

- Pregabalin (2,8)[A]

- Used for the treatment of PDN, spinal cord injury, PHN, fibromyalgia (3)[A]
- Dosing: 300 to 600 mg in two doses
- Precautions: reduce dosages in renal insufficiency
- Common side effects: sedation, dizziness, peripheral edema, weight gain

---

P.713

- Tricyclic antidepressants (2,8)[A]

- Nortriptyline, desipramine, amitriptyline, clomipramine, imipramine

- Dosing: start at 10 to 25 mg at bedtime, then increase by 10 to 25 mg every 4 to 7 days up to 150 mg/day to efficacy and side effects
- Precautions: cardiac disease, glaucoma, prostatic adenoma, seizure, tramadol use
- Geriatric considerations: patients (dose <sup>2</sup>75 mg daily)
- Common side effects: somnolence, anticholinergic effects, weight gain

- Serotonin-norepinephrine reuptake inhibitors (SNRIs) (2,8)[A]

- Duloxetine

- Dosing: 30 mg once daily/60 mg twice daily. Effective doses 60 to 120 mg daily
- Precautions: hepatic disorder, tramadol use, hypertension
- Common side effects: nausea

- Venlafaxine

- Dosage: 37.5 mg once or twice daily/225 mg daily. Effective doses 150 to 225 mg daily
- Precautions: cardiac disease, hypertension; tramadol use
- Common side effects: nausea, hypertension at high dosages

- Topical lidocaine (first line for elderly, frail patients only)

- Lidocaine, 5% plasters (2,8)[A]

- Dosage: 1 to 3 patches/3 patches for 12 hours to cover the painful area

- Precautions: none
- Common side effects: local erythema, itch, rash
- Carbamazepine (9)[A]

## *Second Line*

- Topical treatments (2)[A]
  - Lidocaine patches
    - (See *Topical Lidocaine*)
  - Capsaicin high-concentration patches (8%)
    - Dosage: 1 to 4 patches to cover the painful area, repeat every 3 months; 30 minutes application to feet, 60 minutes application to remainder of body; avoid use on face
    - Precautions: caution in progressive neuropathy
    - Common side effects: pain, erythema, itching, rare hypertension (initial increase in pain)
- Tramadol (2)[A]
  - Dosage: 50 mg once or twice daily/400 mg daily as long-acting drug. Increase by 50 to 100 mg every 3 to 7 days
  - Precautions: history of substance abuse, suicide risk
  - Geriatric considerations: use of antidepressant in elderly patients.
  - Common side effects: nausea, vomiting, constipation, dizziness, somnolence

## *Third Line*

- Opioids (2)[A]
  - Morphine, oxycodone
    - Dosage: 10 to 15 mg morphine every 4 hours or as needed (equianalgesic doses for other opioids)/up to 300 mg morphine has been used
    - Precautions: history of substance abuse, suicide risk, risk of misuse on long-term use
  - Botulinum toxin type A
    - Dosage: 50 to 300 units subcutaneously to the painful area; repeat every 3 months
    - Precautions: infection of area

- Common side effects: pain at injection site

## ***ISSUES FOR REFERRAL***

Referral to pain clinic if refractory to initial treatment or additional therapies below are warranted.

## ***ADDITIONAL THERAPIES***

- Cannabinoids (dronabinol and nabilone): The appropriateness of medical marijuana for a patient should be comprehensive assessments that revolve around risk-benefit discussion (8,10).
- Neural stimulation (11)
- Spinal cord stimulation (SCS): Pain that is continuous and unchanging responds best. The most common indication is failed back surgery syndrome with leg pain. Less common indications are peripheral nerve injury, CRPS, and painful peripheral neuropathy (11).
- Dorsal root ganglion stimulation to treat challenging pain syndromes that do not respond to conventional SCS (11).
- Peripheral nerve stimulation (PNS): indications include pain in the distribution of an accessible peripheral nerve. The most common nerves treated are the supraorbital, infraorbital, greater occipital, ulnar, median, suprascapular, intercostal, ilioinguinal, iliohypogastric, genitofemoral, lateral femoral cutaneous, saphenous, sciatic, posterior tibial, superficial peroneal, and sural nerves (11).
- Intrathecal drug delivery considered invasive and labor intensive, may be used when other conservative therapies fail (11).
- Transcutaneous electrical nerve stimulation is widely used, evidence is poor in supporting the efficacy (11).
- Osteopathic manipulative treatment should be offered to all patients. Myofascial trigger point release can be an effective primary technique. Indirect or passive myofascial techniques may be used to address all regions of tissue texture change (12).
- Hypnosis can reduce pain and anxiety related to the pain.
- Acupuncture

## ***SURGERY/OTHER PROCEDURES***

Nerve destructive procedures haven't shown effectiveness and may cause additional insult/injury (an exception is treatment of terminal cancer) (11).

- Sympathectomy dorsal root entry zone lesion (dorsal rhizotomy)

- Lateral cordotomy
- Trigeminal nerve ganglion ablation (13)[A]

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Multidisciplinary team
- Periodic evaluation to rule out other treatable conditions (2)

### *Patient Monitoring*

- Pain management requires ongoing evaluation, patient education, and reassurance
- Patient compliance and adequacy of analgesic drug titrations should be continually evaluated and documented.

### *PROGNOSIS*

Chronic course of pain symptoms often requires management with numerous medications and adjunctive therapies.

### **COMPLICATIONS**

Long-term disability and drug addiction are possible.

## Codes

&NA;

### ICD10

- M79.2 Neuralgia and neuritis, unspecified
- E10.40 Type 1 diabetes mellitus with diabetic neuropathy, unsp
- E11.40 Type 2 diabetes mellitus with diabetic neuropathy, unsp

# Clinical Pearls

## **&NA;**

- Neuropathic pain is a chronic pain syndrome, affecting between 2% and 8% of people with a major impact on quality of life.
- The ongoing challenge for clinicians (and patients) is being able to determine which treatment is most likely to work for any one individual.
- The first line of treatment is pharmacologic and may be more beneficial with additional therapies.
- Generally resistant to acetaminophen or NSAIDs

# Neuropathy, Peripheral

Amy Chen, MD, PhD

David N. Herrmann, MBBCh

## BASICS

### DESCRIPTION

- Peripheral neuropathy (PN) is a functional or structural disorder of the peripheral nervous system (PNS).
- PN affects any combination of motor, sensory, or autonomic nerves.
- The motor PNS comprises spinal cord motor neurons, their nerve roots that combine to form plexus, and branches that form individual nerves innervating skeletal muscles. Peripheral motor involvement causes muscle atrophy, weakness, cramps, and fasciculations.
- The sensory PNS consists of sensory organs, which transmit touch, vibration, and position sensation in large-diameter myelinated fibers; pain and temperature in small-diameter, lightly myelinated and unmyelinated C fibers to the dorsal root ganglia. Sensory signals are relayed to the central nervous system (CNS) for integration. Disorders of sensory nerves produce negative phenomena (loss of sensibility, lack of balance) or heightened phenomena (tingling or pain). Large sensory fiber dysfunction impairs touch and vibration sensation, whereas small fiber sensory neuropathy (SFN) affects pin and thermal sensation and causes neuropathic pain.
- The autonomic nervous system (ANS) includes the sympathetic and parasympathetic systems. ANS dysfunction causes cardiovascular, gastrointestinal, and sudomotor symptoms.
- The PNS can be affected from the cell body (sensory ganglionopathy or motor neuronopathy), root (radiculopathy), or plexus (plexopathy) to the nerve (demyelinating or axonal neuropathy).

### EPIDEMIOLOGY

#### *Prevalence*

Approximately 2.4% of general population or 8% of people >55 years old, are affected by distal symmetric PN, the most common form of PN.

### ETIOLOGY AND PATHOPHYSIOLOGY

- PN can be acquired or hereditary.
- The most common cause of acquired PN is diabetes.
- Other categories of acquired PN with illustrative examples are the following:
  - Vascular: ischemia, vasculitis
  - Infectious: HIV, hepatitis C, cryoglobulinemia, Lyme disease
  - Traumatic: compression, crush, or transection
  - Autoimmune: rheumatoid arthritis, Sjögren, postinfectious Guillain-Barré syndrome (GBS), chronic inflammatory demyelinating polyneuropathy (CIDP)
  - Metabolic: diabetes, renal failure, hypothyroidism, vitamin B<sub>12</sub> deficiency, celiac disease
  - Iatrogenic/toxic: chemotherapy, platinum, taxanes, metronidazole, colchicine, infliximab, alcoholism
  - Idiopathic: 30% of PN
  - Neoplastic/paraneoplastic: paraproteinemia, Waldenström macroglobulinemia, multiple myeloma, amyloidosis, neurofibromatosis
- PN occurs due to demyelination or axonal degeneration.
- Demyelination results from Schwann cell dysfunction, mutations in myelin protein genes, or direct damage to myelin sheaths.
- Axonal degeneration occurs when injury/dysfunction occurs at the cell body or axon.

## Genetics

- Approximately 50% of undiagnosed PN is hereditary.
- Currently, there are over 70 known genetic causes of hereditary PN.
- Charcot-Marie-Tooth (CMT) neuropathies: the most common hereditary PN
  - *CMT1A* (duplication of the *PMP22* gene) is the most common CMT.
  - A *PMP22* deletion causes hereditary neuropathy with liability to pressure palsy (HNPP)

## RISK FACTORS

Systemic disorders predispose to PN.

## GENERAL PREVENTION

- Healthy nutrition and avoidance of alcoholism and of pressure at nerve entrapment sites

- Surveillance for glucose dysmetabolism and tight glycemic control may prevent diabetic PN.

## DIAGNOSIS

### HISTORY

- A detailed inquiry for symptoms of sensory, motor, or autonomic dysfunction:
  - Numbness, tingling, prickling, burning pain, a “tightly wrapped” sensation, and an “unsteady gait”
  - Distal weakness manifests as foot drop (tripping, foot slapping) or difficulty with grip; proximal weakness (e.g., difficulty arising from a chair) is less common.
  - Orthostatic dizziness, abnormal sweating, constipation, or voiding difficulties
- Symptom onset:
  - Acute: Consider infection (e.g., Lyme disease), postinfectious dysimmune process (e.g., GBS), ischemia (e.g., vasculitis), toxin, or trauma.
  - Subacute: Consider metabolic, neoplastic, paraneoplastic, or dysimmune processes.
  - Chronic: Consider dysimmune process (CIDP), idiopathic, or hereditary.
- Progression: stable or indolent; slowly or rapidly progressive; monophasic or relapsing or remitting
- Anatomic pattern: focal, multifocal, diffuse

### PHYSICAL EXAM

- Based on exam, a functional (*sensory*: small-fiber vs. large-fiber vs. mixed, *sensorimotor*, *motor*, *autonomic*) and anatomic pattern of PN (*distal symmetric*, *multifocal*, or *focal*) should be established.
- Cognition preserved in isolated PN.
- Cranial nerves may be involved with focal or multifocal PN (e.g., bifacial weakness may occur with GBS, Lyme disease, sarcoidosis, among other causes).
- Stocking/glove sensory loss is typical of distal symmetric sensory PN (e.g., diabetes).
- Isolated reduced pin or thermal sensation or allodynia suggests a pure SFN.
- Reduced vibration and joint position sense suggests large-fiber sensory neuropathy; when severe, a Romberg sign is present, and gait is wide-based or ataxic.

- Distal muscle atrophy and weaknesses of toe extension and finger abduction are often present with distal symmetric axonal PN.
- In acquired demyelinating PN (e.g., GBS or CIDP), weakness is commonly both proximal and distal.
- Deep tendon reflexes may be reduced or absent, distally at the ankles in large-fiber axonal PN, or diffusely in demyelinating PN.
- High arched or flat feet or hammer toes suggest hereditary PN.

### **ALERT**

Hemibody deficits or sensory loss below a spinal cord level suggest a CNS process.

### **ALERT**

Hyperreflexia and spasticity are upper motor neuron signs not seen with isolated PN.

## *DIFFERENTIAL DIAGNOSIS*

The following categories of PN can be identified (differential diagnosis [DDx] listed when applicable):

- Pure sensory neuropathy
  - DDx: SFN, sensory ganglionopathy, polyradiculopathy
- Distal symmetric sensorimotor axonal PN
  - Most common type of PN
  - DDx: distal acquired demyelinating symmetric PN (DADS)
- Motor predominant PN
  - DDx: motor neuron disease, polyradiculopathy, immune-mediated multifocal motor neuropathy (MMN)
- Mononeuropathy
  - Most likely due to compression, entrapment, or trauma
  - DDx: monoradiculopathy
- Mononeuropathy multiplex
  - DDx: plexopathy, polyradiculopathy

# DIAGNOSTIC TESTS & INTERPRETATION

## *Initial Tests (lab, imaging)*

- Nerve conduction studies and electromyography (NCS/EMG)
  - Best performed by physicians with specialty training in electrodiagnostic medicine
  - Delineate axonal versus demyelinating, anatomic pattern, chronicity, and severity of PN.
- Blood tests
  - CBC, BUN, creatinine, fasting glucose, HgA1C, vitamin B<sub>12</sub>, serum protein electrophoresis, and immunofixation
- Specialized skin biopsy
  - In clinically suspected SFN if NCS/EMG is normal
  - Analysis of lower limb epidermal nerve fiber density (ENFD) (1)[A]
- Autonomic tests
  - Not routinely done but useful to characterize autonomic PN
- Neuroimaging
  - Generally not indicated in evaluation of PN but useful in evaluation of brachial plexopathies, radiculopathies, or where findings are attributable to the CNS

## *Follow-Up Tests & Special Considerations*

- Additional blood tests are done based on the medical history, the PN type, and NCS/EMG findings.
- Genetic testing for diagnosis of hereditary PN should be ordered by neurologists with expertise in PN.
- Screen patients with distal symmetric PN for unhealthy alcohol use with CAGE-AID or AUDIT-C.

P.715

### **ALERT**

Ordering of laboratory batteries (e.g., peripheral nerve antibody panels) without careful consideration of the clinical and NCS/EMG features should be avoided.

## *Diagnostic Procedures/Other*

Nerve biopsy (sural or superficial peroneal nerve): useful if vasculitis, amyloidosis, granulomatous disorders, or neoplastic infiltration is suspected; rarely helpful in late-onset chronic, slowly progressive distal symmetric PN

- Lumbar puncture
  - Cytoalbuminologic dissociation in GBS or CIDP
  - Infection, inflammation, or neoplasia in polyradiculopathies

## *Test Interpretation*

- Demyelinating PN: disproportionate slowing of conduction velocities or prolonged distal latencies on NCS
- Axonal PN: reduced amplitude in sensory or motor responses, with relatively preserved conduction velocities on NCS
- Reduced ENFD on distal leg skin biopsies is supportive of SFN.

## **TREATMENT**

### *GENERAL MEASURES*

Manage associated medical conditions; diseasemodifying therapy for specific forms of PN (e.g., CIDP); symptomatic relief of pain and dysautonomia; rehabilitation to optimize function.

### *MEDICATION*

#### *First Line*

- Treatment of neuropathic pain: evidence of efficacy derived from clinical trials in diabetic painful neuropathy (DPN) and postherpetic neuralgia (PHN):
  - Pregabalin: for DPN and PHN
  - Duloxetine: for DPN
  - Lidocaine patch: for PHN
  - Gabapentin: (off-label) for DPN
  - Tricyclic antidepressants: (off-label) for DPN
  - Venlafaxine: (off-label) for DPN
  - Tramadol: (off-label) for DPN

Targeted treatment for underlying systemic conditions:

- Glycemic control, thyroid hormone supplementation, vitamin supplementation, antimicrobial therapy (e.g., Lyme disease, HIV), glucocorticoids for sarcoidosis, and cytotoxic therapy for vasculitis
- Immunotherapy for dysimmune PN
  - Intravenous immunoglobulin (IVIG): within the first 2 weeks of GBS to hasten recovery (2)[A]; as a first-line alternative to corticosteroids for treatment of CIDP (3)[A]; and for prevention of secondary axonal loss in MMN (4)[A]
    - Loading dose 2 g/kg body weight divided into 2 to 5 days; maintenance regimen variable for CIDP and MMN
    - Adverse effects (AE): headache, fever, hypertension, and rarely, pulmonary embolism
  - Plasma exchange: first agent shown to improve functional outcome for patients with GBS (5)[A]; short-term benefit in CIDP (6)[A]
    - AE: catheter complication, hypotension, and others
  - Corticosteroids: a first-line option in treatment of CIDP (7)[C]; oral or pulsed IV regimen can induce remission
- Treatment of autonomic symptoms
  - Compression stockings, hydration, midodrine, and fludrocortisone for orthostatic hypotension
  - Pyridostigmine for immune-mediated dysautonomia (off-label)

## *ISSUES FOR REFERRAL*

- Rapidly progressive symptoms, suspected demyelinating PN, or hereditary PN should be referred to a neurologist with expertise in neuromuscular disorders.
- Patients with vasculitic PN should be referred to rheumatology.
- Patients with paraproteinemia should have a skeletal bone survey and be referred to hematology.
- Patients with imbalance, ataxia, or falls should be referred to physical therapy for gait and balance training.

## *ADDITIONAL THERAPIES*

- Combination therapy (e.g., gabapentin with TCA or venlafaxine or tramadol) can be more

effective than monotherapy for neuropathic pain.

- Long-acting opiates can be considered for refractory neuropathic pain.
- Additional immunosuppressant agents (e.g., cyclophosphamide) may be used in refractory chronic dysimmune PN.

### **ALERT**

Opiates have significant side effects and may cause rebound headaches, tolerance, and dependence.

## ***SURGERY/OTHER PROCEDURES***

- Decompressive surgery for entrapment neuropathy (e.g., carpal tunnel syndrome)
- Foot and ankle surgery to improve symptoms or function in hereditary PN
- Radiation, surgery, or bone marrow transplantation for plasmacytoma or osteosclerotic myeloma or POEMS syndrome
- Liver transplantation for amyloidotic PN

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Low-intensity transcutaneous electrical nerve stimulation (TENS), acupuncture, meditation

### **ALERT**

Vitamin B<sub>6</sub> supplementation may cause peripheral neurotoxicity and should be avoided except for a deficiency state.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Patients with suspected GBS should be admitted for diagnosis, monitoring (30-60% may develop cardiovascular or respiratory failure), and for acute treatment.
- Elective intubation may be required in GBS when forced vital capacity is <15 mL/kg body weight.
- Other rapidly progressive undiagnosed PNs that impair independent ambulation may require admission.

**ONGOING CARE**

## FOLLOW-UP RECOMMENDATIONS

- Physical therapy and gait assistive devices as needed
- Flu vaccination should be avoided in the first year following GBS.

## PROGNOSIS

- Late-onset idiopathic distal symmetric axonal PN are indolent
- 80% of GBS have a near complete or good recovery. 80% of CIDP have moderate or good response with treatment but can be relapsing.

**&NA;**

## **ICD10**

- G62.9 Polyneuropathy, unspecified
- G60.9 Hereditary and idiopathic neuropathy, unspecified
- G60.8 Other hereditary and idiopathic neuropathies

## **Clinical Pearls**

**&NA;**

- There are many causes of PN. Diagnosis is made by history and physical exam, targeted laboratory testing, NCS/EMG, skin biopsy, or ANS testing.
- Consider hereditary neuropathy if patient has an early age of PN symptom onset, family history of PN, or foot deformity.
- GBS is monophasic and progresses for up to 4 weeks; CIDP progresses beyond 8 weeks, and if untreated, usually has a progressive course.

# Nicotine Addiction

Benjamin N. Schneider, MD

Kamala Nyamathi, MD

## BASICS

### *DESCRIPTION*

Nicotine addiction is the constellation of signs of dependence and compulsive use despite knowledge of its adverse effects.

### *EPIDEMIOLOGY*

#### *Incidence*

20-25% of the U.S. population use nicotine.

#### *Prevalence*

70 million people in the United States <sup>3</sup>12 years of age reported current use of tobacco (58.7 million smoked cigarettes, 13.3 million cigars, 2.1 million pipes, and 8.6 million used smokeless tobacco) (1).

#### *Pediatric Considerations*

Nicotine use is common and underrecognized in this population. Use of cigarettes; smokeless tobacco; and now, e-cigarettes in the past month: 8th graders: 4%, 3%, and 8.7%; 10th graders: 7.2%, 5.3%, and 16.2%; 12th graders: 13.6%, 8.4%, and 17% (2).

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Similar to other addictive drugs, nicotine affects neural pathways that control reward and pleasure.
- Nicotinic acetylcholine receptors (nAChRs) are thought to play a major role in nicotine's effect on brain chemistry via their influence of glutamate, GABA, dopamine, serotonin, acetylcholine, and norepinephrine.
- Through these neurotransmitters, nicotine induces euphoria, assists in information processing, and reduces anxiety and fatigue.

Polymorphisms in neuronal nAChR genes are associated with increased susceptibility to dependence.

- Specific genes associated with nicotine dependence have been linked with decreased activity of CYP2B86 (an enzyme that breaks down brain nicotine) and are thought to cause increased cravings. These patients are 1.5 times more likely to fail treatment.

## ***RISK FACTORS***

- Mental illness (depression, posttraumatic stress disorder, bipolar disorder, and schizophrenia)
- Low socioeconomic status
- Low educational status
- Early first-hand nicotine experience
- Concurrent substance abuse
- Home and peer influence

## ***GENERAL PREVENTION***

- The U.S. Preventive Services Task Force (USPSTF) strongly recommends clinicians screen all:
  - Adults for tobacco use and provide cessation interventions for those who screened positive (Grade A).
  - Pregnant women for tobacco use and provide pregnancy-tailored counseling to those who screened positive (Grade A).
- The USPSTF recommends that clinicians provide interventions, including education or brief counseling to prevent initiation of tobacco use among schoolaged children and adolescents (Grade B).

## ***Pregnancy Considerations***

- Carbon monoxide and nicotine interfere with fetal oxygen supply, resulting in decreased birth weights and possible intrauterine growth restriction
- Maternal smoking adversely affects fetal lung development, with lifelong decreases in pulmonary function and increased asthma risk.
- Smoking is associated with increased risk of spontaneous abortion, sudden infant death syndrome, learning and behavioral problems, and increased risk of childhood obesity.

## ***COMMONLY ASSOCIATED CONDITIONS***

- Chronic obstructive pulmonary disease (COPD) (emphysema and chronic bronchitis)
- Cancers (lung, oral/pharyngeal, kidney, bladder, cervical, anal)
- Atherosclerotic disease
- Periodontal disease

## DIAGNOSIS

### HISTORY

- Identify types of nicotine products used.
- Amount and duration of nicotine use
- Previous attempts to quit (methods and efficacy)

### PHYSICAL EXAM

- Cardiovascular exam
- Pulmonary exam

### DIFFERENTIAL DIAGNOSIS

Not applicable

### DIAGNOSTIC TESTS & INTERPRETATION

- Low-dose CT scan: recommended by The American College of Chest Physicians for individuals age 55 to 75 years old with a history of 30+ pack years who are currently smoking or have quit within the past 15 years (unless they have comorbidities that are anticipated to limit life expectancy)
- Spirometry: not recommended for routine screening, only if COPD is suspected

## TREATMENT

### COUNSELING (3)[A]

- Advice from providers improves quit rate number needed to treat [NNT] 75.
- Providing brief, simple advice about cessation increases the likelihood of sustained cessation at 12 months.
- More intensive advice (i.e., motivational interviewing) may result in higher rates of quitting.

- Providing follow-up support may increase quit rates slightly.
- Brief strategies to help the patient willing to quit tobacco use the O5 AsO (4)[A]
  - Ask patient if he or she uses nicotine.
  - Advise him or her to quit.
  - Assess willingness to make a quit attempt.
  - Assist those willing to make a quit attempt.
  - Arrange for follow-up contact to prevent relapse.
- Enhancing motivation to quit the O5 RsO (4)[A]
  - Relevance: Encourage patient to indicate why quitting is personally relevant.
  - Risks: Ask patient to identify potential negative consequences of use.
  - Rewards: Ask patient to identify potential benefits of cessation.
  - Roadblocks: Ask patient to identify barriers or impediments to quitting and provide treatment (e.g., problem-solving counseling or medication) that could address barriers.
  - Repetition: This motivational intervention should be repeated each visit.
- Users should be given a choice of quitting methods.
- Quit rates are equivalent for tapering nicotine use versus abrupt cessation. Patient preference should be part of the plan.

## **MEDICATION**

- Seven FDA-approved medications exist: nicotine replacement therapy (NRT), both long acting (i.e., patch) and short acting (i.e., gum, inhaler, lozenge, nasal spray), and non-NRT meds like bupropion SR and varenicline.
- With few exceptions, the choice of a first-line medication depends on patient preference.
- Combination NRT: All forms of NRT increase quit rate (5)[A] 50-70%. Combining long-acting and short-acting NRTs is more effective than using any single method alone. Heavier users may need higher doses. Starting NRT before planned quit date may increase the chances of success.
- Nicotine replacement (Gum: pregnancy Category C all other formulations are pregnancy Category D).
  - Nicotine transdermal (NicoDerm CO): For > 10 cigarettes/day, start with 21 mg patch/day for 6 weeks, then 14 mg patch/day for 2 weeks, then 7 mg patch/day for 2 weeks; for use of <10 cigarettes/day, start with 14 mg patch/day for 6 weeks, then 7 mg patch/day for 2

weeks. Extending use of the patch beyond 8 to 10 weeks may improve abstinence rates.

## **ALERT**

May cause insomnia or vivid dreams when left on overnight. Patients may remove the patch overnight to curb these symptoms (rates of smoking cessation don't differ between continuous use vs. overnight removal).

- Nicotine gum (Nicorette): For >25 cigarettes/day habit, use 4 mg gum q1-2h for 6 weeks; for <25 cigarettes/day habit, use 2 mg gum q1-2h for 6 weeks; decrease dosing by q1-2h for 3 weeks; chew then tuck between cheek and gingiva once nicotine flavor is released, repeat up to 30 minutes then discard.
- Nicotine lozenge (Commit): for patients who smoke their first cigarette within 30 minutes of waking, 4 mg lozenge PO q1-2h for 6 weeks; first cigarette >30 minutes after waking, 2 mg lozenge PO q1-2h for 6 weeks; decrease dosing by q1-2h for 3 weeks
- Nicotine nasal (Nicotrol NS): 1 to 2 sprays (0.5 mg/spray) each nostril q1h for 8 weeks, then taper; max 10 sprays/hr and 80 sprays/day
- Nicotine inhaler (Nicotrol inhaler): 6 to 16 cartridges inhaled (4 mg/cartridge) per day for 6 to 12 weeks, then taper; incorporates the behavioral and sensory aspects of smoking
- Varenicline is a nicotinic acetylcholine partial agonist. Trials have suggested this agent may be more efficacious than bupropion (6)[A]. Longer term therapy (up to 24 weeks) may delay or prevent relapse:
  - Starter pack: 0.5 mg/day for 3 days, 0.5 mg BID for 4 days, 1 mg/day starting on day 7
    - Maintenance pack 1 mg BID continue for 12 weeks total; if successful in quitting, may continue for another 12 weeks.

P.717

## **ALERT**

Varenicline carries a black box warning for risks of serious neuropsychiatric events. Use only with extreme caution in patients with serious psychiatric disorders, as use may exacerbate these conditions. Varenicline may also increase the risk of cardiovascular events in patients with known CVD, although data is limited and of unclear significance.

- Varenicline + bupropion has not been shown to be more effective than either agent alone but with increased side effects.
- Varenicline + nicotine replacement has been shown to be more effective at 6 months than varenicline alone (NNT 6 [B]).

- Bupropion SR is an atypical antidepressant and norepinephrine-dopamine reuptake inhibitor.
  - Start 1 week before a target quit date due to time needed to reach steady state.
  - Use 150 mg/day for 3 days, then 150 mg twice a day for 7 to 12 weeks.

## **ALERT**

1:1,000 risk of seizure, its use is contraindicated in patients with a history of epilepsy.

- Nortriptyline is a tricyclic antidepressant.
  - Start 25 mg/day, gradually increase to target dose of 75 to 100 mg/day and continue for 12 weeks.
  - Stop smoking 2 to 4 weeks after starting treatment.

## **ALERT**

Contraindicated in narrow-angle glaucoma or heart disease (acute myocardial infarction, atrioventricular or bundle-branch block, long QT)

## **ADDITIONAL THERAPIES**

- Users who get support from partners and others are more likely to quit.
- Group programs double cessation rates compared to self-help materials. It is unclear whether groups are better than individual counseling or other advice, but they are more effective than no treatment. Not all users making a quit attempt want to attend meetings, but for those who do, they are likely to be helpful.
- E-cigarettes improve abstinence at 1 month versus placebo, but this effect is lost at 3- and 6-month follow up. Adverse effects include dry cough (26-32%), throat irritation (7-32%), and shortness of breath (2-20%) (7).
- New data suggest that certain e-cigarette flavorings may alter lung functioning on a cellular level (8).

## **Pregnancy Considerations**

- Smoking is associated with decreased intrauterine growth restriction, placenta previa, abruptio placentae, decreased maternal thyroid function, preterm premature rupture of membranes, low birth weight, perinatal mortality, and ectopic pregnancy.
- Quitting smoking before 15 weeks' gestation provides the greatest benefit for both the woman and fetus, but quitting any time is beneficial.

There is still insufficient data regarding the safety and efficacy of NRT in pregnancy (gum is considered as Category C, while remaining NRTs are Category D).

- Similarly, little is known about the effects of varenicline and bupropion on fetal development (Category C).
- It is recommended that pregnant women be offered behavioral therapy and education with NRT and medications reserved for patients in need of additional assistance (9).
- NRT is metabolized faster in pregnant women, so higher doses may be required.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Acupuncture: no consistent evidence of efficacy
- Hypnotherapy: no consistent evidence of efficacy

## ***INPATIENT CONSIDERATIONS***

- Programs to stop use that begin during hospitalization and include follow-up support after discharge are effective.
- Programs are effective for all hospitalized users, regardless of admitting diagnosis (10)[A].
- Consider NRT for all inpatients who use nicotine to decrease withdrawal symptoms (10)[A].

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Patients motivated to quit smoking and who have initiated therapy should follow up 1 to 2 weeks after initiation of therapy to monitor response and observe for any medication side effects.
- Encourage routine exercise as a component of smoking-cessation treatment.

### ***DIET***

Weight gain (4 to 5 kg over 10 years) possible after smoking cessation

### ***PATIENT EDUCATION***

- <http://smokefree.gov/>
- <http://women.smokefree.gov/>
- <http://teen.smokefree.gov>

- <http://www.nicotine-anonymous.org>
- <https://quitnet.meyouhealth.com/#/>
- 1-877-44U-QUIT (1-877-448-7848)

## PROGNOSIS

- >85% of those who try to quit on their own relapse, most within a week.
- Approximately 50-60% of women who quit smoking in pregnancy return to smoking within 1-year postpartum.
- Cessation medications and techniques listed above significantly improve cessation.

## Codes

&NA;

### ICD10

- F17.200 Nicotine dependence, unspecified, uncomplicated
- F17.201 Nicotine dependence, unspecified, in remission
- F17.203 Nicotine dependence unspecified, with withdrawal

## Clinical Pearls

**&NA;**

- Nicotine and particularly smoking cessation should be encouraged for all patients who use.
- Consider NRT for all hospitalized patients who smoke to decrease withdrawal symptoms.
- Treatments, including but not limited to medications significantly increase the rate of long-term abstinence.
- No single type of NRT/medication is best; thus, the choice should be based on patient preference and risk factors for side effects.
- Nicotine dependence is a chronic disease and will often require repeated interventions and multiple cessation attempts.

# Nonalcoholic Fatty Liver Disease (NAFLD)

Jill T. Wei, MD

Daniel T. Lee, MD, MA

## BASICS

- A spectrum of fatty liver diseases not due to excess alcohol consumption ranging from nonalcoholic fatty liver (NAFL) to steatohepatitis and cirrhosis with hepatocyte injury with/without fibrosis.
- Leading cause of chronic liver disease; implicated in up to 90% of patients with asymptomatic, mild aminotransferase elevation not caused by alcohol, viral hepatitis, or medications

## DESCRIPTION

- NAFL (1)
  - Reversible condition in which large vacuoles of triglyceride fat accumulate in hepatocytes
  - Liver biopsy: fatty deposits in >30% of cells, no hepatocyte ballooning, no necrosis, no fibrosis
  - Alanine aminotransferase/aspartate aminotransferase (ALT/AST) enzymes usually normal but may be elevated, rarely >3 to 4 times ULN
  - Minimal risk of progression to cirrhosis and liver failure
  - Synonym: steatosis
- Nonalcoholic steatohepatitis (NASH): progressive form of NAFL (1)
  - Liver biopsy: fatty deposits in >50% of cells with ballooning, acute/chronic inflammation, ± fibrosis
  - ALT and AST elevated, generally <3 to 4 times ULN
  - May progress to cirrhosis, liver failure, and rarely hepatocellular cancer; 30% with NASH may progress to fibrosis over 5 years.
- NASH cirrhosis (1)
  - Presence of cirrhosis with current or previous histologic evidence of steatosis or steatohepatitis

## EPIDEMIOLOGY

- NAFLD: most common chronic liver disease globally; usually benign, asymptomatic
- Predicted to become the most frequent indication for liver transplantation by 2030 (2)
- NASH may be symptomatic with progressive inflammation and fibrosis.
  - Predominant age: 40s to 50s; can occur in children
  - Predominant sex: male > female (slight)

### Incidence

Estimates vary widely from 31 to 86 cases of NAFLD per 10,000 person-years to 29/100,000 person-years (1)

### Prevalence

- United States estimate: 30-40% (3)
- Worldwide: 6-33%, median 20% (1)
- Present in 58-74% of obese persons (BMI >30) and 90% of morbidly obese persons (BMI >39) (1)
- Among individuals with T2DM, rate of 69-87%; in patients with dyslipidemia, rate of 50% (1)

## ETIOLOGY AND PATHOPHYSIOLOGY

Primary mechanism is *insulin resistance*, which leads to increased lipolysis, triglyceride synthesis, and increased hepatic uptake of fatty acids.

- NAFLD: excessive triglyceride accumulation in the liver and an impaired ability to remove fatty acids
- NASH: 2-hit hypothesis: (i) macrovesicular steatosis due to increased hepatic lipid synthesis, reduced transfer of lipids, and increased insulin resistance with hepatic oxidative stress and (ii) mitochondrial damage leading to impaired restoration of ADT stores, lipid peroxidation, and resultant inflammatory injury (1)
- Other possible mechanism is lipotoxicity. Free fatty acid metabolites cause endoplasmic reticular stress, hepatocyte apoptosis, necrosis, and inflammation. Hepatocellular injury triggers fibrogenesis and inflammation, hastening disease progression (3).

### Genetics

Largely unknown: Some familial clustering and increased heritability. NAFL: more first-degree

relatives with cirrhosis than matched controls; NASH: 18% with affected first-degree relative. Carriers of hemochromatosis gene are more likely to be affected. Patatin-like phospholipase domain-containing 3 (PNPLA3) I148M polymorphism may play a role in NAFLD, hypertriglyceridemia, and insulin resistance (1,2).

## ***RISK FACTORS***

- Obesity (BMI >30), visceral obesity (waist circumference >102 cm for men or >88 cm for women), hypertension, dyslipidemia, high serum triglycerides and low serum high-density lipoprotein (HDL) levels, metabolic syndrome
- Type 2 diabetes, cardiovascular disease, and chronic kidney disease (2)
- Possible associations with hypothyroidism, hypopituitarism, hypogonadism, obstructive sleep apnea, pancreatoduodenal resection, osteoporosis, psoriasis, and polycystic ovary syndrome (2)
- Increasing age associated with increased prevalence, severity, advanced fibrosis, and mortality
- High fructose intake linked to intestinal dysbiosis and metabolic stress (4)
- Protein-calorie malnutrition; total parenteral nutrition (TPN) >6 weeks
- Severe weight loss (starvation, bariatric surgery)
- Organic solvent exposure (e.g., chlorinated hydrocarbons, toluene); vinyl chloride; hypoglycin A
- Gene for hemochromatosis/other conditions with increased iron stores
- Smoking (5)
- Drugs: tetracycline, glucocorticoids, tamoxifen, methotrexate, valproic acid, fialuridine, many chemotherapy regimens, and nucleoside analogues

## ***Pregnancy Considerations***

Acute fatty liver of pregnancy: Rare but serious complication in 3rd trimester. 50% of cases are associated with preeclampsia (6).

- Symptoms: nausea, vomiting, headache, fatigue, right upper quadrant or epigastric pain, jaundice
- Elevated ALT and AST >300 IU/L but usually <1,000 IU/L; elevated bilirubin
- Liver biopsy confirms diagnosis but should not delay treatment.
- Early recognition and prompt delivery is key
- Recurrence is rare (6)

## *Pediatric Considerations*

- Increasing prevalence of NAFLD among children parallels rise in pediatric obesity.
- Reports of NAFLD as early as age 2 years and NASH-related cirrhosis as early as age 8 years
- Treat with intensive lifestyle modification. Vitamin E may be of possible benefit.
- Reye syndrome: fatty liver syndrome with encephalopathy usually following viral illness
  - Vomiting with dehydration
  - Confusion, progressive CNS damage
  - Hepatomegaly with extensive fatty vacuolization
  - Hypoglycemia (7)
- Etiology unknown; viral URIs and drugs (especially salicylates) have been implicated.
- Mortality rate: 50%
- Treat with mannitol, IV glucose, and FFP.

## **GENERAL PREVENTION**

- Avoid excess alcohol: <sup>2</sup>3 standard drinks/day (men); <sup>2</sup>2 standard drinks/day (women)
- Maintain appropriate BMI.
- Prevention and optimal management of diabetes
- Avoid hepatotoxic medications.
- HAV and HBV vaccination if not immune
- Pneumococcal and annual influenza vaccinations

## **COMMONLY ASSOCIATED CONDITIONS**

Central obesity; HTN; type 2 diabetes; insulin resistance; hyperlipidemia; preeclampsia in pregnancy; CVD; hypothyroidism; hypogonadism; OSA (2)

## **DIAGNOSIS**

- Routine screening not recommended
- Consider NAFLD in patients with asymptomatic aminotransferase elevations (1)[A].
- Can occur with normal AST/ALT levels (1)[A]

- NAFLD has no distinguishing historical/lab features to distinguish from other chronic liver disorders.
- Index of suspicion is higher with risk factors such as metabolic syndrome, insulin resistance, or obesity.
- May present as cryptogenic cirrhosis
- Noninvasive biomarkers of steatosis/fibrosis are not sufficiently reliable. Liver biopsy is the definitive diagnostic test but should only be considered when results are likely to change management.

## **HISTORY**

- Typically asymptomatic
- Possible fatigue and/or abdominal fullness
- Vague right upper quadrant pain
- History of medications, alcohol use, family history

## **PHYSICAL EXAM**

Most common signs (all are infrequent)

- Liver tenderness
- Mild to marked hepatomegaly
- Splenomegaly
- In advanced cases: cutaneous stigmata of chronic liver disease or portal hypertension, for example, palmar erythema, spider angiomas, ascites

## **DIFFERENTIAL DIAGNOSIS**

- Viral hepatitis
- Alcoholic fatty liver
- Drug- or toxin-induced hepatitis
- Metabolic liver disease
- Autoimmune hepatitis
- Celiac disease
- Muscle disease, if nonhepatic cause of elevated enzymes are possible

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Both ALT and AST may be elevated.
  - Nonalcoholic, usually ALT:AST >1
  - If alcohol-induced, usually AST:ALT <sup>3</sup>2
  - Nonspecific enzyme abnormalities may exist or may be normal with advanced cirrhosis (1).
- Level of enzyme elevation does NOT correlate with degree of fibrosis (1).
- Serum ferritin (1.5 times normal), alkaline phosphatase (2 to 3 times normal), and total and direct bilirubin may be elevated (1).

P.719

- Severity and chronicity are characterized by defects in ability to produce plasma proteins (serum albumin, PT) and thrombocytopenia (1).
- Lipids abnormalities are common and include elevated cholesterol, low-density lipoprotein (LDL), and triglyceride and decreased HDL (1).
- Biomarkers of inflammation, increased oxidative stress, or hepatocyte apoptosis such as leptin, adiponectin, CRP, serum caspase, and cytokeratin 18 may help differentiate NASH from NAFLD (1)[B].
- Serologic studies to exclude other etiologies of liver disease, for example, celiac, *&agr*-1-antitrypsin, iron, copper, HepA IgG, HepB SAg, HepC SAb, anti-smooth muscle antibody, ANA, serum gammaglobulin (1)[B]
- Ultrasound (US) is first-line imaging modality for assessing liver chemistry abnormalities: fatty liver is hyperechoic on US. MRI/CT may also be used (1)[B].

## Follow-Up Tests & Special Considerations

- Imaging modalities such as FibroScan (which detects tissue elasticity in cases of suspected hepatic fibrosis) and MR spectroscopy (to assess changes in hepatic fat) are currently being evaluated to better characterize NAFLD (8)[B].
- No imaging modality can distinguish simple steatosis from steatohepatitis.

## Diagnostic Procedures/Other

- Liver biopsy is the gold standard for diagnosis. To perform procedure, biopsy must have likelihood of changing management (1)[B].
- NAFLD fibrosis score age (>50 years), BMI (>30), platelet count, albumin, and AST/ALT ratio identifies patients at risk of developing fibrosis/cirrhosis (9)[B].

## Test Interpretation

- Liver biopsy is the gold standard for prognosis (1).
- In NASH, steatosis, ballooning, and lobular inflammation are minimal criteria for diagnosis. Other common findings include mild to moderate portal inflammation, acidophil bodies, perisinusoidal zone 3 fibrosis, megamitochondria, and Mallory-Denk bodies (hyaline) in hepatocytes (1).
- Staging is based largely on the extent of fibrosis (1).

## TREATMENT

- Sustained weight loss through lifestyle modification of at least 3-5% of body weight is most successful treatment (1,9)[A].
- Foregut bariatric surgery not yet proven to specifically treat NASH (1)[B]
- Aerobic exercise 3 to 5 times weekly for 20 to 45 minutes with reduced calorie intake/diet modifications (1)[B]
- Tight control of diabetes (1,9)[B]
- Treatment of metabolic syndrome—hypertension, dyslipidemia, and obesity (1,9)[B]
- Limit alcohol consumption (<21 drinks/week for men and <14 drinks/week for women) (9)[A].
- Avoid hepatotoxic medications (1)[B].

## MEDICATION

Currently no effective medication treatment (1,9)[A]

Several promising agents include the following:

- Thiazolidinediones (pioglitazone) (1)[B]
- Vitamin E (1)[B]
- Other drugs studied in small studies (1,9,10)[B,C]
  - Statins, but study excluded cases with AST and AST >1.5 times normal limit
  - Gemfibrozil; omega-3 fatty acids
  - Angiotensin receptor blockers; probiotics
  - Obeticholic acid (bile acid derivative)
  - Ursodeoxycholic acid

## ***ISSUES FOR REFERRAL***

Persistent AST/ALT elevations 2 to 3 times above upper limit of normal without diagnosis or those with fibrosis on biopsy benefit from hepatology evaluation (1)[A].

## ***SURGERY/OTHER PROCEDURES***

Bariatric procedures: NAFLD is not a contraindication in otherwise eligible obese patients. There is a lack of data to definitively assess benefits and harms of surgery in treating patients with NASH (1)[B].

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Annual monitoring of LFTs (1,9)[B]
- Consider surveillance monitoring with US or CT scan to evaluate disease progression/improvement (9)[B]. Improvements can provide motivation for ongoing lifestyle changes.
- Routine liver biopsy is not recommended but may be repeated 5 years after baseline biopsy if progression of fibrosis is suspected (1,9)[B].
- Hepatic fibrosis staging is the strongest predictor for all-cause and disease-specific mortality in patients with histologically confirmed NAFLD (2)[B].

### ***DIET***

Low in saturated and trans fat; low in simple carbohydrates; avoid excessive alcohol (protective or worsening effect of light/moderate consumption inconclusive).

### ***PATIENT EDUCATION***

Extensive counseling on sustained lifestyle changes in nutrition, exercise, and alcohol use.

### ***PROGNOSIS***

Within the spectrum of NAFLD, only NASH has been shown to be progressive, potentially leading to cirrhosis, hepatocellular carcinoma, cholangiocarcinoma, and/or liver failure (11):

- Cirrhosis develops in up to 15-20% of patients. Approximately 2-3% of patients with cirrhosis will develop HCC each year (3).
- Transplantation is effective, but NASH may recur after transplantation due to ongoing risk

factors.

## COMPLICATIONS

Progressive disease may lead to decompensated cirrhosis and portal hypertension with complications such as ascites, encephalopathy, bleeding varices, and hepatorenal or hepatopulmonary syndromes.

## Codes

&NA;

### ICD10

K76.0 Fatty (change of) liver, not elsewhere classified

## Clinical Pearls

&NA;

- NAFLD: major cause of liver disease. Spectrum ranges from NAFL to NASH, advanced fibrosis, and cirrhosis.
- NAFLD: most common chronic liver disease in children; parallel rise in childhood obesity and NAFLD
- Lifestyle changes with targeted weight loss are the cornerstones of therapy for NAFLD.
- NAFLD is a common cause of asymptomatic mild serum aminotransferase elevation.

# Nosocomial Infections

Cheryl Durand, PharmD

Edward L. Yourtee, MD, FACP

## BASICS

### DESCRIPTION

- Health care-associated infections (HAIs)
- Infection must not have been present or incubating on admission to a health care facility.
- CDC categories:
  - Catheter-associated urinary tract infection (CAUTI)
  - Surgical site infection (SSI)
  - Ventilator-associated pneumonia (VAP)
  - Central line-associated bloodstream infection (CLABSI)
  - *Clostridium difficile* infection (C. diff, C. difficile, CDAD, CDI)
- The National Healthcare Safety Network (NHSN) at [www.cdc.gov/nhsn](http://www.cdc.gov/nhsn) monitors emerging HAI pathogens and their mechanisms of resistance to promote current prevention strategies.
- *Medicare and Medicaid will not pay for the treatment of certain HAI including CAUTIs, CLABSIs, and SSIs.*

### EPIDEMIOLOGY

- General
  - 13/1,000 patient-days in the ICU (1)
  - 7/1,000 patient-days in high-risk nurseries
  - 2.6/1,000 patient-days in nurseries (1)
  - Estimated cost of HAIs is \$20 billion per year (2).
- Infection specific
  - CAUTI

- Hospital stay increased by 1 to 3 days.
- Cost up to \$600/infection
- VAP
  - Hospital stay increased by 6 days.
  - Cost up to \$5,000/infection
- CLABSI
  - Hospital stay increased by 7 to 20 days.
  - Cost up to \$56,000/infection
- SSI
  - Hospital stay increased by 7.3 days.
  - Cost >\$3,000/infection
  - May not be apparent until 1 month after surgery
- *C. difficile* infection (see topic *Clostridium difficile* Infection)

## *Incidence*

- 1 out of 25 inpatients in the United States has at least one HAI (3).
  - 722,000 HAIs in U.S. acute care hospitals in 2011 (3)
  - UTI: 13% of HAIs (3)
  - Pneumonia: 22% of HAIs (3)
  - Bloodstream infection: 10% of HAIs (3)
  - SSI: 22% of HAIs (3)
  - 107,000 *C. difficile* cases in 2011(4)[A]
- Infections caused by gram-negative rods resistant to almost all antibiotics are increasing. Up to 70% of nosocomial infections are resistant to at least one previously active antimicrobial.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Endogenous spread: Patient host flora causes invasive disease (most common).
- Exogenous spread: Flora acquired from within health care facility.
- Causative organisms

- UTI: *Escherichia coli*, *Klebsiella* spp., *Serratia* spp., *Enterobacter*, *Pseudomonas aeruginosa*, *Enterococcus* spp., *Candida albicans* (3)
- Pneumonia: aerobic gram-negative bacilli, *Staphylococcus aureus*, *P. aeruginosa*, *Streptococcus* spp. (3)
- Bloodstream infection: *Staphylococcus* spp., *Candida* spp., *Enterococcus* spp., gram-negative bacilli (3)
- SSI: *S. aureus*, gram-negative bacilli, *Enterococcus* spp., *Streptococcus* spp., *Enterobacter* spp., *Bacteroides* spp. (3)

## RISK FACTORS

- Extremes of age
- Invasive surgical procedures (abdominal surgeries, orthopedic surgeries, urogynecologic surgeries, neurosurgery)
- Use of indwelling medical devices.
- Chronic disease (including diabetes, renal failure, and malignancy)
- Immunodeficiency
- Malnutrition
- Medications (recent antibiotics, proton pump inhibitors, and sedatives)
- Colonization with pathogenic strains of flora
- Breakdown of mucosal/cutaneous barriers, including trauma and battle wounds
- Anesthesia
- Lack of attention to detail with universal precautions

## GENERAL PREVENTION

- Prevention should target both patient-specific and facility-related risk factors.
- Hand hygiene—thoroughly wash hands (5)[C]
  - On entering and leaving any patient room (5)
  - After contact with blood, excretions, body fluids, wound dressings, nonintact skin, mucous membranes (5)
  - Before using and after removing gloves (gloves are permeable to bacteria)
  - When moving hands from contaminated to clean body site (5)

- Alcohol-based products are satisfactory when hands are not visibly soiled (5).
- Soap and water should be used when surfaces are visibly soiled or when contact with spores is anticipated.
- Antibiotic stewardship—Appropriate selection of antimicrobial therapy includes the following:
  - Judicious use of antibiotics to reduce the emergence of multidrug-resistant organisms and the occurrence of *C. difficile* infection (2).
  - Use of narrow-spectrum early-generation antibiotics when possible.
  - Taking an antibiotic “time out” at 72 hours to review the patient's clinical status and culture results, and eliminate (“streamline”) any redundant or unnecessary antibiotics
  - Use shorter courses of antibiotics when appropriate.
- Hospital-based surveillance programs and antibiograms
- Infection control programs with specially trained employees (5)[C]
- Employee education on HAIs (5)[C]
- Disinfection of hospital rooms with hydrogen peroxide vapor or UV irradiation in addition to standard cleaning reduces environmental contamination and the risk of infection with multidrug-resistant organisms.
- Minimize invasive procedures.
- Caregiver stethoscope cleaning
  - Stethoscope bacterial contamination is common. Regular cleaning with alcohol-based preparations reduces bacterial load. Evidence is lacking to confirm whether stethoscope contamination causes nosocomial infections.
- Isolation of known pathogen carriers (5)[A]
  - Contact precautions
    - Institute for known pathogens spread by direct contact including methicillin-resistant *S. aureus* (MRSA), vancomycin-resistant *Enterococcus* (VRE), *C. difficile*, extended-spectrum *&agr;-*lactamase-producing gram-negative rods, and carbapenemase-producing gram-negative rods. Glove when entering room (5)[B]
    - Gown if clothing will touch patient or environment (5)[B]
  - Droplet precautions
    - Infectious particles measure  $>5 \mu\text{m}$ .

- Institute for pathogens shed via talking, coughing, sneezing, mucosal shedding, airway suctioning, and bronchoscopy. These include *Neisseria meningitidis*, influenza, *Haemophilus influenzae*, *Corynebacterium diphtheriae*, and *Bordetella pertussis*.
- Mask when entering room (5)[B]
- Airborne precautions
  - Infectious particles measure  $<5 \mu\text{m}$ .
  - Institute for pathogens shed via coughing including tuberculosis, varicella-zoster virus, and measles.
  - Fit-tested National Institute of Occupational Safety and Health (NIOSH)-approved <sup>3</sup> N-95 respirator on entering room (5)[B]
- Infection-specific measures
  - CAUTI
    - Employee education on urinary catheters (indications, placement, maintenance)
    - Sterile catheter placement technique (6)[C]
    - Closed urine collection system (6)[C] Use catheter only for necessary duration and remove as early as possible (6)[B].
    - Use of nurse-driven protocols for guideline-driven catheter removal.
    - Do not confuse catheter-associated asymptomatic bacteriuria with CAUTI.
    - Do not screen for bacteriuria by routinely performing a urine culture when the catheter is withdrawn.
  - VAP
    - Intubate only when clinically necessary (7)[C]
    - Perform oral decontamination with oral chlorhexidine (8)[A].
    - Avoid nasotracheal intubation (7)[B].
    - Inline suctioning (7)[C]
    - Elevate head to 30 to 45 degrees (7)[C].
  - CLABSI
    - Educate staff about appropriate use of IV catheters (indications, placement, maintenance) (9)[A]. Place catheters using sterile technique (including chlorhexidine prep and maximal barrier precautions) (9)[A].

- Use order bundles to improve adherence to catheter insertion guidelines.
  - Remove catheter promptly when no longer clinically indicated (9)[A].
  - Hand hygiene in addition to glove use (9)[A]
  - Regularly monitor catheter site (9)[A].
  - With introduction of these measures, CLASBI rates fell 46% between 2008 and 2011 (10) [A].
- SSI
    - Proper surgical hand hygiene (2)[B]
    - Prophylactic antibiotic therapy when indicated (2)[A]; eliminate underlying infections before surgery if possible (2)[A].
- 
- P.721
- Remove hair with electric clippers/depilatory agent prior to incision (2)[B].
  - Poor postoperative blood sugar control increases risk of infection.
- *C. difficile* infection
    - Gloves combined with hand hygiene with soap and water (spores are resistant to alcohol-based products) (2)
    - Restrict use of fluoroquinolones, cephalosporins, and clindamycin when possible (2).
    - *C. difficile* is associated with the use of proton pump inhibitors: H<sub>2</sub> blockers is preferred for acid suppression (11)[A].
    - Probiotics may reduce nonspecific antibiotic-associated diarrhea; the effectiveness of probiotics for prevention of *C. difficile* is unclear (11).
  - Bloodstream infections
    - Use of chlorhexidine-impregnated washcloths to bathe ICU patients reduces bloodstream infections by 28% (12)[B].
    - Routine surveillance for systemic inflammatory response syndrome (SIRS) using established criteria

## DIAGNOSIS

Consistent with nature of infection

## HISTORY

- Exposure to health care facility
- Recent surgery/open wounds
- History of invasive procedure
  - Urinary catheter placement
  - Indwelling vascular catheter
- Recent intubation/mechanical ventilation
- History of past infections (MRSA, VRE, etc.)

## *PHYSICAL EXAM*

Consistent with nature of infection; site-specific exam for infections of skin, catheter sites, wounds, signs of sepsis, or pneumonia

## *DIFFERENTIAL DIAGNOSIS*

- Community-acquired infection
- Sepsis/SIRS
- Other causes of infectious diarrhea

## *DIAGNOSTIC TESTS & INTERPRETATION*

Specific to condition

- CBC, blood culture
- Wound culture
- Urine culture
- Chest x-ray
- Stool culture

## *Test Interpretation*

Consistent with underlying infection

## **TREATMENT**

## *GENERAL MEASURES*

- Treat with appropriate antibiotics.

- Order bundles improve adherence to sepsis guidelines and improves survival.
- UTI: Remove urinary catheters.
- CLABSI: Remove IV catheter.
- *C. difficile*: Stop all antibiotics not being used to treat *C. difficile* infection.

## **MEDICATION**

### **First Line**

- Targeted antimicrobial therapy
- Several agents have been recently approved for the treatment of antibiotic-resistant infections and should be considered for second-line therapy.
  - Daptomycin, telavancin, dalbavancin, ceftaroline, oritavancin, tedizolid, ceftolozane-tazobactam, and ceftazidime-avibactam

## **ISSUES FOR REFERRAL**

- Failure to respond to initial therapy
- Some emerging resistant gram-negative infections are resistant to nearly all antibiotics and require expert consultation for management.

## **SURGERY/OTHER PROCEDURES**

- Screening for nasal carriage and isolation reduce the nosocomial spread of MRSA.
- Treating proven nasal carriers of *Staphylococcus* or MRSA with mupirocin prevents *S. aureus* nosocomial infections after surgery, as long as the prevalence of mupirocin resistance is low (13)[B].

## **INPATIENT CONSIDERATIONS**

### **IV Fluids**

As needed for hemodynamic support

### **Nursing**

- Hand washing should be performed on entering and exiting the patient room even when there is no direct contact with the patient.
- Isolation precautions as indicated

## Discharge Criteria

When infection has resolved or patient is stable and not an infectious risk

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### Patient Monitoring

Risk for recurrence is generally low in immunocompetent patients. Manage underlying comorbidities (risk factors).

### PROGNOSIS

- 99,000 deaths in 2002 in the United States (1)
- Bloodstream infection mortality: 27%
- Pneumonia mortality: 33-50%
- SSI mortality: 11%

### COMPLICATIONS

Related to specific nature of infection

---

**Codes**

**&NA;**

## ICD10

- T83.51XA Infect/inflm reaction due to indwell urinary catheter, init
- T81.4XXA Infection following a procedure, initial encounter
- J95.851 Ventilator associated pneumonia

## Clinical Pearls

### &NA;

- Nosocomial infections increase mortality, length of hospital stay, and cost of hospitalization.
- Preventive efforts should address patient-specific and facility-related risk factors.
- Proper hand hygiene, using an alcohol-based hand product or soap and water should be carried out before and after each patient encounter, even when gloves are used. Alcohol-based hand rubs are not effective for killing spores formed by *C. difficile*. Hand washing with soap and water is preferred in this situation.
- Adherence to contact, droplet, or airborne precautions reduces the spread of infection.
- The risk of developing a resistant nosocomial infection can be reduced by antibiotic streamlining, use of narrow-spectrum antibiotics, and frequent patient reevaluation to ensure the necessity of continuing antibiotics.

# Obesity

Maya Leventer-Roberts, MD, MPH

## BASICS

### DESCRIPTION

- Obesity is the state of excess adipose tissue, frequently characterized in adults by body mass index (BMI), body weight (kg)/(body height [m<sup>2</sup>]), of  $\geq 30$  kg/m<sup>2</sup>.
- Obesity is associated with negative health outcomes (1), and the concurrent presence of abdominal obesity increases the risk of morbidity and mortality.
- System(s) affected: endocrine/metabolic, cardiac, respiratory, gastrointestinal, musculoskeletal, dermatologic, mental health
- Synonym(s): overweight; adiposity

### Geriatric Considerations

Note: Underweight BMI ( $\leq 18$ ) is associated with an increased risk of mortality. The most likely explanation is that this is a secondary effect; severe chronic conditions can cause anorexia and weight loss.

### EPIDEMIOLOGY

- Predominant age: Incidence rises in the early 20s.
- Predominant sex: female > male

### Prevalence

- Mean prevalence of obesity among adults is 35% in the United States (2,3).
- Overweight: 40% of men and 25% of women
- Obese: 20% of men and 25% of women

### Pediatric Considerations

- Pediatric obesity is defined as have a BMI at  $\geq 95$ th percentile, as by age and sex specific WHO or CDC growth curves.

- Obesity during adolescence and young adulthood is strongly associated with obesity in adulthood.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Obesity is caused by an imbalance among food intake, absorption, and energy expenditure.
- Underlying organic causes include psychiatric disturbances, hypothyroidism, hypothalamic disorders, insulinoma, and Cushing syndrome.
- Medications can contribute to obesity, including corticosteroids, neuroleptics (particularly atypical antipsychotics), and antidepressants.

## *Genetics*

- Genetic syndromes such as Prader-Willi and Bardet-Biedl are found in a minority of people with obesity.
- Studies are insufficiently powered to isolate specific genes as independent predictors of obesity.

## *RISK FACTORS*

- Parental obesity
- Sedentary lifestyle
- Consumption of calorie-dense food
- Low socioeconomic status
- >2 hours per day of television viewing

## *GENERAL PREVENTION*

- Encourage at least 1 hour of daily exercise, limited television viewing, and moderation in portion size.
- Avoid calorie-dense and nutrient-poor foods such as sweetened beverages and processed foods.

## **DIAGNOSIS**

### **HISTORY**

- Diet and exercise habits
- Prior attempts at weight loss

- Reported readiness to change lifestyle
- Social support and resources
- Comorbidities: diabetes mellitus type 2, hypertension, hyperlipidemia, sleep apnea
- Psychiatric history
- Symptoms suggesting hypothyroidism, Cushing syndrome, and genetic syndromes

## *PHYSICAL EXAM*

- Elevated BMI:
  - Overweight: BMI = 25 to 29.9 kg/m<sup>2</sup>
  - Obese: BMI 30 to 39.9 kg/m<sup>2</sup>
  - Morbid obesity: BMI  $\geq$ 40 kg/m<sup>2</sup>
- Abdominal circumference:
  - Measuring around the abdomen at the level of the umbilicus.
    - Elevated:
      - Male: >40 inches (102 cm)
      - Female: >35 inches (88 cm)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Yearly screening and laboratory assessment (4)[C]
- Screen for underlying physiologic causes as well as associated comorbid conditions.
- Labs should be done while fasting (nonfasting labs within normal limits are considered adequate).
- Preserved glucose, total insulin, hemoglobin A1C
- Serum lipid panel
- Thyroid function tests
- LFTs
- Imaging interpretation

- Hypertrophy and/or hyperplasia of adipocytes
- Cardiomegaly
- Hepatomegaly

## TREATMENT

### GENERAL MEASURES

- Begin with the following assessment:
  - Motivation to lose weight (5)[A]
  - Patient-specific goals of therapy
  - Referral for intensive counseling for diet, exercise, and behavior modification
  - Long-term follow-up plan
- Goal for therapy is to achieve and sustain long-term weight loss up of at least 10% of body weight.
- Tracking of caloric intake and exercise
- Use of commercial weight loss programs (e.g., Weight Watchers) can be more effective than Östandard of careÓ counseling (6)[B].
- Behavior therapy and cognitive-behavioral methods can result in modest weight loss but are most effective when combined with dietary and exercise treatments.

### MEDICATION

- National Institute of Health guidelines suggest nonpharmacologic treatment for at least 6 months (5)[C].
- Medication treatment may be initiated for unsatisfactory weight loss in those with:
  - BMI  $\geq 30$
  - BMI  $\geq 27$  combined with associated risk factors (e.g., coronary artery disease, diabetes, sleep apnea, hypertension, hyperlipidemia)
- Diet, exercise, and behavior therapy *must* be included with pharmacologic treatment for those without comorbid conditions.
- Relapse may occur after discontinuation of medication.
- Treatment for comorbidities (such as diabetes and hyperlipidemia) should be considered.

## First Line

- Medications may produce modest weight loss (7)[B].
- The lipase inhibitor orlistat (Xenical) decreases the absorption of dietary fat. Dose: 120 mg PO TID with meals containing fat; omit dose if meal is skipped or does not contain fat. Patients must avoid taking fat-soluble vitamin supplements within 2 hours of taking orlistat. The FDA has approved orlistat (Alli) 60 mg PO TID to be sold over the counter as a weight loss aid (8) [B]; adverse effects mainly GI (cramps, flatus, fecal incontinence)
- Contraindications
  - Orlistat: chronic malabsorption syndromes, cholestasis, pregnancy

## Second Line

- Appetite suppressants recommended for short-term treatment ( $\leq 6$  months) (9)[A]
  - Only beneficial in patients who exercise and eat reduced calorie diet
    - Naltrexone/bupropion (Contrave): 8 mg naltrexone/90 mg bupropion per tablet; slow titration up to 2 tablets PO BID by week 4; contraindicated if uncontrolled HTN, seizure disorder, chronic opioid use, pregnancy
    - Liraglutide (Saxenda): 3.0 mg SC once daily; GLP-1 agonist recently approved for obesity; discontinue if weight loss is  $< 4\%$  after 16 weeks.
    - Topiramate: Initiate with 25 mg BID and increase by 50 mg/week up to 100 mg PO BID; not FDA-approved for the treatment of obesity; tolerance is a concern (paresthesias, somnolence, difficulty concentrating).
  - Schedule IV drugs
    - Lorcaserin (Belviq) 10 mg PO BID (D/C if weight loss is  $< 5\%$  after 12 weeks); works as serotonin agonist; avoid in those with CrCl  $< 30$  mL/min; contraindicated in pregnancy; avoid use with other serotonergic drugs.
    - Phentermine: 15, 30, 37.5 mg PO every morning; discontinue if tolerance or no response after 4 weeks; contraindicated if history of CV disease, hyperthyroidism, history of substance abuse, pregnancy
- 
- Phentermine/topiramate (3.75 to 23 mg, 7.5 to 46 mg, 11.25 to 69 mg, 15 to 92 mg); initiate 3.75 to 23 mg PO once daily; requires enrollment into Risk Evaluation and Mitigation Strategy (REMS); women of childbearing age require negative pregnancy test prior to initiation and monthly thereafter

- Diethylpropion: 25 mg PO before meals TID; discontinue if no response after 4 weeks.  
Contraindicated if severe HTN, hyperthyroidism, history of substance abuse

## *Pregnancy Considerations*

During pregnancy, obese women should gain fewer pounds than recommended for nonobese women.

## ***SURGERY/OTHER PROCEDURES***

Patients meeting criteria should be evaluated for gastric bypass or lap band procedures (10)[C].

- Requires complex presurgical evaluation, surgery, and follow-up in a skilled treatment center.
- Surgical treatment is the most effective long-term weight-loss treatment available for morbidly obese patients, but there is insufficient evidence on longterm outcomes (11)[A].

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Exercise is an integral part of any weight loss program, yet exercise alone rarely results in significant weight loss.
- Combination of weight training and aerobic activity is preferred over aerobic activity alone.

### ***Patient Monitoring***

Long-term routine follow-up may prevent relapse after weight loss or further weight gain.

### ***DIET***

- Long-term studies suggest net calorie reduction of 500 to 1,000 kcal/day and ease of use are more important than the diet composition for long-term results (12)[A]:
  - A reduction of 500 kcal/day intake can result in  $\div$ 1 lb (0.45 kg) weight loss per week.
  - Portion-controlled servings are recommended.
- Very low-calorie diet (400 to 800 kcal/day consumption)
  - Can result in more rapid weight loss than higher calorie diets but are less effective in the long term
  - Complications can include dehydration, orthostatic hypotension, fatigue, muscle cramps, constipation, headache, cold intolerance, and relapse after discontinuation.

- Contraindications: recent myocardial infarction or cerebrovascular accident, renal disease, cancer, pregnancy, insulin-dependent diabetes mellitus, and some psychiatric disturbances

## ***PATIENT EDUCATION***

- Emphasize the value of a healthy BMI.
- Recommended Web site:
  - [www.nal.usda.gov/fnic/foodcomp/search](http://www.nal.usda.gov/fnic/foodcomp/search) for the FDA nutritional content in common foods

## ***PROGNOSIS***

- Lowest mortality associated with a BMI of 22
- Long-term maintenance of weight loss is difficult to achieve.
- A motivated patient is most likely to achieve successful weight loss (13).

## **COMPLICATIONS**

- Cardiovascular disease
- Stroke (in men)
- Thromboembolism
- Heart failure
- Hypertension
- Hypoventilation and sleep apnea syndromes
- Higher death rates from cancer: colon, breast, prostate, endometrial, gallbladder, liver, kidney
- Diabetes mellitus
- Skin changes
- Hyperlipidemia
- Gallbladder disease
- Osteoarthritis
- Gout
- Poor self-esteem
- Discrimination
- Increased sick leave

## Codes

**&NA;**

### **ICD10**

- E66.9 Obesity, unspecified
- E66.3 Overweight
- R63.5 Abnormal weight gain

## **Clinical Pearls**

**&NA;**

- Drug treatment with a first-line medication may be indicated when nonpharmacologic treatment for 6 months has been ineffective and the patient has a BMI >30 or a BMI >27 with associated risk factors. Medications may achieve a modest longterm weight loss.
- Surgical treatment may be indicated in patients with a BMI >40 who have failed more conservative treatment, particularly when there are associated risk factors, such as diabetes mellitus.
- No convincing evidence supports a specific diet method.

# Obsessive-Compulsive Disorder (OCD)

Amar Kapur, DO, CPT, MC, USA

## BASICS

### DESCRIPTION

- A psychiatric condition classified as an anxiety disorder characterized by pathologic obsessions (recurrent intrusive thoughts, ideas, or images) and compulsions (repetitive, ritualistic behaviors or mental acts) causing significant patient distress
- Not to be confused with obsessive-compulsive personality disorder

### EPIDEMIOLOGY

#### *Incidence*

- Predominant age: mean age of onset 22 to 36 years
  - Male = female (males present at younger age)
  - Child/adolescent onset in 33% of cases
  - 1/3 of cases present by age 15 years
  - 85% of cases present at <35 years of age
  - Diagnosis rarely made at >50 years of age
- Predominant gender: female > males but males more commonly affected in childhood

#### *Pediatric Considerations*

Insidious onset; consider brain insult in acute presentation of childhood obsessive-compulsive disorder (OCD).

#### *Geriatric Considerations*

Consider neurologic disorders in new-onset OCD in the elderly.

#### *Prevalence*

- 2.3% lifetime in adults

- 1-2.3% prevalence in children/adolescents

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Exact pathophysiology is unknown.
- Dysregulation of serotonergic pathways
- Dysregulation of corticostriatal-thalamic-cortico (CSTC) pathway
- Exact etiology unknown
- Genetic and environmental factors
- Pediatric autoimmune disorder associated with streptococcal infections

## *Genetics*

- Greater concordance in monozygotic twins
- Positive family history: prevalence rates of 7-15% in first-degree relatives of children/adolescents with OCD

## *RISK FACTORS*

- Exact cause of OCD is not fully elucidated.
- Combination of biologic and environmental factors likely involved the following:
  - Link between low serotonin levels and development of OCD
  - Link between brain insult and development of OCD (i.e., encephalitis, pediatric streptococcal infection, or head injury)

## *GENERAL PREVENTION*

- OCD cannot be prevented.
- Early diagnosis and treatment can decrease patient's distress and impairment.

## *COMMONLY ASSOCIATED CONDITIONS*

- Major depressive disorder
- Panic disorder
- Phobia/social phobia
- Tourette syndrome/tic syndromes and other movement disorders

Substance abuse

- Eating disorder/body dysmorphic disorder

## DIAGNOSIS

### HISTORY

- Patient presents with either obsessions or compulsions, which cause marked distress, are time-consuming (>1 hr/day) and cause significant occupational/social impairment.
- Four criteria support diagnosis of obsessions:
  - Patients are aware that they are thinking the obsessive thoughts; thoughts are not imposed from outside (as in thought insertion).
  - Thoughts are not just excessive worrying about real-life problems.
  - Recurrent thoughts are persistent, intrusive, and inappropriate, causing significant anxiety and distress.
  - Attempts to suppress intrusive thoughts are made with some other thought/activity.
- Two criteria support a diagnosis of compulsions:
  - The response to an obsession is to perform repetitive behaviors (e.g., hand washing) or mental acts (e.g., counting silently) rigidly.
  - Although done to reduce stress, the responses are either not realistically connected with the obsession or they are excessive.
  - In children, check for precedent streptococcal infection.

### PHYSICAL EXAM

- Dermatologic problems caused by excessive hand washing may be observed.
- Hair loss caused by compulsive pulling/twisting of the hair (trichotillomania) may be observed.

### DIFFERENTIAL DIAGNOSIS

- Obsessive-compulsive personality disorder
  - In personality disorder, traits are ego-syntonic and include perfectionism and preoccupation with detail, trivia, or procedure and regulation. Patients tend to be rigid, moralistic, and stingy. These traits are often rewarded in the patient's job as desirable.
- Impulse-control disorders: compulsive gambling, sex, or substance abuse: The compulsive

behavior is not in response to obsessive thoughts, and the patient derives pleasure from the activity.

- Major depressive disorder
- Eating disorder
- Tics (in tic disorder) and stereotyped movements
- Schizophrenia: Patient perceives thought to be true and coming from an external source.
- Generalized anxiety disorder, phobic disorders, separation anxiety: similar response on heightened anxiety, but presence of obsessions and rituals signifies OCD diagnosis
- Anxiety disorder due to a general medical condition: Obsessions/compulsions are assessed to be a direct physiologic consequence of a general medical condition.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

According to *DSM-5*, diagnostic criteria for OCD are (1)[C]:

- Presence of obsessions, compulsions, or both
- Obsessions are defined by:
  - Recurrent or persistent thoughts, urges, or images that are experienced at some time during the disturbance, as intrusive and unwanted, and that in most individuals cause marked anxiety or distress
  - The individual attempts to ignore or suppress such thoughts, urges, or images or to neutralize them with some other thought or actions (i.e., by performing compulsion).
- Compulsions are defined by the following:
  - Repetitive behavior (e.g., hand washing, ordering, checking) or mental acts (e.g., praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly.
  - The behavior or mental acts are aimed at preventing or reducing anxiety or distress or preventing some dreaded event or situation. However, these behavior or mental acts are not connected in a realistic way with what they are designed to neutralize or prevent or are clearly excessive.
- The obsessions or compulsions are time-consuming (e.g., take >1 hr/day) or cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.
- The obsessive-compulsive symptoms are not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication, or other medical condition).

- The disturbance is not better explained by the symptoms of another mental disorder (e.g., excessive worries, as in generalized anxiety disorder, preoccupation with appearance, as in body dysmorphic disorder or skin picking etc.).
- Specify if:
  - With good or fair insight: The individual recognizes the OCD beliefs are definitely or probably not true or that they may or may not be true.
  - With poor insight: The individual thinks that OCD beliefs are probably true.
  - With absent insight/delusional beliefs: The individual is completely convinced that OCD beliefs are true.
- Specify if:
  - Tic related: The individual has a current or past history of tic disorder.

### *Diagnostic Procedures/Other*

- Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) or CY-BOCS for children (2)[C]
- Maudsley Obsessive-Compulsive Inventory (MOCI) (3)[C]

### *Test Interpretation*

- Compulsions are designed to relieve the anxiety of obsessions; they are not inherently enjoyable (egodystonic) and do not result in completion of a task.
- Common obsessive themes
  - Harm (i.e., being responsible for an accident)
  - Doubt (i.e., whether doors/windows are locked or the iron is turned off)
  - Blasphemous thoughts (i.e., in a devoutly religious person)
  - Contamination, dirt, or disease
  - Symmetry/orderliness
- Common rituals or compulsions
  - Hand washing, cleaning
  - Checking
  - Counting
  - Hoarding

- Ordering, arranging
- Repeating
- Neither obsessions nor compulsions are related to another mental disorder (i.e., thoughts of food and presence of eating disorder).
- 80-90% of patients with OCD have obsessions and compulsions.
- 10-19% of patients with OCD are pure obsessional.

## TREATMENT

### GENERAL MEASURES

- Combined medications and cognitive-behavioral therapy (CBT) is most effective (1,2)[A].
- Family psychoeducation
- Parent behavior management training if patient is a child/adolescent
- Brain modulation available for severe OCD includes electroconvulsive therapy and transcranial magnetic stimulation in small groups of patients.

### MEDICATION

#### *First Line*

- Adequate trial at least 10 to 12 weeks
- Doses may exceed typical doses for depression.
- Optimal duration for pediatrics unknown but recommended minimum of maintenance treatment: 6 months
- SSRIs recommended first-line agents (4,5)[A]
  - Fluoxetine (Prozac)
    - Adults: 20 mg/day; increase by 10 to 20 mg every 4 to 6 weeks until response; range: 20 to 80 mg/day
    - Children (7 to 17 years of age): 10 mg/day; increase 4 to 6 weeks until response; range: 20 to 60 mg/day
- Sertraline (Zoloft)

- Adults: 50 mg/day; increase by 50 mg every 4 to 7 days until response; range: 50 to 200 mg/day; may divide if above 100 mg/day
- Children (6 to 17 years of age): 25 mg/day; increase by 25 mg every 7 days until response; range: 50 to 200 mg/day
- Paroxetine (Paxil)
  - Adults: 20 mg/day; increase by 10 mg every 4 to 7 days until response; range: 40 to 60 mg/day
  - Children: Safety and effectiveness in patients <18 years have not been established.
- Fluvoxamine (Luvox)
  - Adult: 100 mg/day; increase by 50 mg every 4 to 7 days until response; range: 200 to 300 mg/day
  - Children (8 to 17 years of age): 25 mg/day; increase by 25 mg every 4 to 7 days until response; range: 50 to 200 mg/day
- Absolute SSRI contraindications
  - Hypersensitivity to SSRIs
  - Concomitant use within 14 days of monoamine oxidase inhibitor (MAOI)
- Relative SSRI contraindications
  - Severe liver impairment
  - Seizure disorders (lower seizure threshold)
- Precautions
  - Watch for suicidal behavior/worsening depression during first few months of therapy/after dosage changes with antidepressants, particularly in children, adolescents, and young adults.
  - Long half-life of fluoxetine (>7 days) may be troublesome if patient has an adverse reaction.
  - May cause drowsiness and dizziness when therapy was initiated; warn patients about driving and heavy equipment hazards.

