- Dedication
- Preface
- Evidence-Based Medicine
- Acknowledgments

TABLE OF CONTENTS

- Diagnosis and Treatment: An Algorithmic Approach
- Abnormal (Dysfunctional) Uterine Bleeding
- Abnormal Pap and Cervical Dysplasia
- Abortion, Spontaneous (Miscarriage)
- Acetaminophen Poisoning
- ACL Injury
- Acne Rosacea
- Acne Vulgaris
- Acute Coronary Syndromes: NSTEMI-ACS (Unstable Angina and NSTEMI)
- Acute Coronary Syndromes: STEMI
- Acute Kidney Injury
- Addison Disease
- Adenomyosis
- Adenovirus Infections
- Adhesive Capsulitis (Frozen Shoulder)
- Adoption, International
- Alcohol Abuse and Dependence
- Alcohol Withdrawal
- Alopecia
- Alzheimer Disease
- Amenorrhea
- Anal Fissure
- Anemia, Aplastic
- Anemia, Chronic Disease
- Anemia, Iron Deficiency
- Anemia, Sickle Cell
- Aneurysm of the Abdominal Aorta

- Angioedema
- Ankle Fractures
- Ankylosing Spondylitis
- Anorectal Fistula
- Anorexia Nervosa
- Antiphospholipid Antibody Syndrome
- Antithrombin Deficiency
- Anxiety (Generalized Anxiety Disorder)
- Aortic Valvular Stenosis
- Appendicitis, Acute
- Arteritis, Temporal
- Arthritis, Juvenile Idiopathic
- Arthritis, Rheumatoid (RA)
- Arthritis, Septic
- Arthropod Bites and Stings
- Ascites
- Asthma
- Atelectasis
- Atrial Fibrillation and Atrial Flutter
- Atrial Septal Defect
- Attention Deficit/Hyperactivity Disorder, Adult
- Attention Deficit/Hyperactivity Disorder, Pediatric
- Atypical Mole (Dysplastic Nevus) Syndrome
- Autism Spectrum Disorders
- Babesiosis
- Back Pain, Low
- Bacteriuria, Asymptomatic
- Balanitis, Phimosis, and Paraphimosis
- Barotrauma of the Middle Ear, Sinuses, and Lung
- Barrett Esophagus
- Basal Cell Carcinoma
- Bed Bugs
- Behavioral Problems, Pediatric
- Bell Palsy

- Bipolar I Disorder
- Bipolar II Disorder
- Bites, Animal and Human
- Bladder Cancer
- Blepharitis
- Borderline Personality Disorder
- Brain Injury, Traumatic
- Breast Abscess
- Breast Cancer
- Breastfeeding
- Bronchiectasis
- Bronchiolitis
- Bronchitis, Acute
- Bulimia Nervosa
- Bunion (Hallux Valgus)
- Burns
- Bursitis, Pes Anserine (Pes Anserine Syndrome)
- Candidiasis, Mucocutaneous
- Carbon Monoxide Poisoning
- Cardiomyopathy
- Carotid Stenosis
- Carpal Tunnel Syndrome
- Cataract
- Celiac Disease
- Cellulitis
- Cellulitis, Orbital
- Cellulitis, Periorbital
- Cerebral Palsy
- Cervical Hyperextension Injuries
- Cervical Malignancy
- Cervicitis, Ectropion, and True Erosion
- Chickenpox (Varicella Zoster)
- Child Abuse
- Chlamydia Infection (Sexually Transmitted)
- Chlamydomydia Pneumoniae

- Cholelithiasis
- Chronic Cough
- Chronic Fatigue Syndrome
- Chronic Kidney Disease
- Chronic Obstructive Pulmonary Disease and Emphysema
- Chronic Pain Management: An Evidence-Based Approach
- Cirrhosis of the Liver
- CLOSTRIDIUM DIFFICILE INFECTION
- Colic, Infantile
- Colitis, Ischemic
- Colonic Polyps
- Colorectal Cancer
- Complementary and Alternative Medicine
- Complex Regional Pain Syndrome
- Condylomata Acuminata
- Conjunctivitis, Acute
- Constipation
- Contraception
- Cor Pulmonale
- Corneal Abrasion and Ulceration
- Corns and Calluses
- Coronary Artery Disease and Stable Angina
- Costochondritis
- Counseling Types
- Crohn Disease
- Croup (Laryngotracheobronchitis)
- Cryptogenic Organizing Pneumonia
- Cryptorchidism
- Cushing Disease and Cushing Syndrome
- Cutaneous Drug Reactions
- Cystic Fibrosis
- De Quervain Tenosynovitis
- Deep Vein Thrombophlebitis
- Dehydration
- Delayed Sleep-Wake Phase Disorder (DSWPD)

- Delirium
- Dementia
- Dementia, Vascular
- Dental Infection
- Depression
- Depression, Adolescent
- Depression, Geriatric
- Depression, Postpartum
- Depression, Treatment Resistant
- Dermatitis Herpetiformis
- Dermatitis, Atopic
- Dermatitis, Contact
- Dermatitis, Diaper
- Dermatitis, Seborrheic
- Dermatitis, Stasis
- Diabetes Mellitus, Type 1
- Diabetes Mellitus, Type 2
- Diabetic Ketoacidosis
- Diabetic Polyneuropathy
- Diarrhea, Acute
- Diarrhea, Chronic
- Diffuse Interstitial Lung Disease
- Diverticular Disease
- Domestic Violence
- Down Syndrome
- Drug Abuse, Prescription
- Ductal Carcinoma in Situ
- Dupuytren Contracture
- Dyshidrosis
- Dysmenorrhea
- Dyspareunia
- Dyspepsia, Functional
- Dysphagia
- Ectopic Pregnancy

- Ejaculatory Disorders
- Elder Abuse
- Encopresis
- Endocarditis, Infective
- Endometrial Cancer and Uterine Sarcoma
- Endometriosis
- Endometritis and Other Postpartum Infections
- Enuresis
- Eosinophilic Esophagitis
- Epicondylitis
- Epididymitis
- Episcleritis
- Epistaxis
- Erectile Dysfunction
- Erysipelas
- Erythema Multiforme
- Erythema Nodosum
- Esophageal Varices
- Essential Tremor Syndrome
- Eustachian Tube Dysfunction
- Factor V Leiden
- Failure to Thrive
- Female Athlete Triad
- Fever of Unknown Origin (FUO)
- Fibrocystic Changes of the Breast
- Fibromyalgia
- Folliculitis
- Food Allergy
- Food Poisoning, Bacterial
- Frostbite
- Furunculosis
- Galactorrhea
- Gambling Addiction
- Ganglion Cyst
- Gastritis

- Gastroesophageal Reflux Disease
- Genito-Pelvic Pain/Penetration Disorder (Vaginismus)
- Giardiasis
- Gilbert Disease
- Gingivitis
- Glaucoma, Primary Closed-Angle
- Glaucoma, Primary Open-Angle
- Glomerulonephritis, Acute
- Glomerulonephritis, Postinfectious
- Glucose Intolerance
- Gonococcal Infections
- Gout
- Granuloma Annulare
- Granuloma, Pyogenic
- Graves Disease
- Guillain-Barré Syndrome
- Gynecomastia
- Hammer Toes
- Hand-Foot-and-Mouth Disease
- Headache, Cluster
- Headache, Migraine
- Headache, Tension
- Hearing Loss
- Heart Failure, Acutely Decompensated
- Heart Failure, Chronic
- Heat Exhaustion and Heat Stroke
- Hematuria
- Hemochromatosis
- Hemophilia
- Hemorrhoids
- Henoch-Schönlein Purpura
- Heparin-Induced Thrombocytopenia
- Hepatic Encephalopathy
- Hepatitis A
- Hepatitis B

- Hepatitis C
- Hernia
- Herpes Eye Infections
- Herpes Simplex
- Herpes Zoster (Shingles)
- Herpes, Genital
- Hiccups
- Hidradenitis Suppurativa
- Hirsutism
- HIV/Aids
- Hodgkin Lymphoma
- Homelessness
- Hordeolum (Stye)
- Horner Syndrome
- Hydrocele
- Hydrocephalus, Normal Pressure
- Hydronephrosis
- Hypercholesterolemia
- Hyperemesis Gravidarum
- Hyperkalemia
- Hyponatremia
- Hyperparathyroidism
- Hyperprolactinemia
- Hypersensitivity Pneumonitis
- Hypersplenism
- Hypertension, Essential
- Hypertension, Secondary and Resistant
- Hyperthyroidism
- Hypertriglyceridemia
- Hypoglycemia, Diabetic
- Hypoglycemia, Nondiabetic
- Hypokalemia
- Hyponatremia
- Hypoparathyroidism

- Hypothermia
- Hypothyroidism, Adult
- ID Reaction
- Immune Thrombocytopenia (ITP)
- Impetigo
- Incontinence, Fecal
- Incontinence, Urinary Adult Female
- Incontinence, Urinary Adult Male
- Infectious Mononucleosis, Epstein-Barr Virus Infections
- Infertility
- Influenza
- Ingrown Toenail
- Injury and Violence
- Insomnia
- Intellectual Disability (Intellectual Developmental Disorder)
- Interstitial Cystitis
- Interstitial Nephritis
- Irritable Bowel Syndrome
- Kawasaki Syndrome
- Keratoacanthoma
- Keratosis, Actinic
- Keratosis, Seborrheic
- Knee Pain
- Labyrinthitis
- Lacrimal Disorders (Dry Eye Syndrome)
- Lactose Intolerance
- Laryngitis
- Laxative Abuse
- Lead Poisoning
- Legionnaires' Disease
- Leukemia, Acute Lymphoblastic in Adults (ALL)
- Leukemia, Acute Myeloid
- Leukemia, Chronic Lymphocytic
- Leukemia, Chronic Myelogenous
- Leukoplakia, Oral

- Lichen Planus
- Lichen Simplex Chronicus
- Lipoma
- Long QT Interval
- Lung, Primary Malignancies
- Lupus Erythematosus, Systemic (SLE)
- Lupus Nephritis
- Lyme Disease
- Lymphangitis
- Lymphedema
- Macular Degeneration, Age-Related
- Malaria
- Marfan Syndrome
- Marijuana (Cannabis) Use Disorder
- Mastalgia
- Mastitis
- Mastoiditis
- Measles (Rubeola)
- Measles, German (Rubella)
- Medial Tibial Stress Syndrome (MTSS)/Shin Splints
- Melanoma
- Ménière Disease
- Meningitis, Bacterial
- Meningitis, Viral
- Meningococcal Disease
- Meniscal Injury
- Menopause
- Menorrhagia (Heavy Menstrual Bleeding)
- Mesenteric Adenitis
- Mesothelioma
- Metabolic Syndrome
- Metatarsalgia
- Methicillin-Resistant Staphylococcus Aureus (MRSA) Skin Infections
- Mild Cognitive Impairment
- Mitral Regurgitation

- Mitral Stenosis
- Mitral Valve Prolapse
- Molluscum Contagiosum
- Morton Neuroma (Interdigital Neuroma)
- Motion Sickness
- Multiple Myeloma
- Multiple Sclerosis
- Mumps
- Muscular Dystrophy
- Myasthenia Gravis
- Myelodysplastic Syndromes
- Myeloproliferative Neoplasms
- Narcolepsy
- Nasal Polyps
- Near Drowning/Nonfatal Drowning
- Nephrotic Syndrome
- Neurofibromatosis Type 1
- Neuropathic Pain
- Neuropathy, Peripheral
- Nicotine Addiction
- Nonalcoholic Fatty Liver Disease (NAFLD)
- Nosocomial Infections
- Obesity
- Obsessive-Compulsive Disorder (OCD)
- Ocular Chemical Burns
- Onychomycosis
- Optic Neuritis
- Osgood-Schlatter Disease (Tibial Apophysitis)
- Osteoarthritis
- Osteomyelitis
- Osteoporosis
- Otitis Externa
- Otitis Media
- Otitis Media with Effusion

- Ovarian Cancer
- Ovarian Cyst, Ruptured
- Ovarian Tumor (Benign)
- Palliative Care
- Pancreatic Cancer
- Pancreatitis, Acute
- Pancreatitis, Chronic
- Panic Disorder
- Parkinson Disease
- Paronychia
- Parotitis, Acute and Chronic
- Parvovirus B19 Infection
- Patellofemoral Pain Syndrome
- Pediculosis (Lice)
- Pelvic Inflammatory Disease
- Pemphigoid, Bullous
- Pemphigus Vulgaris
- Peptic Ulcer Disease
- Perforated Tympanic Membrane
- Pericarditis
- Periodic Limb Movement Disorder
- Perioral Dermatitis
- Peripheral Arterial Disease
- Peritonitis, Acute
- Personality Disorders
- Pertussis
- Pharyngitis
- Pilonidal Disease
- Pinworms
- Pituitary Adenoma
- Plantar Fasciitis
- Pleural Effusion
- Pneumonia, Bacterial
- Pneumonia, Mycoplasma
- Pneumonia, Pneumocystis Jiroveci

- Pneumonia, Viral
- Polyarteritis Nodosa
- Polycystic Kidney Disease
- Polycystic Ovarian Syndrome (PCOS)
- Polycythemia Vera
- Polymyalgia Rheumatica
- Polymyositis/Dermatomyositis
- Popliteal (Baker) Cyst
- Portal Hypertension
- Postconcussion Syndrome (Mild Traumatic Brain Injury)
- Posttraumatic Stress Disorder (PTSD)
- Preeclampsia and Eclampsia (Toxemia of Pregnancy)
- Premenstrual Syndrome (PMS) and Premenstrual Dysphoric Disorder (PMDD)
- Prenatal Care and Testing
- Preoperative Evaluation of the Noncardiac Surgical Patient
- Presbycusis
- Pressure Ulcer
- Preterm Labor
- Priapism
- Prostate Cancer
- Prostatic Hyperplasia, Benign (BPH)
- Prostatitis
- Protein C Deficiency
- Protein S Deficiency
- Proteinuria
- Prothrombin 20210 (Mutation)
- Pruritus Ani
- Pruritus Vulvae
- Pseudofolliculitis Barbae
- Pseudogout (Calcium Pyrophosphate Dihydrate)
- Psoriasis
- Psychosis
- Pulmonary Arterial Hypertension
- Pulmonary Edema
- Pulmonary Embolism

- Pulmonary Fibrosis
- PYELONEPHRITIS
- Pyloric Stenosis
- Rabies
- Rape Crisis Syndrome
- Raynaud Phenomenon
- Reactive Arthritis (Reiter Syndrome)
- Refractive Errors
- Renal Tubular Acidosis
- Respiratory Distress Syndrome, Acute (ARDS)
- Respiratory Distress Syndrome, Neonatal
- Respiratory Syncytial Virus Infection
- Restless Legs Syndrome
- Retinal Detachment
- Retinopathy, Diabetic
- Reye Syndrome
- Rh Incompatibility
- Rhabdomyolysis
- Rhabdomyosarcoma
- Rheumatic Fever
- Rhinitis, Allergic
- Rocky Mountain Spotted Fever
- Roseola
- Rotator Cuff Impingement Syndrome
- Salivary Gland Calculi/Sialadenitis
- Salmonella Infection
- Sarcoidosis
- Scabies
- Scarlet Fever
- Schizophrenia
- Sciwora Syndrome (Spinal Cord Injury Without Radiologic Abnormality)
- Scleritis
- Scleroderma
- Seasonal Affective Disorder

- Seizure Disorder, Absence
- Seizure Disorder, Partial
- Seizures, Febrile
- Sepsis
- Serotonin Syndrome
- Sexual Dysfunction in Women
- Shoulder Pain
- Sinusitis
- Sjögren Syndrome
- Sleep Apnea, Obstructive
- Sleep Disorder, Shift Work
- Smell and Taste Disorders
- Somatic Symptom (Somatization) Disorder
- Spinal Stenosis
- Sprain, Ankle
- Sprains and Strains
- Squamous Cell Carcinoma, Cutaneous
- Stevens-Johnson Syndrome
- Stress Fracture
- Stroke Rehabilitation
- Stroke, Acute
- Subconjunctival Hemorrhage
- Substance Use Disorders
- Suicide
- Superficial Thrombophlebitis
- Syncope
- Syncope, Reflex (Vasovagal Syncope)
- Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH)
- Syphilis
- Tarsal Tunnel Syndrome
- Teething
- Telogen Effluvium
- Temporomandibular Joint Disorder (TMD)
- Testicular Malignancies
- Testicular Torsion

- Testosterone Deficiency
- Thalassemia
- Thoracic Outlet Syndrome
- Thrombophilia and Hypercoagulable States
- Thrombotic Thrombocytopenic Purpura
- Thyroid Malignant Neoplasia
- Thyroiditis
- Tinea (Capitis, Corporis, Cruris)
- Tinea Pedis
- Tinea Versicolor
- Tinnitus
- Tobacco Use and Smoking Cessation
- Tourette Syndrome
- Toxoplasmosis
- Tracheitis, Bacterial
- TRANSIENT ISCHEMIC ATTACK (TIA)
- Transient Stress Cardiomyopathy
- Trichomoniasis
- Trichotillomania
- Trigeminal Neuralgia
- Trigger Finger (Digital Stenosing Tenosynovitis)
- Trochanteric Bursitis (Greater Trochanteric Pain Syndrome)
- Tuberculosis
- TUBERCULOSIS, LATENT (LTBI)
- Typhoid Fever
- Typhus Fevers
- Ulcer, Aphthous
- Ulcerative Colitis
- Upper Respiratory Infection (URI)
- Urethritis
- Urinary Tract Infection (UTI) in Females
- Urinary Tract Infection (UTI) in Males
- Urolithiasis
- Urticaria
- Uterine and Pelvic Organ Prolapse

- Uterine Myomas
- Uveitis
- Vaginal Adenosis
- Vaginal Bleeding During Pregnancy
- Vaginal Malignancy
- Vaginitis and Vaginosis
- Varicose Veins
- Vasculitis
- Venous Insufficiency Ulcers
- Ventricular Septal Defect
- Vertigo
- Vertigo, Benign Paroxysmal Positional (BPPV)
- Vincent Stomatitis
- Vitamin B12 Deficiency
- Vitamin D Deficiency
- Vitamin Deficiency
- Vitiligo
- Vocal Cord Dysfunction
- Von Willebrand Disease
- Vulvar Malignancy
- Vulvodynia
- Vulvovaginitis, Estrogen Deficient
- Vulvovaginitis, Prepubescent
- Warts
- Wilms Tumor
- Zollinger-Ellison Syndrome

## Editor-in-Chief

### **Frank J. Domino MD**

*Professor and Director of Predoctoral Education  
Department of Family Medicine and Community Health  
University of Massachusetts Medical School  
Worcester, Massachusetts*

## Associate Editors

### **Robert A. Baldor, MD, FAAFP**

*Professor and Senior Vice-Chairman  
Department of Family Medicine and Community Health  
University of Massachusetts Medical School  
Worcester, Massachusetts*

### **Jeremy Golding, MD, FAAFP**

*Professor of Family Medicine and Obstetrics & Gynecology  
University of Massachusetts Medical School  
Quality Officer  
Department of Family Medicine and Community Health  
University of Massachusetts Memorial Health Care  
Hahnemann Family Health Center  
Worcester, Massachusetts*

### **Mark B. Stephens, MD, MS, FAAFP, CAPT, MC, USN**

*Professor and Chair  
Department of Family Medicine  
Uniformed Services University  
Bethesda, Maryland*

## Contributing Authors

### **Adil Abdalla, MD**

*Department of Gastroenterology  
CHI Health  
Omaha, Nebraska*

**Basmah Abdalla, MD**

*Clinical Instructor*

*Kidney Transplant Program*

*Department of Medicine*

*David Geffen School of Medicine at UCLA*

*Los Angeles, California*

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United States Government.*

**Thomas L. Abell, MD**

*Arthur M. Schoen, MD Chair in*

*Gastroenterology*

*Department of Gastroenterology*

*University of Louisville*

*Louisville, Kentucky*

**Alain Michael P. Abellada, MD**

*Medical Director*

*Family Medicine Hospitalist Service*

*Blanchfield Army Community Hospital*

*Fort Campbell, Kentucky*

**George M. Abraham, MD, MPH**

*Associate Chief of Medicine*

*Saint Vincent Hospital*

*Professor of Medicine*

*University of Massachusetts Medical School*

*Worcester, Massachusetts*

**Mohammed Abunada, MD**

*Colorectal Surgeon*

*Hamad Medical Corporation*

*Doha, Qatar*

**Anne Claire Adams, MD**

*Family Medicine Resident*

*Department of Family Medicine*

*The Christ Hospital  
University of Cincinnati College of  
Medicine  
Cincinnati, Ohio*

**Rae Adams, MD**

*Associate Professor of Family and  
Community Medicine  
Texas A&M Health Science Center  
College of Medicine  
Bryan, Texas*

**Faraz Ahmad, MD**

*Family Medicine Resident  
Preventative Medicine Resident  
Family Medicine Residency Program  
Department of Family Medicine and  
Community Health  
University Hospitals Case Medical Center  
Cleveland, Ohio*

**Nadir Ahmad, MD, FACS**

*Division Head  
Otolaryngology-Head & Neck Surgery  
Associate Professor  
Director  
Head & Neck Cancer Program  
Cooper University Health Care  
MD Anderson at Cooper Cancer Center  
Cooper Medical School of Rowan University  
Camden, New Jersey*

**Shahla Ahmad, MD**

*Family and Community Medicine Resident  
Department of Family and Community  
Medicine  
Penn State Milton S. Hershey Medical  
Center  
Penn State College of Medicine*

*Hershey, Pennsylvania*

**Sumera R. Ahmad, MD**

*Pulmonary and Critical Care Fellow  
Department of Pulmonary and Critical  
Care  
University of Massachusetts Memorial  
Medical Center  
Worcester, Massachusetts*

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United States Government.*

**Yasir Ahmed, MD**

*Resident  
Penn State Hershey Eye Center  
Penn State College of Medicine  
Hershey, Pennsylvania*

**Jowhara Al-Qahtani, MD**

*General Surgery Resident  
Maimonides Medical Center  
Brooklyn, New York*

**Bedoor Alabbas, MD**

*George Washington University Hospital  
Washington, DC*

**Gillian Alex, MD**

*Surgery Resident  
Rush University Medical Center  
Chicago, Illinois*

**Andrew G. Alexander, MD**

*Assistant Clinical Professor of Family  
Medicine  
University of California, Riverside School  
of Medicine*

*Riverside, California*

**Mohammed Algod, MD**

*Clinical Study Supervisor  
Cardiology  
Montefiore Medical Center  
Bronx, New York*

**Fozia Akhtar Ali, MD**

*Assistant Professor/Clinical  
Department of Family and Community  
Medicine  
University of Texas Health Science  
Center at San Antonio  
San Antonio, Texas*

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United States Government.*

**Jason B. Alisangco, DO, FAAFP**

*Sports Medicine Fellow  
Fort Belvoir Community Hospital  
Fort Belvoir, Virginia*

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United States Government.*

**Shahriar Alizadegan, MD**

*Medical College of Wisconsin  
Milwaukee, Wisconsin*

**Andrew S. Allegretti, MD**

*Fellow in Nephrology  
Division of Nephrology  
Brigham and Women's Hospital  
Massachusetts General Hospital  
Harvard Medical School*

*Boston, Massachusetts*

**J. Aaron Allgood, DO**

*Assistant Professor*

*Clinical Medicine and Public Health*

*A.T. Still University School of Osteopathic  
Medicine*

*Mesa, Arizona*

**Richard W. Allinson, MD**

*Associate Professor*

*Department of Surgery*

*The Texas A&M University System Health  
Sciences Center*

*Senior Staff Physician*

*Baylor Scott & White Clinic*

*Waco, Texas*

**Ziad Alnabki, MD**

*Fellow*

*University of Louisville*

*Louisville, Kentucky*

**Melanie Dawn Altizer, MD**

*Assistant Professor*

*Department of Obstetrics and Gynecology*

*Carilion Clinic*

*Roanoke, Virginia*

**Angelic M. Alvarez, MD**

*Resident*

*Universidad Central del Este College of  
Medicine*

*San Pedro de Macoris, Dominican  
Republic*

**Felix N. Alvarez, MD**

*Internal Medicine Hospitalist*

*Yuma Regional Medical Center*

Yuma, Arizona

**Crystal Amadi, MD**

*Resident Physician*

*Department of Family and Community  
Medicine*

*University of Texas Health Science*

*Center at San Antonio*

*San Antonio, Texas*

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United States Government.*

**David L. Anderson, MD**

*Resident Physician*

*Department of Family Medicine*

*Dwight D. Eisenhower Army Medical  
Center*

*Augusta, Georgia*

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United States Government.*

**Garland Edward Anderson II, MD**

*Clinical Instructor of Family Medicine*

*Rural Family Medicine Program*

*Louisiana State University*

*Our Lady of the Angels Hospital*

*Bogalusa, Louisiana*

**Jennifer Anderson, PharmD**

*Oncology Pharmacy Resident*

*University of Illinois at Chicago College  
of Pharmacy*

*Chicago, Illinois*

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United*

*States Government.*

**Roger Allan Anderson, MD**

*Staff Ophthalmologist  
Department of Ophthalmology  
Madigan Army Medical Center  
Tacoma, Washington*

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United States Government.*

**Adam Anglyn, DO**

*Campbell University College of  
Osteopathic Medicine  
Lumberton, North Carolina*

**Tanya E. Anim, MD**

*Fellow in Women's Health with Obstetrics  
Focus  
Florida Hospital Family Medicine  
Residency Program  
Winter Park, Florida*

**Shari Anthony, MD**

*Resident  
Department of Family Medicine  
Bayfront Family Health Center  
St. Petersburg, Florida*

**Tad Antognini, MD**

*University of Massachusetts Medical  
School  
Worcester, Massachusetts*

**Kashif S. Anwar, MD**

*Physician  
Department of Family Medicine  
University Hospitals Portage Medical*

Center  
Ravenna, Ohio

**Michael Apostolis, MD**

Department of Pulmonology  
St. Elizabeth Youngstown Hospital  
Youngstown, Ohio

**Paul M. Arguin, MD**

Captain  
United States Public Health Service  
Chief, Domestic Unit  
Malaria Branch  
Center for Global Health  
Centers for Disease Control and Prevention  
Atlanta, Georgia

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United States Government.*

**Michael Argyle, DO**

Resident  
David Grant USAF Medical Center  
Travis Air Force Base, California

**Forest W. Arnold, DO, MSc**

Associate Professor and Hospital  
Epidemiologist  
Division of Infectious Diseases  
University of Louisville School of Medicine  
Louisville, Kentucky

**James J. Arnold, DO, FAAFP**

Senior Associate Program Director  
National Capital Consortium Family  
Medicine Residency  
Fort Belvoir Community Hospital  
Fort Belvoir, Virginia

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United States Government.*

*Department Head, Branch Health Clinic  
United States Naval Hospital  
United States Navy  
Naples, Italy*

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United States Government.*

**Aneel A. Ashrani, MD, MS**

*Assistant Professor  
Division of Hematology  
Department of Internal Medicine  
Mayo Clinic  
Rochester, Minnesota*

**Anne R. Atalig, MD, CPT**

*Department of Family Medicine  
Dwight D. Eisenhower Army Medical  
Center  
Fort Gordon, Georgia*

*The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, the Department of Defense, or the United States Government.*

**Patricia Ruth Atchinson, DO**

*Emergency Medicine Resident  
Dartmouth Hitchcock Medical Center  
Lebanon, New Hampshire*

**Carlos Atore, MD**

*Dell Medical School, University of Texas  
at Austin*

*Austin, Texas*

**Maximos Attia, MD**

*Clinical Assistant Professor  
Guthrie/Robert Packer Hospital Family  
Medicine Residency Program  
Medical Director  
Walk-in Clinic and Anti-coagulation  
Clinics  
Sayre, Pennsylvania*

**Stephen E. Auciello, MD**

*Resident Physician  
Family Medicine Residency Program  
OhioHealth Riverside Methodist Hospital  
Columbus, Ohio*

**Sudeep K. Aulakh, MD, FACP, FRCPC**

*Director of Ambulatory Education  
Baystate Internal Medicine Residency  
Co-Director of Baystate Primary Care  
Residency  
Assistant Professor of Medicine  
Baystate Health Medical Center  
Tufts University School of Medicine  
Springfield, Massachusetts*

**Gerard P. Aurigemma, MD**

*Professor of Medicine and Radiology  
University of Massachusetts Medical School  
Director, Noninvasive Cardiology  
University of Massachusetts Memorial  
Medical Center  
Worcester, Massachusetts*

**Philip H. Aurigemma, MD**

*Orthopedic Surgery Resident  
Department of Orthopedic Surgery and  
Rehabilitation*

*University of Massachusetts Medical School  
Worcester, Massachusetts*

**Swati Avashia, MD, FAAP**

*Assistant Professor of Medicine*

*Department of Internal Medicine/Pediatrics/Integrative and Holistic  
Medicine*

*Family Medicine Residency Program*

*Dell Medical School, University of Texas*

*at Austin*

*Austin, Texas*

*The views expressed are those of the authors and do not reflect the official policy of the  
Department of the Army, Department of the Navy, the Department of Defense, or the United  
States Government.*

**Nida S. Awadallah, MD**

*Assistant Clinical Professor*

*Department of Family Medicine*

*Rose Family Medicine Residency*

*University of Colorado*

*Denver, Colorado*

**Jennifer L. Ayres, PhD**

*Director of Behavioral Health Services*

# Dedication

*Deciding how to apply medical data to an individual requires us to develop an approach, a method, to delivering a population-based science to an individual. We learned this method from someone, a wise mentor, in our past. In medical school, my mentor was a pediatric surgeon; in my current world, my mentors are my good friends and colleagues. We sit around a coffee or meal and challenge each other's approaches and absorb some of their vision in the process.*

*This year's 5-Minute Clinical Consult is dedicated to our mentors in medicine. Our mentors in life deserve our gratitude for our personal development. Our mentors in medicine deserve our gratitude every time we sit with a patient.*

*A very good friend (and mentor) has a saying, "Don't wait for the eulogy." Not tomorrow, but today, give your medical mentor a call, or drop a note (ideally on paper, but email if you must), and say thanks. Thanks for their influence on you, and thanks from your patients for helping them get the great care you provide.*

*Now pay it forward. Expand your role as a mentor. Take a learner in your office, be it a medical, NP, or PA student. Do it every year. Your knowledge may not be as current as theirs, but your wisdom on how to deliver care is exceptional. This is the gift of the mentor, and it cannot be taught by book, video, or televised debate. The Hippocratic Oath challenges us to "teach them my art." "Doctor" literally means teacher. Give thanks to your mentors, and give the gift of being one in return.*

Frank J. Domino, MD

# Preface

**There can be no happiness if the things we believe are different from the things we do.**

**---FREYA STARK**

A colleague was recently overheard describing all that was wrong with health care—the electronic record, ICD-10 and the new billing rules, conflicting guidelines, and the loss of the “old days.” Delivering health care has always required learning what is new and juggling a variety of needs. Delivering personalized health care is an even greater challenge.

Medicine is also the most rewarding of careers and it is the best “job.” We collaborate with others who share a mission to help people live better and partner with patients to meet their goals and provide care as they suffer through their illnesses.

We are so incredibly fortunate to have a job where we deliver, on a daily basis, care which is congruent with our belief that we can make the world better, one patient at a time. Consider your friends outside of medicine, can they say their daily work is consistent with making the world a better place? I suspect it is far greater a challenge for them to find happiness.

We picnic in summer, despite the mosquitoes, and we endure the cold to ski (or, at least enjoy a place by the fireplace with a good book). The annoyances should never prevent us from seeing the incredible good we do and from missing the happiness it provides.

Welcome to the 2017 edition of *The 5-Minute Clinical Consult*. This is a book of diseases, diagnostic methods, and treatment recommendations. Much of the work provided by primary care providers is focused on helping the patients help themselves to be healthier. Diet, exercise, safety, and prevention are the interventions that provide the greatest number of people with the greatest return on longevity and its enjoyment.

In our role, we do more than diagnose and treat disease. Yet, when you listen to patients' stories, or touch them, their burden is in some way lifted. We are a place for patients to turn when they are in need, sometimes when they have no place else to turn.

Our role is more than preventing and treating illness. We are leaders. Asking a recently widowed person how he or she will get through tomorrow is more than a condolence, it is a therapeutic intervention. Prompting an “at-risk” teen to use contraception, avoid drugs, or consider higher education are all therapeutic interventions. Dropping an email to your state legislator about a pressing issue affecting your patient population and stating publicly your opinion about important community issues are all components of your position and role and more valued than you

probably imagine.

This year's *The 5-Minute Clinical Consult* is here to assist in fulfilling our role as a health care provider. In each patient interaction, in addition to bringing your clinical expertise, remember how others view you, as a leader, and the power of your words and actions. Encourage them to dream more, learn more, do more, and to be more.

Our editorial team has collaborated with hundreds of authors so that you may deliver your patients the best care. Each topic provides you with quick answers you can trust, where and when you need them most, either in print or online at [www.5MinuteConsult.com](http://www.5MinuteConsult.com).

This highly organized content provides you with the following:

- Differential diagnosis support from our expanded collection of algorithms
- Current evidence-based designations highlighted in each topic
- 570+ commonly encountered diseases in print, with an additional 1,400 online topics, including content from *The 5-Minute Pediatric Consult* and *Rosen & Barkin's 5-Minute Emergency Medicine Consult*
- FREE point-of-care CME and CE: 1/2 hour credit for every digital search
- Thousands of images to help support visual diagnosis of all conditions
- Video library of procedures, treatment, and physical therapy
- A to Z drug database from Facts & Comparisons™
- Laboratory test interpretation from *Wallach's Interpretation of Diagnostic Tests*
- More than 3,000 patient handouts in English and Spanish
- ICD-10 codes and *DSM-5* criteria; additionally, SNOMED codes are available online.

Our website, [www.5MinuteConsult.com](http://www.5MinuteConsult.com), delivers quick answers to your questions. It is an ideal resource for patient care. Integrating *The 5-Minute Clinical Consult* content into your workflow is easy and fast. And our patient education handouts can assist in helping you meet meaningful use compliance.

If you purchased the Premium Edition, your access includes 1 year FREE; the Standard Edition includes a free 10-day trial! The site promises an easy-to-use interface, allowing smooth maneuverability between topics, algorithms, images, videos, and patient education materials as well as more than 1,400 online-only topics.

Evidence-based health care is the integration of the best medical information with the values of the patient and your skill as a clinician. We have updated our EBM content so you can focus on how to best apply it in your practice.

We have solved the health maintenance challenge by including the link to the U.S. Preventive

Services Task Force calculator. Enter a patient's gender and age and you are presented with the best recommendations to keep that specific patient healthy.

The algorithm section includes both diagnostic and treatment algorithms. This easy-to-use graphic method helps you evaluate an abnormal finding and prioritize treatment. They are also excellent teaching tools, so share them with the learners in your office.

In our role as clinicians, caring for those who are ill or helping to prevent illness, we use tests and prescribe treatments, hoping they improve outcomes. More important, our words and actions, even a shared smile, can make a huge difference. Thank you for being a leader in your practice and community.

*The 5-Minute Clinical Consult* editorial team values your observations, so please share your thoughts, suggestions, and constructive criticism through our website, [www.5MinuteConsult.com](http://www.5MinuteConsult.com).

Frank J. Domino, MD

**JANUARY 31, 2016**

# Evidence-Based Medicine

## WHAT IS EVIDENCE-BASED MEDICINE?

Remember when we used to treat every otitis media with antibiotics? These recommendations came about because we applied logical reasoning to observational studies. If bacteria cause an acute otitis media, then antibiotics should help it resolve sooner, with less morbidity. Yet, when rigorously studied (via a systematic review), we found little benefit to this intervention.

The underlying premise of evidence-based medicine (EBM) is the evaluation of medical interventions and the literature that supports those interventions, in a systematic fashion. EBM hopes to encourage treatments proven to be effective and safe. And when insufficient data exists, it hopes to inform you on how to safely proceed.

EBM uses end points of real patient outcomes, morbidity, mortality, and risk. It focuses less on intermediate outcomes (bone density) and more on patient conditions (hip fractures).

Implementing EBM requires three components: the best medical evidence, the skill and experience of the provider, and the values of the patients. Should this patient be screened for prostate cancer? It depends on what is known about the test, on what you know of its benefits and harms, your ability to communicate that information, and that patient's informed choice.

This book hopes to address the first EBM component, providing you access to the best information in a quick format. Although not every test or treatment has this level of detail, many of the included interventions here use systematic review literature support.

The language of medical statistics is useful in interpreting the concepts of EBM. Below is a list of these terms, with examples to help take the confusion and mystery out of their use.

**Prevalence:** *proportion of people* in a population who have a disease (in the United States, 0.3% [3 in 1,000] people >50 years have colon cancer)

**Incidence:** How many *new cases of a disease* occur in a population during an interval of time; for example, the estimated incidence of colon cancer in the United States is 104,000 in 2005.

**Sensitivity:** Percentage of people with disease who test positive; for mammography, the sensitivity is 71-96%.

**Specificity:** Percentage of people without disease who test negative; for mammography, the specificity is 94-97%.

Suppose you saw ML, a 53-year-old woman, for a health maintenance visit, ordered a *screening* mammogram, and the report demonstrates an irregular area of microcalcifications. She is waiting in your office to receive her test results, what can you tell her?

Sensitivity and specificity refer to characteristics of people who are *known to have disease* (sensitivity) or those who are *known not to have disease* (specificity). But, what you have is an abnormal test result. To better explain this result to ML, you need the positive predictive value.

**Positive predictive value (PPV):** Percentage of *positive* test results that are truly positive; the PPV for a woman aged 50 to 59 years is approximately 22%. That is to say that only 22% of abnormal screening mammograms in this group truly identified cancer. The other 78% are false positives.

You can tell ML only one out of five abnormal mammograms correctly identify cancer; the four are false positives, but the only way to know which mammogram is correct is to do further testing.

**The corollary of the PPV is the negative predictive value (NPV),** which is the percentage of negative test results that are truly negative.

The PPV and NPV tests are population-dependent, whereas the sensitivity and specificity are characteristics of the test, and have little to do with the patient in front of you. So when you receive an abnormal lab result, especially a screening test such as mammography, understand their limits based on their PPV and NPV.

**Treatment information is a little different.** In discerning the statistics of randomized controlled trials of interventions, first consider an example. The Scandinavian Simvastatin Survival Study (4S) (*Lancet*. 1994;344[8934]:1383-1389) found using simvastatin in patients at high risk for heart disease for 5 years resulted in death for 8% of simvastatin patients versus 12% of those on placebo; this results in a relative risk of 0.70, a relative risk reduction of 33%, and a number needed to treat of 25.

There are two ways of considering the benefits of an intervention with respect to a given outcome. The absolute risk reduction is the difference in the percentage of people with the condition before and after the intervention. Thus, if the incidence of myocardial infarction (MI) was 12% for the placebo group and 8% for the simvastatin group, the absolute risk reduction is 4% (12% - 8% = 4%).

The relative risk reduction reflects the improvement in the outcome as a percentage of the

original rate and is commonly used to exaggerate the benefit of an intervention. Thus, if the risk of MI were reduced by simvastatin from 12% to 8%, then the relative risk reduction would be 33% ( $4\%/12\% = 33\%$ ); 33% sounds better than 4%, but the 4% is the absolute risk reduction and reflects the true outcome.

Absolute risk reduction is usually a better measure of *clinical* significance of an intervention. For instance, in one study, the treatment of mild hypertension has been shown to have relative risk reduction of 40% over 5 years (40% fewer strokes in the treated group). However, the absolute risk reduction was only 1.3%. Because mild hypertension is not strongly associated with strokes, aggressive treatment of mild hypertension yields only a small clinical benefit. Don't confuse relative risk reduction with relative risk.

**Absolute (or attributable) risk (AR):** the percentage of people in the placebo or intervention group who reach an end point; in the simvastatin study, the absolute risk of death was 8%.

**Relative risk (RR):** the risk of disease of those treated or exposed to some intervention (i.e., simvastatin) divided by those in the placebo group or who were untreated

---

P.x

Ñ If RR is  $<1.0$ , it reduces riskÑthe smaller the number, the greater the risk reduction.

Ñ If RR is  $>1.0$ , it increases riskÑthe greater the number, the greater the risk increase.

**Relative risk reduction (RRR):** the relative decrease in risk of an end point compared to the percentage of that end point in the placebo group

If you are still confused, just remember that the RRR is an over-estimation of the actual effect.

**Number needed to treat (NNT):** This is the number of people who need to be treated by an intervention to prevent one adverse outcome. A "good" NNT can be a large number ( $>100$ ) if risk of serious outcome is great. If the risk of an outcome is not that dangerous, then lower ( $<25$ ) NNTs are preferred.

The NNT should be compared to a similar statistic, the number needed to harm (NNH). This is the number of people who have to be given treatment before one excess side effect or harm occurs. When the NNT is compared to the NNH, you and the patient can judge whether the benefit of the intervention is great enough to outweigh the risk of harm.

# EVIDENCED-BASED GRADING

To help you interpret diagnostic and treatment recommendations within *The 5-Minute Clinical Consult*, we have graded the best information within the text and highlighted this content.

An **Ⓐ** grade means the reference is from the highest quality resource, such as a systematic review. A *systematic review* is a summary of the medical literature on a given topic that uses strict, explicit methods to perform a thorough search of the literature and then provides a critical appraisal of individual studies, concluding in a recommendation. The most prestigious collection of systematic reviews is from the Cochrane Collaboration ([www.cochrane.org](http://www.cochrane.org)).

A **Ⓑ** grade means the data referenced comes from high-quality randomized controlled trials performed to minimize bias in their outcome. Bias is anything that interferes with the truth; in the medical literature, it is often unintentional, but it is much more common than we appreciate. In short, always assume some degree of bias exists in any research endeavor.

A **Ⓒ** grade implies the reference used does not meet the A or B requirements; they are often treatments recommended by consensus groups (such as the American Cancer Society). In some cases, they may be the standards of care. But implicit in a group's recommendation is the bias of the author or the group that supports the reference. For example, the American Urological Society's recommendation around screening for prostate cancer may be motivated by their narrow scope and financial benefit. Compare this to the recommendations of the U.S. Preventive Services Task Force ([www.ahrq.gov](http://www.ahrq.gov)), which recommends against screening for prostate cancer.

## BIAS

Bias is anything that interferes with the truth. There are many types of bias that should be considered by the publishers of medical information. Below describes a number of bias types that often affect our care without us knowing it is present.

**Publication bias** occurs when research is not published; this is often when a study finds data that does *not* support an intervention. The motivation to publish information that "didn't work" is low. It is estimated that up to 40% of all medical research never gets published. When you read of an effective intervention, wonder if other studies did not show benefit and went unpublished.

**Comparator bias** occurs when research compares an intervention to placebo, when placebo is not the standard of care. Knowing a new antibiotic is more effective than placebo for treating a condition is not helpful if you typically use a drug or procedure. Why not release research comparing the new drug to the standard of care? Sometimes the new treatment is no better than the current standard. And if a study was done to see if the new is better than the old and not published, you have an

example of publication bias.

**Selection bias** involves choosing study populations that might be different than the average patient or just reporting a just subset of study participants from a study. Either will result in the data being skewed because it can only be applied to small subset of people.

**Attrition bias and the concept of intention to treat.** Attrition bias is when researchers do not fully acknowledge and address how a study deals with participants who do not adhere to the research protocol or drop out completely. Intention to treat analysis hopes to diminish attrition bias by statistically considering the nonadhering or dropped out patients as unsuccessfully benefiting from the intervention.

**Commercial (funder) bias** involves who paid for the research being done, and do they have a vested interest in the outcome. If the developer of a new drug does a large study, or a researcher has a personal financial interest in seeing a study succeed, they may consciously or unconsciously alter what is reported in a study. The data may be accurate, but until this is studied by less vested interests, some feel its outcome cannot be clinically applied.

Have you been annoyed how one week you learn of a randomized controlled trial that supports a treatment, to be followed the next week with a contradictory article? Statisticians have figured out how to resolve this using something called a systematic review.

**A systematic review** gathers all the literature on a topic, say using antibiotics to treat otitis media, and combines the data to determine if the sum of all the trials tells a different story than any single trial. The large number of participants in this type of research results in a much more statistically (and clinically) significant conclusion than any single paper. Want more? Check this out: <http://community.cochrane.org/about-us/evidence-based-health-care>.

**A meta-analysis** is a quantitative systematic review and demonstrates its outcomes in the form of a forest plot. The bottom line with interpretation of a forest plot is to look for the diamond on the bottom. If it is to LEFT of the vertical line, it means risk of an outcome was reduced by the intervention. If it is fully to the RIGHT, then risk of that outcome was increased. And if the diamond touches the vertical line, it means there was no statistical influence of the intervention on the outcome.

We hope this brief introduction to EBM has been informative, clear, and helpful. If any of the

information above seems unclear, or if you have a question, please contact us via [www.5MinuteConsult.com](http://www.5MinuteConsult.com).

# Acknowledgments

This is the 25th edition of *The 5-Minute Clinical Consult*, a comprehensive point-of-care tool to assist in the care of patients. From beginning to end, one cannot find a more current and easy-to-use collection of clinically useful content.

Developing and maintaining a book and website of this magnitude requires an equally broad effort from its supporting team. I wish to thank the dedication and tireless efforts of many: executive editor, Rebecca Gaertner; product development editor, Leanne Vandetty; marketing manager, Rachel Mante Leung; and publisher, Lisa McAllister.

This 2017 edition is the direct result of the dedication and insights of our associate editors. I wish to thank Drs. Robert Baldor, Jeremy Golding, and Mark Stephens for their hard work and overwhelming commitment to *The 5-Minute Clinical Consult*. And to Dr. Jill Grimes for her continued support while away.

I wish to especially thank my wife, Sylvia, and my daughter, Molly, who have given greatly for this book.

The challenge of completing a book covering this broad a spectrum of medicine requires insights and skills far beyond my own. Many thanks to my mentors Bob Baldor and Mark Quirk who have been an enormous support—always there to encourage, reassure, and impart wisdom.

Many in the academic and health care worlds are due thanks for support, insight, and friendship: Daniel Lasser, Alan Chuman, Michele Pugnaire, Karen Rayla, Phil Fournier, Erik Garcia, Jeff Stovall, Jim Comes, Len Levin, Judy Norberg, J. Herb Stevenson, Robert Jenal, Michael Kidd, Zainab Nawab, Sanjiv and Amita Chopra, Vasilios (Bill) Chrisostomidis, James (Jay) Broadhurst, Danuta Antkowiak, Atreyi Chakrabarti, Kerry Morse, Kate Peasha, the staff of Shrewsbury Family Medicine, Mark Powicki, Steve Messineo, and the faculty and amazing students of the University of Massachusetts Medical School.

Medicine is a challenge I have fortunately not had to meet alone. Thanks to my parents, Frank and Angela (Jean); my brother, John and his family, Marylou, Cate, and Jane; Frank, Mary Anne, Diane, and David Christian; the Diana and Hymie Lipschitz family; and the Bob and Ruth Pabreza family; they are responsible for who I am and my success in life.

I am blessed with the best of friends; without them, I would not be a physician. Thanks to Bob Bacic, Ron Jautz, Richard Onorato, John Horcher, Auguste Turnier, Bob Smith, Paul Saivetz, Bob and Nancy Gallinaro, Drew and Jill Grimes, Louay Toma, Laurie, Alan, Daniel, Jenny and Matt Bugos, Alan Ehrlich, Andy Jennings, Bill Demianiuk, Mark Steenbergen, John and Kathleen Polanowicz, Phil and Carol Pettine, Mark Shelton, Steve Bennett, Vicki Triolo, and Michael

Bernatchez.

Frank J. Domino, MD

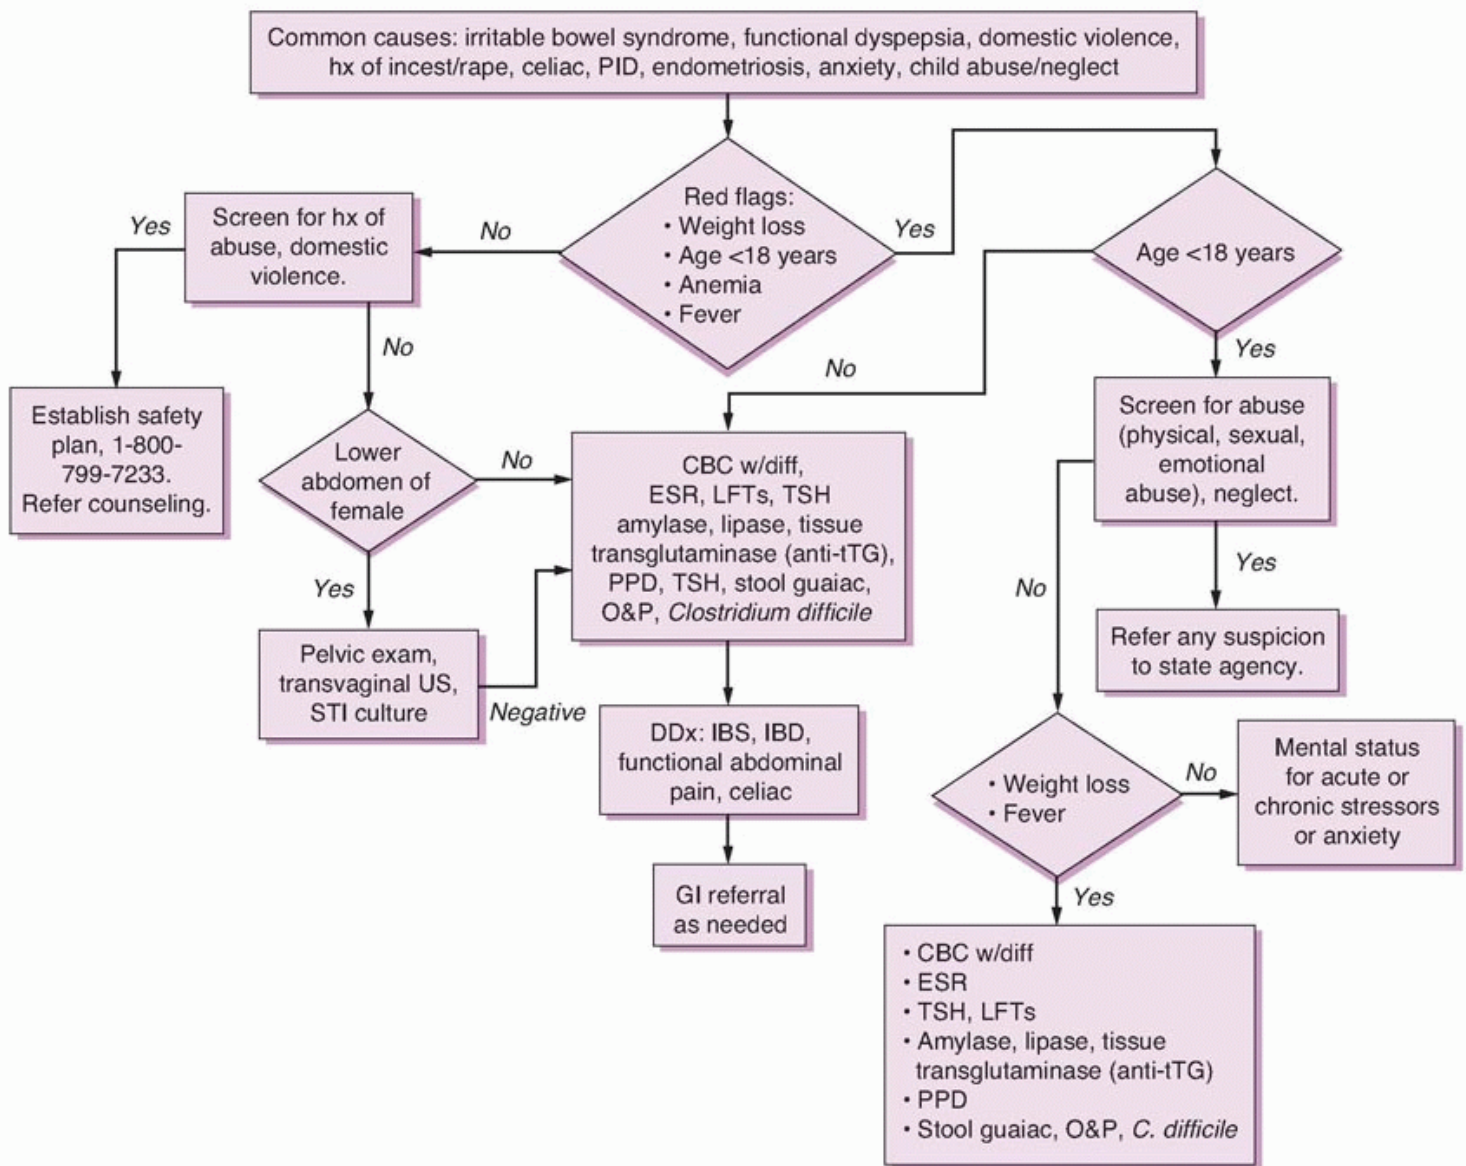

# Diagnosis and Treatment: An Algorithmic Approach

This section contains flowcharts (or algorithms) to help the reader in the diagnosis of clinical signs and symptoms and treatment of a variety of clinical problems. They are organized by the presenting sign, symptom, or diagnosis.

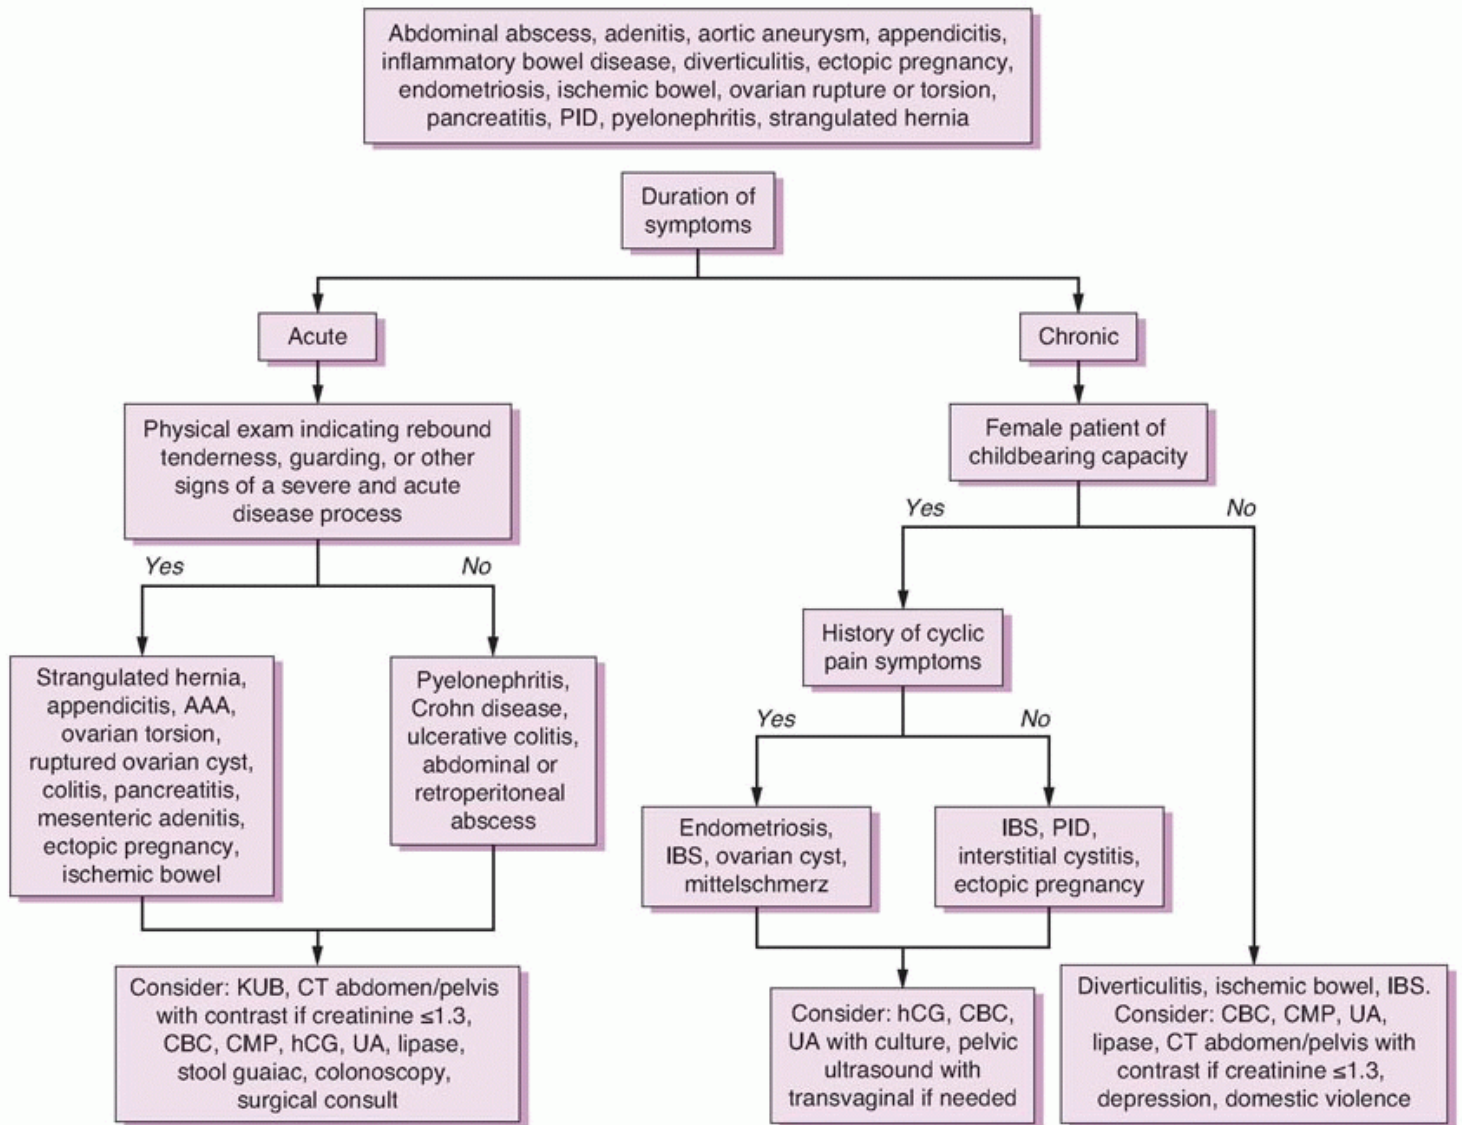

These algorithms were designed to be used as a quick reference and adjunct to the reader's clinical knowledge and impression. They are not an exhaustive review of the management of a problem, nor are they meant to be a complete list of diseases.

## ABDOMINAL PAIN, CHRONIC

## ALCOHOL WITHDRAWAL, TREATMENT

**History:** duration and quantity of alcohol intake, time since last drink, previous episodes of alcohol withdrawal, concurrent substance use, preexisting medical and psychiatric conditions, prior detoxification admissions, prior seizure activity, living situation, social supports, stressors, triggers

**Physical:** VS (fever, tachycardia, tachypnea, hypertension), **CIWA** (see below), MSE, (arousal, orientation, hallucinations), HEENT (diaphoresis, scleral icterus), CV (arrhythmias, M/R/G), evaluate s/sx of liver failure (ascites, varices, caput medusae, asterixis, palmar erythema), neuro (nystagmus, tremor, seizure activity).

Include assessment of conditions likely to *complicate, exacerbate, or precipitate* alcohol withdrawal: arrhythmias, CHF, CAD, dehydration, GI bleeding, infections, liver disease, pancreatitis, neurologic deficits.

**Clinical Institute Withdrawal Assessment (CIWA) of Alcohol Scale**

- Nausea and vomiting 0-7 (0, none; 4, intermittent; 7, constant nausea; frequent dry heaves/vomiting)
- Tremor 0-7 (0, none; 4, moderate; 7, severe; even with arms not extended)
- Paroxysmal sweats 0-7 (0, none; 4, beads of sweat; 7, drenching sweats)
- Anxiety 0-7 (0, none; 4, moderate; 7, acute panic state)
- Agitation 0-7 (0, none; 4, moderately restless; 7, constantly thrashing about or pacing)
- Tactile disturbances 0-7 (0, none; 4-7 for hallucinations; 1-3 for pruritus or paresthesias)
- Auditory disturbances 0-7 (0, none; 4-7 for hallucinations; 1-3 for increased sensitivity)
- Visual disturbances 0-7 (0, none; 4-7 for hallucinations; 1-3 for increased sensitivity)
- Headache 0-7 (0, no headache; 4, moderate; 7, extremely severe)
- Orientation 0-4 (0, fully oriented; 1, cannot do serial additions or is uncertain about date; 2, disoriented to date but within 2 calendar days; 3, disoriented to date by >2 days; 4, disoriented to place or person)

**Mild withdrawal—CIWA 0-7** onset 5-8 hours after cessation or significant decrease in consumption: anxiety, restlessness, agitation, mild nausea, decreased appetite, sleep disturbance, facial sweating, mild tremulousness, fluctuating tachycardia and hypertension, possible mild cognitive impairment

**Moderate withdrawal—CIWA 8-14** onset 24-72 hours after cessation: marked restlessness and agitation, moderate tremulousness with constant eye movement, diaphoresis, nausea, vomiting, anorexia, diarrhea

**Severe withdrawal/delirium tremens—CIWA 15-30** onset 72-96 hours after alcohol cessation: marked tremulousness, fever, drenching sweats, severe hypertension and tachycardia, delirium

**Good candidate for outpatient therapy:**

- Not pregnant
- No comorbid illnesses requiring hospitalization
- No history of seizures
- Not a suicide risk
- Low risk of delirium tremens
- No history of unsuccessful outpatient detoxification
- Good access to follow-up medical care
- Tolerating oral medication
- Adequate social support available

**Outpatient therapy contraindicated:** pregnant, history of seizures or withdrawal seizures, chronic or acute comorbid illness requiring inpatient observation, lack of ability to follow-up

**High risk of delirium tremens:**

- Age >30 years
- Heavy drinking >8 years
- Drinking >100 g ethanol/day
- Random BAC >200 mg/dL
- Elevated MCV
- Cirrhosis

**Admit to inpatient ward/detoxification program**

- Private room if possible
- VS q4h
- CIWA q1-3h
- Institute seizure precautions
- Intravenous fluids

**Admit to ICU for inpatient detoxification**

- VS q30min
- CIWA q1h
- NPO, intravenous fluids
- Lateral decubitus position, restrain if necessary
- Glucose, sodium, potassium, phosphate, and magnesium replacement as needed

**Labs:**

- Toxicology screen/EtOH level to assess need for and timing of withdrawal regimen
- CBC, electrolytes, phosphate, magnesium; B<sub>12</sub> and folate to be repleted regardless of blood levels
- Amylase/lipase if suspected pancreatitis
- PT, PTT if suspected liver failure

**Imaging:**

- Head CT if history of trauma, mental status changes greater than expected, or focal neurologic changes.
- Consider addition of EEG if focal neurologic signs or prolonged postictal state seizure.

**Medications:**

- Diazepam 5-20 mg IV q10min until calm, then q1h to maintain light somnolence for duration of delirium
- If severe liver disease, severe asthma or respiratory failure, elderly, debilitated, or low serum albumin:
- Lorazepam 1-4mg IV q10min until calm, then q1h to maintain light somnolence for duration of delirium

**Treat as outpatient**

- Thiamine 100 mg once daily for 5 days
- Folic acid 1 g once daily for 5 days
- Evaluate daily until symptoms decrease
- Assess blood pressure, heart rate, and CIWA-Ar score at each follow-up visit.
- Perform alcohol breath analysis randomly.
- Facilitate entry into a long-term outpatient therapy program (Alcoholics Anonymous).
- If patient misses an appointment or resumes drinking, refer to addiction specialist or inpatient treatment facility.

**Example outpatient regimen:**

**Fixed diazepam schedule**

Day 1: 10 mg q6h  
Day 2: 10 mg q8h  
Day 3: 10 mg q12h  
Day 4/5: 10 mg at bedtime

**Symptom-triggered diazepam schedule: Give dose if CIWA >8.**

Day 1: 10 mg q4h PRN  
Day 2: 10 mg q6h PRN  
Day 3: 10 mg q6h PRN  
Days 4/5: 10 mg twice a day PRN

**Discharge planning:**

- CIWA scores <8-10 for 24 hours
- Begin 1:1 or group therapy
- Discharge to treatment center, day program, home
- Facilitate entry into Alcoholics Anonymous.
- Evaluate for outpatient treatment with benzodiazepine.
- Nutrition/social work consultation

**Medications:**

**Nutritional replacement**

- Thiamine 100 mg IV/IM or PO once daily for 5 days
- Folic acid 1 g PO once daily for 5 days

**Sympatholytic adjunctive therapy** (no effect on prevention of withdrawal seizure and should be used with benzodiazepine therapy)

- Atenolol 50-100 mg once daily
- Clonidine 0.2 mg 3 times daily

**For hallucinations associated with withdrawal:**

- Haloperidol 2-5 mg IM/PO q1-4h max 5 mg/day
- Use only in conjunction with benzodiazepines and with extreme caution as haloperidol may lower seizure threshold.

**Medications:**

Long-acting benzodiazepines (diazepam) have rapid onset of action and provide smooth treatment course with fewer breakthrough symptoms.

- Diazepam 20 mg PO q1-2h until CIWA <8
- OR**
- Diazepam 2-5 mg IV/min—maximum 10-20 mg q1h

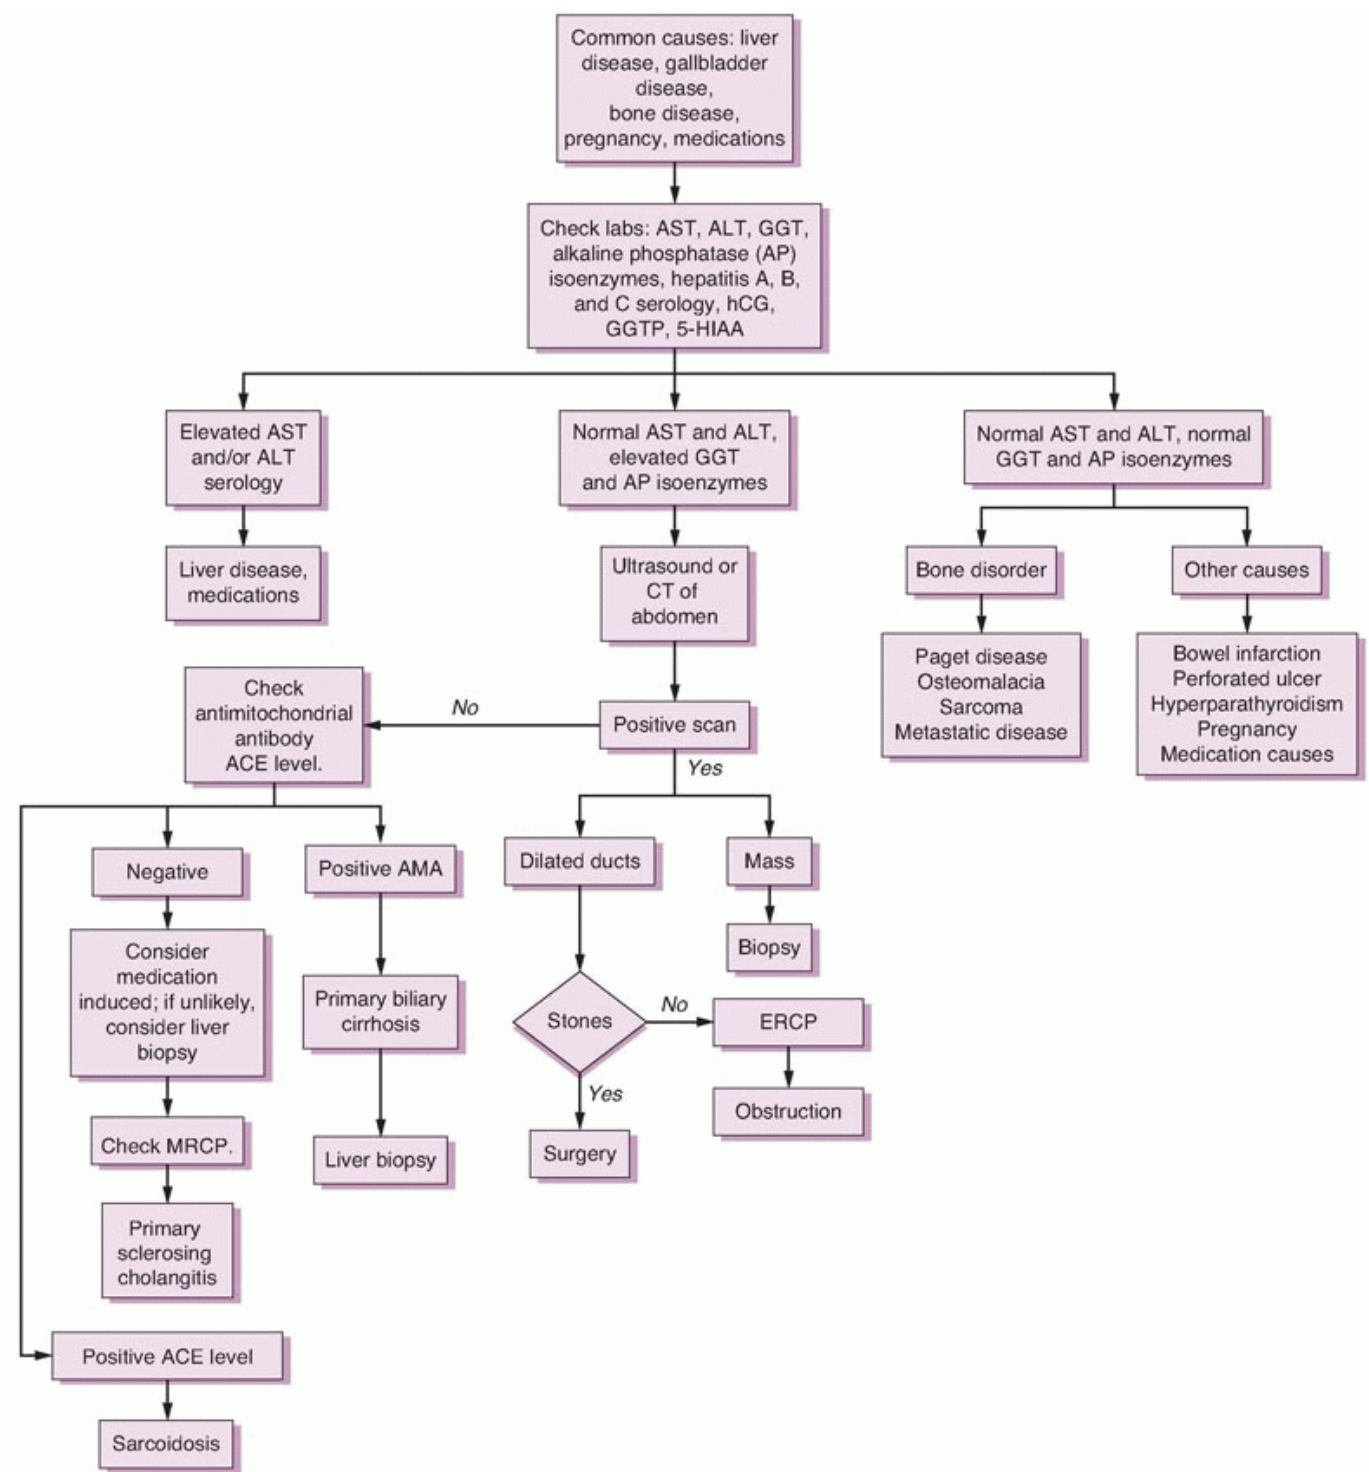

Short-acting benzodiazepines (lorazepam) may have lower risk when there is concern about prolonged sedation, for example, elderly patients or those with severe hepatic insufficiency.

- Lorazepam 1-2 mg PO q2-4h until CIWA <8

## ASTHMA EXACERBATION, PEDIATRIC ACUTE

**Initial evaluation:** brief history of present illness, physical exam  
**Asthma history:** emergency department visits, hospital and ICU admissions, home medications, frequency of oral steroid use, history of intubation, rapidly progressive episodes, food allergies  
**Physical exam:** auscultation, use of accessory muscles, ability to speak, heart rate, oxygen saturation, PEF, or FEV<sub>1</sub>

Severity	Respiratory rate		Wheezing	Inspiration: expiratory ratio	Accessory muscle use	Oxygen saturation (room air)
	(<6 years)	(>6 years)				
Normal	30	20	None	2:1	None	99–100%
Mild	31–35	21–35	End expiration	1:1	+	96–98%
Moderate	46–60	36–50	Entire expiration	1:2	++	93–95%
Severe	>60	>50	Inspiration and expiration (may have silent chest)	1:3	+++	<93%

Jasmit S. Minhas, MD and John A. Saryan, MD

National Asthma Education and Prevention Program. Expert Panel Report 3 (EPR-3): guidelines for the diagnosis and management of asthma-summary report 2007. *J Allergy Clin Immunol.* 2007;120(5)(Suppl):S94-S138.

## ASTHMA, INITIAL TREATMENT

**Management of chronic asthma**  
Classification of asthma severity in youth >12 years of age and adults

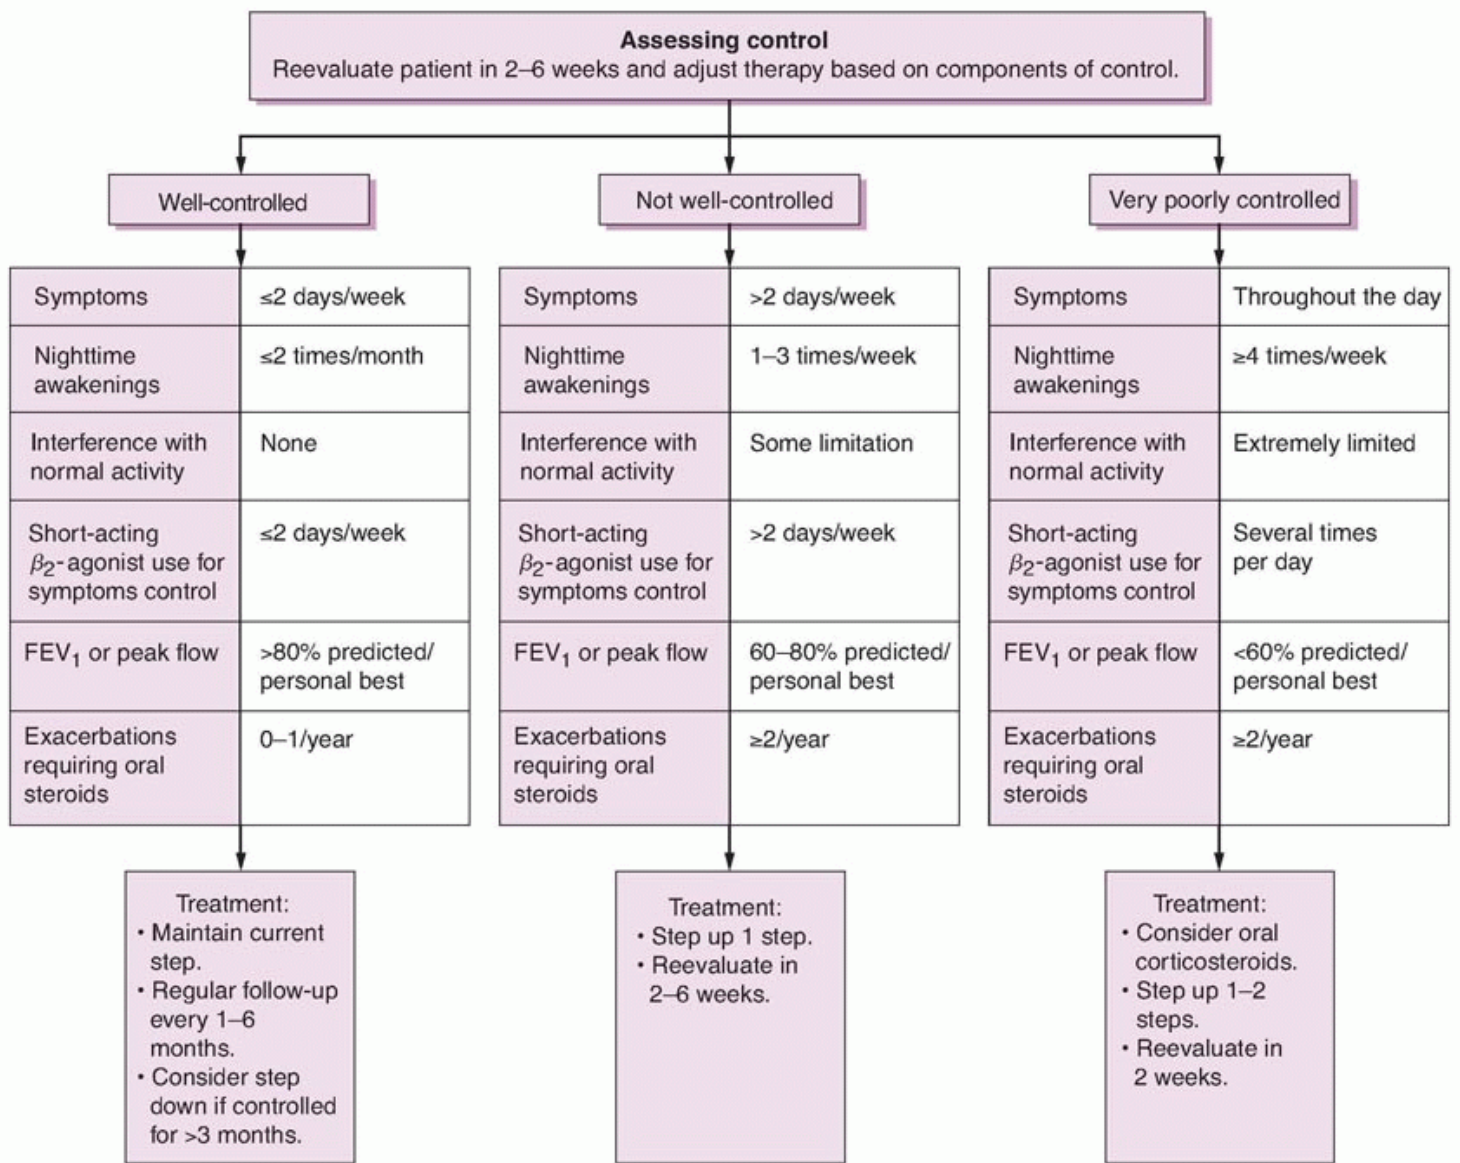

Components of severity	Intermittent	Mild persistent	Moderate persistent	Severe persistent
Daytime symptoms	<2 days/week	>2 days/week but not every day	Daily	Throughout the day
Nighttime awakenings	<2 times/month	3 or 4 times/month	>1 time weekly but not nightly	Often 7 times weekly
Short-acting $\beta_2$ -agonist use for symptom control	<2 days/week	>2 days/week but not daily and not >1 time on any day	Daily	Several times daily
Interference with normal activity	None	Minor limitation	Some limitation	Extremely limited
Lung function	<ul style="list-style-type: none"> <li>• Normal FEV<sub>1</sub> between exacerbations</li> <li>• FEV<sub>1</sub> &gt;80% predicted</li> <li>• FEV<sub>1</sub>/FVC normal</li> </ul>	<ul style="list-style-type: none"> <li>• FEV<sub>1</sub> &gt;80% predicted</li> <li>• FEV<sub>1</sub>/FVC normal</li> </ul>	<ul style="list-style-type: none"> <li>• FEV<sub>1</sub> &gt;60%, but &lt;80% predicted</li> <li>• FEV<sub>1</sub>/FVC reduced 5%</li> </ul>	<ul style="list-style-type: none"> <li>• FEV<sub>1</sub> &lt;60% predicted</li> <li>• FEV<sub>1</sub>/FVC reduced &gt;5%</li> </ul>
Asthma exacerbations requiring oral steroids	0–1/year	≥2/year	≥2/year	≥2/year

Recommended step for initiating treatment	Step 1	Step 2	Step 3	Step 4, 5, or 6
Preferred and alternative pharmacotherapy based on step	<p><b>Preferred:</b> Short-acting <math>\beta_2</math>-agonist as needed</p>	<p><b>Preferred:</b> Low-dose ICS</p> <p><b>Alternative:</b> Leukotriene modifier or theophylline</p>	<p><b>Preferred:</b> Low-dose ICS + LABA or medium-dose ICS</p> <p><b>Alternative:</b> Low-dose ICS + leukotriene modifier, theophylline, or zileuton</p>	<p><b>Step 4</b></p> <p><b>Preferred:</b> Medium-dose ICS + LABA</p> <p><b>Alternative:</b> Medium-dose ICS + leukotriene modifier, theophylline, or zileuton</p> <p>Identify triggers (cold air, dust, allergic exposures/pets), and control exposures.</p> <p><b>Step 5</b></p> <p><b>Preferred:</b> High-dose ICS + LABA, and consider omalizumab for patients with allergies</p> <p>Identify triggers and control exposures.</p> <p><b>Step 6</b></p> <p><b>Preferred:</b> High-dose ICS + LABA + oral corticosteroid, and consider omalizumab for patients with allergies</p> <p>Identify patients at risk for reactions to aspirin and NSAIDs, and avoid exposure.</p>
	At each step, discuss patient education, environmental control, and management of comorbidities.

## CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD), DIAGNOSIS AND TREATMENT

Suspect COPD if

- Chronic cough and/or sputum production
- History of smoking or chemical exposure
- Dyspnea at rest and exertion

Spirometry with pre- and postbronchodilator

Severity of COPD

	FEV <sub>1</sub> /FVC	FEV <sub>1</sub>
Mild	<0.7	>80%
Moderate	<0.7	50–80%
Severe	<0.7	30–50%
Very severe	<0.7	<50%

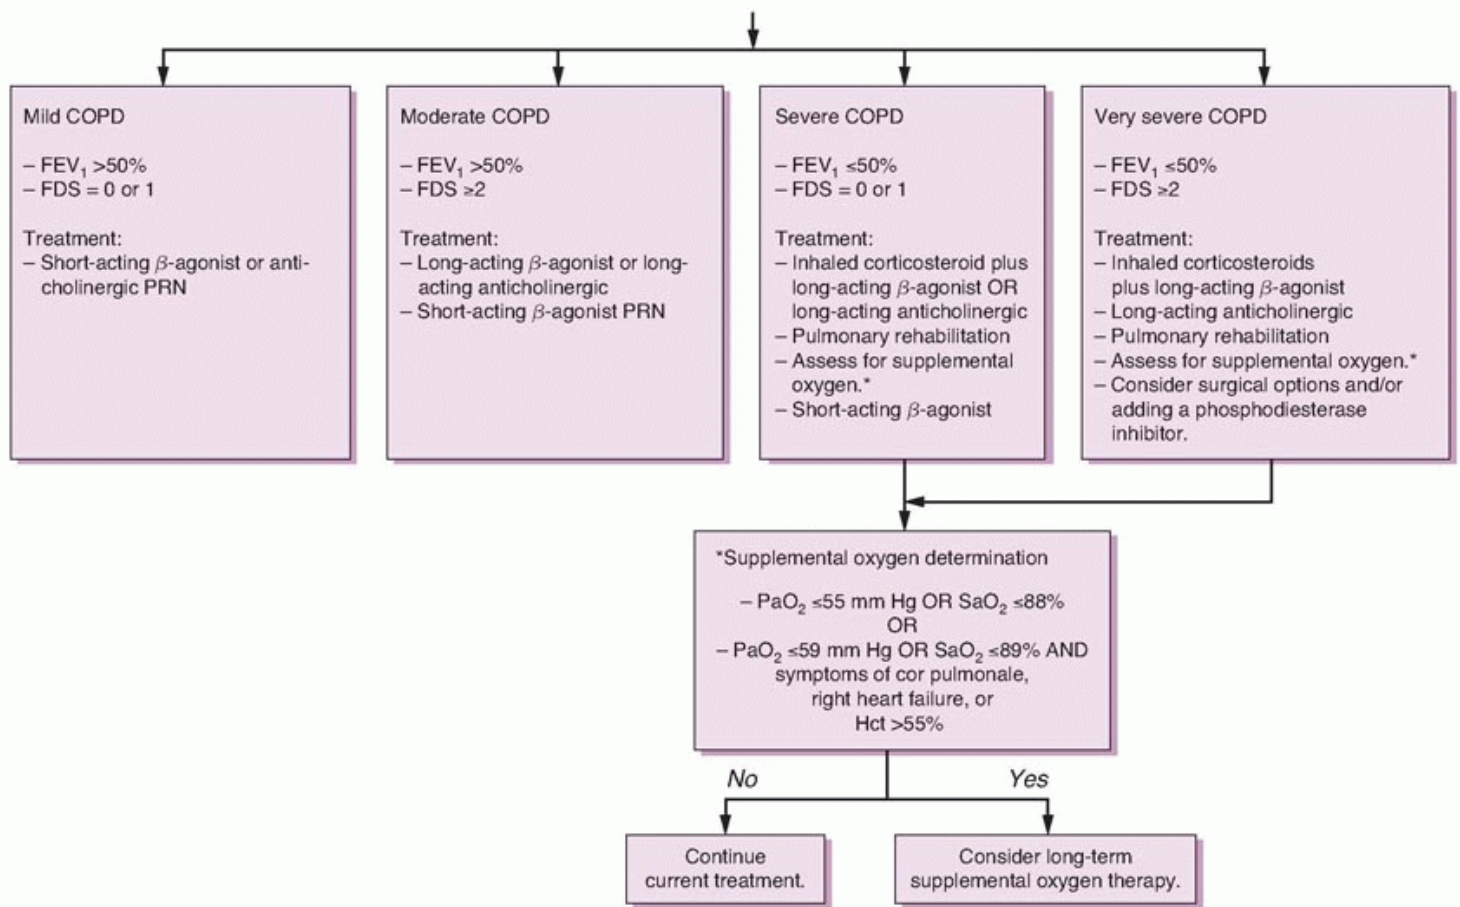

Functional Dyspnea Scale

- 0 Not troubled with breathlessness except with strenuous exercise
- 1 Troubled by shortness of breath when hurrying or walking up a slight hill
- 2 Walks slower than people of same age due to breathlessness or has to stop for breath when walking at own pace on the level
- 3 Stops for breath after walking ~100 m or after a few minutes on the level
- 4 Too breathless to leave the house or breathless when dressing or undressing

Diagnosis confirmed, initiate preventative measures:

Influenza vaccine (yearly), 23-valent pneumococcal vaccine once before age of 65 years and every 5 years until age of 65 years; 23-valent and 13-valent pneumococcal vaccines once after age of 65 years

Aggressive smoking cessation counseling if actively smoking

## CONCUSSION, SIDELINE EVALUATION

Stable, No C-spine injury

**Concussion:** traumatic event AND change in neurologic function OR one of the following signs/symptoms: **somatic** (HA, nausea/vomiting [N/V], dizziness, vertigo, visual problems, sensitivity to light or sound, numbness/tingling), **cognitive** (LOC, memory problems, feeling "foggy," slower reaction times, confusion), **emotional/behavioral** (i.e., irritability, sadness), **sleep** (i.e., drowsiness, difficulty falling asleep)

A. Follow up with medical professional in next 24 hours.

- History and PE (including complete neurologic exam) using Sport Concussion Office Assessment Tool (SCOAT) available online [www.sportsconcussion.co.za/Documents/SCOAT.pdf](http://www.sportsconcussion.co.za/Documents/SCOAT.pdf)
- Consider neuropsych testing.
- If at neurologic baseline, review Return to Play protocol.
- If not at neurologic baseline, consider ED evaluation or neuroimaging, close follow-up, and symptomatic treatment.

B. Consider neuropsych testing (paper-and-pencil, ImPACT, CogState, HeadMinder, ANAM, etc.).

- The ideal timing, frequency, and type of neuropsych testing have not been determined.
- Most concussions can be managed appropriately without the use of neuropsych testing.
- Neuropsych testing may be most helpful for high-risk athletes, those with prior concussions, and those who may downplay symptoms in an effort to return to play sooner.

C. Return to Play protocol

- No athlete may return to play the same day.
- Once asymptomatic at a stage for 24 hours, may move on to next stage; if symptoms arise, must take a 24-hour period of complete rest before dropping back one stage and starting from there.
- Most athletes should return no sooner than 6 days after concussion.
  - Stage 1: no activity (complete physical AND cognitive rest)
  - Stage 2: light aerobic exercise (walking, swimming, or stationary cycling at <70% max HR)
  - Stage 3: sport-specific exercise (sport-specific drills such as skating or running, no head impact activities)
  - Stage 4: noncontact training drills (progression to more complex training drills such as passing, may start progressive resistance training)
  - Stage 5: full contact practice
  - Stage 6: return to game play (should also be free of any medicines that could mask symptoms of concussion)
- Please note initial cognitive rest, and a graded resumption of typical cognitive activity is also important. Patients may require accommodations such as a shortened school day, reduced academic workload, extended time for tests, and so on, when recovering from a concussion.

D. Symptom management: If concussive symptoms (typically HA, sleep, cognitive, and mood disturbances) are persistent and interfering with function, consider symptomatic treatment.

- In the acute setting, ASA and NSAIDs should be used with caution due to increased risk of intracranial bleeding. Acetaminophen and physical modalities are OK.
- If HA persists for a few days, consider typical abortive treatment. There is no established role for pharmacotherapy in the acute treatment of concussion-induced sleep, cognitive, or mood disturbances.
- If symptoms persist beyond a few weeks, consider referral to specialist (neurology, sports medicine, etc.). Multidisciplinary approach is often needed.
- If symptoms do not resolve despite appropriate evaluation and treatment, consider terminating athletic season or athletic career (no clear guidelines have been established; this decision should be made on a case-by-case basis).

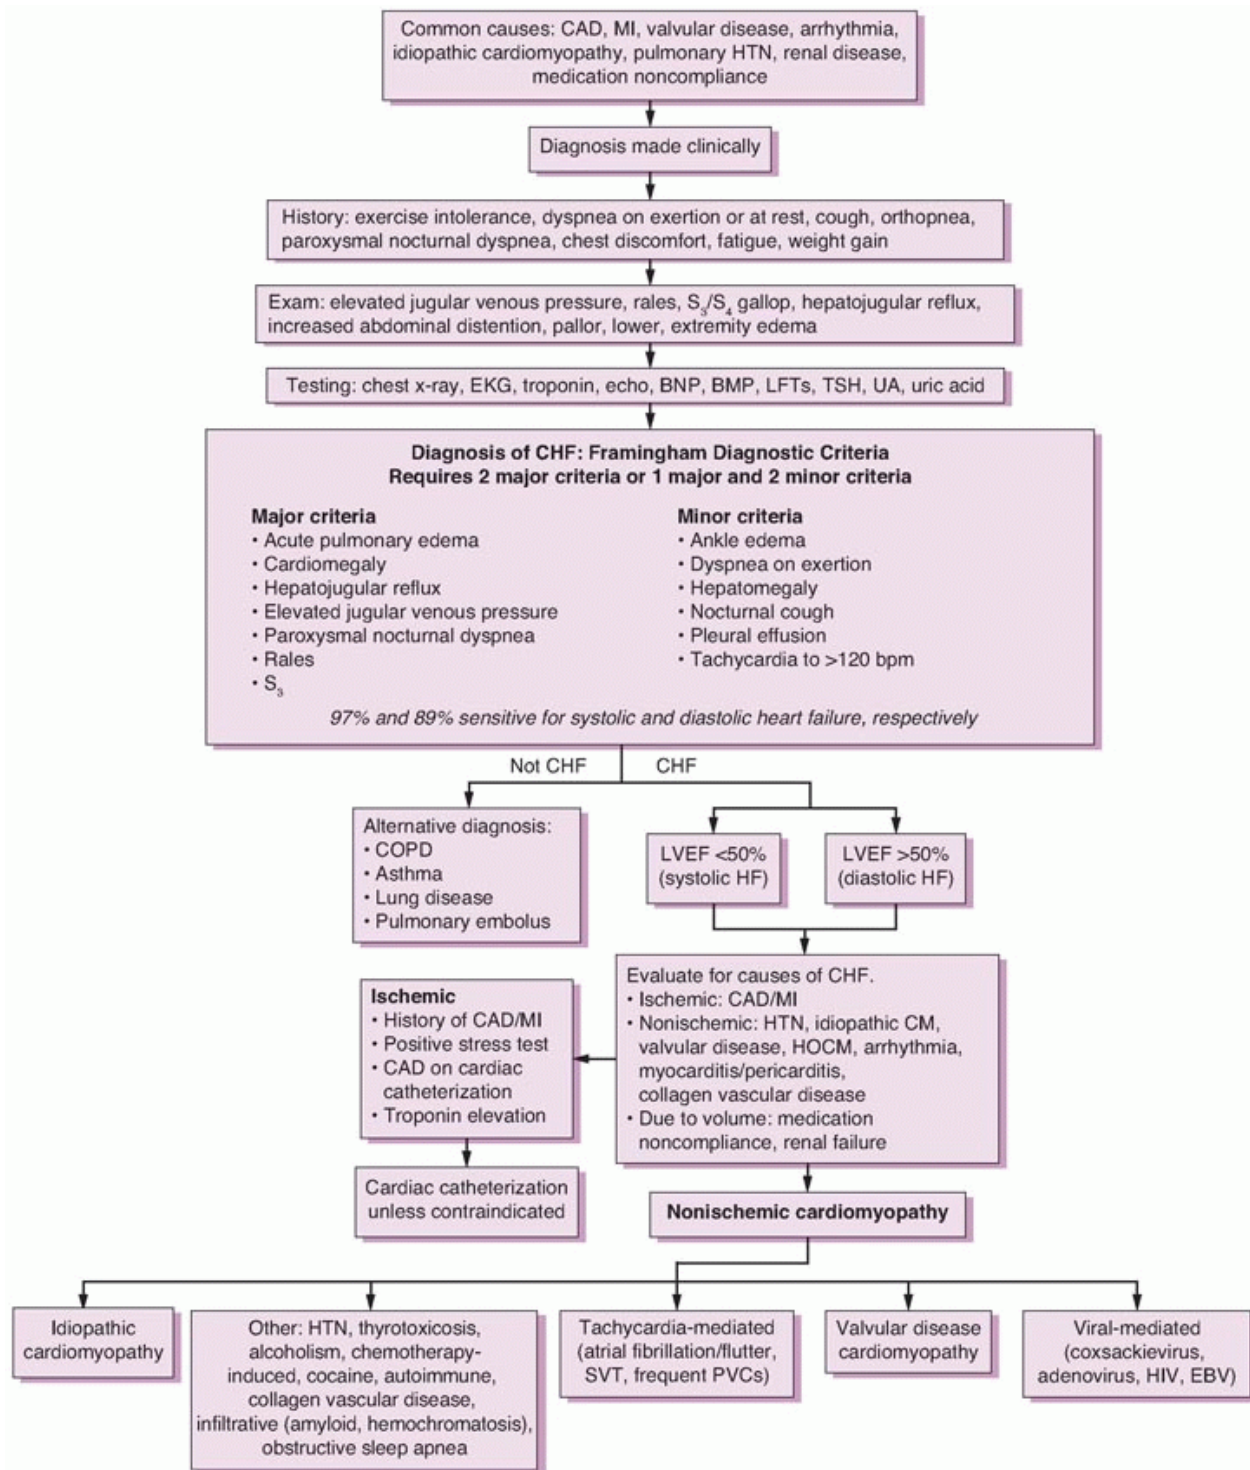

\* Signs of altered mental status: agitation, somnolence, repetitive questioning, or slow response to verbal communication  
 ‡ Severe mechanism of injury: motor vehicle crash with patient ejection, death of another passenger, or rollover; pedestrian or bicyclist without helmet struck by motorized vehicle; falls of >3 ft for patients <2 years old or >5 ft for patients ≥2 years old; or head struck by high-impact object

## DYSPEPSIA

Common causes: peptic ulcer (<10%), gastroesophageal cancer (<1%), gastroparesis, functional dyspepsia (>70%)

Main forms of functional dyspepsia: **epigastric pain syndrome** (intermittent pain/burning in epigastrium at least weekly) and **postprandial distress syndrome** (at least several episodes weekly of bothersome fullness after meals or early satiety). The two syndromes may both be present in the same patient.

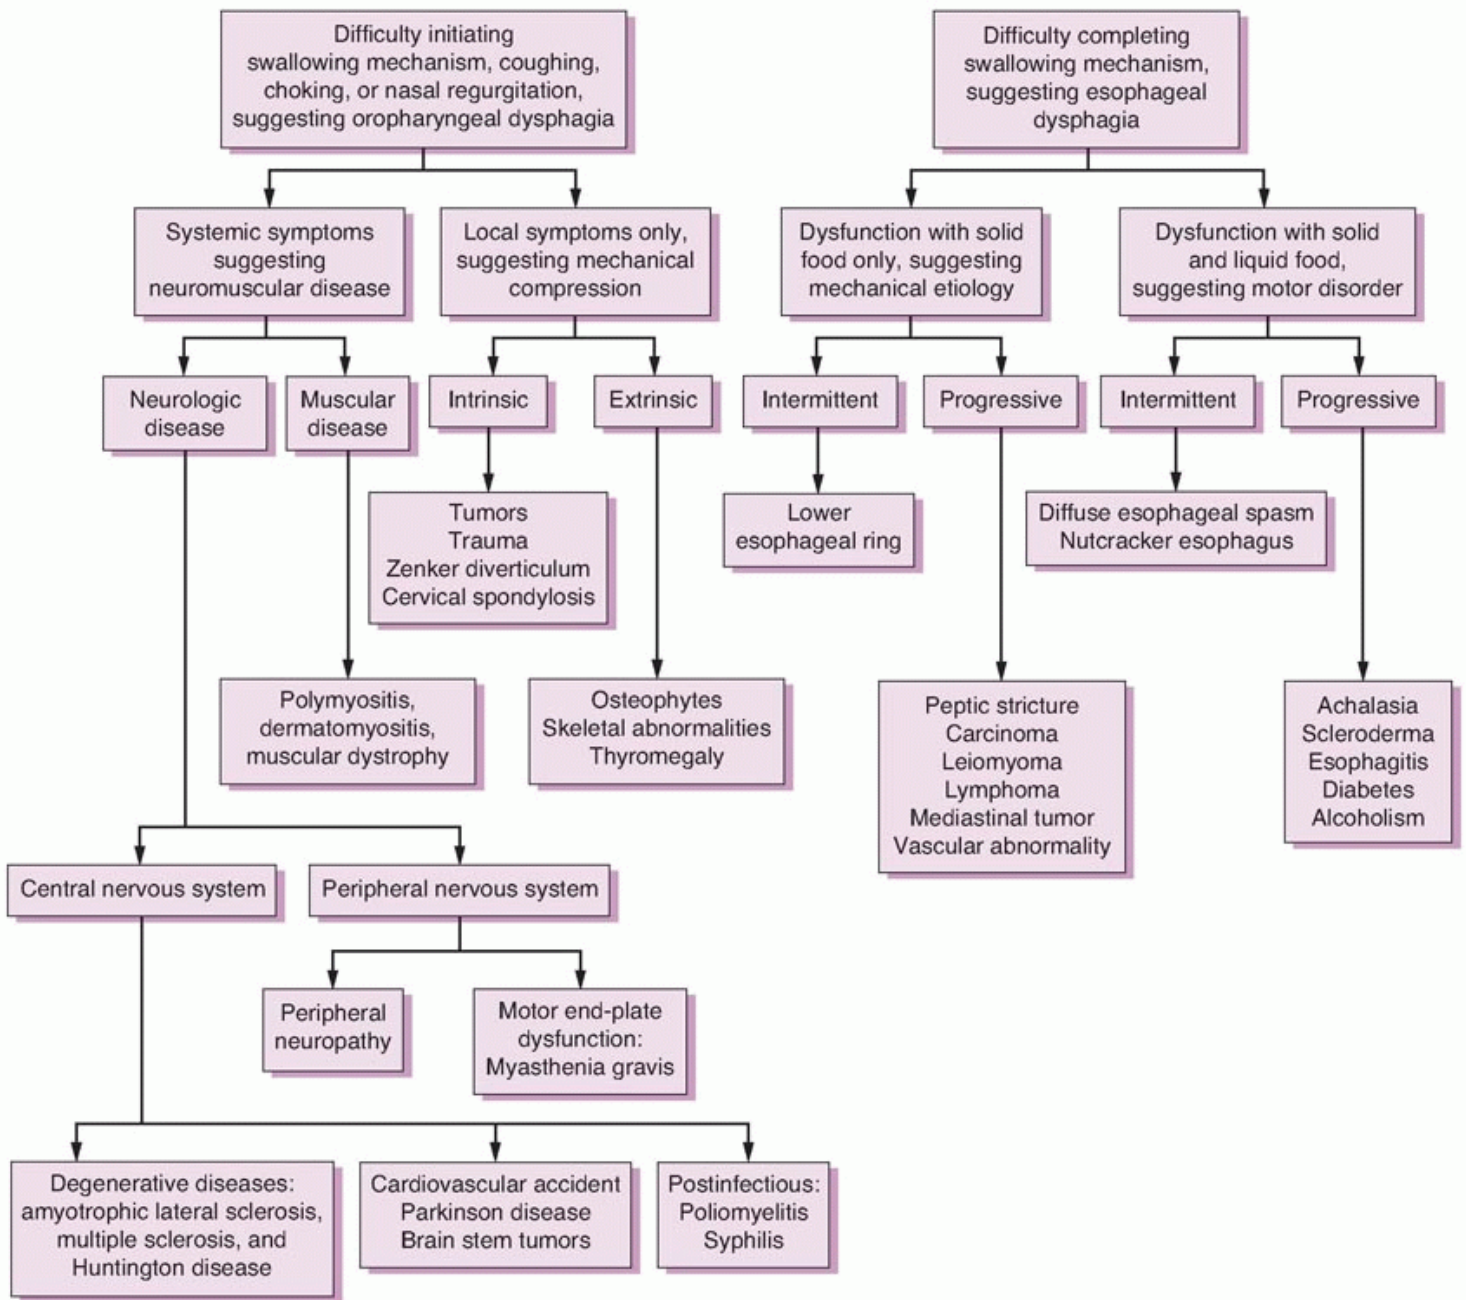

GI red flags: onset at age 55 years or later (lower threshold in areas where gastric cancer is common, e.g., Southeast Asia); overt GI bleeding; dysphagia; persistent vomiting; unintentional weight loss; family hx gastric or esophageal cancer; palpable abdominal/epigastric mass; abnormal adenopathy; iron-deficiency anemia

## JAUNDICE

Jaundice: a yellow discoloration of skin, sclera, and mucous membranes by bilirubin, a bile pigment formed by the breakdown of heme rings; detected when the serum bilirubin level >3 mg/dL. Bilirubin is a product of hemoglobin breakdown in the spleen. Heme is converted to unconjugated bilirubin, bound to albumin, and then sent to the liver where it is then conjugated.

Common causes: Gilbert syndrome, hemolysis, hepatitis, and choledocholithiasis

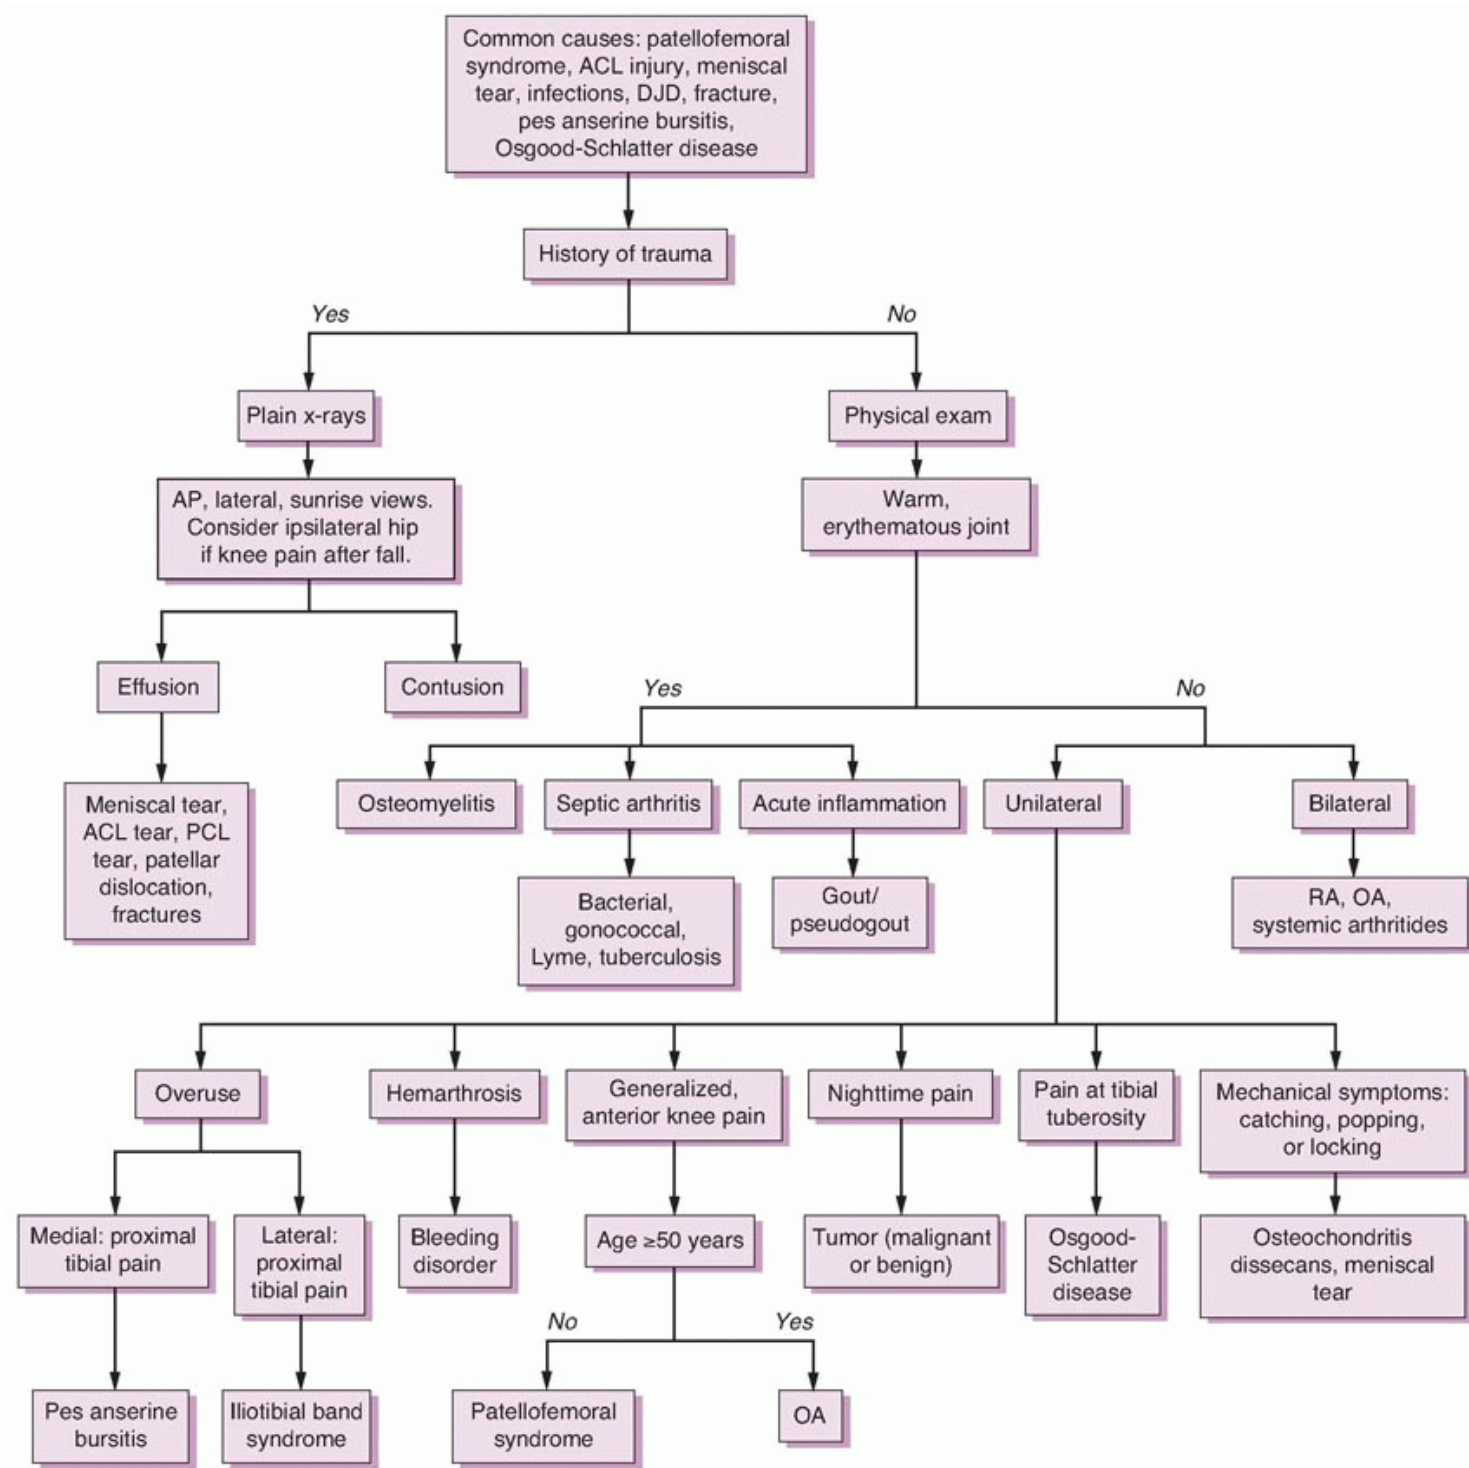

CBC w/ diff, LFTs: ALT, AST, serum alkaline phosphatase (AP), total bilirubin (TB) and direct bilirubin (DB), haptoglobin, hepatitis serologies, amylase, lipase, hCG, urinalysis with urine bilirubin. US or CT

# Abnormal (Dysfunctional) Uterine Bleeding

Stephen D. Cagle Jr., MD, Capt, USAF, MC

Matthew J. Snyder, DO

## BASICS

### DESCRIPTION

- Abnormal uterine bleeding (AUB) is irregular menstrual bleeding (usually heavy, prolonged, or frequent); it is a diagnosis of exclusion after establishment of normal anatomy and the absence of other medical illnesses.
- The International Federation of Gynecology and Obstetrics (FIGO) revised the terminology system and now uses AUB rather than dysfunctional uterine bleeding (DUB).
- Commonly associated with anovulation

### EPIDEMIOLOGY

Adolescent and perimenopausal women are affected most often.

#### *Incidence*

5% of reproductive age women will see a doctor in any given year for AUB.

#### *Prevalence*

10-30% of reproductive age women have AUB.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Anovulation accounts for 90% of AUB.
  - Loss of cyclic endometrial stimulation
  - Elevated estrogen levels stimulate endometrial growth.
  - No organized progesterone withdrawal bleeding
  - Endometrium eventually outgrows blood supply, breaks down, and sloughs from uterus.
  - 6-10% will have polycystic ovarian syndrome (PCOS).
- Adolescent AUB is usually due to an immature hypothalamic-pituitary-ovarian (HPO) axis that

leads to anovulatory cycles.

- AUB can be broadly divided into anovulatory bleeding (usually irregular and unpredictable menses) or ovulatory bleeding (usually heavy regular menses) after pathologic causes of abnormal bleeding have been ruled out.
  - Pregnancy: ectopic pregnancy, threatened or incomplete abortion, or hydatidiform mole
  - Reproductive pathology and structural disorders
    - Uterus: leiomyomas, endometritis, hyperplasia, polyps, trauma
    - Adnexa: salpingitis, functional ovarian cysts
    - Cervix: cervicitis, polyps, STIs, trauma
    - Vagina: trauma, foreign body
    - Vulva: lichen sclerosus, STIs
- Malignancy of the vagina, cervix, uterus, and ovaries
- Systemic diseases
  - Inflammatory bowel disease
  - Hematologic disorders (e.g., von Willebrand disease, thrombocytopenia)
  - Advanced or fulminant liver disease
  - Chronic renal disease
- Diseases causing anovulation
  - Hyperthyroidism/hypothyroidism
  - Adrenal disorders
  - Pituitary disease (prolactinoma)
  - PCOS
  - Eating disorders
- Medications (iatrogenic causes)
  - Anticoagulants
  - Steroids
  - Tamoxifen
  - Hormonal medications: intrauterine devices (IUDs)

- Selective serotonin reuptake inhibitors (SSRIs)
- Antipsychotic medications
- Other causes of AUB
  - Excessive weight gain
  - Increased exercise

## *Genetics*

Unclear but can include inherited disorders of hemostasis

## **RISK FACTORS**

Risk factors for endometrial cancer (which can cause AUB)

- Age >40 years
- Obesity
- PCOS
- Diabetes mellitus
- Nulliparity
- Early menarche or late menopause (>55 years of age)
- Hypertension
- Chronic anovulation or infertility
- Unopposed estrogen therapy
- History of breast cancer or endometrial hyperplasia
- Tamoxifen use
- Family history: gynecologic, breast, or colon cancer

## **DIAGNOSIS**

### **HISTORY**

- Menstrual history
  - Onset, severity (quantified by pad/tampon use, presence and size of clots), timing of bleeding (unpredictable or episodic)
  - Menorrhagia with onset of menarche is suggestive of a coagulation

disorder.

- Menopausal status
- Association with other factors (e.g., coitus, contraception, weight loss/gain)
- Gynecologic history: gravidity and parity, STI history, previous Pap smear results
- Review of systems (exclude symptoms of pregnancy and of bleeding disorders, bleeding from other orifices, stress, exercise, recent weight change, visual changes, headaches, galactorrhea)
- Medication history: Evaluate for use of aspirin, anticoagulants, hormones, and herbal supplements (1,2).

## **ALERT**

Postmenopausal bleeding is any bleeding that occurs >1 year after the last menstrual period; cancer must always be ruled out (2)[C].

## *PHYSICAL EXAM*

Discover anatomic or organic causes of AUB

- Evaluate for
  - Body mass index (obesity)
  - Pallor, vital signs (anemia)
  - Visual field defects (pituitary lesion)
  - Hirsutism or acne (hyperandrogenism)
  - Goiter (thyroid dysfunction)
  - Galactorrhea (hyperprolactinemia)
  - Purpura, ecchymosis (bleeding disorders)
- Pelvic exam
  - Evaluate for uterine irregularities and Tanner stage.
  - Check for foreign bodies.
  - Rule out rectal or urinary tract bleeding.
  - Include Pap smear and tests for STIs (2)[C].

## *Pediatric Considerations*

Premenarchal children with vaginal bleeding should be evaluated for foreign bodies, physical/sexual abuse, possible infections, and signs of precocious puberty.

## ***DIFFERENTIAL DIAGNOSIS***

See Etiology.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Everyone: urine human chorionic gonadotropin (hCG; rule out pregnancy and/or hydatidiform, mole) and complete blood count (CBC) (1)
  - For acute bleeding, a type and cross should be obtained (3)[C].
- If disorder of hemostasis is suspected, a partial thromboplastin time (PTT), prothrombin time (PT), activated partial thromboplastin time (aPTT), and fibrinogen level is appropriate (3)[C].
- If anovulation is suspected: thyroid stimulating hormone (TSH) level, prolactin level (1)
- Consider other tests based on differential diagnosis.
  - Follicle-stimulating hormone (FSH) level to evaluate for hypo- or hypergonadotropism
  - Coagulation studies and factors if coagulopathy is suspected (1)
  - 17-hydroxyprogesterone if congenital adrenal hyperplasia is suspected
  - Testosterone and/or dehydroepiandrosterone sulfate (DHEA-S) if PCOS
  - Screening for STI
- Endometrial biopsy (EMB) should be performed as part of the initial evaluation for postmenopausal uterine bleeding and in premenopausal women with risk factors for endometrial carcinoma (1)[A].
- TVUS, sonohysterography, and hysteroscopy may be similarly effective in detection of intrauterine pathology in premenopausal women with AUB (1)[A],(2)[C].
- If normal findings following imaging in patients without known risk factors for endometrial carcinoma, a biopsy should be performed if not done so previously (2)[C].

### ***Diagnostic Procedures/Other***

- Pap smear to screen for cervical cancer if age >21 years (2)[C]
- EMB should be performed in
  - Women age >35 years with AUB to rule out cancer or premalignancy

- Postmenopausal women with endometrial thickness >5 mm
- Women aged 18 to 35 years with AUB and risk factors for endometrial cancer (see Risk Factors)
- Perform on or after day 18 of cycle, if known; secretory endometrium confirms ovulation occurred.
- Dilation and curettage (D&C)
  - Perform if bleeding is heavy, uncontrolled, or if emergent medical management has failed.
  - Perform if unable to perform EMB in office (2)[C].
- Hysteroscopy if another intrauterine lesion is suspected

### *Test Interpretation*

Pap smear could reveal carcinoma or inflammation indicative of cervicitis. Most EMBs show proliferative or dyssynchronous endometrium (suggesting anovulation) but can show simple or complex hyperplasia without atypia, hyperplasia with atypia, or endometrial adenocarcinoma.

## **TREATMENT**

Attempt to rule out other causes of bleeding prior to instituting therapy.

P.3

### **GENERAL MEASURES**

NSAIDs (naproxen sodium 500 mg BID, mefenamic acid 500 mg TID, ibuprofen 600 to 1,200 mg/day) (1)[B]

- Decreases amount of blood loss compared with placebo, with no one clearly superior NSAID
- Diminishes pain

### **MEDICATION**

#### *First Line*

- Acute, emergent, nonovulatory bleeding
  - Conjugated equine estrogen (Premarin): 25 mg IV q4h (max 6 doses) or 2.5 mg PO q6h should control bleeding in 12 to 24 hours (4)[A]
  - D&C if no response after two to four doses of Premarin or sooner if bleeding >1 pad/hr (2)

[C]

- Then change to oral contraceptive pill (OCP) or progestin for cycle regulation, that is, IUD (5)[A]
- Acute, nonemergent, nonovulatory bleeding
  - Combination OCP with  $>30 \mu\text{g}$  estrogen given as a taper. An example of a tapered dose: 4 pills/day for 4 days; 3 pills/day for 3 days; 2 pills/day for 2 days, daily for 3 weeks then 1 week off, then cycle on OCP for at least 3 months.
- Nonacute, nonovulatory bleeding (ranked in order as the best option based on efficacy, cost, side effects, and consumer acceptability) (5)[A]
  - Levonorgestrel IUD (Mirena) is the most effective form of progesterone delivery and is not inferior to surgical management.
  - Progestins: medroxyprogesterone acetate (Provera) 10 mg/day for 5 to 10 days each month. Daily progesterone for 21 days per cycle results in significantly less blood loss.
  - OCPs: 20 to 35  $\mu\text{g}$  estrogen plus progesterone
- Do not use estrogen if contraindications, such as suspicion for endometrial hyperplasia or carcinoma, history of deep vein thrombosis (DVT), or the presence of smoking in women  $>35$  years of age (relative contraindication), are present.
- Precautions
  - Failed medical treatment requires further workup.
  - Consider DVT prophylaxis when treating with high-dose estrogens (2)[C].

## *Second Line*

- Leuprolide (varying doses and duration of action); gonadotropin-releasing hormone (GnRH) agonist
- Danazol (200 to 400 mg/day for a maximum of 9 months) is more effective than NSAIDs but is limited by androgenic side effects and cost. It has been essentially replaced by GnRH agonists.
- Antifibrinolytics such as tranexamic acid (Lysteda) 650 mg, 2 tablets TID (max 5 days during menstruation) (1)[A]
- Metformin or Clomid alone or in combination in women with PCOS who desire ovulation and pregnancy (6)[A]

## *ISSUES FOR REFERRAL*

If an obvious cause for vaginal bleeding is not found in a pediatric patient, refer to a pediatric endocrinologist or gynecologist (7).

- Patients with persistent bleeding despite medical treatment require reevaluation and referral to a gynecologist (7).

## ***ADDITIONAL THERAPIES***

- Antiemetics if treating with high-dose estrogen or progesterone (2)[C]
- Iron supplementation if anemia (usually iron deficiency) is identified

## ***SURGERY/OTHER PROCEDURES***

- Hysterectomy in cases of endometrial cancer or if medical therapy fails or if other uterine pathology is found
- Endometrial ablation is less expensive than hysterectomy and is associated with high patient satisfaction; failure of primary medical treatment is not necessary (1,4)[A].
  - This is a permanent procedure and should be avoided in patients who desire continued fertility.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Significant hemorrhage causing acute anemia with signs of hemodynamic instability; with acute bleeding, replace volume with crystalloid and blood, as necessary (1)[A].

### ***Nursing***

Pad counts and clot size can be helpful to determine and monitor amount of bleeding.

### ***Discharge Criteria***

- Hemodynamic stability
- Control of vaginal bleeding (2)[C]

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Once stable from acute management, recommend follow-up evaluation in 4 to 6 months for

further evaluation (5).

- Routine follow-up with a primary care or OB/GYN provider

## *Patient Monitoring*

Women treated with estrogen or OCPs should keep a menstrual diary to document bleeding patterns and their relation to therapy.

## *DIET*

No restrictions, although a 5% reduction in weight can induce ovulation in anovulation caused by PCOS (7)[C].

## *PATIENT EDUCATION*

- Explain possible/likely etiologies.
- Answer all questions, especially those related to cancer and fertility.
- <http://www.acog.org/Patients>

## *PROGNOSIS*

- Varies with pathophysiologic process
- Most anovulatory cycles can be treated with medical therapy and do not require surgical intervention.

## **COMPLICATIONS**

- Iron deficiency anemia
- Uterine cancer in cases of prolonged unopposed estrogen stimulation

## Codes

### ICD10

- N93.9 Abnormal uterine and vaginal bleeding, unspecified
- N93.8 Other specified abnormal uterine and vaginal bleeding
- N91.2 Amenorrhea, unspecified

### Clinical Pearls

- AUB is irregular bleeding that occurs in the absence of pathology, making it a diagnosis of exclusion.
- Anovulation accounts for 90% of AUB.
- An EMB should be performed in all women >35 years of age with AUB to rule out cancer or premalignancy, and it should be considered in women aged 18 to 35 years with AUB and risk factors for endometrial cancer.
- It is appropriate to initiate medical therapy in females <35 years of age with no apparent risk of endometrial cancer prior to performing an EMB.

# Abnormal Pap and Cervical Dysplasia

Fozia Akhtar Ali, MD

Tharani Vadivelu Prasad, MD

## BASICS

### DESCRIPTION

- Cervical dysplasia: Premalignant cervical disease that is also called cervical intraepithelial neoplasia (CIN). Precancerous epithelial changes in the transformation zone of the uterine cervix almost always associated with human papillomavirus (HPV) infections.
- CIN encompasses a range of histologic diagnoses.
  - CIN I: mild dysplasia; low-grade lesion; cellular changes are limited to the lower 1/3 of the squamous epithelium.
  - CIN II: moderate dysplasia; high-grade lesion; cellular changes are limited to the lower 2/3 of the squamous epithelium.
  - CIN III or carcinoma in situ: severe dysplasia; high-grade lesion; cellular changes involve the full thickness of the squamous epithelium.
- System(s) affected: reproductive

### ALERT

Incidence of cervical cancer has decreased by >50% in the last 30 years due to cervical cytology screening.

### *Pediatric Considerations*

Cervical cancer is rare before age 21 years. Screening women younger than age 21 years (regardless of sexual history) does not reduce cervical cancer incidence and mortality compared with beginning screening at age 21 years. Screenings of adolescents lead to unnecessary evaluation and overtreatment of cervical lesions, which are highly likely to spontaneously regress (1)[A].

### *Geriatric Considerations*

- Women age >65 years who have had adequate prior screening and no history of CIN II+ in the last 20 years should not be screened for cervical cancer. Adequate prior screening is

defined as three consecutive, negative cytology results or two consecutive, negative HPV results within 10 years before cessation of screening (with the most recent test within the last 5 years).

- Routine screening should continue for at least 20 years after spontaneous regression or appropriate management of a high-grade precancerous lesion, even if this extends screening past the age 65 years.

### *Pregnancy Considerations*

- Squamous intraepithelial lesions can progress during pregnancy but often regress postpartum.
- Colposcopy only to exclude the presence of invasive cancer in high-risk women
- Endocervical curettage is contraindicated during pregnancy (2).
- Unless cancer is identified or suspected, treatment of cervical intraepithelial neoplasia is contraindicated during pregnancy.

## **EPIDEMIOLOGY**

- Cervical cancer is the 3rd most common cancer among women worldwide and ranks 14th for cancer deaths in women (3).
- Predominant age: can occur at any age, but incidence of CIN III peaks between ages 25 and 29; invasive disease peaks 15 years later. Cervical cancer most commonly occurs in women aged 35 to 55 years.

### *Incidence*

The American Cancer Society estimates that, in 2014, 12,360 women will be diagnosed with invasive cervical cancer and 4,020 women will die from cervical cancer (4). Large declines in incidence rates over the past decades have begun to taper off. From 2006 to 2010, cervical cancer incidence rates have been stable in women younger than 50 years and decreasing by 3.1% per year in women 50 years and older.

### *Prevalence*

- ÷80% of sexually active women will have acquired a genital HPV infection by 50 years of age.
- Overall, 26.8% of women are HPV positive. Point prevalence of HPV positivity is highest in those 18 to 22 years of age (as high as 70%), falling off rapidly as women enter their 30s.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

HPV DNA is found in virtually all cervical carcinomas and precursor lesions worldwide.

- High-risk HPV types: 16, 18, 31, 33, 35, 45, 52, and 58 are common oncogenic virus types for cervical cancer.
- HPV 16 is the most carcinogenic HPV genotype and accounts for 55-60% of all cervical cancers.
- HPV 18 is the next most carcinogenic HPV genotype. HPV 18 causes a greater proportion of glandular cancers, adenocarcinoma, and adenosquamous carcinoma than squamous cell carcinoma.
- Most HPV infections are transient, becoming undetectable within 1 to 2 years. Persistent infections are what place women at significant risk for developing precancerous lesions.
- Low-risk types: HPV viral types 6, 11, 42, 43, and 44 are considered common low-risk types and may cause genital warts. HPV 6 and 11 (cause 90% of benign anogenital warts) can lead to low-grade squamous intraepithelial lesion (LSIL) and CIN I.

## *RISK FACTORS*

- Previous or current HPV infection
- HIV infection and other immunosuppressive conditions
- In utero exposure to diethylstilbestrol
- Previous treatment of a high-grade precancerous lesion or cervical cancer
- Cigarette smoking
- Early age at first coitus (<20 years) and multiple sexual partners
- Some correlation with low socioeconomic status, high parity, oral contraceptive use, and poor nutrition

## *GENERAL PREVENTION*

- Immunization: Immunization decreases high-risk HPV infections and cervical pathology for at least 5 to 7 years but has not yet been shown to decrease cervical cancer.
  - Ideally, HPV immunization of girls, boys, and women should be initiated prior to first intercourse.
    - Gardasil (quadrivalent: HPV 4):
      - Reduces dysplasia due to HPV types 16 and 18 (70% of cervical cancer) and types 6 and 11 (anogenital warts)
      - Three doses at 0, 2, and 6 months, approved for use in females ages 9 to 26 years. Only the quadrivalent vaccine is approved for males (ages 9 to 26 years) for

prevention of anogenital warts.

- Cervarix (bivalent: HPV 2): reduces dysplasia due to HPV 16 and 18 infection and CIN. Three doses at 0, 1, and 6 months, approved for use in females ages 10 to 25 years.
- Gardasil 9: approved in December 2014 for use in females ages 9 to 26 and males ages 9 to 15; adds protection against five additional HPV types which cause approximately 25% of CIN II+ lesions
- Safe sex practices: condom use
- Screening
  - Pap smear is the main screening test for cervical cellular pathology.
  - Screening recommendations by age and source (see algorithm "Pap, Normal and Abnormal in Nonpregnant Women Ages 25 Years and Older" and separate algorithm "Pap, Normal and Abnormal in Women Ages 21-24 Years")
    - <21 years: Do not screen (5) (USPSTF/ASCCP/ACS/ASCP/ACOG).
  - Frequency of screening recommendation: USPSTF/ASCCP/ACS/ASCP generally agree by age and screen.
    - 21 to 29 years: Screen with cytology (Pap smear) every 3 years (5)[A]. Do not screen with HPV testing alone or combined with cytology (5).
    - 30 to 65 years: Screen with cytology every 3 years (acceptable) or cotesting (cytology/HPV testing) every 5 years (preferred).
    - >65 years (who have had adequate prior screening and are not high risk): Do not screen (5).
- Special circumstances: women after hysterectomy with removal of the cervix and with no history of CIN II+: Do not screen (6)[A].

## DIAGNOSIS

### HISTORY

Usually asymptomatic until there is invasive disease. Patients may present with vaginal discharge, abnormal vaginal bleeding, postcoital bleeding, pelvic pain, cervical mass, or bladder obstruction.

### PHYSICAL EXAM

Pelvic exam occasionally reveals external HPV lesions. Examine for exophytic or ulcerative cervical

lesions, with or without bleeding.

## ***DIFFERENTIAL DIAGNOSIS***

Acute or chronic cervicitis; cervical glandular hyperplasia; cervical polyp; cervical fibroid; HPV infection; invasive cervical malignancy; uterine malignancy

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Current evidence indicates no clinically important differences between conventional cytology and liquid-based cytology in detecting cervical cancer precursors (6)[A]. Conventional Pap smear involves a cervical sample plated on a microscope slide with fixative. Thin prep is a liquid-based collection and thin-layer preparation.
- Sensitivity of a single Pap smear for HSIL  $\div$ 60-70%; specificity of  $\div$ 90%. Pap smears done routinely at recommended intervals increase the sensitivity further.
- HPV viral typing: High-risk HPV subtype testing is more sensitive but less specific for identifying women with prevalent CIN III+.
- Cytology report component: specimen type (conventional Pap smear or liquid based), adequacy (presence of endocervical cells), and categorization (negative for intraepithelial lesion or malignancy or epithelial cell abnormality; i.e., squamous/glandular)

---

P.5

- Bethesda system (cytologic grading) epithelial cell abnormalities
  - Squamous cell
    - Atypical squamous cell (ASC) (of undetermined significance [ASC-US], cannot exclude high-grade squamous intraepithelial lesion [ASC-H])
    - HPV, mild dysplasia, CIN I
    - Moderate/severe dysplasia CIS, CIN II, and CIN III
  - Glandular cell
    - AGCs (atypical glandular cells)
      - AGCs: not otherwise specified
      - AGCs: favor neoplasia
    - AIS (adenocarcinoma in situ)
    - Adenocarcinoma

## *Diagnostic Procedures/Other*

Algorithms differ for women age 21 to 24 years; see ASCCP guidelines (2) and algorithm Pap, Normal and Abnormal in Women Ages 21-24 Years. Below recommendations for ages as noted.

- HPV positive, cytology negative (30 years of age and older)
  - Option 1: HPV DNA typing: if HPV 16 or 18+, proceed to colposcopy; if negative, repeat cotesting at 1 year (6)[B].
  - Option 2: Repeat cotesting at 1 year: if ASC or HPV positive, proceed to colposcopy; if negative, repeat cotesting at 3 years.
- ASC-US: (>24 years of age)
  - Option 1: HPV testing (preferred)
    - If HPV positive, proceed to colposcopy (2)[B].
    - If HPV negative, repeat cotesting at 3 years (2)[B].
  - Option 2: Repeat cytology at 1 year (acceptable) (2)
    - If repeat cytology ASC or greater, proceed to colposcopy.
    - If repeat cytology is negative, proceed to routine screening in 3 years.
- ASC-H: Colposcopy is required.
- LSIL: (>24 years of age)
  - LSIL with negative HPV test: Repeat cotesting at 1 year (preferred).
    - If repeat cotesting is negative, repeat cotesting in 3 years.
    - If cotesting is positive, proceed to colposcopy.
  - LSIL with no HPV test or positive HPV test: Proceed to colposcopy.
  - LSIL in pregnancy: Colposcopy is preferred, but it is acceptable to defer colposcopy to postpartum (2).
- HSIL: loop electrosurgical excision procedure (LEEP) or colposcopy (2)[B]
- Atypical glandular cells: colposcopy with endocervical sampling and endometrial sampling (if 35 years or older or at risk for endometrial neoplasia) (2)[A]
- Atypical endometrial cells: endometrial and endocervical sampling
  - If negative, perform colposcopy.

- Women with no lesion on colposcopy or CIN I (preceded by lesser abnormalities such as ASC-US, LSIL, HPV 16+, HPV 18+, and persistent HPV)
  - Follow-up without treatment: cotesting at 12 months
  - If both HPV and cytology are negative, age-appropriate retesting 3 years later
  - If either positive, proceed to colposcopy. If persistent CIN I for at least 2 years, proceed to treatment with ablative or excisional methods.
- Ages 21 to 24: Management is slightly different than above; see ASCCP guidelines (2) or algorithm Pap, Normal and Abnormal in Women Ages 21-24 Years.
- Age >30: If cytology is negative but HPV is positive, repeat cotesting at 1 year is acceptable.

## *Test Interpretation*

Atypical squamous or columnar cells, coarse nuclear material, increased nuclear diameter, koilocytosis (HPV hallmark)

## **TREATMENT**

ASCCP guidelines: Evidence-based management algorithms guide Pap smear and postcolposcopic diagnostics and therapeutics and are available online at <http://www.asccp.org/Guidelines> (2).

## **GENERAL MEASURES**

Office evaluation and observation; promote smoking cessation; promote protected intercourse; promote immunization.

## **MEDICATION**

- Infective/reactive Pap smear: Treat trichomoniasis, symptomatic candida, or shift in flora suggestive of bacterial vaginosis found on Pap smear results.
- Condyloma acuminatum: may be treated with cryotherapy or podophyllin topically q1-2wks or podofilox 0.5% applied BID x 3 days then off 4 days, repeated for 1 to 4 weeks, OR trichloroacetic acid applied topically by a physician and covered for 5 to 6 days, OR imiquimod cream 3 times per week at bedtime, up to 16 weeks

## **SURGERY/OTHER PROCEDURES**

- Persistent CIN I, II, or III: ablative or excisional methods. If inadequate colposcopy for CIN II or III or recurrent CIN II or III, diagnostic excisional procedure is done. For adenocarcinoma in situ, hysterectomy is preferred.

- Cryotherapy, laser ablation, LEEP/large loop excision of transition zone, or cold-knife conization are all effective but require different training and with different side effects for patient. If cervical malignancy, see Cervical Malignancy.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

After treatment (excision or ablation) of CIN II or III, women may reenter routine screening only after negative cotesting between 12 and 24 months. Screening should be continued for 20 years (6)[B].

### *DIET*

Promote increased intake of antioxidant-rich foods.

### *PATIENT EDUCATION*

HPV vaccination, smoking cessation, protected intercourse, regular screening with Pap smear per guidelines

### *PROGNOSIS*

- Progression of CIN to invasive cervical cancer is slow, and the likelihood of regression is high: Up to 43% of CIN II and 32% of CIN III lesions may regress. CIN III has a 30% probability of becoming invasive cancer over a 30-year period, although only about 1% if treated.
- CIN III becomes invasive (7). Lesions discovered early are amenable to treatment with excellent results and few recurrences.
- One- and five-year relative survival rates for cervical cancer patients are 87% and 68%, respectively. The 5-year survival rate for patients diagnosed with localized disease is 91% (4).

### **COMPLICATIONS**

Aggressive cervical surgery may be associated with cervical stenosis, cervical incompetence, and scarring affecting cervical dilatation in labor.

- Algorithm: Pap, Normal and Abnormal in Nonpregnant Women Ages 25 Years and Older; Pap, Normal and Abnormal in Women Ages 21-24 Years

## ICD10

- R87.619 Unspecified abnormal cytological findings in specimens from cervix uteri
- N87.9 Dysplasia of cervix uteri, unspecified
- N87.1 Moderate cervical dysplasia

## Clinical Pearls

- HPV is present in virtually all cervical cancers (99.7%), but most HPV infections are transient.
- Vaccine should be offered prior to onset of any sexual activity for maximum effectiveness.
- Know and adhere to recognized screening guidelines to avoid the harms of overscreening.

# Abortion, Spontaneous (Miscarriage)

Clara M. Keegan, MD

## BASICS

### DESCRIPTION

- Spontaneous abortion (SAb) (miscarriage) is the failure or loss of a pregnancy before 13 weeks' gestational age (WGA).
- Related terms
  - Anembryonic gestation: gestational sac on ultrasound (US) without visible embryo after 6 WGA
  - Complete abortion: entire contents of uterus expelled
  - Ectopic pregnancy: pregnancy outside the uterus
  - Embryonic or fetal demise: cervix closed; embryo or fetus present in the uterus without cardiac activity.
  - Incomplete abortion: abortion with retained products of conception, generally placental tissue
  - Induced or therapeutic abortion: evacuation of uterine contents or products of conception medically or surgically
  - Inevitable abortion: cervical dilatation or rupture of membranes in the presence of vaginal bleeding
  - Recurrent abortion: <sup>3</sup>3 consecutive pregnancy losses at <15 WGA
  - Threatened abortion: vaginal bleeding in the 1st trimester of pregnancy
  - Septic abortion: a spontaneous or therapeutic abortion complicated by pelvic infection; common complication of illegally performed induced abortions
- Synonym(s): miscarriage; early pregnancy loss
  - Missed abortion and blighted ovum are used less frequently in favor of terms representing the sonographic diagnosis.

## *EPIDEMIOLOGY*

Predominant age: increases with advancing age, especially >35 years; at age 40 years, the loss rate is twice that of age 20 years.

### *Incidence*

- Threatened abortion (1st-trimester bleeding) occurs in 20-25% of clinical pregnancies.
- Between 10% and 15% of all clinically recognized pregnancies end in SAb, with 80% of these occurring within 12 weeks after last menstrual period (LMP) (1).
- When both clinical and biochemical ( $\beta$ -hCG detected) pregnancies are considered, about 30% of pregnancies end in SAb.
- One in four women will have a SAb during her lifetime (1).

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Chromosomal anomalies (50% of cases)
- Congenital anomalies
- Trauma
- Maternal factors: uterine abnormalities, infection (toxoplasma, other viruses, rubella, cytomegalovirus, herpesvirus), maternal endocrine disorders, hypercoagulable state

### *Genetics*

Approximately 50% of 1st-trimester SAb have significant chromosomal anomalies, with 50% of these being autosomal trisomies and the remainder being triploidy, tetraploidy, or 45X monosomies.

## *RISK FACTORS*

Most cases of SAb occur in patients without identifiable risk factors; however, risk factors include the following:

- Chromosomal abnormalities
- Advancing maternal age
- Uterine abnormalities
- Maternal chronic disease (antiphospholipid antibodies, uncontrolled diabetes mellitus, polycystic ovarian syndrome, obesity, hypertension, thyroid disease, renal disease)
- Other possible contributing factors include smoking, alcohol, cocaine use, infection, and luteal phase defect.

## GENERAL PREVENTION

- Insufficient evidence supports the use of aspirin and/or other anticoagulants, bed rest, hCG, immunotherapy, progestogens, uterine muscle relaxants, or vitamins for general prevention of SAb, before or after threatened abortion is diagnosed.
- By the time hemorrhage begins, 1/2 of pregnancies complicated by threatened abortion already have no fetal cardiac activity.
- Recurrent abortion: Women with a history of <sup>33</sup> prior SAb may benefit from progestogens (OR 0.39, 95% CI 0.21-0.72) (2)[A].
- Antiphospholipid syndrome: The combination of unfractionated heparin and aspirin reduces risk of SAb in women with antiphospholipid antibodies and a history of recurrent abortion (RRR 46%, 95% CI 0.29-0.71) (3)[A].

## DIAGNOSIS

### HISTORY

- The possibility of pregnancy should be considered in a reproductive-age woman who presents with nonmenstrual vaginal bleeding.
- Vaginal bleeding
  - Characteristics (amount, color, consistency, associated symptoms), onset (abrupt or gradual), duration, intensity/quantity, and exacerbating/precipitating factors
  - Document LMP if known: allows calculation of estimated gestational age
- Abdominal pain/uterine cramping, as well as associated nausea/vomiting/syncope
- Rupture of membranes
- Passage of products of conception
- Prenatal course: toxic or infectious exposures, family or personal history of genetic abnormalities, past history of ectopic pregnancy or SAb, endocrine disease, autoimmune disorder, bleeding/clotting disorder

### PHYSICAL EXAM

- Orthostatic vital signs to estimate hemodynamic stability
- Abdominal exam for tenderness, guarding, rebound, bowel sounds (peritoneal signs more likely with ectopic pregnancy)

- Speculum exam for visual assessment of cervical dilation, blood, and products of conception (confirms diagnosis of SAb)
- Bimanual exam to assess for uterine size-dates discrepancy and adnexal tenderness or mass

## *DIFFERENTIAL DIAGNOSIS*

- Ectopic pregnancy: potentially life-threatening; must be considered in any woman of childbearing age with abdominal pain and vaginal bleeding
- Physiologic bleeding in normal pregnancy (implantation bleeding)
- Subchorionic bleeding
- Cervical polyps, neoplasia, and/or inflammatory conditions
- Hydatidiform mole pregnancy
- hCG-secreting ovarian tumor

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Quantitative hCG
  - Particularly useful if intrauterine pregnancy (IUP) has not been documented by US.
  - Serial quantitative serum hCG measurements can assess viability of the pregnancy. Serum hCG should rise at least 53% every 48 hours through 7 weeks after LMP. An inappropriate rise, plateau, or decrease of hCG suggests abnormal IUP or possible ectopic pregnancy.
- Complete blood count (CBC) with differential
- Rh type
- Cultures: gonorrhea/chlamydia
- US exam to evaluate fetal viability and to rule out ectopic pregnancy (4)[A]
  - hCG >2,000 mIU/mL necessary to detect IUP via transvaginal US (TVUS), >5,500 mIU/mL for abdominal US
  - TVUS criteria for nonviable intrauterine gestation: 7-mm fetal pole without cardiac activity or 25-mm gestational sac without a fetal pole, IUP with no growth over 1 week, or previously seen IUP no longer visible
  - Structures and timing: with TVUS, gestational sac of 2 to 3 mm generally seen around 5 WGA; yolk sac by 5.5 WGA; fetal pole with cardiac activity by 6 WGA

## *Follow-Up Tests & Special Considerations*

- In the case of vaginal bleeding with no documented IUP and hCG <2,000 mIU/mL, follow serum hCG levels weekly to zero.
- If levels plateau, consider ectopic pregnancy or retained products of conception. If levels are very high, consider gestational trophoblastic disease.
- If initial hCG level does not permit documentation of IUP by TVUS, follow serum hCG in 48 hours to document appropriate rise.
- Repeat US once hCG is at a level commensurate with visualization on US (see above).
- Provide patient with ectopic precautions in interim: worsening abdominal pain, dizziness/syncope, nausea/vomiting.
- In a pregnancy of unknown location with hCG rise <53% in 48 hours, offer methotrexate for treatment of presumed ectopic pregnancy.

## *Diagnostic Procedures/Other*

- Fetal heart tones can be auscultated with Doppler starting between 10 and 12 WGA in a viable pregnancy.
- In threatened abortion, fetal cardiac activity at 7 to 11 WGA is 90-96% predictive of continued pregnancy.

## **TREATMENT**

### **GENERAL MEASURES**

- Discuss contraception plan at the time of diagnosis of SAb, as ovulation can occur prior to resumption of normal menses.
- Expectant management (Òwatchful waitingÓ) is 90% effective for incomplete abortion, although it may take several weeks for the process to be complete (1)[A]. This approach is only recommended in the 1st trimester and is more effective in women with symptoms of impending pregnancy loss (5)[C].

### **MEDICATION**

- Long-term conception rate and pregnancy outcomes are similar for women who undergo expectant management, medical treatment, or surgical evacuation.

- Postinfection rates are lower with medical versus surgical management.

## *First Line*

- Misoprostol: most common agent for inducing passage of tissue in missed or incomplete abortion
  - Off-label use; has not been submitted to the FDA for consideration for use in treatment of early pregnancy failure. Recognized by the World Health Organization (WHO) as a life-saving medication for this indication.
  - Efficacy: complete expulsion of products of conception in 71% by day 3, 84% by day 8
  - Efficacy depends on route of administration, gestational age of pregnancy, and dose.
  - Recommended dose is 800  $\mu\text{g}$  vaginally; alternate regimens include the WHO regimen of 600  $\mu\text{g}$  sublingually q3h for up to 3 doses; multidose regimens and oral dosing (including buccal and sublingual) may result in increased side effects.
- Common adverse effects include abdominal pain/cramping, nausea, and diarrhea. Pain increases at higher doses but is manageable with oral analgesia. There is no increase in nausea/diarrhea with a higher dose.
- Recommended for stable patients who decline surgery but do not want to wait for spontaneous passage of products of conception.

## *Second Line*

- Rh-negative patients should be given Rh immunoglobulin (RhoGAM) 50  $\mu\text{g}$  IM following a SAb.
- Women with evidence of anemia should receive iron supplementation.

## *ISSUES FOR REFERRAL*

Patients should be monitored for up to 1 year for the development of pathologic grief. There is insufficient evidence to support counseling to prevent development of anxiety or depression related to grief following SAb.

## *SURGERY/OTHER PROCEDURES*

- Uterine aspiration (suction dilation and curettage [D&C] or manual vacuum aspiration [MVA]) is the conventional treatment.
- Indications: septic abortion, heavy bleeding, hypotension, patient choice
- Risks (all rare): anesthesia (usually local), uterine perforation, intrauterine adhesions, cervical trauma, infection that may lead to infertility or increased risk of ectopic pregnancy

- When compared with expectant management, surgical intervention leads to fewer days of vaginal bleeding, with a lower risk of incomplete abortion and heavy bleeding but a higher risk of infection (6)[A].
- Vacuum aspiration (manual or electric) is considered preferable to sharp curettage, as aspiration is less painful, takes less time, involves less blood loss, and does not require general anesthesia. The WHO supports use of suction curettage over rigid metal curettage.
- Although data from induced abortions suggest that antibiotic prophylaxis with doxycycline 100 mg BID reduces the already rare risk of postprocedure infection, data are insufficient to support use of antibiotics after aspiration for SAb (7)[A].

## COMPLEMENTARY & ALTERNATIVE MEDICINE

A systematic review of Chinese herbal medicine alone and in conjunction with Western medicine showed benefit over Western medicine alone in achieving continued viability at 28 weeks (number needed to treat [NNT] = 4.8 pregnancies with combined therapy). However, the available studies did not meet international standards for reporting quality (8)[C].

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

If the patient has orthostatic vital signs, initiate resuscitation with IV fluids and/or blood products, if needed.

### *IV Fluids*

Hemodynamically unstable patients may require IV fluids and/or blood products to maintain BP.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

All patients should be offered follow-up in 2 to 6 weeks to monitor for resolution of bleeding, return of menses, and symptoms related to grief, as well as to review the contraception plan.

### *Patient Monitoring*

- If SAb occurs in setting of previously documented IUP and abortion is completed with resumption of normal menses, it is not necessary to check or follow serum hCG to 0.
- After medical management, confirm complete expulsion with US or serial serum  $\beta$ -hCG (5)[C].
- If pregnancy is not immediately desired, offer effective contraception. Immediate insertion of

an intrauterine device is both acceptable and safe.

- If pregnancy is desired, provide preconception counseling. There is no evidence that it is necessary to wait a certain number of cycles before attempting conception again.

## **DIET**

NPO if patient is to undergo D&C under general anesthesia

## **PATIENT EDUCATION**

- Pelvic rest for 1 week after D&C or MVA
- Advise patients to call with excessive bleeding (soaking two pads per hour for 2 hours), fever, pelvic pain, or malaise, which could indicate retained products of conception or endometritis.
- A patient fact sheet on miscarriage is available through the American Academy of Family Physicians at <http://www.aafp.org/afp/2011/0701/p85.html>.

## **PROGNOSIS**

- Prognosis is excellent once bleeding is controlled.
- Recurrent abortion: Prognosis depends on etiology; up to 70% rate of success with subsequent pregnancy

## **COMPLICATIONS**

- D&C or MVA: uterine perforation, bleeding, adhesions, cervical trauma, and infection that may lead to infertility or increased risk of ectopic pregnancy. Bleeding and adhesions more common with D&C than with MVA; all complications rare
- Retained products of conception

## See Also

- Ectopic Pregnancy
- Algorithm: Abortion, Recurrent

## ICD10

- O03.9 Complete or unspecified spontaneous abortion without complication
- O03.4 Incomplete spontaneous abortion without complication
- O02.1 Missed abortion

## Clinical Pearls

- Any pregnant woman with abdominal pain and/or vaginal bleeding must be evaluated to rule out ectopic pregnancy, which is potentially life threatening.
- As all options have similar long-term outcomes, patient preference should determine whether management is expectant, medical, or surgical.

# Acetaminophen Poisoning

Dawn Sloan, MD

## BASICS

### DESCRIPTION

- A disorder characterized by hepatic necrosis following large ingestions of acetaminophen. Symptoms may vary from initial nausea, vomiting, diaphoresis, and malaise to jaundice, confusion, somnolence, coma, and death. The clinical hallmark is the onset of symptoms within 24 hours of ingestion of acetaminophen-only or combination products. Ideally, ingestion is treated before symptoms develop.
- Acetaminophen poisoning is most often encountered following large, single ingestions of acetaminophen-containing medications. Usual toxic doses are >10 g in adults and >200 mg/kg in children. However, poisoning also occurs after acute and chronic ingestions of lesser amounts in susceptible individuals, including those who regularly abuse alcohol, are chronically malnourished, or take medications that affect hepatic metabolism of acetaminophen.
- Therapeutic adult doses are 0.5 to 1 g q4-6h, up to a maximum of 4 g/day. Therapeutic pediatric doses are 10 to 15 mg/kg q4-6h, not to exceed 5 doses in 24 hours.
- System(s) affected: gastrointestinal, cardiovascular, renal/urologic
  - Multisystem organ failure can occur.
- Synonym(s): paracetamol poisoning

### Geriatric Considerations

Hepatic damage may be increased if chronically taking hepatotoxic medications.

### Pediatric Considerations

Hepatic damage at toxic acetaminophen levels is decreased in young children. This may be due to larger glutathione stores.

### Pregnancy Considerations

- Increased incidence of spontaneous abortion, especially with overdose at early gestational age
- Incidence of spontaneous abortion or fetal death appears to be increased when *N*-

acetylcysteine (NAC) treatment is delayed.

- IV NAC is generally preferred in pregnancy since it may offer greater bioavailability.

## ***EPIDEMIOLOGY***

- Predominant age: children and adults
- Predominant sex: no reported association

### ***Incidence***

>24,000 ED visits per year on average from 2004 to 2012 for acetaminophen-related overdoses in the United States

### ***Prevalence***

- >38,000 hospitalizations per year on average from 1998 to 2011 for acetaminophen-related poisonings in the United States
- <1% of hospitalizations in those <18 years old had coexistent liver toxicity.

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

- Accidental or intentional ingestion of acetaminophen or combination medications containing acetaminophen
- 96% of ingested acetaminophen is metabolized in the liver, with only 2-4% excreted unchanged in the urine. When taken in therapeutic doses, 90-95% of hepatic metabolism occurs via glucuronidation and sulfation and results in the formation of benign metabolites. 5-10% of hepatic metabolism is by oxidation through the cytochrome P<sub>450</sub> enzyme system (CYP 3A4 and CYP 2E1), which results in the formation of the toxic metabolite *N*-acetyl-*p*-benzoquinoneimine (NAPQI). NAPQI is rapidly conjugated with glutathione to form a nontoxic metabolite. The metabolites are excreted in the urine along with a small amount of unchanged drug. Hepatocellular damage typically occurs when toxic doses of acetaminophen result in saturation of the glucuronidation and sulfation pathways with subsequent production of excessive amounts of NAPQI. Available glutathione stores become depleted, NAPQI accumulates, and hepatocellular damage occurs.

## ***RISK FACTORS***

- Concurrent poisoning with other substances
- Psychiatric illness
- Previous toxic ingestions or suicide attempts

- Regular ingestion of large amounts of alcohol

## GENERAL PREVENTION

Parent/caregiver education essential:

- Education during well-child exams regarding poisoning prevention
- Emergency telephone numbers

## DIAGNOSIS

- May present asymptomatic with history of ingestion in the last 8 hours, as signs and symptoms are related to liver toxicity and develop over the first 24 hours following large ingestions; may last as long as 8 days
- Symptoms may develop gradually following long-term ingestion of near-maximal therapeutic amounts of acetaminophen. Such patients may present in stages 1 to 3, without a history of ingestion of the usual toxic doses.
- Severe symptoms indicate large ingestions or coingestants:
  - Stage 1: first 24 hours after time of ingestion:
    - Nausea
    - Vomiting
    - Diaphoresis
  - Stage 2: 24 to 48 hours:
    - Right upper quadrant pain
    - Typically less nausea, vomiting, diaphoresis, and malaise than in stage 1
  - Stage 3: 72 to 96 hours:
    - Nausea, vomiting, and malaise reappear.
    - Severe poisonings may result in jaundice, confusion, somnolence, and coma.
  - Stage 4: 7 to 8 days:
    - Resolution of clinical signs in survivors
- Fulminant hepatic failure occurs in <1% of adults and is very rare in children <6 years of age.
- Patients with an unexplained rise in liver function tests (LFTs) with negative acetaminophen

levels may be overdose patients presenting in stage 3.

## HISTORY

Ingestion or suspected ingestion of acetaminophen-containing product

## DIFFERENTIAL DIAGNOSIS

- Consider presence of coingestants, especially alcohol and aspirin.
- Other ingested toxins that produce severe acute hepatic injury, including the mushroom *Amanita phalloides* and products containing yellow phosphorus or carbon tetrachloride

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Plasma acetaminophen levels should be drawn on all patients <sup>3</sup>4 hours after ingestion (levels prior to 4 hours not helpful).
- **ALT**, AST, PT/NR, bilirubin, lactate dehydrogenase (LDH)
- Electrolytes, glucose, BUN, creatinine
- Pregnancy screen in females (urine or serum)
- Urinalysis
- Consider arterial blood gas (ABG) if pH disturbance is suspected on clinical or lab grounds.
- Screens for suspected coingestants (aspirin, iron, etc.) may be positive (especially when suicide attempt is a possibility).
- With toxic ingestions, aspartate transaminase (AST; serum glutamic-oxaloacetic transaminase), alanine transaminase (ALT; serum glutamic-pyruvic transaminase), and bilirubin levels begin to rise in stage 2 and peak in stage 3.
- In severe poisonings, the prothrombin time (PT)/international normalized ratio (INR) will parallel these changes and should be monitored.
- Markedly elevated ALT levels are consistent with the diagnosis, and improvement in ALT is a good sign.
- Laboratory abnormalities usually resolve by stage 4.
- Renal function abnormalities are common in patients with hepatotoxicity.
- Evidence of damage to pancreas and heart may present following severe poisonings.
- Anion-gap metabolic acidosis due to accumulation of 5-oxoprolene may rarely be seen.

Drugs that may alter lab results: none with clinically significant cross-reactivity with plasma acetaminophen assay

- Disorders that may alter lab results: diseases or toxic substances that damage the liver, particularly alcohol
- No specific imaging required

## *Follow-Up Tests & Special Considerations*

ABG after hydration if pH is acidotic

## *Test Interpretation*

Centrilobular hepatic necrosis

## **TREATMENT**

- Contact a regional/local poison control center for recommendations. In the United States: (800) 222-1222
- NAC should be given when plasma acetaminophen concentrations measured <sup>34</sup> hours after ingestion are in the "possible risk" or higher levels on the Rumack-Matthew nomogram. This corresponds to acetaminophen levels >150 µg/mL (993 µmol/L), >75 µg/mL (497 µmol/L), and >37 µg/mL (244 µmol/L) at 4, 8, and 12 hours after ingestion, respectively. See [http://www.ars-informatica.ca/toxicity\\_nomogram.php?calc=acetamin](http://www.ars-informatica.ca/toxicity_nomogram.php?calc=acetamin) or [http://www.merckmanuals.com/professional/resources/clinical\\_calculators/name/calculator.html?WT.z\\_resource=ClinicalCalculators](http://www.merckmanuals.com/professional/resources/clinical_calculators/name/calculator.html?WT.z_resource=ClinicalCalculators).
- NAC should be started within 8 hours of ingestion for best chance of hepatic protection. Patients presenting near 8 hours should empirically receive NAC while waiting for labs.
- All patients with acetaminophen liver injury (even after 8 hours) should receive NAC.
- NAC therapy may be effective up to <sup>336</sup> hours after ingestion.

P.9

- Single-dose activated charcoal may be used if given within 1 hour of ingestion (especially in cases of coingestants) (1,2)[C],(3)[A], but not within 1 hour of administration of oral NAC. Never delay NAC for activated charcoal.
- Ipecac and gastric lavage are no longer recommended for routine use at home or in health care facilities (3)[C].

## **MEDICATION**

## *First Line*

- Acetylcysteine (NAC, Mucomyst) should be initiated within 8 hours of ingestion whenever possible; single-dose activated charcoal (1 g/kg PO) may be effective if given within 1 hour of ingestion. *Never* delay oral NAC for activated charcoal.
- Acetylcysteine may be given PO or IV, depending on situation and availability:
  - IV loading dose of Acetadote 150 mg/kg over 60 minutes followed by an infusion of 50 mg/kg over 4 hours (12.5 mg/kg/hr); this is followed by an infusion of 100 mg/kg over the next 16 hours (6.25 mg/kg/hr) (20-hour regimen)
  - Oral loading dose of 140 mg/kg, followed by 70 mg/kg q4h for 17 additional doses (72-hour regimen)
- Contraindications: medication allergies
- Precautions:
  - Oral NAC may cause significant nausea and vomiting due to its sulfur content; consider nasogastric tube.
  - Nausea can be treated with metoclopramide (Reglan), 1 to 2 mg/kg IV, or ondansetron (Zofran), 0.15 mg/kg IV (for age >4 years, usually 4 mg/dose).
  - IV NAC (Acetadote) may cause anaphylactoid reactions, including rash, bronchospasm, pruritus, angioedema, tachycardia, or hypotension (higher rates seen in asthmatics and those with atopy) (4,5)[C].
- Reactions usually occur with loading dose. Slow or temporarily stop the infusion; may concurrently treat with antihistamines
- Significant possible interactions: Activated charcoal given within 1 hour of oral NAC may adsorb NAC, limiting its effectiveness.

## *Second Line*

Oral racemethionine (methionine)

## *ISSUES FOR REFERRAL*

- Psychological evaluation in emergency room and close follow-up after intentional ingestions.
- Consider child abuse reporting if neglect led to overdose.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Toxic and intentional ingestions
- Any reported ingestion with increased LFTs, acidosis on ABG, elevated creatinine, and so forth.
- Initiate aggressive age- and weight-appropriate IV hydration.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- All patients should be evaluated at a health care facility.
- Patients with evidence of organ failure, increased LFTs, or coagulopathy should be evaluated for transfer to a site capable of liver transplant.
- Activity may be restricted if significant hepatic damage is present.
- Outpatient management of nontoxic accidental ingestions

### *Patient Monitoring*

Ask about possible ingestion by others (i.e., suicide pacts).

### *DIET*

No special diet, except with severe hepatic damage

### *PATIENT EDUCATION*

- Patients should be counseled to avoid Tylenol if already using combination product(s) containing acetaminophen.
- Education of parents/caregivers during well-child visits
- Anticipatory guidance for caregivers, family, and cohabitants of potentially suicidal patients
- Education of patients taking long-term acetaminophen therapy

### *PROGNOSIS*

- Complete recovery with early therapy
- <1% of adult patients develop hepatic failure. King criteria (pH <7.3, PT >100 s [INR >65], creatinine >3.4 mg/dL [ $>300 \mu\text{mol/L}$ ]) is associated with a poor prognosis and possible need for liver transplant (6)[C]. Early referral increases the chance for transplant success (5)[A].
- Hepatic failure is very rare in children <6 years of age.

## COMPLICATIONS

Rare following recovery from acute poisoning

## Codes

- T39.1X4A Poisoning by 4-Aminophenol derivatives, undetermined, init
- K71.10 Toxic liver disease with hepatic necrosis, without coma
- T39.1X1A Poisoning by 4-Aminophenol derivatives, accidental, init

## Clinical Pearls

- Contact a regional poison control center for management recommendations. In the United States: (800) 222-1222.
- NAC should be given when plasma acetaminophen concentrations measured <sup>34</sup> hours after ingestion are in the  $\hat{O}$ possible risk $\hat{O}$  or higher levels on the Rumack-Matthew nomogram. This corresponds to acetaminophen levels  $>150 \mu\text{g/mL}$  ( $993 \mu\text{mol/L}$ ),  $>75 \mu\text{g/mL}$  ( $497 \mu\text{mol/L}$ ), and  $>40 \mu\text{g/mL}$  ( $265 \mu\text{mol/L}$ ) at 4, 8, and 12 hours after ingestion, respectively.
- NAC should be started within 8 hours of ingestion for best chance of hepatic protection. Patients presenting near 8 hours should empirically receive NAC while waiting for labs.
- All patients with acetaminophen liver injury (even after 8 hours) should receive NAC.

# ACL Injury

Jeff Wang, MD, MPH

J. Herbert Stevenson, MD

## BASICS

### DESCRIPTION

- The anterior cruciate ligament (ACL) is a primary knee stabilizer that serves to prevent excessive anterior translation and internal rotation of the tibia on the femur.
  - During dynamic movement, the ACL and posterior cruciate ligament (PCL) work together to stabilize the knee.
- ACL injuries are common and can occur through multiple mechanisms. >70% of ACL injuries are caused by noncontact forces.
- Although partial tears occur, complete ACL tears are more common.
- Due to differences in pelvic architecture and lower extremity alignment, female athletes are at 2 to 5 times higher at risk of ACL tear.
- ACL injury is associated with early onset of knee osteoarthritis.

### EPIDEMIOLOGY

#### *Incidence*

- 250,000 ACL injuries annually in the United States
- Female incidence 2- to 5-fold > male (1)
- Greater incidence of noncontact ACL injuries in sports requiring cutting, pivoting, and rapid deceleration, such as basketball and soccer (1)

#### *Prevalence*

- Young athletes (15 to 25 years) sustain >50% of all ACL injuries (1)[B].
- > 2/3 of patients with complete ACL tear have associated meniscal and/or articular cartilage injury.

## *Pediatric Considerations*

- Rule out physeal injuries in skeletally immature patients.
- The incidence of ACL tears in patients with open physes has increased in recent years.
- ACL injury rates increase for both boys and girls after age 11 years.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Noncontact mechanisms: torsional or hyperextension forces creates anterior translation of the tibia relative to the femur. This creates excessive stress across the ACL with resultant rupture.
- Direct trauma: most often, a valgus blow to the knee with resultant trauma to ACL, medial collateral ligament, and lateral meniscus (Òunhappy triadÓ)

## *Genetics*

A genetic predisposition has been identified. An association has been found between the genes encoding proteoglycans and the risk of ACL tears (7)[B].

## *RISK FACTORS*

- Female athletes have increased risk.
  - Hormonal influence
    - Alterations in hormonal balance hypothesized to increase risk, but no conclusive evidence linking menstrual phase to ACL injury risk.
  - Anatomic gender differences
    - Increased Q angle, increased genu valgum, narrower femoral notch size, smaller ACL
    - Neuromuscular imbalances (increased quadriceps activation, decreased hamstring activity during landings)
  - Movement patterns (sudden deceleration, change-of-direction cutting movements, landing from a jump in hyperextension)

## *GENERAL PREVENTION*

- Neuromuscular training with proprioceptive, plyometric, and strength exercises significantly reduce noncontact ACL injuries in female athletes if performed several times a week for >6 weeks (2)[C].
- Prophylactic knee bracing does not prevent ACL injury.

## COMMONLY ASSOCIATED CONDITIONS

- Meniscal tear
- Collateral ligament tear
- PCL tear
- Tibia or femur fractures
- Osteochondral injury
- Early-onset degenerative joint disease

## DIAGNOSIS

### HISTORY

Describe mechanism

- Noncontact
  - Sudden deceleration
  - Cutting, sudden change in direction
  - Landing from a jump with the knee in extension
- Contact with player, object
- May recall sudden pop or snap
- Sudden pain and giving way
- Marked effusion/hemarthrosis within 4 to 12 hours
- “Pop” with deceleration or twisting movement associated with early effusion and inability to continue with participation are highly suggestive of ACL tear.

### PHYSICAL EXAM

- Inspect for malalignment (fracture, dislocation).
- Palpate for effusion.
- Decreased range of motion (ROM)
  - Deficits may be secondary to pain, effusion, mechanical blocks (meniscal tear, loose body, torn ACL stump).
- Joint instability
- Difficulty bearing weight

- Evaluate integrity of extensor mechanism
- Special maneuvers (Lachman; anterior drawer; pivot shift) to assess ACL integrity
- Lachman test: most sensitive and highly specific diagnostic test for ACL injury in acute setting (3)[B]
  - Knee is placed in 20 to 30 degrees of flexion. Tibia is translated anteriorly with femur stabilized by the opposite hand. Increased anterior translation compared with uninjured knee indicates injury. Lack of a solid end point indicates rupture.
- Pivot shift test: less sensitive, but more than Lachman test: specific for ACL tear (3)[B]
  - Knee is placed in extension. Knee is flexed while valgus and internal rotation stress is applied. A positive test is anterior subluxation at 20 to 40 degrees of flexion.
- Anterior drawer test (3)[B]
  - Low sensitivity for ACL integrity, especially in acute setting
- Posterior drawer test assesses PCL integrity.
- McMurray test assesses for meniscal tears.
- Valgus/varus stress test for medial collateral ligament/lateral collateral (MCL/LCL) integrity

## *DIFFERENTIAL DIAGNOSIS*

- Fracture
- Meniscal injury
- Patellar dislocation/subluxation
- Tendon disruption
- PCL injury
- Collateral ligament injury

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Radiographs to rule out associated bony injury
- Anterior-posterior (AP), lateral, and tunnel views
  - Segond fracture: avulsion fracture of the lateral capsular margin of the tibia
  - Tibial eminence avulsion fracture

- Fracture of proximal tibia or distal femur
- Osteochondral injuries

## *Follow-Up Tests & Special Considerations*

- MRI is the gold standard for imaging ligamentous and intra-articular structures. The sensitivity of MRI is 87-94%, specificity 88-93% (4).
- Secondary signs of ACL injury on MRI include contusion of the anterior femoral condyle and/or posterior tibial plateau, anterior translation of the tibia, an uncovered or displaced posterior horn of the lateral meniscus, PCL buckling, or a Segond fracture (an avulsion fracture of the lateral tibial condyle).
- Ultrasound is an emerging technique that is fast and noninvasive (5)[B].

## *Diagnostic Procedures/Other*

Surgical management should be considered in the active population, young or old.

## **TREATMENT**

### *GENERAL MEASURES*

- Acute injury: protection, relative rest, ice, compression, elevation, medications, modalities (PRICE/EMM) therapy
- Crutches may be useful until patient is able to ambulate without pain.
- Locked knee brace may be used initially for comfort. Use with caution and transition to a hinged knee brace as soon as possible to avoid quadriceps atrophy and stiffness.
- Aspiration of large effusion may alleviate pain and increase ROM.

---

P.11

### *MEDICATION*

#### *First Line*

- Nonsteroidal anti-inflammatory drugs (NSAIDs)
  - Acute ligament sprains
    - Ibuprofen: 200 to 800 mg TID
    - Naproxen: 250 to 500 mg BID

- Acetaminophen: 3 g/day divided TID
- Opioids for severe pain (e.g., acetaminophen-hydrocodone)

## *ISSUES FOR REFERRAL*

The decision to manage ACL tears surgically or non-surgically (conservatively) can be difficult. Consider surgical management in active patients or if the injury interferes with activities of daily living.

- Physical therapy is essential whether an athlete chooses nonsurgical or surgical treatment. Proper rehabilitation is time-consuming (6 to 12 months) and hard work. Physical therapy restores ROM, strength, and proprioception.
- Preoperative phase
  - Increase ROM and quadriceps strength, minimize inflammation.
- Early postoperative phase: weeks 2 to 4
  - ROM: Full extension is the primary goal. Rehabilitation begins immediately.
  - Progress to full weight bearing
- Intermediate postoperative phase: weeks 4 to 12
  - ROM: full flexion, hyperextension
  - Quadriceps and hamstring strengthening proprioceptive training, normalize gait
- Late postop phase: >3 months postop
  - Straight-line running
  - Increase speed, duration over 6 to 8 weeks
  - Progress to cutting and sport-specific drills
  - Strength and proprioceptive training

## *Geriatric Considerations*

Management is based on anticipated activity level, associated injuries, coexisting medical conditions, and acute versus long-standing ACL deficiency.

## *SURGERY/OTHER PROCEDURES*

- The decision for surgery depends on patient's activity level, age, associated injuries, and presence of osteoarthritis.

- There is an insufficient evidence to recommend surgery over conservative management in skeletally immature patients.
- No significant difference in patient-reported knee function or muscle strength between surgical and nonsurgical management (6)[B].
- In young, active adults with acute ACL tears, rehabilitation plus early ACL repair was not superior to a strategy of initial rehabilitation with delayed repair if rehabilitation alone failed. Rehabilitation alone results in an overall reduction of ACL reconstructions (6)[B].
- Reconstruction techniques
  - Bone-patella tendon-bone autograft
  - Hamstring autograft
  - Allograft tendon (from cadaver)
- No consistent significant differences in outcome between patellar tendon and hamstring tendon autografts
- In the hamstring autograft approach, double bundle is superior to the single bundle (7)[B].
- Concomitant meniscal tears are repaired at the time of ACL reconstruction.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Outpatient

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- ROM exercises to regain full flexion and extension
- Advance activity as tolerated

### *Patient Monitoring*

Assess functional status, rehabilitative exercise compliance, and pain control at follow-up visit.

## *PROGNOSIS*

- Athletes typically are out of competitive play for 6 to 9 months after injury for reconstructive surgery and rehabilitation.

- High prevalence of OA, even in those with early ACL reconstruction
- Delaying surgical repair of torn ACL increases risk of secondary meniscal injury.

## COMPLICATIONS

- Instability
- Secondary meniscal and articular cartilage injury
- Early-onset degenerative arthritis
- Surgical risks
  - Infection, pulmonary embolism (PE), subsequent ACL graft rupture, laxity due to failure of graft remodeling

Algorithm: Knee pain

## Codes

### ICD10

- S83.519A Sprain of anterior cruciate ligament of unsp knee, init
- M23.619 Oth spon disrupt of anterior cruciate ligament of unsp knee
- S83.511A Sprain of anterior cruciate ligament of right knee, init

## Clinical Pearls

- Lachman test is the most sensitive and specific physical examination maneuver for diagnosing acute ACL injury.
- Bone contusion of the anterior femoral condyle and/or posterior tibial plateau on MRI is highly suggestive of ACL tear.
- 2/3 of complete ACL tears have associated meniscal or articular injuries.
- The decision for surgical repair is based on patient age, activity level, and associated symptoms.

# Acne Rosacea

Daniel R. DiBlasi, DO

Shane L. Larson, MD

## BASICS

### DESCRIPTION

- Rosacea is a chronic condition characterized by recurrent episodes of facial flushing, erythema (due to dilatation of small blood vessels in the face), papules, pustules, and telangiectasia (due to increased reactivity of capillaries) in a symmetric, central facial distribution. Sometimes associated with ocular symptoms (ocular rosacea).
- Four subtypes:
  - Erythematotelangiectatic rosacea (ETR)
  - Papulopustular rosacea (PPR)
  - Phymatous rosacea
  - Ocular rosacea
- System(s) affected: skin/exocrine
- Synonym(s): rosacea

### Geriatric Considerations

- Uncommon >60 years of age
- Effects of aging might increase the side effects associated with oral isotretinoin used for treatment (at present, data are insufficient due to lack of clinical studies in elderly patients <sup>365</sup> years).

### EPIDEMIOLOGY

#### Prevalence

- Predominant age: 30 to 50 years
- Predominant sex: female > male. However, males are at greater risk for progression to later stages.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- No proven cause
- Possibilities include the following:
  - Thyroid and sex hormone disturbance
  - Alcohol, coffee, tea, spiced food overindulgence (unproven)
  - Demodex follicular parasite (suspected)
  - Exposure to cold, heat
  - Emotional stress
  - Dysfunction of the GI tract

### *Genetics*

People of Northern European and Celtic background commonly afflicted

## *RISK FACTORS*

- Exposure to spicy foods, hot drinks
- Environmental factors: sun, wind, cold, heat

## *GENERAL PREVENTION*

No preventive measures known

## *COMMONLY ASSOCIATED CONDITIONS*

- Seborrheic dermatitis of scalp and eyelids
- Keratitis with photophobia, lacrimation, visual disturbance
- Corneal lesions
- Blepharitis
- Uveitis

## **DIAGNOSIS**

### **HISTORY**

- Usually have a history of episodic flushing with increases in skin temperature

in response to heat stimulus in mouth (hot liquids), spicy foods, alcohol, sun exposure (solar elastosis)

- Acne may have preceded onset of rosacea by years; nevertheless, rosacea usually arises de novo without preceding history of acne or seborrhea.
- Excessive facial warmth and redness are the predominant presenting complaints. Itching is generally absent.

## *PHYSICAL EXAM*

- Rosacea has typical stages of evolution:
  - The rosacea diathesis: episodic erythema, flushing and blushing
  - Stage I: persistent erythema with telangiectases
  - Stage II: persistent erythema, telangiectases, papules, tiny pustules
  - Stage III: persistent deep erythema, dense telangiectases, papules, pustules, nodules; rarely persistent solid edema of the central part of the face (phymatous)
- Facial erythema, particularly on cheeks, nose, and chin. At times, entire face may be involved.
- Inflammatory papules are prominent; pustules and telangiectasia may be present.
- Comedones are absent (unlike acne vulgaris).
- Women usually have lesions on the chin and cheeks, whereas the nose is commonly involved in men.
- Ocular findings (mild dryness and irritation with blepharitis, conjunctival injection, burning, stinging, tearing, eyelid inflammation, swelling, and redness) are present in 50% of patients.

## *DIFFERENTIAL DIAGNOSIS*

- Drug eruptions (iodides and bromides)
- Granulomas of the skin
- Cutaneous lupus erythematosus
- Carcinoid syndrome
- Deep fungal infection
- Acne vulgaris
- Seborrheic dermatitis
- Steroid rosacea (abuse)

- Systemic lupus erythematosus
- Lupus pernio (sarcoidosis)

## **DIAGNOSTIC TESTS & INTERPRETATION**

Diagnosis is based on physical exam findings.

### *Test Interpretation*

- Inflammation around hypertrophied sebaceous glands, producing papules, pustules, and cysts
- Absence of comedones and blocked ducts
- Vascular dilatation and dermal lymphocytic infiltrate

## **TREATMENT**

### **GENERAL MEASURES**

- Proper skin care and photoprotection are important components of management plan (1)[B]. Use of mild, nondrying soap is recommended; local skin irritants should be avoided.
- Avoidance of triggers
- Reassurance that rosacea is completely unrelated to poor hygiene
- Treat psychological stress if present.
- Topical steroids should not be used, as they may aggravate rosacea.
- Avoid oil-based cosmetics:
  - Others are acceptable and may help women tolerate symptoms
- Electrodesiccation or chemical sclerosis of permanently dilated blood vessels
- Possible evolving laser therapy
- Support physical fitness.

---

P.13

## **MEDICATION**

### *First Line*

- Topical metronidazole preparations once (1% formulation) or twice (0.75% formulations) daily for 7 to 12 weeks was significantly more effective than placebo in patients with moderate to

severe rosacea. A rosacea treatment system (cleanser, metronidazole 0.75% gel, hydrating complexion corrector, and sunscreen SPF 30) may offer superior efficacy and tolerability to metronidazole (2)[A].

- Azelaic acid (Finacea) is very effective as initial therapy; azelaic acid topical alone is effective for maintenance (3)[A].
- Topical ivermectin 1% cream (2)[A]
  - Recently found to be more effective than metronidazole for treatment of PPR
- Topical brimonidine tartrate 0.5% gel is effective in reducing erythema associated with ETR (4)[A].
  - $\alpha_2$ -Adrenergic receptor agonist; potent vasoconstrictor
- Doxycycline 40-mg dose is at least as effective as 100-mg dose and has a correspondingly lower risk of adverse effects but is much more expensive (5)[A].
- Precautions: Tetracyclines may cause photosensitivity; sunscreen is recommended.
- Significant possible interactions:
  - Tetracyclines: Avoid concurrent administration with antacids, dairy products, or iron.
  - Broad-spectrum antibiotics: may reduce the effectiveness of oral contraceptives; barrier method is recommended.

## *Second Line*

- Topical erythromycin
- Topical clindamycin (lotion preferred)
  - Can be used in combination with benzoyl peroxide; commercial topical combinations are available
- Possible use of calcineurin inhibitors (tacrolimus 0.1%; pimecrolimus 1%). Pimecrolimus 1% is effective to treat mild to moderate inflammatory rosacea (6)[A].
- Permethrin 5% cream; similar efficacy compared to metronidazole (7)[B]. For severe cases, oral isotretinoin at 0.3 mg/kg for a minimum of 3 months.

## *Pediatric Considerations*

Tetracyclines: not for use in children <8 years

## *Pregnancy Considerations*

- Tetracyclines: not for use during pregnancy
- Isotretinoin: teratogenic; not for use during pregnancy or in women of reproductive age who are not using reliable contraception; requires registration with iPLEDGE program

## ***ADDITIONAL THERAPIES***

Cyclosporine 0.05% ophthalmic emulsion may be more effective than artificial tears for ocular rosacea.

## ***SURGERY/OTHER PROCEDURES***

Laser treatment is an option for progressive telangiectasias or rhinophyma.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Outpatient treatment

#### ***Patient Monitoring***

- Occasional and as needed
- Close follow-up and laboratory assessment for women using isotretinoin per prescribing instructions and iPLEDGE program guidance.

### ***DIET***

Avoid alcohol, excessive sun exposure, and hot drinks of any type.

### ***PROGNOSIS***

- Slowly progressive
- Subsides spontaneously (sometimes)

### **COMPLICATIONS**

- Rhinophyma (dilated follicles and thickened bulbous skin on nose), especially in men
- Conjunctivitis
- Blepharitis
- Keratitis
- Visual deterioration

## See Also

- Acne Vulgaris; Blepharitis; Dermatitis, Seborrheic; Lupus Erythematosus, Discoid; Uveitis
- Algorithm: Acne

## Codes

### ICD10

- L71.9 Rosacea, unspecified
- L71.8 Other rosacea

## Clinical Pearls

- Rosacea usually arises de novo without any preceding history of acne or seborrhea.
- Rosacea may cause chronic eye symptoms, including blepharitis.
- Avoid alcohol, sun exposure, and hot drinks.
- Medication treatment resembles that of acne vulgaris, with oral and topical antibiotics.

# Acne Vulgaris

Gary I. Levine, MD

## BASICS

### DESCRIPTION

- Acne vulgaris is a disorder of the pilosebaceous units. It is a chronic inflammatory dermatosis notable for open/closed comedones, papules, pustules, or nodules.
- Systems affected: skin/exocrine

### Geriatric Considerations

Favre-Racouchot syndrome: comedones on face and head due to sun exposure

### Pregnancy Considerations

- May result in a flare or remission of acne
- Erythromycin can be used in pregnancy; use topical agents when possible.
- Isotretinoin is teratogenic; pregnancy Category X
- Avoid topical tretinoin as it may cause retinoid embryopathy; class C (1).
- Contraindicated: isotretinoin, tazarotene, tetracycline, doxycycline, minocycline

### Pediatric Considerations

- Neonatal acne (neonatal cephalic pustulosis) (2)
  - Newborn to 8 weeks; lesions limited to face; responds to topical ketoconazole 2% cream (3)
- Infantile acne
  - Newborn to 1 year; lesions on face, neck, back, and chest; no Rx required (3)
- Early-mid childhood acne
  - 1 to 7 years; rare; consider hyperandrogenism (3)
- Preadolescent acne

7 to 11 years; common, 47% of children, usually due to adrenal awakening

- Do not use tetracycline in those <8 years of age (2,3); other therapies similar to adolescent acne

## **EPIDEMIOLOGY AND PATHOPHYSIOLOGY**

- Predominant age: early to late puberty, may persist in 20-40% of affected individuals into 4th decade
- Predominant sex
  - Male > female (adolescence)
  - Female > male (adult)

### **Prevalence**

- 80-95% of adolescents affected. A smaller percentage will seek medical advice.
- 8% of adults aged 25 to 34 years; 3% at 35 to 44 years
- African-Americans 37%, Caucasians 24%

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Androgens (testosterone and dehydroepiandrosterone sulfate [DHEA-S]) stimulate sebum production and proliferation of keratinocytes in hair follicles (4).
- Keratin plug obstructs follicle os, causing sebum accumulation and follicular distention.
- *Propionibacterium acnes*, an anaerobe, colonizes and proliferates in the plugged follicle.
- *P. acnes* promote proinflammatory mediators, causing inflammation of follicle and dermis.

### **Genetics**

- Familial association in 50%
- If a family history exists, the acne may be more severe and occur earlier.

## **RISK FACTORS**

- Increased endogenous androgenic effect
- Oily cosmetics, cocoa butter
- Rubbing or occluding skin surface (e.g., sports equipment such as helmets and shoulder pads), telephone, or hands against the skin

- Polyvinyl chloride, chlorinated hydrocarbons, cutting oil, tars
- Numerous drugs, including androgenic steroids (e.g., steroid abuse, some birth control pills)
- Endocrine disorders: polycystic ovarian syndrome, Cushing syndrome, congenital adrenal hyperplasia, androgen-secreting tumors, acromegaly
- Stress
- High-glycemic load and possibly high-dairy diets may exacerbate acne (4,5).
- Severe acne may worsen with smoking.

## *COMMONLY ASSOCIATED CONDITIONS*

- Acne fulminans, pyoderma faciale
- Acne conglobata, hidradenitis suppurativa
- Pomade acne
- SAPHO syndrome (synovitis, acne, pustulosis, hyperostosis, and osteitis)
- Pyogenic arthritis, pyoderma gangrenosum, and acne (PAPA) and seborrhea, acne, hirsutism, and alopecia (SAHA) syndromes
- Behçet syndrome, Apert syndrome
- Dark-skinned patients: 50% keloidal scarring and 50% acne hyperpigmented macules

## **DIAGNOSIS**

### **HISTORY**

- Ask about duration, medications, cleansing products, stress, smoking, exposures, diet, and family history.
- Females may worsen 1 week prior to menses.

### *PHYSICAL EXAM*

- Closed comedones (whiteheads)
- Open comedones (blackheads)
- Nodules or papules
- Pustules (ÖcystsÓ)
- Scars: ice pick, rolling, boxcar, atrophic macules, hypertrophic, depressed, sinus tracts

- Grading system (American Academy of Dermatology, 1990) (4)
  - Mild: few papules/pustules; no nodules
  - Moderate: some papules/pustules; few nodules
  - Severe: numerous papules/pustules; many nodules
  - Very severe: acne conglobata, acne fulminans, acne inversa.
- Most common areas affected are face, chest, back, and upper arms (areas of greatest concentration of sebaceous glands) (4).