## *Pregnancy Considerations*

All SSRIs are pregnancy Category C, except paroxetine, which is Category D.

## *Second Line*

- Try switching to another SSRI.
- 40-60% of patients will remain refractory to SSRI
- Tricyclic acid (TCA), clomipramine (Anafranil)
  - Adults: 25 mg/day; increase gradually over 2 weeks to 100 mg/day, then to 250 mg/day (max dose) over next several weeks, as tolerated.
  - Children (10 to 17 years of age): 25 mg/day; titrate as needed and tolerated up to 3 mg/kg/day or 200 mg/day (whichever is less).
  - Absolute clomipramine contraindications
    - Within 6 months of a myocardial infarction (MI)
    - Hypersensitivity to clomipramine or other TCA
    - Concomitant use within 14 days of an MAOI
    - 3rd-degree atrioventricular (AV) block
  - Relative clomipramine contraindications
    - Narrow-angle glaucoma (increased intraocular pressure)
    - Prostatic hypertrophy (urinary retention)
    - 1st- or 2nd-degree AV block, bundlebranch block, and congestive heart failure (proarrhythmic effect)
    - Pregnancy Category C
  - Precautions
    - Dangerous in overdose
    - Pretreatment ECG for patients >40 years of age
    - Watch for suicidal behavior/worsening depression during first few months of therapy or after dosage changes with antidepressants, particularly in children, adolescents, and young adults.
    - May cause drowsiness and dizziness when therapy is initiated; warn patients about driving and heavy equipment hazards.

## *ISSUES FOR REFERRAL*

- Psychiatric referral for CBT (in vivo exposure and prevention of compulsions)

- Psychiatric evaluation if obsessions and compulsions significantly interfere with patient's functioning in social, occupational, or educational situations

## ***ADDITIONAL THERAPIES***

Dopamine receptor antagonists (antipsychotic agents) alone are not effective in treatment of OCD. They can be used as augmentation to SSRI therapy for treatment-resistant OCD; they also can worsen OCD symptoms (4)[C]. Some evidence show that addition of quetiapine or risperidone to antidepressants will increase efficacy; data with olanzapine are too limited to draw conclusions (4)[A].

- Risperidone (Risperdal): initial dose: 0.5 mg/day; target dose: 0.5 to 2 mg/day
- Quetiapine (Seroquel): initial dose: 25 mg/day; target dose: 600 mg/day

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Y-BCOS or MOCI surveys to track progress

### ***Patient Monitoring***

Monitor for decrease in obsessions and time spent performing compulsions.

### ***DIET***

No dietary modifications/restrictions recommended

### ***PATIENT EDUCATION***

- Importance of medication adherence
- Importance of psychotherapy (CBT)
- International OCD Foundation, Boston, MA 617-973-5801: <https://iocdf.org/>
- Obsessive Compulsive Anonymous, New Hyde Park, NY:  
<http://obsessivecompulsiveanonymous.org>

### ***PROGNOSIS***

- Chronic waxing and waning course in most patients:
  - 24-33% fluctuating course
  - 11-14% phasic periods of remission

- 54-61% chronic progressive course
- Early onset a poor predictor

## COMPLICATIONS

- Depression in 1/3 patients with OCD
- Avoidant behavior (phobic avoidance)
  - Children may drop out of education.
  - Adults may become homebound.
- Anxiety and panic-like episodes associated with obsessions

## Additional Reading

&NA;

Ruscio AM, Stein DJ, Chiu WT, et al. The epidemiology of obsessive-compulsive disorder in the National Comorbidity Survey Replication. *Mol Psychiatry*. 2010;15(1):53-63.

**&NA;**

## **ICD10**

- F42 Obsessive-compulsive disorder
- F63.9 Impulse disorder, unspecified
- F63.3 Trichotillomania

## **Clinical Pearls**

**&NA;**

- CBT is the initial treatment of choice for mild OCD.
- CBT plus an SSRI or an SSRI alone is the treatment choice for more severe OCD.
- The majority of patients with OCD respond to first SSRI treatment.
- Improvement in symptoms however, is often incomplete, ranging from 25% to 60%.

# Ocular Chemical Burns

Robert J. Hyde, MD, MA, NRP, FACEP

Patricia Ruth Atchinson, DO

## BASICS

### DESCRIPTION

- Chemical exposure to the eye can result in rapid, devastating, and permanent damage and is one of the true emergencies in ophthalmology.
- Separate alkaline from acid chemical exposure
  - Alkali burns: more severe. Alkaline compounds are lipophilic, penetrating rapidly into eye tissue; saponification of cells leads to necrosis and may produce injury to lids, conjunctiva, cornea, sclera, iris, and lens (cataracts).
  - Acid burns: Acid usually does not damage internal structures because its associated anion causes protein denaturation, creating a barrier to further acid penetration. (Hydrofluoric acid is an exception to this rule; see below.) Injury is often limited to lids, conjunctiva, and cornea.
- System(s) affected: nervous, skin/exocrine
- Synonym(s): chemical ocular injuries

### EPIDEMIOLOGY

- Predominant age: can occur at any age, peak from 20 to 40 years of age
- Predominant sex: male > female

### Incidence

- Estimated 300/100,000 per year
- Alkali burns twice as common as acid burns

### ETIOLOGY AND PATHOPHYSIOLOGY

- Acidic compounds

- Anion leads to protein denaturing and protective barrier formation by coagulation necrosis forming an eschar. This more superficial mechanism of injury tends to have prominent scarring that may lead to vision loss:
  - Hydrofluoric acid is an exception. In its nonionized form, it behaves like an alkaline substance, capable of penetrating the corneal stroma and leading to extensive anterior segment lesions. When ionized, it may combine with intracellular calcium and magnesium to form insoluble complexes, leading to potassium ion movements and cell death. Once systemically absorbed, severe hypocalcemia can occur.
- Alkaline compounds
  - Lipophilic compounds that penetrate into deep structures on disassociation into cations and hydroxide
  - Hydroxide causes saponification of fatty acids in cell membranes, leading to cell death.
  - Cation causes hydration of glycosaminoglycans, leading to corneal opacification and hydration of collagen, resulting in rapid shortening and thickening of collagen fibrils that leads to an acute elevation in intraocular pressure secondary to shrinking and contraction of the cornea and sclera.
  - Long-term elevation in intraocular pressure may occur from accumulation of inflammatory debris within the trabecular meshwork.
  - Penetration into deep structures may also affect perfusing vessels, leading to ischemia of affected area.

### Sources of Alkaline and Acidic Compounds

<b>Alkaline Compounds</b>	<b>Typical Sources</b>
Calcium hydroxide (lime)	Cement, whitewash
Sodium hydroxide (lye)	Drain cleaner, airbags
Potassium hydroxide (lye)	Drain cleaner
Ammonia	Cleaning agents
Ammonium hydroxide	Fertilizers
<b>Acidic Compounds</b>	<b>Typical Sources</b>
Sulfuric acid	Car batteries

Sulfurous acid	Bleach
Hydrochloric acid	Chem labs, swimming pools
Acetic acid	Vinegar
Hydrofluoric acid	Glass polish

## ***RISK FACTORS***

- Construction work (plaster, cement, whitewash)
- Use of cleaning agents (drain cleaners, ammonia)
- Automobile battery explosions (sulfuric acid)
- Industrial work, including work in industrial chemical laboratories
- Alcoholism
- Any risk factor for assault (÷10% of injuries due to deliberate assault)

## ***GENERAL PREVENTION***

Safety glasses to safeguard eyes

## ***COMMONLY ASSOCIATED CONDITIONS***

Facial (including eyelids) cutaneous chemical or thermal burns

## **DIAGNOSIS**

### **HISTORY**

- Most often complaints of pain, photophobia, blurred vision, and a foreign body sensation
- In alkali burns, can have initial pain that later diminishes
- Mild burns: pain and blurred vision
- Moderate to severe burns: severe pain and markedly reduced vision

## ***PHYSICAL EXAM***

- Acidic compound may present with a ground-glass appearance secondary to superficial scar formation.
- Alkaline compounds may present with corneal opacification secondary to glycosaminoglycan

hydration; however, severe acid burns may also present with this finding.

- Mild burns
  - Blurry vision
  - Eyelid skin erythema and edema
  - Corneal epithelial defects or superficial punctate keratitis
  - Conjunctival chemosis, hyperemia, and hemorrhages without perilimbal ischemia
  - Mild anterior chamber reaction
- Moderate to severe burns
  - Reduced vision
  - 2nd- and 3rd-degree burns of eyelid skin
  - Corneal edema and opacification
  - Corneal epithelial defects
  - Marked conjunctival chemosis and perilimbal blanching
  - Moderate anterior chamber reaction
  - Increased intraocular pressure
  - Local necrotic retinopathy

## *DIFFERENTIAL DIAGNOSIS*

- Thermal burns
- Ocular cicatricial pemphigoid
- Other causes of corneal opacification
- Ultraviolet radiation keratitis

## *DIAGNOSTIC TESTS & INTERPRETATION*

Not necessary unless suspicion of intraocular or orbital foreign body is present. In this case, CT should be used and MRI is contraindicated.

### *Diagnostic Procedures/Other*

- Measure pH of tear film with litmus paper or electronic probe:
  - Irrigating fluid with nonneutral pH (e.g., normal saline has pH of 4.5) may alter results.

- Careful slit-lamp exam, fundus ophthalmoscopy, tonometry, and measurement of visual acuity
- Full extent of damage from alkali burns may not be apparent until 48 to 72 hours after exposure.

## *Test Interpretation*

- Corneal epithelial defects or superficial punctate keratitis, edema, opacification
- Conjunctival chemosis, hyperemia, and hemorrhages
- Perilimbal ischemia
- Anterior chamber reaction
- Increased intraocular pressure

## **TREATMENT**

Copious irrigation and removal of corneal or conjunctival foreign bodies are always the initial treatment (1,2,3)[A]:

- Passively open patient's eyelid and have patient look in all directions while irrigating.
- Be sure to remove all reservoirs of chemical from the eyes.
- Continue irrigation until the tear film and superior/inferior cul-de-sac is of neutral pH ( $7 \pm 0.1$ ) and pH is stable (2)[C]:
  - Severe burns should be irrigated for at least 15 minutes to as much as 2 to 4 hours; this irrigation should not be interrupted during transportation to hospital (2)[C].
  - Irrigation via Morgan lens (polymethylmethacrylate scleral lens) is a good way to achieve continuous irrigation over a prolonged period of time.
  - It is impossible to overirrigate.
- Initial pH testing should be done on both eyes even if the patient claims to only have unilateral ocular pain/irritation so that a contralateral injury is not neglected.

P.727

- Use whatever nontoxic fluid is available for irrigation on scene. In hospital, sterile water, normal saline, normal saline with bicarbonate, balanced salt solution (BSS), or lactated Ringer solution may be used:
  - No therapeutic difference in effectiveness has been noted between types of solutions (1)[C].
- A topical anesthetic can be used to provide patient comfort (e.g., proparacaine, tetracaine).

- Sweep the conjunctival fornices every 12 to 24 hours to prevent adhesions (2)[C].
- Eye patching may relieve pain but has not been shown to improve outcomes (4)[C].

## MEDICATION

### First Line

- Further treatment (depending on severity and associated conditions)
  - Topical prophylactic antibiotics: any broad-spectrum agent (e.g., bacitracin-polymyxin B [Polysporin] ointment q2-4h, ciprofloxacin [Ciloxan] drops q2-4h, chloramphenicol [Chloroptic] ointment q2-4h) (1)[C]:
    - Some experts suggest that systemic tetracycline 250 mg PO q6h and especially derivatives such as doxycycline 100 mg PO BID may be beneficial to encourage healing of persistent corneal epithelial defects by inhibiting metalloproteinases (5)[C].
  - Tear substitutes: hydroxypropyl methylcellulose (HypoTears PF, Refresh Plus) drops q4h, carboxymethylcellulose (Refresh PM) ointment at bedtime (1)[C]:
    - Most beneficial in those with impaired tear production (elderly patients)
  - Cycloplegics for photophobia and/or uveitis: cyclopentolate 1% TID or scopolamine 1/4% BID (1)[C]
  - Antiglaucoma for elevated intraocular pressure: latanoprost (Xalatan) 0.005% q24h, timolol (Timoptic) 0.5% BID, *or* levobunolol (Betagan) 0.5% BID, *and/or* acetazolamide (Diamox) 125 to 250 mg PO q6h, *or* methazolamide (Neptazane) 25 to 50 mg PO BID, *and/or* IV mannitol 20% 1 to 2 g/kg as needed (1)[C]
  - Corticosteroids for intraocular inflammation: prednisolone (Pred-Forte) 1% or equivalent q1-4h for 7 to 10 days; if severe, prednisone 20 to 60 mg PO daily for 5 to 7 days. Taper rapidly if epithelium is intact by this time (1)[C]:
    - Use of corticosteroids >10 days may do harm by inhibiting repair and cause corneoscleral melt (1,6)[C].
  - Vitamin C (ascorbic acid) 500 mg PO QID and topical 10% ascorbate solution in artificial tears reduces the incidence of corneal thinning and ulceration (2)[C].
  - Acetylcysteine (Mucomyst) 10-20% topically q4h to promote wound healing (2)[C]
- Precautions
  - Timolol and levobunolol: history of heart failure (HF) or chronic obstructive pulmonary disease (COPD)

- Acetazolamide and methazolamide: history of nephrolithiasis or metabolic acidosis
- Mannitol: history of HF or renal failure
- Scopolamine: history of urinary retention
- Topical corticosteroids must be used with caution in the presence of damaged corneal epithelium because iatrogenic infection can occur. Daily follow-up or consultation with an ophthalmologist is recommended.

## ***SURGERY/OTHER PROCEDURES***

- Goal of subacute treatment is restoration of the normal ocular surface anatomy, control of glaucoma, and restoration of corneal clarity.
- Surgical options include the following:
  - Debridement of necrotic tissue (1)[C]
  - Conjunctival/tenon advancement (tenoplasty) to restore vascularity in severe burns (1)[C]
  - Tissue adhesive (e.g., isobutyl cyanoacrylate) for impending or actual corneal perforation of
    - Tectonic keratoplasty for acute perforation >1 mm (1)[C]
  - Limbal autograft transplantation for epithelial stem cell restoration (1)[C]
  - Amniotic membrane transplantation (6)[C] or umbilical cord serum drops (\*)[B] to promote epithelial regeneration (6)[C]
  - Conjunctival or mucosal membrane transplant to restore ocular surface in severe injury (1)[C]
  - Lamellar or penetrating keratoplasty for tectonic stabilization or visual rehabilitation (1)[C]

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Based on ophthalmologic consultation and concomitant burn injuries

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Depending on severity of ocular injury
  - From daily to weekly visits initially
- May be inpatient
- If on mannitol or prednisone, consider frequent serum electrolytes.

## *PATIENT EDUCATION*

- Safety glasses
- Need for immediate ocular irrigation with any available water following chemical exposure to the eyes

## *PROGNOSIS*

- Depends on severity of initial injury: Increased limbal involvement in clock hours and greater percentage of conjunctival involvement correlate with poorer prognosis (Dua classification system).
- For mildly injured eyes, complete recovery is the norm.
- For severely injured eyes, permanent loss of vision is not uncommon.

## **COMPLICATIONS**

- Orbital compartment syndrome
- Persistent epitheliopathy
- Fibrovascular pannus
- Corneal ulcer/perforation
- Corneal scarring
- Progressive symblepharon
- Neurotrophic keratitis
- Lid malposition secondary to cicatricial ectropion and entropion
- Glaucoma
- Cataract
- Hypotony
- Phthisis bulbi
- Blindness

Burns

## Codes

**&NA;**

### ICD10

- T26.50XA Corrosion of unsp eyelid and periocular area, init encntr
- T26.60XA Corrosion of cornea and conjunctival sac, unsp eye, init
- S05.00XA Inj conjunctiva and corneal abrasion w/o fb, unsp eye, init

## Clinical Pearls

**&NA;**

- Prompt irrigation of all chemical burns, even prior to arrival to the emergency department, is essential to ensure best outcomes. It is impossible to overirrigate.
- All patients with chemical injuries to their eyes should have urgent ophthalmology consultation and/or referral.

# Onychomycosis

Lauren M. Simon, MD, MPH, FAAFP, FACSM

## BASICS

### DESCRIPTION

- Fungal infection of fingernails/toenails
- Caused mostly by dermatophytes but also yeasts and nondermatophyte molds
- Toenails are more commonly affected than fingernails.
- System(s) affected: skin, exocrine
- Synonym(s): tinea unguium; ringworm of the nail

### EPIDEMIOLOGY

#### Prevalence

- Occurs in 2-10% of general population
- Predominant age: 20% in adults >60 years of age
- Rare before puberty
- Prevalence 15-40% in persons with human immunodeficiency infection (1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Dermatophytes: *Trichophyton* (*Trichophyton rubrum* most common), *Epidermophyton*, *Microsporum*
- Yeasts: *Candida albicans* (most common), *Candida parapsilosis*, *Candida tropicalis*, *Candida krusei*
- Molds: *Scopulariopsis brevicaulis*, *Hendersonula toruloidea*, *Aspergillus* sp., *Alternaria tenuis*, *Cephalosporium*, *Scytalidium hyalinum*
- Dermatophytes cause 90% of toenail and most of fingernail onychomycoses.
- Fingernail onychomycosis is more often caused by yeasts, especially *Candida*.
- Dermatophytes can invade normal keratin, whereas nondermatophyte molds invade altered

keratin (dystrophic/injured nails).

## **RISK FACTORS**

- Older age
- Tinea pedis
- Occlusive footwear
- Cancer/diabetes/psoriasis
- Peripheral vascular disease
- Cohabitation with others with onychomycosis
- Immunodeficiency
- Communal swimming pools
- Smoking
- Peripheral vascular disease
- History of nail trauma
- Autosomal dominant genetic predisposition

## **COMMONLY ASSOCIATED CONDITIONS**

- Immunodeficiency/chronic metabolic disease (e.g., diabetes)
- Tinea pedis/manuum

## **DIAGNOSIS**

### **PHYSICAL EXAM**

- Dermatophytes: commonly preceded by dermatophyte infection at another site; 80% involve toenails, especially hallux; simultaneous infection of fingernails and toenails is rare. Five clinical forms occur.
  - Distal/lateral subungual onychomycosis (most common): mainly due to *T. rubrum*. Spreads from distal/lateral margins to nail bed to nail plate; subungual hyperkeratosis; onycholysis; nail dystrophy; discolorationÑyellow-white or brownblack, yellow streaking laterally; can progress proximally, *bois vermoulu* (Öworm-eaten woodÓ); onychomadesis
  - Proximal subungual onychomycosis (rare <1% of cases): hands/feet; leukonychiaÑbegins at proximal part of nail plate, appearing to occur from the proximal underside of the nail (or

direct invasion of the nail plate from above); spreads to nail plate and lunula; seen with immunosuppressive conditions

- Superficial (formerly known as superficial white onychomycosis) about 10% of cases: hallux is preferentially affected; infection of outer surface of nail plate; opaque white spots on nail plate eventually merge to involve entire surface of the nail. Most commonly due to *Trichophyton mentagrophytes*
  - Endonyx onychomycosis involves interior of nail plate, sparing nail bed. Nail develops milky white appearance with indentations. Subungual hyperkeratosis is absent.
  - Totally dystrophic onychomycosis causes complete destruction of nail plate by fungus, resulting in thickened and ridged nail bed covered with keratotic debris.
- Candidal
    - Hands, 70%, especially for the dominant hand
    - Middle finger is most common.
    - Pain is mild, unless secondarily infected.
    - Increases on prolonged contact with water
    - Primarily affects tissue surrounding nail
    - Begins with cuticle detachment
    - White or white-yellow nail discoloration
    - Secondary ungual changes: convex, irregular, striated nail plate with dull, rough surface
    - Onycholysis, especially on hands
    - Distal subungual onychomycosis may occur.
    - Primary involvement of the nail plate is uncommon (thin, crumbly, opaque, brownish nail plate deformed by transverse grooves).
    - Periungual edema/erythema may occur (clubshaped, bulbous fingertips).
  - Molds (nondermatophyte)
    - More common in those >60 years of age
    - More common in nails of hallux
    - Resembles distal and lateral onychomycosis

## *Pediatric Considerations*

- Candidal infection presents more commonly as superficial onychomycosis.

- The U.S. Food and Drug Administration (FDA) has not approved any systemic antifungal agents for treatment of onychomycosis in children. Efficacy and safety profiles in children for some systemic antifungals are similar to those previously reported in adults (2).

## ***DIFFERENTIAL DIAGNOSIS***

- Psoriasis (most common alternate diagnosis)
- Traumatic dystrophy
- Lichen planus
- Onychogryphosis (Oram's horn nails)
- Eczematous conditions
- Hypothyroidism
- Drugs and chemicals
- Yellow nail syndrome
- Neoplasms (0.7-3.5%) of all melanoma cases are subungual. In a brownish yellow nail, if dark pigment extends into periungual skin fold, consider subungual melanoma.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Accurate diagnosis requires both laboratory and clinical evidence.
- About 50% of nail dystrophy seen on visual inspection is not fungal in origin, so laboratory assessment improves diagnostic accuracy.
- If onychomycosis is suspected clinically and initial diagnostic laboratory tests are negative, the tests should be repeated.
- A nail plate biopsy or partial/full removal of nail with culture is needed to diagnose proximal subungual onychomycosis.

### ***Initial Tests (lab, imaging)***

- Direct microscopy with potassium hydroxide (KOH) preparation (1)[C]
  - Clean nail with 70% isopropyl alcohol.
  - Using sterile clippers, remove diseased, discolored nail plate.
  - Collect debris from stratum corneum of most proximal area (beneath nail or crumbling nail itself) with 1-mm curette/scalpel.
  - Place sample on microscope slide with drop of 5-10% KOH. View after 5 minutes.

- Gentle heat applied to slide can enhance keratin breakdown.
  - High sensitivity if >2 preparations were examined
  - Look for hyphae, pseudohyphae, or spores.
- Cultures: False-negative finding in 30% (secondary to loss of dermatophyte viability; improved by immediate culture on Sabouraud cell culture medium); results may take 3 to 6 weeks.
  - In office dermatophyte test, medium culture indicates dermatophyte growth with yellow-to-red color change of the medium; results in 3 to 7 days; limited studies.
  - Histologic examination of nail clippings/nail plate punch biopsy: proximal lesions; stain both with periodic acid-Schiff (PAS) stain (1)[C].
  - KOH-treated nail clipping stained with PAS: significantly higher rates of detection of onychomycosis as compared with standard methods of KOH preparation and fungal culture (3) [C]
  - Polymerase chain reaction (PCR) increases sensitivity of detection of dermatophytes in nail specimen, results available within 3 days can be used as complementary to direct microscope exam and fungal culture; not widely available.
  - Fluorescence microscopy can be used as a rapid screening tool for identification of fungi in nail specimens.
  - Commercial laboratories may use KOH with calcofluor white stain to improve view of fungal elements in fluorescent microscopy.
  - Discontinue all topical medication for at least 1 week before obtaining a sample.

## *Test Interpretation*

Pathogens within the nail keratin

## **TREATMENT**

### **GENERAL MEASURES**

- Avoid factors that promote fungal growth (i.e., heat, moisture, occlusion, tight-fitting shoes).
- Treat underlying disease risk factors.
- Treat secondary infections.

### **MEDICATION**

## Pregnancy Considerations

Oral antifungals and ciclopirox are pregnancy Category B (terbinafine, ciclopirox) or C (itraconazole, fluconazole, and griseofulvin). Griseofulvin is not advised in pregnancy due to risks of teratogenicity and conjoined twins. Ideally postpone treatment of onychomycosis until after pregnancy.

P.729

### First Line

- Oral antifungals are preferred due to higher rates of cure but have systemic adverse effects and many drug-drug interactions.
- Terbinafine: 250 mg/day PO for 6 weeks for fingernails and 12 weeks for toenails; most effective in cure and prevention of relapse compared with other antifungals and with itraconazole pulse in metaanalysis for toenail onychomycosis I (4)[A]
- Itraconazole pulse: 200 mg PO BID for 1 week, then 3 weeks off, repeat for two cycles for fingernails and three to four cycles for toenails; does not need to monitor liver function tests (LFTs) with pulse dosing
- Itraconazole continuous: 200 mg/day PO for 6 weeks for fingernails and 12 weeks for toenails (less effective than itraconazole pulse for dermatophytes, more effective than terbinafine for *Candida* and molds)

### Second Line

- Fluconazole pulse: 150 to 300 mg PO weekly for 6 months (lower cure rate); not FDA-approved for onychomycosis
- Griseofulvin: 500 to 1,000 mg/day PO for up to 18 months (lower cure rate, continue until the diseased nail is replaced)
- Posaconazole: 100, 200, or 400 mg once daily for 24 weeks; 400 mg once daily for 12 weeks; higher cost
- Topical agents: Use limited to disease not involving the lunula (proximal nail plate). Topical therapy does not cause systemic toxicity but is less effective than oral therapy. Head-to-head comparison of efficacy of available agents is generally not available.
- Ciclopirox: 8% nail lacquer (available generically): Apply once daily to affected nails (if without lunula involvement) for up to 48 weeks; remove lacquer with alcohol every 7 days, then file away loose nail material and trim nails (low-cure rate, avoids systemic adverse effects, less cost-effective). Application after PO treatment may reduce recurrences. Systematic review >60% failure rate after 48 weeks of use (5)[A],(6)
- Tavaborole 5% solution, a topical oxaborole antifungal is indicated for onychomycosis of the

toenails due to *Trichophyton rubrum* or *Trichophyton mentagrophytes*. Complete or almost-complete cure 15-18% after 48 weeks (NNT compared to vehicle approx 7)

- Efficacy of efinaconazole solution 10% (7). Complete or almost-complete cure after 48 weeks in range of 15-18% (NNT compared to vehicle 7 to 10)
- Contraindications for oral antifungals
  - Hepatic disease
  - Pregnancy (see Pregnancy Considerations)
  - Current/history of congestive heart failure (CHF) (itraconazole)
  - Ventricular dysfunction (itraconazole)
  - Porphyria (griseofulvin)
- Precautions/adverse effects
  - Oral antifungals
    - Hepatotoxicity/neutropenia
    - Hypersensitivity
    - Photosensitivity, lupus-like symptoms, proteinuria (griseofulvin)
    - Chronic kidney disease (avoid terbinafine for patients with creatine clearance [CrCl] <50 mL/min, decrease fluconazole dose)
    - CHF, peripheral edema, pulmonary edema (itraconazole)
    - Rhinitis (itraconazole)
- Ciclopirox: rash, nail disorders; avoid contact with skin except along nail edge; caution with broken skin or vascular compromise
- Oral agents: numerous significant drug-drug interactions. Need to check each medication:
  - Terbinafine (inhibits cytochrome P450 2D6 isozyme [CYP2D6]): for example, *β*-blockers, monoamine oxidase inhibitors (MAOIs), SSRIs, tricyclic antidepressants (TCAs), warfarin, oxycodone
  - Itraconazole, fluconazole (inhibit CYP3A4): for example, antiarrhythmics, benzodiazepines, ergot alkaloids, 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitors, calcium channel blockers, corticosteroids, hydrochlorothiazide, hypoglycemics, oral contraceptives (OCPs), warfarin, zolpidem
  - Griseofulvin: for example, OCPs, salicylates, warfarin

## ***SURGERY/OTHER PROCEDURES***

- Nail debridement to remove infected keratin (efficacy not well studied): Use for few nails involved or if not, for candidate of systemic therapy.
  - Mechanical: Soften with occlusive dressing with 40% urea gel; detach from nail bed with tweezers, file with abrasive stone or curette.
  - Chemical: Protect peripheral tissue with adhesive strips; apply ointment of 30% salicylic acid, 40% urea, or 50% potassium iodide under occlusive dressing.
  - Debridement may be combined with topical antifungal therapy.
  - Surgical avulsion if few nails are involved; for pain control.
- Laser treatment has shown some positive results but limited efficacy data (7).
- Photodynamic therapy using topical photosensitizing agents and irradiation with appropriate light source some success for treatment of superficial nail infections; limited data.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- *Melaleuca alternifolia* (tea tree oil) Cochrane review found no evidence of benefit (5).
- Vicks VapoRub application to nails daily for 48 weeks has been found safe, but efficacy is uncertain.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Formation of a new fingernail takes 4 to 6 months, and a new toenail takes 12 to 18 months.
- Cure defined as:
  - Clinical cure, 100% absence of clinical signs, and/or
  - Mycotic cure, negative mycology with <sup>3</sup>1 of the following clinical signs:
    - Distal subungual hyperkeratosis/onycholysis leaving <10% of the nail plate affected
    - Nail plate thickening that does not improve with treatment because of comorbid condition

### ***Patient Monitoring***

- Topical agents: Slow response is expected; visits every 6 to 12 weeks.
- Terbinafine, griseofulvin: baseline, and as needed, LFTs and CBC

- Itraconazole continuous: baseline, and as needed, LFTs

## **PATIENT EDUCATION**

- Advise patient to:
  - Keep affected area clean and dry.
  - Avoid rubber/other occlusive, tight-fitting footwear.
  - Wear absorbent cotton socks.
  - Launder clothing and towels frequently in hot water.
  - Avoid sharing nail implements or use on both normal and abnormal nails.
- Cure of all toenails may not be attainable.
- Nails may not appear normal after cure.

## **PROGNOSIS**

- Complete clinical cure in 25-50% (higher mycologic cure rates) with oral therapy
- Recurrence is 10-50% (relapse/reinfection).
- Poor prognostic factors
  - Areas of nail involvement >50%
  - Significant proximal/lateral disease
  - Subungual hyperkeratosis >2 mm
  - White/yellow or orange/brown streaks in the nail (includes dermatophytoma)
  - Total dystrophic onychomycosis (with matrix involvement)
  - Nonresponsive organisms (e.g., *Scytalidium* mold)
  - Patients with immunosuppression
  - Diminished peripheral circulation

## **COMPLICATIONS**

- Secondary infections with progression to soft tissue infection/osteomyelitis
- Toenail discomfort/pain that can limit physical mobility or activity
- Anxiety, negative self-image

## Codes

&NA;

## ICD10

- B35.1 Tinea unguium
- B37.2 Candidiasis of skin and nail

## Clinical Pearls

&NA;

- Psoriasis and chronic nail trauma are commonly mistaken for fungal infection.
- Diagnosis should be based on both clinical and mycologic laboratory evidence.

# Optic Neuritis

Olga M. Cer—n, MD

Pablo I. Hernandez Itriago, MD, MS, FAAFP

## BASICS

### DESCRIPTION

- Inflammation of the optic nerve (cranial nerve II)
- Most common form is acute demyelinating optic neuritis (ON), but other causes include infectious disease and systemic autoimmune disorders.
- Optic disc may be normal in appearance at onset (retrobulbar ON, 67%) or swollen (papillitis, 33%).
- Key features:
  - Abrupt visual loss (typically monocular)
  - Periorbital pain with eye movement (90%)
  - Pain in the distribution of the first division of the trigeminal nerve
  - Dyschromatopsia: color vision deficits
  - Relative afferent pupillary defect (RAPD)
- Usually unilateral in adults; bilateral disease is more common in children.
- Presenting complaint in 25% of patients with multiple sclerosis (MS)
- In children, headaches are common.
- System(s) affected: nervous
- Synonym(s): papillitis; demyelinating optic neuropathy; retrobulbar ON

### EPIDEMIOLOGY

#### Incidence

- 1 to 5/100,000 cases per year
- More common in northern latitudes

- More common in whites than in other races
- Predominant age: 18 to 45 years; mean age 30 years
- Predominant sex: female > male (3:1)

## ETIOLOGY AND PATHOPHYSIOLOGY

- In both MS-associated and isolated monosymptomatic ON, the cause is presumed to be a demyelinating autoimmune reaction.
- Possible mechanisms of inflammation in immunemediated ON are the cross-reaction of viral epitopes and host epitopes and the persistence of a virus in CNS glial cells.
- Neuromyelitis optica (NMO) IgG autoantibody, which targets the water channel aquaporin-4
- Primarily idiopathic
- MS
- Viral infections: measles, mumps, varicella-zoster, coxsackievirus, adenovirus, hepatitis A and B, HIV, herpes simplex virus, cytomegalovirus
- Nonviral infections: syphilis, tuberculosis, meningococcus, cryptococcosis, cysticercosis, bacterial sinusitis, streptococcus B, *Bartonella*, typhoid fever, Lyme disease, fungus
- Systemic inflammatory disease: sarcoidosis, systemic lupus erythematosus, vasculitis
- Local inflammatory disease: intraocular or contiguous with the orbit, sinus, or meninges
- Toxic: lead, methanol, arsenic, radiation
- Vascular lesions affecting the optic nerve
- Posterior uveitis (i.e., birdshot retinochoroidopathy, toxoplasmosis, toxocariasis)
- Tumors
- Medications: ethambutol, chloroquine, isoniazid, chronic high-dose chloramphenicol, tumor necrosis factor *&agr;*-antagonist, infliximab (Remicade), adalimumab (Humira), etanercept (Enbrel)

## COMMONLY ASSOCIATED CONDITIONS

- MS (common): ON is associated with an increased risk of MS.
- Other demyelinating diseases: Guillain-Barré syndrome, Devic NMO, multifocal demyelinating neuropathy, acute disseminated encephalomyelitis

# DIAGNOSIS

## HISTORY

- Decreased visual acuity, deteriorating in hours to days, usually reaching lowest level after 1 week
- Usually unilateral but can also be bilateral
- Brow ache, globe tenderness, deep orbital pain exacerbated by eye movement (92%)
- Retro-orbital pain may precede visual loss.
- Desaturation of color vision (dull or faded colors), especially red tones
- Apparent dimness of light intensities
- Impairment of depth perception (80%); worse with moving objects (Pulfrich phenomenon)
- Transient increase in visual symptoms with increased body temperature and exercise (Uhthoff phenomenon)
- May present with a recent flulike viral syndrome
- Detailed history and review of systems, looking for a history of demyelinating, infectious, or systemic inflammatory disease

## PHYSICAL EXAM

Complete general exam, full neurologic exam, and ophthalmologic exam looking for the following:

- Decreased visual acuity and color perception
- Central, cecocentral, arcuate, or altitudinal visual field deficits
- Papillitis: swollen disc  $\pm$  peripapillary flame-shape hemorrhage or often normal disc exam
- Temporal disc pallor seen later at 4 to 6 weeks (1)[A]
- RAPD (Marcus-Gunn pupil): The pupil of the affected eye dilates with a swinging light test unless disease is bilateral.

## DIFFERENTIAL DIAGNOSIS

- Demyelinating disease, especially MS
- Infectious/systemic inflammatory disease
- Neuroretinitis: virus, toxoplasmosis, *Bartonella*
- Toxic or nutritional optic neuropathy

- Acute papilledema (bilateral disc edema)
- Compression:
  - Orbital tumor/abscess compressing the optic nerve
  - Intracranial tumor/abscess compressing the afferent visual pathway
  - Orbital pseudotumor
  - Carotid-ophthalmic artery aneurysm
- Temporal arteritis or other vasculitides
- Trauma or radiation
- NMO (Devic disease)
- Anterior ischemic optic neuropathy
- Leber hereditary optic neuropathy
- Kjer-type autosomal dominant optic atrophy
- Severe systemic hypertension
- Diabetic papillopathy

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- In typical presentations, ESR is standard, but other labs are unnecessary. Antinuclear antibodies (ANAs), angiotensin-converting enzyme level, fluorescent treponemal antibody absorption (FTA-ABS), and chest radiograph have been shown to have no value in typical cases (1)[A].
- In atypical presentations, including absence of pain, a very swollen optic nerve, >30 days without recovery or retinal exudates, labs may be indicated to rule out underlying disorders:
  - CBC
  - ANA test
  - Rapid plasma reagin test
  - FTA-ABS test
- MRI of brain and orbits: thin cuts (2 to 3 mm) gadolinium-enhanced and fat-suppression images to look for Dawson fingers of MS (periventricular white matter lesions oriented perpendicular to the ventricles) and also to look for enhancement of the optic nerve

- CT scan of chest to rule out sarcoidosis if clinical suspicion is high.
- Ocular coherence tomography (OCT) of the retinal nerve fiber layer (RNFL); a noninvasive imaging technique of the optic nerve. May serve as a diagnostic tool to quantify thickness of the nerve fiber layer objectively and, thus, monitor structural change (axonal loss) of the optic nerve in the course of the disease.

### *Follow-Up Tests & Special Considerations*

- Visual field test (Humphrey 30-2) to evaluate for visual field loss: diffuse and central visual loss more predominant in the affected eye at baseline (2)[A]
- Low-contrast visual acuity (as a measure of disease progression)
- A novel blood test called *NMO-IgG* checks for antibodies for NMO.

### *Diagnostic Procedures/Other*

- In atypical cases, including bilateral deficits, young age, or suspicion of infectious etiology, lumbar puncture (LP) with neurology consultation is indicated.
- LP for suspected MS is a physician-dependent decision. Some studies indicate that it may not add value to MRI for MS detection (1)[A] but no consensus on the subject exists.

P.731

## **TREATMENT**

Most persons with ON recover spontaneously.

## **MEDICATION**

### *First Line*

- IV methylprednisolone has been shown to speed up the rate of visual recovery but without significant long-term benefit; consider for patients who require fast recovery (i.e., monocular patients or those whose occupation requires high-level visual acuity). For significant vision loss, parenteral corticosteroids may be considered on an individualized basis: Optic Neuritis Treatment Trial (ONTT):
  - Observation and corticosteroid treatment are both acceptable courses of action.
  - High-dose IV methylprednisolone (250 mg q6h for 3 days) followed by oral corticosteroids (1 mg/kg/day PO for 11 days, taper over 1 to 2 weeks) (3)[A]
- Others use IV Solu-Medrol infusion (1 g in 250 mL D<sub>5</sub> 1/2 normal saline infused over 1 hour

daily for 3 to 5 days):

- No evidence of long-term benefit (1)[A],(4)[B]
  - May decrease recovery time (3)[A],(4)[B]
  - May decrease risk of MS at 2 years but not 5 years (3)[A]
- Give antiulcer medications with steroids.

## Second Line

- Disease-modifying agents, such as interferon- $\beta$ 1a (IFN- $\beta$ 1a; Avonex, Rebif) and IFN- $\beta$ 1b (Betaseron), are used to prevent or delay the development of MS in people with ON who have  $\geq 2$  brain lesions evident on MRI.
  - These medications have been proposed for use in patients with one episode of ON (clinically isolated syndrome) at high risk of developing MS (1+ lesion on brain MRI).
- The Controlled High Risk Avonex Multiple Sclerosis (CHAMPS) trial study has shown that IFN- $\beta$ 1a reduces the conversion to clinically definite MS in high-risk patients by  $\approx 50\%$  (5) [A].
- Decisions should be made individually with neurology consultation.

### **ALERT**

Never use oral prednisone alone as the primary treatment because this may increase the risk for recurrent ON (3)[A].

## Pediatric Considerations

- No systematic study defining high-dose corticosteroids in children with ON have been conducted.
  - Consensus recommends: 3 to 5 days of IV methylprednisolone (4 to 30 mg/kg per day), followed by a 2 to 4 week taper of oral steroids (6)[C]
- Optic disc swelling and bilateral disease are more common in children as is severe loss of visual acuity (20/200 or worse).
- Consider infectious and postinfectious causes of optic nerve impairment.

## ISSUES FOR REFERRAL

Referral to a neurologist and/or ophthalmologist

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Monthly follow-up to monitor visual changes and steroid side effects

### *PATIENT EDUCATION*

- Provide reassurance about recovery of vision.
- If the disease is believed to be secondary to demyelinating disease, patient should be informed of the risk of developing MS.
- For patient education materials favorably reviewed on this topic, contact:
  - National Eye Institute, Information Officer, Department of Health and Human Services, 9000 Rockville Pike, Bethesda, MD 20892, 301-496-5248
  - North American Neuro-Ophthalmology Society (NANOS), 5841 Cedar Lake Road, Suite 204, Minneapolis, MN 55416, 952-646-2037, fax: 952-545-6073, <http://www.nanosweb.org/i4a/pages/index.cfm?pageid=3280>

### *PROGNOSIS*

- Orbital pain usually resolves within 1 week.
- Visual acuity
  - Rapid spontaneous improvement at 2 to 3 weeks and continues for several months (may be faster with IV corticosteroids)
  - Often returns to normal or near-normal levels (20/40 or better) within 1 year (90-95%), even after near blindness
- Other visual disturbances (e.g., contrast sensitivity, stereopsis) often persist after acuity returns to normal.
- Recurrence risk of 35% within 10 years: 14% affected eye, 12% contralateral, 9% bilateral; recurrence is higher in MS patients (48%).
- ON is associated with an increased risk of developing MS; 35% risk at 7 years, 58% at 15 years (7)[A]:
  - Brain MRI helps to predict risk:

- 0 lesions: 16%
- 1 to 2 lesions: 37%
- 3+ lesions: 51%
- Poor prognostic factors:
  - Absence of pain
  - Low initial visual acuity
  - Involvement of intracanalicular optic nerve
- Children with bilateral visual loss have a better prognosis than adults.

## COMPLICATIONS

Permanent loss of vision

Multiple Sclerosis

## Codes

&NA;

### ICD10

- H46.9 Unspecified optic neuritis
- H46.00 Optic papillitis, unspecified eye
- H46.10 Retrobulbar neuritis, unspecified eye

## Clinical Pearls

&NA;

- MRI is the procedure of choice for determining relative risk and possible therapy for MS prevention.
- The ONTT showed that high-dose IV methylprednisolone followed by oral prednisone accelerated visual recovery but did not improve the 6-month or 1-year visual outcome compared with placebo, whereas treatment with oral prednisone alone did not improve the outcome and was associated with an increased rate of recurrence of ON (1,2,8)[A], (9)[B],(10)

[C].

# Osgood-Schlatter Disease (Tibial Apophysitis)

David P. Sealy, MD

Robert J. Tiller, MD, FAAFP

## BASICS

### DESCRIPTION

- Osgood-Schlatter Disease (OSD) is a syndrome associated with traction apophysitis and patellar tendinosis that is most common in adolescent boys and girls.
  - Patients present with pain and swelling of the anterior tibial tubercle
- System(s) affected: musculoskeletal
- Synonym: Tibial tubercle apophysitis

### EPIDEMIOLOGY

#### *Incidence*

Incidence in girls increasing with increased participation in organized youth sports; still more common in boys

#### *Prevalence*

- A common apophysitis in childhood and adolescence affecting athletes (21%) and nonathletes (4.5%) (1)[B]
- Approximately 10% remain symptomatic as adults (2)[C].
- 10% of all adolescent knee pain is due to OSD.

### ETIOLOGY AND PATHOPHYSIOLOGY

Traction apophysitis of the tibial tubercle due to repetitive strain on the secondary ossification center of the tibial tuberosity, concurrent patellar tendinosis, and disruption of the proximal tibial apophysis

- Basic etiology unknown, exacerbated by exercise
  - Jumping and pivoting sports place highest strain on the tibial tubercle. Repetitive trauma is

the most likely inciting factor.

- Possible association with tight hip flexors and tight quadriceps; increased quadriceps strength in adolescence relative to hamstring strength
- Early sports specialization increases the risk for OSD 4-fold (3)[B].

## **RISK FACTORS**

- Affects children and adolescents most commonly from the ages of 8 to 18 years
  - Girls 8 to 14 years
  - Boys 10 to 18 years
- OSD is slightly more common in boys.
- Rapid skeletal growth
- Participation in repetitive-jumping sports and sports with heavy quadriceps activity (football, volleyball, basketball, hockey, soccer, skating, gymnastics)
- Ballet (2-fold risk compared with nonathletes)
- Potential increased risk of OSD in adolescents with ADD/ADHD (4)[C]

## **GENERAL PREVENTION**

- Avoid sports with heavy quadriceps loading (especially deceleration activitiesÑeccentric loading).
- Patients may compete if pain is minimal.
- Increase hamstring and quadriceps flexibility.

## **COMMONLY ASSOCIATED CONDITIONS**

- Shortened (tight) rectus femoris found in 75% with OSD
- Possible association with ADD/ADHD; adolescents with ADD/ADHD are at risk for other musculoskeletal injuries.
- Sinding-Larsen-Johansson apophysitis

## **DIAGNOSIS**

### **HISTORY**

- Unilateral or bilateral (30%) pain of the tibial tuberosity

- Pain exacerbated by exercise, especially jumping and landing after jumping
- Pain upon kneeling on the affected side(s)
- Antalgic or straight-legged gait

## *PHYSICAL EXAM*

- Knee pain with squatting or crouching
- Absence of effusion or condyle tenderness
- Tibial tuberosity swelling and tenderness
- Pain increased with resisted knee extension or kneeling
- Erythema over tibial tuberosity
- Functional testing: Single-leg squat (SLS) and standing broad jump reproduce pain (3)[C].

## *DIFFERENTIAL DIAGNOSIS*

- Stress fracture of the proximal tibia
- Pes anserinus bursitis
- Quadriceps tendon avulsion
- Patellofemoral stress syndrome
- Chondromalacia patellae (retropatellar pain)
- Proximal tibial neoplasm
- Osteomyelitis of the proximal tibia
- Tibial plateau fracture
- Sinding-Larsen-Johansson syndrome (patellar apophysitis)Ñpain over inferior patellar tendon
- Patellar fracture
- Infrapatellar bursitis
- Patellar tendinitisÑpain over inferior patellar tendon and inferior pole of patella

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Generally a clinical diagnosis. No tests are indicated unless other diagnoses are under consideration.

- Radiographic imaging of the proximal tibia and knee may show heterotopic calcification in the patellar tendon:
  - X-rays are rarely diagnostic, but appearance of a separate fragment at the tibial tuberosity identifies candidates for potential surgical intervention.
  - Calcified thickening of the tibial tuberosity with irregular ossification at tendon insertion on the tibial tubercle (5)[B]

## *Diagnostic Procedures/Other*

- Bone scan may show increased uptake in the area of the tibial tuberosity:
  - Increased uptake in apophysis is normal in children, but with OSD, there *may be more uptake on the opposite side*.
- Ultrasound is an excellent alternative, showing thickening of the distal patellar tendon and infrapatellar bursa effusion.
- MRI shows fragmentation of the tibial tubercle and bone edema.

## *Test Interpretation*

Biopsy is not necessary but would show osteolysis and fragmentation of the tibial tubercle.

## **TREATMENT**

### **GENERAL MEASURES**

- Frequent ice applications 2 to 3 times per day for 15 to 20 minutes
- Rest and activity modification—avoid activities that increase pain and/or swelling.
- Physical therapy helps with hamstring and quadriceps strengthening and stretching.
- Open- and closed-chain eccentric quadriceps strengthening
- Avoid aggressive stretching if pain is significant to avoid risk of tibial tubercle avulsion (1)[B].
- Consult orthopedic surgery for tibial tuberosity fracture or complete avulsion.
- Electrical stimulation and iontophoresis may be beneficial (1)[B].
- Patients with marked pronation may benefit from orthotics.
- A single study showed benefit from an infrapatellar strap and many experts recommend the use of a knee brace with an H- or U-shaped buttress (1)[C].

## MEDICATION

### *First Line*

- Any analgesic may be considered.
- NSAIDs may help control pain.
- Opioids are not recommended as first line.

### *Second Line*

- More potent analgesics, such as opioids, may be considered for short-term use in extreme situations.
- Corticosteroid injections are not recommended.
- Hypertonic glucose and/or Xylocaine injections have shown recent benefit (6)[C].

## ISSUES FOR REFERRAL

When conservative therapy is unsuccessful, consider surgical referral.

## SURGERY/OTHER PROCEDURES

- Debridement of a thickened, cosmetically unsatisfactory tibial tubercle (rare) or removal of mobile heterotopic bone
- Surgical excision of a painful tibial tubercle is rarely needed (<5%) and may be successfully done with arthroscopy instead of an open procedure (5)[C].
- Recent report of successful pain elimination in OSD with percutaneous screw fixation of the tibial tuberosity (2)[C]
- 75% return to normal sport activity and 89% are not restricted from competition due to recurrent pain.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Athletes may return to play if pain is controlled.
- Presence of pain does not preclude competition.

## Patient Monitoring

With worsening of symptoms only

## PATIENT EDUCATION

- Avoid jumping sports or reduce activities that increase pain and swelling.
- Assure family that symptoms and findings will diminish with time and rest.
- Patients can safely play sports with mild pain.
- Quadriceps stretching and strengthening are important.

## PROGNOSIS

- Except in rare cases, this is a self-limiting illness that resolves within 2 years of full skeletal maturation.
- 10% of patients with OSD as adolescents will have symptoms in adulthood. Up to 60% of adults with prior OSD report occasional symptoms and pain with kneeling.
- Most patients with OSD have residual ÒknotsÓ of tibial tubercles that never completely resolve.

## COMPLICATIONS

- Rarely, a heavily fragmented and inflamed tibial ossicle will avulse and require surgery.
- Rare complications in adulthood include pseudoarthrosis of the tibial tubercle, genu recurvatum, patella alta, and ossicle fragmentation possibly leading to osteoarthritis of the knee.

## Codes

&NA;

### ICD10

- M92.50 Juvenile osteochondrosis of tibia and fibula, unsp leg
- M92.51 Juvenile osteochondrosis of tibia and fibula, right leg
- M92.52 Juvenile osteochondrosis of tibia and fibula, left leg

## Clinical Pearls

## **&NA;**

- Infrapatellar pain in an adolescent athlete undergoing a rapid growth spurt is OSD, patellar tendinosis, or Sinding-Larsen-Johansson syndrome.
- Always consider lumbar disc disease, osteogenic sarcoma, or hip pathology in the differential diagnosis of OSD.
- OSD is generally self-limited. Athletes should modify activity based on pain. Mild pain is not a contraindication to athletic participation.
- Treatment focuses on strengthening and stretching of the hamstrings and quadriceps.
- 10% of adolescents with OSD will be symptomatic as adults.

# Osteoarthritis

Patrick Wakefield Joyner, MD, MS, LCDR

## BASICS

### DESCRIPTION

- Progressive loss of articular cartilage with reactive changes at joint margins and in subchondral bone
- Primary
  - Idiopathic: categorized by clinical features (localized, generalized, erosive)
- Secondary
  - Posttraumatic
  - Childhood anatomic abnormalities (e.g., congenital hip dysplasia, slipped capital femoral epiphysis [SCFE], Legg-Calv $\check{z}$ -Perthes disease)
  - Inheritable metabolic disorders (e.g., Wilson disease, alkaptonuria, hemochromatosis)
  - Neuropathic arthropathy (Charcot joints)
  - Hemophilic arthropathy
  - Endocrinopathies: acromegalic arthropathy, hyperparathyroidism, hypothyroidism
  - Paget disease
  - Noninfectious inflammatory arthritis (e.g., rheumatoid arthritis [RA], spondyloarthropathies)
  - Gout, calcium pyrophosphate deposition disease (pseudogout)
  - Septic or tuberculous arthritis
- System(s) affected: musculoskeletal
- Synonym(s): osteoarthrosis; degenerative joint disease (DJD)

### EPIDEMIOLOGY

- Symptomatic osteoarthritis (OA) is most common in patients >40 years of age.
- Leading cause of disability in patients >65 years old

- Radiographic evidence of OA: 33-90% in those >65 years old
- Predominant sex: male = female
- 90% of hip OA is primary. Hip OA is more common in whites.

## *Prevalence*

- ÷60 million patients
- Increases with age; radiographic evidence of OA is nearly universally present in patients >65 years old.
- Moderate to severe hip OA in 3-6% of whites; <1% in East Indians, blacks, Chinese, and Native Americans

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Failure of chondrocytes to maintain the balance between degradation and synthesis of extracellular collagen matrix. Collagen loss results in alteration of proteoglycan matrix and increased susceptibility to degenerative change.
- Biomechanical, biochemical, inflammatory, and immunologic factors contribute to cartilage loss. Attempts at repair most commonly manifest as osteophyte formation.

## *Genetics*

- Up to 65% of OA may have a genetic link.
- The heritability of end-stage hip OA has been estimated to be as high as 27%.
- Twin studies in women show 50% (hip; knee) to 65% (hip) heritability rates of OA.

## *RISK FACTORS*

- Increasing age: >50 years
- The effect of age as a risk factor is greatest for hip and knee OA, especially after 70 years of age.
- Hand OA is most common in postmenopausal women.
- Obesity (weight-bearing joints)
- Prolonged occupational or sports stress
- Injury to a joint from trauma, infection, or preexisting inflammatory arthritis
- Female gender (knee and hand)

# DIAGNOSIS

## HISTORY

- Distinguish OA from other types of arthritis by:
  - Absence of systemic findings
  - Minimal articular inflammation
  - Distribution of involved joints (e.g., distal and proximal interphalangeal joints)
- OA characterized by slowly developing joint pain. Pain often described as aching or burning in nature. Anecdotally, many patients describe pain changes with alterations in weather conditions.
- Transient stiffness (especially after awakening in morning and after sitting) that tends to lessen 10 to 15 minutes after joint movement.
- OA is more commonly affects hands, spine, and large weight-bearing joints (hip, knee).

## PHYSICAL EXAM

- Joint bony enlargement (Heberden nodes of distal interphalangeal joints; Bouchard nodes of proximal interphalangeal joints)
- Decreased range of motion of affected joints
- Tenderness usually absent; may occur along joint margin if synovitis is persistent
- Crepitation is a late sign.
- Weakness and wasting of muscles around the joint
- Local pain and stiffness with OA of spine. Radicular pain (if compression of nerve roots)
- Changes in joint alignment (genu varum [bow-legs] and genu valgum [knock-knees])

## DIFFERENTIAL DIAGNOSIS

- Crystalline arthropathies (gout; pseudogout): inflammatory arthritides (RA); spondyloarthropathies (reactive arthritis; psoriatic arthritis); septic arthritis
- Fibromyalgia; avascular necrosis; Lyme disease

## DIAGNOSTIC TESTS & INTERPRETATION

## *Initial Tests (lab, imaging)*

- Routine chemistries are not helpful in diagnosis.
- X-rays are usually normal early in disease process.
- As OA progresses, plain films show:
  - Narrowed, asymmetric joint space
  - Osteophyte formation
  - Subchondral bony sclerosis
  - Subchondral cyst formation
- Erosions may occur on surface of distal and proximal interphalangeal joints (erosive OA).

## **Follow-Up Tests & Special Considerations**

- May be useful in monitoring treatment with NSAIDs (renal insufficiency and GI bleeding)
- In secondary OA, underlying disorder may have abnormal lab results (e.g., hemochromatosis [abnormal iron studies]).

## *Diagnostic Procedures/Other*

### Joint aspiration

- May help to distinguish OA from chronic inflammatory arthritis
- OA: cell count usually  $<500$  cells/mm<sup>3</sup>, predominantly mononuclear
- Inflammatory: cell count usually  $>2,000$  cells/mm<sup>3</sup>, predominantly neutrophils
- Birefringent crystals in gout (-) and pseudogout (+)

## *Test Interpretation*

- Macroscopic patchy cartilage damage and bony hypertrophy
- Histologic phases:
  - Extracellular matrix edema and cartilage microfissures
  - Subchondral fissuring and pitting
  - Erosion and formation of osteocartilaginous loose bodies
- Subchondral bone trabecular microfractures and sclerosis with osteophyte formation
- Degradation secondary to release of proteolytic and collagenolytic enzymes, prostaglandins,

and associated immune response.

## TREATMENT

### GENERAL MEASURES

- Weight management
- Heat or cold applications for symptomatic relief
- Physical therapy to maintain or regain joint motion and muscle strength
  - Quadriceps-strengthening exercises relieve knee pain and disability.
- Muscle strengthening improves pain in general.
- Aerobic exercise improves long-term functional outcomes.
- Exercise must be maintained; benefits are lost 6 months after exercise cessation.
- Protect joints from overuse; ambulatory aides are beneficial (e.g., cane, crutches, walker) as is proper fitting footwear.
- Assess for bracing, joint supports, or insoles in patients with biomechanical joint pain or instability:
  - Bracing is more beneficial in patients with unicompartmental disease of the knee.
- For knee OA in particular, **nonpharmacologic modalities are strongly recommended:** aerobic, aquatic, and/or resistance exercise and weight loss.
- Nonpharmacologic modalities that are conditionally recommended for knee OA include medial wedge insoles for valgus knee OA, subtalar strapped lateral insoles for varus knee OA, medially directed patellar taping, manual therapy, walking aids, thermal agents, tai chi, self-management programs, and psychosocial intervention.

---

P.735

### MEDICATION

#### *First Line*

- Manage pain and inflammation:
  - Acetaminophen up to 1,000 mg TID-QID: effective for pain relief in OA of knee and hip
  - Topical NSAID gels, creams have short-term (<4 weeks) benefits. Topical NSAIDs should be a core treatment for knee and hand OA.

- If acetaminophen or topical NSAIDs are insufficient, consider an oral NSAID/COX-2 inhibitor. Use the lowest effective dose for the shortest time possible. Use is associated with renal insufficiency, hypertension, edema, and GI bleeding.
  - May use nonacetylated salicylates (e.g., salsalate, choline-magnesium salicylate) or low-dose ibuprofen  $\approx 1,600$  mg/day
  - Topical NSAIDs and capsaicin is effective as adjuncts and alternatives to PO analgesic/anti-inflammatory agents in knee OA.
- NSAID contraindications:
    - All PO NSAIDs/COX-2 inhibitors have analgesic effects of a similar magnitude but vary in their potential GI and cardiorenal toxicity.
    - NSAIDs should be avoided in patients with renal disease, CHF, HTN, active peptic ulcer disease, and previous hypersensitivity to an NSAID or aspirin (asthma, nasal polyps, hypotension, urticaria/angioedema).
    - Combination of NSAIDs and full strength aspirin (325 mg) is contraindicated due to risk of adverse reactions.
    - In patients at high cardiovascular risk: Combination of a nonselective NSAID and low-dose aspirin (81 mg) is recommended.
    - Oral or parenteral corticosteroids are contraindicated.
- Precautions:
    - If PO NSAID/COX-2 inhibitor use is necessary for a patient aged >65 years or a patient <65 years with increased GI-bleeding risk factors, protonpump inhibitors are recommended.
    - Significant possible interactions:
      - NSAIDs reduce effectiveness of ACE inhibitors and diuretics.
      - Aspirin and NSAIDs (except COX-2 inhibitors) may increase effects of anticoagulants.
      - Salicylates reduce effectiveness of spironolactone (Aldactone) and uricosurics.
      - Corticosteroids and some antacids increase salicylate excretion, whereas ascorbic acid and ammonium chloride reduce salicylate excretion and may cause toxicity.

## *Pregnancy Considerations*

- ASA and NSAIDs have reported fetal risk during 1st and 3rd trimesters of pregnancy.
- Compatible with breastfeeding

## *Second Line*

- Topical capsaicin is an adjunct therapy for knee and hand OA; may cause local burning
- Topical NSAIDs (e.g., diclofenac gel) can lower gastric and renal risks associated with oral NSAIDs.
- Rubefacients (e.g., oil of wintergreen) are not recommended.
- Physical therapy: Core strengthening for hip OA and knee muscle strengthening for knee OA decrease joint reactive forces on the affected joint and can relieve pain.
- Bracing; Medial and lateral unloader braces are effective; long leg alignment x-rays can help determine the appropriate brace (1).

## *Third Line*

- Intra-articular corticosteroid injections can be used for acute flares and for patients failing first and second-line treatments. Minimize injections (<2/joint/year).
- Current recommendations do not support the use of viscosupplementation injections for OA.
- Platelet-rich plasma (PRP) is more effective than HA injections for early stage knee OA (2).
- PRP injections appear to be more effective for early OA when done in a series of three (3).
- Glenohumeral joint OA managed with HA injections and corticosteroid injection have similar outcomes (4).
- TENS is effective for pain relief in large joint OA.
- Ultrasound improves injection accuracy.

## **ADDITIONAL THERAPIES**

Address psychosocial factors (i.e., self-efficacy, coping skills). Screen for and appropriately treat anxiety and depression. Improve social support.

## **SURGERY/OTHER PROCEDURES**

Surgery (e.g., osteotomy, debridement, removal of loose bodies, joint replacement, fusion) may be indicated in advanced disease.

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Nutritional supplements (glucosamine and chondroitin sulfate) may benefit some patients and have low toxicity. There is lack of standardized outcome assessments. Trial results using glucosamine and chondroitin have been mixed. If no response is apparent within 6 months, treatment should be discontinued.

- TENS units and acupuncture have shown benefit.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Regularly assess joint range of motion and functional status.
- Monitor for GI blood loss, cardiac, renal, and mental status in older patients on NSAIDs or aspirin.
- Periodic CBC, renal function tests, stool for occult blood in patients on chronic NSAID therapy

### *PATIENT EDUCATION*

- American College of Rheumatology:  
<http://www.rheumatology.org/public/factsheets/index.asp?aud=pat>
- Arthritis Foundation: <http://www.arthritis.org>

### *PROGNOSIS*

- Progressive disease: early in course, pain relieved by rest; later, pain may persist at rest and at night.
- Joint effusions and enlargement may occur (especially in knees), as disease progresses.
- Osteophyte (spur) formation, especially at joint margins
- Advanced stage with full-thickness loss of cartilage at which point joint replacement is a consideration

### **COMPLICATIONS**

- Leading cause of musculoskeletal pain and disability
- Decompensated CHF, GI bleeding, decreased renal function on chronic NSAID or aspirin therapy

## Codes

&NA;

### ICD10

- M19.90 Unspecified osteoarthritis, unspecified site
- M19.91 Primary osteoarthritis, unspecified site
- M19.93 Secondary osteoarthritis, unspecified site

## Clinical Pearls

**&NA;**

- Patients with OA typically have morning stiffness lasting for <15 minutes.
- OA most commonly affects the hips, knees, and hands (PIP and DIP joints).
- Intra-articular steroid injections should be limited to no more than 2 per joint per year (if used at all).
- Consider PRP for early stage knee OA.
- American Academy of Orthopaedic Surgeons (AAOS) recommends against the use of HA injections for OA.
- Long-term therapy should be based on individual patient goals and expectations, particularly regarding pain management and activity level.

# Osteomyelitis

Tricia Elaine VanWagner, MD

## BASICS

### DESCRIPTION

- An acute or chronic infection and inflammation of the bone; can occur as a result of hematogenous seeding, contiguous spread of infection, or direct inoculation into intact bone (trauma or surgery)
- Two major classification systems:
  - Lew and Waldvogel classification
    - Classified according to duration (acute or chronic) and the mechanism of infection (hematogenous, contiguous)
  - Cierny-Mader classification
    - Based on the portion of bone affected, the physiologic status of the host, and other risk factors
    - Stage 1: medullary bone (typically monomicrobial)
    - Stage 2: bony surface (deep soft tissue infection or ulcer)
    - Stage 3: advance local infection (polymicrobial); often associated with open fracture or infected orthopedic hardware
    - Stage 4: Extensive disease (multiple tissue layers) requires combination medical and surgical therapy.
    - Class A host: otherwise normal
    - Class B host: immunocompromised
    - Class C host: Treatment risk outweighs benefit.
- Special situations
  - Vertebral osteomyelitis
    - Acute, subacute, or chronic

- May result from hematogenous seeding, direct inoculation, or contiguous spread
- Back pain is most common initial symptom.
- Lumbar spine is most commonly involved, followed by thoracic spine.
- Infections of prosthetic joints
  - Obtaining specific diagnosis and targeted therapy quicker (easy access)
  - X-ray, then 3-phase bone scan, as MRI/CT is limited use in this circumstance
  - Treat with combination of antibiotics, including rifampin.
- Posttraumatic infections
  - Depends on type of fracture, level of contamination, and severity of tissue injury
  - Tibia is the most commonly involved.
- System(s) affected: musculoskeletal

## *EPIDEMIOLOGY*

- Predominant age: more common in older adults
- Predominant sex: male > female
- Hematogenous osteomyelitis
  - Adults (most >50 years of age): vertebral
  - Children: long bones
- Contiguous osteomyelitis: related to trauma and surgery in younger adults and decubitus ulcers and infected total joint arthroplasties in older adults

## *Incidence*

Generally low; normal bone is resistant to infection.

## *Prevalence*

Up to 66% of diabetics with foot ulcers

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Infection is caused by biofilm bacteria (protects bacteria from antimicrobial agents and host immune responses).
- Acute: suppurative infection of bone with edema and vascular compromise leading to

sequestra

- Chronic: presence of necrotic bone or sequestra or recurrence of previous infection
- Hematogenous osteomyelitis (typically monomicrobial)
  - *Staphylococcus aureus* (most common)
  - Coagulase-negative staphylococci and aerobic gram-negative bacteria
  - *Salmonella* sp. (sickle cell disease)
  - *Mycobacterium tuberculosis* and fungi (rare) in endemic areas or in immunocompromised hosts
- Contiguous focus osteomyelitis (commonly polymicrobial)
  - Diabetes or vascular insufficiency
    - Coagulase-positive and coagulase-negative staphylococci
    - Streptococci, gram-negative bacilli, anaerobes (*Peptostreptococcus* sp.)
  - Prosthetic device
    - Coagulase-negative staphylococci and *S. aureus*

## RISK FACTORS

- Diabetes mellitus
- Recent trauma/surgery
- Foreign body (e.g., prosthetic implant)
- Neuropathy and vascular insufficiency
- Immunosuppression
- Sickle cell disease
- Injection drug use
- Previous osteomyelitis

## GENERAL PREVENTION

- Antibiotic prophylaxis
  - Clean bone surgery
    - Administer IV antibiotics within an hour of skin incision and continue no longer than 24

hours after the procedure.

- Closed fractures
  - Cefazolin, cefuroxime, clindamycin (*&bgr*;-lactam allergy), or vancomycin (*&bgr*;-lactam allergy or MRSA infection)
- Open fractures
  - In patients who can receive antibiotics within 3 hours of injury with prompt operative treatment, 1st-generation cephalosporins are preferred (clindamycin or vancomycin if allergy exists). Add aminoglycoside if type III fracture and penicillin for anaerobic coverage if farm injury or possible bowel contamination.
- All diabetic patients should have an annual foot examination.

## COMMONLY ASSOCIATED CONDITIONS

See ÒRisk Factors.Ó

## DIAGNOSIS

### HISTORY

- Fever, chills, lethargy (particularly in children)
- Pain, swelling, erythema in affected area
- Hematogenous osteomyelitis
  - Elicit a history of conditions predisposing to bacteremia (diabetes, renal insufficiency, invasive procedures, IV drug use)
- Contiguous osteomyelitis and vascular insufficiency
  - Recent trauma/surgery within 1 to 2 months
  - Presence of prosthetic device
  - History of diabetes
- Chronic osteomyelitis
  - History of acute osteomyelitis

## PHYSICAL EXAM

- Fever
- Restriction of movement of the involved extremity or refusal to bear weight

- Pain or tenderness in the infected area
- Signs of localized inflammation
- Motor and sensory deficits (vertebral infection)
- Visible defect: probe to bone
- Ulcer >2-cm wide and >2-cm deep increases likelihood in diabetic foot ulcers.
- In patients with diabetes, classic signs and symptoms of infection may be masked due to vascular disease and neuropathy.

## *DIFFERENTIAL DIAGNOSIS*

- Systemic infection from other source
- Aseptic bone infarction
- Localized inflammation or infection of overlying skin and soft tissues (e.g., gout)
- Brodie abscess (subacute osteomyelitis)
- Neuropathic joint disease (Charcot foot)
- Fractures/trauma
- Tumor

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

#### Labs

- WBC is not reliable (can be normal with infection).
- CRP is usually elevated but nonspecific.
- ESR is high in most cases:
  - ESR >70 mm/hr increases likelihood.
- Antimicrobial agents given prior to culture may alter culture results.
- Disorders that may alter lab results: immunosuppression (including diabetes), chronic inflammatory disease, other/adjacent sites of infection (1)[C]
- Routine radiography is first-line imaging: Classic triad for osteomyelitis is demineralization, periosteal reaction, and bone destruction:
  - Bone destruction is not apparent on plain films until after 10 to 21 days of infection.

- Bone must undergo 30-50% destruction before damage is evident on films.
- Bone scan is typically first test after plain x-ray in setting of joint prosthesis.
- Radionuclide scanning (e.g., technetium, indium, or gallium) is useful when diagnosis is ambiguous or extent of disease is in question but is limited by low sensitivity and specificity.
- MRI
  - Best for visualization of septic arthritis, spinal infection, and diabetic foot infections (1)[C]
  - T1-weighted image: low signal intensity
  - T2-weighted image: high signal intensity
  - MRI with gadolinium: sensitivity and specificity range from 60-100% to 50-90%, respectively
  - MRI is not helpful in assessing the response to therapy due to persistence of bony edema.
- CT
  - Better than standard radiography in fragments and sequestration, but inferior to MRI in soft tissue and bone marrow assessment
  - Helps define soft tissues and identify sequestra

## Follow-Up Tests & Special Considerations

- A persistently elevated CRP (4 to 6 weeks) can be associated with persistent osteomyelitis.
- Patients receiving prolonged antimicrobial therapy should be monitored with:
  - Weekly CBC
  - Liver and kidney function tests

## *Diagnostic Procedures/Other*

- Cultures
  - Definitive diagnosis is made by blood culture (hematogenous) or by needle aspiration/bone biopsy, with identification of the microorganism by culture and sensitivity or histology.
  - Patients with positive blood cultures and with radiographic evidence of osteomyelitis may not need bone culture.
  - Wound swabs and sinus tract cultures correlate well with the presence of *S. aureus* in deep cultures.

- Image-guided bone biopsy for vertebral osteomyelitis (unless positive blood culture and positive radiographic evidence)

## *Test Interpretation*

Inflammatory process of bone with pyogenic bacteria, necrosis

## **TREATMENT**

### *GENERAL MEASURES*

- Adequate nutrition
- Smoking cessation
- Control diabetes

### *MEDICATION*

- Direct empiric therapy toward probable organism and tailor once culture results are available.
- Optimal antimicrobial concentration at infection site is essential (consider vascular perfusion to site).
- Antibiotic dosing altered for renal function
- Duration of therapy 4 to 6 weeks for acute osteomyelitis and generally >8 weeks for chronic osteomyelitis or MRSA infection
- In children, early transition from IV to oral therapy, (after 3 to 4 days if responding well) followed by oral therapy for 3 weeks may be as effective as longer courses for uncomplicated acute osteomyelitis (2)[B].

### *First Line*

- *S. aureus* or coagulase-negative staphylococci
  - MSSA:  $\beta$ -lactam at high dose (nafcillin or oxacillin 2 g IV q4h) or cefazolin 2 g IV q8h
  - MRSA: vancomycin 15 mg/kg IV q8-12h (use q8h interval if CrCl >70 mL/min) with target trough of 15 to 20 mg/mL
- *Streptococcus* sp.
  - Ceftriaxone 2 g IV q24h or cefazolin 2 g IV q8h
- *Enterobacter* sp.

- Fluoroquinolone (levofloxacin 750 mg IV/PO q24h) *or* ceftriaxone 2 g IV q24h
- *Pseudomonas aeruginosa*
  - Ciprofloxacin 750 mg PO BID *or* levofloxacin 750 mg PO q24h
- Anaerobes
  - Clindamycin 600 mg IV q8h (300 to 450 mg PO q6-8h)

## Second Line

- *S. aureus*
  - MSSA: fluoroquinolone plus rifampin (levofloxacin 750 mg IV/PO q24h plus rifampin 300 mg PO q12h *or* 600 mg PO q24h)
  - MRSA: linezolid 600 mg PO/IV q12h *or* daptomycin 6 mg/kg IV q24h
- *Streptococcus* sp.
  - Penicillin G 4 million U q4-6h
- *Enterobacter* sp. (quinolone-resistant, including extended-spectrum  $\beta$ -lactamase-producing *Escherichia coli*)
  - Carbapenem (imipenem/cilastatin) 500 mg IV q6h
- *P. aeruginosa*
  - Cefepime *or* ceftazidime 2 g IV q8h (consider adding aminoglycoside)
- Anaerobes
  - Metronidazole 500 mg IV/PO q6-8h

## ADDITIONAL THERAPIES

- Hyperbaric oxygen therapy may be a useful adjunct.
- Negative pressure wound therapy is a possible adjunctive treatment.

## SURGERY/OTHER PROCEDURES

Surgical drainage, dead space management, adequate soft tissue coverage, restoration of blood supply, and removal of necrotic tissues improve cure rates.

## *Pediatric Considerations*

Medullary osteomyelitis (stage 1) in children may be treated without surgical intervention (2)[B].

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

Correct electrolyte imbalances, hyperglycemia, azotemia, and acidosis; control pain.

### *Nursing*

Bed rest and immobilization of the involved bone and/or joint

### *Discharge Criteria*

Clinical and laboratory evidence of resolving infection and appropriate outpatient therapy

## **ONGOING CARE**

## **FOLLOW-UP RECOMMENDATIONS**

### *Patient Monitoring*

Blood levels of antimicrobial agents, ESR, CRP, and repeat plain radiography as clinical course dictates

## **PATIENT EDUCATION**

Diabetic glycemic control and foot care

## **PROGNOSIS**

- Superficial and medullary osteomyelitis treated with antimicrobial and surgical therapy have a response rate of 90-100%.
- Up to 36% recurrence rate in diabetics
- Increased mortality after amputation

## **COMPLICATIONS**

- Abscess formation
- Bacteremia
- Fracture/nonunion
- Loosening of prosthetic implant

- Postoperative infection
- Sinus tract formation can be associated with neoplasms, especially in presence of long-standing infection.

## Codes

&NA;

## ICD10

M86.9 Osteomyelitis, unspecified

- M86.00 Acute hematogenous osteomyelitis, unspecified site
- M86.10 Other acute osteomyelitis, unspecified site

## Clinical Pearls

**&NA;**

- Hematogenous osteomyelitis is usually monomicrobial, whereas osteomyelitis due to contiguous spread or direct inoculation is usually polymicrobial.
- Acute osteomyelitis typically presents with gradual onset of pain.
- Treatment of osteomyelitis often requires both surgical débridement and at least 6 weeks of antimicrobial therapy.

# Osteoporosis

David A. Ross, MD

Rahul Kapur, MD, CAQSM

## BASICS

### *DESCRIPTION*

A skeletal disease characterized by low bone mass, deterioration of bone tissue, and disruption of bone architecture that leads to compromised bone strength and an increased risk of fracture.

### *EPIDEMIOLOGY*

- Most common bone disease in humans
- Predominant age: elderly >60 years of age
- Predominant sex: female > male (80%/20%)

### *Incidence*

Of persons age >50 years, 9% had osteoporosis at either the femoral neck or lumbar spine.

### *Prevalence*

- >9.9 million Americans have osteoporosis.
- Women >50 years of age: 24%
- Men >50 years of age: 7.5%
- 50% of postmenopausal women will have an osteoporotic fracture during their lifetime and 15% will experience a hip fracture.
- Two million fractures are attributed to osteoporosis on an annual basis in the United States.

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Imbalance between bone resorption and bone formation
- Aging
- Hypoestrogenemia

## Genetics

- Familial predisposition
- More common in Caucasians and Asians than in African Americans and Hispanics

## RISK FACTORS

- Nonmodifiable
  - Advanced age (>65 years)
  - Female gender and menopause
  - Caucasian or Asian
  - Family history of osteoporosis
  - History of atraumatic fracture
- Modifiable
  - Low body weight (58 kg or body mass index [BMI] <21)
  - Calcium/vitamin D deficiency
  - Inadequate physical activity
  - Cigarette smoking
  - Excessive alcohol intake (>3 drinks/day)
  - Medications: see "Commonly Associated Conditions"

## GENERAL PREVENTION

The aim in the prevention and treatment of osteoporosis is to prevent fracture:

- Regularly perform weight-bearing exercise.
- Consume a diet that includes adequate calcium (1,000 mg/day for men aged 50 to 70; 1,200 mg/day for women aged 51 + years and men 70 + years) and vitamin D (800 to 1,000 IU/day).
- The USPSTF has concluded that vitamin D supplementation is effective in preventing falls in community-dwelling adults aged  $\geq$ 65 years who are at increased risk for falls (1)[B].
- Evidence is insufficient to assess the balance of the benefits and harms of daily supplementation with >400 IU of vitamin D<sub>3</sub> and >1,000 mg of calcium for the primary prevention of fractures in noninstitutionalized postmenopausal women (1)[B].

- USPSTF recommends against daily supplementation with <400 IU of vitamin D<sub>3</sub> and <1,000 of calcium for the primary prevention of fractures in noninstitutionalized postmenopausal women (1)[B].
- Avoid smoking.
- Limit alcohol consumption (<3 drinks/day).
- Fall prevention (vitamin D supplementation, home safety assessment, correction of visual impairment)
- Screen (USPSTF recommendations):
  - All women <sup>3</sup>65 years of age (1)[B]
  - Women >50 years of age with <sup>3</sup>10-year fracture risk (using the WHO's Fracture Risk Assessment [FRAX] Tool) >9.3%
  - The current evidence is insufficient to assess the balance of benefits and harms of screening for osteoporosis in men; however, The National Osteoporosis Foundation recommends screening men age >70 years, especially if at increased risk.

## COMMONLY ASSOCIATED CONDITIONS

- Malabsorption syndromes: gastrectomy, inflammatory bowel disease, celiac disease
- Hypoestrogenism: menopause, hypogonadism, eating disorders, female athlete triad
- Endocrinopathies: hyperparathyroidism, hyperthyroidism, hypercortisolism, diabetes mellitus
- Hematologic disorders: hemophilia, sickle cell disease, multiple myeloma, thalassemia, hemochromatosis
- Other disorders: multiple sclerosis, end stage renal disease, rheumatoid arthritis, lupus, chronic obstructive pulmonary disease (COPD), HIV/AIDS
- Medications: antiepileptics, aromatase inhibitors (raloxifene), chronic corticosteroids (>5 mg prednisone or equivalent for >3 months), medroxyprogesterone acetate, heparin, SSRI, thyroid hormone (in supraphysiologic doses), proton pump inhibitors

## DIAGNOSIS

### HISTORY

- Review modifiable and nonmodifiable risk factors
- Online risk factor assessment tools are available:
  - FRAX <http://www.shef.ac.uk/FRAX/>

- Assess for any commonly associated conditions.

## **PHYSICAL EXAM**

- Thoracic kyphosis, poor balance, deconditioning
- Historical height loss >1.5 cm (difference between current height and peak height at age 20)
- Prospective height loss >2 cm (difference between current height and previously documented height)

## **DIFFERENTIAL DIAGNOSIS**

- Multiple myeloma/other neoplasms
- Osteomalacia
- Type I collagen mutations
- Osteogenesis imperfecta

## **DIAGNOSTIC TESTS & INTERPRETATION**

Dual-energy x-ray absorptiometry (DEXA) of the lumbar spine/hip is considered the gold standard for the diagnosis of osteoporosis.

### ***Initial Tests (lab, imaging)***

Consider in screening for secondary osteoporosis:

- Serum 25-hydroxyvitamin D and parathyroid hormone
- CBC
- Serum chemistry, including calcium, phosphorus, magnesium, total protein, albumin, liver enzymes, creatinine, alkaline phosphatase, and thyroid stimulating hormone
- Urinalysis (24-hour collection) for calcium, sodium, and creatinine (to identify calcium malabsorption or hypercalciuria)
- DEXA of the lumbar spine/hip is the gold standard for measuring bone mineral density (BMD).
- A BMD at the hip or lumbar spine that is  $\geq 2.5$  standard deviations (SDs) below the mean BMD of a young-adult reference population is diagnostic of osteoporosis.
- A minimum of 2 years may be needed to reliably measure a change in BMD.
- BMD is expressed in terms of T-scores and Z-scores:
  - T-score is the number of SDs a patient's BMD deviates from the mean for young, normal

(age 25 to 40 years) control individuals of the same sex.

- WHO defines normal BMD as a T-score  $\geq -1$ , osteopenia as a T-score between  $-1$  and  $-2.5$ , and osteoporosis as a T-score  $\leq -2.5$ .
- WHO thresholds can be used for postmenopausal women and men  $>50$  years of age.
- The Z-score is a comparison of the patient's BMD with an age-matched population.
- A Z-score  $< -2$  should prompt evaluation for causes of secondary osteoporosis.
- Quantitative ultrasound densitometry does not measure BMD directly but may be used clinically in predicting fractures in postmenopausal women and in men  $>65$  (2).
- Plain radiographs lack sensitivity to diagnose osteoporosis, but an abnormality (e.g., widened intervertebral spaces, rib fractures, vertebral compression fractures) should prompt evaluation.

## Follow-Up Tests & Special Considerations

Further labs depending on initial evaluation, Z-score  $\leq -2.5$  or young age

- Iron and ferritin (hemochromatosis)
- Testosterone levels (hypogonadism in men)
- Serum protein electrophoresis and free  $\kappa$ ; and  $\lambda$ ; light chains (multiple myeloma)
- Urinary-free cortisol (Cushing disease)
- Tissue transglutaminase antibodies (celiac disease)
- Markers of bone resorption (urine N-telopeptides of type 1 collagen, serum C-telopeptides of type 1 collagen, serum N-terminal propeptide of type 1 procollagen): no prospective studies supporting use in osteoporosis diagnosis and management; potential role for identifying patients at high risk for fracture and monitoring response to therapy

## Diagnostic Procedures/Other

Bone biopsy may be recommended for patients with bone disease and renal failure to establish the correct diagnosis as it can assess the degree of mineralization and microarchitecture and specific bone loss mechanisms.

## Test Interpretation

- In osteoporosis can see reduced skeletal mass; trabecular bone thinned or lost more than cortical bone
- Can assess osteoclast and osteoblast relative activity
- Can rule out other metabolic bone diseases

- Can assess if bone marrow is normal or atrophic

## TREATMENT

- All patients with a T-score  $\geq -2.5$  with no risk factors
- All postmenopausal women who have had an osteoporotic vertebral/hip fracture
- All postmenopausal women who have BMD values consistent with osteoporosis (T-score  $\geq -2.5$ ) at the lumbar spine, femoral neck, or total hip region
- Postmenopausal women with T-scores from -1.0 to -2.5 and a 10-year risk, based on FRAX calculator, of an osteoporotic fracture (spine, hip, shoulder, and wrist) of at least 20% or hip of at least 3%
- Treat men  $>50$  years of age who present with a hip or vertebral fracture or a T-score  $< -2.5$  after appropriate evaluation; however, evidence for the effectiveness of treatment of osteoporosis in men is limited.

## MEDICATION

Calcium 1,200 mg/day and vitamin D 800 IU/day

### First Line

- Bisphosphonates
  - Alendronate 10 mg PO daily or 70 mg PO weekly
  - Risedronate 5 mg PO daily, 35 mg PO weekly, 75 mg PO twice monthly, or 150 mg PO monthly
  - Ibandronate 150 mg PO once monthly or 3 mg IV every 3 months
  - Zoledronic acid 5 mg IV yearly
- These drugs become incorporated into skeletal tissue, where they inhibit the resorption of bone by osteoclasts (3,4).
- Alendronate, risedronate, and zoledronic acid reduce the incidence of vertebral and nonvertebral fractures while Ibandronate reduces vertebral fracture only.
- The side effects are similar for all bisphosphonates and include gastrointestinal problems such as difficulty swallowing and inflammation of the esophagus and stomach.
- Osteonecrosis of the jaw has been associated with bisphosphonates, particularly in patients

with cancer who receive high doses (5).

- There is a possible risk of midfemur fractures in patients receiving bisphosphonates for >5 years (6).
- Avoid oral bisphosphonates in patients with
  - Delayed esophageal emptying
  - Inability to stand/sit upright for at least 30 to 60 minutes after taking the bisphosphonates
  - Hypocalcemia (correct prior to initiating therapy)
  - Severe renal impairment (creatinine clearance [CrCl]  $\geq$  30 to 35 mL/min for alendronate, risedronate, and ibandronate and  $\geq$  35 mL/min for zoledronic acid)

## *Second Line*

- Raloxifene 60 mg PO daily
  - Selective estrogen receptor modulator with positive effects on BMD and vertebral fracture risk but no stimulatory action on breasts/uterus
  - Nonvertebral or hip fracture efficacy has not been demonstrated; increases risk of thromboembolism.
  - Additional side effects include menopausal symptoms (hot flashes and night sweats).
- Teriparatide 20 mg SC daily
  - Recombinant formulation of PTH
  - Works anabolically to stimulate the growth of bone through osteoblastic activation
  - Studies have shown a reduction in the incidence of vertebral fractures by 65% and nonvertebral fractures by 53%.
  - No data exist on its safety and efficacy after >2 years of use (7).
- Denosumab: 60 mg SQ every 6 months
  - Human monoclonal antibody receptor activator of nuclear factor kappa-B ligand (RANKL) receptor
  - Inhibits osteoclast formation
- Estrogen 0.625 mg PO daily (with progesterone if patient has a uterus): effective in prevention and treatment of osteoporosis (34% reduction in hip and vertebral fractures after 5 years of use), but the risks (e.g., increased rates of myocardial infarction, stroke, breast cancer, pulmonary embolus, and deep vein thrombosis) must be weighed against the benefits

- Strontium 2 g PO daily
  - Appears to inhibit bone resorption and increase bone formation
  - Available for use in Europe
- Calcitonin
  - PTH antagonist that reduces osteoclastic activity, therefore decreasing bone turnover
  - FDA approved for treatment of osteoporosis in women who are at least 5 years postmenopausal when alternative treatments are not suitable.
  - Calcitonin reduces vertebral fracture occurrence in those with prior vertebral.
  - Has been associated with an increased risk for malignancy

## *ISSUES FOR REFERRAL*

Endocrinology for recurrent bone loss/fracture

## *ADDITIONAL THERAPIES*

- Weight-bearing exercise 30 minutes 3 times per week
- Smoking cessation
- Physical therapy to help with muscle strengthening

## *SURGERY/OTHER PROCEDURES*

Options for patients with painful vertebral compression fractures failing medical treatment:

- Vertebroplasty: Orthopedic cement is injected into the compressed vertebral body.
- Kyphoplasty: A balloon is expanded within the compressed vertebral body to reconstruct volume of vertebrae. Cement is injected into the space.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Isoflavones not better than placebo for fracture risk
- Beneficial effect of Chinese herbal medicines in improving BMD is still uncertain.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Inpatient care for pain control of acute back pain secondary to new vertebral fractures and for acute treatment of femoral and pelvic fractures

## *Discharge Criteria*

Rehabilitation, nursing home, or home care may be needed following hospitalization for fractures.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Weight-bearing exercises, such as walking, jogging, stair climbing, and tai chi, have been shown to decrease falls and fracture risk.
- Yearly height measurement is essential to determination of osteoporosis treatment efficacy. Patients who lose >2 cm in height should have repeat vertebral imaging to determine if any new vertebral fractures have occurred (2).
- While there is no consensus, most recommendations suggest BMD testing by DEXA scanning retesting 2 years after starting bisphosphonate therapy.
- For many women, 3 to 5 years of treatment with a bisphosphonate is as good as 10 years of treatment.
- A comprehensive risk assessment should be performed after 3 to 5 years of treatment. Those at high risk for vertebral fracture or with very low BMD may benefit by continuing treatment beyond 5 years.
- Physicians prescribing bisphosphonates should advise patients of the small risk of osteonecrosis and encourage dental examinations (2).

#### *DIET*

- Diet to maintain normal body weight
- Calcium and vitamin D (see *General Prevention*)

#### *PATIENT EDUCATION*

National Osteoporosis Foundation: <http://nof.org/>

#### *PROGNOSIS*

- With treatment, 80% of patients stabilize skeletal manifestations, increase bone mass and mobility, and have reduced pain.

15% of vertebral and 20-40% of hip fractures may lead to chronic care and/or premature death.

## COMPLICATIONS

Severe, disabling pain and recurrent fractures

## Codes

&NA;

## ICD10

- M81.0 Age-related osteoporosis w/o current pathological fracture
- M80.00XA Age-rel osteopor w current path fracture, unsp site, init

- M80.08XA Age-rel osteopor w current path fracture, vertebra(e), init

## Clinical Pearls

**&NA;**

- Screen all women  $\geq 65$  years of age with DEXA scans.
- Premenopausal women with osteoporosis should be screened for secondary causes, such as malabsorption syndromes, hyperparathyroidism, hyperthyroidism, and medication sensitivity.
- Evaluate and treat all patients presenting with fractures from minimal trauma.
- Bisphosphonates are first line for treatment of osteoporosis in most patients.
- If the patient is not responding to treatment, consider screening for a secondary, treatable cause of osteoporosis.

# Otitis Externa

Douglas S. Parks, MD

## BASICS

### *DESCRIPTION*

Inflammation of the external auditory canal:

- Acute diffuse otitis externa: the most common form; an infectious process, usually bacterial, occasionally fungal (10%)
- Acute circumscribed otitis externa: synonymous with furuncle; associated with infection of the hair follicle, a superficial cellulitic form of otitis externa
- Chronic otitis externa: same as acute diffuse but of longer duration (>6 weeks)
- Eczematous otitis externa: may accompany typical atopic eczema or other primary skin conditions
- Necrotizing malignant otitis externa: an infection that extends into the deeper tissues adjacent to the canal; may include osteomyelitis and cellulitis; rare in children
- System(s) affected: skin/exocrine
- Synonym(s): swimmer's ear

### *EPIDEMIOLOGY*

#### *Incidence*

- Unknown; higher in the summer months and in warm, wet climates
- Predominant age: all ages
- Predominant sex: male = female

#### *Prevalence*

- Acute, chronic, and eczematous: common
- Necrotizing: uncommon

## ETIOLOGY AND PATHOPHYSIOLOGY

- Acute diffuse otitis externa
  - Traumatized external canal (e.g., from use of cotton swab)
  - Bacterial infection (90%): *Pseudomonas* (67%), *Staphylococcus*, *Streptococcus*, gram-negative rods
  - Fungal infection (10%): *Aspergillus* (90%), *Candida*, *Phycomycetes*, *Rhizopus*, *Actinomyces*, *Penicillium*
- Chronic otitis externa: bacterial infection: *Pseudomonas*
- Eczematous otitis externa (associated with primary skin disorder)
  - Eczema
  - Seborrhea
  - Psoriasis
  - Neurodermatitis
  - Contact dermatitis
  - Purulent otitis media
  - Sensitivity to topical medications
- Necrotizing otitis externa
  - Invasive bacterial infection: *Pseudomonas*, increasing incidence of methicillin-resistant *Staphylococcus aureus* (MRSA)
  - Associated with immunosuppression

## RISK FACTORS

- Acute and chronic otitis externa
  - Traumatization of external canal
  - Swimming
  - Hot, humid weather
  - Hearing aid use
- Eczematous: primary skin disorder
- Necrotizing otitis externa in adults

- Advanced age
- Diabetes mellitus (DM)
- Debilitating disease
- AIDS
- Immunosuppression
- Necrotizing otitis externa in children (rare)
  - Leukopenia
  - Malnutrition
  - DM
  - Diabetes insipidus

## *GENERAL PREVENTION*

- Avoid prolonged exposure to moisture.
- Use preventive antiseptics (acidifying solutions with 2% acetic acid [white vinegar] diluted 50/50 with water or isopropyl alcohol, or 2% acetic acid with aluminum acetate [less irritating]) after swimming and bathing.
- Treat predisposing skin conditions.
- Eliminate self-inflicted trauma to canal with cotton swabs and other foreign objects.
- Diagnose and treat underlying systemic conditions.
- Use ear plugs when swimming.

## **DIAGNOSIS**

### **HISTORY**

Variable-length history of itching, plugging of ear, ear pain, and discharge from ear

### *PHYSICAL EXAM*

- Ear canal: red, containing purulent discharge and debris
- Pain on manipulation of the pinnae
- Possible periauricular adenitis

- Possible eczema of pinna
- Cranial nerve (VII, IX to XII) involvement (extremely rare)

## *DIFFERENTIAL DIAGNOSIS*

- Idiopathic ear pain
- Otitis media with perforation
- Hearing loss
- Cranial nerve (VII, IX to XII) palsy with necrotizing otitis externa
- Wisdom tooth eruption
- Basal cell or squamous cell carcinoma

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Gram stain and culture of canal discharge (occasionally helpful)
- Antibiotic pretreatment may affect results.
- Radiologic evaluation of deep tissues in necrotizing otitis externa with high-resolution CT scan, MRI, gallium scan, and bone scan

## *Test Interpretation*

- Acute and chronic otitis externa: desquamation of superficial epithelium of external canal with infection
- Eczematous otitis externa: pathologic findings consistent with primary skin disorder; secondary infection on occasion
- Necrotizing otitis externa: vasculitis, thrombosis, and necrosis of involved tissues; osteomyelitis

## **TREATMENT**

Outpatient treatment, except for resistant cases and necrotizing otitis externa

## *GENERAL MEASURES*

- Cleaning the external canal may facilitate recovery.
- Analgesics as appropriate for pain
- Antipruritic and antihistamines (eczematous form)

- Ear wick (Pope) for nearly occluded ear canal

## MEDICATION

- Resistance is an increasing problem. *Pseudomonas* is the most common bacteria, and it is more susceptible to fluoroquinolones such as ciprofloxacin or ofloxacin, whereas *Staphylococcus* is equally susceptible to both fluoroquinolones and polymyxin B combinations (1)[B]. If a patient has recurring episodes or is not improved in 2 weeks, change the class of antibacterial and consider cultures and sensitivities.
- There is evidence that using a topical antibiotic with a corticosteroid shortens time to symptom resolution, although there is no evidence that it increases overall cure rate. There is not enough evidence to demonstrate that any antibiotic regimen is clearly superior to any other (2) [B].
- Oral antibiotics are indicated only if there is associated otitis media. Oral antibiotics alone are not effective and markedly increase the risk of progressing to chronic otitis externa.
- Analgesics as needed; narcotics may be necessary. Recurrent otitis externa may be prevented by applying equal parts white vinegar and isopropyl alcohol (over-the-counter [OTC] rubbing alcohol) to external auditory canals after bathing and swimming.

P.741

### First Line

- Acute bacterial and chronic otitis externa
  - Ciprofloxacin 0.3% and dexamethasone 0.1% suspension: 4 drops BID for 7 days or ofloxacin: 0.3% solution 10 drops once a day for 7 days (3)[A]. Less ototoxicity and reported antibiotic resistance (4)[A], but branded drugs are far more expensive.
  - Neomycin/polymyxin B/hydrocortisone (Cortisporin): 5 drops QID. If the tympanic membrane is ruptured, use the suspension; otherwise, the solution may be used; may be ototoxic and resistance-developing in *Staphylococcus* and *Streptococcus* sp. (5)[B]; least expensive.
  - Acetic acid 2% with hydrocortisone 1%: 3 to 5 drops q4-6h for 7 days; may cause minor local stinging. This is as effective as neomycin-polymyxin B (6)[B] but is expensive. It may take up to 2 days longer to achieve resolution of symptoms (2)[A]. A wick may be helpful in severe cases by keeping the canal open and keeping antibiotic solution in contact with infected skin (7)[C].
- Fungal otitis externa
  - Topical therapy, antiyeast for *Candida* or yeast: 2% acetic acid 3 to 4 drops QID;

clotrimazole 1% solution; itraconazole oral

- Parenteral antifungal therapy: amphotericin B
- Patients with Ramsay-Hunt syndrome: acyclovir IV
- Eczematous otitis externa: topical therapy
  - Acetic acid 2% in aluminum acetate
  - Aluminum acetate (5%; Burow solution)
  - Steroid cream, lotion, ointment (e.g., triamcinolone 0.1% solution)
  - Antibacterial, if superinfected
- Necrotizing otitis externa
  - Parenteral antibiotics: antistaphylococcal and antipseudomonal
  - 4 to 6 weeks of therapy
  - Fluoroquinolones PO for 2 to 4 weeks

## *Second Line*

- Acute bacterial and chronic otitis externa
  - Betamethasone 0.05% solution may be as effective as a polymyxin B combination without the risk of ototoxicity or antibiotic resistance. However, the data are not very robust, and more study is needed (2)[A].
- Azole antifungals for fungal otitis externa

## *ISSUES FOR REFERRAL*

Resistant cases or those requiring surgical intervention

## *SURGERY/OTHER PROCEDURES*

For necrotizing otitis externa or furuncle

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- OTC white vinegar; 3 drops in affected ear for minor case
- Tea tree oil in various concentrations has been used as an antiseptic (8)[B]. Ototoxicity has been reported in animal studies at very high doses.
- Grapefruit seed extract in various concentrations has been described as useful in the lay

literature.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Necrotizing otitis media requiring parenteral antipseudomonal antibiotics

### *Discharge Criteria*

Resolution of infection

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

No restrictions

### *Patient Monitoring*

- Acute otitis externa
  - 48 hours after therapy instituted to assess improvement
  - At the end of treatment
- Chronic otitis externa
  - Every 2 to 3 weeks for repeated cleansing of canal
  - May require alterations in topical medication, including antibiotics and steroids
- Necrotizing otitis externa
  - Daily monitoring in hospital for extension of infection
  - Baseline auditory and vestibular testing at beginning and end of therapy

### *DIET*

No restrictions

### *PROGNOSIS*

- Acute otitis externa: rapid response to therapy with total resolution
- Chronic otitis externa: With repeated cleansing and antibiotic therapy, most cases will resolve. Occasionally, surgical intervention is required for resistant cases.

- Eczematous otitis externa: Resolution will occur with control of the primary skin condition.
- Necrotizing otitis externa: usually can be managed with débridement and antipseudomonal antibiotics; recurrence rate is 100% when treatment is inadequate. Surgical intervention may be necessary in resistant cases or if there is cranial nerve involvement. Mortality rate is significant, probably secondary to the underlying disease.

## COMPLICATIONS

- Mainly a problem with necrotizing otitis externa; may spread to infect contiguous bone and CNS structures
- Acute otitis externa may spread to pinna, causing chondritis.

Algorithm: Ear Pain

## Codes

&NA;

### ICD10

- H60.90 Unspecified otitis externa, unspecified ear
- H60.339 Swimmer's ear, unspecified ear
- H60.509 Unsp acute noninfective otitis externa, unspecified ear

## Clinical Pearls

&NA;

- Acute diffuse otitis externa is the most common form: bacterial (90%), occasionally fungal (10%).
- Acute circumscribed otitis externa is associated with infection of a hair follicle.
- Chronic otitis externa is the same as acute diffuse but of longer duration (>6 weeks).
- Eczematous otitis externa may accompany typical atopic eczema or other primary skin conditions.
- Necrotizing malignant otitis externa is an infection that extends into the deeper tissues adjacent to the canal. It may include osteomyelitis and cellulitis; it is rare in children.

# Otitis Media

Paul George, MD, MHPE

## BASICS

### DESCRIPTION

- Inflammation of the middle ear; usually accompanied by fluid collection
- Acute otitis media (AOM): inflammation of the middle ear. Rapid onset; cause may be infectious, either viral (AOM-v) or bacterial (AOM-b), but there is also a sterile etiology (AOM-s).
- Recurrent AOM: <sup>3</sup>3 episodes in 6 months or <sup>3</sup>4 episodes in 1 year with <sup>3</sup> 1 in the past 6 months
- Otitis media with effusion (OME): fluid in the middle ear without signs or symptoms of infection
- Chronic otitis media with or without cholesteatoma
- System(s) affected: nervous, ENT
- Synonym(s): secretory or serous otitis media

### EPIDEMIOLOGY

#### Incidence

- AOM
  - Predominant age: 6 to 24 months; declines >7 years; rare in adults
  - Predominant gender: male > female
  - By age 7 years, 93% of children have had <sup>3</sup>1 episodes of AOM; 39% have had <sup>3</sup>6.
  - Placement of tympanostomy tubes is second only to circumcision as the most frequent surgical procedure in infants.
  - Increased incidence in the fall and winter
- OME
  - By age 4 years, 90% of children have had at least one episode.

## Prevalence

- Most common infection for which antibacterial agents are prescribed in the United States
- Diagnosed 5 million times per year in the United States

## ETIOLOGY AND PATHOPHYSIOLOGY

- AOM-b (bacterial): usually, a preceding viral upper respiratory infection (URI) produces eustachian tube dysfunction
  - *Streptococcus pneumoniae*: 20-35%, *Haemophilus influenzae*: 20-30%, *Moraxella (B.) catarrhalis*: 15%, group A streptococci: 3%, *Staphylococcus aureus*: 12% produce  $\beta$ -lactamases that hydrolyze amoxicillin and some cephalosporins.
- AOM-v (viral): 15-44% of AOM infections are caused primarily by viruses (e.g., respiratory syncytial virus, parainfluenza, influenza, enteroviruses, adenovirus, human metapneumovirus, and parechovirus).
- AOM-s (sterile/nonpathogens): 25-30%
- OME: Eustachian tube dysfunction; allergic causes are rarely substantiated.

## Genetics

- Strong genetic component in twin studies for recurrent and prolonged AOM
- May be influenced by skull configuration or immunologic defects

## RISK FACTORS

- Age
- Bottlefeeding while supine
- Routine daycare attendance
- Frequent pacifier use after 6 months of age
- Environmental smoke exposure
- Male gender
- Absence of breastfeeding
- Low socioeconomic status
- Family history of recurrent otitis

- AOM before age 1 year is a risk for recurrent AOM
- Presence of siblings in the household
- Underlying ENT disease (e.g., cleft palate, Down syndrome, allergic rhinitis)

## GENERAL PREVENTION

- Pneumococcal vaccine (PCV)-7 immunization reduces the number of cases of AOM by about 6-28% (however, evidence shows that this is offset by an increase in AOM caused by other bacteria). The effect of the introduction of the PCV-13 vaccine on the incidence of AOM has yet to be studied (1,2)[B].
- Influenza vaccine reduces AOM.
- Breastfeeding for <sup>3</sup>6 months is protective.
- Avoiding supine bottlefeeding, passive smoke, and pacifiers >6 months may be helpful.
- Secondary prevention: Adenoidectomy and adenotonsillectomy for recurrent AOM has limited short-term efficacy and is associated with its own adverse risks.
- Vitamin D supplementation (1,000 U/day to maintain vitamin D levels >30) may be helpful in reducing recurrent AOM (3)[B].

## COMMONLY ASSOCIATED CONDITIONS

URI

## DIAGNOSIS

### HISTORY

- AOM: acute history, signs, and symptoms of middle ear inflammation and effusion
  - Earache
  - Preceding or accompanying URI symptoms
  - Decreased hearing
- In adults, earache without fever or hearing loss may be the only presenting feature.

### ALERT

- AOM in infants and toddlers:
  - May cause few symptoms in the first few months of life

Irritability may be the only symptom.

- OME: usually asymptomatic
  - Decreased hearing

## *PHYSICAL EXAM*

- Infectious AOM:
  - Fever (not required for diagnosis)
  - Decreased eardrum mobility (with pneumatic otoscopy)
  - Moderate to severe bulging of tympanic membrane
  - Otorrhea
  - Redness alone is not a reliable sign.
- OME:
  - Eardrum often dull but not bulging
  - Decreased eardrum mobility (pneumatic otoscopy)
  - Presence of air-fluid level
  - Weber test is positive to affected ear for an ear with effusion.

## *DIFFERENTIAL DIAGNOSIS*

- Tympanosclerosis
- Trauma
- Referred pain from the jaw, teeth, or throat
- TMJ in adults
- Otitis externa
- Otitis-conjunctivitis syndrome
- Temporal arteritis in adults

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

WBC count may be higher in bacterial AOM than in sterile AOM, but this is almost never useful.

## Diagnostic Procedures/Other

- To document the presence of middle ear fluid, pneumatic otoscopy can be supplemented with tympanometry and acoustic reflex measurement.
- Hearing testing is recommended when hearing loss persists for <sup>3</sup>3 months or at any time suspecting language delay, significant hearing loss, or learning problems.
- Language testing should be performed for children with hearing loss.
- Tympanocentesis for microbiologic diagnosis is recommended for treatment failures; may be followed by myringotomy.

## TREATMENT

- Significant disagreement exists about the usefulness of antibiotic treatment for this often self-resolving condition. Studies suggest that ÷15 children need to be treated with antibiotics to prevent one case of persisting AOM pain at 1 to 2 weeks; the number needed to treat to cause harm (primarily diarrhea) is 8 to 10 (2)[B].
- If antibiotics are not used, 81% of patients >2 years of age are better in 1 week versus 94% if antibiotics are used.
- Delay of antibiotics found a modest increase in mastoiditis from 2/100,000 to 4/100,000.
- American Academy of Pediatrics/American Academy of Family Physicians (AAP/AAFP) guidelines recommend the following for observation versus antibacterial therapy, although these guidelines are not rigorously evidence-based (2)[B]:
  - <6 months of age: No recommendation (2004 guidelines suggest treatment with antibiotic therapy to any child diagnosed with otitis media < 6 months of age)
  - >6 months: Antibacterial therapy is recommended when the diagnosis with severe otitis media (i.e., moderate to severe otalgia or fever <sup>3</sup>39°C in the previous 24 hours) or otorrhea or bilateral otitis media between 6 months and 2 years of age
  - Observation is an option with nonsevere otitis media.
- OME: Watchful waiting for 3 months per AAP/AFPP guidelines for those not at risk (see ÒComplicationsÓ). Of these cases, 25-90% will recover spontaneously over this period. No benefit of antihistamines, decongestants, or antibiotics or systemic steroids (4)[A].

## GENERAL MEASURES

Assess pain.

- Although unusual in adults, the treatment is the same.
- Acetaminophen, ibuprofen, benzocaine drops (additional but brief benefit over acetaminophen)

## **MEDICATION**

### ***First Line***

- AOM: AAP/AAFP consensus guideline recommends amoxicillin, 80 to 90 mg/kg/day in 2 divided doses; (5)[A] OR
- Amoxicillin-clavulanate 90 mg/kg/day of amoxicillin, with 6.4 mg/kg/day of clavulanate in 2 divided doses; recommended in children who have taken amoxicillin in the previous 30 days and those with concurrent conjunctivitis or history of AOM unresponsive to amoxicillin
- Treatment duration: 10-day course for children <2 years; 7-day course for children 2 to 5 years; 5- to 7-day course for children 6 years and older
- If penicillin allergic:
  - Non-type 1 hypersensitivity reaction: cefdinir, 14 mg/kg/day in 1 to 2 doses; cefpodoxime, 10 mg/kg/day BID; or cefuroxime 30 mg/kg/day BID
  - Type 1 hypersensitivity to penicillin: azithromycin (10 mg/kg/day [max dose 500 mg/day] as a single dose on day 1 and 5 mg/kg/day [max dose 250 mg/day] for days 2 to 5)
- A single dose of parenteral ceftriaxone (50 mg/kg) is as effective as a full course of antibiotics in uncomplicated AOM.
- A single dose of azithromycin has been approved by the FDA, but studies did not include otitis-prone children or have criteria for AOM diagnosis.
- Consider treatment of children between ages 6 months and 2 years with antibiotics to reduce duration of symptoms (6)[A].
- OME: See "General Measures"; no benefit to treatment. Medications promote transitory resolution in 10-15%, but the effect is short-lived.

### ***Second Line***

- Alternative antibiotics are indicated for the following AOM patients:
  - Persistent symptoms after 48 to 72 hours of amoxicillin
  - AOM within 1 month of amoxicillin therapy
  - Severe earache

- Age <6 months with high fever
- Immunocompromised
  - Amoxicillin-clavulanate, 90 mg/kg to 6.4 mg/kg/day, divided BID
  - Ceftriaxone, 50 mg/kg IM or IV q24h for 3 consecutive days can be reserved for those who are too sick to take oral medications or who unsuccessfully took amoxicillin-clavulanate. Neither erythromycin-sulfisoxazole nor trimethoprim-sulfamethoxazole should be used as a 2nd-line agent in treatment failures.
- Recurrent AOM: Antibiotic prophylaxis for recurrent AOM (>3 distinct, well-documented episodes in 6 months) is not recommended.

## *SURGERY/OTHER PROCEDURES*

- Recurrent AOM: Consider referral for surgery if <sup>33</sup> episodes of well-documented AOM within 6 months, <sup>34</sup> episodes within 12 months with <sup>31</sup> episode in previous 6 months, or AOM episodes occur while on chemoprophylaxis.
- Tympanostomy tubes may be effective in selective patients, particularly children age <2 years with recurrent AOM (7)[A].
- Adenoidectomy has limited or no effect.
- Adenotonsillectomy reduced the rate of AOM by 0.7 episode per child only in the 1st year after surgery and had a 15% complications rate.
- OME: Referral for surgery for tympanostomy should be individualized. It can be considered if >4 to 6 months of bilateral OME and/or >6 months of unilateral OME and/or hearing loss >25 dB or for high-risk individuals at any time.
- Tympanostomy tubes may reduce recurrence of AOM minimally, but it does not lower the risk of hearing loss (8)[A].
- Adenoidectomy is indicated in specific cases; tonsillectomy or myringotomy is never indicated.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- It is unclear whether alternative and homeopathic therapies are effective for AOM, including mixed evidence about the effectiveness of zinc supplementation of reducing AOM.
- Xylitol, probiotics, herbal ear drops, and homeopathic interventions may be beneficial in reducing pain duration, antibiotic use, and bacterial resistance.

## *INPATIENT CONSIDERATIONS*

## Admission Criteria/Initial Stabilization

Outpatient, except if surgery is indicated, or for AOM in febrile infants age <2 months or children requiring ceftriaxone who also require monitoring for 24 hours

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

Patients with otitis media who do not respond within 48 to 72 hours should be reevaluated:

- If therapy was delayed and diagnosis is confirmed, start therapy with high-dose amoxicillin.
- If therapy was initiated, consider changing the antibiotic; options are limited because macrolides have limited benefit against *Haemophilus influenzae* over amoxicillin, and most oral cephalosporins have no improved outcomes.

### Patient Monitoring

- AOM: Up to 40% may have persistent middle ear effusion at 1 month, with 10-25% at 3 months.
- OME: Repeat otoscopic or tympanometric exams at 3 months, as indicated, as long as OME persists or sooner if there are red flags (see earlier discussion).

### PROGNOSIS

- See "General Measures."
- Recurrent AOM and OME: Usually subsides in school-aged children; few have complications.

### COMPLICATIONS

- AOM: Serious complications are rare: tympanic membrane perforation/otorrhea, acute mastoiditis, facial nerve paralysis, otitic hydrocephalus, meningitis, hearing impairment.
- OME: Speech and language disabilities may occur. Hearing loss is not caused by OME, but in children who are at risk for speech, language, or learning problems (e.g., autism spectrum, syndromes, craniofacial disorders, developmental delay, and children already with speech/language delay), it could lead to further problems because they are less tolerant of a hearing impairment.
- Recurrent AOM and OME: atrophy and scarring of eardrum, chronic perforation and otorrhea, cholesteatoma, permanent hearing loss, chronic mastoiditis, other intracranial suppurative complications

**See Also**

**&NA;**

Algorithm: Ear Pain

## Codes

**&NA;**

### ICD10

- H66.90 Otitis media, unspecified, unspecified ear
- H66.40 Suppurative otitis media, unspecified, unspecified ear
- H65.199 Other acute nonsuppurative otitis media, unspecified ear

## Clinical Pearls

**&NA;**

- Pneumatic otoscopy is the single most specific and clinically useful test for diagnosis.
- Consider a delay of antibiotics for 24 to 48 hours in uncomplicated presentations (>2 years of age) who do not have severe illness or otorrhea.
- First-line treatment is amoxicillin, 80 to 90 mg/kg/day for 10 days for children age <2 years; consider a 5- to 7-day course in >2 years of age.
- Erythema and effusion can persist for weeks.
- Antibiotics, antihistamines, and steroids are not indicated for OME.
- OME rarely develops in adults. Persistent unilateral effusion should be investigated to rule out neoplasm, particularly if there is a cranial nerve palsy.

# Otitis Media with Effusion

Hobart Lee, MD, FAAFP

## BASICS

### DESCRIPTION

- Also called serous otitis media, mucoid otitis media, or Òglue earÓ
- Otitis media with effusion (OME) is defined as the presence of fluid in the middle ear in the absence of acute signs or symptoms of infection.
- More commonly, a pediatric disease
- May occur spontaneously from poor eustachian tube function or as an inflammatory response after acute otitis media

### EPIDEMIOLOGY

#### *Incidence*

Approximately 90% of children have OME before school age, mostly between the ages of 6 months and 4 years.

#### *Prevalence*

- Approximately 2.2 million new cases annually in the United States
- Less prevalent in adults and is usually associated with an underlying disorder

### ETIOLOGY AND PATHOPHYSIOLOGY

- Chronic inflammatory condition where an underlying stimulus causes an inflammatory reaction with increased mucin production creating a functional blockage of the eustachian tube and thick accumulation of mucin-rich middle ear effusion
- Young children are more prone to OME due to shorter and more horizontal eustachian tubes, which become more vertical around 7 years of age.
- Biofilms, anatomic variations, and acute otitis media (AOM) caused by viruses or bacteria have been implicated as stimuli causing OME. The common pathogens causing AOM include nontypeable *Haemophilus influenzae*, *Streptococcus pneumoniae*, and *Moraxella catarrhalis*.

- In adults, OME is often associated with paranasal sinus disease (66%), smoking-induced nasopharyngeal lymphoid hyperplasia and adult onset adenoidal hypertrophy (19%), or head and neck tumors (4.8%).

## **RISK FACTORS**

- Risk factors include a family history of OME, early daycare, exposure to cigarette smoke, bottlefeeding, and low socioeconomic status (1).
- Eustachian tube dysfunction may be a predisposing factor, although the evidence is unclear (2).
- Gastroesophageal reflux is associated with OME (2).

## **GENERAL PREVENTION**

OME is generally not preventable, although lowering smoke exposure, breastfeeding, and avoiding daycare centers at an early age may decrease the risk (3).

## **DIAGNOSIS**

### **HISTORY**

- OME is transient and asymptomatic in many pediatric patients.
- Most common reported symptom is hearing loss (2). There may be mild discomfort present in the ear, fullness, or “popping” (1).
- Infants may have ear rubbing, excessive irritability, sleep problems, or failure to respond appropriately to voices or sounds (1).
- Clinical features may include “a history of hearing difficulties, poor attention, behavioral problems, delayed speech and language development, clumsiness, and poor balance” (2).
- There may be a history of recent or recurrent episodes of acute otitis media or a recent upper respiratory tract infection (2).

## **PHYSICAL EXAM**

- Cloudy tympanic membrane (TM) with distinctly impaired mobility. Air-fluid level or bubble may be visible in the middle ear (1,2).
- Color may be abnormal (yellow, amber, or blue), and the TM may be retracted or concave (2).
- Distinct redness of the tympanic membrane may be present in approximately 5% of OME cases (1).

- Clinical signs and symptoms of acute illness should be absent in patients with OME (1).

## ***DIFFERENTIAL DIAGNOSIS***

- Acute otitis media
- Bullous myringitis
- Tympanosclerosis (may cause decreased/absent motion of the TM)
- Sensorineural hearing loss

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Diagnostic Procedures/Other***

- The primary standard to make the diagnosis is pneumatic otoscopy, which demonstrates reduced/absent mobility of the TM secondary to fluid in the middle ear. Pneumatic otoscopy has 94% sensitivity and 80% specificity for diagnosing OME. Accuracy of diagnosis with an experienced examiner is between 70% and 79% (1)[C].
- Myringotomy is the gold standard but is not practical for clinical use (2)[C].
- Tympanometry may also be used to support or exclude the diagnosis in infants >4 months old, especially when the presence of middle ear effusion is difficult to determine (1)[C].
- Acoustic reflectometry (64% specificity and 80% sensitivity) may be considered instead of tympanometry (4)[B].
- Audiogram may show mild conductive hearing loss (2)[C].
- Hearing tests are recommended for OME lasting >3 months (1)[C].
- Language testing is recommended for children with abnormal hearing tests (1)[C].

## **TREATMENT**

- OME improves or resolves without medical intervention in most patients within 3 months, especially if secondary to AOM (1)[C].
- Current guidelines support a 3-month period of observation with optional serial exams, tympanometry, and language assessment during that wait time (1,2)[C].
- Adults found to have OME should be screened for an underlying disorder and treated accordingly (2)[C].

## ***MEDICATION***

- The 2004 AAFP/AAOHNS/AAP guideline and a 2012 Cochrane review recommend against routine use of antibiotics in treatment of OME. No long-term benefits of antibiotics have been proven, and often prescribed antibiotics have adverse side effects such as diarrhea, vomiting, rashes, and allergic reactions (1)[C],(5)[A].
- The 2004 AAFP/AAOHNS/AAP and a 2006 Cochrane review found that antihistamines and decongestants have no benefit over placebo in the treatment of OME with possible adverse side effects such as insomnia, hyperactivity, and drowsiness (1)[C],(5)[A].
- The 2004 AAFP/AAOHNS/AAP guideline recommends against administering oral or intranasal corticosteroids. No long-term benefit was shown and adverse side effects such as weight gain and behavioral changes are possible (1)[C].

P.745

- In adults, eustachian tube dysfunction secondary to allergic rhinitis or recent upper respiratory infection can be the cause of OME. It is unknown whether decongestants, antihistamines, or nasal steroids improve outcomes in adults.

## *ISSUES FOR REFERRAL*

The following are indications for referral to a surgeon for evaluation of tympanostomy tube placement (6)[C]:

- Chronic bilateral OME ( $\geq$ 3 months) with hearing difficulty
- Chronic OME with symptoms (e.g., vestibular problems, poor school performance, behavioral issues, ear discomfort, or reduced quality of life)
- At-risk children (speech, language, or learning problems due to baseline sensory, physical, cognitive, or behavioral factors) with chronic OME or type B (flat) tympanogram

## *ADDITIONAL THERAPIES*

- Hearing aids may be an acceptable alternative to surgery (2)[C].
- Autoinflation, which refers to the process of opening the eustachian tube by raising intranasal pressure (e.g., by forced exhalation with closed mouth and nose) may be beneficial in improving patients' tympanogram or audiometry results beyond 1 month (6)[A].

## *SURGERY/OTHER PROCEDURES*

- Tympanostomy tubes are recommended as initial surgery. Risks include purulent otorrhea, myringosclerosis, retraction pockets, and persistent tympanic membrane perforations (1,2)[C].
- Adenoidectomy with myringotomy has similar efficacy to tympanostomy tubes in children  $>4$  years of age but with added surgical and anesthetic risks (1)[C].

- Adenoidectomy should not be performed in children with persistent OME alone unless there is a distinct indication for the procedure for another problem (e.g., adenoiditis/chronic sinusitis/nasal obstruction) (1)[C].
- Adenoidectomy (and concurrent tube placement) may be considered when repeat surgery for OME is necessary (e.g., when effusion recurs after tubes have fallen out or are removed). In these cases, adenoidectomy has been shown to decrease the need for future procedures for OME (1,2)[C].
- Tonsillectomy or myringotomy alone is not recommended for treatment (1)[C].

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Children who are at risk for speech, language, or learning problems and whose OME persists for <sup>3</sup>3 months should undergo hearing evaluation (1)[C].
- Reevaluation and repeat hearing tests should be performed every 3 to 6 months until the effusion has resolved or until the child develops an indication for surgical referral (1)[C].

### PROGNOSIS

Approximately 50% of children >3 years of age have OME resolution within 3 months.

### COMPLICATIONS

- The most significant complication of OME is permanent hearing loss, leading to possible language, speech, and developmental delays.
- Underventilation of the middle ear can cause a cholesteatoma (1)[C].

## Codes

&NA;

### ICD10

- H65.90 Unspecified nonsuppurative otitis media, unspecified ear

- H65.00 Acute serous otitis media, unspecified ear
- H65.20 Chronic serous otitis media, unspecified ear

## Clinical Pearls

### &NA;

- Otitis media with effusion (OME) is defined as the presence of a middle ear effusion in the absence of acute signs of infection.
- In children, OME most often arises following an acute otitis media. In adults, it often occurs in association with eustachian tube dysfunction.
- The primary standard for diagnosis is pneumatic otoscopy.
- There is no benefit to the routine use of antibiotics, antihistamines, decongestants, or corticosteroids for the treatment of OME in children.
- Management includes watchful waiting and surgery (when indicated); which strategy is chosen depends on many factors, including the risk/presence of any associated speech, language, or learning delays and on the severity of any associated hearing loss.

# Ovarian Cancer

Celeste Straight, MD

Susan Zweizig, MD

## BASICS

There are >22,000 new cases of ovarian cancer annually, and >15,000 women will die of their disease, making this the most lethal of gynecologic cancers.

## DESCRIPTION

Malignancy that arises from the epithelium (90%), stroma, or germ cells of the ovary; also, tumors metastatic to the ovary; histologic types include the following:

- Epithelial
  - Serous (tubal epithelium)
  - Mucinous (cervical and GI mucinous epithelium)
  - Endometrioid (endometrial epithelium)
  - Clear cell (mesonephroid)
  - Brenner (transitional cell epithelium)
  - Carcinosarcoma
- Stromal
  - Granulosa cell tumor
  - Theca cell tumor
  - Sertoli-Leydig cell tumors
  - Gynandroblastoma
  - Lipid cell tumor
- Germ cell
  - Teratoma (immature)
  - Dysgerminoma

- Embryonal carcinoma
- Gonadoblastoma
- Endodermal sinus tumor
- Embryonal carcinoma
- Choriocarcinoma
- Metastatic disease from the following:
  - Breast
  - Endometrium
  - Lymphoma
  - GI tract (Krukenberg tumor)
  - Primary peritoneal
- System(s) affected: GI, reproductive, endocrine, metabolic

## *EPIDEMIOLOGY*

### *Incidence*

- 21,990 new cases/year in the United States; 15,460 deaths/year
- Leading cause of gynecologic cancer death in women; mortality from ovarian cancer has decreased only slightly during the past 4 decades (1)[A].
- 75% diagnosed at advanced stage
- Predominant age
  - Epithelial: mid-50s
  - Germ cell malignancies: usually observed in patients <20 years of age

### *Prevalence*

Lifetime risk for general population: 1 in 70 women develop ovarian cancer.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Malignant transformation of the ovarian epithelium from repeated trauma during ovulation may lead to this change. Many of these cancers originate in the distal fallopian tube.
- Most ovarian cancer (75%) presents as advanced disease. Metastatic disease may develop at

the same time as the primary tumor (1).

## Genetics

- Hereditary breast/ovarian cancer syndrome: earlyonset breast or ovarian cancer, autosomal dominant transmission, usually associated with *BRCA-1* or *BRCA-2* mutation
- Lynch II syndrome: autosomal dominant inheritance; increased risk for colorectal, endometrial, stomach, small bowel, breast, pancreas, and ovarian cancers; defect in mismatch repair genes

## RISK FACTORS

- 90% of ovarian cancer is sporadic and not inherited, but family history is the most significant risk factor. Multiple relatives with breast or ovarian cancer increases risk: Refer these patients for genetic counseling. Individuals in families with familial cancer syndromes have 20-60% risk of developing ovarian cancer.
- Nulligravidity (or infertility), early menarche, late menopause, endometriosis
- Environmental (talc, smoking, obesity)

## GENERAL PREVENTION

For epithelial cancer, frequency of ovulation appears to be important. The following factors are protective (1)[A]:

- Use of oral contraceptives: 5 years of use decreases risk by 20%; 15 years by 50%.
  - The progestin component of oral contraceptive preparations (OCPs) may protect against ovarian cancer by regulating apoptosis of the ovarian epithelium (2)[A].
- Multiparity
- Breastfeeding
- Tubal ligation or hysterectomy
- Recent studies have shown no clear association exists between ovarian cancer and use of ovulationinduction agents such as clomiphene, but more long-term studies are necessary.
- NSAIDs and acetaminophen use have been shown to reduce risk of ovarian cancer.
- Recommendations for high-risk (family history of a hereditary ovarian cancer syndrome) population
  - Women should undergo pelvic examinations, CA-125 level measurement, and transvaginal US every 6 to 12 months beginning at age 25 to 35 years.
  - Women with family histories of ovarian cancer or premenopausal breast cancer should be

referred for genetic counseling.

- Prophylactic oophorectomy is advised for mutation carriers after childbearing is completed or by age 35 years.
  - Risk of primary peritoneal carcinoma is 1% after prophylactic oophorectomy.
- Screening: No effective screening exists for ovarian cancer (1)[A].
  - Routine use of CA-125 and transvaginal US for screening in women of average risk is discouraged. Annual pelvic examinations are recommended, particularly in postmenopausal women. An adnexal mass in a premenarchal female or a palpable adnexa in a postmenopausal female warrants further evaluation.

## COMMONLY ASSOCIATED CONDITIONS

- Ascites
- Pleural effusion
- Decrease of serum albumin
- Breast carcinoma
- Bowel obstruction
- Carcinomatosis

## DIAGNOSIS

### HISTORY

- Bloating
- Early satiety, anorexia, dyspepsia
- Sense of abdominal fullness, increased abdominal size
- Abdominopelvic pain or cramping
- Urinary frequency or urgency in absence of infection
- Fatigue
- Dyspareunia
- Weight loss
- Severe pain secondary to ovarian rupture or torsion; most frequent in germ cell tumors
- Precocious puberty (choriocarcinoma, embryonal carcinoma) (3)[B]

## *PHYSICAL EXAM*

- Ascites
- Cul-de-sac and/or pelvic nodularity
- Pelvic mass
- Pleural effusion
- Omental mass
- Cachexia
- Adenopathy
- Hirsutism in androgen-secreting germ cell tumors

## *DIFFERENTIAL DIAGNOSIS*

- GI, fallopian, or endometrial malignancies
- Irritable bowel syndrome
- Colitis
- Hepatic failure with ascites
- Diverticulitis
- Pelvic kidney
- Tubo-ovarian abscess or hydrosalpinx
- Uterine fibroids
- Endometriomas
- Physiologic cysts
- Benign or borderline neoplasms

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Obtain only with confirmed or suspected disease.
- CA-125 (not specific for ovarian cancer, not to be used for screening)
- Liver function tests (LFTs) to rule out hepatic disease
- CBC

- Urinalysis
- Serum albumin
- Carcinoembryonic antigen (CEA) if GI primary suspected
- If nonepithelial tumor suspected: chorionic gonadotropin ( $\beta$ -hCG [dysgerminoma, choriocarcinoma, embryonal carcinoma]),  $\alpha$ -fetoprotein (endodermal sinus tumor, embryonal carcinoma), lactate dehydrogenase (LDH [dysgerminoma]), or inhibin (granulosa cell tumor)
- Pelvic US
- CXR
- Abdominopelvic CT scan with contrast material

## Follow-Up Tests & Special Considerations

Disorders that may alter lab results: CA-125 may be elevated from gynecologic causes (e.g., menses, pregnancy, endometriosis, peritonitis, myomas, pelvic inflammatory disease) and with ascites, pleural effusion, congestive heart failure (CHF), pancreatitis, systemic lupus erythematosus (SLE), or liver disease.

- Patients with ovarian cancer need current mammography.
- Barium enema or colonoscopy if a colon primary is suspected

## Diagnostic Procedures/Other

- Endometrial biopsy if abnormal bleeding present
- Surgery is necessary for definitive diagnosis.
- Paracentesis if patient with symptomatic ascites and not an operative candidate

## Test Interpretation

Epithelial ovarian cancer commonly involves the peritoneal surfaces of the abdomen and pelvis, especially the cul-de-sac, paracolic gutters, and diaphragmatic surfaces.

## TREATMENT

## MEDICATION

## *First Line*

- After surgery, most patients will require chemotherapy or adjuvant therapy. Stage 1a, grade 1 and most stage 1b, grade 1 tumors do not require adjuvant therapy. Patients with clear cell carcinomas, grade 3 tumors, or tumors staged 1c or worse do require adjuvant therapy. Patients should be encouraged to participate in clinical trials whenever possible.
- Paclitaxel (Taxol) or docetaxel are recommended in combination with platinum-based therapy (carboplatin or cisplatin) as the first-line treatment of epithelial ovarian cancer.
- Intraperitoneal (IP) chemotherapy in combination with IV chemotherapy improves survival in advanced ovarian cancer. IP chemotherapy is associated with more toxicity (4)[A].
- Germ cell cancers: bleomycin, etoposide, platinum agent
- Contraindications: poor functional status, excessive toxicity, hypersensitivity
- Precautions: All regimens cause bone marrow suppression. Cisplatin is associated with ototoxicity, renal toxicity, and peripheral neuropathy. Taxol can cause neutropenia and neuropathy.
- Antiemetic: ondansetron (Zofran), dronabinol (Marinol), metoclopramide (Reglan), prochlorperazine (Compazine), promethazine (Phenergan)

## *Second Line*

- Liposomal doxorubicin
- Carboplatin/gemcitabine
- Topotecan
- Etoposide
- Bevacizumab
- Cyclophosphamide
- Tamoxifen may be used in recurrent disease when chemotherapy is not appropriate (5)[A].

## **ADDITIONAL THERAPIES**

Some patients with advanced disease and poor functional status and/or extreme tumor burden are managed with preoperative chemotherapy (neoadjuvant treatment) followed by interval cytoreductive surgery. These patients receive more chemotherapy after tumor debulking.

## **SURGERY/OTHER PROCEDURES**

- Surgical exploration with staging and debulking is critical. Maximal cytoreduction of tumor

burden enhances effectiveness of adjuvant therapy and is associated with longer survival.

- For epithelial malignancies, careful staging, tumor excision/debulking includes the following:
  - Cytologic evaluation of peritoneal fluid (or washings from peritoneal lavage)
  - Bilateral salpingo-oophorectomy with hysterectomy and tumor reductive surgery
  - Excision of omentum
  - Inspection and palpation of peritoneal surfaces
  - Cytologic smear of right hemidiaphragmatic surface
  - Biopsy of adhesions or any suspicious areas
  - Biopsy of paracolic recesses, pelvic sidewalls, posterior cul-de-sac, and bladder peritoneum
  - Pelvic and para-aortic lymph node biopsies
- Germ cell cancers (less likely to be bilateral): salpingo-oophorectomy (unilateral if only one ovary involved) in young patient

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Physical exam every 3 months for the first 2 years after diagnosis; every 6 months until 5 years and then annually thereafter
- If CA-125 elevated at diagnosis, follow levels after treatment to detect recurrence (is often elevated 2 to 5 months before clinical detection of relapse).
- Germ cell/sex-cord stromal cancer: physical exam and tumor markers every 3 months for the first 2 years after diagnosis
  - Tumor markers for sex-cord stromal cancers should be checked every 6 months for 10 years, as recurrences can occur remote from initial diagnosis.
- CT scan of chest, abdomen, and pelvis and/or PET scan when recurrence suspected
- Screening with CXR, MRI, CT, or PET not recommended; insufficient data to support (6)[B]

### *PROGNOSIS*

- Recurrence rates

- Early-stage disease: 25%
- Advanced disease: >80%
- 5-year survival rates for ovarian cancer based on International Federation of Gynecology and Obstetrics (FIGO) data
- For most recent FIGO staging criteria, see "References" (7)[A].

Stage I     a 90%    b 86%    c 83%

Stage II    a 71%    b 66%    c 71%

Stage III   a 47%    b 42%    c 33%

Stage IV    19%      Ñ        Ñ

## COMPLICATIONS

- Pleural effusion
- Pseudomyxoma peritonei
- Ascites
- Toxicity of chemotherapy
- Bowel obstruction
- Malnutrition
- Electrolyte disturbances
- Fistula formation

## Codes

&NA;

### ICD10

- C56.9 Malignant neoplasm of unspecified ovary
- C56.1 Malignant neoplasm of right ovary
- C56.2 Malignant neoplasm of left ovary

## Clinical Pearls

&NA;

- Family history of ovarian cancer or early-onset breast cancer is the most significant risk factor for the development of ovarian cancer; yet, the vast majority of cases remain sporadic.

- The diagnosis of ovarian cancer should be suspected in women with persistent bloating, upper abdominal discomfort, or GI symptoms of unknown etiology.
- Surgery is the mainstay of diagnosis and treatment for ovarian cancer. Many patients benefit from adjuvant chemotherapy.
- The prognosis of advanced ovarian cancer is poor and requires close follow-up by physical exam, tumor markers, and imaging when indicated.

# Ovarian Cyst, Ruptured

Heather O'Connor Greer, MD

Patricia Beauzile, MD

## BASICS

- Ovarian cysts are frequent in reproductive-aged women.
- Most ovarian cysts are benign physiologic follicles created by the ovary at the time of ovulation.
- Ovarian cysts can cause symptoms when they become enlarged and exert a mass effect on surrounding structures, or when they rupture and the cyst contents cause irritation of the peritoneum or nearby pelvic organs.
- Patients with a symptomatic ruptured cyst will usually complain of acute onset unilateral lower abdominal pain.
- Evaluation of the patient should include exclusion of ectopic pregnancy, ovarian torsion, and nongynecologic sources of acute unilateral lower abdominal pain.
- Once the diagnosis of a ruptured cyst is confirmed, most patients can be managed conservatively as outpatients with adequate pain control. Surgical intervention is rarely indicated.

## DESCRIPTION

A suspected ruptured ovarian cyst should be treated as an unknown adnexal mass (mass of the ovary, fallopian tube, and surrounding tissue) until proven otherwise.

## EPIDEMIOLOGY

- The actual incidence of ovarian cysts is difficult to calculate as many ruptured cysts are asymptomatic or found incidentally.
- Ovarian cysts can be seen on transvaginal ultrasounds in nearly all premenopausal women and in up to 18% of postmenopausal women. The vast majority of these cysts are benign or functional.
- Most ruptured ovarian cysts are self-limiting, and expectant management with pain control is usually sufficient.

- About 13% of ovarian masses in reproductive-aged women are malignant, as opposed to 45% in postmenopausal women.

## **RISK FACTORS**

As benign physiologic cysts are a result of ovulation; medications or conditions associated with increased ovulation increase risk of cyst rupture. Examples include:

- Ovulation induction agents (i.e., Clomid, aromatase inhibitors, GnRH agonists)
- Tamoxifen increases the risk of ovarian cysts in reproductive-aged women.
- Rare risk factors for increased ovarian cyst formation include fibrous dysplasia/McCune-Albright syndrome.

## **GENERAL PREVENTION**

Ovulation suppression with combined oral contraceptives is the mainstay therapy for prevention of recurrent ovarian cysts.

## **DIAGNOSIS**

- When a ruptured ovarian cyst is suspected, a pregnancy test should be performed to rule out an ectopic pregnancy.
- Ultrasound imaging is standard for determining whether or not a patient with a ruptured cyst can be managed conservatively, or immediate intervention is indicated. Hemoperitoneum or hemodynamic instability is an indication for emergent intervention (1)[B].
- Sonographic imaging can also determine the characteristics of the cysts and can aid in separating malignant versus benign etiologies.
- Additionally, ultrasound is useful in confirming normal Doppler flow to affected ovary.

## **HISTORY**

- A general past medical and surgical history should be reviewed.
- Specific questions that should be addressed if you suspect a ruptured cyst include:
  - Onset and characteristics of pain
  - Pain associated with sexual intercourse or strenuous activity
  - Date of last menstrual period
  - Vaginal bleeding
  - Nausea or vomiting

- Shoulder pain
- Symptoms of circulatory collapse, including palpitation, shortness of breath, sensation of being hot or clammy, dizziness
- Additional information that will guide diagnosis should include patient age, symptom onset, particularly in relation to menstrual cycle, anatomic location, and imaging studies.

## **ALERT**

Patients with bleeding diathesis or undergoing anticoagulation therapy may experience significant bleeding from hemorrhagic cysts.

## *PHYSICAL EXAM*

- Vital signs are usually normal unless significant blood loss has occurred.
- Rupture characterized by significant blood loss may be present in the form of pallor, pale mucosal membranes, and tachycardia.
- Patient will have significant tenderness to palpation or an acute abdomen if the peritoneum is irritated or inflamed.
- On some occasions, a palpable adnexal mass can be felt on bimanual exam. Care should be taken not to cause further injury with a forceful exam.

## *DIFFERENTIAL DIAGNOSIS*

Should include all causes of acute abdominal pain, both gynecologic and nongynecologic

## **ALERT**

- Ectopic pregnancy should always be excluded with a negative pregnancy test.
- Benign nongynecologic causes of acute lower abdominal pain include:
  - Appendicitis
  - Diverticulitis
  - Infections of the urinary tract
  - Renal colic
- Malignant nongynecologic causes of acute lower abdominal pain can be attributed to neoplastic processes of the lower GI tract.
- Benign gynecologic etiologies include:
  - Functional ovarian cysts
  - Ovarian torsion

- Ectopic pregnancy
  - Tubo-ovarian abscess
  - Teratomas
  - Fibroids
  - Endometrioma
  - Cystadenoma (mucinous or serous)
  - Hydrosalpinx
- Malignant gynecologic etiologies can usually be attributed to the various gynecologic cancers of the reproductive tract.

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Urinalysis, STD testing, and a complete blood count should be obtained to evaluate for infectious causes, PID, or symptomatic renal stones. There are no laboratory tests that can definitively diagnose ovarian cyst rupture (2)[C].
- A type and screen is indicated if surgical intervention is planned or blood products are being considered.
- Transvaginal ultrasound is helpful in determining the presence of an ovarian mass, its characteristics, and the presence of intraperitoneal fluid (1)[A].
- CT, MRI, or PET imaging are not indicated for initial evaluation; however, these modalities are useful if malignancy is suspected (1)[A].

## **TREATMENT**

### **GENERAL MEASURES**

- Cyst rupture in a stable healthy patient can be managed conservatively with analgesia, bleeding and symptoms precautions, and outpatient follow-up (1)[A].

P.749

- For many patients, pain associated with a ruptured cyst will be transient and self-limiting.
- Scheduled NSAIDs or oral narcotics can be prescribed depending on pain severity.
- Unstable patients with hemodynamic compromise or patients with significant intraperitoneal fluid should be resuscitated, and laparoscopy or a laparotomy should be considered. Surgical exploration should also be considered if there is a concern for malignancy.

## *ISSUES FOR REFERRAL*

- OB-GYN
  - Consider referral to an obstetrician if an adnexal mass is diagnosed during pregnancy. Such masses have a low risk of malignancy or acute complication for the pregnancy.
- GYNECOLOGIC ONCOLOGY
  - Referral to a gynecologic oncologist should be considered for complex adnexal masses with an elevated CA125 and associated symptoms concerning for malignancy such as ascites, early satiety, pleural effusion, enlarging abdominal mass, or bowel obstruction.
- GENERAL SURGERY
  - Acute lower abdominal pain that is nongynecologic and suspicious for bowel involvement should be referred to general surgery or a gastroenterologist.

## *SURGERY/OTHER PROCEDURES*

- Although the need for surgical intervention is rare, it is usually of an emergent nature.
- In most cases, laparoscopy will be sufficient to evaluate intra-abdominal bleeding. The decision to proceed with cystectomy or oophorectomy should be made intraoperatively after a thorough evaluation of the intra-abdominal environment has been completed.
- The advantages of a laparoscopic approach include a shorter length of stay, and most patients can be discharged home the same day. Postoperative recovery time as well as patient satisfaction is significantly improved with a minimally invasive approach.
- Laparotomy should be performed in cases of critical hemodynamic instability or lack of laparoscopically trained surgeons. If there is concern for malignancy or metastases, laparotomy may be the preferred method of surgery.

## *INPATIENT CONSIDERATIONS*

Patients who require inpatient management should be managed with serial abdominal exams, analgesia, and intravenous resuscitation as indicated by their initial presentation.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

- Follow up for patients managed conservatively should be scheduled 1 to 2 weeks from the initial onset of symptoms. Patients should present sooner for new or worsening symptoms.

- Patients with complete resolution of symptoms within a few days can follow-up as needed. However, these patients should be counseled on ovarian cysts and options for prevention.
- Patient in whom surgical intervention was indicated, postop follow-up should be scheduled 2 weeks from the date of surgery.
- Patients in whom an ovarian cyst was diagnosed incidentally should follow-up based on the size of their cyst.
- Simple cysts up to 10 cm in diameter on ultrasound findings are almost always benign and may safely be followed without intervention in pre- and postmenopausal patients. These patients should also be referred to a gynecologist (3)[B].

### *Pregnancy Considerations*

Adnexal masses in pregnancy have a low risk of malignancy or acute complications to the pregnancy, so in most cases, they can be managed expectantly (1)[C].

## **PATIENT EDUCATION**

Reassurance of the benign nature of most ovarian cysts is an important cornerstone of patient education.

## Codes

&NA;

### ICD10

- N83.20 Unspecified ovarian cysts
- N83.0 Follicular cyst of ovary
- N83.1 Corpus luteum cyst

## Clinical Pearls

&NA;

- Functional ovarian cysts are very common in reproductive-age women and are usually self-limiting.
- Always exclude ectopic pregnancy.
- Management of symptomatic ruptured cysts is usually accomplished with outpatient pain control with follow-up.
- In cases where the patient with a ruptured cyst is unstable or presents with signs of an acute abdomen, surgical intervention is indicated.

# Ovarian Tumor (Benign)

Kristin D'Orsi, DO

Mark J. Manning, DO, MsMEL

## BASICS

### DESCRIPTION

- The ovaries are a source of many tumor types (benign, malignant, low malignant potential) because of the histologic variety of their constituent cells.
- Benign ovarian tumors create difficulties in differential diagnosis because of the need to identify malignancy and discriminate tumor from cysts, infectious lesions, ectopic pregnancy, and endometriomas.
- Tumors are often clinically silent until well developed; may be solid, cystic, or mixed; and they may be functional (producing sex steroids as with arrhenoblastomas and gynandroblastomas) or nonfunctional.
- System(s) affected: endocrine/metabolic, reproductive

### *Geriatric Considerations*

Because incidence of malignancy increases with age, postmenopausal patients warrant comprehensive evaluation and follow-up.

### *Pediatric Considerations*

Malignancy must be ruled out in premenarchal patients. Early neonatal cysts are rare.

## EPIDEMIOLOGY

### *Incidence*

- 30% of regularly cycling females
- 50% of women without regular cycles
- Predominant age: Premenarchal girls have a 6-11% risk of cancer in an ovarian tumor, and postmenopausal women have a 29-35% risk. A high percentage of ovarian tumors are malignant in girls <15 years of age.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Endometriosis with localized, repeated ovarian hemorrhage
- Physiologic cysts
- Tumorigenesis, with genetics as yet poorly defined

## RISK FACTORS

- Cigarette smoking doubles the relative risk for developing functional ovarian cysts.
- Possible contributory factors are early menarche, obesity, infertility, and hypothyroidism.
- Tamoxifen increases risk of ovarian cyst formation (15-30%) (1).
- Risks for ovarian cancer include age >60 years; early menarche; late menopause; nulligravidity; infertility; endometriosis; polycystic ovarian syndrome; family history of ovarian, breast, or colon cancer; a personal history of breast/colon cancer; or *BRCA* mutation.
- Risk for ovarian cancer is decreased in women who have used oral contraceptive pills (OCPs), are multiparous, have a history of a tubal ligation, or who have breastfed.

## GENERAL PREVENTION

- OCPs do not appear to increase rates of cyst resolution, they do decrease the risk for forming new ovarian cysts (1).
- Resection of benign cysts has no impact on future risk for ovarian cancer.
- A case-control study of 299 women found no evidence that ovulation-induction treatment predisposes women to the development of borderline ovarian growths (2).

## DIAGNOSIS

- A careful history is important.
- Usually asymptomatic
- Pain is related to torsion, endometriosis, or rupture.

## HISTORY

- Early satiety
- Dyspepsia/bloating
- Increased abdominal girth
- Bowel pressure or bladder pressure sensations

- Menstrual irregularities
- Dyspareunia
- Hormonal status (OCPs, hormone replacement therapy [HRT] or fertility drugs)

## *PHYSICAL EXAM*

- Severe acne
- Examine lymph nodes for enlargement.
- Chest auscultation can reveal a pleural effusion.
- Abdominal exam may identify ascites, masses, or increased abdominal girth.
- Hirsutism/sexual precocity
- Pelvic exam
- Rectovaginal exam
- Virilization

## *DIFFERENTIAL DIAGNOSIS*

- Ovarian malignancies
- Ovarian tumor of low malignant potential (Borderline tumor)
- Endometrioma
- Serous cystadenoma
- Mucinous cystadenoma
- Teratoma
- Hemorrhagic cyst
- Granulosa cell tumor
- Theca Lutein cyst
- Diverticulitis/bowel abscess
- Pelvic inflammatory disease (PID) with tubo-ovarian abscess
- Ectopic pregnancy
- Hydrosalpinx
- Paraovarian cyst

- Peritoneal inclusion cysts
- Functional cysts (follicular and corpus luteum cysts)
- Polycystic ovaries
- Ovarian fibroma
- Neoplasm metastatic to ovary

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Serum  $\beta$ -human chorionic gonadotropin ( $\beta$ -hCG)
- CBC for WBCs is helpful if PID or ovarian torsion is suspected.
- Urinalysis
- Serum estrogens and androgens if signs of androgen excess (although only as part of polycystic ovarian [PCO] workup)
- Serum tumor markers may be considered but often confuse rather than help to resolve diagnosis; choose carefully (3)[B].
  - CA-125 should not be ordered in a premenopausal patient for screening purposes. If an ovarian tumor in a premenopausal patient is highly suspicious for cancer by ultrasound, a CA-125 level  $>200$  U is concerning. In a postmenopausal patient, cancer must be ruled out and a CA-125  $>35$  U is concerning (value is lab dependent) (4)[B].
  - $\alpha$ -Fetoprotein and hCG can be ordered for suspected germ cell tumor.
  - Inhibin A and Inhibin B for suspected granulosa cell tumor
  - Lactate dehydrogenase (LDH) and  $\alpha$ -fetoprotein (AFP) for suspected germ cell tumors
- Human epididymis protein 4 (HE4) may offer superior specificity compared to CA-125 for the differentiation of benign and malignant adnexal masses in premenopausal women (2)[B].
- Disorders that may alter lab results are the following:
  - CA-125: endometriosis, peritonitis, PID, Meigs syndrome, uterine fibroids, hepatitis, pancreatitis, systemic lupus erythematosus (SLE), diverticulitis
  - $\beta$ -hCG: pregnancy, hydatidiform mole
  - $\alpha$ -Fetoprotein: hepatocellular carcinoma, hepatic cirrhosis, acute/chronic hepatitis
- Transvaginal ultrasound is the best means to determine the architecture of an ovarian cyst or mass (5)[B].

- Transvaginal ultrasonography may differentiate tumors from other pelvic lesions and identify features that place the patient at greater risk for malignancy (e.g., solid component; papillations; multiple septations; ascites, bilaterality, fixed and irregular, rapidly enlarging, accompanied by cul-de-sac nodules).
- Transabdominal ultrasonography can help identify ascites.
- MRI can be helpful in better defining masses in women with low risk of ovarian cancer but who have an indeterminate mass on ultrasound. Usually not necessary, as decision for surgery can proceed without MRI if indicated; can add greatly to cost of care.
- Abdominopelvic CT scan with contrast material, if MRI is unavailable, although ultrasound still far superior (6)
- Mathematical models and calculators have been created to evaluate the risk of malignancy of ovarian tumors (7)[A].

### *Diagnostic Procedures/Other*

- Exploratory laparoscopy or laparotomy
- Aspiration of cyst fluid (contraindicated in postmenopausal women)

### *Test Interpretation*

- Ultrasound findings should include size and consistency of the mass such as cystic, solid, or mixed and if unilateral or bilateral.
- Thin-walled sonolucent, unilocular cysts with regular borders are most likely benign.
- Septations, mural nodules, papillary excrescences, or ascites are concerning for malignant etiology.
- Endometriomas (extrauterine endometrial tissue) are often homogeneous appearing cysts with low level echoes.
- Cystic teratomas (dermoid cysts) are often hypoechoic with multiple small homogenous interfaces.
- Follicular cysts are the most common ovarian cysts in the premenopausal nonpregnant female.

### *Pregnancy Considerations*

- Most cysts discovered during pregnancy are corpus luteum/follicular cysts.
- The two most commonly encountered tumors during pregnancy are cystadenomas (serous/mucinous) and dermoid cysts.

## TREATMENT

### GENERAL MEASURES

- In premenopausal patients cystic lesions <10 cm in diameter, simple observation for 4 to 6 weeks is acceptable.
- Premenopausal women should have a repeat ultrasound ideally during their follicular phase (day 3 to 10 of cycle) (8)[C].
- In premenopausal patients, simple and hemorrhagic cysts <3 cm are not suspicious and do not likely need follow-up (8)[C].
- If a large cyst remains unchanged after 4 to 6 weeks of observation, then surgical exploration is indicated.
- In postmenopausal patients cysts <1 cm are likely benign (8)[C].

### MEDICATION

#### *First Line*

- NSAIDs or opioids may be helpful for discomfort.
- Oral contraceptives do not hasten the resolution of functional ovarian cysts. Most cysts resolve without treatment within a few cycles (9)[B].

### SURGERY/OTHER PROCEDURES

- Cystectomy/wedge resection for cyst with benign features
- Surgical removal of tumor to establish diagnosis when:
  - Premenopausal cysts >5 cm that persist >12 weeks
  - Mass is solid.
  - Mass is >10 cm.
  - Mass in a premenarchal/postmenopausal female
  - Suspicion of torsion/rupture
  - Postmenopausal cysts
  - Cysts with worrisome features on ultrasound (e.g., papillations, septations)
  - For masses that are worrisome for cancer, consider referral to a gynecologist/oncologist for

initial surgery.

- Bilateral salpingo-oophorectomy may be appropriate in postmenopausal patients to reduce the risk of future pelvic surgery.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Most require only yearly exams.
- Varies by diagnosis

### PATIENT EDUCATION

A variety of excellent patient education materials (e.g., "Ovarian Cyst") can be downloaded from the American Association of Family Physicians and American College of Obstetricians and Gynecologists Internet sites: [http://www.aafp.org/journals/afp.html?cmpid=\\_van\\_188](http://www.aafp.org/journals/afp.html?cmpid=_van_188) and <http://www.acog.org/>.

### PROGNOSIS

Complete cure

### COMPLICATIONS

Complications of untreated dermoid and mucinous cysts may include rupture, torsion, and pseudomyxoma peritonei.

## Codes

**&NA;**

### ICD10

- D27.9 Benign neoplasm of unspecified ovary
- D27.0 Benign neoplasm of right ovary
- D27.1 Benign neoplasm of left ovary

## Clinical Pearls

**&NA;**

- In perimenopausal patients, follicles and simple cysts <3 cm are normal physiologic findings.
- Transvaginal pelvic ultrasound is the imaging test of choice to initially determine the architecture of an ovarian cyst or mass.
- Malignancy must be ruled out in both premenarchal and postmenopausal patients.
- Do not order CA-125 on premenopausal patients with an ovarian mass unless it is highly suspicious for cancer.

# Palliative Care

Erika Oleson, DO, MS

## BASICS

Palliative care is a specialty that focuses on preventing and alleviating suffering of patients (and their families) living with life-limiting illness at any stage of that illness.

## DESCRIPTION

- Palliative care's principal aim is to prevent and alleviate suffering—whether physical (pain, breath-lessness, nausea, etc.), emotional, social, or spiritual regardless of underlying diagnosis.
- The goal of palliative care is to improve or maintain quality of life of both patient and family despite serious illness.
- Palliative care is available for patients with serious, life-limiting illness, at any stage of their disease, with or without concurrent curative care.
- Location of care: Patients and their families may access palliative care services in hospital, rehabilitative or skilled nursing facility, and ambulatory setting.
- Hospice: In the United States, hospice is available for patients whose average life expectancy is 6 months or less and whose principal goal is to stay home (including long-term care or assisted living facility), avoid hospitalizations, and disease-directed care with a curative intent. Unlike regular nursing services in the home, hospice does not require a patient to be homebound and offers backup support for patients 24 hours a day and 7 days per week.