## ***DIFFERENTIAL DIAGNOSIS***

- Folliculitis: gram negative and gram positive
- Acne (rosacea, cosmetica, steroid-induced)
- Perioral dermatitis
- Chloracne
- Pseudofolliculitis barbae
- Drug eruption
- Verruca vulgaris and plana
- Keratosis pilaris
- Molluscum contagiosum
- Sarcoidosis
- Seborrheic dermatitis
- Miliaria

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

Only indicated if additional signs of androgen excess; if so, test for free and total testosterone, DHEA-S, LH, and FSH (6)

## **TREATMENT**

- Comedonal (grade 1): keratinolytic agent (7)[A] (see as follows for specific agents)

Mild inflammatory acne (grade 2): benzoyl peroxide ± topical antibiotic + keratinolytic agent

- Moderate inflammatory acne (grade 3): add systemic antibiotic to grade 2 regimen
- Severe inflammatory acne (grade 4): as in grade 3, or isotretinoin (7)[A]
- Topical retinoid plus a topical antimicrobial agent is 1st-line treatment for more than mild disease (8).
- Topical retinoid + antibiotic (topical or PO) is better than either alone for mild/moderate acne (7)[A].
- Topical retinoids are 1st-line agents for maintenance. Avoid long-term antibiotics for maintenance.
- Avoid topical antibiotics as monotherapy.
- Recommended vehicle type
  - Dry or sensitive skin: cream or ointment
  - Oily skin, humid weather: gel, solution, or wash
  - Hair-bearing areas: lotion, hydrogel, or foam
- Apply topical agents to entire affected area, not just visible lesions.
- Mild soap daily to control oiliness; avoid abrasives
- Avoid drying agents with keratinolytic agents.
- Gentle cleanser and noncomedogenic moisturizer help decrease irritation.
- Oil-free, noncomedogenic sunscreens
- Stress management if acne flares with stress

## MEDICATION

### ALERT

Most prescription of topical medications are very expensive, costing from \$100 to several hundred dollars per tube.

- Keratinolytic agents (alpha-hydroxy acids, salicylic acid, azelaic acid) (side effects include dryness, erythema, and scaling; start with lower strength, increase as tolerated) (6,7)[A].
- Tretinoin (Retin-A, Retin A Micro, Avita, Atralin) varying strengths and formulations: apply at bedtime; wash skin, let skin dry 30 minutes before application
  - Retin-A Micro, Atralin, and Avita are less irritating, and stable with BP
  - May cause an initial flare of lesions; may be eased by 14-day course of oral antibiotics

- Avoid in pregnant and lactating women.
  - Adapalene (Differin): 0.1%, apply topically at night
    - Effective; less irritation than tretinoin or tazarotene (7)[A]
    - May be combined with benzoyl peroxide (Epiduo)~very effective in skin of color
  - Tazarotene (Tazorac): apply at bedtime
    - Most effective and most irritating; teratogenic
  - Azelaic acid (Azelex, Finevin): 20% topically, BID
    - Keratinolytic, antibacterial, anti-inflammatory
    - Reduces postinflammatory hyperpigmentation in dark-skinned individuals
    - Side effects: erythema, dryness, scaling, hypopigmentation
    - Less effective in clinical use than in studies
    - Effective in postadolescent acne
  - Salicylic acid: 2%, less effective and less irritating than tretinoin
  - Alpha-hydroxy acids: available over-the-counter
- 
- Topical antibiotics and anti-inflammatories
    - Topical benzoyl peroxide (6,7)[A]
      - 2.5% as effective as stronger preparations
      - Gel penetrates better into follicles
      - When used with tretinoin, apply benzoyl peroxide in morning and tretinoin at night
      - Side effects: irritation; may bleach clothes; photosensitivity
  - Topical antibiotics (6,7)[A]
    - Erythromycin 2%
    - Clindamycin 1%
    - Metronidazole gel or cream: apply once daily
    - Azelaic acid (Azelex, Finevin): 20% cream: enhanced effect and decreased risk of resistance when used with zinc and benzoyl peroxide

- Benzoyl peroxide-erythromycin (Benzamycin): especially effective with azelaic acid
- Benzoyl peroxide-clindamycin (BenzaClin, DUAC, Clindoxyl)
  - Benzoyl peroxide-salicylic acid (Cleanse & Treat, Inova): similar in effectiveness to benzoyl peroxide-clindamycin
  - Sodium sulfacetamide (Sulfacet-R, Novacet, Klaron): useful in acne with seborrheic dermatitis or rosacea
  - Dapsone (Aczone) 5% gel: may cause yellow/orange skin discoloration when mixed with benzoyl peroxide
- Oral antibiotics: use for at least 6 to 8 weeks after initiation, discontinue after 12 to 18 weeks' duration; indicated when acne is more severe, trunk involvement, unresponsive to topical agents, or at greater risk for scarring (6,7,9)[A]
    - Tetracycline: 500 to 1,000 mg/day divided BID; high dose initially, taper in 6 months. Side effects: photosensitivity, esophagitis
    - Minocycline: 100 to 200 mg/day, divided daily BID; side effects include photosensitivity, urticaria, grayblue skin, vertigo, hepatitis
    - Doxycycline: 50 to 200 mg/day, divided daily BID; side effects include photosensitivity
    - Erythromycin: 500 to 1,000 mg/day; divided BID-QID; decreasing effectiveness as a result of increasing *P. acnes* resistance
    - Trimethoprim-sulfamethoxazole (Bactrim DS, Septra DS): 1 daily or BID
    - Azithromycin (Zithromax): 500 mg 3 days/week × 1 month, then 250 mg every other day × 2 months
  - Oral retinoids
    - Isotretinoin: 0.5 to 1 mg/kg/day divided BID to maximum 2 mg/kg/day divided BID for very severe disease; 60-90% cure rate; usually given for 12 to 20 weeks; maximum cumulative dose - 120 to 150 mg/kg; 20% of patients relapse and require retreatment (4,6,7)[A], 0.25 to 0.40 mg/kg/day in moderately severe acne
      - Side effects: teratogenic, pancreatitis, excessive drying of skin, hypertriglyceridemia, hepatitis, blood dyscrasias, hyperostosis, premature epiphyseal closure, night blindness, erythema multiforme, Stevens-Johnson syndrome, suicidal ideation, psychosis
      - Avoid tetracyclines or vitamin A preparations during isotretinoin therapy.
      - Monitor for pregnancy, psychiatric/mood changes, complete blood count (CBC), lipids, glucose, and liver function tests at baseline and every month.

Must be registered and adhere to manufacturer's iPLEDGE program  
([www.ipledgeprogram.com](http://www.ipledgeprogram.com))

- Medications for women only
  - Oral contraceptives (4,6,7)[A],(10)
    - Norgestimate/ethinyl estradiol (OrthoTricyclen), norethindrone acetate/ethinyl estradiol (Estrostep), drospirenone/ethinyl estradiol (Yaz, Yasmin) are USFDA approved.
    - Levonorgestrel/ethinyl estradiol (Alesse) and most combined contraceptives effective
    - Spironolactone (Aldactone); 25 to 200 mg/day; antiandrogen; reduces sebum production

## ***ISSUES FOR REFERRAL***

Consider referral/consultation to dermatologist

- Refractory lesions despite appropriate therapy
- Consideration of isotretinoin therapy
- Management of acne scars

## ***ADDITIONAL THERAPIES***

- Acne hyperpigmented macules (11)
  - Topical hydroquinones (1.5-10%)
  - Azelaic acid (20%) topically
  - Topical retinoids
  - Corticosteroids: low dose, suppresses adrenal androgens (6)[B]
  - Dapsone 5% gel (Aczone): topical, anti-inflammatory; use in patients over 12 years
  - Sunscreen for prevention
- Light-based treatments
  - Ultraviolet A/ultraviolet B (UVA/UVB), blue or blue/red light; pulse dye, KTP, or infrared laser
  - Photodynamic therapy for 30 to 60 minutes with 5-aminolevulinic acid × 3 sessions is effective for inflammatory lesions.
    - Greatest use when used as adjunct to medications or if can't tolerate medications

## ***SURGERY/OTHER PROCEDURES***

- Comedo extraction after incising the layer of epithelium over closed comedo (6)[C]
- Inject large cystic lesions with 0.05 to 0.3 mL triamcinolone (Kenalog 2 to 5 mg/mL); use 30-gauge needle, inject through pore, slightly distend cyst (6)[C].
- Acne scar treatment: retinoids, steroid injections, cryosurgery, electrodesiccation, micro/dermabrasion, chemical peels, laser resurfacing

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Evidence suggests tea tree oil, seaweed extract, Kampo formulations, Ayurvedic formulations, rose extract, basil extract, epigallocatechin gallate, and tea extract may be useful (12).

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Use oral or topical antibiotics for 3 months; taper as inflammatory lesions resolve. Do not use topical and oral antibiotic together.

### ***DIET***

Avoid high-glycemic index foods and milk (13)

### ***PATIENT EDUCATION***

- There may be a worsening of acne during first 2 weeks of treatment.
- Results are typically seen after a minimum of 4 weeks of treatment

### ***PROGNOSIS***

Gradual improvement over time (usually within 8 to 12 weeks after beginning therapy)

### **COMPLICATIONS**

- Acne conglobata: severe confluent inflammatory acne with systemic symptoms
- Facial scarring and psychological distress, including anxiety, depression, and suicidal ideation (4)
- Postinflammatory hyperpigmentation, keloids, and scars are more common in skin of color

## See Also

- Acne Rosacea
- Algorithm: Acne

## Codes

### ICD10

- L70.0 Acne vulgaris
- L70.4 Infantile acne
- L70.1 Acne conglobata

## Clinical Pearls

- Expect worsening for the first 2 weeks of treatment. Full results for changes in therapy take 8 to 12 weeks.
- Decrease topical frequency to every day or to every other day for irritation.
- Use BP every time a topical or oral antibiotic is used.

# Acute Coronary Syndromes: NSTEMI-ACS (Unstable Angina and NSTEMI)

Brendan Merchant, MD

Louis J. Berk, MD

## BASICS

### DESCRIPTION

- Unstable angina (UA) and non-ST-segment elevation myocardial infarction (NSTEMI) are acute coronary syndromes (ACS) without ST-segment elevation (NSTEMI-ACS).
- NSTEMI is defined by the rise and fall of cardiac biomarker values (preferably cardiac troponin) higher than the 99th percentile upper reference limit and accompanied by one of the following: symptoms of ischemia, new ST-segment T-wave changes, development of pathologic Q waves on ECG, or imaging evidence of new regional wall motion abnormality (1).
- UA, although clinically indistinguishable from NSTEMI (in an appropriate clinical setting, new-onset anginal chest pain, or change in typical anginal pattern, or development of angina at rest, or change in typical anginal equivalent), can be differentiated from NSTEMI by a lack of elevation in cardiac biomarkers based on two or more samples collected at least 6 hours apart. Just as with NSTEMI, nonspecific ECG changes, such as ST-segment depressions or T-wave inversions, may be present (1).

### EPIDEMIOLOGY

- Incidence of UA/NSTEMI increases with age (2).
- Presentation of coronary events in women is, on average, 10 years later than in men, with comparable rates of occurrence (2).

#### *Incidence*

Age-adjusted coronary heart disease (CHD) incidence rates (per 1,000 person-years): white men, 12.5; black men, 10.6; white women, 4.0; and black women, 5.1 (2)

#### *Prevalence*

For adults <sup>3</sup>20 years of age: 8.3% for men and 6.1% for women (2)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Platelet-rich thrombus forming on a disrupted plaque
- Dynamic obstruction triggered by intense spasm of a coronary artery, for example, Prinzmetal angina or coronary spasm induced by cocaine or methamphet-amine abuse
- Progressive mechanical limitation of coronary flow
- Coronary arterial inflammation
- Coronary dissection/rupture and thrombogenesis
- Myocardial oxygen demand exceeds supply
- UA/NSTEMI is usually caused by acute rupture of an atherosclerotic plaque, causing thrombosis and partial or total occlusion of a coronary artery (1).

## *RISK FACTORS*

- Age
- Hypertension
- Tobacco use
- Diabetes mellitus
- Dyslipidemia
- Family history of early coronary artery disease (CAD)
- Sedentary lifestyle
- Overweight/obesity
- Psoriasis and other systemic inflammatory conditions

## *GENERAL PREVENTION*

- Smoking cessation, healthy diet, weight control, physical activity
- If risk factors are present: BP control, lipid-lowering therapy, daily aspirin (in select patients)

## *COMMONLY ASSOCIATED CONDITIONS*

- Cardiovascular disease (atherosclerotic, aneurysmal, autoimmune, peripheral)
- Other forms of heart disease (myocardial, valvular, high-output states)

# DIAGNOSIS

## HISTORY

- Chest heaviness/tightness, with or without exertion, and increasing in frequency
- Pain or discomfort radiating to the neck, jaw, interscapular area, upper extremities, or epigastrium
- Associated symptoms of dyspnea, nausea, diaphoresis, light-headedness, dysphoria
- History of myocardial ischemia (stable or unstable angina, MI, coronary bypass surgery, or percutaneous coronary intervention [PCI])
- Family history of CAD or MI
- Risk factors for CAD and bleeding
- Use of phosphodiesterase-5 inhibitors (e.g., sildenafil) and concomitant nitrates
- Use of cocaine or amphetamines
- Medications and recent medication changes

## PHYSICAL EXAM

- General: abnormal vital signs including tachycardia or bradycardia, hypertension or hypotension, widened pulse pressure, tachypnea, fever
- Neurologic: dizziness, syncope, fatigue, weakness, altered mental status
- Cardiovascular: dysrhythmia, jugular venous distention (JVD), new murmur, rub or gallop, diminished peripheral pulses, carotid bruits
- Respiratory: tachypnea, increased work of breathing, crackles
- Musculoskeletal: Sharp pain reproducible with movement or palpation is unlikely to be cardiac.
- Skin: cool skin, pallor, diaphoresis, signs of dyslipidemia (xanthomas, xanthelasma)

## DIFFERENTIAL DIAGNOSIS

- Aortic dissection
- Pulmonary embolism
- Pleuropericarditis
- Perforating ulcer

- Gastroesophageal reflux disease (GERD) and spasm
- Esophageal perforation
- Biliary or pancreatic pain
- Dysrhythmia

### *Geriatric Considerations*

Elderly patients, as well as women and those with diabetes, may have an atypical presentation without classic anginal symptoms.

## **DIAGNOSTIC TESTS & INTERPRETATION**

### *Initial Tests (lab, imaging)*

- 12-lead ECG (1)[A]: applies to both UA and NSTEMI
  - ST-segment depression and/or T-wave inversion:
    - <sup>3</sup> 1-mm ST depression in <sup>3</sup>2 contiguous leads
    - T-wave inversions, other changes
    - ST depression and/or tall R wave in V<sub>1</sub>/V<sub>2</sub> with upright T waves may indicate transmural STEMI of posterior wall.
    - If initial ECG is nondiagnostic but symptoms persist with suspicion for ACS, perform serial ECGs at 15- to 30-minute intervals.
- Serum biomarkers (negative by definition in UA)
  - NSTEMI is strictly defined as a rise and fall in serum biomarkers (usually troponin I or T, as they are more sensitive for detecting NSTEMI) exceeding the 99th percentile of a normal reference population. Troponin concentration rises 3 to 6 hours after onset of ischemic symptoms but can be delayed from 8 to 12 hours (troponin T is not specific in patients with renal dysfunction).
  - With contemporary troponin assays, CK-MB and myoglobin are not useful in the diagnosis of ACS (3)[A].
  - Patients with negative biomarkers within 6 hours of the onset of symptoms should have biomarkers remeasured 8 to 12 hours from onset of symptoms
- Chest x-ray
- Consider transthoracic echocardiography if not recently performed (1)[B].

## *Follow-Up Tests & Special Considerations*

- Patients with ischemia are recommended to undergo an assessment of left ventricle (LV) function to identify impaired function and/or need for appropriate medications such as ACE inhibitors,  $\beta$ -blockers, and aldosterone antagonists.
- Fasting lipid profile, preferably within 24 hours
- Complete blood count (CBC), basic metabolic panel, activated partial thromboplastin time (aPTT)
- Other laboratory tests:
  - Lactate dehydrogenase: increases within 24 hours, peaks 3 to 6 days, baseline 8 to 12 days (not routinely ordered)
  - Leukocytes: increase within several hours after MI, peak in 2 to 4 days
  - Brain natriuretic peptide (BNP): increases with MI, may not indicate heart failure

## *Pregnancy Considerations*

Findings mimicking NSTEMI in pregnancy: ST depression after anesthesia, increase in CK-MB after delivery, and mild increase in troponin in preeclampsia and gestational hypertension. Spontaneous coronary dissection is a rare cause of ST elevation in pregnancy.

## *Diagnostic Procedures/Other*

- Coronary angiography (discussed under "Treatment")
- If serial cardiac enzymes are negative and symptoms have resolved, consider stress testing, including either standard exercise treadmill test (ETT), stress echocardiography, or stress nuclear study (1)[B].
- Transesophageal echocardiography, contrast chest CT scan, or MRI generally are reserved for differentiating ACS and other causes of chest pain from aortic dissection.

## *Test Interpretation*

- Subendocardial myocardial necrosis may be present.
- Atherosclerosis

## **TREATMENT**

## *GENERAL MEASURES*

- Bed/chair rest with continuous ECG monitoring
- Antiarrhythmics as needed
- Anxiolytics as needed
- Deep vein thrombosis prophylaxis
- Continuation of aspirin, clopidogrel or prasugrel or ticagrelor,  $\beta$ -blockers, ACE inhibitors (or ARBs if ACE intolerant), lipid-lowering therapy

P.17

- Tight BP control
- Treatment for depression PRN (common post-MI)
- Cardiac rehabilitation and increased physical activity
- Smoking cessation
- Annual influenza vaccine

## MEDICATION

### First Line

- Aspirin, non-enteric-coated, initial dose of 162 to 325 mg PO or chewed to all patients (1)[A]
- P2Y<sub>12</sub> Inhibitors
  - Clopidogrel, loading dose 300 to 600 mg followed by 75 mg/day (1)[B]; or ticagrelor, loading dose 180 mg followed by 90 mg BID (1)[B]. Clopidogrel is favored in patients with  $\geq 2$ -degree heart block, hemoglobin <10 g/dL, platelet count <100,000 cell/mm<sup>3</sup>, or liver disease.
  - Prasugrel is reserved for post-PCI patients treated with coronary stents, no history of stroke or TIA, <75 years, and weight >60 kg (1)[B].
  - Patients unable to take aspirin should receive a loading and maintenance dose of clopidogrel, ticagrelor, or prasugrel.
- Nitroglycerin (NTG) sublingual 0.4 mg every 5 minutes for total of three doses, then assess need for intravenous (IV) NTG (1)[C].
- Supplemental oxygen 2 to 4 L/min, maintaining arterial oxygen saturation >90% (1)[B]
- Morphine sulfate 2 to 4 mg IV (with increments of 2 to 8 mg IV repeated at 5- to 15-minute intervals) (1)[A]
- Oral  $\beta$ -blocker in patients without signs of heart failure, cardiogenic shock, or other

contraindications (1)[B]. (IV  $\beta$ -blockers are potentially harmful when risk factors for shock are present.)

- In patients with concomitant ACS, stabilized heart failure, and reduced systolic function (LVEF <40%), the recommended  $\beta$ -blockers are metoprolol succinate, carvedilol, and bisoprolol (1) [C].
- Lipid-lowering therapy: initiate or continue high-intensity statin therapy (preferred due to nonlipid benefit on vascular function) (1)[A]; niacin or fibrates (1)[C] if statin use not possible
- Risk stratify using the TIMI or GRACE score to select use of early invasive approach (within 12 to 24 hours of admission) versus ischemia-guided therapy.
- Risks and benefits of the early invasive approach:
  - 33% relative risk reduction for both the end points of refractory angina and rehospitalization at 6 to 12 months (2)[A]
  - 27% and 22% relative risk reduction in rates of MI at 6 to 12 months and 3 to 5 years, respectively (2)[A]
  - Doubled risk of procedure-related MI and increased risk of minor periprocedural bleeding (1)[A]
- Invasive management
  - Benefits are more pronounced in higher risk patients, such as those with ECG changes or diabetes (2).
- Subsequent recommendations (1)[A]: For patients with elevated risk for clinical events or refractory angina or hemodynamic or electrical instability, initiate anticoagulant: enoxaparin or unfractionated heparin (UFH) or bivalirudin. Prior to angiography, add GP IIb/IIIa inhibitor (eptifibatid or tirofiban) or thienopyridine (clopidogrel or ticagrelor).
- Ischemia-guided therapy
  - For low-risk or selected intermediate-risk patients, based on patient or physician preference, or in chronic renal insufficiency stage IV: Initiate anticoagulant therapy: enoxaparin or UFH or fondaparinux; enoxaparin or fondaparinux preferable. Initiate clopidogrel or ticagrelor (1) [B].
- Contraindications: Prasugrel contraindicated in patients  $\geq 75$  years or those with history of CVA/TIA or increased bleeding risk. Ticagrelor contraindicated in  $\geq 2$ -degree heart block.

## Second Line

- ACE inhibitor in patients with pulmonary congestion or left ventricular ejection fraction (EF)

240%. Substitute ARB for ACE-intolerant patients (1)[A].

- Nondihydropyridine calcium channel blocker (CCB) (verapamil or diltiazem) to reduce myocardial oxygen demand when  $\beta$ -blockers are contraindicated if normal EF (1)[B]. Use oral long-acting CCB only after  $\beta$ -blockers and nitrates have been fully used (1)[C].
- Long-term nitrate therapy for recurrent angina/ischemia or heart failure (1)[C].
- Sublingual NTG at discharge (1)[C]

## ***ISSUES FOR REFERRAL***

Cardiology consultation is appropriate for likely UA/NSTEMI, particularly regarding the complexities of anticoagulation/antiplatelet therapy.

## ***SURGERY/OTHER PROCEDURES***

- Coronary reperfusion
  - PCI with stent placement
  - CABG surgery
- Intra-aortic balloon pump for severe ischemia, hypotension, refractory pain

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- All patients with definite or suspected acute MI, ongoing pain, positive cardiac markers, ST deviations, hemodynamic abnormalities, probable or definite ACS
- Bed rest with continuous ECG monitoring, assess for reperfusion therapy, relieve ischemic pain, treat life-threatening complications, admit to coronary care unit.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- It is reasonable in patients with possible ACS who have normal serial ECGs and cardiac troponins to have a treadmill ECG, stress myocardial perfusion imaging, or stress echocardiography before discharge or within 72 hours after discharge (2)[A],(3)
- Follow up within 2 to 6 weeks (low risk) and 14 days (high risk).
- Refer to cardiac rehabilitation.

## DIET

- Diet low in saturated fat, cholesterol, and sodium
- Request dietary consult.

## PATIENT EDUCATION

- Education on new medications, diet, exercise, smoking cessation, lifestyle modification
- Resume exercise, sexual activity after outpatient reevaluation

## PROGNOSIS

UA/NSTEMI patients have lower in-hospital mortality than those with STEMI but a similar or worse longterm outcome.

## COMPLICATIONS

- Cardiogenic shock
- Heart failure
- Myocardial rupture
- Ventricular aneurysm
- Dysrhythmia
- Acute pulmonary embolism
- Acute thromboembolic stroke
- Pericarditis/Dressler syndrome
- Depression (increases mortality risk)
- Hyperglycemia

## Codes

### ICD10

- I24.9 Acute ischemic heart disease, unspecified
- I20.0 Unstable angina
- I21.4 Non-ST elevation (NSTEMI) myocardial infarction

## Clinical Pearls

- Discontinue NSAIDs, nonselective or selective cyclo-oxygenase (COX)-2 agents, except for ASA, due to increased risks of mortality, reinfarction, hypertension, heart failure, and myocardial rupture.
- Discontinue clopidogrel or prasugrel or ticagrelor 5 to 7 days before elective CABG.
- Do not use nitrate products in patients who recently used a phosphodiesterase-5 inhibitor (24 hours of sildenafil or vardenafil, or 48 hours of tadalafil).
- Duration of antithrombotic therapy after NSTEMI depends on type of stent received and medications administered.
- Avoid  $\beta$ -blockers in cocaine or methamphetamine user.

# Acute Coronary Syndromes: Stemi

Kassie S. Johnson, MD

Fozia Akhtar Ali, MD

## BASICS

### DESCRIPTION

Acute myocardial infarction (AMI) is the rapid development of myocardial necrosis resulting from a sustained and complete absence of blood flow to a portion of the myocardium. ST-segment elevation myocardial infarction (STEMI) occurs when coronary blood flow ceases following thrombotic occlusion of a large coronary artery (usually) affected by atherosclerosis, causing transmural ischemia. This is accompanied by release of serum cardiac biomarkers and ST elevation (and likely a Q wave when infarction develops) on an ECG.

### EPIDEMIOLOGY

#### *Incidence*

In the United States, estimated annual incidence of MI is 600,000 new and 320,000 recurrent attacks. In 2009, ÷683,000 patients were discharged from United States hospitals diagnosed with acute coronary syndromes (ACS).

#### *Prevalence*

- Leading cause of morbidity and mortality in the United States
- ÷7.5 million people in the United States are affected by MI.
- Prevalence increases with age and is higher in men (5.5%) than in women (2.9%).

### ETIOLOGY AND PATHOPHYSIOLOGY

- Atherosclerotic coronary artery disease (CAD)
- Nonatherosclerotic
  - Emboli: for example, thrombi from left ventricle or atrium
  - Mechanical obstruction: chest trauma, dissection of aorta or coronary arteries
  - Increased vasomotor tone, variant angina

- Arteritis, others: hematologic (disseminated intravascular coagulation [DIC]), aortic stenosis, cocaine, IV drug use, severe burns, prolonged hypotension
- Atherosclerotic lesions may be smooth and concentric or rough, eccentric, and fissured. Plaques that are rough and eccentric are more unstable, thrombogenic, and prone to rupture.

## **RISK FACTORS**

Advancing age, hypertension, tobacco use, diabetes mellitus, dyslipidemia, family history of premature onset of CAD, sedentary lifestyle

## **GENERAL PREVENTION**

Smoking cessation, healthy diet, weight control, regular physical activity, maintain goal blood pressure

## **COMMONLY ASSOCIATED CONDITIONS**

Abdominal aortic aneurysm, extracranial cerebrovascular disease, atherosclerotic peripheral vascular disease

## **DIAGNOSIS**

### **HISTORY**

- Classically, sudden onset of chest heaviness/tightness, with or without exertion, lasting at least minutes
- Pain/discomfort radiating to neck, jaw, interscapular area, upper extremities, and epigastrium
- Previous history of myocardial ischemia (stable or unstable angina, MI, coronary bypass surgery, or percutaneous coronary intervention [PCI])
- Assess risk factors for CAD, history of bleeding, noncardiac surgery, family history of premature CAD.
- Medications: Ask if recent use of phosphodiesterase-5 inhibitors (if recent use, avoid concomitant nitrates).
- Alcohol and drug abuse (especially cocaine)

## **PHYSICAL EXAM**

- General: restless, agitated, hypothermia, fever
- Neurologic: dizziness, syncope, fatigue, asthenia, disorientation (especially in the elderly)

Cerebrovascular (CV): dysrhythmia, hypotension, widened pulse pressure, S<sub>3</sub> and S<sub>4</sub>, jugular venous distention (JVD)

- Respiratory: dyspnea, tachypnea, crackles
- GI: abdominal pain, nausea, vomiting
- Musculoskeletal: pain in neck, back, shoulder, or upper limbs
- Skin: cool skin, pallor, diaphoresis

## *Geriatric Considerations*

Elderly patients may have an atypical presentation, including silent or unrecognized MI, often with complaints of syncope, weakness, shortness of breath, unexplained nausea, epigastric pain, altered mental status, delirium. Patients with diabetes mellitus may have fewer and less dramatic chest symptoms.

## **DIFFERENTIAL DIAGNOSIS**

Unstable angina, aortic dissection, pulmonary embolism (PE), perforating ulcer, pericarditis, dysrhythmias, gastroesophageal reflux disease (GERD) and spasm, biliary/pancreatic pain, hyperventilation syndrome

## **DIAGNOSTIC TESTS & INTERPRETATION**

### **ALERT**

The third universal definition for MI issued in 2012 by the American College of Cardiology, American Heart Association, European Society of Cardiology, and World Heart Federation revises older definitions of MI. It establishes the level of troponin necessary to diagnose MI in various clinical situations (e.g., after cardiac and noncardiac procedures). According to the definition, an MI diagnosis requires a cardiac troponin (I or T) level above the 99th percentile of a normal reference population, plus one or more of the following:

- Symptoms of ischemia
- New significant ST/T wave changes or left bundle branch block (LBBB)
- Pathologic Q waves on ECG
- New loss of viable myocardium or regional wall motion abnormality, as observed on imaging
- Intracoronary thrombus diagnosed by angiography or autopsy

## *Initial Tests (lab, imaging)*

Coronary angiography with measurement of fractional flow reserve (FFR)

- 12-lead ECG: ST-segment elevation in a regional pattern <sup>3</sup> 1 mm ST elevation, with or without abnormal Q waves. ST depression ± tall R wave in V<sub>1</sub>/V<sub>2</sub> may be STEMI of posterior wall. Absence of Q waves represents partial or transient occlusion or early infarction. New ST- or T-wave changes indicative of myocardial ischemia or injury. Consider right-sided and posterior chest leads if inferior MI pattern (examine V<sub>3</sub>R, V<sub>4</sub>R, V<sub>7</sub>-V<sub>9</sub>).
- ECG with continuous monitoring
  - 2D and M-mode echocardiography is useful in evaluating regional wall motion in MI and left ventricular function.
  - Portable echo can clarify diagnosis of STEMI if concomitant LBBB.
  - Useful in assessing mechanical complications and mural thrombus

## *Follow-Up Tests & Special Considerations*

- Serum biomarkers
  - Troponin I and T (cTnI, cTnT) rise 3 to 6 hours after onset of ischemic symptoms.
  - Elevations in cTnI persist for 7 to 10 days, whereas those in cTnT persist for 10 to 14 days after MI.
  - Myoglobin fraction of creatine kinase (CK-MB): rises 3 to 4 hours after onset of myocardial injury; peaks at 12 to 24 hours and remains elevated for 2 to 3 days; CK-MB adds little diagnostic value in assessment of possible ACS to troponin testing.
  - Myoglobin: early marker for myocardial necrosis; rises 2 hours after onset of myocardial necrosis, reaches peak at 1 to 4 hours, and remains elevated for 24 hours; myoglobin adds little diagnostic value in assessment of possible ACS to troponin testing.
- Fasting lipid profile, CBC with platelets, electrolytes, magnesium, BUN, serum creatinine, and glucose; international normalized ratio (INR) if anticoagulation contemplated; brain natriuretic peptide (BNP) is elevated in acute MI; may or may not indicate heart failure

## *Pregnancy Considerations*

Findings mimicking acute MI in pregnancy: ST-segment depression after anesthesia, increase in CK-MB after delivery, and mild increase in troponin I levels in preeclampsia and gestational hypertension

## *Diagnostic Procedures/Other*

High-quality portable chest x-ray; transthoracic and/or transesophageal echocardiography,

contrast chest CT scan, or MRI may occasionally be of value acutely. Coronary angiography is definitive test.

## **ALERT**

Isosmolar contrast medium or low-molecular-weight contrast medium other than ioxaglate or iohexol is indicated in patients with chronic kidney disease undergoing angiography who are not having chronic dialysis.

## *Test Interpretation*

Myocardial necrosis and atherosclerosis, if etiologic

## **TREATMENT**

### *GENERAL MEASURES*

- Admit to telemetry/coronary care unit (CCU) with continuous ECG monitoring and bed rest. Anxiolytics, if needed; stool softeners
- Antiarrhythmics, as needed, for unstable dysrhythmia; deep vein thrombosis (DVT) prophylaxis
- Continuation of aspirin 81 mg/day and clopidogrel 75 mg/day or prasugrel 10 mg/day or ticagrelor 90 mg twice daily, BB, ACE inhibitors (or ARB if ACE-intolerant), lipid-lowering therapy, tight BP control, progressively increased physical activity, smoking cessation, annual influenza vaccine

P.19

- Assess for depression, and treat with an SSRI or psychotherapy if present, as depression is present in 20% of patients post-MI and is a potent predictor for poor prognosis. Although it is unclear yet if treatment improves mortality, it does improve quality of life.

### *MEDICATION*

Medication recommendations based on 2009 ACC/AHA (1) focused guideline updates [A] and [B] level recommendations and 2012 ESC STEMI guidelines (2)[A,B]

#### *First Line*

- Supplemental oxygen 2 to 4 L/min for patients with arterial oxygen saturation <90% or respiratory distress
- Nitroglycerin (NTG) sublingual 0.4 mg q5min for total of 3 doses, followed by nitroglycerin IV if ongoing pain and/or hypertension and/or management of pulmonary congestion if no contraindications exist (systolic <90 mm Hg or 30 mm Hg below baseline, right ventricle (RV)

infarct, use of sildenafil within 24 hours or within 48 hours of tadalafil)

- Morphine sulfate 2 to 4 mg IV with increments of 2 to 8 mg IV repeated at 5- to 15-minute intervals to relieve pain or pulmonary congestion
- Antiplatelet agents
  - Aspirin (ASA), non-enteric-coated, initial dose 162 to 325 mg chewed (1)[A]
  - A loading dose of a thienopyridine is recommended for patients with STEMI for whom PCI is planned.
    - 600 mg of clopidogrel should be given as early as possible before or at the time of primary or nonprimary PCI.
    - Prasugrel 60 mg should be given as soon as possible for primary PCI. Do not use in patients likely to undergo coronary artery bypass graft (CABG) or with active bleeding, history of transient ischemic attack (TIA) or stroke, or additional risk factors for bleeding (body weight <60 kg or concomitant use of medications that increase risk of bleeding). (Generally, not recommended for patients age <sup>≥</sup>75 years.)
    - Ticagrelor 180 mg loading dose
    - Duration of therapy with a thienopyridine varies. At least 12 months for patients receiving drug-eluting stent (DES) during PCI for ACS and up to 12 months for patients receiving bare-metal stent (BMS). Consider earlier discontinuation if risk of morbidity due to bleeding outweighs the benefits of therapy. Discontinue clopidogrel for at least 5 days or prasugrel at least 7 days prior to planned CABG. Management of patients on dual antiplatelet therapy (DAPT) who are referred for surgical procedures depends on the level of emergency and the thrombotic and bleeding risk of the individual patient.
  - For patients with STEMI undergoing nonprimary PCI
    - Continue clopidogrel in a patient who has received fibrinolytic therapy and has been given clopidogrel.
    - Administer loading dose of clopidogrel 600 mg if patient received a fibrinolytic without a thienopyridine or ticagrelor 180 mg or once the coronary anatomy is known and PCI is planned; administer a loading dose of prasugrel as soon as possible but not later than 1 hour after PCI. Administer loading dose of clopidogrel 300 mg in patients <75 years of age who received fibrinolytic therapy or who did not receive reperfusion therapy.
    - Clopidogrel 75 mg should be given with aspirin in patients with STEMI regardless of reperfusion therapy.
- $\beta$ -blocker (BB) within 24 hours, if no contraindications exist (signs of congestive heart failure [CHF], low output state)

- Glycoprotein IIb/IIIa receptor antagonists at time of primary PCI in selected patients: abciximab, eptifibatide, or tirofiban
- ACE inhibitors should be initiated orally within 24 hours of STEMI in patients with anterior infarction, HF, or ejection fraction (EF  $\geq 0.40$ ) unless contraindicated.

PCI versus fibrinolysis: goal is to keep total ischemic time within 120 minutes. Door to needle time should be within 30 minutes or door to balloon time within 90 minutes.

- Coronary reperfusion therapy
  - Primary PCI (balloon angioplasty, coronary stents)
    - Symptom onset of  $\leq 12$  hours
    - Symptom onset of  $\leq 12$  hours and contraindication to fibrinolytic therapy irrespective of time delay
    - Cardiogenic shock or acute severe HF irrespective of time delay from onset of MI
    - Evidence of ongoing ischemia 12 to 24 hours after symptom onset
    - If substantial risk for intracranial hemorrhage (ICH)
    - Age  $< 75$  years with STEMI or LBBB who develop shock within 36 hours of AMI
- Fibrinolysis
  - If EMS has fibrinolytic capability and the patient qualifies for therapy, prehospital fibrinolysis should be started within 30 minutes of EMS arrival on scene.
  - If presenting at a hospital without PCI capability and cannot be transferred to a PCI-capable facility to undergo PCI within 90 minutes of first medical contact
  - If no contraindications, administer within 12 hours, but not beyond 24 hours of onset of symptoms to patients with STEMI in  $\geq 2$  contiguous leads and/or new or presumably new LBBB.
    - Alteplase (rt-PA): 15-mg IV bolus, followed by 0.75 mg/kg (up to 50 mg) IV over 30 minutes, then 0.5 mg/kg (up to 35 mg) over 60 minutes; maximum 100 mg over 90 minutes
    - Reteplase (r-PA): 10 units IV bolus over 2 minutes, give 2nd bolus 30 minutes later.
    - Tenecteplase (TNK-tPA): 30 to 50 mg (based on weight) IV bolus over 5 to 10 seconds
  - Combination reperfusion with abciximab and half-dose r-PA or TNK-tPA
  - Use anticoagulants (unfractionated heparin [UFH], enoxaparin, or fondaparinux) as ancillary therapy to reperfusion therapy for minimum 48 hours and duration of admission (up to 8

days). Avoid UFH if >48 hours of anticoagulant required. Recommend supportive anticoagulant regimens in patients proceeding to primary PCI who have been treated with ASA and thienopyridine. Administer additional boluses of UFH as needed to maintain therapeutic clotting time levels in patients who received prior treatment with UFH. Bivalirudin recommended as a supportive measure for primary PCI in patients with or without prior treatment with UFH.

## *Second Line*

- Long-acting nondihydropyridine calcium channel blocker (CCB) when BB is ineffective or contraindicated if EF is normal; do not use of immediate release nifedipine
- See chapter on Heart Failure, Chronic for additional medication management.

## ***SURGERY/OTHER PROCEDURES***

Intra-aortic balloon pump for cardiogenic shock; PCI of the left main coronary artery with stents as an alternative to CABG in patients with favorable anatomy and comorbid conditions that may increase risk of adverse surgical outcomes if CABG chosen

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

All patients with STEMI should be admitted to a CCU for evaluation and treatment. Transfer high-risk patients who receive fibrinolytic therapy as primary reperfusion therapy at a non-PCI-capable facility to a PCI-capable facility as soon as possible. Also admit suspected acute MI, ACS/positive cardiac markers or ST deviations, and hemodynamic abnormalities.

### ***IV Fluids***

Right ventricular infarction may need fluid resuscitation for hypotension.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Follow up in 3 to 6 weeks of discharge. Identify highrisk patients for implantable cardioverter defibrillator (ICD) placement (especially those with EF <30%). Consider exercise-based cardiac rehabilitation program.

### ***DIET***

NPO for first 4 to 12 hours due to risk of emesis or aspiration

## PATIENT EDUCATION

May resume sexual activity within 10 days, consistent with current exercise capacity. Driving can resume 1 week after discharge. Low-fat diet

## COMPLICATIONS

Heart failure, myocardial rupture/left ventricular aneurysm, pericarditis, dysrhythmias, acute mitral regurgitation, severe depression (common)

## Codes

### ICD10

- I24.9 Acute ischemic heart disease, unspecified
- I21.3 ST elevation (STEMI) myocardial infarction of unspecified site
- I25.10 Atherosclerotic heart disease of native coronary artery w/o ang pctrs

## Clinical Pearls

- Discontinue clopidogrel at least 5 to 7 days before elective CABG.
- For elective surgeries in patients on dual antiplatelet therapy (DAPT), it is recommended to wait until completion of mandatory regime and continue ASA perioperatively.

# Acute Kidney Injury

Jason Kurland, MD

## BASICS

### DESCRIPTION

Abrupt loss of kidney function is defined as a rise in serum creatinine (SCr) of  $\geq 0.3$  mg/dL within 48 hours, or a 50% increase in SCr within 7 days, or oliguria of  $< 0.5$  mL/kg/hr for  $> 6$  hours, resulting in retention of nitrogenous waste as well as electrolyte, acid-base, and volume homeostasis abnormalities (1).

### EPIDEMIOLOGY

#### Incidence

5% of hospital and 30% of ICU admissions have a diagnosis of acute kidney injury (AKI). 25% of patients develop AKI while in the hospital, and 50% of those cases are iatrogenic. Development of AKI in the inpatient setting is associated with a  $> 4$ -fold increased risk of death (2).

### ETIOLOGY AND PATHOPHYSIOLOGY

Can be divided into three categories: prerenal, intrarenal, and postrenal based on BUN/creatinine ratio

- Prerenal (BUN/creatinine ratio  $\geq 20:1$ ;  $\div 55\%$ )
  - Hypotension, volume depletion (GI losses, excessive sweating, diuretics, hemorrhage); renal artery stenosis/embolism; burns; heart failure; liver failure
  - Secondary to decreased renal perfusion (often due to hypovolemia) leading to a decrease in glomerular filtration rate (GFR); reversible if factors decreasing perfusion are corrected; otherwise, it can progress to an intrarenal pathology known as *ischemic acute tubular necrosis*.
- Intrarenal (BUN/creatinine  $< 10:1$ ;  $\div 40\%$ )
  - Acute tubular necrosis (ATN) (from prolonged prerenal state, radiographic contrast material, aminoglycosides, NSAIDs, or other nephrotoxic substances); glomerulonephritis (GN); acute interstitial nephritis (drug-induced); arteriolar insults; vasculitis; accelerated hypertension; cholesterol embolization (common after arterial procedures); intrarenal deposition/sludging

(uric acid nephropathy and multiple myeloma [Bence-Jones proteins])

- Postrenal (BUN/creatinine 10 to 20:1;  $\pm$ 5%)
  - Extrinsic compression (e.g., benign prostatic hypertrophy [BPH], carcinoma, pregnancy); intrinsic obstruction (e.g., calculus, tumor, clot, stricture, sloughed papillae); decreased function (e.g., neurogenic bladder)
  - Secondary to extrinsic (e.g., BPH) or intrinsic (e.g., stones) obstruction of the urinary collection system

## *Genetics*

No known genetic pattern

## **RISK FACTORS**

- Chronic kidney disease (CKD)
- Comorbid conditions (e.g., diabetes, hypertension, heart failure, liver failure) (3)
- Advanced age
- Radiographic contrast material exposure
- Medications that impair autoregulation of GFR (NSAIDs, ACE-I/ARB, cyclosporine/tacrolimus)
- Nephrotoxic medications (e.g., aminoglycoside antibiotics, platinum-based chemotherapy)
- Volume depletion (e.g., diuretics, hemorrhage, GI losses)
- Sepsis (4)
- Surgery
- Rhabdomyolysis
- Solitary kidney (risk in nephrolithiasis)
- BPH
- Malignancy (e.g., multiple myeloma)

## **GENERAL PREVENTION**

See  $\text{\textcircled{T}}$ Treatment; General Measures.

## **COMMONLY ASSOCIATED CONDITIONS**

Hyperkalemia, hyperphosphatemia, hypercalcemia, hyperuricemia, hydronephrosis, BPH, nephrolithiasis, congestive heart failure (CHF), uremic pericarditis, cirrhosis, CKD, malignant

hypertension, vasculitis, drug reactions, sepsis, severe trauma, burns, transfusion reactions, recent chemotherapy, rhabdomyolysis, internal bleeding, dehydration

## DIAGNOSIS

### HISTORY

- General: PO intake, urine output, body weight, baseline creatinine (to assess magnitude of change), and medication use
- Prerenal: thirst, orthostatic dizziness
- Intrarenal: nephrotoxic medications, radiocontrast material, other toxins
  - Fever, arthralgias, and pruritic rash suggest allergic interstitial nephritis (AIN); although this triad is only present in 10% of cases.
  - Edema, hypertension, and oliguria with nephritic urine sediment (RBCs and RBC casts) point to glomerulonephritis or vasculitis
  - Livedo reticularis, SC nodules, and ischemic digits despite good pulses suggest atheroembolization.
  - Flank pain suggests occlusion of the renal artery or vein.
- Postrenal: Colicky flank pain that radiates to the groin suggests a ureteric obstruction such as a stone; nocturia, frequency, and hesitancy suggest prostatic disease; suprapubic and flank pain are usually secondary to distension of the bladder and collecting system; ask about anticholinergic drugs that could lead to neurogenic bladder.
- Uremic Sx: lethargy, nausea/vomiting, anorexia, pruritus, restless legs, sleep disturbance, hiccups

### PHYSICAL EXAM

- Uremic signs: altered sensorium, seizures, asterixis, myoclonus, pericardial friction rub, peripheral neuropathies
- Prerenal signs: tachycardia, decreased jugular venous pressure (JVP), orthostatic hypotension, dry mucous membranes, decreased skin turgor; look for stigmata of associated comorbid conditions such as liver and heart failure, as well as sepsis.
- Intrinsic renal signs: pruritic rash, livedo reticularis, SC nodules, ischemic digits despite good pulses
- Postrenal signs: suprapubic distension, flank pain, enlarged prostate

# DIFFERENTIAL DIAGNOSIS

See ÒEtiology.Ó

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Urinalysis: dipstick for blood and protein; microscopy for cells, casts, and crystals
- Casts: transparent hyaline castsÑprerenal etiology; pigmented granular/muddy brown castsÑ ATN; WBC castsÑacute interstitial nephritis; RBC castsÑGN
- Urine eosinophils: ≥1% eosinophils by Hansel stain suggestive of acute interstitial nephritis (sensitivity, 67%; specificity, 83%)
- Urine electrolytes in an oliguric state
  - $FE_{Na} = [(U_{Na} \times P_{Cr}) / (P_{Na} \times U_{Cr})] \times 100$ , where U = urine, P = plasma, Na = sodium, Cr = creatinine;  $FE_{Na} < 1\%$ , likely prerenal;  $> 2\%$ , likely intrarenal
  - If patient is on diuretics, use  $FE_{urea}$  instead of  $FE_{Na}$ :  $FE_{urea} = [(U_{urea} \times P_{Cr}) / (P_{BUN} \times U_{Cr})] \times 100$ ;  $FE_{urea} < 35\%$  suggests prerenal etiology (5)[B].
- CBC, BUN, SCr, electrolytes (including Ca/Mg/P); consider arterial blood gases (ABGs).
- Common lab abnormalities in AKI
  - Increased:  $K^+$ , phosphate, Mg, uric acid
  - Decreased: Hct, Na, Ca
- Calculate creatinine clearance (CrCl) to ensure that medications are dosed appropriately.
  - Cockcroft-Gault equation for CrCl (mL/min) =  $(140 - \text{age}) \times (\text{weight in kilograms}) \times (0.85 \text{ if female}) / (72 \times \text{serum creatinine})$
  - Note that estimating equations of CrCl/GFR are only valid when renal function (SCr) is at steady-state; anuria implies CrCl of 0.
  - Renal ultrasound (US): first-line; excludes postrenal causes if negative; identifies kidney size, hydronephrosis, and nephrolithiasis
  - Doppler-flow renal US: evaluates for renal artery stenosis/thrombosis; operator-dependent
  - Abdominal x-ray (kidney, ureter, bladder [KUB]): identifies calcification, renal calculi, kidney size
- Several novel biomarkers such as urinary IL-18, neutrophil gelatinase-associated lipocalin

(NGAL), kidney injury molecule-1 (KIM-1), and plasma cystatin C, are currently being validated for their role in the initial evaluation and management of AKI (6)[C].

## *Follow-Up Tests & Special Considerations*

- Consider CK (if suspect rhabdomyolysis) and immunologic testing (if suspect GN/vasculitis).
- More advanced imaging techniques should be considered if initial tests do not reveal etiology.
  - Prerenal: ultrasound as effective as CT for evaluating for obstruction
  - Noncontrast helical CT scan: considered most sensitive study for detecting nephrolithiasis
  - Radionucleotide renal scan: evaluates renal perfusion, function (GFR), and presence of obstructive uropathy and extravasation
  - MRI: Acute tubulointerstitial nephritis can show an increased T2-weighted signal. Gadolinium contrast is contraindicated if GFR <30 mL/min due to risk of nephrogenic systemic fibrosis.

## *Diagnostic Procedures/Other*

Cystoscopy with retrograde pyelogram evaluates for bladder tumor, hydronephrosis, obstruction, and upper tract abnormalities without risk of contrast nephropathy.

## *Test Interpretation*

Kidney biopsy: last resort if patient does not respond to therapy or other tests; do not reveal a diagnosis; most useful for evaluation of intrinsic AKI of unclear cause, such as AIN, GN, vasculitis, or renal transplant rejection

P.21

## **TREATMENT**

### **GENERAL MEASURES**

Identify and correct all prerenal and postrenal causes.

- Stop nephrotoxic drugs and renally dose others.
- Strictly record intake/output and daily weights.
- Optimize cardiac output to maintain renal perfusion.
- Follow nutrition suggestions and be aware of infections; treat aggressively if they occur.
- Avoid aspirin to reduce bleeding tendency.

- Indications for initiating hemodialysis in patients with AKI: volume overload, severe or progressive hyperkalemia, or severe metabolic acidosis refractory to medical management; advanced uremic complications (pericarditis, encephalopathy, bleeding diathesis)

## MEDICATION

### First Line

- Focus on treating the underlying cause and associated complications.
- Monitor and adjust fluids and electrolytes to prevent fluid overload, hyperkalemia, hyperphosphatemia, and hypermagnesemia.
  - If patient is oliguric and not volume overloaded, a fluid challenge may be appropriate with diligent monitoring for volume overload.
- Furosemide is ineffective in preventing and treating AKI (7)[A] but can judiciously be used to manage volume overload and/or hyperkalemia.
- Dopamine, natriuretic peptides, insulin-like growth factor, and thyroxine also have no benefit in the treatment of AKI.
- Fenoldopam, a dopamine agonist, has been equivocal in decreasing risk of RRT and mortality in setting of AKI; not currently recommended for use, large RCT in progress (1)[C]
- Hyperkalemia with ECG changes: Give IV calcium gluconate, isotonic sodium bicarbonate (only if acidemic, and avoid use of hypertonic  $\text{NaHCO}_3$ ), glucose with insulin, and/or high-dose nebulized albuterol (to drive  $\text{K}^+$  into cells); Kayexalate and/or furosemide (to increase  $\text{K}^+$  excretion); hemodialysis if severe/refractory
- Fluid restriction may be required for oliguric patients to prevent worsening hyponatremia.
- Metabolic acidosis (particularly  $\text{pH} < 7.2$ ): Sodium bicarbonate can be given; be aware of volume overload, hypocalcemia, hypokalemia.
- Effective strategies for AKI prevention: IV isotonic hydration, once-daily dosing of aminoglycosides (8)[A]; use of lipid formulations of amphotericin B, use of iso-osmolar nonionic contrast media
- Risk of contrast-induced AKI may be reduced by avoidance of hypovolemia: isotonic saline 1 mL/kg/hr morning of procedure and continued until next morning, or isotonic  $\text{NaHCO}_3$  3 mL/kg/hr  $\times$  1 hour before and 1 mL/kg/hr  $\times$  6 hours after contrast administration (9)[B]. N-acetylcysteine, although previously recommended, shown to have no benefit in recent large-scale RCT (10)[A].

## *Second Line*

- Tamsulosin or other selective  $\alpha$ -blockers for bladder outlet obstruction secondary to BPH
- Dihydropyridine calcium channel blockers may have a protective effect in posttransplant ATN.

## *ISSUES FOR REFERRAL*

- Consider nephrology consultation.
- Urology consults for obstructive nephropathy

## *SURGERY/OTHER PROCEDURES*

- Relief of obstruction with retrograde ureteral catheters/percutaneous nephrostomy
- Hemodialysis catheter placement

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Many herbal and dietary supplements can be nephrotoxic (aristolochic acid, licorice [*Glycyrrhiza glabra*], ephedra, star fruit [*Averrhoa carambola*], others).

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Most patients with AKI will require admission; consider discharge in a stable patient with mild AKI and a clearly identified, reversible cause.

- Evaluate for and treat potentially life-threatening complications: hyperkalemia, metabolic acidosis, volume overload, advanced uremia
- If volume depleted, give isotonic IV fluids.
- Place a Foley catheter.

### *IV Fluids*

Isotonic fluids should be used to treat hypovolemia.

### *Nursing*

Place a Foley catheter; strict I/Os, daily weights

### *Discharge Criteria*

- Stabilization of renal function and a concrete plan for continued treatment, if necessary

- Some patients may require dialysis until renal recovery.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Nephrology follow-up if persistent renal impairment and/or proteinuria

### *DIET*

- Total caloric intake should be 20 to 30 kcal/kg/day to avoid catabolism (1).
- Restrict Na<sup>+</sup> to 2 g/day (unless hypovolemic).
- Consider K<sup>+</sup> restriction (2 to 3 g/day) if hyperkalemic.
- If hyperphosphatemic, consider use of phosphate binders, although no evidence of benefit in AKI.
- Avoid magnesium- and aluminum-containing compounds.

### *PATIENT EDUCATION*

Keep well-hydrated. Avoid nephrotoxic drugs, such as NSAIDs and aminoglycosides.

### *PROGNOSIS*

- Depending on the cause, comorbid conditions, and age of patient, mortality ranges from 5% to 80%
- In cases of prerenal and postrenal failure, very good rates of recovery are positively correlated with shorter duration of AKI. Intrarenal etiologies usually take more time to recover. Overall, average recovery takes from days to months.
- Even with complete recovery from AKI, affected patients are at higher subsequent risk of developing CKD and ESRD (11).

### **COMPLICATIONS**

Death, sepsis, infection, seizures, paralysis, peripheral edema, CHF, arrhythmias, uremic pericarditis, bleeding, hypotension, anemia, hyperkalemia, uremia

- Algorithm: Anuria or Oliguria

## Codes

### ICD10

- N17.9 Acute kidney failure, unspecified
- N17.0 Acute kidney failure with tubular necrosis
- N00.9 Acute nephritic syndrome with unspecified morphologic changes

## Clinical Pearls

- Three categories of AKI: prerenal, intrarenal, and postrenal
  - Prerenal: decreased renal perfusion (often from hypovolemia) leading to a decrease in GFR; reversible if perfusion is restored
  - Intrarenal: intrinsic kidney damage; ATN is the most common cause via ischemic/nephrotoxic injury to the kidney.
  - Postrenal: secondary to extrinsic/intrinsic obstruction of the urinary collection system
- Recognize the need for emergent hemodialysis: severe hyperkalemia, metabolic acidosis, or volume overload refractory to conservative therapy; uremic pericarditis, encephalopathy, or neuropathy; and selected alcohol and drug intoxications

# Addison Disease

Tya-Mae Y. Julien, MD

## BASICS

### DESCRIPTION

- Primary adrenal gland insufficiency, which results from partial or complete destruction of the adrenal cells with inadequate secretion of glucocorticoids and mineralocorticoids
- ÷80% of cases are caused by an autoimmune process, followed by tuberculosis (TB), AIDS, systemic fungal infections, and adrenoleukodystrophy
- Addison disease (primary adrenocortical insufficiency) can be differentiated from secondary (pituitary failure) and tertiary (hypothalamic failure) causes because mineralocorticoid function usually remains intact in secondary and tertiary causes.
- Addisonian (adrenal) crisis: acute complication of adrenal insufficiency (circulatory collapse, dehydration, hypotension, nausea, vomiting, hypoglycemia); usually precipitated by an acute physiologic stressor(s) such as surgery, illness, exacerbation of comorbid process, and/or acute withdrawal of longterm corticosteroid therapy
- System(s) affected: endocrine/metabolic
- Synonym(s): adrenocortical insufficiency; corti-coadrenal insufficiency; primary adrenocortical insufficiency

### EPIDEMIOLOGY

- Predominant age: all ages; typical age of presentation is 30 to 50 years
- Predominant sex: females > males (slight)
- No racial predilection

### Incidence

0.6:100,000

### Prevalence

4 to 6:100,000; possibly higher

# ETIOLOGY AND PATHOPHYSIOLOGY

- Autoimmune adrenal insufficiency (÷80% of cases in the United States)
- Infectious causes: TB (most common infectious cause worldwide), HIV (most common infectious cause in the United States, often with concomitant infections such as cytomegalovirus), Waterhouse-Friderichsen syndrome (most commonly meningococcus), fungal disease
- Bilateral adrenal hemorrhage and infarction (for patients on anticoagulants, 50% are in the therapeutic range)
- Antiphospholipid antibody syndrome
- Lymphoma, Kaposi sarcoma, metastasis (lung, breast, kidney, colon, melanoma); tumor must destroy 90% of gland to produce hypofunction
- Drugs (e.g., ketoconazole, fluconazole, etomidate)
- Surgical adrenalectomy, radiation therapy
- Sarcoidosis, hemochromatosis, amyloidosis
- Congenital enzyme defects (deficiency of 21-hydroxylase enzyme is most common), neonatal adrenal hypoplasia, congenital adrenal hyperplasia, familial glucocorticoid insufficiency, autoimmune polyglandular autoimmune syndromes 1 and 2, adrenoleukodystrophy
- Idiopathic
- Destruction of the adrenal cortex resulting in deficiencies in cortisol, aldosterone, and androgens

## Genetics

- Autoimmune polyglandular syndrome (APS) type 2 genetics are complex and are associated with adrenal insufficiency, type 1 diabetes, and Hashimoto disease. APS type 2 is more common than APS type 1.
- APS type 1 is caused by mutations of the autoimmune regulator gene. Nearly all have the following triad: adrenal insufficiency, hypoparathyroidism, and mucocutaneous candidiasis before adulthood.
- Adrenoleukodystrophy is an X-linked recessive disorder resulting in toxic accumulation of unoxidized long-chain fatty acids.
- Increased risk with cytotoxic T-lymphocyte antigen 4 (CTLA-4)

## RISK FACTORS

40% of patients have a 1st- or 2nd-degree relative with associated disorders.

- Chronic steroid use, then experiencing severe infection, trauma, or surgical procedures

## *GENERAL PREVENTION*

- No preventive measures known for Addison disease; focus on prevention of complications
  - Anticipate adrenal crisis and treat before symptoms begin.
- Elective surgical procedures require upward adjustment in steroid dose.

## *COMMONLY ASSOCIATED CONDITIONS*

- Diabetes mellitus
- Graves disease
- Hashimoto thyroiditis
- Hypoparathyroidism
- Hypercalcemia
- Ovarian failure
- Pernicious anemia
- Myasthenia gravis
- Vitiligo
- Chronic moniliasis
- Sarcoidosis
- Sjögren syndrome
- Chronic active hepatitis
- Schmidt syndrome

## **DIAGNOSIS**

### **HISTORY**

- Weakness, fatigue
- Dizziness
- Anorexia, nausea, vomiting
- Abdominal pain

- Chronic diarrhea
- Depression (60-80% of patients)
- Decreased cold tolerance
- Salt craving

## *PHYSICAL EXAM*

- Weight loss
- Low BP, orthostatic hypotension
- Increased pigmentation of high friction areas (extensor surfaces, plantar or palmar creases, dentalgingival margins, buccal and vaginal mucosae, lips, areolae, pressure points, scars, tanning, freckles)
- Vitiligo
- Hair loss in females

## *DIFFERENTIAL DIAGNOSIS*

- Secondary adrenocortical insufficiency (pituitary failure)
  - Withdrawal of long-term corticosteroid use
  - Sheehan syndrome (postpartum necrosis of pituitary)
  - Empty sella syndrome
  - Radiation to pituitary
  - Pituitary adenomas, craniopharyngiomas
  - Infiltrative disorders of pituitary (sarcoidosis, hemochromatosis, amyloidosis, histiocytosis X)
- Tertiary adrenocortical insufficiency (hypothalamic failure)
  - Pituitary stalk transection
  - Trauma
  - Disruption of production of corticotropin-releasing factor
  - Hypothalamic tumors
- Other
  - Myopathies
  - Syndrome of inappropriate antidiuretic hormone

- Heavy metal ingestion
- Severe nutritional deficiencies
- Sprue syndrome
- Hyperparathyroidism
- Neurofibromatosis
- Peutz-Jeghers syndrome
- Porphyria cutanea tarda
- Salt-losing nephritis
- Bronchogenic carcinoma
- Anorexia nervosa

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Basal plasma cortisol and adrenocorticotrophic hormone (ACTH) (low cortisol and high ACTH indicative of Addison disease) (1)[C]
- Standard ACTH stimulation test: Cosyntropin 0.25 mg IV; measure preinjection baseline and 60-minute postinjection cortisol levels (patients with Addison disease have low to normal values that do not rise).
- Insulin-induced hypoglycemia test
- Metapyrone test
- Autoantibody tests: 21-hydroxylase (most common and specific), 17-hydroxylase, 17-alpha-hydroxylase (may not be associated), and adrenomedullin
- Circulating very-long-chain fatty acid levels if boy or young man
- Low serum sodium
- Elevated serum potassium
- Elevated BUN, creatinine, calcium, thyroid-stimulating hormone (TSH)
- Low serum aldosterone
- Hypoglycemia when fasting
- Metabolic acidosis
- Moderate neutropenia

- Eosinophilia
- Relative lymphocytosis
- Anemia, normochromic, normocytic

### *Follow-Up Tests & Special Considerations*

- Plasma ACTH levels do not correlate with treatment and should not be used for routine monitoring of replacement therapy.
- TSH: Repeat when condition has stabilized.
  - Thyroid hormone levels may normalize with the treatment of Addison disease.
- Drugs that may alter lab results: digitalis
- Disorders that may alter lab results: diabetes

### *Diagnostic Procedures/Other*

- Abdominal CT scan: small adrenal glands in autoimmune adrenalitis; enlarged adrenal glands in infiltrative and hemorrhagic disorders
- Abdominal radiograph may show adrenal calcifications.
- Chest x-ray may show small heart size and/or calcification of cartilage.
- MRI of pituitary and hypothalamus if secondary or tertiary cause of adrenocortical insufficiency is suspected.
- CT-guided fine-needle biopsy of adrenal masses may identify diagnoses.

### *Test Interpretation*

- Atrophic adrenals in autoimmune adrenalitis
- Infiltrative and hemorrhagic disorders produce enlargement with destruction of the entire gland.

## **TREATMENT**

### *GENERAL MEASURES*

Consider the 5 S's for the management of adrenal crisis:

- Salt, sugar, steroids, support, and search for a precipitating illness (usually infection, trauma, recent surgery, or not taking prescribed replacement therapy)

## MEDICATION

### First Line

- Chronic adrenal insufficiency
  - Glucocorticoid supplementation (2)[A]
    - Dosing: hydrocortisone 15 to 30 mg (or therapeutic equivalent) PO in 2 to 4 divided doses (to include morning rising and bedtime doses); dosage may vary and is usually lower in children and the elderly.
    - Precautions: hepatic disease, fluid disturbances, immunosuppression, peptic ulcer disease, pregnancy, osteoporosis
    - Adverse reactions: immunosuppression, osteoporosis, gastric ulcers, depression, hyperglycemia, weight gain, glaucoma
    - Drug interactions: concomitant use of rifampin, phenytoin, or barbiturates
  - Mineralocorticoid supplementation
    - Dosing: fludrocortisone 0.05 to 0.2 mg/day PO
  - May require salt supplementation
- Addisonian crisis
  - Hydrocortisone 100 mg IV followed by 10 mg/hr infusion or hydrocortisone 100 mg IV bolus q6-8h
  - IV glucose, saline, and plasma expanders
  - Fludrocortisone 0.05 mg/day PO (typically not required; high-dose hydrocortisone is an effective mineralocorticoid)
- Acute illnesses (fever, stress, minor trauma)
  - Double the patient's usual steroid dose, taper the dose gradually over a week or more, and monitor vital signs and serum sodium.
- Supplementation for surgical procedures
  - Administer hydrocortisone 25 to 150 mg or methylprednisolone 5 to 30 mg IV on the day of the procedure in addition to maintenance therapy; taper gradually to the usual dose over 1 to 2 days.

## *Second Line*

- Addition of androgen therapy:
  - Dehydroepiandrosterone (DHEA) 25 to 50 mg PO once daily is sufficient to restore androgen levels to within normal range with minimal side effects and may improve well-being and sexuality in some women (3,4)[A].

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Presence of circulatory collapse, dehydration, hypotension, nausea, vomiting, hypoglycemia
- ICU admission for unstable cases
- Addisonian crisis:
  - Airway, breathing, and circulation management
  - Establish IV access; 5% dextrose and normal saline.
  - Administer hydrocortisone 100 mg IV bolus q6-8h; replacement with fludrocortisone is not necessary (high-dose hydrocortisone is an effective mineralocorticoid).
  - Correct electrolyte abnormalities.
  - BP support for hypotension
  - Antibiotics if infection suspected

### *IV Fluids*

IV saline containing 5% dextrose and plasma expanders

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Verify adequacy of therapy: normal BP, serum electrolytes, plasma renin, and fasting blood glucose level
- Periodically assess for the development of longterm complications of corticosteroid use, including screening for osteoporosis, gastric ulcers, depression, and glaucoma.
- Lifelong medical supervision for signs of adequate therapy and avoidance of overdose

- Monitor for development of new autoimmune diseases.

## DIET

Maintain water, sodium, and potassium balance.

## PATIENT EDUCATION

- National Adrenal Diseases Foundation, Great Neck, NY 11021, (516) 487-4992 (<http://www.nadf.us>)
- Patient should wear or carry medical identification about the disease and the need for hydrocortisone or other replacement therapy.
- Instruct patient in self-administration of parenteral hydrocortisone for emergency situations.

## PROGNOSIS

Requires lifetime treatment: Life expectancy approximates normal with adequate replacement therapy; without treatment, the disease is 100% lethal.

## COMPLICATIONS

- Hyperpyrexia
- Psychotic reactions
- Complications from underlying disease
- Over- or underuse of steroid treatment
- Hyperkalemic paralysis (rare)
- Addisonian crisis

## See Also

Algorithm: Adrenocortical Insufficiency

## Codes

### ICD10

- E27.1 Primary adrenocortical insufficiency
- A18.7 Tuberculosis of adrenal glands
- E27.2 Addisonian crisis

## Clinical Pearls

- 80% of cases are caused by an autoimmune process; the average age of diagnosis in adults is 40 years.
- Consider the 5 S's for the management of Addison disease: salt, sugar, steroids, support, and search for an underlying cause.
- The goal of steroid replacement therapy should be the lowest dose that alleviates patient symptoms while preventing adverse drug events.
- Plasma ACTH levels do not consistently correlate with treatment and should not be used alone for routine monitoring for efficacy of replacement therapy.
- Long-term use of steroids predisposes patients to the development of osteoporosis; screen accordingly and encourage calcium and vitamin D supplementation.

# Adenomyosis

Bradley M. Turner, MD, MPH, MHA

Amanda Martin Kelley, MD, MPH&TM

## BASICS

### DESCRIPTION

- Benign invasion of the endometrium into the myometrium, producing a diffusely enlarged uterus
- Microscopically, there are ectopic, nonneoplastic endometrial glands and stroma surrounded by hypertrophic and hyperplastic myometrium.
- Can be either diffuse or focal, depending on the extent of myometrial invasion
- In some cases, it may manifest as a circumscribed myometrial mass referred to as an adenomyoma.
- Most commonly affects the posterior wall of the uterus
- Typically associated with the uterus; however, the term Adenomyosis can also be applied to benign hyperplastic changes in the bile ducts, gallbladder, and ampulla of Vater.

### EPIDEMIOLOGY

- Most frequently presents in the 4th and 5th decades
- Wide variation among racial and ethnic groups and among different geographic regions

### Incidence

- Variability in the criteria used for diagnosis make an accurate determination of true incidence difficult.
- Depending on the criteria used for diagnosis, the incidence has been estimated as between 5% and 50%.
- The incidence has been reported to be higher (35-50%) in women presenting with pelvic pain and infertility.

### Prevalence

- As with incidence, an accurate determination of prevalence is difficult due to the variability in the criteria used for diagnosis.
- Depending on the criteria used for diagnosis, the prevalence has been reported to vary from 5% to 70%, with the mean frequency of adenomyosis at hysterectomy given as approximately 20-30%.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Adenomyosis has been described as an abnormal ingrowth and invagination of the basal endometrium into the inner layer of the myometrium (junctional zone [JZ]).
- The exact mechanism regarding how this occurs and is maintained is not clear and likely to be multifactorial.
- In women with adenomyosis, the JZ may represent a region of morphologic dysfunction and structural weakness, with varying susceptibility to invagination of endometrial stromal cells.
- Increased uterine pressure associated with pregnancy, leiomyomas, or other pathology may modulate the JZ environment, making it more susceptible to invagination of endometrial stromal cells.
- Other theories for pathogenesis include the following:
  - *Metaplasia theory*: metaplasia of myometrial smooth muscle cells
  - *Müllerian remnants theory*: de novo development from müllerian rests in the myometrium
  - *Tissue remodeling theory*: ectopic endometrial tissue arising secondary to tissue remodeling associated with uterine trauma either physiologic (e.g., during menstruation, childbirth, or spontaneous abortion) or iatrogenic (e.g., during uterine surgery)
  - *Multipotential perivascular theory*: Multipotential perivascular stem cells may be associated with increased angiogenesis and pathophysiologic vascular remodeling, leading to vascular smooth muscle hypertrophy, proliferation, or migration.
  - *Epithelial-mesenchymal transition theory*: Increased estrogen concentrations may enhance endometrial tissue growth, angiogenesis, and invagination into the JZ.
  - *Hyperproliferation of uterine smooth muscle cell theory*: Activation of the MAPK/ERK pathway has been associated with hyperproliferative uterine smooth cells in women with adenomyosis.
  - *Mast cell activation theory*: Nerve growth factor, a mast cell-derived mediator, can be used as an indicator for the severity of adenomyosis. This and other mast cell-derived mediators may contribute to the differentiation and development of the myometrium and maintenance of adenomyosis.

## Genetics

- DNA microarray and proteomics analysis have identified specific genes that are differentially expressed in adenomyosis and matched eutopic endometrium.
- Data suggest that genetic and epigenetic abnormalities contribute to the pathogenesis of adenomyosis.

## RISK FACTORS

- Age >35 years, however, the disease may cause dysmenorrhea and chronic pelvic pain in women of younger age, including adolescents. Reports suggest that early-stage adenomyosis might present a different clinical phenotype compared to late-stage disease.
- Multiparity
- Tamoxifen treatment
- Other possible risk factors:
  - Previous uterine surgery (studies have been inconsistent)
  - Smoking (studies have been inconsistent)

## COMMONLY ASSOCIATED CONDITIONS

- Leiomyomas (uterine fibroids)
- Endometriosis
- Endometrial polyps
- Urinary tract dysfunction

## DIAGNOSIS

Pelvic pain, dysmenorrhea, and an enlarged uterus are the usual cues that prompt imaging by ultrasound or MRI; endometrial or uterine biopsies may be indicated in some cases.

## HISTORY

- Presenting symptoms are nonspecific and the patient is often asymptomatic.
- Symptoms often include (1,2,3,4) the following:
  - Menorrhagia
  - Dysmenorrhea
  - Chronic pelvic pain

- Abnormal uterine bleeding
- Urinary tract symptoms (e.g., stress urinary incontinence, urgency, daytime frequency, and urge urinary incontinence) have recently been associated with an increased incidence of adenomyosis; however, data are limited (5,6).

## *PHYSICAL EXAM*

Uterus may be enlarged and tender (7).

## *DIFFERENTIAL DIAGNOSIS*

- Pregnancy
- Benign uterine tumors
- Malignant uterine tumors
- Metastatic disease

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Transvaginal ultrasound (TVUS) is the imaging method of choice for initial evaluation of suspected adenomyosis (2,4,7)[A].
- TVUS can be either two or three-dimensional (2)[A].
- Three-dimensional TVUS can provide JZ thickness.
- TVUS has a sensitivity of 72-82.5% and a specificity of 81-84.6% (4,7)[A].
- TVUS is less sensitive than MRI in differentiating adenomyosis from leiomyoma (2,7)[A].
- TVUS with power color flow Doppler can be used to differentiate adenomyosis from leiomyoma (2,4)[B], depending on the operator (2,7)[C].
- Although MRI is more sensitive (4,7)[A] than TVUS, the higher cost of the procedure limits its use as a first-line diagnostic tool.
- MRI has a sensitivity of 77-93% and a specificity of 67-99% (4,7)[A].
- Leiomyomas are associated with adenomyosis in 36-50% of cases, making MRI an ideal imaging method (4)[A].
- MRI should be considered when TVUS cannot provide a definitive diagnosis.

### *Diagnostic Procedures/Other*

- Uterine biopsy with histologic interpretation
- Uterine-sparing operative treatment with histologic interpretation
- Hysterectomy with histologic interpretation

## *Test Interpretation*

- The two-dimensional sonographic markers of adenomyosis include the following (2,4,7)[A]:
  - Uterine enlargement (with no visualized leiomyoma)
  - Cystic anechoic spaces or lakes in the myometrium
  - Uterine wall thickening
  - Subendometrial echogenic linear striations
  - Heterogeneous echo texture
  - Obscure endometrial/myometrial border
  - Thickening of the transition zone
- With three-dimensional TVUS, a JZ maximum (JZmax) <sup>3</sup>8 mm and a JZ maximum - JZ minimum (JZmin) <sup>3</sup>4 mm have been reported as significantly more associated with adenomyosis than two-dimensional features (2)[B].
- Features of adenomyosis on MRI include low-intensity widening of the JZ on T2-weighted images, which corresponds to smooth muscle hyperplasia and thickening of the JZ (2,4,7)[A].
- Three objective parameters have been identified for an MRI diagnosis of adenomyosis:
  - Thickening of the JZ to at least 8 to 12 mm (2)[B],(7)[A]
  - JZmax/total myometrium >40% (2,7)[B]
  - JZmax-JZmin >5 mm (2)[B]
- Histologic interpretation has traditionally been considered the most practicable way to establish a definitive diagnosis of adenomyosis (4,7)[C].

---

P.25

- Pathologic interpretation of uterine biopsy:
  - Presence of endometrial glands and stromal elements within the myometrium
  - Often difficult to definitively diagnose adenomyosis due to sampling bias and/or biopsy artifact (1)[A]
- Pathologic interpretation of uterine-sparing operative treatment and hysterectomy:

- In morcellated specimens, diagnostic difficulty arises due to modification of the spatial arrangement of the tissue, leading to difficulty in referencing the surface. Sampling bias can also be an issue (1)[A].
- Even in cases where the surface is accurately referenced, criteria vary among pathologists regarding the depth of invasion, which definitively defines adenomyosis (1,4,7,8)[A].

## TREATMENT

- The mainstay of treatment has been surgical therapy.
- Medical therapy shows promise in certain patients.

## MEDICATION

- The levonorgestrel-releasing intrauterine system (Mirena) has been shown to result in a reduction of symptoms (6,9)[B].
- Gonadotropin-releasing hormone analogs have shown promise in several studies (9)[B].

## ADDITIONAL THERAPIES

- Danazol has shown promise in several case series (8)[B].
- Immunomodulators of angiogenesis, and oral progestins (dienogest), may offer future options for medical treatment of adenomyosis (9,10)[B].

## SURGERY/OTHER PROCEDURES

- Hysterectomy is curative.
- Uterine-sparing operative treatment (USOT) might be considered for women who wish to preserve fertility or do not wish to have a hysterectomy.
- USOT **excisional** techniques (1,8,11)[B]:
  - Complete excision (adenomyomectomy)
  - Cytoreduction (partial adenomyomectomy)
- USOT **nonexcisional** techniques (1,8,11,12,13)[B]:
  - Laparoscopic techniques including electrocoagulation, uterine artery ligation
  - Hysteroscopic techniques including endometrial ablation, endomyometrial resection
  - MRI or ultrasound-guided high-frequency ultrasound ablation (high-intensity focused

ultrasound [HIFU])

- Uterine artery embolization
- Other reported techniques include the following: alcohol instillation (cystic adenomyosis), radiofrequency ablation (focal adenomyosis), microwave ablation, and thermoablation (diffuse adenomyosis)
- Of the nonexcisional techniques, HIFU and uterine artery embolization (UAE) seem to offer the most encouraging results (1)[C],(12,13)[B].
- Increasing percentages of necrosis after UAE may be an important factor associated with decreased recurrence of symptoms (14)[B].
- The impact of USOT on fertility outcomes are encouraging; however, data are lacking (11)[A].

## **ONGOING CARE**

### *PATIENT EDUCATION*

Adenomyosis, PubMed health, at <http://www.ncbi.nlm.nih.gov/pubmedhealth/PMHT0024411/>

### *PROGNOSIS*

- Adenomyosis is a benign proliferation of endometrial tissue.
- Symptoms usually resolve after menopause.
- Hysterectomy is curative.
- Additional studies are needed to determine the impact of untreated adenomyosis and USOT on fertility and reproductive outcomes.
- Additional studies are needed to clarify the role of medical treatment in women with adenomyosis.
- A consensus on the criterion for diagnosing adenomyosis needs to be reached.

### **COMPLICATIONS**

- Anemia from blood loss associated with heavy periods
- Patients with adenomyosis have been reported to be at increased risk for malignant disease; however, to date, there has not been sufficient morphologic, genetic, or epigenetic evidence to substantiate the malignant transformation of adenomyosis.

## Codes

### ICD10

N80.0 Endometriosis of uterus

## Clinical Pearls

- Adenomyosis is often asymptomatic.

- Both TVUS and MRI are very accurate for the diagnosis of adenomyosis.
- MRI is more sensitive than TVUS, particularly in differentiating adenomyosis from leiomyoma. Differentiation of adenomyosis from leiomyoma is critical because the former is often treated with hysterectomy, whereas the latter is often treated with uterine conservation.
- Various medical and surgical therapeutic options, including uterine-sparing operative techniques, are available for adenomyosis.
- Hysterectomy is curative.

# Adenovirus Infections

Crystal Amadi, MD

Fozia Akhtar Ali, MD

## BASICS

### DESCRIPTION

- Acute, typically self-limited, febrile illnesses characterized by inflammation of mucous membranes including the conjunctivae, and the respiratory and GI tracts.
- Adenovirus infections occur in epidemic and endemic situations:
  - Common types are as follows:
    - Acute febrile respiratory illness— affects primarily children
    - Acute respiratory disease— affects adults
    - Viral pneumonia— affects children and adults
    - Acute pharyngoconjunctival fever— affects children, particularly after summer swimming
    - Acute follicular conjunctivitis— affects all ages
    - Epidemic keratoconjunctivitis— affects adults
    - Intestinal infections leading to enteritis, mesenteric adenitis, and intussusception
  - Conjunctivitis
- System(s) affected: cardiovascular; GI; hematologic/lymphatic/immunologic; musculoskeletal; nervous; pulmonary; renal/urologic; ophthalmologic

### *Geriatric Considerations*

Complications more likely in elderly populations

### *Pediatric Considerations*

Viral pneumonia in infants and neonates (may be fatal)

### EPIDEMIOLOGY

Predominant age: <10 years, but epidemics in all ages

- Predominant sex: male = female
- Occurs worldwide and throughout the year but more frequently in warmer months

## *Incidence*

- Common infection: 2-5% of all upper respiratory infections (URIs) and >10% of URIs in children
- Most individuals show evidence of prior adenovirus infection by age 10 years.
- Many adenovirus infections are subclinical or asymptomatic.
- 15-70% of conjunctivitis worldwide

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- DNA virus 60 to 90 nm in size, 6 species (A-F) with over 50 known serotypes
- Adenovirus can remain dormant in lymphoreticular tissue (adenoids and tonsils) after exposure and viral shedding may persist for months (1).
- Transmission
  - Aerosol droplets, fomites, fecal-oral
  - Virus can survive on skin and environmental surfaces.
  - Incubation period is 5 to 9 days (2).
- Most common known pathogens:
  - Types 1 to 5, 7, 14, and 21 cause upper respiratory illness and pneumonia.
  - Types 3, 7, and 21 cause pharyngoconjunctival fever.
  - Types 31, 40, and 41 cause gastroenteritis.
  - Types 8, 19, 37, 53, and 54 cause epidemic keratoconjunctivitis.
  - Types 5, 7, 14, and 21 cause more severe illness.

## *RISK FACTORS*

- Large number of people gathered in a confined area (e.g., military recruits, college students, daycare centers, summer camps, community swimming pools)
- Immunocompromised are at risk for severe disease.

## GENERAL PREVENTION

- Live, enteric-coated oral type 4 and type 7 adenovirus vaccine available for military recruits (or other personnel at high risk ages 17 to 50 years); reduces incidence of acute respiratory disease (3)
- Frequent hand washing
- Decontamination of environmental surfaces using chlorine, bleach, formaldehyde, or heat
- Universal precautions, particularly when examining patients with epidemic keratoconjunctivitis; droplet precautions if suspected adenoviral respiratory infection.
- Health care providers with suspected bilateral adenoviral conjunctivitis should avoid direct patient contact for 2 weeks after onset of symptoms in second eye.

## COMMONLY ASSOCIATED CONDITIONS

- Otitis media
- Conjunctivitis
- Bronchiolitis
- Viral enteritis
- Less frequent syndromes (seen primarily in immunocompromised individuals): meningoencephalitis, hepatitis, myocarditis, pancreatitis, genital infections, intussusception and mesenteric adenitis hemorrhagic cystitis, and interstitial nephritis.

## DIAGNOSIS

### HISTORY

Depends on type (see "Differential Diagnosis"). Common symptoms with most respiratory forms (4,5)

- Headache, malaise
- Sore throat
- Cough, coryza
- Fever (moderate to high)
- Vomiting, diarrhea, abdominal pain
- Ear pain
- Urinary symptoms/hematuria
- Eye redness and pain

- Irritative voiding symptoms (bladder involvement)

## *PHYSICAL EXAM*

- Fever
- Tonsillar erythema/exudate
- Cervical lymphadenopathy
- Otitis media
- Conjunctivitis

## *DIFFERENTIAL DIAGNOSIS*

- The following are the primary characteristics of the major adenovirus infections:
  - Acute respiratory illness
    - Mostly in children
    - Incubation period: 2 to 5 days
    - Malaise, fever, chills, headache, pharyngitis, hoarseness, dry cough
    - Fever lasting 2 to 4 days
    - Illness subsiding in 10 to 14 days
    - DDx: rhinovirus, influenza, parainfluenza, RSV
  - Viral pneumonia
    - Sudden onset of high fever, rapid infection of upper and lower respiratory tracts, skin rash, diarrhea
    - Occurs mostly in children aged a few days up to 3 years
    - DDx: bacterial pneumonia, RSV, influenza, parainfluenza
  - Acute pharyngoconjunctival fever
    - Spiking fever, headache, pharyngitis, conjunctivitis (typically unilateral), rhinitis, cervical adenitis
    - Subsides in 1 week
    - DDx: bacterial conjunctivitis, enterovirus, herpes simplex virus (HSV)
  - Epidemic keratoconjunctivitis

- Usually unilateral onset of ocular redness and edema, periorbital edema, periorbital swelling, foreign body sensation
- Lasts 3 to 4 weeks
- DDx: bacterial conjunctivitis, enterovirus, HSV
- Viral enteritis
  - Nausea/vomiting, diarrhea, abdominal pain
  - DDx: bacterial enteritis, bowel obstruction

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Confirmation necessary only in severe cases and epidemics.
- Viral cultures from respiratory, ocular, or fecal sources
  - Pharyngeal isolate suggests recent infection.
- Adenovirus-specific ELISA; rapid but less sensitive than culture (6)[A]
- Adenovirus DNA via polymerase chain reaction (PCR)
- Rapid pathogen screening, Adeno Detector, is available for detecting adenoviral conjunctivitis (sensitivity, 89%; specificity, 94%); results in 10 minutes (7)[B]

---

P.27

- Antigen detection in stool for enteric serotypes
- Serologies (complement fixation) with a fourfold rise in serum antibody titer, identify recent adenoviral infection.
- Radiographs: bronchopneumonia in severe respiratory infections

### *Diagnostic Procedures/Other*

Biopsy (lung or other) may be needed in severe or unusual cases; usually only in immunocompromised patients

### *Test Interpretation*

- Varies with each virus
  - Severe pneumonia may show extensive intranuclear inclusions.
- *Bronchiolitis obliterans* may occur.

## TREATMENT

### GENERAL MEASURES

- Treatment is supportive and symptomatic.
- Infections are usually benign and of short duration.

### MEDICATION

#### *First Line*

- Acetaminophen 10 to 15 mg/kg PO for analgesia (avoid aspirin)
- Antivirals and immunotherapy for immunocompromised individuals and patients with severe disease are as follows:
  - No controlled trials showing benefit of any antiviral agents against human adenovirus infection; however, cidofovir (1 mg/kg every other day) is most commonly used.
  - For adenoviral conjunctivitis, topical ganciclovir 0.15% ophthalmic gel has been suggested for off-label use.

### COMPLEMENTARY & ALTERNATIVE MEDICINE

Echinacea has not been shown to be better than placebo for treatment of viral URIs (8)[B].

### INPATIENT CONSIDERATIONS

#### *Admission Criteria/Initial Stabilization*

Severely ill infants or immunocompromised patients with severe illness

#### *Nursing*

Hospitalized patients with adenoviral infections should be placed on contact precautions with droplet precautions added for those with respiratory illness.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

Rest during febrile phases

## Patient Monitoring

For severe infantile pneumonia and conjunctivitis, daily physical exam until well.

## DIET

No special diet

## PATIENT EDUCATION

- Avoid aspirin in children.
- Give instructions for saline nasal spray, cough preparations, frequent hand washing, and surface cleaning.

## PROGNOSIS

- Self-limited, usually without sequelae
- Severe illness and death in neonates and in immunocompromised hosts can occur; severe pneumonia in children <2 years can have a mortality rate as high as 16%.

## COMPLICATIONS

Few, if any, recognizable long-term problems

## Codes

### ICD10

- B34.0 Adenovirus infection, unspecified
- B30.1 Conjunctivitis due to adenovirus
- J12.0 Adenoviral pneumonia

## Clinical Pearls

- Adenovirus can mimic streptococcus pharyngitis with tonsillar exudates and cervical adenitis.
- Most common cause of strep-negative tonsillitis in young children
- Diagnosis only needs to be confirmed in severe cases and epidemics.
- Average incubation time is 5 to 6 days.
- Adenovirus conjunctivitis is highly contagious, handwashing and universal precautions help prevent spread.

# Adhesive Capsulitis (Frozen Shoulder)

Brandon David Hecht, DO

## BASICS

### DESCRIPTION

- Painful, gradual loss of both active and passive glenohumeral (GH) motion due to progressive fibrosis/contracture of the GH joint capsule
- The clinical course of adhesive capsulitis (AC) follows a predictable progression
  - Stage 1, freeze/pain: subacute onset of diffuse vague pain, lasting 2 to 9 months
  - Stage 2, frozen/adhesive: insidious onset of stiffness, lasting 4 to 12 months
  - Stage 3, thaw/recovery: gradual resolution over 5 to 24+ months. Resolution may be protracted (symptoms lasting >36 months) and incomplete but rarely results in a functional limitation.
- AC categorized as primary (idiopathic) and secondary (underlying or associated condition)
- System(s) affected: musculoskeletal
- Synonym(s): pericapsulitis; scapulohumeral peri arthritis

### EPIDEMIOLOGY

- Predominant age: 40 to 60 years
- Predominant sex: female > male

### Prevalence

- General population: 2-5%
- Diabetics type 1 and type 2: 10-20%

### ETIOLOGY AND PATHOPHYSIOLOGY

- Synovial inflammation and capsular fibrosis resulting in contracture of the rotator cuff, coracohumeral ligament, and anterior shoulder capsule restricting movement of the shoulder
- A poorly understood chronic inflammatory response with fibroblastic proliferation, possibly

immunomodulated

## *Genetics*

No known genetic predispositions

## **RISK FACTORS**

- Sedentary vocation or lifestyle
- Age <sup>3</sup>40 years
- History of AC: 20-30% will develop the condition in contralateral shoulder.
- Minor injury: 20-30% of those with AC will report recent minor trauma to the shoulder.
- Systemic diseases: endocrinopathies, autoimmune disorders, atherosclerotic disease (see *Commonly Associated Conditions*)

## **GENERAL PREVENTION**

No current evidence regarding prevention

## **COMMONLY ASSOCIATED CONDITIONS**

- Idiopathic AC associated with a history of Dupuytren contractures
- Secondary AC is associated with diabetes, thyroid disease, autoimmune diseases, rotator cuff injury or minor shoulder trauma, shoulder immobilization, history of stroke, or myocardial infarction.

## **DIAGNOSIS**

### **HISTORY**

- Insidious onset of progressive, diffuse shoulder pain and stiffness
- Pain predominates early in the course of the disease:
  - Night pain often interrupts sleep.
  - Debilitating pain: achy at rest, sharper with movement, and poorly localized
  - Muscle spasm/pain in the neck, shoulder, acromioclavicular joint, and posterior thorax due to scapular overcompensation
- Stiffness predominates as pain begins to wane in later stages of disease:
  - Difficulties with activities of daily living (ADLs)

- Inability to reach overhead or into back pocket
- Weakness
- Preceding injury, illness, or immobilization (secondary AC)

## ***PHYSICAL EXAM***

- Limited active and passive shoulder range of motion (ROM) in >1 plane of motion: Document ROM for forward flexion, abduction, and external and internal rotation at each visit.
- Diffuse shoulder tenderness with deep palpation
- Loss of natural arm swing with gait
- Normal strength (weakness may be present if pain inhibits effort, but objective strength testing typically reveals 5/5 strength in all planes)
- Special tests (Neer, Hawkins, etc.) are not diagnostic.
- No neurovascular deficits.

## ***DIFFERENTIAL DIAGNOSIS***

- Rotator cuff strain/tear/impingement syndrome
- GH or acromioclavicular joint osteoarthritis (OA)
- Cervical strain/radiculopathy/OA
- Myofascial pain syndrome
- Calcific tendonitis
- Fracture, dislocation
- Bony neoplasm/metastases

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

No lab is diagnostic for primary (idiopathic) AC. Labs may help rule out underlying systemic diseases associated with secondary AC: Hbg A1C, TSH, and ESR.

- Plain radiograph (anteroposterior [AP], axillary, supraspinatus outlet views) to rule out OA, calcific tendinitis, avascular necrosis, osteomyelitis, fracture, dislocation, and tumor
- Radiographs are typically normal but may demonstrate disuse osteopenia of the proximal humerus in late AC.

- In secondary AC, MRI demonstrates characteristic thickening of the axillary pouch and helps to rule out other shoulder disorders.

## *Follow-up Tests & Special Considerations*

- Serial exams in patients who present with nonspecific shoulder pain and normal radiographs. At follow-up visits, the diagnosis of AC is supported if progressive motion restriction is identified in >1 plane of motion.
- Early in stage 1, pain is the predominant feature and restriction of motion may be difficult to identify. At 8-week follow-up, the patient may not complain of stiffness, but the loss of passive ROM may be easier to identify on exam.
- Early on, AC is difficult to distinguish from subacromial bursitis. The loss of passive external rotation may be the only finding that differentiates early AC from subacromial bursitis. The only other condition that may cause insidious loss of passive external rotation is GH arthritis.

## *Diagnostic Procedures/Other*

Diagnostic subacromial anesthetic injection can help to differentiate AC from rotator cuff pathologies:

- Resolution of pain and restoration of ROM after subacromial injection suggests rotator cuff pathology or other cause of subacromial bursitis.
- Intact muscle strength with persistent active and passive ROM deficits and a firm mechanical end point are consistent with AC.

## *Test Interpretation*

If performed, arthroscopy demonstrates capsular thickening and synovial inflammation with adhesions to the humerus.

## **TREATMENT**

- Treatment is guided by the stage of AC at presentation. Conservative therapy is recommended initially (the first 4 to 6 months).
- Therapy includes combination of physical therapy, oral medications, and joint/bursal injections (1)[A].
- Structured physical therapy is superior to home exercises (2)[A].
- Patient education should include the following:
  - Expectations for a protracted recovery (months to years) characterized by resolution of pain

prior to the return of function

- Full ROM may never be recovered; however, functional limitations are uncommon.

## GENERAL MEASURES

- Control pain, preserve mobility, and allow for restful sleep.
- Codman pendulum exercises: Lean forward onto table or chair with unaffected arm bending at the waist; let the affected arm dangle. Swing the affected arm slowly by moving the torso. Try smaller and then bigger circles (clockwise and counterclockwise).
- Climbing the wall: Put the hand flat on a wall in front of you; use the fingers to climb the wall; pause 30 seconds every few inches. Repeat the exercise after turning 90 degrees to wall (abduction).
- Heat and/or ice: may temporarily improve pain and secondary spasm
- Address underlying causes of secondary AC (see Commonly Associated Conditions).
- Patient reassessment must be ongoing to reinforce expectations and determine patient's goals.

---

P.29

## MEDICATION

### First Line

- NSAIDs: widely used in the treatment of AC and thought to be most beneficial in stage 1 when pain is the predominant feature. If contraindicated, alternatives include acetaminophen or opioid analgesics. Concomitant use of NSAIDs with oral or injectable corticosteroids has no added benefit.
- Oral corticosteroids: rarely used in clinical practice, may have short-term improvement in pain and ROM (up to 6 weeks early in the course of the disease (stage 1 and early stage 2)
  - Prednisolone: 30 mg/day for 3 weeks (alternatively 10 mg × 4 weeks, then 5 mg × 2 weeks)
- Subacromial (SA) corticosteroid injection: At any stage, SA injection in conjunction with physical therapy provides short-term (16 weeks) benefit in pain and ROM.
- Intra-articular (IA) corticosteroid injection short-term (16 weeks) improvement in pain and ROM if used in conjunction with physical therapy
  - No additional benefit with ultrasound guidance (3)[A]
  - Equal efficacy to scheduled NSAID therapy (4)[A]

## *Second Line*

Tricyclic antidepressants (amitriptyline) have been used as neuromodulators. No evidence exists to support use in AC.

## *ISSUES FOR REFERRAL*

- Some cases do not respond to nonoperative treatment.
- Orthopedic referral should be considered if patient has not responded adequately to conservative treatment within 4 to 6 months.

## *ADDITIONAL THERAPIES*

- Physical therapy: additive effect when used in conjunction with other treatments (NSAIDs, injections, manipulation under anesthesia [MUA], surgical release), but there is no evidence to support the use of physical therapy alone in the treatment of AC (1,2)[A].
- Iontophoresis (electromotive drug administration) is generally not recommended in this condition.
- Although not commonly used, supervised neglect is a plausible treatment option for some patients as condition can resolve spontaneously over time.
- Capsular hydrodilatation (arthrography distention): IA injection of large-volume saline with steroid or hyaluronic acid has demonstrated some short-term improvements (12 weeks) in pain and function (5)[A].
- IA hyaluronic acid: A systematic review showed no benefit when compared to IA corticosteroid when used in conjunction with physical therapy (6)[A].
- Suprascapular nerve block: may help with short-term pain relief
- Low-power laser therapy: superior to placebo (1)[A]
- Botox: Evidence suggests no benefit.

### **ALERT**

Indications for more invasive options remain highly subjective and need to be individualized to each patient.

## *SURGERY/OTHER PROCEDURES*

- Arthroscopic capsular release: most common surgical method for treating recalcitrant AC
  - Short-term benefits: improved pain and function
  - Long-term benefits: superior to conservative therapies in recalcitrant cases (5)[A]

- MUA: Outcomes are similar to those with conservative, noninvasive therapies; contraindicated in posttraumatic/postsurgical AC (5)[A]
- Transcatheter arterial embolization: Early evidence suggests benefit (7)[B].

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Acupuncture: Insufficient evidence exists regarding the effectiveness of acupuncture for AC.
- Osteopathic manipulative technique: Evidence is equivocal.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Outpatient care

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Reinforce the natural course of the disease. Many patients are more likely to request invasive procedures (injections, capsular distension, MUA, surgery) when stiffness starts to affect ADLs.

### *Patient Monitoring*

A multidisciplinary team approach helps reinforce the natural history of AC and provides patient encouragement.

### *DIET*

No restrictions

### *PATIENT EDUCATION*

Long-term course of treatment until resolution of symptoms; stretching and ROM exercises daily during and after improvement

### *PROGNOSIS*

- Although AC is considered self-limiting, up to 50% of patients will have permanent restrictions of ROM (usually external rotation).
- Rare functional disability results

## **COMPLICATIONS**

Surgical complications and complications due to MUA can be disabling but are uncommon.

## Codes

### ICD10

- M75.00 Adhesive capsulitis of unspecified shoulder
- M75.01 Adhesive capsulitis of right shoulder
- M75.02 Adhesive capsulitis of left shoulder

## Clinical Pearls

- Early-stage AC is difficult to distinguish from rotator cuff pathology. Restriction of external ROM suggests AC.
- Diagnostic subacromial bursa injection may help differentiate early AC from impingement syndrome. In AC, ROM deficits persist and strength is intact after injection.
- Normal radiographs in the setting of progressive restriction of motion in >1 plane confirms AC.
- Initial AC treatment is conservative.
- Invasive treatment options (capsular distention, MUA, and arthroscopy) can be considered after 4 to 6 months of conservative therapy. This is necessary in only about 10% of cases.

# Adoption, International

Theodore R. Brown, DO, MPH, FAAFP

## BASICS

### DESCRIPTION

Although international adoptions have decreased in the past 10 years, they still represent a significant portion of the roughly 135,000 yearly U.S. adoptions. The demographics of those children and their homelands have shifted significantly during that time. Diverse birth countries, disease exposures, and unknown health histories of these children make them a population that requires special attention. Although specialty clinics are becoming more prevalent, many adoptive parents will look to their primary care provider for their adoption health care needs.

### EPIDEMIOLOGY

#### *Incidence*

- 7,092 children were adopted internationally in 2013.
- Approximately 5% of all U.S. adoptions are international, decreased from 17% in 2004.
- In 2013, the most common countries of origin for internationally adopted children were the following in descending order: China, Ethiopia, Ukraine, Haiti, Democratic Republic of Congo, Uganda, Russia, Nigeria, Philippines, and Bulgaria.
- In 2013, 8% of internationally adopted children were <1 year of age, 54% were ages 1 to 4 years, 29% were ages 5 to 12 years, and 9% were <sup>3</sup> 13 years. 55% were girls.

### RISK FACTORS

- Unknown birth, medical, and vaccination histories
- Possible exposure to toxins and/or inadequate nutrition in utero
- Exposures to infectious diseases are not commonly seen in the United States (1).
- Previous living conditions
  - Overcrowding
  - Institutionalization (orphanages)

- History of neglect, deprivation, or abuse
- For adoptive family, risks associated with required foreign travel (2)

## ***GENERAL PREVENTION***

- Required to be examined by a U.S. State Department physician in their native country before immigration to the United States; limited examination targeted at identifying diseases that would exclude qualifying for a visa
- Should be examined by a U.S. physician within 2 weeks of arrival or sooner if indicated (2)
- A follow-up visit 4 to 6 weeks after their postadoption appointment is recommended.
- All internationally adopted children should be screened for hearing, vision, growth, and developmental delays (3).
- Travel medicine visit for all family members traveling to adopted child's country (2)
- A preadoption visit between the adoptive family and physician can be helpful in clarifying medical diagnoses, reviewing available medical records, as well as photos and/or video that can help to confirm/refute specific diagnoses (1).

## ***COMMONLY ASSOCIATED CONDITIONS***

- 60% of international adoptees have a mild to moderate medical or developmental issue (4)
  - 20% have no issue; 20% have a severe problem.
- Infectious diseases, including the following:
  - Hepatitis A/B/C
  - Intestinal parasites
  - Tuberculosis (TB), primarily latent
  - Syphilis, including inadequately treated
  - HIV
  - *Helicobacter pylori*
- Emotional or behavioral problems
- Developmental delay
- Fetal alcohol syndrome
- Feeding difficulties, malnutrition, rickets
- Anemia

- Congenital conditions (e.g., cleft lip/palate, orthopedic deformities)
- Prematurity or low birth weight
- Inadequate immunizations
- Lead poisoning
- Sensorineural and conductive hearing loss
- Strabismus, blindness

## DIAGNOSIS

### HISTORY

- Immunization records and titers (records that are “too perfect” should be reviewed carefully)
  - Some vaccinations are (e.g., *Haemophilus influenzae* type B [Hib], pneumococcal, varicella) not routine in other countries.
- Birth/prenatal history, including exposures
- Known family history of birth parents
- Prenatal and perinatal disease or toxin exposures
- Documented history of emotional or nutritional deprivation, or physical or sexual abuse
- Duration of time, if any, spent in orphanage
- Growth charts when available: The earliest sign of malnutrition is failure to gain weight; followed by slowed linear growth; and finally, lagging head circumference.
- Development, behavior, attachment, parent stress, and parent-child interactions should also be routinely monitored.

### PHYSICAL EXAM

- Comprehensive unclothed physical exam, paced to child's comfort; particular attention to
  - Growth parameters
  - General appearance; presence of features suggestive of genetic disorder, syndromes, or congenital defects
  - Skin, for infection or signs of prior abuse (4)[C]

Genitalia, for signs of abuse or ritual cutting

- Neurologic findings
- May be child's first comprehensive exam; remain sensitive to child's cues and consider translator for older children.
- Evaluate for signs of dental decay, and refer for prompt treatment.
- Developmental assessment, especially for those with unknown date of birth (1)[C]

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Developmental screening: validated developmental screening tools at each visit to screen for potential developmental delay and to assess improvement, decline, and need for additional services
- Age-appropriate hearing and vision screening

### ***Initial Tests (lab, imaging)***

- Obtain: (1,5)[C],(2,6)[A]
  - Hepatitis A (Hep A IgM, Hep A IgG)
  - Hepatitis B (HBsAg, HBsAb, HBcAb)
  - Hepatitis C (enzyme immunoassay [EIA])
  - HIV 1 and 2 antibody testing/ELISA
  - Syphilis: nontreponemal (RPR, VDRL, or ART) and treponemal (MHA-TP, FTA-ABS, or TPPA)
  - Tuberculin skin test (TST) in all ages or interferongamma release assay ages <sup>3</sup> 5 years
  - Three stool specimens for ova and parasites, specific request for *Giardia intestinalis* and *Cryptosporidium* species testing of one sample
  - CBC with indices and differential
  - Blood lead concentration for ages <sup>2</sup>6 years
  - Thyroid-stimulating hormone (TSH)
  - Urinalysis
  - Hemoglobinopathy/blood disorder screen: sickle cell, thalassemia, glucose-6-phosphate dehydrogenase (G6PD) deficiency
- Consider based on clinical presentation:
  - Serologic testing for antibody titers depending on the availability/reliability of immunization

records (see ÒMEDICATIONÓ) (7)[C]

- Stool cultures for bacterial pathogens (for children with diarrhea) (1)[C]
- *H. pylori* testing (for children with dyspepsia, abdominal pain, or anemia) (5)[C]
- Ca<sup>++</sup>, PO<sub>4</sub>, alkaline phosphate, and 25 vitamin D level (if signs of rickets) (1)[C]
- > 12 months of age: for Chagas disease via *Trypanosoma cruzi*, serologic testing in adoptees from endemic countries (Mexico, Central and South America)
- >24 months of age: for lymphatic filariasis in those with eosinophilia if from endemic countries (sub-Saharan Africa, Egypt, Southern Asia, Western Pacific Islands, the NE coast of Brazil, Guyana, Haiti, and the Dominican Republic) (6)[A]

## Follow-Up Tests & Special Considerations

### ALERT

If initially negative, repeat of HIV, Hep B, Hep C, and TB testing are recommended at 6 months; negative tests may represent a “window” period or be falsely negative due to malnutrition in the case of TST (5)[C].

- HIV: if antibody positive in children <18 months, confirm with DNA PCR (may represent maternal antibody) (2)[A].
- Hep C: confirm positive tests with recombinant immunoblot assay (RIBA) and/or HCV RNA PCR; an initial positive in children <18 months may be due to maternal antibody, repeat after 18 months of age.
- Positive TST (TB) must NOT be attributed to bacille Calmette-Gužrin (BCG) vaccine and must be investigated; if not active disease, treat latent TB (5)[C].
- GI tract signs or symptoms occurring years after immigration: test for intestinal parasites.
- Eosinophilia >450 cells/mm<sup>3</sup> with negative stool ova and parasites: serologic testing for *Schistosoma*; add *Strongyloides* for adoptees from sub-Saharan African, Latin American, and Southeast Asian countries (1)[C].
- Developmental screening: repeat at each visit and follow progress; 50-90% of internationally adopted children are delayed on adoption; however, most have normal cognition at long-term follow-up (3)[C].
- Social history screening: Behavioral concerns may first present during adolescence, even for children adopted in infancy.
- Serial evaluations to age 12 months for children with history of treated congenital syphilis: ophthalmologic, audiologic, neurologic, and developmental (5)[C]

## TREATMENT

### GENERAL MEASURES

- Regular diet for children who arrive malnourished
- Monitor linear growth.
- If developmental delay is diagnosed, consider early services (e.g., early intervention) or referral to developmental specialist.
- Recommend local support groups for parents.
- Attention to parental interactions: Postadoption depression may occur.

### MEDICATION

- Immunizations/Catch-up per CDC schedule (<http://www.cdc.gov/vaccines/schedules/>)
  - No further Hep B vaccine needed if: HBsAg positive; HBsAb and HBcAb positive; or HBsAb positive and HB vaccine given appropriately
  - MMR should be used for vaccination for mumps and rubella, even in presence of measles antibodies (7)[C].
- Multiple approaches to children vaccinated outside the United States are acceptable (6)[A]:
  - Repeating questionable vaccinations negates the need to obtain serologic tests.
  - To minimize/avoid vaccine administration, check antibody titers.
- The following antibody titers can be measured:
  - Infants 6 to 12 months of age: polio, diphtheria, tetanus (latter two can serve as marker for DPT)
  - Children > 12 months: Hep A, measles, mumps, rubella, varicella (7)[C]
- Adoptive parents, caretakers, and household members should be up to date on Tdap, Hep A, Hep B, and measles (2)[A],(4)[C].

### ISSUES FOR REFERRAL

- Referrals are often necessary for diagnostic and treatment expertise; however, they should be minimized and planned carefully to ensure adjustment to the new home (1)[C].

- Elective surgical procedures should likewise be deferred until the child has grown accustomed to his or her new home (3)[C].
- Individual or family counseling considered for all adoptive families for adjustment support
- Internationally adopted children may exhibit self-stimulating behaviors (e.g., rocking, head banging); may be related to prior sensory deprivation. These behaviors typically decrease with time, and no treatment is necessary if otherwise developing normally. If in doubt, refer to developmental pediatrics or occupational therapy.
  - If a child continues to have disruptive behaviors, or would rather self-soothe than seek nurturing human interaction, consider a thorough developmental evaluation.
  - Persistent behavioral issues in the parent-child interactions should be evaluated by a pediatric psychologist or psychiatrist (3)[C].
- Vision (strabismus in 10-25% of previously institutionalized adoptees): Refer to pediatric ophthalmology.
- Hearing (higher rates of conductive and sensorineural hearing loss): Refer to audiology and/or ENT for concerns, questionable screening results, or if slow to acquire language skills (3)[C].
- Pediatric dental evaluation by 12 months of age; sooner if signs of dental pathology are present (1)[C].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Regular well-child visits, particularly within first months of entry into the United States
- Close monitoring of developmental milestones, behavior, and individual attachment

#### *DIET*

- Regular diet
- Up to 68% fall >2 standard deviations below the mean for one or more growth parameters; most begin to follow a curve <2 deviations from the mean within 9 to 12 months (3).

### *PATIENT EDUCATION*

- Eating: Allow access to as much healthy food as the child wants so the child can learn self-regulatory behaviors of eating that may not have been learned in an institution (hunger,

satiety) and can build trust with the parent(s) who feed him or her.

- Toileting: Some children may not be trained yet, others who were may regress and have accidents in their new home. Time, positive reinforcement, and avoiding punishment will resolve this issue as the child becomes comfortable with the new surroundings.
- Sleeping: Children must learn to trust their new home and parents, and thus, this is not a time for aggressive sleep rules. Parents should be present, physically and emotionally, just enough to let the child know that he or she is safe; establishing and then gently reinforcing a bedtime ritual on arrival.
- Language: Adoptive family should learn key phrases in the child's native language prior to adoption. A translator should be available for school-aged children for the first few weeks; avoid the perception on the child's part that a translator's presence signifies potential return to his or her country.
- Adopted children may experience grieving of lost family, relationships, and culture, which is common, expected, and healthy behavior; encourage parents to acknowledge and work through this loss with their children, considering formal counseling, if needed (3).
- Children and families should be encouraged to learn about the culture of the birth country and the ethnic group of origin, including forming relationships with others of the same racial or ethnic group (4).

## *PROGNOSIS*

- Degree of recovery of developmental delays is likely dependent on duration of time spent in an institution
  - Likelihood of long-term developmental, behavioral, or academic problems increases with adoption age.
  - Rate of recovery appears to exceed rate of normal development over a period of years and continues indefinitely (2).
- Some children may regress in previously acquired skills (1).
- When the child reaches adolescence, a desire to search for his or her biologic family is common (4).
- Adoption medicine is an evolving specialty, with an ever-increasing number of resources available, including the American Academy of Pediatrics' Council on Foster Care, Adoption, & Kinship Care (<http://www2.aap.org/sections/adoption/index.html>).

## ICD10

- Z02.82 Encounter for adoption services
- Z62.821 Parent-adopted child conflict

## Clinical Pearls

- Initial labs: Hep B, Hep A, Hep C, HIV 1 and 2, syphilis, CBC, TSH, lead, G6PD deficiency, hemoglobin electrophoresis; PPD/TST (or IGRA ages <sup>3</sup>5 years), ova and parasites (three stool specimens, including single specimen for *Giardia* and *Cryptosporidium* antigens), urinalysis
- If initially negative, repeat of HIV, Hep B, Hep C, and TST testing are recommended at 6 months; negative tests may represent a "window" period or be falsely negative due to malnutrition in the case of TST.
- Immunizations per CDC schedule with catch-up (<http://www.cdc.gov/vaccines/schedules/>), as needed; ensure that adoptive family and caretakers are current on Tdap, Hep A, Hep B, measles.
- Internationally adopted children may exhibit self-stimulating behaviors (e.g., rocking, head banging), will typically decrease with time, and do not require treatment if otherwise developing normally; refer to developmental pediatrics or occupational therapy if there are concerns.
- Adoption medicine is an evolving specialty, with an ever-increasing number of resources available, including the American Academy of Pediatrics' Council on Foster Care, Adoption, & Kinship Care (<http://www2.aap.org/sections/adoption/index.html>).

# Alcohol Abuse and Dependence

Gennine M. Zinner, RNCS, ANP

## BASICS

### DESCRIPTION

- Any pattern of alcohol use causing significant physical, mental, or social dysfunction; key features are tolerance, withdrawal, and persistent use despite problems.
- Alcohol abuse: maladaptive pattern of alcohol use manifested by <sup>3</sup> 1 of:
  - Failure to fulfill obligations at work, school, or home
  - Recurrent use in hazardous situations
  - Recurrent alcohol-related legal problems
  - Continued use despite related social or interpersonal problems
- Alcohol dependence: maladaptive pattern of use manifested by <sup>3</sup> 3 of the following:
  - Tolerance
  - Withdrawal
  - Using more than intended
  - Persistent desire or attempts to cut down/stop
  - Significant amount of time obtaining, using, or recovering from alcohol
  - Social, occupational, or recreational activities sacrificed for alcohol use
  - Continued use despite physical or psychological problems
- National Institute on Alcohol Abuse and Alcoholism criteria for *at-risk* drinking: men: > 14 drinks a week or >4 per occasion; women: >7 drinks a week or >3 per occasion
- System(s) affected: nervous, gastrointestinal (GI)
- Synonym(s): alcoholism, alcohol abuse, alcohol dependence

### Geriatric Considerations

- Common and underdiagnosed in elderly; less likely to report problem; may exacerbate normal

age-related cognitive deficits and disabilities

- Multiple drug interactions
- Signs and symptoms may be different or attributed to chronic medical problem or dementia.
- Common assessment tools may be inappropriate.

### *Pediatric Considerations*

- Children of alcoholics are at increased risk.
- In 2004, 28% of persons 12 to 20 years reported use in past month, one in five binge drink; binge drinkers are seven times more likely to report illicit drug use.
- Negative effect on maturation and development
- Early drinkers are four times more likely to develop a problem than those who begin >21 years.
- Depression, suicidal or disorderly behavior, family disruption, violence or destruction of property, poor school or work performance, sexual promiscuity, social immaturity, lack of interests, isolation, moodiness

### *Pregnancy Considerations*

- Alcohol is teratogenic, especially during the 1st trimester; women should abstain during conception and throughout pregnancy.
- 10-50% of children born to women who are heavy drinkers will have fetal alcohol syndrome.
- Women experience harmful effects at lower levels and are less likely to report problems.

## **EPIDEMIOLOGY**

- Predominant age: 18 to 25 years, but all ages affected
- Predominant sex: male > female (3:1)

### *Prevalence*

- Lifetime prevalence: 13.6%
- 20% in primary care setting
- 48.2% of 21-year-olds in the United States reported binge drinking in 2004.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Multifactorial: genetic, environment, psychosocial

- Alcohol is a CNS depressant, facilitating  $\gamma$ -aminobutyric acid (GABA) inhibition and blocking N-methyl-D-aspartate receptors.

## *Genetics*

50-60% of risk is genetic.

## ***RISK FACTORS***

- Family history
- Depression (40% with comorbid alcohol abuse)
- Anxiety
- Other substance abuse
- Tobacco
- Male gender
- Low socioeconomic status
- Unemployment
- Peer/social approval
- Family dysfunction or childhood trauma
- Posttraumatic stress disorder
- Antisocial personality disorder
- Bipolar disorder
- Eating disorders
- Criminal involvement

## ***GENERAL PREVENTION***

Counsel with family history and risk factors

## ***COMMONLY ASSOCIATED CONDITIONS***

- Cardiomyopathy, atrial fibrillation
- Hypertension
- Peptic ulcer disease/gastritis
- Cirrhosis, fatty liver, cholelithiasis

- Hepatitis
- Diabetes mellitus
- Pancreatitis
- Malnutrition
- Upper GI malignancies
- Peripheral neuropathy, seizures
- Abuse and violence
- Trauma (falls, motor vehicle accidents [MVAs])
- Severe psychiatric disorders (depression, bipolar, schizophrenia): >50% of patients with these disorders have a comorbid substance abuse problem.

## DIAGNOSIS

### HISTORY

- Behavioral issues
  - Anxiety, depression, insomnia
  - Psychological and social dysfunction, marital problems
  - Social isolation/withdrawal
  - Domestic violence
  - Alcohol-related legal problems
  - Repeated attempts to stop/reduce
  - Loss of interest in nondrinking activities
  - Employment problems (tardiness, absenteeism, decreased productivity, interpersonal problems, frequent job loss)
  - Blackouts
  - Complaints about alcohol-related behavior
  - Frequent trauma, MVAs, ED visits
- Physical symptoms
  - Anorexia
  - Nausea, vomiting, abdominal pain
  - Palpitations
  - Headache

- Impotence
- Menstrual irregularities
- Infertility

## *PHYSICAL EXAM*

- Physical exam may be completely normal.
- General: fever, agitation, diaphoresis
- Head/eyes/ears/nose/throat: plethoric face, rhinophyma, poor oral hygiene, oropharyngeal malignancies
- Cardiovascular: hypertension, dilated cardiomyopathy, tachycardia, arrhythmias
- Respiratory: aspiration pneumonia
- GI: stigmata of chronic liver disease, peptic ulcer disease, pancreatitis, esophageal malignancies, esophageal varices
- Genitourinary: testicular atrophy
- Musculoskeletal: poorly healed fractures, myopathy, osteopenia, osteoporosis, bone marrow suppression
- Neurologic: tremors, cognitive deficits (e.g., memory impairment), peripheral neuropathy, Wernicke-Korsakoff syndrome
- Endocrine/metabolic: hyperlipidemias, cushingoid appearance, gynecomastia
- Dermatologic: burns (e.g., cigarettes), bruises, poor hygiene, palmar erythema, spider telangiectasias, caput medusae, jaundice

## *DIFFERENTIAL DIAGNOSIS*

- Other substance use disorders
- Depression
- Dementia
- Cerebellar ataxia
- Cerebrovascular accident (CVA)
- Benign essential tremor
- Seizure disorder
- Hypoglycemia

- Diabetic ketoacidosis
- Viral hepatitis

## DIAGNOSTIC TESTS & INTERPRETATION

### Screening:

- CAGE Questionnaire: (Cut down, Annoyed, Guilty, and Eye opener): >2 "yes" answers is 74-89% sensitive, 79-95% specific for alcohol use disorder; less sensitive for white women, college students, elderly. Not an appropriate tool for less severe forms of alcohol abuse (1)[A]
- Single question for unhealthy use: "How many times in the last year have you had X or more drinks in 1 day?" (X = 5 for men, 4 for women); 81.8% sensitive, 79% specific for alcohol use disorders (2)[C]
- Alcohol Use Disorders Identification Test (AUDIT): 10 items, if >4: 70-92% sensitive, better in populations with low incidence of alcoholism (3)[A]:  
<http://www.nams.sg/addictions/Alcohol/Pages/Self-Assessment-Tool.aspx>

### Initial Tests (lab, imaging)

- CBC; liver function tests (LFTs); electrolytes; BUN/creatinine; lipid panel; thiamine; folate; hepatitis A, B, and C serology
- Amylase, lipase (if GI symptoms present)
- Serum levels increased in chronic abuse:
  - AST/ALT ratio >2.0
  - $\gamma$ -glutamyl transferase (GGT)

---

- Carbohydrate-deficient transferrin
- Elevated mean corpuscular volume (MCV)
- $\uparrow$  Prothrombin time
- Uric acid
- $\uparrow$  Triglycerides and cholesterol (total)
- Often decreased
  - Calcium, magnesium, potassium, phosphorus
  - BUN
  - Hemoglobin, hematocrit

- Platelet count
- Serum protein, albumin
- Thiamine, folate
- Blood alcohol concentration
  - > 100 mg/dL in outpatient setting
  - > 150 mg/dL without obvious signs of intoxication
  - > 300 mg/dL at any time
- CAT scan or MRI of brain: cortical atrophy, lesions in thalamic nucleus, and basal forebrain
- Abdominal ultrasound (US): ascites, periportal fibrosis, fatty infiltration, inflammation

### *Test Interpretation*

- Liver: inflammation or fatty infiltration (alcoholic hepatitis), periportal fibrosis (alcoholic cirrhosis occurs in only 10-20% of alcoholics)
- Gastric mucosa: inflammation, ulceration
- Pancreas: inflammation, liquefaction necrosis
- Heart: dilated cardiomyopathy
- Immune system: decreased granulocytes
- Endocrine organs: elevated cortisol levels, testicular atrophy, decreased female hormones
- Brain: cortical atrophy, enlarged ventricles

## **TREATMENT**

- For management of acute withdrawal, please see "Alcohol Withdrawal."
- For outpatient withdrawal treatment, see "Alcohol Withdrawal, Treatment" or <http://www.aafp.org/afp/2005/0201/p495.html>

## **GENERAL MEASURES**

- Brief interventions and counseling by clinicians have proven efficacy for problem drinking (4) [B].
- Treat comorbid problems (sleep, anxiety, etc.); but do not prescribe medications with cross tolerance to alcohol (benzodiazepine).

- Group programs and/or 12-step programs may have benefit in helping patients accept treatment.
- Research shows the benefit of referring patients with alcohol dependence to an addiction specialist or treatment program (3)[A].

## MEDICATION

### *First Line*

- Adjuncts to withdrawal regimens:
  - Naltrexone: 50 to 100 mg/day PO or 380 mg IM once every 4 weeks; opiate antagonist reduces craving and likelihood of relapse, decreases number of heavy drinking days in recalcitrant alcohol abusers (IM route may enhance compliance and thus efficacy) (3,5)[A].
  - Acamprosate (Campral): 666 mg PO TID beginning after completion of withdrawal; reduces relapse risk. If helpful, recommended to use for 1 year (6)[A].
  - Topiramate (Topamax): 25 to 300 mg/day PO or divided BID; enhances abstinence (3,5)[B] (not approved by FDA for use in alcohol dependence; off-label use)
- Supplements to all
  - Thiamine: 100 mg/day (1st dose IV prior to glucose to avoid Wernicke encephalopathy)
  - Folic acid: 1 mg/day
  - Multivitamin: daily
- Contraindications
  - Naltrexone: pregnancy, acute hepatitis, hepatic failure
  - Monitor LFTs.
- Precautions: organic pain, organic brain syndromes
- Significant possible interactions: alcohol, sedatives, hypnotics, naltrexone, and narcotics

### **ALERT**

Treat acute symptoms if in alcohol withdrawal; give thiamine 100 mg/day with 1st dose prior to glucose.

### *Second Line*

- Disulfiram: 250 to 500 mg/day PO; unproven efficacy; may provide psychological deterrent. Most effective if used with close supervision (5)[A]

- Selective serotonin reuptake inhibitors may be beneficial if comorbid depression exists (5)[A].

## *ISSUES FOR REFERRAL*

Addiction specialist, 12-step or long-term program, psychiatrist

## *INPATIENT CONSIDERATIONS*

Assess medical and psychiatric condition (CIWA >8).

### *Admission Criteria/Initial Stabilization*

- Correct electrolyte imbalances, acidosis, hypovolemia (treat if in alcohol withdrawal).
- Thiamine: 100 mg IM, followed by 100 mg PO; folic acid: 1 mg/day
- Benzodiazepines used to lower risk of alcohol withdrawal, seizures

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Outpatient detoxification: daily visits (not recommended for heavy alcohol abuse)
- Early outpatient rehabilitation: weekly visits
- Detoxification alone is not sufficient.

### *PATIENT EDUCATION*

- American Council on Alcoholism: (800) 527-5344 or <http://www.aca-usa.com/> (treatment facility locator, educational information)
- National Clearinghouse for Alcohol and Drug Information: (800) 729-6686 or <http://www.health.org/>
- Center for Substance Abuse Treatment: (800) 662-HELP or <http://www.samhsa.gov/about-us/who-we-are/offices-centers/csat>
- Alcoholics Anonymous: <http://www.aa.org/>
- Rational Recovery: <https://rational.org/index.php?id=1>
- Secular Organizations for Sobriety: <http://www.centerforinquiry.net/sos>
- <http://www.alcoholanswers.org/>: An evidence-based website for those seeking credible

information on alcohol dependence and online support forums.

## PROGNOSIS

- Chronic relapsing disease; mortality rate more than twice general population, death 10 to 15 years earlier
- Abstinence benefits survival, mental health, family, employment
- 12-step programs, cognitive behavior, and motivational therapies are often effective during 1st year following treatment.

## COMPLICATIONS

- Cirrhosis (women sooner than men)
- GI malignancies
- Neuropathy, dementia, Wernicke-Korsakoff syndrome
- CVA
- Ketoacidosis
- Infection
- Adult respiratory distress syndrome
- Depression
- Suicide
- Trauma

# Alcohol Withdrawal

Neela Bhajandas, PharmD

Matthew Hinton, PharmD

Paul N. Williams, MD, FACP

## BASICS

### DESCRIPTION

Alcohol withdrawal syndrome (AWS) is a spectrum of symptoms that results from abrupt cessation of alcohol in a dependent patient. Symptoms can begin within 5 hours of the last drink and persist for 5 to 10 days, ranging in severity.

### EPIDEMIOLOGY

Each year, 8.2 million Americans meet diagnostic criteria for alcohol dependence. Data suggest that 2-9% of patients seen in a family physician's office have alcohol dependence. It is more prevalent among men, whites, Native Americans, younger and unmarried adults, and those with lower socioeconomic status; only 24% of those with dependence are ever treated. <5% of U.S. adults will experience withdrawal, but 8% of hospitalized patients exhibit signs and symptoms of withdrawal

### ETIOLOGY AND PATHOPHYSIOLOGY

- Consumption of alcohol potentiates the effect of the inhibitory neurotransmitter  $\gamma$ -aminobutyric acid (GABA). With chronic alcohol ingestion, this repeated stimulation downregulates the inhibitory effects of GABA.
- Concurrently, alcohol ingestion inhibits the stimulatory effect of glutamate on the CNS, with chronic alcohol use upregulating excitatory NMDA glutamate receptors.
- When alcohol is abruptly stopped, the combined effect of a downregulated inhibitory neurotransmitter system (GABA-modulated) and upregulated excitatory neurotransmitter system (glutamatemodulated) results in brain hyperexcitability when no longer suppressed by alcohol; clinically seen as AWS.

### Genetics

There is some evidence for a genetic basis of alcohol dependence.

## RISK FACTORS

- High tolerance, prolonged use, high quantities
- Previous alcohol withdrawal episodes, detoxifications, alcohol withdrawal seizures, and delirium tremens (DTs)
- Serious medical problems
- Concomitant benzodiazepine (BZD) dependence

## Geriatric Considerations

Elderly dependent on alcohol are more susceptible to withdrawal, and chronic comorbid conditions place them at higher risk of complications from withdrawal.

## Pregnancy Considerations

Hospitalization or inpatient detoxification is usually required for treatment of acute alcohol withdrawal.

## GENERAL PREVENTION

- Routinely screen all adults for alcohol misuse (1)[B].
- Screen with the **CAGE** or similar questionnaire
  - Feeling the need to **C**ut down
  - **A**nnoyed by criticism about alcohol use
  - **G**uilt about drinking/behaviors while intoxicated
  - **E**ye opener to quell withdrawal symptoms
  - Useful to detect problematic alcohol use, positive screen is <sup>3</sup>2 **E**yes responses.
- 10-question AUDIT screening test is also useful to identify problem drinking.
- The **5 A's** is a screening tool used in primary care settings (Assess, Advise, Agree, Assist, Arrange).

## COMMONLY ASSOCIATED CONDITIONS

- General: poor nutrition, electrolyte abnormalities (hyponatremia, hypomagnesemia, hypophosphatemia), thiamine deficiency, and dehydration
- GI: hepatitis, cirrhosis, varices, GI bleed
- Heme: splenomegaly, thrombocytopenia, macrocytic anemia

- Cardiovascular: cardiomyopathy, hypertension, atrial fibrillation, other arrhythmias
- CNS: trauma, seizure disorder, generalized atrophy, Wernicke-Korsakoff syndrome
- Peripheral nervous system: neuropathy, myopathy
- Pulmonary: aspiration pneumonitis or pneumonia; increased risk of anaerobic infections
- Psychiatric: depression, posttraumatic stress disorder, bipolar disease, polysubstance abuse

## DIAGNOSIS

- *Diagnostic and Statistical Manual of Mental Disorders* AWS criteria are diagnosed when <sup>3</sup>2 of the following present within a few hours to several days after the cessation or reduction of heavy and prolonged alcohol ingestion (2)[C]:
  - Autonomic hyperactivity (sweating, tachycardia)
  - Increased hand tremor
  - Insomnia
  - Psychomotor agitation
  - Anxiety
  - Nausea
  - Vomiting
  - Grand mal seizures
  - Transient (visual, auditory, or tactile) hallucinations or illusions
- Criteria for DTs include <sup>3</sup>2 of the criteria for AWS and disturbances in orientation, memory, attention, awareness, visuospatial ability, or perception
- These should cause clinically significant distress or impair functioning and not be secondary to an underlying medical condition or mental disorder.
- There are three stages of AWS:
  - Stage 1 (minor withdrawal; onset 5 to 8 hours after cessation)
    - Mild anxiety, restlessness, and agitation
    - Mild nausea/GI upset and decreased appetite
    - Sleep disturbance
    - Sweating

- Mild tremulousness
- Fluctuating tachycardia and hypertension
- Stage 2 (major withdrawal; onset 24 to 72 hours after cessation)
  - Marked restlessness and agitation
  - Moderate tremulousness with constant eye movements
  - Diaphoresis
  - Nightmares
  - Nausea, vomiting, diarrhea, anorexia
  - Marked tachycardia and hypertension
  - Alcoholic hallucinosis (auditory, tactile, or visual) may have mild confusion but can be reoriented.
- Stage 3 (DTs; onset 72 to 96 hours after cessation)
  - Fever
  - Severe hypertension, tachycardia
  - Delirium
  - Drenching sweats
  - Marked tremors
  - Persistent hallucinations
- Alcohol withdrawal-associated seizures are often brief, generalized tonic-clonic seizures, and typically occur 6 to 48 hours after last drink.

## **HISTORY**

Essential historical information should be as follows:

- Duration and quantity of alcohol intake, time since last drink
- Previous episodes/symptoms of alcohol withdrawal, prior detox admissions
- Concurrent substance use
- Preexisting medical and psychiatric conditions, prior seizure activity
- Social history: living situation, social support, stressors, triggers, and so forth

## **PHYSICAL EXAM**

Should include assessment of conditions likely to complicate or that are exacerbated by AWS

- Cardiovascular: arrhythmias, heart failure, coronary artery disease
- GI: GI bleed, liver disease, pancreatitis
- Neuro: oculomotor dysfunction, gait ataxia, neuropathy
- Psych: orientation, memory (may be complicated by hepatic encephalopathy)
- General: hand tremor (6 to 8 cycles per second), infections

## ***DIFFERENTIAL DIAGNOSIS***

- Cocaine intoxication
- Opioid, marijuana, and methamphetamine withdrawal
- Anticholinergic drug toxicity
- Neuroleptic malignant syndrome
- ICU delirium
- Liver failure
- Sepsis, CNS infection, or hemorrhage
- Mania, psychosis
- Thyroid crisis (3)[C]

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Blood alcohol level, urine drug screen
- CBC; comprehensive metabolic panel
- CNS imaging if acute mental status changes

## **TREATMENT**

The goal is to prevent and treat withdrawal symptoms (e.g., seizures, DTs, cardiovascular events). This is done primarily with BZDs, which reduce the duration of symptoms and raise the seizure threshold.

- Exclude other medical and psychiatric causes.
- Provide a quiet, protective environment.

- The Clinical Institute Withdrawal Assessment for Alcohol Scale revised (CIWA-Ar) is useful for determining medication dosing and frequency of evaluation for AWS. Severity of symptoms are rated on a scale from 0 to 7, with 0 being without symptoms and 7 being the maximum score (except orientation and clouding of sensorium, scale 0 to 4)
    - Nausea and vomiting
    - Tremor
    - Paroxysmal sweats
    - Anxiety
    - Agitation
    - Tactile disturbances
    - Auditory disturbances
- 
- Visual disturbances
  - Headache or fullness in head
  - Orientation and clouding of sensorium
- The maximum CIWA-Ar score achievable is 67.
    - Scores >8 are associated with mild withdrawal that will likely resolve without medication.
    - Scores between 8 and 15 are associated with moderate withdrawal which often require management with medication.
    - Scores > 15 are considered severe withdrawal and are associated with the highest risk of seizures and development of DTs.
  - Frequent reevaluation with CIWA-Ar score is crucial.

## MEDICATION

### *First Line*

- BZD monotherapy remains the treatment of choice (4)[A]; it is associated with fewer complications compared with neuroleptics (5)[A].
- BZD should be chosen by the following considerations:
  - Agents with rapid onset control agitation more quickly (e.g., IV diazepam [Valium]).
  - Long-acting BZDs (diazepam, chlordiazepoxide [Librium]) are more effective at preventing breakthrough seizures and delirium management.

- Short-acting BZDs (lorazepam [Ativan], oxazepam [Serax]) are preferable when prolonged sedation is a concern (e.g., elderly patients or other serious concomitant medical illness) and preferable when severe hepatic insufficiency may impair metabolism (5)[A].
- BZD dosages will vary by patients. Given as symptom-triggered or fixed-schedule regimens. Symptom-triggered regimens have been found to require less BZD amounts and reduce hospitalization time (3)[A].
- Symptom-triggered regimen: Start with chlordiazepoxide 50 to 100 mg PO, repeat CIWA-Ar hourly and if score is  $\geq 8$ , give additional dose of chlordiazepoxide 50 mg PO. Continue to reevaluate with CIWA-Ar hourly until adequate sedation achieved (score chlordiazepoxide with respective doses of diazepam, lorazepam, or oxazepam) (3)[C].

## *Second Line*

- Thiamine: 100 mg daily IV or IM for at least 3 days (5)[C]
  - Note that IV glucose administered before treatment with thiamine may precipitate Wernicke encephalopathy and Korsakoff psychosis.
- $\beta$ -Blockers (e.g., atenolol [Tenormin]) and  $\alpha_2$ -agonists (e.g., clonidine [Catapres]) help to control hypertension and tachycardia and can be used with BZDs (3)[C]. Not used as monotherapy due to their inability to prevent DTs and seizures. May worsen underlying delirium
- Carbamazepine: not recommended as first-line therapy; associated with reduced incidence of seizures but more studies are needed
- If the patient exhibits significant agitation and alcoholic hallucinosis, an antipsychotic (4,6)[C] (haloperidol [Haldol]) can be used, but this requires close observation, as it lowers the seizure threshold (3)[C].
- Neuroleptic agents are not recommended as monotherapy due to their association with increased mortality, longer duration of delirium, and complications when compared with sedative agents (7)[A].

## *ADDITIONAL THERAPIES*

Peripheral neuropathy and cerebellar dysfunction merit physical therapy evaluation.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- CIWA-Ar score  $>15$ , or severe withdrawal

- Concurrent acute illness requiring in patient care
- Poor ability to follow up or no reliable social support
- Pregnancy
- Seizure disorder or history of severe alcohol-related seizures
- Suicide risk
- Concurrent BZD dependence
- Age >40 years old
- Prolonged heavy drinking >8 years
- Consumes > 1 pint of alcohol or 12 beers per day
- Random blood alcohol level > 200 mg/dL
- Elevated MCV, BUN
- Cirrhosis, liver failure

## *Discharge Criteria*

CIWA-Ar scores of <10 on three consecutive determinations

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Discharge arrangements include transfer to a treatment facility (e.g., sober house or residential program), outpatient substance abuse counseling, peer support groups (Alcoholics Anonymous), and the use of adjuvant treatment such as disulfiram (Antabuse), acamprosate (Campral), or naltrexone (ReVia, Vivitrol).
- Disulfiram: irreversibly inhibits aldehyde dehydrogenase, blocking alcohol metabolism, leading to an accumulation of acetaldehyde; therefore, it reinforces the individual's desires to stop drinking by providing a disincentive associated with increased acetaldehyde.
  - 250 to 500 mg/day PO for 1 to 2 weeks; maintenance 250 mg/day PO
  - Contraindications: concomitant use of metronidazole and ethanol-containing products, psychosis, severe myocardial disease, and coronary occlusion
- Acamprosate (666 mg PO TID): Glutamate and GABA modulator indicated to reduce cravings
  - Contraindications: renal impairment (CrCl <30 mL/min)

- Naltrexone (50 mg/day PO; 380 mg IM every 4 weeks): opiate receptor antagonist, theorized to attenuate pleasurable effects of alcohol and reduce craving. Initiate therapy after patient is opioid-free for at least 7 days.
  - Contraindications: acute hepatitis/liver failure, concomitant opioid therapy

## *Patient Monitoring*

Frequent follow-up to monitor for relapse

## **PATIENT EDUCATION**

- Alcoholics Anonymous: <http://www.aa.org/>
- SMART Recovery (Self-Management and Recovery Training): <http://www.smartrecovery.org/> (not spiritually based)
- National Institute on Alcohol Abuse and Alcoholism: <http://www.niaaa.nih.gov/guide/>
- FamilyDoctor.Org: alcoholism (Spanish resources available)

## **PROGNOSIS**

Mortality from severe withdrawal (DTs) is 1-5%.

## **COMPLICATIONS**

Occurs more frequently in individuals who have prior episodes of withdrawal or concomitant illnesses.

Substance Use Disorders

## Codes

### ICD10

- F10.239 Alcohol dependence with withdrawal, unspecified
- F10.230 Alcohol dependence with withdrawal, uncomplicated
- F10.231 Alcohol dependence with withdrawal delirium

## Clinical Pearls

- The kindling phenomenon has postulated that longterm exposure to alcohol affects neurons, resulting in increased alcohol craving and progressively worse withdrawal episodes (also known as allostasis).
- Any BZD dose should be patient-specific, sufficient to achieve and maintain a 0light

somnolence (e.g., sleeping but easily arousable) and should be tapered off carefully even after AWS resolves to prevent BZD withdrawal.

- Administer thiamine before patient receives glucose, so as not to precipitate Wernicke encephalopathy.
- There should be frequent outpatient follow-up to monitor for relapse.
- Counsel patients taking disulfiram to avoid over-the-counter products that contain alcohol (i.e., mouthwashes).
- Avoid administering diazepam and lorazepam intramuscularly because of erratic absorption.

# Alopecia

Amy M. Zack, MD, FAAFP

## BASICS

### DESCRIPTION

- Alopecia: absence of hair from areas where it normally grows
  - Anagen phase: growing hairs, 90% scalp hair follicles at any time, lasts 2 to 6 years
  - Catagen phase: regression of follicle, <1% follicles, lasts 3 weeks
  - Telogen phase: Resting phase lasts 2 to 3 months, 50 to 150 telogen hairs shed per day.
- Classified as scarring (cicatricial), nonscarring, or structural
- Scarring (cicatricial) alopecia
  - Inflammatory disorders leading to permanent hair loss and follicle destruction
  - Includes lymphocytic, neutrophilic, and mixed subtypes
- Nonscarring alopecia
  - Lack of inflammation, no destruction of follicle
  - Includes focal, patterned, and diffuse hair loss such as androgenic alopecia, alopecia areata, telogen effluvium, anagen effluvium, syphilitic hair loss
- Structural hair disorders
  - Brittle or fragile hair from abnormal hair formation or external insult

### EPIDEMIOLOGY

- Androgenic alopecia: onset in males between 20 and 25 years of age. Onset in females prior to 40 years of age, affecting as many as 70% of women >65 years of age
- Alopecia areata: onset usually prior to 30 years of age; men and women are equally affected. Well-documented genetic predisposition

### Incidence

Incidence greatest in Caucasians, followed by Asians, African Americans, and Native Americans. In females, 13% premenopausal, with as many as 70% females >65 years of age

## *Prevalence*

- Androgenic alopecia: in males, 30% Caucasian by 30 years of age, 50% by 50 years of age, and 80% by 70 years of age
- Alopecia areata: 1/1,000 with lifetime risk of 1-2%
- Scarring alopecia: rare, 3-7% of all hair disorder patients

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Scarring (cicatricial) alopecia
  - Slick smooth scalp without follicles evident
  - Inflammatory disorders leading to permanent destruction of the follicle; it is not known what causes inflammation to develop.
  - Three major subtypes based on type of inflammation: lymphocytic, neutrophilic, and mixed.
  - Primary scarring includes discoid lupus, lichen planopilaris, dissecting cellulitis of scalp, primary fibrosing, among others.
  - Secondary scarring from infection, neoplasm, radiation, surgery, and other physical trauma, including tinea capitis
- Nonscarring alopecia
  - Focal alopecia
  - Alopecia areata
    - Patchy hair loss, usually autoimmune in etiology, T-cell-mediated inflammation resulting in premature transition to catagen then telogen phases
    - May occur with hair loss in other areas of the body (alopecia totalis [entire scalp]), alopecia universalis (rapid loss of all body hair)
    - Nail disease frequently seen
    - High psychiatric comorbidity (1)
  - Alopecia syphilitica: Òmoth-eatenÓ appearance, secondary syphilis
  - Postoperative, pressure-induced alopecia: from long periods of pressure on one area of scalp
  - Temporal triangular alopecia: congenital patch of hair loss in temporal area, unilateral or

bilateral

- Traction alopecia: patchy, due to physical stressor of braids, ponytails, hair weaves
- Pattern hair loss
  - Androgenic alopecia: hair transitions from terminal to vellus hairs
  - Male pattern hair loss: androgen-mediated hair loss in specific distribution; bitemporal, vertex occurs where androgen sensitive hairs are located on scalp. This is a predominately-hereditary condition (2,3).
    - Increased androgen receptors, increased 5-alpha reductase leads to increased testosterone conversion in follicle to dihydrotestosterone (DHT). This leads to decreased follicle size and vellus hair (2,3).
    - Norwood Hamilton classification type I-VII
    - Female pattern hair loss: thinning on frontal and vertex areas (Ludwig classification, grade I-III). Females with low levels of aromatase have more testosterone available for conversion to DHT (4). This carries an unclear inheritance pattern (3).
    - Polycystic ovarian syndrome, adrenal hyperplasia, and pituitary hyperplasia all lead to androgen changes and can result in alopecia.
  - Drugs (testosterone, progesterone, danazol, adrenocorticosteroids, anabolic steroids)
- Trichotillomania: intentional pulling of hair from scalp. May present in variety of patterns
- Diffuse alopecia
  - Telogen effluvium: sudden shift of many follicles from anagen to telogen phase resulting in decreased hair density but not bald areas
    - May follow major stressors, including childbirth, injury, illness. Occurs 2 to 3 months after event.
    - Can be chronic with ongoing illness, including SLE, renal failure, IBS, HIV, thyroid disease, pituitary dysfunction.
    - Adding or changing medications (oral contraceptives, anticoagulants, anticonvulsants, SSRIs, retinoids,  $\beta$ -blockers, ACE inhibitors, colchicine, cholesterol-lowering medications, etc.)
    - Malnutrition from malabsorption, eating disorders; poor diet can contribute
  - Anagen effluvium
    - Interruption of the anagen phase without transition to telogen phase. Days to weeks

after inciting event

- Chemotherapy is most common trigger.
- Radiation, poisoning, and medications can also trigger.
- Structural hair disorders
  - Multiple inherited hair disorders including Menkes disease, monilethrix, and so forth. These result in the formation of abnormal hairs that are weakened.
  - May also result from chemical or heat damaging from hair processing treatments

## *Genetics*

- Family history of early patterned hair loss is common in androgenic alopecia, also in alopecia areata.
- Rare structural hair disorders may be inherited.

## **RISK FACTORS**

- Genetic predisposition
- Chronic illness including autoimmune disease, infections, cancer
- Physiologic stress including pregnancy
- Poor nutrition
- Medication, chemotherapy, radiation
- Hair treatments, braids, weaves

## **GENERAL PREVENTION**

Minimize risk factors where possible.

## **COMMONLY ASSOCIATED CONDITIONS**

- See Etiology and Pathophysiology.
- Vitiligo 4.1% patients with alopecia areata (AA), may be the result of similar autoimmune pathways (5).

## **DIAGNOSIS**

## **HISTORY**

- Description of hair loss problem: rate of loss, duration, location, degree of hair loss, other symptoms including pruritus, infection, hair care, and treatments
- Medications
- Medical illness including chronic disease, recent illness, surgeries, pregnancy, thyroid disorder, iron deficiency, poisonings, exposures
- Psychological stress
- Dietary history and weight changes
- Family history of hair loss or autoimmune disorders

## *PHYSICAL EXAM*

- Pattern of hair loss
  - Generalized, patterned, focal
  - Assess hair density, vellus versus terminal hairs, broken hair.
- Scalp scaling, inflammation, papules, pustules
- Presence of follicular ostia to determine class of alopecia
- Hair pull test
  - Pinch 25 to 50 hairs between thumb and forefinger and exert slow, gentle traction while sliding fingers up.
    - Normal: 1 to 2 dislodge
    - Abnormal:  $\geq 6$  hairs dislodged
    - Broken hairs (structural disorder)
    - Broken-off hair at the borders patch that are easily removable (in alopecia areata)
- Hair loss at other sites, nail disorders, skin changes
- Clinical signs of thyroid disease, lupus, or other diseases
- Clinical signs of virilization: acne, hirsutism, acanthosis nigricans, truncal obesity

## *DIFFERENTIAL DIAGNOSIS*

Search for type of alopecia and then for reversible causes.

## *DIAGNOSTIC TESTS & INTERPRETATION*

## Initial Tests (lab, imaging)

- No testing may be indicated depending on clinical appearance.
- Nonandrogenic alopecia
  - TSH, CBC, ferritin
  - Consider: LFT, BMP, zinc, VDRL, ANA, prolactin all depending on clinical history and exam
- Androgenic alopecia: especially in females
  - Consider free testosterone and dehydroepiandrosterone sulfate.

P.37

## Diagnostic Procedures/Other

- Light hair-pull test: Pull on 25 to 50 hairs; <sup>3</sup>6 hairs dislodged is consistent with shedding (effluvium, alopecia areata).
- Direct microscopic exam of the hair shaft
  - Anagen hairs: elongated, distorted bulb with root sheath attached
  - Telogen hairs: rounded bulb, no root sheath
  - Exclamation point hairs: club-shaped root with thinner proximal shaft (alopecia areata)
  - Broken and distorted hairs may be associated with multiple hair dystrophies.
- Biopsy: most important in scarring alopecia
- Ultraviolet light fluorescence and potassium hydroxide prep (to rule out tinea capitis)

## TREATMENT

### GENERAL MEASURES

- Consider potential harms and benefits to the patient prior to treatment. Many will gain an improved quality of life that is of benefit (3)[A].
- Stop any possible medication causes if possible; this will often resolve telogen effluvium (6)[C].
- Treat underlying medical causes (e.g., thyroid disorder, syphilis).
- Traction alopecia: Change hair care practices; education.
- Trichotillomania: often requires psychological intervention to induce behavior change

# MEDICATION

- **Nonscarring Androgenic alopecia:** Treatment must be continued indefinitely. Can use in combination
  - Minoxidil (Rogaine): 2% topical solution (1 mL BID) for women, 5% topical solution (1 mL BID) or foam (daily) for men. Works in 60% of cases (2,4)[A]
    - Unclear mechanism of action; appears to prolong anagen phase (2)[A]
    - Adverse effects: skin irritation, hypertrichosis of face/hands, tachycardia. Category C in pregnancy (2,4)[A]
  - Finasteride (Propecia): 1 mg/day for men and women (off label) (7,8)[A] 30-50% improvement in males, poor data in females (3)[A].
    - 5-alpha reductase inhibitor, reduces DHT in system, increases total and anagen hairs, slows transition of terminal to vellus hairs
    - Works best on vertex, least in anterior, temporal areas (2)[A]
    - Adverse effects: loss of libido, gynecomastia, depression. Caution in liver disease. Absolutely no use or contact during pregnancy, category X, reliable contraception required in female use (8)[A]
  - Spironolactone (Aldactone): 100 to 200 mg/day (off-label) (4)[C]
    - Aldosterone antagonist, antiandrogen; blocks the effect of androgens, decreasing testosterone production
    - Adverse effects: dose-dependent, hyperkalemia, menstrual irregularity, fatigue; Category D in pregnancy
  - Ketoconazole: decreases DHT levels at follicle, works best with minoxidil in female androgenic alopecia (8)[A]
  - Combination: Finasteride + minoxidil has superior efficacy to monotherapy (3)[A]. **Alopecia areata:** no FDA-approved treatment; high rate of spontaneous remission in patchy AA. Treatments all focus on symptom management rather than etiology (9)[B].
- Intralesional steroids
  - Triamcinolone: 2.5 to 5 mg/mL (4)[C]
    - First line if <50% scalp involved
    - Inject 0.1 mL into deep dermal layer at 0.5 to 1 cm intervals with 1/2 in 30-gauge needle, every 4 to 6 weeks. Maximum 20 mg/session (1)[C]

- Adverse effects: local burning, pruritus, skin atrophy
- Topical steroids: very limited evidence for efficacy
- Betamethasone: 0.1% foam shows limited hair regrowth (1)[C].
  - Adverse effects: folliculitis, high relapse rate after discontinuation
- Systemic glucocorticoids: use in extensive, multifocal AA. May induce regrowth but requires long-term monthly treatment to maintain growth (1,9)[B].
  - Adverse effects: hyperglycemia, adrenal insufficiency, osteoporosis, cataracts, obesity
  - Psychiatric: SSRIs, psychiatric care, support groups
- PUVA light therapy + prednisone: moderate effectiveness in diffuse AA (9)[B]
- Tinea capitis: see ÒTinea (Capitis, Corporis, Cruris)Ó

## ***SURGERY/OTHER PROCEDURES***

- Hair transplantation
- Wigs, hairpieces, extensions
- Surgical: graft transplantation, flap transplantation, or excision of the scarred area; used primarily in scarring alopecia
- Laser therapies to promote growth: lacks evidence (2)[A]

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Many herbal medications are available; no clear evidence at this time.
- Volumizing shampoos can help remaining hair look fuller.

## **ONGOING CARE**

### ***DIET***

If nutritional deficit noted, supplementation may be necessary.

### ***PATIENT EDUCATION***

National Alopecia Areata Foundation: [www.naaf.org](http://www.naaf.org)

### ***PROGNOSIS***

*Androgenic alopecia*: Prognosis depends on response to treatment.

- *Alopecia areata*: Often regrows within 1 year even without treatment. Recurrence common. 10% have severe, chronic form. Poor prognosis more likely with long duration, extensive hair loss, autoimmune disease, nail involvement, and young age
- *Telogen effluvium*: maximum shedding 3 months after the inciting event and recovery following correction of the cause. Usually subsides in 3 to 6 months but takes 12 to 18 months for cosmetically significant regrowth. Rarely, permanent hair loss, usually with long-term illness
- *Anagen effluvium*: Shedding begins days to a few weeks after the inciting event, with recovery following correction of the cause. Rarely, permanent hair loss
- *Traction alopecia*: Excellent prognosis with behavior modification
- *Cicatricial alopecia*: hair follicles permanently damaged; prognosis depends on type of alopecia and available treatments
- *Tinea capitis*: Excellent prognosis with treatment

### See Also

- Tinea (Capitis, Corporis, Cruris); Syphilis; Lupus Erythematosus, Systemic (SLE); Polycystic Ovarian Syndrome (PCOS); Lichen Planus; Hyperthyroidism
- Algorithm: Alopecia

### Codes

#### ICD10

- L65.9 Nonscarring hair loss, unspecified
- L64.9 Androgenic alopecia, unspecified
- L63.9 Alopecia areata, unspecified

## Clinical Pearls

- History and physical are necessary in determining type of alopecia for appropriate treatment.
- Treatment of underlying medical condition or removal of triggering medication will often resolve hair loss.
- Educating the patient about the nature of the condition and expectations is key to care.
- Alopecia can affect the psychological condition of the patient, and it may be necessary to

address this in any type of hair loss.

# Alzheimer Disease

Jill Ann Grimes, MD

## BASICS

### DESCRIPTION

- Alzheimer disease (AD) is the most common cause of dementia in the elderly.
- Degenerative neurologic disease with progressive impairment in <sup>32</sup>:
  - Memory, executive function, attention, language, or visuospatial skills
  - With significant interference in ability to function in work, home, or social interactions
- *New diagnostic criteria* released in 2011 emphasize full spectrum of disease (1)[A]:
  - Preclinical AD (*research purposes only*: biomarkers present; subtle decline evident to patient but cognitive tests in ÒnormalÓ range)
  - Mild cognitive impairment (MCI): Social, occupational, and functional skills are preserved despite significant decline in cognition.
  - Alzheimer dementia
- System(s) affected: nervous
- Synonym(s): presenile dementia; senile dementia of the Alzheimer type

### Geriatric Considerations

Asymptomatic screening is not recommended.

### EPIDEMIOLOGY

- Predominant age: >65 years
- 2/3 females, 1/3 males in United States

### Incidence

1 in 8 Americans age >65 years (13%); nearly 50% once >85

### Prevalence

>5.2 million in United States

- 200,000 younger onset (<65 years)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Unknown but involves amyloid beta accumulation initially, then synaptic dysfunction, neurodegeneration, and eventual neuronal loss
- Age, genetics, systemic disease, behaviors (smoking), and other host factors may influence the response to amyloid beta and/or the pace of progression toward the clinical manifestations of AD.

### *Genetics*

- Positive family history in 50%, but 90% of AD is sporadic:
  - APOE4 increases risk but full unclear
- Familial/autosomal dominant AD accounts for <5% AD:
  - Amyloid precursor protein (APP), presenilin-1 (PS-1), and presenilin-2 (PS-2)

## *RISK FACTORS*

- Aging, family history, APOE4, Down syndrome
- Cardiovascular and carotid artery disease
- Smoking (2- to 4-fold increase)
- Head trauma

## *GENERAL PREVENTION*

- NSAIDs, estrogen, and vitamin E do NOT delay AD; insufficient evidence for statins (2)[A].
- Intellectual challenge (puzzles) and regular physical exercise may offer preventive benefit.
- Control vascular risk factors (e.g., hypertension); lowering cholesterol may retard pathogenesis of AD.
- Ginkgo biloba may be beneficial for cognition but not activities of daily living.
- Physical activities and omega-3 fatty acids may help to prevent or delay cognitive decline.
- Ultrasound (US) may help to identify asymptomatic patients at increased risk with chronic brain hypoperfusion secondary to cardiovascular or carotid artery pathology.

## COMMONLY ASSOCIATED CONDITIONS

- Down syndrome
- Depression

## DIAGNOSIS

Degenerative neurologic disease with *progressive impairment in 3 areas*:

- Memory, executive function, attention, language, or visuospatial skills AND
- Significant interference in ability to function in work, home, or social interactions

## HISTORY

- Include family members in interview (for accuracy and for behavioral assessment).
- Progressive and disruptive memory loss
- Depression, anhedonia, or apathy
- Intellectual decline, difficulty with calculations, multiple missed appointments
- Loss of interest, social withdrawal
- Date or time confusion
- Occupational dysfunction or personality change
- Restlessness and sleep disturbances

## PHYSICAL EXAM

- Neurologic exam to rule out other causes
- Folstein Mini-Mental State Exam (MMSE): copyrighted but available (<http://www.aafp.org/afp/20010215/703.html>)
- Counting coins test: "If I gave you a nickel, quarter, dime, and penny, how much is that?"
- No focal neurologic signs
- Short-term memory loss
- Acalculia (e.g., cannot balance checkbook)
- Agnosia: inability to recognize objects
- Apraxia: inability to carry out movements
- Confabulation

- Delusions
- Impaired abstraction
- Decreased attention to hygiene
- Visuospatial distortion
- Late signs: psychotic features, mutism

## *DIFFERENTIAL DIAGNOSIS*

- Depression
- Vascular dementia, multi-infarct dementia
- Lewy body disease
- Dementia associated with Parkinson disease
- Normal pressure hydrocephalus
- Creutzfeldt-Jakob disease
- End-stage multiple sclerosis
- Brain tumor: primary or metastatic
- Subdural hematoma
- Progressive multifocal leukoencephalopathy
- Metabolic dementia (hypothyroidism)
- Drug reactions, alcoholism, other addictions
- Dementia pugilistica
- Toxicity from liver and kidney failure
- Vitamin and other nutritional deficiencies
- Vasculitis
- Neurosyphilis

## *DIAGNOSTIC TESTS & INTERPRETATION*

Neuropsychological testing: Order if clinical picture is confusing or to help determine level of independence for skills such as balancing checkbooks, driving, or managing medicines.

### *Initial Tests (lab, imaging)*

- To help rule out other causes of dementia

- CBC, ESR
- Chemistry panel
- Thyroid-stimulating hormone
- Folate and B<sub>12</sub> levels
- Venereal disease reaction level (VDRL) or rapid plasma reagin (RPR)
- HIV antibody (selected cases)
- APOE4 or biomarker testing *is not routine*.
- **Imaging:** Controversy exists; may identify moderate cortical atrophy or ventricular enlargement.
  - Consider MRI or CT scan if
    - Cognitive decline is recent and rapid; age <60 years; history of stroke; gait disturbance or focal neurologic signs
    - Cancer, urinary incontinence, bleeding disorder, or current use of anticoagulants
  - Single-photon emission computed tomography (SPECT) and positron emission tomography (PET): only if diagnostic uncertainty after CT or MRI; *insufficient evidence to use alone*
  - Medicare pays for PET to distinguish AD from frontotemporal dementia under specific requirements; *this should not be routine*.

## *Follow-Up Tests & Special Considerations*

Genetic testing for APOE4 or for familial AD types; discuss with genetic counselor

## *Test Interpretation*

- Gross: diffuse cerebral atrophy in hippocampus, amygdala, and some subcortical nuclei
- Microscopic
  - Neuritic senile plaques
  - Neurofibrillary tangles
  - Pyramidal cell loss
  - Decreased cholinergic innervation (other neurotransmitters variably decreased)
  - Degeneration of locus ceruleus and basal forebrain nuclei of Meynert; amyloid angiopathy

## TREATMENT

### GENERAL MEASURES

- Optimize treatment of associated comorbid conditions (including hearing and vision loss).
- Analyze environment for safety and security, and avoid sudden changes in environment.
- Assess spouse/caregiver burnout.
- Advance directives, living will, power of attorney

### MEDICATION

#### *First Line*

2014 meta-analysis shows cholinesterase inhibitors (ChEIs) and memantine are able to stabilize or slow decline in cognition, function, behavior, and global change (3)[A].

- Debate continues regarding the clinical significance and cost-effectiveness of AD medication.

P.39

- ChEIs
  - Equally effective; all have potential for GI side effects; monitor for bradycardia/syncope; associated with abnormal dreams
  - When used for at least 6 months, provide mild benefit in cognition, ADL, and behavior. (No deterioration for 6 months is evidence of efficacy.)
  - Shown to reduce nursing home placement by 20% after 25 months of treatment
  - Best in mild to moderate disease (MMSE 10 to 24); *may* be effective in Lewy body dementia
  - Donepezil (Aricept): start at 5 mg/day PO; may increase to 10 mg/day after 1 month
  - Tablets disintegrating tablets; generic available
  - Caution with digoxin or beta-blockers (can cause 3rd-degree heart block)
  - Aricept 23-mg tablet approved in 2010
  - Rivastigmine (Exelon): start at 1.5 mg PO BID, increase by 1.5 mg BID every 2 weeks; maintenance 6 to 12 mg/day total
  - Capsule, solution, or patch (patch greatly reduces side effects)
  - Indicated for both AD and Parkinson dementia
  - Galantamine (Razadyne): start at 4 mg BID for 4 weeks, then increase by 4 mg BID every

month with goal of 16 to 24 mg/day dose

- Tablets, solution, extended-release (ER) capsule, and transdermal formulations (ER and transdermal have daily dosing)
- *N*-methyl-D-aspartate (NMDA) receptor antagonists (for moderate to severe AD; MMSE 5 to 14)
  - Monotherapy or in combination with acetylcholinesterase inhibitors
  - Memantine (Namenda): start 5 mg/day, with titrate to target dose of 10 mg BID after 4 weeks
  - Often improves behavioral issues
  - Beneficial for cognition and physician's global impression; increases risk of somnolence, weight gain, confusion, hypertension, nervous system disorders, and falling (4)[A]
- For depression (occurs in 1/3 of patients), SSRIs preferred first line.
- Insomnia
  - Trazodone 25 to 100 mg at bedtime, zolpidem (Ambien) 5 mg at bedtime, zaleplon (Sonata) 5 to 10 mg at bedtime, ramelteon (Rozerem) 8 mg at bedtime
  - Avoid diphenhydramine in elderly due to negative cognitive effects and risk of urinary retention (males).
- Moderate anxiety/restlessness: Consider low-dose, short-acting benzodiazepines, buspirone, or SSRIs (efficacy unproven).
- Severe aggressive agitation
  - Behavioral techniques and environmental modification help more than medications for wandering, restlessness, uncooperativeness, hoarding, and irritability:
    - Consider changing environment, rewards, behavioral redirection, hearing aids, and bright light therapy.
  - Memantine (Namenda): start at 5 mg/day, with starter pack titrating to target dose of 10 mg BID after 4 weeks
  - Antipsychotics (both conventional and atypical) are associated with increased mortality and acute care hospital admissions in elderly patients with dementia.
  - Antiepileptic agents (carbamazepine valproate, lamotrigine) have been used for their mood stabilizing properties.
- Precautions

- Avoid anticholinergic drugs, such as tricyclic antidepressants and antihistamines.
- Ginkgo biloba: Avoid anticoagulants and aspirin.
- Benzodiazepines may produce paradoxical excitation or daytime drowsiness.
- Triazolam (Halcion) can produce confusion, memory loss, and psychotic behavior.
- Benzodiazepines may increase serum phenytoin concentration.
- Cimetidine may increase benzodiazepine concentration.
- Donepezil (Aricept): use with caution with anticholinergic medication, in sick sinus syndrome, or history of peptic ulcers
- Paroxetine increases donepezil levels.

## *Second Line*

Vitamin E, statins, estrogen, and NSAIDs should not be routinely recommended due to lack of evidence and safety concerns (1,2)[A].

## *ISSUES FOR REFERRAL*

- Assess driving safety (vision, spatial relations, hearing, judgment):
  - <http://www.nhtsa.gov/people/injury/olddrive/Driving%20Safely%20Aging%20Web/>
- Support groups for patient and family: Alzheimer Association: <http://www.alz.org/>

## *ADDITIONAL THERAPIES*

- Exercise to reduce restlessness
- Cognitive challenge; traditional and computerized training both effective
- Occupational, music, aroma, and pet therapy

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Huperzine A 400 mg (herbal ChEIs) may improve cognition with minimal side effects (5)[A].
- Ginkgo biloba extracts (120 mg/day) show conflicting efficacy in treatment of AD but may be beneficial.
- Coenzyme Q10 is not effective.
- Acupuncture continues to be assessed and may enhance effectiveness of drugs in treating Alzheimer disease.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Schedule regular follow-up (3 months) to assess medical complications, provide support for family, and assess need for placement.
- Serial mental status testing is potentially helpful, but bedside tests (Folstein MMSE) offer wide variability and lack of sensitivity.

### PATIENT EDUCATION

- Alzheimer Association: <http://www.alz.org/>
- Explain progressive nature of the disease and start advance directives planning as early as possible.

### PROGNOSIS

Poor: Average survival from diagnosis is 4 to 8 years (diagnosis is often delayed).

### COMPLICATIONS

- Behavioral: hostility, agitation, wandering, falls
- Metabolic: infection, dehydration, drug toxicity
- "Sundowning" (increase full-spectrum lights), depression (1/3 of patients), suicide

## Codes

### ICD10

- G30.9 Alzheimer's disease, unspecified
- G30.0 Alzheimer's disease with early onset
- G30.1 Alzheimer's disease with late onset

## Clinical Pearls

- Daily intellectual stimulation, such as puzzles, and moderate physical exercise may help prevent AD.
- Imaging studies have low yield in patients with a history typical of AD.
- Encourage families to join a chapter of the Alzheimer Association and to pursue advanced directive planning early in the course of the disease.
- Atypical antipsychotic medications increase mortality.

# Amenorrhea

Heidi L. Gaddey, MD

Stephanie W. Reiser, DO

## BASICS

### DESCRIPTION

- Primary amenorrhea
- Gonadal abnormalities
  - No menses by age 13 to 14 years with absence of secondary sexual characteristics OR
  - No menses by age 15 to 16 years with normal secondary characteristics
- Secondary amenorrhea: absence of menses for 3 months in a woman with previously normal menstruation or 6 months in a woman with a history of irregular cycles
- System(s) affected: endocrine/metabolic; reproductive

### Pregnancy Considerations

Pregnancy is by far the most common cause of secondary amenorrhea.

### EPIDEMIOLOGY

#### Prevalence

- Primary amenorrhea: <1% of female population
- Secondary amenorrhea: 3-5% of female population
- No evidence for race and ethnicity affecting prevalence

### ETIOLOGY AND PATHOPHYSIOLOGY

- Primary amenorrhea
  - Hypothalamic-pituitary abnormalities
  - Constitutional delay of puberty
    - Eating disorder

- Stress/exercise
- Central lesions (tumors, hypophysitis, granulomas)
- Pituitary dysfunction (hyperprolactinemia, abnormal secretion of follicle-stimulating hormone [FSH], luteinizing hormone [LH], or GnRH)
- Thyroid dysfunction
- Gonadal abnormalities
  - Chromosomal abnormalities (androgen insensitivity syndrome)
  - Euchromosomal gonadal agenesis or dysgenesis (Turner syndrome, Swyer syndrome, and pure gonadal dysgenesis)
  - Polycystic ovarian syndrome (PCOS)
  - Abnormal gonadotropin function
  - Autoimmune gonadal failure
  - Idiopathic gonadal failure
- Anatomic abnormalities
  - Imperforate hymen
  - Transverse vaginal septum
  - Congenital absence of the cervix
  - Müllerian agenesis
- Secondary amenorrhea
  - Pregnancy
  - Thyroid disease
  - Functional hypothalamic amenorrhea (stress, weight loss, and/or excessive exercise)
  - Hyperprolactinemia (altered metabolism, ectopic production, breastfeeding/stimulation, hypothyroidism, medications, empty sella syndrome, pituitary adenoma)
  - If pregnancy, thyroid disease, and hyperprolactinemia are ruled out, consider the following:
    - Normogonadotropic amenorrhea: hyperandrogenic anovulation (acromegaly, androgen-secreting tumors, Cushing disease, exogenous androgens, nonclassical congenital adrenal hyperplasia, PCOS); outflow tract obstruction (Asherman syndrome, cervical stenosis, fibroids, polyps)

- Hypergonadotropic hypogonadism: normal menopause; premature ovarian failure (autoimmune, chemotherapy, galactosemia, fragile X premutation and other genetic causes, 17-hydroxylase deficiency, idiopathic, mumps oophoritis, pelvic radiation)
  - Hypogonadotropic hypogonadism: eating disorders, CNS tumors, chronic illness, cranial radiation, excessive weight loss/exercise/malnutrition, hypothalamic or pituitary destruction, Sheehan syndrome
- Pathophysiology varies, depending on etiology.
  - Primary amenorrhea should be evaluated in the context of presence or absence of secondary sexual characteristics.
  - Can result from dysfunction in hypothalamic-pituitary-gonadal axis, anatomic abnormalities, or another endocrine gland disorder

## *Genetics*

May occur with Turner syndrome or testicular feminization

## *RISK FACTORS*

- Obesity
- Overtraining (prolonged, excessive exercise)
- Eating disorders
- Malnutrition
- Anovulatory disorders
- Psychosocial crisis
- Treatment with antipsychotic medications

## *GENERAL PREVENTION*

Maintenance of proper body mass index (BMI) and healthy lifestyle with respect to food and exercise

## *COMMONLY ASSOCIATED CONDITIONS*

- Premature ovarian failure may be associated with autoimmune abnormalities (autoimmune thyroiditis, type 1 diabetes).
- PCOS is associated with insulin resistance and obesity.
- Decreased exposure to estrogen may increase risk for osteopenia or osteoporosis.

## DIAGNOSIS

### HISTORY

- Review of systems including weight change, symptoms of pregnancy or menopause, virilizing changes, cyclic pelvic pain, galactorrhea, headaches, vision changes, fatigue, palpitations, polyuria/polydipsia
- Growth and pubertal development history, including age of breast development, pubertal growth spurt, and adrenarche
- History of chronic illness, trauma, surgery, medications, prior chemotherapy or radiation
- Psychiatric history
- Social history, including diet and exercise history, drug abuse, and sexual history
- Family history of delayed or absent puberty

### PHYSICAL EXAM

- General appearance
- Vital signs, height, weight, growth percentile and BMI, hypotension, bradycardia, hypothermia (anorexia nervosa)
- HEENT exam: evidence of dental erosions, trauma to palate (bulimia), visual field defect, funduscopic changes, cranial nerve findings (prolactinoma), webbed neck (Turner syndrome), thyromegaly
- Skin exam: evidence of androgen excess (acne, hirsutism), acanthosis nigricans (PCOS), fine downy hair on body (anorexia nervosa), striae
- Breast: state of development, evidence of galactorrhea (prolactinoma), shield chest (Turner syndrome)
- Pelvic exam: presence or absence of pubic hair (if sparse: androgen insensitivity or deficiency); clitoromegaly (androgen excess); distention or bulging of external vagina (imperforate hymen); thin, pale vaginal mucosa without rugae (estrogen deficiency and ovarian failure); presence of cervical mucus (evidence for estrogen production); blind vaginal pouch (Müllerian agenesis, androgen insensitivity syndrome); ovarian enlargement (tumors, PCOS, autoimmune oophoritis)

### DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- Primary amenorrhea
  - Serum prolactin (PRL) and thyroid-stimulating hormone (TSH)
  - If no secondary sexual characteristics, measure serum FSH and LH.
    - FSH/LH <5 IU/L suggests primary hypothalamic or pituitary etiology.
    - FSH >20 and LH >40 IU/L suggests gonadal failure, and karyotype analysis should be performed.
  - If secondary sexual characteristics are present, evaluate for anatomic abnormalities. If uterus is absent or abnormal, perform karyotype analysis, testosterone level, and dehydroepiandrosterone sulfate (DHEA-S).
- Secondary amenorrhea
  - Exclude pregnancy with hCG.
  - Serum TSH: Elevated in hypothyroidism, decreased in hyperthyroidism
  - Consider (low yield): serum chemistry, CBC, urinalysis to rule out underlying disease
  - PRL:
    - >100 ng/mL suggests empty sella syndrome or pituitary adenoma; perform MRI for evaluation.
    - <100 ng/mL: Evaluate for other etiologies, of which medications are most common.
- If PRL and TSH are normal, perform progestin challenge (see "Treatment").
  - If withdrawal bleed: normogonadotropic amenorrhea related to hyperandrogenic chronic anovulation, most commonly PCOS
  - If no withdrawal bleed: Follow up with estradiol priming (see "Diagnostic Procedures/Other" and "Treatment") and repeat progestin challenge:
    - If no bleed: Consider outflow tract obstruction.
    - If bleed occurs: Check FSH/LH: elevated in hypergonadotropic hypogonadism, decreased in pituitary tumors or hypogonadotropic hypogonadism
- If virilizing signs and significant acne are present, measure free testosterone, DHEA-S, and 17-OH progesterone levels. Initiate evaluation for androgen-secreting tumor if testosterone >200 ng/dL.
- Imaging is not generally indicated as a first approach.

- US may show ovarian cysts (PCOS), presence or absence of uterus, and endometrial thickness.
- An MRI of the pelvis can clarify any uterine or vaginal anomalies suggested by US or if pediatric patient is unable to tolerate transvaginal US probe.
- An MRI of the sella turcica if prolactinoma suspected (elevated PRL > 100), and consider with functional hypothalamic amenorrhea (other adenomas)

## *Follow-Up Tests & Special Considerations*

- Women <30 years with ovarian failure (see below) should have karyotype analysis and be investigated for premutations of FMR1 gene (fragile X syndrome) and for adrenal antibodies.
- If absence of uterus or foreshortened vagina, karyotype analysis should also be performed.
- Laparoscopy: diagnosis of streak ovaries (Turner syndrome) or polycystic ovaries
- Hysterosalpingogram: Rule out Asherman syndrome and other etiologies of outflow obstruction.

## *Diagnostic Procedures/Other*

- If constitutional delay is suspected, obtain bone age.
- If hypothalamic amenorrhea from functional suppression is suspected, consider dual-energy x-ray absorptiometry (DEXA) scan to assess bone loss (1).

## **TREATMENT**

### *GENERAL MEASURES*

Treatment depends on the underlying cause.

### *MEDICATION*

- Progesterone challenge and replacement: medroxyprogesterone (Provera): 10 mg/day for 10 days will result in withdrawal bleed if hypothalamic-pituitary-gonadal axis is intact although experts disagree (2).
- Estrogen replacement: Cycling with a combination oral contraceptive (containing 35 or 50 µg of estrogen) or conjugated estrogen (Premarin) 0.625 mg for 25 days with progesterone added as above for the last 10 days will result in a withdrawal bleed if the uterus and lower genital tract are normal.
- Use of hormonal therapies will not correct the underlying problem. Other drugs might be

required to treat specific conditions (e.g., bromocriptine for hyperprolactinemia).

- Use of hormonal replacement therapy is not recommended for long-term management of amenorrhea in older women.
  - May be safe for symptom management in young women
  - Give to maintain secondary sex characteristics and to prevent osteoporosis in adolescents and young women (3)[A].
- Combination estrogen/progesterone contraceptives (oral contraceptive pills [OCPs], patch, ring) replace estrogen and prevent pregnancy.
  - Have a positive effect on bone mineral density in oligo-/amenorrheic women but not in functional hypothalamic amenorrhea (4)[A]
  - Can decrease hirsutism in PCOS
- Calcium supplementation: 1,500 mg/day if cause is hypoestrogenism
- Because PCOS is related to insulin resistance, metformin (Glucophage) has been used (start at 500 mg BID) to correct metabolic abnormalities, improve ovulation, and restore normal menstrual patterns. Of note, treatment with metformin has shown an increase in clinical pregnancy rates but not in live birth rates (5)[A].
- Functional hypothalamic amenorrhea appears to improve with administration of exogenous leptin (still under investigation) (6)[C].
- Contraindications to estrogen administration
  - Pregnancy, thromboembolic disease, previous myocardial infarct or cerebrovascular accident, estrogen-dependent malignancy, severe hepatic impairment or disease
- Precautions
  - Patients with amenorrhea who desire pregnancy should not be given hormone replacement therapy but should receive treatment for infertility based on the specific cause.

## *ISSUES FOR REFERRAL*

Many causes of amenorrhea require referral to specialists in ob/gyn, endocrine, surgery, and/or psychiatry.

## *SURGERY/OTHER PROCEDURES*

- Hymenectomy for primary amenorrhea if due to imperforate hymen
- Lysis of adhesions in Asherman syndrome is often effective in restoring regular menses and fertility.

- If karyotype is XY, gonads must be removed due to increased risk of tumors.
- Patients with congenital short vagina can undergo surgery to create a functioning vagina.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

If overtraining is suspected, activity level should be reduced by 25-50%.

### *Patient Monitoring*

- Depends on the cause and treatment chosen
- If hormonal replacement is used, discontinue after 6 months to assess spontaneous resumption of menses.

### *DIET*

- Correct overweight or underweight by dietary management and behavior modification.
- If PCOS is the etiology, a weight-loss diet will help restore ovulation.

### *PATIENT EDUCATION*

- Educate on the circumstances and complications of her condition and its underlying etiology.
- Specific educational resources are helpful (e.g., prenatal classes and menopause support groups).
- Discuss the expected duration of amenorrhea (temporary or permanent), effect on fertility, and the long-term sequelae of untreated amenorrhea (e.g., osteoporosis, vaginal dryness).
- Appropriate contraceptive advice should be given because fertility returns before menses.
- Additional support may be needed if the amenorrhea is associated with a reduction in, or loss of, fertility.

### *PROGNOSIS*

Reflects the underlying cause. In functional hypothalamic amenorrhea, one study demonstrated 83% reversal rate in presence of obvious contributing factor.

### **COMPLICATIONS**

- Estrogen-deficiency symptoms (e.g., hot flashes, vaginal dryness) and osteoporosis in prolonged hypoestrogenic amenorrhea

- Increased risk of endometrial cancer in patients whose amenorrhea is secondary to anovulation with estrogen excess (obesity, PCOS)
- Premature ovarian failure may increase cardiovascular risk.

## Codes

### ICD10

- N91.2 Amenorrhea, unspecified
- N91.0 Primary amenorrhea
- N91.1 Secondary amenorrhea

### Clinical Pearls

- First evaluate whether amenorrhea is primary or secondary and exclude pregnancy. TSH and PRL are usual first blood tests.
- Progestin challenge may cause withdrawal bleed in women with intact hypothalamic-pituitary-gonadal axis.

# Anal Fissure

Anne Walsh, MMSc, PA-C, DFAAPA

Kashyap Trivedi, MD

## BASICS

### DESCRIPTION

Anal fissure (fissure in ano): longitudinal tear in the lining of the anal canal distal to the dentate line, most commonly at the posterior midline; characterized by a knifelike tearing sensation on defecation, often associated with bright red blood per rectum. This very common benign anorectal condition is often confused with hemorrhoids. May be acute (<6 weeks) or chronic (>6 weeks) in duration

### EPIDEMIOLOGY

- Affects all ages. Common in infants 6 to 24 months; not common in older children, suspect abuse, or trauma. Elderly is less common due to lower resting pressure in the anal canal.
- Sex: male = female; women are more likely to get anterior midline tears (25% vs. 8%).

### Incidence

Exact incidence is unknown. Patients often treat with home remedies and do not seek medical care.

### Prevalence

- 80% of infants, usually self-limited
- 20% of adults, most of whom do not seek medical advice

### ALERT

- Lateral fissure: Rule out infectious disease.
- Atypical fissure: Rule out Crohn disease.

### ETIOLOGY AND PATHOPHYSIOLOGY

High-resting pressure within the anal canal (usually as a result of constipation/straining) leads to ischemia of the anoderm, resulting in splitting of the anal mucosa during defecation and spasm of

the exposed internal sphincter.

## *Genetics*

None known

## **RISK FACTORS**

- Constipation (25% of patients)
- Diarrhea (6% of patients)
- Passage of hard or large-caliber stool
- High-resting of internal anal sphincter (prolonged sitting, obesity)
- Trauma (sexual abuse, childbirth, mountain biking)
- Inflammatory bowel disease (Crohn disease)
- Infection (chlamydia, syphilis, herpes, tuberculosis)

## **GENERAL PREVENTION**

All measures to prevent constipation; avoid straining and prolonged sitting on toilet.

## **COMMONLY ASSOCIATED CONDITIONS**

Constipation, irritable bowel syndrome, Crohn disease, tuberculosis, leukemia, and HIV

## **DIAGNOSIS**

### **HISTORY**

- Severe, sharp rectal pain, often with and following defecation but can be continuous; some patients will see bright red blood on the stool or when wiping.
- Occasionally, anal pruritus or perianal irritation

## **PHYSICAL EXAM**

- Gentle spreading of the buttocks with close inspection of the anal verge will reveal a smooth-edged tear in the anodermal tissue, typically posterior midline, occasionally anterior midline, rarely eccentric to midline.
- Minimal edema, erythema, or bleeding may be seen.
- Chronic fissures may demonstrate rolled edges, hypertrophic papillae at proximal end, and a

sentinel pile (tag) at distal end.

## *DIFFERENTIAL DIAGNOSIS*

- Thrombosed external hemorrhoid: swollen, painful mass at anal verge
- Perirectal abscess: tender, warm erythematous induration or fluctuance
- Perianal fistula: abnormal communication between rectum and perianal epithelium with purulent drainage
- Pruritus ani: shallow excoriations rather than true fissure

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Diagnostic Procedures/Other*

- Avoid anoscopy/sigmoidoscopy initially unless necessary for other diagnoses.
- Rarely, due to pain, some patients may require exam under anesthesia in order to confirm the diagnosis.

## **TREATMENT**

The goal of treatment is to avoid repeated tearing of the anal mucosa with resultant spasm of the internal anal sphincter by decreasing the patient's high sphincter tone and addressing its underlying cause.

## *GENERAL MEASURES*

- Wash area gently with warm water; consume high fiber diet, increase fluids, add daily fiber supplement; avoid constipation, maintain healthy weight.
- Medical therapy for chronic fissures usually initiated in a stepwise manner: nitrates, calcium channel blockers, botulinum toxin (1)[B]

## *MEDICATION*

### *First Line*

Acute fissures ~50% heal spontaneously with supportive measures:

- Stool softeners (docusate) daily
- Osmotic laxatives if needed (polyethylene glycol)
- Fiber supplements (e.g., psyllium, methylcellulose, inulin) and increased fluid intake

- Topical analgesics (2% lidocaine gel)
- Topical lubricants/emollients (Balneol cream)
- Sitz baths (sit in hot water bath for 10 to 20 minutes 2 to 3 times daily)

## *Second Line*

Chronic fissures require medical therapy (1,2)[A]:

- Chemical sphincterotomy
  - Topical nitroglycerin ointment 2% diluted to 0.2-0.4% applied QID; nitroglycerin 0.4% ointment available commercially (Rectiv): marginally but significantly better than placebo in healing (48.6% vs. 37%); late recurrence common (50%) (1)[A]; effect is to reduce resting anal pressure through the release of nitric oxide. Headache is a major side effect (20-30%).
  - Calcium channel blockers (e.g., nifedipine, diltiazem), oral or topical: no better than nitrates but with fewer side effects; effect is to relax the internal sphincter muscle, thereby reducing the resting anal pressure (3)[A].
  - Botulinum toxin 4 mL (20 units) injected into the internal sphincter muscle: no better than topical nitrates but with fewer side effects; effect is to inhibit the release of acetylcholine from nerve endings to inhibit muscle spasm (4)[B].

---

P.43

## *ISSUES FOR REFERRAL*

- Late recurrence is common (50%) particularly if the underlying issue remains untreated (constipation, irritable bowel, etc.).
- Medical therapy usually is tried for 90 to 120 days prior to colorectal surgery referral.

## *ADDITIONAL THERAPIES*

Anococcygeal support (modified toilet seat) may offer some advantage in chronic fissures to avoid surgery.

## *SURGERY/OTHER PROCEDURES*

- Surgery reserved for failure of medical therapy; involves division of the internal sphincter muscle
- Lateral internal sphincterectomy is the surgical procedure of choice (90% healing) (5)[A].
  - Risk for fecal or flatus incontinence: 45% short term, 6-8% long term

- Botulinum toxin injections also first-line treatment; less effective (60-80% healing) than surgery but fewer complications (6)[C]
  - Risk for fecal or flatus incontinence: 18% short term, no long term
  - May be repeated as needed with same efficacy; higher doses are more effective.
- Controlled pneumatic balloon dilation may be used by gastroenterologists if surgical referral is not available; should not be used first line as benefits are not well documented. Uncontrolled manual dilation is no longer recommended (5,6)[C].

## ONGOING CARE

### DIET

High fiber (>25 g/day; augment with daily fiber supplements); increase fluid intake.

### PATIENT EDUCATION

- Avoid prolonged sitting or straining during bowel movements; drink plenty of fluids; avoid constipation; lose weight if obese.
- Avoid use of triple antibiotic ointment and longterm use of steroid creams to anal area.

### PROGNOSIS

Most acute fissures heal within 6 weeks with conservative therapy. Medical therapy is less likely to be successful for chronic anal fissures; 40% failure rate.

### COMPLICATIONS

Fecal and flatus incontinence, primarily associated with surgery (5-45% postop), which may become permanent (up to 8% long term, primarily to flatus)

## Codes

### ICD10

- K60.2 Anal fissure, unspecified
- K60.0 Acute anal fissure
- K60.1 Chronic anal fissure

## Clinical Pearls

- Avoid anoscopy or sigmoidoscopy initially unless necessary for other diagnoses.
- Best chance to prevent recurrence is to treat the underlying cause (e.g., chronic constipation).
- No medical therapy approaches the cure rate of surgery for chronic fissure.

# Anemia, Aplastic

Muthalagu Ramanathan, MD

Jan Cerny, MD, PhD

## BASICS

### DESCRIPTION

- Pancytopenia due to hypocellular bone marrow without infiltrates or fibrosis. Classified as acquired (much more common) and congenital
- Acquired aplastic anemia: insidious onset; due to exogenous insult triggering an autoimmune reaction; often responsive to immunosuppression
- Congenital forms: rare, mostly present in childhood (exception is atypical presentation of Fanconi syndrome in adults; 30s for males and 40s for females)
- The occurrence of specific mutations in genes of the telomere complex in acquired aplastic anemia has blurred the distinction between the congenital and acquired forms.
- System(s) affected: heme/lymphatic/immunologic
- Synonym(s): hypoplastic anemia; panmyelophthisis; refractory anemia; aleukia hemorrhagica; toxic paralytic anemia

### ALERT

- Early intervention for aplastic anemia greatly improves the chances of treatment success.
- Hematopoietic growth factors require close monitoring in newly diagnosed patients.

### *Geriatric Considerations*

The elderly are often exposed to large numbers of drugs and therefore, may be more susceptible to acquired aplastic anemia.