## COMMONLY ASSOCIATED CONDITIONS

Symptoms/syndromes commonly treated in palliative care:

- Pain
  - Chronic pain
  - Headache
  - Neuropathic pain
  - Pain from bone metastases

## Pruritus

- GI symptoms (÷60% incidence)
  - Ascites
  - Anorexia/cachexia
  - Nausea (and vomiting)
    - Think of the underlying etiology and treat accordingly.
      - GI causes: constipation, bowel (full or partial) obstruction, ileus, heart burn, reflux, inflammation
      - Intrathoracic causes: cardiac, effusions (cardiac, pulmonary), mediastinal causes, esophageal
      - Autonomic dysfunction
      - Centrally mediated: intracranial pressure change, inflammation, cerebellar, vestibular, medication or metabolic cause stimulating vomiting center and/or chemoreceptor trigger zone
  - Bowel obstruction
  - Constipation and impaction of stool
  - Diarrhea
  - Dysphagia
  - Mucositis/stomatitis
  - Sialorrhea
- General medical
  - Delirium (40-85%)
- Pulmonary symptoms
  - Cough, chronic
  - Breathlessness or dyspnea (60%): often due to heart failure, COPD, lung cancer, and so forth
- Psychological symptoms
  - Anxiety
  - Depression

- Insomnia
- Skin
  - Decubitus ulcer
  - Pruritus
  - Complex wounds (fungating tumors, etc.)

## DIAGNOSIS

The PEACE tool evaluates the following (1):

- Physical symptoms
- Emotive and cognitive symptoms
- Autonomy and related issues
- Communication: contribution to others and closure of life affairs-related issues
- Economic burden and other practical issues, also transcendent and existential issues

## HISTORY

A comprehensive palliative care assessment includes addressing the following:

- Underlying medical conditions and their associated physical symptoms
- Comprehensive pain and symptom assessment and review of systems (consider use of Edmonton Symptom Assessment Tool)
- Psychological symptom assessment
- Cultural, social, and practical concerns
- Spiritual and existential issues
  - FICA assessment (**F**aith, **I**mportance and influence, **C**ommunity, **A**ddress—how does the patient wish to be addressed?) (2)
  - HOPE (sources of **H**ope/strength/comfort, **O**rganized religion's role, **P**ersonal spirituality and practices, **E**ffects on medical care and end-of-life care) (3)
- Patient's identified presence and sources of suffering: personhood concerns
- Goals of care: including posthospital care, practical needs, hopes, and fears
- Prognosis: including functional status and patient's interest in knowing prognosis

## PHYSICAL EXAM

Comprehensive physician examination is warranted, especially as directed by underlying diagnosis, symptoms, and functional decline.

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

Per diagnosis and symptoms

## TREATMENT

### GENERAL MEASURES

- Targeted interventions to maximize quality of life and minimize symptom burden while taking into consideration the patient's values, goals, fears, and social setting.
- Treatment should involve an interdisciplinary team addressing potential and realized suffering, whether physical, emotional, social, or spiritual.

### MEDICATION

- Attempt to minimize polypharmacy
- Consider trimming medications that offer little improvement in the quality of life.
- Medication should focus on symptom management.
- Continue to use appropriate disease-modifying medications especially if they lessen symptom burden and enhance immediate quality of life.
- Improve compliance by addressing patient/caregiver understanding.

P.753

- *Pain* (4)[A]
  - Use immediate-release opioids PO/IV/SC and titrate to control.
  - Once pain is controlled, convert to long-acting **opioids** with short-acting agents made available as tolerance develops and/or patient develops breakthrough pain.
- Bone pain: NSAIDs added to narcotics are more effective than narcotics alone.

### ALERT

Avoid morphine in patients with renal failure, can induce delirium, hyperalgesia, agitation, and seizures.

- *Vomiting* associated with a particular opioid may be relieved by substitution with an equianalgesic dose of another opioid or a sustained-release formulation (5).
  - Dopamine receptor antagonists (metoclopramide, prochlorperazine, promethazine) are commonly used. Haloperidol may help with nausea.
  - Droperidol: insufficient evidence to advise on the use for the management of nausea and vomiting
- *Constipation*: Consider prophylactic stool softeners (docusate) and stimulants (bisacodyl or senna) or osmotic laxatives (6)[A].

## ALERT

Laxatives should be started when opioid treatment has begun to avoid constipation.

- SC methylnaltrexone is effective in inducing bowel movements without inducing withdrawal with opioid-induced constipation (7)[A].
- *Dyspnea*: Consider oxygen, if congestive heart failure (CHF); diuretics and/or long-acting nitrates, **benzodiazepines**
  - In addition to treating the underlying cause of breathlessness, as the disease advances, low-dose opioids may be beneficial to patients (4,8)[C]. Immediate-release **opioids** PO/IV treat dyspnea effectively and typically at doses lower than necessary for the relief of moderate pain.
- *Delirium*: lowest doses necessary of **benzodiazepines** or **antipsychotics** (haloperidol, etc.)
  - Monitor patient safety and use nonpharmacologic strategies to assist orientation (clocks, calendars, environment, and redirection).
  - Droperidol: When cause of delirium cannot be identified/corrected rapidly, consider neuroleptics (haloperidol or risperidone).
- *Pruritus*: no optimal therapy (9)[A]
- *Anxiety*: insufficient data for recommendations of specific medication, but anxiolytics and/or other agents may be tried (10)[A].
- Megestrol acetate improves appetite and slight weight gain in patients with anorexia-cachexia syndrome (11)[A].

## ISSUES FOR REFERRAL

- Referral to palliative care

- Any patient with a serious, life-limiting illness who could benefit from help with burdensome symptoms or suffering and/or complex goals of care discussion (12)[A].
  - Early referral to palliative care may improve quality of life and longevity for patients with advanced cancer (13)[A].
- Referral to hospice care
    - Any patient with an average life expectancy of 6 months or less. Consider the question, "Would you be surprised if the patient died within the next 6 months?" If the answer is no, they likely meet prognostic criteria for hospice.
      - Consider patients who have multiple hospitalizations and/or emergency department visits in the prior 6 months.
      - Refer to local hospice guidelines for additional disease-specific criteria.

## Codes

&NA;

### ICD10

Z51.5 Encounter for palliative care

## Clinical Pearls

&NA;

- Early referral to palliative care may help enhance the quality of life and potential longevity of patients living with serious illness.
- Bone pain: NSAIDs added to narcotics are more effective than narcotics alone.
- Laxatives should be started when opioid treatment has begun to avoid constipation.

# Pancreatic Cancer

Alma M. Guerrero, MD

Edward Feller, MD, FACP, FACG

## BASICS

### DESCRIPTION

- Adenocarcinoma of the exocrine pancreas (85% of pancreatic cancers) is the fourth most common cause of cancer death in the United States (1).
- Rarely curable: overall 5-year relative survival rate of 6.7%
- 60-70% occurs in the head, 20% in the body and tail, 20% diffusely involve the gland.
- As few as 10% are localized at diagnosis. For localized, small cancers (<2 cm) with no lymph node metastases and no extension beyond the capsule, surgical resection has 5-year survival of about 25%.
- Majority of tumors have metastasized at diagnosis and are thus, largely incurable and have a 5-year survival rate of 2-3%.
- In apparently resectable disease, 20-40% have unresectable lesions at surgery.
- Ampullary, duodenal, or distal bile duct tumors may mimic pancreatic carcinoma and are more likely to be resectable and curable.
- For advanced or unresectable cancers, survival is <1% at 5 years; most patients die within 1 year.

### EPIDEMIOLOGY

During 2003 to 2007, median age at diagnosis = 72 years; rare <45 years; after 45 years of age, occurrence rises (2).

#### *Incidence*

- An estimated 46,000 people diagnosed in 2014; 40,000 deaths (3)[A].
- More common in black and white races, 16.7 and 10.3 in 100,000 men and 14.4 and 10.3 in 100,000 women, respectively. Among Hispanic and Asian/Pacific Islanders, there is an incidence of 10.9 and 8.3 in 100,000 men and 10.1 and 8.3 in 100,000 women, respectively.

## Prevalence

In 2008, in the United States,  $\approx$  34,600 men and women (16,811 men and 17,846 women) were alive who had a history of pancreatic cancer.

## RISK FACTORS

- Smoking: relative risk (RR) = 2 to 3; correlates with amount smoked
- Diabetes: RR = 2.1 (95% CI [1.6, 2.8]); 1 in 6 become diabetic within 6 months before diagnosis
- Prior partial gastrectomy or cholecystectomy: 2- to 5-fold increased risk 15 to 20 years after gastrectomy
- Familial aggregation/genetic factors: 5-10% of patients have a first-degree relative with the disease, which confers a 9-fold increase in risk versus the general population; subgroup may carry germline mutations of DNA repair genes (*BRCA2*).
- Hereditary chronic pancreatitis (autosomal dominant, highly penetrant): cumulative risk by ages 50 and 75 years is 10% and 54%, respectively.
- Peutz-Jeghers syndrome: RR 30 to 40
- Sporadic chronic pancreatitis
- Non-O blood type: RR 1 to 2
- High intake of dietary fat and obesity
- Alcohol: Recent data indicate a modest increase in risk confined to heavy alcohol consumers.
- Coffee intake and NSAID use *NOT* regarded as risk factors.

## GENERAL PREVENTION

No effective screening modality exists to detect early cancer. Even with a strong family history or predisposition syndromes, use and cost-effectiveness of screening are unclear.

## COMMONLY ASSOCIATED CONDITIONS

- Chronic pancreatitis, diabetes mellitus, cystic fibrosis (4)
- Subsets of familial pancreatic cancer involve germline cationic trypsinogen or *PRSS1* mutations (hereditary pancreatitis), *BRCA2* mutations (usually with hereditary breast-ovarian cancer syndrome), *CDKN2* mutations (familial atypical mole, multiple melanoma), or DNA repair gene mutations (e.g., *ATM* and *PALB2*, apart from *BRCA2*).
- Majority of familial pancreatic cancers have no genetic underpinnings.

- Precursor lesions are potentially curable—pancreatic intraepithelial neoplasia, intraductal papillary mucinous neoplasia, and mucinous cystic neoplasms.

## DIAGNOSIS

### HISTORY

- Depends on tumor location; majority become symptomatic late in disease. Most pancreatic cancers develop in the pancreatic head and block the periampullary bile duct, causing obstructive jaundice.
- Weight loss 90%; pain 75% (progressive midepigastriac dull ache that often radiates to the back); malnutrition 75%; jaundice 70%; anorexia 60%; pruritus 40%; diabetes mellitus 15%; weakness, fatigue, malaise 30-40%; alcoholic stools, dark urine, steatorrhea; depression is common.
- Pancreatic cancer is a consideration in acute pancreatitis in the elderly and with new-onset diabetes, but most new-onset diabetes is not associated with cancer; thus, evaluation for cancer is warranted only in selected cases.
- Uncommon: unexplained thrombophlebitis; acute pancreatitis from tumor obstruction of pancreatic duct; duodenal obstruction or GI bleeding

### PHYSICAL EXAM

- Muscle wasting and malnutrition are common; skin lesions are indicative of pruritus. Exam can be normal.
- Palpable abdominal mass or ascites in 20%
- Jaundice: 70% if tumor obstructs bile duct; 10% with body or tail carcinoma
- Courvoisier sign (painless jaundice with a palpable gallbladder): uncommon; usually associated with pancreatic head tumors, periampullary or primary bile duct tumors; hepatomegaly in advanced disease
- Virchow node (left supraclavicular) and Sister Mary Joseph node (umbilical) in metastatic disease; palpable rectal shelf (nonspecific sign of carcinomatosis)
- Migratory thrombophlebitis (Trousseau sign) (uncommon) due to hypercoagulability in mucinproducing pancreatic cancer
- GI bleeding from tumor erosion into adjacent viscera (colon); portal hypertension-related bleeding (uncommon)
- Pancreatic panniculitis: subcutaneous areas of nodular fat necrosis

## *DIFFERENTIAL DIAGNOSIS*

- Chronic pancreatitis, duodenal cancer, cholangiocarcinoma, lymphoma, islet cell tumor, sarcoma, cystic neoplasms, tumor metastatic to pancreas (rare)
- Nonmalignant conditions: choledocholithiasis, acute or chronic pancreatitis, biliary tract stricture, adenoma; chronic mesenteric ischemia
- Tuberculosis or fungal abscess in AIDS
- Patients may present with back pain mimicking musculoskeletal disease.

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Cross-sectional imaging (usually CT scan as first-line choice) to evaluate symptoms or abnormal lab results
- Endoscopic ultrasound-guided biopsy: best modality for tissue diagnosis; sensitivity 75-90%; specificity  $\div$  100% for diagnosis of a mass
- Routine laboratory tests may reveal elevated serum bilirubin and alkaline phosphatase (cholestasis), anemia, or decreased serum albumin (malnutrition).

### *Initial Tests (lab, imaging)*

- Most patients do not require measurement of serum tumor markers (CA19-9) for diagnosis or management. Some evidence suggests use in predicting outcome and response to adjuvant chemotherapy.
- CEA and CA19-9 are not recommended as screening tests; useful in following patients with known disease (3)[A]
- Elevated CA19-9 antigen: 80% sensitivity; 90% specificity; individuals with Lewis-negative blood group antigen phenotype (5-10%) are unable to synthesize CA19-9; elevations can occur in benign pancreatic or biliary diseases and in nonpancreatic malignancy.

### *Follow-Up Tests & Special Considerations*

- During therapy, increase in CA19-9 may identify progressive tumor growth. Normal CA19-9 does not exclude recurrence.
- CT scan (pancreatic protocol) using thin section, multiphase multidetector helical CT with a pancreatic protocol is the choice for diagnosis and staging: 85-90% sensitivity; 90-95% specificity; useful for evaluation of distant metastasis and prediction of resectability.
- Abdominal ultrasound: common initial test to assess jaundice and duct dilatation; less sensitive than CT for pancreatic masses

- Endoscopic ultrasound (EUS) is accurate for tissue biopsy, local tumor and node staging, predicting vascular invasion (90% specificity; 73% sensitivity), and when no mass is identified on CT.
- Endoscopic retrograde cholangiopancreatography (ERCP): 90% sensitivity; 95% specificity for ductal cancer; useful if endoscopic stent is indicated for biliary obstruction; generally confined to high probability for therapeutic intervention on biliary or pancreatic ductal systems
- MRI: no advantage over contrast-enhanced CT
- MR cholangiopancreatography: 90% sensitivity; 95% specificity. Preferred in specific settings: gastric outlet or duodenal stenosis or after surgical rearrangement (Billroth II) or ductal disruption; to detect bile duct obstruction, after attempted ERCP is unsuccessful or provides incomplete information
- Cystic pancreatic lesions may be benign or malignant; must be differentiated from pancreatic pseudocysts. Cystadenocarcinomas have better prognoses than typical pancreatic cancers.

### *Diagnostic Procedures/Other*

- Percutaneous fine-needle biopsy with US or CT guidance: 80-90% sensitivity; 98-100% specificity
- EUS-guided biopsy: 85-90% sensitivity; virtually 100% specificity for pancreatic mass
- Staging laparoscopy and US: 92% sensitivity; 88% specificity; 89% accuracy
- Positive peritoneal cytology has a positive predictive value of 94%; specificity of 98%; sensitivity of 25% for determining unresectability.
- PET scan: 90% sensitivity but 70% specificity; limited anatomic information
- Tumor staging
  - Stage I: tumors limited to the pancreas
  - Stage II: regionally invasive; may involve lymph nodes but without celiac or mesenteric artery involvement
  - Stage III: direct involvement of celiac or superior mesenteric artery involvement
  - Stage IV: distant metastases

### *Test Interpretation*

- Duct cell carcinoma: 90%
- Other less common tumors: acinar, papillary mucinous, signet ring, adenosquamous,

mucinous, giant or small cell, cystadenocarcinoma, undifferentiated, unclassified carcinoma

## **ALERT**

Chronic pancreatitis can present with similar pain, weight loss, jaundice, and an inflammatory mass on imaging.

## **TREATMENT**

- Surgical resection: only chance of cure; no role for pancreatic resection in metastatic disease. As few as 15-20% are candidates for resection.
- Criteria for unresectability: extrapancreatic spread, encasement or occlusion of major vessels, distant metastases
- New combination chemotherapy regimens may offer advantages over gemcitabine. Standard therapies remain unsatisfactory; thus, patients should be considered for clinical trials (3).

## **MEDICATION**

- Analgesics
- Stages I and II
  - Radical pancreatic resection plus chemotherapy
  - ESPAC-3 trial after resection: compared with 5-fluorouracil (5-FU) and folinic acid, gemcitabine did not improve overall survival.
  - Currently, postoperative gemcitabine alone or in combination with 5-FU-based chemoradiation is the current standard of care; preoperative neoadjuvant treatment trials are in progress.
- Stage III
  - Standard: Chemotherapy with gemcitabine-based regimens; added chemoradiation is controversial.
  - FLOFIRINOX and gemcitabine+nab-paclitaxel were recently shown to have a benefit in patients with metastatic disease; may be tried in patients with locally advanced disease
  - Palliation of biliary obstruction by endoscopic, surgical, or radiologic methods
  - Intraoperative radiation therapy and/or implantation of radioactive substances
- Stage IV
  - Chemotherapy: Gemcitabine with erlotinib, or paclitaxel, or a fluoropyrimidine may modestly

prolong survival compared with gemcitabine alone.

- Pain-relieving procedures (celiac or intrapleural block); supportive care; palliative decompression

## ***ADDITIONAL THERAPIES***

- For resected tumors: postoperative radiation therapy with other chemotherapeutic agents
- Intraoperative radiation therapy and/or implantation of radioactive substances (ongoing trials)
- Biliary decompression with endoprosthesis or transhepatic drainage for bile duct obstruction
- Celiac axis and intrapleural nerve blocks can provide effective pain relief for some patients.
- Opiates may be needed for pain control.

## ***SURGERY/OTHER PROCEDURES***

- Standard treatment options
  - Pancreaticoduodenectomy, Whipple procedure, en bloc resection of the head of the pancreas, distal common bile duct, duodenum, jejunum, and gastric antrum
  - Total pancreatectomy
  - Distal pancreatectomy for body and tail tumors
- Nonstandard surgeries
  - Pylorus-preserving pancreaticoduodenectomy, regional pancreatectomy
  - Palliative bypass
    - Biliary decompression; gastrojejunostomy for gastric outlet obstruction; duodenal endoprosthesis for obstruction

## **ONGOING CARE**

### ***DIET***

- Anorexia, asthenia, pain, and depression may contribute to cachexia.
- Fat malabsorption due to exocrine pancreatic insufficiency may contribute to malnutrition; pancreatic enzyme replacement may help to alleviate symptoms.
- Fat-soluble vitamin deficiency may require replacement therapy.

## PROGNOSIS

- 90% diagnosed with pancreatic cancer die from the disease, predominantly from metastatic disease (3).
- 5-year survival: ±30% if node-negative; 10% if node-positive. Median survival: 10 to 20 months
- Metastatic cancer: 1-2% 5-year survival
- For localized disease and small cancers (<2 cm) with no lymph node involvement and no extension beyond the capsule, complete surgical resection can yield a 5-year survival of 18-24%.
- Detection of curable precursor lesions is a focus of current efforts to improve diagnosis and prognosis.

## COMPLICATIONS

- Diabetes mellitus, malabsorption, thrombophlebitis
- Duodenal or distal bile duct obstruction
- Surgical complications: intra-abdominal abscess, postgastrectomy syndromes, pancreaticojejunostomy, gastric and biliary anastomotic leaks; operative mortality varies.

**Codes**

&NA;

## ICD10

- C25.9 Malignant neoplasm of pancreas, unspecified
- C25.0 Malignant neoplasm of head of pancreas
- C25.1 Malignant neoplasm of body of pancreas

## Clinical Pearls

### &NA;

- Sudden onset of diabetes mellitus in nonobese adults aged >40 years may warrant consideration of pancreatic cancer in selected cases.
- Cancer of the exocrine pancreas is rarely curable; overall 5-year survival rate of <4%. Fewer than 20% of cases are localized at diagnosis.
- Be wary of chronic pancreatitis, which can present with similar pain pattern, weight loss, jaundice, and an inflammatory mass on imaging.
- Because of the dismal prognosis on standard therapy, all patients with pancreatic cancer should be considered for appropriate clinical trials

# Pancreatitis, Acute

Robert L. Frachtman, MD, FACC

Marni Martinez, APRN

## BASICS

### *DESCRIPTION*

Acute inflammatory process of the pancreas with variable involvement of regional tissue or remote organ systems

- Inflammatory episode with symptoms related to intrapancreatic activation of enzymes with pain, nausea and vomiting, and associated intestinal ileus
- Varies widely in severity, complications, and prognosis, accounting for 280,000 hospital admissions per year in the United States
- Complete structural and functional recovery if there is no necrosis or pancreatic ductal disruption.

### *EPIDEMIOLOGY*

#### *Incidence*

- 1 to 5/10,000
- Predominant age: none
- Predominant sex: male = female

#### *Prevalence*

Acute: 19/10,000

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Alcohol
- Gallstones (including microlithiasis)
- Trauma/surgery
- Acute discontinuation of medications for diabetes or hyperlipidemia

- Following endoscopic retrograde cholangiopancreatography (ERCP)
- Medications (most common, not an exhaustive list)
  - ACE inhibitors
  - Angiotensin receptor blockers (ARBs)
  - Thiazide diuretics and furosemide
  - Antimetabolites (mercaptopurine and azathioprine) (1)
  - Corticosteroids
  - Glyburide
  - Exenatide (Byetta) (2)
  - Mesalamine
  - Pentamidine
  - Sulfamethoxazole/trimethoprim
  - Valproic acid
  - HMG-CoA reductase inhibitors, especially simvastatin (1)
  - Review all medications and continue only if the benefit outweighs risk, if medication is causally implicated.
- Metabolic causes
  - Hypertriglyceridemia (>1,000 mg/dL)
  - Hypercalcemia
  - Acute renal failure
  - Diet with high glycemic load (3)[B]
  - Systemic lupus erythematosus/polyarteritis
  - Autoimmune pancreatitis, associated with elevated IgG4
  - Infections (list not exhaustive)
    - Mumps, coxsackie, cryptosporidiosis
- Penetrating peptic ulcer (rare)
- Cystic fibrosis and *CFTR* gene mutations
- Tumors (e.g., pancreatic, ampullary) (4)

- Pancreas divisum
- Sphincter of Oddi dysfunction
- Scorpion venom
- Vascular disease
- Acute fatty liver of pregnancy
- Idiopathic/autoimmune
- Pathophysiology: Enzymatic "autodigestion" of the pancreas, interstitial edema with severe interstitial acute fluid accumulation (3rd spacing), hemorrhage, necrosis, release of vasoactive peptides (within 6 weeks), pseudocyst or acute necrotic collection (>6 weeks), pancreatic ductal disruption, injury to surrounding vascular structures like splenic vein (thrombosis) and splenic artery (pseudoaneurysm)

## Genetics

Hereditary pancreatitis is rare. Autosomal dominant

## GENERAL PREVENTION

- Avoid excess alcohol consumption.
- Tobacco cessation
- Correct underlying metabolic processes (hypertriglyceridemia or hypercalcemia).
- Discontinue offending medications.
- Cholecystectomy (symptomatic cholelithiasis)
- Diet with low glycemic load (3)[B]

## COMMONLY ASSOCIATED CONDITIONS

- Alcohol withdrawal, alcoholic hepatitis, diabetic ketoacidosis, and ascending cholangitis
- Obesity increases severity, local complications, and mortality (5).

## DIAGNOSIS

Symptoms do not always correlate directly with objective findings (imaging, amylase/lipase).

## HISTORY

- Acute onset of "boring" epigastric pain, which may radiate posteriorly toward the back

- Nausea/vomiting
- Alcohol use
- Personal or family history of gallstones
- Medication use
- Abdominal trauma
- Recent significant rapid weight loss

## *PHYSICAL EXAM*

- Vital signs—assess hemodynamic stability; fever
- Abdominal findings: epigastric tenderness, loss of bowel sounds
- Other findings: jaundice, rales/percussive dullness
- Rare (with hemorrhagic pancreatitis)
  - Flank discoloration (Grey-Turner sign) or umbilical discoloration (Cullen sign)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Interpret laboratory and radiographic findings in the context of the clinical history, as false-positive and false-negative findings are common.
- American College of Gastroenterology require at least 2 of the 3 following elements to make a diagnosis of acute pancreatitis: characteristic abdominal pain, specific radiographic findings, and lipase level 3 times the ULN.
- Elevated serum amylase >3 times upper limit of normal (ULN) (severity is not related to degree of elevation)
- Elevated serum lipase >3 times ULN (may stay elevated longer than amylase in mild cases)
- Elevated total bilirubin. If >3 mg/dL, consider common bile duct obstruction.
- Transaminases rise quickly with acute bile duct obstruction. They also fall rapidly as alkaline phosphatase rises; a 3-fold elevation in the alanine aminotransferase (ALT) in the setting of acute pancreatitis has a 95% positive predictive value for gallstone pancreatitis. Triglyceride levels >1,000 mg/dL suggest hypertriglyceridemia as the cause.
- Glucose is increased in severe disease.
- Calcium is decreased in severe disease.
- WBC elevation to 10,000 to 25,000/*mmgr*;L possible and not indicative of active infection
- Rising hemoglobin is a poor prognostic sign (severe 3rd spacing-hemoconcentration). Rising

blood urea nitrogen (BUN) and creatinine imply volume depletion or acute renal failure.

## *DIFFERENTIAL DIAGNOSIS*

- Penetrating peptic ulcer
- Acute cholecystitis or cholangitis
- Macroamylasemia, macrolipasemia
- Mesenteric vascular occlusion and/or infarction
- Perforation of a viscus
- Intestinal obstruction
- Aortic aneurysm (dissecting or rupturing)
- Inferior wall myocardial infarction
- Lymphoma

## *Initial Tests (lab, imaging)*

- Use follow-up labs to assess renal function, hydration, sepsis, biliary obstruction, and tissue oxygenation status.
- Plain film of abdomen helps rule out mechanical small bowel obstruction. Ileus is common.
- Chest x-ray (CXR) to evaluate for early acute respiratory distress syndrome (ARDS) and pleural effusion; can also rule out free subdiaphragmatic air.
- Ultrasound to rule out cholelithiasis; choledocholithiasis can occasionally be seen.
- CT scan
  - Confirms the diagnosis, assesses severity, establishes a baseline, and rules out other possibilities. CT does not rule out noncalcified cholelithiasis.
  - IV contrast is not essential on the initial CT scan and should be avoided in volume-depleted patients.
  - If not contraindicated, a CT scan with IV contrast at day 3 can assess the degree of necrosis when necrotizing pancreatitis is suspected because of O<sub>2</sub> saturation <90%, systolic BP <90 mm Hg, and so forth.
- MRCP helps assess for choledocholithiasis, pancreas divisum, a dilated pancreatic duct, and chronic ductal changes.
- Esophagogastroduodenoscopy (EGD) may be necessary to rule out a penetrating duodenal ulcer or an obstructing ampullary neoplasm if suggested by laboratory or imaging studies.

- ERCP may be necessary to decompress common bile duct due to an impacted stone.
- Endoscopic ultrasonography (EUS) is useful when a patient presents with Idiopathic pancreatitis (4)[B].
- FNA may be added to EUS if autoimmune pancreatitis is suspected (6)[C].

## *Follow-Up Tests & Special Considerations*

If renal function is stable, a contrast-enhanced CT scan at day 3 to assess for necrosis. Later in the course, if there is a spike in the temperature, CT-guided aspiration can help assess secondary infection.

P.757

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Analgesia: no consensus; guidelines vary widely on types and dosing for analgesia (7).
  - Hydromorphone (Dilaudid) 0.5 to 1 mg IV q1-2h PRN
  - AVOID Demerol due to the potential of accumulation of a toxic metabolite.
- Antibiotics
  - The use of prophylactic antibiotics is no longer recommended, even with necrotizing pancreatitis, in the absence of infection.
  - In patients with ascending cholangitis or necrotizing pancreatitis, *&bgr;-lactam/&bgr;-lactamase inhibitor* (e.g., piperacillin/tazobactam 4.5 g IV q8h) can be considered for initial treatment, before cultures (especially of aspirated collections) return, if there is a strong suspicion of active infection.
  - Levofloxacin 500 mg QD IV if cholangitis and there is an allergy to penicillin
  - Be vigilant for monial superinfections when giving prophylactic antibiotics.

### *GENERAL MEASURES*

Most cases of acute pancreatitis require hospitalization; ICU if multiorgan dysfunction or hypotension/respiratory failure. 15-20% of cases of acute pancreatitis progress from mild to severe (including persistent organ failure).

- Fluid resuscitation
  - Significant volume deficit due to 3rd spacing
  - Infuse bolus of 1,000 to 2,000 mL (lactated Ringers may be better than normal saline, unless hypercalcemic) (8)[C], followed by 250 to 300 mL/hr, adjusted on the basis of age, weight, hemodynamic response, and comorbid conditions.
  - Target urine output should be 0.5 to 1 mL/kg/hr. Lower infusion rate when this goal is achieved or once BUN decreases; 4 L should be the maximum fluid on day 1.
- Eliminate unnecessary medications, especially those potentially causing pancreatitis.
- Nasogastric (NG) tube for intractable emesis
- Follow renal function, volume status, calcium, and oxygenation. Organ failure is more important prognostic indicator than pancreatic necrosis.
- Intermittent pneumatic compression device
- Begin oral alimentation after pain, tenderness, and ileus have resolved; small amounts of highcarbohydrate, low-fat, and low-protein foods; advance as tolerated; NPO or NG tube if vomiting persists.
- Enteral nutrition at level of ligament of Treitz if oral feeding not possible within 5 to 7 days (preferable to total parenteral nutrition [TPN] due to decreased infection rate and decreased mortality). Discontinue with increases in pain, amylase/lipase levels, or fluid retention.
- TPN (without lipids if triglycerides are elevated) if oral or nasoenteric feedings are not tolerated (9).

## *ISSUES FOR REFERRAL*

Refer to a tertiary center if pancreatitis is severe or actively evolving and when advanced imaging or endoscopic therapy is being considered.

## *SURGERY/OTHER PROCEDURES*

- Consider cholecystectomy before discharge in patients with cholelithiasis and nonnecrotizing pancreatitis to reduce risk of recurrent acute gallstone pancreatitis.
- Necrosectomy should be performed nonsurgically for either infected or noninfected necrosis. Walled off necrosis should be observed for 4 weeks (treated with antibiotics if infected), followed by percutaneous or dual-modality drainage if available (10,11)[B].
- ERCP early if evidence of acute cholangitis or at 72 hours if evidence of ongoing biliary obstruction. ERCP with pancreatic ductal stent placement, if ductal disruption persists longer than 1 to 2 weeks.

- Resection or embolization for bleeding pseudoaneurysms
- Plasma exchange with insulin if necrotizing pancreatitis secondary to hypertriglyceridemia

## *INPATIENT CONSIDERATIONS*

### *Discharge Criteria*

- Pain controlled
- Tolerating oral diet
- Alcohol rehabilitation and tobacco cessation
- Low-grade fever and mild leukocytosis do not necessarily indicate infection and may take weeks to resolve. Infections may occur even after 10 days (33% of patients with necrotizing pancreatitis) due to secondary infection of necrotic material, requiring surgical débridement.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Follow-up imaging studies in several weeks, if the original CT scan showed a fluid collection or necrosis or if the amylase/lipase continues to be elevated. Follow-up findings may include:
  - Pseudocyst (occurs in 10%) or abscess (sudden onset of fever): Conservative management is an option for asymptomatic pseudocysts up to 6 cm in diameter.
  - Splenic vein thrombosis (gastric variceal hemorrhage rarely occurs)
  - Pseudoaneurysm (splenic, gastroduodenal, intrapancreatic) hemorrhage can be life-threatening.
- Mild exocrine and endocrine dysfunction is usually subclinical. Patients with necrotizing pancreatitis, steatorrhea, or ductal obstruction should receive enzyme supplementation.

### *DIET*

Continue to advance diet as tolerated. Dietary modification to reduce dietary fats, alcohol, and added sugars.

### *PROGNOSIS*

85-90% of cases of acute pancreatitis resolve spontaneously; 3-5% mortality (17% in necrotizing pancreatitis)

## Codes

### &NA;

## ICD10

- K85.9 Acute pancreatitis, unspecified
- K85.8 Other acute pancreatitis
- K85.2 Alcohol induced acute pancreatitis

## Clinical Pearls

### &NA;

- BISAP score is easier to apply than Ranson criteria and just as accurate in predicting mortality in acute pancreatitis.
- Review all medications upon admission and discontinue any that are implicated as causing pancreatitis.
- Patients with mild pancreatitis can progress to severe pancreatitis over the initial 48 hours, often due to inadequate fluid replacement.
- Referral to tertiary center is needed if acute pancreatitis is severe or evolving/worsening.

# Pancreatitis, Chronic

Robert L. Frachtman, MD, FACP

Marni Martinez, APRN

## BASICS

### DESCRIPTION

- Long-standing and progressive destruction of the pancreas due to persistent inflammation
- Results in exocrine and/or endocrine insufficiency
- Major features
  - Pain
  - Malabsorption
  - Diabetes mellitus (type 3)
  - Increased risk of pancreatic cancer

### EPIDEMIOLOGY

#### *Incidence*

Predominant age

- 35 to 45 years (usually related to alcohol)
- Predominant sex: male > female
- Hospitalization more common for blacks than whites

#### *Prevalence*

8/10,000

#### *Genetics*

Hereditary pancreatitis is a rare condition with an autosomal dominant inheritance pattern. Mutations in *PRSSI* gene and *SPINK1* gene

## GENERAL PREVENTION

- Avoid tobacco.
- Avoid excess alcohol.

## DIAGNOSIS

As with acute pancreatitis, symptoms and objective findings (imaging, amylase/lipase) do not always directly correlate.

### HISTORY

- Epigastric pain, often radiating to the back
- Flare-ups may mimic acute pancreatitis.
- Persistent nausea and vomiting
- Chronic vague abdominal pain; may worsen post-prandially or with alcohol consumption
- Alcohol use
- Cigarette smoking
- Steatorrhea and/or diarrhea
- Weight loss
- Children
  - Recurrent postprandial epigastric pain
  - Family history of chronic pancreatitis
  - Growth failure
  - Diabetes

### PHYSICAL EXAM

- Acute superimposed on chronic pancreatitis
  - See "Pancreatitis, Acute"
  - Epigastric tenderness
  - Loss of bowel sounds
  - Fever
  - Tachycardia
  - Hypotension/shock

- Jaundice
- Rales/percussive dullness
- Chronic pancreatitis
  - Mild, diffuse tenderness
  - Ascites

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Interpret laboratory and radiographic findings in chronic pancreatitis within the context of each patient presentation due to common false-positive and false-negative findings.

### ***Initial Tests (lab, imaging)***

Features and considerations

- Amylase and lipase usually normal or near normal
- Hyperglycemia
- Steatorrhea (fecal fat >7 g/day on 100 g of fat per day diet), with other malabsorptive consequences such as low B<sub>12</sub> level
- Elevated alkaline phosphatase and bilirubin imply obstruction of the intrapancreatic common bile duct.
- Autoimmune pancreatitis: elevated serum IgG4 (type I, not type II), autoantibodies to lactoferrin and carbonic anhydrase (1)
- Pancreatic insufficiency: fecal elastase-1 <200 *&mgr;*g/g in moderate to severe pancreatic insufficiency
- Plain film of abdomen: pancreatic calcification if severe
- Ultrasound (US): helps assess common bile duct diameter, less useful for visualizing pancreas
- CT scan of abdomen: pseudocysts, pancreatic duct dilation, and calcifications, which are most commonly associated with alcohol, cigarette smoking, and hereditary pancreatitis and may take 5 to 10 years to develop (1)
- Magnetic resonance cholangiopancreatography (MRCP): pancreatic ductal deformities/strictures (with or without pancreatic ductal stones), retained common bile duct stones
- Endoscopic US (EUS): might help identify pancreatic cancer. Fine needle aspiration may be added if autoimmune pancreatitis is suspected (2)[B].

## *Follow-Up Tests & Special Considerations*

Disorders that alter results for amylase or lipase

- Biliary tract disease
- Penetrating peptic ulcer
- Intestinal obstruction, ischemia, or infarction
- Ruptured ectopic pregnancy
- Renal insufficiency
- Burns
- Macroamylasemia; macrolipasemia

## *DIFFERENTIAL DIAGNOSIS*

- Pancreatic cancer
- Lymphoma
- Other malabsorptive processes, such as bacterial overgrowth or celiac disease

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Analgesics (no consensus on specific medications or doses)
  - Tramadol 50 mg q6h PO is commonly used as a first-line.
  - Chronic opioid (morphine, fentanyl) therapy may be required in some patients.
  - Gabapentin, pregabalin, SNRIs, or TCAs may be used as adjunctive therapy.
  - Traditional pancreatic enzyme supplements are microencapsulated and do not require acid inhibition for protection. Dosage is 25,000 to 40,000 IU at the beginning of the meal.
  - Uncoated enzymes (Viokase) may be more efficacious for pain control (when given with proton pump inhibitors [PPIs] to protect their integrity) compared with coated enzymes (3,4). There is a theoretical benefit to using PPIs, even with coated enzymes, in patients with vitamin deficiency to allow faster release of enzymes into the proximal duodenum where fat soluble vitamin absorption occurs (1).

- Octreotide 25 to 50  $\mu$ g/hr IV infusion can be supplemental therapy for pancreatic ductal fistulae, which can later be changed to long-acting SC administration.
- Individualized doses of corticosteroids for autoimmune pancreatitis

## GENERAL MEASURES

- Discontinue tobacco use, which can exacerbate chronic pancreatitis (5).
- Analgesia: Consider pain management consultation for chronic opioid management.

P.759

- Exocrine and endocrine replacement therapy (enzymes and insulin)
- Consider more advanced therapy for pain: celiac ganglion block via EUS and endoscopic or surgical decompression of partially obstructed pancreatic duct.

## SURGERY/OTHER PROCEDURES

- Pseudocyst drainage
  - Conservative approach if asymptomatic
  - Endoscopic (via EUS) or surgical approach if mature wall
  - Percutaneous approach if rapidly enlarging or if thin wall
  - Endoscopic drainage and percutaneous drainage have similar clinical success rates, but percutaneous drainage requires more reintervention and longer hospital stay (6)[C].
- Pancreatic ascites with disruption of the main pancreatic duct
  - Endoscopic placement of pancreatic ductal stent is preferred, if possible.
  - Lateral pancreaticojejunostomy if endoscopic therapy is not possible
- Biliary obstruction (secondary to chronic pancreatitis, not choledocholithiasis)
  - Placement of retrievable metal stent or multiple plastic stents, if possible
  - Choledochojejunostomy if endoscopic therapy is not possible
- Pancreatic ductal obstruction by stone
  - Endoscopic pancreatic sphincterotomy with stone extraction
- Total pancreatectomy and islet autotransplantation
  - Favorable outcomes with pain reduction
  - Indication for timing of procedure uncertain

- Lithotripsy for chronic calcific pancreatitis may improve pain and decrease dependence on narcotic analgesics (7)[B].

## *INPATIENT CONSIDERATIONS*

### *Discharge Criteria*

- Pain control
- Resolution of problems secondary to ductal disruption, if present
- Alcohol rehab and smoking cessation, if needed

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Depends on the source of the pain and whether a ductal disruption exists

### *DIET*

- Small meals high in protein,  $\pm$ 20 g/day of fat; adjust if diabetes is present. Patients with decreased endocrine function from chronic pancreatitis can be prone to hyper- or hypoglycemia (8)[C].
- Pancreatic enzyme replacement therapy (coated/microencapsulated for pancreatic insufficiency but noncoated with PPI for pancreatic pain)
- Vitamin A and vitamin E deficiency are not very common. Levels should be checked and supplements provided only if deficiencies are noted (8)[C].

### *PROGNOSIS*

- Patients with recurrent episodes of acute pancreatitis are more likely to develop chronic pancreatitis.
- May "burn out" with resolution of symptoms
- Narcotic addiction occurs frequently.
- Pancreatic exocrine and/or endocrine insufficiency may occur years later.
- Patients with chronic pancreatitis have an increased mortality, particularly from pancreatic cancer (9).
- 25% of patients with chronic pancreatitis have osteoporosis. Perform routine bone health

## Clinical Pearls

&NA;

- EUS can help differentiate chronic pancreatitis from pancreatic cancer.
- Chronic pain management is an essential element of managing chronic pancreatitis.
- Pancreatic enzyme replacement therapy and the avoidance of tobacco and alcohol are cornerstone therapies for chronic pancreatitis.

# Panic Disorder

Anub G. John, MD

Yash Kothari, MD

Hugh R. Peterson, MD, FACP

## BASICS

### DESCRIPTION

- A classic panic attack that is characterized by rapid onset of a brief period of sympathetic nervous system hyperarousal accompanied by intense fear.
- In panic disorder, multiple panic attacks occur (including at least one without a recognizable trigger). Worried anticipation of additional attacks, which can be disabling, is present for at least 1 month, and often, maladaptive (e.g., avoidance) behaviors develop.

### EPIDEMIOLOGY

#### *Incidence*

- Predominant age: All ages; in school-aged children, panic disorder can be confused with conduct disorder and school avoidance.
- Peak age of onset is early to mid-20s.
- Predominant sex: female > male (2:1)

#### *Prevalence*

- Lifetime prevalence: 4.7% (1)
- 4-8% of patients in a primary care practice population have panic disorder.
- Of patients presenting with chest pain in the emergency room, 25% have panic disorder.
- Chest pain is more likely due to panic if atypical, younger age, female, and known problems with anxiety.

### ETIOLOGY AND PATHOPHYSIOLOGY

Unknown

- Biologic theories focus on limbic system malfunction in dealing with anxiety-evoking stimuli.
- Psychological theories posit deficits in managing strong emotions such as fear and anger.
- Noradrenergic neurotransmission from the locus coeruleus causes increased sympathetic stimulation throughout the body.
- Current neurobiologic research focuses on abnormal responses to anxiety-producing stimuli in the hippocampus, amygdala, and prefrontal cortex; for example, there appears to be limbic kindling in which an original frightening experience dominates future responses even when subsequent exposures are not objectively threatening.
- Brain pH disturbances (e.g., excess lactic acid) from normal mentation in genetically vulnerable patients may activate the amygdala and generate unexpected fear responses.

## *Genetics*

Twin and family studies support a genetic predisposition.

## **RISK FACTORS**

- Life stressors of any kind can precipitate attacks.
- History of sexual abuse and physical abuse, anxious and overprotective parents
- Substance abuse, bipolar disorder, major depression, obsessive-compulsive disorder (OCD), and simple phobia

## **COMMONLY ASSOCIATED CONDITIONS**

- Of patients with panic disorder, >70% also have <sup>31</sup> other psychiatric diagnoses: PTSD (recalled trauma precedes panic attack), social phobia (fear of scrutiny precedes panic attack), simple phobia (fear of something specific precedes panic), major depression, bipolar disorder, substance abuse, OCD, separation anxiety disorder.
- Panic disorder is more common in patients with asthma, migraine headaches, hypertension, mitral valve prolapse, reflux esophagitis, interstitial cystitis, irritable bowel syndrome, fibromyalgia, nicotine dependence, and suicidality.

## **DIAGNOSIS**

- Panic attack: an abrupt surge of intense fear, reaching a peak within minutes in which <sup>34</sup> of the following symptoms develop abruptly: (i) palpitations, pounding heart, or accelerated heart rate; (ii) sweating; (iii) trembling or shaking; (iv) sensations of shortness of breath or feeling smothered; (v) a choking sensation; (vi) chest pain or discomfort; (vii) nausea or abdominal

distress; (viii) feeling dizzy, unsteady, lightheaded, or faint; (ix) derealization (feelings of unreality) or depersonalization (feeling detached from oneself); (x) fear of losing control or going crazy; (xi) fear of dying; (xii) paresthesias; (xiii) chills or hot flushes (2)[C]

- Panic disorder: recurrent unexpected panic attacks not better accounted for by another psychiatric condition (e.g., PTSD, OCD, separation anxiety disorder, social anxiety disorder, or specific phobia) *and* not induced by drugs of abuse, medical conditions, or prescribed drugs *and* with >1 month of at least one of the following: (i) worry about additional attacks; (ii) worry about the implications of the attack (e.g., losing control, having a heart attack, going crazy); and/or (iii) a significant maladaptive change in behavior related to the attacks (2)[C]
- Unlike *DSM-IV*, *DSM-5* defines agoraphobia as separate from panic disorder (2)[C].

## HISTORY

- The best way to get a good history is through tactful, nonjudgmental questioning after the worst of the attack is over. Use open-ended questions and be unhurried. Interviewing family members may also be helpful.
- A thorough medication and substance abuse history is important.
- Patients must have a month of fear of out-of-the-blue panic attacks to diagnose panic disorder.

## PHYSICAL EXAM

- During an attack, there will be tachycardia, hyperventilation, and sweating.
- Check the thyroid for fullness or nodules.
- Cardiac exam to check for a murmur or arrhythmias
- Lung exam to rule out asthma (limited airflow, wheezing)

## DIFFERENTIAL DIAGNOSIS

- Medication use may mimic panic disorder and create anxiety: Antidepressants to treat panic may paradoxically initially cause panic; antidepressants in bipolar patients can cause anxiety/mania/panic; short-acting benzodiazepines (alprazolam), *β*-blockers (propranolol), and short-acting opioids can cause interdose rebound anxiety; benzodiazepine treatment causes panic when patients take too much and run out of these medicines early; bupropion, levodopa, amphetamines, steroids, albuterol, sympathomimetics, fluoroquinolones, and interferon can cause panic.
- Substances of abuse: alcohol withdrawal, benzodiazepine withdrawal, opioid withdrawal, caffeine, marijuana (panic with paranoia), amphetamine abuse, MDMA, hallucinogens (PCP, LSD), dextromethorphan abuse, synthetic cathinones (bath salts) abuse.

- Medical conditions: hypo-/hyperthyroidism, asthma/chronic obstructive pulmonary disease (COPD), reflux esophagitis with hyperventilation, tachyarrhythmias, premenstrual dysphoric disorder, menopause, pregnancy, hypoglycemia (in diabetes), hypoxia, inner ear disturbances (labyrinthitis), myocardial infarction, pulmonary embolus, transient ischemic attacks (TIAs), carcinoid syndrome, pre- and postictal states (e.g., in TLE), autoimmune disease, pheochromocytoma, Cushing syndrome, hyperaldosteronism, Wilson disease
- Psychiatric conditions that have overlapping symptomatology include mood, anxiety, and personality disorders such as major depression, bipolar disorder, PTSD, borderline personality disorder, social phobia, OCD, and generalized anxiety disorder. In PTSD, there is always a recollection or visual image that precedes the panic attack. In social phobia, fear of scrutiny precedes the panic attack. In bipolar disorder, major depression, borderline personality disorder, and particularly substance abuse, the patient often complains first of panic symptoms and anxiety and minimizes other potentially relevant symptoms and behaviors.
- Somatic symptom disorder is also an illness of multiple unexplained medical symptoms, but the presenting picture is usually one of chronic symptoms rather than the acute, dramatic onset of a panic attack. Somatic symptom disorder and panic disorder can be (and often are) diagnosed together.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Consider ECG and pulse oximetry to rule out certain serious causes of panic; consider Holter monitoring. No specific lab tests are indicated except to rule out conditions in the differential diagnosis.

- Finger-stick blood sugar in acute setting in a diabetic patient
- Thyroid-stimulating hormone (TSH), electrolytes, CBC
- Consider ordering echocardiogram if you suspect mitral valve prolapse.

---

P.761

### ***Diagnostic Procedures/Other***

If a medical cause of anxiety is strongly suspected, do the workup appropriate for that condition.

## **TREATMENT**

Combined antidepressant therapy and psychotherapy is superior to either alone during initial treatment for panic disorder (3)[A]. Cognitive-behavioral therapy (CBT) provides long-lasting treatment, often without subsequent need for medications.

## GENERAL MEASURES

CBT, tailored for panic disorder, consists of several steps: education, changing cognitions about the attack and the illness, relaxation and controlled breathing techniques, and, if appropriate, exposure to anxiety-provoking conditions coupled with in vivo relaxation exercises.

## MEDICATION

- Medication management is indicated if psychotherapy is not successful (or not available) and may be combined with psychotherapy.
- Patient preference plays a big part in this decision.
- Because patients typically are anxious about their treatment, the therapeutic alliance is critical for the chronic care of this disorder.
- If medications are started, they should be maintained for at least 6 months after symptom control.

### *First Line*

- FDA-approved choices for the treatment of panic disorder include sertraline, paroxetine, fluoxetine, alprazolam, and clonazepam, but avoid giving benzodiazepines to those with a history of substance abuse or who are currently abusing alcohol or benzodiazepines, unless following a detoxification protocol.
- Most antidepressants except bupropion may treat panic disorder, but fluoxetine and selegiline patch can cause more initial nervousness than other antidepressants.
- In nonbipolar patients, start a low-dose SSRI (e.g., 5 mg (escitalopram), 25 mg sertraline, 10 mg paroxetine) and consider doubling the dose after 2 or 3 weeks; while waiting for the antidepressant to work, schedule frequent visits, give the patient reassurance, teach a relaxation technique, encourage the patient to do vigorous aerobic exercise as soon as a panic attack begins (if medically appropriate and in an appropriate situation); refer the patient to a competent therapist for CBT (4)[A].
- In bipolar patients, panic symptoms often resolve when treated with a mood stabilizer rather than an antidepressant (which may cause mania).

### *Second Line*

- Among serotonin-norepinephrine reuptake inhibitors, Venlafaxine extended release (ER) is effective. Start at 37.5 mg/day and titrate up to 75 mg/day after 7 days (maximum dose of 225 mg/day). Taper slowly over weeks to discontinue. Risk of hypertension at higher doses (5) [A].
- Tricyclic antidepressants, particularly imipramine (start 25 mg/day in the evening and increase

up to 25 mg every 3 days to a maximum of 200 mg/day); slower titration and lower doses are often as effective. Imipramine is as efficacious as SSRIs in the treatment of panic disorder. Tricyclic antidepressants are considered second line because of difficulty in dosing, more side effects, and greater risk associated with overdose compared with SSRIs (6)[A].

- Benzodiazepines like alprazolam (start 0.5 mg TID and up to 5 mg/day) and clonazepam (0.25 mg BID to target 1 mg/day) are FDA approved for panic disorder. Clonazepam has a longer half life, less interdose anxiety and lower abuse potential than alprazolam.

## **ISSUES FOR REFERRAL**

Consider referral to a psychiatrist for panic disorder that is comorbid with bipolar disorder, borderline personality disorder, schizophrenia, suicidality, alcohol, or substance abuse.

## **ADDITIONAL THERAPIES**

Aerobic exercise reduces symptoms better than placebo (7)[B].

## **INPATIENT CONSIDERATIONS**

### **Admission Criteria/Initial Stabilization**

- If certain life-threatening mimics of panic disorder have not been ruled out, such as a myocardial infarction (MI) or pulmonary embolus (PE), hospitalize patient to complete the evaluation.
- If a panic disorder patient has concrete suicidal ideation, a psychiatric admission is indicated.

## **ONGOING CARE**

### **PATIENT EDUCATION**

- [www.nlm.nih.gov/medlineplus/panicdisorder.html](http://www.nlm.nih.gov/medlineplus/panicdisorder.html)
- Patient information handouts in *American Family Physician*. 2005;71:740 and 2006;74:1393.
- <http://www.nimh.nih.gov/health/publications/panic-disorder-when-fear-overwhelms/index.shtml>

### **PROGNOSIS**

- Most patients recover with treatment.
- It can recur, but treatment of recurrence is usually successful.

## COMPLICATIONS

- Iatrogenic benzodiazepine dependence
- Iatrogenic mania in bipolar patients treated for panic with unopposed antidepressants
- Misdiagnosis of more difficult-to-treat psychiatric conditions as panic and vice versa

Algorithm: Anxiety

## Codes

**&NA;**

### ICD10

- F41.0 Panic disorder without agoraphobia
- F40.01 Agoraphobia with panic disorder
- F43.0 Acute stress reaction

## Clinical Pearls

**&NA;**

Encouraging patients (who are medically able) to do 10 minutes of vigorous aerobic exercise the moment a panic attack seems to be starting is often a very effective way to help patients feel safe during panic attacks. Always evaluate a patient with panic for suicidality. Patients with panic disorder are at increased risk for suicide, particularly if depressed.

# Parkinson Disease

Theresa T. Vo, MD

C. Jack Fraim, MD

## BASICS

### DESCRIPTION

- Parkinson disease (PD) is a progressive neurodegenerative disorder caused by degeneration of dopaminergic neurons in the substantia nigra pars compacta.
- Cardinal symptoms include resting tremor, rigidity, bradykinesia, and postural instability.
- Diagnosis is based primarily on history and examination.

### EPIDEMIOLOGY

#### *Incidence*

- Average age of onset:  $\approx$ 60 years
- Slightly more common in men than women

#### *Prevalence*

- Second most common neurodegenerative disease after Alzheimer disease
- 0.3% of general population and 1-2% of those  $\geq$ 60 years of age and up to 4% of those  $\geq$ 80 years of age
- Affects approximately 1 million people in the United States and 5 million worldwide

### ETIOLOGY AND PATHOPHYSIOLOGY

Dopamine depletion in the substantia nigra and the nigrostriatal pathways results in the major motor complications of PD.

- Pathologic hallmark: selective loss of dopamine-containing neurons in the pars compacta of the substantia nigra
- Loss of neurons accompanied by presence of Lewy bodies, pale bodies (predecessor of the Lewy body), and Lewy neuritis

## Genetics

Mutations in multiple autosomal dominant and autosomal recessive genes have been linked to PD/parkinsonian syndrome particularly when the age at symptom onset is <50 years. Genes investigated in PD include *SNCA*, *Parkin*, *Pink-1*, *DJ-1* and *LRRK2*.

## RISK FACTORS

- Age and family history of PD or tremor are the greatest risk factors.
- History of smoking as well as coffee and caffeine intake may reduce risk.
- Weak association with exposure to toxins (herbicides and insecticides); however, relationship is not clear.

## COMMONLY ASSOCIATED CONDITIONS

Non-motor-associated symptoms include cognitive abnormalities, autonomic dysfunction (e.g., constipation, urinary urgency), sleep disturbances, mental status changes (depression, psychosis, hallucinations, dementia), orthostatic hypotension, and pain.

## DIAGNOSIS

- Diagnosis is based on clinical impression.
- Gold standard for diagnosis is neuropathologic exam.
- Generally, bradykinesia plus either tremor or rigidity must be present in order to make the diagnosis of idiopathic PD.
- Clinical features supportive of the diagnosis include unilateral onset, resting tremor, persistent asymmetry with the side of onset most affected, and significant response to dopaminergic therapy.

## HISTORY

Symptoms often subtle or attributed to aging:

- Decreased emotion displayed in facial features
- General motor slowing and stiffness (one or both arms do not swing with walk)
- Resting tremor (often initially one hand)
- Speech soft/mumbling
- Falls/difficulty with balance (tends to occur with disease progression)

## *PHYSICAL EXAM*

- Tremor
  - Resting tremor (4 to 6 Hz) that is often asymmetric.
  - Disappears with voluntary movement
  - Frequently emerges in a hand while walking and may present as pill rolling
  - May also present in jaw, chin, lips, tongue
- Bradykinesia
- Rigidity: cogwheel (catching and releasing) or lead pipe (continuously rigid)
- Postural instability

## *DIFFERENTIAL DIAGNOSIS*

- Essential tremor: Bradykinesia is not present; often symmetric and occurs mostly during action or when holding hands outstretched
- SWEDD: scans without evidence of dopaminergic deficit; isolated upper extremity resting and postural tremor resembling PD but failing to progress to generalized PD; no akinesia
- Dementia with Lewy bodies: characterized clinically by visual hallucinations, fluctuating cognition, and parkinsonism, dementia occurs concomitantly with or before the development of parkinsonism
- Corticobasal degeneration: asymmetric parkinsonism, absence of tremor, no response to levodopa
- Multiple system atrophy: presents with parkinsonism but with varying degrees of dysautonomia, cerebellar involvement, and pyramidal signs
- Progressive supranuclear palsy: impairment in vertical eye movements (particularly down gaze), hyperextension of neck, and early falling; pseudobulbar palsy
- Idiopathic basal ganglia calcification
- Associated neurodegenerative disorders: late stages of Alzheimer disease, Huntington disease, frontotemporal dementia, spinocerebellar ataxias
- Secondary parkinsonism
  - Drug-induced: reversible; may take weeks/months after offending medication is stopped
    - Neuroleptics (most common cause)
    - Antiemetics (e.g., prochlorperazine and promethazine), metoclopramide

- SSRIs
- Calcium channel blockers (e.g., flunarizine and cinnarizine) metoclopramide
- Amiodarone
- Lithium
- Cholinergics
- Chemotherapeutics
- Amphotericin B
- Estrogens
- Valproic acid

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Diagnosis is mainly clinical and there are no physiologic or blood tests to confirm the diagnosis.
- Excellent response to an acute dopaminergic challenge test supports the diagnosis
- MRI of brain is nondiagnostic but can be used to rule out structural abnormalities.
- DaTscan: Striatal dopamine transporter imaging can distinguish PD and other parkinsonian syndromes but cannot differentiate between them.
- PET and single-photon emission CT may be helpful with diagnosis but are not required.

## **TREATMENT**

### *GENERAL MEASURES*

- Multidisciplinary rehabilitation with standard physical and occupational therapy components to improve functional outcomes.
- Physiotherapy to help with gait reeducation, enhancement of aerobic capacity, improvement in movement initiation, improvement in functional independence, and help with home safety

### *MEDICATION*

- PD goal: Improve motor and nonmotor deficits.
- Agents are chosen based on patient age and symptoms present.

- No treatment shown to slow progression

## *First Line*

- First-line agents in early PD: levodopa, dopamine agonists, monoamine oxidase B (MAO-B) inhibitors (1)[A]
    - Levodopa combined with carbidopa is still the most effective treatment for symptoms of PD, particularly bradykinesia.
    - Levodopa versus dopamine agonist is controversial (2)[B]:
      - Most patients eventually will develop motor fluctuations with levodopa. Younger patients are more likely to develop motor fluctuations. Some recommend delaying initiation of levodopa to decrease drug-induced motor fluctuations early in the disease.
      - Older patients often are less able to tolerate the adverse events of dopamine agonists.
      - All patients eventually will require levodopa.
    - MAO-B inhibitors (rasagiline) should be considered as initial monotherapy; investigated for potential neuroprotective effects (2)[B]
  - Carbidopa + levodopa (carbidopa inhibits peripheral conversion of levodopa)
    - Immediate release (Sinemet)
      - Tablets (mg): 10/100, 25/100, 25/250
      - Usual initial maintenance dose: 25/100 mg PO TID. Most patients require 25 mg of carbidopa to inhibit peripheral conversion of levodopa.
      - Watch for nausea/vomiting, orthostatic hypotension, sedation, and vivid dreams.
    - Orally disintegrating (Parcopa)
      - Tablets (mg): 10/100, 25/100, 25/25
    - Sustained release (Sinemet CR):
      - Tablets (mg): 25/100, 50/200
      - Dose agents initially BID
- 
- Carbidopa + levodopa + entacapone (Stalevo)
    - Tablets (mg): 12.5/50/200, 18.75/75/200, 25/100/200, 31.25/125/200, 37.5/150/200, 50/200/200

- Addition of entacapone as a single agent should be initiated prior to use of this combination:
  - Once-daily dose of carbidopa/levodopa has been identified; may convert to Stalevo
  - Dose of levodopa may need to be decreased with the addition of entacapone.
- Side effects are the same, plus diarrhea and brownish orange urine.
- Dopamine agonists (nonergot): side effects: nausea, vomiting, hypotension, sedation, edema, vivid dreaming, compulsive behavior, confusion, lightheadedness, and hallucinations:
  - Pramipexole (Mirapex): tablets (mg): 0.125, 0.25, 0.5, 1, 1.5
    - Start with 0.125 mg TID, gradually increase every 5 to 7 days; usual maintenance of 0.5 to 1.5 mg TID
    - CrCl 30 to 59 mL/min 0.125 mg PO BID
    - CrCl 15 to 29 mL/min 0.125 mg PO daily
  - Pramipexole ER (Mirapex ER): tablets (mg): 0.375, 0.75, 1.5, 3, 4.5; start with 0.375 PO daily
  - Ropinirole (Requip): tablets (mg): 0.25, 0.5, 1, 2, 3, 4, 5; start with 0.25 mg TID, increase gradually to 3 to 8 mg TID
  - Requip XL: tablets (mg): 2, 4, 6, 8, 12; start at a 2-mg dose once daily, increase in 1 to 2 weeks
- Selective MAO-B inhibitors: side effects: insomnia, jitteriness, hallucinations; mostly found with selegiline; rasagiline similar adverse events as placebo in clinical trials. Rasagiline is metabolized via *CYP1A2*; caution with other medications using this enzyme system (e.g., ciprofloxacin):
  - Both agents contraindicated with meperidine and numerous other agents metabolized via *CYP1A2*
  - At therapeutic doses, unlikely to induce a *Ù*cheese reaction<sup>Ó</sup> (tyramine storm)
- Selegiline (Eldepryl)
  - Tablets: 5 mg; initiate 5 mg PO BID
  - Orally disintegrating tablet (Zelapar): 1.25 mg; 1.25 mg PO daily for 6 weeks; increase as needed to max of 2.5 mg daily
- Rasagiline (Azilect): tablets: 0.5 mg, 1.0 mg; initiate 0.5 to 1 mg daily

## Second Line

- Second-line agents in early PD: *α*-adrenergic antagonists (postural tremor), amantadine, anticholinergics (young patients with tremor); there is lack of good evidence for symptom control (1)[A].
- Dopamine agonists (ergot): increased adverse event profile makes these agents nonpreferred to nonergot dopamine agonists; bromocriptine (Parlodel)
- Treatment of levodopa-induced motor complications
  - End of dose wearing off
    - Entacapone (with each levodopa dose) or rasagiline preferred (3)[B]
    - May also consider dopamine agonist, apomorphine, selegiline (4)[B]
  - Dyskinesias
    - Typically occur at peak dopamine level
    - Amantadine may be considered; however, its efficacy is questionable (1)[B].
- Anticholinergic agents: usually avoided due to lack of efficacy (only useful for tremor) and increased adverse event profile, including blurred vision, confusion, constipation, dry mouth, memory difficulty, sedation, and urinary retention
  - Trihexyphenidyl
    - Tablets: 2 mg, 5 mg
    - Start with 1 to 2 mg daily, increase by 2 mg every 3 to 5 days until usual dose is 6 to 10 mg in 3 to 4 divided doses
  - Benztropine (Cogentin)
    - Tablets: 0.5 mg, 1 mg, 2 mg
    - Start with 0.5 to 1 mg in 1 to 2 divided doses; increase by 0.5 mg every 5 to 6 days; usual dose is 1 to 2 mg/day in divided doses.
- *N*-methyl-D-aspartic acid antagonist: Exact mechanism is unknown and efficacy is questionable; however, it may be useful for dyskinesias. Side effects include confusion, dizziness, dry mouth, livedo reticularis, and hallucinations:
  - Amantadine (Symmetrel)
    - Tablets: 100 mg
    - Start with 100 mg BID; may increase to 300 mg daily in divided doses; renally adjusted
- Catechol-O-methyl transferase (COMT) inhibitors: entacapone preferred due to hepatotoxicity

associated with tolcapone. Adverse events include nausea and orthostatic hypotension:

- Entacapone (Comtan)
  - Tablets: 200 mg
  - 200 mg with each dose of carbidopa/levodopa; max dose, 1,600 mg/day
- Tolcapone (Tasmar)
  - Tablets: 100 mg, 200 mg
  - Start 100 mg TID; max dose 600 mg/day; must be taken with carbidopa/levodopa
  - Requires LFT monitoring
- Apomorphine (Apokyn): nonergot-derived dopamine agonist given SC for off episodes in advanced disease; adverse events: nausea, vomiting, dizziness, hallucinations, orthostatic hypotension, somnolence
  - Only for off episodes with levodopa therapy
  - Requires initial test dose (2 mg); monitor for orthostatic hypotension after initial dose; this is a potent emetic, so initiate an antiemetic (e.g., trimethobenzamide) 3 days prior to start and continue for 2 months. Avoid ondansetron (combination contraindicated due to profound hypotension) and dopamine antagonists, such as prochlorperazine and metoclopramide.
  - Effective dose ranges from 2 to 6 mg/injection.

## *ISSUES FOR REFERRAL*

Early specialty referral for patients with suspected PD for an accurate diagnosis and management

## *ADDITIONAL THERAPIES*

- Emotional and psychological support of patient family
- Physical therapy and manual medicine has been shown to improve balance, muscle strength, and walking speed.
- Speech therapy: may be helpful in improving speech volume and maintaining voice quality

## *SURGERY/OTHER PROCEDURES*

Deep brain stimulation (bilateral subthalamic nucleus/globus pallidus interna) is an effective therapeutic option for patients with motor complications refractory to best medical treatment who are healthy, have no significant comorbidities, are responsive to levodopa, and do not have

depression or dementia.

## ONGOING CARE

### DIET

- Increase dietary fluids and fiber and increase activity for constipation.
- For dysphagia, consider soft food, swallowing evaluation, and increased time for meals.
- Avoid large, high-fat meals that slow digestion and interfere with medication absorption.

### PATIENT EDUCATION

- [www.apdaparkinson.org](http://www.apdaparkinson.org)
- [www.parkinson.org](http://www.parkinson.org)
- [www.michaeljfox.org](http://www.michaeljfox.org)

### PROGNOSIS

- PD is a chronic progressive disease; prognosis varies based on patient-specific symptoms.
- Increased mortality in PD; on average, PD survival reduced by 5% every year of follow-up (4).

### COMPLICATIONS

Most commonly the result of adverse effects of medications used to treat

### REFERENCES

## Codes

**&NA;**

### ICD10

- G20 Parkinson's disease
- G21.9 Secondary parkinsonism, unspecified
- G31.83 Dementia with Lewy bodies

## Clinical Pearls

**&NA;**

- Emphasize the importance of exercise and movement to help preserve function.
- Pharmacotherapeutic regimens need to be individualized based on patient-specific symptoms and age.

# Paronychia

Nancy V. Nguyen, DO

## BASICS

### DESCRIPTION

- Superficial inflammation of the lateral and posterior folds of skin surrounding the fingernail or toenail
  - Acute: characterized by pain, erythema, and swelling; usually a bacterial infection, appears after trauma. It can progress to abscess formation.
  - Chronic: characterized by swelling, tenderness, cuticle elevation, and nail dystrophy and separation lasting at least 6 weeks, or recurrent episodes of acute eponychial inflammation and drainage.
  - May be considered work-related among bartenders, waitresses, nurses, and others who often wash their hands
- System(s) affected: skin and nail bed
- Synonym(s): eponychia; perionychia

### Pediatric Considerations

Less common in pediatric age groups. Thumb/fingersucking is a risk factor (anaerobes and *Escherichia coli* may be present).

### EPIDEMIOLOGY

#### Incidence

- Common in the United States
- Predominant age: all ages
- Predominant sex: female > male

### ETIOLOGY AND PATHOPHYSIOLOGY

- Acute: *Staphylococcus aureus* (1) most common and *Streptococcus pyogenes* (1); less

frequently, *Pseudomonas pyocyanea* and *Proteus vulgaris*. In digits exposed to oral flora especially in pediatric age group, consider *Eikenella corrodens*, *Fusobacterium*, and *Peptostreptococcus*.

- Chronic: eczematous reaction with secondary *Candida albicans* (÷95%) (2)
- A paronychia infection commonly starts in the lateral nail fold.
- Recurrent inflammation, persistent edema, and fibrosis of nail folds cause nail folds to round up and retract, exposing nail grooves to irritants, allergens, and pathogens.
- Inflammation compromises ability of proximal nail fold to regenerate cuticle leading to decreased vascular supply. This can cause decrease efficacy of topical medications.
- Early in the course, cellulitis alone may be present. An abscess can form if the infection does not resolve quickly.

## **RISK FACTORS**

- Acute: direct or indirect trauma to cuticle or nail fold, manicure/sculptured nails, nail biting, and thumb sucking and predisposing conditions such as diabetes mellitus (DM)
- Chronic: frequent immersion of hands in water with excoriation of the lateral nail fold (e.g., chefs, bartenders, housekeepers, swimmers, dishwashers, nurses), DM, immunosuppression (reported association with antiretroviral therapy for HIV and with use of epidermal growth factor inhibitors) (3)

## **GENERAL PREVENTION**

- Acute: Avoid trauma such as nail biting; prevent thumb sucking.
- Chronic: Avoid allergens; keep fingers/hands dry; wear rubber gloves with a cotton liner. Prevent excoriation of the skin.
- Keep nails short. Avoid manicures. Apply moisturizer after washing hands.
- Good glycemic control in diabetic patients

## **COMMONLY ASSOCIATED CONDITIONS**

- DM
- Eczema or atopic dermatitis
- Certain medications: antiretroviral therapy (3) (especially protease inhibitors, indinavir, and lamivudine, in which toes more commonly involved) (3)
- Immunosuppression (4)

# DIAGNOSIS

## HISTORY

- Localized pain or tenderness, swelling, and erythema of posterior or lateral nail folds
  - Acute: fairly rapid onset
  - Chronic: 4 to 6 weeks' duration
- Previous trauma (bitten nails, ingrown nails, manicured nails)
- Contact with herpes infections
- Contact with allergens or irritants (frequent water immersion, latex) (4)

## PHYSICAL EXAM

- Acute: red, warm, tender, tense posterior or lateral nail fold ± abscess
- Chronic: swollen, tender, boggy nail fold ± abscess
- Occasional elevation of nail bed
- Separation of nail fold from nail plate
- Red, painful swelling of skin around nail plate
- Fluctuance, purulence at the nail margin, or purulent drainage
- Secondary changes of nail platelike discoloration
- Suspect *Pseudomonas* if with green changes in nail (chloronychia) (5).
- Positive fluctuation when mild pressure over the area causes blanching and demarcation of the abscess
- Chronic: retraction of nail fold and absence of adjacent healthy cuticle, thickening of nail plate with prominent transverse ridges known as Beau lines and discoloration

## DIFFERENTIAL DIAGNOSIS

- Felon (abscess of fingertip pulp; urgent diagnosis required)
- Contact dermatitis
- Herpetic whitlow (similar in appearance, very painful, often associated with vesicles)
- Acute osteomyelitis of the distal phalanx
- Psoriasis especially acute flare

- Allergic contact dermatitis (latex, acrylic)
- Reiter disease
- Pustular psoriasis
- Proximal/lateral onychomycosis (nail folds not predominantly involved)
- Malignancy: squamous cell carcinoma of the nail, malignant melanoma, metastatic disease

## **DIAGNOSTIC TESTS & INTERPRETATION**

None required unless condition is severe; resistant to treatment or if recurrence or methicillin-resistant *S. aureus* (MRSA) is suspected, then

- Gram stain
- Culture and sensitivity
- Potassium hydroxide wet mount plus fungal culture especially in chronic
- Drugs that may alter lab results: Use of over-the-counter antimicrobials or antifungals.

## **Diagnostic Procedures/Other**

- Incision and drainage recommended for suppurative cases or cases not responding to conservative management or empiric antibiotics
- Tzanck testing or viral culture in suspected viral cases
- Biopsy in cases not responding to conservative management or when malignancy suspected

## **TREATMENT**

### **GENERAL MEASURES**

- Acute: warm compresses, elevation, splint protection if pain severe
- Chronic: Keep fingers dry; apply moisturizing lotion after hand washing; avoid exposure to irritants; improved diabetic control

### **MEDICATION**

#### **First Line**

- Tetanus booster when indicated
- Acute (mild cases, no abscess formation)

- Topical antibiotic cream alone or in combination with a topical steroid (6)[B]
- 
- Antibiotic cream applied TID-QID after warm| soak (e.g., mupirocin or gentamicin/neomycin/polymyxin B) for 5 to 10 days
  - If eczematous: low-potent topical steroid applied BID (e.g., betamethasone 0.05% cream) for 7 to 14 days (7)[B]
- Acute (no exposure to oral flora)
    - Dicloxacillin 250 mg TID for 7 days
    - Cephalexin 500 mg TID-QID for 7 days
  - Acute (suspected MRSA)
    - Trimethoprim/sulfamethoxazole 160 mg/800 mg BID for 7 days
    - Doxycycline 100 mg BID for 7 days
  - Acute (exposure to oral flora)
    - Amoxicillin clavulanate: 875 mg/125 mg BID or 500 mg/125 mg TID for 7 days; pediatric, 45 mg/kg q12h (for <40 kg)
    - Clindamycin 300 to 450 mg TID-QID for 7 days; pediatric, 10 mg/kg q8h; *plus* either doxycycline or trimethoprim/sulfamethoxazole
  - Chronic
    - Topical steroids: betamethasone 0.05%; applied BID for 7 to 14 days (8)[B]
    - Topical antifungal: clotrimazole or nystatin; applied topically TID for up to 30 days
    - Other topical: Tacrolimus 0.1% ointment BID for up to 21 days has been shown to be effective but is more expensive.

## Second Line

- Systemic antifungals (rarely needed, use if topical fails)
  - Itraconazole 200 mg for 90 days (may have longer action because it is incorporated into nail plate); pulse therapy may be useful (i.e., 200 mg BID for 7 days, repeated monthly for 2 months) (1)[C],(8)
  - Terbinafine 250 mg/day for 6 weeks (fingernails) or 12 weeks (toenails)
  - Fluconazole 100 mg daily for 7 to 14 days

- Ciclopirox 0.77% topical suspension BID for 2 to 4 weeks along with strict irritant avoidance (7)[B]
- Antipseudomonal drugs (e.g., ceftazidime, aminoglycosides) when pseudomonas is suspected

## *ISSUES FOR REFERRAL*

Chronic; in treatment failure, consider biopsy and/or, in cases of chronic paronychia, referral for possible partial excision of the nail fold or eponychial marsupialization with or without complete nail removal.

## *SURGERY/OTHER PROCEDURES*

- Incision and drainage of abscess, if present
- A subungual abscess or ingrown nail requires partial or complete removal of nail with phenolization of germinal matrix.
- Recalcitrant cases may also need nail removal.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

Chronic: Avoid frequent immersion, triggers, allergens, or nail biting and finger sucking.

## *DIET*

If patient is diabetic, consider appropriate dietary and medication changes for better control.

## *PATIENT EDUCATION*

- Avoid trimming cuticles; avoid nail trauma; and stress importance of good diabetic control and diabetic education.
- Avoid contact irritants; use rubber gloves with cotton liners to avoid exposure to excess moisture.
- Use moisturizing lotion after washing hands; do not bite nails/suck on fingers.

## *PROGNOSIS*

- With adequate treatment and prevention, healing can be expected in 1 to 2 weeks.
- Chronic paronychia may respond slowly to treatment, taking weeks to months.
- If no response in chronic lesions, rarely benign or malignant neoplasm may be present and

referral should be considered.

## COMPLICATIONS

- Acute: subungual abscess
- Chronic: nail thickening, discoloration of nail, and nail loss

**&NA;**

Onychomycosis

## Codes

**&NA;**

### ICD10

- L03.019 Cellulitis of unspecified finger
- L03.039 Cellulitis of unspecified toe

## Clinical Pearls

**&NA;**

- Consider tetanus booster when indicated.
- Consider incision and drainage when appropriate. Send culture.
- For chronic paronychia, topical steroid is first-line treatment. Consider other differentials in nonresponders (e.g., rare causes: Raynaud, metastatic cancer, psoriasis, drug toxicity)
- For chronic nonhealing lesion, consider dermatology referral.
- Consider possibility of cancer if chronic inflammatory process is unresponsive to treatment.

- Consider presence of more than one nail disease at the same time (e.g., paronychia and onychomycosis).