### *Pediatric Considerations*

- Congenital forms of aplastic anemia require different treatment regimens than acquired forms.
- Acquired aplastic anemia is seen in children exposed to ionizing radiation or treated with

cytotoxic chemotherapeutic agents.

## *Pregnancy Considerations*

- Pregnancy is a real but rare cause of aplastic anemia. Symptoms may resolve after delivery and with termination.
- Complications in pregnancy can occur from low platelet counts and paroxysmal nocturnal hemoglobinuria-associated aplastic anemia.

## *EPIDEMIOLOGY*

- Predominant age: (1) biphasic 15 to 25 years (more common) and >60 years
- Predominant sex: male = female

## *Incidence*

- 2 to 3 new cases per million per year in Europe and North America
- The incidence is 3-fold higher in Thailand and China versus the Western world.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Idiopathic (≈70% of the cases)
- Drugs: phenylbutazone, chloramphenicol, sulfonamides, gold, cytotoxic drugs, antiepileptics (felbamate, carbamazepine, valproic acid, phenytoin)
- Viral: HIV, Epstein-Barr virus (EBV), nontypeable postinfectious hepatitis (not A, B, or C), parvovirus B19 (mostly in the immunocompromised), atypical mycobacterium
- Toxic exposure (benzene, pesticides, arsenic)
- Radiation exposure
- Immune disorders (systemic lupus erythematosus, eosinophilic fasciitis, graft vs. host disease)
- Pregnancy (rare)
- Congenital (Fanconi anemia, dyskeratosis congenita, Shwachman-Diamond syndrome, amegakaryocytic thrombocytopenia)
- The immune hypothesis: Activation of T cells with associated cytokine production leading to destruction or injury of hematopoietic stem cells. This leads to a hypocellular bone marrow without marrow fibrosis (2).
- The activation of T cells likely occurs because of both genetic and environmental factors. Exposure to specific environmental precipitants, diverse host, genetic risk factors, and

individual differences in characteristics of immune response likely account for variations in its clinical manifestations and patterns of responsiveness to treatment.

- Telomerase deficiency leads to short telomeres. This leads to impaired regenerative capacity and hence, a reduction in marrow progenitors and qualitative deficiency in the repair capacity of hematopoietic tissue.
- Reduction of natural killer cells in the bone marrow

## *Genetics*

- Telomerase mutations found in a small number of patients with acquired and congenital forms. These mutations render carriers more susceptible to environmental insults.
- Mutations in genes called TERC and TERT were found in pedigrees of adults with acquired aplastic anemia who lacked the physical abnormalities or a family history typical of inherited forms of bone marrow failure. These genes encode for the RNA component of telomerase.
- HLA-DR2 incidence in aplastic anemia is twice that in the normal population.

## *RISK FACTORS*

- Treatment with high-dose radiation or chemotherapy
- Exposure to toxic chemicals
- Use of certain medications
- Certain blood diseases, autoimmune disorders, and serious infections
- Tumors of thymus (red cell aplasia)
- Pregnancy, rarely

## *GENERAL PREVENTION*

- Avoid possible toxic industrial agents.
- Use safety measures when working with radiation.

## **DIAGNOSIS**

### **HISTORY**

- Solvent and radiation history; family, environmental, travel, and infectious disease history
- Patients are often asymptomatic but may have frequent infections, fatigue,

shortness of breath, headache, or bleeding/bruising.

## *PHYSICAL EXAM*

- Mucosal hemorrhage, petechiae
- Pallor
- Fever
- Hemorrhage, menorrhagia, occult stool blood, melena, epistaxis
- Dyspnea
- Palpitations
- Progressive weakness
- Retinal flame hemorrhages
- Systolic ejection murmur
- Weight loss
- Signs of congenital aplastic anemia
  - Short stature
  - Microcephaly
  - Nail dystrophy
  - Abnormal thumbs
  - Oral leukoplakia
  - Hyperpigmentation (café au lait spots) or hypopigmentation

## *DIFFERENTIAL DIAGNOSIS*

Includes other causes of bone marrow failure and pancytopenia

- Marrow replacement
  - Acute lymphoblastic leukemia
  - Lymphoma
  - Hairy cell leukemia (increased reticulin and infiltration of hairy cells)
  - Large granular lymphocyte leukemia
  - Fibrosis

- Megaloblastic hematopoiesis
  - Folate deficiency
  - Vitamin B<sub>12</sub> deficiency
- Paroxysmal nocturnal hemoglobinuria, hemolytic anemia (dark urine), pancytopenia, and venous thrombosis (classically hepatic veins)
- Systemic lupus erythematosus
- Prolonged starvation or anorexia nervosa (bone marrow is gelatinous with loss of fat cells and increased ground substance)
- Transient erythroblastopenia of childhood
- Drug-induced agranulocytosis that may be reversible on withdrawal of drug.
- Overwhelming infection
  - HIV with myelodysplasia
  - Viral hemophagocytic syndrome

## ***DIAGNOSTIC TESTS & INTERPRETATION***

Screening tests to exclude other etiologies

- CBC and absolute reticulocyte count
- Blood smear exam
- Cytogenetic studies of peripheral lymphocytes if <35 years of age to exclude Fanconi anemia
- Liver function test
- Viral serology: hepatitis A, B, C; EBV; cytomegalovirus (CMV); HIV
- Vitamin B<sub>12</sub> and folate levels
- Autoantibody screening antinuclear antibody (ANA) and anti-DNA
- Flow cytometry looking for glycosylphosphati-dylinositol (GPI), negative neutrophils and RBCs for detecting paroxysmal nocturnal hemoglobinuria
- Fetal hemoglobin in children
- Red cell adenosine deaminase (pure red cell aplasia)
- Cytogenetic analysis of bone marrow

*Initial Tests (lab, imaging)*

- CBC: pancytopenia, anemia (usually normocytic), leukopenia, neutropenia, thrombocytopenia
- Decreased absolute number of reticulocytes
- Increased serum iron secondary to transfusion
- Normal total iron-binding capacity (TIBC)
- High mean corpuscular volume (MCV) > 104
- CD 34+ cells decreased in blood and marrow
- Urinalysis: hematuria
- Abnormal liver function tests (hepatitis)
- Increased fetal hemoglobin (Fanconi)
- Increased chromosomal breaks under specialized conditions (Fanconi)
- Molecular determination of abnormal gene (Fanconi)

P.45

- CT of thymus region if thymoma-associated RBC aplasia suspected
- Radiographs of radius and thumbs (if congenital anemia suspected)
- Renal ultrasound (to rule out congenital anemia or malignant hematologic disorder)
- Chest x-ray to exclude infections such as mycobacterial infection

### *Diagnostic Procedures/Other*

Bone marrow aspiration and biopsy

### *Test Interpretation*

- Normochromic RBC
- Bone marrow
  - Decreased cellularity (<10%): no fibrosis, no malignant cells seen
  - Decreased megakaryocytes
  - Decreased myeloid precursors
  - Decreased erythroid precursors
  - Prominent fat spaces and marrow stroma, polyclonal plasma cells

## TREATMENT

Early treatment increases the chance of success. Two major options: immunosuppressive therapy (1) and hematopoietic stem cell transplantation. Treatment decisions are based on age of the patient, severity of disease, and availability of a human leukocyte antigen (HLA)-matched sibling donor for transplantation.

### GENERAL MEASURES

- Supportive measures: RBC and platelet transfusions. Use only irradiated leuko-reduced or CMV-negative blood initially if patient is a candidate for hematopoietic stem cell transplantation.
- Antibiotics, antifungals, antivirals when appropriate, especially if ANC  $<200$  cells/ $\mu$ L
- Oxygen therapy for severe anemia
- Good oral hygiene
- Control menorrhagia with norethisterone or oral contraceptive pills.
- Avoid/discontinue causative agents/isolation if necessary.
- HLA testing on all patients and their immediate families
- Transfusion support (judiciously prescribed RBCs for severe anemia; platelets for severe thrombocytopenia)
  - Transfuse when
- Hb  $<8$  g/dL or if Hb  $<9$  g/dL and symptomatic  $\pm$  CHF (congestive heart failure)
- Platelet count is  $<10 \times 10^9$  or if  $<20 \times 10^9$  with fever

### MEDICATION

#### First Line

- Corticosteroids (methylprednisolone) are often given with immunosuppressive regimens.
- Immunosuppressive therapy (3)
  - A combination of antithymocyte globulin (ATG) plus cyclosporine. ATG eliminates lymphocytes, and cyclosporine blocks T-cell function.
- ATG
  - Horse serum containing polyclonal antibodies against human T cells

- First choice treatment for patients >40 years of age and for younger patients without a compatible donor. Consider in patients 30 to 40 years of age.
- May be used as a single agent but has better response in combination with cyclosporine
- Cyclosporine following initial ATG therapy for minimum of 6 months (4)
  - Monitor through blood levels. Normal values for assays vary.
  - Granulocyte-colony stimulating factor (G-CSF)
    - May be used in conjunction with ATG and cyclosporine
    - Shows faster neutrophil recovery but survival is not improved.
    - Treatment is costly and is disputed in two randomized trials.
  - Note: Relapses may occur after the initial response to the immunosuppressive therapy if cyclosporine is discontinued too early. Restarting cyclosporine can lead to a response in up to 25% of patients.
- Stem cell transplant: matched sibling allogeneic stem cell transplant for age <20 years and absolute neutrophil count (ANC) <500 or age 20 to 40 years and ANC <200

## *Second Line*

- Rabbit ATG + cyclosporine
- Campath
- Androgen in a subset of patients who have anemia as a predominant feature
- Matched unrelated donor stem cell transplant
- Eltrombopag (5)
- Clinical trials: thrombopoietin (TPO) receptor agonists (6):  
<http://patientrecruitment.nhlbi.nih.gov/AplasticAnemia.aspx>

## *SURGERY/OTHER PROCEDURES*

- First-line hematopoietic stem cell transplantation is recommended for patients with an HLA-identical donor and severe aplastic anemia when age <20 years and ANC <500 or age 20 to 40 years and ANC <200. Consider in patients 40 to 50 years of age in good general medical condition.
- Patients > 40 years of age have higher rates of graft versus host disease and graft rejection.
- Unrelated donor transplants should be considered for patients age <40 years without HLA-matched sibling donor who failed first-line immunosuppressive therapy.

- Thymectomy for thymoma

## *INPATIENT CONSIDERATIONS*

### *Nursing*

If neutropenic, use antiseptic mouthwash such as chlorhexidine.

## **ONGOING CARE**

### *DIET*

If neutropenic, avoid foods that can expose patient to bacteria, such as uncooked foods.

## *PATIENT EDUCATION*

- Stay away from people who are sick; avoid large crowds.
- Wash your hands often.
- Brush and floss your teeth; get regular dental care to reduce risk of infections.
- Pneumonia vaccine and annual flu shot.
- Printed patient information available from Aplastic Anemia & MDS International Foundation, Inc., 800-747-2828. Web site: <http://www.aamds.org/aplastic>

## *PROGNOSIS*

- Hematopoietic stem cell transplantation with HLA-matched sibling
  - Age < 16 years, 91% at 5 years
  - Age > 16 years, 70-80% at 5 years
- Immunosuppressive therapy using ATG and cyclosporine: overall survival of 75%; 90% among responders at 5 years

## **COMPLICATIONS**

- Infection (fungal, sepsis)
- Graft versus host disease in bone marrow transplant recipients (acute 18%; chronic 26%)
- Side effects of immunosuppressant medications
- Hemorrhage

Transfusion hemosiderosis

- Transfusion hepatitis
- Heart failure
- Development of secondary cancer: leukemia or myelodysplasia (15-19% risk at 6 to 10 years)
- Refractory pancytopenia

## Codes

## ICD10

- D61.9 Aplastic anemia, unspecified
- D61.89 Oth aplastic anemias and other bone marrow failure syndromes
- D61.01 Constitutional (pure) red blood cell aplasia

## Clinical Pearls

- Acquired aplastic anemia has an insidious onset, and is caused by an exogenous insult triggering an autoimmune reaction. This form is usually responsive to immunosuppressive therapy.
- Immunosuppressive therapy using ATG and cyclosporine: overall survival of 75%; 90% among responders at 5 years

# Anemia, Chronic Disease

Christopher Lin-Brandt, MD

Amy M. Davis, MD

## BASICS

### DESCRIPTION

- Otherwise known as anemia of chronic inflammation
- During chronic systemic infection, inflammation, or malignancy, the production of proinflammatory mediators causes inhibition of erythropoiesis as well as the imbalance in iron homeostasis (1).
- Anemia of chronic disease (ACD) is characterized as a normocytic, normochromic, hypoproliferative anemia and classically has low serum iron levels, elevated ferritin levels, and elevated total ironbinding capacity (TIBC) (1,2,3).
- Anemia is typically mild to moderate with hemoglobin rarely <8 g/dL.

### EPIDEMIOLOGY

#### Prevalence

ACD is the second most common anemia after iron deficiency anemia (IDA) due to the aging population and the high prevalence of chronic infections and inflammatory disorders in the United States (4).

### ETIOLOGY AND PATHOPHYSIOLOGY

- Production of red blood cells is decreased as a result of functional iron deficiency.
- In general, the severity of the anemia will correspond with the severity of the underlying disease (1).
- Proinflammatory cytokines such as interleukins (IL), tumor necrosis factor (TNF), bone morphogenic proteins (BMP), and interferons (IFN) create changes in iron homeostasis in several ways (1,4):
  - Dysregulating iron homeostasis
  - Diminishing proliferation as well as differentiation of red blood cell progenitor cells

- Blunting the erythropoietic response
- Increasing erythrocyte phagocytosis and apoptosis
- Iron overload and the proinflammatory cytokines IL-1, IL-6, and BMP6 increase the production of the iron-regulating hormone hepcidin in hepatocytes, macrophages, and enterocytes (1,4).
  - Hepcidin binds to ferroportin causing internalization and degradation, which prevents efflux of iron from stores in macrophages and hepatocytes (reticuloendothelial cell iron blockade) and prevents iron absorption by duodenal enterocytes.
    - This results in low serum iron levels and inhibited erythropoiesis known as iron-restricted erythropoiesis.
  - As a result, iron delivery to erythroid progenitor cells within bone marrow is reduced and erythropoiesis is diminished, causing anemia.
- Erythropoietin (EPO) production and the response to EPO by erythroid bone marrow is suppressed by proinflammatory cytokines such as IL-1, TNF- $\alpha$ , and IFN- $\gamma$  (1).
- Inflammatory cytokines may also cause erythrophagocytosis and oxidative damage, reducing RBC survival.

## *COMMONLY ASSOCIATED CONDITIONS*

- Chronic systemic diseases (2)
  - Rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), sarcoidosis, temporal arteritis, inflammatory bowel disease (IBD), systemic inflammatory response syndrome (SIRS)
- Hepatic disease or failure
- Congestive heart failure or coronary artery disease
- Chronic kidney disease (CKD)
- Acute or chronic infections
  - Viral
    - HIV, HCV
  - Bacterial
    - Abscess, subacute bacterial endocarditis, tuberculosis, osteomyelitis
  - Fungal

- Parasitic
- Malignancies
- Cytokine dysregulation (anemia of aging)
- Hypometabolic states
  - Protein malnutrition, thyroid disease, panhypopituitarism, diabetes mellitus, Addison disease

## DIAGNOSIS

### HISTORY

- ACD is often discovered incidentally on routine CBC with differential.
- ACD presents with the underlying causative infectious, inflammatory, or malignant process without any source of occult bleeding; often patients will have mild and vague anemia symptoms, such as fatigue, light-headedness, and palpitations (1).
- Those with a cardiovascular condition may experience symptoms of angina, shortness of breath, and reduced exercise capacity with even a moderate hemoglobin (Hgb) level (10 to 11 g/dL).

### PHYSICAL EXAM

Physical exam findings are associated with the underlying condition.

### DIFFERENTIAL DIAGNOSIS

- IDA
- Anemia of CKD
- Drug-induced marrow suppression or hemolysis
- Endocrine disorders
- Thalassemia
- Sideroblastic anemia
- Dilutional anemia

### DIAGNOSTIC TESTS & INTERPRETATION

*Initial Tests (lab, imaging)*

- Hgb/Hct, MCV, reticulocyte count, ferritin, B<sub>12</sub>/folate, serum iron, TIBC
- Hgb (1)
  - Typically, <13 g/dL in males or 12 g/dL in females
  - An Hgb of <8 g/dL typically suggests a concurrent secondary cause for the anemia.
- Mean corpuscular volume (MCV)
  - Usually normal (80 to 100 fL), but microcytosis may be present with concurrent iron deficiency or long-standing disease (<25% of cases)
- RBC morphology
  - Normocytic and normochromic
  - Increased protoporphyrin levels
- Serum ferritin
  - Nonspecific acute phase reactant
  - Normal or slightly elevated (30 to 200 µg/L)
  - In CKD, ferritin can reach 800 µg/L.
  - Serum ferritin levels <30 µg/L suggests coexisting iron deficiency.
- Serum iron levels
  - Low due to increased retention and decreased release from the RES
  - <50
- TIBC
  - Extremely low
  - <300
- Absolute reticulocyte count
  - Inappropriately low (reticulocyte index <20,000-25,000/µL) due to reduced erythropoiesis
- Serum B<sub>12</sub> and folate
  - Diminished due decreased absorption or lacking in diet

**IDA**

**ACD**

**IDA+ACD**

Iron	Low	Low	Low
Reticulocyte count	Low	Low	Low
Transferrin, TIBC	High	Low	Normal/high
Transferrin saturation	Low	Normal	Low
Ferritin	Low	Normal/high	Normal
sTfR index	High	Low	High
Hepcidin	Low	High	Normal
Inflammatory markers	Normal	High	High

### *Diagnostic Procedures/Other*

- Traditional gold standard: bone marrow biopsy with Prussian blue stainable iron combined with anemia, hypoferrremia, and low TSAT (1,2,4)
  - Staining is qualitative and may not be accurate.
- Reticulocyte Hgb concentration <28 pg (3)
- Soluble transferrin receptor (sTfR) and the sTfR/log ferritin index (5)[A]
  - Ratio reflects erythropoiesis within bone marrow and differentiates among ACD, IDA, and ACD + IDA.
    - However, sTfR alone may have greater clinical value than the sTfR index because transferrin is not affected by chronic disease/inflammation, unlike ferritin.
- Functional test: supplemental iron increase H/H in iron deficiency anemia and little effect on anemia of chronic disease
- Although a known cause of anemia may be present, iron, B<sub>12</sub>, and folate deficiencies should be ruled out.

## **TREATMENT**

### *GENERAL MEASURES*

- Primary management should focus on the underlying cause of ACD (1,2,4).

- Treatment of the primary disease will generally restore Hgb back to baseline.
  - In cases where primary treatment is not possible (e.g. terminal cancer, end-stage renal disease), additional treatment can be considered.
    - The two main forms of treatment are erythropoietin stimulating agents (ESAs) and transfusions.
    - ACD is frequently responsive to ESAs (epoetin-*α*, darbepoetin) in pharmacologic doses (6).
    - Replete iron to maximize ESA effectiveness.
    - Transfusion should only be initiated in severe anemia or acute symptoms.
  - Currently, no target Hgb exists but treatment to Hgb > 13 g/dL is associated with adverse outcomes (1).
  - Coexisting B<sub>12</sub>, or folate deficiency should be considered and corrected in severe cases of anemia (7)[B].
    - Reduced dietary intake of nutrients is common among patients who are chronically ill.
    - Patients who regularly undergo hemodialysis will often lose these during treatment.
- 

## MEDICATION

- Erythropoietin-stimulating agents (ESAs)
  - Specifically approved for CKD, but there is evidence that they may also have applications in RA, IBD, HIV, and cancer
  - Indication for ESA therapy is an Hgb <10 g/dL (6)[C].
  - ESAs do not improve symptoms or outcomes in mild anemia of CHF (8)[A].
  - Do not use in certain cancers: breast, cervical, head and neck, lymphoid, and nonsmall cell lung cancers. Do not administer to patients with active malignancy not receiving curative therapy.
- Epoetin-*α* (1,6,9)
  - Indications
    - Hgb <10 g/dL
    - Fatigue or exertional intolerance
    - CKD (eGFR <60 mL/min)

Anemia due to IBD, RA, hepatitis C

- Chemotherapy in patients with specific malignancies (palliative therapy)
- Dosing and schedule
  - Lowest effective dose to maintain a Hgb level generally between 10 and 12 g/dL (1,6,9)
  - CKD associated: Start 50 to 100 U/kg SC/IV 3 times per week.
- Patients with cancer who are undergoing chemotherapy: 150 U/kg SQ 3 times per week or 40,000 units once a week.
- Adverse affects:
  - Increased risk of cardiovascular complications, mortality, and thromboembolism
  - Pure red cell aplasia (decrease in Hgb, low reticulocyte count, normal WBC and platelets)
  - Risk of tumor progression in certain cancer patients
- Darbepoetin- $\alpha$ 
  - Long-acting, molecularly modified EPO preparation with a half-life 3 to 4 times longer than recombinant human EPO, reducing the frequency of injections to weekly or biweekly
  - Dosing and schedule
    - Administer SC/IV q1-2wk; hold if Hgb > 12 g/dL; IV route is preferred in hemodialysis patients.
  - Adverse affects
    - Similar to EPO
- Epoetin- $\alpha$  or darbepoetin- $\alpha$  dose adjustments
  - Follow FDA-approved labeling.
  - Treatment beyond 6 to 8 weeks without appropriate rise of Hgb (>1 to 2 g/dL) is not recommended.

## ***ADDITIONAL THERAPIES***

- Iron (6)
  - Indications
    - Coexisting iron deficiency
    - Resistance to EPO

- Forms
  - Oral: ferrous sulfate. Poorly tolerated (GI side effects), incomplete absorption (due to hepcidin)
  - Intravenous: ferric gluconate, iron sucrose, iron dextran (potential allergic and anaphylactoid reactions), ferumoxytol
- Adverse effects
  - May stimulate hepcidin production and exacerbate iron restriction
- Benefits
  - Relatively safe
  - Inexpensive
  - May decrease ESA requirements (DRIVE study)
- Transfusions
  - 1 to 2 U packed red blood cells (1)
  - Indications
    - Life-threatening/severe anemia: A restrictive threshold of Hgb 7 to 8 g/dL to guide transfusion in asymptomatic patients should be used (10)[A].
    - Patients with underlying cardiac or pulmonary disease, active ACS, elderly patients, or patients with acute bleeding or hemorrhagic shock may require transfusion at Hgb of higher threshold (>10 g/dL).
    - Symptomatic anemia (chest pain, SOB, reduced exercise capacity), and/or EKG changes
    - Lack of response to medical therapy
  - Possible adverse effects
    - Infection (HIV, hepatitis)
    - Volume overload
    - Transfusion reaction
  - Specific benefits
    - Rapid correction of anemia
  - When an infection occurs during EPO therapy, it is best to cease EPO therapy and rely on

transfusion therapy instead until the infection is properly treated.

- Future directions (1,4)
  - Antihepcidin antibodies, hepcidin-production inhibitors
  - Anti-BMP, anti-IL-6 antibodies
  - Ferroportin stabilizers
  - Vitamin D (lowers hepcidin)
  - Heparin (impairs hepcidin transcription)

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Referral to a hematologist is not always warranted.

#### *Patient Monitoring*

- Hgb should not be increased > 11 to 12 g/dL because normalization of hemoglobin has been associated with higher mortality (9).
- Baseline and periodic monitoring of transferrin saturation, and ferritin levels every 3 months may be of value (6).

### *PATIENT EDUCATION*

Patients receiving medical therapy should be advised about the following possible risks:

- Mortality, cardiovascular complications, thromboembolism, progression of cancer

### *PROGNOSIS*

ACD does not typically progress.

### **COMPLICATIONS**

- Adverse effects of ACD:
  - Mortality
  - Cardiovascular complications
  - Symptoms affecting daily life
- Adverse effects of ESAs:

Heightened risk of mortality and/or cardiovascular complications in CKD patients

- Heightened risk of mortality and/or tumor progression in cancer patients
- Elevated risk of thromboembolism

### See Also

Iron Deficiency Anemia

### Codes

#### ICD10

- D63.8 Anemia in other chronic diseases classified elsewhere
- D63.0 Anemia in neoplastic disease
- D63.1 Anemia in chronic kidney disease

## Clinical Pearls

- ACD is the second most common anemia seen clinically.
- One of the most common diagnostic problems is making the distinction between ACD, IDA,

and combined ACD + IDA.

- Iron level is usually nondiagnostic.
- Use markers such as transferrin/TIBC, TSAT, and ferritin to distinguish. New markers are under development (hepcidin, sTfR, sTfR index).
- IV iron should be given to all patients treated with ESAs.
- Hemoglobin should be kept in low to normal range.

# Anemia, Iron Deficiency

Deborah R. Erlich, MD, MMedEd

## BASICS

### DESCRIPTION

- Low serum iron associated with low hemoglobin (Hgb) or microcytic, hypochromic red blood cells (RBCs)
- Onset acute (rapid blood loss) or chronic (slow blood loss, deficient iron intake or absorption)
- Both low Hgb per RBC and fewer RBC in total lead to blood oxygen deficiency, which can have serious systemic consequences.
- System(s) affected: hematologic, lymphatic, immunologic, cardiac, gastrointestinal

### Geriatric Considerations

Iron deficiency anemia is associated with increased hospitalization and mortality in older adults (1).

### Pediatric Considerations

Infants who drink cow's milk or juice, live in poverty, are from developing countries or are of black or Native American descent are at high risk of iron deficiency anemia and should get iron supplements (2)[B].

### Pregnancy Considerations

Iron supplements are recommended during pregnancy to improve maternal hematologic indexes, though significant clinical outcomes have not yet been proven (3)[A] other than neonatal birth weight (2)[B].

### EPIDEMIOLOGY

- Iron deficiency is the most common nutritional deficiency in the world (4,5) and iron deficiency anemia (IDA) is the most common cause of anemia (50%) (4,6).
- Predominant age: all ages but especially toddlers and menstruating and pregnant women
- Predominant sex: female

- Predominant race: Mexican-American and black females (4)
- Common in both developing and developed countries

### *Incidence*

- Adults: men 2%, women 15-20% annually
- Infants and toddlers: 3-5% annually
- Pregnant patients: maybe as high as 20% (2)

### *Prevalence*

2 billion people worldwide (5)

- Infants and children age <12 years: 4-7%
- Men: 2-5%
- Menstruating women: 30% (5)

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Depletion of iron stores leads to decrease in both reticulocyte count and production of Hgb.

Causes:

- Blood loss (menses, GI bleeding, trauma)
- Poor iron intake
- Poor iron absorption (e.g., atrophic gastritis, postgastrectomy, celiac disease)
- Increased demand for iron (e.g., infancy, adolescence, pregnancy, breastfeeding)

## **RISK FACTORS**

- Premenopausal woman
- Frequent blood donor
- Pregnancy/lactation, young maternal age
- Strict vegan diet
- Use of NSAIDs
- Hospitalized with frequent blood draws
- Living in or visiting countries with endemic hookworm infection

## GENERAL PREVENTION

- Screen asymptomatic pregnant women and high risk children at 1 year of age (6).
- Supplementation in asymptomatic children aged 6 to 12 months if at risk for IDA (e.g., malnutrition, abuse, cow's milk <12 months) (2,3)
- Iron- and vitamin C-rich diet for menstruating women
- Iron 30 mg/day for asymptomatic pregnant women (3)

## COMMONLY ASSOCIATED CONDITIONS

- GI tract malignancy, peptic ulcer disease (PUD), *Helicobacter pylori* infection, irritable bowel disease
- Hookworm or other parasitic infestations
- Hypermetrorrhagia
- Pregnancy
- Obesity treated with gastric bypass surgery
- Malnutrition
- Medications such as NSAIDs or antacids

## DIAGNOSIS

### HISTORY

- Asymptomatic in most cases
- Weakness, fatigue, and/or malaise
- Exertional dyspnea
- Angina with coronary artery disease
- Headaches or inability to concentrate
- Melena
- Pica

## PHYSICAL EXAM

- Pallor (skin, conjunctivae, sublingual)
- Tachycardia, tachypnea
- Cool extremities

- Brittle nails/hair
- Signs of heart failure

## ***DIFFERENTIAL DIAGNOSIS***

- GI bleeding (e.g., gastritis, PUD, carcinoma, varices, celiac disease)
- Chronic intravascular hemolysis (e.g., paroxysmal nocturnal hemoglobinuria, malfunctioning prosthetic valve)
- Defective iron usage (e.g., thalassemia trait, sideroblastosis, G6PD deficiency)
- Defective iron reutilization (e.g., infection, inflammation, cancer, hypothyroid, chronic diseases)
- Hypoproliferation (e.g., decreased erythropoietin from hypothyroidism, renal failure)
- Other anemias such as anemia of chronic disease, thalassemia, lead poisoning

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Screen asymptomatic pregnant women and high risk children at 1 year of age (6).
- Test with signs and symptoms of anemia, and fully evaluate if iron deficiency is confirmed (2,5).
- Hgb (to define anemia):
  - <13 g in men and < 12 g in women (WHO standards) (7)
  - Patients with comorbidities (e.g., chronic hypoxemia, smokers, high altitudes) may be anemic at higher Hgb levels.
- Mean corpuscular volume (MCV): <80 fL
  - MCV may be low normal in mild anemia, or hidden by large cells (reticulocytes, macrocytes).
- Ferritin is most sensitive and specific for diagnosing iron deficiency as cause of anemia (5):
  - <15  $\mu\text{g/L}$  diagnoses IDA (<45  $\mu\text{g/L}$  likely) (2)
  - > 100  $\mu\text{g/L}$  rules out iron deficiency
- Iron studies:
  - Decreased: ferritin, serum iron, transferrin saturation

- Increased: total iron-binding capacity (TIBC), transferrin
- Red cell distribution width (RDW) increases with a mixed population of cells (e.g., mixed IDA and B<sub>12</sub> deficiency).
- CBC with differential, peripheral smear, reticulocyte count, and index
  - Peripheral smear usually shows hypochromia and microcytosis, but may be normal, and reticulocyte production index is low (2).
- Consider testing for G6PD deficiency
- Evaluate for thalassemia
  - Very low MCV <80, elevated Hgb A2 or Hgb F, family history, and especially high or high normal RBC count
  - Microcytosis with ovalocytosis and unresponsive to iron suggests the thalassemia trait.
- IgA antiendomysial antibodies (IgA anti-EmA) and/or IgA antitissue transglutaminase (IgA-anti-TTG) for Celiac
- TSH for hypothyroidism
- An empiric trial of iron at 3 mg/kg/day may help diagnose decreased iron stores in children; reticulocytes become elevated in 7 to 10 days or Hgb increases > 1 g/dL weekly, indicating iron deficiency.
- Drugs that may alter lab results:
  - Iron supplements or multivitamin-mineral preparations that contain iron
- Disorders that may alter lab results:
  - Elevated ferritin: acute or chronic liver disease, Hodgkin disease, acute leukemia, solid tumors, fever, acute inflammation, renal dialysis
  - Elevated Hgb: smoking, chronic hypoxemia, high altitude

### *Diagnostic Procedures/Other*

- Stool guaiac
- Stool for ova and parasites if at risk
- Colonoscopy and endoscopy to evaluate for bleeding sites, and especially colorectal and gastric carcinoma for:
  - Premenopausal women with negative GYN workup and/or lack of response to iron

- Men and postmenopausal women (6)[C]
- Bone marrow aspiration rarely performed

## TREATMENT

### GENERAL MEASURES

- Search for underlying cause and correct
- Avoid transfusions, except in rare cases.

### MEDICATION

- Elemental iron 60 to 200 mg/day for adults (5,8)[C]
- Elemental iron 60 to 120 mg/day for pregnant women for treatment (8), 30 mg for prevention (3)[C]

P.49

- Elemental iron 15 mg/day for patients > age 80
- Elemental iron 3 to 6 mg/kg/day for children
- Ferrous sulfate 325 mg TID or ferrous gluconate 300 mg 1 to 3 tablets BID-TID, or ferrous fumarate 324 mg 1 tablet BID on an empty stomach 1 hour before meals (6)[C]
- Constipation will occur in  $\div 1/4$  of patients. Consider a stool softener along with iron.
  - Medications that reduce gastric acid secretion such as proton pump inhibitors and H<sub>2</sub> antagonists reduce iron absorption (6).
  - Special oral iron formulations (including enteric-coated iron) and compounds are expensive and reduce symptoms only to the degree that they reduce the delivery of iron.
- Liquid iron preparations (used for children) can also be used in adults when tablets are not absorbed or low tolerance requires a dose reduction.
  - Continued bleeding and untreated hypothyroidism are causes for failure to respond to iron.
  - Formula to determine elemental iron needed (7): Elemental iron (mg) = Dose (mL) =  $0.0442 (\text{Desired Hb} - \text{Observed Hb}) \times \text{LBW} + (0.26 \times \text{LBW})$ 
    - Desired Hb = target Hgb in g/dL
    - Observed Hb = current Hgb in g/dL

- LBW = lean body weight in kg
- For males:  $LBW = 50 \text{ kg} + 2.3 \text{ kg for each inch of height over 5 feet}$
- For females:  $LBW = 45.5 \text{ kg} + 2.3 \text{ kg for each inch of height over 5 feet}$
- Normal Hgb (males and females)
  - $>15 \text{ kg (33 lbs)} \hat{=} 14.8 \text{ g/dL}$
  - $<15 \text{ kg (33 lbs)} \hat{=} 12.0 \text{ g/dL}$
- Consider parenteral iron for patients with an Hgb level  $<6 \text{ g/dL}$ , malabsorption, chronic kidney disease, or failure to respond to higher oral doses with concomitant vitamin C (5).
- Issues for parenteral iron formulations:
  - Give test dose for iron dextran prior to first dose to avoid anaphylaxis; ferric gluconate or iron sucrose may be safer alternatives. Dimercaprol increases risk of nephrotoxicity.
  - Dosing is product dependent; refer to individual product for suggested dosing
- Blood transfusion for severe acute blood loss or severely symptomatic patients (e.g., demand ischemia due to anemia). Hgb threshold varies by risk factors and clinical scenario (5,9)[C].
- Relative contraindications (oral iron):
  - Tetracycline
  - Allopurinol
  - Antacids
  - Penicillamine
  - Fluoroquinolones
  - Vitamin E
- Precautions
  - Iron may cause dark stools and constipation.
  - Iron overdose is highly toxic; absorption is limited to 1 to 2 mg daily (5); keep tablets and liquids out of reach of small children.

## *ISSUES FOR REFERRAL*

- Men and postmenopausal women with IDA (test for colon cancer)
- Pregnant women with Hgb level  $<9 \text{ g/dL}$

- Men or nonpregnant women with an Hgb level <6 g/dL
- Failure to respond to a 4- to 6-week trial of oral iron therapy

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Monitor patients every 3 to 12 months after Hgb normalizes (6)[C].
- Hgb increases 1 g/dL every 3 to 4 weeks.
- Iron stores may take up to 4 weeks to correct after Hgb normalizes.

#### *DIET*

- Iron-rich foods include red meat, poultry, and fish (all heme iron sources, best absorbed), and ironfortified breads/cereals, lentils, beans, dark green vegetables, and raisins (all nonheme iron sources, less well absorbed) (10)
- Foods and beverages containing ascorbic acid (vitamin C) enhance iron absorption when taken simultaneously (7).
- Avoid milk or dairy products within 2 hours of iron tablet ingestion.
- Limit milk to 16 oz/day (adults).
- Limit tea, coffee, and caffeinated beverages.
- Increase fluid and dietary fiber to decrease likelihood of constipation.
- Limit foods with high levels of chemicals (phytates and polyphenols).

#### *PATIENT EDUCATION*

- <http://familydoctor.org/familydoctor/en/diseases-conditions/anemia.html>
- <http://patient.info/pdf/4392.pdf>

#### *PROGNOSIS*

- IDA can be resolved with iron therapy if the underlying cause is discovered and appropriately treated.
- Treat coexisting subclinical hypothyroidism and IDA together. Failure to treat hypothyroidism results in poor response to iron therapy.

## COMPLICATIONS

- Hidden bleeding, particularly a bleeding malignancy
- Ischemic events or heart failure, especially in elderly
- Poor growth, failure to thrive, developmental delay in children (2,4)

Algorithm: Anemia

## Codes

### ICD10

- D50.9 Iron deficiency anemia, unspecified
- D62 Acute posthemorrhagic anemia
- D50.0 Iron deficiency anemia secondary to blood loss (chronic)

# Clinical Pearls

- IDA due to poor dietary iron intake is the most common anemia.
- Blood loss and reduced iron stores due to malabsorption or poor utilization are major risk factors for IDA.
- Premenopausal women and children are at the greatest risk for IDA.
- Cow's milk should not be given to any child age <12 months.
- Oral iron supplementation is the standard treatment for IDA.

# Anemia, Sickle Cell

Tipsuda Junsanto-Bahri, MD

## BASICS

### DESCRIPTION

- Hereditary, hemoglobinopathy marked by chronic hemolytic anemia, periodic acute episodes of painful crises, and increased susceptibility to infections
- The heterozygous condition (Hb A/S), sickle cell trait, is usually asymptomatic without anemia.
- Synonym(s): sickle cell disease (SCD); Hb SS disease

### Pediatric Considerations

- Sequestration crises and hand-foot syndrome seen typically in infants/young children
- Strokes occur mainly in childhood.
- Adolescence/young adulthood
  - Frequency of complications and organ/tissue damage increases with age
  - Psychological complications: body image, interrupted schooling, restriction of activities, stigma of disease, low self-esteem

### Pregnancy Considerations

- Complicated, especially during 3rd trimester and delivery
  - Fetal mortality 35-40%. Fetal survival is >90% if the fetus reaches the 3rd trimester.
  - High prevalence of small for gestational age (SGA) babies
- Increased risk of thrombosis, preterm delivery, pain, toxemia, infection, pulmonary infarction, phlebitis
- Partial exchange transfusion in 3rd trimester may reduce maternal morbidity and fetal mortality, but this is controversial.
- Chronic transfusions have been effective in diminishing pain episodes in pregnant women. However, this method should be used with caution due to risk of alloimmunization.

# EPIDEMIOLOGY

## Prevalence

- ≈90,000 Americans have sickle cell anemia (SCA) and 3.5 million people in the United States have sickle cell trait.
- The condition affects mainly people of African descent. Hispanic, Middle-eastern, and Asian Indian ancestry may also be affected.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Hemoglobin S results from the substitution of the amino acid valine for glutamic acid at the sixth position of the  $\beta$ -globin chain
- HbS polymerizes in the RBC in the deoxygenated state resulting in RBC sickling.
- Sickle RBCs are inflexible, causes increased blood viscosity, stasis, obstruction of small arterioles and capillaries, and ischemia.
- Chronic anemia; crises
  - Vaso-occlusive crisis: tissue ischemia and necrosis; progressive organ failure/tissue damage from repeated episodes
  - Hand-foot syndrome: Vessel occlusion/ischemia affects small blood vessels in hands or feet.
  - Aplastic crisis: suppression of RBC production by severe infection (e.g., parvoviral and other viral infections)
  - Suppression of RBC production
  - Hyperhemolytic crisis: accelerated hemolysis with reticulocytosis; increased RBC fragility/shortened lifespan
  - Sequestration crisis: splenic sequestration of blood (only in young children as spleen is later lost to autoinfarction)
- Susceptibility to infection: impaired/absent splenic function leading to decreased ability to clear infection; defect in alternate pathway of complement activation.
- Increased RBC destruction causes decreased hemoglobin levels and results in anemia and fatigue.
- Sickle cells exhibit increased adhesion and decreased ability to maneuver through small vessels, leading to vaso-occlusion.

## Genetics

- Autosomal recessive. Homozygous condition, Hb SS; heterozygous condition, Hb A/S
- The heterozygote condition can also be combined with other hemoglobinopathies: sickle-hemoglobin C disease (HbSC) and  $S\beta^+$  thalassemia are clinically similar to the heterozygous condition, whereas,  $S\beta$  thalassemia is clinically similar to the homozygous condition.

## RISK FACTORS

- Vaso-occlusive crisis (Òpainful crisisÓ): hypoxia, dehydration, fever, infection, acidosis, cold, anesthesia, strenuous physical exercise, smoking
- Aplastic crisis (suppression of RBC production): severe infections, human parvovirus B19 infection, folic acid deficiency
- Hyperhemolytic crisis (accelerated hemolysis with reticulocytosis): acute bacterial infections, exposure to oxidant

## GENERAL PREVENTION

- Prevention of crises
  - Avoid hypoxia, dehydration, cold, infection, fever, acidosis, and anesthesia.
  - Prompt management of fever, infections, pain
  - Hydration
  - Avoid alcohol and smoking.
  - Avoid high-altitude areas.
- Minimizing trauma: Aseptic technique is imperative.

## DIAGNOSIS

Diagnosis is often made by newborn screening programs.

### HISTORY

- Often asymptomatic in early months of life due to presence of fetal hemoglobin
- In those >6 months of age, earliest symptoms are irritability and painful swelling of the hands and feet (hand-foot syndrome). May also see pneumococcal sepsis or meningitis, severe anemia and acute splenic enlargement (splenic sequestration), acute chest syndrome, pallor, jaundice, or splenomegaly.

Manifestations in older children include anemia, severe or recurrent musculoskeletal or abdominal pain, aplastic crisis, acute chest syndrome, splenomegaly or splenic sequestration, and cholelithiasis.

- Painful crises in bones, joints, abdomen, back, and viscera account for 90% of all hospital admissions.
- Acute chest syndrome: tachycardia, fever, bilateral infiltrates caused by pulmonary infarctions

## *PHYSICAL EXAM*

Fever, pale skin and nail beds, mild jaundice

## *DIFFERENTIAL DIAGNOSIS*

Anemia: other hemoglobinopathies

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Screening test: Sickledex test/Hb electrophoresis (diagnostic test of choice); SCA (FS pattern)
  - 80-100% Hb S, variable amounts of Hb F, and no Hb A1
  - Sickle cell trait (FS pattern): 30-45% Hb S, 50-70% Hb A1, minimal Hb F
- Hemoglobin  $\pm$ 5 to 10 g/dL; RBC indices: mean corpuscular volume (MCV) normal to increased; mean corpuscular hemoglobin concentration (MCHC) increased; reticulocytes 3-15%
- Leukocytosis; bands in absence of infection, platelets elevated; peripheral smear: sickled RBCs, nucleated RBCs, Howell-Jolly bodies
- Serum bilirubin mildly elevated (2 to 4 mg/dL); ferritin very elevated in multiply transfused patients; serum lactate dehydrogenase (LDH) elevated
- Fecal/urinary urobilinogen high
- Haptoglobin absent or very low
- Urine analysis: hemoglobinuria, hematuria (sickle cell trait may have painless hematuria), increased albuminuria (monitor for progressive kidney disease)
- Need for imaging depends on clinical circumstances
  - Bone scan to rule out osteomyelitis
  - CT/MRI to rule out CVA; high index of suspicion required for any acute neurologic symptoms other than mild headache.

- Chest x-ray: may show enlarged heart; diffuse alveolar infiltrates in acute chest syndrome
- Transcranial Doppler: start at age 2 years; repeat yearly. Transcranial Doppler ultrasound identifies children age 2 to 16 years at higher risk of stroke.
- ECG to detect pulmonary hypertension and echocardiogram every other year from age 15 years and older.

## Test Interpretation

Hyposplenism due to autosplenectomy is common; hypoxia/infarction in multiple organs

## TREATMENT

### GENERAL MEASURES

- Painful crises: hydration, analgesics; oxygen regardless of whether the patient is hypoxic (1) [A]
  - Retinal evaluation starting at school age to detect proliferative sickle retinopathy (1,2)[A]
  - Occupational therapy, cognitive and behavioral therapies, support groups
  - All standard childhood vaccinations should be administered accordingly.
  - Special immunizations
    - Influenza vaccine yearly
    - Conjugated pneumococcal vaccine (PCV13) at ages 2, 4, and 6 months; booster at 12 to 15 months.
    - Patients <5 years of age with incomplete vaccination history should receive catch-up doses accordingly.
    - Adults age <sup>3</sup> 19 years who have functional asplenia and have not received pneumococcal vaccination should receive one dose PCV13, followed by administration of PPSV23 at least 8 weeks later (2)[A].
- 
- Meningococcal vaccine:
    - 6 weeks old: Hib-MenCY at ages 2, 4, 6, and 12 months
    - 9 months old: two doses of MCV4 separated by 3 months
    - <sup>3</sup>2 years of age: two doses of MCV4-D-CRM separated by 2 months; boosters recommended

every 5 years

## MEDICATION

### First Line

- Prophylactic penicillins indicated in infants and children starting at 2 months: A dose of 125 mg BID is recommended for children <5 years. A dose of 250 mg BID is recommended for children >5 years. Amoxicillin 20 mg/kg/day is an alternative to penicillin; if high risk remains, continue until puberty. Rising pneumococcal resistance to penicillin may change future recommendations (3)[A].
- Supplemental oxygen
- Painful crises (mild, outpatient)
  - Nonopioid analgesics (ibuprofen)
- Painful crises (severe, hospitalized)
  - Parenteral opioids (e.g., morphine on fixed schedule); patient-controlled analgesia (PCA) pump may be useful (2)[A].
- Hydroxyurea for prevention of painful acute chest syndrome, vaso-occlusive episodes, and very severe anemia. Increases fetal hemoglobin concentration. Adults: Start with 15 mg/kg/day single daily dose; Children: 20 mg/kg/day; titrate upward every 8 weeks (max dose of 35 mg/kg/day). Monitor blood counts satisfactory (avoid severe neutropenia, thrombocytopenia) (2)[A].
- Acute chest syndrome: may deteriorate quickly; monitor patients with vaso-occlusive crisis with incentive spirometry. Treat with aggressive management with oxygen, analgesics, antibiotics, simple or exchange transfusion (2)[A].
- Empiric antibiotics to cover *Mycoplasma pneumoniae*, and *Chlamydia pneumoniae* (cephalosporins or azithromycin) (1)[A]. If osteomyelitis, cover for *Staphylococcus aureus* and *Salmonella* (e.g., ciprofloxacin). Precautions: Avoid high-dose estrogen oral contraceptives; consider Depo-Provera. G-CSF use is contraindicated as it may lead to vaso-occlusive episodes and multiorgan failure.

### Second Line

Folic acid: 0 to 6 months: 0.1 mg/day; 6 to 12 months: 0.25 mg/day; 1 to 2 years: 0.5 mg/day; >2 years of age: 1 mg/day

## ADDITIONAL TREATMENT

## Transfusions and additional therapies (4)[A]

- Transfusion for aplastic crises, severe complications (i.e., CVA), prophylactically before surgery, and treatment for acute chest syndrome; prophylactic transfusions for primary or secondary stroke prevention in children
- Preoperative transfusions have been shown to reduce the risk of perioperative complications.
- Avoid blood hyperviscosity.
- Consider chelation with deferasirox, an oral agent, if the patient is multiply transfused (after age 2 years). Red cell exchange transfusion minimizes risk of iron overload.

## *SURGERY/OTHER PROCEDURES*

- Targeted fetal hemoglobin induction treatment (5)[A]
- Hematopoietic stem cell transplant (HSCT) (6)[A]: curative, but with significant morbidity and mortality; limited to individuals < 16 years old.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Severe pain, suspected infection or sepsis, evidence of acute chest syndrome

### *IV Fluids*

The preferred maintenance IV fluid is 1/2 NS, as NS may theoretically increase the risk of sickling.

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Treat infections early. Parents/patients: Any temperature of  $\geq 101^{\circ}\text{F}$  ( $38.3^{\circ}\text{C}$ ) requires immediate medical attention.
- For patients who receive chronic transfusions, monitor for hepatitis C and hemosiderosis.
- Periodic eye evaluations: starting age 10 years to detect proliferative sickle retinopathy; re-screen 1 to 2 year intervals (3)[A]
- Biannual examination for hepatic, renal, and pulmonary dysfunction
- Neuroimaging screening for risk of stroke: transcranial Doppler beginning at age 2 years and

continuing up to age 16 years

- Baseline pulmonary evaluation at each visit to assess for wheezing, shortness of breath, or cough (indicators of disease severity and pulmonary hypertension). Echocardiography for symptomatic patients; right heart catheterization for diagnosis
- Consider venous thromboembolism (VTE) prophylaxis as there is an increased incidence of thromboembolism.

## **DIET**

- Folic acid supplementation; avoid alcohol (leads to dehydration); maintain hydration
- Multivitamin without iron is recommended as there is high incidence of vitamin D deficiency and decreased bone marrow density in SCD patients.

## **PATIENT EDUCATION**

- SickCellKids.org Education Web site for children with sickle cell anemia:  
<http://www.sicklecelldisease.org>
- American Sickle Cell Anemia Association: <http://www.ascaa.org>

## **PROGNOSIS**

- Anemia occurs in infancy; sickle cell crises at 1 to 2 years of age; some children die in their first year.
- In adulthood, fewer crises, but more complications. Median age of death is 42 years for men and 48 years for women. Complications are mentioned below.

## **COMPLICATIONS**

- Alloimmunization, bone infarct and osteomyelitis, aseptic necrosis of femoral head
- CVA (peak age 6 to 7 years), impaired mental development, even without history of stroke
- Cholelithiasis/abnormal liver function
- Chronic leg ulcers, poor wound healing
- Impotence, priapism, hematuria/hyposthenuria, renal complications (proteinuria)
- Retinopathy, splenic infarction (by age 10 years)
- Acute chest syndrome (infection/infarction) leading to chronic pulmonary disease

- Infections (pneumonia, osteomyelitis, meningitis, pyelonephritis); sepsis (leading cause of morbidity and mortality)
- Hemosiderosis (secondary to multiple transfusions)
- Substance abuse related to chronic opioid use

Algorithm: Anemia

## Codes

### ICD10

- D57.1 Sickle-cell disease without crisis
- D57.3 Sickle-cell trait
- D57.00 Hb-SS disease with crisis, unspecified

## Clinical Pearls

- Over 90,000 Americans have SCA (÷ 1 in 375 African Americans). The preferred maintenance IV fluid is 1/2 NS, as NS may theoretically increase the risk of sickling.
- Painful crises in bones, joints, abdomen, back, and viscera account for 90% of all hospital admissions.
- Acute chest syndrome: tachycardia, fever, bilateral infiltrates caused by pulmonary infarctions

# Aneurysm of the Abdominal Aorta

Michael J. Gray, MD, MA, MS, ATC

## BASICS

### DESCRIPTION

- An infrarenal aorta  $\geq 3$  cm in diameter is considered aneurysmal (1,2,3,4,5).
- Types
  - Fusiform aneurysm: involves the whole circumference or wall of the artery
  - Saccular aneurysm: does not involve the full circumference; often appears as an asymmetrical bleb or blister on side of aorta
- Clinical presentation relates to aneurysm location, size, type, and comorbid factors affecting patient. The majority are asymptomatic but may present with rupture, embolism, or thrombosis. Treatment and indications for surgical repair are dictated by risk of rupture, risk of surgical repair, and estimated patient life expectancy.
- Second most common disease to affect the aorta (5)
- System(s) affected: cardiovascular; neurologic; heme/lymphatic/immunologic
- Synonym(s): aortic aneurysms; AAA

### Geriatric Considerations

Incidence of AAA, risk of rupture, and operative morbidity and mortality all rise with age.

### Pediatric Considerations

Rare in children; may be associated with umbilical artery catheters, connective tissue diseases, arteritides, or congenital abnormalities

### EPIDEMIOLOGY

- Frequency increases  $>50$  years of age.
- Predominant sex: male  $>$  female (5:1) (1)

### Incidence

- > 15,000 deaths per year in United States
- 10th leading cause of death in men 65 to 75 years
- 3.9-7.2% males >50 years (3)
- 1.0-1.3% females >50 years (3)
- Females with 2 to 4 times increased risk of rupture (6)

## Prevalence

- Depends on risk factors associated with AAA
- Prevalence of AAAs 2.9 to 4.9 cm in diameter ranges from 1.3% for men aged 45 to 54 years to 12.5% for men 75 to 84 years. Data for women are 0% and 5.2%, respectively; however, when detected, women presented at an older age and were more likely to present with a ruptured AAA. Female sex is an independent risk factor for *death* from AAA (2).

## ETIOLOGY AND PATHOPHYSIOLOGY

- Vascular inflammatory degenerative disease, with major role of matrix metalloproteinases and inflammatory markers that result in aortic medial degeneration (4,6)
- Gradual and/or sporadic expansion of aneurysm and accumulation of mural thrombus (4)
- Mural thrombus can contribute to an area of localized hypoxia, thus, further weakening the aneurysm (4).
- Aneurysms tend to expand over time. (Laplace law:  $T$  [wall tension] = pressure  $\times$  radius. Wall tension directly related to BP and radius of artery.) When wall tension exceeds wall tensile strength, rupture occurs (2,4).
- Average small AAA (<5.5 cm) grows at rate of 2.6 to 3.2 mm/year. Larger aneurysms grow faster rate as do aneurysms in current smokers; otherwise, no identifiable risk factors to assess which small AAAs will advance to require further intervention.
- Annual growth rate of 2.2 mm/year average for small aneurysms but increased in smokers; decreased in diabetics (4)
- 60-80% of AAAs between 40 and 49 mm will enlarge and require surgery in 5 years.
- Degenerative: atherosclerotic (80%); other causes: inflammatory diseases (5%), trauma, connective tissue disorders, infection (*Brucella*, *Salmonella*, *Staphylococcus*, tuberculosis)

## Genetics

- Familial aggregations exist: Aneurysms may develop at an earlier age.

- 2 times risk of AAA if first-degree relative with AAA (1,2,6)
- 12-19% of patients with repair had first-degree relative with AAA (2).
- Marfan syndrome
- Ehlers-Danlos syndrome
- Polycystic kidney disease
- Tuberous sclerosis

## **RISK FACTORS**

Older age, male, Northern European ethnicity, family history, smoking, hypertension (HTN), hyperlipidemia, peripheral vascular disease, peripheral aneurysms, chronic obstructive peripheral disease (COPD), obesity (2,4,5,6)

## **GENERAL PREVENTION**

- Address cardiovascular disease risk factors.
- Follow screening guidelines: US screening for detection of AAA in male patients, 65 to 75 years, who have ever smoked.

## **COMMONLY ASSOCIATED CONDITIONS**

- HTN, myocardial infarction (MI), heart failure, carotid artery, and/or lower extremity peripheral arterial disease
- Screening for thoracic aneurysm should also be considered.
- 20% of patients with AAA have concurrent thoracic aneurysm (5).

## **DIAGNOSIS**

- Screening: recommended one-time US for AAA in men 65 to 75 years who have EVER smoked (3)[B], selective offer one-time US in men 65 to 75 years who have NEVER smoked (3)[C]
- U.S. Preventive Services Task Force recommends against routine screening for women who have NEVER smoked and states that there is insufficient evidence to make a recommendation for women 65 to 75 years old who have EVER smoked.
- Most often asymptomatic: discovered during exams for other complaints (1)
- Symptomatic: embolization, thrombosis, vague abdominal or back pain, syncope, lower extremity paralysis

- Rupture

## ALERT

- The triad of shock, pulsatile mass, and abdominal pain always suggests rupture of AAA, and immediate surgical evaluation is recommended (2)[B].
  - Shock may be absent if rupture is contained.
  - Palpable pulsatile mass may be absent in up to 50% of patients with rupture.
  - Pain may radiate to the back, groin, flank (mimics urolithiasis), buttocks, or legs.
- Unusual presentations:
  - Primary aortoenteric fistula: erosion/rupture of AAA into duodenum
  - Aortocaval fistula: erosion/rupture of AAA into vena cava or left renal vein: 3-6%
  - Inflammatory aneurysm: encasement by thick inflammatory rind; can cause chronic abdominal pain, weight loss, and elevated ESR. Surrounding viscera is densely adherent.

## HISTORY

Abdominal or back pain; AAA risk factors

## PHYSICAL EXAM

- Pulsatile supraumbilical mass
- Only 30-40% of AAA were detected by physical exam (6).
- Physical exam will only detect 76% of aneurysms >5 cm (6).
- 14% of AAA associated with femoral or popliteal aneurysms and 62-85% of patients with femoral or popliteal aneurysms will have an AAA (5,6); therefore, recommended AAA evaluation for all patients with known femoral or popliteal aneurysms (2)[B]
- Vague abdominal tenderness: may radiate to the back or flank
- Encroachment by aneurysm
  - Vertebral body erosion, gastric outlet obstruction, ureteral obstruction
  - Lower extremity ischemia secondary to embolization of mural thrombus
- Rupture leads to tachycardia, hypotension, evidence of shock and anemia, possible flank contusion (Grey-Turner sign) (6).

# DIAGNOSTIC TESTS & INTERPRETATION

## *Initial Tests (lab, imaging)*

- If rupturing AAA is considered: complete blood chemistry (chemistries, PT/INR, PTT, type and cross), ECG
- US: simplest and least expensive diagnostic procedure
- Multiple studies have demonstrated high sensitivity (94-100%) and specificity (98-100%) of US (3,6).
- Although effective in detecting AAA, US is a poor test to show leakage or rupture if bleeding is into the retroperitoneal space.
- Surveillance of asymptomatic aneurysm
  - 2.6 to 2.9 cm: Screen at 5-year intervals (6)[C].
  - 3.0 to 3.9 cm: Screen at 3-year intervals (2)[B],(6)[C].
  - 4.0 to 5.4 cm: Screen every 6 to 12 months (2)[A].
- CT scans are preferred preoperative study (caution with IV contrast in renal failure) (5).
- MRI/MRA can visualize AAA but is often not possible in emergent situations.
- Aortography does not define outer dimensions of aneurysm.
- Abdominal x-rays can be diagnostic if calcifications exist; not a diagnostic tool of choice (1,2)
- Ongoing research is exploring alternative diagnostic measurements, including measurement of total aortic volume versus single axial diameter measurement and measurement of total thrombus burden associated with AAA because this appears to have a greater risk association (2,4).

## *Follow-Up Tests & Special Considerations*

- Evaluation for coronary artery disease is appropriate prior to elective AAA repair (i.e., cardiac clearance), including stress test, echocardiography, and ECG if appropriate (1).
- If AAA was discovered at any location, then full assessment of entire aorta including thoracic aorta and aortic valve is recommended (5)[C].
- Since AAA patients tend to have the same risk factor profile as coronary artery disease, general preventative cardiovascular disease measures should be initiated (5)[C].

### **ALERT**

Use clinical judgment: Patients with known AAA having abdominal or back pain symptoms may be rupturing despite a negative CT scan.

## **DIFFERENTIAL DIAGNOSIS**

- Other abdominal masses
- Other causes of abdominal or back pain (e.g., peptic ulcer disease, renal colic, diverticulitis, appendicitis, incarcerated hernia, bowel obstruction, GI hemorrhage, arthritis, metastatic disease, MI)

## **TREATMENT**

### **GENERAL MEASURES**

- Treat atherosclerotic risk factors (2,5)[C].
- Medical optimization of cardiac, renal, and pulmonary conditions
- Smoking cessation (increased rate of expansion of 20-25% with continued smoking) and exercise (2)[B]
- Emergent treatment in unstable or symptomatic patients is immediate vascular surgery consultation, adequate IV access and resuscitation, type and cross for multiple units, and rapid bedside US.
- Less acute treatment of AAA/prevention of rupture is elective repair and risk factor modification.

### **MEDICATION**

- $\beta$ -Blockers should be used perioperatively in absence of contraindications (2,6)[A]; bronchodilators should be used for 2 weeks prior to repair for patients with COPD (6)[C].
- No medication has been proven to decrease the rate of growth or rupture (5).
- $\beta$ -Blockers, statins, and aspirin may decrease risk of cardiovascular related mortality but no definitive decrease in AAA mortality (5).
- Doxycycline, previously theorized to decreased wall inflammation, has not been shown to have any effect on AAA (5).

# SURGERY/OTHER PROCEDURES

## Current recommendations

- Elective
  - 5.5-cm diameter is the threshold for repair in an average patient (2)[B].
  - Younger, low-risk patients with long life expectancy may prefer early repair.
  - Women or AAA with high risk of rupture: Consider elective repair at 4.5 to 5 cm.
  - Consider delayed repair in high-risk patients.
  - 5% perioperative mortality for open elective repair (2)
- High risk of rupture
  - Expansion >0.6 cm/year
  - Smoking/COPD severe/steroids
  - Family history; multiple relatives
  - Hypertension if poorly controlled
  - Shape is nonfusiform.
- High-risk patients for elective repair
  - Risk factors for open repair include age >70 years, COPD, chronic renal insufficiency (CRI), suprarenal clamp site, with 1-year mortality if no risk factors present of 1.2% and 67% for all four risk factors present.
  - Other poor prognostic factors include inactive/poor stamina, congestive heart failure, significant coronary artery disease, liver disease, family history of AAA.
  - Consider coronary revascularization prior to aneurysm repair if coronary artery disease (6) [B].
  - Discontinue thienopyridine (clopidogrel and others); use 10 days prior to AAA repair, and restart immediately postoperatively (6)[C].
  - Transfusion to hematocrit >28.0 if elective open repair was planned (6)[C]
- Emergent/symptomatic repair: traditionally, open repair; however, candidates with appropriate anatomy can have endovascular repair, with an estimated mortality of 32% for endovascular versus 44% open.
- Open repair versus endovascular repair (EVAR)
  - Open repair or EVAR in patients who are good or average surgical candidates (6)[B]

- Open repair for patients who are unable to comply with the recommended periodic long-term surveillance (6)[B]
- EVAR for patients at high surgical risk due to significant cardiac, pulmonary, or renal disease, but no significant mortality improvement compared with no therapy (6)[B]
- EVAR tends to have improved procedural mortality (1.8% vs. 4.3%), but long-term mortality over 6 years is similar (7.5 deaths/patient-years for EVAR versus 7.7 deaths/patient-years for open repair), and EVAR patients require lifelong follow-up for monitoring (2,3).

## ***INPATIENT CONSIDERATIONS***

Risk of abdominal compartment syndrome after repair, 4-12%; usually associated with large fluid resuscitation

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

CT or MRI evaluation of the graft for EVAR surveillance at 1 month, 6 months, then annually (2) [B]

### ***Patient Monitoring***

BP and fasting lipid values: Control as for atherosclerotic disease (6)[C].

### ***DIET***

Low-fat, low-salt, and low-caffeine diet; nutrition optimized prior to elective repair; parenteral nutrition started within 7 days postoperatively if unable to have enteral feeds

### ***PATIENT EDUCATION***

Smoking cessation, aerobic exercise

### ***PROGNOSIS***

- Annual risk of rupture: (1)
  - <4-cm diameter: ÷0% 4 to 4.9 cm: ÷0.5-5%
  - 5 to 5.9 cm: ÷3-15% 6 to 6.9 cm: ÷10-20%
  - 7to 7.9 cm: ÷20-40% >8 cm: 30-50%

Patients with AAAs measuring  $\geq 5.5$  cm should undergo repair as should all patients with symptomatic AAA. Recommended routine surveillance at 1 year and every 5 years following repair (2).

- Only  $\approx 18\%$  of patients with ruptured AAA survive.
- Despite a 5:1 ratio of AAA between males and females, women have higher AAA-associated mortality and morbidity, regardless of open or endovascular repair (2).
- 59-83% mortality if rupture occurs prior to hospitalization (3)

## COMPLICATIONS

- Nonoperative: rupture, dissection, thromboembolization. Elective operative (conventional): death 2-8%, all cardiac 10-12% (MI 2-8%) (6)
- 5.1% of patients with EVAR repair required reintervention compared with 1.7 for open repair group.
- Pneumonia 5%, renal insufficiency 5-12%, bleeding 2-6%, DVT 5-8%, stroke 1-2%, rare  $< 1\%$  include graft thrombosis, graft infection, ureteral injury (6)

## Codes

### ICD10

- I71.4 Abdominal aortic aneurysm, without rupture
- I71.3 Abdominal aortic aneurysm, ruptured

## Clinical Pearls

- US is the procedure of choice for screening for AAA in any male >65 years with any history of tobacco use.
- Suspect AAA for any elderly patient with back, abdominal, or groin pain. Triad of hypotension/shock, pulsatile abdominal mass, and abdominal/back pain always suggests rupture, which requires emergent evaluation for surgery.
- 5.5 cm is the threshold diameter for elective surgical treatment (with some exceptions).

# Angioedema

Michelle T. Martin, PharmD, BCPS, BCACP

Jamie L. Berkes, MD

## BASICS

### DESCRIPTION

- Angioedema (AE) is an acute, localized swelling of skin, mucosa, and submucosa caused by extravasation of fluid into the affected tissues. It often resolves in hours to days, but it can be life-threatening if the upper airway is involved.
- Hereditary AE (HAE) and acquired AE (AAE) are diseases of the complement cascade that result in recurrent episodes of AE of the skin, upper airway, and GI tract.
- Synonym(s): angioneurotic edema; Quincke edema

### EPIDEMIOLOGY

- Predominant age
  - Allergen, medication, or other triggers can affect all ages.
  - HAE: infancy to 2nd decade of life
  - AAE: Typically patients in 4th decade of life
- Predominant gender: male = female (except type III HAE, which affects more women than men)

### Prevalence

- AE occurs in ÷15% of the population over a lifetime.
- AE: 0.1-2.2% of patients receiving ACE inhibitors: African Americans have a four to five times greater risk of ACE inhibitor-induced AE than Caucasians.
- HAE: 1:10,000 to 50,000 population in the United States

### ETIOLOGY AND PATHOPHYSIOLOGY

- Idiopathic

- Medication-induced
  - ACE inhibitors cause 10-25% of AE cases, mostly occurring within the 1st month of use. However, onset may be delayed by years.
  - Angiotensin-receptor blockers (ARBs) also can cause AE but more rarely than ACE inhibitors.
- Allergic triggers
  - Food allergens such as shellfish, nuts, eggs, milk, wheat, soy
  - Medications such as aspirin, NSAIDs, antibiotics, narcotics, and oral contraceptives
  - Latex, venom
- Physically induced: cold, heat, pressure, vibration, trauma, emotional stress, ultraviolet light
- Hereditary or acquired C1 INH deficiency
- Thyroid autoimmune disease-associated AE
- Type I hypersensitivity reaction
- Increase in vascular permeability secondary to IgE-mediated mast cell-stimulated histamine release or from activation of the complement system and an elevation in bradykinin (HAE)
- Attacks of HAE are triggered by prolonged mechanical pressure, cold, heat, trauma, emotional stress, menses, illness, and inflammation:
  - Type I HAE, the most common form, caused by decreased production of C1 esterase inhibitor (C1 INH), has autosomal dominant inheritance.
  - Type II HAE has functionally impaired C1 INH and autosomal dominant inheritance.
  - Type III (HAE-FXII) involves mutations in coagulation factor XII gene (occurs more frequently in women, often estrogen dependent, associated with estrogen administration); also, type III HAE-unknown exists.
- AAE is a rare condition:
  - Type I is associated with lymphoproliferative diseases or paraneoplastic diseases.
  - Type II is due to autoimmune disorders (anti-C1 INH antibody).
  - Affected patients have circulating antibodies directed either against specific immunoglobulins expressed on B cells (type I) or against C1 INH (type II).
  - AAE typically presents later in life (>40 years), and patients lack family history of AE.

## Genetics

- HAE types I and II are autosomal dominant, whereas type III is dominant X-linked.
- HAE occurs in 25% of patients as a result of spontaneous genetic mutations.

## *RISK FACTORS*

- Consuming medications and foods that can cause allergic reactions
- Preexisting diagnosis of HAE or AAE

## *GENERAL PREVENTION*

- Avoid known triggers.
- Do not use ACE inhibitors in patients with C1 INH deficiency.

## *COMMONLY ASSOCIATED CONDITIONS*

- Quincke disease (AE of the uvula)
- Urticaria

## **DIAGNOSIS**

### **HISTORY**

- Identify potential triggers, including medication history, recent exposure to allergens, physical elements, or trauma.
- In comparison with urticaria, AE typically is nonpruritic, but it can cause a burning sensation.
- Family history

## *PHYSICAL EXAM*

- Acute onset of asymmetric localized swelling, usually of the face (eyelids, lips, ears, nose), tongue, larynx, and, less often, of the extremities or genitalia
- GI tract involvement may manifest as intermittent unexplained abdominal pain.

### **ALERT**

10-35% of patients present with severe respiratory compromise requiring endotracheal intubation.

## *DIFFERENTIAL DIAGNOSIS*

Urticaria (with AE in 40-50% of patients); allergic contact dermatitis; connective tissue disease: lupus, dermatomyositis; anaphylaxis; cellulitis, erysipelas; lymphedema; diffuse SC infiltrative process

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- If AE with urticaria and/or anaphylaxis, check for allergen-specific IgE to verify suspected trigger. Serum tryptase is elevated during acute AE (1)[C].
- Without a clear etiology and recurrence in AE and urticaria, check CBC and ESR:
  - Macrocytosis implies a pernicious anemia.
  - Eosinophilia may imply atopy or, rarely, a parasitic infection.
  - Elevated ESR may imply systemic disorders (1)[C].
- In recurrent AE without a clear etiology and without urticaria, consider ordering serum C4 level:
  - Low serum C4 is a sensitive but nonspecific screening test for hereditary and acquired C1 INH deficiency.
  - If C4 is normal, determine C1 INH level and function and recheck C4 during an acute attack.
  - If C4 level and C1 INH level and function are still normal, consider other causes (i.e., medications or HAE type III) for AE (2)[C].
  - If C4 level, C1 INH level, and C1 INH function are low, this indicates HAE type I.
  - HAE type II is characterized by low C4 and low C1 INH function, but C1 INH level can be normal or elevated (2)[C].
- C1q is decreased in  $\div$ 75% of AAE but is usually normal in all types of HAE (2)[C].
- Abdominal radiographs and CT scan can demonstrate GI AE or ileus.
- C1 INH deficiency may occur in association with internal malignancy, so AE rarely can be a paraneoplastic disease. Imaging (CT scan, radiography, etc.) then would be done as part of a neoplastic workup for patients with AAE.

### ***Follow-Up Tests & Special Considerations***

If C4 and C1q are low (as in AAE), neoplastic and autoimmune workup is warranted. CBC, a peripheral smear, protein electrophoresis, immunophenotyping of lymphocytes, and imaging studies are often undertaken to rule out hematologic malignancies or cancer (1)[C].

## Diagnostic Procedures/Other

Skin biopsy (may be nonspecific)

### Test Interpretation

- Edema of deep dermis and SC tissue
- Variable perivascular and interstitial infiltrate

## TREATMENT

### GENERAL MEASURES

Intubation if airway is threatened

### MEDICATION

#### First Line

- Acute allergic AE (with airway compromise)
  - Epinephrine 1:1,000; 0.3 mL IV or SC (1)[C]
  - Glucocorticoids (hydrocortisone 200 mg IV or Solu-Medrol 40 mg IV) (1)[C]
  - Diphenhydramine 50 mg IV
  - If medication induced, stop the causative agent.
- Idiopathic recurrent AE
  - 1st-generation antihistamines for acute AE (cause drowsiness)
  - Older children and adults: hydroxyzine (Vistaril) 5 mg/5 mL, 25-mg tablets 10 to 25 mg TID, or diphenhydramine (Benadryl) 25 to 50 mg q6h (3)[C]
  - Children <6 years of age: diphenhydramine 12.5 mg (elixir) q6-8h (5 mg/kg/day) (2)[C]
  - 2nd-generation H<sub>1</sub> blockers: fexofenadine (Allegra) 180 mg/day BID, cetirizine (Zyrtec) 10 mg/day, desloratadine (Clarinex) 5 mg/day (3)[C]; use with caution in pregnancy and in the elderly.

- 
- HAE chronic prophylaxis
    - A nanofiltered plasma-derived C1 INH (pdC1 INH) concentrate (Cinryze) dosed at 1,000 units/10 mL IV, rate of 1 mL/min (for 10 min) q3-4d. Administration setting options include

clinic, home health care, and after proper training, home self-administration; risk of thromboembolic events (4)[C],(5)[B].

- Attenuated androgens increase hepatic production of C1 INH: oral danazol 50 to 200 mg/day or oral stanozolol 2 mg/day; use lowest effective dose. Side effects include, but are not limited to, headache, weight gain, liver dysfunction, hirsutism, and menstrual disturbances. Monitor CBC, liver function tests, creatinine kinase, lactic dehydrogenase, fasting lipid profile, and urinalysis at baseline and q6mo. Abdominal US to be performed annually or q6mo if dose of danazol >200 mg/day. Danazol is not to be used in children, during the first 2 trimesters of pregnancy, during lactation, and in patients with hepatitis or cancer (2)[C].
- HAE short-term prophylaxis
  - Minor procedures (dental work): If C1 INH is available, no prophylaxis; otherwise, danazol 2.5 to 10 mg/kg/day (max 600 mg/day) and stanozolol 4 to 6 mg/day for 5 days prior to and 2 to 5 days after event (2)[C].
  - Major procedures (including intubation): C1 INH 1 (max 6) hour prior with additional dose on hand during procedure. If unavailable, danazol 2.5 to 10 mg/kg/day (max 600 mg/day) and solvent/detergent-treated plasma (SDP). If SDP unavailable, use fresh frozen plasma (FFP) 10 mL/kg; 2 to 4 units (400 to 800 mL) for an adult 1 to 6 hours prior
- Acute HAE treatment
  - C1 INH concentrate IV, dosed at 1,000 units if <50 kg; 1,500 units if 50 to 100 kg; 2,000 units if > 100 kg (2)[C]
  - Recombinant human C1 INH isolated from the milk of transgenic rabbits (Ruconest<sup>®</sup> formerly Rhucin) was approved for acute HAE attacks. Trained patients may self-administer 50 IU/kg if <84 kg and 4,200 IU if ≥84 kg IV over 5 minutes. No more than two doses may be administered over 24 hours. Headache, nausea, and diarrhea may occur; and thromboembolic events or anaphylaxis are possible (6)[C].
  - Pasteurized human pdC1 INH (Berinert), dosed at 20 units/kg (available in 500 units/10 mL, max infusion rate of 4 mL/min IV via peripheral vein (4,7)[B]; DO NOT SHAKE (will denature the protein). Worsening of HAE pain was reported as the most severe adverse event.
  - Ecallantide (Kalbitor), a kallikrein inhibitor, is dosed in patients aged ≥ 16 years at 30 mg SC with three separate 10 mg/mL injections in the abdomen, thigh, or upper arm, and a second 30-mg dose may be repeated within 24 hours if needed (4,8)[B]. Injection-site rotation is not necessary but must be 2 inches away from attack site. A black box warning of anaphylaxis (potential adverse event) mandates administration in health care setting.
  - Icatibant (Firazyr), a bradykinin receptor-2 antagonist, is dosed at 30 mg SC over at least

30 seconds in the abdomen in patients aged <sup>3</sup> 18 years and supplied in a prefilled 10 mg/mL (3 mL) syringe for home administration. Subsequent doses of 30 mg may be repeated in 6-hour intervals (max 90 mg/24 hours) (4)[C],(9)[B].

- Antihistamines and glucocorticoids typically do not benefit patients with HAE. Epinephrine can offer transient stabilization/improvement in laryngeal AE but is not sufficient for full treatment and does not alter the course of attack.
- Therapy under investigation for acute HAE treatment:
  - Cinryze has been studied for use during acute attacks (4)[C].
- Acute AAE treatment
  - C1 INH concentrate and FFP
  - Treatment of underlying lymphoproliferative disease is often curative in AAE type I.
  - Immunosuppressive therapy to suppress antibody production

## *Second Line*

- HAE chronic prophylaxis: If pdC1 INH is unavailable and if patient cannot tolerate attenuated androgens, antifibrinolytic agents (plasmin inhibitors) such as tranexamic acid (not approved by the FDA in United States) 25 to 50 mg/kg/day divided BID or TID (3 to 6 g/day max) or ε-aminocaproic acid could be used. They are less effective than attenuated androgens and have many side effects. On rare occasions, they have been linked to (but not proven to cause) thrombophlebitis, embolism, or myositis (2)[C].
- Acute HAE: FFP if C1 INH concentrate is not available, but it can potentially worsen attack.
- Idiopathic AE: Oral doxepin (Sinequan) may be effective for AE (10 to 25 mg at bedtime).
- H2RA: Oral ranitidine (Zantac) 150 mg/day BID

## *SURGERY/OTHER PROCEDURES*

Tracheostomy if progressive laryngeal edema prevents endotracheal intubation

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria*

Ensure patent airway. If anaphylaxis, epinephrine (1:1,000) SC 0.3 to 0.5 mg q10-15min

### *IV Fluids*

Given if needed to stabilize patient

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Diagnostic workup if symptoms are severe, persistent, or recurrent
- Protect airway if mouth, tongue, or throat is involved.

#### *DIET*

Avoid known dietary allergens.

### PATIENT EDUCATION

Educate on avoidance of triggers (i.e., food, medication, other physical stimuli), types of treatment, when to seek emergency care, and wearing Medic Alert bracelet.

### PROGNOSIS

- AE symptoms often resolve in hours to 2 to 4 days. If airway is compromised, AE can be life-threatening.
- Patients with HAE have an average of 20 attacks/year; each may last 3 to 5 days. Prophylaxis can decrease the frequency of events and number of missed days of school or work.

### COMPLICATIONS

Anaphylaxis

## Codes

### ICD10

- T78.3XXA Angioneurotic edema, initial encounter
- D84.1 Defects in the complement system

## Clinical Pearls

- AE is an acute, localized swelling of skin, mucosa, and submucosa caused by extravasation of

fluid into the affected tissues. It often resolves in hours to days, but it can be life-threatening if the upper airway is involved.

- HAE and AAE are diseases of the complement cascade that result in recurrent episodes of AE of the skin, upper airway, and GI tract.
- Trigger identification and avoidance are key in the prevention of AE.
- Patients with a history of allergies and AE should be prescribed an epinephrine autoinjector.

# Ankle Fractures

Wendy Hin-Wing Wong, MD, MPH

Jeffrey P. Feden, MD, FACEP

## BASICS

- Bones: tibia, fibula, talus
- Mortise: tibial plafond, medial and lateral malleolus
- Ligaments: syndesmotic, lateral collateral, and medial collateral (deltoid) ligament

## DESCRIPTION

- Two common classification systems help describe fractures (but do not always predict fracture stability)
  - Danis-Weber system: based on level of the fibular fracture in relationship to the syndesmosis
    - Type A: below syndesmosis (of tibiofibular joint). Usually stable (30% of ankle fractures)
    - Type B (most common): at syndesmosis. Can be stable or unstable (63%)
    - Type C: above syndesmosis. Usually unstable (7%)
  - Lauge-Hansen (LH): based on foot position and direction of applied force relative to the tibia
    - Supination-adduction (SA)
    - Supination-external rotation (SER): most common, 40-75% of fractures
    - Pronation-abduction (PA)
    - Pronation-external rotation (PER)
- Stability-based classification
  - Stable
    - Isolated lateral malleolar fractures (Weber A/B) without talar shift and with negative stress test

## Isolated nondisplaced medial malleolar fractures

- Unstable
  - Bi- or trimalleolar fractures
  - High fibular fractures (Weber C) or lateral malleolar fracture with medial injury and positive stress test
  - Lateral malleolar fracture with talar shift/tilt (bimalleolar equivalent)
  - Displaced medial malleolar fractures
- Pilon fracture: tibial plafond fracture due to axial loading (unstable)
- Maisonneuve: fracture of proximal 1/3 of fibula associated with ankle fracture (unstable); high risk of peroneal nerve injury

## *Pediatric Considerations*

- Ankle fractures are more common than sprains in children compared to adults because ligaments are stronger than physis.
- Talar dome: osteochondral fracture of talar dome; suspect in child with nonhealing ankle sprain or recurrent effusions
- Tillaux: isolated Salter-Harris III of distal tibia with growth plate involvement
- Triplane fracture: Salter-Harris IV with fracture lines oriented in multiple planes: 2-, 3-, and 4-part variants

## *EPIDEMIOLOGY*

- Ankle fractures are responsible for 9% of all adult and 5% of all pediatric fractures
- Peak incidence: females 45 to 64 years; males 8 to 15 years. Average is 46 years.

## *Incidence*

- 107 to 184 per 100,000 people per year
- 3-fold increase in incidence predicted 2000 to 2030 in adults >60 years old

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Most common: falls (38%), inversion injury (32%), sports-related (10%)
- Plantar flexion (joint less stable in this position)
- Axial loading: tibial plafond or pilon fracture

## *RISK FACTORS*

- Age, fall, fracture history, polypharmacy, intoxication
- Obesity, sedentary lifestyle
- Sports, physical activity
- History of smoking or diabetes
- Alcohol or slippery surfaces

## *GENERAL PREVENTION*

- Nonslip, flat, protective shoes
- Fall precautions in elderly

## *COMMONLY ASSOCIATED CONDITIONS*

- Most ankle fractures are isolated injuries, but 5% have associated fractures, usually in ipsilateral lower limb.
- Ligamentous or cartilage injury (sprains)
- Ankle or subtalar dislocation
- Other axial loading or shearing injuries (i.e., vertebral compression or contralateral pelvic fractures)

## **DIAGNOSIS**

### **HISTORY**

- Location of pain, timing, and mechanism of injury (key historical element is exact mechanism)
- Weight-bearing status after injury
- History of ankle injury or surgery
- Tetanus status
- Assess for safety and fall risk (especially in elderly).

## *PHYSICAL EXAM*

- Examine skin integrity (open vs. closed fracture).

Assess point of maximal tenderness.

- Assess neurovascular status, pulses, motor/sensory exam, and ability to bear weight.
- Evaluate for compartment syndrome.
- Consider associated injuries (secondary survey).
- Assess ankle stability: anterior drawer test for the anterior talofibular ligament (ATFL), talar tilt test for lateral and medial ligaments, squeeze test and external rotation stress test for the tibiofibular syndesmosis

## *DIFFERENTIAL DIAGNOSIS*

- Ankle sprain
- Other fractures: talus, 5th metatarsal, calcaneus

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Plain films: first line for suspected fractures (1)[A]
- Ottawa Ankle Rules (OAR): Overall sensitivity of 98% in adults, increases to 99.6% if applied within the first 48 hours after trauma (2)[A].
- OAR suggest films in patients aged 18 to 55 years if:
  - Tenderness at the posterior edge or tip of the medial malleolus, OR
  - Tenderness at the posterior edge or tip of the lateral malleolus, OR
  - Inability to bear weight both immediately and in the ED for four steps, OR
  - Tenderness at navicular or 5th metatarsal (Ottawa Foot Rules)
- If symptoms persist past 48 to 72 hours, obtain x-rays.
- In children > 1 year old, OAR sensitivity is 98.5%.
- OAR not valid for intoxicated patients, those with multiple injuries, or sensory deficits (neuropathy)
- Three standard views
  - Anteroposterior (AP)
  - Lateral: talar dome/distal tibia incongruity indicate instability
  - Mortise (15- to 25-degree internal rotation view): symmetry of mortise; space between the medial malleolus and talus should be  $\geq 4$  mm
  - Additional stress view may demonstrate instability: increased medial clear space with

manual external rotation

## *Pediatric Considerations*

- Consider tenderness over distal fibula with normal films as Salter-Harris I.
- Stress views unnecessary in children and may cause physal damage (3)[C].
- Salter-Harris V often missed, diagnosed when leg length discrepancy or angular deformity after Salter-Harris I; rare, 1% of fractures (3)[C]

## *Follow-Up Tests & Special Considerations*

- CT recommended for operative planning in trimalleolar, Tillaux, triplane, pilon fractures, or fractures with intra-articular involvement (1)[A].
- MRI not routinely indicated; does not increase sensitivity for detecting complex ankle fractures (4)[C]
  - MRI useful for chronic instability, osteochondral lesions, occult fractures, and unexpected stiffness in children

## *Diagnostic Procedures/Other*

- Ultrasound for soft tissue injury associated with displaced fractures (1)[A]
- Bone scan or MRI for stress fracture

## **TREATMENT**

### **GENERAL MEASURES**

- Immobilize in temporary cast/splint and protect with crutches/nonweight bearing
  - 1 to 2 weeks to allow decreased swelling, if not open or irreducible fracture (5)[C]
- Ice and elevate the extremity; pain due to swelling best controlled with elevation (6)[A]
  - Compression stockings offer no benefit for swelling (7)[A].
- Closed ankle fractures: stable versus unstable
  - Stable = nonoperative (1)[A]
  - Unstable = surgery
  - Lateral shift of talus  $\geq 2$  mm or displacement of either malleolus by 2 to 3 mm = surgery (5)

[C]

- In adults with displaced fractures: insufficient evidence if surgery or nonoperative management produces superior long-term outcomes (8)[A]
- Stable syndesmosis injury = nonoperative
- Fracture dislocations: urgent reduction
  - Do not wait for imaging if neurovascular compromise or obvious deformity.
  - Flex hip and knee 90 degrees for easier reduction.
  - Post reduction: neurovascular exam and x-rays

## MEDICATION

### *First Line*

- NSAIDs and/or acetaminophen for pain (1)[A]
- Initial IM pain injection (i.e., Ketorolac, <sup>3</sup>50 kg adult: 60 mg or 30 mg q6h, max 120 mg daily; children 2 to 16 years old, <50 kg or <sup>3</sup> age 65 years: 1 mg/kg, 30 mg, or 15 mg q6h, max 60 mg daily) (6)[A]

---

P.57

- For suspected open fractures: tetanus booster, broad-spectrum cephalosporin and aminoglycoside within 3 hours post injury (5)[C]
- Intra-articular or hematoma block (1)[A]

### *Second Line*

Opioid analgesics as adjunctive therapy (1)[A]

## ISSUES FOR REFERRAL

- Consultation for neurovascular compromise, tenting of skin or open fracture, displaced or unstable fracture, compartment syndrome
- All other fractures: follow-up within 1 week and remain nonweight bearing. Consult orthopedics if not comfortable with routine fracture management.

## ADDITIONAL THERAPIES

- Nonoperative = cast immobilization
  - No difference in type of immobilization (air-stirrup, cast, orthosis) (7)[A]

- Initially nonweight bearing with crutches, then advance to 50% with crutches. Full weight bearing after 6 weeks post injury (6)[A]
- If removable cast, gentle range of motion exercises at 4 weeks (6)[A]
- Open ankle fractures (2%)
  - Remove gross debris/contamination in ED.
  - Duration of optimal antibiotic therapy controversial
  - Surgical emergency, best if repaired within 24 hours

## ***SURGERY/OTHER PROCEDURES***

- Surgical options
  - Open reduction internal fixation (ORIF); preferred in athletes and unstable fractures
  - External fixation may be preferred in extreme tissue injury or comminuted fractures; may have more malunion compared to ORIF, but no difference in wound complications
- Timing of surgery
  - Immediately if neurovascular compromise, open fracture, unsuccessful reduction, tissue necrosis (5)[C]
  - Otherwise delay > 5 days post injury because inflammation can affect wound healing (5) [C].
- Length of recovery: usually 6 to 8 weeks

## ***Pediatric Considerations***

- Salter-Harris I and II = nonoperative
  - Distal tibia: long leg cast for 4 to 6 weeks, then short leg cast for 2 to 3 weeks (4)[C]
  - Distal fibula: posterior splint or ankle brace 3 to 4 weeks, weight bearing. If displaced, then short leg cast 4 to 6 weeks, nonweight bearing (4)[C]
  - Limit reduction attempts because of potential injury to growth plate (3,4)[C].
  - Reduction not recommended if presenting <sup>3</sup> 1 week post injury (4)[C]
  - Intra-articular displacement of <sup>3</sup> 2 mm in child with > 2 years growth remaining = ORIF (3) [C]
- Salter-Harris III and IV:

- Distal tibia: if > 2 mm displacement = ORIF (3)[C]
- Distal fibula: rare, usually stable after tibial reduction (3)[C]
- Tillaux and triplane: ORIF if displaced  $\geq 2$  mm (3,4)[C]

## *Geriatric Considerations*

- Higher surgical risk due to age/comorbidities
- Osteoporosis increases risk of implant/fixation failure (8)[A].
- Risks from surgery/anesthesia: wound healing problems, pulmonary embolism, mortality, amputation, reoperation

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Admit if:

- Emergency surgery required
- Patient nonadherent, lacks social support, unable to maintain non-weight-bearing status or has significant associated injuries
- Concerning mechanism of injury (i.e., syncope, myocardial infarction, head injury)

### *Nursing*

Nonweight bearing, maintain splint/cast, apply ice, keep leg elevated, pain control, assist in ADLs

### *Discharge Criteria*

- Ambulates with walker or crutches
- Medical workup (if needed) completed
- Orthopedic follow-up arranged

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Orthopedic follow-up: serial x-rays

- In children, sclerotic lines on x-ray (Parker-Harris growth arrest lines) indicate growth disturbance (4)[C].
- Immobilize for 4 to 6 weeks, then progressive activity, weight bearing, with removable splint or boot (7)[A]
- Physical therapy referral: no difference in outcomes between stretching, manual therapy, exercise program (7)[A]

## DIET

NPO if surgery is being considered.

## PATIENT EDUCATION

- Ice and elevate for 2 to 3 weeks, use crutches/cane as instructed, splint/cast care (avoid getting wet, etc.)
- Notify physician if swelling increases, paresthesias, pain, or change in color of extremity

## PROGNOSIS

- Good results can be achieved without surgery if fracture is stable.
  - Most return to activity within 3 to 4 months
- Most athletes return to preinjury activity levels.
- Increasing age, *NOT* injury severity, associated with worsening mobility after fracture (9)[B]

## COMPLICATIONS

- Displaced fracture or instability
- Delayed union, malunion, or nonunion (0.9-1.9%)
- Postsurgical wound problems: loss of fixation, further surgery, amputation
- Deep venous thrombosis
- Complex regional pain syndrome, extensor retinaculum syndrome in children (4)[C]
- Infection (osteomyelitis)
- Posttraumatic arthritis, degenerative joint disease, growth arrest in children

## Codes

### ICD10

- S82.899A Oth fracture of unsp lower leg, init for clos fx
- S82.899B Oth fracture of unsp lower leg, init for opn fx type I/2
- S82.56XA Nondisp fx of medial malleolus of unsp tibia, init

# Clinical Pearls

- OAR are nearly 100% sensitive in determining the need for x-rays.
- Assess neurovascular status, ability to bear weight, associated injuries.
- Assess joint above (Maisonneuve).
- Normal x-rays with point tenderness indicate Salter-Harris type I fractures in children.

# Ankylosing Spondylitis

Damon F. Lee, MD

## BASICS

### DESCRIPTION

- Ankylosing spondylitis (AS) is an axial inflammatory spondyloarthropathy (axSpA) characterized by radiologic evidence of sacroiliitis.
- System(s) affected: musculoskeletal; eyes; cardiac; neurologic; pulmonary
- Synonym(s): Marie-Strömpell disease; Bamboo spine

### EPIDEMIOLOGY

- Onset usually in early 20s; rarely occurs after age 40
- Male > female (approximately 2 to 3:1)

### Incidence

Age- and gender-adjusted rate of 6.3 to 7.3/100,000 person-years

### Prevalence

÷0.55% for AS and ÷1.4% for all axSpA in the United States (1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Autoinflammation at sites of bacterial exposure (e.g., intestines) or mechanical stress in genetically susceptible individuals (2)
- Inflammation at the insertion of tendons, ligaments, and fasciae to bone (enthesopathy) causes erosion, remodeling, and new bone formation
- Inflammation-independent pathways of bony changes have also been hypothesized (2).

### Genetics

- 80-90% of patients with AS are HLA-B27-positive.
- Other genetic associations include endoplasmic reticulum aminopeptidase 1 (ERAP1),

interleukin 23 receptor (IL23R), and gene deserts on chromosome 2p15 and 21q22 (2).

## RISK FACTORS

- HLA-B27
  - 1-8% of HLA-B27-positive adults have AS.
- Positive family history
  - HLA-B27-positive child of a parent with AS has a 10-30% risk of developing the disease.

## COMMONLY ASSOCIATED CONDITIONS

- Uveitis/iritis (up to 40%)
- Enthesopathy: Achilles tendonitis, plantar fasciitis
- Dactylitis (sausage digit) from oligoarthritis
- Peripheral spondyloarthritis (SpA): psoriatic arthritis, reactive arthritis, inflammatory bowel disease (IBD)-related arthritis, juvenile idiopathic arthritis
- Aortitis and cardiac conduction defects

## DIAGNOSIS

### HISTORY

- Inflammatory back pain
  - Insidious onset
  - Duration >3 months
  - Morning stiffness in spine lasting >1 hour
  - Night time awakenings secondary to back pain
  - Pain and stiffness increase at rest and improve with activity
- Alternating buttock/hip pain is common.
- Constitutional symptoms (fatigue, weight loss, lowgrade fever) are common.
- Inspirational chest pain due to enthesitis at costochondral junction and diminished chest wall expansion
- Other symptoms associated with enthesopathy (Achilles pain, plantar fascia pain); dactylitis (oligoarthritis); iritis (painful red eye, photophobia, vision changes)

## *PHYSICAL EXAM*

- Sacroiliac joint tenderness, loss of lumbar lordosis, and cervical spine rotation
- Diminished range of motion in the lumbar spine in all three planes of motion
- Modified Wright-Schober test for lumbar spine flexion:
  - Mark patient's back over the L5 spinous process (or at dimples of Venus) and measure 10 cm above and 5 cm below this point. Normal is at least 5 cm of expansion between these two marks on maximal forward flexion.
- Thoracocervical kyphosis (usually after at least 10 years of symptoms)
- Occiput-wall distance increased (distance between occiput and wall when standing with back flat against a vertical surface; zero is normal)
- Respiratory excursion of chest wall
  - Normal is >5 cm of maximal respiratory excursion of chest wall measured at 4th intercostal space; <2.5 cm is consistent with AS.
- Tenderness of insertional sites—Achilles, plantar fascia
- Peripheral oligoarthritis/dactylitis seen mostly with peripheral SpA
- Cauda equina syndrome rarely occurs in late disease.
- Extra-articular manifestations: uveitis, psoriasis, IBD
- Aortic regurgitation murmur (1%)

## *DIFFERENTIAL DIAGNOSIS*

- Nonradiographic axSpA (features AS without x-ray evidence of sacroiliitis; MRI detects changes earlier than plain films); other SpA
- Osteoarthritis of the axial spine
- Diffuse idiopathic skeletal hyperostosis (DISH)
- Osteitis condensans ilii: benign sclerotic changes in the iliac portion of the SI joint after pregnancy
- Infectious arthritis or discitis, unilateral sacroiliitis: tuberculosis, brucellosis, bacterial infection (particularly in IV drug users)

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Up to 10% of Caucasian population and 4% of African American population are HLA-B27-

positive. Genetic testing is not necessary as part of initial evaluation, particularly with a consistent history and exam.

- ESR and C-reactive protein (CRP) may be mildly elevated or normal; if high, correlates with disease activity and prognosis.
- Absence of rheumatoid factor
- Mild normochromic anemia (15%)
- Synovial fluid: mild leukocytosis
- SI joints: Oblique projection is preferred.
  - X-ray changes may not be apparent for up to 10 years after disease onset. MRI is more sensitive; increased signal from the bone and bone marrow suggests osteitis and edema.
  - Sequential radiographic changes over time: widening of SI joint, erosions, sclerosis on both sides of joint not extending >1 cm from articular surface, and (lastly) ankyloses.
- Spine
  - Early plain radiograph changes: "Shiny corners" due to osteitis and sclerosis at site of annulus fibrosus attachments to the corners of vertebral bodies with "squaring" due to erosion and remodeling of vertebral body; contrast-enhanced MRI is more sensitive for detecting early changes.
  - Late changes: ossification of annulus fibrosus resulting in bony bridging between vertebral bodies (syndesmophytes) giving classic "bamboo spine" appearance; ankylosis of apophyseal joints, ossification of spinal ligaments, and/or spondylo-discitis also occurs.
- Peripheral joints
  - Asymmetric pericapsular ossification, sclerosis, loss of joint space, and erosions may occur.

### *Diagnostic Procedures/Other*

- ECG: conduction defects
- Echocardiogram: aortic valvular abnormalities
- Dual energy x-ray absorptiometry scan may reveal osteopenia/osteoporosis.

### *Test Interpretation*

- Erosive changes and new bone formation at bony attachment of the tendons and ligaments result in ossification of periarticular soft tissues.
- Synovial hypertrophy and pannus formation, mononuclear cell infiltrate into subsynovium and

subchondral bone marrow inflammation in the SI joint with erosions, followed by granulation tissue formation, and finally obliteration of joint space by fusion of joint and sclerosis of para-articular bone

## TREATMENT

### GENERAL MEASURES

- Aggressive physical therapy is the most important nonpharmacologic management.
- Posture training and spinal range-of-motion exercises are essential.
- Firm bed; sleep in supine position without a pillow
- Breathing exercises 2 to 3 times per day
- Smoking cessation

### MEDICATION

#### *First Line*

- Nonsteroidal anti-inflammatory drugs (NSAIDs) are first line for pain and stiffness in AS (3)[C].
- NSAIDs provide rapid and dramatic symptomatic relief, which may be diagnostic. No single NSAID preferred. Higher doses tend to be more efficacious.
- Continuous NSAID therapy may slow radiographic disease progression but may not be superior to intermittent therapy for symptom control (4)[A].
- Precautions
  - Consider CVD, GI, and renal risks of NSAIDs.
  - Consider GI prophylaxis (PPIs or misoprostol) while on NSAIDs in patients with hx of PUD, gastritis, or age >60 years
  - Use NSAIDS with caution in patients with a bleeding diathesis or patients receiving anticoagulants.
- Injection of intra-articular corticosteroids into SI joints and prostheses can provide transient relief, but systemic corticosteroids are usually ineffective.

#### *Pregnancy Considerations*

Infants exposed to NSAIDs in 1st trimester may have a higher incidence of cardiac malformations

(5)[A].

## *Second Line*

- Biologic agents: tumor necrosis factor (TNF)- $\alpha$  antagonists
  - Recommended for high disease activity or when a trial of two NSAIDs over 4 weeks have failed (3)[C]
  - FDA-approved agents for AS include etanercept (recombinant TNF receptor fusion protein), infliximab (chimeric monoclonal IgG1 antibody to TNF- $\alpha$ ), adalimumab (fully humanized IgG1 monoclonal antibody to TNF- $\alpha$ ), and golimumab (human IgG1 kappa monoclonal antibody to TNF- $\alpha$ ).
  - Approved agents improve pain, function, and symptoms of AS as compared to placebo (6) [A].
  - No definitive evidence for TNF- $\alpha$  blockers with regards to disease remission, prevention of radiologic progression, or prevention of extra-articular manifestations (7).
  - Monoclonal TNF- $\alpha$  blockers are preferred when IBD is involved (3)[C].
  - Further investigation as to the effectiveness of TNF blocker therapy with NSAIDs is needed (8).
- Precautions with TNF- $\alpha$  blockers
  - Anti-TNFs increase the risk of serious bacterial, mycobacterial, fungal, opportunistic, and viral infections. Screen for tuberculosis and hepatitis B.
  - Monitor for reactivation of tuberculosis and invasive fungal infections, such as histoplasmosis, in all patients, especially those who travel to (or residents in) endemic areas.
  - Lymphomas, nonmelanoma skin cancers, and other malignancies have been reported in patients receiving anti-TNFs.
  - Immunizations (especially live vaccines) should be updated before initiating anti-TNFs; live vaccines are contraindicated once patients receive anti-TNFs.
- Disease-modifying antirheumatic drugs (DMARDs), such as methotrexate and sulfasalazine, are ineffective for axial disease; sulfasalazine may be effective for peripheral arthritis (3)[C].

## *ISSUES FOR REFERRAL*

- Physical therapy can assist with treatment plan (including home regimens).
- Coordinate care with a rheumatologist for diagnosis, monitoring, and management (anti-TNF

therapy).

- Management of aortic regurgitation, uveitis, spinal fractures, pulmonary fibrosis, hip joint involvement, renal amyloidosis, and cauda equina syndrome may require referral to appropriate specialty.

## ***ADDITIONAL THERAPIES***

- Bisphosphonate medications if osteopenia or osteoporosis is present
- Monitoring and management of CVD risk factors and comorbidities

## ***SURGERY/OTHER PROCEDURES***

- Evaluate for C-spine ankylosis/instability before intubation in patients with AS undergoing surgery.
- Total hip replacement if necessary to restore mobility and to control pain.
- Vertebral osteotomy can improve posture for patients with severe cervical or thoracolumbar flexion.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- Symptom control and maintenance of mobility and function are primary treatment goals.
- Monitor posture and range of motion with 6- to 12-month visits; increase frequency if higher disease activity.
- Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) or Ankylosing Spondylitis Disease Activity Score (ASDAS) can be used to measure disease activity.

### ***PATIENT EDUCATION***

- Maintain physical activity and posture.
- Swimming, tai chi, and walking are excellent activities.
- Avoid trauma/contact sports.
- Appropriate ergonomic modification of workplace
- Counsel about risk of spinal fracture.

- MedicAlert bracelet (helpful if intubation required)
- Arthritis Foundation: <http://www.arthritis.org>
- Spondylitis Association of America: <http://www.spondylitis.org>

## PROGNOSIS

- Extent and rapidity of progression of ankylosis are highly variable.
- Progressive limitation of spinal mobility necessitates lifestyle modification.

## COMPLICATIONS

- Spine
  - Spinal fusion causing kyphosis
  - Cervical spine fracture or subluxation carries high mortality rate; fracture can occur at any level of ankylosed spine.
  - Cauda equina syndrome (rare)
- Pulmonary: restrictive lung disease, upper lobe fibrosis (rare)
- Cardiac: conduction defects at atrioventricular (AV) node, aortic insufficiency, aortitis, pericarditis (extremely rare)
- Eye: uveitis and cataracts
- Renal: IgA nephropathy, amyloidosis (<1%)
- GI: microscopic, subclinical ileal, and colonic mucosal ulcerations in up to 50% of patients, mostly asymptomatic

- M45.8 Ankylosing spondylitis sacral and sacrococcygeal region

### Clinical Pearls

- Diagnosis of AS is suggested by a history of inflammatory back pain, evidence of limited chest wall expansion, restricted spinal movements in all planes, radiographic evidence of sacroiliitis, and a therapeutic response to NSAIDs.
- HLA-B27 testing supports the diagnosis if clinical features are not definitive.
- MRI is more sensitive at detecting SI joint inflammation than plain radiography.
- Physical therapy is important in helping to maintain posture and mobility.
- NSAIDs and TNF- $\alpha$  blockers are the mainstays of pharmacologic treatment of AS.

# Anorectal Fistula

Nihal K. Patel, MD

David A. Greenwald, MD

## BASICS

### DESCRIPTION

- An anorectal fistula is an open communication between an anal abscess and the perirectal skin.
- Anorectal fistulas typically form from an abscess of the anal crypt glands.
- The classification of fistulas grades severity and guides treatment. Five subtypes are described:
  - Submucosal or superficial: The fistula tracks beneath the submucosa and does not involve the sphincter mechanism (not classified under original Park classification).
  - Intersphincteric: The fistula travels along the intersphincteric plane (Park type 1).
  - Transsphincteric: The fistula traverses through the internal and external sphincter (type 2).
  - Suprasphincteric: The fistula originates at the dentate line and loops over the external sphincter, to the ischiorectal fossa (type 3).
  - Extrasphincteric (rare): high in the anal canal, (proximal to dentate line), does not involve sphincter complex (type 4)
- Fistulas can also be classified as low or high:
  - Low fistulas involve the distal 1/3 of the external sphincter muscle.
  - High fistulas involve more of the external sphincter.
- Fistulas may be simple or complex:
  - Simple fistulas are low and include superficial, intersphincteric, or low transsphincteric fistulas. They also involve only one communicating tract and are not associated with inflammatory bowel disease (IBD) or other organs (bladder).
  - Complex fistulas are higher along the gastrointestinal (GI) tract, have multiple tracts, involve other organs, are recurrent, or are associated with IBD or radiation.
  - System(s) affected: GI; skin/exocrine

- Synonym(s): fistula-in-ano; anal fistula

## *EPIDEMIOLOGY*

- The true prevalence is unknown because anorectal pain is commonly attributed to hemorrhoids.
- Mean age of presentation for anal abscess and fistula is 40 years (range 20 to 60).
- Predominant sex: Males are twice as likely to develop an abscess and/or fistula compared with females.
- Lifetime risk of developing fistula is 20-40% in Crohn disease patients.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Inspissated debris in an obstructed anal crypt gland results in suppuration and abscess formation along the path of least resistance in the perianal and perirectal spaces (cryptoglandular theory).
- Abscess rupture or drainage leads to an epithelialized track or fistula formation in  $\div 1/3$  of patients.
- Fistula formation also occurs in patients with IBD.
- Patients undergoing pelvic radiation are predisposed to fistula formation.
- Immunocompromised patients with primary perianal actinomycosis can (rarely) develop fistula-in-ano.
- Anorectal mucosal laceration due to rectal foreign bodies or trauma can cause abscess and fistula formation.

## *RISK FACTORS*

- IBD (Crohn disease)
- Pelvic radiation
- Perianal trauma; previous anorectal abscess
- Pelvic carcinoma or lymphoma
- Ruptured anal hematoma
- Abscess formation due to acute appendicitis, salpingitis, or diverticulitis
- Tuberculosis (rare); syphilis; lymphogranuloma venereum
- Immunocompromised state (actinomycosis)

## GENERAL PREVENTION

- Perianal hygiene
- Prevention or prompt treatment of anorectal abscess; management of commonly associated conditions or risk factors

## COMMONLY ASSOCIATED CONDITIONS

- Anorectal abscess
- IBD (Crohn disease)
- Diabetes
- Chronic steroid treatment

## DIAGNOSIS

### HISTORY

- Perianal pain, pruritis, purulent (often malodorous) perianal drainage, and perirectal skin lesions
- Intermittent rectal pain is worse with defecation or sitting.
- Fever most common with abscesses, generally not common with fistulas

## PHYSICAL EXAM

- Excoriations or inflammation of perianal skin
- Visible orifice; induration if opening is incomplete or blind
- Anorectal abscess palpated as an indurated or fluctuant tender perianal mass or small tender palpable lesion on rectal exam at level of anal crypt
- Anoscopy may reveal an internal orifice.
  - Goodsall rule can assist in determining course of the fistula tract (more predictive with posterior external anal openings):
    - If external opening is *anterior* to an imaginary line drawn transversely through the anal canal, fistula usually runs directly (radially) into the anal canal.
    - If external opening is within 3 cm of anal verge and *posterior* to line, fistula leads to a curved tract, with an internal opening in posterior commissure (except for a long anterior fistula).

- In children, tract is usually straight.

## ***DIFFERENTIAL DIAGNOSIS***

- Pilonidal sinus; Hidradenitis suppurativa
- Hemorrhoids; Anal fissure, ulcer, or sores
- Infected inclusion cyst
- Urethroperineal fistulas
- Ischiorectal or high muscular abscess
- Rule out: Crohn disease, carcinoma, lymphoma, tuberculosis, chronic *Chlamydia trachomatis* infection, actinomycosis in immunocompromised, acute untreated pelvic inflammatory condition

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Imaging helps define perianal anatomy.
- MRI and endoscopic ultrasound are preferred.
- MRI has ÷80-90% overall concordance with surgical examination under anesthesia; accuracy improves with dedicated pelvic MRI to allow better resolution.
- Angulation of fistula from internal opening correlates with the type of fistula (acute angle likely high transsphincteric; obtuse angle likely lower fistula).
- Fistulography (insertion of catheter into external opening of fistula and injection of radiographic contrast material) is *not* preferred and generally not accurate when evaluating perianal disease. Fistulography is reserved for patients who may have a fistula between the rectum and another organ (such as bladder).
- CT is limited in evaluating perianal fistula tracts; more helpful for large perianal abscesses and inflammation
- Consider testing for syphilis for recurrent fistulas in sexually active patients.

### ***Diagnostic Procedures/Other***

- Anoscopy or sigmoidoscopy
- Colonoscopy and esophagogastroduodenoscopy if Crohn disease is suspected
- Probing into the tract may be done under anesthesia prior to surgery to determine course of

fistula.

- Injection of dilute methylene blue or hydrogen peroxide intraoperatively may help identify internal opening.

## TREATMENT

### GENERAL MEASURES

- Surgical treatment is definitive (1)[A].
- Optimal surgical treatment based on correct fistula classification
- Goals of treatment include resolving the inflammatory process, maintaining continence, and preventing recurrence.
- Sitz baths 3 to 4 per day until definitive surgery

### MEDICATION

- Medical management with antibiotics and immunosuppressive agents plays a role in the treatment of fistulas due to Crohn disease, particularly if patients are minimally symptomatic.
- Studies have shown improvement (reduced pain, discharge, and induration) and healing in up to 80% of patients with 8 weeks of treatment using oral metronidazole in patients with Crohn disease.
- Use of infliximab has also been shown to be effective in healing perianal Crohn fistulas but has been associated with a high rate of recurrence.
- Antibiotics may be indicated if patients have signs of sepsis or an active infection with a concurrent anorectal abscess.
- Consider surgery in Crohn patients who fail longterm medical therapy.

### SURGERY/OTHER PROCEDURES

- Choice of surgical procedure is a balance between achieving cure, avoiding recurrence, and maintaining fecal incontinence (2)[A].
- Low transsphincteric and simple intersphincteric fistulas can be treated with simple fistulotomy or fibrin sealant (fistula plug) (3)[A].
- Fistula plugs can be used as initial treatment for high transsphincteric fistulas. If the fistula recurs, then an advancement flap may be necessary.

- Complex fistulas should be treated with an endorectal advancement flap, which closes the internal opening of the fistula with a mobilized flap of healthy mucosal and submucosal tissue.
- Fistulotomy opens (ÙunroofsÓ) the entire fistula tract (4)[B].
  - Fistula tract is cauterized or curetted and tract is marsupialized to promote healing.
  - Lower rates of recurrence compared to incision and drainage alone
  - Fistulotomy results in incontinence in about 12% of patients with simple fistulas, compared with almost 50% of patients with complex fistulas.
- A seton is a reactive suture or elastic that is used for drainage (noncutting seton) or to allow scarring of the tract (cutting seton). Cutting setons are tightened at regular intervals to allow slow cutting through the tract and causing scarring. Setons may be placed for complex fistulas treated with fistulotomy, for those that involve >30% of the external sphincter, are proximal to the dentate line, or are categorized as high transsphincteric fistulas.
- Postoperative: typically a same-day procedure; Sitz baths (Sit in warm bath for 20 minutes 3 to 4 times per day and after bowel movements.)
- Aggressive bowel regimen to prevent constipation
- Patients undergoing anal fistulotomy may benefit postoperatively from the use of topical application of sucralfate.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Resumption of activity as tolerated after surgery

#### *Patient Monitoring*

Anoscopy at 3 to 6 months following procedure; frequent follow-up to ensure complete healing and assess continence

#### *DIET*

High-fiber diet

### *PROGNOSIS*

Postoperative healing:

- 4 to 5 weeks for perianal fistulas
- 12 to 16 weeks for deeper fistulas

- Postoperative healing may occur within 2 to 3 weeks in children.
- Healing may be delayed in Crohn disease.

## COMPLICATIONS

- Fecal incontinence
- Constipation
- Rectovaginal fistula
- Delayed wound healing
- Low-grade carcinoma may develop in long-standing fistulas.
- Recurrent anorectal fistula if fistula is incompletely treated

## Codes

### ICD10

- K60.5 Anorectal fistula
- K60.3 Anal fistula
- K60.4 Rectal fistula

## Clinical Pearls

- Suspect anorectal fistula in patients with perianal pain, pruritis, purulent drainage, and perirectal skin lesions.
- Surgery is the traditional mainstay of treatment in patients who do not have Crohn disease.
- MRI or endoscopic ultrasound are the modalities of choice to define the anatomy of anorectal fistulas.

# Anorexia Nervosa

Umer Farooq, MD, MBBS

Wajiha Ilyas, MD

## BASICS

### DESCRIPTION

- Restriction of energy intake leading to significantly low weight in the context of age, sex, developmental trajectory, and physical health, with intense fear of weight gain and body image disturbance. Significantly low weight is defined as weight that is less than minimally normal/expected.
- *Diagnostic and Statistical Manual of Mental Disorders*, 5th edition (DSM-5), divides anorexia into two types:
  - Restricting type: not engaged in binge eating or purging behaviors for last 3 months
  - Binge eating/purging type: regularly engages in binge eating or purging behaviors (last 3 months)
- System(s) affected: cardiovascular, endocrine, metabolic, gastrointestinal, nervous, reproductive
- Severity of anorexia nervosa (AN) is based on BMI (per *DSM-5*):
  - Mild: BMI  $\geq 17$  kg/m<sup>2</sup>
  - Moderate: BMI 16 to 16.99 kg/m<sup>2</sup>
  - Severe: BMI 15 to 15.99 kg/m<sup>2</sup>
  - Extreme: BMI <15 kg/m<sup>2</sup>

### EPIDEMIOLOGY

- Predominant age: 13 to 20 years
- Predominant sex: female > male (10:1 female-to-male ratio)

### Incidence

- 8 to 19 women/2 men per 100,000 per year

## *Prevalence*

- 0.4% in women
- Less is known; however, an estimate suggests 0.3% in men (higher in gay and bisexual men).

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Complex relationship among genetic, biologic, environmental, psychological, and social factors that result in the development of this disorder
- Subsequent malnutrition may lead to multiorgan damage.
- Serotonin, norepinephrine, and dopamine neuronal systems are implicated.

## *Genetics*

- Underlying genetic vulnerability is likely but not well understood, some evidence of higher concordance rates in monozygotic twins than in dizygotic
- First-degree female relative with eating disorder increases risk 6- to 10-fold.

## *RISK FACTORS*

- Female gender
- Adolescence
- Body dissatisfaction
- Perfectionism
- Negative self-evaluation
- Academic pressure
- Severe life stressors
- Participation in sports or artistic activities that emphasize leanness or involve subjective scoring: ballet, running, wrestling, figure skating, gymnastics, cheerleading, weight lifting
- Type 1 diabetes mellitus
- Family history of substance abuse, affective disorders, or eating disorder

## *GENERAL PREVENTION*

Prevention programs can reduce risk factors and future onset of eating disorders (1)[A]:

- Target adolescents and young women 15 years of age or older.
- Encourage realistic and healthy weight management strategies and attitudes.
- Promote self-esteem.
- Reduce focus on thin as ideal.
- Decrease co-occurring anxiety/depressive symptoms and improve stress management.

## COMMONLY ASSOCIATED CONDITIONS

- Mood disorder (major depression)
- Social phobia, obsessive-compulsive disorder
- Substance abuse disorder
- High rates of cluster C personality disorders

## DIAGNOSIS

### HISTORY

- Onset may be insidious or stress-related.
- Patient unlikely to self-identify problem (lack of insight into the illness); corroborate with parent/relative
- Restriction of energy intake relative to requirement, leading to significantly low body weight in the context of age, sex, developmental trajectory, and physical health
- Fear of weight gain and/or distorted body image
- Report feeling fat even when emaciated.
- Preoccupation with body size, weight control
- Elaborate food preparation and eating rituals.
- Other possible signs and symptoms:
  - Extensive exercise
  - Amenorrhea (primary or secondary)
  - Weakness, fatigue, cognitive impairment
  - Cold intolerance
  - Constipation, bloating, early satiety
  - Growth arrest, delayed puberty
  - History of fractures (decreased bone density)

---

## *PHYSICAL EXAM*

- May be normal
- Abnormal vital signs: hypothermia, bradycardia, orthostatic hypotension
- Body weight <85% of expected
- Cardiac: dysrhythmias, midsystolic click of mitral valve prolapse
- Skin/extremities: dry skin; lanugo hair on extremities, face, and trunk; hair loss; edema
- Neurologic and abdominal exams: to rule out other causes of weight loss and vomiting

## *DIFFERENTIAL DIAGNOSIS*

- Hyperthyroidism, adrenal insufficiency
- Inflammatory bowel disease, malabsorption
- Immunodeficiency, chronic infections
- Diabetes
- CNS lesion
- Bulimia, body dysmorphic disorder
- Depressive disorders with loss of appetite
- Anxiety disorder, food phobia
- Conversion disorder

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Psychological self-report screening tests may be helpful, but diagnosis is based on meeting the *DSM-5* criteria.
- Most findings are related directly to starvation and/or dehydration. All findings may be within normal limits.
- Screening tools:
  - SCOFF questionnaire (2)[B]
  - Eating Disorder Screen for Primary Care

## *Initial Tests (lab, imaging)*

- CBC: anemia, leukopenia, thrombocytopenia

- Low serum luteinizing hormone, follicle-stimulating hormone; low serum testosterone in men
- Thyroid function tests: low thyroid-stimulating hormone with normal T<sub>3</sub>/T<sub>4</sub>
- Liver function tests: abnormal liver enzymes
- Chem 7: altered BUN, creatinine clearance; electrolyte disturbances
- Hypoglycemia, hypercholesterolemia, hypercortisolemia, hypophosphatemia
- Low sedimentation rate
- 12-Lead electrocardiogram to assess for prolonged QT interval
- Dual-energy x-ray absorptiometry of bone to assess for diminished bone density, only if underweight for >6 months

### *Test Interpretation*

- Osteoporosis/osteopenia, pathologic fractures
- Sick euthyroid syndrome
- Cardiac impairment

### **ALERT**

AN may exist concurrently with chronic medical disorders such as diabetes and cystic fibrosis.

## **TREATMENT**

### *GENERAL MEASURES*

- Initial treatment goal geared to weight restoration; most managed as outpatients (OPs)
- OP treatment:
  - Interdisciplinary team (primary care physician, mental health provider, dietician)
  - Average weekly weight gain goal: 0.5 to 1.0 kg, with stepwise increase in calories
  - Cognitive-behavioral therapy (CBT), interpersonal psychotherapy, family-based therapy
  - Focus on health, not weight gain alone.
  - Build trust and a treatment alliance.
  - Involve the patient in establishing diet and exercise goals.

- Challenge fear of uncontrolled weight gain; help the patient to recognize feelings that lead to disordered eating.
- In chronic cases, goal may be to achieve a safe weight rather than a healthy weight.
- Inpatient treatment:
  - If possible, admit to a specialized eating disorders unit.
  - Assess risk for refeeding syndrome (metabolic shift from a catabolic to anabolic state).
  - Monitor vital signs, electrolytes, cardiac function, edema, and weight gain.
  - Initial supervised meals may be necessary.
  - Stepwise increase in activity
  - Tube feeding or total parenteral nutrition is used only as a last resort.
  - Supportive symptomatic care as needed

---

P.63

- Most patients should be treated as OPs using an interdisciplinary team.
- Behavioral therapies (e.g., cognitive-behavioral, interpersonal, or family therapy) should be offered (3,4,5)[A].
- CBT has demonstrated effectiveness as a means of improving treatment adherence and minimizing dropout among patients with AN (6)[A].

## *MEDICATION*

### *First Line*

- No medications are available that effectively treat patients with AN, but pharmacotherapy may be used as an adjuvant to CBTs (5,7)[A].
- If medications are used, start with low doses due to increased risk for adverse effects.
- SSRIs may:
  - Help to prevent relapse after weight gain
  - Treat comorbid depression or obsessive-compulsive disorder.
  - Use of atypical antipsychotics is being studied with mixed findings to date. Olanzapine is potentially beneficial as an adjuvant treatment of underweight individuals in the inpatient settings.
- Attend to black box warnings concerning antidepressants.

## *Second Line*

- Management of osteopenia:
  - Primary treatment is weight gain.
  - Elemental calcium 1,200 to 1,500 mg/day plus vitamin D 800 IU/day
  - No indication for bisphosphonates in AN
  - Weak evidence for use of hormone-replacement therapy
- Psyllium (Metamucil) preparations to prevent constipation

## *ISSUES FOR REFERRAL*

Patients with AN require an interdisciplinary team (primary care physician, mental health provider, nutritionist). An important step in management is to arrange OP mental health therapist.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Suggested physiologic values: heart rate <40 beats/min, BP <90/60 mm Hg, symptomatic hypoglycemia, potassium <3 mmol/L, temperature <97.0°F (36.1°C), dehydration, other cardiovascular abnormalities, weight <75% of expected, rapid weight loss, lack of improvement while in OP therapy
- Suggested psychological indications: poor motivation/insight, lack of cooperation with OP treatment, inability to eat, need for nasogastric feeding, suicidal intent or plan, severe coexisting psychiatric disease, problematic family environment

### *Pediatric Considerations*

- Children often present with nausea, abdominal pain, fullness, and inability to swallow.
- Additional indications for hospitalization: heart rate <50 beats/min, orthostatic BP, hypokalemia or hypophosphatemia, rapid weight loss even if weight not <75% below normal
- Children and adolescents should be offered family-based treatment.

### *Geriatric Considerations*

Late-onset AN (>50 years of age) may be long-term disease or triggered by death of loved one, marital discord, or divorce.

### *Discharge Criteria*

Discharge when medically stable. Arrange OP appointment with mental health provider and primary care provider.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Close follow-up until patient demonstrates forward progress in care plan
- Family and individual therapy is extremely important for the long-term benefits/outcomes.
- CBT is very helpful for the treatment of AN and may be helpful for the prevention of relapse.
- Emphasize importance of moderate activity for health, not thinness.

### *Patient Monitoring*

- Level of exercise activity
- Weigh weekly until stable, then monthly
- Depression, suicidal ideation

### *DIET*

- Dietary consultation while patient is hospitalized.
- Nutritional education programs

### *PATIENT EDUCATION*

- Provide patients and families with information about the diagnosis and its natural history, health risks, and treatment strategies.
- <http://www.mayoclinic.org/diseases-conditions/anorexia/home/ovc-20179508>
- The National Alliance on Mental Illness: <http://www.nami.org/Learn-More/Mental-Health-Conditions/Eating-Disorders>

### *PROGNOSIS*

- Prognosis: ÷50% recover, 30% improve, 20% are chronically ill.
- Outcomes in men are likely better than in women.
- Mortality: 3%
- High risk of suicide in patients suffering from AN (8)[A]

## COMPLICATIONS

- Refeeding syndrome
- Cardiac arrhythmia, cardiac arrest
- Cardiomyopathy, congestive heart failure
- Delayed gastric emptying, necrotizing colitis
- Seizures, Wernicke encephalopathy, peripheral neuropathy, cognitive deficits
- Osteopenia, osteoporosis

## ***Pregnancy Considerations***

- Fertility may be affected.
- Behaviors may persist, decrease, or recur during pregnancy and the postpartum interval.
- Increased risk for preterm labor, operative delivery, and infants with low birth weight; anemia, genitourinary infections, and labor induction should be managed as high risk.

- Algorithm: Weight Loss

## Codes

### ICD10

- F50.00 Anorexia nervosa, unspecified
- F50.01 Anorexia nervosa, restricting type
- F50.02 Anorexia nervosa, binge eating/purging type

## Clinical Pearls

- "Are you satisfied with your eating patterns?" and/or "Do you worry that you have lost control over how you eat?" may help to screen those with an eating problem.
- Studies have shown patients with AN will not accept medications unless combined with

psychotherapy.

- To care for a patient with AN, an interdisciplinary team that includes a medical provider, a dietician, and a behavioral health professional is the most accepted approach.
- Family analysis is necessary for the patients with AN to determine what kind of therapy would be most helpful.
- 3 months amenorrhea is no longer the criteria needed for the diagnosis of AN.

# Antiphospholipid Antibody Syndrome

Ho Phong Pham, MD

Dausen J. Harker, MD

## BASICS

### DESCRIPTION

Antiphospholipid antibody syndrome (APS) is an autoantibody-mediated thrombophilic disorder characterized by recurrent arterial or venous thrombosis and/or recurrent fetal loss in the presence of antiphospholipid antibodies (APAs). The APAs enhance clot formation by interacting with phospholipid-binding plasma proteins. The resulting APS can cause significant morbidity and mortality in both pregnant and nonpregnant individuals:

- Types of APS (based on clinical presentation)
  - Primary: occurs without associated underlying disease
  - Secondary: associated with autoimmune diseases (systemic lupus erythematosus [SLE] is most common); transient APAs linked to certain infections, drugs, and malignancies
  - Catastrophic APS (CAPS) a.k.a Asherson syndrome (<1%)
    - Most severe form of disease; characterized by thrombotic microangiopathy and associated with multiorgan failure
    - High mortality if treatment is delayed
    - Severe thrombocytopenia, hemolytic anemia, and DIC are additional features.
  - Associated clinical manifestations: livedo reticularis, cardiac valvular disease, thrombocytopenia, nephropathy, hemolytic anemia, coronary artery disease, and cognitive impairment

### *Pregnancy Considerations*

- Complications include maternal thrombosis (stroke, venous thromboembolism [VTE]), fetal death, preeclampsia and placental insufficiency, fetal growth retardation, and preterm birth.
- Low-dose aspirin and low-molecular-weight heparin (LMWH) or unfractionated heparin are the drugs of choice in pregnancy.

- Prophylactic-dose heparin is recommended in the postpartum period (unless patient is on therapeutic anticoagulation) given high risk of thrombosis during this time. With adequate treatment, >70% of patients with APS deliver viable infants.

## *EPIDEMIOLOGY*

- The prevalence of APAs increases with age but is not necessarily associated with a higher risk of thrombosis.
- For APS, female > male

### *Incidence*

- In patients with positive APAs without prior risk of thrombosis, the annual incident risk of thrombosis is 0-3.8%. This risk is up to 5.3% in those with triple positivity (anticardiolipin antibodies, lupus anticoagulant (LAC), and anti- $\beta$ 2 glycoprotein-1 (GP1) antibodies positive).
- 10-15% of recurrent abortions are attributable to APS.

### *Prevalence*

APAs are present in 1-5% of the general population and in  $\div$ 40% of those with SLE. A higher prevalence is seen in those with VTE and stroke.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Anti- $\beta$ 2-GP1 antibodies play a central role in the pathogenesis of APS. The procoagulant effect is mediated by various possible mechanisms:
  - Endothelial effects: inhibition of prostacyclin production and loss of annexin V cellular shield
  - Platelet activation resulting in adhesion and aggregation
  - Interference of innate anticoagulant pathways (such as inhibition of protein C)
  - Complement activation
- Pregnancy-related complications are also a result of autoantibody-mediated effects:
  - Interference with expression of trophoblastic adhesion molecules resulting in abnormal placentation and placental thrombosis
- Proposed mechanisms: excess production of natural antibodies, molecular mimicry due to infections, exposure of phospholipid antigens during platelet activation, cardiolipin peroxidation, and genetic predisposition
- A "second hit" by environmental factors may be required to produce thrombosis.

## Genetics

Most cases of APS are acquired. There are a few studies of familial occurrence of anticardiolipin antibodies and LAC. A valine 247/leucine polymorphism in  $\beta 2$ -GP1 could be a genetic risk for the presence of anti- $\beta 2$ -GP1 antibodies and APS.

## RISK FACTORS

- Age >55 years in males, >65 years in females
- Cardiovascular risk factors (hypertension, diabetes, obesity, smoking, combined oral contraceptive use)
- Underlying autoimmune disease (SLE, rheumatoid arthritis, collagen vascular disease, Sjögren syndrome, idiopathic thrombocytopenic purpura, Behçet syndrome)
- Surgery, immobilization, pregnancy

## GENERAL PREVENTION

Risk factor modification: Control HTN and diabetes; smoking cessation; avoidance of oral contraceptives in high-risk patients; start thromboprophylaxis in established cases.

## COMMONLY ASSOCIATED CONDITIONS

- Autoimmune diseases: SLE (most common), scleroderma, Sjögren syndrome, dermatomyositis, and rheumatoid arthritis
- Malignancy
- Infections: viral, bacterial, parasitic, and rickettsial
- Certain drugs associated with APA production without increased risk of thrombosis: phenothiazines, hydralazine, procainamide, and phenytoin
- Hemolysis, elevated liver enzymes, and low platelet count in association with pregnancy (HELLP) syndrome
- Sneddon syndrome (APS variant syndrome with livedo reticularis, HTN, and stroke)

## DIAGNOSIS

Sapporo criteria, revised 2006:

- At least one of the following clinical criteria:
  - Vascular thrombosis

- <sup>3</sup> 1 clinical episodes of arterial, venous, or small vessel thrombosis, occurring within any tissue or organ and confirmed by unequivocal imaging studies or histopathology
- Superficial venous thrombosis does not meet the criteria for APS.
- Complications of pregnancy (any one of the following):
  - <sup>3</sup>3 consecutive spontaneous abortions before the 10th week of pregnancy, unexplained by maternal/paternal chromosomal abnormalities or maternal anatomic/hormonal causes
  - <sup>3</sup>1 unexplained deaths of morphologically normal fetuses (documented by ultrasonography or by direct examination) at <sup>3</sup> 10th week of gestation
  - <sup>3</sup> 1 premature births of morphologically normal newborn babies at <sup>2</sup>34th week of pregnancy due to severe preeclampsia, eclampsia, or placental insufficiency
- AND the presence of at least one of three laboratory findings (confirmed on <sup>3</sup> 2 occasions at least 12 weeks apart):
  - LAC detected in blood
  - Anticardiolipin IgG and/or IgM antibodies present at moderate or high levels in the blood (>40 GPL or MPL or >99th percentile) via a standardized ELISA
  - Anti- $\beta$ 2-GP1 IgG and/or IgM antibodies in blood at a titer >99th percentile by standardized ELISA

## HISTORY

- History of VTE or arterial thrombosis (stroke, MI)
- History of fetal loss or other obstetric complications
- Bleeding from thrombocytopenia if severe or acquired factor II deficiency
- Personal or family history of autoimmune disease

## PHYSICAL EXAM

- Signs of venous thrombosis in extremities
- Skin manifestations, including a vasculitic rash in the form of palpable purpura or livedo reticularis or lower extremity ulcers
- Livedo reticularis
- Cardiac murmurs
- Focal neurologic or cognitive deficits

## *DIFFERENTIAL DIAGNOSIS*

- Thrombophilic conditions
  - Inherited: deficiency of protein C, protein S, antithrombin III; mutation of factor V Leiden, prothrombin gene mutation
  - Acquired: neoplastic and myeloproliferative disorders, hyperviscosity syndromes, nephrotic syndrome
- Embolic disease secondary to atrial fibrillation, LV dysfunction, endocarditis, cholesterol emboli
- Heparin-induced thrombocytopenia
- Atherosclerosis
- CAPS: hemolytic-uremic syndrome, TTP, or malignant hypertension

## *DIAGNOSTIC TESTS & INTERPRETATION*

- LAC assay and IgG and IGM anticardiolipin antibodies by ELISA, and anti- $\beta$ 2-GP1 IgG and IgM antibodies are diagnostic tests of choice.
- The LAC assay combines at least two out of three screening tests (prolongation of aPTT, dilute Russell viper venom time [dRVVT], and kaolin clotting) with two confirmatory tests.
- Anti- $\beta$ 2-GP1 antibodies are important in the pathogenesis of thrombosis. A positive LAC assay recognizes antibodies against  $\beta$ 2-GP1 and prothrombin.
- The clinical significance of other autoantibodies (annexin V, phosphatidylserine, and phosphatidylinositol) remains unclear.

### *Initial Tests (lab, imaging)*

- CBC, PT/INR, aPTT, LAC, anticardiolipin antibodies, anti- $\beta$ 2-GP1 antibodies (1)[B]

---

P.65

- Further testing for secondary causes such as SLE when clinically suspected
- Imaging is based on clinical picture, suspected sites of thrombosis, and organ involvement.

### *Follow-Up Tests & Special Considerations*

- The results of LAC are difficult to interpret in patients treated with warfarin. Unfractionated heparin or LMWH and fondaparinux do not affect the LAC assay.
- Repeat testing at 12 weeks for persistence of APA.

## *Diagnostic Procedures/Other*

Biopsy of the affected organ system may be necessary to distinguish from vasculitis.

## *Test Interpretation*

Usual finding is thrombosis and minimal vascular or perivascular inflammation:

- Acute changes: capillary congestion and noninflammatory fibrin thrombi
- Chronic changes: ischemic hypoperfusion, atrophy, and fibrosis

## **TREATMENT**

### *MEDICATION*

#### *First Line*

- Primary thromboprophylaxis: Low-dose aspirin is indicated in asymptomatic carriers of APAs with SLE and in pregnancy. It may be considered in other asymptomatic carriers. Hydroxychloroquine is recommended in all antiphospholipid-positive SLE patients.
- Secondary thromboprophylaxis: All symptomatic, nonpregnant patients with APS need indefinite anticoagulation. The target INR depends on the severity and type of thrombosis:
  - Venous thrombosis (first episode): warfarin with target INR of 2.0 to 3.0
  - Arterial thrombosis or recurrent venous thrombosis despite anticoagulation: warfarin with target INR 3.0 to 4.0
  - LMWH and fondaparinux are alternatives.
- New oral anticoagulants such as rivaroxaban, apixaban, and dabigatran; all have been approved for treatment of DVT/PE; studies in APS are lacking; a prospective randomized controlled trial of warfarin versus rivaroxaban in patients with thrombotic APS and with a target INR or 2.5 is underway.
  - Rituximab may be an option in severe cases, possibly in those with hematologic and microthrombotic/microangiopathic manifestations (2,3)[B].
- Danaparoid, fondaparinux, and argatroban can be considered in APS patients with heparin-induced thrombocytopenia.
- Newer oral anticoagulants (dabigatran, apixaban, and rivaroxaban) may be alternatives to warfarin with few drug interactions and no need for monitoring. The presence of APA interferes with hemostatic mechanisms and can interfere with anticoagulants. Ongoing phase

III trials will help evaluate the role of new oral anticoagulants.

- Statins can decrease proinflammatory and prothrombotic state in APS. At this time, although they are not recommended in the absence of hyperlipidemia, APA-positive patients with recurrent thrombosis while adequately anticoagulated may benefit from statin therapy.
- B-cell inhibition may help in recalcitrant APS cases.
- Complement inhibition may be useful in cases refractory to anticoagulation, but further evaluation is needed.
- Peptide therapy may be a future treatment for APA-positive patients.
- Autologous hematopoietic stem cell transplantation may be an effective option for patients with concurrent complicated SLE and APS (4).
- Vitamin D deficiency/insufficiency should be corrected in all APA-positive patients, but its role in APS needs further study.
- Low-dose aspirin is superior to low-dose aspirin with low-dose warfarin due to decreased bleeding risk with no differences in number of thrombosis (5).
- CAPS: Anticoagulants and high-dose steroids may suffice in less severe cases. Aggressive treatment with either IVIG or plasmapheresis is often required in this life-threatening condition. These measures have improved survival to 66%.
- Treatment in pregnancy are as follows:
  - For women with no prior history of thrombosis and <sup>3</sup>2 early miscarriages, either 81 mg ASA alone or in combination with unfractionated heparin (5,000 to 10,000 units SC q12h) or LMWH (prophylactic dose). In those with a previous late pregnancy loss (>10 weeks' gestation) or preterm (<34 weeks) delivery due to severe preeclampsia, a combination of ASA and heparin is recommended.
  - In those with a history of thrombosis, low-dose ASA plus either therapeutic low-dose heparin (dosed every 8 to 12 hours to maintain mid-interval aPTT or factor Xa levels) or LMWH (therapeutic dose)
  - Refractory cases: Up to 30% of patients have recurrent pregnancy loss despite the use of ASA and heparin. There is no role for warfarin due to risk of teratogenicity (early pregnancy) and fetal bleeding (late pregnancy). Such cases are best managed in consultation with a maternal-fetal medicine specialist.

## ***SURGERY/OTHER PROCEDURES***

Patients with thrombosis may require thrombectomy or an IVC filter (depending on site) when anticoagulation is contraindicated.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Standard guidelines for monitoring to maintain INR at goal with warfarin therapy
- Close monitoring is required during pregnancy.

#### *DIET*

Heart-healthy diet. Patients on warfarin should avoid foods rich in vitamin K (kale, spinach, sprouts, greens).

#### *PATIENT EDUCATION*

- Compliance with warfarin therapy to keep INR at goal
- Awareness of drug and diet interactions with warfarin
- Avoid oral hormonal contraceptives.

#### *PROGNOSIS*

- Pulmonary HTN, neurologic involvement, myocardial ischemia, nephropathy, gangrene of extremities, and catastrophic APS are associated with a worse prognosis.
- 30% risk of recurrent thrombosis in the absence of adequate anticoagulation

#### **COMPLICATIONS**

- Pregnancy complications and pulmonary HTN are associated with higher morbidity and mortality.
- Thrombotic complications are the most common cause of death.

## Codes

### ICD10

- D68.61 Antiphospholipid syndrome
- D68.69 Other thrombophilia
- D68.62 Lupus anticoagulant syndrome

# Clinical Pearls

- APS can be either primary, secondary, or present as a severe microvascular disease known as CAPS.
- Both clinical and laboratory criteria are required for diagnosis. The latter must be confirmed on two separate occasions at least 12 weeks apart.
- Thrombotic manifestations of APS can be either venous or arterial. Patients require lifelong anticoagulation.

# Antithrombin Deficiency

Ryan Wargo, PharmD, BCACP

Michelle I. Henne, MD

Holly L. Baab, MD

## BASICS

### DESCRIPTION

- Antithrombin is a glycoprotein that inhibits thrombin by forming an irreversible complex.
- There are two active sites: one that binds to heparin and one that binds to thrombin/target enzyme
- Antithrombin can also inhibit factors Xa, IXa, and XIa. This process is catalyzed by the presence of heparin.
- Patients deficient in antithrombin have an increased incidence of venous thrombosis, including deep vein thrombosis (DVT) of the lower extremity. Arterial thrombosis is much less common in patients deficient in antithrombin.
- System(s) affected: cardiovascular, nervous, pulmonary, reproductive, hematologic, lymphatic/immunologic hemic/lymphatic/immunologic
- Synonym(s): antithrombin III deficiency

### EPIDEMIOLOGY

- Predominant age: Mean age of 1st thrombosis is in 2nd decade, usually after puberty.
- Predominant sex: male = female
- No racial or ethnic predisposition

### Incidence

1/20 to 1/200 with thrombophilia (1)

### Prevalence

1/2,000 to 1/5,000 of normal individuals (1)

## ETIOLOGY AND PATHOPHYSIOLOGY

- Hereditary deficiency (2)
  - Type I deficiency is characterized by low levels of antigen (decreased synthesis). Plasma levels of antithrombin are often <50%.
  - Type II deficiency is found when the antithrombin molecule is dysfunctional (decreased function).
  - Type II deficiencies are due to mutations in either the active center of antithrombin that binds the target enzyme or the heparin-binding site.
  - No patients homozygous for defects in the active center have been described, suggesting that this is a lethal condition. Patients heterozygous for mutations in the heparin-binding site rarely have thrombotic episodes.
- Acquired deficiency (2)
  - Many clinical conditions are associated with antithrombin deficiency, such as those listed under "Follow-Up Tests & Special Considerations," but limited evidence suggests these deficiencies contribute to increased thrombosis.

### *Genetics*

Autosomal dominant with variable clinical penetrance

## RISK FACTORS

- Oral contraceptives, pregnancy, surgery, trauma, and the use of hormone replacement therapy (HRT) increase the risk of venous thrombosis in patients with antithrombin deficiency.
- Patients with antithrombin deficiency and another prothrombotic state, such as factor V Leiden or the prothrombin G20210A mutation, have increased rates of thrombosis.

### *Pregnancy Considerations*

Increased thrombotic risk from 18% to 70% and specific complications may include preeclampsia, eclampsia, placental abruption, HELLP, premature birth, and recurrent pregnancy loss (3).

## GENERAL PREVENTION

Patients with antithrombin deficiency without a history of thrombosis do not require prophylactic treatment.

## COMMONLY ASSOCIATED CONDITIONS

Venous thromboembolism

# DIAGNOSIS

## HISTORY

- Previous thrombosis
- Family history of thrombosis
- Family history of antithrombin deficiency
- Recurrent pregnancy loss

## PHYSICAL EXAM

Signs consistent with a deep or superficial venous thrombosis or pulmonary embolism

## DIFFERENTIAL DIAGNOSIS

- Factor V Leiden
- Protein C deficiency
- Protein S deficiency
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocystinemia
- Prothrombin G20210A mutation
- Elevated factor VIII levels

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- For evaluation of a new clot in a patient at risk: CBC with peripheral smear, PT/INR, aPTT, thrombin time, lupus anticoagulant, antiphospholipid antibodies, factor VIII, anticardiolipin antibody, anti-B2 glycoprotein antibody, activated protein C resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A, homocysteine
- Testing should be done off heparin and at least 2 weeks after the 3 to 6 months course of oral anticoagulation.
- Another test to consider in the workup of antithrombin deficiency:

- Antithrombin-heparin cofactor assay measures the ability of heparin to bind to antithrombin, which neutralizes the action of thrombin and factor Xa. This is an indirect measure of factor Xa and thrombin inhibition; the factor Xa inhibition activity being more specific. This assay will detect all currently recognized subtypes of hereditary antithrombin deficiency.
- Drugs that may alter lab results: heparin (increased clearance), estrogen, and L-asparaginase (decreased synthesis) can lower antithrombin levels.

## *Follow-Up Tests & Special Considerations*

- The role of family screening for antithrombin deficiency is unclear because most patients with this mutation do not have thrombosis. Screening may be offered to pregnant women with a family history of factor protein S deficiency considering using oral contraceptives or pregnancy.
- Antithrombin levels are low in:
  - DIC
  - Sepsis
  - Burns
  - Severe trauma
  - Acute thrombosis
  - Pregnancy or postpartum
  - Liver disease
  - Nephrotic syndrome
  - Malignancy
  - Myeloproliferative disorders
- Antithrombin levels could be elevated by oral contraceptive pills.
- US to diagnose DVT if clinically indicated
- If DVT diagnosis in question, a negative D-dimer will help to rule out DVT.
- Spiral CT or V/Q scan to diagnose pulmonary embolism (PE) if clinically indicated
- V/Q scan may be difficult to interpret in patients with other lung disease.

## *Test Interpretation*

Venous thrombosis

## TREATMENT

### GENERAL MEASURES

Routine anticoagulation for asymptomatic patients with antithrombin deficiency is not recommended (3,4)[C].

### MEDICATION

#### First Line

- Patients with antithrombin deficiency and a first thrombosis should be anticoagulated initially with unfractionated heparin followed by oral anticoagulation with warfarin (5)[C].
- Heparin can be stopped after 5 total days of therapy provided the INR is 2 to 3 (5)[C].
- Oral anticoagulant should be started with the initial administration of heparin. Warfarin (Coumadin) 10 mg/day PO for the first 2 days, then adjusted to INR of 2 to 3. Patients should be maintained on warfarin for at least 6 months (5)[C].
- Recurrent thrombosis requires indefinite anticoagulation.
- Contraindications:
  - Active bleeding precludes anticoagulation; risk of bleeding is a relative contraindication to longterm anticoagulation.

---

P.67

- Precautions:
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Avoid IM injections.
  - Periodically check stool and urine for occult blood and monitor CBCs, including platelets.
  - Heparin-induced thrombocytopenia and/or paradoxical thrombosis with thrombocytopenia
- Significant possible interactions:
  - Agents that intensify the response to oral anticoagulants: Common anti-infective agents that potentially increase the effect of warfarin include ciprofloxacin, clarithromycin, erythromycin, metronidazole, trimethoprim-sulfamethoxazole, and azole antifungals. Additional interacting agents include alcohol, allopurinol, amiodarone, anabolic steroids, androgens, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfinpyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, and acetaminophen

Agents that diminish the response to oral anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

- See *Diet*.

## *Second Line*

- Argatroban: 0.4 to 0.5  $\mu\text{g}/\text{kg}/\text{min}$ . Case reports describing the use of this direct thrombin inhibitor in patients with antithrombin deficiency have been published (5)[C].
- Antithrombin III (ATnativ, Thrombate III): 50 to 100 IU/min IV titrated to antithrombin level desired. Precise role in therapy remains unclear (5)[C].
- Low-molecular-weight heparin (LMWH) is difficult to manage in this population but is preferred during pregnancy (3,5)[C].

## *ISSUES FOR REFERRAL*

- Recurrent thrombosis on anticoagulation
- Difficulty anticoagulating
- Genetic counseling

## *ADDITIONAL TREATMENT*

- Patients with severe antithrombin deficiency may require plasma replacement of thrombin in order for heparin to be effective.
- Compression stockings for prevention

## *SURGERY/OTHER PROCEDURES*

Thrombectomy may be indicated in complicated cases.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Complicated thrombosis, such as PE. Heparin initial bolus of 80 U/kg followed by infusion of 18 U/kg/hr. Frequent monitoring of the partial thromboplastin time (PTT) is important, as  $\pm 50\%$  of patients deficient in antithrombin require  $>40,000$  U of heparin daily to adequately prolong PTT.

### *Discharge Criteria*

Stable on anticoagulation

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

Warfarin use requires periodic INR measurements (monthly after initial stabilization) with a goal of 2 to 3.

#### *DIET*

Foods high in vitamin K may interfere with anticoagulation on warfarin. Consider nutrition consultation.

### PATIENT EDUCATION

- Patients should be educated about:
  - Use of oral anticoagulant therapy
  - Avoidance of NSAIDs while on warfarin
- The role of family screening is unclear, as most patients with this mutation do not have thrombosis. In a patient with a family history of factor V Leiden, consider screening during pregnancy or if considering oral contraceptive use.

### PROGNOSIS

- The odds ratio of thrombosis in a patient with antithrombin deficiency is much higher than in patients with other thrombophilic conditions. The recurrence rate is similarly high.
- There is no difference in clinical severity between patients with type I defects and type II mutations.
- Overall, prognosis is good, if appropriately anticoagulated.

### COMPLICATIONS

Recurrent thrombosis (requires indefinite anticoagulation)

Deep Vein Thrombophlebitis

## Codes

### ICD10

D68.59 Other primary thrombophilia

## Clinical Pearls

- Antithrombin levels will be low on heparin and during acute thrombosis.
- Diagnosis can be difficult. Conditions causing low levels of antithrombin III, such as pregnancy, liver disease, sepsis, and DIC, must be ruled out.

- Testing should be done off heparin and at least 2 weeks after the 3 to 6 months course of oral anticoagulation.
- For pregnant women with antithrombin deficiency but no prior history of VTE, antepartum and postpartum vigilance are recommended. Postpartum prophylaxis with prophylactic or intermediate-dose LMWH or vitamin K antagonists with target INR 2 to 3 for 6 weeks is only recommended if there is positive family history of VTE.

# Anxiety (Generalized Anxiety Disorder)

Jay A. Brieler, MD

Clarice Nelson, MD

## BASICS

### DESCRIPTION

- Persistent, excessive, and difficult-to-control worry associated with significant symptoms of motor tension, autonomic hyperactivity, and/or disturbances of sleep or concentration.
- System(s) affected: nervous (resulting in increased sympathetic tone and increased catecholamine release); may have secondary effects on other symptoms such as cardiac (tachycardia) and GI (nausea, irregular bowels)

### EPIDEMIOLOGY

#### Prevalence

- 12-month prevalence rate: 2-3%
- Lifetime prevalence rate: 5%
- Onset can occur any time in life but is typically during adulthood; median age of onset in the United States is 31 years.
- Predominant sex: female > male (2:1) (1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- May be mediated by abnormalities of neurotransmitter systems (i.e., serotonin, norepinephrine, and  $\gamma$ -aminobutyric acid [GABA])
- Associated with altered regional brain function (increased activity in the amygdala and prefrontal cortex) (2)

#### Genetics

- Strongly linked to depression in heritability studies
- A variant of the serotonin transporter gene (*5HT1A*) may contribute to both conditions; other genes (such as that for glutamic acid decarboxylase) also may play a role.

## **RISK FACTORS**

- Caucasian race
- Adverse life events: stress, medical illness, disability, unemployment, and childhood physical and mental abuse
- Family history
- Lack of social support
- Obesity
- Comorbid psychiatric disorders (3)

## **GENERAL PREVENTION**

- Regular exercise is associated with decreased anxiety and depression.
- CBT and parental intervention in children with social withdrawal or early anxiety may protect against the development of GAD (3).

## **COMMONLY ASSOCIATED CONDITIONS**

- Major depressive disorder (>60%), dysthymia, bipolar disorder
- Alcohol/drug abuse
- Cigarette smoking in adolescence
- Panic disorder, agoraphobia, simple phobia, social anxiety disorder, anorexia nervosa

## **DIAGNOSIS**

### **HISTORY**

- Diagnosis is primarily made through history taking. Pathologic anxiety must be distinguished from normal anxiety reactions.
- *DSM-5* criteria are as follows:
  - Symptoms of excessive anxiety and worry must occur more often than not for at least 6 months.
  - Patient finds it difficult to control the worry.
  - At least three additional criteria are required for diagnosis of GAD in adults; only one is required in children.

Restlessness or feeling keyed up or on edge

- Easily fatigued
- Difficulty concentrating or mind going blank
- Irritability
- Muscle tension
- Sleep disturbances (difficulty falling or staying asleep)
- Difficulty controlling worry
- Persistent worry must cause significant distress or impairment in social, occupational, or other areas of functioning.
- Focus of anxiety and worry is not consistent with or limited to the occurrence of other types of psychiatric disorders and is not directly related to posttraumatic stress disorder (PTSD).
- Symptoms are not the result of a substance or other *DSM-5* diagnosis (4).

## **PHYSICAL EXAM**

Useful for identifying other differential diagnosis (see below). No specific physical findings in GAD, but patient may exhibit irritability, bitten nails, tremor, or clammy hands.

## **DIFFERENTIAL DIAGNOSIS**

- Cardiovascular: ischemic heart disease, valvular heart disease (mitral valve prolapse), cardiomyopathies, arrhythmias, congestive heart failure
- Respiratory: asthma, chronic obstructive pulmonary disease, pulmonary embolism
- CNS: stroke, seizures, dementia, migraine, vestibular dysfunction, neoplasms
- Metabolic and hormonal: hyper- or hypothyroidism, pheochromocytoma, adrenal insufficiency, Cushing syndrome, hypokalemia, hypoglycemia, hyperparathyroidism
- Nutritional: thiamine, pyridoxine, or folate deficiency; iron deficiency anemia
- Drug-induced anxiety: alcohol, sympathomimetics (cocaine, amphetamine, caffeine), corticosteroids, herbals (ginseng)
- Withdrawal: alcohol, sedative-hypnotics
- Psychiatric: other disorders (e.g., panic disorder, obsessive-compulsive disorder, PTSD, social phobia, adjustment disorder, and somatization disorder)

## **DIAGNOSTIC TESTS & INTERPRETATION**

## *Initial Tests (lab, imaging)*

- Laboratory tests are normal. Initial tests may include thyroid-stimulating hormone, CBC, basic metabolic panel, urine drug screen, and ECG.
- GAD-2: 2-question self-reporting scale (22% positive predictive value [PPV]/78% negative predictive value [NPV])
- PHQ-4 provides a very brief screen for both anxiety and depression (3).

## *Diagnostic Procedures/Other*

### Psychological testing

- GAD-7: 5 additional questions; provides more detailed information for treatment (29% PPV/71% NPV); also may be indicative of panic disorder (GAD-7: 29% PPV/71% NPV).
- Hamilton Anxiety Scale (HAM-A), Anxiety Disorders Interview Schedule (ADIS-IV)
- In pediatric populations: ADIS-IV Parent and Child Version, Multidimensional Anxiety Scale for Children (MASC), Screen for Child Anxiety Related Emotional Disorders (SCARED)

## **TREATMENT**

### *GENERAL MEASURES*

- Assess for suicidality given increased risk.
- Identify and treat coexisting substance abuse and other psychiatric conditions.

### *MEDICATION*

#### Psychotherapeutic approaches

- Psychological treatments are effective in treating GAD: number needed to treat (NNT) = 2 (5) [A].
- Cognitive-behavioral therapy (CBT): Most well-studied psychological treatment; may improve comorbid conditions such as depression. Treatment of choice when available (3)[A]
- Relaxation/mindfulness training (3)[A]
- Psychodynamic psychotherapy: Treatment is focused on patient discovering and verbalizing unconscious conflicts (3)[C].
- Insufficient evidence to compare efficacy of the various treatment types at this time (5)[A]

## First Line

- SSRI and SNRI antidepressants have demonstrated efficacy, are well-tolerated, do not cause abuse/dependence, and treat comorbid depression. Data to compare between agents are limited (6)[A].
- SSRIs
  - Paroxetine (Paxil): initially 10 to 20 mg/day; may titrate to a maximum of 50 mg/day (no added benefit more than 20 mg/day)
  - Escitalopram (Lexapro): initially 10 mg/day; may titrate to a maximum of 20 mg/day
  - Sertraline (Zoloft): initially 25 mg/day; may titrate to a maximum of 200 mg/day
  - Fluoxetine (Prozac) and citalopram (Celexa) likely have efficacy for GAD but do not have FDA indications
- SNRIs
  - Duloxetine (Cymbalta): initially 30 mg/day; may titrate to a maximum of 120 mg/day
  - Venlafaxine XR (Effexor XR): initially 37.5 to 75 mg; may titrate up by 75 mg every 4 days to a maximum of 225 mg/day

## Second Line

- Benzodiazepines (efficacious in the short-term but less effective long-term), risk for dependence (5)[A]
  - Clonazepam (Klonopin): 0.25 mg BID; may increase to 4 mg/day divided BID
  - Diazepam (Valium): 2 to 5 mg BID-QID; may increase to a maximum of 40 mg/day
  - Lorazepam (Ativan): 0.5 mg BID-TID; may increase to 6 mg/day divided TID
  - Alprazolam (Xanax): 0.25mg TID; may increase to 4 mg/day
- Hydroxyzine (Vistaril, Atarax): CNS depressant, antihistamine, anticholinergic; decreased risk of dependence compared with benzodiazepines: usual dose: 50 to 100 mg PO QID; limit use in the elderly (3)[B]

---

P.69

- Azapirones: buspirone (BuSpar): less risk of dependence, although may be less effective. 15 mg/day divided BID-TID initially; maximum of 60 mg/day divided BID-TID (6)[A]
- Quetiapine (Seroquel): optimal dose 150 mg/day. Second-generation antipsychotic. Efficacious but less well-tolerated than SSRIs (6,7)[A].
- Pregabalin (Lyrica): has shown promise in decreasing anxiety scores and preventing relapse at

75 to 300 mg BID; may cause less sexual dysfunction and sleep disruption than SSRIs (6)[A]

- Tricyclic antidepressants (TCAs): imipramine (Tofranil): initially 25 to 50 mg/day; maximum of 300 mg/day, 100 mg/day in the elderly

## *Geriatric Considerations*

- Avoid TCAs and long-acting benzodiazepines; benzodiazepines may cause delirium.
- Pregabalin may cause dizziness and somnolence.

## *Pediatric Considerations*

- Black box warning (SSRIs): Antidepressants increase the risk of suicidal thinking and behavior in children, adolescents, and young adults.
- However, studies have also shown increase in suicide attempts in adolescents after SSRI discontinuation.
- Medications other than SSRIs have not been well-tested in pediatric populations.
- Anxiety and ADHD often co-occur.

## *Pregnancy Considerations*

- Buspirone: Category B: secreted in breast milk; inadequate studies to assess risk
- Benzodiazepines: Category D: may cause lethargy and weight loss in nursing infants; avoid breastfeeding if the mother is taking chronically or in high doses
- SSRIs: if possible, taper and discontinue. After 20 weeks' gestation, there is increased risk of pulmonary hypertension; mild transient neonatal syndrome of CNS; and motor, respiratory, and GI signs. Studies regarding risk of autism show mixed results. Most are Category C:
  - Paroxetine: Category D: conflicting evidence regarding the risk of congenital cardiac defects and other congenital anomalies
  - Hydroxyzine: Category C: Case reports of neonatal withdrawal exist.

## **ALERT**

### Precautions

- Benzodiazepines: age >65 years, hepatic insufficiency, respiratory disease/sleep apnea, renal insufficiency, suicidal tendency, contraindicated with narrow-angle glaucoma, precaution with open-angle glaucoma; sudden discontinuation, especially of alprazolam, increases seizure risk. Long-term use has potential for tolerance and dependence; use with caution in patients with history of substance abuse.

- Buspirone: hepatic and/or renal dysfunction; monoamine oxidase inhibitor (MAOI) treatment
- TCAs: advanced age, glaucoma, benign prostatic hypertrophy, hyperthyroidism, cardiovascular disease, liver disease, urinary retention, MAOI treatment
- SSRIs: use caution in those with comorbid bipolar disorder; may trigger mania. Avoid with medications that may increase risk of serotonin syndrome.

## *ISSUES FOR REFERRAL*

Concomitant depression or other comorbidities may warrant a psychiatric evaluation in light of increased suicide risk.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Patients frequently engage in complementary and alternative medicine (CAM); providers should be familiar with common therapies.
- Probable benefit but more study needed on several complementary therapies, including acupuncture, yoga, tai chi, and aromatherapy (8)[A].
- Kava: Some evidence for benefit over placebo in mild to moderate anxiety, but concern regarding potential hepatotoxicity persists. Safety is potentially affected by many factors, including manufacturing quality, plant part used, dose, and interactions with other substances (8)[A].
- Limited evidence to support other herbal medicines and St. John's wort likely not effective (8) [A]
- Strong evidence to support regular physical activity to relieve anxiety symptoms (8)[A]

## *INPATIENT CONSIDERATIONS*

Patients at risk of suicide should be treated as inpatients; may be considered as well for patients with substantial interference in daily function.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Follow up within 2 to 4 weeks from starting new medications.
- Medications should be continued past the initial period of response and probably for at least 6 months (6)[A].

- Monitor mental status on benzodiazepines and avoid drug dependence.
- Monitor BP, heart rate, and anticholinergic side effects of TCAs.
- Monitor all patients for suicidal ideation but especially those on SSRIs, SNRIs, and imipramine.

## **DIET**

- Limit caffeine intake.
- Avoid alcohol (drug interactions, high rate of abuse, potential for increased anxiety).

## **PATIENT EDUCATION**

- Regular exercise, especially yoga, may be beneficial for both anxiety and comorbid conditions.
- Psychoeducation regarding normal versus pathologic anxiety, the fight or flight response, and the physiology of anxiety can be extremely helpful.
- Moderate caffeine use; avoid alcohol and nicotine if possible.

## **PROGNOSIS**

- Probability of recovery is approximately 40-60%, but relapse is common.
- Comorbid psychiatric disorders and poor relationships with spouse or family make relapse more likely (1).

## Codes

### ICD10

- F41.9 Anxiety disorder, unspecified
- F41.1 Generalized anxiety disorder
- F41.8 Other specified anxiety disorders

## Clinical Pearls

- Psychiatric comorbidities, especially depression, are extremely common with GAD; patients are at increased risk for suicidality.
- CBT and SSRIs (possibly in combination) are the treatments of choice.
- Starting antidepressant medication at low doses, with careful titration to full therapeutic dosing, helps minimize side effects while maximizing efficacy.
- Benzodiazepines may be used initially but should be tapered and withdrawn if possible.
- CAM use is common, and certain therapies may be effective.

# Aortic Valvular Stenosis

Michael T. Tanoue, MD

Parag Goyal, MD

James M. Horowitz, MD, FACC

## BASICS

### DESCRIPTION

Aortic stenosis (AS) is a narrowing of the aortic valve area causing obstruction to left ventricular (LV) outflow. The disease has a long asymptomatic latency period, but development of severe obstruction or onset of symptoms such as syncope, angina, and congestive heart failure (CHF) are associated with a high mortality rate without surgical intervention.

### EPIDEMIOLOGY

- Most common cause of LV outflow obstruction in both children and adults
- Predominant age
  - <30 years: congenital
  - 30 to 65 years: congenital or rheumatic fever
  - >65 years: degenerative calcification of aortic valve

### Prevalence

- Affects 1.3% of population 65 to 74 years old, 2.4% 75 to 84 years old, 4% >84 years old (1)
- Bicuspid aortic valve: 1-2% of population. Bicuspid aortic valve predisposes to development of AS at an earlier age (1).

### ETIOLOGY AND PATHOPHYSIOLOGY

- Progressive aortic leaflet thickening and calcification results in LV outflow obstruction. Obstruction causes increased afterload and over time, decreased cardiac output.
- Increase in LV systolic pressure is required to preserve cardiac output; this leads to development of concentric left ventricular hypertrophy (LVH). The compensatory LVH preserves ejection fraction but adversely affects heart functioning.

- LVH impairs coronary blood flow during diastole by compression of coronary arteries and reduced capillary ingrowth into hypertrophied muscle.
- LVH results in diastolic dysfunction by reducing ventricular compliance.
- Diastolic dysfunction necessitates stronger left atrial (LA) contraction to augment preload and maintain stroke volume. Loss of LA contraction by atrial fibrillation can induce acute deterioration.
- Diastolic dysfunction may persist after relief of aortic stenosis due to the presence of interstitial fibrosis.
- Angina: increased myocardial demand due to higher LV pressure. Myocardial supply is compromised due to LVH.
- Syncope (exertional): can be multifactorial from inability to augment cardiac output due to the fixed obstruction to LV outflow; arrhythmias; or most commonly, abnormal baroreceptor response resulting in failure to appropriately augment blood pressure
- Heart failure: Eventually, LVH cannot compensate for increasing afterload resulting in high LV pressure and volume, which are accompanied by an increase in LA and pulmonary pressures.
- Degenerative calcific changes to aortic valve (2)
  - Mechanism involves mechanical stress to valve leaflets as well as atherosclerotic changes to the valve tissue. Bicuspid valves are at higher risk for mechanical stress.
  - Early lesions: subendothelial accumulation of oxidized LDL and macrophages and T lymphocytes (inflammatory response)
  - Disease progression: fibroblasts undergo transformation into osteoblasts. Protein production of osteopontin, osteocalcin, and bone morphogenetic protein-2 (BMP-2), which modulates calcification of leaflets.
- Congenital: unicuspid valve, bicuspid valve, tricuspid valve with fusion of commissures, hypoplastic annulus
- Rheumatic fever: chronic scarring with fusion of commissures

## **RISK FACTORS**

- Congenital unicommissural valve or bicuspid valve (1)
  - Unicommissural valve: Most cases were detected during childhood.
  - Bicuspid valve: predisposes to the development of AS earlier in adulthood (4th to 5th decade) compared to tricuspid valve (6th to 8th decade)
- Rheumatic fever (1)

- Prevalence of chronic rheumatic valvular disease has declined significantly in the United States.
- Most cases are associated with mitral valve disease.
- Degenerative calcific changes
  - Most common cause of acquired AS in the United States
  - Risk factors are similar to that of coronary artery disease (CAD) and include the following: hypercholesterolemia, hypertension, smoking, male gender, age, and diabetes mellitus.

## COMMONLY ASSOCIATED CONDITIONS

- CAD (50% of patients)
- Hypertension (40% of patients): results in double-loaded left ventricle (dual source of increased afterload as a result of obstruction from AS, and hypertension)
- Aortic insufficiency (common in calcified bicuspid valves and rheumatic disease)
- Mitral valve disease: 95% of patients with AS from rheumatic fever (RF) also have mitral valve disease
- LV dysfunction and CHF
- Acquired von Willebrand disease: Impaired platelet function and decreased vWF results in bleeding (ecchymosis and epistaxis) in 20% of AS patients. Severity of coagulopathy is directly related to severity of AS.
- Gastrointestinal arteriovenous malformations (AVMs)
- Cerebral or systemic embolic events due to calcium emboli

## DIAGNOSIS

### HISTORY

- Primary symptoms: angina, syncope, and heart failure (3). Angina is the most frequent symptom. Syncope is often exertional. Heart failure symptoms include fatigue, exertional dyspnea, orthopnea, paroxysmal nocturnal dyspnea, and shortness of breath.
- Palpitations
- Neurologic events (transient ischemic attack or cerebrovascular accident) secondary to embolization
- Geriatric patients may have subtle symptoms such as fatigue and exertional

dyspnea.

- Note: Symptoms do not always correlate with valve area (severity of AS) but most commonly occur when aortic valve area is  $< 1 \text{ cm}^2$ , jet velocity is  $> 4.0 \text{ m/s}$ , or the mean transvalvular gradient is  $> 40 \text{ mm Hg}$ .

## PHYSICAL EXAM

- Auscultation (3)
  - Harsh, systolic crescendo-decrescendo murmur is best heard at 2nd right sternal border and radiates into the carotid arteries. Peak of murmur correlates with severity of stenosis; later peaking murmur suggests greater severity.
  - High-pitched blowing diastolic murmur suggests associated aortic insufficiency.
  - Paradoxically split S2 or absent A2. Note: Normally split S2 reliably excludes severe AS.
  - S4 due to stiffening of the left ventricle
- Other associated signs (3) include *Pulsus parvus et tardus*: decreased and delayed carotid upstroke. LV heave. Findings of CHF: pulmonary and/or lower extremity edema

## DIFFERENTIAL DIAGNOSIS

- Mitral regurgitation: high-frequency, pansystolic murmur, best heard at the apex, often radiates to the axilla
- Hypertrophic obstructive cardiomyopathy: also systolic crescendo-decrescendo murmur but best heard at left sternal border and may radiate into axilla. Murmur intensity increases by changing from squatting to standing and/or by Valsalva maneuver.
- Discrete fixed subaortic stenosis: 50-65% has associated cardiac deformity (patent ductus arteriosus [PDA], ventricular septal defect [VSD], aortic coarctation)
- Aortic supralvalvular stenosis: Williams syndrome, homozygous familial hypercholesterolemia

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Chest x-ray (CXR) (1)
  - May be normal in compensated, isolated valvular AS
  - Boot-shaped heart reflective of concentric hypertrophy
  - Poststenotic dilatation of ascending aorta and calcification of aortic valve (seen on lateral PA

CXR)

- ECG: often normal ECG (ECG is nondiagnostic), or may show LVH, LA enlargement, and nonspecific ST-and T-wave abnormalities
- Echo indications
  - Initial workup
- Doppler echocardiogram: primary test in the diagnosis and evaluation of AS
- Assesses valve anatomy and severity of disease
- Assesses LV wall thickness, size, and function, and pulmonary artery pressure
  - In known AS and changing signs/symptoms
  - In known AS and pregnancy due to hemodynamic changes of pregnancy
- Echo findings
  - Aortic valve thickening, calcification
  - Decreased aortic valve excursion
  - Reduced aortic valve area
  - Transvalvular gradient across aortic valve
  - LVH and diastolic dysfunction
  - LV ejection fraction
  - Wall-motion abnormalities suggesting CAD
  - Evaluate for concomitant aortic insufficiency or mitral valve disease.
- AS severity based on echo values (4)
  - Stage A (at risk): bicuspid aortic valve, sclerosis, or other congenital abnormality; mean pressure gradient: 0 mm Hg; jet vel. <2 m/s

---

  - Stage B (progressive): bicuspid or trileaflet valve
    - Mild: mean pressure gradient: <20 mmHg; jet vel. 2.0 to 2.9 m/s
    - Moderate: mean pressure gradient: 20 to 40 mm Hg; jet vel. 3.0 to 3.9 m/s
  - Stage C (asymptomatic severe AS):
    - C1 (without LV dysfunction): AVA  $\geq$ 1.0 or AVAi  $\geq$ 0.6 cm<sup>2</sup>/m<sup>2</sup>; mean pressure gradient: 40

P.71

to 60 mm Hg; jet vel.  $\geq 4$  to 5 m/s

- C2 (with LV dysfunction): AVA  $\geq 1.0$  or AVAi  $\geq 0.6$  cm<sup>2</sup>/m<sup>2</sup>; mean pressure gradient:  $\geq 40$  mm Hg; jet vel.  $\geq 4$  m/s
- Stage D (symptomatic severe AS):
  - D1 (high-gradient): AVA  $\geq 1.0$  cm<sup>2</sup>; mean pressure gradient:  $>40$  mm Hg; jet vel.  $>4$  m/s
  - D2 (low-flow/low-gradient with reduced EF  $<50\%$ ): AVA  $\geq 1.0$  cm<sup>2</sup>; mean pressure gradient:  $<40$  mm Hg; jet vel.  $<4$  m/s
  - D3 (low-gradient, normal EF  $\geq 50\%$  or paradoxical low-flow severe AS): AVA  $\geq 1.0$  cm<sup>2</sup>; AVAi  $\geq 0.6$  cm<sup>2</sup>/m<sup>2</sup> and stroke volume index  $<35$  mL/m<sup>2</sup>; mean pressure gradient:  $<40$  mm Hg; jet vel.  $<4$  m/s

## *Diagnostic Procedures/Other*

- Exercise stress testing
  - Asymptomatic patients with severe AS (5)[B]: helpful to uncover subtle symptoms or changes, abnormal BP (increase  $<20$  mm Hg), and ECG changes (ST depressions). 1/3 of patients develop symptoms with exercise testing; STOP testing at this point.
  - Symptomatic patients (5)[B]: DO NOT perform exercise stress testing, as it may induce hypotension or ventricular tachycardia.
  - CHF patients (5)[B]: Dobutamine stress echocardiography is reasonable to evaluate patients with low-flow/low-gradient AS and LV dysfunction.
- Cardiac catheterization
  - Perform prior to aortic valve replacement in patients with suspected CAD (5)[B]. Determines need for coronary artery bypass graft (CABG). If unambiguous diagnosis of AS, perform only coronary angiography.
  - Can also use if noninvasive testing is inconclusive or if there is discrepancy between severity of symptoms and findings on echo
  - Measures transvalvular flow and transvalvular pressure gradient, which facilitates calculation of effective valve area
  - Hemodynamic measurements with infusion of dobutamine can be useful for evaluation of patients with low-flow/low-gradient AS and LV dysfunction.

## *TEST INTERPRETATION*

- Aortic valve: nodular calcification on valve cusps (initially at bases), cusp rigidity, cusp thickening, and fibrosis
- LVH, myocardial interstitial fibrosis
- 50% incidence of concomitant CAD

## TREATMENT

### MEDICATION

- No effective medical therapy for severe or symptomatic AS
- Prevention: currently no recommended medical therapy. Statins have been thought to slow progression if initiated during mild disease. However, this has not been supported by large, randomized controlled trials.
- Antibiotic prophylaxis against recurrent RF is indicated for patients with rheumatic AS (penicillin G 1,200,000 U IM q4wk; duration varies with age and history of carditis).
- Antibiotic prophylaxis is no longer indicated for prevention of infective endocarditis (5).
- Comorbidities: hypertension: angiotensin-converting enzyme (ACE) inhibitors, start with low dose and increase cautiously. Be cautious of vasodilators, which may cause hypotension.

### SURGERY/OTHER PROCEDURES

- The only proven treatment for AS is valve replacement.
- Indications for aortic valve replacement (AVR) surgery:
  - Symptomatic and severe high-gradient AS by history or exercise testing (4)[B]
  - Asymptomatic, severe AS and LVEF < 50% (4)[B]
  - Severe AS (stage C or D) when undergoing other cardiac surgery (4)[B]
- AVR surgery is reasonable in patients who are:
  - Asymptomatic with severe AS (C1) with jet vel.  $\geq 5$  m/s and low surgical risk, decreased exercise tolerance, or have an exercise fall in blood pressure (4)[B]
  - Symptomatic stage D2, with a low-dose dobutamine stress with jet vel.  $\geq 4.0$  m/s or mean pressure gradient  $\geq 40$  mm Hg with  $\geq 1.0$  cm<sup>2</sup> at any dobutamine dose (4)[B]
  - Symptomatic stage D3 with LVEF >50% if clinical and hemodynamic data support valve obstruction as likely cause of symptoms (4)[C]

- Stage B who are undergoing other cardiac surgery, or asymptomatic stage C1 with rapid disease progression and low surgical risk (4)[C]

## **ALERT**

Note: If the aortic valve area is  $> 1.5 \text{ cm}^2$  and the gradient is  $< 15 \text{ mm Hg}$ , there is no benefit from AVR.

- Transcatheter aortic valve replacement (TAVR) offers a less invasive option for some patients (6).
  - For those who are high at surgical risk and considered inoperable, TAVR has demonstrated superiority to medical therapy.
  - For those who are high at surgical risk, TAVR has demonstrated noninferiority to surgical AVR (6).
  - For those who are intermediate at surgical risk, TAVR may emerge as a reasonable alternative to surgical risk, though this indication has not yet been approved in the United States.
  - Valve-in-valve TAVR can be considered in high-risk patients with failed surgically implanted bioprosthetic valves.
- Percutaneous balloon valvuloplasty may have role in palliation or as a bridge to valve replacement in hemodynamically unstable or high-risk patients (5)[C] but is not recommended as an alternative to valve replacement.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Advise patients to immediately report symptoms referable to AS.
- Asymptomatic patients: yearly history and physical (5)[C]
- Serial ECHO: yearly for severe AS, every 1 to 2 years for moderate AS, every 3 to 5 years for mild AS (5)[B]

### *PATIENT EDUCATION*

#### Physical activity limitations

- Asymptomatic mild AS: no restrictions
- Asymptomatic moderate to severe AS: Avoid strenuous exercise. Consider exercise stress test

prior to starting exercise program.

## PROGNOSIS

- 25% mortality/year in symptomatic patients who do not undergo valve replacement; average survival is 2 to 3 years without AVR surgery.
- Median survival in symptomatic AS (3): heart failure: 2 years; syncope: 3 years; angina: 5 years
- Perisurgical mortality: AVR surgery has 4% mortality rate; AVR + CABG has 6.8% mortality rate
- Adverse postoperative prognostic factors: age, heart failure (HF) New York Heart Association (NYHA) class III/IV, cerebrovascular disease, renal dysfunction, CAD

# Codes

## ICD10

- I35.0 Nonrheumatic aortic (valve) stenosis
- I06.0 Rheumatic aortic stenosis
- Q23.0 Congenital stenosis of aortic valve

## Clinical Pearls

- AS is diagnosed on physical exam by a systolic crescendo-decrescendo murmur and delayed and diminished pulses.
- Symptomatic AS most commonly presents as angina, syncope, and heart failure.
- Symptomatic AS has a very poor prognosis, unless treated with surgical intervention.

# Appendicitis, Acute

Anila Khaliq, MD

Komel Safdar, MBBS

Fariah Hanna, MBBS

## BASICS

### DESCRIPTION

- Acute inflammation of the vermiform appendix, first described by Reginald Fitz in 1886
- Arising from the base of the cecum in right lower quadrant (RLQ); can be localized anterior, posterior, medial, lateral to the cecum, as well as in the pelvis. Vascular supply by appendicular artery, a branch of the ileocolic artery. Nerve supply derived from the superior mesenteric plexus.
- Most common cause of acute surgical abdomen

### EPIDEMIOLOGY

- Predominant age: 10 to 30 years: rare in infancy
- Predominant sex: slight male predominance:
  - Ages 10 to 30: male > female (3:2)
  - Age >30: male = female

### Incidence

- 1 case per 1,000 people per year
- Lifetime incidence 1 in every 15 persons (7%)

### Pregnancy Considerations

- Most common extrauterine surgical emergency
- No more common in pregnant versus nonpregnant women
- Higher rate of perforation; more likely to present with peritonitis

## ETIOLOGY AND PATHOPHYSIOLOGY

The cause is thought to be obstruction of the appendiceal lumen. This leads to distention, ischemia, and bacterial overgrowth. Without intervention, most cases of appendicitis will lead to perforation and subsequently abscess formation or generalized peritonitis. Causes of obstruction:

- Fecaliths (most common)
- Lymphoid tissue hyperplasia (in children)
- Vegetable, fruit seeds, and other foreign bodies
- Intestinal worms (ascarids)
- Strictures, fibrosis, neoplasms

### Genetics

First-degree relative with history of appendicitis increases risk, although no direct genetic link has been found.

## RISK FACTORS

Adolescent males, familial tendency, intra-abdominal tumors

## DIAGNOSIS

- Diagnosis of acute appendicitis relies on the history and physical examination with supporting laboratory studies and imaging.
- Scoring systems
  - Modified Alvarado Scoring System (MASS): The use of MASS in the diagnosis of acute appendicitis has been reported to improve the diagnostic accuracy and consequently reduces negative appendectomy and complication rates.
  - Use of MASS in for acute appendicitis in female patients should be supplemented by additional investigations like abdominal ultrasound or laparoscopy.
  - A MASS score above 7 should indicate appendectomy without the need for further imaging.
- A cutoff point of 6 for the MASS score will yield higher sensitivity and a better diagnosis of appendicitis but provides an increase in negative appendectomy.
- Pediatric Appendicitis Score—this has been developed to help predict the likelihood of acute appendicitis, although diagnosis is still considered a clinical decision.

## HISTORY

- Classic history is vague periumbilical pain, followed by anorexia/nausea/vomiting. Over the next 4 to 48 hours, pain migrates to the RLQ.
- Only 50% of patients present with this classic history.
- Pain before vomiting (~100% sensitive), abdominal pain (~100%), pain migration (50%)
- Anorexia (~100%), nausea (90%), vomiting (75%), obstipation
- Atypical symptoms and pain associated with a retrocecal or pelvic appendix

## *PHYSICAL EXAM*

- Fever; temperature > 100.4°F (may be absent); tachycardia
- RLQ tenderness; maximal tenderness at McBurney point (1/3 the distance from the anterior superior iliac spine to the umbilicus)
- Voluntary and involuntary guarding
- Rovsing sign: RLQ pain with palpation of left lower quadrant
- Psoas sign: pain with right thigh extension (retrocecal appendix)
- Obturator sign: pain with internal rotation of flexed right thigh (pelvic appendix); local and suprapubic pain on rectal exam (pelvic appendix)
- Pelvic and rectal exams are necessary to rule out other causes of lower abdominal pain (e.g., pelvic inflammatory disease, prostatitis).
- Serial exams can be useful in indeterminate cases.

## *DIFFERENTIAL DIAGNOSIS*

- GI:
  - Gastroenteritis, inflammatory bowel disease
  - Diverticulitis, ileitis
  - Cholecystitis, pancreatitis
  - Intussusception, volvulus
- Gynecologic:
  - Pelvic inflammatory disease, ectopic pregnancy
  - Ovarian cyst, ovarian torsion, tubo-ovarian abscess

Endometriosis

- Ruptured Graafian follicle
- Urologic:
  - Testicular torsion, epididymitis
  - Kidney stones, prostatitis, cystitis, pyelonephritis
- Systemic:
  - Diabetic ketoacidosis
  - Henoch-Schönlein purpura
  - Sickle cell crisis
  - Porphyria
- Other:
  - Acute mesenteric lymphadenitis
  - No organic pathologic condition
  - Hernias
  - Psoas abscess
  - Rectus sheath hematoma
  - Epiploic appendagitis
  - Pneumonia (basilar)

### *Pediatric Considerations*

- Decreased diagnostic accuracy of history and physical exam
- Higher fever, more vomiting and diarrhea

### *Pregnancy Considerations*

- Difficult diagnosis
- Normal response to infection/inflammation is suppressed.
- Appendix displaced out of pelvis by gravid uterus

### *Geriatric Considerations*

Decreased diagnostic accuracy, more likely to be atypical presentation

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- Leukocytosis: WBC  $>10,000/\text{mm}^3$  (70%)
- Polymorphonuclear predominance or left shift ( $>90\%$ )
- Human chorionic gonadotropin (hCG) (if negative, rule out ectopic pregnancy)
- Urinalysis: hematuria, pyuria ( $\div 30\%$ )
- C-reactive protein: nonspecific inflammatory marker. When paired with an elevated WBC can increase the likelihood of appendicitis.
- Drugs may alter lab results: antibiotics, steroids.
- Imaging used in cases of suspected appendicitis when the diagnosis is not clear; is helpful to detect complications (abscess, perforation)
- Plain films: little utility, nonspecific findings, may visualize fecalith
- CT scan with contrast: sensitivity  $\div 91-98\%$ ; specificity 95-99%; imaging modality of choice. However, growing concern regarding radiation dose, particularly in young patients (1)[A].
- Ultrasound: alternative in pregnant patients, children, and in women with suspected gynecologic pathology. Sensitivity and specificity vary by report and accuracy depends on the skill of the ultrasonographer. Can rule in appendicitis but cannot reliably exclude the diagnosis. Starting with an ultrasound and, if negative, obtaining a CT scan has been proposed as an effective workup strategy (2)[B].
- MRI: growing in popularity for diagnosing pregnant patients but also may be useful for patients with contrast allergies and/or patients with renal failure. Limitations include cost, availability, and time required to complete study.
- Radioisotope-labeled WBC scans: may be used in patients with indeterminate CT scans and suspected appendicitis as an alternative to observation or surgery. Limitations include availability and time required to complete study.

## Diagnostic Procedures/Other

Exploratory laparotomy/laparoscopy: Acceptable nontherapeutic appendectomy rates vary based on age and gender and may be higher for females of childbearing age than males.

## Test Interpretation

- Acute appendiceal inflammation, local vascular congestion, obstruction
- Gangrene, perforation with abscess (15-30%)
- Fecalith

## TREATMENT

### GENERAL MEASURES

Surgery (appendectomy) is the standard of care for acute, uncomplicated appendicitis.

### MEDICATION

#### *First Line*

- Uncomplicated acute appendicitis: perioperative dose of antibiotic (3)[A]: single dose of cefoxitin or ampicillin/sulbactam (Unasyn) or cefazolin plus metronidazole
- Gangrenous or perforating appendicitis:
  - Broadened antibiotic coverage for aerobic and anaerobic enteric pathogens
  - Piperacillin and tazobactam (Zosyn) or ticarcillin and clavulanate (Timentin) or a 3rd-generation cephalosporin plus metronidazole are initial options.
  - Adjust dosage and choice of antibiotic based on intraoperative cultures.
  - Continue antibiotics for at least 7 days postoperatively or until patient becomes afebrile with normal WBC count.

#### *Second Line*

- Among patients with CT-proven, uncomplicated appendicitis, antibiotic treatment did not meet the prespecified criterion for noninferiority compared with appendectomy. Most patients randomized to antibiotic treatment for uncomplicated appendicitis did not require appendectomy during the 1-year follow-up period, and those who required appendectomy did not experience significant complications.
- In the case of acute appendicitis complicated by abscess formation or phlegmon in pediatric patients, some studies show initial conservative management with antibiotics alone to carry fewer risks and complications than emergent appendectomy (4)[A].
- Uncomplicated acute appendicitis: clindamycin plus one of the following: ciprofloxacin, levofloxacin, gentamicin, or aztreonam
- Gangrenous or perforated appendicitis: ciprofloxacin or levofloxacin plus metronidazole or

monotherapy with a carbapenem (imipenem and cilastatin, meropenem, ertapenem)

## ***ISSUES FOR REFERRAL***

All cases of appendicitis require emergent surgical consultation.

## ***SURGERY/OTHER PROCEDURES***

- Inpatient surgery is indicated.
- Patients presenting within 72 hours of onset:
  - Immediate appendectomy; laparoscopic favored unless perforation (5)[A]
  - Drainage of abscess, if present
- Patients who present late (>4 to 5 days after symptom onset) may be treated initially with antibiotics, bowel rest, and drainage of any abscess. Later (4 to 10 weeks) appendectomy can then be performed in this subgroup only.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

All patients with appendicitis should be admitted.

### ***IV Fluids***

Fluid resuscitation with normal saline (NS) or lactated Ringer (LR) solution. Correct fluid and electrolyte deficits.

### ***Nursing***

Preoperative preparation

### ***Discharge Criteria***

Tolerating PO; return of bowel function; afebrile; normal WBC

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

- Return to work is usually possible 1 to 2 weeks following most uncomplicated appendicitis.
- Restrict activity for 4 to 6 weeks after surgery: No heavy lifting (> 10 lb) or strenuous physical activity.