# Parotitis, Acute and Chronic

Colleen W. Meehan, MD, MPH

Kathleen Ferrer, MD, AAHIVS

## BASICS

### DESCRIPTION

- Parotitis is inflammation of the parotid gland caused by infection (viral or bacterial), noninfectious systemic illnesses, mechanical obstruction, or medications.
- Parotitis can be unilateral or bilateral, acute or chronic. Unilateral parotitis is usually associated with duct obstruction, whereas bilateral parotitis more commonly indicates a systemic cause.
- The parotid gland is the largest of the salivary glands, located lateral to the masseter muscle anteriorly and extending posteriorly over the sternocleidomastoid muscle behind the angle of the mandible. It produces exclusively serous secretions, which lack the bacteriostatic properties of mucinous secretions, making the parotid gland more susceptible to infection than other salivary glands.
- The parotid duct, also called Stensen duct, pierces the buccinator muscle to enter the buccal mucosa just opposite the second maxillary molar.
- The branches of the 7th cranial nerve or Òfacial nerveÓ divide the gland into lobes.
- The parotid gland contains lymph nodes.

### EPIDEMIOLOGY

- Viral parotitis is the most common cause of parotitis in children, though the exact incidence is unknown and has decreased since the advent of the mumps vaccine.
- Acute bacterial parotitis occurs more frequently in elderly patients, neonates (especially preterm infants), and postoperative patients.
- Neonatal parotitis and juvenile recurrent parotitis are more common in males than females.
- Juvenile recurrent parotitis is the second most common inflammatory cause of parotitis in children in the United States; first episode usually occurs between the ages of 3 and 6 years.
- Chronic parotitis mainly affects adults, more often females. The average age of presentation is between 40 and 60 years.

- Chronic bilateral parotid enlargement is a common manifestation of HIV infection; for perinatally HIV-infected children, the average age of onset for parotid enlargement is 5 years.

## *RISK FACTORS*

- Acute viral parotitis: lack of mumps, measles, rubella (MMR) vaccination
- Acute bacterial parotitis
  - Conditions that predispose to salivary stasis such as dehydration, debilitation, poor oral hygiene, Sjögren syndrome, cystic fibrosis, bulimia/anorexia, sialolithiasis (stones), ductal stenosis, trauma
  - Immunosuppression, HIV, chemotherapy, radiation, malnutrition, alcoholism
- Neonatal parotitis: prematurity, low birth weight, ductal obstruction, oral trauma, structural abnormalities, immunosuppression
- Juvenile recurrent parotitis: dental malocclusion, congenital duct malformation, genetic factors, immunologic anomalies
- Drug-induced parotitis: medications such as anticholinergics, antihistamines, diuretics, tricyclic antidepressants, antipsychotics, antineoplastic agents, and iodine
- Chronic parotitis: ductal stenosis, HIV, tuberculosis, Sjögren syndrome, and sarcoidosis

## *GENERAL PREVENTION*

- MMR vaccination with the first dose between 12 and 15 months and second dose between 4 and 6 years of age; of note, mumps vaccination does not guarantee prevention, possibly due to waning immunity in adolescence
- Maintain adequate hydration and good dental hygiene.
- Suck on hard or sour candy and use hot compresses with parotid massages to stimulate salivary flow and prevent salivary stasis.
- Smoking cessation, abstinence from alcohol, and avoidance of chronic purging

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Acute viral parotitis begins as a systemic infection that localizes to the parotid gland, resulting in inflammation and swelling of the gland.
  - Mumps, or paramyxovirus, has a predilection for the parotid gland and classically has been linked to parotitis.
- Acute bacterial parotitis results from stasis of salivary flow that allows retrograde introduction

of bacterial pathogens into the parotid gland, resulting in localized infection.

- Acute parotitis pathogens
  - Viral
    - Paramyxovirus (mumps), parainfluenza virus types 1 and 3, influenza A, coxsackie viruses, Epstein-Barr virus (EBV)
    - Cytomegalovirus (CMV) and adenovirus have been seen in patients with HIV.
  - Bacterial
    - *Staphylococcus aureus* and anaerobes (oral flora) are most commonly seen.
    - *Streptococcus pneumoniae*, viridans streptococci, *Escherichia coli*, and *Haemophilus influenza* (less common)
    - Gram-negative rods such as *E. coli*, *Klebsiella*, *Enterobacter*, and *Pseudomonas* can be seen in chronically ill or hospitalized patients.
  - Fungal
    - *Candida* has been isolated in chronically ill or hospitalized patients.
    - *Actinomyces* can be found in patients with a history of trauma or dental caries.
- Acute, recurrent parotitis
  - Juvenile recurrent parotitis may be secondary to chronic inflammation; etiology is unknown, but a genetic predisposition may exist.
  - Mechanical: sialolithiasis, ductal stenosis; repeated sialolith formation can lead to ductal wall damage, fibrosis, and stricture formation, which further decreases salivary flow and perpetuates obstruction
  - Pneumoparotitis may occur when air is trapped in the ducts of the parotid gland; may be seen in wind instrument players, glass blowers, scuba divers, and with dental cleaning.
  - Medications: anticholinergics, antihistamines, tricyclic antidepressants, antipsychotics (especially phenylbutazone, thioridazine, clozapine), iodine (especially contrast media), and L-asparaginase (1)[C]
  - Other: diabetes, alcoholism, bulimia, Anesthesia mumps (possible mechanisms include transient mechanical compression of Stensen duct by airway devices, loss of muscle tone around the Stensen orifice after neuromuscular relaxants, increased salivary secretion, and increased flexion or rotation of the head during general anesthesia)
- Chronic parotitis may occur due to chronic ductal stenosis but is often due to a chronic

infectious or inflammatory condition

- HIV
- Tuberculosis, syphilis (rare)
- Autoimmune: Sjögren syndrome (parotid enlargement, xerostomia, and keratoconjunctivitis)
- Inflammatory: sarcoidosis
  - Heerfordt syndrome (parotid enlargement, facial palsy, and uveitis) is a rare manifestation of sarcoidosis.
- Chronic parotitis in HIV-infected patients can be due to the presence of benign lymphoepithelial cysts, follicular hyperplasia of parotid lymph nodes, or diffuse infiltrative lymphocytosis syndrome (DILS), causing infiltration of the parotid gland by CD8 cells.
  - Parotitis may also be secondary to immune reconstitution after initiation of combination antiretroviral therapy in HIV-infected patients.

## COMMONLY ASSOCIATED CONDITIONS

HIV, Sjögren syndrome, sarcoidosis, sialolithiasis

## DIAGNOSIS

### HISTORY

- Acute parotitis presents with sudden-onset pain and swelling of the cheek usually extending to and obscuring the angle of the mandible.
  - Viral parotitis is usually bilateral and accompanied by a prodrome of malaise, anorexia, headaches, myalgias, arthralgias, and fever; typically, overlying skin is not warm or erythematous, and no pus is reported at the opening of Stensen duct.
  - Bacterial parotitis is typically unilateral with induration, warmth, and erythema over the affected cheek; fever is often present.
  - Juvenile recurrent parotitis is usually unilateral; pain and swelling usually resolve within 2 weeks, and exacerbations occur until puberty; purulent exudate is not typical, but superinfection may occur.
  - Sialolithiasis is characterized by recurrent acute swelling and pain, exacerbated by eating; sialolithiasis affects the submandibular gland more frequently.
  - Other frequently reported symptoms include trismus (inability to open

mouth), pain exacerbated by chewing or worsened by foods that stimulate production of saliva (i.e., sour candies), dry mouth with abnormal taste, difficulty with drinking/eating, anorexia, or dehydration.

- Chronic parotitis presents with recurrent or chronic nontender swelling of one or both parotid glands; can have periods of remission lasting weeks to years.
  - Sjögren syndrome, sarcoidosis, HIV, tuberculosis
  - Chronic parotitis may predispose to superinfection, which would present similarly to an acute parotitis.

## PHYSICAL EXAM

- Parotitis is characterized by swelling or enlargement of the parotid gland(s) overlying the masseter muscle; it may obscure the angle of the mandible or cause the ear to protrude upward and outward.
- Palpation of the parotid gland is best done by using one hand to start at the attachment of the earlobe

P.767

and palpating anteriorly and inferiorly along the mandibular ramus while the other hand simultaneously palpates the Stensen duct orifice.

- Tender and bilateral suggests viral etiology, whereas tender, erythematous, warm, and unilateral suggests bacterial etiology.
- Nontender in HIV, tuberculosis, Sjögren syndrome, sarcoidosis
- Trismus may be noted.
- Pus from Stensen duct is suggestive of bacterial parotitis or superinfection; opening of duct may appear edematous and erythematous in both bacterial and viral parotitis.
- In juvenile recurrent parotitis, Stensen duct is often enlarged, dilated, erythematous, and swollen.
- Halitosis and dental decay are often associated with acute exacerbations.
- Facial nerve palsy can be seen in severe cases.

## DIFFERENTIAL DIAGNOSIS

- Lymphoma, neoplasm, lymphangitis, cervical adenitis, otitis externa, dental abscess, odontogenic infections, Ludwig angina, and cellulitis should be considered in the differential.
- Parotid swelling or enlargement typically obscures the angle of the mandible (unlike cervical adenitis).

- Involvement of Stensen duct is unique to parotitis.

## *DIAGNOSTIC TESTS & INTERPRETATION*

- History and physical exam are usually sufficient for diagnosis of parotitis.
- Performing aerobic culture and Gram stain of purulent drainage from Stensen duct or aerobic and anaerobic culture from needle aspiration of gland or abscess can be helpful to identify causative organism.
  - Anaerobic culture from Stensen duct will likely contain oropharyngeal contamination; hence, it is recommended to perform anaerobic cultures only from needle aspirate fluid.
- Acute bacterial parotitis often demonstrates an elevated white blood cell count and amylase.
- For suspected mumps, obtain mumps IgM antibody or mumps reverse transcription-polymerase chain reaction (RT-PCR). A 4-fold increase of mumps IgG antibody indicates infection.
- Consider sending EBV titers and respiratory virus PCR panel if viral parotitis suspected; CMV titers should be sent in immunocompromised patients.
- For chronic, recurrent, or nontender parotitis, obtain HIV test, PPD, SS-A SS-B antibodies, rheumatoid factor, and antinuclear antibodies to evaluate for underlying etiology.
- Consider obtaining ultrasound or CT scan of parotid area to assess for abscess, cystic masses, parotid tumors, ductal stenosis, or sialolithiasis if no response to initial treatment.
- Consider sialography with chronic parotitis to assess the anatomy and functional integrity of the gland; can be diagnostic and therapeutic.

### *Diagnostic Procedures/Other*

Consider performing a biopsy or fine-needle aspiration of gland if there is suspicion for tuberculosis, Sjögren syndrome, or sarcoidosis.

### *Test Interpretation*

- Findings characteristic of HIV are described in the ÒEtiology and PathophysiologyÓ section.
- Noncaseating granulomas may be seen in sarcoidosis, and caseating granulomas may be found in tuberculosis.

## **TREATMENT**

## GENERAL MEASURES

- Usually a self-limiting course that requires primarily supportive treatment with rest, adequate hydration, analgesia, and antipyretics
  - Can stimulate glands to produce saliva by sucking on hard candies or glycerin swabs
  - Local heat and gentle massage of gland can provide symptomatic relief.
  - For chronic presentations, encourage good dental hygiene and treat underlying etiology of parotitis (HIV, Sjögren syndrome, etc.).
- Patients diagnosed with mumps should be isolated with standard and droplet precautions for 5 days after onset of parotid swelling.

## MEDICATION

- Viral parotitis: with an uncertain diagnosis or toxic presentation, can empirically initiate antibiotics to cover *Staphylococcus aureus*, anaerobes (oral flora), and *Streptococcus pneumoniae*
- Acute bacterial parotitis
  - Outpatient management: amoxicillin/clavulanate, first-generation cephalosporin, clindamycin
  - Chronically ill or hospitalized: ampicillin/sulbactam or clindamycin and nafcillin; if methicillin resistance is probable, consider vancomycin or linezolid
- Pilocarpine and cevimeline can stimulate saliva production and inhibit ascending infection as well as provide symptomatic relief for patients with underlying Sjögren syndrome.

## SURGERY/OTHER PROCEDURES

- Consider needle aspiration for bacterial parotitis with abscess formation or clinical deterioration with increasing pain, erythema, and swelling not responding to medication.
- May perform serial drainage for symptomatic cysts
- Consider superficial parotidectomy for severe recurrent parotid infections in patients with underlying predisposing etiology (such as Sjögren syndrome).
- Sialendoscopy with cortisone irrigation is effective and safe for the treatment of juvenile recurrent parotitis; cortisone irrigation alone may be just as effective (2)[A].(3)[C].
- For sialolithiasis, ductal stenosis, or for patients with >1 recurrence per year, consult otolaryngologist for possible duct ligation, ductoplasty, or parotidectomy.
- Sclerotherapy with methyl violet or tetracycline has been shown to be effective in the treatment of cysts in HIV parotitis and is also considered definitive treatment for chronic

parotitis (4)[C].

## INPATIENT CONSIDERATIONS

Admission is recommended for patients with comorbidities, systemic involvement, and inability to tolerate PO, as well as neonates and patients for whom close outpatient follow-up is not feasible.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

Antibiotic therapy initiated at diagnosis combined with adequate hydration should result in improvement within 48 hours. If not, patient should be reevaluated.

### DIET

- Ensure adequate fluid intake.
- Hard or sour candies to promote salivary flow

### PROGNOSIS

- Viral infection in immunocompetent individuals often resolves with excellent prognosis.
- Parotid cysts found in HIV-infected patients are usually benign lymphoepithelial lesions with infrequent malignant transformation.
- Increased incidence of malignant lymphoma or lymphoepithelial carcinoma may be seen in patients with Sjögren syndrome.

### COMPLICATIONS

- For mumps, potential complications include orchitis, oophoritis, mastitis, meningitis, pancreatitis, sensorineural hearing loss, and nephritis.
- Untreated bacterial parotitis can lead to local extension, abscess formation, and facial paralysis.

## Codes

### &NA;

## ICD10

- K11.20 Sialoadenitis, unspecified
- K11.21 Acute sialoadenitis
- K11.23 Chronic sialoadenitis

## Clinical Pearls

### &NA;

- History and physical exam are usually sufficient for diagnosis (parotid swelling and tenderness with or without purulent drainage from Stensen duct).
- In recurrent or chronic cases, consider other underlying etiologies such as HIV.

- *S. aureus* and anaerobes (oral flora) are the most common organisms isolated in acute bacterial parotitis.
- Encouraging good oral hygiene and adequate hydration in chronically ill, debilitated, and hospitalized patients can reduce parotitis occurrence.

# Parvovirus B19 Infection

David L. Anderson, MD

Thomas P. Garigan, MD, MA

## BASICS

### DESCRIPTION

- Human parvovirus B19 is the primary cause of acute erythema infectiosum (EI, or fifth disease).
- Complications in susceptible individuals with increased RBC turnover (e.g., sickle cell anemia [SS]) include transient aplastic crisis (TAC). In immunocompromised individuals, pure red cell aplasia (PRCA) and chronic anemia are significant complications. In normal hosts, arthritis and arthralgias are common.
- System(s) affected: hematologic/lymphatic/immunologic, musculoskeletal, skin/exocrine, possibly central nervous system, cardiac, renal

### *Pregnancy Considerations*

A documented acute infection during pregnancy should prompt referral to a maternal-fetal medicine specialist. Maternal parvovirus B19 infection between 9 and 20 weeks' gestation may carry a significant fetal risk.

### EPIDEMIOLOGY

- Infection is common in childhood.
- EI has an extremely low mortality rate.
- Peak age for EI is 4 to 12 years.
- Males and females are equally affected.
- Adult females are more likely to develop postinfectious arthritis.
- No known racial predilection
- In temperate climates, infections often occur from late winter to early summer.
- Local outbreaks may occur every 2 to 4 years.

## *Prevalence*

Extremely common in the United States. Based on IgG serology:

- 1 to 5 years of age: 2-15% seropositive
- 6 to 15 years of age: 20-40% seropositive
- 16 to 40 years of age: 50-60% seropositive
- >40 years of age: 70-85% seropositive

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Small (20 to 25 nm), nonenveloped, single-stranded DNA virus in *Parvoviridae* family
  - Only known parvovirus to infect humans; does not cross-infect dogs or cats
- Natural host of B19 is human erythroid progenitor.
- Respiratory, hematogenous, and vertical transmission are sources of human spread.
- 4- to 14-day incubation. Rash and joint symptoms occur 2 to 3 weeks after initial infection.
- Most contagious 5 to 10 days after exposure
- EI rash thought to be autoimmune due to IgM complexes concurrent with viral clearance.
- Cytotoxic infection of proerythroblasts reduces RBC production.

## *Genetics*

Erythrocyte P antigen-negative individuals are resistant to infection.

## *RISK FACTORS*

- School-related epidemic and nonimmune household contacts have a secondary attack rate of 20-50%.
- Highest secondary attack rates are for daycare providers and school personnel in contact with affected children.
- Those with increased cell turnover (e.g., hemoglobinopathy, SS, thalassemia) are at risk for TAC.
- Immunodeficiency (e.g., HIV, congenital) increases risk of PRAC and chronic anemia.
- As many as 40% of pregnant women are not immune. 1.5% seroconversion rate per year

## *GENERAL PREVENTION*

Respiratory spread. Standard measures include hand washing and barrier protection.

- Droplet precautions are recommended around patients with TAC, chronic infection, or anemia.
- Difficult to eliminate exposure because the period of maximal contagion occurs prior to the onset of clinical symptoms (rash).
- Pregnant health care workers should avoid caring for patients with TAC.
- No significant risk of infection based on occupational exposure. Exclusion from the workplace is neither necessary nor recommended.
- No preventive vaccine is available.

## *COMMONLY ASSOCIATED CONDITIONS*

- Nondegenerative arthritis
  - In adults, 80% of patients may manifest polyarthritis and/or arthralgia (female > male).
  - In children, joint symptoms are less common.
  - Knees, hands, wrists, and ankles (frequently symmetric) are most commonly involved.
  - Joint symptoms usually subside within 3 weeks but may persist for months. Routine radiography is not necessary.
- TAC
  - Involves patients with increased RBC turnover (SS, spherocytosis, thalassemia) or decreased RBC production (iron deficiency anemia).
  - Patients present with fatigue, weakness, lethargy, and pallor (anemia).
  - Aplastic event may be life-threatening but is typically self-limited. Reticulocytes typically reappear in 7 to 10 days and full recovery in 2 to 3 weeks.
  - In children with sickle cell hemoglobinopathies and heredity spherocytosis, fever is the most common symptom (73%). Rash is uncommon in these patients.
- Chronic anemia
  - Seen in immunocompromised individuals (HIV, cancer, transplant) with poor IgM response
  - Usually no clinical manifestations (fever, rash, or joint symptoms)
- Fetal/neonatal infection (1)
  - Risk of transplacental spread of virus is ÷33% in infected mothers.
  - Test pregnant women with a rash or arthralgias consistent with parvovirus B19.

- Clinical manifestations vary. Many patients are seroconvert without symptoms and have a normal pregnancy. Other patients develop variable degrees of fetal hydrops. 2nd- and 3rd-trimester pregnancy loss can occur without hydrops.
  - Suspect B19 infection in cases of nonimmune fetal hydrops.
  - Fetal bone marrow is primarily impacted. RBC survival is shortened, resulting in anemia and (potentially) high-output cardiac failure.
  - >95% of fetal complications (fetal hydrops and death) occur within 12 weeks of acute maternal parvovirus B19 infection.
  - Risk of fetal loss is highest (2-5%) in the 1st trimester.
  - Infants requiring intrauterine transfusions due to parvovirus B19 infection are at risk for long-term neurodevelopmental impairment.
- Papular purpuric gloves and socks syndrome (PPGSS) is an uncommon dermatosis associated with parvovirus B19 infection. It results in a petechial and ecchymotic rash of the hands and feet associated with febrile tonsillopharyngitis and oral ulcerations (2).

## DIAGNOSIS

### HISTORY

- Rash
- Headache
- Pharyngitis
- Coryza and rhinorrhea
- Arthralgias and arthritis
- Nausea and GI disturbances are more frequent and severe in adults (nonspecific flulike illness).
- Pruritus (especially soles of feet)
- Fever, myalgia, and malaise

### PHYSICAL EXAM

- "Slapped cheek" appearance is a well-known facial rash that spares the nasolabial folds.
- A lacy, reticular rash on the trunk, buttocks, and limbs often follows 1 to 4 days later lasting 1 to 6 weeks.
- The rash may be pruritic and recurrent, exacerbated by bathing, exercise, sun exposure, heat, or emotional stress.

- B19 may manifest as painful pruritic papules and purpura on the hands and feet.

## *DIFFERENTIAL DIAGNOSIS*

- Rubella
- Enteroviral disease
- Systemic lupus erythematosus
- Drug reaction
- Lyme disease
- Rheumatoid arthritis

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- No need for routine lab studies in typical cases. Diagnosis is clinical; illness is mild and self-limiting.
- IgG and IgM serology in immunocompetent patients
- B19-specific DNA polymerase chain reaction (PCR) testing for fetal infection (via cord blood or amniotic fluid) as well as for patients with chronic infection or those who are immunocompromised

---

P.769

- PCR increases diagnostic sensitivity and specificity to confirm infections in IgM-negative patients.
- For patients with TAC, CBC with reticulocyte count shows anemia and reticulocytopenia. IgM antibodies are present by day 3, and IgG antibodies are detectable at time of clinical recovery. PCR shows high levels of viremia.
- Pregnant women exposed to B19 require serial IgG and IgM serology to assess fetal risk.

### *Follow-Up Tests & Special Considerations*

Fetal/neonatal infection (3)[C]

- To exclude congenital B19 in infants with negative B19 IgM, follow IgG serology over the 1st year of life.
- Maternal serum *&agr*-fetoprotein may be increased with hydrops fetalis.
- Documented acute maternal infection in the 1st trimester warrants serial fetal ultrasound to

assess for hydrops: ascites, pericardial effusion, oligohydramnios, cardiomegaly, and placental thickening.

- Weekly peak systolic velocity measurements of the middle cerebral artery by Doppler US is recommended to evaluate for heart failure fetal anemia and the potential need for intrauterine transfusion ( $>1.5$  MoM).
- Cerebral MRI to explore CNS damage in infected neonates with prolonged hydrops fetalis or hematocrit  $<15\%$ .

### *Diagnostic Procedures/Other*

- Skin biopsy is usually normal but may show mild inflammation consisting of perivascular infiltrations of mononuclear cells.
- In stillbirths related to maternal B19 infection, virus can be detected in all tissues.
- In hydrops fetalis, nucleated RBCs may have intranuclear inclusion bodies.

## **TREATMENT**

### *GENERAL MEASURES*

- No therapy is usually needed (4)[C].
- Cessation of immunosuppressive therapy allows some patients to clear chronic infections.
- B19-associated anemia in HIV-positive patients may resolve with highly active antiretroviral therapy.

### *MEDICATION*

#### *First Line*

- Anti-inflammatory agents for arthritic symptoms
- Antipyretics for fever. Avoid aspirin in children.

#### *Second Line*

- RBC transfusions for aplastic crisis
- Intravenous immunoglobulin (IVIG) for B19-related refractory anemia or PRAC, especially in immunodeficient states (5)[C]
- Intrauterine RBC transfusions reduce mortality in cases of fetal hydrops.

## *ISSUES FOR REFERRAL*

- Acute infection during pregnancy should prompt referral to a maternal-fetal medicine specialist.
- TAC patients require treatment by a hematologist.
- Patients with chronic or abnormal B19 infections may benefit from consultation with immunology or infectious disease specialists.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Outpatient management is typical for EI.
- Inpatient management for aplastic crisis, which may require RBC transfusions

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Periodic blood counts for anemic patients

### *PATIENT EDUCATION*

- Parvovirus B19 (fifth disease): <http://www.cdc.gov/parvovirusB19/fifth-disease.html>
- Parvovirus B19: What You Should Know: <http://www.aafp.org/afp/2007/0201/p377.html>
- Parvovirus B19 infection and pregnancy: <http://www.cdc.gov/parvovirusB19/pregnancy.html>
- March of Dimes Fifth Disease and Pregnancy:  
<http://www.marchofdimes.org/complications/fifth-disease-and-pregnancy.aspx>
- Counsel pregnant women regarding prevention of maternal B19 infection.
- Pregnant women should avoid exposure to patients with active/chronic infections. Exclusion of pregnant women from the workplace where EI is occurring is not recommended because they have likely been exposed.
- Children with typical rash are no longer infectious and may attend childcare or school.

## *PROGNOSIS*

- Usually self-limited
- Joint symptoms subside in weeks (often by 2 weeks but may last months).
- ÷20% of infections result in delayed virus elimination and viremia persisting for several months to years.
- Full recovery from aplastic crisis in 2 to 3 weeks

## COMPLICATIONS

Conditions associated with B19 but where causality is unconfirmed.

- Chronic fatigue syndrome
- Glomerulonephritis, nephrotic syndrome, and other renal diseases
- Hepatitis
- Neurologic manifestations/stroke/meningoencephalitis
- Henoch-Schönlein purpura, idiopathic thrombocytopenic purpura, and vasculitis
- Myocarditis and pericarditis
- Hemophagocytic syndrome

### Codes

### &NA;

## ICD10

- B34.3 Parvovirus infection, unspecified
- B08.3 Erythema infectiosum [fifth disease]

## Clinical Pearls

### &NA;

- Parvovirus B19 infection is usually a benign, self-limited illness with no long-term effects.

- The rash of EI, a "slapped cheek" appearance, signifies that the patient is no longer infectious.
- Patients with increased RBC turnover (SS, thalassemia) are at risk for TAC.
- Immunocompromised patients may be at risk for chronic anemia.
- Documentation of acute infection in pregnant women under 20 weeks' gestation merits maternal-fetal consultation.

# Patellofemoral Pain Syndrome

Rathna Nuti, MD

Robert J. Dimeff, MD

## BASICS

### DESCRIPTION

- Pain in or around the patella that increases after prolonged sitting, squatting, kneeling, and stair climbing (1)
- System(s) affected: musculoskeletal

### EPIDEMIOLOGY

#### Prevalence

- Most frequently diagnosed condition in patients <50 years old with knee complaints (1)
- Women have higher incidence than men (1,2).
- More predominant in female adolescents and physically active young adults (3)
- High incidence in physically active populations (3)
- Incidence of 15-25% in the general population (3)
- Accounts for 25% of all knee injuries (4)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Multifactorial etiology (1)
- Direct relationship with hip weakness and poor functional control of the femur during weight-bearing tasks (5)
- Structural anomalies and lower extremity malalignment also contribute (1).
- Shortened quadriceps results in increased contact time and force between the retropatellar cartilage and the trochlear groove (4).

#### Genetics

Unknown

## *RISK FACTORS*

- Weak quadriceps (1)
- Female gender;
- Q angle >20 degrees (1)
- Limited quadriceps and gastrocnemius flexibility (6)
- Excessive knee valgus during landing (6)
- Subtalar hyperpronation (6)
- Tight iliotibial band and/or lateral retinaculum (6)
- Decreased strength (or timing) of (between) the medial quadriceps and the gluteus medius (6)
- Decreased hamstring flexibility (5)
- Decreased explosive strength (5)
- Improper training equipment (5)
- Decreased trochlear groove depth (5)
- Increased medial patellar mobility (5)
- Patella alta (5)
- Increased medial tibial intercondylar distance (5)

## *GENERAL PREVENTION*

- Mitigate risk factors (1)
- Strengthening exercises (1)
- Reduce training volume (7)

## *COMMONLY ASSOCIATED CONDITIONS*

- Overuse
- Knee ligament injury/surgery
- Patellar tendinopathy
- Prolonged synovitis
- Iliotibial band friction syndrome

# DIAGNOSIS

## HISTORY

- An accurate history should differentiate retropatellar pain from knee instability (e.g., pain quality, swelling, giving way, mechanical symptoms, and grinding, inciting events, overuse, and history of trauma)
- Most common symptom: anteromedial knee pain exacerbated by physical activity
- Pain often exacerbated when squatting (3)[A].
- Anterior knee pain when descending/ascending stairs, ambulating over uneven surfaces, or running
- Pain after activity as well as during activity

## PHYSICAL EXAM

- Patellar tilt test: With patient supine, grasp patella between thumb and forefinger and try to lift up the outside edge of the patella using the thumb (3)[A].
- Squatting (3)[A]
- Vastus medialis coordination test: While patient is laying down supine, place fist under patient's knee and ask the patient to extend the knee slowly without pressing down or lifting away from you (3)[A].
- Apprehension sign: Compress the patella against the femur and ask the patient to contract quadriceps muscles; pain upon contraction is consistent with patellofemoral pain syndrome, although pain may be present in normal individuals as well (3)[A].
- Compression test: reproduction of pain with compression of patella against the trochlea (3)[A]

## DIFFERENTIAL DIAGNOSIS

- Prepatellar bursitis; patellar and quadriceps tendinitis/tendinopathy
- Patellofemoral arthrosis; patellar subluxation and dislocation
- ACL, PCL, and meniscal pathology
- Soft tissue and bony tumors
- Iliotibial band syndrome
- Plica syndrome
- Patellar fat pad inflammation; patellofemoral osteoarthritis

- Chondromalacia patella/osteochondral defect
- Sinding-Larsen-Johansson syndrome
- Osgood-Schlatter disease
- Referred pain from hip or spine
- Traction apophysitis

## DIAGNOSTIC TESTS & INTERPRETATION

- None indicated. *In general, imaging is unnecessary and not helpful in diagnosing patellofemoral pain syndrome.* If imaging is indicated because of severity, atypical symptoms, or persistence of symptoms despite treatment, four views (plain films) of the knee are recommended to view patellar tilt:
  - Lateral
  - Merchant (also called sunrise)
  - Standing anteroposterior
  - Posteroanterior tunnel views:
- Radiographic findings may not correlate with symptoms.

## Follow-Up Tests & Special Considerations

Radiographic images may be normal until late stages, when the posterior patellar surface becomes irregular and cartilage erosion becomes radiographically detectable.

### Test Interpretation

Generally a clinical diagnosis. Tests not necessary.

P.771

## TREATMENT

Conservative therapy is the gold standard (5)[A].

## GENERAL MEASURES

- Stretching and strengthening exercises, especially hip strengthening (5)[A]
- Taping and bracing (5)[A]
- Activity modification (5)[A]

- Cast immobilization (5)[A]
- NSAIDs for pain management (5)[A]
- Neuromuscular retraining interventions (especially with physical therapy) (5)[A]
- Supervised exercise therapy program including quadriceps training (1)[A]
- Foot orthoses (8)[A]
- Electrotherapy and biofeedback (8)[A]

## ***MEDICATION***

- NSAIDs for pain management (5)[A]
- The evidence for beneficial effects of glucosamine and chondroitin supplementation is conflicting and merits further investigation. They may have anti-inflammatory effects and function as articular cartilage and synovial fluid precursors.
- Nandrolone may be effective, but it is too controversial to recommend for treatment.

## ***ISSUES FOR REFERRAL***

Referral for surgery is a last resort after all conservative measures fail. Surgery is rarely needed.

## ***ADDITIONAL THERAPIES***

Ice packs after activity improve clinical symptoms.

## ***SURGERY/OTHER PROCEDURES***

- No additional benefits of surgery compared to conservative treatment (8)[A].
- Attempts to correct maltracking of the patellofemoral joint with a lateral retinacular release or tibial tubercle transposition have shown variable results (5)[A].
- Rarely indicated

## **ONGOING CARE**

### ***PATIENT EDUCATION***

Patient education and exercises:

<http://familydoctor.org/online/famdocen/home/healthy/physical/injuries/479.html>

## ***PROGNOSIS***

- Patellofemoral pain syndrome often improves spontaneously with relative rest and physical therapy.
- Conversely, established chondromalacia patella, which involves actual injury to the patellofemoral joint cartilage has a poorer prognosis.

## See Also

&NA;

Algorithm: Knee Pain

## Codes

&NA;

### ICD10

- M25.569 Pain in unspecified knee
- M25.561 Pain in right knee
- M25.562 Pain in left knee

## Clinical Pearls

&NA;

- Patellofemoral pain syndrome is the most common cause of anterior knee pain in active adults. Women are more commonly affected.
- The diagnosis is made through an accurate history and physical exam. The apprehension sign

is the most sensitive finding on physical exam.

- Well-designed exercises targeting quadriceps strengthening, hamstring, and IT band flexibility and hip stabilizer stretching/strengthening are the most effective evidence-based treatment.

# Pediculosis (Lice)

Kaelen C. Dunican, PharmD

Cynthia Jeremiah, MD

## BASICS

### DESCRIPTION

- A contagious parasitic infection caused by ectoparasitic blood-feeding insects (lice)
- Two species of lice infest humans:
  - *Pediculus humanus* has two subspecies: the head louse (var. *capitis*) and the body louse (var. *corporis*). Both species are 1- to 3-mm long, flat, and wingless and have three pairs of legs that attach closely behind the head.
  - *Phthirus pubis* (pubic or crab louse): resembles a sea crab and has widespread claws on the second and third legs
- System(s) affected: skin/exocrine
- Synonym(s): lice; crabs

### EPIDEMIOLOGY

#### Incidence

- In the United States: 6 to 12 million new cases per year
- Predominant age
  - Head lice: most common in children 3 to 12 years of age; more common in girls than boys
  - Pubic lice: most common in adults

#### Prevalence

Head lice: 1-3% in industrialized countries

### ETIOLOGY AND PATHOPHYSIOLOGY

- Infestation by lice: *P. humanus* (var. *capitis*), *P. humanus* (var. *corporis*), or *P. pubis*

- Characteristics of lice:
  - Adult louse is dark grayish and moves quickly but does not jump or fly.
  - Eggs (nits) camouflage with the individuals' hair color and are cemented to the base of the hair shaft (within 4 mm of the scalp).
  - Nits (empty egg casings) appear white (opalescent) and remain cemented to the hair shaft.
  - Lice feed solely on human blood by piercing the skin, injecting saliva (anticoagulant properties to allow for blood meal), and then sucking blood.
  - Itching is a hypersensitivity reaction to the saliva of the feeding louse.
- Transmission: direct human-to-human contact
  - Head lice: direct head-to-head contact or contact with infested fomite (less likely)
  - Body lice: contact with contaminated clothing or bedding
  - Pubic lice: typically transmitted sexually (fomite transmission much less likely)

## *RISK FACTORS*

- General: overcrowding and close personal contact
- Head lice
  - School-aged children, gender (girls; longer hair)
  - Sharing combs, hats (including helmets), clothing, and bed linens
  - African Americans rarely have head lice; theories include twisted hair shaft and increased use of pomades
- Body lice: poor hygiene, homelessness
- Pubic lice: promiscuity (very high transmission rate)

## *GENERAL PREVENTION*

- Environmental measures: Wash, dry-clean, or vacuum all items that may have come in contact with infected individuals.
- Screen and treat affected household contacts.
- Head lice: Follow-up by school nurses may help to prevent recurrence and spread.
- Pubic lice: Limit the number of sexual partners (condoms do not prevent transmission nor does shaving pubic hair).

Body lice: proper hygiene

## COMMONLY ASSOCIATED CONDITIONS

Up to 1/3 of patients with pubic lice have at least one concomitant STI.

## DIAGNOSIS

### HISTORY

- Pruritus is common, mostly at night.
- Often associated with “outbreak” in school settings
- Investigate contacts of infected individuals.

### PHYSICAL EXAM

- Diagnosis is confirmed by visualization of live lice.
- *P. capitis* (head lice)
  - Found most often on the back of the head and neck and behind the ears (warmer areas)
  - Eyelashes may be involved.
  - Eggs, found cemented on the base of a hair shaft, are difficult to remove.
  - Pruritus may be accompanied by local erythema and small papules.
  - May see excoriations around hairline
  - Scratching can cause inflammation and secondary bacterial infection.
  - Pyoderma and lymphadenopathy may occur in severe infestation.
- *P. corporis* (body lice)
  - Poor general hygiene
  - Adult lice and nits in the seams of clothing
  - Intense pruritus involving area covered by clothing (trunk, axillae, and groin)
  - Uninfected bites present as erythematous macules, papules, and wheals.
  - Pyoderma and excoriation may be seen.
- *P. pubis* (pubic lice)
  - Pubic hair is the most common site, but lice may spread to hair around anus, abdomen, axillae, chest, beard, eyebrows, and eyelashes.

- Eggs are present at the base of hair shafts.
- Anogenital pruritus
- Blue macules may be seen in surrounding skin.
- Delay in treatment may lead to development of groin infection and regional adenopathy.

## *DIFFERENTIAL DIAGNOSIS*

- Scabies and other mite species that can cause cutaneous reactions in humans
- Dandruff and other hair debris sometimes look like head lice eggs and nits but is less adherent.

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Diagnosis is based on visualization of live louse.
- Head lice: Comb hair thoroughly with a fine-toothed louse comb (0.2 to 0.3 mm between teeth) to identify live lice (1)[C]. Wet hair may limit static electricity. Simple visual inspection has same sensitivity as wet combing but is only ÷25% as effective as dry combing with a metal comb (2).
- Body lice: Examine the seams of clothing to locate lice and eggs (3).
- Lice and eggs are more easily visualized under a microscope.
- In contrast to dandruff, eggs and nits cannot be removed easily from a hair shaft.

## **Follow-Up Tests & Special Considerations**

- Empty nits remain on hair shafts for months after eradication of the live infestation. On Wood lamp exam, live nits fluoresce white and empty nits fluoresce gray.
- Pubic lice: Evaluate for concurrent STIs.

## **TREATMENT**

### *MEDICATION*

Permethrin (over the counter [OTC]), synergized pyrethrin (OTC), spinosad (Rx), benzyl alcohol (Rx), malathion (Rx), and topical ivermectin (Rx) are all effective for head lice (1)[A],(2)[C]. Permethrin, synergized pyrethrin, and malathion are effective for pubic lice (2)[C]:

- Permethrin generally preferred because it has residual activity for up to 3 weeks. However, newer shampoos and conditioners may reduce the residual effect (1)[C].

- Malathion and spinosad are considered second line for head lice but may not require a second application due to ovicidal activity (1)[B],(2)[C].
- Ivermectin 0.5% lotion is also effective for head lice (2)[C].

## *First Line*

- Head and pubic lice
- Pyrethrum insecticides: permethrin 1% cream rinse (Nix) or pyrethrins 0.33% with piperonyl butoxide 4% (synergized pyrethrin, Rid, Pronto): are first line unless there is proven resistance in the community.
  - Apply for 10 minutes, then wash.
  - Reapply synergized pyrethrin in 7 to 10 days (day 9 is optimal). Also be necessary with permethrin, if live lice are observed.
  - Side effects: application-site erythema, ocular erythema, and application-site irritation
- Body lice: best treated with synergized pyrethrin lotion applied once and left on for several hours
- Eyelash infestation: Apply petroleum jelly BID for 10 days.
- Precautions
  - Pyrethrin: Avoid in patients with ragweed allergy (may cause respiratory symptoms).
  - Pediculicides should never be used to treat eyelash infections.

## *Second Line*

Head lice and pubic lice

- Malathion 0.5% lotion (Ovide)
  - Apply for 8 to 12 hours, then wash off
  - Excipients isopropyl alcohol (78%) and terpineol (12%) may contribute to its efficacy:
    - Flammable and has a bad odor
    - Despite ovicidal activity, a second application may be necessary after 7 to 10 days (day 9 is optimal) if live lice are observed.
  - Lindane 1% shampoo, no longer recommended by the American Academy of Pediatrics
    - Apply for 4 minutes, then wash (should *not* be repeated).

Side effects: neurotoxicity (seizures, muscle spasms), aplastic anemia

- Contraindications: uncontrolled seizure disorder, premature infants

P.773

- Precautions: Do not use on excoriated skin, in immunocompromised patients, conditions that increase seizure risk, or with medications that decrease seizure threshold.
- Possible interactions: concomitant use with medications that lower the seizure threshold

- Head lice

- Spinosad 0.9% lotion (Natroba)

- Apply to dry hair and scalp for 10 minutes, then rinse with warm water. Repeat in 7 days if live lice are observed.
- Side effects: application-site erythema, ocular erythema, and application-site irritation

- Benzyl alcohol 5% lotion (Ulesfia)

- Apply to dry hair using enough to saturate scalp and hair (amount depends on hair length), rinse after 10 minutes, and repeat in 7 days.
- Side effects: pruritus, erythema, pyoderma, ocular irritation, application-site irritation

- Ivermectin 0.5% lotion (Sklice)

- Apply to dry hair by using enough to saturate the scalp and hair (max. 4 oz) then rinse after 10 minutes.
- Side effects: burning sensation at application site, dandruff, dry skin, eye irritation

- Mechanical removal of lice and nits by wetting hair and then systematically combing with a fine-toothed comb every 3 to 4 days for 2 weeks to remove all lice as they hatch

## **ALERT**

Lindane: FDA black box warning of severe neurologic toxicity (use only when first-line agents have failed). The National Pediculosis Association strongly advises against using lindane at all.

## **GENERAL MEASURES**

- Head lice: Clean items that have been in contact with the head of the infected individual within 48 hours.
- Wash all bedding, towels, clothes, headgear, combs, brushes, and hair accessories in hot water (60°C).

- Vacuum furniture and carpets
- Seal any personal articles that cannot be washed in hot water, dry cleaned, or vacuumed in a plastic bag and store for at least 2 weeks.
- Examine and treat household members and close contacts concurrently.
- Insecticide sprays are not necessary.
- Pubic lice: Avoid sexual activity until both partners are successfully treated.
- Nit and egg removal
  - Remove eggs that are within 1 cm of the scalp to prevent reinfestation.
  - After treatment with shampoo or lotion, eggs and nits remain in the scalp or pubic hair until mechanically removed. Hair conditioner facilitates nit removal.
  - Eggs and nits are best removed with a very fine nit comb.

### *Pediatric Considerations*

- Avoid synergized pyrethrin and permethrin in infants <2 months of age. Avoid benzyl alcohol, topical ivermectin, and spinosad in children <6 months of age; and avoid malathion in children <2 years of age.
- Lindane: not recommended in patients <50 kg

### *Pregnancy Considerations*

Permethrin, synergized pyrethrin, malathion, spinosad, and benzyl alcohol are pregnancy Category B. Lindane and topical ivermectin are Category C.

## **ADDITIONAL THERAPIES**

- For difficult to treat cases of head lice, oral ivermectin 400  $\mu\text{g}/\text{kg}$  (not approved by the FDA for lice), given twice at a 7-day interval, is superior to topical 0.5% malathion lotion (4,5) [B].
- Ivermectin: 200  $\mu\text{g}/\text{kg}$  PO repeated in 10 days or 300  $\mu\text{g}/\text{kg}$  PO repeated in 7 days
  - Should not be used in children <15 kg; pregnancy Category C
  - Not approved by the FDA for lice
- Dual therapy with 1% permethrin and oral trimethoprim/sulfamethoxazole (TMP/SMX) only for cases of multiple treatment failures or suspected cases of lice-related resistance to therapy (TMP/SMX is not approved by the FDA for lice).
- Permethrin 5% cream (Rx) is not FDA approved for lice and is unlikely to be effective for lice

that are resistant to 1% cream rinse (1)[B].

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

### Head lice

- Dry-on, suffocation-based pediculicide: Cetaphil lotion
  - Apply thoroughly to hair, comb, dry with hair dryer, shampoo after 8 hours.
  - Repeat once a week until cured, up to a maximum of three applications.
  - Not approved by the FDA for lice
- Dimethicone 4% lotion: Apply to hair for 8 hours; repeat in 1 week (not approved by the FDA for lice).
- No home remedies (e.g., vinegar, isopropyl alcohol, olive oil, ylang ylang oil, mayonnaise, melted butter, and petroleum jelly) have been proven effective to treat head lice infestations.
- Herbal shampoos and pomades have not been evaluated in clinical trials and are not approved by the FDA for lice.
- Lavender oil and tea tree oil have been implicated in triggering prepubertal gynecomastia in boys and should not be used to treat lice.
- Electronic louse combs have not proven effective and are not approved by the FDA.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Children may return to school after completing topical treatment, even if nits remain in place. No-nit policies are not necessary.

### ***Patient Monitoring***

Drug resistance should be suspected if no dead lice are observed in 8 to 12 hours after treatment.

### ***PATIENT EDUCATION***

- National Pediculosis Association: <http://www.headlice.org/>
- CDC: <http://www.cdc.gov/parasites/lice/>
- <http://www.guideline.gov/content.aspx?id=46429&search=lice>

## PROGNOSIS

- With appropriate treatment, >90% cure rate
- Recurrence is common, mainly from reinfection or treatment nonadherence. Resistance to synthetic pyrethroids is increasing.

## COMPLICATIONS

- Poor sleep due to pruritus
- Persistent itching may be caused by too frequent use of the pediculicide.
- Missed school; social stigma
- Secondary bacterial infections
- Body lice can transmit typhus and trench fever.

- B85.1 Pediculosis due to *Pediculus humanus corporis*
- B85.3 Phthiriasis

## Clinical Pearls

&NA;

- School-based no-nit policies are not necessary because empty nits may remain on hair shafts for months after successful eradication.
- Proper product application is essential; consider improper product application when assessing treatment failure.
- Prevalence of resistant infestations is increasing, so if no dead lice are observed in 8 to 12 hours after treatment, suspect resistance and use an alternative agent.
- Routine retreatment on day 9 is recommended for nonovicidal products (permethrin and synergized pyrethrin).
- With all treatment options, reinspect hair after 7 to 9 days and, if live lice are detected, repeat treatment on day 9.

# Pelvic Inflammatory Disease

Fozia Akhtar Ali, MD

Paula A. Shelton, MD

## BASICS

### DESCRIPTION

- Pelvic inflammatory disease (PID) is an infectious and inflammatory disorder of the upper female genital tract, including the uterus, fallopian tubes, ovaries, and adjacent pelvic structures. It is community acquired from sexually transmitted organisms (1).
- Salpingitis is the most important component due to its impact on future fertility.
- Diagnosis may be challenging and incorrect in up to 1/3 of cases. No set of criteria is both sensitive and specific for the disease.
- System(s) affected: reproductive

### EPIDEMIOLOGY

- Predominant age: 15 to 25 years; this number has remained constant since early 1900s.
- Predominant sex: female only (1)

### Incidence

Over 770,000 cases of acute PID are diagnosed annually in the United States. Incidence decreased from 1885 to 2001. The CDC has estimated that more than 1 million women experience an episode of PID every year. The disease leads to approximately 2.5 million office visits, 200,000 hospitalizations, and 100,000 surgical procedures yearly. The cost of PID is approximately \$2 billion annually; however, costs have decreased over the past decade (2).

### ETIOLOGY AND PATHOPHYSIOLOGY

Multiple organisms may be etiologic agents in PID. Most cases are polymicrobial.

- *Chlamydia trachomatis*, *Neisseria gonorrhoeae*, genital tract mycoplasmas (particularly *Mycoplasma genitalium*), aerobic and anaerobic (*Bacteroides fragilis*), and vaginal flora (e.g., *Prevotella*, *Peptostreptococci*, *Gardnerella vaginalis*, *Escherichia coli*, *Haemophilus influenzae*) are recognized as etiologic agents (1,3,4).

- Many nongonococcal, nonchlamydial microorganisms recovered from upper genital tract in acute PID are associated with bacterial vaginosis (especially *Prevotella bivia*, *Prevotella disiens*, and *Prevotella capillosus*) (2).
- The precise mechanism by which microorganisms ascend from the lower genital tract is unclear. Possible mechanisms include the following: (i) travel from cervix to endometrium to salpinx to peritoneal cavity; (ii) lymphatic spread via infection of the parametrium (from an IUD); and (iii) hematogenous route, although this is rare.
- Of cases, 75% occur within 7 days of menses, when cervical mucus favors ascent of organisms.

## RISK FACTORS

- Sexually active and age <25 years (5)
- First sexual activity at young age (<15 years)
- New/multiple sexual partners
- Nonbarrier contraceptive methods (i.e., oral contraceptive pills)
- Previous history of PID; 20-25% will have a recurrence.
- Cervical ectopy
- History of *C. trachomatis*; 10-40% will develop PID.
- History of gonococcal cervicitis; 10-20% will develop PID.
- Gynecologic procedures such as endometrial biopsy, curettage, and hysteroscopy break the cervical barrier, predisposing women to ascending infections.

## GENERAL PREVENTION

- Educational programs about safer sex practices such as barrier contraceptives, especially condoms and spermicidal creams or sponges, provide some protection (5).
- The U.S. Preventive Services Task Force recommends screening for chlamydia in all sexually active women <25 years and in those 25 years and older at increased risk (new sex partner/multiple sex partners).
- Routine STI screening in pregnancy
- Early medical care with occurrence of genital lesions or abnormal discharge

## COMMONLY ASSOCIATED CONDITIONS

- If PID is suspected in a patient with an IUD and a pelvic abscess is present; an *Actinomyces*

infection requiring penicillin treatment may be present.

- Rupture of an adnexal abscess is rare but life-threatening. Early surgical exploration is mandatory (3).
- Chlamydial or gonococcal perihepatitis may occur with PID. This combination is called Fitz-Hugh-Curtis (FHC) syndrome and is characterized by severe pleuritic right upper quadrant pain. FHC syndrome complicates 10% of PID cases.
- Plasma cell endometritis has also been seen in the majority of females with PID; the density of plasma cell infiltration has been related to severity of symptoms (3).

## DIAGNOSIS

- The diagnosis of PID is based primarily on clinical evaluation. Clinical diagnosis alone is 87% sensitive and 50% specific.
- Physicians must consider PID in the differential diagnosis in women 15 to 44 years of age who present with lower abdominal or pelvic pain and cervical motion or pelvic tenderness, even if these symptoms are mild.
- The CDC recommends empiric treatment for PID if <sup>3</sup>1 of the following minimum criteria are present on pelvic exam in an at-risk patient: cervical motion tenderness, uterine tenderness, and adnexal tenderness in the presence of lower abdominal or pelvic pain.
- Additional criteria used to enhance specificity: fever >101°F, new/abnormal vaginal discharge, presence of abundant numbers of WBCs on wet prep, elevated ESR, and laboratory documentation of cervical infection with *N. gonorrhoeae* or *C. trachomatis* (1,6)
- Most specific criteria for diagnosing PID: Endometrial biopsy reveals endometritis/plasma cells; transvaginal ultrasound showing thickened, fluid-filled salpinges; and laparoscopic abnormalities consistent with PID (1).

## HISTORY

- Lower abdominal or pelvic pain: typically described as dull, aching or crampy, bilateral, and constant; accentuated by motion, exercise, or coitus
- New/abnormal vaginal discharge (~75% of cases)
- Fever, chills, cramping, dyspareunia
- Low back pain
- Urinary discomfort
- Unanticipated vaginal bleeding, often postcoital, is reported in about 40% of cases.

Recent hysterosalpingogram (HSG)

- IUD insertion within the past 21 days (1,3)

## *PHYSICAL EXAM*

- Fever
- Lower abdominal pain and particularly cervical motion tenderness
- Findings of cervicitis with/without vaginal discharge (1)

## *DIFFERENTIAL DIAGNOSIS*

- Appendicitis
- Constipation
- Gastroenteritis
- Ectopic pregnancy
- Ovarian tumor/torsion
- Hemorrhagic/ruptured ovarian cyst
- Endometriosis/dysmenorrhea
- Functional pelvic pain
- Inflammatory bowel disease
- Diverticulitis
- UTI/pyelonephritis
- Nephrolithiasis (1)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Pregnancy test must be performed to rule out ectopic pregnancy and complications of an intrauterine pregnancy.
- Specific testing for chlamydia and gonorrhea (usually nucleic acid amplification test [NAAT] and/or ligase chain reaction)
- Urinalysis (3,4)
- Saline microscopy of vaginal fluid (for WBC)

- Consider CBC: WBC count  $\geq 10,500/\text{mm}^3$ , although  $\approx 25\%$  of PID cases present with leukocytosis
- CRP (optional)
- Consider transvaginal ultrasound: not necessary for diagnosis; may show thickened, fluid-filled tubes (hydrosalpinges)  $\pm$  free fluid, or tubo-ovarian abscess (TOA)

### *Follow-Up Tests & Special Considerations*

- ESR  $>15$  mm/hr or elevated C-reactive protein used in some diagnostic criteria
- Consider HIV testing in patients with PID.
- Follow-up ultrasound as outpatient for resolution of adnexal abscess.

### *Diagnostic Procedures/Other*

- Culdocentesis with culture is rarely necessary.
- Laparoscopy is best used for confirming, as opposed to making, the diagnosis of PID and should be reserved for the following situations:
  - Ill patient with competing diagnosis (e.g., appendicitis)
  - Ill patient who has failed outpatient treatment.
  - Any patient not improving after 72 hours of inpatient treatment
- Endometrial biopsy (rarely indicated): reveals endometritis/plasma cells (3)

P.775

## **TREATMENT**

- Outpatient treatment, if appropriate
- Criteria for hospitalization and parenteral treatment are described below.

### **GENERAL MEASURES**

Avoid intercourse until treatment is completed (7)[C]. IUD removal is NOT required for mild PID.

### **MEDICATION**

#### *First Line*

- Several antibiotic regimens are highly effective, with no single regimen of choice (3)[A].

- Outpatient treatment regimen
  - Ceftriaxone 250 mg IM single dose *plus*
  - Doxycycline 100 mg PO BID for 14 days  $\pm$
  - Metronidazole 500 mg PO BID for 14 days
- On the basis of the recent emergence of fluoroquinolone-resistant gonococci, the CDC no longer recommends the use of fluoroquinolones for the treatment of gonococcal infections and associated conditions such as PID.
- Metronidazole should be considered in cases where risk of infection with anaerobic organisms is considered high.

## *Second Line*

- Because of emerging resistance in gonococcus, resistance testing and confirmation of treatment success is advisable (3).
- Outpatient treatment regimen
  - Cefoxitin 2 g IM single dose and probenecid 1 g PO administered concurrently in single dose *plus*
  - Doxycycline 100 mg PO BID for 14 days +/-
  - Metronidazole 500 mg PO BID for 14 days
- In persons with documented severe allergic reactions to penicillin or cephalosporins, azithromycin or spectinomycin might be an option for therapy of uncomplicated gonococcal infections.
- Special consideration
  - Refer sex partners for appropriate evaluation and treatment if they had sexual contact with patient during preceding 60 days or most recent sexual contact. Partners should be treated, irrespective of evaluation, with regimens effective against chlamydia and gonorrhea (3).

## ***SURGERY/OTHER PROCEDURES***

Reserved for failures of medical treatment and for suspected ruptured adnexal abscess with resulting acute surgical abdomen

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Hospitalization recommended in the following (3)[C]:
  - Surgical emergencies (e.g., appendicitis)
  - Suspected pelvic abscess
  - Pregnancy
  - Severe illness, nausea, vomiting, or high fever
  - Intolerance/inability to adhere to outpatient regimen
  - Failure to respond to outpatient therapy
- For inpatient treatment of PID, the CDC also lists two currently accepted treatment regimens (6):
  - Parenteral regimen A
    - Cefotetan 2 g IV q12h or cefoxitin 2 g IV q6h + doxycycline 100 mg PO or IV q12h (6)[A]
    - Parenteral therapy for 24 hours after clinical improvement (6)[C]. Continue doxycycline for a total of 14 days.
  - Parenteral regimen B
    - Clindamycin 900 mg IV q8h + gentamicin loading dose IV or IM (2 mg/kg of body weight) followed by a maintenance dose (1.5 mg/kg) q8h (6)[A]
    - Parenteral therapy for 24 hours after clinical improvement; continue doxycycline as aforementioned or clindamycin 450 mg PO QID for a total of 14 days.
- During pregnancy: PID is rare in pregnant patients; however, may appear prior to 12 weeks' gestation before mucous plug appears. Change doxycycline to azithromycin + second-generation cephalosporin (6).

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Review at 72 hours is recommended particularly for patients with moderate or severe clinical presentation (8)[C].
- Close observation of clinical status, particularly for fever, symptoms, degree of peritonitis, serum WBC

- Retest for gonorrhea and chlamydia in 3 to 6 months. The likelihood of reinfection is high.
- Follow adnexal abscess size and position with serial ultrasound (6).

## **PATIENT EDUCATION**

- Abstinence from any type of sexual contact until treatment of patient/partner (if necessary) is complete.
- Consistent and correct condom use should be enforced.
- Hepatitis B and human papilloma virus (HPV) vaccines should be given to patients who meet criteria.
- Advise comprehensive STI screening (6).

## **PROGNOSIS**

- Wide variation with good prognosis if early effective therapy is instituted and further infection is avoided.
- Poor prognosis related to late therapy and continued high-risk sexual behavior
- Nongonococcal, nonchlamydial PID is more often associated with severe PID and with worse prognosis for future fertility (2).

## **COMPLICATIONS**

- TOA will develop in ~7-16% of patients with PID.
- Recurrent infection occurs in 20-25% of patients.
- Risk of ectopic pregnancy is increased 7- to 10-fold among women with a history of PID.
- Tubal infertility occurs in 8%, 19.5%, and 40% of women after 1, 2, and 3 episodes of PID, respectively.
- Chronic pelvic pain occurs in 20% of cases and is related to adhesion formation, chronic salpingitis, or recurrent infection (1,2).
- Hydrosalpinx: After PID resolves, fallopian tube may fill with sterile fluid and become blocked; it may be associated with pain and infertility related to negative outcomes with IVF (9).

## Codes

&NA;

### ICD10

- N73.9 Female pelvic inflammatory disease, unspecified
- N73.0 Acute parametritis and pelvic cellulitis
- N70.93 Salpingitis and oophoritis, unspecified

# Clinical Pearls

## &NA;

- Most often, PID starts with gonorrhea or chlamydia infection, but it can be polymicrobial.
- Physicians should treat on the basis of clinical judgment without waiting for confirmation from laboratory or imaging tests. PID is a common cause of infertility.
- Complications include hydrosalpinx, adhesions, pelvic pain, and 10-fold increased risk of ectopic pregnancy.
- Three major predictors of preserved post-PID fertility: (i) short duration of symptoms (<72 hours) prior to initiation of treatment, (ii) first episode of PID, and (iii) nongonococcal PID.

# Pemphigoid, Bullous

John P. Fardal, DO

Lisa Clemons, MD

## BASICS

### DESCRIPTION

- Bullous pemphigoid (BP) is a chronic, acquired autoimmune subepidermal blistering skin disorder caused by linear deposition of autoantibodies against the epithelial basal membrane zone.
- Pruritic, tense, symmetric, localized, widespread bullae, or urticarial plaques
- Flexural surface (80%), axillary, inguinal folds, and abdomen (20%)
- Oral lesions develop in 10-20% of cases, rarely affecting mucosae of eyes, nose, pharynx, and anogenital zones.

### EPIDEMIOLOGY

- Most common autoimmune blistering disease
- Typical between 60 and 80 years old, but juvenile bullous pemphigoid can occur
- Affects both females and males, possibly with higher incidence in females
- No association with race or geographic location

### Incidence

- BP incidence increases with age (1).
- 6 to 13 new cases/million per year

### ETIOLOGY AND PATHOPHYSIOLOGY

- Autoantibodies react against hemidesmosomal proteins: the 230-kDa BP antigen (BPAg1) within basal keratinocytes and 180-kDa (BPAg2 or type XVII collagen) in the basement membrane zone (BMZ).
- IgG is usually the predominant autoantibody leading to C3 complement activation, recruitment of inflammatory cells, and liberation of proteolytic enzymes that break down the

dermoepidermal junction.

- The noncollagenous 16A domain (NC16A) located at the membrane proximal region of BP180 is considered the major target epitope and is recognized in 80-90% of BP patients.
- It has recently been shown that IgE antibodies correlate with a severe form of BP, and those who test positive for IgE anti-BP180 antibodies required longer duration for remission and therapy.

## *Genetics*

- Certain class II antigens of the major histocompatibility complex (MHC) alleles DQB1\*0301 predominate in the United States.
- Expression of this allele on antigen-presenting cells is thought to be involved in the presentation to autoreactive T cells in patients with BP.
- Molecular mimicry has been proposed as a mechanism by which exogenous agents may trigger the immune response.

## *RISK FACTORS*

- Advanced age
- No clear precipitating factors but can be related to infections such as hepatitis B, hepatitis C, *Helicobacter pylori*, *Toxoplasma gondii*, cytomegalovirus (CMV)
- Associated with autoimmune disorders and inflammatory dermatoses like lichen planus, psoriasis, and other forms of bullous disease
- Increased risk in patients with neurologic disorders such as multiple sclerosis, dementia, stroke, Parkinson disease, and psychiatric disorders
- Although drug-induced BP is rare, chronic intake of neuroleptics, aldosterone antagonists, furosemide, dopaminergic drugs, opioids, salicylates, NSAIDs, and phenacetin have been associated.
- Less frequent: trauma, burns, surgical scars, UV radiation, and x-ray therapy

## *COMMONLY ASSOCIATED CONDITIONS*

- Underlying malignancy can be found in patients with BP, but it may be age related, and the correlation is marginal.
- Several autoimmune disorders such as rheumatoid arthritis, Hashimoto thyroiditis, dermatomyositis, lupus erythematosus, inflammatory dermatoses-like psoriasis, and lichen planus have been reported but are rare.

## DIAGNOSIS

### HISTORY

- BP occurs sporadically without any obvious trigger factor.
- Prodromal nonbullous phase: mild to severe pruritus, associated with excoriated, eczematous, and often urticarial plaques
- Mucosal lesions can be mild, transient, and are often seen with extensive cutaneous disease.
- Bullous stage: single or numerous tense bullae on erythematous, noninflammatory, urticarial skin
- Unusual clinical presentations
  - Localized form: 30% of cases (e.g., disease limited to lower leg, anogenital region, site of trauma)
  - Vegetative form: uncommon, vegetating plaques in intertriginous areas
  - Lichen planus pemphigoides: rare variant, bullae on site of previously normal skin or mucosa, after the onset of lichen planus

### PHYSICAL EXAM

- Lesions usually are 1 to 3 cm round or oval, tense blisters localized on either normal or inflamed skin.
- 80-90% appear in the lower trunk, axilla, and groin, and 10-20% in oral and intertriginous spaces.
- Blister rupture leads to painful erosions that may become crusted and occasionally invaded by organisms.
- Fluid is clear but sometimes presents with hemorrhagic exudates.
- Negative active acantholysis (Nikolsky sign) and no extension of bullae into the surrounding, unblistered skin when vertical pressure is applied to the top of the bulla (Asboe-Hansen sign) support the diagnosis.

### DIFFERENTIAL DIAGNOSIS

- Blistering diseases with antibodies: pemphigus, cicatricial pemphigoid, pemphigoid gestationis, epidermolysis bullosa acquisita, linear IgA dermatosis, dermatitis herpetiformis, bullous erythema multiforme
- Blistering diseases without antibodies: erythema multiforme, toxic epidermal necrolysis,

porphyria, epidermolysis bullosa, allergic contact dermatitis, bullous impetigo, staphylococcal scaled-skin syndrome, friction blisters

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- Diagnosis of BP is based on a combination of clinical features, and the key is immunopathologic findings on skin biopsy.
- Half of patients will have elevated total serum IgE.
- ÷50% of patients have peripheral blood eosinophilia that does not correlate with serum IgE levels.
- Diagnosis of atypical and nonbullous variants relies on findings of direct and indirect immunofluorescence from specific circulating antibodies.
- Considerations
  - BP has a waxing and waning course with spontaneous remission in the absence of treatment.
  - ELISA for the NC16A domain of BP180 is available at some centers, reported sensitivity 82-94%; specificity 93-99.9%
  - Old age and poor general health along with presence of anti-BP180 have been related with poor prognosis.

### ***Diagnostic Procedures/Other***

- Diagnosis is made by skin biopsy with direct immunofluorescence exam.
- Histopathology: 4-mm punch biopsy from the edge of an intact bulla (perilesional skin). Staining shows subepidermal blister and multiple eosinophils.
- Immunohistochemistry: Studies have suggested that the detection of C3d deposits at the dermoepidermal junction in formalin-fixed tissue is helpful for the diagnosis and is the most consistent finding.
- Direct immunofluorescence (DIF): Second 4-mm perilesional punch biopsy will show linear deposition of IgG and/or C3 along BMZ.
- Serologic studies: Indirect immunofluorescence (IIF) and ELISA are done when DIF is negative, there is a strong suspicion of BP, and when the skin biopsy cannot be performed. Both detect circulating IgG antibodies against 230BP (specificity 96%) and 180BP (specificity 90%).

## TREATMENT

### GENERAL MEASURES

- Discontinue trigger factors.
- In oral lesions: Avoid hard consistency, spicy, and hot food. Soft and liquid meals should be given instead.
- Strict control of wounds to avoid complications.

### MEDICATION

#### First Line

- Primary objectives are to control the skin eruption and minimize serious side effects of treatments, particularly in the elderly (2)[C].
  - Potent topical corticosteroids are considered first line.
    - Topical clobetasol propionate 0.05% cream: 40 g/day used twice daily, noted to be as effective as 0.5 mg/kg prednisone (3)[B]
    - Side effects: skin atrophy, striae, hypertrichosis, acne, and ecchymosis
- 
- Systemic therapy has more side effects than topical
    - Oral prednisolone: 0.5 mg/kg/day for disease control. Goal is to achieve the lowest maintenance dosage that will prevent new lesion formation and reduce adverse reactions.
    - Clinical response is usually obtained within 1 to 2 weeks and is indicated by healing of existing lesions and cessation of new blister formation.
    - Evidence shows that higher doses >0.75 mg/kg/day do not improve healing rate but do increase mortality.
    - Taper the dose gradually within 1 to 2 years to avoid relapse; consider transition to steroid-sparing agent.
    - Side effects: cutaneous atrophy, osteoporosis, GI ulcers, Cushing syndrome, diabetes mellitus, hypertension
    - Tetracycline and nicotinamide may be beneficial in disease control and longer remission period (4)[C].

P.777

## *Second Line*

- Although evidence is limited, immunosuppressive agents like azathioprine, mycophenolate mofetil, and methotrexate may be used in severe cases; especially in conjunction with systemic corticosteroids.
  - Addition of azathioprine to prednisone regimen reduces the total maintenance dose of prednisone by 45% without increasing serious side effects or mortality.
  - Azathioprine: 0.5 to 2.5 mg/kg/day, most common side effect: myelosuppression; caution for lethal hypersensitivity syndrome
  - Mycophenolate mofetil: 1.5 to 2 g/day, most common side effect: GI disturbance
- Methotrexate: 5 to 20 mg/week, low dose usually initiated (5 mg/week) plus folic acid replacement. Adverse effects: myelosuppression, hepatotoxicity. Higher rate of remission with the use of prednisone
- Dapsone: 25 to 50 mg daily, most common side effect: hemolytic anemia; watch for agranulocytosis.

## *Third Line*

- Cyclosporine: caution with renal disease
- Plasmapheresis: Reduce the amount of prednisolone required to achieve disease control.
- Omalizumab: used in patients who have high levels of IgE antibodies
- IVIG: for patients who did not respond to first-line therapy or at risk of potentially fatal side effects from conventional therapy. The recommended dose is 1 to 2 g/kg divided over a 3- or 5-day cycle every 3 to 4 weeks.
- Rituximab has limited data (5)[C].

## *ISSUES FOR REFERRAL*

- Dermatology for systemic management and/or scarring, which may suggest mucous membrane pemphigoid
- Gastroenterology, otorhinolaryngology referral in patients who have esophageal, pharyngeal, laryngeal involvement
- Ophthalmologic consult when patient complains of burning sensation, itching, visual changes, and in those patients who require high doses of steroids

## *INPATIENT CONSIDERATIONS*

## *Admission Criteria/Initial Stabilization*

Extensive denuding of skin, dehydration, and electrolyte imbalance requiring IV fluid reposition

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Taper medication when disease is stable and control side effects.
- Perform periodic skin examination for new lesions.
- Frequent bacterial cultures of cutaneous erosions are essential to identify early infections.

#### *DIET*

- Liquid or soft diet with active oral lesions
- After lesions are resolved, advance diet. Avoid hard or crunchy foods, as they may cause flare ups.
- Supplement with calcium and vitamin D for patients on systemic corticosteroids

### *PATIENT EDUCATION*

- Symptoms of infection, worsening lesions
- Education in good skin hygiene and wound care
- Wash clothing and linens if they come in contact with oozing, crusting, or infected skin.
- Protect from sun exposure and physical trauma to the skin.

### *PROGNOSIS*

- Disease length can persist from weeks to years even under treatment.
- Around 47% of patients experience relapse within 1 year of therapy, and ~50% of patients can achieve remission within 2.5 to 6 years.
- Yearly mortality varies from 6% to 40%.
- Poor prognosis and high mortality: old age, poor general condition, and the presence of antibodies in serum
- Other factors that may be included are age >80 years, prednisolone dose >37 mg/day after

hospitalization, serum albumin levels of <3.6 g/dL, ESR >100 mm/hr.

## COMPLICATIONS

- Most often secondary to medication: osteoporosis, cataracts, adrenal insufficiency, bone marrow suppression
- Skin infections
- Dehydration and electrolytes imbalance

## Codes

&NA;

### ICD10

L12.0 Bullous pemphigoid

## Clinical Pearls

&NA;

- Tense bullae differentiates the lesions of bullous pemphigoid from the flaccid bullae of pemphigus vulgaris.
- Low doses of potent topical steroid have been shown to be just as effective as larger amounts in the initial therapy of BP.

# Pemphigus Vulgaris

Byron M. Ingram, DO

Robert M. Hasty, DO, FACOI, FACP

## BASICS

Pemphigus is derived from the Greek word *pemphix* meaning "bubble" or "blister." Pemphigus vulgaris is the most common form of pemphigus.

## DESCRIPTION

- Rare, potentially fatal autoimmune mucocutaneous blistering disease due to loss of keratinocyte to keratinocyte adhesion that involves the skin and the mucous membranes
- Flaccid, painful, nonhealing bullae, pustules, or ulcerations that appear spontaneously on the skin and mucosal surfaces, typically begin in the oropharynx, and then may spread to the skin, having a predilection for the scalp, face, chest, axillae, groin, and pressure points.
- Patient often presents with erosions and no intact bullae.
- System(s) affected: skin, GI, genitourinary

## EPIDEMIOLOGY

### Incidence

- Disease of the middle-aged population, typically occurring after the age of 50 years, although some cases have been reported in younger adults and children
- Affects both sexes equally
- 0.1 to 3.2 cases per 100,000 individuals annually worldwide

### Prevalence

- Uncommon, affects <200,000 people in the United States
- Seen more frequently in people of Mediterranean descent and Ashkenazi Jew

## ETIOLOGY AND PATHOPHYSIOLOGY

- Autoantibodies (IgG) are directed against desmoglein (Dsg) 1 and 3 adhesion molecules. Dsgs

interact with desmosomes, which hold epidermal cells together. The antibodies against Dsg molecules cause intraepidermal blister formation and acantholysis.

- Dsg 3 is predominantly expressed in oral epithelium, whereas both Dsg 1 and Dsg 3 are expressed in the skin.
- Dsg 1 is expressed more intensely in the superficial layer, whereas Dsg 3 is found more abundantly in basal and suprabasal layers.
- Additionally, autoantibodies against Dsg 4, the acetylcholine receptor, and pemphaxin have been identified in patients with pemphigus vulgaris (PV). The exact pathogenesis of pemphigus has yet to be fully explained and is likely a "multiple hit" process. Autoimmune; stimulus is unknown.
- Inducing factors include physical trauma, such as thermal burns, UV light, and ionizing radiation; neoplasm, emotional stress, drugs, and infections. Most patients lack a recognized inducing factor.

## Genetics

Strong association with certain human leukocyte antigens (HLA), especially HLA DR4, DR14, DRB1, DQB1, DQ1, and DQ3, although the susceptibility gene differs depending on ethnic origin.

## COMMONLY ASSOCIATED CONDITIONS

- Thymoma
- Myasthenia gravis
- Paraneoplastic pemphigus is a type of pemphigus defined by the fact that the patient has a malignancy at the time the pemphigus is diagnosed.
- Gastric adenocarcinoma

## DIAGNOSIS

### HISTORY

- Multiple, painful, nonhealing ulcers in the mouth—commonly the buccal and labial mucosa, palate, and tongue (1)[C]
- Progression (weeks to months) to small, clear fluid-filled blisters on the skin—commonly the scalp, face, and upper torso. Blisters rupture easily, forming ulcerations (1)[C].
- Consider laryngeal and nasal involvement in patients with hoarseness, odynophagia, or nasal congestion (1)[C].

- Drug-induced: penicillamine, ACE inhibitors, thiolcontaining compounds, rifampin

## *PHYSICAL EXAM*

- Mucosal lesions: Intact bullae are rare; commonly are ill-defined, irregularly shaped gingival, buccal, or palatine erosions that are painful and slow-healing; most often affected area is the oral cavity; may involve conjunctiva, oropharynx esophagus, labia, vagina, cervix, penis, urethra, and anus (1)[C].
- Cutaneous lesions: painful, flaccid blisters with clear fluid found on normal skin or on erythematous base; fragile bullae rupture easily, forming painful, superficial, coin-sized, sharply demarcated erosions (1)[C]. Pruritus is usually absent. Palms and soles are usually spared (2)[C]. Nails: Acute or chronic paronychia, onychomadesis, subungual hematomas, and nail dystrophies may be present.
- Nikolsky sign: involves application of pressure to skin causing intraepidermal cleavage that allows the superficial skin to slip free from the deeper layers, producing an erosion; can be elicited on normal skin or at the margin of a blister (1)[C]
- Asboe-Hansen sign: Lateral pressure on the edge of a blister may spread the blister into clinically unaffected skin.

## *DIFFERENTIAL DIAGNOSIS*

- Predominance of oral mucous lesions: herpes simplex virus (HSV), aphthous ulcers, lichen planus, erythema multiforme
- Predominance of widespread cutaneous lesions: bullous pemphigoid, cicatricial pemphigoid, bullous drug eruptions, pemphigus erythematosus, pemphigus foliaceus, paraneoplastic pemphigus, impetigo, contact dermatitis, dermatitis herpetiformis, erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis, pemphigoid gestationis, and linear IgA dermatosis

## *DIAGNOSTIC TESTS & INTERPRETATION*

Diagnosis is achieved via different parameters: perilesional tissue biopsy, clinical, histologic, and immunologic examinations along with serologic findings. The clinical assessment should include a review of the patient's medications since clinical and laboratory studies cannot reliably distinguish between idiopathic pemphigus and drug-induced pemphigus.

### *Initial Tests (lab, imaging)*

- Shave or 4-mm punch biopsy of edge of fresh bullous lesion

- A second 4-mm punch biopsy of the perilesional skin is sent for direct immunofluorescence (DIF).
- Serum for indirect immunofluorescence (IDIF) is positive for circulating autoantibodies against Dsgs in 80-90% if DIF is positive.
- ELISA testing can be used to distinguish pemphigus from the other blistering disorders. The sensitivity of ELISA exceeds 90% (3)[C]. In order to distinguish PV from BP, immunoblot assay is needed. These tests are not widely available so may not be accessible by all institutions.

## *Follow-Up Tests & Special Considerations*

IDIF corresponds loosely to disease activity and may be useful to gauge disease activity.

## *Test Interpretation*

- Light microscopy: intradermal blister; loss of cohesion between epidermal cells (acantholysis) with an intact basement membrane; Row of tombstones appearance
- DIF looking for deposits of IgG between epidermal cells
- In women with cervical involvement, the histologic findings of pemphigus vulgaris may be mistaken for cervical dysplasia in Papanicolaou smears.

## **TREATMENT**

Reduce inflammatory response and autoantibody production by suppression of the immune system to decrease blister formation and promote healing of blisters and erosions.

## **GENERAL MEASURES**

- Minimize activities that may cause trauma to skin and precipitate blisters.
- Avoid use of dental plates, dental bridges, dental floss or contact lenses that may precipitate or exacerbate mucosal disease.
- Wound care: Daily gentle cleaning, topical agents to promote wound healing, and use of nonadhesive dressings. Clobetasol propionate 0.05% ointment 2 times daily in conjunction with systemic steroids for hard-to-treat lesions
- Oral analgesics: Use before eating for painful oral lesions (viscous lidocaine, Benadryl).