## *PATIENT EDUCATION*

Contact physician for postoperative development of:

- Anorexia, nausea, vomiting
- Abdominal pain, fever, chills
- Signs/symptoms of wound infection

## *PROGNOSIS*

- Generally uncomplicated course in young adults with unruptured appendicitis
- Factors increasing morbidity and mortality: extremes of age, presence of appendiceal rupture
- Morbidity rates:
  - Nonperforated appendicitis: 3%
  - Perforated appendicitis: 47%
- Mortality rates:
  - Unruptured appendicitis: 0.1%
  - Ruptured appendicitis: 3%
  - Patients >60 years of age make up 50% of total deaths from appendicitis.
  - Older patients with ruptured appendix: 15%

## *Pediatric Considerations*

- Rupture earlier
- Rupture rate: 15-60%

## *Pregnancy Considerations*

- Rupture rate: 40%
- Fetal mortality rate: 2-8.5%

## *Geriatric Considerations*

Rupture rate: 67-90%

## **COMPLICATIONS**

Wound infection, intra-abdominal abscess; lower rate with antibiotic prophylaxis (6)[A], intestinal fistulas

- Intestinal obstruction, paralytic ileus, incisional hernia
- Liver abscess (rare), pyelophlebitis

Algorithm: Abdominal Rigidity

## Codes

### ICD10

- K35.80 Unspecified acute appendicitis
- K35.2 Acute appendicitis with generalized peritonitis
- K35.3 Acute appendicitis with localized peritonitis

## Clinical Pearls

- Classic history of anorexia with periumbilical pain localizing to RLQ is the cornerstone of diagnosis for acute appendicitis.
- Diagnosis is much more challenging in children, pregnant patients, and the elderly due to varying symptoms and signs.
- In equivocal cases, CT of abdomen and pelvis is the diagnostic test of choice, although ultrasound and MRI are useful alternatives.
- Acute appendicitis is the most common surgical emergency during pregnancy.

# Arteritis, Temporal

Cynthia M. Waickus, MD, PhD

## BASICS

### DESCRIPTION

- Technically termed giant cell arteritis (GCA)
- A chronic, generalized, cellular, and humoral immune-mediated vasculitis of large- and mediumsized vessels, predominantly affecting the cranial arteries originating from the aortic arch, although vascular involvement may be widespread. Inflammation of the aorta is observed in 50% of cases (1,2).
- Frequent features include fatigue, headaches, jaw claudication, loss of vision, scalp tenderness, polymyalgia rheumatica (PMR), and aortic arch syndrome (decreased or absent peripheral pulses, discrepancies of blood pressure, arterial bruits) (3).

### EPIDEMIOLOGY

- The mean age of onset is approximately 75 years; rare <50 years.
- Women are affected about 2 times as often as men.
- Most common vasculitis in individuals of Northern European decent (Scandinavian countries)
- Rare in Asians and African Americans

### Incidence

- Prevalence in individuals > 50 years: 1 in 500 (1,4,5)
- Cyclic incidence: peaking every 5 to 7 years

### ETIOLOGY AND PATHOPHYSIOLOGY

- The exact etiology of GCA remains unknown, although current theory suggests that advanced age, ethnicity, and specific genetic predisposition lead to a maladaptive response to endothelial injury, intimal hyperplasia, and ultimately vascular stenosis.
- Temporal arteritis (TA) is a chronic, systemic vasculitis primarily affecting the elastic lamina of medium- and large-sized arteries. Histopathology of affected arteries is marked by transmural

inflammation of the intima, media, and adventitia, as well as patchy infiltration by lymphocytes, macrophages, and multinucleated giant cells. Mural hyperplasia can result in arterial luminal narrowing, resulting in subsequent distal ischemia (1,4,5).

- Current theory regarding the etiology of TA is that a maladaptive response to endothelial injury leads to an inappropriate activation of T cell-mediated immunity via immature antigen-presenting cells. The subsequent release of cytokines within the arterial vessel wall can attract macrophages and multinucleated giant cells, which form granulomatous infiltrates and give diseased vessels their characteristic histology. This also leads to an oligoclonal expansion of T cells directed against antigens in or near the elastic lamina. Ultimately, this cascade results in vessel wall damage, intimal hyperplasia, and eventual stenotic occlusion (5,6).
- In recent years, GCA and polymyalgia rheumatica (PMR) have increasingly been considered to be closely related conditions (3,4).

## Genetics

The gene for HLA-DRB1-04 has been identified as a risk factor for TA, and polymorphisms of ICAM-1 have also been implicated (2).

## RISK FACTORS

- Increasing age >70 years is the greatest risk factor.
- Genetic predisposition
- Environmental factors influence susceptibility (6,7,8).
- Heavy smoking and atherosclerotic disease are risk factors for females but not for males.

## COMMONLY ASSOCIATED CONDITIONS

Polymyalgia rheumatica (PMR) may develop either before or after the arteritis (4,6).

## DIAGNOSIS

### HISTORY

- Most common presenting symptom is headache (2/3 of patients) (1,3,7)[A].
- Constitutional symptoms (fever, fatigue, weight loss)
- Any visual disturbances (amaurosis fugax, diplopia)
- Vision loss (20% of patients)
- Jaw claudication (presence of symptom significantly increases likelihood of a positive biopsy)

- Scalp tenderness or sensitivity
- Claudication of upper extremities or tongue
- Symptoms of polymyalgia rheumatica (shoulder and hip girdle pain and stiffness)
- Distal extremity swelling/edema
- Upper respiratory symptoms

## PHYSICAL EXAM

- Temporal artery abnormalities (beading, prominence, tenderness)
- Typically appear *ÒillÓ*
- Decreased peripheral pulses in the presence of large vessel diseases
- Funduscopic exam shows pale and edema of the optic disk, scattered cotton wool patches, and small hemorrhages.
- Unlike other forms of vasculitis, GCA rarely involves the skin, kidneys, and lungs.

## DIFFERENTIAL DIAGNOSIS

- *Classification criteria are as follows:*
  - Age >70 years
  - New localized headache
  - Temporal artery abnormality (tenderness to palpation, decreased or absent pulses)
  - ESR >50 mm/hr
  - Abnormal temporal artery biopsy showing vasculitis with predominance of mononuclear cell infiltration or granulomatous inflammation
- Three or more of the above symptoms: 95% sensitivity/91% specificity for GCA diagnosis (The American College of Rheumatology criteria for the classification of GCA)

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- ESR >50 mm/hr (86% sensitivity), although nonspecific (27%); infrequently, may be normal (3,7)[A]
- C-reactive protein (CRP) >2.45 mg/dL is a more sensitive marker of inflammation (97% sensitivity) and is associated with increased odds of a positive biopsy result.

- A normal ESR and/or CRP renders the diagnosis of GCA unlikely.
- Platelet count  $>400 \times 10^3$
- Acute-phase reactants (fibrinogen, interleukin-6) are frequently elevated, but very nonspecific, and reserved for diagnostically difficult cases.
- Mild anemia: very nonspecific but may be associated with a lower rate of ischemic complications.
- Color Doppler US of the temporal artery may identify vascular occlusion, stenosis, or edema (Halo sign); it is low cost and noninvasive but also very operator dependent and does not significantly improve on the clinical exam. It may aid in the diagnosis of larger vessel involvement (9).
- MRI and MRA allow for noninvasive evaluation of both the vessel lumen and the vessel wall and assess mural thickness (edema) and lumen diameter (occlusion). The information may aid in diagnosis, but results are affected by prior glucocorticoid treatment, perhaps indicating more value in assessing the disease course or relapse. Cost, logistics, and lack of validity data preclude its routine usefulness.
- Positron emission tomography (PET), like MRI/MRA and color Doppler, may be useful in diagnostically difficult cases to quantify the inflammatory burden and early in the course of disease, as the metabolic changes occur prior to structural vascular damage, but it also lacks studies to support its use (10).

### *Follow-Up Tests & Special Considerations*

- Development of aortic aneurysms (late and potentially serious complication of GCA) can lead to aortic dissection.
- Due to the risk of irreversible vision loss, treatment with high-dose steroids should be started on strong clinical suspicion of temporal arteritis, prior to the temporal biopsy being done.

### *Diagnostic Procedures/Other*

- Gold standard diagnostic study: histopathologic examination of the temporal artery biopsy specimen
- Overall sensitivity is 87%.
- The temporal artery is chosen because of its accessibility in the systemic disease, but any accessible cranial artery may be chosen.
- Length of biopsy specimen should be at least 2 cm to avoid false-negative results, as skip lesions may occur.

- Diagnostic yield of biopsy may be increased if procedure is coupled with imaging (high-resolution MRI or color Doppler US).
- Bilateral temporal artery biopsy should not be performed unless the initial histopathology is negative and the suspicion for GCA remains high.
- May be negative in up to 42% of patients, especially in large vessel disease
- Biopsy results are not affected by prior glucocorticoids, so treatment should not be delayed.

## *Test Interpretation*

- Inflammation of the arterial wall, with fragmentation and disruption of the internal elastic lamina
- Multinucleated giant cells are found in <50% of cases and are not specific for the disease.
- Temporal arteritis occurs in three histologic patterns: classic, atypical, and healed.

P.75

## **TREATMENT**

### *MEDICATION*

#### *First Line*

Glucocorticoids:

- Prolonged treatment with glucocorticoids has been the mainstay of treatment and should be initiated immediately when the diagnostic suspicion for GCA is high (3)[A],(11)[B].
- Because of the risk of irreversible vision loss, treatment with high-dose steroids should be started on strong clinical suspicion of temporal arteritis, prior to the temporal biopsy being done.
- The typical dose of prednisone is 60 mg/day (or 1 mg/kg/day). Steroids should not be in the form of alternate day therapy, as this is more likely to lead to a relapse of vasculitis.
- The initial dose of steroids is continued for 2 to 4 weeks and slowly tapered over 9 to 12 months. Tapering may require <sup>3</sup>2 years.
- Oral steroids are at least as effective as IV steroids, except in the treatment of acute visual loss where IV steroids appear to offer significant benefit over oral steroids.
- It has been suggested that low-dose aspirin might be effective for patients with GCA (12)[B].
- Patients on corticosteroids should be placed on therapy to minimize osteoporosis unless there

are contraindications.

## *Second Line*

- Methotrexate as an adjunct to glucocorticoid therapy may have a modest effect in decreasing the relapse rate of temporal arteritis (13)[B],(14,15)[A].
- Therapies directed at TNF as adjunct to steroids have not shown significant benefit (15,16)[B]. Therapies directed at IL-6 blockade (tocilizumab - TCZ), and cyclophosphamide, have shown some benefit in patients who have not adequately responded to glucocorticoids (17,18)[A].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Sun avoidance and protection of the head and the face from photodamage may eventually prove to be important preventive measures for TA.

### *Patient Monitoring*

- TA is typically self-limited and lasts several months or years.
- Overall, TA does not seem to decrease longevity. Nevertheless, it may lead to serious complications such as visual loss, which occurs in about 15-20% of patients.
- Another complication of GCA is the development of aortic aneurysms, usually affecting the ascending aorta. Yearly chest x-rays may be useful to identify this problem (19).
- About 50% of the patients with GCA will eventually develop polymyalgia rheumatica (stiffness of shoulder and hip girdle).

### *DIET*

Calcium and vitamin D supplementation

### *PATIENT EDUCATION*

- Consequences of discontinuing steroids abruptly (adrenal insufficiency, disease relapse)
- Risks of long-term steroid use (infection, hyperglycemia, weight gain, impaired wound healing, osteoporosis, hypertension)
- Possibility of relapse and importance of reporting new headaches and vision changes to provider immediately

## PROGNOSIS

- Life expectancy is not affected by the disease unless severe aortitis is present.
- Once vision loss has occurred, it is unlikely to be recovered, but treatment resolves the other symptoms and prevents future vision loss and stroke.
- In most patients, glucocorticoid therapy can eventually be discontinued without complications. In a few patients, however, the disease is chronic and prednisone must be continued for years.
- Disease relapse is a distinct possibility.

## COMPLICATIONS

- Vision loss with delayed diagnosis
- Glucocorticoid-related toxicity

### Codes

#### ICD10

- M31.6 Other giant cell arteritis
- M31.5 Giant cell arteritis with polymyalgia rheumatica

## Clinical Pearls

- Due to the risk of irreversible vision loss, treatment with high-dose steroids (prednisone 60 mg/day) should be started immediately in patients suspected of temporal arteritis.
- Temporal artery biopsy is the gold standard for diagnosis. Temporal artery biopsy is not likely to be affected by a few weeks of treatment.
- Treatment consists of a very slow steroid taper. Bone protection therapy and low-dose aspirin should be considered.
- Normal ESR level = value of age/2 for men and age + 10/2 for women

# Arthritis, Juvenile Idiopathic

Donna-Marie McMahon, DO, FAAP

Kathleen M. Vazzana, DO

## BASICS

### DESCRIPTION

- Juvenile idiopathic arthritis (JIA) is the most common chronic pediatric rheumatologic disease.
- JIA is associated with significant disability
  - Age of onset: <16 years
  - Joint swelling, restricted range of motion, warmth, redness, or pain are the most common symptoms.
  - <sup>3</sup>6 weeks of symptoms before diagnosis is common.
- Seven (International League of Associations for Rheumatology-ILAR) subtypes, determined by clinical characteristics in the first 6 months of illness (1):
  - Systemic (Still disease): 10%; preceded by febrile onset of <sup>3</sup>2 weeks with rash, serositis, hepatosplenomegaly, or lymphadenopathy (1)
  - Polyarticular rheumatoid factor (RF) (+): 5-10%; <sup>3</sup>5 joints involvement (1); large and small joints; RF positive on two tests <sup>3</sup>3 months apart (2)
  - Polyarticular RF (-): 10-30%; <sup>3</sup>5 (large and small) joints involved (1); RF negative (2)
  - Oligoarticular: 30-60%; involvement of 1 to 4 joints; risk for chronic uveitis in ANA (+) females (1) and axial skeletal involvement in older boys (2). Types: (i) monoarthritis (50%): knee, ankle, elbow; (ii) extended type: >4 joints after first 6 months
  - Psoriatic arthritis: 5%; arthritis with psoriasis or arthritis with >2 of the following: dactylitis, nail changes, psoriasis in a first-degree relative (1)
  - Enthesitis arthritis: 1-7%; oligo-polyarthritis in small or large joints and enthesitis plus two of the following: sacroiliac or lumbosacral pain, Reiter syndrome family history or presence of acute anterior uveitis, HLA-B27 (+), ankylosing spondylitis, inflammatory bowel disease (1) [C]
  - Undifferentiated arthritis: arthritis that does not fulfill above categories or patients

overlapping 32 categories (2)

- System(s) affected: musculoskeletal, hematologic, lymphatic, immunologic
- Synonyms: juvenile chronic arthritis; juvenile arthritis; juvenile rheumatoid arthritis (JRA); Still disease (2)

## ***EPIDEMIOLOGY***

- Male = female (1); onset: throughout childhood; 54% of cases occur in children 0 to 5 years (3).
- Polyarticular RF (+): female > male, 3:1 (2); onset: late childhood or adolescence (1)
- Polyarticular RF (-): female > male, 3:1; onset: early peak, 2 to 4 years; late peak, 6 to 12 years (2)
- Oligoarticular: female > male, 5:1; onset: 2 to 4 years (2)
- Psoriatic: female > male, 1:0.95 (2); onset: early peak, 2 to 3 years; late peak, 10 to 12 years (1)
- Enthesitis: female > male, 1:7; onset: early peak, 2 to 4 years; late peak, 6 to 12 years (2)
- Affected patients have an increased risk of developing cancer, although short-term risk is low (4).

## ***Incidence***

2 to 20/100,000 children <16 years in developed nations

## ***Prevalence***

16 to 150/100,000 children <16 years in developed nations (1)

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

- Immunodysregulation of both humoral and cellular immunity. T lymphocytes play a key role.
- Genetic predisposition. IL2RA/CD25 and VTCN1 have been implicated as genetic loci.
- Environmental triggers, possibly infectious
  - Rubella or parvovirus B19 (5)
  - Heat shock proteins (5)
- Immunoglobulin or complement deficiency

## ***Genetics***

- Human leukocyte antigen (HLA) class I and II alleles
- HLA-A2 = early onset oligoarthritis in females
- HLA-DRB1\*11 increases risk of systemic and oligo-JIA.
- HLA-B27 increases risk of enthesitis-related arthritis.
- HLA-DR4 is associated with polyarthritis RF (+) (5).

## **RISK FACTORS**

Female gender 3:1

## **GENERAL PREVENTION**

None identified.

## **COMMONLY ASSOCIATED CONDITIONS**

Other autoimmune disorders, chronic anterior uveitis (iridocyclitis), nutritional impairment, growth issues (5)

## **DIAGNOSIS**

Clinical criteria: age of onset <16 years and >6 weeks duration of objective arthritis (swelling or restricted range of motion of a joint accompanied by heat, pain, or tenderness with no other form of childhood arthritis) in ≥3 joints

### **HISTORY**

- Arthralgias, fever, fatigue, malaise, myalgias, weight loss, morning stiffness, rash
- Limp, if lower extremity involvement
- Arthritis for ≥6 weeks

## **PHYSICAL EXAM**

- Arthritis: swelling, effusion, limited range of motion, tenderness, pain with motion, warmth
- Rash, rheumatoid nodules, lymphadenopathy, hepato- or splenomegaly, enthesitis, dactylitis

## **DIFFERENTIAL DIAGNOSIS**

- Legg-Calve-Perthes, toxic synovitis, growing pains, Perthes disease
- Septic arthritis, osteomyelitis, viral infection, mycoplasmal infection, Lyme disease

- Reactive arthritis: postinfectious, rheumatic fever, Reiter syndrome
- Inflammatory bowel disease: Crohn disease or ulcerative colitis
- Hemoglobinopathies, rickets
- Leukemia (particularly acute lymphocytic leukemia), bone tumors (osteoid osteoma), neuroblastoma
- Vasculitis, Henoch-Schönlein purpura, Kawasaki disease
- Systemic lupus erythematosus, dermatomyositis, mixed connective tissue disease, sarcoidosis, systemic sclerosis, collagen disorders
- Farber disease
- Accidental or nonaccidental trauma

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- CBC: leukocyte count is normal or markedly elevated (systemic), lymphopenia, reactive thrombocytosis, anemia. LFT (rule out hepatitis) and renal function studies (prior to therapy with potentially nephrotoxic drugs)
- Joint-fluid aspiration/analysis: Exclude infection.
- ESR and C-reactive protein are typically elevated. CRP often disproportionately elevated.
- Myeloid-related proteins (MRP 8/14) associated with flares
- Antinuclear antibodies (ANA)-positive patients have increased risk of uveitis. ANA positive in up to 70% with oligoarticular JIA
- RF (+): 2-10% (usually polyarticular); poor prognosis
- HLA-B27 positive: enthesitis-related arthritis
- Diagnostic radiography, MRI, US, and CT; no one modality has superior diagnostic value (6) [A].
- Radiograph of affected joint(s): **early** radiographic changes: soft tissue swelling, periosteal reaction, juxta-articular demineralization; **later** changes: joint space loss, articular surface erosions, subchondral cyst formation, sclerosis, joint fusion
- If orthopnea, obtain ECG to rule out pericarditis.
- Radionuclide scans: for infection/malignancy
- CT is best for bony abnormalities. MRI can assess synovial hypertrophy and cartilage

degeneration. Also more sensitive to monitor clinical responsiveness to treatment in peripheral joints and disease activity

## *Follow-Up Tests & Special Considerations*

- RF and ANA are present in mixed connective tissue disease (7)[B].
- When interpreting results of dual energy x-ray photon absorptiometry scans, it is important to use pediatric, not adult, controls as normative data.

## *Diagnostic Procedures/Other*

**Synovial biopsy:** if synovial fluid cannot be aspirated or if infection is suspected in spite of negative synovial fluid culture

## *Test Interpretation*

Synovial biopsy→ synovial cells hyperplasia, hyperemia, infiltration of small lymphocytes, and mononuclear cells

## **TREATMENT**

### **GENERAL MEASURES**

- Goal is to control active disease, extraarticular manifestations, and achieve clinical remission.
- All patients require regular (every 3 to 4 months for oligo-JIA and in ANA-positive patients) ophthalmic exams to uncover asymptomatic eye disease, particularly for 3 years following diagnosis.
- Moist heat or electric blanket for morning stiffness
- Splints for contractures
- Aerobic exercise: weight-bearing or aquatic therapy to improve functional capacity (8)

### **MEDICATION**

#### *First Line*

- 24 joints
- NSAIDs: adequate in ~50%, symptoms often improve within days, full efficacy 2 to 3 months
- Drugs for children include the following:
  - Ibuprofen: 30 to 50 mg/kg/day, divided QID; max dose 2,400 mg/day

- Naproxen: 10 mg/kg/day, divided BID; max dose 1,250 mg/day
- Tolmetin sodium: 20 mg/kg/day, TID or QID; max dose 30 mg/kg/day
- Diclofenac: 2 to 3 mg/kg, divided TID; max dose 50 mg TID

- Indomethacin: 1 to 2 mg/kg/day, divided BID to QID; max dose of 4 mg/kg/day
  - NSAIDs are contraindicated if known allergy.
  - Precautions: may worsen bleeding diatheses; use caution in renal insufficiency and hypovolemic states; take with food.
  - Significant possible interactions: may lower serum levels of anticonvulsants and blunt the effect of loop diuretics. NSAIDs may increase serum methotrexate levels.
- Intra-articular long-acting corticosteroids: immediately effective. Improve synovitis, joint damage, and contractures and prevent leg length discrepancy (7)[B].
    - Indication: patients with oligoarthritis who have failed a 2-month NSAID trial or with poor prognosis factors (9)[C]
    - Example: triamcinolone hexacetonide
  - 35 Joints
    - If high disease activity or a failed 1 to 2 months NSAID trial→methotrexate (9)[C]

## Second Line

- 30-40% of patients require addition of disease-modifying antirheumatic drugs (DMARDs): methotrexate, sulfasalazine, leflunomide, and tumor necrosis factor (TNF) antagonists (etanercept, infliximab, adalimumab); newer biologic therapies, including IL-1 and IL-6 receptor antagonists, are currently under investigation
- Methotrexate: 10 mg/m<sup>2</sup>/wk PO or SC (7)[B]
  - Plateau of efficacy reached with 15 mg/m<sup>2</sup>/wk; further increase in dosage is not associated with therapeutic benefit (10)[A].
- Sulfasalazine: oligoarticular and HLA-B27 spondyloarthritis (7)[B]
- Etanercept: 0.8 mg/kg (max of 50 mg/dose) given SC q1wk or 0.4 mg/kg SC twice a week (max of 25 mg/dose)
- Infliximab: 5 mg/kg q6-8wk
- Adalimumab: if weight 15 kg to <30 kg, 20 mg SC q2wk; if weight ≥30 kg, 40 mg SC q2wk

- Tocilizumab: IL-6 antibody demonstrating efficacy in phase III open label trials; ongoing studies to evaluate efficacy and appropriate dosing (7)[B]
- Anakinra: IL-1 receptor antibody under investigation with phase II and III clinical trials for systemic JIA(7)[B]
- Begin treatment with TNF- $\alpha$  inhibitors in children with a history of arthritis in <sup>2</sup>4 joints and significant active arthritis despite treatment with methotrexate or arthritis in <sup>3</sup>5 joints and any active arthritis following an adequate trial of methotrexate (9)[C].
- Begin treatment with anakinra in children with systemic arthritis and active fever whose treatment requires a second medication, in addition to systemic glucocorticoids (9)[C].
- Analgesics, including narcotics for pain control

## *ISSUES FOR REFERRAL*

- Pediatric rheumatologist for management of JIA
- Orthopedics as needed for articular complications
- Ophthalmology: for suspected uveitis
- Physical therapy to maintain range of motion, improve muscle strength and prevent deformities
- Occupational therapy to maintain and improve appropriate age-related functional activities
- Behavioral health if difficulty coping with disease

## *SURGERY/OTHER PROCEDURES*

- Total hip and/or knee replacement for severe disease
- Soft tissue release if splinting/traction unsuccessful
- Correct limb length or angular deformities
- Synovectomy is rarely performed.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Patient nonambulatory
- Signs/symptoms of pericarditis
- Persistent fever or diagnostic confusion to facilitate evaluation and workup

- Need for surgery

## *Discharge Criteria*

Resolution of fever and swelling or serositis

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Determined by medication and disease activity

- NSAIDs: periodic CBC, urinalysis, liver function tests (LFTs), renal function tests
- Aspirin and/or other salicylates: transaminase and salicylate levels, weekly for 1st month, then every 3 to 4 months
- Methotrexate: monthly LFTs, CBC, BUN, creatinine

#### *DIET*

Regular diet with special attention to adequate calcium, iron, protein, and caloric intake

### *PATIENT EDUCATION*

- Ongoing education of patients and families with attention to psychosocial needs; school issues; educational needs; behavioral strategies for dealing with pain and noncompliance; use of health care resources; support groups
- Printed and audiovisual information available from local arthritis foundation

### *PROGNOSIS*

- 50-60% ultimately remit, but functional ability depends on adequacy of long-term therapy (disease control, maintaining muscle and joint function).
- Poor prognosis is noted in patients with active disease at 6 months, polyarticular disease, extended pauciarticular disease course, female gender, RF (+), ANA (+), persistent morning stiffness, rapid appearance of erosions, hip involvement

### **COMPLICATIONS**

- Blindness, band keratopathy, glaucoma, short stature, micrognathia if temporomandibular joint involvement, debilitating joint disease, disseminated

intravascular coagulation, hemolytic anemia

- NSAIDs: peptic ulcer, GI hemorrhage, CNS reactions, renal disease, leukopenia
- DMARDs: bone marrow suppression, hepatitis, renal disease, dermatitis, mouth ulcers, retinal toxicity (antimalarials; rare)
- TNF antagonists: higher risk of infection
- Osteoporosis, avascular necrosis
- Methotrexate: Folate supplementation decreases hepatic/GI symptoms; may reduce stomatitis (11)[A].
- Macrophage activation syndrome: decreased blood cell precursors secondary to histiocyte degradation of marrow

## Codes

### ICD10

- M08.90 Juvenile arthritis, unspecified, unspecified site
- M08.80 Other juvenile arthritis, unspecified site
- M08.00 Unsp juvenile rheumatoid arthritis of unspecified site

## Clinical Pearls

- JIA is the most common form of arthritis in children.
- JIA should be included in the differential diagnosis for a limping child.

- High-titer RF correlates with disease severity; positive RF titers confer poorer prognosis.
- DMARDs improve JIA-associated symptoms (12)[A].

# Arthritis, Rheumatoid (RA)

Mariya Milko, DO, MS

Rubaiya Mallay, DO, FACOI, ACR

## BASICS

### DESCRIPTION

- Chronic systemic autoimmune inflammatory disease with symmetric polyarthritis and synovitis
- Progressive chronic inflammation leads to large and small joint destruction, deformity, decline in functional status, and premature morbidity/mortality.
- System(s) affected: musculoskeletal, skin, hematologic, lymphatic, immunologic, muscular, renal, cardiovascular, neurologic, pulmonary

### Geriatric Considerations

- Increased contribution of age-related comorbidities
- Decreased medication tolerance; increased incidence of hydroxychloroquine-associated maculopathy and sulfasalazine-induced nausea/vomiting, NSAID-induced gastric ulcers, and corticosteroid induced diabetes

### Pregnancy Considerations

- Use effective contraception in patients taking disease-modifying antirheumatic drugs (DMARDs).
- Methotrexate and other DMARDS such as Arava, cyclophosphamide, and cyclosporine are teratogenic. Appropriate medication regimens for pregnant or breastfeeding patients is important.
- 50-80% of patients improve during pregnancy because of immunologic tolerance. Most relapse in 6 months. First episode may occur in pregnancy or postpartum.

### EPIDEMIOLOGY

#### Incidence

- 25 to 30/100,000 cases for males

- 50 to 60/100,000 cases for females
- Peak age is 35 to 50 years.

## *Prevalence*

General population: 0.3-1%

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- An insult (e.g., infection, smoking, trauma) precipitates an initial autoimmune reaction where antibody-complement complex activation ultimately results in endothelial activation, synovial hypertrophy, and joint inflammation. RA is a systemic disorder. Pathogenesis is mediated by abnormal B- and T-cell interactions and overproduction of cytokines such as TNF and IL-6.
- Multifactorial disease with genetic, host (hormonal, immunologic), and environmental (socioeconomic, smoking) factors

## *Genetics*

- RA is 50% attributable to genetic causes. HLA-DR4 is a shared epitope in over 50% of cases.
- Monozygotic twin concordance 15-20%, suggesting that nongenetic roles also contribute to development of RA
- HLA DR4 and DRB1, STAT4, and CD40+ persons have increased relative risk.

## **RISK FACTORS**

- Family history: First-degree relatives have 2- to 3-fold increased risk.
- Smokers have elevated relative risk of 1.4-2.2%
- Pregnancy and breastfeeding for 24 months lowers risk.
- Women affected 3:1, difference diminishes with age.

## **COMMONLY ASSOCIATED CONDITIONS**

Accelerated atherosclerosis, pericarditis, amyloidosis, Felty syndrome (RA, splenomegaly, neutropenia), interstitial lung disease, pulmonary nodules, rheumatoid nodules, vasculitis, lymphomas, and carpal tunnel syndrome

## **DIAGNOSIS**

### **HISTORY**

- Symmetric polyarthritis most commonly affecting the hands and feet
- Constitutional symptoms: fatigue, malaise, weight loss, low-grade fevers (1,2)[A],(3)[C]
- Articular symptoms: tender/swollen joints, early morning stiffness (at least 60 minutes), and difficulty with activities of daily living (ADL) (1,2)[A],(3)[C]
- Extra-articular involvement: skin, pulmonary, cardiovascular, and ocular symptoms; onset is typically insidious. Patients rarely present with abrupt onset of symptoms and extra-articular manifestations (1,2)[A],(3)[C].

## PHYSICAL EXAM

- Evaluate for swollen, boggy, or tender joints:
  - Small joints: metacarpophalangeal (MCP), proximal interphalangeal (PIP) leading to Boutonnière and swan-neck deformities, wrist, 2nd to 5th metatarsophalangeal (MTP), and thumb interphalangeal (IP) joints. Pain and decreased ROM; usually symmetric and affected first
  - Large joints: shoulders, elbows (rheumatoid nodules), hips, knees, and ankles will show evidence of effusions.
- Joint deformity, nodules, and fusion are late findings.
- Extra-articular findings associated with RA:
  - Splenomegaly, lymphadenopathy, subcutaneous nodules, peripheral neuropathy, and atlantoaxial joint instability. Axial migration of dens into foramen magnum may contribute to occipital headaches.
  - Cardiovascular mortality increased with RA → evaluate rhythm, presence of murmurs (valvular dysfunction), and for effusion
  - Pulmonary disease typically manifests as effusion and fibrosis (dullness, rales).

## DIFFERENTIAL DIAGNOSIS

Sjögren syndrome, systemic lupus erythematosus (SLE), systemic sclerosis, adult Still disease, psoriatic arthritis, polymyalgia rheumatica (older), seronegative polyarthritis, erosive osteoarthritis, crystal arthropathy, septic arthritis, chronic Lyme disease, viral-induced arthritis (parvovirus B19, hepatitis C [with cryoglobulinemia]), occult malignancy, vasculitis (Behçet syndrome), inflammatory bowel disease, RS3PE hemochromatosis, sarcoidosis (3)[B]

## DIAGNOSTIC TESTS & INTERPRETATION

## *Initial Tests (lab, imaging)*

- CBC: Mild anemia and thrombocytosis are common and relate to disease activity (3)[C].
- ESR and C-reactive protein (CRP) are nonspecific markers used to assess disease activity (1)[A].
- Rheumatoid factor (RF): >1:80 in 70-80% of patients with RA (most commonly IgM Ab) (1)[A]
- Anticyclic citrullinated peptide antibodies (anti-CCP antibodies); specificity >90% (1)[A]
- Antinuclear antibody: present in 20-30%
- Electrolytes, creatinine, liver function, and urinalysis to assess comorbid states, establish baseline, and to assist with medication management (4)[C]
- Radiographic findings help establish diagnosis and monitor treatment (2)[C].
- MRI of hands and wrists looking for erosions, pannus, synovitis
- Diagnostic ultrasound: to assess for synovial thickening/erosions.
- Plain film radiographs are preferred for RA:
  - Initial radiographs of the hands, wrists, and feet
  - Hallmark is a lack of bony remodeling and symmetric joint space narrowing.
  - Earliest pattern of erosions is loss of cortical distinctness, followed by dot-dash pattern of cortical bone loss. Marginal erosions at cortical bone within joint capsule not covered by cartilage result in mouse-ear erosions.

## *Follow-Up Tests & Special Considerations*

- 2010 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria
- Patients with symptoms in at least one joint and definite clinical synovitis not explained by another disease
- A score of  $\geq 6$  is needed for to classify as definite RA
  - Joint score
    - 1 large joint: 0
    - 2 to 10 large joints: 1
    - 1 to 3 small joints (with or without large joints; distal interphalangeal [DIP], 1st MCP, and 1st MTP joints are excluded from assessment.): 2
    - 4 to 10 small joints (with/without large joints): 3

- > 10 joints (at least 1 small joint): 5
- Serology score: At least one test is needed: negative RF (rheumatoid factor) and negative ACPA (anticitrullinated protein antibody): 0; low positive RF or low positive ACPA: 2; high positive RF or high positive ACPA: 3
- Acute-phase reactants score: At least one result is needed. Normal CRP and normal ESR: 0; abnormal CRP or ESR: 1
- Self-reported symptom duration score: <6 weeks: 0; ≥6 weeks: 1
- Patients with a score of <6/10 do not meet RA criteria, and reevaluation is likely necessary over time (3)[C].

## *Diagnostic Procedures/Other*

- Joint aspiration can exclude crystal arthropathy and septic arthritis.
- Synovial fluid
  - Gram stain, cell count, culture, crystal analysis, and overall appearance
  - Yellowish-white, turbid, poor viscosity in RA
  - WBC increased (3,500 to 50,000 cells/mm<sup>3</sup>)
  - Protein: >4.2 g/dL (42 g/L)
  - Serum-synovial glucose difference >30 mg/dL (>1.67 mmol/L)

## **TREATMENT**

Goals: Control disease activity and progression, relieve pain, maintain or improve function, and promote self-management to maximize activities of daily living.

P.79

## **GENERAL MEASURES**

- Target treatment to achieve remission or minimize disease activity, prevent structural damage and disability (5)[A].
- Early, aggressive treatment prevents structural damage and disability (1)[A],(2,3,4)[C].
- Periodic evaluation of disease activity and extent of synovitis is important (1)[A].
- Arthritis self-management education (1)[A]

# MEDICATION

- Early DMARD therapy to slow disease progression and induce remission is standard of care (1) [A].
- Symptomatic therapy in addition to DMARDs:
  - NSAIDs: naproxen (500 mg BID) or ibuprofen (800 mg TID) for symptomatic relief. If poor response to initial NSAID after 2 weeks, try alternative NSAID (1)[A].
  - If still poor response, prednisone (5 to 30 mg/day); taper off NSAID or prednisone as soon as effective control of disease activity with DMARD is achieved (1)[A].
- Notes on DMARD therapy History of hepatitis, malignancy, and heart failure (HF) may alter first-line therapy (4)[C].
- Nonbiologic DMARDs
  - Should be started within 3 months of making the diagnosis of RA (1)[A]
  - Due to greater convenience, lower toxicity profiles and quicker onset of action, initial therapy is a nonbiologic DMARD: methotrexate, sulfasalazine, and leflunomide have comparable efficacy (1)[A].
  - Methotrexate is the first-line DMARD in patients with active RA; the optimal dosage should be reached within no more than 4 to 8 weeks (5)[A].
  - Methotrexate (MTX) (Rheumatrex): 7.5 to 25 mg/week PO. DMARD with the most predictable benefit; many significant side effects, but the addition of folate reduces toxicity. Monitor CBC and renal and liver function every month × 3 months. Give with folic acid 1 mg PO daily. Contraindicated in renal and hepatic diseases, pregnancy, and breastfeeding (1) [A].
  - Sulfasalazine (SSZ): 500 mg/day, increase to 2 g/day over 1 month; max: 2 to 3 g/day; 6-month trial. Monotherapy for low disease activity. Monitor CBC, liver enzymes every 2 weeks × 3 months, then every month × 3 months, then every 3 months. Screen for G6PD deficiency.
  - Leflunomide (Arava): loading dose 100 mg/day × 3 days, then 10 to 20 mg/day. GI side effects and potentially teratogenic; contraindicated in pregnancy. Monitor CBC, LFTs, and phosphate monthly for the first 6 months. Stop use if ALT >3× upper limit normal.
  - Antimalarials: hydroxychloroquine (HCQ) (Plaquenil) 400 mg QHS for 2 to 3 months, then 200 mg at bedtime; 6-month trial is usual. Usually used to treat milder forms or in combination with other DMARDs. Ophthalmologic exam every 6 to 12 months due to potential maculopathy. Adjust dose in renal insufficiency.
  - Minocycline (100 mg BID)

- Biologic DMARDs:
  - TNF inhibitors: IV infliximab (Remicade), SC adalimumab (Humira), and SC etanercept (Enbrel). No evidence that one is superior. Certolizumab pegol (Cimzia) and golimumab (Simponi), approved in moderate to severe disease.
  - Janus kinase (JAK) inhibitor: Xeljanz, Interleukin-6 (IL-6) receptor antagonist: Actemra is approved to treat moderate to severe active rheumatoid arthritis in which methotrexate did not work well.
  - Abatacept (Orencia) and Anakinra (Kineret) no longer considered cost-effective or efficacious treatment for RA (1)[A].
  - Rituximab (Rituxan) is recommended with or without MTX for active moderate to severe RA with inadequate response to other DMARDs or failed anti-TNF agent (1)[A].
- All biologics are best used in combination with methotrexate (5)[A].
- Optimal dosage and duration of treatment unclear. Check purified protein derivative (PPD or QuantiFERON gold) prior to treatment and periodic CBC. Risk of lymphoma and CHF (1)[A].
- Ensure vaccinations are up-to-date prior to starting biologic agents. Recommended vaccinations: Pneumococcal, HPV, hepatitis B, influenza, varicella zoster (4)[C]
- Flare-ups
  - Intra-articular steroids: If disease is well-controlled after ruling out intra-articular infection (1)[A]. Can also use Acthar, a repository corticotropin injection. (5)[A].

## *ADDITIONAL THERAPIES*

- Capsaicin cream: Apply 3 to 4 times per day. Best results are seen after 2 to 4 weeks of continuous use.
- Interdisciplinary care and management including physical therapy to minimize the consequences of loss of function, joint damage, maladaptive coping, and social isolation (1,4,6)[A]

## *SURGERY/OTHER PROCEDURES*

- Surgical treatment including synovectomy, tendon reconstruction, joint fusion, and joint replacement may be considered to prevent disability in RA unresponsive to therapy or in advanced RA (1)[A].
- Important to get flexion/extension films of cervical spine prior to any surgery due to high risk of atlantoaxial joint instability and subluxation

## ONGOING CARE

The goals of comprehensive, interdisciplinary care are to inhibit the disease process, reduce pain, optimize symptom management (fatigue and stiffness), preserve joint integrity and joint function, maintain social and occupational roles, and maximize quality of life.

### *FOLLOW-UP RECOMMENDATIONS*

- Encourage full activity as tolerated. Avoid heavy work or exercise during active (flare) phases. Emphasize exercise, mobility, and reduction of joint stress.
- Promote general health and psychosocial well-being.

### *Patient Monitoring*

Address risk factors and evaluate for cardiovascular disease and osteoporosis. Disease Activity Score (DAS28) questionnaire for disease activity periodically and Health Assessment Questionnaire (HAQ) for functional status yearly.

### *DIET*

Most beneficial diets for symptom control are glutenfree and vegetarian. Some benefits have been noted for Óallergen-free, Ó elemental, and Mediterranean diets.

### *PROGNOSIS*

- Poor prognostic findings
  - Persistent moderate to severe disease; early or advanced age at disease onset
  - Many affected joints; swelling and pain in affected joints, positive MCP squeeze test, and PIP and MCP symmetric involvement
- 50% cannot function in their primary jobs within 10 years of onset.

## Codes

### ICD10

- M06.9 Rheumatoid arthritis, unspecified
- M05.60 Rheu arthritis of unsp site w involv of organs and systems
- M05.30 Rheumatoid heart disease w rheumatoid arthritis of unsp site

### Clinical Pearls

- RA is an idiopathic, chronic, and systemic inflammatory disease characterized by symmetric polyarthritis and synovitis.
- Rheumatoid arthritis occurs in 1% of the U.S. population.
- Females have more articular disease; males have more systemic manifestations.
- Plain films are the imaging modality of choice in RA.
- Treatment with DMARDs within 3 months of diagnosis slows disease progression and improves chance for remission.
- Methotrexate is the first-line DMARD in patients with active RA.
- Atlantoaxial joint involvement leads to instability; avoid unnecessary manipulation of the

cervical spine.

# Arthritis, Septic

Jeffrey P. Feden, MD, FACEP

## BASICS

### DESCRIPTION

- Infection due to bacterial invasion of the joint space
- Systems affected: musculoskeletal
- Synonyms: suppurative arthritis; infectious arthritis; pyarthrosis; pyogenic arthritis; bacterial arthritis

### EPIDEMIOLOGY

- May occur at any age; higher incidence in very young and elderly
- Incidence:
  - 4 to 10/100,000 annual case rate (1)
- Prevalence: 27% of patients presenting with monoarticular arthritis have nongonococcal septic arthritis (2).
- Gender differences:
  - Gonococcal: female > male
  - Nongonococcal: male > female

### ETIOLOGY AND PATHOPHYSIOLOGY

- Many different pathogenic organisms
- Nongonococcal:
  - *Staphylococcus aureus* (most common organism in adults)
- MRSA risk increased in elderly, intravenous drug users (IVDU), postsurgical
  - *Streptococcus* spp. (second most common in adults)
  - Gram-negative rods (GNR): IVDU, trauma, extremes of age, immunosuppressed

- *Neisseria gonorrhoea* (most common in young, sexually active adults)
- Other: rickettsial (e.g., Lyme), fungal, mycobacterial
- Risk by specific age (3):
  - <1 month: *Streptococcus aureus*, Group B strep (GBS), GNR
  - 1 month to 4 years: *Streptococcus aureus*, *Streptococcus pneumoniae*, *Neisseria meningitidis*
  - 16 to 40 years: *N. meningitidis*, *S. aureus*
  - >40 years: *S. aureus*
- Specific high-risk groups:
  - Rheumatoid arthritis: *S. aureus*
  - IVDU: *S. aureus*, GNR, opportunistic pathogens
  - Neonates: GBS
  - Immunocompromised: gram-negative bacilli, fungi
  - Trauma patients with open injuries: mixed flora
- Pathogenesis:
  - Hematogenous spread (most common)
  - Direct inoculation by microorganisms secondary to trauma or iatrogenesis (e.g., joint surgery)
  - Adjacent spread (e.g., osteomyelitis)
- Pathophysiology:
  - Microorganisms initially enter through synovial membrane and spread to the synovial fluid.
  - Resulting inflammatory response releases cytokines and destructive proteases leading to joint damage.
  - Microbial surface components recognizing adhesive matrix molecules (MSCRAMMs) on bacteria influence disease progression (4).

## RISK FACTORS

- Age >80 years
- Low socioeconomic status; alcoholism

Cellulitis and skin ulcers

- Prior violation of joint capsule
  - Prior orthopedic surgery
  - Intra-articular steroid injection
  - Trauma
- History of previous joint disease
  - Inflammatory arthritis (rheumatoid arthritis [RA]: 10-fold increased risk)
  - Osteoarthritis
  - Crystal arthritides
- Systemic illness
  - Diabetes mellitus, liver disease, HIV, malignancy, end-stage renal disease/hemodialysis, immunosuppression, sickle cell anemia
- Risks for hematogenous spread
  - IVDU, severe sepsis/systemic infection

## GENERAL PREVENTION

- Prompt treatment of skin and soft tissue infections
- Control risk factors
- Immunization (*S. pneumoniae*; *N. meningitidis*)

## DIAGNOSIS

### HISTORY

- Typical presentation includes a combination of joint pain, swelling, warmth, and decreased range of motion.
- Nongonococcal arthritis: predominantly monoarticular (80%)
  - Typically large joints (knee in 50% of cases)
  - Most patients report fever.
  - IV drug users may develop infection in axial joints (e.g., sternoclavicular joint).
  - Prosthetic joints may show minimal findings and present with draining

sinus over the joint.

- Patients on chronic immunosuppressive drugs and those receiving steroid joint injections may present atypically (no fever or joint pain).
- Pediatric considerations
  - Infants may present with refusal to move limb (can be mistaken as neurologic problem).
  - Hip joint pain may refer to the knee or thigh.
- Gonococcal arthritis
  - Bacteremic phase: migratory polyarthritis, tenosynovitis, high fever, chills, pustules (dermatitis-arthritis syndrome)
  - Localized phase: nonoarticular, low-grade fever

## *PHYSICAL EXAM*

- Physical exam generally has poor sensitivity and specificity in the context of septic arthritis. Common findings include:
  - Limited range of motion
  - Joint effusion and tenderness
  - Erythema and warmth over affected joint
  - Pain with passive range of motion
- Septic arthritis of hip and shoulder involvement may reveal severe pain on range of motion and less obvious swelling on exam.
- Pediatric consideration: Infants with septic hip arthritis, keep the joint flexed and externally rotated.

## *DIFFERENTIAL DIAGNOSIS*

- Crystal arthritis: gout, pseudogout, calcium oxalate, cholesterol
- Infectious arthritis: fungi, spirochetes, rheumatic fever, HIV, viral
- Inflammatory arthritis: RA, spondyloarthropathy, systemic lupus erythematosus, sarcoidosis
- Osteoarthritis
- Trauma: meniscal tear, fracture, hemarthrosis
- Other: bursitis, cellulitis, tendinitis

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- Synovial fluid analysis (gold standard):
  - Obtain prior to antibiotic therapy if possible
  - Include Gram stain, culture, cell count/differential, and crystal analysis.
  - Use blood culture bottles to increase yield.
  - Gram stain (positive in 50%) and culture (positive in 50-70%) should be sent with understanding of limitations.
  - >50,000 WBCs/HPF with >90% polymorphonuclear leukocytes is considered suggestive; however, *synovial WBC (sWBC) count alone is insufficient to rule in or rule out septic arthritis (3)[A]*.
  - The presence of crystals (e.g., urate or calcium pyrophosphate) *does not exclude concurrent infectious arthritis (5)*.
  - Prosthetic joint: WBC count is unreliable; a lower number of sWBCs may indicate infection.
- Serum tests:
  - WBC count alone is neither sensitive nor specific.
  - ESR with cutoff of >15 mm/hr has sensitivity up to 94% but poor specificity (6)[B].
  - CRP >20 mg/L has sensitivity of 92% (6)[B].
  - Serum procalcitonin >0.4 ng/mL has 85% sensitivity and 87% specificity (7)[B].
  - Synovial lactate is a potential biomarker (8,9)[C].
  - Blood cultures are positive in 50% of cases.
- Other tests:
  - Disseminated gonococcus: culture blood, cervix, urine, urethra, pharynx in addition to joint fluid
  - Suspected Lyme arthritis: send serum Lyme titers
- Pediatrics: No single lab test distinguishes septic arthritis from transient synovitis.
  - The combination of fever, non-weight bearing, and elevated ESR and CRP is suspicious, but synovial fluid should still be obtained.
- Imaging: helpful to identify effusion but does not differentiate septic from other forms of

## arthritis

- Plain films:
  - Nondiagnostic for septic arthritis. Useful for other pathology such as trauma, soft tissue swelling, osteoarthritis, or osteopenia
  - May show nonspecific changes of inflammatory arthritis (i.e., erosions, joint destruction, joint space loss)
- Ultrasound:
  - Identifies joint space to guide arthrocentesis
  - Recommended for aspiration of the hip
- MRI:
  - Highly sensitive for effusion; increasing role to distinguish between transient synovitis and septic arthritis in children (10)[B]
- Other imaging techniques:
  - CT is not routinely indicated.
  - Bone scans are not performed unless there is suspicion for osteomyelitis.

P.81

## *Diagnostic Procedures/Other*

Arthrocentesis in all suspected cases (prior to initiation of antibiotics). Avoid contaminated tissue (e.g., overlying cellulitis) when performing arthrocentesis.

## *Test Interpretation*

Synovial biopsy shows polymorphonuclear leukocytes and possibly the causative organism.

## **TREATMENT**

### **GENERAL MEASURES**

- Admit for parenteral antibiotics and monitoring. Antibiotics should begin immediately after arthrocentesis is performed and cultures requested.
- Removal of purulent material is *required* in these cases:
  - Pediatric: Surgical drainage and irrigation is recommended if hip involved due to high risk of

avascular necrosis.

- Prosthetic joint: Antibiotics and consult with orthopedics for consideration of replacement arthroplasty, resection arthroplasty, or debridement (11)[B].
- Treat for a total of 4 to 6 weeks in most cases.
  - Exception: gonococcal (2 to 3 weeks)
- Intra-articular antibiotics are not recommended.
- IV dexamethasone in conjunction with antibiotics may reduce long-term sequelae and improve recovery time in pediatric patients (12)[A].

## MEDICATION

### First Line

- Initial antibiotic choice is guided by Gram stain or most likely organism based on age and clinical history.
- Nongonococcal (13)[A]:
  - Gram-positive cocci:
    - Vancomycin 15 to 20 mg/kg 2 to 3 times daily or linezolid 600 mg twice daily
  - Gram-negative bacilli:
    - Cefepime 2 g twice daily or ceftriaxone 2 g daily or ceftazidime 2 g, 3 times daily or cefotaxime 2 g, 3 times daily
    - For cephalosporin allergy: Consider treatment with ciprofloxacin 400 mg, 3 times daily.
  - Negative Gram stain:
    - Vancomycin 15 to 20 mg/kg 2 to 3 times daily plus 3rd-generation cephalosporin until cultures and susceptibilities return
  - Duration of therapy: typically 2 weeks of IV and an additional 2 to 4 weeks PO while monitoring therapeutic response
- Gonococcal (14)[A]:
  - Ceftriaxone 1 g IV/IM daily for 7 to 14 days (and at least 24 to 48 hours after symptoms resolve)
  - May require concurrent drainage of affected joint
  - Concomitant treatment for *Chlamydia* (doxycycline 100 mg twice daily or azithromycin 1 g

daily)

- Other considerations:
  - Narrow antibiotic therapy based on culture results
  - Consider *Salmonella* in pediatric patients with a history of sickle cell disease: 3rd-generation cephalosporin helpful in this instance.
  - Lyme arthritis: doxycycline 100 mg PO twice daily or amoxicillin 500 mg PO 3 times daily for 28 days if no neurologic involvement, otherwise ceftriaxone 2 g IV daily (15)[A]

## ISSUES FOR REFERRAL

- Infectious disease and orthopedic consultations
- IVDU and immunosuppression warrant infectious disease consultation to guide therapy. Prosthetic joint infection is best managed with orthopedic consultation.

## SURGERY/OTHER PROCEDURES

- Consider drainage in all cases, particularly shoulder, hip, and prosthetic joints.
- Other treatment options include repeat needle aspiration, arthroscopy, or arthrotomy.

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### *Patient Monitoring*

- Monitor synovial fluid to verify decreasing WBC and sterile fluid after initial treatment.
- If no improvement within 24 hours, reevaluate and consider arthroscopy.
- Follow-up at 1 week and 1 month after stopping antibiotics to ensure no relapse.

## PROGNOSIS

- Early treatment improves functional outcome.
- Delayed recognition/treatment is associated with higher morbidity and mortality.
- Elderly, concurrent rheumatoid arthritis, *S. aureus* infections, and infection of hip and shoulder also increase risk of poor outcome.

## COMPLICATIONS

- Mortality rate estimated at 11% (2)
- Limited joint range of motion, ankylosis
- Secondary osteoarthritis
- Flail, fused, or dislocated joint
- Sepsis, septic necrosis
- Sinus formation
- Osteomyelitis, postinfectious synovitis
- Limb length discrepancy (in children)

---

## Codes

### ICD10

- M00.9 Pyogenic arthritis, unspecified
- M00.20 Other Streptococcal arthritis, unspecified joint
- M00.00 Staphylococcal arthritis, unspecified joint

## Clinical Pearls

- Because history, exam, and serum markers often confer little diagnostic benefit, arthrocentesis and synovial fluid analysis are mandatory in cases of suspected septic arthritis.

- Early IV antibiotics and drainage of infected joints are critical to successful management.
- Crystalline disease may coexist with septic arthritis.
- Initial antibiotic therapy is guided by results of aspiration (Gram stain), age, and patient-specific risk factors.

# Arthropod Bites and Stings

James E. Powers, DO, FACEP, FAAEM

## BASICS

### DESCRIPTION

Arthropods make up the largest division of the animal kingdom; two classes, insects and arachnids, have the greatest medical impact on humans. Arthropods affect humans by inoculating poison or irritative substances through a bite or sting, by invading tissue, or by contact allergy to their skin, hairs, or secretions. The greatest medical importance is transmission of infectious microorganisms that may occur during insect feeding. Sequelae to arthropod bites, stings, or contact may include the following:

- Local redness with itch, pain, and swelling: common, usually immediate and transient
- Large local reactions increasing over 24 to 48 hours
- Systemic reactions with anaphylaxis, neurotoxicity, organ damage, or other systemic toxin effects
- Tissue necrosis or secondary infection
- Infectious disease transmission: presentation may be delayed weeks to years

### EPIDEMIOLOGY

#### *Incidence*

- Difficult to estimate, as most encounters unreported
- ÷40 deaths per year in the United States from fatal anaphylactic reaction to insects but likely underreported (1)
- Unrecognized anaphylactic reactions to *Hymenoptera* stings may be cause of 1/4 of sudden and unexpected deaths outdoors (2).

#### *Prevalence*

Widespread, with regional and seasonal variations

### ETIOLOGY AND PATHOPHYSIOLOGY

- Arthropods: four medically important classes
  - Insects: *Hymenoptera* (bees, wasps, hornets, fire ants), mosquitoes, bed bugs, flies, lice, fleas, beetles, caterpillars, and moths
  - Arachnids: spiders, scorpions, mites, and ticks
  - Chilopods (centipedes)
  - Diplopods (millipedes)
- Four general categories of pathophysiologic effects: toxic, allergic, infectious, and traumatic
  - Toxic effects of venom: local (tissue inflammation or destruction) versus systemic (neurotoxic or organ damage)
  - Allergic: Antigens in saliva may cause local inflammation. Exaggerated immune responses may result in anaphylaxis or serum sickness.
  - Trauma: Mechanical injury from biting or stinging causes pain, swelling, and portal of entry for bacteria and secondary infection. Retention of arthropod parts can cause a granulomatous reaction.
  - Infection: Arthropods are vectors and can transmit bacterial, viral, and protozoal diseases.

## *Genetics*

Family history of atopy may be a factor in the development of more severe allergic reactions.

## **RISK FACTORS**

- Previous sensitization is a key to most severe allergic reactions, but exposure history may not be recalled.
- Although most arthropod contact is inadvertent, certain activities, occupations, and travel increase risk.
- Greater risk for adverse outcome in young, elderly, immune compromised, or those with unstable cardiac or respiratory status
- Increased risk of anaphylaxis following insect sting in patients with mastocytosis (1)

## **GENERAL PREVENTION**

- Avoidance of common arthropod habitats
- Insect repellents (not effective for bees, spiders, scorpions, caterpillars, bed bugs, fleas, ants)
  - N,N-diethyl-meta-toluamide (DEET)

- Most effective broad-spectrum repellent against biting arthropods (3)
- Formulations with higher concentrations (20-50%) are 1st-line choice when visiting areas of endemic arthropod-borne diseases (3).
- Concentrations >30% give longer duration of effect
- Safe for children >6 months of age and pregnant and lactating women (3)
- Icaridin (formerly known as *picaridin*)
  - Use of concentrations <20% may require more frequent application to maintain effectiveness.
- P-menthane-3,8-diol (PMD): component of lemon eucalyptus extract
  - Recommended alternative repellent to DEET at concentrations >20% (3)
  - May be used in children >6 months of age (3)
- IR3535: less effective in most studies
- Other botanical oils (citronella etc.): less effective than DEET; not for disease-endemic areas
- Barrier methods: clothing, bed nets
  - Use of light-colored pants, long-sleeved shirts, and hats may reduce arthropod impact.
  - Permethrin: Synthetic insecticide derived from chrysanthemum plant should not be applied to skin, but permethrin-impregnated clothing provides good protection against arthropods.
  - Mosquito nets: Insecticide-treated nets are advised for all travelers to disease-endemic areas at risk from biting arthropods (3).
  - WHO-recommended nets are Permanet 2.0 (Vestergaard), Olyset (Sumitomo), and Interceptor (BASF) (3).
- Desensitization 75-95% effective for *Hymenoptera*-specific venom
  - Skin tests are needed to determine sensitivity.
  - Refer to allergist/immunologist if candidate
- Fire ant control (but not elimination) possible
  - Baits; sprays, dusts, aerosols; biologic agents
- Risk of tick-borne diseases decreased by prompt removal of ticks within 24 hours of attachment.

## DIAGNOSIS

### HISTORY

- Sudden onset of pain or itching with visualization of arthropod
- Many cases unknown to patient or asymptomatic initially (bed bugs, lice, scabies, ticks). Consider in patients presenting with localized erythema, urticaria, wheals, papules, pruritus, or bullae.
- May identify insect by its habitat or by remnants brought by patient
- History of prior exposure useful but not always available or reliable
- Travel, occupational, social, and recreational history important

### PHYSICAL EXAM

- If stinger is still present in skin, remove by flicking or scraping away from skin.
- Anaphylaxis is a clinical diagnosis. Essential to examine for signs and symptoms of anaphylaxis (4,5)
  - Erythema, urticaria, angioedema
  - Itching/edema of lips, tongue, uvula; drooling
  - Persistent vomiting
  - Respiratory distress, wheeze, repetitive cough, stridor, dysphonia
  - Hypotension, dysrhythmia, syncope, chest pain
- If anaphylaxis not present, exam focuses on the sting or bite itself. Common findings include local erythema, swelling, wheals, urticaria, papules, or bullae; excoriations from scratching.
- Thorough exam to look for arthropod infestation (lice, scabies) or attached ticks. Body lice usually found in seams of clothing. Skin scraping to identify scabies.
- Signs of secondary bacterial infection after 24 to 48 hours: increasing erythema, pain, fever, lymphangitis, or abscess
- Delayed manifestations of insect-borne diseases

### DIFFERENTIAL DIAGNOSIS

- Urticaria and localized dermatologic manifestations:
  - Contact dermatitis, drug eruption, mastocytosis, bullous diseases, dermatitis herpetiformis, tinea, eczema, vasculitis, pityriasis, erythema multiforme, viral exanthem, cellulitis, abscess,

impetigo, folliculitis, erysipelas, necrotizing fasciitis

- Anaphylactic-type reactions
  - Cardiac, hemorrhagic, or septic shock; acute respiratory failure, asthma; angioedema, urticarial vasculitis; flushing syndromes (catecholamines, vasoactive peptides); panic attacks, syncope
  - Differential diagnosis of the acute abdomen should include black widow spider bite.

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

Seldom needed; basic lab parameters usually normal. Some findings may help confirm diagnosis of anaphylaxis:

- Plasma histamine levels elevated briefly after mast cell activation
- Serum tryptase within 15 minutes to 3 hours after onset of symptoms with second sample 24 hours later (5)

### *Follow-Up Tests & Special Considerations*

- Severe envenomations may affect organ function and require monitoring of lab values (CBC, comprehensive metabolic panel, prothrombin time/international normalized ratio)
- Labs for arthropod-borne diseases, as indicated
  - Ticks: Lyme disease, Rocky Mountain spotted fever, relapsing fever, anaplasmosis, babesiosis, tularemia
  - Flies: tularemia, leishmaniasis, African trypanosomiasis, bartonellosis, loiasis
  - Fleas: plague, tularemia, murine typhus
  - Chigger mites: scrub typhus
  - Body lice: epidemic typhus, relapsing fever
  - Kissing bugs: Chagas disease
  - Mosquitoes: malaria, yellow fever, dengue fever, West Nile virus, equine encephalitis, chikungunya
- Refer to allergist for formal testing with history of anaphylaxis, significant systemic symptoms, progressively severe reactions (4,5)

## TREATMENT

### ALERT

- The more rapidly anaphylaxis develops, the more likely the reaction is to be severe and potentially life-threatening. Most deaths due to anaphylaxis occur within 30 to 60 minutes of sting.
- Epinephrine should be given as soon as diagnosis of anaphylaxis is suspected. Delay of epinephrine is associated with fatal anaphylaxis (4,5).
- Antihistamines and steroids do not replace epinephrine in anaphylaxis, and no direct outcome data regarding their effectiveness in anaphylaxis are available (4,5).
- Airway management critical if angioedema

## GENERAL MEASURES

Local wound care, ice compress, elevation, analgesics

## MEDICATION

### First Line

- For arthropod bites/stings **with anaphylaxis**
  - There are no randomized controlled trials on treatments, so the following recommendations are all based on expert opinion consensus (5)[C].
  - Epinephrine: **most important:** IM injection in midanterolateral thigh (vastus lateralis muscle):
    - IM injection: epinephrine 1:1,000 (1 mg/mL): adult: 0.3 to 0.5 mg per dose; pediatric: give 0.01 mg/kg to a maximum dose of 0.5 mg per dose, can repeat every 5 to 15 minutes (5)
  - Positioning: supine with legs elevated
  - Oxygen 6 to 8 L/min up to 100%, as needed
  - IV fluids: Establish 1 to 2 large-bore IV lines. Normal saline rapid bolus 1 to 2 L IV; repeat as needed (pediatrics 20 to 30 mL/kg)

- H<sub>1</sub> antihistamines: diphenhydramine 25 to 50 mg IV (pediatrics 1 to 2 mg/kg)
- $\beta_2$  agonists: albuterol for bronchospasm nebulized 2.5 to 5 mg in 3 mL
- Emergency treatment of refractory cases: consider epinephrine infusion, dopamine, glucagon, vasopressin, large-volume crystalloids (4,5)
- Arthropod bites/stings **without anaphylaxis**
  - Tetanus booster, as indicated
  - Oral antihistamines
    - Diphenhydramine
    - Cetirizine
    - H<sub>2</sub> blockers: ranitidine
  - Oral steroids: consider short course for severe pruritus; prednisone or prednisolone 1 to 2 mg/kg once daily
  - Topical intermediate-potency steroid cream or ointment × 3 to 5 days
    - Desoximetasone 0.05%
    - Triamcinolone 0.1%
    - Fluocinolone 0.025%
  - Wound care: antibiotics *only* if infection
  - Other specific therapies:
    - Scorpion stings: Treat excess catecholamine release (nitroprusside, prazosin,  $\beta$ -blockers). Diazepam for muscle spasms. Atropine for hypersalivation (6). Only one FDA-approved scorpion antivenom in United States and should be administered in conjunction with toxicologist. Black widow bites: Treat muscle spasms with diazepam and opioid analgesics PO or IV (6). Antivenom: available but should be administered in conjunction with toxicologist.
    - Poison control should be consulted for questions regarding management of envenomation. Poison Control hotline: 1-800-222-1222.
  - Fire ants: characteristically cause sterile pustules. Leave intact: Do not open or drain.
  - Brown recluse spider: pain control, supportive treatment; surgical consult if dēbridement needed
  - Ticks: early removal. Review guidelines for disease prophylaxis and treatment.

- Pediculosis: head, pubic, and body lice
  - First line: permethrin 1% (Nix) topical lotion. Apply to affected area, wash off in 10 minutes.
  - Alternatives: pyrethrin or malathion 0.5% lotion, ivermectin (not FDA approved for pediculosis) orally
  - Repeat above treatment in 7 to 10 days.
  - For eyelash infestation: Apply ophthalmic-grade petroleum jelly BID for 10 days.
- *Sarcoptes scabiei* scabies
  - Permethrin 5% cream: Apply to entire body. Wash off after 8 to 14 hours. Repeat in 1 week.
  - Ivermectin: 200  $\mu\text{g}/\text{kg}$  PO once; repeat in 2 weeks (not FDA approved for this use)
  - Crothamiton 10% cream or lotion less efficacious; apply daily for 2 days after bathing.

## Second Line

Second-line options for **anaphylaxis**:

- Ranitidine
- Methylprednisolone 1 mg/kg for 3 to 4 days or hydrocortisone 200 mg (5)

## ISSUES FOR REFERRAL

Refer to allergist with history of anaphylaxis, severe systemic symptoms, or progressively severe reactions

## SURGERY/OTHER PROCEDURES

Debridement and delayed skin grafting may be needed for brown recluse spider and other bites.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Some stings may be treated with a paste of 3 tsp of baking soda and 1 tsp water.
- None well tested

## INPATIENT CONSIDERATIONS

### Admission Criteria/Initial Stabilization

Anaphylaxis, vascular instability, neuromuscular events, pain, GI symptoms, renal damage/failure

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

- Immunotherapy as recommended by allergist/consultant for anaphylaxis or serious reactions; venom immunotherapy cornerstone of treatment for *Hymenoptera*.
- Patient-administered epinephrine must be provided to patients with anaphylaxis. Consider Òmed-alertÓ identifiers (4,5).

### *Patient Monitoring*

- Monitor for delayed effects, including infectious diseases from arthropod vectors.
- Serum sickness reactions, vasculitis (rare)

### *PATIENT EDUCATION*

Avoidance and prevention

### *PROGNOSIS*

- Excellent for local reactions
- For systemic reactions, best response with early intervention to prevent cardiorespiratory collapse

### **COMPLICATIONS**

- Scarring
- Secondary bacterial infection
- Arthropod-associated diseases as mentioned earlier
- Psychological effects, phobias

## ICD10

- T63.481A Toxic effect of venom of arthropod, accidental, init
- T63.301A Toxic effect of unsp spider venom, accidental, init
- T63.484A Toxic effect of venom of oth arthropod, undetermined, init

## Clinical Pearls

- Urgent administration of epinephrine is a key to anaphylaxis treatment.
- Local treatment and symptom management are sufficient in most insect bites and stings.

# Ascites

Daniel J. Stein, MD, MPH

Stephen K. Lane, MD, FAAFP

## BASICS

### DESCRIPTION

- Accumulation of fluid in the peritoneal cavity; may occur in conditions that cause generalized edema.
- Men generally have no fluid in peritoneal cavity; women may have up to 20 mL depending on menstrual phase.
- Ascites comes from Greek word *askos* (bag).

### EPIDEMIOLOGY

- Children: nephrotic syndrome and malignancy most common
- Adults: cirrhosis (81%), cancer (10%), heart failure (3%), other (6%)

### Incidence

÷ 50-60% of patients with cirrhosis will develop ascites within 10 years (1).

### Prevalence

10% of patients with liver cirrhosis have ascites.

### ETIOLOGY AND PATHOPHYSIOLOGY

Portal hypertensive versus nonportal hypertensive etiologies

- Cannot reliably establish/confirm etiology without paracentesis
- Serum-ascites albumin gradient (SAAG), which is the (serum albumin level) - (ascites albumin level) differentiates causes

High portal pressure (SAAG  $\geq$  1.1)

- Cirrhosis

Hepatitis (alcoholic, viral, autoimmune, medications)

- Acute liver failure
- Liver malignancy (primary or metastatic)
- Elevated right-sided filling pressures from heart failure or constrictive pericarditis
- Hepatic venous thrombosis (Budd-Chiari syndrome)
- Portal vein thrombosis

Normal portal pressure (SAAG <1.1)

- Peritoneal carcinomatosis
- Tuberculosis
- Severe hypoalbuminemia (nephrotic syndrome; severe enteropathy with protein loss)
- Meigs syndrome (ovarian cancer)
- Lymphatic leak (chylous ascites)
- Pancreatitis
- Inflammatory (vasculitis, lupus serositis, sarcoidosis)
- Other infections (parasitic, fungal)
- Hemoperitoneum from trauma or ectopic pregnancy

Pathophysiology of ascites is partially understood. It is best described for portal hypertensive (typically cirrhotic) ascites

- Most ascites is due to portal hypertension, with preferentially dilated splanchnic vasculature causing systemic hypotension.
- Reduced renal and carotid perfusion activates systemic vasoconstrictors and antinatriuretic mechanisms. This stimulates the sympathetic nervous system and renin-angiotensin-aldosterone system, culminating in sodium and water retention ascites and edema.

## DIAGNOSIS

### HISTORY

- Progressive abdominal distention, which may be painless or painful.
- Weight gain, dyspnea/orthopnea, edema, early satiety, and nausea
- Patients with spontaneous bacterial peritonitis may present with fever, abdominal tenderness, and altered mentation.

- Individuals with underlying malignancy may present with weight loss.
- Address risk factors (e.g., EtOH use, TB exposure, prior malignancies, sexual partners, transfusion history)
- Obesity, hyperlipidemia and type 2 diabetes are associated with nonalcoholic steatohepatitis, which can progress to cirrhosis over time.

## PHYSICAL EXAM

- Abdominal distention, flank dullness, shifting dullness, and puddle splash are most sensitive (83%) and specific (56%) exam findings (1).
- Edema (penile/scrotal, pedal), pleural effusion, rales
- Stigmata of cirrhosis (palmar erythema, spider angiomas, dilated abdominal wall collateral veins)
- Other signs of advanced liver disease: jaundice, muscle wasting, gynecomastia, leukonychia
- Signs of underlying malignancy: cachexia; umbilical (Virchow) node suggests upper abdominal malignancy.

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Diagnostic paracentesis for fluid analysis should be obtained in all patients with ascites requiring hospital admission and in any new-onset or new-to-treatment patients with ascites (1)[C] to determine etiology and rule out infection.
  - Paracentesis has a complication rate of 1% (despite high prevalence of coexisting coagulation abnormalities). Routine attempts to correct platelet or coagulation defects are not needed (1)[B].
  - Ascitic fluid analysis should include (1)[C]:
    - Cell count and differential:
      - Polymorphonuclear leukocytes  $\geq 250$  cells/mm<sup>3</sup> suggests infection.
    - Albumin level to calculate SAAG:
      - $< 1.1$  g indicates a low portal pressure exudative process (i.e., inflammatory, biliary/pancreatic, carcinomatosis, TB)
      - $\geq 1.1$  g indicates portal hypertensive/transudative process (cirrhosis, CHF, constrictive pericarditis, thrombosis)

- Total protein (low in cirrhosis, nephrotic disease, and high in cardiac ascites. Cutoff approximately 25 g/L)
- Other tests based on clinical scenario (1)[C]:
  - Bacterial gram stain/culture, if infection suspected (cirrhotic patients with ascites can fail to mount adequate fever or significant leukocytosis)
    - Fluid cultures are positive in 50-90% of cases of SBP.
    - Yield improved if inoculated to blood culture bottles at bedside and obtained before first dose of antibiotics.
  - Amylase (suspicion for bowel perforation, choledocholithiasis, or pancreatitis)
  - Triglyceride if fluid appears milky
  - Cytology if concern for malignancy (less sensitive in the absence of carcinomatosis)
  - Lactate dehydrogenase (LDH): An ascitic fluid-to-serum LDH ratio >1.0 can indicate infection, perforation, or tumor.
  - Carcinoembryonic antigen and alkaline phosphatase (elevated in viscous perforation)
- Myobacterial culture/TB complex PCR for suspicion of tuberculosis.
- Blood tests: BUN/creatinine, electrolytes (renal function)
  - Brain natriuretic peptide (heart failure)
  - Liver function tests and hepatitis serologies (hepatitis)
  - Albumin (needed for SAAG)
- Abdominal ultrasound can confirm ascites; highly sensitive, cost-effective, involves no radiation
- Portal Doppler can be obtained with ultrasound as first line to evaluate for thrombosis or cirrhosis.
- CT scan to rule out intra-abdominal pathology (e.g., malignancy)
- MRI preferred for evaluation of liver disease or confirmation of portal vein thrombosis

## *Diagnostic Procedures/Other*

Laparoscopy: preferred if imaging and paracentesis are nondiagnostic

- Allows for direct visualization and biopsy of peritoneum, liver, and intra-abdominal lymph nodes
- Preferred for evaluating suspected peritoneal tuberculosis or malignancies

## Test Interpretation

Cytology may reveal malignant cells: adenocarcinoma (ovary, breast, GI tract) or primary peritoneal carcinoma (most commonly associated with ascites)

## TREATMENT

For all patients:

- Daily weight
- Restrict dietary sodium to  $\leq 2$  g/day if the cause is due to portal hypertension (high SAAG) (1) [A].
- Water restriction (1 to 1.5 L/day) only necessary if serum sodium  $< 120$  to  $125$  mEq/L (1)[C]
- Creatinine  $> 2.0$  mg/dL: decrease diuretic doses, peritoneal paracentesis
- Avoid alcohol and ensure adequate nutrition if liver disease (1)[A].
- Baclofen may be used to reduce alcohol craving/consumption (1)[C].

## MEDICATION

### ALERT

Carefully approach diuresis; aggressive diuresis can induce prerenal acute kidney injury, encephalopathy, and hyponatremia. Monitor creatinine and electrolytes closely. Serum creatinine  $> 2$  mg/dL or serum sodium  $< 120$  mmol/L should prompt withdrawal of diuretics. NSAIDs may cause (or worsen) oliguria or azotemia and should be avoided. ACE inhibitors and angiotensin receptor blockers (ARBs) may be harmful in patients with cirrhosis/ascites due to an increased risk of hypotension and renal failure (1)[C]; ACE inhibitors and ARBs should be avoided in refractory ascites (1)[B]. Consider discontinuing  $\beta$ -blockers in patients with refractory ascites, worsening hypotension, or azotemia (1)[B].

## First Line

- Sodium restriction and diuretics are the mainstay of treatment for patients with elevated portal pressures (1)[A]; other causes (e.g. carcinomatosis) are less likely to respond to medical therapy.
  - Spironolactone 100 to 400 mg daily PO; typical initial dose is 100 to 200 mg given in AM
    - Diuretic of choice due to its antialdosterone effects; can be used as single agent in patients with minimal ascites

- Furosemide 40 to 160 mg daily PO (avoid IV if possible); typical initial dose is 40 mg given in AM
  - Antinatriuretic effect helps to achieve negative sodium balance.
  - Not first-line as monotherapy but is an effective adjunct to potentiate the effect of spironolactone
- Most common (and preferred) regimen is spironolactone and furosemide together (maintaining a 100:40 ratio) for maximum efficacy and to maintain potassium homeostasis.
  - Titrate dose to desired result and monitor renal function regularly.
  - Follow daily weight.
- Diuretic-intractable ascites (10% of patients): persistent or worsening ascites despite maximum doses of spironolactone (400 mg/day) and furosemide (160 mg/day) and sodium restriction *or* progressive rise in creatinine to 2.0
  - *Ensure compliance with dietary sodium restriction using 24-hour urine sodium excretion: in general, if <78 mEq/day, patient is compliant with 2-g dietary sodium restriction.*
  - Therapeutic paracentesis or serial large-volume paracentesis (LVP) (see *ÒSurgery/Other ProceduresÓ*)

## Second Line

- Midodrine 7.5 mg TID can be added to diuretic resistant or hypotensive patients and may improve survival (1)[B].
- Alternatives to spironolactone: amiloride up to 40 mg/day; triamterene up to 200 mg/day in divided doses (1)[C]
- Alternatives to furosemide: torsemide up to 100 mg/day; bumetanide up to 4 mg per day (1)[C]
- Vaptans may have a beneficial effect on hyponatremia and ascites, but routine use in ascites is not yet supported (2)[A].

## ISSUES FOR REFERRAL

Consider referral for liver transplant in patients with decompensated liver disease, whether or not ascites is present/controlled. Liver transplant is the definitive treatment for portal hypertension (1)[B].

# *SURGERY/OTHER PROCEDURES*

- Therapeutic paracentesis
  - Initial therapy if tense ascites is present (1)[C].
  - Serial (generally every 2 weeks) paracentesis can be used as second-line after diuretics in patients with elevated portal pressures (3)[B].
  - Complications: infection, hemodynamic collapse, acute renal failure
  - Similar complication rate as diuretics (3)[B]
  - Replace albumin when removing >5 L of ascites: 5.5 to 8 g albumin for each liter removed has been shown to decrease renal dysfunction, hyponatremia post paracentesis, and overall morbidity (4)[A] for patients with portal hypertension; likely not needed for malignant ascites
  - Continue diuretics at 1/2 previous dose if transitioning to serial paracentesis in patients who fail diuretics alone.
- Transjugular intrahepatic portosystemic shunt (TIPS)
  - Used only in patients with elevated portal pressures
  - Fluoroscopically placed conduit from portal to hepatic vein for intractable ascites (5)[A]
    - At time of placement, portal pressure should drop  $\geq 20$  mm Hg or to <12 mm Hg, and ascites should be readily controlled with diuretics.
    - Yearly US to confirm shunt is functional.
    - 4 weeks after TIPS, urinary sodium and serum creatinine improve significantly and can normalize after 6 to 12 months in combination with diuretics (5). Dilation/replacement may be needed after 2 years.
    - Encephalopathy is a primary complication.
    - TIPS is superior to paracentesis for controlling ascites. No difference in mortality (5)[A].
- Peritoneovenous shunt (LeVeen or Denver shunt): drains ascites directly into the inferior vena cava
  - Clinical trials show poor long-term shunt patency, no survival advantage compared with medical therapy.
  - Complications include:
    - Bacteremia, bowel obstruction, and variceal bleed as a result of rapid volume overload from ascitic fluid into systemic circulation

- Usually reserved for patients with refractory ascites who are not candidates for TIPS or liver transplant, and who have numerous abdominal adhesions, making repeated paracentesis unsafe (1)[A].
- Indwelling catheters with external drainage
  - Most useful in malignant ascites as a palliative measure
  - Overall low rate of infection
  - Can be drained at home
- Percutaneous endoscopic gastrostomy should be avoided in patients with ascites due to an associated high mortality rate following this procedure (1)[B].

## COMPLEMENTARY & ALTERNATIVE MEDICINE

Caution advices with many herbal and other dietary supplements (risk drug interactions, hepatotoxicity, coagulopathy)

## ONGOING CARE

## PROGNOSIS

- Prognosis varies depending on underlying cause.
- Ascites in itself is rarely life threatening but can signify life-threatening disease (e.g., cancer, end-stage liver disease)

## COMPLICATIONS

- Spontaneous bacterial peritonitis (SBP)
  - Ascitic fluid polymorphonuclear (PMN) leukocyte count  $\geq 250$  cells/mm<sup>3</sup> or positive culture
    - Broad-spectrum antibiotics are as follows: Cefotaxime 2 g q8h or similar 3rd-generation cephalosporin is the treatment of choice for suspected SBP. Covers 95% of flora (including *Escherichia coli*, *Klebsiella*, pneumococci) (1)[A]
    - Lifetime antibiotic prophylaxis with norfloxacin or trimethoprim-sulfamethoxazole (TMP-SMX) is indicated in some patients who survive an episode of SBP (1)[A]. Reduced incidence of SBP, delayed development of hepatorenal syndrome, and improved survival in cirrhosis (6)[C]

- Suspect primary bacterial peritonitis (PBP) due to bowel perforations when ascitic fluid  $>250$  cells/mm<sup>3</sup> (often  $>5,000$  cells/mm<sup>3</sup>), and any two of the following:
  - Ascitic fluid total protein  $>1$  g/dL (often  $>3$  g/dL)
  - Ascitic fluid glucose  $<50$  mg/dL (or 2.8 mmol/L)
  - Ascitic fluid LDH that is 3-fold greater than serum LDH
- Hepatorenal syndrome: acute worsening of renal function diagnosed when possible causes of acute renal failure are excluded, and at least 2 days of diuretic withdrawal and maximal intravascular volume expansion with albumin (see “Hepatorenal Syndrome”)
- Cellulitis is increasingly common in obese patients with brawny edema and should be treated with diuretics and appropriate antibiotics (1)[B].

### Codes

#### ICD10

- R18.8 Other ascites
- R18.0 Malignant ascites
- K70.31 Alcoholic cirrhosis of liver with ascites

## Clinical Pearls

- Cirrhosis remains the most common cause of ascites.
- Patients with new-onset ascites or hospitalized patients with ascites should have a diagnostic paracentesis.
- ACE inhibitors, ARBs, and  $\beta$ -blockers should be avoided in patients with ascites.
- Most common cause of  $\text{O}$ diuretic-intractable ascites $\text{O}$  is noncompliance with dietary sodium restriction.
- First-line management of ascites is diuretics. Serial paracentesis or TIPS are second-line therapies.
- Ensure early referral of cirrhosis patients who are potential candidates for liver transplant.

# Asthma

Urooj Najm, MBBS

Najm Hasan Siddiqui, MD

## BASICS

### DESCRIPTION

- Chronic, reversible inflammatory airway disease characterized by recurrent attacks of breathlessness and wheezing
- Four major classifications of asthma severity used primarily to initiate therapy (1,2):
  - Intermittent: symptoms  $\leq 2$  days/week, nighttime awakenings  $\leq 2$  times per month, short-acting  $\beta$ -agonist use  $\leq 2$  days/week, no interference with normal activity, and normal forced expiratory volume in 1 second ( $FEV_1$ ) between exacerbations with  $FEV_1$  (predicted)  $>80\%$  and  $FEV_1$ /forced vital capacity (FVC)  $>80\%$
  - Mild persistent: symptoms  $>2$  days/week but not daily, nighttime awakenings 3 to 4 times per month, short-acting  $\beta$ -agonist use  $>2$  days/week but not daily, minor limitations in normal activity, and  $FEV_1$  (predicted)  $>80\%$  and  $FEV_1$ /FVC  $>80\%$
  - Moderate persistent: daily symptoms, nighttime awakenings  $\geq 1$  times per week but not nightly, daily use of short-acting  $\beta$ -agonist, some limitation in normal activity, and  $FEV_1$  (predicted) 60-80% and  $FEV_1$ /FVC 75-80%
  - Severe persistent: symptoms throughout the day, nighttime awakenings often  $>7$  times per week, short-acting  $\beta$ -agonist use several times a day, extremely limited normal activity, and  $FEV_1$  (predicted)  $<60\%$  and  $FEV_1$ /FVC  $<75\%$

### EPIDEMIOLOGY

#### Prevalence

- Affects 5-10% of population
- One of the most common chronic diseases of childhood, affecting 7 million children
- In children, more common in boys than girls

In adults, more common in women than men, African Americans than Caucasians

## *Pregnancy Considerations*

In the United States, maternal asthma complicates approximately 4-8% of all pregnancies.

## *Geriatric Considerations*

Prevalence of asthma in seniors (age  $\geq$  65 years) is 5.3%.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Airway inflammation begins with inflammatory cell infiltration, sub-basement fibrosis, mucus hypersecretion, epithelial injury, smooth muscle hypertrophy, angiogenesis that then leads to intermittent airflow obstruction, and bronchial hyperresponsiveness.
- Remodeling of airways may occur (1).

## *Genetics*

- Inheritable component with complex genetics and environment interaction
- A gene-by-environment interaction occurs in which the susceptible host is exposed to environmental factors that are capable of generating immunoglobulin (Ig) E and sensitization occurs.

## **RISK FACTORS**

- Host factors: genetic predisposition, gender, race, BMI
- Environmental: viral infections, animal and airborne allergens, tobacco smoke, and so on
- Exercise, obesity, and emotional stress
- Aspirin or NSAIDs hypersensitivity or  $\beta$ -blockers
- Food allergies and asthma → increased risk for fatal anaphylaxis from those foods

## **GENERAL PREVENTION**

- Eliminate or modify exposure to asthma triggers (e.g., allergens, smoking, aspirin, NSAIDs).
- Consider allergen immunotherapy.
- Treat comorbidities such as allergic rhinitis.
- Annual influenza vaccine (inactivated influenza vaccine) for age  $<$  6 months
- Patients at risk for anaphylaxis should carry an EpiPen.

## COMMONLY ASSOCIATED CONDITIONS

- Atopy: eczema, allergic conjunctivitis, allergic rhinitis
- Obesity (associated with higher asthma rates)
- Sinusitis
- Gastroesophageal reflux disease (GERD)
- Obstructive sleep apnea (OSA)
- Allergic bronchopulmonary aspergillosis (rare)
- Stress/depression

## DIAGNOSIS

It is important to classify asthma severity.

### HISTORY

- Question frequency of symptoms and rescue inhaler use.
- Symptoms include the following:
  - Cough (particularly if worse at night)
  - Wheeze
  - Chest tightness/difficulty breathing

## PHYSICAL EXAM

- May be normal
- Focus on
  - General appearance: signs of respiratory distress such as use of accessory muscles
  - Upper respiratory tract: rhinitis, nasal polyps, swollen nasal turbinates
  - Lower respiratory tract: wheezing, prolonged expiratory phase
  - Skin: eczema

## DIFFERENTIAL DIAGNOSIS

- In children
  - Upper airway diseases (allergic rhinitis or sinusitis)

- Large airway obstruction (foreign body aspiration, vocal cord dysfunction, vascular ring or laryngeal web, laryngotracheomalacia, lymph nodes, or tumor)
- Small airway obstruction (viral bronchiolitis, cystic fibrosis, bronchopulmonary dysplasia, heart disease)
- Other causes (recurrent cough *not* due to asthma, aspiration/GERD)
- In adults
  - Chronic obstructive pulmonary disease, congestive heart failure, pulmonary embolism, benign or malignant tumor, pulmonary infiltration with eosinophilia, Churg-Strauss syndrome, drugs such as an ACE inhibitor, vocal cord dysfunction

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Blood tests are not required but may find eosinophilia or elevated serum IgE levels.
- Spirometry: Normal test does not rule out asthma. It measures the FVC and the FEV<sub>1</sub>. A reduced predicted ratio of FEV<sub>1</sub>/FVC with reversibility (increase of 200 mL or 12% of FEV<sub>1</sub>/FVC) after using a short-acting bronchodilator establishes the diagnosis.
- Bronchoprovocation (methacholine, histamine, cold air, or exercise) is used to simulate bronchoconstriction, which is very useful in atypical presentation/normal baseline spirometry. Abnormal test is not entirely specific for asthma, but normal test excludes asthma.
- Peak expiratory flow rates are inappropriate for diagnosis. Typically used for monitoring of symptoms in diagnosed asthma patients.
- Chest x-ray is used to exclude alternative diagnoses and to evaluate patients for complicating cardiopulmonary processes.

### *Follow-Up Tests & Special Considerations*

Asthma action plan: Patients monitor their own symptoms and/or peak flow measurements.

### *Diagnostic Procedures/Other*

- Allergy skin testing is not useful for diagnosis of asthma but may be considered to evaluate atopic triggers.
- Sweat testing in diagnosis of cystic fibrosis.
- Arterial blood gases are indicated for patients with respiratory distress and hypoxia.

## Test Interpretation

Inflammatory cell infiltration, edema, goblet cell hyperplasia, smooth muscle hyperplasia, thickened basement membrane

## TREATMENT

### GENERAL MEASURES

- Identify triggers and control exposures.
- Identify patients at risk for reactions to aspirin and NSAIDs and avoid exposure.
- All patients requiring inhaled agents should be prescribed with spacer (holding chamber) device.

### MEDICATION

#### First Line

- Short-acting  $\beta$ -agonist (SABA) for quick relief of acute symptoms and to prevent exercise-induced bronchospasm (1)[A]
  - SABA include albuterol and levalbuterol (Xopenex) (3).
- Anticholinergic agent
  - Ipratropium bromide: used in combination with SABA for acute treatment, mainly in the ED (1)[A]
- Systemic corticosteroids can be used
  - In all patients with acute asthma exacerbations (4)[A]
  - In moderate to severe asthma as adjunct
  - Prednisolone 1 to 2 mg/kg/day or equivalent for up to 7 days in adults and for 3 days in children with no need for tapering (4)[A]

#### ALERT

- Use of holding chambers ("spacers") improves clinical benefit of inhaled agents and should be prescribed for all.
- HFA inhalers provide smaller particle size, better lung deposition, and less oropharyngeal deposition.
- All metered-dose inhalers (MDIs) need to be primed before use.

- Reserve nebulized delivery of medication for those unable to use spacer (e.g., infants, those intubated).
- All short-acting agents are pregnancy Category C.

## Second Line

For long-term control

- Inhaled corticosteroids (ICS)
  - Most potent and effective long-term controller therapy for children and adults with persistent asthma and persistent asthma during pregnancy (1)[A]
  - Advise patients to rinse their mouth after inhalation to reduce adverse effects (1)[B].
  - Long-acting  $\beta_2$ -agonists (LABA)
    - Salmeterol or formoterol
    - Should not be used as monotherapy (1)[A]; doing so leads to an increased risk of severe outcomes, including death
  - Combination products, including LABA and ICS, are available and are indicated if ICS alone do not provide control; preferred in moderate and severe persistent disease (1,3)[A]. This is not recommended to treat acute symptoms or exacerbation (1)[D].
  - Leukotriene receptor agonists: alternative, not preferable for mild and moderate persistent asthma (1)[A]
- Montelukast or zafirlukast (patients  $\geq 5$  years)
  - Lipoxygenase pathway inhibitor: alternative, not preferred for adjunctive treatment in adults (1)[D]: zileuton (patients  $\geq 12$  years)
  - Theophylline: not preferred as adjunctive therapy with inhaled corticosteroids (1)[A]. Monitoring of serum theophylline level is essential.
  - Cromolyn sodium and nedocromil are also alternatives; not preferred options for mild persistent asthma (1)[A]; can also be used before exercise and exposure to allergens for prevention of asthma
  - Immunomodulators
    - Omalizumab: adjunctive; not preferred therapy for patients  $\geq 12$  years with allergies and severe persistent asthma (1)[B]

## *ISSUES FOR REFERRAL*

Referral to an asthma specialist (either a pulmonologist or an allergist) should be considered when

- Diagnosis unclear
- Additional asthma education needed
- Comorbidities: rhinitis, GERD, sinusitis, OSA
- Specialized testing (e.g., bronchoprovocation, skin testing)
- Specialized treatments (e.g., immunotherapy, anti-IgE therapy)
- Poorly controlled, moderate to severe persistent asthma in adults
- Moderate to persistent asthma in children
- Poorly controlled asthma: multiple emergency room visits for asthma

## *Pregnancy Considerations*

- Poorly controlled asthma results in low birth weight, increased prematurity, and perinatal mortality.
- Albuterol is the preferred SABA, and budesonide is the preferred ICS due to excellent safety profile (1).
- Other ICS agents are pregnancy Category C, but no data indicate their unsafety in pregnancy (1). Montelukast and zafirlukast are Category B but are not studied extensively in pregnancy.

## *ADDITIONAL THERAPIES*

- Allergen immunotherapy when clear relationship between symptoms and exposure to an unavoidable allergen
- Omalizumab (Xolair): anti-IgE therapy, approved for patients > 12 years with moderate to severe asthma

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

No single measure is predictive.

- Dyspnea/hypoxia
- Poor or no response to SABA

Peak expiratory flow (PEF) or FEV<sub>1</sub> <40%

- Decision for admission should be based on duration and severity of symptoms, severity of airflow obstruction, response to ED treatment, course and severity of prior exacerbations, access to medical care and medication, and adequacy of home condition (1).
- Supplemental oxygen to correct hypoxemia
- Repeated doses or continuous administration of SABA (1)[A]
- Ipratropium bromide may be used in the ED but is not for inpatient treatment (1)[B].
- Systemic corticosteroids for acute exacerbations (1)[A].
- Adjunctive therapy with MgSO<sub>4</sub> or helium-oxygen mixture (heliox) may be considered in severe cases (1)[B].

### *IV Fluids*

- Avoid aggressive hydration in older children and adults.
- Monitor electrolytes.

### *Nursing*

- Careful respiratory monitoring including vital signs, pulse oximetry, response and duration of response to SABA, and when possible, an objective measure of lung function such as PEF or FEV<sub>1</sub>
- Asthma education

### *Discharge Criteria*

- Minimal or absent asthma symptoms
- Hypoxia has resolved.
- FEV<sub>1</sub> or PEF <sup>3</sup> 70% predicted or personal best
- Bronchodilator response sustained <sup>3</sup>60 minutes

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Smoking cessation counseling or elimination of secondhand smoke, if applicable

## *Patient Monitoring*

- Quality-of-life measures: impact on activities, sleep, ED visits/hospitalizations, and so forth
- Pharmacotherapy: efficacy, compliance, side effects, technique
- Peak flow to evaluate if cough is due to exacerbation in those with known asthma.

## *DIET*

Food allergies and sulfites (in food and wine) can precipitate symptoms for some patients.

## *PATIENT EDUCATION*

- Patients' care plan and inhaled medication technique at every visit.
- American Academy of Allergy, Asthma & Immunology: 800-822-2762 or <http://www.aaaai.org/>
- American Lung Association: [www.lungusa.org](http://www.lungusa.org)
- Asthma and Allergy Foundation of America: 800-727-8462 or <http://www.aafa.org/>
- Mattress and pillow covers DO NOT improve outcomes and should not be recommended.

## *PROGNOSIS*

- Prognosis is good for male patients, nonsmokers, and children with mild disease.
- Asthma worsens in 1/3 of women during pregnancy and improves in another 1/3.

## **COMPLICATIONS**

- Atelectasis
- Pneumonia
- Air leak syndromes: pneumomediastinum, pneumothorax
- Medication-specific side effects/adverse effects/interactions
- Respiratory failure
- Death: ~50% of asthma deaths occur in the elderly (age >65 years), and mortality is increasing in that population (5).

Algorithm: Asthma Exacerbation, Pediatric Acute

### Codes

#### ICD10

- J45.909 Unspecified asthma, uncomplicated
- J45.901 Unspecified asthma with (acute) exacerbation
- J45.20 Mild intermittent asthma, uncomplicated

## Clinical Pearls

- SABA is the most effective rescue therapy for acute asthma symptoms.
- Holding chambers should be used by all
- ICSs are the preferred long-term control therapy for patients of all ages.

- Peak flow is an inexpensive and easily available monitoring device once the diagnosis of asthma has been established.

# Atelectasis

**Bruce Jay Gardner, MD**

**Fahad Pervez, MD**

## BASICS

### DESCRIPTION

- Incomplete expansion of lung tissue with resultant loss of lung volume and function, leading to impaired airway mucus clearance
- Broadly categorized as:
  - Obstructive: blockage within an airway
  - Nonobstructive: loss of contact between the parietal and visceral pleurae, replacement of lung tissue by scarring or infiltrative disease, surfactant dysfunction, and parenchymal compression
- Symptoms depends on the rapidity with which bronchial occlusion occurs, the size of the lung area affected, and the presence or absence of lung disease and comorbidities.
- Reduced respiratory gas exchange can lead to hypoxemia and other pulmonary complications.

### EPIDEMIOLOGY

- Affects all ages; mean age is 60 years.
- Male = female. No racial predilection.

### Incidence

- Round atelectasis (see "Initial Tests (lab, imaging)") is high in asbestos workers (65-70%).
- Incidence of lobar atelectasis depends on the collateral ventilation within each individual lung lobe.

### Prevalence

Postoperative atelectasis is extremely common, affecting up to 90% of surgical patients, especially after major cardiac or GI procedures.

# ETIOLOGY AND PATHOPHYSIOLOGY

- Obstructive (resorptive) atelectasis is more common and is caused by intrinsic respiratory blockage
  - Due to luminal blockage (foreign body, mucus plug, asthma, cystic fibrosis, trauma, tumor) or airway wall abnormality (congenital malformation, emphysema)
  - Distal to the obstruction, air is reabsorbed from the alveoli into the deoxygenated venous system, causing complete collapse of the alveolar tissue.
  - There are three collateral ventilation systems in each lobe: the pores of Kohn, canals of Lambert, and fenestrations of Boren. The patency and formation of the systems depends on multiple factors including age, lung disease, and  $FiO_2$ .
  - Age: Due to the late development of collaterals in children, atelectasis is frequently diagnosed after foreign body aspiration.
  - Emphysema: The fenestra of Boren in emphysematous patients often becomes enlarged; this enlargement can lead to a delay in atelectasis despite an obstructing lesion or mass.
  - $FiO_2$ : Oxygen rapidly dissociates from alveoli to deoxygenated vessels in an obstructed airway. The 79% nitrogen in atmospheric air has a slower rate of dissociation from the alveoli, and thereby prevents collapse by maintaining positive pressure inside the alveoli. With increased  $FiO_2$ , the concentration of nitrogen is decreased predisposing patients to rapid development of atelectasis at the onset of obstruction.
- Nonobstructive atelectasis
  - Passive atelectasis: results from pleural membrane separation of the visceral and parietal layers
    - Pleural effusion, pneumothorax
  - Compression atelectasis: alveoli compression leading to diminished resting volume (functional residual capacity [FRC]):
    - Space-occupying lesions, lymphadenopathy, cardiomegaly, abscess, chest wall pressure
  - Adhesive atelectasis: surfactant dysfunction resulting in increased surface tension and alveoli collapse
    - Respiratory distress syndrome, acute respiratory distress syndrome (ARDS), radiation exposure, smoke inhalation, uremia
  - Cicatrization: pleural or parenchymal scarring

Granulomatous disease, toxic inhalation, drug-induced fibrosis (e.g., amiodarone), radiation exposure

- Replacement atelectasis: diffuse tumor manifestation resulting in complete lobar collapse
  - Bronchioalveolar cell carcinoma
- Rounded atelectasis: distinct form of atelectasis following asbestos exposure
- Others
  - Hypoxemia due to pulmonary embolus
  - Muscular weakness (anesthesia, neuromuscular disease)

## *RISK FACTORS*

- General anesthesia: positive fluid balance, <sup>34</sup> units blood transfusion, use of nasogastric tube, long-acting muscle relaxants, hypothermia, postoperative epidural anesthesia, ventilator settings with high tidal volume and plateau pressure
- Surgical procedures: cardiothoracic, upper GI, neurosurgery, oromaxillofacial, ENT, vascular
- Patient risk factors for developing postoperative atelectasis:
  - Age >60 and <6 years, chronic obstructive pulmonary disease (COPD), obstructive sleep apnea, CHF, alcohol abuse, pulmonary hypertension, albumin <3.5 g/dL, hemoglobin <10 g/dL, BMI >27 kg/m<sup>2</sup> (weak evidence), ASA class II + functional dependence in activities of daily living (ADL), heart failure, smoking
- Intensive care and prolonged immobilization
- Brock syndrome: recurrent right middle lobe collapse secondary to airway disease, infection, or a combination thereof. The right middle lobe airway is long and thin and has the poorest drainage and clearance of the lobes, resulting in trapped mucus.

## *GENERAL PREVENTION*

- Early mobilization, deep breathing exercises, coughing, and frequent changes in body position
- Preoperative physical therapy lowered rates of atelectasis, PNA, and LOS in elective cardiac surgery without improving other postoperative pulmonary complications or mortality (1)[A]. Further large RCTs are needed before conclusions can be made regarding the effect of chest physiotherapy and incentive spirometry.
- Mechanical ventilation settings with high tidal volumes ( $V_t > 10$  mL/kg), high plateau pressures (>30 cm H<sub>2</sub>O), and without positive end-expiratory pressure (PEEP) are associated with

postoperative pulmonary complications such as pneumonia and respiratory failure:

- Ventilator-induced lung injury can be minimized by using low Vt and plateau pressures at sufficient PEEP while maintaining lower FiO<sub>2</sub> during anesthetic induction and intraoperatively.
- Application of continuous positive airway pressure (CPAP) during anesthesia induction and reversal of anesthesia-induced atelectasis after intubation by a recruitment maneuver may decrease postoperative pulmonary complications (2)[C].

## COMMONLY ASSOCIATED CONDITIONS

- COPD and asthma
- Trauma
- ARDS, neonatal respiratory distress syndrome, pulmonary edema, pulmonary embolism
- Neuromuscular disorders (muscular dystrophy, spinal muscular atrophy, spinal cord injury), cystic fibrosis
- Respiratory syncytial virus (RSV), bronchiolitis
- Bronchial stenosis, pulmonic valve disease, pulmonary hypertension
- Pneumonia, pleural effusion, pneumothorax

## DIAGNOSIS

### HISTORY

- Frequently asymptomatic
- Tachypnea and sudden-onset dyspnea
- Nonproductive cough
- Pleuritic pain on affected side
- History of smoking, COPD, pulmonary insufficiency, exposure to radiation, asbestos, or other air pollutants

## PHYSICAL EXAM

- Signs of hypoxia or cyanosis
- Tracheal or precordial impulse displacement toward the affected side; dullness to percussion
- Bronchial breathing if airway is patent

- Wheezing or absent breath sounds if airway is occluded
- Diminished chest expansion

## *DIFFERENTIAL DIAGNOSIS*

See Etiology and Pathophysiology.

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- CBC and sputum culture if infection suspected
- ABG: despite hypoxemia, the PaCO<sub>2</sub> level is usually normal or low
- Chest x-ray (CXR), PA and lateral
  - Raised diaphragm, flattened chest wall, movement of fissures and mediastinal structures toward the atelectatic region
  - Unaffected lung may show compensatory hyperinflation.
  - Wedge-shaped densities: obstructive atelectasis
  - Small, linear bands (Fleischner lines) often at lung bases: discoid (subsegmental or plate) atelectasis
  - Lobar collapse
    - Direct signs: displacement of fissures and opacification of the collapsed lobe. Right upper lobe collapse may display the inverted S sign of Golden, suggesting neoplastic shift of the minor fissure.
    - Indirect signs: displacement of the hilum, mediastinal shift toward the side of collapse, loss of volume of ipsilateral hemithorax, elevation of ipsilateral diaphragm, crowding of the ribs, compensatory hyperlucency of remaining lobes, and silhouetting of the diaphragm or heart border

---

P.89

- Air bronchograms: Evidence of pleural fluid or air may indicate compressive atelectasis.
- Adhesive atelectasis may present as a diffuse reticular granular pattern, progressing to a pulmonary edema pattern, and finally to bilateral opacification in severe cases.
- Pleural-based round density on CXR: round atelectasis
- Complete atelectasis of entire lung: opacification of the entire hemithorax and an ipsilateral shift of the mediastinum

## *Follow-Up Tests & Special Considerations*

- Chest CT or MRI may be indicated to visualize airway and mediastinal structures and identify cause of atelectasis.
- Pulmonary function tests (PFTs) may detect restrictive disease, decreased respiratory muscle pressures, or airflow obstruction.
- Low serum albumin (<3.5 g/L) is a powerful marker of increased risk for postoperative pulmonary complications, including atelectasis.

## *Diagnostic Procedures/Other*

Bronchoscopy can be considered in unexplained or refractory cases.

## **TREATMENT**

### **GENERAL MEASURES**

- Prevention following surgery or general anesthesia using PEEP (2)[C]
- Treat the underlying cause.
- Ensure patient is lying on the unaffected side to promote drainage:
  - Maximize mobility and encourage frequent coughing and deep breathing.
- Incentive spirometry every hour while awake
  - Lack of evidence for incentive spirometry preventing postoperative pulmonary complications after coronary artery bypass graft (CABG) (3)[A]
- Initiate intubation and mechanical ventilation with PEEP in severe respiratory distress or hypoxemia:
  - Lower tidal volume (6 mL/kg) and lower end-inspiratory values (<30 mm Hg) are associated with reduced mortality.
  - PEEP 15 to 20 mL may be necessary to maintain arterial O<sub>2</sub> saturation in surfactant-impaired states.
- Postsurgical measures include positive airway pressure, continuous or intermittent.

### **MEDICATION**

## *First Line*

Pharmacotherapy should be tailored to address underlying cause:

- Antibiotics for infection
- Chemo/radiation therapy for tumor
- Steroids for asthma
- Effective analgesia to permit deep inspiration and coughing
- Mucolytics can be considered to promote airway clearance (NAC and saline most commonly studied).

## *Pediatric Considerations*

- RhDNase may be effective clearing mucinous secretions in refractory mucous plugging in children.
- Chest physiotherapy (i.e., percussion, drainage, deep insufflation, and saline lavage) is a common treatment modality in the hospital setting. Caution must be practiced when interpreting the possible positive effects as the number of patients studied is small, the results are not consistent across trials, data on safety are insufficient, and there may be limited applicability to current guidelines.
- Application of continuous distending pressure has some benefit in the treatment of preterm infants with respiratory distress syndrome and has the potential to reduce lung damage particularly if applied early (4)[A].

## *Second Line*

Bronchofibroscope in aspiration of inspissated secretions to improve airway clearance has been efficacious in several studies. However, debate continues regarding its efficacy in the treatment of atelectasis.

## *Pediatric Considerations*

In obstructive atelectasis, bronchoscopy remains controversial. In the presence of a mucus plug or cast, bronchoscopy may be beneficial.

## ***SURGERY/OTHER PROCEDURES***

- Appropriate surgical resection for underlying disease (e.g., tumor, severe lymphadenopathy)
- Bronchoscopy

## ***INPATIENT CONSIDERATIONS***

## *Admission Criteria/Initial Stabilization*

Ensure adequate oxygenation (may start with 100% FiO<sub>2</sub> then taper) and humidification

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Depends on underlying cause and comorbidities
- In uncomplicated cases of atelectasis associated with asthma or infection, outpatient monitoring is appropriate.

### *PATIENT EDUCATION*

Maximize patient mobility and encourage frequent coughing and deep breathing.

### *PROGNOSIS*

- For postoperative atelectasis, spontaneous resolution usually occurs within 24 hours but can persist for days after surgery.
- The prognosis of lobar atelectasis secondary to endobronchial obstruction depends on treatment of the underlying disease or malignancy.
- Surgical therapy is needed only for resectable causes or if chronic infection and bronchiectasis supervene.

### **COMPLICATIONS**

- Pneumonia and pulmonary infections
- Acute atelectasis
  - Hypoxemia and respiratory failure
  - Postobstructive drowning of the lung
- Chronic atelectasis
  - Bronchiectasis
  - Pleural effusion and empyema

## ICD10

J98.11 Atelectasis

## Clinical Pearls

- No strong clinical evidence supports atelectasis as an early cause of postoperative fever.
- Anesthesia-induced atelectasis occurs in almost all anesthetized patients.
- Bronchogenic carcinoma, which may present with atelectasis, must be excluded in all patients >35 years.
- In complete atelectasis of an entire lung, the mediastinal ipsilateral shift separates atelectasis from massive pleural effusion.
- Low serum albumin is a powerful predictor of postoperative pulmonary complications, including atelectasis.

# Atrial Fibrillation and Atrial Flutter

Youhua Zhang, MD, PhD

Bianca Lee, DO, MS

## BASICS

This topic covers both atrial fibrillation (AFib) and atrial flutter (AFlut).

### DESCRIPTION

- AFib: Paroxysmal or continuous supraventricular tachyarrhythmia characterized by rapid, uncoordinated atrial electrical activity and an irregularly irregular ventricular response. In most patients, the ventricular rate is rapid because the atrioventricular (AV) node is bombarded with very frequent atrial electrical impulses (400 to 600 bpm).
- AFlut: Paroxysmal or continuous supraventricular tachyarrhythmia with rapid but organized atrial electrical activity. The atrial rate is typically between 250 and 350 bpm and is often manifested as sawtooth flutter (F) waves on the ECG, particularly in the inferior leads and  $V_1$ . AFlut commonly occurs with 2:1 or 3:1 AV block, so the ventricular response may be regular and typically at a rate of  $\div 150$  bpm.
- AFib and AFlut are related arrhythmias, sometimes seen in the same patient. Distinguishing the two is important, as there may be implications for management.
- Clinical classifications:
  - Paroxysmal: self-terminating episodes, usually  $<7$  days
  - Persistent: sustained  $>7$  days, usually requiring pharmacologic or DC cardioversion to restore sinus rhythm
  - Permanent: Sinus rhythm cannot be restored or maintained. It is a shared decision between patient and clinician as to when to cease further attempts to restore and/or maintain sinus rhythm.
- Lone AFib occurs in patients  $<60$  years (with possible genetic predisposition) who have no clinical or echocardiographic evidence of cardiovascular disease, including hypertension (HTN).

### EPIDEMIOLOGY

- Incidence/prevalence increases significantly with age.

- Young patients with AFib, particularly lone AFib, are most commonly males.

## *Incidence*

- AFib: from <0.1%/year <40 years to >1.5%/year >80 years
- Lifetime risk: 25% for those <sup>3</sup>40 years
- AFlut is less common.

## *Prevalence*

- Estimated at 0.4-1% in general population, with 2.7 million patients in America
- Increase with age, up to 8% in those <sup>3</sup>80 years

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Cardiac: HTN, ischemic heart disease, heart failure, valvular heart disease, cardiomyopathy, pericarditis, and infiltrative heart disease
- Pulmonary: pulmonary embolism (PE), chronic obstructive pulmonary disease (COPD), obstructive sleep apnea, pneumonia
- Ingestion: ethanol, caffeine
- Endocrine: hyperthyroidism, diabetes
- Obesity
- Postoperative: cardiac, pulmonary, or esophageal
- Idiopathic: lone AFib
- Patients with paroxysmal episodes are usually associated with premature atrial beats and/or bursts of tachycardia, originating in pulmonary vein ostia or other sites.
- Many patients with AFib are thought to have some degree of atrial fibrosis or scarring. This is often subclinical and usually not detectable with current cardiac imaging techniques but plays an important role in the pathogenesis of the arrhythmia.
- Autonomic (vagal and sympathetic) tone may play a role in triggering the arrhythmia.
- The presence of AFib is associated with electrical and structural remodeling processes that promote arrhythmia maintenance in the atria, termed "AFib begets AFib."

## *Genetics*

Familial forms are rare but do exist. There are ongoing efforts to identify the genetic underpinnings of such cases.

## **RISK FACTORS**

Age, HTN, and obesity are the most important risk factors for both AFib and AFlut.

## **GENERAL PREVENTION**

Adequate control of HTN may prevent development of AFib due to hypertensive heart disease and is the most significant modifiable risk factor for AFib. Weight reduction may decrease the risk of AFib in obese patients. Ethanol consumption may trigger AFib in some.

## **COMMONLY ASSOCIATED CONDITIONS**

HTN and other cardiac diseases

## **DIAGNOSIS**

### **HISTORY**

Symptoms vary from none to mild (palpitations, lightheadedness, fatigue, poor exercise capacity) to severe (angina, dyspnea, syncope).

## **PHYSICAL EXAM**

- AFib: irregularly irregular heart rate and pulse, frequently tachycardiac, pulse deficit
- AFlut: similar to AFib but may have regular pulse

## **DIFFERENTIAL DIAGNOSIS**

- Multifocal atrial tachycardia
- Sinus tachycardia with frequent atrial premature beats
- Paroxysmal supraventricular tachycardia (Wolff-Parkinson-White [WPW], atrioventricular nodal reentry tachycardia [AVNRT])

## **DIAGNOSTIC TESTS & INTERPRETATION**

- AFib: The ECG is diagnostic, with findings of low-amplitude fibrillatory waves without discrete P waves and an irregularly irregular pattern of QRS complexes. There is often tachycardia in the absence of heart rate-controlling medications (1).
- AFlut: The ECG is again diagnostic. Saw-tooth flutter waves are the classic sign, generally best seen in the inferior leads, although ventricular rate may need to be slowed to see the waves. QRS complexes may be regular or irregular; there is usually tachycardia (1).

- Ambulatory rhythm monitoring (e.g., telemetry, Holter monitoring, event recorders) is helpful in diagnosing paroxysmal AFib or AFLut and monitoring for recurrence (1)[C].

### *Initial Tests (lab, imaging)*

TSH, electrolytes, CBC, 2-D transthoracic echocardiogram, PT/INR (if anticoagulation is contemplated); digoxin level (if appropriate)

### *Follow-Up Tests & Special Considerations*

- Occasional Holter monitoring and/or exercise stress testing to assess for adequacy of rate and/or rhythm control
- Chest x-ray (CXR) for cardiopulmonary disease
- ECG for signs of cardiac hypertrophy, ischemia, and/or other arrhythmias
- Transesophageal echocardiogram to detect left atrial appendage thrombus if cardioversion is planned
- Sleep study may be useful if sleep apnea is suspected.

### *Test Interpretation*

- Atrial dilatation and fibrosis
- Atrial thrombus, especially in atrial appendage
- Valvular/rheumatic disease
- Cardiomyopathy

## **TREATMENT**

### *MEDICATION*

- Two primary issues in the management of AFib and/or AFLut:
  - Decisions on heart rate control (control ventricular rate while allowing AFib to continue) or rhythm control (terminate AFib and restore normal sinus rhythm)
  - Anticoagulation therapy to prevent thromboembolism (primarily stroke)
- Anticoagulation guidelines (the same for AFib and AFLut) (1,2)[C]:
- CHA<sub>2</sub>DS<sub>2</sub>VASc scoring (**CHF** [1 point], **HTN** [1 point], **Age** <sup>3</sup>75 [2 points], **DM** [1 point], prior **Stroke** or **TIA** [2 points]), **V**ascular disease (1 point), **A**ge 65 to 74 years (1 point), female **S**ex

category (1 point) (1,2,3). CHA<sub>2</sub>DS<sub>2</sub>VASc is the recommended stroke risk assessment for patients with nonvalvular AFib (1)[B].

- In patients with nonvalvular AFib and a CHA<sub>2</sub>DS<sub>2</sub>VASc score of 0, antithrombotic therapy may be omitted (1)[B].
- In patients with nonvalvular AFib and a CHA<sub>2</sub>DS<sub>2</sub>VASc score of 1, no antithrombotic therapy or oral anticoagulant or aspirin is recommended (1)[C].
- Unless contraindicated, patients with nonvalvular AFib with any high-risk factors for stroke (prior transient ischemic attack [TIA]/cerebrovascular accident [CVA]/thromboembolism) or a CHA<sub>2</sub>DS<sub>2</sub>VASc score <sup>3</sup>2 should receive oral anticoagulants. The following oral anticoagulants include warfarin maintaining an INR of 2.0 to 3.0 (1,3)[A], dabigatran (1)[B], rivaroxaban (1)[B], or apixaban (1)[B]. Patients with mechanical valves should maintain an INR of 2.0 to 3.0 or 2.5 to 3.5 dependent on the type and location of the prosthesis (1)[B]. For patients with AFib and mitral stenosis, a target INR range of 2.0 to 3.0 is recommended (2)[B].
- Dabigatran (Pradaxa), a direct thrombin inhibitor, and apixaban (Eliquis) and rivaroxaban (Xarelto), factor Xa inhibitors, have recently been approved as alternatives to warfarin for the prevention of first and recurrent stroke in patients with nonvalvular AFib (1,3)[B]. The selection of an antithrombotic should be individualized (1)[B]; consider the risks of each agent, cost, patient preference, and tolerability (1)[C].
  - ALERT: Renal function should be evaluated prior to initiation of direct thrombin or factor Xa inhibitors (1)[B]. Dosing of such agents may in fact need individualized adjustment.
  - ALERT: Direct thrombin inhibitor dabigatran should not be used in patients with AF and a mechanical heart valve (1)[B].
- Anticoagulation recommendations are independent of AFib pattern (paroxysmal, persistent, and permanent) (1,2)[B] although ongoing efforts to better understand who may be at greater and lesser risk of thromboembolism continue.
- Four classes of medications are available to achieve ventricular rate control:  $\beta$ -blockers (i.e., metoprolol), nondihydropyridine calcium channel blockers (i.e., verapamil, diltiazem), digoxin, and amiodarone. Optimal target for ventricular rate has not been firmly established, but there is evidence that aggressive control of the ventricular rate (<80 bpm) offers no benefit beyond more modest rate control (i.e., resting heart rate <110 bpm) (1,4)[B].
- Preventing rapid ventricular response (RVR) rates using AV nodal blocking medications is also often effective at controlling a patient's symptoms associated with AFib or AFLut. Patients in

whom rate control cannot be achieved or who continue to have persistent symptoms despite reasonable heart rate control may require attempts at restoration of sinus rhythm.

- Of note, ventricular rate control can often be difficult to achieve in AFLut due to the more organized nature of the atrial electrical activity. For this reason, conversion to sinus rhythm is often the preferred strategy, and catheter ablation is also considered as a first-line treatment in recurrent AFLut (1).
- Restoration of sinus rhythm using electrical or pharmacologic cardioversion may significantly reduce the symptom burden of AFib or AFLut in many patients and may also be useful for controlling ventricular rate. Cardioversion does not impact the long-term risk/benefit ratio of anticoagulation:
  - Cardioversion is most often performed electrically, but may also be achieved using antiarrhythmic drug therapy in some instances, by experienced clinicians (1)[A].
  - If duration of AF is >48 hours or unknown, anticoagulate for <sup>3</sup>3 weeks before cardioversion to reduce the risk of stroke. Alternatively, once anticoagulation is established, a transesophageal echo may be performed to exclude the presence of left atrial thrombus, allowing cardioversion to proceed. After cardioversion, anticoagulation should be continued for <sup>3</sup>4 weeks in all patients in whom duration of AFib/AFLut is >48 hours, as the postcardioversion period is a time of increased stroke risk (1,2)[B].
- Randomized clinical trials (AFFIRM and RACE) comparing the outcomes of rate versus rhythm control found no difference in morbidity, mortality, and stroke rates in patients assigned to one therapy or the other (1).
- Chronic PO antiarrhythmic therapy to suppress AFib recurrence is available for appropriately selected patients. Expert consultation is recommended owing to the complexities of safe antiarrhythmic drug selection.

## ***ISSUES FOR REFERRAL***

Management of AFib or AFLut refractory to standard medical therapy (i.e., unable to achieve adequate rate control with medication or development of significant bradycardia with treatment) may require the use of more aggressive treatments. These may include pacemaker implantation (to allow for more intensive pharmacologic blocking of the AV node) or an ablation procedure. AFLut in particular is often very amenable to ablation; thus, consideration should be given to early expert referral in appropriate patients. Antiarrhythmic drug therapy can often be very effective but should be prescribed by experienced practitioners.

## ***SURGERY/OTHER PROCEDURES***

- Electrophysiologic study and ablation may be considered for patients with either AFib or AFLut. In the case of AFLut, ablation is often a relatively straightforward procedure generally viewed

as a first-line therapy due to its high rate of success in appropriate candidates. Ablation of AFib is a much more complex procedure with a more variable success rate; it continues to evolve. Thus, it is typically reserved for drug refractory patients.

- Cardiac surgery (e.g., the maze procedure, ligation of the left atrial appendage) may be considered in patients planning to undergo cardiac surgery for other reasons. Surgical therapy in isolation is rarely indicated for AFib or AFLut.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Patients with significant symptoms, RVR, AFib/AFlut triggered by an acute process (e.g., MI, CHF, PE), or in whom antiarrhythmic therapy is being started likely require admission to the hospital for a period of stabilization.
- Outpatient management is reasonable for low-risk patients with controlled ventricular rates.
- Acute therapy for symptomatic or hemodynamically compromised patients with AFib or AFLut:
  - IV  $\beta$ - or nondihydropyridine calcium channel blockers for control of ventricular rate. Once hemodynamically stable, oral medications may be administered (1)[B].
- Commonly used therapies in the acute setting include (1):
  - Metoprolol tartrate: 2.5-5.0 mg IV bolus over 2 minutes; up to 3 doses
  - Diltiazem: 0.25 mg/kg IV bolus over 2 minutes, then 5 to 15 mg/hr
  - Some patients will be far more responsive to one class of agents than another. For this reason, if rate control is difficult to achieve, switching drug classes may be useful.
- Urgent cardioversion should be performed in hemodynamically unstable patients (1)[B]. It is somewhat unusual for AFib or AFLut alone to cause marked hemodynamic insult; thus, the possibility of a concurrent process should be considered in this setting.
- Consider the initiation of PO anticoagulation therapy. Inpatients may be bridged with IV or SC heparin or SQ low-molecular-weight heparin (LMWH) while waiting for warfarin to become effective (1)[C].

### *Discharge Criteria*

Adequate rate or rhythm control without symptoms; long-term plan for anticoagulation established

## ONGOING CARE

Many patients may benefit from elective expert consultation. In patients with no significant symptoms, if ventricular rate control or sinus rhythm is easily achieved and the choice of thromboembolic prevention is clear, management in a primary care setting may be appropriate.

## FOLLOW-UP RECOMMENDATIONS

### *Patient Monitoring*

Adequate anticoagulation levels (if warfarin is employed) should be determined at least weekly during initiation and monthly when stable (1)[A]. Ventricular rate control should be assessed on a regular basis.

### *DIET*

Patients on warfarin should attempt to consume a stable amount of vitamin K.

## PROGNOSIS

Anticoagulation reduces the annual embolic stroke rate from  $\div$ 5-6% per year to 1-2% for most patients. AFib and AFLut may increase morbidity and mortality, but the overall prognosis is a function of underlying heart disease and adherence with therapy. Reported risk of anticoagulation varies but lies between 1% and 4% per year for major hemorrhage.

## COMPLICATIONS

- Embolic stroke
- Peripheral arterial embolization
- Bleeding with anticoagulation
- Tachycardia-induced cardiomyopathy with prolonged periods of inadequate rate control

## Codes

### ICD10

- I48.91 Unspecified atrial fibrillation
- I48.92 Unspecified atrial flutter
- I48.0 Paroxysmal atrial fibrillation

## Clinical Pearls

- Primary decision in persistent AFib is whether to strive for rate control or rhythm control. Younger patients often do better with a rhythm control strategy, whereas older patients often do well with rate control. Decision is complex.
- Anticoagulation recommendations are based on the risk of thromboembolism irrespective of the AFib pattern.

# Atrial Septal Defect

Edlira Yzeiraj, DO, MS

Edward A. Gotfried, DO, FACOS

## BASICS

### DESCRIPTION

- Anatomy
  - Opening in the atrial septum allowing flow of blood between the two atria
  - Patent foramen ovale is also an open communication between the atria, but it is not considered an ASD because no septal tissue is missing.
- Types (by location in the interatrial septum) (1)
  - Classified based on their different anatomic location and abnormal embryogenesis: secundum ASD, primum ASD, sinus venosus ASD, coronary sinus ASD.
  - 70%: Ostium secundum defect occurs in the fossa ovalis region.
  - 15-20%: Ostium primum defect occurs in the inferior septum; often associated with cleft mitral valve and failure of endocardial cushion development.
  - 5-10%: Sinus venosus defect occurs in the superior-posterior septum near the orifice of the superior vena cava; usually associated with partial anomalous right upper pulmonary venous return.
  - Less than 1%: Coronary sinus defect: part of the entire common wall between the coronary sinus and the LA is absent.
- Hemodynamic effects
  - Left-to-right shunting in late ventricular systole and early diastole
  - Degree depends on size of the defect and relative pressures of the two ventricles.
  - Causes excessive blood flow through the rightsided circulation, ultimately leading to reactive pulmonary hypertension and heart failure
- Systems affected: cardiovascular; pulmonary

## *Pediatric Considerations*

- Most cases of ASD are detected and corrected in the pediatric population.
- The smaller the defect and the younger the child, the greater the chance of spontaneous closure.

## *EPIDEMIOLOGY*

### *Incidence*

- Predominant age: present from birth, may be diagnosed at any age
- Slight female predominance (2)
- No race predilection
- 2/1,000 live births (3)

### *Prevalence*

- ASDs account for 13% of congenital heart disorders (3)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Flow across ASD usually left-to-right shunt because of higher left-sided pressures:
  - Minimal right-to-left shunting in early ventricular systole, especially during inspiration
  - Increased right-sided pressure/pulmonary hypertension can cause reversal of shunt flow (Eisenmenger syndrome) with resulting cyanosis and clubbing.
- Symptoms typically occur due to right ventricular and pulmonary vascular volume overload and rightsided heart failure.

### *Genetics*

- Most cases are spontaneous.
- 5% with chromosomal abnormalities; other rare mutations exist
- 25% prevalence in Down syndrome

## *RISK FACTORS*

- Other congenital heart defects
- Family history (÷7-10% recurrence)

Thalidomide, alcohol exposure in utero, smoking, maternal age >35 years, and elevated blood glucose have been associated with increased risk (2).

## COMMONLY ASSOCIATED CONDITIONS

- ASDs may occur as a component of other complex cardiac structural defects.
- Important to exclude anomalous pulmonary venous return
- Occasionally can indicate underlying genetic syndromes, for example: Holt-Oram (ASD present in 66%), Ellis-van Creveld, VACTERL syndrome, or Noonan syndrome.
- Overall, ÷ 70% isolated (1)

## DIAGNOSIS

### HISTORY

- Most ASDs are small and do not cause symptoms in infancy and childhood and are often found on routine physical examination when a cardiac murmur is detected incidentally.
- Infants with large ASDs may present with right-sided heart failure (more advanced, only 10% at diagnosis), recurrent respiratory infections, or failure to thrive.
- Should be considered in children with other congenital heart defects, Down syndrome
- In uncorrected defects, most people become symptomatic by age 40. Common symptoms in adults include atrial arrhythmias (the most frequent presenting symptom), exercise intolerance, dyspnea, and fatigue.

## PHYSICAL EXAM

- Signs vary according to extent of shunting.
- Cardiac auscultation
  - *Fixed, widely split S<sub>2</sub> (key physical finding)*
  - May also have
    - Systolic ejection murmur (pulmonic flow murmur)
    - Low-pitched diastolic rumble (tricuspid flow murmur)
    - Diastolic murmur (pulmonic regurgitation)

- Systolic murmur (mitral regurgitation)
- Right ventricular heave
- Palpable pulmonary artery pulse at left upper sternal border
- If heart failure has developed, may hear a 4th heart sound (right-sided)
- Signs of Eisenmenger syndrome:
  - Cyanosis and clubbing
  - Jugular venous distention and edema

## *DIFFERENTIAL DIAGNOSIS*

- Other congenital heart disease
- Right bundle branch block (for widely split S<sub>2</sub>)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Echocardiography is the test of choice (1)[C].
- Generally start with transthoracic Doppler imaging of the entire atrial septum (sensitivity is ÷89% for secundum, ÷100% for primum, and ÷44% of sinus venosus ASDs), with progression to transesophageal echocardiography (TEE) if transthoracic echocardiography (TTE) is nondiagnostic
- Patients with right ventricular overload by TTE but an otherwise negative study should have further testing.
- Oximetry: Cyanosis may suggest Eisenmenger syndrome (right-to-left shunting).
- ECG is not typically diagnostic, but findings include the following:
  - Right axis deviation
  - Right atrial enlargement (tall P in inferior leads)
  - Right ventricular conduction delay
  - Q wave in lead V<sub>1</sub>
  - Right bundle branch block
  - Leftward axis, inverted P wave in lead III (sinus venosus)
  - Leftward axis (ostium primum)

## *Follow-Up Tests & Special Considerations*

- Bubble contrast enhancement may be helpful.
- TEE may be required to define ASD morphology and to locate the pulmonary veins; often used prior to percutaneous closure. TEE has excellent sensitivity and specificity.

## *Diagnostic Procedures/Other*

- Cardiac catheterization (1)[C]
  - Demonstrates right ventricle enlargement, location/fraction of the shunt, size of the ASD, any valvular disease, and overall anatomy
  - Used to assess pulmonary vascular resistance if pulmonary hypertension is suspected, particularly if surgery is planned
  - Generally not used in young patients for initial diagnosis, more often reserved for use when
- Part of a planned interventional closure
- Evaluating other disease simultaneously (e.g., coronary artery disease)
- Visualization by other methods insufficient
- Cardiac magnetic resonance: a noninvasive follow-up to echo that allows viewing the defect/pulmonary veins and measurement of shunt fraction and right ventricular function—particularly useful for sinus venosus defects (2)
- Exercise testing: useful to quantify symptoms not consistent with clinical findings or to document change over time (1)[C]
- Chest x-ray: may demonstrate right ventricular and pulmonary artery enlargement, increased pulmonary vascular markings
- Cardiac CT scans can also define ASDs but with significant radiation exposure.

## **TREATMENT**

### **GENERAL MEASURES**

- 75% of small secundum ASDs (<8 mm) will close spontaneously by 18 months of age; however, close follow-up is warranted (2).
- The likelihood of spontaneous closure is mainly determined by defect diameter: >10 mm at time of diagnosis is unlikely to spontaneously close (4).

- Primum and sinus venosus defects do not generally close and generally require surgical closure (2).

## *MEDICATION*

### *First Line*

- Treatment of secondary atrial fibrillation/supra-ventricular tachycardia with anticoagulation and cardioversion, followed by anticoagulation with maintenance of sinus rhythm if possible, or rate control if this fails (1)[A]
- Pulmonary vasodilator therapy may be considered for adults with progressive/severe pulmonary vascular disease (1)[B].
- Treatment of heart failure (diuretics, oxygen, digoxin, etc.)

---

P.93

### *Second Line*

- Antibiotic prophylaxis is NOT recommended for unrepaired/isolated ASDs.
- The American Heart Association (AHA) recommends antibiotic prophylaxis against infective endocarditis during dental procedures for 6 months after the repair in patients whom a device or prosthetic material is used (5)[B].
  - In patients with repaired ASD who have a residual defect at or adjacent to the device, prophylaxis is recommended indefinitely.
  - If prophylaxis is indicated, for dental procedures, amoxicillin 2 g (adults) or 50 mg/kg (children). Other options include cephalosporins (e.g., ceftriaxone 1 g [adults] or 50 mg/kg [children] IM or IV) or clindamycin 600 mg PO (adults) or 20 mg/kg PO (children) or azithromycin 500 mg PO (adults) or 15 mg/kg (children) in patients who are penicillin-sensitive (5,6)[B].
- To prevent thrombus formation after device deployment, aspirin alone or a combination of aspirin and clopidogrel 75 mg for at least 6 months is recommended (7).

## *SURGERY/OTHER PROCEDURES*

- The majority of small secundum defects, <6 mm, close spontaneously by 2 years of age, and some as late as 5 years. Closure is generally indicated in children with:
  - Defect >8 mm (unlikely to close) in children older than 2 years of age (to allow time for spontaneous closure, even though uncommon)
  - Defects of any size in a child older than 5 years with related symptoms

- Closure for secundum defects is not recommended in asymptomatic patients before 2 years of age given the possibility of spontaneous closure.
- In adults, secundum closure via percutaneous trans-catheter device or surgery to reduce subsequent morbidity and mortality, if:
  - Right side heart enlargement regardless of symptoms (1)[B]
  - Pulmonary systemic flow ratio is 2:1 (or >1.5:1 and <21 years old according to the AHA)
  - Symptoms such as documented orthodeoxia/platypnea or paradoxical embolism (1)[C]
- Surgical repair is standard for a sinus venosus, coronary sinus, or primum ASD (1,2)[B]. These defects rarely close spontaneously and are not considered amenable to percutaneous closure.
- Percutaneous closure is considered the treatment of choice of secundum ASD in adults (8)[A]. It is a safe and effective with satisfactory long-term clinical follow up. In addition, the use of closure device does not significantly affect aortic or mitral valve function (8)[B].
- Secundum ASDs that are suitable for percutaneous closure should be  $\pm$ 35 mm in stretched balloon diameter and should have a sufficient rim of surrounding atrial tissue.
- Closure is not indicated for patients who have developed irreversible severe pulmonary hypertension without continued shunting or those who never develop symptoms and have an ASD <5 mm (1)[B].
- Overall, closing small asymptomatic secundum ASDs is controversial and not often done.
- Maze procedure may be considered before or after closure for patients with intermittent or chronic atrial tachyarrhythmias (1)[C].

## ***FOLLOW-UP RECOMMENDATIONS***

Echocardiography can be used to monitor both repaired and unrepaired ASDs.

### ***Patient Monitoring***

- In otherwise asymptomatic healthy children, follow up until defect has closed or become negligible in size.
- Appropriate evaluation and management for atrial tachyarrhythmias in patients with long-term follow-up (1)[C]
- If ASD repaired as an adult, periodic long-term follow-up is indicated (1)[C].
- ASDs repaired in childhood generally do not have late complications.
- In female patients with unrepaired ASD and Eisenmenger syndrome, pregnancy is not recommended due to increased risk of maternal and fetal mortality (1)[C].

- Pregnancy is well tolerated in patients with repaired ASD and small unrepaired ASDs (1)[A].
- Scuba diving and high-altitude travel must be approached with caution in patients with unrepaired ASDs; consultation is recommended.

## **PATIENT EDUCATION**

For patient education materials on this topic, consult the following:

- American Heart Association: <http://www.heart.org>
- Mayo Clinic information: <http://www.mayoclinic.com/health/atrial-septal-defect/DS00628>

## **PROGNOSIS**

- ASD closure in asymptomatic or minimally symptomatic adults reduces morbidity but not mortality (9).
- ASD closure before age 25 years in symptomatic adults reduces morbidity and likely also mortality.
- ASD repair deferred until after adolescence may not decrease long-term risk of future atrial arrhythmias.
- Up to 50% mortality by age 50 years in untreated symptomatic patients with large defects.

## **COMPLICATIONS**

- Unrepaired: congestive heart failure, stroke, pulmonary hypertension/Eisenmenger syndrome, atrial arrhythmias, increased infection risk (pulmonary, cerebral abscess, infective endocarditis)
- Surgically repaired: late-onset arrhythmias 10 to 20 years after surgery (5%), perioperative atrial tachyarrhythmias in 10-13% of patients
- Device closure: device embolization (1%), cardiac perforation, thrombus formation, endocarditis, supraventricular arrhythmias, and device erosions

## Codes

### ICD10

- Q21.1 Atrial septal defect
- Q21.2 Atrioventricular septal defect

## Clinical Pearls

- ASD is often missed due to subtle clinical presentation.
- Ideally, hemodynamically significant ASDs should be closed in early childhood, although some benefit from closure is present in older patients.
- Many ASDs can be treated by catheter-directed percutaneous closure rather than open-heart surgery.
- Routine endocarditis prophylaxis is not recommended for unrepaired ASDs.
- Generally, symptomatic and hemodynamically significant ASDs are repaired; management of asymptomatic small ASDs is debated.
- Patent foramen ovals, unlike large ASDs, are very common and generally require no treatment in asymptomatic individuals.

# Attention Deficit/Hyperactivity Disorder, Adult

Yash Kothari, MD

Hugh R. Peterson, MD, FACP

## BASICS

- Adult attention deficit hyperactivity disorder (adult ADHD) is a psychiatric condition resulting in inattention and/or hyperactivity or impulsivity. It is typically associated with a combination of low self-esteem, dysfunctional or unstable social relationships, and impaired academic/job performance.
- Adult ADHD has been shown to affect a significant portion of the adult population; >30% of patients diagnosed with ADHD as a child will continue to meet criteria as adults. Some others who no longer meet strict criteria still have significant residual ADHD traits (1).
- During transition from pediatric to adult care, poor control of high-risk behaviors during a hiatus of ADHD treatment can lead to increased morbidity.

## DESCRIPTION

- Symptoms include difficulty concentrating, impulsivity, and hyperactivity/overactivity
- The three main types of ADHD are (i) hyperactivity-impulsivity predominant, (ii) inattentive predominant, and (iii) mixed.
- Cost to society in 2010 U.S. dollars estimated to be \$105 to \$194 billion from decreased productivity, lost income, and spillover costs (\$33 to \$43 billion) paid by families (1).

## EPIDEMIOLOGY

### Prevalence

General population prevalence for adult ADHD 2.5-4.4%, but population prevalence declines with age (2,3).

### Genetics

ADHD patients often have first-degree relatives with ADHD. Some genes have been correlated with ADHD, although not necessary or sufficient for diagnosis (4).

## RISK FACTORS

History of childhood and adolescent ADHD diagnosis, particularly symptoms of hyperactivity and/or impulsivity, persisting into adulthood. ADHD is more frequent in males than females (3).

## COMMONLY ASSOCIATED CONDITIONS

- Substance use and substance abuse disorders
- Mood disorders
- Anxiety disorders
- Intellectual disabilities
- Obsessive-compulsive disorder (OCD)
- Tic disorders

## DIAGNOSIS

- Diagnosis is made from patient's history and detailing patient's current level of functioning in at least two different settings (e.g., work and home).
- It is particularly important to gather history of patient's childhood and school performance. ADHD symptoms should be present before age 12 years. If no diagnosis or concern for ADHD as a child, it is unlikely to be diagnosed as an adult.
- *DSM-5* criteria are used for adults as well as children.

## HISTORY

- History of childhood ADHD symptoms before age 12 years
- *DSM-5* criteria include 5 hyperactivity/impulsivity symptoms and/or 5 inattentive symptoms. These symptoms must be present for 6 months.
- Symptoms must result in maladaptive behavior that impairs the patient's function.
- There must be clear evidence of impaired function due to inattention/hyperactivity in 2 settings (e.g., home and work).
- These symptoms must not be related to a psychotic episode, mood disorder, or an autistic spectrum disorder and must not be better explained by another *DSM* diagnosis.
- CAGE and substance abuse questions can help identify substance abuse issues but cannot determine whether substance abuse or adult is the primary disorder.

- Personal and family history of cardiac disease or sudden death should be documented.
- History of exposure to lead or other toxins
- History of thyroid disease

## *PHYSICAL EXAM*

- Physical exam is key to ruling out other medical conditions.
- Focus on thyroid and neurologic examinations; look for findings suggestive of substance abuse.
- Record BP and baseline weight; monitor if starting medical treatment.

## *DIFFERENTIAL DIAGNOSIS*

Hearing impairment; hyperthyroidism/hypothyroidism; sleep deprivation; sleep apnea; phenylketonuria; OCD; lead toxicity; substance abuse (5)[A]

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Adult ADHD screening tools: Retrospective scales include the Childhood Symptom Scale and the Wender Utah Rating Scale; current symptom scales include the Adult ADHD Rating Scale IV, Adult Self Report Scale Symptom Checklist, and the Connor Adult Rating Scale. These scales can take 5 to 20 minutes to complete.
- Provider/patient screening checklist
  - <http://help4adhd.org/documents/AdultADHDSelfReportScale-ASRS-v1-1.pdf>
  - [http://webdoc.nyumc.org/nyumc\\_d6/files/psych\\_adhd\\_screener.pdf](http://webdoc.nyumc.org/nyumc_d6/files/psych_adhd_screener.pdf)
- ECG with concerns for cardiac disease in patient or family history
- Record baseline blood pressure, pulse, and BMI.

## *Initial Tests (lab, imaging)*

- Thyroid-stimulating hormone (TSH)
- Liver function test monitoring (with atomoxetine)
- Rapid plasma reagin (RPR) or VDRL (Venereal Disease Research Laboratory) test
- Serum lead levels (pending history)

## *Follow-Up Tests & Special Considerations*

- A history of childhood behaviors is helpful, but adult patients often don't accurately recall childhood symptomology.
- Seek the patient's permission to speak with family/friends/prior physicians and to seek school records and results of any psychological assessments.
- Inquire about family history of ADHD, family and personal substance abuse, and tic disorders to facilitate formulation of an accurate diagnosis and recognition of high-risk behaviors.
- Caution against stimulant use in pregnancy because of high risk of low fetal birth weight and preterm birth. Risks and benefits of treatment must be discussed in detail with patient and preferably with her spouse (6)[B].
- Caution against use of stimulants in adult patients with cardiac history.

## **ALERT**

Mood disorders, generalized anxiety disorders, and substance abuse can also coexist with adult ADHD; treating both the ADHD and comorbid conditions will improve the patient's prognosis.

## **TREATMENT**

- Most of the research and medication trials have been performed in children.
- There is increasing evidence that stimulants and nonstimulants used in children are also effective in adults (5)[A].

## **ALERT**

Because stimulant medication may induce dependency, substance abuse, and diversion, it is necessary to do pill counts, screen urine for drugs, monitor behavior, and query prescription databases. Misuse of amphetamines may cause sudden death and serious cardiovascular adverse events.

## **GENERAL MEASURES**

When prescribing stimulant medications for adults with ADHD, watch for misuse, abuse, and diversion of prescription medications. When substance abuse is not present, stimulants are first-line treatment for ADHD and highly efficacious. There are multiple formulations of stimulants, and patients may require trials of different dosages, formulations, and medications before an optimal response in symptoms and functions is achieved.

## **MEDICATION**

- Psychotropic medications play a large part in the treatment of ADHD symptoms. Medications should be titrated slowly to effective dose to avoid side effects.
- Stimulants are more effective than antidepressants or nonstimulants, but up to 30% discontinue medications because of side effects.
- Stimulants can be divided into two different classes: Methylphenidate and amphetamine come in both short- and long-acting preparations.
- Antidepressants studied for ADHD include bupropion, which has been shown to have a medium effect compared with stimulants (6)[A].

## *First Line*

- Stimulants: methylphenidate (Concerta, Ritalin), dexamethylphenidate (Focalin), dextroamphetamine/amphetamine (Adderall), dextroamphetamine (Dexedrine), lisdexamfetamine (Vyvanse)
  - Methylphenidate preparations are available in short-acting, intermediate-acting, long-acting, and patch formulations.
  - Ritalin LA may be used for patient's naive to stimulants. It can be started at 20 mg daily and dose titrated by 10 mg increments weekly to symptoms response. Maximum dose of 60 mg/day.
  - Concerta ER is another option in adults up to 65 years of age. Starting dose of 18 mg/day; adjust in increments of 18 mg weekly until symptoms improve. Maximum dose of 72 mg/day. Concerta also has an oral osmotic release to decrease abuse potential.
  - Amphetamines also come in immediate-release preparations and sustained-release preparations.
  - Dextroamphetamine is commonly used (half-life of 4 to 6 hours) with an initial dose of 5 mg twice daily; titrate up by 5 mg weekly to maximum of 20 mg twice daily. Caution: Immediate-release preparations have high abuse potential.
  - Dextroamphetamine/amphetamine (Adderall) is a 75%/25% mix that also comes in an extended-release form. Initial dosing can be started at 5 mg twice daily for short-acting or 20 mg once daily for long-acting, and increased by 5 mg/week for short-acting and 10 mg/week long-acting to a maximum of 40 to 60 mg total daily.
  - Lisdexamfetamine (Vyvanse) is an extended-release stimulant that is a prodrug requiring metabolism to active component, dextroamphetamine.
  - Dextroamphetamine can be initiated at 30 mg daily and titrated by 10 to 20 mg weekly to a maximum of 30 to 70 mg daily.
  - Common side effects of stimulants include hypertension (HTN), tachycardia, insomnia,

weight loss, stomach upset, increased anxiety/irritability, or worsening of tics (6)[A].

- Nonstimulants: Atomoxetine (Strattera) has been shown effective in adults with ADHD when compared to placebo (7)[B]. It may be given as a single dose or split dose and has low abuse potential, making it a better choice over a stimulant medication for patients with substance abuse history. Onset of effect may take up to 4 weeks. Atomoxetine may require dose adjustments with strong inhibitors of cytochrome P2D6 (e.g., Paxil or Prozac). Also, there are rare cases of liver damage associated with these medications. Monitor for increased suicidal thinking.
- Antidepressants: best used for those at high risk or with history of substance abuse disorder
  - Bupropion (Wellbutrin) is an antidepressant effective in adults with ADHD symptoms (6)[A].

## *ISSUES FOR REFERRAL*

Patients with comorbid conditions may need referral for diagnosis and treatment. Consider cardiology consult for patients with known cardiac issues who may require stimulant treatment. Consider referral to obstetrician experienced in high-risk pregnancies when treating pregnant women with ADHD.

## *ADDITIONAL THERAPIES*

Cognitive-behavioral therapy can be useful in conjunction with medication to help patient modify and cope with symptoms.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

Vitamin-mineral supplementation is an area of active research that holds promise for improved ADHD treatment (8)[A].

## **ONGOING CARE**

Transfer from pediatric to adult care must be closely coordinated to avoid hiatus in treatment.

## *FOLLOW-UP RECOMMENDATIONS*

- Close follow-up of medication as dose is titrated.
- Continue to monitor for medication side effects.
- Repeat screening checklists to quantify benefit of interventions as needed.
- Reinforce behavioral change (e.g., self-initiated through cognitive-behavioral therapy), which is the essential goal of long-term management.

## Codes

### ICD10

- F90.9 Attention-deficit hyperactivity disorder, unspecified type
- F90.1 Attn-defct hyperactivity disorder, predom hyperactive type
- F90.0 Attn-defct hyperactivity disorder, predom inattentive type

### Clinical Pearls

- Adult ADHD results in inattention, easy distractibility, hyperactivity, and impulsive behavior; it is associated with low self-esteem, problematic interpersonal relationships, and difficulty meeting academic and job expectations.
- Psychotropic medications plus cognitive-behavioral treatments are the cornerstone of management.
- Substance abuse is a common comorbidity; recommend use of nonstimulant medication in those at high risk

# Attention Deficit/Hyperactivity Disorder, Pediatric

Laura Novak, MD

Christina Emanuel, MD

## BASICS

### DESCRIPTION

- Attention deficit hyperactivity disorder (ADHD) is a neurodevelopmental problem that manifests in early childhood characterized by distractibility, impulsivity, hyperactivity, and/or inattention.
- Three subsets: predominantly hyperactivity impulsive (ADHD-HI), predominantly inattentive (ADHD-I), or combined (ADHD-C)
- System(s) affected: nervous
- Synonym(s): attention deficit disorder; hyperactivity

### EPIDEMIOLOGY

- Predominant age: onset <12 years; lasts into adolescence and adulthood; 50% meet diagnostic criteria by age 4 years
- Predominant sex: male > female (2:1); inattentive type (ADHD-I) may be more common in girls

### Prevalence

11% of children 4 to 17 years old were diagnosed with ADHD as of 2011. Of those, 6.1% are receiving a medication for ADHD.

### ETIOLOGY

Not definitive

### Genetics

Familial pattern

### RISK FACTORS

- Family history
- Medical causes (affecting brain development)
- Environmental causes (toxins such as lead, fetal alcohol, and nutritional deficiencies)

## GENERAL PREVENTION

- Children are at risk for abuse, depression, and isolation.
- Parents need regular support and advice.

## COMMONLY ASSOCIATED CONDITIONS

- Depression (in up to 1/3 of cases)
- Oppositional defiant disorder
- Conduct disorder
- Anxiety disorder
- Learning disabilities

## DIAGNOSIS

- American Academy of Pediatrics (AAP) guidelines recommend *DSM-5* criteria to establish diagnosis.
- *DSM-5* criteria for children < 17 years: <sup>36</sup> inattention criteria and/or <sup>36</sup> hyperactivity/impulsivity criteria. Symptoms must occur often, be present before age of 12 years, for >6 months, be noticed in <sup>32</sup> settings (e.g., home, school), reduce quality of social or scholastic functioning, be excessive for development level of child, and are not better explained by or occur with another mental disorder (e.g., mood, anxiety, or personality disorder) (1)[A].
- Inattention
  - Careless mistakes in tasks; difficulty sustaining attention or in organizing tasks; does not seem to listen, follow through, or finish tasks; avoids tasks that require sustained mental effort; loses things; forgetful in daily activities
- Hyperactivity/impulsivity
  - Fidgets; difficulty remaining seated; runs/climbs excessively or inappropriately; difficulty playing quietly; acts as if driven by a motor or seeming to always be on the go; talks excessively; blurts out answers before question is complete; has difficulty waiting turn;

interrupts others

- Children undergoing extreme stress (parent's divorce, illness, homelessness, abuse) may demonstrate ADHD behaviors secondary to stress (1). This can be assessed using the American Academy of Child and Adolescent Psychiatry (AACAP) screening tool.
- If diagnostic behaviors are noted in only one setting, explore the stressors in that setting.
- The diagnostic behaviors are more noticeable in tasks that require concentration or boredom tolerance than in free play or office situations.

## **HISTORY**

- Birth and development history
- Psychosocial evaluation of home environment
- School performance history and school absences
- Psychiatric history or comorbid disorder(s)
- Cardiac history

## **PHYSICAL EXAM**

- Baseline weight for future monitoring
- Note any soft neurologic signs, such as tics, clumsiness, mixed handedness
- Assess hearing and vision.

## **DIFFERENTIAL DIAGNOSIS**

- Activity level appropriate for age
- Language or communication disorders
- Hearing/vision disorder
- Dysfunctional family situation
- Learning disability (e.g., dyslexia)
- Autism spectrum disorders
- Oppositional/defiant disorder or conduct disorder
- Tourette syndrome: motor and verbal tics
- Absence seizures (inattentive type ADHD only)
- Lead poisoning
- Sequelae of central nervous system infection/trauma

- Medication (decongestant, antihistamine, theophylline, phenobarbital)
- Sleep disorder (e.g., obstructive sleep apnea [OSA]) leading to daytime behavioral problems

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Behavior rating scales must be completed by parents, caregivers, and teachers prior to initiation of therapy and then repeated after therapy is started to gauge treatment efficacy.
- Forms are available from the ADHD toolkit at <http://www.nichq.org/adhd.html> (Vanderbilt Assessment Scales)
- Testing for learning disability (e.g., dyslexia) through the school may be needed.

### ***Initial Tests (lab, imaging)***

Lead level if high risk

### ***Diagnostic Procedures/Other***

- EEG if symptoms are highly suggestive of absence seizure disorder
- EKG if high risk

## **TREATMENT**

### ***GENERAL MEASURES***

- Parent/school/patient education
- Work closely with teacher.
- Behavioral therapy/environmental changes

### ***MEDICATION***

- 2011 AAP guideline recommends behavioral interventions for age 4 to 5, and behavioral interventions plus stimulant medications as first-line treatment for age 6 to 17 (2,3)[A].
- Stimulant choice should be based on cost, formulary, convenience, and duration. A second type of stimulant should be tried if the first treatment fails. All stimulant capsules can be opened and sprinkled (note Concerta is a pill)

### ***First Line***

Stimulant:

- Dexmethylphenidate
  - **Focalin:** initial: 2.5 mg BID; increase total daily by 2.5 to 5 mg weekly up to maximum dose of 20 mg/day
  - **Focalin XR:** initial: 5 mg in AM; increase daily dose by 5 mg weekly up to maximum dose of 30 mg/day
- Methylphenidate
  - SHORT-ACTING
    - Ritalin, Methylin: initial 5 mg BID before breakfast and lunch; increase by 5 to 10 mg weekly to maximum dose of 60 mg/day (2 or 3 divided doses)
  - INTERMEDIATE-ACTING
    - Ritalin SR: 20 mg once in AM; increase by 10 mg weekly up to 40 to 60 mg
    - Metadate ER: 10 mg BID; increase by 10 mg weekly to 40 to 60 mg
  - LONG-ACTING
    - Metadate CD: 20 mg in AM; increase by 10 to 20 mg weekly to 40 to 60 mg
    - Quillivant XR: 20 mg in AM; increase 10 to 20 mg weekly until 40 to 60 mg
    - Ritalin LA: 10 to 20 mg in AM; increase 10 mg weekly until 40 to 60 mg
    - Concerta: 18 to 36 mg in AM; increase by 18 mg weekly until 54 to 72 mg
    - Daytrana transdermal patch: 10 mg patch on (hip area) 2 hours before effect is needed; patch removed 9 hours after application; increase to next higher patch weekly until 30 mg patch if needed
- Dextroamphetamine
  - **Dexedrine spansule** (long-acting): 5 mg BID; increase by 5 mg weekly to maximum dose of 40 mg daily
- Dextroamphetamine and amphetamine
  - SHORT-ACTING
    - Adderall: 5 mg daily or BID; increase by 5 to 10 mg weekly to a maximum dose of 40 mg daily divided into 1 to 3 doses
  - LONG-ACTING
    - Adderall XR: 5 to 10 mg in AM; increase by 5 to 10 mg weekly until maximum dose of 30

mg/day

- Lisdexamfetamine
  - **Vyvanse:** 30 mg in AM; increase by 10 to 20 mg weekly up to a maximum of 70 mg/day

P.97

## **ALERT**

The FDA recommends that a personal or family history of congenital heart disease or sudden death be screened with an ECG and possible cardiology consultation before beginning stimulant medication.

- Precautions:
  - If not responding, check compliance and consider another diagnosis.
  - Some children experience withdrawal (tearfulness, agitation) after a missed dose or when medication wears off. A small, short-acting dose at 4 PM may help to prevent this.
  - Stimulants are drugs of abuse and should be monitored carefully.
  - Drug holidays are not recommended.
- Common adverse effects:
  - Anorexia, insomnia, GI effects, and headache
- Significant possible interactions: may increase levels of anticonvulsants, SSRIs, tricyclics, and warfarin
- High caffeine energy drinks, albuterol inhalers and decongestants may increase side effects.
- The FDA reports permanent skin discoloration with Daytrana patches.

## *Pregnancy Considerations*

Medications are Category C: caution in pregnancy

## *Second Line*

*Nonstimulant:*

- *SNRI*
  - **Atomoxetine** (Strattera):
    - <sup>2</sup>70 kg: 0.5 mg/kg/day initial; increase after a minimum of 3 days to target dose of 1.2 mg/kg/day; maximum of 1.4 mg/kg/day

- >70 kg: 40 mg daily; increase after minimum of 3 days to target dose of 80 mg/day; dose may be increased to maximum of 100 mg/day after additional 2 to 4 weeks
- *α<sub>2</sub>-Agonist*
  - Modest efficacy, high side effects. Consider consultation before use.
    - **Clonidine XR (Kapvay)**: 0.1 mg once daily at bedtime; increase by 0.1 mg weekly; doses should be taken twice daily with equal or higher split dosage given at HS; maximum of 0.4 mg/day; taper when discontinued
    - **Guanfacine XR (Intuniv)**: 1 mg daily; increase by 1 mg weekly until 1 to 4 mg daily; taper when discontinued

## ALERT

- **Atomoxetine** carries a “black box” warning regarding potential exacerbation of suicidality (similar to SSRIs). Close follow-up is recommended.
  - Associated with hepatic injury in a small number of cases; check liver enzymes if symptoms develop.
  - Interacts with **paroxetine** (Paxil), **fluoxetine** (Prozac), and **quinidine**

## ISSUES FOR REFERRAL

Should be considered for children <6 years old for psychological or medical complications, developmental disorder or intellectual disability, or poor response to medication

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Surveys have shown that parents of children with ADHD use herbals and complementary treatments frequently (20-60%).
- Omega-3 fatty acids (found in fish oil and some supplements) showed improvement in rating scales in two double-blind, placebo-controlled studies of 116 and 130 patients (4).

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### Patient Monitoring

- Parent/teacher rating scales
- Office visits to monitor side effects and efficacy: End points are improved grades, rating scales,

family interactions, and peer interactions.

- Monitor growth (especially weight) and BP.

## **DIET**

- Insufficient evidence to suggest that dietary interventions reduce the symptoms of ADHD (4).
- The AAP recommends that For a child without a medical, emotional, or environmental etiology of ADHD behaviors, a trial of a preservative-free food coloring-free diet is a reasonable intervention (4).

## **PATIENT EDUCATION**

- Excellent reference: <http://www.parentsmedguide.org>
- Key points for parents:
  - Find things the child is good at and emphasize these; reinforce good behavior; give one task at a time; stop behavior with quiet discipline; coordinate homework with teachers; have external organization tools—charts, schedules, tokens
  - Develop an individualized education plan (IEP) with the school.
- Support groups:
  - Children and Adults with Attention Deficit Disorder (CHADD): <http://www.chadd.org>
  - Attention Deficit Disorder Warehouse: <http://www.addwarehouse.com>
  - National Information Center for Children and Youth with Disabilities: <http://www.nichcy.org>

## **PROGNOSIS**

- May last into adulthood; plan for a transition at age 17 years
- Relative deficits in academic and social functioning may persist into late adolescence/adulthood.
- Encourage career choices that allow autonomy and mobility.

## **COMPLICATIONS**

- Untreated ADHD can lead to failing in school, parental abuse, social isolation, and poor self-esteem.
- Possible withdrawal when medication wears off.
- Monitor growth with stimulant use. If appetite is poor, eat before the

medication is given and after it wears off. Consider a shorter duration medication.

- Risk of substance abuse is controversial and seems to decrease with treatment of ADHD increased automobile accidents and injuries; decreases with medication

## Codes

### ICD10

- F90.9 Attention-deficit hyperactivity disorder, unspecified type
- F90.0 Attn-defct hyperactivity disorder, predom inattentive type

- F90.1 Attn-defct hyperactivity disorder, predom hyperactive type

## Clinical Pearls

- AAP recommends the use of stimulant medications as the first-line treatment.
- Children undergoing extreme stress (parent's divorce, illness, homelessness, abuse) may demonstrate ADHD behaviors secondary to stress.
- ADHD is 2 to 8 times more common in persons who have a first-degree relative with the condition.

# Atypical Mole (Dysplastic Nevus) Syndrome

Anne R. Atalig, MD, CPT

Mary DiGiulio, DO

## BASICS

Atypical mole syndrome (AMS), also known as dysplastic nevi syndrome (DNS), B-K mole syndrome, or Clark nevi syndrome, is a condition characterized by a large number of pigmented nevi with architectural disorder, which arise sporadically or by inheritance, and are associated with an increased risk of melanoma.

## DESCRIPTION

- There is no consensus on criteria for AMS.
- Elevated total body nevi count, including clinically atypical nevi, is usually >50 and often >100.
  - Larger number in hereditary AMS versus sporadic atypical nevi (as few as <10 in sporadic)
- Increased risk of melanoma (1,2)
  - Up to 90% occurrence by age 80 years in certain high-risk individuals
  - Earlier onset than sporadic melanoma cases
  - Most arise de novo than from an existing nevus
  - Higher risk for appearance at unusual sites (e.g., scalp)
- AMS terminology often used interchangeably with DNS, familial atypical multiple mole melanoma (FAMMM) syndrome, and B-K mole syndrome.
- Median age of diagnosis for melanoma in AMS is 10 to 20 years earlier than the general population, with documented cases of melanoma as early as in the 2nd and 3rd decades of life (3). Melanomas, in the setting of AMS, are most often superficial spreading or nodular type.

## EPIDEMIOLOGY

### Incidence

- Uncertain due to phenotype variability, limited data
- Up to 8% in Caucasian populations (4)

## Prevalence

At least 32,000 cases in the United States per National Institutes of Health (NIH) (5)

## ETIOLOGY AND PATHOPHYSIOLOGY

- Cyclin-dependent kinase inhibitor 2A (*CDKN2A*) mutations have been observed in familial DNS and multiple melanomas. The *CDKN2A* gene on 9p21 encodes for the proteins p16 and p14. p16 binds to CDK4/6 and is a negative cell-cycle regulator via inhibition of the CDK-cyclin D interaction needed for cell cycle progression from G1 to S. p14 functions by stabilizing the tumor-suppressor protein p53 in the G1 phase of the cell cycle.
- Familial cases of germline *CDKN2A* mutations are transmitted in an autosomal dominant fashion.
- No clear somatic mutation patterns in sporadic cases

## Genetics

*CDKN2A* mutation observed in 25-40% of hereditary cases, with autosomal dominant inheritance but variable expressivity and incomplete penetrance

## RISK FACTORS

Family history of melanoma or multiple nevi, sun exposure, neonatal blue-light phototherapy (6,7), history of painful sunburns

## GENERAL PREVENTION

- No currently available prevention strategies
- Treatment is directed toward secondary prevention of melanoma complications with routine skin exams, biopsy of suspect lesions, and environmental risk mitigation (e.g., sun protection and sun avoidance).
- Experimental early detection protocols for pancreatic cancer is used with some high-risk individuals.

## COMMONLY ASSOCIATED CONDITIONS

- Malignant melanoma, including ocular melanoma
- Ocular nevi
- Pancreatic cancer in *CDKN2A* mutation

## DIAGNOSIS

AMS is a clinical diagnosis with various classifications schemes proposed. Although not widely accepted, diagnostic criteria, as defined by the NIH, require the three features of (i) malignant melanoma in <sup>3</sup>1 first-or second-degree relatives; (ii) numerous melanocytic nevi (frequently >50), some of which are clinically atypical; and (iii) nevi that have certain histologic features on pathologic examination (8).

### HISTORY

- Changing lesions: bleeding, scaling, size, texture, nonhealing, hyper- or hypopigmentation
- Large number of nevi
- Congenital nevi
- Sun exposure habits
- Prior skin biopsies
- Prior melanoma
- Immunosuppression (e.g., AIDS, chemotherapy, pancreatic cancer)
- First- or second-degree relatives with:
  - AMS
  - Melanoma
  - Pancreatic cancer

### PHYSICAL EXAM

- Full body skin exams
- Goal to distinguish melanoma from AMS
- ABCDE mnemonic for skin lesions concerning for melanoma: Asymmetry, Border irregularity, Color variegation, Diameter >6 mm, and Evolving lesion
  - Atypical mole (AM) is often defined as <sup>3</sup>5 mm + at least two other features.
  - Melanoma typically with several characteristics of ABCDEs, with increased specificity for melanoma using >6 mm for diameter
- Ugly duckling sign (9)[B]
  - Melanoma screening strategy of identifying malignant nevi straying from the predominant nevus pattern when numerous atypical nevi are present.

Most common features of AM on dermoscopy magnification per the pattern analysis method include the following (10)[C]:

- Atypical pigment network
  - Irregular/peripheral depigmentation areas
  - Irregular distribution of brown globules
  - Pigmentation with central heterogeneity and abrupt termination
- Some dermatoscopic features more suggestive of melanoma include the following (11)[C]:
- Depigmented areas
  - Whitish veil
  - Homogenous areas distributed irregularly, in multiple areas, or >25% of total lesion
  - 34 colors

## *DIFFERENTIAL DIAGNOSIS*

- Common nevus: acquired or congenital
- Melanoma
- Seborrheic keratosis
- Dermatofibroma
- Lentigo
- Pigmented actinic keratosis
- Pigmented basal cell carcinoma
- Blue rubber bleb nevus syndrome

## *DIAGNOSTIC TESTS & INTERPRETATION*

Diagnosis is first suspected with history and physical exam, and then confirmed by biopsy and histopathology.

### *Initial Tests (lab, imaging)*

- Dermoscopy can be used for more detailed exam to distinguish between benign and malignant lesions, and for further classification to 1 of 11 subtypes.
- Genetic testing is available for *CDKN2A* mutations, but it is not recommended outside of research studies as results cannot be adequately used for management or surveillance (11)[C].

- When the total nevus count is high and following each nevus is impractical, total body photography may aid in the evaluation of evolving nevi as well as in documenting new nevi (12)[C].

### *Diagnostic Procedures/Other*

- Biopsy is recommended for any lesion where melanoma cannot be excluded.
- Biopsy entails full-thickness biopsy of the entire lesion with a narrow 1- to 3-mm margin of normal skin down to fat for adequate depth assessment (12)[C].
  - Excisional biopsy, elliptical or punch excision provides the most accurate diagnosis and should be performed when possible.
  - Scoop shave biopsy can also be used, but care must be taken to not transect the lesion.
- Reexcision of mild to moderately dysplastic nevi with positive margins may not change pathologic diagnosis, but for severely dysplastic nevi, consider reexcision, with surgical margins of 2 to 5 mm (13)[C].

### *Test Interpretation*

Dysplastic nevus is a term more accurately reserved for histological findings. Features may include melanocyte proliferation in the dermoepidermal junction, bridging of rete ridges by melanocytic nests, dermal fibrosis, and interstitial lymphocytic inflammation.

## **TREATMENT**

### *MEDICATION*

No medications are available to treat AMS.

P.99

### *ISSUES FOR REFERRAL*

- Consider referral to a dermatologist for routine skin exam in patients at high risk for melanoma.
- Ophthalmologic exams for ocular nevi/melanoma screening/papilledema
- Oncology or specialized genetics study group involvement if strong family predisposition to pancreatic cancer
- Cosmetic surgery consultation for cosmetically poor excision outcomes

## *ADDITIONAL THERAPIES*

- Topical chemo- and immunotherapies have been unsuccessfully attempted to treat atypical moles.
- Laser treatment should be avoided because it is both unsafe and ineffective for melanocytic nevi.

## *SURGERY/OTHER PROCEDURES*

Surgical excision of all atypical nevi is not recommended because most melanomas in AMS appear de novo on healthy skin and the procedure leads to both poor cosmetic outcomes and a false sense of security. Lesions suspicious for melanoma should be biopsied or removed surgically.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Close follow-up with a dermatologist or other experienced physician:

- Total body skin exam (including nails, scalp, genital area, and oral mucosa) every 6 months initially, starting at puberty; may be reduced to annually once nevi are stable
- Dermoscopic evaluation for suspect lesions
- Ocular exam for those with familial AMS
- Excision of suspect lesions
- Total body photography at baseline

### *Patient Monitoring*

- Monthly self-exams of skin
- Sun avoidance and sun protection

### *PATIENT EDUCATION*

For young adults aged 10 to 24 years with fair skin, counsel to minimize exposure to ultraviolet radiation to reduce risk of skin cancer (USPSTF Grade B)[A]. No evidence for adults >24 years (USPSTF Grade I)[A]

- Fair skin: light eye, hair, or skin color, freckles
- Educate on sun avoidance, proper application of sunscreen, use of protective clothing (e.g., hats), avoidance of tanning booths and sunburns.

- Teach "ABCDE" mnemonic + "Ugly duckling" sign to assess nevi and identify potential melanomas.
- Provide instruction on skin self-exam techniques.
- A sample listing of patient-centric review sources on this topic are as follows:
  - American Academy of Dermatology (<http://cancer.about.com/od/skincancermelanoma/p/abcdeskincancer.htm>)
  - Skin Cancer Foundation (<http://www.skincancer.org/skin-cancer-information/dysplastic-nevi>)
  - Melanoma Research Foundation (<http://www.melanoma.org/understand-melanoma/what-is-melanoma>)

## PROGNOSIS

- Most AM either regress or do not change.
- Multiple classification schemes have been developed over the years to delineate risk of melanoma in patients with AMS. Individuals with a family history of melanoma are at greatest risk. A classification system developed by Rigel (14) is simple and readily applied in the clinical setting. Points are assigned based on incidence of melanoma, with 1 point given for a personal history with melanoma and 2 points for each family member with melanoma (modified nuclear family consisting of first-degree relatives plus grandparents and uncles/aunts) and stratified as follows:
  - Score = 0, Rigel group 0, 6% 25-year accumulated risk for melanoma
  - Score = 1, Rigel group 1, 10% risk
  - Score = 2, Rigel group 2, 15% risk
  - Score <sup>3</sup>3, Rigel group 3, 50% risk
- The *CDKN2A* mutation has also been associated with a 60-90% risk of melanoma by age 80 years and a 17% risk for pancreatic cancer by age 75 years.

## COMPLICATIONS

- Malignant melanoma
- Poor cosmetic outcomes from biopsy

## Codes

### ICD10

- D22.9 Melanocytic nevi, unspecified
- D22.4 Melanocytic nevi of scalp and neck
- D22.30 Melanocytic nevi of unspecified part of face

## Clinical Pearls

- Melanoma in AMS tends to arise from healthy skin despite a large number of atypical nevi.
- ÷20% of individuals with familial AMS will develop pancreatic cancer by age 75 years.
- Patients with AMS tend to produce neoplasms in unusual sites such as the scalp, eyes, and sunprotected areas (e.g., gluteal folds).

# Autism Spectrum Disorders

Macario C. Corpuz, MD, MBA, FAAFP

Jennifer Luo Powell, DO

## BASICS

### DESCRIPTION

- Group of neurodevelopmental disorders of early childhood: *DSM-5* has included autism spectrum disorders (ASDs) to include autistic disorder, childhood disintegrative disorder, Asperger disorder, pervasive developmental disorder not otherwise specified (PDD-NOS); and now, it also encompasses early infantile autism, childhood autism, Kanner autism, high-functioning autism, and atypical autism (1)[A].
- Two symptom clusters
- Social/communication
- Impairment of effective social skills and absent or impaired communication skills
- Fixed interests/repetitive behaviors
- Repetitive and/or stereotyped behaviors and interests, especially in inanimate objects (2)[A]
- Severity levels
  - Level 1: requiring support
  - Level 2: requiring substantial support
  - Level 3: requiring very substantial support
- Important to distinguish autism disorder from social (pragmatic) communication disorder. Separate *DSM-5* criteria for individuals with social communication deficits but do not meet autism-spectrum criteria.

### EPIDEMIOLOGY

- Predominant age: onset in early childhood
- Predominant sex: male > female (5:1)

### Pediatric Considerations

Symptom onset seen in children <3 years of age (except for childhood disintegrative disorder)

## *Prevalence*

- According to the Centers for Disease Control and Prevention (CDC), an estimated 1/68 to 1/175 children, depending on the community
- Among 6 to 17 years-aged children within the United States, in 2011 to 2012, there is found to be a 2% (1 in 50) parent-reported prevalence compared to 1.16% (1 in 86) as reported in 2007.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- No single cause has been identified.
- General consensus: A genetic abnormality leads to altered neurologic development.
- No scientific evidence relating vaccines, such as vaccines for measles, mumps, or rubella (MMR), or thimerosal causing ASDs (3)[C]
- Pathophysiology is incompletely understood.

## *Genetics*

- High concordance in monozygotic twins
- Increased recurrence risk (2-18%) in subsequent siblings

## *RISK FACTORS*

Siblings of affected children have a five times greater risk of developing autism. Prevalence ranging from 2% to 8%

## *GENERAL PREVENTION*

- Early screening for early treatment means a better prognosis.
- Some ASDs are caused by genetic or chromosomal disorders.
- Economic costs
  - An additional \$17,000 to \$21,000 is an estimated cost for raising an ASD child.
  - Medical costs for those with ASD in 2011 were estimated to be 4 to 6 times, ranging from \$2,191 to \$11,590 per child (4)[B].
  - An estimated lifetime cost of services for an individual with ASD in 2011 is \$3.8 million (5) [C].

- Due to caretaker burden, family earnings are found to be 28% less among families with ASD compared to children without health conditions (6)[C].

## COMMONLY ASSOCIATED CONDITIONS

- Mental retardation, ADHD, anxiety, depression, or obsessive behavior
- Phenylketonuria (PKU), tuberous sclerosis, fragile X syndrome, Angelman syndrome, and fetal alcohol syndrome (rare)
- Seizures (increased risk if severe mental retardation)
- Maternal use of selective serotonin reuptake inhibitors (SSRIs) during pregnancy

## DIAGNOSIS

### HISTORY

- Impairment in social interaction
  - Impairment in nonverbal behaviors such as eye-to-eye gaze, facial expression
  - Unable to develop peer relationships
  - Does not smile nor share emotions
  - Loss of social or emotional reciprocity
- Communication impairment
  - Delay or lack of development in language skills
  - Inability to initiate or sustain conversation
  - Stereotyped and repetitive use of language
  - Preoccupation with parts of toys or body parts
- Repetitive and stereotyped patterns of behavior
  - Excessively lines up toys or other objects
  - Unusually attached to one particular toy or object
  - Repetitive odd movements (toe walking, hand flapping)
  - Adherence to specific routines or rituals
- Prenatal, neonatal, and developmental history
- Seizure disorder
- Family history of autism, genetic disorders, learning disabilities, psychiatric illness, neurologic disorders, genetic disorders, or mental retardation

- Commonly associated with sleep disorders

## *PHYSICAL EXAM*

- Macrocephaly in 25%; head circumference growth peaks at age 6 months and begins to decline by 1 year.
- Dysmorphic features consistent with genetic disorder (fragile X syndrome)
- Hypotonia occurs in autism but should prompt imaging.
- Wood lamp skin exam to rule out tuberous sclerosis

## *DIFFERENTIAL DIAGNOSIS*

- Other mental and CNS disorders
- Obsessive-compulsive disorder
- Elective mutism
- Language disorder/hearing impairment
- Intellectual disability/global developmental delay
- Stereotyped movement disorder
- Severe early deprivation/reactive attachment disorder
- Anxiety disorder
- Social communication disorder
- Developmental language disorder

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Checklist for Autism in Toddlers (CHAT) to screen for ASDs at 18 months of age. (To order: <http://www.autism.org.uk/working-with/health/screening-and-diagnosis/checklist-for-autism-in-toddlers-chat.aspx>)
- The Pervasive Developmental Disorders Screening Test-II (PDDST-II) to screen for ASDs beginning at 18 months
- Modified Checklist for Autism in Toddlers (M-CHAT) to screen for ASDs at 16 to 30 months
- Social Communication Questionnaire (SCQ) (formerly Autism Screening Questionnaire) Used with children age 4+ years the gold standard diagnostic interview used in research studies

## *Initial Tests (lab, imaging)*

- Lead and PKU screening
- Karyotype and DNA analysis (fragile X, PKU, tuberous sclerosis, and others)
- Metabolic testing if signs of
  - Lethargy, limited endurance, unusual habits, hypotonia, recurrent vomiting and dehydration, developmental regression, or specific food intolerance
- MRI is useful only if focal neurologic symptoms.

## *Follow-Up Tests & Special Considerations*

- Hearing tests: audiometry and brainstem auditory evoked response (BAERS)
- Comprehensive speech and language evaluation
- Evaluation by multidisciplinary team: includes a psychiatrist, neurologist, psychologist, speech therapist, and other autism specialists
- Intellectual level needs to be established and monitored, as it is one of the best measures of prognosis.
- Test used to follow autism are the following:
  - Autism Behavior Checklist (ABC)
  - Gilliam Autism Rating Scale (GARS)
  - Childhood Autism Rating Scale (CARS)
  - Autism Diagnosis Interview-Revised (ADI-R)
  - Autism Diagnostic Observation Schedule-Generic (ADOS-G) Imaging

## *Diagnostic Procedures/Other*

EEG if history of seizures or spells

## **TREATMENT**

### *GENERAL MEASURES*

- Comprehensive structured educational programming of a sustained and intensive design, most commonly applied behavioral analysis therapy
- Core features of a successful education program
  - High staff-student ratio 1:2, or less

- Individualized programming
  - Specialized teacher training with ongoing evaluation of teachers and programs
  - 25 hours a week minimum of specialized services
  - A structured routine environment that emphasizes attention, imitation, communication, socialization, and play interactions (7)[C]
  - Functional analysis of behavioral problems
  - Transition planning and involvement of the family
- Currently no cure for ASDs. Early diagnosis and initiation of multidisciplinary intervention help enhance functioning in later life.
  - Early intensive behavioral intervention (EIBI) involving treatment for 20 to 40 hours per week is a well-established treatments for ASD.
  - School-based special education for older children
  - Some evidence indicates social skill groups can improve social competence for some children and adolescents with ASD.
  - Find alternative methods of communication: sign language; picture exchange communication system

## *MEDICATION*

- Autism behavior issues should be managed with maximal behavioral management prior to medication.
- Medication directed at managing symptoms

### *First Line*

- No true first-line medical therapy; medications used to treat targeted symptoms
- Stimulants (such as methylphenidate): Efficacious in treating concomitant symptoms of ADHD such as impulsiveness, hyperactivity, and inattention; however, the magnitude of response is less than in typically developing children and adverse effects are more frequent.
- SSRIs have limited evidence for autism. It has shown help in reducing ritualistic behavior and improving mood and language skills. Initial choice for anxiety and depressive mood (8)[B]
- Risperidone has shown short-term efficacy for treatment for irritability, repetitious behaviors, and social withdrawal (9)[B]. Aripiprazole has shown efficacy for treating short-term irritability, hyperactivity, and repetitive movements (10)[B].

- Melatonin used for patients with concomitant sleep disorders

## *Second Line*

- Vitamin B<sub>6</sub> and magnesium: inconclusive evidence in improving behavior, speech, and language of children with ASD (11)[C]
- Tricyclic antidepressants have limited and conflicting evidence of effect (12)[B].

## *ISSUES FOR REFERRAL*

- Refer early to
  - Early learning for evaluation of behavior and language, genetic counseling, and audiology
- Consider referrals to psychiatry, ophthalmology, otolaryngology, neurology, and nutrition (13).
- Refer family members to parent support groups and respite programs.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

- Parent-mediated early intervention for young children with autism spectrum has sufficient evidence of benefit in child outcomes related to language understanding and severity of autism characteristics (14)[A].
- Music therapy has been shown to improve communication skills in autistic patients; however, more research is needed (15)[C].
- Theory of mind, or related skills, can be taught to ASD patients, but further research is needed (16)[C].
- No evidence to support use of auditory integration therapy or other sound therapies as an effective treatment for ASD (17)[B].
- No evidence to support acupuncture for treatment of ASD (6)[C].
- IV secretin and pharmaceutical chelation has shown no evidence of efficacy and is not currently recommended as a treatment for ASD (18,19)[C].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Constant monitoring by caregivers

- Reevaluation every 6 to 12 months by physician for seizures, sleep and nutritional problems, and prescribed medical management
- Intellectual and language testing every 2 years in childhood

## DIET

- Gluten- and casein-free diets: Current evidence for efficacy is poor (20)[C].
- Omega-3 fatty acids supplementation has not been found to improve outcomes (21)[C].

## PROGNOSIS

- Beginning treatment at a young age (2 to 4 years) results in better outcomes.
- Prognosis is closely related to initial intellectual abilities, with only 20% functioning above the mentally retarded level.
- Communicative language development before 5 years is also associated with a better outcome.
- The general expected course is for a lifelong need for supervised structured care.

## COMPLICATIONS

- Increasing incidents of seizure disorders in up to 1 in 4 children
- Increased risk for physical and sexual abuse
- With pica, increased risk of lead poisoning
- Limited variety of food consumed due to dietary obsessions
- Increased risk for GI symptoms, including weight abnormalities and abnormal stool patterns

Algorithm: Intellectual Disability

## Codes

## ICD10

- F84.0 Autistic disorder
- F84.5 Asperger's syndrome
- F84.3 Other childhood disintegrative disorder

## Clinical Pearls

- ALARM mnemonic from the American Academy of Pediatrics (AAP)
- **ASD** is prevalent (screen ALL children between 18 and 24 months).
- Listen to parents when they feel something is wrong.
- **Act** early: Screen all children who fall behind in language and social developmental milestones (use early learning to help with evaluation).
- **Refer** to multidisciplinary teams (speech and language evaluation, genetic screening, social support groups).
- **Monitor** support for patient and families.

# Babesiosis

Frederick W. Nielson, MD, Captain USAF

J. David Honeycutt, MD, FAAFP, FAWM

## BASICS

### DESCRIPTION

- Rare tick-borne hemolytic disease caused by intraerythrocytic protozoan parasites of the genus *Babesia*
- Infrequently reported outside the United States
  - Sporadic cases have been reported from
    - France, Italy, the United Kingdom, Ireland, the former Soviet Union, Mexico (1)
    - China has reported a reemergence of cases.
  - In the United States, infections have been reported in many states, but most endemic areas are:
    - Islands off the coast of Massachusetts (including Nantucket and Martha's Vineyard)
    - New York (including Long Island, Shelter Island, and Fire Island)
    - Connecticut
    - In these areas, asymptomatic infection is common (1).
- Incubation period varies from 5 to 33 days:
  - Most patients do not recall specific tick exposure.
  - After transfusion of infected blood, the incubation period can be up to 9 weeks (1).
- System(s) affected: cardiovascular, gastrointestinal, hemic/lymphatic/immunologic, musculoskeletal, nervous, pulmonary, renal/urologic

### *Pediatric Considerations*

Transplacental and perinatal transmission have been rarely reported (1,2).

## Geriatric Considerations

- Morbidity and mortality are higher in patients >60 years.
- Cases occurring in patients >70 years are more common in those with medical comorbidities.

## EPIDEMIOLOGY

Babesiosis affects patients of all ages. Most patients present in their 40s or 50s (1).

### Incidence

- In 2012, there were 911 cases reported to the CDC.
- Prevalence is difficult to estimate due to lack of surveillance and asymptomatic infections.
- Transfusion-associated babesiosis and transplacental/perinatal transmission have been reported (1).
- A 1-year seroconversion study of patients in New York, at high risk for tick-borne diseases, showed antibodies to *Babesia microti* in 7 of 671 individuals (1%) (1).

## ETIOLOGY AND PATHOPHYSIOLOGY

- *B. microti* (in the United States) and *Babesia divergens* and *Babesia bovis* (in Europe) cause most human infections (1). *B. divergens* and a new strain *Babesia ducani* appear to be more virulent. Other species have been identified in case reports. All share morphologic, antigenic, and genetic characteristics (1).
- Ixodid (hard-bodied) ticks, particularly *Ixodes dammini* (*Ixodes scapularis*: deer tick) and *Ixodes ricinus*, are the primary vectors. The white-footed mouse is the primary reservoir.
- Infection is passed to humans through the saliva of a nymphal-stage tick during a blood meal. Sporozoites introduced at the time of the bite enter red blood cells form merozoites through binary fission (classic morphology on blood smear). Humans are a dead-end host for *B. microti*.

## RISK FACTORS

- Residing in endemic areas
- Asplenia
- Immunocompromised state

## GENERAL PREVENTION

- Avoid endemic regions during the peak transmission months of May to September (1).

- Appropriate insect repellent is advised during outdoor activities, especially in wooded or grassy areas:
  - 10-35% N,N-diethyl-meta-toluamide (DEET) provides adequate protection (1).
- Early removal of ticks via daily skin checks; the tick must remain attached for at least 24 hours before the transmission of *B. microti* occurs (1).
- Examine pets for ticks.

## COMMONLY ASSOCIATED CONDITIONS

- Coinfection with *Borrelia burgdorferi* and *B. microti*, particularly in endemic areas (1)
- Coinfection with *Ehrlichia* (1).

## DIAGNOSIS

### HISTORY

- Travel/exposure history
- Comorbidities (immunosuppression, chronic disease)
- Fever (68-89%), fatigue, (78-79%), chills (39-68%), sweats (41-56%), headache (32-75%), myalgia (32-37%), anorexia (24-25%), cough (17-23%), arthralgias (17-32%), nausea (9-22%). Other symptoms reported by case reports include abdominal pain, vomiting, diarrhea, and emotional lability.

### PHYSICAL EXAM

- High fever (up to 40°C [104°F])
- Hemodynamic instability (shock in extremely ill)
- Hepatomegaly and splenomegaly (mild if noted)
- Rash (uncommon)
- CNS involvement includes headache, photophobia, neck and back stiffness, altered sensorium, and emotional lability.
- Jaundice and dark urine may develop later in course of illness.

### DIFFERENTIAL DIAGNOSIS

- Bacterial sepsis

- Hepatitis
- Lyme disease
- Ehrlichiosis
- Leishmaniasis
- Malaria
- HIV
- EBV

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Requires a high index of clinical suspicion. Nonspecific laboratory clues include evidence of mild to severe hemolytic anemia, normal to slightly depressed leukocyte count (1), elevated LDH or transaminase level, elevated BUN and Cr, proteinuria with hemoglobinuria (1,2).
- Definitive diagnosis is made by blood smear
  - A Wright- or Giemsa-stained peripheral blood smear demonstrates intraerythrocytic parasites (2)[B].
  - Dividing "cross-like" tetrads of merozoites (Maltese cross) are pathognomonic (2).
  - Serial blood smears may be required as low parasite load early in the illness may make identification difficult (2).
  - Can be confused with *Plasmodium falciparum* on peripheral smear
- If blood smears are negative but suspicion remains, IgM serologies through indirect immunofluorescent antibody testing (IFAT) for *B. microti* antigen are available:
  - The cutoff titer for a positive result varies by laboratory protocol. Titers of >1:64 or a 4-fold increase from baseline are consistent with *B. microti* infection (3). Titers may exceed >1:1,024 in acute infection (2)[B]. Titers often persists for 8 to 12 months and can last for years.
  - In New England, seroprevalence varies between 0.5% and 16% (3).
- Detection of *B. microti* by polymerase chain reaction (PCR) is more sensitive and equally specific in acute cases. PCR can also be used to monitor disease progression (2)[B]. Newer real-time PCR tests have a sensitivity and specificity approaching 100%.
- When lab tests are inconclusive and infection is strongly suspected, inoculation of laboratory

animals with patient blood reveals *B. microti* organisms in the blood of the animal within 2 to 4 weeks (2).

## Follow-Up Tests & Special Considerations

Monitoring intraerythrocytic parasitemia helps guide treatment (4)[C].

P.103

## Diagnostic Procedures/Other

Based on blood smear, history, and epidemiologic information (2)

## TREATMENT

### GENERAL MEASURES

- In areas endemic for Lyme disease and ehrlichiosis, consider adding doxycycline (Vibramycin) 100 mg BID PO until serologic testing is completed (1)[C].
- Resistance to standard medications has emerged in severely immunocompromised patients (2).
- Consider treating asymptomatic patients if parasitemia persists for >3 months; otherwise, do not treat in absence of symptoms (1),(4)[C].

### MEDICATION

#### First Line

- Mild to moderate infection with *B. microti*: 7 to 10 days of atovaquone 750 mg PO BID plus azithromycin 500 to 1,000 mg/day PO on day 1, followed by 250 mg/day afterward. Pediatrics: atovaquone 20 mg/kg (max 750 mg) BID and azithromycin 10 mg/kg (max 500 mg) on day 1, then 5 mg/kg (max 250 mg) (4)[B]. For severe *B. microti* infection: oral quinine 650 mg TID or QID plus oral clindamycin 600 mg TID for 7 to 10 days. Pediatrics: clindamycin 7 to 10 mg/kg (max 600 mg) TID or QID and quinine 8 mg/kg (max 650 mg) TID. IV formulations can be used (4)[C].
- Persistent or relapsing babesiosis: Treat for 6 weeks, including 2 weeks after *Babesia* is no longer detected on blood smear (5)[B].

#### Second Line

- Combination of quinine sulfate 650 mg PO TID and clindamycin 600 mg PO TID or 1.2 g parenterally BID for 7 to 10 days is the most commonly used treatment. Pediatric: quinine 8

mg/kg (max 650 mg) every 6 to 8 hours for 7 to 10 days and clindamycin 7 to 10 mg/kg (max 600 mg) PO q6-8h for 7 to 10 days. Some experts prefer this regimen for severe infections (4) [C].

- Other drugs including tetracycline, primaquine, sulfadiazine (Microsulfon), and sulfadoxine/pyrimethamine (Fansidar) have been evaluated. Results vary. Pentamidine (Pentam) is moderately effective in diminishing symptoms and decreasing parasitemia (1)[C].

## **ALERT**

Clindamycin can lead to *Clostridium difficile*-associated diarrhea.

## **ISSUES FOR REFERRAL**

Severe disease: Consider consultation with hematology and infectious disease for exchange transfusion in extremely ill patients (blood parasitemia >10%, massive hemolysis, and asplenia) (2)[C].

## **ONGOING CARE**

### **FOLLOW-UP RECOMMENDATIONS**

- If left untreated, silent babesiosis may persist for months or years (2).
- 139 hospitalized cases in New York State between 1982 and 1993:
  - 9 patients (7%) died.
  - 25% of the patients were admitted to the ICU.
  - 25% hospitalized for >14 days.
- Alkaline phosphatase levels >125 U/L, WBC counts >5 × 10<sup>9</sup>/L, history of cardiac abnormality, history of splenectomy, presence of heart murmur, and parasitemia of 4% or higher are associated with disease severity (6)[B].

### **Patient Monitoring**

The need for clinical and lab monitoring depends on disease severity. Severe infections: Follow hematocrit and parasitemia levels until clinical improvement and parasitemia is <5%. Mild to moderate: Expect clinical improvement within 48 hours and complete resolution within 3 months (4)[C].

## **COMPLICATIONS**

While many remain asymptomatic, a case series noted the following complications in hospitalized patients: CHF (12%), DIC (18%), ARDS (21%),

renal failure (6%), coma/lethargy (9%), death (9%). Other reported complications include neutropenia and myocardial infarction.

## Codes

### ICD10

B60.0 Babesiosis

## Clinical Pearls

- If left untreated, silent babesial infection may persist for months or even years.
- Most patients do not recall tick exposure, and incubation can last up to a month.
- Ticks must remain in place for 24 hours to transmit infection—encourage daily “tick checks” if people are exposed in high-risk areas.
- First-line treatment for mild or moderate disease is atovaquone plus azithromycin.
- Patients with mild to moderate disease should show clinical improvement within 48 hours after starting therapy. Symptoms should fully resolve within 3 months.
- Coinfection with *B. burgdorferi* and *Ehrlichia* species is common in endemic areas. In areas endemic for Lyme disease and ehrlichiosis, consider adding doxycycline until serologic testing is completed.

# Back Pain, Low

Millicent King Channell, DO, MA, FAAO

## BASICS

### DESCRIPTION

- Low back pain (LBP) is extremely common and includes a wide range of symptoms involving the lumbosacral spine and pelvic girdle.
- LBP can be characterized by duration or associated symptoms.
- **Duration** (1)[A]
  - Acute (<6 weeks)
  - Subacute (>6 weeks but <3 months)
  - Chronic (>3 months)
- **Associated symptoms** (1)[A]
  - Localized/nonspecific ÒmechanicalÓ LBP
  - Back pain with lower extremity symptoms
  - Systemic and visceral symptoms
- A specific cause is not found for most patients with LBP. Most cases resolve in 4 to 6 weeks.
- Rule out ÒredÓ flag symptoms indicating the need for immediate intervention.
- System(s) affected: musculoskeletal, neurologic
- Synonym(s): lumbago, lumbar sprain/strain, low back syndrome

### EPIDEMIOLOGY

#### *Incidence*

- 1-year incidence: 6-15% (1)[A]
- LBP is one of the most common primary care complaints (1)[A].

#### *Prevalence*

- Lifetime prevalence: 84% (1)[A]
- Global point prevalence: 9% (1)[A]
- Predominant sex: male = female
- Age: The highest incidence is in the 3rd decade (20 to 29 years); overall prevalence increases with age until age 65 years and then declines (1)[A].

## **ETIOLOGY AND PATHOPHYSIOLOGY**

A clear etiology is not found in most patients. Age-related degenerative changes of the lumbosacral spine, and atrophy of supporting musculature may contribute (2)[A].

## **RISK FACTORS**

- Age (1)[A.]
- Activity (lifting, sudden twisting, bending) (1)[A]
- Obesity (1)[A]
- Sedentary lifestyle (1)[A]
- Physically strenuous work (1)[A]
- Psychosocial factors—Anxiety, depression, stress (1)[A]
- Smoking (1)[A]

## **GENERAL PREVENTION**

- Maintain normal weight (1)[A].
- Adequate physical fitness and activity (1)[A].
- Stress reduction (1)[A]
- Proper lifting technique and good posture
- Smoking cessation
- There is insufficient evidence to recommend for or against routine preventive measures in adults.

## **DIAGNOSIS**

### **HISTORY**

- Onset of pain (sudden or gradual) (1)[A]

- Pain from spinal structures (musculature, ligaments, facet joints, and disks) can refer to the thigh region but rarely below the knee (1)[A].
- Sacroiliac pain often refers to the thigh and can also radiate below the knee (1)[A].
- Irritation, impingement, or compression of lumbar nerve roots often results in more leg pain than back pain (1)[A].
- Pain from the L1-L3 nerve roots radiates to the hip and/or thigh, whereas pain from the L4-S1 nerve roots radiates below the knee.
- **Red flags**
  - Recent trauma
  - Neurologic deficits
    - Bowel/bladder incontinence or urinary retention
    - Saddle anesthesia
    - Weakness, falls
  - Night pain, sweats, fever, weight loss
  - Age >70 years with or without trauma
  - Age >50 years with minor trauma
  - History of cancer
  - Osteoporosis
  - Immunosuppression, prolonged glucocorticoid use
- **Yellow flags** predicting poor long-term prognosis
  - Lack of social support
  - Unsupportive work environment
  - Depression and/or anxiety
  - Abuse of alcohol or other substances
  - History of physical or sexual abuse
- Pain can be provoked with motion: flexion-extension, side-bending rotation, sitting, standing, and lifting. Pain often relieved with rest.
- Radicular pain may radiate to buttocks, thighs, and lower legs.

### ***Pediatric Considerations***

Back pain is not normal in children and must be carefully evaluated. Patients participating in gymnastics or other high impact sports (such as skateboarding and cheerleading) frequently land on their feet or buttocks. These can result in a vertebral fracture and/or damage to the intervertebral discs.

## *PHYSICAL EXAM*

- Observe gait, position on examination table, and facial expressions.
- Test lumbar spine range of motion.
- Evaluate for point tenderness or muscle spasm.
  - Neurologic examination. Inspection: signs of muscle atrophy
  - Completely evaluate reflexes, strength, pulses, sensation
  - Straight leg test
  - FABER test (flexion, abduction, and external rotation)
  - Stork test: Stand on one leg with opposite hip held in flexion. Extend back. Pain in lumbosacral area is a positive test.

## *DIFFERENTIAL DIAGNOSIS*

- Localized/nonspecific mechanical LBP (87%) (1)[A]
- Lumbar strain/sprain (70%)
  - Disc/facet degeneration (10%)
  - Osteoporotic compression fracture (4%)
  - Spondylolisthesis (2%)
  - Severe scoliosis, kyphosis
  - Asymmetric transitional vertebrae (<1%)
  - Traumatic fracture (<1%)
- Back pain with lower extremity symptoms (7%) (1)[A]
  - Disc herniation (4%)
  - Spinal stenosis (3%)
- Systemic and visceral symptoms (1)[A]
  - Neoplasia (0.7%)
    - Multiple myeloma; metastatic carcinoma
    - Lymphoma/leukemia
    - Spinal cord tumors, retroperitoneal tumors

- Infection (0.01%)
  - Osteomyelitis
  - Septic discitis
  - Paraspinous abscess; epidural abscess
  - Shingles
- Inflammatory disease (0.03%)
  - Ankylosing spondylitis, psoriatic spondylitis
  - Reactive arthritis
  - Inflammatory bowel disease
- Visceral disease (0.05%)
  - Prostatitis
  - Endometriosis
  - Chronic pelvic inflammatory disease
  - Nephrolithiasis, pyelonephritis
  - Perinephric abscess
  - Aortic aneurysm
  - Pancreatitis; cholecystitis
  - Penetrating ulcer
- Other
  - Osteochondrosis
  - Paget disease

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Imaging studies are unnecessary during the first 6 weeks if no red flag signs or symptoms.
- X-ray of the lumbar spine (1,3,4)[A]
  - Not recommended for initial presentation or without red flags including trauma. Defer films for 6 weeks unless there is a high risk of disease.

- Useful for bony etiology (e.g., fracture)
- MRI of the lumbar spine (1,3,4)[A] for patients presenting with neurologic deficits, failure to improve with 6 weeks of conservative treatment, or if there is a strong suspicion of cancer or cauda equina syndrome.
  - Useful for suspected herniated disc, nerve root compression, or metastatic disease
- CT scan of the lumbar spine (1,3,4)[A]
  - Appropriate alternative to MRI for patient with pacemaker, metallic hardware, or other contraindication to MRI
- Labs are unnecessary with initial presentation if no related red flags, signs, or symptoms present (1,3,4)[A]
- If infection or bone marrow neoplasm is suspected, consider (1,3,4)[A]
  - Complete blood count (CBC) with differential
  - Erythrocyte sedimentation rate (ESR)
  - C-reactive protein (CRP) level

## *Diagnostic Procedures/Other*

Neurosurgical consult for acute neurologic deficits or suspected cauda equina syndrome (1,4)[A]

## **TREATMENT**

The primary goal is to provide supportive care and allow return to functional activity. Patients should be aware of alarm symptoms that prompt a return visit.

### *First Line*

- Patient education (4)[A]
  - Reassure patients that pain is usually self-limited; treatment should relieve pain and improve function.
  - Encouraging activity as tolerated leads to quicker recovery.
- Medications (1,3,5)[A]
  - Acetaminophen 325 to 650 mg PO q4-6h PRN pain (max 4 g/day)
  - NSAIDs

- Ibuprofen 400 to 600 mg PO 3 to 4 times daily (max 3,200 mg/day)
- Naproxen 250 to 500 mg PO q12h (max 1,500 mg/day)
- Manual medicine (4)[A], osteopathic manipulative treatments (OMT) (4)[A],(6)[B]: myofascial, counter-strain, bilateral ligamentous techniques, as well as muscle energy, if tolerated
- **Obstetric considerations** (6,7)[B]
  - Use medications cautiously in pregnancy benefit must clearly outweigh risk.
- OMT and chiropractic care may be used in a multi-disciplinary approach in the general population as well as the obstetric patient.

## *Second Line*

- Second-line therapy for moderate to severe pain (1,3,5)[A]
  - Cyclobenzaprine 5 to 10 mg PO up to TID PRN (max 30 mg/day)
  - Tizanidine 2 mg PO up to TID PRN
  - Hydrocodone 2.5 to 10 mg PO q4-6h PRN pain; use of hydrocodone or other opioids for LBP is based on clinical judgment.
- Other treatments (1,3)[A]
  - Antidepressants (1,3,5)[A]
    - Tricyclic antidepressants (amitriptyline, nortriptyline, desipramine) have been shown in randomized trials to provide a small pain reduction in patients. No clear evidence that SSRIs are more effective than placebo in cases of chronic LBP.
- Injections (8)[A]
  - Facet: lumbar radiofrequency neurotomy, therapeutic facet joint nerve blocks in the lumbar spine, and lumbar intra-articular injections have all shown benefit
  - Epidural: provides short-term relief of persistent pain associated with documented radicular symptoms caused by herniated disc (1,3,4,8)[A]

## *Geriatric Considerations*

- Older persons taking nonselective NSAIDs should use a proton pump inhibitor or misoprostol for gastrointestinal protection.

Patients taking a COX-2 selective inhibitor with aspirin should use a proton pump inhibitor or misoprostol for gastrointestinal protection.

- Age-related decline in cytochrome P-450 function and polypharmacy (common in elderly patients) increases risk for adverse medication reactions.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture is superior to no treatment, but evidence is mixed regarding the effectiveness of acupuncture over other treatment modalities (1,3,4)[A].
- Yoga can help with chronic LBP (1,3,4)[A].

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

- Regular exercise (3,9)[A]
- Patient education regarding chronicity, recurrence, and red flags (3,9)[A]

### Patient Monitoring

- Reassurance is key. Follow up within 2 to 4 weeks of initial presentation to monitor progress. Most patients spontaneously improve.
  - Assess severity and quality of pain as well as range of motion and other historical features (red flags).
- Reevaluate for possible underlying organic causes for pain if patients fail to improve.

### COMPLICATIONS

- Regular NSAID use can increase risk of gastrointestinal toxicity and nephrotoxicity (1,4)[A].
- Acetaminophen has potential hepatotoxicity (1,4)[A].
- Centrally acting skeletal muscle relaxants and opioid agonists carry the risk for sedation, confusion, dependence, and abuse (1,4)[A].

## See Also

- Lumbar (Intervertebral) Disc Disorders
- Algorithm: Low Back Pain, Acute

## Codes

### ICD10

- M54.5 Low back pain
- G89.29 Other chronic pain

## Clinical Pearls

- LBP is one of the most common complaints in primary care. Most patients do not have an identifiable cause of pain, and most cases resolve spontaneously within 4 to 12 weeks of onset.
- Assess for red flag symptoms in every patient.
- Labs and imaging studies are unnecessary for most cases of back pain if no red flag symptoms

are present.

- In the absence of red flags, physical activity as tolerated speeds recovery.

# Bacteriuria, Asymptomatic

Mony Fraer, MD, FACP, FASN

Kantima Phisitkul, MD

## BASICS

### DESCRIPTION

Asymptomatic bacteriuria (ASB) is diagnosed when significant bacteriuria is not accompanied by signs and symptoms attributable to urinary tract infection (UTI).

### EPIDEMIOLOGY

#### Incidence

- General population: 3.5%
- Pregnancy: 7-10%
- Older women: 16-18%

#### Prevalence

- Variable, increased with age, female gender, sexual activity, and presence of genitourinary (GU) abnormalities
- Pregnancy: 2-10%
- Short- and long-term indwelling catheter 9-23% and 100%, respectively
- Long-term care residents in women 25-50% and men 15-40%

### ETIOLOGY AND PATHOPHYSIOLOGY

- Microbiology is similar to that of other UTI, with bacteria originating from periurethral area, vagina, or gut.
- Organisms are less virulent in ASB than those causing UTI.
- The most common organism is *Escherichia coli*. Other common organisms are *Klebsiella pneumoniae*, *Enterobacter*, *Proteus mirabilis*, *Staphylococcus aureus*, group B *Streptococcus* (GBS), and *Enterococcus*.

## *Genetics*

Genetic variations that reduce toll-like receptor-4 function (TLR4) have been associated with ASB by lowering innate immune response and delaying bacterial clearance.

## **RISK FACTORS**

- Older age
- Female gender
- Sexual activity, use of diaphragm with spermicide
- GU abnormalities: neurogenic bladder, urinary retention, urinary catheter use (indwelling, intermittent, or condom catheter)
- Institutionalized residents
- Diabetes mellitus
- Immunocompromised status
- Spinal cord injuries or functional impairment
- Hemodialysis
- Pregnancy (decreased peristalsis of the urinary tract)

## **COMMONLY ASSOCIATED CONDITIONS**

Depends on the risk factors

## **DIAGNOSIS**

### **HISTORY**

- Asymptomatic
- Lack of symptoms attributable to UTI such as fever, acute dysuria (<1 week), new or worsening urinary urgency/frequency/incontinence, or acute gross hematuria

## **PHYSICAL EXAM**

- Afebrile
- No suprapubic and costovertebral angle tenderness

## **DIFFERENTIAL DIAGNOSIS**

- UTI
- Contaminated urine specimen

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Urinalysis (UA):
  - The presence of pyuria, leukocyte esterase, and nitrite in ASB is common.
- Urine culture
- Screening urine culture in asymptomatic patients is indicated in only two conditions:
  - Pregnancy: screening between 12 and 16 weeks' gestation or at first prenatal visit if later (1)[A]
  - Prior to transurethral resection of prostate (TURP) (1)[A] or any urologic interventions when mucosal bleeding is anticipated (1)[C].
- Screening for ASB in men and nonpregnant women is not recommended.

### *Follow-Up Tests & Special Considerations*

- Noncontaminated urine specimen should be used for urine culture.
- In pregnancy, periodic screening urine culture should be done after ASB treatment (1)[A] but not required in GBS bacteriuria (2,3)[C].

### *Test Interpretation*

- Patient with significant bacteriuria with or without pyuria and without symptoms referable to UTI should be diagnosed as ASB per Infectious Diseases Society of America.
  - Significant bacteriuria is defined based on type of urine specimen, sex, and the amount of bacteria.
    - By midstream, clean catch specimen
      - Male: >100,000 CFU/mL of single bacteria species
      - Female: the same criteria as male but needs two positive consecutive specimens
    - By catheterized specimen male and female: >100 CFU/mL of one bacterial species. Required one-time collection only

The presence of pyuria or leukocyte esterase is common but not a marker of infection.

- Positive nitrite is an indicator of the presence of bacteriuria, but cannot differentiate UTI from ASB or poor collection technique.

## TREATMENT

### GENERAL MEASURES

#### ALERT

- Antibiotic treatment of ASB is indicated in two conditions:
  - Pregnancy (1)[A]
    - Rationale: Treatment has been shown to significantly reduce the incidence of acute pyelonephritis and low birth weight.
  - Prior to urologic procedure particularly TURP (1)[A]
    - Rationale: Antibiotic treatment can effectively prevent postprocedure bacteremia and sepsis.
- Treatment of ASB in other conditions (nonpregnant women, diabetic women, indwelling catheter, patients with spinal cord injury, or the elderly living in the community) does not provide any known clinical benefit, does not reduce the risk of symptomatic infection nor improve morbidity or mortality. It increases health care cost, adverse drug side effects, development of resistant organisms, and reinfection rate (1,4).
- Inadequate evidence to guide management in nonurologic procedure and solid organ transplant (1,4)

P.107

### MEDICATION

- Pregnancy
  - Intrapartum antibiotic prophylaxis with IV penicillin or clindamycin (penicillin allergy) is recommended for women with GBS bacteriuria occurring at any stage of pregnancy and of any colony count to prevent GBS disease in the newborn (2)[C].
  - No consensus on choice of antibiotics and duration of treatment in pregnancy; however, the cure rate is higher for the 4 to 7 days of treatment than one-day treatment (1)[A].
  - Choice of antibiotics should be guided by bacterial pathogen, local resistance rate, adverse effects, and comorbidities of patients (5).

- Common oral antibiotics (FDA-B) that have been used
  - Nitrofurantoin 100 mg BID for 5 days (low level of resistance, may cause hemolysis in glucose-6-phosphate dehydrogenase deficiency)
  - Amoxicillin/clavulanate 500/125 BID for 5 to 7 days
  - Cefuroxime 250 mg BID for 5 days
  - Cephalexin 500 mg BID for 5 days
  - Fosfomycin 3 g for 1 single dose (not effective when glomerular filtration rate is less than 30 mL/min, may be used in highly resistant bacteria such as methicillin-resistant *Staphylococcus aureus* [MRSA], vancomycin-resistant enterococci [VRE], and extended-spectrum beta-lactamase [ESBL]-producing organism bacteria) (6)
- Avoid trimethoprim in 1st trimester and near term. Avoid sulfa after 32 weeks' gestation.
- Contraindicated: fluoroquinolones (FDA-C), tetracyclines (FDA-D)
- Prior to invasive urologic interventions
  - Initiate antibiotic the night before or immediately before the procedure (1)[A].
  - Antibiotic should be continued until the indwelling catheter is removed postprocedure (1) [B].

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

No consensus on screening frequency of ASB in pregnancy, but monthly screening of urine culture after ASB treatment is recommended except GBS (1,2).

### *Patient Monitoring*

Development of any signs/symptoms of UTI should warrant antibiotic treatment.

### *DIET*

Daily cranberry juice may reduce the frequency of ASB during pregnancy, but it has not been confirmed in large study (see Additional Reading).

### *PATIENT EDUCATION*

Patient should seek medical attention when UTI symptoms develop.

## COMPLICATIONS

- Late pregnancy pyelonephritis occurs in 20-35% of women with untreated bacteriuria (20- to 30-fold higher than women with negative initial screening urine cultures or in whom bacteriuria was treated). Pyelonephritis is associated with premature delivery and worse fetal outcomes (infant with group B streptococcal infections, low-birth-weight infant). Antimicrobial treatment will decrease the risk of subsequent pyelonephritis from 20-35% to 1-4% and the risk of having a low-birth-weight baby from 15% to 5%.
- If bacteriuria remains untreated in patients who undergo traumatic urologic procedures, up to 60% develop bacteremia after the procedure and 5-10% progress to severe sepsis/septic shock.

## Codes

### ICD10

- N39.0 Urinary tract infection, site not specified
- B96.20 Unsp Escherichia coli as the cause of diseases classd elswhr
- B96.1 Klebsiella pneumoniae as the cause of diseases classd elswhr

## Clinical Pearls

- ASB is a common and benign disorder for which treatment is not indicated in most patients.
- The presence of pyuria, leukocyte esterase, and nitrite is common in ASB and not an indication for antimicrobial treatment.
- Antibiotic treatment is indicated for ASB in pregnancy and patients who require urologic procedure in which mucosal bleeding is anticipated.
- Treatment of ASB in other conditions does not decrease the frequency of UTI or improve outcome.
- Overtreatment of ASB may result in negative consequences such as antimicrobial resistance, adverse drug reaction, and unnecessary cost.

# Balanitis, Phimosis, and Paraphimosis

James P. Miller, MD

## BASICS

### DESCRIPTION

- Balanitis:
  - An inflammation of the glans penis
  - Posthitis is an inflammation of the foreskin.
  - Balanitis xerotica obliterans (BXO) is lichen sclerosus of the glans penis (uncommon).
- Phimosis and paraphimosis:
  - Phimosis: tightness of the distal penile foreskin that prevents it from being drawn back from over the glans
  - Paraphimosis: constriction by foreskin of an uncircumcised penis, preventing the foreskin from returning to its position over the glans; occurs after the retracted foreskin becomes swollen and engorged; a urologic emergency
- System(s) affected: renal/urologic; reproductive; skin/exocrine

### ALERT

- Recurrent infection and irritations (condom catheters) can lead to phimosis.
- Recurrent balanitis, either chemical or infectious, can lead to an acquired phimosis.
- Inappropriate forced reduction of a physiologic foreskin can lead to chronic scarring and acquired phimosis. Unfortunately, many times done due to instructions from health care providers.

### EPIDEMIOLOGY

- Balanitis: predominant age: adult; predominant gender: male only
- Phimosis/paraphimosis: predominant age: infancy and adolescence; unusual in adults; risk returns in geriatrics; predominant sex: male only

## *Incidence*

Balanitis: will affect 3-11% of males

## *Prevalence*

Phimosis: in the United States: 8% of boys age 6 years and 1% of men >16 years of age (1)

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Balanitis:
  - Allergic reaction (condom latex, contraceptive jelly)
  - Infections (*Candida albicans*, *Borrelia vincentii*, streptococci, *Trichomonas*, HPV)
  - Fixed-drug eruption (sulfa, tetracycline)
  - Plasma cell infiltration (Zoon balanitis)
  - Autodigestion by activated pancreatic transplant exocrine enzymes
- Phimosis:
  - Physiologic: present at birth; resolves spontaneously during the first 2 to 3 years of life through nocturnal erections, which slowly dilate the phimotic ring
  - Acquired: recurrent inflammation, trauma, or infections of the foreskin
- Paraphimosis:
  - Often iatrogenically or inadvertently induced by the foreskin not being pulled back over the glans after voiding, cleaning, cystoscopy, or catheter insertion

## *Geriatric Considerations*

Condom catheters can predispose to balanitis.

## *Pediatric Considerations*

Oral antibiotics predispose male infants to *Candida balanitis*. Inappropriate care of physiologic phimosis can lead to acquired phimosis by repeated forced reduction of the foreskin.

## **RISK FACTORS**

- Balanitis:
  - Presence of foreskin
  - Morbid obesity

- Poor hygiene
- Diabetes; probably most common
- Nursing home environment
- Condom catheters
- Chemical irritants
- Edematous conditions: CHF, nephrosis
- Phimosis:
  - Poor hygiene
  - Diabetes by repeated balanitis
  - Frequent diaper rash in infants
  - Recurrent posthitis
- Paraphimosis:
  - Presence of foreskin
  - Inexperienced health care provider (leaving foreskin retracted after catheter placement)
  - Poor education about care of the foreskin

## GENERAL PREVENTION

- Balanitis:
  - Proper hygiene and avoidance of allergens
  - Circumcision
- Phimosis/paraphimosis:
  - If the patient is uncircumcised, appropriate hygiene and care of the foreskin are necessary to prevent phimosis and paraphimosis.

## DIAGNOSIS

### HISTORY

- Balanitis:
  - Pain

- Drainage
- Dysuria
- Odor
- Ballooning of foreskin with voiding
- Redness
- Phimosis:
  - Painful erections
  - Recurrent balanitis
  - Foreskin balloons when voiding
  - Inability to retract foreskin at appropriate age
- Paraphimosis:
  - Uncircumcised
  - Pain
  - Drainage
  - Voiding difficulty

## *PHYSICAL EXAM*

- Balanitis:
  - Erythema
  - Tenderness
  - Edema
  - Discharge
  - Ulceration
  - Plaque
- Phimosis:
  - Foreskin will not retract.
  - Secondary balanitis
  - Physiologic phimosis↳preputial orifice appears normal and healthy
  - Pathologic phimosis↳preputial orifice has fine white fibrous ring of scar
- Paraphimosis:

- Edema of prepuce and glans
- Drainage
- Ulceration

## *DIFFERENTIAL DIAGNOSIS*

- Balanitis:
  - Leukoplakia
  - Lichen planus
  - Psoriasis
  - Reiter syndrome
  - Lichen sclerosus et atrophicus
  - Erythroplasia of Queyrat
  - BXO: atrophic changes at end of foreskin; can form band that prevents retraction
- Phimosi/paraphimosi:
  - Penile lymphedema, which can be related to insect bites, trauma, or allergic reactions
  - Penile tourniquet syndrome: foreign body around penis, most commonly hair
  - Anasarca

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Microbiology culture
- Wet mount
- Serology for syphilis
- Serum glucose; ESR (if concerns about Reiter syndrome)
- STD testing
- HIV testing
- Gram stain

### *Diagnostic Procedures/Other*

Biopsy, if persistent

## *Pathologic Findings*

Plasma cells infiltration with Zoon balanitis

---

P.109

## **TREATMENT**

### *GENERAL MEASURES*

- Consider circumcision for recurrent balanitis and paraphimosis.
- Warm compresses or sitz baths
- Local hygiene

### *MEDICATION*

- Balanitis:
  - Antifungal:
    - Clotrimazole (Lotrimin) 1% BID
    - Nystatin (Mycostatin) BID-QID
    - Fluconazole: 150 mg PO single dose
  - Antibacterial:
    - Bacitracin QID
    - Neomycin-polymyxin B-bacitracin (Neosporin) QID
    - If cellulitis, cephalosporin or sulfa drug PO or parenteral:
      - Dermatitis: topical steroids QID
      - Zoon balanitis: topical steroids QID
- Phimosis:
  - 0.05% fluticasone propionate daily for 4 to 8 weeks with gradual traction placed on foreskin (2)[B]
  - 1% pimecrolimus BID for 4 to 6 weeks. Not for use in children <2 years (3)[C].
- Paraphimosis:

- Manual reduction, if possible (should be done with the patient sedated). Place the middle and index fingers of both hands on the engorged skin proximal to the glans. Place both thumbs on glans and, with gentle pressure, push on the glans and pull on the foreskin to attempt reduction. If unsuccessful, a dorsal slit will be necessary, with eventual circumcision after the edema resolves.
- Osmotic agents: granulated sugar placed on edematous tissue for several hours to reduce edema
- Puncture technique: Multiple punctures of foreskin with a 21-gauge needle will allow edematous fluid to escape and thus allow reduction.
- Dorsal slit; done by surgeon or urologist
- BXO:
  - 0.05% betamethasone BID
  - 0.1% tacrolimus BID

## *ISSUES FOR REFERRAL*

Recurrent infections or development of meatal stenosis

## *SURGERY/OTHER PROCEDURES*

- Balanitis and phimosis: Consider circumcision as preventive measure.
- For paraphimosis:
  - Represents a true surgical emergency to avoid necrosis of glans
  - Dorsal slit with delayed circumcision, if reduction is not possible
  - Operative exploration if the possibility of penile tourniquet syndrome cannot be eliminated. Hair removal cream can be applied if a hair is thought to be the cause of the tourniquet.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Uncontrolled diabetes
- Sepsis

### *Nursing*

Appropriate hygiene if condom catheters are used

## *Discharge Criteria*

Resolution of problem

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

Balanitis:

- Every 1 to 2 weeks until etiology has been established
- Persistent balanitis may require biopsy to rule out malignancy or BXO.
- Evaluation for resolution of phimosis

#### *DIET*

Weight reduction, if obese

### *PATIENT EDUCATION*

- Need for appropriate hygiene
- Appropriate foreskin care
- Avoidance of known allergens
- No sexual activity for 2 to 3 weeks after circumcision

### *PROGNOSIS*

Should resolve with appropriate treatment

### **COMPLICATIONS**

- Meatal stenosis
- Premalignant changes from chronic irritation
- UTIs
- Acquired phimosis
- Unreducible paraphimosis can lead to gangrene
- Posthitis (inflammation of the prepuce)

## See Also

Reactive Arthritis (Reiter Syndrome)

## Codes

### ICD10

- N48.1 Balanitis
- N47.1 Phimosis

## Clinical Pearls

- Balanitis is an inflammation of the glans penis. Posthitis is an inflammation of the foreskin. BXO is lichen sclerosus of the glans penis.
- With recurrent infections and a plaque, a biopsy should be done to rule out BXO or malignancy.
- If there is a true phimosis that interferes with appropriate hygiene, treat the phimosis with steroids or circumcision to help with hygiene.

# Barotrauma of the Middle Ear, Sinuses, and Lung

Stephen L. Cook, MD

J. David Honeycutt, MD, FAAFP, FAWM

## BASICS

### DESCRIPTION

- Barotrauma is tissue damage resulting from the direct effects of pressure changes or imbalances between ambient pressure and pressure within an enclosed body cavity.
- Body cavities at greatest risk for barotrauma
  - Middle ear (otic barotrauma)
  - Paranasal sinuses (sinus barotrauma)
  - Lungs (pulmonary barotrauma)
- Dental barotrauma
  - Dental work can create small pockets of air, which can damage teeth in scuba divers or aviators during ambient pressure changes.
- Synonym(s): dysbarism; aerotitis; otitic barotrauma; middle ear barotrauma; barotitis; barosinusitis

### ALERT

- Dizziness and sensorineural hearing loss warrant immediate ENT referral for inner ear involvement.
- Valsalva maneuver can spread nasopharyngeal infection into the middle ear.

### EPIDEMIOLOGY

#### Incidence

- Pulmonary barotrauma is second only to drowning as a leading cause of death among divers.
- Pulmonary barotrauma affects 2-3% of mechanically ventilated patients (1).

- Otic barotrauma is common in air travel, particularly among flight personnel (2).

## *Pediatric Considerations*

- Children have difficulty opening the eustachian tube and commonly develop upper respiratory infections. This combination results in higher risk for otic and sinus barotraumata with smaller pressure changes than adults.
- Mechanical ventilation of neonates is associated with barotrauma and contributes to bronchopulmonary dysplasia.

## *Pregnancy Considerations*

Increased nasal congestion in pregnancy increases the risk of barotitis media (barotrauma of the middle ear).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Boyle law relating volume and pressure of gases applies to all forms of barotrauma. When gas is trapped in a confined space, such as the middle ear, paranasal sinus, or lungs, a sudden decrease in ambient pressure causes expansion of the gas within the cavity.
- Otalgia (earache) and hearing loss occur as a result of stretching and deformation of the tympanic membrane.
- Sudden pressure differentials between middle and inner ear may lead to rupture of the round or oval window. This can create a labyrinthine fistula, which consequently can allow leakage of perilymph. Damage to inner ear may be permanent.
- When the transalveolar pressure disrupts the structural integrity of the alveolus, the alveolar wall can rupture, leading to interstitial emphysema, pneumothorax, or pneumomediastinum.
- Otic and sinus barotrauma:
  - Associated with rapid or extreme changes in ambient pressure: air travel, mountain climbing, scuba diving
    - Nasal congestion or eustachian tube dysfunction increases risk of damage.
    - Failure of eustachian tube to equilibrate pressure may distort the tympanic membrane, causing discomfort or rupture.
    - Rupture of round or oval membrane may cause inner ear barotrauma, vertigo, and sensorineural hearing loss.
- Pulmonary barotrauma
  - Iatrogenic complication of mechanical ventilation or hyperbaric oxygen treatment

- Complication of rapid ascent or descent during scuba diving

## *RISK FACTORS*

- Otic or sinus
  - Participation in high-risk activities without adequate pressure equilibration
    - Scuba diving, especially with rapid ascent or breath-holding
    - Airplane flight
    - Sky diving
    - High-altitude travel
    - High-impact sports: boxing, soccer, water skiing
  - Upper respiratory infections
  - Nasal congestion or allergic rhinitis
  - Eustachian tube dysfunction
  - Blast exposure
  - The most common complication of hyperbaric oxygen treatment is middle ear barotrauma, which can lead to permanent hearing loss and vertigo.
  - Pregnancy (associated nasal congestion)
  - Anatomic obstruction in the nasopharynx
    - Deviated nasal septum
    - Nasal polyps
    - Congenital anomalies, including cleft palate
  - Previous history of ear trauma
- Pulmonary
  - Iatrogenic:
    - Mechanical ventilation, especially in the presence of asthma, chronic interstitial lung disease, acute respiratory distress syndrome
    - Hyperbaric oxygen therapy
  - Scuba diving or other underwater activities

- Air travel with preexisting pulmonary pathology

## GENERAL PREVENTION

- Pulmonary barotrauma
  - Cautious use of mechanical ventilation, employing lung-protective vent settings (lower end-inspiratory airway pressures, lower tidal volumes of 6 mL/kg, higher positive end-expiratory pressures of 6 to 12 cm H<sub>2</sub>O) (1)[A]
  - Cautious use of hyperbaric oxygen therapy
  - Avoid breath holding during ascent while scuba diving.
- Otic barotrauma
  - Avoid altitude changes or scuba diving with eustachian tube dysfunction.
  - Treat upper respiratory congestion.
- Equilibration of pressure: Valsalva maneuver, yawning, swallowing, drinking, or chewing gum

## DIAGNOSIS

### HISTORY

- History of high-risk activity
- Otic (middle ear) barotrauma:
  - Otolgia, sensation of fullness or pressure in the ear
  - Hearing loss
  - Vertigo
  - Transient facial paralysis
  - Otorrhea
- All patients with middle ear barotrauma should be evaluated for inner ear barotrauma:
  - Hearing loss
  - Tinnitus
  - Vertigo
  - Disorientation
- Sinus barotrauma
  - Facial pain, sensation of fullness or pressure

- Pulmonary barotrauma: Ask about scuba diving, mechanical ventilation, air travel with preexisting lung disease:
  - Chest pain
  - Dyspnea
  - Shortness of breath
  - Hemoptysis

## *PHYSICAL EXAM*

- Otic barotrauma
  - Otoscope exam: otorrhea, pneumotoscopy
  - Assess balance and hearing.
  - Palpate eustachian tube for tenderness.
- Otic (middle ear) barotrauma
  - Conductive hearing loss with Weber and Rinne tests
  - Transient facial paralysis
- All patients with middle ear barotrauma should be evaluated for inner ear barotrauma:
  - Sensorineural hearing loss with Weber and Rinne tests
- Sinus barotrauma
  - Facial tenderness
- Pulmonary barotrauma
  - Hypoxia, hypotension
  - Auscultation, percussion
  - Assessment of respiratory distress

## *DIFFERENTIAL DIAGNOSIS*

- Acute and chronic otitis media
- Otitis externa
- Temporomandibular joint syndrome
- Pulmonary: pulmonary embolism; complications of mechanical ventilation

# DIAGNOSTIC TESTS & INTERPRETATION

## *Initial Tests (lab, imaging)*

- Otic or sinus
  - CT to rule out underlying pathology, if suspected
    - Nasopharyngeal tumor (if enlarging facial/neck mass with or without nasal obstruction, recurrent epistaxis)
    - Chronic sinus disease (sinus pain, pressure, fullness, chronic posterior nasal drip/congestion)

---

P.111

- Pulmonary
  - Chest radiograph
  - Chest CT if unclear diagnosis by CXR
  - Arterial blood gases (ABG)
- Other: ultrasound

## *Diagnostic Procedures/Other*

- Otic barotrauma
  - Tympanometry
  - Audiometry: conductive (middle ear) versus sensorineural (inner ear) hearing loss
  - Surgical exploration to rule out inner ear involvement, if suspected
- Pulmonary barotrauma: chest tube insertion, if clinically indicated, for pneumothorax

## *Test Interpretation*

- Tympanic membrane (TM) retraction or bulging
  - Teed 0: no visible damage
  - Teed 1: congestion around umbo
  - Teed 2: congestion of entire TM
  - Teed 3: hemorrhage into middle ear

Teed 4: extensive middle ear hemorrhage; TM may rupture.

- Teed 5: entire middle ear filled with deoxygenated blood
- Inner ear involvement with rupture of the round or oval windows, perilymphatic fistula, and leakage of perilymph into the middle ear
- Pulmonary barotrauma
  - Alveolar rupture may progress to interstitial emphysema, pneumoperitoneum, and pneumothorax.
- Petechial hemorrhages in area covered by diver's mask, as well as subconjunctival hemorrhages

## TREATMENT

### GENERAL MEASURES

- Prevention/avoidance is best: Avoid flying or diving when risk factors are present.
- Autoinflate the eustachian tube during pressure changes (3)[B].
  - Valsalva during ascent and descent in air travel
  - Infants: breastfeeding, pacifier use, or bottle feed
  - <sup>3</sup>4 years: chewing gum
  - <sup>3</sup>8 years: blowing up a balloon
  - Adults: chewing gum, swallowing, or yawning
- The nasal balloon is effective for prevention (4)[B].
- Pressure-equalizing earplugs are not recommended in air travel and do not prevent ear barotrauma (5)[B].
- For inner ear barotrauma
  - Bed rest with head elevated to avoid leakage of perilymph
  - Tympanotomy and repair of round or oval window may be necessary.
  - Sudden or progressive sensorineural hearing loss accompanied by dizziness following barotrauma should prompt consideration of a perilymph fistula. Early surgical exploration is recommended to improve hearing and vestibular symptoms (6)[C].
- Lung protective settings during mechanical ventilation (1)[A]

- Acute lung injury: NNT = 16
- Lung injury: NNT = 11
- Treatment of pneumothorax
  - Removal of air from pleural space (chest tube; Heimlich valve)
- Correct iatrogenic cause (e.g., adjustment of mechanical ventilation).

## *MEDICATION*

- Treat predisposing conditions (e.g., upper respiratory congestion prior to air travel):
  - Oral decongestants
  - Nasal decongestants
  - Antihistamines
- Antibiotics are not indicated for middle ear effusion secondary to barotrauma.
- Analgesics for pain control

## *ISSUES FOR REFERRAL*

- Refer to otolaryngology if inner ear is exposed, perilymphatic fistula is present, or sensorineural hearing loss is experienced.
- Consult with a hyperbaric specialist if recompression is required.
- Chest tube placement

## *SURGERY/OTHER PROCEDURES*

- If necessary, myringotomy or tympanoplasty
- Tympanotomy and repair of round or oval window may be necessary for inner ear barotrauma.
- Tube thoracostomy for persistent pneumothorax

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Patients with complicating emergencies (e.g., incapacitating pain requiring myringotomy, large tympanic perforation requiring tympanoplasty)
- Inner ear barotrauma with hearing loss

- Management of pneumothorax

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- No flying or diving until complete resolution of all signs and symptoms and Valsalva maneuver succeeds in equalizing pressure
- Complete bed rest for inner ear barotrauma
- No high-risk activities or air travel until pneumothorax is completely resolved

### *Patient Monitoring*

- Repeat physical examination until symptoms are clear.
- Audiograms and tympanometry if tympanic rupture

### *PATIENT EDUCATION*

- Demonstrate proper Valsalva maneuver.
- Appropriately treat sinus infections.
- American Academy of Pediatrics travel safety tips: <https://www.aap.org/en-us/about-the-aap/aapress-room/news-features-and-safety-tips/Pages/travel-safety-tips.aspx>.
- Divers Alert Network of Duke University Medical Center information line: (919) 684-2948

### *PROGNOSIS*

- Mild barotitis media may resolve spontaneously.
- Tympanic rupture takes weeks to months for healing.
- Hearing loss may be permanent in barotitis externa.
- Prognosis of pulmonary barotrauma depends on the extent of underlying pathology.

### **COMPLICATIONS**

- Permanent hearing loss
- Ruptured tympanic membrane
- Chronic tinnitus, vertigo
- Fluid exudate in middle ear
- Perilymphatic fistula

- Sensorineural hearing loss

## Codes

### ICD10

- T70.0XXA Otitic barotrauma, initial encounter
- T70.1XXA Sinus barotrauma, initial encounter
- T70.29XA Other effects of high altitude, initial encounter

# Clinical Pearls

- Small children can equalize eustachian tube pressure by breastfeeding or sucking on bottles or pacifiers. Crying also serves as autoinflation.
- Pulmonary barotrauma is the second leading cause of death among divers.
- Otic barotrauma is common in air travel, especially among flight personnel.
- Pulmonary barotrauma is noted in 2-3% of mechanically ventilated patients.
- Sudden or progressive sensorineural hearing loss accompanied by dizziness following barotrauma suggests a perilymphatic fistula. Early surgical exploration is recommended to preserve hearing and vestibular functions.

# Barrett Esophagus

Eric Ji-Yuan Mao, MD

Harlan G. Rich, MD, FACP, AGAF

## BASICS

### DESCRIPTION

- Metaplasia of the distal esophageal mucosa from native stratified squamous epithelium to abnormal columnar (intestinalized) epithelium, likely as a consequence of chronic GERD
- Predisposes to the development of adenocarcinoma of the esophagus

### EPIDEMIOLOGY

- Predominant age: >50 years
- May occur in children (rare <5 years)

### Incidence

- 10-15% of patients undergoing endoscopy for evaluation of reflux symptoms (1)
- Esophageal adenocarcinoma incidence is rising in the United States (1,2). From 1975 to 2001, there was nearly a 6-fold increase from 4 to 23 cases per million person-years.
- Attributed to changes in smoking and obesity rather than reclassification or overdiagnosis

### Prevalence

- Difficult to ascertain because of different populations studied, varying definitions, and asymptomatic cases
- As many as 1.5 to 2.0 million adults in the United States (extrapolated from a 1.6% prevalence in Swedish general population) (1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Chronic gastric reflux injures the esophageal mucosa, triggering columnar metaplasia. Refluxed bile acids likely induce differentiation in gastroesophageal junction (GEJ) cells.
- Columnar cells in the esophagus have higher malignant potential than squamous cells.

Activation of *CDX2* gene and overexpression of HER2/neu (ERBB2) oncogene promotes carcinogenesis.

- Elevated levels of COX-2, a mediator of inflammation and regulator of epithelial cell growth, are associated with Barrett esophagus (2).
- Classic progression: normal epithelium → esophagitis → metaplasia (Barrett esophagus) → dysplasia (low-or high-grade) → adenocarcinoma

## *Genetics*

- Familial predisposition to GERD and Barrett esophagus and multiple genetic markers have been identified.
- Acquired genetic changes lead to adenocarcinoma and are being investigated as biomarkers for risk stratification and early detection.

## **RISK FACTORS**

- Chronic reflux (>5 years)
- Hiatal hernia
- Age >50
- Male gender
- White ethnicity  
Incidence in white males is much higher than white women and African American men
- Smoking history
- Intra-abdominal obesity
- Family history with at least one first-degree relative with Barrett esophagus or esophageal adenocarcinoma

## **GENERAL PREVENTION**

Weight loss, smoking cessation, robust dietary intake of fruits and vegetables, and moderate wine consumption may decrease risk of Barrett esophagus and lower progression to esophageal cancer (3)[C].

## **COMMONLY ASSOCIATED CONDITIONS**

GERD, obesity, hiatal hernia

# DIAGNOSIS

## HISTORY

- Assess underlying risk factors.
- Common GERD symptoms: heartburn, regurgitation
- Less common symptoms include chest pain, odynophagia, chronic cough, water brash, globus sensation, laryngitis, or wheezing.
- Symptoms suggestive of complicated GERD or cancer include weight loss, anorexia, dysphagia, odynophagia, hematemesis, or melena.

## ALERT

Up to 25% of patients with Barrett esophagus are asymptomatic (2).

## PHYSICAL EXAM

No abnormal findings on physical exam are specific for Barrett esophagus. Perform a general physical examination including vital signs, oral examination, cardiopulmonary examination, abdominal examination, and lymph node examination.

## DIFFERENTIAL DIAGNOSIS

- Erosive esophagitis
- GERD

## DIAGNOSTIC TESTS & INTERPRETATION

Endoscopy with multiple biopsies for histologic examination are required to diagnose Barrett esophagus.

- Gastric fundic-type epithelium on pathology does not have clear malignant significance and may reflect sampling error.
- Specialized intestinal metaplasia at the GEJ: cancer risk difficult to assess with varying definitions of GEJ landmarks

## ALERT

Screening for Barrett esophagus in the general population with GERD is **not** recommended. However, endoscopic screening for Barrett esophagus is suggested in men >60 years old with prolonged GERD symptoms ( > 10 years) (4)[C].

## Initial Tests (lab, imaging)

None:

- *Helicobacter pylori* testing is *not* indicated. Metaanalyses show an inverse relationship between *H. pylori* infections and Barrett esophagus, which may be related to decreased acid production (5)[C].
- No biomarkers are currently effective for diagnosis; many are under investigation for risk stratification (1),(3)[B].

## Diagnostic Procedures/Other

- Endoscopy: visual identification of columnar epithelium (reddish, velvety appearance) replacing the squamous lining of the distal esophagus
- Disease extent: Long-segment ( $\geq 3$  cm) versus short-segment (<3 cm)
- The Prague C (circumference) and M (maximum extent) criteria is a consensus-driven grading system used to describe Barrett esophagus using landmarks of the squamocolumnar junction, GEJ, extent of circumferential columnar lining, and extent of proximal extension of columnar mucosa.
  - White light endoscopy (preferably high resolution) is the standard for diagnosis. Advanced imaging techniques, such as narrow band imaging (NBI) and confocal laser endomicroscopy, may help identify dysplasia but are preliminary (1)[A].
- Systematic biopsies from endoscopy showing columnar epithelium confirm the diagnosis:
  - Seattle protocol: four-quadrant biopsies at regular intervals with additional biopsies of visible mucosal irregularities; more time-consuming but higher diagnostic yield than random biopsies (3)[A]
  - Capsule endoscopy is still developing and has lower sensitivity than conventional endoscopy (6)[B].

## Test Interpretation

- Specialized intestinal metaplasia (also called specialized columnar epithelium) is diagnostic: Benign Barrett esophagus diagnosis is established by a single pathologist report (4)[C].
- Diagnosis of dysplasia (and grade) should be confirmed by two specialist gastrointestinal pathologists before treatment (4)[C].
- Cardia-type columnar epithelium may predispose to malignancy (unclear risk); International Consensus Group currently recommends defining Barrett esophagus by the presence of columnar mucosa in the esophagus with modifier of whether intestinal metaplasia is present.

(4)[C].

## TREATMENT

### ALERT

Neither suppression of gastric acid production via high-dose proton pump inhibitors (PPIs) nor reduction in esophageal acid exposure via antireflux surgery induces regression of Barrett esophagus. These therapies may, however, decrease cancer risk.

## MEDICATION

- The goal of medical therapy is to control GERD to reduce esophagitis.
- Therapy usually does not result in reversal of Barrett esophagus but may decrease risk of progression to cancer (1,2)[A],(6,7)[B].

### First Line

- Unlike the stepwise management of GERD without evidence of Barrett esophagus, patients with Barrett esophagus and GERD symptoms should be treated initially with a once-daily PPI.
- PPIs should be dosed 30 minutes before a meal (ideally, the first meal of the day).

### ALERT

PPI therapy should be titrated to symptoms; pH monitoring is **not** recommended (1,2)[C].

- Chemoprevention of neoplastic progression is under active investigation.
- Case-controlled studies have shown that aspirin, and NSAIDs may prevent progression to esophageal cancer due to COX-2 inhibition:
  - COX-2 selective inhibitor celecoxib use not shown to affect progression of Barrett dysplasia to adenocarcinoma (2)[A].
  - Use of aspirin and a PPI for chemoprevention of esophageal cancer is under investigation (1,2,3).
  - Consider low-dose aspirin in patients with Barrett esophagus who also have risk factors for cardiovascular disease (2)[C].

- 
- Statins, alone or in combination with aspirin or NSAIDs, appear to be effective in

chemoprevention but are not yet routinely recommended (3)[B],(8)[A].

## *Second Line*

If once-daily PPI does not control symptoms, move to twice-daily dosing (6)[A].

## **ISSUES FOR REFERRAL**

- Initiate PPI therapy prior to endoscopy to reduce reactive esophagitis/atypia (6)[C].
- Refer patients considering esophagectomy to a high-volume institution.

## **ADDITIONAL THERAPIES**

- Endoscopic eradication is any combination of endoscopic mucosal resection (EMR), photodynamic therapy (PDT), and radiofrequency ablation (RFA) to eliminate all Barrett epithelium.
- EMR: eradication rate 86-100%, excision to submucosa, allows staging, preferred for visible irregularities
- PDT: eradication rate 77-100% but strictures in 40%
- RFA: eradication rate 54-90%, comparable efficacy to PDT, fewer adverse effects
- Focal EMR combined with RFA of other areas is considered most effective eradication therapy (3)[B].
- Additional studies are still required before cryotherapy and other ablative procedures can be recommended.
- **Barrett esophagus with visible lesions:**
  - EMR with ablation if high-grade dysplasia or intramucosal cancer detected (4)[C]
- **Low-grade dysplasia:** Treatment is controversial.
  - Offer treatment such as RFA for low-grade dysplasia and high-risk features (multifocality, long segment length, persistence) (4)[C]. Endoscopic eradication may prevent progression to high-grade dysplasia or esophageal adenocarcinoma (3)[B],(9)[A].
- Endoscopic eradication therapy is recommended **for High-grade dysplasia**, without or with very limited submucosal invasion (stage T1SM1 or lower by endoscopic ultrasound) (1,2,6)[B].

### **ALERT**

Endoscopic eradication is **not** recommended for Barrett esophagus without dysplasia. Surveillance should be continued in these patients.

## SURGERY/OTHER PROCEDURES

Antireflux surgery such as fundoplication may control GERD symptoms but are not convincingly shown to reverse Barrett esophagus, decrease risk of cancer, or be superior to medical therapy (1,2)[A],(6)[B].

### ALERT

Available data suggest that antireflux surgery does **not** decrease risk of esophageal cancer.

- Esophagectomy is definitive and should be offered as an alternative to endoscopic eradication therapy for high-grade dysplasia (1,3)[B]:
  - Preferred for patients with evidence of submucosal invasion (stage T1SM2 or higher)
  - Added benefit of lymph node removal
  - Mortality rate: <5% in patients with high-grade dysplasia who are otherwise healthy
  - Serious postoperative complications: 30-50%
  - Should ideally be performed by an experienced surgeon in a high-volume center (2,3)[A]

## COMPLEMENTARY & ALTERNATIVE MEDICINE

A prospective study of 339 men and women with Barrett esophagus found those taking either a multivitamin, vitamin C, or vitamin E once a day were less likely to develop esophageal adenocarcinoma (10)[B].

### *Geriatric Considerations*

Surveillance or no treatment may be preferable to endoscopic eradication therapy or esophagectomy in patients who are poor operative candidates.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

- Surveillance (to detect high-grade dysplasia or early carcinoma), while controversial, is recommended in patients with histologically confirmed Barrett-especially for those in high-risk groups.
- Surveillance intervals depend on the grade of dysplasia (3)[C].

**No dysplasia:** 3 to 5 years

- Discontinue surveillance if life expectancy is  $\geq 25$  years (4)[C].
- **Low-grade dysplasia:** 6 to 12 months
  - Routine surveillance if patients have confirmed absence of low-grade dysplasia after two consecutive endoscopies (4)[C]
- **Indefinite for dysplasia:** within 1 year
  - Increase acid suppression (4)[C].
- **High-grade dysplasia without eradication therapy:** 3 months

### **ALERT**

- Adherence to recommended surveillance protocols may improve rates of dysplasia and cancer detection.
- Continue surveillance even if the patient has had endoscopic ablation therapy, antireflux surgery, or esophagectomy.

### **DIET**

Avoid foods that can trigger reflux: caffeine, alcohol, chocolate, peppermint, carbonated drinks, garlic, onions, spicy foods, fatty foods, citrus, and tomato-based products.

### **PATIENT EDUCATION**

- Lifestyle modifications: smoking cessation, weight loss, avoid supine position after meals, avoid tight-fitting clothes, elevate head of bed
- No evidence that treating GERD reverses Barrett esophagus or prevents esophageal cancer.

### **PROGNOSIS**

Annual incidence of esophageal cancer in patients with Barrett esophagus is  $\approx 0.33\%$  per year (2,3)[B]:

- Low-grade dysplasia: may be transient; cancer risk 0.5-0.6% per year
- High-grade dysplasia: cancer risk 5-7% per year

### **COMPLICATIONS**

Same as GERD: stricture, bleeding, ulceration

## Codes

### ICD10

- K22.70 Barrett's esophagus without dysplasia
- K22.719 Barrett's esophagus with dysplasia, unspecified
- K22.710 Barrett's esophagus with low grade dysplasia

## Clinical Pearls

- The incidence of esophageal carcinoma is rising faster than any other major malignancy. Barrett esophagus is a known precursor.
- Highest incidence is among white males >50 years.
- Endoscopic eradication therapy is preferred for high-grade dysplasia with or without submucosal invasion.
- Esophagectomy offers definitive therapy: Consider for all patients with high-grade dysplasia; preferred for patients with submucosal invasion.
- Promising areas for future research include the use of biomarkers for risk stratification, chemoprevention of neoplastic progression, capsule endoscopy for screening and the use of vitamins and antioxidants for prevention and treatment.

# Basal Cell Carcinoma

William Farkas, DO, CPT, MC, USA

Sean R. Wise, MD

## BASICS

### DESCRIPTION

Basal cell carcinoma (BCC) is the most common cancer, originating from the basal cell layer of the skin appendages.

- Rarely metastasizes but capable of local tissue destruction

### *Geriatric Considerations*

Greater frequency in geriatric patients (ages 55 to 75 years have 100 times the incidence when compared with those aged <20 years)

### *Pediatric Considerations*

- Rare in children, but childhood radiation treatment is contributory, as are frequent or severe sunburns.
- The Centers for Disease Control and Prevention recommend against using tanning beds and lamps in their guidelines for cancer prevention in school-age children.

### EPIDEMIOLOGY

Worldwide, the most common form of cancer

### *Incidence*

- Incidence in the United States: with squamous cell carcinoma, over 2 million cases each year. 4 to 5 times more common than squamous cell carcinoma.
- Predominant age: generally >40 years, although incidence increasing in younger populations
- Predominant sex: male > female (2:1 ratio)

### ETIOLOGY AND PATHOPHYSIOLOGY

- UV-induced inflammation and cyclooxygenase activation in skin

- In chromosome 9q22, mutation of *PTCH1* (patched homolog 1), a tumor-suppressor gene that inhibits the hedgehog signaling pathway
- UV-induced mutations of the *TP53* (tumor protein 53), a tumor-suppressor gene
- Activation of *BCL2*, an antiapoptosis proto-oncogene

## Genetics

- Several genetic conditions increase the risk of developing BCC:
  - Albinism (recessive alleles)
  - Xeroderma pigmentosum (autosomal recessive)
  - Bazex syndrome (rare, X-linked dominant)
  - Nevoid BCC syndrome/Gorlin syndrome (rare, autosomal dominant)
  - Cytochrome P-450 CYP2D6 and glutathione S-transferase detoxifying enzyme gene mutations (especially in truncal BCC, marked by clusters of BCCs and a younger age of onset)

## RISK FACTORS

- Chronic sun exposure (UV radiation). Most common in the following phenotypes
  - Light complexion: skin type I (burns but does not tan) and skin type II (usually burns, sometimes tans)
  - Red or blond hair
  - Blue or green eyes
- Tendency to sunburn
- Male sex, although increasing risk in women due to lifestyle changes, such as tanning beds
- History of nonmelanoma skin cancer
  - After initial diagnosis of skin cancer, 35% risk of new nonmelanoma skin cancer at 3 years and 50% at 5 years
- Family history of skin cancer
- 3 to 4 decades after chronic arsenic exposure
- 2 decades after therapeutic radiation
- Chronic immunosuppression: transplant recipients (10 times higher incidence), patients with

HIV or lymphomas

## GENERAL PREVENTION

- Use broad-spectrum sunscreens of at least SPF 30 daily and reapply after swimming or sweating.
- Avoid overexposure to the sun by seeking shade between 10 AM and 4 PM, and wearing wide-brimmed hats and long-sleeved shirts.
- The American Cancer Society recommends cancer related checkups every 3 years in patients 20 to 40 years old, and yearly in patients older than 40 years.

## COMMONLY ASSOCIATED CONDITIONS

- Cosmetic disfigurement because head and neck most often affected
- Loss of vision with orbital involvement
- Loss of nerve function due to perineural spread or extensive and deep invasion
- Ulcerating neoplasms are prone to infections.

## DIAGNOSIS

### HISTORY

Exposure to risk factors, family history

## PHYSICAL EXAM

- 80% on face and neck, 20% on trunk and lower limbs (mostly women)
- Nodular: most common (60%); presents as pinkish, pearly papule, plaque, or nodule, often with telangiectatic vessels, ulceration, and a rolled periphery usually on face (1)
  - Pigmented: presents as a translucent papule with Öfloating pigmentÖ; more commonly seen in darker skin types; may give a blue, brown, or black appearance and be confused with melanoma (1)
- Superficial: 30%; light red, scaly plaque resembling eczema or psoriasis, but with raised, pearly white borders similar to the nodular subtype, usually on trunk or extremities; least invasive of BCC subtypes
- Morpheaform: 5-10%; resembles localized scleroderma; mass is ill-defined and often extends beyond visible lesion.

# *DIFFERENTIAL DIAGNOSIS*

- Sebaceous hyperplasia
- Epidermal inclusion cyst
- Intradermal nevi (pigmented and nonpigmented)
- Molluscum contagiosum
- Squamous cell carcinoma (SCC)
- Nummular dermatitis
- Psoriasis
- Melanoma (pigmented lesions)
- Atypical fibroxanthoma
- Rare adnexal neoplasms

# *DIAGNOSTIC TESTS & INTERPRETATION*

## *Diagnostic Procedures/Other*

- Clinical diagnosis and histologic subtype are confirmed through skin biopsy and pathologic examination.
- Shave biopsy is typically sufficient; however, punch biopsy is more useful to assess depth of tumor and perineural invasion.
- If a genetic disorder is suspected, additional tests may be needed to confirm it.

## *Test Interpretation*

- Nodular BCC
  - Extending from the epidermis are nodular aggregates of basaloid cells.
  - Tumor cells are uniform; rarely have mitotic figures; large, oval, hyperchromatic nuclei with little cytoplasm, surrounded by a peripheral palisade
  - Early lesions are usually connected to the epidermis, unlike late lesions.
  - Increased mucin in dermal stroma
- Cleft formation (retraction artifact) common between BCC nests and stroma due to mucin shrinkage during fixation and staining
- Superficial BCC

- Appear as buds of basaloid cells attached to undersurface of epidermis
- Peripheral palisading
- Morpheaform BCC
  - Thin cords and strands of basaloid cells; embedded in dense, fibrous, scar-like stroma
  - Less peripheral palisading and retraction, greater subclinical involvement
- Infiltrating BCC
  - Like morpheaform BCC but no scar-like stroma and thicker, more spiky, irregular strands
  - Less peripheral palisading and retraction, greater subclinical involvement
- Micronodular BCC
  - Small, nodular aggregates of tumor cells
  - Less retraction artifact and higher subclinical involvement than nodular BCC

## TREATMENT

### MEDICATION

- May be especially useful in those who cannot tolerate surgical procedures and in those who refuse to have surgery, as well as for low risk superficial and/or nodular BCC
  - 5-fluorouracil cream inhibits thymidylate synthetase, interrupting DNA synthesis for superficial lesions in low-risk areas; primary treatment only; 5% applied BID for 3 to 10 weeks.
- 
- Imiquimod (Aldara) cream approved for treatment of low-risk superficial BCC; daily dosing for 6 to 12 weeks; 90% histologic cure (1,2)[A]
  - Neither imiquimod nor 5-FU is considered appropriate primary monotherapy for infiltrative or nodular BCC (1)[A].
  - Topical treatment failure may yield skip lesions that yield false negative margins, making Mohs and excisional surgery potentially less effective (1)[A].
  - Emerging therapies:
    - Vismodegib, a sonic hedgehog pathway inhibitor; for patients with advanced BCC when other options are exhausted; not considered appropriate therapy for low-risk tumors (1)[A].
    - Intralesional IFN- $\alpha$ -2B injection: some efficacy for small (<1 cm) nodular and superficial

P.115

BCCs; relatively high cost, and frequent side effects (1,3)[A]

## *ADDITIONAL THERAPIES*

- Radiation therapy
  - Useful for patients, typically older, who cannot or will not undergo surgery (1)[C]
  - Used following surgery, particularly if margins of tumor were not cleared
  - Cure rate is  $\div$  90%.
  - Tumors that recur in areas previously treated with radiation are harder to treat, and the area is more difficult to reconstruct.
  - Local treatment
  - Recurrence rates are 7-8%
- Photodynamic therapy (PDT)
  - 5-aminolevulinic acid, a photosensitizer, is activated by specific wavelengths of light, creating singlet oxygen radicals that destroy local tissue (no damage to surrounding or deep tissues).
  - Useful in areas where tissue preservation is cosmetically or functionally important; considered inferior to surgical excision in terms of efficacy (2)
  - When examining 5-year recurrence rates, may be equivalent to cryotherapy

## *SURGERY/OTHER PROCEDURES*

- Surgical excision is first line treatment (3)[A]; specific treatment selection varies with extent and location of lesion as well as tumor border demarcation.
- High-risk areas
  - Inner canthus, nasolabial sulcus, philtrum, preauricular area, retroauricular sulcus, lip, temple, Òmask areasÓ of the face (2)[C]
- Curettage and electrodesiccation
  - If nodular lesion <1 cm, in low-risk area, not deeply invasive
  - Avoid in the hair-bearing areas due to risk of the tumor extending down follicular structures.
  - 5-year cure rate of 92%; recurrence as high as 27% for high risk lesions
- Excision with postoperative margin assessment

- Treatment of choice for low risk lesions <2 cm in diameter
- Goal is 4 mm margin
- 5-year cure rate of 98%
- Cryosurgery
  - Reserved for nodular and superficial BCC, not indicated for tumors with depth exceeding 3 mm
  - Typically for tumors with low risk of recurrence
  - May want pre- and posttreatment biopsies (2)[C]
  - 5-year cure rate of 99%
- Mohs surgery
  - Preferred microscopically controlled surgical treatment for lesions in high-risk areas, recurrent lesions, and lesions exhibiting an aggressive growth pattern (1,2)[A]
  - Gold standard for maximizing tissue sparing for functional or cosmetic reasons (1)[A]
  - 5-year survival rate of 99%
  - Requires referral to appropriately trained dermatologic surgeon

## *INPATIENT CONSIDERATIONS*

Outpatient, unless extensive lesion

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

- Avoid sun exposure.
- Oral retinoids may prevent the development of new BCCs in patients with Gorlin syndrome, renal transplant recipients, and patients with severe actinic damage.

## *Patient Monitoring*

- Every 6 to 12 months for life
- Increased risk of other skin cancers
- Recurrence:

Local: follow NCCN 2015 guidelines for primary treatment

- Regional: surgery and/or radiation therapy
- Metastatic: multidisciplinary tumor board consultation

## PATIENT EDUCATION

- Teach patient-appropriate sun-avoidance techniques, sunscreens, and so forth.
- Monthly skin self-exam
- Educate patients concerning adequate vitamin D intake.

## PROGNOSIS

- Proper treatment yields 90-95% cure.
- Most recurrences happen within 5 years.
- Development of new BCCs: Some patients (36%) will develop a new lesion within 5 years.

## COMPLICATIONS

- Local recurrence and spread
- Usually, recurrences will appear within 5 years.
- Metastasis: rare (<0.1%), but metastatic disease usually fatal within 8 months

## REFERENCES

1. Firnhaber JM. Diagnosis and treatment of basal cell and squamous cell carcinoma. *Am Fam Physician*. 2012;86(2):161-168.
2. Clark CM, Furniss M, Mackay-Wiggan JM. Basal cell carcinoma: an evidence-based treatment update. *Am J Clin Dermatol*. 2014;15(3):197-216.
3. Bath-Hextall FJ, Perkins W, Bong J, et al. Interventions for basal carcinoma of the skin. *Cochrane Database Syst Rev*. 2007;(1):CD003412.

## Additional Reading

- Kundu RV, Patterson S. Dermatologic conditions in skin of color: part I. Special considerations

for common skin disorders. *Am Fam Physician*. 2013;87(12):850-856.

- Wong CS, Strange RC, Lear JT. Basal cell carcinoma. *BMJ*. 2003;327(7418):794-798.

## Codes

### ICD10

- C44.91 Basal cell carcinoma of skin, unspecified
- C44.31 Basal cell carcinoma of skin of other and unspecified parts of face
- C44.41 Basal cell carcinoma of skin of scalp and neck

## Clinical Pearls

- Nodular: pearly papule, plaque, or nodule often with telangiectatic vessels, ulceration, and a rolled periphery, usually on face
- Pigmented: presents as a translucent papule with "floating pigment"; more commonly seen in darker skin types
- Superficial: scaly papule or plaque with atrophic center, ringed by translucent micropapules, usually on trunk or extremities; more common in men
- Morpheaform: firm, smooth, flesh-colored, scar-like papule or plaque with ill-defined borders
- Use diagnostic keys above to differentiate between BCC and cutaneous SCC. SCC arises from actinic keratosis in 60% of cases and generally presents as an asymptomatic hyperkeratotic lesion. If unsure, biopsy or refer to a specialist.
- Some hyperpigmented BCCs may appear similar to melanoma. Remember the ABCDEs of melanoma recognition: **A**symmetry, **B**order irregularities, **C**olor variability, **D**iameter >6 mm, **E**nlargement. If unsure, refer to a specialist.
- The USPSTF concludes insufficient evidence and recommends for or against routine total body skin exams for melanoma, BCC, or SCC. Exams should be based on risk factors, including exposure and family and prior medical history. All patients should receive education about risks and self-exam.

# Bed Bugs

Fawn Winkelman, DO

Adam Strosberg, DNP, ARNP-BC

## BASICS

### DESCRIPTION

- Nocturnal obligate blood parasites that take refuge on furniture and bedding
- 5 to 7 mm oval, reddish brown, flat, wingless

### EPIDEMIOLOGY

#### Incidence

- According to the 2013 "Bugs Without Borders" survey, bed bug infestations are increasing and continue to remain the most difficult pest to treat, more difficult than cockroaches, termites, and ants (1)[B].
- Resurgence is due to the use of less toxic, less persistent insecticides as well as increased travel, use of secondhand furniture, and a high-turnover rate of residents in hotels.

#### Prevalence

- Infestations are increasing across the United States.
- Sharp increase in prevalence, as only 11% of survey respondents reported bed bug calls >10 years ago.
- Bed bug encounters have become more common in public places (schools, hospitals, hotels/motels, aircrafts) than in previous years, increasing by 10-30% (2)[B].

### ETIOLOGY AND PATHOPHYSIOLOGY

- Insect family Cimicidae
- Three species that bite humans: *Cimex lectularius*, *Cimex hemipterus*, and *Leptocimex boueti* (2)[B]
- Most prevalent species are the *C. lectularius* (2)[B].

- Found in tropical or temperate climates
- Hide in crevices of mattresses, box springs, headboards, and baseboards
- Infestations occur in hotels/motels, hospitals, cinemas, transportation vehicles, aircrafts, and homes.
- Reactions range from an absent or minimal response to a more typical reaction presenting as pruritic, erythematous macules and papules or a less common urticarial and anaphylactic response.
- Skin reactions are due to host immunologic response to the parasite salivary proteins.
- Papular urticarial reactions are mediated via immunoglobulin (Ig) G antibody response to salivary proteins (3)[B].
- Bullous reactions are caused by an IgE-mediated hypersensitivity to nitrophenol, the substance that transports nitric oxide in bed bug saliva (3)[B].
- Bed bugs locate warmth and carbon dioxide production, which allows them to migrate to humans (4).

## **GENERAL PREVENTION**

- Bed bug monitors and traps can be purchased, which contain carbon dioxide as well as heat to attract and trap the bugs but can be cost-prohibitive (5)[B].
- Avoidance of bed bugs: vacuum regularly, reduce clutter, seal cracks in walls, inspect luggage and clothing
- Launder all bedding and cloth items in 130°F (50°C) or hotter for 2 hours or 20°F (-5°C) or cooler for 5 days.
- If present in the home, eradication is essential via professional extermination. Some pest control companies have employed pest control canines to detect live bed bugs and eggs based on pheromones from the bed bugs but are expensive and generate false positives and negatives depending on the training of the dog (5)[B].

## **RISK FACTORS**

- Immunologically weak or compromised
- Recent travel
- High turnover environment
- Secondhand furniture in home

# DIAGNOSIS

## HISTORY

- Recent travel
- Blood specks on sheets
- Bed bug sighting
- New skin lesions in the morning
- Intense pruritus, pain, or burning

## PHYSICAL EXAM

- Characteristic lesions are erythematous pruritic papules in an irregular linear pattern.
- Found on body surfaces exposed during sleeping such as face, neck, arms, legs, and shoulders
- May appear hours to days after being bitten
- Patients are usually asymptomatic but may be anaphylactic and present with papular urticaria, diffuse urticaria, and/or bullous lesions.

## DIFFERENTIAL DIAGNOSIS

- Urticaria
- Insect or spider bite
- Scabies
- Dermatitis herpetiformis

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Skin scraping with mineral oil preparation
- Skin biopsy

### *Test Interpretation*

- Skin scraping is negative with mineral oil, which helps to exclude scabies.
- Skin biopsy shows nonspecific perivascular eosinophilic infiltrate consistent with arthropod bite reaction.

## TREATMENT

### GENERAL MEASURES

- Self-limited and resolves within 1 to 2 weeks
- Treat symptomatically
- Avoidance of the bed bugs by inspection
- Prevention by laundering bedding and cloth

### MEDICATION

#### *First Line*

- Disease is self-limited; treat symptoms.
- Oral antihistamines (i.e., diphenhydramine, hydroxyzine)
- Topical antipruritics (i.e., pramoxine/calamine ointment or doxepin cream)
- Topical low to midpotency corticosteroids for 2 weeks (i.e., hydrocortisone, triamcinolone)
- Systemic corticosteroids (severe cases)

### ADDITIONAL THERAPIES

- If secondarily infected, use topical or oral antibiotics against *Staphylococcus* and *Streptococcus* spp. (i.e., cephalexin, tetracycline, doxycycline, clindamycin, topical mupirocin).
- Epinephrine for anaphylaxis
- Professional extermination may be necessary.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

- Not necessary as disease is self-limited
- Recommended in extreme cases or if anaphylaxis ensues

### PATIENT EDUCATION

- Avoid scratching to prevent superinfection.
- Inspect bedding, furniture, and luggage regularly.
- CDC: <http://www.cdc.gov/parasites/bedbugs/>
- EPA: <http://www2.epa.gov/bedbugs>
- MYTH 1: *Bed bugs are invisible.* They actually are nocturnal and hide during the daytime and adult bugs are about 1/4-inch long while eggs are the size of a pin head (6).
- MYTH 2: *Bed bugs reproduce rapidly.* Their life cycles are about 4 to 5 weeks (6), which is longer than the typical house fly.
- MYTH 3: *Bed bugs can live without feeding.* Bugs can only live about 3 to 5 months without a blood meal depending on climate (6).

## COMPLICATIONS

- Bed bug dermatitis, allergic reactions, asthma exacerbations, anaphylaxis
- Significant psychological distress (insomnia, depression, anxiety, delusional parasitosis) (3)
- Secondary bacterial infections.
- Transmission of blood-borne diseases (rare)

## Codes

### ICD10

- S00.96XA Insect bite (nonvenomous) of unspecified part of head, initial encounter
- S10.96XA Insect bite of unspecified part of neck, initial encounter
- S40.269A Insect bite (nonvenomous) of unspecified shoulder, initial encounter

## Clinical Pearls

- 90% of infestations occur within 3 feet of beds.
- Wash bedding/clothing regularly in hot water.
- Vacuum carpet daily or steam clean daily.
- Inspect furniture, bedding, and luggage regularly.
- Use professional services if necessary.
- Patient education and vigilance is paramount for bed bug prevention and avoidance.
- Over-the-counter (OTC) products that contain pyrethroids are ineffective at killing bed bugs as they have become resistant over the years. These products can be identified with a suffix -thrin including permethrin, cyfluthrin, bifenthrin, and deltamethrin or fluvalinate and esfenvalerate (6).

# Behavioral Problems, Pediatric

William G. Elder, PhD

## BASICS

### DESCRIPTION

Behavior that disrupts at least one area of psychosocial functioning. Commonly reported behavioral problems are as follows:

- **Noncompliance:** active or passive refusal to do as requested by parent or other authority figure
- **Temper tantrums:** loss of internal control provoked by overtiredness, physical discomfort, or fear that leads to crying, whining, breath-holding, or in extreme cases, aggressive behavior
- **Sleep problems:** sleep patterns that are distressing to caregivers or child; difficulty going to sleep or staying asleep at night, nightmares, and night terrors
- **Nocturnal enuresis:** enuresis that occurs only at night in children >5 years of age with no medical problems
  - **Primary:** children who have never been dry at night
  - **Secondary:** children dry at night for at least 6 months
- **Functional encopresis:** repeated involuntary fecal soiling that is not caused by organic defect or illness
- **Problem eating:** Picky eating, difficult mealtime behaviors
- **Normative sexual behaviors:** developmentally appropriate behaviors in children in the absence of abuse
- **Thumb-sucking:** an innate reflex that is self-soothing; may be protective against sudden infant death. If persists, past eruption of primary teeth can affect teeth alignment and mouth shape.

### EPIDEMIOLOGY

- **Noncompliance:** may manifest as children develop autonomy; males have a modestly greater likelihood of being noncompliant; decreases with age.
- **Temper tantrums:** 70% of 18- to 24-month-old children; 7% of 3- to 5-year-old children; in children with severe tantrums, 52% have other behavioral/emotional problems (1).

- Sleep problems
  - Night waking in 25-50% of infants 6 to 12 months; bedtime refusal in 10-30% of toddlers
  - Nightmares in 10-30% of preschoolers; peaks between ages 6 and 10 years
  - Night terrors in 1-6.5% early childhood; peaks between ages 4 and 12 years
  - Sleepwalking frequently in 3-5%; peaks between ages 5 and 8 years (2)
- Nocturnal enuresis
  - At least 20% of children in the 1st grade wet the bed occasionally; 4% wet <sup>3</sup>2 times per week.
  - At 10 years of age, 9% in boys, 3% in girls (3)
- Functional encopresis
  - Rare before age 3 years, most common in 5- to 10-year-olds; more common in boys (4)
- Problem eating
  - Prevalence peaks at 50% at 24 months of age; no relation to sex/ethnicity/income (5)
- Normative sexual behaviors
  - Rare in infancy, except hand to genital contact
  - Increased in 3- to 5-year-olds; less observed in >5-year-olds because more covert (6)
- Thumb-sucking: decreases with age; most children spontaneously stop between 2 and 4 years.

## *COMMONLY ASSOCIATED CONDITIONS*

- Noncompliance: if exceeds what seems normative, rule out depression, compulsive patterns, adjustment disorder, inappropriate discipline
- Temper tantrums: difficult child temperament, stress
- Sleep problems: often with inconsistent bedtime routine or sleep schedule, stimulating bedtime environment; can be associated with hyperactive behavior, poor impulse control, and poor attention in young children (2). Acute or chronic anxiety is associated with insomnia.
- Enuresis: secondary often with medical problems, especially constipation, and frequent behavior problems, especially ADHD
- Functional encopresis: enuresis, UTIs, ADHD
- Normative sexual behaviors: family stressors such as separation or divorce (6)

# DIAGNOSIS

## HISTORY

- Noncompliance: complete history from caregivers and teachers, if applicable; direct observation of child or child-caregiver interaction
  - Criteria is problematic for at least some adults, leading to difficult interactions for at least 6 months.
  - Reduces child's ability to take part in structured activities
  - Creates stressful relationships with compliant children
  - Disrupts academic progress; places child at risk for physical injury
- Temper tantrums: history, with focus on development, family functioning, or violence; may consist of stiffening limbs and arching back, dropping to the floor, shouting, screaming, crying, pushing/pulling, stamping, hitting, kicking, throwing, or running away (1)
- Sleep disorders: screening questions about sleep during well-child visit, such as the Bedtime problems, Excessive daytime sleepiness, Awakenings during the night, Regularity and duration of sleep, and Snoring (BEARS) screen; bedtime routine (2)[C]
- Nocturnal enuresis: severity, onset, and duration; daytime wetting or any associated genitourinary symptoms; family history of enuresis; medical and psychosocial history; constipation; child and caregiver's motivation for treatment (7)[C]
- Problem eating: review of child's diet, growth curves, nutritional needs, and caregiver's response to behavior (5)[C]
- Normative sexual behaviors: When was behavior first noticed? Any recent changes or stressors in family? Behavior solitary or with another; if with another, what age? Changes in frequency or nature of behaviors; occurs at home, daycare, school? Is behavior disruptive, intrusive, or coercive? (6) (See "Child Sexual Behavior Inventory" in the following discussion.)

## PHYSICAL EXAM

- Nocturnal enuresis
  - Physical exam of abdomen for enlarged bladder, kidneys, or fecal masses; rectal exam if history of constipation; back for spinal dysraphism seen in dimpling or hair tufts
  - Neurologic exam: focus on lower extremities

- Genitourinary exam
  - Males: meatal stenosis, hypospadias, epispadias, phimosis
  - Females: vulvitis, vaginitis, labial adhesions, ureterocele at introitus; wide vaginal orifice with scar or healed laceration may be evidence of abuse.
- Functional encopresis
  - Height and weight; abdominal exam for masses or tenderness; rectal exam for tone, size of rectal vault, fecal impaction, masses, fissures, hemorrhoids; back for signs of spinal dysraphism seen in dimpling or hair tufts (4)

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- For nocturnal enuresis: urinalysis (dipstick test OK); if abnormal, consider urine culture.
  - For secondary enuresis: serum glucose, creatinine, thyrotropin (8)[C]
  - Urinary tract imaging and urodynamic studies if significant daytime symptoms with history or diagnosis of UTI or history of structural renal abnormalities (8)[C]
- For functional encopresis: tests for hypothyroidism or celiac disease if poor growth or family history; urinalysis and culture if enuresis or features of UTI (4)
  - Spine imaging if evidence of spinal dysraphism or if both encopresis and daytime enuresis; barium enema if suspect Hirschsprung disease

### *Follow-Up Tests & Special Considerations*

Sleep disorders: Sleep studies may be performed in children if there is a history of snoring and daytime ADHD-type symptoms (2).

### *Diagnostic Procedures/Other*

- Pediatric symptom checklist:  
[https://brightfutures.org/mentalhealth/pdf/professionals/ped\\_sympton\\_chklst.pdf](https://brightfutures.org/mentalhealth/pdf/professionals/ped_sympton_chklst.pdf)
- National Initiative for Children's Healthcare Quality (NICHQ) Vanderbilt Assessment (ADHD screen): <http://www.myadhd.com/vanderbiltparent6175.html>
- Child Sexual Behavior Inventory: Completed by female caregiver to assist with differentiation of normative versus abnormal behaviors particularly those related to sexual abuse:  
<http://www.nctsnct.org/content/child-sexual-behavior-inventory-csbi>

## TREATMENT

- General: Educate caregiver about specific behavioral problem.
  - Parent management training programs and techniques are effective for many child behavior problems (9)[A].
  - Noncompliance: In the case of extreme child disobedience, consider parent training programs. Child may need to be formally screened for ADHD, obsessive-compulsive disorder (OCD), oppositional defiant disorder (ODD), or conduct disorder (CD).
  - Temper tantrums: Remind caregiver this is a normal aspect of early childhood.
    - Educate caregiver that tantrums are not attention-seeking; although they may reveal that the child needs more attention from caregiver. This attention should be developmentally appropriate and not occur when the child is tantruming but at other times and prior to the tantrum.
    - If tantrum is set off by external factors, such as hunger or overtiredness, then correct.
    - Other methods for dealing with a tantrum include one of the following:
      - Ignore the tantrum; remove the child and place him or her in time-out (1 minute for each year of age); hold/restrain child until calmed down; provide child with clear, firm, and consistent instructions as well as enough time to obey.
- 
- P.119
- Sleep problems: Intervention consists largely of education of the caregiver who may need a roadmap for dealing with this difficult and distressing problem. Developmental stages; environmental factors and cues; caregiver emotions and reactions; and child fears, stress, and habits are all important factors in sleep onset and maintenance that should be explored and explained to the caregiver.
  - Specific recommendations may also consist of other interventions including the following (2) [A]:
    - Graduated extinction: Caregiver ignores cries for specified period; can check at a fixed time or increasing intervals.
    - "Fading": gradual decrease in direct contact with the child as child falls asleep; goal is for the caregiver to exit the room and allow child to fall asleep independently.
    - Consider the "5S Intervention" for settling problems in toddlers (used to comfort infants in nurseries): swaddling, sucking, shushing, stomach/side position, and swinging.
    - If fearful, preferred routines or inert sprays or glitter spread by the child (while avoiding the

eyes) may help the child feel more secure.

- Nocturnal enuresis
  - Bedwetting alarm: first-line therapy for caregivers who can overcome objection of having their sleep disturbed; about 2/3 of children respond while using the alarm; if enuresis recurs after use, it will often resolve with a second trial (7)[A].
  - Decrease fluids an hour before bedtime.
  - Little evidence from clinical trials but good empirical evidence for behavioral training, including positive reinforcement (small reward for each dry night) or responsibility training (if developmentally able, child is responsible for changing or washing sheets), encouraging daily bowel movements, and frequent bladder emptying during the day
- Functional encopresis
  - First disimpaction: PO with polyethylene glycol solution or mineral oil; if unsuccessful, manual mineral oil enemas
  - Maintenance therapy
    - Medical: osmotics, such as polyethylene glycol, fiber, lactulose; stimulants, such as senna or bisacodyl
    - Behavior modification: toileting after meals for 10 minutes 2 to 3 times a day, star charts, and rewards (4)[C]
- Problem eating
  - Avoid punishment, prodding, or rewards. Offer a variety of healthy foods at every meal; limit milk to 24 oz/day and decrease juice (5)[C].
- Normative sexual behavior: No treatment needed; caregivers may need encouragement not to punish or admonish child and to use gentle distraction to redirect behavior when in public setting.
- Thumb-sucking: Recommendations to caregivers include praising children when not sucking their thumb, offer alternatives that are soothing (e.g., stuffed toys), provide reminders or negative reinforcement in the form of a bandage around or bitters on the thumb (5)[C].

## **MEDICATION**

Most pediatric behavioral issues respond well to nonpharmacologic therapy:

- Sleep disorders
  - For certain delayed sleep-onset disorders, after behavioral methods are exhausted,

melatonin 0.5 to 10 mg PO can be tried while behavior modification is continued. Sleep latency is likely to be reduced. However, this is not approved by the FDA for children. Expect rebound insomnia. Daytime exposure to bright or sunlight should be assured before treatment.

- Nocturnal enuresis
  - Desmopressin can decrease urine output to reduce enuresis episodes. Not before age 6 years; begin with 0.2 mg tablet nightly 1 hour before bedtime; titrate to 0.6 mg (8)[B]. However, use is questionable because its effects do not persist posttreatment (10)[A]. Intranasal formulations can cause severe hyponatremia, resulting in seizures and death in children. Behavioral interventions should be first-line treatment (7)[C].

## ***ISSUES FOR REFERRAL***

- A patient who exhibits self-injurious behaviors, slow recovery time from tantrums, more tantrums in the home than outside the home, or more aggressive behaviors toward others may require referral to a psychologist or psychiatrist.
- Children with chronic insomnia or anxiety that interferes with sleep should be referred to a psychologist or psychiatrist.
- A child with loud nightly snoring, with observed apnea spells, daytime excessive sleeping, and neurobehavioral signs such as mood changes, ADHD-like symptoms, or academic problems should be referred for sleep studies (2).
- With enuresis and obstructive sleep apnea symptoms, refer for sleep studies because surgical correction of airway obstruction often improves or cures enuresis and daytime wetting (8).
- Must distinguish sexual behavior problems: Developmentally inappropriate behaviors—greater frequency or much earlier age than expected—becomes a preoccupation, recurs after adult intervention/corrective efforts. If abuse is not suspected, consider referral to a child psychologist. If abuse is suspected, must report to child protective services (6).
- If disimpaction by either manual or medical methods is unsuccessful, consult gastroenterology or general surgery. Patients who show no improvement after 6 months of maintenance medical therapy should be referred to gastroenterology (4).
- Thumb-sucking resistant to behavioral intervention and threatening oral development may be evaluated by a pediatric dentist for use of habit-breaking dental appliances (5)[C].

## **ONGOING CARE**

### ***DIET***

Nutrition is very important in behavioral issues. Avoiding high-sugar foods and caffeine and providing balanced meals has been shown to decrease aggressive and noncompliant behaviors in children.

## Codes

### ICD10

- F91.9 Conduct disorder, unspecified
- F91.1 Conduct disorder, childhood-onset type
- F91.2 Conduct disorder, adolescent-onset type

## Clinical Pearls

- Well-child visits provide opportunities for systematic screening for these common conditions.
- Parental education, including a review of age-appropriate discipline, is a key component of treatment.

# Bell Palsy

Irina Pechenko, MD

Jeffrey B. Lanier, MD, FAAFP

## BASICS

### *DESCRIPTION*

A peripheral lower motor neuron facial palsy, usually unilateral, which arises secondary to inflammation and subsequent swelling and compression of cranial nerve VII (facial) and the associated vasa nervorum

### *EPIDEMIOLOGY*

- Affects 0.02% of the population annually
- Predominant sex: male = female
- Median age of onset is 40 years but affects all ages.
- Accounts for 60-75% of all cases of unilateral facial paralysis
- Occurs with equal frequency on the left and right sides of the face
- Most patients recover, but as many as 30% are left with facial disfigurement and pain.

### *Incidence*

- 20 to 30 cases per 100,000 people in the United States per year
- Lowest in children <sup>2</sup>10 years of age; highest in adults <sup>3</sup>70 years of age
- Higher among pregnant women

### *Prevalence*

Affects 40,000 Americans every year

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Results from damage to the facial cranial nerve (VII)
- Inflammation of cranial nerve VII causes swelling and subsequent compression of both the nerve and the associated vasa nervorum.

- May arise secondary to reactivation of latent herpesvirus (herpes simplex virus [HSV] type 1 and herpes zoster virus) in cranial nerve ganglia or due to ischemia from arteriosclerosis associated with diabetes mellitus

## *Genetics*

May be associated with a genetic predisposition, but it remains unclear which factors are inherited

## **RISK FACTORS**

- Pregnancy, specially associated with severe preeclampsia (1)[A]
- Diabetes mellitus
- Age >30 years
- Exposure to cold temperatures
- Upper respiratory infection (e.g., coryza, influenza)
- Chronic HTN (1)[A]
- Obesity (1)[A]
- Migraine headache (2)[A]

## **COMMONLY ASSOCIATED CONDITIONS**

- HSV
- Lyme disease
- Diabetes mellitus
- Hypertension
- Herpes zoster virus
- Ramsay-Hunt syndrome
- Sjögren syndrome
- Sarcoidosis
- Eclampsia
- Amyloidosis

**DIAGNOSIS**

## HISTORY

- Time course of the illness (rapid onset)
- Predisposing factors: recent viral infection, trauma, new medications, hypertension, diabetes mellitus
- Presence of hyperacusis or history of recurrent Bell palsy (both associated with poor prognosis)
- Any associated rash (suggestive of herpes zoster, Lyme disease, or sarcoid)
- Weakness on affected side of face, often sudden in onset
- Pain in or behind the ear in 50% of cases, which may precede the palsy in 25% of cases
- Subjective numbness on the ipsilateral side of the face
- Alteration of taste on the ipsilateral anterior 2/3 of the tongue (chorda tympani branch of the facial nerve)
- Hyperacusis (nerve to the stapedius muscle)
- Decreased tear production

## PHYSICAL EXAM

- Neurologic
  - Determine if the weakness is caused by a problem in either the central or peripheral nervous systems.
  - Flaccid paralysis of muscles on the affected side, including the forehead
    - Impaired ability to raise the ipsilateral eyebrow
    - Impaired closure of the ipsilateral eye
    - Impaired ability to smile, grin, or purse the lips
    - Bell phenomenon: upward diversion of the eye with attempted closure of the lid
  - Patients may complain of numbness, but no deficit is present on sensory testing.
  - Examine for involvement of other cranial nerves.
- Head, ears, eyes, nose, and throat
  - Carefully examine to exclude a space-occupying lesion.
  - Perform pneumatic otoscopic exam.
- Skin: Examine for erythema migrans (Lyme disease) and vesicular rash (herpes zoster virus).

# *DIFFERENTIAL DIAGNOSIS*

Etiologies include the following:

- Infectious
  - Acute or chronic otitis media
  - Malignant otitis externa
  - Osteomyelitis of the skull base
- Cerebrovascular
  - Brainstem stroke involving anteroinferior cerebellar artery
  - Aneurysm involving carotid, vertebral, or basilar arteries
- Neoplastic (Onset of palsy is usually slow and progressive and accompanied by additional cranial nerve deficits and/or headache.)
  - Tumors of the parotid gland
  - Cholesteatoma
  - Skull base tumor
  - Carcinomatous meningitis
  - Leukemic meningitis
- Traumatic
  - Temporal bone fracture
  - Mandibular bone fracture
- Other
  - Multiple sclerosis
  - Myasthenia gravis (should be considered in cases of recurrent or bilateral facial palsy)
  - Guillain-Barré syndrome (may also present with bilateral facial palsy)
  - Sjögren syndrome
  - Sarcoidosis
  - Amyloidosis
  - Melkersson-Rosenthal syndrome
  - Mononeuritis or polyneuritis

# DIAGNOSTIC TESTS & INTERPRETATION

## *Initial Tests (lab, imaging)*

- Blood glucose level (if diabetes a consideration)
- Lyme titer, ELISA, and Western blot for immunoglobulin (Ig) M, IgG for *Borrelia burgdorferi*
- ESR
- Consider CBC.
- Consider rapid plasma reagin test.
- Consider HIV test.
- In appropriate clinical circumstances, consider titers for varicella-zoster virus, cytomegalovirus, rubella, hepatitis A, hepatitis B, and hepatitis C.

## *Follow-Up Tests & Special Considerations*

- CSF analysis
  - CSF protein is elevated in 1/3 of cases.
  - CSF cells show mild elevation in 10% of cases with a mononuclear cell predominance.
  - Not routinely indicated
- Salivary polymerase chain reaction for HSV1 or herpes zoster virus (largely reserved for research purposes)
- Facial radiographs
  - In the setting of trauma, evaluate for fracture.
- IV contrast-enhanced head CT
  - Evaluate for fracture.
  - Evaluate for stroke, if stroke is in the differential.
- IV contrast-enhanced brain MRI
  - Evaluate for central pontine, temporal bone, and parotid neoplasms.
  - Not routinely indicated

## *Diagnostic Procedures/Other*

- Electromyograph: Nerve conduction on affected and nonaffected sides can be compared to determine the extent of nerve injury, especially if there is dense palsy or no recovery after several weeks.
- Electroneurography: Evoked potentials of affected and nonaffected sides can be compared.

## *Test Interpretation*

Invasive diagnostic procedures are not indicated because biopsy could further damage cranial nerve XII.

## **TREATMENT**

### *GENERAL MEASURES*

- Artificial tears should be used to lubricate the cornea.
- The ipsilateral eye should be patched and taped shut at night to avoid drying and infection.

### *MEDICATION*

- Corticosteroids decrease inflammation and limit nerve damage, thereby reducing the number of patients with residual facial weakness.

P.121

- Routine use of antiviral medication is not recommended. Antiviral agents targeting herpes simplex, when administered concurrently with corticosteroids, may further reduce the risk of unfavorable outcomes in patients with a dense Bell palsy (3)[A]:
  - Antivirals alone are less likely to produce full recovery than corticosteroids.
  - A combination of valacyclovir and steroids provides only minimal added benefit over steroid use alone (4)[B].
- Corticosteroids
  - Prednisolone: total of 500 mg over 10 days, 25 mg PO BID
    - Treatment with prednisolone within 48 hours of palsy onset has shown higher complete recovery rates and less synkinesis compared with no prednisolone (5)[B].
    - Antivirals in combination with corticosteroids
      - Valacyclovir: 1,000 mg TID for 7 days plus prednisolone 60 mg/day for 5 days; then tapered by 10 mg/day for total treatment length of 10 days (4)[B].

Steroids are recommended for all cases of Bell palsy.

- Controversial whether antiviral treatment is necessary with steroids
  - American Academy of Otolaryngology-Head and Neck Surgery recommends antiviral treatment in all cases of Bell palsy cases (6)[A].
- There is a strong recommendation to use corticosteroids for all patients with Bell palsy and strong recommendation against of antiviral treatment alone (6)[A].
- Contraindications
  - Documented hypersensitivity
  - Preexisting infections, including tuberculosis (TB) and systemic mycosis
- Precautions: Use with discretion in pregnant patients and those with peptic ulcer disease and diabetes.
- Significant possible interactions: measles-mumps-rubella, oral polio virus vaccine, and other live vaccines

### *Pregnancy Considerations*

Steroids should be used cautiously during pregnancy; consult with an obstetrician.

### *ISSUES FOR REFERRAL*

Patients may need to be referred to an ear, nose, and throat specialist or a neurologist.

### *ADDITIONAL THERAPIES*

- Physical therapy: strong evidence that physical therapy combined with drug treatment has positive effect on grade and time of recovery compared with drug treatment only (7,8,9)[A].
- Electrostimulation and mirror biofeedback rehabilitation have limited evidence of effect (10)[C].
- Acupuncture with strong stimulation has shown some therapeutic promise.
- Routine use of eye-protective measures for patients with incomplete eye closure is recommended (6)[A].

### *SURGERY/OTHER PROCEDURES*

- Surgical treatment of Bell palsy remains controversial and is reserved for intractable cases.
- There is an insufficient evidence to decide whether surgical intervention is beneficial or harmful in the management of Bell palsy (11)[B].

In those cases where surgical intervention is performed, cranial nerve XII is surgically decompressed at the entrance to the meatal foramen where the labyrinthine segment and geniculate ganglion reside.

- Decompression surgery should not be performed >14 days after the onset of paralysis because severe degeneration of the facial nerve is likely irreversible after 2 to 3 weeks.
- A routine surgical decompression is not recommended (6)[B].

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Patients should start steroid treatment immediately and be followed for 12 months.
- Patients who do not recover complete facial nerve function should be referred to an ophthalmologist for tarsorrhaphy.

### *PATIENT EDUCATION*

American Academy of Family Physicians: <http://www.aafp.org/afp/2007/1001/p1004.html>

### *PROGNOSIS*

- Most patients achieve complete spontaneous recovery within 2 weeks. >80% recover within 3 months.
- 85% of untreated patients will experience the first signs of recovery within 3 weeks of onset.
- 16% are left with a partial palsy, motor synkinesis, and autonomic synkinesis.
- 5% experience severe sequelae, and a small number of patients experience permanent facial weakness and dysfunction.
- Poor prognostic factors include the following:
  - Age >60 years
  - Complete facial weakness
  - Hypertension
  - Ramsay-Hunt syndrome
- The Sunnybrook and House-Brackmann facial grading systems are clinical prognostic models that identify Bell palsy patients at risk for nonrecovery at 12 months.

- Treatment with prednisolone or no prednisolone and the Sunnybrook score are significant factors for predicting nonrecovery at 1 month (12)[C].
- Patients with no improvement or progression of symptoms should be referred to ENT (6)[A] and may require neuroimaging to rule out neoplasms (6)[A].

## COMPLICATIONS

- Corneal abrasion or ulceration
- Steroid-induced psychological disturbances; avascular necrosis of the hips, knees, and/or shoulders
- Steroid use can unmask subclinical infection (e.g., TB).

## Codes

### ICD10

G51.0 Bell's palsy

## Clinical Pearls

- Initiate steroids immediately following the onset of symptoms.
- Look closely at the voluntary movement on the upper part of the face on the affected side; in Bell palsy, all of the muscles are involved (weak or paralyzed); whereas in a stroke, the upper muscles are spared (because of bilateral innervation).
- Protect the affected eye with lubrication and taping.
- In areas with endemic Lyme disease, Bell palsy should be considered to be Lyme disease until proven otherwise.

# Bipolar I Disorder

Wendy K. Marsh, MD, MSc

## BASICS

### DESCRIPTION

- Bipolar I (BP-I) is an episodic mood disorder of at least one manic or mixed (mania and depression) episode that causes marked impairment, psychosis, and/or hospitalization, major depressive episodes are not required, but usually occur.
- Symptoms are not caused by a substance (e.g., drug), a general medical condition, or a medication.

### *Geriatric Considerations*

New onset in older patients (>50 years of age) requires a workup for organic or chemically induced pathology.

### *Pediatric Considerations*

Diagnosis less well defined, more rapid cycling, and mixed states. Depression often presents as irritable mood. There is an overlap with symptoms of attention deficit hyperactivity disorder (ADHD) and oppositional defiant disorder (ODD).

### *Pregnancy Considerations*

- Potential teratogenic effects of commonly used medications (e.g., valproic acid)
- Postpartum carries risk of severe acute episode with psychosis and/or infanticidal ideation.

### EPIDEMIOLOGY

- Onset usually between 15 and 30 years of age
- More common in separated/widowed/divorced persons

### *Prevalence*

- 1.0-1.6% lifetime prevalence
- Equal among men and women (manic episodes more common in men; depressive episodes

more common in women)

- Equal among races; however, clinicians tend to diagnose schizoaffective in African Americans with BP-I.

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

Genetic predisposition and major life stressors can trigger initial and subsequent episodes:

- Dysregulation of biogenic amines or neurotransmitters (particularly serotonin, norepinephrine, and dopamine)
- MRI findings suggest abnormalities in prefrontal cortical areas, striatum, and amygdala that predate illness onset (1)[C].

### ***Genetics***

- Monozygotic twin concordance 40-70%
- Dizygotic twin concordance 5-25%
- 50% have at least one parent with a mood disorder
- First-degree relatives are 7 times more likely to develop BP-I than the general population.

## ***RISK FACTORS***

Genetics, major life stressors (especially loss of parent or spouse), or substance abuse

## ***GENERAL PREVENTION***

Treatment adherence and education can help to prevent relapses.

## ***COMMONLY ASSOCIATED CONDITIONS***

Substance abuse (60%), ADHD, anxiety disorders, and eating disorders

## **DIAGNOSIS**

- The diagnosis of BP-I requires at least one manic or mixed episode (simultaneous mania and depression). Although a depressive episode is not necessary for the diagnosis, 80-90% of people with BP-I also experience depression.
- Manic episode, *DSM-5* criteria (2)
  - Distinct period of abnormally and persistently elevated, expansive, or irritable mood lasting plus increased activity or energy for at least 1 week (or any duration if hospitalization is

necessary)

- During the period of mood disturbance, three or more of the ØDIG FASTÓ symptoms must persist (four if the mood is only irritable) and must be present to a significant degree.
  - Distractibility
  - Insomnia, decreased need for sleep
  - Grandiosity or inflated self-esteem
  - Flight of ideas or racing thoughts
  - Agitation or increase in goal-directed activity
  - Speech-pressured/more talkative than usual
  - Taking risks: excessive involvement in pleasurable activities that have a high potential for painful consequences (e.g., financial or sexual)
- Mixed specifier: when three or more symptoms of opposite mood pole are present during primary mood episode, For example, mania with mixed features (of depression).

## **HISTORY**

- Collateral information makes diagnostics more complete and is often necessary for a clear history.
- History: safety concerns (e.g., Suicidal/homicidal ideation? Safety plan? Psychosis present?), physical well-being (e.g., Number of hours of sleep? Appetite? Substance abuse?), personal history (e.g., Talkative? Speeding? Spending sprees or donations? Credit card debt? Promiscuous? Other risk-taking behavior? Legal trouble?)

## **PHYSICAL EXAM**

- Mental status exam in acute mania
  - General appearance: bright clothing, excessive makeup, disorganized or discombobulated, psychomotor agitation
  - Speech: pressured, difficult to interrupt
  - Mood/affect: euphoria, irritability/expansive, labile
  - Thought process: flight of ideas (streams of thought occur to patient at rapid rate), easily distracted
  - Thought content: grandiosity, paranoia, hyperreligious
  - Perceptual abnormalities: 3/4 of manic patients experience delusions, grandiose, or

paranoia.

- Suicidal/homicidal ideation: Irritability or delusions may lead to aggression toward self or others; suicidal ideation is common with mixed episode.
- Insight/judgment: poor/impaired
- See "Bipolar II Disorder" for an example of a mental status exam in depression.
- With mixed episodes, patients may exhibit a combination of manic and depressive mental states.

## ***DIFFERENTIAL DIAGNOSIS***

- Other psychiatric considerations: unipolar depression ± psychotic features, schizophrenia, schizoaffective disorder, personality disorders (particularly antisocial, borderline, histrionic, and narcissistic), ADD ± hyperactivity, substance-induced mood disorder
- Medical considerations: epilepsy (e.g., temporal lobe), brain tumor, infection (e.g., AIDS, syphilis), stroke, endocrine (e.g., thyroid) disease, multiple sclerosis
- In children, consider ADHD and ODD.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- BP-I is a clinical diagnosis.
- The Mood Disorder Questionnaire is a self-assessment screen for bipolar disorders (sensitivity 73%, specificity 90%) (3).
- Patient Health Questionnaire-9 helps to determine the presence and severity of a depressive episode.

### ***Initial Tests (lab, imaging)***

- TSH, CBC, BMP, LFTs, ANA, RPR, HIV, ESR
- Drug/alcohol screen with each presentation
- Dementia workup if new onset in seniors
- Consider brain imaging (CT, MRI) with initial onset of mania to rule out organic cause (e.g., tumor, infection, or stroke), especially with onset in elderly and if psychosis is present.

### ***Diagnostic Procedures/Other***

Consider EEG if presentation suggests temporal lobe epilepsy (hyperreligiosity, hypergraphia).

## TREATMENT

- Ensure safety.
- Psychotherapy (e.g., cognitive-behavioral therapy, social rhythm therapy)
- Stress reduction
- Patient and family education

## GENERAL MEASURES

- Psychotherapy for depression (e.g., cognitive-behavioral therapy, social rhythm, interpersonal) in conjunction with medications
- Regular daily schedule, exercise, a healthy diet, and sobriety

## MEDICATION

### *First Line*

- Treatment mood stabilizer(s) or other psychotropic medications. When combining, use different classes (e.g., an atypical antipsychotic and/or an antiseizure medication and/or lithium).
- Lithium (Lithobid, Eskalith, generic): dosing: 600 to 1,200 mg/day divided BID-QID; start 600 to 900 mg/day divided BID-TID, titrate based on blood levels. Warning: caution in kidney and heart disease; use can lead to diabetes insipidus or thyroid disease. Caution with diuretics or ACE inhibitors; dehydration can lead to toxicity (seizures, encephalopathy, arrhythmias). Pregnancy Category D (Ebstein anomaly). Monitor: Check ECG >40 years, TSH,

P.123

BUN, creatine, electrolytes at baseline and every 6 months; check level 5 to 7 days after initiation or dose change, then every 2 weeks × 3, then every 3 months (goal: 0.8 to 1.2 mmol/L).

- Antiseizure medications
  - Divalproex sodium, valproic acid (Depakote, Depakene, generic): dosing: start 250 to 500 mg BID-TID; maximum 60 mg/kg/day. Black box warnings: hepatotoxicity, pancreatitis, thrombocytopenia, pregnancy Category D. Monitor CBC and LFTs at baseline and every 6 months; check level 5 days after initiation and dose changes (goal: 50 to 125 µg/mL).
  - Carbamazepine (Equetro, Tegretol, generic): dosing: 800 to 1,200 mg/day PO divided BID-QID; start 100 to 200 mg PO BID and titrate to lowest effective dose. Warning: Do not use with TCA or within 14 days of an MAOI. Caution in kidney/heart disease; risk of aplastic

anemia/agranulocytosis, enzyme inducer; pregnancy Category D. Monitor CBC and LFTs at baseline and every 3 to 6 months; check level 4 to 5 days after initiation and dose changes (goal: 4 to 12  $\mu\text{g/mL}$ ).

- Lamotrigine (Lamictal, generic): dosing: 200 to 400 mg/day; start 25 mg/day for 2 weeks, then 50 mg/day for 2 weeks, then 100 mg/day for 1 week, then 150 mg/day. (Note: Use different dosing if adjunct to valproate). Warning: Titrate slowly (risk of Stevens-Johnson syndrome); caution with kidney/liver/heart disease; pregnancy Category C
- Oxcarbazepine (Trileptal) dosing: 300 mg PO QD. Titrate to 1,800 to 2,400/day max.
- Atypical antipsychotics
  - Side effects: orthostatic hypotension, metabolic side effects (glucose and lipid dysregulation, weight gain), tardive dyskinesia, neuroleptic malignant syndrome (NMS), prolactinemia (except Abilify), increased risk of death in elderly with dementia-related psychosis, pregnancy Category C
  - Monitor LFTs, lipids, glucose at baseline, 3 months, and annually; check for extrapyramidal symptoms (EPS) with Abnormal Involuntary Movement Scale (AIMS) and assess weight (with abdominal circumference) at baseline, at 4, 8, and 12 weeks, and then every 3 to 6 months; monitor for orthostatic hypotension 3 to 5 days after starting or changing dose.
  - Risperidone (Risperdal, Risperdal Consta, generic): dosing: 1 to 6 mg/day divided QD-QID. IM preparation available (q2wk)
  - Olanzapine (Zyprexa, Zydys, generic): dosing: 5-20 mg/day; most likely to cause metabolic side effects (weight gain, diabetes)
  - Quetiapine (Seroquel, Seroquel XR, generic): dosing: in mania, 200 to 400 mg BID; in bipolar depression, 50 to 300 mg QHS. XR dosing 50 to 400 mg QHS
  - Aripiprazole (Abilify): dosing: 15 to 30 mg/day; less likely to cause metabolic side effects
  - Ziprasidone (Geodon): dosing: 40 to 80 mg BID; less likely to cause metabolic side effects. Caution: QTc prolongation (>500 ms) has been associated with use (0.06%). Consider ECG at baseline.
  - Asenapine: dosing: 5 to 10 mg sublingual BID
  - Lurasidone: dosing: 20 to 60 mg/day. FDA-approved for depression
  - Cariprazine: dosing: 1.5 to 6 mg/day. Start 1.5 mg

## *Second Line*

- Antidepressants (in addition to mood stabilizers) have mixed evidence to support use.
- Benzodiazepines (for acute agitation with mania, associated anxiety)

- Sleep medications

## *ISSUES FOR REFERRAL*

- Refer to psychiatry, depends on knowledge level of the doctor, stability of patient.
- Patients benefit from a multidisciplinary team, including a primary care physician, psychiatrist, and therapist.

## *ADDITIONAL THERAPIES*

- Electroconvulsive therapy can be helpful in acute or treatment-resistant mania and depression.
- Modest evidence supports transcranial magnetic stimulation, vagus nerve stimulation, ketamine infusion, sleep deprivation, and hormone therapy (e.g., thyroid) in bipolar depression.

## *INPATIENT CONSIDERATIONS*

Admit if dangerous to self or others.

### *Admission Criteria/Initial Stabilization*

To admit involuntarily, the patient must have a psychiatric diagnosis (e.g., BP-I) and present a danger to self or others or the mental disease must be inhibiting the person from obtaining basic needs (e.g., food, clothing).

### *Nursing*

Alert staff to potentially dangerous or agitated patients. Acute suicidal threats need continuous observation.

### *Discharge Criteria*

Determined by safety

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Regularly scheduled visits support adherence with treatment.
- Frequent communication among primary care doctor, psychiatrist, and therapist

## Patient Monitoring

Mood charts are helpful to monitor symptoms.

## PATIENT EDUCATION

- National Alliance on Mental Illness (NAMI): <http://www.nami.org/>
- National Institutes of Mental Health (NIMH): <http://www.nimh.nih.gov/index.shtml>

## PROGNOSIS

- Frequency and severity of episodes are related to medication adherence, consistency with therapy, quality of sleep, and support systems (4)[B].
- 40-50% of patients experience another manic episode within 2 years of first episode.
- 25-50% attempt suicide and 15% die by suicide.
- Substance abuse, unemployment, psychosis, depression, and male gender are associated with a worse prognosis.

## Codes

### ICD10

- F31.9 Bipolar disorder, unspecified
- F31.10 Bipolar disorder, current episode manic without psychotic features, unspecified
- F31.30 Bipolar disord, crnt epsd depress, mild or mod severt, unsp

## Clinical Pearls

- BP-I is characterized by at least one manic or mixed episode that causes marked impairment, major depressive episodes usually occur, but are not necessary.
- 25-50% of BP-I patients attempt suicide and 15% die by suicide.
- There is no known way to prevent BP-I, but treatment adherence and education helps reduce further episodes.
- Goal of treatment is to decrease the intensity, length, and frequency of episodes as well as greater mood stability between episodes.

# Bipolar II Disorder

Wendy K. Marsh, MD, MSc

## BASICS

### DESCRIPTION

Bipolar II (BP-II) is a mood disorder characterized by at least one episode of major depression (with or without psychosis) and at least one episode of hypomania, a nonsevere mood elevation.

### Geriatric Considerations

New onset in older patients (>50 years) requires a workup for organic or chemically induced pathology.

### Pediatric Considerations

- Overlap with symptoms of attention deficit hyperactivity disorder (ADHD) and oppositional defiant disorder (ODD)
- Depression often presents as irritable mood.

### Pregnancy Considerations

- Counsel women of childbearing age about potentially teratogenic effects of commonly used medications (e.g., valproic acid).
- Postpartum carries risk of severe acute episode with psychosis and/or infanticidal ideation.

### EPIDEMIOLOGY

More common in women

### Prevalence

0.5-1.1% lifetime prevalence

### ETIOLOGY AND PATHOPHYSIOLOGY

- Dysregulation of biogenic amines or neurotransmitters (particularly serotonin, norepinephrine, and dopamine)

## Genetics

- Major life stressors increase risk of episode onset.

## Genetics

Heritability estimate: >77%

## GENERAL PREVENTION

No way to prevent the onset of BP-II, but treatment adherence and education can help to prevent further episodes.

## COMMONLY ASSOCIATED CONDITIONS

Substance abuse or dependence, ADHD, anxiety disorders, and eating disorders

## DIAGNOSIS

- *DSM-5* criteria: one hypomanic episode and at least one major depressive episode. The symptoms cause unequivocal change in functioning noticed by others but not severe enough to cause marked impairment (1)[C].
- Hypomania is a distinct period of persistently elevated, expansive, or irritable mood, different from usual euthymic mood, including increase in activity or energy lasting at least 4 days:
  - The episode must include at least three of the *ODIG FASTÓ* symptoms *plus increased energy* below (four if the mood is only irritable):
    - Distractibility
    - Insomnia, decreased need for sleep
    - Grandiosity or inflated self-esteem
    - Flight of ideas or racing thoughts
    - Agitation or increase in goal-directed activity (socially, at work or school, or sexually)
    - Speech-pressured/more talkative than usual
    - Taking risks: excessive involvement in pleasurable activities that have high potential for painful consequences (e.g., sexual or financial)
- Major depression
  - Depressed mood or diminished interest and four or more of the *OSIG E CAPSÓ* symptoms are present during the same 2-week period:

- **Sleep disturbance** (e.g., trouble falling asleep, early-morning awakening)
- **Interest: loss or anhedonia**
- **Guilt** (or feelings of worthlessness)
- **Energy, loss of**
- **Concentration, loss of**
- **Appetite changes**, increase or decrease
- **Psychomotor changes** (retardation or agitation)
- **Suicidal/homicidal thoughts**
- Rapid cycling is <sup>34</sup> mood episodes in 12 months (major depression or hypomania).
- Mixed specifier: When three or more symptoms of opposite mood pole are present during primary mood episode, for example, hypomania with mixed features (of depression)
- Note: If symptoms have *ever* met criteria for a full manic episode or hospitalization was necessary secondary to manic/mixed symptoms or psychosis was present, then the diagnosis is BP-I.

## **HISTORY**

Collateral information makes diagnostics more complete and is often necessary for a clear history.

## **PHYSICAL EXAM**

- Mental status exam in hypomania
  - General appearance: usually appropriately dressed, with psychomotor agitation
  - Speech: may be pressured, talkative, difficult to interrupt
  - Mood/affect: euphoria, irritability/congruent, or expansive
  - Thought process: may be easily distracted, difficulty concentrating on one task
  - Thought content: usually positive, with  $\bar{O}$ big $\bar{O}$  plans
  - Perceptual abnormalities: none
  - Suicidal/homicidal ideation: low incidence of homicidal or suicidal ideation
  - Insight/judgment: usually stable/may be impaired by their distractibility
- Mental status exam in acute depression
  - General appearance: unkempt, psychomotor retardation, poor eye contact

- Speech: low, soft, monotone
- Mood/affect: sad, depressed/congruent, flat
- Thought process: ruminating thoughts, generalized slowing
- Thought content: preoccupied with negative or nihilistic ideas
- Perceptual abnormalities: 15% of depressed patients experience hallucinations or delusions.
- Suicidal/homicidal ideation: Suicidal ideation is very common.
- Insight/judgment: often impaired

## *DIFFERENTIAL DIAGNOSIS*

- Other psychiatric considerations
  - BP-I disorder, unipolar depression, personality disorders (particularly borderline, antisocial, and narcissistic), ADD with hyperactivity, substance-induced mood disorder
- Medical considerations
  - Epilepsy (e.g., temporal lobe), brain tumor, infection (e.g., AIDS, syphilis), stroke, endocrine (e.g., thyroid disease), multiple sclerosis

## *DIAGNOSTIC TESTS & INTERPRETATION*

- BP-II is a clinical diagnosis.
- Mood Disorder Questionnaire, self-assessment screen for BP, sensitivity 73%, specificity 90% (2)[B]
- Hypomania Checklist-32 distinguishes between BP-II and unipolar depression (sensitivity 80%, specificity 51%) (3)[B].
- Patient Health Questionnaire-9 helps to determine the presence and severity of depression.

### *Initial Tests (lab, imaging)*

- Rule out organic causes of mood disorder during initial episode.
- Drug/alcohol screen is prudent with each presentation.
- Dementia workup if new onset in seniors
- With initial presentation: Consider CBC, chem 7, TSH, LFTs, ANA, RPR, HIV, and ESR.
- Consider brain imaging (CT, MRI) with initial onset of hypomania to rule out organic cause, especially with onset in the elderly.

## TREATMENT

- Ensure safety.
- Medication management
- Psychotherapy (e.g., cognitive-behavioral therapy [CBT], social rhythm therapy, interpersonal therapy)
- Stress reduction
- Patient and family education
- Refer to psychiatrist.

## GENERAL MEASURES

- Psychotherapy (e.g., CBT, social rhythm, interpersonal, family focused) in conjunction with medications
- Regular daily schedule, exercise, a healthy diet, and sobriety have been shown to help.

## MEDICATION

- Less research has been conducted on the appropriate treatment of BP-II, but current consensus is to treat with the same medications as BP-I.
- Antidepressant medications must be used with caution during depressive episodes, because they may increase risk of hypomania or increase cycling (less common than with BP-I).

---

P.125

### *First Line*

- When combining mood stabilizers, consider adding different classes (e.g., an atypical antipsychotic and/or an antiseizure medication and/or lithium).
- Lithium (Lithobid, Eskalith, generic): dosing 600 to 1,200 mg/day divided BID-QID, titrate based on blood levels:
  - Caution in kidney or heart disease; use can lead to diabetes insipidus, thyroid disease; caution in sodium-depleted patients (diuretics, ACE inhibitors); dehydration can lead to toxicity, which may cause seizures, encephalopathic syndrome, arrhythmias; pregnancy Category D (Ebstein anomaly with 1st-trimester use)
  - Monitor electrocardiogram in patients >40 years, TSH, BUN, creatinine, electrolytes at

baseline and q6mo; check level 5 to 7 days after initiation or dose change, then q1-2wk × 3, then q3mo (goal: 0.8 to 1.2 mmol/L).

- Anticonvulsants

- Valproic acid, divalproex sodium: dosing: Start 250 to 500 mg BID-TID, max 60 mg/kg/day. Warning: hepatotoxicity, pancreatitis, thrombocytopenia, pregnancy Category D (neural tube defects). Monitor CBC, LFTs at baseline and q6mo; check valproic acid level 5 days after initiation and dose changes (goal: 50 to 125  $\mu\text{m}/\text{mL}$ ).
- Carbamazepine: dosing: 800 to 1,200 mg/day PO divided BID-QID, start 100 to 200 mg PO BID and titrate to lowest effective dose. Do not use with tricyclic antidepressants or within 14 days of monoamine oxidase inhibitor; caution with kidney or heart disease, may cause aplastic anemia/agranulocytosis. Monitor CBC, LFTs at baseline and q3-6mo; check level 4 to 5 days after initiation and dose changes (goal: 4 to 12  $\mu\text{m}/\text{mL}$ ).
- Lamotrigine: treats depression only. Dosing: 200 mg/day start 25 mg for 2 weeks, then 50 mg for 2 weeks, then 100 mg for 1 week. (Note: different dosing if adjunct to valproate) Selected warnings: Titrate slowly (risk of Stevens-Johnson syndrome); caution with kidney, liver, or heart impairment. Monitor patient to monitor for rash.

- Atypical antipsychotics (AAs)

- Side effects of AAs: orthostatic hypotension, negative metabolic side effects (effect glucose and lipid regulation, weight gain), tardive dyskinesia, neuroleptic malignant syndrome, prolactinemia increased risk of mortality in elderly with dementia-related psychosis, pregnancy Category C
- Monitor LFTs, lipids, glucose at baseline, 3 months, and annually; check for extrapyramidal symptoms with Abnormal Involuntary Movement Scale (AIMS) and assess weight (with abdominal circumference) at baseline, then 4, 8, and 12 weeks, then q3-6mo; monitor for orthostatic hypotension 3 to 5 days after starting or changing dose.
- Antimanic is a presumed class effect.
- Aripiprazole: dosing: 15 mg/day, max 30 mg/day, less likely to cause metabolic side effects
- Olanzapine: dosing: 5 to 20 mg/day, most likely AA to cause metabolic side effects (weight gain, diabetes mellitus)
- Quetiapine: dosing: hypomania 200 to 400 mg BID; depression: 50 to 300 mg QHS
- Risperidone: dosing: 1 to 6 mg/day QD-BID; generic and q2wk IM preparations available
- Ziprasidone: dosing: 40 to 80 mg BID take with food. Less likely to cause metabolic side effects. Warning: QTc prolongation (>500 ms): consider baseline ECG.
- Asenapine: dosing: 5 to 10 mg sublingual BID

- Lurasidone: dosing: 20 to 60 mg/day. FDA-approved for depression.
- Cariprazine: dosing: 1.5 to 6 mg/day. Start 1.5 mg

## *Second Line*

- Antidepressants (in addition to mood stabilizers) have better data in BP-II than BP-I.
- Sleep medications

## *ISSUES FOR REFERRAL*

Patients benefit from care by a multidisciplinary team, including a primary care physician, therapist, and psychiatrist.

## *ADDITIONAL THERAPIES*

- Electroconvulsive therapy for severe or treatment-resistant depression or mood elevation
- Modest evidence exists to support transcranial magnetic stimulation, vagal nerve stimulation, ketamine infusion, sleep deprivation, and hormone therapy (e.g., thyroid) in bipolar depression.

## *INPATIENT CONSIDERATIONS*

If hospitalized for mood elevation symptoms, then diagnosis is mania and bipolar I. May be hospitalized for depression and be bipolar II

## *Admission Criteria/Initial Stabilization*

To admit patients (> 18 years) to a psychiatric unit involuntarily, they must have a psychiatric diagnosis and present a danger to themselves or others, or their mental disease must be inhibiting them from providing their basic needs (e.g., food, clothing, shelter).

## *Nursing*

Acute suicidal threats require close observation.

## *Discharge Criteria*

Determined by safety

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

- Regularly scheduled visits support treatment adherence.
- Frequent communication between primary care doctor, psychiatrist, and therapist ensures comprehensive care.

## *Patient Monitoring*

Mood charts are helpful adjuncts to care.

## **PATIENT EDUCATION**

- Support groups for patients and families are recommended.
- National Alliance on Mental Illness: <http://www.nami.org/>

## **PROGNOSIS**

- Frequency and severity of problematic episodes are related to medication adherence, consistency with psychotherapy, sleep, support systems, regularity of daily activities, and social history.
- Substance abuse, unemployment, persistent depression, and male gender are associated with a worse prognosis.
- Although data are limited, evidence indicates that patients with BP-II may be at greater risk of both attempting and completing suicide than with BP-I and unipolar depression.

Algorithm: Depressive Episode, Major

## Codes

### ICD10

F31.81 Bipolar II disorder

## Clinical Pearls

- BP-II is characterized by at least one episode of major depression and one episode of hypomania.
- Patients may not recognize symptoms and or decline treatment during a hypomanic episode; they may enjoy the elevated mood and productivity.
- Patients with BP-II are at great risk of both attempting and completing suicide.

# Bites, Animal and Human

Kathryn Samai, PharmD, BCPS

Brian James Kimbrell, MD, FACS

## BASICS

### DESCRIPTION

- Animal bites to humans from dogs (60-90%), cats (5-20%), rodents (2-3%), humans (2-3%), and rarely other animals, including snakes
- System(s) affected: potentially any

### *Pediatric Considerations*

Young children are more likely to sustain bites and have bites that include the face, upper extremity, or trunk.

### EPIDEMIOLOGY

- Predominant age: all ages but children > adults
- Predominant gender: dog bites, male > female; cat bites, female > male

### *Incidence*

- 2 to 5 million animal bites per year in the United States
- Account for 1% of all emergency room visits
- 1-2% will require hospital admission, and 10 to 20 victims will die from bites annually (1).

### ETIOLOGY AND PATHOPHYSIOLOGY

- Most dog bite wounds are from a domestic pet known to the victim.
- 89% of cat bites are provoked.
- Males, pit bull terriers, and German shepherds are most commonly associated with dog bites (2).
- Human bites are often the result of one person striking another in the mouth with a clenched fist.

- Bites can also occur incidentally in the case of paronychia due to nail biting, or thumb sucking, or Òlove nipsÓ to the face, breasts, or genital areas.
- Animal bites can cause tears, punctures, scratches, avulsions, or crush injuries.
- Contamination of wound with flora from the mouth of the biting animal or from the broken skin of the victim can lead to infection.

## **RISK FACTORS**

- Male dogs and older dogs are more likely to bite.
- Clenched-fist human bites are frequently associated with the use of alcohol.
- Patients presenting >8 hours following the bite are at greater risk of infection.

## **GENERAL PREVENTION**

- Instruct children and adults about animal hazards and strongly enforce animal control laws.
- Educate dog owners.

## **DIAGNOSIS**

### **HISTORY**

- Obtain detailed history of the incident (provoked or unprovoked).
- Type of animal
- Vaccine status
- Site of the bite
- Geographic setting

### **PHYSICAL EXAM**

- Dog bites (60-90% of bites)
  - Hands and face most common site of injury in adults and children, respectively
  - More likely to have associated crush injury
- Cat bites (5-20% of bites)
  - Predominantly involve the hands, followed by lower extremities, face, and trunk
- Human bites (2-3% of bites)

- Intentional bite: semicircular or oval area of erythema and bruising, with or without break in skin
- Clenched-fist injury: small wounds over the metacarpophalangeal joints from striking the fist against another's teeth
- Signs of wound infection include fever, erythema, swelling, tenderness, purulent drainage, and lymphangitis.

## **ALERT**

Cat bites (often puncture wounds) are twice as likely to cause infection as dog bites, with higher risks of osteomyelitis, tenosynovitis, and septic arthritis.

## *Pediatric Considerations*

If human bite mark on child has intercanine distance >3 cm, bite probably came from an adult and should raise concerns about child abuse.

## **DIAGNOSTIC TESTS & INTERPRETATION**

### *Initial Tests (lab, imaging)*

- Drainage from infected wounds should be Gramstained and cultured (3)[A].
  - If wound fails to heal, perform cultures for atypical pathogens (fungi, *Nocardia*, and mycobacteria) and ask lab to keep bacterial cultures for 7 to 10 days (some pathogens are slow-growing).
- 85% of bite wounds will yield a positive culture, with an average of five pathogens.
- Aerobic and anaerobic blood cultures should be obtained before starting antibiotics if bacteremia suspected (e.g., fever or chills).
- Previous antibiotic therapy may alter culture results.

## **ALERT**

If bite wound is near a bone or joint, a plain radiograph is needed to check for bone injury and to use for comparison later if osteomyelitis is subsequently suspected (3)[B].

- Radiographs are needed to check for fractures in clenched-fist injuries.

## *Follow-Up Tests & Special Considerations*

Subsequent suspicion of osteomyelitis warrants comparison of plain radiograph or MRI. Severe skull bites warrant a CT scan and ultrasound can be useful for detection of abscess.

## Diagnostic Procedures/Other

Surgical exploration may be needed to ascertain extent of injuries or to drain deep infections (such as tendon sheath infections), especially in serious hand wounds.

## Test Interpretation

- Dog bites (4,5)
  - *Pasteurella* species is present in 50% of bites.
  - Also found: viridans streptococci, *Staphylococcus aureus*, *Staphylococcus intermedius*, *Bacteroides*, *Capnocytophaga canimorsus*, *Fusobacterium*
- Cat bites (5)
  - *Pasteurella* species is present in 75% of bites.
  - Also found: *Streptococcus* spp. (including *Streptococcus pyogenes*), *Staphylococcus* spp. (including methicillin-resistant *Staphylococcus aureus* [MRSA]), *Fusobacterium* spp., *Bacteroides* spp., *Porphyromonas* spp., *Moraxella* spp.
- Human bites
  - *Streptococcus* spp., *Staphylococcus aureus*, *Eikenella corrodens* (29%), and various anaerobic bacteria (e.g., *Fusobacterium*, *Peptostreptococcus*, *Prevotella*, and *Porphyromonas* spp.)
  - Although rare, case reports have suggested transmission of viruses such as hepatitis, HIV, and herpes simplex.
- Reptile bites
  - If from a venomous snake, use antivenom. Bacteria: *Pseudomonas aeruginosa*, *Proteus* spp., *Salmonella*, *Bacteroides fragilis*, and *Clostridium* spp.
- Rodent bites
  - *Streptobacillus moniliformis* or *Spirillum minor*, which causes rat-bite fever
- Monkey bites
  - All monkey bites can transmit rabies, and bites of a macaque monkey may transmit herpes B virus, which is potentially fatal.

### ALERT

Asplenic patients and those with underlying hepatic disease are at risk of bacteremia and fatal sepsis after dog bites infected with *Capnocytophaga*

*canimorsus* (gram-negative rod).

## TREATMENT

### GENERAL MEASURES

- Elevation of the injured extremity to prevent swelling
- Contact the local health department regarding the prevalence of rabies in the species of animal involved (highest in bats).
- Snake bite: If venomous, patient needs rapid transport to facility capable of definitive evaluation. If envenomation has occurred, patient should receive antivenom. Be sure patient is stable for transport; consider measuring and/or treating coagulation and renal status along with any anaphylactic reactions before transport.
- Monkey bite: Providers should contact CDC and administer an antiviral, such as valacyclovir, active against herpes B virus.

### MEDICATION

- Consider need for antirabies therapy: rabies immunoglobulin and human diploid cell rabies vaccine for those bitten by wild animals (in the United States, primary vector is bat bite), rabid pets, unvaccinated pets, or if animal cannot be quarantined for 10 days.
- Tetanus toxoid (Td) for those previously immunized but >10 years since their last dose (3)[C]; tetanus, diphtheria, and pertussis (Tdap) is preferred over Td (3)
- A patient negative for anti-HBs and bitten by an HBsAg-positive individual should receive both hepatitis B immunoglobulin (HBIG) and hepatitis B vaccine.
- HIV postexposure prophylaxis is generally not recommended for human bites, given the extremely low risk for transmission, unless blood exposure to broken skin.
- Preemptive antibiotics are only recommended for human bites and high-risk wounds (deep puncture, crush injury, venous or lymphatic compromise, hands or near joint, face or genital area, immunocompromised hosts, requiring surgical repair, asplenic, advanced liver, edema).

P.127

- For preemptive and for empiric treatment of established infection, amoxicillin and clavulanate is first-line (3)[B],(6)
  - Adults: amoxicillin 875 mg/clavulanate 125 mg PO BID
  - Children: <3 months: 30 mg/kg/day PO q12h; <sup>3</sup>3 months and <40 kg: 45 mg/kg/day q12h;

>40 kg, use adult dosing

- Averse reaction: Amoxicillin and clavulanate should be given with food to decrease GI side effects.
- Precautions: Dose antibiotics by body weight and renal function.
- Significant possible interactions: Antibiotics may decrease efficacy of oral contraceptives.
- Duration of therapy: preemptive, 3 to 5 days; treatment of cellulitis/skin abscess, 5 to 10 days; bacteremia, 10 to 14 days
  - Adults: clindamycin (300 mg PO TID) plus either
  - Trimethoprim-sulfamethoxazole (TMP-SMX; 1 DS tablet PO BID-TID) or
  - Ciprofloxacin (500 mg PO BID) for 7 to 21 days
  - Children: clindamycin (5 to 10 mg/kg IV [to a maximum of 600 mg] followed by 10 to 30 mg/kg/day in 3 to 4 divided doses to a maximum of 300 mg per dose) plus
  - TMP-SMX (8 to 10 mg/kg/day of trimethoprim) in 2 divided doses
- Avoid 1st-generation cephalosporins (e.g., cephalexin), penicillinase-resistant penicillins (e.g., dicloxacillin), macrolides (e.g., erythromycin), and clindamycin (when not administered with another agent) as they lack activity against *Pasteurella multocida* (dog/cat bites) and *E. corrodens* (human bites).

## *Pregnancy Considerations*

- Penicillin-allergic pregnant women
  - Azithromycin 250 to 500 mg PO every day
- Observe closely and note potential increased risk of failure.

### **ALERT**

Consider community-acquired MRSA as possible pathogen (from human skin or colonized pet). If high suspicion, doxycycline or TMP-SMX provide good coverage (7).

## *ISSUES FOR REFERRAL*

- Deep wounds to the hand and face should be referred to a hand surgeon or plastic surgeon, respectively.
- Bites from primates or unusual species of animals should be referred to infectious disease specialist.

## ***SURGERY/OTHER PROCEDURES***

- Copious irrigation of the wound with normal saline via a catheter tip is needed to reduce risk of infection.
- Devitalized tissue needs débridement.
- Débridement of puncture wounds is not advised.
- Primary closure can be considered if the wound is clean after irrigation and bite is <12 hours old and in bites to the face (cosmesis).
- Infected wounds and those at risk of infection (cat bites, human bites, bites to the hand, crush injuries, presentation >12 hours from injury) should be left open (8).
- Delayed primary closure in 3 to 5 days is an option for infected wounds.
- Splint hand if it is injured.
- Large, gaping wounds should be reapproximated with widely spaced sutures or Steri-Strips.

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Patients with deep or severe wound infections, systemic infections requiring IV antibiotics, those requiring surgery, and the immunocompromised require ABCs for associated trauma or severe infection and IV antibiotic therapy

- Adults: ampicillin and sulbactam 1.5 to 3 g IV q6h *or* piperacillin and tazobactam 3.375 g IV q6h (3). Alternative: ciprofloxacin 400 mg IV q12h *or* levofloxacin 750 mg IV every day with metronidazole 500 mg IV q8h (3)
- Children: ampicillin and sulbactam 200 mg/kg/day IV given in 4 divided doses to a maximum of 3 g per dose

### ***Discharge Criteria***

Pending clinical improvement

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

### ***Patient Monitoring***

- Patient should be rechecked in 24 to 48 hours if not infected at time of first encounter.
- Daily follow-up is warranted for infections.
- Subsequent revisions of empiric antibiotic therapy should be based on culture results and clinical response.

## ***PATIENT EDUCATION***

Educate parents at well-child checks about how to avoid animal bites.

## ***PROGNOSIS***

Wounds should steadily improve and close over by 7 to 10 days.

## **COMPLICATIONS**

- Septic arthritis
- Osteomyelitis
- Extensive soft tissue injuries with scarring
- Hemorrhage
- Gas gangrene
- Sepsis
- Meningitis
- Endocarditis
- Posttraumatic stress disorder
- Death

Cellulitis; Rabies; Snake Envenomation; *Bartonella* Infections

## Codes

### ICD10

- S61.459A Open bite of unspecified hand, initial encounter
- S01.85XA Open bite of other part of head, initial encounter
- S20.97XA Other superficial bite of unspecified parts of thorax, initial encounter

## Clinical Pearls

- Wound cleansing, débridement, and culture are essential. Most wounds should be left open.
- Prophylaxis is recommended for human bites and high-risk wounds.
- Consider rabies and tetanus vaccination.
- Antibiotic and duration of therapy should be adjusted based on culture results and clinical improvement.
- Patients bitten by animals or humans require close follow-up to monitor for infection.

# Bladder Cancer

Margaret E. Thompson, MD, FAAP

## BASICS

### DESCRIPTION

- Primary malignant neoplasms arising in the urinary bladder
- Most common type is transitional cell carcinoma (90%).
- Other types include adenocarcinoma, small cell carcinoma, and squamous cell carcinoma.
- Rhabdomyosarcoma of the bladder may occur in children.

### EPIDEMIOLOGY

#### *Incidence*

- Increases with age (median age at diagnosis is 73 years) (1)
- More common in Caucasians than in Asians or African Americans
- Male > female (4:1), but in smokers, risk is 1:1
- 35.8/100,000 men per year (1)
- 8.7/100,000 women per year (1)
- 20.5/100,000 men and women per year (1)

#### *Prevalence*

In 2012, 577,403 cases in the United States (1)

### ETIOLOGY AND PATHOPHYSIOLOGY

Unknown, other than related to risk factors:

- 70-80% is nonmuscle invasive (in lamina propria or mucosa):
  - Usually highly differentiated with long survival
  - Initial event seems to be the activation of an oncogene on chromosome 9 in superficial cancers.

- 20% of tumors are muscle invasive (deeper than lamina propria) at presentation:
  - Tend to be high grade with worse prognosis
  - Associated with other chromosome deletions

## *Genetics*

Hereditary transmission is unlikely, although transitional cell carcinoma pathophysiology is related to oncogenes.

## **RISK FACTORS**

- Smoking is the single greatest risk factor (increases risk 4-fold) and increases risk equally for men and women (2).
- Use of pioglitazone for >1 year may be associated with an increased risk of bladder cancer. The risk seems to increase with duration of therapy and may also be present with other thiazolidinediones.
- Other risk factors:
  - Occupational carcinogens in dye, rubber, paint, plastics, metal, carbon black dust, and automotive exhaust
  - Schistosomiasis in Mediterranean (squamous cell) cancer
  - Arsenic in well water
  - History of pelvic irradiation
  - Chronic lower UTI
  - Chronic indwelling urinary catheter
  - Cyclophosphamide exposure
  - High-fat diet
  - Coffee consumption associated with reduced risk (RR 0.83; 95% CI, 0.73-0.94) (3)

### **ALERT**

Any patient who smokes and presents with microscopic or gross hematuria or irritative voiding symptoms such as urgency and frequency not clearly due to UTI should be evaluated by cystoscopy for the presence of a bladder neoplasm.

## **GENERAL PREVENTION**

- Avoid smoking and other risk factors.

- Counseling of individuals with occupational exposure
- The U.S. Preventive Services Task Force has concluded that there is an insufficient evidence to determine the balance between risk and harm of screening for bladder cancer (4)[B].

## DIAGNOSIS

### HISTORY

- Painless hematuria is the most common symptom.
- Urinary symptoms (frequency, urgency)
- Abdominal or pelvic pain in advanced disease
- Exposures (see “Risk Factors”)

### PHYSICAL EXAM

Normal in early cases, pelvic or abdominal mass in advanced disease, wasting in systemic disease

### DIFFERENTIAL DIAGNOSIS

- Other urinary tract neoplasms
- UTI
- Prostatism
- Bladder instability
- Interstitial cystitis
- Urolithiasis
- Interstitial nephritis
- Papillary urothelial hyperplasia

### DIAGNOSTIC TESTS & INTERPRETATION

#### *Initial Tests (lab, imaging)*

- Urinalysis is the initial test in patients presenting with gross hematuria or urinary symptoms such as frequency, urgency, and dysuria.
- Urine cytology (consult your local lab for volume needed and proper fixative/handling)
- Cystoscopy with biopsy is the gold standard for at-risk patients with painless hematuria.

Macroscopic hematuria (55% sensitivity, positive predictive value [PPV] 0.22 for urologic cancer) (5)[C]

## *Follow-Up Tests & Special Considerations*

- Urine cytology: 54% sensitivity overall (lower in less advanced tumors), 94% specific (6)[A]
- Other urine markers (of little clinical benefit):
  - Nuclear matrix protein-22 (NMP22): 67% sensitive, 78% specific (6)[A]
  - Bladder tumor-associated antigen stat: 70% sensitive, 75% specific, may be falsely positive in inflammatory conditions (6)[A]
  - Fluorescence in situ hybridization (FISH) assay: 69% sensitive, 78% specific (PPV 27.1, negative predictive value 95.3) for all tumors, more sensitive and specific for higher grade (7)[B]
  - *FGFR3* mutation has high specificity (99.9%) but low sensitivity (34.5%); PPV 95.2% (8)[A].
- *Bottom line: None of the urine markers is sensitive enough to rule out bladder cancer on its own.*
- Liver function tests, alkaline phosphatase if metastasis suspected
- Done for staging and to evaluate extent of disease but not for diagnosis itself:
  - CT urogram replacing IVP to image upper tracts if there is a suspicion of disease there
  - Diffusion-weighted MRI and multidimensional CT scan are undergoing study for use in diagnosis and staging of bladder tumors.
  - For invasive disease, metastatic workup should include chest x-ray.
  - Bone scan should be performed if the patient has bone pain or if alkaline phosphatase is elevated.
- Urologic CT scan (abdomen, pelvis, with and without contrast) or MRI (40-98% accurate), with MRI slightly more accurate, is recommended if metastasis is suspected (9)[B].
- Regular cystoscopy (initiated at 3 months postprocedure) is indicated after transurethral resection of bladder tumor (TURBT) and intravesical chemotherapy for superficial bladder cancers.

## *Diagnostic Procedures/Other*

- Cystoscopy with biopsy is the gold standard for diagnosis, but one study showed that 33% of patients had residual tumor after TURBT (9)[B].

Using photodynamic diagnosis (PDD; employing a photosensitizing agent in the bladder that is taken up by tumor cells and visualized using a particular wavelength of light, which is changed to a different wavelength by the photosensitizing agent) has been shown to increase detection and identification of cancerous superficial tumors when compared with plain white light cystoscopy. A recent meta-analysis shows that this increases the likelihood of total resection (10)[A].

## *Test Interpretation*

- Characterized as superficial (nonmuscle invasive) or invasive (muscle invasive)
- 70-80% present as superficial lesion.
- Superficial lesions
  - Carcinoma in situ: flat lesion, high grade
  - Ta: noninvasive papillary carcinoma
  - T1: extends into submucosa, lamina propria
- Invasive cancer
  - T2: invasion into muscle
    - pT2a: invasion into superficial muscle
    - pT2b: invasion into deep muscle
  - T3: invasion into perivesical fat
    - pT3a: microscopic
    - pT3b: macroscopic
  - T4: invasion into adjacent organs
    - aT4a: invades prostate, uterus, or vagina
    - aT4b: invades abdominal or pelvic wall
- N1-N3: invades lymph nodes
- M: metastasis to bone or soft tissue

## **TREATMENT**

For nonmuscle-invasive bladder cancer, the treatment is generally removal via cystoscopic surgery (see earlier discussion re: PDD). For muscle-invasive cancer, a radical cystectomy with

pelvic lymphadenectomy is preferred (11)[B].

## MEDICATION

### First Line

- A recent meta-analysis demonstrated neoadjuvant chemotherapy using platinum-based combination chemotherapy (with <sup>3</sup> 1 of doxorubicin/epirubicin, methotrexate, or vinblastine), but not platinum alone, confers a significant survival advantage in patients with invasive bladder cancer, with an increase in survival at 5 years from 45% (without neoadjuvant treatment) to 50% (with treatment) (combined hazard ratio 0.86; 95% CI, 0.77-0.95) (12)[A].

P.129

- Intravesical bacillus Calmette-Gužrin (BCG) after TURBT in high-grade lesions has been shown to decrease recurrence in Ta and T1 tumors (13)[A].

### Second Line

- Chemotherapy is the first-line treatment for metastatic bladder cancer:
  - Methotrexate-vinblastine-doxorubicin-cisplatin (MVAC) is the preferred regimen.
- A recent review showed that gemcitabine plus cisplatin may be better tolerated and result in equivalent survival to MVAC, making it a possible first choice in metastatic bladder cancer.

## ISSUES FOR REFERRAL

Patients with microscopic or gross hematuria not otherwise explained or resolving should be referred to a urologist for cystoscopy.

## ADDITIONAL THERAPIES

Radiotherapy:

- In the United States, used for patients with muscle-invasive cancer who are not surgical candidates
- Preoperative (radical cystectomy) radiotherapy also an option
- Treatment of choice for muscle-invasive cancer in some European and Canadian centers:
  - 65 to 70 Gy over 6 to 7 weeks is standard.

## SURGERY/OTHER PROCEDURES

- Surgery is definitive therapy for superficial and invasive cancer:

- Superficial cancer: TURBT sometimes followed by intravesical therapy
- Invasive cancer
  - Radical cystectomy for invasive disease that is confined to the bladder is more effective than radical radiotherapy. There is insufficient evidence to recommend one form of urinary diversion over another (14).

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

Need for surgery or intensive therapy

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Superficial cancers
  - Urine cytology alone has not been shown to be sufficient for follow-up.
  - Cystoscopy every 3 months for 18 to 24 months, every 6 months for the next 2 years, then annually
- Follow-up for invasive cancers depends on the approach to treatment.
- Patients treated with BCG require lifelong follow-up.

## *DIET*

Continue adequate fluid intake.

## *PATIENT EDUCATION*

Smoking cessation

## *PROGNOSIS*

- 5-year relative survival rates (1)
  - Overall survival: 77.4%
    - In situ 95.9%
    - Localized: 69.9%

Regional metastasis: 34.0%

◦ Distant metastasis: 5.4%

- Superficial bladder cancer
  - BCG treatment prevents recurrence versus TURBT alone; difference 30%, NNT 3.3
  - BCG prevents progression versus TURBT alone, difference 8%
- Invasive cancer
  - T2 disease: Radical cystectomy results in 60-75% 5-year survival.
  - T3 or T4 disease: Radical cystectomy results in 20-40% 5-year survival.
  - Neoadjuvant chemotherapy with cystectomy has led to varying degrees of increased survival.
  - Radiation with chemotherapy has led to varying degrees of increased survival.
- Metastatic cancer:
  - MVAC resulted in mean survival of 12.5 months.

## COMPLICATIONS

- Superficial bladder cancer
  - Local symptoms
    - Dysuria, frequency, nocturia, pain, passing debris in urine
    - Bacterial cystitis
    - Perforation
  - General symptoms
    - Flulike symptoms
    - Systemic infection
- Invasive cancer
  - Symptoms related to definitive treatment, including incontinence, bleeding
  - Patients with neobladder at risk for azotemia and metabolic acidosis

- Hematuria
- Algorithm: Hematuria

## Codes

### ICD10

- C67.9 Malignant neoplasm of bladder, unspecified
- C67.4 Malignant neoplasm of posterior wall of bladder
- C67.3 Malignant neoplasm of anterior wall of bladder

## Clinical Pearls

- Painless hematuria in smokers should be evaluated with cystoscopy.

- Be aware of potential link between pioglitazone treatment and risk for bladder cancer.
- The U.S. Preventive Services Task Force recommends against routine screening for bladder cancer.

# Blepharitis

**Barton L. Blackorby, MD**

**Erin S. Seefeldt, MD**

## **BASICS**

### *DESCRIPTION*

- Common, usually chronic, inflammatory reaction of the eyelid margin
- Commonly presents as irritation, burning, redness, flaking, and crusting of the eyelids worse in morning
- Defined as anterior or posterior blepharitis with considerable overlap
  - Anterior blepharitis:
    - Staphylococcal
      - Seborrheic
  - Posterior blepharitis:
    - Meibomian gland dysfunction (MGD)
- Areas affected: cornea, eyelid
- Can be primary or secondary to a systemic disease

### *EPIDEMIOLOGY*

#### *Incidence*

- Very common
- All ethnic groups (Asians > Caucasians)
- Predominant age:
  - Nonstaphylococcal (average age: 50)
  - Staphylococcal (average age: <42)
- Predominant sex:

- Nonstaphylococcal: male = female
- Staphylococcal: male < female

## **RISK FACTORS**

- Seborrheic dermatitis
- Contact dermatitis
- Herpes simplex dermatitis
- Varicella-zoster dermatitis
- Acne rosacea
- Immunocompromised state (e.g., AIDS, chemotherapy)
- Isotretinoin use
- Dry eye syndrome
- *Demodex folliculorum* infestation
- Giant papillary conjunctivitis

## **ETIOLOGY**

- Seborrheic
  - Anterior eyelid inflammation secondary to increased and abnormal meibomian gland secretions
  - Eyelid erythema, crusting, and oily appearance
  - Can be associated with keratitis presenting as punctate epithelial erosions
  - Associated with acne rosacea
- Staphylococcal
  - Infection of the glands of the eyelid margin
  - Commonly caused by *Staphylococcus aureus* and coagulase-negative *Staphylococcus*, with occasional concomitant *Moraxella lacunata* infection
  - Crusting (golden) around eyelashes that is worse in the morning, collarette formation around lashes, scaling, crusting, and erythema
  - Severe cases are associated with keratitis and eyelid ulceration.
- Meibomian gland dysfunction: chronic obstruction and inflammation of the meibomian glands;

associated with acne rosacea, acne vulgaris, and oral retinoid therapy

- Other types of blepharitis:
  - Contact dermatitis/blepharitis:
    - Develops from type IV hypersensitivity; common causes include ocular medications, topical anesthetics, antivirals, and cosmetics.
    - May occur with secondary *Staphylococcus* infection
  - Eczematoid blepharitis
    - Caused by type I hypersensitivity reaction to exotoxins and antigens from local flora
    - Strong association with eczema and asthma
    - Staphylococcal infection common
  - Parasitic blepharitis
    - Cylindrical sleeves along lashes
    - Found in 30% of chronic blepharitis

## PATHOPHYSIOLOGY

- The exact etiopathogenesis is unknown.
- Suspected to be multifactorial
  - Chronic low-grade infections of the ocular surface with bacteria
  - Infestations with certain parasites such as the mite *Demodex*
  - Inflammatory skin conditions such as atopy and seborrhea

## COMMONLY ASSOCIATED CONDITIONS

See ÒRisk FactorsÓ and ÒDifferential Diagnosis.Ó

## DIAGNOSIS

### HISTORY

- Duration of symptoms
- Unilateral or bilateral presentation
- Note any exacerbating conditions (e.g., smoke, allergens, wind, contact

lenses).

- Pertinent past medical history: rosacea, herpetic zoster, autoimmune disease
- Current and recent medication use
- Recent exposure to infected individuals
- Frequently reported in all types of blepharitis
  - Burning
  - Itching
  - Eyelid erythema
  - Conjunctival infection (red eyes)
  - Lacrimation, tearing
  - Tear deficiency
  - Foreign body sensation
  - Photophobia (light sensitivity)
  - Impaired vision

## *PHYSICAL EXAM*

- Test of visual acuity
- External exam (skin and eyelids)
  - Staphylococcal
    - Recurrent sty (external or internal hordeolum)
    - Missing, broken, or misdirected eyelashes (trichiasis)
    - Eyelid deposits: matted, hard scales; collarettes (ring-like formation around the lash shaft)
    - Ulcerations at base of eyelashes (rare)
    - Eyelid scarring may occur.
  - Seborrheic blepharitis
    - Eyelid deposits: dry flakes; oily or greasy secretions on lid margins and/or lashes
    - Associated dandruff of scalp and eyebrows
  - Meibomian gland dysfunction
    - Eyelash misdirection may occur with longstanding disease.

- Eyelid deposits: fatty deposits; may be foamy
- Eyelid margin thickening
- Plugged meibomian gland orifices
  - No expression of fluid upon gentle pressure of lid
- Chalazion (sometimes multiple)
- Eyelid scarring (notching) with long-term disease
- Association with ocular rosacea
- Mixed blepharitis: Signs and symptoms of >1 type of blepharitis may be present.

## *DIFFERENTIAL DIAGNOSIS*

- Masquerade syndrome (1)
  - Persistent inflammation and thickening of eyelid margin may indicate squamous cell, basal cell, or sebaceous cell carcinoma masquerading as blepharitis. These carcinomas also may mimic styes or chalazia.
- Impetigo/erysipelas
- Herpetic zoster ophthalmicus
- Viral infections
- Contact or atopic dermatitis
- Medicamentosa

## *DIAGNOSTIC TESTS & INTERPRETATION*

### **Follow-Up Tests & Special Considerations**

- Consider masquerade syndrome in all cases of recurrent, persistent, or atypical chalazion; chronic unilateral unresponsive blepharoconjunctivitis; diffuse or nodular tumors of the eyelid; orbital mass developing after removal of an eyelid or caruncular tumor; and any tumor developing in a person with a history of ocular radiotherapy.
- Cultures in atypical blepharitis
- Biopsy in atypical cases for carcinoma
- Slit-lamp biomicroscopy
  - Examine tear film, eyelid margins, eyelashes, tarsal and bulbar conjunctiva, and cornea.

- Fluorescein eye stain to evaluate for punctate epithelial keratitis
- Inspect for loss of lashes (madarosis), whitening of the lashes (poliosis), trichiasis, crusting, eyelid margin ulcers, and lid irregularities.

## TREATMENT

### GENERAL MEASURES

- Promote proper eyelid hygiene (2,3)[C].
  - Apply warm compresses for several minutes at least once a day to soften adherent encrustations.
  - The eyelid margins then are scrubbed gently with eyelid cleanser or diluted baby shampoo twice a day to remove adherent material and clean the meibomian gland orifices (4)[C].
- Gentle vertical massage of the eyelids can help to express meibomian secretions in patients with meibomian gland dysfunction (2)[C].
- Discontinue soft contact lenses use during an acute case of blepharitis (3)[B].

### MEDICATION

#### First Line

- According to Cochrane 2012, topical antibiotics provided some symptomatic relief and were effective in eradicating bacteria from the eyelid margin for anterior blepharitis. Lid hygiene may provide symptomatic relief for anterior and posterior blepharitis. The effectiveness of other treatments for blepharitis, such as topical steroids and PO antibiotics, was inconclusive (5)[A].
- No strong evidence supports any of the treatments in terms of curing chronic blepharitis (5)[A].
- Topical treatment to lid, if *Staphylococcus* likely:
  - Bacitracin ointment: 500  $\mu\text{g/g}$  or (second choice)
  - Erythromycin: 0.5% ophthalmic ointment
    - The frequency and duration of treatment are guided by the severity (2)[C].
    - Topical corticosteroids (short term) should be used cautiously and briefly if at all and only for severe eyelid or ocular surface inflammation. The minimum effective dose and

duration should be used; long-term use should be avoided if possible (6)[C].

- For patients with meibomian gland dysfunction inadequately controlled with eyelid hygiene, consider doxycycline 100 mg/day or tetracycline 1,000 mg/day in divided doses, tapered after clinical improvement (2 to 4 weeks) to doxycycline 50 mg/day or tetracycline 250 to 500 mg/day (2)[C].
- Oral azithromycin (500 mg/day for 3 days in three cycles with 7-day intervals) has been used successfully in the management of blepharitis associated with acne rosacea as an alternative to oral tetracyclines (2)[C].
- Because aqueous tear deficiency is common in blepharitis, use twice-daily artificial tears in addition to eyelid hygiene and medications.
- Contraindications: Allergy to medication; tetracyclines are not for use in pregnancy, nursing women, or children <8 years of age.
- Precautions
  - Tetracyclines can cause photosensitization, gastrointestinal upset, vaginitis, and rarely, azotemia. Tetracyclines have been implicated in cases of pseudotumor cerebri, and their metabolism may alter the effectiveness of certain medications (2).
  - Corticosteroids may increase intraocular pressure and risk of cataract.
  - Oral azithromycin can cause problems in patients with heart disease as it may cause irregular heart rhythms (2).

## *Second Line*

Topical fluoroquinolones (e.g., gatifloxacin 0.3%, levofloxacin 0.5%, or moxifloxacin 0.5%) may be helpful for persistent or recurrent staphylococcal blepharitis or for those patients who prefer a solution.

## *ISSUES FOR REFERRAL*

- Chronic recurrent blepharitis requires referral to an ophthalmologist for evaluation whether patient should continue soft lens use.
- A patient with chronic blepharitis that does not respond to therapy, particularly if associated with loss of eyelashes or corneal changes.

## *ADDITIONAL THERAPIES*

Various commercial products are marketed to consumers and prescribed to patients; however, there is no substantial evidence of effectiveness (5)[A].

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- Patients should schedule a return visit if their condition worsens despite treatment.
- Return visit intervals for patients with severe disease vary.
- If corticosteroid is prescribed, reevaluate within a few weeks to measure intraocular pressure and determine response to therapy.

### PATIENT EDUCATION

- ÒBlepharitis Fact SheetÓ from the American Academy of Ophthalmology
- Advise patient that blepharitis is a chronic condition likely to recur if eyelid hygiene is not maintained after antibiotic treatment is discontinued.

### PROGNOSIS

Blepharitis cannot be permanently cured, and successful management is dependent on patient compliance with treatment regimen.

### COMPLICATIONS

- Stye and chalazion
- Scarring of eyelid margin
- Corneal infection
- Superficial keratopathy
- Corneal neovascularization and ulceration
- Ectropion/entropion

## See Also

Lacrimal Disorders (Dry Eye Syndrome)

## Codes

### ICD10

- H01.009 Unspecified blepharitis unspecified eye, unspecified eyelid
- H01.019 Ulcerative blepharitis unspecified eye, unspecified eyelid
- L21.8 Other seborrheic dermatitis

## Clinical Pearls

- Blepharitis is often a chronic condition; symptoms frequently can be lessened but rarely are eliminated.
- Promote proper eyelid hygiene.
- Bacitracin or erythromycin ophthalmic ointment is the first-line treatment if *Staphylococcus* is suspected.

# Borderline Personality Disorder

Daniel E. Melville, MD

William G. Elder, PhD

## BASICS

### DESCRIPTION

Beginning no later than adolescence or early adulthood, borderline personality disorder (BPD) is a consistent and pervasive pattern of labile affect and sense of self, impulsivity, and volatile interpersonal relationships (1):

- Common behaviors and variations:
  - Self-mutilation: pinching, scratching, cutting
  - Suicide: ideation, history of attempts, plans
  - Splitting: idealizing then devaluing others
  - Presentation of helplessness or victimization
  - High utilization of emergency department and resultant inpatient hospitalizations for psychiatric treatment
  - BPD patients are frequent users of primary care (2).
- High rate of associated mental disorders
- Typically display little insight into behavior

### *Geriatric Considerations*

Illness (both acute and chronic) may exacerbate BPD and may lead to intense feelings of fear and helplessness.

### *Pediatric Considerations*

Diagnosis is rarely made in children. Axis I disorders and general medical conditions are more probable.

### *Pregnancy Considerations*

Physical, emotional, and social concerns may transiently mimic symptoms of BPD: Consider delay

in diagnosis until pregnancy completed. Pregnancy may also induce stress or increased fears, resulting in escalation of borderline behaviors.

## *EPIDEMIOLOGY*

Predominant age: Onset no later than adolescence or early adulthood (may go undiagnosed for years)

### *Prevalence*

- General population: 0.5-5.9% of U.S. population (2)
- Estimated lifetime prevalence: 10-13% (2)
- 10% of all psychiatric outpatients and between 15% and 25% of patients in psychiatry inpatient settings have BPD (2).
- 20-30% of patients in primary care outpatient settings have a personality disorder.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Undetermined, but generally accepted that psychiatric disorders are due to a combination of the following:

- Hereditary temperamental traits
- Environment (i.e., history of childhood sexual and/or physical abuse, history of childhood neglect, ongoing conflict in home)
- Stress is theorized to exert damaging effects on the brain, specifically the hippocampus (2,3).
- Neurobiologic research of BPD continues to increase the understanding of the etiology:
  - Abnormalities of the frontolimbic circuitry in relation to poor emotional stability (2)
  - Potential alterations in the sensitivity of opioid receptors and/or deficiencies with endogenous opioids (4)
  - Heightened activity in brain circuits involved in the experience of negative emotions and reduced activation that normally suppresses negative emotion once it is generated (5).

### *Genetics*

First-degree relatives are at greater risk for this disorder (undetermined if due to genetic or psychosocial factors).

## *RISK FACTORS*

- Genetic factors contribute; however, no specific genes have yet been identified as causative

(2).

- Childhood sexual and/or physical abuse and neglect
- Disrupted family life
- Physical illness and external social factors may exacerbate borderline personality behaviors.

## **GENERAL PREVENTION**

- Tends to be a multigenerational problem
- Children, caregivers, and significant others should have some time and activities away from the borderline individual, which may protect them.

## **COMMONLY ASSOCIATED CONDITIONS**

Other psychiatric disorders, including:

- Co-occurring personality disorders, frequent
- Mood disorders, common
- Anxiety disorders, common
- Substance-related disorders, common
- Eating disorders, common
- Posttraumatic stress disorder, common
- BPD does not appear to be independently associated with increased risk of violence.

## **DIAGNOSIS**

- The comprehensive evaluation should focus on (6)[B]:
  - Comorbid conditions
  - Functional impairments
  - Adaptive/maladaptive coping styles
  - Psychosocial stressors
  - Patient strengths; needs/goals
- Initial assessment should focus on determining treatment setting (6)[B]:
  - Establish treatment agreement with patient and outline treatment goals.

- Assess suicide ideation and self-harm behavior.
- Assess for psychosis.
- Hospitalization is necessary if patient presents a threat of harm to self or others.

## HISTORY

- Clinic visits for problems that do not have biologic findings
- Conflicts with medical staff members
- Idealizing or unexplained anger at physician
- History of unrealistic expectations of physician (e.g., "I know you can take care of me." "You're the best, unlike my last provider.")
- Obtain collateral information (i.e., from family, partner) about patient behaviors
- History of interpersonal difficulties, affective instability, and impulsivity
- History of self-injurious behavior, possibly with suicidal threats or attempts (7)

## PHYSICAL EXAM

- BPD patients should have a thorough physical examination to help lower suspicion of organic disease (especially thyroid disease) (1,2).
- Often physical examination reveals no gross abnormalities, other than related to scarring from self-mutilation.

## DIFFERENTIAL DIAGNOSIS

- Mood disorders:
  - Look at baseline behaviors when considering BPD versus mood disorder.
  - BPD symptoms increase the likelihood of misdiagnosing bipolar disorder.
  - In particular, disruptive mood dysregulation disorder, a new diagnosis appearing in *DSM-5* and characterized by severe recurrent temper outbursts manifesting verbally or behaviorally and grossly out of proportion to the situation, may appear quite similar to the acting out and intense emotions seen in BPD. Look for other symptoms characteristic of BPD to differentiate (1).
- Psychotic disorder:
  - With BPD, typically only occurs under intense stress and is characterized as òmicropsychotic.Ó

- Other PD:
  - Thoughts, feelings, and behavior will differentiate BPD from other PDs.
- GMC:
  - Traits may emerge due to the effect of a GMC on the CNS.
- Substance use

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Consider age of onset. To meet criteria for BPD, borderline pattern will be present from adolescence or early adulthood.
- Formal psychological testing
- Rule out personality change due to a general medical condition (GMC) (1)[C]:
  - Traits may emerge due to the effect of a GMC on the CNS.
- Rule out symptoms related to substance use.
- If symptoms begin later than early adulthood or are related to trauma (e.g., after a head injury), a GMC, or substance use, then consider other diagnoses.

## *Diagnostic Procedures/Other*

According to *DSM-5* criteria, patient must meet at least five of the following criteria (1)[C]:

- Attempt to avoid abandonment
- Volatile interpersonal relationships
- Identity disturbance
- Impulsive behavior:
  - In <sup>3</sup>2 areas
  - Impulsive behavior is self-damaging.
- Suicidal or self-mutilating behavior
- Mood instability
- Feeling empty
- Is unable to control anger, or finds it difficult
- Paranoid or dissociative when under stress

- With advent of *DSM-5*, an alternative model is being promulgated that may come to define the diagnosis as impairments in personality functioning AND the presence of pathologic traits. Attention to these features may ultimately enhance provider understanding, diagnosis, and treatment of patients with personality dysfunction.
  - Criteria regarding personality functioning refer to impairments of self-functioning (i.e., identity or self-direction) AND interpersonal functioning (i.e., empathy or intimacy).
  - Pathologic personality traits refer to characteristics in the domains of negative affectivity (i.e., emotional lability, anxiousness, separation insecurity, depressivity); disinhibition (i.e., impulsivity, risk taking); OR antagonism (1).

## TREATMENT

- Outpatient psychotherapy for BPD is the preferred treatment (2,6)[B]:
  - Dialectical behavior therapy (DBT) combines cognitive-behavioral techniques for emotional regulation and reality-testing with concepts of distress tolerance, acceptance, and self-awareness.
    - Following a dialectal process, therapists are tough-minded allies, who validate feelings and are unconditionally accepting, while also reminding patients to accept their dire level of emotional dysfunction and to apply better alternative behaviors.
    - DBT may be done individually and in groups.
- Consider transference-focused psychotherapy.
- Patient may need to be placed on suicide watch.
- Brief inpatient hospitalizations are ineffective in changing Axis II disorder behaviors:
  - Hospitalizations should be limited, and of short duration to adjust medications, implement psychotherapy for crisis intervention, and to stabilize patients from psychosocial stressors.
- Extended inpatient hospitalization should be considered for the following reasons (6)[B]:
  - Persistent/severe suicidal ideation or risk to others
  - Comorbid substance use and/or nonadherence to outpatient or partial hospitalization treatments
  - Comorbid Axis I disorders that may increase threat to life for the patient (i.e., eating disorders, mood disorders).

## GENERAL MEASURES

Focus on patient management rather than on "fixing" behaviors:

- Schedule consistent appointment follow-ups to relieve patient anxiety.
- Meet with and rely on treatment team to avoid splitting of team by patient, and to provide opportunity to discuss patient issues.
- Treatment is usually most effective when both medications and psychotherapy are used simultaneously.

## MEDICATION

- Although no specific medications are approved by the FDA to treat BPD, American Psychiatric Association (APA) guidelines recommend pharmacotherapy to manage symptoms (2)[A],(6)[B].
- Treat Axis I disorders (6)[B].
- Consider high rate of self-harm and suicidal behavior when prescribing (2)[A].
- APA guideline recommendations (6)[B]:
  - Affective dysregulation: mood stabilizers, SSRIs, and monoamine oxidase inhibitors (MAOIs)
  - Impulsive-behavioral control: SSRIs and mood stabilizers
  - Cognitive-perceptual symptoms: antipsychotics
- With more neurobiologic causes considered in relation to BPD, there is more emphasis on mood stabilizers and atypical antipsychotics, but research is uncertain and inconclusive (8)[B].
- Antipsychotics have short-lived benefit and offer no value other than transient treatment of cognitive perceptual symptoms (9)[B].

## ISSUES FOR REFERRAL

- If hospitalized, consider for suicide risk, mood or anxiety disorders, or substance-related disorders.
- Urgency for scheduled follow-up depends on community resources (e.g., outpatient day programs for suicidal patients; substance abuse programs):
  - With increased risk for self-harm or self-defeating behaviors and low community resources, the patient can/will have increased need for frequent visits.

## ADDITIONAL THERAPIES

Consider referring patient for specialized mental health behavioral services, including partial

hospital therapy.

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Omega-3 fatty acid dietary supplementation has shown beneficial effects (2)[B].

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

Admit for inpatient services immediately in presence of psychosis or threat of injury to self or others; include police, as necessary, for safety measures.

- Assess suicidal ideation.
- Consider trial of antipsychotic medications for psychosis.

### ***Nursing***

Nurses can be instrumental in managing and caring patients, potentially relieving patient stress.

### ***Discharge Criteria***

- Patient should not present risk of harm to self or others and have a safety plan.
- Follow-up should be scheduled with a mental health specialist and primary care provider.

## **ONGOING CARE**

## **FOLLOW-UP RECOMMENDATIONS**

- Schedule visits that are short, more frequent, and focused to relieve patients' anxiety about relationships with their physician/provider and to help reduce risk of provider burnout.
- Maintain open lines of communication with mental health professionals providing psychological support.
- Emphasize importance of healthy lifestyle modifications (i.e., exercise, rest, diet).

### ***Patient Monitoring***

Monitor for suicidal or other self-harm behaviors.

## **PATIENT EDUCATION**

Include patients in the diagnosis so they can make sense of their disease process and participate in the treatment strategy (6,9)[C].

## PROGNOSIS

- Borderline behaviors may decrease with age and over time.
- Patients in treatment improve at a rate of seven times compared with following natural course (10).
- Treatment is complex and takes time.
- Medical focus includes patient management and caring for medical and Axis I disorders.

## Codes

### ICD10

F60.3 Borderline personality disorder

## Clinical Pearls

- View BPD as a chronic condition with waxing and waning features. It is important to adjust medications/treatments as clinically appropriate when symptoms change.
- If there are problems with the patient disrespecting the physician or support staff, clear guidelines should be established with the treatment team and then with the patient.
- When considering terminating care, the patient may improve if empathetically confronted about certain behaviors and is given clear guidelines on how to behave in the clinic. It is the patient's job to follow the guidelines, and it is you and your team's job to enforce the guidelines. Designate a case management nurse or well-trained support staff person who can be the primary contact person for the patient.
- Have an agenda when you visit with BPD patients. Be cordial—they deserve the same professionalism any patient gets. Have and identify 1 to 2 issues to be discussed per clinic visit. Frequently scheduled visits can help with this.
- Regularly scheduled psychotherapy treatment helps physician performance by becoming the “home” for mental health treatment, leaving the physician to focus on the patient's immediate medical issues.

# Brain Injury, Traumatic

Caleb J. Mentzer, DO

James R. Yon, MD

## BASICS

### DESCRIPTION

- Traumatic brain injury (TBI) is defined as an alteration in brain function, or other evidence of brain pathology, caused by an external force.
- System(s) affected: neurologic; psychiatric; cardiovascular; endocrine/metabolic; gastrointestinal
- Synonym(s): head injury, concussion

### EPIDEMIOLOGY

#### *Incidence*

- 2.2 million ED visits and 280,000 hospitalizations/year
- 50,000 deaths/year; ÷30% of all injury-related deaths
- Incidence in males twice that of females with 4-fold risk of fatal trauma

#### *Prevalence*

- Predominant age: 0 to 4 years, 15 to 19 years, and >65 years
- Predominant gender: male > female (2:1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Falls (40%)
- Motor vehicle accidents (14%)
- Assault (10%)
- Child abuse (24% of TBI age 2 years and younger)
- Recreational activities (21% of pediatric TBI, peak seasons spring/summer; peak ages 10 to 14)

years)

- Primary insult: direct mechanical damage
- Secondary insult: actuation of complex cellular and molecular cascades that promote cerebral edema, ischemia, and apoptotic cell death

## **RISK FACTORS**

Alcohol and drug use, prior/recurrent head injury, contact sports, seizure disorder, ADHD, male sex, luteal phase of female menstrual cycle

### *Geriatric Considerations*

Subdural hematomas are common after a fall or blow in elderly; symptoms may be subtle and not present until days after trauma. Many elderly patients are on antiplatelet or anticoagulation therapy.

## **GENERAL PREVENTION**

- Safety education
- Seat belts; bicycle and motorcycle helmets
- Protective headgear for contact sports

### *Pediatric Considerations*

Child abuse: Consider if dropped or fell <4 feet (e.g., off bed, couch), suspicious history, significant injury present, or any retinal hemorrhages.

## **DIAGNOSIS**

### **HISTORY**

- Loss of consciousness (LOC), headache, vomiting, amnesia
- Epidural hemorrhage from blunt trauma: 30% with a “lucid interval” (initial LOC followed by recovery of consciousness, then LOC recurs and persists)

### **PHYSICAL EXAM**

- Neurologic and cognitive testing is important.
- Repeat neurologic exams every 30 minutes until 2 hours after GCS reaches 15, then hourly for 4 hours, then every 2 hours.
- Evidence of increased intracranial pressure (ICP) (elevated BP, decreased pulse rate, or

slow/irregular breathing [Cushing triad] (Only 30% have all 3)

- Decorticate or decerebrate posturing
- Signs of basilar skull fracture: raccoon eyes, Battle sign, hemotympanum, CSF rhinorrhea or otorrhea)

## ***DIFFERENTIAL DIAGNOSIS***

Other causes of altered mental status (e.g., toxicologic, infectious, metabolic, vascular)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Mild TBI and concussions cognitive screening tests
  - Sports Concussion Assessment Tool V3 (SCAT3)
  - Child SCAT3
  - Concussion Recognition Tool (CRT)
  - Standardized Assessment of Concussion (SAC)
  - King-Devick Test
  - Balance Error Scoring System (BESS)
- Evaluate for coagulopathy.
- Type and screen for possible surgical intervention.
- Perform drug and alcohol screening.
- CT, noncontrast, is the study of choice to review bone windows, tissue windows, and subdural space.
- NEXUS II study demonstrated that if all eight clinical criteria are absent, there is a low likelihood of significant TBI:
  - Evidence of significant skull fracture (depressed, basilar, or diastatic)
  - Altered level of alertness
  - Neurologic deficit
  - Persistent vomiting
  - Presence of scalp hematoma
  - Abnormal behavior

- Coagulopathy
- Age >65 years

## *Follow-Up Tests & Special Considerations*

Blast-related TBI: much higher rates of postconcussive syndrome, PTSD, depression, and chronic pain. Chronic impairment is strongly correlated with psychological factors. Return to battlefield guidelines similar to return to play in sports (see "General Measures") (1)[A]

## *Pediatric Considerations*

Skull radiographs are not indicated unless abuse is suspected in which case they can detect fractures not seen under CT. No return to activity until they are asymptomatic, and return to school should precede return to sport/physical activity (2)[A].

## *Diagnostic Procedures/Other*

- CSF rhinorrhea
  - Contains glucose; nasal mucus does not.
  - Check for the double-halo sign: If nasal discharge contains CSF and blood, two rings appear when placed on filter paper—a central ring followed by a paler ring.
- ICP monitors are associated with lower mortality, but use is not superior to nonuse (3)[A].

## **TREATMENT**

### *GENERAL MEASURES*

- Acute management depends on injury severity. Most patients need no interventions.
- Immediate goal: Determine who needs further therapy, imaging studies (CT), and hospitalization to prevent further injury.
- For the mildly injured patient
  - Early education is beneficial for recovery (4)[A].
  - **Return to play (RTP)**
    - Never RTP on same day.
    - Strict guidelines for graduated return to cognitive and physical activity when there are no evident signs or symptoms (physical, cognitive, emotional, or behavioral) on neuropsychological and clinical evaluation (2)[A]

- For the moderate to severely injured patient
  - Avoid hypotension or hypoxia. Head injury causes increased ICP secondary to edema, and cerebral perfusion pressure (CPP) should be maintained between 60 and 70 mm Hg (5)[A].
  - 30-degree head elevation decreases ICP and improves CPP.
  - Hyperventilation (hypocapnia)
    - Use should be limited to patients with impending herniation while preparing for definitive treatment or intraoperatively. Risk of worsening cerebral ischemia and organ damage (5,6,7)[A]
    - Addition of tromethamine can offset deleterious effects and lead to better outcomes (7) [A].
  - Mild systematic hypothermia lowers ICP but leads to increased rates of pneumonia. Selective brain cooling may also decrease ICP with improved outcomes at 2 years post injury (7)[A].
- Seizure prophylaxis
  - Does not change morbidity or mortality. Consider phenytoin or levetiracetam for 1 week post injury or longer for patients with early seizures, dural-penetrating injuries, multiple contusions, and/or subdural hematomas requiring evacuation (8)[A].

## MEDICATION

### First Line

- Pain
  - Morphine: 1 to 2 mg IV PRN, with caution, because it can depress mental status, further altering serial neurologic evaluations

### **ALERT**

Bolus doses increase ICP and decrease CPP (9)[A].

- Increased ICP
  - Hypertonic saline: 2 mL/kg IV decreases ICP without adverse hemodynamic status; preferred agent (5,9)[A]
  - Mannitol: 0.25 to 2 g/kg (0.25 to 1 g/kg in children) given over 30 to 60 minutes in patients with adequate renal function. Prophylactic use is associated with worse outcomes (9)[A].

- Sedation
  - Propofol: preferred due to short duration of action. Avoid high doses to prevent propofol infusion syndrome. When combined with morphine, it can also effectively decrease ICP and decrease use of other meds (9)[A].
  - Midazolam: similar sedating effect to propofol but may cause hypotension (9)[A]
- Seizures
  - Phenytoin (Dilantin): 15 mg/kg IV (1 mg/kg/min IV, not to exceed 50 mg/min). Stop infusion if QT interval increases by >50%.

**ALERT**

Avoid corticosteroid use, as it increases mortality rates and risk of developing late seizures (9)[A]. Avoid barbiturates due to risk of hypotension (9)[A].

**ISSUES FOR REFERRAL**

Consult neurosurgery for:

- All penetrating head trauma
- All abnormal head CTs

**ADDITIONAL THERAPIES**

- Emerging therapies with limited but promising evidence: coma arousal therapy: amantadine, zolpidem, and levodopa/carbidopa; post coma therapy: bromocriptine
- Limited role for therapeutic hypothermia with defined physiologic parameters (10)[A]

**SURGERY/OTHER PROCEDURES**

- Early evacuation of trauma-related intracranial hematoma decreases mortality especially with GCS <6 and CT evidence of hematoma, cerebral swelling, or herniation (11)[A].
- Decompressive craniectomy reduces ICP especially when a large bone flap is removed. ONLY for adults and ONLY with GCS >6 (7)[A].
- Hyperbaric oxygen temporarily lowers ICP and improves mortality, but evidence is conflicting about outcomes at 6 to 12 months post injury (7)[A]. The combination of hyperbaric and normobaric hyperoxia reduces ICP and improves overall morbidity/mortality (12)[B].
- CSF drainage reduces ICP but has not been demonstrated to have long-term benefit (7)[A].
- CSF leakage often resolves in 24 hours with bed rest, but if not, may require surgical repair (5)

[A].

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Music therapy in conjunction with multimodal stimulation improves awareness in comatose TBI patients (10)[B].

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

- Abnormal GCS or CT
- Clinical evidence of basilar skull fracture
- Persistent neurologic deficits (e.g., confusion, somnolence)
- Patient with no competent adult at home for observation
- Possibly admit: LOC, amnesia, patients on anticoagulants with negative CT
- ABCs take priority over head injury.
- C-spine immobilization should be considered in all head trauma.

### ***IV Fluids***

Use normal saline for resuscitation fluid.

### ***Discharge Criteria***

Normal CT with return to normal mental status and responsible adult to observe patient at home (see "Patient Monitoring")

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Schedule regular follow-up within a week to determine return to activities.
- Rehabilitation indicated following a significant acute injury. Set realistic goals.
- For patients on anticoagulants, net benefit to restarting therapy after discharge despite increased bleeding risk.

### ***Patient Monitoring***

Patient should be discharged to the care of a competent adult with clear instructions on signs and

symptoms that warrant immediate evaluation (e.g., changing mental status, worsening headache, focal findings, or any signs of distress). Patients should be monitored but not awakened from sleep.

## **DIET**

As tolerated, monitor for signs of nausea.

## **PATIENT EDUCATION**

Proper counseling, symptomatic management, and gradual return to normal activities are essential.

## **PROGNOSIS**

- Gradual improvement may continue for years.
- 30-50% of severe head injuries may be fatal.
- Predicting outcome is difficult; many with even minor to moderate injuries have moderate to severe disability at 1 year, whereas prolonged coma may be followed by satisfactory outcome.
- Patients may have new-onset seizures over 2 years following trauma.
- Poor prognostic factors: low GCS on admission, nonreactive pupils, old age, comorbidity, midline shift

## **COMPLICATIONS**

- Chronic subdural hematoma, which may follow even "mild" head injury, especially in the elderly; often presents with headache and decreased mentation
- Delayed hematomas and hydrocephalus
- Emotional disturbances and psychiatric disorders resulting from head injury may be refractory to treatment
- Seizures: seen in 50% of penetrating head injuries, 20% of severe closed head injuries, and <5% of head injuries overall. Hematomas increase risk of epilepsy.
- Postconcussion syndrome can follow mild head injury without LOC and includes headaches, dizziness, fatigue, and subtle cognitive or affective changes.
- Second-impact syndrome occurs when the CNS loses autoregulation. An individual with a minor head injury is returned to a contact sport and, following even minor trauma (e.g., whiplash), the patient loses consciousness and may quickly herniate, with a 50% mortality. A similar syndrome of

malignant edema can occur in children with even a single injury.

- Increased risk for Alzheimer disease, Parkinson disease, and other brain disorders whose prevalence increases with age

## Codes

### ICD10

- S06.9X0A Unsp intracranial injury w/o loss of consciousness, init
- S06.5X0A Traum subdr hem w/o loss of consciousness, init
- S06.6X0A Traum subrac hem w/o loss of consciousness, init

### Clinical Pearls

- TBI involves two distinct phases: the primary mechanical insult and secondary dysregulation of the cerebrovascular system with cerebral edema, ischemia, and cell-mediated death.
- Indications for imaging include evidence of skull fracture, altered consciousness, neurologic deficit, persistent vomiting, scalp hematoma, abnormal behavior, coagulopathy, age >65 years.
- Strict criteria exist for patients to return to normal sport activity following head injury to avoid the second-impact syndrome, which has 50% mortality.

# Breast Abscess

Lindsay Petersen, MD

Andrea Madrigrano, MD

## BASICS

### *DESCRIPTION*

- Localized collection of pus within the breast parenchyma
- Can be associated with lactation or fistulous tracts secondary to squamous epithelial neoplasm or duct occlusion
- System(s) affected: skin/exocrine
- Synonym(s): mammary abscess; peripheral breast abscess; subareolar abscess; puerperal abscess

### *Pregnancy Considerations*

Most commonly associated with postpartum lactation

### *EPIDEMIOLOGY*

- Predominant age
  - Puerperal abscess: lactational
  - Subareolar abscess: postmenopausal
- Predominant sex: female
- Higher incidence in African American women

### *Incidence*

- 0.1-0.5% of breastfeeding women
- Puerperal abscess rare after first 6 weeks of lactation

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Delayed treatment of mastitis

- Puerperal abscesses: blocked lactiferous duct
- Subareolar abscess: squamous epithelial neoplasm with keratin plugs or ductal extension with associated inflammation
- Peripheral abscess: stasis within the duct leading to microbial accumulation and secondary abscess formation
- Microbiology
  - *Staphylococcus aureus* is most common cause.
  - Less common causes
    - *Streptococcus pyogenes*; *Escherichia coli*; *Bacteroides*
    - *Corynebacterium*
    - *Pseudomonas*
    - *Proteus*
- Methicillin-resistant *Staphylococcus aureus* (MRSA) is increasing. Risk factors for postpartum *S. aureus* (SA) breast abscess have not changed with rise in community-associated MRSA.