## **MEDICATION**

### *First Line*

- High-dose systemic glucocorticoids (e.g., prednisone 1 to 2 mg/kg/day) are the mainstay of treatment (4)[B],(5)[C],(6)[A].
- Glucocorticoids can be used alone; however, combination with other steroid-sparing immunosuppressive drugs is most effective (azathioprine—most commonly used [starting at 1 mg/kg/day and increasing by 0.5 mg/kg/day every 2 to 3 weeks to reach a maintenance dose of 2.5 mg/kg/day]; other nonsteroidal adjunctive therapies include dapsone [50 to 200 mg/day] or mycophenolate mofetil [MMF] [2 to 3 g/day]) (6)[A].
- Rituximab is becoming a first-line treatment and may be a safer alternative to steroids. Dosing: 4 weekly infusions 375 mg/m<sup>2</sup> or 1,000 mg ×2 separated by 2 weeks (5)[C]
- For mild to moderate disease: Combination therapy of nonsteroidal adjunctive treatment and prednisone is an effective treatment regimen to achieve rapid and complete control of PV. For those patients who fail treatment, rituximab is an efficacious alternative therapy (7)[C].
- Rapidly progressive lesions necessitate high prednisone dose (1.5 to 2.5 mg/kg/day) for early and adequate control of the disease. Patients with impaired physical status, especially those with

P.779

relatively stable lesions at baseline, might safely and effectively be treated with low-dose oral prednisone on alternate days plus azathioprine every day (Lever's minitreatment [LMT]) for oral pemphigus (4)[B].

- For oropharyngeal disease: Perilesional/intralesional triamcinolone acetonide injections combined with conventional immunosuppressive therapy shortened the time of complete clinical remission and reduced the total amount of corticosteroids used.

## Second Line

For refractory disease

- Rituximab alone or in combination with intravenous immunoglobulin (IVIg) is an effective therapy for patients with refractory PV (8)[A].
- Other options: methotrexate (10 to 20 mg/week), hydroxychloroquine, gold, plasmapheresis (5)[C]
- Cyclosporine (2.5 to 5 mg/kg/day) may be ineffective as a steroid-sparing agent (6)[A].
- Tumor necrosis factor (TNF)-*α* antagonist, etanercept, may be an effective therapeutic agent and may reduce healing time of skin lesions in PV and for patients presenting with recalcitrant disease (6)[A].
- IVIg is a recommended and effective treatment for patients who are not able to tolerate the standard treatment (9)[A].

- For persistent lesions: intralesional triamcinolone acetonide (20 mg/mL)

## *ISSUES FOR REFERRAL*

- Ophthalmologist referral in suspected ocular involvement and prolonged use of high-dose steroids
- Referral to a dentist and/or otolaryngologist for patients with extensive oral disease

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Secondary infections requiring IV antibiotics
- Severe oral lesions leading to dehydration requiring fluid resuscitation

## **ONGOING CARE**

A minority of (10%) achieve complete remission after initial treatment and do not need continued drug therapy; most require maintenance therapy to stay in remission.

## *FOLLOW-UP RECOMMENDATIONS*

- Patients taking steroids long-term should be screened for osteopenia/osteoporosis, avascular necrosis, HPA-axis suppression, cataract, cushingoid features, hyperlipoproteinemia, myopathy, mood changes, and immunosuppression. Patients on systemic steroids should maintain adequate vitamin D and calcium intake through diet and supplements.
- Patients taking azathioprine should have CBC, Cr, and LFT checked at baseline and every 2 weeks, the first 3 months, then every 3 months after.
- PV can be exacerbated by sun exposure, dental work, trauma, stress, and radiographs. Patients undergoing dental work should be treated prophylactically with 20 mg of prednisone per day for 5 to 7 days in addition to their regular treatment regimen.
- Minimizing sun exposure, use of broad-spectrum sunscreen, and wearing protective clothing is recommended.

### *Patient Monitoring*

Seek medical care for any unexplained blisters and if treated for PV and develop any of the following symptoms:

- Fever, chills

- General ill feeling
- Myalgias, joint pain
- New blisters or ulcers

## *DIET*

- Patients with active oral lesions may benefit from liquid or soft diet and then advance as tolerated.
- Avoid spicy and acidic food when oral ulcers are present.
- Hard food that may cause mechanical trauma to epithelium, such as nuts, chips, and hard vegetables and fruits, may be best avoided in cases of active oral disease.

## *PATIENT EDUCATION*

- Minimize activities that may cause trauma to skin and precipitate blisters, such as contact sports. Nontraumatic exercises, such as swimming, may be helpful.
- Explain wound care of erosions: daily gentle cleaning, covering open areas with clean petrolatum and nonadhesive dressings, as it will take longer for you to recover from infections if you are taking corticosteroids or immunosuppressants.
- Educate patients about the chronicity of the disease and the need for long-term follow up:
  - For oral pemphigus:
    - Soft diets and soft toothbrushes help to minimize local trauma.
    - Explain the need for meticulous oral hygiene to prevent dental decay. Encourage gentle tooth brushing, dental flossing, and visits to the dentist/dental hygienist at least every 6 months.
    - Discuss how dental plates, dental bridges, or contact lenses may precipitate or exacerbate mucosal disease.
    - Topical analgesics or anesthetics (e.g., benzydamine hydrochloride 0.15% or viscous lidocaine) may be useful in alleviating oral pain, particularly prior to eating or tooth brushing.
    - Patients may also contact the International Pemphigus & Pemphigoid Foundation (IPPF) for support groups.

## *PROGNOSIS*

- Mortality rate with combination therapy is ÷5%, with most deaths due to drug-induced

complications, including sepsis.

- 10% of patients achieve complete remission after initial treatment; most require maintenance therapy to stay in remission.
- Morbidity and mortality are related to the extent of disease, the maximum dose of oral steroids required to induce remission, and the presence of other diseases. Prognosis is worse in older persons and patients with extensive disease.
- Most deaths occur during the first few years of the disease; if a patient survives 5 years, prognosis is good.

## COMPLICATIONS

- Secondary infection, localized to skin or systemic, may occur because of impaired immune response due to use of immunosuppressive drugs. Most frequent cause of death is *Staphylococcus aureus* septicemia.
- Within the 1st year, patients are at the highest risk for the development of secondary infections. Older patients and potentially diabetic patients carry an increased risk.
- Consider secondary infections to include bacterial, fungal, and viral; particularly herpes simplex in nonhealing ulcers when the patient is receiving adequate treatment.
- Osteoporosis in patients requiring long-term systemic steroids
- Adrenal insufficiency has been reported following prolonged use of glucocorticoids.
- Bone marrow suppression and malignancies have been reported in patients receiving immunosuppressants, with an increased incidence of leukemia and lymphoma.
- Growth retardation has been reported in children taking systemic corticosteroids and immunosuppressants.

Leshem YA, Gdalevich M, Ziv M, et al. Opportunistic infections in patients with pemphigus. *J Am Acad Dermatol*. 2014;71(2):284-292.

## Codes

&NA;

## ICD10

L10.0 Pemphigus vulgaris

## Clinical Pearls

**&NA;**

Pemphigus vulgaris is a rare, chronic, potentially fatal autoimmune vesiculobullous disease of the mucous membranes and skin. Biopsy immediately with rush processing. When clinical suspicion is high, initiate therapy without delay using systemic corticosteroids. Minimize activities that may cause trauma to skin and precipitate blisters, such as contact sports.

# Peptic Ulcer Disease

Fozia Akhtar Ali, MD

Paula A. Shelton, MD

## BASICS

### DESCRIPTION

- Duodenal ulcer
  - Most common form of peptic ulcer
  - Usually located in the proximal duodenum
  - Multiple ulcers or ulcers distal to the second portion of duodenum raise possibility of gastrinoma (Zollinger-Ellison syndrome).
- Gastric ulcer
  - Less common than duodenal ulcer in absence of NSAID use
  - Commonly located along lesser curvature of the antrum
- Esophageal ulcers
  - Located in the distal esophagus; usually secondary to gastroesophageal reflux disease (GERD); also seen with gastrinoma
- Ectopic gastric mucosal ulceration
  - May develop in those with Meckel diverticulum (1)

### GENERAL PREVENTION

- NSAID ulcers: Avoid salicylates and NSAIDs (1).
  - Alternatives include acetaminophen and tramadol. COX-2 inhibitor use is controversial due to potential cardiac risks.
  - If NSAIDs are needed, adjust to decrease risk of ulcerogenesis, and add a proton pump inhibitor (PPI) or misoprostol.
  - To reduce ulcer risk, consider testing for and eradicating *Helicobacter pylori* before starting

therapy with NSAIDs.

- Maintenance therapy with PPIs or H<sub>2</sub> blockers is indicated for patients with a history of ulcer complications, recurrences, refractory ulcers, or persistent *H. pylori* infection.
- Consider maintenance PPI treatment in patients with *H. pylori*-negative, non-NSAID-induced ulcer.
- Imbalance between aggressive factors (e.g., gastric acid, pepsin, bile salts, pancreatic enzymes) and defensive factors maintaining mucosal integrity (e.g., mucus, bicarbonate, blood flow, prostaglandins, growth factors, cell turnover)
- May be multifactorial
- *H. pylori* infection: 90% of duodenal ulcers and 70-90% of gastric ulcers
  - Lifetime risk for peptic ulcer disease (PUD) in *H. pylori*-infected people: 10-20%
  - Annual risk of developing duodenal ulcer in *H. pylori*-infected people: 21%
- Ulcerogenic drugs (e.g., NSAIDs)
- Hypersecretory syndromes (e.g., gastrinoma)
- Retained gastric antrum
- Less common: Crohn disease, vascular insufficiency, radiation therapy, cancer chemotherapy, smoking

## EPIDEMIOLOGY

### *Incidence*

- Predominant sex: male = female
- Predominant age
  - 70% of ulcers occur between ages 25 to 64 years.
  - Ulcer incidence increases with age.
- Peptic ulcer: 500,000 new cases/year
- Recurrence: 4 million/year
- Global incidence rate: 0.1-0.19%

### *Prevalence*

- Peptic ulcer: 2% in the United States

- Lifetime prevalence is 5-10% for patients not infected with *H. pylori*; 10-20% if infected

## Genetics

Increased incidence of PUD in families is likely due to familial clustering of *H. pylori* infection and inherited genetic factors reflecting response to the organism (1).

## RISK FACTORS

- *H. pylori* infection (1)
- NSAID use (5-20%)
- Tobacco use
- Family history of ulcers
- Stress (after acute illness, ventilator support, extensive burns, head injury)
- Gastrinoma
- Alcohol use
- Medications: corticosteroids (high-dose and/or prolonged therapy), bisphosphonates, potassium chloride, chemotherapeutic agents (e.g., IV fluorouracil)

## COMMONLY ASSOCIATED CONDITIONS

- Gastrinoma (Zollinger-Ellison syndrome)
- Multiple endocrine neoplasia type 1
- Carcinoid syndrome
- Chronic illness: Crohn disease, chronic obstructive pulmonary disease (COPD), chronic renal failure, hepatic cirrhosis, cystic fibrosis
- Hematopoietic disorders (rare): systemic mastocytosis, myeloproliferative disease, hyperparathyroidism, polycythemia rubra vera

## DIAGNOSIS

### HISTORY

- Signs and symptoms:
  - Episodic gnawing or burning epigastric pain
  - Pain occurring after meals or on empty stomach
  - Nocturnal pain

- Pain relieved by food intake (duodenal), antacids, or antisecretory agents
- Nonspecific dyspeptic complaints: indigestion, nausea, vomiting, loss of appetite, and heartburn, epigastric fullness
- Alarm symptoms:
  - Anemia, hematemesis, melena, or heme-positive stool suggest bleeding
  - Vomiting and early satiety suggest obstruction.
  - Anorexia/weight loss
  - Persisting upper abdominal pain radiating to the back suggests penetration.
  - Severe, spreading upper abdominal pain suggests perforation.
  - Jaundice, dysphagia
  - Previous gastric surgery
- NSAID-induced ulcers are often silent; perforation or bleeding may be the initial presentation (1).

## **PHYSICAL EXAM**

Physical exam for uncomplicated peptic ulcer may be unreliable and nonspecific: vital signs for hemodynamic stability, conjunctival pallor (anemia); epigastric tenderness (absent in at least 30% of older patients); guaiac-positive stool from occult blood loss (1)

## **DIFFERENTIAL DIAGNOSIS**

Functional dyspepsia, gastritis, GERD, biliary colic, pancreatitis, cholecystitis, Crohn disease, intestinal ischemia, cardiac ischemia, GI malignancy

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- Lab tests to consider when evaluating PUD:
  - CBC: Rule out anemia.
  - Fecal occult blood test
  - If multiple/refractory ulcers: Consider fasting serum gastrin to rule out gastrinoma (1).
- Indications for *H. pylori* testing: new-onset PUD, prior history of PUD, persistent symptoms after empiric antisecretory therapy, gastric mucosa-associated lymphoid tissue (MALT) lymphoma, noninvestigated dyspepsia in patients <50 years of age without alarm symptoms (2)

- *H. pylori* diagnostic tests: False-negative results may occur if patient was recently treated with antibiotics, bismuth, or PPIs; or in patients with active bleeding. Diagnostic yield improved by checking 2 different tests:
  - Noninvasive tests (2)[A]:
    - Serology antibody: commonly used in primary care, slow to normalize after treatment, cannot be used to document successful eradication (sensitivity, 85%; specificity, 79%)
    - Urea breath test: identifies active *H. pylori* infection; also used for posttreatment testing (sensitivity, >95%; specificity, >90%)
    - Stool antigen: can be used for screening and posttreatment testing (sensitivity, 91%; specificity, 94%)
  - Invasive tests:
    - Upper endoscopy with gastric biopsy; Steiner stain for direct visualization of organism (sensitivity, >95%; specificity, >95%)
    - Rapid urease test: conducted on gastric biopsies (sensitivity, 93-97%; specificity, 95%)
- Barium or Gastrografin contrast radiography (double-contrast hypotonic duodenography): indicated when endoscopy is unsuitable or not feasible

## *Diagnostic Procedures/Other*

Indications for upper endoscopy: patients with suspected peptic ulcers who are >55 years of age, those who have alarm symptoms, and those with ulcers that do not respond to treatment (3)[B]

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Acid suppression: PPIs
  - Omeprazole 20 mg/day PO; lansoprazole 30 mg/day PO; rabeprazole 20 mg/day PO; esomeprazole 40 mg/day PO; pantoprazole 40 mg/day PO; dexlansoprazole 30 mg/day PO
  - Administer PPIs before breakfast.
- H<sub>2</sub> blockers: ranitidine or nizatidine 150 mg PO BID or 300 mg PO at bedtime; cimetidine 400 mg PO BID or 800 mg PO at bedtime; famotidine 20 mg PO BID or 40 mg PO at bedtime (4)

- Treat ulcers for 8 to 12 weeks or until healing is confirmed in patients with complicated ulcers (4).
  - PPIs heal peptic ulcers more rapidly (4).
  - Precautions:
    - Renal insufficiency: Decrease H<sub>2</sub> blocker dosage by 50% if CrCl <50 mL/min (2).
    - Cimetidine: Use caution with theophylline, warfarin, phenytoin, and lidocaine.
    - PPIs may decrease bone density. Obtain interval bone densitometry with long-term PPI use (5).
- 
- P.781
- PPIs may cause hypomagnesemia. Consider baseline and interval levels in patients, especially for long-term use and in patients taking diuretics.
  - PPIs may be associated with increased risk of *Clostridium difficile* infection (5). Short-term use associated with development of community-acquired pneumonia; long-term use does not appear to have an increased risk.
  - Despite earlier concerns, PPIs do not appear to decrease the efficacy of clopidogrel (5).
- NSAID-induced ulcers
    - Discontinue NSAID use.
    - Treat acutely with PPIs for 8 to 12 weeks; may use longer as maintenance for patients with recurrent, complicated, or idiopathic ulcers; or in patients who require long-term aspirin or NSAID use.
  - *H. pylori*-induced ulcers
    - *H. pylori* eradication regimens: Preferred duration of therapy is 14 days.
    - Triple therapy: standard dose PPI given BID plus clarithromycin 500 mg PO BID plus amoxicillin 1 g PO BID or metronidazole 500 mg PO BID in patients with allergy to amoxicillin (2)
  - Bacterial resistance: clarithromycin 10%; amoxicillin 1.4%; metronidazole 37%: Culture-guided choice of triple therapy is preferred (6).

## Second Line

- For *H. pylori* eradication: Use second-line therapy if first-line fails (6):
  - Bismuth quadruple therapy for 14 days

- Bismuth subsalicylate 525 mg PO QID plus
  - Metronidazole 250 mg PO QID plus
  - Tetracycline 500 mg PO QID plus
  - Standard dose PPI PO twice daily
- Sequential therapy
    - Standard-dose PPI PO twice daily plus amoxicillin 1,000 mg PO QID for 5 days followed by
    - Standard-dose PPI PO twice daily plus clarithromycin 500 mg PO BID plus tinidazole (or metronidazole) 500 mg PO BID for 5 days
      - Levofloxacin 250 mg PO BID may be substituted in those with PCN allergy or in areas of high clarithromycin resistance rates.
    - Another alternative salvage therapy:
      - Rifabutin 300 mg PO daily plus
      - Amoxicillin 1,000 mg PO BID plus
      - PPI orally BID
    - Alternative ulcer-healing drugs:
      - Sucralfate and antacids are additional options; however, antisecretory options are preferred.
- Significant possible interactions:
    - Cimetidine inhibits cytochrome P450 isozymes (avoid with theophylline, warfarin, phenytoin, and lidocaine).
    - Omeprazole may prolong elimination of diazepam, warfarin, and phenytoin.
    - Sucralfate reduces absorption of tetracycline, norfloxacin, ciprofloxacin, and theophylline; it leads to subtherapeutic levels.

## *Pregnancy Considerations*

PPIs are *not* associated with an increased risk for major congenital birth defects, spontaneous abortions, or preterm delivery.

## *Breastfeeding*

Both ranitidine and esomeprazole are secreted in breastmilk; however, at considerably lower doses than those used for treatment in infants with reflux disease. Use in breastfeeding women is

generally safe (7).

## ***SURGERY/OTHER PROCEDURES***

- Endoscopy is indicated for patients age >50 years with new onset of dyspeptic symptoms, those who do not respond to treatment, and those of any age with alarm symptoms, such as bleeding and weight loss (8)[B].
- At endoscopy:
  - Biopsy stomach for *H. pylori* testing (CLO test).
  - Biopsy margin of gastric ulcer to exclude malignancy.
  - Interventions to stop active bleeding or prevent rebleeding in those with certain stigmata include injection with epinephrine, heater probe treatment, or placement of endoscopic clips (3).
- Indications for surgery: Ulcers that are refractory to treatment and patients at high risk for complications (e.g., transplant recipients, patients dependent on steroids/NSAIDs); surgery also may be needed acutely to treat perforation and bleeding refractory to endoscopic therapy (8).
- Surgical options:
  - Duodenal ulcers: truncal vagotomy and drainage (pyloroplasty/gastrojejunostomy), selective vagotomy (preserving the hepatic and/or celiac branches of the vagus) and drainage, or highly selective vagotomy (3)
  - Gastric ulcers: partial gastrectomy, Billroth I or II
  - Perforated ulcers: laparoscopy/open patching (3)

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Discontinue ulcerogenic agents (e.g., NSAIDs) (1).
- Bleeding peptic ulcers
  - Stable: Give PPI to reduce transfusion requirements, need for surgery, and duration of hospitalization (9).
  - Unstable: Fluid/packed RBC resuscitation followed by emergent esophagogastroduodenoscopy (EGD); use IV PPI.
  - Insufficient evidence for concluding superiority, inferiority, or equivalence of high-dose PPI

treatment over lower doses in peptic ulcer bleeding (5)[A]

- Oral PPIs are as effective as IV after endoscopic treatment (9).
- Perforated peptic ulcers: Free peritoneal perforation with bacterial peritonitis is a surgical emergency (3).

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- *H. pylori* eradication: expected in >90% (with double antibiotic regimen): Confirm eradication by urea breath test.
- Acute duodenal ulcer: Monitor clinically.
- Acute gastric ulcer: Confirm healing via endoscopy after 12 weeks (if biopsy not done initially) to confirm that the lesion is benign.
- Tobacco cessation

### PROGNOSIS

After *H. pylori* eradication (10):

- Low ulcer relapse rate; if relapse, consider surreptitious use of NSAIDs.
- Reinfection rates <1% per year
- Low risk of rebleeding
- Decreased NSAID ulcer recurrence (10)

### COMPLICATIONS

- Hemorrhage: up to 25% of patients (initial presentation in 10%)
- Perforation: <5% of patients
- Gastric outlet obstruction: up to 5% of duodenal or pyloric channel ulcers; male predilection found
- Risk of gastric adenocarcinoma is increased in *H. pylori*-infected patients (2).
- Refractory peptic ulcer disease (5-10% after eradication of *H. pylori*, or completion of 12 weeks of PPI) (11)

**&NA;**

## **ICD10**

- K27.9 Peptic ulc, site unsp, unsp as ac or chr, w/o hemor or perf
- K26.9 Duodenal ulcer, unspecified as acute or chronic, without hemorrhage or perforation
- K25.9 Gastric ulcer, unspecified as acute or chronic, without hemorrhage or perforation

## **Clinical Pearls**

**&NA;**

- In patients with PUD, *H. pylori* should be eradicated to assist in healing and to reduce the risk of gastric and duodenal ulcer recurrence.
- Upper endoscopy is indicated in patients with suspected peptic ulcers who are >55 years of age, those who have alarm symptoms, and those who do not respond to treatment.

# Perforated Tympanic Membrane

Timothy R. Takagi, MD

## BASICS

### DESCRIPTION

- The tympanic membrane (TM), or "ear drum" is a thin, trilaminar barrier that separates the external auditory canal (EAC) from the middle ear. Along with the ossicles of the middle ear, it transmits and amplifies sound vibrations to the cochlea.
- The TM consists of an outer squamous layer, contiguous with the EAC skin, the middle fibrous layer of both peripheral annular fibers and central radial fibers that provide support, and the inner mucosal layer, contiguous with the middle ear lining.
- Rupture of the TM can disrupt hearing and can allow pathogens access to the middle ear space from the EAC.
- Perforations may be classified by location:
  - *Central*: doesn't involve the annulus and is more likely to heal, spontaneously
  - *Marginal*: lies in the periphery, involves the annulus; may be associated with cholesteatoma; is less likely to heal and harder to repair
  - Involvement of the malleus decreases chance of healing.
  - Perforations of the posterior superior quadrant overly the ossicles and the cochlea and are associated with more extensive damage.
  - When a TM perforation heals, the mucosal and squamous layers reepithelialize, but the fibrous layer won't, resulting in a thinner membrane (paradoxically termed "monomeric")
- Classification of perforations by etiology:
  - Infectious: acute/chronic suppurative otitis media
  - Traumatic: barotrauma, (e.g., diving), acoustic trauma, (e.g., explosion), self-inflicted/penetrating (cotton tips)
  - Middle ear mass: cholesteatoma or neoplasm
  - Iatrogenic: persistent perforation after myringotomy tube placement or secondary acquired cholesteatoma

- The TM possesses the ability for spontaneous closure resulting in formation of a dimeric membrane (outer squamous and inner mucosal). However, if this does not occur, a persistent perforation will result.

## *EPIDEMIOLOGY*

Incidence in the general population is unknown because many perforations heal spontaneously.

### *Genetics*

Genetic susceptibility has been reported for recurrent acute otitis media (AOM) and chronic otitis media with effusion (COME), two of the etiologies of perforations (1).

## *GENERAL PREVENTION*

Preservation of eustachian tube function, avoiding insertion of foreign bodies and objects into the EAC, and prompt treatment of significant infection and inflammation of the ear, reduces the chances of perforation.

## *RISK FACTORS*

- Eustachian tube dysfunction and inability to equalize middle ear pressures
- Rapid changes in ambient pressures (air flight or diving)
- Insertion of objects into ears
- Head trauma, exposure to explosions

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Barotrauma: Sudden of large changes in the pressure differential across the TM (such as in air flight or diving underwater)
- Direct penetration of the TM by a foreign object (e.g., cotton swab)
- Otitis media: Purulent, inflammatory process leads to ischemia and necrosis of the TM
- Inflammation and erosion results from neoplasm, cholesteatoma, and localized infection (e.g., otomycosis).

## *COMMONLY ASSOCIATED CONDITIONS*

- Chronic eustachian tube (craniofacial abnormalities, such as cleft may predispose)
- OME
- Recurrent AOM

- Cholesteatoma
- Tympanosclerosis
- Ossicular chain damage (if traumatic perforation)

## DIAGNOSIS

### HISTORY

- Otorrhea/ear drainage (pus, blood, or clear fluid)
- Otalgia or earache consistent with AOM (perhaps associated with sudden relief)
- Tinnitus or buzzing
- Self-audible whistling from the ear with Valsalva maneuver or nose blowing
- Hearing loss or change
- Difficulty equalizing pressures, especially with altitude change or diving underwater
- Ear surgery (e.g., prior placement of PE tubes)
- Recurrent ear infections

### PHYSICAL EXAM

- Otoscope exam: Pay attention to location and size of any TM defect, as well as involvement of the annulus or the malleus. Also, inspect ear canal to look for evidence of otomycosis.
- Pneumatic otoscopy will reveal no motion because air passes freely into the middle ear space, and may induce vertigo (positive ÒfistulaÓ sign).
- Fogging of the otoscope, in what otherwise appears to be a dry ear, may reveal occult perforation (2)[C].
- Note foreign bodies (cotton swabs, PE tubes). Batteries are a particular concern, due to the risk of acid leakage.
- Retraction pocket (chronic eustachian tube dysfunction and possible resulting cholesteatoma) typically in the posterosuperior quadrant
- Thinned TM segment indicates past, healed perforation.
- Keratin debris consistent with cholesteatoma (pearly white +/- chronic drainage)
- Mass in the middle ear space behind the TM (cholesteatoma, paragangliomas, CN VII schwannomas, etc.)

- An ulceration of the EAC, contiguous with the TM annulus, should lead to suspicion of squamous cell carcinoma.
- If history of hearing loss on that side: Weber (512-kHz tuning fork to center of forehead; if conductive hearing loss, sound should lateralize to the perforated side) and Rinne tests (place tuning fork to mastoid; when vibration no longer heard, transfer tuning fork next to outside ear canal; air conduction should be greater than bone conduction)
- Facial nerve palsy is uncommon to have with an isolated TM perforation. This is likely due to more occult pathology.
- Inspection of oropharynx for tonsillar asymmetry or neoplasm, that can cause eustachian tube obstruction.
- Hemotympanum

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Audiogram can reveal normal hearing or a mild conductive hearing loss:
  - A simple perforation will typically result in a low-frequency conductive hearing loss.
  - An audiogram that demonstrates a worse-than-expected conductive hearing loss or sensorineural hearing loss is more suspicious for ossicular chain damage or middle ear pathology.
- Tympanometry demonstrates an increased volume in the ear and decreased pressure (can demonstrate perforation even if not present on otoscopic exam); acoustic immittance demonstrates a volume >2 mL.
- MRI and CT imaging are not indicated for routine TM perforations.
- If there is suspicion for cholesteatoma or CN VII palsy, then obtain noncontrast CT of the temporal bone as initial imaging study.

## *DIFFERENTIAL DIAGNOSIS*

- Tympanosclerosis may be confused with early cholesteatoma.
- Prior perforation (thin, healed membrane may be hard to discern)
- Cholesteatoma without perforation may still demonstrate chronic drainage.

## **TREATMENT**

## *GENERAL MEASURES*

- Most TM perforations are nonurgent and do not require immediate evaluation by an otolaryngologist. Often, these can be managed with drops and pain control to decrease inflammation; ENT follow-up in few days to a week
- A significant portion of TM perforations heal spontaneously without additional intervention due to the TM's regenerative capacity.
- Observation of >3 months is a feasible option in select patients with uncomplicated, small perforations.
- Debate exists over dry ear precautions. But conservatively, patients should avoid getting water into the EAC and into middle ear space. Typical showering is less of an issue, but swimming in rivers/swimming pools should be avoided until the perforation has healed.

P.783

- Treatment of purulence with topical antibiotic drops will reduce otorrhea.
- If significant bleeding, topical Afrin can also be instilled in the ear canal.
- Most perforations are associated with minimal hearing loss (<40 dB) and lack vestibular complaints.
- Perforations with hearing loss >40 dB, any degree of ipsilateral facial weakness, those associated with vestibular symptoms, or those associated with cholesteatoma require referral to ENT; for traumatic perforation, obtain evaluation within 48 hours.
- For some patients with chronic eustachian tube dysfunction, having a perforated TM is a favorable situation because it allows for the equalization of pressure in the middle ear that would otherwise be more difficult because of the decreased eustachian tube function, thus obviating the need for tympanostomy tube placement later. For these patients, dry ear precautions are recommended.

## **MEDICATION**

- Topical antibiotic and combined antibiotic/anti-inflammatory drops are the mainstay of treatment for AOM with perforation. These can be used for 5 to 7 days. Topical antibiotic drops should be continued if persistent otorrhea; may need evaluation by an otolaryngologist if drainage does not resolve with ototopical medication.
- Some topical antibiotics (gentamicin, neomycin sulfate, or tobramycin) may rarely cause ototoxicity with TM perforations because they absorb through the round window into the inner ear.
- While nonototoxic drops are preferred, cost and availability may be relevant considerations given the rarity of oto- and vestibulotoxicity (3)[C].
- Oral antibiotics are not recommended for AOM with perforations because antibiotic drops are

more effective. Oral antibiotics should be used in AOM prior to perforation.

- Oral antibiotics are not indicated for the isolated TM perforation.

### *First Line*

- Ciprofloxacin ear drops ± dexamethasone
- Ofloxacin ear drops

## **ADDITIONAL THERAPIES**

- Dry ear precautions (cotton ball with petroleum jelly while showering and use of hairdryer to dry out ear if water enters the EAC)
- Dry ear precautions should be used if patients will be swimming in lakes/rivers, to minimize the introduction of pathogens into the EAC/middle ear cavity.
- Prevent infection primarily with eardrops or oral antibiotics as a secondary measure.

## **SURGERY/OTHER PROCEDURES**

- For patients who participate in water sports as a part of daily life, such as swimmers and divers, repair is recommended to provide the patient a safe ear.
- A case-by-case risk-benefit analysis must be performed in cases of conductive hearing loss because surgery entails the risk of hearing loss.
- Myringoplasty can be performed if the perforation is small and appears to be favorable. This is often performed with gel, paper patch, or other material (silk), which provides a scaffold across which the TM can heal.
- Tympanoplasty is performed for larger perforations, persistent perforations, or anteriorly based perforations. Perichondrium, fat, cartilage, pericranium, and temporalis fascia are often used in reconstructing the TM.
- A combined tympanoplasty/mastoidectomy surgery might be required for large perforations, chronic draining ears, presence of cholesteatoma, damage to the ossicular chain, or with evidence of mastoid disease.
- Surgery is often an outpatient procedure and may be done under sedation and local anesthesia. General anesthesia can also be used.
- Patients can receive mastoid compressive dressings and instructions for postoperative antibiotics.
- Potential major complications of surgery include worsening of hearing, facial nerve damage, CSF leak, bleeding, and repair failure.

- Ossiculoplasty might also be performed if pathology involves the ossicular chain; full repair of the ossicular chain can be performed as a primary procedure or as a second look.
  - If ossicular chain discontinuity is repaired, patients will require postoperative audiogram to evaluate airborne gap.

## *INPATIENT CONSIDERATIONS*

The presence of comorbid disease like mastoiditis or meningitis would require inpatient stabilization with IV antibiotics/imaging and appropriate care for those disorders.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Follow-up should be done to confirm TM healing and to obtain an audiogram.
- It is vital to reexamine the ear, especially after an episode of infection associated with a perforation, to rule out underlying cholesteatoma or chronic eustachian tube dysfunction, which may be contributing to the perforation.

#### *DIET*

No dietary restrictions

### *PATIENT EDUCATION*

- Dry ear precautions
- Avoid cotton swabs in the ear.
- Call physician for worsening hearing loss, vertigo, **facial nerve palsy**, fever, or persistent drainage.

### *PROGNOSIS*

- Most perforations will heal spontaneously; however, large perforations and those associated with a chronic draining ear often require surgery.
- Mortality associated with this condition is low, but there is a potential for infection to spread to the mastoid, leading to meningitis, if proper aural care is not maintained.

## **COMPLICATIONS**

- Nonhealing perforation
- Infection (chronic suppurative otitis media, mastoiditis, meningitis)
- Conductive hearing loss
- Facial paralysis (rare and likely due to additional pathology)
- Ossicular chain disruption (traumatic induced)

## Codes

&NA;

### ICD10

- H72.90 Unsp perforation of tympanic membrane, unspecified ear
- H72.00 Central perforation of tympanic membrane, unspecified ear

- H72.2X9 Other marginal perforations of tympanic membrane, unsp ear

## Clinical Pearls

**&NA;**

- To evaluate a patient with a suspected TM perforation, history and physical exam will usually suffice and does not require imaging.
- Nonhealing perforations associated with malodorous or recurrent infections are often associated with cholesteatoma and an otolaryngology consultation is recommended.
- Retraction pockets and history of AOM are suspicious for chronic eustachian tube dysfunction.
- Tympanoplasty surgery might be required for a perforation that does not spontaneously heal.
- Sudden sensorineural hearing loss warrants urgent referral and initiation of steroid therapy the same day.
- Sudden facial paralysis warrants urgent referral and initiation of steroid therapy ± antiviral treatment.

# Pericarditis

Veronica J. Ruston, DO, Capt, USAF, MC

Angela M. Riegel, DO

## BASICS

### DESCRIPTION

Inflammation of the pericardium, with or without associated pericardial effusion. Myopericarditis or perimyocarditis refers to cases that have myocardial involvement in addition to the pericardial sac.

### EPIDEMIOLOGY

#### *Incidence*

Epidemiologic studies are lacking. Exact incidence is unknown but occurs in up to 5% of patients evaluated in the ER for chest pain without myocardial infarction (MI); appears to be a slightly increased prevalence in men.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Inflammation of the pericardial sac can be *acute* or *chronic* (recurrent). Chronic/recurrent inflammation may result in constrictive pericarditis.
- Can produce serous/purulent fluid/dense fibrinous material (depending on etiology), which may or may not lead to hemodynamic compromise

#### *Genetics*

No known genetic factors:

- Idiopathic: 85-90% of cases; likely related to viral infection, which may trigger immune-related process
- Infectious
  - Viral: coxsackievirus, echovirus, adenovirus, Epstein-Barr virus, cytomegalovirus, hepatitis viruses, influenza virus, HIV, measles, mumps, varicella
  - Bacterial: gram-positive and gram-negative organisms

- Fungal (more common in immunocompromised populations): *Blastomyces dermatitidis*, *Candida sp.*, *Histoplasma capsulatum*
- Mycobacterial: *Mycobacterium tuberculosis*
- Parasites: *Echinococcus*
- Noninfectious causes
  - Acute MI (2 to 4 days after MI), Dressler syndrome (weeks to months after MI)
  - Aortic dissection
  - Renal failure, uremia, dialysis-associated
  - Malignancy (e.g., breast cancer, lung cancer, Hodgkin disease, leukemia, lymphoma)
  - Radiation therapy
  - Trauma
  - Postpericardiotomy
  - After cardiac procedures (e.g., catheterization, pacemaker placement, ablation)
  - Autoimmune disorders: connective tissue disorders, systemic lupus erythematosus (SLE), rheumatoid arthritis, scleroderma, hypothyroidism, inflammatory bowel disease, spondyloarthropathies, Wegener granulomatosis
  - Sarcoidosis
- Medication induced: dantrolene, doxorubicin, hydralazine, isoniazid, mesalamine, methysergide, penicillin, phenytoin, procainamide, rifampin

## COMMONLY ASSOCIATED CONDITIONS

Depends on etiology

## DIAGNOSIS

### HISTORY

- Prodrome of fever, malaise, myalgias
- Acute, sharp, stabbing chest pain
- Duration typically hours to days
- Pleuritic pain
- Pain reduced by leaning forward, worsened by lying supine
- Shortness of breath

---

## PHYSICAL EXAM

- Heart rate is usually rapid and regular.
- Pericardial friction rub: coarse, high-pitched sound best heard during end expiration at left lower sternal border with patient leaning forward. Highly specific for diagnosis (but not sensitive); may be transient and mono-, bi-, or triphasic
- New S<sub>3</sub> may suggest myopericarditis.
- Cardiac tamponade
- Diagnostic clinical criteria
  - Acute pericarditis (at least two of four criteria)
    - Typical (pleuritic) chest pain
    - Pericardial friction rub
    - ECG changes with widespread ST elevation
    - New/increasing pericardial effusion
  - Myopericarditis
    - Definite pericarditis *plus*
    - Symptoms (dyspnea, chest pain, or palpitations) *and* ECG changes not previously documented (ST/T wave abnormalities, supraventricular/ventricular tachycardia) *or* focal/diffuse depressed left ventricular (LV) function documented on imaging study
    - Absence of evidence of other cause
    - One of the following: elevated cardiac enzymes (creatinine kinase [CK]-MB, troponin I or T) *or* new focal/diffuse depressed LV function *or* abnormal imaging consistent with myocarditis (MRI with gadolinium, gallium-67 scanning, antimyosin antibody scanning)
  - Case definitions
    - *Suspected myopericarditis*: criteria 1, 2, and 3
    - *Probable myopericarditis*: criteria 1, 2, 3, and 4
    - *Confirmed myopericarditis*: histopathologic evidence of myocarditis by endomyocardial biopsy (EMB) or autopsy (Note: In the clinical setting, for self-limited cases with predominantly pericarditis, EMB is rarely indicated.)

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- It is not necessary to order tests for uncomplicated cases or when the diagnosis is clear. Following labs may be helpful (1)[C]:
  - CBC: typically shows leukocytosis
  - Inflammatory markers: elevated erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and lactodehydrogenase (LDH)
  - Cardiac biomarkers: typically elevated creatine kinase, troponins
    - Elevated troponins associated with younger age, male sex, pericardial effusion at presentation, and ST segment elevation on ECG
    - Adverse outcomes are not predicted by elevated troponin.
- ECG: Findings include widespread upward concave ST segment elevation and PR segment depression that may evolve through four stages. ECG may be normal/show nonspecific abnormalities:
  - Stage 1: diffuse ST segment elevation and PR segment depression
  - Stage 2: Normalization of the ST and PR segments and T waves begin to flatten and invert.
  - Stage 3: widespread T wave inversions
  - Stage 4: normalization of T waves; may have persistent inversions if chronic pericarditis
- ECG may demonstrate low voltage and electrical alternans with tamponade.
- Transthoracic echocardiogram is recommended to evaluate for the presence of pericardial effusion, tamponade, or myocardial disease (presence of effusion helps to confirm diagnosis of pericarditis) (1)[C].
- Chest x-ray (CXR) is performed to rule out pulmonary/mediastinal pathology. Enlarged cardiac silhouette suggests large pericardial effusion (at least 200 mL).
- CT and MRI allow visualization of pericardium to assess for complications or if initial workup is inconclusive (1)[C].
- Additional testing (if clinically appropriate based on history or atypical presentation or course) may include tuberculin skin test, sputum cultures, rheumatoid factor, antinuclear antibody, and HIV serology (1)[C].
- Viral cultures and antibody titers rarely clinically useful (1)[C]

## *Diagnostic Procedures/Other*

- Pericardiocentesis indicated for cardiac tamponade; for suspected purulent, tuberculous, or neoplastic pericarditis; and for effusions >20 mm on echocardiography (2)[C]
- Surgical drainage with pericardial biopsy recommended if recurrent tamponade, ineffective pericardiocentesis, or hemodynamic instability (2)[C]

## *Test Interpretation*

- Microscopic examination may reveal hyperemia, leukocyte accumulation, or fibrin deposition.
- Purulent fluid with neutrophilic predominance if bacterial etiology
- Lymphocytic predominance in viral, tuberculous, and neoplastic pericarditis

## **TREATMENT**

- Goal of treatment is to relieve pain and reduce complications (e.g., recurrence, tamponade, chronic restrictive pericarditis).
- Outpatient therapy is reported to be successful in 85% patients with low-risk features.

## **GENERAL MEASURES**

Specific therapy directed toward underlying disorder for patients with identified cause other than viral/idiopathic disease.

## **MEDICATION**

### *First Line*

- NSAIDs are considered the mainstay of therapy for acute pericarditis:
  - Ibuprofen 400 to 800 mg TID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper (3) [C]
  - Aspirin 650 to 975 mg TID to QID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper; preferable for patients with recent MI because other NSAIDs impair scar formation in animal studies (4)[C]
  - Indomethacin 50 mg TID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper; should avoid in elderly due to flow restrictions to coronaries (3)[C]
  - Ketorolac 15 to 30 mg IV/IM q6h while inpatient; maximum duration of 5 days (3)[C]
  - GI protection should be provided (3)[C].

- Tapering should be done only if the patient is asymptomatic and CRP/ESR are normal and are done every 1 to 2 weeks (3)[C].
  - Treatment duration using NSAIDs for initial attacks is 1 to 2 weeks, but for recurrences, consider 2 to 4 weeks of therapy (3)[C].
  - Monitoring: NSAIDs: CBC and CRP at baseline and weekly until CRP normalizes
  - Contraindications: hypersensitivity to aspirin or NSAIDs, active peptic ulcer/GI bleeding
  - Precautions: Use with caution in patients with asthma, 3rd-trimester pregnancy, coagulopathy, and renal/hepatic dysfunction.
- Colchicine: common practice to use in combination with NSAIDs; 0.6 mg BID for up to 3 months (up to 6 months for recurrence); taper is not required. Efficacious as therapy for initial occurrence and if multiple recurrences. This is the only agent proven to prevent recurrences in RCTs. Adjunctive therapy can reduce rate of recurrence by 50% (2)[A]. Monitoring: Consider CBC, CRP, transaminases, creatine kinase, and creatinine at baseline and at least after 1 month.
  - Pregnant: <20 weeks' gestation: Aspirin is first choice, but NSAIDs and prednisone are also allowed; >20 weeks' gestation: Prednisone is allowed with avoidance of NSAIDs, aspirin, and colchicine (1)[C].

## Second Line

- Corticosteroid treatment is indicated in connective tissue disease, tuberculous pericarditis, or severe recurrent symptoms unresponsive to NSAIDs or colchicine; should be avoided in uncomplicated acute pericarditis. *Corticosteroid use alone has been found to be an independent risk factor for recurrence* (4)[C].
- If steroids are used, consider low dose (0.25 to 0.5 mg/kg/day for 2 weeks for first attack; 0.25 to 0.5 mg/kg/day for 2 to 4 weeks for recurrence); then slow taper (if >50 mg: 10 mg/day every 1 to 2 weeks; if 25 to 50 mg: 5 to 10 mg/day every 1 to 2 weeks; if 15 to 25 mg: 2.5 mg/day every 2 to 4 weeks; if <15 mg: 1 to 2.5 mg/day every 2 to 6 weeks) following remission. Remember adequate prophylaxis treatment for osteoporosis prevention (4)[C].
- If unable to taper from steroids, resume lowest steroid dose and begin slow taper of 1 to 2 mg every 2 to 4 weeks (3)[C].
- Intrapericardial administration of steroids may be effective and limits systemic side effects.

## ISSUES FOR REFERRAL

- Refractory cases include those on unacceptably high long-term steroid doses (>25 mg/day).

- Consider trial of aspirin and/or NSAIDs plus steroid and colchicine.
- Uremic or dialysis-related cases require more frequent or urgent dialysis without significant benefit from pharmacologics (1)[C].

## ***SURGERY/OTHER PROCEDURES***

- Pericardiocentesis is indicated in cases of cardiac tamponade, high likelihood of tuberculous/purulent/neoplastic pericarditis, and large symptomatic effusions refractory to medical therapy.
- Pericardial biopsy may be considered for diagnosis in those with persistent worsening pericarditis without a definite diagnosis.
- Pericardioscopy for targeted diagnostic imaging may be performed at experienced tertiary referral centers in refractory and difficult cases.
- Pericardial window may be performed in cases of recurrent cardiac tamponade with large pericardial effusion despite medical therapy and severe symptoms.
- Pericardiectomy can be considered. The 2004 European Society of Cardiology guidelines recommend pericardiectomy (Class IIa) for frequent and highly symptomatic recurrences of pericarditis refractory to medical therapy. However, this is rarely performed in the United States and has high morbidity and mortality (1)[C].

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Inpatient therapy recommended for pericarditis associated with clinical predictors of poor prognosis:

- Major predictors: fever  $>38.3^{\circ}\text{C}$ , subacute onset, large pericardial effusion, cardiac tamponade, lack of response to NSAID/aspirin therapy after at least 1 week (5)[C]
- Minor predictors: immunosuppressed state, trauma, oral anticoagulation therapy, myopericarditis (5)[C]

### ***IV Fluids***

IV fluids considered for hypotension or in the setting of pericardial tamponade

### ***Discharge Criteria***

- Response to therapy with symptom improvement
- Hemodynamic stability

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- 7 to 10 days to assess response to treatment
- 1 month to check CBC and CRP and thereafter if symptoms continue to be present
- Those with clinical predictors of poor prognosis may require closer follow-up based on lab data and echocardiographic findings.

### *Patient Monitoring*

#### Myopericarditis

- Use lower doses of anti-inflammatory drugs to control symptoms for 1 to 2 weeks while minimizing deleterious effects on myocarditic process.
- Exercise restrictions for 4 to 6 weeks or until symptoms resolved and biomarkers normalized (2)[C].
- Echocardiographic monitoring at 1, 6, and 12 months (especially in those with left ventricular dysfunction)

### *DIET*

No restrictions

### *PROGNOSIS*

Overall good prognosis; disease usually benign and self-limiting; purulent and tuberculosis pericarditis with high mortality

### **COMPLICATIONS**

- Recurrent pericarditis: occurs in ~30% of patients, with most instances resulting from idiopathic, viral, or autoimmune pericarditis; inadequate treatment of the initial attack; and, less commonly, neoplastic etiologies. Recurrence usually within 1st weeks following initial episode but may occur months to years later; rarely associated with tamponade/constriction
- Cardiac tamponade: rare complication with increased incidence in neoplastic, purulent, and tuberculous pericarditis
- Effusive-constrictive pericarditis: Reported in 24% of patients undergoing surgery for constrictive pericarditis and in 8% of patients undergoing pericardiocentesis and cardiac catheterization for cardiac tamponade. Failure

of right atrial pressure to fall by 50% or to a level below 10 mm Hg after pericardiocentesis is diagnostic.

- Constrictive pericarditis: rare complication in which rigid pericardium produces abnormal diastolic filling with elevated filling pressures. Pericardiectomy remains definitive therapy.

## Codes

**&NA;**

## **ICD10**

- I31.9 Disease of pericardium, unspecified
- I30.9 Acute pericarditis, unspecified
- I30.1 Infective pericarditis

## **Clinical Pearls**

**&NA;**

- Consider *major* and *minor* predictors in deciding which patients should be admitted.
- Therapy aimed at symptomatic relief and NSAIDs are first-line treatment. Colchicine is recommended as an adjunct to NSAIDs.
- Pericardiocentesis is recommended in the setting of cardiac tamponade or possible purulent pericarditis.

# Periodic Limb Movement Disorder

Donald E. Watenpaugh, PhD

John R. Burk, MD

## BASICS

### DESCRIPTION

- Sleep-related movement disorder with these features:
  - Episodes of periodic limb movements (PLMs) during sleep
  - Movements consist of bilateral ankle dorsiflexion, sometimes with knee and hip flexion.
  - Arm or more generalized movements occur less commonly.
  - Movements may cause brief microarousals from sleep unbeknownst to the patient.
  - Complaints include insomnia, unrestorative sleep, daytime fatigue, and/or somnolence.
  - Bed partner may complain of movements.
  - Another sleep disorder (e.g., obstructive sleep apnea) does not cause the PLMs.
- System(s) affected: musculoskeletal, nervous
- Synonym(s): nocturnal myoclonus; sleep myoclonus; periodic leg movements of sleep

### EPIDEMIOLOGY

#### *Incidence*

- Increases with age: 1/3 of patients >60 years exhibit PLMs but not necessarily periodic limb movement disorder (PLMD).
- Predominant sex: male = female
- PLMs in 15% of insomnia patients

#### *Prevalence*

- PLMs in sleep: common and often of no clinical consequence
- PLMs constituting PLMD (causing sleep complaints and/or daytime consequences) much less

common: <5% of adults (but underdiagnosed)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Unstudied
- Primary: probable CNS dopaminergic impairment
- Secondary:
  - Iron deficiency
  - Peripheral neuropathy
  - Arthritis
  - Renal failure
  - Synucleinopathies (multiple-system atrophy)
  - Spinal cord injury
  - Pregnancy
  - Medications:
    - Most antidepressants (not bupropion or desipramine)
    - Some antipsychotic and antidementia medications
    - Antiemetics (metoclopramide)
    - Antihistamines

## *Genetics*

Unstudied, but see "Restless Legs Syndrome" (RLS)

## *RISK FACTORS*

- Family history of RLS
- Iron deficiency and associated conditions (e.g., pregnancy, gastric surgery, renal disease)
- Attention deficit hyperactivity disorder (ADHD)
- Aging
- Peripheral neuropathy
- Arthritis, orthopedic problems
- Chronic limb pain or discomfort

## *GENERAL PREVENTION*

- Regular physical activity
- Adequate nightly sleep
- Avoid causes of secondary PLMD.
- Avoid causes of RLS.

## *COMMONLY ASSOCIATED CONDITIONS*

- RLS
- Rapid eye movement (REM) sleep behavior disorder
- Narcolepsy
- Iron deficiency
- Renal failure
- Cardiovascular disease; stroke
- Gastric surgery
- Pregnancy
- Arthritis
- Synucleinopathies (multiple-system atrophy)
- Lumbar spine disease; spinal cord injury
- Peripheral neuropathy
- Insomnia, insufficient sleep
- ADHD
- Depression

## *Pediatric Considerations*

- PLMD may precede overt RLS by years.
- Association with RLS is more common than in adults.
- Symptoms may be more consequential than in adults.
- Associated with ADHD

## *Pregnancy Considerations*

- May be secondary to iron or folate deficiency
- Most severe in 3rd trimester
- Usually subsides after delivery

## *Geriatric Considerations*

- May become a significant source of sleep disturbance
- May cause or exacerbate circadian disruption and "sundowning"
- Many medications given to the elderly cause or exacerbate PLMs, which can lead to PLMD or RLS.

## **DIAGNOSIS**

### **HISTORY**

- Episodes of PLMs during sleep (often reported by bed partner) (1)[A]
- Insomnia: difficulty maintaining sleep
- Unrestorative sleep
- Daytime fatigue, tiredness, and/or somnolence
- Oppositional behaviors
- Memory impairment
- Depression
- ADHD, particularly in children

## *PHYSICAL EXAM*

No specific findings

## *DIFFERENTIAL DIAGNOSIS*

- When PLMs occur along with RLS, REM sleep behavior disorder, or narcolepsy, those disorders are diagnosed as "with PLMs," and PLMD is not diagnosed separately.
- Obstructive sleep apnea: Limb movements (LMs) occur during microarousals from apneas; treatment of sleep apnea eliminates these LMs.
- Sleep starts: nonperiodic, generalized, occur only at wake-sleep transition, <0.2 seconds duration

- Sleep-related leg cramps: isolated and painful
- Fragmentary myoclonus: 75 to 150 ms of EMG activity, minimal movement, no periodicity
- Nocturnal seizures: epileptiform EEG, motor pattern incongruent with PLMs
- Fasciculations, tremor: no sleep association
- Sleep-related rhythmic movement disorder: voluntary movement during wake-sleep transition; higher frequency than PLMs

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Polysomnography with finding of repetitive, stereotyped LMs (1)[A]:
  - Tibialis anterior electromyographic (EMG) activity lasting 0.5 to 10 seconds
  - EMG amplitude increases  $>8 \mu\text{V}$  from baseline.
  - Movements occur in a sequence of  $\approx 4$  at intervals of 5 to 90 seconds.
  - Children:  $\approx 5$  movements per hour; adults, 15
  - Movement may also involve arms.
  - Associated with heart rate variability from autonomic-level arousals
  - Most PLM episodes occur in the first hours of non-REM sleep.
  - Significant night-to-night PLM variability
- Serum ferritin to assess for iron deficiency

---

P.787

### *Diagnostic Procedures/Other*

- Ankle actigraphy for in-home use
- EMG or nerve conduction studies for peripheral neuropathy/radiculopathy

### *Test Interpretation*

Serum ferritin should be  $>75$  ng/mL.

## **TREATMENT**

Treatment paradigm similar to that for RLS, except that all medications are off-label for PLMD

## *GENERAL MEASURES*

- Daily exercise
- Adequate nightly sleep
- Warm the legs (long socks, leg warmers, electric blanket, etc.).
- Hot bath before bedtime
- Avoid nicotine and evening caffeine and alcohol.

## *MEDICATION*

- Use minimum effective dose.
- Consider risks, side effects, and interactions individually (e.g., benzodiazepines in elderly).
- Daytime sleepiness is unusual with the doses and timing employed for PLMD.

### *First Line*

- Dopamine agonists: Take 1 hour before bed; titrate weekly to optimal dose (1,2)[B]:
  - Pramipexole (Mirapex): 0.125 to 0.5 mg; titrate by 0.125 mg
  - Ropinirole (Requip): 0.25 to 4 mg; titrate by 0.25 mg
  - Transdermal rotigotine (Neupro): 1 to 3 mg/24 hr patch; initiate with 1 mg/24 hr; titrate by 1 mg weekly to effectiveness.
- Avoid dopamine agonists in psychotic patients, especially if taking dopamine antagonists.

### *Second Line*

- Anticonvulsants: useful for associated neuropathy (1,2)[B]:
  - Gabapentin enacarbil (Horizant): 600 mg/day
  - Pregabalin (Lyrica): 50 to 300 mg/day
- Opioids: low risk for tolerance with bedtime dose
  - Hydrocodone: 5 to 20 mg/day
  - Oxycodone: 2.5 to 20 mg/day
- Benzodiazepines and agonists (1,2)[B]:
  - Clonazepam (Klonopin): 0.5 to 3 mg/day
  - Zaleplon, zolpidem, temazepam, triazolam, alprazolam, diazepam

## *Pediatric Considerations*

- First-line treatment is nonpharmacologic.
- Assess/correct iron deficiency.
- Consider low-dose clonidine or clonazepam.

## *Pregnancy Considerations*

- Initial approach: iron supplementation, nonpharmacologic therapies
- Avoid medications class C or D.
- In 3rd trimester, low-dose clonazepam or opioids may be considered.

## *Geriatric Considerations*

In weak or frail patients, avoid medications that may cause dizziness or unsteadiness.

## **ADDITIONAL THERAPIES**

- If iron-deficient, iron supplementation:
  - 325 mg ferrous sulfate with 200 mg vitamin C between meals TID
  - Repletion may require months.
  - Symptoms continue without other treatment.
- Vitamin/mineral supplements, including calcium, magnesium, B<sub>12</sub>, folate
- Clonidine: 0.05 to 0.1 mg/day
- Relaxis leg vibration device

## **SURGERY/OTHER PROCEDURES**

Correction of orthopedic, neuropathic, or peripheral vascular problems

## **INPATIENT CONSIDERATIONS**

- Control during recovery from orthopedic procedures
- Addition or withdrawal of medications that affect PLMD
- Changes in medical status may require medication changes (e.g., Mirapex contraindicated in renal failure and Requip contraindicated in liver disease).

## *IV Fluids*

- Consider iron infusion when oral supplementation is ineffective, not tolerated, or contraindicated.
- When NPO, consider IV opiates.

## *Nursing*

- Evening walks, hot baths, leg warming
- Sleep interruption risks prolonged wakefulness.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- At monthly intervals until stable
- Annual and PRN follow-up thereafter
- If iron-deficient, remeasure ferritin to assess repletion.

#### *DIET*

Avoid caffeine and alcohol late in the day.

### *PATIENT EDUCATION*

- National Sleep Foundation: <http://sleepfoundation.org/>
- American Academy of Sleep Medicine: <http://www.sleepeducation.org/>

### *PROGNOSIS*

- Primary PLMD: lifelong condition with no current cure
- Secondary PLMD: may subside with resolution of cause(s)
- Current therapies usually control symptoms.
- PLMD often precedes emergence of RLS.

### **COMPLICATIONS**

- Tolerance to medications requiring increased dose or alternatives
- Augmentation (increased PLMs and sleep disturbance, emergence of RLS)

from prolonged use of dopamine agonists:

- Higher doses increase risk.
  - Iron deficiency increases risk.
  - Add alternative medication, then detitrate dopaminergic agent.
- Iatrogenic PLMD (from antidepressants, etc.)

Restless Legs Syndrome

## Codes

&NA;

## ICD10

G47.61 Periodic limb movement disorder

## Clinical Pearls

**&NA;**

- Many patients with PLMs may not require treatment; however, when sleep disturbance from PLMs causes insomnia and/or daytime consequences, PLMD exists and should be treated.
- Many antidepressants and some antihistamines cause or exacerbate PLMs.
- Sleep disturbance, including that from PLMs, may cause or exacerbate ADHD.

# Perioral Dermatitis

Heather Summe, MD, MS

Nikki A. Levin, MD, PhD

## BASICS

### DESCRIPTION

- A common facial eruption of women and children
- Presents as tiny, flesh-colored, or erythematous monomorphic papules or pustules around the mouth with characteristic sparing of the area immediately adjacent to the vermilion border
- May also involve the periocular, perinasal, and glabellar regions of the face
- Etiology is unknown, but a relation to topical steroid use has been suggested.
- Without treatment, the course is usually fluctuating and chronic.
- Variants in children include granulomatous periorificial dermatitis (GPD) and facial Afro-Caribbean childhood eruption.
- Synonym(s): periorificial dermatitis (POD); chronic papulopustular facial dermatitis; granulomatous perioral dermatitis; light-sensitive seborrhea; lupus-like perioral dermatitis; papulopustular facial dermatitis; rosacea-like dermatitis; stewardess disease

### EPIDEMIOLOGY

- Occurs worldwide, especially in fair-skinned populations
- Predominantly affects children between 6 months and 16 years and women aged 17 to 45 years
- ÷90% of adult cases are in women (1).
- 55% of childhood cases occur in females (2).
- All races are affected, but the granulomatous form is more common in African American and darkskinned children.
- Some believe the number of cases peaked in the 1960s to 1970s and decreased in the 1980s to 1990s when the side effects of topical steroids were recognized. Others believe that cases are still increasing.

## *Incidence*

- Peak incidence is in the 2nd and 3rd decades of life.
- In children, peak incidence is in the prepubertal period.

## *Prevalence*

- Represents ÷2% of patients presenting to dermatology clinics (3)
- ÷3% of children using inhalational steroids develop some form of POD (4).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Exposure to an irritant results in breakdown of the epidermal barrier and subsequent water loss and sensation of dryness; this encourages use of facial products and corticosteroids, which may worsen the condition.
- This inflammatory cycle eventually leads to clinical features of the disease.
- The exact cause is unknown, and there may be more than one contributing factor.
- The most widely cited factor implicated in POD is use of potent topical corticosteroids on the face.
- Inhaled corticosteroids, especially when used with a spacer and nebulizer or mask, have also been reported to cause POD.
- Intranasal steroids have been associated with POD beginning in the nasolabial folds.
- Two cases associated with systemic steroid use have been reported in children (5).
- Use of foundation, moisturizer, and night cream was associated with a 13-fold increased risk of POD in one study (6).
- Other factors are implicated but not proven:
  - Drugs: oral contraceptives
  - Toothpastes: fluoridated, tartar control, whitening
  - Physical factors: UV light, heat, wind, salivary leakage
  - Infectious factors: fusiform bacteria, *Candida* species, *Demodex folliculorum*
  - Miscellaneous factors: atopy, GI disturbances, stress, contact allergy, lip-licking, immunosuppression, bubble gum, formaldehyde, varicella vaccination

## *Genetics*

55% of pediatric patients with POD have a family history of atopy (6).

## **RISK FACTORS**

See Etiology and Pathophysiology.

## **GENERAL PREVENTION**

- Avoid using potent topical corticosteroids on the face.
- Avoid using excessive foundation, moisturizer, and night cream.
- Avoidance of tartar-control and whitening toothpastes may also be helpful.

## **COMMONLY ASSOCIATED CONDITIONS**

Atopic dermatitis

## **DIAGNOSIS**

### **HISTORY**

- Patient reports a history of facial rash, which may improve with use of topical corticosteroids and flare with discontinuation.
- Affected skin may be pruritic or have a burning sensation.
- Course may be chronic and fluctuating.
- Recent topical, inhaled, or systemic steroid use in 72% of patients (7)
- May worsen with sun exposure

## **PHYSICAL EXAM**

- Monomorphic, minute, flesh-colored to erythematous papules or pustules, sometimes surmounted with scale, in a perioral distribution, often asymmetrical, with sparing of the vermilion border 3 to 5 mm around the lips
- Granulomatous form can usually be distinguished clinically by the absence of pustules and the presence of yellow-brown papules.
- Common locations are alar creases, nasolabial folds, chin, periocular skin, eyelids, and glabella.
- Diameter of lesions is usually 1 to 2 mm.
- Distribution (3)
  - Perioral area (39%)

- Perinasal (13%)
  - Periorcular (1%)
  - Perioral and perinasal (14%)
  - Perioral and periorcular (6%)
  - Perinasal and periorcular (6%)
  - Perioral, perinasal, and periorcular (10%)
- Lupus-like variant diagnosed by yellowish discoloration of lesions on diascopy

## ***DIFFERENTIAL DIAGNOSIS***

- Acne vulgaris
- Contact dermatitis
- Rosacea
- Seborrheic dermatitis
- Lip-licker's dermatitis
- Papular sarcoidosis
- *Demodex* infestation
- Acrodermatitis enteropathica
- Biotin deficiency
- Glucagonoma syndrome
- Xanthomas
- Eruptive syringomas
- Polymorphous light eruption
- Acne agminata
- Lupus miliaris disseminatus faciei
- Haber syndrome (familial rosacea-like dermatosis)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Diagnosis is usually clinical.

- No laboratory abnormalities are expected.
- Prick tests and IgE testing may show evidence of atopy but are not routinely done.

- Patch testing may be used to rule out contact dermatitis.
- Scrapings for *Demodex* mites

## *Diagnostic Procedures/Other*

Skin biopsy is not routinely performed but can be helpful in atypical cases.

## *Test Interpretation*

Histopathology of skin biopsy

- Mild, nonspecific inflammation with variable perifollicular or perivascular lymphohistiocytic infiltrate
- Eczematous changes, acanthosis, parakeratosis, and spongiosis
- Occasionally, follicular abscesses are seen.
- Older lesions may contain diffuse hypertrophy of connective tissue and hyperplasia of sebaceous follicles with occasional noncaseating granulomas in the dermis (1).
- Caseating granulomas are seen with granulomatous variant.

## **TREATMENT**

### *GENERAL MEASURES*

Zero therapy can be an effective treatment in adherent patients (3)[B]:

- Reduce use of facial soaps, makeup, and moisturizers, and wash with only water.
- Discontinue use of potent topical corticosteroids on the face.
  - This may result in a flare.
  - Flares may be decreased with use of less-potent topical steroids, calcineurin inhibitors, or IM steroid injection.
- Discontinue use of fluoridated, whitening, and tartar-control toothpaste.

### *MEDICATION*

Based on disease severity and patient's tolerance for adverse effects

#### *First Line*

- Severe disease
  - Oral antibiotics
    - Tetracycline has been proven as an effective treatment (3)[A].
    - 250 to 500 mg BID for 8 to 10 weeks
    - Dose may be halved after 3 to 4 weeks if improvement is noted.
    - Contraindicated in children <8 years of age and pregnant women.
    - Common side effects: photosensitivity, GI upset, rash, candidiasis, headache, dizziness, and tinnitus
  - Doxycycline or minocycline (6)[C]
    - 50 to 100 mg BID for 6 to 8 weeks
    - Dose may be halved after 3 to 4 weeks if improvement is noted.
    - Contraindicated in children <8 years of age and pregnant women.
    - Common side effects of doxycycline: GI upset, esophagitis, joint pain, upper respiratory infection (URI) symptoms, rash, dysmenorrhea, candidiasis, headache, dizziness, photosensitivity, and elevated BUN
    - Common side effects of minocycline: GI upset, lightheadedness, vertigo, ataxia, headache, fatigue, tinnitus, rash, urticaria, candidiasis, and hyperpigmentation
  - Alternatively, doxycycline 40 mg/day modified-release capsule may achieve the anti-inflammatory effect without the microbial activity that promotes emergence of resistant bacterial strains (8)[C].
  - Erythromycin (6)[C] may be used when tetracycline are contraindicated or not tolerated.
    - 250 mg BID-TID for 6 to 8 weeks
    - Dose may be halved after 3 to 4 weeks if improvement noted.
    - May be used in children or pregnant women
    - Common side effects: GI upset, diarrhea, rash, and urticaria
    - Rarer serious side effects: erythema multiforme, pancreatitis, convulsions, QT prolongation, and ventricular arrhythmias
- Moderate disease
  - Topical antibiotics

May be slower than systemic antibiotics in clearing lesions

- Metronidazole cream 0.75% BID (3)[B]
- Erythromycin 2% gel, solution, or ointment BID (3)[B]
- Clindamycin 1% gel, lotion, or cream BID
- Mild disease
  - Zero therapy (see "General Measures") (3)[B]

## *Second Line*

- Severe disease
  - Azithromycin (2) or clarithromycin (250 mg/day) may be used when tetracycline and erythromycin (3)[C] are contraindicated or not tolerated.
    - Common side effects: GI upset, headache, rash, abnormal taste sensation, and urticaria
  - Oral isotretinoin may be useful in granulomatous cases that are not responsive to a full dose of tetracycline (1)[C].
    - 0.2 mg/kg initially, followed by 0.1 mg/kg after notable improvement
    - Isotretinoin is a pregnancy Category X drug and may cause severe birth defects. Use with caution in women of reproductive age. Physician and patient must register with iPLEDGE program.
    - Common side effects: dry skin, cheilitis, arthralgias/myalgias, hypertriglyceridemia, elevated liver function tests (LFTs), hair loss, visual disturbances, depression, and tinnitus
  - Pimecrolimus 1% cream may accelerate healing (3)[A], and tacrolimus 0.1% ointment use has been reported with success (3).
    - Rare cases of lymphoma and skin malignancies have been reported. Avoid long-term use
- Moderate disease
  - Topical therapies
    - Other antiacne drugs, such as sodium sulfacetamide (2), azelaic acid, and adapalene (3), may be helpful.
    - Ichthyol (ammonium bituminosulfonate) (3)

## ***ADDITIONAL THERAPIES***

A number of other therapies have been reported in the literature, including photodynamic therapy with 5-aminolevulinic acid (3), radiotherapy, and liquid nitrogen. There has also been a case reported of oral metronidazole (250 mg BID) resulting in complete clearance of GPD without scarring after 1 month of use (9). Most recently, a randomized controlled trial showed significant improvement after 4 weeks of treatment with praziquantel 3% ointment BID (10).

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Compress with chamomile tea or physiologic solution may be used if the patient struggles with zero therapy (1).

## **ONGOING CARE**

### ***DIET***

No restrictions

### ***PATIENT EDUCATION***

- Lesions may take many weeks to resolve.
- Symptoms may temporarily worsen, especially with discontinuance of steroids.
- Recurrence is rare.
- Topical corticosteroid use on the face should be avoided in the future.

### ***PROGNOSIS***

- Most cases resolve without recurrence.
- Oral or topical antibiotics usually lead to remission within 6 to 10 weeks.
- Untreated disease may persist for months to years and be characterized by unpredictable flares.
- Disease is not associated with significant morbidity.

### **COMPLICATIONS**

- Most cases resolve without complications.
- Emotional stress can result from bothersome appearance of lesions and chronic course of disease.
- Scarring may be problematic with lupus-like variant.

## Codes

**&NA;**

### ICD10

L71.0 Perioral dermatitis

## Clinical Pearls

**&NA;**

- Suspect POD when an acneiform eruption involves the perioral, perinasal, or periocular areas with characteristic sparing of the skin immediately adjacent to the vermilion border.
- Ask patients about a history of recent corticosteroid use, facial product use, and use of fluoridated, whitening, or tartar-control toothpastes.
- Substitution of low-potency steroids may allow patients to discontinue higher potency steroids while avoiding a rebound flare.

# Peripheral Arterial Disease

Zhen Lu, MD

## BASICS

### *DESCRIPTION*

Peripheral arterial disease (PAD) is a manifestation of systemic atherosclerosis in which there is partial or total blockage in the arteries, exclusive of the coronary and cerebral vessels. Objectively, PAD is defined as a resting ankle-brachial index (ABI) of  $<0.90$ .

### *EPIDEMIOLOGY*

- Predominant age:  $>40$  years
- Predominant sex: male  $>$  female (2:1), based on the Framingham study
- Patients with symptomatic PAD have a 5-year mortality rate of 30%.
- Highly prevalent syndrome that affects 8 to 12 million individuals in the United States

### *Incidence*

Incidence overall: 1 to 3/1,000/year

### *Prevalence*

- U.S. prevalence: 2.7 to 4.1%
- Age-adjusted prevalence of PAD is close to 12%.
- Up to 29% among patients in primary care practices

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- In patients with PAD, arterial stenoses cause inadequate blood flow in distal limbs, which fails to meet the metabolic demand during exertion:
  - The degree of ischemia is proportional to the size and proximity of the occlusion to the end organ.
  - Acidic products of anaerobic metabolism build up within the muscle and result in claudication clinically.

- Arterial occlusion also causes significantly diminished distal pressure in patients with PAD due to atherosclerotic lesions.
- Most common cause of arterial stenoses is atherosclerosis.

## *Genetics*

Current NIH-funded research focuses on single-nucleotide polymorphisms in candidate genes that are regulated in the vasculature in an attempt to explore genetic factors responsible for PAD.

## **RISK FACTORS**

- Age >40 years
- Cigarette smoking
- Diabetes mellitus
- Obesity
- Hypertension
- Hyperlipidemia
- Hyperhomocysteinemia

## **GENERAL PREVENTION**

Control risk factors.

## **COMMONLY ASSOCIATED CONDITIONS**

- See "Risk Factors."
- Associated with other common complications of atherosclerosis, including myocardial infarction (MI), transient ischemic attack (TIA), stroke, and limb amputation
- Occurs in ~40% of patients with cardiovascular disease

## **DIAGNOSIS**

### **HISTORY**

- Intermittent claudication, with symptoms typically resolving within 2 to 5 minutes of rest (although it is regarded as the classic symptom for PAD, intermittent claudication is present in only 10% of patients with PAD)
- Rest leg pain (especially in a supine position)

Skin ulceration (in advanced PAD)

- Gangrene (in advanced PAD)
- Impotence

## *PHYSICAL EXAM*

- Skin pallor when leg is elevated above the level of the heart (in mild PAD)
- Dependent rubor
- Dry and scaly skin
- Poor nail growth
- Hair loss
- Reduced/absent extremity pulses (in advanced PAD)

## *DIFFERENTIAL DIAGNOSIS*

- Arterial embolism
- Deep venous thrombosis
- Thromboangiitis obliterans (Buerger disease)
- Osteoarthritis
- Restless legs syndrome
- Peripheral neuropathy
- Spinal stenoses (pseudoclaudication)
- Intervertebral disc prolapse

## *DIAGNOSTIC TESTS & INTERPRETATION*

Serum glucose is recommended screening for diabetes mellitus in suspected or confirmed PAD.

### *Initial Tests (lab, imaging)*

- Fasting lipid profile is indicated for risk assessment of hyperlipidemia.
- Duplex ultrasonography and Doppler color-flow imaging, which are useful in detecting stenosed segments and assessing lesion severity, are initial imaging tests of choice.
- Magnetic resonance angiography, coupled with 3D reconstruction, is highly sensitive and specific for the localization of occluded lesions.

CT scanning has a limited role in the evaluation of PAD.

- Angiography remains the gold standard in the diagnosis of PAD.

## *Diagnostic Procedures/Other*

- Doppler ABI measures the ratio of the higher systolic BPs between the dorsalis pedis and the posterior tibial artery versus the higher of the systolic BPs in the two brachial arteries: Values for the ABI should be reported as "incompressible" if  $>1.40$ , "normal" if  $1.00$  to  $1.40$ , "borderline" if  $0.91$  to  $0.99$ , and "abnormal" if  $\geq 0.90$ . ABI  $<0.4$ : severe ischemia
- Segmental limb pressures: usually obtained if abnormal ABI measurement is identified; a  $\geq 20$ -mm Hg reduction in pressure is considered significant for PAD.
- Treadmill exercise test assesses the severity of claudication and the response to treatment.
- Segmental volume plethysmography: often used in conjunction with segmental limb pressures to measure the volume changes in an organ or limb; the study is indicated for calcified vessel when the ABI cannot be applied diagnostically.

## **TREATMENT**

### *GENERAL MEASURES*

- Claudication exercise rehabilitation program: patient to walk until symptoms develop, then rest and start again, for a total of 30 minutes initially; walking then is increased by 5 minutes until 50 minutes of intermittent walking is achieved.
- Modification of risk factors, including smoking cessation, diabetes mellitus, hypertension, and hyperlipidemia:
  - Weight loss is associated with a decrease in the risk of cardiovascular disease but has not been shown to improve PAD.
  - Antiplatelet therapy (aspirin) is recommended for patients with PAD when there is no other contraindication; however, neither the addition of an anticoagulant nor anticoagulant therapy alone has demonstrated superior outcome in PAD patients.
  - Lipid-lowering therapy with moderate-intensity statin; simvastatin (20 to 40 mg/day) has been shown to reduce the incidence of new intermittent claudication from 3.6% to 2.3% in patients with coronary artery disease (CAD).
  - No statistical significance for overall improvement of exercise performance or reduction in claudication symptoms for patients on niacin extended-release/lovastatin-combined therapy.
  - *&bgr;*-Adrenergic antagonists should be used with caution in individuals with severe PAD.

- Smoking cessation is likely to reduce the severity of claudication.

## MEDICATION

### *First Line*

Antiplatelet therapy has been the mainstay treatment to prevent ischemic events in patients with PAD. However:

- The effect of aspirin on the risk reduction of overall ischemic events is inconclusive. Some suggest that aspirin delays disease progression and reduces the need for surgical intervention. AHA/ACCF guidelines (1)[A] note that the use of antiplatelet therapy to reduce cardiovascular risks in asymptomatic patients with borderline ABIs is characterized as "not well-established." Aspirin is recommended to reduce the risk of MI, stroke, and vascular death in symptomatic patients with PAD.
- Low-dose aspirin (75 to 150 mg/day) is as effective as higher doses of aspirin.

---

P.791

### *Second Line*

- Clopidogrel (75 mg/day) is approved by the FDA for the secondary prevention of thrombotic events in patients with symptomatic lower extremity PAD and is recommended as an alternative to aspirin.
- Vorapaxar (Zontivity) 2.08 mg PO daily is a platelet aggregation inhibitor different in mechanism from existing antiplatelet drugs (TRAP inhibitor). It is contraindicated if history of CVA, TIA, or intracranial hemorrhage; concern for bleeding risk; and is expensive
- Other medications that may improve symptoms of claudication include pentoxifylline (1.2 g/day), cilostazol (100 mg BID), and naftidrofuryl (600 mg/day).
- Neither vasodilators nor anticoagulant therapy (e.g., heparin, low-molecular-weight heparin, or oral anticoagulant) has shown any clinically proven efficacy for the treatment of claudication and may be harmful.
- Cilostazol (100 mg BID) improves walking distance in people with intermittent claudication secondary to PAD. There is currently insufficient data on whether taking cilostazol results in a reduction of all-cause mortality and cardiovascular events or an improvement in quality of life (2)[A].
- Other medications that may reduce claudication include pentoxifylline (1.2 g/day), naftidrofuryl (600 mg/day), and prostaglandins (120 &mgr;g/day). Ticlopidine (250 mg BID) reduces the risk of MI, stroke, and death in patients with PAD, but it has a complication of thrombocytopenia in 2-3% of patients.