## RISK FACTORS

- Puerperal mastitis
  - 5-11% progression to abscess:
    - Most often due to inadequate therapy
  - Risk factors (stasis):
    - Infrequent or missed feeds
    - Poor latch (1)
    - Damage or irritation of the nipple
    - Use of breast pump (2)
    - Illness in mother or baby
    - Rapid weaning
    - Blocked nipple or duct
- General factors
  - Smoking (3)

- Diabetes (3)
- Rheumatoid arthritis
- Obesity (3)
- Medically induced factors
  - Steroids
  - Silicone/paraffin implant
  - Lumpectomy with radiation
  - Oral antibiotics during breastfeeding (mastitis) (2)
  - Topical antifungal medication during breastfeeding (mastitis) (2)
- Nipple retraction
- Nipple piercing (mastitis, subareolar abscess) (3)
- Higher recurrence rate if polymicrobial abscess

## **GENERAL PREVENTION**

Early treatment of mastitis with milk expression, antibiotics, and compresses

## **COMMONLY ASSOCIATED CONDITIONS**

Lactation

## **DIAGNOSIS**

### **HISTORY**

- Tender breast lump, usually unilateral
- Breastfeeding
- Postmenopausal
- Systemic malaise (usually less than with mastitis)
- Localized erythema, edema, and pain
- Fever, nausea, vomiting, or spontaneous nipple drainage

## **PHYSICAL EXAM**

- Fever, tachycardia

Erythema of overlying skin

- Tenderness, fluctuance on palpation
- Draining pus or skin ulceration
- Local edema
- Nipple and skin retraction
- Regional lymphadenopathy

## ***DIFFERENTIAL DIAGNOSIS***

- Carcinoma (inflammatory or primary squamous cell)
- Engorgement
- Galactocele
- Tuberculosis (may be associated with HIV infection)
- Sarcoid; granulomatous mastitis
- Syphilis
- Foreign body reactions (e.g., to silicone and paraffin)
- Mammary duct ectasia

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- CBC (leukocytosis)
- Elevated ESR
- Ultrasound (US) helps identify fluid collection within breast tissue.
- Culture and sensitivity of abscess fluid or expressed breast milk to identify pathogen (usually *Staphylococcus* or *Streptococcus*)
- MRSA is an increasingly important pathogen in both lactational and nonlactational abscesses.
- Other bacteria:
  - Nonlactational abscess and recurrent abscesses associated with anaerobic bacteria
    - *E. coli*, *Proteus*; mixed bacteria less common
- Mammogram to rule out carcinoma (generally not in acute phase)

## ***Diagnostic Procedures/Other***

Aspiration of abscess for culture (not accurate to exclude carcinoma)

## *Test Interpretation*

- Squamous metaplasia of the ducts
- Intraductal hyperplasia
- Epithelial overgrowth
- Fat necrosis
- Duct ectasia

## **TREATMENT**

### *GENERAL MEASURES*

- Cold compresses for pain control
- Important to continue to breastfeed or express milk to drain the affected breast

---

P.137

### *MEDICATION*

Combination of antibiotics and drainage for cure:

- Culture midstream sample of milk for mastitis.
- Culture abscess fluid for breast abscess.
- There is insufficient evidence regarding the effectiveness of antibiotic therapies for lactational mastitis alone (4)[A].

#### *First Line*

- NSAIDs for analgesia and/or antipyresis
- Dicloxacillin 500 mg QID for 10 to 14 days (5)[A]
- If no response in 24 to 48 hours, switch to cephalexin 500 mg QID for 10 to 14 days.
  - Or amoxicillin-clavulanate (Augmentin) 250 to 500 mg TID
- Clindamycin 300 mg QID if anaerobes are suspected
- If MRSA is a concern, TMP-SMZ DS 1 to 2 PO BID for 10 to 14 days. Clindamycin 300 mg PO QID as alternative

- *Contraindications:* antibiotic allergy
- In severe infections, vancomycin as an inpatient may be necessary.
  - Dose (30 mg/kg) IV in 2 divided doses every 24 hours may be necessary until culture results are available.
  - A 3rd-generation or a combination of a beta-lactam and beta-lactamase agent may need to be added as well.

## ***SURGERY/OTHER PROCEDURES***

- Aspiration with or without US guidance (6)[A]
- Consider US-guided percutaneous catheter placement if abscess >3 cm (6)[A].
- Serial aspirations under US may be necessary (q2-3d) if patients fail to respond (7)[C].
- Needle aspiration alone (without antibiotics) may be effective for small breast abscesses (8) [A].
- Consider incision and drainage if abscess is recurrent, chronic, or >5 cm (6)[A].
- Biopsy nonpuerperal abscesses to rule out carcinoma.
- Open all fistulous tracts, especially abscesses in nonlactating patients.
- US-guided aspiration with judicious use of antibiotics is superior to incision and drainage (9) [A].

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Lecithin supplementation
- Acupuncture may help with breast engorgement, and prevention of breast abscess (10)[A].

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Outpatient, unless systemically immunocompromised or septic

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

Ensure resolution to exclude carcinoma.

## **PATIENT EDUCATION**

- Wound care
- Continue with breastfeeding or pumping (if breastfeeding is not possible due to location of abscess) to prevent engorgement.

## **PROGNOSIS**

- Complete healing expected in 8 to 10 days
- Subareolar abscesses frequently recur, even after incision and drainage (I&D) and antibiotics; may require surgical removal of ducts

## **COMPLICATIONS**

- Fistula: mammary duct or milk fistula
- Poor cosmetic outcome

## Codes

### ICD10

- N61 Inflammatory disorders of breast
- O91.13 Abscess of breast associated with lactation
- O91.12 Abscess of breast associated with the puerperium

## Clinical Pearls

- 5-11% of cases of puerperal mastitis go on to abscess (most often due to inadequate therapy for mastitis). Risk factors for mastitis are those that result in milk stasis (infrequent feeds, missing feeds).
- Abscesses not associated with lactation should be treated with antibiotics that cover anaerobic bacteria.
- The treatment of choice for most breast abscesses is the combination of antibiotics and aspiration.
- US-guided aspiration of breast abscess is preferred to incision and drainage in most cases.
- Continuing to empty the breast (feeding, pumping or expression of breast milk) is recommended during the presence of lactation-associated breast infection.

# Breast Cancer

Heather A. Dalton, MD

Amy M. Davis, MD

## BASICS

### DESCRIPTION

- Malignant neoplasm of cells native to the breast—epithelial, glandular, or stroma
- Types: DCIS, infiltrating ductal carcinoma, infiltrating lobular carcinoma, Paget disease, phyllodes tumor, inflammatory breast cancer, angiosarcoma
- Molecular subtypes: luminal A (HR+/HER2-), triple negative (HR-/HER2-), luminal B (HR+/HER2+), HER2-enriched (HR-/HER2+)

### EPIDEMIOLOGY

#### Incidence

- Estimated new female breast cancer (BC) cases for in situ 60,290; invasive 231,840 in 2015
- Estimated new male BC cases 2,350
- Estimated deaths in 2015 for females 40,290; males 440
- Second most common newly diagnosed cancer, leading cause of cancer death for U.S. women

#### Prevalence

Estimated 3.1 million of 162 million U.S. women (1.9%) as of January 1, 2014 (1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Genes such as *BRCA1* and *BRCA2* function as tumor suppressor genes and mutation leads to cell cycle progression and limitations in DNA repair (2)
- Mutations in estrogen/progesterone induce cyclin D1 and *c-myc* expression, leading to cell cycle progression
- Additional tumors (33%) may cross-talk with estrogen receptors and epidermal growth factors receptors (EGFR), leading to similar abnormal cellular replication

## Genetics

- Criteria for additional risk evaluation/gene testing in *affected individual* (2)[A]
  - BC at age <sup>2</sup>50 years
  - BC at any age and <sup>3</sup> 1 family member with BC <sup>2</sup>50 years of age or ovarian/fallopian tube/primary peritoneal CA any age or <sup>3</sup>2 family members with BC or pancreatic CA any age or population at increased risk (e.g., Ashkenazi Jew with BC or ovarian CA at any age)
  - Triple-negative BC (ER-, PR-, HER2-)
  - Two BC primaries in single patient
  - Ovarian/fallopian tube/primary peritoneal CA
  - 1 + family member with BC and CA of thyroid, adrenal cortex, endometrium, pancreas, CNS, diffuse gastric, aggressive prostate (Gleason >7), leukemia, lymphoma, sarcoma, dermatologic manifestations, and/or macrocephaly, GI hamartomas
  - Male BC
  - Known BC *susceptibility gene* mutation in family
- Criteria for additional risk evaluation/gene testing in *unaffected BC individual*
  - First- or second-degree relative with BC <sup>2</sup>45 years of age
  - <sup>3</sup>2 breast primaries in one individual or <sup>3</sup>1 ovarian/fallopian tube/primary peritoneal CA from same side of family or <sup>3</sup>2 w/ breast primaries on same side of family
  - 1 + family member with BC and CA of thyroid, adrenal cortex, endometrium, pancreas, CNS, diffuse gastric, aggressive prostate (Gleason >7), leukemia, lymphoma, sarcoma, dermatologic manifestations, and/or macrocephaly, GI hamartomas
  - Ashkenazi Jewish with breast/ovary cancer at any age
  - Male BC
  - Known BC *susceptibility gene* mutation in family
- *BRCA1* and *BRCA2* account for 5-10% of female and 5-20% male cancers; 15-20% familial BCs
  - Mutations higher in Ashkenazi Jewish descent (2%)
  - Mutation in *BRCA* raises risk to 45-65% from 7% at age 70
- Other genes: *ATM*, *BARD1*, *BRIP1*, *CDH1*, *PTEN*, *STK11*, *CHEK2*, *p53*, *ERBB2*, *DIRAS3*, *NBN*, *RAD50*, *RAD51*
- Cowden syndrome (*PTEN*): autosomal dominant, BC, hamartomas of skin, intestine, oral

mucosa (trichilemmoma), microencephaly, endometrial CA, nonmedullary thyroid CA, benign thyroid lesions

- Li-Fraumeni syndrome (*TP53*): autosomal dominant, BC and CA in CNS, leukemia, sarcoma, osteosarcoma, adrenal cortex
- Ataxia-telangiectasia (*ATM*): autosomal recessive, ataxia, telangiectasia, lymphoma, leukemia, CA of breast, stomach, ovary
- Peutz-Jeghers (*STK11*): autosomal dominance; hamartomatous polyps of GI tract, mucocutaneous melanin in lips, buccal mucosa, fingers, toes; CA in GI, lung, breast, uterus, ovary

## RISK FACTORS

- Risk Assessment Tool: <http://www.cancer.gov/bcrisktool/>
- >4.0 increase in relative risk: age >65, atypical hyperplasia, *BRCA* mutation, DCIS, LCIS, personal history <40, 2 or more first-degree relatives at early age
- 2.1 to 4.0 RR: post-menopausal, radiation history, dense breasts (>50%), single first-degree relative
- 1.1 to 2.0 RR: EtOH, Ashkenazi Jewish, DES exposure, early menarche, high socioeconomic status, first pregnancy >30, fibroadenoma, never breast fed, no full term pregnancies, obesity, personal history >40, personal history of endometrial, ovarian, colon cancer, HRT long term, recent OCP use
- 20-25% lifetime risk: *BRCA* mutation, first-degree relative with *BRCA* mutation, history of radiation age 10 to 30 years, Li-Fraumeni or Cowden syndrome or first-degree relative with the same
- 15-20% lifetime risk: personal history of BC, DCIS, LCIS, atypical ductal hyperplasia, atypical lobular hyperplasia, dense or unevenly dense breasts

## GENERAL PREVENTION

- Maintain healthy weight—lean, avoid weight gain, limit high calorie foods, drinks
- Be physically active—150 minutes of moderate-intensity or 75 minutes vigorous activity weekly
- Eat healthy diet—limit processed/red meat, 2 1/2 cups of vegetables and fruits daily, limit refined-grain
- Limit EtOH to no more than 1 drink daily for women, 2 for men
- Clinical breast exam (CBE):
  - ACS: Does not recommend in average-risk

- USPSTF: Insufficient evidence to assess clinical benefits and harms (3)[A]
- Mammography:
  - ACS: women 45 to 54 annually, >55 until <10 year life expectancy biennial; 40 to 44 optional
  - USPSTF: women biennial at age 50 to 74 (3)[B]

## DIAGNOSIS

### HISTORY

- Painless lump in breast or axilla
- Breast pain, heaviness
- Swelling, thickening, redness of skin
- Nipple discharge (bloody), erosion, or retraction

### PHYSICAL EXAM

- Visualize breasts with patient sitting for skin dimpling, peau d'orange, asymmetry
- Palpation of breast and regional lymph node exam: supraclavicular, infraclavicular, axillary

### DIFFERENTIAL DIAGNOSIS

- Benign breast disease: fibrocystic disease, fibroadenoma, intraductal papilloma (bloody nipple discharge), duct ectasia, cyst, sclerosing adenosis, fat necrosis (s/p breast trauma)
- Infection: abscess, cellulitis, mastitis

### DIAGNOSTIC TESTS & INTERPRETATION

#### *Initial Tests (lab, imaging)*

- Mammography BI-RADS: Breast Imaging-Reporting and Data System is a quality assurance (QA) method published by the American Radiology Society.
- BI-RADS interpretation: 0: incomplete (need additional imaging); 1: negative; 2: benign; 3: probably benign; 4: suspicious; 5: highly suggestive of malignancy; 6: known biopsy-proven malignancy
- All newly diagnosed BC: history and physical, CBC, LFTs, ALP, pathology review, ER/PR and HER2 status determination, genetic counseling if high risk, fertility counseling if indicated

- Palpable mass <sup>3</sup>30 years: Obtain mammogram.
  - If BI-RADS 1 to 3, then get ultrasound ± biopsy.
  - If BI-RADS 4 to 6, then get core needle biopsy ± surgical excision.
- Palpable mass <30 years: Obtain ultrasound ± mammogram ± biopsy; if low clinical suspicion, observe for 1 to 2 menstrual cycles for resolution.
- Spontaneous, reproducible nipple discharge: Obtain mammogram, ± ultrasound.
  - If BI-RADS 1 to 3, then get ductogram or MRI.
  - If BI-RADS 4 to 5, then surgical excision
- Asymmetric thickening/nodularity <sup>3</sup>30 years: Obtain mammogram + ultrasound ± biopsy.
- Asymmetric thickening/nodularity <30 years: Obtain ultrasound ± mammogram ± biopsy.
- Skin changes, peau d'orange: Obtain mammogram ± ultrasound ± biopsy.

### *Follow-Up Tests & Special Considerations*

- Early disease (clinical stage I and IIB)
- Consider additional studies only if signs and symptoms warrant.
- Advanced disease (stage IIIA or higher)
- Chest diagnostic CT, abdominal ± pelvis CT, FDG positron emission tomography (PET)/CT scan, bone scan or sodium fluoride PET/CT if FDG-PET/CT indeterminate
- Most common metastasis: lungs, liver, bone, brain
- Bone scan: localized pain, elevated alkaline phosphatase
- Abdominal ± pelvis CT: abdominal symptoms, elevated alkaline phosphatase, abnormal LFTs
- Chest imaging: pulmonary symptoms
- MRI: CNS/spinal cord symptoms

### *Diagnostic Procedures/Other*

- Primary tumor: FNA, ultrasound-guided core needle biopsy, stereotactic-guided core needle biopsy ± wire localization, sentinel lymph node, surgical excision, sentinel lymph node biopsy; post biopsy may get inflammatory changes/hematoma.
- Genomic assay on formalin-fixed tissue for select + ER, -HER2, node negative tumor to assess chemotherapy responsiveness

## Test Interpretation

- Ductal/lobular/other: tumor size, inflammatory component, invasive/noninvasive, margins, nodal involvement
- Nodal micrometastases: increased risk of disease recurrence
- ER, PR, HER2 assay

## TREATMENT

### MEDICATION

- Secondary prevention
  - ASA use at least once per week may be associated with as much as a 50% reduction in death from BC (see *Additional Reading*)
  - Chemoprevention/hormone therapy for patients ages <sup>3</sup>35 years
  - Risk reduction for ER-positive tumors
- Hormone therapy for ER-positive tumors
  - Tamoxifen: premenopausal at diagnosis: 5-year treatment and consider for additional 5 years; avoid during lactation, pregnancy, or with history of deep venous thrombosis/pulmonary embolism; routine CYP2D6 testing not recommended; use strong CYP2D6-inhibiting medications with caution in conjunction
  - Aromatase inhibitors: postmenopausal women, 5-year treatment following tamoxifen for 4.5 to 6 years, or tamoxifen for up to 10 years
  - Ovarian ablation or suppression with luteinizing hormone-releasing hormone agonists: premenopausal women
  - Anti-HER2/neu antibody (e.g., trastuzumab) in select HER2/neu-positive patients
  - Monitor cardiac toxicity via ECG, especially with anthracycline.
- Neoadjuvant chemotherapy: Premenopausal women should be counseled on potential effect of chemotherapy on fertility, refer to fertility expert.
  - Locally advanced, inoperable advanced BC (stage III)
  - Early operable BC for breast conservation surgery
  - Triple negative BC

- Cytotoxic therapy: anthracyclines, taxanes, alkylating agents, antimetabolites
  - Higher risk patients with nonmetastatic operable tumors
  - Patients with high risk of recurrence after local treatment (serial/parallel [s/p] surgery ± radiation)
  - Online tool to estimate recurrence risk and benefits of adjuvant chemotherapy (<http://www.adjuvantonline.com/online.jsp>)
- Dose-dense chemotherapy demonstrates overall survival advantage in early BC (4)[A].
- Advanced disease
  - Hormone therapy
  - Cytotoxic therapy
  - Bisphosphonates to decrease skeletal complications
  - Antivascular endothelial growth factor antibody
  - Anti-HER2/neu antibody in select HER2/neu-positive patients
- Metastatic disease
  - Monitoring metastatic disease: system assessment, physical examination, performance status, weight, LFT/CBC, CT scan/chest/abdomen/pelvis, bone scan, PET/CT, tumor markers

## ***SURGERY/OTHER PROCEDURES***

### Secondary prevention

- Risk-reducing mastectomy and bilateral salpingo-oophorectomy for breast and ovary CA syndromes
- Breast-conserving partial mastectomy/lumpectomy, if possible
- Negative margins; tumor usually <5 cm
- No prior breast radiation, relative contraindication: connective tissue disease (lupus, scleroderma)
- Modified radical mastectomy
- Large tumors; multicentric disease; young women with known *BRCA*; consider immediate or delayed reconstruction
- RT should be initiated without delay
- After breast-conserving therapy (BCT), stage I, IIA, IIB treatable with BCT + radiation

- Postmastectomy in select high-risk patients; palliation of metastatic disease; cord compression

## *Pregnancy Considerations*

- TREATMENT varies on trimester
- Surgical: mastectomy or breast conservation: mastectomy preferred due to limitations of radiation during pregnancy.
- Sentinel lymph node biopsy: safe to use with lymphoscintigraphy
- Chemotherapy: appropriate in 2nd and 3rd trimesters, trastuzumab contraindicated
- RT: Avoid until after delivery.

## *INPATIENT CONSIDERATIONS*

### *Discharge Criteria*

#### Postmastectomy

- Complications: seroma, phantom breast syndrome, cellulitis, chest wall/axilla/arm pain, long thoracic nerve damage leading to winged scapula sign
- Lymphedema; avoid having BP taken on side of surgery

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Every 4 to 6 months for 5 years, then annually
- No evidence to support the use of routine CBC, LFTs, tumor markers, bone scan, CXR, liver ultrasound, CT scans, MRI, PET
- Mammogram/imaging 1 year after initial mammogram but 6 to 12 months postradiation, then annually
- Annual gynecologic exam for women on tamoxifen; bone mineral density at baseline and follow-up for women on aromatase inhibitors or with ovarian failure secondary to treatment

## *PROGNOSIS (5)*

### **Stage 5-year Relative Survival Rate**

0

100%

I	100%
II	93%
III	72%
IV	22%

## COMPLICATIONS

- Hypercalcemia, metastatic disease, lymphedema
- Emotional issues (depression, body-image alteration)

**Codes**

## ICD10

- C50.919 Malignant neoplasm of unsp site of unspecified female breast
- D05.90 Unspecified type of carcinoma in situ of unspecified breast
- Z12.31 Encntr screen mammogram for malignant neoplasm of breast

## Clinical Pearls

- BC is most common CA death in U.S. women, lifetime risk of 1 in 8.
- High alcohol use, high body mass index (BMI), and physical inactivity are modifiable risk factors.
- Pursue/refer all abnormal breast physical examination/imaging findings.
- If patient <sup>3</sup>30 years of age with palpable mass, obtain mammogram, if <30 years of age obtain ultrasound.
- Normal mammography does not exclude possibility of CA with a palpable mass.

# Breastfeeding

Angelia Leipelt, BA, IBCLC, ICCE, CLE

Ronald G. Chambers Jr., MD, FAAFP

## BASICS

- Breastfeeding is the natural process of feeding infant human milk directly from the breast.
- Breast milk is the preferred nutritional source and the normal and physiologic way to feed all newborns and infants.
- The American Academy of Pediatrics (AAP), the American Academy of Family Physicians (AAFP), WHO, and other medical organizations recommend exclusive breastfeeding for 6 months, with continuation of breastfeeding for <sup>3</sup> 1 year as desired by the mother and infant (1)[A].

## DESCRIPTION

- Maternal benefits (as compared with mothers who do not breastfeed) include the following (2):
  - Rapid involution/decreased postpartum bleeding (due to oxytocin release)
  - Association of decreased risk of postpartum depression and increased bonding
  - Associated postpartum weight loss
  - Decreased risk of breast cancer
  - Association of decreased risk of premenopausal ovarian cancer
  - Decreased risk of type 2 diabetes, hypertension, hyperlipidemia, rheumatoid arthritis and cardiovascular disease
  - Decreased risk of prematurity due to child spacing
  - Convenience and economic savings
- Infant benefits (as compared with children who are formula-fed) include the following (1,2):
  - Ideal food: easily digestible, nutrients well absorbed, less constipation
  - Lower rates of virtually all infections via maternal antibody protection

Fewer respiratory and GI infections

- Decreased incidence of otitis media
- Decreased risk of bacterial meningitis, pneumonia, and sepsis
- Decreased incidence of necrotizing enterocolitis
- Decreased incidence of obesity and type 1 and 2 diabetes
- Decreased incidence of allergies, clinical asthma, and atopic dermatitis in childhood
- Decreased risk of developing celiac disease and inflammatory bowel disease
- Decreased risk of childhood leukemia
- Decreased risk of sudden infant death syndrome (SIDS) and decreased mortality
- Higher intelligence scores and better neurodevelopmental outcomes
- Increased attachment between mother and baby
- Decreased child abuse

## *EPIDEMIOLOGY*

### *Incidence*

- According to the most recent breastfeeding scorecard, United States breastfeeding rates are on the rise. Based on the CDC, in 2014: any breastfeeding: 79.2% (however, differs among different sociodemographic and culture) (3)
- Breastfeeding at 6 months: 49.4%
- Breastfeeding at 12 months: 26.7%
- Exclusive breastfeeding at 3 months: 40.7%
- Exclusive breastfeeding at 6 months: 18.8%

## *ETIOLOGY AND PATHOPHYSIOLOGY*

The overarching mechanism of milk production is based on supply and demand.

- Stimulation of areola causes secretion of oxytocin.
- Oxytocin is responsible for let-down reflex when myoepithelial cells contract and milk is ejected into milk ducts (4).
- Sucking stimulates secretion of prolactin, which triggers milk production.
- Endocrine/metabolic: Cystic fibrosis, diabetes, galactosemia, phenylketonuria, and thyroid

dysfunction may cause delayed lactation or decreased milk.

## GENERAL PREVENTION

- Most vaccinations can be given to breastfeeding mothers. The CDC recommends that the diphtheria-tetanus-acellular pertussis, hepatitis B, inactivated influenza virus (as opposed to live attenuated), measles-mumps-rubella (MMR), and inactivated polio and varicella vaccines can be given. The CDC recommends avoiding the yellow fever or smallpox vaccine in breastfeeding mothers (5).
- The inactivated influenza virus is preferred to the live attenuated virus in women with infants' age 6 to 23 months, regardless of whether these infants are being breastfed (5).

## DIAGNOSIS

### PHYSICAL EXAM

Examine breasts, ideally during pregnancy, looking for scars, lumps, or inverted nipples. Confirm history of infertility, breast pathology, and previous breastfeeding problems.

#### ALERT

A breast lump should be followed to complete resolution or worked up if present and not just attributed to changes from lactation.

## TREATMENT

### GENERAL MEASURES

- Breastfeeding initiation
  - Initiate breastfeeding immediately after birth, ideally placing the infant on mother's chest, skin-to-skin, IN FIRST HOUR (1,6)[A].
  - Mother placed in a comfortable position, usually sitting or leaning back, with baby on chest allowing baby to move toward breast.
  - As baby opens wide, bring baby close, tucking baby in. Line baby's nose to nipple, baby tilts its head back with wide open mouth, bring baby close as baby latches to ensure baby's gum takes in more of the areola.
  - Baby's lips are flanged, rounded cheeks, no clicking or popping sounds and absence of nipple pain when latched.

Feed baby on demand. Room-in and watch for hunger cues and cluster feeding.

- Feed 2 to 8 times for first 24 hours and 8 to 15 times per 24 hours, feeding 10 or more minutes, emptying and alternating breasts.
- Observation of a nursing session by an experienced physician, nurse, or lactation consultant
- Avoid supplementation with formula or water unless medically indicated.
- Contraindications to breastfeeding are few (WHO) (1).
  - Maternal HIV (in industrialized world) or human T-cell leukemia virus (HTLV) infection
  - Active untreated tuberculosis
  - Active herpes simplex virus (HSV) lesions on the breast\*
  - Substances of abuse without evaluation and review medications that will pass into human milk
  - Infants with galactosemia or maple syrup urine disease should not be fed with breast milk. Infants with phenylketonuria may be fed breast milk under close observation.
  - Mothers who develop varicella 5 days before through 2 days after delivery\*
  - Mothers acutely infected with influenza H1N1 until afebrile\*
  - Maternal hepatitis is NOT a contraindication.
  - \*Expressed milk can be used.

## ***ISSUES FOR REFERRAL***

- Refer to trained physician, nurse, or IBCLC lactation consultant for inpatient and/or outpatient teaching.
- Frequent follow-up if having problems with latching, sore nipples, breast pain, or inadequate milk production.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Galactagogues (7)[C]

- Metoclopramide, domperidone, oxytocin, fenugreek, goat's rue, and milk thistle have mixed results in improving milk production but efficacy and safety data are lacking in literature.

**ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

See mother and baby within a few days of hospital discharge, especially if first time breastfeeding.

- Risk factors for suboptimal initiation
  - Breast surgery, especially reduction surgery, prior to pregnancy may disrupt breast milk production in the future.
  - Severe postpartum hemorrhage may lead to Sheehan syndrome, which is associated with difficulty breastfeeding due to poor milk production.
  - Other factors: delivery mode, duration of labor, gestational age, maternal infection, parity, culture, mother-baby separation, maternal anxiety, artificial nipple, and nonbreast milk fluids.

### *Patient Monitoring*

- Monitor infant's weight, behavior, and output closely.
- Supplementation with infant formula is recommended only if infant has lost <sup>3</sup>8-10% of birth weight or signs of dehydration such as decreased urine output.
- Supplementation without persistent breast stimulation with frequent feedings or breast pump use will decrease milk production and decrease breastfeeding success.

### *DIET*

- For mothers:
  - Drink plenty of fluids: 8 glasses of liquid a day
  - Breastfeeding mothers require ÷500 more calories a day than prepregnancy needs (1).
  - Gassy foods can cause baby to be fussy.

---

- Limit caffeine to 300 mg/day.
- Alcohol should be avoided. 1 to 2 drinks/week of alcohol may be okay, but mothers should avoid nursing 2 to 3 hours after a drink. <2% of alcohol is passed to baby via breast milk.
- Continue prenatal vitamin supplements.
- For infants:
  - In 2008, the AAP increased its recommended daily intake of vitamin D for infants from 200 to 400 IU. For exclusively breastfed babies, this will require taking a vitamin supplement,

such as Poly-Vi-Sol or Vi-Daylin vitamin drops, 0.5 mL/day, beginning in the first few days of life (1).

- In 2010, the AAP recommended adding supplementation for breastfed infants with oral iron 1 mg/kg/day beginning at age 4 months.
  - Preterm infants fed by human milk should receive an iron supplement of 2 mg/kg/day by 1 month of age, and this should be continued until the infant is weaned to iron-fortified formula or begins eating complementary foods that supply the 2 mg/kg of iron.
  - Fluoride supplement is unnecessary until 6 months of age (1).

## *PATIENT EDUCATION*

- Primary care-initiated interventions and support measures to normalize breastfeeding have been shown to be successful with respect to child and maternal health outcomes (8).
  - U.S. Preventive Services Task Force (USPSTF) recommends structured breastfeeding education and behavioral counseling programs to promote breastfeeding.
    - Regular promotion of the advantages of breastfeeding/risks of not breastfeeding (6)[A]
    - Emphasize importance of exclusive breastfeeding for first 4 weeks of life to allow adequate buildup of sufficient milk supply.
- Milk usually transitions to mature milk about postpartum day 3 to 5.
- Frequent nursing (8-12 feedings per 24 hours by day 2)
- Baby should have 6 to 8 wet diapers/day and 3 to 4 bowel movements/day by day 6 to 8.
- Signs of adequate nursing
  - Baby feeding on demand.
  - Proper latching and positioning, nipples intact.
  - Hard breasts become soft after feeding.
  - Baby satisfied; appropriate weight gain (average 1 oz/day in first few months)
- Weaning
  - Solid food may be introduced at 6 months with continuation of breastfeeding.
  - Mothers returning to work/school should be introduced to alternative feeding methods 1 to 2 weeks prior. Initiate pumping to supply expressed breastmilk.
- Family planning

- Lactational amenorrhea method (LAM): Breastfeeding may be used as effective birth control option if (i) infant is <6 months old, (ii) infant is exclusively breastfeeding, and (iii) mother is amenorrheic.
- Other options include barrier methods, implants, Depo-Provera, PO contraception, and intrauterine devices (IUDs). ACOG recommends that progesterone-only pills be used 2 to 3 weeks postpartum, and that Depo-Provera, IUDs, combined OCPs, and Implanon can be used 6 weeks postpartum. However, ACOG recommends delaying use of combined OCPs until after 6 weeks postpartum when lactation is well established.

## COMPLICATIONS

- Breast milk jaundice should be considered if jaundice persists for >1 week in an otherwise healthy, well-hydrated newborn. It peaks at 10 to 14 days.
- Plugged duct
  - Mother is well except for sore lump in one or both breasts and is without fever.
  - Use moist, hot packs on lump prior to, and during, nursing; more frequent nursing on affected side.
- Mastitis (see topic "Mastitis")
  - Sore lump in one or both breasts plus fever and/or redness on skin overlying lump
  - Use moist, hot packs on lump prior to, and during, nursing.
  - Antibiotics covering for *Staphylococcus aureus* (most common organism)
  - Other possible sources of fever should be ruled out, that is, endometritis and pyelonephritis.
  - Mother should get increased rest; use acetaminophen (Tylenol) PRN.
  - Fever should resolve within 48 hours or consider changing antibiotics. Lump should resolve. If it continues, an abscess may be present, requiring surgical drainage.
- Milk supply inadequate
  - Check infant weight gain.
  - Review signs of adequate supply; technique, frequency, and duration of nursing.
  - Check to see if mother has been supplementing with formula, thereby decreasing her own milk production.
- Sore nipples

Check technique and improve latch-on.

- Baby should be taken off the breast by breaking the suction with a finger in the mouth.
  - Air-dry nipples after each nursing and/or coat with expressed breast milk.
  - Use lanolin cream to help in healing.
  - Do not wash nipples with soap and water.
  - Check for signs of thrush in baby and on mother's nipple. If affected, treat both.
  - Check for evidence of ankyloglossia (tongue tie) in the infant. Correction of ankyloglossia leads to decreased nipple soreness and improved breastfeeding.
  - Nipple bleb due to improper positioning. Moist heat and improve latching techniques.
- Flat or inverted nipples
    - When stimulated, inverted nipples will retract inward, flat nipples remain flat; check for this on initial prenatal physical.
    - Nipple shells, a doughnut-shaped insert, can be worn inside the bra during the last month of pregnancy to force the nipple gently through the center opening of the shell.
  - Engorgement
    - Develops after milk first comes in (day 3 or 4 postpartum), resolves within a day or 2
    - Signs are warm, hard, sore breasts.
      - To resolve, offer baby more frequent nursing; breastfeed long enough to empty breasts.

## Codes

### ICD10

Z39.1 Encounter for care and examination of lactating mother

## Clinical Pearls

- Women who do not receive support are at risk for shorter durations of breastfeeding (8).
- Breast milk is the optimal food for infants, with myriad health benefits for mothers and children.
- USPSTF recommends regular, structured education during pregnancy to promote breastfeeding.
- Vitamin D and iron supplementation should begin at birth and 4 months of age, respectively, for exclusively breastfed infants.

# Bronchiectasis

Sumera R. Ahmad, MD

Scott E. Kopec, MD

## BASICS

### DESCRIPTION

- Bronchiectasis is an irreversible dilatation of <sup>3</sup> 1 airways accompanied by recurrent transmural bronchial infection/inflammation and chronic mucopurulent sputum production.
- Generally classified into cystic fibrosis (CF) and noncystic fibrosis (non-CF) bronchiectasis

### EPIDEMIOLOGY

- Predominant age: most commonly presents in 6th decade of life
- Predominant sex: female > male

### Incidence

Incidence has decreased in the United States for two reasons:

- Widespread childhood vaccination against pertussis
- Effective treatment of childhood respiratory infections with antibiotics

### Prevalence

- Prevalence in adult U.S. population estimated to be > 110,000 affected individuals.
- Internationally, prevalence increases with age from 4.2/100,000 persons aged 18 to 34 years to 271.8/100,000 among those aged 75 years and older (1).

### ETIOLOGY AND PATHOPHYSIOLOGY

- CF bronchiectasis: bronchiectasis due to CF
- Non-CF bronchiectasis
  - Most cases are idiopathic.
  - Most commonly associated with non-CF bronchiectasis is childhood infection.

- Vicious circle hypothesis: Transmural infection, generally by bacterial organisms, causes inflammation and obstruction of airways. Damaged airways and dysfunctional cilia foster bacterial colonization, which leads to further inflammation and obstruction.

## **RISK FACTORS**

- Nontuberculous mycobacterial infection is both a cause and a complication of non-CF bronchiectasis.
- Severe respiratory infection in childhood (measles, adenovirus, influenza, pertussis, or bronchiolitis)
- Systemic diseases (e.g., rheumatoid arthritis and inflammatory bowel disease)
- Chronic rhinosinusitis
- Recurrent pneumonia
- Aspirated foreign body
- Immunodeficiency
- Congenital abnormalities

## **GENERAL PREVENTION**

- Routine immunizations against pertussis, measles, *Haemophilus influenzae* type B, influenza, and pneumococcal pneumonia
- Genetic counseling if congenital condition is etiology
- Smoking cessation

## **COMMONLY ASSOCIATED CONDITIONS**

- Mucociliary clearance defects
  - Primary ciliary dyskinesia
  - Young syndrome (secondary ciliary dyskinesia)
  - Kartagener syndrome
- Other congenital conditions
  - $\alpha$ 1-antitrypsin deficiency
  - Marfan syndrome
  - Cartilage deficiency (Williams-Campbell syndrome)

- Chronic obstructive pulmonary disease
- Pulmonary fibrosis, causing traction bronchiectasis
- Postinfectious conditions
  - Bacteria (*H. influenzae* and *Pseudomonas aeruginosa*)
  - Mycobacterial infections (tuberculosis [TB] and *Mycobacterium avium* complex [MAC])
  - Whooping cough
  - Aspergillus species
  - Viral (HIV, adenovirus, measles, influenza virus)
- Immunodeficient conditions
  - Primary: hypogammaglobulinemia
  - Secondary: allergic bronchopulmonary aspergillosis (ABPA), posttransplantation
  - Sequelae of toxic inhalation or aspiration (e.g., chlorine, luminal foreign body)
- Rheumatic/chronic inflammatory conditions
  - Rheumatoid arthritis
  - Sjögren syndrome
  - Systemic lupus erythematosus
  - Inflammatory bowel disease
- Miscellaneous
  - Yellow nail syndrome

## DIAGNOSIS

- Typical symptoms include chronic productive cough, wheezing, and dyspnea.
- Symptoms are often accompanied by repeated respiratory infections (2).
- Once diagnosed, investigate etiology.

## HISTORY

- Any predisposing factors (congenital, infectious, and/or exposure-related)
- Immunization history

## *PHYSICAL EXAM*

Symptoms are commonly present for many years and include the following:

- Chronic cough (90%)
- Sputum: may be copious and purulent (90%)
- Rhinosinusitis (60-70%)
- Fatigue: may be a dominant symptom (70%)
- Dyspnea (75%)
- Chest pain: may be pleuritic (20-30%)
- Hemoptysis (20-30%)
- Wheezing (20%)
- Bibasilar crackles (60%)
- Rhonchi (44%)
- Digital clubbing (3%)

## *DIFFERENTIAL DIAGNOSIS*

- CF
- Chronic obstructive pulmonary disease
- Asthma
- Chronic bronchitis
- Pulmonary TB
- ABPA

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Spirometry
  - Moderate airflow obstruction and hyperresponsive airways
  - Forced expiratory volume in the 1st second of expiration ( $FEV_1$ ):  $<80\%$  predicted and  $FEV_1/FVC <0.7$
- Special tests
  - Ciliary biopsy by electron microscopy

- Sputum culture
  - *H. influenzae*, nontypeable form (42%)
  - *P. aeruginosa* (18%)
  - Cultures may also be positive for *Streptococcus pneumoniae*, *Moraxella catarrhalis*, MAC, and *Aspergillus*.
  - Of all isolates, 30-40% will show no growth.
- Special tests
  - Sweat test for CF
  - Purified protein derivative (PPD) test for TB
  - Skin test for *Aspergillus*
  - HIV
  - Serum immunoglobulins to test for humoral immunodeficiency
  - Protein electrophoresis to test for  $\alpha$ 1-antitrypsin deficiency
  - Barium swallow to look for abnormalities of deglutition, achalasia, esophageal hypomotility
  - pH probe to characterize reflux
  - Screening tests for rheumatologic diseases
- Chest radiograph
  - Nonspecific; increased lung markings or may appear normal
- Chest computed tomography (CT)
  - Noncontrast high-resolution chest CT is the most important diagnostic tool.
  - Bronchi are dilated and do not taper, resulting in tram track sign; parallel opacities seen on scan.
  - Varicose constrictions and balloon cysts may be seen.
  - For focal bronchiectasis, rule out endobronchial obstruction.
  - For exclusively upper lobe bronchiectasis, consider CF and ABPA.

### *Diagnostic Procedures/Other*

- Bronchoscopy may be used to obtain cultures and evacuate sputum.
- Bronchoscopy for hemoptysis

- Bronchoscopy may be useful to rule out airway-obstructing lesions with focal bronchiectasis.

## *Test Interpretation*

Bronchoscopy findings include the following:

- Dilatation of airways and purulent secretions
- Thickened bronchial walls with necrosis of bronchial mucosa
- Peribronchial scarring

## **TREATMENT**

- Treat underlying conditions.
- Recognize an acute exacerbation with 4 out of 9 criteria (3)
  - Change in sputum production
  - Increased dyspnea
  - Increased cough
  - Fever
  - Increased wheezing
  - Malaise, fatigue, lethargy
  - Reduced pulmonary function
  - Radiographic changes
  - Changes in chest sounds
- Non-CF bronchiectasis: determine cause of exacerbations; promote good bronchopulmonary hygiene via daily airway clearance.
- Consider surgical resection of damaged lung for focal disease that is refractory to medical management.
- Medical management: Reduce morbidity by controlling symptoms and preventing disease progression.
- Patients with non-CF bronchiectasis may not respond to CF treatment regimens in the same way as patients with CF do.

## GENERAL MEASURES

- Maintain hydration (nebulized hypertonic saline, 3% or 7% may be used to help increase mucus clearance) (4)[A].
- Noninvasive positive-pressure ventilation

## MEDICATION

- Insufficient evidence exists to support efficacy of short-course antibiotics in adults and children with bronchiectasis (5)[A].
- Frequent exacerbations may be treated with prolonged and aerosolized antibiotics (2)[A].
- Role of mucolytics, antiinflammatory agents, and bronchodilators is still unclear (2)[A].

### First Line

- Antibiotics
  - Potentially useful in acute exacerbations
  - Chronic therapy decreases sputum volume and purulence, but it does not diminish the frequency of exacerbations (6)[A].
  - Patients may require twice the usual dose and longer treatment for 14 days (7)[C].
  - Sputum culture and sensitivity should direct therapy; antibiotic selection is complicated by a wide range of pathogens and resistant organisms.
  - Should be administered IV in cases of severe infection
    - Augmentin: 500 mg PO q8-12h. Pediatric: base dosing on amoxicillin content
    - Trimethoprim (TMP)/sulfamethoxazole (SMX) : 160 mg TMP/800 mg SMX PO q12h. Pediatric: <sup>3</sup>2 months, 8 mg/kg TMP and 40 mg/kg SMX PO/24 hours, administered in two divided doses q12h
    - Doxycycline and cefaclor given PO are also effective.
    - Nebulized aminoglycosides (tobramycin): 300 mg by aerosol BID (8)[B]
    - Ciprofloxacin: 750 mg PO q12h for adults for susceptible strain of *Pseudomonas*
    - Macrolides: appear to have immunomodulatory benefits
- Chronic use of azithromycin as an oral macrolide for 6 to 12 months in non-CF bronchiectasis has been shown to reduce exacerbations (9,10). Needs caution with respect to cardiovascular deaths, where it is a QTc-prolonging medication (9).

## Bronchodilators

- Chronic use of  $\beta$ 2-agonists (e.g., albuterol) reverses airflow obstruction.
- Inhaled corticosteroids
  - Insufficient evidence exists to recommend use of inhaled steroids with stable bronchiectasis (11)[A].
  - A therapeutic trial of inhaled steroids may be justified in adults with difficult-to-control symptoms (11)[A].
  - Decrease sputum and tend to improve lung function
    - Fluticasone propionate: 110 to 220  $\mu$ g inhaled BID
  - Potential synergistic effect of long-acting  $\beta$ 2-agonists with inhaled corticosteroids, allowing for lower steroid dose (12):
    - Budesonide 160  $\mu$ g/Formoterol 4.5  $\mu$ g 2 puffs inhaled BID

## *Second Line*

Other broad-spectrum antimicrobials, including those with antipseudomonal coverage

## **ADDITIONAL THERAPIES**

Sputum clearance techniques, including physiotherapy (percussion and postural drainage) and pulmonary rehabilitation (improves exercise tolerance)

## **SURGERY/OTHER PROCEDURES**

- Surgery if area of bronchiectasis is localized and symptoms remain intolerable despite medical therapy or if disease is life-threatening (2)[A]
- Surgery effectively improves symptoms in 80% of these cases.

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

Bronchiectasis can present as a life-threatening massive hemoptysis. In this situation, in addition to airway protection and resuscitation, bronchial artery embolization or surgical intervention is necessary to control bleeding.

**ONGOING CARE**

Long-term outpatient treatment recommendations for bronchiectasis in children (13)[B]:

- Children with CF and non-CF-related bronchiectasis should be treated by comprehensive interdisciplinary chronic disease management programs.
- Pathogen-directed aerosolized tobramycin treatment should be used long-term on a regular basis to improve the course of CF-related bronchiectasis.
- PO macrolide antibiotic use long term (up to 6 months) improves lung function among children with CF-related bronchiectasis.
- Long-term antibiotic use (PO or aerosolized) in children with non-CF-related bronchiectasis has not been studied enough to warrant routine use.
- Hypertonic saline administered by inhalation used long-term (48 weeks) improves lung function and is safer when used with pretreatment bronchodilator therapy among children who have CF.
- Nebulized dornase improves multiple pulmonary outcomes of children who have CF and is indicated for long-term use.
- Risks for long-term oral corticosteroid use outweigh pulmonary benefits in the treatment of CF-related bronchiectasis.
- High-dose ibuprofen therapy reduces the rate of decline among children with mild CF-related bronchiectasis and is indicated for long-term use.
- Mucolytic agents, airway-hydrating treatments, antiinflammatory therapy, chest physical therapy (CPT), and bronchodilator therapy have not been studied sufficiently long term in children with non-CF-related bronchiectasis to merit their routine use.

## *FOLLOW-UP RECOMMENDATIONS*

Regular exercise is recommended.

### *Patient Monitoring*

- Serial spirometry, every 2 to 5 years, to monitor the course of the disease
- Chest CTs to monitor progression of disease may be indicated with some conditions such as bronchiectasis with MAC infections.
- Routine microbiological sputum analysis

## *PATIENT EDUCATION*

<http://www.lungusa.org/>

## PROGNOSIS

- Mortality rate (death due directly to bronchiectasis) is 13%.
- *Pseudomonas* infection is associated with poorer prognosis.

## COMPLICATIONS

- Hemoptysis
- Recurrent pulmonary infections
- Pulmonary hypertension
- Cor pulmonale
- Lung abscess

## Codes

### ICD10

- J47.9 Bronchiectasis, uncomplicated
- J47.1 Bronchiectasis with (acute) exacerbation
- J47.0 Bronchiectasis with acute lower respiratory infection

### Clinical Pearls

- Symptoms of bronchiectasis include chronic productive cough, wheezing, and dyspnea, often accompanied by repeated respiratory infections.
- A chest x-ray has poor sensitivity and specificity for the diagnosis; a noncontrast high-resolution chest CT is the most important diagnostic tool.
- Current practice guidelines recommend treating acute exacerbations with a 14-day course of antibiotics. Frequent exacerbations may be treated with prolonged and aerosolized antibiotics.

# Bronchiolitis

Dennis E. Hughes, DO, FACEP

## BASICS

### DESCRIPTION

- Inflammation and obstruction of small airways and reactive airways generally affecting infants and young children  
Upper respiratory infection (URI) prodrome followed by increased respiratory effort and wheezing
- Usual course: insidious, acute, progressive
- Leading cause of hospitalizations in infants and children in most Western countries
- Predominant age: newborn-2 years (peak age <6 months). Neonates are not protected despite transfer of maternal antibody.
- Predominant sex: male > female

### EPIDEMIOLOGY

#### *Incidence*

- 21% in North America
- May be seasonal (October-May in the Northern Hemisphere) and often occurs in epidemics
- 18.8% (90,000 annually) of all pediatric hospitalizations (excluding live births) in children <2 years
- Incidence increasing since 1980 (with concomitant increase in relative rate of hospitalization from 2002 to 2007).

### ETIOLOGY AND PATHOPHYSIOLOGY

RSV accounts for 70-85% of all cases (children <12 months of age), but rhinovirus, parainfluenza virus, adenovirus, influenza virus, *Mycoplasma pneumoniae*, and *Chlamydomphila pneumoniae* have all been implicated:

- Infection results in necrosis and lysis of epithelial cells and subsequent release of inflammatory mediators.

- Edema and mucus secretion, which combined with accumulating necrotic debris and loss of cilia clearance, results in airflow obstruction.
- Ventilation-perfusion mismatching resulting in hypoxia
- Air trapping is caused by dynamic airways narrowing during expiration, which increases work of breathing.
- Bronchospasm appears to play little or no role.

## *RISK FACTORS*

- Secondhand cigarette smoke
- Low birth weight, premature birth
- Immunodeficiency
- Formula feeding (little or no breastfeeding)
- Contact with infected person (primary mode of spread)
- Children in daycare environment
- Congenital cardiopulmonary disease
- < 12 weeks of age

## *GENERAL PREVENTION*

- Handwashing or use of alcohol-based hand rubs (preferred)
- Contact isolation of infected babies
- Persons with colds should keep contact with infants to a minimum.
  - Breastfeeding of infants has been associated with reduced morbidity of disease.
- Palivizumab (Synagis), a monoclonal product, administered monthly, October-May, 15 mg/kg IM; used for RSV prevention ONLY in high-risk patients

## *Pediatric Considerations*

Prior infection does not seem to confer subsequent immunity.

## *COMMONLY ASSOCIATED CONDITIONS*

- Upper respiratory congestion
- Conjunctivitis

Pharyngitis

- Otitis media
- Diarrhea

## DIAGNOSIS

History and physical examination should be the basis for the diagnosis of bronchiolitis.

### HISTORY

- Irritability
- Anorexia
- Fever
- Noisy breathing (due to rhinorrhea)
- Cough
- Grunting
- Cyanosis
- Apnea
- Vomiting

### PHYSICAL EXAM

- Tachypnea
- Retractions (increased work of breathing)
- Rhinorrhea
- Wheezing
- Upper respiratory findings: pharyngitis, conjunctivitis, otitis

### DIFFERENTIAL DIAGNOSIS

- Other pulmonary infections such as pertussis, croup, or bacterial pneumonia
- Aspiration
- Vascular ring
- Foreign body
- Asthma

Heart failure

- Gastroesophageal reflux
- Cystic fibrosis

## **DIAGNOSTIC TESTS & INTERPRETATION**

Laboratory and other ancillary testing (including chest x-ray) are not required if clinical diagnosis is bronchiolitis.

### ***Initial Tests (lab, imaging)***

- Arterial oxygen saturation by pulse oximetry. Results need to be interpreted in clinical context. Transient hypoxemia is a common phenomenon in healthy infants (1).
- Rapid respiratory viral antigen testing is not necessary during RSV season because the disease is managed symptomatically but may be useful for epidemiologic, hospital cohorting, or in the very young to reduce unnecessary other workup; also indicated in infants admitted while receiving palivizumab prophylaxis (if positive, prophylaxis may be discontinued).
- The American Association of Pediatrics (AAP) does not recommend routine RSV testing in infants and children with bronchiolitis.
- Chest x-ray findings are variable and may include atelectasis, peribronchial cuffing, hyperinflation, and perihilar infiltrates.

## **TREATMENT**

The cornerstone of therapy is supportive to include upper airway suctioning, prevention of significant and prolonged hypoxia, and dehydration. The other interventions noted have historically varying effect on the course of the illness despite numerous studies. Recent clinical practice guidelines do not support the routine use of corticosteroids, bronchodilators, or epinephrine. Parental education and support is vital (1)[A].

## **MEDICATION**

### ***First Line***

- Humidified oxygen for hypoxia of  $<90\%$  (pulse oximetry should be interpreted in context of clinical appearance of infant) (1)[C]
- Nebulized hypertonic saline (3%) can be effective in reducing LOS in hospitalized patients but not recommended use in the ED (1,2)[B].
- Antibiotics only if secondary bacterial infection present (rare). Not indicated for routine use (1)

[B].

- Positive-pressure ventilation (PPV) in the form of continuous positive airway pressure (CPAP) can be used in cases of respiratory failure. There is limited clinical evidence other than observational studies (3)[C].
- High-flow nasal cannula oxygen widely used in various settings to improve oxygen saturation with resultant reduction in end-tidal CO<sub>2</sub> (ETCO<sub>2</sub>) and respiratory rate, but overall effectiveness remains unproven to date (3)[C].

---

P.145

## *ADDITIONAL THERAPIES*

- Ribavirin (palivizumab) for patients at high risk (for prophylaxis per CDC/AAP guidelines) (4)[A]
- Heliox therapy (70% helium and 30% oxygen) may be of benefit early in moderate to severe bronchiolitis to reduce degree of respiratory distress due to air flow restriction, but Cochrane review found little evidence of sustained benefit at 24 hours (5)[A].
- Although not routinely recommended, inhaled  $\beta$ -agonists (albuterol) can be effective in selected cases (particularly in patients with a history of bronchospasm).

## *INPATIENT CONSIDERATIONS*

Bronchiolitis can be associated with apnea in children <6 weeks of age.

### *Admission Criteria/Initial Stabilization*

- Respiratory rate >45 breaths/min with respiratory distress or apnea
- Hypoxia is common so clinical criteria are more helpful (pulse oximetry <94% used by many as cutoff).
- Ill or toxic appearance
- Underlying heart condition, respiratory condition, or immune suppression
- High risk for apnea (age <30 days, preterm birth [<37 weeks])
- Dehydrated or unable to feed
- Uncertain home care
- Use of Respiratory Distress Assessment Instrument may aid in determining admission. The five best predictors of admission, age, respiratory rate, heart rate, oxygen saturation, and duration of symptoms, were recently incorporated into a scoring instrument.
- Supplemental oxygen for pulse oximetry <94% on room air if clinically indicated. AAP recommends O<sub>2</sub> saturation >90% if infant otherwise well.

## *IV Fluids*

Indicated only if tachypnea precludes oral feeding; weight-based maintenance rate plus insensible losses.

## *Discharge Criteria*

Normal respiratory rate and no oxygen requirement: Recent small studies suggest that after a period of observation, children can be safely discharged on home oxygen with home health follow-up.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Hospitalization is usually required only if oxygen is a requirement or unable to feed/drink.
- For a hospitalized patient, monitor as needed depending on the severity of the infection.
- If the patient is receiving home care, follow daily by telephone call for 2 to 4 days; the patient may need frequent office visits.

### *PATIENT EDUCATION*

- American Academy of Pediatrics: <http://www.aap.org>
- American Academy of Family Physicians: <http://www.familydoctor.org>

### *PROGNOSIS*

- Recovery time is variable. 40% can have symptoms at 14 days and 10% at 4 weeks.
- Mortality statistics differ but probably <1%.
- High-risk infants (bronchopulmonary dysplasia, congenital heart disease) may have a prolonged course.

### **COMPLICATIONS**

- Bacterial superinfection
- Bronchiolitis obliterans
- Apnea

- Respiratory failure
- Death
- Increased incidence of development of reactive airway disease (asthma)

## Codes

### ICD10

- J21.9 Acute bronchiolitis, unspecified

- J21.0 Acute bronchiolitis due to respiratory syncytial virus
- J21.8 Acute bronchiolitis due to other specified organisms

## Clinical Pearls

- Bronchiolitis is the leading cause of hospitalizations in infants and children—especially <3 months of age.
- Diagnosis is a clinical one.
- Parental education and support is essential.
- Nasal and upper airway suctioning mainstay of treatment

# Bronchitis, Acute

Alan Cropp, MD, FCCP

Ghazaleh Bigdeli, MD, FCCP

## BASICS

### DESCRIPTION

- Inflammation of trachea, bronchi, and bronchioles resulting from a respiratory tract infection or chemical irritant (1)
- Cough, the predominant symptom, may last as long as 3 weeks (2,3).
- Generally self-limited, with complete healing and full return of function (2)
- Most infections are viral if no underlying cardiopulmonary disease is present (2).
- Synonym(s): tracheobronchitis

### Geriatric Considerations

Can be serious, particularly if part of influenza, with underlying COPD or CHF (3)

### Pediatric Considerations

- Usually occurs in association with other conditions of upper and lower respiratory tract (trachea usually involved) (4)
- If repeated attacks occur, child should be evaluated for anomalies of the respiratory tract, immune deficiencies, or for chronic asthma.
- Acute bronchitis caused by RSV may be fatal.
- Antitussive medication not indicated in patients younger than age 6 years (2).

### EPIDEMIOLOGY

- Predominant age: all ages
- Predominant gender: male = female

### Incidence

÷5% of adults per year (5)

- Common cause of infection in children (4)

## *Prevalence*

Results in 10 to 12 million office visits per year

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Viral infections such as adenovirus, influenza A and B, parainfluenza virus, coxsackie virus, RSV, rhinovirus, coronavirus (types 1 to 3), herpes simplex virus, metapneumonia virus (2)
- Bacterial infections, such as *Chlamydia pneumoniae* TWAR agent, *Mycoplasma*, *Bordetella pertussis*, *Haemophilus influenzae*, *Streptococcus pneumoniae*, *Moraxella catarrhalis*, and *Mycobacterium tuberculosis* (2)
- Secondary bacterial infection as part of an acute upper respiratory infection
- Possibly fungal infections
- Chemical irritants
- Acute bronchitis causes an injury to the epithelial surfaces, resulting in an increase in mucous production and thickening of the bronchiole wall (1).

## *Genetics*

No known genetic pattern

## *RISK FACTORS*

- Infants
- Elderly
- Air pollutants
- Smoking
- Secondhand smoke
- Environmental changes
- Chronic bronchopulmonary diseases
- Chronic sinusitis
- Tracheostomy or endobronchial intubation
- Bronchopulmonary allergy

- Hypertrophied tonsils and adenoids in children
- Immunosuppression
  - Immunoglobulin deficiency
  - HIV infection
  - Alcoholism
- Gastroesophageal reflux disease (GERD)

## *GENERAL PREVENTION*

- Avoid smoking and secondhand smoke.
- Control underlying risk factors (i.e., asthma, sinusitis, and reflux).
- Avoid exposure, especially daycare.
- Pneumovax, influenza immunization

## *COMMONLY ASSOCIATED CONDITIONS*

- Allergic rhinitis
- Sinusitis
- Pharyngitis
- Epiglottitis (rare but can be rapidly fatal)
- Coryza
- Croup
- Influenza
- Pneumonia
- Asthma
- COPD/emphysema
- GERD

## **DIAGNOSIS**

### **HISTORY**

- Sudden onset of cough and no evidence of pneumonia, asthma, exacerbation

of COPD, or the common cold (3)

- Cough is initially dry and nonproductive, then productive; later, mucopurulent sputum, which may indicate secondary infection
- Cough lasts more than 5 days (1)
- Dyspnea, wheeze, and fatigue may occur.
- Possible contact with others who have respiratory infections (1)
- Fever is uncommon and may suggest pneumonia or influenza infection (1).

## *PHYSICAL EXAM*

- Fever
- Tachypnea
- Pharynx injected
- Rales, rhonchi, wheezing
- No evidence of pulmonary consolidation

## *DIFFERENTIAL DIAGNOSIS*

- Common cold
- Acute sinusitis
- Bronchopneumonia
- Influenza
- Bacterial tracheitis
- Bronchiectasis
- Asthma
- Reactive airways dysfunction syndrome (RADS)
- Allergy
- Eosinophilic pneumonitis
- Aspiration
- Retained foreign body
- Inhalation injury
- Cystic fibrosis

Bronchogenic carcinoma

- Heart failure
- GERD
- Chronic cough

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- None normally needed; diagnosis is based on history and physical exam showing no postnasal drip or rales (1,3).
- For a complicated picture, consider the following:
  - WBC with differential
  - Sputum culture/sensitivity if CXR is abnormal (3)
  - Influenza titers (if appropriate for time of year) (1)
  - Viral panel
- No testing needed unless concerned about pneumonia
- CXR
  - Lungs normal, if uncomplicated
  - Helps to rule out other diseases (pneumonia) or complications

### ***Follow-Up Tests & Special Consideration***

- Arterial blood gases: hypoxemia (rarely)
- Pulmonary function tests (seldom needed during acute stages): increased residual volume, decreased maximal expiratory rate (2)
- Procalcitonin level may influence use on antibiotics (6).
- Sputum culture in those patients intubated or with tracheostomy

## **TREATMENT**

### **GENERAL MEASURES**

- Outpatient treatment unless elderly or complicated by severe underlying disease

- Rest
- Stop smoking or avoid smoke.
- Steam inhalations
- Vaporizers
- Adequate hydration
- Antitussives
- Antibiotics are usually not recommended (1,3,7)[A].
- Treat associated illnesses (e.g., GERD).

## MEDICATION

### **ALERT**

Antibiotics are not recommended (1,3,6)[A] unless a treatable pathogen has been identified or significant comorbidities are present. This should be explained to patients who likely expect an antibiotic to be prescribed (3)[B].

### *First Line*

- Supportive; increased fluids (cough results in increased fluid loss)
- Antipyretic analgesic such as aspirin, acetaminophen, or ibuprofen
- Decongestants if accompanied by sinus condition
- Cough suppressant for troublesome cough (not with COPD); honey, benzonatate (Tessalon), guaifenesin with codeine or dextromethorphan. Not indicated in children younger than age 6 years (2)[C]
- Mucolytic agents are not recommended (3)[B].
- Inhaled  $\beta$ -agonist (e.g., albuterol) or in combination with high-dose inhaled corticosteroids for cough with bronchospasm (2)[B]
- If influenza is highly suspected and symptom onset is <48 hours: oseltamivir (Tamiflu) or zanamivir (Relenza) (2)[B]
- Antibiotics ONLY if a treatable cause (i.e., pertussis) is identified (2)[A].
  - Clarithromycin (Biaxin): 500 mg q12h or azithromycin (Zithromax) Z-Pak for atypical or pertussis infection (1)[A]
  - In patients with acute bronchitis of a suspected bacterial cause, azithromycin tends to be

more effective in terms of lower incidence of treatment failure and adverse events than amoxicillin or amoxicillin-clavulanic acid (8)[B].

- Doxycycline: 100 mg/day × 10 days if *Moraxella*, *Chlamydia*, or *Mycoplasma* suspected
- Quinolone for more serious infections or other antibiotic failure or in elderly or patients with multiple comorbidities
- Contraindication(s): Doxycycline and quinolones should not be used during pregnancy or in children.
- Precautions:
  - Multiple antibiotics have the potential to interfere with the effectiveness of PO contraceptives.
  - Antibiotic use can be associated with *Clostridium difficile* infections.
  - Cough and cold preparations should not be used in children <6 years (2)[B].

## *Second Line*

Other antibiotics if indicated by sputum culture

## **ISSUES FOR REFERRAL**

- Complications such as pneumonia or respiratory failure
- Comorbidities such as COPD
- Cough lasting >3 months

## **ADDITIONAL THERAPIES**

- Antipyretic for fever (e.g., acetaminophen, aspirin, or ibuprofen)
- Inhaled  $\beta$ -agonist (e.g., albuterol) or in combination with high-dose inhaled corticosteroids for cough with bronchospasm (2)[B]
- Oral corticosteroids probably not indicated (2)[C]

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

Throat lozenges for pharyngitis

## **INPATIENT CONSIDERATIONS**

### *Admission Criteria/Initial Stabilization*

- Hypoxia may require supplemental oxygen
- Respiratory failure that may require CPAP/bilevel ventilation
- Severe bronchospasm
- Exacerbation of underlying disease
- Bronchodilators if patient is bronchospastic.

### *IV Fluids*

May be helpful if patient is dehydrated

### *Nursing*

- Ensure patient comfort and monitor for signs of deterioration, especially if underlying lung disease exists.
- May need to follow oxygen saturation in patients with underlying lung disease

### *Discharge Criteria*

Improvement in symptoms and comorbidities

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- Usually a self-limited disease not requiring follow-up
- Cough may linger for several weeks.
- In children, if recurrent, need to consider other diagnoses, such as asthma (7)

### *Patient Monitoring*

- Oximetry until no longer hypoxemic
- Recheck for chronicity.

### *DIET*

Increased fluids (3 to 4 L/day) while febrile

### *PATIENT EDUCATION*

- For patient education materials favorably reviewed on this topic, contact the American Lung

Association: 1740 Broadway, New York, NY 10019 (212) 315-8700; [www.lungusa.org](http://www.lungusa.org)

- American Academy of Family Physicians: [www.familydoctor.org](http://www.familydoctor.org)

## PROGNOSIS

- Usual: complete resolution
- Can be serious in the elderly or debilitated
- Cough may persist for several weeks after an initial improvement.
- Postbronchitic reactive airways disease (rare)
- Bronchiolitis obliterans and organizing pneumonia (rare)

## COMPLICATIONS

- Superinfection such as bronchopneumonia
- Bronchiectasis
- Hemoptysis
- Acute respiratory failure
- Chronic cough

## Codes

### ICD10

- J20.9 Acute bronchitis, unspecified
- J68.0 Bronchitis and pneumonitis due to chemicals, gases, fumes and vapors
- B97.0 Adenovirus as the cause of diseases classified elsewhere

## Clinical Pearls

- Acute bronchitis is a common and generally self-limited disease.
- It usually does not require treatment with antibiotics. This needs to be explained to patients who expect antibiotics to be prescribed.
- Cough may linger for several weeks.
- Recurrent or seasonal episodes may suggest another disease process, such as asthma.
- Fever is uncommon and should prompt investigation for pneumonia or influenza.

# Bulimia Nervosa

Umer Farooq, MD, MBBS

Wajiha Ilyas, MD

## BASICS

### DESCRIPTION

- A pattern of discrete periods of binge eating (within 2-hour period) along with lack of control over eating, followed by compensatory behaviors such as self induced vomiting, misuse of laxatives, and so forth.
- Both binge eating and compensatory behaviors happening at least once per week for 3 months
- *DSM-5* classifies bulimia nervosa as
  - Mild: 1 to 3 episodes of compensatory behaviors
  - Moderate: 4 to 7 episodes of compensatory behaviors
  - Severe: 8 to 13 episodes of compensatory behaviors
  - Extreme: 14 or more episodes of compensatory behaviors
- System(s) affected: oropharyngeal, endocrine/metabolic, gastrointestinal, dermatologic, cardiovascular, nervous

### EPIDEMIOLOGY

- Predominant age: adolescents and young adults
- Mean age of onset: 18 to 21 years
- Predominant sex: female > male (10:1)

### Incidence

28.8 women, 0.8 men per 100,000 per year

### Prevalence

- More prevalent than anorexia nervosa
- 1-3% in women age 16 to 35 years

- 0.5% in young men (higher among gay and bisexual men)

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Combination of biologic, psychological, environmental, and social factors. Unique contribution of any specific factor remains unclear.
- Strong evidence of serotonergic dysregulation in bulimia nervosa
- Substantial literature shows genetic evidence for bulimia nervosa (1)[B].

## *RISK FACTORS*

- Female gender
- History of obesity and dieting
- Body dissatisfaction
- Critical comments about weight, body shape, or eating
- Severe life stressor
- Low self-esteem
- Perceived pressure to be thin
- Perfectionist or obsessive thinking
- Poor impulse control, substance abuse
- Environment stressing high achievement, physical fitness (e.g., armed forces, ballet, cheerleading, gymnastics, or modeling)
- Family history of substance abuse, affective disorders, eating disorder, or obesity
- Type 1 diabetes
- Sexual abuse is not causally related to bulimia.

## *GENERAL PREVENTION*

- Prevention programs can reduce risk factors and future onset of eating disorders (2)[A].
- Target adolescents and young women <sup>3</sup> 15 years
- Realistic and healthy weight management strategies and attitudes
- Decrease body dissatisfaction and promote self-esteem.
- Reduce focus on thin as ideal.

Decrease anxiety/depressive symptoms and improve stress management.

## COMMONLY ASSOCIATED CONDITIONS

- Major depression and dysthymia
- Anxiety disorders
- Substance use disorder
- Bipolar disorder
- Obsessive-compulsive disorder
- Borderline personality disorder

## DIAGNOSIS

### HISTORY

- Patients unlikely to self-identify binge eating or purging behaviors; corroborate with parent/relative
- Unhappiness and/or preoccupation with weight and diet attempts
- Pattern of binge eating and compensatory behaviors
  - Binge is context-specific (usually within 2-hour period, they will eat what would be an unusually large amount for most people)
  - Vomiting (often with little effort)
  - Vigorous aerobic exercise
  - Distress/shame-related to loss of control
- Depressed mood and self-depreciation following the binges
- Other possible signs and symptoms
  - Requesting weight loss help and mildly underweight to overweight
  - Diet pill, diuretic, laxative, ipecac, and thyroid medication use/abuse
  - Menstrual disturbance
  - Fatigue and lethargy
  - Abdominal pain, bloating, constipation, diarrhea, rectal prolapse
  - Sore throat
  - Thermal tooth sensitivity
  - Frequent fluctuations in weight
  - Omission/underdosing insulin in diabetes patients

---

## *PHYSICAL EXAM*

- Often normal
- Bradycardia
- Eroded tooth enamel
- Perimyolysis
- Cheilosis
- Gingivitis
- Sialadenosis
- Asymptomatic, noninflammatory parotid gland enlargement
- Epigastric tenderness to palpation
- Calluses, abrasions, bruising on hand, thumb (Russell sign)
- Peripheral edema

## *DIFFERENTIAL DIAGNOSIS*

- Anorexia, binge eating/purging type
- Major depressive disorder
- Addison disease
- Celiac disease
- Diabetes mellitus
- Hyperthyroidism, hypothyroidism
- Hyperpituitarism
- Hypothalamic brain tumor
- Kleine-Levin syndrome
- Body dysmorphic disorder
- Borderline personality disorder

## *DIAGNOSTIC TESTS & INTERPRETATION*

All lab results may be within normal limits and are not necessary for diagnosis.

- Psychological self-report screening tests may be helpful, but diagnosis is based on meeting the

DSM-5 criteria:

- SCOFF Questionnaire (3)[B]
- Eating Disorder Screen for Primary Care

### *Initial Tests (lab, imaging)*

- Blood work, CBC, and CMP
  - Hypokalemia, hypochloremia
  - Hypomagnesemia, hyponatremia, hypocalcemia, hypophosphatemia
  - Serum amylase levels
  - Alkalosis
  - Elevated BUN
  - Hypoglycemia
- Urinalysis
  - Increased urine specific gravity

### *Diagnostic Procedures/Other*

- Electrocardiogram
- Bradycardia or arrhythmias
- Conduction defects
- Depressed ST segment due to hypokalemia

### *Test Interpretation*

- Esophagitis
- Acute pancreatitis
- Cardiomyopathy and muscle weakness due to ipecac abuse
- Melanosis coli
- Cathartic colon syndrome
- Delayed or arrested skeletal growth
- Stress fracture

Irreversible dental erosions

- Osteopenia/osteoporosis

## TREATMENT

- Cognitive-behavioral therapy (CBT) should be considered as first-line treatment (4,5)[A].
- Interpersonal therapies and group therapies have been found to be helpful.

## GENERAL MEASURES

- Multidisciplinary team
    - Primary care physician, behavioral health provider, nutritionist
  - Build trust; increase motivation for change.
  - Assess psychological and nutritional status.
  - Consider evidence-based self-help program.
  - CBT for bulimia nervosa (4,5)[A]
    - Sixteen to twenty 50-minute appointments
    - Involve patient in establishing goals.
- 
- P.149
- Self-monitoring of food intake, frequency of binges/purges, related antecedents, consequences, thoughts, and emotions
  - Self-monitoring of weight once per week
  - Educate about ineffectiveness of purging for weight control and adverse outcomes.
  - Establish prescribed eating plan to develop regular eating habits and realistic weight goal.
  - Gradually introduce feared foods into diet.
  - Problem-solve how to cope with triggers.
  - Decrease ruminations about calories, weight, and purging.
  - Challenge fear of loss of control.
  - Establish relapse prevention plan.
  - Gradual laxative withdrawal
- Interpersonal therapy

- May act more slowly than CBT
- Transdiagnostic CBT
- Dialectical behavior therapy
- Family therapy for adolescents
- Nutritional education, relaxation techniques
- Educate patient to brush teeth and use baking soda to rinse mouth after vomiting.

## *MEDICATION*

### *First Line*

- Selective serotonin reuptake inhibitors (SSRIs) (6)[A], (7)[B], particularly fluoxetine (Prozac) titrated to 60 mg/day, are effective in reducing symptoms with relatively few side effects. Higher doses than standard doses for depression are often needed.
  - Combination of medication and CBT has been shown to have added benefit over medication or therapy alone.
- To prevent relapse, maintain antidepressant at full therapeutic dose for at least 1 year.
- Avoid bupropion: contraindicated due to its association with seizures in patients who purge
- Precautions
  - Serious toxicity following overdose is common.
  - Patients may vomit medications.

### *Second Line*

- Select different SSRI.
- Ondansetron (Zofran) 4 to 8 mg TID between meals can help prevent vomiting.
- Psyllium (Metamucil) preparations, 1 tbs QHS with glass of water, can prevent constipation during laxative withdrawal.

## *ISSUES FOR REFERRAL*

Patients with bulimia require a multidisciplinary team, including a primary care physician, behavioral health provider, and a nutritionist. Important part of treatment is to arrange mental health therapist for psychotherapy.

## ***ADDITIONAL THERAPIES***

Most patients can be treated as outpatients.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Bright light therapy may help.

## ***INPATIENT CONSIDERATIONS***

- If possible, admit to a specialized eating disorders unit.
- Supervised meals and bathroom privileges
- Monitor weight and physical activity.
- Monitor electrolytes.
- Gradually shift control to patients as they demonstrate improvement.

## ***Admission Criteria/Initial Stabilization***

Hospitalize if severe malnutrition, dehydration, electrolyte disturbances, cardiac dysrhythmia, uncontrolled bingeing and purging, psychiatric emergency (threat to self/others), or if outpatient treatment failed

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

### ***Patient Monitoring***

- Binge-purge activity, including antecedents and consequences
- Level of exercise activity
- Self-esteem, comfort with body and self
- Ruminations and depressive symptoms
- Repeat any abnormal lab values weekly or monthly until stable.

## ***DIET***

- Balanced diet, normal eating pattern
- Reintroduce feared foods.

## PATIENT EDUCATION

- Astrachan-Fletcher E, Maslar M. *The Dialectical Behavior Therapy Skills Workbook for Bulimia: Using DBT to Break the Cycle and Regain Control of Your Life*. Oakland, CA: New Harbinger; 2009.
- <http://www.nami.org/helpline/bulimia.htm>

## PROGNOSIS

- After effective CBT
  - In the short term, 50% of treated individuals do not meet criteria for diagnosis.
  - In the long term (2 to 10 years), 70% may be asymptomatic.
  - Symptomatic individuals may demonstrate remissions, relapses, subclinical, or other eating disorder-related behaviors.
- Untreated
  - Likely to remain chronic/relapsing problem
- Greater weight fluctuations, other impulsive behaviors, childhood obesity, low self-esteem, family history of alcohol abuse, psychiatric comorbidity, and personality disorder diagnoses (e.g., avoidant personality disorder) may predict poor prognosis.
- Mortality rate: 0.4%

## COMPLICATIONS

- Substance use disorder
- Osteopenia/osteoporosis
- Stress fracture
- Gastric dilatation
- Boerhaave syndrome
- Mallory-Weiss tears
- Pseudo-Bartter syndrome
- Spontaneous pneumomediastinum
- Potassium depletion, cardiac arrhythmia, cardiac arrest
- Suicide

## ***Pregnancy Considerations***

Maternal and fetal problems if pregnant

- Binging/purging behaviors may persist, increase, or decrease with pregnancy.

- Increased risk for preterm delivery, operative delivery, and infants with low birth weight should be managed as high risk.

## See Also

- Anorexia Nervosa; Hyperkalemia; Laxative Abuse; Salivary Gland Tumors
- Algorithm: Weight Loss

## Codes

### ICD10

F50.2 Bulimia nervosa

## Clinical Pearls

- Asking "Are you satisfied with your eating patterns?" and/or "Do you worry that you have lost control over how much you eat?" may help to screen for an eating problem.
- Weight is not severely lowered as in anorexia nervosa.
- Consider using a stepped care approach. Start with a guided self-help program using instructional aids; next, begin CBT (e.g., 16 to 20 sessions over 4 to 5 months).
- SSRIs, particularly fluoxetine (60 mg daily), may be helpful as a first step or as an adjunctive treatment with CBT.

# Bunion (Hallux Valgus)

Jennifer G. Chang, MD

## BASICS

### DESCRIPTION

- Lateral deviation of the great toe. Hallux valgus derives from the Latin for "big toe askew"; also commonly known as a bunion
- Lateral deviation of the great toe with medial deviation of the 1st metatarsal leads to a medial prominence of the 1st metatarsophalangeal (MTP) joint and a potentially painful and/or debilitating deformity.
- Progressive subluxation of the 1st MTP joint is common.
- System(s) affected: musculoskeletal/skin

### EPIDEMIOLOGY

- Predominant age: more common in adults
  - Estimated 23% in adults aged 18 to 65 years
  - Estimated 35.7% in elderly >65 years
- Predominant sex: female > male by 2:1

### Prevalence

- Prevalence increases with age particularly in females.
- Juvenile hallux valgus
  - More common in girls (>80% of cases)
- Commonly bilateral
- Pain is not usually the presenting symptom.

### ETIOLOGY AND PATHOPHYSIOLOGY

Multifactorial. Contributing factors include the following:

- Valgus deviation of the hallux promotes varus position of the 1st metatarsal.
- Medial MTP joint capsule stretches and attenuates while the lateral capsule contracts.
- Metatarsal head moves medially, shifting the sesamoid bones to a more lateral position.
- Extensor hallucis longus deviates laterally.
- Lateral and plantar migration of abductor hallucis moves the great toe into plantar flexion and lateral pronation.
- Medial collateral ligament stretches and eventually ruptures due to this deviation, decreasing stability and causing progressive subluxation of the 1st MTP joint.

## *RISK FACTORS*

- Familial predisposition
- Abnormal biomechanics (i.e., flexible flat feet)
- Joint laxity; pronation of hindfoot; Achilles tendon contracture; pes planus (fallen arches)
- Metatarsus primus varus
- Amputation of second toe
- Inflammatory joint disease
- Neuromuscular disorders
- Improper footwear, narrow toe box

## *GENERAL PREVENTION*

Proper footwear may decrease the progression of the disease.

## *COMMONLY ASSOCIATED CONDITIONS*

- Medial bursitis of the 1st MTP joint (most common)
- Hammertoe deformity of the 2nd phalanx
- Plantar callus
- Metatarsalgia
- Degeneration of 1st metatarsal head cartilage
- Pronated feet; ankle equinus
- Onychocryptosis (ingrown toenail)
- Entrapment of the medial dorsal cutaneous nerve

- Synovitis of the MTP joint

## DIAGNOSIS

- Based on clinical exam
- Radiographs are used for staging

### HISTORY

- Painful MTP joint (most common symptom in adults)
- Abnormal position of great toe
- Enlargement of the MTP joint medially (patients complain of a “bump”)
- Shoes don't fit properly
- Pain on ambulation
- Skin irritation, blistering, callus formation at 1st MTP

### PHYSICAL EXAM

- Observe gait; may be antalgic due to pain
- Increased distal metatarsal articular angle (DMAA)
- Medial prominence at the MTP joint
- Medial inflammation and ulceration at the MTP joint
- Skin changes: inflammation, blistering, callus
- Great toe over- or underriding the second toe
- Examine the entire first ray for:
  - 1st MTP range of motion
  - 1st tarsometatarsal mobility
  - Neurovascular integrity
  - Degenerative osteoarthritis

### DIFFERENTIAL DIAGNOSIS

- Trauma
  - Turf toe; sesamoiditis; stress fracture

- Infection
  - Osteomyelitis; septic arthritis
- Joint disorder
  - Osteoarthritis; rheumatoid arthritis; pseudogout; gout
- Tendon disorder
  - Tendinosis; tenosynovitis; tendon rupture
- Other
  - Bursitis; ganglia; foreign body granuloma

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Weight-bearing AP and lateral radiographs (sesamoid view optional) to assess:
  - Joint congruency and degenerative changes
  - Lateral sesamoid bone displacement (1)[A]
  - Rounded 1st MT head (1)[A]
  - Longer 1st metatarsal (1)[A]
- Radiographic parameters:
  - Hallux valgus angle (HA): Long axis of the 1st MT and proximal phalanx is normally <15 degrees.
  - Intermetatarsal angle (IM): Between long axis of 1st and 2nd MT is normally <9 degrees.
  - DMAA: Between 1st MT long axis and line through base of distal articular cap is normally <15 degrees.
  - Hallux valgus interphalangeus: Between long axis of distal phalanx and proximal phalanx is normally <10 degrees.

## **TREATMENT**

- Primary indication for treatment is pain.
- There are conservative and surgical approaches.
- Surgical treatment is generally more effective in improving pain but has attendant risks.

## GENERAL MEASURES

Nonoperative treatment options may improve symptoms and delay the progression of hallux valgus deformity, although high-quality evidence is limited:

- Proper fitting footwear: low-heeled, wide-toe shoes to decrease stress on MTP joint (i.e., wide toe box)
- Orthoses to correct foot alignment (pes planus and overpronation). Improving gait may prevent bunion formation and reduce pressure on the MTP.
- Night splinting: In theory, splinting stabilizes and balances soft tissue structures around the MTP. Limited evidence shows improvement in degree of angulation in mild hallux valgus.
- Manual and manipulative therapy (MMT): stretches contracted soft tissue
- Foot exercises and stretching to improve intrinsic foot muscle strength and increase range of motion
- Pads/spacers: Pads decrease friction on the MTP joint. A toe spacer in the 1st interdigital space can straighten the hallux and may reduce pain (2)[C].

## MEDICATION

- Topical and PO medications (NSAIDs) can be used to relieve pain and swelling. Other topical options include capsaicin cream.
- Corticosteroid injections improve pain.

## ADDITIONAL THERAPIES

Custom orthoses are a safe intervention that may decrease pain at 6 and 12 months compared with no treatment; however, this improvement is less than that seen with surgical intervention (3) [B].

---

P.151

## SURGERY/OTHER PROCEDURES

- Surgery is indicated if patient has severe pain, dysfunction, or persistent symptoms that do not abate with conservative therapy.
- Surgery is beneficial for patients with severe symptoms (3)[B]:
  - >150 different surgical techniques to treat hallux valgus; none has been proven to be superior, and no universally accepted standard exists for selecting a particular procedure over another.
  - Choice of surgical technique depends on the severity of disease, the HA and IM angles,

congruency and subluxation of the MTP joint, patient-specific factors, and the pathologic element the surgeon determines needs correcting. Examples include the following:

- Arthrodesis: fusion of the 1st MTP joint; reserved for severe and/or recurrent hallux valgus
  - Arthroplasty: removing the joint or replacing it with a prosthesis
  - Exostectomy/bunionectomy: removing the medial bony prominence of the MTP joint
  - Soft tissue realignment: alters the function of surrounding ligaments and tendons; used for minor, flexible deformities
  - Osteotomy and realignment: can correct large deformities, but evidence of long-term outcome is lacking (4)[C]
  - Mini-tight rope procedure: use of a Fiberwire to correct the misalignment of the deformity; reportedly allows for faster recovery and earlier weight bearing (5)[C] but may have high complication and failure rates (6)[C]
- Surgery can decrease pain and increase foot alignment. Some patients may have little to no improvement in symptoms despite interventions.
  - Establish realistic expectations prior to surgery (7)[C].
  - In pediatric patients, surgery should generally be delayed until skeletal maturity (8)[C].

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

Marigold ointment may reduce pain and soft tissue swelling (9)[C].

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Postoperative treatment includes physical therapy, physiotherapy, supportive footwear, continuous passive motion, or manual manipulation.
- Time until full weight bearing depends on the surgical procedure.

### ***PROGNOSIS***

Patient outcome varies depending on biomechanical factors, severity of the deformity, and treatment modality used. The radiologic HA angle predicts surgical outcomes. Patients with an HA angle <37 degrees have a higher chance of having the deformity successfully corrected with surgery compared with patients with an HA angle >37 degrees.

## COMPLICATIONS

- Risks associated with surgery include infection, persistent pain, and poor cosmetic result.
- Additional risks vary with the surgical procedure.
- Other complications may include:
  - Early swelling
  - Hallux varus
  - Recurrence of bunion
  - Metatarsal fracture
  - Decreased sensation over the 1st metatarsal or phalanx

## Codes

### ICD10

- M20.10 Hallux valgus (acquired), unspecified foot
- M20.11 Hallux valgus (acquired), right foot
- M20.12 Hallux valgus (acquired), left foot

## Clinical Pearls

- Avoid footwear with high heels, pointed toe boxes, or inadequate toe space to reduce development or progression of bunions.

- Surgery generally results in superior outcomes for pain relief in appropriately selected patients.
- No single surgical method has shown to be superior for long-term pain relief.
- Establish realistic expectations prior to surgery to improve patient satisfaction with surgical outcomes.

# Burns

Caleb J. Mentzer, DO

James R. Yon, MD

## BASICS

### DESCRIPTION

- Tissue injuries caused by application of heat, chemicals, electricity, or irradiation
- Extent of injury (depth of burn) is a result of intensity and duration of exposure.
  - 1st degree involves superficial layers of epidermis.
  - 2nd degree involves varying amounts of epidermis (with blister formation) and part of the dermis.
  - 3rd degree involves destruction of all skin elements (full thickness) with coagulation of subdermal plexus.
- System(s) affected: endocrine/metabolic, pulmonary, skin/exocrine

### Geriatric Considerations

- Prognosis is worse for severe burns.
- Patients >60 years of age account for 11% all of burns.

### Pediatric Considerations

Consider child abuse or neglect when dealing with hot water burns in children; abuse accounts for 15% of pediatric burns. Special concerns are sharply demarcated wounds, immersion injuries, and suspect stories. Involve child welfare services early.

### EPIDEMIOLOGY

- Predominant age: 30 years; 13% infants; 11% >60 years of age
- Predominant gender: males account for 70%

### Incidence

Per year in the United States

- 1.2 to 2 million burns; 700,000 emergency room visits; 45,000 to 50,000 hospitalizations; 3,900 deaths owing to burn-related complications
- In children: 250,000 burns; 15,000 hospitalizations; 1,100 deaths
- Estimated total cost of \$2 billion annually for burn care
- House fires cause 75% of deaths.
- Burn deaths decreasing nationally due to improved prevention and treatment
- Increase in burns from the illegal production of methamphetamines. Patients can present with a combination of chemical burn, thermal burn, and explosion injury.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Open flame and hot liquid are the most common causes of burns (heat usually  $345^{\circ}\text{C}$ ): Flame burns are more common in adults; scald burns are more common in children.
- Caustic chemicals or acids (may show little signs or symptoms for the first few days)
- Electricity (may have significant injury with very little damage to overlying skin)
- Excess sun exposure

## *RISK FACTORS*

- Water heaters set too high
- Workplace exposure to chemicals, electricity, or irradiation
- Young children and older adults with thin skin are more susceptible to injury.
- Carelessness with burning cigarettes: related to 18% of fatal fires in 2006
- Inadequate or faulty electrical wiring
- Lack of smoke detectors: Lacking or nonfunctioning smoke alarms are implicated in 63% of residential fires.
- Arson: cause of 12.4% of fires that resulted in fatalities in 2012

## *GENERAL PREVENTION*

Home safety education should be a key mechanism for injury prevention.

- Families educated on home safety were more likely to have safe hot water temperatures.
- Safety education results in more families having functioning smoke alarms and increased use of fireguards.

## COMMONLY ASSOCIATED CONDITIONS

### Smoke inhalation syndrome

- May involve thermal burn to respiratory mucosa (e.g., trachea, bronchi) as well as carbon monoxide inhalation
- Occurs within 72 hours of burn
- Should be suspected in all burns occurring in an enclosed space or exposure to explosions

## DIAGNOSIS

### HISTORY

- History of source of burn
- In children or elderly: Check for consistency between the history and the burn's physical characteristics.

## PHYSICAL EXAM

- 1st degree: Erythema of involved tissue, skin blanches with pressure, skin may be tender.
- 2nd degree: Skin is red and blistered, skin is very tender.
- 3rd degree: Burned skin is tough and leathery; skin is nontender.
- Rule of 9s (1)[C]
  - Each upper extremity: adult and child 9%
  - Each lower extremity: adult 18%; child 14%
  - Anterior trunk: adult and child 18%
  - Posterior trunk: adult and child 18%
  - Head and neck: adult 10%; child 18%
- Quick estimate: The surface area of the patient's hand (palmar surface plus fingers) is 1% of the body surface area (BSA).
- Careful documentation of extent of burn and the estimated depth of burn
- Check for any signs suggestive of potential airway involvement: singed nasal hair, facial burns, carbonaceous sputum, progressive hoarseness, inflamed oropharynx, circumferential burns around the neck, tachypnea

## DIAGNOSTIC TESTS & INTERPRETATION

- Children: glucose (hypoglycemia may occur in children because of limited glycogen storage)
- Smoke inhalation: arterial blood gas, carboxyhemoglobin
- Electrical burns: ECG, urine myoglobin, creatine kinase isoenzymes

### *Initial Tests (lab, imaging)*

- Labs: hematocrit; type and crossmatching; electrolytes, including BUN and creatinine; urinalysis
- Imaging: Chest radiograph; Xenon scan is useful in suspected smoke inhalation.

### *Diagnostic Procedures/Other*

Bronchoscopy may be necessary in smoke inhalation to evaluate lower respiratory tract (2)[A].

## TREATMENT

- Prehospital care (1)[C]
  - Remove the patient from the source of burn.
  - Extinguish and remove all burning clothing.
  - Room-temperature water may be poured onto burn but only in the first 15 minutes following burn exposure.
  - Wrap patient to prevent hypothermia.
  - All patients to receive 100% oxygen via face mask
- Hospitalization for all serious burns
  - 2nd-degree burns > 10% of BSA
  - Any 3rd-degree burn
  - Burns of hands, feet, face, or perineum
  - Electrical or lightning burns
  - Inhalation injury
  - Chemical burns
  - Circumferential burn

Transfer to burn center for (3)[C]

- 2nd- and 3rd-degree burns > 10% of BSA in patients <10 years and >50 years of age
- 2nd-degree burns >20% of BSA and full-thickness burns >5% BSA in any age range
- 3rd-degree burns in any age group
- Burns of hands, feet, face, or perineum
- Electrical or lightning burns
- Inhalation injury
- Chemical burns
- Circumferential burn
- Burns in patients with additional trauma (fractures, etc.) in which the burn is the more severe injury; otherwise, send to trauma center for stabilization.
- Burn injuries in patients with preexisting medical conditions that could affect management, mortality, or recovery

## *GENERAL MEASURES*

- Based on depth of burns and accurate estimate of total BSA involved (rule of 9s)
- Tetanus prophylaxis (if not current)
- Remove all rings, watches, and other items from injured extremities to avoid tourniquet effect.
- Remove clothing and cover all burned areas with dry sheets.
- Flush area of chemical burn (for ÷2 hours).
- For all major burns, use 100% oxygen administration; consider early intubation.
- Do not apply ice to burn site.
- Nasogastric tube (high risk of paralytic ileus)
- Foley catheter
- Analgesia
- ECG monitoring in the first 24 hours following electrical burn
- Whirlpool hydrotherapy followed by silver sulfadiazine (Silvadene) occlusive dressings in severe burns
- Daily or BID cleansing with dressing changes
- Burn fluid resuscitation (1)[C]

- Calculate fluid resuscitation from time of burn, not from time treatment begins.
- 2 to 4 mL lactated Ringer × body weight (kg) × % BSA burn (1/2 given in first 8 hours, in second

8 hours, and in third 8 hours); in children, this is given in addition to maintenance fluids and is adjusted according to urine output and vital signs. Protocol-based resuscitation leads to superior outcomes.

- Colloid solutions are not recommended during the first 12 to 24 hours of resuscitation (1)[C],(4)[A].
  - Other: Use of biologic membranes or skin substitutes may be indicated for burn coverage.
- Inhalation injury
    - Intubation, ventilation with positive end-expiratory pressure assistance
    - Hyperbaric oxygen treatment may be useful in patients with carbon monoxide levels >25%, patients with coma, focal neurologic deficit, ischemic ECG changes, and pregnant patients (1)[C].

## MEDICATION

### First Line

- IV morphine or hydromorphone (Dilaudid) for severe pain
- Oral analgesics, such as acetaminophen (Tylenol) with codeine, acetaminophen with oxycodone (Percocet), or acetaminophen with hydrocodone (Lortab) for moderate pain
- Silver sulfadiazine (Silvadene): Apply topically to burn site (can cause leukopenia). Do not use in sulfa-allergic patients, women who are pregnant/breastfeeding, or infants <2 months)
- Neosporin or bacitracin ointment: Apply to facial burns.
- Mupirocin: has potent inhibitory activity against methicillin-resistant *Staphylococcus aureus* (MRSA) (5)[B]
- Acticoat A.B. (a dressing consisting of two sheets of high-density polyethylene mesh coated with nano-crystalline silver) has a more controlled, prolonged release of silver, allowing less frequent dressing changes (5)[B].
- Electrical burn with myoglobinuria will require alkalization of urine and mannitol.
- Consider H<sub>2</sub> blockers (e.g., famotidine) or proton pump inhibitors (e.g., lansoprazole, pantoprazole) for stress ulcer prophylaxis in severely burned patients.

- Tetanus toxoid/tetanus immunoglobulin
- There is no clear indication for prophylactic systemic antibiotics (5)[B].
- Use of negative pressure wound therapy may result in a low-protease environment with higher levels of angiogenic factor (vascular endothelial growth factor [VEGF]) during wound healing, leading to more chaotic, hyperkeratinized, thickened epidermis when compared with a standard hydrocolloid dressing (6)[C].

## *Second Line*

- Mafenide (Sulfamylon) for full-thickness burn, best against *Pseudomonas* (*Caution*: metabolic acidosis, painful)
- Silver nitrate 0.5% (messy, leeches electrolytes from burn, causes water toxicity)
- Povidone-iodine (Betadine) may result in iodine absorption from burn and Òtan eschar, Ó makes dŽbridement more difficult.
- Travase (enzymatic debridement)

## **SURGERY/OTHER PROCEDURES**

- Escharotomy may be necessary in constricting circumferential burns of extremities or chest due to compartment syndrome.
- Tangential excision with split-thickness skin grafts: Early excision of burns results in a significant reduction in mortality (excluding patients with inhalational injury) and a significant decrease in hospital length of stay (7)[B].
- Various dressings (e.g., biosynthetic, biologic) are available to help reduce the number of dressing changes and promote healing.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Early mobilization is the goal.

### ***DIET***

- High-protein, high-calorie diet when bowel function resumes
- Nasogastric tube feedings may be required in early postburn period.
- Total parenteral nutrition if NPO is expected for >5 days

- Early initiation of enteral nutrition in the first 24 hours of admission results in shorter intensive care unit (ICU) stay and lower wound infection rates

## *PATIENT EDUCATION*

- Use of sunscreen: Skin grafts or newly epithelialized skin is highly sensitive to sun exposure and thermal extremes.
- Prevent access to electrical cords/outlets.
- Isolate household chemicals.
- Use low-temperature setting for water heater (<54°C).
- Household smoke detectors with special emphasis on maintenance
- Family/household evacuation plan
- Proper storage and use of flammable substances
- Burn management: <http://www.aafp.org/afp/2000/1101/p2029.html>
- Burn prevention: <http://www.aafp.org/afp/2000/1101/p2032.html>

## *PROGNOSIS*

- 1st-degree burn: complete resolution
- 2nd-degree burn: epithelialization in 10 to 14 days (deep 2nd-degree burns probably will require skin graft)
- 3rd-degree burn: no potential for reepithelialization; skin graft is required.
- Baux score (sum of age and TBSA burned) and Denver 2 score (pulmonary score ranging 0 to 3, using PaO<sub>2</sub>/FiO<sub>2</sub> cutoffs of 100, 175, and 250), renal score (0 to 3, using creatinine cutoffs of 1.8, 2.5, and 5.0 mg/dL), hepatic score (0 to 3, using bilirubin cutoffs of 2, 4, and 8 mg/dL), and cardiac score (0 to 3, based on number and dosage of inotropes) can be used to estimate mortality (8)[B].
- Length of hospital stay and need for ICU care depend on extent of burn, smoke inhalation, comorbidities, and age.
- Burn size is correlated to complications; >60% TBSA burned in children and >40% in adults are at increased risk for mortality and morbidity (8)[B].
- A 50% survival rate can be expected with a 62% burn in patients aged 0 to 14 years, 63% burn in patients aged 15 to 40 years, 38% burn in patients aged 40 to 65 years, and 25% burn in patients >65 years of age (1)[C].
- 90% of survivors can be expected to return to an occupation comparable to their preburn

employment.

## COMPLICATIONS

- Gastroduodenal ulceration (Curling ulcer)
- Marjolin ulcer: malignant squamous cell carcinoma developing in old burn site
- Signs of infection: discoloration, green fat, edema, eschar separation, and conversion of 2nd-degree to 3rd-degree wound
- Biopsy is the best way to diagnose wound infection.
- Burn wound sepsis: most commonly *S. aureus* (including MRSA), vancomycin-resistant enterococci, and gram-negative organisms (5)[B].
- Pneumonia
- Decreased mobility with possibility of future flexion contractures
- Hypertrophic scarring is common with burns.

## Codes

### ICD10

- T30.0 Burn of unspecified body region, unspecified degree
- T30.4 Corrosion of unspecified body region, unspecified degree

### Clinical Pearls

- 1st degree: erythema of involved tissue; skin blanches with pressure. Skin may be tender.
- 2nd degree: Skin is red and blistered. Skin is very tender.
- 3rd degree: Burned skin is tough and leathery. Skin is not tender.

# Bursitis, Pes Anserine (Pes Anserine Syndrome)

Jennifer B. Schwartz, MD

## BASICS

### DESCRIPTION

- The pes anserinus (ÒgoosefootÓ) is the combined insertion of the sartorius, gracilis, and semitendinosus (ÒSGTÓ-from medial to lateral) tendons on the anteromedial tibia.
- The pes anserine muscles help flex the knee and resist valgus stress
- The pes anserine bursa lies deep to the SGT tendons and superficial to the tibial attachment of the medial collateral ligament.
- *Pes anserine syndrome* is due to irritation of the bursa and/or tendons in this area

### EPIDEMIOLOGY

#### *Incidence*

Inflammation of the pes anserine bursa is detected in up to 2.5% of MRI studies of patients with knee pain. The overall incidence is likely higher.

### ETIOLOGY AND PATHOPHYSIOLOGY

Pes anserine bursitis occurs due to:

- Overuse injury
- Excessive valgus and rotary stresses
- Mechanical forces and degenerative changes
- Direct trauma

### RISK FACTORS

- Obesity
- Age, female gender
- Pes planus; genu valgum

Knee joint laxity/ligamentous injury

- Long distance running, hill running; change in mileage
- Swimming (Öbreaststroker's kneeÓ); cycling
- Sports with side-to-side (cutting) activity (soccer, basketball, racquet sports)

## COMMONLY ASSOCIATED CONDITIONS

- Osteoarthritis (OA)
  - Knee pain due to OA is often associated with pes anserine bursitis, both of which may need specific treatment.
  - Higher grades of OA associated with a thicker pes anserine bursa and larger area of bursitis (1,2)[C]
- Valgus knee deformity
- Obesity
- Diabetes mellitus (questionable association)

## DIAGNOSIS

### HISTORY

- Medial knee pain is the most common complaint.
- Changes in training regimen or mileage often accompany knee pain.
- Pain is located 4 to 6 cm distal to the medial joint line on the anteromedial aspect of the tibia.
- Pain exacerbated by knee flexion:
  - Going up or down stairs
  - Getting out of a chair

### PHYSICAL EXAM

- Common findings include:
  - Tenderness to palpation at the pes anserine insertion
    - 30% of asymptomatic patients will have tenderness to deep palpation in this area.
  - Pain worsens with flexion of the knee against resistance.

- Localized swelling of the pes anserine insertion
- Findings that suggest an alternative diagnosis: joint effusion, tenderness directly over the joint line, erythema or warmth, locking of the knee, systemic signs such as fever or pain with passive knee movement

## *DIFFERENTIAL DIAGNOSIS*

- Medial collateral ligament injury
- Medial meniscal injury
- Medial plica syndrome
- Medial compartment OA
- Semimembranosus bursitis
- Popliteal/meniscal cyst
- Tibial stress fracture
- Septic arthritis

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Primarily a clinical diagnosis
- Lab work not indicated. If infection is suspected: CBC, ESR, C-reactive protein, and joint fluid analysis are indicated.
- Imaging is not indicated unless there is concern for bony injury/fracture, ligamentous injury, or meniscal tear.

### *Follow-Up Tests & Special Considerations*

- Ultrasound (US)
  - Can demonstrate focal edema within the pes anserine bursa but has poor correlation with clinical findings
  - Many patients with the clinical diagnosis of pes anserine bursitis have no morphologic changes of the pes anserine complex on US (3)[C].
- MRI: can demonstrate inflammation of the bursa, and delineate the pes anserine bursa from other structures. T2-weighted axial images are best on MRI (4)[C].

No large studies have evaluated the correlation between the clinical diagnosis of pes anserine bursitis and radiographic evidence of pes anserine pathology on MRI.

- May see fluid in the pes bursa on MRI in 5% of asymptomatic patients (5)[C]

## TREATMENT

Pes anserine bursitis is often self-limited. Conservative therapy is most common:

- Relative rest and activity modification to avoid offending movements (especially knee flexion)
- Ice to the affected area
- Physical therapy for knee strengthening and range of motion activities
- NSAIDs for pain control
- Corticosteroid injection for pain relief and as an antiinflammatory
- Weight loss to improve biomechanical forces at the knee

## MEDICATION

### *First Line*

NSAIDs, such as ibuprofen (800 mg PO TID) or naproxen (500 mg PO BID), are common 1st-line therapy.

### *Second Line*

- Corticosteroid injection combined with local anesthetic provides relief in many patients (6)[C].
  - Inject at the point of maximal tenderness using standard aseptic technique
  - ÷2 mL of anesthetic (i.e., 1% lidocaine) and 1 mL of steroid (i.e., 40 mg of methylprednisolone ) is injected into the bursa using a small (e.g., 25-gauge, 1-inch) needle.
- US-guided injection is superior to blind injection (8)[C].
- Platelet-rich plasma injections also provide pain relief (9)[C].
- Injection of steroid and anesthetic provides pain relief, which allows for physical therapy and

rehabilitative efforts.

## **ADDITIONAL THERAPIES**

Physical therapy

- Hamstring and Achilles stretching
- Quadriceps strengthening—particularly of the vastus medialis (terminal 30 degrees of knee extension)
- Adductor strengthening

## **SURGERY/OTHER PROCEDURES**

- No role for surgery in routine isolated cases
- Drainage or removal of bursa may be used in severe/refractory cases.

## **ONGOING CARE**

Home exercise program focusing on flexibility and strengthening

## **DIET**

Consider dietary changes as part of a comprehensive weight-loss program if obesity is a contributing factor.

## **PROGNOSIS**

Most cases of pes anserine syndrome respond to conservative therapy. Recurrence is common, and multiple treatments may be required.

## Codes

### ICD10

- M70.50 Other bursitis of knee, unspecified knee
- M70.51 Other bursitis of knee, right knee
- M70.52 Other bursitis of knee, left knee

# Clinical Pearls

- Consider pes anserine syndrome in patients presenting with medial knee pain.
- Pes anserine syndrome is relatively common in athletes and in older, obese patients with OA.
- Tenderness over the insertion of the pes anserine tendon on the medial aspect of the tibia 4 to 6 cm distal to the joint line is common in asymptomatic patients as well—correlation of the entire clinical picture is necessary for accurate diagnosis.
- Consider pes anserine syndrome in patients who have persistent symptoms associated with medially-sided OA
- Treatment is typically conservative. A local steroid/anesthetic injection may provide pain relief and enhance rehabilitation.

# Candidiasis, Mucocutaneous

Hugh Silk, MD, MPH, FAAFP

Sheila O. Stille, DMD

Azra Borogovac, MD

## BASICS

### DESCRIPTION

- Heterogeneous mucocutaneous disorder caused by infection with *Candida* species
- Characterized by superficial infection of the skin, mucous membranes, and nails
- >20 *Candida* species cause infection in humans. *Candida albicans* is most common.
- Candidiasis affects:
  - Aerodigestive system
    - Oropharyngeal candidiasis (thrush): mouth, pharynx
    - Angular cheilitis: corner of the mouth
    - Esophageal candidiasis
    - Gastritis and/or ulcers, associated with thrush; alimental or perianal
  - Other systems
    - Candida vulvovaginitis: vaginal mucosa and/or vulvar skin
    - Candidal balanitis: glans of the penis
    - Candidal paronychia: nail bed or nail folds
    - Folliculitis
    - Interdigital candidiasis: webs of the digits
    - Candidal diaper dermatitis and intertrigo (within skin folds)
- Synonym(s): monilia; thrush; yeast; intertrigo

### ALERT

Vaginal antifungal creams and suppositories can weaken condoms and

diaphragms.

## *Pregnancy Considerations*

- Vaginal candidiasis is common during pregnancy.
- Topical treatment during pregnancy should be extended by several days.
- Vaginal yeast infection at birth increases the risk of newborn thrush but is of no overall harm to baby.

## **EPIDEMIOLOGY**

- Common in the United States; particularly with immunodeficiency and/or uncontrolled diabetes
- Age considerations
  - Infants and seniors: thrush and cutaneous infections (infant diaper rash)
  - Women of childbearing age: vaginitis
  - Prepubertal or postmenopausal: yeast vaginitis
  - Predominant sex: female > male

## *Incidence*

Unknown—mucocutaneous candidiasis is common in immunocompetent patients. Complication rates are low.

## *Prevalence*

*Candida* species are normal flora of oral cavity, pharynx, esophagus, and GI tract that are present in >70% of the U.S. population.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

*C. albicans* (responsible for 80-92% vulvovaginal and 70-80% oral isolates). Altered cell-mediated immunity against *Candida* species (either transient or chronic) increases susceptibility to infection.

## *Genetics*

Chronic mucocutaneous candidiasis is a heterogeneous, genetic syndrome with infection of skin, nails, hair, and mucous membranes; typically presents in infancy.

## **RISK FACTORS**

- Immunosuppression

- Antibacterial therapy (broad-spectrum antibiotics)
- Douches, chemical irritants, and concurrent vaginitides alter vaginal pH predisposing to candidal vaginitis.
- Denture wear
- Birth control pills; intrauterine devices
- Hyperglycemia; diabetes
- Uncircumcised men at higher risk for balanitis

## **GENERAL PREVENTION**

- Use antibiotics and steroids judiciously; rinse mouth after inhaled steroid use (1)[A].
- Avoid douching. Treat other vaginal infections.
- Minimize perineal moisture (wear cotton underwear; frequent diaper changes).
- Clean dentures often; use well-fitting dentures, and remove during sleep.
- Optimize glycemic control in diabetics.
- Use preventive regimens during cancer treatments (2)[A].
- Treat with HAART in HIV-infected patients
- Antifungal prophylaxis against oral candidiasis is not recommended in HIV-infected adults unless patients have frequent or severe recurrences (3)[A].

## **COMMONLY ASSOCIATED CONDITIONS**

- HIV
- Leukopenia
- Diabetes mellitus
- Cancer and other immunosuppressive conditions

## **DIAGNOSIS**

### **HISTORY**

- Infants/children
  - Oral: adherent white patches on oral mucosae or on the tongue that do not wipe away easily

Perineal: erythematous rash with characteristic satellite lesions; painful if skin layer eroded. 40-75% of diaper rashes lasting >3 days are *C. albicans* (4,5)[A].

- Angular cheilitis: painful fissures in corners of mouth
- Adults
  - Vulvovaginal lesions; whitish “curd-like” discharge; pruritus; burning
- Immunocompromised hosts
  - Oral: white, raised, painless, distinct patches; red, slightly raised patches
  - Esophagitis: dysphagia, odynophagia, retrosternal pain; usually concomitant thrush
  - GI symptoms: abdominal pain
  - Balanitis: erythema, erosions, scaling; dysuria
  - Folliculitis: follicular pustules
  - Interdigital: redness, itchiness at base and web-spaces of fingers and/or toes, possible maceration

## PHYSICAL EXAM

- Infants/children
  - Oral: white, raised, distinct patches within the mouth; when wiped off reveals red base
  - Perineal: erythematous maculopapular rash with satellite pustules or papules
  - Angular cheilitis: tender fissures in mouth corners, often cracked and bleeding
- Adults
  - Vulvovaginal: thick, whitish, cottage cheese-like discharge; vagina or perineum erythema
- Immunocompromised hosts
  - Oral: white, raised, nontender, distinct patches; red, slightly raised patches; thick, dark-brownish coating; deep fissures
  - Esophagitis: often, oral thrush is visible.
  - Balanitis: erythema, linear erosions, scaling
  - Folliculitis: follicular pustules
  - Interdigital: redness, excoriations at base of fingers and/or toes, often maceration

# DIFFERENTIAL DIAGNOSIS

- For oral candidiasis
  - Leukoplakia; lichen planus; geographic tongue
  - Herpes simplex; erythema multiforme
  - Pemphigus
- Baby formula or breast milk can mimic thrush—easier to remove than thrush (no red base when wiped away)
- Hairy leukoplakia: does not rub off; dorsum and lateral margins of tongue
- Angular cheilitis from vitamin B or iron deficiency, staphylococcal infection, or edentulous overclosure
- *Bacterial vaginosis* and *Trichomonas vaginalis* tend to have more odor, itch, and a different discharge.

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- 10% KOH slide preparation: mycelia (hyphae) or pseudo-mycelia (pseudohyphae) yeast forms; few WBC
- Associated with normal vaginal pH (<4.5)
- Barium swallow: cobblestone appearance, fistulas, or dilatation (denervation)

## Diagnostic Procedures/Other

- If 1st-line treatment fails, obtain samples for culture
- Esophagitis may require endoscopy with biopsy (if suspicious for cancer).
- HIV seropositive patients with thrush and dysphagia relieved by antifungal have *Candida* esophagitis.

## Test Interpretation

Biopsy: epithelial parakeratosis with polymorphonuclear leukocytes in superficial layers; periodic acid-Schiff staining reveals presence of candidal hyphae.

## TREATMENT

# GENERAL MEASURES

Screen for immunodeficiency.

## MEDICATION

### First Line

- Vaginal (choose 1)
  - Miconazole (Monistat) 2% cream: one applicator or 200 mg (one suppository), intravaginally qhs for 7 days
  - Clotrimazole (Gyne-Lotrimin, Mycelex): intravaginal tablets (100 mg qhs for 7 days; 200 mg qhs for 3 days; 500 mg daily for 1 day) or 2% cream (one applicator qhs for 3 days)
  - Fluconazole 150 mg PO single dose

---

P.157

- Oropharyngeal
  - Mild disease
    - Clotrimazole (Mycelex): oral 10 mg troche; 20 minutes 5 times daily for 7 to 14 days
    - Nystatin suspension: 100,000 U/mL swish and swallow 400,000 to 600,000 U 4 times per day
    - Nystatin pastilles: 200,000 U each, QID daily for 7 to 14 days (6)[B],(7)[A]
    - Denture wearers
      - Nystatin ointment: 100,000 U/g under denture and corners of mouth for 3 weeks
      - Remove dentures at night; clean 2× weekly with diluted (1:20) bleach.
  - Moderate to severe disease
    - Fluconazole: 200 mg load then 100 to 200 mg (>14 days of age: 6 mg/kg × 1 dose, then 3 mg/kg q24h × 7-14 days [max 100 mg/day])
- Esophagitis
  - Fluconazole: PO 400 mg load then 200 to 400 mg/day for 14 to 21 days or IV 400 mg (6 mg/kg) daily if oral therapy not tolerated

### Pregnancy Considerations

2% miconazole cream, intravaginally, for 7 days in uncomplicated candidiasis. Systemic

amphotericin B for invasive candidiasis in pregnancy.

## Second Line

- Vaginal
  - Terconazole (Terazol): 0.4% cream (one applicator qhs for 7 days of induction therapy); 0.8% cream/80-mg suppositories (one applicator or one suppository qhs for 3 days)
  - For recurrent cases (<sup>3</sup>4 symptomatic episodes in 1 year): induction therapy with 10 to 14 days of topical or oral azole, then, fluconazole, 150 mg once per week for 6 months (6)[A]
    - In HIV patients: Concerns with this regimen include emergence of drug resistance (8)[A].
- Oropharyngeal
  - Miconazole oral gel (20 mg/mL): QID, swish and swallow
  - Itraconazole (Sporanox) suspension: 200 mg (20 mL) daily; swish-swallow for 7 to 14 days
  - Posaconazole (Noxafil) oral suspension: 400 mg BID for 3 days, then 400 mg daily for up to 28 days
  - Amphotericin B (Fungizone) oral suspension (100 mg/mL): 1 mL QID daily, swish and swallow; use between meals
- Esophagitis
  - Amphotericin B (variable dosing) IV dose of 0.3 to 0.7 mg/kg daily; or an echinocandin should be used for patients who cannot tolerate oral therapy.
  - For refractory disease:
    - Itraconazole (Sporanox) oral solution: 200 mg daily
    - Posaconazole (Noxafil) oral suspension: 400 mg BID
    - Voriconazole (Vfend) 100 to 200 mg q12h PO or IV for 14 to 21 days (6)[A]
- Continue treatments for 2 days after infection gone:
  - Contraindications
    - Ketoconazole, itraconazole, or nystatin (if swallowed): severe hepatotoxicity
    - Amphotericin B: can cause nephrotoxicity
  - Precautions
    - Miconazole: can potentiate the effect of warfarin but drug of choice in pregnancy

- Fluconazole: renal excretion: rare; hepatotoxicity: resistance frequent
- Itraconazole: Doubling the dosage results in  $\pm$ 3-fold increase in itraconazole plasma concentrations.
- Possible interactions (rarely seen with creams, lotions, or suppositories)
  - Fluconazole
    - Rifampin: decreased fluconazole concentrations
    - Tolbutamide: decreased concentrations
    - Warfarin, phenytoin, cyclosporine: altered metabolism; check levels.
  - Itraconazole: potent CYP 3A4 inhibitor. Carefully assess all coadministered medications.

## ISSUES FOR REFERRAL

- Patients without obvious reasons for recurrent superficial candidal infections should be evaluated for concurrent immunodeficiency.
- GI candidiasis

## ADDITIONAL THERAPIES

- For infants with thrush: Boil pacifiers and bottle nipples; assess mother's breasts/nipples for concurrent candida infection.
- For denture-related candidiasis: disinfect dentures (using soak solution of benzoic acid, 0.12% chlorhexidine gluconate, 1:20 NaOCl or alkalize proteases), and treat orally

## COMPLEMENTARY & ALTERNATIVE MEDICINE

Probiotics: *Lactobacillus* and *Bifidobacterium* may inhibit *Candida* spp.

## INPATIENT CONSIDERATIONS

### Nursing

Proper oral hygiene. Protocols for brushing, denture care, and oral cavity moistening reduce oral candidiasis.

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

## Patient Monitoring

Immunocompromised persons benefit from regular evaluation and screening.

## DIET

Active-culture yogurt or other live lactobacillus may decrease colonization; indeterminate evidence.

## PATIENT EDUCATION

- Advise patients at risk for recurrence about overgrowth with antibacterial therapy.
- Azole medications are pregnancy Category C.

## PROGNOSIS

- Benign prognosis in immunocompetent patients
- For immunosuppressed persons, *Candida* may become an AIDS-defining illness with significant morbidity.

## COMPLICATIONS

In HIV patients, moderate immunosuppression (e.g., CD4 200 to 500 cells/mm<sup>3</sup>) may be associated with chronic candidiasis. With more severe immunosuppression (e.g., CD4 <100 cells/mm<sup>3</sup>), esophagitis or systemic infection are possible.

## Codes

### ICD10

- B37.9 Candidiasis, unspecified
- B37.0 Candidal stomatitis
- B37.49 Other urogenital candidiasis

## Clinical Pearls

- Candidiasis is generally a clinical diagnosis. KOH preparations are a simple confirmatory test in the office setting. Culture and biopsy are rarely needed to identify resistant strains.
- Person-to-person transmission is rare.
- If tongue pain continues after treatment, consider burning mouth syndrome. Obtain a biopsy if there is concern for oral cancer.
- Oral antifungal medications are hepatically metabolized and may have serious side effects.

# Carbon Monoxide Poisoning

Viren Kaul, MD

Faruq Pradhan, MBBCh

Anthony W. Gray Jr., MD

## BASICS

### DESCRIPTION

- Carbon monoxide (CO) is an odorless, tasteless, colorless gas that has the potential to cause sudden illness and even death if inhaled; it is a leading cause of poisoning death in the United States.
- CO is produced by combustion of carbon-containing compounds (wood, charcoal, oil, gas):
  - CO inhalation leads to displacement of oxygen from binding sites on hemoglobin.
  - Detrimental effects are related to tissue hypoxia from decreased oxygen content and a shift of the oxyhemoglobin dissociation curve to the left, further impairing oxygen unloading from hemoglobin.
- CO also binds to mitochondrial cytochrome oxidase, impairing adenosine triphosphate (ATP) production. It also binds to myoglobin thereby affecting muscle function.
- System(s) affected: cardiovascular, pulmonary, musculoskeletal, nervous

### *Pregnancy Consideration*

Tissue hypoxia affects the fetal tissue. CO poisoning may cause significant fetal abnormalities, depending on the developmental stage. CO has a greater affinity for, and longer half-life when bound to fetal hemoglobin. Therefore, a pregnant mother potentially may be unaffected while the fetus is affected.

### EPIDEMIOLOGY

#### *Incidence*

- ≈50,000 emergency department visits annually (1)
- 235 CO exposure-related deaths were reported to U.S. poison centers between 2000 and 2009; however, this is likely an underestimation with closer 500 deaths occurring per year, on

review of previous data. Unintentional poisoning is most common during winter months in cold climates, but can also occur in warm climates with use of generators, boats, and so forth.

- Intentional CO poisoning is  $\div 10$  times higher than unintentional poisonings.
- Likely markedly underdiagnosed because vague symptoms do not prompt individuals to seek medical attention

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

- CO is rapidly absorbed in lungs.
- CO has  $\div 240$  times the affinity for hemoglobin compared to oxygen.
- CO binds to hemoglobin to form carboxyhemoglobin (COHb), resulting in impaired oxygen-carrying capacity, utilization, and delivery:
  - Leftward shift of the oxyhemoglobin dissociation curve occurs.
  - CO interferes with peripheral oxygen utilization by inactivating cytochrome oxidase.
- Delayed neurologic sequelae, related to lipid peroxidation by toxic oxygen species generated by xanthine oxidase
- The half-life of CO while the patient is breathing room air is  $\div 320$  minutes, while breathing 100% oxygen via a tight-fitting, nonrebreathing face mask is  $\div 74$  minutes, and with 100% hyperbaric oxygen is  $\div 30$  minutes.
- CO exposure also causes inflammation through separate pathways than those that cause cardiac and neurologic sequelae (2).
- Inhaled or ingested methylene chloride (from paint remover [dichloromethane]) is metabolized to CO by the liver, causing CO toxicity in the absence of ambient CO.

## ***RISK FACTORS***

- Alcohol use (3)
- Smoke inhalation
- Being in a closed or improperly ventilated space with a faulty furnace, stove, running engine, or any fuel-burning device
- Cigarette smoking
- Use of generators during power outages
- Extremes of age
- Predisposing cardiovascular disease, anemia, chronic respiratory conditions

- Exposure to exhaust (for example, riding in the back of enclosed pickup trucks or swimming near a motor boat) in precatalytic converter era automobiles.
- Employment in a coal mine, as an auto mechanic, paint stripper, or in the solvent industry
- Increased endogenous production in patients with hemolytic anemia

## GENERAL PREVENTION

- Appropriate ventilation, especially where there are fuel-burning devices.
- Use of CO monitors
- Public education
- Determining the mechanism of exposure is critical in cases of accidental poisoning in order to limit future risk.
- Victims must not be discharged back to a contaminated environment.

## COMMONLY ASSOCIATED CONDITIONS

- CO and cyanide poisoning can occur simultaneously following smoke inhalation (synergistic effect).
- Consider CO poisoning in a burn victim who has been in an enclosed space.

## DIAGNOSIS

- Acute CO poisoning is suggested by history, physical exam, and an elevated COHb.
- Chronic CO intoxication is difficult to diagnose.
- The newest pulse CO-oximeters can screen for CO exposure using different wavelengths of light.
- Older pulse oximeters do not differentiate carboxyhemoglobin from oxyhemoglobin, causing normal pulse oximeter readings in hypoxic patients.
- A level  $>3\%$  in a nonsmoker and  $>10\%$  in a smoker confirms exposure, but the level does not correlate well with the severity of the acute illness or the long-term prognosis (2).

## HISTORY

- No single symptom is sensitive or specific but may include the following:
  - Headaches: occurs in 84% patients
  - Dizziness

- Nausea, vomiting, diarrhea
- Weakness or fatigue
- Confusion or impaired judgment
- Seizures
- Chest pain
- Shortness of breath
- Loss of consciousness
- Visual disturbances

## *PHYSICAL EXAM*

- "Cherry red" appearance of the lips and skin (<1% cases)
- Respiratory depression or tachypnea
- Cyanosis
- Visual-field defects, papilledema, or nystagmus
- CNS depression or coma, ataxia, seizure
- Tachycardia, hypotension, cardiac dysrhythmias, or even (cardiac) arrest

## *DIFFERENTIAL DIAGNOSIS*

- Cyanide toxicity
- Viral syndromes
- Methylene chloride (dichloromethane) inhalation or ingestion
- Psychological disorders including major depressive disorder
- Other causes of mental status changes:
  - Infections such as meningitis or encephalitis
  - Metabolic causes such as hypoglycemia
  - Drugs: alcohol (EtOH) intoxication, opiates, acetylsalicylic acid (ASA) overdose
  - Trauma
  - CNS lesions

## *DIAGNOSTIC TESTS & INTERPRETATION*

## *Initial Tests (lab, imaging)*

- Measurement of COHb (may be low despite significant poisoning if patient had been treated with O<sub>2</sub> or has been breathing room air for a significant period of time before the level is drawn).
- ABG (looking for metabolic acidosis)
  - Blood PO<sub>2</sub> (PaO<sub>2</sub>) tends to be normal as O<sub>2</sub> dissolved in blood is not affected by CO.
- Blood glucose
- Chemistries
- Anion gap = ([Na<sup>+</sup>] + [K<sup>+</sup>]) - ([Cl<sup>-</sup>] + [HCO<sub>3</sub><sup>-</sup>]). HCO<sub>3</sub> decreased reflecting metabolic acidosis; anion gap >16
- Pregnancy test in all women of childbearing age
- Toxicology screen
- ECG in all patients
- Hemoglobin/hematocrit
- CK to evaluate rhabdomyolysis
- Cardiac enzymes in:
  - >65 years
  - Patient with cardiac risk factors or anemia
  - Patients with symptoms suggestive of cardiac ischemia
- Head CT/MRI scan is helpful to rule out other causes of neurologic decompensation. May also show infarction due to hypoxia/ischemia

---

P.159

## *Follow-Up Tests & Special Considerations*

- Think of CO poisoning in younger patients with chest pain or symptoms suggestive of ischemia.
- Consider the diagnosis and inquire about exposure in afebrile patients with ÖflulikeÖ symptoms, especially in the winter when flu and CO poisoning are both more common.
- Look for clusters of patients (coworkers, family members, school children) with similar symptoms.

Patients with intentional poisoning require psychiatric evaluation when medically stable.

## TREATMENT

### GENERAL MEASURES

- Prompt removal from the CO source
- Supportive care as necessary
- Intubation and mechanical ventilation may be necessary for severe intoxication, if patient is not able to protect airway, or has significant respiratory depression.
- Contact Poison Control Center at 800-222-1222 (United States only).

### MEDICATION

Rapid reduction in tissue hypoxia with 100% oxygen via nonrebreathing reservoir face mask (4) [A] until COHb is normal (<3%) and patient is asymptomatic.

### ADDITIONAL THERAPIES

- Hyperbaric oxygen has been somewhat controversial (4,5)[A]. Existing randomized trials do not establish whether the administration of hyperbaric oxygen to patients with CO poisoning reduces the incidence of adverse neurologic outcomes (5)[A].
- Despite this, hyperbaric oxygen recommended for levels >25-30%, evidence of cardiac involvement, severe acidosis, LOC, neurologic impairment, abnormal neuropsychiatric testing, age >36 years (6)[C].
- Hyperbaric oxygen has been shown to be safe in pregnant woman, but there have been no prospective studies of efficacy (4)[A]. International consensus favors it as part of a more aggressive role in treating pregnant women (6)[C].
- If no improvement occurs in cardiovascular or neurologic function within 4 hours, transport the patient to the nearest facility with hyperbaric oxygen, regardless of distance.

### INPATIENT CONSIDERATIONS

#### *Admission Criteria/Initial Stabilization*

Patients whose symptoms do not improve after 4 to 5 hours of 100% O<sub>2</sub> should be transported to the nearest facility with hyperbaric oxygen. Those who demonstrate ECG or laboratory evidence of severe poisoning, who have evidence of end-organ damage, who require hyperbaric treatment, or who have another medical or social cause of concern should be hospitalized.

## *Discharge Criteria*

Patients with mild symptoms from accidental poisoning can be managed in the ED and safely discharged.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

All patients treated for acute CO poisoning should be seen for clinical follow-up in 1 to 2 months after they are safely discharged (4). Patients should undergo neuropsychological testing if suspicion of cognitive impairment. Consider evaluation of family members or cohabitants.

### *Patient Monitoring*

- Measurement of carboxyhemoglobin levels
- Arterial blood gases

### *PATIENT EDUCATION*

- Professional installation and maintenance of combustion devices: 1-800-638-2772; Consumer Products Safety Commission hotline
- Some states require CO detector installation in homes, especially near bedrooms and potential sources.
- Annual furnace inspections (7)[B]

### *PROGNOSIS*

Most survivors recover completely, with only a minority developing chronic neuropsychiatric impairment.

### **COMPLICATIONS**

- Cardiac:
  - Myocardial infarction
  - Dysrhythmia
- Pulmonary:
  - Pulmonary edema
  - Pneumonia (aspiration)
- Neurologic:

- Anoxic encephalopathy
- Intellectual deterioration
- Memory impairment
- Parkinsonism
- Behavioral:
  - Irritability
  - Aggressiveness
  - Violence
  - Moodiness

### ***Geriatric Considerations***

Higher incidence of cardiovascular and neurologic disease, increasing complications

## Codes

### ICD10

- T58.91XA Toxic effect of carb monx from unsp source, acc, init
- T58.8X1A Toxic effect of carb monx from oth source, accidental, init
- T58.01XA Toxic effect of carb monx from mtr veh exhaust, acc, init

## Clinical Pearls

- The most appropriate intervention in the management of a CO-poisoned patient is a prompt removal from the source of CO and institution of 100% oxygen by high-flow face mask or endotracheal tube.
- A pregnant woman may appear normal while her fetus is severely affected.
- Consider CO poisoning in younger patients with chest pain or ischemia or in patients who present in clusters.
- COHb levels do not correlate well with symptoms, severity of illness, or outcome, so manage

the patient, not the level.

# Cardiomyopathy

Timothy P. Fitzgibbons, MD, PhD

Theo E. Meyer, MD, DPhil

## BASICS

### DESCRIPTION

- Cardiomyopathy encompasses a large group of diseases of the myocardium that commonly result in mechanical pump dysfunction. The current classification scheme attempts to differentiate between myocardial diseases confined to the myocardium (primary) and those due to systemic disorders (secondary). Specific causes of myocardial dysfunction due to other cardiovascular disorders are considered a third, separate category (1).
- Classification of cardiomyopathy
  - Primary
    - Genetic
      - Hypertrophic cardiomyopathy (HCM)
      - Arrhythmogenic right ventricular cardiomyopathy/dysplasia (ARVC/D)
      - Left ventricular (LV) noncompaction (LVNC)
      - Glycogen storage (Danon type, PRKAG2)
      - Conduction defects
      - Mitochondrial myopathies
      - Ion channel disorders: long QT syndrome, Brugada, short QT syndrome, catecholaminergic ventricular tachycardia (CVPT), Asian SUNDS
    - Mixed
      - Dilated cardiomyopathy (DCM) (genetic or nongenetic)
      - Restrictive
    - Acquired
      - Myocarditis, stress cardiomyopathy, peripartum, tachycardia-induced, infants of type 1

diabetic mothers

- Secondary (see list below)

- Specific

- Ischemic
- Valvular
- Hypertensive
- Congenital heart disease

- Patients with end-stage cardiomyopathy have stage D heart failure or severe symptoms at rest refractory to standard medical therapy.
- System(s) affected: cardiovascular; renal

### *Pediatric Considerations*

Etiology: idiopathic, viral, congenital heart disease, and familial

### *Pregnancy Considerations*

May occur in women postpartum

## **EPIDEMIOLOGY**

Predominant age: Ischemic cardiomyopathy is the most common etiology; predominantly in patients aged >50 years. Consider uncommon causes in young.

### *Incidence*

- 60,000 patients <65 years old die each year from end-stage heart disease.
- 35,000 to 70,000 people might benefit from cardiac transplant or chronic support.

### *Prevalence*

Most rapidly growing form of heart disease

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Ischemic heart disease: most common etiology; up to 66% of patients
- Hypertension
- Valvular heart disease

- Primary genetic causes
- Congenital heart disease
- Peripartum/postpartum
- Endocrine
  - Diabetes mellitus
  - Hyperthyroidism
  - Hypothyroidism
  - Hyperparathyroidism
  - Pheochromocytoma
  - Acromegaly
- Nutritional deficiencies
  - Beriberi, pellagra, scurvy, selenium, carnitine, kwashiorkor
- Autoimmune/collagen
  - Systemic lupus erythematosus
  - Dermatomyositis
  - Rheumatoid arthritis
  - Scleroderma
  - Polyarteritis nodosa
- Infectious causes
  - Viral (e.g., HIV, coxsackievirus, adenovirus)
  - Bacterial and mycobacterial (e.g., diphtheria, rheumatic fever)
  - Parasitic (e.g., toxoplasmosis, *Trypanosoma cruzi*)
- Infiltrative (2)
  - Amyloidosis
  - Gaucher disease
  - Hurler disease
  - Hunter disease
  - Fabry disease

- Storage
  - Hemochromatosis
  - Fabry disease
  - Glycogen storage disease (type II, Pompe)
  - Niemann-Pick disease
- Neuromuscular/neurologic
  - Duchenne and Emery-Dreifuss muscular dystrophies
  - Friedreich ataxia
  - Myotonic dystrophy
  - Neurofibromatosis
  - Tuberous sclerosis
- Toxic
  - Alcohol
  - Drugs and chemotherapy: anthracyclines, cyclophosphamide, Herceptin
  - Radiation
  - Heavy metal, chemical agents
- Inflammatory (granulomatous):
  - Sarcoidosis
- Idiopathic
- Endomyocardial
  - Endomyocardial fibrosis
  - Hypereosinophilic syndrome (Loeffler endocarditis)

## *Genetics*

Autosomal dominant HCM is the most common form of primary genetic cardiomyopathy (1/500 in the general population). Genetic causes of DCM are less common, accounting for 1/3 cases, with mostly autosomal dominant inheritance. LNC and ARVC are also inherited in an autosomal dominant fashion in addition to LQTS and other ion-channel disorders.

## *RISK FACTORS*

- Hypertension
- Hyperlipidemia
- Obesity
- Coronary artery disease
- Diabetes mellitus
- Smoking
- Physical inactivity
- Excessive alcohol intake
- Dietary sodium
- Obstructive sleep apnea
- Chemotherapy

## *GENERAL PREVENTION*

Reduce salt and water intake; home BP and daily weight measurement

## **DIAGNOSIS**

### **HISTORY**

- Dyspnea at rest or with exertion
- Paroxysmal nocturnal dyspnea
- Orthopnea
- Postprandial dyspnea
- Right upper quadrant pain or bloating
- Midabdominal pain
- Fatigue
- Syncope
- Edema

## *PHYSICAL EXAM*

- Tachypnea
- Cheyne-Stokes breathing

- Low pulse pressure
- Cool extremities
- Jugular venous distention
- Bibasilar rales
- Tachycardia
- Displaced point of maximal impulse (PMI)
- S<sub>3</sub> gallop
- Blowing systolic murmur
- Hepatosplenomegaly
- Ascites
- Edema

## *DIFFERENTIAL DIAGNOSIS*

- Severe pulmonary disease
- Primary pulmonary hypertension
- Recurrent pulmonary embolism
- Constrictive pericarditis
- Some advanced forms of malignancy
- Anemia

## *DIAGNOSTIC TESTS & INTERPRETATION*

- ECG: LV hypertrophy, interventricular conduction delay, atrial fibrillation, evidence of prior Q-wave infarction
- Hyponatremia
- Prerenal azotemia
- Anemia
- Mild elevation in troponin
- Elevated B-type natriuretic peptide (BNP) or pro-BNP
- Mild hyperbilirubinemia

- Elevated liver function tests
- Elevated uric acid

### *Initial Tests (lab, imaging)*

- ECG
- Chest radiograph
  - Cardiomegaly
  - Increased vascular markings to the upper lobes
  - Pleural effusions may or may not be present.

P.161

- Echocardiography
  - In DCM, 4-chamber enlargement and global hypokinesis are present.
  - In HCM, severe LV hypertrophy is present.
  - Segmental contraction abnormalities of the LV are indicative of previous localized myocardial infarction.
- Cardiac MRI
  - May be useful to characterize certain nonischemic cardiomyopathies
- Stress myocardial perfusion imaging (MPI)
  - Recommended in those with new-onset LV dysfunction or when ischemia is suspected.

### *Diagnostic Procedures/Other*

#### Cardiac catheterization

- Helpful to rule out ischemic heart disease
- Characterize hemodynamic severity
- Pulmonary artery catheters may be reasonable in patients with refractory heart failure to help guide management.

## **TREATMENT**

See Heart Failure, Chronic for detailed treatment protocols.

## GENERAL MEASURES

- Reduction of filling pressures
- Treatment of electrolyte disturbances

## MEDICATION

### First Line

- Systolic failure syndromes
  - ACE inhibitors: All considered equally effective; initiate at low doses and titrate as tolerated to target doses (3)[A].
  - ENTRESTO, a combination drug containing a neprilysin inhibitor and valsartan, was recently approved for the treatment of systolic HF (EF <40%) as an alternative to an ACE/ARB (4) [A].
  - Loop diuretics
    - May need to be given IV initially and then orally as patient stabilizes
  - Furosemide, 40 to 120 mg/day or TID (3)[A]
  - $\beta$ -Blockers
    - Use with caution in acutely decompensated or low-cardiac output states.
    - Initiate with low doses and titrate as tolerated.
  - Metoprolol succinate, 12.5 to 200 mg/day; carvedilol, 3.125 to 25 mg BID; or bisoprolol, 1.25 to 10 mg/day (3)[A]
  - Patients with New York Heart Association (NYHA) II-IV heart failure, ejection fraction (EF) <35%, on standard therapy: aldosterone antagonists: spironolactone or eplerenone (3)[A]
  - Digoxin, 0.125 to 0.25 mg/day for symptomatic patients on standard therapy (3)[B]
  - Combination hydralazine/isosorbide dinitrate is first-line treatment in African American patients with class III-IV symptoms already on standard therapy and for all patients with reduced EF and symptoms incompletely responsive to ACE inhibitor and  $\beta$ -blocker (3)[A].
    - Contraindications
  - $\beta$ -Blockers: low cardiac output, 2nd- or 3rd-degree heart block
  - Avoid use of diltiazem and verapamil in patients with systolic dysfunction.
  - Aldosterone antagonists: oliguria, anuria, renal dysfunction

- Loop diuretics: hypokalemia, hypomagnesemia
- ACE inhibitors: pregnancy, angioedema
- Precautions
  - In patients with chronic kidney disease, digoxin dosage should be  $\geq 0.125$  mg/day and drug levels followed carefully to avoid toxicity.
  - Closely monitor electrolytes.
  - ACE inhibitors: Initiate with care if BP is low. Begin with low-dose captopril, such as 6.25 mg TID.
  - $\beta$ -Blockers: Avoid in patients with evidence of poor tissue perfusion; they may further depress systolic function.
  - Milrinone, dobutamine: long-term use associated with increased mortality
- Medications TO AVOID
  - NSAIDs
  - Glitazones
  - Cilostazol

## *Second Line*

- Angiotensin receptor blockers as an alternative to ACE inhibitors
- Inotropic therapy (e.g., dobutamine or milrinone) for cardiogenic shock and support prior to surgery or cardiac transplantation (3)[B]
- Continuous inotrope infusion may be considered in stage D outpatients for symptom control in those who are not eligible for transplantation or mechanical circulatory support (3)[B].

## *ISSUES FOR REFERRAL*

Management by a heart failure team improves outcomes and facilitates early transplant referral.

## *ADDITIONAL THERAPIES*

- Prophylactic implantable cardioverter defibrillator (ICD) should be considered for patients with a left ventricular ejection fraction (LVEF)  $< 35\%$  and mild to moderate symptoms (3)[A].
- Cardiac resynchronization therapy (CRT) is recommended and should be considered for patients in sinus rhythm with a QRS  $> 150$  ms, LVEF  $< 35\%$ , in functional class (FC) I-III and ambulatory FC IV patients (3)[A].

- Patients with severe, refractory heart failure with no reasonable expectation of improvement should not be considered for an ICD.
- Consideration of an LV assist device as permanent or destination therapy or cardiac transplantation is reasonable in selected stage D patients.

## ONGOING CARE

### DIET

Low fat, low salt, fluid restriction

### PROGNOSIS

÷20-40% of patients in NYHA FC IV die within 1 year. With a transplant, 1-year survival is as high as 94%.

### COMPLICATIONS

Worsening congestive heart failure syncope, renal failure, arrhythmias, or sudden death

## Codes

### ICD10

- I42.9 Cardiomyopathy, unspecified
- I42.0 Dilated cardiomyopathy
- I42.5 Other restrictive cardiomyopathy

## Clinical Pearls

- Cardiomyopathy represents the end-stage of a large number of disease processes involving the heart muscle.
- Ischemic, hypertensive, postviral, familial, alcoholic, and incessant tachycardia-induced are the most common cardiomyopathy varieties seen in the United States.
- Core therapy for heart failure applies salt restriction, diuretics, ACE inhibitors,  $\beta$ -blockers, digoxin, and electrical treatments, such as cardiac resynchronization and implantable defibrillators, as appropriate.

# Carotid Stenosis

Edlira Yzeiraj, DO, MS

Maria M. Plummer, MD

## BASICS

Carotid stenosis may be caused by atherosclerosis, intimal fibroplasia, vasculitis, adventitial cysts, or vascular tumors; *atherosclerosis* is the most common etiology.

## DESCRIPTION

- Narrowing of carotid artery lumen is typically due to atherosclerotic changes in the vessel wall. Atherosclerotic plaques are responsible for 90% of extracranial carotid lesions and up to 30% of all ischemic strokes.
- A hemodynamically significant carotid stenosis produces a drop in pressure, reduction in flow, or both and corresponds approximately to a 60% diameter-reducing stenosis (1).
- Carotid lesions are classified by the following:
  - Symptom status
    - Asymptomatic: tend to be homogenous and stable
    - Symptomatic (stroke, transient cerebral ischemic event): tend to be heterogeneous and unstable
  - Degree of stenosis
    - High grade: 80-99% stenosis
    - Moderate grade: 50-79% stenosis
    - Low grade: <50% stenosis

## EPIDEMIOLOGY

More common in men and with increasing age (see Risk Factors)

### Incidence

Unclear (asymptomatic patients often go undiagnosed)

## Prevalence

- Moderate stenosis (2)
  - Age <50 years: men 0.2%, women 0%
  - Age >80 years: men 7.5%, women 5%
- Severe stenosis (2)
  - Age <50 years: men 0.1%, women 0%
  - Age >80 years: men 3.1%, women 0.9%

## ETIOLOGY AND PATHOPHYSIOLOGY

- Atherosclerosis begins during adolescence, consistently at carotid bifurcation. The carotid bulb has unique blood flow dynamics. Hemodynamic disturbances cause endothelial injury and dysfunction. Plaque formation in vessel wall results and stenosis then ensues.
- Initial cause not well understood, but certain risk factors are frequently present (see *Risk Factors*). Tensile stress on the vessel wall, turbulence, and arterial wall shear stress seem to be involved.

## Genetics

- Increased incidence among family members
- Genetically linked factors
  - Diabetes mellitus (DM), race, hypertension (HTN), family history, obesity
  - In a recent single nucleotide polymorphism study, the following genes were strongly associated with worse carotid plaque: *TNFSF4*, *PPARA*, *TLR4*, *ITGA2*, and *HABP2*.

## RISK FACTORS

- Nonmodifiable factors: advanced age, male sex, family history, cardiac disease, congenital arteriopathies (1)
- Modifiable factors: smoking, diet, dyslipidemia, physical inactivity, obesity, HTN, DM

## GENERAL PREVENTION

- Antihypertensive treatment to maintain BP <140/90 mm Hg (systolic BP of 150 mm Hg is target in elderly) (3)[A]
- Smoking cessation to reduce the risk of atherosclerosis progression and stroke (3)

- Lipid control: regression of carotid atherosclerotic lesions seen with statin therapy (3)

## COMMONLY ASSOCIATED CONDITIONS

- Transient ischemic attack (TIA)/stroke
- Coronary artery disease (CAD)/myocardial infarction (MI)
- Peripheral vascular disease (PVD)
- HTN
- DM
- Hyperlipidemia

## DIAGNOSIS

Screening for carotid stenosis is not recommended. However, in the setting of symptoms suggestive of stroke or TIA, workup for this condition may be indicated.

### HISTORY

- Identification of modifiable and nonmodifiable comorbidities (see “Risk Factors”)
- History of cerebral ischemic event
- Stroke, TIA, amaurosis fugax (monocular blindness), aphasia
- Coronary artery disease/MI
- Peripheral arterial disease
- Review of systems, with focus on risk factors for
  - Cardiovascular disease
  - Stroke (HTN and arrhythmia)

### PHYSICAL EXAM

- Lateralizing neurologic deficits: contralateral motor and/or sensory deficit
- Amaurosis fugax: ipsilateral transient visual obscuration from retinal ischemia
- Visual field defect
- Dysarthria and in the case of dominant (usually left) hemisphere involvement, aphasia
- Carotid bruit (low sensitivity and specificity)

# *DIFFERENTIAL DIAGNOSIS*

- Aortic valve stenosis
- Aortic arch atherosclerosis
- Arrhythmia with cardiogenic embolization
- Migraine
- Brain tumor
- Metabolic disturbances
- Functional/psychological deficit
- Seizure

# *DIAGNOSTIC TESTS & INTERPRETATION*

## *Initial Tests (lab, imaging)*

Workup for suspected TIA/stroke may include the following:

- CBC with differential
- Basic metabolic panel
- ESR (if temporal arteritis a consideration)
- Glucose/glycated hemoglobin (HbA1c)
- Fasting lipid profile
- Duplex ultrasonography is the recommended initial diagnostic test in asymptomatic patients with known or suspected carotid stenosis (3)[C].
- Duplex ultrasound (US) identifies >50% stenosis, with 98% sensitivity and 88% specificity.

## *Follow-Up Tests & Special Consideration*

- Proceed to imaging if there is suggestion of stenosis from history or physical exam.
- Other noninvasive imaging techniques can add detail to duplex results:
  - CT angiography
    - 88% sensitivity and 100% specificity
    - Requires contrast load with risk for subsequent renal morbidity
  - MR angiography

- 95% sensitivity and 90% specificity
- Evaluates cerebral circulation (extracranial and intracranial) as well as aortic arch and common carotid artery
- The presence of unstable plaque can be determined if the following characteristics are seen:
  - Presence of thin/ruptured fibrous cap
  - Presence of lipid-rich necrotic core
- Tends to overestimate degree of stenosis

## *Diagnostic Procedures/Other*

Cerebral (catheter) angiography is the traditional gold standard for diagnosis:

- Delineates anatomy pertaining to aortic arch and proximal vessels
- However, procedure is invasive and has multiple risks:
  - Contrast-induced renal dysfunction (1-5% complication rate)
  - Thromboembolic-related complications (1-2.6% complication rate) and neurologic complications
  - Should be used only when other tests are not conclusive

## *Test Interpretation*

- Stenosis consistently occurs at carotid bifurcation, with plaque formation most often at proximal internal carotid artery:
  - Plaque is thickest at the carotid bifurcation.
  - Plaque occupies the intima and inner media and avoids outer media and adventitia.
- Plaque histology
  - Homogenous (stable) plaques seldom hemorrhage or ulcerate:
    - Fatty streak and fibrous tissue deposition
    - Diffuse intimal thickening
  - Heterogenous (unstable) plaques may hemorrhage or ulcerate:
    - Presence of lipid-laden macrophages, necrotic debris, cholesterol crystals
    - Ulcerated plaques

- Soft and gelatinous clots with platelets, fibrin, and red and white blood cells

## TREATMENT

Smoking cessation, BP control, use of antiplatelet medication, and statin medication are the primary treatments for both asymptomatic and symptomatic carotid stenosis.

## GENERAL MEASURES

- Lifestyle modifications: dietary control and weight loss, exercise of 30 min/day at least 5 days/week.
- Patients should be advised to quit smoking and offered smoking cessation intervention to reduce the risk of atherosclerotic progression and stroke.
- Control of HTN with antihypertensive agents to maintain BP <140/90 mm Hg (3)[A]; <150/90 mm Hg in the elderly

---

P.163

## MEDICATION

- Antihypertensive treatment (<140/90 mm Hg) (3)[A], <150/90 mm Hg in the elderly
- Diet, smoking cessation, and exercise are useful adjuncts to therapy.
- Statin initiation is recommended to reduce LDL cholesterol <100 mg/dL (3)[B]; choose moderate- to high-intensity statin therapy for anti-inflammatory benefit.
- In statin intolerance, LDL-lowering therapy with bile acid sequestrants and/or niacin is reasonable (3)[B].
- Aspirin: 75 to 325 mg/day (3)[A]
- If patient has sustained ischemic stroke or TIA, antiplatelet therapy with
  - Aspirin alone (75 to 325 mg/day) (3)[B] *or*
  - Clopidogrel alone (75 mg/day) (3)[B], *or*
  - Aspirin plus extended-release dipyridamole (25 and 200 mg BID, respectively) (3)[B]
  - A combination of clopidogrel plus aspirin is NOT recommended within 3 months post TIA or CVA (3)[B].

## ISSUES FOR REFERRAL

For acute symptomatic stroke, order imaging and contact neurology.

- For known carotid stenosis, some suggest duplex imaging every 6 months if stenosis is >50% and patient is a surgical candidate.

## ***SURGERY/OTHER PROCEDURES***

- Symptomatic carotid stenosis
  - Carotid endarterectomy (CEA) is recommended in symptomatic patients with a carotid stenosis of 70-99% without near-occlusion. Benefit in patients with carotid near-occlusion is uncertain in the long term (4)[A].
  - CEA is recommended for patients with a life expectancy of at least 5 years. The anticipated rate of perioperative stroke or mortality must be <6% (3)[A].
  - Treatment with aspirin (81 to 325 mg/day) is recommended for all patients who are having CEA. Aspirin should be started prior to surgery and continued for at least 3 months postsurgery but may be continued indefinitely (5)[B].
  - Carotid artery stenting (CAS) provides similar long-term outcomes as CEA (6)[A]. Age should be considered when planning a carotid intervention.
    - CAS has an increased risk of adverse cerebrovascular events in the elderly compared to the young but similar mortality risk. CEA is associated with similar neurologic outcomes in the elderly and young, at the expense of increased mortality (7)[A].
    - CAS is suggested in select patients with neck anatomy unfavorable for arterial surgery and those with comorbid conditions that greatly increase the risk of anesthesia and surgery (3)[A].
    - Dual antiplatelet therapy with aspirin (81 to 325 mg/day) plus clopidogrel (75 mg/day) is recommended for 30 days post CAS (3)[C].
- Asymptomatic patients
  - CEA is recommended by some for asymptomatic men who have 60-99% stenosis, have a life expectancy of at least 5 years, and the perioperative risk of stroke and death is <3% (6),(8)[B].
  - The advantage of surgical compared with medical therapy has decreased with contemporary medical management. It is not possible to make an evidence-based recommendation for or against surgical therapy with current literature (9)[A].

## ***INPATIENT CONSIDERATIONS***

## *Admission Criteria/Initial Stabilization*

Any patient with presentation of acute symptomatic carotid stenosis should be hospitalized for further diagnostic workup and appropriate therapy.

Rapid evaluation for symptoms compatible with TIA should be obtained in the emergency department (ED) or inpatient setting.

## *Discharge Criteria*

24 to 48 hours post CEA, if ambulating, taking adequate PO intake, and neurologically intact

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Duplex at 2 to 6 weeks postop
- Duplex every 6 to 12 months
- Reoperative CEA or CAS is reasonable, if there is rapidly progressive restenosis (3)[A].
- Patients with any of the following: renal failure, heart failure, diabetes, and age >80 years have a high-readmission rate following CEA; thus, intensive medical therapy and rigorous follow-up is recommended (10).

#### *DIET*

Low-fat, low-cholesterol, low-salt diet at discharge

### *PATIENT EDUCATION*

For patient education materials on this topic, consult the following:

- American Heart Association: <http://www.heart.org>
- Mayo Clinic Information: <http://www.mayoclinic.org/diseases-conditions/carotid-artery-disease/basics/definition/con-20030206>

### **COMPLICATIONS**

- Untreated: TIA/stroke (risk of ipsilateral stroke approximately 1.68% per year [10])
- Postoperative (s/p CEA)
  - Perioperative (within 30 days)

- Stroke/death, cranial nerve injury, hemorrhage, hemodynamic instability, MI
- Late (>30 days postop)
  - Recurrent stenosis, false aneurysm at surgical site

## See Also

Algorithms: Transient Ischemic Attack and Transient Neurologic Defects; Stroke

## Codes

### ICD10

- I65.29 Occlusion and stenosis of unspecified carotid artery
- I65.21 Occlusion and stenosis of right carotid artery
- I65.22 Occlusion and stenosis of left carotid artery

## Clinical Pearls

- Atherosclerosis is responsible for 90% of all cases of carotid artery stenosis.
- Duplex US is the best initial imaging modality.

- Antiplatelet therapy and aggressive treatment of vascular risk factors are the mainstays of medical therapy.
- Compared with CEA, CAS increases the risk of any stroke and decreases the risk of MI. For every 1,000 patients opting for stenting rather than endarterectomy, 19 more patients would have strokes and 10 fewer would have MIs.

# Carpal Tunnel Syndrome

Philip H. Aurigemma, MD

Marci D. Jones, MD

## BASICS

### DESCRIPTION

- Carpal tunnel syndrome (CTS) is a symptomatic compression neuropathy of the median nerve.
- Increased pressure within the carpal tunnel leads to compression of the median nerve and characteristic of motor-sensory findings.
- The dorsal element of the carpal tunnel is composed of the carpal bones. The transverse carpal ligament defines the palmar boundary:
  - The carpal tunnel contains nine flexor tendons in addition to the median nerve.
- Symptoms most commonly affect the dominant hand; >50% of patients will experience bilateral symptoms.
- System(s) affected: musculoskeletal, nervous

### ALERT

Pregnancy: increased incidence during pregnancy (up to 20-45% of patients)

### EPIDEMIOLOGY

- Predominant age: 40 to 60 years
- Predominant sex: female > male (3:1 to 10:1)

### Incidence

- Two peaks: late 50s (women), late 70s (both genders)
- Incidence up to 276/100,000 has been reported.
- Incidence increases with age.

### Prevalence

9% in women and 6% in men; 50 cases per 1,000 individuals per year in United States (1)[C]

- 14% in diabetics without neuropathy and 30% in patients with diabetic neuropathy
- Rising prevalence may be the result of increasing lifespan and increasing prevalence of diabetes.

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- Combination of mechanical trauma, inflammation, increased pressure, and ischemic injury to the median nerve within the carpal tunnel
- Acute CTS caused by rapid and sustained pressure in carpal tunnel, usually secondary to trauma, may require urgent surgical decompression.
- Chronic CTS divided into four categories (1)[C]:
  - Idiopathic: combination of edema and fibrous hypertrophy without inflammation
  - Anatomic: persistent median artery, ganglion cyst, infection, space-occupying lesion in carpal tunnel
  - Systemic: associated with conditions such as obesity, diabetes, hypothyroidism, rheumatoid arthritis, amyloidosis, scleroderma, renal failure, and drug toxicity
  - Exertional: repetitive use of hands and wrists, repeated palmar impact, use of vibratory tools. Repetitive use is an objective cause of CTS.

### *Genetics*

Unknown; however, a familial type has been reported.

## *RISK FACTORS*

- Prolonged postures in extremes of wrist flexion and extension; repetitive exposure to vibration
- Alterations of fluid balance: pregnancy, menopause, obesity, renal failure, hypothyroidism, congestive heart failure (CHF), and oral contraceptive use
- Neuropathic factors, such as diabetes, alcoholism, vitamin deficiency, or exposure to toxins, can elicit CTS symptoms.

## *GENERAL PREVENTION*

There is no known prevention for CTS. It is recommended to take occasional (hourly) breaks when doing repetitive work involving hands.

## *COMMONLY ASSOCIATED CONDITIONS*

- Diabetes, obesity; pregnancy; hypothyroidism
- Osteoarthritis of small joints of hand and wrist
- Hyperparathyroidism, hypocalcemia
- Miscellaneous associations include the following:
  - Acromegaly; lupus erythematosus; leukemia
  - Pyogenic infections; sarcoidosis
  - Primary amyloidosis; Paget disease
  - Hormone replacement therapy

## DIAGNOSIS

### HISTORY

- Patients report nocturnal pain, numbness, and tingling in the thumb, index, long, and radial portion of the ring fingers; patients may not localize and describe the entire hand as being affected.
- Hand weakness during tasks as opening jars is often noted early in the disorder.
- Atypical presentation involves paresthesias in radial digits, with pain radiating proximally along median nerve to elbow and sometimes the shoulder (1)[C].
- Symptoms characteristically are relieved by shaking or rubbing the hands.
- During waking hours, symptoms occur when driving, talking on the phone, and occasionally when using the hands for repetitive maneuvers.
- Presence of predisposing factors, such as diabetes, obesity, acromegaly, pregnancy

### PHYSICAL EXAM

- Positive Tinel sign: Tapping over the palmar surface of the wrist proximal to the carpal tunnel may produce an electric sensation along the distribution of the median nerve (50% sensitivity; 77% specificity).
- Positive Phalen sign: Holding the wrist in fully flexed position for 60 seconds precipitates paresthesias (68% sensitivity; 73% specificity).
- Durkan compression test: Direct compression of median nerve at carpal tunnel for 30 seconds elicits symptoms (87% sensitivity; 90% specificity) (1)[C].

- Wasting of thenar musculature is a late sign.
- Loss of 2-point discrimination
- Ulceration of tips of fingers is associated with loss of protective sensation.

## *DIFFERENTIAL DIAGNOSIS*

- Cervical spondylosis (carpal tunnel may also occur with cervical spine disease; Double crush)
- Generalized peripheral neuropathy
- Brachial plexopathy, in particular upper trunk
- CNS disorders (multiple sclerosis, cerebral infarction)
- Thoracic outlet syndrome
- Pronator syndrome
- Anterior interosseous syndrome
- Musculoskeletal disorders of the wrist:
  - Trauma or distal radius fracture
  - Degenerative joint disease
  - Rheumatoid arthritis
  - Ganglion cyst
- Scleroderma

## *DIAGNOSTIC TESTS & INTERPRETATION*

No laboratory test is diagnostic.

- Normal serum thyrotropin (thyroid-stimulating hormone [TSH]) and normal serum can exclude secondary conditions associated with CTS.

### *Initial Tests (lab, imaging)*

- Special tests
  - Electrodiagnostic studies
    - Sensitivity 85%; specificity 95%
    - Nerve conduction studies compare latency and amplitude of median nerve across the carpal tunnel.

- Prolonged distal latency of the median motor and/or sensory fibers may be seen. Axon loss is suggested with decreased amplitudes.
- The most sensitive indicator is median sensory distal latency, which is prolonged in CTS. Sensory nerve action potentials may be reduced or unobtainable.
- Electromyographic changes are indicative of long-standing or severe nerve dysfunction.
- Ulnar nerve stimulation should be performed to exclude generalized polyneuropathy.
- Standard radiographs of the wrist evaluate bony anatomy and degenerative joint disease.
- Special radiographic views of the carpal tunnel are of limited use.
- Magnetic resonance imaging and ultrasound are of limited benefit in diagnosis of CTS.

## TREATMENT

### GENERAL MEASURES

- Splinting of the wrist in a neutral position while sleeping may provide significant symptom relief:
  - Limited evidence indicates that splints worn at night are more effective than no treatment in the short term. Insufficient evidence to recommend a specific splint design or wearing regimen (2)[A].
- Splinting (sometimes prolonged) typically promotes symptom resolution.
- Corticosteroid injections are effective for up to 3 months compared with placebo (3)[A].
- Outcomes at 1 year show no benefit for local steroid injections compared to placebo (3)[A].

P.165

### MEDICATION

#### *First Line*

NSAIDs, such as ibuprofen or naproxen sodium, are commonly used. There is insufficient evidence to determine their routine efficacy:

- Contraindications: GI intolerance
- Precautions: GI side effects of NSAIDs may preclude their use in selected patients.

#### *Second Line*

- Local steroid injection: Methylprednisolone injections are more effective than systemic steroids or placebo at 1 and 3 months and more effective than splinting at 6 months (4)[A].
- Response to injections can help confirm diagnosis of CTS and predict a better response to surgery.
- Side effects include reduction of collagen and proteoglycan synthesis, limiting tenocytes, and reducing mechanical strength of tendon, leading to further degeneration and risk for rupture.
- Oral steroids may provide a short-term improvement (2 to 8 weeks) in symptoms.
- The long-term risks of even a short course of steroids should be balanced with the limited potential benefit of symptom improvement.

## *ISSUES FOR REFERRAL*

Preoperative electrodiagnostic studies are generally obtained prior to any surgical intervention.

## *SURGERY/OTHER PROCEDURES*

- Completely dividing the transverse carpal ligament provides symptom relief in >95% of patients.
- Surgical decompression is an outpatient procedure performed under local or regional anesthesia.
- Healing of the incision generally takes 2 weeks; an additional 2 weeks may be required before using the affected hand for tasks requiring strength.
- Long-term results of open carpal tunnel release are excellent. Patients experience consistent pain relief for 10 to 15 years (5)[B].
- Recent randomized, controlled studies indicate that surgery leads to better functional improvements at 1 year compared with nonoperative management.
- Open versus endoscopic surgical procedures produce similar outcomes at 6 months. The approach should be based on surgeon and patient preference.
- Endoscopic carpal tunnel release allows a faster return to work.
- Risk of transient nerve injuries is higher with endoscopic release (6)[A].
- Therapeutic ultrasound, exercise, and mobilization techniques have limited benefit compared with other nonsurgical interventions. Poor quality evidence shows ultrasound may be more effective than placebo (7,8)[A].

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

No trial data support the use of vitamin B<sub>6</sub> in the prevention or treatment of CTS.

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

Outpatient

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

### *Patient Monitoring*

- Patients treated nonoperatively (splinting, injections) require follow-up over 4 to 12 weeks to ensure adequate progress.
- There is only limited, low-quality evidence to suggest that rehabilitation exercises such as wrist immobilization, ice therapy, and multimodal hand rehabilitation are beneficial.
- 7-20% of patients treated surgically may experience recurrence.

## PATIENT EDUCATION

- American Society for Surgery of the Hand:  
<http://www.assh.org/Public/HandConditions/Pages/CarpalTunnelSyndrome.aspx>
- For patient education materials, contact: American Academy of Family Physicians Foundation, P.O. Box 8418, Kansas City, MO 64114 (800) 274-2237, Ext. 4400.

## PROGNOSIS

- Patients with severe CTS may not recover completely after surgical release. Paresthesias and weakness may persist, but night symptoms generally resolve.
- If untreated, more severe cases of CTS can lead to numbness and weakness in the hand, atrophy of the thenar muscles, and permanent loss of median nerve function.

## COMPLICATIONS

- Postoperative infection (rare)
- Injury to the median nerve or its recurrent (motor) branch

## Codes

### ICD10

- G56.00 Carpal tunnel syndrome, unspecified upper limb
- G56.01 Carpal tunnel syndrome, right upper limb
- G56.02 Carpal tunnel syndrome, left upper limb

## Clinical Pearls

- Paresthesias associated with CTS are characteristically confined to the thumb, index, long, and radial 1/2 of the ring fingers of the affected hand.
- Thenar atrophy is a late finding, indicating severe nerve damage.
- Durkan (carpal compression) test is superior to Tinel sign (tapping on median nerve over carpal tunnel) and Phalen maneuver (holding wrists in flexion) for the clinical diagnosis of CTS.
- Steroid injections offer short-term relief, but clinical outcomes at 1 year are no different than placebo.

# Cataract

Yasir Ahmed, MD

Ingrid U. Scott, MD, MPH

## BASICS

### DESCRIPTION

- A cataract is any opacity or discoloration of the lens, localized or generalized; the term is usually reserved for changes that affect visual acuity (1,2).
- Etymology: from Latin *catarractes*, for "waterfall"; named after foamy appearance of opacity
- Leading cause of blindness worldwide, estimated 20 million people (1,2)
- Types include the following:
  - Age related: 90% of total
  - Metabolic (diabetes via accelerated sorbitol pathway, hypocalcemia, Wilson disease)
  - Congenital (1/250 newborns; 10-38% of childhood blindness)
  - Systemic disease associated (myotonic dystrophy, atopic dermatitis)
  - Secondary to associated eye disease, so-called complicated (e.g., uveitis associated with juvenile rheumatoid arthritis or sarcoid, tumor such as melanoma or retinoblastoma)
  - Traumatic (e.g., heat, electric shock, radiation, concussion, perforating eye injuries, intraocular foreign body)
  - Toxic/nutritional (e.g., corticosteroids)
- Morphologic classification:
  - Nuclear: exaggeration of normal aging changes of *central* lens nucleus, often associated with myopia due to increased refractive index of lens (some elderly patients consequently may be able to read again *without spectacles*, so-called second sight of the aged)
  - Cortical: outer portion of lens; may involve anterior, posterior, or equatorial cortex; radial, spoke-like opacities
  - Subcapsular: Posterior subcapsular cataract has more profound effect on vision than nuclear or cortical cataract; patients particularly troubled under conditions of miosis; near vision

frequently impaired more than distance vision.

- System(s) affected: nervous

### *Geriatric Considerations*

Some degree of cataract formation is expected in all people >70 years of age.

### *Pediatric Considerations*

See "Congenital Cataract"; may present as leukocoria.

### *Pregnancy Considerations*

See "Congenital Cataract" (i.e., medications, metabolic dysfunction, intrauterine infection, and malnutrition).

## **EPIDEMIOLOGY**

### *Incidence*

- ÷48% of the 37 million cases of blindness worldwide result from cataracts (1,2).
- Leading cause of treatable blindness and vision loss in developing countries (1,2)
- Predominant age: depends on type of cataract
- Predominant sex: male > female

### *Prevalence*

- Cataract type and prevalence are highly variable based on population demographic.
- An estimated 50% of people 65 to 74 years of age and 70% of people >75 years of age have age-related cataract.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Age-related cataract:
  - Continual addition of layers of lens fibers throughout life creates hard, dehydrated lens nucleus that impairs vision (nuclear cataract).
  - Aging alters biochemical and osmotic balance required for lens clarity; outer lens layers hydrate and become opaque, adversely affecting vision.
- Congenital:
  - Usually unknown etiology

- Drugs (corticosteroids in 1st trimester, sulfonamides)
- Metabolic (diabetes in mother, galactosemia in fetus)
- Intrauterine infection during 1st trimester (e.g., rubella, herpes, mumps)
- Maternal malnutrition
- Other cataract types:
  - Common feature is a biochemical/osmotic imbalance that disrupts lens clarity.
  - Local changes in lens protein distribution lead to light scattering (lens opacity).

## *Genetics*

- Congenital (e.g., chromosomal disorders [Down syndrome])
- Genetics of age-related cataract are not yet established but likely multifactorial contribution.

## *RISK FACTORS*

- Aging
- Cigarette smoking
- Ultraviolet (UV) sunlight exposure
- Diabetes
- Prolonged high-dose steroids
- Positive family history
- Alcohol

## *GENERAL PREVENTION*

- Use of UV protective glasses
- Avoidance of tobacco products
- Effective control of diabetes
- Care with high-dose, long-term steroid use (systemic therapy > inhaled treatment)
- Protective methods using pharmaceutical intervention (e.g., antioxidants, acetylsalicylic acid [ASA], hormone replacement therapy [HRT]) show no proven benefit to date.

## *COMMONLY ASSOCIATED CONDITIONS*

- Diabetes (especially with poor glucose control)
- Myotonic dystrophy (90% of patients develop visually innocuous change in 3rd decade; becomes disabling in 5th decade)
- Atopic dermatitis (AD) (10% of patients with severe AD develop cataracts in 2nd to 4th decades, often bilateral)
- Neurofibromatosis type 2
- Associated ocular disease or secondary cataract (e.g., chronic anterior uveitis, acute [or repetitive] angle-closure glaucoma or high myopia)
- Drug induced (e.g., steroids, chlorpromazine)
- Trauma

## DIAGNOSIS

### HISTORY

- Age-related cataract:
  - Decreased visual acuity, blurred vision, distortion, or “ghosting” of images (1,2)
  - Problems with visual acuity in any lighting condition
  - Falls or accidents; injuries (e.g., hip fracture)
- Congenital: often asymptomatic, leukocoria, parents notice child's visual inattention or strabismus
- Other types of cataract:
  - May also present with decreased visual acuity
  - Appropriate clinical history or signs to help with diagnosis

### PHYSICAL EXAM

- Visual acuity assessment for all cataracts
- Age-related cataract: lens opacity on eye examination
- Congenital:
  - Lens opacity present at birth or within 3 months of birth
  - Leukocoria (white pupil), strabismus, nystagmus, signs of associated syndrome (as with Down or rubella syndrome)

- *Note:* must always rule out ocular tumor; early diagnosis and treatment of retinoblastoma may be lifesaving
- Other types of cataract: may present with decreased visual acuity associated with characteristic physical findings (e.g., metabolic, trauma)

## ***DIFFERENTIAL DIAGNOSIS***

- An opaque-appearing eye may be due to opacities of the cornea (e.g., scarring, edema, calcification), lens opacities, tumor, or retinal detachment. Biomicroscopic examination (slit lamp) or careful ophthalmoscopic exam should provide diagnosis.
- In the elderly, visual impairment is often due to multiple factors such as cataract and macular degeneration, both contributing to visual loss.
- Age-related cataract is significant if symptoms and ophthalmic exam support cataract as a major cause of vision impairment.
- Congenital lens opacity in the absence of other ocular pathology may cause severe amblyopia.
- *Note:* Cataract *does not* produce a relative afferent pupillary reaction defect. Abnormal pupillary reactions mandate further evaluation for other pathology.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Visual quality assessment: Glare testing, contrast sensitivity is sometimes indicated.
- Retinal/macular function assessment: potential acuity meter testing
- Workup of underlying process

---

P.167

### ***Test Interpretation***

Consistent with lens changes found in the type of cataract; however, diagnosis is made by clinical examination.

### **TREATMENT**

- Outpatient (usually)
- ÷1.64 million cataract extractions in the United States yearly (3,4)

### ***GENERAL MEASURES***

Eye protection from UV light

## *MEDICATION*

There are currently no medications to prevent or slow the progression of cataracts.

## *ISSUES FOR REFERRAL*

If patient has cataract and symptoms do not seem to support recommended surgery, a second opinion by another ophthalmologist may be indicated.

## *SURGERY/OTHER PROCEDURES*

- Age-related cataract:
  - Surgical removal is indicated if visual impairment-producing symptoms are distressing to the patient, interfering with lifestyle or occupation, or posing a risk for fall or injury (3,4)[A].
  - Because significant cataract may develop gradually, the patient may not be aware of how it has changed his or her lifestyle. Physician may note a significant cataract, and patient reports "no problems." Thus, evaluation requires effective physician-patient exchange of information.
  - Surgical technique: Cataract extraction via small incisions, followed by implantation of a prosthetic intraocular lens; lenses have power calculated based on size of the eye and curvature of cornea usually to correct for distance vision; surgery performed on one (worse) eye, with contralateral surgery only after recovery and if deemed necessary; generally takes <1 hour depending on surgical technique
  - Anesthesia: usually regional injection or topical with sedation and monitoring of vital signs
  - Preoperative evaluation: by the primary care physician:
    - Patients on anticoagulants may need to be temporarily discontinued 1 to 2 weeks before surgery if possible (but not always necessary; thus, need to discuss with ophthalmologist).
    - Patients who have ever taken an  $\alpha$ -blocker such as tamsulosin (Flomax) should alert their ophthalmologist (increased risk of intraoperative floppy iris syndrome [IFIS] even in patients who no longer use these drugs).
  - Postoperative care: usually protective eye shield as directed, topical antibiotic, NSAIDs, and steroid ophthalmic medications; avoid lifting or bending over for a few weeks.
- Congenital cataract:
  - Treatment is surgical removal of cataract. Newborns may require surgery within days to reduce risk of severe amblyopia. Use of lens implants is controversial because the eyes are growing.

- Postoperative care: long-term patching program for good eye to combat amblyopia; refractive correction of operative eye, with multiple repeat examinations; challenging for physician and parents

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- As cataract progresses, an ophthalmologist may change spectacle correction to maintain vision. When this is no longer successful and interferes with patient's activities of daily living, surgery is indicated.
- Following surgery, spectacle correction may be required to maximize near and/or far visual acuity. Refraction is usually prescribed several weeks after surgery.

### *PATIENT EDUCATION*

Medline Plus on cataracts at: <https://www.nlm.nih.gov/medlineplus/cataract.html>

### *PROGNOSIS*

- Ocular prognosis is good after cataract removal if no prior or coexisting ocular disease: 94.3% of otherwise healthy eyes achieve best corrected visual acuity of 20/40 or better. Success rates are lower with comorbidities such as diabetes and glaucoma (5).
- In congenital cataracts, prognosis often is poorer because of the high risk of amblyopia.

### **COMPLICATIONS**

- Vary widely from delay in visual recovery or protracted visual discomfort to blindness and loss of eye
- Nearly all reported complications occur rarely (<2% of eyes) except for posterior capsule opacification (14.7-42.7% of eyes, usually treated with Nd-YAG laser capsulotomy in office with a rate of 4-25.3%) (6,7)[B].
- Poor preoperative visual acuity is related to surgical complications (8).

## See Also

- Algorithm: Cataracts
- Floppy Iris Syndrome

## Codes

### ICD10

- H26.9 Unspecified cataract
- H25.9 Unspecified age-related cataract

- Q12.0 Congenital cataract

## Clinical Pearls

- Cataracts are the leading cause of blindness worldwide; 90% are age-related.
- Primary indication for cataract surgery is visual impairment leading to significant lifestyle changes for the patient.
- For congenital cataracts, must always rule out ocular tumor because early diagnosis and treatment of retinoblastoma may be lifesaving.
- Before prescribing an  $\alpha$ -blocker for an older adult with hypertension or a prostate or urinary retention problem, consider whether the patient has cataracts (due to increased risk of IFIS).

# Celiac Disease

Jason E. Domagalski, MD, FAAFP

Matthew W. Short, MD, FAAFP

## BASICS

### DESCRIPTION

- Autoimmune condition characterized by an immunemediated reaction to dietary gluten (found in wheat, barley, rye) primarily affecting the small intestine in genetically predisposed individuals
- Presentations
  - Typical
    - Diarrheal illness characterized by villous atrophy with symptoms of malabsorption (steatorrhea, weight loss, vitamin deficiencies, anemia). Resolves with a gluten-free diet
    - <50% of adults present with GI symptoms.
  - Atypical
    - Minor GI symptoms, with a myriad of extraintestinal manifestations (e.g., anemia, dental enamel defects, neurologic symptoms, infertility)
  - Asymptomatic (silent) disease
    - Found when screening first-degree relatives
  - Latent
    - Positive laboratory tests and genetics, without signs/symptoms
- System(s) affected: gastrointestinal
- Synonym(s): celiac sprue; gluten enteropathy

### EPIDEMIOLOGY

#### Incidence

- 1 to 13 per 100,000 worldwide (1)

- 6.5 per 100,000 in United States (2)
- Primarily impacts individuals of Northern European ancestry
- Predominant sex: female > male (3:2)

## *Prevalence*

- 0.7% in United States; an estimated 3 million Americans have celiac disease (3).
- Prevalence is 8 to 204 per 100,000 worldwide and increasing (1).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Sensitivity to gluten, specifically gliadin fraction. Tissue transglutaminase (tTG) modification of protein leads to immunologic cross-reactivity, inflammation, and tissue damage (villous atrophy) with subsequent malabsorption.

## *Genetics*

Homogeneity for *HLA-DQ2* increases the risk of celiac disease and enteropathy-associated T-cell lymphoma.

## **RISK FACTORS**

- First-degree relatives: 5-10% incidence (4)
- Monozygotic twins: 70% incidence
- 25% risk in family members with an autoimmune disease

## *Pediatric Considerations*

No associations found with breastfeeding duration, age, concurrent infection, or gastroenteritis at time of gluten introduction.

## **GENERAL PREVENTION**

Avoid gluten-containing products (wheat, barley, rye, and possibly oat products).

## **COMMONLY ASSOCIATED CONDITIONS**

- *Dermatitis herpetiformis*: 85% of patients have celiac disease. All patients should follow gluten-free diet (4).
- Secondary lactase deficiency
- Osteopenia

- Thyroid disease: Hashimoto thyroiditis
- 3-10% of patients with type 1 diabetes also have celiac disease.
- Symptomatic iron deficiency, 10-15% have celiac disease
- Elevated AST and ALT (with no direct cause)
- Hyposplenism
- Irritable bowel syndrome (IBS)
- Restless leg syndrome
- Celiac disease is associated with increased risk for adenocarcinoma and lymphoma of the small bowel.
  - The risk of lymphoproliferative malignancies depends on small intestinal histopathology.
  - Little to no increased risk in latent celiac disease (seropositive but normal biopsy) (5)[A].
- Other autoimmune disorders

### *Pregnancy Considerations*

- Prevalence of celiac disease: 2.5 to 3.5 times higher in women with unexplained infertility
- Up to 19% of men with celiac disease have androgen resistance. Semen quality and likelihood of pregnancy increase with gluten-free diet.
- Higher rates of low birth weight, spontaneous abortions, and stillbirths

### *Pediatric Considerations*

Failure to thrive and delayed growth may be early manifestations. Some children may outgrow wheat intolerance after prolonged gluten-free diets but should watch for recurrence in middle age.

## **DIAGNOSIS**

### **HISTORY**

- Diarrhea, cramping, most common GI symptoms
- Steatorrhea (fatty stools)
- Muscle cramps
- Iron deficiency anemia
- Nervousness, depression

- Weight loss
- Failure to thrive (slowing velocity of weight gain)
- Weakness, fatigue
- Flatulence (can be explosive)
- Abdominal pain, nausea, vomiting
- Recurrent aphthous stomatitis
- Abdominal distention
- Delayed puberty
- Tingling numbness in hands, feet
- Bone or joint pain
- Migraines

## **PHYSICAL EXAM**

*Often normal but look for*

- Oropharynx: aphthous stomatitis
- Skin: dermatitis herpetiformis (symmetric erythematous papules and blisters on elbows, knees, buttocks, and back)
- Abdomen: distention

## **DIFFERENTIAL DIAGNOSIS**

- Short bowel syndrome
- Dyspepsia, gastroesophageal reflux disease (GERD)
- Pancreatic insufficiency
- Crohn disease; Whipple disease; tropical sprue
- Hypogammaglobulinemia
- Intestinal lymphoma
- HIV enteropathy
- Acute enteritis; radiation enteritis, eosinophilic gastroenteritis
- Giardiasis
- Pancreatic disease

# DIAGNOSTIC TESTS & INTERPRETATION

## Initial Tests (lab, imaging)

- Do not base diagnosis on serology alone. Patients with symptoms highly suggestive of celiac disease or those with positive serologies should undergo endoscopy for biopsy. Tissue biopsy is the gold standard for diagnosis.
- IgA antitissue transglutaminase (IgA-anti-tTG) is the preferred single serologic test in patients >2 (4)[C].
- Total serum IgA

### **ALERT**

Positive IgA tTG has high sensitivity and specificity (sensitivity, 90-98%; specificity, 98%) if on normal (non-gluten-free) diet for at least 4 weeks.

- IgA-deficient patients have false-negative IgA anti-tTG antibodies.
- IgA deficiency is 10 to 15 times more prevalent in patients with celiac disease.
- The tTG antibody test is the preferred test (over the deamidated gliadin peptide [DGP] antibody) (6,7,8)[A].

## Follow-Up Tests & Special Considerations

- If patient is IgA deficient OR if IgA anti-tTG are negative, follow up blood tests.
  - Anti-DGP IgA and IgG
    - Sensitivity, 94%; specificity, 99% (±anti-TTG)
- Do not use HLA DQ serotyping for initial diagnosis. Consider if discrepant serology-histology results in patients unable to test on gluten-free diet and children with Down syndrome (4)[C].
- Consider bone mineral density testing at diagnosis and after 1 year if osteopenia/osteoporosis on initial testing or 2 years if normal initially and patient still symptomatic or noncompliant.

## Pediatric Considerations

- Antigliadin antibody (AgA-IgG and IgA) may be used for children age <2 years because tTG and endomysial (EMA) antibodies may be absent.
- Anti-DGP test is sensitive in children.
- IgA tTG >10 times normal with positive EMA testing and HLA-DQ2 has PPV of 97.4% and may not need confirmatory intestinal biopsies for diagnosis (4)[C].

## Diagnostic Procedures/Other

- Endoscopy with a minimum of four biopsies of the distal duodenum and two of the duodenal bulb at time of initial evaluation correctly diagnosed 95% of children (4)[C].

P.169

- Video capsule endoscopy is a promising alternative with a sensitivity and specificity of 80% and 95%. Particularly helpful if antibody screening and clinical picture are consistent with celiac disease despite nondiagnostic duodenal biopsies (9)[A].

## Test Interpretation

### Small bowel biopsy

- Villous atrophy, hyperplasia and lengthening of crypts, infiltration of plasma cells, and intraepithelial lymphocytosis in lamina propria
- Villous atrophy also caused by Crohn disease, radiation enteritis, giardia and other food intolerances

## TREATMENT

### GENERAL MEASURES

- Remove gluten from the diet.
  - Rice, corn, and soybean flour are safe and palatable substitutes (4)[C].
- Levels of IgA antigliadin normalize with gluten abstinence.
- LIFELONG abstinence is required; immune response to gluten will recur with resumption of gluten consumption.

### MEDICATION

#### First Line

Usually no medications: Gluten-free diet is the treatment.

#### Second Line

- In refractory disease, consider
  - Steroids (prednisone, 40 to 60 mg/day PO in cases of refractory sprue)
  - Azathioprine (used with caution; use may lead to lymphoma)

- Cyclosporine
  - Infliximab
  - Cladribine
- Patients may develop nutritional deficiencies depending on the severity of the disease.

### *Third Line*

There are numerous clinical trials testing the efficacy of intraluminally acting agents such as *Lactobacilli* to gluten endopeptidases, inhibitors of transepithelial gliadin uptake, immunomodulation, and even vaccination (10). Findings are largely awaiting further validation.

## **ISSUES FOR REFERRAL**

- Additional nutritional support
- Refractory disease

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Consultation with registered dietitian
- Screen for osteoporosis and treat accordingly.

### ***Patient Monitoring***

- Repeat EGD if no clinical response to gluten-free diet or relapse in symptoms (4)[C].
- Follow anti-tTG IgA or deaminated antigliadin antibodies as a measure of response/compliance with diet (vs. antigliadin IgA or IgG).

### ***DIET***

- Remove gluten: wheat, rye, barley, and products with gluten additives.
- Dietary change is challenging (especially learning sources of hidden gluten) and should be coordinated with a skilled registered dietitian.

### ***PATIENT EDUCATION***

- Discuss how to recognize gluten in various products.
- Highlight potential complications and outcomes of failing to follow a gluten-free diet.

## PROGNOSIS

- Good prognosis if adherent to gluten-free diet
- Patients should feel better within 7 days of dietary modification.
- Symptoms usually disappear in 4 to 6 weeks.
- It is unknown whether strict dietary adherence decreases cancer risk.

## COMPLICATIONS

- Malignancy: <10% of patients (50% of whom develop small bowel lymphoma)
- Refractory disease (rare ~1-2% of all patients)
  - May respond to prednisone 40 to 60 mg/day PO
  - May need total parenteral nutrition
  - Two types: Type 2 has poor prognosis with 5-year survival of 44%.
- Chronic ulcerative jejunoileitis
  - Associated with multiple ulcers, intestinal bleeding, strictures, perforation, obstruction, and peritonitis.
  - 7% mortality
- Osteoporosis
- Dehydration
- Electrolyte depletion

## See Also

Algorithms: Diarrhea, Chronic; Malabsorption Syndrome

## Codes

### ICD10

K90.0 Celiac disease

## Clinical Pearls

- Test for celiac disease in patients with presumed IBS, dermatitis herpetiformis, or unexplained transaminitis.
- Test total IgA levels along with IgA anti-tTG antibodies in patients >2 years of age.
- Positive serology is not definitive; endoscopic biopsy is the gold standard for diagnosis.
- Standard of treatment is a gluten-free diet. Patient symptoms should improve within 7 days if fully compliant.

# Cellulitis

Jowhara Al-Qahtani, MD

Amer Homsy, MD

Bakr Nour, MD, PhD, FACS

## BASICS

### DESCRIPTION

- An acute bacterial infection of the dermis and subcutaneous tissue
- Types and locations:
  - Periorbital cellulitis: bacterial infection of the eyelid and surrounding tissues (anterior compartment)
  - Orbital cellulitis: Infection of the eye posterior to the septum; sinusitis is the most common risk factor.
  - Facial cellulitis: preceded by upper respiratory infection or otitis media
  - Buccal cellulitis: infection of cheek in children associated with bacteremia (common before *Haemophilus influenzae* type B vaccine)
  - Peritonsillar cellulitis: common in children associated with fever, sore throat, and hot potato speech
  - Abdominal wall cellulitis: common in morbidly obese patients
  - Perianal cellulitis: sharply demarcated, bright, perianal erythema
  - Necrotizing cellulitis: gas-producing bacteria in the lower extremities; common in diabetics
- System(s) affected: skin/exocrine

### EPIDEMIOLOGY

- Predominant sex: male = female (common in elderly and adults, except perianal cellulitis which is common in children)
- All-cause mortality for patient admitted with cellulitis is 7%. Recurrence rate of cellulitis is 8-20% (1)[A].

## *Incidence*

200/100,000 patient/years

## *Prevalence*

The exact prevalence is uncertain as cellulitis is common and not reportable. It affects all age groups and all races; however, certain types of cellulitis/microorganisms occur in certain populations. Community-acquired methicillin-resistant *Staphylococcus aureus* [CA-MRSA] has increased in athletes in contact sports (i.e., wrestling).

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Cellulitis is caused by bacterial penetration through a break in the skin. Hyaluronidase mediates subcutaneous (SC) spread.

- Microbiology
  - $\beta$ -Hemolytic streptococci (groups A, B, C, G, and F), *S. aureus*, including MRSA and gramnegative aerobic bacilli, are the most common.
  - *S. aureus*: periorbital and orbital cellulitis and IV drug users
  - *Pseudomonas aeruginosa*: diabetics and other immunocompromised patients
  - *Aeromonas hydrophila* and *Vibrio vulnificus*: cellulitis caused by waterborne pathogens
  - *H. influenzae*: buccal cellulitis
  - Clostridia and non-spore-forming anaerobes: necrotizing cellulitis (crepitant/gangrenous)
  - *Streptococcus agalactiae*: cellulitis following lymph node dissection
  - *Pasteurella multocida* and *Capnocytophaga canimorsus*: cellulitis preceded by bites
  - *Streptococcus iniae*: immunocompromised hosts
  - Rare causes: *Mycobacterium*, fungal (mucormycosis, aspergillosis, syphilis)

## *Genetics*

No genetic pattern

## **RISK FACTORS**

- Disruption of skin barrier: trauma, infection, insect bites, injection drug use, body piercing
- Inflammation: eczema or radiation therapy
- Edema due to venous insufficiency. Lymphatic obstruction due to surgical procedures or congestive heart failure

- Elderly, diabetes, hypertension, obesity
- Recurrent cellulitis:
  - Cellulitis recurrence score (2)[A]
  - Recurrent cellulitis is seen in immunocompromised patients (HIV/AIDS, steroids and TNF- $\alpha$  inhibitor therapy, diabetes, hypertension, cancer, peripheral arterial or venous diseases, chronic kidney disease, dialysis, IV or SC drug use (2)[A].