## ADDITIONAL THERAPIES

- Weight reduction, smoking cessation, and BP control are essential in treating claudication.
- Exercise programs are of significant benefit compared with placebo or usual care in improving walking time and distance in people with leg pain from intermittent claudication who were considered to be fit for exercise intervention (3)[A]. A walking program should include walking at least 3 times per week for 30 to 60 minutes each time and has been shown to improve quality of life as much as or more so than medication.
- A healthy diet high in complex carbohydrates (e.g., whole grains and pastas), fruits and vegetables, and low in salt and animal fats

## SURGERY/OTHER PROCEDURES

Surgical interventions, such as revascularization, are warranted for individuals who have debilitating intermittent claudication, ischemic rest pain, or tissue loss:

- Transluminal balloon angioplasty is a percutaneous method of dilating arterial stenoses or recanalizing occluded vessels with or without stents (reserved for short, isolated, and hemodynamically significant lesions of the iliac or proximal superficial femoral artery).
- Bypass surgery is the standard operative treatment for lower extremity peripheral occlusive disease.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture, biofeedback, chelation therapy, and supplements such as *Ginkgo biloba*, omega-3 fatty acids, and vitamin E have been studied.
- *Ginkgo biloba* modestly reduces the symptoms of intermittent claudication (120 mg/day for up to 6 months) and can be considered as an adjunct to exercise therapy. Inconclusive evidence exists for the use of vitamin E.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

- An exercise training program composed of walking/bicycle riding improves maximal treadmill walking distance and, therefore, enhances functional capacity.
- However, little added benefit exists from *Ginkgo biloba* treatment when added to supervised exercise training in patients with PAD as compared with patients in exercise training program alone.

## DIET

A low-fat cardiac diet is recommended.

## PROGNOSIS

- Among patients with intermittent claudication, 15-20% will experience worsening claudication; 5-10% will undergo lower extremity bypass surgery; and 2-5% will need primary amputation (rates for smokers and diabetics are much higher).
- 30,000 to 50,000 people in the United States undergo amputations annually because of PAD.

## Clinical Pearls

**&NA;**

- Screening of a general medical population for PAD is not recommended. Studies have indicated that screening for PAD among asymptomatic adults in the general population could lead to false-positive results and unnecessary workups. The prevalence among the general public who are asymptomatic is low.
- A patient already receiving medical treatment should be referred for further surgical evaluation for any of the following scenarios:
  - Unsatisfactory results despite medical therapy.
  - No definitive diagnosis can be made.
  - Critical limb ischemia is present, such as rest pain, gangrene, or ulceration.
- The clopidogrel (75 mg/day) versus aspirin (325 mg/day) study in the patients at risk of ischemic events (CAPRIE) trial found a 23.8% relative risk ratio for MI, stroke, or cardiovascular death in PAD patients treated with clopidogrel compared with aspirin but no statistically significant difference in overall mortality reduction. Clopidogrel is much more expensive than aspirin.

# Peritonitis, Acute

Justin Thomas Ertle, BS, MD

Marie L. Borum, MD, EdD, MPH

## BASICS

### DESCRIPTION

- Definition: inflammation of the peritoneum
- Classification:
  - Aseptic: due to chemical irritation or systemic inflammation of peritoneum
  - Bacterial: due to infection of peritoneal fluid
- Bacterial peritonitis types:
  - Primary/spontaneous bacterial peritonitis (SBP): infection of ascitic fluid without known source; typically monomicrobial
  - Secondary bacterial peritonitis: infection of peritoneal fluid from a detectable intra-abdominal source (i.e., perforation); typically polymicrobial
  - Tertiary bacterial peritonitis: persistent infection despite adequate therapy

### EPIDEMIOLOGY

#### *Incidence*

- In patients with ascites, the incidence of SBP in a 1-year period is 10-25% (1).
- Secondary bacterial peritonitis correlates with incidence of the underlying pathology (e.g. colitis, appendicitis, diverticulitis, PUD).
- 57% of patients with secondary bacterial peritonitis progressed to tertiary peritonitis (2).

#### *Prevalence*

- SBP: In asymptomatic patients with cirrhosis and ascites, the prevalence is <3.5% in outpatients and 8-36% in the nosocomial setting (3).
- In patients with cirrhosis and ascites, 5% of peritonitis is secondary rather than SBP (4).

# ETIOLOGY AND PATHOPHYSIOLOGY

- Mechanism
  - SBP:
    - Primary mechanism is bacterial translocation via lymphatic spread through mesenteric lymph nodes into ascitic fluid.
    - Cirrhotic patients have multiple secondary mechanisms:
      - Small intestinal bacterial overgrowth (SIBO) and increased intestinal mucosal permeability to bacteria both increase bacterial translocation.
      - Decreased cellular and humoral immunity increases susceptibility to bacterial translocation
  - Secondary bacterial peritonitis
    - Spillage/translocation of bacteria from inflamed or perforated intraperitoneal organs or introduction of bacterial through instrumentation—for example, peritoneal dialysis, intraperitoneal chemotherapy
  - Tertiary bacterial peritonitis
    - Occurs in secondary peritonitis with inadequacy of source control or altered host immunity
- Microbiology
  - SBP
    - *Escherichia coli* (46%), *Streptococcus* spp. (30%), *Klebsiella* (9%), and *Staphylococcus* (6%). Increasing rate of gram-positive and resistant organisms (e.g., extended-spectrum *β*-lactamase-producing [ESBL] *E. coli*, MRSA, enterococcus) in the nosocomial setting
  - Secondary bacterial peritonitis:
    - *E. coli*, *Klebsiella*, *Proteus*, *Streptococcus*, *Enterococcus*, *Bacteroides*, *Clostridium*

## RISK FACTORS

- SBP: advanced cirrhosis with ascites, bacterascites, malnutrition, upper GI bleed, PPI usage, prior SBP
  - Acid suppression with PPIs been shown to promote SIBO increasing SBP, and hospitalized cirrhotics receiving PPIs are at increased risk of developing SBP (3).

- 70% of cases of SBP are seen in patients with Child-Pugh class C cirrhosis (1).
- Secondary bacterial peritonitis: Factors associated with perforation or fluid translocation, for example, peritoneal dialysis, *H. pylori* and NSAIDs causing ulcers, vascular disease causing bowel ischemia, ETOH abuse causing pancreatitis

## GENERAL PREVENTION

- SBP prophylaxis is beneficial when risk factors are present, including ascitic fluid protein concentration <1.0 g/dL, esophageal varices, or history of previous SBP
  - Prior SBP: prophylactic norfloxacin or TMP/SMX PO daily (5)[A].
  - Cirrhosis and GI bleed: 7-day course of ceftriaxone 2 g IV daily or norfloxacin BID, IV while bleeding, PO as tolerated (5)[A]
  - Cirrhotic ascites with low ascitic fluid protein (<1.5 g/dL) and either renal impairment (creatinine <sup>3</sup>1.2, BUN <sup>3</sup>25, or serum Na <sup>2</sup>130) or liver failure (Child score <sup>3</sup>9, bilirubin <sup>3</sup>3): prophylactic norfloxacin PO daily (3,5)[A]
- Limit use of PPIs to only proven indications, as PPIs increase incidence of SIBO (5)[B].

## DIAGNOSIS

### HISTORY

- SBP: history of cirrhosis or ascites, fever, mental status changes, abdominal pain, chills, nausea/vomiting, GI bleed
- Secondary bacterial peritonitis: history of perforation, abscess or peritoneal dialysis, acute abdominal pain, nausea, vomiting, anorexia, fever, mental status changes
- Tertiary: persistent signs and symptoms despite initial treatment, or history of recurrent peritonitis

### ALERT

30% of patients are asymptomatic (1)[C].

### *Geriatric Considerations*

Signs and symptoms are frequently absent, particularly in pediatric and elderly patients (1)[B].

## PHYSICAL EXAM

Tachycardia, fever, tachypnea, altered mental status

- Abdominal distention, ascites, abdominal wall guarding and rigidity, rebound tenderness, hypoactive/absent bowel sounds

## **DIFFERENTIAL DIAGNOSIS**

- Liver disease: acute hepatitis, decompensated cirrhosis
- Luminal disease: abscess formation, ileus, volvulus, intussusception, mesenteric adenitis, pancreatitis, cholecystitis, malignancy, peritoneal carcinomatosis
- Extraluminal disease: ruptured ectopic pregnancy, tubo-ovarian abscess, PID, severe UTI, and/or pyelonephritis
- Systemic disease: tuberculosis, pneumonia, MI, porphyria, SLE

## **DIAGNOSTIC TESTS & INTERPRETATION**

### *Initial Tests (lab, imaging)*

#### **ALERT**

Early diagnosis is essential to reduce mortality. Paracentesis should be performed in any patient with new ascites, including suspected SBP (5)[B].

- Immediate evaluation
  - Perform paracentesis, blood, and urine cultures before administration of antibiotics (1,5)[B].
  - Ascitic fluid studies should minimally include culture (use aerobic and anaerobic blood culture bottles), Gram stain, cell count with differential, and albumin (1)[B]; if assessing for secondary peritonitis also include LDH, total protein and glucose.

#### **ALERT**

Lab interpretation: Ascitic fluid culture is negative in up to 50% of patients with SBP (1)[A].

- SBP: bacterascites and ascitic fluid PMN  $>250$  cells/mm<sup>3</sup>
- Culture-negative neutrocytic ascites: negative ascites culture, ascitic fluid PMN  $>250$  cells/mm<sup>3</sup>
- Nonneutrocytic bacterascites: positive ascites culture, ascitic fluid PMN  $<250$  cells/mm<sup>3</sup>
- Secondary peritonitis: PMN  $>250$  cells/mm<sup>3</sup> on ascitic fluid analysis, with any of the following criteria:
  - Polymicrobial culture or two of the following: ascitic fluid total protein  $>1$  g/dL, glucose  $<50$

mg/dL, or LDH >225 mU/mL. Sensitivity for perforation 96%, sensitivity for nonperforation secondary peritonitis 50% (5)[B]

- Secondary peritonitis with perforation is likely with alkaline phosphatase >240 U/l or CEA >5 ng/mL, sensitivity 92% (5)[B].

## **ALERT**

Imaging: Criteria or clinical suspicion for secondary peritonitis necessitates emergent CT scan. CT diagnostic for secondary peritonitis in 85% (5)[B].

- Ultrasound or CT scan with enteral and IV contrast shows intra-abdominal mass, ascites, abscess, or extravasation of contrast in secondary peritonitis
- Abdominal or chest x-ray may show free air in peritoneal cavity, large/small bowel dilatation, intestinal wall edema in secondary peritonitis.

## *Follow-Up Tests & Special Considerations*

- If asymptomatic bacterascites, recent antibiotic exposure, nosocomial atypical organism, or no clinical improvement, repeat paracentesis in 48 hours to resolution, defined as decrease in PMNs of 25% or negative cultures (1)[C].
- In hemorrhagic ascites, PMN count can be corrected by subtracting 1 PMN per 250 RBCs (3) [A].

## **TREATMENT**

### *GENERAL MEASURES*

- For SBP, control the effects of cirrhosis/ascites with salt restriction, spironolactone +/- furosemide, albumin infusion after large volume paracentesis, and/or lactulose for encephalopathy (5)[A].
- Avoid nephrotoxic medications (e.g., NSAIDs) or other renal insults (5)[C].

P.793

### *MEDICATION*

- SBP empiric first-line treatment
  - Community-acquired SBP w/o recent *&bgr;*-lactam antibiotic use: 3rd-generation cephalosporins, preferably cefotaxime, 2 g IV q8h for 5 days (5)[A]
  - SBP in absence of previous quinolone use/prophylaxis, vomiting, shock, hepatic

encephalopathy, or serum creatinine >3 mg/dL: Ofloxacin 400 mg PO can be substituted for cefotaxime (5)[B].

- Nosocomial SBP or recent *&bgr*-lactam antibiotic: Empiric therapy based on local susceptibility of patients with cirrhosis for resistant bacteria (e.g., ESBL *Enterobacteriaceae*, MRSA) (6)[B]
- Symptomatic bacterascites with PMN count <250 cells/mm<sup>3</sup>: cefotaxime 2 g IV q8h while awaiting sensitivities (5)[B]
- Second-line antibiotic regimens include fluoroquinolones (levofloxacin), piperacillin/tazobactam, or vancomycin (5)[C].
- SBP with renal or hepatic impairment (serum creatinine >1 mg/dL, BUN >30 mg/dL, or total bilirubin >4 mg/dL): Add albumin 1.5 g/kg within 6 hours and 1 g/kg on day 3 (1)[A],(5)[B].
- Secondary bacterial peritonitis
  - Empiric broad spectrum antibiotic coverage for polymicrobial infection; IV cefotaxime or other 3rd- to 4th-generation cephalosporin plus metronidazole is one option for an initial regimen.
  - In peritoneal dialysis associated infection, intraperitoneal route superior to IV (6)[A]
- Tertiary bacterial peritonitis
  - If no unrepaired perforations or leaks, conservative medical management. This includes antibiotics (guided by prior susceptibilities if available) and early enteral nutrition to prevent atrophy and maintain immunocompetence (2)[B].
  - In recurrent or persistent peritoneal dialysis associated infection, removal of the PD catheter is warranted (6)[A].

## ***SURGERY/OTHER PROCEDURES***

- SBP
  - Medical management
- Secondary bacterial peritonitis
  - Emergent surgical management, including source control with open laparotomy to repair any perforated viscus and eradicate infected material, is the first-line treatment (2)[A],(5)[B].
- Tertiary bacterial peritonitis

- If no unrepaired perforations or leaks, additional surgery for severe abdominal infection is correlated with deterioration and significant mortality (2).

## **ALERT**

Mortality of SBP approaches 80% if the patient receives unnecessary exploratory laparotomy; conversely, mortality of secondary bacterial peritonitis approaches 100% if not treated surgically (1,3).

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

- Acute peritonitis typically warrants inpatient admission.
- In patients with cardiogenic or septic shock, invasive monitoring with early goal-directed fluid therapy
- Patients who present with peritonitis can be severely hypovolemic. In these cases, volume resuscitation is critical. In patients with significant renal or hepatic dysfunction, albumin decreases mortality (1)[A],(5)[B].
- Cirrhotic patients often take  $\beta$ -blockers as part of their outpatient regimen, but during an episode of SBP,  $\beta$ -blockers increase mortality, hepatorenal syndrome, and hospital stay in SBP patients (5)[B].
- Nasogastric tube placement can prevent aspiration in patients with vomiting or GI bleeding.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

Normalization of vital signs with resolution of leukocytosis indicates improvement.

- SBP: If follow-up paracentesis is performed after 48 hours to evaluate resolution, PMN decrease >25% is expected.
- Development of leukopenia indicates immune exhaustion and poor prognosis.

#### ***DIET***

- NPO, total parental nutrition as necessary
- Resume enteral feeding after return of bowel function

- Sodium restriction can reduce future ascites (3)[A].

## PROGNOSIS

- SBP
  - For inpatients with first episode of SBP, mortality ranges from 10% to 50% (3).
  - Prognosis is improved if antibiotics are started early, prior to onset of shock or renal failure.
  - Strongest negative prognostic indicator is renal insufficiency.
  - Other poor prognostic factors include nosocomial acquisition, old age, high Child-Pugh-Turcotte or MELD score, malnutrition, malignancy, peripheral leukopenia, and antibiotic resistance (3).
  - Patients with prior SBP have 1-year recurrence rate of 40-70% and 1-year mortality of 31-93% (1,3).
- Secondary bacterial peritonitis:
  - In-hospital mortality of treated patients is 67% (4).
  - Mortality approaches 100% if not treated surgically, especially if secondary to perforation (2,4).
  - Prognosis is worse in perforated etiologies.

## COMPLICATIONS

- Renal failure, liver failure, encephalopathy, coagulopathy
- Secondary infection, iatrogenic infection, abscess, fistula formation, abdominal compartment syndrome
- Sepsis/septic shock, cardiovascular collapse, adrenal insufficiency, respiratory failure, ARDS

## See Also

&NA;

Appendicitis, Acute; Cirrhosis of the Liver; Diverticular Disease; Peptic Ulcer Disease

## Codes

&NA;

### ICD10

- K65.0 Generalized (acute) peritonitis
- K65.2 Spontaneous bacterial peritonitis
- K65.8 Other peritonitis

## Clinical Pearls

&NA;

- Maintain a high index of suspicion for SBP in cirrhotic patients with ascites. SBP occurs in preexisting ascites and carries a high mortality, especially if presenting with GI bleed.
- Early diagnosis and treatment reduces mortality.
- Paracentesis is necessary to diagnose SBP.
- Emergent CT scan should be performed if there is suspicion of secondary bacterial peritonitis.
- Distinguishing SBP from secondary bacterial peritonitis is essential, as SBP treatment consists of antibiotic therapy whereas secondary bacterial peritonitis necessitates emergent surgical intervention.
- Renal function is an important prognostic indicator for SBP. Albumin administration decreases the incidence of renal failure and mortality in patients with renal or hepatic impairment or large-volume paracentesis.

# Personality Disorders

Moshe S. Torem, MD, DLFAPA

## BASICS

### DESCRIPTION

- Personality disorders (PDs) are a group of conditions, with onset at or before adolescence, characterized by enduring patterns of maladaptive and dysfunctional behavior that deviates markedly from one's culture and social environment, leading to functional impairment and distress to the individual, coworkers, and family.
  - These behaviors are perceived by patients to be "normal" and "right," and they have little insight as to their ownership, responsibility, and abnormal nature of these behaviors.
  - These conditions are classified based on the predominant symptoms and their severity.
- System(s) affected: nervous/psychiatric
- Synonym(s): character disorder; character pathology

### *Geriatric Considerations*

Coping with the stresses of aging is challenging.

### *Pediatric Considerations*

A history of childhood neglect, abuse, and trauma is not uncommon.

### *Pregnancy Considerations*

Pregnancy adds pressures in coping with the activities of daily living (ADLs).

## EPIDEMIOLOGY

### *Prevalence*

- General population: 15% (1)
- Cluster A: 5.7%
- Cluster B: 6.0%

Cluster C: 9.1%

- Outpatient psychiatric clinic: 3-30% (2)
- In male prisoners, the prevalence of antisocial personality disorder is ÷60%.
- Predominant age: starts in adolescence and early 20s and persists throughout patient's life
- Predominant sex: male = female; some PDs are more common in females, and others are more common in males.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Environmental and genetic factors (3)
- Criteria for a PD includes an enduring pattern of the following:
  - Inner experience and behavior that deviates markedly from the expectations of one's culture in <sup>3</sup>2 of the following areas: cognition, affectivity, interpersonal functioning, or impulse control.
  - Inflexibility and pervasiveness across a broad range of personal and social situations
  - Significant distress or impairment in social or occupational functioning
  - The pattern is stable and of long duration.
  - The enduring pattern is not better explained as a manifestation of another psychiatric disorder.
  - The enduring pattern is not attributable to the effects of a drug or a medical condition.
- PDs are classified into three major clusters:
  - Cluster A: eccentricism and oddness
    - *Paranoid PD*: unwarranted suspiciousness and distrust of others
    - *Schizoid PD*: emotional, cold, or detached; socially isolated
    - *Schizotypal PD*: eccentric behavior, odd belief system/perceptions, social isolation, and general suspiciousness
  - Cluster B: dramatic, emotional, or erratic behavioral patterns
    - *Antisocial PD*: aggressive, impulsive, irritable, irresponsible, dishonest, deceitful
    - *Borderline PD*: unstable interpersonal relationships, high impulsivity from early adulthood, intense fear of abandonment, mood swings, poor self-esteem, chronic boredom, and feelings of inner emptiness
    - *Histrionic PD*: needs to be the center of attention, with self-dramatizing behaviors and

attention seeking in a variety of contexts

- *Narcissistic PD*: grandiose sense of self-importance and preoccupation with fantasies of success, power, brilliance, beauty, or ideal love; lack of empathy for other people's pain or discomfort, demanding to get their way
- Cluster C: anxiety, excessive worry, fear, and unhealthy patterns of coping with emotions
  - *Avoidant PD*: social inhibition, feelings of inadequacy, hypersensitivity to negative evaluation, avoidance of occupational and interpersonal activities that involve the risk of criticism by others, views self as socially inept and personally unappealing or inferior to others
  - *Dependent PD*: excessive need to be taken care of, leading to submissive and clinging behavior with fears of separation, avoids expressing disagreements with others due to fear of losing support and approval, usually seeks out strong and confident people as friends or spouses and feels more secure in such relationships
  - *Obsessive-compulsive PD*: preoccupation with cleanliness, orderliness, perfectionism; preoccupation with excessive details, rules, lists, order, organization, and schedules to the extent that the major point of the activity is lost.
- Personality change due to another medical condition. It is a persistent personality disturbance that is caused by the physiologic effects of a medical condition such as frontal lobe lesion, epilepsy, MS, Parkinson disease, lupus, head trauma, post encephalitis or meningitis, and so forth.
- Other specified *PD and unspecified PD*: A category provided for two situations: (i) the individual's personality pattern meets the general criteria for PD and traits of several PDs are present, but the criteria for any specific PD are not met; (ii) the individual's personality pattern meets the general criteria for PD, but the individual is considered to have a PD that is not included in *DSM-5* classification such as passive-aggressive PD, depressive PD, masochistic PD, and dangerous and severe PD.

## Genetics

Major character traits are inherited; others result from a combination of genetics and environment.

## RISK FACTORS

- Positive family history
- Pregnancy risk factors
  - Nutritional deprivation

- Use of alcohol or drugs.
- Viral and bacterial infections
- Dysfunctional family with child abuse/neglect

## COMMONLY ASSOCIATED CONDITIONS

Depression; other psychiatric disorders in patient and family members

## DIAGNOSIS

### HISTORY

- Comprehensive interview and mental status examination
- Screen to rule out alcohol and drug abuse.
- Interview of relatives and friends is helpful in establishing an enduring pattern of behavior.

## DIAGNOSTIC TESTS & INTERPRETATION

Psychological testing (e.g., MMPI-II)

### *Initial Tests (lab, imaging)*

- CBC
- Comprehensive metabolic panel
- Thyroid-stimulating hormone
- HIV
- Toxicology screen for substance abuse

### *Follow-Up Tests & Special Considerations*

- EEG to rule out a chronic seizure disorder
- CT and MRI of the brain may be necessary in newly developed symptoms to rule out organic brain disease (e.g., frontal lobe tumor).

## DIAGNOSTIC TESTS & INTERPRETATION

- Medical disorders with behavioral changes
- Other psychiatric disorders with similar symptoms

- In obsessive-compulsive disorder (OCD), symptoms are ego-dystonic (i.e., perceived as foreign and unwanted). In addition, OCD has a pattern of relapse and partial remission.
- In obsessive-compulsive personality disorder (OCPD), symptoms are perceived as desirable behaviors (ego-syntonic) that the patient feels proud of and wants others to emulate. In addition, OCPD has a lifelong pattern (i.e., without significant relapse or remission).

## TREATMENT

Psychotherapy with family involvement is the foundation of treatment. No specific drugs are indicated to treat PDs; some medications can reduce the intensity, frequency, and dysfunctional nature of certain behaviors (4)[B].

P.795

## GENERAL MEASURES

- Long-term psychotherapy and cognitive-behavioral therapy (5)[B]
- Group therapy is helpful in the use of therapeutic confrontation and increasing one's awareness of and insight regarding the damaging effects of dysfunctional behavior patterns (6) [B].

## MEDICATION

Medications are effective in the treatment of comorbid conditions such as anxiety and depression.

### *First Line*

- Symptom management (7)[B]
  - Mini psychosis (associated with paranoid, schizoid, borderline, and schizotypal PDs): atypical antipsychotics: risperidone (Risperdal), quetiapine (Seroquel), olanzapine (Zyprexa), ziprasidone (Geodon), aripiprazole (Abilify), asenapine (Saphris), lurasidone (Latuda); start with a low dose, gradually adjusting to the patient's needs.
  - Anxiety: anxiolytics (benzodiazepines, buspirone [Buspar], and serotonin reuptake inhibitors)
  - Depressed mood: antidepressants
  - Many patients with borderline PD respond well to small doses of atypical neuroleptics and mood stabilizers (8)[B].
- Precautions: Some atypical neuroleptic drugs may be associated with hyperglycemia and insulin-resistant metabolic syndrome.

## *Second Line*

Mood stabilizers: lithium carbonate, lamotrigine (Lamictal), carbamazepine (Tegretol, Equetro), and valproate (Depacon, Depakene, Depakote) (9)[B]

## **ISSUES FOR REFERRAL**

- When psychiatric comorbidity of Axis I disorders is present (e.g., mood disorders, anxiety disorders, substance abuse, etc.)
- Suicidal ideation or attempts

## **ADDITIONAL THERAPIES**

- Dialectical behavior therapy
- Psychoanalytic therapy
- Interactive psychotherapy
- Group therapy

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

Disorders with complications of suicide attempts

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Continue outpatient treatment, potentially long term

### *Patient Monitoring*

- Regular physical exercise (e.g., 30 to 45 min/day, helps with stress and improving the ADLs)
- If substance abuse is suspected, check drug screens.
- Infrequent sessions with relatives or friends are helpful in monitoring behavioral progress.

### *DIET*

Emphasize variety of healthy foods; avoid obesity.

## PATIENT EDUCATION

- Bibliotherapy and writing therapy, specific assignments, and watching certain movies to better understand the nature and origin of one's specific condition are helpful.
  - Kreger R. *The Essential Family Guide to Borderline Personality Disorder*. Center City, MN: Hazelden; 2008.
  - Mason PT, Kreger R. *Stop Walking on Eggshells*. Oakland, CA: New Harbinger Publishers; 2010.
- The movie *As Good as It Gets* illustrates someone with obsessive-compulsive behaviors and their impact on ADLs and relationships with family and friends.
- The movie series *The Godfather* includes several characters with antisocial PD and shows how this affects their interpersonal relationships and their own physical and mental health.
- The movie *What About Bob?* illustrates the challenges involved in treating certain patients with a borderline PD, especially in the management of boundaries in the doctor-patient relationship.
- The movie *A Streetcar Named Desire* illustrates an example of a woman with a histrionic PD.
- The movie *Wall Street* illustrates an example of a person with a narcissistic PD.
- The movie *The Caine Mutiny* illustrates an example of a person with a paranoid PD.
- The movie *Four Weddings and a Funeral* illustrates an example of a person with an avoidant PD.

## PROGNOSIS

PDs are enduring patterns of behavior throughout one's lifetime and are not readily responsive to treatment.

### COMPLICATIONS

- Disruptive family life with frequent divorces and separations, alcoholism, substance abuse, and drug addiction
- Disruptive behaviors in the workplace may cause absenteeism and loss of productivity.
- Violation of the law and disregard for the concerns and rights of others

## Codes

**&NA;**

### ICD10

- F60.9 Personality disorder, unspecified
- F60.0 Paranoid personality disorder
- F60.1 Schizoid personality disorder

## Clinical Pearls

**&NA;**

- PDs are enduring patterns of behavior throughout one's lifetime and are not readily responsive to treatment.
- No specific drugs are effective to treat PDs; however, specific medications can reduce the intensity, frequency, and dysfunctional nature of certain behaviors, thoughts, and feelings.
- Most patients with a PD require a well-trained and experienced mental health professional.
- A stable, trustful alliance with the patient is the foundation for any therapeutic progress.
- Showing genuine interest in the patient as a whole person including the patient's life history and current life circumstances may be helpful in establishing a therapeutic and working alliance that are necessary for continuing treatment of PD patients.

# Pertussis

Mary Cataletto, MD, FAAP, FCCP

Margaret J. McCormick, MS, RN

## BASICS

Highly contagious disease; aka whooping cough

### DESCRIPTION

- Human host: adults most common reservoir
- Can affect all ages
- Worldwide distribution
- May be endemic or epidemic with outbreaks every 3 to 5 years
- Seasonality: can occur year-round; peaks late summer-autumn
- Transmission: person to person via aerosolized respiratory droplets
- Effective vaccine available but neither vaccine nor infection confer lifelong or 100% immunity.
- System(s) affected: respiratory
- Synonym(s): whooping cough

### EPIDEMIOLOGY

#### *Incidence*

2012 was the most recent peak year with 48,277 reported cases in the United States (1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Toxin mediated
- Infectious process with predilection for ciliated respiratory epithelium
- *Bordetella pertussis* (responsible for ~95% of cases)
- *Bordetella parapertussis*

### RISK FACTORS

- Exposure to a confirmed case
- Non- or underimmunized infants and children

- Pregnancy
- Premature birth
- Chronic lung disease
- Immunodeficiency (e.g., AIDS)
- Infants <6 months of age account for ÷90% pediatric pertussis hospitalizations (2).

## GENERAL PREVENTION

- Public health measures
  - Surveillance activities
  - Prevention programs
  - Outbreak management
- Care of exposed persons
  - Household and close contacts
  - Child care workers
  - Health care workers
- Immunization
  - Vaccine products
  - Boosters
  - CDC and the Advisory Committee on Immunization Practices recommends one Tdap (tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis) vaccination to all adolescents 11 to 12 years of age and one dose of Tdap for all adults age 18 years and older to provide increased herd immunity.

### *Pediatric Considerations*

- Primary immunization series against pertussis followed by boosters
- Maternal immunization and cocooning are important strategies to help reduce neonatal pertussis (3).

### **ALERT**

Tdap vaccine recommended with each pregnancy, preferably after 20 weeks' gestation regardless of Tdap/Td history (4)

### *Geriatric Considerations*

The incidence of pertussis in individuals age 50 years and older has increased between 2006 and 2010 (5).

## COMMONLY ASSOCIATED CONDITIONS

Apnea

- Secondary bacterial pneumonia
- Sinusitis
- Seizures
- Encephalopathy
- Urinary incontinence

## DIAGNOSIS

### HISTORY

- Exposure to pertussis
- Incubation period 7 to 10 days (range 5 to 21 days)
- Classic symptoms are more common in adults and adolescents and include paroxysmal cough, posttussive whoop, and/or vomiting.
- Infants with pertussis may present with apnea or sudden death.

### PHYSICAL EXAM

- Classic pertussis has three phases, which occur over 6 to 10 weeks:
  - Catarrhal phase: rhinorrhea, mild cough, low-grade fever
  - Paroxysmal phase: Cough occurs in bursts, with increased intensity and frequency, often followed by an inspiratory whoop and/or posttussive vomiting.
  - Convalescent phase: Coughing paroxysms decrease in frequency and intensity.
- In the absence of paroxysms or complications, the physical exam may be normal.

### ALERT

Infants <6 months of age may have atypical presentations.

### DIFFERENTIAL DIAGNOSIS

- *B. parapertussis*
- *Mycoplasma pneumoniae*
- *Chlamydia trachomatis*
- *Chlamydophila pneumoniae*
- *Bordetella bronchiseptica*
- Respiratory syncytial virus
- Adenovirus

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Nasopharyngeal culture (gold standard): 100% specific and permits strain identification and antimicrobial resistance testing. Collect secretions from the back of the throat through the nose, using a Dacron or calcium alginate swab or syringe filled with saline. For best results, collect specimen during the first 2 weeks of cough—sensitivity decreases after 2 weeks (6)[C].
- Polymerase chain reaction (PCR) assays: Most commonly used because of improved sensitivity and turnaround time (6)[C].
- Specificity may vary between assays and must be interpreted within clinical context and local pertussis epidemiology. CDC “Best Practice” guidelines exist for PCR assays, although they have not yet received FDA approval. Six accurate results can be obtained during the first 3 weeks from onset of cough. Dacron swabs should be used as calcium alginate swabs are inhibitory to PCR (2,3).
- Serology: available commercially; however, there is no FDA-approved test or standardization
  - The CDC uses single point serology obtained between 2 and 8 weeks following cough onset when titers are expected to be at their peak (3).

### *Follow-Up Tests & Special Considerations*

- Evaluation and follow-up for associated conditions and complications
- Chest radiograph (2 views) to evaluate for the presence of pneumonia
- EEG/neuroimaging may be considered in infant with seizures or acute life-threatening events (ALTEs).
- Infants <1 month of age who are treated with macrolides should be monitored for the possible development of hypertrophic pyloric stenosis.

## TREATMENT

### GENERAL MEASURES

Waiting rooms, during transport and procedures: Patients with suspected pertussis should wear masks.

### MEDICATION

Pertussis illness may be less severe only if antibiotics are started early, that is, before the onset of paroxysms or during the catarrhal phase (2). Antibiotics can also help to prevent the spread of pertussis to close contacts and is necessary for stopping the spread of pertussis.

### *First Line*

- Empiric antibiotic therapy should be initiated at the time diagnostic testing is performed if sufficient

clinical suspicion for pertussis is present.

- Azithromycin is the first line of treatment for treatment and for postexposure prophylaxis (5-day course) (6)[C].
- If administered during catarrhal stage, these antibiotics may ameliorate disease.
- If administered after cough is established, antibiotics will have no individual benefit but may help to limit spread (6)[C].

### **ALERT**

Risk of infantile hypertrophic pyloric stenosis has been associated with the use of macrolides in infants <1 month of age, but are still the drugs of choice. Consultation and monitoring are recommended.

### **ALERT**

Due to reports of *fatal cardiac dysrhythmias* with azithromycin, consider alternate drugs in the elderly and in those with cardiovascular disease (7)[C].

## *Second Line*

Trimethoprim-Sulfamethoxazole (TMP-SMX) (for persons >2 months of age) if:

- They cannot tolerate macrolides.
- They are infected with a macrolide-resistant strain.

### **ALERT**

- TMP-SMX is *contraindicated* in infants <2 months of age (6)[C].
- Clarithromycin is not recommended in infants <1 month of age (6)[C].

## *ISSUES FOR REFERRAL*

Evaluation and treatment of infants <6 months of age, especially those born prematurely, who are unimmunized and those who require hospitalization.

## *ADDITIONAL THERAPIES*

Symptomatic treatment of the cough in pertussis (e.g., corticosteroids, &  $\beta_2$ -adrenergic agonists, pertussis-specific immunoglobulin, antihistamine, and leukotriene receptor antagonist) have not shown consistent benefit (4)[B].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Small, frequent meals may be necessary to ensure adequate nutrition.
- Correct fluid and electrolyte abnormalities.

- Infants may require IV fluids.

## *IV Fluids*

Indicated for dehydration and when oral fluids are either contraindicated or poorly tolerated.

## *Nursing*

- In addition to standard precautions, hospitalized patients should be isolated with respiratory precautions for 5 days after the initiation of effective antibiotic treatment and for 3 weeks after onset of paroxysms in older patients if antibiotics are not used.
- Gentle suctioning of nasal secretions
- Avoid stimuli that trigger paroxysms.
- Respiratory monitoring including pulse oximetry
- Educate each family about the importance of immunizations.
- Discuss chemoprophylaxis with each family.

## *Discharge Criteria*

- Clinically stable
- Able to tolerate oral feedings

## **ONGOING CARE**

## *Supportive*

## *FOLLOW-UP RECOMMENDATIONS*

- Monitor infants who received EES or azithromycin for pyloric stenosis.
- Neurologic and/or pulmonary follow-up as necessary

## *Patient Monitoring*

ICU care may be necessary for severely ill or compromised patients.

## *DIET*

IV fluids/nutrition may be required to treat dehydration or supplement poor oral intake.

## *PATIENT EDUCATION*

- American Academy of Pediatrics: <http://www.aap.org>
- Centers for Disease Control and Prevention: <http://www.cdc.gov>

## PROGNOSIS

- Complete recovery in most cases
- Most severe morbidity and highest mortality in infants <6 months of age

## COMPLICATIONS

- Highest and most severe in infants; may include apnea, cyanosis, and sudden death
- In children: may include conjunctival hemorrhage, inguinal hernia, pneumonia, and seizures
- More frequent in adults than adolescents: may include sinusitis, otitis media, pneumonia, weight loss, fainting, rib fracture, urinary incontinence, seizures, encephalopathy, and death

- Wang K, Bettiol S, Thompson MJ, et al. Symptomatic treatment of the cough in whooping cough. *Cochrane Database Syst Rev*. 2014;(9):CD003257.

## Codes

&NA;

### ICD10

- A37.90 Whooping cough, unspecified species without pneumonia
- A37.80 Whooping cough due to other Bordetella species w/o pneumonia
- A37.10 Whooping cough due to Bordetella parapertussis w/o pneumonia

## Clinical Pearls

&NA;

- Pertussis is a highly contagious infection.
- A high index of suspicion is needed. During the primary or catarrhal phase, the presentation may be nonspecific.
- Immunization (primary series and boosters), isolation, and early treatment of affected cases as well as chemoprophylaxis are key components to controlling the spread of pertussis.

# Pharyngitis

Bryce L. Coombs, DO

David A. Moss, MD

## BASICS

### DESCRIPTION

- Acute or chronic inflammation of the pharynx
- Most commonly caused by acute viral infection
- Group A *Streptococcus* (GAS) pharyngitis is a common clinical focus due to its potential for preventable suppurative (e.g., retropharyngeal or peritonsillar abscess) and nonsuppurative (e.g., rheumatic sequelae) complications.
- Synonym(s): sore throat; tonsillitis; Østrep throatÓ
- Generally infection mediated but can be due to caustic injury, allergies, gastroesophageal reflux disease (GERD), smoking, endotracheal intubation, or trauma-related

### EPIDEMIOLOGY

- Estimated 15 million cases diagnosed yearly
- Accounts for 1-2% of all outpatient visits and 6% of all pediatric visits to primary care physicians.
- Most commonly viral (40-60%)
- GAS is the most common bacterial cause of acute pharyngitis, accounting for 15-30% of pediatric and 5-15% of adult cases.
- Rheumatic fever is rare in the United States (incidence <1 per 100,000). Early antibiotic intervention has significantly diminished disease rates.
- All age groups, but some etiologies may predilect specific age groups
- No gender predilection

### *Pediatric Considerations*

Rheumatic fever has its greatest incidence in children aged 5 to 18 years, but is currently a rare

sequela of streptococcal pharyngitis in modern medicine.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Acute, viral (lower grade fever)
  - Rhinovirus
  - Adenovirus (associated with conjunctivitis)
  - Parainfluenza virus
  - Coxsackievirus (hand-foot-mouth disease)
  - Coronavirus
  - Echovirus
  - Herpes simplex virus (vesicular lesions)
  - Epstein-Barr virus (EBV/mononucleosis)
  - Cytomegalovirus
  - HIV
- Acute, bacterial (higher fevers)
  - Group A *β*-hemolytic streptococci
  - *Neisseria gonorrhoeae*
  - *Corynebacterium diphtheriae* (diphtheria)
  - *Haemophilus influenzae*
  - *Moraxella catarrhalis*
  - *Chlamydia pneumonia*
  - *Fusobacterium necrophorum* (20% young adult cases)
  - Group C or G streptococcus
  - *Arcanobacterium haemolyticum*
  - *Francisella tularensis* (tularemia)
- Acute, noninfectious
  - Various caustic, mechanical, or trauma-related (incl. endotracheal intubation)
- Chronic

More likely noninfectious

- Chemical irritation (GERD)
- Smoking
- Neoplasms
- Vasculitis
- Radiation changes

## *Genetics*

Patients with a positive family history of rheumatic fever have a higher risk of rheumatic sequelae following an untreated group A *β*-hemolytic streptococcal infection.

## *RISK FACTORS*

- Epidemics of group A *β*-hemolytic streptococcal disease occurrence
- Cold and flu seasons
- Age (especially children/adolescents)
- Family history of rheumatic fever
- Close contact with infectious individuals (home, daycare, military barracks)
- Immunosuppression
- Fatigue
- Smoking/second-hand smoke exposure
- Acid reflux
- Oral sex
- Diabetes mellitus
- Recent illness (secondary postviral bacterial infection)
- Chronic colonization of bacteria in tonsils/adenoids

## *GENERAL PREVENTION*

- Avoid close contact with infectious patients.
- Wash hands frequently.
- Avoid first- or second-hand smoke.
- Home humidifier at home

- Manage preventable causes (e.g., GERD).

## DIAGNOSIS

### HISTORY

- Sore throat
- Difficulty swallowing (odynophagia)
- Cough (though rarely associated with GAS pharyngitis)
- Hoarseness
- Fever
- Anorexia
- Chills
- Malaise
- Contacts with similar symptoms or diagnosed infection

### PHYSICAL EXAM

- Enlarged tonsils (tonsillar exudate or possible peritonsillar abscess/deep neck space infection)
- Pharyngeal erythema
- Cervical adenopathy
- Fever (higher in bacterial infections)
- Pharyngeal ulcers (CMV, HIV, Crohn, other autoimmune vasculitides)
- Scarlet fever rash: punctate erythematous macules with reddened flexor creases and circumoral pallor suggests streptococcal pharyngitis
- Tonsillar/soft palate petechiae suggests infectious mononucleosis (EBV/CMV).
- Gray oral pseudomembrane suggests diphtheria and occasionally infectious mononucleosis (EBV/CMV).
- Characteristic erythematous-based clear vesicles suggests HSV.
- Conjunctivitis suggests adenovirus.

### DIFFERENTIAL DIAGNOSIS

- Viral syndrome
- Streptococcal infection

- Allergic rhinitis/postnasal drip
- GERD
- Malignancy (lymphoma or squamous cell carcinoma)
- Irritants/chemicals (detergent/caustic ingestion)
- Atypical bacterial (e.g., gonococcal, chlamydial, syphilis, pertussis, diphtheria)
- Oral candidiasis (patients typically complain mostly of dysphagia)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Acute pharyngitis evaluation includes Prediction Rule Use to determine further testing (see below)
- Additional testing generally not needed if viral-like clinical features (e.g., cough, rhinorrhea, hoarseness, oral ulcers, diarrhea, conjunctivitis, rash) (1)[A].
- Avoid testing for GAS pharyngitis in children <3 years old as acute rheumatic flare is rare, unless there is a close sick contact who is GAS-positive (1)[B].
- Modified Centor clinical prediction rule for group A streptococcal infection (2)[A]:
  - +1 point: tonsillar exudates
  - +1 point: tender anterior chain cervical adenopathy
  - +1 point: absence of cough
  - +1 point: fever by history
  - +1 point: age <15 years
  - 0 point: age 15 to 45 years
  - -1 point: age >45 years
- Scoring:
  - If 4 points, positive predictive value of ÷80%; treat empirically.
  - If 2 to 3 points, positive predictive value of ÷50%, rapid strep antigen; treat if GAS-positive.
  - If 0 or 1 point, positive predictive value <20%; do not test; treat empirically with follow-up as needed.

### *Initial Tests (lab, imaging)*

- Testing, if performed, is usually for the presence of group A *&bgr;-*hemolytic streptococci.

Options include the following:

- Rapid strep antigen test from throat swab with agglutination or molecular kits; provides quicker, more practical alternative to throat culture with 96% specificity and 86% sensitivity (though sensitivity varies by modality kit) (3)[A].
- Blood agar throat culture from swab. Gold standard of diagnosis (3)[A]
- Antistreptolysin-O (carrier state suspected if positive culture, and unchanged ASO titers)
- Special tests usually done only if history is suggestive of a different diagnosis.
  - Warm Thayer-Martin plate or antigen testing for *Neisseria gonorrhoeae*
  - Viral cultures for HSV and so forth, though expensive and often not indicated.
  - Monospot for EBV

## Test Interpretation

Bacitracin disk sensitivity of hemolytic colonies suggests group A *β*-hemolytic streptococcus.

## TREATMENT

### GENERAL MEASURES

Conservative therapy recommended for most cases, (unless bacterial etiology suspected):

- Salt water gargles
- Viscous lidocaine (2%) 5 to 10 mL PO q4h swish/spit
- Acetaminophen 10 to 15 mg/kg/dose q4h PRN pain or fever (pediatric). In adults, do not exceed >3 g per day.

---

P.799

- NSAIDs for pain or fever
- Anesthetic lozenges
- Cool-mist humidifier
- Hydration (PO or IV)

### Pediatric Considerations

Opioids not recommended due to black box warnings.

## MEDICATION

- Antibiotics (particularly penicillin) are chosen primarily to prevent rheumatic fever and peritonsillar abscess (quinsy) in streptococcal infections, though supportive data lacking.
  - 60-70% primary care visits by children with pharyngitis result in antibiotic prescriptions (4). Empiric therapy results in overuse of antibiotic.
  - Treatment duration generally 10 days (1)[A]
  - Antibiotics do not reduce risk of poststreptococcal glomerulonephritis.
  - Antibiotics shorten duration of symptoms by approximately 16 hours (5)
  - Antibiotics may prevent pharyngitis/fever by day 3 (NNT 4 if GAS-positive, 6.5 if GAS-negative, 14.4 if untested) (5)[A].
- Ulcers related to autoimmune diseases usually require systemic or intralesional injectable steroids.
- HIV-related ulcers are due to decreasing counts of CD4 and respond when patients' CD4 titers increase.

### First Line

The following first-line therapies are recommended by 2012 IDSA guidelines (1)[A]:

- Penicillin V: children (<27 kg): 250 mg PO TID (BID dosing sufficient if good compliance); adolescents and adults (>27 kg): 250 mg PO QID or 500 mg PO BID
- Amoxicillin: 50 mg/kg PO once daily (max 1,000 mg/dose or 25 mg/kg PO BID (max = 500 mg/dose)).

### **ALERT**

Use with caution if diagnosis is unclear because using amoxicillin with EBV infection may induce rash.

- Penicillin G: children (<27 kg): 600,000 units IM injection times one dose; adolescents/adults (≥27 kg): 1.2 million units IM injection times one dose.

### Second Line

- If no history of anaphylactic penicillin allergy:
  - Cephalexin 20 mg/kg PO BID or (children) 25 to 50 mg/kg/day divided BID or (adults) 1000 mg PO QID (max = 4 g/day)
  - Cefadroxil 30 mg/kg PO once daily (max = 1 g/day)

- If history of anaphylactic penicillin allergy:
  - Azithromycin 12 mg/kg PO once daily for 5 days (max = 500 mg/dose)
  - Clarithromycin 7.5 mg/kg PO BID (max = 250 mg/dose) or (adults) 250 to 500 mg PO BID
  - Clindamycin 7 mg/kg PO TID (max = 300 mg/dose) or (children) 10 to 30 mg/kg/day PO divided TID-QID or (adults) 150 to 450 mg PO TID-QID
- Penicillin is the most documented treatment to prevent rheumatic sequelae, but cephalosporins have a lower rate of antimicrobial failure against streptococcal pharyngitis.
- Newer macrolides, though effective against streptococcal pharyngitis, are more expensive and unproven at preventing rheumatic complications.
- Macrolide-resistant strains of GAS are currently <10% in the United States but more prevalent worldwide.
- IDSA recommends against adjunctive corticosteroid therapy (1)[B].

## *ISSUES FOR REFERRAL*

Each GAS-confirmed episode should be documented to support the need for future tonsillectomy and adenoidectomy.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Patient should complete a full course of antibiotic therapy, regardless of symptom response.
- Patients are generally noninfectious after 24 hours of antibiotics.
- Follow-up culture for group A strep is not recommended (1)[A].

### *DIET*

As tolerated. Encourage the consumption of fluids.

### *PROGNOSIS*

- Streptococcal pharyngitis runs a 5- to 7-day course with peak fever at 2 to 3 days.
- Symptoms will resolve spontaneously without treatment, but rheumatic complications are still possible.

## **COMPLICATIONS**

- Rheumatic fever (e.g., carditis, valve disease, arthritis)
- Poststreptococcal glomerulonephritis
- Peritonsillar abscess (a.k.a. quinsy tonsillitis): considered a clinical diagnosis and does not warrant ultrasound/computed tomography. Will generally require percutaneous/transoral drainage. Surgery may also involve a quinsy tonsillectomy, which is merely a tonsillectomy in the setting of acute infection. This is generally not advocated unless for special circumstances, as most otolaryngologists recommend infectious resolution before surgery.
- Acute airway compromise (rare) can typically be bypassed with nasal trumpets. Consult anesthesiologist/otolaryngologist.
- Repeated episodes of GAS pharyngitis may represent recurrent viral infections in a chronic pharyngeal GAS carrier (1)[B]. IDSA recommends against repeated diagnostic efforts/antibiotic therapy in a known chronic pharyngeal GAS carrier, as they are seldom contagious or at risk for serious complications.
- Evidence remains controversial for tonsillectomy as a treatment for chronic/recurrent throat infections. IDSA recommends against it (1)[A] while the American Academy of Otolaryngology proposes tonsillectomy only if there is also one of the following: fever, cervical adenopathy, tonsillar exudate, or confirmed GAS (6)[C]

## Codes

&NA;

### ICD10

- J02.9 Acute pharyngitis, unspecified
- J02.0 Streptococcal pharyngitis
- J31.2 Chronic pharyngitis

## Clinical Pearls

&NA;

- Most cases of pharyngitis are viral and do not require antibiotics.
- Risk of undiagnosed group A streptococcal infection is rheumatic sequelaeÑa rare complication.

- Use Modified Centor Score to guide testing and treatment.
- Penicillin is still first-line therapy for group A streptococcal infection.

# Pilonidal Disease

Tam Nguyen, MD, FAAFP

## BASICS

### DESCRIPTION

- Pilonidal disease results from an abscess, or sinus tract, in the upper part of the natal (gluteal) cleft.
- Synonym(s): jeep disease

### EPIDEMIOLOGY

#### Incidence

- 16 to 26/100,000 per year
- Predominant sex: male > female (3 to 4:1)
- Predominant age: 2nd to 3rd decades, rare >45 years
- Ethnic consideration: whites > blacks > Asians

#### Prevalence

Surgical procedures show male:female ratio of 4:1, yet incidence data are 10:1.

### ETIOLOGY AND PATHOPHYSIOLOGY

Pilonidal means "nest of hair"; hair in the natal cleft allows hair to be drawn into the deeper tissues via negative pressure caused by movement of the buttocks (50%); follicular occlusion from stretching, and blocking of pores with debris (50%).

- Inflammation of SC gluteal tissues with secondary infection and sinus tract formation
- Polymicrobial, likely from enteric pathogens given proximity to anorectal contamination

#### Genetics

- Congenital dimple in the natal cleft/spina bifida occulta
- Follicular-occluding tetrad: acne conglobata, dissecting cellulitis, hidradenitis suppurativa,

pilonidal

## **RISK FACTORS**

- Sedentary/prolonged sitting
- Excessive body hair
- Obesity/increased sacrococcygeal fold thickness
- Congenital natal dimple
- Trauma to coccyx

## **GENERAL PREVENTION**

- Weight loss
- Trim hair in/around gluteal cleft weekly
- Hygiene
- Ingrown hair prevention/follicle unblocking

## **DIAGNOSIS**

### **HISTORY**

Three distinct clinical presentations

- Asymptomatic: painless cyst or sinus at the top of the gluteal cleft
- Acute abscess: severe pain, swelling, discharge from the top of the gluteal cleft that may or may not have drained spontaneously
- Chronic abscess: persistent drainage from a sinus tract at the top of the gluteal cleft

### **PHYSICAL EXAM**

- Common: inflamed cystic mass at the top of the gluteal cleft with limited surrounding erythema ± drainage or a sinus tract
- Less common: significant cellulitis of the surrounding tissues near the gluteal cleft

### **DIFFERENTIAL DIAGNOSIS**

- Furunculosis
- Hidradenitis suppurativa

- Anal fistula
- Perirectal abscess
- Crohn disease

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Consider CBC and wound culture but generally not necessary for less-severe infections.
- MRI might be considered to differentiate between perirectal abscess and pilonidal disease.

## **TREATMENT**

### *GENERAL MEASURES*

Shave area; remove hair from crypts weekly.

### *MEDICATION*

- Antibiotics not indicated unless there is significant cellulitis (1).
- If antibiotics are needed, a culture to direct therapy might be useful.
- Cefazolin plus metronidazole or amoxicillin-clavulanate are often used empirically if cellulitis is suspected.

### *ISSUES FOR REFERRAL*

- Patients who cannot comply with frequent dressing changes required after incision and drainage (I&D)
- Patients who have recurrence after I&D
- Patients who have complex disease with multiple sinus tracts

### *ADDITIONAL THERAPIES*

- I&D with only enough packing to allow the cyst to drain; overpacking not indicated
- Antibiotics only if significant cellulitis; temporizing, not curative
- Negative pressure wound therapy (2)[A]
- Laser epilation of hair in the gluteal fold (3,4)[B]

## ***SURGERY/OTHER PROCEDURES***

Six levels of care based on severity or recurrence of disease; recent innovations in technique are aimed at expediting healing and minimizing recurrence

- I&D, remove hair, curette granulation tissue (5,6)[A].
- Excision of midline ÒpitsÓ allows drainage of lateral sinus tracts (pit picking) (7,8)[A].
- Pilonidal cystotomy: Insert probe into sinus tract, excise overlying skin, and close wound (7,9) [B].
- Marsupialization: Excise overlying skin and roof of cyst, and suture skin edges to cyst floor (5,10)[B].
- Excision: use of flap closure. No clear benefit for open healing over surgical closure (11)[B]
- Off-midline surgical excision (cleft lift or modified Karydakis procedure): A systematic review showed a clear benefit in favor of off-midline rather than midline wound closure. When closure of pilonidal sinuses is the desired surgical option, off-midline closure should be the standard management (5,7,12)[A].

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Severe cellulitis
- Large area excision

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Frequent dressing changes required after I&D
- Follow-up wound checks to assess for recurrence.

### ***Patient Monitoring***

Monitor for fever, more extensive cellulitis.

## ***PATIENT EDUCATION***

- Wash area briskly with washcloth daily.

- Shave the area weekly.
- Remove any embedded hair from the crypt.
- Avoid prolonged sitting.

## PROGNOSIS

- Simple I&D has a 55% failure rate; median time to healing is 5 weeks.
- More extensive surgical excisions involve hospital stays and longer time to heal.

## COMPLICATIONS

Malignant degeneration is a rare complication of untreated chronic pilonidal disease.

## Codes

&NA;

## ICD10

- L05.91 Pilonidal cyst without abscess
- L05.92 Pilonidal sinus without abscess
- L05.01 Pilonidal cyst with abscess

## Clinical Pearls

**&NA;**

- Avoid prolonged sitting.
- Lose weight.
- Trim hair in gluteal cleft weekly.
- Refer recurring infections for more definitive surgical management.

# Pinworms

Jonathan MacClements, MD, FAAFP

## BASICS

### DESCRIPTION

- Intestinal infection with *Enterobius vermicularis*
  - Characterized by perineal and perianal itching
  - Usually worse at night
- System(s) affected: gastrointestinal; skin/exocrine
- Synonym(s): enterobiasis

### EPIDEMIOLOGY

Predominant age: 5 to 14 years

### Prevalence

- Most common helminthic infection in the United States
  - 20 to 42 million people harbor the parasite
- ÷30% of children are infected worldwide.

### Pediatric Considerations

More common in children, who are more likely to become reinfected.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Small white worms (2 to 13 mm) inhabit the cecum, appendix, and adjacent portions of the ascending colon following ingestion.
- Female worms migrate to the perineal areas at night to deposit eggs; this causes local irritation and itching.
- Scratching leads to autoingestion of the eggs and continuation of pinworm's life cycle within the host. Eggs incubate 1 to 2 months in the host small intestine. When mature, female

pinworms migrate to the colon where they lay eggs around the anus at night and the lifecycle continues.

- Infestation by the intestinal nematode *E. vermicularis*

## **RISK FACTORS**

- Institutionalization
- Crowded living conditions
- Poor hygiene
- Warm climate
- Handling of infected children's clothing or bedding

## **GENERAL PREVENTION**

- Hand hygiene, especially after bowel movements
- Clip and maintain short fingernails.
- Wash anus and genitals at least once a day, preferably during shower.
- Avoid scratching anus and putting fingers near nose (pinworm eggs can also be inhaled) or mouth.

## **COMMONLY ASSOCIATED CONDITIONS**

Pruritus ani

## **DIAGNOSIS**

### **HISTORY**

Many patients are asymptomatic. Common symptoms include the following:

- Perianal or perineal itching
- Vulvovaginitis
- Dysuria
- Abdominal pain (rare)
- Insomnia (typically due to pruritus)

## **PHYSICAL EXAM**

Perineal and perianal exam. Particularly in early morning to look for evidence of migrating worms.

## ***DIFFERENTIAL DIAGNOSIS***

- Idiopathic pruritus ani (1)[A]
- Atopic dermatitis, contact dermatitis
- Psoriasis; lichen planus
- Human papillomavirus (HPV)
- Herpes simplex virus (HSV)
- Fungal infections; erythrasma
- Scabies
- Vaginitis; hemorrhoids

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Adhesive tape test (2)[A]
  - Place cellophane tape on the perianal skin in the early morning before bathing and affixed to a microscope slide to look for pinworm eggs.
  - If performed on three consecutive mornings, this test has 90% sensitivity
  - Alternatively, anal swabs or a pinworm paddle coated with adhesive material can be useful.
  - Scrapings from under fingernails of affected individuals can reveal pinworm eggs.
- Digital rectal exam with saline slide preparation of stool on gloved finger
- Stool samples are not helpful.
- *Routine stool examination for ova and parasites is positive in only 10-15% of infected patients.*

### ***Test Interpretation***

Identification of ova on low-power microscopy or direct visualization of the female worm (10-mm long); ova are asymmetric, flat on one side, and measure  $56 \times 27 \text{ }\mu\text{m}$ .

## **TREATMENT**

### ***MEDICATION***

#### ***First Line***

- Treatment options include:

- Mebendazole (Vermox): chewable 100-mg tablet as a single dose in adults and children >2 years of age; may repeat in 2 to 3 weeks; use with caution in children <2 years of age (3,4) [A].
- Albendazole (Albenza): 400 mg PO as a single dose in adults and children >2 years of age; may repeat in 2 to 3 weeks; 200 mg PO as a single dose repeated in 7 days in children ≥2 years of age (3,4)[A].

P.803

- Pyrantel pamoate (Pin-X, Reese's Pinworm Medicine): oral liquid or tablet 11 mg/kg as a single dose in adults and children >2 years of age; maximum dose 1 g. Use with caution in children <2 years of age (3,4)[A].
- Repeat treatment after 2 weeks is often recommended due to the high frequency of reinfection. Refractory cases may (rarely) require retreatment every 2 weeks for 4 to 6 cycles.
- All symptomatic family members should be treated.

### *Pregnancy Considerations*

Avoid drug therapy in pregnancy. Treat after delivery. Breastfeeding is OK during mebendazole therapy (3,4)[A].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Unnecessary unless symptoms recur after initial therapy

### *PATIENT EDUCATION*

- Take medicine with food.
- Practice good hygiene: hand washing and perianal hygiene; particularly after bowel movements
- Encourage frequent and careful hand washing.
- Clip fingernails.
- Wash clothing and bedding after diagnosis to prevent reinfection. Do not shake linen and clothing before laundering because this may spread the eggs.
- Do not share washcloths.
- Do not allow children to bathe during treatment and for 2 weeks after; showering is

preferred.

## PROGNOSIS

- Asymptomatic carriers are common.
- Drug therapy is 90% curative.
- Reinfection is common, especially among children.

## COMPLICATIONS

- Perianal scratching may lead to bacterial superinfection.
- Females: vulvovaginitis, urethritis, endometritis, and salpingitis (4,5)[A]
- UTIs
- Rarely, ectopic disease with granulomas of the pelvis, genitourinary tract, and appendix

## See Also

&NA;

Pruritus Ani

## Codes

&NA;

### ICD10

B80 Enterobiasis

## Clinical Pearls

&NA;

- Nocturnal or early morning perianal itch with restless sleep or insomnia (particularly in children), is hallmark of symptomatic pinworm infection.
- Treatment includes of mebendazole, albendazole, or pyrantel pamoate.
- Treat close contacts.
- Retreatment after 2 weeks is typically recommended.

# Pituitary Adenoma

Anup K. Sabharwal, MD, MBA, FACE, CCD

Lewis S. Blevins Jr., MD

## BASICS

### DESCRIPTION

Typically benign, slow-growing tumors that arise from cells in the pituitary gland

- Pituitary adenomas have been identified as the third most frequent intracranial tumor; accounts for 10-25%.
- Subtypes (hormonal): prolactinoma (PRL) 50%, nonfunctioning pituitary adenomas 30%, somatotroph adenoma (growth hormone [GH]) 15-20%, corticotroph adenoma (adrenocorticotrophic hormone [ACTH]) 5-10%, thyrotroph adenoma (thyroid-stimulating hormone [TSH]) <1%, gonadotropinoma (luteinizing hormone/follicle-stimulating hormone [LH/FSH]), mixed
- Defined as microadenoma <10 mm and macroadenoma  $\geq$ 10 mm
- May secrete hormones and/or cause mass effects

### EPIDEMIOLOGY

- Predominant age: Age increases incidence.
- Predominant sex: female > male (3:2) for microadenomas (often delayed diagnosis in men)

### Incidence

- Autopsy studies have found microadenomas in 3-27% and macroadenomas in <0.5% of people without any pituitary disorders.
- MRI scans illustrate abnormalities consistent with pituitary adenoma in 1/10 persons.
- Clinically apparent pituitary tumors are seen in 18/100,000 persons.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Monoclonal adenohypophysial cell growth
- Hormonal effects of functional microadenomas often prompt diagnosis before mass effect.

- Prolactin increased by functional prolactinomas or inhibited dopaminergic suppression by stalk effect

## Genetics

- Carney complex
- Familial isolated pituitary adenomas: ÷15% have mutations in the aryl hydrocarbon receptor-interacting protein gene (*AIP*); present at a younger age and are larger in size (1)
- McCune-Albright syndrome
- Multiple endocrine neoplasia type 1 (*MEN1*)-like phenotype (*MEN4*): germline mutation in the cyclindependent kinase inhibitor 1B (*CDKN1B*) (1)

## RISK FACTORS

Multiple endocrine neoplasias

## DIAGNOSIS

### HISTORY

- Common
  - Hyperprolactinemia: infertility, amenorrhea, galactorrhea, gynecomastia, impotence
  - Headache (sellar expansion)
  - Visual disturbances: bitemporal hemianopsia
- Less common
  - Hypersomatotropinemia: acromegaly (coarse facial features, hand/foot swelling, carpal tunnel syndrome, hyperhidrosis, left ventricular hypertrophy)
  - Hyposomatotropinemia: failure to thrive (FTT) (children), asymptomatic (adults)
  - Intracranial pressure (ICP) elevation: headache, nausea, seizures
  - Hypercorticotropinemia: Cushing disease (supraclavicular/dorsocervical fat pad thickening, moon face, hirsutism, acne, plethora, abdominal striae, centripetal obesity with thin limbs, easy bruising and bleeding, hyperglycemia)
- Rare

- Apoplexy: headache, sudden collapse
- Secondary hyperthyroidism: palpitations, diaphoresis, heat intolerance, diarrhea
- Secondary adrenal insufficiency: weakness, irritability, anorexia, nausea/vomiting
- Hypothalamic compression: temperature, thirst/appetite disorders

## *PHYSICAL EXAM*

- Common
  - Visual disturbances: bitemporal hemianopsia
  - Hyperprolactinemia: hypogonadism, galactorrhea, gynecomastia
  - Hypersomatotropinemia: acromegaly (coarse features, hand/foot swelling, diaphoresis)
  - Hyposomatotropinemia: FTT (children)
- Less common
  - ICP elevation: papilledema, dementia
  - Cushing disease: centripetal obesity, supraclavicular fat pad thickening, moon face, hirsutism, acne
- Rare
  - Apoplexy: hypotension, hypoglycemia, tachycardia, oliguria
  - Secondary hyperthyroidism: tachycardia, tachypnea, diaphoresis, warm/moist skin, tremor
  - Adrenal crisis: orthostatic hypotension
- Hypothalamic compression: temperature dysregulation, obesity, increased urination

## *DIFFERENTIAL DIAGNOSIS*

Pituitary hyperplasia (e.g., pregnancy, primary hypothyroidism, menopause), Rathke cleft cyst, granulomatous disease (e.g., tuberculosis), lymphocytic hypophysitis, metastatic tumor, germinoma, craniopharyngioma

## *DIAGNOSTIC TESTS & INTERPRETATION*

Select based on dysfunction(s) suspected

- Somatotrophic (GH secreting: 40 to 130/million)

- Acromegaly/hypersomatotropinemia: serum IGF-1 elevated; oral glucose tolerance test with GH given at 0, 30, and 60 minutes (normally suppresses GH to <1 g/L)
- Hyposomatotropinemia: low growth hormone-releasing hormone response
- Corticotropic
  - Cushing disease/hypercorticotropinemia
  - 24-hour urinary-free cortisol >50  $\mu\text{g}/\text{g}$
  - Overnight low-dose dexamethasone suppression test (DMST): normal free plasma cortisol (FPC) >1.8  $\mu\text{g}/\text{dL}$  at 8 AM (after 1 mg given at 11 PM on night prior)
  - ACTH level assay (if DMST results abnormal): <20 pg/mL = adrenal tumor;  $\geq 20$  pg/mL = ectopic/pituitary source
  - Hypocorticotropinemia/secondary glucocorticoid deficiency: high-dose corticotropin stimulation test: FPC <10  $\mu\text{g}/\text{dL}$  at baseline, with an increase of <25% 1 hour after 250  $\mu\text{g}/\text{g}$ ; metyrapone test: 11-deoxycortisol <150 ng/L after 2 g given (prepare to give steroids because test may worsen insufficiency)
- Gonadotrophic/hypogonadotropinism: gonadotropin-releasing hormone stimulation of LH/FSH blunted in pituitary hypergonadism but increased in primary hypogonadism
- Lactotrophic (prolactin secreting): hyperprolactinemia: serum PRL >20 ng/mL
- Thyrotrophic (TSH secreting): hyper-/hypothyroidism: TSH and free  $T_4$  both increased for pituitary hyperthyroidism and both decreased for pituitary hypothyroidism

### *Initial Tests (lab, imaging)*

- A typical panel for asymptomatic tumors: prolactin, GH, IGF-1, ACTH, 24-hour urinary-free cortisol or overnight DMST,  $\beta$ -HCG, FSH, LH, TSH, free  $T_4$
- Maintain the same GH and IGF-1 through patient management (2)[C].
- Screening for *AIP* mutations may be offered to families of patients with pituitary adenoma, where available.
- MRI preferred (>90% sensitivity and specificity) after biochemically confirmed
- Octreotide scintigraphy is useful in identifying tumors with somatostatin receptors (2)[B].

### *Diagnostic Procedures/Other*

Inferior petrosal sinus sampling: ACTH sampled from inferior petrosal sinuses to distinguish Cushing disease (pituitary source) from ectopic ACTH

## Test Interpretation

- Cell types identified by immunohistochemistry
- Light microscope: eosinophilic (GH, PRL), basophilic (FSH/LH, TSH, ACTH), chromophobic

## TREATMENT

Medical therapy is primary therapy for prolactinomas and adjunct for other tumors.

## MEDICATION

### First Line

- Hyperprolactinemia: Dopamine agonists increase dopaminergic suppression of PRL.
  - Cabergoline (Dostinex): D<sub>2</sub> receptor-specific
    - Initial dose: 0.25 mg PO once or twice weekly
    - Maintenance dose: Increase q4wk by 0.25 mg 2 times/week per PRL (max 2 mg/week).
    - Contraindications: hypersensitivity (ergots), uncontrolled hypertension (HTN), pregnancy
    - Precautions: caution with liver impairment
    - Interactions: may be inhibited by tricyclic antidepressants, phenothiazines, opiates
    - Adverse reactions: orthostatic hypotension, vertigo, dyspepsia, hot flashes
  - Bromocriptine (Parlodel): D<sub>2</sub> receptor-specific
    - Initial dose: 1.25 to 2.5 mg PO daily (give with food)
    - Maintenance dose: increase by 2.5 mg/day q2-7d (max 15 mg/day)
    - Contraindications: hypersensitivity (ergots), uncontrolled HTN, pregnancy; preferred over cabergoline if required
    - Precautions: caution with liver impairment
    - Interactions: may be inhibited by tricyclic antidepressants, phenothiazines, opiates
    - Adverse reactions: orthostatic hypotension, seizures, hallucinations, stroke, myocardial infarction
- Somatotropinoma
  - Long-acting analogues of somatostatin (Sandostatin LAR and lanreotide Autogel)

- Sandostatin LAR: 20 mg q28d (2)[A]; lanreotide Autogel 90 mg q28d; titrate per package insert.

- Contraindication: hypersensitivity

P.805

- Precautions: caution with biliary, thyroid, cardiac, liver, or kidney disease
- Interactions: pimozide increases risk of QT prolongation; variable effects with *&bgr*;-blockers, diuretics, oral glyceic agents
- Adverse reactions: ascending cholangitis, arrhythmias, congestive heart failure, glyceic instability
- More effective as adjuvant than as primary treatment for somatotropinomas
- Consider use of somatostatin analogue or pegvisomant in patients with severe residual disease (2)[A].
- Consider use of cabergoline in patients with mild residual disease (3)[B].

- Pegvisomant (Somavert): GH receptor antagonist

- Initial dose: 40 mg SC × 1, then 10 mg daily and titrate by 5 mg every 4 to 6 weeks based on IGF-1 levels (max 30 mg/day maintenance dose)
- Contraindication: hypersensitivity
- Precautions: caution if GH-secreting tumors, diabetes mellitus, impaired liver function
- Interactions: NSAIDs, opiates, insulins, oral glyceic agents
- Adverse reactions: hepatitis, tumor growth, GH secretion

- Corticotropinemia: peripheral inhibitors

- Mitotane (Lysodren)

- Initial dose: 2 to 6 g/day divided PO TID (max 19 g/day)
- Maintenance dose: 2 to 16 g TID
- Contraindication: hypersensitivity
- Precautions: caution with liver dysfunction and brain damage
- Interactions: contraindicated with rotavirus vaccine; caution with other vaccines
- Adverse reactions: HTN, orthostatic hypotension, hemorrhagic cystitis, rash

- Ketoconazole

- Dosing: 200 mg PO TID (max 1,200 mg/day)

- Contraindications: hypersensitivity, achlorhydria, fungal meningitis, impaired liver function
- Precautions: caution with liver dysfunction
- Interactions: contraindicated with dronedarone, methadone, statins, pimozide, sirolimus; caution with other antifungals
- Adverse reactions: adrenal insufficiency, thrombocytopenia, hepatic failure, hepatotoxicity, anaphylaxis, leukopenia, hemolytic anemia
- Signifor (pasireotide)
  - Dosing: initially, 0.6 to 0.9 mg twice daily, then 0.3 to 0.9 mg twice daily
  - Contraindication: none
  - Precautions: hypocortisolism, hyperglycemia, bradycardia or QT prolongation, liver test elevations, cholelithiasis, and other pituitary hormone deficiencies
- Korlym (mifepristone):
  - Dosing: Administer PO once daily with a meal. The recommended starting dose is 300 mg once daily. Not to exceed 600 mg daily in renal impairment
- Contraindication: pregnancy, use of simvastatin or lovastatin and CYP3A substrates with narrow therapeutic range, concurrent long-term corticosteroid use, women with history of unexplained vaginal bleeding, women with endometrial hyperplasia with atypia or endometrial carcinoma
- Precautions: adrenal insufficiency, hypokalemia, vaginal bleeding and endometrial changes, QT interval prolongation, use of strong CYP3A inhibitors
- Interactions: potential interactions with drugs metabolized by CYP3A, CYP2C8/9, CYP2B6, and hormonal contraceptives. Nursing mothers should discontinue drug or discontinue nursing.
- Adverse reactions: most common adverse reactions in Cushing syndrome (<sup>3</sup>20%): nausea, fatigue, headache, decreased blood potassium, arthralgia, vomiting, peripheral edema, HTN, dizziness, decreased appetite, endometrial hypertrophy
- Gonadotropinemia
  - Bromocriptine: See earlier discussion.
- Thyrotropinemia
  - Somatostatin analogues: See earlier discussion.

## *Second Line*

- Corticotropinemia: peripheral inhibitors
  - Metyrapone
    - Dose: 250 mg PO QID
    - Contraindication: porphyria
    - Precautions: caution in liver/thyroid disease
    - Interactions: Dilantin increases metabolism.
    - Adverse reactions: nausea, hypotension
- Gonadotropinemia
  - Octreotide: See earlier discussion.

## *ISSUES FOR REFERRAL*

- Neurosurgery consultation for symptomatic tumors (except for prolactinoma)
- Ophthalmologist evaluation prior to surgery

## *ADDITIONAL THERAPIES*

- Fractionated radiotherapy: often effective as adjunctive when surgery is inadequate (3)[B]
- Stereotactic radiosurgery: alternative to surgery in high-risk patients or as adjunct (3)[B]

## *SURGERY/OTHER PROCEDURES*

- Most are now done endoscopically via translabial/transsphenoidal approach (4)[A].
- Indications: symptoms or treatment-resistant
- Follow-up: serial neurologic/hormonal evaluations to evaluate complications (e.g., diabetes insipidus, CNS damage) and need for more treatment
- Remission rates: 72-87% for microadenoma but only 50-56% for macroadenomas

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Outpatient management unless apoplexy or adrenal crisis

Treat pituitary apoplexy immediately to prevent death (see *Complications*) (4)[A].

- Consider stress-dose steroids in frail or hemodynamically unstable patients.
- Maintain BP with fluids and/or pressor agents.
- Check serum sodium, serum osmolality, and urine specific gravity if polyuric or electrolytes are imbalanced.
- Contact neurosurgery.

### *IV Fluids*

- Diabetes insipidus: hyposmolar IV fluids
- Adrenal crisis: normal saline

### *Nursing*

- Pituitary apoplexy: Monitor inputs/outputs (I/Os), central venous pressure and ICP, and do frequent neurologic checks.
- Adrenal crisis: Monitor BP and I/Os.

### *Discharge Criteria*

Keep as inpatient postoperatively until diabetes insipidus and/or adrenal insufficiency is managed.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Follow-up MRIs at 6 and 12 months after discharge
- Involved hormone(s) are followed postoperatively, especially after radiation because hypopituitarism may develop 10 to 15 years after treatment.

### *PROGNOSIS*

Depends on type, size, symptoms, therapy

### *COMPLICATIONS*

- Postoperative diabetes insipidus and/or hypogonadism (usually transient/common)

Pituitary apoplexy (acute/uncommon): acute hemorrhagic pituitary infarction; adrenal crisis with severe headache; surgical decompression required to prevent shock, coma, and death

- Nelson syndrome (subacute/uncommon): rapid adenoma growth postadrenalectomy
- Pituitary hormone insufficiency (chronic/uncommon): often years after treatment
- Optic nerve neuropathy and brain necrosis after >60 Gy radiotherapy (chronic/rare)

## Codes

&NA;

## ICD10

D35.2 Benign neoplasm of pituitary gland

## Clinical Pearls

&NA;

An incidentaloma is an asymptomatic microadenoma found on imaging. General labs include PRL, GH, IGF-1, ACTH, 24-hour urinary-free cortisol/overnight DMST,  $\alpha$ -subunit FSH, LH, TSH, and free T<sub>4</sub>. Obtain follow-up MRIs at 6 and 12 months if normal, but consult endocrinology if not.

- Initial treatment selected for symptomatic pituitary adenoma includes a dopamine agonist for prolactinomas and surgical resection for all others.
- Pituitary apoplexy is a rapid hemorrhagic pituitary infarction due to compression of the blood supply. It is fatal within hours unless surgically decompressed.

# Plantar Fasciitis

Alan J. Williamson, MD, Lr Col, USAF, MC

Amber C. Taylor, MD

## BASICS

### DESCRIPTION

- Degenerative change of plantar fascia at origin on medial tuberosity of calcaneus
- Pain on plantar surface, usually at calcaneal insertion of plantar fascia upon weight bearing, especially in morning or on initiation of walking after prolonged rest

### EPIDEMIOLOGY

#### Prevalence

- Lifetime: 10-15% of population
- Data suggest persistence with BMI >30.
- Condition is typically self-limiting, resolving within 10 months.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Repetitive microtrauma and collagen degeneration of plantar fascia
- Chronic degenerative change (-osis/-opathy rather than -itis) of plantar fascia generally at insertion on medial tuberosity of calcaneus

### RISK FACTORS

- Dancers, runners, court sport athletes
- Obesity (BMI >30)
- Pes planus (flat feet), pes cavus (high arch), overpronation, leg length discrepancy
- Occupations with prolonged standing, especially on hard surfaces (nurses, letter carriers, warehouse/factory workers)
- Female, pregnancy

Age (>40 to 60 years)

- Hamstring, calf tightness
- Decreased ankle range of motion in dorsiflexion (tight heel cord; <15 degrees of dorsiflexion)
- Systemic connective tissue disorders

## GENERAL PREVENTION

- Maintain normal body weight.
- Avoid prolonged standing on bare feet, sandals, or slippers.
- Avoid training errors (increasing intensity, distance, duration, and frequency of high-impact activities too rapidly).
- Proper footwear (appropriate cushioning and arch support)
- Runners should replace footwear after every 250 to 500 miles.
- Avoid overtraining.