## GENERAL PREVENTION

- Good skin hygiene
- Support stockings to decrease edema
- Maintain tight glycemic control and proper foot care in diabetic patients.

## DIAGNOSIS

Primarily a clinical diagnosis

### HISTORY

- Previous trauma, surgery, animal/human bites, dermatitis, fungal infection; all serve as a portal of entry for bacterial pathogens.
- Pain, itching, and/or burning
- Fever, chills, and malaise

## PHYSICAL EXAM

- Localized pain and tenderness with erythema, induration, swelling, and warmth
- Peau d'orange appearance
- Regional lymphadenopathy
- Purulent drainage (from abscesses)
- Orbital cellulitis: proptosis, globe displacement, limitation of ocular movements, vision loss, diplopia
- Facial cellulitis: malaise, anorexia, vomiting, pruritus, burning, anterior neck swelling

## DIFFERENTIAL DIAGNOSIS

Toxic shock syndrome, venous stasis dermatitis (commonly mistaken as cellulitis), bursitis, acute

dermatitis or intertrigo, herpes zoster or herpetic whitlow, deep vein thrombosis or thrombophlebitis, acute gout or pseudogout, necrotizing fasciitis or myositis, gas gangrene, osteomyelitis, erythema chronicum migrans or malignancy, drug reaction, sunburn, or insect stings. Spider bites and MRSA cellulitis can present similarly.

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- If there are signs of systemic disease (fever, heart rate >100 bpm, or systolic blood pressure <90 mm Hg): blood cultures, CPK, CRP. Consider serum lactate levels.
- WBC has 84% specificity and 43% sensitivity; whereas CRP had a sensitivity of 67% and specificity of 95% (PPV 95% and NPV 68%).
- Aspirates from point of maximum inflammation yield 45% positive culture compared with 5% from leading edge
- Blood cultures: Pathogens are isolated in <5% of patients. Blood cultures in children are more likely to show a contaminant than true positive.
- Swab open cellulitis wounds for culture.
- Plain radiographs, CT, or MRI are useful if osteomyelitis, fracture, necrotizing fasciitis, or retained foreign body is suspected or underlying abscess.
- Gallium<sup>67</sup> scintillography helps detect cellulitis superimposed on chronic limb lymphedema.

### *Diagnostic Procedures/Other*

Consider lumbar puncture in children with *H. influenzae* type B or if meningeal signs and facial cellulitis.

## TREATMENT

### GENERAL MEASURES

- Immobilize and elevate the involved limb to reduce swelling.
- Sterile saline dressings or cool aluminum acetate compresses for pain relief
- Edema: compression stocking, pneumatic pumps. Diuretic therapy for CHF patients
- Mark the area of cellulitis to monitor progression.
- Tetanus immunization if needed, particularly if there is an open (traumatic) wound

# MEDICATION

## First Line

- Target treatment in the setting of known pathogens or certain exposure (animal bites)
- Antibiotic selection relies on clinical presentation:
  - Nonpurulent cellulitis
    - With nonpurulent drainage, target treatment toward  $\beta$ -hemolytic streptococci and MSSA.
    - Outpatient: treatment duration of 5 to 10 days
      - Oral: for mild cellulitis
        - Cephalexin 500 mg PO q6h; children: 25 to 50 mg/kg/day in 3 to 4 doses
        - Dicloxacillin 500 mg PO q6h; children: 25 to 50 mg/kg/day in 4 doses
        - Clindamycin 300 to 450 mg PO q6-8h; children: 20 to 30 mg/kg/day in 4 doses
      - IV: for rapidly progressing cellulitis
        - Cefazolin 1 to 2 g IV q8h; children: 100 mg/kg/day IV in 2 to 4 divided doses
        - Oxacillin 2 g IV q4h; children: 150 to 200 mg/kg/day IV in 4 to 6 doses
        - Nafcillin 2 g IV q4h; children: 150 to 200 mg/kg/day IV in 4 to 6 doses
        - Clindamycin 600 to 900 mg IV q8h; children: 25 to 40 mg/kg/day IV in 3 to 4 doses

---

P.171

- Purulent cellulitis (probable CA-MRSA)
  - Culture all purulent wounds and follow up in 48 hours.
  - Incise and drain abscess and start empiric antibiotic therapy. Modify based on culture results; tailor duration based on clinical response (3)[B]:
    - Oral
      - Clindamycin 300 to 450 mg PO; children: 40 mg/kg/day in 3 to 4 doses
      - Trimethoprim-sulfamethoxazole (TMP-SMZ) 1 DS tab PO BID; children: dose based on TMP at 8 to 12 mg/kg/day divided in 2 doses
      - Doxycycline 100 mg PO BID; children >8 years of age:  $\leq 45$  kg: 4 mg/kg/day divided in 2 doses; >45 kg: 100 mg PO BID
      - Minocycline 200 mg PO once, then 100 mg PO BID; children >8 years old: 4 mg/kg

PO once, then 4 mg/kg PO BID

- Linezolid 600 mg PO BID; children <12 years: 10 mg/kg/dose (max 600 mg/dose) PO TID; >12 years: 600 mg PO BID
- Tedizolid 200 mg PO once daily; children: Dosing is not established.

○ IV

- Vancomycin 15 to 20 mg/kg/dose IV every 8 to 12 hours
  - Daptomycin 4 mg/kg/dose IV once daily; if bacteremia is present or suspected: 6 mg/kg IV once daily
  - Linezolid 600 mg IV BID
  - Tedizolid 200 mg IV once daily
  - Ceftaroline 600 mg IV q12h
  - Tigecycline 100 mg IV once, thereafter 50 mg IV q12h
- Necrotizing cellulitis: requires broad-spectrum coverage to cover clostridial and anaerobic species: ampicillin-sulbactam 1.5 to 3.0 g q6-8h IV or piperacillin-tazobactam 3.37 g q6-8h IV plus ciprofloxacin 400 mg q12h IV plus clindamycin 600 to 900 mg q8h IV
  - Freshwater exposure: penicillinase-resistant: penicillin plus gentamicin or fluoroquinolone; in salt water exposure: doxycycline 200 mg IV in 2 divided doses
  - Bites: The combination of amoxicillin and clavulanic acid is recommended for human and dog bites. Ticarcillin and clavulanic acid or the combination of a 3rd-generation cephalosporin (i.e., ceftriaxone) plus metronidazole provides adequate parenteral therapy for animal or human bites. If allergic to penicillin, use fluoroquinolone plus metronidazole.
  - Facial cellulitis in adults: ceftriaxone IV
  - Diabetic foot infection: ampicillin/sulbactam or imipenem/cilastatin or meropenem; alternative: combinations of targeting anaerobes as well as gram-positive and gram-negative aerobes
  - If severe infection, toxicity, immunocompromised patients, or worsening infection despite empirical therapy, admit for empiric antibiotic therapy covering MRSA.
  - Recurrent streptococcal cellulitis: penicillin 250 mg BID, or if penicillin-allergic, use erythromycin 250 mg BID

## *Pediatric Considerations*

- Avoid doxycycline in children <sup>3</sup>8 years old and during pregnancy.

## *Second Line*

Mild infection

- Penicillin allergy: erythromycin 500 mg PO q6h
- Cephalexin remains a cost-effective therapy for outpatient management of cellulitis at current estimated MRSA levels.

## *SURGERY/OTHER PROCEDURES*

- Debridement for gas and purulent matter
- Intubation or tracheotomy may be needed for cellulitis of the head or neck.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Severe infection, suspicion of deeper or rapidly spreading infection, tissue necrosis, or severe pain
- Marked systemic toxicity or worsening symptoms that do not resolve after 24 to 48 hours of therapy
- Patients with underlying risk factors or severe comorbidities

## **ONGOING CARE**

## *FOLLOW-UP RECOMMENDATIONS*

### *Patient Monitoring*

- Repeat relevant labs (blood culture, CBC, potentially LP) if patient is toxic or not improving.
- Consider deep vein thrombosis prophylaxis.
- Cutaneous inflammation may worsen in the first 24 hours due to release of bacterial antigens. Symptomatic improvement usually occurs in 24 to 48 hours, but visible improvement may take 72 hours.

## *DIET*

Glucose control in diabetics

## *PATIENT EDUCATION*

Good skin hygiene.

## PROGNOSIS

With adequate antibiotic treatment, prognosis is good.

- Low-dose penicillin prophylaxis in patients with recurrent cellulitis decreases recurrence (4)[A].

## COMPLICATIONS

- Local abscess or bacteremia, sepsis
- Superinfection with gram-negative organisms
- Lymphangitis, especially if recurrent
- Thrombophlebitis or venous thrombosis
- Bacterial meningitis
- Gangrene

## Codes

### ICD10

- L03.90 Cellulitis, unspecified
- H05.019 Cellulitis of unspecified orbit
- L03.211 Cellulitis of face

## Clinical Pearls

- *S. aureus* and group A *Streptococcus* are the most common organisms that cause cellulitis.
- Consider MRSA if cellulitis is not responding to antibiotics in the first 48 hours.
- Rapid expansion of infected area with red/purple discoloration and severe pain may suggest necrotizing fasciitis, requiring urgent surgical evaluation.

# Cellulitis, Orbital

Robert Thomas Carlisle, MD, MPH

## BASICS

### DESCRIPTION

- Acute, severe, vision-threatening infection of orbital contents posterior to orbital septum. Preseptal (previously referred to as periorbital) cellulitis is anterior to the septum. Distinguishing location determines the appropriate workup and treatment (1).
- Synonym(s): postseptal cellulitis

### ALERT

- Differentiating orbital from preseptal cellulitis is the critical diagnostic step. Preseptal cellulitis can be identified at exam or, if needed, by CT scan.
- Diplopia, proptosis, vision loss, and fever suggest orbital involvement.
- Contrast CT is the imaging method of choice and should be done for suspicion of orbital cellulitis.
- Treat with immediate IV antibiotics; hospital admission and ophthalmology referral.
- Monitor frequently for vision loss, cavernous sinus thrombosis, abscess, and meningitis.
- Intraorbital foreign body (FB) may cause delayed orbital cellulitis.

### EPIDEMIOLOGY

- No difference in frequency between genders in adults
- More common in children; mean age of surgical cases: 10.1 years; medical pediatric cases: 6.1 years
- Much less common than preseptal cellulitis

### Incidence

Orbital cellulitis has declined since *Haemophilus influenzae* type b (Hib) vaccine was introduced in 1985. In 2000, incidence per 100,000 in California was 3.5 in whites, 6.1 in blacks, and 3.2 in

Hispanics, compared to 6.5 in whites, 10.2 in blacks, and 5.5 in Hispanics in 1990.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Sinusitis is a major risk factor.
- The ethmoid sinus is separated from the orbit by the lamina papyracea (Ölayer of paperÓ), a thin bony separation, and is often the source of contiguous spread of infection to the orbit.
- The orbital septum is a connective tissue barrier that extends from the skull into the lid and separates the preseptal from the orbital space.
- Cellulitis in the closed bony orbit causes proptosis, globe displacement, orbital apex syndrome (mass effect on the cranial nerves), optic nerve compression, and vision loss.
- Orbital abscess (medial wall most common), meningitis, and cavernous sinus thrombosis may occur.
- Blood cultures are often negative.
- Cultures of surgical specimens in adults often grow multiple organisms, but >1/3 of cases have no pathogen recovered (2)[B].
- Most common organisms (3,4)[C]:
  - *Staphylococcus aureus*, *Streptococcus pneumoniae*, *Streptococcus anginosus*
- Less common organisms:
  - *Moraxella catarrhalis*, *H. influenzae*, group A  $\beta$ -hemolytic *Streptococcus*, *Pseudomonas aeruginosa*, anaerobes, phycomycosis (mucormycosis), aspergillosis, *Mycobacterium tuberculosis*, *Mycobacterium avium* complex, trichinosis, *Echinococcus*
- Hib was the most common organism prior to Hib vaccine, Since routine Hib vaccination in 1992, *Haemophilus* is no longer the leading cause of orbital cellulitis (3,4)[B].

## Genetics

No known genetic predisposition

## RISK FACTORS

- Sinusitis is present in 80-90% of cases (3)[C].
- Orbital trauma, retained orbital FB, ophthalmic surgery
- Dental, periorbital, skin, or intracranial infection; acute dacryocystitis and acute dacryoadenitis
- Immunosuppressed patients at increased of adverse outcomes

## GENERAL PREVENTION

- Routine Hib vaccination
- Appropriate treatment of bacterial sinusitis
- Proper wound care and perioperative monitoring of orbital surgery and trauma
- Avoid trauma to the sinus passages.
- High index of suspicion in febrile patients presenting with eyelid and conjunctival pain, swelling, and erythema.

## COMMONLY ASSOCIATED CONDITIONS

- >80% cases have contiguous sinusitis.
- Trauma and intraorbital FB
- Preseptal cellulitis
- Adverse outcomes of orbital apex syndrome, vision loss, ophthalmoplegia, abscess, meningitis, or cavernous sinus thrombosis

## DIAGNOSIS

### HISTORY

- Complaints of acute onset red, swollen, tender eye or eyelid and pain with eye movements (5)[C]
- History of surgery, trauma, sinus or upper respiratory infection, dental infection
- Malaise, fever, stiff neck, mental status changes
- Specific signs of orbital cellulitis include:
  - Proptosis, double vision, ophthalmoplegia, vision loss (or decreased field of vision), pain with eye movement, decreased color vision (5)[C]

### ALERT

- Severe septic appearance, mental status changes, contralateral cranial nerve palsy, or bilateral orbital cellulitis may indicate CNS involvement.
- MRSA orbital cellulitis may present without associated upper respiratory infection.

## *PHYSICAL EXAM*

- Vital signs
  - Assess visual acuity (with glasses if required).
  - Lid exam and palpation of the orbit
  - Pupillary reflex for afferent pupillary defect
  - Extraocular movements; assess for pain with eye movement—if present, concerning for orbital cellulitis.
  - Red desaturation: Patient views red object with one eye and compares to the other; reduced red color may indicate optic nerve involvement.
  - Confrontation visual field testing

## *DIFFERENTIAL DIAGNOSIS*

- Preseptal cellulitis
  - Eyelid erythema with or without conjunctival erythema, afebrile, no pain on eye movement, no diplopia, normal eye exam, vision intact (5)[C]
- Metastatic tumors and autoimmune inflammation may masquerade as orbital cellulitis in rare cases. Usually present with painless slow onset of symptoms
- Idiopathic orbital inflammatory disease (orbital pseudotumor) (3)[C]
  - Afebrile, normal WBCs; usually subacute, may have pain, responds to steroids
- Orbital FB
- Arteriovenous fistula (carotid-cavernous fistula)
  - Spontaneous or due to trauma; bruit may be present. Insidious, subacute onset
- Cavernous sinus thrombosis
  - Signs of orbital cellulitis with cranial nerves III, IV, V, and VI findings; often bilateral and acute
  - Severely ill
- Acute thyroid orbitopathy
  - Afebrile; possible signs of thyroid disease
  - Bilateral orbital involvement

- Orbital tumor
  - Acute rhabdomyosarcoma in children; acute lymphoblastic leukemia, or metastatic
  - Unilateral
  - Slow onset
- Trauma, insect bite, ruptured dermoid cyst (6)
- Clinical signs help distinguish preseptal from orbital cellulitis. Preseptal infection causes erythema, induration, and tenderness of the eyelid and/or periorbital tissues, and patients rarely show signs of systemic illness. Local skin trauma, lacerations, or bug bites can be seen. Extraocular movements and visual acuity are intact.
- Orbital cellulitis also presents with complaints of a red, swollen, painful eye or eyelid. It also results in proptosis, conjunctival edema, ophthalmoplegia (diminished ocular movement), or decreased visual acuity (7)[C].
- Staging in cases resulting from acute sinusitis (3)[A]
  - Stage I: no abscess
  - Stage IIa, b, c: small, large, or extending medial subperiosteal abscess
  - Stage III: orbital abscess
- Chandler staging: (6)[C]
  - Stage I: periorbital cellulitis (considered different entity)
  - Stage II: orbital lining edema, chemosis, proptosis, limitation of extraocular movement, fever
  - Stage III: includes stage II with subperiosteal abscess and occasional vision loss
  - Stage IV: orbital abscess, ophthalmoplegia with vision loss
  - Stage V: extension to cavernous sinus, subdural space, meninges, or brain (3,7)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- CBC with differential, C-reactive protein, ESR
- Cultures of eye secretions or nasopharyngeal aspirates are often contaminated by normal flora but may identify causative organism(s).
- Cultures from orbital and sinus abscesses more often yield positive results but should be limited

to cases where invasive procedures are indicated. Cultures from sinus aspirates and abscesses may grow multiple organisms.

- Blood cultures (often negative) should be obtained prior to initiation of antibiotic therapy.

### *Initial Tests (lab, imaging)*

- CT scan of orbits and sinuses with axial and coronal views, with and without contrast, is the diagnostic modality of choice (8)[C]. US and MRI are alternatives (9)[B].
  - Thin section (2 mm) CT, coronal and axial views with bone windows to differentiate preseptal from orbital cellulitis, confirm extension into orbit, detect coexisting sinus disease, and identify orbital or subperiosteal abscesses that may require surgery.
  - Deviation of medial rectus indicates intraorbital involvement.
- MRI offers superior soft tissue resolution for identification of cavernous sinus thrombosis but is less effective for bone imaging.
- US is used to rule out orbital myositis, locate FBs or abscesses, and follow progression of drained abscess.

### *Follow-Up Tests & Special Considerations*

- Consider a full-septic evaluation (including LP) before antibiotics in toxic patients or if meningitis is suspected (6)[C].
- Frequent eye exam and vital signs (q4h) are essential for timely treatment of associated conditions, such as meningitis or orbital abscess.

### *Diagnostic Procedures/Other*

Consult ophthalmology for slit lamp and dilated funduscopic exam; exophthalmometry measurement for proptosis, color vision, automated visual field; and need for surgery.

## **TREATMENT**

Admit patients with orbital cellulitis for monitoring of ocular status and treatment with broad-spectrum antibiotics (2).

## **MEDICATION**

- Empiric antibiotic therapy to cover pathogens associated with acute sinusitis (*S. pneumoniae*, *H. influenzae*, *M. catarrhalis*, *Streptococcus pyogenes*), as well as for *S. aureus*, *S. anginosus*, and anaerobes

- Modify IV antibiotic treatment when sensitivities are available. Duration of IV therapy is usually a week, with additional PO therapy depending on response.
- PO antibiotic therapy for 2 to 3 weeks or longer (3 to 6 weeks) is recommended for patients with severe sinusitis and bony destruction.

## *First Line*

- Ampicillin/sulbactam (Unasyn) or ceftriaxone plus metronidazole or clindamycin if anaerobic infection is suspected (2)
  - Ampicillin/sulbactam: 3 g IV q6h for adult; 200 to 300 mg/kg/day divided q6h for children
  - Ceftriaxone: 1 to 2 g IV q12h for adults or 100 mg/kg/day divided BID in children with max 4 g/day
  - Clindamycin: 600 mg IV q8h for adults; 20 to 40 mg/kg/day IV q6-8h for children (10)
  - Metronidazole: 500 mg IV q8 h for adult; 30 to 35 mg/kg/day divided q8h for children
- ALERT: In severe orbital cellulitis and in suspected or culture-proven MRSA infection, vancomycin remains the parenteral drug of choice. Use in conjunction with agents to cover gram-negative bacteria.
  - Vancomycin: 1 g IV q12h for adults; 40 mg/kg/day IV divided q8-12h, max daily dose 2 g for children (2)

## *ADDITIONAL THERAPIES*

- Steroid use is controversial (3)[C].
- PO steroids as an adjunct to IV antibiotics for orbital cellulitis may speed resolution of inflammation (11)[C].
- Topical erythromycin or nonmedicated ophthalmic ointment protects the eye from exposure in cases with severe proptosis.
- PO antibiotics for 3-2 weeks are traditionally recommended following IV treatment.
- Children may be treated with amoxicillin/clavulanate 20 to 40 mg/kg/day divided TID or in adults 250 to 500 mg TID.

## *ISSUES FOR REFERRAL*

Always admit to the hospital and consult with ophthalmology. Consider consultation with ID and ENT for orbital cellulitis; neurology/neurosurgery if intracranial spread is suspected

## ***SURGERY/OTHER PROCEDURES***

- IV antibiotic therapy is the initial therapy.
- Surgical intervention warranted for visual loss, complete ophthalmoplegia, or well-defined large abscess (>10 mm) on presentation or no clinical improvement after 24 to 48 hours of antibiotic therapy
- Trauma cases may need debridement or FB removal.
- Orbital abscess may need surgical drainage.
- Surgical drainage with 4 to 8 weeks of antibiotics is the treatment of choice for brain abscess.
- Surgical interventions may include external ethmoidectomy, endoscopic ethmoidectomy, uncinectomy, antrostomy, and subperiosteal drainage.

## ***INPATIENT CONSIDERATIONS***

Patients with orbital cellulitis should be admitted for IV antibiotics and serial eye exams to evaluate progression of infection or involvement of optic nerve.

- Follow temperature, WBC, visual acuity, pupillary reflex, ocular motility, and proptosis.
- Repeat CT scan, or surgical intervention, may be required for worsening orbital cellulitis cases.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

Serial visual acuity testing and slit lamp exams

#### **ALERT**

Bedside exam q4h is indicated, as complications can develop rapidly.

### ***PATIENT EDUCATION***

- Maintain proper hand washing and good skin hygiene.
- Avoid skin or lid trauma.

#### **COMPLICATIONS**

- Vision loss, CNS involvement, and death
- Permanent vision loss

- Corneal exposure
- Optic neuritis
- Endophthalmitis
- Septic uveitis or retinitis
- Exudative retinal detachment
- Retinal artery or vein occlusions
- Globe rupture
- Orbital compartment syndrome
- CNS complications
  - Intracranial abscess, meningitis, cavernous sinus thrombosis (4)[B]

## Codes

### ICD10

- H05.019 Cellulitis of unspecified orbit
- H05.011 Cellulitis of right orbit
- H05.012 Cellulitis of left orbit

## Clinical Pearls

- Most orbital cellulitis cases result from sinusitis.
- MRSA orbital cellulitis may present without associated upper respiratory infection.
- CT of orbits and sinuses with axial and coronal views with and without contrast is diagnostic modality of choice for suspected cases of orbital cellulitis.
- Patients with orbital cellulitis should be admitted for visual monitoring and IV antibiotic therapy.
- Older age (>10 years) and diplopia may predict need for surgical intervention in children.
- Ophthalmoplegia, mental status changes, contralateral cranial nerve palsy, or bilateral orbital cellulitis raise suspicion for intracranial involvement.

# Cellulitis, Periorbital

Fozia Akhtar Ali, MD

Mohammad Ansar Mughal, MD

## BASICS

### DESCRIPTION

- An acute bacterial infection of the skin and subcutaneous tissue anterior to the orbital septum; not involving the orbital structures (globe, fat, and ocular muscles)
- Synonym(s): preseptal cellulitis

### ALERT

It is essential to distinguish periorbital cellulitis from orbital cellulitis. Orbital cellulitis is a potentially life-threatening condition. *Orbital cellulitis is posterior to the orbital septum; symptoms include restricted eye movement, pain with eye movement, proptosis, and vision changes.*

### EPIDEMIOLOGY

- Occurs more commonly in children; mean age 21 months
- 3 times more common than orbital cellulitis (1)[C]

### Incidence

- Increased incidence in the winter months (due to increased cases of sinusitis) (1)[C]

### ETIOLOGY AND PATHOPHYSIOLOGY

- The anatomy of the eyelid distinguishes periorbital (preseptal) from orbital cellulitis:
  - A connective tissue sheet (orbital septum) extends from the orbital bones to the margins of the upper and lower eyelids; it acts as a barrier to infection deep in the orbital structures.
  - Infection of tissues anterior to the orbital septum is periorbital (preseptal) cellulitis.
  - Infection deep to the orbital septum is orbital (postseptal) cellulitis.
- Periorbital cellulitis classically arises from a contiguous infection of soft tissues of the face.

- Sinusitis (via lamina papyracea) extension
- Local trauma; insect or animal bites
- Foreign bodies
- Dental abscess extension
- Hematogenous seeding
- Common organisms (1)[C]
  - *Staphylococcus aureus*, typically MSSA (MRSA is increasing)
  - *Staphylococcus epidermidis*
  - *Streptococcus pyogenes*
- Atypical organisms
  - *Acinetobacter* sp.; *Nocardia brasiliensis*
  - *Bacillus anthracis*; *Pseudomonas aeruginosa*
  - *Neisseria gonorrhoeae*; *Proteus* sp.
  - *Pasteurella multocida*; *Mycobacterium tuberculosis*; *Trichophyton* sp. (ringworm)
- Since vaccine introduction, the incidence of *Haemophilus influenzae* has decreased. This organism should still be suspected in unimmunized or partially immunized patients.

## Genetics

No known genetic predisposition.

## RISK FACTORS

- Contiguous spread from upper respiratory infection
- Sinusitis
- Local skin trauma/puncture wound
- Insect bite
- Bacteremia

## GENERAL PREVENTION

- Avoid dermatologic trauma around the eyes.
- Avoid swimming in fresh or salt water with facial skin abrasions.

- Routine vaccination: particularly *H. influenzae* type B and *Streptococcus pneumoniae*

## DIAGNOSIS

### HISTORY

- Induration, erythema, warmth, and/or tenderness of periorbital soft tissue, usually with normal vision and normal eye movements
- Chemosis (conjunctival swelling), proptosis; pain with extraocular eye movements can occur in severe cases of periorbital cellulitis, although these symptoms are more common with (and concerning for) orbital cellulitis.
- Fever (not always present)

### ALERT

Pain with eye movement, fever, and conjunctival swelling raise the suspicion for orbital cellulitis.

### PHYSICAL EXAM

- Vital signs and general appearance. (Patients with orbital cellulitis often appear systemically ill.)
- Thorough inspection of the eye and surrounding structures—lids, lashes, conjunctiva, and skin
- Erythema, swelling, and tenderness of lids without orbital congestion
  - Violaceous discoloration of eyelid is more commonly associated with *H. influenzae*.
- Evaluate for any skin break.
- Look for vesicles to rule out herpetic infection.
- Inspect nasal vaults and palpate sinuses for signs of acute sinusitis.
- Examine oral cavity for dental abscesses.
- Test ocular motility and visual acuity.

### DIFFERENTIAL DIAGNOSIS

- Orbital cellulitis
  - Orbital cellulitis may have the same signs and symptoms as periorbital cellulitis, with more extensive proptosis, chemosis, ophthalmoplegia, decreased visual acuity, or fever.
- Abscess

- Dacryocystitis
- Hordeolum (stye)
- Allergic inflammation
- Orbital or periorbital trauma
- Idiopathic inflammation from orbital pseudotumor
- Orbital myositis
- Rapidly progressive tumors
  - Rhabdomyosarcoma
  - Retinoblastoma
  - Lymphoma
- Leukemia

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- CBC with differential
- Blood cultures (low yield) (2)[C]
- Wound culture of purulent drainage (if present)
- Imaging is indicated if there is suspicion for orbital cellulitis (marked eyelid swelling, fever, and leukocytosis or those who fail to improve on appropriate antibiotics in 24 to 48 hours).
- CT can evaluate the extent of infection and detect orbital inflammation or abscess (3)[B]:
  - The classic sign of orbital cellulitis on CT scan is bulging of the medial rectus.
  - CT should be performed with contrast, thin sections (2 mm); coronal and axial views with bone windows.

### *Follow-Up Tests & Special Considerations*

- Children with periorbital or orbital cellulitis often have underlying sinusitis.
- If a child is febrile, <15 months old, and appears toxic, admit for blood cultures, antibiotic therapy, and consider lumbar puncture.

## TREATMENT

### MEDICATION

- Empiric antibiotic treatment to cover the most likely organisms (*Staphylococcus* and *Streptococcus*) (3)[C]
- Observe local prevalence of MRSA to determine need for coverage therapy.
- No evidence that IV antibiotics are more effective than PO in reducing recovery time or preventing secondary complications in the management of simple periorbital cellulitis (1)[C].
- No evidence for steroid use

P.175

### First Line

- Uncomplicated posttraumatic
  - Usually due to skin flora, including *Staphylococcus* and *Streptococcus*
  - Cephalexin 500 mg PO q6h or dicloxacillin 500 mg PO q6h
  - Clindamycin 300 mg PO TID, doxycycline 100 mg PO BID, or trimethoprim-sulfamethoxazole (TMP-SMX) 1 to 2 DS tablets PO q12h if MRSA is suspected.
- Extension from sinusitis
  - Amoxicillin-clavulanate 875 mg PO BID
  - 3rd-generation cephalosporin (e.g., cefdinir 300 mg PO BID)
- Dental abscess
  - Amoxicillin-clavulanate 875 mg PO BID or clindamycin 300 mg PO TID
- Bacteremic cellulitis
  - May be associated with meningitis
  - Ceftriaxone 1 g IV q24h plus vancomycin 15 mg/kg/dose IV q8-12h or clindamycin 600 to 900 mg IV q8h to cover MRSA
- Duration of therapy should be 7 to 10 days
  - If symptoms do not improve within 24 hours, IV antibiotic therapy is indicated.

### ISSUES FOR REFERRAL

Consult ENT and ophthalmology if there is concern of orbital cellulitis or when 1st-line treatment has failed (4).

## ***SURGERY/OTHER PROCEDURES***

- Usually not indicated in uncomplicated cases
- If there is an abscess or potential compromise of critical structures, orbital surgery is indicated.
- Diplopia is the strongest clinical predictor of surgery.

## ***INPATIENT CONSIDERATIONS***

Mild cases in adults and children >1 year of age can be managed on an outpatient basis, if the patient is stable and there are no systemic signs of toxicity.

### ***Admission Criteria/Initial Stabilization***

- Consider hospitalization and IV antibiotics:
  - If patient appears systemically ill
  - Children <1 year of age (4,5)[C]
  - Patients not immunized against *S. pneumoniae* or *H. influenzae*
  - If no signs of clinical improvement are apparent after 24 hours of antibiotic therapy
  - Cases with high suspicion of orbital cellulitis (eyelid swelling with reduced vision, diplopia, abnormal light reflexes, or proptosis)

### ***Discharge Criteria***

- No strict guidelines indicate when to switch from parenteral to PO therapy. In general, switch to PO therapy after the patient is afebrile and the skin findings have begun to resolve (typically 2 to 3 days).
- Continue therapy for 10 to 14 days for orbital cellulitis or complicated periorbital cellulitis.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

Follow for signs of orbital involvement, including decreased visual acuity or painful/limited ocular motility.

## ***PATIENT EDUCATION***

- Maintain good skin hygiene.
- Avoid skin trauma.
- Report early skin changes (swelling, redness, and pain) if recurrent after a course of therapy.

## ***PROGNOSIS***

- With timely treatment, patients do well.
- A 10-day course of antibiotics is generally sufficient.
- Recurrent periorbital cellulitis occurs with <sup>33</sup> periorbital infections in 1 year with at least 1 month of in between episodes; must be differentiated from treatment failure due to antibiotic resistance (1)[C].

## **COMPLICATIONS**

- Orbital cellulitis; orbital abscess formation
- Scarring
- Vision loss
- Cavernous sinus thrombosis
- Osteomyelitis

## Codes

### ICD10

L03.211 Cellulitis of face

## Clinical Pearls

- Periorbital (preseptal) and orbital (postseptal) cellulitis occur most commonly in children.
- It is critical to differentiate between periorbital cellulitis and orbital cellulitis; the latter is more dangerous and can be life threatening. Orbital cellulitis typically has fever, pain with eye movement, diplopia and/or proptosis. Prompt imaging is necessary if there is a concern for orbital cellulitis.
- CT scan of the patient's sinuses and orbits can be used to differentiate periorbital cellulitis from orbital cellulitis.
- The two most important predisposing factors for periorbital cellulitis are upper respiratory infections and eyelid trauma; sinusitis is more typically associated with orbital cellulitis (5)[C].

# Cerebral Palsy

Christina Mezzone, DO, MS

Maria Lombardi, DO

## BASICS

### DESCRIPTION

Cerebral palsy (CP) is a group of clinical syndromes characterized by motor and postural dysfunction due to permanent and nonprogressive disruptions in the developing brain. Motor impairment resulting in activity limitation is necessary for this diagnosis. CP is classified by the nature of the movement disorder and its functional severity. Individuals with this disorder are affected with secondary musculoskeletal and neurologic problems (intellectual, sensory, speech and language impairment, and seizures).

### EPIDEMIOLOGY

#### Incidence

- Overall, 1.5 to 2.5/1,000 live births
- Incidence increases as gestational age (GA) at birth decreases:
  - 146/1,000 for GA of 22 to 27 weeks
  - 62/1,000 for GA of 28 to 31 weeks
  - 7/1,000 for GA of 32 to 36 weeks
  - 1/1,000 for GA of 37+ weeks

#### Prevalence

3 to 4/1,000 of the population

### ETIOLOGY AND PATHOPHYSIOLOGY

- Multifactorial; CP results from static injury or lesions in the developing brain, occurring prenatally, perinatally, or postnatally.
- Neuropathology linked to GA at time of brain insult

Cytokines, free radicals, and inflammatory response are likely contributing factors.

- Etiology is most likely multifactorial and depends on timing of brain insult: prenatally, perinatally, or postnatally (see *Risk Factors*).
- Spastic CP is most common, usually related to premature birth, with either periventricular leukomalacia or germinal matrix hemorrhage.
- Dystonic or athetotic CP, often resulting from kernicterus, is now rare due to improved management of hyperbilirubinemia.

## *Genetics*

There are reports of associations between CP and polymorphisms of certain genes: thrombophilic, cytokines, and apolipoprotein E.

## **RISK FACTORS**

- Prenatal: congenital anomalies, multiple gestation, in utero stroke, intrauterine infection (cytomegalovirus [CMV], varicella), intrauterine growth retardation (IUGR), clinical and histologic chorioamnionitis, antepartum bleeding, maternal factors (cognitive impairment, seizure disorders, hyperthyroidism), abnormal fetal position (e.g., breech)
- Perinatal: preterm birth, low birth weight, periventricular leukomalacia, perinatal hypoxia/asphyxia, intracranial hemorrhage/intraventricular hemorrhage, neonatal seizure or stroke, hyperbilirubinemia
- Postnatal: traumatic brain injury or stroke, sepsis, meningitis, encephalitis, asphyxia, and progressive hydrocephalus

## **GENERAL PREVENTION**

- Treating mothers with magnesium sulfate during preterm delivery is neuroprotective for fetus and may reduce the risk of CP. Effect on term fetus is unknown.
- Improved management of hyperbilirubinemia with decrease in kernicterus has greatly reduced dyskinetic CP.
- Prevention or reduction of chorioamnionitis and premature births

## **COMMONLY ASSOCIATED CONDITIONS**

- Seizure disorder (22-40%)
- Intellectual impairment (23-44%)
- Behavioral problems

- Speech and language impairment (42-81%)
  - May have an impact on expressive and/or receptive language
  - May be nonverbal
- Sensory impairments
  - Hearing deficits
  - Visual (62-71%): poor visual acuity, strabismus (50%), or hemianopsia
- Feeding impairment, swallowing dysfunction, and aspiration: when severe, may require gastrostomy feedings
- Poor dentition, excessive drooling
- GI conditions: constipation (59%), vomiting (22%), gastroesophageal reflux
- Decreased linear growth and weight abnormalities (under- and overweight)
- Osteopenia
- Bowel and bladder incontinence
- Orthopedic: contractures, hip subluxation/dislocation, scoliosis (60%)

## DIAGNOSIS

- A clinical diagnosis including
  - Delayed motor milestones
  - Abnormal tone
  - Abnormal neurologic exam suggesting a cerebral etiology for motor dysfunction
  - Absence of regression (not losing function)
  - Absence of underlying syndromes or alternative explanation for etiology
- Although the pathologic lesion is static, clinical presentation may change as the infant grows and develops.
- Accurate early diagnosis remains difficult. Neurologic abnormalities observed in the first 1 to 2 years of life may resolve; be cautious of diagnosing CP before age 2 years.
- Serial exams are often required for a definitive diagnosis.

## HISTORY

Presentation: concerns over movements or delayed motor development

- Ask about
  - Prenatal, perinatal, and postnatal risk factors
  - Neurobehavioral signs
    - Poor feeding/frequent vomiting
    - Irritability
  - Timing of motor milestones: Delay in milestones is not sensitive or specific until after 6 months of age.
  - Abnormal spontaneous general movements
  - Asymmetry of movements such as early hand preference
- Regression of motor skills does not occur with CP.

## *PHYSICAL EXAM*

- Assess for more than one type of neurologic impairment:
  - Spasticity: increased tone/reflexes/clonus
  - Dyskinesia: abnormal movements
  - Hypotonia: decreased tone
  - Ataxia: abnormal balance/coordination
- Areas of exam
  - Tone: may be increased or decreased
  - Trunk and head control: often poor but may be advanced due to high tone
  - Reduced strength and motor control
  - Persistence of primitive reflexes
  - Asymmetry of movement or reflexes
  - Decreased joint range of motion and contractures
  - Brisk deep tendon reflexes
  - Clonus
  - Delayed motor milestones: serial exams most effective
  - Gait abnormalities: scissoring, toe-walking
- CP is classified by the following:

- Muscle tone or movement disorder
  - Spasticity
    - Unilateral: hemiplegic
    - Bilateral: diplegic (lower extremity [LE] > upper extremity [UE] involvement) or quadriplegic (UE <sup>3</sup> LE involvement)
  - Dystonia: hypertonia and reduced movement
  - Choreoathetosis: irregular spasmodic involuntary movements of the limbs or facial muscles
  - Ataxia: loss of orderly muscular coordination
- Motor function severity
  - The Gross Motor Function Classification System (GMFCS) scores I-IV
    - Score of I: ambulates without limitation
    - Score of II: ambulates without assistive devices but some limitation
    - Score of III: ambulates with assistive mobility devices
    - Score of IV: Self-mobility is limited, but technology can help.
    - Score of V: Self-mobility is severely limited, even with technology.
  - The Manual Ability Classification System (MACS) can be used to assess upper extremity and fine motor function.

## ***DIFFERENTIAL DIAGNOSIS***

Benign congenital hypotonia, brachial plexus injury, familial spastic paraplegia, dopa-responsive dystonia, transient toe-walking, muscular dystrophy, metabolic disorders (e.g., glutaric aciduria type 1), mitochondrial disorders, genetic disorders (e.g., Rett syndrome)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

CP is a clinical diagnosis based on history, physical, and risk factors. Laboratory testing is not needed to make diagnosis but can help exclude other etiologies.

- Testing for metabolic and genetic syndromes (1)[C]
  - Not routinely obtained in the evaluation for CP.
  - Considered if no specific etiology is identified by neuroimaging or there are atypical features

in clinical presentation.

- Detection of certain brain malformations may warrant genetic or metabolic testing to identify syndromes.
- Screening for coagulopathies: Diagnostic testing for coagulopathies should be considered in children with hemiplegic CP with cerebral infarction identified on neuroimaging (1)[C].

### *Initial Tests (lab, imaging)*

- Neuroimaging is not essential, but it is recommended in children with CP for whom the etiology has not been established (1)[C].
- MRI is preferred to CT if need to determine etiology and timing of a brain insult (1)[C].

P.177

- Abnormalities found in 80-90% of patients: brain malformation, cerebral infarction, intraventricular or other intracranial hemorrhage, periventricular leukomalacia, ventricular enlargement, or other CSF space abnormalities

### *Diagnostic Procedures/Other*

- The Communication Function Classification System has recently been developed as another means of assessing verbal performance.
- International Classification of Functioning, Disability and Health for CP have been newly developed to standardize functional assessments.
- Screening for comorbid conditions: developmental delay/intellectual impairment, vision/hearing impairments, speech and language disorders, feeding/swallowing dysfunction, or seizures
- EEGs should only be obtained if there is a history of suspected seizures.

### *Test Interpretation*

Perinatal brain injury may include the following:

- White matter damage
  - Most common in premature infants
  - Periventricular leukomalacia: gliosis with or without focal necrosis with resulting cysts and scarring; may be multiple lesions of various ages. Necrosis can lead to cysts/scarring.
  - Germinal matrix hemorrhage: may lead to intraventricular hemorrhage
- Gray matter damage: more common in term infants; cortical infarcts, focal neuronal damage, myelination abnormalities

## TREATMENT

Focuses on control of symptoms; treatments reduce spasticity to prevent painful contractures, manage comorbid conditions, and optimize functionality and quality of life.

### GENERAL MEASURES

- Early intervention programs for preterm infants influences motor and cognitive outcomes (2) [A].
- Referral to early intervention for children ages 0 to 3 years is essential.
- Various therapy modalities enhance functioning:
  - Physical therapy to improve posture stability and gait, motor strength and control, and prevent contractures
  - Occupational therapy to increase functional activities of daily living and other fine motor skills
  - Speech therapy for verbal and nonverbal speech and to aid in feeding
- Equipment optimizes participation in activities:
  - Orthotic splinting (ankle-foot orthosis) maintains functional positioning and prevents contractures.
  - Spinal bracing (body jacket) may slow down scoliosis.
  - Augmentative communication with pictures, switches, or computer systems for nonverbal individuals
  - Therapeutic and functional electrical stimulation decreases activity limitation in gait.
  - Use of adaptive equipment such as crutches, walkers, gait trainers, and wheelchairs for mobility and standers for weight bearing

### MEDICATION

#### *First Line*

- Diazepam (3)[A]
  - Short-term treatment for generalized spasticity; insufficient evidence on motor function
  - A  $\gamma$ -aminobutyric acid-A ( $GABA_A$ ) agonist that facilitates CNS inhibition at spinal and supraspinal levels to reduce spasticity

- Adverse effects: ataxia and drowsiness
- Adult dose: 2 to 12 mg/dose PO q6-12h
- Pediatric dose (<12 years and <15 kg): <8.5 kg: 0.5 to 1 mg HS; 8.5 to 15 kg: 1 to 2 mg HS; children 5 to 16 years of age and ≥15 kg: 1.25 mg TID
- Botulinum toxin type A (3)[A]
  - Acts at neuromuscular junction to inhibit the release of acetylcholine to reduce tone
  - Injected directly into muscles of interest for localized spasticity; insufficient evidence on motor function
  - Higher functional benefit when combined with occupational therapy
  - Lasts for 12 to 16 weeks following injection

## *Second Line*

- Baclofen (3)[A]
  - GABA<sub>B</sub> agonist, facilitates presynaptic inhibition of mono- and polysynaptic reflexes
  - Adverse effects: drowsiness and sedation
  - Abrupt withdrawal symptoms: spasticity, hallucinations, seizures, confusion, hyperthermia
  - Adults: Initial dose is 5 mg TID; increase dosage every 3 days to an average maintenance dose of 20 mg TID 80 mg/day maximum
  - Pediatric dose (>2 years): initial 10 to 15 mg/day. Titrate to effective dose (maximum 40 mg/day). <8 years old: 60 mg/day maximum; >8 years old: 60 mg/day maximum
- Intrathecal baclofen (baclofen pump) (4)[A]
  - Continuous intrathecal route allows greater maximal response with smaller dosage to reduce spasticity.
  - May help ambulatory individuals with gait, but no improvement is seen in nonambulatory patients.
  - Adverse effects: infection, catheter malfunction, CSF leakage

## *ADDITIONAL THERAPIES*

- Multidisciplinary care including ophthalmology; neurology; orthopedics; physiatry along with physical, occupational, and speech therapists
- A primary care "medical home" that coordinates medical and community services, provides

support for the patient and the patient's family

## ***SURGERY/OTHER PROCEDURES***

- Dorsal root rhizotomy selectively cuts dorsal rootlets from L1-S2. Best for patients with normal intelligence with spastic diplegia. Decreases spasticity in lower limbs when done in conjunction with physiotherapy but associated with adverse effects. Evidence is lacking as to long-term outcomes.
- Surgical treatment of joint dislocations/subluxation, scoliosis management, tendon lengthening, gastrostomy

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Hyperbaric oxygen is controversial and not recommended in those who do not suffer hypoxic ischemic encephalopathy (5)[A].
- Therapeutic horse riding or hippotherapy improves postural control and balance.
- Aquatherapy improves gross motor function in patients with various motor severities (6)[B].

## **ONGOING CARE**

## ***PROGNOSIS***

Reduced lifespan strongly associated with level of functional impairment and intellectual disability

## Codes

### ICD10

- G80.9 Cerebral palsy, unspecified
- G80.1 Spastic diplegic cerebral palsy
- G80.2 Spastic hemiplegic cerebral palsy

## Clinical Pearls

- Management should focus on maximizing functioning and quality of life using multidisciplinary team approach.

- Regression of motor skills does not occur with CP.

# Cervical Hyperextension Injuries

Shane L. Larson, MD

Derek G. Zickgraf, DO

## BASICS

### DESCRIPTION

- Class of neck injuries typically seen in rapid, forceful extension of the cervical spine (head extends posteriorly)
- Usually from motor vehicle accidents (MVAÑ whiplash), falls, or sports-related injuries (1)
- May involve
  - Injury to vertebral and paravertebral structures: fractures, dislocations, ligamentous tears, and disc disruption/subluxation
  - Spinal cord injury (SCI): traumatic central cord syndrome (CCS) secondary to cord compression or vascular insult, SCI without radiologic abnormality (see ÒSCIWORAÓ)
  - Blunt cerebrovascular injury (BCVI): vertebral artery or carotid artery dissection
  - Soft tissue injury: cervical strain/sprain (i.e., whiplash), cervical stingers (see ÒBrachial PlexopathyÓ)

### EPIDEMIOLOGY

- Predominant age: Trauma and sports injuries are more common in young adults (average age 29.4 years); however, CCS mostly seen in older population (average age is 53 years)
- Predominant sex: male > female (1)

### Incidence

In the United States

- Cervical fractures: 2 to 5/100 blunt trauma patients
- CCS: 3.6/100,000 people/year
- BCVI: estimated 1/1,000 of hospitalized trauma patients; incidence increased with cervical spine or thoracic injury

- Cervical strain: 3 to 4/1,000 people/year
- Whiplash is the most common injury in MVAs and accounts for 28% of all ED visits for MVAs (2).
- Incidence of whiplash is 70 to 328/100,000 with rates peaking in 20- to 24-year-old females (3).
- 5% of trauma patients have spinal fractures and 20% of those have SCI.
- The incidence of traumatic SCI ranges from 2.3 to 83 cases per million population per year (2).

## *ETIOLOGY AND PATHOPHYSIOLOGY*

Blunt trauma due to MVAs, sports injuries, falls, and assaults

## *RISK FACTORS*

- Whiplash, initial injury: no seat belt use, female gender (3)[C]
- Chronic pain and/or disability: litigation, previous neck pain or injury, low education level (4,5) [C]
- Fractures: osteoporosis, conditions predisposing to spinal rigidity, such as ankylosing spondylitis or other spondyloarthropathies
- CCS: Preexisting spinal stenosis is present in >50% of cases, which may be
  - Acquired: prior trauma, spondylosis
  - Congenital: Klippel-Feil syndrome (congenital fusion of any 2 cervical vertebra)

## *GENERAL PREVENTION*

Seat belts, use of proper safety equipment, rule changes, and technique-coaching emphasis in sports activities can potentially prevent or minimize injury.

## *COMMONLY ASSOCIATED CONDITIONS*

Closed head injuries, whiplash-associated disorders (WAD), SCI, soft-tissue trauma

## **DIAGNOSIS**

### **HISTORY**

Usually acute presentation with mechanism of cervical hyperextension (see "Etiology and Pathophysiology") and complaints of neck pain, stiffness, or headaches ± neurologic symptoms

## *PHYSICAL EXAM*

- External signs of trauma on the head and neck such as abrasions, lacerations, or contusions are clues to mechanism and associated injuries.
- Presence, severity, and location of neck tenderness often helps localize involved structure(s):
  - Posterior midline, bony tenderness concerning for fracture
  - Paraspinal or lateral soft tissue tenderness suggests muscular/ligamentous injury.
  - Anterior tenderness concerning for vascular injury
- Carotid bruit suggests carotid dissection.
- Neurologic exam: Paresthesias, weakness suggests SCI or stroke secondary to BCVI:
  - CCS often presents as
    - Distal > proximal symptom distribution, upper extremity > lower extremity
    - Extremity weakness/paralysis predominates.
    - Variable sensory changes below level of lesion (including paresthesias and dysesthesia)
    - Bladder/bowel incontinence may occur.

## *DIFFERENTIAL DIAGNOSIS*

- Acute or chronic disc pathology (including herniation or internal disruption)
- Osteoarthritis
- Cervical radiculopathy
- For CCS
  - Bell criciate palsy
  - Bilateral brachial plexus injuries
  - Carotid or vertebral artery dissection

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Low-risk patients can be cleared clinically (without imaging) using either the Canadian C-spine Rule (CCR) or the National Emergency X-Ray Utilization Study (NEXUS) criteria (6)[B]:

- CCR: Clinically clear a stable, adult patient with no history of cervical spine disease/surgery if all of the following conditions are met:
  - Glasgow Coma Scale (GCS) <sup>3</sup>15
  - Nonintoxicated patients without a distracting injury
  - No dangerous mechanism or extremity paresthesias
  - Age <65 years
  - At least 1 "low-risk factor" (i.e., simple rear-end MVA, ambulation at the accident scene, no midline cervical tenderness, delayed onset of neck pain, or sitting position at the time of exam)
- NEXUS: Clinically clear if all of the following are met:
  - No alteration of mental status or intoxication
  - No focal/neurologic deficits
  - No distracting injury
  - No posterior, midline C-spine tenderness
- Reported sensitivity/specificity: CCR (99.4%/45.1%), NEXUS (90.7%/36.8%)
- In patients with high-risk mechanism or any concerning historical/physical exam elements, imaging should strongly be considered. Choose from the following options based on the suspected injury and level of clinical suspicion:
  - Plain radiographs: recommended by some in patients who cannot be cleared clinically but still are in low-suspicion category: sensitivity for C-spine injury 39%:
    - Dynamic: flexion/extension; only if asymptomatic and no neurologic deficits or mental impairment, poor identification of ligamentous injury, limited diagnostic value (7)[A]
  - CT: axial CT from occiput to T1 with coronal and sagittal reconstructions; has replaced plain radiography as the test of choice for cases with moderate to high clinical suspicion of C-spine injury, given high sensitivity (90-100%)
  - MRI: test of choice in CCS with direct visualization of traumatic cord lesions (edema or hematomyelia), soft tissue compressing cord, and/or stenosis of canal. Detects ligamentous injury and abnormalities of intervertebral discs and soft tissues. MRI is poor with fractures due to false-positive results from nonspecific findings.
  - CT angiography: visualization of cervical and cerebral vascular structures to detect BCVI, with reported sensitivity approaching 100% when a <sup>3</sup>16-slice CT scanner is used. MR angiography is an alternative modality, although accessibility and reported sensitivities of

47-50% limit its use settings.

## *Test Interpretation*

- Vertebral fractures: See "General Measures."
- CCS: currently thought to be due to axonal disruption within the white matter of the lateral column, particularly the corticospinal tracts
- BCVI: intimal disruption, leading to thrombosis and embolization
- Acute cervical strain/sprain: Models based on animal, cadaver, and postmortem studies show myofascial tearing, edema, and inflammation.

## *Geriatric Considerations*

- Degenerative changes of the C-spine may be confused with acute traumatic change, and osteopenia may limit fracture visualization on x-ray. CT more accurately makes this differentiation.
- Degenerative disease and osteopenia increases the risk of upper cervical spine injuries despite low-velocity trauma (3)[B].

## *Pediatric Considerations*

Consider SCI without radiographic abnormality (SCIWORA): high incidence at <9 years and accounts for up to 50% of all pediatric cervical spine injuries. MRI may help detect the injury.

## **TREATMENT**

### **GENERAL MEASURES**

- Whiplash, WAD
  - Limited or no benefit to cervical collar; if needed, use for <72 hours (8)[C]
  - No advantage to engaging early multiprofessional intervention (e.g., pain management and psychology) (9)[C]
  - No evidence of different outcomes with physical therapy versus passive (immobilization, rest) treatment. Advance activity levels as tolerated.
  - Lack of clear effective treatments in current medical literature in absence of fracture (4)[B]

- Fractures

- Stability determined by imaging; decompression, and stabilization are indicated in
  - Incomplete SCIs with spinal canal compromise
  - Clinical deterioration or failure to improve despite conservative management
- Hangman fracture: traumatic spondylolisthesis of C2 with bilateral fractures through C2 pedicles, often with anterior subluxation of C2 over C3; can be unstable:
  - Managed with halo vest immobilization for 12 weeks until flexion/extension films normalize
- Odontoid fractures: treated according to type:
  - I: through apex; usually stable; external immobilization with a cervical collar (less often halo vest) for up to 12 weeks
  - II: most common, at base of dens, usually unstable; nonunion rates of up to 67% with halo immobilization alone, especially with dens displacement >6 mm or age >50 years
  - III: through C2 body, usually stable; immobilization in halo or cervical collar for 12-20 weeks
- Hyperextension teardrop fractures
  - If stable, rigid collar or cervicothoracic brace for 8 to 14 weeks
  - If unstable, halo brace for up to 3 months
- CCS: neck immobilization with cervical collar, physical therapy/occupational therapy (PT/OT)
- Cervical strain: No difference in outcomes with active (PT) versus passive (immobilization, rest) treatment; may use soft cervical collar for 10 days for symptomatic relief, then mobilize and increase activity as tolerated.
- Lack of clear effective treatments in current medical literature in absence of fracture (4)[B]

## **MEDICATION**

- Fractures: pain control as needed with analgesics
- CCS: Within 8 hours of injury, consider methylprednisolone 30 mg/kg IV over 15 minutes, then continuous infusion 5.4 mg/kg/hr IV for 23 hours. Further improvement in motor function recovery may be seen if infusion is continued for 48 hours, especially if initial bolus administration is delayed by 3 to 8 hours after injury (10)[A].
- BCVI: Anticoagulation with IV heparin, followed by warfarin therapy for 3 to 6 months, then long-term antiplatelet therapy is a common practice. However, an antiplatelet agent is used as the sole initial therapy in patients with contraindications to anticoagulation. To date, no

randomized controlled trials compare the efficacy of antiplatelet versus anticoagulant therapy, so evidence-based recommendations are unavailable.

- Cervical strain: muscle relaxants, acetaminophen/NSAIDs ± opiate analgesics are commonly used.

## *ISSUES FOR REFERRAL*

- When cervical spine injury is suspected, the patient should be immobilized and sent to the ED.
- Emergent consultation from a spine surgeon for any concern for unstable fracture or SCI

## *SURGERY/OTHER PROCEDURES*

- Fractures
  - Hangman fracture: surgical fixation for excessive angulation or subluxation, disruption of intervertebral disc space, or failure to obtain alignment with external orthosis
  - Odontoid fractures
    - Type II: Early surgical stabilization is recommended in setting of age >50 years, dens displacement >5 mm, and specific fracture patterns.
    - Type III: Surgical intervention is often reserved for cases of nonunion/malunion after trial of external immobilization.
- CCS: Surgical decompression/fixation is indicated in setting of unstable injury, herniated disc, or when neurologic function deteriorates.
- BCVI: Surgical and/or angiographic intervention may be required if there is evidence of pseudoaneurysm, total occlusion, or transection of the vessel.

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Varies by injury; clinical judgment, imaging findings, concomitant injuries, and need for operative intervention
- Advanced Trauma Life Support protocol with backboard and collar

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

## Patient Monitoring

Patients with known injuries will often be followed with serial imaging under the care of a specialist.

## PATIENT EDUCATION

For patient instruction on prevention: ThinkFirst Foundation: <http://www.thinkfirst.org>

## PROGNOSIS

- Presenting neurologic status is the most important.
- Fractures
  - Hangman fracture: 93-100% fusion rate after 8 to 14 weeks external immobilization
  - Odontoid fracture, fusion rate by type: type I ÷ 100% with external immobilization alone; type II nonunion rates of up to 67% with halo immobilization alone, especially with dens displacement >6 mm or age >50 years; type III, 85% with external immobilization, 100% with surgical fixation
- BCVI: With early diagnosis and initiation of antithrombotic therapy, patients may have fewer neurologic sequelae.
- CCS
  - Spontaneous recovery of motor function in >50% of cases over several weeks, with younger patients more likely to regain function
  - Leg, bowel, and bladder functions return first, followed by upper extremities.
- WAD: Prognostic factors for development of late whiplash syndrome (>6 months of symptoms affecting normal activity) include increased initial pain intensity, pain-related disability, and cold hyperalgesia (8).

## COMPLICATIONS

- Fractures: instability or malunion/nonunion necessitating second operation, reactions, and infection related to orthosis
- BCVI: embolic ischemic events and pseudoaneurysm formation

Spine Injury: Cervical

## Codes

### ICD10

- S13.4XXA Sprain of ligaments of cervical spine, initial encounter
- S13.101A Dislocation of unspecified cervical vertebrae, init encntr
- S14.109A Unsp injury at unsp level of cervical spinal cord, init

## Clinical Pearls

- Follow NEXUS or Canadian Cervical Spine rules on every patient with potential neck injury to determine imaging needs, but they do not supercede clinical judgment!
- Inquire about preexisting cervical spine conditions, especially in the elderly, as they may increase risk of injury or change radiographic interpretation.
- Suspect SCI until exam and imaging suggest otherwise.
- Consider BCVI when neurologic deficits are inconsistent with level of known injury or significant mechanism exists.

# Cervical Malignancy

**Benjamin P. Brown, MD**

**Meaghan Tenney, MD**

## **BASICS**

### *DESCRIPTION*

- Invasive cancer of the uterine cervix
- Commonly involves the vagina, parametria, and pelvic side walls
- Invasion of bladder, rectum, and other pelvic sites in advanced disease

### *EPIDEMIOLOGY*

#### *Incidence*

- In the United States, cervical cancer is the third most common gynecologic malignancy.
- It is the second most common cancer among women in the developing world, with these patients representing >80% of reported cases.
- The disease has a bimodal distribution, with the highest risk among women aged 40 to 59 years and >70 years.

#### *Prevalence*

- In 2015, the American Cancer Society (ACS) estimated there were 12,900 new cases in the United States, with 4,100 deaths from the malignancy.
- African Americans and women in lower socioeconomic groups have the highest cervical cancer death rates.
- Hispanic and Latina women have the highest incidence of the malignancy.

### *ETIOLOGY AND PATHOPHYSIOLOGY*

- Arises from preexisting dysplastic lesions, usually following persistent human papillomavirus (HPV) infection
- May be exophytic or endophytic

- Lymphatic spread
- Local tumor extension involving the bladder, ureters, rectum, and distant metastasis from hematogenous spread (Halstedian growth)
- Epidemiologic and experimental evidence supports HPV strains 16 and 18 as etiologic agents in ÷70% of cervical cancers.
- Association with E6 and E7 oncogenic proteins responsible for malignant cell transformation by inactivation of p53 and Rb tumor suppressor genes
- Slow progression from dysplasia to invasive cancer allows time for screening and treatment of preinvasive disease.

## *Genetics*

Not an inherited disease, except in very rare cases of Peutz-Jeghers syndrome

## ***RISK FACTORS***

- Causative agent in the majority of cases is persistent HPV infection.
- Other risk factors include the following:
  - Lack of regular Pap smears
  - Early coitarche
  - Multiple sexual partners
  - Unprotected sex
  - A history of sexually transmitted diseases (STDs)
  - Low socioeconomic status
  - High parity
  - Cigarette smoking
  - Immunosuppression
  - Diethylstilbestrol (DES) exposure in utero

## ***GENERAL PREVENTION***

- Patient education regarding safer sex
- Smoking cessation
- HPV vaccines

- Gardasil vaccines: quadrivalent and 9-valent options; FDA approved in females and in males (for prevention of genital warts and anal cancer)
  - Cervarix vaccine: bivalent vaccine against oncogenic HPV strains 16 and 18
  - No vaccine yet conclusively shown to prevent cancer
  - Recommended age of vaccination is 11 to 12 years (prior to coitarche), but Gardasil is approved from 9 to 26 years and Cervarix from 10 to 25 years.
- Regular Pap smears and pelvic exams at appropriate intervals. In patients with no history of abnormal Paps, current guidelines from the American College of Obstetricians and Gynecologists (ACOG) are as follows:
    - Cytology alone every 3 years between 21 and 30 years
    - Cytology plus HPV testing every 5 years after 30 years (1)[C]
  - The International Federation of Gynecology and Obstetrics (FIGO) recommends visual inspection with acetic acid (VIA) or Lugol's iodine (VILI) as alternatives to Pap smears in resource-poor settings (2)[C].
  - Despite HPV vaccination, cervical cancer screening will remain the main preventive measure for both vaccinated and nonvaccinated women.

## COMMONLY ASSOCIATED CONDITIONS

- Condyloma acuminata
- Preinvasive/invasive lesions of the vulva and vagina

## DIAGNOSIS

### HISTORY

- May be asymptomatic
- Most common symptom is vaginal bleeding, often postcoital.
- Other gynecologic symptoms include intermenstrual or postmenopausal bleeding and vaginal discharge.
- Other less common symptoms include low back pain with radiation down posterior leg, lower extremity edema, vesicovaginal and rectovaginal fistula, and urinary symptoms.

## PHYSICAL EXAM

Disease is staged clinically, not surgically.

- Thorough pelvic exam is essential:
  - Many patients have a normal exam, especially with microinvasive disease.
  - Lesions may be exophytic, endophytic, polypoid, papillary, ulcerative, or necrotic.
  - May have watery, purulent, or bloody discharge
- Bimanual and rectovaginal examination for uterine size, vaginal wall, rectovaginal septum, parametrial, uterosacral, and pelvic sidewall involvement
- Enlarged supraclavicular or inguinal lymphadenopathy, lower extremity edema, ascites, or decreased breath sounds with lung auscultation may indicate metastases or advanced stage disease.

## *DIFFERENTIAL DIAGNOSIS*

- Marked cervicitis and erosion
- Glandular hyperplasia
- Sexually transmitted infection
- Cervical condyloma, leiomyoma, or polyp
- Metastasis from endometrial carcinoma or gestational trophoblastic neoplasia

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

- Biopsy of gross lesions and colposcopically directed biopsies are the definitive means of diagnosis.
- CBC may show anemia.
- Urinalysis may show hematuria.
- In advanced disease, BUN, creatinine, and liver function tests (LFTs) may be helpful.
- CT scan of the chest, abdomen, and pelvis and/or a positron emission tomography (PET) scan
- Apart from chest x-ray (CXR) and intravenous pyelogram (IVP), imaging does not alter tumor stage.
- MRI may be helpful in evaluating parametrial involvement in patients who are surgical candidates or for radiation treatment planning.

## Follow-Up Tests & Special Consideration

Prompt multidisciplinary plan of care

- Exam under anesthesia may help in determining clinical stage and disease extent and determine if patient is a surgical candidate.
- Endocervical curettage and cervical conization as indicated to determine depth of invasion and presence of lymphovascular involvement
- Cystoscopy to evaluate bladder invasion
- Proctoscopy for invasion into rectum

## Test Interpretation

- Majority of cases (80%) are invasive squamous cell types usually arising from the ectocervix.
- Adenocarcinomas comprise 10-15% of cervical cancer arising from endocervical mucus-producing glandular cells. Often, no exophytic lesion but a bulky barrel-shaped cervix present on exam.
- Other cell types that may be present include rare mixed cell types, neuroendocrine tumors, sarcomas, lymphomas, and melanomas.

## TREATMENT

### GENERAL MEASURES

Improve nutritional state, correct any anemia, and treat any vaginal and/or pelvic infections.

### MEDICATION

- Chemoradiation with cisplatin-containing regimen has superior survival rates over pelvic and extended-field radiation alone (3)[A].
- Neoadjuvant chemotherapy may improve survival for early and locally advanced tumors, but more data are needed (4)[A].
- Adjuvant chemotherapy after chemoradiation may improve progression-free survival in patients who receive primary chemoradiation for stages IIB-IVA tumors. The OUTBACK trial will further investigate these findings (<http://www.clinicaltrials.gov>).

- 
- The addition of bevacizumab to standard combination chemotherapy (cisplatin/topotecan or cisplatin/paclitaxel) for recurrent, persistent, or metastatic disease has been shown to improve overall survival (5)[A].

## *ISSUES FOR REFERRAL*

Multidisciplinary management of patients as needed and in a timely fashion

## *ADDITIONAL THERAPIES*

- Chemoradiation (without surgery) is the first-line therapy for tumors stage IIB and higher (gross lesions with obvious parametrial involvement) and for most bulky stage IB2 tumors (6) [A].
- Combination of external beam pelvic radiation and brachytherapy is usually employed.
- If para-aortic lymph node metastases are suspected, extended-field radiation or lymph node dissection prior to radiation therapy may be performed.

## *SURGERY/OTHER PROCEDURES*

- Surgical management is an option for patients with early-stage tumors.
- Removal of precursor lesions (cervical intraepithelial neoplasia [CIN]) by loop electrosurgical excision procedure (LEEP), cold knife conization, laser ablation, or cryotherapy
- Stage IA1 (lesions with <3-mm invasion from basement membrane) without lymphovascular space invasion: option of conization or simple extrafascial hysterectomy (6)[A]
- Stage IA2 (lesions with >3-mm but <5-mm invasion from basement membrane): option of radical hysterectomy with lymph node dissection or radiation, depending on clinical setting (6) [A]
- Stages IA2-IB1: Fertility-sparing radical trachelectomy may be considered in selected patients (6)[A].
- Stages IB1-IIA (gross lesions without obvious parametrial involvement): option of radical hysterectomy with lymph node sampling or primary chemoradiation with brachytherapy and teletherapy, depending on clinical setting (6)[A]
- Stage IVA (lesions limited to central metastasis to the bladder and/or rectum): Primary pelvic exenteration may be feasible (6)[A].
- Stage IVB disease is treated with goal of palliation. Early referral to palliative care should be made (6)[A],(7)[C].

## *Pregnancy Considerations*

- Management is guided by consideration of stage of lesion, gestational age, and maternal assessment of risks and benefits from treatment.

- Abnormal cytology is best followed up by colposcopy with directed biopsies.
- CIN1 or less: postpartum follow-up
- CIN2-3: management per established guidelines
- Microinvasive carcinoma: conization or trachelectomy. If depth of invasion  $\geq 3$  mm, follow up at the 6-week postpartum visit
- Invasive carcinoma: definitive therapy, with timing determined by maternal preference, stage of disease, and gestational age

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Signs of active bleeding
- Urinary symptoms
- Dehydration
- Complications from surgery, chemotherapy, or radiation
- Active vaginal bleeding can be controlled with timely vaginal packing and radiation therapy.
- Recognition of ureteral blockage, hydronephrosis, urosepsis, and timely intervention

### *Discharge Criteria*

Discharge criteria based on multidisciplinary assessment

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- With completion of definitive therapy and based on individual risk factors, patients are evaluated with physical/pelvic examinations:
  - Every 3 to 6 months for 2 years
  - Every 6 to 12 months until the 5th year
  - Yearly thereafter (8)[C]
- Pap smears may be performed yearly but have a low sensitivity for detecting recurrence (8) [C].

- CT and PET scan are useful in locating metastases when recurrence is suspected (8)[C].
- Signs of recurrence include vaginal bleeding, unexplained weight loss, leg edema, and pelvic or thigh pain.

## ***PATIENT EDUCATION***

Patient education material available through the ACOG at <http://www.acog.org>, the Society of Gynecologic Oncology at <http://www.sgo.org>, the Foundation for Women's Cancer at <http://www.foundationforwomenscancer.org>, the American Cancer Society at <http://www.cancer.org>, and the National Cancer Institute at <http://www.cancer.gov>.

## ***PROGNOSIS***

### **Stage    5-y Survival (%)**

1	76-98
2	66-73
3	40-42
4	9-22

## **COMPLICATIONS**

- Loss of ovarian function from radiotherapy or indication for bilateral oophorectomy
- Hemorrhage
- Pelvic infection
- Genitourinary fistula
- Bladder dysfunction
- Sexual dysfunction
- Ureteral obstruction with renal failure
- Bowel obstruction
- Pulmonary embolism
- Lower extremity lymphedema

## See Also

Abnormal Pap and Cervical Dysplasia

## Codes

### ICD10

- C53.9 Malignant neoplasm of cervix uteri, unspecified
- C53.0 Malignant neoplasm of endocervix
- C53.1 Malignant neoplasm of exocervix

## Clinical Pearls

- Cervical cancer is the third most common gynecologic malignancy in the United States. Improving access to screening is likely to have the greatest impact in reduction of burden of disease.
- Women with cervical cancer may be asymptomatic and have a normal physical exam.
- Surgical management is an option for patients with early-stage tumors.
- Chemoradiation is the first-line therapy for higher stage tumors.

# Cervicitis, Ectropion, and True Erosion

Cecilia M. Kipnis, MD

Gillian R. Wackowski, DO

## BASICS

### DESCRIPTION

- Cervicitis is an acute or chronic cervical inflammation; can be infectious or noninfectious.
- Ectropion is the eversion of the endocervix, exposing the columnar cells to the vaginal environment. This is more common in adolescents and pregnancy and can be confused for cervicitis.
- A true erosion occurs with the loss of overlying cervical epithelium due to trauma (e.g., forceful insertion of vaginal speculum in patient with atrophic mucosa).
- System(s) affected: reproductive

### Geriatric Considerations

- Chronic cervicitis or a true erosion in postmenopausal women may be related to low levels of estrogen.
- Infectious cervicitis should not be overlooked in geriatric patients as many remain sexually active.

### Pregnancy Considerations

All pregnant women should be screened for infectious cervicitis at the first prenatal visit by screening for *chlamydia*, and those with new or multiple sexual partners should also be screened for gonorrhea a (1).

### Pediatric Considerations

Infectious cervicitis in children should lead to an investigation of possible sexual abuse.

## EPIDEMIOLOGY

### Incidence

Cervicitis: most commonly due to infectious etiologies, including, but not limited to the following:

- Chlamydia: 1,401,906 cases were reported to the CDC in 2013, 67% of reported cases occurring among 15- to 24-year-olds (2). Actual incidence is significantly higher.
- Gonorrhea: second most commonly reported notifiable disease after chlamydia in the United States; 333,004 cases reported to the CDC in 2013 (2)
- HSV and *Trichomonas*: these are not routinely reported to CDC but trend data show *Trichomonas* infections are up for a third year in a row (3).
- *Mycoplasma genitalium*: increasingly recognized as a common sexually transmitted pathogen among high-risk, sexually active women (4)
- Ectropion: typically related to higher levels of estrogen; ectropion is common among adolescents, women using combined oral contraceptive pills (OCPs), and pregnant women.
  - Present in 14-37% of outpatients (5)
- True erosion: can be seen in women with cervical trauma

## ETIOLOGY AND PATHOPHYSIOLOGY

- Cervicitis: Often, no specific etiology is identified.
  - Infectious: *Chlamydia trachomatis*, *Neisseria gonorrhoeae* are the most commonly identified pathogens; they affect the columnar epithelium of the endocervix. *Trichomonas vaginalis* and herpes simplex virus (HSV; especially primary infections of HSV-2) affect the squamous epithelium. Mycoplasmas (e.g., *M. genitalium*) are becoming increasingly recognized as causative organism.
  - Noninfectious: physical or chemical irritation (e.g., douching, latex exposure, contraceptive creams, or vaginal foreign bodies such as tampons, cervical caps), radiation therapy, inflammatory diseases, malignancy
- Ectropion
  - Hormonal changes with puberty, oral contraceptive use, or pregnancy
  - Resulting from cervical laceration during childbirth
- True erosion: injury to atrophic epithelium; estrogen-deficient states such as menopause

## RISK FACTORS

- Infectious cervicitis (6)

- Ages 15 to 25 is strongest predictor of risk
- Multiple sexual partners
- New sexual partner
- Unprotected sex or sporadic use of condoms
- History of sexually transmitted infection (STI)
- Exchanging sex for money or drugs
- Black and Hispanic race
- Other reproductive tract infections: bacterial vaginitis, pelvic inflammatory disease (PID)
- Noninfectious cervicitis
  - Foreign objects: pessary, diaphragm, cervical cap, and so forth.
- Ectropion: adolescence, pregnancy, use of OCP
- True erosion: estrogen deficiency, trauma from foreign body

## GENERAL PREVENTION

- STIs (chlamydia, gonorrhea, trichomoniasis)
- Advise use of condoms and safer sexual practices to prevent STIs. Follow USPTF-recommended screening measures (6)[A]:
- Annual screening for *C. trachomatis* infection of all sexually active women <sup>≥</sup>25 years and all older women at increased risk. Screen all pregnant women at the first prenatal visit.
- Annual screening for *N. gonorrhoeae* among sexually active women <sup>≥</sup>25 years and all older women at increased risk (new or multiple partners, from communities with high prevalence). Screen among pregnant women at risk early in pregnancy (4).
- At least annual screening of trichomoniasis among HIV-positive women
- Treat sexual partners of infected women.
- Estrogen deficiency: estrogen replacement therapy

## DIAGNOSIS

### HISTORY

- Can be asymptomatic (4,6) or have increased or abnormal vaginal discharge
- Dyspareunia

- Lower abdominal pain/pelvic pain
- Postcoital or intermenstrual bleeding/spotting (4)

## PHYSICAL EXAM

- Cervicitis: most evident is mucopurulent/purulent discharge from cervix and/or cervical friability (4)
- Other symptoms: erythema, ulceration (HSV), punctate hemorrhage (strawberry cervix appearance in trichomoniasis). Consider coexistence with PID with cervical motion tenderness on bimanual exam (6).
- Ectropion: Cervix appears red due to the color of the columnar epithelium.
- True erosion: vaginal bleeding, sharply defined ulcers of cervix

## DIFFERENTIAL DIAGNOSIS

- Cervical dysplasia
- Cervical neoplasm
- Cervical polyp or fibroid
- Ruptured nabothian cyst
- Postcervical procedure (biopsy, LEEP, IUD insertion/removal, aggressive pap smear)
- Bacterial vaginosis (discharge is noninflammatory)

## DIAGNOSTIC TESTS & INTERPRETATION

- Nucleic acid amplification test (NAAT) is the recommended test by USPTF and CDC for *C. trachomatis*/*N. gonorrhoeae* detection (6)[A].
- Urine specimens are slightly less sensitive than clinical endocervical or self-collected vaginal swabs (4).
- NAAT is also the most sensitive test for *M. genitalium*, although testing for this is not widely available (4).
- Cultures may be used when evaluating a potential *N. gonorrhoeae* treatment failure (7).
- Vaginal wet mount for *T. vaginalis*
  - Culture, antigen assays, and NAAT should be considered when microscopy is unavailable or inconclusive. Sensitivity for microscopy is low (÷50%).
  - Pap smears should not be used to diagnose trichomoniasis.

- If ulcerations are present, culture for HSV.

## Diagnostic Procedures/Other

Colposcopy may be helpful in cases of chronic inflammation, with biopsy of suspicious areas.

## TREATMENT

### MEDICATION

#### First Line

- If infectious cervicitis suspected in high-risk patient, presumptive treatment is appropriate: ceftriaxone 250 mg single dose IM, followed by either azithromycin 1 g single dose or doxycycline 100 mg PO BID × 7 days. Option of ceftriaxone and azithromycin removes patient-compliance factor because they are 1-time doses and can be administered in office.
  - Chlamydia: for nonpregnant women, azithromycin 1 g PO single dose or doxycycline 100 mg BID PO × 7 days; for pregnant women, azithromycin 1 g single dose or erythromycin base 500 mg QID PO × 7 days or erythromycin ethylsuccinate 800 mg QID × 7 days
  - Gonorrhea: Due to increased resistance to antibiotics, the CDC currently recommends ceftriaxone 250 mg single dose IM, followed by either azithromycin 1 g PO single dose or doxycycline 100 mg PO BID × 7 days regardless of the chlamydial coinfection status.
  - Trichomoniasis: metronidazole 2 g PO single dose or 500 mg PO BID × 7 days. A single oral dose of 2 g of tinidazole is also effective (6)[A].
  - *M. genitalium*: azithromycin 1 g PO as a single dose or 500 mg PO once followed by 250 mg PO daily × 4 days
  - Ectropion: none, unless patient is extremely symptomatic with copious discharge. In that case, acid-buffered vaginal jelly can be used to decrease discharge.
  - True erosion: conjugated estrogen cream applied vaginally daily for 1 to 2 weeks, followed by maintenance dosing twice weekly or oral hormone replacement therapy (HRT)
  - Contraindications:
    - Metronidazole: The manufacturer states that metronidazole is contraindicated in the 1st trimester in pregnancy but more recent meta-analyses suggest absence of teratogenicity.
- 
- Doxycycline: do not use during pregnancy or lactation
  - Estrogen: See extended list of contraindications to estrogen use in standard texts.

- Precautions:
  - Metronidazole and tinidazole: Avoid alcohol and breastfeeding during treatment and 12 to 24 hours after completion of treatment with metronidazole and 72 hours after completion of treatment with tinidazole (4)[A].
  - Doxycycline: possible fetal harm if used during pregnancy; staining of the infant's teeth if used during breastfeeding; allergy; photosensitization
  - Erythromycin: nausea or vomiting
  - Estrogens: history of estrogen-dependent neoplasms; history of thromboembolic diseases. See extended list of contraindications to estrogen therapy in standard texts.
- Significant possible interactions:
  - Metronidazole: ethanol
  - Doxycycline: dairy products, iron preparations, warfarin, and oral contraceptives (advise use of alternative contraceptive method)
  - Erythromycin: theophylline (elevated theophylline level)
  - Estrogen: N/A

## Second Line

- Chlamydia
  - Levofloxacin 500 mg PO daily × 7 days
  - Ofloxacin 300 mg PO BID × 7 days (4)[A]
- Gonorrhea: If an injectable cephalosporin is not an option, oral cephalosporin therapy with azithromycin or doxycycline can be considered as 2nd-line therapy:
  - Cefixime: 400 mg PO single dose is an acceptable alternative to ceftriaxone, (however, necessitates that the patient return in 1 week for a test of cure) plus azithromycin 1 g single dose or doxycycline 100 mg PO BID × 7 days (8)[A].
  - In the case of a true penicillin allergy, alternative regimens include the following:
    - Azithromycin: 2 g PO as a single dose; however, due to evidence of increasing resistance to macrolides, use should be limited. Test of cure is recommended
    - CDC no longer recommends fluoroquinolones for treatment of gonorrhea due to emergence of fluoroquinolone-resistant *N. gonorrhoeae* in United States (8)[A].
    - *M. genitalium*: moxifloxacin 400 mg PO daily × 7 to 10 days (7)[C] in patients with

persistent *M. genitalium* despite azithromycin treatment, although studies are limited

- Estrogen deficiency: A number of estrogen vaginal preparations are available commercially.

## *Pregnancy Considerations*

Doxycycline and the quinolones are contraindicated in pregnancy.

## **SURGERY/OTHER PROCEDURES**

- Ectropion: Symptomatic lesions can be treated with silver nitrate, or cryo and electrocautery (5).
- Chronic cervicitis with negative cultures and treatment failure may be treated with cryosurgery, electrocautery, or loop excision.
- Surgical management and cautery is generally considered overly invasive and should only be used in select patients with severe/significant symptoms who do not respond to other treatments. Adverse effects can include continued or increased discharge, recurrence of lesion, and cervical stenosis which may affect fertility.

## **ONGOING CARE**

### **FOLLOW-UP RECOMMENDATIONS**

#### *Patient Monitoring*

- Test of cure for *C. trachomatis* is recommended in pregnant patients to document eradication of infection; perform at least 3 weeks following treatment.
- Reinfection with *Trichomonas*, gonorrhea, and chlamydia is common; repeat screening should be performed routinely for all patients 3 to 4 months following treatment (4)[A].
- Estrogen deficiency: Reexamine in 1 month to confirm healing.

#### **ALERT**

For *C. trachomatis*, the test of cure with nucleic acid amplification tests should not be done <3 weeks after treatment because of false-positive results due to dead organisms. For gonorrhea, however, the test of cure should be done at the infected anatomic site 1 week after treatment. The test of cure ideally should be performed with NAAT or culture.

### **PATIENT EDUCATION**

If the etiology of cervicitis is a confirmed STI, the patient's sex partners within the preceding 60

days must be evaluated for *N. gonorrhoeae* or *C. trachomatis* and treated accordingly. Patient should abstain from sexual intercourse for 7 days after a single-dose regimen or after completion of a 7-day regimen to avoid reinfection.

## PROGNOSIS

- Cervicitis: excellent after bacterial infection is eradicated
- Ectropion: spontaneous regression postpartum and with cessation of use of oral contraceptives
- True erosion: spontaneous healing

## COMPLICATIONS

- Cervicitis due to *C. trachomatis* or *N. gonorrhoeae* carries an 8-10% risk of developing subsequent PID. Adolescents should be screened at least once yearly because they are a high-risk group for reinfection with sexually transmitted organisms.
- *M. genitalium* may be associated with PID.
- Women positive for HIV with cervicitis have an increased risk of viral shedding and transmission to sexual partners.

Codes

## ICD10

- N72 Inflammatory disease of cervix uteri
- N86 Erosion and ectropion of cervix uteri

## Clinical Pearls

- If infectious cervicitis is suspected, treatment of choice is ceftriaxone 250 mg IM plus azithromycin 1 g PO × 1 dose. Do not wait for test results.
- Sexual partner(s) need to be treated.
- Positive results for *N. gonorrhoeae* or chlamydia should be reported to local or state health department.

# Chickenpox (Varicella Zoster)

Kay A. Bauman, MD, MPH

## BASICS

### DESCRIPTION

- Common, highly contagious generalized exanthem characterized by crops of pruritic vesicles on the skin and mucous membranes following exposure to varicella-zoster virus (VZV)
- VZV is spread by respiratory (airborne) droplets and direct contact with vesicles.
- VZV establishes latency in the dorsal root ganglia; reactivation results in zoster (shingles).
- Outbreaks tend to occur late winter through early spring in temperate climates.
- Usual incubation period is 14 to 16 days (range, 10 to 21). Patients are infectious from  $\pm$ 48 hours before appearance of vesicles until the final lesions have crusted. Historically, most people acquired chickenpox during childhood and developed lifelong immunity. Varicella is now part of recommended primary vaccination schedule.
- System(s) affected: nervous, skin/exocrine
- Synonym(s): varicella

### EPIDEMIOLOGY

- Predominant age: peak incidence in preschoolers through 9 years but may occur at any age
- Predominant gender: male = female

### Incidence

- Decreasing incidence since routine vaccination; estimated 3.5 million cases annually prior to vaccine, with an incidence of 8-9% in children age 1 to 9 years
- Reported U.S. varicella cases: 1991, 147,076; 2013, 11,359 cases (1,2)
- Prior to vaccine,  $\pm$ 100 deaths/year were reported in the United States; in 2013, there were 3 reported deaths (2).
- U.S. rates: 1994, prior to vaccine: 135.8/100,000 persons; 2012: 4.3/100,000 persons
- Rates of varicella in the United States dropped after vaccine introduction until mid-2000s when

they plateaued; second dose of vaccine was recommended in 2006, and rates have again declined.

- In developing countries, varicella is still associated with a severe disease burden.
- Susceptible (immunologically naive) individuals exposed to varicella are at risk to develop disease and are also potentially infectious for 21 days.

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

- Skin lesions are histologically identical to herpes simplex virus.
- In fatal cases, intranuclear inclusions are found in vascular endothelium and most organs.
- VZV is a double-stranded DNA virus of the  $\alpha$ -Herpesviridae subfamily.
- Humans are primary disease reservoir.

## ***RISK FACTORS***

- No history of prior varicella infection or immunization
- Immunocompromised patients (especially children with leukemia/lymphoma in remission or receiving high-dose corticosteroids)
- Pregnancy

## ***Geriatric Considerations***

- Infection is more severe in adults than in children.
- Reactivation of latent infection causes zoster (shingles).
- Herpes zoster vaccine, a live attenuated vaccine licensed in 2006, is recommended as a single dose for all persons >60 years regardless of prior clinical history of shingles or chickenpox. It can be administered to persons >60 years who are receiving therapy to induce low-level immunosuppression but should not be given to highly immunocompromised patients. Giving the vaccine prior to starting chemotherapy significantly lowers risk of zoster (<http://www.cdc.gov/vaccines/vpd-vac/shingles/hcp-vaccination.htm>).
- Most common cause of death: primary viral pneumonia

## ***Pediatric Considerations***

- Neonates born to mothers who develop chickenpox from 5 days before to 2 days after delivery are at risk for serious disease and should receive varicellazoster immune globulin (VZIG).
- Newborns are at highest risk for severe disease during the 1st month of life, especially if mother is seronegative.

- Delivery prior to 28 weeks increases risk.
- Varicella bullosa is seen mainly in children <2 years. Lesions appear as bullae instead of vesicles. The clinical course is similar.
- Most common cause of death: septic complications and encephalitis
- Avoid aspirin/acetylsalicylic acid in children because of link to Reye syndrome.

## *Pregnancy Considerations*

- 25% risk of transplacental infection after maternal infection
- Congenital malformations are seen in 2% of patients when the fetus is infected during the 1st or 2nd trimesters, characterized by limb atrophy and scarring of the skin of the extremities and occasional CNS and eye manifestations.
- Morbidity (e.g., pneumonia) is increased in women infected during pregnancy.

## **GENERAL PREVENTION**

- Isolate hospitalized patients.
- When indicated, passive immunization with IM VZIG should be given within 96 hours (but can be as long as up to 10 days) after exposure (3).
  - VZIG is recommended for people exposed to chickenpox or shingles who are immunocompromised, newborns of mothers with onset of chickenpox <5 days before delivery or <2 days after delivery, premature infants (<28 weeks) exposed in neonatal period either whose mothers are not immune, or babies who weigh <1,000 g regardless of maternal immunity (3).
- Active immunization after exposure prevents or reduces the severity of varicella if given within 72 hours postexposure.
- Active immunization: varicella virus vaccine (Varivax): live attenuated vaccine approved by FDA in 1995 for pediatric immunization and recommended by ACIP for immunization of healthy patients >12 months who have not had chickenpox
  - 12 months to 12 years: initial dose 0.5 mL SC at age 12 to 15 months; second dose at age 4 to 6 years. Prelicensure studies showed efficacy rates: 70-90% against any disease and 95% against severe disease 7 to 10 years after vaccination. Other studies showed 100% efficacy at 1 year and 98% at 2 years after vaccination. Single dose is 85-94% effective in preventing severe disease. The two-dose regimen is 96-98% effective. Breakthrough disease generally has <50 lesions, shorter duration, and lower fever incidence (4)[A].
  - <sup>3</sup>13 years: two 0.5 mL SC doses 4 to 8 weeks apart, seroconversion rates 78-82% after one

dose, 99% after two doses. Adult efficacy in lower end of this range

- 2013 U.S. estimate: 91% one or more-dose vaccine coverage for children ages 19 to 35 months (5)
- Vaccine side effects are pain and redness at the vaccine site. 1 in 10 develops fever. 1 in 25 will develop a mild varicella-like rash up to 1 month after vaccination.
- Vaccine contraindications (6)
  - Severe allergic reaction (e.g., anaphylaxis) to a previous dose or vaccine component
  - Severe immunodeficiency (e.g., severely immunocompromised HIV patients, on chemotherapy, congenital immunodeficiency, or long-term immunosuppressive therapy)
  - Pregnancy
- MMRV vaccine, which combines the measles, mumps, and rubella vaccine with varicella, is equally effective. There are rare reports of an increased risk of febrile seizures 5 to 12 days after vaccination in 1/2,300 to 2,600 patients (7)[A].
- May be considered for a subset of HIV-positive children in CDC class I with CD4 >25%
  - Vaccine recipients who develop a rash should avoid contact with immunocompromised people, pregnant women who have never had chickenpox, and their newborns.
  - Children needing catch-up vaccination need at least 3 months between doses 1 and 2.

## DIAGNOSIS

### HISTORY

- Prodromal symptoms: fever, malaise, anorexia, mild headache
- Malaise, muscle aches, arthralgias, and headache are more common in adults.
- Subclinical in ~4% of cases
- Characteristic rash

### PHYSICAL EXAM

- Characteristic rash: crops of vesicles on erythematous bases (Òdewdrops on a rose petalÓ)
- Lesions erupt in successive crops.
- Progress from macule to papule to vesicle, then begin to crust
- Pruritic rash is present in various stages of development.

- Lesions may be present on mucous membranes, both oral and vaginal.

## ***DIFFERENTIAL DIAGNOSIS***

- Herpes simplex: herpes zoster
- Smallpox
- Impetigo
- Coxsackievirus infection
- Scabies
- Dermatitis herpetiformis
- Drug rash
- Rickettsial pox infection

---

P.185

## ***DIAGNOSTIC TESTS & INTERPRETATION***

The diagnosis of chickenpox is based primarily on clinical grounds. Other testing is generally used for complicated cases and epidemiologic studies.

### ***Initial Tests (lab, imaging)***

- Leukocyte count varies.
- Marked leukocytosis suggests secondary infection.
- Multinucleated giant cells on Tzanck smear from vesicle scrapings
- Isolate virus from human tissue culture.

### ***Follow-Up Tests & Special Considerations***

- Serologies can show response to acute infection (IgM) or prior infection (IgG).
- Visualization by electron microscopy, tissue culture (costly), and various methods of acute and convalescent sera collection: latex agglutination (most available), enzyme immunoassay, indirect immunofluorescence antibody, fluorescent antibody to membrane assay, or polymerase chain reaction (PCR) assay, which can detect wild from vaccine viral strains
- Vaccine-modified cases can be more difficult to diagnose; PCR testing of skin lesions (8)[B] is most sensitive and specific for diagnosing varicella, especially in vaccinated persons.

## TREATMENT

Outpatient, except for complicated cases

### GENERAL MEASURES

- Supportive/symptomatic treatment
- Antihistamines and/or oatmeal baths for itch
- Acetaminophen and/or ibuprofen for pain and fever
- Nail clipping in children can help prevent scarring or secondary infection from itching.

### MEDICATION

#### *First Line*

- Supportive: antipyretics for fever; avoid aspirin in children.
- Local and/or systemic antipruritic agents for itching
- VZIG available for passive immunization for
  - Immunocompromised patients, newborn infants whose mothers have signs and symptoms of varicella around the time of delivery, premature infants born at 28 weeks or more whose mothers do not have evidence of immunity to varicella, and premature infants <28 weeks' gestation or who weigh <1,000 g regardless of mothers' evidence of immunity, VZIG should be given within 96 hours after exposure to be most beneficial (9).
- Acyclovir: decreases duration of fever and shortens time of viral shedding; recommended for adolescents, adults, and high-risk patients; most beneficial if initiated early in the disease (24 hours)
  - 2- to 16-year-old patients: 20 mg/kg/dose (max 800 mg/dose) QID for 5 days
  - Adults: 800 mg 5 times daily for 5 days
- Contraindication
  - Hypersensitivity to the drug
- Precautions
  - Renal insufficiency with acyclovir
  - Concurrent administration of probenecid increases half-life; increased effects with zidovudine (e.g., drowsiness, lethargy)

## *Second Line*

- Famciclovir: 500 mg TID for 7 to 10 days (adults)
- Valacyclovir: 1 g TID for 7 to 10 days (adults)

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Usually none is needed in mild cases. If complications occur, intensive supportive care may be required.
- Activity as tolerated. Children may return to school when lesions have completely scabbed.

#### *DIET*

No special diet

### *PATIENT EDUCATION*

- In a healthy child, chickenpox is rarely serious and recovery is complete.
- Native chickenpox typically confers lifelong immunity.
- Second attack is rare, but subclinical infection can occur; happens occasionally after vaccination in children
- Infection becomes latent and may recur years later as herpes zoster in adults (and sometimes in children).
- Fatalities are rare.

### **COMPLICATIONS**

- Although only 2% of cases are reported after 2nd decade, 35% of deaths occur in this age group.
- Secondary bacterial infection: cellulitis, abscess, erysipelas, sepsis, septic arthritis/osteomyelitis, or staphylococcal pyomyositis
- Pneumonia: 20-30% of adults with chickenpox have lung involvement; 1/400 is hospitalized.
- Encephalitis (the most common CNS complication)

Meningitis

- Reye syndrome
- Purpura, thrombocytopenia
- Glomerulonephritis
- Arthritis
- Hepatitis

### See Also

Herpes Zoster

### Codes

#### ICD10

- B01.9 Varicella without complication
- B02.9 Zoster without complications
- P35.8 Other congenital viral diseases

## Clinical Pearls

- Varicella zoster infection is more likely to produce serious illness in adults than in children.
- Introduction of the varicella vaccine has reduced morbidity and mortality. Currently, two doses of vaccine are recommended.
- Herpes zoster vaccine is recommended for persons <sup>≥</sup>60 years of age to prevent shingles.

# Child Abuse

Karen A. Hulbert, MD

## BASICS

### DESCRIPTION

- Types of abuse: neglect (most common and highest mortality), physical abuse, emotional/psychological abuse, sexual abuse
- Neglect includes: physical (e.g., failure to provide necessary food or shelter or lack of appropriate supervision), medical (e.g., failure to provide necessary medical or mental health treatment), educational (e.g., failure to educate a child or attend to special education needs), and emotional (e.g., inattention to a child's emotional needs, failure to provide psychological care, or permitting the child to use alcohol or other drugs)
- System(s) affected: gastrointestinal (GI), endocrine/metabolic, musculoskeletal, nervous, renal, reproductive, skin/exocrine, psychiatric
- Synonym(s): suspected nonaccidental trauma; child maltreatment; child neglect

### EPIDEMIOLOGY

#### Incidence

- The National Incidence Study (NIS) estimates the incidence of neglect in the United States using estimates from child protective services (CPS) statistics and other sources. Most recent *NIS-4* (published 2010) looked at data from 2004 to 2009.
- Using the stringent Öharm standardÓ definition, >1.25 million children experience maltreatment (1 in 58).
- Using the Öendangerment standard,Ó 3 million children experienced maltreatment (1 child in 25) (1).

#### Prevalence

- In 2013, a nationally estimated 3 million referrals were made to CPS. Of those referrals, 677,997 were substantiated (60.9%). The number of child fatalities nationwide was 1,484 (2).
- The most common age of victims of abuse and neglect was <1 year old (2).

- The top three perpetrators (in order of prevalence) were parent, then Other relative, then unmarried partner (2).

## *RISK FACTORS*

- All ages; male = female:
  - Risk of physical abuse increases with age.
  - Risk of fatal abuse is more common in those <2 years.
  - Physical abuse is 2.1 times higher among children with disabilities (2).
- Poverty, drug abuse, lower educational status, parental history of abuse, mentally ill parent/maternal depression, poor support network, and domestic violence:
  - Child abuse is 4.9 times more likely in family with spouse abuse (3).
  - Children in households with unrelated adults, 50 times more likely to die of inflicted injuries (3)
  - Adults who were abused as children are at higher risk of becoming abusers than those not abused.

## *GENERAL PREVENTION*

- Know your patients and document their family situations; have increased suspicion to screen for risk factors at prenatal, postnatal, and pediatric visits.
- Physicians can educate parents on range of normal behaviors to expect in infants and children:
  - Anticipatory guidance on ways to handle crying infants; methods of discipline for toddlers
- Train first responders—teachers, childcare workers—to look for signs of abuse.
- Some studies suggest developing screening tools to identify high-risk families early and offer interventions such as early childhood home visitation programs.

## *COMMONLY ASSOCIATED CONDITIONS*

- Failure to thrive
- Prematurity
- Developmental deficits
- Poor school performance
- Poor social skills

- Low self-esteem, depression

## DIAGNOSIS

- Relatively minor injuries, frenulum tears, or bruising in precruising infants may be the first indications of child physical abuse; these minor, suspicious injuries have been termed "sentinel injuries" (4)[B].
- In a retrospective study of infants who were definitely abused, 27.5% had a sentinel injury (80% had a bruise), and in 41.9% of those cases, the parent reported that a medical provider was aware of the injury (4)[B].
- Documentation
  - The medical record is an important piece of evidence for investigation and litigation (5)[C].
  - Critical elements include the following (5)[C]:
    - Brief statement of child's disclosure or caregiver's explanation, including any alternate explanations offered
    - Time the incident occurred and date/time of disclosure
    - Whether witnesses were present
    - Developmental abilities of child
    - Objective medical findings
- DO NOT use terms such as "rule out," "R/O," and "alleged." They may cause ambiguity; clearly state physician opinion (5)[C].
- Documentation should include disposition of patient and record any report made to CPS (5)[C].

## HISTORY

- History of a sentinel injury should prompt consideration of abuse; it may be the first and only abusive injury; there may be escalating and repeated violence instead of a single event of momentary loss of control (4)[B].
- Use nonjudgmental, open-ended questions (ask: who, what, when, and where; NEVER why).
- Use quotes whenever possible.
- Document past medical and developmental history, child's temperament, and interactions among family members.
- Suggestive of intentional trauma

No explanation or vague explanation (3)[C]

- Important detail of explanation changes dramatically (3)[C].
- Explanation is inconsistent with pattern, age, or severity (3)[C].
- Explanation is inconsistent with child's physical or developmental abilities (3)[C].
- Different witnesses provide markedly different history (3)[C].
- Considerable delay in seeking treatment
- Nonspecific symptoms of abuse:
  - Behavior changes; self-destructive behavior
  - Anxiety and/or depression
  - Sleep disturbances, night terrors
  - School problems

## *PHYSICAL EXAM*

- Explain what the exam will involve and why procedures are needed.
- Examine child in a comfortable setting.
- Allow child to choose who will be in the room.
- Use appropriate positions to examine the anal and genital areas of children.
- General assessment for signs of physical abuse, neglect, and self-injurious behaviors
- Thorough physical exam
  - Skin, head, eyes, ears, nose, and mouth
  - Chest/abdomen
  - Genital (consider exam under sedation) or refer to emergency department (ED)
  - Extremities, with focus on inner arms and legs
  - Growth data
- Maintain high index of suspicion for occult head, chest, and abdominal trauma.
- Physical abuse
  - Skin markings (e.g., lacerations, burns, ecchymoses, linear/shaped contusions, bites)
  - Immersion injuries with clearly distinguished outlines (e.g., from boiling water)
  - Oral trauma (e.g., torn frenulum, loose teeth)

- Ear trauma (e.g., signs of ear pulling)
- Eye trauma (e.g., hyphema, hemorrhage)
- Head/abdominal blunt trauma
- Fractures
- Sexual abuse
  - Unexplained penile, vaginal, hymenal, perianal, or anal injuries/bleeding/discharge
  - Pregnancy or STIs
  - Sperm is a definitive finding of child abuse.
- Neglect
  - Child may be low weight for height, unclean, or unkempt.
  - Rashes
  - Fearful or too trusting
  - Clinging to or avoiding caregiver
  - Flat or balding occiput
  - Abnormal development or growth parameters
- Measurements, photographs, and careful descriptions are critical for accurate diagnosis.
- Collaboration with specialist and child abuse assessment team (3)[C]

## *DIFFERENTIAL DIAGNOSIS*

- Physical trauma
  - Accidental injury; toxic ingestion
  - Bleeding disorders (e.g., classic hemophilia)
  - Metabolic or congenital conditions
  - Conditions with skin manifestations (e.g., Mongolian spots, Henoch-Schönlein purpura, meningococemia, erythema multiforme, hypersensitivity, car seat burns, staphylococcal scalded skin syndrome, chickenpox, impetigo)
  - Cultural practices (e.g., cupping, coining)
- Neglect
  - Endocrinopathies (e.g., diabetes mellitus)

- Constitutional
  - GI (clefts, malabsorption, irritable bowel)
  - Seizure disorder
  - Sudden infant death syndrome (SIDS)
  - Skeletal trauma
    - Obstetrical trauma
    - Nutritional (scurvy, rickets)
    - Infection (congenital syphilis, osteomyelitis)
    - Osteogenesis imperfecta
- 

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- Directed by history and physical exam:
  - Urinalysis (e.g., abdominal/flank/back/genital trauma), urine DNA probe for STIs
  - Complete blood chemistry. Consideration of coagulation studies and platelet count (e.g., rule out bleeding disorder, abdominal trauma) as appropriate.
  - Electrolytes, creatinine, BUN, glucose
  - Liver and pancreatic function tests (e.g., abdominal trauma)
  - Guaiac stool (abdominal trauma)
- In cases of suspected neglect:
  - Stool exam, calorie count, purified protein derivative and anergy panel, sweat test, lead and zinc levels
- In cases of suspected sexual abuse:
  - STI testing: gonorrhea, chlamydia, *Trichomonas*; also consider HIV, herpes simplex virus (HSV), hepatitis panel, syphilis
  - Serum pregnancy test
- Skeletal survey is recommended for:
  - Infants <6 months with bruising, regardless of pattern (given rarity of accidental bruising in

young nonmobile infants)

- Children with bruising attributed to abuse or domestic violence
- Children <12 months with bruising on the cheek, eye area, ear, neck, upper arm, upper leg, hand, foot, torso, buttocks, or genital area (6)[B]
- All children with fractures and children with suspicious injuries <2 years:
  - Skeletal survey: X-rays include two views of each extremity; skull, anteroposterior (AP) and lateral; spine, AP and lateral; chest x-ray; and/or rib (posterior), abdomen, pelvis, hands, and feet.
  - Consider bone scan for acute rib fractures and subtle long bone fractures.
- Intracranial and extracranial injury:
  - CT scan of head
  - Consider MRI of head/neck for better dating of injuries, looking at subtle findings, intercerebral edema, or hemorrhage.
- Intra-abdominal injuries:
  - CT scan of abdomen

## *Follow-Up Tests & Special Considerations*

- Bruising is a common presenting feature:
  - Bruising in babies who are not independently mobile is very uncommon (<1%).
- Patterns suggestive of abuse
  - Bruises seen away from bony prominences
  - Bruises to face, back, abdomen, arms, buttocks, ears, hands
  - Multiple bruises in clusters or uniform shape
  - Patterned injuries (such as bite marks or the imprint of an object like a belt or cord) should be considered inflicted until proven otherwise.
- Red flags (3)[B]
  - History that is inconsistent with the injury
  - No explanation offered for the injury or injury blamed on sibling or another child
  - History that is inconsistent with the child's developmental level

- Sexual abuse
  - Consider photocolposcopy.
  - <72 hours from time of abuse: Collect samples for the forensic laboratory (contact authorities for appropriate protocol).

## *Test Interpretation*

- Spiral fractures in nonambulatory patients (children who are not walking or cruising should not have bruising or fractures from falls)
- Chip or bucket-handle fractures
- Epiphyseal/metaphyseal rib fractures in infants
- Rupture of liver/spleen in abdominal blunt trauma
- Retinal hemorrhages in shaken baby syndrome
- Recent literature notes a greater risk of abuse with skull and femur fractures, unexplained injuries, and a delay in seeking care (7)[C].

## **TREATMENT**

### *GENERAL MEASURES*

Test for STIs before treatment.

### *MEDICATION*

#### *First Line*

Antibiotics as indicated for STIs

#### *Second Line*

Consider antidepressants if needed.

### **ALERT**

Emergency contraception reduces rate of pregnancy after sexual assault:

- Levonorgestrel: single dose of 1.5 mg or two 0.75 mg doses taken together or 12 hours apart. Take as soon as possible; effective up to 72 hours (8)[A]
- Ulipristal (Ella): 30-mg single dose as soon as possible; effective up to 120 hours (8)[A]

## ***ISSUES FOR REFERRAL***

- Consider managing in ED to collect forensic specimens and maintain chain of evidence.
- Mandatory reporting to child protective authorities

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

- Moderate to severe injuries or unstable
- Acute psychological trauma
- If safety of child outside the hospital cannot be guaranteed

### ***Discharge Criteria***

- Child should be sent to another relative or into foster care if the suspected abuser lives with the child.
- Counseling for individual and family
- After initial evaluation, consider referral to sexual assault center.

## **ONGOING CARE**

## ***FOLLOW-UP RECOMMENDATIONS***

As clinically indicated

### ***Patient Monitoring***

- Refer to the state protective services.
- Monitor injury healing over time.
- Follow-up assessment for STIs that may not present acutely (e.g., HPV)

## ***PROGNOSIS***

Without intervention, child abuse is often a chronic and escalating phenomenon.

## **COMPLICATIONS**

Growing evidence that sexual, physical, and emotional abuse in childhood are risk factors for poorer adult mental and physical health.

## ICD10

- T74.12XA Child physical abuse, confirmed, initial encounter
- T74.32XA Child psychological abuse, confirmed, initial encounter
- T74.22XA Child sexual abuse, confirmed, initial encounter

## Clinical Pearls

- When a bruise is present, it should be considered as potentially sentinel for physical abuse if no plausible explanation is given (4)[B].
- High index of suspicion is important for prevention and recognition of abuse.
- Neglect is the most common and lethal form of abuse and should be aggressively reported.
- Detailed exam with documentation is key.
- Mandated reporting is required for suspected child abuse and neglect; the physician does not have to prove abuse before reporting.
- Child Abuse Hotline <https://www.childwelfare.gov/topics/responding/reporting/how/>

# Chlamydia Infection (Sexually Transmitted)

Cassandra Cashman, MD, FAAFP

## BASICS

### DESCRIPTION

- *Chlamydia trachomatis* is an intracellular membrane-bound prokaryotic organism. Chlamydia derives from the Greek word for "cloak."
- Chlamydia is the most common bacterial sexually transmitted infection (STI) in the United States (1)[A].
- Transmitted through vaginal, anal, or oral sex; transmitted vertically during vaginal delivery
- Most cases are asymptomatic, especially in females. Untreated disease can lead to pelvic inflammatory disease (PID), ectopic pregnancy, and infertility.
- System(s) affected: reproductive

### Pregnancy Considerations

Perinatal acquisition may result in neonatal pneumonia and/or conjunctivitis.

### EPIDEMIOLOGY

#### Incidence

- Mandatory reporting started in 1985; there has generally been a steady increase in incidence since
- 1.4 million *reported* cases in 2013. Increasing incidence reflects broader screening, improved testing, and better reporting (as opposed to a large increase in disease burden). 2012 to 2013 is the first time since national reporting began that the rate of reported cases decreased.
- Swedish new variant chlamydia (nvCT) first reported in 2006; often produces false-negative tests; largely confined to Nordic countries.

#### Prevalence

- 446/100,000 people in the United States in 2012
- Populations most affected: young females, ethnic minorities

- Peak incidence: age 18 to 20 years
- Predominant sex: females > males. Females have >2.5 times higher reported incidence and prevalence than males. This likely reflects increased testing in females. Increasing use of urine screening may increase identification in males.
- Infection rates >7 times higher in blacks than whites. Rates are higher in larger urban areas.
- Highest male prevalence in heterosexual adolescents
- Estimated to affect ÷2% of young sexually active individuals in the United States

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

*C. trachomatis* serotypes D-K associated with genital tract infections. Chlamydia is an obligate intracellular organism. Chlamydia has biphasic life cycle. Exists extracellularly as elementary body (EB) that is metabolically inactive and infectious. Once taken up by host cell (typically columnar epithelium of the genital tract), the EB prevents lysosomal phagocytosis and transforms to reticulate body (RB) which requires energy from host cell to synthesize RNA, DNA, and proteins. After taking up host cell residence, EB are released and are capable of infecting neighboring cells or spreading the infection through sexual contact.

## ***RISK FACTORS***

Risk correlates with:

- Number of lifetime sexual partners and number of concurrent sexual partners
- No use of barrier contraception during intercourse
- Younger age (highest in females 15 to 19 years, males 20 to 24 years)
- Black/Hispanic/Native American and Alaskan Native ethnicity

## ***GENERAL PREVENTION***

- Screen populations with prevalence >5% at least annually (1)[A].
- Screening recommended if new or >1 sex partner in past 6 months; attending an adolescent clinic, family-planning clinic, STD or abortion clinic, or attending a jail or other detention center clinic. Screen if rectal pain, discharge or tenesmus, testicular pain; test all individuals with urethral or cervical discharge.
- All sexually active women <sup>≥</sup>25 years of age should be screened at least yearly. Repeat testing in ÷3 months is recommended for those who screen positive because reinfection rate is high regardless of whether the sexual partner is treated (2)[A].
- Consider screening sexually active men <sup>≥</sup>25 years of age particularly in high-risk populations.

- Screen men who have sex with men annually.
- Nucleic acid amplification test (NAAT) is the preferred screening test in all circumstances except child sexual abuse involving boys or rectal/oropharyngeal testing in prepubescent girls. For these situations, culture and susceptibility testing is preferred (3)[A].
- Acceptable to screen women for chlamydia on same day as intrauterine device insertion—treat if positive (no need to remove IUD in this circumstance) (4)[B]

## COMMONLY ASSOCIATED CONDITIONS

- Females
  - PID: ÷10% develop PID within 12 months if untreated.
  - Infertility, ectopic pregnancy
  - Chronic pelvic pain
  - Urethral syndrome (dysuria, frequency, and pyuria in the absence of infection)
  - Arthritis (less common)
  - Spontaneous abortion
- Males
  - Epididymitis and nongonococcal urethritis
  - Reiter syndrome (HLA-B27)
  - Proctitis
- Neonates
  - Inclusion conjunctivitis (occurs in ÷40% of exposed neonates)
  - Otitis media
  - Pneumonia
  - Pharyngitis
- Diseases caused by other chlamydial species
  - Lymphogranuloma venereum (LGV): *C. trachomatis* serotypes L1 to L3
  - Trachoma: *C. trachomatis* serotypes A-C

# DIAGNOSIS

Many patients are asymptomatic.

## *Pregnancy Considerations*

- Test all patients at first prenatal visit.
- Test of cure 3 months after treatment for all pregnant patients
- Repeat test in 3rd trimester (2)[A].

## HISTORY

- Complete sexual history, including number of sex partners (lifetime and past year), prior history of STIs, use of barrier protection, commercial sex work, oral or anal receptive intercourse, and partner fidelity
- In females, the most common symptoms are:
  - Mucopurulent vaginal discharge, dysuria (urethral syndrome), bartholinitis, abdominopelvic pain (endometritis, salpingitis/PID), right upper quadrant pain (Fitz-Hugh-Curtis syndrome)
- In males, the most common symptoms are:
  - Dysuria, urethral discharge (urethritis), scrotal pain (epididymitis), rectal pain or discharge (proctitis), acute arthritis (Reiter syndrome)

## PHYSICAL EXAM

- Men and women: external genitalia (rash, lesions), urethral discharge, inguinal lymphadenopathy, pharyngeal exudate, and perianal lesions
- In addition, for women: cervix (discharge, motion tenderness), bimanual examination for cervical motion tenderness, uterine tenderness, ovarian or adnexal tenderness or mass
- LGV (*C. trachomatis* serovars L1, L2, or L3): Primary lesion is a small papule that may ulcerate at the site of transmission after an incubation period of 3 to 30 days. Unilateral tender lymphadenopathy. With rectal transmission, LGV causes an invasive proctocolitis.

## DIFFERENTIAL DIAGNOSIS

- *Neisseria gonorrhoeae*: urethritis, proctitis, epididymitis, cervicitis, PID, Bartholin abscess
- *Mycoplasma* or *Ureaplasma urealyticum*: urethritis, epididymitis, Reiter disease, PID
- *C. trachomatis* (serotypes L1 to L3): LGV, proctitis
- Trichomoniasis

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- *Test of choice is NAAT: sensitivity >95%; specificity >99%*
- Urine is as sensitive as cervical swab.
- Patient self-collected vaginal swabs is also effective.
- Lab tests may remain positive for 3 weeks after successful treatment.
- Test for concurrent STIs, including gonorrhea, HIV, syphilis; perform cervical cancer (PAP) screening if clinically appropriate.

### *Follow-Up Tests & Special Considerations*

See Patient Monitoring.

P.189

## TREATMENT

### GENERAL MEASURES

- Offer patients concurrent testing for gonorrhea, HIV (after counseling and consent), and possibly syphilis. Also, ensure females are up to date with cervical cancer screening.
- Consider treating gonorrhea empirically.
- All partners (most recent partner and all partners within the past 60 days) should be tested and treated.

### MEDICATION

#### *First Line*

- <http://www.cdc.gov/std/treatment/2010/chlamydial-infections.htm>
- Treatment of chlamydial urethritis, cervicitis (including sexual partners of infected persons)
- Azithromycin 1 g PO single dose *or*
- Doxycycline 100 mg PO BID for 7 days
- First-line PID treatment (outpatient)
  - Ceftriaxone 250 mg IM × 1 PLUS doxycycline 100 mg PO for 14 days with or without

metronidazole 500 mg PO BID for 14 days *or*

- Cefoxitin 2 g IM × 1 with probenecid 1 g PO × 1 *PLUS* doxycycline 100 mg PO for 14 days with or without metronidazole 500 mg PO BID for 14 days
- Azithromycin and ceftriaxone may be given simultaneously in the office to treat both chlamydia and gonorrhea. This reduces nonadherence (2)[A].
- Asymptomatic rectal chlamydia can be treated with doxycycline 100 mg BID for 7 days. Azithromycin 1 g for 1 day is slightly less effective but can also be used, especially if compliance or medication availability is an issue (5,6)[A].

## **ALERT**

Use azithromycin with caution in patients with known QT prolongation, hypokalemia, hypomagnesemia, bradycardia, or who are currently treated with antiarrhythmics.

## *Pregnancy Considerations*

- Tetracyclines (doxycycline) and quinolones (ofloxacin, levofloxacin) are contraindicated in pregnant women.
- Consider the following:
  - Azithromycin 1 g PO *OR*
  - Amoxicillin 500 mg PO TID for 7 days (2)[A] *OR*
  - Erythromycin base 500 mg PO QID for 7 days

## **ALERT**

Tetracyclines and quinolones are contraindicated in young children:

- <45 kg: erythromycin base or ethinyl succinate 500 mg/kg/day PO QID for 14 days
- >45 kg but <8 years: azithromycin 1 g PO for 1 day
- >8 years: adult regimen
- Rule out sexual abuse in children with chlamydial infections.

## *Second Line*

For chlamydial urethritis/cervicitis

- Erythromycin base 500 mg PO QID for 7 days *OR* erythromycin ethylsuccinate 800 mg PO QID for 7 days

Levofloxacin 500 mg PO daily for 7 days or ofloxacin 300 mg PO BID for 7 days

## ***ADDITIONAL THERAPIES***

Patient delivered partner therapy (PDPT) or expedited partner therapy (EPT): Provide medications or prescriptions to take to sexual partners of persons infected with STIs without clinical assessment.

- EPT reduces recurrence more effectively than traditional partner referral.
- <http://www.cdc.gov/std/ept/legal/>

## ***INPATIENT CONSIDERATIONS***

The following patients are recommended for inpatient treatment of PID: pregnancy, lack of response or intolerance to oral medicines, suspicion of poor compliance, severe clinical illness, pelvic abscess, and possible need for surgical intervention

### ***Admission Criteria/Initial Stabilization***

Outpatient treatment, unless moderately or severely ill

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Patient and all partners should abstain from sexual contact until at least 7 days after completing treatment.

### ***Patient Monitoring***

- Test of cure: not routinely recommended, except in pregnancy
- Sexual partners should be treated.

### ***PATIENT EDUCATION***

- Counseling regarding safe sexual practices, use of barrier protection, and abstinence
- Patient and partner should complete antibiotic course.

### ***PROGNOSIS***

Prognosis is good following therapy.

## **COMPLICATIONS**

- Both sexes: Chlamydial infection enhances transmission of and susceptibility to HIV.
- Females: tubal infertility (most common cause of acquired infertility), tubal (ectopic) pregnancy, chronic pelvic pain
  - Annual screening of sexually active women would prevent 61% of chlamydia-related PID.
- Males: transient oligospermia and postepididymitis urethral stricture (rare)

Cervicitis, Ectropion, and True Erosion; Epididymitis; Gonococcal Infections; HIV/AIDS; Pelvic Inflammatory Disease (PID); Syphilis; Urethritis

## Codes

### ICD10

- A56.8 Sexually transmitted chlamydial infection of other sites
- A56.01 Chlamydial cystitis and urethritis
- A56.02 Chlamydial vulvovaginitis

## Clinical Pearls

- *C. trachomatis* is common in young sexually active individuals. Annual screening is recommended in sexually active women 25 years of age and younger.
- To prevent recurrence, treat patients and their partners concurrently.
- Test of cure is recommended for pregnant patients at 3 weeks. Pregnant women diagnosed in the 1st trimester should have a second test of cure 3 months after treatment.

# Chlamydophila Pneumoniae

Fozia Akhtar Ali, MD

Teny Anna Philip, MD

## BASICS

### DESCRIPTION

- Chlamydophila pneumoniae (formerly known as Chlamydia pneumoniae) is an obligate intracellular gram-negative bacterium causing atypical pneumonia or bronchitis in adolescents and young adults (1).
- Associated with a more severe, persistent, latent infection in older adults
- Humans are the only known reservoir.

### EPIDEMIOLOGY

- Responsible for 10-20% of community-acquired pneumonia (CAP) among adults, 2nd to mycoplasma in cases of atypical pneumonia (1)
- Epidemiologic studies suggest 4-year peaks.
- The incubation period is  $\div$ 3 to 4 weeks.
- Most infected persons are asymptomatic.
- Typically presents as mild upper respiratory infection (URI). Bronchitis and pneumonia may follow in 1 to 4 weeks.
- Primary infection more common in ages 7 to 40 years; reinfection pneumonia more common in elderly
- Serologic evidence of previous infection is found in 50% of adults and 75% of elderly.
- Male > female (60-90%); possibly due to smoking

### Incidence

- Outbreaks have occurred among military recruits, university students, and nursing home residents, with incidence highest in elderly.
- The overall incidence is unknown. Each year, an estimated 2 to 5 million cases of pneumonia

(all causes) and 500,000 pneumonia-related hospitalizations occur in the United States (2).

## *Prevalence*

10-20% of CAP cases among adults

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- The elementary body is the infectious form.
  - Rigid cell wall and relative metabolic inactivity allows the organism to survive outside of the host cell for a limited time.
- The elementary body infects the host cell by receptor-mediated endocytosis and becomes a reticulate body (3).
- Reticulate bodies divide intracellularly, forming intracytoplasmic inclusions that divide and release chlamydial antigens. This elicits a host immune response leading to mucus production in the nasal passages, sinuses, bronchial tree, and alveoli, along with nasopharyngeal and airway inflammation and bronchospasm.
- After 48 to 72 hours, the reticulate bodies become elementary bodies and are released by cell lysis.

## *RISK FACTORS*

- Close quarters—classrooms, military barracks, shelters, and nursing homes.
- All ages at risk, but most common in school-age children. In the United States, 50% of adults have evidence of past infection by age 20. Reinfection throughout life appears to be common (2).

## *GENERAL PREVENTION*

- Transmission is by respiratory droplets. Hand washing and avoiding exposure to infected persons are key preventive steps.
- Incidence high among military recruits during basic training; weekly azithromycin prophylaxis reduces case rate.

## *COMMONLY ASSOCIATED CONDITIONS*

- Chronic obstructive pulmonary disease
- Asthma
- HIV infection

- Cystic fibrosis
- Diabetes mellitus

## DIAGNOSIS

### HISTORY

- Illness varies in clinical severity from mild, self-limited URI to fulminant pneumonia.
- Onset is typically gradual.
- Sore throat and hoarseness may precede cough by a week or more, leading to biphasic constellation of symptoms (uncommon in *Legionella*, less common with *Mycoplasma*, *Streptococcus pneumoniae*, and *Haemophilus influenzae*).
- Dry cough
- Low-grade fever (usually early in illness); chills
- Rhinitis
- Headache, malaise, myalgias
- Sinus congestion
- Nausea
- Altered mental status; elderly patients are less likely to exhibit respiratory symptoms with pneumonia and may present with altered mental status or falls.

### PHYSICAL EXAM

- General appearance usually nontoxic
- Fever
- Tachypnea
- Tachycardia
- Crackles or wheezing
- Bronchial breath sounds
- Percussion dullness and egophony less sensitive but more specific for pneumonia
- Pharyngeal erythema without exudate

### DIFFERENTIAL DIAGNOSIS

- Other causes of atypical pneumonia, including *Mycoplasma pneumoniae* and *Legionella pneumophila*
- Other bacterial causes of pneumonia, including *S. pneumoniae*, *H. influenzae*, *Moraxella catarrhalis*, and *Staphylococcus aureus*
- Respiratory viruses: adenovirus, influenza A, influenza B, parainfluenza virus, and respiratory syncytial virus
- Endemic fungal pathogens: coccidioidomycosis, histoplasmosis
- Opportunistic fungal pathogens: *Candida* species, *Aspergillus* species, *Mucor* species, *Cryptococcus neoformans*
- Other: psittacosis, Q fever, TB, tularemia
- Conditions that mimic CAP: acute respiratory disease syndrome, idiopathic pulmonary fibrosis, neoplasm, pulmonary embolus, sarcoidosis, congestive heart failure

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- Microimmunofluorescence (MIF) test is most commonly used (and most practical) initial test.
  - Sensitivity of 50-90% if using paired sera
  - IgM 1:16 or higher
  - IgG 1:512 or higher
  - IgM may not be detectable early in the disease.
- Culture with oropharyngeal swab is the gold standard diagnostic method (not widely available).
  - Specificity 100%; sensitivity 50-70% (4)
  - Specimen should be kept cool and transported in specific media.
  - Most easily cultured using HL or HEP2 cells (5)
- PCR from pharyngeal swab or bronchioalveolar lavage specimen (30-95% sensitivity, >95% specificity) (4); during an outbreak, one study showed PCR was less sensitive (68% vs. 79%) but more specific (93% vs. 86%) than MIF IgM (6).
- White blood count is usually normal.
- Alkaline phosphatase levels may be elevated.
- Blood cultures are recommended if patient is toxic and requires ICU admission; otherwise less helpful.

- Complement fixation for *Chlamydia* is available but cannot distinguish *C. pneumoniae* from *Chlamydophila psittaci*.
- Chest x-ray (CXR) (7)[A] has no characteristic radiograph findings; CXR most commonly shows a single subsegmental infiltrate in the lower lobes.
- Pleural effusion seen in 20-25% of cases. ARDS is rare.
- Histologically, intra-alveolar inflammation with mild interstitial reaction is characteristic of chlamydial pneumonias. Alveolar lining cells contain intracytoplasmic inclusions.

## *Diagnostic Procedures/Other*

Although serology is 95% specific, definitive diagnosis requires a positive culture or PCR testing.

## **TREATMENT**

### *MEDICATION*

Empiric coverage of atypical pathogens in patients with CAP has shown mortality benefit (8)[A].

#### *First Line*

Tetracyclines and macrolides are first choice (2).

- Doxycycline: 100 mg PO BID for 10 to 14 days (may use IV in inpatient setting) *OR*
- Azithromycin: 500 mg on day 1, then 250 mg on days 2 to 5 *OR*
- Clarithromycin: 500 mg q12h for 10 to 14 days *OR*
- Tetracycline: 500 mg PO QID for 10 to 14 days
  - Tetracyclines not for use during pregnancy or in children <8 years
  - Tetracyclines may cause photosensitivity; sunscreen is recommended.

#### *Second Line*

Alternative drugs

- Levofloxacin: 250 to 500 mg/day (PO or IV) or other respiratory fluoroquinolones have good bioavailability and the convenience of once-daily dosing but are recommended for use only when patients have failed treatment with a 1st-line drug, have had recent antibiotics, significant comorbidities, or have allergies to 1st-line medications.

## *Pregnancy Considerations*

Avoid tetracyclines in pregnant women.

## **INPATIENT CONSIDERATIONS**

- Usually outpatient care. Those with severe pneumonia or coexisting illness may require hospitalization.
- Pneumonia severity index can help predict morbidity and need for hospitalization (7).

## *Admission Criteria/Initial Stabilization*

Infection in debilitated or hospitalized patients can be severe; ventilatory support for respiratory failure

## *Discharge Criteria*

Reversal of respiratory distress, tolerating PO medications, otherwise stable medically, and clinically stable for discharge

## **ONGOING CARE**

## **FOLLOW-UP RECOMMENDATIONS**

### *Patient Monitoring*

- Monitor patients weekly until well.
- Follow-up CXR can document resolution.
- Reinfection is possible.

## **PROGNOSIS**

- Pneumonia is more likely to be life-threatening in older adults and patients with other underlying pulmonary disease (e.g., asthma, chronic obstructive pulmonary disease [COPD]) or the immune compromise (e.g., diabetes), with an overall 0.5-29% mortality rate.
- Death usually from secondary infection or underlying comorbidity

## **COMPLICATIONS**

- Reactive airway disease
- Erythema nodosum
- Endocarditis

- Pericarditis or myocarditis
- Meningoencephalitis
- Possible association with atherosclerotic disease: *C. pneumoniae* has been cultured from atherosclerotic plaque in patients with coronary artery disease and stroke. Treatment for *C. pneumoniae* has not been shown to affect cardiovascular mortality.
- *C. pneumoniae* infection is associated with an increased risk for lung cancer (9).
- ARDS is rare.

## Codes

&NA;

### ICD10

J16.0 Chlamydial pneumonia

## Clinical Pearls

&NA;

- Consider *C. pneumoniae* in well-appearing young patients presenting with CAP.
- Culture is the gold standard for diagnosis of *C. pneumoniae*. Serodiagnosis is used for acute infection.
- Tetracyclines or macrolides are initial drugs of choice.

# Cholelithiasis

Hongyi Cui, MD, PhD

## BASICS

### DESCRIPTION

- Cholelithiasis is the presence of cholesterol, pigment, or mixed stones (calculi) within the gallbladder.
- Synonym(s): gallstones

### *Pediatric Considerations*

- Uncommon at <10 years
- Most gallstones in children are pigment stones associated with blood dyscrasias.

### EPIDEMIOLOGY

#### *Incidence*

- Increased in Native Americans and Hispanics
- Increases with age by 1-3% per year; peaks at 7th decade; 2% of the U.S. population develops gallstones annually.

#### *Prevalence*

- Population: 8-10% of the United States; gallstones present in 20% >65 years of age
- Predominant sex: female > male (2 to 3:1)

### ETIOLOGY AND PATHOPHYSIOLOGY

- Gallstone formation is a complex process mediated by genetic, metabolic, immune, and environmental factors. Gallbladder sludge (a mixture of cholesterol crystals, calcium bilirubinate granules, and mucin gel matrix) serves as the nidus for gallstone formation.
- Production of bile supersaturated with cholesterol (cholesterol stones) from excess cholesterol secretion precipitates as microcrystals that aggregate and expand. Stone formation is enhanced by biliary stasis or impaired gallbladder motility.

- Decrease in bile content of either phospholipid (lecithin) or decreased bile salt secretion
- Excess unconjugated bilirubin in patients with hemolytic diseases; passage of excess bile salt into the colon with subsequent absorption of excess unconjugated bilirubin in patients with inflammatory bowel disease (IBD) or after distal ileal resection (black or pigment stones)
- Hydrolysis of conjugated bilirubin or phospholipid by bacteria in patients with biliary tract infection or stricture (brown stones or primary bile duct stones; rare in the Western world and common in Asia)

## ***RISK FACTORS***

- Age (peak in 60s to 70s)
- Female gender, pregnancy, multiparity, obesity, and metabolic syndrome
- Caucasian, Hispanic, or Native American descent
- High-fat diet rich in cholesterol
- Cholestasis or impaired gallbladder motility in association with prolonged fasting, long-term total parenteral nutrition (TPN), and rapid weight loss
- Hereditary (p.D19H variant for the hepatic canalicular cholesterol transporter ABCG5/ABG8)
- Short gut syndrome, terminal ileal resection, inflammatory bowel disease
- Hemolytic disorders (hereditary spherocytosis, sickle cell anemia, etc.), cirrhosis (black/pigment stones)
- Medications (birth control pills, estrogen replacement therapy at high doses, and long-term corticosteroid or cytostatic therapy)
- Viral hepatitis, biliary tract infection and stricture (promotes intraductal formation of pigment stones)

## ***GENERAL PREVENTION***

- Ursodiol (Actigall) taken during rapid weight loss prevents gallstone formation.
- Regular exercise and dietary modification may reduce the incidence of gallstone formation.
- Lipid-lowering drugs (statins) may prevent cholesterol stone formation by reducing bile cholesterol saturation.

## ***COMMONLY ASSOCIATED CONDITIONS***

90% of people with gallbladder carcinoma have gallstones.

# DIAGNOSIS

## HISTORY

- Mostly asymptomatic (80%): 2% become symptomatic each year. Over their lifetime, <math><1/2</math> of patients with gallstones develop symptoms.
- Episodic right upper quadrant or epigastric pain lasting >15 minutes and sometimes radiating to the back (biliary colic), usually postprandially; pain sometimes awakens the patient from sleep; most patients develop recurrent symptoms after the first episode of biliary colic.
- Nausea, vomiting; indigestion or bloating sensation; fatty food intolerance

## PHYSICAL EXAM

- Physical exam is *usually normal* in patients with cholelithiasis in the absence of an acute attack.
- Epigastric and/or right upper quadrant tenderness (Murphy sign) is the traditional physical finding associated with cholecystitis.
- Charcot triad: fever, jaundice, right upper quadrant pain
- Reynold pentad: fever, jaundice, right upper quadrant pain, hemodynamic instability, mental status changes; classically associated with ascending cholangitis
- Flank and periumbilical ecchymoses (Cullen sign and Grey-Turner sign) in patients with acute hemorrhagic pancreatitis
- Courvoisier sign: palpable mass in the right upper quadrant in patient with obstructive jaundice most commonly due to tumors within the biliary tree or pancreas

## DIFFERENTIAL DIAGNOSIS

- Peptic ulcer diseases and gastritis
- Hepatitis
- Pancreatitis
- Cholangitis
- Gallbladder cancer
- Gallbladder polyps
- Acalculous cholecystitis
- Biliary dyskinesia

- Choledocholithiasis

## **DIAGNOSTIC TESTS & INTERPRETATION**

No lab study is specific for cholelithiasis.

### **Initial Tests (lab, imaging)**

- Leukocytosis and elevated C-reactive protein level are associated with acute calculus cholecystitis.
- Ultrasound is the preferred imaging modality. US detects gallstones in 97-98% of patients.
- Thickening of the gallbladder wall ( $\geq 3$  mm), pericholecystic fluid, and direct tenderness when the probe is pushed against the gallbladder (sonographic Murphy sign) are associated with acute cholecystitis.
- CT scan has no advantage over US except in detecting distal common bile duct stones.
- MR cholangiopancreatography (MRCP) is reserved for cases of suspected common bile duct stones. MRCP is recommended as a secondary imaging study if ultrasonography does not clearly demonstrate acute cholecystitis or gallstones (1)[C].
- Endoscopic US is as sensitive as endoscopic retrograde cholangiopancreatography (ERCP) for detection of common bile duct stones in patients with gallstone pancreatitis.
- Hepatobiliary iminodiacetic acid (HIDA) scan is useful in diagnosing acute cholecystitis secondary to cystic duct obstruction. It is also useful in differentiating acalculous cholecystitis from other causes of abdominal pain. False-positive results in fasting state, insufficient resistance of the sphincter of Oddi, and gallbladder agenesis.
- Cholecystokinin (CCK)-HIDA is specifically used to diagnose gallbladder dysmotility (biliary dyskinesia).
- 10-30% of gallstones are radiopaque calcium or pigment-containing gallstones and are more likely to be visible on plain x-ray. A porcelain gallbladder is a calcified gallbladder, visible by x-ray; associated with gallbladder cancer.

### **Test Interpretation**

- Pure cholesterol stones are white or slightly yellow.
- Pigment stones may be black or brown. Black stones contain polymerized calcium bilirubinate, most often secondary to cirrhosis or hemolysis; these almost always form in the gallbladder.
- Brown stones are associated with biliary tract infection, caused by bile stasis, and as such may form either in the bile ducts or gallbladder.

## TREATMENT

### GENERAL MEASURES

- Treat symptomatic cholelithiasis.
- Conservative therapy is preferred during pregnancy. Surgery in the 2nd trimester if necessary.
- Prophylactic cholecystectomy for patients with calcified (porcelain) gallbladder (risk for gallbladder cancer), patients with large stones (>3 cm), patients with sickle cell disease, patients planning an organ transplant, and patients with recurrent pancreatitis due to microlithiasis
- In morbidly obese patients, simultaneous cholecystectomy may be performed in combination with bariatric procedures (2) to reduce subsequent stone-related comorbidities.

### *Geriatric Considerations*

Gallstones are more common in the elderly. Age alone should not alter the therapeutic plan.

### MEDICATION

#### *First Line*

- Analgesics for pain relief
  - NSAIDs are the first-choice treatment for pain control equivalent to opioid therapy (2)[A].
  - Opioids are an option for patients who cannot tolerate or fail to respond to NSAIDs.
- Antibiotics for patients with acute cholecystitis
- Prophylactic antibiotics in low-risk patients do not prevent infections during laparoscopic cholecystectomy (3,4)[A].

---

P.193

### ISSUES FOR REFERRAL

Patients with retained or recurrent bile duct stones following cholecystectomy should be referred for ERCP.

### SURGERY/OTHER PROCEDURES

- Surgery should be considered for patients who have symptomatic cholelithiasis or gallstone-related complications (cholecystitis) or in asymptomatic patients with immune suppression, calcified gallbladder, or family history of gallbladder cancer. Open or laparoscopic

cholecystectomy (LC) has similar mortality and complication rates. LC offers less pain and quicker recovery. In well-selected patients, single-incision LC (SILC) and robotic LC are novel methods for the treatment of symptomatic cholelithiasis. SILC has not been shown to be superior to conventional multiport LC in terms of pain and risk of complications (5)[A]. Natural orifice transluminal endoscopic surgery (NOTES) is investigational. Surgery-related complications include common bile duct injury (0.5%), right hepatic duct/artery injury, retained stones, duct leak, biloma formation, and bile duct stricture.

- Conversion to open procedure is based on clinical judgment. Male gender, previous upper abdominal surgery, thickened gallbladder wall, and acute cholecystitis increase the likelihood of need to convert to an open procedure.
  - In 10-15% of patients with symptomatic cholelithiasis, common bile duct (CBD) stones are detected by intraoperative cholangiogram (IOC). CBD stone(s) can be removed by laparoscopic CBD exploration or postoperative ERCP.
  - IOC helps delineate bile duct anatomy when dissection is difficult. Routine use of IOC is debatable but may be associated with decreased incidence of bile duct injury.
- Early LC (<24 hours after diagnosis of biliary colic) decreases hospital stay and operating time (6)[A].
  - For patients with acute cholecystitis, early LC (<7 days of clinical presentation) seems safe and may shorten the total hospital stay versus delayed LC (>6 weeks after index admission with acute cholecystitis) (7)[A].
  - Percutaneous cholecystostomy (PC) is used in high-risk patients with cholecystitis or gallbladder empyema. Interval cholecystectomy is advisable.
  - Symptomatic patients who are not candidates for surgery or those who have small gallstones (5 mm or smaller) in a functioning gallbladder with a patent cystic duct are candidates for oral dissolution therapy (Actigall). However, the recurrence rate is >50% once the medication is discontinued.
  - Extracorporeal shock wave lithotripsy is a noninvasive therapeutic alternative for symptomatic patients who are not candidates for surgery. It is useful for breaking down large bile duct stones before ERCP. Complications include biliary pancreatitis, hepatic hematoma, incomplete ductal stone clearance and recurrence, and so forth.

## ***INPATIENT CONSIDERATIONS***

For patients with symptomatic cholelithiasis, laparoscopic cholecystectomy is typically an outpatient procedure. For patients with complications (i.e., cholecystitis, cholangitis, pancreatitis), inpatient care is necessary.

## *Admission Criteria/Initial Stabilization*

- Acute phase: NPO, IV fluids, and antibiotics
- Adequate pain control with narcotics and/or NSAIDs

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Follow for signs of symptomatic cholelithiasis
- Patients on oral dissolution agents should be followed with serial liver enzyme, serum cholesterol, and imaging studies.

#### *DIET*

A low-fat diet may be helpful.

### *PATIENT EDUCATION*

- Change in lifestyle (e.g., regular exercise) and dietary modification (low-fat diet and reduction of total caloric intake) reduce gallstone-related hospitalizations.
- Patients with asymptomatic gallstones should be educated about the typical symptoms of biliary colic and gallstone-related complications.

### *PROGNOSIS*

- <1/2 of patients with gallstones become symptomatic.
- Cholecystectomy: mortality <0.5% elective, 3-5% emergency; morbidity <10% elective, 30-40% emergency
- ÷10-15% of the patients will have associated choledocholithiasis.
- After cholecystectomy, stones may recur within the biliary tree.

### **COMPLICATIONS**

- Acute cholecystitis (90-95% secondary to gallstones)
- Gallstone pancreatitis
- Common bile duct stones with obstructive jaundice and acute cholangitis
- Biliary-enteric fistula and gallstone ileus; Bouveret syndrome is a variant of

gallstone ileus where the gallstone lodges in the duodenum or pylorus causing a gastric outlet obstruction.

- Gallbladder cancer
- Mirizzi syndrome (extrinsic bile duct obstruction caused by gallstones lodged in gallbladder or cystic duct)

&NA;

Cholangitis, Acute; Choledocholithiasis

## Codes

&NA;

### ICD10

- K80.20 Calculus of gallbladder w/o cholecystitis w/o obstruction
- K80.21 Calculus of gallbladder w/o cholecystitis with obstruction
- K80.01 Calculus of gallbladder w acute cholecystitis w obstruction

## Clinical Pearls

&NA;

- Most patients with gallstones are asymptomatic.
- Transabdominal ultrasound is the preferred imaging modality for diagnosis of cholelithiasis

(sensitivity, 97%; specificity, 95%).

- Laparoscopic cholecystectomy is the preferred procedure for symptomatic cholelithiasis; lithotripsy and oral dissolution therapy may be considered in rare circumstances.
- Acute acalculous cholecystitis is associated with bile stasis and gallbladder ischemia.
- Prophylactic cholecystectomy is not indicated in patients with asymptomatic gallstones.

# Chronic Cough

Jacqueline L. Olin, MS, PharmD, BCPS, FASHP, FCCP

Brian Hertz, MD

J. Andrew Woods, PharmD, BCPS

## BASICS

### DESCRIPTION

- Chronic cough is defined as a cough that persists for >8 weeks in adults.
- In children, chronic cough is often defined as a cough of >4 weeks in duration.
- Subacute cough describes a cough lasting 3 to 8 weeks.
- Patients present because of fear of the causative illness (e.g., cancer) as well as annoyance, self-consciousness, and hoarseness.
- System(s) affected: gastrointestinal (GI), pulmonary

### EPIDEMIOLOGY

- Predominant age: all age groups
- Predominant sex: male = female, with females more likely to seek out medical attention

### Incidence

Recurrent cough has been reported at 3-40% by various population estimates.

### Prevalence

Chronic cough is one of the most common reasons for primary care visits.

### ETIOLOGY AND PATHOPHYSIOLOGY

Varies with findings and disorders implicated

- Often multiple etiologies, but most are related to bronchial irritation. Most frequent etiologies (account for >90% of cases) in nonsmokers include the following:
  - Upper airway cough syndrome (UACS) (formerly referred to as *postnasal drip syndrome*) and other upper airway abnormalities, including allergic and vasomotor rhinitis syndromes

- Asthma
- Gastroesophageal reflux disease (GERD)
- Other causes:
  - ACE inhibitors
  - Chronic smoking or exposure to smoke or pollutants
  - Aspiration
  - Bronchiectasis
  - Infections (e.g., pertussis, tuberculosis)
  - Nonasthmatic eosinophilic bronchitis (NAEB)
  - Cystic fibrosis
  - Sleep apnea
  - Restrictive lung diseases (e.g., chronic interstitial lung disease)
  - Neoplasms: bronchogenic or laryngeal
  - Psychogenic (habit cough)
- Cough reflex hypersensitivity or cough hypersensitivity syndrome define a syndrome of cough with characteristic trigger symptoms not adequately explained by other medical conditions (1).

## **RISK FACTORS**

Although various conditions may contribute to chronic cough, the main causes include smoking and pulmonary diseases.

## **COMMONLY ASSOCIATED CONDITIONS**

Patients with UACS, asthma, and GERD may present with chronic cough as the only symptom and not the usual symptoms associated with the diagnoses.

## **DIAGNOSIS**

### **HISTORY**

- Patient age, associated signs/symptoms, medical history, medication history (i.e., ACE inhibitors), environmental and occupational exposures, potential for aspiration, and smoking history may make some causes more likely.
- The character of cough or description of sputum quality is rarely helpful in

predicting the underlying cause.

- Cough diaries have not correlated well with objective measures.
- Hemoptysis or signs of systemic illness preclude empiric therapy.

## *PHYSICAL EXAM*

- Signs and symptoms are variable and related to the underlying cause; usually, a nonproductive cough with no other signs or symptoms.
- Possible signs and symptoms of UACS, sinusitis, GERD, congestive heart failure, chronic stressors
- Absence of additional signs/symptoms of a particular condition not necessarily helpful
  - For example, 5% of patients with GERD have no other signs or symptoms and sometimes have poor response to empiric proton pump inhibitor (PPI) trials.

## *DIAGNOSTIC TESTS & INTERPRETATION*

- Evaluation often starts with empiric therapy directed at likely underlying etiology and/or simple testing such as a chest x-ray (CXR).
- Extensive testing only if indicated by the history and physical

### *Pediatric Considerations*

Children with chronic cough not responsive to an inhaled *&bgr*:-agonist and without overt stressors should undergo spirometry (if age-appropriate) and foreign body evaluation (CXR).

### *Initial Tests (lab, imaging)*

- Evaluation will be dictated by findings in the comprehensive history and physical.
- Evaluation of peak flow may be indicated.
- If considering neoplasm, heart failure, or infectious etiologies, CXR or B-type natriuretic peptide (BNP) may be indicated.
- In cases of failure to respond to initial trial of empiric therapy, CXR may also be beneficial.

### *Follow-Up Tests & Special Considerations*

- Examples:
  - If considering chronic obstructive pulmonary disease (COPD), asthma, or restrictive lung disease: spirometry

- If suspicious of cystic fibrosis: sweat chloride testing
- If suspicious of hypereosinophilic syndrome, tuberculosis, or malignancy: sputum for eosinophils and cytology
- If abnormal CXR, suspected neoplasm, or underlying pulmonary disorder, consider a chest CT.
- Consider pulmonary consultation.
- Refer to gastroenterologist for endoscopy.

## *Diagnostic Procedures/Other*

If diagnosis suggested and inadequate response to initial measures, other procedures can be considered:

- Pulmonary function testing
- Purified protein derivative (PPD) skin testing
- Allergen testing
- 24-hour esophageal pH monitor
- Bronchoscopy, if history of hemoptysis or smoking with normal CXR
- Endoscopic or video fluoroscopic swallow evaluation or barium esophagram
- Sinus CT
- Ambulatory cough monitoring and cough challenge with citric acid, capsaicin, or other bronchodilator (at specialized cough clinic)
- Echocardiogram

## *Test Interpretation*

Specific to underlying cause

## **TREATMENT**

- With chronic cough, empiric treatment should be directed at the most common causes as clinically indicated (UACS, asthma, GERD) (2)[C].
- Oral antihistamine/decongestant therapy with a 1st-generation antihistamine or nasal steroid spray can be used as initial empiric treatment (2)[C].
- In patients with cough associated with the common cold, nonsedating antihistamines were not found to be effective in reducing cough (2)[C].

- In stable patients with chronic bronchitis, therapy with ipratropium bromide may reduce chronic cough (3)[C].
- Centrally acting antitussive drugs (dextromethorphan, hydrocodone) may be used for short-term symptomatic relief of coughing in patients with chronic bronchitis but have limited efficacy in cough due to upper respiratory infections (3)[C].
- For cough associated with lung cancer, narcotic cough suppressants are recommended (3)[C].
- The American Academy of Pediatrics does not recommend central cough suppressants for treating any kind of cough (2)[B].
- In children <14 years, when pediatric recommendations are not available, adult recommendations should be used with caution (2)[C].
- Some children with recurrent cough and no evidence of airway obstruction may benefit from an inhaled *β*<sub>2</sub>-agonist (4)[C].
- In infants and children with nonspecific chronic cough, trials of empiric PPI therapy were not effective (5)[C].

## GENERAL MEASURES

- In patients with chronic cough, considerations for potential etiology should include asthma (2)[B] or UACS (2)[C].
- With concomitant complaints of heartburn and regurgitation, GERD should be considered as a potential etiology (2)[C].
- 90% of patients will have resolution of cough after smoking cessation (2)[A].
- When indicated, ACE inhibitor therapy should be switched in patients in whom intolerable cough occurs (3)[A]. It may take several days or weeks for cough to resolve after stopping ACE inhibitor therapy.
- Empirically treat postnasal drip and GERD.
- Consider nonpharmacologic options, such as warm fluids, hard candy, or nasal drops. In infants and children, try clearing secretions with a bulb syringe.
- Attempt maximal therapy for single most likely cause for several weeks, then search for coexistent etiologies.

## MEDICATION

- Treatments (nasal steroids, classic antihistamines, antacids, bronchodilators, inhaled corticosteroids, PPIs, antibiotics) should be directed at the specific cause of cough.

- If history and physical exam suggest GERD, may want to trial H<sub>2</sub> blocker or PPI therapy prior to further diagnostic testing.
- A comparative effectiveness review of 49 studies with common opioid and nonanesthetic antitussives stated there is some efficiency for treating cough in adults, but evidence is limited (6)[C].
- The FDA issued a public health advisory stating that OTC cough and cold medicines, including antitussives, expectorants, nasal decongestants, antihistamines, or combinations, should not be given to children <2 years. Subsequently, manufacturers have changed labeling to state "Do not use" in children <4 years. National estimates have shown a decline in emergency department visits in children <2 years related to adverse events from cough and cold medicine ingestion (7).
- Routine empiric treatment of children with chronic cough with leukotriene receptor antagonists lacks evidence and cannot be recommended (8)[C]. A small pilot study with montelukast in adults demonstrated some symptom relief after 2 weeks of treatment (9)[A].

### *First Line*

- In adults, oral antihistamine/decongestant therapy can be empiric treatment. Multiple formulations are available OTC in combination with other ingredients. Advise patients to review labels carefully or consult pharmacist:
  - Chlorpheniramine 2 mg/phenylephrine 5 mg/acetaminophen 325 mg (Tylenol Allergy Multi-Symptom) 2 caplets or gel caps PO q4h (maximum 12 caplets or gel caps in 24 hours; for patients >12 years)
  - Nasal steroids: fluticasone, budesonide, others, 1 spray BID
- Central cough suppressants for short-term symptomatic relief of nonproductive cough
  - Dextromethorphan 10 to 20 mg PO q4h for patients >12 years; use 5 to 10 mg PO q4h for patients 6 to 12 years
    - Concomitant use of dextromethorphan and agents with serotonergic activity (e.g., SSRIs) should be avoided due to risk of serotonin syndrome.
  - Narcotics: codeine 15 to 30 mg PO q6h; hydrocodone/acetaminophen (Vicodin) 5 mg PO q6h; hydrocodone/chlorpheniramine (Tussionex Pennkinetic) 10 mg (5 mL) PO q12h for patients ≥12 years (no benefit in children; no good efficacy data in adults)

### *Second Line*

- A peripherally acting antitussive agent has been used:

- In patients >10 years, benzonatate (Tessalon Perles) 100 to 200 mg PO TID as needed (maximum 600 mg/day)
- Results from a small randomized placebo-controlled trial ( $n = 27$ ) demonstrated subjective cough score improvement in patients using slow-release morphine sulfate. Patients had failed with other antitussive therapies. Side effects included constipation and drowsiness, and there were no discontinuations due to adverse events (10)[A].
  - Morphine was administered 5 to 10 mg PO BID.
- An analysis of studies evaluating inhaled corticosteroid use in chronic cough for patients without additional indication such as asthma did not show consistent benefits (11)[C].

## *ISSUES FOR REFERRAL*

Patients with chronic cough may benefit from evaluation by pulmonary, gastroenterology, ear-nose-and-throat (ENT), and/or allergy specialists.

## *SURGERY/OTHER PROCEDURES*

Fundoplication may be effective for cough secondary to refractory GERD.

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

Consider stepwise withdrawal of medications after resolution of cough.

### *Patient Monitoring*

Frequent follow-up is necessary to assess the effectiveness of treatment

### *DIET*

Dietary modification: Patients with GERD may benefit by avoiding ethanol, caffeine, nicotine, citrus, tomatoes, chocolate, and fatty foods.

### *PATIENT EDUCATION*

- Reassure patient that most cases of chronic cough are not life-threatening and that the condition can usually be managed effectively.
- Counsel that several weeks to a month may be needed for significant reduction or elimination of cough
- Prepare the patient for the possibility of multiple diagnostic tests and therapeutic regimens

because the treatment is very often empiric.

## PROGNOSIS

- >80% of patients can be effectively diagnosed and treated using a systematic approach.
- Cough from any cause may take weeks to months until resolution, and resolution depends greatly on efficacy of treatment directed at underlying etiology.

## COMPLICATIONS

- Cardiovascular: arrhythmias, syncope
- Stress urinary incontinence
- Abdominal and intercostal muscle strain
- GI: emesis, hemorrhage, herniation
- Neurologic: dizziness, headache, seizures
- Respiratory: pneumothorax, laryngeal, or tracheobronchial trauma
- Skin: petechiae, purpura, disruption of surgical wounds
- Medication side effects
- Other: negative impact on quality of life

## Codes

**&NA;**

## **ICD10**

- R05 Cough
- J44.9 Chronic obstructive pulmonary disease, unspecified
- J41.0 Simple chronic bronchitis

## **Clinical Pearls**

**&NA;**

- Chronic cough is defined as a cough that persists for >8 weeks in adults.
- In patients with chronic cough, most frequent etiologies include a history of smoking, asthma, UACS, and GERD.
- The FDA issued a public health advisory stating that OTC cough and cold medicines should not be given to children <2 years. OTC cough expectorant and suppressant product labels state "do not use" in children <4 years.

# Chronic Fatigue Syndrome

Anthony Valdin, MD, MS, FACP, FAAFP

## BASICS

### DESCRIPTION

- A condition characterized by profound mental and physical exhaustion, with at least 6 months presence of multiple systemic and neuropsychiatric symptoms, and at least four of eight associated conditions are required per CDC definition:
  - Impaired memory
  - Sore throat
  - Tender lymph nodes
  - Persistent muscle or joint pain
  - New headaches
  - Nonrefreshing sleep
  - Postexertional malaise >24 hours
- Must have a new or definite onset (not lifelong)
- Fatigue is not relieved by rest and results in >50% reduction in previous activities (occupational, educational, social, and personal). Other potential medical causes must be ruled out (1).
- Exclusions: See *History*.

### EPIDEMIOLOGY

- Predominant age: 20 to 50 years
- Predominant sex: male < female
- All socioeconomic groups
- Associations between ethnicity and incidence have been reported. Higher rates found in ethnic minorities (Native Americans and African Americans) compared with white populations based on population studies. Service-based studies (tertiary care) have reported higher rates among whites or no association between incidence and ethnicity (2).

## Prevalence

Estimates vary widely and depend on case definition and population studied, but a reasonable estimate using a strict case definition is 100 cases per 100,000 population. Community-based studies have reported prevalence rates of 0.23 and 0.42%.

## ETIOLOGY AND PATHOPHYSIOLOGY

- Unknown and likely multifactorial
  - Possible interaction between genetic predisposition, environmental factors, an initiating stressor, and perpetuating factors
- A recent theory attributes possible neuroendocrine immunologic and biochemical effects in CFS to dysbiosis of the gut microbiome.
- Physiologic or environmental stressor could be precipitant.
- Many patients with chronic fatigue recall significant stressors (e.g., major medical procedure, loss of a loved one, loss of employment) in months before symptoms began.
- Systems hypothesized to contribute to altered physiology include the following:
  - Neuroendocrine (e.g., diminished cortisol response to increased corticotropin concentrations)
  - Immune (e.g., increased C-reactive protein and *&bgr;-2* microglobulin)
  - Neuromuscular (e.g., dysfunction of oxidative metabolism)
  - Autonomic (Orthostatic hypotension is reported in a proportion of chronic fatigue syndrome [CFS] sufferers.)
  - Serotonergic (e.g., hyperserotonergic mechanisms or upregulation of serotonin receptors)

## Genetics

Higher concordance among monozygotic twins compared with dizygotic twins

## RISK FACTORS

Possible predisposing factors include the following: (3)

- Personality characteristics (neuroticism and introversion)
- Lifestyle
  - Childhood inactivity or overactivity

- Inactivity in adulthood after infectious mononucleosis
- Familial predisposition
- Comorbid mood disorders of depression and anxiety
- Long-standing medical conditions in childhood
- Childhood trauma (emotional, physical, sexual abuse) (4)
- Prolonged idiopathic chronic fatigue
- Postinfectious fatigue and CFS have followed: mononucleosis, Ross River virus, *Coxiella burnetii*, herpes zoster, Q fever, and *Giardia lamblia*
- Because of concern for a possible "as yet undiscovered" infectious etiology, CFS patients were excluded from donating blood by the American Red Cross in 2010.

## COMMONLY ASSOCIATED CONDITIONS

Common comorbidities include the following:

- Fibromyalgia (more common in women)
- Irritable bowel syndrome
- Gynecologic conditions (pelvic pain, endometriosis) and GYN surgeries (hysterectomy, oophorectomy) (5)
- Anxiety disorders
- Major depression
- Posttraumatic stress disorder (including physical and/or past sexual abuse)
- Domestic violence
- Attention deficit hyperactivity disorder (ADHD)
- Postural orthostatic tachycardia syndrome (POTS)
- Sleep disorders, including OSA
- Reduced left ventricular size and mass

## DIAGNOSIS

### HISTORY

- Discrete onset

- Profound mental and physical exhaustion
- At least 6 months presence of multiple systemic and neuropsychiatric symptoms
- Significantly interferes with daily activities/work
- At least four of eight associated conditions per CDC definition:
  - Impaired memory, sore throat, tender lymph nodes, persistent muscle or joint pain, new headaches, nonrefreshing sleep, postexertional malaise
- Exclusion criteria
  - <2 years after recovery of substance/alcohol abuse
  - Any past or current dx of anorexia nervosa or bulimia, dementia, schizophrenia, or bipolar disease
  - BMI  $\geq 30$
  - Malignancy
  - Previously diagnosed medical condition, unresolved clinically (e.g., hepatitis B or C)

## *PHYSICAL EXAM*

Complete physical exam to rule out other medical causes for symptoms. Note: Tender adenopathy is one of the defining criteria.

### **ALERT**

Detailed mental status examination (or referral to psychiatrist) to rule out other primary etiologies or comorbidities

## *DIFFERENTIAL DIAGNOSIS*

- Idiopathic chronic fatigue (i.e., fatigue of unknown cause for >6 months without meeting criteria for CFS)
- Psychiatric disorders
  - Major depression
  - Somatization disorder
- Physiologic fatigue (inadequate or disrupted sleep, menopause)
- Pregnancy until 3 months postpartum
- Insomnia: primary (no clear etiology) versus secondary (e.g., due to anxiety, depression, environmental factors, poor sleep hygiene)

- Other known or defined systemic disease
- Endocrine disorder (hypothyroidism, Addison disease, Cushing syndrome, diabetes mellitus)
- Localized infection (e.g., occult abscess)
- Chronic or subacute bacterial disease (e.g., endocarditis)
- Lyme disease
- Fungal disease (e.g., histoplasmosis, coccidioidomycosis)
- Parasitic disease (e.g., amebiasis, giardiasis, helminth infestation)
- HIV or related disease
- Iatrogenic (e.g., medication side effects)
- Toxic agent exposure
- Obesity
- Malignancy
- Autoimmune disease
- Chronic inflammatory disease (sarcoidosis, Wegener granulomatosis)
- Neuromuscular disease (multiple sclerosis, myasthenia gravis)

## ***DIAGNOSTIC TESTS & INTERPRETATION***

No single diagnostic test available and finding an abnormal result is not always the same as discovering the cause of fatigue. Be prepared to renew the search for the cause if the problem is treated and the patient remains fatigued.

### ***Initial Tests (lab, imaging)***

- Standard laboratory tests are recommended to rule out other causes for symptoms:
  - Chemistry panel
  - CBC
  - Urinalysis
  - Thyroid-stimulating hormone (TSH)
  - ESR or C-reactive protein
  - Liver function
  - Screen for drugs of abuse

- Age/gender-appropriate cancer screening
- Additional studies, if clinical findings are suggestive or patient at risk:
  - Antinuclear antibodies and rheumatoid factor (if elevated ESR)
  - Creatine kinase
  - Tuberculin skin test
  - Serum cortisol
  - HIV
  - Venereal Disease Research Laboratory or rapid plasma reagin
  - Lyme serology
  - IgA tissue transglutaminase
- No applicable imaging tests available; however, EEG and/or MRI may be useful if patient has CNS symptoms; polysomnography, if patient is sleepy (4).

### *Follow-Up Tests & Special Considerations*

- Assess for comorbid psychiatric disorders.
- Assess for personality and psychosocial factors and maladaptive coping styles.

P.197

- In patients with sleep disturbance, polysomnography may reveal a treatable comorbid disease.

## **TREATMENT**

Focus on changes in lifestyle and insight, with a goal to avoid complicating treatments (e.g., addicting medications, invasive testing) or interventions that support secondary gain.

## **GENERAL MEASURES**

### **ALERT**

Treatment cornerstones include both cognitive-behavioral therapy (CBT) and graded exercise therapy. Medication is of little value. Two treatments have been shown effective, often used in combination (6)[A]:

- Individual CBT: Challenge fatigue-related cognition; plan social and occupational rehabilitation.
- Graded exercise therapy (GET): Track amount of exercise patient can do without exacerbating symptoms and gradually increase intensity and duration. Both involve a careful balance

between activity and rest (7)[A]. Fear of movement and avoidance of physical activity are common in CFS.

- Patients learn how to gradually increase activity in a way that will not exacerbate their illness. Vigorous exercise can trigger relapse, perhaps related to immune dysregulation.
- Improves functional capacity and diminishes sense of fatigue
- GET is more effective with educational interventions using telephone reminders.
- Duration of illness does not predict treatment outcome; aggressive combined care is indicated for all.

## ***MEDICATION***

- No established pharmacologic treatment recommendations
- Studies have been conducted with antivirals, antidepressants, immunoglobulins, hydrocortisone, and modafinil. None has shown clear benefit.
- Agomelatine, an antidepressant with agonist activity at melatonin receptors, is promising in early studies (8)[C].
- If insomnia is present, use of nonaddicting sleep aids (hydroxyzine, trazodone, doxepin, etc.) may improve outcomes.

## ***ISSUES FOR REFERRAL***

- Psychiatrist to assist in managing comorbid disorders if needed
- Rehabilitative medicine

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Insufficient to recommend any complementary and alternative medicine option for all (9)
- Social support groups have not proven to be effective.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

- Gradual increase in physical exercise with scheduled rest periods
- Avoid extended periods of rest.

### ***Patient Monitoring***

Although no consensus exists, periodic reevaluation is appropriate for support, relief of symptoms, and assessment for other possible causes of symptoms.

## *DIET*

- No diet has been shown to be effective for treatment of CFS.
- Whether weight loss improves symptoms in obese CFS patients has yet to be tested.

## *PATIENT EDUCATION*

- Patient education is an important part of treatment of CFS, such as education on the benefits of cognitive therapies, lifestyle changes, and pharmacologic therapy directed at specific-associated symptoms.
- Chronic Fatigue and Immune Dysfunction Syndrome Association of America:  
<http://solvecfs.org/>
- CDC, Chronic Fatigue Syndrome: <http://www.cdc.gov/cfs/>

## *PROGNOSIS*

- Fluctuating course is common.
- Generally, improvement is slow, with a course of months to years.
- An estimated 5% fully recover.
- Patients with poor social adjustment, a strong belief in an organic etiology, financial secondary gain, or age >50 years are less likely to improve (10).

## **COMPLICATIONS**

- CFS patients may reduce physical activity out of fear that it may worsen symptoms.
- Depression
- Unemployment: Although studies document improvement with treatment, <1/3 of patients in trials return to work.
- The U.S. Social Security Administration lists CFS as a bona fide form of disability.
- Receipt of government payments (secondary gain) has been associated with treatment nonresponse.
- Polypharmacy
- Chronic immune activation or an infection associated with CFS may play a role in an increased risk for non-Hodgkin lymphoma in elderly (>80 years)

## See Also

**&NA;**

Algorithm: Fatigue

## Codes

**&NA;**

### ICD10

R53.82 Chronic fatigue, unspecified

## Clinical Pearls

## **&NA;**

- CFS and depression can be comorbid. However, to differentiate between the two, sore throat, tender lymph nodes, and postexercise fatigue are much more characteristic of CFS.
- No universal pharmacologic agents (e.g., antidepressants, immune modulators) have been shown to be consistently effective.
- ÷70% of patients show improvement with CBT, compared to 55% with GET; in many cases, these two treatments can be undertaken in combination.
- There are many more patients with idiopathic chronic fatigue than true CFS. To diagnose CFS, CDC criteria need to be met; standardized instruments (SF-36, symptom index and Multidimensional Fatigue Inventory [MFI]) have been shown to be of use in the empirical diagnosis of CFS and may be helpful for following patients' progress.

# Chronic Kidney Disease

Urooj Najm, MBBS

Najm Hasan Siddiqui, MD

## BASICS

Chronic kidney disease (CKD) is defined as structural or functional abnormalities of the kidney for  $\geq 3$  months, as determined by either pathologic abnormalities or markers of damage—including abnormalities in blood or urine tests, histology, imaging studies, or history of kidney transplant—*or* a GFR  $< 60$  mL/min/1.73 m<sup>2</sup> for  $\geq 3$  months.

## DESCRIPTION

- In 2012, Kidney Disease Improving Global Outcome (KDIGO) classified CKD in six categories by GFR estimation:
  - G1: kidney damage with normal or increased GFR  $\geq 90$  mL/min/1.73 m<sup>2</sup>
  - G2: mild  $\downarrow$  GFR 60 to 89 mL/min/1.73 m<sup>2</sup>
  - G3a: mild to moderate  $\downarrow$  GFR 45 to 59 mL/min/1.73 m<sup>2</sup>
  - G3b: moderate to severe  $\downarrow$  GFR 30 to 44 mL/min/1.73 m<sup>2</sup>
  - G4: severe  $\downarrow$  GFR 15 to 29 mL/min/1.73 m<sup>2</sup>
  - G5: kidney failure: GFR  $< 15$  mL/min/1.73 m<sup>2</sup> or dialysis
- CKD per albumin-to-creatinine ratio (ACR) category:
  - A1: normal to mildly increased:  $< 30$  mg/g or  $< 3$  mg/mmol
  - A2: moderately increased: 30 to 300 mg/g or 3 to 30 mg/mmol (formerly called microalbuminuria)
  - A3: severely increased:  $> 300$  mg/g or  $> 30$  mg/mmol (formerly called macroalbuminuria)
- System(s) affected: renal/urinary, cardiovascular, skeletal, endocrine, metabolic, hematologic, lymphatic, immune, neurologic
- Synonym(s): chronic renal failure; chronic renal insufficiency

## *Geriatric Considerations*

GFR normally decreases with age, despite normal creatinine (Cr). Adjust renally cleared drugs for GFR in the elderly.

## *Pediatric Considerations*

CKD definition is not applicable for children <2 years because of lower GFR even when corrected for body surface area. Calculated GFR based on serum Cr is used in this age group.

## *Pregnancy Considerations*

- Renal function in CKD may deteriorate during pregnancy. Cr >1.5 and hypertension (HTN) are major risk factors for worsening renal function.
- Increased risk of premature labor, preeclampsia, and/or fetal loss
- ACE inhibitors and angiotensin receptor blockers (ARBs) are contraindicated due to teratogenicity. Use diuretics with caution.

## **EPIDEMIOLOGY**

- Majority of people with CKD in stages 1 to 3
- African Americans are 3.6 times more likely to develop CKD than Caucasians.
- Predominant sex: Similar in both sexes; however, incidence rate of end-stage renal disease (ESRD) is 1.6 times higher in males than females.

## *Incidence*

Estimated annual incidence of 1,700/1 million population

## *Prevalence*

Overall prevalence of CKD is 14.2%. Unadjusted prevalence/incidence rates of ESRD (stage 5) are 1,752 and 362.4/1 million, respectively. Numbers do not reflect the burden of earlier stages of CKD (stages 1 to 4), which are estimated to affect 13.1% of the population nationwide or 26.3 million in the United States.

## **ETIOLOGY AND PATHOPHYSIOLOGY**

Progressive destruction of kidney nephrons; GFR will drop gradually, and plasma Cr values will approximately double, with 50% reduction in GFR and 75% loss of functioning nephrons mass. Hyperkalemia usually develops when GFR falls to <20 to 25 mL/min. Anemia develops from decreased renal synthesis of erythropoietin.

- Renal parenchymal/glomerular

- Nephritic: hematuria, RBC casts, HTN, variable proteinuria
  - Focal proliferative: IgA nephropathy, systemic lupus erythematosus (SLE), Henoch-Schönlein purpura, Alport syndrome, proliferative glomerulonephritis, crescentic glomerulonephritis
  - Diffuse proliferative: membranoproliferative glomerulonephritis, SLE, cryoglobulinemia, rapidly progressive glomerulonephritis (RPGN), Goodpasture syndrome
- Nephrotic: proteinuria (>3.5 g/day), hypoalbuminemia, hyperlipidemia, and edema
  - Minimal change disease, membranous nephropathy, focal segmental glomerulosclerosis
  - Amyloidosis, diabetic nephropathy
- Vascular: HTN, thrombotic microangiopathies, vasculitis (Wegener), scleroderma
- Interstitial-tubular: infections, obstruction, toxins, allergic interstitial nephritis, multiple myeloma, connective tissue disease, cystic disease
- Postrenal: obstruction (benign prostatic hyperplasia), neoplasm, neurogenic bladder

## *Genetics*

- Alport syndrome, Fabry disease, sickle cell anemia, SLE, and autosomal dominant polycystic kidney disease can lead to CKD.
- Polymorphisms in gene that encodes for podocyte nonmuscle myosin IIA are more common in African Americans than Caucasians and appear to increase risk for nondiabetic ESRD.

## *RISK FACTORS*

- Type 1 or 2 diabetes mellitus (DM); most common
- Age >60 years
- Cardiovascular disease (e.g., HTN [common], renal artery stenosis, atheroemboli)
- Previous kidney transplant
- Urinary tract obstruction (e.g., benign prostatic hyperplasia)
- Autoimmune disease, vasculitis/connective tissue disorder
- Family history of CKD
- Nephrotoxic drugs (lithium, salicylate, high-dose or chronic NSAIDs, sulfa)
- Congenital anomalies, obstructive uropathy, renal aplasia/hypoplasia/dysplasia, reflux nephropathy

- Hyperlipidemia
- Low income/education/ethnic minority status
- Obesity/smoking/heroin use
- Chronic infection (hepatitis B, hepatitis C, HIV)

## GENERAL PREVENTION

- Treat reversible causes: hypovolemia, infections, diuretics, drugs (NSAIDs, aminoglycosides, IV contrast).
- Treat risk factors: DM, HTN, hyperlipidemia, smoking, and obesity; adjust medication doses to prevent renal toxicity.

## COMMONLY ASSOCIATED CONDITIONS

HTN, DM, cardiovascular disease

## DIAGNOSIS

### HISTORY

Patients with CKD stages 1 to 3 are usually asymptomatic; can present with

- Oliguria, nocturia, polyuria, hematuria, change in urinary frequency
- Bone disease
- Edema, HTN, dyspnea
- Fatigue, depression, weakness
- Pruritus, ecchymosis
- Metallic taste in mouth, anorexia, nausea, vomiting
- Hyperlipidemia, claudication, restless legs
- Erectile dysfunction, decrease libido, amenorrhea

### PHYSICAL EXAM

- Volume status (pallor, BP/orthostatic; edema; jugular venous distention; weight)
- Skin: sallow complexion, uremic frost
- Ammonia-like odor (uremic fetor)
- Cardiovascular: Assess for murmurs, bruits, pericarditis.

Chest: pleural effusion

- Rectal: enlarged prostate
- CNS: asterixis, confusion, seizures, coma, peripheral neuropathy

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Tests (lab, imaging)

- GFR can be estimated by multiple equations (freely available in medical calculators), including MDRD equation:
  - $GFR (mL/min/1.73 m^2) = 175 \times [(serum Cr \text{ &mgr;mol}/1/88.4)^{-1.154}] \times [age (years)^{-0.203}] \times 0.742$  for females *or* 1.21 for African American
  - Often used as estimate in electronic health records
- Cr clearance (CrCl) can be calculated using Cockcroft-Gault formula
  - $CrCl (male) = ([140 - age] \times weight (kg))/(serum Cr \times 72)$
  - $CrCl (female) = CrCl (male) \times 0.85$
  - Formula used for determining cut points for renally adjusted medications
- Urine analysis
  - Urine microscopy: WBC casts in pyelonephritis, RBC casts in glomerulonephritis/vasculitis, dysmorphic RBCs
  - Urine electrolytes: sodium, Cr, urea (if on loop diuretics)
  - Proteinuria/albuminuria
    - 24-hour urine collection: >30 to 300 mg/24 hr (20 to 200 &mgr;g/min) is microalbuminuria and >300 mg/24 hr (>200 &mgr;g/min) is macroalbuminuria.
    - Albumin/Cr ratio (ACR): See Description.

---

P.199

- Hematology: normochromic, normocytic anemia; increased bleeding time
- Chemistry
  - Elevated BUN, Cr, hyperkalemia, metabolic acidosis
  - Increased parathyroid hormone, decreased 25-(OH) vitamin D, hypocalcemia, hyperphosphatemia

Hyperlipidemia, decreased albumin

## **ALERT**

Drugs that may alter lab result:

- Cimetidine: inhibits Cr tubular secretion
- Trimethoprim: inhibits Cr and K<sup>+</sup> secretion and may cause/worsen hyperkalemia
- Cefoxitin and flucytosine: increases serum Cr
- Diltiazem and verapamil (like ACE/ARBs) have significant antiproteinuric effects in patients with CKD.
- Ultrasound (initial test of choice): Small, echogenic kidneys; may see obstruction (e.g., hydronephrosis); cysts; kidneys may be enlarged with HIV and diabetic nephropathy.
- Doppler ultrasound to assess for renovascular disease, thrombosis
- Noncontrast CT scan: obstruction, calculi, cysts, neoplasm, renal artery stenosis
- MRI/MRA: Avoid gadolinium because of the risk of nephrogenic systemic fibrosis.
- Renal arteriogram for renal artery stenosis can be therapeutic (angioplasty or stenting).
- Renal scan to screen for differential function between kidneys
- Retrograde pyelogram: if strong suspicion for obstruction despite negative finding on ultrasound

## *Follow-Up Tests & Special Considerations*

- Serology: antinuclear antibody (ANA); double-stranded DNA, antineutrophil cytoplasmic antibody; complements (C3, C4, CH50); anti-glomerular basement membrane (GBM) antibodies; hepatitis B, C; and HIV screening
- Serum and urine immunoelectrophoresis

## *Diagnostic Procedures/Other*

Biopsy: hematuria, proteinuria, acute/progressive renal failure, nephritic or nephrotic syndrome

## **TREATMENT**

### *GENERAL MEASURES*

- Lowering salt intake to <2 g/day of sodium in adults, unless contraindicated (1)[C]

- Minimize radiocontrast exposure; prehydrate; *N*-acetylcysteine use is controversial. Avoid nephrotoxins (NSAIDs, aminoglycosides, etc.).
- Renal replacement: Prepare for dialysis or transplant when GFR <30 mL/min/1.73 m<sup>2</sup>.
- Vaccines: pneumococcal, influenza
- Encourage smoking cessation, encourage weight loss (if applicable), and limit alcohol consumption.

## MEDICATION

- HTN: Goal is BP <130/80 mm Hg (in nonhemodialysis patients) and <140/90 mm Hg (in patients on hemodialysis) in the nephrology literature, but more recent analysis based on outcomes suggests a universal BP target of <140/90 mm Hg (2).
- Antihypertensive agents should be selected based on the type of CKD and presence of cardiovascular disease.
- Long-acting (once daily) agents should be prescribed preferentially and given at bedtime.
- ACE inhibitors (drugs of choice) or ARBs for BP control and antiproteinuric effect
  - Potential for hyperkalemia
  - Can tolerate up to 30% rise in serum Cr unless hyperkalemia develops
  - If goal is not reached, add diuretic; thiazides are recommended for GFR <sup>≥</sup>30 mL/min/1.73 m<sup>2</sup>; loop diuretics are recommended for GFR <30 mL/min/1.73 m<sup>2</sup>, followed by diltiazem or verapamil or a *β*-blocker.
- Secondary hyperparathyroidism
  - Cinacalcet, paricalcitol (decrease PTH levels)
- Recommended serum phosphate maintenance levels for CKD patients:

Stage	mg/day	mmol/L
Normal range (may vary by institution)	2.5-4.5	0.81-1.45
Stages 3 and 4 CKD (not on dialysis)	2.7-4.6	0.87-1.49
Stage 5 and ALL stages on dialysis	3.5-5.5	1.13-1.78

- Stages 3 to 5 CKD (not on dialysis): Restrict dietary phosphate to 800 to 1,000 mg/day.
  - Calcium-containing phosphate binders (with meals): calcium carbonate, calcium acetate

(risk of hypercalcemia)

- Noncalcium phosphate binders (with meals): sevelamer, lanthanum
- Vitamin D: inactive vitamin D 25 (ergocalciferol or cholecalciferol), calcitriol (active vitamin D 1,25 [OH]): Vitamin D may increase absorption of phosphate by intestines and should not be started until serum phosphate concentration is controlled.
- Anemia: ferrous sulfate, erythropoietin-stimulating agents (ESAs): Before starting ESAs, nonrenal causes of anemia/iron stores should be checked. Start when Hgb <10 g/dL; goal range 10 to 11 g/dL, not to exceed 11.5 g/dL
- Hyperlipidemia: Statins with low-density lipoprotein (LDL) goal is similar to coronary heart disease patients (LDL <70 to 100).
- Glycemic control: Target HbA1c 7.0%, but it should be individualized based on life expectancy of patient, risk for adverse events related to glucose control, and patient preference (1). Tighter control may slow progression of microalbuminuria but may not reduce progression to ESRD and death in patients with type 2 diabetes. Use of metformin is not advised with serum Cr <sup>3</sup>1.5 mg/dL in males and <sup>3</sup> 1.4 mg/dL in females because of possible risk of lactic acidosis.
- Metabolic acidosis: Start treatment when bicarb <20 mEq/L; goal 23 to 29 mEq/L
  - Sodium bicarbonate: daily dose of 0.5 to 1 mEq/kg/day *or* sodium citrate (should be avoided in patients taking aluminum-containing antacid)

## ***ISSUES FOR REFERRAL***

- Nephrology consult: GFR <15: immediate
- GFR 15 to 29: urgent
- GFR 30 to 59: nonurgent referral
- GFR 60 to 89: not required unless with comorbidities

## ***SURGERY/OTHER PROCEDURES***

Placement of dialysis access or transplantation

## ***INPATIENT CONSIDERATIONS***

### ***Admission Criteria/Initial Stabilization***

Uremia: nausea/vomiting, fluid overload, pericarditis, uremic encephalopathy, resistant HTN, hyperkalemia, metabolic acidosis, hyperphosphatemia

## ONGOING CARE

### DIET

Nutrition consult for CKD diet: Protein restriction in early CKD is controversial but may be beneficial in ESRD; restricted intake of phosphates; sodium and water restriction to avoid volume overload; potassium restriction if hyperkalemic

### PATIENT EDUCATION

National Kidney Federation patient Web site at: <http://www.kidney.org/patients>

### PROGNOSIS

Patients with CKD gradually progress to ESRD, with bad prognoses. 5-year survival rate for U.S. patients on dialysis is ~35%.

### COMPLICATIONS

HTN, anemia, secondary hyperparathyroidism, renal osteodystrophy, sleep disturbances, infections, malnutrition, electrolyte imbalances, platelet dysfunction/bleeding, pseudogout, gout, metabolic calcification, sexual dysfunction

## Codes

&NA;

### ICD10

- N18.9 Chronic kidney disease, unspecified
- Q63.9 Congenital malformation of kidney, unspecified
- N18.3 Chronic kidney disease, stage 3 (moderate)

## Clinical Pearls

&NA;

- Maintaining BP <140/90 mm Hg is imperative (in patients not on dialysis).
- Avoid nephrotoxins including ACE/ARB in acute kidney injury (AKI) with or without CKD.
- CKD is a CHD risk equivalent.

# Chronic Obstructive Pulmonary Disease and Emphysema

Alan Cropp, MD, FCCP

Michael Apostolis, MD

## BASICS

### DESCRIPTION

- Chronic obstructive pulmonary disease (COPD) usually describes a mixture of chronic bronchitis and emphysema. It is characterized by airflow limitation that is not fully reversible, inflammation, and is progressive (1,2).
- Chronic bronchitis is defined clinically by increased mucus production and recurrent cough present on most days for at least 3 months per year during at least two consecutive years without another cause.
- Emphysema, the destruction of interalveolar septa, occurs in the distal or terminal airways and involves both airways and lung parenchyma.

### EPIDEMIOLOGY

#### *Incidence*

Affects more than 5% of adults in the United States and is the 12th leading cause of morbidity (1)

#### *Prevalence*

- Third leading cause of death in the United States (1)
- Projected to be the third leading cause of death globally by 2020 (2)

### ETIOLOGY AND PATHOPHYSIOLOGY

Cigarette and/or cannabis smoking, air pollution (including indoor), antiprotease deficiency (&agr;<sub>1</sub>-antitrypsin), occupational exposure (firefighters), infection (viral), occupational pollutants (cadmium, silica)

- Impaired gas (carbon dioxide and oxygen) exchange

- Chronic bronchitis: airway obstruction (3)
- Emphysema: destruction of lung parenchyma

## *Genetics*

- Chronic bronchitis is not a genetic disorder.
- Antiprotease deficiency (due to  $\alpha_1$ -antitrypsin deficiency) is an inherited, rare disorder due to two autosomal codominant alleles.

## **RISK FACTORS**

- Smoking: passive smoking, especially adults whose parents smoked; cannabis use (one joint is equivalent to 2.5 to 5 cigarettes) (1,2,3)
- Severe pneumonia early in life including viral (4)
- Aging
- Lower level of education and poverty (4)
- Airway hyperactivity
- Indoor pollution (open fire for cooking or heating) (4)
- Occupational organic or inorganic dusts (4)

## **GENERAL PREVENTION**

- Avoidance of smoking is the most important preventive measure.
- Early detection through pulmonary function tests (PFTs) in high-risk patients may be useful in preserving remaining lung function.

## **COMMONLY ASSOCIATED CONDITIONS**

- Pulmonary: lung cancer, chronic respiratory failure, acute bronchitis, sleep apnea, pulmonary hypertension, asthma
- Cardiac: coronary artery disease, arrhythmia
- Ear, nose, and throat (ENT): chronic sinusitis, laryngeal carcinoma
- Miscellaneous: malnutrition, osteoporosis, muscle dysfunction, depression

**DIAGNOSIS**

## **HISTORY**

- Discuss patient's use of tobacco and cannabis.
- Consider indoor pollution (coal furnace) (4).
- Review possible causes of exacerbation (e.g., recent infection) and history of cough, sputum, dyspnea
- Chronic bronchitis: cough, sputum production, frequent infections, intermittent dyspnea, wheeze, hemoptysis, morning headache, pedal edema
- Emphysema: minimal cough, scant sputum, dyspnea, weight loss, occasional infections

## **PHYSICAL EXAM**

- Rarely diagnostic for COPD (2)
- Chronic bronchitis: cyanosis, wheezing, weight gain, diminished breath sounds, distant heart sounds
- Emphysema: barrel chest, minimal wheezing, accessory muscle use, pursed lip breathing, cyanosis slight or absent, breath sounds diminished

## **DIFFERENTIAL DIAGNOSIS**

- Asthma (including occupational)
- Bronchiectasis
- Lung cancer
- Acute bronchitis
- Normal aging of lungs
- Chronic pulmonary embolism
- Sleep apnea
- Primary alveolar hypoventilation
- Chronic sinusitis
- Reactive airways dysfunction syndrome (RADS)
- Congestive heart failure (CHF)
- Bronchiolitis obliterans
- Gastroesophageal reflux disease
- Cystic fibrosis

## DIAGNOSTIC TESTS & INTERPRETATION

Spirometry (the most reliable/objective measurement of airflow obstruction) (1,2,3)[A]

### *Initial Tests (lab, imaging)*

- Spirometry (1,2,3) (see "Diagnostic Procedures")
- Chronic bronchitis
  - Arterial blood gases (ABGs) may show hypercapnia and hypoxia.
  - Hemoglobin may be increased.
- Emphysema
  - Normal serum hemoglobin or polycythemia
  - Normal PaCO<sub>2</sub> on ABGs unless forced expiratory volume in 1 second (FEV<sub>1</sub>) <1 L, in which case it can be elevated
  - Mild hypoxia
- Chronic bronchitis CXR: increased bronchovascular markings and cardiomegaly
- Emphysema CXR: small heart, hyperinflation, flat diaphragms, and possibly bullous changes

### *Follow-Up Tests & Special Considerations*

- Check continuous overnight oximetry in selected patients.
- $\alpha_1$ -Antitrypsin screening for those with COPD age <45 years, have a blood relative with this disease, or spirometry out of proportion to tobacco use
- Chest CT may show diffuse bullous changes or upper lobe predominance. Also, small lung nodules may be identified (5).

### *Diagnostic Procedures/Other*

- PFTs (1,2)[A]
  - Not indicated during acute exacerbation (3)
  - Decreased FEV<sub>1</sub> and resulting reduction in FEV<sub>1</sub>: FVC (forced vital capacity) ratio
  - Poor or absent reversibility to bronchodilator
  - Normal or reduced FVC

- Normal or increased total lung capacity
- Increased residual volume and functional residual capacity
- Diffusing capacity is normal or reduced.
- Staging: Global Initiative for Obstructive Lung Disease (GOLD) criteria (3)
  - Mild COPD: FEV<sub>1</sub> ≥80% predicted
  - Moderate COPD: FEV<sub>1</sub> 50-80% predicted
  - Severe COPD: FEV<sub>1</sub> 30-50% predicted
  - Very severe COPD: FEV<sub>1</sub> <30% predicted or FEV<sub>1</sub> <50% predicted plus chronic respiratory failure

### *Test Interpretation*

- Chronic bronchitis: bronchial mucous gland enlargement, increased number of secretory cells in surface epithelium, thickened small airways from edema and inflammation, smooth muscle hyperplasia, mucus plugging, bacterial colonization of airways
- Emphysema: entire lung affected, bronchi usually clear of secretions, anthracotic pigment, alveoli enlarged with loss of septa, cartilage atrophy, bullae

## **TREATMENT**

### *GENERAL MEASURES*

- Smoking cessation: This is the most important intervention to decrease risk (1,2)[A].
- Aggressive treatment of infections (3)[B]
- Treat any reversible bronchospasm.
- Home oxygen: may improve survival; should be initiated partial pressure of arterial oxygen (PaO<sub>2</sub>) ≤55 mm Hg or pulse oximetry trends ≤88% (1)[A]
- Influenza and pneumococcal immunizations (2)[B]
- Tiotropium (Spiriva) may slow disease progression (6)[B].

### *MEDICATION*

Medications help reduce symptoms and exacerbations (1).

## First Line

- All patients should have a short-acting  $\beta_2$ -agonist (albuterol) to use as a rescue drug (1).
- Anticholinergics (2)[A]
  - Ipratropium (Atrovent), tiotropium (Spiriva), aclidinium bromide (Tudorza) AND/OR
- Long-acting  $\beta_2$ -agonists
  - Salmeterol (Serevent), formoterol (Foradil), one inhalation q12h; or arformoterol (Brovana), formoterol (Perforomist), nebulized q12h (1,2)[A]

### ALERT

Acute exacerbation: Use oxygen, inhaled  $\beta_2$ -agonists, inhaled anticholinergic agents, and oral or IV corticosteroids prednisone (up to 1 mg/kg/day commonly 40 mg/day for 5 days) (7)[A]. Antibiotics should be given for those with moderate/severe exacerbations showing clinical signs of bacterial infection (increased sputum volume, increased sputum purulence); optimal antibiotic therapy has not been determined (3)[B].

## Second Line

- Trial of inhaled corticosteroids for moderate or severe disease (2)[A]
  - May initiate earlier if suggestion of asthmatic component to disease
  - Systemic corticosteroids: Prednisone (Deltasone) can be given orally 7.5 to 15 mg/day in selected patients.

---

- Long-term monotherapy with steroids (oral or inhaled) is not recommended (2,3)[A].
- Inhaled corticosteroids are associated with an increased risk of pneumonia (3).
- Continuous home oxygen: may improve survival; should be initiated for severe resting hypoxemia ( $\text{PaO}_2 \leq 55$  mm Hg or oxygen saturation  $\leq 88\%$ ) or  $\text{PaO}_2$  56 to 59 mm Hg with evidence of hypoxia (i.e., polycythemia or pulmonary hypertension) or pulse oximetry trends  $\leq 88\%$  (1)[A]
- Theophylline if other long-term treatment is unavailable or unaffordable: 400 mg/day; increase by 100 to 200 mg in 1 to 2 weeks, if necessary (4)[B]
  - Reduce dosage in patients with impaired renal or liver function, age >55 years, or CHF
  - Monitor serum level. Therapeutic range is 8 to 13  $\mu\text{g/mL}$ .
  - Low-dose theophylline may help inflammatory component (4)[B].

P.201

- Combination of inhaled corticosteroid, long-acting  $\beta_2$ -agonist, and anticholinergic indicated for severe disease. Several combination medications are now available (2)[A].
- Mucolytic agents may improve secretions but do not improve outcomes.
- Phosphodiesterase-4 inhibitor (PDE4) inhibitor (roflumilast) in severe chronic bronchitis may reduce exacerbations (2)[B].
- $\alpha_1$ -Antitrypsin, if deficient: 60 mg/kg/week to maintain level >80 mg/dL
- Precautions
  - Sympathomimetics: excessive use may be dangerous. May need to reduce dosage or use levalbuterol (Xopenex) in patients with cardiovascular disease, hypertension (HTN), hyperthyroidism, diabetes, or seizures. Anticholinergics: narrow-angle glaucoma, benign prostatic hyperplasia, bladder neck obstruction
  - Corticosteroids: weight gain, diabetes, adrenal suppression, osteoporosis, infection (pneumonia)
- Sympathomimetics may be aerosolized.
- Anticholinergics: Ipratropium (Atrovent) may be aerosolized or combined with albuterol (Combivent Respimat).

## ***ISSUES FOR REFERRAL***

Severe exacerbation, frequent hospitalizations, age <40 years, rapid progression, weight loss, severe disease, or surgical evaluation

## ***ADDITIONAL THERAPIES***

- Adequate hydration and pulmonary hygiene
- Consider postural drainage, flutter valve, or other devices to assist mucus clearance.
- Pulmonary rehabilitation (1,2,3)[A]
- Intermittent, noninvasive ventilation may help in severe chronic respiratory failure.
- Short course of antibiotics (5 to 10 days) for acute exacerbations (2)[B]
- Immunizations
- Supplemental oxygen if indicated

## ***SURGERY/OTHER PROCEDURES***

- Lung reduction surgery (selected cases)

- Lung transplantation (selected cases)

## *INPATIENT CONSIDERATIONS*

### *Admission Criteria/Initial Stabilization*

- Outpatient treatment is usually adequate.
- Exacerbation with acute decompensation (hypoxemia, hypercarbia)
- Serious comorbidities (i.e., decompensated CHF)
- Systemic steroids reduce recovery time and improve hypoxia (2,7)[A]
- Supplemental oxygen and short-acting bronchodilators should be given (3).

### **ALERT**

If not already in place, have patient delineate an advance directive.

- [www.agingwithdignity.org](http://www.agingwithdignity.org), [www.putitinwriting.org](http://www.putitinwriting.org)
- Progressive nature of disease and severity of treatment methods (ventilation, etc.) make revisiting patient preferences beneficial.
- Acute respiratory failure may require ICU and invasive or noninvasive ventilation (NIV) (2)[A].
- Systemic steroids (prednisone 40 mg/day for 5 days or equivalent) have been shown to reduce recovery time and improve hypoxia (7)[A].

### *Nursing*

Teach proper inhaler use.

### *Discharge Criteria*

- Ability to ambulate (3)
- Hypoxia can be treated with home oxygen (may only be temporary) (2)[A].
- Inhaled short-acting  $\beta_2$ -agonist therapy no more frequently than q4h (3)
- Ability to eat and sleep without interruption caused by dyspnea (3)

## **ONGOING CARE**

### *FOLLOW-UP RECOMMENDATIONS*

- May taper or stop oral steroids as outpatient

- If pneumonia caused exacerbation, need to follow CXR or chest CT until clear or stable
- Pulmonary rehabilitation for exertional dyspnea (1)[A]

## *Patient Monitoring*

- Severe or unstable patients should be seen monthly. When stable, see every 6 months.
- Check theophylline level with dose adjustment, then check every 6 to 12 months.
- With use of home oxygen, check ABGs yearly or with change in condition. Frequently monitor saturation (pulse oximetry). Some patients only desaturate at night, thus only need nocturnal oxygen.
- Yearly spirometry
- Travel at high altitude with supplemental oxygen if necessary.
- Baseline chest CT for patients aged 55 to 74 years with a 30 pack/year smoking history to look for lung nodules (5)[B]
- Discuss advance directive and health care proxy.

## *DIET*

A high-protein low-carbohydrate diet may benefit those with hypercarbia.

## *PATIENT EDUCATION*

American Lung Association: [www.lung.org/lung-disease/copd/](http://www.lung.org/lung-disease/copd/)

## *PROGNOSIS*

- Patient's age and postbronchodilator FEV<sub>1</sub> are the most important predictors of prognosis.
- Supplemental O<sub>2</sub>, when indicated, is shown to increase survival (may only need at night) (1) [A].
- Smoking cessation improves prognosis—consider E-cigarettes (2).
- Malnutrition, cor pulmonale, hypercapnia, and pulse >100 indicate a poor prognosis.

## **COMPLICATIONS**

- Malnutrition, poor sleep quality, infections, secondary polycythemia
- Acute or chronic respiratory failure, bullous lung disease, pneumothorax
- Arrhythmias, cor pulmonale, pulmonary HTN

**&NA;**

Bronchitis, Acute

## Codes

**&NA;**

## ICD10

- J44.9 Chronic obstructive pulmonary disease, unspecified
- J43.9 Emphysema, unspecified
- J42 Unspecified chronic bronchitis

## Clinical Pearls

### &NA;

- Consider screening PFTs on any high-risk patient.
- Overnight oximetry if daytime SaO<sub>2</sub> is borderline.
- Influenza/pneumococcal vaccines should be current.
- Advance directive before patient is seriously ill.
- Consider chest CT for patients age 55 to 74 years with a 30 pack/year smoking history for lung cancer screening.

# Chronic Pain Management: An Evidence-Based Approach

Jennifer Reidy, MD, MS, FAAHPM

## BASICS

- Chronic pain is pain persisting beyond the time of normal tissue healing, usually >3 months.
- Over time, neuroplastic changes in the CNS transform pain into a chronic disease itself. Pain levels can exceed observed pathology on exam or imaging.
- Pain experience is inherently related to emotional, psychological, and cognitive factors.
- An epidemic of undertreated pain coexists with an epidemic of prescription drug abuse in the United States.
- Use a system-based practice to safely and effectively prescribe opioids when indicated for chronic nonmalignant pain.

## EPIDEMIOLOGY

### *Incidence*

Incidence is rising, but exact rate is unclear. The annual economic cost of chronic pain in the United States is estimated at \$560 to \$635 billion (1)[B].

### *Prevalence*

In the United States, an estimated 100 million adults live with chronic pain—more than the total affected by heart disease, cancer, and diabetes combined (1)[B].

Chronic pain accounts for 20% of outpatient visits and 12% of all prescriptions (2)[B].

## ETIOLOGY AND PATHOPHYSIOLOGY

- With intense, repeated, or prolonged stimulation of damaged or inflamed tissues, the threshold for activating primary afferent pain fibers is lowered, the frequency of firing is higher, and there is increased response to noxious and/or normal stimuli (peripheral and central sensitization). The amygdala, prefrontal cortex, and cortex are thought to relay emotions and thoughts that create the pain experience, and these areas may undergo structural and functional changes with chronic pain.

- Many patients have an identifiable etiology (most commonly musculoskeletal problems or headache), but pain levels can be worse than observable tissue injury. A significant percentage of patients have no obvious cause of chronic pain.

## *Genetics*

Current research suggests genetic polymorphism in opioid receptors, which may affect patient's response and/or side effects to individual opioids.

## **RISK FACTORS**

- Traumatic: motor vehicle accidents, repetitive motion injuries, sports injuries, work-related injuries, and falls
- Postsurgical: any surgery but especially back surgeries, amputations, and thoracotomies
- Medical conditions: See "Commonly Associated Conditions" later.
- Psychiatric comorbidities: substance abuse, depression, posttraumatic stress disorder (PTSD), personality disorders
- Aging: increased incidence with age but should not be considered a "normal" part of aging

## **GENERAL PREVENTION**

- Avoidance of work-related injuries through the use of ergonomically correct workplace design
- Exercise and physical therapy to help prevent work-related low back pain
- Varicella vaccine and rapid treatment of shingles to lower risk of postherpetic neuralgia
- Tight glycemic control for diabetic patients, alcohol cessation for alcoholics, smoking cessation

## **COMMONLY ASSOCIATED CONDITIONS**

Any chronic disease and/or its treatment can cause chronic pain, including diabetes, cardiovascular disease, HIV, progressive neurologic conditions, lung disease, cirrhosis, autoimmune disease, cancer, renal failure, depression, and mental illness.

## **DIAGNOSIS**

Chronic pain can be divided into two general categories:

- Nociceptive pain (two types)
  - Somatic: skin, bone, soft tissue disease; described as well-localized, sharp, stabbing, aching
  - Visceral: visceral inflammation/injury; described as poorly localized, dull, aching; may refer

to sites remote from lesion

- Neuropathic\_pain: damaged peripheral or central nerves; described as burning, tingling, and/or numbness
  - Sympathetically mediated pain: Peripheral nerve injury can cause severe burning pain, swelling of the affected limb, and focal changes in sweat production and skin appearance. Example: complex regional pain syndrome

## **HISTORY**

- Obtain pain history: location, onset, intensity, duration, quality, temporal pattern, exacerbating agents, alleviators, prior treatments
- Assess and document how pain affects patient's functioning and quality of life and what they expect from treatment.
- Screen for personal or family history of substance abuse (including tobacco addiction), mental health conditions, domestic violence, or sexual abuse.
- Use standardized tools: pain severity—Brief Pain Inventory (short form); mood—Patient Health Questionnaire-9 (PHQ-9); substance abuse— Screener and Opioid Assessment for Patients with Pain (SOAPP), multiple versions
- Use screening to risk stratify patients for risks of chronic opioid therapy and increased monitoring; a positive screen does not automatically exclude patients from opioid therapy.

## **PHYSICAL EXAM**

Exam is guided by history and must include functional and mental assessments.

## **DIFFERENTIAL DIAGNOSIS**

- The causes of pain are numerous, and clinic presentations are protean, depending on the individual patient.
- There is a spectrum of aberrant drug-taking behaviors, and differential diagnosis includes
  - Inadequate analgesia (ÒpseudoaddictionÓ), disease progression, opioid-resistant pain, opioid-induced hyperalgesia, addiction, opioid tolerance, self-medication of nonpain symptoms, criminal intent (diversion)

## **DIAGNOSTIC TESTS & INTERPRETATION**

Testing is based on differential diagnosis of pain syndrome to elucidate etiology.

## *Initial Tests (lab, imaging)*

- Urine drug screen: Order qualitative analysis for drugs of abuse and quantitative analysis for the drug you are prescribing.
- Most tests are immunoassays, which usually detect morphine and heroin but often not other opioids. Laboratory-based chromatography/spectrometry can identify specific drugs. Clinicians should be aware of uses and limitations of local laboratory testing (<http://www.aafp.org/afp/2010/0301/p635.html>).

## *Follow-Up Tests & Special Considerations*

If patient is taking chronic opioid therapy, order random urine drug screens as part of the "universal precautions" approach (see "Ongoing Care").

## *Diagnostic Procedures/Other*

- Consider interventional pain clinic for complicated joint injections and nerve root blocks, which can be diagnostic.
- If complex regional pain syndrome is suspected, a sympathetic block can be diagnostic and possibly prevent chronic pain.

## **TREATMENT**

- Goals of treatment are restoring function and a decrease in pain while balancing risks and benefits of therapies.
- Intradisciplinary teams offer most effective approach to chronic pain, including its physical, emotional, and psychological aspects. These teams may include the patient, family, primary care doctor, nurse, pain management specialist, pharmacist, psychologist, psychiatrist, physical and occupational therapists, physiatrist, complementary medicine practitioners, social worker, and (if needed) addiction medicine specialist (3)[B].
- Treatment should always include nonpharmacologic therapies such as exercise, cognitive-behavioral therapy (CBT), patient and family education, yoga, massage, relaxation techniques, support groups, meditation, and acupuncture.

## **GENERAL MEASURES**

Keep a pain and function diary to record pain and activity level and how much medication is taken.

## **MEDICATION**

- Always begin with exercise, physical therapy, CBT, and self-management skills before or with pain medications. Use sequential time-limited trials of medications, starting at low doses, and gradually increasing until either effect or dose-limiting side effects are reached. Rational polypharmacy may be indicated (such as an opioid + neuropathic agent).
- For mild to moderate chronic pain
  - Acetaminophen: daily dose not to exceed total 4 g in healthy adults and 2 g in the elderly or those with hepatic disease or active or past history of alcohol use
  - NSAIDs: COX-2 selective inhibitors should be used with caution because of cardiac risks but may have less gastric risk. If high cardiac risk consider nonselective COX inhibitor (such as naproxen) with or without gastric prophylaxis (depending on ulcer risk).

P.203

- Weak opioids, including tramadol. Caution: Opioid analgesic combinations can lead to serious acetaminophen or NSAID toxicities if patients exceed safely prescribed doses.
  - Topical agents: NSAIDs, lidocaine (gel is less expensive than patch), ketamine, capsaicin
- For neuropathic pain
  - Classes of medications include (i) tricyclic antidepressants (desipramine and nortriptyline have fewer side effects); (ii) serotonin-norepinephrine reuptake inhibitor (SNRI) antidepressants (duloxetine); (iii) anticonvulsants (alpha 2-delta ligands, gabapentin, and pregabalin); (iv) opioids, including tramadol. Example: combination of nortriptyline + gabapentin
  - See Neuropathic Pain.
- For moderate to severe chronic pain
  - Strong opioids, including morphine, oxycodone, hydromorphone, oxymorphone, fentanyl. Check opioid equianalgesic tables for dosing by route of administration.
  - No evidence supports any of these strong opioids as superior or having improved side effect profile.
  - In patients with chronic back pain, opioids may be efficacious for short-term use, but long-term benefits and side effects are unclear; in addition, aberrant medication-taking behaviors range from 5% to 24%.
    - Morphine should be avoided in patients with significant renal insufficiency.
    - Methadone should only be prescribed by experienced providers. The only opioid that also acts as *N*-methyl-D-aspartate receptor antagonist, methadone has many drug interactions and can contribute to potentially fatal cardiac arrhythmias.

- Once stable dose of opioids is established, change to sustained-release formulations if pain is constant or very frequent. Short-acting formulations are only for breakthrough or episodic pain.
- Common side effects: constipation: Senna should be prescribed at time opioids are started; also nausea, sedation, mental status changes, and pruritus

## **ALERT**

Patients on chronic opioid therapy must agree to monitoring. Clinicians should use universal precautions and systems-based practice, including written agreements, random urine drug screens, pill/patch counts, and other measures (see “Ongoing Care”) (4,5)[B].

## ***SURGERY/OTHER PROCEDURES***

Consider interventional procedures, including joint injections, nerve blocks, spinal cord stimulation, and intrathecal medication among others, as needed.

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Acupuncture: efficacy in chronic neck and back pain and fibromyalgia
- Exercise: efficacy in low back pain and fibromyalgia
- Improved mood and coping skills, decreased disability with CBT
- Mind-body interventions: yoga, tai chi, hypnosis, progressive muscle relaxation, meditation

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

#### ***Patient Monitoring***

- It can be difficult to identify appropriate pain relief-seeking behavior from inappropriate drug-seeking, but consistent patient-clinician relationships over time can often discern the difference.
- Always maintain a risk-benefit stance and avoid judging a patient.
- Assess and document benefits, pain levels, functioning, and quality of life. In general, patients successfully taking opioids for pain become more engaged (better relationships and productive work).
- At each visit, assess and document harm, using universal precautions approach. This system-

based practice includes the following:

- Informed consent for opioid therapy
- Written or electronic agreement between patient and clinician
- One prescribing clinician (or designee) and one pharmacy
- No after-hours prescriptions or early refills
- Mandatory police reports for medication thefts
- Random urine drug tests, pill/patch counts
- Requirements for patient to continue with physical therapy, counseling, psychiatric medications, or other necessary treatments
- Participate in state's prescription drug monitoring program: See [www.pmpalliance.org](http://www.pmpalliance.org).
- Taper and discontinue medications (10% dose reduction per week) if patient does not benefit, if side effects outweigh benefits, or if medications are abused or diverted. If addiction is suspected, always offer treatment for substance abuse (4,5)[B].

## ***PATIENT EDUCATION***

American Chronic Pain Association: <http://theacpa.org/>

### **COMPLICATIONS**

- Rate of addiction in chronic pain patients is unclear (3-19% in published literature), but it may reflect rate in the general population.
- Definitions
  - Addiction: chronic biopsychologic disease characterized by impaired control over drug use, compulsive use, and continued use despite harm
  - Physical dependence: withdrawal syndrome produced by abrupt cessation or rapid dose reduction; is not addiction but a physiologic phenomenon
  - Tolerance: state of adaptation when a drug induces changes that diminish its effects over time
  - Diversion: selling drugs or giving them to persons other than for whom they are prescribed

### **ALERT**

Caution: From 1999 to 2007, the rate of unintentional overdose death increased by 124%, largely due to prescription opioid overdoses (especially methadone). In 2011, prescription narcotic overdose was the leading cause of accidental death in the United States

**&NA;**

## **ICD10**

- G89.29 Other chronic pain
- G89.21 Chronic pain due to trauma
- G89.28 Other chronic postprocedural pain

## **Clinical Pearls**

**&NA;**

- Start with the presumption that the patient's pain is *real*, even if pathophysiologic evidence for it cannot be found.
- Emphasize that being pain-free may not be possible but that better function and quality of life can be shared goals.
- Use a multidisciplinary approach with nonpharmacologic therapies, exercise, patient self-management strategies and thoughtful medication use with clear goals, expectations, and documentation of care plan.
- Use universal precautions and systems-based practice to safely and effectively prescribe opioids for chronic pain.

# Cirrhosis of the Liver

Kathleen M. Donahue, DO

## BASICS

### DESCRIPTION

A chronic hepatocellular disease involving inflammation, necrosis, and fibrosis potentially leading to liver failure and/or cancer

### EPIDEMIOLOGY

- Predominant age: 40 to 50 years old
- Predominant sex: male > female; more women get cirrhosis from alcohol abuse.
- Ninth leading cause of death among U.S. adults

### ETIOLOGY AND PATHOPHYSIOLOGY

- Chronic hepatitis C (26%)
- Alcohol abuse (21%)
- Hepatitis C with alcoholic liver disease (15%)
- Nonalcoholic steatohepatitis/obesity (÷10%)
- Hepatitis B plus hepatitis D infection (15%)
- Other: hemochromatosis, autoimmune hepatitis, primary biliary cirrhosis, secondary biliary cirrhosis, primary sclerosing cholangitis, Wilson disease,  $\alpha_1$ -antitrypsin deficiency, granulomatous disease (e.g., sarcoidosis); drug-induced liver disease (e.g., methotrexate,  $\alpha$ -methyl dopa, amiodarone); venous outflow obstruction (e.g., Budd-Chiari syndrome, veno-occlusive disease); chronic right-sided heart failure; tricuspid regurgitation; and rare genetic, metabolic, and infectious causes

### Genetics

Hemochromatosis, Wilson disease, and  $\alpha_1$ -antitrypsin deficiency in adults are associated with cirrhosis.

## RISK FACTORS

Alcohol abuse, intravenous drug abuse, obesity, blood transfusion

## GENERAL PREVENTION

- Mitigate risk factors (e.g., alcohol abuse): *>80% of chronic liver disease is preventable.*
- Limit alcohol consumption and advise weight loss in overweight or obese patients.
  - Elevated BMI and alcohol have an additive effect on liver disease (1).

## COMMONLY ASSOCIATED CONDITIONS

Diabetes, alcoholism, drug abuse, depression, obesity

## DIAGNOSIS

### HISTORY

- Review risk factors (alcohol abuse, viral hepatitis, family history of primary liver cancer, other liver disease, or autoimmune disease)
- Symptoms
  - Fatigue, malaise, weakness
  - Anorexia, weight loss (weight gain if ascites/edema)
  - Right upper abdominal pain
  - Absent/irregular menses, chronic anovulation
  - Diminished libido, erectile dysfunction
  - Tea-colored urine, clay-colored stools
  - Edema, abdominal swelling/bloating
  - Bruising, bleeding, hematemesis, hematochezia, melena, pruritus
  - Night blindness

## PHYSICAL EXAM

Physical exam may be normal until end-stage disease.

- Skin changes: spider angiomas, palmar erythema, jaundice, scleral icterus, ecchymoses, caput medusa, hyperpigmentation
- Hepatomegaly (small, fibrotic liver in end-stage disease)
- Splenomegaly (if portal hypertension)

- Central obesity
- Abdominal fluid wave, shifting dullness (ascites)
- Gynecomastia
- Dupuytren contractures
- Pretibial, presacral pitting edema and clubbing (especially in hepatopulmonary syndrome)
- Asterixis, mental status changes
- Muscle wasting, weakness
- Feter hepaticus with severe portal-systemic shunting

## ***DIFFERENTIAL DIAGNOSIS***

Steatohepatitis, other causes of portal hypertension (e.g., portal vein thrombosis, lymphoma); metastatic or multifocal cancer in the liver; vascular congestion (e.g., cardiac cirrhosis); acute alcoholic hepatitis

## ***DIAGNOSTIC TEST & INTERPRETATION***

### ***Initial Test (lab, imaging)***

- Aspartate aminotransferase/alanine aminotransferase (AST/ALT): mildly elevated, typically AST > ALT; enzymes normalize as cirrhosis progresses.
- Elevated alkaline phosphatase (ALP), gamma-glutamyl transpeptidase (GGT), and total/direct bilirubin
- Anemia from hemolysis, folate deficiency, and/or splenomegaly
- Decreased platelet count
- Impaired synthetic liver function
  - Low albumin and cholesterol
  - Prolonged prothrombin (PT), international normalized ratio (INR), partial thromboplastin time (PTT). Vitamin K-dependent clotting factors (II, VII, IX, X)
- Progressive cirrhosis
  - Elevated ammonia level, BUN, sodium, and potassium
- $\alpha$ -Fetoprotein level to screen for hepatocellular carcinoma
- Abdominal ultrasound q6-12mo to screen for hepatocellular carcinoma

- Doppler ultrasound to assess liver parenchyma and hepatic/portal veins
- MRI best follow-up test for HCC if  $\alpha$ -fetoprotein elevated and/or liver mass found on ultrasound
- Noninvasive modalities, such as elastography, are being researched as an alternative to liver biopsy (2).

## *Follow-Up Tests & Special Considerations*

Consider the following:

- Hepatitis serologies (particularly B and C)
- Serum ethanol and GGT if alcohol abuse suspected
- Antimitochondrial antibody to screen for primary biliary cirrhosis
- Anti-smooth muscle and antinuclear antibodies to screen for chronic active (autoimmune) hepatitis
- Iron saturation (>50%) and ferritin (markedly increased) to screen for hemochromatosis; if abnormal, check hemochromatosis (HFE) genetics/mutation analysis.
- $\alpha$ <sub>1</sub>-antitrypsin phenotype screen
- Ceruloplasmin level to screen for Wilson disease; if low, check copper excretion (serum copper plus 24-hour urine copper).

## *Diagnostic Procedures/Other*

- Liver biopsy: required for definitive diagnosis, percutaneous if INR <1.5 and no ascites; otherwise, transjugular. Serologic testing gaining use as a surrogate for biopsy.
- Ultrasound-based elastography: noninvasive alternative to liver biopsy, not widely available; relies on increased stiffness of abnormal tissue to evaluate for fibrosis
- Endoscopy if portal hypertension to rule out esophageal varices/portal hypertensive gastropathy (3)[C]

## *Test Interpretation*

- Fibrous bands and regenerative nodules are classic biopsy features of cirrhosis.
- Other histologic findings vary with etiology
  - Alcoholic liver disease: steatosis, polymorphonuclear (PMN) leukocyte infiltrate, ballooning degeneration of hepatocytes, Mallory bodies, giant mitochondria

Chronic hepatitis B and C: periportal lymphocytic inflammation

- Nonalcoholic steatohepatitis (NASH): identical to alcoholic liver disease; steatosis may be absent in advanced disease (burned-out NASH).
- Biliary cirrhosis: PMN infiltrate in wall of bile ducts, inflammation increased in portal spaces, progressive loss of bile ducts in portal spaces.
- Hemochromatosis: intrahepatic iron stores increased (iron stain or weighted biopsy tissue)
- $\alpha_1$ -antitrypsin deficiency: positive periodic acid-Schiff (PAS) bodies in hepatocytes

## TREATMENT

Outpatient care except for major GI bleeding, altered mental status, sepsis/infection, rapid hepatic decompensation and renal failure.

## GENERAL MEASURES

- Abstain from alcohol, drugs, hepatotoxic medications, and hepatotoxic herbs.
- Pneumococcal, hepatitis A/B, and influenza vaccines
- NASH: weight reduction, exercise, optimal control of lipids/glucose

## MEDICATION

### First Line

Treat the underlying cause first (*note prescribing precautions in decompensated cirrhosis*).

- Hepatitis C: Goal of treatment is to eradicate hepatitis C virus (HCV) RNA in serum. Combination therapy of pegylated interferon (PEG-IFN) with ribavirin is the standard of care for most genotypes.
- Hepatitis B: Goal of treatment is to achieve HBeAg seroconversion. Adefovir 10 mg PO daily, entecavir 0.5 to 1.0 mg PO daily, telbivudine 600 mg PO daily, or lamivudine 100 mg PO daily for minimum of 1 year, or continue for at least 6 months after HBeAg seroconversion; alternatively, PEG-IFN  $\alpha$ -2a 180  $\mu$ g SC weekly for 48 weeks. Lamivudine is no longer recommended as first-line agent due to high rates of resistance.
- Alcoholic hepatitis: Treat withdrawal; discriminant function  $>32$  may benefit from prednisolone, 40 mg/day for 28 day with 2 to 4 weeks taper, to reduce mortality. Pentoxifylline for patients unable to tolerate steroids
- Biliary cirrhosis: ursodeoxycholic acid (ursodiol) 13 to 15 mg/kg PO divided BID-QID with food

(4)[A]; bile acid sequestrants (BAS) are first-line therapy for pruritus: cholestyramine 4 to 8 g PO BID; antihistamines; rifampicin 150 to 300 mg PO BID, or opiate antagonists such as naltrexone 50 mg/day can be used for pruritus if ursodiol is ineffective.

- Wilson disease: initial treatment with penicillamine 1,000 to 1,500 mg/day PO BID-QID or trientine 750 to 1,500 mg/day PO BID-TID on empty stomach. Trientine (Syprine) is better tolerated. After 1 year, zinc acetate 150 mg/day PO BID-TID for maintenance. Zinc for presymptomatic, pregnant, and pediatric populations.
- Autoimmune (chronic active) hepatitis: prednisone 30 to 60 mg/day initially, maintenance 5 to 20 mg/day with or without azathioprine (Imuran) 0.5 to 1.0 mg/kg; adjust to keep transaminase levels normal. The combination is preferred. Discontinue maintenance after at least 24 months of treatment if AST and ALT are normal.
- Esophageal varices: propranolol 40 to 160 mg or nadolol 40 mg daily to lower portal pressure by 20 mm Hg, systolic pressure from 90 to 100 mm Hg, and pulse rate by 25% (3)[A].
- Ascites/edema: low-sodium (<2 g/day) diet and spironolactone 100 to 400 mg/day with or without furosemide 40 to 160 mg/day PO; torsemide may substitute for furosemide.
- Encephalopathy: lactulose 15 to 45 mL BID, titrate to induce three loose bowel movements daily. Combination therapy with rifaximin (550 mg PO BID) is recommended regimen to prevent recurrent hepatic encephalopathy (5)[B].
- Pruritus: ursodiol, cholestyramine, or antihistamines (e.g., hydroxyzine)
- Renal insufficiency: Stop diuretics and nephrotoxic drugs, normalize electrolytes, and hospitalize for plasma expansion or dialysis.
- Prophylactic antibiotics for invasive procedures, GI bleeding, or history of spontaneous bacterial peritonitis (3)[A]
- Proton pump inhibitor for esophageal varices requiring banding or portal hypertensive gastropathy (6)[A]

## ***ISSUES FOR REFERRAL***

Evaluate for liver transplant at onset of complications (ascites, variceal bleeding, encephalopathy), jaundice, or liver lesion suggestive of hepatocellular carcinoma and/or when evidence of hepatic dysfunction develops (Child-Turcotte-Pugh >7 and Model for End-stage Liver Disease [MELD] >10).

## ***SURGERY/OTHER PROCEDURES***

- Varices: endoscopic ligation, typically 4 to 6 treatments (if acute bleed, use pre-esophagogastroduodenoscopy [EGD] octreotide as vasoconstrictor); transjugular intrahepatic

shunt (TIPS) second-line or salvage therapy for acute bleed (3)

- Ascites: if tense, therapeutic paracentesis every 2 weeks PRN; caution if pedal edema absent
- Fulminant hepatic failure: liver transplantation
- Hepatocellular carcinoma: curable if small with radiofrequency ablation or resection and transplant

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Zinc sulfate 220 mg BID may improve dysgeusia and appetite; adjunct for hepatic encephalopathy
- Milk thistle (silymarin) may lower transaminases and improve symptoms.
- Danshen and huang qi injections may promote improvement; further studies needed (7)[B].
- Hepatotoxicity and drug interactions are common with many herbal medications (8).

## INPATIENT CONSIDERATIONS

### *Admission Criteria/Initial Stabilization*

Major GI bleeding, altered mental status, sepsis/infection, rapidly progressing hepatic decompensation, renal failure

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Regular physical conditioning may help with fatigue.

### *Patient Monitoring*

- Once stable, monitor liver enzymes, platelets, and PT q6-12mo.
- Patients over 55 years with chronic hepatitis B or C, elevated INR, or low platelets are at highest risk for HCC. Serial  $\alpha$ -fetoprotein and liver ultrasound screening q6-12mo in patients with cirrhosis (9)[C].
- Endoscopy at diagnosis and every 3 years (compensated) and every 1 year (decompensated) to screen for varices (3)[C]

## DIET

- Protein (1.0 to 1.5 g/kg body weight), high fiber, daily multivitamin (without iron), and sodium

(<2 g/day, essential if ascites/edema)

- Protein restriction is no longer recommended (10).
- Coffee consumption has a graded and inverse association with liver cancer (11)[A].

## **PATIENT EDUCATION**

- Educate about when to seek emergency care (e.g., hematemesis, altered mental status).
- Maintain sobriety and smoking cessation (no cannabis).
- Update required immunizations; hepatitis C transmission precautions

## **PROGNOSIS**

- At diagnosis of cirrhosis, expect 5 to 20 years of asymptomatic disease.
- After onset of complications, death typically within 5 years without transplant
  - 5% per year develop HCC.
  - 50% of cirrhotics develop ascites over 10 years; 50% 5-year survival once ascites develops
  - Acute variceal bleeding is the most common fatal complication; 30% mortality
  - Median survival after complications (ascites, variceal bleeding, encephalopathy) develop is 1.5 years (7).
  - With transplant, 85% survive 1 year; after transplant, ÷5% annual mortality
- <25% of eligible patients receive a transplant because of donor organ shortage.

## **COMPLICATIONS**

Ascites, edema, infections, encephalopathy, GI bleeding, esophageal varices, gastropathy, colopathy, hepatorenal syndrome, hepatopulmonary syndrome, hepatocellular carcinoma, fulminant hepatic failure, complications after transplant (e.g., surgical, rejection, infections)

## See Also

&NA;

Algorithm: Cirrhosis

## Codes

&NA;

### ICD10

- K74.60 Unspecified cirrhosis of liver
- K70.30 Alcoholic cirrhosis of liver without ascites
- K74.69 Other cirrhosis of liver

## Clinical Pearls

&NA;

- 80% of chronic liver disease that leads to cirrhosis is preventable (primarily alcohol abuse).
- Check abdominal ultrasound every 6 months for early detection of hepatocellular carcinoma.
- Update necessary immunizations and treat underlying cause (hepatitis C, alcohol abuse, etc.).

# CLOSTRIDIUM DIFFICILE INFECTION

Darren S. Bryan, MD

James R. Yon, MD

## BASICS

### DESCRIPTION

- *Clostridium difficile* is a gram-positive, spore-forming anaerobic bacillus that releases toxins to produce clinical disease.
- Infection caused by *C. difficile* is frequently associated with antibiotic use, hospitalization, and age.
- Severity of infection can range from diarrhea to pancolitis, perforation, and death.
- System(s) affected: gastrointestinal
- Synonyms(s): *C. difficile*-associated disease or diarrhea (CDAD); *C. difficile* colitis; *C. difficile*

### EPIDEMIOLOGY

#### Incidence

- *C. difficile* infection is among the most common causes of hospital-acquired infection. The incidence appears to be rising (1).
- There are approximately 15 new cases per 1,000 clinical discharges. Higher with increased age (2)
- Rates of complications associated with *C. difficile* such as treatment failure and recurrence are also increasing (1).

#### Prevalence

- *C. difficile* causes ÷25% of all cases of antibiotic-associated diarrhea
- Prevalence of community-acquired *C. difficile* infection is increasing. Up to 40% of patients will require hospitalization (2).
- *C. difficile* is present as a commensurate organism in 2-5% of the adult U.S. population.

## ETIOLOGY AND PATHOPHYSIOLOGY

- *C. difficile* are motile bacteria existing in vegetative and spore forms. Spores can survive for months in harsh conditions and outside of the body.
- Spread by fecal-oral contact. Acid-resistant spores pass through stomach, and reside predominantly in the colon.
- Colonic colonization causes disruptions in barrier functions of the normal microbiome (2).
- *C. difficile* is noninvasive. Toxins are produced that mediate disease:
  - Toxins A (enterotoxin) and B (cytotoxin) attract neutrophils and monocytes, degrading colonic epithelial cells, and causing clinical disease.
- BI/NAP1/027 strain of *C. difficile* has been shown to produce a much more virulent form of disease, with increased endotoxin concentrations. It is associated with increased rates of colectomy and death.

## Genetics

No known genetic factors

## RISK FACTORS

- Host risk factors
  - Age >65 years
  - Hospitalization or stay in long-term health care facility. The length of stay is directly correlated with the risk for *C. difficile* infection.
  - Comorbidities, including inflammatory bowel disease, immunosuppression, tube feeding, chronic liver disease, and end-stage renal disease
  - Previous *C. difficile* infection
- Factors that disrupt normal colonic microbiota:
  - Exposure to almost all antibiotics (including perioperative prophylaxis) is associated with an increased risk for *C. difficile* infection.
  - Most commonly implicated antibiotics include: ampicillin, amoxicillin, clindamycin, cephalosporins, and fluoroquinolones
- Recurrence from prior infection
  - Recurrence rates approximately 20% after initial episode. More likely to have recurrence with each additional episode (2)

- Patients who have had colectomy for *C. difficile* infection can have colonization of the ileum. Community-acquired *C. difficile* infections (no overnight admission in >12 weeks) are more frequent in patients without other risk factors (younger, no recent antibiotic exposure).

## Geriatric Considerations

*C. difficile* is the most common cause of acute diarrheal illness in long-term care facilities. Elderly patients also commonly have multiple other risk factors (comorbid disease, antibiotic exposure, medication use).

## Pediatric Considerations

- Neonates have a higher rate of *C. difficile* colonization (25-80%) but are generally less symptomatic than adults (possibly due to immature toxin receptors)
- Frequently serve as carrier for symptomatic infection in adults

## GENERAL PREVENTION

- A comprehensive infection control program decreases the incidence of *C. difficile* infection.
- 2010 Society for Healthcare Epidemiology of America (SHEA)/Infectious Diseases Society of America (IDS) guidelines:
  - For health care workers, patients, and visitors:
    - Contact precautions, including gloves and gowns, on entry to room
    - Alcohol-based hand sanitizers not effective. Hand hygiene with soap and water before and after patient interaction
    - Accommodate patients with *C. difficile* infection in private rooms, if possible.
  - Environmental cleaning and disinfection
    - Disinfection with hypochlorite solution or other spore-killing solutions
    - Identification and reduction of environmental sources of *C. difficile*, including the use of nondisposable rectal thermometers
  - Antimicrobial use restrictions
    - Minimize the frequency and duration of antibiotic therapy.

## COMMONLY ASSOCIATED CONDITIONS

Pseudomembranous colitis, toxic megacolon, sepsis, colonic perforation

# DIAGNOSIS

## HISTORY

- Age and underlying comorbidities
- Recent antibiotic use
- Diarrhea (defined as >3 stools in 24 hours) that is watery, foul-smelling, and sometimes bloody (1)
- Fever (<10%), anorexia, nausea
- Recent hospitalization or stay at nursing facility

## PHYSICAL EXAM

Physical exam findings range from mild abdominal pain to peritoneal findings and shock:

- Mild or moderate disease: mild lower abdominal pain, often cramping pain
- Severe disease: fever, nausea/vomiting, dehydration
- Severe, complicated disease: shock, peritonitis, ileus

## DIFFERENTIAL DIAGNOSIS

- Antibiotic-associated diarrhea
- Inflammatory bowel disease
- Enteric infections
- Food poisoning

## DIAGNOSTIC TESTS & INTERPRETATION

- SHEA/IDSA guidelines (2)
  - Mild or moderate disease: leukocytosis with white blood cell (WBC) count <15,000 cells/ $\mu$ m<sup>3</sup>;L and a serum creatinine level <1.5× the premorbid level
  - Severe, uncomplicated disease: leukocytosis with WBC count > 15,000 cells/ $\mu$ m<sup>3</sup>;L or a serum creatinine level >1.5× the premorbid level
  - Severe, complicated disease: markers of severe infection include hypotension, sepsis, markedly elevated WBC count, and bacteremia
    - Other signs seen on imaging include obstruction, perforation, toxic megacolon, and colonic wall thickening

## Initial Tests (lab, imaging)

- Polymerase chain reaction (PCR)-based testing is preferred for *C. difficile*. Rapid, highly sensitive, and highly specific (2)[B]
- Alternative to PCR: screening and confirmatory testing. *C. difficile* common antigen tests: Tests for glutamate dehydrogenase (GDH), found in both toxic and nontoxic strains of *C. difficile* (sensitivity, 85-95%; specificity, 89-99%).
- Confirmatory: enzyme immunoassay for toxins (A/B or A); rapid results, inexpensive, easy to use (sensitivity 63-94%)
- Stool culture is the most sensitive test; however, non-toxin-producing strains also detected.
- Repeat testing during the same episode of diarrhea is not recommended. Stool carriage persists for 3 to 6 weeks after successful treatment (2)[A].

## Diagnostic Procedures/Other

- Endoscopy can be used to evaluate for pseudomembranes and exclude other conditions
  - While not all patients with *C. difficile* infection have pseudomembranes, their presence is pathognomonic for *C. difficile*.
- Flexible sigmoidoscopy may miss 15-20% of pseudomembranes present in the proximal colon.
- Colonoscopy evaluates the entire colon: used when diagnosis is in doubt or severity demands rapid diagnosis
- Plain films may show thumbprinting and colonic distension.
- CT may show mucosal wall thickening, thickened colonic wall, and pericolonic inflammation.

## Test Interpretation

Pseudomembranes consist of inflammatory and cellular debris that forms visible exudates that can obscure the underlying mucosa. These exudates have a yellow to grayish color.

P.207

## TREATMENT

### GENERAL MEASURES

- Avoid antimotility agents and opiates.
- Avoid indiscriminate use of antibiotics.

- Proton pump inhibitors associated with recurrent infection, however have not shown to be causal
- Discontinue offending antibiotic, if possible.

## MEDICATION

### First Line

- Mild or moderate infection (3)[A]
  - Oral metronidazole is the drug of choice for mild to moderate *C. difficile* infection:
    - 500 mg PO TID for 10 to 14 days
    - If patient is unable to take oral medications, then intravenous (IV) metronidazole or intraluminal vancomycin can be used.
- Severe infection (3)[A]
  - Enteral vancomycin is 1st-line therapy in patients with severe or fulminant *C. difficile* infection:
    - 125 mg PO QID for 10 to 14 days
    - Vancomycin retention enema if unable to take PO, or if there is evidence of poor gastrointestinal motility
- Severe, complicated infection—consider surgical and critical care consultation (3)[A]
  - Vancomycin: 500 mg PO QID and metronidazole 500 mg PO TID
- 1st recurrence
  - Treat the same as 1st episode
- 2nd recurrence
  - Vancomycin taper and/or pulse: vancomycin 125 mg PO QID for 10 to 14 days, then 125 mg PO BID for 7 days, then 125 mg PO once daily for 7 days, then 125 mg PO every 2 to 3 days for 2 to 8 weeks:
    - Pulse dosing every 2 to 3 days allows spores to germinate and then be killed.

### ALERT

When using vancomycin for treatment of *C. difficile* infection, oral or rectal formulations must be used. IV formulations are not excreted into the colonic

lumen.

## Second Line

- Vancomycin: indicated for patients who cannot tolerate or have failed metronidazole therapy and for those who are pregnant
- Fidaxomicin is another option 200 mg PO BID. Similar cure rates to vancomycin and lower recurrence rates, however can be cost prohibitive.
- Fidaxomicin rapidly kills *C. difficile* whereas vancomycin inhibits growth. Fidaxomicin has a narrow antimicrobial spectrum and helps preserve normal anaerobic flora.
- Fecal transplant: stool from healthy, screened donor. Administered via either rectal or oral route. Highly effective treatment for recurrent infections (>90% cure rate) when offending antibiotic stopped. Recipient gut flora have been transformed in as few as 3 days following fecal transplantation (4)[A].

## SURGERY/OTHER PROCEDURES

- Most patients improve with conservative management and oral antibiotics.
- Patients with severe fulminant colitis develop paralytic ileus, leading to distention (megacolon), and potential perforation.
- Severe lower quadrant abdominal pain or signs of hemodynamic instability in the setting of known infection should prompt surgical and critical care consultation.

### ALERT

BI/NAP1/027 strain associated with fulminant colitis, often requiring surgical intervention. More common in younger patients with severe disease.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Adjunctive therapy with intravenous immunoglobulin (IVIG) has shown initial promise, but more data are required before routine clinical use.
- Probiotics have an (strain-specific) inhibitory effect on *C. difficile* and may play a role in prevention.
- Other investigational treatment options:
  - New antibiotics (Rifalazil, Tolevamer, and Ramoplanin)
  - Monoclonal antibodies to directly modulate the effects of toxins
  - Vaccine form of *C. difficile* antitoxin antibody

# INPATIENT CONSIDERATIONS

## Admission Criteria/Initial Stabilization

- Hypovolemia
- Inability to keep up with enteric losses
- Hematochezia
- Electrolyte disturbances

## IV Fluids

To maintain volume status

## Discharge Criteria

- Decreased diarrhea severity and frequency
- Tolerating oral diet and medications
- Do not repeat testing for toxins, as they may shed for weeks following an acute infection.

## ONGOING CARE

## FOLLOW-UP RECOMMENDATIONS

Many patients can be treated as outpatients.

## Patient Monitoring

- Relapses of colitis occur in 15-30%
- Relapses typically occur 2 to 10 days after discontinuing antibiotics.

## DIET

Regular diet or NPO if severe and surgical evaluation required

## PATIENT EDUCATION

Educate patients about *C. difficile* transmission, the importance of hand washing, and the appropriate use of antibiotics.

### **ALERT**

Alcohol-based hand sanitizers are not effective against *C. difficile*. Wash with

soap and water.

## PROGNOSIS

- Most patients improve with conservative management and oral antibiotics.
- 1-3% of patients develop severe/fulminant colitis requiring emergency colectomy.

Codes

**&NA;**

## **ICD10**

A04.7 Enterocolitis due to *Clostridium difficile*

## **Clinical Pearls**

**&NA;**

- *C. difficile* is spread by fecal-oral contact.
- Alcohol-based hand sanitizers are ineffective against *C. difficile*. Wash hands with soap and water.
- Testing and treatment of asymptomatic patients is not recommended.
- PCR is the preferred initial test.
- Patients may shed organism or toxin for weeks after treatment. Repeat toxin assays following treatment are not helpful.
- Metronidazole remains the drug of choice for mild to moderate disease.

# Colic, Infantile

Daniel T. Lee, MD, MA

Arthur Ohannessian, MD

## BASICS

### DESCRIPTION

- Colic is defined as excessive crying in an otherwise healthy baby.
- A commonly used criteria is the Wessel criteria or the Rule of Three: crying lasts for:
  - >3 hr/day
  - >3 days/week
  - Persists >3 weeks
- Many clinicians no longer use the criterion of persistence for >3 weeks because few parents or clinicians will wait that long before evaluation or intervention.
- Some clinicians feel that colic represents the extreme end of the spectrum of normal crying, whereas most feel that colic is a distinct clinical entity.

### EPIDEMIOLOGY

#### *Incidence*

- Predominant age: between 2 weeks and 4 months of age
- Predominant sex: male = female

#### *Prevalence*

- Probably between 10% and 25% of infants
- Range is somewhere between 8% and 40% of infants.

#### *Pediatric Considerations*

This is a problem during infancy.

## ETIOLOGY AND PATHOPHYSIOLOGY

The cause is unknown. Factors that may play a role include the following:

- Infant gastroesophageal reflux disease
- Allergy to cow's milk, soy milk, or breast milk protein
- Fruit juice intolerance
- Swallowing air during the process of crying, feeding, or sucking
- Overfeeding or feeding too quickly; underfeeding also has been proposed.
- Inadequate burping after feeding
- Family tension
- Parental anxiety, depression, and/or fatigue
- Parent-infant interaction mismatch
- Baby's inability to console him- or herself when dealing with stimuli
- Increased gut hormone motilin, causing hyperperistalsis
- Functional lactose overload (i.e., breast milk that has a lower lipid content can have faster transit time in the intestine, leading to more lactose fermentation in the gut and hence gas and distension) (1)[C]
- Tobacco smoke exposure

## RISK FACTORS

- Physiologic predisposition in infant but no definitive risk factors have been established. However, emerging data suggest maternal smoking or exposure to nicotine replacement therapy during pregnancy is associated with higher incidence of infantile colic (2)[B].
- Infants with a maternal history of migraine headaches are twice as likely to have colic (3)[B].

## GENERAL PREVENTION

Colic is generally not preventable.

## DIAGNOSIS

### HISTORY

- Evaluation for Wessel criteria: crying lasts for >3 hr/day, >3 days/week, and persists >3 weeks.

- The colicky episodes may have a clear beginning and end.
- The crying is generally spontaneous, without preceding events triggering the episodes.
- The crying is typically different from normal crying. Colicky crying may be louder, more turbulent, variable in pitch, and appear more like screaming.
- The infant may be difficult to soothe or console regardless of how the parents try to help.
- The infant acts normally when not colicky.
- Assess the support system of caregivers and families, including coping skills.

## *PHYSICAL EXAM*

- A comprehensive physical exam is normal.
- Because excessive crying may be a risk factor for shaken baby syndrome or other forms of child abuse (4)[B], be sure to examine the child carefully for signs of shaken baby syndrome or other types of child abuse.

## *DIFFERENTIAL DIAGNOSIS*

Any organic cause for excessive or qualitatively different crying in infants such as:

- Infections (e.g., meningitis, sepsis, otitis media, or UTI)
- GI issues such as gastroesophageal reflux disease, intussusception, lactose intolerance, constipation, anal fissure, or strangulated hernia
- Trauma, which includes foreign bodies, corneal abrasion, occult fracture, digit or penile hair tourniquet syndrome, or child abuse

## *DIAGNOSTIC TESTS & INTERPRETATION*

### *Initial Tests (lab, imaging)*

Clinical diagnosis; no testing is done unless clinical symptoms imply other cause (UTI, weight loss, etc.).

### *Diagnostic Procedures/Other*

A thorough history and physical exam should be performed to rule out other causes. Otherwise, no diagnostic procedures or imaging is indicated.

## TREATMENT

### GENERAL MEASURES

- Soothe by holding and rocking the baby.
- Use a pacifier.
- Use of gentle rhythmic motion (e.g., strollers, infant swings, car rides).
- Place near white noise (e.g., vacuum cleaner, clothes dryer, white noise machine).
- Crib vibrators or car ride simulators have not proven to be helpful (5)[B].
- Increased carrying or use of infant carrier has not been shown to improve colic (5)[B].
- Burping does not significantly lower colic events and can cause significant increase in regurgitation episodes (6)[B].
- Employ the 5 Ss (need to be done concurrently):
  - Swaddling: tight wrapping with blanket; may be especially beneficial in infants <8 weeks old (7)[B]
  - Side: laying baby on side
  - Shushing: loud white noise
  - Swinging: rhythmic, jiggly motion
  - Sucking: sucking on anything (e.g., nipple, finger, pacifier)

### MEDICATION

- None as no medication found to be beneficial and safe. Probiotics are safe and effective (see Complementary and Alternative Medicine).
- Dicyclomine (Bentyl) has been proven beneficial, but the potential serious adverse effects (apnea, seizures, and syncope) have precluded its use. Furthermore, the manufacturer has made the medication contraindicated for infants <6 months (8)[B].
- Simethicone has not been shown to be beneficial (8)[B].
- Omeprazole has not been shown to be beneficial (9)[B].

### ISSUES FOR REFERRAL

Excessive vomiting, poor weight gain, recurrent respiratory diseases, or bloody stools should prompt referral to a specialist.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- Recent data from a large randomized controlled study involving nine neonatal units in Italy found that prophylactic use of *Lactobacillus reuteri* was beneficial. At 3 months of age, the mean duration of crying time (38 vs. 71 minutes;  $p < .01$ ), the mean number of regurgitations per day (2.9 vs. 4.6;  $p < .01$ ), and the mean number of evacuations per day (4.2 vs. 3.6;  $p < .01$ ) for the *L. reuteri* DSM 17938 and placebo groups, respectively, were significantly different (10)[A].
  - However, the effect of *L. reuteri* has not been as robust in infants already diagnosed with colic. A placebo-controlled study of 50 infants given *L. reuteri* had significantly reduced median daily crying times throughout the study (370 to 35 min/day vs. 300 to 90 min/day in placebo group). However, weight gain, stooling frequency, and incidence of regurgitation were similar in both groups (11)[B].
  - *L. reuteri* is available as over-the-counter drops, but it is not regulated by the FDA.
    - A 2013 systematic review found probiotics effective for breastfed infants but not formula-fed infants. Infant massage and crib vibrator were found to reduce colic symptoms by 50% in a small RCT (12)[B].
  - Anecdotal evidence that car rides, both real and simulated via podcast ([https://www.youtube.com/watch?v=8KAXmle-T\\_4](https://www.youtube.com/watch?v=8KAXmle-T_4)), or running a vacuum cleaner near the baby may be effective.
  - Herbal teas and supplements may help but are not recommended because of limited, inconclusive evidence. Examples:
    - One study concluded that herbal teas containing mixtures of chamomile, vervain, licorice, fennel, and balm-mint used up to T1D may be beneficial (4)[C]. However, the study used high dosages, raising clinical concerns that this therapy may impair needed milk consumption in infants and be impractical to administer. In addition, preparations used in the study may not be commercially available in the United States.
- 
- A second double-blind, randomized trial of 0.1% fennel seed oil emulsion versus placebo demonstrated a decrease in colic symptoms according to the Wessel criteria. However, this preparation of fennel seed oil is not commercially available in the United States, and the long-term health effects are unknown (13)[B].
  - A home-based intervention focusing on reducing infant stimulation and synchronizing infant sleep-wake cycles with the environment, as well as parental support, has been shown to be effective (14)[B].
  - Use of music may help (15,16)[C].

- Chiropractic treatment has shown no benefit over placebo.
- Infant massage has not been shown to be helpful.

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Frequent outpatient visits as needed for parental reassurance, education, and monitoring and to ensure the health of the infant and parents

### *Patient Monitoring*

Follow for proper feeding, growth, and development.

### *DIET*

- If breastfeeding:
  - Continue breastfeeding. Switching to formula probably will not help.
  - Possible therapeutic benefit from eliminating milk products, eggs, wheat, and/or nuts from the diet of breastfeeding mothers (5)[B]
  - Along with eliminating the preceding foods from the maternal diet, removing soy, nuts, and fish may be beneficial.
- If formula feeding:
  - Feeding the infant in a vertical position using a curved bottle or bottle with collapsible bag may help to reduce air swallowing.
  - If no intervention or dietary change has improved the situation, consider a 1-week trial of hypoallergenic formulas such as whey hydrolysate (e.g., Good Start) or casein hydrolysate (e.g., Alimentum, Nutramigen, Pregestimil) (5)[B],(8)[C].
  - The American Academy of Pediatrics concluded that there is no proven role for soy formula in the treatment of colic (17)[C].
  - Adding fiber to formula also has not been shown to be helpful (5,15)[B].
- Supplementing with sucrose solution may be helpful, but the effect may be short-lived (<1 hour) (5,8)[B].
- Despite the proposed mechanism of functional lactose overload, use of lactase enzymes in formula or breast milk or given directly to the infant has no therapeutic benefit (5)[B].

## PATIENT EDUCATION

- Reassure parents that colic is not the result of bad parenting, and advise parents about having proper rest breaks, adequate sleep, and help in caring for the infant.
- Explain the spectrum of crying behavior.
- Avoid over- or underfeeding.
- Instruct in better feeding techniques such as improved bottles (low air, curved) and sufficient burping after feeding.
- Colic information at American Family Physician: [www.aafp.org/afp/2004/0815/p741.html](http://www.aafp.org/afp/2004/0815/p741.html)

## PROGNOSIS

- Usually subsides by 3 to 6 months of age, often on its own
- Despite apparent abdominal pain, colicky infants eat well and gain weight normally.
- A handful of studies indicate temper tantrums may be more common among formerly colicky infants as studied in toddlers up to 4 years old (18,19)[C].
- Colic has no bearing on the baby's intelligence or future development.

## COMPLICATIONS

- Colic is self-limiting and does not result in lasting effects to infant or maternal mental health (20)[C].
- However, case-control studies have shown an increased incidence of diagnosing childhood migraine headaches in patients with a history of colic during infancy (21)[B].

R10.83 Colic

## Clinical Pearls

**&NA;**

- Colic is defined as excessive crying in an otherwise healthy baby.
- Excessive crying may be a risk factor for shaken baby syndrome or other forms of child abuse.
- Usually subsides spontaneously by 3 to 6 months of age
- Provide advice, support, and reassurance to parents.
- Prevent caregiver burnout by advising parents to get proper rest breaks, sleep, and help in caring for the infant.

# Colitis, Ischemic

Pia Prakash, MD

Mohammed Abdalaziz Wazzan, MD, MBBS

Marie L. Borum, MD, EdD, MPH

## BASICS

Ischemic colitis (IC) results from decreased blood flow to the colon with resultant inflammation and tissue damage.

## DESCRIPTION

- More common in the elderly but can affect patients of all ages
- Patients present in several ways:
  - *Nonacute IC* from a chronic process with irreversible ischemic injury
  - *Acute process* with self-limited transient mucosal ischemia
- IC is self-limited and reversible in 80% of patients:
  - 20% of patients progress to full-thickness necrosis requiring surgical intervention.
- Most commonly, ischemia is related to a nonocclusive reduction in blood flow:
  - Occlusive events are less common.
- Presentation varies, but patients with acute IC typically present with localized abdominal pain and tenderness. Frequent loose, bloody stools may be seen within 12 to 24 hours of onset.
- Laboratory and radiographic findings are nonspecific and must be correlated with clinical presentation.
- Colonoscopy is the gold standard for diagnosis of IC.
- In the absence of complications, most patients recover with supportive care including IV fluids, bowel rest, and clinical monitoring.

## EPIDEMIOLOGY

- Men and women are at equal risk.
- Patients with inflammatory bowel disease or COPD have an increased risk.

- Evidence of IC seen in 1 of every 100 endoscopies

## *Geriatric Considerations*

Rare in patients <60 years old. 70 years is the average age at diagnosis.

## *Incidence*

- 4.5 to 44 cases per 100,000 in the general population
- 1 of every 2,000 hospital admissions
- True incidence may be underestimated due to nonspecific clinical manifestations.

## *Prevalence*

19 cases per 100,000 in the general population

## **ETIOLOGY AND PATHOPHYSIOLOGY**

- Reduced blood flow to the colon, compromises the ability to meet metabolic demands
- Most commonly, an acute, self-limited process
- The colon is perfused by both the superior and inferior mesenteric arteries (SMAs and IMAs) and branches of the internal iliac arteries. Occlusion of branches of the SMA or IMA rarely leads to ischemic consequences due to extensive collateral circulation.
- Watershed areas of the colon (splenic flexure and rectosigmoid junction) are most susceptible to ischemic damage. Blood is carried by narrow branches of the SMA and IMA to these areas, putting them at increased risk for ischemia. The splenic flexure is supplied by the terminal branches of the SMA, and the rectosigmoid junction is supplied by the terminal branches of the IMA.
- Left colon is more commonly affected than the right.
- The rectum is often spared because of additional blood supply from the internal iliac arteries.
- Poor perfusion may result from systemic disease, local vascular compromise, and anatomic or functional changes in the colon itself. An occlusion of large vessels is usually not identified.
  - Hypoperfusion from shock, trauma
  - Embolic occlusion of mesenteric vessels
  - Hypercoagulable states, vasculitis
  - Sickle cell disease

Arterial thrombosis; venous thrombosis

- Mechanical colonic obstruction (e.g., tumor, adhesions, hernia, volvulus, prolapse, diverticulitis)
  - Surgical complications (e.g., related to abdominal aortic aneurysm repair)
  - Medications (intestinally active vasoconstrictive substances, medications that induce hypotension and thus, hypoperfusion)
  - Cocaine abuse
  - Aortic dissection
  - Strenuous physical activity (e.g., long-distance running)
- Acute IC is largely self-limited and often resolves without long-term complications.
  - Repeated episodes of ischemia and inflammation may result in chronic colonic ischemia, possible stricture formation, recurrent bacteremia, and sepsis. These patients may have unresolving areas of colitis and require segmental colonic resection.

## ***RISK FACTORS***

- Age >60 years (90% of patients)
- Smoking (most common cause of recurrent IC) (1)
- Hypertension, diabetes mellitus
- Rheumatologic disorders/vasculitis
- Cerebrovascular disease, ischemic heart disease
- Recent abdominal surgery
- Constipation-inducing medications
- History of vascular surgery
- Hypoalbuminemia; hemodialysis
- Smoking, hypercoagulability, oral contraceptive (2)
- AAA repair (IMA ligation) (2)
- IBS-C (related to treatment with serotonin antagonist) (2)

## **DIAGNOSIS**

- Diagnosis is based on history, risk factors, and physical examination (3)[A].

- Laboratory values and radiographic findings are usually nonspecific (3)[A].
- Colonoscopy is diagnostic (3)[A].

## **HISTORY**

- Abdominal pain is the most common symptom (4).
- Symptoms vary depending on severity (5)[A].
- Sudden-onset, mild to moderate abdominal pain with tenderness over the affected segment of bowel (3)[A]
- Sudden urge to defecate followed by passage of either bright red or maroon stool (5)[A]
- Lower GI bleeding is rarely heavy (3)[A].
- Loose, bloody bowel movements may occur, typically within 12 to 24 hours of abdominal pain onset (5)[A].

## **PHYSICAL EXAM**

- Individual signs and symptoms are poorly predictive of IC (6)[A].
- Vital signs: hypotension; tachycardia
- Tenderness to palpation over the involved segment of bowel (5)[A]
- Abdominal distention with vomiting due to an associated ileus (3)[A]
- In the uncommon setting of transmural ischemia, patients may develop peritoneal signs such as rebound and guarding (7)[A].

## **DIFFERENTIAL DIAGNOSIS**

- Infectious colitis (7)[A]
- Inflammatory bowel disease (ulcerative colitis, Crohn disease) (7)[A]
- Colon cancer (7)[A]; diverticulitis (7)[A]
- Pseudomembranous colitis (6)[A]

## **DIAGNOSTIC TESTS & INTERPRETATION**

- Depends on the clinical presentation, extent of colonic involvement, transmural involvement, and acuity (3)[A].
- CT scan is the initial diagnostic test for patients with nonspecific abdominal pain (6)[A].
- Colonoscopy is the most sensitive diagnostic test (3)[A].

- Radiographic tests and laboratory values are nonspecific (6)[A].

### *Initial Tests (lab, imaging)*

- The following lab markers of ischemia are not specific to IC and are more common in severe ischemia (6)[A]:
  - CBC (leukocytosis) (6)[A]
  - BMP, ABG (signs of metabolic acidosis) (6)[A]
  - Lactate (6)[A], CPK (6)[A]
  - Alkaline phosphatase (6)[A]
  - Lactate dehydrogenase (LDH) (6)[A], amylase (6)[A]
  - Procalcitonin (8)
  - Hypoxia inducible factor 1-alpha (9)
  - Abdominal plain film should be obtained:
    - 20% of patient show signs of IC such as thumbprinting and mural thickening (7)[A].
    - Necessary to rule out bowel perforation and pneumoperitoneum (7)[A]
- No role for routine mesenteric angiography (3)[A], but it can help detect the cause of IC (10).
- Abdominal CT scan with contrast should be obtained in suspected IC (3)[A]:
  - The most common CT findings are moderate continuous circumferential thickening of colonic wall and pericolonic fat stranding (10).
  - Other common CT findings include hyperdense mucosa, submucosal edema, and mesenteric inflammation (3)[A].
  - Pneumatosis, pneumoperitoneum, and free peritoneal fluid suggest advanced ischemia (3)[A].

### *Follow-Up Tests & Special Considerations*

- Stool cultures, fecal leukocytes, stool ova, and parasites to rule out infection (6)[A]
- Patients undergoing aortic surgery may need postoperative colonoscopy within 2 to 3 days to look for signs of IC (5)[A].
- Cardiac workup including electrocardiogram, Holter monitoring, or transthoracic echocardiogram to exclude cardiogenic embolism as indicated (6)[A].

## *Diagnostic Procedures/Other*

- Colonoscopy is gold standard; sigmoidoscopy also used (3)[A]
- Cyanotic hemorrhagic tissue and edematous mucosa suggests ischemia (5)[A].
  - Segmental distribution (watershed), hemorrhagic nodules, and rectal sparing (5)[A]
  - Colon single-stripe sign is a single line of erythema, with a 75% histopathologic yield (5)[A].
  - Routine biopsy is no longer advised, as results are typically nonspecific (3)[A].
- In cases of isolated right colon ischemia, noninvasive vascular imaging studies are recommended to evaluate acute SMA occlusion (5)[A].

## *Test Interpretation*

- Fulminant gangrenous IC seen in 15% of cases requires surgical intervention (3)[A].
- Acute transient IC seen in 85% of cases requires clinical evaluation for further workup (3)[A].
- Biopsied specimens reveal mucosal infarction and ghost cells, which show normal cellular outlines but lack intracellular contents (3)[A].

## **TREATMENT**

- Treatment depends on disease severity (3)[A].
- Continuous clinical monitoring, including vital signs and serial abdominal exams (7)[A]
- In the absence of colonic necrosis or perforation, most patients respond to supportive care (5)[A]:
  - Bowel rest (5)[A]
  - IV fluids to maintain hemodynamic stability (5)[A]
  - Broad-spectrum antibiotics to cover aerobic and anaerobic bacteria to avoid bacterial translocation secondary to colonic mucosal damage (5)[A]
    - Ciprofloxacin 400 mg IV BID or 500 mg PO BID
    - Metronidazole 500 mg PO/IV TID
  - Avoid intestinally active vasoconstrictive medications (5)[A].
  - Avoid systemic corticosteroids, which may worsen ischemic damage and increase risk of

perforation (3)[A].

- If ileus is present, place nasogastric tube (3)[A].
- If radiographic abnormalities are present, serial abdominal x-rays help follow improvement (5)[A].
- If signs of clinical deterioration are present despite supportive care, including increased abdominal pain, peritoneal signs, persistent diarrhea, bleeding, or sepsis, consider surgery (3)[A].

## **MEDICATION**

- Broad-spectrum antibiotics (i.e., metronidazole, ciprofloxacin) (5)[A]
- If cardiac workup reveals CHF or cardiac arrhythmias, initiate appropriate medical treatment (5)[A].

## **ADDITIONAL THERAPIES**

Stem cell implantation in ischemic colonic wall in a rat model enhanced tissue healing by promoting angiogenesis (11)[B].

## **SURGERY/OTHER PROCEDURES**

- 20% of patients require surgical intervention (12)[A].
- Evidence of pneumatosis intestinalis, portal vein air, or free peritoneal air are indications for immediate surgery (3)[A].
- Surgery may be indicated for the following:
  - Peritoneal signs, increased abdominal tenderness, new-onset shock, lactic acidosis, or acute renal failure (3)[A]
  - Diarrhea, lower GI bleeding, or exudative colitis persisting past 14 days (3)[A]
- Most common surgical intervention is colectomy with end ileostomy (6)[A].
  - Cholecystectomy may prevent resuscitation-related acute acalculous cholecystitis (3)[A].

## **ONGOING CARE**

### **DIET**

- Bowel rest until symptoms resolve

- Parenteral nutrition for patients needing prolonged bowel rest who have contraindications to surgery.

## PROGNOSIS

- In most patients, IC symptoms resolve in 24 to 48 hours.
- Radiographic or endoscopic resolution within 2 weeks.
- Right-sided IC appears to be the most significant predictor of outcome. Patients with right-sided IC have a 2-fold increase in mortality and a 5-fold increase in morbidity.
- Secondary cardiovascular prevention minimizes recurrence.
- Male gender, low hemoglobin, low serum albumin, high BUN, and presence of metabolic acidosis are poor prognostic factors (2)
- Chronic kidney disease, COPD, long-term care facilities increase mortality in IC (2,13)

## COMPLICATIONS

20-30% of patients develop chronic IC, with persistent diarrhea or stricture formation requiring surgical intervention.

## Codes

**&NA;**

## **ICD10**

- K55.9 Vascular disorder of intestine, unspecified
- K55.0 Acute vascular disorders of intestine
- K55.1 Chronic vascular disorders of intestine

## **Clinical Pearls**

**&NA;**

- Suspect IC in patients with multiple risk factors who present with abdominal pain and loose bloody stools.
- Colonoscopy is the diagnostic gold standard.
- Most often, IC is self-limited, responding well to conservative management with IV fluids, bowel rest, and empiric broad-spectrum antibiotics.
- Peritoneal signs or lack of clinical improvement suggests more extensive ischemia and require surgical intervention.
- Right-sided IC is associated with higher morbidity and mortality.

# Colonic Polyps

Marcelle Meseeha, MD

Maximos Attia, MD

## BASICS

### DESCRIPTION

- Intraluminal colonic protrusions; most commonly sporadic, or part of polyposis syndromes.
- Classified according to size:
  - Diminutive  $\leq$ 5 mm, small 6 to 9 mm, large  $\geq$ 10 mm (1)
- Morphologic classification:
  - Depressed, flat, sessile, or pedunculated
- Clinical significance:
  - >95% of colon adenocarcinoma arise from polyps.

### EPIDEMIOLOGY

Colorectal polyps are more common in:

- Western countries
- Men
- Non-Caucasian (2)

### Incidence

Incidence increases with age.

### Prevalence

- 15-20% of all adults
- 30% of U.S. population >50 years
- 6% of children (2)

12% of children with lower GI bleed (2)

## ETIOLOGY AND PATHOPHYSIOLOGY

Divided into:

- Mucosal
  - Neoplastic
    - Adenomatous polyps (tubular >80%, villous 5-15%, tubulovillous 5-15%)
    - Serrated polyps
      - Sessile serrated polyps are common, more in proximal colon, with low malignant potential if with no dysplasia, and significant malignant potential if dysplastic.
      - Traditional serrated adenoma is uncommon, more often noted in distal colon, with significant malignant potential (1).
  - Non-neoplastic polyps (hyperplastic, juvenile polyps, hamartomas, inflammatory pseudopolyps)
    - Hyperplastic polyps are very common, more in distal colon, with very low malignant potential (1).
    - Juvenile polyps are common in childhood, benign hamartomas, more in rectosigmoid, and not premalignant (2).
- **Submucosal** (lipomas, lymphoid aggregates, carcinoids)

## Genetics

- Inactivation of tumor suppressor genes as adenomatous polyposis coli (APC) or mismatch repair genes (*MLH1*) causes polyps to grow into cancer.
- Familial adenomatous polyposis (FAP) is autosomal dominant. By age 40, almost all patients develop colorectal cancer (CRC).
- MUTYH-associated polyposis (MAP) is autosomal recessive caused by biallelic mutations in MUTYH gene.
- Juvenile polyposis syndrome (JPS) is autosomal dominant. 50-60% of patients have a mutation in the *SMAD4* or *BMPR1A* gene. By age 35, 20% of patients develop CRC (2).

## RISK FACTORS

- Family history of intestinal polyposis, polyps, or CRC

- Advancing age
- Male
- High-fat, low-fiber diet
- Tobacco use
- Excessive alcohol intake: >8 drinks a week
- Inflammatory bowel disease is associated with a decreased prevalence of colon polyps (IBD associated with higher risk of colon cancer).

## ***GENERAL PREVENTION***

- Low-fat, high-fiber diet
- Avoid smoking.
- Decrease alcohol intake.
- Use of NSAIDs and calcium is associated with decreased incidence and recurrence of polyps (3)[A].
- No lower rates of CRC with azathioprine, 6-mercaptopurine, folate, calcium, multivitamins, or statins

## ***COMMONLY ASSOCIATED CONDITIONS***

Hereditary polyposis syndromes:

- Adenomatous
  - Familial adenomatous polyposis (FAP)
    - Classic (CFAP)
    - Attenuated (AFAP)
  - MUTYH-associated polyposis (MAP)
  - FAP variants:
    - Gardner syndrome
    - Turcot syndrome
- Hamartomatous
  - Peutz-Jeghers syndrome (PJS)
  - Juvenile polyposis syndrome (JPS)

- Familial juvenile polyposis
- Cowden syndrome

## **ALERT**

JPS impose a higher risk of CRC, although juvenile polyps are not premalignant.

## **DIAGNOSIS**

### **HISTORY**

- Usually normal
- Generally asymptomatic
- Painless rectal bleeding, bright or dark red, mixed with stools, dripping, or on wiping
- Diarrhea or mucous stool
- Abdominal pain
- Constipation
- Chronic bleeding resulting in iron deficiency anemia
- McKittrick-Wheelock syndrome; large hypersecretory rectosigmoid villous adenoma, resulting in persistent severe diarrhea, electrolyte disorder, dehydration, and prerenal acute renal failure
- Social and family history

### **PHYSICAL EXAM**

- Usually normal
- Rectal polyps noted as prolapsed or palpated on DRE
- FOBT by DRE is less effective than FOBT by stool passed spontaneously.

### **DIAGNOSTIC TESTS & INTERPRETATION**

#### *Initial Tests (lab, imaging)*

- CBC; anemia with chronic bleeding
- Basic metabolic panel; electrolyte disorder with hypersecretory adenomas
- Fecal occult blood test (FOBT), an insensitive screening test, as small polyps don't usually bleed, includes:

- Guaiac (gFOBT)Ñuses a chemical indicator with color change in presence of blood
- Immunochemical (iFOBT or fecal immunochemical test [FIT])Ñuses antibodies against human hemoglobin
- Stool DNA test is more sensitive and less specific than fecal immunochemical test (FIT).

## *Diagnostic Procedures/Other*

- Colonoscopy is the gold standard test for detection of polyps and polypectomy. Not a perfect screening test, with increased miss rate with right-sided colon polyps, smaller polyp size, low quality of colon prep, less endoscopist experience
- Computed tomographic colonography (CTC) is less sensitive with flat polyps and requires excellent bowel preparation.
- Double-contrast barium enema
- Colon capsule endoscopy
- Enhanced optical technologies can potentially differentiate between neoplastic and non-neoplastic colonic lesions (4)[A].
- Enhanced optical technologies include:
  - Narrowed spectrum endoscopy (narrow-band imaging [NBI])
  - Image-enhanced endoscopy (i-scan)
  - Fujinon intelligent chromoendoscopy (FICE)
  - Confocal laser endomicroscopy (CLE)
- Patients with >10 colorectal adenomas should get genetic testing for APC and MUTYH (5)[C].

## *Test Interpretation*

- Tubular adenoma
  - Gross: tend to be polypoid
  - Micro: dysplastic epithelium with a tubular architecture
- Villous adenoma
  - Gross: tend to be sessile
  - Micro: dysplastic epithelium with fine finger-like projections
- Tubulovillous adenomas have a combination of tubular and villous architecture.

- Hyperplastic polyps are composed of hyperplastic colonic mucosa.
- Hamartomatous polyps include muscularis mucosa.
- Juvenile polyp
  - Gross: pedunculated, smooth, red mass, 1 to 3 cm (2).

## TREATMENT

### *SURGERY/OTHER PROCEDURES*

- Colonic polypectomy; diagnostic, therapeutic
- Techniques are as follows:
  - Snare polypectomy with electrocautery for pedunculated polyps
  - Endoscopic mucosal resection for sessile polyps
  - Endoscopic submucosal dissection

P.213

- Colorectal surgery; prophylactic in FAP and MAP and when there are numerous polyps or persistent bleeding (2,5)[C]:
  - Total colectomy ileorectal anastomosis
  - Proctocolectomy ileal pouch anal anatomosis
- Chemoprevention: NSAIDs and calcium may reduce incidence and recurrence of polyps in patients with FAP and MAP (3)[A].

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

Follow-up colonoscopy in:

- 10 years if no polyps or distal small hyperplastic polyps (<10 mm) (1)[B]
- 5 to 10 years if 1 to 2 small tubular adenomas (<10 mm) (1)[B]
- 3 years if 3 to 10 adenomas if any polyp  $\geq 6$  mm (1)[B] or if all polyps <6 mm (1)[C]
- <3 years if >10 adenomas (1)[B]

3 years if one or more adenomas  $\geq 10$  mm (1)[A]

- 3 years if one or more adenomas with villous features of any size or with HGD (1)[B]
- 5 years if sessile serrated polyp(s)  $< 10$  mm with no dysplasia (1)[C]
- 3 years if sessile serrated polyp(s)  $\geq 10$  mm or with dysplasia or traditional serrated adenoma (1)[C]
- 1 year if serrated polyposis syndrome (1)[B]

## *Patient Monitoring*

- Colonoscopy for CRC screening starts at age 50 years and earlier for at-risk patients.
- Stop screening if life expectancy is  $< 10$  years.
- In CFAP and AFAP, screen for extracolonic manifestations: thyroid cancer, desmoid tumors, and gastroduodenal polyposis (every 6 months to 5 years) (5)[C]
- In families, lifetime screening is indicated in mutation carriers (5)[C]:
  - In CFAP: with sigmoidoscopy or colonoscopy every 1 to 2 years starting at age of 10 to 11 years
  - In AFAP and MAP: with colonoscopy every 1 to 2 years starting at age of 18 to 20 years
- After colorectal surgery, surveillance of the rectum (every 6 to 12 months) or pouch (every 6 months to 5 years) is indicated (5)[C].
- First-degree relatives of patients with JPS require screening by colonoscopy and upper endoscopy after age 12 (2)[C].

## *DIET*

Low-fat, high-fiber diet has been recommended but with insufficient evidence.

## *PATIENT EDUCATION*

Importance of colonoscopy as a screening tool for reduction of incidence of colorectal cancer

## *PROGNOSIS*

- Regression or no change in size, more with small hyperplastic polyps and with patients on NSAIDs
- Recurrence: Juvenile polyps recur in 45% of children with multiple polyps and 17% of children with solitary polyps (2).
- Increase in size, more with large adenomas

- Progression to cancer
- Risk factors for colon cancer (6)[A]:
  - Polyp pathology
    - Adenomatous
    - Serrated
    - With high-grade dysplasia
    - With >25% villous histology
    - Polyp size >1 cm in diameter
    - Polyps located in proximal colon
    - More than three polyps
- Recurrence rates <10% postpolypectomy

## COMPLICATIONS

- Polyps: progression to cancer
- Polypectomy: bleeding 2-11%, perforation 0-1%, higher with endoscopic submucosal dissection
- Colonoscopy: complications related to anesthesia and procedure itself

## See Also

### &NA;

## Codes

**&NA;**

### ICD10

- K63.5 Polyp of colon
- D12.6 Benign neoplasm of colon, unspecified
- K51.40 Inflammatory polyps of colon without complications

## Clinical Pearls

**&NA;**

- Progression from normal mucosa to polyp to carcinoma is a sequence that takes years to develop.
- Colonoscopy is the gold standard tool for diagnosis of polyps and reduction of CRC incidence.
- Small hyperplastic polyps should be biopsied to differentiate adenomatous and serrated polyps.
- Use of NSAIDs and calcium is associated with decreased incidence and recurrence of polyps.

# Colorectal Cancer

Stephen Scott, MD, MPH

## BASICS

### DESCRIPTION

- Colorectal cancer (CRC) denotes a neoplasm that develops in the colon or rectum.
- CRC is the second leading cause of cancer deaths and is the third most common cancer in men and women in the United States.
- Screening for CRC reduces the incidence of and mortality from CRC.

### EPIDEMIOLOGY

#### *Incidence*

93,090 new cases of colon cancer; 39,610 new cases of rectal cancer; and 49,700 deaths from colon and rectal cancer combined were estimated in the United States in 2015 (1).

#### *Prevalence*

- The lifetime risk for developing CRC in the United States is about 1 in 21 (4.8%).
- Incidence and death rates have been declining due to improved screening, prevention, and treatment.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Progression from the first abnormal cells to the appearance of CRC usually occurs over 10 to 15 years; a disease characteristic that contributes to the effectiveness of prevention.
- High-risk polyp findings include multiple polyps, villous polyps, and larger polyps.
- Hyperplastic polyps are less likely to evolve into CRC.
- Multiple genetic and environmental factors have been linked to the development of CRC.

#### *Genetics*

- There does not seem to be a single genetic pathway to CRC.

- <10% of CRC cases are linked to an inherited gene
  - APC, a tumor suppressor gene, is altered in familial adenomatous polyposis (FAP).
  - Genes encoding DNA mismatch repair (MMR) enzymes are implicated in hereditary nonpolyposis colon cancer (HNPCC): MLH1, MSH2, MSH6, PMS1, PMS2, and others.
  - STK11, a tumor suppressor gene, is altered in Peutz-Jeghers syndrome.
- Sporadic cases of CRC have been linked to oncogenes: Kras, c-Myc, c-Src, HER-2/neu, and others.

## *RISK FACTORS*

- Age: >90% of people diagnosed with CRC are >50 years of age.
- Personal history of colorectal polyps
  - Risks increase with multiple polyps, villous polyps, and larger polyps.
- Personal history of cancer
  - Rectal cancer has higher incidence of local recurrence than proximal cancers (20-30% vs. 2-4%).
- History of inflammatory bowel disease
  - Prevalence of CRC in ulcerative colitis and Crohn disease is  $\div$ 3%, with a cumulative risk of CRC of 2% at 10 years, 8% at 20 years, and 18% at 30 years.
- Family history of CRC
  - Having a single first-degree relative with a history of CRC increases risk 1.7-fold.
  - Risk is more than double for those who have a history of CRC or polyps in:
    - Any first-degree relative <60 years of age
    - $\geq$  2 first-degree relatives, regardless of age
- Inherited syndromes
  - HNPCC also called Lynch syndrome.
    - Often develops at younger age (Average age at diagnosis of CRC is 44 years.)
    - Lifetime risk of CRC is 52-69%.
    - Accounts for  $\div$ 2% of all CRCs
  - FAP

- Affected individuals develop hundreds to thousands of polyps in colon and rectum.
- CRC usually present by age 40 years.
- Accounts for ÷1% of CRCs
- Peutz-Jeghers syndrome
  - Individuals may have freckles (mouth, hands, feet) and large polyps in GI tract.
  - Greatly increased risk for CRC and cancers
- Race and ethnicity
  - African Americans have the highest CRC incidence and mortality rates in the United States.
  - Several different gene mutations have been identified among Ashkenazi Jews.
- Miscellaneous
  - Patients with obesity, diabetes, acromegaly, smoking, and alcohol use are at increased risk.

## **GENERAL PREVENTION**

- Diets high in fruits and vegetables have been linked with decreased risk; those high in red and processed meats may increase CRC risk.
- Some studies suggest that vitamin D, calcium, folate, and fiber may lower CRC risk; more research is needed to understand how diet affects risks of CRC.
- People who are physically inactive are at higher risk for CRC.
- Long-term smokers are more likely than nonsmokers to develop and die from CRC.
- CRC has been linked to heavy alcohol consumption; may be related to low folate intake or absorption
- NSAIDs may reduce risk in some groups; experts do not recommend NSAID use as a cancer prevention strategy in people at average risk for CRC.
- Colon cancer screening is one of the most powerful tools in preventing colon cancer.

### **ALERT**

The U.S. Preventive Services Task Force (USPSTF) strongly recommends that clinicians screen men and women between the ages of 50 and 75 years for CRC using fecal occult blood testing, sigmoidoscopy, or colonoscopy.

- American Cancer Society recommendations for screening include the following (2):

Fecal occult blood testing annually

- Fecal immunochemical test (FIT) annually
  - Flexible sigmoidoscopy every 5 years
  - Colonoscopy every 10 years
  - CT colonography every 5 years (colonoscopy completed if positive)\*
  - Double-contrast barium enema every 5 years\*
  - Stool DNA test (sDNA) every 3 years\*
  - \*The USPSTF does not recommend barium enema as a screening test and concludes the evidence is insufficient to assess the benefits and harms of CT colonography and stool DNA testing as screening modalities for CRC.
- Screening in high-risk groups
    - People with a personal history of polyps need more frequent colonoscopy screening, depending on risk (i.e., 1 or 2 <1-cm polyps with low-grade dysplasia is deemed low-risk and may warrant repeat colonoscopy in 5 to 10 years; decision is influenced by family history, age, quality of initial colonoscopy, and patient comorbidities).
    - People who have a family history of CRC or adenomatous polyps before age 60 years should begin colonoscopy at age 40 or 10 years younger than the age of relative at cancer diagnosis, whichever is earlier.
    - People with inflammatory bowel disease should have regular surveillance colonoscopy with biopsies to detect dysplasia; guidelines for timing and location vary by professional society but generally indicate starting surveillance by  $\pm$ 8 years of onset of disease followed by surveillance every 1 to 2 years.
    - Genetic testing may be appropriate for individuals with a strong family history of CRC or polyps:
      - Family members of a person affected by HNPCC should start colonoscopy surveillance as early as age 20 years.
      - Individuals with suspected FAP should have yearly flexible sigmoidoscopy beginning at age 10 to 12 years; those who test positive for the gene linked to FAP may consider colectomy.

## DIAGNOSIS

### HISTORY

- Many patients with CRC are asymptomatic.
- Common presenting symptoms and signs in symptomatic patients include the following:
  - Abdominal pain or cramping
  - Change in bowel habits (constipation, diarrhea, narrowing of stool)
  - Rectal bleeding, dark stools, or blood in stool
  - Weakness or fatigue
  - Anemia
  - Weight loss
- Other presentations may include symptoms due to the presence of metastatic lesions (lymph nodes, liver, lung, peritoneum), fever of unknown origin, and *Streptococcus bovis* or *Clostridium septicum* sepsis.

## PHYSICAL EXAM

- Weight loss
- Signs of anemia (i.e., conjunctival pallor)
- Palpable abdominal mass

## DIFFERENTIAL DIAGNOSIS

- >95% of CRCs are adenocarcinomas.
- Other colonic tumors include carcinoid tumors, lymphomas, and Kaposi sarcoma in HIV.
- Many conditions can mimic CRC, including other cancers, hemorrhoids, inflammatory bowel disease, infection, and extrinsic masses (i.e., cysts, abscesses).

---

P.215

## DIAGNOSTIC TESTS & INTERPRETATION

### *Initial Tests (lab, imaging)*

- CBC (to evaluate anemia)
- Liver function (CRC may spread to the liver)
- Colonoscopy
- CT colography if colonoscopy incomplete

## *Follow-Up Tests & Special Considerations*

- Carcinoembryonic antigen (CEA) should be obtained preoperatively to assist with follow-up screening.
- CT to evaluate presence of metastatic disease
- Chest x-ray to evaluate presence of chest metastases
- Endoscopic ultrasound (EUS) may be used to evaluate the extent of rectal cancers; endorectal MRI may also provide further detail.
- Intraoperative US may be used to evaluate solid organs (e.g., the liver) after tumor resection.
- Positron emission tomography (PET) may be used in some cases to detect metastatic disease.

## *Diagnostic Procedures/Other*

- Biopsy is usually performed (most often during colonoscopy) if CRC is suspected.
- CT needle-guided biopsy may be needed to evaluate a suspected tumor or metastasis.

## *Test Interpretation*

The American Joint Committee on Cancer (AJCC) TNM staging is preferred

- Stage 0: limited to the mucosa (carcinoma in situ or intramucosal carcinoma (Tis, N0, M0)
- Stage I: invades mucosa (T1) or muscularis propria (T2); no invasion of lymph nodes or distant sites (T1, N0, M0 or T2, N0, M0)
- Stage IIA: invades pericolorectal tissues; no lymph nodes or distant sites (T3, N0, M0)
- Stage IIB: penetrates to surface of visceral peritoneum; no lymph nodes or distant sites (T4a, N0, M0)
- Stage IIC: directly invades or adherent to other organs or structures (T4b, N0, M0)
- Stage IIIA: invades submucosa or muscularis propria with spread to 1 to 3 lymph nodes; no distant sites (T1, N1, M0 or T2, N1, M0)
- Stage IIIB: invades pericolorectal tissues or surface of visceral peritoneum + spread to 1 to 3 lymph nodes; no distant sites (T3, N1, M0, or T4a, N1, M0)
- Stage IIIC: invades pericolorectal tissues or peritoneum or other organs and to <sup>3</sup>/<sub>4</sub> nearby lymph nodes; no distant sites (any T3 or T4, N2, M0)
- Stage IVA: any level of invasion with spread to one organ or site (any T, any N, M1a)
- Stage IVB: any level of invasion with spread to more than one organ or site or peritoneum (any T, any N, M1b)

## TREATMENT

### MEDICATION

Surgical resection is the primary treatment for CRC, as noted in the following texts. Adjuvant chemotherapy is most clearly beneficial for stage III (node-positive) disease, in which improvements of  $\div 30\%$  may be achieved in both disease recurrence and overall survival, compared with nontreated controls. Chemotherapeutic regimens for metastatic disease may extend overall survival from 6 months to  $\div 2$  years (3)[B].

#### *First Line*

Combination chemotherapy is common and may include oxaliplatin, irinotecan, fluorouracil, leucovorin, and capecitabine.

#### *Geriatric Considerations*

Elderly patients tend to tolerate CRC chemotherapy and should be considered for treatment.

#### *Second Line*

Targeted therapies may be used alongside first-line agents or alone if first-line agents are ineffective

- Bevacizumab (Avastin) is a monoclonal antibody that targets vascular endothelial growth factor (VEGF); inhibits angiogenesis
- Cetuximab (Erbix) and panitumumab (Vectibix) are monoclonal antibodies that target epidermal growth factor receptor (EGFR).
- Aflibercept and regorafenib are newer agents with actions on VEGF.

### SURGERY/OTHER PROCEDURES

- Surgery is the primary treatment for localized CRC
  - May involve segmental resection, hemicolectomy, or colectomy, as well as resection of nodes, depending on size and invasion
  - Laparoscopic-assisted colectomy is an emerging option for earlier stage tumors.
  - Surgery for rectal cancer may include local transanal, low anterior, or abdominoperineal resection or pelvic exenteration.
- Radiation therapy is most often used for peritoneal or rectal cancers; it may also be used to

relieve symptoms.

## COMPLEMENTARY & ALTERNATIVE MEDICINE

- May serve as an adjunct to treatment for CRC
- 70-75% of cancer survivors report using at least one type of complementary and alternative medicine (CAM), and almost all report that the alternative therapy improved well-being.

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### *Patient Monitoring*

- People with a personal history of proximal cancer (nonrectal) should have follow-up colonoscopy in 1 year and, if normal, in 3 and 5 years subsequently.
- CEA and/or CA 19-9 are used to detect recurrence in people treated for CRC. (Note: CEA levels may be elevated in ulcerative colitis, nonmalignant GI tumors, liver disease, lung disease, and in smokers.)

### PATIENT EDUCATION

- NIH: Colorectal cancer: <http://www.nlm.nih.gov/medlineplus/colorectalcancer.html>
- NCI: Colorectal cancer: <http://www.cancer.gov/types/colorectal>
- AAFP: Colorectal Cancer: <http://www.aafp.org/afp/2015/0115/p93-s1.html>

### PROGNOSIS

5-year relative survival rate is determined by stage (adjusted for patients dying of other diseases): stage I: 93%; stage II: 72-85%; stage III: 44-83%; stage IV: 8%.

### COMPLICATIONS

- Colorectal surgery: pain, deep vein thrombosis, anastomotic leaks, infection, scarring, bowel obstruction
- Chemotherapy: hair loss, nausea, vomiting, bruising, fatigue, increased risk for infections
- Radiation therapy: skin irritation, nausea, rectal pain, incontinence, bladder irritation, fatigue, and sexual problems

## Codes

&NA;

### ICD10

- C19 Malignant neoplasm of rectosigmoid junction
- C18.9 Malignant neoplasm of colon, unspecified
- C20 Malignant neoplasm of rectum

## Clinical Pearls

&NA;

- The USPSTF recommends screening beginning at age 50 years and notes that evidence supports fecal occult blood testing (yearly), sigmoidoscopy, or colonoscopy (every 10 years).
- High-risk polyp findings include multiple polyps, villous polyps, and larger polyps; hyperplastic polyps are less likely to become cancerous.

- 10% of cases of CRC occur in people <50 years of age. People who have a family history of CRC without other risks (i.e., polyposis syndrome) should begin colonoscopy at age 40 years or 10 years younger than the age of relative at cancer diagnosis, whichever is earlier.
- Iron deficiency anemia in the elderly should prompt a search for CRC and should not be attributed to normal aging.

# Complementary and Alternative Medicine

Paul Crawford, MD

## BASICS

- Complementary and alternative medicine (CAM) are medical and health care systems, practices, and products not presently considered part of conventional medicine.
- The National Center for Health Statistics (NCHS) 2012 survey (1) reports nonvitamin, nonmineral dietary supplements, chiropractic or osteopathic manipulation, yoga, and massage therapy were the most common complementary health approaches used.
- Medical professionals who incorporate CAM into their medical practice will often refer to their health care model as *Integrative medicine*.

## DESCRIPTION

- Definitions and additional terms
  - *Complementary medicine* is used with conventional medicine to address a health concern. For example, massage plus physical therapy to address low back pain or medication plus osteopathic manipulation to address recurrent headaches.
  - *Alternative medicine* is used in place of conventional medicine to promote healing of conditions that cannot be explained by the conventional biomedical model or for which the effectiveness of therapy is not yet established by clinical research.
  - *Integrative medicine* is the combination of allopathic medicine with CAM and may be provided to the patient by a single licensed medical professional trained in CAM or by a group of diverse health care providers.
  - *Holistic* is a descriptive term for a practitioner's approach to patient care. A holistic practitioner assesses the emotional, spiritual, mental, and physical state of wellness of the client, then works to provide comprehensive care. A holistic practice may include practitioners of different disciplines to best address all aspects of wellness or illness.
- *Biologically based therapies*: diets, herbals, vitamins, supplements, flower essences
- Manipulative and body-based methods
  - Massage therapy is the manipulation of the body's soft tissues, whereby the licensed practitioner uses knowledge of anatomy and physiology to restore function, promote

relaxation, and relieve pain. There are several different types of massage.

- Osteopathic manipulative medicine focuses on the musculoskeletal system. It includes indirect techniques (e.g., muscle energy, myofascial release, osteopathy in the cranial field, and strain-counterstrain approach), as well as direct action techniques (high-velocity thrusts).
  - Craniosacral therapy is a gentle manual treatment focusing on the release of bony and fascial restrictions in the craniosacral system (cranium, sacrum, spinal cord, meninges, CSF).
  - Chiropractic therapy focuses on the musculoskeletal and nervous systems and how imbalances in these systems can affect general health. It is used to treat back, neck, and joint pain. Doctors of Chiropractic (DCs) complete 4 to 5 years of intensive training in anatomy, physiology, and manipulation.
- Mind-body medicine
    - Meditation is a practice of detachment in which a person sits quietly, generally focusing on the breath, while releasing all thoughts from the mind with the intention to center the self, restore balance, and enhance well-being. Mindfulness meditation involves making oneself aware of the most immediate of activities in order to gain control over actions and anxiety.
    - Spiritual practices; for example, prayer
    - Yoga is an exercise of mindfulness, meditation, strength, and balance. It is composed of *asanas* (postures) and *pranayamas* (focused breathing).
    - Aromatherapy uses highly concentrated plant extracts to stimulate healing processes. These aromatic oils are rubbed on the skin, aerosolized, or used in compresses.
    - Relaxation techniques include breathing exercises, progressive muscle relaxation, and guided imagery.
    - *Tai chi* and *qi gong* are Chinese exercise systems that combine meditation, regulated breathing, and flowing dance-like movements to enhance and balance *chi* (*qi*), or life force energy.
  - Alternative medical systems
    - Traditional Chinese medicine incorporates Chinese herbs and acupuncture. Acupuncture is the practice of regulating *chi* by inserting hair-thin needles at specific points along meridian pathways of the body. *Chi* movement is responsible for animating and protecting the body; relieving pain; and regulating blood, oxygen, and nourishment to every cell.
    - Ayurvedic medicine originated in India and is one of the world's oldest medical systems. It uses healing modalities and herbs to integrate and balance the body, mind, and spirit.

- Homeopathy is a system of therapy based on the concept that very dilute quantities of an offending agent can stimulate the body's own immune system to produce a reaction against this offense, thereby healing itself. In general, homeopathic remedies are considered safe and unlikely to cause serious adverse reactions. Only three states license homeopaths.
- Naturopathy is based on providing natural and minimally invasive options for prevention and treatment of disease. Treatment regimens can include herbs, vitamins, supplements, dietary counseling, homeopathic remedies, manipulative therapies, acupuncture, and hydrotherapy. Four-year doctoral training programs are available; however, only 20 states/territories have licensing laws for naturopathic practitioners.
- Energy therapies
  - *Reiki*, which means "source energy," is a healing practice from Japan. Laying hands lightly on the patient or holding the hands just above the body, the *reiki* practitioner facilitates spiritual and physical healing by stimulating a patient's life force energy.
- Common reasons patients choose CAM
  - Additive therapy to address aspects not provided for in conventional medical treatment
  - Conventional medicine has been unsuccessful in fully addressing ailment.
  - Preventive health care
  - Desire for a holistic and natural approach to well-being
  - Preference for noninvasive treatment options
  - Concern about side effects of medication
  - Desire for spiritual support to be incorporated into healing practice
  - Cultural or familial belief system may be more aligned with "natural" solutions not provided for or supported by the standard allopathic model of health care.

## EPIDEMIOLOGY

- All ages use CAM, but it is most prevalent among adults aged 30 to 69 years.
- Gender ratio: female > male
- College graduates and residents from western states are more likely to use CAM.
- Cancer survivors are more likely than the general population to use CAM.
- Six most used CAM therapies based on the NCHS 2012 survey. These CAM therapies were used by the indicated percentage of survey participants:
  - Nonvitamin, nonmineral dietary supplements (17.9%)

- Chiropractic and osteopathic manipulation (8.5%)
- Yoga (8.4%)
- Massage (6.8%)
- Meditation (4.1%)
- Special diets (3.0%)

## TREATMENT

- Variable evidence supports safety and efficacy of
    - Meditation for lowering BP (2)[C]
    - Acupuncture for chronic low back pain (3)[B]
    - Acupuncture to improve fertility (4)[C]
    - Spinal manipulative therapy for prophylactic treatment of headaches
    - Ginger for nausea, including that associated with chemotherapy
    - Manipulation, massage, and mobilization for acute low back and posterior neck pain
    - Massage therapy to promote weight gain in preterm infants
    - Massage (30 minutes × 3) during labor shortens the second stage and reduces pain (5)[A].
    - Acupuncture for chemotherapy-induced nausea and vomiting
    - Tai chi for improving balance and decreasing the risk of and fear of falling in elderly
    - Mind-body techniques for migraines, chronic pain, and insomnia
    - Homeopathic remedy for the treatment of chemotherapy-induced stomatitis in children
    - Riboflavin for migraine prophylaxis
    - Horse chestnut seed extract to improve lower leg venous tone, pain, and edema
    - Glucosamine for osteoarthritis and knee pain
    - Yoga and meditation appear to improve endothelial function in patients with CAD and can have potential beneficial effects on depressive disorders.
    - Yoga throughout pregnancy shortens labor by 140 to 190 minutes
- 
- Exercise in both preconception and early pregnancy reduces chance of gestational diabetes mellitus (6)[A].

- Breast stimulation in late pregnancy increases successful induction of labor (NNT 3.2) and reduces postpartum hemorrhage (NNT 19) (7)[A].
- Oral probiotics in preterm infants to decrease necrotizing enterocolitis and reduce mortality (8)[A].
- Oral probiotics to prevent URIs in children and influenza in the elderly (9,10)[A]
- Oral probiotics to shorten the duration of acute and antibiotic-associated diarrhea and as prophylaxis for traveler's diarrhea (10),(11)[A],(12,13)
- Vitamin D 800 IU/day may reduce falls and fractures in the elderly (14)[A].
- *Acupuncture* for recurrent headache
- Evidence supports safety, but evidence regarding efficacy is inconclusive:
  - *Homeopathy* for induction and augmentation of labor
  - Chondroitin sulfate is ineffective for osteoarthritis.
  - *Sterile water injections* do not reduce pain in labor.
  - Omega-3 fatty acids may reduce inflammation and anxiety in young healthy adults.
  - *Dietary fat reduction* for certain types of cancer
  - *Mind-body techniques* for metastatic cancer
  - *Copper and magnetic bracelets* for pain
  - *Vitamin D levels* >30 ng/mL correlate with lower risk of some cancers. Adequate vitamin D intake may decrease atopy and asthma symptoms.
- Evidence supports efficacy, but evidence regarding safety is inconclusive:
  - St. John's wort extract for short-term treatment of depression in adults
  - Licorice for gastritis
- Evidence indicates serious risk:
  - Black cohosh, blue cohosh, and evening primrose oil are unsafe to induce labor.
  - Delay in seeking medical care or replacement of curative conventional treatment
  - Use of toxic herbs or substances
  - Known herb-drug interactions

## ONGOING CARE

### PATIENT EDUCATION

The National Center for Complementary and Integrative Health (<https://nccih.nih.gov/>)

#### COMPLICATIONS

##### ALERT

Ginkgo and St. John's wort account for most herb-drug interactions described in the medical literature.

- Herbs with possible adverse effects
  - Serious adverse events from herbal remedies remain uncommon.
  - Some ethnic medicines, as those prescribed by practitioners of Ayurveda or traditional Chinese medicine, may intentionally contain heavy metals or other toxic substances. These are usually listed by their pharmacopeial names, for example, Qian Dan = lead oxide.
  - Bitter orange (*Citrus sinensis*): sympathomimetic; increases heart rate (HR), BP
  - California poppy (*Eschscholzia californica*): may cause respiratory depression, drowsiness; contains opioids
  - Cascara sagrada (*Frangula purshiana*): depletes serum potassium
  - Chaparral (*Larrea tridentata*): hepatotoxic
  - Ephedra (*Ephedra* spp.): sympathomimetic; increases HR, BP; insomnia, gastric distress
  - Ginkgo (*Ginkgo biloba*): extravasation, increased bleeding time
  - Guarana (*Paullinia cupana*): tachycardia, hypertension; contains caffeine
  - Kava (*Piper methysticum*): decreases use of niacin; possibly hepatotoxic
  - Licorice (*Glycyrrhiza* spp.): Long-term use depletes serum potassium.
  - Lily of the valley (*Convallaria majalis*): contains cardiac glycosides
  - Poke root (*Phytolacca species*): strong gastric irritant, may cause sedation
  - Senna (*Cassia senna*): depletes serum potassium
  - Snakeroot (*Aristolochia* spp.): nephrotoxic
  - St. John's wort (*Hypericum perforatum*): numerous drug interactions; induces CYP(3a4) pathway, speeding metabolism of many drugs
  - Wormwood (*Artemisia absinthium*): elevates serotonin level, may raise BP

Yohimbe (*Pausinystalia yohimbe*): elevates BP

### **Geriatric Considerations**

Gingko biloba commonly interacts with Coumadin.

### **Pediatric Considerations**

#### **ALERT**

Iron is a leading cause of accidental poisoning in children <6 years of age. Minerals (i.e., potassium, calcium, magnesium, zinc, copper, and selenium) may cause toxicity.

- Vitamin A is most common cause of hypervitaminosis.
- Beta-carotene may have a limited potential for overdose.

## Codes

**&NA;**

Z76.89 Persons encountering health services in other specified circumstances

## Clinical Pearls

**&NA;**

- Oral probiotics reduce respiratory and diarrheal infections and reduce mortality in preterm infants.
- Acupuncture is effective for back pain, headaches, and infertility.

- Yoga and breast stimulation shorten labor.
- Ginkgo and St. John's wort account for most herb-drug interactions described in the medical literature.

# Complex Regional Pain Syndrome

Dennis E. Hughes, DO, FACEP

## BASICS

### DESCRIPTION

- Complex regional pain syndrome (CRPS) is a pain syndrome that is seemingly disproportionate in time or degree to any known trauma or lesion.
  - Type I: no nerve injury (reflex sympathetic dystrophy [RSD])
  - Type II: associated with a demonstrable nerve injury (causalgia)
- Synonym(s): traumatic erythromelalgia; Weir Mitchell causalgia; causalgia; reflex sympathetic dystrophy; posttraumatic neuralgia; sympathetically maintained pain

### EPIDEMIOLOGY

- Incidence of 5.46/100,000 and prevalence of 20.57/1,000,000 in United States
- Peak age 50 to 70 years
- Predominant gender: female > male (3:1, 60-81%); favoring postmenopausal
- Recent studies found 3.8% occurrence after wrist fracture and 7% occurrence after intra-articular ankle fracture—both independent high risk for CRPS (1)[B].
- More prevalent in patients that report higher than usual expected pain in early phases of trauma (1)[B].

### ETIOLOGY AND PATHOPHYSIOLOGY

- Poorly understood activation of abnormal sympathetic reflex that lowers pain threshold.
  - Increased excitability of nociceptive neurons in the spinal cord; Ócentral sensitizationÓ
  - Exaggerated responses to normally nonpainful stimuli (hyperalgesia, allodynia)
- Other than known nerve injury (type II or causalgia), no known definitive pathogenesis

### Genetics

No known genetic pattern

## *RISK FACTORS*

- Minor or severe trauma (upper extremity fracture noted in 44%)
- Surgery (particularly carpal tunnel release)
- Lacerations
- Burns
- Frostbite
- Casting/immobilization after extremity injury
- Penetrating injury
- Polymyalgia rheumatica
- Myocardial infarction (MI)
- Cerebral vascular accident

## *GENERAL PREVENTION*

- Early mobilization after fracture, stroke, and MI has proven benefit in reducing incidence of CRPS.
- One study of wrist fractures found that addition of 500 mg/day of vitamin C lowered rates of CRPS.
- There is evidence that limiting use of tourniquets, liberal regional anesthetic use, and ensuring adequate perioperative analgesia can reduce the incidence of CRPS-I.

## *COMMONLY ASSOCIATED CONDITIONS*

- Serious injury to bone and soft tissue
- Herpes zoster
- Postherpetic neuralgia results from partial or complete damage to afferent nerve pathways.
- Pain occurs in dermatomes as a sequela of herpes zoster.

## **DIAGNOSIS**

Unprovoked pain is the hallmark of the condition, and the diagnosis of CRPS is excluded by the existence of conditions that would otherwise account for the degree of symptoms. Clinical diagnostic criteria (2):

## **HISTORY**

- Continuing pain which is disproportionate to any inciting event.
- One reported symptom in 3 of the 4 following categories:
  - Sensory: hyperalgesia and/or allodynia
  - Vasomotor: skin, temperature, color asymmetry
  - Sudomotor/edema: edema, sweating changes, or sweating asymmetry
  - Motor/trophic: decreased range of motion or motor dysfunction and/or trophic changes (hair, nail, skin) (1)

## **PHYSICAL EXAM**

At least one sign at evaluation in 2 of the following:

- Sensory: hyperalgesia (to pinprick) or allodynia (to light touch, pressure, or joint movement)
- Vasomotor: evidence of temperature, skin, color asymmetry
- Sudomotor/edema: evidence of edema or sweating changes or asymmetry
- Motor/trophic: decreased range of motion, motor dysfunction, or trophic changes in hair, nails, skin (1)

## **DIFFERENTIAL DIAGNOSIS**

- Infection
- Hypertrophic scar
- Bone fragments
- Neuroma
- CNS tumor or syrinx
- Deep vein thrombosis or thrombophlebitis
- Thoracic outlet syndrome

## **DIAGNOSTIC TESTS & INTERPRETATION**

### ***Initial Tests (lab, imaging)***

- CBC
- Erythrocyte sedimentation rate (ESR)
- Plain radiographs may show patchy demineralization within 3 to 6 weeks of onset of CRPS that

are more pronounced than would be seen from disease alone.

- 3-phase bone scanning has varying sensitivity but is most accurate for support of the diagnosis when there is diffuse activity (especially on phase 3).
- Bone density

## *Diagnostic Procedures/Other*

- Electromyography (EMG) shows nerve injury with type II CRPS.
- Sudomotor function testing (resting sweat testing, resting skin temperature, quantitative sudomotor axon reflex testing) all related to increased autonomic activity of the affected limb)

## *Test Interpretation*

- Partial or complete damage to afferent nerve pathways and probably reorganized central pain pathways
- Nerves most commonly involved are median and sciatic.
- Atrophy in affected muscles
- Incomplete nerve plexus lesion

## **TREATMENT**

### **GENERAL MEASURES**

Discourage maladaptive behaviors (pain medication seeking, secondary gain). Principle of functional restoration is a stepwise and multidisciplinary approach.

### **MEDICATION**

#### *First Line*

- NSAIDS recommended early in course but mixed support in literature
- The following have literature support of either limited or suggestive benefit in treatment of CRPS-I:
  - Corticosteroids (prednisone 30 mg/day for 2 to 12 weeks with taper) are the only class of drugs that have direct clinical trial support early in the course.
  - Gabapentin 600 to 1,800 mg/day for 8 weeks following diagnosis
  - 50% DMSO cream applied to affected extremity up to 5 times daily

- N-acetylcysteine 600 mg TID
- Bisphosphonates (alendronate) at 40 mg/day (however, optimal dose uncertain)
- Nifedipine 20 mg/day showed benefit early in the course of the condition.

- Although many have advocated the use of tricyclic antidepressants in the treatment of CRPS, there is no credible evidence of improvement of pain. They may be helpful in controlling depressive symptoms that develop with disease progression (2).

## *ISSUES FOR REFERRAL*

- After 2 months of the illness, psychological evaluation is generally indicated to identify and treat any comorbid conditions.
- Identifying local resources and early referral for expert management give increased likelihood of long-term success in controlling condition.

## *ADDITIONAL THERAPIES*

### Type I

- Physical and occupational therapy (beneficial to the overall prognosis for recovery)
  - Should be started early
  - Mirror therapy has shown good results.
- Transcutaneous nerve stimulation
- Psychotherapy
- Use of subdissociative (0.2 to 0.5 mg/kg) infusions of ketamine has shown some promise but effects seem to be time limited (3)[B].

## *SURGERY/OTHER PROCEDURES*

- Type II responds more favorably to nerve-directed treatment
  - Sympathetic blocks
  - Cervicothoracic or lumbar sympathectomies have little data to support their use and should be used judiciously after all other therapies have failed (4)[A].
- Anesthetic blockade (chemical or surgical) of sympathetic nerve function
  - Transient relief suggests that chemical or surgical sympathectomy will be helpful.

Little in the way of quality clinical trials exist to support local sympathetic blockage as the gold standard of therapy.

- IV regional sympathetic block with guanethidine or reserpine by pain specialist or anesthetist
- Transcutaneous electric nerve stimulation (controversial)
- Inject myofascial painful trigger points
- Spinal cord stimulation (quality of life improved only with implanted system)
- Intrathecal analgesia
- Amputation as a last resort in severe cases, with patients reporting improved quality of life

## **COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Vitamin C (500 mg/day) may help to prevent CRPS in those with wrist fracture.
- Briskly rub the affected part several times per day
- Acupuncture
- Hypnosis can be suggested.
- Relaxation training (alternate muscle relaxing and contracting)
- Biofeedback
- Whirlpool baths

## **INPATIENT CONSIDERATIONS**

### ***Admission Criteria/Initial Stabilization***

Only for proposed surgical therapy

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Weekly, to monitor progress and initiate additional modalities as needed

### ***PATIENT EDUCATION***

- Stress need to remain active physically
- Instruct carefully about any prescribed medications.
- Reflex Sympathetic Dystrophy Syndrome Association, <http://rsds.org/>, 203-877-3790

- American RSD Hope Group, [www.rsdhope.org](http://www.rsdhope.org), 207-583-4589

## PROGNOSIS

Most improve with early treatment, but symptoms may be lifelong if there is limited response to initial treatments.

## COMPLICATIONS

- Depression
- Disability
- Opioid dependence

Codes

**&NA;**

## **ICD10**

- G90.50 Complex regional pain syndrome I, unspecified
- G90.519 Complex regional pain syndrome I of unspecified upper limb
- G90.529 Complex regional pain syndrome I of unspecified lower limb

## **Clinical Pearls**

**&NA;**

- A pain syndrome disproportioned to injury
- Pain control and early mobility are the key to recovery.
- Avoid use of opiate analgesics.
- Use a multidisciplinary approach.

# Condylomata Acuminata

Morgan Ashleigh Smith, DO

Tayseer Husain Chowdhry, MD, MA

E. James Kruse, DO

## BASICS

### DESCRIPTION

- Condylomata acuminata are soft, skin-colored, fleshy lesions (commonly called genital warts) that are caused by human papillomavirus (HPV):
  - Warts appear singly or in groups (a single wart is a ÒcondylomaÓ; multiple warts are ÒcondylomasÓ or ÒcondylomataÓ); small or large; typically appear on the anogenital skin (penis, scrotum, introitus, vulva, perianal area); and may occur in the anogenital tract (vagina, cervix, rectum, urethra, anus); also conjunctival, nasal, oral, and laryngeal warts
- System(s) affected: skin/exocrine, reproductive, occasionally respiratory
- HIV considerations:
  - Treatment of external genital warts should not be different for HIV-infected persons (1).
  - Lesions may be larger or more numerous (1)
  - May not respond as well to therapy as immunocompetent persons (1)

### Pediatric Considerations

- Consider sexual abuse if seen in children, although children can be infected by other means (e.g., transfer from wart on another child's hand or prolonged latency period) (2).
- American Academy of Pediatrics recommends all school-aged children who present with lesions be evaluated for abuse and screened for other STDs (2).

### Pregnancy Considerations

- Warts often grow larger during pregnancy and regress spontaneously after delivery.
- Virus does not cross the placenta. Treatment during pregnancy is somewhat controversial. Cesarean section is not absolutely indicated for maternal condylomata (3)[A].

- Cervical infection has been found to be a risk factor for preterm birth (3)[A].
- Few documented cases of laryngeal papillomas due to HPV transmission at the time of delivery. Although rare, the condition is life-threatening (4).
- HPV vaccination is contraindicated in pregnancy.
- The safety of imiquimod, sinecatechins, podophyllin, and podofilox during pregnancy has not been established (3)[C].

## ***EPIDEMIOLOGY***

- HPV types 6 and 11 associated with 90% of condylomata acuminata. Types 16, 18, 31, 33, and 35 may be found in warts and may be associated with high-grade intraepithelial dysplasia in immunocompromised states such as HIV.
- Highly contagious; incubation period may be from 1 to 8 months. Initial infections may very well go unrecognized, so a "new" outbreak may be a relapse of an infection acquired years prior.
- Predominant age: 15 to 30 years
- Predominant sex: 1:1 male to female
- Most infections are transient and clear spontaneously within 2 years.

## ***Incidence***

One study population demonstrated that from 2007 to 2010, with the introduction of HPV vaccines, the incidence of genital warts decreased 35% (from 0.94% per year to 0.61% per year) in females <21 years, and decreased 19% in males <21.

## ***Prevalence***

- Most common viral sexually transmitted infection (STI) in the United States. Most sexually active men and women will have acquired a genital HPV infection, usually asymptomatic, at some time.
- Peak prevalence in ages 17 to 33 years
- 10-20% of sexually active women may be actively infected with HPV. Studies in men suggest a similar prevalence.
- Pregnancy and immunosuppression favor recurrence and increased growth of lesions.

## ***ETIOLOGY AND PATHOPHYSIOLOGY***

HPV is a circular, double-stranded DNA molecule. There are >120 HPV subtypes. HPV types that

cause genital warts do not cause anogenital cancers.

## ***RISK FACTORS***

- Usually acquired by sexual activity
  - Young adults and adolescents
  - Multiple sexual partners; short interval between meeting new sex partner and first intercourse
  - Not using protective barriers
  - Young age of commencing sexual activity
  - History of other STI
- Immunosuppression (particularly HIV)

## ***GENERAL PREVENTION***

- Sexual abstinence or monogamy
- Quadrivalent HPV vaccine available against genital warts and cervical cancer. This vaccine is targeted to adolescents before the period of their greatest risk for exposure to HPV. The vaccine does not treat previous infections:
  - Immunity has been documented to last at least 5 years after HPV vaccination.
  - The HPV quadrivalent vaccine (Gardasil) protects against the two most common HPV serotypes (types 6 and 11, which cause most anogenital warts) and the two most cancer-promoting types (16 and 18) (5).
  - Quadrivalent vaccine is indicated for females and males ages 9 to 26 years: Vaccine is administered IM; 3 doses at 0, 2, and 6 months to achieve optimal seroconversion (6).
  - Vaccine efficacy for preventing external genital warts is related to age of administration of 1st dose: 76% if aged <20 years, 93% if <14 years.
- Bivalent HPV vaccine is available but does not cover the HPV types that cause most condyloma lesions (Cervarix) (5).
- Quadrivalent vaccine has been proven effective in prevention of external lesions in males 16 to 26 years of age (5).
- Use of condoms is partially effective, although warts may be easily spread by lesions not covered by a condom (e.g., 40% of infected men have scrotal warts).
- Abstinence until treatment completed

## COMMONLY ASSOCIATED CONDITIONS

- >90% of cervical cancer associated with HPV types 16, 18, 31, 33, and 35
- 60% of oropharyngeal and anogenital squamous cell carcinomas are associated with HPV
- STIs (e.g., gonorrhea, syphilis, chlamydia), AIDS

## DIAGNOSIS

### HISTORY

- Explore sexual history, contraception use, and other lifestyle topics.
- Most warts are asymptomatic but symptoms include
  - Pruritus, burning, redness, pain, bleeding
  - Vaginal discharge
  - Large warts may cause obstructive symptoms in the anus (with defecation) or vaginal canal (with intercourse or childbirth)

### PHYSICAL EXAM

- Lesions often have a typical rough, warty appearance with multiple fingerlike projections but may be soft, sessile, and smooth.
- Large lesions are cauliflower-like and may grow to >10 cm.
- Most common sites: penis, vaginal introitus, and perianal region
- May be seen anywhere on the anogenital epithelium or in the anogenital tract
- Warts often occur in clusters.
- Bleeding or irritation of the lesions may be noted.

### DIFFERENTIAL DIAGNOSIS

- Condylomata lata (flat warts of syphilis)
- Lichen planus
- Normal sebaceous glands
- Seborrheic keratosis
- Molluscum contagiosum
- Keratomas, micropapillomatosis

- Scabies
- Crohn disease
- Skin tags
- Melanocytic nevi
- Vulvar intraepithelial neoplasia
- Squamous cell carcinoma

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Diagnosis is usually clinical, made by unaided visual examination of the lesions.
- Biopsy
- Acetowhitening test: Subclinical lesions can be visualized by wrapping the penis with gauze soaked with 5% acetic acid (vinegar) for 5 minutes. Using a 10× hand lens or colposcope, warts appear as tiny white papules. A shiny white appearance of the skin represents foci of epithelial hyperplasia (subclinical infection), but because of low specificity, the CDC recommends against routine use of this test to screen for HPV mucosal infection.

### ***Initial Tests (lab, imaging)***

- Usually not required for diagnosis
- Serologic tests for syphilis may be helpful to rule out condylomata lata.
- Other testing for STIs
- Pap smear may be indicated.

### ***Follow-Up Tests & Special Considerations***

Because squamous cell carcinoma may resemble or coexist with condylomata, biopsy may be considered for lesions refractory to therapy.

### ***Diagnostic Procedures/Other***

- Biopsy with highly specialized identification techniques, such as HPV DNA detected through polymerase chain reaction, is rarely useful.

---

P.221

- Colposcopy, anoscopy, anoscopy, and urethroscopy may be required to detect anogenital tract lesions.
- Screening men who have sex with men (MSM) with anal Pap smears is controversial.

## TREATMENT

### GENERAL MEASURES

- May resolve spontaneously
- Change therapy if no improvement after 3 treatments, not complete clearance after 6 treatments, or therapy's duration or dosage exceeds manufacturer's recommendations.
- Appropriate screening/counseling of partners

### MEDICATION

#### *First Line*

- No single therapy for genital warts is ideal for all patients or clearly superior to other therapies.
- Recommendations for external genital warts, patient-applied:
  - Podofilox (Condylox): antimitotic action; apply 0.5% solution or gel to warts twice daily (allowing to dry) for 3 consecutive days at home followed by 4 days of no therapy; may repeat up to 4 total cycles; maximum of 0.5 mL/day or area less than 10 cm<sup>2</sup> (3)[A],(7)
  - Imiquimod (Aldara): immune enhancer; self-treatment with a 5% cream applied once daily at bedtime 3 times weekly until warts resolve for up to 16 weeks. Wash off with soap and water 6 to 10 hours after application. Imiquimod has been noted to weaken condoms and diaphragms; therefore, patients should refrain from sexual contact while the cream is on the skin (3)[A],(8).
  - Sinecatechins (Veregen): immune enhancer and antioxidant, extract from green tea; apply a 0.5-cm strand of ointment 3 times daily for up to 16 weeks. Do not wash off after use (3)[A].
- Recommendations for external genital warts, provider-applied:
  - Cryotherapy: liquid nitrogen applied to warts for two 10-second bursts with thawing in between; usually requires 2 to 3 weekly sessions (3)[A]
  - Podophyllin 10-25% in tincture of benzoin. Apply directly to warts, air-dry in office before coming into contact with clothes. Wash off in 1 to 4 hours. Repeat every 7 days in office until gone (3)[A],(7).
  - Trichloroacetic acid (TCA): 80% solution. Apply only to warts; powder/talc to remove unreacted acid. Repeat in office at weekly intervals; ideal for isolated lesions in pregnancy (3)[A].

- Recommendations for exophytic cervical warts: biopsy to exclude high-grade squamous intraepithelial lesion (SIL) (3)[A]
- Recommendations for vaginal warts: cryotherapy or TCA or bichloroacetic acid (BCA) 80-90% (3)[A]
- Recommendations for urethral meatus warts: cryotherapy or podophyllin 10-25% in compound tincture of benzoin (3)[A]
- Recommendations for anal warts: cryotherapy, TCA or BCA 80-90%, or surgery; specialty consultation for intra-anal warts (3)[A]

### *Pregnancy Considerations*

Cryotherapy, surgery, or TCA. Medications contraindicated in pregnancy: podophyllin, podophyllotoxin, sinecatechins, interferon, and imiquimod (3)[C]

### *Second Line*

Intralesional interferon, photodynamic therapy, topical cidofovir (3)[A]

## ***SURGERY/OTHER PROCEDURES***

- Larger warts may require surgical excision, laser treatment, or electrocoagulation (including infrared therapy):
  - Precaution: Laser treatment may create smoke plumes that contain HPV. CDC recommendation is for the use of a smoke evacuator no less than 2 inches from the surgical site. Masks are recommended; N95 the most efficacious (9)[A].
- Intraurethral, external (penile and perianal), anal, and oral lesions can be treated with fulgurating CO<sub>2</sub> laser. Oral or external penile/perianal lesions can also be treated with electrocautery or surgery.

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

No restrictions, except for sexual contact

### ***Patient Monitoring***

- Patients should be seen every 1 to 2 weeks until lesions resolve.
- Patients should follow up 3 months after completion of treatment.

- Persistent warts require biopsy.
- Sexual partners require monitoring.

## **PATIENT EDUCATION**

- Provide information on HPV, STI prevention, and condom use.
- Explain to patients that it is difficult to know how or when a person acquired an HPV infection; a diagnosis in one partner does not prove sexual infidelity in the other partner.
- Emphasize the need for women to follow recommendations for regular Pap smears.

## **PROGNOSIS**

- Asymptomatic infection persists indefinitely.
- Treatment has not clearly been shown to decrease transmissible infectivity.
- Warts may clear with treatment or resolve spontaneously. However, recurrences are frequent, particularly in the first 3 months, and may necessitate repeated treatments.

## **COMPLICATIONS**

- Cervical dysplasia (probably does not occur with type 6 or 11, which cause most warts)
- Malignant change: Progression of condylomata to cancer rarely, if ever, occurs, although squamous cell carcinoma may coexist in larger warts.
- Urethral, vaginal, or anal obstruction from treatment
- The prevalence of high-grade dysplasia and cancer in anal canal is higher in HIV-positive than in HIV-negative patients, probably because of increased HPV activity.

# Codes

**&NA;**

## ICD10

A63.0 Anogenital (venereal) warts

## Clinical Pearls

**&NA;**

- Condylomata acuminata are soft, skin-colored, fleshy lesions caused by HPV subtypes 6, 11, 16, 18, 31, 33, and 35.
- Quadrivalent HPV vaccine addresses the two most common HPV serotypes to be contracted in warts types 6 and 11 and the two most cancer-promoting types 16 and 18 (Gardasil).
- Vaccine: 0.5 mL IM first dose and at months 2 and 6
- The majority of sexually active men and women will have acquired a genital HPV infection, usually asymptomatic, at some time.
- No single therapy for genital warts is ideal for all patients or clearly superior to other therapies.
- Quadrivalent HPV vaccine is effective in preventing HPV infection, particularly if administered prior to the onset of engaging in sexual activity. Gardasil is approved and recommended for use in males and females aged 9 to 26 years.

# Conjunctivitis, Acute

Frances Yung-tao Wu, MD

## BASICS

### DESCRIPTION

- Inflammation of the bulbar and/or palpebral conjunctiva of <4 weeks' duration
- System(s) affected: nervous, skin/exocrine
- Synonym(s): pink eye

### Geriatric Considerations

- Suspect autoimmune, systemic, or irritative conditions.
- If purulent, risk of bacterial cause increases with age, the combo of age >65 years and bilateral lid adherence = risk >70% (1)[B].

### Pediatric Considerations

- Neonatal conjunctivitis may be gonococcal, chlamydial, irritative, or related to dacryocystitis.
- Pediatric ER study; 78% positive bacterial culture, mostly *Haemophilus influenzae*; 13% no growth; other studies showed >50% adenovirus.
- Children <5 years were 7 times more likely to be bacterial than were older children or adults.
- Daycare regulations sometimes require any child with presumed conjunctivitis to be treated with a topical antibiotic, despite lack of evidence (2)[A].

### EPIDEMIOLOGY

- Predominant age
  - Pediatric: viral, bacterial
  - Adult: viral, bacterial, allergic
- Predominant sex: male = female

### Incidence

In the United States: variable, but accounts for 1-2% of all ambulatory office visits

## ETIOLOGY AND PATHOPHYSIOLOGY

- Viral
  - Adenovirus (common cold), coxsackievirus (implicated in recent hemorrhagic conjunctivitis epidemics in Asia and Middle East)
  - Enterovirus (acute hemorrhagic conjunctivitis)
  - Herpes simplex
  - Herpes zoster or varicella
  - Measles, mumps, or influenza
- Bacterial
  - *Staphylococcus aureus* or *epidermidis*
  - *Streptococcus pneumoniae*
  - *H. influenzae* (children)
  - *Pseudomonas* spp. or anaerobes (in contact lens users)
  - *Acanthamoeba* from contaminated contact lens solution may cause keratitis.
  - *Neisseria gonorrhoeae* and *meningitidis*
  - *Chlamydia trachomatis*: gradual onset >4 weeks
- Allergic
  - Hay fever, seasonal allergies, atopy
- Nonspecific
  - Irritative: topical medications, wind, dry eye, UV light exposure, smoke
  - Autoimmune: Sjögren syndrome, pemphigoid, Wegener granulomatosis
  - Rare: Rickettsia, fungal, parasitic, tuberculosis, syphilis, Kawasaki disease, chikungunya, Graves, gout, carcinoid, sarcoid, psoriasis, Stevens-Johnson, Reiter syndrome

## RISK FACTORS

- History of contact with infected persons
- Sexually transmitted disease (STD) contact: gonococcal, chlamydial, syphilis, or herpes

Contact lenses: pseudomonal or acanthamoeba keratitis

- Epidemic bacterial (streptococcal) conjunctivitis reported in school settings

## GENERAL PREVENTION

- Wash hands frequently.
- Demonstrate eyedropper technique: While eye is closed and head back, several drops over nasal canthus; then open eyes to allow liquid to enter. Never touch tip of dropper to skin or eye.

## COMMONLY ASSOCIATED CONDITIONS

- Viral infection (e.g., common cold)
- Possible STD

## DIAGNOSIS

### HISTORY

#### ALERT

Red flag: Any decrease in visual acuity is not consistent with conjunctivitis alone; must document normal vision for diagnosis of isolated conjunctivitis.

- Viral: contact or travel
  - May start with one eye, then both
  - If herpetic, recurrences or vesicles on skin
- Bacterial: difficult to distinguish from viral, unless contact lens user. Assume bacterial in contact lens wearer unless cultures are negative. If recent STD, suspect chlamydia or gonococcus.
- Allergic: itching, atopy, seasonal, dander
- Irritative: Feels dry, exposure to wind, tear film deficit may persist 30 days after acute conjunctivitis, chemicals, or drug: atropine, aminoglycosides, iodide, phenylephrine, antivirals, bisphosphonates, retinoids, topiramate, chamomile, COX-2 inhibitors.
- Foreign body: Redness may persist 24 hours after removal.

## PHYSICAL EXAM

- General: common to all types of conjunctivitis
  - Red eye, conjunctival injection
  - Foreign body sensation
  - Eyelid sticking or crusting, discharge
  - Normal visual acuity and pupillary reactivity
- Viral
  - Palpable preauricular lymphadenopathy may be present.
  - Hemorrhagic coxsackievirus-related epidemics were reported.
  - Severe viral: herpes simplex or zoster:
    - Burning sensation, rarely itching
    - Unilateral, herpetic skin vesicles in herpes zoster
    - Palpable preauricular node
- Bacterial (non-STD): may be epidemic
  - Mild pruritus, discharge mild to heavy
  - Conjunctival chemosis/edema
  - If contact lens user, must rule out pseudomonal (or other bacterial) keratitis.
- Bacterial: gonococcal (or meningococcal) hyperacute infection
  - Rapid onset 12 to 24 hours
  - Severe purulent discharge
  - Chemosis/conjunctival/eyelid edema
  - Rapid growth of superior corneal ulceration
  - Preauricular adenopathy
  - Signs of STDs (chlamydia, GC, HIV, etc.)
- Allergic
  - Itching predominant
  - Seasonal or dander allergies
  - Chemosis/conjunctival/eyelid edema

Nonspecific irritative

- Dry eyes, intermittent redness, chemical/drug exposure
- Foreign body: may have redness and discharge 24 hours after removal
- Must document normal visual acuity.
- Cornea should be clear and without fluorescein uptake. Cloudy or ulcerated signifies keratitis; consult ophthalmologist.
- Recommend fluorescein exam: Evert lid to inspect for foreign bodies.
- Skin: Look for herpetic vesicles, nits on lashes (lice), scaliness (seborrhea), or styes.
- Limbal flush at corneal margin if uveitis
- If pupil is irregular (i.e., penetrating foreign body), emergent referral is warranted.
- Discharge but no conjunctival injection: blepharitis

## ***DIFFERENTIAL DIAGNOSIS***

- Uveitis (iritis, iridocyclitis, choroiditis): limbal flush (red band at corneal margin), hazy anterior chamber, and decreased visual acuity
- Penetrating ocular trauma: emergently hospitalize
- Acute glaucoma (emergency): headache, corneal clouding, poor visual acuity
- Corneal ulcer(s) or foreign body: lesions on fluorescein exam
- Dacryocystitis: tenderness and swelling over tear sac (below medial canthus)
- Scleritis and episcleritis: red injected vessels radially oriented, sectoral (pie wedge), nodularity of sclera
- Pingueculitis: inflammation of a yellow nodular or wedge-like area of chronic conjunctival degeneration (pinguecula)
- Ophthalmia neonatorum: neonates in the first 2 days of life (gonococcal; 5 to 12 days of life): chlamydial, HSV, very rare *N. meningitidis*. Consider specialty consultation for required systemic therapy.
- Blepharitis: Lid margins are inflamed producing itching, scale, or discharge, but no conjunctival injection.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

- Usually not needed initially for the most common causes

Culture swab if STD is suspected, very severe symptoms, or patient is a contact lens user

- Viral swab for detection of adenovirus is not yet in common use.

## *Diagnostic Procedures/Other*

- Fluorescein exam for ulcer or abrasion on cornea
- Small superficial foreign bodies may be removed with irrigation or moistened swab.

## **TREATMENT**

### *GENERAL MEASURES*

- Infectious conjunctivitis rarely needs antibiotics and resolve on their own.
- Clean eyelid with wet cloth up to QID.
- Stop use of contact lenses while red.
- Patching of eye is not beneficial.

---

P.223

### *MEDICATION*

#### *First Line*

- Viral (nonherpetic)
  - Artificial tears for symptomatic relief
  - Vasoconstrictor/antihistamine (e.g., naphazoline/pheniramine) QID for severe itching
  - May consider topical antibiotic (see bacterial below) if return to daycare requires treatment
- Viral (herpetic) (by ophthalmologist)
  - Ganciclovir gel: 0.15%, 5 times per day for 7 days (3)[B]
  - Acyclovir: PO 400 mg 5 times per day for herpes simplex virus (HSV); 800 mg for zoster for 7 days
- Bacterial (non-STI): 3 days cool compress before starting any antibiotic showed no adverse consequences and decreased unnecessary Rx (4)[A].
  - After 3 days, consider topical antibiotics (NNT 7 at day 6) as a reasonable option for delayed treatment: Polymyxin B-Bacitracin ophthalmic ointment: Apply 4 times per day for 5 to 7 days.

- Polymyxin B-trimethoprim solution 1 gtt 4 times per day for 5 to 7 days
- Erythromycin ophthalmic ointment: 1/2 inch BID-QID for 5 days
- Sodium sulfacetamide (10% solution) (Bleph-10): 2 drops q4h (while awake) for 5 days
- Tobramycin or gentamicin: 0.3% ophthalmic drops/ointment q4h (drops) to q8h (ointment) for 7 days
- Bacterial (gonococcal)
  - Neonates: Hospitalize for IV therapy.
  - Adults: ceftriaxone: 1 g IM as single dose and topical bacitracin ophthalmic ointment 1/2 inch QID. Neonates 25 to 50 mg/kg IV or IM, not to exceed 125 mg, as a single dose. Chlamydia in neonates requires oral erythromycin ethylsuccinate: 50 mg/kg/day divided q6h PO for 14 days, max 3 g/day.
- Allergic and atopic (listed by approximate, increasing cost, from lowest to highest): All are efficacious, but evidence favoring one over another is inconclusive (5)[A].
  - Ketotifen (Zaditor, Alaway, and other generics over-the-counter [OTC]): 0.25% 1 drop BID
  - Cromolyn (Opticrom): 4% QID
  - Azelastine: 0.05% 1 gtt BID
  - Pemirolast (Alamast): 0.1% 1 gtt QID
  - Alcaftadine (Lastacaft): 0.25% 1 gtt QD
  - Emedastine: 0.05% 1 drop QID
  - Epinastine (Elestat): 0.05% BID
  - Ketorolac (Acular): 0.1% 1 drop QID
  - Olopatadine (Pataday, Patanol): 0.1% 1 drop BID or 0.2% 1 drop daily
  - Bepotastine (Bepreve): 1.5% 1 gtt BID
  - Lodoxamide tromethamine (Alomide): 0.1% 1 gtt QID
  - Nedocromil (Alocril): 2% 1 gtt BID
  - Oral nonsedating antihistamines (cetirizine [Zyrtec] 10 mg/day, fexofenadine [Allegra] 60 mg BID, etc.) may treat nasal symptoms but cause ocular drying. Oral antihistamine (e.g., diphenhydramine 25 mg TID) in severe cases of itching
- Contraindications: Avoid topical steroids unless able to monitor intraocular pressure. Also, case report of HSV keratitis presenting without distinguishing findings from viral conjunctivitis would

discourage initial use of steroids. Steroids were not beneficial in treatment of bacterial keratitis (6)[A]. Topical immune modulators (tacrolimus, cyclosporine) should be reserved for specialist use only in the most difficult cases.

- Precautions
  - Do not allow dropper to touch the eye.
  - Case reports of eye irritation from gentamicin in infants, moxifloxacin in adults, sulfacetamide in allergic individuals
  - Vasoconstrictor/antihistamine: rebound vasodilation after prolonged use

## *Second Line*

- Viral and allergic: numerous OTC products
- Bacterial: second line (quinolones used as postop or known resistant organisms)
  - Ofloxacin: 0.3% 1 gtt 4 times per day for 7 days
  - Ciprofloxacin: 0.3% 1 gtt 4 times per day for 7 days
  - Levofloxacin: 0.3% 1 gtt 4 times per day for 7 days
  - Gatifloxacin: 0.3% 1 gtt 3 times per day for 7 days
  - Moxifloxacin: 0.5% 1 gtt 3 times per day for 7 days
  - Besifloxacin: 0.6% 1 gtt 3 times per day for 7 days
  - Azithromycin: 1.5% 2 times per day for 3 days

## *ISSUES FOR REFERRAL*

Any significantly decreased visual acuity, herpetic keratitis, or contact lens-related bacterial conjunctivitis warrants ophthalmologic consultation.

## *COMPLEMENTARY & ALTERNATIVE MEDICINE*

As condition is usually benign and self-limited, saline flushes, cool compresses, and similar treatments help.

## *INPATIENT CONSIDERATIONS*

Acute gonococcal conjunctivitis (or very rare case of meningococcal conjunctivitis) requires inpatient treatment with ceftriaxone 50 mg/kg IV everyday (pediatric), 1 g IM for 1 (adult) along with ophthalmologic consultation.

## Admission Criteria/Initial Stabilization

Penetrating ocular trauma, gonococcal conjunctivitis

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

- If not resolved within 5 to 7 days, alternate diagnoses should be considered or consultation obtained, although some epidemic keratoconjunctivitis and other adenoviral conjunctivitis typically last 1 to 2 weeks.
- Children may be excluded from school until eye is no longer red, if viral or bacterial, depending on school policy. Allergic conjunctivitis should be able to return to school with doctor's note.

### PATIENT EDUCATION

- Patients should not wear contacts until their eyes are fully healed (typically 1 week).
- Patients should discard current pair of contacts.
- Patients should discard any eye makeup that they have been using, especially mascara.
- Cool, moist compress can ease irritation and itch.

### PROGNOSIS

- Viral: 5 to 10 days for pharyngitis with conjunctivitis, 2 weeks with adenovirus
- Herpes simplex: 2 to 3 weeks
- Most common bacterial-H flu, staph, strep: self-limited; 74-80% resolution within 7 days, whether treated or not

### COMPLICATIONS

- Corneal scars with herpes simplex
- Lid scars or entropion with varicella zoster and chlamydia
- Corneal ulcers or perforation, very rapid with gonococcal
- Hypopyon: pus in anterior chamber
- Chlamydial neonatal (ophthalmic): could have concomitant pneumonia
- Otitis media may follow *H. influenzae* conjunctivitis.
- The very rare *N. meningitidis* conjunctivitis may be followed by meningitis.

Narayana S, McGee S. Bedside diagnosis of the Red eye a systematic review. *Am J Med.* 2015;28(11):1220.e1-1224.e1.

### See Also

&NA;

- Rhinitis, Allergic
- Algorithm: Eye Pain

### Codes

**&NA;**

## **ICD10**

- H10.30 Unspecified acute conjunctivitis, unspecified eye
- H10.33 Unspecified acute conjunctivitis, bilateral
- H10.32 Unspecified acute conjunctivitis, left eye

## **Clinical Pearls**

**&NA;**

- Conjunctivitis does *not* alter visual acuity; decreased acuity or photophobia should prompt consideration of more serious ophthalmic disorders.
- Culture discharge in all *contact lens wearers*, consider referral, and remind patient to throw away current contacts and avoid contacts until eyes are fully healed.
- Antibiotic therapy is of no value in viral conjunctivitis (most cases of infectious conjunctivitis) and does not significantly alter the course of most types of bacterial conjunctivitis (therefore, it is optional in these cases).

# Constipation

S. Mimi Mukherjee, PharmD

Sandhya Ventrapragada, MBBS, MD

## BASICS

Unsatisfactory defecation characterized by infrequent stools, difficult stool passage, or both. Characteristics include <3 bowel movements a week, hard stools, excessive straining, prolonged time spent on the toilet, a sense of incomplete evacuation, and abdominal discomfort/bloating.

## DESCRIPTION

- System(s) affected: gastrointestinal (GI)
- Synonym(s): obstipation

## Geriatric Considerations

Colorectal neoplasms may be associated with constipation; new-onset constipation after age 50 years is a red flag. Use warm water enemas for impaction instead of sodium phosphate enema in geriatric patients. Sodium phosphate enemas have been associated with fatalities and severe electrolyte disturbances (1)[B].

## Pediatric Considerations

Consider Hirschsprung disease (absence of colonic ganglion cells): 25% of all newborn intestinal obstructions, milder cases diagnosed in older children with chronic constipation, abdominal distension, decreased growth; 5:1 male-to-female ratio; associated with inherited conditions such as Down syndrome

## Pregnancy Considerations

Avoid misoprostol. Other agents consider risks versus benefits.

## EPIDEMIOLOGY

- More pronounced in children and elderly
- Predominant sex: female > male (2:1)
- Nonwhites > whites

## *Incidence*

- 5 million office visits annually
- 100,000 hospitalizations

## *Prevalence*

÷ 15% of population affected

## *ETIOLOGY AND PATHOPHYSIOLOGY*

- As food leaves the stomach, the ileocecal valve relaxes (gastroileal reflex) and chyme enters the colon (1 to 2 L/day) from the small intestine. In the colon, sodium is actively absorbed in exchange for potassium and bicarbonate. Water follows the osmotic gradient. Peristaltic contractions move chyme through the colon into the rectum. Chyme is converted into feces (200 to 250 mL).
- Normal transit time is 4 hours to reach the cecum and 12 hours to reach the distal colon.
- Defecation reflexively follows once stool reaches the rectal vault. This reflex can be inhibited by voluntarily contracting the external sphincter or facilitated by straining to contract the abdominal muscles while voluntarily relaxing the anal sphincter. Rectal distention initiates the defecation reflex. The urge to defecate occurs as rectal pressures increase. Distention of the stomach by food also initiates rectal contractions and a desire to defecate (gastrocolic reflex).
- Primary constipation
  - Slow colonic transit time (13%)
  - Pelvic floor/anal sphincter dysfunction (25%)
  - Functional: normal transit time and sphincter function, subjective symptoms (bloating, abdominal discomfort, perceived difficulty defecating, presence of hard stools) (69%)
- Secondary constipation
  - Irritable bowel syndrome (IBS)
  - Endocrine dysfunction (diabetes mellitus, hypothyroid)
  - Metabolic disorder (increased calcium, decreased potassium)
  - Mechanical (obstruction, rectocele)
  - Pregnancy
  - Neurologic disorders (Hirschsprung, multiple sclerosis, spinal cord injuries)
- Medication effect

- Anticholinergic effects (antidepressants, narcotics, antipsychotics)
- Antacids (calcium, aluminum)
- Nondihydropyridine calcium channel blockers, especially verapamil

## *Genetics*

Unknown but may be familial

## **RISK FACTORS**

- Extremes of life (very young and very old)
- Polypharmacy
- Sedentary lifestyle or condition
- Improper diet and inadequate fluid intake

## **GENERAL PREVENTION**

High-fiber diet, adequate fluids, exercise, and training to obey the urge to defecate

## **COMMONLY ASSOCIATED CONDITIONS**

- General debilitation (disease or aging)
- Dehydration
- Hypothyroidism
- Hypokalemia
- Hypercalcemia

## **DIAGNOSIS**

### **ALERT**

Red flags:

- New onset after age of 50 years
- Hematochezia/melena
- Unintentional weight loss
- Anemia

- Neurologic defects

## **HISTORY**

Rome III criteria (2)[C]:

- At least two of the following for 12 weeks in the previous 6 months:
  - <3 stools/week
  - Straining at least 1/4 of the time
  - Hard stools at least 1/4 of time
  - Need for manual assist at least 1/4 of time
  - Sense of incomplete evacuation at least 1/4 of time
  - Sense of anorectal blockage at least 1/4 of time
- Loose stools rarely seen without use of laxatives.

## **PHYSICAL EXAM**

- Vital signs, height, weight
- Digital rectal exam (masses, pain, stool, fissures, hemorrhoids, anal tone)
- Abdominal/gynecologic exam (masses, pain)
- Neurologic exam

## **DIFFERENTIAL DIAGNOSIS**

Congenital

- Hirschsprung disease/syndrome
- Hypoganglionosis
- Congenital dilation of the colon
- Small left colon syndrome

## **DIAGNOSTIC TESTS & INTERPRETATION**

Primarily a clinical diagnosis

### ***Initial Tests (lab, imaging)***

CBC, glucose, TSH, calcium, and creatinine routinely and sigmoid/colonoscopy if red flags are present

## *Follow-Up Tests & Special Considerations*

- If condition is refractory, pursue further testing:
  - Colonoscopy
  - Barium enema to look for obstruction and/or megarectum, megacolon, or Hirschsprung disease
- Additional testing
  - Measure colonic transit time by ingesting radiopaque (Sitz-Mark) markers.
  - Plain abdominal film obtained 5 days later (120 hours): Retention of >20% markers indicates slow transit.
  - Markers seen exclusively in distal colon/rectum suggests defecatory disorder.

## *Diagnostic Procedures/Other*

Consider referral in refractory cases:

- Balloon expulsion
- Defecography using a barium paste
- Anorectal manometry with a rectal catheter

## *Test Interpretation*

- Most cases are functional.
- Paucity or absence of intramural enteric ganglia in certain cases of congenital or acquired megacolon
- Neuromuscular abnormalities in certain cases of pseudo-obstruction

## **TREATMENT**

Address immediate concerns:

- Bloating/discomfort/straining: osmotic agents
- Postoperative, after childbirth, hemorrhoids, fissures: stool softener to aid defecation
- If impacted: manual disimpaction, then treat the chronic underlying condition

## **GENERAL MEASURES**

- Attempt to eliminate medications that may cause or worsen constipation.
- Increase fluid intake.
- Increase fiber in diet.
- Enemas if other methods fail

## *MEDICATION*

In patients with no known secondary causes of constipation, conservative nonpharmacologic treatment is recommended.

- Regular exercise
- Increased fluid intake
- Bowel habit training

### *First Line*

Bulking agents (must be accompanied by adequate amounts of liquid to be useful):

- Hydrophilic colloids (bulk-forming agents)
  - Psyllium (Konsyl, Metamucil, Perdiem Fiber): 1 tbsp in 8-oz liquid PO daily up to TID
  - Methylcellulose (Citrucel): 1 tbsp in 8-oz liquid PO daily up to TID
  - Polycarbophil (Mitrolan, FiberCon): 2 caplets with 8-oz liquid PO up to QID
- Stool softeners
  - Docusate sodium (Colace): 100 mg PO TID
- Osmotic laxatives
  - Polyethylene glycol (PEG) (MiraLax) 17 g/day PO dissolved in 4 to 8 oz of beverage (current evidence shows PEG to be superior to lactulose) (3)[B]
  - Lactulose (Chronulac) 15 to 60 mL PO QHS (flatulence, bloating, cramping)
  - Sorbitol: 15 to 60 mL PO QHS (as effective as lactulose)
  - Magnesium salts (milk of magnesia) 15 to 30 mL PO once daily; avoid in renal insufficiency

### *Second Line*

- Stimulants (irritate bowel, causing muscle contraction; usually combined with a softener; work in 8 to 12 hours)

- Senna/docusate (Senokot-S, Ex-lax, Peri-Colace): 1 to 2 tablets or 15 to 30 mL PO at bedtime
- Bisacodyl (Dulcolax, Correctol): 1 to 3 tablets PO daily
- Lubricants (soften stool and facilitate passage of the feces by its lubricating oily effects)
  - Mineral oil (15 to 45 mL/day)
  - Short-term use only. Can bind fat-soluble vitamins, with the potential for deficiencies; may similarly decrease absorption of some drugs
  - Avoid in those at risk for aspiration (lipoid pneumonia)
- Suppositories
  - Osmotic: sodium phosphate
  - Lubricant: glycerin
  - Stimulatory: Bisacodyl
  - Enemas: saline (Fleet enema)
- Lubiprostone (Amitiza): a selective chloride channel activator; 24  $\mu$ g PO BID
- Linaclotide (Linzess): guanylate cyclase-C agonist; dose: 145  $\mu$ g PO once daily; adult use only
  - Avoid in children <6 years.
  - Peripherally acting  $\mu$ -opioid receptor antagonists, indicated for opioid-induced constipation
- Methylnaltrexone (Relistor): dose: 38 to <62 kg: 8 mg; 62 to 114 kg: 12 mg SC every other day PRN
  - Naloxegol (Movantik): dose: 12.5 to 25.0 mg PO daily, discontinue other laxatives for 3 days when initiating naloxegol, avoid in patients on strong Cyp3A4 inhibitors due to increased naloxegol levels and risk of opioid withdrawal
- Prokinetic agents (partial 5-HT<sub>4</sub> agonists) have been withdrawn due to cardiac side effects; only available via IND protocols: tegaserod (Zelnorm), cisapride (Propulsid)
- Other agents not approved by the FDA:
  - Misoprostol (Cytotec): a prostaglandin that increases colonic motility
  - Colchicine: neurogenic stimulation to increase colonic motility

## ***ADDITIONAL THERAPIES***

Other nonpharmacologic therapies include the following:

- Biofeedback therapy
- Behavior therapy
- Probiotics
- Electric stimulation

## ***SURGERY/OTHER PROCEDURES***

Surgery rarely indicated

## ***INPATIENT CONSIDERATIONS***

Toxic megacolon

### ***Nursing***

Manual disimpaction occasionally required in chronic refractory cases

## **ONGOING CARE**

### ***FOLLOW-UP RECOMMENDATIONS***

Encourage exercise and physical activity.

### ***Patient Monitoring***

If functional constipation persists, consider organic cause.

### ***DIET***

Increase fiber (bloating and gas can be problematic):

- Gradually increase intake to 25 g/day over a 6-week period.
- Bran (hard outer layer of cereal grains)
- Vegetables and fruits
- Whole grain foods
- Encourage liberal intake of fluids.

## ***PATIENT EDUCATION***

- Occasional mild constipation is normal.
- Bowel training: the best time to move bowels is in the morning, after eating breakfast, when the normal bowel transit and defecation reflexes are functioning.

## PROGNOSIS

- Occasional constipation responsive to simple measures is harmless.
- Habitual constipation can be a lifelong nuisance.
- Patients with neurologic compromise can suffer from ill effects such as obstipation, impaction, and toxic megacolon.
- No evidence for laxative dependence
- No evidence for harm from stimulant use; melanosis coli may develop, but it is a benign condition.

## COMPLICATIONS

- Volvulus
- Toxic megacolon
- Acquired megacolon in severe, long-standing cases
- Fluid and electrolyte depletion: laxative abuse
- Rectal ulceration (stercoral ulcer) related to recurrent fecal impaction
- Anal fissures

## Codes

## &NA;

## ICD10

- K59.00 Constipation, unspecified
- K59.01 Slow transit constipation
- K59.09 Other constipation

## Clinical Pearls

## &NA;

- Constipation is unsatisfactory defecation with infrequent stools, difficult stool passage, or both for 3 months.
- Functional constipation (normal transit time and sphincter function) is most common.
- Workup red flags: onset >50 years, hematochezia/melena, unintentional weight loss, anemia, neurologic defects
- Osmotic agents (PEG) have the most evidence supporting clinical effectiveness.

# Contraception

Kim Michal Stein, MD

Melissa J. Fullerton, MD

## BASICS

### DESCRIPTION

- Medications or procedures that control timing of pregnancies and prevent unintended pregnancies
- Contraception options are divided into two major categories: hormonal and nonhormonal.
- The most effective methods of contraception are vasectomy, female sterilization, and the long-acting reversible contraceptives (LARCs).

### EPIDEMIOLOGY

#### *Incidence*

- The estimated prevalence of contraception use among reproductive age women is 63% worldwide and 77% in the United States (1).
- 49% of all pregnancies in the United States are unintended, and half occur in women using a form of reversible contraception.
- 43% of all unintended pregnancies in the United States result in termination.
- The most frequently used forms of contraception in the United States (in order of prevalence) are oral contraceptive pills (OCPs), female sterilization, male condom, male sterilization, and depot injectables.
- Although LARCs are one of the most effective forms of contraception, they are among the least used methods in the United States.

### RISK FACTORS

- Unintended pregnancy: higher rates among women ages 18 to 24 and >40 years, unmarried/cohabitating women, women with less than a college education, and minority women
- Contraception discontinuation or nonuse: patient or partner dissatisfaction with prior methods

of contraception or intolerable side effects

## DIAGNOSIS

### HISTORY

- Review past medical history, family history, social history, as well as sexual and pregnancy history, and prior experience with contraceptives and prior STDs.
- Important history/contraindications
  - Estrogen-progestin contraceptives
    - Absolute: age  $\geq$  35 years and smoking  $\geq$  15 cigarettes per day, SBP  $\geq$  160 mm Hg or DBP  $\geq$  100 mm Hg, multiple CAD risk factors, prior venous thromboembolism (or known hypercoagulability), ischemic heart disease, stroke, complicated valvular disease, systemic lupus, migraine with aura, breast cancer, cirrhosis, or hepatocellular adenoma or malignant hepatoma
    - Relative: age  $\geq$  35 years and smoking  $<$  15 cigarettes per day, breastfeeding, HTN 140 to 159 mm Hg or diastolic 90 to 99 mm Hg (or well-controlled on medications), migraines without aura but  $\geq$  35 years, or breast cancer history in remission  $>$  5 years
  - Progestin-only pill/Depo/Implant
    - No absolute
    - Relative: bariatric surgery, ischemic heart disease, history of stroke, lupus, migraine with aura, breast cancer, severe cirrhosis, hepatocellular adenoma, or malignant hepatoma
  - IUD-Mirena
    - Absolute: postseptic abortion, postpartum sepsis, cervical cancer, gestational trophoblastic disease, endometrial cancer, unexplained vaginal bleeding, symptomatic PID, distorted uterine cavity, current purulent cervicitis or known chlamydia/gonorrhea
    - Relative: ischemic heart disease, lupus, severe cirrhosis, hepatocellular adenoma or malignant hepatoma, increased risk of STDs, solid organ transplant
  - IUD-ParaGard
    - Absolute: same as Mirena

Relative: severe thrombocytopenia, increased risk of STDs, solid organ transplant

## *DIAGNOSTIC TESTS & INTERPRETATION*

- A negative pregnancy test (urine or serum) is advised prior to initiating contraception.
- Testing for gonorrhea and chlamydia should be considered but is not required prior to IUD insertion, although need to rule out symptomatic infections.
- Pap smear if otherwise indicated
- Screen for hypertension [A].
- In family history of thrombophilia, testing can be considered before initiation of estrogen-containing contraception, especially if specific defect is known.

## **TREATMENT**

### *GENERAL MEASURES*

- Methods should be selected based on patient preference, effectiveness, desire for sexually transmitted disease (STD) prevention, side effects, and contraindications.
- General categories included hormonal and nonhormonal methods.
  - Nonhormonal methods include condoms, diaphragm, cervical cap, copper IUD, vasectomy, female sterilization, fertility awareness, sponge, spermicides, and abstinence.
  - Hormonal methods include combined oral contraceptives (COCs), patch, ring, injectables, intrauterine devices (IUDs), and implants.

### *MEDICATION*

- Estrogen-progestin contraceptives
  - Mechanism of action: Work by suppression of ovulation, thickening cervical mucus, and endometrial changes that interfere with transport of sperm to egg and with implantation
  - Efficacy: failure rate of about 4.8% at 1 year
  - Side effects: nausea, bloating, headaches, mastalgia, depression, acne, and hirsutism
  - Side effect management: Breakthrough bleeding is usually self-limiting after 3 months; if persists, change pill. Amenorrhea: rule out pregnancy
  - Combined oral contraception (COCs): Pill

- All COCs contain the same type of estrogen (ethinyl estradiol) but differ in the level of estrogen (range of 10 to 50  $\mu\text{g}$ ) and the type of progestin
- Newer progestins (such as norgestimate and desogestrel) are less androgenic but may have increased rate of venous thromboembolism (VTE).
- Start with a pill that is inexpensive (generic); contains an average amount of estrogen (30 to 35  $\mu\text{g}$ ).
- Dosing: Most pills have a 21/7 regimen (21 active days and 7 placebo). Alternatively, can take active pills continuously with four yearly scheduled withdrawal bleeds.
- Initiation: first day start (begin the pill on the first day of menses), quick start (begin pill on day medication is obtained), or Sunday start (begin pill on first Sunday)
- Weekly hormonal patch (Ortho Evra): releases 20  $\mu\text{g}/\text{day}$  ethinyl estradiol and 150  $\mu\text{g}/\text{day}$  norelgestromin
- Applied transdermally and changed weekly
- Produces higher serum estrogen levels than oral 20  $\mu\text{g}$  pill and may be associated with a slightly increased risk of blood clot
- Patch may cause local skin irritation; not as reliable in women >90 kg.
- Vaginal contraceptive ring (NuvaRing):
  - Flexible polymer ring with 15  $\mu\text{g}/\text{day}$  of ethinyl estradiol and 120  $\mu\text{g}/\text{day}$  of etonogestrel absorbed via vaginal wall
  - Inserted into vagina for 3 weeks/cycle or use continuous cycling for 4 weeks then replace immediately with a fresh ring (off label)
  - Though systemic exposure to estrogen is about 50% of exposure with COCs, the risk of blood clots is about the same.
- Progestin-only birth control
  - Mechanism of action: thickening cervical mucus and thinning endometrial lining
  - Progestin-only pill (Micronor)
    - Efficacy: failure rate of about 0.3% with perfect use, 9% with typical use at 1 year
    - Can be used in women with contraindication for estrogen, including breastfeeding women after 6 weeks postpartum.
    - Dosing: 1 pill taken daily, no placebo days; needs to be taken at the same time daily
    - Side effects: irregular bleeding

- Injectable contraceptive (medroxyprogesterone)
  - Efficacy: failure rate of 0.2% with perfect use, 6% with typical use at 1 year
  - Dosing: Depo-Provera 150 mg IM or Depo-SubQ Provera 104 mg SQ, both are given every 3 months. Contraceptive levels of hormone persist for up to 4 months (2- to 4-week margin of safety).
  - Side effects include irregular bleeding, weight gain (average of 5 lb/year of use), and amenorrhea.
- LARCs: IUDs and implantable devices [A]
  - Mirena (levonorgestrel IUD):
    - Mechanism of action: sterile inflammatory reaction due to foreign body that is toxic to sperm and ova, thickens cervical mucus, endometrial decidualization and glandular atrophy, inhibiting sperm-egg binding, partial inhibition of ovarian follicular development and ovulation
    - Efficacy: failure rate of 0.2% with both perfect and typical use at 1 year
    - Dosing: IUD releases 20  $\mu\text{g}/\text{day}$  of levonorgestrel (very low serum levels).
    - Approved for use up to 5 years; has been used off label for up to 7 years
    - Safe in nulliparous women/teenagers
    - Can be inserted immediately postpartum or immediately following dilation and curettage for miscarriage or abortion, but these are associated with higher rates of expulsion compared to delayed placement (6 to 10 weeks)
    - Side effects: irregular menstrual spotting for the first 3 to 6 months that usually resolves after 6 months of use; may see absence of menses after 1 year
    - Side effect management: Consider trial of COCs or estrogen alone for spotting and cramps.
    - Can reduce heavy bleeding in women with menorrhagia
  - Skyla (levonorgestrel-releasing intrauterine system):
    - Similar to Mirena but releases lower hormone dose (14  $\mu\text{g}/\text{day}$  initially, down to 5  $\mu\text{g}/\text{day}$

of levonorgestrel), slightly smaller, and lasts 3 years. Smaller insertion tube might make this an easier IUD for nulliparous women. More bleeding days than Mirena

### ParaGard (Copper IUD):

- Mechanism of action: In addition to sterile inflammatory reaction due to foreign body, free copper and copper salts enhance the cytotoxic inflammatory reaction-toxic to sperm and ova.
- Efficacy: failure rate of 0.6% with perfect use, 0.8% with typical use at 1 year
- Approved for up to 10 years
- Same insertion timing as Mirena
- Side effects: blood loss and cramping
- Nexplanon (etonogestrel implant):
  - Mechanism of action: same as progestin-only pill or medroxyprogesterone
  - Efficacy: failure rate of 0.05% with perfect use, 0.3% with typical use at 1 year
  - Dosing: 40 mm × 2 mm semi-rigid plastic rod containing 68 mg of etonogestrel. Initially releases 60 to 70  $\mu\text{g/day}$ , down to 25 to 30  $\mu\text{g/day}$  at the end of the third year
  - Effective for up to 3 years
  - Must be inserted only by certified providers
  - Side effects: menstrual irregularities (common first 6 to 12 months), amenorrhea after 1 year
- Emergency contraception: should be initiated as soon as possible post-unprotected intercourse. Copper IUD is the most effective, followed by levonorgestrel, ulipristal and Yuzpe method (least effective) (2)[A]
  - Copper-bearing IUD (ParaGard): Insert up to 5 days after intercourse; failure rate of 0.04-0.19%.
  - Levonorgestrel: 1.5 mg taken as two 0.75-mg tablets (Plan B) or one 1.5-mg tablet (Plan B 1-Step). 1.1-2.4% failure rate. Less nausea than Yuzpe regimen. Available over the counter; may be less expensive if prescribed. Most effective within 72 hours, efficacy declines with time
  - Ulipristal acetate (Ella): 30 mg × 1 dose; Selective progesterone modulator, effective up to 5 days after unprotected intercourse with minimal decline in efficacy. About 2% failure rate
  - Estradiol/levonorgestrel (Preven, Lo Ovril, Ogestrel): Yuzpe regimen 50  $\mu\text{g}/0.25$  mg, 2 tablets q12h (4 tablets total). Any OC may be used as long as the dose of estrogen component  $\geq 100 \mu\text{g/dose}$ . About 3.2% failure rate. *Note:* Antiemetic should be given 1 to 2 hours before each dose.

## ***ADDITIONAL THERAPIES***

- Condoms: failure rate of 2% with perfect use, 18% with typical use at 1 year
- Spermicides: All contain nonoxynol-9; may alter vaginal flora and mucosal barrier. 28% failure at 1 year with typical use
- Sponge (Today Sponge): Soft foam disk contains nonoxynol-9. Moisten with water before use; effective for 24 hours; must leave in for 6 hours after use; less effective in parous women. 12-24% failure at 1 year with typical use
- Diaphragm: dome-shaped device made of latex or silicone with flexible spring-activated rim, works by preventing sperm from entering cervix; used with spermicides. 12-16% failure at 1 year with typical use.

## ***SURGERY/OTHER PROCEDURES***

### Permanent sterilization

- Female: tubal ligation or Essure (micro-insert system placed hysteroscopically). Essure requires confirmation of tubal occlusion with hysterosalpingogram 3 months postprocedure. 0.5% failure at 1 year
- Male: vasectomy. Less complicated than female. 0.15% failure at 1 year

## ***COMPLEMENTARY & ALTERNATIVE MEDICINE***

- Fertility awareness methods: calendar method, cervical mucus method, temperature method. Low cost but generally not as effective as other methods. 24% failure at 1 year with typical use
- Withdrawal method: Male partner withdraws from vagina before ejaculation. Failure if not timed accurately. 22% failure at 1 year with typical use
- Lactational amenorrhea method: Breastfeeding is effective contraception only if (i) the infant is <6 months old, (ii) the infant is exclusively breastfeeding, and (iii) the mother has not resumed regular menses. 7% failure at 1 year with typical use

## ***Pediatric Considerations***

- AAP and ACOG recommend LARCs as the most effective in sexually active adolescents.
- Contraception counseling should include anticipated adverse effects, need to use condoms for STD prevention, and indications for emergency contraception (including options and how to obtain).

## ONGOING CARE

### *FOLLOW-UP RECOMMENDATIONS*

#### *Patient Monitoring*

- Pelvic exam, Pap smear, and STI testing per guidelines and routine follow-up 2 to 3 months postinitiation of all methods to assess tolerance
- Check for IUD strings 1 month after insertion; spontaneous expulsion rate highest in the first month.
- BP check within 3 months of initiation in patients on estrogen containing methods

#### *DIET*

St. John's wort may alter estrogen levels, reducing efficacy or causing breakthrough bleeding.

### *PATIENT EDUCATION*

- Diaphragm: device inspected prior to each use, 1 tablespoon of spermicide in hollow of the dome, diaphragm is inserted into the vagina, additional applicator of spermicide placed in vagina. If placed >6 hours prior to intercourse need additional applicator of spermicide. Position needs to be checked post intercourse, and additional spermicide applied prior to each new episode of intercourse. Diaphragm should remain in place for at least 6 hours after the last episode of intercourse to maximize effectiveness.
- Male condoms: New condom is placed on the penis before genital contact, remains intact until the penis is withdrawn, new condom needs to be used with every act of intercourse.
- IUD: Patient should monitor presence of the string monthly following menses.
- OCP: Pill should be taken at approximately the same time each day. Back up birth control method is needed for the first 7 days with quick start and Sunday start methods.

### **COMPLICATIONS**

- Estrogen-progestin contraceptives:
  - Serious (requires discontinuation): stroke, thromboembolism, hypertension, myocardial infarction, and cholestatic jaundice
  - Overall 5-fold increased risk of venous thrombosis compared to nonusers, comparable to the 4-fold increased risk of venous thrombosis during pregnancy (3)[B]
- Injectable contraceptive:

- Potential for decreased bone mineral density (BMD) if used for 2 years. Mostly recovers after discontinuation. Consider calcium/vitamin D supplementation if prolonged use.
- Nexplanon: insertion site reaction including pain, bleeding, paresthesias, and infection
- IUDs:
  - Pelvic inflammatory disease (PID): Treat without removal unless serious infection or failure to respond to therapy.
  - Uterine perforation
  - Absolute risk of ectopic pregnancy is reduced with IUD, but if pregnancy does occur, there is a higher risk that it will be ectopic.
- Sponge and diaphragm: rarely associated with toxic shock syndrome

- CDC Medical Eligibility Criteria for Contraceptive Use, 2010. Available as chart, app for smartphone (CDC Contraception)
- Chart comparing contraceptive methods: ARHP Method Match at <http://www.arhp.org/methodmatch/>

**&NA;**

## **ICD10**

- Z30.9 Encounter for contraceptive management, unspecified
- Z30.41 Encounter for surveillance of contraceptive pills
- Z30.431 Encounter for routine checking of intrauterine contracep dev

## **Clinical Pearls**

**&NA;**

- Hormonal and IUD contraceptives may be initiated immediately if the likelihood of pre-existing pregnancy is low.
- Contraception method should be chosen based on individual patient needs.
- LARC methods provide high efficacy and convenience for patients.
- All patients should be counseled on emergency contraception options.

# Cor Pulmonale

Parag Goyal, MD

Sergey G. Gurevich, MD

James M. Horowitz, MD, FACC

## BASICS

### DESCRIPTION

- Enlargement and subsequent dysfunction and failure of the right ventricle (RV) in the presence of pulmonary hypertension secondary to abnormalities of the pulmonary system, including disorders of the lung parenchyma, pulmonary circulation, chest wall, and ventilatory mechanisms.
- For the purposes of this review, pulmonary arterial hypertension (WHO Group I) will not be considered as a cause of cor pulmonale.
- May occur in acute or chronic setting
  - Acute: rapid increase of pulmonary arterial pressure resulting in RV overload, dysfunction, and potential cardiovascular collapse
  - Chronic: progressive hypertrophy and dilation of the RV over months to years, leading to dysfunction, and potentially failure

### EPIDEMIOLOGY

- ÷6-7% of all types of adult heart disease in United States
- Estimated 10-30% of heart failure admissions in the United States are the result of cor pulmonale, most commonly related to chronic obstructive pulmonary disease (COPD).

### *Incidence*

Difficult to assess: Best estimate is 1/10,000 to 3/10,000/year.

### *Prevalence*

Difficult to assess: Best estimate is 2/1,000 to 6/1,000.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Acute: A sudden event, such as large pulmonary embolism (PE), increases resistance to blood flow in the pulmonary vasculature, causing a quick and significant increase of pressure proximally. The RV is unable to overcome this pressure, leading to low RV cardiac output, which ultimately leads to low left ventricle (LV) cardiac output. Increased RV pressures in conjunction with a low cardiac output may cause coronary ischemia, further impairing cardiac output and potentially causing complete cardiovascular collapse.
- Chronic: A disorder of the pulmonary system causing chronic hypoxia leads to vasoconstriction of the pulmonary vasculature. Over time, the pulmonary vasculature hypertrophies and the intrinsic vasodilatory mechanisms (mediated by nitric oxide) become dysregulated, leading to increases in pulmonary vasculature resistance. The resulting pulmonary hypertension (WHO Group III) transmits increased pressures and volumes to the thin-walled, low-pressure RV, causing maladaptive remodeling (concentric hypertrophy, followed by eccentric dilation frequently with associated tricuspid regurgitation) and subsequent impairment in RV systolic and diastolic function.
- Pulmonary disorders
  - Lung parenchymal disease: COPD (most common), interstitial lung disease (ILD)
  - Pulmonary circulation: thromboembolic disease (associated with pulmonary hypertension WHO Group IV)
  - Chest wall: severe obesity, kyphoscoliosis
  - Ventilation: obstructive sleep apnea (OSA) and obesity hypoventilatory syndrome, neuromuscular diseases such as Guillain-Barré syndrome, muscular dystrophy, myasthenia gravis, spinal cord injuries
- LV failure is not considered a cause of cor pulmonale.

## *RISK FACTORS*

- Acute cor pulmonale (most commonly caused by PE)
  - Risk factors associated with PE:
    - Vessel injury
    - Stasis
    - Hypercoagulable states
- Chronic cor pulmonale (most commonly caused by underlying pulmonary disorder)
  - Risk factors associated with pulmonary disorders

Tobacco use (COPD)

- Occupational exposures (ILD)
- Hypercoagulable state (chronic thromboembolic disease)
- Obesity, age (chest wall abnormalities)

## GENERAL PREVENTION

Management of underlying pulmonary disorder, including aggressive correction of hypoxia and acidosis, which may contribute to worsening pulmonary hypertension.

## COMMONLY ASSOCIATED CONDITIONS

Pulmonary hypertension, defined as the presence of a resting mean pulmonary artery pressure (PAP) >25 mm Hg

## DIAGNOSIS

### HISTORY

- Dyspnea is the most common symptom, although nonspecific; may be present at rest, with exertion, or occur as paroxysmal nocturnal dyspnea
- Other pulmonary symptoms: pleuritic chest pain, cough, hemoptysis
- General heart failure symptoms: fatigue, lethargy, syncope; exertional angina less likely
- Right-sided heart failure symptoms: anorexia, early satiety, right upper quadrant discomfort from hepatic congestion, lower extremity edema
- Hoarseness secondary to compression of the left recurrent laryngeal nerve by enlarged pulmonary vessels
- Cardiovascular collapse, shock, and/or cardiac arrest may occur in acute or advanced chronic setting.

## PHYSICAL EXAM

- Peripheral edema is the most common sign of right-sided heart failure, although it is nonspecific.
- General: pallor, diaphoresis, cyanosis, tachypnea
- Neck: jugular venous distension, with prominent *a*-wave
- Lungs: tachypnea, wheezing

- Heart
  - Increased intensity of pulmonic component of second heart sound ( $P_2$ )
  - Splitting of  $S_2$  over the cardiac apex with inspiration
  - Audible right-sided  $S_3$  or  $S_4$
  - Jugular venous pressure (JVP), with prominent v-wave
  - RV heave
  - Pansystolic murmur heard best at right midsternal border increasing with inspiration, consistent with tricuspid regurgitation (typically a late sign)
  - Early diastolic murmur heard best at left upper sternal border, consistent with pulmonary regurgitation
- Abdomen: hepatomegaly
- Extremities: clubbing, bilateral lower extremity edema, also signs of deep vein thrombosis (DVT) such as tenderness or unilateral swelling

## *DIFFERENTIAL DIAGNOSIS*

Other causes of right-sided failure:

- Left-sided heart failure (WHO Group II)
- WHO Groups I and V pulmonary hypertension
- Right-sided intrinsic cardiomyopathy

## *DIAGNOSIS TESTS & INTERPRETATION*

- 2D echocardiogram (1)[C]
  - Initial diagnostic test of choice
  - Elevated PAP
  - Right ventricular hypertrophy
  - Bulging of the interventricular septum into the LV with systole
  - Flattening of the interventricular or interatrial septum
  - Dilation and hypokinesis of the RV
  - Tricuspid regurgitation
  - Dilation of the right atrium

- Acute thromboembolic pulmonary disease as evidenced by right ventricular hypokinesis with sparing of the apex (McConnell sign)
- Echocardiography can over- or underestimate the PAP depending on image quality or operator. PAP should therefore be verified by catheter.
- MRI
  - If echocardiography is inconclusive or as a substitute
  - Most accurate modality for diagnosing emphysema and ILD
  - Can assess pressures, size, function, myocardial mass, and viability
  - Despite being superior to echocardiogram, diagnosis of cor pulmonale still requires assessment via catheterization.
- Right heart catheterization (1)[C]
  - Gold standard for diagnosis of pulmonary hypertension, and therefore critical for diagnosis of cor pulmonale
  - Elevated central venous pressure (CVP)
  - Mean PAP >25 mm Hg at rest
  - Absence of left heart failure (pulmonary capillary wedge pressure <15 mm Hg)

### *Initial Tests (lab, imaging)*

- CBC may show signs of polycythemia due to chronic hypoxia.
- Basic metabolic panel (BMP) may demonstrate elevated creatinine secondary to poor cardiac output.
- Liver function tests (LFTs) may be abnormal due to hepatic congestion or poor cardiac output secondary to RV failure.

---

P.229

- Brain natriuretic peptide (BNP) and cardiac troponin can be elevated secondary to right ventricular strain.
- D-dimer may be positive as evidence of underlying thromboembolic pulmonary disease.
- Arterial blood gas may show hypercapnia due to COPD.
- ECG often shows signs of right-sided enlargement.
  - Right axis deviation
  - An R/S wave ratio >1 in V

- Right ventricular hypertrophy (R wave in V<sub>1</sub> and V<sub>2</sub> with S waves in V<sub>5</sub> and V<sub>6</sub>)
- Right atrial enlargement as evidenced by P pulmonale (increased amplitude of P wave in lead II)
- Incomplete or complete right bundle branch block
- S<sub>1</sub>S<sub>2</sub>S<sub>3</sub> pattern or S<sub>1</sub>Q<sub>3</sub>T<sub>3</sub> inverted pattern
- Chest x-ray
  - Cardiomegaly
  - Enlargement of the central pulmonary arteries and reduced size of peripheral vessels (oligemia)
  - Reduced retrosternal space due to right ventricular enlargement on lateral views
  - Enlargement of the right atrium resulting in prominence of the right heart border
  - Evidence of COPD, ILD, and structural disease (i.e., kyphosis)
  - Evidence of PE (Westermark sign and Hampton hump)
- Spiral CT scan of chest
  - Diagnosis of acute PE
  - Diagnosis of COPD and ILD
- Ventilation/perfusion scan (V/Q)
  - High specificity and sensitivity for acute and chronic thromboembolic disease
  - May be used for diagnosis of acute thromboembolic disease if contraindication to chest spiral CT
  - May be preferred to chest spiral CT for diagnosis of chronic thromboembolic pulmonary disease, given higher sensitivity (can detect peripheral pulmonary emboli otherwise missed by spiral CT)
  - Diagnosis of chronic thromboembolic disease may warrant confirmation by pulmonary angiography.
- Pulmonary angiography
  - Gold standard in diagnosis of chronic thromboembolic pulmonary disease
- Polysomnography

- Gold standard for diagnosis of OSA
- Pulmonary function tests (PFTs)
  - Impaired diffusion capacity
  - Obstructive or restrictive ventilatory defects (ILD, structural abnormalities, and COPD)

## TREATMENT

Reduce symptoms and improve quality of life and survival. Reduce disease burden via oxygenation, preservation of cardiac function, and attenuation of pulmonary hypertension.

### GENERAL MEASURES

- Treat underlying disease (2)[A].
  - For underlying pulmonary disease, bronchodilators and/or steroids may be beneficial.
  - For underlying chronic thromboembolic disease, anticoagulation may be indicated.
- Supportive therapy as necessary
  - Continuous positive airway pressure/bilevel positive airway pressure may be used for hypoxia/sleep disorders.
  - Ventilation using positive-pressure masks, negative-pressure body suits, or mechanical ventilation is suggested for patients with neuromuscular disease.
  - Phlebotomy may be indicated for severe polycythemia (hematocrit >55%).

### MEDICATION

- Oxygen (3)[A]
  - Long-term continuous oxygen therapy improves the survival of hypoxemic patients with COPD and cor pulmonale.
  - All patients with pulmonary hypertension whose PaO<sub>2</sub> is consistently <55 mm Hg or saturation <sup>2</sup>88% at rest, during sleep, or with ambulation should be prescribed oxygen to keep O<sub>2</sub> >92 mm Hg.
- Preservation of cardiac function (4)[B]
  - Inotropes: Dobutamine and milrinone may improve cardiac output; should be reserved for hemodynamically unstable patients

- Diuretics: decrease RV filling pressures; also reduces peripheral edema secondary to RHF
  - Excessive volume depletion should be avoided.
  - Monitor closely for metabolic alkalosis, as this may suppress ventilatory drive and contribute to hypoxia.
- Ameliorate pulmonary hypertension (1,4)[C]
  - Treatment of underlying disease is hallmark of management.
  - When refractory to traditional medical treatment, advanced therapies may be beneficial, although evidence is lacking.
  - For chronic thromboembolic associated pulmonary hypertension (WHO Group IV), riociguat and macitentan may be used.

## *ISSUES FOR REFERRAL*

Patients with cor pulmonale should be referred to a specialized center for expert consultation.

## *SURGERY/OTHER PROCEDURES*

- Endarterectomy for chronic thromboembolic disease (WHO Group IV)
- Moderate to severe disease refractory to medication may require lung and/or heart transplantation.

## **ONGOING CARE**

### *DIET*

Salt and fluid restriction

### *PATIENT EDUCATION*

- Smoking cessation and avoidance of exposure to secondary smoke is strongly recommended.
- Level of physical activity should be discussed with physician.
- Pregnancy should be avoided.

### *PROGNOSIS*

- Patients with cor pulmonale resulting from COPD have a greater likelihood of dying than do similar patients with COPD alone.

- Pulmonary arterial pressure is a reliable indicator of prognosis; higher pressure is associated with a worse prognosis.
- In patients with COPD and mild disease (PAP 20 to 35 mm Hg), 5-year survival is 50%.

## Clinical Pearls

**&NA;**

- Treatment of cor pulmonale requires treatment of the underlying disease.
- Continuous, long-term oxygen therapy improves life expectancy and quality of life in cor pulmonale.
- Referral of patients with cor pulmonale to a specialized center is strongly recommended.

# Corneal Abrasion and Ulceration

Caroline A. Coicou, MD

Christine S. Persaud, MD

## BASICS

### DESCRIPTION

- Corneal abrasions result from scratching, denuding, abrading, or cutting of the epithelial layer of the cornea. They are usually traumatic and accidental but can occur spontaneously as well.
- Corneal ulcers usually represent an infection deeper in the cornea by bacteria, viruses, or fungi as a result of breakdown in the protective epithelial barrier.
- Both corneal abrasions and ulcerations can result in scarring, which may impair vision.
- Both lesions can occur centrally or marginally.

### EPIDEMIOLOGY

#### Incidence

- Corneal abrasion is the most common ophthalmologic visit to the emergency department and is a commonly seen problem in urgent care:
  - 64% of cases are caused by direct minor trauma to eye.
  - 12% of cases are due to contact lens-related problems.
- Ulceration is also common in the United States.

### ETIOLOGY AND PATHOPHYSIOLOGY

- Corneal abrasions most commonly result from accidental trauma (e.g., fingernail scratch, makeup brush):
  - Dirt, sand, sawdust, or other foreign body gets caught under eyelid.
- Corneal ulcers result from presence of an entryway to the external eye through dry eye; burns; abrasion; contact lenses; inappropriate use of topical anesthetics, antibiotics, or antiviral drops; immunosuppressant drugs; diabetes; or immunodeficiency. Causes of ulcerations include the following:

- Infection with gram-positive organisms ÷29-53% (*Staphylococcus aureus* and coagulase-negative *Streptococcus* are common ones)
- Infection with gram-negative organisms ÷47-50% (*Pseudomonas* being most common, followed by *Serratia marcescens*, *Proteus mirabilis*, and gram-negative enteric bacilli)

## ALERT

Patients with contact lenses may have colonization of the cornea with *Pseudomonas* and other gram-negative bacteria and should be treated with ophthalmic quinolones or aminoglycosides to prevent corneal ulceration and infection (1)[A].

- Viral infections, especially herpes
- Fungal infections (*Candida*, *Aspergillus*, *Fusarium*, *Acanthamoeba*) in agricultural workers or associated with ocular corticosteroid use
- Autoimmune disorders, such as rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and scleroderma, are the usual cause of peripheral ulcerative keratitis.
- Vitamin A deficiency may cause corneal necrosis or keratomalacia.

## RISK FACTORS

- Any abrasive injury
- Foreign body in eye
- Contact lenses (especially soft lenses and extended-wear lenses)
- Blepharitis
- Dry eye syndrome
- Entropion (with lashes scratching cornea)
- Chronic topical steroid use
- Abuse of topical anesthetics
- Autoimmune disorders
- Vitamin A deficiency
- Chronic corneal exposure (e.g., Bell palsy, exophthalmos)
- Recent eye surgery: Trendelenburg position is newly identified as a risk factor for corneal abrasion (2).
- Immunosuppression and trigeminal nerve abnormalities

- Flash burn (welding burn or prolonged gazing directly at bright sunlight; symptoms often begin several hours after exposure)

## *GENERAL PREVENTION*

- Eye protection to avoid injury during work, crafts, and sports
- Proper contact lens handling
  - Do not sleep while wearing contact lens.
- Artificial tears for those with inability to blink or known dry eyes
- Lenses to block UV rays (e.g., welding helmets)

## *COMMONLY ASSOCIATED CONDITIONS*

- Chronic ulcerations may be associated with neurotrophic keratitis due to lack of 5th nerve innervation of the cornea. Individuals with thyroid disease, diabetes, or immunosuppressive conditions are particularly at risk.
- Any cause of fat malabsorption may be associated with vitamin A deficiency.

## **DIAGNOSIS**

### **HISTORY**

- Sudden onset of eye pain, photophobia, tearing, foreign body sensation, blurring of vision, and/or conjunctival injection
- Abrasions and ulcerations are usually unilateral.
- History remarkable for contact lens use, dry eyes, rubbing eye, history of trauma from foreign body, or chemical burn
- History of connective tissue disorder

### *PHYSICAL EXAM*

- Visual acuity may be decreased if abrasion or ulcer is centrally located.
- Conjunctival injection
- Increased lacrimation on affected side
- Photophobia
- Blepharospasm

- Lesion seen on slit-lamp exam and area of damage shows fluorescein uptake; staining seen using Wood lamp or cobalt blue slit lamp:
  - Dendritic staining pattern with fluorescein indicative of viral keratitis
- Examine for foreign body under eyelids or in cornea (rust ring)

## ***DIFFERENTIAL DIAGNOSIS***

- Foreign body in eye
- Unilateral iritis
- Acute or chronic glaucoma
- Keratitis
- Scleritis with corneal melting
- Herpes simplex or zoster
- Bilateral or true idiopathic lesions may suggest basement membrane dystrophy.

## ***DIAGNOSTIC TESTS & INTERPRETATION***

### ***Initial Tests (lab, imaging)***

- Culture ulcer and contact lens, if applicable.
- Pretreatment with topical antibiotics may alter culture results.

### ***Diagnostic Procedures/Other***

Scrapings of the corneal ulcer for culture and sensitivity ideally should be obtained before beginning local antibiotics. The sample should be plated directly onto the culture medium.

### ***Test Interpretation***