## COMMONLY ASSOCIATED CONDITIONS

- Usually isolated
- Heel spurs common but not a marker of severity
- Posterior tibial neuropathy

## DIAGNOSIS

### HISTORY

- Pain on plantar surface of foot, usually at fascial insertion at calcaneus (medial calcaneal tubercle), but can have pain anywhere along length of plantar fascia
- Pain is typically worse with first few steps in the morning or after prolonged rest (poststatic dyskinesia).
- Pain typically improves after first few steps only to recur toward the end of the day.
- Pain can be dull and constant in chronic plantar fasciitis.
- Pain with prolonged ambulation or standing
- Limp with excessive toe walking
- Numbness and burning of medial hindfoot when associated with posterior

## *PHYSICAL EXAM*

- Point tenderness on medial tuberosity of calcaneus at insertion of plantar fascia
- Pain along plantar fascia with dorsiflexion of foot
- Windlass test: pain with passive dorsiflexion of the toes; high specificity, low sensitivity; sensitivity improves (13.5→31.8%) if performed while standing.
- Decreased passive range of motion with dorsiflexion
- Evaluate for pes planus, pes cavus, and overpronation.
- Loss of heel fat pad suggests heel fat pad syndrome.
- Point tenderness on posterosuperior aspect of heel suggests Achilles tendinopathy.

## *DIFFERENTIAL DIAGNOSIS*

- Calcaneal stress fracture
- Heel fat pad syndrome (painful or atrophic heel pad)
- Longitudinal arch strain
- Nerve entrapment (posterior tibial nerve—tarsal tunnel syndrome, medial calcaneal branch of posterior tibial nerve, abductor digiti quinti)
- Achilles tendinopathy
- Calcaneal contusion
- Plantar calcaneal bursitis
- Tendonitis of posterior tibialis
- Plantar fascia tear
- Calcaneal apophysitis (Sever disease)—adolescents

## *DIAGNOSTIC TESTS & INTERPRETATION*

- None necessary; typically a clinical diagnosis
- Consider further imaging only if diagnosis is in question.
- Two radiographic views of foot can rule out fracture, tumor, cyst, periostitis, bony erosions; weightbearing films preferred
- Ultrasound: hypoechoic at insertion, thickened plantar fascia (<sup>3</sup>4 mm)

- MRI can evaluate for other soft tissue etiologies.
- CT or technetium-99 bone scan can rule out calcaneal stress fracture and evaluate for infection.
- Nerve conduction studies can rule out nerve entrapment.

## TREATMENT

Nonoperative management is mainstay of treatment.

### GENERAL MEASURES

- Supportive footwear with stable midfoot; avoid sandals or walking barefoot.
- Relative rest/activity modification
- Stretching: plantar fascial stretches more effective than Achilles tendon/gastrocnemius-soleus stretches
- Weight reduction if BMI >25
- Orthotics
  - Custom orthotics show no benefit over prefabricated orthotics and are more costly.
  - Improved effectiveness of night splints when used in association with orthotics.
- Strengthen calf and interosseous muscles, using the towel drag/pick-up exercise
- Night splints: can be uncomfortable for the first few nights but generally become less bothersome with time; especially effective with calf and Achilles tightness
- Ice (frozen water bottle roll)
- Massage (golf or tennis ball roll)

### MEDICATION

#### *First Line*

Adjunct to control pain

- NSAIDs: naproxen 500 mg PO BID *or* ibuprofen 600 to 800 mg PO TID PRN for pain
- Acetaminophen 1,000 mg PO TID PRN for pain

#### *Second Line*

None

## *ISSUES FOR REFERRAL*

- Podiatry, surgery: Consider referral if conservative measures fail after 3 to 6 months.
- Consider physical therapy for patient instruction on proper stretching and strengthening techniques.

## *ADDITIONAL THERAPIES*

- Corticosteroid injections (1)[A]
  - Short-term pain relief for up to one month, benefit fades with time
  - Recommend ultrasound guidance when possible.
  - Risk for plantar fascial rupture and calcaneal fat pad atrophy with resultant permanent heel pain
  - Can cause injection and postinjection pain for up to 5 to 7 days
- Extracorporeal shock wave therapy (ESWT) (2,3)[B]
  - Growing body of evidence showing benefit
  - Multiple meta-analyses and systematic reviews show level I evidence of benefit; mixed recommendations on low- versus high-intensity ESWT.
  - Uncomfortable to patients but less risk than injection or surgery
  - Consider prior to surgery and (possibly) prior to steroid injection.
  - Delivery not yet standardized

---

P.807

- Low-dye and calcaneal taping
  - Limited, short-term evidence
  - Less effective in severe cases
- Promising therapies with inconsistent supporting evidence
  - Platelet-rich plasma injections (4)[B]: A systematic review demonstrated PRP improved baseline symptoms and was comparable to prolotherapy and better than corticosteroid injections in the short and long term (up to 12 months).
  - Prolotherapy (4)[B]: Comparable in efficacy to PRP for treatment of baseline symptoms, better than corticosteroid injections.

- Low-level laser therapy
- Botulinum toxin (BT) A injection (5)[B]
  - RCT comparing steroid injection to BT injection showed similar results in pain reduction and other measures of foot function at 1 month; improvements in these areas persisted at 6 months more so with BT than with steroid injection.
  - Randomized, multicenter, double-blind, placebo-controlled study comparing BT injection to placebo showed no statistical difference in pain and global assessment.
- Radiofrequency nerve ablation (6)[B]: Prospective, RCT with sham treatment and crossover demonstrated efficacy; also, retrospective case series demonstrated benefit at 1 and 2 years after treatment.
- Myofascial trigger point manual therapy
- Intralesional autologous blood injection
- Plantar iontophoresis

## ***SURGERY/OTHER PROCEDURES***

- Necessary in <10% of patients
- Recommended if conservative treatment fails after 6 to 12 months and pain is unrelenting.
- Open/endoscopic plantar fasciotomy (less risk and complications with endoscopic technique but requires specialized equipment and skills; is not widely used)
- Calcaneal spur resection
- More likely beneficial in severely obese
- No RCTs support surgery

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Heel cup with magnet has proven ineffective.
- Acupuncture shows limited benefit in a few studies.

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

- Ensure patient adherence to proper stretching technique.

Following 3 to 6 months of unsuccessful conservative treatment, consider additional therapies or referrals.

## **PATIENT EDUCATION**

- Weight reduction if BMI >25
- Proper footwear (adequate cushion and arch support)
- Stretch plantar fascia: Pull toes into dorsiflexion prior to walking after prolonged sitting or sleep
- Ice the foot using a frozen water bottle: Roll foot over bottle for 10 minutes in the morning and after work.
- Massage plantar fascia: Roll foot over a golf ball.
- Strengthen foot muscles: Grab cloth or carpet by plantar flexing the toes.
- Decrease repetitive stress.

## **PROGNOSIS**

- Generally good
- Self-limited (resolves within 2 years) in up to 85-90% of patients

## **COMPLICATIONS**

- Rupture of plantar fascia (more common with repeated corticosteroid injections)
- Chronic pain
- Gait abnormality

## See Also

&NA;

Algorithm: Heel Pain

## Codes

&NA;

### ICD10

M72.2 Plantar fascial fibromatosis

## Clinical Pearls

&NA;

- Plantar fasciitis is due to degeneration of plantar fascia at origin (medial calcaneal tuberosity) with characteristic pattern of pain.
- Pain with weight bearing (especially first few steps in the morning or after prolonged rest) is hallmark presentation.
- Conservative treatment is preferred. Wear supportive footwear to avoid excess pronation and provide adequate cushion. Modify activity, stretch plantar fascia, ice (water bottle roll), massage (golf ball roll), and provide arch support.

# Pleural Effusion

Felix B. Chang, MD, DABMA, FAAMA

## BASICS

Abnormal accumulation of fluid in the pleural space

### DESCRIPTION

Types: transudate, exudate

- Congestive heart failure 40%: transudate
- Pneumonia 25%, malignancy 15%, and pulmonary embolism (PE) 10% account for exudative effusions
- Malignant: lung cancer and metastases of breast, ovary, and lymphoma

### EPIDEMIOLOGY

#### *Incidence*

Estimated 1.5 million cases/year in the United States; CHF: 500,000; pneumonia: 300,000; malignancy: 150,000; PE: 150,000; cirrhosis: 150,000; TB: 2,500; pancreatitis: 20,000; collagen vascular disease: 6,000

#### *Prevalence*

- Estimated 320 cases/100,000 people in industrialized countries; in hospitalized patients with AIDS, prevalence is 7-27%.
- No gender predilection:  $\div$  2/3 of malignant pleural effusions occurs in women.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Pleural fluid formation exceeds pleural fluid absorption.
- Transudates result from imbalances in hydrostatic and oncotic forces.
  - Increase in hydrostatic and/or low oncotic pressures; increase in pleural capillary permeability; lymphatic obstruction or impaired drainage; movement of fluid from the peritoneal or retroperitoneal space

- Transudates
  - CHF: 40% of transudative effusions; 80% bilateral. Constrictive pericarditis, atelectasis; superior vena cava syndrome
  - Cirrhosis (hepatic hydrothorax); nephrotic syndrome, hypoalbuminemia; myxedema
  - Urinothorax, central line misplacement; peritoneal dialysis
- Exudates
  - Lung parenchyma infection, bacterial (parapneumonic, tuberculous pleurisy), fungal, viral, parasitic (amebiasis, *Echinococcus*)
  - Cancer: lung cancer, metastases (breast, lymphoma, ovaries), mesothelioma
  - PE: 25% of PEs are transudate.
  - Collagen vascular disease: rheumatoid arthritis, systemic lupus erythematosus, Wegener granulomatosis, sarcoidosis, Churg-Strauss
  - GI: pancreatitis, esophageal rupture, abdominal abscess, after liver transplant. Chylothorax: thoracic duct tear, malignancy
  - Hemothorax: trauma, PE, malignancy, coagulopathy, aortic aneurysm
  - Others: after coronary artery bypass graft; Dressler syndrome; uremia, asbestos exposure, radiation; drug-induced: nitrofurantoin, bromocriptine, amiodarone, procarbazine, hydralazine, procainamide, quinidine, methotrexate, and methysergide
  - Meigs syndrome; yellow nail syndrome; ovarian stimulation syndrome; lymphangiomatosis; acute respiratory distress syndrome (ARDS)
  - Chylothorax: thoracic duct tear, malignancy, associated with lymphoma

## RISK FACTORS

- Occupational exposures/drugs
- PE, TB, bacterial pneumonias
- Opportunistic infections (in HIV patients when CD4 count is <150 cells/ $\mu$ m<sup>3</sup>;L)

## COMMONLY ASSOCIATED CONDITIONS

Hypoproteinemia, heart failure, cirrhosis

**DIAGNOSIS**

Presumptive diagnosis in 50% of cases. Small pleural effusions, radiographic area <2 intercostal spaces (<300 mL) are asymptomatic.

## HISTORY

Dyspnea, fever, malaise, and weight loss; chest pain, cough, hemoptysis, and dull pain

## PHYSICAL EXAM

- Pleural effusion >300 mL: tachypnea, asymmetric expansion of the thoracic cage; decrease/absent tactile fremitus; dullness to percussion; decreased/inaudible breath sounds, egophony, pleural friction rub
- Ascites suggest the following: hepatic hydrothorax, ovarian cancer, and Meigs syndrome.
- If associated with unilateral swelling in lower extremity, consider DVT with PE.

## DIFFERENTIAL DIAGNOSIS

Empyema, malignancy, inflammatory, fungal, tuberculosis

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Pleural fluid: appearance, pH, WBC differential, total protein, lactate dehydrogenase (LDH), glucose, Gram stain and culture, and acid-fast bacilli staining. Consider polymerase chain reaction (PCR) for *Mycobacterium tuberculosis* and *Streptococcus pneumoniae* (1,2)[A].
- If comorbidities implying risk, consider amylase, triglycerides, cholesterol, lupus erythematosus (LE) cells, cytology, antinuclear antibodies (ANAs), adenosine deaminase, tumor markers, rheumatoid factor, cytology, creatinine (2)[A]
- Light criteria, transudate versus exudate (98% sensitivity; 80% specificity); fluid is considered an exudate if any of the following (2)[A]:
  - Ratio of pleural fluid-to-serum protein levels >0.5; ratio of pleural fluid-to-serum LDH levels >0.6; pleural fluid LDH level >2/3 the upper limit for serum LDH level (1,3)[A]
- Other exudate criteria (4)[A]:
  - Serum-effusion albumin gradient  $\geq 1.2$  (sensitivity 87%; specificity 92%); cholesterol effusion >45 mg/dL and LDH effusion >200 mg/dL (sensitivity 90%; specificity 98%)
- Empyema: pus, putrid odor; culture. A putrid odor suggests an anaerobic empyema: LDH levels >1,000 IU/L (normal serum = 200 IU/L); glucose, <60 mg/dL; low pH

- Malignancy: cytology, red, bloody; glucose, normal to low, depending on the tumor burden; RBCs,  $>100,000/\text{mm}^3$
- Lupus pleuritis: LE cells present; pleural fluid-to-serum ANAs ratio  $>1$ ; glucose  $<60$  mg/dL; pleural fluid-to-serum glucose ratio  $<0.5$
- Fungal: positive KOH, culture; peritoneal dialysis: protein,  $<1$  g/dL; glucose, 300 to 400 mg/dL
- Urinothorax: creatinine: pleural/blood  $>0.5$ ; high LDH pleural fluid, with low protein levels
- Hemothorax: hematocrit: pleural/blood  $>0.5$ ; benign asbestos effusion: unilateral, exudative; have elevated eosinophil count
- TB pleuritis: lymphocytes  $>80\%$  predominance effusion; elevated levels of adenosine deaminase  $>50$  U/L and interferon- $\gamma$ ;  $>140$  pg/mL; positive acid-fast bacillus (AFB) stain, culture; total protein  $>4$  g/dL
- Chylothorax: milky; triglycerides  $>110$  mg/dL; lipoprotein electrophoresis (chylomicrons)
- Amebic liver abscess: anchovy paste effusion; Waldenström macroglobulinemia and multiple myeloma: protein  $>7$  g/dL
- Esophageal rupture: high salivary amylase; pleural fluid acidosis, pH  $<6$ ; amylase-rich: acute pancreatitis, chronic pancreatic pleural effusion, malignancy, esophageal rupture; rheumatoid pleurisy: glucose  $<60$  mg/dL; pleural fluid/serum glucose  $<0.5$
- Lymphocytosis: tuberculous pleurisy, lymphoma, sarcoidosis, chronic rheumatoid pleurisy, yellow nail syndrome, or chylothorax (80-95% of the nucleated cells). Carcinomatosis in half of cases (50-70% are lymphocytes)
- Pleural fluid eosinophilia ( $>10\%$  of total nucleated cells): pneumothorax, hemothorax, malignancy, drugs, pulmonary infarction, fungal (coccidiomycosis, cryptococcosis, histoplasmosis), benign asbestos pleural effusion
- Low glucose ( $<60$  mg/dL): TB, malignancy, rheumatoid pleurisy, parapneumonic, empyema, hemothorax, paragonimiasis, Churg-Strauss syndrome
- RBC count  $>100,000/\text{mm}^3$ : trauma, malignancy, PE, injury after cardiac surgery, asbestos pleurisy, pancreatitis, TB
- Pleural fluid LDH  $>1,000$  IU/L: suggests empyema, malignant effusion, rheumatoid effusion, or pleural paragonimiasis
- pH  $>7.3$ : rheumatoid pleurisy, empyema, malignant effusion, TB, esophageal rupture, or lupus nephritis
- Mesothelial cells in exudates: TB is unlikely if there are  $>5\%$  of mesothelial cells.
- *Streptococcus pneumoniae* accounts for 50% of cases of parapneumonic effusions in AIDS

patients, followed by *Staphylococcus aureus*, *Haemophilus influenzae*, *Mycoplasma pneumoniae*, *Legionella*, *Nocardia*, and *Bordetella bronchiseptica*. Exudate with low count of nucleated cells

- *Pneumocystis jirovecii* is an uncommon cause in HIV. Usually it is a small effusion, unilateral or bilateral, and serous to bloody in appearance. Demonstration of the trophozoite or cyst is mandatory.

---

P.809

- Cancer-related HIV pleural effusion: Kaposi sarcoma, Castleman disease, and primary effusion lymphoma. Kaposi sarcoma: mononuclear predominance, exudate, pH >7.4; LDH, 111 to 330 IU/L; glucose >60 mg/dL.
- Chest x-ray (CXR): posteroanterior-anteroposterior views
  - Upright x-rays show a concave meniscus in the costophrenic angle that suggests >250 mL of pleural fluid; homogeneous opacity, with visibility of pulmonary vessels through diffuse haziness and absence of air bronchogram; 75 mL of fluid will obliterate the posterior costophrenic sulcus.
  - Lateral x-rays show blunting of the posterior costophrenic angle and the posterior gutter; decubitus x-rays to exclude a loculated effusion and underlying pulmonary lesion or pulmonary thickening
  - Supine x-rays show costophrenic blunting, haziness, obliteration of the diaphragmatic silhouette, decreased visibility of the lower lobe vasculature, and widened minor fissure.
- Ultrasonography (US): detects as 5 to 50 mL of pleural fluid; identifies loculated effusions; site for thoracentesis, pleural biopsy, or pleural drainage
- Chest CT scan with contrast for patients with undiagnosed pleural effusion. CT pulmonary angiography if PE is suspected.

### *Follow-Up Tests & Special Considerations*

- 75% of patients with exudative effusions have a non-CHF cause.
  - NT-ProBNP: biomarker of CHF-associated effusion; >1,500 pg/mL; sensitivity and specificity 94% (2)[A]
  - Observation in uncomplicated asymptomatic patients (i.e., CHF, cirrhosis), viral pleurisy, thoracic or abdominal surgery

### *Diagnostic Procedures/Other*

Diagnostic thoracentesis indicated for the following:

- Clinically significant pleural effusion (>10 mm thick on US or lateral decubitus x-ray with no known cause)
- CHF: asymmetric effusion, fever, chest pain, or failure to resolve after diuretics
- Parapneumonic effusions

## TREATMENT

Oxygen support

### GENERAL MEASURES

- Therapeutic thoracentesis, if symptomatic
- Chest tube thoracostomy drainage: >1/2 hemithorax; complicated parapneumonic effusion (positive Gram stain or culture, pH <7.2, or glucose <60 mg/dL); empyema; hemothorax. Recommended limit is 1,000 to 1,500 mL in a single thoracentesis procedure (5)[B].

### MEDICATION

#### *First Line*

CHF: diuretics (75% clearing in 48 hours); parapneumonic effusion: antibiotics; rheumatologic conditions/inflammation: steroids and NSAIDs

#### *Second Line*

Symptomatic nonmalignant effusions that are refractory to treatment may be managed with repeated therapeutic thoracentesis or pleurodesis.

### ISSUES FOR REFERRAL

- Uncertain etiology; malignant effusion; high-risk diagnostic thoracentesis; decortication
- Video-assisted thoracoscopy for sclerosis; peritoneal shunts for symptomatic recurrence

### ADDITIONAL THERAPIES

- Pleurodesis for symptomatic patients whose pleural effusion reaccumulates too quickly for repeat therapeutic thoracentesis
- Tunneled pleural catheter is the preferred treatment for patients with malignant pleural effusion and limited survival.
- Sclerosing agents for malignant effusions: doxycycline, bleomycin, talc, and minocycline; talc is

more efficacious. The relative risk of nonrecurrent effusion was 1.34 (95% CI 1.16-1.55) in favor of talc compared with bleomycin, tetracycline, or mustine.

## ***SURGERY/OTHER PROCEDURES***

- Percutaneous pleural biopsy if a cause is not clear after thoracentesis
  - Close pleural biopsy: Pleura is diffusely involved (TB pleuritis, noncaseating granuloma in rheumatoid pleuritis).
  - CT-guided needle biopsy: pleural mass; video-assisted thoracoscopic pleural biopsy: negative percutaneous biopsy, patchy disease, or CT scan does not show obvious mass.
- Parapneumonic effusion should be sampled if free-flowing, but layer is >10 mm on a lateral decubitus film. Loculated, thickened pleura on a contrast-enhanced CT scan, clearly delineated by US open pleural biopsy by thoracotomy
- Contraindications for thoracentesis: anticoagulation, bleeding diathesis, thrombocytopenia <20,000/mm<sup>3</sup>, mechanical ventilation
- Bronchoscopy: when malignancy is suspected (pulmonary infiltrate or mass on CXR or CT scan, hemoptysis, massive pleural effusion, or shift of the mediastinum toward the side of effusion)
- Thoracoscopy

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Treat any underlying medical disorder.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Check for the amount and quality of fluid drained, air leak (bubbling), and oscillation.
- Repeat a CXR when drainage decreases to <100 mL/day to evaluate complete clearing.
- For a large effusion, reevaluate catheter position; if positioned appropriately, consider fibrinolytics.

## ***DIET***

Cardiac diet in patients with heart failure; correct hypoproteinemia.

## PROGNOSIS

- Malignant effusion: poor
- Low-pH malignant effusions have shorter survival and poorer response to chemical pleurodesis than those with pH >7.3.
- Low pleural fluid pH (<7.15): high likelihood of pleural space drainage

## COMPLICATIONS

- Pleural effusion: constrictive fibrosis, pleurocutaneous fistula
- Thoracentesis: pneumothorax (5-10%); hemothorax (~1%); empyema; spleen/liver laceration; reexpansion pulmonary edema (if >1.5 L is removed)

**&NA;**

## **ICD10**

- J90 Pleural effusion, not elsewhere classified
- J91.0 Malignant pleural effusion
- J94.0 Chylous effusion

## **Clinical Pearls**

**&NA;**

- Clinical presentation and pleural fluid analysis allow to diagnose the cause of effusion in 75% of patients at first evaluation.
- Bilateral pleural effusion suggest heart failure, malignancy in absence of cardiomegaly, and tuberculosis or parasitic infection in children.
- Loculation suggest pleural inflammation and may occur with the following: empyema, hemothorax, and TB.
- Parapneumonic effusion should be tapped ASAP.
- Ascites and pleural effusion suggest hepatic hydrothorax, ovarian cancer, or Meig syndrome
- Consider diagnostic thoracentesis in patient with heart failure: fever, pleuritic chest pain, unilateral effusion or effusion of markedly disparate size, effusion not associated with cardiomegaly, effusion fails to respond to management of heart failure
- Most common cause of exudative effusion are pneumonia, neoplasms, and thromboembolism.

# Pneumonia, Bacterial

Rahele Lamah, MD

## BASICS

Bacterial pneumonia is an infection of the pulmonary parenchyma by a bacterial organism.

## DESCRIPTION

Bacterial pneumonia can be classified as the following:

- Community-acquired pneumonia (CAP): lower respiratory tract infection not acquired in a hospital, long-term care facility, or during other recent contact with the health care system
- Medical care-associated pneumonia
  - Hospital-acquired pneumonia (HAP): pneumonia within <sup>3</sup>48 hours after admission and did not appear to be incubating at time of admission
  - Ventilator-associated pneumonia (VAP): Pneumonia that develops >48 to 72 hours after endotracheal intubation.
  - Health care-associated pneumonia (HCAP): Pneumonia that occurs in a nonhospitalized patient with extensive health care contact, such as the following:
    - IV therapy/wound care within past 30 days
    - Residing in a nursing home/long-term care
    - Hospitalization in an acute care hospital for <sup>3</sup>2 days within the past 90 days
    - Visited a hospital/hemodialysis clinic within the past 30 days (1,2)

## EPIDEMIOLOGY

- Influenza and pneumonia are the 8th leading cause of death in the United States, with about 53,692 deaths in 2010.
- In 2006, 55,477 people died of pneumonia (3).
- HAP is the leading cause of death among hospitalacquired infections and is the primary cause of death in the ICU.
- Rates of infection are three times higher in African Americans than in whites and are 5 to 10

times higher in Native American adults and 10 times higher in Native American children (2).

- Mortality rate in children is approximately 1.6 million a year (4). Hospitalization rate for children with CAP is still highest among the very young ages (<18 months). Respiratory viruses are the most commonly detected causes of pneumonia (5).

## *Incidence*

- CAP: 5 to 11 cases/1,000 persons with increased incidence occurring in the winter months.
- HAP: 5 to 10 cases/1,000 admissions; incidence increase 6- to 20-fold in ventilated patients (6) [A].

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Adults, CAP
  - Typical (85%): *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Staphylococcus aureus*, group A *Streptococcus*, *Moraxella catarrhalis*
  - Atypical (15%): *Legionella* sp., *Mycoplasma pneumoniae*, *Chlamydia pneumoniae*
- Adults, HCAP/HAP/VAP
  - Aerobic gram-negative bacilli: *Pseudomonas aeruginosa*, *Escherichia coli*, *Klebsiella pneumoniae*, and *Acinetobacter* sp.
  - Gram-positive cocci: *Streptococcus* sp. and *S. aureus* (including MRSA)
- Children
  - Birth to 20 days: *E. coli*, group B *Streptococci*, *Listeria monocytogenes*
  - 3 weeks to 3 months: *Chlamydia trachomatis*, *S. pneumoniae*
  - 4 months to 18 years
    - Typical: *S. pneumoniae*
    - Atypical: *C. pneumoniae*, *M. pneumoniae*

## *RISK FACTORS*

### CAP

- Age >65 years
- HIV/immunocompromised
- Recent antibiotic therapy/resistance to antibiotics

- Asthma, CAD, COPD, chronic renal failure, CHF, diabetes, liver disease, VAP, HAP, HCAP
- Hospitalization for <sup>3</sup>2 days during past 90 days
- Severe illness
- Antibiotic therapy in the past 6 months
- Poor functional status as defined by activities of daily living score
- Immunosuppression (including steroid users)

## GENERAL PREVENTION

- All children 2 to 59 months of age should be routinely vaccinated with pneumococcal conjugate (PCV13); given at 2, 4, and 6 months of age; a fourth dose at 12 to 15 months of age. PCV13 is also FDA approved for those >50 years of age.
- For adults aged 65 years or older who have not received any pneumonia vaccination, ACIP currently recommends PCV13 followed by pneumococcal polysaccharide (PPSV23) with 6 to 12 months interval. If they received PPSV23 vaccine before age 65 years, they should receive another dose of the vaccine at age 65 years or later if at least 5 years have passed since their previous dose.
- PPSV23 is also indicated at age 19 to 64 years who are immunocompromised, including asthma and cigarette smokers. A second dose of PPSV23 is recommended 5 years after the first dose for persons aged 19 to 64 years with functional or anatomic asplenia and for persons with immunocompromising conditions. ACIP does not recommend multiple revaccinations due to uncertainty about safety and benefit of revaccination.
- Annual influenza vaccine is recommended according to current guidelines.

## DIAGNOSIS

### History

- Fever, chills, rigors, malaise, fatigue
- Dyspnea
- Cough, with/without sputum
- Pleuritic chest pain
- Myalgias
- GI symptoms

## **ALERT**

High fever ( $>104^{\circ}\text{F}$  [ $40^{\circ}\text{C}$ ]), male sex, multilobar involvement, and GI and neurologic abnormalities have been associated with CAP caused by *Legionella* infection.

## *Geriatric Considerations*

Older adults with pneumonia often present with weakness, mental status change, or history of falls.

## **PHYSICAL EXAM**

- Fever  $>100.4^{\circ}\text{F}$  ( $38^{\circ}\text{C}$ ), tachypnea, tachycardia
- Rales, rhonchi, egophony, increased fremitus, bronchial breath sounds, dullness to percussion, asymmetric breath sounds, abdominal tenderness

## **DIFFERENTIAL DIAGNOSIS**

Bronchitis, asthma exacerbation, pulmonary edema, lung cancer, pulmonary tuberculosis, pneumonitis

## **DIAGNOSTIC TESTS & INTERPRETATION**

### *Initial Tests (lab, imaging)*

- Routine laboratory testing to establish an etiology in outpatients with CAP is usually unnecessary.
- For hospitalized patients with CAP, a CBC, sputum Gram stain, and two sets of blood cultures
- More extensive diagnostic testing in patients with CAP is recommended if:
  - Blood cultures: ICU admission, cavitary infiltrates, leukopenia, alcohol abuse, severe liver disease, asplenia, positive pneumococcal urine antigen test (UAT), pleural effusion
  - Sputum Gram stain and cultures: ICU admission, failure of outpatient treatment, cavitary infiltrates, alcohol abuse, severe COPD/structural lung disease, positive *Legionella* UAT, positive pneumococcal UAT, pleural effusion
  - *Legionella* UAT: ICU admission, failure of outpatient treatment, alcohol abuse, travel in past 2 weeks, pleural effusion
  - Pneumococcal UAT: ICU admission, failure of outpatient treatment, leukopenia, alcohol abuse, severe liver disease, asplenia, pleural effusion
- A chest x-ray (CXR) is indicated when pneumonia is suspected or with an acute respiratory

infection and

- Vital signs: temperature  $>100^{\circ}\text{F}$  ( $37.8^{\circ}\text{C}$ ); heart rate (HR)  $>100$  beats/min; respiratory rate (RR)  $>20$  breaths/min
- At least two of the following clinical findings: decreased breath sounds, rales, no asthma
- Early in disease course, CXR may be negative.
- Evidence of necrotizing/cavitary pneumonia should raise suspicion for MRSA pneumonia, especially with history of prior MRSA skin lesions.

## *Diagnostic Procedures/Other*

- For VAP/HAP: By bronchoscopic or nonbronchoscopic means, obtain a lower respiratory tract sample for culture prior to initiation/change of therapy. Serial evaluations may be needed (6) [A].
- Safe cessation of antibiotics can be done from a good quality negative sputum culture.

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Adults
  - CAP, outpatient
    - No significant differences in efficacy between antibiotic option in adults (7)[A]
    - Previously healthy, no antibiotics in past 3 months
      - Azithromycin 500 mg PO 1 time, then 250 mg PO daily for 4 days; clarithromycin 500 mg PO BID for 10 days; erythromycin 500 mg PO BID for 10 days, or
      - Doxycycline 100 mg PO BID for 10 days
    - Comorbid conditions, immunosuppressed, antibiotic use in past 3 months
      - Levofloxacin 750 mg PO daily for 5 days; moxifloxacin 400 mg PO daily for 10 days; or
      - Amoxicillin 1 g PO TID; amoxicillin-clavulanate 2 g PO BID + macrolide
      - Treatment may be stopped if
        - Afebrile for  $>48$  hours

- Supplemental oxygen no longer needed

- No more than one of the following:

- A. HR >100 beats/min
- B. RR >24 breaths/min
- C. Systolic BP  $\geq$ 90 mm Hg

- CAP, inpatient (non-ICU)

- IV antibiotics initially, then switch to oral after clinical improvement
- Cefotaxime; ceftriaxone; ampicillin-sulbactam + macrolide (clarithromycin; erythromycin) for 14 days or
- Moxifloxacin; levofloxacin for 14 days
- If *Pseudomonas* is a consideration.
  - Piperacillin-tazobactam; cefepime; imipenem; meropenem + levofloxacin or
  - Piperacillin-tazobactam; cefepime; imipenem; meropenem + aminoglycoside and azithromycin or
  - Piperacillin-tazobactam; cefepime; imipenem; meropenem + aminoglycoside + levofloxacin
- If MRSA is a consideration.
  - Add vancomycin or linezolid.

- HCAP/HAP/VAP

- Use IV antibiotics.
- Early onset (<5 days) and no risk factors for multidrug-resistant pathogens
  - Ceftriaxone; ampicillin-sulbactam; ertapenem or
  - Levofloxacin; moxifloxacin
- Late onset ( $\geq$ 5 days) or risk factors for multidrug-resistant pathogens (antibiotic therapy in preceding 90 days; high frequency of antibiotic resistance in community/hospital; immunosuppressive disease/therapy; risk factors for HCAP)
  - MRSA coverage: linezolid or vancomycin + *&bgr*-lactam cefepime; ceftazidime; imipenem; meropenem; piperacillin-tazobactam + either fluoroquinolone (levofloxacin)

or aminoglycoside (amikacin; gentamicin; tobramycin) (level II)

- Short-course versus prolonged-course antibiotic therapy for HAP in critically ill adults is only as effective and reduced recurrence of VAP-associated multidrug resistance (8).
- Drug-resistant *S. pneumoniae* should be treated with high-dose amoxicillin, amoxicillin/clavulanate, cefpodoxime with a macrolide, or a respiratory fluoroquinolone.
- Adult IV antibiotic doses
  - *&bgr;*-Lactams (ampicillin-sulbactam 3 g q6h; aztreonam 2 g q6h; cefepime 1 to 2 g q8-12h; cefotaxime 1 g q6-8h; ceftazidime 2 g q8h; ceftriaxone 1 g daily; imipenem 500 mg q6h; meropenem 1 g IV q8h)
  - Aminoglycosides (amikacin 20 mg/kg daily; gentamicin 7 mg/kg daily; tobramycin 7 mg/kg daily)
  - Fluoroquinolones (levofloxacin 750 mg daily; moxifloxacin 400 mg daily)
  - Macrolides (azithromycin 500 mg daily; clarithromycin 500 mg daily; erythromycin 500 to 1,000 mg q6h)
  - Vancomycin 15 mg/kg q12h
  - Linezolid 600 mg q12h
  - Telavancin is an antibiotic which covers MRSA infection, and it was approved by FDA in 2013. Telavancin is approved for the treatment of HAP and VAP caused by *S. aureus*. This medication is indicated only when alternative agents cannot be used (3).
- Pediatric, outpatient (<sup>3</sup>3 months)
  - Antibiotic treatment in preschool-aged children is not routinely required because viral pathogens are more common (9)[A].
  - Oral antibiotics are as efficacious as IV in CAP (length of stay and oxygen requirement were reduced in those given oral antibiotics).
  - Typical bacterial pneumonia
    - Amoxicillin 90 mg/kg/day PO BID (max 4 g/day) (9)[A]
    - Amoxicillin-clavulanate 90 mg/kg/day PO BID (max 4 g/day) (9)[A]
    - Alternative: levofloxacin 16 to 20 mg/kg/day PO BID for children 6 months to 5 years, 10 mg/kg/day daily for children <sup>3</sup>5 years (max 750 mg/day) (9)[C]
  - Atypical bacterial pneumonia

- Azithromycin 10 mg/kg PO on day 1 (max 500 mg), then 5 mg/kg/day (max 250 mg) on days 2 to 5 (8)[C]
- Clarithromycin 15 mg/kg/day PO BID (max 1 g/day) (8)[C]
- Erythromycin 40 mg/kg/day PO daily (8)[C]

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Clinical judgment and use of a validated severity of illness score are recommended to determine if inpatient management is indicated.
- The Pneumonia Severity Index (PSI) is a clinical prediction rule used to calculate the probability of morbidity and mortality among patients with CAP. PSI is risk stratified from I to V. PSI risk class from I to III can be treated as outpatients and IV to V should be hospitalized. PSI can be calculated at <http://pda.ahrq.gov/clinic/psi/psicalc.asp>
- The CURB-65 or CRB 65 (confusion, urea nitrogen-respiratory rate, blood pressure, age >65 years) (<http://www.mdcalc.com/curb-65-severity-score-community-acquired-pneumonia/>) is a severity of illness score for stratifying adults with CAP into different management groups (7).
- The SMART-COP (systolic BP, multilobar chest radiography, albumin, respiratory rate, tachycardia, confusion, oxygen level, and arterial pH) is a new method to predict which patients will require intensive respiratory/vasopressor support. A score of  $\geq 3$  has sensitivity of 92% to identify those patients who will receive intensive treatment (7).
- Patients with COPD or CHF are more likely to require ICU admission when suffering from CAP.
- Clinical prediction tools do not replace a physician's clinical judgment.

### *Pediatric Considerations*

Inpatient treatment of children is recommended in the following settings: infants  $\geq 3$  to 6 months; presence of respiratory distress (tachypnea, dyspnea, retractions, grunting, nasal flaring, apnea, altered mental status,  $O_2$  sat  $< 90\%$ ); or if known to have CAP as result of a virulent pathogen such as community-associated MRSA should be hospitalized (10).

### *Discharge Criteria*

Clinical stability: temperature  $\leq 100.4^\circ F$  ( $37.8^\circ C$ ); HR  $\leq 100$  beats/min; RR  $\leq 24$  breaths/min; systolic BP  $\geq 90$  mm Hg;  $O_2$  sat  $\geq 90\%$  or  $PaO_2 \geq 60$  mm Hg on room air; ability to maintain oral intake; normal mental status

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

Consider chest CT if patient is failing to improve on current management.

#### *PATIENT EDUCATION*

Smoking cessation, vaccinations

#### **COMPLICATIONS**

Necrotizing pneumonia, respiratory failure, empyema, abscesses, cavitation, bronchopleural fistula, sepsis

## Codes

**&NA;**

### ICD10

- J15.9 Unspecified bacterial pneumonia
- J15.4 Pneumonia due to other streptococci
- J14 Pneumonia due to Hemophilus influenzae

## Clinical Pearls

**&NA;**

- Bacterial pneumonia can usually be treated empirically based on its classification as CAP or HCAP/HAP/VAP.
- A severity of illness score is helpful in determining the need for hospitalization of adult patients but does not replace a physician's clinical judgment.

# Pneumonia, Mycoplasma

Jonathan D. Reves, DO

Robert M. Hasty, DO, FACOI, FACP

## BASICS

### DESCRIPTION

- Bronchopulmonary infection caused by the *Mycoplasma* species, *Mycoplasma pneumoniae*
- Smallest free-living organism; fastidious and slowgrowing; first isolated in cattle in 1898
- Most frequently affects children/young adults but can also occur in the elderly; often causes epidemics in close communities
- Infection may be asymptomatic, most often confined to the upper respiratory tract; however, may progress to pneumonia (5-10%).
- Course is usually acute with an incubation period of 2 to 3 weeks.
- Synonym(s): primary atypical pneumonia (PAP); Eaton agent pneumonia; cold agglutinin-positive pneumonia; walking pneumonia

### Geriatric Considerations

Uncommonly isolated as a single agent in elderly patients

### Pediatric Considerations

- Unusual in infants and children <5 years; (pneumonia <5 years is more commonly viral)
- Increased incidence of asthma exacerbation in older children
- All infants 3 to 6 months with suspected bacterial pneumonia should be hospitalized.

### EPIDEMIOLOGY

#### Incidence

- Estimated 1 million cases per year in the United States
- Responsible for 20% of community-acquired pneumonia (CAP) requiring hospitalizations annually

- Infection occurs most frequently in fall/winter seasons but may develop year round.

## Prevalence

- Predominant sex: male = female
- Predominant age group affected: 5 to 20 years
  - May occur at any age
  - Rare in children <5 years of age
- Responsible for 15-20% of all cases of CAP yearly
  - Most common cause of pneumonia in school children and young adults who do not have a chronic underlying condition

## ETIOLOGY AND PATHOPHYSIOLOGY

- *M. pneumoniae* is a short-rod mucosal pathogen, which lacks a cell wall and thus not visible on Gram stain.
- Can grow under both aerobic and anaerobic conditions
- Highly contagious, *M. pneumoniae* is transmitted by contact and aerosols.
- Pathogenicity linked to its filamentous tips, which adhere selectively to respiratory epithelial cell membrane proteins with production of H<sub>2</sub>O<sub>2</sub> and superoxide radicals, damaging cilia
- Many pathogenic features of infection are believed to be immune-mediated, not directly induced.
- Decreased ciliary movement produces prolonged paroxysmal, hacking cough.

### ALERT

- Macrolide-resistant *M. pneumoniae* has emerged in cases of adult CAP and pediatric pneumonias in Asia, France, Italy, Israel, and the United States.
- Infection by *M. pneumoniae* has come to be recognized as a worldwide cause of CAP.
- *M. pneumoniae* infection may worsen asthma symptoms as well as cause wheezing in children without asthma.

## RISK FACTORS

- Immunocompromised state (e.g., HIV, transplant recipients, chemotherapy)
- Smoking

- Close community living (e.g., military bases, prisons, hospitals, fraternity houses, schools, household contacts)

## GENERAL PREVENTION

Consider droplet isolation of active cases.

## COMMONLY ASSOCIATED CONDITIONS

- Asthma exacerbations as a result of proinflammatory cytokine release
- Chronic obstructive pulmonary disease

## DIAGNOSIS

### HISTORY

- Infection may be asymptomatic.
- Gradual onset of headache, malaise, low-grade fevers, chills
- Symptoms of upper respiratory infection then occur, including incessant, nonproductive, worsening cough (which may become mildly productive late in the disease); rhinorrhea; pharyngitis; and sinusitis (1)[A]
- Pneumonia may occur with associated pleural effusion; however, dyspnea is rare.
- The presence of pleuritic chest pain warrants a higher suspicion of *M. pneumoniae* (1)[A].
- Extrapulmonary findings may develop in 5-10% of patients, including arthralgias, skin rashes, cervical adenopathy, hemolysis, congestive heart failure (CHF), and cardiac conduction abnormalities.
- Neurologic symptoms develop more commonly in children and may include encephalitis, aseptic meningitis, cranial nerve palsies, cerebellar ataxia, ascending paralysis, and coma (2)[C].
- Persistent cough is common during convalescence; other sequelae are rare.

## PHYSICAL EXAM

- Patients generally appear nontoxic.
- Hacking/pertussis-like cough may be present along with fever and lassitude.
- Normal lung findings with early infection, but rhonchi, rales, and/or wheezes may develop several days later (1)[A].

- Mild pharyngeal injection without exudates
- Minimal/no cervical adenopathy
- Erythematous tympanic membranes or bullous myringitis in patients >2 years of age is an uncommon but unique sign.
- Some patients may develop a pleural friction rub.
- Various exanthems, including erythema multiforme and Stevens-Johnson syndrome

## ***DIFFERENTIAL DIAGNOSIS***

- Viral/bacterial/fungal pneumonia
- Tuberculosis
- Other atypical pneumonias, including *Chlamydia pneumoniae*, *Chlamydophila psittaci*, *Coxiella burnetii* (Q fever), *Francisella tularensis* (tularemia), *Pneumocystis jiroveci*, *Legionella pneumophila*

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Microbial diagnosis is uncommon in outpatients as empiric treatment usually successful.
- PCR is the diagnostic test of choice, when available.
- No clinical or radiographical findings can differentiate between *M. pneumoniae* and other atypical pneumonia pathogens (*Chlamydia/Legionella*).

### ***Initial Tests (lab, imaging)***

- WBC count may be normal or elevated.
- Hemolytic anemia has been described but is rare.
- Elevated erythrocyte sedimentation rate (ESR) may be present but is nonspecific.
- When available, polymerase chain reaction (PCR) for *M. pneumoniae* DNA in respiratory secretions, CSF, and tissue samples may be the most sensitive and specific
- CXR shows reticulonodular pattern with patchy areas of lower lobe consolidation, although this is not specific. Small pleural effusion may be present in 10-15% cases.

### ***Follow-Up Tests & Special Considerations***

- Sputum Gram stains are not helpful because *M. pneumoniae* lacks a cell wall and cannot be stained.

- *M. pneumoniae* is difficult to culture and requires 7 to 21 days to grow; culturing is successful in 40-90% of cases but does not provide information to guide treatment, thus infrequently performed.
- Complement fixation serologic assay shows 4-fold rise in IgM antibody titer at 2 to 4 weeks after symptom onset; this is an older technique.
- Positive cold agglutinins (titer of  $\geq 1:128$  or rising 4-fold) in 50% of infections but can take 1 to 2 weeks to develop; not sensitive/specific; not routinely recommended
- CT of chest may show a combination of patchy tree-in-bud opacities with segmental ground glass opacities.

## TREATMENT

### GENERAL MEASURES

- Avoid sick contacts.
- Treatment is usually empiric and must be comprehensive to cover all likely pathogens in the context of the clinical setting.
- Calculation of pneumonia severity score (CAP score: [www.mdcalc.com/psi-port-score-pneumonia-severity-index-adult-cap](http://www.mdcalc.com/psi-port-score-pneumonia-severity-index-adult-cap)) may be helpful in determining inpatient versus outpatient treatment.

### ALERT

There is insufficient evidence regarding the efficacy of antibiotics in pediatric patients infected with *M. pneumoniae*. However, some studies show benefit to treating with a macrolide and amoxicillin to cover *M. pneumoniae* in addition to other likely agents causing CAP (3,4)[A].

### Pregnancy Considerations

- Azithromycin: pregnancy Category B (preferred treatment)
- Clarithromycin, levofloxacin, and moxifloxacin: pregnancy Category C
- Doxycycline: pregnancy Category D

## MEDICATION

### First Line

- Azithromycin

- <3 months of age: not established
- >3 months of age: day 1, 10 mg/kg PO × 1 (not to exceed 500 mg); days 2 to 5: 5 mg/kg PO daily (not to exceed 250 mg/day)

P.813

- Adults: 500 mg PO × 1 followed by 250 mg PO daily for 4 days (5)[A]
- Clarithromycin
  - Children <6 months of age: not established
  - Patients >6 months of age: 15 mg/kg/day PO divided q12h for 10 to 14 days
  - Adults: 250 to 500 mg PO BID for 10 to 14 days
- Erythromycin
  - Children: 20 to 50 mg/kg/day (base) PO divided q6-8h for 10 to 14 days
  - Adults: 500 mg (base) PO q6h for 10 to 14 days (5)[A],(6)[B]
- Doxycycline
  - Children <8 years of age: not recommended
  - Children >8 years of age (<sup>2</sup>45 kg): 2 to 4 mg/kg/day up to 200 mg/day PO divided BID for 10 to 14 days
  - Children >8 years of age (<sup>3</sup>45 kg): Refer to adult dosing.
  - Adults: 100 mg PO BID for 7 to 14 days (5)[A],(6)[B]
  - Useful in macrolide-resistant strains of *M. pneumoniae*.

## Second Line

- Levofloxacin
  - Children <18 years of age: not recommended
  - Adults: 500 mg PO daily for 7 to 10 days (5)[A]
- Moxifloxacin
  - Children <18 years of age: not recommended
  - Adults: 400 mg/day PO for 7 to 10 days
- Levofloxacin and moxifloxacin show good activity against *M. pneumoniae*. Consider use with comorbid conditions and other pneumonia pathogens; also useful if macrolide resistance is

suspected.

## *ADDITIONAL THERAPIES*

- Albuterol inhaler: 2 puffs q4-6h as needed for wheezing
- Dexamethasone may downregulate cytokine release (7)[B].
- Acetaminophen/ibuprofen as needed for fever
- Up to 10.9% of hospitalized patients may require mechanical ventilation.
- Plasmapheresis in cases of severe hemolytic anemia.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- CAP score risk class IV/V
- Advanced age with comorbidities
- Complicating neoplastic disease
- Significant cerebrovascular, cardiac, renal, liver, or GI symptoms
- Altered mental status
- Inability to maintain oxygen saturation
- Tachycardia/tachypnea
- Hypotension
- Neurologic symptoms
- Signs of Stevens-Johnson syndrome
- Significant hemolysis (autoimmune hemolytic anemia, cold agglutinin disease)

### *Discharge Criteria*

- Change from IV to PO antibiotic may be made when:
  - Respiratory distress and hypoxia have resolved.
  - Patients are tolerating oral hydration.
  - No significant complications are present.
- Generally, no need for 24-hour observation on PO antibiotics prior to discharge.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Clearing of condition on CXR should be documented in patients >50 years of age (4)[A].
- In smokers, document a clear CXR in 6 to 8 weeks.
- Worsening symptoms/development of rash or meningeal/neurologic signs should prompt immediate presentation to medical attention.
- Antibiotic prophylaxis for exposed contacts is not routinely recommended.
- For household contacts who may be predisposed to severe mycoplasmal infection, macrolide or doxycycline prophylaxis should be used.

### *DIET*

- No special diet considerations
- Ensure adequate hydration.

### *PATIENT EDUCATION*

- Smoking cessation
- Contact and droplet precautions
- Adequate handwashing techniques

### *PROGNOSIS*

- Symptoms usually resolve in 2 weeks.
- Some constitutional symptoms may persist for several weeks.
- With correct therapy, even most severe cases can expect complete recovery.

### **COMPLICATIONS**

- All complications are rare, except reactive airway disease, hemolytic anemia, and erythema multiforme.
- Reactive airway disease may persist indefinitely and can cause acute chest syndrome in patients with sickle cell anemia.
- Meningoencephalitis
- Aseptic meningitis
- Peripheral neuropathy

- Transverse myelitis/acute transverse myelitis
- Cerebellar ataxia
- Acute disseminated encephalomyelitis
- Guillain-Barré syndrome
- Encephalitis (especially in children)
- Polyneuritis/polyarthritis
- Stevens-Johnson syndrome
- Pericarditis/myocarditis
- Respiratory distress syndrome
- Cerebral ataxia
- Thromboembolic phenomena
- Pleural effusion
- Nephritis
- Occasional deaths occur primarily among the elderly and persons with sickle cell disease.

## Codes

&NA;

### ICD10

J15.7 Pneumonia due to *Mycoplasma pneumoniae*

# Clinical Pearls

## &NA;

- Most common atypical respiratory pathogens include *M. pneumoniae*, *C. pneumoniae*, and *L. pneumophila*.
- Atypical pneumonia is typically a clinical diagnosis; if labs are indicated, PCR is the mainstay of diagnosis with serology if PCR is not available.
- Watch closely for complicating symptoms that could indicate worsening disease.
- Atypical pneumonia with *M. pneumoniae* is typically self-limiting, difficult to identify, and usually responds to empiric treatment.
- Outbreaks of *M. pneumoniae* can be seen in close communities of young people.
- Onset of infection is typically have a gradual onset of symptoms, normal WBC, and less respiratory distress.

# Pneumonia, Pneumocystis Jiroveci

Cameron M. Shawver, DO

Marvin H. Sineath Jr., MD, CAQSM

## BASICS

### DESCRIPTION

- *Pneumocystis jiroveci* causes pneumonia primarily in immunocompromised patients.
- The fungus that causes this pneumonia in humans was previously called *Pneumocystis carinii*.
- The name was formally changed to *Pneumocystis jiroveci* in 2001, following the discovery that the fungus that infects humans is unique and distinctive from the fungus that infects animals (1).
- *P. jiroveci* is extremely resistant to traditional antifungal agents, including both amphotericin and azole agents (2).
- To prevent confusion, the term PCP, which used to represent *P. carinii* pneumonia, now represents *Pneumocystis* pneumonia (3).

### ALERT

No combination of symptoms, signs, blood chemistries, or radiographic findings is diagnostic of *P. jiroveci* pneumonia (4).

### EPIDEMIOLOGY

- *P. jiroveci* has a worldwide distribution, and most children have been exposed to the fungus by 2 to 4 years (5).
- The reservoir and mode of transmission for *P. jiroveci* is still unclear.
  - Human studies favor an airborne transmission model, with person-to-person spread being the most likely mode of infection acquisition (4).

### Incidence

- Infants with HIV infection have a peak incidence of PCP between 2 and 6 months (5).
- HIV-infected infants have a high mortality rate, with a median survival of only 1 month.

## Prevalence

- The prevalence of *P. jiroveci* colonization among healthy adults is 0-20% (2).
- Recent studies have demonstrated the transient nature of *P. jiroveci* colonization in asymptomatic, immunocompetent patients (4).
- 50% of patients with PCP are coinfecting with <sup>3</sup>2 strains of *P. jiroveci* (5).
- There is evidence that distinct strains are responsible for each episode in patients who develop multiple episodes of PCP (5).

## ETIOLOGY AND PATHOPHYSIOLOGY

Mode of transmission is unknown; likely respiratory from infected host

## RISK FACTORS

Individuals at risk (4)

- Patients with HIV/AIDS infection, especially if not receiving prophylactic treatment for PCP
- Patients who are receiving high doses of glucocorticoids
- Patients who have an altered immune system not due to HIV
- Patients who are receiving chronic immunosuppressive medications
- Patients who have hematologic or solid malignancies resulting in malignancy-related immune depression

## GENERAL PREVENTION

- Indications for prophylaxis
  - HIV-infected adults (5)
    - Should start when CD4 count is  $<200$  cells/ $\mu$ L or if the patient develops oropharyngeal candidiasis
  - HIV-infected children (5)
    - Prophylaxis should be provided for children <sup>3</sup>6 years based on adult guidelines.
    - For children aged 1 to 5 years, start when CD4 count is  $<500$  cells/ $\mu$ L.
    - For infants  $<12$  months, start when the CD4 percentage is  $<15\%$ .
  - Non-HIV-infected adults receiving immunosuppressive medications or with underlying immune system deficits should receive PCP prophylaxis, but currently there are no specific

guidelines on when to start this.

- Medication
  - Trimethoprim-sulfamethoxazole (TMP-SMX)
    - Adults: 1 double-strength tablet daily or 1 double-strength tablet 3 times per week
    - Children >2 months: 150 mg TMP/m<sup>2</sup>/day in divided doses q12h for 3 days per week
  - Atovaquone suspension
    - Adults: 1,500 mg PO once daily with food
    - Children: not to exceed 1,500 mg/day
      - 1 to 3 months: 30 mg/kg/day PO once daily
      - 4 to 24 months: 45 mg/kg/day PO once daily
      - >24 months: 30 mg/kg/day PO once daily
      - Adolescents <sup>3</sup>13 years: Refer to adult dosing.
  - Dapsone
    - Adults only: 50 mg BID or 100 mg once daily
  - Pentamidine
    - Adults only: 300 mg aerosolized every 4 weeks
- Discontinuation of prophylaxis
  - When CD4+ cell counts are >200 cells/*&mgr*;L for a period of 3 months in the adult population (2)[C]
  - There are no clear guidelines for discontinuation of prophylaxis in children.

## COMMONLY ASSOCIATED CONDITIONS

- HIV/AIDS
- Chronic obstructive pulmonary disease (COPD)
- Interstitial lung disease
- Connective tissue diseases treated with corticosteroids
- Cancer and organ transplant patients on immunosuppressive medication

# DIAGNOSIS

## HISTORY

- HIV-infected patients
  - Subacute onset over several weeks
    - Progressively worsening dyspnea
    - Tachypnea
    - Cough: nonproductive or productive of clear sputum
    - Low-grade fever, chills
    - Weakness, fatigue, malaise
- Non-HIV-infected immunocompromised patients
  - More acute onset with fulminant respiratory failure
    - Abrupt tachypnea, dyspnea
    - Fever
    - Dry cough

## PHYSICAL EXAM

- Fever
- Tachypnea
- Tachycardia
- Lung exam is normal or near normal.

## DIFFERENTIAL DIAGNOSIS

- Tuberculosis
- Bacterial pneumonia
- Fungal pneumonia
- Viral pneumonia

## DIAGNOSTIC TESTS & INTERPRETATION

*P. jiroveci* cannot be cultured. Therefore, a diagnosis relies on detection of the organism by colorimetric or immunofluorescent stains or by polymerase chain reaction (PCR) (5)[C].

- ABG: reveals hypoxemia and increased alveolar-arterial gradient that varies with severity of disease
- LDH: Serum lactate dehydrogenase is frequently increased (nonspecific; likely due to underlying lung inflammation and injury).
- CD4 cell count is generally  $<200$  cells/ $\mu\text{m}^3$  in HIV-infected patients with PCP.
- S-adenosylmethionine levels are significantly lower in a patient with PCP. The levels increase with successful treatment (6)[B].
- Comprehensive metabolic profile
- Chest x-ray (CXR) (4)[C]
  - Bilateral, symmetric, fine, reticular interstitial infiltrates involving perihilar areas; becomes more homogeneous and diffuse as severity of infection progresses
  - Less common patterns include upper lobe involvement in patients receiving aerosolized pentamidine, solitary or multiple nodular opacities, lobar infiltrates, pneumatoceles, and pneumothoraces.
  - May be normal in up to 30% of patients with PCP (3)[C]
- High-resolution CT is more sensitive than CXR.

### *Diagnostic Procedures/Other*

- Fiber-optic bronchoscopy with bronchoalveolar lavage (BAL) is the preferred diagnostic procedure to obtain samples for direct fluorescent antibody staining.
  - Sensitivities range from 89% to  $>98\%$ .
- *Pneumocystis* trophic forms or cysts obtained from induced sputum, BAL fluid, or lung tissue, which can be visualized using conventional stains
- PCR can detect *Pneumocystis* from respiratory sources, but the potential remains for false positives (4)[C].

## **TREATMENT**

The recommended duration of therapy differs in patients who are with/without AIDS:

- In patients with PCP who do not have AIDS, the typical duration of therapy is 14 days.
- Treatment of PCP in patients who have AIDS was increased to 21 days due to the risk for

relapse after only 14 days of treatment (4)[C].

## MEDICATION

- TMP-SMX (2,4)[C]
- Adult dosing
  - TMP: 15 to 20 mg/kg/day, PO or IV, divided into 4 doses
- Pediatric dosing (>2 months) (4)[C]
  - TMP: 15 to 20 mg/kg/day in divided doses q6-8h
- Reduce doses of TMP-SMX in patients with renal failure.
- Treatment response to *Pneumocystis* therapy often requires at least 7 to 10 days before clinical improvement is documented (2)[C].
- Pregnancy risk factor: Category C (4)[C]
- Precautions
  - History of sulfa allergy
  - There is an emergence of drug-resistant PCP, especially against TMP-SMX.

## Second Line

- Pentamidine (for moderate to severe cases)
  - Adults and children: 4 mg/kg IV or IM once daily
- Dapsone + trimethoprim (adults only)
  - Dapsone 100 mg PO once daily, *plus*
  - Trimethoprim 5 mg/kg PO TID
    - Check the glucose-6-phosphate dehydrogenase level before beginning dapsone, as hemolysis may result.
- Clindamycin + primaquine (adults only)
  - Clindamycin 600 to 900 mg IV q8h or 300 to 450 mg PO QID, *plus*
  - Primaquine 30 mg PO once daily
- Atovaquone
  - Adults: 750 mg PO BID (>13 years of age)

- Children: 40 mg/kg/day PO divided BID (max 1,500 mg)
- Note: Pentamidine has greater toxicity than TMP-SMX: hypotension, hypoglycemia, pancreatitis (4)[C].

## ADDITIONAL THERAPIES

Adjunctive corticosteroid (prednisone or methylprednisolone) (4)[C],(7)[A]

- Adjunctive corticosteroids are shown to provide benefits in patients who have AIDS and symptoms of moderate to severe PCP.
- Corticosteroids provide the greatest benefit to HIV patients who have hypoxemia manifested as a partial pressure of arterial oxygen <70 mm Hg or an alveolar-arterial gradient >35 mm Hg on room air.
- Adults and children >13 years of age: prednisone, 40 mg PO BID on days 1 to 5; 40 mg daily on days 6 to 11; 20 mg daily on days 12 to 21

## INPATIENT CONSIDERATIONS

- No set criteria for hospital admission
- Five predictors of mortality in HIV-associated *Pneumocystis* pneumonia (8)
  - Increased age of the patient
  - Recent IV drug use
  - Total bilirubin >0.6 mg/dL
  - Serum albumin <3 g/dL
  - Alveolar-arterial oxygen gradient  $\geq$ 50 mm Hg (8)[C]

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

In patients with HIV/AIDS: Patients with previous episodes of PCP should receive lifelong secondary prophylaxis unless they respond well to highly active antiretroviral therapy (HAART) and have a CD4 count >200 cells/ $\mu$ mL for at least 3 months.

### Patient Monitoring

Serum lactate dehydrogenase levels, pulmonary function test results, and ABG measurements

generally normalize with treatment.

## DIET

No special diet needed

HIV/AIDS

## Codes

&NA;

## ICD10

B59 Pneumocystosis

## Clinical Pearls

&NA;

- Colonization with *P. jiroveci* is common in the pediatric population.
- PCP only occurs in immunocompromised patients.
- Patients with HIV are at risk once their CD4 count is  $<200$  cells/ $\mu\text{g}$ ;L. At that time, TMP-SMX should be initiated as prophylaxis. Prophylaxis may end after HAART has been initiated and the CD4 count is  $>200$  cells/ $\mu\text{g}$ ;L for 3 months.
- Patients who are immunocompromised are also at risk. Currently, no clear clinical guidelines are available as to when to initiate or end prophylaxis.
- The first-line treatment is TMP-SMX. The typical duration of therapy is 14 days in non-AIDS-infected patients and 21 days in AIDS-infected patients.

# Pneumonia, Viral

R. Aaron Lambert, MD

## BASICS

### *DESCRIPTION*

- Inflammatory disease of the lungs due to a viral infection
- Most viral pneumonia results from exposure infection in the form of aerosolized secretions.
- Hematogenous and direct spread are also possible.

### *Geriatric Considerations*

High rates of morbidity and mortality in the elderly

### *Pediatric Considerations*

- Adenoviral infections in children are serious.
- More serious respiratory viral infections are almost always seen in infants and in immunocompromised patients.

### *Pregnancy Considerations*

- Pregnant patients should avoid contact with anyone who has a viral infection.
- Influenza vaccination is recommended for all pregnant women during the influenza season.

## *EPIDEMIOLOGY*

### *Incidence*

- Predominant age: children <5 years
- Predominant sex: male = female

### *Prevalence*

- Prevalence is variable with seasonal outbreaks, but the disease is more common during winter months.

- ÷90% of all cases of childhood pneumonias have a viral cause.
- Between 4% and 39% of pneumonia diagnosed in adults has been attributed to viral causes.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Overall: Influenza A and respiratory syncytial virus (RSV) are the leading causes followed by adenovirus and the parainfluenza viruses:

- Adults
  - Influenza A, B, and C
  - Influenza H1N1
  - Adenovirus
  - Parainfluenza
  - Coronavirus/SARS
- Children
  - Influenza A, B, and C
  - Influenza H1N1
  - Rhinovirus
  - Adenovirus
  - Parainfluenza
  - Rubeola (measles)
  - RSV (particularly for those born prematurely)
- Miscellaneous
  - Cytomegalovirus (CMV) (particularly in immunocompromised patients)
  - Varicella
  - Herpes simplex virus (HSV)
  - Enterovirus
  - Rubeola
  - Epstein-Barr virus
  - Hantavirus
  - Human metapneumovirus

## Genetics

No known genetic pattern has been recognized.

## RISK FACTORS

- Seasonal: epidemic upper respiratory illness
- Living in close quarters
- Recent upper respiratory infection
- Travel to endemic area
- Nonvaccinated person
- Age >65 years or <5 years
- Altered mental status (due to dysphagia)
- Cardiac disease
- Chronic pulmonary disease (e.g., COPD, emphysema)
- Immunocompromised (HIV, transplant recipient, medication-induced)
- Cystic fibrosis
- Kartagener syndrome

## GENERAL PREVENTION

- General hand-hygiene techniques are the first-line prevention in transmission of infectious particles.
- Influenza vaccination: Routine vaccination is now recommended for ALL persons aged <sup>3</sup>6 months.
  - Children who are 6 months to 8 years of age and receiving seasonal vaccination for the *first* time should receive two doses 4 weeks apart.
  - Children who are 6 months to 8 years of age who received two doses of the influenza vaccine should receive one dose of the seasonal influenza vaccine the following year.
  - See the CDC guidelines (1)[A] regarding the use of live attenuated vaccine versus inactivated vaccine.
- For those patients who are unable to receive influenza vaccine (e.g., with an egg allergy or other) and are at very high risk because of age, comorbid illness, or another risk factor, oseltamivir or zanamivir may be used for the duration of the season, with special recognition

for potential viral resistance.

- For those who did not receive the vaccine and have been exposed to influenza, use of oseltamivir or zanamivir is recommended for up to 10 days following exposure.

## COMMONLY ASSOCIATED CONDITIONS

- Rate of mixed viral-bacterial coinfection is  $\div$ 20% and can lead to more severe illness or hospitalization.
- Fungal infection and *Pneumocystis jiroveci* pneumonia in immunocompromised patients

## DIAGNOSIS

### HISTORY

- Gradual onset
- Fever/chills
- Headache
- Myalgias
- Malaise
- Anorexia/decreased feeding in adults/infants
- Cough (with or without purulent sputum production)
- Dyspnea
- Rhinorrhea is predictive (OR 3.52) (2)[B].
- Pharyngitis
- Pleurisy
- Upper abdominal pain in children

### PHYSICAL EXAM

- Fever
- Tachypnea
- Tachycardia
- Hypoxemia with severe disease
- Altered breath sounds (bronchophony, tactile fremitus, whispered pectoriloquy)
- Pulmonary rales and rhonchi

Friction rub

- Possible associated rash (i.e., measles, HSV)

## ***DIFFERENTIAL DIAGNOSIS***

- Bacterial pneumonia (especially atypical etiologies: *Chlamydia pneumoniae* and *C. psittaci*, *Mycoplasma pneumoniae*, *Legionella pneumophila*)
- Pulmonary edema
- *Pneumocystis pneumonia/P. jiroveci* pneumonia
- Aspiration pneumonia
- Hypersensitivity pneumonitis
- Bronchiolitis obliterans, with organizing pneumonia
- Pulmonary embolus/infarction
- Cystic fibrosis (in infants)
- Severe acute respiratory syndrome or severe acute respiratory syndrome-associated coronavirus

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- No standard labs to diagnose viral pneumonia
- Specific lab investigations should be based on the clinical scenario.

### ***Initial Tests (lab, imaging)***

- CBC
  - Normal or near-normal granulocyte count, occasionally leukopenic with increased lymphocyte percentage
  - Hemoconcentration (hantavirus)
- Chest x-ray (CXR)
  - interstitial or alveolar infiltrates
  - peribronchial thickening
- Ground-glass opacities (GGO) are predictive (OR 4.68) (2)[B].
- ESR/CRP may be helpful in children.

## Follow-Up Tests & Special Considerations

Clinicians can also consider additional testing, as clinically indicated:

- Appropriate direct fluorescent antibody or enzyme immunoassay from throat nasopharyngeal washings (children) or swab (adults), tracheal aspirate, or bronchoalveolar lavage specimens (HSV, varicella-zoster virus, influenza viruses A and B, RSV, adenovirus)

P.817

- Viral culture
  - Limitations: Results take 3 to 14 days. False-negative results occur with lower viral titers.
  - Rapid antigen detection: nasopharyngeal swab for rapid influenza testing
  - Cytopathology (cytoplasmic inclusion bodies [CMV], HSV, measles virus)
  - Serology (4-fold rise in acute compared with convalescent titers): Confirm diagnosis retrospectively but not clinically useful.
  - Serologic testing for hantavirus: enzyme immunoassay if available from health departments
  - Polymerase chain reaction (PCR) detection if modality is available:
    - Highly sensitive and specific, but a positive result does not imply causality.
- Sputum Gram stain and culture to identify bacterial copathogens, if present
- Chest CT may show consolidations surrounded by GGOs.

## Diagnostic Procedures/Other

Bronchoscopy with bronchoalveolar lavage

## TREATMENT

- Outpatient treatment for most patients
- Inpatient treatment for infants <4 months of age, elderly or for any patient with diffuse, severe infection (e.g., hypoxemia, hypercarbia, hypotension or shock, acute respiratory distress syndrome [ARDS]) or significant comorbidity (e.g., congestive heart failure [CHF], coronary artery disease, COPD)
- The Pneumonia Severity Index Calculator (3)[A] (<http://www.mdcalc.com/psi-port-score-pneumonia-severity-index-adult-cap/>) may be used to assess the need for hospitalization as well as mortality risk.
- Consider concomitant treatment for bacterial coinfection if severely ill or not responding to

treatment.

## MEDICATION

### First Line

- Influenza viruses A and B
  - Oseltamivir (Tamiflu): adults and children >40 kg, 75 mg PO q12h for 5 days; dosage is adjusted to 75 mg PO q24h in cases where creatinine clearance rate is <30 mL/min. Children <40 kg, weight-based effectiveness is maximal when started within 48 hours of symptom onset.
  - Zanamivir (Relenza): patients >7 years of age, 2 inhalations (10 mg) q12h for 5 days
    - Shown to shorten symptoms by ÷12 hours but not risk of complications (4)[B]
- Varicella-zoster virus
  - Acyclovir
    - Adults: for immunocompetent patients, 800 mg PO 5 times per day for 5 to 7 days
    - Children >2 years: for immunocompetent patients, 80 mg/kg/day PO divided q6h for 5 days. Start within 24 hours of symptom onset; immunocompromised patients 30 mg/kg/day PO divided q6h for 5 days. Start within 24 hours of symptom onset; immunocompromised patients 30 mg/kg/day IV divided q8h for 7 to 10 days.
- CMV or HSV
  - Acyclovir
    - Immunocompromised adults: 5 mg/kg IV q8h for 7 days
    - Children: Contact an infectious disease specialist or an experienced pharmacist regarding dosing.
  - Ganciclovir: Use should be in conjunction with infectious disease consultation.
- RSV
  - Ribavirin: Indicated in few, select cases (20 mg/mL via continuous aerosol administration for 12 to 18 hr/day for 3 to 7 days). Ribavirin is teratogenic and should not be administered by pregnant health care personnel: Its cost is high and benefits are marginal.

### Second Line

- Influenza: Amantadine and rimantadine are no longer recommended due to high levels of

resistance among circulating influenza A viruses (5)[B].

- Influenza: Peramivir 600 mg for 1 dose is an IV formulation available for acute illness in hospitalized patients (1).
- CMV, HSV, varicella virus infections
  - Foscarnet (Foscavir): 60 mg/kg/dose IV q8h in conjunction with infectious disease consultation

## **GENERAL MEASURES**

- Most healthy individuals will only require symptomatic treatment.
- Encourage coughing and deep breathing exercises to clear secretions.
- Careful disposal of secretions/universal precautions.
- Hydration
- Respiratory isolation with negative pressure room for varicella virus, which is highly contagious

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Physical exams
- Repeat a CXR only if warranted by clinical presentation. A CXR may take weeks to resolve after clinical illness has resolved.
- Oxygenation if illness severe enough for hospitalization

### ***PATIENT EDUCATION***

- For patient education materials on this topic, contact American Lung Association, 1301 Pennsylvania Avenue, NW, Suite 800, Washington, DC 20004; 800-LUNG-USA
- Centers for Disease Control and Prevention. Seasonal influenza (flu). <http://www.cdc.gov/flu/>

### ***PROGNOSIS***

- Usually favorable prognosis, with illness lasting several days to a week
- Postviral fatigue is common.

- Death can occur, especially in pediatric or bone marrow transplant recipients with adenovirus infections or in older people with influenza.
- The 2009 H1N1 influenza pandemic resulted in higher-than-usual mortality rates among the pediatric, young adult, and pregnant populations.

## COMPLICATIONS

- Superimposed bacterial infections, such as *Streptococcus pneumoniae*, *Staphylococcus aureus*, *Haemophilus influenzae*, and others
- Respiratory failure requiring mechanical ventilation
- ARDS
- Reye syndrome after influenza in children (avoid aspirin)

## Clinical Pearls

**&NA;**

- Laboratory testing may confirm the diagnosis of viral pneumonia, but this may not change therapy and must not replace clinical judgment.
- Influenza vaccination is recommended for all persons age <sup>3</sup>6 months.
- Most patients recover with conservative therapy.
- Monitor for concomitant bacterial infections.
- Amantadine and rimantadine are no longer recommended for use against influenza.

# Polyarteritis Nodosa

Katherine S. Upchurch, MD

Rajandeep S. Paik, MD

## BASICS

### DESCRIPTION

- Polyarteritis nodosa (PAN) is an antineutrophil cytoplasmic antibody (ANCA)-negative necrotizing arteritis of medium or small arteries without glomerulonephritis or vasculitis of arterioles, capillaries, or venules (1).
- Involved systems include GI tract, peripheral nervous system (sensory and motor), central nervous system (CNS), renal (without glomerulonephritis), skin, testes/epididymis, heart (1,2,3)
- Features depend on location of vasculitis: mesenteric ischemia-related symptoms, new onset or worsening hypertension, mononeuritis multiplex, purpuric or nodular skin lesions, or livedo reticularis (3).
- Renal disease in PAN usually manifests as hypertension (HTN) and mild proteinuria with/without azotemia. Renal infarction may occur (3).
- PAN formerly encompassed several distinct entities (classic PAN, microscopic PAN, cutaneous PAN). With the advent of ANCA testing, microscopic PAN appears unrelated to the other two, pathophysiologically.
  - Patients with classic PAN are *typically ANCA-negative* (1,4).
  - Patients with microscopic PAN have ANCAs directed against myeloperoxidase (MPO) and (generally) involvement of small arterioles (microscopic polyangiitis [MPA]). This is now classified as ANCA-associated vasculitis (1).
  - Cutaneous (or limited) PAN is a chronic disease with cutaneous lesions with characteristic histopathologic features of PAN. There are few systemic manifestations, although myalgias and peripheral motor neuropathy (mononeuritis multiplex) or sensory neuropathy may be present. ANCA positivity is variable (5).
- Synonym(s): periarteritis; panarteritis; necrotizing arteritis

### EPIDEMIOLOGY

## *Incidence*

- Predominant age: Peak onset is in the 5th to 6th decade; incidence rises with age.
- 1.5:1 male predominance (6)

## *Prevalence*

Rare: 2 to 33 cases/1 million adults (6)

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Segmental, transmural, necrotizing inflammation of medium and small muscular arteries, with intimal proliferation, thrombosis, and ischemia of the organ/tissue supplied by the affected arteries. Aneurysm formation at vessel bifurcations (3)
- Hepatitis B-related PAN results in direct injury to the vessel due to viral replication or deposition of immune complexes, with complement activation and subsequent inflammatory response (3).
- Most cases are idiopathic; 20% are related to hepatitis B or C infection (7).
- In patients with PAN and hepatitis B, HBsAg has been recovered from involved vessel walls (7).

## *Genetics*

Mutations of adenosine deaminase 2 (ADA 2) have been identified in families with PAN (8).

## **RISK FACTORS**

Hepatitis B infection >> hepatitis C infection (cutaneous PAN) (7)

## **COMMONLY ASSOCIATED CONDITIONS**

- Hepatitis B (strong association with classic PAN) (7)
- Hepatitis C (less strongly linked to cutaneous PAN)
- Hairy cell leukemia
- 27 existing case reports of systemic PAN following hepatitis B vaccination (9)
- Minocycline (symptoms resolve on stopping drug, reoccur if rechallenged) (10)
- Case reports also associating PAN with CMV infection, amphetamines, and interferon (11)

## DIAGNOSIS

There are no formal diagnostic criteria for PAN (1,3). Suspect PAN in patients with the following:

- Acute, sometimes fulminant multisystem disease with a relatively short prodrome (i.e., weeks to months)
- Vasculitic skin rash with sensorimotor symptoms/findings
- Recent-onset HTN with systemic symptoms
- Unexplained sensory and/or motor neuropathy with systemic symptoms
- Hepatitis B infection with multisystem disease

## HISTORY

General: systemic symptoms with multiorgan involvement (3)

- Constitutional symptoms (fever, weight loss, malaise)
- Organ-specific symptoms
  - Focal muscular weakness/extremity numbness
  - Myalgia and arthralgia
  - Rash
  - Recurrent postprandial pain, intestinal angina, nausea, vomiting, and bleeding
  - Altered mental status, headaches, mononeuritis multiplex
  - Testicular/epididymal pain, neurogenic bladder (rare)

## PHYSICAL EXAM

Related to involved organ system (may dominate clinical picture and course) (2,3)

- Peripheral nervous system: peripheral neuropathy
- Renal: HTN
- Skin: purpura, urticaria, polymorphic rashes, subcutaneous nodules (uncommon, but characteristic), livedo reticularis; deep skin ulcers, especially in lower extremities; Raynaud phenomenon (rare); single digit gangrene (rare)
- GI: acute abdomen; rebound, guarding, tenderness
- CNS: seizures, altered mental status, papillitis
- Lung: signs of pleural effusion—dullness to percussion; decreased breath sounds
